Results: Patient characteristics are shown in Table 1. In total, 19 patients developed new bone formation at week 108. Baseline serum levels of MASP-1, MASP-2, and C3dg were elevated in patients with new bone formation, whereas baseline serum levels of MASP-3 were decreased (all p<0.05). Baseline MASP-1, MASP-3, and C3dg predicted the development of new bone formation in a univariate logistic regression analysis, whereas CRP did not. Baseline MASP-1, MASP-3, and C3dg remained significant in a multivariate logistic regression analysis. L-ficolin and C3dg levels at week 108 were elevated in patients with new bone formation, and the serum levels at week 108 predicted development of new bone formation in a univariate logistic regression analysis. In a multivariate regression analysis, C3dg remained significant (p<0.05).

Conclusion: In this study, complement activation measured by C3dg and serum levels of MASP-1 and MASP-3, prior to TNF-I therapy, predicted development of new bone formation at week 108. Furthermore, elevated levels of C3dg and L-ficolin at week 108 were associated with new bone formation. These findings support the involvement of complement activation in new bone formation in r-axSpA.

POS0044 EVIDENCE OF A CAUSAL RELATIONSHIP BETWEEN HYPERLIPIDEMIA AND PSORIASIS AND PSORIATIC ARTHRITIS: A MENDELIAN RANDOMIZATION STUDY

Keywords: Genetics/Epigenetics, Spondyloarthritis

Q. LI[1], A. Dohey[2], D. Codner[2], P. Rahman[2]. [1]*Princess Margaret Cancer Centre, Genetics,Toronto, Canada;* [2]*Memorial University of Newfoundland, Medicine, St. John's, Canada*

Background: Psoriatic disease (psoriasis and psoriatic arthritis) is a common inflammatory disease associated with obesity. However, recent studies suggest that lipid changes, rather than obesity, may independently drive psoriatic disease [1]. Mendelian randomization (MR) can assess the causal effect of modifiable exposure by measuring the variation of genes of known function.
Objectives: In this study, we perform a two-sample mendelian randomization to investigate the possible causal relationship between polygenic hyperlipidemia and psoriatic disease (psoriasis and psoriatic arthritis).
Methods: The study cohorts (psoriasis, psoriatic arthritis, hyperlipidemia, and controls of European ancestry) were identified from the FinnGen biobank, an academia/industry collaboration aiming to identify genotype-phenotype correlations in the Finnish founder population. Hyperlipidemia was identified by code E4_HYPERLIPNAS, which represents disorders of lipoprotein metabolism and other lipidaemias [2]. The L12_psoriasis code and psoriatic arthritis by M13_PSORIARTH code identified psoriatic arthritis. The control population was selected after excluding E4_MEABOLIA, psoriasis, and psoriatic arthritis when appropriate. Genome-wide association studies (GWAS) and summarized data were extracted from public IEU datasets. The single-nucleotide polymorphisms (SNPs) were used as instrumental variables (IV) to identify the potential causal effect. The SNP selection was performed by considering the genome-wide significance, clumping, linkage disequilibrium, and minor allele frequency. The effect alleles were harmonized for exposures and outcomes. An inverse variance weighted (IVW) model was used to estimate causality for each IV in this two-sample MR study. Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated for causal estimations. The MR was performed in both directions to explore the possibility of reverse causality.
Results: 4535 patients with hyperlipidemia, 4510 with psoriasis, and 1553 patients with psoriatic arthritis (PsA) were identified from the FinnGenn biobank based on their id as noted above. The control patients ranged from 147,221 to 212,242, depending on the cohort being compared. Genetic instruments comprising 5 SNPs for hyperlipidemia, 16 SNPs for psoriasis and 4 SNPs for PsA were used for this two-sample MR. A significant causal effect was noted in hyperlipidemia and psoriasis (OR 1.26 (95% CI 1.097-1.439; p < 0.00009) and hyperlipidemia and PsA (OR 1.35 (95% CI 1.08-1.68; p=0.007) but no causal effect was noted in the reverse direction with psoriasis leading to hyperlipidemia OR 1.02 (95% CI 0.977-1.07; p=0.31) and PsA leading to hyperlipidemia OR 1.03 (95% CI 0,987 to 1.08; p=0.15).
Conclusion: Our two-sample MR study genetically predicted that hyperlipidemia has a potential causal association with psoriatic disease, which leads to a higher risk of psoriasis and PsA. Further validation and molecular studies are required to understand this relationship. If these results were to be validated, targeted reduction of hyperlipidemia may help modify the expression of psoriatic disease.

POS0045 CHILDHOOD INFECTIONS AND PERINATAL FACTORS AS RISK FACTORS FOR ANKYLOSING SPONDYLITIS – RESULTS FROM A NATIONWIDE CASE-CONTROL STUDY

Keywords: Spondyloarthritis, Epidemiology, Registries

M. Morin[1], U. Lindström[2], K. Hellgren[1], T. Frisell[1]. [1]*Karolinska Institute, Clinical Epidemiology Division, Department of Medicine, Solna, Stockholm, Sweden;* [2]*Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*

Background: A growing body of evidence suggests that there are associations between perinatal factors or early life exposures and later development of chronic inflammatory diseases. For ankylosing spondylitis (AS), previous studies have found increased risks associated with birth order and childhood respiratory tract infections, while breast-feeding and childhood appendicitis have been found protective.
Objectives: To identify early life risk factors for AS, with focus on perinatal characteristics and childhood infections.
Methods: People with AS from the Swedish National Patient Register, born 1973-2004, were matched 1:5 on age, sex, and place of residence to general population controls. Conditional logistic regression was used to compare odds ratios for AS in relation to potential risk factors identified in the Medical Birth Register and the National Patient Register.
Results: People with AS (n=5427) had significantly more hospitalizations for infections before age 16 compared to controls (n=21523), and had more often gone through a tonsillectomy (table 1). People with AS were also more likely to be born in the winter months, and to have an older sibling, while having a sibling overall (older or younger) resulted in an odds ratio for AS of 1.01 (0.93-1.11). No association was seen with factors such as maternal age, Caesarean delivery, or a 1 SD change in weight for gestational age (table 1). Odds ratios for AS associated with being born small or large for gestational age (>2 SD below or above sex-specific mean weight) was 1.10 (0.93-1.30) and 0.89 (0.74-1.08), respectively. In line with previous data, childhood appendectomy was associated with an odds ratio <1, but the estimate did not reach statistical significance.

Table 1. Perinatal factors and childhood infections in people with AS and general population controls, with odds ratios from conditional logistic regression

	AS cases* (n=5472)	Controls* (n=21523)	OR (95% CI)	Adj. OR† (95% CI)

POS0046 AUTOINFLAMMATORY GENETIC VARIANTS ARE OVER-REPRESENTED IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS COMPARED TO RHEUMATOID ARTHRITIS AND PSORIASIS

Keywords: Spondyloarthritis, Innate immunity, Genetics/Epigenetics

Q. LI[1], A. Dohey[2], D. Codner[2], P. Rahman[2]. *[1]Princess Margaret Cancer Centre, Genetics,Toronto, Canada; [2]Memorial University, Medicine, St. John's, Canada*

Background: Ankylosing Spondylitis (AS) and psoriatic arthritis (PsA) are chronic inflammatory diseases of undetermined etiology. Both entities exhibit features of autoimmunity (exhibited by clonal expansion of T cell populations) and autoinflammation, as noted by the aberrant activity of innate and innate-like cells [1].

Objectives: In this study, we screen for genetic variants associated with known autoinflammatory disease in patients with AS, PsA, and compare it to rheumatoid arthritis (RA) and psoriasis (Ps).

Methods: The UK genome biobank identified exomes of AS, PsA, RA, and Ps patients. Autoinflammatory genes were selected from the blueprint autoinflammatory syndrome panel [2]. Twenty thousand nine hundred five missense mutations were identified from the 47 autoinflammatory genes in the blueprint panel and screened in these four cohorts. Mutational burden, mutation number, and mutation rate in these 47 genes were calculated.

Results: Exonic mutations of 1264 in AS, 886 in PsA, 5361 in RA and 5567 in Ps patients from the UK biobank were enrolled and analyzed in this study. The number of autoinflammatory variants identified was 937 in AS, 780 in PsA, 2081 in RA and 2015 in Ps. The average mutation rate in 47 genes is around 0.26 for these four diseases. The autoinflammatory panel's average mutation burden was not significantly different between these diseases (116 in AS and PsA, 118 in RA and Ps). However, when we accounted for the number of individuals screened, AS and PsA had a higher mean number of autoinflammatory variants than RA and Ps. Specifically, AS and PsA patients had a mean number of 0.741 and 0.880 variants per individual, respectively, compared to 0.388 and 0.362 for RA and Ps, respectively.

Conclusion: This study strengths the role of autoinflammation in AS and PsA as we report an overabundance of autoinflammatory variants in AS and PsA compared to RA and psoriasis. Consideration of autoinflammatory etiology may impact current diagnostic and therapeutic approaches.

POS0047 THE COMPLEMENT FACTOR H-RELATED PROTEIN-5 EXACERBATES PATHOLOGICAL BONE FORMATION OF ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Animal Models

C. N. Son[1], J. Lee[1], S. Jo[2], I. H. Sung[3], T. H. Kim[2,4]. *[1]Kemyung University School of Medicine, Internal Medicine, Daegu, Korea, Rep. of (South Korea); [2]Hanyang University Institute for Rheumatology Research, Rheumatology, Seoul, Korea, Rep. of (South Korea); [3]Hanyang University Hospital, Orthopaedic Surgery, Seoul, Korea, Rep. of (South Korea); [4]Hanyang University Hospital for Rheumatic Diseases, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: The complement factor H-related protein-5 (FHR-5), a member of the human factor H protein family, enhances complement activation. The influence of complement activation on bone and joint was recognized in bone fracture healing, arthritis, and osteomyelitis. Recently, FHR-5 has been linked to eye, kidney, infection, cancer and autoimmune diseases. FHR-5 was also significantly up-regulated in proteomic analysis of serum and synovial fluid for ankylosing spondylitis (AS).

Objectives: We aimed to evaluate whether FHR-5 exacerbates bone inflammation and ectopic formation of AS.

Methods: The study included 65 patients with AS and 25 healthy controls (HC). Collected sera were divided into three groups according to HC, two AS groups (low CRP and high CRP) based on the CRP 0.8. Human TNF, IL6, IL-17, IL-23, and FHR-5 in three groups were measured with ELISA and human FHR-5 levels were compared to TNF, IL-6, IL-17, and IL-23 levels. In addition, soluble FHR-5 proteins were administered with Curdlan-injected SKG mice 2 time for a week and monitored for 5 weeks *In vivo* model. Foot and ankle were evaluated by micro-CT, Hematoxylin and Eosin for histological observation, and Safranin O for cartilages. Moreover, these finding were further assessed in the AS-osteoprogenitor *In vitro* model.

Results: In consistent with human data, proinflammatory cytokines (TNF, IL-6, IL-17A, and IL-23) and CFHR5 were elevated in AS group compared to HC group. FHR5 levels were not significantly correlated with proinflammatory cytokines, whereas FHR5 levels in AS were only positively correlated with the high CRP group. Notably, treatment with soluble FHR5 has no effect on clinical arthritis scores and thickness at hindpaw in Curdlan-injected SKG, but significantly increased the ectopic bone formation at the calcaneus and tibia bones of ankle as revealed by micro-CT image and quantification. Basal FHR5 expression was upregulated in AS-osteoprogenitors compared to control cells. Also, treatment with FHR5 remarkedly induced bone mineralization status of AS-osteoprogenitors during osteogenic differentiation accompanied by MMP13 expression.

Conclusion: We provide the first evidence demonstrating that FHR-5 can exacerbate pathological bone formation of AS. Therapeutic modulation of FHR-5 could be promising for future treatment of AS.

POS0048 LIPOPOLYSACCHARIDE ACTIVATED ENTHESEAL MYELOID CELL INHIBITION WITH UPADACITINIB PARADOXICALLY INCREASES MYELOID PRO-INFLAMMATORY CYTOKINES INCLUDING TNF AND IL-23 BY RESTRAINING AN IL-10 NEGATIVE FEEDBACK-BUT T-CELL TNFA AND IL-17 IS STRONGLY BLOCKED

Keywords: Enthesitis, Cytokines and chemokines, Targeted synthetic drugs

S. Giryes[1,2], T. Macleod[1], C. Wong[1], M. Harland[1], N. Mcdermott[1], C. Bridgewood[1], A. S. Rao[3], A. Khan[3], P. Loughenbury[3], D. Mcgonagle[1,4].

[1]University of Leeds, 1. Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRMM), University of Leeds, Leeds, UK., Leeds, United Kingdom; [2]Rambam Health Care Campus, 2. B. Shine Rheumatology Institute, Haifa, Israel; [3]Leeds General Infirmary, Leeds teaching hospitals, Leeds, United Kingdom; [4]Leeds Teaching Hospitals NHS, Leeds,UK, National institute for health Research, Leeds Biomedical Research Centre, leeds, United Kingdom

Background: Upadacitinib is effective in spondyloarthritis (SpA) associated arthropathy and is licensed for ankylosing spondylitis and psoriatic arthritis. Collectively SpA is linked to enthesitis with both myeloid lineage and T-lineage cells contributing to the IL-23/IL-17 and TNF axes that underscore disease.
Objectives: To investigate the effect of upadacitinib on an in vitro human enthesis model by focusing separately on the IL-23/IL-17 axis component myeloid and T-cells to better elucidate mechanisms of action in vivo.
Methods: Normal spinous process enthesis (n=26) was obtained from patients undergoing spinal decompression or surgery for scoliosis correction as previously described [1]. Enthesis cells were subsequently isolated by mechanical digestion. Entheseal myeloid cells were stimulated with LPS with and without upadacitinib. IL-23, TNFα and other proinflammatory cytokines in the supernatants were quantified using ELISA. IL-23 levels were measured after myeloid cell stimulation with LPS in the presence of upadacitinib and IL-10. IL-23 levels were also measured after stimulation with LPS in the presence of an IL-10Rα blocking antibody. Entheseal cells were stimulated with anti-CD3 with or without LPS, Th17-driving cytokines (IL-23 and IL-1β) and upadacitinib. Supernatants were measured by ELISA and cytokine-positive cell populations assessed by intracellular flow cytometry.
Results: Unexpectedly, upadacitinib significantly increased myeloid cell secretion of IL-23, TNFα and other proinflammatory cytokines after stimulation with LPS (Figure 1) (LPS = 51.2 pg/ml vs LPS + 1 μM Upa = 1048 pg/ml IL-23, n= 11). Addition of recombinant IL-10 attenuated such IL-23. Blockade of the IL-10 receptor with a blocking antibody increased IL-23 secretion from myeloid cells after stimulation with LPS (100 ng/ml IL-10 = 2.79 mean fold increase in IL-23, n=5). Despite this effect, upadacitinib strongly blocked TNFα and IL-17 from Th17 and Tc17 entheseal derived cells stimulated with exogenous IL-23 (138.19 pg/ml vs 14.2 pg/ml IL-17A after addition of 1 μM Upa to Th17 driving conditions, n = 5). Furthermore, addition of upadacitinib to LPS + anti-CD3 activated entheseal cells strongly downregulated T-cell derived IL-17 and TNFα despite a simultaneous increase in myeloid IL-23.
Conclusion: LPS activated myeloid cells, predominantly monocyte lineage further increase key cytokines IL-23 and TNFα post upadacitinib. This involves IL-10 pathway inhibition. However, in this system T-cell derived cytokine production is completely blocked despite elevation of myeloid IL-23 and TNFα. These unexpected findings highlight the pivotal role of T-cell derived cytokines in SpA given the known efficacy of JAK inhibition and these findings merit consideration in other domains such as intestinal inflammation that may have a greater innate immune driven component.

Background: Tapering of disease modifying antirheumatic drugs (DMARDs) to achieve drug-free remission is a goal for the growing group of rheumatoid arthritis (RA) patients in remission. However, the long-term effects of tapering or withdrawal of DMARDs remain unclear.
Objectives: To compare the 3-year clinical and radiographic outcomes of three conventional synthetic DMARD (csDMARD) treatment strategies (continued stable treatment, half-dose treatment and tapering to withdrawal) among patients in sustained RA remission.
Methods: ARCTIC REWIND was a randomized, multicenter, open-label, clinical trial enrolling 160 RA patients in sustained remission for ≥1 year on stable csDMARD therapy from 10 different Norwegian rheumatology departments.(1) At baseline, patients were randomized 2:1:1 to stable csDMARDs, half-dose csDMARDs, or half-dose csDMARDs for one year, followed by withdrawal of all csDMARDs ("tapering to withdrawal"). The primary endpoint was absence of disease activity flare over the 3-year study period. A flare was defined as a combination of disease activity score (DAS)>1.6, an increase in DAS ≥0.6 units since the previous visit and ≥2 swollen joints, or if the physician and patient agreed that a clinically significant flare had occurred. Full-dose csDMARD treatment was reinstated upon flare. Secondary endpoints included remission (DAS, ACR/EULAR Boolean) at 1, 2 and 3 years, and 3-year change in radiographic joint damage evaluated by van der Heijde-Sharp score (vdHSS). Data were analyzed using Kaplan-Meier, Mann-Whitney test, Cox and mixed effect logistic regression, with stratification or adjustment for study center.
Results: Of 156 patients who received the allocated treatment strategy, 139 patients completed 3-years follow-up without major protocol violation. Mean baseline methotrexate dose/week was 19.0 mg in the stable group, 19.4 mg in half-dose, and 19.5 mg in the withdrawal group, and mean DAS at baseline was 0.8 in all groups. During the 3-year study period, 80.1% remained flare-free in the stable csDMARD group, 59.5% in the half-dose and 40.8% in the withdrawal group (**Figure 1**), with corresponding adjusted hazard ratio (aHR) for flare of 2.7 (95% CI: 1.3 to 5.5) in the half-dose group and 4.1 (2.1 to 8.0) in the withdrawal group, compared to stable csDMARD. The aHR was 1.5 (0.8 to 3.0) in the withdrawal group compared to the half-dose group. For all groups, a majority were in remission at 1, 2 and 3 years **(Table 1)**, with the only significant group difference for ACR/EULAR Boolean remission at 3 years, with risk difference for withdrawal vs stable dose -25% (-45 to -6). Mean/median change in vdHSS after 3 years were 0.3/0.0 in the

stable group, 1.0/0.5 in the half-dose group, and 0.7/0.0 in the tapering to withdrawal group, with significant difference between the stable and half-dose group, p<0.01. Sensitivity analyses in the full analysis population gave similar results.
Conclusion: These 3-year data show that 41% of patients in the tapering to withdrawal arm achieved long-term drug-free remission, indicating that this is a realistic option for some RA patients in sustained remission. The two tapering strategies were associated with an increased risk of flares compared to full-dose csDMARD, and the half-dose group had more radiographic change. However, there were no differences in DAS-remission at the end of the study period. Further research identifying prognostic factors for successful tapering is needed.

POS0050 TAPERING GLUCOCORTICOIDS AND RISK OF FLARE IN RHEUMATOID ARTHRITIS ON BIOLOGICAL DISEASE MODIFYING ANTIRHEUMATIC DRUGS (bDMARDS)

Keywords: Real-world evidence, Tapering, Rheumatoid arthritis

G. Adami[1], A. Fassio[1], D. Gatti[1], C. Benini[1], O. Viapiana[1], D. Bertelle[1], M. Rossini[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*

Background: Glucocorticoids are still a mainstream of rheumatoid arthritis (RA) treatment. Reducing glucocorticoids should be attempted in all patients. However, choosing the right tapering strategy is challenging.
Objectives: The primary aim of our study is to determine the dose-response association between glucocorticoid tapering and risk of flare in RA.
Methods: We conducted a case-crossover study to determine the factors associated to higher risk of flare in patients with RA. In case-crossover studies time-varying factors are assessed before events (hazard periods) and before control periods. We defined hazard periods as the 6 months immediately preceding flares of RA. Control periods were the 6 months prior to visits without flare. Exposure of interest was the tapering of glucocorticoids to various doses. The time-variant independent variable of interest (exposure) was the tapering of glucocorticoids during the hazard periods vs control periods. Tapering of glucocorticoids was defined as the reduction of glucocorticoids dose from prior visit. Conditional logistic regression analysis was employed to determine the association between tapering of glucocorticoids with flare risk. We adjusted, as per case-crossover design, for relevant time-varying confounders (i.e., bDMARD use, csDMARD use, NSAID use and disease activity).
Results: 508 RA patients were included in the study and 267 (52.5%) had at least a flare and served as the case-crossover study population. 1,545 visits were available for analysis and 345 (22.3%) flares were recorded. Tapering of glucocorticoids was done in 176 (81.5% of 216) patients and discontinuation was attained, at least once, in 125 (57.8% of 216) patients. Definitive discontinuation was achieved in 101 patients (46.7%) at a median follow-up of 884 days (IQR 700-976 days). Discontinuation of glucocorticoids (i.e., tapering to doses of 0 mg/day) and tapering to 0-2.5 mg/day was associated with higher risk of flare (aOR of 1.45 [95% CI 1.13-2.24] and aOR of 1.37 [95% CI 1.06-2.01] respectively). Tapering to doses >2.5 mg/day was not associated with significantly higher risk of flare. In **figure 1** is depicted the smoothed line for dose-response association between glucocorticoid tapering and risk of flare. Apparently, tapering the doses to >2.5 mg/day did not result in an increased risk of flare.
Conclusion: We found that tapering to doses of >2.5 mg/day was generally effective in terms of risk of flare. Flare risk was higher when glucocorticoids were tapered to doses ≤2.5 mg/day. Our study might help design new tapering strategies in patients with RA on bDMARDs.

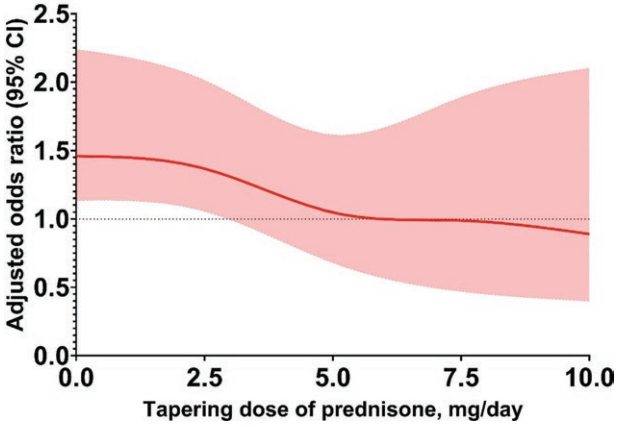

Figure 1. Dose-response association between tapering of glucocorticoids and risk of flare *The curve was interpolated using the conditional logistic regression model. The curve was smoothed with restricted cubic splines with knots at 0-2.5 mg/day, 2.5-5 mg/day, 5-7.5 mg/day and ≥7.5 mg/day. The reference was not tapering.*

Background: 2022 EULAR recommendation announced that both biological disease-modifying antirheumatic drugs (bDMARDs) and janus kinase inhibitors (JAKi) are considered in the phase II treatment of rheumatoid arthritis (RA). However, we still lack reliable evidence of direct comparison between these agents' retention, which may reflect effectiveness and safety.

Objectives: The aim of this multi-center (7 university-related hospitals)[1]-[3], retrospective study is to clarify the factors affecting treatment retention of bDMARDs and JAKi in a real-world setting.

Methods: This study assessed 6,666 treatment courses of bDMARDs and JAKi introduced from 2001 to 2022 (TNF inhibitors [TNFi]=3,577, anti-IL-6 receptor antibody [aIL-6R]=1,497, cytotoxic T lymphocyte-associated antigen-4-Ig [CTLA4-Ig]=1,139, JAKi=453; Bio/JAK naive cases 55.4%, baseline age 58.8 years, female 82.6%, disease duration 9.7 years, DAS28-ESR 4.3, concomitant methotrexate [MTX] [52.8%], other csDMARDs [26.0%], and oral glucocorticoid [GC] [36.4%]). Reasons for discontinuation were classified into four categories by each attending physician: 1) lack of effectiveness (primary and secondary), 2) toxic adverse events (infection, malignancies, and cardiovascular events, et al.), 3) non-toxic reasons (patient preference, change in hospital, and pregnancy, et al.), and 4) remission. Retention rates of each discontinuation reason were estimated at 36 months using the Kaplan-Meier method and adjusted for potential clinical confounders (age, sex, concomitant GC, MTX, and other csDMARDs, switched number of bDMARDs or JAKi, and prior use of TNFi, aIL-6R, CTLA4-Ig, or JAKi) using Cox proportional hazards modeling.

Results: Adjusted retention rates for each discontinuation reason were as follows: due to lack of effectiveness was aIL-6R=80.9%, JAKi=75.2%, CTLA4-Ig=73.6%, and TNFi=66.1% (Cox P<0.001 between 4 groups) (figure 1a), due to toxic adverse events was CTLA4-Ig=88.0%, JAKi=86.4%, aIL-6R=84.1%, and TNFi=83.6% (Cox P=0.052) (figure 1b), due to non-toxic reasons was aIL-6R=86.9%, TNFi=85.9%, JAKi=85.9%, and CTLA4-Ig=82.6% (Cox P=0.064), and due to remission was JAKi=97.1%, CTLA4-Ig=96.7%, aIL-6R=96.0%, and TNFi=94.9% (Cox P=0.18). Compared to TNFi, aIL-6R (hazard ratio [HR]=0.54, 95%CI=0.47–0.61, P<0.001), JAKi (HR=0.69, 95%CI=0.56–0.85, P<0.001), and CTLA4-Ig (HR=0.75, 95%CI=0.66–0.86, P<0.001) showed lower discontinuation rate due to lack of effectiveness. Compared to TNFi, CTLA4-Ig showed lower discontinuation rate due to toxic adverse events (HR=0.77, 95%CI=0.63–0.93, P=0.008) and remission (HR=0.67, 95%CI=0.46–0.98, P=0.041). Other factors increasing drug discontinuation due to lack of effectiveness was switched number of bDMARDs or JAKi (HR=1.42, 95%CI=1.24–1.63, P<0.001), concomitant GC (HR=1.17, 95%CI=1.06–1.29, P=0.0018), and prior aIL-6R use (HR=1.24, 95%CI=1.05–1.45, P=0.011). On the other hand, higher age (HR=1.01, 95%CI=1.00–1.02, P<0.001) and concomitant GC (HR=1.29, 95%CI=0.47–0.61, P<0.001) increased drug discontinuation due to toxic adverse events.

Conclusion: Adjusted by potential confounders, aIL-6R showed lowest discontinuation due to lack of effectiveness, and CTLA4-Ig showed lowest discontinuation due to toxic adverse events. Besides the difference of bDMARDs and JAKi, concomitant GC increased drug discontinuation due to lack of effectiveness and toxic adverse events.

Background: Radiographic joint damage progresses in 20-30% of rheumatoid arthritis (RA) patients despite fulfilling clinical remission criteria [1]. Osteitis assessed on MRI predicts subsequent bone damage progression [2]. Therefore, targeting absence of osteitis combined with clinical remission may improve long-term radiographic outcomes.

Objectives: To investigate whether a 2-year MRI treat-to-target (MRI T2T) strategy targeting absence of osteitis combined with clinical remission, compared to a conventional T2T strategy targeting clinical remission only, could reduce radiographic joint damage progression over 5 years in RA patients.

Methods: IMAGINE-more was designed as a three-year observational extension study of the 2-year IMAGINE-RA randomized clinical trial [3]. IMAGINE-RA included 200 RA patients in clinical remission (DAS28-CRP<3.2 and no swollen joints), with erosive disease (bone erosion on conventional radiography), and treated with csDMARDs. The objective was to investigate whether an MRI T2T strategy targeting absence of osteitis combined with clinical remission (DAS28-CRP≤3.2 and no swollen joints) as compared to a conventional T2T strategy, targeting clinical remission only, could improve remission rates and prevent radiographic joint damage progression. If treatment target was not met, treatment was intensified stepwise starting with increment in csDMARDs and subsequently adding biologics. Participants in the IMAGINE-more study were managed in routine clinical practice in outpatient clinics. Clinical examinations and radiographs of hands and feet (also obtained at baseline, year 1 and 2 in IMAGINE-RA) were done year 3, 4 and 5. The primary endpoint was the proportion of patients with no radiographic progression (increase in total van der Heijde-modified Sharp score (vdHSS) ≤0) from baseline to year 5. Secondary endpoints were 0-5 years changes in total vdHSS, vdHSS erosion and joint space narrowing (JSN) scores. Dichotomous endpoints were estimated by logistic regression, while median differences were calculated for the continuous outcome measures.

Results: Informed consent to participation in IMAGINE-more was obtained from 131 patients (59 from the original MRI T2T group). Of these, 14 patients (24%) in the MRI T2T group and 19 patients (26%) in the conventional T2T group had no radiographic progression from baseline to year 5 (OR 0.70 [0.28 to 1.71]). As illustrated in the Table 1 and Figure 1, the median progression in total vdHSS from baseline to 5 years was low, with no differences between treatment groups.

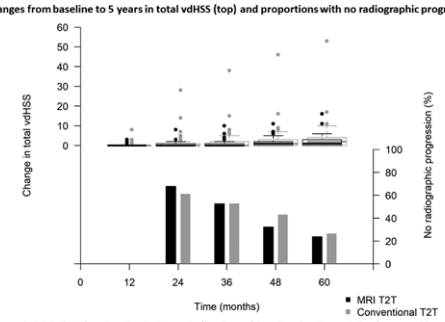

Table 1. Radiographic endpoints at 5 years (change from baseline - year 0)*

	n	MRI T2T	n	Conventional T2T	Difference between groups	P value
Primary endpoint						
No radiographic progression, No. (%)	59	14 (24%)	72	19 (26%)	OR=0.70 (0.28 to 1.71)	0.431
Key secondary endpoint						
Change in total vdHSS (0-448)	47	1.0 [0.0-3.0]	56	2.0 [0.0-4.0]	0.0 (-1.0 to 0.0)	0.515
Other secondary endpoints						
Change in erosion (0-280)	47	1.0 [0.0-2.0]	56	1.0 [0.0-3.0]	0.0 (0.0 to 0.0)	0.967
Change in JSN (0-168)	47	0.0 [0.0-0.5]	56	0.0 [0.0-1.3]	0.0 (0.0 to 0.0)	0.565

Group contrasts are presented as No. (%) for dichotomous data and medians [IQR] for continuous data. OR (95%CI) were estimated from logistic regression adjusted for a propensity score and with non-responder imputation. For endpoints with continuous data median differences (95%CI) were calculated based on the ITT population (no manual imputation)

*In addition to the radiographic endpoints, the full IMAGINE-more study includes a clinical co-primary endpoint, and several secondary endpoints.

Figure: Changes from baseline to 5 years in total vdHSS (top) and proportions with no radiographic progression (bottom)

Illustrates the change in total vdHSS from baseline to 60 months (i.e., 5 years) based on the ITT population (no manual imputation done), as well as the proportions with no radiographic progression (delta total vdHSS<0) in each group from baseline to 60 months, with non-responder imputation.

Conclusion: A 2-year combined MRI T2T and clinical T2T strategy, compared with a conventional clinical T2T strategy alone, did not result in reduced radiographic progression in the long term over 5 years in RA patients with erosive disease in clinical remission.

POS0053

EARLY DIAGNOSIS, PROMPT INITIATION OF METHOTREXATE AND TREATMENT STEERED-TO-TARGET DO NOT ABROGATE THE RISK OF BEING MULTIDRUG REFRACTORY FOR PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Disease-modifying Drugs (DMARDs), Rheumatoid arthritis, Prognostic factors

B. D'onofrio[1], V. Morandi[1], F. Maggiore[1], M. DI Lernia[1], L. De Stefano[1], C. Montecucco[1], S. Bugatti[1]. *[1]IRCCS Foundation, Polyclinic San Matteo, Internal Medicine and Therapeutics, University of Pavia, Pavia, Italy*

Background: The management of rheumatoid arthritis (RA) has substantially improved during the last few decades; despite that, a significant proportion of patients remain refractory to conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs), as well as to one or more biologic/target-synthetic (b/ts) DMARDs. It is estimated the overall proportion of refractory RA is around 3-17%. Refractory disease has been defined among patients with established, long-standing, RA. However, at present time, it is not known whether early diagnosis, prompt institution of DMARD within the window of opportunity and treatment steered-to-target are efficacious to prevent multidrug failure in patients with new-diagnosed RA.

Objectives: First, to assess if an Early Arthritis Clinic (EAC) background – early diagnosis and treatment within the "window of opportunity", disease management according to treat-to-target (T2) strategy – reduces the risk of being DMARDs refractory; secondly, to detect possible predictors of refractoriness in patients escalated to b/tsDMARDs.

Methods: Data were retrieved from a prospective monocentric cohort of 810 patients with early RA (symptoms duration <12 months at inclusion) diagnosed between 2005-2017 and treated with csDMARDs (methotrexate in 90.4% of the cases) according to a T2T strategy in the setting of an EAC. The population of interest included all patients escalated to b/tsDMARDs because of inefficacy/intolerance to csDMARDs. The frequency and factors associated with failure to first and second b/tsDMARDs were analysed by logistic regression.

Results: A total of 135/816 (16.5%) early RA patients required treatment escalation to a b/tsDMARDs after a median (IQR) of 18.5 (11-39) months from diagnosis; of them, 117 had follow-up visits available for a median (IQR) of 96 (37-122.5) months after treatment initiation. Fifty-six patients (50.4%) failed the first b/tsDMARD after a median (IQR) of 14 (7.3-44.3) months due to inefficacy/side effects. The rates of failure of the second and third b/tsDMARD were 20.5% and 19.7%. Thirteen patients (11.1%) could be defined D2T, having failed a median (IQR) number of 2 (2-3) b/tsDMARDs with different mechanisms of action, and 3 (2.8-4) different b/tsDMARDs in general. By logistic regression, significant predictors of first b/tsDMARD failure were disease duration ≤24 months

and autoantibody-negativity (respectively HR 1.89, 1.01-4.12, p=0.03; HR 1.66, 1.00-3.15, p=0.04). The latter confirms to be a significant predictor of second b/tsDMARD failure as well (HR 2.13, 1.08-4.17, p=0.03). At univariable analysis, significant predictors of D2T were concomitant diagnosis of fibromyalgia, autoantibody-negative status and lower doses of methotrexate. At bivariate logistic regression, fibromyalgia and autoantibody-negative RA maintained independent association with adjusted ORs (95% CI) of 3.6 (1.02-16.4) and 4.3 (1.01-24.1), respectively.

Conclusion: Early diagnosis, prompt initiation of methotrexate and management according to T2T strategy have substantially improved RA outcomes, and only about 16% of patients require escalation to second-line therapies. However, in those refractory to csDMARD, EAC setting seems not to ameliorate treatment persistence, as retention rates of b/tsDMARDs are similar to those observed in established disease. Early methotrexate inefficacy and autoantibody-negative disease appear to be predictive of first b/tsDMARD failure; moreover, patients with autoantibody-negative disease maintain a higher risk of failure of subsequent lines of therapies. Collectively, our findings suggest the need for a more tailored approach to refractory RA patients, especially to autoantibody-negative ones.

POS0054 SOCIOECONOMIC DEPRIVATION IS ASSOCIATED WITH REDUCED RESPONSE AND LOWER TREATMENT PERSISTENCE WITH ANTI-TNF THERAPIES IN PEOPLE WITH RHEUMATOID ARTHRITIS

Keywords: Epidemiology, bDMARD, Rheumatoid arthritis

S. S. Zhao[1], L. Kearsley-Fleet[1], K. Rogers[2], K. Watson[1], A. Bosworth[3], J. Galloway[4], S. Verstappen[1], J. Humphreys[1,5], A. Barton[5,6], K. Hyrich[1,5].

Background: Recent global health crises have highlighted the importance of socioeconomic (SE) inequalities and its influence on health provision and outcomes. The impact of SE deprivation on treatment of rheumatoid arthritis (RA) is understudied in contemporary biologic-treated populations.

Objectives: To investigate the association between SE deprivation and outcomes of TNF inhibitor (TNFi) treatment.

Methods: Individuals commencing their first TNFi in the BSR Biologics Register for RA from 2001 to 2020 were included. SE deprivation was proxied using the Index of Multiple Deprivation (IMD), which measures relative deprivation of geographic areas. Using the participants' residential postcode, each individual was assigned a relative rank score and categorised into the 20% most deprived, middle 40%, and 40% least deprived; thresholds were chosen because IMD gives greater distinction within the most deprived areas. DAS28, low disease activity (LDA) and EULAR response at 6 months were compared using linear, logistic and ordinal logistic regression models with the 40% least deprived as referent. Risk of drug discontinuation was compared using Cox models. Models were first unadjusted, then adjusted for potential confounders and/or mediators, namely age, gender, baseline DAS28, BMI, HAQ, number of comorbidities, age at diagnosis, ever smoking status and rheumatoid factor status. Multiple imputation was used for missing data.

Results: 17,117 individuals were included (mean age 56 (SD12) years, 76% female), of whom 3002 (18%) were in the 20% most, 6999 (41%) in the middle 40%, and 7116 (41%) in the 40% least deprived groups (Table 1). The 20% most deprived group had higher DAS28 at 6 months (beta=0.30, 95%CI 0.22-0.37) and were less likely to achieve LDA (OR 0.76; 0.68-0.84) and EULAR response (OR 0.73; 0.67-0.80) in unadjusted models. They were also more likely to discontinue treatment (HR 1.19; 1.13-1.25). Adjusted estimates were broadly similar (Table 1).

Conclusion: SE deprivation is associated with reduced response to TNFi and increased risk of treatment discontinuation. Estimates were largely unchanged despite adjusting for potential mediators. SE inequality embodies a multitude of factors that can be intervened upon, including behaviours and biases of clinicians or institutes, which should be a focus of future research.

Table 1. Baseline characteristics and treatment outcome across groups of socioeconomic deprivation.

Background: Early treatment, within the window of opportunity, treat-to-target-(T2T) and tight control (TC) are fundamental principles of management in rheumatoid arthritis (RA). The Brasília Cohort of Early Rheumatoid Arthritis (BSB Cohort) is a real-life cohort designed and conducted under these principles.[1] The REAL study (Rheumatoid Arthritis in Real Life in Brazil) is a prospective multicentric cohort of patients with RA encompassing 11 public healthcare centers in Brazil, designed to reflect real-life, conventional managements conditions.[2]

Objectives: To compare early-treated patients with RA managed under the principles of T2T and TC vs. those exposed to conventional management in the long term, as for relevant clinical and radiographic outcomes, in real-life settings.

Methods: Participants from the BSB Cohort (under T2T and TC management) were compared to three randomly selected subsamples from the REAL study (REAL1, REAL2 and REAL3, exposed to conventional management). All patients initiated treatment with disease-modifying drugs (DMARD) within one

year of symptom onset. The groups were compared regarding the occurrence of erosive disease, use of corticosteroids (CE) and immunobiologicals (bDMARD), remission rates according to DAS 28-ESR and physical function (Health Assessment Questionnaire - HAQ).

Results: A total of 256 patients were included (64 from the BSB Cohort and 64 patients from each of the REAL1, 2 and 3 subsamples), predominantly female (88.3%), white (52%), with a mean age of 53.7 years, positive rheumatoid factor (73.4%), mean total disease duration of 94.1 months and delay time between first symptoms and use of first DMARD of 6.94 months. The groups compared did not differ significantly in terms of gender (χ^2 =6.19, p=0.103), race (χ^2 =7.68, p=0.053), age (F=1.28, p=0.279), presence of positive rheumatoid factor (χ^2 =1.89, p=0.594), mean disease duration (F=1.96, p=0.120) and time delay of symptoms until use of the first DMARD (F=0.34, p =0.793). The BSB Cohort showed significantly less frequency of erosive disease, use of CE and bDMARD, and higher DAS 28-ESR remission rate (Figure 1). Mean HAQ score was lower in the BSB Cohort (0.546) than in the REAL1 (1.033), REAL2 (0.821) and REAL3 (0.748), F=5,23, p=0,02. Mean DAS 28-ESR was lower in the BSB Cohort (2,90) than in the REAL1 (3,68), REAL2 (3,44) and REAL3 (3,21), F=3,43, p=0,018.

Conclusion: Under real-life conditions, in the long-term, adherence to T2T and TC principles was found essential to preserve the expected benefits of the early RA treatment within the window of opportunity, in terms of less occurrence of erosive disease, less use of CE and bDMARD, higher DAS 28-ESR remission rate and better physical function (lower HAQ score).

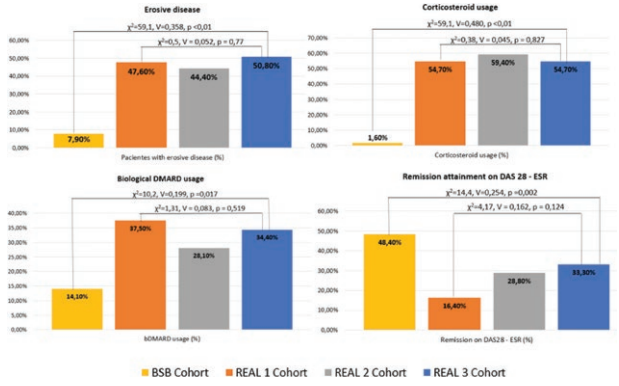

Figure 1. Comparison of the occurrence of erosive disease, CE and bDMARD use and the DAS 28-ESR remission rate in the BSB Cohort (strict control) and REAL cohorts 1, 2 and 3 (conventional control).Note: χ^2=chi squared; V=Crammer's V, p=p value (significant at <0.05).

LYME ARTHRITIS. A RARE BUT IMPORTANT CAUSE OF MONO – OR OLIGO ARTHRITIS IN DENMARK: A CASE SERIES OF LYME ARTHRITIS IN FOUR DANISH MALE PATIENTS

Keywords: Inflammatory arthritides, Infection-related RMDs

A. Ünlü[1], N. S. Andersen[2], S. Skarphedinsson[3], S. L. Larsen[2], S. Chrysidis[1], P. Lage-Hansen[1]. *[1]Esbjerg Hospital, Rheumatology, Esbjerg, Denmark; [2]Odense University Hospital, Clinical Microbiology, Odense, Denmark; [3]Odense University Hospital, Infectious Diseases Q, Odense, Denmark*

Background: Lyme arthritis (LA) is a rare manifestation of Lyme borreliosis in Denmark with an unknown incidence [1-2]. Typically, LA present with persistent or intermittent mono-arthritis in large joints especially the knees [3-4]. Clinically, LA does not differ significantly from other rheumatological oligoarthritic disorders, and due to a supposed low incidence, it poses a differential diagnostic challenge with risk of misdiagnosis.

Objectives: To describe a case series of four Danish patients diagnosed with LA from 2021-2022.

Methods: A case series.

Results: We describe a case series consisting of four Danish patients diagnosed with LA at the Department of Rheumatology, Esbjerg Hospital within a year (2021-2022). All patients presented with recurrent knee joint swelling, yet one patient also had arthritis in the upper extremities. All four patients reported previous tick bite, but none had a history of erythema migrans. The diagnosis was delayed up to one year due to lack of attention to LA as a potential differential diagnosis. The diagnosis was established based on the Borrelia burgdorferi sensu lato complex (B.b.s.l.) anti-IgG antibodies in patient serum and detection of B.b.s.l. DNA by real-time PCR of synovial fluid. All patients received antibiotics in a four-weeks period. However, one patient was re-treated because of recurrence of joint swelling in the upper extremities and detection of B.b.s.l. DNA by PCR in synovial fluid from the wrist joint, after completing the first line-antibiotic regimen. Three patients have fully recovered and have shown no sign of arthritis in a period ranging from 4 to 15 months. One patient is currently treated with Methotrexate.

Conclusion: This case series demonstrates that LA is an important differential diagnosis in persistent or intermittent mono – or oligo arthritis, especially in the knee joint. Lack of routine assessment of tick risk behavior, antibody status and/or assessment of the presence of B.b.s.l. DNA in synovial fluid by PCR methods, can lead to underdiagnosed cases. Obviously, insufficient examination can lead to a falsely assumed low incidence. It could be considered that the low incidence of LA in Denmark partly is caused by lack of attention to B.b.s.l. as a possible explanation for mono- or oligo arthritis. Clearly, this can lead to mistreatment.

POS0057

WHICH ADVANCED TREATMENT SHOULD BE USED FOLLOWING THE FAILURE OF A FIRST-LINE ANTI-TNF IN PATIENTS WITH RHEUMATOID ARTHRITIS? 15 YEARS OF EVIDENCE FROM THE QUEBEC REGISTRY RHUMADATA™

Keywords: Rheumatoid arthritis, Registries, Real-world evidence

D. Choquette[1], L. Bessette[2], L. Choquette Sauvageau[1], J. Brown[2], I. Ferdinand[1], P. Haraoui[1], M. Joly-Chevrier[3], A. Masetto[4], F. Massicotte[1], V. Nadon[1], J. P. Pelletier[1], J. P. Raynauld[1], D. Sauvageau[1], A. Turcotte[2], É. Villeneuve[1], L. Coupal[1]. *[1]Institut de rhumatologie de Montréal, Rhumatologie, Montréal, Canada; [2]Centre de l'ostéoporose et de rhumatologie de Québec (CORQ), Rhumatologie, Québec, Canada; [3]Université de Montréal, Médecine, Montréal, Canada; [4]Clinique de santé Jacques-Cartier, Rhumatologie, Sherbrooke, Canada*

Background: Since 2000, advanced therapies (AT) have revolutionized rheumatoid arthritis (RA) treatment. Initially, TNF-targeted therapies were the only options. Then, therapies with different modes of action (OMA) appeared. Habits and medication availability often determine second-line AT choices. Research suggests that specific sequences provide better long-term effectiveness [1,2].
Objectives: Evaluate which alternative medication provides the best sustainability following first-line TNF failure.
Methods: Data from AT prescribed since January 2007 was extracted from RHUMADATA™. Patients were followed until treatment discontinuation, loss to follow-up, or November 25, 2022. A descriptive statistic was used to compare patient characteristics. Kaplan-Meier was used to compare treatment discontinuation rates.
Results: A total of 611 patients (320 TNFi and 291 1237 OMA were included. The mean age at diagnosis was 44.5 (14.4) and 43.9 (14.8) in the TNFi and OMA groups, and disease duration at treatment initiation (TI) was 14.1 (11.1) and 12.9 (12.9). Women made up 72.8% and 81.1% of these groups. The age-adjusted Charlson Comorbidity index (ACCI) was 2.15 (1.7) and 2.1 (1.7). Patients reported more comorbidities, pain and fatigue, longer duration of morning stiffness, and higher HAQ score and disease activity in the OMA group (Table 1). The physician's global assessment of disease activity and the number of swollen and tender joints were also higher in the OMA group. OMAs retention was higher (Figure 1, logrank=0.0134) than TNFi retention following initial TNFi-IR. In a stratified analysis, rituximab (adjusted (Sidak) logrank=0.0048) had higher retention.
Conclusion: When a first TNFi fails, switching to an OMA, especially rituximab, appears to be the best strategy. Adequate assessment of more recent agents require longer observation periods.

POS0058

OBESITY ASSOCIATES WITH HIGHER LEVELS OF INFLAMMATION DURING THE DISEASE COURSE, BUT ONLY IN ACPA-POSITIVE RA

Keywords: Rheumatoid arthritis, Comorbidities, Outcome measures

N. Den Hollander[1], A. M. P. Boeren[2], A. Van der Helm – van Mil[1,2], H. W. Van Steenbergen[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [2]Erasmus MC, Rheumatology, Rotterdam, Netherlands*

Background: Obese rheumatoid arthritis(RA) patients have higher disease activity scores(DAS) and lower odds of achieving remission. Although it has been convincingly shown that obese RA-patients experience more pain and have lower wellbeing scores, results are conflicting whether obesity has "pro-inflammatory effects" measured by higher swollen joint count(SJC) and CRP-levels. Additionally, associations of obesity with the DAS-components have not been studied longitudinally and it is unknown whether "pro-inflammatory effects" are similarly present in ACPA-positive and -negative RA. As in vitro data suggested that ACPA can enhance inflammatory-responses, we hypothesized that the association of obesity with SJC and CRP is strongest in ACPA-positive RA.
Objectives: To increase the understanding regarding the effect of obesity on the course of disease activity by studying associations of obesity with DAS-components in ACPA-positive and ACPA-negative RA.
Methods: We studied 649 RA-patients (358 ACPA-positive, 291 ACPA-negative), consecutively included in Leiden Early Arthritis Clinic from May 2011 onwards, and with a total of 2871 DAS-measurements over 5 years. Courses of DAS44 and

DAS-components (SJC-44, TJC-53, CRP and VAS(0-100)) were compared between RA-patients with normal weight (BMI 18.5-24.9; reference category), overweight (25.0-29.9) and obese patients(≥30.0), stratified for ACPA-positivity. Linear mixed models and Poisson mixed models with a knot at 4 months were used.

Results: Obese patients had a 0.32 units higher DAS compared to normal weight at diagnosis, this persisted during follow-up. Stratification for ACPA revealed that obese ACPA-positive patients had a 0.43 units(95%CI 0.22,0.64) higher DAS over time, whereas this difference was smaller and not statistically significant in ACPA-negative RA (0.19 units; 95%CI -0.01, 0.38). In ACPA-positive RA, all DAS-components were significantly higher during all 5 years of follow-up in obese patients compared to normal weight: SJC +60% (IRR1.60; 95%CI 1.18, 2.16), CRP +3.7mg/L (95%CI 0.95, 6.53), TJC +55% (IRR1.55; 95%CI 1.15, 2.10) and VAS +9 units (95%CI 4.09, 14.16; Figure 1). However, in ACPA-negative RA, obese patients only had a statistically non-significant trend towards (22%) higher TJC (IRR1.22; 95%CI 0.96, 1.55) and (4 units) higher VAS (95%CI -0.41, 9.00). Moreover, in ACPA-negative RA obesity was not associated with higher SJC and CRP.

Conclusion: Although obesity confers risk for higher DAS-scores over time, the effects of obesity on higher SJC and CRP-levels are restricted to ACPA-positive RA. This is the first demonstration that the influence of obesity on the course of RA is different for the two RA-subtypes.

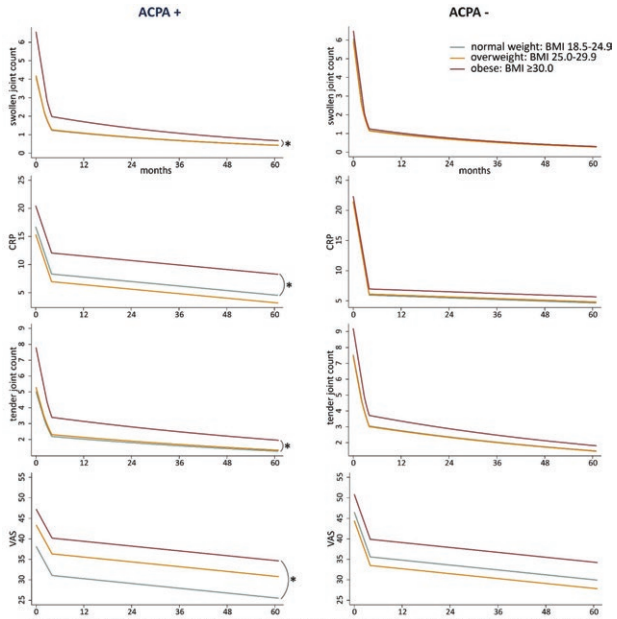

Figure 1. Obesity is associated with more swollen joints and higher CRP-levels over time in ACPA positive but not in ACPA negative RA patients

POS0059 **WITHDRAWN**

PARE Poster Tour 1

POS0060-PARE **UNDERSTANDING THE PATIENT PERSPECTIVE IN LIVING WITH AND TREATING SPONDYLOARTHRITIS**

Keywords: Quality of life, Spondyloarthritis, Patient information and education

H. Lapidus Glassner[1], B. Schneider[2], E. Luce[2], E. Peacock[3]. *[1]MyHealthTeam, Research, 94104, United States of America; [2]MyHealthTeam, Research, San Francisco, United States of America; [3]MyHealthTeam, CEO, San Francisco, United States of America*

Background: Spondyloarthritis (SpA), the group of conditions that includes ankylosing spondylitis, psoriatic arthritis, and non-radiographic axial spondyloarthritis, among others, can lead to symptoms of pain, stiffness, and swelling. The burden of disease can affect patients' quality of life.
Objectives: Patient research was undertaken to explore the impact of spondyloarthritis on quality of life, patients' ability to manage the disease, as well as experiences with healthcare providers. Better understanding is crucial to improving HCP-patient interactions, helping patients get on the right treatment path, and improving health outcomes.
Methods: In July 2022 an email invitation to an online survey was sent to members of MySpondylitisTeam, a social network of over 88,000 people. In total, 361 members completed the 25-question survey.
Results: 92% of members report that spondyloarthritis interrupts their quality of life (62% strongly agree and 30% somewhat agree) (Figure 1). SpA takes both a physical and emotional toll. 88% report it makes it hard to do everyday activities (54% strongly agree and 34% somewhat agree). Symptoms extend well beyond lower back, joint and hip pain (92%, 84%, and 81% experienced in the past year respectively). Virtually all experience fatigue (91%). Additionally, 61% have experienced symptoms of depression (63%) or anxiety (61%) in the past year. At the same time, just 52% believe they can ask doctors and have meaningful discussions about SpA and how best to manage it (27% strongly agree and 25% somewhat agree) (Figure 2). Only 35% are satisfied with the care they receive from the doctor who primarily treats their SpA. 38% indicate that the doctor recommends treatment based on their personal needs, and 36% indicate that the doctor addresses their SpA symptoms.

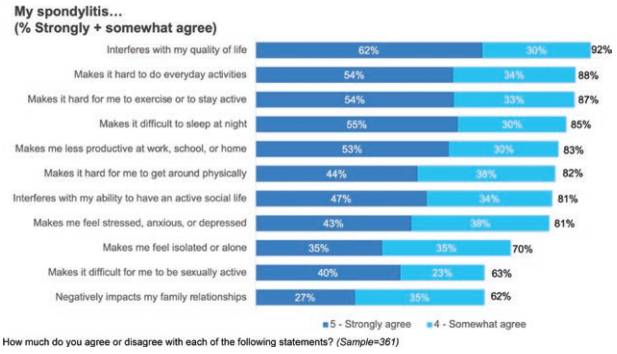

Figure 1. Impact on Quality of Life

How much do you agree or disagree with each of the following statements? *(Sample=361)*

Discussions with the doctor who primarily treats spondylitis *Among all who see a doctor*	
Listens to me and understands my specific needs	35%
Recommends treatment based on my personal needs	38%
Recommends regular check-ups to assess how I am doing	46%
Has developed a long-term treatment plan	20%
Provides information on potential side effects of different treatments	25%
Provides information on potential effectiveness of different treatments	29%
Addresses symptoms of spondylitis such as pain or fatigue	36%
None of the above	30%

Figure 2. Patient Discussions With Doctors

Which of the following reflect the discussions you have with the doctor who primarily treats your spondylitis? Please select all that apply. *(Sample=304)*

Conclusion: Understanding the needs of SpA patients provides significant opportunities for rheumatologists and primary care physicians to better support and educate their patients. This includes discussing potential treatment options, listening to patient concerns, and acknowledging the mental health challenges.

POS0061-PARE **DEVELOPMENT OF AN EDUCATIONAL MATERIAL TO PROMOTE HEALTH IN FIBROMYALGIA FOR THE SUBWAY IN THE CITY OF SÃO PAULO, BRAZIL**

Keywords: Fibromyalgia, Non-pharmacological interventions, Patient information and education

L. Couto[1], A. Lira[1], M. Antunes[1], M. Pinheiro[1], I. M. B. De Souza[1], A. Cruz[1], P. Januário[1], A. Pasqual Marques[1]. *[1]University of São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy (FOFITO), São Paulo, Brazil*

Background: The recommendations reviewed by the European League Against Rheumatism (EULAR) for the management of fibromyalgia indicate the importance of combining pharmacological and non-pharmacological interventions. In addition, these guidelines highlight that the initial non-pharmacological strategy should be patient education centered on the process of adapting and coping with fibromyalgia in quality of life.
Objectives: Develop and validate an educational material to promote health in fibromyalgia and disseminate it to the community in the subway of São Paulo - SP, Brazil.
Methods: For the construction of educational material for dissemination, the following steps were followed: Step 1: Identification of the needs of individuals with fibromyalgia and health professionals in which a qualitative research was carried out, through a focus group (a group of patients with fibromyalgia and another of health professionals). Twelve individuals with fibromyalgia and 10 health

Figure 1. Educational material to promote health in fibromyalgia in Brazil.Source: the authors.

professionals in Brazil were invited to participate. The group meeting sought to identify, through the participants' speech, what are the needs and problems reported by individuals with fibromyalgia and the possibilities of guidance by an interdisciplinary team of professionals to meet the needs and solve the problems. Qualitative data were analyzed using the content analysis method proposed by Bardin. The construction of the educational material used the Paulo Freire method, which began with an important survey to identify the primary needs of the participants so that they could be worked on so that, subsequently, the awareness process would take place. The researchers developed educational material containing information that was listed by individuals with fibromyalgia and health professionals. The educational material was made in online format.

Results: The educational material was developed based on the contents proposed in the previous phases and is shown in Figure 1.

Conclusion: The present study can contribute to the dissemination of educational strategies that promote health in fibromyalgia, for patients and for community, in order to disseminate scientific knowledge about the syndrome.

POS0062-PARE GREAT SUCCESS FOR THE GERMAN PATIENT RESEARCH PARTNERS (PRPS): FROM THE CALL TO TENDER TO WINNING THE AWARD

Keywords: Patient-led research, Best practices, Patient information and education

C. Elling-Audersch[1]. [1]*Deutsche Rheuma-Liga Bundesverband e.V., Voluntary assistant, Bonn, Germany*

Background: The Deutsche Rheuma-Liga is a patient organisation with about 270 000 members. We have a long history of an established PRP network. We enjoy an excellent cooperation with our professional PRP-facilitator from the steering committee of our organisation. Our patient organisation provides tools, the PRP reference-cards and a helpful brochure, and takes care of the continuing education of the PRPs.

Objectives: In 2022, the Deutsche Rheumastiftung (DRS; German Rheumatism Foundation) for the first time launched the call for the „Projektpreis". Four prizes were awarded with 10.000 € per prize; and at least one of them had to be a participatory research project. This was the starting point for the German PRP network. The immediate aim was to win at least one of the awards. The overarching aim was to realise, for the first time in the field of German rheumatology, a research project initiated by PRPs.

Methods: In order to forward the call and set out the details of the applications, the first meeting was organised by our research facilitator. We discussed various ideas and evaluated whether the objectives can be achieved or not. The subsequent meetings were organised by the PRPs themselves. We improved the initial ideas and searched for supporting researchers, in order to substantiate the planned research projects and write the applications.

Results: Not all ideas from our PRPs were submitted, because of time limitations and difficulties in finding an adequate researcher. In the end, three participatory research projects from German PRPs applied for the "Projektpreis". The topics of the applications were a) money for disseminating the outcomes of a participatory research project addressing fatigue in Lupus patients, b) initiation of a participatory research project investigating how patients search, find and use web-based disease information in everyday life and c) initiation of a participatory research project investigating biomarkers for fibromyalgia. The total number of applications submitted to the DRS was 14. Finally, two participatory research projects from German PRPs won two of the four prizes. The award ceremony took place during the scientific congress of the German Society for Rheumatology in Berlin.

Conclusion: It was a great honour for the German PRPs receiving the awards for applications based on their own initial ideas. For the Deutsche Rheuma-Liga this was a great success in terms of supporting participatory research. This example shall encourage other patient organisation to be confident in finding and creating their own participation-research project.

POS0063-PARE PIONEERING HEALTH CENTER FOR RMD PATIENTS BY HELLENIC LEAGUE AGAINST RHEUMATISM (KAVALA BRUNCH)

Keywords: Best practices, Quality of care, Quality of life

T. Makidou[1], G. Foteinopoulos[1], A. Lygera[1], S. Foteinopoulou[1], G. Kabatzi[1], M. Kostaki[1], A. Emmannouilidou[1], G. Efthymiou[1], E. Kostoglou[1], N. Paraschaki[1], A. Nasi[1], T. Temekonidis[1], P. Kitsos[1], M. Kontostoli[1], K. Antonopoulou[2], A. Pappa[2], N. Malliou[3], S. Argyriadoy[1]. [1]*Hellenic League Against Rheumatism, Pioneering Healt Center For RMD Patients, Kavala, Greece;* [2]*hellenic League Against Rheumatism, Headquartes, Athens, Greece;* [3]*hellenic League Against Rheumatism, Thessaloniki Branch, Thessaloniki, Greece*

Background: It is common ground, especially in rural and semi-rural areas, that Rheumatic Diseases (RD) patients are, usually, treated by the health and social care system as "consumers" rather than "partners". Moreover, the same system restricts specialized professionals (occupational-therapists, physiotherapists, etc.), of the proper exercise of their duties, that is providing psychological and social support to the patients.

Objectives: The creation of a pioneering health center for RMD patients, with patient – centered structure, free of charge, with access to a variety of services and supported by a multidisciplinary team of volunteers.

Methods: The health center is staffed by 18 persons. They are 14 health professionals in general medicine, rheumatology, physiotherapy, psychiatry, nutrition, occupational therapy, nursing, gymnastics, social working, pedo-physiotherapy and 4 for secretariat. They are all working voluntarily.

The services provided by HELAR/ELEANA's branch in Kavala in the pioneering Health Center are:

A. Assistance to RMD patients by
   - informing and guiding
   - providing psychological support
   - consulting about professional re-orientation
   - providing healthcare with medication

B. Raising awareness about the importance of RD's to the general public and all competent agencies and stakeholders

C. Promoting research for better understanding and treatment of RMDs.

The team adopts an integrated, comprehensive approach with patients' autonomy, values and expectations at its core.

Results: During the period 13/11/22 - 23/12/22, 68 patients were examined by the team, 61 females (average age 63.29 (sd=4.9) and 7 males average age 66.7 (sd=6.4). 42 out of the total were from Chrisoupolis, with basic education level, and low economic status. According Arithmetical Pain Scale (NRS) males scored average 6.71 (sd1.1) and females 6.33 (sd=1.4). Analysis showed a strong correlation between pain and rigidity (p=0.001). More than 3 specialists were used for every patient. All patients had a follow-up visit and are still being followed up by our team.

Conclusion: The pioneering Health Center of HELAR/ELEANA offers its services to patients whose medical needs can be met within the capability of its staff and facilities. The population served at Health Center includes all ages regardless of national or ethnic origin, economic status, lifestyle, creed, or philosophical beliefs. Patients can expect appropriate procedures, treatments, interventions and care will be provided according to established policies, procedures, protocols and order sets that have been developed to ensure patient safety and positive outcomes. Appropriateness of procedures, treatments, interventions, and care are based upon patient assessments, re-assessments, and desired outcomes. Respect for patient individual needs, rights and confidentiality are maintained. The scientific evaluation of the effects of RMDs will help us to improve their clinical picture as a whole. Future use of specific tools and scales is expected to be implemented to measure broader and more specific indicators to evaluate the effectiveness of Health Center's services.

Acknowledgements: In this effort, we were granted institutional support from Nestos' Municipality, providing us with the building and covering all the fixed costs.
Disclosure of Interests: None Declared.

POS0064-PARE PATIENT REPORTED BENEFITS OF PARTICIPATING IN AN ONLINE HEALTH COMMUNITY IN MANAGING RHEUMATOID ARTHRITIS

Keywords: Quality of life, Rheumatoid arthritis, Self-management

B. Schneider[1,1], K. Benny[1], E. Luce[1], E. Peacock[2]. *[1]MyHealthTeam, Research, San Francisco, United States of America; [2]MyHealthTeam, CEO, San Francisco, United States of America*

Background: Previous research has shown that participation in online health communities can increase patient engagement, improve patient education, and help empower patients to achieve better health outcomes. This study was designed to measure the impact of one such community on patient outcomes.
Objectives: Patient research was undertaken to better understand the impact of rheumatoid arthritis (RA) on quality of life (QoL) and the perceived benefit that participating in a patient social community in RA has on improving health outcomes. This includes better QoL, better understanding of and adherence to treatments and improved relationships with one's doctor.
Methods: In August 2022, an email invitation to an online survey was sent to US members of myRAteam, a social network of over 197,000 people. In total, 745 members completed the survey. All respondents were 21 or older and self-reported as diagnosed with RA.
Results: The far-reaching impact of RA on QoL was evident in that most respondents reported that they find it hard to exercise (90%) and do everyday chores (90%). Respondents also reported that RA interferes with sleep (83%) and having an active social life (80%). The emotional toll of RA manifested with respondents feeling isolated/alone (71%), anxious (75%), and depressed (77%). While RA patients had a good understanding of the role medications play in slowing RA progression (91%) and potential symptoms they might experience (90%), only half (53%) felt they could avoid triggers that worsen RA. Top reasons for joining myRAteam included seeking information/ways to manage RA and being able to connect with others living with RA. Specifically, respondents were looking to gain insights from others' experiences (65%), gather information about RA (60%), better understand treatment options (59%) and have a way to connect with others (45%) for support and tips for living with RA. Newly diagnosed patients were much more likely to join myRAteam to understand what to expect after their diagnosis (68% versus 38% for those living with RA for more than a year), to get information about RA (70% versus 59%) and to better manage their symptoms (67% versus 52%). Almost all (90%) reported benefiting from joining myRAteam, including gaining knowledge about RA (77%), having better knowledge of/ability to stay on medication (56%) and having an improved relationship with their doctor (68%). Additionally, 66% benefited from receiving some form of social/emotional support from others. Specifically, they felt less isolated or alone (41%), better able to cope with the emotional toll of RA overall (37%) and less anxious or depressed (20%). Benefits were particularly evident for frequent visitors. For example, 85% of daily visitors to myRAteam are able to find information/resources to manage RA and 75% have experienced an improved relationship with their doctor. And 53% of frequent visitors feel less isolated/alone versus 29% of less active users.

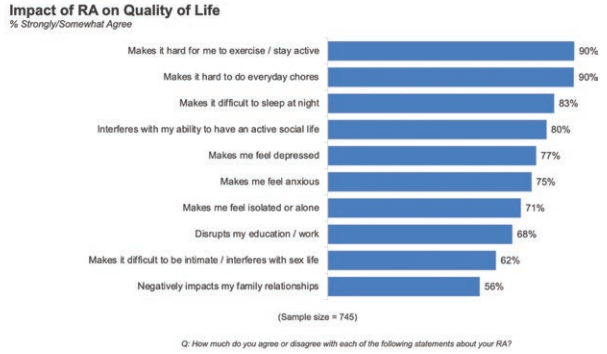

Figure 1.

Table 1.

Benefits of Joining myRAteam	Total Sample (N = 745)
Net Improved Knowledge About RA	**77%**
Understand symptoms of RA	55%
Find useful ideas to improve QoL	48%
Net Social Impact	**66%**
Feel less isolated/alone	41%
Better able to cope with emotional burden	37%
Net Medication Awareness/Adherence	**56%**
Discover different treatment options	44%
Better manage medication side effects	21%
Stay on prescribed treatment longer	16%
Net Improved HCP Relationship	**68%**
Ask better informed questions	47%
Raise concerns about RA symptoms	37%
Have quality conversations	30%

Conclusion: People with RA, particularly those recently diagnosed, are turning to online communities to find disease-specific medical information and support that they are not getting elsewhere. The majority of those surveyed report several benefits from participating in this community that are linked to improved health. Educating patients on the benefits of participating in a health-related social community can lead to less isolation and other mental health challenges, better informed patients, better treatment adherence and more empowered and productive conversations with the treating doctor. Reaching newly diagnosed patients can help lessen the burden of disease and set patients on the right treatment course to slow progression from the onset.

POS0065-PARE EDUCATION FOR PATIENTS, DESIGNED BY PATIENTS: THE EXPERIENCE IN THE DESIGN OF A RHEUMATOID ARTHRITIS PRIMER

Keywords: Patient information and education, Rheumatoid arthritis, Education

F. Rodriguez[1], L. Realpe[2], Z. Castaño[2], G. S. Rodríguez-Vargas[3], A. Rojas-Villarraga[4], P. Santos-Moreno[5]. *[1]BIOMAB, Patients education, Bogotá, Colombia; [2]UniversitAR, Expert Patient, Bogotá, Colombia; [3]BIOMAB, Scientific Direction, Bogotá, Colombia; [4]Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia; [5]BIOMAB, Rheumatology, Bogotá, Colombia*

Background: In 2018, thanks to the support of a government entity, the UniversitAR multi-component educational program was launched; which trained more than 300 patients and certified 50 expert patients in Rheumatoid Arthritis in 2021. In this educational process, patients received training in various knowledge topics for disease care: definitions, signs and symptoms, treatment, medical team, therapeutic adherence, quality of life and transformation of personal behavior to manage relationships and situations. As a result, the educational program proposed the design of educational material that would be useful for the patient population.
Objectives: The objective of this project was to design a primer for patients with rheumatoid arthritis, which helps them understand the disease and the importance of long-term treatment, understand and apply therapeutic adherence, and change the way in which patients assume their role in treatment.
Methods: An editorial committee was created to write the primer. This committee was made up of 8 patient experts in rheumatoid arthritis, 1 rheumatologist, a coordinator of education programs for chronic patients, and a team of content reviewers. The writing of the primer began with a selection of the thematic contents with the greatest impact in their educational process and the writing of the initial manuscript began (by patients for patients). Afterwards, a first revision of the manuscript was made and some contents were adjusted according to the clinimetric standards for international rheumatology. Finally, the manuscript was submitted for review by the team of rheumatologists and the interdisciplinary team, thus creating the final version of the primer.
Results: In December 2022, an event for patients with Rheumatoid Arthritis was held. In this event the primer was presented and its purposes were explained. The primer gathers topics such as: disease definitions, signs and symptoms, diagnosis and treatment, disease impact, therapeutic adherence, myths and beliefs, the medical team, health literacy, and expert patients (See figure 1). In 2023, this primer will be delivered to all patients so that they can have a source of consultation and information.

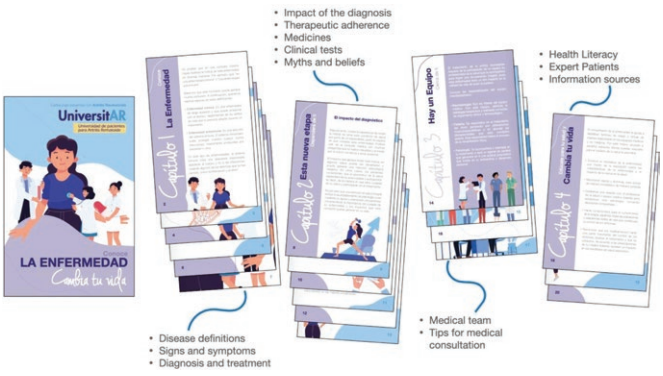

Figure 1.

Conclusion: It is important to support the dissemination of educational content so that patients have reliable, accurate and oriented information to improve their participation with medical teams in shared decision-making to achieve therapeutic objectives together.

Acknowledgements: We thank the Ministry of Science, Technology and Innovation MINCIENCIAS for allowing us to design this primer and for being able to train our patients. Also, we thank the patients who are part of the editorial committee that designed this primer.

POS0066-PARE LIFE WITH A CHRONIC ILLNESS - WHAT NOW? HOW TO LIVE WITH AXIAL SPONDYLOARTHRITIS, A LIFELONG ILLNESS

Keywords: Spondyloarthritis

L. Wermskog[1], L. M. Eidet[1], K. Lilleby[2]. [1]*Spondyloarthritis Association Norway, N/A, Oslo, Norway;* [2]*Novartis, Oslo, Oslo, Norway*

Background: Axial spondyloarthritis is a chronic inflammatory joint disease, which mainly attacks the pelvis, back, neck and thorax, but peripheral joints can also be affected. This patient group is affected to a very varying degree and the disease varies throughout the course of the disease. Some have mild symptoms and may be without ailments for long periods of time. Others have major ailments and may experience increasing stiffness in the back. The average age at the onset of symptoms of AS is 26 years.

Objectives: The aim of this campaign is to focus on life with a chronic illness. How to mentally master your illness and accept it, but also how to be active with the disease. The campaign aims to break down prejudices and discrimination that chronic sufferers are faced with in society, for example that they are weaker or lazier than others. These prejudices help to make the disease a strain mentally as well. Many patients struggle to accept that they have contracted a chronic illness, a disease that stays with you for life.

Methods: Giving this campaign a face, we used a world-renowned photographer and social debates Morten Krogvold to take pictures of Felix Baldauf, world champion in wrestling, living with axial spondyloarthritis. Films were made of Felix's story, about the road to a diagnosis and about the afterlife diagnosis. In the films, Felix honestly tell how tough and difficult this road has been for him, but at the same time he talks about how life has changed now that he has been diagnosed and properly treated. His goal is now a gold medal in wrestling at the 2024 Olympics, even though he's living with axial spondyloarthritis, which shows that it is possible to live a good life with the disease and have an active physical life. In order to get as much attention as possible about the campaign, it was launched at political week in Arendal. The films and photos are being shared in social media, and we have published digital booklet with artistic photos. The main film has so far reached 3200 people. We had an event at Litteraturhuset in Oslo together with a rheumatologist and a physiotherapist where we talked about being able to live a good life with the disease. We also recorded a podcast about the campaign.

Results: By using famous people the campaign has gained a familiar face and at the same time received a lot of attention. Felix tells about a great mental strain not knowing what was wrong with him, but it is fantastic to see that it is possible to live well with the disease when getting treatment.

Conclusion: The campaign gives hope and inspiration to patients that it is possible to live well with the disease. It shows that you can be very physically active, but at the same time show that there are both ups and downs with the disease. Felix's openness about the disease leaves hope for other patients, that one can live a good and active life with the disease.

Acknowledgements: The patient campaign is supported by the Norwegian Directorate of Health, Novartis, AbbVie.

POS0067-PARE USING AI BASED TECHNOLOGY TO GAIN INSIGHTS FROM OSTEOARTHRITIS PATIENTS IN THE UK VIA SOCIAL LISTENING

Keywords: Osteoarthritis, Real-world evidence, Artificial Intelligence

N. Betteridge[1], G. Petersen[2], T. Andreu[3], M. Hartung[4]. [1]*Neil Betteridge Associates Limited, Director, London, United Kingdom;* [2]*Grünenthal, Medical Affairs, Aachen, Germany;* [3]*Semalytix GmbH, Deployment Strategy, Bielefeld, Germany;* [4]*Semalytix GmbH, Research & Development Office, Bielefeld, Germany*

Background: Osteoarthritis (OA) is a chronic degenerative joint condition associated with joint pain, stiffness, and mobility problems. More than half of OA patients live with moderate or severe pain[1], impacting all aspects of their lives and decreasing their overall Quality of Life (QoL). Social listening enables insight generation beyond the healthcare setting, demonstrating a more comprehensive view on disease burden and patient experiences. This study utilizes a unique approach based on Artificial Intelligence that analyses high volumes of data both quantitatively and qualitatively of patient-authored content.

Objectives: The study aims at exploring patient-generated online data as a source for capturing the real-world experience of OA patients, as reported by a large online population in the UK. A particular focus is on understanding the individually perceived disease burden in terms of symptoms, patient-reported QoL[2] and surgical treatment options.

Methods: A sample of real-world data from online health communities in the UK was collected between Oct 2019 until Jan 2022, resulting in a data set comprising n=6,354 algorithmically identified OA patients and n=42,353 posts (documents). OA-specific concepts to identify patient experiences were algorithmically coded using supervised machine learning, natural language processing (NLP) and knowledge graph tagging. An algorithmic stack of 40+ dedicated NLP analyzers was applied to detect key concepts and their relations of the patient experience in the posts (symptoms, their severity, impacts on QoL facets, perception of treatment options). Data were collected and processed in an anonymized, secure, and reliable way to ensure privacy and ethical aspects.

Results: Age could be algorithmically determined for N=1,012 patients (16 % of total patients), 56% of whom are older than 50 years. Pain was the most discussed symptom (58% of patients; N=3,703). N=1,508 patients underwent surgeries, with hip (N=762) and knee replacements (N=674) as most reported procedures. Recreation & Leisure and Mobility were the most prominent QoL aspects (31% and 28% of patients). Healthcare availability (e.g. access to treatments) was raised by N=668 patients (11%); a proportion of these (N=150) also underwent hip or knee replacement, with more than half reporting having been on a "waiting list" for their surgical procedure.

Figure 1 shows five QoL aspects most relevant for patients with knee or hip replacement, together with improvement or worsening of the respective QoL aspect. Notably, a majority of patients in both groups report mobility and healthcare availability to deteriorate rather than improve.

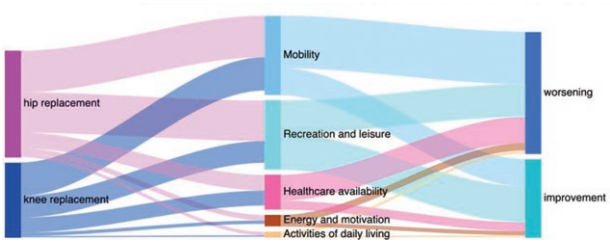

Figure 1. Sankey chart illustrating improvement or worsening (right) of the five most mentioned QoL aspects (middle) of patients with a knee or hip replacement procedure (n=266 documents)

Conclusion: This social listening study indicates pain as the most burdensome OA symptom and sheds light on the QoL impact of surgical procedures. Given limitations of social listening studies (e.g. number of identifiable age groups or gender)[3], the results need to undergo further validation by patient representatives and clinical experts. Yet, this novel method complements common approaches by providing an understanding of patients' perspectives outside the clinic, representing the voices of vulnerable populations who may not otherwise participate in clinical or epidemiological studies.

POS0068-PARE VITORIA, A VIRTUAL ASSISTANT TO PROMOTE EDUCATION AND AWARENESS ON JUVENILE RHEUMATIC MUSCULOSKELETAL DISEASES

Keywords: Patient information and education, Non-pharmacological interventions, Self-management

J. Borda D'água[1], A. P. Cláudio[1], M. B. Carmo[1], M. Guerreiro[2], A. Cavaco[3], D. Piedade[4], C. F. Gomes[4,5], A. Pais[4], E. Mateus[5]. *[1]Faculdade de Ciências da Universidade de Lisboa, Informática, LASIGE, Lisboa, Portugal; [2]Egas Moniz School of Health & Science, Egas Moniz Center for Interdisciplinary Research, Lisboa, Portugal; [3]Faculdade de Farmácia da Universidade de Lisboa, imed — Research Institute for Medicines, Lisboa, Portugal; [4]National Association of Patients with Juvenil Arthritis, ANDAI, Lisboa, Portugal; [5]Portuguese League Against Rheumatic Diseases, LPCDR, Lisboa, Portugal*

Background: The range of musculoskeletal and connective tissue conditions that manifest in children is referred to as paediatric rheumatic diseases[1]. Juvenile idiopathic arthritis (JIA) is the most common childhood chronic rheumatic disease[2]. This disease is the most frequent cause of chronic pain in young people, which negatively affects their quality of life. To mitigate the burden of chronic condition, self-management (e.g., lifestyle) should be combined with medical management. More effective information strategies are required to respond to the needs of those living with rheumatic diseases and their caregivers. Virtual Humans (VH) have been utilized in interactive computational simulations to boost users' acceptability and knowledge of health conditions while also promoting lifestyle changes in healthy individuals or in the management of chronic illnesses, such as juvenile rheumatic musculoskeletal diseases (RMDs)[3,4].

Objectives: This project aimed to develop a web application to support education for disease management and health promotion, in children and young people with RMDs, their caregivers and peers[5].

Methods: The use of gamification as well as a virtual character incorporated in a narrative, with the dual goal of maintaining user engagement and improving the play experience, was the core idea underpinning the development of our application. Group discussions with youngsters (members of the patient organisation ANDAI) were used to obtain feedback and experiences from application users during the requirement phase, intermediate feedback and testing the developed application. The application was also assessed by an evaluation survey following the testing phase.

Results: A virtual assistant was developed to communicate with users through speech (voice and subtitles) as well as face and body motions[6]. This 2D animated young female model, portrays a character with juvenile RMDs and shares information about her lived experiences with the illness. An assessment of user knowledge follows each interaction. Users are encouraged to play and learn more by awarding points and digital badges for right answers or by displaying the solutions when incorrect answers are chosen. In short, on a scale of 1 to 5, 83% of the participants in application testing rated the application with maximal punctuation, indicating that users, which were children with RMDs, their young relatives and/or friends, found this tool useful.

Conclusion: A virtual assistant web application that uses a narrative approach and gamification concepts to encourage education on juvenile RMDs was successfully developed. This web application is intended to be lodged on the ANDAI website to convey easy access. In addition, this tool will be also made available in tablets at the waiting room of paediatric rheumatology services, facilitating education when children are diagnosed.

POS0069-PARE HOW TO REACH MORE PEOPLE WITH RMD THROUGH DIGITAL COUNSELLING

Keywords: Self-management, Mental health, Patient information and education

N. B. Hartz[1]. *[1]Gigtforeningen, Rådgivningen, Gentofte, Denmark*

Background: The Danish Rheumatism Association has a professional counselling service, where our 82.000 members can call or write to get help and answers to their questions. The association had planned to make our counselling offers more digital over time but due to corona in 2020 we decided to advance the launch of these digital offers since all our usual meetings and activities got cancelled overnight.

Objectives: The association wants to be as relevant as possible to all people with RMD and therefore we wish to be present, not only at our usual platforms, but also through digital solutions. Since 2020 the professional counselling has, in collaboration with the communication department, made short videos on SoMe and broadcasted live events on relevant topics with experts, where the viewers have the possibility to interact with questions and emoji's during the live events. It is also possible to watch the live events afterwards. Since 2022 the association has increased the digital offers within counselling to also include explainer videos and livestreaming from public meetings at hospitals. Our aim is to give relevant information that help people with RMD to improve their capability of self-management and get them to connect and interact even more with us.

Methods: The first digital events were made with a handheld mobile camera and the sound was not very good. The events were transmitted live on the association's Facebook page. This new way of approaching people with RMD with professional counselling through live events was successful and had more viewers than we had expected even though the quality in the beginning was poor. This shows that even with scarce resources you can still reach many people with RMD through digital solutions. After a while we hired a professional company to make our live events more professional with correct light and sound, and today we are on a much higher level than at the beginning of our digital transmissions. We have also expanded our ways of making live events from 1-2 experts talking on a specific topic to also include panel discussions, live broadcasting from large public events, explainer videos, live interviews with medical doctors at hospitals etc.

Results: In 2022 the professional counselling service have produced 2 explainers, 8 live events and 12 videos. The topics of the broadcasts were for example pain, sexuality, exercise, mental health, social issues, newly diagnosed etc. The number of people we have reached with the digital counselling will be elaborated on the EULAR congress. We have indications showing that more young people are aware of the association and our professional counselling after having provided more digital services with the possibility to interact or to watch it whenever it suits the person. Furthermore it is a cost effective way to reach a lot of people at one time compared to our 1-on-1 phone consultations in our professional counselling. The downside of doing digital events is that you do not get the personal and direct connection between the professional and the person with RMD and the advice that is given will be more general compared to a telephone conversation. Furthermore, it requires access to the Internet and a Facebook account or similar. Some elderly people can therefore not participate

in these events. However, in 2022 we offered physical events as well. We are trying to reach out as broadly as we can in order to meet the different needs from people with RMD.
Conclusion: The use of live events and videos is a way to unfold the professional counselling service in order to give help and advice to a broader audience. It has been a huge success with many viewers who interact with us. These digital offers are contributing to make the Danish Rheumatism Association appear as a modern and progressive association. An important notice when wanting to become more digitalized as a patient organization is, that even on a low budget you can reach many people with RMD as long as the content is relevant. We will for sure develop even more digital offers in the future regarding patient information and education in order to improve the quality of life for more people with RMD.

POS0070-PARE **CAREGIVER BURDEN AMONG IDIOPATHIC INFLAMMATORY MYOPATHY (IIM) CAREGIVERS**

Keywords: Myositis, Patient-led research, Quality of life

M. Lubinus[1], Y. P. Hu[1], L. Wilson[1], J. Williams[1], A. Bhashyam[2], S. Bhai[3].
[1]Myositis Support and Understanding, Patient-Centered Research, Lincoln, DE, United States of America; [2]Massachusetts General Hospital -, Surgery, Boston, United States of America; [3]U of Texas Southwestern Medical Center, Neurology, Dallas, United States of America

Background: Idiopathic inflammatory myopathies (IIMs) often lead to severe impairments in quality-of-life related to physical and emotional burdens. While the healthcare delivery burden in patients with specific types of IIMs has been explored[1], little is known about caregivers' burden, especially in rare diseses.[2]
Objectives: Myositis Support and Understanding (MSU), a non-profit patient-led advocacy organization for IIMs, distributed a survey to its members to better understand caregiver burden. The aim of this study was to evaluate the association between caregiver burden by IIM subtype and factors that impact caregiver wellbeing.
Methods: *Data Source:* An anonymous survey was distributed via RedCAP to MSU members worldwide. A total of 120 caregivers (age range: 30-89) responded to the survey over the course of 4 weeks. *Survey*: Demographic, diagnostic information, and disease duration data was collected from participants and their caregivers. The Zarit Burden Interview (ZBI), a validated instrument for a diverse range of patients and caregivers, was used to determine caregiver burden, testing domains including health, mental well-being, personal relationships, physical overload, social support, and home environment[3]. *Statistical analysis*: Pearson chi-square test was performed to assess the association between duration of caregiving, myositis type, and caregiver age on the social well-being of caregivers. Regression analysis was also conducted to identify risk factors for increased caregiver burden. Significance was set at $p<0.05$.
Results: Most of the caregivers in this study were responsible for the care of participants with inclusion body myositis (IBM, 64%) followed by dermatomyositis (DM, 22%). Caregivers reported that 74% of IIM patients under their care had moderate to severe difficulties with mobility and required help some or most of the time. A total of 102 caregivers completed the ZBI: reported burden was mild to moderate in 44%, moderate to severe in 25%, and severe in 4% of caregivers. There was a high degree of at least moderate severity burden in IBM (33%), DM (25%), and polymyositis (25%).
Conclusion: Caregivers face a high degree of burden, most evident in IBM. Burden positively correlated with disease duration with an inflection time of 6 years, thereafter caregivers reported increased burden. The domains that were most impacted include personal strain, social and family life, role strain, and loss of control over one's life. Insights from this study can help create specific emotional coping strategies for myositis patients and their caregivers.

HPR Poster Tour: Diverse interventions and patient perspectives

POS0071-HPR **PHYSICAL THERAPY, PHYSICAL ACTIVITY AND PHYSICAL FITNESS IN PSORIATIC ARTHRITIS: A SYSTEMATIC REVIEW**

Keywords: Physical therapy/Physiotherapy, Psoriatic arthritis, Systematic review

M. Kaerts[1], J. Eelen[2], N. Plancke[2], F. Van Loock[2], A. Liekens[2], K. De Vlam[1,3], R. Lories[1,3], W. Dankaerts[2], T. W. Swinnen[1,2,3], B. Neerinckx[1,3]. *[1]KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium; [2]KU Leuven, Research Group for Musculoskeletal Rehabilitation, Leuven, Belgium; [3]University Hospitals Leuven, Division of Rheumatology, Leuven, Belgium*

Background: Patients with psoriatic arthritis (PsA) have a remarkable increased risk for cardiometabolic comorbidities impacting their disease management and functioning. Studies in the general population have demonstrated that higher levels of physical activity, better cardiorespiratory fitness and muscle strength improve cardiovascular and all-cause mortality risk.[1] Physical therapy is highly recommended as part of the non-pharmacological management of PsA patients.[2-4] Physical activity recommendations were composed but specific guidance on the type, duration or intensity was not provided.[5] Therefore, a summary of the available evidence on physical therapy, physical activity and physical fitness in PsA patients is needed to strengthen the non-pharmacological management.
Objectives: This study aimed to systematically review and appraise the quality of research on physical therapy, physical activity and physical fitness in PsA patients.
Methods: The protocol was prospectively registered at the PROSPERO database (ID 255501). A systematic literature search was performed in May 2022, using four different databases (Medline, Embase, Web of Science and Cochrane library). We included papers examining physical therapy, physical activity and physical fitness (cardiorespiratory and muscular fitness) in PsA patients, with a minimum age of 18 years and diagnosed by a physician, classification criteria or self-reported. A mixed population of patients with rheumatic and musculoskeletal diseases was allowed if the proportion of PsA patients was at least 10%. All eligible interventional or observational (quantitative or qualitative) studies with a full-text paper written in English or Dutch were included without restrictions regarding the publication year. The quality was assessed through the Newcastle-Ottawa Scale and the Revised Cochrane risk-of-bias tool for randomized trials. A meta-analysis was not possible due to the wide variety of interventions and outcomes. Therefore, a narrative synthesis was used.
Results: After deduplication, a total of 6026 abstracts were retrieved, of which 380 abstracts were selected for full-text analysis. Ultimately, 85 papers published between 1994 and 2022 were included, of which 6 papers were added from screening references. Most studies were cross-sectional (n=31) or randomized controlled trials (RCT; n=18). Forty-seven % of the studies consisted of PsA patients only. Low risk of bias was scored in 2 RCTs, 1 cohort study (n=3), 4 case-control (n=9) and 7 cross-sectional studies. The risk of bias was mainly increased due to selection bias, the use of non-validated and/or patient-reported outcomes and the lack of blinding possibilities in case of physical therapy intervention. In 23 papers physical activity was measured, of which 8 studies used a validated questionnaire and only 1 study used an objective method. Cardiorespiratory and muscular fitness were assessed in 5 and 9 studies respectively. A variety of physical therapy interventions were studied: resistance training (n=1), cardiorespiratory training (n=2), mind-body exercises (n=3), behavioural change programs (n=2), therapeutic modalities (n=4) and mixed rehabilitation programs (n=5). One RCT with low risk of bias evaluated an increase in cardiorespiratory fitness and a reduction in truncal fat percentage in PsA patients after 11 weeks of high intensity interval training. Qualitative research (n=11) emphasized the need of patients for education.
Conclusion: Scientific evidence on physical therapy, physical activity and physical fitness in PsA is limited. Further research is needed on non-pharmacological interventions and aspects in general, especially on physical fitness.

POS0072-HPR EXERCISES TRAINING AS A TREATMENT FOR RHEUMATOID CACHEXIA IN RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Non-pharmacological interventions, Rheumatoid arthritis, Physical therapy/Physiotherapy

M. Karapinar[1], A. KaraİbrahİmoğIu[2], F. Baskurt[1], Z. Baskurt[1]. *[1]Suleyman Demirel University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, 32000, Turkey; [2]Süleyman Demirel University Faculty of Medicine, Department of Biostatistics and Medical Informatics, Isparta, Turkey*

Background: Rheumatoid arthritis (RA) is a systemic inflammatory autoimmune disease that characterized by chronic, symmetric and erosive synovitis that may lead to severe disability and impairments. RA patients frequently have adverse changes in their body composition, with a decrease in muscle mass and an increase in fat mass, a syndrome that is termed rheumatoid cachexia (RC). RC is associated with chronic inflammation, impaired muscle mass and strength and body mass loss, all of which are classical targets of exercise training.
Objectives: This systematic review and meta-analysis aimed to determine the effects of exercise training on body composition included fat mass, lean body mass and muscle strength in patients with rheumatoid arthritis.
Methods: We searched PubMed/Medline, Web of Science, EMBASE, CINHAL, Scopus, Cochrane Library, Google Scholar and Science Direct for relevant articles until November 2022. Systematic review included randomised controlled trials and controlled trials. Pre- and post- exercises intervention data on our primary outcomes included body composition [e.g., using BMI, bioelectrical impedance analysis, fat-free mass index (FFMI)] and isometric knee muscle strength. Two authors independently screened records and data were extracted using Microsoft Excel and exported to STATA version 15.0 software for analysis. Risk of bias was assessed and a random-effects model was used to pool effect sizes by standardized mean differences (SMD).
Results: Six studies with a total of 119 patients with RA in the meta-analysis. Exercises interventions had a median (range) duration of 14 (12-24) weeks and including progressive resistance training, high-intensity resistance training, proprioceptive exercises and water-based exercises programs. Exercises interventions a superior effect compare to control on both fat mass [SDM -0.20 (%95 CI – 1.20, 0.79), p<0.001, I^2; %91], lean body mass [SDM 0.66 (%95 CI -0.77, 2.09), p< 0.001, I^2; %95] and isometric knee extensor muscle strength [SDM 3.01 (0.59, 5.43), p<0.001, I^2; %97] (Figure 1).
Conclusion: Our meta-analysis indicates different exercises trainings effectively decreased fat mass and increased isometric extensor muscle strength and lean mass in patients with RA thereby slowing or reversing RC.

POS0073-HPR APPLICABILITY OF THE DIGITAL PHYSIOTHERAPY INTERVENTIONS FOR RHEUMATIC AND MUSCULOSKELETAL CONDITIONS IN TURKEY: A MIX METHOD STUDY

Keywords: Physical therapy/Physiotherapy, Qualitative research methods, Telemedicine

N. Sermenli Aydın[1], C. Torlakcık[2], E. Tonga[3]. *[1]Marmara University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, İstanbul, Turkey; [2]Marmara University Institute of Health Science, Department of Physiotherapy and Rehabilitation, İstanbul, Turkey; [3]University of Leicester, Leicester Lifestyle and Health Research Group, Leicester, United Kingdom*

Background: Physiotherapy and rehabilitation have been impacted by digitalization in the healthcare system [1]. For the transfer and dissemination of the developed digital health interventions (DHI) to the clinic, the perspectives of physiotherapists—one of the stakeholders in the rehabilitation process—on digital health practices are essential [2].
Objectives: The aim is to determine the usability of digital health technologies in rheumatic and musculoskeletal physiotherapy and rehabilitation and determine the perspective of physiotherapists, perceived facilitating factors and barriers.
Methods: Both quantitative and qualitative data were collected for this study. In the qualitative part of the study, 21 physiotherapists who are working with rheumatic and musculoskeletal conditions were included in the study. Three focus group interviews were conducted with 7 physiotherapists in each group. In the quantitative part of the study, 393 physical therapists were reached through the snowball sampling method. A questionnaire created by the research team was conducted. The SPSS22 program was used for quantitative data statistics, while the NVivo12 program was used to analyze the qualitative data.
Results: Following the focus group interviews, five themes emerged. The themes are as follows: Digital health applications used by physiotherapists for self-educational purposes, DHI used in physiotherapy, barriers to the use of DHI in physiotherapy, benefits of using DHI in physiotherapy, and popularizing the use of DHI in physiotherapy. The themes are summarized in Table 1. The participants reported utilizing DHI in assessment (29.3%), treatment (34.4%), and follow-up (44,8%). The main perceived benefits to use of DHI in physical therapy settings were facilitating patients' follow up (90.8%), and participation (81.7%).

The main perceived barriers to use of DHI in physical therapy settings were high cost (77.8%), and lack of appropriate DHI to Turkish population (71.5%).
Conclusion: This study is the first to present the views of physiotherapists in Turkey on the use of DHI in physiotherapy. Participants are willing to use digital health interventions, but due to obstacles that prevent their use in physiotherapy, there are still some limitations on their use. They contend that for DHI to be widely used, physiotherapists and patients must be educated about them, and the state must support their use and multidisciplinary development.

POS0074-HPR EFFICACY OF E-CONSULTS COMPARED TO IN-PERSON REFERRALS OF ANA POSITIVE PATIENTS TO RHEUMATOLOGY CLINIC

Keywords: Descriptive Studies, Health Services Research, Telemedicine

J. Par-Young[1], J. Young[2], F. Kennedy[1], I. Kang[1], X. Dong[1]. *[1]Yale University, Internal Medicine, New Haven, United States of America; [2]Yale University, Psychiatry, New Haven, United States of America*

Background: Antinuclear antibodies (ANA) are autoantibodies associated with several autoimmune diseases but are also present in healthy individuals due to their role in the body's biological immune response. Thus, testing for ANA in an ambulatory setting could be inappropriately ordered and misinterpreted. Yet, delay in proper management of patients with rheumatologic presentations could result in increased morbidity and health care expenditure. Electronic consultation, or eConsults, could be utilized by primary care providers (PCPs) as a convenient tool to expedite access to rheumatology specialists and optimize care.
Objectives: To assess the efficacy of eConsults in terms of resource utilization and time to referral when compared to in-person referrals of ANA+ patients.
Methods: In this retrospective cohort study, we reviewed the charts of 131 ANA+ patients within the Yale New Haven Health System seen from August 2019 to September 2022. The charts were divided into cases referred by eConsult and by in-person referrals. Time from chart order to eConsult or in-person consultation, diagnosis after consult completion, and laboratory workup results were evaluated. Relative risks (RR) were calculated to compare the efficacy of eConsults vs. in-person referrals in diagnosing connective tissue diseases (CTD) and initiating appropriate referrals. A chi-square test of independence was conducted to determine if there was an association between ESR/CRP levels and conversion to in-person follow-up appointments in eConsult patients.
Results: Among the 131 ANA+ patients seen by their PCPs, 91 (69.5%) were referred through eConsult and 40 (30.5%) were in-person referrals to a rheumatologist. The average time from the initial eConsult request to completion of the consult was 1.46 ± 2.54 days while in-person consults required longer wait times of 76.63 ± 48.61 days.

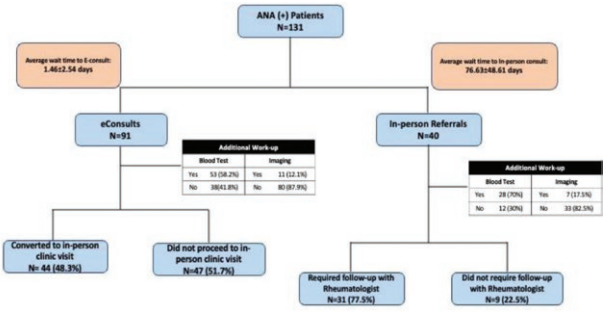

Figure 1. Flow Diagram of ANA+ patients referred for eConsult and In-person Rheumatology specialty clinic

Of the 91 eConsult patients, 44 (48.4%) were converted to face-to-face (FTF) consultation with a rheumatologist. Patients evaluated through eConsults were less likely to be referred to a rheumatologist (RR = 0.61, 95% CI 0.46 – 0.80) when compared to in-person referrals. Patients referred through eConsults were twice as likely to be diagnosed with CTD relative to those that were not scheduled for an FTF visit after an eConsult was completed (RR = 2.49, 95% CI 1.28 – 4.84). For the converted patients, 21 (47.7%) were diagnosed with CTD. For those that did not convert to a FTF referral, only 9 (19.1%) were eventually diagnosed with a CTD. Of the 40 in-person patient referrals, 31 (77.5%) were scheduled to follow-up with a rheumatologist; the majority of which (N = 30, 96.8%) were ultimately diagnosed with CTD. Elevated ESR/CRP levels were found in 19 (43.2%) eConsult patients that had converted and 16 (34%) patients that did not convert to FTF. For eConsult patients, there was no significant relationship found between ESR/CRP levels and conversion to a FTF appointment ($\chi^2(1, N = 74) = 3.299$, $p = 0.07$).

Conclusion: Electronic consultation is an easy and timely method for referral to the rheumatology clinic. In this study, ANA+ patients requiring an urgent consultation were identified earlier through an eConsult compared to an in-person referral. eConsults were also capable of identifying cases that required specialist treatment; 80.9% of patients that weren't referred would not receive a CTD diagnosis in the future. Thus, eConsults should be considered an effective and efficient tool in properly referring patients with rheumatologic presentations and parsing out cases that would not require specialist care.

POS0075-HPR OPPORTUNITIES AND CHALLENGES IN WEB-BASED PATIENT EDUCATION FROM THE PERSPECTIVE OF PATIENTS WITH RHEUMATOID ARTHRITIS – A QUALITATIVE STUDY

Keywords: Self-management, Patient information and education, Rheumatoid arthritis

L. Raunsbæk Knudsen[1,2], K. Lomborg[3,4], E. M. Hauge[1,2], H. A. Zangi[5,6], A. De Thurah[1,2]. *[1]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; [2]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [3]Steno Diabetes Center Copenhagen, Steno Diabetes Center, Copenhagen, Denmark; [4]Copenhagen University, Department of Clinical Medicine, København, Denmark; [5]Diakonhjemmet Hospital, REMEDY - Center for treatment of Rheumatic and Musculoskeletal Diseases, Oslo, Norway; [6]VID Specialized University, Faculty of Health, Oslo, Norway*

Background: Self-management skills are important for people with inflammatory rheumatic diseases, and can be supported through patient education (PE) (1, 2). Following an increasing use of telehealth (3), digital PE is gaining ground to support patients' self-management skills, but the evidence is still limited. Currently, we are testing the effectiveness of a digital PE e-learning program designed for people with rheumatoid arthritis (RA), the WebRA trial [4]. In the present qualitative study, we aimed to provide in-depth insight into patient perspectives of the e-learning program.
Objectives: To explore patients' perceptions of taking part in web-based PE, and how this contributes to self-management of RA.
Methods: We conducted 20 individual qualitative interviews based on the 'Interpretive Description' methodology, an inductive research strategy implying an iterative process of data collection and analysis. Newly diagnosed RA-patients were recruited from the intervention group of the WebRA trial after having finalized their one-year follow-up period [4]. A purposive sampling strategy was used to achieve information power by inclusion of participants with different sex, age, and sociodemographic background. The analysis contained a descriptive part followed by interpretation and extraction of main messages.
Results: Overall, participants had positive perceptions of the e-learning program, and only minor technical difficulties were identified. Advantages of e-learning were flexibility, the possibility for repetition, varied and entertaining presentation forms, availability, and learning in familiar and calm surroundings. Disadvantages were described as missing the dialogue with health care providers (HCPs), and therefore unmet relational support needs. The degree to which e-learning perceived to play a role for acquiring knowledge about RA differed. For the majority, a need for insight and clarity into the condition led to an active approach in using e-learning, whereas a minor group had a more hesitant approach, and postponed the use of the program, e.g. because of mental distress following the diagnosis or by oversight. The program was mostly used immediately after having received the diagnosis and only to a limited extent in the time hereafter. This was explained by fulfilled informational needs, a need for normality and a desire for focusing on everyday life. Participants found that the e-learning program facilitated learning and contributed to self-management of their disease. Patients, however, relied on more than knowledge in their self-management including the interaction between information and knowledge, relational support from HCPs, own experiences, and an underlying positive attitude towards living with the disease.
Conclusion: Most patients consider web-based PE to be a well-suited solution for self-management support. The opportunities of e-learning are related to information and knowledge support whereas challenges cover relational and emotional support needs. Thus, it is suggested that future organization of PE offer different forms and combinations of PE to accommodate different needs and preferences of patients throughout the disease course.

POS0076-HPR EXERCISE COMBINED WITH ACCEPTANCE AND COMMITMENT THERAPY FOR ADULTS WITH CHRONIC PAIN: A RANDOMIZED CONTROLLED TRIAL ONE YEAR FOLLOW-UP

Keywords: Physical therapy/Physiotherapy, Randomized control trial, Pain

M. Casey[1], S. Takemasa[2], B. Fullen[3], T. O'reilly[3], M. Leamy[3], E. MC Kearney[3], M. Buckley[3], K. Smart[3], C. Hearty[4], C. Doody[3]. *[1]Trinity College Dublin, Discipline of Physiotherapy, School of Medicine, Dublin, Ireland; [2]University College Dublin, School of Public Health, Physiotherapy and Sports Science, Dublin, Ireland; [3]University College Dublin, School of Public Health, Physiotherapy and Sports Science, Dublin, Ireland; [4]Mater Misericordiae University Hospital, Department of Pain Medicine, Dublin, Ireland*

Background: Acceptance and Commitment Therapy (ACT) is a type of Cognitive Behavioral Therapy (CBT) that has demonstrated positive outcomes in individuals with chronic pain. There has been limited research to date investigating the efficacy of ACT when combined with physical exercise.
Objectives: The purpose of this randomized controlled trial (RCT) was to compare the effect of an 8-week combined Acceptance and Commitment Therapy (ACT) and supervised exercise program (ExACT) with a supervised exercise program for people with chronic pain at one-year follow-up. The results for 12-week follow up for this RCT have previously been published[1].
Methods: 175 people with chronic pain were randomly assigned to the ExACT or supervised exercise only group. The ExACT group completed an 8-week ACT programme with a clinical psychologist in addition to supervised exercise classes with a physiotherapist. The control group attended an 8-week supervised exercise class only. Adults (aged ≥ 18 years) with any type of chronic pain (other than cancer pain) diagnosed by a medical doctor, and who reported a score of ≥2 on the Brief Pain Inventory Interference Scale (BPI-IS) were eligible for inclusion in the study. Outcome measures including the primary outcome BPI-IS, Pain Catastrophizing Scale (PCS), Patient Health Questionnaire (PHQ 9), General Anxiety Disorder (GAD 7), Chronic Pain Acceptance Questionnaire (CPAQ) and Pain Self Efficacy Questionnaire (PSEQ) were administered at baseline, post intervention, at 12-month follow-up and 1 year following completion of the intervention. Data were analyzed using a linear mixed-effects model.
Results: No significant differences were observed between groups for the primary outcome BPI-IS at 1-year follow up. There were clinically and statistically significant improvements between groups for the PCS total scale and 3 PCS subscales ($P<0.005$) in favour of the ExACT group. Significant differences were observed within both groups at 1-year follow-up for the PHQ-9, GAD-7, and CAPQ, and in the ExACT group only for the PSEQ.
Conclusion: Long-term improvements in pain catastrophizing, and within-group improvements in pain interference and severity, suggest that exercise combined with ACT may be an effective intervention for the long-term management of chronic pain. Future studies could investigate factors that predict a response to these types of interventions with a view to enhancing treatment outcomes for people with chronic pain.

ENHANCING CURRENT GUIDANCE FOR PSORIATIC ARTHRITIS AND ITS COMORBIDITIES: RECOMMENDATIONS FROM AN EXPERT CONSENSUS PANEL OF HEALTHCARE PROFESSIONALS IN THE UK

Keywords: Quality of care, Best practices, Psoriatic arthritis

L. Coates[1], M. Bukhari[2], A. Chan[3], E. Choy[4], J. Galloway[5], N. Gullick[6], A. Kent[7], L. Savage[8], S. Siebert[9], W. Tillett[10], N. Wood[11], P. G. Conaghan[12]. *[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [2]Lancaster University, Department of Rheumatology, Lancaster, United Kingdom; [3]Royal Berkshire NHS Foundation Trust, Department of Rheumatology, Reading, United Kingdom; [4]Cardiff University, Cardiff Regional Experimental Arthritis Treatment and Evaluation (CREATE) Centre, Cardiff, United Kingdom; [5]King's College London, Centre for Rheumatic Diseases, London, United Kingdom; [6]University Hospitals of Coventry & Warwickshire, Rheumatology Department, Coventry, United Kingdom; [7]Salisbury NHS Foundation Trust, Department of Rheumatology, Salisbury, United Kingdom; [8]University of Leeds, Department of Dermatology, Leeds, United Kingdom; [9]University of Glasgow, School of Infection and Immunity, Glasgow, United Kingdom; [10]Royal National Hospital for Rheumatic Disease, Rheumatology Department, Bath, United Kingdom; [11]Royal Devon University Healthcare NHS Foundation Trust, The Wooda Surgery, Bideford, Devon, United Kingdom; [12]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis occurring in 20–30% of patients with psoriasis.[1] Timely diagnosis is important because untreated PsA can lead to irreversible joint damage[1] and functional disability.[2] While existing national and international guidelines, such as those provided by EULAR, BSR, ACR/National Psoriasis Foundation and GRAPPA, cover a wide range of aspects of diagnosis and pharmacological management of PsA, gaps have been identified relating to the application of guidance in clinical practice, ongoing non-pharmacological management, and quality of care benchmarking, often related to a lack of evidence. In response, an expert UK consensus group aimed to enhance current guidance.

Objectives: To develop an evidence- and consensus-based set of recommendations for the management of PsA in routine clinical practice that adds value to existing guidelines, suggests minimum and best quality standards for day-to-day PsA management and provides a set of practical strategies to achieve these quality standards, with the aim of supporting clinicians.

Methods: A steering committee (SC) was formed of 12 experts in the fields of rheumatology, dermatology and primary care. At an initial meeting, consensus themes were discussed and agreed (PsA diagnosis, disease assessment, comorbidities, and management) and consensus questions were drafted. A targeted literature review of PubMed and Embase following a PICO framework was conducted to gather scientific evidence supporting a selection of the questions, while others were agreed to be more appropriate to answer using expert clinical experience. At a second meeting, recommendations were drafted in response to the identified questions, covering gaps in current guidelines. For the next stage, an extended faculty was recruited including rheumatologists (32), dermatologists (6), primary care representatives (3), specialist nurses (5), academics (12) and members of the Brit-PACT patient group [6]. In an online voting platform, the SC and extended faculty entered an agreement score for each recommendation. Consensus was achieved when 75% of respondents agreed in the range of 7–9 on a 9-point scale.

Results: The SC and extended faculty agreed on 34 statements covering 15 questions on PsA diagnosis, disease assessment, comorbidities, and management. The diagnosis theme focussed on strategies to identify PsA early and refer appropriately, the assessment of diagnostic indicators, and guidance on the use of screening tools. The use of imaging to support diagnosis, and appropriate referral time frames were also covered in detail. Recommendations on disease assessment centred on holistic consideration of disease activity, functional impairment and impact from a patient perspective, as well as how to implement shared decision-making. Specific guidance for measurements to be performed at clinic visits was included. For comorbidities, recommendations were made for assessment and management, with specific guidance for high-impact conditions, such as depression and obesity, and those with implications for PsA pharmacological therapy. Management statements (which excluded guidance on pharmacological therapies in extant guidelines) covered multidisciplinary team working, implementation of lifestyle modifications, and treat-to-target strategies built upon the parameters of greatest importance to individual patients. The use of corticosteroids was recommended to be minimised where feasible.

Conclusion: This expert consensus programme identified critical areas beyond pharmacological therapy where existing guidance on PsA management could be enhanced and be of greater practical relevance to clinicians. This work will also be developed into a clinical resource to support healthcare professionals in the care of patients with PsA.

INVESTIGATING THE ROLE OF BIOPSYCHOSOCIAL FEATURES IN DISEASE MANAGEMENT OF INDIVIDUALS DIAGNOSED WITH SYSTEMIC SCLEROSIS

Keywords: Mental health, Pain, Systemic sclerosis

M. O. Tüfekçi[1], S. Buran[2], A. Akdoğan[3], E. Ünal[2]. *[1]Hacettepe University Institute of Health Sciences, Department of Basic Physiotherapy and Rehabilitation, Ankara, Turkey; [2]Hacettepe University Faculty of Physical Therapy and Rehabilitation, Department of Heart and Respiratory Physiotherapy and Rehabilitation, Ankara, Turkey; [3]Hacettepe Universiy Faculty of Medicine, Department of Rheumatology, Ankara, Turkey*

Background: Systemic sclerosis (SSc) is a rare chronic rheumatic disease that causes heterogeneous clinical symptoms with involvement of the skin and internal organs. SSc causes chronic pain and fatigue in the musculoskeletal system as well as many emotional and psychological disorders that affect their functionality. Therefore, it has been reported that evaluation of biopsychosocial characteristics may be important in the disease management of these individuals (1, 2).

Objectives: The aim of this study was to investigate the role of biopsychosocial characteristics in disease management of individuals with SSc.

Methods: The study included 71 individuals who are diagnosed with SSc, and their demographic information was recorded. The Cognitive Exercise Therapy Approach-Biopsychosocial Questionnaire (BETY-BQ) is used in individuals with rheumatism as a scale developed on individuals with rheumatologic diseases and can evaluate the individual holistically. The BETY-BQ has a content that provides biopsychosocial measurement with the subheadings of pain, functionality, emotional status, sociability, sexuality, and sleep quality. Biopsychosocial characteristics of individuals were evaluated with the BETY-BQ [3]. Correlation coefficients and statistical significance were analyzed using "Spearman" correlation test.

Results: The mean age of the individuals included in the study was 50.38 ± 12.39 years. The median value of the BETY-BQ was 52 (min: 0 max: 112) and the median values of the sub-headings were as follows; pain 10 (min: 0 max: 20), functionality 12 (min: 0 max: 35), emotional status 16 (min: 0 max: 40), sociability 4 (min: 0 max: 12), sexuality 3 (min: 0 max: 8), sleep quality 3 (min: 0 max: 4). High and very high positive correlations were found between the BETY-BQ total score and all parameters, and significant positive correlations were found between the parameters themselves (p<0.005) (Table 1).

Table 1. BETY-BQ correlation coefficients of individuals with SSc

BETY-BQ (rho)	Total Score	Pain	Functionality	Emotional Status	Sociability	Sexuality	Sleep quality
Total Score	1						
Pain	0,809**	1					
Functionality	0,849**	0,581**	1				
Emotional Status	0,930**	0,795**	0,664**	1			
Sociability	0,799**	0,597**	0,556**	0,791**	1		
Sexuality	0,625**	0,360*	0,557**	0,496**	0,468**	1	
Sleep quality	0,707**	0,610**	0,573**	0,612**	0,527**	0,436**	1

*p<0,05, **p<0,001

Conclusion: According to the results of this study, it was observed that the biopsychosocial characteristics of individuals with SSc were affected by each other. Biopsychosocial status was most affected by emotional status and least affected by sexuality. It was found that pain, functionality, and sleep quality were mostly related to emotional status; sociality was most related to pain and sexuality was most related to functionality. The effect of good emotional status of individuals with SSc on other parameters was remarkable. The results were interpreted as demonstrating the need for biopsychosocial approaches focusing on biopsychosocial effects, especially emotional status, in the disease management of individuals with SSc.

POS0079-HPR PATIENT-REPORTED OUTCOMES MEASURES FOR SYSTEMIC LUPUS ERYTHEMATOSUS: AN EXPERT DELPHI CONSENSUS TO GUIDE IMPLEMENTATION IN ROUTINE CARE

Keywords: Systemic lupus erythematosus, Patient reported outcomes

I. Castrejon[1], L. Cano Garcia[2], M. J. Cuadrado Lozano[3], J. Borrás[4], M. Galindo-Izquierdo[5], T. C. Salman Monte[6], C. Amorós[7], C. San Román Gutiérrez[8], A. Muñoz[9]. *[1]Hospital Universitario Gregorio Marañón, Reumatología, Madrid, Spain; [2]Hospital regional de Málaga, Enfermería Reumatología, Málaga, Spain; [3]Hospital Clínica Universitaria de Navarra, Reumatología, Madrid, Spain; [4]Hospital de Sagunto, Farmacia Hospitalaria, Valencia, Spain; [5]Hospital 12 de Octubre, Reumatología, Madrid, Spain; [6]Hospital del Mar, Reumatología, Barcelona, Spain; [7]GSK, Market Access Department, Madrid, Spain; [8]GSK, Medical Department, Madrid, Spain; [9]Hospital Universitario Virgen del Rocío, Reumatología, Sevilla, Spain*

Background: Patient-reported outcome measures (PROMs) are useful to incorporate the patient's perspective in the disease decision-making process, which has been identified as one of the main challenges in the management of Systemic Lupus Erythematosus (SLE) patients [1,2].

Objectives: To establish expert recommendations to incorporate PROMs on the current management and empowerment of patients with SLE.

Methods: After a scoping review of the literature and structured interviews with SLE patients (n=9) a survey-based questionnaires were developed by a scientific committee (5 rheumatologists, 1 H. pharmacist and 1 nurse). Using a Delphi approach, consensus was reached regarding the role of PROMs in SLE patients, strategies and more feasible measures to be incorporated in routine care.

Results: A total of 59 experts participated: 51% rheumatologist, 17% internists, 8% nephrologist, 3% dermatologist, and 20% other health professionals in rheumatology (nurses, pharmacists, and psychologists). Around 50% of participants were women, with a mean of 18 years of experience managing SLE patients. Panelists agreed on the following recommendations: incorporating the patient's perspective through the use PROMs (83%), utility of a digital tool to collect PROMs connected to the electronic medical record (85%), incorporating other health professionals to support patients to complete PROMs (77%), a multidisciplinary approach to improve specialists' interaction/coordination (79%), and incorporating H. pharmacists to improve medication management (70%). Panelists agreed that PROMs can facilitate patient participation in decision-making with an adherence to treatment improvement (72%). Consensus was reached on the appropriateness of the following PROMs in routine care: a Visual Analog Scale (VAS) 0-100 for pain (83%), fatigue (73%), and patient global assessment (76%), the Functional Assessment of Chronic Illness Therapy Fatigue (FACIT) for fatigue (75%), and the Lupus Impact Tracker (LIT) (75%) to evaluate health-related quality of life.

Conclusion: Strategies to promote a holistic and integrated approach including the creation of multidisciplinary teams and the incorporation of patient's perspective using PROMs, such as VAS-pain, VAS-fatigue, FACIT-Fatigue, VAS-PGA and LIT, are recommended to improve SLE management in routine care.

POS0080-HPR LONG-TERM EFFECTIVENESS OF A LIFESTYLE PROGRAM FOR RHEUMATOID ARTHRITIS: ONE-YEAR FOLLOW-UP OF THE "PLANTS FOR JOINTS" RANDOMIZED CLINICAL TRIAL

Keywords: Diet and Nutrition, Non-pharmacological interventions, Rheumatoid arthritis

C. Wagenaar[1,2], W. Walrabenstein[1,2,3], M. Van der Leeden[1,4,5], F. Turkstra[1], J. Twisk[6], M. Boers[6], H. Van Middendorp[7], P. Weijs[3,8], D. Van Schaardenburg[1,2]. *[1]Reade, Rheumatology, Amsterdam, Netherlands; [2]Amsterdam UMC, locatie AMC, Rheumatology and immunology center, Amsterdam, Netherlands; [3]Amsterdam University of Applied Sciences, Nutrition & Dietetics, Amsterdam, Netherlands; [4]Amsterdam UMC, locatie VUmc, Rehabilitation Medicine, Amsterdam, Netherlands; [5]Amsterdam Movement Sciences Research Institute, Movement Sciences, Amsterdam, Netherlands; [6]Amsterdam UMC, locatie VUmc, Epidemiology and Data Science, Amsterdam, Netherlands; [7]Leiden University, Institute of Psychology, Health, Medical, & Neuropsychology unit, Leiden, Netherlands; [8]Amsterdam UMC, locatie VUmc, Nutrition & Dietetics, Amsterdam, Netherlands*

Background: The 16-week Plants for Joints (PFJ) multidisciplinary lifestyle program, based on a whole-food plant-based diet, physical activity, and stress management, significantly reduced 28-joint Disease Activity Score (DAS28) score compared to usual care in patients with rheumatoid arthritis (RA).[1,2]

Objectives: To determine the long-term effectiveness of the PFJ lifestyle program on disease activity in patients with RA.

Methods: In the PFJ assessor-blind randomized clinical trial, patients with RA and a DAS28 score ≥ 2.6 and ≤ 5.1 were randomized to receive the PFJ program in addition to usual care, or the control group which received usual care. After this 16-week period the control group also received the PFJ program. After completion of the PFJ program all participants were followed-up for one year with biannual visits and 6 adherence-promoting webinars. If participants had a DAS28 score <2.6 they were instructed to taper anti-rheumatic medication following a pre-specified protocol. Medication changes were assessed at one year as an "increase," "stable," or "decrease" compared to baseline by an independent committee. Secondary outcomes included anthropometric and metabolic markers. A paired sample T-Test between 1-year follow-up and start of intervention was performed.

Results: Of 77 participants who completed the initial 16-week clinical trial 92% were female with a mean (SD) age of 55 (12) and body mass index of 26 (4) kg/m² at baseline. The 65 (84%) participants who completed the one-year follow-up had a greater average change in DAS28 score (–0.9 vs. –0.05) compared to non-completers. In the year after completing the PFJ program the DAS28 score continued to improve slightly whereby a mean 1.01-point difference was observed after one year for the completed cases compared to baseline values (95% CI 0.76 to 1.26; $p < 0.001$) (Figure 1). All components of the DAS28 improved significantly compared to before the program (Table 1). Significant improvements were found in both the seropositive and seronegative subgroups. Of the 61 participants using anti-rheumatic medication at baseline, 27 (44%) were able to decrease the dosage or stop one or more medications. Antirheumatic medication was stable for 16 participants, and increased for 13, of which 5 newly started using medication. 45 participants (58%) had improved DAS28 scores (of which 20 had a DAS28 <2.6) with stable or less medication compared to baseline. After the 1-year follow-up period there was no longer a significant difference in weight or HbA1c although LDL cholesterol remained significantly lower compared to baseline.

Conclusion: The PFJ lifestyle program significantly decreased disease activity in patients with RA and its effects were sustained until one year after program completion, with slightly less anti-rheumatic medication. Metabolic benefits found after the lifestyle intervention were only partially sustained possibly indicating attenuated adherence to the lifestyle program in the 1-year follow-up.

PATIENTS' PERCEPTIONS OF LIFESTYLE INTERVENTIONS IN EARLY RHEUMATOID ARTHRITIS – A QUALITATIVE STUDY

Keywords: Rheumatoid arthritis, Lifestyles, Qualitative research methods

K. Drake Af Hagelsrum[1], I. Larsson[2,3,4], A. Bremander[1,4,5,6], E. Lindqvist[1,7], E. Mogard[1,7]. *[1]Lund University, Section of Rheumatology, Department of Clinical Sciences Lund, Lund, Sweden; [1]Lund University, Section of Rheumatology, Department of Clinical Sciences Lund, Lund, Sweden; [3]Halmstad University, School of Health and Welfare, Halmstad, Sweden; [4]Spenshult, Research and Development Centre, Halmstad, Sweden; [5]University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; [6]University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark; [7]Skane University Hospital, Department of Rheumatology, Lund, Sweden*

Background: Patients with early rheumatoid arthritis (RA) benefit from combining pharmacological and non-pharmacological interventions to prevent damage to cartilage and bone, relieve symptoms, and improve or normalize physical function, quality of life, and social and work capacity. Healthy lifestyle habits, including regular physical activity, a healthy diet, and smoking cessation can lower the increased risk of cardiovascular diseases and improve symptoms and quality of life in patients with RA. In addition, smoking and alcohol may interfere with anti-inflammatory medication, which is why lifestyle interventions are essential in managing patients with early RA. According to international and national recommendations, healthcare professionals are expected to discuss healthy lifestyle habits with all patients with inflammatory arthritis [1]. Despite this, the effect of lifestyle discussions and how patients perceive lifestyle interventions in rheumatology care are scarcely studied.

Objectives: To explore how patients with early RA perceive lifestyle interventions in rheumatology care.

Methods: In this explorative qualitative study, 18 patients with RA followed at an early RA clinic with tight control by a rheumatologist and a rheumatology nurse during the first 2 years, were included. This also included a multidisciplinary team contact with a physiotherapist and an occupational therapist 8-12 weeks after treatment initiation and, if needed, a social worker and additional contacts with the team. Individual interviews were conducted with 12 women and 6 men, aged 23 to 74, with a disease duration of 2-3 years at the time of the interview. The main question was: "Can you tell me about your perceptions of lifestyle interventions in rheumatology care?" The interviews were analyzed with latent qualitative content analysis (2), and three categories and an overarching theme emerged (Table 1).

Results: Patients perceived that lifestyle interventions in rheumatology care enable self-management in early RA. The usefulness of lifestyle interventions was perceived to depend on personal preferences of lifestyle support and prioritization of lifestyle interventions. The design of lifestyle interventions should be based on a person-centred approach, patient education, and recurrent lifestyle support. To promote healthy lifestyle habits, the outcome of lifestyle interventions should contribute to the knowledge of healthy lifestyle habits, motivation for lifestyle changes, and empowerment in patients with early RA.

Conclusion: Patients perceived that the usefulness, design, and outcome of lifestyle interventions in rheumatology care are essential when enabling self-management in patients with early RA.

APPLICATION OF THE NEW 2022 ACR/EULAR CLASSIFICATION CRITERIA FOR CALCIUM PYROPHOSPHATE DEPOSITION DISEASE (CPPD) IN A COHORT OF PATIENTS DIAGNOSED WITH SERONEGATIVE RHEUMATOID ARTHRITIS

Keywords: Crystal Arthritis, Descriptive Studies, Rheumatoid arthritis

H. Codes-Mendez[1], L. Sainz Comas[1], H. Park[1,2], A. M. Millán Arciniegas[1], B. Magallares[1,2], P. Moya[1,2], J. L. Tandaipan[1,2], S. P. Fernandez-Sanchez[1], S. Ros[1], A. Laiz[1,2], I. Castellvi[1,2], H. Corominas[1,2], C. Díaz-Torné[1,2]. *[1]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; [2]Universitat Autònoma de Barcelona, Medicine, Bellaterra, Spain*

Background: The ACR/EULAR group released the first-ever provisional classification criteria for calcium pyrophosphate deposition disease (CPPD) at the ACR congress in November 2022. These criteria are based on an adjusted domain scoring system including demographic, clinical and radiological characteristics, and synovial fluid crystal analysis. The differential diagnosis in CPPD must be made with rheumatoid arthritis (RA) and monosodium urate crystal deposition disease.
Objectives: To study the percentage of patients diagnosed with seronegative RA who meet the new 2022 ACR/EULAR classification criteria for CPPD (final score ≥57). To determine the clinical and demographic differences between patients with a diagnosis of seronegative RA who meet or not the classification criteria for CPPD.
Methods: An observational retrospective cross-sectional study was performed including all the patients from a monographic RA clinic between September and December 2022. Demographic, clinical, analytical and imaging variables (simple radiology and ultrasound) were collected. The 2022 ACR/EULAR provisional classification criteria for CPPD were applied.
Results: Overall, 364 patients with RA were identified and those with seropositivity for RF and/or ACPAs were excluded. A total of 96 (24.4%) patients were included, 74.7% females, with a mean age at onset of symptoms of 59.3 (±16.4) years and 8.35 years of disease duration. A total of 18 patients (18.9%) met the classification criteria for CPPD. The characteristics and differences between the patients who met or not the criteria are shown in Table 1. The patients who met the CPPD criteria were older (p=0.048) and had a different clinical presentation (p=0.010) relating to the time-course of inflammatory arthritis (persistent, 1 typical episode, >1 typical episode, others). No significant differences were observed between groups in the location of joint clinical involvement. There was a statistically significant association (p=0.000) between the presence of radiological chondrocalcinosis (CC) and the fulfillment of criteria for CPPD, being detected in 66.6% of patients with CPPD versus none with seronegative RA without CPPD. Similarly, there was a significant association (p=0.000) between osteoarthritis in typical locations for CPPD (bilateral radiocarpal, scaphoid/trapezium/trapezoid without rhizarthrosis, 2nd and 3rd MCF) and compliance with criteria for CPPD, being detected in 55.5% of patients with CPPD. A higher prevalence of erosions was detected in patients with CPPD (44.4%) versus seronegative RA without CPPD (27.3%), without statistical significance. No significant treatment differences were observed in both subgroups. Of the patients with criteria for CPPD, 74% were being treated with synthetic of biological disease modifying antirheumatic drugs (DMARDs).

Table 1. Characteristics of the sample according to the fullfilment or not of the new 2022 ACR/EULAR classification criteria for CPPD.

	Total (n=95)	Seronegative RA with CPPD* (n=18)	Seronegative RA without CPPD (n=77)	p
Female gender, n (%)	71 (74.7%)	16 (88.8%)	55 (71.4%)	0.142
Age at onset (years), p50	63	69.5	61	**0.048**
Disease duration (years), p50	7	6	7	0.952
Time-course, n (%)				**0.010**
- Persistent arthritis	38 (40%)	4 (21.1%)	34 (44.5%)	
- 1 typical episode	0 (0%)	0 (0%)	0 (0%)	
- >1 typical episode	39 (41.1%)	13 (72.2%)	26 (33.8%)	
- Others	18 (18.8%	1 (5.3%)	17 (22.1%)	
Erosions, n (%)	29 (30.5%)	8 (44.4%)	21 (27.3%)	0.091
Treatment, n (%)				0.854
Prednisone	21 (21.9%)	4 (21.1%)	17 (22.1%)	
sDMARD	45 (46.9%)	10 (52.6%)	35 (45.5%)	
bDMARD	19 (20%	3 (16.6%)	4 (20.8%)	
Combination therapy	10 (10.4%)	1 (5.3%)	9 (11.7%)	

Conclusion: A total of 18 (18.9%) patients with seronegative RA from a monographic RA unit met the new 2022 ACR/EULAR provisional classification criteria for CPPD. Age at diagnosis and clinical presentation were different between patients with RA who met criteria for CPPD and those who did not.

A SYSTEMATIC LITERATURE REVIEW INFORMING THE EULAR RECOMMENDATIONS FOR THE USE OF IMAGING IN CRYSTAL-INDUCED ARTHRITIS IN CLINICAL PRACTICE

Keywords: Gout, Crystal Arthritis, Imaging

I. Gessl[1], G. Sakellariou[2], G. Filippou[3], P. Mandl[1], B. Wildner[4], M. A. D'agostino[5], V. Navarro-Compán[6]. *[1]Medical University of Vienna, Div. of Rheumatology, Dept. of Internal Medicine III, Wien, Austria; [2]University of Pavia and Istituti Clinici Scientifici Maugeri IRCCS, Department of Internal Medicine and Medical Therapy, Pavia, Italy; [3]Luigi Sacco University Hospital, Rheumatology Department, Milan, Italy; [4]Medical University of Vienna, University Library, Wien, Austria; [5]Agostino Gemelli University Policlinic, Rheumatology Unit, Rome, Italy; [6]University Hospital La Paz, IdiPaz, Rheumatology, Madrid, Spain*

Background: The increased availability of imaging techniques has led to their more extensive use in rheumatological practice. In the context of crystal-induced arthritis (CiA), evidence-based recommendations for their use are lacking.
Objectives: To systematically assess current literature regarding the use of imaging in CiA.
Methods: After the identification of the areas of interest and 14 research questions for the application of imaging in CiA, we performed 4 separate systematic literature searches (per disease and per indication) in Embase, Medline, and Central regarding the use of imaging for the diagnosis, monitoring and prediction of outcome and treatment effects of gout, calcium pyrophosphate dihydrate crystal deposition disease (CPPD) and basic calcium phosphate/hydroxyapatite crystal deposition disease (BCPD), as well as for guiding intra-articular procedures and patient education. Titles and abstracts were screened, the full-text of the eligible articles were reviewed and data of the included studies were extracted. Risk of bias was assessed validated instruments based on study type.
Results: The overview of the included studies for each research question and imaging modality is shown in Table 1. For gout, out of 2915 studies, 88 studies were finally included (table 1, figure 1). The majority of diagnostic studies reported good to excellent (≥80%) sensitivity and specificity of DECT and US for diagnosis. Conventional radiographs (CR) and computed tomography (CT) showed high specificity but lower sensitivity in most studies. The majority of the follow-up studies showed a significant change of crystal deposition by US and DECT and inflammatory signs by US. An increase of structural damage was shown in some studies by CR and CT, mainly after a follow-up of at least 2 years. For CPPD, out of 687 studies, 50 studies were included (table 1, figure 1). Diagnostic studies on CR and US generally showed high specificity in all joints, in particular wrists and knees, while sensitivity was more variable, but generally high. There was a single study on monitoring, while 9 studies assessed the prognostic role of CPPD on CR and MRI in patients with OA, with contradicting results. Evidence on the application of DECT was scarce. For BCPD/HADD, out of 1389 abstracts, 55 studies were included (table 1, figure 1). There were 2 diagnostic studies, one on CR, reporting good performance, and one on MRI, with suboptimal performance. The utility of imaging in monitoring was assessed in 43 studies, mostly on CR and US of the shoulder, the majority reporting a reduction in the size of deposits, while 12 studies with contrasting results assessed the role of CR, US and MRI for prediction of treatment response. The search on patient education retrieved 254 studies, of which 2 could be included, which suggest a potential role of DECT in patient education. No studies on the role of imaging to guide procedures in CiA could be included in the final review (table 1, figure 1).
Conclusion: The present SLR has provided background evidence for the development of EULAR recommendations on the use of imaging in CiA in clinical practice.

THE NOMENCLATURE OF CALCIUM PYROPHOSPHATE DEPOSITION (CPPD) DISEASE – RESULTS OF A SYSTEMATIC LITERATURE REVIEW FOR THE GOUT, HYPERURICEMIA AND CRYSTAL-ASSOCIATED DISEASE NETWORK (G-CAN) CPPD NOMENCLATURE PROJECT

Keywords: Crystal Arthritis, Descriptive Studies, Systematic review

S. Sirotti[1], E. Cipolletta[2], C. Jauffret[3], D. Cirillo[4], L. Ingrao[4], A. Lucia[4], E. Cumbo[1], A. Adinolfi[5], E. Filippucci[2], T. Pascart[3], S. Tedeschi[6], R. Terkeltaub[7], N. Dalbeth[8], G. Filippou[1]. *[1]IRCCS Istituto Ortopedico Galeazzi, Rheumatology Department, Milan, Italy; [2]Polytechnic University of Marche, Rheumatology Unit, Department of Clinical and Molecular Sciences, Ancona, Italy; [3]Saint-Philibert Hospital, Lille Catholic University, Rheumatology Department, Lille, France; [4]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [5]ASST Great Metropolitan Niguarda, Rheumatology Unit, Milan, Italy; [6]Brigham and Women's Hospital and Harvard Medical School, Division of Rheumatology, Inflammation and Immunity, Boston, United States of America; [7]University of California, Veterans Affairs San Diego Healthcare System, San Diego, United States of America; [8]University of Auckland, Bone and Joint Research Group, Department of Medicine, Faculty of Medical and Health Sciences, Auckland, New Zealand*

Background: Despite prior attempts at standardising terminology of calcium pyrophosphate deposition (CPPD) disease (including the 2011 EULAR recommendations for CPPD terminology), many different terms are still used interchangeably to describe the disease, its elements, and its states (Tedeschi SK, Curr Rheumatol Rep 2019). This confusing nomenclature has important implications for research and for patient care. The G-CAN has developed a CPPD Nomenclature Project which aims to achieve international consensus about the nomenclature of CPPD.

Objectives: In this first step of the project, the aim was to identify the definitions, the disease elements and the clinical states of CPPD and their corresponding labels in the scientific literature.

Methods: A systematic literature search was performed in the PubMed database starting from 01/01/2000 to 31/01/2022. The search was restricted to studies on humans and in English language. Eight reviewers independently extracted terms related to disease definition, aetiology, pathogenesis, clinical presentation, imaging features and clinical states of CPPD. An *a priori* list of disease elements and clinical states was generated by the authors and further elements were added during data collection as appropriate. Labels for each identified disease element and clinical state were extracted and analysed to determine their frequency. An additional analysis was performed to evaluate the uptake of the 2011 EULAR recommendations on CPPD terminology after 2011.

Results: A total of 2392 articles were identified using the search criteria. We preliminarily evaluated 623 articles of which 246 were included. The list of evaluated elements is showed in **Figure 1**. There was great inconsistency in the terminology used for the disease, its elements and its states. The 3 most common labels used to identify the disease were "pseudogout", "calcium pyrophosphate deposition disease" and "chondrocalcinosis". The most common acronym used was "CPPD", mostly with the meaning of "calcium pyrophosphate deposition disease" or "calcium pyrophosphate deposition" (**Table 1**). The 2 most commonly used labels describing "an episode of acute CPPD arthritis" were "pseudogout" (31%), and "acute calcium pyrophosphate crystal arthritis" (10%). For "more than one episode of acute CPPD arthritis", "recurrent pseudogout" (17%) or "recurrent arthritis" (10%) were the most used labels. "Chronic calcium pyrophosphate crystal arthritis" (13%) and "pseudo-rheumatoid arthritis" (11%) were the most commonly used labels to describe "persistent inflammatory arthritis due to CPPD". The most used labels used to identify "osteoarthritis with evidence of CPPD" were "pseudo-osteoarthritis" (11%) and "calcium pyrophosphate crystal deposition with osteoarthritis" (9%). The use of "pseudo-form" labels mostly occurred before the 2011 EULAR recommendations.

Conclusion: These preliminary results demonstrate the variability and lack of precision in the labels used to describe CPPD disease. The next steps of the project will be to achieve agreement about CPPD disease nomenclature through a Delphi exercise and consensus meeting, and to develop an easily understandable common language definition to facilitate communication with patients.

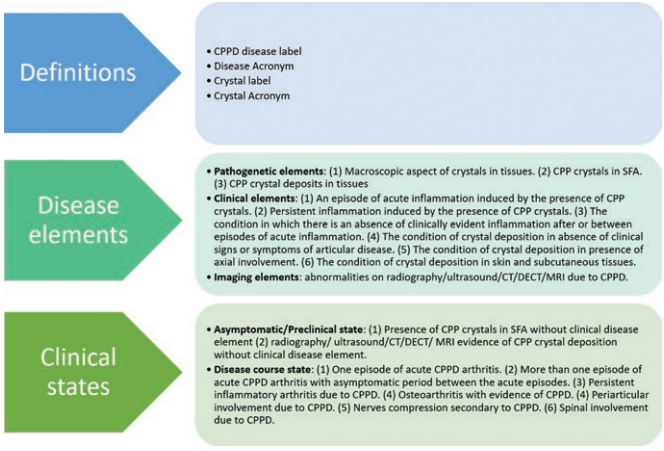

Figure 1. List of definitions, disease elements and clinical states

Table 1. Example of labels extracted for calcium pyrophosphate deposition disease

Element	Label	Frequency
CPPD disease label	Pseudogout	28%
	Calcium pyrophosphate deposition disease	14%
	Chondrocalcinosis	14%
	Calcium pyrophosphate dihydrate deposition disease	9%
	Calcium pyrophosphate dihydrate crystal deposition disease	7%
	Other	28%
Acronym	CPPD	68%
	CPDD	11%
	CC	9.4%
	CPPD-CDD	2.4%
	CPPDD	1.6%
	Other	7.6%
Acronym meaning	Calcium pyrophosphate deposition disease	26%
	Calcium pyrophosphate deposition	19.7%
	Calcium pyrophosphate dihydrate deposition disease	9.4%
	Calcium pyrophosphate crystal deposition	9.4%
	Chondrocalcinosis	9.4%

MICROSCOPIC AND ULTRASONOGRAPHIC EXAMINATION OF CRYSTAL RELATED ARTHRITIS IN PATIENTS WITH KNEE EFFUSION

Keywords: Ultrasound, Crystal Arthritis

H. Ogun[1], D. Palamar[2], K. Akgun[2], F. M. Saridogan[2]. *[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Physical Medicine and Rehabilitation Department, Istanbul, Turkey*

Background: Routine search for crystals is recommended in all synovial fluid (SF) aspirates from undiagnosed arthritis. Definitive diagnosis of crystal related arthritis (CRA) is based on identification of crystals in SF. However, SF analysis is sometimes difficult to perform. Therefore, assessment of imaging techniques can be useful. In the latest recommendations for the diagnosis and management of CRA, the diagnostic potential of ultrasound (US) has been recognized[1,2].
Objectives: The aim of this study was to evaluate the contribution of ultrasonography to the SF analysis, which should be performed routinely in patients with knee effusion to exclude infection and to detect CRA.
Methods: Patients, in outpatient clinic, above 18 years of age with unilateral knee effusion were included. Ultrasonography of the involved knees were performed in all patients after the evaluation and physical examination. In ultrasonographic examination; hyperechoic bands within the femoral hyaline cartilage (sandwich appearance) and/or hyperechoic sparkling spots in meniscal fibrocartilage (meniscus calcification) were considered indicative of Calcium pyrophosphate deposition disease (CPPD); in addition, hyperechoic spots in the effusion and tendon calcifications were recorded. Ultrasonography guided synovial fluid aspiration was performed. The sample was examined macroscopically and microscopically. Then, radiographic evaluations were done for searching chondrocalcinosis.
Results: Eighty-five patients (56 F,29 M) with unilateral knee effusion were evaluated. Mean age was 60.98 ±11,95 years. CPPD was diagnosed with detecting calcium pyrophosphate (CPP) crystals in synovial fluid analysis in 15 of 85 patients. Two of these patients had previous diagnosis of rheumatoid arthritis (RA), 1 spondyloarthritis, 1 gout and 11 osteoarthritis. Of the remaining 70 patients, 1 was considered as spondyloarthritis, 4 as RA and 65 as exacerbation of osteoarthritis. The detection of CPP crystal in the microscopic examination was accepted as the gold standard for the diagnosis of CPPD, sensitivity and specificity values were 93.33% and 80% for ultrasonography, 46.67% and 98.57% for radiography, respectively (Table 1). Inter-rater agreement for US was found to be 93.3% (kappa value: 0.81; very good agreement) with the evaluation of 40 patients separately by two physicians. Intra-rater agreement for US was found to be 96.67% (kappa value: 0.83; very good agreement) when the recorded images were re-evaluated.
Conclusion: When crystal related arthritis is suspected especially in elderly patient with knee effusion, ultrasonography found as a useful diagnostic method in clinical practice because it is highly sensitive and specific in determining crystal accumulations.

A TRANSVERSAL STUDY OF 826 UNTREATED GOUT PATIENTS SHOWS THAT ECHOGENICITY OF THE RENAL MEDULLA INCREASES WITH GOUT DURATION/SEVERITY AND STEROID USE

Keywords: Kidneys, Gout, Ultrasound

T. Bardin[1,2], Q. Nguyen[2], K. Tran[2], C. Tran[2], D. Huynh[2], D. M. Do[3], P. Richette[1,4], J. M. Correas[5], M. Resche-Rigon[6,7]. *[1]Universite Paris-Cite, INSERM U1132, Hôpital Lariboisiere, Paris, France; [2]Vien Gut Medical Center, French-Vietnamese Research Center on Gout and Chronic Diseases, Ho Chi Minh City, Vietnam; [3]University of Medicine and Pharmacy at Ho chi Min City, Center for Molecular Biomedicine, Ho Chi Minh City, Vietnam; [4]Hôpital Lariboisiere, Rhumatologie, Paris, France; [5]Hôpital Necker, Radiolgy, Paris, France; [6]Hôpital Saint Louis, Biostatistics, Paris, France; [7]Université de Paris-Cite, UMR U1153 ECSTRA team INERM, Paris, France*

Background: Diffuse hyperechogenicity of the kidney pyramids, detected by kidney ultrasound (US) scan, has been reported as a frequent finding in severe, untreated, tophaceous gout. It seemed related to crystal deposition in the renal medulla and correlated with kidney function decrease, reviving the concept of gouty microcrystalline nephropathy [1].
Objectives: To confirm this finding and to detect its progression with gout duration.
Methods: Patients fulfilled the ACR/EULAR criteria, were not treated by urate-lowering drugs (ULD) at the time of examination; 44 % had received short courses of ULD in the past. They underwent kidney US scans by an experienced radiologist, who classified each kidney into 3 grades according to the presence and degree of hyperechogenicity of the renal pyramids, as compared to the renal cortex. Grade 0 was defined as no medulla hyperechogenicity; grade 1 by the observation of hyperechogenic spots in 1 or 2 renal pyramids; grade 3 as a diffuse hyperechogenicity of at least 3 pyramids (out of 5 scanned). Demographic variables, comorbidities, gout and biochemical features were retrieved from electronic files. US scans of the

PPV: Positive predictive value, NPV:: Negative predictive value, CPP: Calcium pyrophosphate, US: Ultrasound

MTP joints allowed gradation of double contours from 0 to 3. Links between patients 'features and renal medulla staging were assessed by Fisher exact or Kruskall and Wallis tests according to the type of variables. Multivariable analysis included all statistically significant features, with model selection on p.value using a proportional odds logistic regression model. All test were two-sided.

Results: 826 consecutive new patients were included from August 1 to December 24, 2022. 88 % were males, median age was 49 years, median BMI 24.22kg/m^2, median gout duration 5 years, 70 % of patients had clinical tophi, median uricemia was 488,6 µmol/l, median creatininemia 83.5 mmol/l, median eGFR 93ml/min. Both kidneys were classified at the same grade in every all patients. 65.5% of patients were at grade 0, 17.8 % at grade 1 and 16.7 % at grade 3. Table 1 shows links of the extent of medulla hyperechogenicity with patients 'features. By multivariable analysis, positive correlation was found with male sex, hypertension, gout duration, tophi, double contours and uricemia; BMI, eGFR and cortilsolemia negatively correlated.

Conclusion: Hyperechogenicity of the renal medullas progressively increased with gout duration, MSU deposition and steroid treatment, and associated with decrease of renal function and hypertension. These observations reinforce the early indication of ULDs in gouty patients.

ADHERENCE TO EULAR SERUM URATE MONITORING GUIDELINES AMONGST OLDER ADULTS WITH GOUT IN ONTARIO, CANADA: A POPULATION-BASED STUDY

Keywords: Quality of care, Gout, Crystal Arthritis

T. Kwok[1,2], B. Kuriya[1,2], G. A. Hawker[1,2], P. Li[3], G. Choy[1], J. Widdifield[2,3,4].

[1]University of Toronto, Division of Rheumatology, Department of Medicine, Toronto, Canada; [2]Institute of Health Policy, Management & Evaluation, Dalla Lana School of Public Health, Toronto, Canada; [3]ICES, ICES Central, Toronto, Canada; [4]Sunnybrook Research Institute, Holland Bone & Joint Program, Toronto, Canada

Background: Serum urate (SUA) monitoring plays an important role in the treat-to-target recommendations of gout. Adherence to SUA monitoring recommendations after initiation of urate lowering therapy (ULT) is unknown.

Objectives: We assessed the proportion of older adults with gout undergoing SUA testing 6-months after ULT initiation and associated patient and physician-level factors.

Methods: This population-based retrospective cohort study identified patients aged ≥ 66 with gout and newly dispensed ULT between January 1, 2010 and March 31, 2019 from physician billing and pharmacy claims data in Ontario, Canada. We characterized the proportion of patients that received SUA testing within 6-months after ULT dispensation. Multi-level logistic regression clustered by ULT prescriber evaluated factors associated with SUA monitoring by 6-months including patient, prescriber characteristics, prescription information and health-care usage factors.

Results: 44,438 patients with mean (SD) age of 76.0 (7.3) years and 64.4% males were included. Family physicians prescribed 79.1% of all ULTs. SUA testing was lowest in 2010 at 56.4% and rose over time to 71.3% in 2019 (p <0.0001). By 2019, SUA monitoring was highest amongst rheumatologists (93.9%) and lowest amongst family physicians (67.4%) (Figure 1). Compared with rheumatologists, family physicians (OR 0.26, 95% CI: 0.23–0.29), internists (OR 0.34, 95% CI: 0.29–0.39), nephrologists (OR 0.37, 95% CI: 0.30–0.45) and other specialties (OR 0.25, 95% CI: 0.21–0.29) were less likely to test SUA, as were male physicians (OR 0.87, 95% CI: 0.83–0.91). Patient factors associated with lower odds of SUA monitoring included: rural residence (OR 0.81, 95% CI: 0.77–0.86), lower socioeconomic status (OR 0.91, 95% CI: 0.85–0.97) and patient comorbidities. Correlates of SUA monitoring included: chronic kidney disease (OR 1.40, 95% CI: 1.32–1.49) hypertension (OR 1.11, 95% CI: 1.04–1.18), diabetes (OR 1.17, 95% CI: 1.12–1.22) and co-prescription of colchicine/oral corticosteroids (OR 1.31, 95% CI: 1.23–1.40) (Table 1).

Conclusion: While most gout patients under rheumatology care were adherent to EULAR monitoring recommendations, at the population-level, SUA monitoring is suboptimal amongst older adults with gout initiating ULT but improving over time. ULT prescriber, patient and prescription characteristics affected SUA monitoring. These findings suggest care variations and the need to mobilize quality improvement activities in chronic gout management.

POS0088 WORK PRODUCTIVITY IN GOUT – RESULTS FROM THE NOR-GOUT LONGITUDINAL 2-YEAR TREAT-TO-TARGET STUDY

Keywords: Work-related issues, Crystal Arthritis, Epidemiology

T. Uhlig[1], L. F. Karoliussen2, J. Sexton[3], S. Aarrestad Provan[3], T. K. Kvien[3], E. A. Haavardsholm[2], H. B. Hammer[2]. *[1]Diakonhjemmet Hospital, Center for treatment of Rheumatic Musculoskeletal Diseases (REMEDY), Oslo, Norway; [1]Diakonhjemmet Hospital, Center for treatment of Rheumatic Musculoskeletal Diseases (REMEDY), Oslo, Norway; [3]Diakonhjemmet Hospital, joesexton0@gmail.com, Oslo, Norway*

Background: Gout causes pain and reduced health related quality of life. There are no longitudinal studies on work productivity in patients who are being treated-to target for their serum urate in clinical practice.
Objectives: We examined whether work productivity in gout patients changed over 2 years after intensive treatment with ULT, and if disease related factors could predict changes in work productivity.
Methods: Patients with crystal-proven gout and a recent gout flare and increased serum urate (sUA) level (>360 µmol/L) were consecutively included in the NOR-Gout observational study [1]. They were treated to target with an educational intervention by a study nurse and escalating urate lowering medication (allopurinol or febuxostat) with frequent control visits to achieve low serum urate at target. Work productivity and activity impairment were assessed using the Work Productivity Activity Index (WPAI) questionnaire at baseline, after 3 months, 6 months, 1 and 2 years. The WPAI consists of six questions to determine employment status during the last 7 days: hours missed from work due to the disease; hours missed from work for other reasons; hours worked, the degree to which the disease affected work productivity while at work; and the degree to which the disease affected activities outside of work. Four scores were derived: percentage of missed work (absenteeism), percentage of impaired productivity while at work (presenteeism), overall work impairment that combines absenteeism and presenteeism, and percentage of impairment in activities performed outside of work. Greater scores indicate greater impairment. Questions related to absenteeism and presenteeism were applicable only for patients who were working. Other assessments included clinical, demographic and lifestyle variables, and questionnaires, comorbidities from the Self-Administered Comorbidity Questionnaire, pain, physical function from the Health Assessment Questionnaire (HAQ), SF-36 physical and mental components, self-efficacy, and the Beliefs about Medicines Questionnaire (BMQ) with subscales of beliefs in harm, overuse, necessity, and concerns about medication. Descriptive statistics used ANOVA, and linear regression model after logarithmic transformation of the 4 WPAI outcomes. Final regression models were also adjusted for baseline, age, gender, disease duration and comorbidities.
Results: Patients were predominantly male (95%) with mean age 56.4 years (SD 13.7 years) and disease duration almost 8 years, 17% had subcutaneous tophi. At baseline 64.4 % were working, 64.0% at year one and 61.3% after 2 years. sUA was at target <360µmol/L in 85% after one and 79% after 2 years, while a flare was experienced by 81% and 26% during year 1 and year 2, respectively. WPAI scores were at baseline: 5.0% work missed, 19.1% work impairment, 21.4% overall work impairment and 32.1% activity impairment (Figure 1). Scores were at 3 months, after the recent flare leading to inclusion into the study, improved and remained then stable over 2 years. Baseline assessments of work productivity, comorbidities as well as concerns about medication independently predicted changes in work productivity outcomes at 1 year.
Conclusion: In patients with gout who were intensively treated to the sUA target, work productivity and activity impairment were largely unchanged over 2 years and at 1 year and were predicted by comorbidities and patient concerns about medication.

POS0089 A DIAGNOSTIC PERFORMANCE STUDY ON RAMAN SPECTROSCOPY INTEGRATED WITH POLARIZED LIGHT MICROSCOPY FOR THE IDENTIFICATION OF MONOSODIUM URATE IN GOUT

Keywords: Gout, Crystal Arthritis, Diagnostic Tests

T. Niessink[1,2], T. Giesen[2], A. Comarniceanu[2], M. Efde[2], M. Janssen[2], C. Otto[1], T. Jansen[2]. *[1]University of Twente, Medical Cell Biophysics group, Enschede, Netherlands; [2]VieCuri Medical Centre, Rheumatology, Venlo, Netherlands*

Background: The diagnosis in gout and other crystallopathies is commonly based on polarized light microscopy (PLM) of synovial fluid aspirates. This technique is flawed, however, due to subjectivity, limited reproducibility, and oversensitivity due to artifacts [1]. There is a need for innovative methods to perform synovial fluid analysis with more objectivity/reproducibility. Raman spectroscopy has been applied for identification of MSU in gout, with different technical approaches [2]. Although results are promising, there are no real diagnostic accuracy measures available for any application of Raman spectroscopy in rheumatology.
Objectives: To enhance the chemical analytical performance of PLM, we have integrated a Raman spectroscope within a standard polarized light microscope (iRPolM). In this study, we investigated the performance of iRPolM as a next-generation method for synovial fluid analysis in gout.
Methods: This is a prospective study, including 200 samples from a peripheral swollen joint subject for diagnostic analysis. The participants formed a consecutive series. Diagnostic performance was measured against the 2015 ACR/EULAR gout classification criteria set, which includes PLM analysis. Furthermore, we compared the analytical performance of iRPolM to identify MSU crystals with ordinary PLM analysis by an experienced rheumatologist.
RESULTS:

Table 1. Diagnostic and analytical performance of iRPolM. Values given with 95% confidence intervals.

	Diagnostic performance of iRPolM against 2015 ACR/EULAR classification criteria	Analytical performance of iRPolM against PLM by rheumatologist
Sensitivity	77.6% (95% CI 65.8-86.9%)	91.2% (95% CI 80.7-97.1%)
Specificity	97.7% (95% CI 93.5-99.5%),	97.6% (95% CI 93.0-99.5%)
Positive predictive value	94.5% (95% CI 84.9-98.2%)	94.6% (95% CI 85.0-98.2%),
Negative predictive value	89.7% (95% CI 84.7-93.1%),	96.0% (95% CI 91.2-98.2%)
Accuracy	91.0% (95% CI 86.2-94.6%)	95.6% (95% CI 91.4-98.2%)
Positive likelihood ratio	34.4 (95% CI 11.2-106.1)	37.4 (95% CI 12.2-114.7)
Negative likelihood ratio	0.23 (95% CI 0.15-0.36)	0.09 (95% CI 0.04 to 0.21)

67 patients were classified as gout according to 2015 ACR/EULAR classification criteria. 55 samples were positive for MSU according to PLM analysis. iRPolM identified MSU in 55 patients, 52 of which positive for gout. The inter-rater agreement between PLM and iRPolM was very high ($\kappa = 0.90$).

Conclusion: We demonstrate that Raman spectroscopy integrated with polarized light microscopy has a high diagnostic performance as it comes to identification of MSU in synovial fluid samples. Furthermore, Raman Spectroscopy could provide definitive outcomes in cases where analysists with polarized light

microscopy faced uncertainties or lookalikes, for example by identifying birefringent objects as glass slivers, microplastics or other non-MSU crystal types. These results show that Raman spectroscopy is a powerful analytical tool for clinicians, and a potential candidate for replacement or enhancement of PLM in clinical care where higher specificity is needed. Raman spectroscopy gives an excellent specificity on the nature of a birefringent object even with lookalikes, improving the specificity of a difficult microscopical diagnosis.

Background: Hyperuricemia is a pre-requisite for gout, and often co-occurs with other metabolic diseases[1]. Emerging evidence suggests that gut microbiota is an important factor in the development of metabolic diseases[2]. Moreover, altered gut microbiota, ascertained using 16S rRNA-based sequencing method, has been linked to hyperuricemia[3]. However, the 16S rRNA technique has limited resolution to differentiate closely related species. Therefore, the hyperuricemia associated specific species and underlying mechanism remain unclear. Additionally, cross-talk between bile acid metabolites and the gut microbiome has been implicated in metabolic diseases, implying potential effect of bile acid metabolism in the pathogenesis of hyperuricemia.

Objectives: The aim of this study was to examine the relation of gut microbiome based on shotgun metagenomic sequencing to prevalent hyperuricemia and potential mediators of bile acids.

Methods: Participants were derived from a community-based observational study, the Xiangya Hyperuricemia Study. Hyperuricemia was defined as serum urate level > 404 μmol/L. Gut microbial composition was determined using shotgun metagenomic sequencing and plasma bile acids were measured by high-performance liquid chromatography mass spectrometry. The Chao1 index (i.e., richness) and Shannon index (i.e., diversity) of microbial genes and taxa and the difference of microbial composition, indicated by Bray-Curtis distance between participants with and without hyperuricemia were assessed. The association between gut microbiome and prevalence of hyperuricemia and the extent to which the association was mediated by plasma bile acids were also evaluated.

Results: Among 1,379 participants, the prevalence of hyperuricemia was 13.4% (n = 185) (Figure 1 A). Decreased microbial richness and diversity, altered composition of gut microbiome and lower relative abundance of seventeen key species *Coprococcus comes*, *Dorea longicatena*, *Desulfovibrio piger*, *Ruminococcus sp003526955*, *Holdemanella sp002299315*, *Ruminococcus sp000437175*, *Ruminococcus sp000437095*, *Coprococcus eutactus*, *Blautia sp900066335*, *Blautia sp900066205*, *Blautia sp900066505*, *Ruminococcus sp003011855*, *Blautia sp900120195*, *Blautia sp000285855*, *Dorea formicigenerans*, *Acetatifactor sp900066365* and *Blautia wexlerae* were significantly associated with prevalent hyperuricemia (Figure 1 B and C). High levels of taurochenodeoxycholic acid (TCDCA) and low levels of deoxycholic acid (DCA) were associated with high prevalence of hyperuricemia (Figure 1 D and E). Inversely associations between these key species and hyperuricemia were partially mediated through their effect on the levels of TCDCA and DCA. For instance, the indirect effects (OR) of relative abundance of *Coprococcus comes* on hyperuricemia through DCA and TCDCA were 0.97 (95% CI: 0.94 to 1.00) and 0.98 (95% CI: 0.97 to 1.00), respectively, and the corresponding percentage of mediation were 12.0% and 7.4% respectively. The indirect effects of *Dorea longicatena* on hyperuricemia via DCA and TCDCA were 0.97 (95% CI: 0.95 to 1.00) and 0.98 (95% CI: 0.97, 1.00), and the percentage of their mediation effect were 10.1% and 6.0%, respectively (Figure 1 F).

Conclusion: We identified several key species of gut microbiome for hyperuricemia and demonstrated that the association between gut microbiome dysbiosis and prevalent hyperuricemia is partially mediated via bile acids. These findings provide new sights into the role of microbiome and bile acids in the development of hyperuricemia and may contribute to translational opportunities.

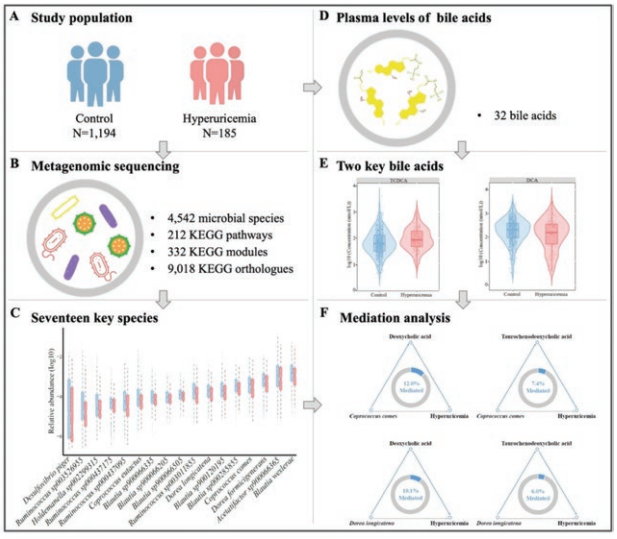

Figure 1 (A) 1194 healthy control and 185 participants with hyperuricemia were included in this study. **(B, C)** Gut microbial composition was determined using shotgun metagenomic sequencing and seventeen key microbiome species were significantly associated with prevalent hyperuricemia. **(D, E)** Plasma bile acids were measured by high-performance liquid chromatography mass spectrometry and two key bile acids, taurochenodeoxycholic acid (TCDCA) and deoxycholic acid (DCA), were associated with prevalence of hyperuricemia. **(F)** Examples of mediating effects of bile acids on the relationship between key species and prevalence of hyperuricemia.

POS0091 **USE OF HIGH-PLEX DATA REVEALS NOVEL INSIGHTS INTO THE TEMPORAL ARTERY OF GIANT CELL ARTERITIS**

Keywords: Biomarkers, Vasculitis, Treat to target

S. Parreau[1,2,3], E. Molina[4,5], S. Dumonteil[2], R. Goulabchand[6], M. Bois[7], T. Naves[3], M. O. Jauberteau[3], A. L. Fauchais[2,3], E. Liozon[2], W. Cornelia[1], K. Ly[2,3]. *[1]Mayo Clinic, Rheumatology, Rochester, United States of America; [2]Dupuytren University Hospital, Internal Medicine, Limoges, France; [3]Faculty of Medicine, INSERM U1308 - CAPTuR "Control of cell activation, Tumor progression and Therapeutic resistance", Limoges, France; [4]University of California San Diego, Sanford Consortium for Regenerative Medicine, La Jolla, United States of America; [5]Salk Institute for Biological Studies, Next Generation Sequencing Core, San Diego, United States of America; [6]University Hospital of Nimes, Internal Medicine, Nîmes, France; [7]Mayo Clinic, Pathology, Rochester, United States of America*

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis that triggers acute arterial occlusion and can even lead to death over the age of 50 [1]. While mechanism underlying GCA are predominantly derived from inflammatory response, none of the anti-inflammatory drugs currently used limit efficiently patient's disease course. It was previously shown that histopathological lesions involve the three layers of the artery wall called adventitia, media, and intima. Activation of adventitial dendritic cells is the initial trigger of the vascular remodeling in GCA leading to intimal hyperplasia but the early molecular mechanism that activates those cells remains unknown. Our hypothesis is that each layer of the artery, perivascular tissue included, shows a unique transcriptomic signature which could define and explain the different molecular events in the inflammatory and vascular remodeling processes in GCA. For that, whole tissue spatial transcriptomics analysis offers advanced opportunities in elucidating functional mechanisms of pathologic tissues with complex organization such as GCA especially in human temporal artery, the most frequently affected artery in GCA.
Objectives: Uncover the key coding genes to define new biomarkers or pathways associated with GCA by performing the first *in situ* spatial profiling characterization of molecular actors involved in temporal arteries from GCA patients in comparison to normal arteries.
Methods: From human formalin-fixed paraffin-embedded temporal artery biopsy samples (GCA n=9; controls n=7), we performed a whole transcriptome analysis by using NanoString GeoMx Digital Spatial Profiler (DSP) [2]. A total of 59 individual regions of interest (ROIs) were created within each of the 4 layers for each individual artery. After ROIs collection and library construction, samples were sequenced on the Illumina NovaSeq 6000 platform and reads were digitally quantified and normalized using GeoMx DSP Data Analysis software. Differential expressed genes (DEGs) (fold change >2 or <-2, p-adjusted <0.05) were compared for each layer, to build a spatial and pharmacogenomic network in disease course.
Results: Overall, we found that most of the transcriptome studied (12076 genes) was upregulated in GCA arteries. Precisely, 350, 340, 142 and 5 DEGs were found in intima, media, adventitia, and perivascular tissue respectively. Enrichment analysis highlighted that inflammation/immune-related functions and vascular remodeling were significantly limited to intima and media layers. Upregulated immune-related functions concerned macrophage differentiation & T cell, B cell, complement activations. Regarding vascular remodeling pathways, we found an upregulation of: (i) collagen metabolic process and fibroblast proliferation concerning the 3 artery layers, (ii) angiogenesis & epithelial cell migration in intima and media layers, (iii) smooth muscle cell proliferation & ossification in intima layer. Our pharmacogenomic network analysis identified genes that could potentially be targeted by immunosuppressive drugs currently approved or new immunotherapies.
Conclusion: Our findings provide the first *in situ* spatial profiling characterization of molecular actors involved in GCA which is essential for the discovery of potential new therapeutic targets to cure this disease. The differential spatial upregulation of genes involved in inflammatory process and vascular remodeling suggests a differential chronological involvement of each layer of the artery.

POS0092 **SPATIAL DISTRIBUTION OF DISTINCT FIBROBLAST SUBTYPES IN GIANT CELL ARTERITIS**

Keywords: Descriptive Studies, Vasculitis

S. Xu[1], W. F. Jiemy[1], J. C. Graver[1], Y. Van Sleen[1], K. Van der Geest[1], P. Heeringa[2], E. Brouwer[1], A. Boots[1], M. Sandovici[1]. *[1]University Medical Center Groningen, University of Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]University Medical Center Groningen, University of Groningen, Pathology and Medical Biology, Groningen, Netherlands*

Background: Giant cell arteritis (GCA) is a systemic vasculitis of large- and medium-sized arteries which is characterized by granulomatous inflammation and vascular remodeling. The pathogenesis of GCA starts in the adventitia where fibroblasts are the major cell population. Fibroblasts are recognized for synthesizing and remodeling the extracellular matrix (ECM), but their phenotype and role in GCA-affected blood vessels is largely unknown.
Objectives: To explore the distribution of fibroblast phenotypes and their link to vascular remodeling in GCA.
Methods: Temporal artery biopsies (TABs) from patients with GCA (n=9) and controls (n=9), and aorta tissues from GCA (n=9) and atherosclerosis (AS, n=11)-related aneurysm were examined. Immunohistochemical staining for CD90 (pan-fibroblast), fibroblast activation protein alpha (FAP, activated fibroblast marker), podoplanin (immunofibroblast marker), CD248 (fibrosis-related marker), alpha-smooth muscle actin (αSMA, myofibroblast marker) was performed to evaluate the distribution of fibroblast subtypes. The expression of transforming growth factor beta (TGFβ), fibroblast growth factor 21 (FGF21), platelet derived growth factor AA (PDGFAA) and PDGFB as markers of active remodeling pathways was also determined. For each marker the percentage of positive cells was determined by Qupath 0.3.0.
Results: TABs from GCA patients showed increased expression of CD90, FAP, podoplanin, CD248, FGF21, PDGFAA and PDGFB in the adventitia and intima compared with the controls. Isolated higher expression of TGFβ in the adventitia and αSMA in the intima was also documented. $CD90^+FAP^+$ activated fibroblasts and $CD90^+$podoplanin$^+$ immunofibroblasts were predominantly located in the adventitia, whereas αSMA^+ myofibroblasts were observed mainly in the intima, and $CD248^+$ fibroblasts in the adventitia-media border and intima. High expression of FAP, CD248, FGF21 and PDGFB in the media-intima was associated with intimal hyperplasia in GCA-positive TABs. GCA-affected aortas showed different patterns: $CD90^+FAP^+$ activated fibroblasts, $CD90^+$podoplanin$^+$ immunofibroblasts and $CD248^+$ fibroblasts accumulated especially in the structurally disrupted media, which was associated with abundant expression of PDGFB and FGF21. These three fibroblast phenotypes were hardly observed in AS-affected aortas. We also observed expression of CD90, FAP, podoplanin and CD248 in the artery tertiary lymphoid organs (ATLOs) of the adventitia in GCA-affected aortas. αSMA^+ myofibroblasts were expressed at similar levels in GCA and AS-affected aorta tissues, being mainly located in the intima.
Conclusion: This study documents a distinct spatial distribution pattern of fibroblast subtypes in GCA-affected temporal arteries and aorta tissues and their association with markers of active remodeling pathways. Further research is needed to dissect the precise role of these fibroblast subtypes in the pathobiology of GCA.

TRANSCRIPTOMIC AND METHYLOMIC PROFILING OF CD4+ T-CELLS IN GIANT CELL ARTERITIS WITH DIFFERENT DISEASE ACTIVITY

Keywords: -omics, Genetics/Epigenetics, Vasculitis

E. Estupiñán-Moreno[1], J. Hernández-Rodríguez[2], T. Ll[3], L. Ciudad[3], E. Andrés-León[1], L. C. Terron-Camero[1], S. Prieto-González[2], G. Espígol-Frigolé[2], M. C. Cid[2], A. Márquez[1], J. Martin Ibanez[1], E. Ballestar[3], L. Ortiz-Fernández[1]. *[1]Spanish National Research Council (CSIC), Institute of Parasitology and Biomedicine López-Neyra (IPBLN), Granada, Spain; [2]Hospital Clinic, IDIBAPS, University of Barcelona, Department of Autoimmune Diseases, Barcelona, Spain; [3]Josep Carreras Research Institute (IJC), Epigenetics and Immune Disease Group, Badalona, Barcelona, Spain*

Background: Giant cell arteritis (GCA) is an inflammatory large-vessels vasculitis representing an important clinical challenge. First, an early diagnosis of GCA is difficult due to the clinical heterogeneity and the lack of specific biomarkers. In addition, although the therapy generally used are glucocorticoids (GC), relapses are common when GC are tapered [1]. The etiology of this disorder is complex in which multiple genetic and epigenetic factors contribute to its development [1]. Although the pathogenic mechanisms remain insufficiently understood, a central role for CD4+ T-cells has been demonstrated [2]. In this context, understanding how the transcriptome and methylome of this cell type are altered in GCA patients and how they are influenced by GC will yield new insights into the pathogenesis of this vasculitis.
Objectives: To shed light into GCA pathogenesis and to identify molecular mechanisms that might serve as novel biomarkers or potential drug targets, we characterized the transcriptome and methylome signatures of GCA CD4+ T-cells and the way these cells are affected by remission and by the effect of GC.
Methods: Both DNA and RNA were isolated from CD4+ lymphocytes positively sorted by flow cytometry from whole blood. Subsequently, DNA methylation profiling with the Illumina Infinium Methylation EPIC array and RNA-sequencing were carried out. After quality controls, epigenome- and transcriptome-wide association were performed for 81 samples: 23 healthy controls and 58 GCA patients grouped in three different clinical status (active before starting GC [n= 13], in remission with GC [n= 22], and in remission without GC [n= 23]).
Results: The results of this work revealed a profound dysregulation in both the gene expression and DNA methylation patterns of CD4+ T-cells of GCA patients. Particularly, CD4+ T-cells from GCA patients with an active state of the disease before starting GC treatment showed substantial changes in inflammatory processes, such as NOTCH1, interleukin-6 (IL-6), IL-1 and vitamin D receptor signalling pathways, among others. In addition, we also observed alterations in molecular pathways related with angiogenesis, the vascular endothelial growth factor (VEGF) receptor, and with the differentiation of T helper 2 (Th2), including the IL-2/STAT5 and IL-4 pathways. Interestingly, our findings also indicated that the pro-inflammatory expression profiles observed in the active disease are lost when the disease subsides, and that GC therapy significantly remodels both the transcriptome and the methylome of CD4+ T-cells. Particularly, changes in molecular mechanisms related to drug metabolism, such as GC receptor genes and glucuronosyltransferase family genes were also found.
Conclusion: The results of the transcriptome and methylome characterization of GCA CD4+ T-cells have provided new evidences of genes and pathways contributing to the pathogenic role of this cell type in GCA, providing a clearer picture of the molecular processes driving disease activity and how they vary in response to GC treatment.

Background: Giant Cell Arteritis (GCA) is a systemic inflammatory disease that affects large and medium-sized arteries. It is the most common vasculitis in people older than 50 years of age [1]. Temporal artery biopsies (TABs) are routinely performed for diagnosis, giving the invaluable opportunity to analyze inflamed tissues. Different histological patterns of inflammation can be found in TABs: transmural inflammation (TMI) is the most frequent pattern (78% of the positive TABs), while inflammation limited to adventitia (ILA) can be found in 7% of the positive TABs [2]. It is not known if ILA precedes TMI or if they are distinct GCA subsets. Knowledge on disease pathogenesis is growing [3], but high-throughput assays in TABs are still scarce [4-7]. GCA patients are actually treated with glucocorticoids, irrespective of clinical presentations and inflammation patterns. It is necessary to increase the knowledge on the molecular features of GCA to implement precision medicine.
Objectives: To identify differentially expressed genes (DEGs) in TAB from patients with GCA versus controls. To increase the knowledge on TMI and ILA histological patterns in GCA.
Methods: A retrospective cohort of patients subjected to TABs at AUSL-IRCCS at Reggio Emilia (Italy) was included: 42 patients had GCA with TMI; 7 patients had GCA with ILA; 7 patients had normal TABs and received a different diagnosis. All the patients with TMI and normal TABs were naïve from therapy while 4/7 patients with ILA were receiving glucocorticoids at the time of TABs. RNA was extracted from formalin-fixed paraffin-embedded TABs. The expression of 770 genes was profiled with the NanoString nCounter PanCancer Immune Profiling Panel. Data were analyzed with nSolver software 4.0. Background thresholding using the negative control probes was applied, then data were normalized over the positive control probes and 18 housekeeper genes. DEGs with fold changes >2.0 and Benjamini-Yekutieli adjusted p-values <0.05 were considered significant. Unsupervised clustering was performed with nSolver. Pathway analysis was performed with DAVID.
Results: Unsupervised clustering based on the expression of the 770 genes revealed two groups of samples: the first group contained all the normal TABs plus TABs with ILA, while the second group contained 41/42 TABs with TMI. In particular, TNF superfamily genes or genes related to senescence allowed to cluster TABs with TMI from ILA and normal TABs. TABs with TMI showed 31 down- and 268 up-regulated genes compared to normal TABs; 20 down- and 135 up-regulated genes compared to TABs with ILA. TABs with ILA revealed a gene expression profile similar to normal TABs: 47 genes reached fold changes >2.0, but p-values did not maintain statistical significance after correction for multiple testing. These genes were also modulated in TABs with TMI. The chemokine CCL18 was the top up-regulated gene, while the cell adhesion molecule MCAM was the top down-regulated gene in TMI. CD86 costimulatory molecule, a marker of antigen-presenting cells, was detected only in TMI. JAK3 resulted increased in TMI, while JAK1 and JAK2 were not modulated. CD27 activating immune checkpoint was detected in all the TABs with TMI and 6/7 TABs with ILA, while it was not detected in normal TABs. The following pathways were enriched with DEGs: chemokine and TLR signaling, antigen processing and presentation via MHC class II, positive regulation of T cell activation, cellular responses to IL-1, TNF, IFNγ.
Conclusion: TABs with TMI had a distinct transcriptome compared to TABs with ILA. A set of genes were deregulated in TABs both with TMI and ILA versus normal TABs, indicating that ILA might represent the early stages of the disease. Gene profiling allowed to deepen the knowledge on GCA pathogenesis.

SINGLE-CELL LANDSCAPE OF CD4+ T LYMPHOCYTES REVEALS A POTENTIAL ROLE OF CYTOTOXIC CELLS IN GIANT CELL ARTERITIS

Keywords: Vasculitis, Adaptive immunity, -omics

E. Carmona[1,2], J. L. Callejas-Rubio[3], N. Ortego[4], E. Raya[5], R. Ríos Fernández[3], B. Timmermann[6], J. Martin Ibanez[1], A. Márquez[1]. *[1]Institute of Parasitology and Biomedicine López-Neyra (IPBLN) - CSIC, -, Granada, Spain; [2]Systemic Autoimmune Diseases Unit - ibs.GRANADA, -, Granada, Spain; [3]Hospital Clínico San Cecilio, Systemic Autoimmune Diseases Unit, Granada, Spain; [4]Faculty of Medicine - University of Granada, Department of medicine, Granada, Spain; [5]Hospital Clínico San Cecilio, Rheumatology department, Granada, Spain; [6]Max-Planck-Institut für molekulare Genetik, Sequencing core facility, Berlin, Germany*

Background: Giant cell arteritis (GCA) is a systemic vasculitis mediated by an aberrant immunological response against the endothelium of medium- and large-sized blood vessels [1]. Even though the pathogenic mechanisms that drive GCA are yet to be settled, there is strong evidence that CD4$^+$ T lymphocytes play a crucial role in the development of this vasculitis [2]. Recently, single-cell RNA sequencing has resulted in a scientific and technological revolution, enabling the characterization of the gene expression profile of thousands of individual cells in different tissues [3]. This approach has allowed the identification of new cell subtypes, some of them being exclusively represented in pathogenesis, and has also proved useful as a tool for reporting new disease-specific biomarkers.
Objectives: In this study, we aimed to define new pathological mechanisms driving GCA through the comprehensive characterization of the gene expression profile of CD4$^+$ T cells by performing single-cell RNA sequencing in GCA patients and healthy controls.
Methods: CD4$^+$ T cells from whole blood of 16 individuals (eight GCA patients and eight sex- and age-matched healthy controls) were obtained. Based on clinical parameters, five patients were classified as active GCA and 3 of them as patients in remission. Single-cell libraries were prepared from isolated CD4$^+$ T cells using the '*Chromium Single Cell Gene Expression*' (10X Genomics). Sequencing data were pre-processed with the CellRangerV3.0 software. Then, quality control analysis, dimensionality reduction, clustering and differential gene expression profiling were conducted with the R package Seurat V4[4].
Results: A total of 114.799 cells were analyzed and classified into 13 clusters according to their transcriptomic profile. Manual annotation of the different clusters based on canonical markers permitted the identification of 6 distinct CD4$^+$ T cell types including naïve (Tnaïve), central memory (T_{CM}), effector memory (T_{EM}), effector memory expressing granzyme K (T_{EM} *GZMK*$^+$), regulatory (Tregs) and cytotoxic T lymphocytes (CTL). The comparative analysis of cell type composition between the different subgroups showed a significant reduction of the cytotoxic cell compartment in GCA patients in remission compared with active patients (p=0.011) and controls (p=0.045) as well as a decreased frequency of Tregs in active patients compared with healthy individuals (p=0.029). In addition, differential expression analysis evidenced a significant overexpression of granzyme B (*GZMB*) and the zinc finger protein 683 (*HOBIT),* both involved in cytotoxic processes, in CTLs of active patients compared with patients in remission (p=0.017) and controls (p=1.14x10-49), respectively. Moreover, in both active and in remission patients, the Treg compartment showed a reduced expression of genes related to regulatory functions, like *HLA-DRA* (p=3.34x10-7) and *LGALS1* (p=1.14x10-8), compared with healthy controls.
Conclusion: The first single-cell atlas of CD4$^+$ T cells in GCA provided evidence for the first time of a potential pathogenic role of CD4$^+$ T cells with cytotoxic functions in this vasculitis and supported the crucial role of Tregs in the pathogenesis of GCA.

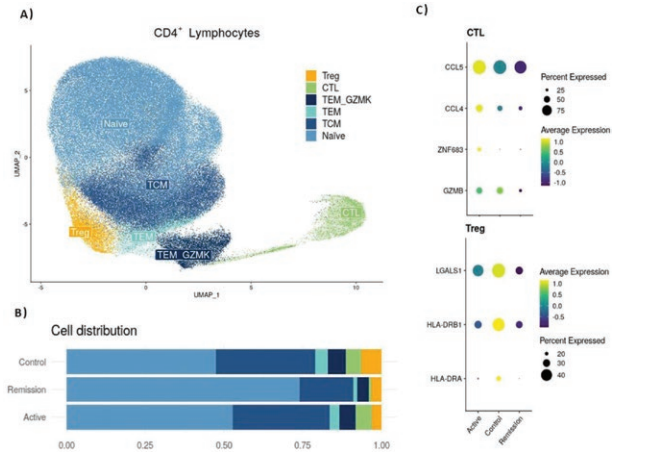

Figure 1. T CD4$^+$ cell overview in GCA. (A) UMAP of CD4$^+$ T cells distributed by expression. (B) Barplot of each T cell sub-type contribution. (C) Dotplot of CTL and Treg clusters for specific genetic markers classified per group. Dot size indicates proportion of cells expressing the gene, color indicates average of expression.

HYPOXIA AND MPO-ANCA IgG INDUCED BIOPHYSICAL CHANGES IN NEUTROPHILS MAY PROMOTE ENDOTHELIAL INJURY IN ANCA ASSOCIATED VASCULITIS

Keywords: Vasculitis

N. Pisacano[1], A. Dhutia[2,3], S. Rothery[1], S. P. Mcadoo[2,3], J. Guck[4], C. P. Pusey[2], E. Chilvers[1], A. Cowburn[1], K. Lodge[1], M. Prendecki[2,3]. *[1]Imperial College London, NHLI, London, United Kingdom; [2]Imperial College London, Immunology and Inflammation, London, United Kingdom; [3]Imperial College Healthcare NHS Trust, Hammersmith Hospital, Imperial College Renal and Transplant Centre, London, United Kingdom; [4]Max Planck, Max Planck Institute for the Science of Light, Erlangen, Germany*

Background: ANCA associated vasculitis (AAV) is characterised by neutrophil-mediated endothelial damage. Neutrophil deformability impacts their ability to traffic through microvasculature. Distinct biophysical properties of neutrophils in patients with active AAV, e.g. in response to ANCA or hypoxia in inflamed tissues, may contribute to endothelial injury.
Objectives: Investigate how MPO-ANCA IgG (ANCA) treatment and/or hypoxia affect the actin cytoskeleton or biophysical properties of neutrophils, and whether this phenotype is replicated in patients with active AAV.
Methods: Whole blood and isolated neutrophils from patients with active AAV (AAV), patients with AAV in remission (rAAV) or healthy controls (HC) was analysed using real time deformability cytometry (RT-DC), a novel microfluidic technique able to identify individual cell biophysical profiles. Deformation was calculated using ShapeOut. Neutrophils were isolated using immunomagnetic separation. Cells were primed with TNF (2 ng/mL, 15 min) and stimulated with healthy donor IgG (CIgG), or ANCA IgG (100 ug/mL, 1 h) under normoxia (21% O_2) or hypoxia (5% O_2). Cells were stained for F actin (AF488 Phalloidin) and imaged using confocal microscopy. Cell area and total percentage phalloidin staining was analysed (ImageJ).
Results: AAV neutrophils (n=27) were significantly stiffer than rAAV (n=25) or HC (n=15), displaying decreased deformation (median 0.085, 0.086, and 0.076 au for HC, rAAV, and AAV respectively, p=0.0001). There was an inverse correlation between AAV neutrophil deformation and disease activity as measured by BVAS score (r=-0.573, p=0.032). This phenotype of decreased deformation was replicated by ANCA stimulation of HC neutrophils (median 0.086, 0.085 and 0.082 for untreated, CIgG, and ANCA respectively, p=0.05). Hypoxia prevented the effect of ANCA stimulation on HC neutrophils (median 0.078, 0.077, and 0.079 au for untreated, CIgG, and ANCA respectively, ns). ANCA stimulation of HC neutrophils increased cell area (mean 51.56/63.07/88.61 um^2, p=0.0008) and total actin signal (mean 27.61/25.86/44.30%, p=<0.0001) (untreated, CIgG, ANCA respectively, Fig 1A-C). At baseline, hypoxic neutrophils were larger with increased actin staining. Under hypoxia the effect of ANCA stimulation was diminished, with a smaller increase in area (mean 60.34/67.48/71.15 um^2, p=0.0011) and total actin signal (mean 38.15/46.01/45.49%, p=0.0255) compared to normoxia (Fig 1D-F). AAV neutrophils (n=8) were significantly larger, with more F-actin at baseline and showed a larger increase in actin following ANCA stimulation compared to HC cells: area (mean 75.73/98.68/121.25 um^2, p=0.0088) and total actin signal (mean 51.74/74.85/83.44%, p=0.0032) (Fig 1G-I).
Conclusion: Neutrophils from patients with active AAV display distinct physical properties, which correlate with disease activity. Similar results are seen when neutrophils are stimulated *in vitro* with ANCA. In keeping with this, increased neutrophil actin polymerisation and marked lamellopodia formation is seen following ANCA stimulation *in vitro*, with the greatest effect seen when cells from patients with active AAV were used. Of interest, incubation under hypoxic conditions diminished the effect of ANCA stimulation suggesting that hypoxia can modulate actin polymerisation. This phenotype of increased cell stiffness in AAV may be due to reorganisation of the actin cytoskeleton and lead to increased neutrophil retention in pulmonary and renal microvasculature, thus increasing the potential for

neutrophil-endothelial cell interactions and microvascular damage. Therefore, targeting cytoskeletal changes in AAV may offer a route to improve clinical outcomes.

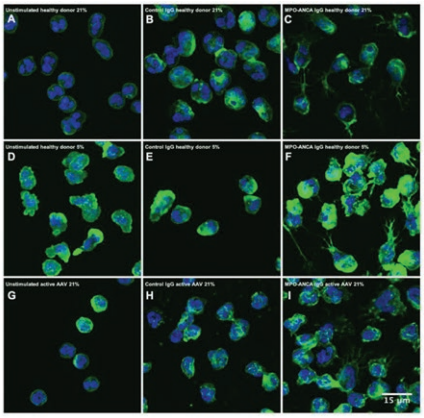

Figure 1: Effect of hypoxia and MPO-ANCA IgG stimulation on neutrophil size and F-actin polymerisation in healthy control and active AAV neutrophils.

Neutrophils ($2x10^5$) were primed with 2 ng/mL TNF for 15 min and stimulated with 100 ug/mL of control or MPO-ANCA IgG for 1 hour. Neutrophils were stained for Phalloidin (AF488, green) and mounted with VectaShield[R] Antifade Mounting Medium with DAPI (blue) and imaged at 63x using confocal microscopy (representative images shown). A-C: HC 21% (n=14); D-F: HC 5% O2 (n=14); G-I: AAV 21% O2 (n=8). A, D, G: Unstimulated; B, E, H: Control IgG; C F, I: MPO-ANCA IgG.

POS0097 ASSOCIATION BETWEEN LOSS OF IMMUNE CHECKPOINT PROGRAMMED CELL DEATH PROTEIN 1 AND ACTIVE ANCA-ASSOCIATED RENAL VASCULITIS

Keywords: Vasculitis, Kidneys

B. Tampe[1]. [1]*University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany*

Background: Immune checkpoint inhibitors (ICIs) have made an important contribution on the survival of patients with certain cancers. ICIs interrupt co-inhibitory signalling pathways mediated by programmed cell death protein 1 (PD-1), programmed cell death protein-ligand 1 (PD-L1), and cytotoxic T lymphocyte-associated antigen (CTLA-4) that result in the elimination of cancer cells by stimulating the immune system.
Objectives: Immune-related adverse events have also been described and attributed to an enhanced immune system activation. Recent observations have suggested dysregulation of immune checkpoints in active antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Therefore, we here aimed to analyze abundance of immune checkpoint molecules PD-1/PD-L1 and its implications in ANCA-associated renal vasculitis.
Methods: We here analyzed intrarenal PD-1 and PD-L1 by immunostaining in a total number of 15 kidney biopsies with ANCA-associated renal vasculitis in correlation with glomerular and tubulointer-stitial lesions. For independent validation, publicly available datasets were analyzed for PD-1 expression (encoded by PDCD1).
Results: We here observed a predominant tubulointerstitial expression of PD-1 that is decreased in ANCA-associated renal vasculitis. Moreover, loss of tubulointerstitial PD-1 correlated with active ANCA-associated renal vasculitis. Consistent to the observed association with active glomerular and tubulointerstitial lesions, we identified that interstitial PD-1 correlated with tubular and/or glomerular PD-L1 positivity. Finally, PD-1 was associated with decreased local synthesis of complement factor B. Interestingly, we did not observe a correlation between PD-1 and complement C5 or its C5a receptor. Combined with our observations, this may implicate a link between im-paired PD-1/PD-L1 signalling, complement factor B, and active ANCA-associated renal vasculitis.
Conclusion: These findings could be of relevance because experimental data have already been described that PD-1 agonism can be used therapeutically to attenuate autoimmunity in multiple disease models. Furthermore, targeted therapy against complement C5/C5a receptor and factor B are both available and currently evolving in the treatment of AAV. Therefore, this pilot study expands our current knowledge and describes a potential interplay between immune checkpoints and the alternative complement pathway in active ANCA-associated renal vasculitis.

POS0098 IDENTIFICATION OF THE CENTRAL TOLERANCE CHECKPOINT FOR AUTOREACTIVE PROTEINASE 3+ B CELLS IN HUMAN BONE MARROW

Keywords: Adaptive immunity, Vasculitis, Biomarkers

A. Berti[1], M. Tomasi[2], I. Pesce[2], E. Lista[3], A. Guella[3], G. Paolazzi[1], R. Bortolotti[1], G. Grandi[2], S. Hillion[4], U. Specks[5], D. Cornec[4]. [1]*Hospital of Trento, University of Trento, Rheumatology - CISMED Center of Medical Sciences, Trento, Italy;* [2]*Hospital of Trento, University of Trento, CIBIO, Trento, Italy;* [3]*Hospital of Trento, Hematology, Trento, Italy;* [4]*INSERM UMR1227, B cells, Autoimmunity and Immunotherapies, Rheumatology, Brest, France;* [5]*Mayo Clinic, Pulmonary medicine, Rochester (MN), United States of America*

Background: Autoreactive proteinase 3 (PR3+) B cells have recently been phenotypically and functionally characterized, and the presence of defective central antigen-independent and peripheral antigen-dependent checkpoints in patients with ANCA-associated vasculitis (AAV) has been shown. This work aimed to investigate the central tolerance-checkpoint controlling immature PR3+ B cells in the bone marrow (BM), before their migration into the periphery as transitional B cells.
Objectives: We investigated the presence and the specific phenotypic features of PR3+ B cells in BM mononuclear cells (BMMC) of non-vasculitis controls (No-AAV), comparing them to paired peripheral blood mononuclear cells (PBMC) of No-AAV and PBMC of PR3-AAV patients, and the central tolerance-checkpoint for PR3+ B cells.
Methods: We used a customized flow-cytometry assay, using PR3 as ligand to target autoreactive PR3+ B cells (PR3+B cells). Adult PR3-ANCA positive AAV (PR3-AAV) patients with a clinical diagnosis of granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) were selected among consecutive subjects with AAV seen in our Rheumatology Unit. Subjects without vasculitis (No AAV) were selected among consecutive subjects undergoing bone marrow aspirate to exclude hematologic conditions of myeloid origin and eventually resulted healthy or in long-term complete remission during follow-up of myeloid neoplasms. PMBC from AAV patients and paired samples of BMMC and PBMC from No AAV were collected and analyzed.
Results: The proportion of PR3+ B cells within BMMC (median [IQR25-75%]; 1.98%[1.77-2.75]) was higher than within PBMC of No-AAV (0.9%[0.63-1.44], $p<0.01$ by paired comparison) and similar to their proportion within PBMC of PR3-AAV patients (1.82%[1.66-3.21]; $p>0.05$). When focusing on immature/transitional CD24++CD38++B cells only in No-AAV, we observed distinct phenotypes within BMMC versus PBMC (i.e. higher proportion of CD27-CD10+ and lower expression of CD21, IgD, IgM within BMMC versus PBMC), representing two separate developmental steps of B cell maturation. Within CD24++CD38++ B cells, BMMC contained the greatest proportion of PR3+ B cells as compared to PBMC (3.35%[1.99-4.92] versus 1.23%[0.62-1.55], $p<0.01$). We observed a significant decline of the PR3+ fraction from T1-like/immature subset (IgD-IgM+; 2.80%[1.23-4.02]) to T2-like/early transitional subset (IgD+IgM+; 1.76%[0.96-2.68], $p<0.01$) in BMMC, while no significant reduction was observed between the latter subset and the transitional compartment of PBMC (1.26%[0.62-1.56], $p>0.05$).
Conclusion: To prevent PR3-related autoimmunity, autoreactive PR3+ B cells pass a stringent selection in the BM, and their removal by central tolerance-checkpoint activity occurs mainly between T1-like/immature to T2-like/early transitional B cells of BMMC.

Background: IgA vasculitis (IgAV) is a small vessel vasculitis occurring predominantly in childhood. Studies concerning the genetic background of IgAV have confirmed that susceptibility to the disease may be influenced by Human Leukocyte Antigens (HLA), with HLA-DRB1 gene showing a strong association with the disease.
Objectives: We aimed to investigate HLA-DRB1 polymorphism among Croatian patients with IgAV and to determine if there are associations with disease susceptibility and clinical heterogeneity.
Methods: 123 IgAV patients, fulfilling the diagnostic EULAR/PRINTO/PRES criteria from three pediatric rheumatology centers and 202 unrelated healthy individuals were enrolled. Genomic DNA was extracted from whole peripheral blood. The HLA-DRB1 alleles were analysed using the Next Generation Sequencing (NGS) method.
Results: Among 123 patients with IgAV, 68 were girls and 55 were boys with median age 6.3 (4.5-8.2) years at the time of diagnosis. All patients had purpuric rash, 75.7% had arthralgia or arthritis, 32.5% had affected gastrointestinal (GI) system, while 25.2% patients developed IgA vasculitis nephritis (IgAVN). The HLA-DRB1*12:01 allele was associated with an increased risk for IgAV (OR 4.45, 95% CI=1.17-16.95, P=0.03), while HLA-DRB1*11:01 allele was associated with an increased risk for GI involvement in patients who developed IgAV (OR 3.29, 95% CI=1.2-8.98, P=0.031). A marginally significant (P=0.068) higher frequency of the HLA DRB1*10:01 allele in patients with GI symptoms was observed. No significant differences were found in the distribution of HLA DRB1 alleles between patients with IgAVN and those who did not develop nephritis.
Conclusion: Our results demonstrated that HLA-DRB1*12:01 allele was associated with susceptibility to IgAV in the Croatian children, while HLA-DRB1*11:01 allele showed association with GI manifestations of the disease.

TARGETING NF-κB SIGNALLING IN B LINEAGE CELLS AS A POTENTIAL NOVEL TREATMENT STRATEGY FOR ANCA-ASSOCIATED VASCULITIS

Keywords: Autoantibodies, Adaptive immunity, Vasculitis

Background: B cells are crucially important in the pathogenesis of many autoimmune diseases, including ANCA-associated vasculitis (AAV), which is further demonstrated by the beneficial clinical effects of rituximab (anti-CD20) B cell targeted therapy. Despite its advantages, this treatment strategy results in long-term B cell depletion and fails to target long-lived plasma cells, rendering an unmet need for more reversible and combined B and plasma cell targeting approaches to achieve long-term disease remission. This aim may be reached by targeting signalling pathways essential for different B cell functions. The canonical and non-canonical NF-κB signalling pathways regulate fundamental B and/or plasma cell responses downstream of various B cell surface receptors, including the B cell receptor, CD40, and TLRs.
Objectives: To study potential alterations in NF-κB signalling in B lineage cells and to evaluate the effects of targeting NF-κB on B cell responses in general, and more specifically on proliferation, plasmablast differentiation and (auto)antibody production in B cells from AAV patients.
Methods: Memory B cells were obtained from AAV patients and healthy donors (HD), and gene expression profiles were generated by RNA-sequencing. Functional assays were performed by culturing PMBCs from AAV patients and HD with stimuli mimicking T cell-dependent (anti-CD40/IL-21) and T cell-independent (CpG/IL-2) conditions. Pharmacological inhibitors of Inhibitor-of-κB-kinase-β (IKKβ, canonical pathway) or NF-κB inducing kinase (NIK, non-canonical pathway) were added to the cultures. Downstream NF-κB signalling was determined by Western blot. After 6-day cultures, B cell proliferation and differentiation were determined by flow cytometry, and ELISA was performed for the detection of (auto)antibody production.
Results: Memory B cells from AAV patients with active disease exhibited an increased expression of NF-κB-associated genes compared to patients in remission and HD. Targeting IKKβ or NIK in AAV and HD B cells effectively blocked downstream canonical or non-canonical NF-κB signalling, respectively. IKKβ and NIK inhibition significantly reduced B cell proliferation in both stimulatory conditions of the functional assay. In addition, IKKβ and NIK inhibitors attenuated B cell differentiation into plasmablasts and antibody production, including anti-proteinase-3 (PR3) autoantibodies. Interestingly, the effects of NIK inhibition appeared to be B cell-specific, as T cell proliferation was largely unaffected.
Conclusion: These data reveal that NF-κB-associated genes are upregulated in memory B cells from AAV patients with active disease and that targeting of NF-κB signalling inhibits B cell responses that are important contributors to the autoimmune process, including autoantibody production. These findings suggest that targeting NF-κB, and particularly NIK, may be developed into a novel more reversible and B cell directed treatment modality for AAV.

Remarkable Findings in OA Clinical Research

POS0101

FRAILTY CHANGES FOLLOWING TOTAL KNEE ARTHROPLASTY ARE ASSOCIATED WITH FUNCTIONAL IMPROVEMENT RATHER THAN PAIN RELIEF IN THE PATIENTS WITH END-STAGE KNEE ARTHROSIS

Keywords: Osteoarthritis, Motor function, Sarcopenia

K. Inui[1,2], S. Maeda[1], S. Yamada[1], K. Mandai[1], T. Hashimura[1], T. Tachibana[1], H. Ohashi[1], T. Ikawa[1]. *[1]Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan; [2]Osaka Metropolitan University Graduate School of Medicine, Orthopaedic Surgery, Osaka, Japan*

Background: Knee joint disorders in the elderly result in physical frailty and limiting healthy living. Although total knee arthroplasty (TKA) achieves significant pain relief and functional improvement, the effect of TKA on Frailty is not clear.
Objectives: This study aimed to investigate the change in frailty at 1 year postoperatively in patients undergoing primary TKA and to examine the correlated factors with this frailty change.

Methods: Patients with end-stage knee arthrosis who underwent primary TKA at our hospital between July 2020 and May 2021 were included with written consent. Basic attributes such as age, gender and BMI, with appendicular skeletal muscle mass (ASMI) by whole-body mode DXA, presence of sarcopenia by Asian Working Group for Sarcopenia 2019 criteria were measured preoperatively, and VAS for pain during walking, clinical assessment of knee joint function (Knee Society Score: KSS), quadriceps muscle strength by dynamometer, range of motion (ROM), and walking speed were measured before and one year after surgery. The relationship between the changes in the degree of frailty (Japanese Cardiovascular Health Study criteria for frailty) before and 1 year postoperatively.
Results: Seventy-five patients (59 women, mean age 75 years) were included in the study. In univariate analysis, KSS, ROM, muscle strength, and VAS for pain were significantly improved at 1 year after TKA compared to preoperative values ($p<0.0001$, 0.0001, 0.0001, 0.0001: pared *t*-test). The number of frail patients was decreased from 24 to 18 following TKA ($p=0.002$: Fisher's exact test). Multivariate analysis of the association of changes in frailty using ordinal logistic regression showed a positive correlation between improvement in walking speed and improvement in muscle strength ($p=0.01$, $p=0.02$), but not with sex, age, preoperative ASMI or presence of sarcopenia, improvement in pain while walking or ROM (Table 1).
Conclusion: The number of patients with frailty significantly decreased 1 year after TKA; the factors associated with changes in frailty were improvements in gait speed and muscle strength, suggesting that functional improvement rather than the pain-relieving effects of TKA contributed to the improvement in frail.

Table 1.

Factor	Odds Ratio	95% Confidence interval	p value
sex (male)	1.35	[0.22, 9.01]	0.75
age (year)	1.00	[0.93, 1.08]	0.99
appendicular skeletal muscle mass index (kg/m^2)	1.77	[0.79, 4.11]	0.17
presence of sarcopenia	1.84	[0.11, 35.30]	0.68
difference in range of motion (degree)	1.01	[0.95, 1.06]	0.85
difference in quadriceps power (N)	0.99	[0.98, 1.00]	0.02*
difference in waling speed (m/sec)	0.08	[0.01, 0.51]	0.01*
difference in VAS for gait pain	0.98	[0.96, 1.00]	0.09

POS0102 CALCIUM CONTAINING CRYSTALS ARE HIGHLY PREVALENT IN JOINT FLUID OF ADVANCED OSTEOARTHRITIS OF THE KNEE

Keywords: Diagnostic Tests, Osteoarthritis, Crystal Arthritis

T. Niessink[1,2], T. Jansen[2], M. Janssen[2], T. Welting[3], C. Otto[1]. [1]*University of Twente, Medical Cell Biophysics group, Enschede, Netherlands*; [2]*VieCuri Medical Centre, Rheumatology, Venlo, Netherlands*; [3]*MUMC+, Experimental Orthopaedics, Maastricht, Netherlands*

Background: Calcium containing crystals in osteoarthritis (OA) are of interest in the field of rheumatology, as they potentially stimulate the NRLP-3 inflammasome and may become treatable with novel therapeutics. Previous studies using scanning electron microscopy and polarization microscopy (PLM) demonstrated a presence of calcium pyrophosphate (CPP) and basic calcium phosphate (BCP) crystals in early and advanced OA [1]. Calcium carbonate crystals have been found in cartilage specimens of advanced OA and have recently been shown to potentially occur early in development of cartilage calcification [2]
Objectives: In this study we attempt to identify calcium containing crystals in joint fluid of patients with late-stage OA using Raman spectroscopy.
Methods: Synovial fluid samples from advanced knee OA cases were collected from the Maastricht University Medical Center (MUMC+) experimental orthopaedics biobank. This biobank contains synovial fluid samples from patients undergoing total knee replacement surgery for advanced osteoarthritis. The population includes both males and females and all patients were above 18 years of age. Samples were frozen at -80°C. No preservatives were used. Maastricht University Medical Hospital (METC azM/UM) approved sample collection. Patients gave written informed consent before collection of their synovial fluid. Samples were analyzed with an integrated Raman polarized light microscope (H-iRPolM, Hybriscan Technologies B.V., Nijkerk, the Netherlands). For each sample, 20 µl of synovial fluid was pipetted on a microscope slide. Birefringent crystals were localized with PLM and then scanned with the integrated Raman spectrometer. For each particle, the Raman spectrum from 0-3600 cm^{-1} was measured for 1 s/pixel with a laser power of 10 mW and a 532 nm laser. Analysis time per particle was 1-2 minutes depending on particle size. Spectra were analysed by a trained analyst (TN, CO). Samples were considered positive for a certain type of crystal if at least one crystal with a distinctive spectrum could be identified.
Results: Calcium containing crystals were present in all (100%) of the 36 samples. 34 (94.4%) of the samples contained calcite (calcium carbonate) crystals. Dolomite (calcium magnesium carbonate) crystals were present in 10 (27.8%) samples, 9 (25.0%) samples contained both types of calcium carbonate crystals. CPP crystals were present in 33.3% of samples. All the CPP crystals were identified as triclinic CPP, amorphic or monoclinic CPP were not identified. Basic calcium phosphate crystals were present in 9 (25.0%) samples, all of which were hydroxyapatite. Calcium oxalate crystals were present in 7 (19.4%) samples, 3 of which were identified as calcium oxalate dihydrate (COD) and 4 of which were identified as calcium oxalate monohydrate. Most of the samples (80.6%) contained more than one type of calcium crystal, but CPP and BCP were never identified simultaneously in one sample. One patient had some MSU crystals. Raman spectra of identified particles are shown in figure 1.

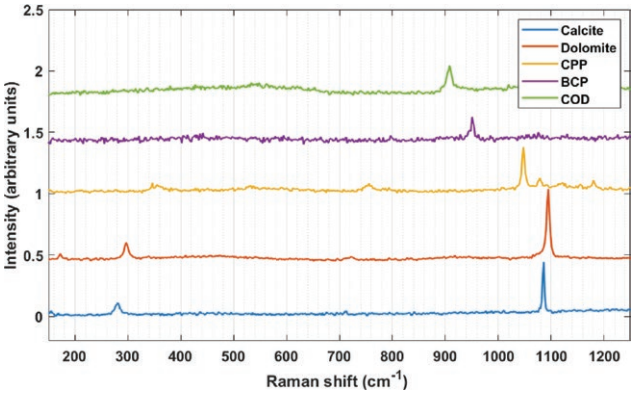

Figure 1. Raman spectra of identified calcium containing crystals.

Conclusion: Calcium containing crystals are common in synovial fluid samples from knee joints in patients with end-stage osteoarthritis. Raman spectroscopy is a novel technique for rheumatology which enables reliable detection and objective identification of crystals such as calcium carbonate. The observation of calcium carbonate (calcite) crystals in synovial fluids of OA patients is novel and a promising subject of further study. Pathways to presentation in synovial fluid and inflammatory properties should be investigated.

Background: The common belief is to consider hand osteoarthritis (HOA) as a less severe disease with a better functional prognosis and a lower global burden than rheumatoid arthritis (RA). However, this paradigm may no longer be true considering the striking efficacy of targeted therapies in RA compared to the weak efficacy of therapies in the most severe form of HOA, namely erosive HOA (EHOA), which impacts 10-20% of symptomatic HOA [1]. Few studies addressed this issue [2].
Objectives: We aimed to compare the burdens of established EHOA and RA. The objectives were to compare pain, functional impairment, quality of life and the prevalence of comorbidities and of cardiovascular diseases (CVD) between established EHOA and RA.
Methods: DIGital Cohort Osteoarthritis Design (DIGICOD) is a French cohort of symptomatic HOA (at least 2 painful joints) with at baseline a mean ± SD disease duration of 12.9 ± 9.6 years [3]. This study involved the EHOA patients, from inclusion visit of DIGICOD, defined by at least 1 erosive joint according to the Verbruggen score. RA patients fulfilling ACR/EULAR 2010 criteria at the 10th year visit were selected from the ESPOIR cohort (Étude et Suivi des Polyarthrites Indifférenciées Récentes), a French cohort of early RA [4]. Pain intensity at rest or mobilization (0-100mm visual analogical scale (VAS)≥40/100), fatigue (VAS fatigue≥25/100), function (normalized (0-100) scores of Health assessment questionnaire for RA, and AUStralian CANadian Osteoarthritis Hand Index for EHOA > 16.7) were analyzed and compared between EHOA and RA using logistic regression models adjusted on age, gender, BMI, comorbidities and socio-educational level. The risk to have ≥2 comorbidities (among CVD, cancer, hemopathy, fracture) or at least 1 CVD (among high blood pressure, diabetes, dyslipidemia, myocardial infarction, stroke) were compared between EHOA and RA adjusted on age, gender, BMI and socio-educational level. Odds ratios (OR) and their 95% confidence intervals (CIs) were reported (EOHA versus RA).
Results: We analyzed 138 patients with EHOA and 379 with RA. The median [interquartile] age of EHOA patients was higher than RA patients (67.3 [64.3; 72.2] vs 48.6 [39.9; 55.6] years, p<0.001). The disease duration, at the evaluation time, was 13.5 [7.0; 20.0] for EHOA and 10.5 years [10.3; 10.7] for RA patients. RA was anti-CCP antibodies positive for 56% of patients and in remission for 61% (DAS28 < 2.6). RA patients were treated by methotrexate (82%), biologics (37%) and 25% by corticosteroids while 20% of EHOA patients received oral non-steroidal anti-inflammatory drugs. EHOA patients had more painful joints in the hands than RA patients (4.0 [2.0;8.8] vs 0.0 [0.0;3.0], p< 0.001). In the adjusted analysis, EHOA was associated with more pain at mobilization (OR = 3.13 95% CI [1.74 to 5.68] p< 0.001) and more functional impairment (OR = 2.27 CI 95% [1.26 to4.17], p = 0.007) (Figure 1). There was no difference for pain at rest and for fatigue VAS. For comorbidities, the proportions of EHOA patients with ≥2 comorbidities were higher than RA patients (37.7% vs 27.5%). However, when we stratified by age, the proportions of patients with ≥2 comorbidities were higher in RA patients between 50 and 70 years old (30.2% vs 47.1%) compared to EHOA patients. In adjusted analysis, the risk to have ≥2 comorbidities was lower in EHOA than in RA patients (OR = 0.25 CI 95% [0.13 to0.48]; p< 0.001) while there was no difference for CVD risk.
Conclusion: After more than 10 years of disease duration, EHOA is associated with more pain and more functional impairment but less comorbidities than RA. This study highlights the significant unmet need for effective therapies for patients with EHOA.

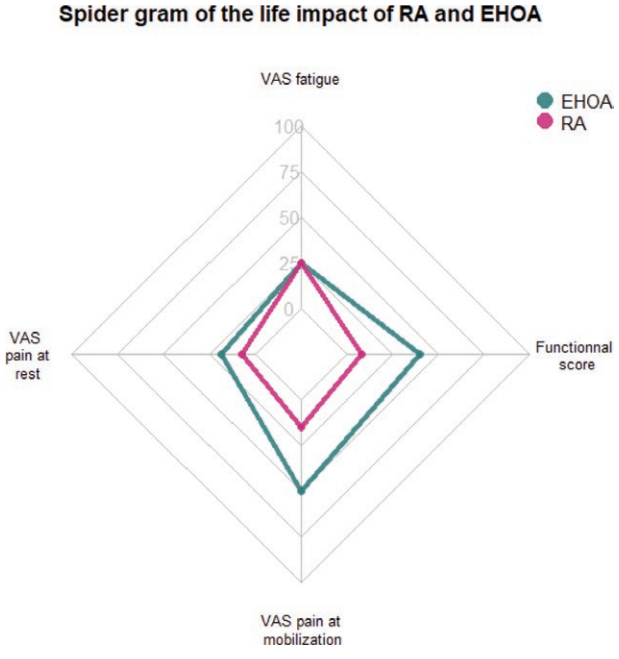

Figure 1. Spider gram of the life impact of RA and EHOA

VAS = visual analogical scale, EHOA = erosive hand osteoarthritis; RA: rheumatoid arthritis.

A PHASE 2B DOUBLE-BLIND PLACEBO-CONTROLLED RANDOMIZED CLINICAL TRIAL OF SB-061, AN AGGRECAN MIMETIC, IN SUBJECTS WITH SYMPTOMATIC KNEE OSTEOARTHRITIS

Keywords: Osteoarthritis, Randomized control trial, Clinical Trials

A. R. Bihlet[1], I. Byrjalsen[1], K. Mundbjerg[1], P. Alexandersen[2], H. Rovsing[3], T. Axelsen[4], J. R. Andersen[5], A. Metnik[1], N. Bachtell[6], A. Brett[7], C. Christiansen[8]. [1]*Nordic Bioscience, Clinical Development, Søborg, Denmark*; [2]*Sanos Clinic, Clinical, Vejle, Denmark*; [3]*Sanos Clinic, Clinical, Gandrup, Denmark*; [4]*Sanos Clinic, Clinical, Herlev, Denmark*; [5]*Nordic Bioscience, Clinical Development, Herlev, Denmark*; [6]*Third Harmonic Bio, SVP Clinical Research, San Francisco, United States of America*; [7]*Stryker Corp, Imorphics, Austin, United States of America*; [8]*Nordic Bioscience, Clinical, Herlev, Denmark*

Background: Osteoarthritis (OA) is a chronic disease characterized by degradation of joint structures including the subchondral bone, the synovium, and cartilage. Aggrecan constitutes a major component of hyaline cartilage and plays an important role for its normal function. In OA, aggrecan is gradually lost, which together with cytokines, proteases, and circulating pro-inflammatory fragments of hyaluronic acid (HA) further accelerates tissue destruction. SB-061 is an aggrecan mimetic, composed of a backbone of chondroitin sulfate conjugated to a HA peptide coating protein. SB-061 is believed to bind HA fragments in the synovium. Hence, SB-061 acts upstream in the inflammatory cascade, thereby potentially reducing both pain as well as structural deterioration [1].
Objectives: To evaluate the efficacy and safety of intra-articular injections of SB-061 in subjects with knee OA.
Methods: This was a randomized, placebo-controlled, double-blind phase II study comparing quarterly intra-articular injections of SB-061 with placebo (isotonic saline) for 52 weeks (EudraCT No. 2019-004515-31). Eligible subjects had a Kellgren-Lawrence (KL) grade of 2 or 3 on X-ray of the target knee and a Western Ontario and McMasters Osteoarthritis Index (WOMAC) pain score ≥20 out of 50 at screening and baseline visits. Subjects having used any medication known to affect the joints up to 3 months prior to the study or having any other knee condition were excluded. Any use of analgesic medication was prohibited during the study, except for rescue medication (paracetamol/acetaminophen). The primary endpoint was the change from baseline (CFB) in WOMAC pain at Week 8 after first injection. Secondary endpoints were CFB in WOMAC function and total, ICOAP and the Patient Global Assessment (PGA), and 20-meter walk test. Exploratory structural endpoints included CFB in knee cartilage thickness and volume, and bone shape as measured by magnetic resonance imaging (MRI), and CFB in the radiographic minimum joint-space width (JSW).
Results: A total of 288 subjects were randomized to SB-061 (n= 145) or placebo (n=143), and of these 252 (87.5%) completed injections. The two groups were well-balanced in terms of the main clinical and radiographic parameters, and reflective of a typical OA clinical trial population. The primary endpoint was not met, as there was no significant difference in the CFB of the WOMAC pain score (0-50) at Week 8 between the groups (LSmean difference: 0.00, 95% CI -4.33; 4.34, p=0.999, nor at any other time point during the trial (Figure 1). Similarly, neither of the secondary endpoints of changes from baseline in WOMAC function, WOMAC total, ICOAP, PGA, and 20-meter walk test indicated any significant difference between SB-061 and placebo. There was no significant difference between groups in CFB in JSW or any of the MRI parameters. The frequency and type of adverse events was similar between groups receiving SB-061 and placebo. SB-061 was well-tolerated.

Conclusion: Intra-articular injections of SB-061 administered quarterly for one year in patients with knee OA was safe but did not show any statistically significant effect on knee pain nor on other symptomatic or structural entities compared to placebo.

POS0105 CHANGES IN RADIOGRAPHIC SIGNS IN PATIENTS WITH HAND OSTEOARTHRITIS DURING 2 YEARS

Keywords: Osteoarthritis, Epidemiology

C. Van der Meulen[1], L. Van de Stadt[2], F. Rosendaal[3], S. Van Beest[1], M. Kloppenburg[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Reade, Rheumatology, Amsterdam, Netherlands*; [3]*Leiden University Medical Center (LUMC), Clinical epidemiology, Leiden, Netherlands*

Background: Hand osteoarthritis is a disorder that often evolves slowly. Some patients may have structural progression over a short term.

Objectives: We aimed to investigate which patients show radiographic progression over 2 years and what their determinants are.

Methods: Data from the ongoing HOSTAS (Hand OSTeoArthritis in Secondary care) cohort were used, consisting of 538 consecutive patients with primary hand OA diagnosed by their rheumatologist, followed for two years. Hand radiographs were obtained at baseline and year two. Questionnaires regarding demographics, disease and patient characteristics and the Australian Canadian Hand osteoarthritis index (AUSCAN) were collected. Hand radiographs were scored blinded, paired and in chronological order, using the Osteoarthritis Research Society International (OARSI) system (osteophytes (OP) and joint space narrowing (JSN), scored 0-3) per joint (summed for total 0-96). Intra-observer reliability was high, (intra-class correlation (ICC) 0.99 and 1.00 at baseline for OP and JSN sumscores, respectively). Reliability for change scores was high (ICC 0.77 and 0.86, for OP and JSN, respectively). The smallest detectable changes were 0.92 for OP (cut-off 1) and 1.32 for JSN (cut-off 2). Cut-offs were used to classify progressors (increase) or non-progressors (stable or decrease). Additionally, baseline radiographs were scored using the Kellgren-Lawrence system (0-4 per joint, total 0-120). Erosive disease was defined as at least 1 joint in the Verbruggen-Veys erosive or remodeling phase. Progressor and non-progressor groups were analysed for determinants using logistic regression.

Results: 442 patients had radiographs assessed at baseline and year 2, with mean (SD) age 61 (8.4) years and 85% female. Median (IQR) baseline OP/JSN sumscores were 9 (5-18) and 9 (4-19), respectively. Based on the SDC, 272/417 (65%) participants progressed on OP scores (median [IQR] change 1 [0-2]) and 135/419 (32%) on JSN scores (median [IQR] change 1 [0-2]). Four and 18 had a decrease in OP and JSN, respectively. Progression of OP was positively associated with erosive disease, measures of radiographic damage at baseline and female sex. Progression of JSN was positively associated with age, erosive disease and radiographic damage at baseline. Progression of JSN showed a positive association with changes in AUSCAN scores over 2 years.

Conclusion: Over 2 years, considerable radiographic progression was seen. Especially patients with erosive disease and the most severe radiographic damage at baseline were at risk for progression. Progression of JSN was associated with changes in pain and function. Progression in JSN was associated with age, whereas OP was with female sex. These findings may potentially represent different underlying pathogenetic mechanisms.

Table 1. Associations with change in osteophytes

	Odds ratio (95% confidence interval)	
	Increase in osteophytes (n=272)	**Increase in joint space narrowing (n=135)**
Patient characteristics at baseline		
Female sex[1]	1.71 (0.95-3.05)	1.03 (0.56-1.94)
Age; mean (SD)[2]	1.00 (0.98-1.03)	1.04 (1.01-1.06)
BMI; mean (SD)[3]	0.97 (0.93-1.02)	0.97 (0.93-1.02)
Radiographic outcomes at baseline		
KL sum score (0-120); median (IQR)	1.03 (1.02-1.05)	1.03 (1.02-1.05)
Osteophyte sum score (0-96); median (IQR)	1.04 (1.01-1.07)	1.05 (1.03-1.07)
Joint space narrowing sum score (0-96); median (IQR)	1.06 (1.04-1.09)	1.04 (1.02-1.06)
Erosive disease	3.15 (1.86-5.53)	2.01 (1.25-3.24)
Patient reported outcome measures		
Change in AUSCAN baseline – year 2	0.98 (0.92-1.03)	1.06 (1.00-1.13)
Pain (0-20)	1.00 (0.97-1.03)	1.06 (1.03-1.11)
Function (0-36)		

Non-progression group as index group for both osteophytes and joint space narrowing. Groups defined according to smallest detectable change in osteophyte/joint space narrowing sum score for both hands. Analyses are adjusted for age, sex and BMI, unless stated otherwise. [1]Adjusted for age and BMI. [2]Adjusted for sex and BMI. [3]Adjusted for age and sex. BMI = body mass index. KL = Kellgren-lawrence. AUSCAN = Australian Canadian hand osteoarthritis index.

POS0106 INTRA-ARTICULAR MM-II, A NOVEL SUSPENSION OF LARGE EMPTY MULTILAMELLAR LIPOSOMES, IN PAINFUL KNEE OSTEOARTHRITIS: A 26 WEEK PHASE 2B RANDOMIZED TRIAL

Keywords: Osteoarthritis, Clinical Trials

P. G. Conaghan[1], H. Rovsing[2], E. Lau[3], S. L. Boll[4], B. Brahmachari[5], R. C. Chou[5], T. Joshi[5], R. Wechsler[6], S. L. Yao[5], S. Weiner[5], A. R. Bihlet[7], T. Schnitzer[8]. [1]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [2]*Sanos Clinic, Gandrup, Denmark*; [3]*Hong Kong Center for Clinical Research, Hong Kong, Hong Kong (SAR)*; [4]*Sanos Clinic, Vejle, Denmark*; [5]*Sun Pharmaceuticals, Inc, Princeton, United States of America*; [6]*Moebius Medical Ltd., Tel Aviv, Israel*; [7]*NBCD A/S, Søborg, Denmark*; [8]*Northwestern University Feinberg School of Medicine, Chicago, United States of America*

Background: MM-II, a novel suspension of empty large multilamellar liposomes composed of dimyristoylphosphatidylcholine (DMPC) and dipalmitoylphosphatidylcholine (DPPC), has demonstrated beneficial effects in OA animal models. In a prior first-in-man study, MM-II demonstrated the ability to lower pain in knee OA patients for up to 3 months.

Objectives: The aims of this phase 2b study were to determine an effective dose, the durability of response, and the safety of MM-II in patients with symptomatic knee OA.

Methods: Consented participants were enrolled in a 6-arm randomized, double-blind, placebo-controlled 26-week trial evaluating a single IA injection of

MM-II at doses of 1ml, 3ml and 6ml (150mM concentration of lipids) and placebo of matching volumes. Key inclusion criteria: age ≥ 40 years, KL grades 2 or 3, ACR OA criteria, WOMAC A pain ≥2 (0-4 Likert scale), VAS ≥50 and ≤90 (100mm scale), and intolerance/inadequate response to NSAIDs or acetaminophen. Primary endpoint was change in WOMAC A pain score at week (Wk) 12; secondary endpoints included weekly average daily pain score (ADP, e-diary) at Wks 12 & 26, WOMAC A pain at 26 wks, Patient Global Assessment (PGA) and WOMAC B and C at Wks 12 & 26, and use of rescue medication. Randomization was stratified by BMI (< 30, 30 ≤BMI<35, and BMI ≥ 35) and baseline knee pain (VAS≤74, VAS≥ 75). Statistical analysis for the primary endpoint was analyzed based on FAS using a mixed model repeated measures (MMRM) with fixed effects for treatment group, visit (Wk 1-12), and treatment-by-visit interaction and covariates of site, baseline WOMAC pain, BMI and VAS groups. Subjects were included as random effects. Treatment differences were estimated using least square means (LSM) with 95% CIs. Step-down Dunnett's hierarchical testing procedure compared the active doses to 3 mL placebo to adjust for multiplicity. Confidence intervals were unadjusted.

Results: 397 participants were randomized with no significant differences in baseline demographics or clinical characteristics across all treatment groups. Mean age was 62.7 (SD 8.1) years; participants were predominantly female (65.0%) and white (67.0%) with mean BMI 30.8 (SD 6.1) kg/m2. Overall, 6.8% of participants discontinued the study. The primary endpoint of WOMAC A change from baseline to Wk 12 showed LSM difference of -0.24, 95% confidence interval (CI) -0.476, -0.004, p = 0.085 for the 3ml group and -0.02, 95% CI -0.269, 0.222, p = 0.85 for the 6ml group, both vs 3ml placebo, adjusted for multiplicity. The results of the 3ml group were sustained to Wk 26. Nominal significance was seen at some time points. When comparing 3ml MM-II to the pooled placebo groups, the LSM difference in change from baseline of the WOMAC A at Wk 12 was -0.28, 95% confidence interval (CI) -0.484, -0.068, p = 0.018 adjusted for multiplicity. The LSM differences in weekly ADP scores were nominally significant at Wks 12 and 26 for the MM-II 3ml group vs 3 ml placebo: -10.9, 95% CI (-18.88, -2.83), p = 0.008 and -11.8, 95% CI (-20.19, -3.34), p =0.006, though the 6ml group was not significant (Figure 1). The changes in use of rescue medication corresponded to changes in symptoms during the trial. Treatment was well tolerated with TEAEs reported in 2.6% of MM-II and 2.9% of control participants. Injection site reactions were similar in the treatment and control groups, 1.9% and 2.9%, respectively.

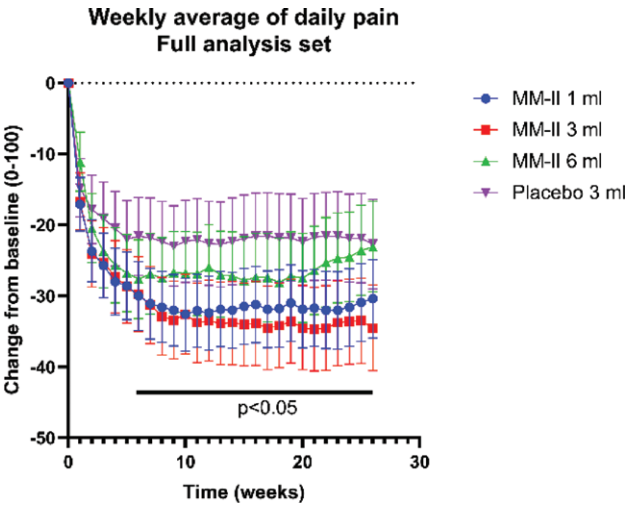

Figure 1.

Conclusion: Differences between MM-II and placebo in WOMAC A were not statistically significant at Wk 12, though WOMAC reductions were nominally significant at some time points, and when comparing 3ml MM-II to the pooled placebo groups, results were nominally significant at Wk 12. MM-II at 3ml dose demonstrated consistent and durable reduction in weekly knee ADP scores, nominally significant compared to placebo, as early as Wk 6, with efficacy maintained through Wk 26. Treatment with MM-II was well tolerated with low levels of adverse events. MMI-II may have the ability to provide durable and relevant pain relief, warranting confirmation in further clinical studies.

Background: Knee osteoarthritis (OA) pain scores only moderately correlate with conventional radiographic findings—likely because pain has a multifactorial etiology. Ultrasound (US) can capture soft tissue structures which are known to be involved in pain pathophysiology but may not be visible in knee radiographs. Importantly, US is a cost-effective and portable imaging technology that can be performed at the point of care by non-radiologists. Therefore, US may have utility in understanding variance in pain attributed to knee OA.

Objectives: Our objective was to demonstrate if adding US features to computer vision analysis of radiographic images improves machine learning-based prediction of Knee injury and Osteoarthritis Outcome Score (KOOS) Pain scores in knee OA.

Methods: 116 subjects with end-stage knee OA were included in the study and were grouped into training and testing sets with an 80:20 split. Posterior anterior flexion view x-rays and standardized knee US images were collected. A fellowship-trained musculoskeletal radiologist read 26 ultrasound continuous and ordinal features. All x-rays were pre-processed by cropping and applying Contrast Limited Adaptive Histogram Equalization. The processed images were resized to 224 x 224 pixels, stacked to form three-channel images, and mean-subtracted with respect to ImageNet (**Figure 1**). We generated the radiograph input feature vectors by using a pretrained ResNet50 model with a global average pooling layer replacing the classification head. We trained models to predict KOOS Pain with only radiograph image embeddings, solely US features, or multimodal inputs by concatenating the two feature vectors. For radiograph image embeddings and ultrasound feature vectors, we applied min-max normalization with the respective extrema of the training dataset for each feature. As a secondary analysis, we trained additional models to predict KOOS Symptoms and KOOS Function in Daily Living (ADL) sub-scores. Across all inputs and target variables, we used five-fold cross-validation for model selection across random forest regressors and histogram-based gradient boosting regression trees from the scikit-learn package, CatBoost regressors, and XGBoost regressors. All models were trained using default hyperparameters defined by the respective model packages during model selection and final training. We report and compare model performance using Pearson r correlation coefficient, mean absolute error, and root mean squared error. All performance metrics were calculated using the scikit-learn and SciPy packages.

Results: When predicting KOOS Pain scores, radiographic image data alone (r = 0.26) or ultrasound scores alone (r = -0.17) did not perform as well as the multimodal model (r = 0.34) where both radiographic and ultrasound measurements were included (**Table 1**). For prediction of KOOS Symptoms scores, an input of radiographic image data alone (r = 0.45) correlated better than when either ultrasound features alone (r = -0.16) or the multimodal model (r = 0.28) were used as inputs. Similarly, when predicting KOOS ADL scores, radiographic image data alone (r = 0.14) correlated better than ultrasound features alone (r = -0.20) or the multimodal model (r = -0.03).

Conclusion: Combining US features with knee radiographs may improve performance for predicting KOOS Pain scores in patients with end-stage knee OA, but did not improve the prediction of KOOS Symptoms or ADL scores. Our results suggest that soft tissue features captured by US can help us understand differences and underlying mechanisms in pain attributed to OA.

Figure 1. Preprocessing pipeline. a) The original image input. b) We manually mask all artifacts using the lowest pixel intensity value of the image, apply contrast limited adaptive histogram equalization (CLAHE), and crop a 140 x 140mm region of interest (ROI) centered on a manually annotated point. c) The cropped ROI is resized to 224 x 224 pixels. d) The grayscale ROI is stacked three times to form a three-channel image. e) Apply ImageNet normalization to the image.

Table 1. Model performance by input

Target	Inputs	Model	MAE	RMSE	Pearson r
KOOS Pain	X-ray	CatBoost	13.32	15.77	0.26
	US	Histogram-based Gradient Boosting Regression	16.58	19.96	-0.17
	X-ray + US	CatBoost	13.11	15.48	0.34
KOOS Symptoms	X-ray	Random Forest	13.97	17.42	0.45
	US	Random Forest	17.40	21.25	-0.16
	X-ray + US	CatBoost	13.91	18.19	0.28

POS0108 WOMAC KNEE PAIN: DOES IT WALK THE WALK?

Keywords: Imaging, Pain, Osteoarthritis

C. K. Kwoh[1], F. Roemer[2], A. Guermazi[3], E. Ashbeck[4]. [1]*University of Arizona, University of Arizona Arthritis Center, Tucson, United States of America*; [2]*University of Erlangen, Department of Radiology, Erlangen, Germany*; [3]*Boston University School of Medicine, Quantitative Imaging Center, Department of Radiology, Boston, United States of America*; [1]*University of Arizona, University of Arizona Arthritis Center, Tucson, United States of America*

Background: Due to its major public health impact, knee osteoarthritis (KOA) has been designated as a serious disease by the US Food and Drug Administration (FDA). Approval of a disease modifying osteoarthritis drug (DMOAD) to slow or prevent disease progression hinges on demonstrating both symptomatic (i.e., how a patient feels or functions) and structural improvement. The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), the questionnaire most commonly used to assess symptomatic improvement, may not adequately reflect pain reporting due to KOA. The lack of DMOAD approval to date has largely been attributed to the lack of clinical translation of structural benefits that also yield symptomatic improvements. Drugs targeting inflammation are an example of a therapeutic approach that has yielded evidence of structural benefit but not symptomatic improvement as assessed by the WOMAC.

Objectives: Evaluate potential heterogeneity of the effects of structural damage on knee pain reporting across activities assessed in the WOMAC pain subscale following recent development of radiographic knee osteoarthritis.

Methods: The Osteoarthritis Initiative is a longitudinal observational study of participants with or at risk of symptomatic knee OA. We identified incident cases of radiographic KOA, defined as Kellgren-Lawrence [KL] grade 2 or 3 based on centrally graded x-rays. Participants underwent bilateral posteroanterior fixed-flexion weight-bearing knee radiography at clinic visits annually or biannually through year 10. Non-contrast 3T MRI was also acquired at clinic visits up to year 8. Musculoskeletal radiologists graded structural damage, including effusion-synovitis (ES), Hoffa-synovitis (HS), bone marrow lesions (BMLs), cartilage and meniscal damage using the MRI Osteoarthritis Knee Score (MOAKS). The WOMAC knee pain subscale is calculated by adding reported pain scores from various activities, including walking on a flat surface, going up or down stairs, at night while in bed, sitting or lying down, and standing, during the last seven days, rated on a 5-point scale from none (0), mild (1), moderate (2), severe (3), or extreme [4]. Pain in each knee was reported separately. We fit a proportional odds logistic regression to model the ordinal pain scores reported for each activity on the WOMAC pain scale using penalized maximum likelihood estimation; predictors included each of the MRI structural damage scores, KL grade, age, and BMI at the same clinic visit, as well as sex and race. We estimated the predicted probability of pain rated moderate or worse ($Pr[Y \geq 2 \mid X]$), and reported nonparametric bootstrap 95% confidence intervals (CI) with cluster sampling at the participant-level.

Results: We identified 690 knees contributed by 623 participants that developed radiographic KOA. The mean participant age was 65 years (SD 9), mean BMI was 29.3 (SD 4.8), 66% reported female sex and 83% self-identified as white. The predicted probability of knee pain rated moderate or worse (≥2) increased with greater ES during walking and stair climbing, but there was no evidence that ES affected knee pain while in bed, sitting or lying down, or standing (Figure 1). We did not find evidence that HS, BMLs, cartilage or meniscal damage affected the WOMAC knee pain items cross-sectionally in our fully adjusted models.

Conclusion: Our study suggests that ES seen on MRI produces heterogeneous effects on pain reporting, depending on the type of activity. Treatments that are developed to target inflammation may reduce pain during some activities, such as walking and stair climbing, but may have little benefit during other activities, such as sitting or lying down. If a treatment effectively reduces or limits structural damage that differentially impacts pain across the activities included in the WOMAC pain subscale, analysis that focuses only on the WOMAC pain subscale score may mask the clinical benefit of the treatment.

Background: This study uses gait measurements and imaging techniques in knee osteoarthritis (OA) patients to investigate the association between gait patterns and joint structure.

Objectives: To analyze whether 1) gait patterns can be explained by joint structure and 2) longitudinal gait alterations can be predicted by joint structure in people with knee OA.

Methods: In the IMI-APPROACH cohort, 297 people with knee OA were included at 5 sites in Europe. At baseline and two years, full gait kinematic data was collected from all participants using the GaitSmart system (Dynamic Metrics Limited, Codicote, UK). Radiographs and MRI scans of their index knee were performed for evaluation of joint structure. The GaitSmart measures included for the current study were range of motion (ROM) of the hip, thigh, knee in swing and stance phase, and calves in the sagittal plane, and medial-lateral movement of the thigh and calf, all for the index leg. Stride duration and speed were included as well. From the radiographs, the minimum joint space width (JSW), femorotibial angle, mean whole-joint subchondral bone density (SBD), and total whole-joint osteophyte area were determined. From the MRI scans, mean whole-joint femorotibial cartilage thickness (FTC) was determined and MOAKS scoring for synovitis, effusion, meniscus signal and meniscal extrusion were performed. For the meniscal parameters, the maximum score across all regions was used. All GaitSmart parameters were compared between baseline and two years with paired t-tests to quantify gait alterations over two years. For the comparisons with joint structure, principal component analyses (PCA) was performed on the gait parameters first, to discover underlying domains. Univariate backwards linear regression models with each of the GaitSmart domains as dependent variable were used to analyze how joint structure influences gait or predicts gait change over two years. Three models were run: one with participant demographics (age, sex, BMI) only, one with structural imaging parameters only, and one combining the first two models.

Results: 284 Participants (age 66.5±7.1, BMI 28.0±5.4, 65 (23%) male, 154 (54%) radiographic OA) had baseline GaitSmart data (211 had two-year data). PCA identified three gait domains: upper leg (speed, duration, thigh ROM and hip ROM), lower leg (knee ROM in stance and swing, calf ROM), and medial-lateral movement (thigh and calf medial-lateral movement). Over two years the lower leg parameters showed a slight deterioration, though only knee ROM in swing phase changed significantly (-1.5±6.9 degree, p=0.002). The upper leg parameters showed minor non-significant improvement over two years; the medial-lateral parameters showed opposing non-significant changes. Results of all models are summarized in Table 1. Cross-sectionally, male sex, higher BMI, higher SBD and synovitis absence were associated with worse upper leg function. Change in upper leg gait was predicted by sex only, with male sex resulting in less function improvement. For lower leg gait, female sex, higher BMI, bigger osteophytes, higher FTC, absence of effusion and presence of synovitis lead to worse function (i.e. larger ROM) cross-sectionally. Worsening lower leg gait could be predicted by higher age and BMI, presence of synovitis and smaller osteophytes. Neither demographics nor joint structure was significantly associated with or predictive for changes in medial-lateral gait.

Conclusion: Joint structure could partially explain gait and even predict gait changes in people with knee OA especially for the lower leg, providing a significant association between OA symptoms and joint structure, although only for a limited part (low R^2 values; Table 1) and not for medial-lateral movement. Surprisingly, synovitis and osteophyte size showed contrasting associations with lower leg gait that may be explained by half of the patients not having radiographic OA and should be investigated further. Parameters indicating more severe OA (e.g. lower JSW and FTC, higher age and SBD) were generally associated with more impaired gait.

Table 1: Baseline associations and two-year prediction of changes in the different gait domains, for participant demographics (model 1), joint structure (model 2), and a combination (model 3).

POS0110 ARTHROSCOPY IS NECESSARY TO DETECT CARTILAGE DAMAGE IN NON-ADVANCED KNEE OA

Keywords: Osteoarthritis

M. Mateos-Fernández[1], F. Lopez-Oliva[2], C. Herencia[1], J. Fernández-Jara[3], I. Masa[2], E. Calvo[2], J. Espinosa[2], E. Naredo[1], R. Largo[1], G. Herrero-Beaumont[1].
[1]*IIS Fundación Jiménez Díaz, Bone and Joint research Unit, Madrid, Spain*; [2]*Hospital Fundación Jimenez Díaz, Department of Orthopedic Surgery, Madrid, Spain*; [3]*Hospital Fundación Jimenez Díaz, Department of Radiology, Madrid, Spain*

Background: Knee osteoarthritis (OA) is characterized by the slow deterioration of articular cartilage that takes years to destroy the tissue. Magnetic resonance imaging (MRI) is commonly used for quantitative assessment of articular cartilage, and thus proposed by many authors as a substitute for X-ray, which requires longer periods of time --at least 3 years between images-- to detect changes. Drug agencies continue to consider X-ray outcomes preferable for clinical trials, as the

superiority of MRI over X-ray is not clear. More importantly, these measurements have not been compared with direct visualization of the cartilage.
Objectives: To evaluate cartilage width as well as early cartilage lesions by X-ray and MRI techniques, comparing these observations with those obtained by direct visualization of cartilage during arthroscopy (ARTH) in a population with non-advanced knee OA.
Methods: We prospectively recruited 105 patients (>18 y.o) with knee pain of more than 3 months´ duration who underwent diagnostic knee ARTH due to uncertain origin knee pain or meniscal tear. WOMAC score was used to assess joint pain and function. Standardized weight-bearing extended anteroposterior digital X-ray were performed aligning the center of the beam with de femorotibial joint space. Images without correct alignment of the tibial plateau were discarded. By X-ray, OA grade was assessed by the Kellgren and Lawrence score (KLS). Medial and lateral joint space width (JSW) was measured on X-ray at the mid-surface of the affected knees in a blind manner. By MRI, cartilage lesions were classified into 3 categories (MRI score, MRI-S): normal (no damage), low grade (fibrillation or thickening <50%) or high grade (thickening >50% or loss). Knee ARTH was performed through two portals according to standard practice and cartilage lesions assessed by Outerbridge score (OBS). Bonferroni-corrected ANOVA test for continuous variables, Chi-square or Fisher's test for discrete variables, normality with Shapiro-Wilk and Kolmogorv-Smirnov tests, concordance between groups with weighted Kappa index, correlation between OBS and cartilage measurement with Spearman's correlation were performed employing Python 3.7 and SPSS25 for Windows 10.
Results: The correlation between X-ray JSW measurement and the OBS was null (r=-0.052). No good agreement was found between the OA grade assessed by KLS and OBS, nor between MRI-S and OBS. Cartilage deterioration evaluated by X-ray and MRI showed a lower degree of tissue damage than that observed by ARTH visualization (Table 1).

Table 1. (a) Agreement between OBS and KLS (64 patients) and between OBS and MRI-S (96 patients) in the medial (b), lateral (c) and femoropatellar (d) compartments of the damaged knee.

		OBS 0	OBS 1	OBS 2	OBS 3	OBS 4	Kappa
KLS	Grade 0	16	3	3	8	3	0,16
(a)	Grade 1	7	1	2	5	3	
	Grade 2	2	1	3	3	3	
	Grade 3	0	0	0	1	0	
	Grade 4	0	0	0	0	0	
MRI-S	Normal	39	7	8	9	6	0,48
medial	Low	5	0	3	0	1	
(b)	High	0	1	1	11	5	
MRI-S	Normal	62	10	5	4	0	0,37
lateral	Low	3	0	0	0	1	
(c)	High	4	2	0	1	4	
MRI-S	Normal	39	6	7	7	0	0,20
femoropatellar	Low	6	0	2	3	0	
(d)	High	12	1	6	6	1	

The WOMAC score was significantly different between patients with different OBS. Then, there was a significant increase in the WOMAC score in patients with OBS 2, 3 and 4 with respect to patients with score 0, p=0.009. In patients with OBS 0, 1, 2, 3, and 4, the WOMAC scores were (mean±SD): 41±22; 47±14; 50±23*; 56±19*; and 60±20*, respectively; *p<0.05 vs. OBS grade 0. However, no significant differences in the WOMAC score between patients with different grades of cartilage deterioration were observed when it was assessed by MRI or X-ray.

Conclusion: ARTH enabled to detect cartilage damage with higher precision than X-ray or MRI. In addition, the ARTH assessment was able to explain the different pain and function levels, since patients with different OBS showed different WOMAC scores. MRI can detect joint lesions in the extra-articular space or related to bone damage, which are not observable with ARTH. Therefore, for clinical trials assessing structure progression, ARTH evaluation combined with MRI would be the most appropriate techniques to accurately measure cartilage deterioration.

A novel journey into SLE, Sjogren and APS

POS0111 **PILOT STUDY ON EVOKED COMPOUND ACTION POTENTIAL CONTROLLED CLOSED-LOOP SPINAL CORD STIMULATION IN TREATMENT OF RAYNAUD'S PHENOMENON**

Keywords: Investor initiated trial, Pain, Imaging

V. Schäfer[1], P. Karakostas[1], B. Dietz[2], G. Bara[3], J. Maciaczyk[3]. [1]*University Hospital Bonn, Rheumatology and Clinical Immunology, Bonn, Germany*; [2]*Saluda Medical, Research, Harrogate, United Kingdom*; [3]*University Hospital Bonn, Stereotactic and Functional Neurosurgery, Bonn, Germany*

Background: Raynaud's Phenomenon (RP) is an episodically occurring vasospasm of the peripheral arteries that leads to paleness, cyanosis and/or erythema, causing severe pain, sometimes paresthesia and rarely leading to ulceration of the digits and toes. In severe cases, RP patients have physical and functional impairments that substantially affect their ability to work. There are few reports, mostly case series, on the utility of spinal cord stimulation (SCS) to treat RP. However, there is a lack of objective evidence on the physiological effects (e.g., vasodilation) of SCS in this condition. Here, we present clinical outcomes of severe RP patients treated with evoked compound action potential (ECAP)-controlled closed-loop SCS.
Objectives: Severe primary and secondary RP patients can be treated with evoked compound action potential (ECAP)-controlled closed-loop SCS. High-resolution Doppler ultrasound can be used as objective evidence on the physiological effects (e.g., vasodilation) of SCS in RP patients.
Methods: This is a prospective, single-center pilot study to evaluate the effectiveness of ECAP-controlled closed-loop SCS in treating RP. Subjects who meet the inclusion/exclusion criteria, complete all baseline assessments, and sign an informed consent will be considered enrolled (10 in total). Patient outcomes such as Raynaud Condition Score, Raynaud Severity Score, Raynaud Frequency Score, Cochin Hand Function Scale, SHAQ RP VAS, EQ-5D-5L, PGIC and objective peripheral circulation assessments using high-resolution Doppler ultrasound of digital arteries will be reported.
Results: The mean age ± standard deviation (± SD) of the ten patients is 45.5 ± 15.5 years. The mean baseline (± standard error mean (SEM); n = 9) weekly attack frequency was 21.8 ± 5.9 and decreased to 7.7 ± 2.1 after the test phase (n = 9), 4.8 ± 1.7 1-month after implantation (n = 8), 12.4 ± 6.2 3-months after implantation (n = 8) and to 12.6 ± 4.6 6-months after implantation (n = 8). The mean baseline (± SEM; n = 9) severity of attacks was 6.7 ± 0.4 which decreased to 4.9 ± 0.6 after the test phase (n = 9), 4.6 ± 0.9 1-month after implantation (n = 9), 3.8 ± 0.9 3-months after implantation (n = 8) and to 3.3 ± 0.6 6-months after implantation (n = 8). The mean baseline (± SEM; n = 9) Raynaud's condition score was 6.6 ± 0.7 and decreased to 4.4 ± 0.7 after the test phase (n = 9), 4.3 ± 1.0 1-month after implantation (n = 9), 3.4 ± 1.0 3-months after implantation (n = 8) and to 2.6 ± 0.7 6-months after implantation (n = 8). The mean baseline (± SEM; n = 9) for pathological arterial occlusion was 8.6 ± 1.5, with hands warmed in a finger bath. After the trial period (trial-end; n = 9), the mean total score (± SEM) for pathological artery occlusions decreased to 1.9 ± 1.0, and to 2.0 ± 1.1 1-month after implantation (1-month; n = 9), and to 2.1 ± 2.0 3-months after implantation (3-months; n = 8), and to 4.9 ± 2.6 6-months after implantation (6-months; n = 8). The mean baseline (± SEM; n = 9) cochin hand function scale score was 31.6 ± 8.2 and decreased to 24.7 ± 8.0 after the test phase (n = 9), 18.9 ± 7.8 1-month after implantation (n = 9), 19.5 ± 7.5 3-months after implantation (n = 8) and to 17.4 ± 7.7 6-months after implantation (n = 8). The mean patient global impression scale score at 1-month was (± SEM; n = 9) 2.4 ± 0.3, 2.8 ± 0.4 3-months after implantation (n = 8) and decreased to 2.3 ± 0.4 6-months after implantation (n = 8).

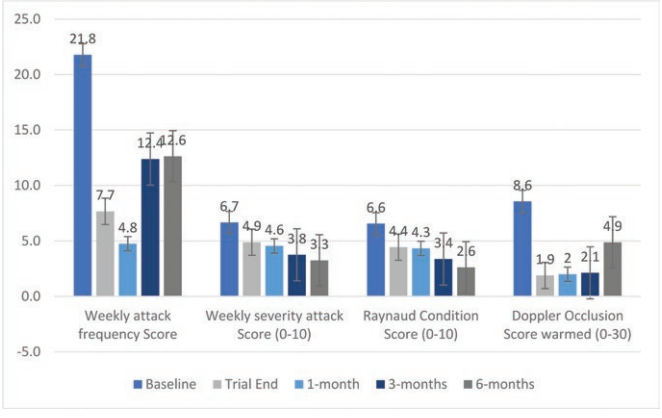

Figure 1.

Conclusion: This study demonstrates for the first time that RP-related pathological arterial occlusions can be treated effectively with a novel ECAP-controlled closed-loop-SCS system. In conclusion, ECAP-controlled closed-loop-SCS alleviates RP symptoms and improves peripheral blood flow. Longer-term follow up and larger controlled studies are needed to confirm these preliminary results.

DEUCRAVACITINIB REDUCES INTERFERONS, B-CELL PATHWAYS, AND SEROLOGICAL BIOMARKERS OF SYSTEMIC LUPUS DISEASE ACTIVITY: PHARMACODYNAMIC ANALYSIS FROM THE PHASE 2 PAISLEY STUDY

Keywords: Systemic lupus erythematosus, Targeted synthetic drugs, Biomarkers

J. M. Kahlenberg[1], I. Sanz[2], C. Wu[3], Y. Hu[4], J. H. Kim[5], S. Singhal[6], I. M. Catlett[7]. *[1]University of Michigan, Rheumatology, Ann Arbor, United States of America*; *[2]Emory University, Rheumatology, Atlanta, United States of America*; *[3]Bristol Myers Squibb, Informatics and Predictive Sciences, Princeton, United States of America*; *[4]Bristol Myers Squibb, Informatics and Predictive Sciences, Princeton, United States of America*; *[5]Bristol Myers Squibb, Translational Bioinformatics, Princeton, United States of America*; *[6]Bristol Myers Squibb, Clinical Development, Princeton, United States of America*; *[7]Bristol Myers Squibb, Translational Medicine, Princeton, United States of America*

Background: Tyrosine kinase 2 (TYK2) mediates signaling of key cytokines (eg, type 1 IFNs, IL-23, and IL-12) involved in systemic lupus erythematosus (SLE) pathogenesis. Deucravacitinib is a first-in-class, oral, selective, allosteric TYK2 inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis.[1,2] Deucravacitinib demonstrated a favorable safety and efficacy profile in a phase 2 trial in patients with psoriatic arthritis[3] and a phase 2 trial in patients with active SLE (PAISLEY; NCT03252587).[4]
Objectives: This analysis evaluated the effect of deucravacitinib on biomarkers of TYK2-mediated pathways, B-cell pathways, and serological biomarkers in patients in the phase 2 PAISLEY SLE trial.
Methods: The 48-week PAISLEY trial randomized 363 patients with SLE 1:1:1:1 to placebo or deucravacitinib 3 mg twice daily (BID), 6 mg BID, or 12 mg once daily (QD). Whole blood transcripts, serum proteins, blood cell subsets, and antibody profiles at screening and baseline through week 48 were measured by immunoassays and flow cytometry. In a substudy, samples were collected from 83 subjects 22 to 114 hours after the initial dose. Samples from demographically matched healthy subjects were collected and measured for comparison.
Results: At screening, 42 genes/modules and 75 proteins were differentially expressed compared with healthy subjects, with fold change >1.5 and adjusted *P* value <0.05. With deucravacitinib treatment, significant reductions were observed in IFNα (at week 48) and IFNλ (week 2 through week 48), and IFNγ was numerically lower after week 12. Deucravacitinib significantly inhibited IFN-regulated gene (IRG) expression from week 4 through week 44 (**Figure 1**). Deucravacitinib, but not placebo, reduced expression of cytokines and chemokines downstream of IFN activity, including BAFF, CXCL10, and MCP2. Adjusted mean percent changes from baseline at week 48 after treatment with deucravacitinib 3 mg BID, 6 mg BID, or 12 mg QD were –26%, –31%, and –30% for MCP2 and –42%, –43%, and –48% for CXCL10, respectively. Selected cytokines and chemokines including IFNλ, CXCL10, CCL19, and MCP2 were significantly reduced in the BID-dosed arms as early as 2 to 3 days after dose initiation. With deucravacitinib treatment, lymphocyte and neutrophil counts and complement levels increased, while markers associated with B-cell activation and differentiation including BLC (CXCL13), CD38 (gene expression), and autoantibodies were reduced.
Conclusion: Deucravacitinib suppressed IFN production, IRG expression, IFN-inducible proteins, B-cell pathway markers, and serological biomarkers, consistent with clinical symptom improvements in SLE patients treated with deucravacitinib.

Figure. Deucravacitinib, but not placebo, reduced biomarkers of IFN-regulated gene expression

*P<0.05; **P<0.01; ***P<0.001. Adjusted *P* values vs placebo. The mixed-effects model included fixed effects of treatment group, analysis visit, treatment-by-analysis visit interaction, and randomization stratum, and the continuous fixed covariate of baseline biomarker.
BID, twice daily; BL, baseline; CI, confidence interval; IFN, interferon; QD, once daily.

Suppression of both IFN and B-cell pathways suggests a broad reduction in lupus pathophysiology. These results provide a molecular framework for understanding how deucravacitinib modifies molecular networks in SLE and support the continued investigation of deucravacitinib as a treatment for SLE in phase 3 trials.

LONG-TERM REMISSIONS AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR AUTOIMMUNE DISEASES – A 25 YEARS SINGLE CENTER EXPERIENCE

Keywords: Systemic sclerosis, Systemic lupus erythematosus, Adaptive immunity

T. Alexander[1,2], R. Biesen[3], G. R. Burmester[3], A. Radbruch[4], R. Arnold[5], F. Hiepe[3,6]. *[1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Rheumatology and Clinical Immunology, Berlin, Germany*; *[2]Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Autoimmunology, Berlin, Germany*; *[3]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Rheumatology and Clinical Immunology, Berlin, Germany*; *[4]Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Cell Biology, Berlin, Germany*; *[5]c, Hematology, Oncology and Tumor Immunology, Berlin, Germany*; *[6]Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Autoimmunology, Berlin, Germany*

Background: The introduction of novel targeted biologic therapies has dramatically improved the treatment landscape for autoimmune diseases (AD). However, although providing more specificity, such therapies routinely depend on continuous or repeated administration, with a cumulative risk of long-term side effects, and are not curative. In contrast, immunoablation followed by hematopoietic stem cell transplantation (HSCT) has emerged as a promising on-off therapy over the past decades, to provide long-term remissions even in patients with severe courses of their disease, through the restoration of immunologic self-tolerance [1].
Objectives: Here, we summarize the outcomes of AD patients receiving HSCT at the Charité – University Medicine between February 1998 and October 2015.
Methods: In this retrospective study, the clinical outcome of 22 patients was analyzed, who received a $CD34^+$-selected autologous HSCT after immunoablation with 200mg/kg cyclophosphamide and 90mg/kg rabbit antithymocyte globulin (ATG) for autoimmune diseases. Indication for transplant were systemic lupus erythematosus (SLE, n=10), systemic sclerosis (SSc, n=4), vasculitis (n=3), multiple sclerosis (MS, n=2), polychondritis (n=1), chronic inflammatory demyelinating polyneuropathy (CIDP, n=1) and autoimmune hemolytic anaemia (AIHA, n=1). The median age at transplant was 29 years (range 16-48), and 82% of patients were female. Multiparamter flow cytometry was applied to characterize peripheral blood lymphocytes subsets, assessment of SIGLEC-1 expression on monocytes as surrogate for type-I interferon (IFN-I) activity in SLE.
Results: With a median follow-up of 78 months (range 0.1-300), the overall survival was 76.4% and progression-free survival 58.2%, respectively. 3 deaths were regarded treatment related (2 infections in SLE and 1 cardiac failure in SSc). One patient had persisting disease (AIHA) and 4 relapses occurred in SLE patients at 18, 36, 81 and 83 months, respectively. Remaining patients are in stable clinical remission for up to 25 years post-transplant, despite discontinuation of immunosuppressive therapy in most cases. HSCT was associated with significant reduction or normalization of autoantibody levels and a profound reconfiguration of the adaptive immune system, the latter characterised by a re-emergence of naïve T cells with markers of recent thymic emigrants, including $Foxp3^+$ Tregs and regeneration of naïve B cells. In SLE patients, SIGLEC-1 expression on monocytes

completely normalized suggesting an abrogation of type I interferon signalling in responding patients.

Conclusion: Our data provide the `proof-of-concept` that a chronic autoimmune system can be reset into a naïve and self-tolerant state by immunoablation and HSCT, providing a potential curative treatment option. Although initially applied as salvage therapy in severely affected patients with poor outcomes, transplantation related mortality has gradually improved over the past years, due to accumulating centre experience, better patient selection and improved supportive care. Therefore, HSCT still resembles a promising treatment option, especially in those patients with insufficient response to standard-of-care, with poor prognosis and live-threatening disease, in which the risk:benefit ratio of HSCT seems acceptable.

Background: Povetacicept (ALPN-303) is an Fc fusion protein of a variant, engineered transmembrane activator and calcium-modulating cyclophilin ligand interactor (TACI) domain which mediates significantly more potent inhibitory activity than wild type (WT) TACI-Fc or B cell activating factor (BAFF)- or a proliferation inducing ligand (APRIL)-specific monoclonal antibodies, with enhanced pharmacokinetic (PK) and immunomodulatory properties versus WT TACI-Fc in preclinical studies. Povetacicept may therefore significantly improve clinical outcomes in systemic lupus erythematosus (SLE) and other B cell-related diseases.

Objectives: This study was designed to evaluate the safety, tolerability, PK, and pharmacodynamics (PD) of povetacicept in adult healthy volunteers (HV).

Methods: In this first-in-human study (NCT05034484), 66 HV were randomized 4:2 into single ascending dose cohorts of intravenous (IV) or subcutaneous (SC) povetacicept or placebo. Participants were followed to assess safety and PK, circulating immunoglobulins (Ig), and circulating leukocyte populations.

Results: Povetacicept has been well tolerated in all cohorts evaluated as single IV or SC doses of up to 960 mg. Overall, it exhibits dose-related PK and expected PD effects, including dose-related reductions in serum IgA, IgM, IgG (Figure 1), and in circulating antibody-secreting cells (ASC; plasmablasts and plasma cells). These PD effects appear greater than those reported for WT TACI-Fc molecules in HV and appear to be saturated at doses ≥80 mg. Coverage of free APRIL was maintained for 2-3 weeks with 80 mg and ≥4 weeks with 240 mg, respectively. The most frequent adverse event (AE) has been mild headache. To date, there have been no imbalances of infections between the placebo and dosed groups, no treatment-related serious AEs, no administration-related reactions other than mild injection site pain (reported in one each of placebo- and povetacicept-treated participants), and no adverse trends in safety laboratories (Table 1).

Conclusion: To date, povetacicept has demonstrated acceptable safety and tolerability and exhibits expected PD effects on circulating Ig and ASC. These findings support future clinical development of povetacicept in patients with SLE and/or other B-cell- and/or autoantibody-related diseases.

POS0115 DAPIROLIZUMAB PEGOL EFFICACY BY SUBGROUPS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A POST HOC ANALYSIS OF PHASE 2 CLINICAL TRIAL DATA

Keywords: Clinical Trials, Systemic lupus erythematosus

A. Askanase[1], C. Stach[2], C. Brittain[3], G. Stojan[4], R. Furie[5]. [1]*Columbia University Irving Medical Center, Department of Medicine, Division of Rheumatology, New York, United States of America*; [2]*UCB Pharma, N/A, Monheim am Rhein, Germany*; [3]*UCB Pharma, N/A, Slough, United Kingdom*; [4]*UCB Pharma, N/A, Atlanta, United States of America*; [5]*Northwell Health, Division of Rheumatology, New York, United States of America*

Background: Systemic lupus erythematosus (SLE) clinical trials are challenged by high placebo response rates. Subgroup analyses of historic SLE clinical trial data have identified acute flares with normal complement levels as potential predictors of high placebo response.
Objectives: To assess the treatment effect of dapirolizumab pegol (DZP; a polyethylene glycol conjugated antigen-binding fragment lacking a functional Fc domain, which inhibits the CD40–CD40 ligand interaction) in patients from the phase 2b trial in SLE,[1] who fulfilled one or both of the characteristics identified as potential predictors of placebo response.
Methods: Post hoc analyses were performed on data from a phase 2b trial (NCT02804763), in which patients received placebo or DZP (6/24/45 mg/kg), alongside standard of care (SOC) for 24 weeks.[1] Efficacy was compared between two subgroups: (**1**) acute flare with low C3/C4 or persistent disease activity, vs (**2**) acute flare without low C3/C4. In the subgroup analyses, disease activity at screening was defined using British Isles Lupus Assessment Group (BILAG) 2004 item level scores either as acute flare (worsening/new symptoms) or persistent (symptoms rated as the same) based on the past 4 weeks compared with the 4 weeks prior to those, and low C3/C4 was defined as below the lower limit of normal at screening. Outcomes assessed were BILAG-based Composite Lupus Assessment (BICLA) response, SLE Responder Index-4 (SRI-4) response, and change from baseline in Physician's Global Assessment (PGA) at Week 24. Binary outcomes were analysed using logistic regression (p-values reported for odds ratio vs acute flare without low C3/C4), and continuous outcomes were analysed using mixed models with repeat measures (p-values reported for difference vs acute flare without low C3/C4).
Results: Figure 1a and **1b** show BICLA responses in the subgroups over time; similar patterns were seen for the other outcomes. At Week 24, higher BICLA response rates were achieved across all treatment arms in the acute flare without low C3/C4 subgroup compared with the other subgroup (**Figure 1c**). This pattern was particularly evident in patients receiving SOC plus placebo, where there was a significant 3-fold difference in BICLA response rates between the subgroups (80.0% vs 24.2%; p=0.005). Patients who received SOC plus placebo in the acute flare without low C3/C4 subgroup also achieved numerically higher SRI-4 response rates than the acute flare with low C3/C4 or persistent disease activity subgroup. A similar pattern was observed for patients who received SOC plus 6 mg/kg DZP; however, comparable SRI-4 response rates were observed between subgroups in patients who received SOC plus 24/45 mg/kg DZP (**Figure 1d**). At Week 24, greater changes from baseline in PGA were achieved in patients receiving SOC plus placebo in the acute flare without low C3/C4 subgroup than in the acute flare with low C3/C4 or persistent disease activity subgroup (least squares mean: –42.0 vs –24.9; p=0.0268). Comparable changes in PGA were seen between subgroups for patients receiving SOC plus DZP (**Figure 1e**).
Conclusion: Despite the limited sample size, patients with acute flare with normal complement levels were more likely to achieve responses to SOC plus placebo, diminishing the DZP treatment effect. These data suggest that SLE trial design may need to consider baseline clinical and serologic activity patterns to adequately assess treatment efficacy.

Figure. Efficacy outcomes by subgroups: (a, b) BICLA response rate over time to Week 24, (c) BICLA response rate at Week 24, (d) SRI-4 response rate at Week 24, (e) change from baseline in PGA at Week 24

*p<0.05; (b) odds ratio vs acute flare without low C3/C4; (e) difference vs acute flare without low C3/C4. Missing data for (a–d) were imputed using mNRI; (e) observed case data with no imputation.

Abbreviations: BICLA: British Isles Lupus Assessment Group-based Composite Lupus Assessment; DZP: dapirolizumab pegol; LS: least square; mNRI: modified non-responder imputation; PGA: Physician's Global Assessment; SOC: standard of care; SRI-4: Systemic Lupus Erythematosus Responder Index-4.

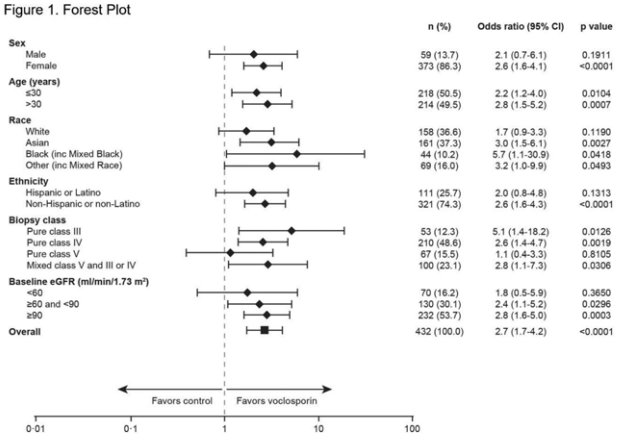
POS0116

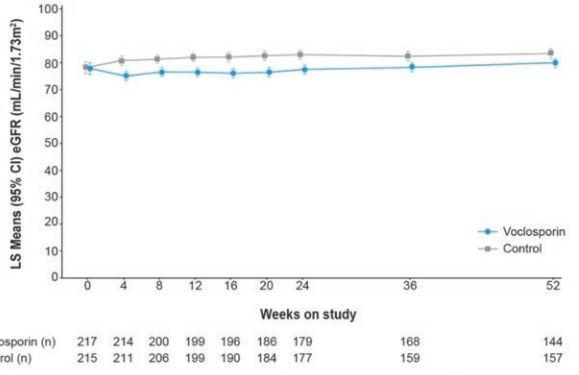
EFFICACY AND SAFETY OF VOCLOSPORIN ACROSS PATIENT SUBGROUPS WITH PROTEINURIA ≥2 MG/MG: AN INTEGRATED ANALYSIS OF THE AURA-LV AND AURORA 1 STUDIES



Keywords: Systemic lupus erythematosus, Clinical Trials

E. Littlejohn[1], S. Almaani[2], V. Birardi[3], E. Yap[3], C. Collins[3]. [1]*Cleveland Clinic Main Campus, Rheumatologic and Immunologic Disease, Cleveland, United States of America*; [2]*The Ohio State University, Nephrology, Columbus, United States of America*; [3]*Aurinia Pharmaceuticals, Medical Affairs, Victoria, Canada*

Background: Proteinuria is the most common manifestation of lupus nephritis (LN) and is a mediator of progressive kidney damage. Early reductions in urine protein creatinine ratio (UPCR) have shown to be predictive of improved long-term outcomes in LN. However, recent studies with monoclonal antibody therapies have demonstrated a lack of efficacy in patients with high proteinuria (UPCR ≥2 to ≥3 mg/mg), potentially due to an increase in renal excretion of drug.[1][4] In a pooled analysis of the Phase 2 AURA-LV and Phase 3 AURORA 1 studies, the addition of voclosporin to mycophenolate mofetil (MMF) and low-dose steroids resulted in earlier and greater reductions in proteinuria across biopsy classes, races, and ethnicities.[5]
Objectives: To further characterize the efficacy and safety of voclosporin in patients with high proteinuria, we have analyzed outcomes in various subpopulations of patients with UPCR ≥2 mg/mg using the pooled dataset.
Methods: Both studies enrolled patients with biopsy-proven LN (Class III, IV, or V ± III/IV) with 6 months (or up to 2 years in AURORA 1) and proteinuria ≥1.5 mg/mg (≥2 mg/mg for Class V). Patients were randomized to voclosporin (23.7 mg BID) or placebo and treated for up to one year (48 weeks [AURA-LV], 52 weeks [AURORA 1]); all patients received MMF and low-dose steroids. For this post-hoc analysis, complete renal response (CRR) rates were evaluated in patients with baseline UPCR ≥2 mg/mg. Complete renal response was defined as UPCR ≤0.5 mg/mg with stable renal function, low-dose steroids, and no rescue medication. Subgroup analyses were based on the following: sex, age, race, ethnicity, biopsy class, and estimated glomerular filtration rate [eGFR] at baseline. Adverse events (AEs) and mean eGFR levels over time were also assessed.
Results: Of the 268 and 266 patients included in the voclosporin and control arms of the pooled analysis, respectively, 217 and 215 patients had a baseline UPCR ≥2 mg/mg (mean [SD], 5.2 [3.4] vs. 4.6 [2.9] mg/mg, respectively). At one year, the change from baseline in least squares (LS) mean (SE) UPCR was -3.8 (0.1) mg/mg in the voclosporin arm compared to -3.1 (0.2) mg/mg in the control arm (difference vs. control, -0.7; p=0.0003). A significantly greater percentage of voclosporin-treated patients achieved CRR at one year compared to the control arm (41.0% vs. 21.9%; odds ratio [OR] 2.48, p<0.0001). CRR rates were numerically greater in voclosporin-treated patients in both sexes and across all ages, races, ethnicities, biopsy classes, and baseline eGFR levels assessed, with OR >1 (Figure 1). Across biopsy classes, the highest rates of CRR were observed in Class III patients treated with voclosporin (50% vs 16.1% in control, p=0.0126), followed by Class IV (44% vs. 23.8%, p=0.0019), Class V with III or IV lesions (37.7% vs. 17% p=0.0306), and Class V (31.3% vs. 28.6%, p=0.81). Similar rates of AEs were reported in both arms, and mean eGFR levels were similar and stable over one year of treatment (Figure 2).
Conclusion: Consistent with results from the overall pooled study population, patients with UPCR ≥2 mg/mg at baseline treated with voclosporin achieved significantly higher renal response rates than patients treated with MMF and low-dose steroids alone regardless of baseline demographics or clinical



characteristics. This is clinically relevant given the lack of safe and effective therapies for patients with high proteinuria.

Figure 1. Forest Plot

Post hoc analysis of patients with baseline UPCR ≥2 mg/mg includes pooled data from the 23.7 mg BID voclosporin arms and control arms in AURA-LV and AURORA 1. Data include up to 48 weeks from AURA-LV and 52 weeks from AURORA 1. Odds ratio (OR) >1 demonstrates treatment benefit of voclosporin. CI, confidence interval; eGFR, estimated glomerular filtration rate; UPCR, urine protein creatinine ratio.

Figure 2. LS Mean eGFR over Time

Voclosporin (n)	217	214	200	199	196	186	179	168	144
Control (n)	215	211	206	199	190	184	177	159	157

Post hoc analysis of patients with baseline UPCR ≥2 mg/mg includes pooled data from the 23.7 mg BID voclosporin arms and control arms of AURA-LV and AURORA 1. Data include up to 48 weeks from AURA-LV and up to 52 weeks from AURORA 1. Renal function was assessed with corrected eGFR (Chronic Kidney Disease Epidemiology Collaboration equation) using a prespecified ceiling of 90 mL/min/1.73 m². CI, confidence interval; eGFR, estimated glomerular filtration rate; LSMean, least squares mean.

POS0117 REMIBRUTINIB SPECIFICALLY DOWNREGULATES MARKERS OF MEMORY B CELL SUBSETS IN SJÖGREN'S PATIENTS (SJS) IN THE LOUISSE PHASE 2 CLINICAL TRIAL

Keywords: Biomarkers, Sjögren syndrome, Clinical Trials

A. Grioni[1], A. Santos Da Costa[1], E. Ferrero[1], V. De Luca[1], R. Hillenbrand[1], A. Da Costa[1], B. Cenni[1], M. Kaul[1], T. Dörner[2], R. Siegel[1]. [1]*Novartis Campus, NIBR, Basel, Switzerland*; [2]*Charité – Universitätsmedizin Berlin | German Rheumatism Research Center, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Remibrutinib is a selective, covalent and potent inhibitor of Bruton's tyrosine kinase (BTK) in development for several autoimmune and auto-allergic indications showing promising clinical safety and efficacy (Kaul et al 2021, Maurer et al 2022). Sjögren's (SjS) is a chronic autoimmune disorder characterized by dryness in the eyes and mouth, fatigue, joint pain, and reduced quality of life (Mariette et al 2018). Remibrutinib may be particularly promising for the treatment of SjS due to its ability to target underlying B cell abnormalities and showed promising efficacy in a Ph2 SjS trial (Dörner et al 2022).

Objectives: The aim of this exploratory biomarker study within the LOUiSSe trial was to identify protein and transcript signatures in the blood of patients with active SjS that are associated with remibrutinib treatment.

Methods: We conducted the LOUiSSe Ph2 clinical trial (NCT04035668) to evaluate the safety and efficacy of remibrutinib in patients with moderate to severe SjS. The study design was a randomized, double-blind, placebo-controlled, multi-center trial. Blood samples were collected at baseline and 24 weeks after treatment began. Protein profiles were generated using a Multiplex 7K aptamer profiling, and transcriptomics analysis was performed on RNA extracted from whole blood. By comparing the treatment and the placebo groups over time using multivariate linear regression models, we identified proteins and genes that were differentially modulated by remibrutinib. The gene signature identified by Yao et al (2009) was used as a reference for the interferon signature.

Results: We observed a consistent downregulation of 35 proteins associated with B cell activity, including CD23, FCRL1, FAIM3, and FCRL4, in all treatment groups receiving remibrutinib compared to the placebo group after 24 weeks of treatment. These modulated proteins are involved in multiple pathways related to B-cell activation and function, including B-cell receptor signaling, Fc receptor signaling, and platelet activation. Whole blood bulk mRNA sequencing revealed that the remibrutinib group showed a significant downregulation of a 34-gene signature, most of which are known to be important for B-cell activation and immunoglobulin production. The top two most significantly downregulated genes, FCRL5 and SOX5, were previously identified as being highly enriched in a circulating tissue-like memory B-cell subset. This observation is also corroborated by the proteomics profiling analysis, where FCRL4 known to co-localize in the same memory B-cell subset (Verstappen et al 2020, Götz et al 2008), was heavily decreased by the treatment. Despite the specific and strong effects on B-cells, estimation of cell type proportions using RNA-seq revealed no significant changes, suggesting that remibrutinib does not affect the overall B-cell numbers and the relative proportions of its major subsets, like plasma cells, naïve and memory B-cells. Results from both proteomics and transcriptomics profiling suggest that remibrutinib treatment does not modulate the interferon signature.

Conclusion: Our analysis of serum proteins and whole blood transcripts showed that remibrutinib treatment was associated with a significant downregulation of proteins and genes enriched in FcRL4+ B cells, a subset of tissue-resident memory B cells that are expanded in inflamed tissues and found in the salivary glands of SjS patients. These findings suggest that remibrutinib may have a particularly strong inhibitory effect on this subset. Additionally, many genes and proteins involved in B-cell activation, differentiation, and maturation were also downregulated, indicating that remibrutinib has a potent effect on multiple B-cell pathways.

POS0118 ADDING HYDROXYCHLOROQUINE IN REFRACTORY OBSTETRIC APS: OBSTETRIC OUTCOMES IN 182 PREGNANCIES

Keywords: Anti-phospholipid syndrome, Pregnancy and reproduction

M. Gerde[1], R. Mac Kenzie[2], D. Viola[1], C. Heer[1], J. Balparda[1], E. Beruti[1]. [1]*Hospital Universitario Austral, Obstetrics and Gynecology, Pilar, Argentina*; [2]*FLENI, Phlebology and Vascular Surgery, Buenos Aires, Argentina*

Background: Pregnancy complications in obstetric APS (OAPS) include recurrent early pregnancy loss, fetal death, or premature birth due to preeclampsia,

intrauterine growth restriction or placental insufficiency. The standard of care (SC) with low dose aspirin (LDA) and heparin has dramatically improved obstetric results, however 20-30% still have adverse outcomes despite treatment. Retrospective studies have shown good results with the addition of Hydroxychloroquine (HCQ). HCQ may have a beneficial effect in APS due to its anti-inflammatory, immunomodulatory and antithrombotic properties. Recently, EULAR recommended its use in refractory cases. Previously, in a retrospective study we reported that the addition of HCQ in women with primary OAPS and a pregnancy failure with SC was associated with a higher rate of live births (97 vs 62%) and a lower frequency of pregnancy complications (8 vs 37%) compared with conventional treatment. In this new study we show obstetric results from a larger cohort of refractory OAPS patients treated with HCQ.

Objectives: To assess pregnancy outcomes in a large cohort of women with refractory OAPS treated with Hydroxychloroquine in addition to conventional treatment.

Methods: This was an observational, retrospective, single-center cohort study. We analyzed pregnancy outcomes in women with refractory primary OAPS (2004-2022) who received HCQ 400 mg + enoxaparin 60 mg + LDA in their subsequent pregnancies.

Results: We evaluated 182 pregnancies in one hundred and seventy- three women (21-51y) treated with the addition of HCQ and a previous failure with conventional treatment; 18,9% of them had triple antibodies positivity. Live birth rate was 94% (CI 95%: 89,5-96,5). Term deliveries occurred in 95% of the pregnancies, mean gestational age at birth was 38 weeks (28-39) and mean weight 3021g (915g-4300g). Sixty percent were cesarean sections and 40 % vaginal deliveries. Pregnancy complications occurred in 12 % of the pregnancies (CI 95%: 7,3-19,5). Early pregnancy losses before 10 weeks occurred in 6% of the pregnancies. There were no late fetal deaths. Six patients who presented mild cutaneous allergy had to interrupt HCQ and were excluded from the analysis.

Conclusion: These results add observational evidence in favor of using Hydroxychloroquine in refractory Obstetric APS patients until results from ongoing RCT are published.

POS0119 XmAb564, A NOVEL POTENCY-REDUCED IL-2 FC FUSION PROTEIN SELECTIVELY EXPANDS REGULATORY T CELLS: RESULTS FROM A SINGLE ASCENDING DOSE STUDY IN HEALTHY ADULT VOLUNTEERS

Keywords: Systemic lupus erythematosus, Randomized control trial, Biomarkers

R. Clynes[1], C. Key[2], Y. Ding[3], L. Ll[4], J. Woo[1], B. Sadler[5], J. Kanodia[6], H. Sun[3], R. Zitnik[7]. [1]*Xencor, Inc., Translational Biology, Monrovia, United States of America*; [2]*ICON, Inc., Early Phase Services, San Antonio, United States of America*; [3]*Xencor, Inc., Bioinformatics, Monrovia, United States of America*; [4]*Xencor, Inc., Biometrics, Monrovia, United States of America*; [5]*ICON, Inc., Quantitative Pharmacology & Pharmacometrics, San Antonio, United States of America*; [6]*Xencor, Inc., Clinical Systems & Pharmacology, Monrovia, United States of America*; [7]*Xencor, Clinical Development, Monrovia, United States of America*

Background: Interleukin 2 (IL-2) signaling is essential for the development, survival, and suppressive function of T regulatory cells (Tregs). Diminished IL-2 signaling and Treg functional impairment are associated with autoimmune diseases, including systemic lupus erythematosus (SLE)[1]-[3]. XmAb564 is a potency reduced, monomeric human IL-2 heterodimeric Fc-fusion protein with extended half-life and increased binding affinity for IL-2 receptor alpha (CD25) to selectively expand Tregs, being developed for the treatment of autoimmune diseases.

Objectives: In this first-in-human, placebo-controlled, double-blind, single ascending-dose study, healthy adult volunteers received XmAb564 and were evaluated for safety, tolerability, pharmacokinetics (PK), and pharmacodynamic (PD) for 30-45 days.

Methods: Subjects received SC doses of XmAb564 at 0.003, 0.007, 0.015, 0.025, 0.040, and 0.065 mg/kg in 6 cohorts (6 active:2 placebo per cohort). Levels of immune cell populations in whole blood were assessed by flow cytometry for total Tregs (CD4+CD25+FoxP3+) and CD25^{bright} Tregs (CD4+CD25brightFoxP3+), as well as NK (CD56+) cells, CD4+ and CD8+ T conventional cells (Tcon).

Results: A single dose of XmAb564 was well tolerated, with no dose-limiting toxicities, no Grade 3 or greater adverse events (AEs), no serious AEs, no deaths, nor clinically significant laboratory safety abnormalities. AEs attributed to XmAb564 were mainly mild to moderate self-limited injection site reactions. Asymptomatic transient elevations of peripheral eosinophils were observed in a dose-dependent manner, similar to those reported with other biologics in the class. After a single dose of subcutaneous administration, XmAb564 exposure increased in a dose-dependent manner with dose-proportional C_{max} and non-linear clearance owing to the expected increase in target receptor expression (CD25) in response to XmAb564 and dynamic target-mediated drug disposition across the range of doses studied from 0.003 to 0.065 mg/kg.

The primary effect of XmAb564 was seen on total Tregs and particularly the CD25^{bright} Treg subset (Figure 1A, B). The elevations peaked at approximately Day 12 and remained elevated for at least 21 days following drug administration. At the highest dose of 0.065 mg/kg, the mean peak increase in numbers of Tregs and CD25^{bright} Tregs were 8-fold and 117-fold above baseline, respectively. At that same 0.065 mg/kg dose level, there was a trend of mean increase of 2.6-fold, 2.3-fold, and 2.2-fold in numbers of NK, CD4$^+$ and CD8$^+$ Tcon cells, respectively.

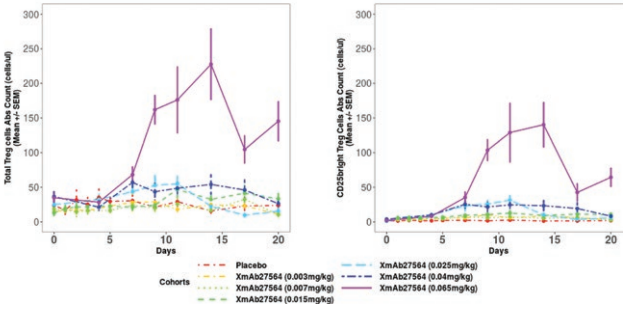

Figure 1.

Conclusion: XmAb564 selectively induced Tregs and was well tolerated. XmAb564 PK and PD potentially supports extended multi-week dosing intervals and has a Treg induction magnitude and durability that may be competitive or superior to other candidates in clinic, providing the rationale for clinical evaluation across a broad range of inflammatory diseases.

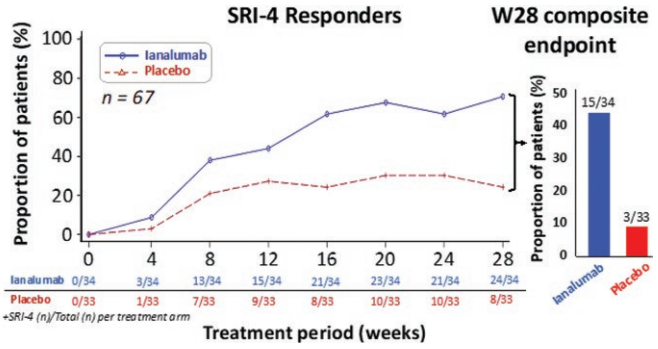
Background: Ianalumab (VAY736) is a novel defucosylated, human IgG1 mAb targeting the receptor for B cell Activating Factor of TNF Family (BAFF-R), providing both enhanced antibody-dependent cellular cytotoxicity-mediated depletion of B cells and blockade of BAFF:BAFF-R signaling that drives B cell differentiation, proliferation and survival.

Objectives: Evaluate safety and efficacy of ianalumab in patients with active SLE.

Methods: Multi-center, randomised, parallel group, double-blind trial consisting of 2 separate, placebo-controlled treatment cohorts for ianalumab and for iscalimab (CFZ533; anti-CD40 mAb) randomised 1:1 between active:placebo. Patients (ianalumab cohort n= 67, iscalimab cohort n= 40) with ANA ≥1:80 and meeting ≥4/11 ACR 1997 SLE classification criteria, with SLEDAI-2K score ≥6 and BILAG-2004 ≥1 'A' or two 'B' scores that included activity in either mucocutaneous and/or musculoskeletal domains were enrolled from 19 Dec 2018 through 31 Jan 2022. Here we report interim analysis results for ianalumab treatment cohort (active n=34, placebo n=33) completing the 28-week blinded treatment period, which comprised of monthly s.c. injection of ianalumab 300 mg or placebo. Outcomes were measured at baseline (BL) and weeks (w) 4, 8, 12, 16, 24 and 28. The primary w28 outcome was proportion of patients meeting composite endpoint requirements consisting of patients who both achieved SRI-4 and also tapered predniso(lo)ne ≤5 mg/d or ≤ BL dose, whichever was lower, by w16 and kept within that range to w28. Other outcomes included safety and tolerability, incidence of BILAG-2004 moderate or severe flares, proportion of patients achieving Lupus Low Disease Activity State (LLDAS), change from BL in SLEDAI-2K and BILAG-2004, physician/patient global visual analog scale (VAS) assessments and laboratory markers of inflammation and immune activation. Post-w28 patients received open-label ianalumab for 20w, then safety follow up off treatment up to 2 years (y).

Results: Median age was 42y and 39y for ianalumab and placebo arms, respectively, with 8 males (ianalumab: 2, placebo: 6). BL median (*range*) values for ianalumab and placebo arms, respectively, were: SLEDAI-2K scores 10 (*6-32*) and 10 (*4-18*), and predniso(lo)ne 10.0 mg (*0-30.0*) and 10.0 mg (*2.5-27.5*). Proportion of patients treated with ianalumab or placebo, respectively, achieving SRI-4 at w28 (Figure 1) was 70.6% (n=24) vs. 24.2% (n=8), and also meeting composite endpoint (Figure 1 insert): 44.1% (n=15) vs. 9.1% (n=3). Ianalumab showed benefit vs placebo in other outcomes (Table 1) for incidence moderate or severe flare, time to moderate or severe flare, achieving w28 LLDAS, and serum levels of complement and autoantibodies. No drug-related SAEs were reported with ianalumab during blinded or subsequent 20w open-label treatment. There were 2 AE-related dropouts occurring during open-label treatment, one in ianalumab arm (morphoea) and one with placebo (worsening of SLE). Pandemic-related discontinuations included one from each arm during the blinded treatment period, and 2 occurring post-w28 in the ianalumab arm: one each in open label and during safety follow up.



Conclusion: Treatment of SLE with ianalumab was well tolerated and met the composite primary endpoint of SRI-4 response with sustained steroid reduction, with additional benefits seen across other study endpoints. These positive results support further evaluation of ianalumab in SLE.

Table 1. Selected secondary and exploratory outcomes

Outcomes		Ianalumab (n=34)	Placebo (n=33)
Incidence of flare*	n (%)	15 (44)	21 (64)
Time to first flare* (Days)	Mean (SD)	108 (73)	87 (39)
	Median (range)	87 (29-276)	84 (30-170)
Week 28 LLDAS	n (%)	9 (27)	3 (9)
Ratio BL at Week 28			
Serum C3	Geo-mean	1.13 (1.05, 1.22)	0.95 (0.88, 1.03)
Serum C4	(95% CI)	1.44 (1.24, 1.67)	1.01 (0.90, 1.13)
Anti-dsDNA		0.52 (0.39, 0.70)	0.88 (0.73, 1.06)
Anti-CXCL13		0.50 (0.37, 0.67)	0.83 (0.68, 1.02)
Anti-C1q		0.70 (0.56, 0.87)	0.85 (0.71, 1.02)

*Moderate or severe: post-BL BILAG 2004 domain activity ≥1 'A' or ≥2 'B'

Background: Pulmonary arterial hypertension (PAH) is a major cause of mortality in systemic sclerosis (SSc). The 2022 ESC/ERS Guidelines recommend a comprehensive risk stratification at PAH diagnosis to guide optimized management. Several risk stratification tools have been developed in PAH. These strategies have not previously been compared, and have not been applied in SSc-PAH using the new haemodynamic definition.

Objectives: To assess the performance of current risk stratification tools to predict mortality in SSc-PAH.

Methods: We included patients from the EUSTAR registry who were diagnosed with SSc-PAH between 2001-2022 (Project Number: CP122). PAH was defined according to the new definition (mean pulmonary arterial pressure >20 mmHg, pulmonary artery wedge pressure ≤15 mmHg and pulmonary vascular resistance >2 WU). Patients with significant interstitial lung disease (ILD), defined as extent of ILD >20% on HRCT or FVC <70% in patients with missing quantification, were excluded. We applied four different approaches:

(I) The 2022 ESC/ERS 3-strata approach includes up to 17 parameters according to the risk table.[1] Each parameter was graded from 1 to 3 representing low to high risk, with the mean defining the risk category.

(II) The 2022 ESC/ERS 4-strata approach equals (I), but divides the intermediate-risk group into two groups based on the mean score.

(III) COMPERA 2.0 stratifies patients into four risk groups based on WHO-functional class (FC), six-minute walk distance (6MWD), and NT-proBNP.[2] Each parameter was graded from 1 to 4 representing low to high risk, with the mean defining the risk category.

(IV) REVEAL Lite 2 stratifies patients into three risk groups based on six weighted variables (WHO-FC, systolic blood pressure, heart rate, 6MWD, NT-pro-BNP, eGFR)[3]

We analysed transplant-free survival and performed Cox regression adjusted for general and SSc-specific factors associated with worse outcome (age, male sex, DLCO, FVC, disease subtype and PAH treatment). Harrell's C-index and ROC analysis with area under the curve (AUC) were applied to compare the performance and discriminating ability of the models with >0.7 considered as acceptable.

Results: Of 955 patients who had right heart catheterization, 430 (45%) were diagnosed with SSc-PAH. Among these, 86% were females, mean age was 65 years, and 82% had limited cutaneous SSc. Over median 40 (Q1-Q3: 17-68) months follow-up, 172 died and 14 had lung transplants. The overall 1-, 3- and 5-year transplant-free survival was 91%, 77% and 60%, respectively. In univariable Cox regression only COMPERA 2.0 had acceptable predictive value with a C-index >0.7 (Table 1). In adjusted multivariable Cox regression, all the risk stratification approaches predicted mortality with increased HR at higher risk scores (Figure 1 A-D). All adjusted models were acceptable, but COMPERA 2.0 was the most accurate to predict mortality (C-index=0.78, AUC=0.74) (Table 1, Figure 1C). However, this model did not discriminate intermediate-low risk from low risk (HR 1.39, 95% CI (0.59, 3.25), p=0.45). The models discriminating abilities were not significantly different (p=0.27).

Table 1. Harrell's C-index and AUC in the four approaches

	Univariable analysis		Adjusted multivariable analysis	
	C-index	AUC (p=0.08)	C-index	AUC (p=0.27)
ESC/ERS 3-strata	0.622	0.641	0.703	0.688
ESC/ERS 4-strata	0.653	0.669	0.710	0.693
COMPERA 2.0	0.728	0.712	0.779	0.737
REVEAL Lite 2	0.697	0.698	0.753	0.718

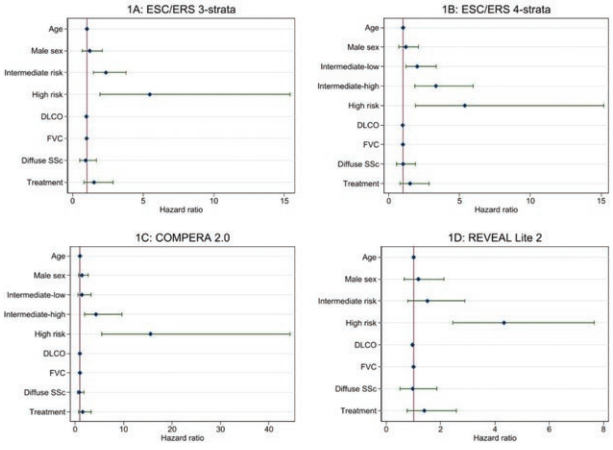

Figure 1. Forest plots of the multivariable cox regression models

Conclusion: In SSc-PAH, we suggest that the application of risk stratification at time of PAH diagnosis should take SSc-specific variables into account. In particular, the COMPERA 2.0 risk stratification model performs best, does not require invasive measurements and uses parameters easily collected at each clinical visit, making it readily applicable in clinical practice. Importantly, this approach identifies patients at intermediate-high and high risk who need more aggressive management.

INVESTIGATION OF SERUM MARKER LEVELS IN CONNECTIVE TISSUE DISEASES DEVELOPING ILD

Keywords: Biomarkers, Systemic sclerosis, Lungs

H. Didriksen[1], H. Fretheim[1], H. Andersson[1], S. Reiseter[2], R. Gunnarsson[1], E. Langballe[1], T. Garen[1], Ø. Midtvedt[1], T. Ueland[3], Ø. Molberg[1], A. M. Hoffmann-Vold[1,4]. *[1]Oslo universitetssykehus HF, Rikshospitalet, Rheumatology, Oslo, Norway*; *[2]Martina Hansens Hospital, Rheumatology, Bærum, Norway*; *[3]Oslo universitetssykehus HF, Rikshospitalet, Research Institute of Internal Medicine, Oslo, Norway*; *[4]University Hospital of Zürich, Rheumatology, Zürich, Switzerland*

Background: Connective tissue disease (CTD) is an umbrella term for a heterogeneous group of autoimmune diseases affecting the connective tissue in various organs. One of the most serious complications associated with CTDs is interstitial lung disease (ILD), which results in significant morbidity and mortality. A subset of CTD-ILD patients shows progressive disease, which is associated with an even worse prognosis. Previous studies have identified dysregulations of biomarkers including CX3CL1, CCL2, CCL17 and CCL18 in systemic sclerosis (SSc) showing an association with ILD [1-4]. For other CTD-ILD it is less clear, which biomarkers are associated with ILD and ILD progression and few studies have assessed circulating biomarkers across CTD-ILDs.

Objectives: To investigate circulating biomarkers in CTD-ILD and in progressive CTD-ILD patients.

Methods: Serum samples from SSc (n=292), primary sjogrens syndrome (pSS) (n=132), mixed connective tissue disease (MCTD) (n=162), anti-syntetase syndrome (ASS) (n=72) patients and healthy controls (HC) (n=100) collected at Oslo University Hospital (OUH) were analyzed by ELISA for selected biomarkers (CX3CL1, CCL2, CCL17, CCL18). SSc samples were used as the reference disease to compare with mean levels of serum markers in pSS, ASS and MCTD. ILD was diagnosed on high resolution computed tomography (HRCT). Forced vital capacity (FVC) was available at baseline and 12 +/- 3 months. ILD progression defined as an absolute FVC% predicted decline of ≥10% was assessed. Descriptive statistics and logistic regression with odds ratio (OR) and 95%CI were performed.

Results: Serum levels of CX3CL1 and CCL18 were significantly higher in all the CTDs (p<0.001) compared to HC. CCL2 and CCL17 levels were significantly higher in SSc (p=0.001 and p<0.001), ASS (p<0.001 and p=0.004) and MCTD (p<0.001 and p<0.001) compared to HC, but not in pSS (p=0.230 and p=0.087). Of all CTD patients, 267/658 (41%) were diagnosed with ILD (table 1). Of these patients 80 (30%) showed ILD progression, where data were obtained for SSc, pSS and ASS (Tabel 1). All the markers were significantly higher in patients with ILD compared to no ILD in SSc and pSS, while only CCL17 was significantly higher inn ASS-ILD and none in MCTD-ILD. When using SSc-ILD as reference disease, serum levels of CX3CL1 were significantly higher in pSS-ILD (p<0.001) and MCTD-ILD (p<0.001), and CCL18 was significantly lower in MCTD-ILD (p<0.001). Serum levels of CCL2 and CCL17 did not significantly differ between SSc-ILD and the other CTD-ILDs (Figure 1A). From logistic regression analysis of the patient with ILD progression, CCL18 (OR: 1.19, 95%CI, p=0.001) were the only marker significantly associated with ILD progression. When adjusting for CTD with SSc as reference disease, the only marker significantly associated with ILD progression was also here CCL18 (OR: 1.06, 95%CI: 1.03-1.09, p<0.001) (Figure 1B).

Conclusion: In this large CTD cohort, we show that CCL2 and CCL17 are increased across all CTD patients with ILD compared to no ILD, which could help us to identify patients with ILD. ILD progression was only associated with CCL18, which was driven by the SSc-ILD subpopulation.

Table 1. Clinical and demographic data

	SSc (n=292)	pSS (n=132)	ASS (n=72)	MCTD (n=162)
Females, no (%)	239 (61)	123 (93)	48 (67)	128 (79)

Background: Prognosis in connective tissue disease associated interstitial lung disease (CTD-ILD) is influenced by the underlying diagnosis and chest imaging pattern. Usual interstitial pneumonia (UIP), non-specific interstitial pneumonia (NSIP), and fibrotic hypersensitivity pneumonitis (fHP) patterns can be found across all CTD-ILD subtypes although their impact on disease evolution and treatment response is unclear.

Objectives: Our goal was to examine the association of lung imaging pattern with CTD-ILD progression, mortality, and immunosuppression response.

Methods: 615 patients with CTD-ILD enrolled in the Canadian Registry for Pulmonary Fibrosis had high-resolution chest computed tomography (HRCT) from their first ILD clinic visit reviewed in standardized multidisciplinary discussion. All CTD diagnoses were rheumatologist-confirmed. Experienced chest radiologists blinded to clinical data categorized each case into five groups: UIP, NSIP, organizing pneumonia (OP), fHP, and other patterns. Longitudinal percent-predicted forced vital capacity (FVC) and transplant-free survival were compared between imaging groups using linear mixed effects and Cox proportional hazards models adjusted for age, sex, smoking pack-years, and baseline FVC. Linear mixed effects models were used to compare pre- and post-treatment rate of FVC decline in patients with ≥6 months follow-up before and after treatment with mycophenolate, azathioprine, rituximab, cyclophosphamide, and/or tocilizumab. UIP was the reference group for all comparisons.

Results: The most frequent CTD subtypes were systemic sclerosis (SSc) (33%), rheumatoid arthritis (RA) (20%), and idiopathic inflammatory myopathy (IIM) (16%) with NSIP pattern present in 54% of all CTD-ILD (Table 1). On multivariable analyses among all CTD-ILD patients, NSIP was associated with a slower rate of FVC decline by 1.1%/year (0.2, 1.9) and a lower mortality HR (95%CI) of 0.65 (0.45, 0.93) compared to UIP. OP was also associated with a slower rate of FVC decline by 3.5%/year (2.0, 4.9) and a lower mortality HR (95%CI) of 0.18 (0.05, 0.57) compared to UIP. In contrast, fHP had a higher mortality HR (95%CI) of 1.58 (1.01, 2.40). The rate of FVC decline after treatment was not significantly different compared to pre-treatment in the UIP group but was slower in the NSIP group by 2.1%/year (1.4, 2.8). Subgroup analyses in RA-ILD and SSc-ILD showed the persistence of fHP having a higher mortality compared to UIP in RA-ILD.

Conclusion: The presence of an NSIP pattern was associated with improved outcomes and immunosuppression response compared to UIP in the overall CTD-ILD group. The findings of fHP associated with worse survival compared to UIP in CTD-ILD and in the RA-ILD are novel. These findings need to be further confirmed in disease specific cohorts and randomized trials of immunosuppression in patients with CTD-ILD.

Table 1. Association between imaging patterns with FVC decline, mortality, and immunosupression response in CTD-ILD

Imaging pattern	Difference in the annualized rate of FVC change between imaging patterns (95%CI)	Mortality Hazard ratio (95%CI)	Difference in the annualized rate of FVC change Pre- vs Post-Treatment (95%CI)
UIP	Reference group	Reference group	0.1 (-1.4,1.7)
NSIP	1.1 (0.2, 1.9)	0.65 (0.45, 0.93)	2.1 (1.4, 2.8)
OP	3.5 (2.0, 4.9)	0.18 (0.05, 0.57	NA
fHP	-0.7 (-2.0, 0.6)	1.58 (1.01, 2.48)	NA
Other	0.2 (-1.0, 1.4)	0.63 (0.36, 1.08)	NA

All models were adjusted for age, sex, smoking pack years, and baseline FVC95%CI = 95% confidence interval, UIP = Usual interstitial pneumonia, NSIP = Nonspecific interstitial pneumonia, OP = organizing pneumonia, fHP = fibrotic hypersensitivity pneumonitis, Other = other imaging patterns including lymphocytic interstitial pneumonia, desquamative interstitial pneumonia, pleuralparenchymal fibroelastosis, unclassifiable

Background: Interstitial lung disease (ILD) is a major cause of mortality in patients with connective tissue diseases (CTDs). Previous studies have shown a worse survival in patients with idiopathic pulmonary fibrosis (IPF) (1-2), however, these studies were mainly focused on patients with rheumatoid arthritis, whereas few data are available for patients with other CTDs.

Objectives: The aim of this study was to assess the 5-year survival in an Italian multicenter cohort of ILD patients suffering from systemic sclerosis (SSc), dermatomyositis (DM), and anti-synthetase syndrome (ASS) compared to IPF patients.

Methods: Demographic and clinical data of patients with SSc, DM and ASS were retrospectively recorded from January 2015 for the purpose of this study. The baseline time was a diagnosis of ILD confirmed by computed tomography (CT) scan of the chest. The IPF cohort was used as control group. Progressive lung disease was defined when the patient presented within 24 months after the diagnosis of ILD with at least one of these characteristics: a) a relative decline in FVC of at least 10% of expected value; b) a relative decline in FVC from 5% to less than 10% of the expected value and a worsening of respiratory symptoms or an increase in the extent of lung fibrosis on high-resolution CT scan; c) a worsening of respiratory symptoms and an increase in the extent of lung fibrosis on high resolution CT scan. All data were reported and analyzed with standard descriptive statistics, as appropriate. The 5-year survival was assessed with the Kaplan-Meyer method; univariate and multivariate Cox-regression models were built to look for possible risk factors. Data were analyzed with SAS/STAT Statistics version 9.4 (SAS Institute, Cary, NC, USA).
Results: The overall cohort included 177 CTD-ILD patients (99 SSc, 25 DM, 53 ASS) and 153 IPF patients. At ILD diagnosis, as expected, CTD patients were younger [median age (IQR); IPF: 68 (63-73) years, SSc 58 (46-66) years, DM 54 (51-65) years and ASS: 59 (60-67) years; p <0.001 vs IPF] and predominantly female (IPF: 23%, SSc 83.5%, DM 81% and ASS 65%; p <0.001 vs IPF). Usual interstitial pneumonia was observed in a low number of CTD patients, evidenced in 11 (11.5%) SSc, 7 (12.9%) ASS and 4 (16.6%) DM patients. At ILD diagnosis, the median (IQR) value of forced vital capacity (FVC%) was similar between IPF [75%(64-91)], DM [79%(60-90)] and ASS [77.5%(64-93)], while was significantly higher in SSc patients [94%(79-106), p<0.001 vs IPF]. At baseline, all CTDs showed a higher mean (SD) value of diffusing capacity for carbon monoxide (DLCO%) [SSc: 63%(18), DM: 62%(23), ASS: 63%(22)] than IPF [50%(15); p<0.001]. During follow-up, 10 (9.7%) patients with SSc, 4 (16%) with DM and 3 (8%) with ASS showed a progressive subset of ILD. CTDs showed better 5-year survival compared to IPF (log rank: p<0.0001) (Figure 1). Multivariate Cox analysis highlighted that male gender (HR: 2.29, 95% CI 1.25-4.18), age at diagnosis (HR: 1.07, 95% CI 1.04-1.10) and DLCO at baseline (HR: 0.95, 95% CI 0.94-0.97) were independent prognostic factors in CTD-ILD.

Figure 1. 5-year survival in patients with systemic sclerosis (SSc), dermatomyositis (DM), Anti-synthetase syndrome (ASS) and idiopathic pulmonary fibrosis (IPF)

Conclusion: The prognosis of CTD patients with lung fibrosis appears to be significantly better than those with IPF. The early detection of lung involvement in at-risk patients like SSc, DM and ASS, and the availability of effective immunosuppressive treatment may explain this discrepancy. Of note male patients, older age and compromised DLCO at baseline represent poor prognostic factors.

POS0125 SUSTAINED COMPLETE B CELL DEPLETION IS ASSOCIATED WITH RITUXIMAB EFFICACY IN CONNECTIVE TISSUE DISORDERS - ASSOCIATED INTERSTITIAL LUNG DISEASE

Keywords: Lungs, Systemic sclerosis

O. Al Tabaa[1], R. Ghossan[1], A. Combier[1], A. Steelandt[1], M. Thomas[1], J. Avouac[1], Y. Allanore[1]. [1]*Cochin Hospital, Rheumatology, Paris, France*

Background: The benefit of RTX has been suggested for interstitial lung disease (ILD) associated with connective tissue disorders (CTD). Preliminary data have suggested that B cell depletion measured 2 weeks after the first RTX infusion was predictive of short-term treatment response at 6 months in systemic sclerosis (SSc)-ILD.
Objectives: To determine whether the quality of B cell depletion was associated with therapeutic response to RTX in CTD-ILD.
Methods: Retrospective monocentric study including all patients treated at least 1 year with RTX for SSc- or MCTD-ILD. The observation period was defined by to the time from the first to the last RTX infusion. ILD was identified based on high-resolution CT. The results of forced vital capacity (FVC) and carbon monoxide diffusion capacity (DLCO) were collected at the time of the first RTX infusion, at month 12 and at the time of the last RTX infusion. B cell immunophenotyping was performed the day of each RTX infusion (Aquios, Beckman Coulter). B cell depletion was defined by CD19 <18/µL. The primary outcome was the absolute change from baseline of FVC (L) at 12 months and at the last RTX infusion according to complete or incomplete B cell depletion within the observation period. Secondary outcomes were the course of DLCO at the same time points according to B cell depletion and the analysis of the % of good RTX responders at 12 months and at the last RTX infusion, defined by at least 5% improvement in %FVC compared to baseline.
Results: 17 patients (12 SSc and 5 MCTD) were included, with a median age of 59 years (95% confidence interval, CI, 48-63 years) and a median disease duration of 8 years (95% CI 5-11 years). The median duration of RTX exposition was 45 months (95% CI 19-90 months), the median number of infusions was 8/patient (95% CI 5-14) and the cumulative RTX dose was 7g (95% CI 5-14g). These parameters were similar in the 9 patients with complete B cell depletion (CD19: 15/µL, 95% CI 14-18/µL, **Figure 1A-B**) and the 8 patients with incomplete B cell depletion (CD19: 70/µL, 95% CI 18-126/µL, **Figure 1A-B**) during RTX exposition. The absolute change from baseline of the FVC was different according to B cell depletion during the observation period. In the subset of patients who maintained complete B cell depletion (**Figure 1C**), median FVC increased from 2.58 L (95% CI 1.13-4.08 L) to 3.08 L (95% CI 1.34-4.64 L) at month 12 (p=0.004) and 3.22 L (95% CI 1.57-4.19 L) at the last RTX infusion (p=0.019) (**Figure 1D**). Conversely, in the subset of patients with constant incomplete B cell depletion (**Figure 1C)**, FVC initially increased from 2.04 L (95% CI 0.99-3.24 L) to 2.23 L (95% CI 0.83-3.35 L) at month 12 (p=0.039) before decreasing to 1.89 L (95% CI 1.00-3.24 L) (p=0.37) (**Figure 1D**). The absolute change from baseline of DLCO did not significantly differ according to B cell depletion. In addition, The percentage of patients with any FVC improvement was higher in the subset of patients who maintained complete BC depletion at 1 year (6/9, 67% vs. 4/8, 50%) and at the last RTX infusion (8/9, 89% vs. 4/8, 50). Conversely, median DLCO did not significantly differ according to BC depletion.
Conclusion: These results highlight the importance of obtaining and maintaining B cell depletion to gain clinically relevant efficacy of RTX in CTD-ILD. CD19 measurement at each infusion is a relevant tool to monitor RTX efficacy in daily practice.

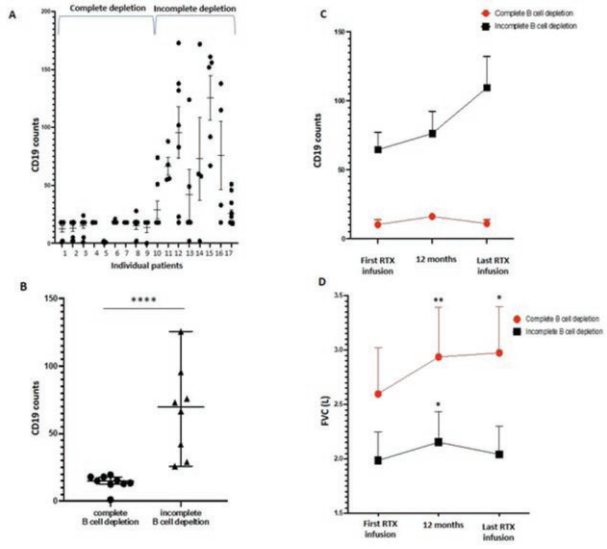

Figure 1. A, Individual CD19 counts measured prior to each RTX infusion. **B,** Comparison of CD19 counts between patients with or without complete B cell depletion. Each point represents the median CD19 value measured at each infusion per patient during the observation period (at least 3 measures per patient). Data are shown as median and 95% confidence interval. **** p<0.0001 by Mann Whitney test. **C,** Course of CD19 during the observation period according to B cell depletion. **D,** Course of FVC during the observation period according to B cell depletion; *p<0.05 and **p<0.01 vs baseline value by the Wilcoxon matched pairs signed rank test.

CONTINUED TREATMENT WITH NINTEDANIB IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE (SSC-ILD): THREE-YEAR DATA FROM SENSCIS-ON

Keywords: Systemic sclerosis, Clinical Trials, Lungs

Y. Allanore[1], M. Vonk[2], O. Distler[3], A. Azuma[4], M. Mayes[5], A. James[6], V. Kohlbrenner[7], M. Alves[8], D. Khanna[9], K. Highland[10]. Background: In the randomised placebo-controlled SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) (mL/year) over 52 weeks by 44%, with adverse events that were manageable for most patients. SENSCIS-ON is an open-label extension study investigating adverse events and decline in FVC in patients with SSc-ILD treated with nintedanib over the longer term.

Objectives: To assess adverse events and decline in FVC in patients treated with open-label nintedanib over 148 weeks of SENSCIS-ON.

Methods: In the SENSCIS trial, patients received nintedanib or placebo until the last patient reached week 52 but for ≤100 weeks. Patients with SSc-ILD who completed SENSCIS or a drug–drug interaction (DDI) study of nintedanib and oral contraceptive in which female patients with SSc-ILD received nintedanib for ≥14 days to approximately 28 days were eligible to enter SENSCIS-ON. We analysed adverse events and changes from baseline in FVC (mL) over 148 weeks in patients who received nintedanib in SENSCIS and continued nintedanib in SENSCIS-ON ("continued nintedanib" group) and in patients who received placebo in SENSCIS or who received nintedanib for ≤28 days in the DDI study ("initiated nintedanib" group). Analyses were descriptive. Analyses of FVC were based on observed data available at the respective time-point.

Results: The continued nintedanib group comprised 197 patients and the initiated nintedanib group comprised 247 patients (231 from SENSCIS, 16 from the DDI study). In these groups, respectively, mean (SD) FVC at the start of SENSCIS-ON was 2379 (754) mL and 70.4 (18.1) % predicted and 2443 (814) mL and 70.8 (17.9) % predicted. In total, 126 (64.0%) and 125 (50.6%) patients in the continued nintedanib and initiated nintedanib groups, respectively, were still receiving nintedanib at week 148 of SENSCIS-ON. Diarrhoea was the most frequent adverse event (Table 1). Serious adverse events were reported in 76 (38.6%) patients in the continued nintedanib group and 95 (38.5%) patients in the initiated nintedanib group. Among patients who continued nintedanib and initiated nintedanib, respectively, 53 (26.9%) and 148 (59.9%) had ≥1 dose reduction and 72 (36.5%) and 131 (53.0%) had ≥1 treatment interruption. Adverse events led to discontinuation of nintedanib in 29 (14.7%) patients in the continued nintedanib group and 72 (29.1%) patients in the initiated nintedanib group. Mean (SE) changes in FVC from baseline to week 148 of SENSCIS-ON were −189.1 (29.5) mL in the continued nintedanib group and −126.4 (26.4) mL in the initiated nintedanib group (Figure 1).

Conclusion: The safety profile of nintedanib over 148 weeks of SENSCIS-ON was consistent with that reported in SENSCIS, characterized mainly by gastrointestinal events that were manageable for most patients. These results support the potential use of nintedanib in the long-term treatment of patients with SSc-ILD.

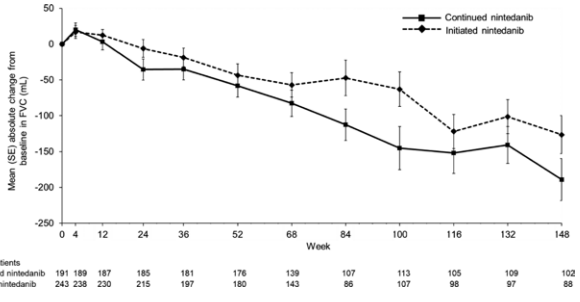

Figure 1. Change in FVC (mL) over 148 weeks in SENSCIS-ON

Table 1. Most frequent adverse events over 148 weeks in SENSCIS-ON

	Continued nintedanib (n=197)	Initiated nintedanib (n=247)
Diarrhoea	152 (77.2)	183 (74.1)
Nausea	43 (21.8)	73 (29.6)
Skin ulcer	48 (24.4)	54 (21.9)
Vomiting	38 (19.3)	59 (23.9)
Liver test abnormalities	31 (15.7)	63 (25.5)
Upper respiratory tract infection	39 (19.8)	33 (13.4)
Nasopharyngitis	31 (15.7)	40 (16.2)
Cough	36 (18.3)	33 (13.4)
Arthralgia	34 (17.3)	32 (13.0)
Weight decreased	23 (11.7)	33 (13.4)
Abdominal pain	10 (5.1)	36 (14.6)
Gastrointestinal oesophageal reflux disease	24 (12.2)	15 (6.1)

Data are n (%) of patients with ≥1 such event reported over 148 weeks (or until 7 days after last trial drug intake for patients who discontinued trial drug before week 148). Adverse events were coded according to preferred terms in the Medical Dictionary for Regulatory Activities (MedDRA) except for liver test abnormalities, which were based on the standardised MedDRA query "liver related investigations, signs and symptoms" (broad definition). Events reported in >12% of patients in either group are shown.

RISK OF NEW-ONSET DEPRESSION IN PATIENTS WITH SYSTEMIC SCLEROSIS: A NATIONWIDE POPULATION-BASED STUDY

Keywords: Systemic sclerosis

S. J. Moon[1], K. D. Han[2]. [1]*Yeouido St. Mary's Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea)*

Background: Systemic sclerosis (SSc) is a rare chronic inflammatory disease characterized by vasculopathy, autoimmunity and progressive fibrosis in various organs including skin, lung, and gastrointestinal tract. The patients with SSc are suffered from various symptoms such as dyspnea, cough, and gradual skin and joint contracture, resulting in significant physical and psychological burden. Psychological symptoms in SSc patients include pain, depression, and concerns about appearance disfigurement. Previous studies have reported that depression

is common in SSc patients, ranging from 36% to 65%. However, no study has unveiled the risk of new-onset depression in SSc patients.

Objectives: The present study was conducted to determine whether SSc is an indeed risk factor for the development of new-onset depression. To determine whether the incidence rate (IR) of new-onset depression in SSc patients is higher than in normal subjects, we used data from a nationwide health care database.

Methods: We selected subjects from National Health Insurance System database who were diagnosed with SSc between 2010 and 2016. Subjects who did not get a general health checkup in the previous 2 years, who were diagnosed with depression before their SSc diagnosis, who were less than 20 years old, or who had missing data were excluded. To minimize the possibility of reverse causality, an analysis with a 1-year lag was performed. Kaplan-Meier analysis was conducted to assess the incidence of new-onset depression, and Cox proportional hazards regression was used to calculate adjusted and unadjusted hazard ratio (HR) and 95% CIs. HR for new-onset depression was adjusted for age, sex, smoking, drinking, physical activity, body mass index (BMI), income, diabetes, hypertension, and dyslipidemia.

Results: A total of 1,063 SSc patients (female 82.4 %) and 3,189 age-, sex-matched non-SSc controls with mean (SD) age of 53.1 (10.6) years were included in the analysis. During follow-up periods after 1 year of lag time, the cumulative incidence of new-onset depression was significantly higher in patients with SSc vs controls (38.7 vs. 27.7 IR per 1000 person-years). After adjusting for covariates (age, sex, smoking, drinking, physical activity, BMI, income, diabetes, hypertension, and dyslipidemia), the presence of SSc was associated with 38.1 % increased risk of new-onset depression (HR 1.381; 95% CI, 1.128-1.691), compared with controls. SSc disease itself was determined as an independent risk factor for new-onset depression in subjects with younger age (age < 65 years; HR 1.41; 95% CI 1.122-1.773), female gender (HR 1.415; 95% CI 1.139-1.759), and absence of regular exercise (HR 1.433; 95% CI 1.143-1.795), after adjusting for covariates. Interestingly, the risk of new-onset depression after SSc diagnosis was found to be relatively higher in the low-income group (HR 1.667; 95% CI 1.121-2.479 vs HR 1.303; 95% CI 1.028-1.650).

Conclusion: The present study suggests that the SSc diagnosis is associated with a significantly increased cumulative incidence and risk of new-onset depression. This association is more pronounced in female gender, younger age group, and those who do not exercise regularly. Regular assessment of the occurrence of depressive symptoms should be more emphasized in the patients with SSc after diagnosis.

POS0128 **WITHDRAWN**

POS0129 **DIFFERENTIALLY EXPRESSED GENES (DEGS) IN PATIENTS WITH DERMATOMYOSITIS AND JUVENILE DERMATOMYOSITIS**

Keywords: Biomarkers, -omics, Myositis

R. Martinez[1], C. Elizondo Solis[1], A. Montoya Rosales[2], M. Salinas Carmona[1], N. Macias-Segura[1]. [1]*Servicio y Departamento de Inmunología, Service and Department of Immunology, Monterrey, Mexico*; [2]*UANL - CIDICS, Immunomodulators Laboratory, Monterrey, Mexico*

Background: Dermatomyositis (DM) and Juvenile Dermatomyositis (JDM) are englobed in the spectrum of inflammatory myopathies. These are autoimmune

diseases that cause heliotropic rash in most patients, which then develop proximal muscles weakness and skin lesions [1]. Key findings in patients with these pathologies include anti-Mi2, anti-Jo1, and anti-P155/P140 antibodies in plasma, as well as B-cells and plasma cells infiltrates with an upregulated Type I Interferon (IFN) signature in muscle biopsies [2]. However, the pathophysiology underlying this condition has not been fully comprehended; even less, diagnostic biomarkers that could identify early stages of the disease.

Objectives: We aimed to identify overlapped genes across datasets of gene expression from patients with DM and JDM doing an integrative bioinformatics analysis.

Methods: A search strategy was designed in the Gene Expression Omnibus platform to identify datasets of gene expression profiling by array experiments in patients with DM and JDM. The inclusion criteria were: 1) Assays performed in humans, 2) Inclusion of healthy controls in the datasets, and 3) Data analysis with GEO2R. The exclusion criteria were 1) Incomplete information of the genes, and 2) Gene expression by RNAseq. DEGs were selected when $p < 0.05$ and log fold change > 2 or < -2. Functional enrichment analysis was realized with free access platforms GeneMania and DAVID with the significant overlapped genes. A protein-protein interaction (PPI) analysis was constructed with STRING and a topological interaction network using CytoHubba to identify genes with the strongest interactions. A prediction of transcription factors that can serve as possible therapeutic targets was realized with iRegulon.

Results: 102 overlapped DEGs from DM and 13 overlapped DEGs from JDM were found within their datasets. Out of those DEGs, 5 were shared between DM and JDM. Prediction analysis yielded 20 co-expressed genes. DAVID analysis showed the top 3 biological processes in which the 25 genes are involved, most of them belonging to the Type I IFN signature (Table 1). Topological analysis yielded 10 genes with the strongest interactions between them, and the transcription factor listed as possible therapeutic target was STAT1.

Table 1. DAVID analysis shows the processes involving those genes, most of them belonging to the Interferon Signature.

Functional Enrichment Analysis		
Term	**Gene Count**	**P-value**
Defense response to virus	19	1,9E-30
Response to virus	13	1,8E-21
Negative regulation of the viral genome	8	9,1E-14

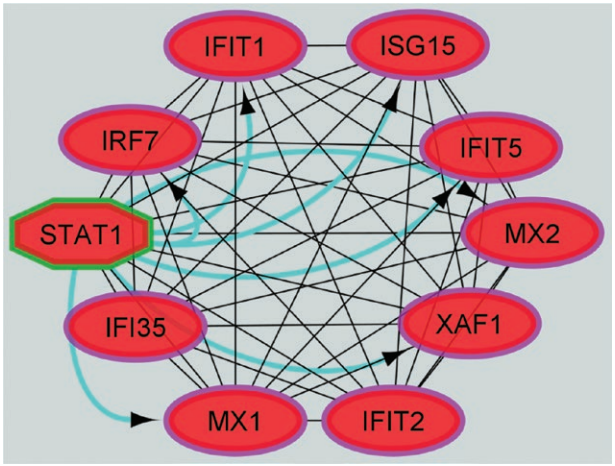

Figure 1. Topologic analysis displays the 10 genes with the strongest interactions. All the genes belong to the Interferon Signature and STAT1 regulates 7 out of 10.

Conclusion: We aimed to identify DEGs that participate in the pathophysiology of DM and JDM. Those genes mostly participate in responses to viral infections, in which the type I IFN signature is present. These genes may serve in the future as possible biomarkers for early diagnosis. An *in vivo* analysis in patients with these diseases is needed to validate these findings. Janus Kinase Inhibitors (Jakinibs) have been used to treat JDM patients, showing positive results [3]. We suggest more clinical trials to test the effectiveness and tolerability of Jakinibs to treat these conditions.

POS0130

INFLAMMATORY ACTIVITY IS ASSOCIATED WITH COGNITIVE IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Cognitive Function, Rheumatoid arthritis, Comorbidities

F. Ortiz-Márquez[1], A. Garcia Studer[1], I. Montañez-Marín[2], T. Ramírez-García[3], P. Cabezudo-García[3], N. Mena-Vázquez[1]. [1]*Instituto de Investigación Biomédica de Málaga (IBIMA)-Plataforma Bionand, Hospital Regional Universitario de Málaga (HRUM), Unidad de Gestión Clínica de Reumatología, Málaga, Spain*; [2]*Universidad de Málaga, Departamento de Medicina, Málaga, Spain*; [3]*Instituto de Investigación Biomedica de Málaga (IBIMA)-Plataforma Bionand, Hospital Regional Universitario de Malaga (HRUM), Servicio de Neurología, Unidad de Gestion Clinica de Neurociencias, Málaga, Spain*

Background: Patients with rheumatoid arthritis (RA) present cognitive impairment at a frequency of 38% to 71%.

Objectives: To study whether there is an association between high sustained inflammatory activity and cognitive impairment in RA patients.

Methods: Design and protocol: controlled cross-sectional observational study of a prospective cohort of patients with RA. Cases: patients with RA from a prospective cohort with onset >16 years and who were selected to start first biologic treatment for moderate-high inflammatory activity. Controls: subjects without inflammatory disease, matched for sex and age with cases. All participants performed the same neuropsychological battery. Variables: the main variable was cognitive impairment defined by a score of < 26 points in the Montreal Cognitive Assessment questionnaire (MoCA test). As secondary variables we included the score in each of the items of the MoCA test separately; the direct and inverse digits span; the STROOP test for the assessment of processing speed (STROOP-P), selective attention (STROOP-C) and inhibition (STROOP-PC); and the Hospital Anxiety and Depression Scale (HADS). Other variables included average inflammatory activity by DAS28-ESR since diagnosis, epidemiological characteristics, comorbidities and treatments.

Results: Sixty-two subjects were included. The baseline characteristics are shown in Table 1. RA patients presented a higher frequency of cognitive impairment than controls (64.5% vs. 38.7%; p=0.042), as well as lower mean (SD) values on the MoCA test (23.1 [3.8] vs. 25.1 [3.8]; p=0.046). Fewer RA patients compared to controls achieved the memory item (22 [81.5] vs 30 [100.0]; p = 0.014), naming (24 [88.0] vs 30 [100.0]; p = 0.031), and presented lower mean (SD) values in attention (3.5 [1.5] vs 4.4 [1.4]; p = 0.039). Scores for all subtests are shown in Figure 1. Factors that were associated in multivariate analysis with cognitive impairment in the total sample were age (OR [95% CI], 1.171 [1.068-1.284]; p=0.001), RA diagnosis (OR [95% CI], 4.712 [1.069-12.772]; p=0.041) and university studies (OR [95% CI], 0.089 [0.010-0.829]; p=0.034) (R2 = 0.405). The model in RA patients found association of cognitive impairment with age (OR [95% CI], 1.230 [1.020-1.485]; p=0.030), and mean DAS28-ESR (OR [95% CI], 1.704 [1.072-4.003]; p=0.048) (R2 = 0.380). Statistical analysis: descriptive analysis, bivariate analysis between patients and controls, as well as between patients with and without cognitive impairment; and two multivariate logistic regression analyses were performed to analyze the factors associated.

Conclusion: Patients with RA and high inflammatory activity more frequently presented cognitive impairment compared to the controls. The most affected domains were memory, naming and attention. Factors associated with cognitive impairment were age, educational level and mean DAS28-ESR.

RELATION BETWEEN COVID-19 AND ANCA VASCULITIS. STUDY IN A SINGLE UNIVERSITY HOSPITAL

Keywords: Vasculitis, Autoantibodies, COVID

F. Benavides-Villanueva[1], V. Calvo-Río[1], J. Loricera[1], J. Irure-Ventura[2], M. Lopez-Hoyos[2], R. Blanco[1]. [1]*Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; [2]*Marqués de Valdecilla University Hospital, Immunology, Santander, Spain*

Background: Anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitis (AAV) is a small vessel vasculitis. Hallmarked by the presence of antibodies against antigens in cytoplasmic granules of neutrophils. Different microbiological agents and vaccines can trigger an AAV, including severe acute respiratory syndrome coronavirus 2 (SARS-CoV2) infection and Coronavirus disease 2019 (COVID-19) vaccine.
Objectives: To compare: a) proportion of positive ANCA (+ANCA) test in 2019 (COVID-19 pre-pandemic) vs 2021 (COVID-19 pandemic), b) clinical features and **c)** vasculitis activity between vasculitis related to COVID 19 vaccination vs non-related.
Methods: All ANCA tests performed in 2019 and 2021 in a referral hospital were reviewed. Additionally, we studied 18 +ANCA patients diagnosed in 2021 and accepted to participate in present study. The patients were divided in two groups: a) +ANCA after SARS-CoV-2 mRNA vaccine (COVID-related) and +ANCA before COVID-19 vaccine (COVID-nonrelated). Diagnosis of underlying AAV was based on ACR/EULAR 2022 criteria. Disease activity was assessed with Birmingham Vasculitis Activity Score (BVAS). ANCA testing was done by chemiluminescence assay using IO-FLASH (Inova, San Diego, CA) according to the instructions of the manufacturer.
Results: ANCA tests were positive in 14 of 1287 cases (1.1%) and in 32 of 1434 (2.2%) cases in 2019 and 2021, respectively (figure 1, the differences were statistically significant (p=0.020). The main features of 18 ANCA+ patients diagnosed in 2021 are summarized in table 1. COVID-19 related patients showed a median of 7 points on BVAS score compared of the median of 5 points on BVAS score on not related patients.
Conclusion: There seems to be an increase of +ANCA at the expense of anti-PR3 antibodies following the COVID-19 vaccine. In patients with +ANCA following vaccination there seems to be an increased disease activity according to BVAS score without reaching statistical significance.

What's new in Paediatric RMDs?

POS0132 OUTCOMES FOLLOWING SWITCHING FROM ORIGINATOR TO BIOSIMILAR IN CHILDREN AND YOUNG PEOPLE WITH JIA

Keywords: bDMARD, Epidemiology

L. Kearsley-Fleet[1], E. Baildam[2], M. Beresford[3,4], S. Douglas[5], H. Foster[6], T. Southwood[7], K. Hyrich[1,8]. *[1]The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester Academic Health Science Centre, Manchester, United Kingdom*; *[2]The Alexandra Hospital, Paediatric Rheumatology, Manchester, United Kingdom*; *[3]Alder Hey Children's NHS Foundation Trust, Department of Paediatric Rheumatology, Liverpool, United Kingdom*; *[4]University of Liverpool, Institute of Life Course and Medical Specialities, Liverpool, United Kingdom*; *[5]Scottish Network for Arthritis in Children, SNAC, Edinburgh, United Kingdom*; *[6]Newcastle University, Population and Health Institute, Newcastle, United Kingdom*; *[7]University of Birmingham, Institute of Child Health, Birmingham, United Kingdom*; *[8]Manchester University NHS Foundation Trust, 8National Institute of Health Research Manchester Biomedical Research Centre, Manchester Academic Health Science Centre, Manchester, United Kingdom*

Background: There are many biosimilar products available to use in children and young people with JIA. Due to competitive pricing, patients are being switched from biologic originator to biosimilar (non-medical switch).
Objectives: This analysis aims to describe characteristics of, and outcomes, following TNF-inhibitor originator to biosimilar switch in JIA.
Methods: All patients in the UK JIA Biologics Register switching from an originator to a biosimilar of the same product were identified. Patient characteristics are presented, including time on originator prior to switch. Patients were followed until their final follow-up form was returned. For those with >1 year of follow-up post-switch, treatment persistence and reasons for stopping are described.
Results: As of 24-Nov-2022, 211 children and young people had switched from originator to biosimilar; 132 adalimumab, 55 etanercept, and 24 infliximab (table 1). Switching was seen in all ILAR categories. Patients were predominantly female (64%), median age at JIA diagnosis six years, 11 years at originator start, 14 years at biosimilar start, median time on originator 2.2 years. Most patients had started originator as their first biologic (73%) and most started biosimilar with no significant treatment gaps. Six patients reported >1 year gap between originator stop and biosimilar start, suggesting a planned period off biologic therapy (two stopped for adverse event, four unknown). Of the 143 patients with >1 year of follow-up available after switching (median 1.9 years per patient), 82 remained on biosimilar at their final follow-up, whilst 61 had stopped therapy. Of those who stopped, 11 had stopped for remission, 13 stopped for ineffectiveness, 20 for adverse event, and 17 other/missing reason. Forty-one patients then re-started biologic therapy (including four of the remission patients); 17 switched back to the originator mostly due to an adverse event on the biosimilar, and 24 started a different biologic therapy mostly due to inefficacy of the biosimilar.

Table 1.

	All patients N=211
Female	134 (64%)
ILAR	
Oligoarticular Persistent	28 (13%)
Oligoarticular Extended	50 (24%)
RF- Polyarticular	75 (36%)
RF+ Polyarticular	10 (5%)
Systemic	1 (<1%)
Psoriatic	9 (4%)
Enthesitis-Related	25 (12%)
Undifferentiated	13 (6%)
Age, years	
At diagnosis	6 (3, 11); N=208
At originator	11 (8, 13)
At switch to biosimilar	14 (11, 16)
Biologic therapy	
Adalimumab	132 (63%)
Etanercept	55 (26%)
Infliximab	24 (11%)
Line of biologic therapy (originator)	N=207
First-line	152 (73%)
Second-line	39 (19%)
Third-(or more)-line	18 (8%)
Time on originator, years	2.2 (1.3, 3.4)
Available follow-up time after switching to biosimilar, years	
Number of patients with available follow-up	N=198
Min-Max	0.03 to 4.66 years
Median (IQR)	1.6 (0.9, 2.2)
Those with one year follow-up: what happened?	
Number of patients with one year of follow-up available	N=143
Min-Max	1.02 to 4.66 years
Median (IQR)	1.9 (1.4, 2.5)
Still on biosimilar	82 (57%)
Stopped biosimilar	
Stop Reason:	61 (43%)
Ineffectiveness	*13/61 (21%)*
Adverse Event	*20/61 (33%)*
Other/Missing	*17/61 (28%)*
Remission	*11/61 (18%)*
Those who stopped: what happened?	
Number of patients who stopped biosimilar therapy	N=61
Switched Biologic	**41 (67%)**
Back to Originator	17/41 (41%)
Reason stopped biosimilar and switched back to originator:	*12 Adverse event* *3 Other/Missing* *2 Remission*
Different Biologic	24/41 (59%)
Reason stopped biosimilar and started a different biologic:	*11 Inefficacy* *2 Adverse event* *9 Other/Missing* *2 Remission*

Conclusion: Many children with JIA have now been switched from TNF-inhibitor originator to biosimilar product, with the majority still receiving their biosimilar after one year. Switching back to originator was uncommon, 12% overall after one year, suggesting good tolerance of non-medical switching in this patient population.

POS0133 TRADITIONAL LABORATORY PARAMETERS AND NEW BIOMARKERS IN MACROPHAGE ACTIVATION SYNDROME (MAS) AND SECONDARY HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS (sHLH)

Keywords: Biomarkers, Cytokines and chemokines, Innate immunity

A. De Matteis[1], D. Pires Marafon[1], I. Caiello[1], M. Pardeo[1], G. Marucci[1], E. Sacco[1], F. Minoia[2], F. Licciardi[3], A. Minaici[4], I. Maccora[5], M. C. Maggio[6], G. Prencipe[1], F. De Benedetti[1], C. Bracaglia[1]. *[1]IRCCS Ospedale Pediatrico Bambino Gesù, Division of Rheumatology, ERN-RITA center, Roma, Italy*; *[2]Fondazione IRCCS Ca' Grande Ospedale Maggiore Policlinico, Pediatric Rheumatology, Milano, Italy*; *[3]Regina Margherita Children's Hospital, Department of Pediatrics and Infectious Diseases, School of Medicine, University of Turin, Torino, Italy*; *[4]S. Orsola-Malpighi Hospital, Department of Pediatrics, University of Bologna, Bologna, Italy*; *[5]Meyer Children's University Hospital, Pediatric Rheumatology Unit, Firenze, Italy*; *[6]University of Palermo, University Department Pro.Sa.M.I."G. D'Alessandro", Palermo, Italy*

Background: Macrophage Activation Syndrome (MAS) and Secondary Hemophagocytic Lymphohistiocytosis (sHLH) are hyperinflammatory conditions, in which IFNγ plays a pivotal role. Prompt recognition and early treatment are essential to improve the outcome and the mortality rate.
Objectives: This is a retrospective multicenter study. We correlated traditional laboratory parameters of hyperinflammation with IL-18 and IFNγ related biomarkers. We have also evaluated the diagnostic and prognostic role of IL-18, CXCL9, CXCL10 and neopterin in patients with MAS and sHLH.
Methods: One hundred-six patients from 6 Italian centers were enrolled: 41 with sHLH, 41 with MAS in the context of sJIA, and 24 with sJIA without MAS. The samples were collected at three different time points: active disease (T0), 7-10 days from starting therapy (T1) and in clinical inactive disease on medication (from 1 to 3 months from onset) (T2). Serum levels of IL-18 and of the IFN-γ related biomarkers (CXCL9, CXCL10, Neopterin) were measured by ELISA.
Results: A total of 378 samples were collected. Laboratory features at T0 are detailed in table 1. Using the 2016 classification criteria for MAS, we can confirm that platelet count is a specific parameter, only 2 patients with sJIA had a value $<181x10^9$/liter. Instead ferritin is a sensitive parameter, 94.4% of patients with

MAS had ferritin >684 mg/ml. Lactate dehydrogenase (LDH) values were statistically higher in MAS and sHLH compared to sJIA. ROC curve of LDH values in MAS showed a statistically significant area under the curve (AUC= 78.2%, p-value <0.0001). A cut-off of 683 U/L had a sensitivity of 73.6% and a specificity of 70.3%. IL-18, CXCL9, CXCL10 and neopterin levels in T0 were significantly higher in MAS and sHLH compared to sJIA. In MAS, IL-18 levels were significantly higher compared to sHLH (p<0.0001). The ROC curves performed for each biomarker showed a statistically significant AUCs (p<0.01), except for IL-18 in sHLH. We have identified a cut off value for each biomarker in MAS (CXCL9 900 pg/ml, CXCL10 260 pg/ml, neopterin 5.0 ng/ml, IL-18 82996 pg/ml) and sHLH (CXCL9 2145 pg/ml, CXCL10 270 pg/ml, neopterin 7.1 ng/ml). In T0 neopterin correlates significantly with IL-18, CXCL9 and CXCL10 in MAS group but not in sHLH. We found also strong correlation between CXCL9 and CXCL10 only in MAS group.

Table 1. Laboratory parameters in T0. Values are shown as median (IQR); p-value: Mann-Whitney U test.

	MAS (N=54)	sHLH (N=48)	sJIA (N=4)	MAS vs sHLH	MAS vs sJIA	sHLH vs sJIA
Ferritin (ng/ml)	4755 (1816-10988)	4098 (2075-16867)	717 (335-2313)	0.77	**<0.0001**	**<0.0001**
Platelet count (x10^9/l)	199 (107-314)	97 (47-184)	450 (343-570)	**0.0003**	**<0.0001**	**<0.0001**
AST (U/L)	85 (51-146)	150 (51-340)	30 (22-44)	0.06	**<0.0001**	**<0.0001**
Triglycerides (mg/dl)	188 (148-263)	226 (166-381)	105 (75-139)	0.11	**<0.0001**	**<0.0001**
Fibrinogen (mg/dl)	337 (222-433)	228 (137-331)	572 (482-692)	**0.003**	**<0.0001**	**<0.0001**
LDH (U/L)	965 (679-1369)	1255 (701-2748)	587 (365-724)	0.10	**<0.0001**	**<0.0001**
CXCL9 (pg/ml)	2236 (675-9670)	4159 (1880-10016)	300 (300-1979)	0.14	**<0.0001**	**<0.0001**
Neopterin (ng/ml)	9.4 (5.0-16.2)	20.3 (9.6-35.0)	4.2 (3.0-7.2)	**0.0018**	**<0.0001**	**<0.0001**
IL-18 (pg/ml)	170338 (83277-287152)	11787 (21881120)	36764 (8958-82714)	**<0.0001**	**<0.0001**	0.19

Conclusion: Platelet count and ferritin have high specificity and sensitivity, respectively, to diagnose MAS in the context of sJIA. Even if LDH is not included in 2016 classification criteria for MAS in sJIA, we have found that this parameter could help to discriminate MAS in sJIA, in addition to the others. Our results confirm that IL-18 and the IFN-γ related biomarkers are significantly higher in patients with MAS and sHLH and might be useful to diagnose MAS/sHLH. IL-18 could help to distinguish sHLH from MAS and MAS from active sJIA.

Schonenberg-Meinema[1]. *[1]Emma Children's Hospital, Amsterdam University Medical Centres (AUMC), University of Amsterdam, Department of Paediatric Immunology, Rheumatology and Infectious Diseases, Amsterdam, Netherlands*; *[2]Amsterdam Institute for Molecular and Life Sciences (AIMMS), Vrije Universiteit Amsterdam, Division of Medicinal Chemistry, Faculty of Science, Amsterdam, Netherlands*; *[3]Sophia Children's Hospital, Erasmus University Medical Centre, Department of Paediatric Rheumatology, Rotterdam, Netherlands*; *[4]Erasmus University Medical Centre, Department of Immunology, Rotterdam, Netherlands*; *[5]Zaans Medisch Centrum, Department of Paediatrics, Zaandam, Netherlands*; *[6]Amsterdam Rheumatology and Immunology Centre, Amsterdam University Medical Centres (AUMC), University of Amsterdam, Department of Rheumatology and Clinical Immunology, and Laboratory for Experimental Immunology, Amsterdam, Netherlands*

Background: In (childhood-onset) systemic lupus erythematosus ((c)SLE), patients have an increased risk of developing premature atherosclerosis [1]. The pathophysiological mechanisms for this atherosclerosis are not completely understood. Besides traditional risk factors, the endothelium plays a major role [2]. Dysregulated endothelial cell markers and proteins involved in endothelial function in SLE are not always correlated to disease activity, which could mean that the endothelium stays in a dysregulated state in SLE, even with low disease activity (Bergkamp et al*., submitted*). However, previous studies were mostly cross-sectional and only performed in adult SLE, while childhood-onset SLE (cSLE) has a longer and more severe course [3,4].

Objectives: To measure the serum levels of a panel of SLE-associated markers involved in endothelial cell (EC) function, in longitudinal samples of cSLE patients (active vs. low SLE disease activity index (SLEDAI)) and to compare them with healthy controls and assess their correlation with disease activity.

Methods: Blood samples and patient characteristics were collected from a multicentre longitudinal cSLE study and compared with age- and sex-matched healthy controls (HC). Disease activity was evaluated by SLEDAI-2K, with cut-offs for active (>4) versus low (≤4) activity. Serum levels of CXCL12 (SDF-1), TWEAK, VEGF, CXCL10 (IP-10), ADAMTS13, Angiopoietin-2, Pentraxin-3, E-Selectin, Thrombomodulin, P-selectin, CCL2 (MCP-1), VCAM-1, ICAM-1, vWF-A2 and Gas6 were measured in two cSLE samples (t=1 and t=2) and in HC (1 sample). Patient groups and healthy controls were compared by t-tests and ANOVA, with significance for $p < 0.05$. Correlations between marker serum levels and SLEDAI were calculated with Pearson correlation.

Results: This study included 47 cSLE patients (30 treatment-naïve) and 42 healthy controls. Mean age at diagnosis in cSLE was 14 (± 2.33) years. Median SLEDAI at t=1 was 12 (IQR 6-18). Median SLEDAI t=2 was 2.5 (IQR 2-6). Time between two blood samples was 14.5 months (IQR 9-24 months). Median disease duration at t=1 was 0 months (IQR 0-18 months) and at t=2 16.5 months (IQR 10-53 months). Ethnic background in patients was 42.6% Caucasian, 36.2% African/Afro-Caribbean, 8.5% North-African/Middle East, 4.3% Asian and 8.5% mixed/other ethnic background. At t=1, serum levels of CXCL10 (p=0.01), Thrombomodulin (p=0.03) and VCAM-1 (p=0.01) were higher in the group with active cSLE compared to those with low disease activity. Serum levels for CXCL10, Pentraxin-3, Thrombomodulin, P-selectin, vWF-A2 and Gas6 correlated with SLEDAI score. Angiopoietin-2 and VCAM-1 were upregulated in cSLE patients versus healthy controls (both p<0.001),but not related to disease activity (figure 1A). Levels of CXCL10, Angiopoietin-2, Pentraxin-3, E-Selectin, CCL2, VCAM-1 and vWF-A2 decreased over time, while serum levels of TWEAK increased over time (all p<0.05) (figure 1B).

Conclusion: At different time points, serum levels of Angiopoietin-2 (t=1), VCAM-1 (t=1) and TWEAK (t=2) were increased in cSLE patients, irrespective of disease activity. These markers represent activation of ECs with vascular inflammation, EC activation and a pro-angiogenic state. The endothelium in cSLE seems to stay in an active state, even in low disease activity (SLEDAI≤4). Our findings suggest that some EC markers might be useful as biomarkers for predicting the ongoing risk for endothelial dysfunction in cSLE.

POS0135 GENETICAL AND PHENOTYPICAL FINDINGS OF CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Genetics/Epigenetics

P. Morán Álvarez[1], C. Passarelli[2], V. Messia[1], M. Pardeo[1], E. Marasco[1], A. Insalaco[1], F. De Benedetti[1], C. Bracaglia[1]. [1]*Ospedale Pediatrico Bambino Gesù, Pediatric Rheumatology, Rome, Italy*; [2]*Ospedale Pediatrico Bambino Gesù, Genetics, Rome, Italy*

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease which leads to inflammation and organ damage caused by immune complex deposition. Classically, childhood SLE has been considered as a polygenic autoimmune disease; however, a pediatric monogenic lupus-like phenotype (LL) is emerging due to the recent recognition of several related novel high-penetrance gene variants. This fact associated to the high degree of concordance among monozygotic twins, supports the importance of genetic background in cSLE pathogenesis.
Objectives: To identify the presence of variants in gene related to monogenic lupus and their relationship with clinical manifestations in cSLE or LL.
Methods: A descriptive, observational, cross-sectional study was carried out in children with cSLE or LL. The genetic analysis (Sanger/Clinical Exome Sequencing) was performed from isolated DNA obtained from blood sample.
Results: Forty-five children were included in the study. The genetic analysis detected at least one variant in 14 (31.1%) children, 5 (35.7%) with cSLE and 9 (64.3%) with LL. Of those who carry a genetic variant, the median age at disease onset was 11 years (range: 2-16) and 85.7% were female; most of them Caucasians (85.7%). Seven (50%) and 3 (21.4%) out of 14 patients had a positive family and/or a personal history for autoimmune diseases, respectively. Regarding clinical manifestations at onset, musculoskeletal were the most frequent (10 patients, 71.4%), followed by hematological (9 patients, 64.3%), cutaneous (9 patients, 64.3%), constitutional with fever (8 patients, 57.1%), neurological (7 patients, 50%), renal (5 patients, 35.7%), cardiac (3 patients, 21.4%) and pulmonary (2 patients, 14.3%) manifestations. Related to immunological parameters, 13 (92.8%) were ANA positive, 7 (50%) anti-dsDNA, 4 (28.6%) ENA and 3 (21.4%) aPL positive. Both C3 and C4 were low in 8 (57.1.4%) children and isolated C3 levels were low in 4 (28.6%) patients. Among the variants, we found that only two patients who carry a *TREX* variant showed normal C3 and C4 levels; one of them presented with lupus pernio as reported in literature. Also, we identified the same *RNASEH2B (c.868G>A)* variant in two siblings with similar phenotypes and *TLR7 (c.1520T>C)* variant in two siblings of other family. The patient who carried the *SHOC2* variant presented polyarthritis and serositis, while the patient with the *TNFRSF13B* variant onset with a glomerulonephritis. Those manifestations have already been described related to these genes. Variants and phenotypes are detailed in Table 1.
Conclusion: Around 30% pediatric patients with cSLE or LL showed at least one variant in gene related to monogenic-lupus and some of them with similar phenotypes to those already described. This fact may suggest the genetics potential contribution to the cSLE pathogenesis. Further studies are necessary to confirm these data.

K. L. Teh[1], Y. X. Book[1], S. F. Hoh[2], X. Gao[2], L. Das[1], T. Arkachaisri[1,3]. *[1]KK Women's and Children's Hospital, Rheumatology and Immunology, Singapore, Singapore*; *[2]KK Women's and Children's Hospital, Department of Nursing, Singapore, Singapore*; *[3]Duke-NUS Medical School, Rheumatology and Immunology, Singapore, Singapore*

Background: Classification criteria for systemic lupus erythematosus (SLE) include the American College of Rheumatology (ACR) 1997, the Systemic Lupus International Collaborating Clinics (SLICC) and the European League Against Rheumatism (EULAR)/ACR criteria[1]. Their performance in a primarily Asian childhood-onset SLE (cSLE) population remains unclear as the clinical manifestation frequencies are different[2].
Objectives: To evaluate the diagnostic performance of ACR-1997, SLICC-2012, and EULAR/ACR-2019 criteria in a cSLE cohort in Singapore.
Methods: Cases were physician-diagnosed cSLE, while controls were children with mixed and undifferentiated connective tissue disease that posed an initial diagnostic challenge. Retrospective data were reviewed to establish the three criteria fulfilled at diagnosis and over time.
Results: The study population included 120 cSLE cases and 36 controls, Table 1. Among cSLE patients, low C3/4 (94.2%), immunologic (93.3%), hematologic manifestations (90.0%) and arthritis (60.8%) were the most common over time. At diagnosis, 102 (85%) patients fulfilled all criteria, Figure 1. SLICC-2012 had the highest sensitivity (97.5%) and negative predictive value (NPV, 89.3%), while ACR-1997 had the highest specificity (91.7%) and positive predictive value (PPV, 97.2%). All criteria had diagnostic accuracies of ≥ 85%. Over time, 113 (94.2%) fulfilled all criteria. SLICC-2012 remained the criteria with highest sensitivity (99.2%) and NPV (94.7%), while ACR-1997 remained the criteria with highest specificity (75.0%) and PPV (92.7%). Only SLICC-2012 and ACR-1997 had ≥ 85% diagnostic accuracy over time.
Conclusion: This is the first study evaluating the SLE classification criteria performance in Southeast Asian cSLE cohort. SLICC-2012 criterion has the highest sensitivity and diagnostic accuracy, with acceptable specificity in our cohort, especially early in the disease course. The EULAR/ACR-2019 criteria does not confer additional benefits compared to the earlier two criteria.

SERIOUS INFECTIONS IN JUVENILE SLE: INCIDENCE, PREDICTORS AND IMPACT ON LONG TERM OUTCOMES IN A SOUTH ASIAN COHORT

Keywords: Prognostic factors, Systemic lupus erythematosus

R. Chatterjee[1], S. S. Pattanaik[2], D. P. Misra[1], V. Agarwal[1], A. Lawrence[1], R. Misra[3], A. Aggarwal[1]. *[1]Sanjay Gandi Postgraduate Institute of Medical Sciences, Department of Clinical Immunology and Rheumatology, Lucknow, India*; *[2]SCB Medical College, Department of Clinical Immunology and Rheumatology, Cuttack, India*; *[3]KIMS, Department of Clinical Immunology and Rheumatology, Bhubaneswar, India*

Background: Infections are a major cause of morbidity and mortality in juvenile systemic lupus erythematosus (SLE).
Objectives: We assessed the incidence and risk factors for major infections in juvenile SLE.
Methods: A retrospective review of 225 patients of juvenile SLE (ACR 1997 criteria) with age <18 years visiting the rheumatology clinic at a single centre between 2000 to 2020 was done from clinical case records and data from the hospital electronic health records. Serious infection was defined as the need for hospitalization, or infection resulting in disability or death. Cox regression was used to determine factors associated with a serious infection and the effect of serious infection on overall survival.
Results: Among the 225 children (197 girls) with a mean age of 13.89 ±3.42 years and a cumulative follow up of 1153.45 person-years. A total of 80 serious infections occurred in 63 (28% of the cohort) individuals at a rate of 69.35 serious infections per 1000 person-years of follow-up. A second serious infection occurred in 12 children and 5 of them developed a third serious infection. Among the microbiologically confirmed cases (78.75% of cases) Bacterial infections were most common (N=33) and included S. Aureus (11), *E. Coli* (7), *K. Pneumoniae* (3), *E. Fecalis* (3), *S. Pneumoniae* (2), *Acinetobacter spp.* (2), Citrobacter (2), Salmonella (2) and *P. Aeruginosa* [1]. Twenty six (32.5%) opportunistic infections occurred: Mycobacterium tuberculosis (18), Cytomegalovirus (3), disseminated Herpes zoster (4) and invasive candidiasis (1) with 15 (83.3%) of the tuberculosis cases being extrapulmonary. On multivariate analysis fever at baseline(HR 8.51, 1.17-61.44), gastrointestinal involvement (HR 4.73, 1.13-19.94), current steroid dose (HR 1.36,1.14-1.62), average cumulative steroid dose per year (HR 1.004, 1.002-1.005) and cyclophosphamide use (HR 2.22, 1.11-4.46) were associated with serious infection (Table 1). Hospitalization rates were significantly higher in those with any serious infection (Rate ratio 2.79, 1.81-3.77). Serious infection led to more damage accrual (SLICC damage index 1.04 vs 0.22). Serious infection-free survival at 1 year, 5 years and 10 years was 84% (79.1-89.2) and 72% (65.4-79.2). There were 19 deaths with infection attributable mortality in 10 (52.6%). Serious infection predisposed to higher overall mortality (Figure 1).

Conclusion: Serious infections are a major cause of mortality and damage accrual in SLE. Constitutional symptoms, gastrointestinal involvement, current and cumulative steroid dose and cyclophosphamide use predict serious infections. TB prophylaxis in patients with SLE should be considered in endemic areas, especially when using high-dose steroid therapy.

Table 1. Cox proportional hazard models for predictors of infection

Covariates	Hazard ratio	95% CI
Fever*	**8.51**	**1.17-61.45**
Serositis	0.81	0.41-1.59
Gastrointestinal involvement*	**4.76**	**1.94-19.94**
Major organ manifestation	1.07	0.49-2.31
SLEDAI-2K	0.99	0.95-1.05
Daily steroid dose (/10mg)*	**1.36**	**1.14-1.62**
Mean cumulative steroid dose*	**1.004**	**1.002-1.005**
Albumin	1.01	0.66-1.55
Absolute lymphocyte count	0.99	0.99-1
Cyclophosphamide use*	**2.22**	**1.11-4.46**

*-significant baseline predictors of serious infection on follow up. Major organ manifestation referes to presence of nephritis or neuropsychiatric lupus.

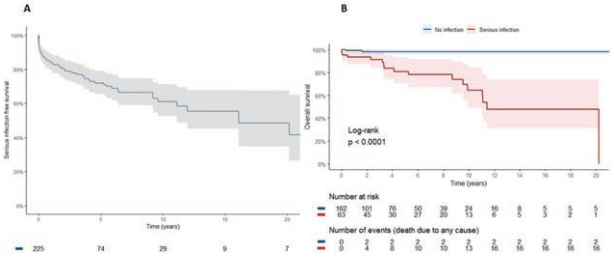

Figure 1. A. The Kaplan meier survival curve depicts time to first serious infection. B. The Kaplan meier survival curve shows the overall survival difference between those with any serious infection ever compared to those with no serious infection in the disease course.

POS0138 EFFICACY AND SAFETY OF BELIMUMAB IN ADULTS WITH CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: PRELIMINARY RESULTS FROM A PROSPECTIVE OBSERVATIONAL STUDY

Keywords: Outcome measures, bDMARD, Systemic lupus erythematosus

D. Dimopoulou[1], M. Trachana[2], P. Pratsidou-Gertsi[2], A. Theodoridou[1], T. Dimitroulas[1], N. Kougkas[1], A. Garyfallos[1]. *[1]Aristotle University, 4th Academic Department of Internal Medicine Clinic, Ippokrateio General Hospital of Thessaloniki, Thessaloniki, Greece*; *[2]Aristotle University, 1st Academic Department of Pediatrics, Aristotle University, Thessaloniki, Greece*

Background: Childhood-onset Systemic Lupus Erythematosus (cSLE) is a rare autoimmune disease with multi-system manifestations, more severe disease course and higher frequency of morbidity than adult-onset SLE. Belimumab is the first treatment for cSLE approved for children ≥5 years of age.
Objectives: To investigate the efficacy and safety of Belimumab in adult patients with cSLE.
Methods: A prospective observational (non-interventional) study, involving adult patients with cSLE was conducted. During the 9-yearstudy period (01/2015 to 12/2022), adults with **a** cSLE diagnosis and Belimumab receivers (by intravenous or subcutaneous administration) for >12 consecutive months were enrolled. All patients met the revised 1997 American College of Rheumatology (ACR) or 2012 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria and were followed at regular intervals (up to 6 months) in the **T**ransition **R**heumatology **O**utpatient **C**linic. SLE activity was defined according to SLEDAI-2K and the SELENA-SLEDAI Physician Global Assessment (PGA), scale 0–3 [1]. At the last follow-up visit, response to therapy was assessed by Lupus Low Disease Activity State (LLDAS), remission state and SLE Responder Index (SRI4). LLDAS was defined as: i) SLEDAI-2K ≤4, with no activity in major systems ii) no new lupus disease activity compared to previous evaluation iii) a SELENA-SLEDAI PGA ≤1 iv) current prednisolone (or equivalent) dose ≤7.5 mg daily and v) standard maintenance doses of immunosuppressive drugs. [2]. Remission was defined as i) clinical SLEDAI-2K=0 ii) dose of prednisone ≤5 mg/day according to the DORIS definition [3]. SRI4 was defined as i) ≥4-point reduction from baseline in SELENA-SLEDAI score, ii) no worsening in PGA and iii) no new BILAG A organ domain score or 2 new BILAG B organ domain scores compared with baseline [4].
Results: A total of 15 patients (14 females) were enrolled in the study. At baseline, the patients' current mean (SD) age was 25.4 (7) years and the interval from disease onset to first Belimumab administration 12.4 (7.3) years. Half of the patients had a history of lupus nephritis and 42.8% were aPL positive. All patients were under hydroxychloroquine treatment and 80% of them were additionally receiving a second immunosuppressive agent (Methotrexate, MMF, Azathioprine). Glucocorticoids (GCs) were concomitantly administered in 13 (86.6%) patients in a dose of ≥7.5mg in 57.1% of them. The patients' SLEDAI-2K mean (SD) score before Belimumab initiation was 12.1 (2.3), indicating high disease activity. The mean (SD) duration of Belimumab administration was 36.2 (1.9) months. At the last follow up visit, ongoing therapy with Belimumab was recorded in 66.7% of the cohort. SLEDAI-2K mean (SD) score was reduced to 3.5 (2.3), 1 patient (6.6 %) was in remission, 9 (60%) patients had mild and none high disease activity. The majority (78.5%) met the LLDAS definition and 78.5% were SRI4 Responders. Half of the patients (53.8%) achieved lower doses or discontinuation of GCs and 26.7% accomplished a reduction of the immunosuppressant's dose. Reasons for Belimumab discontinuation included pregnancy issues, infection and low adherence (3, 1, 1 patient respectively). None of the patients experienced a serious adverse event.
Conclusion: In this cohort of adult patients with cSLE, Belimumab was well-tolerated and effectively reduced disease activity allowing the downstream of GCs's dose.

Background: Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence of 3 in 1 000 000 children. In adult patients there are significant differences between the clinical presentation of diffuse and limited subtypes. We reviewed clinical differences in presentation of subtypes in patients in the juvenile systemic scleroderma inception cohort (jSScC).
Objectives: To study the clinical presentation of jSSc patients with diffuse (djSSc) and limited (ljSSc) subtypes.
Methods: We reviewed the baseline clinical characteristics of the patients, who were recruited to the jSScC till December 2022. jSScC is a prospective cohort of jSSc patients, who developed the first non-Raynaud´s symptom before the age of 16 years and are under the age of 18 years at the time of inclusion.
Results: The JSScC included 232 patients, 68% (n=159) had diffuse subtype. The median age at onset of Raynaud phenomenon was 10.4 years (7.3-12.9), at the first non-Raynaud symptom 10.9 years (7.3-13.0) and median disease duration 2.5 years (1.0-4.6). The female/male ratio was significantly lower in the djSSc subtype

(3:1 versus 5:1, p<0.001). Antibody profile was similar, with the exception of a significantly higher number of anticentromere positive patients in the ljSSc. Decreased FVC<80% was found in approximately 30% and decreased DLCO<80% was found in around 40% in both subtypes. Abnormal HRCT findings were found in 44% of patients. Pulmonary hypertension assessed by ultrasound occurred in approximately 5% in both groups and gastrointestinal involvement in 43% of djSSc and 36% in ljSSc (p=0.303). Patients with djSSc had significantly higher modified Rodnan Skin Score, more frequently sclerodactyly, a history of digital ulceration active ulceration, telangiectasia, a decreased Body Mass Index z score ≤ -2 and decreased joint range of motion. Patients with ljSSc had significantly higher rate of cardiac involvement. Regarding patient related outcomes assessed by VAS 0-100 djSSc patients had more severe disease also physician related outcome assessed by VAS 0-100 were significantly higher in djSSc (see Table 1).

Table 1. Comparison of subtypes at time of inclusion in the cohort

	Whole Group N=232	Diffuse Subtype N=159	Limited Subtype N=73	P value
Anticentromere	5% (7/156)	2% (2/106)	10% (5/50)	0.022
MRSS, median (IQR)	10 (4 – 20)	16 (8 - 27)	4 (0 – 8)	0.001
Gottron Papules	26% (59/228)	31% (48/155)	15% (11/73)	0.011
Sclerodactyly	75% (165/219)	85% (127/150)	55% (38/69)	<0.001
Telangiectasia	37% (77/209)	44%(62/141)	22% (15/68)	0.002
History of ulceration	52% (119/229)	62% (98/158)	30% (21/71)	<0.001
Active ulceration	17% (39/229)	21% (33/158)	8% (6/71)	0.021
Only Cardiac involvement	5% (12/232)	3% (4/159)	11% (8/73)	0.007
BMI < - 2 z score	15% (33/217)	20% (29/148)	6% (4/69)	0.008
Joints with decreased range	59% (136/231)	64% (101/158)	48% (35/73)	0.022
Physician Reported (Median, IQR)				
Physician global disease activity	30 (20 – 45) n=197	35 (20– 50) n=138	20 (10 – 30) n=59	0.001
Physician global disease damage	30 (15 – 40) n=195	30 (20 – 45) n=138	20 (5 – 30) n=57	0.004
Physician ulceration activity	0 (0 – 16) n=216	5 (0 – 20) n=154	0 (0 – 0) n=62	0.018
Patient Reported (Median, IQR)				
Patient global disease activity	40 (20 – 50) n=178	40 (20 – 50) n=129	30 (15 – 55) n=49	0.024
Patient global disease damage	30 (15 – 60) n=177	40 (20 – 60) n=128	25 (5 – 55) n=49	0.001
Patient Raynaud activity	30 (10 – 60) n=202	30 (10 – 60) n=145	15 (0 – 55) n=57	0.001
Patient ulceration activity	0 (0 – 30) n=203	10 (0 – 30) n=145	0 (0 – 20) n=58	0.001

Conclusion: In the largest jSSc cohort in the world, djSSc patients have a significantly more severe disease. Patients and physician related outcomes were significantly more severe in djSSc group. Interestingly, we found no differences regarding interstitial lung disease, pulmonary hypertension or gastrointestinal involvement, although the number of patients with decreased BMI ≤ -2 z score was significantly higher in the djSSc patients.

Kallinich[3], K. Minden[3], M. Moll[3], F. Nuruzzaman[3], A. Patwardhan[3], D. Schonenberg[3], N. Helmus[1]. [1]*Hamburg Centre for Pediatric and Adolescence Rheumatology, An der Schön Klinik Hamburg Eilbek, Hamburg, Germany*; [2]*German Rheumatism Research Center, German Rheumatism Research Center, Berlin, Germany*; [3]*jSSc collaborative group, Hamburg Centre for Pediatric and Adolescence Rheumatology, Hamburg, Germany*

Background: Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence of 3 in 1 000 000 children. The Juvenile Systemic Scleroderma Inception cohort (jSScC) is the largest cohort of jSSc patients in the world. The jSScC collects data prospectively in jSSc, allowing the evaluation of the development of organ involvement and patient and physician reported outcomes in jSSc over time.

Objectives: To review the changes in the clinical characteristics, and patient and physician reported outcomes, over a 24 month observation period from the time of inclusion into the cohort.

Methods: The jSScC cohort enrolls jSSc patients who developed the first non-Raynaud´s symptom before the age of 16 years and are under the age of 18 years at the time of inclusion. We reviewed jSScC patient clinical data and patient and physician reported outcomes, who had 24 months follow up from the time of inclusion until 1st of December 2022.

Results: We extracted data from 90 patients, 77% of them had the diffuse subtype. The female/male ratio was 3.5:1. Median age of onset of Raynaud´s was 9.4 years and the median age of onset of non-Raynaud´s was 10.0 years. Eighty-nine percent of the patients were treated with disease modifying anti-rheumatic drugs (DMARDs) at time of inclusion in the cohort (T0) and 96% after 24 months (T24). Median disease duration was 2.4 years at T0. No patient died during the follow up. Antibody profile stayed unchanged. Only 3 clinical parameters changed and all improved significantly, the median modified Rodnan skin score improved from 11 to 8 (p=0.021), number of patients with joints with pain on motion decreased from 21% to 10% (p=0.04) and the number of patients with muscle weakness decreased from 13% to 4% (p=0.03). All other organ involvement did not show any statistically significant change from T0 to T24. All collected patient reported outcomes improved significantly from T0 to T24: the patient reported disease activity by VAS 0-100 from 40 to 20 (p=0.001), the patient reported disease damage by VAS 0-100 from 35 to 20 (p=0.027), patient reported ulceration activity by VAS 0-100) from 8 to 0 (p=0.001) and the patient reported Raynaud activity by VAS 0-100 from 20 to 10 (p=0.002). Two of the three physician reported outcomes improved significantly, the physician global disease activity by VAS 0-100 from 30 to 20 (p=0.001) and physician reported ulceration activity by VAS 0-100 from 5 to 0 (p=0.017). (Table 1.)

Table 1. Items with significant improvement over 24 months observation period in the cohort

	0 month N=90	24-month follow-up N=90	P Value
MRSS, median (IQR)	11 (5 – 20)	8 (2 – 20)	0.021
Presence of joints with pain on motion	21% (19/89)	10% (9/89)	0.040
Muscle Weakness	13% (10/75)	4% (3/81)	0.030
Physician global disease activity	30 (20 – 45) n=71	20 (10 – 33) n=83	0.001
Physician ulceration activity	5 (0 – 19) n=86	0 (0 – 10) n=89	0.017
Patient global disease activity	40 (20 – 54) n=66	20 (10 – 30) n=76	0.001
Patient global disease damage	35 (20 – 60) n=66	20 (10 – 35) n=76	0.027
Patient Raynaud activity	20 (0 – 50) n=83	10 (0 – 26) n=84	0.002
Patient ulceration activity	8 (0 – 28) n=84	0 (0 – 10) n=84	0.001

Conclusion: Skin and musculoskeletal clinical features improved over 24 months, with almost all patients on DMARDs, supporting the response of these features to therapy. It was promising that internal organ involvement, like cardiac, lung and gastrointestinal, did not significantly worsen or increase. The most striking observation is the positive direction and improvement all patients and two of the three physician reported outcome measures over 24 months in this large international cohort.

[1]*German Rheumatism Research Center, German Rheumatism Research Center, Berlin, Germany*; [2]*Hamburg Centre for Pediatric and Adolescence Rheumatology, An der Schön Klinik Hamburg Eilbek, Hamburg, Germany*; [3]*University of Pittsburgh, Children's Hospital of Pittsburgh, Pittsburgh, United States of America*; [4]*University of Leeds, Leeds Teaching Hospital Trust, Leeds, United Kingdom*; [5]*University of California, University of Florence, Florence, Italy*; [6]*jSSc collaborative group, Hamburg Centre for Pediatric and Adolescence Rheumatology, Hamburg, Germany*

Background: Juvenile systemic sclerosis (jSSc) is a rare disease in childhood. To date, no composite response index exists to assess treatment effect in jSSc patients. ACR CRISS score (probability of improvement ranging from 0 to 1 based on mRSS, FVC%, PtGA, MDGA and HAQ-DI) and revised ACR CRISS (rCRISS, proportion of patients who improve in ≥ 3/5 ACR CRISS core items by a certain percentage, e.g. 30%, except 5% for FVC) were developed by experts in the field as outcome measures in adult patients with SSc. In addition, the Ranked Composite Important Difference (RCID) score was recently introduced as anchor to the ACR CRISS.

Objectives: We aimed to study the applicability and performance of the ACR CRISS, rCRISS and RCID in a prospectively followed cohort of patients with diffuse cutaneous jSSc.

Methods: Data from the international jSSc inceptions cohort were used for this analysis. The ACR CRISS, rCRISS and RCID were calculated between baseline and 12-months follow-up according to the scoring algorithms. Missing values in the core items were estimated by multiple imputation by chained equations. Here we aimed to determine the value of the response measures to detect clinically change defined by the anchor questions about change (much better or little better versus almost the same, little worse or much worse) in patients overall health due to scleroderma since the last visit provided by the treating physicians and parents or patients (aged > 12 years).

Results: We included 95 jSSc patients with diffuse cutaneous subtype with available baseline and 12-months visit. Seventy-nine percent were female, the mean age at enrollment was 13.0 (3.8) and the mean disease duration was 3.1 (2.8) years. Among 95 patients, 57% were treated with steroids, 47% with methotrexate, 27% with MMF and 3% with a biological at baseline. ACR CRISS showed a ceiling effect (>.998) in 51% and a floor effect (<0.005) in 26% of patients. Patients who reported at least moderate improvement had a median ACR CRISS of 0.99 and in mean 2.6 (1.3) core items that improved by ≥20% from baseline to 12-months follow-up. The rCRISS 20/30/50 responses were 59%/49%/33% in patients who reported improvement (table 1) and 25%/25%/8% in patients with worsening. The RCID was approximately normal distributed (mean 20.7, SD 43.4). Mean (SD) RCID for patients who reported worsening was -10.5 (38.6) vs RCID of 20.7 (45.2) for patients who reported improvement. RCID scores for physician reported anchors of worsening or improvement were 6.5 (44.2) and 18 (45.4), respectively. The concordance between a positive RCID score and rCRISS 20/30 was moderate (rCRISS 20 and RCID, 43%, kappa=0.43; rCRISS 30 and RCID, 38%, kappa=0.36).

Table 1. ACR CRISS, rCRISS and RCID score by patients and physicians ratings about scleroderma disease course

	Worsening/ no improvement reported by patients (n=12)	Improvement reported by patients (n=49)	P value	Worsening/ no improvement reported by physicians (n=14)	Improvement reported by physicians (n=50)	P value
Median ACR CRISS score (IQR)	0.0 (0 to 0.75)	0.99 (0 to 1.0)	0.007	0.35 (0 to 0.99)	0.99 (0 to 1.0)	0.037
rCRISS response 20%	3(25%)	29 (59%)	0.034	5 (36%)	29 (58%)	0.140
rCRISS response 30%	3 (25%)	24 (49%)	0.134	2 (14%)	27 (54%)	0.008
rCRISS response 50%	1 (8%)	16 (33%)	0.092	0 (0%)	18 (36%)	0.008
Mean RCID score (SD)	-10.5 (38.6)	20.7 (45.2)	0.031	6.5 (44.2)	18 (45.4)	0.411

CRISS = Composite Response Index in Systemic Sclerosis; RCID=Ranked Compsoite Important Difference; rCRISS = revised Composite Response Index in Systemic Sclerosis; SD = standard deviation

Conclusion: Our data confirmed the presence of a ceiling and floor effect of ACR CRISS as shown in studies of adult SSc patients. The CRISS, rCRISS and RCID response distinguished between patients who rated their disease course since last visit as worsened or improved. Future studies should focus on the determination of specific pediatric weights for the CRISS and RCID components rather than extrapolation from adult SSc. In general, the RCID offers a meaningful tool in order to determine response to therapy in future clinical trials in jSSc patients.

POS0142 THE ASSOCIATION OF AUTOANTIBODIES WITH CLINICAL MANIFESTATIONS AND LONG-TERM REMISSIONS IN COMPARISON WITH JUVENILE- AND ADULT-ONSET IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Autoantibodies, Remission, Myositis

H. Tsuji[1], R. Nakashima[1], T. Sasai[1], M. Shirakashi[1], H. Onizawa[2], R. Hiwa[1], K. Kitagori[1], S. Akizuki[1], A. Onishi[2], H. Yoshifuji[1], M. Tanaka[2], T. Yasumi[3], Y. Ichimura[4], N. Okiyama[4], A. Morinobu[1]. [1]*Kyoto University Graduate School of Medicine, Department of Rheumatology and Clinical Immunology, Kyoto, Japan*; [2]*Kyoto University Graduate School of Medicine, Department of Advanced Medicine for Rheumatic Diseases, Kyoto, Japan*; [3]*Kyoto University Graduate School of Medicine, Department of Pediatrics, Kyoto, Japan*; [4]*Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Department of Dermatology, Tokyo, Japan*

Background: The associations of myositis-specific autoantibodies (MSAs) and myositis-associated autoantibodies (MAAs) with clinical features and remission in idiopathic inflammatory myopathy (IIM) are different between those of juvenile-onset (JIIM) and adult-onset.

Objectives: Since the associations in JIIM had not been fully elucidated, we analyzed them comparing that in adults using clinical information and autoantibodies.

Methods: A total of 320 cases of IIMs (juvenile-onset, 2004-2021, n=34; adult-onset, 2018-2021, n=286) with a history of attendance at our hospital were retrospectively analyzed using medical records. Remission without glucocorticoids and immunosuppressive drugs for 30 years was also examined. MSAs were identified by assays of RNA immunoprecipitation (IP), protein IP, protein IP-blot, and ELISA. Logistic regression analysis, Mann-Whitney U test, Fisher's exact test, and log-rank test were performed.

Results: In JIIM, anti-MDA5 (15%) and anti-TIF1-γ (15%) were the most frequent MSAs, followed by anti-ARS (9%) and anti-NXP2 (6%) (Table 1). In particular, the frequency of anti-ARS was significantly lower in juveniles whereas it was the highest in adults (9% vs. 32%, respectively, p=0.01). Anti-SRP and anti-Mi-2 were not identified in juveniles, although they were identified with low frequencies in adults. In MAAs (juvenile-onset vs. adult-onset), anti-Ku (9% vs. 2%, p=0.03) and anti-U1-RNP (18% vs. 4%, p=0.02) were more common in juveniles while anti-SS-A (15% vs. 16%, p=1) was not significantly different between juveniles and adults. Dermatomyositis tended to be more dominant than polymyositis in juveniles than in adults (76% vs. 59%, p=0.06) (Table 1). Fever was more frequently observed in juveniles (74% vs. 12%, p<0.0001) and interstitial lung disease (ILD) was less frequently observed in juveniles than adults (29% vs. 66%, p<0.0001). Malignancy was observed in 2 juvenile-onset patients (6%) during 14.7±12.3 years while in 32 adult-onset patients (12%) during 6.8±7.5 years (p=0.56). Anti-NXP2 (n=1) and anti-PL12 (n=1) were observed in juveniles. In contrast, anti-TIF1-γ (n=11/32, 34%) was mainly observed in adults. Anti-MDA5 (OR [95%CI]: 14.0 [1.31, 150]) in juveniles and anti-ARS (23.2 [7.07, 76.1]) and anti-MDA5 (13.3 [4.03, 43.8]) in adults were associated with ILD. Anti-MDA5 was poorly associated with muscle symptoms in both juveniles (0.06 [0.004, 0.88]) and adults (0.43 [0.22, 0.85]). The rate of drug-free remission for 30 years in juveniles is higher than that in adults (32% vs 7%, respectively, p<0.0001, Figure 1). The drug-free remission in juveniles was observed in the order of anti-TIF1-γ, anti-NXP2, anti-MDA5, and anti-ARS, reaching a plateau at 5.7 years. In contrast, the remission in adults was observed in the order of anti-MDA5, anti-TIF1-γ, anti-SRP, and anti-ARS. The use of glucocorticoid (88% vs. 91%, p=0.76) was similar in juveniles and adults, while methotrexate (32% vs. 8%, p=0.0002) was used more frequently in juveniles.

Conclusion: There were differences in the clinical characteristics of IIM and autoantibodies between juvenile-onset and adult-onset. Further analysis is needed in a larger sample size.

Background: Idiopathic inflammatory myopathies (IIM) are rare autoimmune systemic diseases characterized by muscle weakness and presence of muscle-infiltrating T cells. IIM represent a clinical challenge due to heterogeneity of symptoms and variability of response to immunosuppressive treatment.
Objectives: We aimed to explore the mechanisms involved in T cell migration and persistence in the muscle tissues of patients with IIM.
Methods: We performed single-cell RNA sequencing on muscle-infiltrating and peripheral blood (PB) memory T cells from patients with recently diagnosed IIM (n=7) from the Rheumatology Clinic, Karolinska University Hospital. Briefly, after enzymatic digestion of fresh muscle tissue, we single-cell sorted T cells from seven patients who also presented muscle infiltrates by histopathological analysis: immune-mediated necrotizing myopathy (IMNM) n=2; inclusion body myositis (IBM) n=2; dermatomyositis (DM) n=1; and antisynthetase syndrome (ASyS) n=1 and a non-inflammatory myopathy. Muscle T cells were sorted based on the co-expression of CD45 and CD3, whereas PB memory T cells were sorted based on the exclusion of naïve $CD45RA^+CCR7^+$ $CD3^+$ T cells. We also aligned the TCR sequences. We had access to additional muscle and PB samples from two patients after immunosuppressive treatment. Description of the methodology is presented in Figure 1.
Results: After quality control, filtering, and normalization processes of the gene expression matrix, the total number of T cells recovered from the analysis was 2,844, out of which 1,427 were isolated from the muscle and 1,417 cells from PB. Muscle and PB T cells grouped separately indicating different gene signature. Three different clusters containing muscle T cells (cluster 1), PB CD8+ T cells (cluster 2) and PB CD4+ T cells (cluster 3) were identified, showing different transcriptomic signature between muscle and PB T cells. After unsupervised clustering of gene expression, we identified 15 distinct T-cell clusters annotated based on differentially expressed genes and visualized by UMAP. We found enrichment in the muscle compartment compared to blood for the following clusters: tissue-resident memory (T_{RM}) T cells, muscle central memory (CM) CD4+ T cells, muscle effector memory (EM)T cells, EGR1hi and T_{RM} genes, and Tregs. All clusters were present in all patients except for the Tregs cluster, which was not detected in the patient with ASyS. A distinct signature between muscle T cells and blood memory T cells was revealed by the differential expression of genes involved in transcription, migration, dephosphorylation, cell cycle, metabolism, cytoskeleton and signalling. Additionally, expanded T-cell clones were observed in all patients' muscle tissue, ranging between 20-50% of all TCR sequences. We could identify expanded T-cell clones persisting at follow-up in the muscle of one patient with IMNM and another with ASyS after immunosuppressive treatment.
Conclusion: Our study reveals a muscle T-cell signature in patients with IIM and a transcriptomic map to identify possible novel therapeutic targets in IIM, where muscle-infiltrating T cells are predominantly composed of cytotoxic, effector memory, tissue-resident, proliferating and regulatory T cells. The expression of tissue-resident memory (T_{RM}) receptors and the presence of clonally expanded T-cell clones in the muscle of all patients with IIM imply the role of these cells in disease pathogenesis.

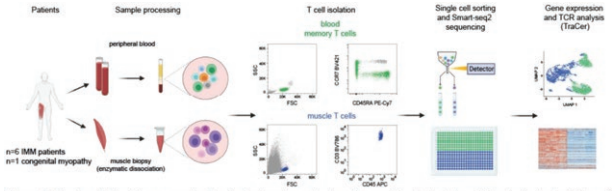

Figure 1. Single cell identifies a muscle T-cell signature in patients with myositis. Technical workflow including isolation of memory T cells from peripheral blood (PB, in green) and muscle T cells (in blue) from muscle biopsies, followed by Smart-seq2 single cell sequencing in six patients with IIM and one with an undefined myopathy.

Background: Idiopathic Inflammatory myopathies (IIM) are heterogeneous systemic autoimmune diseases for which biomarkers are needed. Extracellular vesicles (EVs) are cell-derived nanoparticles regulating several biological functions[1]. Growing evidence supports the role of EVs in the pathogenesis of systemic autoimmune diseases[2].
Objectives: To evaluate the EVs-microRNA (miRNA) profile among distinct clinical manifestations and subsets of IIM, and healthy donors (HD).

Methods: We enrolled adult (≥18 years) consecutive IIM patients (EULAR 2017 criteria) and sex- and age-matched HD. Circulating EVs were isolated from plasma through size exclusion chromatography and ultra-filtration. miRNA isolation was performed using Qiagen miRNeasy Serum/Plasma Advanced kit and miRNA quantification and analysis through next generation sequencing (NGS). Comparisons were carried out using Student's t-test or one-way ANOVA with multiple comparisons.
Results: We included 60 IIM patients (females 61.7%; mean age 56.3±13.1 years; seropositive 78.3%; clinically active 56.7%; on immunosuppressants (any): 63.3%) and 60 HD. miRNA analysis was performed on 21 IIM patients and 21 HD considering a comprehensive pool of 100 miRNAs. Ten miRNAs resulted significantly dysregulated between patients and HD (**Table 1**). Among miRNAs upregulated in patients, some exhibit immunoregulatory functions (hsa-miR-222-3p, hsa-miR185-5p) while others are involved in oncogenesis (hsa-miR-486-5p, has-miR-451a, hsa-miR-15a-5p)[3]. Conversely, downregulated miRNAs in patients usually display anti-inflammatory and anti-neoplastic properties (hsa-let-7 group)[1,3]. More specific EVs-miRNA profiles were identified considering IIM subsets and organ involvement (lung, skin and muscles). Patients with Cancer-associated myositis displayed down-regulated hsa-miR-23b-3p (p=0.03), hsa-miR-374a-5p (p=0.01), hsa-miR-361-5p (p=0.046), hsa-miR-143-3p (p=0.03) and up-regulated hsa-miR-26b-5p (p=0.046). Anti-synthetase syndrome patients showed up-regulated hsa-miR-30c-5p (p=0.033) and hsa-miR-186-5p (p=0.024). Dermatomyositis patients displayed up-regulated hsa-miR-125b-5p (p=0.02), hsa-miR-29c-3p (p=0.027), hsa-miR-361-5p (p=0.039). According to different clinical manifestations, hsa-miR-451a, hsa-miR-29a-3p, hsa-miR-342-2p and hsa-miR-146b-5p were up-regulated in active myositis, and hsa-miR-222-3p, hsa-miR-144-5p, hsa-miR-101-3p, hsa-miR-19b-3p, hsa-miR-25-3p in active skin and Gottron's lesions.
Conclusion: Differential expression of EVs-miRNAs across IIM subsets suggests peculiar epigenetic footprints to distinguish specific IIM phenotypes and clinical manifestations, which may shed light on disease mechanisms and possibly generate tailored treatment targets (**Figure 1**). Circulating EVs might serve as IIM biomarkers and for early stratification of disease manifestations.

POS0145 **CLINICAL AND PATHOGENIC SIGNIFICANCE OF S100A4 OVEREXPRESSION IN SYSTEMIC SCLEROSIS**

Keywords: Innate immunity, Cell biology, Systemic sclerosis

V. Ong[1], X. Shiwen[1], F. Zhang[1], R. Maclean[1], K. Clark[1], S. Borchert[2], R. I. Hussain[2], J. Klingelhöfer[2], J. Hallén[2], C. P. Denton3. *[1]Centre for Rheumatology, University College London Royal Free Campus, London, United Kingdom*; *[2]Arxx Therapeutics, 0349, Oslo, Norway*; *[1]Centre for Rheumatology, University College London Royal Free Campus, London, United Kingdom*

Background: S100A4 belongs to a family of proteins originally defined by solubility of the prototypic members in 100% saturated ammonium sulphate. Preclinical studies suggest that extracellular S100A4 as a Damage Associated Molecular Pattern (DAMP) protein is upregulated upon stress or injury and may be a target for antifibrotic therapy.
Objectives: We explored expression and function of S100A4 as a driver of fibroblast activation in systemic sclerosis (SSc).
Methods: S100A4 protein concentration was measured by ELISA in serum of SSc (n=94) and healthy controls (n=15). Association of serum level with major organ complications and skin score (mRSS) was determined. S100A4 protein expression in supernatant and cell layer of skin fibroblast cultures from diffuse cutaneous SSc (SScF, n=6) and healthy controls (NF, n=6) was assessed. Recombinant S100A4 and a high affinity anti-S100A4 neutralising monoclonal antibody (AX-202) were used to investigate the profibrotic molecular, functional and genomic phenotype in SSc and control fibroblasts.
Results: Median [range] S100A4 (ng/ml) was higher in serum of SSc (89.9 [15.0-240.0]) than healthy controls (71.4 [7.9-131.8]; p=0.027). There was significant association with SSc-ILD (p=0.025, n=55), scleroderma renal crisis (p=0.026, n=4) and trend of increase in pulmonary hypertension (p=0.075, n=7) and a trend for S100A4 to fall in longer disease duration (r=-0.18, p=0.09) and a weak correlation (r=0.28, p=0.07) with current mRSS but not peak mRSS in dcSSc. Median [range] S100A4 (ng/ml) was higher in culture supernatants of SScF (4.19 [0.52-8.42]) than NF (0.28 [0.02-3.29]; p<0.0001) and SSc cell layer had increased levels by Western blot analysis (mean [sd] RDU NF 0.50 [0.91]; SScF 8.16 [2.49]; p<0.0001). S100A4 induced a fibrotic phenotype in NF with concentration-dependent increase in Col1, SMA and CTGF expression, and promotion of migration (scratch wound assay) and 3D type I collagen gel contraction that was attenuated by AX-202. AX-202 also reduced the constitutive profibrotic gene and protein expression phenotype of SScF. The effect of S100A4 was significantly attenuated by SB431524, a specific inhibitor of ALK5 (p<0.0001 ANOVA)

A.

B.

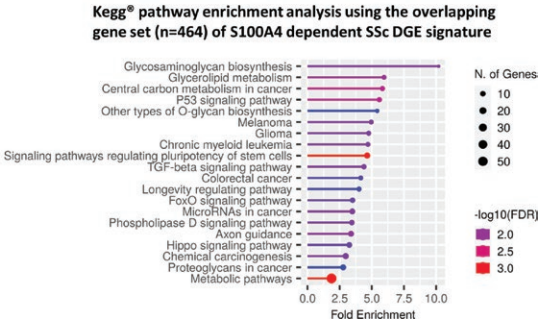

Figure 1.

using qPCR assays across treatment groups for Col1, SMA and CTGF. Gene expression data (qPCR) confirmed protein expression. Genome-wide RNAseq analysis identified an S100A4 activated signature in NF overlapping the hallmark gene expression signature of SScF. Thus, 464 differentially expressed genes (FDR<0.001 and FC>1.5) induced in NF by S100A4, were also constitutively overexpressed, and downregulated by AX-202, in SScF (**Figure 1A**). Pathway mapping of these S100A4 dependent genes in SSc showed the most significant enriched Kegg pathways (FDR<0.001) were regulation of stem cell pluripotency (4.6-fold) and metabolic pathways (1.9-fold) (**Figure 1B**).

Conclusion: Our findings provide compelling evidence supporting a profibrotic role for S100A4 in fibroblast activation in SSc and suggest that serum level may be a biomarker of major organ manifestations and disease severity. This study supports examining the therapeutic potential of targeting S100A4 in SSc are warranted.

POS0146 BIOSAMPLES FROM VEDOSS PATIENTS SHOW CLASSIC PATHOLOGICAL SIGNS OF SCLERODERMA:OPPORTUNITY FOR A BIOLOGICAL DIAGNOSIS OF DISEASE

Keywords: Systemic sclerosis, Autoantibodies, Cytokines and chemokines

R. Ross[1,2], E. Clarke[3], W. Merchant[4], B. Caballero-Ruiz[1], I. Georgiou[1], A. Carriero[5], G. Abignano[1,2], A. Herrick[6], C. P. Denton[7], N. Riobo-Del Galdo[8], F. Del Galdo[1,2]. *[1]University of leeds, LIRMM, Leeds, United Kingdom*; *[2]Leeds Teaching Hospitals, Chapel Allerton Hospital, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*; *[3]University of leeds, Division of Pathology and Data Analytics, Leeds, United Kingdom*; *[4]Leeds Teaching Hospitals NHS Trust, Department of Histopathology, Leeds, United Kingdom*; *[5]San Carlo Hospital of Potenza, Rheumatology Institute of Lucania (IReL) and Rheumatology Department of Lucania, Potenza, Italy*; *[6]University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom*; *[7]UCL, Division of Medicine, London, United Kingdom*; *[8]university of leeds, School of Molecular and Cellular Biology, Leeds, United Kingdom*

Background: The five-year analysis of the EUSTAR multicentre prospective study for Very Early Diagnosis Of Systemic Sclerosis (VEDOSS) has recently indicated that RP patients with one more VEDOSS criteria have an increased risk of SSc progression, indicating a window of opportunity for early detection of SSc and clinical and therapeutic intervention. Furthermore, it warrants further evaluation of VEDOSS biosamples to enhance our understanding of SSc pathogenesis.

Objectives: Here we aimed to determine whether sera, skin or dermal fibroblasts cultured from VEDOSS patients showed any biological hallmark of SSc.

Methods: Sixty-four VEDOSS sera samples were tested for expression of IFN inducible chemokines (CXCL-9,10 and 11 and CCL2, 8 and 19) and biomarker of extracellular matrix turnover (ELF test). 3mm skin biopsies were taken from the forearms from 11 skin biopsies from the forearm of VEDOSS patients and 5 healthy controls and 6 SSc patients. Biopsies was subjected to histology analysis, including haematoxylin and eosin (H&E) and masson trichrome (MT) staining and immunohistological staining (IHC) for CD45, pSTAT1 and MX1. In addition, 7 VEDOSS skin biopsies, along with 2 healthy control and 3 SSc, were used to explant fibroblasts cell lines. mRNA and protein were isolated from primary fibroblasts and processed for RT-qPCR and western blotting analyses and collagen gel contractability assessed.

Results: Sera from VEDOSS patients showed significantly higher IFN-inducible chemokines compared to HC and an intermediate levels compared to SSc [Mean (STDV) HC= 4.69(0.29) vs. VEDOSS= 4.93 (0.39); SSc= 5.30 (0.54)]. ELF score was within normal range for most patients with VEDOSS and showed no statistical difference to HC. Skin biopsies from VEDOSS patients showed evidence of fibrosis and increased collagen bundles within the dermis evidenced in H&E and MT staining, as usually seen in SSc, compared to HC. IHC showed increased number of CD45+ cells in VEDOSS. Semiquantitative analysis of histopathological samples indicated a significant correlation between MT and CD45 staining for VEDOSS (R=0.8828 P=0.0016). In vitro, fibroblasts from VEDOSS patients showed an average 5-fold higher collagen mRNA levels compared to HC fibroblasts, at a similar range to that seen in SSc fibroblasts, confirmed at protein level via western blotting. Furthermore, VEDOSS fibroblasts induced greater gel contraction compared to HC.

Conclusion: Although pilot in nature, this study suggests that patients with no clinical signs of skin fibrosis in their forearms already show biomarker signs of SSc both in their sera, skin biopsies and fibroblast level. Our data indicate that skin thickening is a late manifestation of SSc pathogenesis and early window of opportunity of patients with VEDOSS could be targeted for immune intervention and antifibrotic intervention.

POS0147 αVβ3 INTEGRIN AS A LINKER BETWEEN FIBROSIS AND THYROID HORMONES CROSSTALK

Keywords: Cell biology

S. Tartakover Matalon[1,2], M. Kohon[1,2], M. Zaaroor[1,2], T. Hornik-Lurie[3], A. Shalom[4], A. Berl[4], L. Drucker[5,6], Y. Levy[2,7]. *[1]Tel-Aviv University, Sackler Faculty of Medicine, Tel-Aviv, Israel*; *[2]Meir Medical Center, Autoimmune Laboratory, Kfar-Saba, Israel*; *[3]Meir Medical Center, Data Research Department, Kfar-Saba, Israel*; *[4]Meir Medical Center, Department of Plastic Surgery, Kfar Saba, Israel*; *[5]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel*; *[6]Meir Medical Center, Oncogenetic Laboratory, Kfar-Saba, Israel*; *[7]Meir Medical Center, Internal Medicine E, Kfar Saba, Israel*

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by tissue fibrosis of the skin and internal organs. Key players in SSc are myofibroblast cells (MF) that produce large amounts of extracellular matrix (ECM), which facilitates fibrosis. TGFβ is a key factor involved in MF differentiation and collagen-rich ECM (fibrotic-ECM) secretion. Most of the TGFβ is bound to the ECM through latency-associated peptide (LAP) that contains the amino acid sequence arginine-glycine-asparagine (RGD motif). In order to be active, TGFβ must be released from the ECM by proteases like MMP9 or αv integrins that bind LAP through their RGD recognition site. MF express high levels of the integrin αvβ3. Interestingly, αvβ3 is a special integrin since it also serves as a membrane thyroid hormone (TH) receptor that binds T3 and especially T4. The TH binding sites are located proximal to the RGD binding site. MF also express high levels of the pro-fibrotic miRNA-21, which regulates the TGFβ pathway and the level of DIO3 enzyme, which degrades T3. T3 attenuates fibrotic processes. Since high levels of αvβ3 integrin are expressed by MF in the fibrotic sites and the TH binding site of αvβ3 is close to the RGD recognition site, we hypothesized that the TH binding site of αvβ3 is involved in mediating the fibrotic process.

Objectives: 1. To examine the effect of fibrotic-ECM produced by dermal fibroblasts (DF) triggered by TGFβ, on naive DF phenotype and their αvβ3 expression; 2. To examine the connection between the thyroid hormone binding site of αvβ3 integrin to fibrosis-related processes.

Methods: DF were isolated from healthy skin, cultured without/with TGFβ, and removed by NH_4OH, leaving the normal/ fibrotic ECMs in the wells. ECMs were evaluated for collagen-I and TGFβ levels (Immunohistochemistry, western blot). The effect of the normal/fibrotic ECMs on the following parameters of naïve DF was evaluated: phenotype; expression of MF biomarkers (collagen, elastin and αSMA), expression of αvβ3 integrin, miRNA-21, and DIO3 enzyme; activation of the TGFβ pathway (Smad3 phosphorylation); and MMP9 activity (automatic cell counter, western-blot, RT-qPCR, gelatin zymography). Moreover, the effect of tetraiodothyroacetic acid (tetrac, T4 derivative, and αvβ3 ligand) on the fibrotic-ECM ability to induce DF differentiation into MF and to express αvβ3, miRNA-21 and DIO3 was studied. Last, free T3 levels were measured in 18 SSc patients

of whom 7 had pulmonary arterial hypertension (PAH). The patients were divided according to high (n=6)/low (n=12) T3 levels into 2 groups and the difference in circulating miRNA-21 levels between the groups was evaluated.
Results: Fibrotic-ECMs generated by TGFβ-triggered DF had higher levels of collagen-I and TGFβ in comparison to normal ECM. In comparison to the normal ECM, the fibrotic-ECM increased the followings in the DF: 1) ability to liberate TGFβ from the ECM by increasing MMP-9 activity and αv expression. 2) TGFβ activation and differentiation to MF evidenced by increased expression of phosphorylated Smad3, αSMA, collagen, and elastin, and increased proliferation. 3) Expression of αvβ3, miRNA-21 and DIO3 (all changes in 1-3: 24-123%↑, p≤0.05). The addition of tetrac to DF cultured on fibrotic-ECM downregulated cell proliferation, collagen, elastin and aSMA expression to the levels found in DF cultured on normal ECM. Furthermore, it reduced αvβ3, miRNA-21, and DIO3 levels. Accordingly, decreased miRNA-21 levels were found in the high T3 SSc group, compared to the low T3 group that contained all the PAH patients (p≤0.05).
Conclusion: Our results demonstrated the existence of a vicious cycle: TGF-triggered DF produced a fibrotic-ECM that promoted bystanders' DF differentiation to MF. Using this model, we demonstrated that tetrac binding to αvβ3 integrin inhibited the differentiation of DF to MF, and their ability to activate the αvβ3/miRNA-21/DIO3/T3 pathway. These results suggest that the thyroid hormone binding site of αvβ3 may be a potential target for the treatment of fibrosis.

Background: Persistently activated fibroblasts status leads to progressive extracellular matrix (ECM) deposition and tissue remodeling. The hallmark of systemic sclerosis (SSc) is collagen accumulation in organs, mainly in skin and lung. Despite intensive progress in understanding disease occurence, SSc remains an intriguing disease with unknown pathology and high mortality. Sorbin and SH3 domain-containing protein2, encoded by SORBS2 is a key member of the sorbin homology family of adapter and scaffold proteins. Recent studies suggest that SORBS2 plays a role in cardiac disease, however there is no available data about its role in fibrotic conditions.
Objectives: We aimed to investigate the role of SORBS2 in the pathogenesis of SSc.
Methods: To identify molecules specifically upregulated in persistently activated fibroblasts, human fibroblasts were chronically stimulated with TGF-β and analyzed by RNA-sequencing. To evaluate the functional implication of tissue elasticity on the transcriptome of fibroblasts, multiwell stiffness assays were performed. SORBS2 expression was further analyzed in skin samples of patients with SSc and murine models of fibrosis. Fibroblast specific SORBS2 knockout mice were challenged with bleomycin to induce skin and lung fibrosis. Further specific readouts like collagen content, skin thickness, myofibroblast count, CT scans were performed.
Results: Upon chronic TGF-β stimulation of human normal skin fibroblasts we identified SORBS2, as significantly upregulated molecule. SORBS2 is implicated in cytoskeletal organization, cell adhesion and different signaling pathways. Moreover, extracellular stiffness induced upregulation of SORBS2 mRNA level in fibroblasts. Deletion of SORBS2 in fibroblasts led to a change of the diameter of collagen fibers and modified the elastic index of the tissue. SORBS2 expression is not only elevated in different animal models of fibrosis, but also in fibrotic skin samples of SSc patients. SORBS2 knockout mice (KO) developed significantly less skin fibrosis upon bleomycin challenge in comparison to wild type mice (WT), as assessed by measurement of dermal thickness, myofibroblast counts and hydroxyproline content. *Col1a1*, *Col1a2* and expression of *αSMA* were significantly lower in SORBS2 KO mice in comparison to SORBS2 WT mice. Similarly, fibroblast specific knockout of SORBS2 showed protective effects in bleomycin induced lung fibrosis. CT scans of the lungs showed statistically significant less fibrotic changes in SORBS2 KO mice in comparison to wild type mice.
Conclusion: SORBS2 is engaged in a vicious circle of fibrosis. Triggered by chronic TGF-β stimulation, SORBS2 is further upregulated by the increasing stiffness of the extracellular matrix. This leads to persistently high levels of SORBS2 resulting into further production of ECM products. Deleting SORBS2 has potent antifibrotic effects in animal models of skin and lung fibrosis. As most of the currently used therapeutic approaches are focussed on early stages of the disease, SORBS2 might be an interesting new therapeutic target in established stages of SSc.

Background: Autoantibodies (ab) against G protein-coupled receptors (GPCR), such as ab against angiotensin II receptor type 1 (AT1R), endothelin receptor type A (ETAR) or CXC chemokine receptor 3 and 4 (CXCR3/4) may contribute to the pathogenesis of systemic sclerosis (SSc) [1]. AT1R- and ETAR-ab are associated with SSc-related mortality and CXCR3/4- ab predict a deteriorating pulmonary fibrosis [2,3].
Objectives: We aim to identify new ab targets and ab discriminating healthy controls (HC) from SSc patients or SSc clinical phenotypes, organ involvements and therapy.
Methods: Serum ab levels against a panel of GPCR, GF and GFR were measured by ELISA in SSc (n=177) and compared to HC (n=88). Gender matched and age adjusted data were screened for univariate differences of ab levels in clinical phenotypes, explored for multivariate predictive performance of ab levels by a random-forest classifier and tested for differences of ab correlations.
Results: In SSc ab levels against 19 targets were higher compared to HC. Abs against fibroblast growth factor-2 (FGF-2), beta-adrenergic receptor 1 (ADRB1), and placental growth factor (PIGF) discriminated best SSc patients from HC. Multivariate predictions supported the ranking value of FGF-2 and ADRB1-abs for SSc and abs against ADRB1/2, muscarinic receptor 1 (M1R) and alpha-adrenergic receptor 2 ADRA2 for diffuse cutaneous SSc (dSSc) versus limited cutaneous SSc (lSSc). Ab levels were denser and stronger correlated in SSc than in HC (figure 1), suggesting a disturbed regulation of ab with a prominent role of FGF-2-abs in SSc. Comparing dSSc to lSSc, dSSc showed higher ab levels and correlated with several disease characteristics, but the multivariate classification showed poor accuracy.

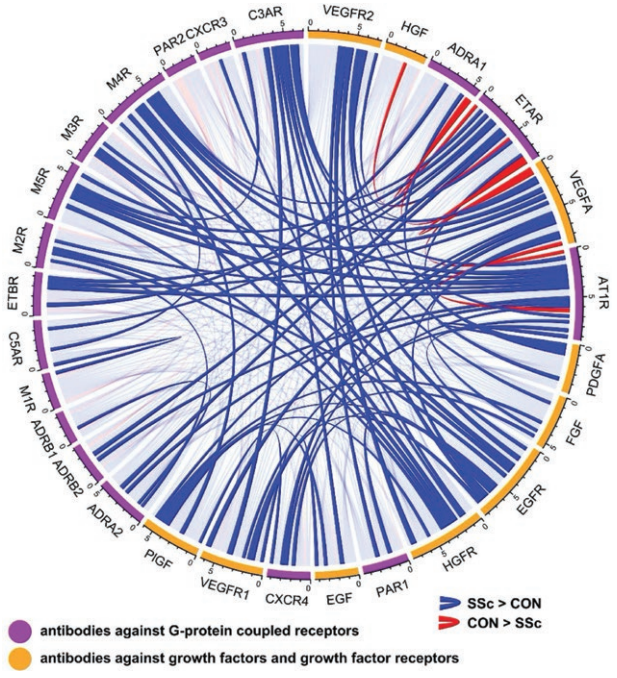

Figure 1. Different univariate correlations between abs in HC and SSc. The correlations of the ab concentrations are generally increased in SSc compared to HC. Largest accumulated differences are found for ETAR, VEGFA, AT1R and EGFR as indicated by the covered degrees in the circle. Dark bands depict significant differences after FDR-correction (p <.05)

Conclusion: SSc is characterized by both quantitative and qualitative alterations in ab levels and ab correlations. This study reveals ab against FGF-2, ADRB1 and PIGF to be new biomarkers of SSc. Alterations within these ab correlation networks could help to identify pathways promoting SSc and its clinical manifestations.

SINGLE-CELL RNA SEQUENCING OF BRONCHOALVEOLAR LAVAGE FLUID AND BLOOD REVEALS DISEASE-SPECIFIC CHARACTERISTICS OF IMMUNE CELLS IN CONNECTIVE TISSUE DISEASE-ASSOCIATED INTERSTITIAL LUNG DISEASE PATIENTS

Keywords: Lungs, Genetics/Epigenetics

A. Hirano[1], W. Fujii[1], A. Sakashita[1], K. Baßler[2], M. Kadoya[3], A. Omoto[3], W. Fukuda[3], T. Seno[1], M. Wada[1], M. Kohno[1], Y. Kawahito[1]. [1]*Kyoto Prefectural University of Medicine, Inflammation and Immunology, Graduate School of Medical Science, Kyoto, Japan*; [2]*Aimed analytics, data analytics, Bonn, Germany*; [3]*Japanese Red Cross Kyoto Daiichi Hospital, Center for Rheumatic Disease, Kyoto, Japan*

Background: Connective tissue disease-associated interstitial lung disease (CTD-ILD) is a serious complication and an important prognostic factor of various autoimmune diseases. Many cell types and both innate and adaptive immune systems are implicated in the pathogenesis of fibrotic lung injury. The presentation and clinical course of CTD-ILD are diverse, and the heterogeneity reflects differences in underlying pathogenic mechanisms.
Objectives: The objective of this study is to reveal the different characteristics of immune cells among diseases.
Methods: We collected bronchoalveolar lavage fluid (BALF) and peripheral blood from patients who newly complicated interstitial lung disease and agreed to participate in this study; 5 patients with Sjögren syndrome (SS), 8 patients with dermatomyositis (DM), 6 patients with rheumatoid arthritis (RA), 7 patients with systemic sclerosis (SSc), 4 patients with ANCA-associated vasculitis (AAV), and 12 patients with idiopathic interstitial pneumonia (IIP) included. We applied Seq-Well, a portable platform of single-cell RNA sequencing[1], to analyze gene expressions in immune cells in BALF and blood. We compared the distribution of immune cells and differential gene expressions in BALF and blood among diseases.
Results: We compared immune cell numbers in BALF among diseases. We found more T cells in patients with DM and SS, more B cells in patients with SS, more neutrophils in patients with RA, and more alveolar macrophages (AMs) in patients with AAV or SSc. We further performed gene ontology enrichment analysis of each immune cells in BALF. In patients with DM, the gene expression pathways related to the response to virus was increased in T cells. On the other hand, in patients with SS, the gene expression pathways involved in innate immunity and antigen presentation were enhanced in B cells. In addition, the gene expression associated with T cell activation was enhanced in T cells. In neutrophils from patients with RA, the gene expression involved in inflammation was increased. We next performed gene ontology enrichment analysis of blood. In monocytes and neutrophils, patients with DM had increased gene expression pathways associated with viruses, while patients with SS had increased gene expression of both innate immune pathways and acquired immunity. These results suggested that the common pathways were enhanced in BALF lymphocytes and in blood monocytes and neutrophils in patients with DM and SS.
Conclusion: Our comprehensive single-cell analysis of BALF and blood from CTD-ILD patients has revealed that the phenotypes and states of immune cells differ among diseases (Figure 1). We found that the common pathways were enhanced in BALF and blood, i.e., pathways associated with response to virus were enhanced in DM while innate immunity and antigen presentation pathways were enhanced in SS, suggesting the relationship between systemic immune abnormality and ILD. These results may lead to the optimal diagnosis and the precision medicine for patients with CTD-ILDs.

PLATELET EXTRACELLULAR VESICLES MODULATE NEUTROPHIL STATE IN SYSTEMIC SCLEROSIS VIA HMGB1

Keywords: Lungs, Innate immunity, Systemic sclerosis

N. Maugeri[1], G. A. Ramirez[1], A. Monno[1], A. Capobianco[1], S. Franchini[1], M. Bianchi[1], P. Rovere-Querini[1], A. Manfredi[1]. [1]*IRCCS San Raffaele Scientific Institute, Autoimmunity and Vascular Inflammation Unit, Milano, Italy*

Background: Platelet extracellular vesicles (Plt-EVs) expressing the damage-associated molecular pattern prototypic signal, high mobility group box 1 (HMGB1), accumulate in the blood of patients with systemic sclerosis (SSc) and per se promote autoimmunity, fibrosis and vascular inflammation [1, 2]. A poorly understood defect in critical players in sprouting angiogenesis, angiopoietins and the angiopoietin receptor, TIE2 is also an hallmark of SSc. Normal neutrophils respond to angiopoietin 1 and other stimuli by undergoing activation and upregulating the Tie2 expression [3].

Objectives: We reasoned that HMGB1 could be a putative candidate signal supporting neutrophils Tie2 overexpression, as it plays a critical role in neutrophil activation and is present as an EV-associated bioactive molecule in the blood of SSc patients[1, 2].

Methods: Neutrophil Tie2 expression was assessed in the blood of 39 patients with SSc and 43 healthy donors (HD) sex- aged matched, by flow cytometry and confirmed by immunogold at electron microscopy. Tie2 expression was determined in freshly purified normal neutrophils stimulated with Plt-EVs from SSc patients or from HD or stimulated with rHMGB1 in vitro. Moreover Plt-EVs purified from the plasma of SSc patients or from HD were injected in the tail vein of NSG mice (that are receptive to human tissues). 18 hours after injection the expression of Tie2 of neutrophils in blood and lung histology were analyzed. Box A and low molecular weight heparin (LMWH) have been used as HMGB1 antagonists in vitro and in vivo.

Results: Most SSc neutrophils express Tie2 (84.7±2.4% vs 8.3±1.1% in HD; p <0.0001) regardless of the extent of systemic inflammation. HMGB1 and Plt-EV expressing HMGB1 purified from the plasma of patients with SSc induced up-regulation of TIE2 *in vitro*. Tie2 induction was abrogated by Box A and LMWH. Plt-EVs from SSc patients (but not from the plasma of HD) injected in immune-deficient NSG mice dramatically upregulated Tie2 neutrophil expression. Neutrophil Tie2 upregulation abated in the presence of HMGB1 inhibitors, BoxA and LMWH. Immunohistochemitry revealed lung fibrosis associated with massive infiltration by Tie2+ neutrophils. Neutrophil ablation by liposome-encapsulated clodronate prevented SSc Plt-EV-induced lung fibrosis, thus causally linking neutrophil activation, Tie2 neutrophil-expressing pulmonary infiltration and tissue remodelling.

Conclusion: Our data highlight the role of the platelet HMGB1/neutrophil axis in SSc vascular inflammation and fibrosis.

New developments in imaging in rheumatology

POS0153 MACROPHAGE [11C]-DPA-713 PET-CT IMAGING TO PREDICT EARLY ANTI-TNF TREATMENT OUTCOME IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Imaging, Qualitative research methods

W. Binsbergen[1], J. De Jongh[1], S. Pieplenbosch[2], M. Yaqub[2], D. Van Schaardenburg[1,3], A. Voskuyl[1], G. C. J. Zwezerijnen[2], C. J. Van der Laken[1]. *[1]Amsterdam UMC, locatie AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[2]Amsterdam UMC, locatie AMC, Radiology and Nuclear Medicine, Amsterdam, Netherlands*; *[3]Reade, Locatie Dr. Jan Van Breemenstraat, Rheumatology, Amsterdam, Netherlands*

Background: Treatment of rheumatoid arthritis (RA) using anti-tumor necrosis factor (TNF) biologics has greatly benefited patients since their introduction, with an expected treatment response rate of up to 50-70% [1]. This however, leaves 30-50% of patients taking ineffective medication whilst being exposed to the potential side-effects of anti-TNF. Current patient care requires clinical evaluation of 3 to 6 months before effectiveness can reliably be assessed. Quantitative macrophage positron emission tomography (PET) has shown potential to predict clinical response at an early stage of treatment [2]. The new generation translocator protein (TSPO) tracer [11C]-DPA-713 has demonstrated excellent properties for imaging of arthritis by targeting synovial macrophages [2, 3].
Objectives: To determine whether quantitative whole body [11C]-DPA-713 PET/CT imaging at 0-4 weeks of anti-TNF treatment in clinically active RA patients is associated with clinical response at 26 weeks.
Methods: Whole body [11C]-DPA-713 PET/CT scans were performed at baseline and after 4 weeks of treatment with anti-TNF in n=20 clinically active RA patients. All patients were either anti-TNF naïve or switched to an anti-TNF agent without previous primary failure to anti-TNF. Co-treatment with DMARD and/or low dose (≤ 10 mg dd) was allowed and was stable for at least 4 weeks. Clinical follow-up was conducted with the Disease Activity Score 44 (DAS44) after 26 weeks of treatment. PET/CT scans were quantitatively analyzed using in-house software. Regions of interest (ROIs) were delineated on PET/CT per individual joint in all joints evaluated using the DAS44 and CT as anatomical reference. Standardized uptake values (SUVs) normalized for body weight were calculated in these ROIs to determine quantitative tracer uptake per joint. PET outcome at baseline and 4 weeks of anti-TNF treatment was compared with the DAS44 scores at 26 weeks of treatment.
Results: Included patients were mostly female (70%) and aged 61.5 ± 12.8. Baseline DAS44 was 2,5 ± 1 and all demonstrated visually enhanced tracer uptake in one or more joints on PET/CT. After 26 weeks 30% showed no response, 20% moderate response and 50% good response to treatment according to EULAR response criteria. Baseline mean PET/CT scores of all joints per patient already correlated significantly with DAS44 at 26 weeks (T=0, R^2 = 0.547, p = <0,001). In smaller joint clusters the highest correlation was found for the metacarpal-phalangeal joints (T=0, R^2 = 0.650, p = <0.001). Furthermore, PET/CT outcomes at 4 weeks of anti-TNF treatment also had significant correlation with DAS44 at 26 weeks for those same measurements: mean score of all joints: T=4, R^2 = 0,530, p = <0,001, mean score MCPs: T=4, R^2 = 0.728, p = <0,001.

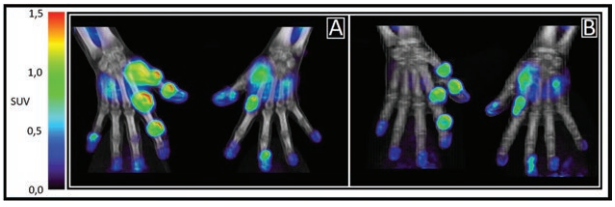

Figure 1. Changes in [11C]-DPA713 uptake in MCP joints of an RA patient responding to anti-TNF treatment, before (A) and after 4 weeks after initiation of anti-TNF treatment (B).

Conclusion: Quantitative whole body macrophage C-11-DPA713 PET/CT joint assessment correlated already at baseline, and also at 4 weeks of anti-TNF treatment with clinical response at 6 months of treatment. Therefore, quantitative non-invasive macrophage PET/CT shows promise for very early prediction and treatment stratification of anti-TNF in RA patients. Further studies will be focused on development of standardized and (semi-)automated PET quantification protocols to facilitate implementation in clinical trials and practice.

POS0154 A DEEP LEARNING MODEL TO LOCATE INFLAMMATORY CHANGES IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Artificial Intelligence, Imaging

T. Hassanzadeh[1], D. Shamonin[1], Y. LI[1], M. Reijnierse[2], A. Van der Helm – van Mil[3], B. Stoel[1]. *[1]Leiden University Medical Center, Division of Image Processing, Department of Radiology, Leiden, Netherlands*; *[2]Leiden University Medical Center, Department of Radiology, Leiden, Netherlands*; *[3]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*

Background: Magnetic Resonance Imaging (MRI) is one of the most sensitive imaging modalities to monitor affected joints and detect inflammatory signs related to Rheumatoid Arthritis (RA). Finding and tracking inflamed areas can help to evaluate patients status, and start treatment in a very early stage. The RAMRIS [1] scoring system is being used to assess the extent of inflammation by scoring specific areas to quantify synovitis, tenosynovitis and bone marrow edema. Deep Learning (DL) may, however, provide more accurate and specific quantifications.
Objectives: We aimed to develop a change map that locates RA progression over time, using MRI scans of the wrist. Our purpose was to develop an automatic, hypothesis-free DL model that considers the entire MRI for detecting all possible longitudinal changes related to RA between baseline and follow-up wrist MRIs.
Methods: Wrist contrast-enhanced T1-weighted fat-suppressed MRI scans of 236 patients from four time points (baseline, with 4, 12, and 24 months follow-up) were collected [1]. An unsupervised DL model was developed together with image processing techniques to detect a pixel-level progression within wrist MRI scans between baseline and the last follow-up MRIs. This model predicts the MRI appearance of the follow-up scan, based on the baseline scan, by learning from MRI time sequences of all patients in the training set. Similarly, the baseline scan was predicted backwards in time, based on the follow-up scan (see Figure 1). Subsequently, by comparing the predicted and true MRI image, pixel-level changes can be determined between the two MRI scans. For prediction, we used a U-Net [2] to reconstruct follow-up images from baseline and vice versa. After pre-training, two copies of the trained model and a joint loss function were used for final training (a dual branch U-Net); the first branch is trained to generate a follow-up image and the second branch to create a baseline image. After final training, two difference maps were obtained by subtracting the baseline image from the predicted follow-up image and by subtracting the follow-up image from the predicted baseline image. Since real changes appear in pixels with positive values, Otsu thresholding was applied only on the positive differences to generate two change maps, where the first change map shows intensity reduction (areas of remission) and the second indicates increased intensity (areas of progression). With fusion of the obtained change maps we obtained the final change map that can highlight the changes in both directions.
Results: As can be seen from Figure 1, the proposed model could find local pixel-level changes, highlighting RA remission/progression over time. The red overlay shows a reduction in intensity, the blue overlay indicate an increase in intensity. To show the performance of the proposed model, the results were compared with a baseline model, that simply subtracts the original follow-up from the baseline image. As can be seen from the provided examples, the proposed model is less sensitive to imaging artifacts.
Conclusion: A comparative DL-model is proposed to find inflammatory changes in wrist MRI scans. Despite being an unsupervised model (sometimes detecting changes, in e.g. vessels, that are presumed to be unrelated to RA), the results are promising, since the change maps contain less artifacts as compared to simple image subtraction.

Background: Peripheral musculoskeletal (MSK) symptoms are the most common extra intestinal manifestations (EIMs) in IBD patients, with substantial impact on quality of life. IBD related spondyloarthritis (IBD-SpA) often requires a multidisciplinary evaluation to enable optimal choice of treatment and patient care, but systematic rheumatological characterisation of this population is scarce [1]. Characterisation of IBD-SpA is challenged by the variety of MSK involvement (from arthralgia to ankylosing spondylitis), the co-existence of osteoarthritis, overuse enthesopathies or fibromyalgia, and by the heterogeneity in methodologies used to describe the SpA features. Recently developed recommendations for endpoints for EIMs in IBD trials [2] were applied in the present study.
Objectives: To determine the prevalence and distribution of inflammatory lesions in peripheral joints and entheses in newly diagnosed IBD patients, assessed for presence of MSK symptoms, and by rheumatological and ultrasound (US) evaluation.
Methods: Patients from the IBD prognosis inception cohort (IBD-Pro) were consecutively included [2]. They reported MSK symptoms using a validated questionnaire (IBD-TASQ). A clinical examination was performed by rheumatologist, as was US examination (grey scale (GS) and colour Doppler (CD)) of 38 peripheral joints and 14 entheses, applying OMERACT-EULAR definitions and scoring systems for synovitis and enthesitis [3]. Synovitis was defined as GS score ≥2 and/or CD≥1 and entheseal inflammation was defined as presence of hypoechogenicity/thickening and/or CD score ≥1. Further, OMERACT-EULAR sum score (GLOESS) was calculated (0-114).
Results: 110 newly diagnosed IBD patients (mean age 42, 39% male) were included (34% Crohn's disease, 59% ulcerative colitis (UC), 5% unclassified IBD). The IBD disease activity scores indicated mild activity in UC patients (Simple Clinical Colitis Activity Index mean (SD) 6.7 (3.6) - max score 19, and low in Crohn (Harvey-Bradshaw Index for Chron's disease 4.5 (2.9)- max score 18). Four patients received systemic glucocorticoids (2%) or biologics (2%) at the time of rheumatological evaluation. History of psoriasis was reported in 2% and uveitis in 5% of the patients. 40% of the patients reported positive history for ≥1 MSK symptom (Figure 1, A1); joint pain and swelling were the most common complaints (30%), followed by heel enthesitis (17%) and dactylitis in 20%. Patient pain VAS was low, mean (SD) 13(25). Clinical examination revealed 53% of all patients having arthritis and/or enthesitis and fulfilled ASAS classification criteria for peripheral SpA (25% ≥1 tender joint, 12% ≥1 swollen joint, 46% ≥1 tender enthesis, 38% both ≥1 tender/swollen joint and ≥1 tender enthesis). Figure 1 (part A2a, A2b) shows joint and enthesis involvement. US found inflammation in ≥1 joint or enthesis in 47% of the IBD patients - synovitis in 30%, mean GLOESS sum score 5.2 SD (4.6) and entheseal inflammation in 33% (US enthesitis sum, mean (SD) 2.6(2). (Figure 1, part A3a, A3b). Among those patients reporting entheseal pain, 71% had ≥1 tender enthesis at clinical evaluation and 64% had entheseal inflammation by US. Among those reporting joint pain, 55% had ≥1 tender or swollen joint, and

41% US synovitis. Figure 1 (part B1, B2) displays the overlap between patient-reported symptoms, clinical and US findings. In the asymptomatic patients (60 %) 59% of the patients with clinical signs of arthritis and 79% of those with enthesitis were asymptomatic. US enthesitis and synovitis were also observed in 69% and 58%, respectively, of the asymptomatic patients.

Conclusion: At the time of IBD diagnosis 53% fulfilled ASAS classification criteria for peripheral SpA and 47% had objectively verified synovitis and/or enthesitis by US indicating that SpA may be underdiagnosed among IBD patients.

BONE DENSITY, MICROSTRUCTURE AND BIOMECHANICS OVER A 7-YEAR OBSERVATION PERIOD IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS - INFLUENCE OF AUTOIMMUNITY, DISEASE ACTIVITY AND BIOLOGICAL DMARD TREATMENT

Keywords: Inflammatory arthritides, Disease-modifying Drugs (DMARDs), Imaging

S. Kemenes[1,2], K. Tascilar[1,2], A. Kleyer[1,2], I. Minopoulou[1,2], F. Fagni[1,2], A. Zekovic[1,2], C. A. Isnardi[1,2], A. M. Liphardt[1,2], S. Bayat[1,2], L. Schuster[1,2], G. Schett[1,2], D. Simon[1,2]. [1]*University Hospital Erlangen and Friedrich-Alexander University (FAU) Erlangen-Nürnberg, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany*; [2]*Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Deutsches Zentrum Immuntherapie (DZI), Erlangen, Germany*

Background: Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) are characterized by a deterioration of bone mass, bone microstructure and biomechanics [1, 2]. However, little evidence is available on the long-term evolution of these bone properties and the impact of autoimmunity, disease activity and targeted anti-inflammatory therapy.

Objectives: To evaluate the longitudinal course of peripheral volumetric bone mineral density (vBMD), microstructure and biomechanics in patients with seropositive RA (RA+), seronegative RA (RA-) and PsA (i) by diagnosis (ii) disease activity and (iii) ever use of biologic/targeted synthetic (b/ts) DMARDs.

Methods: RA+, RA-, PsA patients who had at least one high-resolution CT scan were included. Prospectively collected longitudinal data from the distal radius. vBMD, microstructure and biomechanical properties were assessed and data on treatments and disease activity (DAS-28) were collected. We described and summarized the time course of these measurements, using linear regression models as age and sex adjusted time-conditional means and mean differences by disease category, time-varying weighted average disease activity and intervening b/tsDMARD treatments.

Results: We analyzed 946 scans from 412 patients (193 RA+, 68 RA-, 151 PsA) with a median CT follow-up duration of 24 months (IQR 0 to 47). (Table 1). Overall, bone quality showed a downward course over time. RA+ patients showed lower total and trabecular bone densities compared to patients with psoriatic arthritis throughout the time course. (Figure 1a). RA+ patients also showed decreasing trabecular number with increasing trabecular thickness, trabecular irregularity and trabecular separation over time in comparison to PsA (Figure 1 b) suggesting a gradual disappearance of the thinner trabeculae. We detected significant time/DAS-28 interactions in PSA patients indicating faster cortical bone loss over time with increasing DAS-28 (p interaction =0.049), in RA- patients showing faster trabecular bone loss over time with higher disease activity (p.interaction 0.044) and in RA+ patients for trabecular density (p interaction 0.038), bone stiffness (p interaction 0.022) and failure load (p interaction 0.034) indicating a faster deterioration of bone quality over time with increasing disease activity. Interestingly, RA+ patients exposed to b/tsDMARDs had numerically lower bone density compared to unexposed patients, whereas the temporal pattern suggested a more stable vBMD over time as opposed to a deteriorating pattern in the unexposed. However, the uncertainty in these analyses was large and none of the time-exposure interactions or pairwise differences over time between ever vs. never exposed categories were significant.

Conclusion: Autoimmunity impairs bone health over time and is particularly associated with impaired trabecular bone quality. Good control of disease activity in RA+, RA-, and PsA patients may be helpful in preventing bone loss and deterioration of bone microstructure, and biomechanics. Specific contribution of b/tsDMARDs to the time course of bone quality at the radius needs further clarification.

POS0157 POST-STRESS ELASTOGRAPHIC DIFFERENCES AT ACHILLES ENTHESIS AS AN OUTCOME MEASURE IN THE ASSESMENT OF PATIENTS WITH PSORIATIC ARTHRITIS IN REMISSION

Keywords: Psoriatic arthritis, Physical therapy/Physiotherapy, Ultrasound

C. Guillén-Astete[1], A. Palomeque[1], M. Serrano Warleta[1], R. Manzo[1]. [1]*Ramón y Cajal University Hospital, Rheumatology, Madrid, Spain*

Background: Tendon elastography has demonstrated the ability to discriminate between healthy subjects and patients with spondyloarthritis. Its greatest strength is its ability to reliably quantify the stiffness of a soft structure. However, its use in anatomical load-bearing entheses has not been sufficiently explored. The use of quantifiable enthesis assessment methods would open up multiple possibilities in both the diagnosis and follow-up of inflammatory enthesis diseases.
Objectives: To evaluate the response to mechanical stress through elastography in the enthesis of the Achilles tendon among patients with psoriatic arthritis (PsA) in remission treated with anti-IL17 therapies, with other non-anti-IL17 therapies, and healthy controls.
Methods: Observational, multicenter, non-blind study. The elastography results before and after physical exercise of patients with PsA in remission treated with therapies aIL17, therapies other than aIL17 (non-aIL17) were compared with those of healthy subjects matched by age (+/- 4 years), sex, and body fat percentage (BFP) (+/- 4%). Elastography was performed with a GE Logic S8 sonograph with a linear 6MHz probe. The region of interest (ROI) was the Achilles' enthesis identified distal to the vertex of the pre-Achilles bursa choosing the greatest thickness in the longitudinal plane. Each assessment was the result of the average of five consecutive determinations. Body composition was determined using an OMROM Healthcare model BF511 impedance meter. Physical exercise performed on a SALTER activeHealth PT-0083 magnetic bike, at an intensity of +80% and up to 300Kcal. A before and after analysis was performed using the T-Student's test for interdependent samples. The main outcome variable was the variability of the Achilles enthesis stiffness after physical exertion.
Results: The elastographic results of 14 patients on aIL17 therapies, 15 on non-aIL17 therapies, and 28 healthy controls were compared. The demographic and constitutional distribution was homogeneous in the three groups (p=0.221 for age, p=0.983 for BFP). The Achilles enthesis height ± standard deviation (mm) in controls was 4.27 ± 0.45 in controls, 4.78 ± 0.56 in non-aIL17 patients, and 4.66 ± 0.47 in aIL17 patients (p=.005 in controls vs. non-aIL17). Baseline, enthesis rigidity in the controls, aIL17 and non-aIL17 group was 210.2±21.9, 183.7±7 and 201.17±6.1 Kpa, respectively (p<.001 in controls vs. non-aIL17, p=.016 in non-aIL17). aIL17 vs. aIL17). After exercising, the same measurements were 227.5±21.2, 195.3±8.3, and 219.1±9.1 Kpa (p<.001 in control vs. non-aIL17, p<.001 in non-aIL17 and aIL17). The change experienced in the stiffness after the effort given between the three groups determined a mean change of 17.3±29.5 Kpa (t=3.113, p=.004) in the controls, of 5.1±3 Kpa (t=6.52, p<.001) in the non-aIL17 group and 17.9±6.5 Kpa (t=10.303, p<.001) in the aIL-17 group. The increases in stiffness with exercise were comparable between controls and the aIL-17 group (p=.919), and both were significantly higher than the non-aIL-17 group (p<.001).
Conclusion: In patients in remission, the known immediate adaptability of the entheses to physical exercise through increased rigidity can be verified by elastography in patients with PsA and controls. Patients treated with aIL17 therapies exhibited adaptive elastographic responses to enthesis exercises that were indistinguishable from healthy controls and significantly higher than those not treated with aIL17. These findings lay the groundwork for using elastography as an outcome variable in the evolutionary study of entheses in patients with other forms of spondyloarthritis.

POS0159 **THE OMERACT GIANT CELL ARTERITIS ULTRASONOGRAPHY SCORE: A POTENTIAL USEFUL OUTCOME TO ASSESS THE RISK OF RELAPSE DURING FOLLOW-UP**

Keywords: Vasculitis, Imaging, Ultrasound

J. Molina Collada[1], J. M. Alvaro-Gracia[1], E. De Miguel[2]. *[1]Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain*; *[2]La Paz University Hospital, Rheumatology, Madrid, Spain*

Background: The OMERACT ultrasonography large vessel vasculitis working group has recently developed an ultrasound (US) composite score, the OMERACT giant cell arteritis (GCA) Ultrasonography Score (OGUS), to assess the extent of vascular inflammation by US and to monitor disease activity in patients with GCA[1].
Objectives: Our objective was to assess the sensitivity to change of this score and to determine whether OGUS variations after treatment are associated with the risk of relapse during follow-up.
Methods: Retrospective observational study of patients referred to a US GCA fast track clinic of an academic center over a 2-year period with GCA clinical confirmation. All patients underwent baseline US evaluation at the time of diagnosis and at 3- and 6-month visits per protocol. OGUS was calculated as the sum of intima media thickness (IMT) in every segment divided by the rounded cut-off values of IMTs in each segment (0.4 mm for the common trunk of superficial temporal arteries, 0.3 mm for the parietal and frontal branches and 1 mm for the axillary arteries). The total sum was divided by the number of segments available. OGUS score >1 indicates abnormal exam. EULAR definitions for remission and major and minor relapse were checked for every patient at 3 and 6 months. Patients were treated according to clinical response with standard therapy. Sensitivity to change of OGUS was calculated as negative values of standardized mean difference (SMD) for each visit separately. The t-student test for paired samples was used for comparing baseline and follow-up OGUS assessments. 0-3 and 0-6-months OGUS variations were compared between patients with and without relapse during follow-up and with and without achievement of remission at 6 months.
Results: A total of 35 GCA patients were included for analysis (mean age 77.4 years, 62.9 % females). Ten (28.6%) patients relapsed at 3 or 6 months during follow-up, of whom 8 (22.9%) showed a minor relapse. EULAR definition of remission at 6 months was achieved by 18 (51.4%) patients. Mean (SD) baseline OGUS was 1.34 (0.34). OGUS improved significantly at 3 (1.34 vs 1.14, p=0.013) and 6 months (1.34 vs 1.1, p<0.01). The SMD of OGUS between baseline and 3 and 6 months was -0.49 and -0.61, respectively. 0-3- and 0-6-month OGUS variations in patients with and without relapse during follow-up and patients with and without achievement of remission at 6 months are shown in detail in Table 1. Mean 0-6-month OGUS improvement was significantly lower in patients with relapse during follow-up (-0.08 vs 0.35, p=0.049). On the other hand, mean 0-6-month OGUS improvement was greater in patients achieving remission at 6 months (0.35 vs 0.04, p=0.042).
Conclusion: OGUS shows moderate sensitivity to change in patients with GCA after standard therapy at 3 and 6 months. The absence of OGUS improvement during follow-up is associated with the risk of relapse and the probability of not achieving remission. These findings highlight the usefulness of this tool in clinical practice and may support personalized medicine decisions during treatment tapering.

Background: Ultrasound has been shown to be a valid tool for the evaluation of bone erosions in rheumatoid arthritis (RA), yet a consensual scoring system is lacking.
Objectives: To assess the reliability of a semiquantitative scoring system for assessing structural bone erosion by ultrasound in a web-based reliability exercise.
Methods: A task force of the OMERACT Ultrasound Working Group developed definitions and a scoring system for grading bone erosions which takes both the size and number of erosions into consideration. Pairs of static images (longitudinal and transverse) in DICOM format of metacarpophalangeal and proximal interphalangeal joints 2-5 were acquired prospectively in healthy controls and in RA patients with varying degrees of pathology by the task force members. A dataset of anonymized images, representing various grades was created and utilized in a web-based exercise using the cmrad.com cloud platform which allowed the participants to measure the size of the erosions and use the discrete measures and the number of erosions to grade each joint according to the scoring system. Both the longitudinal and transverse scans were considered and the largest diameter chosen for each erosion. Intra- and inter-reader reliability of the scoring system was assessed using kappa statistics.

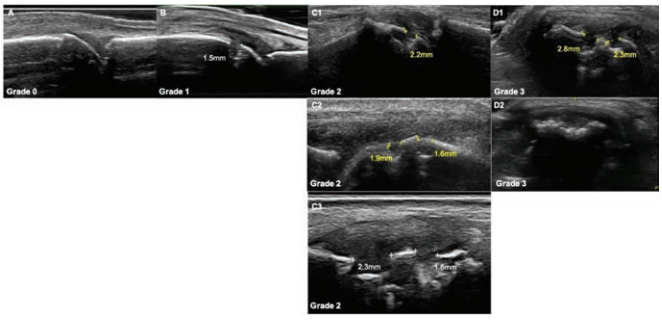

Figure 1. Representative images of the different grades of the scoring system for bone erosion in rheumatoid arthritis. A) grade 0: intact cortical bone; **B)** grade 1: single small erosion (diameter: ≤2mm); **C1)** grade 2: single large erosion (diameter: >2mm); **C2)** grade 2: 2 small erosions; **C3)** grade 2: 1 large and 1 small erosion; **D1)** grade 3: 2 large erosions; **D2)** grade 3: ≥3 erosions, regardless of size

Results: A 4-grade semiquantitative scoring system was developed: grade 0) intact cortical bone; grade 1) single small erosion (diameter: ≤2mm); grade 2) single large erosion (diameter: >2mm) or 2 small erosions or 1 large and 1 small erosion; grade 3) 2 large erosions or ≥3 erosions, regardless of size (Figure 1). A dataset composed of 45 anonymised image pairs (90 single images) was graded by 20 task force members in two rounds separated by 10 days. The intra-reader (mean: 0.79; 95% confidence interval: 0.75-0.84) reliability was excellent and the inter-reader (mean: 0.75; 95% confidence interval: 0.74-0.76) reliability was substantial.
Conclusion: This preliminary OMERACT scoring system for bone erosions of the finger joints in RA has demonstrated excellent reliability on static images. Further studies are required to evaluate the reliability of the combined acquisition and reading of images in patients.

VALIDITY OF SIMPLIFIED ULTRASONOGRAPHIC ASSESSMENTS OF JOINT INFLAMMATION IN RHEUMATOID ARTHRITIS

Keywords: Ultrasound, Rheumatoid arthritis

Z. Rutter-Locher[1], K. Chaabo[2], E. Chan[1], A. Vincent[1], S. Norton[3], L. B. Kirkham[1]. *[1]Guy's Hospital, Rheumatology, London, United Kingdom*; *[2]St George's Hospital, Rheumatology, London, United Kingdom*; *[3]King's College London, Psychology and Inflammation Biology, London, United Kingdom*

Background: Musculoskeletal ultrasound (MSK US) is a valuable tool to aid management of inflammatory arthritis. It's use in clinical practice is limited by the feasibility and time constraints of performing a full 44 or 78 joint ultrasound.
Objectives: Our objective was to determine the validity of four previously published simplified approaches (6 joint[1], 12 joint[2], hands only[3] and data driven[4] US models) in a new patient cohort, in order to guide future choice of targeted MSK US protocol in research and clinical practice.
Methods: Sequential patients with rheumatoid arthritis, diagnosed according the 1987 ACR criteria, with a DAS28ESR score ≥ 3.2 underwent clinical assessment and 44 joint US at Guy's Hospital. Grey scale (GS) and power doppler (PD) were graded semi quantitatively, according to the EULAR-OMERACT criteria. All the joints scored in the simplified 6 joint, 12 joint, hands only and "data driven" models were included in the current 44 joint US. However, the number of synovial recesses examined differed from those in the simplified models. Sensitivity of the simplified models to detect GS and PD signal, compared to the extended 44 joint US was calculated. Content validity was evaluated by correlating the 44-joint US count with the simplified models using Spearman's correlation coefficient. The proportion of information retained by the simplified models compared with the 44 joint US was assessed using linear regression analysis.
Results: 158 patients were enrolled in the study, with a mean age of 58.9 years (SD 12.95), 78.5% Female, 67.7% RhF positive and a median disease duration of 10 years (IQR 5-19.2). Median DAS 28 was 4.8 (IQR 3.9-5.6) and pain VAS 55 (IQR 40-70). GS and PD positivity was most common at the wrist and the MTP joints (Figure 1). All simplified assessment models were sensitive and able to detect >85% of patients with GS≥ 2 PD≥1 evaluated using the 44 joint (6 joint GS≥ 2 135 (88.2%), PD≥1 75 (86.2%), 12 joint GS≥ 2 137 (89.5%), PD≥1 76 (87.4%), Hands only GS≥ 2 138 (90.2%), PD≥1 80 (92%), Data Driven GS≥ 2 149 (97.2%), PD≥1 82 (94.3%). GS, PD and total scores for all the simplified models significantly correlated with the scores from the 44 joint US (Table 1). The "data driven" model had the highest correlation and retained the greatest proportion of information compared with the total 44 joint US scores.
Conclusion: This study validates the use of the 6 joint, 12 joint, hands only and data driven approaches in a new patient cohort. The data driven approach was the most sensitive and retained the greatest proportion of information. Simplified US models enable the routine use of musculoskeletal US in clinical practice.

Systemic lupus erythematosus, Sjogren's syndrome and anti-phospholipid syndrome: clinical aspects

POS0163 PERFORMANCE OF THE SALIVARY GLAND ULTRASONOGRAPHY OMERACT SCORE IN THE ACR-EULAR CLASSIFICATION CRITERIA FOR SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome, Ultrasound, Diagnostic Tests

D. Rebel[1], L. De Wolff[1], K. Delli[2], A. J. Stel[1], H. Kokol[1], A. Vissink[2], F. G. M. Kroese[1], S. Arends[1], H. Bootsma[1]. *[1]University Medical Centre Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]University Medical Centre Groningen, Oral and Maxillofacial surgery, Groningen, Netherlands*

Background: Ultrasonography is a tool to assess the involvement of major salivary glands in patients with Sjögren's syndrome (SS). Recently, the Outcome Measures in Rheumatology (OMERACT) scoring system has been developed for salivary gland ultrasonography (SGUS) in SS.[1] Incorporation of this scoring system in the 2016 American College of Rheumatology (ACR)-European League Against Rheumatism (EULAR) classification criteria might be of aid in the classification of SS.

Objectives: To investigate if addition of the OMERACT SGUS score influences the performance of the 2016 ACR-EULAR classification criteria for SS in daily clinical practice.

Methods: This retrospective, cross-sectional study included consecutive patients of ≥18 years who visited the University Medical Centre Groningen (UMCG) between January 2017 and December 2021 for a diagnostic trajectory to determine whether they had SS. All items of the 2016 ACR-EULAR criteria were collected. Ultrasonographic images were assessed by using the Hocevar score. A transformation table was made by two experienced ultrasonographers (AS and KD) to transform the Hocevar score to the OMERACT SGUS score (range 0-12). Clinical diagnosis by the treating physician was used as gold standard. Receiver operating characteristic (ROC) analysis with area under the curve (AUC) was used to analyse the accuracy of the SGUS OMERACT score, the current ACR-EULAR classification criteria and the ACR-EULAR criteria with addition of the SGUS OMERACT score as well as to explore the optimal cut-off point to predict clinical diagnosis.

Results: Of the 419 included patients, mean age was 53±14 years, 366 (87%) were female and 164 (39%) were diagnosed with SS. Median (IQR) of the SGUS OMERACT score was 7 (4-10) in the SS group versus 1 (0-2) in the non-SS group (Table 1). The SGUS OMERACT score predicted the clinical diagnosis of SS with good accuracy, with an AUC of 0.868 (95% CI 0.830-0.906). The optimal cut-off point of the total OMERACT score to predict clinical diagnosis was ≥5, with a sensitivity of 68.9% and a specificity of 91.4%. An OMERACT score of ≥2 in at least 1 gland showed a sensitivity of 75.6% and a specificity of 85.5%. The current ACR-EULAR classification criteria showed excellent accuracy to predict clinical diagnosis, with an AUC of 0.956 (0.937-0.975). When incorporating the SGUS OMERACT score (defined as total score ≥5) as additional item in the ACR/EULAR criteria, the AUC was 0.968 (0.953-0.983). When incorporating the SGUS OMERACT score (defined as ≥2 points in 1 gland) as an additional item, the AUC was 0.967 (0.951-0.982). With the original ACR/EULAR cut-off score of ≥4 for classification as SS, the sensitivity was 92.7% and the specificity 87.5% for the current ACR-EULAR classification criteria, 93.3% and 87.1% for the ACR-EULAR criteria with addition of SGUS OMERACT positivity based on total score ≥5, and 93.9% and 85.5% for the ACR-EULAR criteria with addition of SGUS OMERACT positivity based on ≥2 points in 1 gland.

Conclusion: Incorporating SGUS in the criteria extends the diagnostics options in patients suspected with SS. The accuracy of the ACR-EULAR classification criteria in predicting the clinical diagnosis of SS remained high after incorporating the SGUS OMERACT score.

Background: Primary Sjögren syndrome (pSS) is a systemic autoimmune disease that may complicate with pulmonary manifestations in up to 16% of patients [1], including interstitial lung disease (SS-ILD) and airway disease (SS-AD).
Objectives: To assess the associated factors with SS-ILD and SS-AD.
Secondary objectives: to describe these manifestations and to investigate their prognosis.
Methods: We performed a retrospective multicentric study involving 9 French centers. We included pSS patients fulfilling the ACR/EULAR 2016 criteria and having a pulmonary disease associated with pSS evidenced by at least one clinician and one computed tomography (CT) report. We collected clinical and biological data at the visit giving access to the most exhaustive collection, pulmonary function test (PFT) and CT scans of the patients. CT scans were reviewed by a radiologist specialist in thoracic diseases. SS-ILD were considered progressive if there were at least a 10% decrease of the forced vital capacity (FVC) between 2 consecutive measurements. SS-ILD and SS-AD were compared to pSS controls with no history of pulmonary involvement, matched on age and disease duration with a 2/1 ratio.
Results: We included 56 SS-ILD, 31 SS-AD and 174 pSS controls. Comparison of SS-ILD, SS-AD and pSS controls is shown in **Table 1**. We found that SS-ILD and SS-AD had higher disease activity (ESSDAI) and B cell biological markers at visit time. Incident lymphomas were more prevalent in SS-ILD. SS-ILD were mostly nonspecific interstitial pneumonia (NSIP, n=16, 36%), usual or probable usual interstitial pneumonia (UIP, n=8, 18%), indeterminate for UIP (n=8, 18%) and lymphoid interstitial pneumonia (LIP, n=4, 9%). Fibrosis features were observed in 43% of cases. 44% of SS-ILD were progressive, independently of pSS characteristics and CT pattern, despite any significant evolution of PFT parameters of overall SS-ILD within 7 years follow-up (**Figure 1A**). We indirectly assessed the impact of the first line of systemic treatments in SS-ILD comparing PFT evolution of treated (43%) and untreated patients. We found that treated SS-ILD tended to have reduce PFT deterioration than non-treated patients with a 6 years follow-up [especially FVC and total lung capacity (TLC)], with a trend to improved FVC and forced expiratory volume (FEV1) with cyclophosphamide and rituximab (**Figure 1C-D**). SS-AD were mostly diffuse, associating bronchiolitis and bronchiectasis in 60% of cases. Here again, we did not find a significant worsening of PFT parameters with 9 years follow-up in SS-AD (**Figure 1B**), despite CT abnormalities worsening in 41% of cases at 6 years.

Table 1. Comparison between SS-ILD, SS-AD and pSS control

	SS-ILD, n=56	pSS control, n=112	SS-AD, n=31	pSS control, n=62
Clinical feature:				
Age, mean	56	56	56	56
Women	49 (87)	103 (92)	30 (97)	58 (93)
Death	7 (13)	7 (6)	2 (7)	3 (5)
Muscular	7 (13)*	3 (3)	3(10)	3 (5)
Splenomegaly	5 (9)*	1 (1)	2 (6)	2 (3)
ESSDAI, mean	16*	4	10*	4
ESSDAI (pulmonary excluded), mean	9*	4	7*	4
Incident lymphoma	5 (9)*	0	1(3)	0
Biology:				
Anti-SSA	41 (76)*	66 (59)	21 (70)	38 (65)
Anti-RNP	11 (22)*	2 (2)	0	1 (2)
Gammaglobulinemia, mean	23*	18	19	18
Beta2-microglobulinemia, mean	3*	2	3*	2

Data are n (%) unless otherwise indicated. Stars indicate significant comparisons to pSS control. Mann-Whitney and Fisher's exact test were used. *: p<0.05.

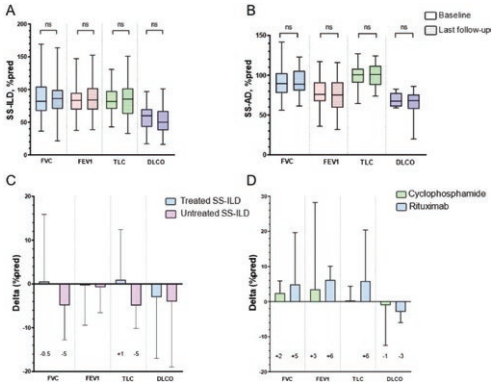

Figure 1. PFT evolution of SS-ILD and SS-AD Comparison of baseline and last follow-up PFT of SS-ILD (A) and SS-AD (B). Delta between last follow-up and baseline PFT of treated compared to untreated SS-ILD (C). Delta between post-therapeutical and pre-therapeutical PFT for cyclophosphamide and rituximab (D). Wilcoxon test was used. *: p<0.05.

Conclusion: SS-ILD are usually fibrosing and progressive manifestations of pSS, associated with disease activity, incident lymphoma and B cell biological markers. Despite the absence of randomized trials in SS-ILD, our results suggest an effect of the therapeutics. SS-AD are also associated with the disease activity and seems to progress slowly.

DETERMINATION OF DISTINCT PHENOTYPES OF PRIMARY SJÖGREN'S DISEASE USING CLUSTER ANALYSIS BASED ON CLINICAL AND BIOLOGICAL MANIFESTATIONS: DATA FROM 458 PATIENTS FROM THE PARIS SACLAY SJÖGREN'S SYNDROME COHORT

Keywords: Sjögren syndrome

Y. Nguyen[1,2], G. Nocturne[1,2], F. Desmoulins[1], J. Henry[1], R. Belkhir[1], E. Bergé[1], X. Mariette[1,2], R. Seror[1,2]. [1]*Bicetre Hospital, Rheumatology, Le Kremlin-Bicêtre, France*; [2]*Center for Immunology of Viral Infections and Auto-immune Diseases (IMVA), INSERM U1184, Autoimmunity team, Le Kremlin-Bicêtre, France*

Background: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease, with heterogenous manifestations. Main symptoms included dryness features due to the exocrinopathy, fatigue, and joint pain. In addition, systemic manifestations occur in approximately 30 to 40% of the patients with pSS. Previous attempts made to determine distinct pSS phenotypes used only symptom-based classifications, neglecting the B-cell biological activity and the systemic manifestations, which are clearly linked with disease prognosis.
Objectives: We aimed to identify distinct phenotypes among pSS patients, based on all disease features, including symptoms, systemic manifestations, and biological features, using a non-supervised hierarchical cluster analysis.
Methods: We included pSS patients enrolled in the prospective French Paris-Saclay cohort, if satisfying the ACR/EULAR criteria. We performed an unsupervised multiple correspondence analysis using 26 selected variables to widely cover pSS manifestations: VAS for pain, fatigue, ocular and oral dryness; systemic manifestations as defined by ESSDAI domains; biological parameters such as rheumatoid factor (RF), anti-SSA, -SSB, -RNP, -centromere, -DNA antibodies, high IgG levels, monoclonal component, cryoglobulinemia, low C4 levels; and abnormal Schirmer's test and presence of focal sialadenitis. The first axes were then considered to perform hierarchical clustering based on the Ward method. The number of clusters was determined visually on the plotted dendrogram and with the gain in inertia.
Results: We included 458 pSS patients in the analyses (95% women, median age 49 yrs). Cluster hierarchical classification yield in three homogenous groups of patients.

1. Cluster 1 (n=121) included patients with high symptom burden (median [IQR] ESSPRI 6.6 [5.6–7.7]), but low systemic activity (ESSDAI 1; [0-2])
2. Cluster 2 (n=110) included a higher proportion of men (15%) and of patients from African ancestry (19%), with high level of dryness (overall dryness VAS 66 [46–81]) and fatigue (VAS 70 [45–84] but low level of pain (pain VAS 53 [20–77]; high systemic activity (ESSDAI 5 [2–8]): lymphadenopathy (11%), cutaneous (7%), pulmonary (12%), PNS (11%), and articular (40%) involvements; frequent other auto-antibodies: anti-RNP (9.2%), anti-centromere (12%), anti-DNA (16%) and cryoglobulinemia (3.5%).
3. Cluster 3 (n=195) included younger patients (median age 44 yrs), with low symptom burden (ESSPRI 4.9 [3.3–6.2]), low systemic activity (ESSDAI 2 [1–4]), but with frequent B-cell activation signs: biological ESSDAI domain (58%), high IgG levels (52%), rheumatoid factors (58%), low C4 levels (22%); and higher rates of anti-SSA (86%) and -SSB (46%) antibodies.

Patients with history of lymphoma were identified in cluster 2 (n=8, 5.6%) and 3 (n=7, 3.6%).
Conclusion: Using an unsupervised clustering method, and including parameter that encompass all disease features, we identified three distinct subgroups of pSS patients that were 1/ high symptom burden without systemic features; 2/ Systemic features 3/ B-cell biologically active with low-symptom burden. Our study highlights the underlying idea of heterogeneous pathophysiological mechanisms and could help further stratifications among pSS patients. Further studies are needed to assess whether disease evolution is different across these subgroups.

Background: In the context of primary Sjögren's syndrome (pSS), only retrospective studies have investigated pregnancy outcomes with heterogeneous methods and contradictory results. An increased adverse pregnancy outcome (APO) frequency was found in most case-control studies, including more miscarriage and intrauterine fetal death (IUFD), preterm delivery, small for gestational age and intra-uterine growth retardation, as well as an elevated number of cesarean sections. Moreover, these studies rarely analyzed the impact of pregnancy on the course of pSS.
Objectives: To describe outcome of pregnancies, identify predictive factors for disease flares and APO in pSS patients and compare their risk of adverse pregnancy, delivery and birth outcomes to those of the general population.
Methods: The GR2 study is a French multicentric prospective cohort of pregnancies in women affected with auto-immune diseases. The ENP 2016 is a French national perinatal survey on a sample of around 14.000 births. We included GR2 pSS women fulfilling ACR/EULAR 2016 criteria with an ongoing pregnancy at 12 weeks' gestation. EULAR Sjögren's Syndrome Disease Activity Index and Patient Reported Index (ESSDAI and ESSPRI) were recorded at the first trimester of each pregnancy (baseline or bESSDAI), each trimester and at delivery, and a cumulative ESSDAI (cESSDAI) was calculated, defined as the sum of each domain maximum score during follow-up before pregnancy. A pSS flare was defined as an increase ≥3 points of the ESSDAI. APO were defined as the occurrence of any of the following events: unexplained IUFD ≥12 weeks, neonatal death, placental insufficiency (intrauterine growth restriction, preeclampsia/eclampsia, HELLP syndrome, and/or placental abruption) leading to a premature delivery <37 weeks or small for gestational age birth weight. To determine predictive factors for pSS flares we excluded pregnancies included after 18 weeks and for APO also excluded twin pregnancies and aborted pregnancies. We compared the risk of adverse pregnancy, delivery and birth outcomes occurring ≥ 20 weeks in pSS pregnancies (including those with congenital atrioventricular block) to general population pregnancies from the ENP 2016, after matching (ratio 1:4) on age, parity, residential area and on the type of pregnancy (singleton vs multiple pregnancy).
Results: 106 pregnancies occurred in 96 pSS women. A history of pSS systemic activity was found in 92/102 (90.2%) patients and a systemic activity at inclusion in 48/106 (45.3%). pSS flares occurred in 12/93 (12.9%) pregnancies. Analyses did not identify any baseline parameter associated with the risk of pSS flare, in particular no association with ethnicity, cESSDAI, bESSDAI, or bESSPRI, biological markers of activity or type of autoantibodies. APO occurred in 6/88 (6.8%) [APO-BLOCK in 13/106 (12.3%)] pregnancies including only one with a pSS flare (Table 1). Women with and without APO had comparable age, weight, smoking status, cESSDAI, bESSDAI or bESSPRI at inclusion. However, women with APO had more often antiphospholipid (aPL) antibodies (n available=55, 50% vs 3.9%, p=0.02) and a trend for more frequent RNP antibodies was found (33.3% vs 5.7%, p=0.07). Treatment exposure did not differ between groups. APO frequency in pSS did not differ from that of the ENP population (8.6% vs. 6.7%, OR= 1.31, 95% IC [0.53-2.98], p=0.52). No difference was found in cesarian section rates (21.9% vs 22.9%, p=0.94) and birth outcomes (including APGAR5 and newborns ICU hospitalizations) between both groups.
Conclusion: pSS flares and APO were observed respectively in 12.9% and 6.8% of pregnancies but rarely occurred together. aPL antibodies were associated with a higher risk of APO and a trend for anti-RNP antibodies was found. Adverse pregnancy, delivery and birth outcomes in pSS women were comparable to those of the general population.

POS0167 THE ANTIMALARIAL PROTECTIVE EFFECT AND A CLEAR CUT-OFF POINT FOR STEROID CUMULATIVE DOSE ASSOCIATED WITH DAMAGE ACCRUAL ON A 10-YEAR FOLLOW-UP SYSTEMIC LUPUS ERYTHEMATOSUS COHORT

Keywords: Organ damage, Systemic lupus erythematosus

R. Montes[1], E. Klumb[2]. [1]*universidade Federal Do Rio De Janeiro, Rheumatology, Rio De Janeiro, Brazil*; [2]*Pedro Ernesto University Hospital, Rheumatology, Rio De Janeiro, Brazil*

Background: Assessing damage accrual (DA) in patients with systemic lupus erythematosus (SLE) is complex but mandatory. Damage might be caused by the disease itself, comorbidities, and/or its pharmacological treatment or both. Among the pharmacological agents used to treat SLE, glucocorticoids (GC) are arguably the main cause of damage followed by lupus flares [1,2].
Objectives: This study aims to identify precise values of damage accrual related to damage in the long-term, the predictive positive and negative values for damage accrual of different steroid burden cut-offs points and the influence of other drugs, socioeconomic, ethnical and clinical aspects with damage in lupus patients.
Methods: A 10-years follow-up cohort of initially 190 patients, 147 alive at the end, with data regarding SLICC/ACR damage index (SDI) [3], clinical, social, economic and ethnical characteristics were recorded. SDI and medications accrual including GC were analyzed yearly both by patients interviews and chart reviews. A receiver operator characteristic (ROC) curve was developed to better comprehend relations among GC and damage, non-parametric data was analyzed by Mann-Whitney test and regression analyses was performed with Pearson test to evaluate factors related to DA over 10 years.
Results: Patients already with damage at baseline (SDI > 0) needed lesser GC accrual to develop new damage (4.2 g x 7.0 g, $p = 0.022$). Mean annual accrual of GC over a cut-off determined by the ROC curve analyses of 3.0 g (mean 8.22 mg per day) was independently associated with damage enhancement by SDI during the 10 years follow-up period compared to less than 3.0 g per year (OR=

5.32 p = 0.001) on multivariate logistic analyses (MLA) using stepwise forward, patients with mean GC annual accrual above this point present a positive predictor value (PPV) for DA of 88.7 %. Other cut-off points were evaluated and even for mean annual GC accrual of 0.5 g (approximately 1.37 mg per day) patients above this lower cut-off point had a PPV for DA greater than 75 % and the negative predictive value for the ones under this point was only 45.8 %. Patients using antimalarials (AMA) showed a protective effect for developing new damage (OR= 0.12, p = 0.009) on MLA and presented a higher proportion of patients under the 3.0 g/year of mean annual GC accrual (p = 0.005). Patients with lupus nephritis (OR= 2.50, p = 0.030), pleuritis (OR= 4.00, p = 0.003), age older than 44 years (OR= 5.14, p = 0.003) at recruitment and the use of azathioprine during the follow-up period (OR = 2.32, p = 0.044) were also independently associated with damage on MLA with stepwise forward.

Conclusion: The present cohort study findings highlight the protective effect of AMA regarding damage and its possible relation with a lower GC burden in the long-term. The harmful effects of GC on DA measured by SDI in patients with lupus is ratified. In contrast with other studies, it is shown that even low doses of GC might be associated with DA when chronically used in the long-term and no safe GC burden was found. There might be no safe GC dose for patients with more than a decade of SLE and physicians might need to pursuit SLE treatment with zero GC dose for the long-term when disease remission is established as soon as possible.

POS0168 IMPACT OF THE HYDROXYCHLOROQUINE LEVEL ON THE ECG QT INTERVAL IN PATIENTS WITH SYSTEMIC RHEUMATIC AUTOIMMUNE DISEASES: A REAL-LIFE STUDY

Keywords: Safety, Systemic lupus erythematosus, Cardiovascular disease

C. Raya-Santos[1], J. Rosas[1], M. Marco[2], A. Pons-Bas[1], R. Gallego-Campuzano[1], J. C. Cortés-Quiroz[1], M. Shalabi[2], J. M. Senabre Gallego[1], G. Santos Soler[1], L. Pons-Canet[1], J. A. Bernal[1], X. Barber[3], J. A. García-Gómez[3]. *[1]Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain*; *[2]Hospital Marina Baixa, Laboratory, Villajoyosa, Spain*; *[3]CIO University of Elche, CIO, Elche, Spain*

Background: NIL.

Objectives: To analyze the impact of the serum level of HCQ on the QTc interval, in patients with rheumatic systemic autoimmune diseases (RSAD), treated with this drug a long time.

Methods: Retrospective study, among patients with RSAD, treated with HCQ > 1 year, dose 200-400 mg/day (cases). Serum HCQ level was measured and the QTc interval of the ECG. Patients with EASR not treated with HCQ were included as a control group for QTc: weight, current treatment, and ECG was performed to obtain QTc. In patients with RSAD, the following was collected: 1) Epidemiological data of the patient 2) RSAD: diagnosis, year of diagnosis, time of evolution of the disease, own clinical and autoimmunity data, treatment and dose 3) HCQ: time in treatment, toxicity, symptoms and serum level. 4) ECG; QTc and heart rate (HR).

Results: 142 patients treated with HCQ for a mean of 8.3 (SD: 6.4) years, at a mean dose of 245 mcg/L (83.8), and 3.7 (1.3) mg/kg/day, are included. 129 (91%) are women, mean age: 57 (14.5) years, weight: 66 (15) kg. Diagnosis distribution: SLE: 72 (50%) patients, RA: 37 (26%), Sjögren syndrome: 18 (13%), palindromic rheumatism: 4 (3%), psoriatic arthritis: 3 (2%), antiphospholipid syndrome: 2 (1%) and other collagen diseases: 2 (1%) patients. Mean HCQ serum level: 185.6 mcg/L (124): 25 (28%) with a level <100 mcg/L (mean: 58 [28.5] mcg/L) and 117 (72%) >100 mcg/L (mean: 224 mcg/L [116]). On ECG, the mean HR: 72 bpm (11) and the mean QTc interval: 419 (33) ms, being prolonged (>440 ms) in 39 (27%) patients (range: 441-510 ms). Ten (7%) patients reported symptoms: palpitations: 7 (70%), dizziness in 2 (20%) and 1 (10%) patient an isolated pseudosyncopal picture (QTc: 441 ms); 58 (41%) patients were receiving treatment with a drug related to the risk of QTc prolongation: Possible (P: authorized doses, no risk of TdP): 8 (14%) patient, Conditional (C: risk in certain circumstances: excessive dose, interactions): 44 (76%), Defined (D: risk of TdP when used in licensed indications): 1 (2%). When comparing the mean QTc result of the EASR group treated with HCQ and the control group without HCQ (n: 32), no differences were detected (419.4 [33] vs 436 [51], p=0.072).

Among patients with HCQ level >100 mcg/L (n: 117/82%) vs <100 mcg/L (n: 25/18%), the mean daily dose of HCQ received (250 mg [87.7] vs 220 mg [57.7], p=0.33) and the one adjusted to the weight of the patient in both is higher (3.76 [1.4] mg/kg vs 3.18 [1] mg/kg, p=0.016). No relationship was observed between the HCQ level and the QTc result. The 39 (27%) patients with QTc >440 ms vs the 103 (73%) with QTc ≤ 440 ms were significantly older (61 [14] years vs 55 [14] years, p=0.007) and higher heart rate (75 [12] bpm vs 71 [10.6] bpm, p=0.016). No differences were detected between QTc result and HCQ dose or level.

Conclusion: In patients with EASR treated with maintenance doses of HCQ: 1) The serum level of HCQ is not related to prolongation of the QTc interval of the ECG. 2) QTc is significantly related to age and heart rate. 3) 40% of patients with prolonged HCQ treatment also receive other common drugs that can influence the QTc, however, it does not seem to cause symptoms of interest. 4) The EASR per se does not affect the QTc result.

Background: Systemic Lupus Erythematosus (SLE) patients experience frequent hospitalizations; lupus flares and infections have been shown to be the two most common causes.
Objectives: The aim of this study is to describe the main causes and predictors of first hospitalizations due to disease activity and infections in SLE patients.
Methods: SLE patients from GLADEL, a multi-ethnic, multi-national Latin-American (LA) cohort were studied. The first hospitalization during these patients' follow-up due to either infection and/or SLE disease activity was examined. Baseline sociodemographic, clinical, damage (SDI) and treatments were evaluated as possible predictors. First, descriptive analyses were performed. Predictors of infection or SLE disease activity associated hospitalization were identified using univariate and multivariate logistic.
Results: A total of 1341 patients were included; 1201 (89.6%) were female. Their median interquartile range (IQR) age at diagnosis was 27 (20-37) years and their median IQR follow up time 27.5 (4.7-62.2) months. 456 (34.9%) patients were hospitalized; 344 (75.4%), 85 (18.6%) and 27 (5.9%) were hospitalized for disease activity, infections, or both, respectively, as depicted in Graph 1. In the multivariable analysis, arthritis was associated with hospitalizations due to infection. Serositis, disease activity and damage were associated with hospitalizations due to disease activity. Older age, higher socioeconomic status and antimalarial use were found to be protective, as depicted in table 1.
Conclusion: In this large LA lupus cohort, one third of the patients had at least one hospitalization; of them, were due to SLE disease activity. Our findings call attention for controlling disease activity and preventing damage using antimalarials early in the disease course disease to prevent the first hospitalization.

Objectives: We aimed to characterise the all-cause mortality rate (MR) and the incidence of cancer in SLE patients receiving biologic and standard of care (SoC) therapies.
Methods: Patients recruited to the BILAG-BR 2010-2021 were included. Demographic and clinical data were recorded at recruitment. Mortality and malignancy data were collected from study centres, the UK Office of National Statistics and the National Cancer Register. Cox regression models were used to estimate the hazard ratios (HRs) of mortality and cancer in biologic-treated patients compared to SoC. Mortality models were adjusted for age, gender, co-morbidity, SLICC damage index (SDI) and hydroxychloroquine (HCQ) use. The standardised mortality ratio (SMR) and standardised incidence ratio (SIR) were calculated using death and cancer rates for the general UK population.
Results: During follow-up, (1463 patients with 5,962 person years [pys]), 32 incident cancers occurred in 31 individuals, a median (IQR) of 1.31 (0.63-3.36) years after registration. The overall incidence was 6.0 (3.8-7.6) per 1000 pys. Compared to the UK general population, the SIR (95% CI) was 1.21 (0.85-1.72). Using SoC as the comparator, the age and gender adjusted HR was 1.49 (0.57-3.92) for rituximab and 2.47 (0.57-10.58) for belimumab. Across the whole cohort, associated risk factors (table 1), included age at recruitment (HR 1.05 [1.02-1.08]) and male sex (HR 2.68 [1.13-6.41]). Following registration, 54 deaths occurred after a median of 1.8 (0.8-3.3) years. Crude MR was 9.15 (7.0-11.9) per 1000 pys. The SMR was 4.74 (3.63-6.19). The most common causes of death were infection (22, 40.7%), SLE (11, 20.3%) and cancer (6, 11.1%). MR was 3.3 (1.3-8.9) per 1000 py in the SoC, 11.3 (8.5-15.0) in the rituximab and 2.5 (0.4-17.9) in the belimumab group. Risk factors included age at recruitment (HR 1.07 [1.05-1.09]) and SDI (HR 1.34 [1.08-1.67]. HCQ use was protective (HR 0.30 [0.14-0.65]). In multivariate analysis, compared to SoC, risk was similar in rituximab (HR 2.36 [0.69-8.10) and belimumab groups (HR 1.41 [0.14-14.14]).
Conclusion: Although overall numbers are low, mortality rate and incidence of cancer appears to be broadly similar in SoC, rituximab and belimumab treated patients.

Table 1. Risk factors associated with risk of cancer and death in a cohort of patients with moderate-severe SLE

PATIENT-DOCTOR COMMUNICATION GAP - RESULTS OF A SPEED-SHOP ON "LUPUS FLARE" AT LUPUS2022 MEETINGS

Keywords: Patient reported outcomes, Quality of care, Systemic lupus erythematosus

A. Cornet[1], F. Marchiori[2], H. Stefánsdóttir[2], M. Mosca[3]. [1]*Lupus Europe, HQ, Brussels, Belgium*; [2]*Lupus Europe, PAN, Brussels, Belgium*; [3]*university of Pisa, department of rhumatology, Pisa, Italy*

Background: The Patient – Doctor communication gap is often discussed, and is one of the obstacles pointed by patients and doctors alike in the fruitful co-working of optimal treatments. Recognizing the difference between doctors and patients approach when confronted to a lupus flare is critical to bridge this gap and increase the effectiveness of jointly agreed treatment plans.
Objectives: Identify potential discrepancies between patient and doctors discussion starting points when facing a lupus flare. Are they "talking the same thing?", "do they have similar concerns in their minds?"
Methods: As part of the SL Euro lupus 2022 congress 57 participants, doctors and patients, took part in a speed-workshop to identify first "what makes them identify an event as a lupus flare" and then their "key concerns when facing a lupus flare". Answers were provided on post-its of different colours per type of participants, forcing short answers focusing on key aspects. The commonalities and discrepancies where then identified for further handling.
Results: A total of 57 statements identifying a lupus flare were collected and classified assessable (visible/ measurable) items, or specific symptoms. The results highlighted that the communication difficulty between patients and doctors starts from the very feeling of what a flare is. 91% of patients include in their recognition of a flare a factor that cannot be "easily" objectivated by a doctor such as fatigue (59.1%), or pain (50%). Only 36% of patients include an externally visible factors, most often fever. In contrast, 88% of doctors require an externally visible/measurable factor to "identify" a flare. These 2 different starting points can create a first communication gap, as well as a difference in the qualification of an event as a flare or not. A total of 93 concerns, sorted in "huge", "big", or "mid" were collected from participants. These items could be classified in 4 key groups: concerns around daily life & logistics; overall anxiety; symptoms and medication. When confronted to an event considered as a flare, patients have a perspective focusing on the impact of flares on their daily life and logistics (35% of huge concerns, 30% of all concerns), and face anxiety over disease/life in the future (30% of all concerns 19% of huge concerns); on the contrary the doctor's focus is on symptoms (67% of huge concerns, 46% of all concerns) and medications (29% of all concerns), with only 7% of the doctors focusing on the patients "immediate" daily life/logistics issues, and 18% on anxiety. This discrepancy of concern also hinders the patient-doctor communication.
Conclusion: Doctors and Patients starting points and concerns with regards to a lupus flare appear perfectly logical and fitting each individual's role in the relationship, with the doctor's primarily focused on the disease, and the patient on "how to live with it". However this different view may create an initial gap which needs to be bridged to enhance the therapeutic relationship. Acknowledging the existence of this gap is likely a first step towards an improved patient-doctor communication.

ARTERIAL STIFFNESS IN ANTIPHOSPHOLIPID SYNDROME: COMPARISON WITH DIABETES MELLITUS AND HEALTHY CONTROLS

Keywords: Anti-phospholipid syndrome, Cardiovascular disease

G. Evangelatos[1,2], G. Konstantonis[1], N. Tentolouris[1], P. Sfikakis[1,2], M. Tektonidou[1,2]. [1]*Medical School, National and Kapodistrian University of Athens, First Department of Propaedeutic Internal Medicine, Athens, Greece*; [2]*Medical School, National and Kapodistrian University of Athens, Joint Academic Rheumatology Program, Athens, Greece*

Background: Patients with Antiphospholipid Syndrome (APS) carry an increased burden of cardiovascular morbidity and mortality and have higher prevalence of traditional cardiovascular risk factors (CVRFs) and subclinical atherosclerosis [1]. Arterial stiffness (ArS) has emerged as an independent predictor of future cardiovascular events and death in the general population, beyond the effect of traditional CVRFs [2].

Objectives: We aimed to compare ArS measures in thrombotic APS patients and age- and sex-matched patients with diabetes mellitus (DM) and healthy controls (HC), and identify potential predictors of increased ArS in patients with APS.
Methods: ArS was evaluated by carotid-femoral Pulse Wave Velocity (cfPWV) and Augmentation Index normalized to 75 beats per minute (AIx@75) using the SphygmoCor device. All participants also underwent ultrasound examination of the carotid and femoral arteries for the detection of atherosclerotic plaques. Multivariate analysis was applied for comparing ArS measures between groups and for the assessment of ArS predictors in the APS group.
Results: One-hundred and ten APS patients (70.9% female, mean age: 45.4 years), and equal numbers of DM patients and HC were included. After adjustment for age, sex, traditional CVRFs and atherosclerotic plaque presence, APS exhibited similar cfPWV (p=0.456) but increased AIx@75 (beta=4.640, 1.668-7.611, p=0.002) versus HC. APS patients had lower cfPWV (p<0.001) but similar AIx@75, (p=0.150) compared to DM patients. Using multiple linear regression analysis, cfPWV in APS group was independently associated with age (beta=0.056, 0.034-0.078, p<0.001), mean arterial pressure (MAP) (beta=0.070, 0.043-0.097, p<0.001), atherosclerotic plaques in femoral arteries (beta=0.732, 0.053-1.411, p=0.035) and anti-β2GPI IgM positivity (beta=0.696, 0.201-1.191, p=0.006). AIx@75 was associated with age (beta=0.334, 0.117-0.551, p=0.003), female sex (beta=7.447, 2.312-12.581, p=0.005) and MAP (beta=0.425, 0.187-0.663, p=0.001).
Conclusion: Patients with APS exhibit comparable cfPWV to healthy individuals but elevated AIx@75, similar to DM, implying impaired vascular health in APS. Age, female sex, MAP, atherosclerotic plaques and anti-β2GPI IgM are linked with enhanced arterial stiffening in APS. Given its prognostic value, ArS evaluation may help to improve cardiovascular risk stratification in APS patients.

bDMARDS in RA 2.0: about the good and the bad___

POS0173 **GENDER DIFFERENCES IN TREATMENT RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TUMOR NECROSIS FACTOR INHIBITOR: A COHORT STUDY FROM THE DANBIO REGISTRY**

Keywords: Gender/diversity issues, bDMARD

K. B. Lauridsen[1,2], K. Duch[2,3], A. S. Mortensen[2], R. Cordtz[2], S. Kristensen[2,4], M. L. Hetland[5,6], L. Dreyer[2,4,7]. *[1]Aalborg Universityhospital, Department of Clinical Immunology, Aalborg, Denmark*; *[2]Center of Rheumatic Research Aalborg (CEERA), Department of Rheumatology, Aalborg University Hospital, Aalborg, Denmark*; *[3]Aalborg University Hospital, Unit of Clinical Biostatistics, Aalborg, Denmark*; *[4]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark*; *[5]University Hospital of Copenhagen Rigshospitalet, DANBIO and Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Glostrup, Denmark*; *[6]Faculty of Health and Medical Sciences, University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*; *[7]DANBIO registry, DANBIO registry, Copenhagen, Denmark*

Background: TNF-inhibitors (TNFI) have improved the treatment of rheumatoid arthritis (RA) over the last two decades, but it is uncertain how much gender affects treatment response and drug adherence.
Objectives: The aim of this population-based study is to investigate effect of gender overall and across different age groups on treatment response and drug adherence in patients with RA treated with their first TNFI.
Methods: The study is an observational, nationwide cohort study using the DANBIO register linked by patients' unique civil registration number to The Danish Civil Registration System and The Danish National Prescription Registry. RA patients starting their first TNFI between 1st of January 2006 and 31st of December 2020 were included. Modified Poisson regression with robust variance estimator was used to calculate the relative risk (RR) with 95% confidence interval (95% CI) of having a good EULAR response at 4 and 12 months, respectively, comparing men to women. Linear regression was used to estimate mean difference in DAS28-CRP. The data was also analyzed in age groups to display a possible age-dependent gender effect. To quantify drug adherence for men compared to women, a crude and adjusted cause-specific Cox regression for treatment termination was performed. Hazard ratios (HR) are presented with 95% CI for 0-1, >1-3 and >3-5 years after TNFi treatment start. The Aalen-Johansen estimator was presented to illustrate cause-specific treatment termination.
Results: From DANBIO, 7386 RA patients starting their first TNFI were identified; and of these 5523 (75%) were women. Women had higher DAS28-CRP at baseline, 4 and 12 months, than men. At 4 months no significant difference in treatment responses was observed, but a tendency of better response in men compared to women was seen among patients ≤50 years (Table 1). At 12 months visit the EULAR over all good response rate was significantly higher among men, RR adjusted was 1.13 (1.05;1.21). The same trend was seen in all age groups at 12 months though not statistically significant. The hazard for termination of first TNFI treatment due to no effect, adverse events, infections, cancer or reason not stated was lower in men compared to women. HR within the first year was 0.90 (0.83;0.96), 1-3 years 0.91 (0.83;0.99), and from 3-5 years 0.93 (0.81;1.06), and did not change when adjusting for age, baseline DAS28-CRP, disease duration, co-treatment with scDMARD, and seropositivity. 10 years drug adherence is shown in figure 1.
Conclusion: After 4 and 12 months of treatment with first TNFI women have slightly higher DAS28-CRP and overall lower chance of achieving EULAR good response. In addition, women have an increased risk of discontinuation which deserves further attention.

POS0174 THE IMPACT OF DIFFERENT DMARDS ON MORTALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PREVALENT INTERSTITIAL LUNG DISEASE

Keywords: Disease-modifying Drugs (DMARDs), Lungs, Rheumatoid arthritis

T. Rudi[1], V. Zietemann[1], M. Schaefer[1], Y. Meissner[1], A. Zink[2], A. Krause[3], A. Strangfeld[1,4]. *[1]German Rheumatism Research Centre, Epidemiology and Health Services Research, Berlin, Germany*; *[2]Scientific Advisory Board, RABBIT, Berlin, Germany*; *[3]Immanuel Krankenhaus, Rheumatology, Berlin, Germany*; *[4]Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: Interstitial lung disease (ILD) is one of the most common extra-articular manifestations of rheumatoid arthritis (RA) with a high mortality risk. Only few studies examined the association between RA treatment and mortality in patients with RA-ILD, and these studies do not include all available DMARDs and tend to be of poor quality [1].
Objectives: To investigate the impact of treatment on all-cause mortality in patients with RA-ILD taking inflammation, traditional risk factors and comorbidities into account.
Methods: RA patients enrolled and observed in the biologics register RABBIT between 01/2007 and 10/2021 with an ILD, reported either at enrolment or during follow-up, were selected for the analysis. Observation started at the time of ILD reporting (= baseline) death, dropout or end of follow-up, whichever came first. Time-varying cox regression (= main model) was applied, taking into account all treatment exposures and covariates on a monthly basis (Figure 1). Sensitivity analyses comprised two alternative treatment exposures: a cumulative model (calculated as cumulative exposure in months for every treatment divided by total months of observation time), and an intention-to-treat model (treatment at baseline as exposure). Missing data was imputed 10 times. All models were adjusted by inverse probability weighting and number of comorbidities as covariate.
Results: Out of 15,566 cohort participants, 381 patients were identified as prevalent ILD cases. The total observed time was 1,258 person years, and 97 patients (25 %) died. Patients exposed to T cell co-stimulation modulator (T cell), B cell targeted therapy (B cell), and Janus kinase inhibitors (JAKi) had higher RA disease scores and multiple comorbidities (Table 1). In contrast, patients with csDMARD therapy or tumour necrosis factor inhibitor (TNFi) were less affected overall. Those receiving interleukin-6 inhibitors (IL6i) were the youngest and had a comparable number of comorbidities as patients with csDMARDs or TNFi. Patients not exposed to any DMARD differed from the other treatment groups in having lower disease activity, but a higher number of comorbidities and prior treatments. The main Cox regression model showed a 2.8-fold higher mortality risk for patients receiving no DMARD treatment compared to TNFi (Figure 1). Numerically, hazard ratios < 1 were observed for IL6i, T cell, B cell, JAKi and csDMARD in reference to TNFi but without statistical significance. The results of the sensitivity analyses pointed in the same direction.
Conclusion: To our knowledge, this is the first study to investigate the risk of all-cause mortality in RA-ILD for all available DMARD treatments jointly, using month-level data. In accordance with the few existing recommendations and studies, all non-TNFi-biologics as well as JAKi showed a protective signal compared to TNFi in all three regression models. Furthermore, patients who did not receive any DMARD had an increased risk of mortality. However, the study sample size was small, the results should thus be interpreted with caution.

POS0175 "DO DISEASE MODIFYING ANTIRHEUMATIC DRUGS INFLUENCE THE FRACTURE RISK IN RHEUMATOID ARTHRITIS?" THE HUNT STUDY, NORWAY

Keywords: Epidemiology, bDMARD, Rheumatoid arthritis

I. Tronstad[1,2], M. Hoff[3,4], J. Horn[1,5], S. A. Vikjord[1,2], V. Videm[6,7], T. Nilsen[8,9], A. Langhammer[1,10]. *[1]Norwegian University of Science and Technology, HUNT Research Centre, Department of Public Health and Nursing, Trondheim, Norway*; *[2]Levanger Hospital, Department of Medicine and Rehabilitation, Levanger, Norway*; *[3]Norwegian University of Science and Technology, Department of Neuromedicin and Movement Science, Trondheim, Norway*; *[4]St. Olav's University Hospital, Department of Rheumatology, Trondheim, Norway*; *[5]Levanger Hospital, Department of Obstetrics and Gynecology, Levanger, Norway*; *[6]Norwegian University of Science and Technology, Department of Clinical and Molecular Medicine, Trondheim, Norway*; *[7]St. Olav's University*

Hospital, Department of Immunology and Transfusion Medicine, Trondheim, Norway; [8]*Norwegian University of Science and Technology, Department of Public Health and Nursing, Trondheim, Norway*; [9]*St. Olav's University Hospital, Clinic of Anaesthesia and Intensive Care, Trondheim, Norway*; [10]*Levanger Hospital, Nord-Trøndelag Hospital Trust, Levanger, Norway*

Background: Rheumatoid arthritis (RA) is associated with reduced bone mineral density and increased fracture risk. Bone sparing properties are reported for biological (b) disease-modifying antirheumatic drugs (DMARDs) (1), but previous studies have not found bDMARDs to reduce fracture risk [2]. Knowledge is sparce regarding fracture risk in individuals with RA using different types of DMARDs compared to the general population.
Objectives: To investigate the effect of RA on fracture risk, and examine if bDMARD treatment influences this association.
Methods: The Trøndelag Health Study (HUNT) is a population-based longitudinal study in central Norway. We included all participants who had attended at least one of the latest three HUNT surveys, using the first participation as baseline. RA status was obtained by linkage to the patient records at the regional hospital using International Classification of Disease codes (ICD9 and 10) for Major Osteoporotic Fractures (MOF), as well as further validation of medical records regarding date of RA diagnosis and use of DMARDs (divided into the following groups: never DMARDs, conventional synthetic(cs) DMARDs only, or ever bDMARDs). All RA diagnoses were validated according to American College of Rheumatology/ European League Against Rheumatism criteria[3]. RA status was registered at baseline and updated if RA was diagnosed later. Participants were followed until the first MOF, death, emigration, or end of follow-up on 21.10.2021. Cox regression was used to estimate hazard ratios (HR) for MOF in RA participants in general and by treatment group, compared to the people without RA. Confounders were identified using directed acyclic graphs (DAGs) and included sex, age at inclusion and smoking status at baseline.
Results: In total, 96,354 participants were included, 1,033 with RA (mean age 55.5 years, 65.8% women) and 95,321without RA (mean age 46.3 years, 53.0% women). Overall, 401 participants were diagnosed with RA before inclusion in HUNT and 632 during follow-up.

Table 1. RA independent of treatment was associated with almost 50% increased risk of MOF compared to non-RA (HR 1.44). By treatment group, never DMARDs had highest risk of MOF, followed by csDMARDs. Treatment with bDMARDs was not associated with MOF. Incidence rates (IR) per 1000 person-years were higher in RA overall and in all DMARD treatment groups compared to non-RA.

	Participants	MOF			Unadjusted	Adjusted	
	n	n	IR	95% CI	HR	HR	95 % CI
Non-RA	95,321	10,503	7.0	6.9-7.2			
RA independent of treatment	1,033	221	18.0	15.8-20.5	2.35	1.44	1.25-1.65
RA treatment group							
Never DMARDs	57	17	33.4	20.7-53.7	4.42	2.05	1.28-3.31
csDMARDs only	727	175	20.5	17.7-23.8	2.68	1.50	1.29-1.75
Ever bDMARDs	230	27	8.8	6.0-12.8	1.13	1.03	0.70-1.50

Adjusted for age at inclusion, sex, and smoking status at baseline. CI: confidence interval. DMARDs group missing for 19 RA participants including 2 individuals with a MOF.

Conclusion: RA was associated with MOF. However, in RA individuals treated with bDMARDs, an association with MOF was not seen. This is an encouraging result and might be of importance when evaluation future treatment regiments in this patient group.

Background: Few studies have addressed what is the optimal therapeutic option in patients with rheumatoid arthritis (RA) who failed treatment with JAK inhibitors (JAKi).
Objectives: The aim of this study was to evaluate the drug retention, efficacy, and safety of biologics or JAKi in patients who showed an inadequate response to JAKi in a multicenter longitudinal cohort.
Methods: Patients who showed an inadequate response to JAKi and then switched to TNF inhibitors [TNFi], IL-6 inhibitors [IL-6i], or other JAKi were enrolled in this study. The drug retention rates of the three treatment groups were estimated at 12 months using the Kaplan-Meier method and compared after adjusting for potential confounders using Cox proportional hazards models. Disease activities evaluated with Clinical Disease Activity Index (CDAI) were also compared at 1, 3, 6, and 12 months between the three groups using the Mann-Whitney U test or the Wilcoxon signed-rank test. The reasons for drug discontinuation were analyzed using Fisher's exact test.
Results: A total of 140 treatment courses (TCs) from 106 patients were included (TNFi: 36 TCs, IL-6i: 34 TCs, and JAKi: 70 TCs). Baseline characteristics showed no difference in sex, disease duration, number of previous biologics/JAKi use, and ACPA positivity between the three groups, but the concomitant PSL dose was significantly lower in the JAKi group than in other groups (P=0.049). After adjusting potential confounders, drug retention rates of the three treatment groups did not differ; however, when limited to patients who initiated subsequent biologics/JAKi within 100 days after the termination of prior treatment with JAKi, the TNFi group exhibited a superior drug retention rate compared to the JAKi group (P=0.048, Figure 1A-1C). Regarding disease activity, the baseline CDAI of the TNFi group was significantly higher than the other groups (P=0.01, Figure 1D, 1E); however, the TNFi group tended to show better improvement in disease activity than the other groups. The reasons for drug discontinuation were not different between the three groups.
Conclusion: TNFi may have a therapeutic advantage compared to other therapeutic options in patients who failed treatment with JAKi.

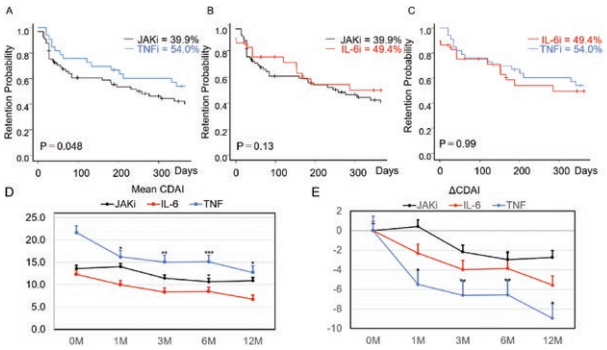

Figure 1. (A) Comparison of drug retention between JAKi and TNFi. (B) Comparison of drug retention between JAKi and IL-6i. (C) Comparison of drug retention between TNFi and IL-6i. (D) Time course of mean CDAI in the three treatment groups. (E) Time course of CDAI improvement compared in the three treatment groups. TNFi, TNF inhibitors; IL-6i, IL-6 inhibitors; JAKi, JAK inhibitors; CDAI, Clinical Disease Activity Index.

INFECTION INCIDENCE, TIMING, AND DOSE DEPENDENCY IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH RITUXIMAB: A RETROSPECTIVE COHORT STUDY

Keywords: Disease-modifying Drugs (DMARDs), Rheumatoid arthritis, bDMARD

L. Veeken[1], M. Opdam[1,2], L. M. Verhoef[1], C. Popa[1], R. Van Crevel[3], A. Den Broeder[1,4]. [1]*Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands*; [2]*Radboud University Medical Center, Radboud Institute for Health Sciences, Nijmegen, Netherlands*; [3]*Radboud University Medical Center, Infectious Diseases, Nijmegen, Netherlands*; [4]*Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*

Background: Rituximab (RTX) is a safe and effective treatment for rheumatoid arthritis (RA). In The Netherlands, RTX is usually administered intravenously every six months in standard low dose (2x500 mg or 1x1000 mg). Ultra-low doses (1x500 or 1x200 mg every six months) have shown to be effective as well for continued treatment for RA patients who are in remission.[1] Despite its efficacy and safety, there are some concerns about infection risk for RTX. Preliminary data suggest a dose and time dependent infection risk with a higher risk in higher doses and shortly after infusion.[1,2]
Objectives: The aim of this study was to compare infection incidence rates (IRs) in a real-life population of RA patients between standard low or ultra-low dosed RTX, with an additional focus on time since last infusion.
Methods: RA patients treated with standard low or ultra-low dosed RTX in the Sint Maartenskliniek (The Netherlands) between 2012 and 2021 were included in this retrospective cohort study. Patient-, disease-, treatment- and infection characteristics were retrieved from electronic health records. Infusions given within 30 days were considered as one RTX treatment. As RTX is usually given every six months, only infections occurring within 6 months after administration were included. In absence of the exact date of an infection, the start date was imputed using single imputation based on the known start week, month or period of infection. Infection IRs, dose-dependency and time relations with RTX infusion were analyzed using mixed-effects Poisson regression with correction for confounders. After Bonferroni correction, results were considered statistically significant if p<0.025.
Results: Among 490 patients followed for 1254 patient years, 819 infections were identified (65/100 patient years). Most infections were mild (89%) and respiratory tract infections were most prevalent (49%). Infection IRs were 41, 54 and 71 per 100 patient years for doses of 200 mg, 500 mg and 1000 mg, respectively. Incidence rate ratio (IRR) was significantly lower only for 200 mg in comparison to 1000 mg (adjusted IRR 0.64 (95% CI 0.45-0.93, p=0.019)). Infections seemed to occur more frequently – although not statistically significant - within the first two months after infusion in comparison to later on in the treatment cycle (table 1).
Conclusion: Ultra-low dosing, and especially 200 mg, of RTX is associated with a lower infection risk in RA. Additionally, a trend of higher IR of infections shortly after infusion was found. Therefore, future optimization focusing on ultra-low dosing and slow release of RTX (e.g. by subcutaneous administration) may further lower infection risk in addition to reducing costs and administration time. In clinical practice, physicians should consider offering 500 mg and especially 200 mg RTX dosage to RA patients in sustained remission, instead of continuing the 1000mg dosage.

DISEASE ACTIVITY GUIDED TAPERING OF RITUXIMAB IN CLINICAL PRACTICE: A RETROSPECTIVE COHORT STUDY OF RHEUMATOID ARTHRITIS PATIENTS

Keywords: Rheumatoid arthritis, Tapering, bDMARD

M. Wientjes[1], J. Van Huissteden[1], L. M. Verhoef[1], A. Den Broeder[1,2]. [1]*Sint Maartenskliniek, Department of Rheumatology, Ubbergen, Netherlands*; [2]*Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands*

Background: The REDO trial (REtreatment with Rituximab in RhEumatoid arthritis: Disease Outcome after Dose Optimisation) showed that ultra-low-dose (500mg or 200mg) rituximab (RTX) was similarly effective to 1000mg in the majority of rheumatoid arthritis (RA) patients. [1] These results led to the implementation of a disease activity guided dose optimization (DAGDO) protocol for RTX at the Sint Maartenskliniek since January 2019. This protocol includes stepwise tapering of RTX (after the initial dose of 1000mg) towards 500mg, 200mg and full withdrawal if DAS28-CRP < 2.4 (or 2.9 in patients with disease duration >3 years).
Objectives: We aimed to validate the findings from the REDO study in clinical practice, by determining the effect of RTX tapering on disease activity and RTX dosage compared to standard low dose RTX treatment (≥1000mg every six months).
Methods: A retrospective cohort was conducted of patients who 1) used RTX between April 2012 and February 2022, 2) had a clinical diagnosis of rheumatoid arthritis (according to either 1987 or 2010 ACR criteria, and/or by clinical diagnosis from the treating rheumatologist, 3) were eligible for dose reduction (i.e. reached a DAS28-CRP score of 3.5 or lower for at least 6 consecutive months during RTX use), and 4) had at least two DAS28-CRP measurements during follow-up. We identified three treatment periods for which we compared the mean disease activity scores: (i) full dose RTX continuation period, (ii) RTX DAGDO period, and (iii) stable RTX dose (and interval) after DAGDO (at least 12 months after the last tapering attempt). Primary outcome was the difference in mean DAS28-CRP between the three treatment periods. This was analysed using a linear mixed-model with a random intercept, including age, disease duration, concomitant csDMARD use (all

at moment of DAS28 measurement), seropositivity for ACPA and/or rheumatoid factor and sex as potential confounders. The mean percentage of the rituximab Daily Defined Dose (%DDD) per treatment period was calculated as secondary outcome, with 1000mg/6months as 100% reference.

Results: A total of 387 patients were included in the cohort, with a mean of 9.2 DAS28-CRP measurements (SD: 6.0) available per patient. Median follow-up time was 46 months (IQR: 25-78). 299 patients attempted tapering during follow-up and entered period 2 at least once, of whom 226 also entered period 3. The mean DAS28-CRP was 2.37 (95% CI: 2.29, 2.44) for period 1, 2.32 (95% CI: 2.24, 2.40) for period 2, and 2.27 (95% CI: 2.18, 2.36) for period 3, the latter significantly lower compared to period 1 (p=0.022). The mean percentage of the DDD for the three time periods was 111% for the continuation period; 64% in the DAGDO period and 71% in the stable RTX dosage period.

Conclusion: This relatively large retrospective cohort study shows that DAGDO of RTX is effective for rheumatoid arthritis patients doing well on full dose rituximab, and leads to relevant dose reduction. The lower mean disease activity scores in period 3 may be affected by survival bias, as solely patients using RTX successfully for a longer time reach period 3. However most patients that entered period 2 also entered period 3, and mean disease activity in period 2 was not increased compared to period 1. Wide implementation of tapering protocols for RTX in RA patients should be contemplated.

POS0179 PAIN CHARACTERISTICS IN PEOPLE WITH ACTIVE RHEUMATOID ARTHRITIS RECEIVING ADALIMUMAB AND ABATACEPT: A FEASIBILITY TRIAL OF NOCICEPTIVE, NEUROPATHIC AND PAIN SENSITISATION COMPONENTS

Keywords: Pain, Clinical Trials, bDMARD

L. Ahmed[1], K. Biddle[1], A. Blundell[1], S. Koushesh[1], P. Kiely[2,3], P. Sedgwick[3], N. Sofat[1]. [1]*St George's University of London, Institute for Infection and Immunity, London, United Kingdom*; [2]*St George's University Hospitals NHS Foundation Trust, Department of Rheumatology, London, United Kingdom*; [3]*St George's University of London, Institute of Medical and Biomedical Education, London, United Kingdom*

Background: There has been recent advancement of our understanding of pain in rheumatoid arthritis (RA). With the advent of biologic disease-modifying anti-rheumatic drugs (DMARDs), clinicians managing RA have a wide range of treatments to manage active disease. Many DMARDs are effective at achieving suppression of inflammation, but pain remains a key issue in RA. Despite nociceptive pain being a major feature of RA, other aspects of RA pain are associated with neuropathic and nociplastic components. Nociplastic pain is described as widespread, without evidence of proportionate tissue or nerve damage. Pain processing by the central nervous system can maintain and increase RA pain.

Objectives: This study aimed to evaluate the causes and underlying mechanisms of pain in RA by conducting a randomised feasibility trial. Our study evaluated the pain characteristics in subjects with RA randomised to different classes of biologic therapy including TNF inhibitors (adalimumab) and T cell modulators (abatacept). In this study, we evaluated distinct aspects of pain including nociception by Visual Analog Scale (VAS), neuropathic (PainDETECT questionnaire) and nociplastic pain components using pain pressure thresholds (PPT) by quantitative sensory testing (QST).

Methods: A total of 25 participants were recruited between August 2020 and October 2022; 13 subjects were randomised to adalimumab and 12 to abatacept. All participants continued with methotrexate therapy during the study ranging between 10-25 mg weekly. The primary outcome measures included change in VAS for pain, painDETECT and PPT after 12 months' treatment in each arm. PPT were measured using a hand-held algometer (Somedic) in the wrist and finger joints, large joints, sternum and malleolus, with 3 readings taken per region and a mean value recorded (kPa) as we have previously described [1]. Subjects were also stratified by CCP antibody status.

Results: The mean age was similar in the two groups (abatacept: mean (SD) 56.5 (13.5) years versus adalimumab: 53.9 (12.4) years). There were 12 (92%) female participants in the abatacept group and 10 (83%) in the adalimumab group. All subjects recruited to the study had a Disease Activity Score (DAS28) greater than 5.1 at baseline. There was an improvement from baseline over 12 months of follow-up in VAS pain, with a mean (SEM) of 3.7 (0.82) in the abatacept group and 2.3 (1.10) in the adalimumab group. For painDETECT measures, there was an improvement in painDETECT scores from baseline over 12 months of treatment (mean (SEM)) by 5.8 (1.93) in the abatacept group and 4.6 (2.54) in the adalimumab group. The change in PPT measures over 12 months is shown in Figure 1. Higher (positive) values for PPT indicate a higher pain threshold, Figure 1 shows a mean improvement with all subjects being able to tolerate more pain on pressure algometry.

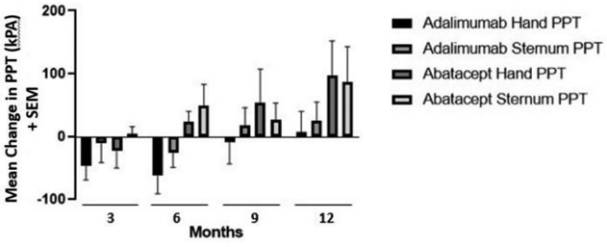

Figure 1. Changes in PPT in the study population over time

Conclusion: This study demonstrates that subjects with active RA demonstrate specific modalities of pain, including nociceptive, neuropathic and nociplastic elements. Furthermore, biologic therapies with different mechanisms of action may improve RA pain through distinct mechanisms. A greater improvement was observed in central (sternum) and peripheral (hand) pain sensitisation with abatacept compared with adalimumab after 12 months' treatment. It is suggested that abatacept, a T-cell modulator, resulted in a greater improvement in pain sensitisation compared with adalimumab. Since T cells are involved in pain mediation, including by infiltrating nerves and impacting memory T cell function, further work is required to investigate the impact of T cell modulation on pain in RA. Larger future studies are required for validation of our findings.

POS0180 ACR20 RESPONSE AS SURROGATE OF ACR70 RESPONSE IN RHEUMATOID ARTHRITIS: A TRIAL-LEVEL ANALYSIS FROM A SYSTEMATIC REVIEW OF RANDOMIZED TRIALS

Keywords: bDMARD, Clinical Trials

A. Ah Koon1, C. Confavreux1, G. Grenet2, S. Mainbourg3, J. P. Larbre1, F. Coury1, J. C. Lega1, E. Massy1. [1]*Hospices Civils de Lyon, Rhumatologie, Lyon, France*; [2]*Hospices Civils de Lyon, Pharmacologie, Lyon, France*; *3Hospices Civils de Lyon, Lbbe, Lyon 1, Lyon, France*

Background: The approval by medicines regulatory agencies of new therapeutic agents in rheumatoid arthritis (RA) is based on results of phase III randomized controlled trials. The RA trials have been mainly used ACR20 response as primary endpoint. Conversely, this outcome is not clinically relevant for significant improvement of patient's quality of lile.
Objectives: We aimed to explore the surrogacy between ACR20 and ACR70 in rheumatoid arthritis.
Methods: We performed a systematic review search by screening randomized clinical trials registered in MEDLINE, EMBASE and the Cochrane Library between January 1990 and June 2021. We included all randomized trials (phase II and III trials, including multiarm design) that compared biotherapies or JAK inhibitors with csDMARDs or placebo with available ACR20 and ACR70 response. The coefficient of determination R2trial between these two outcomes were estimated using weighted metaregression. To validate the surrogacy, the coefficient of determination (R^2trial) should be superior than 0.65 and close to 1. The lower limit of 95% prediction interval needed to be upper than 0.5 to predict a weak surrogacy and upper than 0.72 to predict a strong surrogacy. The 95% prediction interval for R2trial was calculated with the percentile bootstrapping method.
Results: We included 189 randomized trials totalizing 81,734 patients. Using 322 comparisons, the coefficient of determination R^2trial for estimating the relation between ACR20 on ACR70 responses is 0.55 (95% prediction interval 0.47-0.63). In subgroup analyses, the R^2trial for the anti-TNF therapeutic class was 0.69 (95% prediction interval 0.56-0.78). The R^2trial in other subgroup analyses (double-blind design, superiority studies, multicentric studies, year of publication, corticosteroid use, small-study effect, and other therapeutic classes) were not relevant for surrogacy.
Conclusion: There is no surrogacy between ACR20 and ACR70 in RA. The use of ACR20 as primary outcomes should be limited to phase II trials and is not suitable for health technology assessment of benefit-risk ratio.

Background: The impact of autoantibodies on the efficacy of biological disease-modifying antirheumatic drugs (bDMARDs) in patients with rheumatoid arthritis (RA) is not yet clear. Despite the fact that this information has been collected by several randomized controlled trials (RCTs), efficacy data for seropositive and seronegative patients separately have generally not been published.
Objectives: To comprehensively investigate the efficacy of bDMARDs in patients with RA with RF/ACPA compared to patients without these autoantibodies.
Methods: Previous systematic literature reviews performed by EULAR RA management task forces were searched for relevant RCTs published before February 2016[1–3]. RCTs including both autoantibody-positive (≤80% of total population) and -negative RA patients were eligible. We contacted authors and/or sponsors of RCTs to report aggregate results from analyses of individual patient data on clinical efficacy outcomes stratified for the presence of autoantibodies (RF+ vs RF-, ACPA+ vs ACPA-). Per trial, relative risks (RR) or mean differences comparing two groups (RF+ vs RF-, ACPA+ vs ACPA-) were calculated for various outcomes (ACR 20/50/70, DAS28 remission, delta DAS28, delta HAQ and radiographic progression) at the timing of the primary endpoint for the bDMARD-arm and the non-bDMARD-arm separately. Subsequently, relative risk ratios (RRRs) were computed, as the ratio of RR of the bDMARD-arm and the RR from the non-bDMARD-treated arm, reflecting whether seropositivity preferentially affected treatment response to bDMARD therapy. A meta-analysis was conducted using a mixed-effect meta-regression in subgroups of patients according to baseline autoantibody status.
Results: Data from 28 eligible RCTs were analyzed and from 23 pooled: 6 including csDMARD-naïve patients, 14 including csDMARD-inadequate responders (csDMARD-IR) and 3 including tumor necrosis factor inhibitor (TNFi)-IR patients. In csDMARD-naïve and csDMARD-IR, seropositivity was not associated with a better response to bDMARDs: Pooled 6-month ACR20 RRRs were 1.02 (0.88-1.18) and 1.09 (0.90-1.32), respectively (Figure 1A and B). Other outcomes followed the same pattern, with no difference between the groups. In TNFi-IR patients, based on 3 trials, the 6-month ACR20 RRR was 2.28 (1.31-3.95) (Figure 1C), favouring efficacy in seropositive patients. Other outcomes showed a similar effect, although with large confidence intervals and several reflecting a non-significant difference between the groups (Table 1).
Conclusion: In csDMARD-naïve and csDMARD-IR patients, autoantibodies did not have an impact on the efficacy of bDMARDs in RA. In TNFi-IR patients, there is a possible higher efficacy of bDMARDs in the seropositive group, but the low number of trials, large confidence intervals and inconsistent results across outcomes ask for caution in the interpretation. Seronegative TNF-IR patients may have very heterogenous underlying pathophysiological mechanisms, with a lower probability of good treatment response. Overall, in less treatment-resistant patients, the presence of autoantibodies was not associated with the treatment effect of bDMARDs.

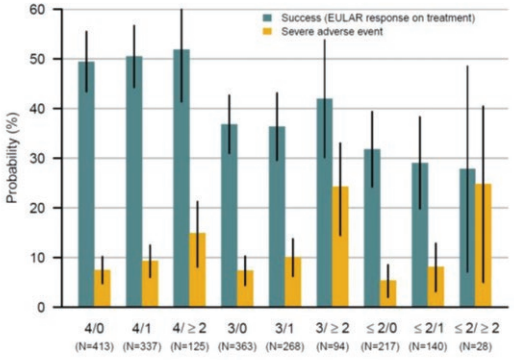
Seror[1,2]. *[1]Bicetre Hospital, AP-HP.Sud, Université Paris Saclay, Rheumatology, Le Kremlin-Bicêtre, France*; *[2]Center for Immunology of Viral Infections and Auto-immune Diseases (IMVA), INSERM U1184, Autoimmunity Team, Le Kremlin-Bicêtre, France*; *[3]Hôpitaux Universitaires de Strasbourg, Rheumatology, Strasbourg, France*; *[4]Center Research Epidemiology And Statistics - Inserm University Paris City, METHODS, Paris, France*; *[5]Lapeyronie Center University Hospital, Rheumatology, Montpellier, France*; *[6]CHU De Rouen, Rheumatology, Rouen, France*; *[7]CHU Purpan, Rheumatology, Toulouse, France*; *[8]CHRU de Lille, Rheumatology, Lille, France*; *[9]CHU de Bordeaux, Rheumatology, Bordeaux, France*

Background: Most randomized clinical trials (RCTs) are explanatory studies examining whether a therapy can work under ideal circumstances. Rituximab (RTX) has been approved for treatment of rheumatoid arthritis (RA) following the results of three RCTs [1–3], including about 1000 patients. However, less than 10% of real-life patients was found to be eligible to these registration trials, because of restrictive inclusion criteria or exclusion criteria such as co-morbidities or undesired co-medication, which questions external validity of these RCTs. Whether the efficacy, tolerance or safety data obtained in highly selected RCTs patients can be extrapolated to a more heterogeneous sample of patients receiving RTX in daily practice, remains to be elucidated.

Objectives: We aimed to identify the main reasons limiting the eligibility of routine care patients in RTX-registration RCTs, and to investigate the relationships between the number of eligibility (both inclusion and exclusion) criteria and RTX efficacy and safety in a real-life scenario.

Methods: The AIR registry is a French nationwide, multicentre, prospective cohort study aiming at investigating efficacy and safety of RTX in a real-life setting. We retrieved eligibility criteria of the drug-registration trials evaluating rituximab for RA and applied them to our population. We compared the EULAR response (moderate-to-good) at 12 months and the incidence of serious adverse events (AEs, including severe infections, malignancies, major adverse cardiovascular events, and death) at 12 months between eligible and non-eligible patients. We modelized the risk-benefit ratios according to the number of fulfilled critical eligibility, defined by those associated with response and severe AEs, respectively, after backward stepwise variable elimination.



Results: Among 1989 RA patients included in the AIR registry, only 9 to 12% fulfilled all main eligibility criteria for the 3 drug-registration trials. The main unfulfilled inclusion criteria were an elevated CRP or ESR level (67.5%), erosive changes on bone X-ray (68.1%), and a swollen joints count ≥4/28 (74.6%). The main exclusion reasons were a history of severe or recurrent infection (35%), another severe uncontrolled disease (16%), neoplasia (14%), a high prednisone dose (≥ 10 mg/day for 26%), the use of another DMARD than methotrexate (16%) and ACR functional class IV disease (15%). Compared with RCT-eligible patients, non-eligible patients had less frequently moderate-to-good EULAR response (40.3% versus 46.9%, P=0.044), and had a smaller change in DAS-28 (-1.2 vs -1.4; 95% CI 0.1 to 0.5; P=0.005) at 12 months. Compared to patients with no exclusion criterion, patients with at least one critical exclusion criterion had a higher risk of severe AEs (HR 3.03, 95% CI 2.25–4.06 for ≥ 3 exclusion criteria compared to none). While the probability of EULAR response decreased with the number of unmet critical inclusion criteria, the probability of severe AEs increased with the number of exclusion criteria (Figure 1), highly decreasing the incremental risk-benefit ratio.

Conclusion: Few RA patients treated with rituximab fulfilled the eligibility criteria of the main drug-registration trials. Non-eligible patients had less chance of treatment response, and a higher risk of severe adverse events. This suggests that the efficacy and safety data from those trials cannot be extrapolated to RA patients in daily practice.

Figure. Probabilities of treatment response and of severe adverse events according to the number of fulfilled critical inclusion and exclusion criteria.

X-axis: Number of met critical inclusion criteria / number of met critical exclusion criteria (number of patients). Critical inclusion criteria included a swollen joints count ≥4/28, a tender joints count ≥4/28, CRP ≥15 mg/L or ESR ≥28 mm, and presence of rheumatoid factor. Critical exclusion criteria included age >80, systemic disease associated with RA, ACR functional class IV, concurrent use of any other DMARD (except methotrexate) and a prednisone dose > 10 mg/day.

All about Crystal arthritis II

POS0183 THE UPDATED CARDIOVASCULAR RISK ESTIMATION SCALE SCORE2 DOES NOT IMPROVE THE PRECISION IN PREDICTING CARDIOVASCULAR EVENTS IN PATIENTS WITH GOUT

Keywords: Gout, Crystal Arthritis

M. D. C. López González[1], E. Tovar-Sugrañes[2], C. Rodríguez Alvear[1], E. Perea Martínez[1], M. Monzó[3], A. Avilés[1], M. Andrés[1]. [1]*Hospital General Universitario Dr. Balmis-ISABIAL, Rheumatology, Alicante, Spain*; [2]*Hospital Uniersitario y Politécnico La Fe- IIS La Fe, Rheumatology, Valencia, Spain*; [3]*Hospital Marina Baixa, Gynecology and Obstetrics, Villajoyosa, Spain*

Background: Cardiovascular (CV) risk in gout is increased due to the accumulation of CV risk factors and persistent inflammation. Therefore, it is necessary to have precise evaluation strategies to categorize the risk of patients with gout in order to optimize their treatment. In previous studies, we have seen that the usual prediction scales SCORE and Framingham Heart Study are not accurate in detecting patients with gout and carotid atheroma plaques (PMID 28093417). The SCORE2 version, an update of the SCORE tool, performed similarly in predicting the presence of those plaques [1], although it remains unknown its predictive capacity of CV events in patients with gout.
Objectives: To evaluate the precision of SCORE2 in predicting CV events in patients with gout, with a comparison with prior SCORE and Framingham Heart Study tools.
Methods: We conducted a retrospective post-hoc study on new patients with crystal-proven gouts, from our inception cohort focused on evaluating their CV risk. The recruitment period was 2014-2018. For the present analysis, we selected patients eligible for SCORE2 calculation (without established CV disease, diabetes with vascular involvement or severe renal disease), and we collected the occurrence of a first major CV event (stroke, acute myocardial infarction (AMI), congestive heart failure (CHF), peripheral artery disease (PAD), and CV death) from their electronic records, occurring from study inclusion up to the event, end of follow-up or 03/31/2022. We calculated their incidence rate (IR) and evaluated the predictive capacity for CV events of SCORE 2, SCORE and REGICOR (Framingham equation calibrated for the Spanish population) (PMID: 2622955) tools using a Cox regression model that allows to estimate their hazard ratio with 95% confidence intervals (CI).
Results: Of the initial sample of 356 patients, 193 (54.2%) were selected for this analysis. They were mainly men (94.8%) of middle age (average 56.8 years), with an average of 8.2 years since the first gout flare. Almost all patients originate from low CV risk geographical regions, but only 32 patients (16.6%) classified at high risk by SCORE2. The median follow-up time was 6.4 years (p25-75 5.1-7.1). During the follow-up, 10 patients had a first CV event (3 cases of stroke, 2 of AMI, 2 of CHF, 2 of PA, and one patient died from a CV cause). The IR of CV events in this subset was 0.83 cases per 100 patient-years. In terms of predicting CV events in patients with gout, the SCORE2 tool did not show a better performance than the SCORE and REGICOR (Framingham) tools **(Table 1)**.

Table 1.

	HAZARD RATIO (IC95%)	*P*
SCORE2 (continuous)	1.10 (0.99-1.21)	0.068
SCORE2 categories		
SCORE2_low risk	1.00 (ref)	-
SCORE2_moderate risk	0.97 (0.19-5.01)	0.973
SCORE2_high risk	2.34 (0.39-14.05)	0.351
SCORE2_high risk (yes/no)	2.39 (0.62-9.27)	0.207
SCORE (continuous)	1.09 (0.91-1.29)	0.349
SCORE categories		
SCORE_low risk	1.00 (ref)	-
SCORE_moderado	0.70 (0.07-6.72)	0.757
SCORE_high risk	1.74 (0.20-14.87)	0.615
SCORE_very high risk	15.20 (0.94-244.85)	0.055
SCORE_very high risk (yes/no)	13.70 (1.72-109.02)	0.013
REGICOR (continuous)	1.10 (1.00-1.22)	0.059
REGICOR categories		
REGICOR_low risk	1.00 (ref)	-
REGICOR_moderate risk	2.58 (0.67-9.98)	0.171
REGICOR_high risk	0.00	0.988
REGICOR moderate-high (yes/no)	2.47 (0.64-9.57)	0.190

Conclusion: The SCORE2 tool significate no improvement on accurately predicting CV events in patients with gout compared to previous SCORE and Framingham Heart Study scales. Our data should be replicated in regions with higher CV risk estimates.

POS0184 U-SHAPED ASSOCIATION OF SERUM URATE WITH ALL-CAUSE MORTALITY IN GOUT PATIENTS: NHANES 2007-2018

Keywords: Gout

N. Chen[1], Q. H. Li[2], S. X. Hu[1], H. Lin[1], L. Dai[2]. [1]*Sun Yat-Sen University, Zhongshan School of Medicine, Guangzhou, China*; [2]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China*

Background: The EULAR guideline for the management of gout recommended a target serum urate (sUA) level of less than 6 mg/dl in gout patients and less than 5 mg/dl in tophaceous gout patients [1]. This recommendation is based on the evidence that achieving these targets will reduce gout attacks and tophi size. However, less is known about the impact of sUA on mortality in gout patients.
Objectives: To explore the relationship between sUA level and all-cause mortality in gout patients.
Methods: The present prospective cohort study included participants 20 years or older with gout enrolled from the 2007-2008 through 2017-2018 annual NHANES cycles. The data of mortality and its underlying causes to 31 December 2019 were obtained from the National Death Index records. The relationship of gout patients between sUA level and mortality were analyzed by Cox proportional hazards analysis, the restricted cubic spline regression analysis and two piece-wise regression model.
Results: A total of 1442 gout patients were included with median follow-up period 63 (interquartile range, 33-102) months. Compared with gout patients with sUA less than 6mg/dl, gout patients with sUA>6mg/dl were characterized by greater age, more often men, higher BMI and higher prevalence of hyperlipidemia (P <0.05). Cox proportional hazards analysis showed that sUA was a risk factor of mortality (HR 1.09, 95% CI 1.02 to 1.16) after adjusted by age, sex, race, education, BMI, smoking, cardiovascular disease, hyperlipidemia, hypertension and diabetes mellitus. However, restricted cubic spline regression analysis showed a U-shaped relationship between sUA and all-cause mortality (Pnon-linear <0.001, Figure 1). Two piece-wise regression model revealed sUA level of 6.2 mg/dl corresponded to the lowest mortality risk. For those patients with sUA less than 6mg/dl, the risk of all-cause death was borderline reduced 12% (HR 0.88, 95% CI 0.72 to 1.07) with each sUA unit increase. After 6 mg/dl, the risk of all-cause death increased 26% (HR 1.26, 95% CI 1.14 to 1.40) for each sUA unit increase.
Conclusion: There is a U-Shaped association of sUA with all-cause mortality in gout patients. Target sUA of less than 6 mg/dl is rational as it corresponds to the interval of lowest mortality. Randomized trials with mortality as an endpoint are warranted to determine target sUA for gout patients.

POS0185 SYSTEMIC IMMUNE-INFLAMMATION INDEX TO ALL-CAUSE MORTALITY IN GOUT PATIENTS: NHANES 2007-2018

Keywords: Crystal Arthritis

H. Lin[1], N. Chen[1], S. X. Hu[1], Q. H. LI[2]. [1]*Sun Yat-Sen University, Zhongshan School of Medicine, Guangzhou, China*; [2]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China*

Background: Systemic immune inflammatory index (SII) is a new marker of inflammation. SII is associated with increased cancer risk and mortality in cardiovascular and cancer patients. However, the effect of SII on mortality in gout patients is rarely reported in the literature.
Objectives: To study the relationship between SII level and all-cause mortality in gout patients.
Methods: This prospective cohort study included participants 20 years or older with gout enrolled from the 2007-2008 through 2017-2018 annual NHANES cycles. The data of mortality and its underlying causes to 31 December 2019 were obtained from the National Death Index records. The SII level was calculated as the platelet counts × neutrophil counts/lymphocyte counts. Gout patients were grouped according to low, middle and high tertile of SII. Generalize linear regression was used to study variables influencing SII. The relationship between SII level and mortality were analyzed by Cox proportional hazards analysis.
Results: A total of 1334 gout patients were included with median follow-up time 68 months (34 months, 106 months). As shown in the Table 1, gout patients with high SII level were characterized by more having chronic kidney diseases, diabetes mellitus and less fiber intake (P <0.05). The generalized linear model found that SII level was positively correlated with diabetes mellitus (P<0.05), and negatively correlated with men, eGFR, fiber intake (P<0.05). Kaplan Meier survival curve showed that mortality was highest in the high SII group (Figure 1). Cox proportional hazards analysis after multivariable adjustment showed that taking low SII group as the reference group, mortality was elevated in the high SII groups (Table 1).
Conclusion: High SII is a predictor of all-cause death in gout patients.

Table 1. Characteristics of gout patients according to low, middle and high tertile of SII.

POS0186 OBSTRUCTIVE SLEEP APNEA: A CONTRIBUTING FACTOR IN GOUT?

Keywords: Epidemiology, Comorbidities, Gout

P. Khandwala[1], D. Desai[2], M. Sen[1]. [1]*Einstein Medical Center Philadelphia, Rheumatology, Philadelphia, United States of America*; [2]*Einstein Medical Center Philadelphia, Hospice and Palliative Medicine, Philadelphia, United States of America*

Background: As per World Health Organization, 7.44 million cases of gout were estimated globally in 2017 (incidence, 0.097%), with a prevalence of 41.22 million cases (0.54%).[1] Obstructive sleep apnea (OSA) is a co-morbidity that has shared risk factors with gout as well as causes pathophysiological mechanisms causing hyperuricemia. The relationship remains contentious. There have been studies, mainly in the UK, which have shown 1.5 times increased risk of gout in patients with OSA [2,3]. While the study by Durme et al shows that the association disappears after statistical adjustment for BMI, renal function, heart failure, and use of diuretics.[4] Thus, it becomes vital to contribute to the existing literature to investigate this relationship further.
Objectives: The aim of the study is to understand the relationship between OSA and Gout.
Methods: TrinetX, a global federated research network that provides a dataset of electronic medical records from different healthcare organizations (HCOs), was utilized. Initial query was made to isolate patients who had a BMI greater than 30 and then 2 groups were made on the presence or absence of OSA. Further, propensity score matching (PSM) was carried out to match age, sex, race, chronic kidney disease, heart failure, and use of diuretics. Compare outcome analytic function was utilized to map the co-relation with Gout.
Results: A total of 3,541,566 patients who had a BMI>30 were identified, out of which 817,638 (23.09%) patients had OSA. Patients in OSA group were older as compared to patients in non-OSA group (59.8 ± 14.3 years vs 54 ± 17.2 years). Females made up 50% of the OSA group while they were predominant (65%) in the non-OSA group. Caucasians were the predominant race, followed by African

Americans. 7.19% of patients with OSA had Gout, while 2.84% without OSA had gout (p<0.0001). The odds of having gout is 2.65 times higher in patients with OSA than patients without OSA (hazard ratio is 2.393, 95% confidence interval (CI) 2.367-2.419, p<0.0001). After PSM, both groups had 801,526 patients. 6.93% patients with OSA had gout while 4.63% of patients without OSA had gout (p<0.0001). Odds ratio =1.533, (95% CI 1.512 - 1.554, p<0.0001) and hazard ratio was 1.404 (95% CI 1.386-1.423).

Conclusion: Our study demonstrated that there is a strong correlation between Gout and OSA. Hypoxia-induced hyperuricemia is the most widespread explanation.[5] However, there are many confounding factors that prompted us to carry out matching for demographics and, more importantly for chronic kidney disease, heart failure as well as the use of diuretics. Statistically significant odds ratio after matching attests to the fact that there is a robust correlation between gout and OSA. Limitation of this study was the lack of testing of this hypothesis on patients with BMI<30. Prospective cohort studies are required to further test the strength of the relationship between OSA and Gout.

POS0187 HEPATIC STEATOSIS AND FIBROSIS IN PATIENTS WITH GOUT DETECTED BY ELASTOGRAPHY

Keywords: Imaging, Comorbidities, Gout

N. Schlesinger[1], A. Patel[2], V. Rustgi[3], A. Yeo[4], P. Lipsky[5]. [1]*Spencer Fox Eccles School of Medicine, Universi,ty of Utah, Medicine, Salt Lake City, United States of America*; [2]*Rutgers, Medicine, New Brunswick, United States of America*; [3]*Rutgers Robert Wood Johnson Medical School, Medicine, New Brunswick, United States of America*; [4]*University of Sidney, health economics, Sidney, Australia*; [5]*AMPEL BioSolutions, AMPEL BioSolutions, Charlottesville*

Background: Gout is associated with non-alcoholic fatty liver disease (NAFLD), but neither the frequency nor severity of NAFLD in gout is well described. Elastography is a well-established ultrasonic method to evaluate both steatosis and fibrosis in the liver but has not been applied to evaluate gout patients.

Objectives: To determine how common hepatic steatosis and fibrosis are in patients with gout using FibroScan technology?

Methods: We employed FibroScan technology, a validated transient elastography method, to evaluate patients with gout. Consecutive gout patients with insurance coverage were evaluated at one center from 11/1/2016 - 11/12021. We assessed the Fibrosis score (kPA) that measures liver stiffness (E score) and the controlled attenuation parameter dB/m (CAP) score that assesses steatosis. In addition, we assessed the four-factor fibrosis (FIB-4) Index formula that combines the patient's age with aspartate aminotransferase (AST), alanine aminotransferase (ALT), and platelet count.

Results: 47 gout patients (7 females, 14.9%; 40 males, 85.1%) were evaluated. The mean age was 59.8 years, and the mean BMI was 30.95 kg/m2. Tophi were present in 11 (26.2% of those with recorded information). The disease's duration ranged from 0-49 years. Comorbidities included: dyslipidemia (86.7%), diabetes (31.1%), hypertension (63.6%), CHF (12.8%), CAD (12.8%), chronic kidney disease (19.15%), known liver disease (33.3%) and current alcohol consumption (46.8%). 53.7% (n=29) had hyperuricemia (serum urate (SU) >6.8 mg/dL) and 54.4% had elevations of either ALT or AST. Hepatic steatosis (CAP >238 dB/m) was found in 40 (85.1%) and was not significantly different in males or females (p=0.37) or those with CHF (p=0.87), CAD (p=0.94), hypertension (p=0.17), diabetes (p=0.68), dyslipidemia (p=0.59) or the presence of known liver diseases (p=0.37). CAP correlated with BMI (r=0.53, p=0.0001) but not age, SU, glucose, triglycerides, ALT, AST, FIB-4, or Fibrosis scores. By FibroScan, 9 (19.1%) had evidence of fibrosis (E score >7), including one with moderate and 8 with severe fibrosis (cirrhosis). Moderate or severe fibrosis was significantly associated with age (p=0.03) and known liver disease (p=0.003), but not ancestry, gender, BMI, triglycerides, HDL, glucose, gout duration, CHF, CAD, hypertension, dyslipidemia, or diabetes. SU was comparable in those with or without moderate or severe fibrosis (p=0.24). The Fib-4 score was significantly greater in those with severe or moderate fibrosis (3.77) versus those with no or mild fibrosis (1.59, p=0.0045). There was a significant correlation between the Fibrosis score and FIB-4 score (r2=0.24, p=0.0009) but not between the Fibrosis score and ALT (p=0.44) or AST(p=0.41).

Conclusion: Hepatic steatosis and fibrosis are common in patients with gout but not associated with typical gout comorbidities. Screening for NAFLD with elastography should confirm the actual frequency of NAFLD in gout and provide a means to manage this comorbidity more effectively.

POS0188 HYPERURICEMIA IS ASSOCIATED WITH CORONARY ARTERY ATHEROSCLEROSIS IN MEN: RESULTS FROM THE SCAPIS STUDY

Keywords: Cardiovascular disease, Crystal Arthritis

P. Drivelegka[1], H. Forsblad-D'elia[1], G. Bergström[2], E. Fagman[3], L. T. H. Jacobsson[1], M. Dehlin[1]. [1]*Medicine, Rheumatology and Inflammation research, Gothenburg, Sweden*; [2]*Medicine, Department of Molecular and Clinical Medicine, Gothenburg, Sweden*; [3]*Clinical Sciences, Radiology, Gothenburg, Sweden*

Background: There is considerable controversy on whether elevated urate levels are independently associated with the development of cardiovascular disease (CVD). Segment involvement score (SIS), as a marker of subclinical atherosclerosis, represents the total number of coronary segments with atherosclerotic plaque, calcified and/or non-calcified, and thus reflects the overall burden of coronary atherosclerosis. Extent of coronary artery disease as quantified by SIS is a strong, independent predictor of cardiovascular events [1]. Whether urate levels are associated with SIS has not been previously studied.

Objectives: To study the association between hyperuricemia and SIS in the participants of the Swedish Cardiopulmonary Bioimage Study (SCAPIS).

Methods: SCAPIS is a nationwide, population-based study aiming to improve CVD risk prediction. The study included randomly selected individuals aged 50-64 years recruited at six university hospitals in Sweden during the period 2013-2018 (N= 30,000 participants). We used data from SCAPIS Gothenburg (N= 4,949 participants), including urate levels and SIS, measured by computed tomography angiography (CTA). Individuals with known coronary heart disease and/or gout were excluded. Hyperuricemia was defined as urate levels ≥ 405 µmol/L. The association between hyperuricemia and SIS was assessed by multivariate logistic regression analysis. We calculated Odds ratios (OR) and 95% confidence intervals (CI), crude and with adjustments for age, smoking, body mass index (BMI), diabetes, dyslipidemia, and hypertension. A SIS score >0 was considered to indicate the presence of coronary atherosclerosis and was used as the cutoff value.

Results: In total, 2,438 men (mean age, 57.3 years) and 2,511 women (mean age, 57.4 years) were included. Urate levels were higher in men than in women (mean levels, 348 *vs* 270 µmol/L respectively). Hyperuricemia was more common in men than in women (18% *vs* 2%). Age, BMI, and hypertension showed no differences between men and women, while diabetes and dyslipidemia were more common in men than in women (4% *vs* 2% and 13% *vs* 9%, respectively). Any CTA-detected atherosclerosis (SIS>0) was found in 1,404 (57.6%) men and 752 (30%) women. Hyperuricemia was significantly associated with SIS>0 in men (OR, 1.3; 95%CI, 1.04-1.6), but not in women (OR, 1.3; 95%CI, 0.7-2.3) in the multivariate logistic regression analysis (Table 1).

Conclusion: Hyperuricemia was independently associated with the presence of coronary artery atherosclerosis, as reflected by SIS, in men but not in women. Findings are compatible with a pathophysiological role of urate in atherosclerosis. Whether the observed difference between sexes reflects biological differences in effect of urate or is explained by other factors, such as later onset of atherosclerosis or less statistical power in women will be examined in follow-up studies.

POS0189 COMPARATIVE RISK OF RETINAL VASCULAR COMPLICATIONS IN PATIENTS WITH GOUT INITIATING FEBUXOSTAT VERSUS ALLOPURINOL: A POPULATION-BASED COHORT STUDY

Keywords: Gout, Real-world evidence

M. J. Kim[1], A. Shin[2], S. R. Choi[2], Y. J. Ha[2], Y. J. Lee[2], E. B. Lee[3], E. H. Kang[2]. *[1]Seoul Metropolitan Government–Seoul National University Hospital Boramae Medical Center, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[2]Seoul National University Bundang Hospital, Division of Rheumatology, Department of Internal Medicine, Seongnam, Korea, Rep. of (South Korea)*; *[3]Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Comparative cardiovascular (CV) safety studies on patients with gout have showed in general a similar risk between allopurinol and febuxostat. However, the data have been derived from macrovascular rather than microvascular CV outcomes.
Objectives: In this study, we aimed to compare the risk of retinal vascular complications among patients with gout initiating febuxostat versus allopurinol.
Methods: Using the 2012-2020 Korean National Health Insurance service database, we conducted a population-based cohort study on patients with gout aged ≥40 years initiating febuxostat or allopurinol. After 1:1 propensity score (PS) matching in non-diabetes (non-DM) and DM subgroups, respectively, on >60 covariates, subgroups were merged for a main cohort. The primary outcome was a composite of retinal vascular complications (retinal vascular occlusions, retinal disorders of retinopathy and vascular changes, degeneration, and hemorrhage, and other retinal disorders). DM retinopathy was investigated as a secondary outcome in DM subgroup. We used Cox proportional hazard models to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) comparing allopurinol and febuxostat users. Subgroup-specific HRs were pooled by a fixed effect model.
Results: We included 89,642 PS-matched pairs of febuxostat and allopurinol users in non-DM subgroup and 28,734 PS-matched pairs in DM subgroup, with 118,876 pairs in total (mean 57.3 years, 83.7% male). During a mean 223 days of follow-up, 1,318 composite outcomes occurred. The pooled HR [95% CI] for retinal microvascular complications was 0.98 [0.83-1.15] with 0.94 [0.76-1.15] in non-DM and 1.05 [0.80-1.39] in DM subgroup. The HR [95% CI] for DM retinopathy of 0.86 [0.67-1.11].
Conclusion: In this large cohort study on patients with gout, we found a similar risk of retinal microvascular complications.

POS0190 INFLUENCE OF AGE, PERIOD, AND BIRTH COHORT EFFECTS ON SECULAR TREND IN GOUT INCIDENCE IN THE UNITED KINGDOM

Keywords: Gout, Descriptive Studies, Epidemiology

J. Ye[1], Y. Zhang[2], W. Zhang[3,4], M. Doherty[3,4], N. Lu[5], C. Zeng[1,6,7], G. Lei[1,6,7], J. Wei[6,8,9]. *[1]Xiangya Hospital, Central South University, Department of Orthopaedics, Changsha, Hunan, China*; *[2]Massachusetts General Hospital, Harvard Medical School, Division of Rheumatology, Allergy, and Immunology, Department of Medicine, and the Mongan Institute, Boston, Massachusetts, United States of America*; *[3]University of Nottingham, City Hospital, Academic Rheumatology, Clinical Sciences Building, Nottingham, United Kingdom*; *[4]University of Nottingham, Pain Centre Versus Arthritis, Nottingham, United Kingdom*; *[5]Arthritis Research Canada, Richmond, British Columbia, Canada*; *[6]Hunan Key Laboratory of Joint Degeneration and Injury, Changsha, Hunan, China*; *[7]Xiangya Hospital, Central South University, National Clinical Research Center for Geriatric Disorders, Changsha, Hunan, China*; *[8]Xiangya Hospital, Central South University, Health Management Center, Changsha, Hunan, China*; *[9]Xiangya School of Public Health, Central South University, Department of Epidemiology and Health Statistics, Changsha, Hunan, China*

Background: The risk of incident gout in the United Kingdom (UK) appears to have declined since 2013.[1] However, whether this is temporary or likely to continue is unclear.
Objectives: To examine the influence of age, calendar year, and year of birth on recent gout incidence in the UK.
Methods: Using data from IQVIA Medical Research Database in the UK, we identified incident gout by READ codes from 1999 to 2019. We grouped age, calendar year, and year of birth into 3-year categories. We assessed the effect of age, calendar year, and birth cohort categories on the incidence rate of gout using the age-period-cohort model among all participants and in men and women separately.
Results: Over the 21 years, there were 164,588 incident gout cases. The incidence rate of gout increased with age until age 80, then leveled off (P for trend <0.001) (Figure 1A). The gout incidence increased from 1999 to 2013, then declined (Figure 1B). The incidence rate of gout was higher in the late birth cohorts than in the early birth cohorts from the Year 1999 to the Year 2013 (Figure 1C); however, such a trend was reversed after the Year 2013, with the incidence rate of gout being higher in the early birth cohorts than that in the late birth cohorts (Figure 1D). Similar patterns were observed in men and women.
Conclusion: Using the age-period-cohort model, we found that the risk of gout in the UK increased from 1999 to 2013 and then declined afterward. These

POS0191 GENETIC EVIDENCE REVEALS A CAUSAL RELATIONSHIP BETWEEN TRIGLYCERIDE AND GOUT

Keywords: Gout, Genetics/Epigenetics, Lifestyles

X. Yang[1,2], Q. Dong[1,2], X. Cao[1,2], Q. Feng[1,2], J. Y. Chen[1,2], Q. Yu[3], P. F. He[3], X. LI[1,2,4], S. X. Zhang[1,2,4]. [1]*Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; [2]*Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, China*; [3]*Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*; [4]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: Gout is caused by hyperuricemia that leads to the formation and deposition of monosodium urate (MSU) crystals, which is characterized by acute episodes of joint inflammation [1]. Epidemiological studies observed increased levels of triglycerides in gout [2,3]. Triglyceride is a kind of adipokine primarily transported by very low-density lipoprotein. Enriched in very low-density lipoprotein triglycerides was significantly associated with gout in hyperuricemia [2]. However, the causal association between triglycerides and gout remains unclear.

Objectives: This study aims to use a two-sample Mendelian randomization (MR) to examine associations of triglycerides with gout.

Methods: Summary data for triglycerides used in this study were obtained from a genome-wide association study (GWAS), which included 441,016 European participants within the UK Biobank [4]. The gout GWAS datasets were from a large-scale meta-analysis, which included 69,374 individuals (2,115 cases and 67,259 controls) from European [5]. We selected genetic variation highly related to triglyceride ($P < 5.00E-8$, r2=0.001) as the potential instrumental variables. Three MR methods, namely inverse-variance weighted (IVW), weighted median, and MR-Egger, were applied for MR analysis. For sensitivity analysis, we used common statistical methods, namely Cochran's Q test, MR-Egger intercept analysis, the funnel plot, and the leave-one-out analysis.

Results: After accounting for LD and the harmonization process, the total number of variants included in the MR investigating the effect of triglycerides on gout was 166. Triglycerides were a risk factor for gout (odds ratio (OR)=1.49, 95% confidence interval (CI):1.22-1.82, P=8.16E-05), which was consistent with the MR-Egger (OR=1.40, 95%CI:1.11-1.89, p= 2.93E-02). Cochran's Q test and MR-Egger intercept showed no evidence of heterogeneity and horizontal pleiotropy (MR-Egger-intercept: 0.0025, P=0.583). The leave-one-out analysis also failed to detect any SNPs that may have a disproportional effect (Figure 1).

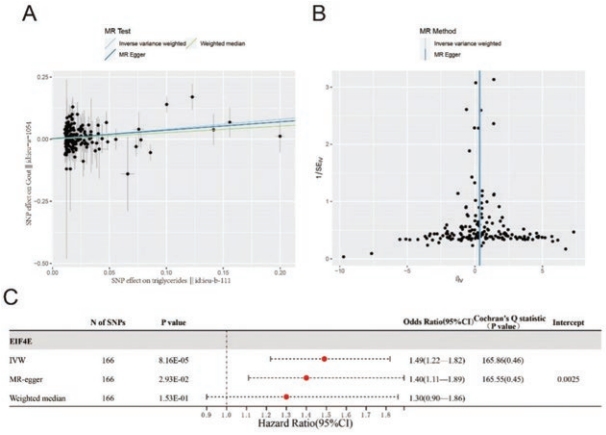

Figure 1. MR analysis results for triglycerides and gout. (A) Scatter plot of single nucleotide polymorphism (SNP) potential effects on triglycerides and gout. The slope of fitted lines represents the estimated MR effect per method. (B) Funnel plot for triglycerides shows the estimation using the inverse of the standard error of the causal estimate with each individual SNP as a tool. (C) Forest plot showing MR analysis results to evaluate the causal association between triglycerides and gout using three methods.

Conclusion: Triglyceride was a hazard factor for gout, even in the absence of hyperuricemia, suggesting that controlling the level of triglyceride and paying attention to diet may be beneficial to prevent the occurrence of gout.

POS0192-PARE TOWARDS A NEW APPROACH ON RESEARCH DESIGNS: PATIENTS AND HEALTHCARE PROFESSIONALS CO-CREATING AND CO-DEVELOPING A MOBILE APPLICATION FOR THE SELF-MANAGEMENT OF CHRONIC PAIN IN OSTEOARTHRITIS. THE TOUS INCLUDE PROJECT

Keywords: Self-management, Patient-led research, Osteoarthritis

N. Malliou[1], P. Antoniou[2], K. Antonopoulou[3], A. Mpillis[2], S. Reppou[2], A. Pappa[3], P. Bamidis[2]. [1]*Hellenic League Against Rheumatism ELEANA, Hellenic League Against Rheumatism (HELAR/ELEANA), Thessaloniki, Greece*; [2]*Aristotle University of Thessaloniki AUTH, Medical Physics and Digital Innovation Lab,*

School of Medicine AUTH, Thessaloniki, Greece; [3]*Hellenic League Against Rheumatism ELEANA, Hellenic League Against Rheumatism (HELAR/ELEANA), Athens, Greece*

Background: Treatment options for pain in osteoarthritis (OA) aim to reduce or help patients manage their pain efficiently. According to guidelines non-pharmacological therapies are the first treatment option and pharmacological therapies follow. But in many cases pharmacological options are the first choice and researchers are trying to find better ways for OA pain management for both patients and HCPs.

Objectives: Aim of this presentation is to showcase an innovative research design where patients are involved in a project from the planning phase to the implementation and development phase step by step working together with healthcare professionals. The project itself, TOUS Include, aims to integrate a digital intervention and educational activities into a patient centered mobile health application for both the patients and the healthcare professionals to use to help them better manage chronic pain of osteoarthritis.

Methods: The project is co-designed and co-developed from one phase to another. Phase I used a mixed methods gap analysis leading to the basic unmet needs that both groups, patients and HCPs, had regarding management and treatment of chronic pain of OA. Moving on to phase II, co-creation sessions in groups of patients and HCPs led to the basic scenarios, common mistakes and incorrect pathways that both groups take when dealing with everyday pain in OA. Meanwhile educational videos and webinars have taken place with participation from both groups for patients and HCPs.

Results: For phase III, developing of the virtual patient scenarios for the mobile health application, which will be one of the main features of the digital intervention, using data from phase I and II, results have already shown that there is a gap in patient and HCPs communication. The qualitative analysis of data showed that patients' health literacy could be a reason for that as well as lack of enough time for consultations. Another main point is that both groups use more frequently (32,7%) medication to manage chronic pain of OA rather than a non-pharmacological option such as physiotherapy (21,8%). Finally, analysis showed that both patients (medium=4.92) and HCPs (medium=4.7) thought that participating in co-creative sessions is very important (1=lowest, 5=highest).

Conclusion: This innovative research design has involved patients from day one. Its planning, conceptualization and implementation has been involving patients not only at the receiving end of an intervention but as an integral part of the research team, the design and implementation. The TOUS Include project is a collaboration of patients, patient organizations, a university department, a professional health care professionals' society and healthcare professionals. It's quite inclusive, thus an example that could easily showcase how research designs for patients could involve them from beginning to end for the benefit of everyone involved.

POS0193-PARE TIME TO RESEARCH - STRENGTHENING PATIENT RESEARCH PARTNER 2022

Keywords: Education, Rheumatoid arthritis, Clinical Trials

S. Dordevic[1], M. Kosanovic[1]. [1]*"Association of patientst with rheumatic diseases of the Republic of Serbia" (ORS), Association of patients, Belgrade, Serbia*

Background: In Europe the role of patients is growing significantly. In Serbia it is not a case. Our aim is to create a PRP network to bring research closer to patients. Through this network, trust between rheumatologists/researchers and patients, should be increased. Looking in the countries around, Serbia has the longest waiting period for permits to introduce studies. Involving patients in research activities and their active role will provide better chances for patients to be introduced and treated with innovative drugs. Patient's perspective is important part of research, their needs, experiences and even doubts will contribute a lot to research. There are more than 70,000 people who suffer from some kind of inflammatory rheumatic diseases (IRD) in Serbia. These diseases are significant burden for our society. There are quite a few innovative drugs in Serbia, but however, innovative drugs are still unavailable for some diagnosis such as Systemic Lupus Erythematosus, Systemic Sclerosis, Vasculitis, Sjogren.

Objectives: The aims of this EULAR campaign were for us to:

- improve patients education about importance of research in order to increase the availability of innovative drugs with colaboration with Rheumatology Association of Serbia (RAS) and Serbian Association of Health Professionals in Rheumatology (SAHPR)
- found national PRP network
- motivate researchers to accept and involve patients in research as equal team member
- encourage patients to participate/take an active role in research to increase patients' trust in studies
- increase the mutual trust between patients and rheumatologists and health professionals.

Methods: Association of Rheumatic Diseases Patients of the Republic of Serbia now have 15 PRPs. They are members of national PRP network in Serbia. ORS improved cooperation with The Association of the manufacturers of innovative drugs INOVIA, with Medicines and Medical Devices Agency of Serbia – ALIMS, with CRA Academy. Director of the Association of Manufacturers of Innovative Medicines INOVIA, and director of CRA Academy invited us from ORS to promote the campaign "Time2Research" on their events in September and December months, ALIMS (Drug and Medical Device Agency) offered its assistance in improving the legislation for PRPs.

Results: Association of Rheumatic Diseases Patients of the Republic of Serbia now have 15 PRPs. They are members of national PRP network in Serbia. ORS improved cooperation with The Association of the manufacturers of innovative drugs INOVIA, with Medicines and Medical Devices Agency of Serbia – ALIMS, with CRA Academy. Director of the Association of Manufacturers of Innovative Medicines INOVIA, and director of CRA Academy invited us from ORS to promote the campaign "Time2Research" on their events in September and December months, ALIMS (Drug and Medical Device Agency) offered its assistance in improving the legislation for PRPs.

Conclusion: As the PRP network is a completely new institution in Serbia we have to explore all the opportunities for its implementation. We are proud that we establish a PRP network of 15 PRPs and we are making a plan how to engageas many of them as we can. We want to include our PRPs who know English well in the EULAR PRP network.

POS0194-PARE PEOPLE WITH AN RMD: MAKING A MEDICATION CHOICE TOGETHER WITH THE HEALTHCARE PROFESSIONALS

Keywords: Outcome measures, Patient reported outcomes, Self-management

P. Borsje,[1], P. Pennings,[2], B. Maat[3], R. Van der Knaap[3], D. Lewinski[3], H. Van de Weijer[3], T. Foekens[3], L. J. Kranenburg - van Koppen[4], A. Pasma[5], G. Willemsen- de Mey[6]. [1]*National Association ReumaZorg Nederland, Patient expert and Coordinator at the Department of Patient participation and Communication, Nijmegen, Netherlands*; [2]*National Association ReumaZorg Nederland, Coordinator at the Department of Patient participation and Communication, Nijmegen, Netherlands*; [3]*National Association ReumaZorg Nederland, Patient research partner at the department of Patient participation and Communication, Nijmegen, Netherlands*; [4]*Erasmus Medical Centre, Rheumatologist at the Department of Rheumatology, Rotterdam, Netherlands*; [5]*Erasmus Medical Centre, Advisor Value Based Healthcare at the Department of Quality and Patientcare, Rotterdam, Netherlands*; [6]*National Association ReumaZorg Nederland, Chairman Board and CEO, Nijmegen, Netherlands*

Background: Research shows that people with Rheumatic and Musculoskeletal Diseases (RMDs), who decide together with their healthcare professionals make better informed treatment choices. They are also more likely to adhere to their treatment or medication use. A conversation aid can help people with an RMD to become aware of their most important preferences and questions about medication. These preferences and questions can set the agenda for a good conversation in the consultation room between the patient and the healthcare professional. Together with the healthcare professional the conversation can focus on the most important benefits, risks and preferences of someone with an RMD, when a medication choice has to be made.

OBJECTIVES:

- To develop conversation aids, that:
- oallow people with an RMD to become aware of the most important preferences in making a medication choice
- oguide people with an RMD in how to discuss these most important aspects with a healthcare professional
- To develop conversation aids that guide healthcare professionals in giving complete information about:
- oall important aspects of the medication
- ohaving a rheumatic and musculoskeletal disease (RMD)

This in order to make the best fitting medication choice together.

Methods: In the first step of the process 2 focus groups were organized. The first focus group consisted of patients of the Erasmus Medical Centre (5 participants) and patient research partners (PRPs) of the National Association ReumaZorg Nederland (RZN) (4 participants). The second focus group consisted of RMD health care professionals (5 rheumatologists, 1 pharmacist, 7 RMD nurses). The aim of the focus groups was to get an overview of important information that has to be shared, when a choice in RMD medication is to be made. In the second step, the output of both focus groups formed the starting point for the content of the conversation aids about medication choices. In the conversation aids all important information, that should be shared when a medication choice has to be made, was formulated in simple short sentences. After that, the content of the conversation aids was assessed by participants of both focus groups. In the third step, a draft version of the conversation aids about medication choices was designed. The conversation aids were designed using the same layout as our earlier developed conversation aids 'What is important to you and how can you talk about this?'. This draft version was again evaluated by participants of both focus groups, until we reached a final version.

Results: A total of 4 conversation aids (https://reumazorgnederland.nl/samen-beslissen-medicijnkaarten/) were developed.

- Who are you?: To allow people with an RMD to share their preferences with regards to shared decision making (SDM), about the way they like to receive information and about the way they prefer to take their medication.
- About medication: To allow healthcare professionals to give a complete overview of the most important aspects of RMD medication and to allow people with an RMD to share their most important questions about RMD medication.
- Groups of medication: To give an overview of the different groups of RMD medications.
- About arthritis: To give an overview of the most important aspects of having an RMD.

The 5th developed conversation aid (https://reumazorgnederland.nl/samen-beslissen-medicijnkaarten/) focused on reliable sources for information.

- More information: A conversation aid with reliable sources to obtain more information about shared decision making, about having a rheumatic and musculoskeletal disease (RMD) and about RMD medication.

EXAMPLE OF THE FIRST PART OF CONVERSATION AID 'WHO ARE YOU?'

Figure 1.

Conclusion: These conversation aids can encourage and advance a good conversation about RMD medication, that best fits the patient's need and preferences, when having an RMD. They stimulate both the patient as well as the healthcare professional to share much-needed information, when making a choice in medication. A patient organisation can play an important role in developing a conversation aid to support patients.

Acknowledgements: A special word of gratitude goes out to the patient research partners who contributed to the patient perspective in this project by either being part of the working group or by sharing their perspectives in the focus group. Our gratitude also goes out to all the RMD professionals who shared their opinion in the focusgroup.

POS0195-PARE PATIENT'S AWARENESS TOWARDS PHYSICAL ACTIVITY IN THE TREATMENT OF AXIAL SPONDYLOARTHRITIS

Keywords: Physical therapy/Physiotherapy, Patient information and education

D. Kiefer[1], J. Braun2, U. Kiltz2, N. Kolle2, S. Lucia2, I. Andreica2, B. Bjoern[3], P. Sewerin[2,4], H. Susanne[5], X. Baraliakos2. *[1]Rheumazentrum Ruhrgebiet - Ruhr-University Bochum, Rheumatology, Herne, Germany*; *[1]Rheumazentrum Ruhrgebiet - Ruhr-University Bochum, Rheumatology, Herne, Germany*; *[3]Bergisches Rheuma-Zentrum Wuppertal - Ruhr-University Bochum, Rheumatology, Wuppertal, Germany*; *[4]Universitätsklinikum Düsseldorf, Hiller Research Center, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University Düsseldorf, Rheumatology, Düsseldorf, Germany*; *[5]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*

Background: The course of axSpA is often characterized by impairments in physical function and mobility. Regular physical activity (PA) is a cornerstone of axSpA management. Recent EULAR recommendations for PA have stressed the importance of their implementation [1].

Objectives: To investigate the awareness on and individual implementation of PA in axSpA patients.

Methods: Patients with axSpA and impaired physical function (BASFI score ≥2.0) were recruited consecutively. All patients underwent a clinical examination including assessments of disease activity, physical function, mobility and global function and also filled out structured questionnaires on knowledge, awareness and individual attitudes to PA.

Results: Out of a total of 100 patients enrolled, 96 were included in the final analysis. Most respondents (n=82, 85.4%) were aware that PA has significant health benefits for patients with axSpA. Even though less than half of the patients (n=44, 45.8%) were aware that recommendations about PA do exist, 45 patients (46.9%) did already fulfil these in terms of frequency/week. 75 (78.1%) of patients knew that every adult should perform activities that maintain or increase muscular strength and endurance for a minimum of 2 days/week, while a majority 90 (93.8%) agree with this statement only 46 (47.9%) did fulfil these recommendations. The majority of patients (n=61, 67.7%) had been informed about the benefits of PA by their physician, and physiotherapy had often been prescribed (n=61, 63.3%). Many patients (n=51, 53.1%) reported to perform individual exercise programs, and some (n=22, 22.9%) supervised PA (Table 1).

Conclusion: Even though the majority of axSpA patients are not aware of the recent EULAR recommendations for PA, many understand and agree that PA is beneficial for their health status, while about half of them already fulfill them in their daily life. Measurements for dissemination and implementations on PA recommendations as a treatment target in a broad patient population need to be developed in order to serve the EULAR recommendations for PA. Part of this work was supported by an unrestricted grant by Novartis Pharma GmbH.

Table 1. Knowledge of WHO and EULAR PA recommendations and personal experience of axSpA patient´s, behavior and strategies with PA (n=96)

Statement,	Knowledge of Statement, yes, n (%)	Agreement with statement, yes, n (%)
The WHO general recommendations propose that all healthy adults aged 18–65 years should participate in moderate intensity aerobic PA for a minimum of 30 minutes on 5 days/week or vigorous intensity aerobic activity for a minimum of 20 min on 3 days/week.	44 (45.8)	73 (76.0)
Physical activity has health benefits for patients with axSpA.	82 (85.4)	86 (89.6)
The general PA recommendations are applicable to patients with axSpA (EULAR recommendations for PA)	41 (42.7)	83 (86.5)
Statement/Question,	**Statement applicable for me, yes, n (%)**	
All healthy adults aged 18–65 years should participate in moderate intensity aerobic PA for a minimum of 30min on 5 days/week or vigorous intensity aerobic activity for a minimum of 20min on 3 days/week.	45 (46.9)	
Every adult should perform activities that maintain or increase muscular strength and endurance for a minimum of 2 days/week.	46 (47.9)	
Did your physician ever promoted PA to you?	65 (67.7)	
Did your physician prescribe physiotherapy for you within the last 6 months?	61 (63.5)	
Do you use electronic applications (apps) for physical activity (e.g. fitness programs, pedometer)?	51 (53.1)	
Do you think that such electronic programs (including apps for the mobile phone) are useful?	72 (75.0)	
Do you perform individual exercise (at least 1x/week)?	51 (53.1)	
Do you perform group training (at least 1x/week)?	20 (20.8)	
Do you perform supervised PA (at least 1x/week)?	22 (22.9)	

PA: Physical Activity, WHO: World Health organization; apps: electronic applications

POS0196-PARE SELF-MANAGEMENT STRATEGIES AND SELF-EFFICACY IN PEOPLE LIVING WITH INFLAMMATORY ARTHRITIS: INSIGHTS FROM A QUALITY IMPROVEMENT PROJECT AT A TERTIARY RHEUMATOLOGY CENTRE

Keywords: Inflammatory arthritides, Self-management, Quality of care

S. S. Ali[1], I. Karafotias[1,2], K. Bechman[1,2], A. Rutherford[1,2], S. Steer[1,1], E. Nikiphorou[1,2]. *[1]King's College Hospital, Rheumatology, London, United Kingdom*; *[2]King's College London, Weston Education Centre, London, United Kingdom*

Background: The 2021 EULAR guidelines on self-management have made recommendations (rec) to aid with the implementation of self-management strategies in inflammatory arthritis (IA) [1]. Their aim is to support patients and encourage a patient-centred care approach which can improve both patient experience and outcomes in IA. Self-management can increase self-efficacy which can in turn improve adherence and outcomes for several self-management strategies [2].

Objectives: To assess the implementation of self-management recommendations into routine clinical care of IA patients at a large tertiary rheumatology centre in London. To explore how implementation (or not) of these recommendations may affect self-efficacy.

Methods: A retrospective analysis of the records of patients attending IA clinics at a large tertiary centre in London was undertaken from January 2022 to November 2022. Inclusion criteria included a diagnosis of either RA, PsA or AS. Specific questions addressing the uptake of the 2021 EULAR recommendations were developed (Table 1). The electronic notes were reviewed by two fellows who additionally interviewed patients via telephone, to explore whether the recommendations were addressed at their clinical encounter with the health care professional. Questions to the patients included specific ones addressing self-efficacy using the validated general self-efficacy (GSE) scale. Comparisons between groups were done with χ^2 tests, paired T-tests and Wilcoxon's Rank sum where appropriate.

Results: Fifty patients were included: 50% with RA, 24% with PsA and 26% with SpA. The mean (SD) age of participants was 48 (13) years. The median DAS was 4 (3-5) in RA, SJC and TJC was 2.0 (0.0-10.0) and 2.0 (0.0-8.0) respectively in PsA patients with the median BASDAI of 4 (2-6) in SpA (Table 1). The median GSE was 14 (12-25), where a higher score indicates more self-efficacy. 78% of patients reported feeling involved in the planning of their care and were made aware of the multidisciplinary team (rec 1). 30% felt they were given enough information on disease management (rec 2). Goals and practical points on physical and psychological interventions (rec 3) were mentioned to 50%. For patients where >50% of the self-management recommendations were addressed the mean GSE was 12.64 compared to a mean of 10.52 when <50% of self-management recommendations were addressed.

Conclusion: This study demonstrates that self-management recommendations are not fully and consistently addressed in routine clinics. Furthermore, patient self-efficacy was low/moderate suggesting that clinicians need to do better at discussing and supporting self-management strategies to improve self-efficacy which may also improve disease outcomes.

POS0197-PARE ANDAI EDUCATIONAL SUMMER CAMP: IMPACT IN CHILDREN AND TEENAGERS WITH JUVENILE RHEUMATIC MUSCULOSKELETAL DISEASES

Keywords: Patient information and education, Non-pharmacological interventions, Best practices

C. F. Gomes[1,2], B. Correia[1], A. Pais[1], F. Oliveira-Ramos[1,3,4], E. Mateus[2]. *[1]National Association of Patients with Juvenil Arthritis, ANDAI, Lisboa, Portugal*; *[2]Portuguese League Against Rheumatic Diseases, LPCDR, Lisboa, Portugal*; *[3]Centro Hospitalar Universitário Lisboa Norte, Paediatric Rheumatology Unit, Lisboa, Portugal*; *[4]Instituto de Medicina Molecular (IMM), Unidade de Investigação em Reumatologia, Lisboa, Portugal*

Background: Paediatric rheumatic diseases include the spectrum of musculoskeletal and connective tissue disorders occurring during childhood[1]. In addition to the physical effects, rheumatic diseases, as chronic conditions, pose a considerable risk for developing psychological distress[2]. Offering an educational camp to children and teenagers with disabilities or chronic diseases is one strategy to enhance adjustment and reduce the psychosocial risk factors related to chronic illness[3]. Thus, a summer camp for children and teenagers with juvenile rheumatic musculoskeletal diseases (RMDs) was created in Portugal in 2018 by the National Association of Patients with Juvenil Arthritis (ANDAI) – the ANDAI Educational Summer Camp (ESC). This annual event (online during the pandemic) provides recreational and supporting facilities for children and teenagers with juvenile RMDs during the summer holiday period. The main goal of ANDAI ESC is to promote the sharing of experiences as well as to support and work on confidence in coping with challenges of a RMD in childhood/youth.

Objectives: This study aims to assess the impact of ANDAI ESC on the lives of children and young people with RMDs. In addition, it also aims to make this project known to the rheumatology community, as well as to inspire other groups and patient associations.

Methods: Participant's data such as age, gender, diagnostic and treatment was collected. The clinical, social and psychological impact of ESC was assessed by a questionnaire applied to the participants after the ANDAI ESC. The perceived impact of the ANDAI ESC by health professionals' volunteers was also evaluated by a different questionnaire.
Results: Forty-five children or young people with RMDs participated in one or more editions of the ANDAI ESC. The median number of participants in ANDAI ESC was 17(9) participants per edition, with a majority of female participants (62%). The median age of participants in the different editions was 12(4) years old. Of those invited to participate in this study, 22 children (48% response rate) and 11 health professionals (53% response rate) completed the survey. The great majority of the participants (95,5%) recognized the positive impact of the ESC on understanding and acceptance of the disease. In fact, after participating in ANDAI ESC, 90.5% of these children claim to have a more optimistic perspective on the evolution of their disease. In addition, when asked on a scale from 0 (no impact) to 10 (significant impact) about the perceived outcome of ESC on their RMD patients, 88.8% of the participating health professionals marked the three higher scaled levels, agreeing that it had a positive effect on these children.
Conclusion: In conclusion this study demonstrates that ANDAI ESC improved patient's confidence in coping with the challenges of a RMD in childhood/youth, reaching the objectives initially defined. Thus, ANDAI ESC proved to be an important resource to the juvenile RMD community in Portugal.

POS0198-PARE CREATING A CAPABILITY BUILDING PROGRAM BASED ON PATIENT COMMUNITY'S ACTUAL NEEDS AND PRIORITIES: THE SJÖGREN EUROPE EXPERIENCE

Keywords: Best practices, Patient information and education, Sjögren syndrome

K. Antonopoulou[1], A. Vieira[2], C. Bouillot[3], J. Koelewijn-Tukker[4], M. Oosterbaan[5], M. Steenackers[6], V. Lopez Gousset[7]. [1]*Sjogren Europe, President, Bienne, Switzerland*; [2]*sjogren Europe, Vice President, Bienne, Switzerland*; [3]*Sjogren Europe, General Secretary, Bienne, Switzerland*; [4]*Sjogren Europe, Treasurer, Bienne, Switzerland*; [5]*Sjogren Europe, Board Member, Bienne, Switzerland*; [6]*Novartis Pharma AG, Global Patient Engagement Director, Immunology, Basel, Switzerland*; [7]*VLG Consulting, PR executive, Paris, France*

Background: Patients & their representatives are an important stakeholder in healthcare discussions. However, these individuals sometimes lack the appropriate knowledge & training to fully contribute to healthcare decision-making. The Sjogren's community in Europe is represented by groups of various capacities & expertise at the country level but with large national disparities. Sjögren Europe, the European Federation of national associations representing Sjögren's patients, seeks to support as widely as possible its members in leveraging their voice systematically & consistently in multi-stakeholder healthcare discussions, including participating in scientific research & collaborating with medical, social & political institutions.
Objectives: The SE Member Capability Building Program was co-created by Sjögren Europe & the Novartis Immunology Global Patient Engagement team to respond to the needs of the European Sjögren's community, as reported by Sjögren Europe member organizations. Specifically, the program supports Sjögren's patient organizations in building capability and capacity in areas that most matter to them, sharing local experiences & best practices & increasing advocates' knowledge, skills & confidence as leaders of their organizations.
Methods: The content of the Capability Building Program was shaped through a self-assessment in which participating organization self-identified strategic priorities, desired areas for expansion, and current barriers to growth. Questions in the self-assessment were taken from validated, third-party resources, including the PatientView methodology for assessing capacity and impact of patient organizations across eight key indicators[1]. These indicators are business stability, e-communication, services to patients, networking with stakeholders, networking with peer patient organizations, reputation, impact on health policy, and resilience. The results of this assessment were discussed individually with patient organization leaders to outline personalized opportunities for growth. The results were also used to inform a broader webinar training series based on commonly shared challenges & prioritized needs.
Results: 7 SE member organizations, representing 7 countries, participated in the self-assessment highlighting various shared gaps & learning opportunities across the community. Organizational strategy, staff recruitment & retention, external communication strategy & financial strategy were identified as current gaps. Patient organization involvement in drug development, approval & reimbursement processes was identified as an area where all groups would like to learn more. The resulting webinar training series addresses each of these areas of interest to the community. The first webinar "External Communication Strategy: Actionable recommendations for creating awareness campaigns and partnering with the media" was offered November 2022 with an overwhelmingly positive response from the community. Additional webinars are planned for 2023 and will be focused on the above topics.
Conclusion: The self-assessment was crucial in detailing where Sjögren Europe member organizations stand today & where they wish to be in the future. This allowed for the creation of a responsive and actionable webinar training program that meets the actual needs and priorities of the Sjögren's community in Europe. The Member organizations have reported feeling heard and valued as a result of this initiative. The very good feedback encourages us to continue these concrete actions for patient organizations. Program is also a great example of a genuine partnership, following the EFPIA code of conduct[2], between a patient organization and the pharmaceutical industry.

POS0199-PARE RHEUMATOLOGICAL PATIENTS' KNOWLEDGE OF, BELIEFS ABOUT, AND PRACTICES IN USING PHYTOTHERAPY: AN EXPLORATORY STUDY

Keywords: Patient information and education, Descriptive Studies

T. Demirci Yildirim[1], F. Basibuyuk[1], M. Birlik[1]. [1]*Dokuz Eylul University, Faculty of Medicine, Rheumatology, Izmir, Turkey*

Background: Phytotherapy has emerged as a new concept and has quickly and widely spread in recent years. Studies on phytopharmaceuticals in rheumatology practice are very limited.
Objectives: In this study, we aimed to examine the knowledge of, beliefs about, and practices in using phytotherapy in patients who use biological agents, which we can classify as the last and most potent step in treating rheumatological diseases.
Methods: In the first part of the questionnaire, there are 11 questions including the demographic data of the person, and in the second part, there are 17 questions that aim to learn the level of knowledge about phytotherapy and the use of phytopharmaceuticals. The questionnaire was administered face-to-face to patients with rheumatology using biological therapy who gave consent to participate.
Results: The questionnaire was completed by 100 patients, 51 of them women. The mean age was 39±9 years. 39% of the patients were postgraduate and 23% were at the high school. Of the participants, 45 were diagnosed with ankylosing spondylitis(AS) and 29 with rheumatoid arthritis(RA). The duration of rheumatologic disease was 12.2 years All patients were followed up with biological therapy, 35% were using infliximab and 15% were using adalimumab. The mean duration of biological treatment was 6 years. Of the 100 participants, 60% had information about phytotherapy, and 35 of them had obtained it from social media and television. In general, participants had a positive opinion about phytotherapy, and most didn't obtain approval from their physicians for the use of phytotherapy. Among phytopharmaceutical, participants mostly used green tea(30%), linden(27%), centaury(26%), curcumin(20%). There were 5 participants who experienced side effects related to the use of phytopharmaceuticals. 68% of the patients thought that phytopharmaceuticals had fewer side effects than biological therapy. 55 patients said that they would not use biological therapy if cured with phytopharmaceutical use.

Conclusion: It is inevitable that patients with chronic diseases want to use phytopharmaceuticals, as determined in our questionnaire results. Healthcare professionals should be careful about establishing a proper and reassuring relationship with patients and avoid criticizing them for preferring these methods. Patients should be informed about the use of phytotherapy, and be warned about its potential risks and side effects.

POS0200-PARE HOW USER INVOLVEMENT INCREASED THE QUALITY OF PROS

Keywords: Quality of care, Patient information and education, Patient reported outcomes

C. Ziegler[1]. [1]*Gigtforeningen, Politics and Knowledge, Gentofte, Denmark*

Background: In the DANBIO Registry patients with inflammatory arthritis have entered PROs for more than 20 years. In 2016 a group of patients suggested that their experiences and opinions about entering PROs should be taken into account, as the they found room for improvement. In 2018 a qualitative research study confirmed knowledge gaps in the use and purpose of DANBIO – gaps among patients, front personal and health care providers. In 2022 new results could be implemented.

Objectives: After the research study three different goals were set up:

[1] To increase knowledge of the DANBIO Registry being used for three different purposes.

[2] To make patients aware that they can enter PROs in different ways.

[3] To assure better quality of PROs by enhancing patient's adherence.

Methods: An interdisciplinary user group was established. The group consisted of patients with different types of inflammatory arhtritis, rheumatologists, nurses etc. The group decided to produce different materials for different platforms. The group produced the materials themselves in a cooperation with room for everyone's professional qualifications. The patients could offer patient's experiences as well as being persons with competences from education and worklife.

Results: Three user guides about the use of DANBIO were produced for three target groups. A group of patients scripted, filmed and produced a 5 minutes video providing the patients with relevant knowledge of PROs in DANBIO. The video was filmed at four different rheumatological departments and in patient's private homes. The video wil be shown in the waiting rooms of the hospitals and it can be seen on the Internet.

Conclusion: The work of the user group created a joint understanding and a multi pronged perspective on what "good quality" means in rheumatological care. By clarifying how the same data was presented and used differently various solutions were created to meet the need for more knowledge from staff, increase patient's confidence in entering PROs and increase knowledge of the DANBIO registry in general. The video is provided with English subtitles and can be shown if this abstract is chosen for presentation.

POS0201-PARE "MOOD IS HAPPY AND DOWNRIGHT WILD" - HEALTH PROMOTION AND WELL-BEING THROUGH PEER-LED GROUP ACTIVITY

Keywords: Patient information and education, Non-pharmacological interventions, Self-management

J. Karvonen[1]. [1]*The Finnish Rheumatism Association, -, Helsinki, Finland*

Background: Self-management refers to an individual's abilities and behavior to maintain and improve their own well-being and monitor and control the physical and psychosocial reactions related to their condition to maintain a satisfactory quality of life [1,2]. Self-management is an essential part of treatment alongside medical care. Peer support is based on sharing of information and experiential knowledge among persons living with the same condition. Peer support is seen more and more important in healthcare, and it has been used to improve overall health and promote health behavior and self-management. [3].

Objectives: To promote the health and well-being of those living with rheumatic and/or musculoskeletal diseases, and to support their ability to cope with illness through peer-led "Reumatroppi" group activity. The aim of the group activity is to help participants notice things that increase well-being and health in their everyday lives and turn their thoughts to positive things.

Methods: The Finnish Rheumatism Association trains volunteers to become "Reumatroppi" group instructors. Trained volunteers set up a group and receive a written material consisting of thirty nonmedical health-related topics that are scientifically studied and relevant in management of rheumatic and/or musculoskeletal diseases. Topics include, for instance, resistance exercise, cardiovascular health, nutrition, recovery and rest. In addition, topics such as literature, music, nature, and creativity are included to broaden the view of self-management. The group meets regularly to discuss varying topics and share their experiences and thoughts. In addition, the group does joyous tasks together both indoors and outdoors. A task related to the topic is also given at home before next meeting. Self-report questionnaires with quantitative and qualitative questions are administered to the participants at the end of the group.

Results: In 2021-2022, 86% of participants (n=80) reported paying more attention to their health behaviors (incl. physical activity, nutrition, rest). Additionally, 91% of the participants stated that they had tried to improve their own well-being and health in their everyday lives. 76% of participants had reduced sitting and sedentary time. It is also noteworthy that 80% of the participants reported better mood, and 81% had experienced more enthusiasm in their everyday lives. In addition, 71% of the participants reported that they had been (physically) more active and found more arts in their lives during the group. 81% of the participants had also found new friends in the group.

Conclusion: Peer-led "Reumatroppi" group activity has been able to raise the awareness for self-management among those living with rheumatic and/or musculoskeletal disease. The participants have paid more attention to their health behavior and found new resources that promote their overall well-being.

POS0202-PARE CHRONICALLY ACTIVE - A PATIENT EMPOWERMENT PROGRAM WITH PEER SUPPORT

Keywords: Work-related issues, Self-management, Best practices

A. Fryxelius[1,2]. [1]*Norsk Revmatikerforbund, Organization and development, oslo, Norway*; [2]*Diakonhjemmet Hospital, REMEDY, Oslo, Norway*

Background: Work life disability as a result from musculoskeletal conditions is a tremendous burden both on society and the individual. In Norway 1/3 of all disability pensions are granted on the background of rheumatic disease and musculoskeletal condition. The actual process of getting access to welfare support or a disability pension is built in such a way that it shames and diminishes the individual's sense of value. The process of getting help is in essence DIS-empowering, and trains the patients to hopelessness. The health care system and state pension system have no effective means of helping people overcome the mental and psychological stigmas and traumas associated with their disability. As Norway's largest patient organization in the musculo-skeletal field, we have a strong core of trained and experienced peer supporters. In 2012 we decided to leverage this base of peer supporters to make a positive, solution oriented, patient led self management course that can help patients break the negative cycle of passivity.

Objectives: To create and test a 5-day intensive intervention leading the patients through a guided empowerment process to learn symptom management and health mastery in a safe setting supported by their peers.

Methods: We combined methods from creative process management with existing science based methods on symptom management, motivation, empowerment and lifestyle change, to build a program for the patients consisting of 5 modules. The modules were designed to lead the participants through a group process that activated each individuals inner motivation for making effective lifestyle changes and healthy choices. As part of the process they received a solid framework for continued social support through their local chapter of the patient organization and in an online community. Each module combines 90 minutes of teaching with 30 minutes of physical activity: One module includes mindfulness practice for stress relief and relaxation. The course was called "Sykt Aktiv" which

roughly translates to "Chronically Active", and was marketed in social media to the age group 25-55. 20 participants were included in the first cohort back in 2014, since then the program has been reiterated, improved and repeated on a yearly basis.

Results: After the course, the participants reported that they had learnt a lot and it felt inspiring. But the interesting results came after 1-2 years, when several of the participants were able to go back to work, and they reported that what they learnt in the #SyktAKTIV/ #ChronicallyActive course had been what helped them find the way back.

Conclusion: A peer supported intervention organized by a patient organization has potential to help people with chronic pain and rheumatic conditions return to work life and lead healthy and active lives despite chronic illness.

Additional information: The creators behind this project have had the intention of sending an abstract about it to EULAR at least for the last 6 years. Unfortunately my organization has not seen itself able to prioritize spending money on sending staff to the EULAR congress for many years. Also, my own rheumatic conditions (I have had Scleroderma and Rheumatoid Arthritis since the age 11 & 19) always flare up during winter, and I am usually unable to work during this time of year. I am aware that this abstract doesn't hold the correct scientific standard, but I don't have the spoons (ref. Spoon Theory) to check all the references and have a scientist help me with getting things right. Luckily - the actual conference is in June, and at that time I am usually in a very much stronger physical condition, so I can guarantee that I will be able to participate and present this project orally.

REFERENCES: As stated above, I don't have the spoons to find all the references for this now, but you can contact my colleagues at REMEDY to vouch for my method and my ability to deliver good oral presentations:

Prof. Dr. Espen Haavardsholm.

PhD. Rikke Helene Moen.

HPR Poster Tour: Challenges in daily life for people with RMDs

POS0203-HPR THE RELATIONSHIP BETWEEN PATIENT-REPORTED QUALITY OF LIFE AND PHYSICIAN-DERIVED CLINICAL OUTCOMES IN RHEUMATOID ARTHRITIS: AN ANALYSIS FROM THE AUSTRALIAN OPAL DATASET

Keywords: Rheumatoid arthritis, Patient reported outcomes, Real-world evidence

G. Littlejohn[1,2], N. Anbumurali[1], C. Osullivan[1], T. Smith[1], T. Racunica[1,3], P. Pentony[1,4], S. Jayaweera[1,4], L. Girgis[1,5,6], C. Deakin[1]. *[1]OPAL Rheumatology Ltd, Rheumatology, Sydney, Australia*; *[2]Monash University, Department of Medicine, Clayton, Australia*; *[3]Southern Rheumatology, Rheumatology, Brighton, Australia*; *[4]RheumatologyACT, Rheumatology, Canberra, Australia*; *[5]University of New South Wales, Rheumatology, Sydney, Australia*; *[6]St Vincent's Hospital Sydney, Rheumatology, Darlinghurst, Australia*

Background: Remission or low disease activity (LDA) are the common therapeutic targets in the treat-to-target strategy for patients with rheumatoid arthritis (RA). Despite achieving these targets however, some patients continue to experience residual symptoms including pain, fatigue and functional loss. Patient reported outcomes (PROs) are an important tool to better understand the lived experience of the patient which is often not adequately captured by traditional disease activity measurements.

Objectives: To describe the levels of pain, fatigue, mood disturbance and physical function in a large cohort of Australian patients with RA and how they correlate with traditional clinical disease activity measures.

Methods: Clinical data were sourced from the OPAL dataset which is an aggregated collection of data extracted from the electronic medical record (EMR, Audit4, Software4Specialists Pty Ltd) of patients receiving routine care from 112 rheumatologists across Australia. Validated PRO questionnaires were electronically delivered to patients through their EMR via email or completed using a smart device in the waiting room prior to the consultation. Completed questionnaires were securely integrated into the patients EMR for review at the next consultation[1]. Patients with a physician diagnosis of RA and ≥6 months of disease activity recorded who had responded to at least one PRO (Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F), Patient Health Questionnaire-2 (PHQ-2), pain visual analogue scale (VAS) or the Multi-Dimensional Health Assessment Questionnaire (MD-HAQ)), between April 2020 and April 2022 were included. Disease activity was assessed using DAS28(3)-CRP which includes swollen and tender joint counts and CRP, but excludes the patient global assessment.

Results: 1,397 patients completed a pain VAS, 2,180 a FACIT-F, 2,101 a PHQ-2 and 2,243 a MD-HAQ during the study window. The median age of patients with a completed questionnaire was 62 years and 77.1% were female. Levels of pain, fatigue, mood disturbance and physical function for patients with RA are shown in Table 1. Overall, a substantial percentage of patients, (n=519, 37.2%), reported experiencing unacceptable pain (>40mm VAS) and clinically relevant fatigue (FACIT-F ≤ 34) (n=867, 39.8%). Higher levels of pain, fatigue and mood disturbance was associated with higher DAS28(3)-CRP disease activity. Of patients in DAS28(3)-CRP remission or LDA, 32.7% reported unacceptable levels of pain, 36.1% reported clinically relevant fatigue and 11.2% reported possible depression.

Conclusion: In general, we found that higher disease activity scores were associated with high levels of pain, fatigue, anhedonia and depressed moods. In addition, there exists a substantial cohort of patients in routine clinical care with swollen and tender joints counts and CRP levels indicative of remission or LDA that continued to experience unacceptable levels of pain and clinically relevant fatigue.

POS0204-HPR THE ROLE OF ARTIFICIAL INTELLIGENCE IN DETECTING DISTINCTIVE FACIAL FEATURES IN PATIENTS WITH SYSTEMIC SCLEROSIS, A PILOT STUDY

Keywords: Systemic sclerosis, Artificial Intelligence, Diagnostic Tests

Y. A. Suliman[1,2], J. E. Lund-Jacobsen[3], R. Christensen[4], L. E. Kristensen[5], D. Furst[6]. *[1]Assiut University hospital, Rheumatology and Rehabilitation, Assiut, Egypt*; *[2]Ain Alkhaleej hospital, Rheumatology, Alain- abu dhabi, United Arab Emirates*; *[3]Founder and CEO of Viceron ApS, Viceron ApS, Copenhagen, Denmark*; *[4]Faculty of Health Sciences at the University of Southern Denmark., Parker Institute, departement of biostatistics and clinical epidemiology at the Department of Clinical Research, Copenhagen, Denmark*; *[5]Faculty of Health Sciences at the University of Southern Denmark., Parker Institute, Copenhagen, Denmark*; *[6]David Geffen School of Medicine at UCLA, Rheumatology Division, Los Angeles, United States of America*

Background: Scleroderma (SSc) is a rare autoimmune fibrosing multisystem disease with high rates of morbidity and mortality. Scleroderma is usually diagnosed by rheumatologists and/or dermatologists. However, a delay in disease recognition may occur due to a delay in referral, as internists and family physicians are not familiar with the disease and its features. Even though, the facial features of the disease are characteristic for scleroderma, diagnosis is usually based on other signs and symptoms (e.g., skin thickening on extremities), and confirmed with investigations such as autoantibody tests, HRCT, and endoscopies. Late presentation of SSc pts. to rheumatologists is commonly reported[1]; patients with dcSSc generally presented to their primary health care Practitioner (HCP) after symptoms had persisted for up to 1 year. **We hypothesize that** facial features of SSc patients are distinctive and can be detected by a trained AI system after processing a mobile phone picture of SSc patient's face through Convolutional Neural Networks (CNN). This system could be used by family practioner and internists, aiding them to increase suspicion of SSc and refer patients in a timely manner.
Objectives: In a pilot study, we aim to examine the ability of an AI facial recognition system to identify SSc related facial features.
Methods: Images of SSc pts were compared to a group of age and sex matched normal faces. Deep Learning (DL) - Artificial Intelligence (AI) algorithms evaluated all the pixels in the facial map and identified their utility in the facial recognition prediction models. Using a transfer learning implementation developed by the Danish Viceron ApS AI company. This core model is well-established and experienced algorithm for AI facial feature recognition, based on > 1 million general public faces for facial feature recognition. AI evaluated multiple layers of mathematical models, either isolated or pooled to generate a predictive model and eliminate unnecessary data. Smoothing and uniformity protocols were established for the obtained through preprocessing for the Convolutional Neural Networks (CNN) (Figure 1).
Results: Images of 60 SSc pts from the internet were compared to a group of age and sex matched normal faces. We developed models among the 60 SSc facial images and matched controls that were able to identify SSc distinctive facial features with variable specificity and sensitivity. Multiple AI models were used on the training set which includes the first 40 patients and as a partial validation step on the other 20 patients with an equal baseline group built from normal faces. The best pre-trained model, fine-tuned on the training set, achieved 80-90% accuracy on the respective datasets. A larger data set, may provide better accuracy, allowing for more generalized facial recognition. The latter is planned, given the initial reasonable success from the pilot study.
Conclusion: Automated pre-processing and the application of AI algorithms in SSc face identification, gave encouraging pilot results (80-90% accuracy). Further testing to develop a larger protocol to establish the effects of race/ethnicity, sex, age, disease duration, disease activity is warranted.

POS0205-HPR

CHARACTERISATION OF RESEARCH PARTICIPANTS: A PRELIMINARY EXPLORATION USING ELECTRONIC PATIENT CASE RECORDS (EPCR)

Keywords: Gender/diversity issues, Descriptive Studies, Health Services Research

Y. Ahmed[1], E. Hawkins[1], R. Wilson[1], H. J'bari[1], L. Tomson[1], R. Taylor Gotch[1], M. Butt[1], M. Castelino[1]. [1]*University Collage London Hospital, Rheumatology, London, United Kingdom*

Background: A priority of the National Institute of Health Research is to ensure that research is inclusive at all levels. Underrepresentation of specific demographics affects the generalisability and external validity of trial findings. Clinical research participants should be a proportional and accurate representation of the patient population using the healthcare services. To ensure meaningful outcomes of clinical research, studies require engagement of participants from varied demographics. In April 2019 a new EPCR system (EPIC) was introduced at University College London Hospital (UCLH) that allows data searches of up to 10,000 records. As a first step towards incorporating these priorities in our research work, we explored the EPCR system to establish the characteristics of our research active population.
Objectives: 1. Compare the demographic identifiers of rheumatology patients at UCLH against the patients that have participated in rheumatology research at UCLH. 2. Establish underrepresented groups within the research cohort.
Methods: We extracted a random dataset of 10,000 patients who were associated with the rheumatology department using the electronic patient record database and identified the subgroup of research participants. The demographic identifiers: ethnicity, age, gender, and postcode were extracted for the entire dataset. The deprivation indices were determined using postcodes (1 most deprived, 10 least deprived)[1]. Ethnicity, age, gender, and indices of deprivation were compared between the groups. For descriptive analysis of this work we used the percentage of the population for each identifier of the rheumatology cohort and compared this to the research subgroup.
Results: There were 990 (9.9%) patients who were recorded as a participant of a research project. The ethnicities that had a higher percentage representation in the research subgroup were Black Caribbean (2.96% v 4.65% difference of 1.68) Other Black Background (1.14% v 2.53% difference of 1.38) and Other Mixed Background (1.29% v 2.32% difference of 1.04). Other White Background (9.49% v 7.27% difference of 2.22), Not Stated/ Unknown (2.99% v 1.11% difference of 1.88%) and White British (56.24% v 54.95% difference of 1.29) ethnic profiles had a lower percentage representation in the research subgroup when compared to the rheumatology cohort.

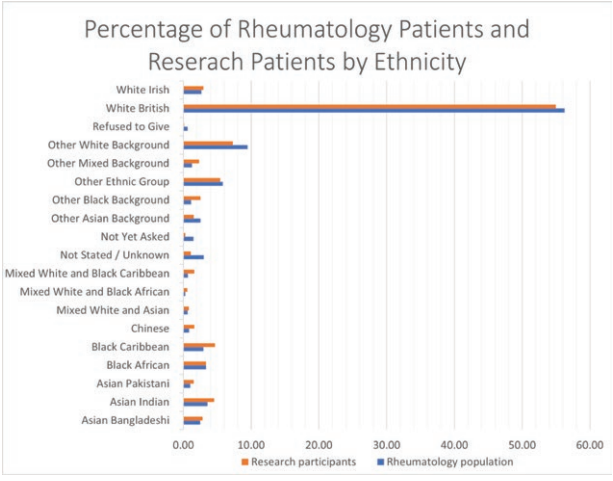

Figure 1.

All patients had a recorded gender of male or female. The rheumatology population was 60.97% female compared to 76.26% in the research subgroup. The deprivation index was 5.39 for the rheumatology cohort compared to the research

population of 5.24. A difference of 12.5 years was seen between the median age of rheumatology patients (61 years) compared to research participants (48.5 years).

Conclusion: From this random dataset analysis approximately 10% of the rheumatology population participated in research. The demographic profile of ethnicity and indices of deprivation were similar across both groups, however proportionately the research subgroup is younger and has higher representation of women compared to the rheumatology population. Limitations of this work include exclusion of research participants prior to the installation of the EPCR, incomplete documentation of research participation within EPCR and sample size limited to 10,000 of the rheumatology population. However, selection bias is reduced due to the large random sample size and generalisability and representativeness is an advantage of this. In view of the low uptake of research participation, it is very important to identify barriers to increasing engagement and involvement in research. Further research is warranted to explore if there are particular age groups that are underrepresented and establish reasons for lack of engagement of men in rheumatology clinical research.

Liu[1,5]. *[1]UMass Chan Medical School, Division of Epidemiology, Department of Population and Quantitative Health Sciences, Worcester, United States of America*; *[2]UMass Chan Medical School, Clinical and Population Health Research Program, Graduate School of Biomedical Sciences, Worcester, United States of America*; *[3]UMass Chan Medical School, Division of Biostatistics and Health Services Research, Department of Population and Quantitative Health Sciences, Worcester, United States of America*; *[4]Stanford University, Division of Immunology and Rheumatology, School of Medicine, Palo Alto, United States of America*; *[5]UMass Chan Medical School, Division of Rheumatology, Department of Medicine, Worcester, United States of America*; *[6]UMass Memorial Medical Center - Memorial Campus, Division of Rheumatology, Worcester, United States of America*

Background: Postpartum depression is a psychiatric illness that occurs after the birth of a child and affects 12.5% of women in the United States (1) and 17.2% of women globally [2]. Women of reproductive age with rheumatic diseases (RD) are at increased risk of clinical depression [3]. However, research examining postpartum depression in women with RD is scarce.

Objectives: We examined postpartum depression among women with axial spondyloarthritis (axSpA), rheumatoid arthritis (RA), or psoriatic arthritis (PsA) compared to a matched population without RD in the United States.

Methods: A retrospective analysis using data from the 2013-2018 IBM MarketScan Commercial Claims and Encounters Database was conducted. Pregnant women with axSpA, RA, or PsA were identified, and the date of delivery was used as the index date. We restricted the sample to women ≤ 55 years with continuous enrollment ≥ 6 months before date of last menstrual period and throughout pregnancy (baseline period). Each patient was matched with four individuals without RD on: 1) maternal age at delivery; 2) prior history of depression; and 2) duration of depression before delivery. The outcome of interest was a diagnosis of depression within one year of the index date. Cox frailty proportional hazards models adjusting for sociodemographic and clinical characteristics in the baseline period were used to estimate the crude and adjusted hazard ratios and 95% confidence interval (CI) of incident postpartum depression among women with axSpA, RA, or PsA (axSpA/RA/PsA group) compared to the matched non-RD comparison group.

Results: Overall, 2,667 women with axSpA, RA, or PsA and 10,668 patients without any RD were included. The average age at baseline was 33 years (SD: 5.0), and nearly two in five women were older than 35 years. The median follow-up time in days was 256 (Interquartile range (IQR): 553) and 265 (IQR: 564) for the axSpA/RA/PsA and matched non-RD comparison groups. Development of postpartum depression was more common in the axSpA/RA/PsA group relative to the matched non-RD comparison group (axSpA/RA/PsA group: 17.2%; matched non-RD comparison group: 12.8%; adjusted hazard ratio: 1.22 [95% CI, 1.09 – 1.36). Factors such as pre-existing comorbidities, maternal complications during pregnancy, and antidepressants use at baseline were associated with development of postpartum depression.

Conclusion: The rate of postpartum depression is significantly higher in women of reproductive age with axSpA, RA, or PsA compared to those without RD. Results from this study demonstrate that strategies to monitor postpartum depression after delivery in patients with RD must be developed and implemented to assure prompt referral of affected mothers for appropriate evaluation and treatment.

POS0207-HPR FEAR OF MOVEMENT MEDIATES THE RELATIONSHIP BETWEEN PAIN CATASTROPHISING AND PHYSICAL FUNCTION IN PEOPLE LIVING WITH AXIAL SPONDYLOARTHRITIS: A CROSS-SECTIONAL MEDIATION ANALYSIS

Keywords: Pain, Spondyloarthritis, Patient reported outcomes

P. Rouse[1], T. Ingram[1], M. Standage[1], R. Sengupta[2]. *[1]University of Bath, Department for Health, Bath, United Kingdom*; *[2]Royal United Hospitals Bath, Rheumatology, Bath, United Kingdom*

Background: Axial spondyloarthritis (axSpA) typically affects the axial skeleton and sacroiliac joints causing patients to experience pain, reduced movement, and impaired physical function. A range of treatment options are available to help axSpA patients reduce pain and maintain physical function and thereby enhance health-related quality of life. The European Alliance of Associations for Rheumatology (EULAR) identified activity as integral to the management of inflammatory arthritides, however, the majority of people living with axSpA are not sufficiently active to maintain physical function [1]. According to the Fear-Avoidance Model of Pain, fear of movement and pain catastrophizing contribute to poorer physical function via reduced activity and disuse [2]. Yet to date, no research has tested the theorized mediating role of fear of movement in the relationship between pain catastrophizing and physical function in people living with axSpA.

Objectives: To examine the mediating role of fear of movement in the relationship between pain catastrophizing and physical function in people living with axSpA.

Methods: Participants (*N* = 98, 70% female, *M* Age = 45.62 SD 12.16) completed an online survey (December 2020 – May 2021) distributed in the United Kingdom via the National Axial Spondyloarthritis Society (n ≈ 3,500; NASS, 2019). The Tampa Scale for Kinesiophobia (TSK-11) was used to measure fear of movement with participants rating 11-items from 1 (strongly disagree) to 4 (strongly agree). The Pain Catastrophising Scale (PCS) contains 13-items, each rated on a scale from 0 (not at all) to 4 (all the time). Both instruments have shown strong internal consistency in people living with axSpA [3,4]. The Bath Ankylosing Spondylitis Functional Index (BASFI) was used to assess physical function with higher scores indicating poorer function. Data were analysed using IBM SPSS (Version 28). The PROCESS SPSS macro was used, and interpretation made using the percentile bootstrap 95% confidence intervals from 5000 bootstrap samples. Standardised effects with values.01,.09, and.25 represent small, medium, and large effects [5].

RESULTS:

Table 1. Descriptive statistics and Bivariate correlations for the variables.

		M	*SD*	2	3
1	Pain Catastrophizing	18.34	13.65	.647**	.419**
2	Fear of Movement	24.99	7.22		.414**
3	Physical Function	3.73	2.59		

Bivariate correlations showed pain catastrophizing to have a significant medium and positive relationship with physical function and a large positive relationship with fear of movement. Mediation analysis (F = 12.67, p <.05, R^2 =.21) revealed that pain catastrophizing had a large positive direct effect on physical function (β=.259) and fear of movement (β=.647). Fear of movement had a large positive direct effect on physical function (β=.246). A significant medium and positive indirect effect of pain catastrophising on physical function via fear of movement was observed (β=.160, CI =.002 -.320).

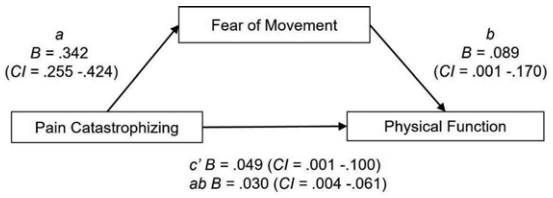

Figure 1. Path model with unstandardised regression coefficients *(B)* and percentile bootstrap confidence intervals (*CI*) identifying the mediating effect of fear of movement in the relationship between pain catastrophising and physical function. *c'* = direct effect, *ab* = indirect effect

Conclusion: Pain catastrophizing is experienced by people living with axSpA and can lead to the avoidance of movement, and as a result, compromised physical function. Our test of the Fear-Avoidance Model showed that pain catastrophizing significantly predicted the physical function of people living with axSpA and that this relationship was mediated by fear of movement. Fear of movement is a modifiable construct that can be a treatment target for health professionals to improve the physical function of people living with axSpA. Identifying modifiable factors that contribute to disease outcomes is critical to improve the care and quality of life for people living with a disease currently without a cure.

POS0208-HPR PATIENT CHARACTERISTICS AND DIAGNOSIS SETTING OF PATIENTS WITH PAIN ASSOCIATED WITH OSTEOARTHRITIS OF THE KNEE IN GERMANY: A RETROSPECTIVE HEALTH CLAIMS DATA ANALYSIS

Keywords: Osteoarthritis, Pain

D. Beier[1], D. Haeckl[2], S. Ivanavicius[3], J. Jerosch[4], H. Liedgens[5]. [1]*InGef - Institut für angewandte Gesundheitsforschung Berlin GmbH, Health Research, Berlin, Germany*; [2]*WIG2, Health Research, Leipzig, Germany*; [3]*Grunenthal GmbH, Global Medical Affairs, Aachen, Germany*; [4]*Medizinisches Wissenschafts- und Gutachten-Institut, Rheumatology, Meerbusch, Germany*; [5]*Grunenthal GmbH, Global HEOR, Aachen, Germany*

Background: Osteoarthritis of the knee (knee OA) is the most prevalent form of OA in Germany as well as globally[1], frequently leading to pain and functional limitations. Several risk factors have been identified for osteoarthritis, which can be divided into those at the person level (age, sex, obesity, genetic predisposition, physical activity and diet) and those at the joint level (injuries, malposition and overstress)[2]. Patients with OA-like symptoms may present to a number of different medical specialties and therefore arrive at a diagnosis of Knee OA via different routes. The Knee OA population is a highly co-morbid one. In addition to obesity, Knee OA patients often present with hypertension and diabetes[3].

Objectives: The study focuses on knee OA in Germany, aiming to determine the prevalence of OA in the years 2015-2020, diagnosis setting and comorbidities of patients between 2015 and 2020.

Methods: A non-interventional, retrospective health claims data analysis, performed with anonymized, age- and sex-representative sample of the Institute for Applied Health Research Berlin GmbH (InGef) database. The database used for this study includes approximately 4.8 million persons from approx. 60 statutory health insurances (SHI) and is representative for the German population [6]. Patients ≥18 years of age were analyzed cross-sectionally for each year 2015-2020. Using ICD-10-GM and ATC codes.

Results: The prevalence of knee OA ranged from 7.1% in 2015 to 7.6% in 2019, dropping to 7.4% in 2020. The incidence showed a less linear pattern ranging from 1.71% of patients in 2015 and 2016, 1.67% in 2017, 1.61% in 2018, 1.67 in 2019 to 1.46% of patients in 2020. Females and patients aged ≥66 years had both a higher prevalence and incidence proportion compared to males and younger persons. First diagnosis for most patients was made in an outpatient setting (93.4%) by orthopedics (49.88%), general practitioners (28.17%) and specialists (Internist; 9.34%). Most prevalent co-morbidities for patients with Knee OA in all years observed was primary hypertension with >70%. Other metabolic disorders like disorders of lipoprotein metabolism (around 50%), overweight and obesity (28-30%), type 2 diabetes mellitus (around 27%) are among the 10 most common ones. Other musculoskeletal disorders are frequent (dorsalgia 54%; spondylosis 33-34%). The percentage of patients with major depressive disorders is high in all years (23%).

Conclusion: The number of patients with knee OA is slowly increasing from 2015-2019 possibly due to the growing German population, however slightly decreasing in 2020. Diagnosis is mainly done by an orthopedist or general practitioner. The increasing number of certain co-morbidities, mainly of the cardiovascular system (hypertension with the highest percentage), but also due to metabolic condition (Disorders of lipoprotein metabolism and other lipidemias, overweight and obesity, type 2 diabetes) demonstrates that the percentage of patients with known risk factors for knee OA is increasing. Treating pain in patients with co-morbidities can be challenging due to managing drug-drug interactions given the considerable number of treatments patients could be receiving. This can be a high risk for these patients as physicians do not always know about non-prescription co-medications. Models of care for patients with knee OA which include tolerable, non-systemic pain treatments, enabling patient physiotherapy and management of other aspects of their health actively may be a key advancement.

POS0210-HPR

PATIENTS WITH ANKYLOSING SPONDYLITIS HAVE AN IMPAIRED DIETARY INTAKE – PRELIMINARY RESULTS FROM PATIENTS IN SWEDEN

Keywords: Diet and Nutrition

E. Hulander[1,2], T. Zverkova Sandstrom[1], J. Backman Renman[3], H. Forsblad-D'elia[1]. [1]*University of Gothenburg, Department of Rheumatology and Inflammation research, Gothenburg, Sweden*; [2]*Sahlgrenska University Hospital, Clinical Nutrition Lab, Gothenburg, Sweden*; [3]*Umeå University, Department of Nursing, Faculty of Medicine, Umeå, Sweden*

Background: Ankylosing Spondylitis (AS) is one of most common chronic inflammatory rheumatic diseases, affecting about 0.2 % of the population. As of today, there is no specific dietary guideline for managing AS patients, and no RCT-studies on diet intervention have been published. Furthermore, there is a lack of data on the relevance of dietary quality on disease outcomes in AS patients.

Objectives: The aim of this study was to assess dietary nutrient intake in AS patients and examine whether it differs compared to persons without AS.

Methods: AS patients (modified NY criteria) at the rheumatology clinic in Region Västerbotten, northern Sweden, were invited to take part in the Backbone study which investigates disease severity and comorbidities [1]. In total, 155 patients were included. Nutritional intake was assessed by the semi-quantitative food frequency questionnaire MiniMealQ [2]. Controls were collected from the Swedish CArdioPulmonary BioImage Study (n = 30154) (3), a study that invited randomly selected participants from the Swedish population register, 50-64 years of age. Out of the 155 patients with AS, 81 (52.3%) were in the same age-span. Four controls were collected for each AS patient, matched on age (± 1 year), sex and geographic location. Data on dietary intake was available for 318 controls. Statistical comparisons between patients with AS and controls were done by T-test, Fisher's exact test and by exact conditional logistic regression analysis, adjusted for country of birth, educational level, single household, weight, smoking status and energy intake. Variables already adjusted for energy intake (energy percentages, fiber density and energy intake itself), were analyzed without additional adjustment for energy intake.

Results: Characteristics of the AS patients and controls are shown in the Table 1. AS patients had a higher proportional intake of carbohydrate coupled with a lower fiber density, a lower intake of marine omega-3 fatty acids (Figure 1). Further, a lower intake of vitamin-D, E and K was seen as well as a lower intake of selenium, folate, magnesium, phosphorus, potassium, vitamin-A and β-carotene (a marker of vegetable and fruit intake).

Conclusion: Our results suggest that AS patients have an impaired dietary intake. Notably, intake was lower in several nutrients theorized to have anti-inflammatory properties (fiber density, marine-omega-3 fatty acids, vitamin-D and selenium). Further, we propose that nutrition screening might be incorporated in the management of AS patients since they appear to have an increased risk of nutritional deficiencies.

POS0211-HPR REDUCED SLEEP QUALITY IS HIGHLY PREVALENT AND ASSOCIATED WITH PHYSICAL FUNCTION AND CARDIORESPIRATORY FITNESS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Physical therapy/Physiotherapy, Rehabilitation, Spondyloarthritis

C. Fongen[1], H. Solveig Dagfinrud[1,2], A. Bilberg[3,4], S. Sveaas[5]. *[1]Diakonhjemmet Hospital, Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Norwegian National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway*; *[2]University of Oslo, Institute of Health and Society, Oslo, Norway*; *[3]Sahlgrenska Academy, University of Gothenburg, Neuroscience and Physiology, Section of Health and Rehabilitation, Gothenburg, Sweden*; *[4]Sahlgrenska University Hospital, Department of Physiotherapy, Gothenburg, Sweden*; *[5]University of Agder, Department of Nutrition and Public Health, Kristiansand, Norway*

Background: Sleep is an important aspect of health for patients with axial spondyloarthritis (axSpA)[1], and it is therefore essential to identify modifiable factors related to reduced sleep quality.
Objectives: To assess sleep quality and the associations between sleep quality and physical function, cardiorespiratory fitness and spinal mobility in patients with axSpA.
Methods: In this cross-sectional study, baseline data from the ESpA trial[2] was used. The assessments included sleep quality (Pittsburg Sleep Quality Index, PSQI) assessing 7 aspects of sleep quality (each scored 0-3, ≥2 reduced sleep quality), summed into a global score (0-21, 21=worst), performance-based physical function (Ankylosing Spondylitis (AS) Performance Index, ASPI; time), patient-reported physical function (Bath AS Functional Index, BASFI; 0-10, 10=worst), cardiorespiratory fitness (VO_2peak, ml/kg/min) and spinal mobility (Bath AS Metrology Index, BASMI; 0-10, 10=worst). Associations between PSQI (global score) and ASPI, BASFI, $V0_2$peak and BASMI were examined in separate models using linear regression analyses, controlling for age and sex.
Results: A total of 99 patients with axSpA were included, 55% male, mean age 46 years and 72% with high disease activity (ASDAS >2.1). Reduced sleep quality (PSQI global score >5) was found in 85% of the patients. The most frequently affected aspect was sleep disturbances (65%) followed by poor subjective sleep quality (53%), daytime dysfunction (41%) and increased sleep latency (41%) (figure 1). Adjusted for age and sex, statistically significant associations were observed between PSQI and ASPI (β=0.10, 95% CI=0.01, 0.19) and BASFI (β=0.85, 95% CI=0.51,1.20) and an inverse association between PSQI and VO_2peak (β= -0.14, 95% CI=-0.27, -0.01) (table 1), indicating that better sleep quality is associated with better performance-based and patient-reported physical function and higher cardiorespiratory fitness. There was no association between PSQI and BASMI.
Conclusion: Reduced sleep quality is highly prevalent in patients with axSpA, with disrupted sleep most frequently reported. Better sleep quality was associated with better physical function and higher cardiorespiratory fitness, but there was no association with spinal mobility. The results signify physical function and cardiorespiratory fitness as modifiable factors that are independently associated with sleep quality in patients with axSpA.

POS0212-HPR VOCATIONAL REHABILITATION FOR PEOPLE WITH INFLAMMATORY ARTHRITIS – AN EMPLOYER PERSPECTIVE

Keywords: Work-related issues, Inflammatory arthritides, Non-pharmacological interventions

C. M. T. Madsen[1,2], J. Frølund[3], W. J. Leach[3], J. Primdahl[2,4,5], A. Bremander[2,4,6], J. Reffstrup Christensen[3,7,8]. *[1]Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark*; *[2]Department of Regional Health Research, University of Southern Denmark, Odense, Denmark*; *[3]User Perspectives and Community-based Interventions, Department of Public Health, University of Southern Denmark, Odense, Denmark*; *[1]Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark*; *[5]Hospital of Southern Jutland, University Hospital of Southern Denmark, Aabenraa, Denmark*; *[6]Section of Rheumatology, Department of Clinical Sciences, Lund University, Lund, Sweden*; *[7]Research Unit of General Practice, Department of Public Health, University of Southern Denmark, Odense, Denmark*; *[8]Research Unit of General Practice, Aarhus University, Aarhus, Denmark*

Background: After diagnosis, people with inflammatory arthritis (IA), i.e., rheumatoid arthritis, psoriatic arthritis and axial spondyloarthritis, often experience reduced work ability and increased sick leave. As a result, they have an increased risk of job loss and permanent exclusion from the labour market.

Vocational rehabilitation (VR) is complex. VR includes a variety of components that aim to increase work ability and prevent sick leave and job loss. Effects of VR for people with IA are sparse [1]. To develop relevant VR in Denmark for people with IA, a good understanding of the employer perspective is important, as their involvement is crucial to effective VR.

Objectives: To explore how employers support their employees with IA to maintain their jobs and prevent sickness absenteeism and job loss.

Methods: A qualitative, explorative design was applied, based on a phenomenological and hermeneutic approach. We invited employer representatives (n=13) from workplaces where people with IA were employed (public and private companies with 11- 380 employees). An interview guide was developed based on qualitative research and the theory of occupational justice [2]. Individual semi-structured interviews were performed from November 2020 to February 2021. Data were analysed using Kirsti Malterud's systematic text condensation.

Results: Three themes were derived from the analysis:

1) *Participation in work*. All employer representatives were aware of and wanted to help solve their employees' challenges at work, but it was complicated and time consuming for them. They supported their employees through adaptation and prioritising of work tasks, arranged flexible working hours and were aware of the employee's need to balance work and family in everyday life. The employer representatives considered that the employees needed to be motivated, if job loss was to be prevented.
2) *Relationship between employer and employee.* In general, the employer representatives found it important for the employee to have trust in the employer and ask for help, in order to receive support. To prevent job loss, the relationship was essential. Furthermore, they made a big effort in supporting the employee. They stretched to meet the needs of their employees and they found that empathy was an important quality.
3) *Multidisciplinary collaboration.* The employer representatives involved the municipal job centres regarding legislative offers when necessary, and they requested the employee for collaboration with the healthcare professionals involved in treating the employees' IA. Furthermore, they asked for guidance from relevant trade unions, to find out about legislation in relation to sick leave.

Conclusion: Overall, the employer representatives wanted to support their employees with IA and to be involved in VR, even though preventing sick leave and job loss was experienced as complicated, time consuming and costly for the companies.

POS0213-HPR ESTIMATING REPLACEMENT OF SEDENTARY TIME WITH LIGHT AND MODERATE INTENSITY PHYSICAL ACTIVITY TO REDUCE CHRONIC MUSCULOSKELETAL PAIN AND FUNCTIONAL LIMITATION IN THE GENERAL POPULATION: THE JOHNSTON COUNTY HEALTH STUDY

Keywords: Osteoarthritis, Physical therapy/Physiotherapy, Rehabilitation

D. White[1], L. Arbeeva[2], B. Cleveland[2], J. Jakiela[1], T. Bye[1], T. Walker[2], S. Savage-Guin[2], Y. Golightly[3]. *[1]University of Delaware, Physical Therapy, Newark, United States of America*; *[2]UNC Chapel Hill, Thurston Arthritis Research Center, Chapel Hill, United States of America*; *[3]University of Nebraska Medical Center, College of Allied Health Professions, Omaha, United States of America*

Background: Chronic musculoskeletal pain (CMP) is a major public health issue given its high prevalence and negative consequences on pain and physical function. One potential approach to mitigate the symptoms of CMP is to replace sedentary time (*i.e*, sitting and resting during waking hours) with light intensity (*e.g.*, playing cards or light cooking) or moderate intensity *(e.g.*, brisk walking) activity. Little is known, however, about what intensity of physical activity (light or moderate) may be needed to replace sedentary behaviors in order to reduce CMP and functional limitation.

Objectives: The purpose of this study was to model replacement of sedentary time with light- and moderate-intensity physical activity and explore its association with reducing risk of CMP and functional limitation in adults from a large general population cohort.

Methods: We used cross-sectional data from the Johnston County Health Study (JoCoHS), which is actively enrolling adults 35-70 years of age from the general population of Johnston County, North Carolina, USA. Physical activity data measured with a hip-worn ActiGraph GT3X monitor were collected over 7 days. We applied standard methods for processing and classifying time spent in sedentary, light, and moderate physical activity. Our study outcomes included CMP, defined as having at least moderate pain on most days of any one month in the last 12 months in any joint, and functional limitation defined as having a walking speed in the slowest sex-specific tertile, which was < 0.6 m/s. We calculated Odds Ratios (OR) with 95% confidence intervals (CI) using logistic regression with Isotemporal Substitution of exposure terms for each intensity of physical activity (light or moderate) and sedentary time. ORs were adjusted for age, sex, and BMI.

Results: As of 12/15/2022, 414 adults had complete clinical and physical activity data (age [mean] (sd) 55.5 years (9.5), BMI 32.9 (8.1), 68% women, 23% Black), 74% had CMP and 33% had functional limitation. Average sedentary time was 9.1 hours/day. Modeling replacement of 10 min/day of sedentary time with 10 min/day of light intensity activity was not associated with CMP (adjusted OR 0.99, 95% CI [0.99, 1.02]), but did reduce the odds of functional limitation by 3% which met statistical significance (adjusted OR 0.97, 95% CI [0.94, 1.00]). Modeling replacement of 10 min/day of sedentary time with 10 min/day of moderate intensity activity reduced the odds of CMP by 11% (adjusted OR 0.89, 95% CI [0.80, 1.00]), and reduced the odds of functional limitation by 12%, though narrowly missing statistical significance (adjusted OR 0.88, 95% CI [0.76. 1.01]).

Conclusion: Substituting light intensity activity for sedentary time was associated with a lower occurrence of functional limitation, but not CMP. Substituting moderate intensity for sedentary time was associated with less CMP with a trend for less functional limitation. These preliminary findings suggest that participation in moderate intensity physical activity may have stronger protective effects for CMP and functional limitation than light intensity physical activity.

Table 1. Preliminary cross-sectional data at baseline showing the relation of removing sedentary time and adding light and moderate physical activity with odds of prevalent chronic musculoskeletal pain and functional limitation from n=414 JoCoHS participants. Bold indicates p<0.05.

Remove	Add	Prevalent Chronic Musculoskeletal Pain (95% CI)*	Prevalent Functional Limitation (95% CI)*
10 min/day sedentary time	10 min/day light intensity activity	0.99 (0.99, 1.02)	**0.97 (0.94, 1.00)**
10 min/day sedentary time	10 min/day moderate intensity activity	**0.89 (0.80, 1.00)**	0.88 (0.76, 1.01)

* Odds Ratios and 95% CI are adjusted for age, sex, and BMI.

Background: Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA), two different ANCA-associated vasculitides (AAV), are clinically heterogeneous. Little is known about potential differences in clinical presentation of disease between females and males and between patients diagnosed at a young versus at an older age. Likewise, associations between different clinical manifestations have not been thoroughly investigated.
Objectives: To improve care and prediction of outcome in patients with AAV, the aims of this study were to identify and thoroughly characterize subgroups of AAV patients, stratified for sex, age at diagnosis and clinical manifestations.
Methods: In a systematic multicenter study, adult patients diagnosed with GPA or MPA were included between 2008-2018. Clinical data including sex, age at diagnosis, ANCA-specificity, relapse and cumulative disease involvement of ear-nose-throat (ENT), lungs, eyes, kidneys, muscles/joints, skin, central nervous system (CNS), peripheral nervous system (PNS), gastrointestinal tract (GI) and heart were collected from medical records. Organ involvements were analyzed for associations with sex, age at diagnosis and relapse, in GPA and MPA, separately, using logistic regression. Agglomerative hierarchical cluster analysis was performed using the Ward method, based on the n number of axes explaining ≥90% of total variability in multiple correspondence analysis of the collected clinical data in GPA and MPA. The optimal number of clusters was estimated by determining the gain in within-cluster inertia achieved at each clustering step[1].
Results: In total, 1156 patients (578 females, 578 males) were included in the study; 922 were classified as GPA, 234 as MPA. In GPA, pulmonary and renal involvement, as well as PR3-ANCA, were significantly associated with male sex, whereas MPO-ANCA was associated with female sex. In MPA, the only difference between the sexes was an older age at diagnosis in males than females. In GPA, the age at diagnosis showed a bimodal pattern with two peaks of incidence with mean (range) at 22.4 (9-31) and 57.1 (32-91) years of age, respectively. Comparing GPA patients younger than 32 years old at diagnosis with those older than 32 identified a significantly higher prevalence of females, ENT- and GI involvement and relapse rate in the younger group and PNS involvement in the older group. In all GPA patients, relapse was associated with pulmonary involvement, whereas in MPA relapse was associated with musculoskeletal involvement. Hierarchical cluster analysis of GPA and MPA identified five and seven distinct clusters, respectively. For both diseases, three of the clusters were defined by heart-, CNS- and GI involvement, respectively. In GPA, the largest cluster was defined by PR3-ANCA and ENT involvement and the fifth cluster by MPO-ANCA, female dominance and a low rate of ENT involvement. The additional four clusters in MPA were defined by i) eye involvement, ii) absence of renal involvement, iii) PR3-ANCA and iv) MPO-ANCA with renal involvement (largest), respectively. In addition, in several of the clusters in both GPA and MPA, there was a significant enrichment or depletion of additional clinical manifestations, in comparison with the largest cluster.

Conclusion: The results of this study indicate distinct disease courses of GPA in females and males, and strongly suggest that sex and age at diagnosis should be considered in the clinical assessment of disease outcome in GPA patients. The identification of associations between different clinical manifestations in the cluster analysis may facilitate the prediction of organ involvements in patients with AAV, and, subsequently, clinical decision-making.

CLASSIC VERSUS ATYPICAL POLYMYALGIA RHEUMATICA: TWO SIDES OF THE SAME COIN OR MISCLASSIFICATION?

Keywords: Imaging, Myositis, Pain

Y. El Miedany[1], M. Toth[2], M. Elgaafary[3], S. Bahlas[4], M. H. Abu-Zaid[5], W. Hassan[6], S. A. A. Tabra[5], W. Elwakil[7], S. Saber[8], N. Kamel[8]. *[1]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom*; *[2]King's College London - Darent Valley Hospital, General Medicine, London, United Kingdom*; *[3]Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt*; *[4]King Abdulaziz University, Rheumatology, Jeddah, Saudi Arabia*; *[5]Faculty Of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt*; *[6]Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Benha, Egypt*; *[7]Faculty of Medicine Alexandria University, Rheumatology and Rehabilitation, Alexandria, Egypt*; *[8]Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt*

Background: PMR is usually diagnosed based on the patient's clinical history and confirmed by the presence of an elevated inflammatory markers ESR and CRP. Once the diagnosis is confirmed, steroid therapy is commenced, and their response is usually rapid and dramatic. However, sometimes patients may present with symptoms similar to PMR but do not meet the 2012 EULAR/ACR criteria. It is not well known if these atypical patients represent a subtype of PMR or another musculoskeletal inflammatory condition.
Objectives: 1. to compare the clinical, laboratory and sonographic patterns in patients presenting with classic PMR versus those with atypical PMR symptoms. 2. To assess whether ultrasonography of the shoulders and hips has added value for PMR subclassification.
Methods: Longitudinal multi-center prospective study of patients presenting with PMR symptoms and their respective US scans of the shoulders and hips. The patients were stratified into a cohort of classic PMR who meet the 2012 EULAR/ACR criteria; and a group of atypical PMR presenting with symptoms similar to classic PMR but did not fulfil the 2012 EULAR/ACR criteria. Every patient was assessed clinically, had blood tests for ESR, CRP, basic rheumatology blood profile, urine analysis (to rule out microscopic hematuria), CK, bone profile, rheumatoid factor, anti-CCP, ANA, TSH and HbA1c. US scan was carried out for both shoulders and hips. The patients were treated according to agreed protocol and monitored for 12-months.
Results: 104 patients (68 women and 36 men) with a mean age±SD of 63.2±9.7 years. Eighty-one (84/104) patients had classic PMR and 20 (19.3%) atypical PMR. Patients with atypical PMR had shorter duration of symptoms (8.1 + 1.3 Vs 14.6 + 1.5 weeks). In the atypical PMR patients, pain in the hip/pelvic girdle was more frequent (100% vs 60.1%), whereas shoulder girdle pain was less (50% vs 98), in comparison to the classic PMR patients. Arthritis was less common in the atypical PMR cohort (15% Vs 42%), similarly GCA was less prevalent in the atypical PMR (5% Vs 20.2%). Patients with classic PMR were more likely to have bilateral abnormal ultrasound findings in the shoulder (particularly subdeltoid bursitis [92%] and biceps tenosynovitis [83.3%]), as well as in the hips [78.6%] than the atypical PMR subjects where US findings tend to be unilateral (shoulder 50% and the hip 75%). Systematic symptoms: fatigue, weight loss, fever were more common in the classic PMR than atypical PMR (%). No significant difference on comparing morning stiffness in both groups. Both patients' groups responded very well to steroid therapy with significant improvement in the symptoms in 2-4 weeks' time.

Conclusion: Patients with atypical PMR could represent an early form of the classic PMR. Atypical PMR used to have a shorter evolution of symptoms, have predominantly hip/pelvic girdle affection. US of the shoulders and hips may have an added value for stratifying PMR patients and differentiating atypical PMR from other musculoskeletal conditions.

POS0216 A PROSPECTIVE COMPARATIVE STUDY OF TEMPORAL ARTERY ULTRASOUND, TEMPORAL ARTERY BIOPSY, TEMPORAL ARTERY MAGNETIC RESONANCE ANGIOGRAPHY AND ACR GCA CLASSIFICATION CRITERIA IN AN INCEPTION GCA COHORT

Keywords: Vasculitis, Diagnostic Tests, Ultrasound

C. Kirby[1], R. Flood[1], D. Landers[2], K. MC Kevitt[3], G. Fulton[4], E. Boyle[3], K. O' Regan[5], R. Mullan[1], G. Murphy6, D. Kane[1]. *[1]Tallaght University Hospital, Rheumatology, Dublin, Ireland*; *[2]Cork University Hospital, Rheumatology, Cork, Ireland*; *[3]Tallaght University Hospital, Vascular Surgery, Dublin, Ireland*; *[4]Cork University Hospital, Vascular Surgery, Cork, Ireland*; *[5]Cork University Hospital, Radiology, Cork, Ireland*; *[2]Cork University Hospital, Rheumatology, Cork, Ireland*

Background: Temporal Artery Biopsy (TAB) is costly, invasive and has a false negative rate as high as 60% [1]. Temporal Artery Ultrasound (TAUS) and Superficial Temporal Artery (STA) MR-Angiography (MRA) have shown widely disparate results in studies to date [1-3]. ACR GCA Classification Criteria are often mis-used in clinical practice as diagnostic criteria.

Objectives: In this prospective study, we compare TAUS, TAB and STA MRA to physician diagnosis of GCA at 6 months.

Methods: We performed a prospective study of all new referrals (n=124) to our Rapid Access GCA clinic over 18 months. US of all 6 branches of the STA and both axillary arteries was performed using a GE P9 device. Abnormalities considered indicative of vasculitis in the STA included the halo sign (Figure 1) and non-compressible arteries with a thickened intima-media complex [4]. In the axillary arteries, a halo sign and an intima-media thickness of >1.0mm was considered positive. A subset of our patients were referred for TAB and/or MRA. MRAs were scored 0-4 based on mural wall thickness and signal intensity of mural peri-adventitial contrast enhancement [5]. We compared results to a clinical diagnosis of GCA at 6 months, verified by 2 rheumatologists. We performed Chi-Square tests with ROC analyses to determine the performance of each diagnostic modality.

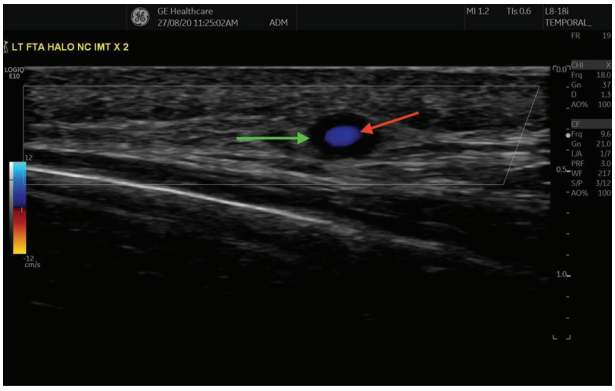

Figure 1. Transverse view of STA, demonstrating a halo sign, as indicated by the anechoic region (green arrow) surrounding the inner Doppler (red arrow) signal.

Results: Sixty-six patients had a clinical diagnosis of GCA of which 58% were males (n=38) with a mean age of 73.3 years. The performance of the various diagnostic tools is outlined in table 1.

Table 1. Sensitivities, Specificities and Area Under the Curve (AUC) values for Temporal and Axillary Artery Ultrasound, ACR GCA Classification Criteria, Temporal Artery Biopsy and Superficial Temporal Artery Magnetic Resonance Angiography for physician-verified diagnosis of GCA at 6 months. CI = Confidence Intervals.

Tool	n=	Sensitivity (%)	Specificity (%)	p-value	AUC	CI	p-value
US	124	86.4	82.8	<0.005	0.846	0.772-0.920	< 0.005
ACR CC	124	72.7	70.7	<0.005	0.717	0.625-0.809	<0.005
TAB	64	40.4	100	<0.05	0.702	0.568-0.836	<0.05
STA MRA	22	47.1%	20%	0.193	0.335	0.072-0.598	0.273

Conclusion: TAUS is a reliable tool for diagnosing GCA with a high degree of sensitivity and specificity. TAUS outperforms TAB, MRA and ACR GCA Classification Criteria when compared to a clinical diagnosis of GCA at 6 months. We propose that TAUS should replace TAB as the gold standard diagnostic test and that all rheumatologists should acquire the necessary skills to accurately perform this investigation as part of routine clinical care.

POS0217 ASSOCIATION BETWEEN VASCULAR FDG UPTAKE AND AORTIC DIMENSIONS IN GIANT CELL ARTERITIS: A PROSPECTIVE STUDY

Keywords: Vasculitis, Imaging

L. Moreel[1,2], W. Coudyzer[3], L. Boeckxstaens[4], A. Betrains[1,2], G. Molenberghs[5], S. Vanderschueren[1,2], E. Claus[3], K. Van Laere[4,6], D. Blockmans[1,2]. *[1]University Hospitals Leuven, Department of General Internal Medicine, Leuven, Belgium*; *[2]KU Leuven, Department of Microbiology, Immunology, and Transplantation, Leuven, Belgium*; *[3]University Hospitals Leuven, Department of Radiology, Leuven, Belgium*; *[4]University Hospitals Leuven, Department of Nuclear Medicine, Leuven, Belgium*; *[5]KU Leuven, Interuniversity Institute for Biostatistics and Statistical Bioinformatics (I-BioStat), Leuven, Belgium*; *[6]KU Leuven, Department of Imaging and Pathology, Nuclear Medicine and Molecular Imaging, Leuven, Belgium*

Background: Patients with giant cell arteritis (GCA) have an increased risk of developing aortic aneurysms. Retrospective studies have shown that ^{18}F-fluorodeoxyglucose (FDG) uptake in large vessels at diagnosis increases the risk of developing aortic complications during follow-up.

Objectives: To prospectively evaluate the association between vascular FDG uptake at diagnosis and the evolution of aortic diameter and volume in patients with GCA.

Methods: GCA patients who had FDG positron emission tomography (PET) imaging at diagnosis within 3 days of initiation of glucocorticoids and who were prospectively followed for at least 2 years were included. PET scans were visually scored (0-3) at 7 vascular areas and a total vascular score (TVS) was calculated, ranging from 0 to 21. Patients underwent a computed tomography (CT) scan at diagnosis and yearly thereafter for a maximum of 10 years. The association between vascular FDG uptake and aortic diameter and volume was estimated by linear mixed effect models with random intercept and slope adjusted for age, sex, cardiovascular risk factors, CT or PET/CT scan and intravenous contrast. The ascending aorta, aortic arch, and descending aorta were considered aneurysmatic when the diameter was ≥45, ≥40, and ≥35 mm, respectively.

Results: Hundred patients (mean age 70 years, 68% females) were included, of which 74 patients had FDG uptake ≥2 in any large vessel, 60 in the thoracic aorta and 49 in the abdominal aorta. Median follow-up was 80 months (IQR 47-110). The increase in ascending and descending aortic diameter and in thoracic aortic volume was higher in patients with vascular FDG uptake ≥2 compared to those without (**Table 1**). This increase was also significantly associated with TVS (**Figure 1**). FDG uptake was not associated with an increase in abdominal aortic diameter nor volume. Thoracic aortic aneurysms were more frequently observed in patients with thoracic aortic FDG uptake (27% versus 10%, aOR 6.6, 95%-CI 1.8-31.0, p=0.009) with a median time since diagnosis of 40 months (IQR 18-61). Two patients with high TVS (15 and 16) needed surgery for thoracic aortic aneurysm.

Conclusion: Thoracic aortic FDG uptake at diagnosis is an independent risk factor for developing thoracic aortic aneurysm in GCA patients. Higher TVS was associated with greater yearly increase in thoracic aortic volume and diameter. Follow-up of aortic dimensions may be necessary in these patients.

Table 1. Evolution of the aortic diameter (in mm) and volume (in cm³) per year in patients with (PET positive) and without (PET negative) vascular FDG uptake ≥2

POS0221 **CLINICAL, LABORATORY AND ULTRASONOGRAPHIC FINDINGS AT BASELINE CAN PREDICT THE LONG-TERM OUTCOME OF POLYMYALGIA RHEUMATICA**

Keywords: Inflammatory arthritides, Ultrasound, Vasculitis

E. Conticini[1], P. Falsetti[1], M. D'alessandro[2], C. Baldi[1], S. Grazzini[1], S. G. Al Khayyat[1], R. D'alessandro[1], S. Gentileschi[1], F. Bellisai[1], C. Barreca[1], C. Acciai[3], E. Bargagli[2], L. Cantarini[1], B. Frediani[1]. [1]*University of Siena, Rheumatology Unit, Siena, Italy*; [2]*University of Siena, Respiratory Diseases and Lung Transplantation Unit, Siena, Italy*; [3]*San Donato Hospital, Rehabilitation Unit, Arezzo, Italy*

Background: No definite clinical, laboratory or imaging finding has been identified to predict prognosis and different clinical course of PMR, nor the risk of further relapses.

Objectives: Primary endpoint was to assess the rate of PMR patients who, during the follow-up, undergo a diagnosis of GCA and arthritis, as well as to assess which clinical, laboratory and US findings are associated to a diagnostic shift and predict the long-term evolution of PMR. Secondary endpoint was to assess the optimal use of US in PMR.

Methods: All patients who were diagnosed with PMR in our Rheumatology Unit from January 2017 to January 2022 and followed-up for at least 12 months were retrospectively included. If performed at the time of diagnosis, musculoskeletal and temporal (TA) and axillary arteries (AxA) US findings were recorded, too.
Results: A total of 201 patients (mean age 73.4 ± 7.63, M/F 89/112) were included. According to the US performed at baseline, patients were subdivided in 4 subgroups: in 32 of them, the diagnosis was only clinical (A); 35 underwent shoulders, hips, wrists and knees US (B); 48 underwent shoulders, hips, TA and AxA US (C), while 86 shoulders, hips, wrists, knees, TA and AxA US (D). At baseline, 14/132 (10.6%) of patients from groups C and D displayed findings consistent with GCA. During the follow-up, 47%, 52.8% and 60% of PMR patients who were re-evaluated at 12, 24 and 36 months, respectively, had a change in diagnosis (**figure 1**). The multivariate logistic regression showed that bilateral LHBT tenosynovitis at onset was the variable that better defined the persistence in PMR diagnosis (p=0.05, OR 8.425), whereas GH synovitis (p=0.022, OR 0.074) and RF positivity (p=0.028, OR 0.993) were the variables associated to a diagnostic shift on the follow-up. The model that better described (AUROC 0.854) a patient with a PMR-onset with subsequent diagnostic shift comprised higher frequency of bilateral GH synovitis, bilateral shoulder PD, higher values of CRP, WBC, PLT and Hb and longer time to obtain remission. On the other hand, the ones maintaining diagnosis of PMR had bilateral exudative LHBT tenosynovitis (OR 8.425) and SA-SD bursitis (OR 2.619), higher values of ESR (OR 1.015), lower values of Hb (OR 0.428) and shorter time to remission (OR 1.076). Continuous variables were included in a hierarchical clustering analysis identifying two groups. Cluster 2 identified older patients, with lower systemic inflammation, lower levels of WBC, PLT and Hb, who had a higher persistence in PMR diagnosis at 12 (42.7% vs 29.3%), 24 (37.2% vs 25.6%) and 36 months (36.4% vs 21.2%). Cluster 2 had lower frequency of PD positivity (PD 0 in 39.1% on shoulders and 47.1% on wrists) or peripheral synovitis (absence of synovitis on knee and MCF in 43.9% and 50% respectively), more frequent flares, and were taking PDN at 12 (until 45.8%) and 24 months (until 30.8%). An environmental trigger before onset were more commonly reported (in 5,8% vaccinations before onset, vs 1.4% in cluster 1) The comparisons among the B, C and D and A showed significant differences in diagnosis at 12 (p=0.0145) and 24 months (p=0.0432) and dosage of GC at 12 months (p=0.0009). At 12 months the complete withdrawal of PDN was achieved in a significant (p=0.002) lower number of patients belonging to group A (6.4%) when compared to group B (28.1%), C (37,5%) and D (12.9%). A direct correlation was obtained between GC dosage at 12 and 24 months (Spearman rho 0.284, p=0.002). Finally, a longer time to remission correlated positively with CRP and negatively with Hb, while fever at disease onset positively with ESR.
Conclusion: More than half patients fulfilling criteria for PMR have their diagnosis changed during follow-up. The early use of US is associated with a more accurate diagnosis at baseline, as well as to a lower cumulative dosage of PDN. The early diagnosis of GCA is possible only in case of AxA and TA US at diagnosis. On the other hand, the lack of US is associated to a prolonged PDN treatment. Patient with a definite subset of clinical (fever, short time to remission), laboratory (lower Hb and CRP, higher ESR) and US findings (lower PD signal, LHBT tenosynovitis) are more prone to maintain the diagnosis of PMR during the follow-up.

EFFICACY AND SAFETY OF AVACOPAN IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS RECEIVING RITUXIMAB IN THE ADVOCATE TRIAL

Keywords: Randomized control trial, Clinical Trials, Vasculitis

D. Geetha[1], A. Dua[2], H. Yue[3], C. Salvarani[4], D. Jayne[5], P. A. Merkel[6]. *[1]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States of America*; *[2]Northwestern University Feinberg School of Medicine, Department of Medicine, Chicago, United States of America*; *[3]Amgen, Inc., Department of Biostatistics, San Carlos, United States of America*; *[4]Azienda Unita Sanitaria Locale di Reggio Emilia, Department of Internal Medicine, Reggio Emilia, Italy*; *[5]University of Cambridge, Department of Medicine, Cambridge, United Kingdom*; *[6]University of Pennsylvania, Department of Medicine, Philadelphia, United States of America*

Background: The randomized, double-blind, double-dummy, controlled Phase 3 ADVOCATE trial tested whether avacopan, an oral selective C5a receptor inhibitor approved for the treatment of ANCA-associated vasculitis (AAV), could replace a glucocorticoid (GC)-tapering regimen. Randomization was stratified according to vasculitis disease status (newly diagnosed or relapsing), ANCA status (anti-proteinase 3 (PR3) positive or anti-myeloperoxidase positive), and immunosuppressive treatment (cyclophosphamide (CYC) or rituximab (RTX)).[1] American College of Rheumatology/Vasculitis Foundation guidelines recommend induction treatment with RTX over CYC.[2] For relapsing disease, EULAR guidelines recommend RTX.[3]
Objectives: To evaluate the efficacy and safety of avacopan in patients in the RTX stratum of the ADVOCATE trial.
Methods: Primary efficacy endpoints were the proportion of patients achieving disease remission at week 26 and sustained remission at week 52 (Birmingham Vasculitis Activity Score (BVAS) of 0 and no GC use for AAV 4 weeks before measurement). RTX was administered intravenously 375 mg/m^2 once weekly for 4 weeks beginning on Day 1. The protocol did not include repeat dosing of RTX, according to its approved labeled regimen at the time.
Results: A total 214 of 330 patients (64.8%) comprised the RTX stratum. At baseline, patients were 60 years old (mean), ~76% had renal vasculitis (based on BVAS), ~46% were PR3-ANCA positive, and ~58% were newly diagnosed. Men constituted 57.0% of the avacopan group and 48.6% of the prednisone group. Baseline estimated glomerular filtration rate (eGFR) was 57.1±32.2 and 56.0±33.4 mL/min/1.73 m^2 (mean±SD), for the avacopan and prednisone groups, respectively. Remission at week 26 was 77.6% in the avacopan group and 75.7% in the prednisone group (**Table 1**). Sustained remission at week 52 was 71.0% in the avacopan group and 56.1% in the prednisone group (**Table 1**), estimated common difference, 16.5 percentage points; 95% confidence interval, 4.3 to 28.6; P=0.004 for superiority. Additionally, there were numerical improvements in relapse rate, albuminuria, and lower GC-associated toxicity in the avacopan group versus the prednisone group. The proportion of patients experiencing a serious treatment emergent adverse event (TEAE) was 34.6% (n = 37) with 62 events in the avacopan group compared to 39.3% (n = 42) with 91 events in the prednisone group (**Table 1**).
Conclusion: This analysis from the ADVOCATE trial of patients with AAV receiving RTX showed a significantly increased sustained remission rate at week 52 in the avacopan group compared to the prednisone group. Compared to the prednisone group, patients in the avacopan group had numerical improvements in remission at week 26, relapse rate, eGFR, albuminuria, and less GC toxicity. There was no increase in serious TEAEs in patients treated with avacopan. These results demonstrate the efficacy of avacopan for achieving and sustaining remission in patients with AAV treated with RTX.

LONG-TERM SURVEILLANCE STUDY OF RITUXIMAB (MABTHERA)-TREATED PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS (GPA) OR MICROSCOPIC POLYANGIITIS (MPA): RITUXIMAB SURVEILLANCE STUDY IN VASCULITIS (RIVAS)

Keywords: Real-world evidence, Vasculitis

L. Uchida[1], C. Loechel[2], M. Nodale[3], S. Bond[3], D. Jayne[1,2]. [1]*University of Cambridge, Department of Medicine, Cambridge, United Kingdom*; [2]*Cambridge University Hospitals National Health Service (NHS) Foundation Trust, Vasculitis and Lupus Clinic, Cambridge, United Kingdom*; [3]*Cambridge University Hospitals NHS Foundation Trust, Cambridge Clinical Trials Unit, Cambridge, United Kingdom*

Background: Rituximab is used for remission induction, and for the prevention of relapse in ANCA-associated vasculitis (AAV). However, the long-term safety of rituximab in the real-world setting remains unclear.
Objectives: To evaluate the incidence of safety events (serious adverse events and adverse events of special interest) and risk profile of rituximab and to compare the time to first safety event between a rituximab cohort and a cohort treated with other therapies over 6 months to 15 years from first exposure.
Methods: RIVAS was a retrospective, observational study including patients with GPA/MPA who had received rituximab (MabThera) or other treatments between 2003 and 2018 at Addenbrooke's hospital, Cambridge, UK. Clinical and laboratory variables were collected at baseline and every 12-18 months until 30 September 2018. To calculate the time to event, Time 0 was defined as either initiation of MabThera treatment for the rituximab cohort or the time of first disease flare/diagnosis for the control cohort. The primary endpoint was the time to first safety event. Key secondary endpoints were time to first pre-categorized safety event such as serious infection and cardiovascular disorders. The time to second safety event was an exploratory endpoint.
Results: 392 GPA/MPA patients were enrolled: 247 in the rituximab and 145 in the control cohort with a total of 2,217 person-years (mean study duration 5.7 years). Mean age was 61 years, 52% were female, 77% had GPA and 23% MPA. The mean disease duration at baseline was 55.3 months (SD 70.2) in the rituximab, while 33.3 months (SD 63.8) in the control arm. Baseline characteristics were not matched between groups reflecting the predominant use of rituximab for relapsing or refractory disease. Five hundred and thirty-three safety events occurred in 164 patients (66%) in the rituximab and 170 in 78 patients (54%) in the control group. Sixty-seven patients (27%) in the rituximab group and 19 patients (13%) in the control group experienced serious infection (Table 1). Thirty patients (12%) in the rituximab group developed severe hypogammaglobulinemia (IgG <3 g/l) requiring treatment/change of treatment or hypogammaglobulinemia requiring IVIg and 19 (8%) received IVIg compared to 3 (2%) and 1 (0.7%) patient in the control group. There were no differences in incidence rates for malignancy, cardiovascular events or renal insufficiency between groups. There was no difference in the time to first safety event between groups (HR 1.32, 95%CI 0.952-1.83, p=0.096), nor in the time to first pre-categorized safety event. However, a shorter time to second safety event was observed in the rituximab group (HR 1.98, 95%CI 1.25-3.13, p=0.004) (Figure 1). Predictors of safety events were older age, higher vasculitis damage scores and chronic pulmonary and renal disease. The relative risk of serious infection was higher in the rituximab group (unadjusted relative risk (RR) 2.07; 95%CI 1.30-3.30).
Conclusion: Over 60% of patients with GPA/MPA experienced a safety event in their disease course. Rituximab did not increase the risk of experiencing a first safety event but the time to second safety event was shorter in the rituximab group. Limitations of the trial design do not permit firm conclusions concerning differences between treatment groups.

Table 1. Safety events by event category for rituximab and control groups

Event type	Events(n)/ Patients (n(%)) Rituximab	Events(n)/ Patients (n(%)) Control
All safety events	533/ 164 (66%)	170/ 78 (54%)
Serious infection	124/ 67 (27%)	29/ 19 (13%)
Cardiovascular disorder	42/ 36 (15%)	22/ 18 (12%)
Haematological events	35/ 31 (13%)	9/ 9 (6%)
Malignant events	28/ 21 (9%)	21/ 16 (11%)
Renal Insufficiency	21/ 15 (6%)	20/ 15 (10%)
PML	1/ 1 (0.4%)	0/ 0 (0%)
Additional safety events	282/ 122 (49%)	69/ 48 (33%)

n, number; PML, progressive multifocal leukoencephalopathy.

Treatment in psoriatic arthritis on the move

POS0224

ENHANCED SURVEILLANCE FOR THE DETECTION OF PSORIATIC ARTHRITIS IN A UK PRIMARY CARE PSORIASIS POPULATION VERSUS USUAL CARE: RESULTS AT 24 MONTHS FROM THE THE TOTAL BURDEN OF PSORIASIS (TUDOR) RANDOMISED CONTROL TRIAL

Keywords: Clinical Trials, Psoriatic arthritis, Randomized control trial

S. Brown[1], L. Coates[2], H. Collier[1], C. Davies[1], P. Helliwell[3], J. Packham[4], M. Ransom[3], W. Tillett[5,6], N. Mchugh[5,6]. Background: Delay in the diagnosis of psoriatic arthritis may be associated with poorer outcome. However, the effectiveness of strategies to enable early detection of psoriatic arthritis in a primary care population with psoriasis have not been investigated in a prospective randomised control trial.
Objectives: The primary objective was to determine whether early detection of undiagnosed PsA in people with psoriasis by an enhanced surveillance (ES) intervention compared to standard care (SC) improves outcome in physical function at 24 months post-registration. Secondary objectives were to compare disease activity and impact of disease between groups in those participants diagnosed with PsA.

Methods: A multi-centre, prospective, parallel group cluster randomised controlled trial in patients with psoriasis with no prior diagnosis of PsA was conducted. GP practices were randomised in a 1:1 allocation ratio with stratification for GP practice list size and Central Commissioning Group (CCG). A total of 133 GP practices and 2226 participants were required to achieve a target sample size for the primary analysis population of 148 participants (74 per group) with a positive diagnosis of PsA; the latter corresponding to 80% power for detecting the MCID in the primary outcome measure of 0.35 units. Participants recruited were managed according to either SC, or ES by annual rheumatological assessment. Participants with suspected inflammatory arthritis were referred, via their GP, to the local rheumatology outpatient clinic at participating hospitals for an assessment of PsA by the 'treating rheumatologist' (ES arm: at baseline, 12 and 24 months; SC arm: at 24 months). Participants diagnosed with PsA then entered the PsA-care pathway element of the trial. The primary outcome measure was the HAQ_DI at 24 months post registration in participants diagnosed with PsA. Secondary outcome measures, PASDAS and PsAID-12, were assessed over time in participants with a positive diagnosis of PsA.

Results: A total of 2225 participants across 135 GP practices were registered, corresponding to 1123 allocated to ES and 1102 to SC; primary analysis population consisted of 87 participants with a positive diagnosis of PsA: 64 in ES, 23 in SC (Figure one). Baseline characteristics were similar across both treatment groups. The adjusted odds ratio (OR) for achieving a HAQ-DI score of 0 at 24 months post registration in ES compared to SC was 0.64 (95% CI (0.17, 2.38)), indicating no evidence of a difference between treatment groups (p=0.5075). Moreover, the adjusted OR of achieving a higher (non-zero) HAQ-DI score at 24 months post registration in ES relative to SC arm was 1.12 (95% CI: 0.67, 1.86), again indicating no evidence of a difference between the two treatment groups (p=0.6612). There was high variability on the impact of the disease between participants over time, although the impact is generally low in this group of participants with an 'early' diagnosis of PsA. Moreover, the overall PASDAS score and component scores over time post PsA diagnosis show high variability in PsA disease activity. No adverse events were reported.

Conclusion: There was insufficient evidence that early diagnosis by ES and subsequent treatment improves physical function compared to SC in patients with psoriasis. Limitations included the trial being underpowered for demonstrating the pre-specified treatment effect; only 6.2% of participants recruited had a positive diagnosis of PsA, much lower than assumed (18%). The imbalance observed between treatment groups (~ 3:1 ratio (ES:SC)), is largely explained by the lower proportion of participants especially in the SC arm attending the screening visit at 24 months, and delays between referral and attending appointment with the treating clinician, all further exacerbated by the Covid-19 pandemic. Furthermore, a longer duration of follow-up may be necessary to detect differences in outcome and is planned.

Background: Power Doppler ultrasound (PDUS) is a powerful diagnostic tool with high accessibility and reproducibility, allowing the visualisation of morphological and inflammatory changes of the synovium. The ULTIMATE study (NCT02662985) was the first large, randomised, double-blind, placebo-controlled, multicentre PDUS phase 3b study in psoriatic arthritis (PsA) that utilised the Global EULAR-OMERACT- Synovitis Score (GLOESS), to demonstrate the responsiveness of PDUS to detect early and continuous decrease in the synovitis score.[1] However, the ultrasound assessment for GLOESS is time-consuming due to the number of joints assessed.

Objectives: The aim of this study was to investigate the performance of different reduced joint sets to predict response to secukinumab, compared with the 24 paired joints included in the validated GLOESS.

Methods: ULTIMATE was a 52-week study, with a 12-week double-blind, placebo-controlled period followed by a 12-week open-label treatment period and a 6-month extension period.[1,2] The GLOESS comprises the sum of PDUS scores of 24 paired joints (potential score range: 0–144). A cluster image map was constructed to identify highly correlated joint clusters, based on the change from baseline of the composite PDUS scores at joint level. A reduced set of joints was selected based on either a mathematical approach that used the correlation clusters along with the joint level variations and joint location (Model 1 and Model 2) or a pragmatic approach that selected joints most frequently found to be active by ultrasound, in PsA in clinical practice (Model 3). Linear models with reduced joint sets predicted the actual GLOESS at each time point utilising 60% of data randomly selected from the study. The remaining 40% were used for model validation and diagnostics.

Results: Three models were established with reduced joint sets (12–18 pairs). The joints included in each linear model are summarised in **Table 1**. **Figure 1** depicts the trajectory of the two mathematical models and the pragmatic model versus the actual GLOESS in the secukinumab and placebo-secukinumab groups assessed by change from baseline to Week 24. Compared to GLOESS, all reduced PDUS joint sets demonstrated similar responsiveness to secukinumab from baseline to Week 24.

Conclusion: These results demonstrated similar responsiveness to secukinumab with reduced joint sets as the validated GLOESS, supporting the development of a scoring system with reduced number of joint evaluations that would increase feasibility by reducing the assessment time. Further studies are needed to confirm the validity and utility of the reduced joint set ultrasound scores in other PsA cohorts.

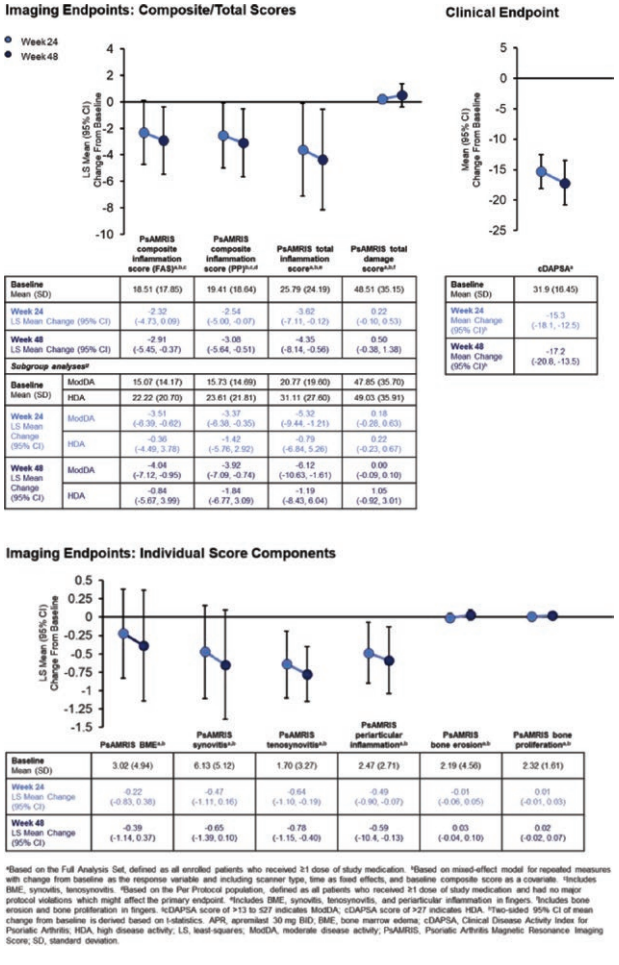
Background: Psoriatic arthritis (PsA) is characterized by inflammatory arthritis, enthesitis, dactylitis, and spondylitis. Apremilast is an oral immunomodulating phosphodiesterase-4 inhibitor approved for the treatment of PsA. The impact of apremilast on objective measures of inflammation and structural progression of PsA has not yet been characterized. Here, we evaluate the efficacy of apremilast 30 mg BID (APR) on inflammation measured by dedicated MRI of the hand.



Objectives: To evaluate the efficacy of APR on inflammation and imaging outcomes and the safety profile of APR in this setting.

Methods: MOSAIC (NCT03783026) was a phase 4, multicenter, single-arm, open-label study in patients (pts) with active PsA (≥3 months but ≤5 years since diagnosis, meeting CASPAR criteria for PsA) evaluating APR as monotherapy or in combination with stable methotrexate. Pts were treated with APR for 48 weeks and had MRI of the hand (contrast-enhanced) performed at baseline (BL), Week 24, and Week 48. All images were read and adjudicated by 2 experienced readers blinded to clinical information and time of acquisition. The primary endpoint was change from BL in the composite score of hand bone marrow edema (BME), synovitis, and tenosynovitis in fingers 2–5, as assessed by the PsA MRI Score (PsAMRIS) at Week 24. Total inflammation score, comprised of BME, synovitis, tenosynovitis, and periarticular inflammation in fingers, was also assessed. Structural progression was assessed by the total hand damage score (determined by bone erosion and bone proliferation in fingers 2–5). Subgroup analyses based on BL disease activity as measured by Clinical Disease Activity Index for Psoriatic Arthritis (cDAPSA) were performed for key endpoints.

Results: A total of 122 pts enrolled and received APR. Mean age was 47 years, 55% were women, and mean duration of PsA was 1.9 years. The Full Analysis Set (FAS) included 98 pts evaluable for the primary endpoint (having BL and Week 24 data); 4 had major protocol deviations and 94 were evaluable as part of the per protocol (PP) population. The least-squares (LS) mean (95% CI) change from BL in the composite inflammation score of BME, synovitis, and tenosynovitis as assessed by PsAMRIS (FAS) was -2.32 (-4.73, 0.09) at Week 24 and -2.91 (-5.45, -0.37) at Week 48 (**Figure 1**). In the PP population, the LS mean (95% CI) change from BL in the composite score at Weeks 24 and 48 indicated a significant reduction of disease activity (**Figure 1**). Significant improvements from BL were seen in total inflammation scores (BME + synovitis + tenosynovitis + periarticular inflammation) in the FAS (**Figure 1**). The structural outcome indicated by the total hand damage score, including bone erosion, showed no significant change from BL to Week 48 (**Figure 1**). Pts also experienced significant improvements from BL in cDAPSA at Weeks 24 and 48 (**Figure 1**). Subgroup analyses based on disease activity at BL showed significant improvements from BL in inflammation in pts with moderate disease activity (ModDA; cDAPSA score >13 to ≤27) and no significant change from BL in total damage (**Figure 1**). Though it was insignificant, pts with high disease activity (HDA; cDAPSA score >27) did have improvement from BL in inflammation indices (**Figure 1**). Common treatment-emergent adverse events were diarrhea (33.6%), nausea (12.3%), headache (10.7%), nasopharyngitis (7.4%), and dyspepsia (6.6%). No new safety signals were identified.

Conclusion: Pts with PsA treated with APR had improvements in both clinical indices and objective MRI indices of inflammation assessed by PsAMRIS in the target hand at Week 24 and Week 48, confirming an effect of APR on clinical and inflammatory manifestations of PsA. Pts with ModDA seemed to have

greater improvement from BL in MRI inflammation scores than pts with HDA. No significant structural progression was observed. These results offer important insights on the effect of apremilast in PsA and highlight the value of using MRI and PsAMRIS as measures of inflammatory disease activity and change following treatment.

[a]Based on the Full Analysis Set, defined as all enrolled patients who received ≥1 dose of study medication. [b]Based on mixed-effect model for repeated measures with change from baseline as the response variable and including scanner type, time as fixed effects, and baseline composite score as a covariate. [c]Includes BME, synovitis, tenosynovitis. [d]Based on the Per Protocol population, defined as all patients who received ≥1 dose of study medication and had no major protocol violations which might affect the primary endpoint. [e]Includes BME, synovitis, tenosynovitis, and periarticular inflammation in fingers. [f]Includes bone erosion and bone proliferation in fingers. [g]cDAPSA score of >13 to ≤27 indicates ModDA; cDAPSA score of >27 indicates HDA. [h]Two-sided 95% CI of mean change from baseline is derived based on t-statistics. APR, apremilast 30 mg BID; BME, bone marrow edema; cDAPSA, Clinical Disease Activity Index for Psoriatic Arthritis; HDA, high disease activity; LS, least-squares; ModDA, moderate disease activity; PsAMRIS, Psoriatic Arthritis Magnetic Resonance Imaging Score; SD, standard deviation.

SERUM EXTRACELLULAR MATRIX BIOMARKERS IDENTIFY RESPONSE TO GUSELKUMAB IN PSORIATIC ARTHRITIS: POST-HOC ANALYSIS FROM A PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY THROUGH 2 YEARS

Keywords: Psoriatic arthritis, Biomarkers

S. Holm Nielsen[1], A. C. Bay-Jensen[1], P. Frederiksen[1], M. Karsdal[1], M. Shawi[2], S. D. Chakravarty[3,4], A. Kollmeier[5], W. Chen[6], S. Gao[6]. Background: Psoriatic arthritis (PsA) is a progressive, joint-degenerative inflammatory disease with cartilage destruction, bone erosion and growth, and synovitis. Extracellular matrix (ECM) remodeling is also observed in skin lesions in patients with PsA. Guselkumab (GUS), an interleukin-23p19-subunit monoclonal antibody, demonstrated robust efficacy compared with placebo in patients with active PsA in two Phase 3 studies, DISCOVER-1 and DISCOVER-2.[1,2] GUS also reduced serum ECM biomarkers shown to be elevated in patients with PsA.[3]

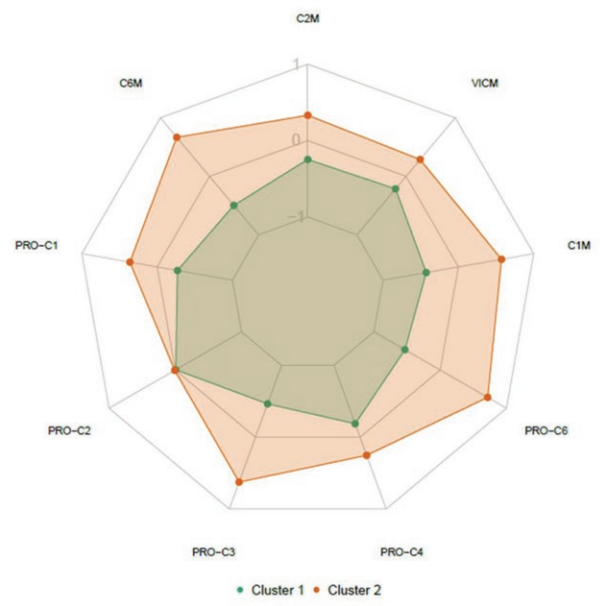
Objectives: To identify treatment responders among PsA patients receiving GUS, using serum biomarkers of collagen formation, degradation, and vimentin degradation.

Methods: Available baseline serum ECM biomarker data from patients who consented to participate in the 2-year DISCOVER-2 trial (NCT0315828) were included in the post hoc analysis. Biomarkers of collagen formation (PRO-C2, PRO-C3, PRO-C4, and PRO-C6), degradation (C1M, C2M, and C6M), and citrullinated and degraded vimentin were measured by immunoassays. Baseline ECM biomarker levels from all available patients were log-transformed and standardized by mean centering and scaling by the standard deviation prior to K-means clustering. In GUS-treated patients, between-cluster comparisons for major demographic and clinical parameters were performed using Mann-Whitney or chi-squared tests. Relationships between observed clinical response (ACR20, ACR50, PASI100) at Week (W)24, W52, and W100 and baseline levels of biomarkers were investigated. Analysis of PASI response was performed in patients with baseline body surface area (BSA) ≥3% and Investigator's Global Assessment (IGA) of psoriasis score ≥2.

Results: Two distinct clusters were identified using baseline serum ECM biomarkers from all patients (Figure 1). Patients in Cluster 1 generally had lower levels of ECM biomarkers than patients in Cluster 2. In GUS-treated patients, those in Cluster 2 had a higher (all $p<0.05$) baseline PASI score (median 7.3 vs 5.1), swollen joint count (12.0 vs 10.0), C-reactive protein (2.0 vs 1.0 mg/dL), and PsA-modified vdH-S score (26.5 vs 13.0). Relative to patients in Cluster 1, GUS-treated patients in Cluster 2 showed a greater ACR20 response rate at W24



(72% vs 57%, p=0.039) and W52 (80% vs 66%, p=0.037) and a greater ACR50 response rate at W100 (64% vs 47%, p=0.031), indicating patients with high levels of these biomarkers were more likely to achieve an ACR response. For patients with at least mild skin disease at baseline (BSA≥3% and IGA≥2), those in Cluster 1 demonstrated a higher PASI100 response rate at W100 than patients in Cluster 2 (71% vs 54%, p=0.046).

Conclusion: Patients with higher levels of baseline ECM biomarkers (Cluster 2) that correspond with greater peripheral joint inflammation demonstrated higher ACR20 and ACR50 response rates when treated with GUS, while patients with lower levels of these ECM biomarkers (Cluster 1) demonstrated higher rates of complete skin clearance (PASI100). These findings may provide a step towards patient stratification and precision medicine for guiding the use of biologic immunomodulatory treatments in patients with PsA.

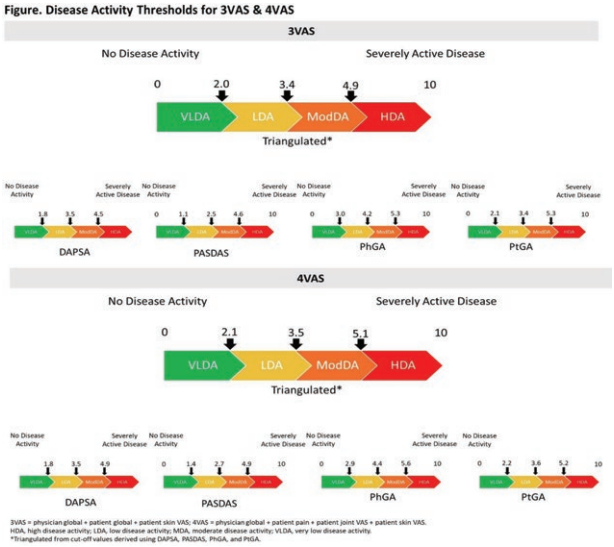
Background: Though continuous composite measures of disease activity for psoriatic arthritis (PsA) assessment exist, abbreviated measures that are more feasible for screening in routine clinical practice are needed. The 3 Visual Analogue Scale (VAS) and 4VAS scores were developed by abridging the Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) Composite Exercise (GRACE) measure to be the first short multidimensional composite measures specifically for use in PsA routine clinical care. The measures were shown to have superior performance than several established composite measures using small datasets.

Objectives: To further test 3VAS/4VAS in observational and trial datasets, as GRAPPA members recommended.

Methods: This post-hoc analysis of the DISCOVER 1/2 and COSMOS studies used pooled data through week (W) 24 from all treatment groups across studies. The correlation of 3VAS/4VAS with Disease Activity Index for PsA (DAPSA), PsA Disease Activity Score (PASDAS), physician global assessment (PhGA), and patient GA (PtGA) was assessed with Pearson's correlation coefficient. Minimal Important Difference (MID) was assessed with 4 distribution-based methods (based on standard error of the measurement, effect size, reliable change index [RCI], and RCI_{diff}). Minimal detectable change (MDC) was assessed with the standard formula: MDC = 1.96*sqrt(2)*sd*sqrt(1-ICC). Clinically relevant thresholds for low, moderate and high disease activity were estimated with receiver operating characteristic analysis and DAPSA (≤4, >4 – ≤14, >14 – ≤28, >28), PASDAS (≤1.9, >1.9 – ≤3.2, >3.2 – <5.4, ≥5.4), and PhGA/PtGA (≤1, >1 – ≤3, >3 – ≤6, >6 cm) as anchors.

Results: 1405 patients were included, of whom 51.3% were male, with a mean (SD) age of 47.1 (11.8) and PsA duration of 6.4 (6.5) years. At baseline, the mean (SD) 3VAS, 4VAS, DAPSA, PASDAS, PhGA, and PtGA scores of 6.4 (1.6), 6.3 (1.6), 45.8 (20.2), 6.5 (1.1), 6.5 (1.6), and 6.7 (2.0), respectively, reflected high levels of disease activity. Through W24, both 3VAS and 4VAS showed very strong correlation with PtGA (r_{3VAS}=0.92, r_{4VAS}=0.94) and PASDAS (r_{3VAS}=0.81, r_{4VAS}=0.82), strong with PhGA (r_{3VAS}=0.77, r_{4VAS}=0.74), and moderate to strong with DAPSA (r_{3VAS}=0.59, r_{4VAS}=0.61). Calculated MIDs were 0.9 (range: 0.7-1.3 across methodologies) for 3VAS and 0.9 (range: 0.6-1.3) for 4VAS (**Table 1**). MDC estimates were 3.3 (range 2.1-4.2 across follow-up intervals) for 3VAS and 3.2 (range: 2.0-4.0) for 4VAS. Cut-off values for low, moderate, and high disease activity were 2.0, 3.4, and 4.9 for 3VAS and 2.1, 3.5 and 5.1 for 4VAS, respectively (**Figure 1**).



Conclusion: Using a large pooled clinical trial dataset of patients with active PsA, we have calculated clinically relevant thresholds for improvement and disease activity for 3VAS and 4VAS. These estimates are generally comparable to those previously reported and can be used to set treatment targets and screen disease activity in routine care when resources are limited or during remote patient monitoring.

Table 1. MID for 3VAS, 4VAS, DAPSA, PASDAS, PhGA, and PtGA

Parameter	Distribution #1	Distribution #2	Distribution #3†	Distribution #4†	Mean‡
3VAS	0.7	0.8	1.3	0.9	**0.9**
4VAS	0.6	0.8	1.3	0.9	**0.9**
PhGA, VAS cm	0.7	0.8	1.6	1.1	**1.1**
PtGA, VAS cm	0.9	1.0	0.9	0.7	**0.9**
DAPSA	6.2	10.1	1.1	0.8	**4.6**
PASDAS	0.4	0.5	1.8	1.3	**1.0**

†Triangulated from MIC values derived from each visit pair (BL to W8, BL to W16, BL to W24, W8 to W16, W16 to W24) ‡Triangulated from MDC values derived from Distribution #1, #2, #3, and #4 **Distribution #1**=Baseline sd * sqrt(1 – Cronbach's Alpha) **Distribution #2**=0.5 * baseline sd **Distribution #3**=(first visit score – last visit score)/((baseline sd*sqrt(1 – Cronbach's Alpha)) **Distribution #4**=(first visit score – last visit score)/(sqrt(2)*(baseline sd*sqrt(1 – Cronbach's Alpha))

Figure. Disease Activity Thresholds for 3VAS & 4VAS

3VAS = physician global + patient global + patient skin VAS; 4VAS = physician global + patient pain + patient joint VAS + patient skin VAS. HDA, high disease activity; LDA, low disease activity; MDA, moderate disease activity; VLDA, very low disease activity. *Triangulated from cut-off values derived using DAPSA, PASDAS, PhGA, and PtGA.

COMBINING MTX DOES NOT RESULT IN AN ADDITIONAL EFFICACY OF UST TREATMENT IN POLYARTHRITIC PSA: SUBGROUP ANALYSIS FROM A RANDOMIZED PLACEBO-CONTROLLED INVESTIGATOR INITIATED CLINICAL TRIAL

Keywords: Outcome measures, Psoriatic arthritis, Randomized control trial

M. Köhm[1,2], A. C. Foldenauer[2], T. Rossmanith[2], H. Kellner[3], U. Kiltz[4], A. Kleyer[5], G. R. Burmester[6], J. Brandt-Juergens[7], D. M. Kofler[8], H. Burkhardt[1,2], F. Behrens[1,2]. [1]*Frankfurt University Hospital, Rheumatology, Frankfurt am Main, Germany*; [2]*Fraunhofer ITMP - Translational Medicine and Pharmacology, Clinical Research, Frankfurt, Germany*; [3]*Prof. Dr. Herbert Kellner, Rheumatology, München, Germany*; [4]*Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*; [5]*University Hospital Erlangen, Rheumatology/Immunology, Erlangen, Germany*; [6]*Charité – Universitätsmedizin Berlin, Rheumatology/Immunology, Berlin, Germany*; [7]*Rheumatologische Schwerpunktpraxis in Berlin Steglitz, Rheumatology, Berlin, Germany*; [8]*University Hospital Köln, Rheumatology/Immunology, Köln, Germany*

Background: BDMARD treatment in PsA patients usually requires treatment failure/intolerance to csDMARDs. The value of MTX in combination with bDMARDs is still unclear; an increase of efficacy is expected in polyarthritis. We designed an investigator-initiated, randomized, placebo-controlled trial (IIT) in active PsA to examine if outcomes of UST in combination with MTX (either newly initiated or ongoing) are different from UST only (+PBO), especially with focus on peripheral arthritic dominant PsA.

Objectives: To compare ACR20/50/70 and MDA response rates at week 24 in treatment groups stratified by number of affected joints (oligo- vs polyarthritis).

Methods: 186 patients with active PsA (defined as TJC≥4, SJC≥4 [68/66 joint count] and DAS28≥3.2) were screened for eligibility, 173 patients were randomized to UST+MTX (new or ongoing) or UST+PBO. 166 patients were included into the analysis. The cohort was stratified by number of affected joints: oligoarthritis (< 5 joints) and polyarthritis (≥ 5 joints.); for polyarthritis with additional subgroups (5-7, 8-10 and with >10 joints affected). Response rates (ACR20, 50, 70 response, MDA and 50% reduction in SJC/TJC) were calculated.

Results: BL data were well-balanced between treatment groups/subgroups (table 1) with exception to TJC/SJC. Independent from the number of affected joints, at week 24 no differences between the response behaviour were seen between UST (UST+PBO) or UST+MTX. By trend, UST+PBO showed better response in oligoarthritis and polyarthritis with >10 joints affected, whereas polyarthritis with affected joints >5 and <10 joints showed similar results for UST+PBO and UST+MTX (figure 1).

Conclusion: IL12/23 inhibition with UST is an effective treatment for active PsA independent of MTX use. Data from this subgroup analysis of the IIT indicate that additional MTX has no positive impact on UST efficacy, especially in focus on the arthritic PsA phenotype independent from the number of affected joints.

Table 1. Baseline Characteristics: Subgroup analysis with stratification by number of affected joints at Baseline

Background: The PsA core domain set developed by the Outcome Measures in Rheumatology working group includes musculoskeletal disease, fatigue, physical function, and structural damage, of which arthritis activity, pain, and fatigue were identified as essential by both patients (Pts) and physicians (Phs).[1-2] Assessing agreement between Pt and Ph global assessments (GA) may provide valuable insight into differential importance of specific PsA manifestations to Pts vs Phs. Although previous studies have assessed Pt/Ph disagreement, they have not evaluated potential variation over time.[3]

Objectives: To assess agreement of PtGA and PhGA through week (W) 24 and identify factors driving disagreement between PtGA and PhGA using pooled data (N=1120) from the phase 3 DISCOVER (D)-1 & -2 studies of the fully human IL-23p19 subunit inhibitor (i), guselkumab (GUS).

Methods: Pts with active PsA despite standard therapies (D1: ≥3 swollen/tender joint counts [SJC/TJC], CRP ≥0.3 mg/dL, ~30% with prior TNFi; D2: ≥5 SJC/TJC, CRP ≥0.6 mg/dL, biologic-naïve) were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, Q8W; or placebo. Pt/Ph agreement was defined as a difference of -15<PhGA-PtGA<15. Determinants of PhGA exceeding PtGA by ≥15 (PhGA>PtGA) and PtGA exceeding PhGA by ≥15 (PtGA>PhGA) among pts with PtGA/PhGA disagreement were assessed with the same logistic regression model considering pt demographics, disease characteristics, and pt-reported outcomes (PROs). The effect of GUS on disease parameters identified as determinants of PtGA vs. PhGA disagreement was assessed with repeated measures mixed models adjusting for treatment group, baseline (BL) levels, prior TNFi use, and BL DMARD use.

Results: At BL, mean (SD) SJC=11.5 (7.4), TJC=20.6 (13.3), FACIT-Fatigue score=29.9 (10.0), PtGA=66.9 (19.9), and PhGA=64.8 (15.9) were consistent with moderate to high disease activity. Agreement between PtGA and PhGA was seen in most instances (61.2%); 23.2% of cases were characterized by PtGA>PhGA and 15.7% by PhGA>PtGA. The proportion of pts with PtGA>PhGA increased to 39.1% at W24, while that with PhGA>PtGA decreased to 11.2%. The main determinant of PtGA>PhGA was higher Pt Pain (all time points); additional factors included worse physical health-related quality of life at BL and worse fatigue at W24 **(Table 1)**. Conversely, Phs emphasized objective disease measures, namely higher SJC (all time points) and TJC (W8 to W24), and elevated CRP (BL to W16). GUS treatment was associated with prompt and sustained significant improvements in all identified determinants, including those driving PtGA>PhGA **(Figure 1)**.

Conclusion: PtGA and PhGA were aligned in most encounters. PtGA>PhGA disagreement was driven by pain, fatigue, and physical health being weighed more by Pts than Phs. These findings have important implications in shared decision making and highlight the need to prioritize treatments addressing the full spectrum of PsA symptoms, including PROs.

Background: Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has shown superior efficacy to 16 weeks (wks) vs placebo (PBO) and tolerability in patients (pts) with active psoriatic arthritis (PsA) in the phase 3 BE OPTIMAL and BE COMPLETE studies.[1,2] Efficacy of BKZ to 52 wks has also been demonstrated in the BE OPTIMAL study of biologic-naïve pts with PsA.[3]

Objectives: To assess long-term efficacy and safety of BKZ treatment up to 52 wks in pts with active PsA and prior inadequate response or intolerance to tumour necrosis factor inhibitors (TNFi-IR).

Methods: BE COMPLETE (NCT03896581) included a 16-wk double-blind, PBO-controlled period. Wk 16 completers were eligible for entry into BE VITAL (NCT04009499; open-label extension). BE VITAL included pts from BE OPTIMAL and BE COMPLETE; data here are for pts randomised at baseline (BL [Wk 0]) of BE COMPLETE only, up to 1 yr. Pts were randomised 2:1 to subcutaneous BKZ 160 mg every 4 wks or PBO. At Wk 16, PBO pts switched to BKZ (PBO/BKZ; received 36 wks of BKZ treatment up to Wk 52). Efficacy data reported are observed case or using non-responder imputation (binary) or multiple imputation (continuous). The number of treatment-emergent adverse events (TEAEs) to Wk 52 are reported for pts who received ≥1 dose of BKZ, including pts who switched from PBO to BKZ at Wk 16.

Results: 388/400 (97.0%) pts completed Wk 16; 377 (94.3%) entered BE VITAL and 347 (86.8%) completed Wk 52. Improved efficacy responses with BKZ treatment were sustained from Wk 16 to Wk 52 (**Table 1**). At Wk 52, 51.7% BKZ and 40.6% PBO/BKZ pts achieved American College of Rheumatology (ACR)50. In pts with BL psoriasis (≥3% body surface area), 65.9% BKZ and 60.2% PBO/BKZ pts achieved Psoriasis Area Severity Index (PASI)100 (complete skin clearance) at Wk 52 (**Figure 1**). At Wk 52, 47.2% BKZ and 33.1% PBO/BKZ pts achieved minimal disease activity (MDA). To Wk 52, 243/388 (62.6%) pts had ≥1 TEAE whilst receiving BKZ (exposure-adjusted incidence rate per 100 pt-years [EAIR/100 PY]: 126.0); 23 (5.9%) pts reported a serious TEAE (7.0/100 PY). Malignancies (excluding non melanomic skin cancers) were reported by 2 (0.7%) pts receiving BKZ (0.77/100PY). *Candida* infections were reported by 25 (6.4%) pts receiving BKZ (7.7/100 PY); all were reported as mild or moderate by investigators; none were systemic. Two cases of oral candidiasis led to study discontinuation. There was one death (sudden death; pt with history of cardiac events), two adjudicated major adverse cardiac events and no definite or probable adjudicated inflammatory bowel disease.

Conclusion: In pts with PsA and TNFi-IR, BKZ demonstrated sustained clinical efficacy from Wk 16 up to Wk 52. The safety profile was consistent with previous reports.[1–3]

Background: The safety of tofacitinib in patients (pts) with rheumatoid arthritis (RA) and psoriatic arthritis (PsA) has been demonstrated in clinical studies with up to 9.5 and 4 years (yrs) of observation, respectively. Real-world

post-marketing surveillance (PMS) safety data comprised of spontaneous and voluntary adverse event (AE) reports for tofacitinib have been published for RA and ulcerative colitis, but not PsA.

Objectives: To further characterise the real-world safety profile of tofacitinib in RA and PsA.

Methods: AE reports were collected from 6 Nov 2012–6 Nov 2021 (RA) and 14 Dec 2017–6 Nov 2021 (PsA) from the Pfizer safety database. Tofacitinib was approved in the US for RA on 6 Nov 2012 (immediate release [IR]) and 24 Feb 2016 (extended release [XR]), and for PsA on 14 Dec 2017 (IR and XR). Safety endpoints included AEs, serious AEs (SAEs), AEs of special interest (AESI) and fatal cases. Pt years (PY) of exposure were estimated from IQVIA commercial sales data from 61 countries and 1 region. Number (N), frequency and reporting rates (RR; number of events/100 PY of estimated exposure) for each endpoint were summarised by indication (RA/PsA) and formulation (IR [5 or 10 mg twice daily], XR [11 mg once daily] or all tofacitinib [IR+XR]). A sensitivity analysis truncated the analysis period to the first 4 yrs post approval for RA (2012–16), to align with the duration of PsA data.

Results: Of the 73 525 case reports (68 131 RA/5394 PsA), 4239/368 (6.2%/6.8%) did not report a formulation and were excluded. Most AE reports were for females (RA: 81.8%/PsA: 71.3%); around half were submitted by healthcare professionals (49.8%/63.1%) and the majority were from North America (80.1%/82.3%). Almost all XR reports (RA/PsA: 93.0%/97.0%) originated from North America (IR reports: 72.3%/68.6%). For both indications, the RR for AEs was higher with XR vs IR; RR and frequency of SAEs, AESIs and fatal cases were mostly similar between XR and IR (Table 1). The most frequently reported AEs in RA and PsA by Preferred Term included drug ineffective, pain, condition aggravated, headache and arthralgia (Figure 1). Off label use was more frequently reported in PsA than RA (Figure 1). In the first 4 yrs post approval of the IR formulation for RA (IR/XR: 49 439/2000 PY), AEs, SAEs and fatal cases RRs were 95.9/147.0, 19.1/24.5 and 0.4/0.4, respectively.

DISEASE COURSE AND PREDICTORS FOR ACHIEVING 6-MONTH MINIMAL DISEASE ACTIVITY IN PATIENTS WITH EARLY PSORIATIC ARTHRITIS FROM THE ITALIAN PROSPECTIVE SIRENA STUDY

Keywords: Disease-modifying Drugs (DMARDs), Psoriatic arthritis, Real-world evidence

A. Zabotti[1], M. M. Luchetti[2], C. Selmi[3], R. Ramonda[4], R. D. Grembiale[5], S. D'angelo[6], S. Marelli[7], E. Favalli[8]. [1]*Academic Hospital S. Maria della Misericordia, University of Udine, Rheumatology Clinic, Department of Medical Area, Udine, Italy*; [2]*Università Politecnica delle Marche, Clinica Medica, Dipartimento Scienze Cliniche e Molecolari, Ancona, Italy*; [3]*Humanitas Research Hospital and Humanitas University, Rheumatology and Clinical Immunology, Rozzano (MI), Italy*; [4]*University of Padova, Rheumatology Unit, Department of Medicine - DIMED, Padova, Italy*; [5]*Università Magna Graecia, Rheumatology Research Unit, Dipartimento di Scienze della Salute, Catanzaro, Italy*; [6]*San Carlo Hospital, Rheumatology Institute of Lucania and Rheumatology Department of Lucania, Potenza, Italy*; [7]*Janssen, Medical Affairs - Immunology, Cologno Monzese (MI), Italy*; [8]*ASST Centro Specialistico Ortopedico Traumatologico Gaetano Pini - CTO, Università degli Studi di Milano, Dipartimento di Reumatologia, Milano, Italy*

Background: Data on Psoriatic Arthritis (PsA) patients naive to any Disease Modifying Anti-Rheumatic Drugs (DMARDs) are limited.

Objectives: To describe the clinical course and predictors for achieving Minimal Disease Activity (MDA) in PsA patients starting DMARDs in a real-world setting.

Methods: PsA patients were enrolled in SIRENA (Clinicaltrials.gov identifier NCT03131661), an Italian Registry of Spondyloarthritis (SpA) patients classified according to ASAS criteria and naive to any DMARDs for SpA [1]. Clinical data were collected at baseline and every 6 months up to the 24-month observation period. Predictors of 6-month MDA were identified through univariate and multivariate analyses.

Results: Out of 350 SpA cases, 203 patients received a diagnosis of PsA (at baseline: mean age 51.2 years; men 51.7%; newly diagnosis 77.3%; time to diagnosis <24 months 68%; mainly axial 4.4%; monoarticular/oligoarticular/polyarticular 9.9/31.5/48.8%; active skin psoriasis 84.3%; enthesitis 38.5%; dactylitis 24%; nail psoriasis 39.7%). At baseline, 100/203 patients (49.3%)

were prescribed conventional DMARDs, 50 (24.6%) biological DMARDs and 27 (13.3%) other systemic treatments, mostly non-steroidal anti-inflammatory drugs. During the 2-year observation period, 79 patients (38.9%) started the first biologic after a conventional DMARD with a median time of 6.8 months and a second biologic after 10.0 months. Clinical and Patient Reported Outcomes markedly improved overtime (Table 1). MDA was achieved by 102/158 patients (64.6%) at least once in the observation period (median time to first MDA according to Kaplan-Meier: 10 months) and by 65/150 patients (43.3%) at 6 months. In univariate analysis, female gender, Body Surface Area (BSA) <3% and higher scores in Health Assessment Questionnaire-Disability Index (HAQ-DI) were associated with a decreased odds ratio of reaching MDA at 6 months while mono-oligoarticular involvement, newly PsA diagnosis and lower Disease Activity in PSoriatic Arthritis (DAPSA) score were associated with an increased odds ratio (Figure 1). Smoking, alcohol, presence of enthesitis/dactylitis/nail psoriasis, Disease Activity Score-28 (DAS-28), number of comorbidities, body mass index and patient VAS global assessment (PtGA) were not significantly associated with 6-month MDA achievement. In multivariate analyses no factor was identified as significant predictor of MDA at 6 months.

Conclusion: In an early PsA population, treatments with predominantly conventional DMARDs and biologics markedly improved disease outcomes, with 43% of patients achieving MDA at 6 months. Female gender, BSA <3% and higher HAQ-DI scores were associated with a decreased odds ratio while new PsA diagnosis, mono-oligoarticular involvement and lower DAPSA score were associated with an increased odds ratio for 6-month MDA.

Background: The p.E148Q variant in pyrin is present in different populations at a frequency up to 29%[1], and has been associated with inflammatory diseases including vasculitis and familial Mediterranean fever (FMF)[2,3]. The pathogenicity of p.E148Q in FMF is unclear, highly debated in the literature especially when observed *in cis or in trans* to a single, typically recessive, mutation. If it could modify the expressivity of a pathogenic allele and acts as a risk factor for diseases is not known.

Objectives: We Interrogated the Australian Autoinflammatory Disease RegistrY (AADRY) to find candidate inheritance patterns for the p.E148Q variant in pyrin. We then performed functional validation to determine whether p.E148Q increases the ability of pyrin to form an active inflammasome complex in cell lines. Finaly, the ability of p.E148Q to increase the effect of a known pathogenic mutation in *cis* or *trans* was assessed.

Methods: The allele p.E148Q in patients with auto-inflammatory diseases and their families in AADRY was assessed. Different pyrin variant combinations were

Figure

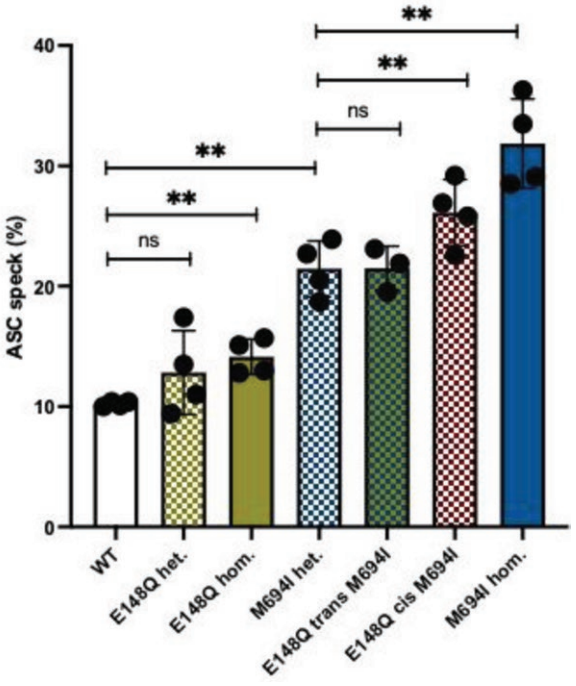

Figure 1. Heterozygous p.E148Q in cis with p. M694I potentiates the effect of p.M694I in response to TcdB

HEK293T cells stably expressing ASC EGFP and transiently co-transfected with mCherry tagged WT pyrin, p.M694I and p.E148Q-M694I then stimulated with TcdB. FACS analysis revealed a statistically increased ASC speck formation for cells expressing the p.E148Q variant compared to the WT allele and for cells co-expressing p.E148Q *in cis* of p.M694I and the WT allele (E148Q cis M694I) compared to the cells expressing p.M694I pyrin (M694I heterozygous). Data are pooled from 4 independent experiments. Error bars represent mean +/- SEM. Statistics used is the paired Student t-test. **P<0.01, ns; non-significant. Het .=heterozygous, Hom.=homozygous.

tested in HEK293T cells stably expressing the adaptor protein apoptosis-associated speck-like (ASC) which were analysed by flow cytometry to visualise inflammasome formation, with and without stimulation by *Clostridium difficile* toxin B (TcdB). Inflammasome dependent cytokine secretion was also quantified by ELISA of supernatants from THP-1 cells transduced with lentiviral expression vectors.

Results: In AADRY, we observed the p.E148Q allele in individuals with autoinflammatory diseases alone or in conjunction with other pyrin variants. Two FMF families harbored the allele p.M694I-E148Q *in cis* with dominant heritability. In vitro, p.E148Q pyrin could spontaneously potentiate inflammasome formation, with increased IL-1β and IL-18 secretion. p.E148Q *in cis* to classical FMF mutations provided significant potentiation of inflammasome formation.

Conclusion: The p.E148Q variant in pyrin potentiates inflammasome activation in vitro. *In cis*, this effect is additive to known pathogenic FMF mutations. These observations may help to explain the association of p.E148Q with FMF and other inflammatory diseases.

POS0235 ANTI-INFLAMMATORY EFFECTS OF TIP-1 AND MIP-2 TREATMENT THROUGH TLRS BLOCKADE IN AOSD ANIMAL MODEL

Keywords: Treat to target, Animal Models

M. H. Ahn[1], Y. S. Choi[2], S. W. Lee[1], S. Choi[2], H. A. Kim[1]. *[1]Ajou University School of Medicine, Rheumatology, Suwon, Korea, Rep. of (South Korea)*; *[2]Ajou University, Molecular Science and Technology, Suwon, Korea, Rep. of (South Korea)*

Background: Adult-onset Still's disease (AOSD) is a rare systemic inflammatory disease manifesting with a typical skin rash, hepatosplenomegaly, persistent high fever, and leukocytosis. There is no suitable animal model to research for AOSD. The signaling of Toll-like receptors (TLR) as pattern-recognizing receptors is necessary for pathogen recognition by the innate immunity. Recent studies have shown the TLR-mediated inflammation could be an important role in pathogenesis of AOSD. TLR inhibitor peptide 1 (TIP-1) and MAL/MyD88 inhibitory peptide 2 (MIP-2) have been evaluated with blocking peptide activity to bind TIR domain, which is recognition of the danger- or pathogen-associated molecular patterns (DAMP or PAMP).

Objectives: This study tried to evaluated that these inhibitory peptides could suppress their inflammation and improve clinical manifestations in animal models of AOSD.

Methods: *Mycobacterium* mixed Freund's complete adjuvant (CFA, 1.5 mg/ml) was subcutaneously injected into IFNγ knock-out (IFNγ KO) mice to inducing AOSD. TIP-1 or MIP-2 (10 nmol/g) was intraperitoneally administered every day for 4 weeks. Fever and body weight were checked every week. The size of lymph node (LN) and spleen was measured when the animals were sacrificed. The level of IL-1β and IL-18 in serum were measured by ELISA. Downstream of TLRs signal pathway, MyD88 and NFκB, were confirmed by WB.

Results: *Mycobacterium* mixed CFA injected IFNγ KO mice showed a significantly higher fever than normal mice (p= 0.0009). These fever were significantly reduced after TLR inhibitory peptide treatment (TIP-1; p=0.008, MIP-2; p=0.029). In addition, hypertrophy of the spleen and LN was found in IFNγ KO mice, which were statistically significantly improved through TLR inhibitor injection (TIP-1 and MIP-2, p<0.05). The level of IL-1β and IL-18 in serum were significantly increased in the CFA injected IFNγ KO mice and increased inflammatory cytokines was decreased by TLR inhibition (TIP-1 and MIP-2, p<0.05). MyD88 and phosphorylated NFκB were increased in LN of CFA injected IFNγ KO mice and the proteins was down-regulated with treatment of TIP-1 or MIP-2. The IL-1β expression in LN and spleen was increased in CFA injected IFNγ KO mice and it decreased in TIP1 or MIP-2 treated mice.

Conclusion: Abnormal fever, lymph node and spleen tissue enlargement, and increase in serum inflammatory cytokines (IL-1β, IL-18), etc., have been confirmed that the symptoms accompanying adult-type Still's disease appear in animals. In addition, it was confirmed that these immune responses were reduced in the TLR inhibitor treatment group. Collectively, these in vivo findings mean that *Mycobacterium* mixed CFA injected IFNγ KO mice was showed pathological features of AOSD and TIP-1and MIP-2 has broad specificity for TLRs and should be effective plausible candidate for the treatment of AOSD.

POS0236 ROLE OF NLRP3 INFLAMMASOME-DERIVED ASC SPECKS IN ADULT-ONSET STILL'S DISEASE

Keywords: Biomarkers, Innate immunity, Rare/orphan diseases

J. Topping[1], J. Poulter[2], F. Nadat[3], C. Carter[3], J. Zernicke[4], I. Consortium[5], J. Rech[6,7], B. Fautrel[8], E. Feist[9], M. Mcdermott[1], S. Background: The NLRP3 inflammasome is a critical multi-molecular platform involved in mediating innate immune responses, and could play a role in Adult onset Still's disease (AOSD). Upon NLRP3 inflammasome activation, a large protein complex assembles, resulting in the re-localisation of apoptosis-associated speck-like protein containing a caspase recruitment domain (ASC), secretion of IL-1β and IL-18, and ASC aggregation into a single inflammasome speck. ASC specks are considered as potential biomarkers for inflammatory disorders, with subsequent release into the bloodstream during pyroptosis. Somatic variants in NLRP3 have also been observed in phenocopies of autoinflammatory disorders and their role in AOSD has been postulated.

Objectives: To investigate the role of NLRP3-derived ASC protein specks as a potential disease activity biomarker and *NLRP3* genetic variants in the pathogenesis of AOSD.

Methods: Sera from 103 AOSD patients [treatment naïve, on treatment, and patients who previously failed several bDMARDs and were involved in CONSIDER clinical trial (n=30)] were analysed. These were compared to Systemic Juvenile Idiopathic Arthritis (sJIA, n=14), Cryopyrin Associated Periodic Syndrome (CAPS, n=9), Schnitzler's syndrome (n=10) and Familial Mediterranean Fever (FMF, n=27) patients. Extracellular NLRP3-derived ASC specks were identified using flow cytometry (double positivity for ASC-PE and NLRP3-APC), gating for events around 1µm in size, in sera. To determine if ASC/NLRP3 speck levels provide additional biological information, the correlation between the specks and known biomarkers (such as IL-18 and C-reactive protein (CRP)) were analysed in sera. This involved cytokine profiling, using 13-plex Inflammatory LEGENDplex assay and high-sensitivity CRP ELISAs. Deep whole exome sequencing (WES x100) (analysis restricted to autoinflammatory panel) was carried out on DNA from the 30 CONSIDER trial patients.

Results: In serological analyses, extracellular ASC/NLRP3 speck levels were increased in AOSD patients compared to 32 healthy control (HC) sera ($p<0.01$, Figure 1A). ASC/NLRP3 levels defined three subgroups of AOSD patients (low, moderate and high). High ASC/NLRP3 levels were present in all pre-treatment sera from CONSIDER trial patients ($p< 0.001$), compared to HC, suggesting their role may be dependent on the stage of the disease process. Interestingly, these patients were still responsive to canakinumab, showing significant reduction in extracellular ASC/NLRP3 levels in CONSIDER clinical trial cohort (baseline to week 12), compared to placebo ($p<0.01$) (Figure 1B) [1]. There was no correlation between ASC/NLRP3 specks and CRP levels (Figure 1C) or ASC/NLRP3 and total IL-18. No germline or somatic variants in *NLRP3* were identified from patients in the CONSIDER cohort despite very high levels of ASC/NLRP3 specks being detected in their serum.

Conclusion: This study involved development of an assay that quantifies extracellular ASC specks as a biomarker of NLRP3 activation, to improve diagnoses and classification of SAIDs, particularly those with sporadic or unknown causes, such as AOSD. Increased levels of extracellular NLRP3-derived ASC specks were found in sera of AOSD compared to HC and autoinflammatory disease controls. Our findings also demonstrate heterogeneity within AOSD cohorts, with high-ASC speck levels in therapy-resistant CONSIDER trial patients suggesting the role of ASC specks may be dependent on the particular stage of the disease. Further analysis of rare somatic variants in genes associated with myelodysplastic syndrome, another condition associated with elevated ASC/NLRP3 specks and systemic inflammation, is currently underway, since this may provide an alternative explanation for our findings.

Background: COVID-19 and autoinflammatory diseases, such as Adult-onset Still's Disease (AOSD), are characterized by a massive production and uncontrolled secretion of pro-inflammatory cytokines. The specialized pro-resolving lipid mediators (SPMs) family is one the most important processes counteracting hyperinflammation inducing tissue repair and homeostasis restoration. Among SPMs, Protectin D1 is able to exert antiviral features in animal models.

Objectives: The aim of this study was to compare the transcriptome of peripheral blood mononuclear cells (PBMCs) from patients with AOSD and COVID-19 and to evaluate the role of PD1 on those diseases, especially in modulating macrophages polarization.

Methods: This study enrolled patients with AOSD, COVID-19, and healthy donors (HD). Next-generation deep sequencing was performed on to identify the differences in PBMCs transcripts profiles. Plasma levels of PD1 were assessed by commercial ELISA kits. Monocytes-derived macrophages were polarized into M1 and M2 phenotype. We analyzed the effect of PD1 on macrophages differentiation. At 10 days, macrophages were analyzed for surface. expression of subtypes markers by flow cytometry. Cytokines production was measured in supernatants using Bio-Plex Pro Human Cytokine 17-plex Assay kit (Bio-Rad).

Results: All COVID-19 participants (n=21) were hospitalized. We found statistically significant higher ferritin levels between intensive care unit (ICU) and non-ICU patients ($p=0.006$), and higher procalcitonin ($p=0.03$). Five patients with AOSD, out of 13, had a systemic score (SS) ≥1. The most frequent manifestations were arthralgia (8/13), arthritis (5/13) and fever (3/13). Moreover, we found higher levels of ferritin and CRP in the AOSD SS ≥1 group as compared to AOSD SS=0 group. We also enrolled thirteen HD age- and sex-matched to AOSD patients. Transcriptome analysis of PBMCs from HD, AOSD, and COVID-19 patients is reported in Figure 1, showing the PCA plot (A), the pathway analysis by Pantherdb.org (B), the volcano plots representing differential expression analysis of genes in COVID-19 vs HD, AOSD vs HD, and COVID-19 vs AOSD (C), and the transcriptome heatmaps (D), showing that inflammation- and lipid catabolism-related genes are specifically dysregulated and those associated with monocytes phenotype and function were upregulated in COVID-19 and AOSD patients compared to HDs.

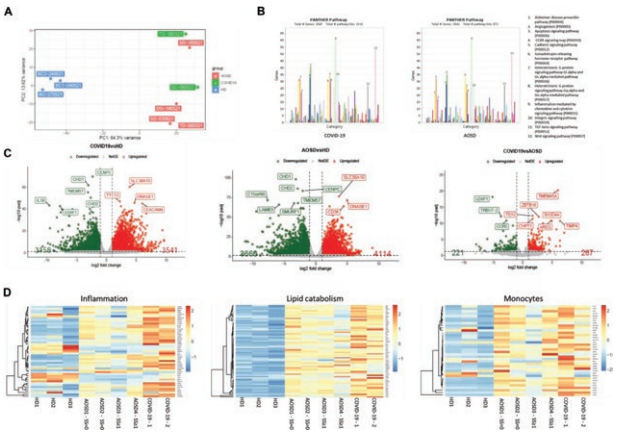

Figure 1.

Patients affected by COVID-19, hospitalized in intensive care unit (ICU), showed higher levels of PD1 compared to not-ICU hospitalized patients and HDs (ICU COVID-19 vs not-ICU COVID-19, p= 0.02; HDs vs ICU COVID-19, p= 0.0006). PD1 levels were increased in AOSD patients with SS ≥1 compared to patients with SS=0 (p=0.028) and HD (p=0.048). PD1 stimulation increased the expression of CD206 in M2 monocytes-derived macrophages from both COVID-19 and AOSD patients (COVID-19: untreated vs PD1, p=0.0098; AOSD: untreated vs PD1 p= 0.0234), whilst PD1 did not affect CD80 expression in both M1 and M2 macrophages and CD206 expression in M1 macrophages. A significant increase of both IL-10 and macrophage inflammatory protein (MIP-1β) was observed in M2 macrophages from COVID-19 patients after PD1 stimulation (IL-10, p= 0.03; MIP-1β, p= 0.003); the same results were found in AOSD patients (IL-10, p= 0.03; MIP-1β, p= 0.03).

Conclusion: PD1 can induce pro-resolutory programs in both AOSD and COVID-19 increasing M2 polarization and inducing their activity. PD1-treated M2 macrophages from AOSD and COVID-19 patients increased the production of IL-10, thus promoting anti-inflammation, and enhanced homeostatic restoration through MIP-1β production.

POS0238 IMPLICATION OF THE CSF1-CSF1R PATHWAY IN THE CROSSTALK BETWEEN SYNOVIAL FIBROBLASTS AND MACROPHAGES IN PIGMENTED VILLONODULAR SYNOVITIS

Keywords: Synovium, Innate immunity, Rare/orphan diseases

R. Dallatorre[1,2], J. De Lima[1], F. Blanchard[1], B. Le Goff[1,2]. [1]*Nantes Université, INSERM, Regenerative Medicine and Skeleton, RMeS, UMR 1229, nantes, France*; [2]*University Hospital of Nantes, Rheumatology, Nantes, France*

Background: Pigmented villonodular synovitis (PVNS) is a rare joint disease with an estimated incidence of 14 per million per year, arising from synovia that results in a secondary inflammatory joint response, pain and destruction. PVNS is associated with abnormal fibroblastic cells, often involving a specific chromosomal translocation, t(1;2) (CSF-1;COL6A3), resulting in the overexpression of colony-stimulating factor 1 (CSF1 or M-CSF), recruitment of CSF1 receptor (CSF1R) macrophages and fusion in giant cells. Despite therapeutic option such as surgery, the risk of recurrence of the synovitis remains high (50%). This has led to the development of systemic therapies targeting the CSF1 pathway (kinase inhibitors such as Imatinib, monoclonal antibodies) that have shown their efficacy is about 30% of patients but with significant and sometimes serious adverse effects. Therefore, there is currently a clear medical need to improve the management of patients with PVNS.

Objectives: To better decipher the mechanisms leading to the development of PVNS and study the crosstalk between synovial fibroblasts and macrophages in this disease.

Methods: Synovial tissue from newly diagnosed PVNS (diffuse or localized forms) patients was used for this analysis. Histology H&E staining and immunohistochemistry was performed. Single cell analysis was performed on 5 patients. We implemented a primary culture of synovial fibroblasts from PVNS biopsies stimulated with pro-inflammatory cytokines. We studied the effect of culture supernatant on blood derived monocytes/macrophages.

Results: Immunohistochemistry revealed the presence of synovial PDPN+ fibroblasts, CD31+ endothelial cells, Ki67+ proliferating cells, MERTK+ and CCR2+ infiltrating the tissues. We performed single-cell RNA sequencing (n=5 patients). Combined with public scRNAseq datasets, we observed that PVNS (n=8) lining PDPN+PRG4+ fibroblasts are the main sources and express higher levels of CSF1 than in osteoarthritis (OA, n=3) or rheumatoid arthritis (RA, n=4). All macrophage subsets (tissue resident TIMD4+ or LYVE1+ or infiltrating inflammatory macrophages) highly express CSF1R that could explain their enrichment (2 folds, p<0.05), especially in the localized forms of PVNS. Ratio between fibroblasts and macrophages was increase in the diffuse forms of the disease. We next study the in vitro crosstalk between fibroblasts and macrophages. For this purpose, we analysed conditioned media (CM) from PVNS synovial fibroblasts (n=3). After treatment with TNFa or IL1b, enhanced secretion of CSF1 was observed and the CM had an enhanced capacity to sustain viability of blood derived monocytes/macrophages (2-3 folds, p<0.05). In this setting, the potent CSF1R inhibitor Imatinib totally reversed macrophage viability to baseline (p<0.05).

Conclusion: This study highlights the key role played by synovial fibroblasts and macrophages in PVNS pathogenesis. An inflammatory vicious cycle takes place between these two cell types, implicating CSF1-CSF1R. Efficient targeting of this pathway is the subject of current research and we already validated a PVNS mouse model using xenografted PVNS human biopsies that will be useful to study for example the local delivery of CSF1R kinase inhibitors or neutralizing antibodies.

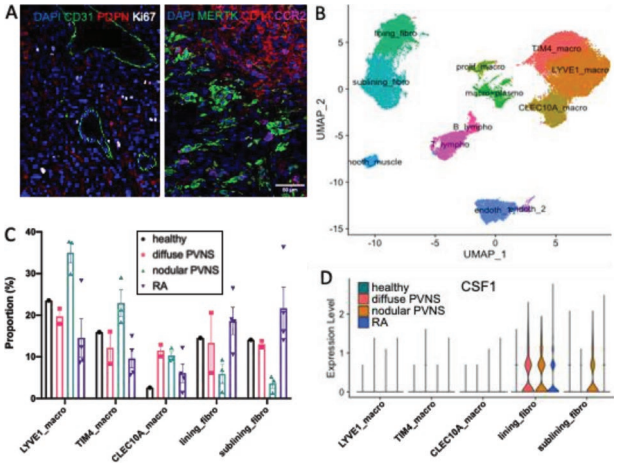

Figure 1. Histology and scRNAseq of PVNS. A. Characterisation of synovial PDPN+ fibroblasts, CD31+ endothelial cells, Ki67+ proliferating cells, MERTK+ and CCR2+ macrophages in a localized PVNS by immunofluorescence. B. scRNAseq analysis (10X genomics) of synovial cells in healthy, diffuse/localized PVNS and RA (n=10 patients). C. Higher proportion of anti-inflammatory TIM4+ and LYVE+ macrophages in localized PVNS. D. High expression of CSF1 in lining fibroblasts of PVNS patients

POS0239 JAK-INHIBITORS SUPPRESS IFN-DEPENDENT ANTIGEN PRESENTATION IN CDC42HICD14+ CELLS

Keywords: Rheumatoid arthritis, Innate immunity, Disease-modifying Drugs (DMARDs)

E. Malmhäll-Bah[1], K. M. Andersson[2], S. Töyrä Silfverswärd[1], M. Erlandsson[1], R. Pullertis[1,3,4], M. I. Bokarewa[1,3]. Background: We have recently shown that Rho GTPase activation in macrophages results in arthritis development in mice. These macrophages show a tight interaction with T cells leading to suppression of cell homing and regulate migration of thymic T regulatory cells to periphery contributing arthritis development[1].
Objectives: To translate findings in experimental arthritis to human RA, we explore the phenotype of *CDC42*^{hi}CD14$^+$ cells in blood and synovial tissue of RA patients and investigate how anti-rheumatic treatment intervene with the Rho GTPase-dependent molecular mechanisms of arthritis.
Methods: We used transcriptome (RNAseq) of CD14$^+$ and CD4$^+$ cells of 77 active RA patients naïve to TNF-inhibitors (TNFi) and of 59 inactive RA patients treated with methotrexate (MTX, n=18), TNFi (n=10) and JAK-inhibitors (JAKi, n=24), or having no DMARD treatment (n=7). In both cohorts, patients were stratified by mean expression of *CDC42* in CD14$^+$ cells to mimic activation of Rho GTPases. Differentially expressed genes (DEG) were identified by DESeq2 (nominal p<0.05). Transcriptomics of CD14$^+$ and CD4$^+$ cells were analyzed and translated into clinical correlates of inflammation and disease activity by DAS28. Additionally, we investigated a cluster of *CDC42*^{hi} macrophages in synovial tissue (STM) using single cell RNAseq in 25 patients[2].
Results: In two independent sets, *CDC42*^{hi}CD14$^+$ cells were characterized by enrichment of DEG operating in the oxidative phosphorylation, proteasome activity and RNA transcription. Many DEG were under transcriptional control of NFE2L1, known to supervise those processes. DEG with strong correlation to *CDC42* defined the metabolic signature (MetSig) of *CDC42*^{hi}CD14$^+$ cells, which summarized the expression of *ATP5BP*, *COX7A2*, *PSMB6*, *PSME3, GTF3C6,* and *GTF2E2*. High MetSig recognized CD14$^+$ cells enriched with MHC transcripts, components in peptide loading and expression of proteasome subunits. MetSig^{hi}CD14$^+$ cells had high chemokine and cytokine production and migratory phenotype. Analyzing STM, we identified *CDC42*^{hi}STM with high MetSig expressing complete set of immunoproteasome genes, high levels of MHC receptors and peptide loading proteins. Additionally, this STM cluster was affected by IFN-γ. We experimentally confirmed that immunoproteasome expression in CD14$^+$ cells was dependent on IFN-γ and not hypoxia, common at inflammation. Examining effect of antirheumatic treatment, we found *CDC42*^{hi}CD14$^+$ cells were infrequent (*OR*= 11.9, [3.4, 49.7], p<0.0001) and the MetSig reduced (p=0.0004) in patients treated with JAKi compared to other DMARDs. Concurrently, CD14$^+$ cells of those patients had low production of TNF-α, IL-6, IL-1β, CXCL8 and IL-10 (all, p<0.05). mRNA of immunoproteasome subunits, peptide loading proteins and MHC-II (including *HLA-DRB1*) were downregulated. Analysis of CD4$^+$ cells of JAKi treated patients showed upregulation of TCR components and high expression of Rho GTPases. This indicated a disruption of CD14$^+$/CD4$^+$ interaction in the immunological synapse. To investigate a direct effect of JAKi on the MetSig genes and immunoproteasome, we treated CD14$^+$ cell cultures with tofacitinib. JAKi upregulated *NFE2L1* and decreased expression of the immunoproteasome subunits, but expression of MetSig remained unchanged. Lastly, we investigated connection between the MetSig and RA disease activity (by DAS28) in a regression model. The model identified patients, which had a strong dependence between these parameters. At bottom of the model were patients with low DAS28 and MetSig, mostly treated with JAKi. Consequently, patients at the upper part may represent suitable candidates for JAKi-treatment.
Conclusion: This study demonstrates that CDC42-related metabolic signature identifies antigen-presenting CD14$^+$ cells that migrate to joints to coordinate autoimmunity. JAKi suppress the antigen presenting capacity of CD14$^+$ cells. The MetSig in CD14$^+$ cells may identify candidate patients for JAKi treatment.

POS0240 EFFECT OF METHOTREXATE UPON OXIDATIVE STRESS MEDIATED TRANS-DIFFERENTIATION OF NEUTROPHILS IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Innate immunity, Disease-modifying Drugs (DMARDs)

A. Bagchi[1], P. Ghosh[2], A. Ghosh[2], M. Chatterjee[1]. [1]*IPGME&R and SSKM Hospital, Pharmacology, Kolkata, India*; [2]*IPGME&R and SSKM Hospital, Clinical Immunology and Rheumatology, Kolkata, India*

Background: Rheumatoid arthritis (RA), a chronic systemic autoimmune disorder, is associated with inflammation coupled with oxidative stress, and translates into infiltration of immune cells in inflamed joints i.e. predominantly neutrophils (~90%). In previous studies, a subpopulation of accumulated neutrophils trans-differentiated into neutrophil-dendritic cell hybrids or N-DCs (CD66b$^+$/CD83$^+$). This N-DCs acquired antigen presenting properties (HLA-DR$^+$/CD80$^+$/CD86$^+$) and generated enhanced reactive oxygen species (ROS), collectively causing oxidative damage in the synovial fluid (SF) [**1**,**2**]. The impact of Methotrexate (MTX) upon redox status along with trans-differentiation and degree of apoptosis in neutrophils remains unclear and was the focus of this study.
Objectives: As oxidative stress is known to facilitate trans-differentiation of neutrophils, a critical factor for disease progression, the impact of MTX was studied on the status of trans-differentiation i.e. CD83$^+$/HLA-DR$^+$ in neutrophils sourced from healthy controls along with their status of activation, generation of ROS and degree of apoptosis.
Methods: In the SF of RA cases (n=25), frequency of trans-differentiation was examined by immunophenotyping (CD66b, CD83, HLA-DR). The *ex-vivo* effect of MTX on neutrophils (+/- Phorbol Myristate Acetate or PMA; to mimic the redox microenvironment in SF of RA) sourced from healthy controls was studied in terms of their status of trans-differentiation (CD66b$^+$/CD83$^+$/HLA-DR$^+$), activation (Myeloperoxidase or MPO$^+$), generation of ROS using CMH_2DCFDA and proportion of apoptosis (Annexin V$^+$, pro-apoptotic Caspase 3$^+$, anti-apoptotic Bcl-2$^+$) in flow cytometer.
Results: In the SF of RA cases, frequency of trans-differentiation (CD66b$^+$/CD83$^+$/HLA-DR$^+$) correlated positively with DAS28-CRP (r= 0.70, p<0.001), culminating in their disease promoting role. MTX (at non-toxic concentrations, 0-100 µM) did not impact on generation of ROS in neutrophils sourced from healthy controls. However, when oxidative stress was induced by PMA, MTX in a dose dependent fashion synergistically facilitated a redox imbalance (enhanced frequency of ROS^{high} neutrophils) coupled with enhanced trans-differentiation (CD83^{high}), antigen presentation (HLA-DR^{high}), activation (%MPO$^+$) and apoptosis i.e increased Annexin V$^+$, Caspase 3$^+$ along with compromised Bcl-2.
Conclusion: Oxidative stress can trigger trans-differentiation of neutrophils, which is a crucial for disease progression, and preventing trans-differentiation can be a potential therapeutic target in RA. Although MTX, an immunomdulator is the drug of choice for treatment of RA, our studies exert a certain degree of caution, as MTX in an enhanced pro-oxidant milieu facilitated generation of oxidative stress, and could impact on disease progression.

Background: The factors contributing to the efficacy of abatacept in patients with rheumatoid arthritis (RA) remain unknown.
Objectives: We aimed to identify cellular, transcriptomic, and proteomic features that predict responses or resistance to abatacept.
Methods: Blood samples were collected from 22 RA patients treated with abatacept at the initiation and after three months of treatment. Response to treatment was defined based on the EULAR response criteria, and seven patients were classified as responders and the others as non-responders. We quantified gene expression levels in peripheral blood mononuclear cells (PBMCs) by RNA-Seq, 67 plasma protein levels by multiplexed immunoassay, and the expression of surface molecules (CD3, 19, and 56) by flow cytometry, in addition to collecting clinical characteristics. Additionally, three gene expression data sets concerning the efficacy of abatacept[1–3], comprising 37 responders and 50 non-responders in total, were used to replicate the current study. We compared the gene expression of responders versus non-responders in each set and meta-analyzed the results.
Results: Among the clinical characteristics, the number of monocytes was significantly higher in the non-responders before treatment (p = 0.01). Regarding the transcriptome data, we found 952 differentially expressed genes (DEGs) between the responders and the non-responders before treatment initiation. A cell-type enrichment analysis showed that the DEGs were enriched in monocytes ($p = 8.7 \times 10^{-212}$, Figure 1A). Additionally, gene set enrichment analysis showed enrichment in the gene module, including *MYD88* and *TIRAP*, with the strongest significance among all of the pathways tested. When we estimated the expression of *MYD88* and *TIRAP* in monocytes by deconvolution analysis, the non-responders had higher expression before treatment initiation (p = 0.04 and 0.03, respectively). Among the 67 protein levels, two exhibited a correlation with the expression of the module ($p < 0.05$). Of these, hepatocyte growth factor (HGF), which is produced by monocytes, was present at significantly higher concentrations in non-responders before treatment (p = 0.02). The analysis of the replication sets identified 1,695 DEGs. These were also enriched for the genes expressed in monocytes ($p = 2.9 \times 10^{-90}$, Figure 1B) but not for the module detected in the current study. Among the DEGs, those expressed in monocytes were enriched for the genes involved in the aerobic electron transport system in mitochondria based on gene set enrichment analysis.

Conclusion: Monocyte-derived transcriptomic features before treatment underlay the differences in abatacept efficacy. The pathway activated in monocytes was the *MYD88*/*TIRAP*-HGF axis in the current study, but that pathway in the replication set was the aerobic electron transport system. Overall, our results highlight the contribution of monocytes as the cells responsible for abatacept-treatment resistance and the heterogeneity of activated pathways within them.

POS0242 RESPONSE TO ABATACEPT IN RHEUMATOID ARTHRITIS PATIENTS REQUIRES A SPECIFIC MACROPHAGE POLARISATION

Keywords: Innate immunity, Rheumatoid arthritis

B. De Maleprade[1,2], B. Gerard[1,2], P. Brevet[1,2], S. Candon[2,3], O. Vittecoq[1,2], M. Freret[1,2], T. Lequerre[1,2]. [1]*Hospital Center University De Rouen, Department of Rheumatology, Rouen, France*; [2]*University of Rouen Normandy, FOCIS Center of Excellence PAn'THER, Inserm, U1234, Rouen, France*; [3]*Rouen University Hospital, Department of Immunology and Biotherapy, Rouen, France*

Background: Abatacept (ABA), a biologic treatment for rheumatoid arthritis (RA), is a recombinant fusion protein composed of the extracellular domain of human CTLA-4 combined with the Fc portion of human IgG1. Lack of response to treatment occurs in 30 % of RA patients, highlighting the need to better understanding its mechanism of action and to identify predictive factors of response. Although ABA is considered to interrupt the costimulatory signal, the importance of this mechanism on the drug effect lacks evidence. Moreover, therapies targeting T cells were disappointing in RA [1]. In contrast, ABA has been shown to induce reverse signaling in antigen-presenting cells, by activating the indolamine 2,3-dioxygenase (IDO) pathway (a strong tolerogenic enzyme) in macrophages and dendritic cells [2]. ABA also acts on nitric oxide (NO) production, a proinflammatory molecule capable of inhibiting IDO action, although conflicting data have been reported.

Objectives: The objective of this study was to evaluate the importance of direct mechanisms on antigen-presenting cells and identify biomarkers of the response to ABA.
Methods: Sera (n = 71) and RNA from whole blood (n = 57) were collected from RA patients before treatment by ABA. Abundance of GM-CSF, gamma interferon (IFNg), IL-10, IDO, iNOS were quantified using ELISA and addressable laser bead assay (ALBIA). RT-qPCR was performed on *IDO1* transcript. Response to ABA was assessed 6 months after its introduction, using EULAR response criteria. A costimulation *in vitro* model was developed: monocytes-derived macrophages (using GM-CSF or M-CSF) from healthy donors were polarized 8 days with LP, with or without IFNg. T cells were cocultured with anti-CD3, with or without ABA, anti-CD28 antibodies or IDO inhibitor (1-MTDT). Proliferation was assessed using CFSE.
Results: Before ABA therapy, GM-CSF, IFNg and IL-10 in sera were increased in serum of good responders compared to non-responders. Our costimulation model showed that in macrophages exposed to GM-CSF, IFNg, LPS, ABA inhibited lymphocyte proliferation by 53%. Inhibition by ABA was only 10% when macrophages has not been exposed to IFNg, suggesting a central role of this cytokines. Furthermore, inhibition was only achieved when both GM-CSF + IFNγ were used, highlighting the need for a combination of these two factors. In presence of GM-CSF with IFNg + LPS + ABA, IDO was increased in macrophages. ABA increased iNOS production in macrophages when either IFNg or GM-CSF were not involved in their polarisation, neutralising IDO and leading to T cell proliferation. These results show a balance between iNOS and IDO in macrophages, modulated by IFNγ and GM-CSF. In RA patients, ABA could release the tolerogenic potential of polarized macrophages, decreasing T cell proliferation. Accordingly, iNOS increased in non-responders' sera after 6 months of ABA treatment while *IDO1* expression increased in good responders whole blood RNA. In fact, in ABA responders, IDO increase in macrophages enabling a tolerogenic effect since iNOS is not induced.
CONCLUSION:

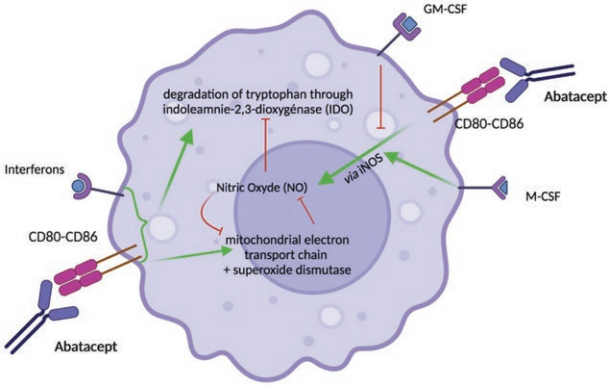

Figure 1. Abatacept direct signaling on antigen presenting cells.

Specific macrophage polarisation with IFNg and GM-CSF, leading to an increase in IDO production without increasing iNOS after treatment, could be the key to achieving a good response to ABA. This finding supports the macrophage-mediated action of ABA and may contribute to the development of a prediction system for abatacept response based on macrophage polarisation.

Background: Following LPS stimulation, extensive transcriptional and metabolic reprogramming leads to metabolic remodeling that allows macrophages to dynamically adopt to environmental cues.[1] A failure to accurately orchestrate macrophage responses can skew immune responses towards inflammation and various disease states.[2]
Objectives: Macrophages have a central role in Rheumatoid arthritis (RA) by promoting chronic inflammation and joint destruction. Although targeted biologicals have transformed treatment options for RA patients, almost half of them fail to achieve clinical remission[2]. Better understanding of the regulation of key immuno-metabolic pathways in macrophages of RA patients will inform on how cellular metabolism and inflammation interlink to identify novel metabolism-related therapeutic targets.
Methods: To delineate disease-specific effects in monocytes and macrophages derived from RA patients compared to healthy individuals we performed whole transcriptome analysis (RNA-Sequencing) and untargeted metabolomics. By integrating these datasets with metabolite assessment in the serum of RA patients, we found upregulation of Indoleamine 2, 3-dioxygenase 1 (IDO1) and cumulation of L-kynurenine (KYN) to be hindered in peripheral blood monocytes and macrophages derived from rheumatoid arthritis (RA) patients compared to healthy individuals in response to LPS.
Results: In macrophages, we identified cumulation of KYN in response to LPS, to limit pro-inflammatory macrophage functions through tricarboxylic acid (TCA) cycle remodeling, characterized by decreased succinate-dehydrogenase (SDH) activity and increased Gluthathione synthesis. Aligning with these findings, kynurenine exerted anti-inflammatory effects when administrated to LPS-activated macrophages in vitro by limiting the production of Interferon gamma (IFNγ) and Tumor Necrosis Factor (TNF). Using the small molecule IDO1 inhibitor Linrodostat and exogenously added KYN we showed that KYN accumulation in response to LPS regulates the glycolytic switch and cumulation of metabolites associated with inflammation such as glycolytic intermediates and the TCA cycle intermediates Succinate and Itaconate.
Conclusion: Collectively, our data highlight KYN as a key immunometabolite that directly interferes with macrophage activation and suggest that dysregulation of the kynurenine pathway in RA patients mediates inflammation and disease progression.

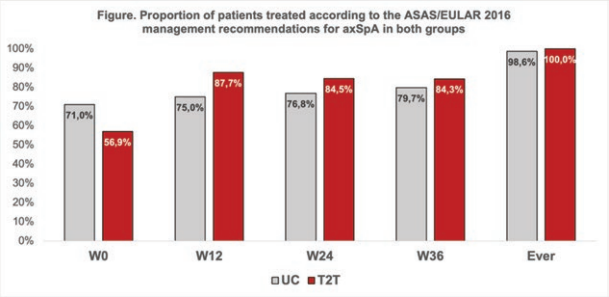
Everything you need to know about managing in axSpA

POS0244 PROTOCOL VIOLATION IN A TREAT-TO-TARGET STRATEGY IN AXIAL SPONDYLOARTHRITIS: DATA FROM THE OPEN-LABEL, PRAGMATIC, CLUSTER-RANDOMISED TICOSPA TRIAL

Keywords: Randomized control trial, Treat to target, Spondyloarthritis



C. López-Medina[1,2], F. Van den Bosch[3], D. Van der Heijde[4], M. Dougados[2], A. Moltó[2]. [1]*Reina Sofia University Hospital, IMIBIC, University of Cordoba, Rheumatology Department, Cordoba, Spain*; [2]*Université de Paris, Centre de recherche épidémiologie et bio statistique de Sorbonne Paris Cité, APHP, Hôpital Cochin, Service de rhumatologie, Paris, France*; [3]*VIB Center for Inflammation Research, Ghent University, Department of Internal Medicine and Pediatrics, Ghent, Belgium*; [4]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*

Background: Despite the ASAS-HI (primary outcome) did not reach statistical significance in the TICOSPA trial, other clinically relevant secondary outcomes were numerically higher in the treat-to-target (T2T) strategy in comparison to Usual Care (UC), including the ASAS-HI. Three hypotheses have been considered to explain this observation: a lack of power, the risk of protocol violations in the T2T arm and the potential optimal care in the UC arm.
Objectives: a) To evaluate the proportion of patients (pts) with protocol violations in the T2T group during the 48 weeks (48W) of follow up as well as the impact and predictive factors of such violation; b) to compare the proportion of pts treated according to the ASAS/EULAR 2016 management recommendations for axSpA over the follow-up period in both arms.
Methods: *Study design:* pragmatic, prospective, cluster-randomized controlled, 48W trial (NCT03043846) with 18 participating centers. *Inclusion criteria*: Pts with a diagnosis of axSpA and fulfilling ASAS criteria, non-optimally treated with NSAIDs, bDMARD-naïve and ASDAS >2.1. *Study treatment regimens:* SpA expert centers were selected to participate in the study: then, they were randomly allocated (1:1) to the treatment arm: a) T2T: the management strategy was pre-specified based on strict application of 2016 ASAS/EULAR axSpA recommendations (Q4W), with a target of ASDAS <2.1; b) UC: treatment decisions at the rheumatologist's discretion (Q12W). *Statistical analysis*: *a) Protocol violations:* in the T2T arm were evaluated at every visit by the question "Was the recommendation for treatment from last visit followed by physician and patient?". Factors associated with at least one protocol violation over the study were evaluated using multivariate logistic regression. Outcomes at 48W were compared between T2T violators (T2T-V) vs. T2T non-violators (T2T-NV) vs. UC using ANOVA test; b) *optimal care in UC:* proportion of pts treated according to the 2016 ASAS/EULAR recommendations over the follow-up period in both arms were compared.
Results: 160 pts initiated the trial (T2T:80 and UC:80). *a) Protocol violations:* In the T2T arm, 41/80 (51.2%) pts violated the protocol during at least one visit. A total of 27.7% violations were represented by a lack of switching to a second NSAID and 41.2% by a lack of initiation of a first bDMARD. Baseline predictive factors independently associated with the protocol violation were the country (France vs. others; OR 3.8 (95%CI 1.1-15.0)), female sex (OR 4.4 (1.5-15.1)), diagnosis delay ≤7 years (OR 3.4 (1.1-11.9)), HLA-B27 negative (OR 6.4 (1.6-32.2)) and CRP≥6mg/L (OR 4.2 (1.3-15.9)). After 48W of follow-up, T2T-NV vs. T2T-V showed similar ratios of ASAS-HI improvement. ASDAS-LDA, ASDAS-ID and ASDAS-CII outcomes were more prevalent in T2T-NV vs. T2T-V, although these differences did not reach statistical significance (Table 1). b) *Optimal care in UC*: the proportion of pts managed according to the 2016 ASAS/EULAR recommendations was very high in both arms, i.e. always above 75% also in the UC arm, although no statistical differences were found (p=0.490) (Figure 1).

Table 1. Impact of protocol violation across groups

	Groups			p-value			
	T2T-NV N = 39	T2T-V N = 41	UC N = 80	ANOVA	T2T-NV vs. T2T-V	T2T-NV vs. UC	T2T-V vs. UC
ASAS40 W48	14 (35.9%)	16 (39.0%)	19 (24.1%)	0.177	0.773	0.177	0.087
ASDAS-LDA W48	24 (61.5%)	19 (46.3%)	32 (40.5%)	0.087	0.173	**0.027**	0.504
ASDAS-ID W48	11 (28.2%)	8 (19.5%)	10 (12.7%)	0.117	0.361	**0.038**	0.319
ASDAS-CII W48	22 (56.4%)	16 (39.0%)	26 (32.9%)	**0.049**	0.120	**0.015**	0.506
ASDAS-MI W48	6 (15.4%)	8 (19.5%)	9 (11.4%)	0.479	0.627	0.565	0.226
ASAS-HI improvement W48	14 (35.9%)	16 (39.0%)	21 (26.6%)	0.322	0.773	0.297	0.162

Conclusion: The prevalence of pts violating the protocol in the T2T arm was high, although it did not explain the non-significance of the primary outcome in the TICOSPA trial (ASAS-HI improvement). In contrast, the proportion of pts managed according to the ASAS/EULAR recommendations in the UC arm was very high, suggesting that the UC group was optimally treated.

POS0245 BLOOD-BASED EXTRACELLULAR MATRIX BIOMARKERS CAN IDENTIFY ENDOTYPES OF PATIENTS WITH AXSPA AND RESPONDERS TO ADALIMUMAB TREATMENT

Keywords: Spondyloarthritis, Biomarkers

H. Port[1], F. Christiansen[2], S. Holm Nielsen[2], P. Frederiksen[2], A. C. Bay-Jensen[2], M. Karsdal[2], I. J. Sørensen[3], M. Østergaard[3,4], S. Juhl Pedersen[4]. [1]*University of Copenhagen, Faculty of Health and Medical Sciences, Copenhagen, Denmark*; [2]*Nordic Bioscience A/S, Immunoscience, Herlev, Copenhagen, Denmark*; [3]*University of Copenhagen, Clinical Medicine, Copenhagen, Denmark*; [4]*Rigshospitalet, Center for Arthritis Research, Glostrup, Denmark*

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease associated with extracellular matrix (ECM) remodelling of the cartilage, bone, and connective tissues. Adalimumab (ADA) is an effective treatment, but not all patients respond, and this may relate to subtypes of the disease (endotypes). Serological quantification of ECM-mediated biomarkers may be useful to identify axSpA endotypes and monitor treatment response to ADA.
Objectives: 1) To identify endotypes of patients with axSpA using blood-based ECM biomarkers at baseline and 2) To investigate differences in response to ADA by BASDAI and ASDAS criteria within the endotypes.
Methods: ECM biomarkers were measured in serum from patients with axSpA in the three studies (MASH (n=41), DANISH (n=49) and ASIM (n= 45)) at baseline [1–3]. MASH was a cross-sectional study while in DANISH and ASIM patients were randomised to receive treatment with ADA 40 mg or placebo every other week (e.o.w.) for 6 or 12 weeks (ASIM and DANISH, respectively) followed by ADA 40 mg e.o.w. for an additional 18 or 12 weeks (ASIM and DANISH, respectively). Biomarkers of type II collagen formation (PRO-C2), type I collagen degradation (C1M), inflammation (CRP, CRPM) citrullinated and degraded vimentin (VICM) and neutrophil activity (CPa9-HNE) were measured by immunoassays. Biomarker data was log-transformed, standardized by mean centering and scaled by the standard deviation prior to principal component analysis (PCA) and K-means clustering. Response to ADA based on BASDAI50 response, ASDAS clinical important improvement (CII) and major improvement (MI) at study week 24 was compared in the PCA components and between clusters using Mann-Whitney tests. Key demographic parameters were also compared between clusters using Mann-Whitney and chi-squared tests.
Results: The variability of baseline ECM biomarker data among patients with axSpA was mainly explained by two dimensions (PC1 and PC2). Type I collagen degradation and inflammation biomarkers (C1M and CRP), reflecting tissue inflammation, were the primary contributors to PC1, whereas type II collagen formation (PRO-C2), reflecting cartilage turnover, contributed the most to PC2 (Figure 1A). In ADA-treated patients, BASDAI50 responders, patients with

ASDAS CII, and ASDAS MI had a higher score in PC1 compared to BASDAI50 non-responders, patients with no ASDAS CII and no ASDAS MI, respectively (p=.05, p<.001, p<.001). No differences were observed in PC2. Two distinct clusters were identified from the PC1 and PC2 (Figure 1). Patients in Cluster 1 had higher levels of ECM biomarkers, a greater BASDAI50 response compared to those in Cluster 2 (89.5% vs. 73.2%) and a higher % of patients with ASDAS CII and ASDAS MI (73.7% vs. 32.1% and 92 % vs. 73%, all p<.05). No significant differences were observed in the demographic parameters between Clusters.

Conclusion: The PCA analysis identified two orthogonal dimensions related to: inflammation (driven by C1M and CRP) and cartilage turnover (driven by PRO-C2). Two clusters were determined. Patients from Cluster 1, associated with high inflammation, demonstrated a greater BASDAI50 response and ASDAS improvement when treated with ADA than those from Cluster 2. These findings may help profiling treatment response within patients with axSpA.

Background: Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has demonstrated consistent and sustained efficacy up to Week (Wk) 52 across the full spectrum of axial spondyloarthritis (axSpA), in patients (pts) with non-radiographic axSpA (nr-axSpA) and radiographic axSpA (r-axSpA; i.e. ankylosing spondylitis).[1,2]

Objectives: To evaluate the impact of BKZ on MRI inflammatory lesions of the sacroiliac joints (SIJ) and spine to Wk 52 in the phase 3 studies BE MOBILE 1 (nr-axSpA) and BE MOBILE 2 (r-axSpA).

Methods: BE MOBILE 1 (NCT03928704) and BE MOBILE 2 (NCT03928743) study designs have been reported previously.[1] From Wk 16, all pts received subcutaneous BKZ 160 mg every 4 wks (Q4W). MRI endpoints (Spondyloarthritis Research Consortium of Canada [SPARCC] SIJ and ASspiMRI-a Berlin modification [hereafter termed 'Berlin spine'] inflammation scores) were assessed at baseline (BL), Wk 16 and Wk 52 via central reading by two independent expert readers with an adjudicator, and were measured in the subset of pts in the MRI sub-studies. SPARCC SIJ and Berlin spine scores range from 0–72 and 0–69, respectively, with lower scores indicating less inflammation. We report observed case mean absolute SPARCC SIJ and Berlin spine scores and the proportion of pts with inflammation of the SIJ/spine at BL achieving MRI remission (SPARCC SIJ <2; Berlin spine ≤2)[3] to Wk 52.

Results: At BL, 60% of pts with nr-axSpA (152/254) and 42% of pts with r-axSpA (138/332) had SPARCC SIJ assessments as part of the MRI sub-studies; 57% (146/254) and 41% of pts (137/332) had Berlin spine assessments, respectively. Of these, 63% of nr-axSpA (BKZ: 50, placebo [PBO]: 46) and 46% of r-axSpA (BKZ: 42, PBO: 21) pts had SIJ inflammation (SPARCC SIJ ≥2)[3] at BL; 21% (BKZ: 17, PBO: 13) and 41% (BKZ: 36, PBO: 20) had spine inflammation (Berlin spine >2)[3] at BL, respectively. At BL, mean SPARCC SIJ and Berlin spine scores were comparable between BKZ- and PBO-randomised pts (**Figure 1**). Reductions in mean absolute SPARCC SIJ and Berlin spine scores observed at Wk 16 were maintained to Wk 52 for continuous BKZ pts; pts who switched from PBO to BKZ at Wk 16 (PBO-switcher) reached similar levels of improvement to continuous BKZ pts at Wk 52 (**Figure 1**). Among pts with SIJ inflammation at BL, a greater proportion of BKZ- vs PBO-randomised pts achieved SPARCC SIJ remission at Wk 16; a similar pattern was observed for pts with inflammation of the spine at BL, with a greater proportion of BKZ- vs PBO-randomised pts achieving Berlin spine remission at Wk 16 (**Table 1**). The proportion of continuous BKZ and PBO-switcher pts achieving MRI remission largely improved to Wk 52 (**Table 1**).

Conclusion: Across the axSpA spectrum, dual inhibition of IL-17A and IL-17F with BKZ resulted in a reduction in MRI inflammatory lesions of the SIJ and spine and an increased proportion of pts achieving MRI remission at Wk 52.

Background: A history of enthesitis or peripheral arthritis has been reported in >30% of patients (pts) with axial spondyloarthritis (axSpA),[1] both of which contribute to disease burden. Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has demonstrated efficacy in phase 3 parallel studies in pts with non-radiographic (nr-)axSpA (BE MOBILE 1) and radiographic axSpA (r-axSpA i.e. ankylosing spondylitis; BE MOBILE 2).[2,3]

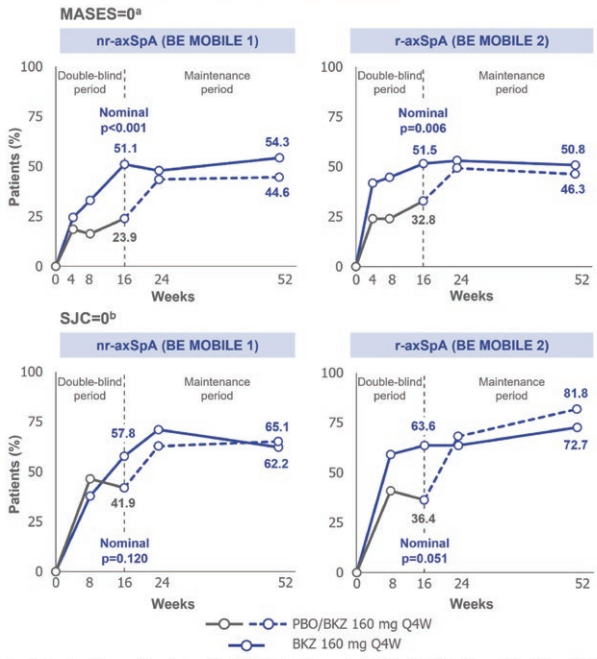
Objectives: To evaluate the impact of BKZ on the main peripheral manifestations of axSpA, to Week (Wk) 52.

Methods: Pts in BE MOBILE 1 (NCT03928704; nr-axSpA) met Assessment of SpondyloArthritis International Society (ASAS) classification criteria, pts in BE MOBILE 2 (NCT03928743; r-axSpA) met both modified New York and ASAS criteria. Pts were randomised to receive subcutaneous BKZ 160 mg every 4 wks (Q4W) or placebo (PBO) to Wk 16. From Wk 16 all pts received BKZ 160 mg Q4W.[2] Among pts with enthesitis (Maastricht Ankylosing Spondylitis Enthesitis [MASES]>0), at least one swollen joint (SJC>0), or at least one tender joint (TJC>0) at baseline (BL), we report mean change from baseline (CfB) using multiple imputation (MI). Pts (%) achieving complete resolution of enthesitis (MASES=0 in pts with MASES >0 at BL) and peripheral arthritis (SJC=0 in pts with SJC >0 at BL, assessed in 44 joints) using non-responder imputation, is also reported.

Results: At BL, 73.2% nr-axSpA pts (BKZ: 94/128, PBO: 92/126) and 59.9% r-axSpA pts (BKZ: 132/221, PBO: 67/111) had enthesitis; peripheral arthritis (SJC >0) was present in 34.6% (BKZ: 45/128, PBO: 43/126) and 19.9% (BKZ: 44/221, PBO: 22/111) of nr-axSpA and r-axSpA pts, respectively. BL MASES, SJC and TJC were largely similar between treatment arms (**Table 1**). Across the axSpA spectrum, greater mean CfB in MASES was achieved with BKZ vs PBO at Wk 16; improvements continued to Wk 52 with continuous BKZ and in pts switching from PBO to BKZ at Wk 16 (**Table 1**). Similarly, >50% BKZ pts achieved complete resolution of enthesitis at Wk 16 vs <33% of PBO pts; by Wk 52, responses of PBO/BKZ-switchers approached those of BKZ pts (**Figure 1**). At Wk 16, greater mean CfB in SJC and TJC was achieved with BKZ vs PBO-randomised pts with nr-axSpA. Improvements largely continued to Wk 52 with BKZ for both continuous BKZ and PBO/BKZ-switcher pts (**Table 1**). Resolution of peripheral arthritis was achieved by >57% of BKZ vs >41% of PBO-randomised pts at Wk 16; by Wk 52, proportions were similar among continuous BKZ and PBO/BKZ-switcher pts (**Figure 1**).

Table 1. Mean BL and CfB in enthesitis and peripheral arthritis [MI]

		BL		Wk 16 CfB			Wk 52 CfB	
Mean (SE)		PBO	BKZ 160 mg Q4W	PBO	BKZ 160 mg Q4W	Nominal p value	PBO/BKZ 160 mg Q4W	BKZ 160 mg Q4W
MASES[a]	nr-axSpA[b]	4.9 (0.4)	4.8 (0.3)	−1.3 (0.3)	−2.4 (0.3)	0.013	−2.9 (0.4)	−3.6 (0.3)
	r-axSpA[c]	4.4 (0.3)	4.2 (0.3)	−1.5 (0.3)	−2.4 (0.3)	0.003	−3.2 (0.3)	−2.9 (0.3)
SJC[d]	nr-axSpA[e]	3.8 (0.5)	4.2 (0.8)	−1.3 (0.6)	−3.1 (0.7)	0.007	−2.9 (0.4)	−2.5 (0.8)
	r-axSpA[f]	3.9 (0.7)	4.7 (0.6)	−2.1 (0.5)	−3.6 (0.5)	0.074	−3.6 (0.8)	−4.2 (0.6)
TJC[g]	nr-axSpA[h]	6.3 (0.6)	6.0 (0.8)	−1.1 (0.5)	−3.0 (0.7)	0.008	−3.5 (0.6)	−4.0 (0.8)
	r-axSpA[i]	5.4 (0.6)	5.3 (0.6)	−2.9 (0.5)	−2.5 (0.4)	0.401	−4.5 (0.6)	−4.0 (0.5)



Randomised set. [a]Assessed in pts with: [a]MASES >0 at BL: [b]PBO n=92; BKZ n=94; [c]PBO n=67; BKZ n=132; [d]SJC >0 at BL: [e]PBO n=43; BKZ n=45; [f]PBO n=22; BKZ n=44; [g]TJC >0 at BL: [h]PBO n=85; BKZ n=78; [i]PBO n=61; BKZ n=116. P values without any multiplicity adjustment are indicated as nominal p values and should not be used as an indicator of statistical significance.

Conclusion: BKZ treatment resulted in sustained improvements in peripheral manifestations across the axSpA spectrum. Resolution of enthesitis was achieved in ~half of BKZ-treated pts by Wk 52; a similar pattern was observed for peripheral arthritis, with more than half of pts achieving resolution to Wk 52.

Background: Fluctuations in tumour necrosis factor inhibitor (TNFi) drug levels in patients with inflammatory arthritis (IA) during disease activity-guided tapering is not well described.

Objectives: To compare TNFi drug-levels in the tapering group, relative to the control group, from baseline to month 18 based on data from the BIODOPT trial.

Methods: BIODOPT was designed as a pragmatic, multicentre, randomised controlled, open-label trial (EudraCT 2017-001970-41) of 18 months duration [1]. Patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) in sustained (≥12 month) low disease activity (LDA) and treated with TNFi at baseline were enrolled and randomised into a disease activity-guided tapering or control in a 2:1 ratio. Blood samples at baseline and month 18 were analysed for TNFi drug levels. Based on previous research, the TNFi drug level category was considered intermediate if values were between: adalimumab 5.0-8.0 mg/L, certolizumab pegol 14.7-40.0 mg/L, etanercept 1.8-4.6 mg/L, golimumab 1.0-3.0 mg/L, or infliximab 1.6-5.0 mg/L. Values greater or lesser were considered as high or low TNFi category, respectively. A mixed Poisson regression with robust variance estimator was used for the analyses on TNFi categories; missing data were imputed as low TNFi category.

Results: Of 129 TNFi-treated patients, 88 were randomised to tapering and 41 to a control arm with standard care. Blood samples at baseline and month 18 were available for: tapering group 89% (78/88) and control group 90% (37/41). As expected, baseline TNFi categories were comparable between groups as presented in ***Figure 1***. At 18 months, fewer patients in the tapering group were in the high TNFi category, relative risk: RR: 0.53 (95%CI 0.31 to 0.90, *P*=0.02), ***Table 1***. Even though more patients in the tapering group were in the low TNFi category at 18 months, the difference was non-significant, RR: 1.47 (95%CI: 0.94 to 2.32, P=0.09). The observed changes in TNFi categories between groups from baseline to 18 months indicates acceptable compliance to the trial interventions. At 18 months, 32% (28/88) in the tapering group and 0% (0/41) in the control group had achieved ≥50% dose reduction of their TNFi and were in LDA. The majority of patients in the tapering group were in the high (39% [11/28]) or intermediate (39% [11/28]) TNFi category at baseline; only 22% (6/28) were in the low TNFi category. Thus, indicating a greater chance of successful tapering for patients with high or intermediate TNFi drug levels at baseline.

Conclusion: Successful TNFi tapering was associated with high or intermediate TNFi levels at baseline. Fewer patients in the tapering group were in the high TNFi category at 18 months; thus, indicating acceptable compliance to the trial interventions. Further research is needed for the implications of therapeutic drug monitoring in the management of rheumatic diseases.

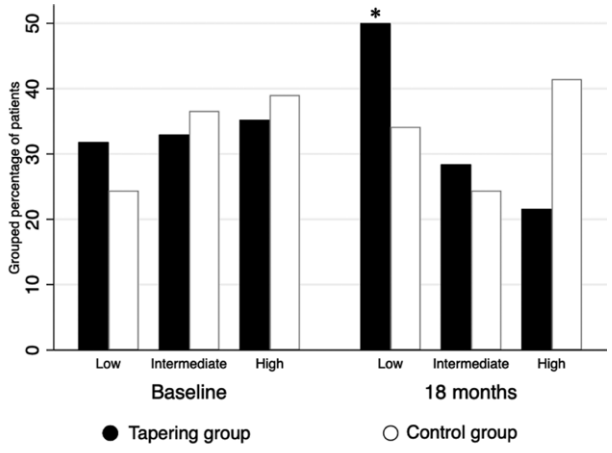

Table 1. TNFi drug level categories at 18 months.

Variable	18 months		
	Tapering group *N=88*	**Control group** *N=41*	**Between group difference RR (95%CI)**
TNFi drug level category:			
High, n (%)	19 (22%)	17 (42%)	0.53 (0.31 to 0.90)
Intermediate, n (%)	25 (28%)	10 (24%)	1.12 (0.60 to 2.09)
Low, n (%)	44 (50%)	14 (34%)	1.47 (0.94 to 2.32)

N: number, RR: relative risk, 95%CI: 95% confidence interval, TNFI: tumour-necrosis factor inhibitor.

Iannone[1], G. Lapadula[1], L. Midtbøll Ørnbjerg[1], J. Twisk[1], I. Van der Horst-Bruinsma[1]. [1]*European Spondyloarthritis Research Collaboration Network (EuroSpA RCN), on behalf of SRQ, DANBIO, ATTRA, TURKBIO, NOR-DMARD, SCQM, Reuma.pt, ROB-FIN, RRBR, biorx.si, ICEBIO, AmSpA, BIOBADASER, GISEA, and BSRBR-AS, Copenhagen, Denmark*

Background: Women with axial spondyloarthritis (axSpA) tend to have higher scores on patient-reported outcome measures (PROMs), such as the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Bath Ankylosing Spondylitis Functional Index (BASFI), compared to men with the same condition. However, it is not well known whether these sex differences are maintained over time during treatment with tumor necrosis factor inhibitors (TNFi), or which factors can potentially explain these sex-based differences.

Objectives: To examine sex differences in BASDAI and BASFI over time in axSpA patients treated with their first TNFi, and to identify potential factors contributing to observed sex differences.

Methods: Pooled data were collected from biologic-naive axSpA patients initiating their first TNFi in the EuroSpA registries. A three-level linear mixed model structure was employed to analyze sex differences in PROMs (BASDAI and BASFI, scale 0-100) over time (sex*time), accounting for correlations between repeated measurements within subjects and between subjects within countries. Baseline characteristics were explored as potential explanatory variables for observed sex differences over time, and interactions between sex, time, and explanatory variables were analyzed. Univariable analysis was performed by incorporating one explanatory variable at a time, while multivariable analysis was used to investigate the effect of multiple explanatory variables on the regression coefficient of sex*time. Only explanatory variables that affected this regression coefficient by more than 10% in univariable analysis were considered for multivariable analysis. A complete case analysis was performed when data were missing for explanatory variables.

Results: This study analyzed data from 11,753 axSpA patients (37% female) with at least two BASDAI measurements over two years, and from 9,780 patients (38% female) with at least two BASFI measurements over the same period. At baseline, women were older and had higher BASDAI/BASFI scores, while men had higher CRP levels, longer disease duration, and higher HLA-B27 positivity. During the follow-up period, women had significantly higher mean BASDAI scores than men (mean difference 6.05; 95% CI 5.27 to 6.83). Additionally, the differences in BASDAI scores between women and men increased by an average of 0.67 (95% CI 0.04 to 1.29) per year. These findings indicate that the sex differences in BASDAI scores persisted and increased over time. In the univariable analysis of explanatory variables, increased age (-8.9%) and longer disease duration (-4.7%) notably explained the sex differences in the BASDAI scores (Figure 1). However, no explanatory variables were eligible for inclusion in the multivariable analysis. We also observed that the sex differences in BASDAI scores were reduced over time in HLA-B27-positive patients, but increased in those with psoriasis (Figure 1). Although women had slightly higher overall BASFI scores than men (mean difference 3.25; 95% CI 2.32 to 4.19), this difference did not vary by time (β = 0.25; 95% CI -0.36 to 0.86).

Conclusion: Women with axSpA treated with their first TNFi had significantly higher mean BASDAI and BASFI scores compared to men over a two-year follow-up period. The mean difference in BASDAI scores increased slightly over time, and the magnitude of this difference was affected by HLA-B27 positivity (reduced) and psoriasis (increased). Further research is needed to understand the mechanisms behind these sex differences and their clinical implications.

Acknowledgements: The EuroSpA Research Collaboration Network was financially supported by Novartis Pharma AG. Novartis had no influence on the data collection, statistical analyses, abstract preparation, or decision to submit the abstract.

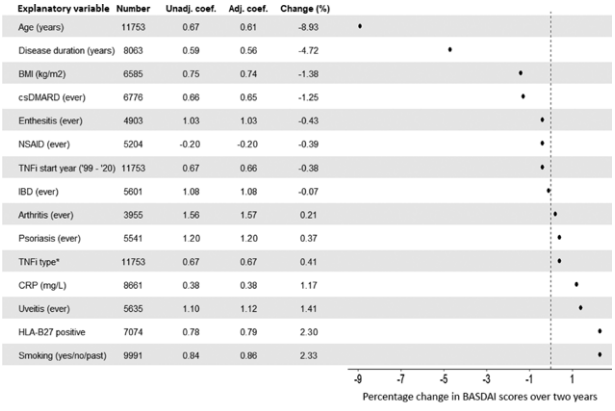

Figure. Explanatory variables and their effect on sex differences in BASDAI scores (scale 0 - 100) over two years of follow-up, where one unit of time is equivalent to one year. The figure presents the unadjusted coefficients (sex*time) and adjusted coefficients for the explanatory variables and the corresponding (percentage) change. There was a relevant interaction between sex, time, and (1) ever having psoriasis (β=5.07) and (2) HLA-B27 positivity (β=-2.46).
*The different TNFi types were: infliximab, etanercept, adalimumab, certolizumab and golimumab.

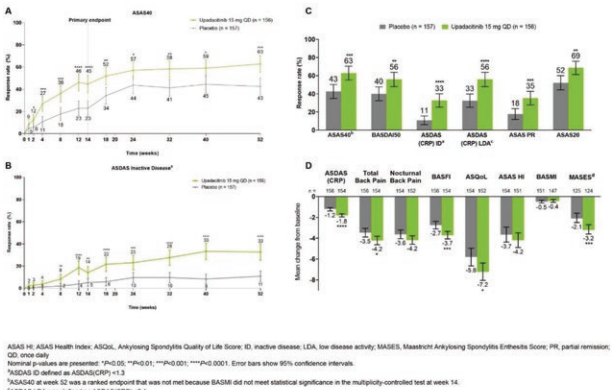
Background: Upadacitinib (UPA), a Janus kinase inhibitor, was effective and well tolerated in patients (pts) with non-radiographic axial spondyloarthritis (nr-axSpA) through 14 weeks (wks) of treatment.[1]

Objectives: This analysis assessed the efficacy and safety of UPA vs placebo (PBO) through 1 year.

Methods: The SELECT-AXIS 2 nr-axSpA study included a 52-wk randomized, double-blind, PBO-controlled period. Enrolled adults had a clinical diagnosis of active nr-axSpA fulfilling the 2009 ASAS classification criteria, objective signs of inflammation based on MRI sacroiliitis and/or elevated C-reactive protein, and an inadequate response to NSAIDs. One-third of pts had an inadequate response to biologic DMARDs. Pts were randomized 1:1 to UPA 15 mg once daily or PBO. Concomitant medications, including NSAIDs, had to be kept stable through wk 52. The study protocol outlined that pts who did not achieve ASAS20 at any two consecutive study visits between wks 24 to 52 should receive rescue therapy with NSAIDs, corticosteroids, conventional synthetic/biologic DMARDs, or analgesics. Cochran-Mantel-Haenszel (CMH) test with non-responder imputation incorporating multiple imputation (NRI-MI) was used to handle missing data and intercurrent events for binary efficacy endpoints. Mixed-effect model repeated measures (MMRM) was used to assess continuous efficacy endpoints. NRI was used for binary endpoints after rescue and as observed analysis excluding data after rescue for continuous endpoints. Treatment-emergent adverse events (TEAEs) are reported through wk 52.



Results: Of the 314 pts randomized, 259 (82%; UPA, n=130; PBO, n=129) completed wk 52 on study drug. More pts achieved an ASAS40 response with UPA vs PBO from wks 14 to 52 with a 20% treatment difference at wk 52 (63% vs 43%; nominal *P* <.001; **Figure 1**). The proportion of pts achieving ASDAS inactive disease with UPA remained higher than PBO at wk 52 (33% vs 11%; nominal *P* <.0001; **Figure 1**). Consistent improvements and maintenance of efficacy were also seen across other disease activity measures. Between wks 24 and 52, fewer pts on UPA (9%) than PBO (17%) received rescue therapy. A similar proportion of pts in each treatment group had a TEAE (**Table 1**). Infections were the most common TEAE; the rates of serious infections and herpes zoster were higher with UPA vs PBO, although no new serious infections were reported from wks 14 to 52. COVID-19 events were balanced between treatment groups. No opportunistic infections, malignancy excluding non-melanoma skin cancer, adjudicated major adverse cardiovascular events, inflammatory bowel disease, or deaths were reported. Two pts (1.3%) on PBO had adjudicated venous thromboembolic events.

Conclusion: UPA showed consistent improvement and maintenance of efficacy vs PBO through 1 year across multiple disease activity measures. No new safety risks were identified with longer-term UPA exposure. These results continue to support the benefit of UPA in pts with active nr-axSpA.

POS0251 RISK OF CARDIOVASCULAR DISEASE ASSOCIATED WITH LONG-TERM USE OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS IN ANKYLOSING SPONDYLITIS

Keywords: Cardiovascular disease, Epidemiology, Spondyloarthritis

J. W. Kim[1], J. S. Yoon[2], H. Lee[1], S. H. Park[1], S. K. Kim[1], J. Y. Choe[1]. [1]*Daegu Catholic University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Daegu, Korea, Rep. of (South Korea)*; [2]*Busan Paik Hospital, Inje University College of Medicine, Department of Internal Medicine, Busan, Korea, Rep. of (South Korea)*

Background: Ankylosing spondylitis (AS) is associated with increased cardiovascular disease, but there are limited data as to whether prolonged treatment with non-steroidal anti-inflammatory drugs (NSAIDs) increases the cardiovascular risk in AS patients. We aimed to examine the risk of cardiovascular disease associated with long-term use of NSAIDs in a large real-world AS cohort.

Objectives: We aimed to examine the risk of cardiovascular disease associated with long-term use of NSAIDs in a large real-world AS cohort.

Methods: A nationwide population-based cohort of patients with AS and matched controls without AS were analysed. The primary outcome was cardiovascular disease, a composite outcome of ischemic heart disease, stroke, or congestive heart failure. Long-term use of NSAIDs was defined as use of NSAIDs for more than 365 cumulative defined daily doses. The association between long-term use of NSAIDs and incident cardiovascular disease was examined using a multivariable Cox proportional hazards regression model in both AS and non-AS populations.

Results: Among 19,775 patients with AS and 59,325 matched controls without AS, there were 1,663 and 4,308 incident cases of cardiovascular disease, showing an incidence of 16.9 and 13.8 per 1,000 person-years, respectively. Long-term use of NSAIDs increased the risk of cardiovascular disease in non-AS controls (adjusted hazard ratio [aHR], 1.29; 95% confidence interval [CI], 1.17–1.43). In contrast, long-term use of NSAIDs did not increase the risk of cardiovascular disease in AS patients (aHR, 0.97; 95% CI, 0.86–1.09; adjusted for age, sex, socioeconomic status, body mass index, smoking status, hypertension, diabetes, hyperlipidemia, and tumor necrosis factor inhibitor use).

Conclusion: Prolonged NSAID treatment in AS patients may not be as harmful as in the general population regarding cardiovascular risk.

POS0252 DIFFERENCES IN SERUM DRUG LEVELS AND ANTI-DRUG ANTIBODIES IN PATIENTS WITH INFLAMMATORY ARTHRITIS TREATED WITH ORIGINATOR VS BIOSIMILAR ADALIMUMAB

Keywords: bDMARD, Inflammatory arthritides

I. Jyssum[1,2], J. E. Gehin[2], E. Kristianslund[1], J. Sexton[1], D. Worren[3], Y. Hu[4], T. K. Kvien[1], E. A. Haavardsholm[1], N. Bolstad[3], S. W. Syversen[1], G. L. Goll[1]. [1]*Diakonhjemmet Hospital, Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*; [2]*University of Oslo, Institute of Clinical Medicine, Oslo, Norway*; [3]*Norwegian Radium Hospital, Department of Medical Biochemistry, Oslo, Norway*; [4]*Lillehammer Hospital, Department of Rheumatology, Lillehammer, Norway*

Background: Serum drug levels and anti-drug antibodies (ADAb) impact the therapeutic effectiveness of most TNF-inhibitors. Possible differences in immunogenicity profile and pharmacokinetics across biosimilar and originator TNFi are still to be elucidated.

Objectives: To compare serum drug levels, ADAb and treatment effect in patients treated with originator (Humira) vs biosimilar (Hyrimoz) adalimumab.

Methods: Patients with a clinical diagnosis of spondyloarthritis (SpA), rheumatoid arthritis (RA), psoriatic arthritis (PsA) or other inflammatory arthritis (adult JIA or unspecified polyarthritis) enrolled in the observational NOR-DMARD study and starting treatment with adalimumab were included in the present analyses. Patients were started on originator adalimumab (Humira) up to January 2020 and biosimilar adalimumab (Hyrimoz) from January 2020, based on a national annual tender system for biological drugs in Norway. Serum drug levels and neutralising ADAb were measured using an in-house fluorescence method and compared between groups by Mann-Whitney U test and $\chi 2$-test respectively, in addition to multivariable regression analyses adjusted for age, sex, previous use of bDMARDs, smoking and co-medication with methotrexate. Treatment response at 3 months was defined by Major or Clinically Important improvement in SpA and EULAR good or moderate response in RA, PsA and other inflammatory arthritis, and, and compared by $\chi 2$-test. Drug survival the first two years of adalimumab treatment was explored by Kaplan-Meier curves and Cox proportional hazard regression analysis.

Results: A total of 378 patients (177 SpA, 98 RA, 70 PsA, 33 other) (median age 45.7 years [SD 14.2], 174 [46%]) female) were included. 240 (63%) patients started originator and 138 (37%) started biosimilar adalimumab. 139/378 (37%) patients used methotrexate as co-medication, the proportions and dosage were comparable for originator and biosimilar adalimumab. Patients on originator adalimumab had lower serum drug levels (6.5 mg/L [IQR 3.0-9.8] vs 8.3 mg/L [IQR 5.4-11.1], p=0.0003) (Figure 1A), and a higher rate of ADAb formation (33 [14%] vs 6 [4%], p= 0.004) compared to patients treated with biosimilar adalimumab. The differences in serum drug levels and ADAb were consistent in multivariable

regression analyses (p= 0.032 and p= 0.020 respectively) and across diagnostic groups. There was no difference in treatment response or drug survival between originator and biosimilar adalimumab. (Table 1 and Figure 1B)

Conclusion: This observational study showed higher occurrence of ADAb formation and lower adalimumab serum levels in patients on adalimumab originator vs biosimilar, indicating differences in the immunogenicity profile. There was, however, no significant difference in clinical outcomes.

Table 1.

	Originator (Humira) (240)	Biosimilar (Hyrimoz) (138)	P-value

POS0253

FACTORS ASSOCIATED WITH TREATMENT PATHWAYS IN EARLY AXIAL SPONDYLOARTHRITIS: A MULTISTATE ANALYSIS OF THE 10-YEAR FOLLOW-UP OF THE DESIR COHORT

Keywords: Descriptive Studies, Spondyloarthritis

E. Portier[1,2], S. Chevret[3], A. Ruyssen-Witrand[4], A. Walter Petrich[3], M. Dougados[1,2], A. Moltó[1,2]. *[1]Cochin Hospital, Rheumatology, PARIS, France*; *[2]ECAMO, INSERM U-1153: Clinical Epidemiology and Biostatistics, PARIS, France*; *[3]Saint Louis Hospital, Biostatistics, PARIS, France*; *[4]University Hospital of Toulouse, Rheumatology, Toulouse, France*

Background: Current recommendations for the management of patients with axial spondyloarthritis (axSpA) emphasize the need of individualized strategy in the therapeutic decision [1,2]. Thus, many factors seem to impact this strategy.

Objectives: The objectives of the study were to describe the therapeutic strategies observed in axSpA, and to assess the factors associated with treatment changes over time.

Methods: This study included patients with axSpA from the French prospective cohort DESIR, with a follow-up of 10 years. A multi-state model was built, including 4 treatment states with an increasing gradation ("none", "non-steroidal anti-inflammatory drugs (NSAID)", "conventional synthetic DMARD (csDMARD)", "TNF inhibitors (TNFi)"), and 6 possible transitions from one state to another. Estimation of the restricted mean sojourn times spent in each state from the state occupation probabilities was performed. Then, Cox regression models were used to study the potential impact of factors on transitions.

Results: 686 of the 708 patients which had more than one visit were analyzed. At cohort entry, 199 (29.0%) were untreated, 427 (62.2%) received NSAID, and 60 (8.7%) received csDMARD. Over the 10 years of follow-up, patients mostly received NSAID (46.4% of the time) followed by TNFi (24.4% of the time). In multivariable analysis (**figure 1**), presence of sacroiliitis on radiography, internal bowel disease and articular index were associated with transition to NSAID. Duration in the previous state was often a significant protective factor associated with transition to csDMARD or TNFi. Finally, the several disease activity outcomes were associated with most transitions.

Conclusion: This was the first study using a multistate model to easily represent the different states, transitions and their associated factors. There appeared to be subcategories of axSpA patients with different management (including some without any treatment), and a significant proportion of patients treated with csDMARD.

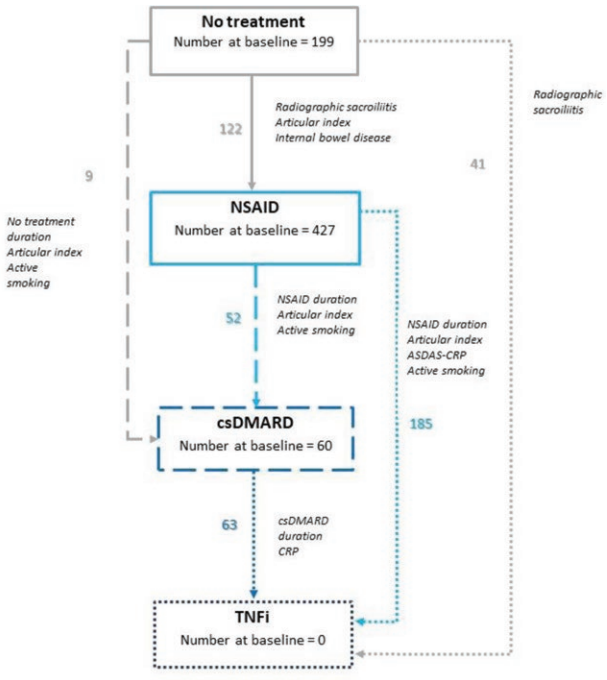

Figure 1. Multistate model representation. Each arrow corresponds to a possible transition (n=6). Number at baseline denotes the number of patients who started from the state at baseline. The number of events and factors significantly associated with each transition in the multivariable analysis are written near to the corresponding arrow.NSAID refers to non-steroids anti-inflammatory drugs, csDMARD stands for conventional synthetic Disease Modifying Anti-Rheumatic Drug, and TNFi for tumor necrosis factor inhibitors.

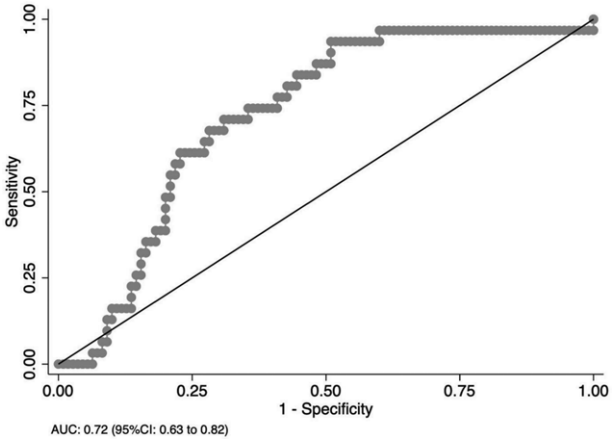
Background: Identification of predictors for successful tapering of biologics in patients with inflammatory arthritis (IA) can help to guide physicians and patients; but, evidence is lacking.

Objectives: To identify possible predictors for successful tapering of biological disease modifying anti-rheumatic drugs (bDMARDs) from baseline characteristics.

Methods: BIODOPT was a randomised, open-label, equivalence trial (EudraCT 2017-001970-41) where adults with rheumatoid arthritis (RA; n=61), psoriatic arthritis (PsA; n=26), or axial spondyloarthritis (axSpA; n=55) in ≥12 months low disease activity (LDA) were randomised 2:1 to disease activity-guided tapering or to continuation of biologics as usual care. Successful tapering at 18 months was pre-defined as patients who could reduce their biologic dose ≥50% while still being in LDA. Modified poisson regression with robust variance estimator was used for the analyses. Univariable analyses were: tapering group, sex, age, education, tobacco use, body mass index, comorbidity, arthritis characteristics i.e., diagnosis, duration, duration from diagnosis to treatment start, on ≥2 conventional synthetic DMARDs, on methotrexate, on tumour necrosis factor inhibitor (TNFi), on first bDMARD, on bDMARD number ≥3, duration of bDMARD, duration of remission on bDMARD, duration of LDA on bDMARD, previous bDMARD tapering, C-reactive protein (CRP) before first bDMARD, Health Assessment Questionnaire Disability Index (HAQ-DI), Pain Visual Analog Scale (VAS), Fatigue VAS, Patient Global Health VAS, Short Form Health Survey 36 (SF-36) physical and mental component summary (PCS and MCS), tender joints, Physician Global Health VAS, CRP, and in remission. Potentially important variables (univariate p<0.10) were included in the multivariable model. C-statistics was used to assess model prediction.



Results: One-hundred-and-forty-two patients were randomised to tapering (n=95) or control (n=47) of which 32% (30/95) and 2% (1/47) achieved successful bDMARD tapering at 18 months. A statistically significant associations (univariate p<0.10) was identified between successful tapering and tapering group, HAQ-DI, Pain VAS, Fatigue VAS, Patient Global Health VAS, SF-36 PCS, and SF-36 MCS, ***Table 1***. However, the only independent predictor for achieving successful tapering in the multivariable model was allocation to the tapering group, risk ratio (RR): 14.0 (95%CI: 1.9-101.3). Interestingly, individuals with a better mental health state (higher SF-36 MCS) were potentially more likely to achieve successful tapering; RR: 1.06 (95%CI: 0.99-1.13). A sensitivity analysis only including tapering group and SF-36 MCS found both variables to be independent predictors, tapering group: RR 14.3 (95%CI: 2.0-101.9) and SF-36 MCS: RR: 1.06 (95%CI: 1.01-1.11). The multivariable model gave reasonable prediction, ***Figure 1***.

Conclusion: One-third of patients with IA achieved successful tapering when the bDMARD dosing interval was spaced after a disease activity-guided tapering algorithm. The choice of initiating tapering (allocation to tapering) was the only independent predictor; therefore, physicians should keep the option in mind when patients are in sustained LDA. Moreover, better baseline mental health seemed to have potential importance which points to the value of patient comprehension and willingness to engage in the tapering approach.

Table 1. Regression analyses on variables included in the multivariable model for prediction of successful tapering at 18 months.

Baseline variables	Univariable analysis RR (95%CI)	P-value	Multivariable analysis RR (95%CI)	P-value
Tapering group	14.8 (2.1-106.3)	0.007	14.0 (1.9-101.3)	0.009
HAQ-DI	0.44 (0.20-1.00)	0.049	0.60 (0.26-1.37)	0.221
Pain VAS	0.96 (0.93-1.00)	0.024	0.99 (0.94-1.04)	0.720
Fatigue VAS	0.99 (0.97-1.00)	0.072	1.01 (0.99-1.02)	0.495
Patient global health VAS	0.97 (0.95-0.99)	0.011	1.00 (0.97-1.03)	0.955
SF-36 PCS	1.06 (1.00-1.11)	0.045	1.00 (0.93-1.07)	0.915
SF-36 MCS	1.06 (1.01-1.12)	0.011	1.06 (0.99-1.13)	0.097

Pain in RMDs

POS0255 A PRO-NOCICEPTIVE POPULATION OF NEUTROPHILS INFILTRATE SENSORY GANGLIA AND MEDIATE CHRONIC WIDESPREAD PAIN IN FIBROMYALGIA SYNDROME

Keywords: Pain, Fibromyalgia, Innate immunity

R. Evans[1], S. Caxaria[1], P. Celik[1], A. M. Fuller[1], S. Bharde[1], S. Sikandar[1]. [1]*William Harvey Research Institute, QMUL, Experimental Medicine and Rheumatology, London, United Kingdom*

Background: Although the aetiology of chronic widespread pain in fibromyalgia syndrome is unknown and generally recognised as a central pain syndrome, several recent studies point towards a peripheral aetiology. Aberrant activity of immune cells and associated cytokine signalling has also been linked to

fibromyalgia syndrome. Neutrophils are polymorphonuclear granulocytes that normally exist in circulation to function as primary mediators of rapid innate host defence, releasing extracellular vesicles as functional mobile units. Surprisingly, neutrophils are found in increased circulatory levels and with enhanced chemotactic and microbicidal properties in fibromyalgia patients. Furthermore, we have recently shown a key role for neutrophils in mediating the spatiotemporal spread of hypersensitivity in a hyperalgesic priming model of chronic widespread pain. Our data also shows a fundamental pro-nociceptive action of neutrophils derived from patients or mice with chronic widespread pain when administered to naïve recipient mice.

Objectives: The mechanisms by which neutrophils can sensitise sensory neurons to cause pain signalling is still unclear but is likely linked to a distinct subpopulation of neutrophils characterised by altered surface protein expression. We aim to identify a specific neutrophil subpopulation that sensitises nociceptive neurons either through cell-cell interactions or mediated via neutrophil-derived extracellular vesicles (NDEVs) to produce chronic widespread pain in fibromyalgia syndrome.

Methods: To identify a pro-nociceptive neutrophil population, we used neutrophils from fibromyalgia patients and pain free controls, characterising proteomic differences between the cohorts by FACS. Furthermore, we have employed functional assays of neutrophil reactivity, including quantification of reaction oxygen species (ROS) production and neutrophil extracellular trap generation (NETosis) to characterise specific functional differences which may responsible their pro-nociceptive capacity. To assess the role of NDEVs in neutrophils pro-nociceptive actions we have isolated and performed phenotypic characterisation of NDEVs from patient and pain-free controls. Finally, we used primary sensory neuron cultures to assess the effect of neutrophils and NDEVs on neuronal excitability using functional assays (calcium imaging and *in vitro* electrophysiology) to demonstrate the capacity of neutrophils to sensitise peripheral sensory neurons.

Results: Proteomic characterisation of neutrophils derived from patients with fibromyalgia pain vs pain free subjects reveals a distinct population of cells, including altered expression of cell surface markers CD62L and CXCR2. Quantification of ROS generation also reveals changes in cells derived from patients when compared to pain free counterparts, alongside increased NETosis which may reflect specific mechanisms employed by cells to sensitise peripheral neurons following trafficking to DRG. We observe increased NDEV release from patient cells alongside specific phenotypic differences, including an upregulation of surface markers, mirroring what we observe within the parent cells.

Moreover, *in vitro* systems, including electrophysiology recording and calcium imaging reveal increased neuronal responses to both patient cells and patient cell-derived NDEVs.

Conclusion: We show a surprising role of neutrophils, a short-lived immune cell, in the aetiology of chronic widespread pain in fibromyalgia syndrome. Our data demonstrates altered proteomic profiles and distinct phenotypic differences in both circulating neutrophils and NDEVs from patients, supporting an immunological basis for chronic widespread pain in fibromyalgia and a novel mechanism of nociplastic pain.

POS0256 IDENTIFICATION OF TWO BIOLOGICAL SUBTYPES OF CRPS

Keywords: Pain, Skin

M. Perez Vertti Valdes[1], A. Juengel[1], I. Kolm[2], L. Opitz[3], H. Rehrauer[1], O. Distler[1], F. Brunner[4], S. Dudli[1]. [1]*University of Zurich, Center of Experimental Rheumatology, Zürich, Switzerland*; [2]*University Hospital of Zürich, Dermatology, Zürich, Switzerland*; [3]*Functional Genomics Center Zurich, Genomics, Zürich, Switzerland*; [4]*Universitätsklinik Balgrist, Physical Medicine and Rheumatology, Zürich, Switzerland*

Background: Patients with Complex Regional Pain Syndrome (CRPS) present prolonged and debilitating pain and tissue damage. To date, treatment remains a challenge. Biological phenotyping has not been performed yet, and thus, molecular therapies are missing.

Objectives: To determine whether different biological CRPS subtypes exist and to provide a molecular profile of these subtypes.

Methods: CRPS patients fulfilling the *Budapest criteria* were included. Body Perception Disturbance (BPD) and pain scores (0-100) questionnaires were recorded. Skin punch biopsies (3 millimetres) from the affected and non-affected sides (n=6+6) and matching blood samples were taken. Biopsies were split in two for transcriptomic and histological analyses. Blood was processed to collect plasma after centrifugation and peripheral blood mononuclear cells (PBMCs) with a Ficoll gradient. Total RNA was isolated from skin biopsies and from PBMCs for bulk sequencing. Differentially expressed genes (DEGs) were determined using DESeq2 generalised linear model (p≤0.01, log2 ratio≥0.5). Hierarchical clustering and principal component analysis (PCA) were performed on raw transcriptomic data to identify patient sub-populations. Cell types were approximated in skin and PBMCs with deconvolution analysis using RNA sequencing databases with known cell frequencies (PRESS cohort and immunedeconv, respectively).

Twenty pro- and anti-inflammatory plasma cytokines were measured using chemiluminescence-based assays (MSD U-PLEX Viral Combo 1). Histological slides were scored (0-3) blinded by a dermato-pathologist based on a panel of 10 morphological and cellular characteristics. Protein levels, histological evaluations and demographic data were compared between CRPS clusters using unpaired t-tests.

Results: Six women with CRPS 1 of the hand (n=5) and foot (n=1) participated in the study. Mean age was 47.3 ± 14.2 yrs and mean symptom duration was 57.8 ± 44.2 weeks. Skin transcriptomics showed 427 DEGs when comparing affected vs. non-affected samples (**Figure 1a**). Samples clustered by patient rather than affected/non-affected side (**Figure 1b**). PCA of only the affected samples displayed two clusters (PC1=56%, PC2=17%) (**Figure 1c**). Further evaluation of all affected samples by deconvolution analysis suggested two distinct cellular signatures, clustering patients in the same way as the PCA. Keratinocyte-related genes were upregulated in cluster 1 (n=3) and strong fibroblast, microvascular endothelial cell, monocyte and M1 macrophage signatures were found in cluster 2 (n=3) (**Figure 1d**). Consequently, gene ontology (GO) of each cluster showed enrichment of epidermis development and downregulation of peptidase terms in cluster 1 and extracellular matrix and collagen fibril organisation in cluster 2. Histopathological examinations did not show any difference between subtypes.

PCA of PBMCs transcriptome validated the same distribution of patients into two clusters (PC1=62%, PC2=16%) (**Figure 1e**). A total of 2'328 DEGs were found between both clusters, with an overrepresentation of immune and inflammatory response, and neutrophil degranulation and chemotaxis-related terms in cluster 1 (n=2) according to GO. Deconvolution analysis confirmed the presence of a stronger signature of neutrophils and M2 macrophages in cluster 1 than cluster 2. Blood cytokine quantification showed that interleukin-1 receptor antagonist (IL-1RA) levels were 1.9 times higher in cluster 1 than in cluster 2 (n=3+3, p=0.02) (**Figure 1f**). Consistently, transcriptomic data indicated that cluster 1 had higher expression of IL-1RA encoding gene (IL-1RN) in matching skin (log2 ratio=0.88, FDR=0.06) and PBMCs (log2 ratio=1.1, FDR≤0.01,) than cluster 2.

There was no significant difference in age or symptoms duration between clusters, but pain and BPD questionnaires revealed differences between groups, suggesting that the clusters might be clinically distinguishable (**Figure 1g**).

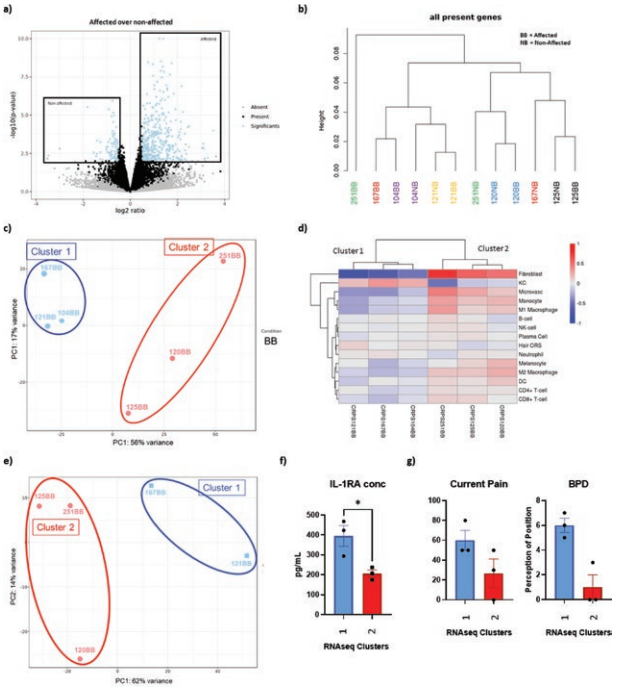

Figure 1.

Conclusion: Our findings suggest the existence of two biological CRPS subtypes. Molecular patterns could facilitate the development of targeted therapies.

POS0257 PAINWAVES: THE POTENTIAL OF MACHINE LEARNING TO DIFFERENTIATE CHRONIC PAIN COHORTS USING ELECTROENCEPHALOGRAPHY

Keywords: Pain, Imaging, Artificial Intelligence

J. Tsigarides[1], A. Rushbrooke[2], A. Bagnall[2]. [1]*University of East Anglia, Norwich Medical School, Norwich, United Kingdom*; [2]*University of East Anglia, Computing Science, Norwich, United Kingdom*

Background: Chronic pain is highly prevalent, debilitating and lacks effective treatments. Experimental and neuroimaging research demonstrates abnormal central pain processing[1]. However, robust brain-based biomarkers that could inform targeted treatments are lacking. Electroencephalography (EEG) is the optimal tool to investigate dynamic abnormalities in pain processing to reveal underlying mechanisms. Early evidence from EEG studies in Fibromyalgia (FM) indicate potential mechanisms such as thalamocortical dysrhythmia[2], demonstrated by alterations in the Alpha and Theta frequency bands. However, existing studies employ rudimentary analyses failing to account for the multivariate and temporal nature of EEG data. State-of-the-art machine learning (ML) approaches provide unique opportunities to generate a deeper understanding of EEG signatures in chronic pain and identify specific biomarkers that could be used to differentiate mechanistic subtypes.
Objectives: This preliminary work aims to establish whether a state-of-the-art ML classifier can differentiate patients with FM from healthy controls based on their EEG characteristics.
Methods: The dataset used was collected through The VIPA Study (ISRCTN46681140). Patients with FM satisfied the 2016 FM classification criteria. High-density 64-channel EEG data using an electrolyte gel-based active electrode system was collected at rest with participants' eyes closed over 2 minutes. Individual Fast Fourier Transforms were applied to overlapping time windows to extract EEG frequency band power whilst retaining temporal information. Frequency bands were used as features to train a classification model (definitions of frequency ranges in Table 1). One of the fastest, most accurate state-of-the-art time-series classification ML algorithms (mini-ROCKET) was used via the sktime python toolkit. To obtain unbiased accuracy estimates across all participants, a 'leave-one-out' strategy was used. Accuracy of the algorithm was reported; defined by the number of correct predictions divided by the total number of predictions for each frequency band (2-class problem, chance estimates 0.5-0.6 based on $p<0.05$).
Results: Data from 23 patients with FM (mean age 46 ±14yrs, 87% female) and 14 healthy controls (mean age 71 ±7yrs, 50% female) were analysed. Patients with FM had moderate self-reported pain (5.5 ±2.3 VAS) and disease severity (mean FIQR 65.4 ±16.6) at baseline. Theta and Alpha were the most discriminatory frequency bands, with mini-ROCKET able to classify participants with 70.7% accuracy. The Beta frequency band was less discriminatory (63.4%) but still above predicted chance estimates. Delta frequency band was least discriminatory (51.2%).
Conclusion: Preliminary results indicate that machine learning can be successfully used to differentiate patients with Fibromyalgia from healthy controls based on EEG measures of the Alpha and Theta frequency bands. Alterations in Alpha and Theta have been demonstrated in previous non-ML research, indicating potential underlying abnormalities in the interaction between the thalamus and cortex which may be related to central mechanisms underlying chronic pain. Further work is required in larger, matched cohorts to validate these findings, but this early work highlights the future potential of EEG and ML in both understanding brain-based pain mechanisms and using EEG features to differentiate chronic pain subgroups.

POS0258 USING REAL-TIME PATIENT-GENERATED DATA FROM MOBILE HEALTH DEVICES TO CHARACTERISE PAIN FLARES IN RHEUMATOID ARTHRITIS

Keywords: Pain, Rheumatoid arthritis

T. C. Hsu[1], K. Druce[1], B. Birlie Yimer[1], J. Mcbeth[1]. [1]*The University of Manchester, Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom*

Background: Pain flares in rheumatoid arthritis (RA) often refer to episodes of increased pain severity accompanied by pain impact. Describing the prevalence and predictors of pain flare occurrence is difficult since there are no agreed classification criteria[1]. Patient-generated data collected in real-time with mobile health (mHealth) devices provide an opportunity to identify individual patterns and triggers in pain dynamics over time[2].
Objectives: We aim to characterise pain flares and pre-flare exposures using real-time mHealth data from patients with RA.
Methods: In a 30-day mHealth study[3] we collected daily reports of pain severity on a five-point scale (ranging from none to very severe pain) via a smartphone app to define the onset and ending criteria for three types of pain flares, including 1) above average: pain severity greater than the personal median score, 2) significant change: two-point increase in pain severity from yesterday, and 3) absolute impact: two-point increase in pain severity from yesterday and pain severity greater than three. All pain flare types end when pain severity returns to the personal median score or lower. Exposures of the preceding periods were self-rated sleep quality, mood, anxiety and fatigue (all scales range 1-5, higher scores are worse) using the same study app, and passively recorded total time asleep (hr), sleep efficiency (%), sleep latency (min) and physical activity (min) via a wrist-worn accelerometer. We report the 30-day monthly pain flare rate, the average duration of pain flares and summarise average exposures one-day and three-day before pain flare onset.
Results: We analysed 253 participants who provided at least seven days of data (81.8% females; mean age = 59.9, average years with RA = 12.1). A total of 6,244 daily reports were included in the analysis. Pain flare occurrence decreased when applying more complex definitions. 31% of participants had pain flares under the most stringent definition of absolute impact, with two episodes per month (Table 1). Across all types, 75% of pain flares lasted two days before returning (Median = 1, IQR = 1-2) but could persist up to 11 days (Figure 1). Pre-flare exposures did not differ between pain flare types nor between the preceding periods. Participants reported fair sleep quality (Median = 3), feeling quite happy (Median = 2), not anxious (Median = 1) and mild fatigue (Median = 2) prior to pain flare onset. Objective exposures showed a daily average of 7-hour sleep with 83% efficiency, under 20 minutes to fall asleep, and approximately 50 minutes being active.

Table 1. Pain flare characteristics

Type	Number of participants with ≥1 pain flare(s) (%)	Total number of pain flares	Monthly pain flare rate (SD)
Above average	224 (88.5)	788	4.3 (2.2)
Significant change	108 (42.7)	171	2.0 (1.1)
Absolute impact	78 (30.8)	116	2.0 (1.1)

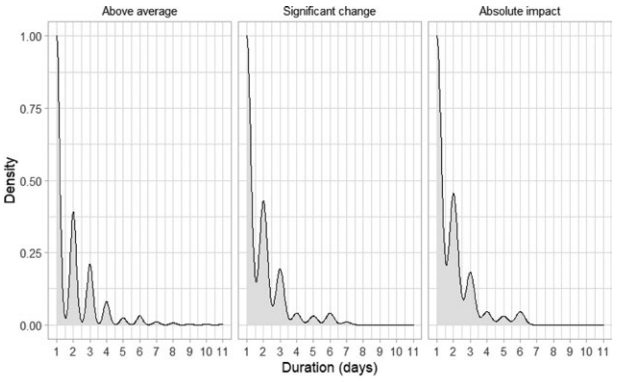

Figure. Pain flare duration

Conclusion: Using three increasingly complex definitions, we found pain flares were common and lasted up to 11 days based on self-reported pain severity. Future analysis should examine the role of pain impact and compare within-person exposures during pre-flare periods with non-flare periods.

POS0259 DO CHRONIC PAIN IN MULTIPLE SITES AND WIDESPREAD PAIN INCREASE RISK OF INCIDENT DEMENTIA?

Keywords: Pain

J. Tian[1], G. Jones[1], X. Lin[1], Y. Zhou[1], A. King[2], J. Vickers[2], F. Pan[1]. [1]*University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*; [2]*University of Tasmania, Wicking Dementia Research and Education Centre, Hobart, Australia*

Background: Chronic musculoskeletal pain has been linked to dementia; however, chronic pain typically occurs in multiple sites, and no study has investigated the associations between number of chronic pain sites and risk of all-cause dementia and its subtypes.

Objectives: To investigate whether greater number of chronic pain sites is associated with a higher risk of dementia and its subtypes.

Methods: Participants (N=356,383) in the UK Biobank who were dementia-free at baseline were included. Pain in the hip, knee, back and neck/shoulder, or 'all over the body' and its duration were assessed. Participants were categorized into six groups: no chronic pain, and chronic pain in 1, 2, 3 and 4-sites and 'all over the body' (widespread pain). All-cause dementia and its subtypes were ascertained using hospital inpatient and death registry records. Cox regression was used to investigate the associations between number of chronic pain sites and incidence of all-cause dementia and its subtypes.

Results: Over a median follow-up of 13 years (interquartile range: 12.6–14.0), 4,959 participants developed dementia. After adjustment for sociodemographic, body mass index, lifestyle, comorbidities, pain medications, psychological problems and sleep factors, greater number of chronic pain sites was associated with an increased risk of incident all-cause dementia (Hazard ratio [HR]=1.08 per 1-site increase, 95%CI 1.06–1.11) and Alzheimer's disease (HR=1.09 per 1-site increase, 95%CI 1.04–1.13) in a dose-response manner, but not vascular and frontotemporal dementia. Relative to participants without chronic pain, participants having chronic pain in 2-, 3-, 4-sites and widespread pain had a higher risk of incident all-cause dementia after adjusting for confounding factors (2-sites: HR=1.18, 95%CI 1.08–1.29; 3-sites: HR=1.22, 95%CI 1.08–1.38; 4-sites: HR=1.42, 95%CI 1.19–1.70; widespread pain: HR=1.52, 95%CI 1.26–1.82). Similar results were observed for Alzheimer's disease.

Conclusion: Greater number of chronic pain sites was associated with an increased risk of incident all-cause dementia and Alzheimer's disease, suggesting that chronic pain in multiple sites may contribute to individuals' dementia risk and is an underestimated risk factor for dementia.

POS0260 CHILDHOOD BULLYING AND MUSCULOSKELETAL PAIN IN ADOLESCENCE: A PROSPECTIVE STUDY OF REPORTED PAIN HISTORY AND QUANTITATIVE SENSORY TESTING

Keywords: Pain, Epidemiology, Patient reported outcomes

R. Lucas[1], S. Fraga[1], S. Soares[1], M. Talih[2]. [1]*Instituto de Saúde Pública da Universidade do Porto (ISPUP), Epidemiology Research Unit, Porto, Portugal*; [2]*Faculdade de Medicina da Universidade do Porto - FMUP, Public Health Sciences, Porto, Portugal*

Background: Psychosocial circumstances are strongly associated with the onset and prognosis of chronic musculoskeletal (MSK) pain. However, it is unknown they precede, coexist with or follow MSK pain conditions. Bullying during youth is a particularly damaging but modifiable social experience that is known to interfere with health status, potentially including pain memories and responses to noxious stimuli.

Objectives: We aimed to quantify the longitudinal associations between bullying profiles and musculoskeletal pain (reported history and pressure pain sensitivity) in a large population-based cohort of adolescents followed since birth.

Methods: We used data from the 10 and 13 years waves of the Generation XXI birth cohort study based in Porto, Portugal. Data on youth pain history were collected during face to face interviews from parents (age 10) and adolescents (age 13) using the Luebeck pain screening questionnaire. MSK pain was considered present when the participant had recurrent pain in one of the following sites: back, neck, shoulders, upper/lower limbs, hips, or generalized MSK pain. A subsample of the cohort underwent quantitative sensory testing using computerized deep tissue cuff pressure algometry in the legs, which allowed estimating pain detection/tolerance thresholds, and measuring pain intensity ratings. Bullying profiles were computed for the 10 and 13 years waves based on responses to the Bully Scale Survey and participants were classified as "victim only", "both victim and aggressor", "aggressor only", or "not involved". Cross-sectional and longitudinal associations between bullying profiles and reported pain were quantified using relative risks (RR) and 95% confidence intervals (95% CI) obtained using Poisson regression. Associations between bullying and pain sensitivity were estimated using linear regression coefficients and 95% CI. Estimates were adjusted for sex and number of Adverse Childhood Experiences adapted from the questionnaire by Felitti et al.

Results: Among the 4049 adolescents examined, bullying profiles at age 10 were associated with MSK pain at age 13, whereas there were no associations between MSK pain at age 10 and bullying profiles at 13. Cross-sectional associations between bullying and MSK pain history were present at 10 and 13 years. When compared to adolescents "not involved" in bullying, those who reported being victims at age 10 had higher risk of reporting MSK pain at age 13: RR (95% CI) 1.28 (1.06, 1.55) for "victims only" and 1.30 (1.06, 1.58) among "both victims and aggressors" (Figure below). "Aggressors only" did not show clear differences in terms of pain history. Among the 1727 adolescents who underwent cuff pressure algometry, those who were "victims only" at age 10 had lower average pain detection and tolerance thresholds at 13 years [linear regression coefficients (95% CI): -1.81 (-3.29, -0.33) for detection and -2.73 (-5.17, -0.29) for tolerance], as well as higher pain intensity ratings [0.37 (0.07, 0.68) and 0.39 (0.06, 0.72)], when compared with adolescents not involved in bullying. No differences were seen for the remaining bullying profiles.

Conclusion: Our study provides prospective evidence that bullying victimization is more likely to lead to negative reported MSK pain experiences than the reverse. Bullying may have long-term influence on the risk of chronic musculoskeletal pain and may interfere with somatosensory responses to painful stimuli.

Background: Pain sensitization is an important component of the pain experience in many persons with osteoarthritis (OA). Knee OA studies have suggested that pain sensitization is associated with functional limitations, but the evidence in hand OA is sparse.
Objectives: To assess whether pain sensitization is associated with physical function in people with hand OA.
Methods: We included 206 participants in cross-sectional analyses from the follow-up visit of the Nor-Hand study. Measures of pain sensitization included pressure pain thresholds (PPTs) by a handheld algometer, and temporal summation (TS) defined as increased pain during repeated stimuli. Pain and function in hands and knees/hips were self-reported on the AUSCAN and WOMAC indices, respectively. Performance-based measures of physical function included hand grip strength, the 30-second chair stand test and the 40-meter walk test (reported as walking speed). Associations between sex-standardized PPT and TS values and physical function were assessed using linear regression adjusted for potential confounders (see Table 1). The possible mediating effect of self-reported pain severity was examined with causal inference-based mediation analyses.
Results: The median (IQR) age was 65 (60-69) years and 86% were female. People with higher PPTs at or near the hand or knee, which may represent less peripheral and/or central sensitization, reported better function in hands and knees/hips and performed better on the performance tests than people with lower PPTs (Table 1), although not statistically significant for all outcomes. Also, a higher PPT at the trapezius muscle, representing less central sensitization, was associated with better function in the lower extremities (Table 1). No associations were found between pain sensitization and the chair stand test (data not shown), or between TS (measure of central sensitization) and hand or lower extremity function. The effects of PPTs on self-reported AUSCAN hand function appeared to be largely mediated through self-reported hand pain (e.g., indirect effect of PPT at the wrist mediated through hand pain: -1.19, 95% CI -1.95, -0.43, and direct effect: -0.20, 95% CI -0.90, 0.51). Effects of PPTs on grip strength were mediated through pain to a lesser extent (e.g., indirect effect of PPT at the wrist mediated through hand pain: 0.12, 95% CI -0.10, 0.34, and direct effect: 1.21, 95% CI 0.29, 2.13). Similarly, the mediating effects of knee/hip pain were larger in analyses of self-reported function than for performance-based measures of lower extremity function (data not shown).
Conclusion: Our results suggest that peripheral sensitization and possibly also central sensitization, are associated with impaired function in hands and lower extremities. For both the hand and lower extremities, measures of sensitization may have direct effects on performance-based measures of function, whereas the effect of sensitization on self-reported function appears to be mediated through self-reported pain severity.

Table 1. Associations between measures of sensitization and function

	AUSCAN hand function (range 0-36)	Grip strength (kg)	WOMAC knee/hip function (range 0-68)	40-meter walk test (m/s)
PPT finger joint	**-1.42 (-2.42, -0.43)**	**1.25 (0.35, 2.14)**	**-1.73 (-3.40, -0.05)**	0.03 (-0.01, 0.06)
PPT wrist	**-1.39 (-2.38, -0.39)**	**1.33 (0.41, 2.24)**	-1.66 (-3.37, 0.04)	0.03 (-0.01, 0.06)
PPT trapezius muscle	-0.80 (-1.81, 0.22)	0.66 (-0.25, 1.57)	**-1.76 (-3.47, -0.05)**	**0.04 (0.00, 0.07)**
PPT tibialis anterior muscle	-0.76 (-1.77, 0.26)	0.74 (-0.17, 1.65)	-1.57 (-3.29, 0.14)	**0.05 (0.01, 0.08)**
Temporal summation	-0.08 (-1.07, 0.91)	-0.28 (-1.17, 0.61)	0.96 (-0.75, 2.67)	-0.01 (-0.05, 0.02)

Adjusted for age, sex, body mass index, education, physical activity, and Kellgren-Lawrence sum score of the hands in the analyses of hand function or ultrasound-detected osteophytes in the knees, hips and feet in the analyses of lower extremity function. Presented as beta (95% CI) per standard deviation of sex-standardized PPT and TS.

POS0262 VALUE OF SMALL FIBER NEUROPATHY IN FIBROMYALGIA PATIENTS IN A RHEUMATOLOGICAL SETTING

Keywords: Patient reported outcomes, Fibromyalgia, Pain

S. Tsiami[1], E. Enax-Krumova[2], D. Sturm[2,3], M. Vorgerd[2], B. Buehring[4], J. Braun[1], X. Baraliakos[1]. *[1]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany*; *[2]Neurologische Klinik Universitätsklinikum Bergmannsheil Bochum, Ruhr-University Bochum, Germany, Bochum, Germany*; *[3]Agaplesion Bethesda - Krankenhaus, Wuppertal, Klinik für Neurologie, Wuppertal, Germany*; *[4]Krankenhaus St. Josef, Wuppertal, Klinik für Internistische Rheumatologie, Wuppertal, Germany*

Background: Small fiber neuropathy (SFN), a polyneuropathy (PNP) affecting A-delta and C-fibers has been described in patients with fibromyalgia (FM). Different patterns of small fiber damage may characterize distinct subtypes of FM.
Objectives: To investigate the value of detecting different degrees of SFN in patients diagnosed with FM.
Methods: Consecutive patients who were treated for pain exacerbation of FM at a university specialized tertiary center were included in the study after informed consent. Patients had to fulfil the 2016 ACR diagnostic criteria for FM and other inflammatory rheumatic musculoskeletal diseases (RMD) were excluded. The rheumatological therapy included pain pharmacotherapy, balneo-physical treatment, physiotherapy and occupational therapy. All patients underwent a careful rheumatologic and neurologic physical clinical examination including a Schirmer-Test for dry eyes and were asked to fill out questionnaires, in which data on pain, depression, neuropathic symptoms, sleep quality, daytime sleepiness, fatigue, and quality of life were assessed. Thereafter small fiber tests were performed in the neurologic department including a skin punch biopsy on the upper and lower leg and a corneal confocal microscopy (CCM).
Results: Overall, 93 patients (86 females, 92.5%, mean age 54±10.1, mean disease duration 4.9±5.3 years) were included, 25 received anticonvulsants (26.9%) and 15 opioids (16.1%) for pain treatment. Intraepidermal nerve fiber density (IENFD) as

Table 1. Scores of the questionnaires of all subgroups

	normal IENFD	reduced IENFD at different biopsy sites	p-value	distally reduced IENFD	p-value	proximally reduced IENFD	p-value	generalized reduced IENFD	p-value

Pittsburgh Sleep Quality Index	13.7±3.3	13.5±3.4	0.914	15.3±2.7	0.275	13.5±3.2	0.937	13.3±3.6	0.628

*criteria fulfilled, **normal

detected by skin biopsy was reduced in 58 patients (62.4%), 43 of whom (74.1%) had reduced IENFD at both proximal and distal sites. CCM showed pathologic findings in 18 patients with reduced IENFD at any site (31%) and in 8 with normal IENFD (22.9%), with dry eyes being present in 13 (22.4%) and 6 (17.1%) of those patients, respectively. There was no difference in pain, depression, neuropathic symptoms, sleep quality, daytime sleepiness, fatigue, or quality of life scores between groups (Table 1).

Conclusion: In this FM population with high disease burden and indication for inpatient therapy, small fiber pathology as found by skin biopsies and CCM was present in more than two third of the FM patients suggesting that there are subgroups. However, there were no significant clinical differences between patients with and without SFN. Further analysis should explore, whether both subgroups differ in their long-term outcome after the inpatient treatment.

POS0263 PREVALENCE OF OCCIPITAL PROTUBERANCE ENTHESOPHYTE IN NON-INFLAMMATORY AND INFLAMMATORY RHEUMATIC DISEASES: SANZ SIGN

Keywords: Spondyloarthritis, Enthesitis, Rheumatoid arthritis

N. De la Torre Rubio[1], J. Campos[1], M. Pavía Pascual[1], M. Machattou[1], P. Navarro Palomo[1], M. Alonso de Francisco[1], C. Navarro Joven[1], C. Merino Argumánez[1], B. Garcia-Magallon[1], M. Fernandez Castro[1], H. Godoy[1], C. Barbadillo Mateos[1], C. Isasi Zaragoza[1], L. F. De Villa[1], J. L. Andréu Sánchez[1], J. Sanz[1]. [1]*Hospital Universitario Puerta de Hierro Majadahonda, Rheumatology, Majadahonda, Spain*

Background: The exostosis of occipital protuberance was described recently in non-inflammatory processes[1]. Despite of enthesophytes are usually seen in radiographs of older asymptomatic population, in the last few years the presence of occipital protuberance enthesophyte (OPE) has been observed frequently in young patients, with a prevalence of 41% in adults younger than 30-year-old[2]. To our knowledge OPE has not been described in inflammatory rheumatic diseases.

Objectives: To determine the prevalence of OPE in non-inflammatory processes (NIP), psoriatic arthritis (PsA), spondyloarthritis (SpA) and rheumatoid arthritis (RA).

Methods: Retrospective descriptive and comparative study of cervical radiographs randomly collected from patients older than 18 years old attended in a rheumatology consult of a tertiary hospital from July 2022 to January 2023 until 30 patients per group were completed (total of 120 patients). We classified patients in four groups by diagnosis: NIP (traffic accident and spine surgery excluded), PsA, SpA and RA. The following variables were collected: sex, age at the time of radiograph was performed, OPE (yes/no) evaluated by a senior rheumatology resident (4 years of experience) and by a senior rheumatologist (25 years of experience). Descriptive statistics were used for the presentation of the results and Cohen's Kappa coefficient was calculated to quantify the degree of agreement in the diagnosis of enthesophyte presence between both rheumatologists. Chi square test with Yates correction was performed to compare sex and prevalence between groups and ANOVA to compare mean age.

Results: A total of 120 patients were collected, 30 patients per group. Seventy point eight per cent were women; mean age was 58.5 years with a standard deviation of 15. The groups were homogeneous (sex was performed by Chi Square test, $p < 0.0001$; mean age was performed by ANOVA, $p = 0.006$). Sixty-one of 120 patients (51 %) had OPE (23 % in non-inflammatory group, 60 % in inflammatory group); OPE prevalence was statistically significant in inflammatory diseases ($p < 0.001$). Stratified analysis by sex ($p = 0.2$) and age ($p = 0.06$) between inflammatory and non-inflammatory pathology showed no differences, although incidence of OPE in non-inflammatory processes tends to increase with older age. Results by group are shown in *Table 1*. *Figure 1* shows different types of enthesophyte morphology. The global degree of agreement according to Cohen's Kappa index was 0.8, representing 89 % agreement (substantial degree); the best degree of agreement was obtained in SpA (Cohen's Kappa index 0.9, representing 97 % agreement, almost perfect degree).

Conclusion: To our knowledge this is the first study about the prevalence of OPE in inflammatory and non-inflammatory rheumatic diseases, being more prevalent in inflammatory diseases 60 % ($p < 0.001$), especially in spondyloarthritis and psoriatic arthritis. The global degree of agreement between a senior rheumatology resident and a senior rheumatologist was substantial, being almost perfect in spondylarthritis. We will conduct a new study to find out whether different morphology of occipital enthesophytes is associated to any inflammatory rheumatic disease.

POS0264 PALMITOYLETHANOLAMIDE (PEA) AND ACETYL-L-CARNITINE (ALC) ACT SYNERGISTICALLY WITH DULOXETINE AND PREGABALIN IN FIBROMYALGIA: PROSPECTIVE AND RETROSPECTIVE ANALYSES

Keywords: Clinical Trials, Fibromyalgia, Diet and Nutrition

F. Salaffi[1], S. Farah[1], V. Giorgi[2], P. Sarzi-Puttini[3], M. DI Carlo[1]. [1]*Polytechnic University of Marche, Rheumatology Department, Jesi (AN), Italy*; [2]*IRCCS Istituto Galeazzi - Sant'Ambrogio, Rheumatology Department, Milan, Italy*; [3]*IRCCS Istituto Galeazzi - Sant'Ambrogio. Milan State University School of Medicine, Rheumatology Department, Milan, Italy*

Background: Fibromyalgia (FM) is characterized by debilitating pain that is unresponsive to standard analgesics and the multi-modal approach, including drugs' combination, represents the standard of care. Combination therapeutic strategies also include the integration of drugs and nutraceuticals. Both palmitoylethanolamide (PEA) and acetyl-L-carnitine (ALC) have demonstrated an effect on chronic widespread pain (CWP).
Objectives: The aim of this study was to evaluate the efficacy of pregabalin (PGB) and duloxetine (DLX) supplemented with palmitoylethanolamide (PEA) and acetyl-L-carnitine (ALC) in FM patients over a 24-week period.
Methods: After 6 months of stable treatment with DLX+PGB, FM patients were randomized to continue the treatment (Group 1) or to add PEA (600 mg BID)+ALC (500 mg BID) at the ongoing treatment (Group 2). Patients were then followed for 24 weeks. Cumulative disease severity, estimated using the Widespread Pain Index (WPI) (primary outcome), the revised Fibromyalgia Impact Questionnaire (FIQR), and the modified Fibromyalgia Assessment Status (FASmod) (secondary outcomes), was calculated every two weeks during the 24-week follow-up and expressed as time-integrated values (AUC).
Results: One hundred and forty-two FM patients started the study (91.5%), 130 completed both steps, respectively 68 patients in Group 1 and 62 in Group 2. After 24 weeks of follow-up after randomization, Group 2 experienced an adjunctive significant improvement in WPI, FIQR (Figure 1), and FASmod, compared to Group 1. Although there was some fluctuation in both Groups throughout the study period, the AUC values of the WPI scores steadily decreased in Group 2 (p=0.048). Group 2 showed better outcomes also in terms of FIQR and FASmod scores' AUC values (p=0.033 and p=0.017, respectively).

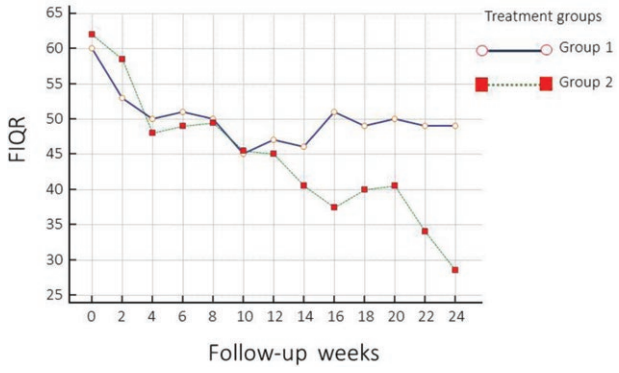

Figure 1. Comparison of the trend of the mean values of the FIQR in the two groups.

Conclusion: This study supports the supplementary value of PEA+ALC in FM patients care and, to best of our knowledge, it is the first study investigating this association treatment.

POS0265 ASSOCIATION OF PREGABALIN VS GABAPENTIN WITH INCIDENT CONGESTIVE HEART FAILURE IN PATIENTS WITH NON-CANCER PAIN

Keywords: Pain, Cardiovascular disease, Heart

E. Park[1], L. Daniel[2], A. Dickson[2], M. Corriere[2], P. Nepal[3], K. Hall[2], D. Plummer[2], W. Dupont[2], K. Murray[2], C. M. Stein[2], W. Ray[2], C. Chung[3]. [1]*Columbia University Irving Medical Center, Rheumatology, New York, United States of America*; [2]*Vanderbuilt University Medical Center, Medicine, Nashville, United States of America*; [3]*University of Miami Miller School of Medicine, Medicine, Miami, United States of America*

Background: Chronic pain affects 30% of all patients in developed countries, accounting for up to 35% of prescriptions in acute care settings. Non-opioid pain medications are widely utilized for treatment of non-cancer chronic pain. Among these, pregabalin is a commonly prescribed anticonvulsant, which works by antagonizing L-type calcium channels, decreasing the release of neurotransmitters[1]. Pregabalin use has been associated with reports of congestive heart failure (CHF), including peripheral and pulmonary edema[2-4]. However, the relationship between CHF incidence and pregabalin use among patients at the highest risk of adverse reactions (i.e., senior patients with various co-morbidities) remains unclear.
Objectives: To compare incident CHF among new users of pregabalin versus gabapentin (the active comparator) in Medicare beneficiaries treated for non-cancer chronic pain.
Methods: This was a retrospective cohort study among Medicare beneficiaries aged 65-89 years old with chronic non-cancer pain, without prior history of CHF. We included patients who were newly prescribed users of pregabalin or gabapentin were followed up between 2015-2018. The outcome was incident CHF, ascertained by hospital admissions or emergency room visits with ICD 9 and or 10 codes in the first position codes. Inverse probability of treatment weighting was used to account for differences between pregabalin and gabapentin users in time-dependent analysis (i.e., Cox proportional-hazards regressions). Covariates used in the propensity scoring were selected based on prior knowledge and literature review, and included categories such as concurrent baseline cardiovascular, neurologic, pain, and psychiatric diagnoses and corresponding medications including opioids and antipsychotics. Non-diagnostic covariates were included, as well as demographics, socioeconomic status, and indicators/metrics of health care utilization.
Results: This study included 17,756 new users of pregabalin and 221,053 new users of gabapentin. The cohort was predominantly female gender (66.7%), and non-Hispanic White (79.9%), with a median age of 73 (IQR: 69-78) years. The most common diagnostic indications for pregabalin and gabapentin were musculoskeletal and back pain. Prior to inverse probability weighting, pregabalin vs gabapentin users had higher daily short-acting opioid morphine equivalent doses (median; 18.0 vs 8.9 mg/d), higher use of coxibs (8.6% vs 4.9%), and higher prevalence of diabetic neuropathy (15.9% vs 11.3%) and fibromyalgia (19.9% vs 13.2%). After propensity score weighting, none of the covariates had a standardized difference>0.10. During 110,439 person-years of follow-up, 1,428 patients developed new CHF. The outcome rate for CHF incidence was 18.67 per 1000 person-years for pregabalin vs 12.57 per 1000-person years for gabapentin (adjusted HR 1.48 [95% CI, 1.20-1.81]).
Conclusion: In this retrospective study of Medicare beneficiaries aged 65-89 years with chronic non-cancer pain, new users of pregabalin had higher rates of incident CHF hospitalizations or emergency room visits compared to new users of gabapentin.

All about COVID-19 in Rheumatology

POS0266 CELLULAR IMMUNE RESPONSE PERSISTENCE AFTER COVID-19 MRNA VACCINES AMONG PATIENTS WITH RHEUMATOID ARTHRITIS UNDER RITUXIMAB

Keywords: Rheumatoid arthritis, Vaccination/Immunization, COVID

J. Marin[1], P. Bourgoin[2], N. Saverna[2], C. Cartagena García[2], P. Lafforgue[1], J. Roudier[1,3], J. M. Busnel[2], N. Balandraud[1,3]. [1]*Sainte Marguerite University Hospital- AP-HM, Rheumatology, Marseille, France*; [2]*Immunotech - Beckman Coulter, Global Research Organization, Marseille, France*; [3]*Inserm and Aix Marseille University, UMRS -1097- Arthrites Autoimmunes, Marseille, France*

Background: Humoral response induced by anti-SARS-CoV-2 mRNA vaccine is significantly lower or even absent in patients with inflammatory rheumatic diseases treated with anti-CD20 therapies such as Rituximab (RTX) than in those treated with cytokine therapies (e.g., anti-TNF or anti-IL6) [1]. However, a specific cellular immune response exists 1 or 2 months after vaccination (2, 3). As

cytotoxic T cells are considered as essential components of the antiviral defense arsenal, and since it is not clear when to do booster shots, analysis of thespecific T response over the long term could be a useful decision-making tool.

Objectives: This study aims to compare the spike-specific T lymphocytes response in a cohort of Rheumatoid Arthritis (RA) patients under RTX or other therapies (csDMARDs, anti-TNF). Our secondary goal was to assess the retention of this response up to 18 months after the last COVID boost (vaccine or infection).

Methods: Patients. Our study cohort included 75 consecutive adult patients with ACPA positive RA, followed at the rheumatology department of Sainte Marguerite Hospital (Marseille, France), prospectively enrolled from April 2022 to October 2022. RA patients fulfilled the 2010 ACR/EULAR criteria for RA and had received at least two doses of SARS-COV-2 mRNA vaccine, whether they had or not a history of COVID.

Samples. Heparin-anticoagulated single blood sample was collected for each patient to assess CD19+ cell count, IgG level, and SARS-CoV-2 serology. Cellular immune response was assessed by flow cytometry with a previously described procedure [4]. Briefly, 250 µL of whole blood were incubated per condition, including a negative control, Spike peptides from JPT* collection and CEFX peptides (mix of viral peptides) as a positive control. Marker expression was measured with a three-laser 13-color CytoFLEX flow cytometer. T lymphocytes were divided into T4 lymphocytes (LT4) or T8 lymphocytes (LT8) depending on CD8 expression. Finally, CD69, CD154, CD137 and CD107a expressions were monitored to characterize LT4 or LT8 activation.

Ethics. All patients gave informed written consent for this study in accordance with Helsinki declaration. Patient data were pseudo-anonymized. Sample collection was approved by the national ethics committee under the number DC-2008-327.

Results: Patient characteristics: 51 RA patients were treated with RTX, 24 were treated with csDMARDs or other bDMARDs.

Humoral response against SARS CoV 2: 30/51 (59%) RA RTX patients versus 13/14 (93%) non RTX patients had a humoral immune response (p = 0.024) with a median titer of 130 BAU/mL versus 688 BAU/mL.

T cell specific response: LT4 and LT8 Spike-specific responses were defined by the difference of response between Spike peptides from SARS CoV 2 stimulation and no peptides stimulation. The response was divided into quartiles, patients in the upper 3 quartiles were considered to have a specific response. In RA RTX patients, specific LT8 response was shown in 90% of patients versus 42% in non RTX patients (p < 0.0001), and specific LT4 response was shown in 76 % of patients versus 75% in non RTX patients (p = 0.42).

Long term T cell specific response (Figure 1). RA patients treated with RTX maintained a specific LT4 and LT8 response against Spike peptides with no decrease up to 18 months after the last SARS-COV-2 boost (vaccine dose or COVID 19 infection).

Conclusion: Specific LT4 response against Spike peptides was similar in the RTX treated and non-treated RA patients. This was even stronger for the specific LT8 response. The Spike specific T-cell response was maintained in both groups up to 18 months after the last vaccine dose or COVID infection independently to the specific humoral response. This method of analyzing the specific T response against the Spike protein could be used in personalized medicine to decide when revaccination is necessary in a given patient.

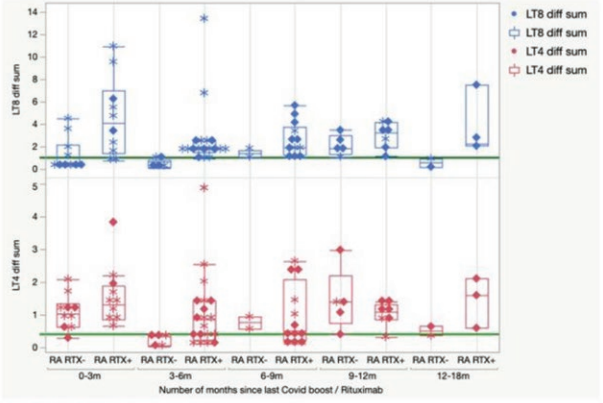

FIGURE 1: Specific T-cell response against Spike peptides among time
RA RTX+: patients with rheumatoid arthritis under RITUXIMAB (RTX).
RA RTX-: patients with rheumatoid arthritis treated with other bDMARD or only csDMARD.
LT diff sum: The LT Spike-specific response is defined by the difference of response between Spike peptides stimulation and no peptides stimulation. Sum is the sum of specific T lymphocytes subtypes response (CD154, CD107a, CD137, CD154/ CD107a, CD137/ CD107a, CD154/ CD137). In RTX treated patients, there is no difference for specific LT4 or LT8 response during time (non-parametric Wilcoxon test for each pair of interval, P>0,05). In non RTX patients, patients had a lower response in the 3-6 months response interval comparing to others (non-parametric Wilcoxon test for each pair of intervals, P< 0,01)
•Patients with a history of COVID-19 infection
Green line: first quartile of response threshold.

MORTALITY OUTCOME OF ACUTE MYOCARDIAL INFRACTION AND ACUTE HEART FAILURE HOSPITALIZATION IN RHEUMATIC DISEASES PATIENTS PRE-COVID-19 VS. COVID-19 PANDEMIC FROM 2016-2020 NATIONAL INPATIENT SAMPLE (NIS) DATABASE

Keywords: Cardiovascular disease, COVID, Outcome measures

Z. Y. LI[1], S. Huang[2], S. Gokcebel[3], A. M. Reginato[4]. [1]*Roger Williams Medical Center, Rheumatology, Providence, United States of America*; [2]*UCSF Fresno, Cardiology, Fresno, United States of America*; [3]*Brown University School of Public Health, Public Health, Providence, United States of America*; [4]*The Warren Alpert Medical School at Brown University, Division of Rheumatology, Brown Medicine, Providence, United States of America*

Background: Rheumatic diseases such as rheumatoid arthritis (RA) and Systemic lupus erythematosus (SLE) were known for increased prevalence and risk of death from cardiovascular disease (CVD) due to systemic inflammation in conjunction with other environmental risk factors and genetic predispositions.[1] The COVID-19 pandemic is of the leading causes for the increased age-adjusted mortality rate in 2020 due to various unforeseeable conditions including unequitable healthcare resource distribution, decrease access to medical treatment other than for COVID-19 infection.

Objectives: To investigate if the presence of the COVID-19 had an impact on the mortality outcome of acute myocardial infraction (AMI) and acute heart failure (AHF) in rheumatic diseases (RDs) including patients with RA, SLE, psoriasis/ psoriatic arthritis, gout, myositis and vasculitis, and sarcoidosis in the United States using the NIS inpatient database from 2016-2020.

Methods: Using NIS database from 2016-2020, we identified patients with a primary admission diagnosis of AMI or AHF using ICD-10 codes. For each admission, we calculated ascertained mortality risk. The association of RDs with inpatient mortality was calculated using multivariable logistic regression. Mortality outcomes from 2016-2019 was compared to 2020, which was the year COVID-19 pandemic initiated.

Results: We identified a total of 691,834 AMI/AHF hospitalizations from 2016-2019, of which 39,047 patients had RDs. During the pre-COVID-19 time, the inpatient mortality was significantly higher in the non-RDs group (4.1% vs 3.3%, *p*=<0.001). In multivariable logistic regression model, after adjusting for age, race, gender, region, income and confounding comorbidities, patients in the RDs group had a lower odd ratio of inpatient mortality in AMI/AHF compared to non-RDs group (OR=0.71, *p*=<0.001). During the pandemic year, total AMI/ AHF hospitalizations were 121,285, and 5,813 of them were patients had RDs. Again the hospitalization mortality was higher in the non-RDs group with clinical significance of *p*= <0.001 (4.8% vs. 3.4%). Interestingly, in terms of the COVID-19 infection rate, patients the non-RDs group had a higher infection rate when comparing to RDs (25% vs 23%, *p*=0.047). The odd ratio for AMI/AHF hospitalization mortality was again significantly lower in RDs groups compared to non-RD's group (OR=0.65, *p*=<0.001).

Conclusion: Based on our analysis, the presence of co-morbid RDs was not associated with an increased mortality in patients hospitalized with AMI/AHF. These results may be attributed to the use of biologic agents in RDs patients in reducing systemic inflammation. The lower COVID-19 infection rate in RDs patients could be related to the early and aggressive implementation of social distancing and telehealth appointments in the US during the COVID-19 pandemic.

PRE-EXPOSURE PROPHYLAXIS WITH TIXAGEVIMAB/CILGAVIMAB IS EFFECTIVE IN LIMITING THE RISK AND THE SEVERITY OF COVID-19 IN PATIENTS WITH AUTOIMMUNE OR INFLAMMATORY DISEASES AT INCREASED RISK OF SEVERE COVID-19 WHO ARE POOR RESPONDERS TO VACCINATION

Keywords: Disease-modifying Drugs (DMARDs), COVID, Vaccination/ Immunization

M. Thomas[1], M. Masson[2], S. Bitoun[3], R. Seror[3], H. Dupuy[4], E. Lazaro[4], C. Richez[5], Y. Allanore[1], J. Avouac[1]. *[1]Cochin Hospital, Rheumatology, Paris, France*; *[2]hôpital purpan, Rheumatology, Toulouse, France*; *[3]Bicetre Hospital, Rheumatology, Le Kremlin-Bicêtre, France*; *[4]Hopital Haut Leveque, Internal Medicine, Pessac, France*; *[5]Hôpital Pellegrin Bordeaux, Rheumatology, Bordeaux, France*

Background: Patients with autoimmune or inflammatory diseases treated with immunosuppressants such as anti-CD20 are at increased risk for severe COVID-19 and have a high probability of insufficient response to vaccination. The monoclonal antibody combination tixagevimab/cilgavimab has received early access approval to reduce the frequency of symptomatic COVID-19 in immunocompromised patients at risk for severe COVID-19 and unresponsive to vaccination.
Objectives: We aim to evaluate the clinical efficacy of tixagevimab/cilgavimab in pre-exposure prophylaxis in patients with increased risk of severe COVID-19 in rheumatology.
Methods: In this multicenter observational study conducted between December 2021 and August 2022, we included patients with autoimmune or inflammatory diseases who received at least one intramuscular injection of tixagevimab/cilgavimab as pre-exposure prophylaxis in 3 French rheumatology units. Occurrence of COVID-19 was assessed during usual follow-up or by phone call. The endpoint was the incidence of COVID-19 and its severity.
Results: tixagevimab/cilgavimab was administered to 115 patients, median age 62 years (52-71), with chronic arthritis (n=53), connective tissue disease (n=38) or vasculitis (n=11). The main background immunosuppressants were rituximab (n=98), methotrexate (n=48), mycophenolate mofetil (n=19), cyclophosphamide (n=15), azathioprine (n=12), and corticosteroids (n=62, median dose 5 mg, CI95% 5-8). During a median follow-up of 128 days (93-173), COVID-19 occurred in 23/115 patients (20%) with Omicron identified for the 8 genotyped patients. During the study period, the average weekly incidence was 1071 per 100.000 inhabitants in Ile-de-France vs. 588 per 100.000 in our patients. Patients who received a 2-injections regimen had a lower risk of infection than patients with a single injection (16/49, 33%, vs. 5/64, 8%, p=0.0012). The COVID-19+ patients did not differ from uninfected patients in terms of age, comorbidities, type and duration of underlying disease, extra-articular organ involvement or background immunosuppressants. All COVID-19 cases were non-severe, there were no deaths. The tolerance of injections was excellent, with no side effects observed.
Conclusion: In a population with autoimmune or inflammatory diseases at increased risk of severe COVID-19 with a poor response to vaccination, pre-exposure prophylaxis by tixagevimab/cilgavimab limited the risk of infection and the severity of COVID-19. This study supports the use of COVID-19 serological tests in this patient population in order to detect those who do not respond adequately to vaccination since pre-exposure treatments and/or early treatments are available.

Background: Despite the increasing number of studies on COVID-19 infection in people with rheumatic and musculoskeletal diseases (RMDs), data on Sjögren's syndrome (SS) is limited.
Objectives: To determine the spectrum and severity of pre-vaccine and post-vaccine breakthrough COVID-19 infections (B-INFs) among patients with SS compared to other connective tissue diseases (CTDs), non-rheumatic autoimmune diseases (nrADs), and healthy controls (HC).
Methods: Data were collected using the COVID-19 Vaccination in Autoimmune Diseases (COVAD) questionnaire (March–December 2021) and analysed to compare frequencies and identify associations with demographic, disease-specific and vaccine-specific variables (for B-INFs).
Results: Among 9462 complete respondents, 356 were patients with SS, of which 129 had primary (p) SS and 227 had SS associated (a) with rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), systemic sclerosis (SSc) or inflammatory myopathies (IM). Patients with SS were compared to 1586 patients with other CTDs (RA, SLE, SSc or IIM)] but without SS, 825 patients with nrADs and 4712 healthy controls (HC). SS patients had mean age of 52.3 years, mean disease duration was 12 years; 94.5% were females, 68% were Caucasian. Overall COVID-19 infection was reported by 14% of patients with SS and 19.2% of HC (odds ratio (OR)=0.7; 95% confidence interval (CI)=0.5-0.9). The majority of cases occurred prior to the first vaccine dose with no differences across groups in the proportion of B-INFs (SS: 21.6%; other CTD: 20%; nrAD: 19.8%; HC: 19.4%). In the SS group, age and disease duration were similar in patients with either pre-vaccine infections or B-INFs. When comparing pSS and aSS, the overall number of COVID-19 infections was comparable, regardless of the timing (before or after vaccination). Over 80% of SS patients were symptomatic and the symptom duration was similar regardless of the timing of infection, however the symptom burden was different, with certain manifestations absent in B-INFs (oral ulcers, nausea/vomiting, skin rashes, loss of smell/taste) (Figure 1). When focusing on pSS and aSS separately, fever was never reported in aSS B-INFs, whereas other symptoms were equally distributed in pre-vaccine infections and B-INFs. When comparing SS to other CTDs and HC, it emerged that during B-INFs, patients with SS had more frequently chest pain (OR=6.5; 95% CI=

1.8-23 vs NC; OR=11.2; 95% CI=1.7-72 vs other CTDs) and headache (OR= 4.6; 95% CI= 1.1-20 vs other CTDs). Hospitalization for B-INF was required by only one patient with SS patient (pSS) who also required oxygen therapy. Conversely 17% of patients with SS (with an equal distribution between pSS and aSS) required hospitalization for pre-vaccine infections. Although the overall hospitalization rate did not differ across groups, patients with SS needed oxygen therapy more frequently than HCs (OR=9; 95% CI=1.04-78) and other CTDs (OR=19.5; 95% CI= 1.8-213). When comparing pSS and aSS, the need for hospitalization and, if hospitalised, the need of oxygen therapy were comparable for infections before vaccination and B-INFs. In pSS, B-INFs mainly occured after BNT162b2 vaccine (37%) and ChAdOx1 nCoV-19 (37%) with few cases after the other vaccines, whereas in aSS B-INFs occurred after either BNT162b2 vaccine (67%) or BBIBP-CorV (33%).

Conclusion: Our data demonstrated that B-INfs in patients with SS are less severe than those observed pre-vaccination. This strengthens the rationale for COVID-19 vaccination in patients with SS.

BURDEN OF COVID-19 IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES: INSIGHTS FROM A SWISS APP-BASED SURVEY

Keywords: COVID, Quality of life, Registries

C. Blapp[1], S. Yaghmaei[2], A. Ciurea[3], A. Scherer[1], M. Kuster[2], K. Lauper[4].
[1]SCQM Foundation, Rheumatoogy, Zurich, Switzerland; *[2]AstraZeneca AG, Vaccines and Infectious Diseases, Baar, Switzerland*; *[3]University Hospital of Zürich, Department of Rheumatology, Zürich, Switzerland*; *[4]Geneva University Hospitals and Faculty of Medicine, Division of Rheumatology, Geneva, Switzerland*

Background: COVID-19 comes with a significant medical risk for patients with inflammatory rheumatic diseases, with an increased risk of infection and severe outcomes[1]. The vulnerability of rheumatologic patients might also affect their quality of life[2], for example by keeping up protective measures (masking, restriction of social contacts, etc.) while the general Swiss public no longer does so.

Objectives: The aim of this study was to better understand the health-related burden of COVID-19 among patients with inflammatory rheumatic diseases and to investigate factors contributing to a different perception of the burden of COVID-19.

Methods: We included all patients registered in the Swiss Clinical Quality Management (SCQM) registry with rheumatoid arthritis (RA), axial spondylarthritis (axSpA), psoriatic arthritis (PsA), undifferentiated arthritis, polymyalgia rheumatica or giant cell arteritis who answered the questionnaire in the mobile My-SCQM app between the 4.11 and 11.12.2022. The questionnaire contained questions about the extent to which the pandemic is affecting patients' personal and social lives. We performed descriptive analysis on the whole population and also in subgroups according to 5 treatment groups, assigned in the following order: rituximab > JAK-inhibitors > other b/tsDMARDs > csDMARDs > none of these treatments. This means that someone taking e.g., both a JAKi and a csDMARD will be assigned to the JAKi category.

Results: The questionnaire was answered by 1357 individuals with a median age of 57 years. 63% of participants were female. 33% are living in a household with children. 36% were diagnosed with RA, 34% with axSpA, 22% with PsA and 8% with another inflammatory rheumatic disease. A total of 100 patients were prescribed csDMARDs, 94 JAKi, 18 rituximab, 695 other b/tsDMARDs, and 450 patients received none of these treatments (Table 1). 10% of patients feel their general lives are affected by COVID-19 at a level of more than 7 out of a 10 scale. 3% of the participants report that COVID-19 impacts their social environment (family and friends) as a potentially dangerous disease at a level of more than 7 out of 10 scale. After being vaccinated against COVID-19, 33% of patients report no fear of the disease, however, 27% of participants still state that their anxiety against the virus remained unchanged. There is a trend towards persistence of fear in those taking rituximab (35%) compared to the participants in other groups (26% and 20% respectively in csDMARDs and JAKi takers). More than half of the population still wear masks, and rituximab users are the most likely to wear them (72% of these individuals still do), followed by individuals on JAKi (65%) (Figure 1).

Conclusion: Our study revealed that after around two years of the COVID-19 pandemic, the burden of COVID-19 in patients with inflammatory rheumatic diseases in Switzerland is generally low, although it appears higher in patients with JAKi and rituximab, and that for a minority the quality-of-life still remains impacted.

Background: The ChAdOx1, Coronavac, BNT162B2 and Janssen vaccines are available for the primary and booster immunization of immunosuppressed patients. However, there are few studies in the literature that assess the immunogenicity and safety of the different platforms COVID-19 vaccines in patients with autoimmune diseases (AID).
Objectives: The present study aims to evaluate the immunogenicity through anti-spike IgG antibodies 28 days after the booster dose in the heterologous boost groups compared with homologous regimen of the vaccine against COVID-19 in patients with AID.
Methods: These data are from SAFER study: "Safety and efficacy on Covid-19 Vaccine in Rheumatic Disease", a multicentric prospective phase IV study, in real life, in Brazil, started on May 2021. Data from this analysis were from 8 centers, from all Brazilian areas, after 2 or 3 doses of vaccine against COVID-19 in patients with AID age ≥ 18 years. Exclusion criteria were pregnancy, previous severe adverse events (AE) to any vaccine or other imunosuppression causes. Demographics, diagnoses and therapeutic regimens were collected via participant report through the Research Electronic Data Capture tool. Available vaccines were adenoviral vectored vaccine (ChAdOx1, Astrazeneca and Ad26.COV2-S, Janssen), mRNA vaccine (BNT162b2, Pfizer–BioNTech) or inactivated SARS-COV-2 vaccine (Coronavac). Participants were followed up by means of blood collection for measurement of IgG antibody against SARS-CoV-2 spike receptor-binding domain by chemiluminescence (SARS-CoV-2-IgG-II Quant assay, Abbott-Laboratories) at baseline and 28 days after the first, 2nd and 3rd doses. The seropositivity was defined for titers IgG-Spike ≥7.1 BAU/mL. The ANOVA, the post-hoc Tukey and pairwise comparisons tests were used to compare the IgG-S titles between the groups. An alpha level of 5% significance was used in all analyses.
Results: A total of 1096 participants were included and followed from the first dose. 709 patients AID received the complete 3-dose regimen: systemic lupus erythematosus (N=238, 33.6%), rheumatoid arthritis (N=143, 20.2%), spondyloarthritis (N=96, 13.5%), primary Sjögren's syndrome (N=56, 7.9),), inflammatory bowel disease (N=50, 7,1%), vasculitis (N=31, 4.4%), systemic sclerosis (N=25, 3.5%), Behçet syndrome (N= 19, 2.7%) myositis (N= 12, 1.7%), other systemic AID (N= 39, 5.5%). Mean age was 41.59 (12.2), female N=556, (78.4%) and admixed race (N=370, 52.2%). Primary immunization was performed with Coronavac in 265 (37.4%), ChAdOx1 in 403 (56.8%) and Pfizer in 41 (5.8%) AID patients. After the 2nd dose (28 days), the booster was performed with Coronavac (N=10, 1.4%), ChAdOx1 (N=226, 31.9%), Pfizer (N=464, 65.4%) and Janssen (N=9, 1.3%). Anti-spike IgG antibodies were analyzed in the 657 patients who received the three doses. All patients had a substantial increase in IgG antibody concentrations 28dy after the booster vaccine with median 275.9 BAU/ml (88.8 - 1000.9) vs. 1217.2 (402.3 - 3213.7) booster vaccine. All heterologous regimens (N=515) had anti-spike IgG responses at day 28 that were superior to homologous booster (N=194) with median titers 1596.5 (543.9-3769.4) vs. 620.3 BAU/mL (180.3-1987.0), p<0.001 (figure 1). The seropositivity rates were higher and similar in both groups (Heterologous 98.4% vs. Homologous 95.9%, p=0.07).

Scheme	N	q1	median	q3	p
Homologous	194	180.3	620.3	1987.0	<0.001
Heterologous	515	543.8	1596.5	3769.4	

Figure 1: Neutralizing antibody titers against SARS-CoV-2 spike receptor-binding domain in patients with autoimmune diseases categorized according to the homologous or heterelogous booster vaccination.

Conclusion: All vaccines administered as third dose induced an increase in IgG-S titers antibodies, which could improve protection against COVID-19 in AID patients. Heterologous booster vaccination produced greater humoral immune responses than homologous booster, which is relevant in this immunosuppressed population.

POS0272

IMPACT OF THE COVID-19 PANDEMIC ON ADHERENCE TO DISEASE MODIFYING DRUGS AMONG PATIENTS WITH RHEUMATIC DISEASES: A POPULATION-BASED, INTERRUPTED TIME SERIES ANALYSIS

Keywords: COVID, Disease-modifying Drugs (DMARDs)

N. Rebić[1,2], E. C. Sayre[2], M. Law[3], M. De Vera[1,2]. [1]*University of British Columbia, Faculty of Pharmaceutical Sciences, Vancouver, Canada*; [2]*Arthritis Research Canada, Vancouver, Canada*; [3]*University of British Columbia, School of Population and Public Health, Vancouver, Canada*

Background: Although studies have quantified adherence to medications among patients with rheumatic diseases (RD) during the COVID-19, lack of direct pre-pandemic comparison precludes understanding of impact of the pandemic.

Objectives: Our objective was to evaluate the effect of the COVID-19 pandemic on adherence to disease modifying drugs (DMARDs) including conventional synthetic (csDMARDs) and targeted synthetic (tsDMARDs).
Methods: We linked population-based health data on all physician visits, hospital admissions, and all dispensed medications, regardless of payer in British Columbia from 01/01/1996 to 3/31/2021. We identified prescriptions for csDMARDs (including methotrexate, hydroxychloroquine) and tsDMARDs, namely anti-TNFs (including infliximab, etanercept, adalimumab) and rituximab using drug identification numbers among indicated individuals with RD. We defined March 11, 2020, as the 'index date' which corresponded to the date that mitigation measures for the COVID-19 pandemic were first introduced. We assessed adherence as proportion days covered (PDC), calculated monthly in the 12 months before and 12 months after the index date. We used interrupted time-series models, namely segmented regression to estimate changes and trends in adherence before and after the index date.
Results: Our analysis showed that the mean PDCs for all included DMARDs stayed relatively steady in the 12 months before and after mitigation measures were introduced (see **Table 1**). Adherence was highest among anti-TNFs, methotrexate, and azathioprine. Anti-TNFs were on a downward trajectory 12 months prior to the index date. Interrupted time-series modeling demonstrated statistically significant differences in the trends in PDCs post- vs. pre-mitigation measures for all anti-TNFS (slope [∂]: 1.38, standard error [SE]: 0.23), infliximab (∂: 1.35, SE: 0.23), adalimumab (∂: 0.82, SE: 0.25), and etanercept (∂: 1.07, SE: 0.25) (see **Figure 1a**). Conversely, the csDMARDs were on a flatter trajectory, and methotrexate (∂: -0.53, SE: 0.16), leflunomide (∂: 0.43, SE: 0.08), mycophenolate (∂: -1.26, SE: 0.48), cyclophosphamide (∂: 0.29, SE: 0.05), minocycline (∂: 0.04, SE: 0.02), chloroquine (∂: 0.02, SE: 0.00) showed statistically significant changes in estimated PDC trajectory after mitigation measures were introduced (see **Figure 1b**).
Conclusion: This population-based study demonstrates that messaging and pandemic mitigation measures did not affect adherence to DMARDs.

Table 1. Mean PDC 1 year before and after mitigation measures for the COVID-19 pandemic were introduced.

Medication		Mean PDC (%) 12 months before index date	Mean PDC (%) 12 months after index date
csDMARDs	methotrexate	28.9	26.8
	azathioprine	21.8	19.5
	sulfasalazine	16.2	14.9
	leflunomide	14.3	13.0
	cyclosporine	13.7	11.5
	hydroxychloroquine	10.5	9.6
	mycophenolate	4.5	2.9
	antimalarials	4.4	3.9
	penicillamine	3.5	3.4
	cyclophosphamide	1.5	0.7
	chlorambucil	1.2	0.4
	minocycline	1.1	0.9
	gold	0.5	0.2
	chloroquine	0.1	0.0
tsDMARDs	anti-TNFs	52.1	49.2
	infliximab	41.8	38.3
	adalimumab	40.3	36.8
	etanercept	31.8	28.9
	rituximab	3.4	2.9

Background: Post COVID-19 syndrome (PCS) is an emerging cause of morbidity and poor quality of life in COVID-19 survivors [1, 2].

Objectives: We aimed to assess the prevalence, risk factors, outcomes, and association with disease flares of PCS in patients with autoimmune rheumatic diseases (AIRDs) and non-rheumatic autoimmune diseases (nrAIDs), both vulnerable groups understudied in the current literature using data from the 2nd COVID-19 Vaccination in Autoimmune Diseases (COVAD) global multicentre patient self-reported e-survey.

Methods: The survey was circulated from February to July 2022 by the international COVAD Study Group (157 collaborators from 106 countries), and demographics, comorbidities, AIRD/nrAID status, COVID-19 history, vaccination details, and PROMIS physical and mental function were recorded. PCS was defined as symptom resolution time >90 days following acute COVID-19. Predictors of PCS were analysed using regression models for the different groups.

Results: 7666 total respondents completed the survey. Of these, 2650 respondents with complete responses had positive COVID-19 infection, and 1677 (45.0% AIRDs, 12.5% nrAIDs, 42.5% HCs) completed the survey >90 days post acute COVID-19. Of these, 136 (8.1%) had PCS. Prevalence of PCS was higher in AIRDs (10.8%) than healthy controls HCs (5.3%) (OR: 2.1; 95%CI: 1.4-3.1, p=0.002). Across the entire cohort, a higher risk of PCS was seen in women (OR: 2.9; 95%CI: 1.1-7.7, p=0.037), patients with long duration of AIRDs/nrAIDs (OR 1.01; 95%CI: 1.0-1.02, p=0.016), those with comorbidities (OR: 2.8; 95%CI: 1.4-5.7, p=0.005), and patients requiring oxygen supplementation for severe acute COVID-19 (OR: 3.8; 95%CI: 1.1-13.6, p=0.039). Among patients with AIRDs, comorbidities (OR 2.0; 95%CI: 1.08-3.6, p=0.026), and advanced treatment (OR: 1.9; 95%CI: 1.08-3.3, p=0.024), or intensive care (OR: 3.8; 95%CI: 1.01-14.4, p=0.047) for severe COVID-19 were risk factors for PCS. Notably, patients who developed PCS had poorer PROMIS global physical [15 (12-17) vs 12 (9-15)] and mental health [14 (11-16) vs 11 (8-14)] scores than those without PCS.

Conclusion: Individuals with AIRDs have a greater risk of PCS than HCs. Associated comorbid conditions, and advanced treatment or intensive care unit admission for severe COVID-19 confer a higher risk of PCS. It is imperative to identify risk factors for PCS for immediate multidisciplinary management in anticipation of poor physical and mental health.

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease, which presents an immune disorder that leads to the production of autoantibodies with potential involvement of multiple organs. Infections are one of the most frequent causes of hospitalization and death in lupus patients, and SARS-CoV-2 infection has been a global threat since March 2020. Immunization of these patients has been strongly recommended, although vaccine evaluation studies have not included this profile of patients.

Objectives: To evaluate the immunogenicity and safety after 2 doses of the vaccine against SARS-CoV2 in patients with SLE.

Methods: Subgroup of SLE patients from the prospective multicenter cohort of patients with immune-mediated diseases "SAFER" – Safety and Efficacy on COVID-19 Vaccine in Rheumatic Disease, a phase IV study. Vaccination against SARS-CoV-2 took place with vaccines approved by Brazilian regulatory bodies CoronaVac (Inactivated SARS-CoV-2 Vaccine), ChadOx-1 (AstraZeneca) and BNT162b2 (Pfizer-BioNTech) and this project followed in line with the guidelines of the National Immunization Plan in Brazil. Patients aged 18 years or older with a previous diagnosis of SLE (according to the 2019 ACR/EULAR criteria) were included. Patients were evaluated by telephone contact and in a face-to-face visit on the 28th day after each dose. Patients were followed up by means of blood collection for measurement of IgG antibody against SARS-COV-2 by chemiluminescence and disease activity assessed using SLEDAI-2K score.

Results: A total of 367 individuals with SLE were included, of whom 207 received 2 doses of CoronaVac, 128 received 2 doses of ChadOx-1 and 32 received 2 doses of BNT162b2. 90% of the subjects were female with a mean age of 37 years. About 42% (154) of the individuals included did not have any other associated comorbidity. 50% (182) of patients were using oral glucocorticoids and azathioprine was the most frequent immunosuppressive therapy. Regarding disease activity parameters, 38% (140) of patients had zero SLEDAI-2K at baseline and 41% (147) had zero SLEDAI-2K 28 days after the 2nd dose. Anti-DNA positivity was 30.7% (16/52) at inclusion and 32.6% (17/52) 28 days after the 2nd dose. Complement consumption was present in 18% (10/55) at inclusion and in 14.5% (8/55) 28 days after the 2nd vaccine dose. The geometric mean titers of IgG antibodies against SARS-COV-2 increased in the different vaccine groups, log 2.27 BAU/mL at inclusion and log 5.58 BAU/mL 28 days after the 2nd dose. Antibody titers after second dose varied between different vaccines, 4.96 BAU/mL CoronaVac, 6.00 BAU/mL ChadOx-1 and 7.31 BAU/mL BNT162b2 vaccine, $p < 0.001$. Only 3.54% (13/367) patients had covid-19 infection after the 15th day of the second dose of immunization, 9 of them having received 2 doses of CoronaVac, 4 of them of ChadOx-1 and none of them receiving BNT162b2, with p-value of 0.63.

Conclusion: This study suggests that vaccines against SARS-COV-2 are safe in SLE patients. Induction of immunogenicity occurred in different vaccine regimens. Only 3.5% of individuals had COVID-19 infection with no difference between the types of vaccines evaluated. Future analyzes to explore the association of the effect of immunosuppressive medication, as well as the impact of booster doses and longer follow-up on clinical outcome will be performed.

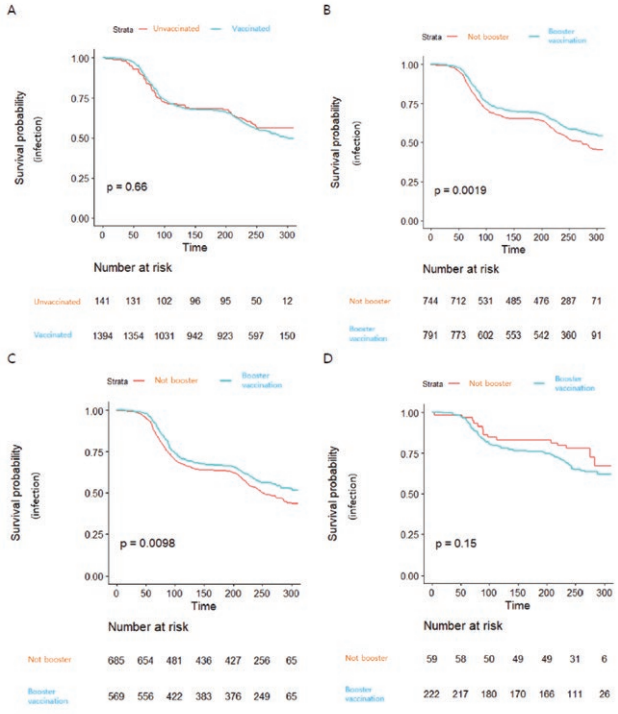
POS0275

COVID-19 INFECTION IN PATIENTS WITH RHEUMATIC DISEASE DURING OMICRON OUTBREAK IN SOUTH KOREA: A SINGLE-CENTER PROSPECTIVE STUDY

Keywords: Epidemiology, COVID

Y. K. Kim[1], J. I. Jung[1], J. K. Park[1], E. Y. Lee[1], E. B. Lee[1], J. W. Park[1]. *[1]Seoul National University Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: High transmissibility and immune evasion of SARS-CoV-2 Omicron variant made it dominant variant worldwide since January 2022. Before Omicron era, several studies demonstrated that autoimmune inflammatory rheumatic disease (AIIRD) patients were vulnerable to COVID-19 infection compared to general population. However, there is a lack of epidemiologic data regarding COVID-19 outbreak in patients with AIIRD in Omicron era.



Objectives: To identify incidence rate, hospitalization rate and potential risk factors for COVID-19 outcomes in AIIRD patients during Omicron outbreak.

Methods: This study was a prospective longitudinal study from January 1 to October 31, 2022. We included patients who visited rheumatology outpatient clinic in a nationwide, tertiary referral center in South Korea. Included patients were classified into two groups (AIIRD and non-AIIRD groups) based on underlying disease. Vaccination and infection history of COVID-19 were obtained through self-report via questionnaire and data from Korea Disease Control and Prevention Agency (KDCA). Main outcome of this study was an incidence of COVID-19 infection during the observation period. Clinical factors associated with the incidence of COVID-19 infection were investigated using Cox proportional hazard model. In the final multivariable model, clinical factors that showed a relevant association ($P < 0.1$) with the outcome in the univariable analysis were included as covariates.

Results: A total of 1,814 patients were analyzed (AIIRD group: 1,535, non-AIIRD group: 279). The COVID-19 incidence in AIIRD group (47.6%) was higher than that reported in general population of South Korea (43.9%) and this trend was prominent in those aged < 70 years. Longitudinal change in COVID-19 incidence during the observation period showed two peaks in March and August in both groups, which was the same trend with general population. There were 30 cases of hospitalization due to COVID-19 infection, with the rate was comparable between AIIRD and non-AIIRD groups (1.7% vs. 1.5%, $P = 0.970$). The incidence rate of COVID-19 in the AIIRD group was comparable to that in the non-AIIRD group (47.6% vs. 44.8%, $P = 0.386$). In the AIIRD group, COVID-19 infection occurred less frequently in patients with old age (≥70 years) and those receiving glucocorticoid treatment. Other clinical factors such as use of DMARDs and biologics, and underlying diseases were not associated with COVID-19 incidence in the multivariable analysis. Of note, at least one COVID-19 vaccination did not lower its incidence (unadjusted HR 1.06 [95% CI 0.82-1.38]). Although patients who received booster vaccination were less likely to be infected with COVID-19 (unadjusted HR 0.79 [0.68-0.92]), this protective effect was significant only in patient younger than 70 years (Figure 1).

Conclusion: During the Omicron outbreak in South Korea, incidence of COVID-19 infection in patients with AIIRD and non-AIIRD was comparable. Immunomodulatory agents and specific rheumatic diseases did not increase the COVID-19 incidence, and booster vaccination against COVID-19 decreased the infection only in patients younger than 70 years.

(Figure) Association between baseline vaccination status and COVID-19 infection in AIIRD group

Baseline vaccination status: (A) at least one vaccination (B) booster vaccination (all age) (C) booster vaccination (age<70) (D) booster vaccination (age≥70)

Background: The SARS-CoV-2 pandemic initially raised concerns about the risk of severe infection in patients with inflammatory rheumatic diseases (IRD).
Objectives: In a setting with an excessive SARS-CoV-2 test strategy and availability of effective vaccines we aimed to investigate if patients with (IRD) face greater risk of contracting SARS-CoV-2 infection and have an increased risk of hospitalization, assisted ventilation and death compared to the general population.
Methods: This large nationwide, population-based register study compared the outcomes of SARS-CoV-2 infection in Danish patients with IRD (n=65.603) to matched population controls (n=656.030), from the first registration of SARS-CoV-2 (March 2020 to October 2022). The IRD population included 1,903 ANCA associated and necrotizing vasculitis; 30,391 rheumatoid arthritis; 2,444 Systemic lupus erythematosus; 1,538 systemic scleroderma; 2,521 sjogren's syndrome; 5,875 giant cell arteritis and 20,931 spondylarthritis and psoriasis arthritis patients. Cox regression analyses were used to calculate incidence rate ratios (IRRs) for SARS-CoV-2 infection outcomes.
Results: We observed a discrete difference in time to first and second positive SARS-COV-2 test in IRD patients compared to the general population (IRR=1.05 95% CI (1.03-1.06) and (IRR=1.17 95% 1.11-1.24). The risk of hospital contact with COVID-19 and severe COVID-19 was increased in IRD patients compared to population controls (IRR=1.92, 95% CI 1.79-2.06) and (IRR= 2.16, 95% CI 1.91-2.45). Also, the risk if hospitalization requiring assisted ventilation (IRR=2.40, 95% CI 1.93-2.99) and for hospitalization with COVID-19 leading to death were increased in the IRD population (IRR=2.02 95% CI 1.66-2.45). The risk of hospitalization with severe COVID-19 was remarkably reduced after third SARS-CoV-2 vaccination.
Conclusion: IRD patients have a risk of SARS-Cov-2 which nearly corresponds to the general population but have a substantial increased risk of hospitalization with COVID-19, severe COVID-19, requiring assisted ventilation and COVID-19 leading to death compared to the general population. A third SARS-CoV-2 vaccination was associated with reduced need for hospitalization with COVID-19 and reduced the risk of death.

Background: Chronic parenchymal lung disease (LD) is a new emerging severe life-threatening complication of sJIA. The number of sJIA patients with LD is apparently increasing and interestingly they are reported more frequently in North America. Data regarding frequency and features of sJIA-LD in Europe are not available.
Objectives: To evaluate the burden of sJIA-LD in Europe.
Methods: Patients with diagnosis of sJIA with LD, including pulmonary alveolar proteinosis (PAP), interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH), followed in European paediatric rheumatology centres were identified through a survey sent to the members of the MAS/SJIA Working Party.
Results: Data from 34 sJIA-LD patients, diagnosed in 15 European paediatric rheumatology centres between 2007 and 2022, were collected. 33 patients were Caucasian and 1 was African-American; 21 were female. The median age at sJIA onset was 6 years and LD occurred after a median time of 2 years. 19 patients had a chronic persistent sJIA course, 14 had a polycyclic course and only 1 patient had a monocyclic course; 29 (85%) had active sJIA at time of LD diagnosis. During the disease course, 28 (82%) patients developed MAS, 12 (35%) of whom had MAS at sJIA onset and 19 (56%) had full-blown MAS at time of LD diagnosis; 23 (68%) patients had >1 MAS episode. 28 (82 %) patients were treated with at least one IL-1 or IL-6 inhibitor before LD diagnosis: 15 with canakinumab, 24 with anakinra and 13 with tocilizumab; 13 (38%) patients experienced drug adverse reaction to a cytokine inhibitor: 9 to tocilizumab and 4 to anakinra. 24 (70%) patients developed ILD, 6 (18%) PAP and 4 (12%) PAH. 15 (44%) patients presented acute digital clubbing; 16 (47%) patients developed hypoxia and 9 (26%) developed pulmonary hypertension. A chest CT scan was performed in all patients with evidence of septal thickening, peri-bronchovascular thickening and ground glass opacities in the majority of patients (26, 18 and 18 respectively). In 17 patients a bronchoalveolar lavage was performed and 12 underwent a lung biopsy. The histopathological pattern was alveolar proteinosis in 5 patients, endogenous lipoid pneumonia in 3, vasculitis in 1 and fibrosis in 1. Half of the patients (17) required ICU admission and 6 (18%) died. All the patients were treated with glucocorticoids (GCs) at time of diagnosis, and 26 received IL-1 or IL-6 inhibitor after the diagnosis (13 canakinumab, 20 anakinra, 14 tocilizumab).
Conclusion: Lung involvement is an emerging life-threatening complication of sJIA and patients are also diagnosed in Europe. Prompt recognition is crucial and new therapeutic strategies are needed to reduce the risk and improve the outcome of this complication.

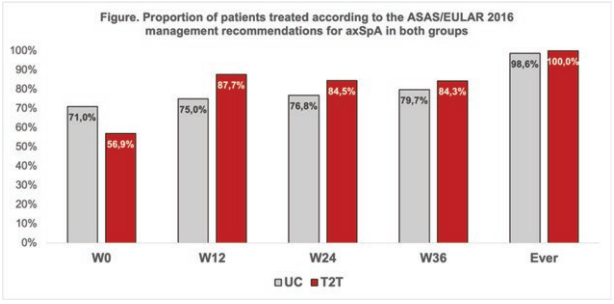
Background: Secukinumab has demonstrated efficacy and safety in patients with enthesitis-related arthritis (ERA) and juvenile psoriatic arthritis (JPsA) categories of juvenile idiopathic arthritis (JIA) for up to 2 years.[1] After completion of a 2-year core study (JUNIPERA), a long-term extension (LTE) study was conducted to evaluate the continued efficacy and safety of secukinumab.
Objectives: To report interim efficacy and safety results of the LTE study of secukinumab in patients with ERA and JPsA.
Methods: In the core study, a total of 86 patients (2 to <18 years of age) received secukinumab up to week 12 in the open-label (OL) period.[1] JIA ACR30 responders at week 12 (n=75) were subsequently randomised to secukinumab (n=37) or placebo (n=38) up to week 100 in study period 2. Those who flared after randomisation (secukinumab, n=10; placebo, n=21) received OL secukinumab up to week 100.[1] A total of 54 out of 61 patients who had completed the core study consented to enter the LTE study and received secukinumab (s.c.) (75/150 mg in patients <50/ ≥50 kg) every 4 weeks up to 4 years. Patients whose signs and symptoms were not fully controlled, as judged by the investigator in



the LTE, could have dose escalation of their secukinumab dose from 75 mg to 150 mg or 150 mg to 300 mg. Median Juvenile Arthritis Disease Activity Scores (JADAS)-27 were presented up to week 156 for efficacy, and adverse events (AEs) and serious AEs were presented for the entire treatment period up to the cut-off date (maximum up to week 232).

Results: JADAS-27 in the core study and in the LTE are presented in the **Figure 1**. A total of 19 patients had dose escalation in the LTE: 8 patients from 75 mg to 150 mg and 11 patients from 150 mg to 300 mg. The overall exposure-adjusted incidence rate per 100 patient-years (PY) of treatment-emergent AEs was 98.4 PY in the entire JIA population. The most commonly reported AEs (preferred term, safety set 5% cut off) were nasopharyngitis (n=9, 16.7%) and arthralgia (n=8, 14.8%). One major adverse cardiovascular event, not related to the study drug, and 2 cases of uveitis were reported. No cases of Crohn's disease or deaths were reported, and no patient discontinued treatment due to an AE.

Conclusion: With secukinumab treatment, the JADAS-27 inactive disease status was sustained from week 104 to week 156 in patients with JIA who had completed the 2-year core study and enrolled in the LTE study. Safety data were consistent with adult and paediatric indications, with no new or unexpected safety signals.

POS0279 IDENTIFICATION OF PREDICTIVE FACTORS OF FLARE AFTER ANAKINRA WITHDRAWAL IN PATIENTS WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS: RESULTS FROM A SINGLE CENTRE

Keywords: Outcome measures, Tapering, Inflammatory arthritides

G. Nardini[1], C. Bracaglia[1], D. Pires Marafon[1], E. Sacco[2], A. De Matteis[1], I. Caiello[3], G. Prencipe[3], F. De Benedetti[1], M. Pardeo[1]. *[1]IRCCS Ospedale Pediatrico Bambino Gesù, Division of Rheumatology, Rome, Italy*; *[2]Fondazione Casa Sollievo della Sofferenza, Pediatria, San Giovanni Rotondo, Italy*; *[3]IRCCS Ospedale Pediatrico Bambino Gesù, Laboratory of Immuno-Rheumatology, Rome, Italy*

Background: Systemic juvenile idiopathic arthritis (sJIA) is a rare autoinflammatory disease of unknown etiology. Several uncontrolled studies showed that early treatment with anakinra is associated with a better outcome, according to the "window of opportunity" hypothesis. However, very limited scientific evidence is available on withdrawal strategy. So far, anakinra withdrawal modalities are heterogeneous among the different rheumatology centres.

Objectives: The aim of this study was to identify predictive factors of disease flare, as elements suggestive of persistent course of the disease, in patients with sJIA after anakinra withdrawal. We also described our withdrawal strategy in sJIA patients who reached clinical inactive disease (CID) off glucocorticoids (GCs).

Methods: We retrospectively analysed data of 39 sJIA patients followed in our centre who stopped anakinra after reaching CID off GCs for at least 6 months before the withdrawal. Eight patients withdrew anakinra abruptly while 31 patients did it after tapering throughout one or two steps (alternate-day and/or once every three days regimens) of anakinra administration. All patients underwent a follow up of 24 months after withdrawal. They were subsequently divided into two groups according to the presence or the absence of disease flare during the follow up. Demographic, clinical and laboratory data of the patients were evaluated in univariate and multivariate analysis as predictors of flare.

Results: During the follow up, 10/39 patients (25.6%) flared after a median time from anakinra withdrawal of 7.9 months. In univariate analysis the variable most strongly related with the absence of flare was the disease duration from the onset to starting of anakinra ($p = 0.0046$), with an optimal cut-off of 3 months. Patients who started anakinra ≥ 3 months after disease onset had an 8-fold higher risk of flare after anakinra discontinuation (CI 95 2.0-32.4; $p = 0.0003$) (Figure 1). Furthermore, we observed that a higher dose of anakinra (≥2 mg/kg/day) was associated with a lower risk of flare ($p = 0.065$). We also demonstrated that patients who tapered therapy before withdrawal were significantly associated with a lower percentage of flare compared to the ones who withdrew anakinra abruptly, with a 4-fold lower risk of flare (CI 95 1.47-10.1; $p = 0.0164$). Lastly, we constructed a model analysing at the same time disease duration, anakinra dose at baseline and anakinra tapering. In this model, disease duration ≥ 3 months at baseline resulted to be the only variable significantly associated with flare after anakinra withdrawal with an Odds Ratio of 15.16 (CI 95 1.7-131.9; $p = 0.014$).

Conclusion: Our results strengthen the evidence on IL-1 inhibition in sJIA treatment and provide new ones supporting the "window of opportunity" hypothesis. Early anakinra treatment may predict a good short-term outcome and also potentially prevent the development of a persistent disease course. These observations have a strong clinical relevance, an early diagnosis and a targeted treatment could control the disease and could also modify its natural history.

POS0280 EARLY EXPERIENCE WITH JAK INHIBITORS IN JIA IN ROUTINE CLINICAL PRACTICE

Keywords: Epidemiology, bDMARD

L. Kearsley-Fleet[1], E. Baildam[2], M. Beresford[3,4], S. Douglas[5], H. Foster[6], T. Southwood[7], K. Hyrich[1,8]. [1]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester Academic Health Science Centre, Manchester, United Kingdom*; [2]*The Alexandra Hospital, Paediatric Rheumatology, Manchester, United Kingdom*; [3]*Alder Hey Children's NHS Foundation Trust, Department of Paediatric Rheumatology, Liverpool, United Kingdom*; [4]*University of Liverpool, Institute of Life Course and Medical Specialities, Liverpool, United Kingdom*; [5]*Scottish Network for Arthritis in Children, SNAC, Edinburgh, United Kingdom*; [6]*Newcastle University, Population and Health Institute, Newcastle, United Kingdom*; [7]*University of Birmingham, Institute of Child Health, Birmingham, United Kingdom*; [8]*Manchester University NHS Foundation Trust, National Institute of Health Research Manchester Biomedical Research Centre, Manchester Academic Health Science Centre, Manchester, United Kingdom*

Background: For the past 20 years, biologic (b)DMARDs have been the main treatment option for children and young people with JIA where an initial conventional-synthetic DMARD has not been effective. Since 2021, tofacitinib, a Janus Kinase (JAK) inhibitor has become available for the treatment of JIA. In the phase 3 randomised controlled withdrawal design trial, tofacitinib demonstrated superior efficacy over placebo, although only 38% of patients had prior bDMARD exposure. There is little information on the use of JAK inhibitor in the real-world.

Objectives: This analysis aims to describe the early experience of children and young people with JIA in a real-world cohort receiving JAK inhibitor in the United Kingdom (UK).

Methods: All patients in the UK JIA Biologics Register starting a JAK inhibitor were identified. Patient characteristics are presented at the time of treatment start, including age, disease duration and prior bDMARDs. Patients were followed until their latest follow-up form was returned. Active joint count (AJC) was reported at start of therapy and after 6 months. Status at their last follow-up was reported including treatment persistence.

Results: As of 21-Nov-2022, 14 children and young people across most ILAR categories had been treated with a JAK inhibitor; 12 baricitinib, 2 tofacitinib (table 1). Median age at JAK inhibitor start was 16 years (interquartile range [IQR] 13-17) and median disease duration was 6 years (IQR 4-7). All patients had prior bDMARD exposure, with 12 out of the 14 having more than 2 prior bDMARDs (range 2-6). Ten patients had follow-up available after the start of JAK inhibitor (median 1.4 years of follow-up available; median 0.8 years on treatment available). At the latest follow-up, 6 patients remained on JAK inhibitor, whilst 4 patients had discontinued (3 for ineffectiveness). No venothromboembolism (VTE) have been reported. In eight patients who had disease activity data available at the start of treatment, median active AJC was 9 (IQR 5-25). In the six patients who had disease activity data available after 6 months of JAK inhibitor treatment, median AJC was 2 (IQR 0-4).

Table 1.

	All patients N=14
Female, n (%)	11 (79%)
ILAR, n (%)	
Oligoarticular (persistent or extended)	3 (21%)
Polyarticular RF-negative	6 (43%)
Polyarticular RF-positive	3 (21%)
Psoriatic arthritis	2 (14%)
Median (IQR) age at JAK inhibitor start (years)	16 (13, 17)
Median (IQR) disease duration at JAK inhibitor start (years)	6 (4, 7)
	N=13
JAK inhibitor, n (%)	
Baricitinib	12 (86%)
Tofacitinib	2 (14%)
Line of b/tsDMARD therapy, n (%)	
First/second-line	2 (14%)
Third-line	4 (29%)
Fourth-line	2 (14%)
Fifth-line	2 (14%)
Sixth-line	2 (14%)
Seventh-line	2 (14%)
Prior Biologics, n	N=13
Prior TNF *(etanercept, infliximab, adalimumab)*	13/13
Prior B-cell depleting agent *(rituximab)*	2/13
Prior T-cell depleting agent *(abatacept)*	3/13
Prior interleukin inhibitor *(tocilizumab, secukinumab)*	8/13
Patients with follow-up available, n	N=10
Median (IQR) time until end of follow-up, years	1.4 (0.5, 1.8)
Median (IQR) time on treatment, years	0.8 (0.3, 1.4)
At last follow-up:	
Still on JAK treatment	*6/10*
Median (IQR) time on treatment, years	*0.9 (0.3, 1.4)*
Stopped treatment	*4/10*
Median (IQR) time on treatment, years	*0.8 (0.3, 1.5)*
Stopped for ineffectiveness	*3/4*

Conclusion: In this cohort, the initial patients with JIA prescribed JAK inhibitor have largely received these drugs prior to marketing authorisation in JIA, with most receiving it as a later stage biologic/targeted-synthetic DMARD. Most patients were still receiving treatment almost 11 months after starting a JAK inhibitor. These data suggest that JAK inhibitors could be a very effective treatment for children and young people with JIA, even after a high number of prior bDMARDs.

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood. The treatment of JIA has been revolutionized by the use of biologic agents. The use of biosimilar disease modifying antirheumatic drugs (bsDMARD) therapy in young adults is not well studied, therefore more evidence regarding drug safety is needed.

Objectives: Our aim is to assess the safety of bsDMARD therapy in JIA.
Methods: Data was obtained from BIOBADASER, a multicenter prospective registry based on routine clinical practice. All patients diagnosed before age 16 in our database between 2000 and 2022 were included in the analysis. JIA is classified into 7 subgroups: systemic, persistent or extended oligoarthritis, RF positive polyarthritis, RF negative polyarthritis, enthesitis-related arthritis, psoriatic arthritis, and undifferentiated arthritis. Due to the registry design, it was not possible to identify each of the JIA subgroups; thus, we classified them into oligo/polyarticular JIA, JIA related to enthesitis, and psoriatic JIA. Adverse events were coded using version 13.0 MedDRA (Medical Dictionary for Regulatory Activities). Proportions, means and standard deviations (SD) were used to describe our population. Incidence rates (IR) of adverse events and 95% confidence intervals were calculated, and Poisson regression was used to estimate incidence rate ratios (IRR), adjusting by sex, diagnosis type, age at start of therapy (≤16 years vs >16 years) and line of treatment as confounding variables.
Results: From a total of 313 patients, 130 (41.5%) use biosimilars therapies, 60.8% of which were women (n= 79). Mean age at diagnosis was 11.2 years (SD= 6.1) and mean age at the start of treatment was 25.1 (SD= 13.4). Patients were classified as oligo/polyarticular JIA (79.2%), JIA related to enthesitis (16.2%) and psoriatic JIA (4.6%). Methotrexate was used in combination in 39.1% of the bsDMARD treatments. The most commonly used drug was Adalimumab (56.8%), followed by Etanercept (28.7%). Table 1 shows incidence rates for adverse events according to severity. For all adverse events, IR is greater in biosimilars compared to original biologic disease modifying antirheumatic drugs (bDMARDs), although the latter have a higher IR of serious adverse events. The IRR was 1.33 (95% CI 1.1-1.6), thus, the risk of adverse events was greater among bsDMARD compared to the original bDMARDs.
Conclusion: The risk of adverse events occurrence is a higher among patients treated with bsDMARD drugs. Although this project allowed us to examine long-term biosimilars safety in JIA, large registries that focus on such patients are needed to better understand rare adverse events.

POS0282 PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA) ON INTENSIVE TREATMENT FREQUENTLY PRESENT ALEXITHYMIA OVER FATIGUE, ANXIETY, AND DEPRESSION, DESPITE LOW DISEASE ASSESSMENT PARAMETERS

Keywords: Inflammatory arthritides, Patient reported outcomes, Quality of life

M. S. Nicoli[1], G. Tarantino[2], E. Marasco[2], E. Betti[1], M. F. Paniccia[1], T. Grimaldi[1], A. Aquilani[2], R. Nicolai[2], F. De Benedetti[2], S. Magni-Manzoni[2]. *[1]IRCCS Bambino Gesù Children's Hospital, Clinical Psycology, Rome, Italy*; *[2]IRCCS Bambino Gesù Children's Hospital, Rheumatology, Rome, Italy*

Background: Psychological factors influence quality of life, disease perception, engagement and adherence to treatment in patients with Juvenile Idiopathic Arthritis (JIA). While anxiety and/or depression have been often documented in JIA, alexithymia has been seldom investigated.

Objectives: 1.To investigate the frequency of psychic symptoms in JIA patients at a single tertiary care center, including depressive, anxiety and alexithymic symptoms. 2.To investigate correlation between psychic symptoms and demographic and clinical parameters.
Methods: JIA patients aged 8-17 years and consecutively seen from March to November 2022 were invited to undergo psychological standardized tests: the Patient Health Questionnaire-9 items (PHQ9), self-administered measure of depressive symptoms; the Generalised Anxiety Disorder (GAD7) test; the Self-administered Psychiatric Scales for Children and Adolescents anxiety-related areas (SAFA-A), depression-related areas (SAFA-D) and somatic areas (SAFA-S); the PedsQL™ Multidimensional Fatigue Scale; PedsQL™ Rheumatology Module Pain and Hurt; the Toronto Alexithymia Scale (TAS-20); the Visual Analogue Scale (VAS) for pain intensity. Demographic data, clinical and laboratory parameters for disease assessment on the same visit were also recorded. Data were analyzed with descriptive statistics. Categorical data were represented as counts and percentages, while continuous data were represented as means and standard deviations or medians and ranges. Data were checked for normality. For normally distributed data, appropriate parametric statistical testes were employed, for non normally distributed data, non-parametric statistical tests were employed. Comparison in the frequency of the psychological symptoms in presence/absence of pain, active, painful/tender or limited joints was assessed. Significant level was set at $p<0.05$. All statistical analyses were performed using R (version R 4.0.3).
Results: Thirty-seven JIA patients were enrolled in the study: 64.9% were females, 38% with persistent oligoarthritis, 22% extended oligoarthritis and 40% polyarthritis, and 32% with chronic uveitis ever. Median age was of 12.6 years (IQR 9.3-15.3), with a median disease duration of 5.5 years (IQR 3.6-7.6). Respectiveley, 96% and 95% of patients were receiving csDMARDS and bDMARDS. All disease parameters showed very low level of disease activity and disability. PHQ9 and GAD7 were pathologic in 41% and 44%, respectively; borderline or clinically pathologic scores were found in 27%, 29%, and 13% for SAFA-D, SAFA-A, SAFA-S, respectively. Of note, TAS-20 was borderline or pathologic in 32% of patients. No psychic symptoms, demographic variables or clinical features showed an association with disease parameters. No significant differences were found between patients with and without pain on VAS, active joints, painful/tender or limited joints.
Conclusion: In a selected cohort of JIA patients on intensive treatment, low disease activity and few limited joints psychological parameters for depression and anxiety were detectable in a sizable proportion; a higher percentage of patients reported fatigue; alexithymia was even more frequent, regardless disease assessment variables. Our findings support the rationale for adopting routine psychological assessment and intervention in JIA patients, and for extending psychological investigations to their parents/guardians.

POS0283 EFFECT OF CUSTOMISED FOOT ORTHOSES ON PEAK PRESSURE AND PRESSURE TIME INTEGRALS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: A RANDOMISED CLINICAL TRIAL

Keywords: Randomized control trial

A. Fellas[1], D. Singh-Grewal[2], J. Chaitow[2], D. Santos[3], M. Clapham[4], A. Coda[1]. *[1]University of Newcastle, College of Health, Medicine and Wellbeing, Callaghan, Australia*; *[2]Sydney Children's Hospital, Randwick, Rheumatology, Randwick, Australia*; *[3]Queen Margaret University, Podiatry, Edinburgh, United Kingdom*; *[4]Hunter Medical Research Institute, Biostatistics, New Lambton Heights, Australia*

Background: Children with juvenile idiopathic arthritis (JIA) often exhibit joint symptoms in the lower limb. Prolonged joint disease may cause further physical and functional impairment, which can lead to significant disturbances in gait such as abnormal pressure distributions and sub-optimal peak plantar pressures [1-3]. Recent studies have shown that children with JIA compared to an age and sex matched cohort displayed significantly higher peak pressures (PP) in most areas of the plantar foot [2]. Research also showed that children with JIA are displaying elevated pressure time integrals (PTI), meaning they are spending higher amounts

of time in the stance phase of gait and less in the swing phase and thus a less propulsive gait [2]. To our knowledge only one previous clinical trial has explored the effect of a mechanical intervention such as foot orthoses (FOs) to improve the distribution of peak plantar pressures in children with JIA [4].

Objectives: The aim of our randomised clinical trial is to further evaluate the effect of customised prefabricated FOs in improving PTI and PP in children with JIA.

Methods: A multicentre, parallel design, single-blinded randomised clinical trial was used to assess the impact of customised preformed FOs on plantar pressures in children with JIA. Children with a diagnosis of JIA, exhibiting lower limb symptoms and aged 5-18 were eligible. The trial group received a low-density full length, Slimflex Simple device which was customised chair side and the control group received a sham device. PP and PTI were used as the main gait outcomes and were measured using portable Tekscan gait analysis technology at baseline, 3 and 6 months. PP were measured using kilo pascals (kPa) and PTI measured kPa per seconds (kPa/s). Differences at each follow-up were assessed using the Wilcoxon rank sum test.

Results: A total of 66 participants were recruited. Customised prefabricated FOs were effective in altering plantar pressures in children with JIA versus a control device. Reductions of PP in the heel (baseline p=<0.001 (-104.33 kPa), 3-month p=0.004 (-126.16 kPa)), forefoot (baseline p=0.027 (-131.5 kPa)), 5th metatarsophalangeal joint (baseline p=0.007 (-37.17 kPa), 3-month p=0.001 (-69.5 kPa), 6-month p=0.016 (-50.91 kPa)) were statistically significant in favour of the trial group. These results were also positively correlated with PTI with the trial group spending less time and pressure on the heel, forefoot and rearfoot than the control. Finally, PP and PTI reductions were also associated with statistically significant increased midfoot contact with the trial device at baseline (29.84 kPa), 3 (24 kPa) and 6-month (43.75 kPa) data collections, showing that the trial intervention was successful in capturing the arch profile of participants and redistributing pressure. The trial intervention was safe and well accepted by participants, which is reflected in the high retention rate (92%).

Conclusion: Clinicians may prescribe customised prefabricated FOs in children with JIA to deflect pressure from painful joints and redistribute from high pressure areas such as the rearfoot and forefoot.

Background: COVID-19 has shaped the world over the last 3 years. Although the risk for severe COVID-19 progression in children is low it might be aggravated by chronic rheumatic disease or treatment with immunosuppressive drugs.

Objectives: We analyzed clinical data of COVID-19 cases among paediatric patients with rheumatic diseases reported to BIKER between March 2020 and December 2022.

Methods: The main task of the German BIKER (Biologics in Pediatric Rheumatology) registry is safety monitoring of biologic therapies in JIA. After the onset of the COVID-19 pandemic, the survey was expanded with a standardized form to proactively interview all participating centers about occurrence, presentation and outcome of SARS-CoV-2 infections in children with rheumatic diseases.

Results: A total of 68 centres participated in the survey. Clinical data from 928 COVID infections in 885 patients with rheumatic diseases could be analyzed. JIA was the most common diagnosis with (717 infections), followed by genetic autoinflammation (103 infections), systemic autoimmune diseases (78 infections), idiopathic uveitis (n=25), vasculitis (n=5). In 374 reported COVID infections (40%), patients were receiving conventional DMARDs, in 331 (36%) biologics, mainly TNF inhibitors (TNFi, n=241 (26%)). In 567 reports (61%) patients used either a biologic or a DMARD, in 339 reports patients (37%) did not use any antirheumatic medication including steroid. Over the last 3 years, COVID-19 occurred in Germany in 5 distinguishable waves, calendar weeks (CW) 10-30 in 2020, CW 21/2020 – 8/2021(both predominantly wild-type variant), CW 9-27 in 2021 (Alpha variant in the majority of infections), CW 28-51 in 2021 (Delta variant), since CW 52/2021 (several Omikron variants; Robert-Koch Institute: VOC_VOI_Tabelle.xlsx; live.com)) In our cohort, patients with SARS-CoV-2 infection were slightly older during the 1st and 2nd wave (mean age 12.7+/-3.5 and 12.8+/-4.3 years) compared to the 4th and 5th wave with 11.4+/-3.9 and 11.4+/-4.2 years; p=0.01. 160 asymptomatic SARS-CoV-2 infections were reported, frequencies of symptoms associated with COVID-19 are shown in table 1. Five patients were hospitalized for 4-7 days. A 3½-year-old female patient succumbed during the first wave with encephalopathy and respiratory failure. The patient had been treated with MTX and steroids for systemic JIA. Genetic testing revealed a congenital immunodeficiency. No other patient needed ventilation or intensive care. One case of uncomplicated PIMS in an MTX treated JIA patient was reported. The duration of SARS-CoV-2 infection-associated symptoms was markably shorter during the 5th wave with 6.7+/-5.1 days, compared with reports from the other 4 waves (Table1). The duration of symptoms was higher in MTX treated patients (10.2+/-8.4 days) compared to patients without treatment (7.7+/-10.8; p=0.004) or patients treated with TNFi (8.2+/-4.8, p=0.002). Although patients treated with steroids also had a longer duration of symptoms (9.7+/-7.0), this was not significant.

Conclusion: Except for one patient with congenital immunodeficiency who died, no case of severe COVID-19 was reported in our cohort. At the time of infection, over 60% of patients had been treated with conventional DMARDs and/or biologics. Although MTX treated patients had a slightly longer duration of symptoms, antirheumatic treatment did not appear to have a negative impact on severity or outcome of SARS-CoV-2 infection.

Table 1. Characteristics and frequency of symptoms in SARS-CoV-2 infections

N or mean (SD)	1st wave N=20	2nd wave N=84	3rd wave N=38	4th wave N=124	5th wave N=662
female	14	53	27	75	432
age at COVID-19, years	12.7 (3.5)	12.8 (4.3)	11.8 (3.5)	11.4 (3.9)	11.4 (4.2)

POS0285 TEMPOROMANDIBULAR JOINT INVOLVEMENT IN JUVENILE IDIOPATHIC ARTHRITIS: THE ROLE OF MAGNETIC RESONANCE IMAGING IN THE EVALUATION OF THE SILENT JOINT

Keywords: Imaging

C. Brusadelli[1,2], D. Mariano[3], A. Pistorio[4], L. Anfigeno[5], F. Magnaguagno[5], M. Valle[5], M. Dl Filippo[1], G. Chiappe[6], N. Laffi[6], C. Malattia[1,3]. *[1]IRCCS G.Gaslini, UOC Clinica Pediatrica e Reumatologia, Genoa, Italy*; *[2]University of Milano-Bicocca, Pediatrics, Milan, Italy*; *[3]University of Genoa, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetic and Maternal Infantile Sciences (DINOGMI), Genoa, Italy*; *[4]IRCCS G.Gaslini, Scientific Direction, Genoa, Italy*; *[5]IRCCS G.Gaslini, Radiology, Genoa, Italy*; *[6]IRCCS G.Gaslini, Department of Paediatric Odontostomatology and Orthodontics, Genoa, Italy*

Background: Temporomandibular joint (TMJ) involvement is frequent in patients with Juvenile Idiopathic Arthritis (JIA) and may cause severe craniofacial growth disturbances. Contrast-enhanced MRI is considered the best available tool for TMJ assessment[1].

Objectives: To investigate the agreement between MRI and physical examination in the detection of TMJ involvement; to describe the evolution of TMJ activity and osteochondral damage by means of MRI during disease course; to evaluate the relationship between socio-demographic, clinical variables and radiologic outcomes in terms of resolution of inflammation and structural damage progression.

Methods: 121 JIA patients with TMJ involvement who underwent at least 2 MRI examinations in our Centre between 2012 and 2022 were included in this retrospective study. TMJ inflammation and damage were evaluated according to the MRI scoring system proposed by the OMERACT (*Outcome Measures in Rheumatology and Clinical Trials*)[2]. The agreement between physical examination and MRI was analysed by means of Cohen's kappa coefficient. The relationship between socio-demographic and clinical variables and radiologic outcomes was estimated by bivariate analyses. Comparison between survival curves for damage progression was done by the Log-Rank test.

Results: 339 TMJ MRIs obtained from 121 JIA patients were reviewed. First MRI was performed at a median time of 0.6 years (0.2-1.5) after TMJ symptoms onset. Baseline MRI showed active synovitis in 85 out of 121 patients (70.2%) and condylar damage in 112 (92.6%) patients. A poor agreement was found between physical examination and MRI (right TMJ Cohen's kappa = 0.15; left TMJ Cohen's kappa = 0.26). MRI showed active TMJ synovitis in 63% of the exams performed in patients who were in clinical remission according to Wallace criteria. During follow-up, synovitis improved in 56.2% of patients and structural damage progression was observed in 21.0% of patients. Younger age (< 9.4 years) at onset of TMJ involvement was associated with the resolution of the inflammatory process (p=0.023) and with a lower rate of structural damage progression (p=0.027). Significant association was observed between persistence of TMJ synovial inflammation and damage progression (p=0.0013). Higher baseline MRI synovitis (p=0.018) and bone erosion scores (p<0.0001) were associated with the development of a severe osteochondral damage at last follow-up MRI.

Conclusion: Our study confirms that TMJ involvement is clinically silent in most of JIA patients and supports the role of MRI in the diagnosis and monitoring of TMJ arthritis. Active TMJ synovitis was found in a substantial proportion of patients in clinical remission with relevant implications for the therapeutic strategy. Old age at TMJ onset, a high degree of synovial inflammation and its persistence over time were negative prognostic factors for the development of severe TMJ damage.

POS0286 TREATMENT OF A LARGE COHORT OF CHILDHOOD CHRONIC IDIOPATHIC UVEITIS: A MULTICENTRIC LARGE COHORT

Keywords: Uveitis, Descriptive Studies, bDMARD

I. Maccora[1,2], C. Guly[3], C. De Libero[4], R. Caputo[4], A. Ramanan[5], G. Simonini[1,2]. *[1]Meyer Children's Hospital IRCCS, Rheumatology Unit, Florence, Italy*; *[2]University of Florence, NeuroFARBA Department, Florence, Italy*; *[3]Bristol Eye Hospital, Ophthalmology, Bristol, United Kingdom*; *[4]Meyer Children's Hospital IRCCS, Ophthalmology Unit, Florence, Italy*; *[5]Bristol Royal Hospital for Children, Paediatric Rheumatology, Bristol, United Kingdom*

Background: Childhood Chronic Idiopathic Uveitis (cCIU) is a severe ocular condition that account for the 40% of uveitis in children. Its timely and proper treatment is critical to prevent severe complications.

Objectives: The purpose of this study was to describe the treatments of a large cohort of cCIU.

Methods: This is a retrospective medical chart review study of cCIU followed at Meyer children's hospital IRCCS and Bristol Royal hospital for children (1st Jan2019 - 31st Jan 2020). Children were included if they have a diagnosis of CIU prior to 16 years old according to SUN. We collected demographic, clinical and laboratory data. Achievement of remission on treatment was evaluated as persistent inactivity for at least 3 months without drops and systemic corticosteroids.

Results: Data about 126 cCIU (61 female, median age at onset 9.3 years (3-16), ANA positive in 33 (77.6%)) were collected. 68 have anterior uveitis, 29 intermediate, 15 anterior + intermediate, 1 posterior and 13 panuveitis. Excluding the patient with posterior involvement, 97 children (77.6%) underwent to at least one systemic treatment, 65 (52%) to two, 18 (14.4%) to three and 2 (1.6%) to four (Infliximab and tacrolimus), with a median follow-up of 46 months (IQR 22-67). The first drug was administered after a median time of 5 months (IQR 2-10). Treatments performed were summarized in table 1. Among the first line treatment, children treated with adalimumab are more likely to achieve remission and maintain remission for a longer time after drug withdrawal compared to the other drugs (χ^2 7.59 p 0.006 and p 0.036 respectively). No significant differences have been evaluated stratifying analysis for anatomical subtype, ANA status, ethnicity,

sex, ESR and CRP at onset for achievement remission with the first line treatment. However, patients treated with methotrexate who did not achieve remission have lower visual acuity in LogMar (0.53 vs 0.36, Mann-Whitney U test p 0.02). The superiority of Adalimumab in terms of remission achievement was confirmed when it was used as second line treatment too (χ^2 6.29 p 0.04), however they relapsed more frequently out of therapy (χ^2 6.6 p 0.03). Moreover, with the II line treatment, panuveitis showed higher proportion of remission achievement with adalimumab and worse response to MMF (χ^2 2 p 0.03).

Conclusion: Treatment of cCIU is extremely challenging, achieving remission with the first line treatment in only the 50% of patients. However, patients treated with adalimumab have better chance to achieve remission and patients who showed worse visual acuity at onset would benefit of a more aggressive treatment with biologics since onset.

POS0287 TOFACITINIB IN JUVENILE IDIOPATHIC ARTHRITIS: FIRST YEAR EXPERIENCE

Keywords: Targeted synthetic drugs, Registries

G. Horneff[1,2], D. Windschall[3], B. Huegle[4], R. Berendes[5], H. Girschick[6], A. Klein[1,2]. [1]*Sankt Augustin, General Paediatrics, Sankt Augustin, Germany*; [2]*University of Cologne, Department of Paediatric and Adolescents Medicine, Cologne, Germany*; [3]*St Josef Stift, Paediatric Rheumatology, Sendenhorst, Germany*; [4]*Deutsches Zentrum Kinder.- und Jugendrheumatologie, Paediatric Rheumatology, Garmisch-Partenkirchen, Germany*; [5]*Marien Hospital, Paediatric Rheumatology, Rosenheim, Germany*; [6]*Vivantes Clinic Berlin, General Paediatrics, Berlin, Germany*

Background: Tofacitinib is an oral Janus kinase inhibitor recently approved for the treatment of polyarticular juvenile idiopathic arthritis (pJIA) and juvenile psoriatic arthritis (jPsA) aged 2 to <18 years. Data out of clinical practice so far are rare.

Objectives: To characterize JIA cohorts treated with tofacitinib and to evaluate efficacy and tolerance in clinical practice.

Methods: The German BIKER data base was screened for JIA patients aged 2 to <18 years who were started on tofacitinib until December. 31st, 2022

Results: Patient demographic and disease characteristics are presented in Table 1. Primary diagnoses were either polyarticular JIA rheumatoid factor positive (n=4) or negative (n=18), extended oligoarthritis (n=7), jPsA (n=2), ERA-JIA (n=2), persistent oligoarthritis (n=1) and systemic onset JIA (n=1). The patient's age varied from 6.9 to 18.0 years at start of treatment and the disease duration range was 2.3 – 16.6 years. In most cases, patients were extensively pretreated with biologics (mean 2.7). One patient had received 7 biologics, four each received 5 or 4 biologics, six received 3, ten received 2 and 8 received 1 biologic before. In a single case, tofacitinib was used directly after failure of methotrexate. Tofacitinib was administered orally BID in 35 JIA patients at a daily total dosage of 0.18 +/-0.06 mg/kg. Tablets with dosages of 5 mg BID were used in 31 patients. Oral solution was used in 4 patients (up to 4 mg BID). Efficacy data and safety data were available from 17 patients. A decrease of the JADAS10 (Median; IQR) from 10.1 (5.5;13.2) to 3.0 (1.3;6.3), of the number of active joints (from 4 (1;6) to 0 (0;1), of the patient's/parent's global VAS (from 30 (6;50) to 11 (2.5;22), the physician's global (from, 28 (18;41) to 7 (0.8;10) was noted. PedACR 30/50/70/90 criteria were fulfilled by 53%/47%/41%/24% at last observation. There were 11 adverse events (AE) in 10/35 patients (29%), including lack of efficacy (n=7), and each one upper respiratory tract infection, COVID19, headache, bone pain. There was no serious AE or severe AE reported. 8 patients (22.9%) discontinued tofacitinib after 0.6-6.7 months. Tofacitinib was stopped in 6 due to inefficacy, in 1 due to bone pain and in 1 because of patient's decision.

Conclusion: In this preliminary analysis of pediatric patients with JIA, tofacitinib use was safe and well tolerated. Treatment was associated with an improvement in signs and symptoms of arthritis and global disease activity at last observation although the cohort of patients has been heavily pretreated with DMARDs and biologics. The BIKER registry is planning to further follow JIA patients.

Molecular and metabolic biomarkers of activity, severity and response to treatment

POS0288 DEGRANULATING PR3+ MYELOID CELLS CHARACTERIZE PROLIFERATIVE LUPUS NEPHRITIS

Keywords: Kidneys, Systemic lupus erythematosus, Cell biology

A. I. Celia[1,2], X. Yang[3], M. A. Petri[1], A. Rosenberg[3], A. Fava[1]. [1]*Johns Hopkins University, Rheumatology, Baltimore, United States of America*; [2]*Sapienza*

University of Rome, Rheumatology, Roma, Italy; [3]*Johns Hopkins University, Pathology, Baltimore, United States of America*

Background: Despite optimal treatment, lupus nephritis (LN) remains associated with irreversible kidney damage[1]. A better understanding of the mechanisms underlying LN pathogenesis is needed to develop better treatment targets. As part of the Accelerating Medicines Partnership (AMP), we discovered that urinary PR3, a myeloid degranulation product, correlated with histological activity implicating neutrophil/monocyte degranulation in proliferative LN, the most aggressive type[2]. PR3 is a serine protease that can mediate kidney damage. Mature neutrophils with classical polylobate nuclei are rare in LN kidney biopsies. However, recent evidence displayed how immature, degranulating myeloid cells have been implicated in the pathogenesis of LN[3], but their role in mediating kidney damage is not completely understood.
Objectives: To investigate PR3+ cells in LN kidney, their association with histopathological features, and define their immunophenotype.
Methods: We performed multiplexed histology using serial immunohistochemistry (sIHC)[4] on archival LN kidney biopsies to quantify the expression of PR3 and multiple cell lineage markers (20-plex). Image analysis including deconvolution, cell segmentation, glomerular annotation, and quantitative histology was performed using Indica HALO. The analysis was limited to renal cortex.
Results: A total of 11 patients with LN who underwent a clinically indicated kidney biopsy were enrolled: 6 (55%) with pure proliferative LN (ISN/RPS class III or IV) and 5 (45%) with pure membranous LN. PR3+ cells were identified in all LN biopsies (range 343-7625 per sample). Most PR3+ cells did not show a polylobate nucleus. The majority of PR3+ cells were in the tubulointersitium (Figure 1A). However, accounting for the smaller glomerular area, there was a higher density of PR3+ cells in the glomeruli (Figure 1A-C). PR3+ cell abundance was higher in proliferative LN, especially in the glomeruli (Figure 1A-C). Glomerular PR3+ cell density very strongly correlated with histological activity measured by the NIH Activity Index (Pearson's r=0.97, p=5*10^{-5}; Figure 1D). Preliminary serial IHC analysis showed that PR3+ cells coexpressed MPO and variably coexpressed CD66b and CD14, but not neutrophil elastase, CD3, or CD20.

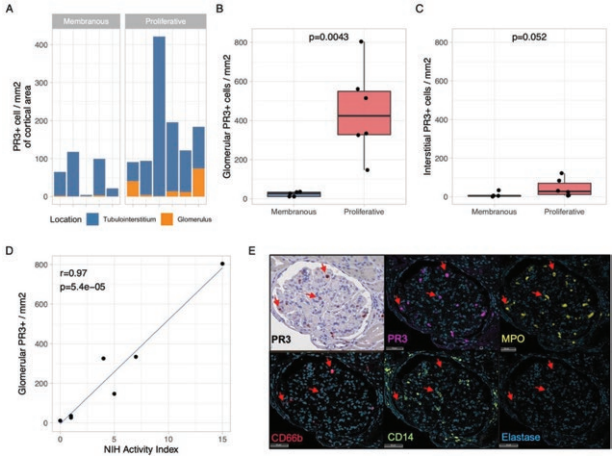

Figure 1.

Conclusion: PR3+ cells are abundant in LN. PR3+ cells are increased in proliferative LN and are strongly associated with histological activity thereby characterizing a more aggressive phenotype. This population densely infiltrated the glomeruli emphasizing a potential role in the endothelial pathogenic process. In preliminary analysis, kidney infiltrating PR3+ cells were not polymorphonucleated, did not express neutrophil elastase, and variably expressed CD14 suggesting a phenotype consistent with degranulating monocyte or an immature myeloid population. We previously showed the association between urinary PR3 and histological activity suggesting that intrarenal PR3+ cells are actively degranulating and therefore likely inducing kidney damage. These findings nominate PR3+ cells as a potential therapeutic target. Spatial transcriptomics and proteomic studies are ongoing to define the lineage and function of these cells.

POS0289 SERUM SOLUBLE MEDIATOR SIGNATURES OF LUPUS NEPHRITIS HISTOLOGICAL FEATURES AND RESPONSE TO TREATMENT

Keywords: Cytokines and chemokines, Systemic lupus erythematosus, Biomarkers

A. Fava[1], C. Guthridge[2], J. Kheir[2], C. Wagner[2], M. Petri[1], J. Buyon[3], B. Diamond[4], T. Accelerating Medicines Partnership in Ra/Sle[5], J. Guthridge[2], J. A. James[2]. [1]*Johns Hopkins University, Division of Rheumatology, Baltimore, United States of America*; [2]*Oklahoma Medical Research Foundation, Arthritis & Clinical Immunology Research Program, Oklahoma City, United States of America*; [3]*New York University, Division of Rheumatology, New York, United States of America*; [4]*Feinstein Institutes for Medical Research, Molecular Medicine and Medicine, Manhasset, United States of America*; [5]*Multipl, Multiple, Multiple, United States of America*

Background: There is a pressing need to identify novel therapeutic approaches and noninvasive biomarkers in lupus nephritis (LN).
Objectives: In this study, we quantified serum soluble mediators in the large Accelerating Medicines Partnership (AMP) LN longitudinal cohort to identify novel biomarkers of histological features and treatment response and provide insights into the pathogenesis of LN.
Methods: SLE patients meeting ACR or SLICC criteria (n=268) undergoing a clinically indicated kidney biopsy with a urine protein/creatinine (UPCR) ≥0.5 were recruited for this study as part of the AMP. Serum samples were collected from patients at the time of diagnostic kidney biopsy and 3-, 6-, and 12-months post-biopsy and from 22 healthy donors (HD). Concentrations of 51 analytes, including cytokines, chemokines, and TNFR superfamily members, were analyzed by xMAP multiplex assays on the Bio-Rad BioPlex200 array system. TACE levels were determined by ELISA. Clinical response was determined at 12-months post-biopsy using the Abatacept and Cyclophosphamide Combination Efficacy and Safety Study definitions in patients with a baseline UPCR >1.0 and International Society of Nephrology/Renal Pathology Society class III, IV, V, or combination thereof.
Results: LN patients demonstrated heterogeneity in serum soluble mediator concentrations (Figure 1A). Most soluble mediators were elevated in LN patients compared to HD. Within LN, patients with proliferative LN (class III +/- V or class IV +/-V) displayed a distinct signature. In particular, patients with pure proliferative LN (class III or IV) had higher serum levels of immune mediators, such as IFNβ and IL-1β, compared to nonproliferative LN, including pure membranous (class V) LN. In addition, several serum immune mediators correlated with intrarenal LN activity (NIH Activity Index), with syndecan-1 (CD138) and TNF-RII exhibiting the highest correlation (Figure 1B). In contrast, stem cell factor (SCF) and TNF-RI had the highest correlation with the chronicity index. In proliferative LN, the concentrations of many immune mediators declined in treatment responders. For example, syndecan-1 and TNF-RII decreased in complete and partial responders but not in nonresponders (Figure 1C). In contrast, SCF levels remained relatively stable regardless of response status.

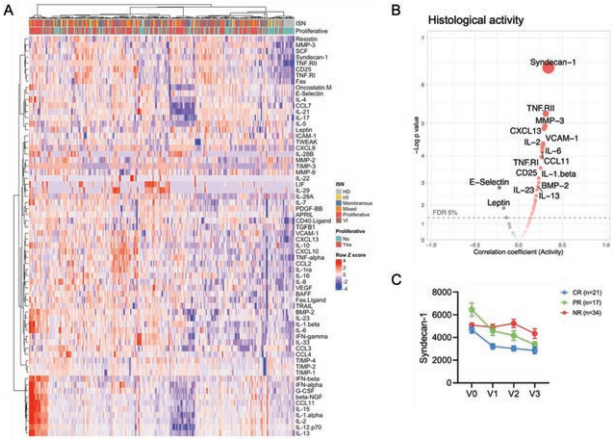

Figure 1.

Conclusion: Distinct histological features of LN are paralleled by specific signatures of circulating soluble mediators. Within LN, proliferative LN is associated with higher circulating levels of inflammatory cytokines, notably, type 1 IFNs. Furthermore, a decline in the titers of several immune mediators correlated with LN activity was associated with treatment response, suggesting a possible role in LN pathogenesis. These signatures and trajectories provide insight into LN pathogenesis, heterogeneity, and biomarker development.

POS0290 NOVEL ANTI-MITOCHONDRIAL ANTIBODIES IDENTIFY PATIENTS WITH PROPENSITY TO THROMBOGENESIS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Autoantibodies, Biomarkers

M. Barguil Macedo[1], J. Chapa[1], T. Wang[1], A. Bengtsson[2], C. Lood[1]. [1]*University of Washington, Division of Rheumatology, Seattle, United States of America*; [2]*Lund University, Division of Rheumatology, Stockholm, Sweden*

Background: Venous and arterial thrombotic events are leading causes of mortality in systemic lupus erythematosus (SLE), amounting to up to a quarter of deaths[1]. Other than traditional risk factors, SLE-specific factors, including chronic inflammation, have also been shown to contribute to thrombosis development. Nonetheless, the four times higher relative risk of thrombosis compared to healthy individuals is not fully accounted to the presence of conventional cardiovascular risk factors and anti-phospholipid antibodies[1]. As such, novel biomarkers of thrombosis are needed in early identification and preventative management of SLE patients.

Objectives: To characterize novel antibodies directed against mitochondrial constituents, and investigate their capacity to stratify patients based on thrombotic events.

Methods: Highly purified mitochondria were isolated from HepG2 cells (ATCC HB-8065TM) as previously described[2]. Briefly, cells were harvested and homogenized by a glass Douncer, followed by sequential centrifugation. Upon DNase-mediated removal of extracellular DNA, ultra-pure mitochondria (confirmed by flow cytometry, qPCR, and Western blot), labeled with MitoTracker, were incubated with sera (diluted 1:100) from SLE patients or healthy individuals. Binding of IgG to the mitochondrial outer membrane was detected using a secondary FITC-conjugated anti-human-IgG antibody, and analyzed by FACS. In some experiments, mitochondria were treated with trypsin (0.05%) prior to incubation with sera. Finally, reactivity towards mitochondrial protein lysate was confirmed using WB. Samples and clinical data from SLE patients (n=92) and healthy individuals (n=80) were provided from Division of Rheumatology, Lund University, Sweden. Statistical analyses were performed on SPSS 22.0. Mann-Whitney test was performed, with a p-value of 0.05 or below deemed as significant. Data protection and patient anonymization were ensured in accordance with regulation by Research Advisory Boards.

Results: Based on our novel flow cytometry assay, quantifying anti-mitochondrial antibodies (AMA) targeting the outer mitochondrial membrane, a large proportion (40.8%) of SLE patients were deemed positive for AMA using the 95th percentile of healthy controls as a cut-off. Presence of AMA was associated with severe SLE manifestations, including history of nephritis (OR = 3.3, p=0.02), anti-phospholipid syndrome (APS; OR = 5.7, p=0.02), and venous thromboembolism (OR = 6.7, p=0.008), the latter which was not seen in our cohort for isolated presence of anti-cardiolipin (aCL) antibodies (OR = 2.2, p=0.17), neither for lupus anticoagulant (OR 5.0, p=0.08) or anti-beta-2 glycoprotein 1 (OR 1.1, p=0.93). Pre-treatment of mitochondria with trypsin induced loss of binding of sera-derived antibodies (p<0.01), suggesting that AMA were targeting protein components of mitochondria, and not phospholipids, as is the case of aCL. WB confirmed presence of reactivity towards mitochondrial protein antigens, in particular of 35 and 60 kDa, though reactivity towards other protein antigens, including 17 kDa ones, were also seen in some patients, with the latter being associated with APS (p=0.008).

Conclusion: SLE patients positive for novel AMAs targeting mitochondrial outer membrane proteins develop severe lupus manifestations, including venous thromboembolism. Future studies are warranted to further characterize the novel antibodies, as well as determine their prognostic value.

POS0291 IDENTIFICATION OF SUBSETS OF SLE PATIENTS RESPONSIVE TO IBERDOMIDE BY TRANSCRIPTOMIC ANALYSIS OF BASELINE SAMPLES

Keywords: Artificial Intelligence, Systemic lupus erythematosus, Clinical Trials

P. Bachali[1], Y. Hu[2], N. Delev[3], P. Schafer[2], P. Lipsky[1]. [1]*AMPEL BioSolutions, Research and Development, Charlottesville, United States of America*; [2]*Bristol Myers Squibb, Research and Development, Princeton, United States of America*; [3]*Bristol Myers Squibb, Research and Development, Princeton, United States of America*

Background: Iberdomide is a high affinity cereblon ligand that promotes ubiquitylation and proteasomal degradation of Ikaros (IKZF1) and Aiolos (IKZF3) transcription factors and, thereby altering specific aspects of immune responsiveness. Iberdomide has been shown to be efficacious in a randomized controlled trial in patients with generalized SLE (NCT03161483) and to be specifically effective in patients with high baseline expression of the interferon gene signature (IGS)[1,2].

Objectives: The goal of this study was to identify subsets of SLE patients responsive to iberdomide more effectively by analyzing baseline gene expression profiles.

Methods: Baseline whole blood samples from 276 female SLE patients from the phase 2b iberdomide trial were utilized for this analysis. These patients had a >/= 6 month history of SLE and disease activity determined by SLEDAI-2K >/=6. Patients were randomized to placebo, or one of three doses of iberdomide (0.15, 0.3 or 0.45 mg per day). Clinical response was determined by the SLE Responder Index 4 (SRI-4) at 24 weeks. RNAseq was performed and analyzed by Gene Set Variation Analysis (GSVA) using 32 informative gene modules and K-means clustering.

Results: Whole blood K-means clustering of the GSVA scores yielded 5 clusters or endotypes (Figure 1). Cluster 0 had the fewest molecular abnormalities, whereas Cluster 1 had the most disturbances in immune function, including enrichments in the interferon gene signature (IGS), immunoproteasome, IL-1/inflammasome pathway, and neutrophil/granulocyte genes. Clusters 2-3 had intermediate degrees of abnormal enrichment in specific gene modules. Cluster 4 had high IGS, immunoproteasome, plasma cells/Ig chains, and IL-23 complex genes. No differences were noted between the subsets with regard to steroid or hydroxychloroquine use and differed only slightly in disease activity as measured by SLEDAI-2K. In general, cluster 1 had the most severe clinical laboratory measures with the highest anti-dsDNA antibodies and lowest C3 and C4. Clinical responses to iberdomide were confined to clusters 1 and 4. Effect sizes of responses in these groups approximated 30%. Other clusters had higher placebo responses and no additional response to iberdomide.

Conclusion: K-means clustering of GSVA scores from baseline samples of the iberdomide trial successfully clustered patients into endotypes that exhibited differences in response to iberdomide treatment, with the greatest responses observed in patients with the highest IGS, immunoproteasome, plasma cell, inflammasome, and IL-23 pathways. Gene expression based subsetting (endotyping) may be useful to enrich trials for responsive patients.

POS0292 TRANSCRIPTOMIC PROFILING OF SJOGREN'S SALIVARY GLANDS IDENTIFIES FOLLICULAR AND EXTRA-FOLLICULAR GENE SIGNATURES ASSOCIATED WITH RHEUMATOID FACTOR SEROPOSITIVITY

Keywords: Autoantibodies, Sjögren syndrome

E. Pontarini[1], D. Lucchesi[2], K. Goldmann[2], M. Lewis[2], Q. Song[3], E. Thomas[3], L. Y. Hao[3], K. Sivils[3], C. Pitzalis[2], M. Bombardieri[2]. [1]*William Harvey Research Institute, Queen Mary University of London, Experimental Medicine and Rheumatology, London, United Kingdom*; [1]*William Harvey Research Institute, Queen Mary University of London, Experimental Medicine and Rheumatology, London, United Kingdom*; [3]*Janssen Pharmaceuticals, Immunology Translational Science, Spring House, PA, United States of America*

Background: The presence of circulating rheumatoid factor (RF) and the formation of ectopic lymphoid structures (ELS) in labial salivary glands (SG) of patients with Sjögren's Syndrome (SS) have been reported as independent risk factors associated with the development of SG B-cell MALT lymphoma (MALT-L). Neoplastic MALT-L B-cells express highly hypermutated B-cell receptors bearing RF immunoreactivity in up to 50% of the cases, but whether their maturation and proliferation is dependent on ELS or is also induced by extrafollicular responses in the SG is currently unclear. The definition of ELS and their association with circulating autoantibodies has so far relied on SG histopathology which bears significant limitations. Conversely, molecular pathology analysis through whole-tissue RNA Sequencing (RNASeq) has allowed a better definition of disease heterogeneity and disease taxonomy.
Objectives: To perform transcriptomic profiling of SS minor SG tissue characterised by different degrees of inflammatory aggregate organization and to identify transcriptomic clusters and gene signatures associated with peripheral and histological biomarkers of disease.
Methods: Labial SG were obtained from 99 patients including SS with and without ELS (respectively ELS+ and ELS-, as assessed by immunohistochemistry) and non-specific chronic sialadenitis (Sicca). Total RNA was extracted, complementary DNA libraries were prepared and sequenced. Differentially expressed genes (DEG), deconvolution and pathway analysis were performed.
Results: Unsupervised gene clustering by differential expression between sicca and SS confirmed a clear transcriptome segregation between the two diagnoses. As expected, in SS SG expression of genes associated with inflammation and adaptive immune responses was upregulated (e.g. CCR7, CD19, CR2, CXCL13, CXCL9, CXCR5, FCRL3, FCRL4, IL21R, MS4A1, PAX5, SLAMF6, TLR10) (Figure A). Bulk RNAseq cell deconvolution confirmed immune cell enrichment (Th, B and plasma cells) in SS SG, especially those ELS+. A three-way comparison among sicca, ELS+ and ELS- SG, showed only a few genes specifically associated to ELS- and sicca, whereas most of the DEGs were either ELS+ specific or common to all SS (Figure B). Results of pathway analysis on ELS+ and SS-associated DEGs showed very similar profiles characterised by adaptive and interferon-associated pathway activation. Weighted Gene Co-Expression Network analysis showed higher activation of anti-viral pathways in ELS-SG, where ELS+ SG were enriched in adaptive immune pathways. Principal component analysis on SS SG mRNA showed that a significant proportion of variability was associated with the presence of RF in the serum of patients independently of the presence of ELS. Surprisingly, transcriptome clustering was closer between ELS+/RF+ and ELS-/RF+ SG than the clustering of ELS+/RF- with ELS-/RF- SG. Accordingly, SG of RF+ patients showed significant upregulation of B cell-associated genes (e.g. CXCL13, MS4A1). However, while SG transcriptomes of ELS+/RF+ were characterised by genes associated with germinal centre formation (e.g IL21, AICDA, LTB), transcriptomes from ELS-/RF+ SG displayed a unique set of DEGs such as BCL2, TRIM22, XAF1, DDX58, DDX60 and IFIT1. Conversely, a similar analysis performed based on anti-Ro/SSA and/or anti-La/SSB did not yield any significant differences in gene expression.
Conclusion: A comprehensive bulk RNA sequencing analysis of SS and sicca patients SG showed that higher tissue inflammation with features of functional germinal centres is associated to the presence of both RF and ELS, rather than ELS alone. Furthermore, the existence of a RF-driven SG transcriptome independent of the presence of ELS suggest that both follicular and extra-follicular responses support the selection of B-cells with RF immunoreactivity within the SG of SS patients and could be involved in B-cell lymphomagenesis.

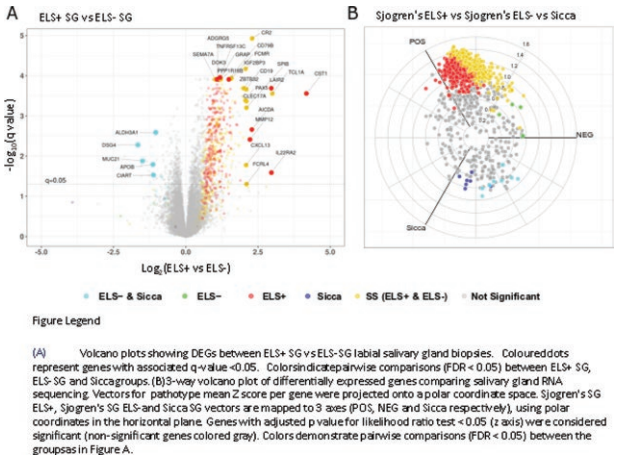

Figure Legend

(A) Volcano plots showing DEGs between ELS+ SG vs ELS- SG labial salivary gland biopsies. Coloured dots represent genes with associated q-value <0.05. Colors indicate pairwise comparisons (FDR < 0.05) between ELS+ SG, ELS- SG and Sicca groups. (B) 3-way volcano plot of differentially expressed genes comparing salivary gland RNA sequencing. Vectors for pathotype mean Z score per gene were projected onto a polar coordinate space. Sjogren's SG ELS+, Sjogren's SG ELS- and Sicca SG vectors are mapped to 3 axes (POS, NEG and Sicca respectively), using polar coordinates in the horizontal plane. Genes with adjusted p value for likelihood ratio test < 0.05 (z axis) were considered significant (non-significant genes colored gray). Colors demonstrate pairwise comparisons (FDR < 0.05) between the groups as in Figure A.

POS0293 METABOLOMIC IN ANTIPHOSPHOLIPID SYNDROME STRATIFIED PATIENTS ACCORDING TO THEIR THROMBOTIC RISK

Keywords: Artificial Intelligence, Cardiovascular disease, Anti-phospholipid syndrome

C. Lopez-Pedrera[1], M. A. Aguirre[1], I. Sanchez-Pareja[1], T. Cerdó[1], L. Muñoz-Barrera[1], P. Seguí Azpilcueta[2], C. Merlo[1], P. Ortiz Buitrago[1], D. Ruiz[3], M. C. Ábalos-Aguilera[1], N. Barbarroja Puerto[3], R. Ortega Castro[1], C. Perez-Sanchez[1]. [1]*IMIBIC/Reina Sofia Hospital/University of Cordoba, Rheumatology, Córdoba, Spain*; [2]*IMIBIC/Reina Sofia Hospital/University of Cordoba, Radiology, Córdoba, Spain*; [3]*IMIBIC/Reina Sofia Hospital/University of Cordoba, Medical and Surgical Science, Córdoba, Spain*

Background: Antiphospholipid syndrome (APS) is a systemic autoimmune disorder inducing hypercoagulable state that causes arterial, venous, or microvascular thrombosis, atherosclerosis, and pregnancy morbidity. Timely diagnosis and truthful monitoring of disease are decisive to improve the accuracy of therapy.
Objectives: 1. To map metabolic signatures in sera of APS patients and investigate its association with clinical features of the disease. 2. To investigate the short-term effects of *in vivo* ubiquinol (reduced coenzyme Q10 [Qred]) supplementation.
Methods: Serum nuclear magnetic resonance (NMR) metabolomics (>250 metabolites, Nightingale) covering glycolysis metabolites, amino acids and 130 lipid measures was performed on a cohort of primary APS patients (n=150) and 43 healthy donors (HD). Extensive clinical and analytical profile of recruited subjects was performed. NMR data were analyzed in MetaboAnalyst 5.0 software platform. To evaluate the contribution of metabolomic profiles to disease features, unsupervised machine learning clustering analyses were developed. Separately, 33 APS patients treated with Ubiquinol (Qred, reduced CoQ10, 200 mg/day) as an adjuvant treatment to standard therapy for one month, were also studied.
Results: Fifty-three metabolites were significantly altered in APS patients compared to HCs, involving decreased atheroprotective HDL subsets, sphingomyelins, phospholipids, and histidine, and increased proatherogenic VLDL subsets and fatty acids (MUFA, omega-3). Unbiased hierarchical clustering of metabolomic data identified two patient groups, presenting different metabolomic profiles. Clinically, although no differences were found in terms of age, gender, disease duration, or treatments, patients belonging to cluster 1 (C1) were characterized by higher thrombotic risk status (aGAPSS over 12), and prevalence of triple positivity for antiphospholipid antibody profile than C2 patients. Besides, C1 patients showed preponderance of arterial thrombosis, and comprised APS patients with

higher CV risk (elevated incidence of atheroma plaques, dyslipidemia, obesity, and hypertension). One hundred and forty-three metabolites were found deregulated between clusters. Thus, compared to C2, C1 had decreased atheroprotective HDL and increased atherogenic VLDL and LDL lipoproteins, increased triglycerides, fatty acids, apolipoproteins (ApoB), glycolysis related metabolites (glucose and pyruvate), amino acids (Leu, Tyr, Val, Phe, Ile), inflammation related metabolites (GlycA), and other lipids involved in immune cells activity, such as phosphatidylcholines, sphingomyelins, phosphoglycerides, and cholines. Of note, 28 metabolites were found altered in patients with thrombosis. Logistic regression analyses identified several metabolites which levels distinguished thrombotic APS patients with high accuracy, including VLDL and HDL subsets, fatty acids, amino acids, glucose and creatinine, all reportedly associated to enhanced CV risk. *In vivo*, Qred supplementation of APS patients partially reversed the altered serum metabolic profile linked to the development of atherosclerosis and thrombosis.

Conclusion: 1. APS patients have a distinctive metabolomic profile, with abnormalities associated with the pathogenesis of the disease, which are partially modified in vivo by Qred supplementation. 2. We have identified for the first time a metabolomic fingerprint able to stratify APS disease according to their thrombotic risk, which might pave the way for the development of new tools to improve their clinical management. POS0294 MITOCHONDRIAL DYSFUNCTION AND SENESCENCE OF NAÏVE T CELLS IN SJÖGREN´S SYNDROME

Keywords: Animal Models, Sjögren syndrome, Cell biology

P. Javorova[1], J. Fessler[2], C. Rammerstorfer[2], M. Zeiler[1], A. S. Muralikrishnan[1], A. Lackner[1], J. Hermann[1], S. Zenz[1], J. Thiel[1], M. Stradner[1]. *[1]Department of Internal Medicine, Division of Rheumatology and Immunology, Graz, Austria*; *[2]Otto Loewi Research Center for Vascular Biology, Immunology and Inflammation, Division of Immunology, Graz, Austria*

Background: Primary Sjögren's Syndrome (pSS) is a systemic autoimmune disorder characterized by lymphocytic infiltrations in exocrine glands. T-cells are considered major players in the pathogenesis of pSS. Previously, we reported premature aging and impaired homeostatic proliferation of pSS naïve CD4+ T-cells leading to peripheral lymphopenia [1]. Id3-deficient mice (Id3KO) develop a Sjögren's-like syndrome and are used as an animal model for pSS [2].

Objectives: As mitochondrial function has been linked to premature aging and homeostasis of T cells, we assessed the mitochondrial status of T cells in pSS patients and the Id3KO mouse model of pSS.

Methods: Total immune cells were isolated from venous blood, lymph nodes and the spleens of Id3KO and wild type (WT) mice. Flow cytometric analysis was performed to characterize markers of cellular senescence p53, senescence-associated β-galactosidase (SA-β-GAL), and apoptotic rate in T-cell subsets. Staining with mitochondrion-selective fluorescent dyes MitoTracker Green, MitoTracker Deep Red, MitoSox Red was performed to assess mitochondrial mass, membrane potential (MtMP) and superoxide production, respectively. Similar analyses were performed on human T-cells from peripheral blood mononuclear cells of pSS patients and matched healthy individuals (HC).

Results: Similar to pSS patients, ID3KO mice show signs of pre-mature aging. The naïve cell compartment in CD4+ and CD8+ T-cells was significantly decreased in all studied tissues when compared to WT mice. Markers of cellular senescence, p53 and SA-β-GAL activity were increased in naïve CD4+ and CD8+ T cells. Apoptotic rate was also higher in Id3 KO T-cells. ID3 KO T-cells also exhibited a remarkable decrease of mitochondrial mass and MtMP. Despite having reduced mitochondrial mass and MtMP, we observed that Id3-deficient T-cells produced a higher amount of mitochondrial superoxide compared to WT mice. Again, naïve CD4+ T-cells were most affected by this increase. In line with our findings in ID3 KO mice, naïve CD4+ and CD8+ T-cells isolated from pSS patients produced significantly higher amounts of mitochondrial superoxide than those of HC.

Conclusion: In human pSS and mice with a pSS phenotype, naïve T cells are diminished and exhibit signs of pre-mature aging associated with significant accumulation of mitochondrial superoxide. ID3 KO mice may serve as a tool to test whether these changes are cause or consequence of pSS pathophysiology.

POS0295 CD4+ T CELLS DEMONSTRATE METABOLIC REPROGRAMMING CHARACTERISED BY INCREASED REACTIVE OXYGEN SPECIES FORMATION AND ENHANCED ATP GENERATION IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Adaptive immunity

C. Wincup[1,2], M. Wilkinson[3], A. Radziszewska[4], G. Robinson[4], A. Rahman[1]. *[1]University College London, Rheumatology, London, United Kingdom*; *[2]King's College Hospital, Rheumatology, London, United Kingdom*; *[3]UCL Great Ormond Street Institute of Child Health, Inflammation and Rheumatology Section, London, United Kingdom*; *[4]University College London, Centre for Adolescent Rheumatology, London, United Kingdom*

Background: Systemic lupus erythematosus (SLE) is characterised by chronic stimulation of the innate and adaptive immune response. Oxidative stress resulting from Reactive Oxygen Species (ROS) generation is another hallmark of the disease. Mitochondria are a primary source of ROS and play a key role in energy metabolism via Oxidative Phosphorylation (OXPHOS), a vital pathway in maintaining the aberrant immunological response seen in the disease. Currently a number of novel therapeutics focusing on abnormal mitochondrial energy metabolism are under investigation in a variety of autoimmune diseases. Understanding abnormal immune cell mitochondrial function therefore represents an important area for identifying potential future targets in the treatment of SLE.

Objectives: To assess for evidence of abnormal mitochondrial function and associated ROS generation in the adaptive immune response in SLE.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from whole blood collected from patients with SLE recruited from the UCLH Lupus Clinic, England (n=37) and age/sex matched healthy controls (HC, n=20). Flow cytometry was used to quantify median fluorescence intensity (MFI) of cellular mitochondrial mass (MitoTracker) and mitochondria derived ROS generation (MitoSOX) in CD4+ and CD8+ T cells plus CD19+ B cells. Real-time CD4+ T cell mitochondrial metabolic function was assessed using SeaHorse Respirometry MitoStress Test. To assess for the role of cellular activation in CD4+ T cells, 24-hour anti-CD3/CD28 stimulation culture was conducted.

Results: Results are outlined in Figure 1. Briefly, mitochondrial mass was significantly higher in SLE CD4+ and CD19+ cells when compared with HC (A). CD8+ cells derived from patients with SLE showed higher amounts of mitochondrial ROS generation (B). When correcting for mitochondrial mass, individual mitochondria-derived ROS generation was significantly higher in CD4, CD8 and CD19+ cells in SLE when compared with HC (C). SeaHorse Respirometry revealed basal CD4+ respiration was higher in SLE when compared with HC (D), although there was no significant difference in maximal mitochondrial respiratory capacity (E). Proton leak, a marker of mitochondrial damage, was significantly higher in SLE than HC (F). CD4+ T cells from patients with SLE also showed enhanced mitochondrial ATP production when compared with HC (G), although spare respiratory capacity was significantly reduced in SLE (H) suggesting that mitochondria function in the disease is close to maximum with little scope for further upregulation. Mitochondrial uncoupling efficacy is an important mechanism through which higher rates of OXPHOS can be achieved and this appears to be downregulated in SLE (I). Activation of SLE CD4+ T cells appeared to drive higher rates of ROS production in both CD4+ and CD8+ cells (J). Interestingly, CD19+ ROS production was also increased, suggesting that T cell secreted cytokines following activation may also induce B cell ROS generation. Stimulation of SLE CD4+ T cells additionally increased basal mitochondrial respiration when compared with unstimulated SLE CD4+ T cells (K).

Conclusion: Increased mitochondrial mass seen in CD4+ and CD19+ SLE cells could be a result of enhanced immune cell senescence, commonly observed in the state of chronic immune activation. At baseline, SLE derived CD4+ T cells were noted to generate ATP through OXPHOS at a higher rate than HC thus suggesting chronic cellulation activation (and is further enhanced following T cell stimulation). CD4+ T cells also demonstrate a number of important pathological abnormalities in SLE, including high levels of proton leak, reduced spare respiratory capacity and lower ability for mitochondrial uncoupling. This may suggest that chronic activation is in turn resulting in mitochondrial damage and less efficient energy metabolism, resulting in ROS generation. Targeting this abnormal immune cell metabolic pathway therefore represents a novel therapeutic strategy.

GENE EXPRESSION IN SLE PATIENTS, DOMINATED BY UNIQUE B CELL PROFILES, DISTINGUISHES THOSE WITH CLINICAL IMPROVEMENT FROM ABATACEPT

Keywords: Clinical Trials, Systemic lupus erythematosus, Biomarkers

K. Thomas[1,2], M. Smith[1], C. Guthridge[1], N. Dominguez[1], S. Macwana[1], W. Dejager[1], P. Schafer[3], S. Kamp[1], A. Thanou[1], C. Arriens[1], J. Merrill[1], J. A. James[1,2], J. Guthridge[1,2]. *[1]Oklahoma Medical Research Foundation, Arthritis & Clinical Immunology, Oklahoma City, United States of America*; *[2]University of Oklahoma, Pathology, Oklahoma City, United States of America*; *[3]Bristol-Myers Squibb, Translational Medicine Disease, Princeton, United States of America*

Background: Abatacept (ABA or CTLA4Ig) is a fusion protein that interferes with co-stimulation of T cells and antigen-presenting cells by inhibiting interactions between CD28 and CD80/86. ABA is effective in rheumatoid arthritis, but clinical trials of patients with Systemic Lupus Erythematosus (SLE) have produced disappointing results. Exploratory analyses of clinical subsets has led to the hypothesis that ABA might benefit some SLE patients depending on disease severity or outcome defnitions[1,2], but identification of reproducible predictors of response remains elusive.
Objectives: We used data and samples collected from previous clinical trials to identify pathways of SLE pathogenesis and potential biomarkers which predict clinical response to ABA.
Methods: Samples were obtained from 20 patients from the ABC study which evaluated ABA in SLE patients without organ-threatening disease on limited background medications and 46 patients from the ACCESS trial of ABA in active nephritis patients on a background of low dose cyclophosphamide followed by azathioprine. Neither trial met their key endpoints vs placebo. Pre-treatment gene expression profiles were compared in those who did or did not achieve clinical response to ABA. HSIC-Lasso[3] was employed to select the top 20 independent features from whole blood transcriptomic profiles which best distinguished responders and non-responders across both trials. B cells, monocytes, and T cells were isolated from ABC patient PBMCs for further cell type-specific transcriptomic profiling. Differentially expressed genes (DEGs) were identified in each cell type by DESeq2 at false discovery rate < 0.1.
Results: Pre-treatment DEGs associated with abatacept responders were cell type-specific, with the most distinctions observed in B cells (Figure 1). These DEGs included FCRLA, CXCR3, and TNFRSF17, indicating baseline differences in B cell activation and differentiation in responding patients. Baseline whole blood expression patterns could distinguish later response vs non-response to ABA in both clinical trials (Figure 1). Transcripts identified by HSIC-Lasso included multiple unannotated lncRNAs and pseudogenes, as well as transcription factors, transporters, and enzymatic components of cell structure and metabolism. Random forest modeling and receiver operating characteristics (ROC) were employed to test the ability of differentiating transcripts to predict response (Figure 1). 5-fold cross validation of the predictor on a training set of 52 samples had 85.8 (± 2.2) % accuracy with ROC AUC: 0.939 (± 0.0166). 14 confirmation samples were similarly modeled and achieved an accuracy of 83.3% with ROC AUC: 0.944.
Conclusion: The pathophysiology of SLE is heterogeneous and complex, but approaches to predict treatment response by patterns of gene expression may help identify patients most likely to benefit from a given treatment.

Background: We employed urine proteomics to define the molecular signatures associated with the histological features quantified by the NIH activity and chronicity indices.
Objectives: We employed urine proteomics to define the molecular signatures associated with the histological features quantified by the NIH activity and chronicity indices.

Methods: Glomerular and interstitial lesions in lupus nephritis were quantified (scored 0-3) based on the revised 2018 International Society of Nephrology/ Renal Pathology Society (ISN/RPS) classification for lupus nephritis and the modified NIH scoring system by a central renal pathologist (JH). Urinary proteins (1200 biomarkers, RayBiotech Kiloplex) were quantified in urine samples collected on the day of (73%) or within 3 weeks of (27%) the diagnostic kidney biopsy. Proteomic signatures of each lesion were defined based on Spearman correlations of each urine protein with each pathologic lesion.
Results: Ninety-one biopsies were included: 32 (35%) with pure proliferative LN, 33 (36%) with pure membranous LN, and 26 (29%) with mixed LN. The 5 most correlated urinary proteins and each pathologic feature are summarized in Figure 1A-B. Most lesions in the activity or chronicity indices shared a similar signature within their respective index. In contrast, fibrous crescents displayed an inflammatory signature (CD73, MMP9, MIP1b, and IL-8) despite being part of the NIH chronicity index. Hierarchical clustering based on proteomic signatures revealed that fibrous crescents were more similar to activity-related lesions (Figure 1C). Interstitial inflammation (activity) was correlated with biomarkers associated with both active and chronic lesions.

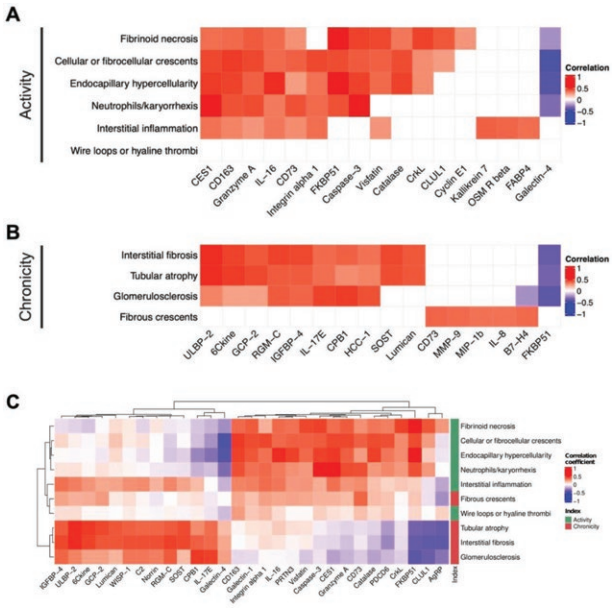

Figure 1.

Conclusion: Although fibrous crescents are considered inactive lesions that follow crescentic glomerulonephritis, urine proteomics revealed inflammatory activity associated with fibrous crescents. Several cell types such macrophages, fibroblasts, neutrophils, lymphocytes, and epithelial cells are critical in the formation of crescents. Higher levels of CD73, IL-8 and MMP9 indicate the presence of an inflammatory response involved in glomerular remodeling after extra-capillary proliferation that have an important role in kidney damage. The presence of fibrous crescents in kidney biopsies may indicate ongoing potentially treatable inflammation. Interstitial inflammation, which is linked to worse clinical outcomes, showed a distinct proteomic signature combining both activity and chronicity. A better understanding of the pathophysiology of processes including fibrous crescents and interstitial inflammation is needed to tailor treatment of these pathways leading to chronic damage.

Background: The International Map of Axial Spondyloarthritis (IMAS) is a global assessment of the impact and burden of axial spondyloarthritis (axSpA) from the patient perspective, and identifying the unmet needs of axSpA patients through a survey. This research started in 2016 with the Atlas of Axial Spondyloarthritis in Spain, expanded in 2017-2018 to 13 European countries giving rise to the European Map of Axial Spondyloarthritis (EMAS) and further expanding worldwide across 27 countries to become the International Map of Axial Spondyloarthritis (IMAS).
Objectives: Here we present the scope of the study, distribution and main characteristics of patients included and instruments to collect data, as well as highlighting the impact of the disease.
Methods: This research is a collaboration between the Axial Spondyloarthritis International Federation (ASIF), the University of Seville and Novartis Pharma AG together with a scientific committee composed of axSpA patient representatives, rheumatologists, psychologists, and researchers. IMAS collected information through an online cross-sectional survey (2017-2022) from unselected axSpA patients from Europe, Asia, North America, Latin America and Africa. The inclusion criteria were: age ≥ 18 years, residents in the specified country, a diagnosis of axSpA (self-reported AS/nr-axSpA) and under the care of an health care professional. Patients completed a comprehensive questionnaire containing over 120 items on socio-demographics, health behaviours, diagnosis and disease characteristics, comorbidities, mental health (General Health Questionnaire- GHQ-12), healthcare resource utilization, pharmacological treatments, disease activity (BASDAI), physical activity and functioning, employment, and disease related fears and hopes.
Results: 5,557 axSpA patients participated in IMAS. The mean age was 43.9±12.8 years, 55.4% were women, 46.2% had university education and 48.5% were employed. 20.6% were on sick leave (temporary or permanent), 71.4% had difficulty finding job due to axSpA and 71.0% reported work-related issues. Patients' diagnostic delay was a mean of 7.4±9.0 years (median: 4.0), and the mean disease duration was 17.1±13.3 years. 75.0% of patients had active disease and 59.4% were at risk of poor mental health. In addition, patients had a mean of 2 physical comorbidities. On average, patients had visited primary care physicians 4.6 times and the rheumatologist 3.6 times in the year prior to the survey. 78.6% had ever taken NSAIDs, 43.6% csDMARDs and 48.8% bDMARDs. The greatest fear of these patients was disease progression (55.9%), while the greatest hope was to be able to relief pain (54.2%).
Conclusion: IMAS is the largest survey in geographical reach and this is the first-time global results are presented. IMAS has shown the global profile of axSpA patients, highlighting unmet needs, including unacceptable delays in diagnosis, and high burden of the disease in axSpA patients worldwide. This global dataset will enable more detailed investigations to obtain evidence on the critical issues that matter to patients around the world in order to improve their care and quality of life.

Map 1. Distribution of IMAS patients by region (N= 5,557)

POS0299 NEUROPATHIC AND NEUROPLASTIC PAIN COMPONENTS DETERMINE THE PRESENCE OF RESIDUAL SYMPTOMS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS RECEIVING BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

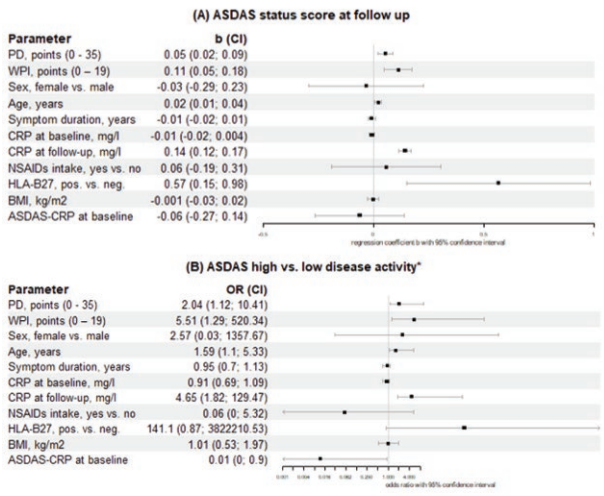
Keywords: Spondyloarthritis, Pain, bDMARD

F. Al Mohamad[1], V. Rios Rodriguez[1], H. Haibel[1], M. Protopopov[1], J. Rademacher[1,2], J. Sieper[1], M. Torgutalp[1], H. Käding[1], F. Proft[1], D. Poddubnyy[1,3]. [1]*Charité - Universitätsmedizin Berlin, Department of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*; [2]*Berlin Institute of Health (BIH), Clinician Scientist Program, Berlin, Germany*; [3]*German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany*

Background: Several studies have investigated neuropathic pain (NP) as a component of chronic pain in patients with axial spondyloarthritis (axSpA)/ ankylosing spondylitis (AS) and showed a wide frequency range from 22 – 56.9% [1, 2]. Neuroplastic processes leading to central sensitization have been described as another component of pain chronification in rheumatic diseases [3]. Widespread pain is considered a characteristic of central sensitization [4]. It is, however, unclear, what is the relevance of neuropathic and neuroplastic components of pain for the treatment response and the presence of residual symptoms in patients with radiographic axSpA (r-axSpA) treated with biological disease-modifying anti-rheumatic drugs (bDMARDs)

Objectives: To investigate the impact of neuropathic pain and neuroplastic/ widespread pain on residual disease activity in patients with r-axSpA receiving (bDMARDs).

Methods: Patients with r-axSpA (AS fulfilling the modified New York criteria) and starting a bDMARD therapy were recruited between 2015 and 2019 and followed up in an extension of the prospective German Spondyloarthritis Inception Cohort (GESPIC). Neuropathic pain was quantified using the pain detect questionnaire (PD), whereas neuroplastic pain was quantified using the Widespread Pain Index (WPI). Disease activity was measured using the Ankylosing Spondylitis Disease Activity Score – C-reactive protein (ASDAS-CRP) score. Simple and multiple linear and logistic regression analyses were performed to determine the effects of NP and WPI on the ASDAS status score under bDMARD treatment.



Results: A total of 130 patients with r-axSpA were included in this cohort. PD and WPI scores were available at at least one follow-up time-point in 99 patients. Of these 70 were receiving bDMARD treatment (n=68 under TNFi and n=2 under IL17 inhibitors) with no missing data and could be included in this analysis. The first follow-up point with available PD and WPI scores while under bDMARD treatment was used for the analysis.

Table 1. Baseline characteristics.

Characteristic	n = 70
Female sex	49(70)
Age, years	37.27±10.77
HLA-B27 positive	64(91.4)
BMI, kg/m²	25.57±4.49
Current smokers	28(40)
Symptom duration, years	12.53±10.83
Elevated CRP, >5 mg/l	43(61.4)
ASDAS-CRP	3.41±0.82
current NSAIDs intake	56(80)

Data are expressed as n(%) or mean ± standard deviation, BMI: Body mass index, CRP: C-reactive protein, ASDAS-CRP: Ankylosing Spondylitis Disease Activity Score – C-reactive protein, NSAIDs: Nonsteroidal anti-inflammatory drugs The mean (±SD) bDMARD treatment duration was 2.79 ± 1.40 (range: 0.27 – 5.01) years at the time point of PD and WPI measurement. Higher PD and WPI scores at follow up showed a significant association with higher ASDAS-CRP scores in a multiple linear regression model. This was also true for age, HLA-B27 and the CRP level at follow-up. Logistic regression analysis showed that a high PD score and a high WPI score were also associated with higher odds of having high/ very high disease activity (ASDAS >2.1) independently of other factors including elevated CRP.

Figure1: Association between the ASDAS-CRP score at follow-up (A) and ASDAS high/very high disease activity at follow-up (B) with the presence of neuropathic (PD) and neuroplastic (WPI) symptoms in multiple regression analyses.

*defined as ASDAS-CRP score higher than 2.1 or lower respectively, PD: Pain detect, WPI: Widespread Pain Index, CRP: C- reactive protein, NSAIDs: Nonsteroidal anti-inflammatory drugs, BMI: Body mass index, ASDAS-CRP: Ankylosing Spondylitis Disease Activity Score – C-reactive protein

Conclusion: Both PD and WPI reflecting neuropathic and neuroplastic components of pain showed association with residual symptoms (as reflected by higher ASDAS) independently of systemic inflammation (as reflected by elevated CRP) in patients with r-axSpA receiving bDMARD treatment.

POS0300 PATIENT ACCEPTABLE SYMPTOM STATE IN RELATION TO DISEASE ACTIVITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS FROM A LARGE STANDARD-OF-CARE COHORT

Keywords: Patient reported outcomes, Outcome measures, Spondyloarthritis

M. Carbo[1], A. Kampman[2], D. Paap[1], F. Wink[2], A. Spoorenberg[1], S. Arends[1]. [1]*University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands*; [2]*Leeuwarden, Department of Rheumatology, Leeuwarden, Netherlands*

Background: The patient acceptable symptom state (PASS) is the level beyond which patients consider themselves well. This concept can help to interpret results of clinical trials and enhance physician-patient communication in daily clinical practice.(1)

Objectives: To explore the association of PASS with disease activity according to ASDAS and other patient- and disease characteristics in a large standard-of-care cohort of patients with in axial spondyloarthritis (axSpA).
Methods: Patients from the Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort visiting the outpatient clinic between May 2016 and October 2019 were included in this cross-sectional analysis. Patient characteristics and clinical assessments were measured according to the standardized GLAS protocol. Additionally, patients were asked to fill out the PASS question: "Considering all the different ways axSpA is affecting you and if you stay in this state for the next months, do you consider your current state satisfactory? ("yes": PASS/"no": non-PASS). Logistic regression analysis was used to explore patient and disease characteristics associated with PASS. ROC analysis with area under the curve (AUC) was used to analyze the accuracy of the ASDAS and the optimal cut-off point to predict PASS according to the highest Youden's index.
Results: Of the 673 included axSpA patients, 63% were male, mean was age 48±14 years, median symptom duration 19 (11-31) years and mean ASDAS 2.3 (±0.9). In total, the vast majority (76%) reported an acceptable symptom state according to the PASS question. Patients in the PASS group had significantly lower ASDAS compared to the non-PASS group (mean 2.0 ±0.8 vs. 3.2 ±0.8). Patients with an acceptable symptom state also had significantly lower BASDAI scores, were more often male, had longer symptom duration, had less tender entheses, used less often NSAIDs, experienced better physical function (BASFI) and quality of life (ASQoL), and had less radiographic damage (mSASSS) (Table 1). In multivariable regression analysis, lower ASDAS (OR: 4.45 (3.26-6.09)), longer symptom duration (OR 0.97 (0.95-0.99)) and absence of tender enthesis (OR 1.74 (1.85-2.79)) were independently associated with presence of PASS (Nagelkerke R^2: 0.38). The ASDAS showed good accuracy to predict PASS, with an AUC of 0.84 (95% CI 0.80-0.85). The optimal cut-off point of ASDAS for presence of PASS was 2.7 (sensitivity 77%, specificity 78%). A total of 214 patients had had an acceptable symptom state but active disease according to the ASDAS cut-off value for active disease of 2.1, this is 44% of patients being in PASS.
Conclusion: In axSpA patients from a standard of care cohort, 76% had an acceptable symptom state. Lower ASDAS, longer symptom duration, and absence of tender enthesis were independently associated with an acceptable symptom state. AxSpA patients experiencing an acceptable symptom state can still have active disease according to the ASDAS.

Table 1. Patient characteristics

	Total n= 673	PASS n=514 (76%)	Non-PASS n= 159 (24%)	p-value
Age (years)	48 (14)	49 (±13)	45 (±14)	<0.01*
Male gender	425 (63%)	336 (65%)	89 (56%)	0.04*
Symptom duration (years)	19 (11-31)	20 (12-31)	15 (7-29)	<0.01*
HLA B27+	539 (78%)	405 (79%)	125 (79%)	0.47

POS0301 IMPACT OF NSAIDS ON 8-YEAR INCIDENCE OF MAJOR CARDIOVASCULAR EVENTS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Cardiovascular disease, Spondyloarthritis

O. Fakih[1], M. Desmarets[2,3], B. Martin[2], C. Prati[1,4], D. Wendling[1,5], E. Monnet[2], F. Verhoeven[1,4]. [1]*Besançon, Service de rhumatologie, CHU de Besançon, Besançon, France*; [2]*Besançon, Centre d'investigation clinique 1431, CHU de Besançon Inserm, Besançon, France*; [3]*UMR 1098 Right, Inserm, Etablissement Français du Sang, Besançon, France*; [4]*Besançon, EA 4267 "PEPITE", UFR Santé, Université de Franche-Comté, Besançon, France*; [5]*EA 4266 "EPILAB", UFR Santé, Université de Franche-Comté, Besançon, France*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease associated with the occurrence of major cardiovascular events (MACEs). The effect of AS treatments on the occurrence of MACEs is poorly studied, especially for non-steroidal anti-inflammatory drugs (NSAIDs), whose cardiovascular risk remains debated in this disease.
Objectives: To determine the incidence of MACEs in patients newly benefiting from long-term illness (LTI) for AS and to study the relationship between AS treatments and MACEs.
Methods: This national cohort study was based on the national health data system Système National des Données de Santé (SNDS), a French national medico-administrative database containing data containing administrative data, data on LTIs, outpatient care and medication consumption, and hospitalizations of all beneficiaries of the French health insurance system. All patients newly benefiting from the LTI #27 "severe spondyloarthritis", with associated diagnostic code M45 (AS), between 2010 and 2013, were included. The use of LTI allowed us to build a cohort of patients with a supposedly active disease, the SNDS, being a medico-administrative database, having no data on the activity of the disease. All patients with active SpA despite NSAID treatment, and therefore requiring disease-modifying anti-rheumatic drugs (DMARDs), were theoretically newly enrolled in the LTI scheme. The end date of follow-up was 31 December 2018. The occurrence of MACEs (stroke and myocardial infarction [MI]) and comorbidities (diabetes, hypertension, dyslipidemia, smoking, obesity, chronic kidney disease, atherosclerosis, and depression) were identified using algorithms previously described in the literature. An analysis taking into account the competitive risk of death and an inverse propensity score weighting (determining the likelihood of NSAID treatment) was performed to compute cumulative incidence functions and determine the subhazard ratios (SHRs) for the occurrence of MACEs for the different treatments of interest.
Results: Between 2010 and 2013, 22929 patients were included (mean age 43.0 (SD 13.9) years, 44.9% male). During follow-up, 344 MACEs (195 strokes, 152 MI) and 415 deaths were identified. The cumulative 8-year incidences of MACE, stroke and MI were 1.81% [1.61-2.05], 0.97% [0.83-1.14] and 0.85% [0.71-1.04] respectively. The occurrence of MACE was associated in univariate analysis with age (SHR: 1.07 [1.06-1.07]), male sex (SHR: 1.61 [1.31-2.00]), diabetes (SHR: 2.21 [1.63-3.00]), dyslipidaemia (SHR: 3.67 [2.96-4.57]), and hypertension (SHR: 3.74 [2.87-7.49]) (p<0.001 in all cases). After inverse propensity score weighting, NSAIDs (SHR: 0.40 [0.32-0.49], p<0.001) and anti-TNFs (SHR: 0.61 [0.47-0.81], p<0.001) were associated with a lower risk of MACE occurrence, which was not the case for conventional synthetic DMARDs (SHR: 0.89 [0.63-1.24]) and anti-IL17 (SHR: 2.06 [0.78-5.44]). Similar results for DMARDs were found when stratifying the analysis on the presence or absence of NSAID treatment (Table 1).
Conclusion: The incidence of MACEs at eight years is low in patients newly benefiting from LTI for AS. Our results support the hypothesis of a protective role of NSAIDs and anti-TNF drugs on cardiovascular risk in these patients.

Table 1. Inverse Probability Treatment Analysis with stabilized weighted subhazard ratio (wSHR) and its 95% confidence interval [95% CI] stratified by non-steroidal anti-inflammatory drugs (NSAIDs) treatment.

	wSHR [95% CI] global	wSHR [95% CI] in patients treated with NSAIDs	wSHR [95% CI] in patients NOT treated with NSAIDs
NSAIDs	0.39*** [0.32-0.50]	N/A	N/A
csDMARDs	0.89 [0.63-1.24]	0.91 [0.58-1.43]	1.02 [0.61-1.71]

Background: Studies have reported that female patients with spondyloarthritis (SpA) have different disease courses and treatment responses compared to male patients. Whether patients' sex, the biological attributes associated with being male or female, is associated with a different outcome after receiving one-year of tight control, treat-to-target (T2T) strategy remain uncertain.
Objectives: This study aimed to evaluate the differences in the clinical response between male and female patients from the Asia Pacific League of Associations for Rheumatology (APLAR) SpA Registry.
Methods: Patients who fulfilled the CASPAR 2006 classification criteria for psoriatic arthritis (PsA) and 2009 ASAS classification for axial spondylitis (AxSpA) were recruited. They received 1 year of protocolized treatment aiming at 1) minimal disease activity (MDA) *or Disease Activity in Psoriatic Arthritis* (DAPSA) low disease activity (LDA) for PsA patients, and 2) *Ankylosing Spondylitis Disease Activity Score* (*ASDAS*) LDA for AxSpA patients. Patients were assessed every 3 monthly and treatment was escalated if target was not reached.
Results: 63 male (age: 45±15 years, 27 PsA, 36 AxSpA) and 36 female (age: 46±12 years, 22 PsA, 14 AxSpA) subjects from 6 Asia-Pacific regions were included. At baseline, male had more tender joints but less severe enthesitis than female. Male AxSpA patients had a lower Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) but male PsA patients had a higher DAPSA. Other baseline characteristics were shown in Table 1. During the study period, the use of conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) decreased slightly, while the use of biologics (bDMARDs) significantly increased across both sexes (Figure 1). After 1-year treatment, there were significant improvements in disease activity in the entire cohort (DAPSA: 15.3±11.6 at baseline vs 10.1±11.2 at 1-year, p=0.002; ASDAS: 2.4±1.0 at baseline vs 1.9±0.9 at 1-year, p=0.003). Despite having lower CRP levels (2.3 ± 2.5mg/L in female vs 8.7±17.7mg/L in male, p=0.008) and higher bDMARDs use in female patients (54% in female vs 45% in male) at 1-year, their clinical responses were less optimal compared to male patients. Female patients had a higher patients' global assessment score (3.9±2.4 in female vs 2.9±2.2 in male, p=0.035). Disease activity in female PsA patients and the number of tender joint count in both PsA and AxSpA increased while that in male patients improved (% change in DAPSA: -47% in male vs +19% in female, p=0.003); % change in tender joint count: -70% in male vs +19% in female, p=0.014). Both patients' and physicians' global assessment scores increased in female SpA patients whilst that in male SpA patients decreased. There was also a trend showing less improvement in other parameters in female patients (Figure 1).

Table 1. Demographics, clinical features and disease activity in patients with Spondyloarthritis in APLAR region at baseline, stratified by gender

[1]For Axial SpA only, [2]for PsA only.

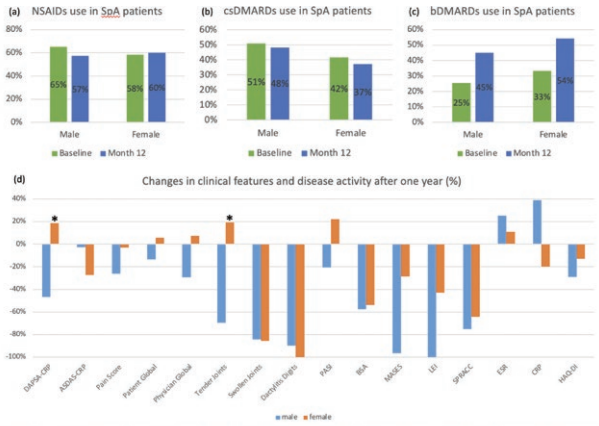

Figure 1 - NSAIDs (a) / csDMARDs (b) / bDMARDs (c) use at baseline and 1-year and changes in clinical features and disease activity after 1-year treatment (d) in male and female SpA patients.

Conclusion: There may be differential treat-to-target responses between male and female SpA patients. The causes of such differential characteristics should be further explored to potentially implement a sex-specific treat-to-target strategy for spondyloarthritis.

POS0303 IMPACT OF PREGNANCY ON SACROILIAC IMAGING IN WOMEN WITH AXIAL SPONDYLOARTHRITIS: RESULTS OF THE ANALYSIS OF THE DESIR COHORT

Keywords: Spondyloarthritis, Descriptive Studies, Imaging

E. Portier[1,2], M. Dougados[1,2], A. Ruyssen-Witrand[3], A. Moltó[1,2]. [1]*Cochin Hospital, Rheumatology, PARIS, France*; [2]*ECAMO, INSERM U-1153: Clinical Epidemiology and Biostatistics, PARIS, France*; [3]*University Hospital of Toulouse, Rheumatology, Toulouse, France*

Background: Axial spondyloarthritis (axSpA) is typically characterized by imaging (radiographs or MRI) abnormalities of the sacroiliac joints (SIJ). Also, inflammatory lesions of the SIJ have been observed in healthy women post-partum [1,2]. However, the impact of pregnancy on imaging abnormalities in women with axSpA is unknown.
Objectives: The objective of this study was to evaluate impact of pregnancy on SIJ imaging in patients with early axSpA.
Methods: Data of all women with early axSpA from the DESIR prospective cohort were included, with a follow-up of 5 years. Description of demographic disease characteristics, obstetric history, and SIJ imaging abnormalities (i.e. sacroiliitis on radiographs and on MRI, based on local and central reading) was performed in all women. SIJ abnormalities were compared depending on the history of past pregnancy (t-test and chi-square as appropriate). Furthermore, in nulligravidae females at baseline who presented an incident pregnancy during follow-up, SIJ abnormalities were compared before/after pregnancy, using paired-test.
Results: 381 patients were included in the analysis. 142 (37%) were nulligravidae at baseline, and were younger (28 vs 39 years old) and had higher educational level (74 vs 52% university level). Sacroiliitis on MRI and X-ray were more frequent in nulligravidae women (16.9% vs 9.9%, p = 0.05 and 33.8% vs 19.4%, p < 0.01, respectively). Among them, 38 (10% of all patients) presented an incident pregnancy during follow-up and had an available imaging before and after pregnancy: overall no significant changes were observed with regard to both radiographic and MRI imaging abnormalities of the SIJ, except for an increase on the New York score of the left SIJ, and surprisingly, a trend towards a reduction on the proportion of MRI sacroiliitis and SPARCC score after pregnancy (**table 1**).

Table 1. Imaging characteristics in women with axSpA who had first pregnancy during follow up, with description before/after delivery and paired-test with Mc Nemar of Student test (for binary and continuous variables, respectively).

Imaging criteria *(mean (sd) or number (%))*	**Before pregnancy (N = 38)**	**After delivery (N = 38)**	**Paired test (Mc Nemar or Student)**
Radiographic criteria			
X-ray sacroiliitis	8 (21.1%)	9 (23.7 %)	p = 0.37
New York score on right sacroiliac joint	0.66 (1.06)	0.67 (0.86)	p = 1
New York score on left sacroiliac joint	0.67 (1.07)	0.95 (0.95)	**p = 0.037**
Any erosion in the sacroiliac joints	9 (23.7%)	9 (23.7%)	p = 0.48
Any joint widening in the sacroiliac joints	0	3 (7.9%)	NA
Any sclerosis in the sacroiliac joints	6 (15.8%)	9 (23.7%)	p = 0.13
Any partial or total ankylosis in the sacroiliac joints	1 (2.6%)	2 (5.3%)	p = 0.48
MRI criteria			
Sacroiliitis on MRI	18 (47.3%)	2 (5.2%)	p = 0.074
SPARCC score	3.94 (7.63)	0.39 (0.74)	p = 0.15
≥ 3 fatty lesions on MRI	4 (10.5%)	1 (2.6%)	p = 1
≥ 3 erosions on MRI	1 (2.6%)	0	NA
≥ 5 fatty lesions and/or erosions on MRI	1 (2.6%)	1 (2.6%)	p = 1
Number of any lesions on sacroiliac joint (0 to 144)	1.81 (3.36)	1.8 (2.92)	p = 0.1
Number of enthesitis (0 to 12)	0 (0)	0 (0)	NA
Number of erosions (0 to 40)	0.84 (2.36)	0.42 (0.7)	p = 1
Number of fatty lesions (0 to 40)	0.97 (2.01)	1 (2.02)	p = 0.15
Number of sclerosis (0 to 40)	0 (0)	0.26 (0.86)	p = 0.29
Number of partial or total ankylosis (0 to 24)	0 (0)	0 (0)	NA

Conclusion: In an early SpA cohort, the occurrence of a first pregnancy did not seem to increase the number of imaging abnormalities of the SIJ.

POS0304 IN-SILICO MODELLING OF THE SACROILIAC JOINTS DEMONSTRATES INFLUENCE OF JOINT FORM VARIATION ON MECHANICAL STRESS

Keywords: Spondyloarthritis, Imaging, Gender/diversity issues

M. Heyland[1], D. Maikath[1], P. Damm[1], K. G. Hermann[2], K. Ziegeler[2]. [1]*Charité – Universitätsmedizin Berlin, Berlin Institute of Health - Julius Wolff Institut, Berlin, Germany*; [2]*Charité Universitätsmedizin Berlin, Radiology, Berlin, Germany*

Background: Recent studies have uncovered an association between atypical joint form morphology and mechanical disease of the sacroiliac joints [1] and sclerosis in healthy controls [2]. A possible explanation for the effect is a change in load distribution in atypical joint forms and thus increased mechanical stress in affected patients.

Objectives: To investigate the effect of joint morphology on joint stress, using finite element models (FEM).

Methods: FE models were computed using dedicated software (Amira Software, Zuse Institute Berlin and Thermo Fisher Scientific, 2021), from CT scans of five patients without disease of the sacroiliac joints from a retrospective patient cohort[2]. Selected were patients with known anatomical variants (accessory joint, crescent-shaped ilium and intra-articular joint form variant; all female individuals) as well as a typical male and a typical female joint, based on radiological assessment. The models included both information on bone elasticity, derived from bone density on CT and stiffness of ligaments and muscles from the literature (visualization in Figure 1). Lastly, loading conditions during bipedal walking were simulated in all models, drawing from in-vivo data. Mean von Mises stress as well as percentage of joint surface above critical stress value (defined as 7 MPa) during y-axis loading (e.g. standing upright) and bipedal walking were compared between different joint morphologies.

Results: Table 1 provides a summary of the results. In axial loading (=y-axis stress) highest median stress and 99th percentile stress was observed in the crescent-shaped ilium with 12.5 Mpa and 28.8 Mpa respectively, while the iliosacral complex exhibited the lowest median stress (7.0 MPa) and the second highest 99th percentile value (25.1 MPa), indicating a less even distribution of stress. For bipedal walking the highest stress was also observed in the crescent shaped ilium with 64.2% of joint surface showing more than 7 Mpa during ipsilateral toe off vs. only 22.7% in the iliosacral complex. In all load scenarios, stresses were higher in the typical female joint than in the typical male joint.

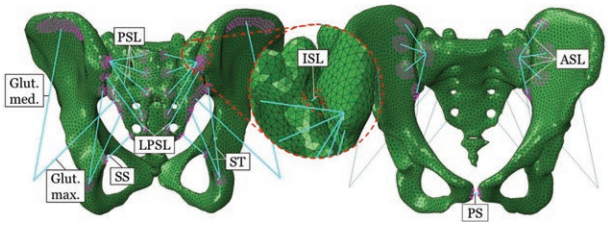

Figure 1. Example of FE-model with ligaments and muscles. Left=posterior view; right=frontal view. Glut. Med.=gluteus medius muscle; Glut. Max.=gluteus maximus mscle; SS=sacrospinous ligament; PSL=posterior sacroiliac ligament; LPSL=long posterior sacroiliac ligament. ST=sacrotuberous ligament; ISL=interosseous sacroiliac ligament; ASL=anterior sacroiliac ligament; PS=pubic symphysis;.

Table 1 . Summary of results. 99th percentile=value, below which 99% of measured values within the joint lie. Static y-axis=axial or downward stress, e.g. during standing upright; IHS=ipsilateral heel strike; CTO=contralateral toe off; CHS=contralateral heel strike; ITO=ipsilateral heel strike.

Joint form	**Von Mises stress [Mpa]**		**%joint surface above 7Mpa**					
	Median	**99th percentile**	**Static y-axis**	**Gait cycle phase**				
				IHS	**CTO**	**Swing**	**CHS**	**ITO**
Typical female	8.1	18.9	61	49	56	34	39	51
Typical male	8.5	18.2	66	38	26	20	39	16
Crescent-shaped	12.5	28.8	92	43	54	27	43	64
Iliosacral complex	7.0	25.1	50	26	21	13	20	23
Accessory joint	9.9	20.0	72	43	38	28	31	46

Conclusion: Finite element modelling revealed differences in load extent and distribution across different sacroiliac joint morphologies, strengthening the evidence, that morphology may play a role in mechanical joint stress. Further studies with larger numbers of computed models per joint form are needed to validate these first exploratory results.

POS0305 CONTINUING TNFI AFTER PREGNANCY DIAGNOSIS IN WOMEN WITH CHRONIC RHEUMATIC INFLAMMATORY DISEASES IS NOT ASSOCIATED WITH WORSE OBSTETRICAL OR INFECTIOUS OUTCOMES: THE RESULTS OF AN EMULATED TARGET TRIAL

Keywords: Spondyloarthritis, Pregnancy and reproduction, Disease-modifying Drugs (DMARDs)

A. Moltó[1], A. Ajrouche[2], D. Tran[2], Y. De-Rycke[2], N. Costedoat-Chalumeau[3], E. Elefant[4], V. Tsatsaris[5], J. Fresson[6], B. Bader-Meunier[7], B. Fautrel[8], F. Tubach[2]. [1]*Cochin Hospital APHP, Rheumatology, Paris, France*; [2]*Assistance Publique Hôpitaux de Paris, CEPHEPI, Paris, France*; [3]*Cochin Hospital APHP, Internal Medicine, Paris, France*; [4]*Trousseau Hospital APHP, CRAT, Paris, France*; [5]*Cochin Hospital APHP, Obstetrics, Paris, France*; [6]*CHU Nancy, Epidemiology, Nancy, France*; [7]*Necker Hospital, Immuno-Hematology and Pediatric Rheumatology, Paris, France*; [8]*Pitié Salpêtrière Hospital, APHP, Rheumatology, Paris, France*

Background: Continuation of biologics during pregnancy in patients with chronic inflammatory diseases during pregnancy is still a difficult medical decision. Many women with chronic rheumatic inflammatory diseases (CRID) decide to stop tumor necrosis factor inhibitors (TNFi) treatment once pregnancy is confirmed to avoid potential adverse fetal events but taking the risk of inflammatory flare.

Objectives: To compare in real life settings the pregnancy outcomes of two treatment strategies among women with CRID: to continue TNFi vs. stop TNFi upon pregnancy diagnosis.
Methods: the French nationwide health insurance database (*Système National des Données de Santé*) was used to emulate a target trial in adult women, with CRID (i.e., rheumatoid arthritis, psoriatic arthritis or spondyloarthritis), having started a singleton pregnancy between 2008 and 2017, and and being treated with TNFi upon pregnancy diagnosis. We compared the frequency of unfavorable pregnancy outcomes (malformations, obstetrical complications, and infections) between the treatment strategies at pregnancy diagnosis, using inverse probability weighted marginal models.
Results: A total of 1466 pregnancies were included, and among them, TNFi treatment was discontinued after pregnancy diagnosis in 74%. Mean (SD) age of women at the start of pregnancy was 31 (5) years and mean (SD) disease duration was 4 (5) years. Continuation of TNFi was not associated with increased frequencies of unfavorable pregnancy outcomes: interestingly, the proportion of pregnancies with at least one unfavorable obstetrical outcome tended to be lower in the group of patients continuing the TNFi after pregnancy diagnosis but without reaching statistical significance: 66 (17.3%) vs. 201 (18.5%) in the group continuing vs. discontinuing, respectively (adjusted RR= 0.79 [95% CI, 0.57; 1.10]). Also, there was a trend for a lower frequency of severe maternal infections in the group continuing the TNFi (7 (1.8%) vs. 36 (3.3%), (aRR=0.43 [0.16; 1.14]). Table.
Limitation: Algorithms rather than clinical data were used to identify patients with CRID, pregnancies, obstetrical outcomes, malformation and serious infections.

Table 1.

	Outcomes	TNFi continuation after pregnancy diagnosis		*p*
		Yes (N, %)	No (N, %)	
Obstetrical	Spontaneous abortion	2 (0.5%)	22 (2.0%)	0.06
	Stillbirth	0 (0.0%)	3 (0.3%)	-
	Medical termination of pregnancy	2 (0.5%)	4 (0.4%)	-
	Preterm birth (GA between 22 and 37 weeks among live birth)	35 (9.2%)	109 (10.1%)	-
	Small for GA (<10th percentile)	29 (7.6%)	75 (6.9%)	-
	Cesarean delivery	99 (25.9%)	273 (25.2%)	0.06
	Eclampsia/Pre-eclampsia	6 (1.6%)	17 (1.6%)	-
	Extra-uterine pregnancy	0 (0.0%)	2 (0.2%)	-
Maternal hospitalization for infection (during pregnancy and 6 weeks post-delivery)		7 (1.8%)	36 (3.3%)	0.09
Major congenital malformation		9 (2.4%)	31 (2.9%)	-

Footnotes: -: *the model did not converge due to the low number of events; GA= gestational age*

Conclusion: In pregnant women with CRID treated with TNFi until pregnancy diagnosis, neither unfavorable obstetrical outcomes nor severe infections were significantly increased in patients continuing TNFi during pregnancy, compared with a strategy of stopping TNFi.

POS0306

INVOLVEMENT OF CENTRAL SENSITIZATION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS; A BIOPSYCHOSOCIAL APPROACH

Keywords: Spondyloarthritis, Pain

Y. Van der Kraan[1], D. Paap[1,2], H. Timmerman[3], F. Wink[4], S. Arends[1], M. Reneman[5], A. Spoorenberg[1]. [1]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; [2]*Saxion University of Applied Sciences, Department of physiotherapy, Enschede, Netherlands*; [3]*University Medical center Groningen, Department of Anesthesiology, Groningen, Netherlands*; [4]*Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands*; [5]*University Medical Center Groningen, Rehabilitation Medicine, Groningen, Netherlands*

Background: Chronic (inflammatory) back pain is a key symptom of axial spondylarthritis (axSpA) and still present in a large proportion of patients on long-term biological treatment. This pain may not only be of inflammatory origin, but also due to altered pain processing of the central nervous system such as central sensitization (CS). Biological, psychological and social factors contribute to the development and maintenance of CS. A high score on the Central Sensitization Inventory (CSI), is associated with disease activity in axSpA.[1] In absence of a gold standard, Quantitative Sensory Testing (QST) is currently understood as an optimal indirect assessment of altered somatosensory function. However, QST is not always feasible in clinical practice, and CSI could serve as an alternative.
Objectives: To explore: 1) to what extent altered somatosensory function related to CS is present in patients with axSpA; 2) associations with QST and psychosocial factors related to CS.
Methods: Consecutive outpatients from the Groningen Leeuwarden axSpA cohort, fulfilling the ASAS classification criteria, were included. Participants underwent QST according to a standardized protocol, including assessment of Pain Pressure Threshold (PPT) at 11 sites, Temporal Summation (TS) at 3 sites and Conditioned Pain Modulation (CPM). Widespread low PPTs, high TS (both pain facilitation) and positive CPM (impaired pain inhibition) are indicators of CS. Participants also filled out the CSI, illness perception (IPQ-R), pain catastrophizing (PCS), fatigue (MFIS), anxiety and depression (HADS), coping (CORS) and physical activity (mSQUASH). Analyses were stratified for CSI cut-off value ≥40 indicating probable CS. Univariable and multivariable linear regression analyses were used to investigate the association of CSI, the questionnaires, QST, and patient and disease related assessments.
Results: 201 patients were included, median age was 50 years [IQR 38-58], 63% were male, 64% were classified as radiographic axSpA, 79% were HLA-B27+, median symptom duration was 12 years [IQR 5-24], mean $ASDAS_{CRP}$ was 2.1 ± 1.0. In total, 40% patients scored ≥40 on the CSI. In these patients PPTs at all sites except the m. trapezius left were significantly lower and TS significantly higher at the non-painful and painful area compared to patients with CSI scores < 40 (Table 1). No significant differences in TS at the non-dominant forearm and CPM were found. In univariable linear regression, sex, ASDAS, BASFI, PPT scores, PCS, IPQ-R identity, IPQ-R emotional representations, IPQ-R consequences, MFIS, HADS anxiety, CORS pain decreasing activities and mSQUASH were all significantly associated with the CSI. In the multivariable regression model, 5 variables (MFIS, IPQ-R Identity, sex, HADS anxiety, and PCS) were independently associated with the CSI. Explained variance of this model was 78%. Excluding the CSI questions with potential overlap with symptoms related to axSpA resulted in a comparable model.
Conclusion: This large study including QST confirms that altered somatosensory function related to CS is present in a subgroup of patients with axSpA. In addition, the CSI strongly reflect psychosocial factors related to CS. These results addresses the importance of the multifactorial biopsychosocial perspective of pain within the management of axSpA.

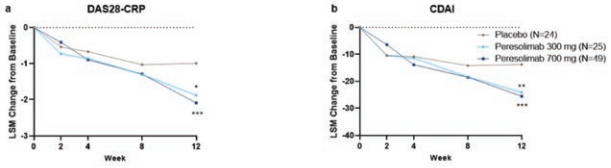
Background: Peresolimab is a humanized immunoglobulin G1 monoclonal antibody that stimulates human programmed cell death protein 1 (PD-1). We hypothesized that peresolimab binding to PD-1, a checkpoint inhibitory receptor, could stimulate physiological immune inhibitory pathways to restore immune homeostasis; this represents a novel approach to treating patients with autoimmune or autoinflammatory diseases.



Objectives: The objective of this study was to evaluate efficacy and safety of peresolimab in adult participants with moderate-to-severe rheumatoid arthritis (RA).

Methods: A Phase 2a, placebo-controlled, double-blind, randomized clinical trial (NCT04634253) evaluated the efficacy and safety of peresolimab in adult participants with moderately to severely active RA, who had an inadequate response to prior disease modifying drugs, either conventional (csDMARDs), biologic (bDMARDs) or synthetic (tsDMARDS). Treatment comparisons versus placebo were made using mixed effects model for repeated measures (MMRM) and using logistic regression model for continuous and binary endpoints, respectively. Nominal p-values are reported. Missing data for binary endpoints were imputed as non-response.

Results: One hundred and one patients were randomly assigned 2:1:1 to receive intravenous peresolimab 700 mg (n = 49), 300 mg (n = 25), or placebo (n = 24) Q4W; 98 participants received at least one dose of study treatment and were included in the analysis. Baseline demographics and disease activity were similar among groups. The majority (83.7%) of participants were female. At baseline, the mean (SD) duration of RA was 10.0 (8.0) years, and the mean (SD) DAS28-CRP score was 5.9 (0.85). This trial met its primary endpoint of a significantly greater improvement from baseline at Week 12 in DAS28-CRP score in participants treated with peresolimab vs participants treated with placebo at both tested doses (700 mg [p < 0.001] and 300 mg [p = 0.017], figure 1a). Significant improvements were seen in CDAI between participants treated with either peresolimab dose (figure 1b) relative to placebo, and for ACR20 (p < 0.05) for participants treated with peresolimab 700 mg relative to placebo by Week 12 (table 1). Peresolimab exhibited a safety and tolerability profile that supports further clinical evaluation in immunologic disease.

Conclusion: Peresolimab, a PD-1 receptor agonist, was superior to placebo at Week 12 for several key endpoints in RA. Safety events were similar between treatment groups.

Figure 1. Change in baseline of DAS28-CRP and CDAI LSM up to Week 12

DAS28-CRP = disease activity score-28 for RA with C-reactive protein. LSM = least squares mean. CDAI = clinical disease activity index. *p value < 0.05, **p value < 0.01, ***p value < 0.001.

Background: FIL is an oral Janus kinase 1 preferential inhibitor for the treatment of moderate to severe active RA. A previous pooled analysis reported long-term safety and efficacy for FIL 200 mg (FIL200) vs FIL 100 mg (FIL100) in pts aged ≥65 and <65 y.[1]

Objectives: To report updated long-term safety and efficacy in 4 subgroups of pts with RA (aged <65 y, ≥65 y, <65 y without CV risk, and ≥65 y or with CV risk), treated with FIL200 vs FIL100.

Methods: This *post hoc* analysis pooled data from phase 2 (DARWIN 1–3; NCT01888874, NCT01894516, NCT02065700) and phase 3 (FINCH 1–4; NCT02889796, NCT02873936, NCT02886728, NCT03025308) trials. Data for long-term extensions (LTEs) were as of May 2, 2022 (DARWIN 3), and May 6, 2022 (FINCH 4). Analyses were by age (<65 vs ≥65 y) and subgroup (<65 y without CV risk factor vs ≥65 y or ≥1 CV risk factor). CV risk factors were: family history of CV disease; history of dyslipidemia, diabetes mellitus or CV disease; hypertension, ischemic vascular conditions, peripheral vascular disease, extra-articular manifestations of RA; or ever smoked. The as-treated analysis set included data for pts receiving ≥1 FIL dose. Exposure-adjusted incidence rates (EAIRs)/100 patient-years of exposure (PYE) of selected adverse events (AEs), and % of pts achieving Disease Activity Score for 28 joints with C-reactive protein (DAS28-CRP) of <2.6 or ≤3.2 through Week 156 in FINCH 4, are reported.

Results: Baseline characteristics by age have been reported.[1] Baseline disease characteristics by age or CV risk factor were similar for disease severity and concurrent treatment. EAIRs for any treatment-emergent AEs (TEAEs) were generally higher in pts aged ≥65 (120.40) vs <65 y (97.86), and higher in pts aged ≥65 y or with CV risk (120.45) vs pts aged <65 y without CV risk (81.83). Pts aged ≥65 y, followed by the broader subgroup with CV risk factors (i.e. ≥65 y or ≥1 CV risk) had higher EAIRs of serious TEAEs and TEAEs leading to discontinuation vs other subgroups, indicating age is a key risk factor alongside other CV risk factors for developing AEs (data not shown). In pts aged ≥65 y, lower incidences of malignancies (excluding non-melanoma skin cancer [NMSC]), NMSC, herpes zoster (HZ) and TEAEs leading to death were observed with FIL100 than FIL200 (**Figure 1**). In the broader subgroup with risk factors (i.e. aged ≥65 y or ≥1 CV risk factor), EAIRs of AEs were generally lower vs pts aged ≥65 y, indicating greater influence of age. EAIRs of AEs for subgroups (aged <65 y without CV risk; ≥65 y or ≥1 CV risk) for FIL200 and FIL100 are shown (**Figure 1**). Rates of DAS28-CRP <2.6 or ≤3.2 in all subgroups (FINCH 4) were maintained with FIL100 and FIL200 to Week 156 (**Table 1**).

Conclusion: This *post hoc* analysis (in pts ≥65 y or with ≥1 CV risk factor) suggests that age is an important risk factor in the evaluation of the FIL200 safety profile. Future studies are needed to address the relative contribution of age to traditional CV risk factors. In FINCH 4, efficacy was maintained in all subgroups.

POS0309 TIME TRENDS IN GLUCOCORTICOID USE IN RHEUMATOID ARTHRITIS DURING THE BIOLOGICS ERA: 1999-2018

Keywords: Epidemiology, Treat to target, Rheumatoid arthritis

L. Crowson[1], J. M. Davis III[2], A. Hanson[3], E. Myasoedova[2], V. Kronzer[2], A. Makol[2], L. Peterson[2], D. Bekele[2], C. S. Crowson[3]. *[1]University of Health Sciences and Pharmacy, Pharmacy, St. Louis, United States of America*; *[2]Mayo Clinic, Rheumatology, Rochester, United States of America*; *[3]Mayo Clinic, Quantitative Health Sciences, Rochester, United States of America*

Background: Clinical guidelines recommend minimizing glucocorticoid use among patients with rheumatoid arthritis (RA) and many new therapeutic options

in recent decades offer alternatives to glucocorticoids, but it is unknown whether glucocorticoid use has declined in patients with RA.

Objectives: To examine time trends in glucocorticoid use among patients diagnosed with rheumatoid arthritis (RA) during the biologic era.

Methods: A population-based inception cohort of RA patients diagnosed during 1999 - 2018 was followed longitudinally through their medical records until death, migration or 12/31/2020. All patients fulfilled 1987 and/or 2010 American College of Rheumatology classification criteria for RA. Glucocorticoid start and stop dates were collected along with dosages in prednisone equivalents. The cumulative incidence of glucocorticoid initiation and discontinuation adjusted for the competing risk of death was estimated. Cox models adjusted for age and sex were used to compare trends between time periods.

Results: The study population was comprised of 399 patients (71% females) diagnosed in 1999 – 2008 and 430 patients (67% females) diagnosed in 2009 – 2018. Glucocorticoid use was initiated within 6 months of meeting RA criteria in 66.7% of patients in 1999-2008 and 70.9% of patients in 2009-2018, corresponding to a 29% increase in hazard for initiation of glucocorticoids in 2009-2018 (adjusted hazard ratio [HR]: 1.29; 95% confidence interval[CI]: 1.09-1.53). Among glucocorticoid users, similar rates of glucocorticoid discontinuation within 6 months after glucocorticoid initiation were observed in patients with RA incidence in 1999 – 2008 and 2009 – 2018 (39.1% versus 42.9%, respectively), with no significant association in adjusted Cox models (HR: 1.11; 95% CI: 0.93-1.31). Even in the 2009-2018 cohort, a large proportion of patients with RA (52%) remained on glucocorticoids beyond 3 months, and 30% were still on glucocorticoids after 2 years. Older patients with RA were more likely to initiate glucocorticoids (HR 1.06 per 10 year increase in age, 95% CI 1.00-1.13) and less likely to discontinue glucocorticoids (HR 0.91 per 10 year increase in age, 95% CI 0.86-0.96). There was no difference in the initiation of glucocorticoids by sex. Although females had a higher discontinuation rate within the first 12 months, afterwards discontinuation rates of glucocorticoids were similar in females and males. Smokers were less likely to discontinue glucocorticoids compared to non-smokers (HR 0.65; 95% CI: 0.51-0.82).

Conclusion: More patients are initiating glucocorticoids early in their disease course now compared to previously despite the availability of biologics and other disease modifying antirheumatic drugs. The rates of glucocorticoid discontinuation are similar. A substantial proportion of patients remain on glucocorticoids for more than 3 months with a large proportion continuing use of glucocorticoidss even beyond 2 years. Real world use of glucocorticoids in patients with RA is not optimal or improving despite advances in RA therapy.

Background: Rheumatoid Arthritis (RA) is an autoimmune chronic disease characterized by the inflammation of multiple joints, ultimately leading to deformity, pain and swelling [1]. Currently, no preventing therapy exists for RA, and 20%-30% of RA patients do not respond to available treatments [2]. These therapies target late phases of the inflammation process (e.g. cytokine signalling) [1], when the microenvironment is highly inflammatory and therefore challenging to control. Developing therapies targeting inflammation upstream (i.e. cytokine secretion) could have a positive impact on refractive RA. In this regard, we have previously identified through an unbiased high-throughput screening a total of 27 small molecules (23 novel and 4 repurposing drugs) with previously unknown anti-inflammatory capabilities.

Objectives: To validate the effects of these small molecules in peripheral blood mononuclear cells (PBMCs) under different types of activation stimuli, and to identify molecules capable of reducing the secretion of proinflammatory cytokines relevant in rheumatic diseases (namely TNF-α and/or IL-1β), employing a high-throughput approach.

Methods: First, different treatment methods were tested on PBMCs to identify those providing the best measuring window for the cytokines of interest. For that purpose, thawed PBMCs were exposed to PAMP (LPS) and/or DAMP (ATP) at different times, and cytokine secretion quantified. Subsequently, the potential cytotoxic effects of the small molecules were analysed at five different concentrations with several viability kits (fixable live/dead stains, AlamarBlue and ATPLite). Finally, for evaluating the anti-inflammatory potential of the small molecules the compounds were added to PAMP-only- and PAMP+DAMP-treated PBMCs at five concentrations, and viability and TNF-α and IL-1β secretion measured at four different time points.

Results: We found that, at different pharmacological concentrations (nM-μM), treatment conditions and time points, the compounds have no cytotoxic effects in PBMCs, with the only exception of one compound being toxic at the highest concentration tested. We then compared the levels of cytokine secretion with vehicle alone *versus* each of the small molecules and considered that a small molecule was of interest if induced at least a 20% reduction on the secretion levels of the cytokine of interest. We observed several combinations of effects (molecules acting on IL-1B, TNF-α or both, or only showing effect with PAMP-only or PAMP+DAMP treatment), suggesting that our molecules target different components of the intracellular machinery. For example, several molecules diminished TNF-α secretion after PAMP treatment, but not when the DAMP was added to the culture, and viceversa. The Figure shows representative results of compounds #7, #28 and #29, which reduce the secretion of TNF-α in PAMP-only treated PBMCs. We then tested the small molecules with the stronger effect at the lowest concentration in PBMCs from treatment-naïve RA patients, analysing both the intracellular and extracellular cytokine levels by flow cytometry and ELISA, respectively.

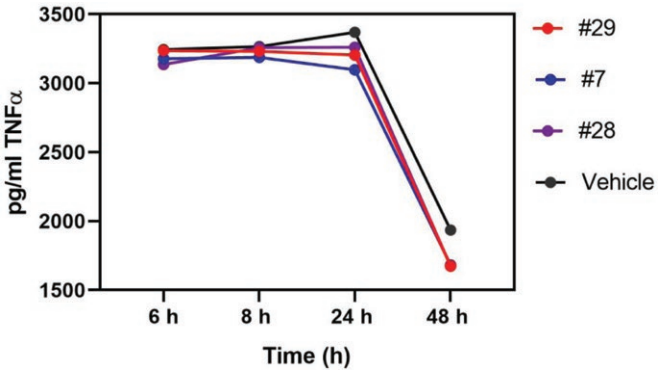

Figure 1. representative example of three novel small molecules (named #7, #28 and #29) capable of reducing the secretion of TNF-α in PAMP-only treated PBMCs at different time points.

Conclusion: We found that our novel and repurposing small molecules showed no cytotoxicity effects in primary PBMCs, and that they induced a reduction on proinflammatory cytokine secretion from PAMP-only and PMAP+DAMP-treated PBMCs. Further characterization of these small molecules, through the identification of their mechanism of action and molecular target, will open new avenues in the treatment of rheumatic diseases, by providing novel drugs targeting novel pathways and that could be administered orally, improving quality of life and adherence to treatment.

Background: To date, there are no head-to-head clinical trials directly comparing the effects between IL-6i and JAKi on bone destruction in RA. In recent years, a series of JAK inhibitors (JAKi) have been introduced, all of which have JAK1 inhibitory activity, and inhibition of IL-6 signaling plays an important role in their pharmacological actions. IL-6 inhibitors (IL-6i) have been also commonly used for rheumatoid arthritis (RA), and several anti-receptor antibodies are in clinical application. Recent studies have revealed the molecular basis of the immune cell-fibroblast-bone triad interactions in RA bone destruction[1-3].
Objectives: To examine changes in peripheral blood gene expression after IL-6i or JAKi treatment, which inhibit common pathways, and to estimate their respective effects on the bone immune system.
Methods: Peripheral blood gene expression changes in 38 RA patients (Tocilizumab (TCZ)=13, Tofacitinib (TOF)=15, Baricitinib (BAR)=10) were analyzed before and 3 months after the initiation of treatment using next generation sequencing. Changes in gene expression of molecules involved in bone immunity were analyzed before and after each treatment.
Results: Comparison of L-6i and JAKi showed that JAKi treatment significantly suppressed RANKL expression in peripheral blood. At the same time, significant suppression of RANK, ETS1, and IL-34 gene expression was also observed with JAKi treatment. Comparison of TOF and BAR treatment showed significant suppression of IL-4 expression in TOF and significant suppression of MMP-2 and IL-12 expression in BAR.
Conclusion: JAKi suppressed RANKL expression significantly compared to IL-6i, suggesting that JAKi is more potent than IL-6i in suppressing bone destruction. Furthermore, assuming that the promoter regions of RANK in synovial osteoclasts and ETS1 in fibroblasts are similar to those in peripheral blood, the following prediction emerges. Namely, JAKi suppresses RANK and ETS1 expression more than IL-6i, suggesting that JAKi may be favorable for preventing bone destruction in terms of (1) suppressing osteoclast differentiation and (2) suppressing tissue-destructive fibroblast generation.

POS0313 INVESTIGATING THE RELATIONSHIP BETWEEN METHOTREXATE ADHERENCE AND BIOLOGIC RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: bDMARD, Rheumatoid arthritis, Disease-modifying Drugs (DMARDs)

A. B. Mohammad Ariff[1], N. Nair[1,2], J. Bluett[1,2], A. Barton[1,2], S. Viatte[3], D. Plant[1,2], K. Hyrich[2,4], A. G. Wilson[5], A. Morgan[6,7], J. Isaacs[8,9]. *[1]The University of Manchester, Division of Musculoskeletal and Dermatological Science, Manchester, United Kingdom*; *[2]NIHR Manchester Biomedical Research Centre, N/A, Manchester, United Kingdom*; *[3]The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom*; *[4]The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; *[5]UCD Conway Institute, University College Dublin, School of Medicine, Dublin, Ireland*; *[6]University of Leeds, School of Medicine, Leeds, United Kingdom*; *[7]NIHR Leeds Biomedical Research Centre, N/A, Leeds, United Kingdom*; *[8]Newcastle University,Therapeutics North East, Newcastle upon Tyne, United Kingdom*; *[9]Newcastle upon Tyne Hospitals, Freeman Hospital, Newcastle upon Tyne, United Kingdom*

Background: In rheumatoid arthritis (RA), methotrexate (MTX) adherence is highly variable and typically suboptimal, with reports of adherence 59% (underuse) to 107% (overuse) [1]. Non-adherence to MTX may explain non-response and the need to start or switch to biologic therapies. Concomitant use of MTX is associated with reduced anti-drug antibodies in patients prescribed biologics such as adalimumab, therefore promoting MTX adherence should be a priority [2]. MTX biochemical adherence can be objectively measured using HPLC-SRM-MS [3]
Objectives: To investigate the biochemical MTX adherence in RA patients commencing a biologic and its association with EULAR response.

Methods: This analysis used data from the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS), a one-year UK prospective cohort study of patients with RA commencing a biological drug. Prior to biologics commencement, demographic and clinical data were collected. Serum samples were sampled for MTX biochemical adherence at baseline (pre-treatment of biologics), then 3 and 6 months post-first dose. MTX concentration was measured by HPLC-SRM-MS. Time to processing variable was also noted by calculating the difference between the time the sample was processed and the time the blood was sampled. Adherence was calculated based on a cut-off limit taken from a validated MTX adherence assay. A chi-square test was used to investigate the association between adherence and biologic response. Linear regression investigated the relationship between MTX level and time to processing.

Results: 582 patients were included; 75% female, mean (S.D.) age 58 (12) years. Table 1 summarises the baseline characteristics for all patients. There was no significant relationship between adherence at pre-treatment with EULAR response at 6 month (p=0.17). However, those who were biochemically adherent to MTX at 6 months had a statistically significantly better response to biologic therapy (p=0.04). It is also found that despite being a responder to the biologic, 37% were non-adherent to MTX. However, there was no significant relationship between MTX level and time to processing thus it is unlikely to be due to the stability of MTX in blood over time.

Conclusion: Patients who were adherent to MTX, assessed biochemically, at 6 months after starting biologic therapy had better response to treatment, which may further strengthens the evidence to support the importance of concomitant use of MTX with biologics.

CAN METHOTREXATE INFLUENCE SEXUAL DYSFUNCTION IN MALE PATIENTS: ANALYSIS OF THE IIEF5 QUESTIONNAIRE AND HORMONAL STATUS

Keywords: Safety, Rheumatoid arthritis, Disease-modifying Drugs (DMARDs)

F. Natalucci[1,2], S. Bisseron[1], T. Sokolova[1], A. Avramovska[1], D. Maiter[3], P. Durez[1]. [1]*Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCLouvain) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium*; [2]*Sapienze University of Roma, Rheumatology, Department of clinical, internistic, anesthesiological and cardiovascular sciences, Roma, Italy*; [3]*Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCLouvain) – Institut de Recherche Expérimentale et Clinique (IREC), Endocrinology, Brussels, Belgium*

Background: Methotrexate (MTX) is the anchor drug of Rheumatoid Arthritis (RA) treatment. It is a safe and handy drug, but it has several well-known side effects mainly not severe such as nausea, fatigue, alopecia, or an increase in transaminases. In the last years, sexual dysfunction has been reported as a rare adverse effect of MTX therapy.

Objectives: To explore this, the aim of this study is to evaluate the impact of MTX on erectile function in male patients through the IIEF5 questionnaire and hormonal dosage.

Methods: Male patients affected by inflammatory arthritis (Rheumatoid Arthritis or Psoriatic Arthritis [PsA]) according to the 2010 EULAR/ACR diagnostic criteria for RA and the 2006 CASPAR criteria for PsA and treated with chronic MTX were enrolled. Age-matched patients affected by chronic arthritis not treated with MTX were enrolled as control. Each patient underwent blood collection for a complete serum sexual hormone evaluation. IIEF5 questionnaire which consists of 5 items with a maximum score of 25 was administered to the patients.

Results: 109 patients were included, 77 in the MTX group (Group A) and 32 in the control group (Group B). The clinical and demographic features of both groups are reported in Table 1. Among the MTX group, 61 have a RA diagnosis, while the remaining 18 were affected by PsA. The median disease duration of RA and PsA patients was respectively 108 months (IQR 138) and 66 months (IQR 114). The median MTX dose was 10 mg (IQR 7.5) with a median MTX duration therapy of 8 years (IQR 17). The total IIEF5 score was lower in patients treated with MTX compared to the control group without reaching a statistically significant result (19 [IQR 11] *versus* 20 [IQR 7.7]; p=0.15, Graph 1A). However, when comparing the IIEF5 score between MTX exposed versus non-exposed patients stratifying by years of treatment, the total IIEF5 score of patients treated with MTX ≥ 5 years was statistically significantly lower when compared to those non MTX- exposed patients (17 [IQR 15] *versus* 20 [IQR 7.7]; p=0.04) and compared to those treated for < 5 years (17 [IQR 15] *versus* 20 [IQR 7]; p=0.01) (Graph 1B).

Table 1.

		Group A	Group B	p
Age	**Median (IQR)**	54 (28)	53.5 (20.5)	0.50
BMI		25.4 (3.85)	25.6 (5.8)	0.78
Arterial Hypertension	**(N%)**	23 (29.1)	23 (71.8)	**<0.0001**
Hypercholesterolemia		18 (33)	11(34.3)	0.20
Type 2 diabetes		3 (3.8)	6 (18.7)	**0.008**
Hyperplasia Prostatic		2 (2.5)	0 (0.0)	0.99
Depression/Psychotropic Therapy		8 (10.1)	5 (15.6)	0.51
Marriage		53 (67)	23 (71.8)	0.65
Alcohol (N° units/ day)		1 (2.5)	1 (2.0)	0.71
Children (N°)		1 (2)	2 (2)	0.73
Total Testosterone Median	**Median (IQR)**	16,3 (8.2)	14,8	**0.04**
SHBG		53,9 (29,15)	47.6	0.07
LH		5,6 (4,15)	5.35	0.59
FSH		5,2 (5,30)	6.65	0.98
E2		24 (13,25)	20	**0.01**
PRL		7 (3,55)	8.05	0.52
DHEA		4,7 (4,1)	3.85	0.64
GH		94 (19)	98	0.34

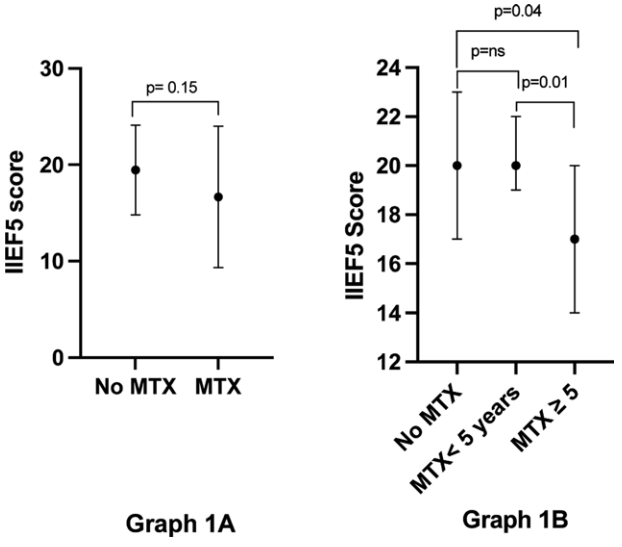

Figure 1. A) Comparison of IIEF5 score in MTX exposed versus non-exposed patients. B) patients stratified by age (< 5 years and ≥ years).

In the univariate analysis, a negative correlation between the total IIEF5 score and MTX exposure (years) has been identified (r= - 0.20 CI [-0.38 - -0.04]; p= 0.039). Age was the variable whit the strongest negative association with the IIEF5 score (r= - 0,42 CI [-0.57 to - 0.25]; p< 0.0001). MTX exposure was still associated with a lower IIEF5 score when adjusted for age (β Estimate= -2,63; CI [-5,13 to -0,13]; p=0,0391). Among the other variables, LH (r=-0,24; CI [-0,42 to -0,04]; p=0,01), FSH (r=-0,21; CI [-0,39 to -0,006]; p=0,04) and E2 (r=-0,21; CI [-0,40 to -0,009]; p=0,03) negatively correlated whit IIEF5 score while DHEA, was the only with a weak positive association (r=0,22; CI [0,02 to 0,40]; p=0,03). Patients affected by arterial hypertension and hypercholesterolemia showed lower scores compared to non-affected patients (p=0.04; p=0.03; p=0.045). In the multivariate analysis, age was the only factor associated with a decrement of IIEF5-score (β -0,21 [-0,32 to -0,094]; p=0,0005).

Conclusion: Long-term MTX exposure was associated with sexual dysfunction reported by a lower IIEF5 score in male patients adjusted for age. The preliminary results need to be confirmed in larger prospective studies.

POS0315 ACUTE CARDIOVASCULAR EVENTS RISK IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOFACITINIB OR TNF INHIBITORS, A NATIONWIDE COHORT STUDY: RELATION STUDY

Keywords: Rheumatoid arthritis, Targeted synthetic drugs, Real-world evidence

J. E. Gottenberg[1], M. Kessouri[2], J. Rudant[2], N. Assi[3], B. Grenier[4], J. Kirchgesner[5]. [1]*Hautepierre Hospital, Rheumatology, Strasbourg, France*; [2]*Pfizer, Medical, Paris, France*; [3]*Heva, Statistique, Lyon, France*; [4]*Heva, RWD, Lyon, France*; [5]*Saint-Antoine Hospital, APHP, gastro-enterology, Paris, France*

Background: Patients with IMID, and notably patients with rheumatoid arthritis (RA), are at increased risk of major adverse cardiovascular event (MACE) compared with the general population [1,2]. It is hence paramount to assess the impact of biological or targeted DMARD (e.g., tofacitinib and TNFi) on the risk of MACE in patients already at-risk, particularly in the context of ORAL Surveillance which showed a higher risk MACE with tofacitinib, in comparison with TNFI, in RA patients [3].

Objectives: To assess the impact of tofacitinib and TNFi on the risk of MACE in patients with RA treated in real-world clinical practice.

Methods: The RELATION study is a retrospective observational cohort study using the French nationwide healthcare database (SNDS). Patients aged 18 years or older, affiliated to the national health insurance with a diagnosis of RA and initiating tofacitinib after November 1, 2017 or TNFi after January 1, 2010 (including adalimumab, etanercept, or other TNFi, without previous exposure to tofacitinib) were followed from treatment initiation to December 31, 2020. Patients with a previous history of MACE in the 4 years preceding cohort entry were excluded. All MACE excluding cardiovascular (CV) death were defined by the first hospitalization for MACE during follow-up. Comorbidities and traditional CV risk factors were identified using hospitalizations, procedures, or medication dispensing in the 4 years prior cohort entry. The unadjusted incidence rate (IR) of MACE excluding CV death was assessed in patients initiating either tofacitinib or a TNFi (with associated 95% confidence intervals (95% CI)). A 1:3 PS matching was conducted to balance the baseline characteristics of patients initiating tofacitinib and TNFi. Cox proportional hazards regression models were used to compare the risk of MACE with tofacitinib vs TNFi during the follow-up period.

Results: Between 2010 and 2020, a total of 39,578 patients with RA were included in the study. Among these, 2,811 initiated tofacitinib and 36,767 initiated a TNFi (adalimumab: 10,621, etanercept: 16,512, other TNFi: 9,634). Patients had a mean age of 53 years at cohort entry, and 72% to 81% were women. Around 61% of the cohort had at least one CV risk factor (66.3%for tofacitinib compared to 60.9% for TNFi). The two major co-medications at treatment initiation in the two groups were methotrexate (60.9%) and corticosteroids (50.8%).

After PS matching, the tofacitinib cohort included 2,628 patients, and the TNFi cohort included 7,884 patients. Over a median follow-up period of 11.21 months (tofacitinib: 8.54 months, TNFi: 12.43 months), 25 incident MACE occurred in the tofacitinib group (IR: 9.86 (6.66–14.60) per 1,000 patient-year (PY)) and 159 occurred in the TNFi group (9.59 (8.21–11.20)). The risk of MACE (overall) was similar with tofacitinib vs TNFi (adjusted HR 1.06 [95% CI 0.68, 1.64]; p=0.8127). Similar results were found for ischemic heart disease (HR 0.71 [95% CI 0.35, 1.44]; p=0.3433) and cerebrovascular disease (HR 1.41 [95% CI 0.73, 2.73]; p=0.3116). For peripheral artery disease, the number of events was too low to perform these analyses.

Conclusion: In this large population-based study, tofacitinib was not associated with an increased risk of MACE in comparison with TNFi in patients with RA treated in real-world settings. Studies with longer follow-up durations may be necessary to understand the long-term implications of tofacitinib vs TNFi on the risk of MACE.

POS0316 SURVIVIN REGULATES T CELL RESPONSES THROUGH DEPOSITION OF HISTONE H3 MARKS AND MODULATES RESPONSE TO TREATMENT WITH JAK-INHIBITORS

Keywords: Targeted synthetic drugs, Adaptive immunity, Rheumatoid arthritis

K. M. Andersson[1], V. Chandrasekaran[1], M. Erlandsson[1], E. Malmhäll-Bah[1], S. Töyrä Silfverswärd[1], R. Pullerits[1,2], M. I. Bokarewa[1,2]. [1]*Gothenburg University, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; [2]*Sahlgrenska University Hospital, Rheumatology Clinic, Gothenburg, Sweden*

Background: Multiple genetic polymorphisms are associated with high risk for rheumatoid arthritis (RA) [1]. The importance of epigenetic processes has been postulated, but precise molecular mechanisms behind these associations remain largely unexplored. Survivin is an important player in RA, which has been recently shown essential for IFNg signaling in CD4 T lymphocytes acting in partnership with IRF1 [2].

Objectives: We study how survivin-dependent epigenetic deposition of histone H3 tails in RA risk loci affects function of $CD4^+$ T cells and response to JAK inhibition.

Methods: Chromatin of $CD4^+$ cells (n=12) was immunoprecipitated with antibodies to histone H3K27ac, H3K4me3, and survivin, and sequenced (ChIP-seq, Illumina). Parallel ChIP-seq and RNA-seq was done in $CD4^+$ cells treated with survivin inhibitor YM155. Peaks with change >30% in deposition of H3K27ac and/or H3K4me3 upon YM155-treatment were annotated to the genomic regulatory elements (RE) via GeneHancer database. Single nucleotide polymorphism (SNP) related to RA risk were identified within those RE. $CD4^+$ T cell transcriptomics by RNA-seq was done in 24 random RA patients and in 59 RA patients treated with MTX (n=18), TNFi (n=10), JAKi (n=24) and having no DMARDs (n=7). The genes differentially expressed (DEG, nominal p<0.05) in $BIRC5^{hi}$ and JAKi-treated $CD4^+$ cells were identified by DESeq2 (R-studio, Bioconductor).

Results: Deposition of 15% (1705/11152) of H3K4me3 and 17% (1943/11530) of H3K27ac peaks changed >30% upon survivin-inhibition. Approximately 50% of these peaks overlapped with survivin peaks. The change in H3K4me3 peaks was significantly larger if the peak colocalized with survivin peak. These peaks were located within 228 RE, 28 of these RE contained 52 RA risk SNPs. Among others, changeable peaks were accumulated within ICOS/CTLA4/CD28 locus and contained 7 SNPs. Majority of genes connected to the SNP-containing RE (110/153 genes) were transcriptionally different in $BIRC5^{hi}CD4^+$T cells and participated in the regulation of immune system (GO:0002682, FDR=4.3e-4), regulation of IL2 production (GO:0032663, FDR=0.019), TNF mediated signaling (GO:0033209, FDR=5.4e-3). These SNP-RE connected genes formed three independent clusters 1) TCR receptor co-stimulators (CD40, ICOS, CTLA4, CD28, CD244, TRAF6 and TBX21, SLAMF1, TNFRSF9), 2) connected to the LCK interacting transmembrane adaptor 1 (LIME1, SLC2A4RG, ZGPAT, GMEB2, TNFRSF6B, RTEL1) and 3) heat-shock proteins (HSPD1, HSP90AB1, HDAC7, KPNB1). The clusters were functionally connected to survivin partners IRF1 and SMAD3. Notably, transcription of CD28, ICOS, and SLAMF1 functionally connected to IRF1, and CHERP, HDAC7, PRPF6 and SRSF10 functionally connected to SMAD3 were significantly changed (all, nominal p<0.05) in CD4+ cells upon survivin inhibition by YM155. Since survivin mediates IFNg-dependent processes [2], we analyzed transcription of 110 SNP-RE connected DEG in $CD4^+$ cells of JAKi-treated RA patients. We found that DEG in the IRF1 and SMAD3 clusters were inversely affected by JAKi, e.g., IRF1-related CD28, ICOS, and SLAMF1 upregulated after survivin inhibition were suppressed

by JAKi, while SMAD3 related CHERP, PRPF6 down-regulated by survivin inhibition were upregulated in CD4+ cells of JAKi-treated patients. Effect of JAKi in the IRF1-related genes was executed only in BIRC5^{lo}CD4^{+} cells and remained unchanged in BIRC5^{hi}CD4^{+} cells.

Conclusion: This study shows that survivin contributes to deposition of histone H3K27ac and H3K4me4 marks in proximity of RA-risk genes and control immune system regulators in CD4 T cells. JAK-inhibitors operate downstream of survivin and high levels of survivin may impede JAKi-treatment.

Early RA and comorbidities

POS0317 IT'S TIME TO END THE STIGMA SURROUNDING INFECTIOUS MUSCULOSKELETAL DISEASES: A Q-METHODOLOGY STUDY

Keywords: Patient reported outcomes, Infection-related RMDs

Y. Mabrouk[1], L. Rouached[1], Z. Syrine[2], A. Ben Ammou[3], S. Larbi[4], S. Akremi[3], A. Ben Abid[3], M. Ben Salah[3]. *[1]charles nicolle hospital, rheumatology, tunis, Tunisia*; *[2]hedi chaker hospital, rheumatology, sfax, Tunisia*; *[3]charles nicolle hospital, orthopedic surgery, tunis, Tunisia*; *[4]Razi hospital, psychiatry, Manouba, Tunisia*

Background: Although it still remains a rare disease, spondylodiscitis has been on the rise in the past decades. Early diagnosis can be difficult, but Improved diagnostic techniques and modern treatments have reduced patient mortality. However, the management of these patients comes up against a certain number of issues, including stigma. This stigmatization of the spondylodiscitis patient represents a real problem on the daily life. This considerably hinders his reintegration.

Objectives: The aim of this study is to explore prevailing prespectives concerning stigma among patients treated for spondyloscitis and so to identify potential determinants of these beliefs.

Methods: A Q- methodology study was carried out on patients treated for spondylodiscitis over a two-year period at a single spine center. The socio-demographic data, clinical, radiological, biological and therapeutic parameters were collected. Participants ranked 20 opinion statements about the impact of their disease on their daily life (social life, mental health, professional life, sex life) on an agreement scale. A by-person factor analysis identified common patterns in the rankings. These patterns represent the different viewpoints among the patients. Data from interviews, in which they explained their ranking, was used to further interpret the viewpoints. All data was collected after patient consent and was analyzed using the SPSS statistical package.

Results: Thirty patients were selected for the study, with a sex ratio (M/ F) of 1.57. Their average age was 56 [18_73].

The analysis revealed four viewpoints. At least 2 participants were significantly associated with each factor ($p<0.05$).

1)« The subject of stigma must be seriously addressed by health professionals and authorities »

2)« lack of self-esteem has limited my social life »

3)« challenged doubly, both by the disease and by the stigma associated with it »

4)« physical changes make me feel less confident about sex ».

In our series, there were positive correlations between gender, VAS (visual analog scale) spinal pain, presence of spinal syndrome and viewpoint 2: p=0.035, p=0.04 and p=0.008, respectively. In the same way, there were positive correlations between high pain catastrophizing scores and viewpoint 3: p=0.02. Viewpoint 4 was associated to depression thoughts, according to the hospital anxiety and depression scale: HAD: p=0.03.

Conclusion: We identified 4 viewpoints on the impact of spondylodiscitis on daily life. In fact, we have noticed that this disease affects relationships and self-confidence. It can lead also to the exclusion of the individual. Therefore, Various strategies are needed to combat the stigma related to infectious musculoskeletal diseases such as spondylodiscitis, which remains a frequent problem with multiple consequences.

POS0318 DISTINCTION AND PROGNOSIS OF EARLY ARTHRITIS PHENOTYPES: AN ANALYSIS IN THREE EUROPEAN COHORTS

Keywords: Real-world evidence, Prognostic factors, Rheumatoid arthritis

A. Sepriano[1], B. Van Dijk[2], S. Ramiro[2], A. Van der Helm – van Mil[2], B. Combe[3], D. Van Schaardenburg[4], M. De Wit[5], A. Kent[5], E. Mateus[5], R. B. M. Landewé[4]. *[1]Nova Medical School, Rheumatology, Lisbon, Portugal*; *[2]Leiden university Medical Center, Rheumatology, Leiden, Netherlands*; *[3]CHU Montpellier, Rheumatology, Montpellier, France*; *[4]Amsterdam University Medical Center, Rheumatology, Amsterdam, Netherlands*; *[5]EULAR Patient Research Partner Network,., Zürich, Switzerland*

Background: Patients (pts) with early arthritis (EA) may present with more or less classical inflammatory disease phenotypes. It is difficult to discern at presentation those who will evolve to a well-defined phenotype (e.g., rheumatoid arthritis; RA) from those who will remain undifferentiated or even will have non-inflammatory disease. The 2010 RA classification criteria were developed to promote early identification of RA and were validated against the external standard of 'expert diagnosis', a well-known approach that -however- may lead to circularity.

Objectives: Obtain a more unbiased insight into the 'Gestalt' of EA, by circumventing expert opinion, and investigating the latent phenotypes underlying EA and whether there are differences in prognosis across these phenotypes over time.

Methods: Three cohorts of pts with EA (Reade, ESPOIR and EAC) were analyzed separately. Clinical data were collected up to 12 (ESPOIR), 13 (Reade) or 24 (EAC) years. Hands and feet radiographs were scored, according to the Sharp van der Heijde method (SvdH) up to 10 (ESPOIR), 13 (Reade) and 14 (EAC) years. Latent class analysis was used to estimate the latent (i.e., unobserved) classes of EA. Each class was labelled by us, according to its most prominent features. Outcomes were functional disability, quantified by the health assessment questionnaire (HAQ), quality of life (QoL) quantified by the short form 36 physical (SF36 PC) and mental (SF36 MC) components (in ESPOIR) and radiographic damage (SvdH score). The association between class-membership and each outcome over time was tested in multivariable GEE models.

Results: In total, 390 (Reade), 798 (ESPOIR) and 1878 (EAC) pts were included. In ESPOIR, 4 latent classes could be distinguished (Figure 1); Two classes had a high likelihood of symmetrical polyarthritis. One of these, labelled as autoimmune inflammatory polyarthritis (AIPA), had a high likelihood of acute phase reactants (APR)-elevation and autoantibody (AB)-positivity, while the other (mild inflammatory polyarthritis; MIPA) had not. The third class had fewer joints involved (oligoarthritis of upper limbs; OAUL) and the fourth included pts with oligoarthritis of the lower limbs (OALL). All classes, except the latter, were also identified in Reade. In the EAC, OAUL could further be divided into autoimmune OAUL (AIOAUL) and mild-inflammatory OAUL (MIOAUL). In all cohorts, SvdH-scores were consistently worse in classes with AB and APR present (AIPA) than in those without. An example from the EAC cohort shows pts in the MIPA-class had on average 18.5 SvdH-units less than patients in the AIPA-class (Table 1). However, the mean HAQ- and SF36-scores were remarkably similar over time across all classes. The few statistically significant effect-sizes were small and of no clinical relevance.

Conclusion: EA pts presenting with elevated (APR and autoantibodies) markers, the phenotype most consistent with the 'classic RA-construct', develop more radiographic damage than those without these markers. However, pts with more damage do not necessarily have worse physical function or QoL (measured up to 24 years). These results may justify immediate DMARD-treatment for preventing damage for the proportion of EA-patients that present with an AIPA-phenotype, but not necessarily for all others.

Table 1. Prognosis of EA phenotypes

POS0319 THE COURSE OF SYMPTOMS IN CLINICALLY SUSPECT ARTHRALGIA AND ITS RELATION WITH SUBCLINICAL JOINT-INFLAMMATION DURING PROGRESSION TO RA: IS IT SIMILAR IN ACPA-POSITIVE AND ACPA-NEGATIVE DISEASE?

Keywords: Patient reported outcomes, Imaging, Rheumatoid arthritis

S. Khidir[1], D. Krijbolder[1], H. K. Glas[2], E. Van Mulligen[1,3], A. Van der Helm – van Mil[1,3]. [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [2]*Reumazorg Zuid-West Nederland, Rheumatology, Goes, Netherlands*; [3]*Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands*

Background: ACPA-positive and ACPA-negative RA have differences in genetic and environmental risk factors and in the severity of the disease course after diagnosis. However, the clinical presentation at RA-diagnosis is similar, as is the clinical presentation in the at-risk stage of clinically suspect arthralgia (CSA). We hypothesized that these clinical similarities at the end of the trajectory of RA-development imply a shared path in symptom development and progression before diagnosis. So far the course of symptoms during progression from CSA to RA and the association with the course of subclinical joint-inflammation is unknown.
Objectives: We studied the course of cardinal symptoms and subclinical joint-inflammation and the longitudinal relation in ACPA-positive and ACPA-negative disease. Relations were also studied in CSA-patients who did not develop RA.
Methods: CSA-patients from the Leiden CSA-cohort (n=664) and the placebo-arm of the TREAT EARLIER trial (n=117) were followed on development of inflammatory arthritis (IA) at physical examination, during which 136 patients developed IA and 645 did not. Symptoms of morning stiffness, pain and fatigue (with a numerical rating scale: 0-100) and presenteeism (productivity loss at work with the WPAI-questionnaire: 0-100%) were assessed at baseline and 4/12/24 months thereafter. Subclinical joint-inflammation (sum of synovitis/tenosynovitis/osteitis) was assessed at baseline and upon IA-development with contrast-enhanced 1.5T MRI of hand/foot. Linear and Poisson mixed models were used.
Results: Of the patients with IA-development, 66 (49%) were ACPA-positive. Both in ACPA-positive and ACPA-negative patients, symptoms (morning stiffness, presenteeism, fatigue) and subclinical joint-inflammation increased towards IA-development, and decreased or stabilized in patients without IA-development (Figure 1A). The course of pain, morning stiffness and presenteeism were significantly associated with the course of subclinical joint-inflammation in ACPA-positive CSA-patients during progression to RA. In ACPA-negative CSA-patients developing ACPA-negative RA, these effect sizes were smaller and not statistically significant (Figure 1B). Although the group-size of ACPA-positive CSA-patients not developing RA was smaller (n=47) than that of ACPA-negative non-progressing CSA (n=555), also here the decrease in symptoms seemed to have a stronger relationship with decreasing joint-inflammation in ACPA-positive than in ACPA-negative patients.
Conclusion: The severity of symptom development before diagnosis in ACPA-positive RA relates more strongly to increasing subclinical joint-inflammation than in ACPA-negative RA. This points towards differences in processes underlying the disease burden in ACPA-positive and ACPA-negative RA.

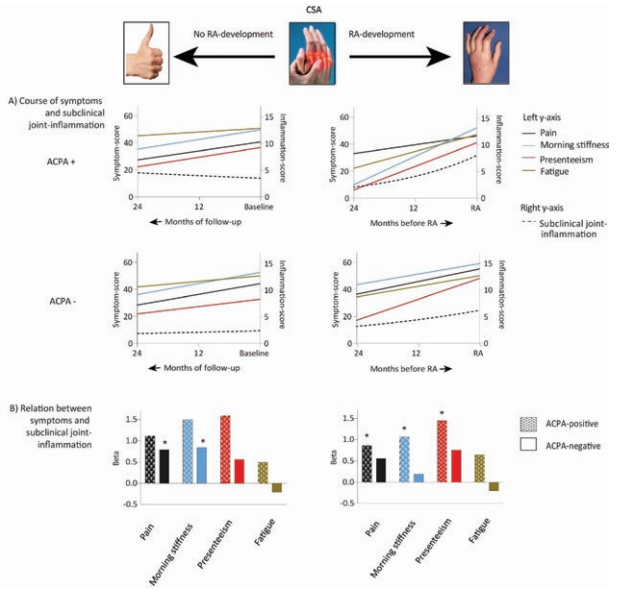

Figure 1. A) The course of symptoms and subclinical joint-inflammation in CSA-patients without and with RA-development and B) their longitudinal relation for ACPA-positive and ACPA-negative patients

Legend: A) Lines depict the course of symptoms (left y-axis) and subclinical joint-inflammation (right y-axis). This is shown separately for CSA-patients who did not develop RA; Figure A left, and those who did develop RA; Figure A right. B) Demonstrated are the effect sizes of 1 point increase in subclinical joint-inflammation over time on increase in symptoms over time. E.g. a beta of 0.8 for pain in ACPA-positive patients developing RA, implies that 1 point increase in inflammation over time gives 0.8 point more pain during the course towards RA-development.
Abbreviations: ACPA= anti-citrullinated protein antibodies; CSA= clinically suspect arthralgia; RA=rheumatoid arthritis.

POS0320 ARTIFICIAL INTELLIGENCE BASED APPROACH TO PREDICT THE DISEASE COURSE IN PATIENTS WITH RHEUMATOID ARTHRITIS

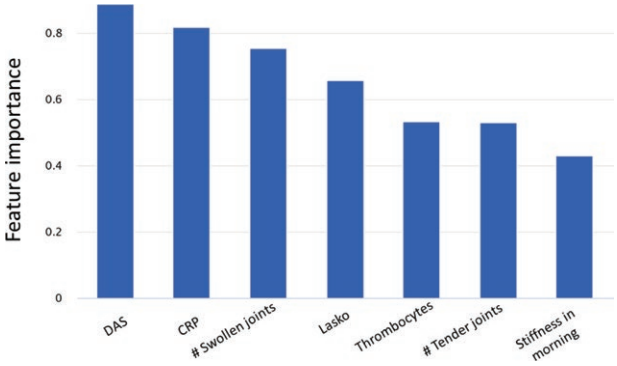
Keywords: Prognostic factors, Artificial Intelligence, Rheumatoid arthritis

J. Salmi[1,2], P. Pihlajisto[3], A. Mustonen[2], H. Relas[3], K. Eklund[3]. [1]*Åbo Akademi University, Computer Science, Turku, Finland*; [2]*BCB Medical Ltd., Life Science, Turku, Finland*; [3]*University of Helsinki, Department of Medicine, Helsinki, Finland*

Background: Rheumatoid Arthritis (RA) is an autoimmune disease which affects approximately 0.8% of the Finnish population. Increasing number of conventional and biological antirheumatic drugs is currently available for the treatment of RA. However, for the optimal use of these drugs and for example for the decision when to start biological medication, it would be of utmost importance to be able to predict the disease course of the patient during the patient's visit at the clinic.
Objectives: The disease course of the patients differs widely and predicting the disease course is challenging. Therefore, our objective was to use patient-specific disease characteristics and to develop an artificial intelligence (AI) method for predicting the future disease course. Our patient material includes 1881 patients, with both sero positive and negative diseases (ICD-10-codes M05 and M06).
Methods: We used a machine learning method which takes as input patient information such as demographic information and clinical variables. The target value that the method tries to predict is the DAS28-CRP disease marker a year from the present time. The train and test sets were balanced so that each DAS28-CRP value is expressed equally. The machine learning model was a voting ensemble with Random

Forest and Extreme Random Trees classifiers and with different scalers (Geurts et al. 2006). The number of training instances was 1504 and test set consisted of 377 patients. The number of features was 30. The patients were classified to 4 classes: inactive, low, high and very high according to the activity marker DAS28-CRP.

Results: The AUC value of the classifier was 0.71. This provides adequate extra information for the clinicians when they consider the patient's treatment. If the method shows that the patient is likely to get worse, treatment can be intensified and extra visits to the policlinic can be scheduled. If the model predicts that disease is getting better, visits can be more infrequent. Figure 1 shows the most important variables used by the classification algorithm. The AI algorithm gives good predictions (Table 1), even though errors between two adjacent activity classes are common. For example, when the true class is very high, the algorithm gives 88 high or very high predictions (94%), and only 6 clearly wrong answers (6%). When the true class is high, the results are more spread, with 42 cases (45%) being in the low or inactive class and 51 (55%) cases in the more active class. The low and inactive classes are predicted quite well.



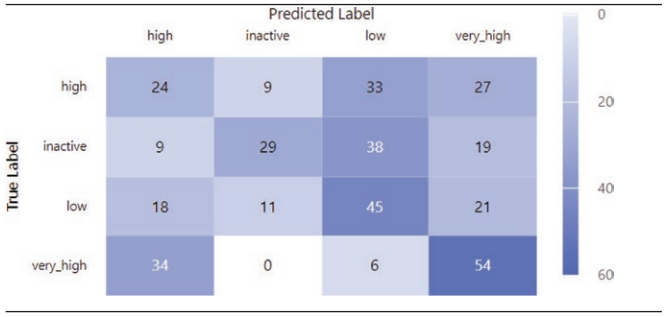


Figure 1. Overall feature importance for all classes. The higher the bar, the more useful the feature is in classifying the patients.

Table 1. A confusion matrix of classifying the test material. In the left are the true labels and on top the predicted labels. The classes low and very high have been most successfully predicted.

Conclusion: The algorithm shows promising results especially in predicting very high disease activity. An algorithm with AUC 0.71 cannot reliably classify patients independently, but it can aid the clinician in giving insights into the patients' current status and how likely the worsening of the disease is. The AI method chosen for this purpose is a white-box approach, meaning that the clinician can immediately see which factors were deemed important by the algorithm to produce this prediction.

LYMPHOCYTE SUBSETS- AND ACPA-BASED PREDICTIVE MODEL FOR PROGRESSION TO CLINICAL ARTHRITIS IN AT-RISK INDIVIDUALS WITH ARTHRALGIA

Keywords: Biomarkers, Autoantibodies, Rheumatoid arthritis

K. Prajzlerová[1], O. Kryštůfková[1,2], N. Kaspříková[3], N. Růžičková[1,2], H. Hulejova[1], P. Hánová[1], J. Vencovský[1,2], L. Šenolt[1,2], M. Filková[1,2]. [1]*Institute of Rheumatology, Department of Experimental Rheumatology, Prague, Czech Republic*; [2]*First Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic*; [3]*Prague University of Economics and Business, Faculty of Informatics and Statistics, Prague, Czech Republic*

Background: The presence of antibodies against citrullinated proteins (ACPA) significantly increases the risk of developing rheumatoid arthritis (RA). The clinical definition of individuals with arthralgia at risk of progression to RA (clinically suspect arthralgia, CSA) was established by EULAR irrespective of the ACPA status. Dysregulation of lymphocyte subpopulations (including NK and B cells) was previously described in early and established RA.

Objectives: To propose the predictive model for progression to arthritis based on peripheral lymphocyte subsets and ACPA in at-risk individuals with arthralgia.

Methods: Individuals from the At Risk of RA (ARRA) prospective observational cohort were defined as having arthralgia without arthritis on the examination of 66 joints at baseline and being either ACPA+ and/or meeting the EULAR definition of CSA (further CSA+, fulfilling at least 3 out of 7 parameters). All individuals signed informed consent prior to study enrolment. Peripheral blood samples were analysed at baseline by flow cytometry. The percentage of CD19+ B cells, CD3+ T cells, CD3+CD4+ Th cells, CD3+CD8+ Tc cells, CD3-CD16/56+ NK cells, CD3+CD16/56+ NK-T cells, and CD3bright γδ-T cells were detected within the CD45+CD14- lymphocyte population. Robust ANOVA was used to evaluate the effect of ACPA positivity or the CSA definition. A logistic regression model with a baseline percentage of lymphocyte subpopulations as predictors was constructed to discriminate between progressors to arthritis and non-progressors. The preselection of the best subset of predictors was performed using a stepwise selection based on the Akaike Information Criterion. The models considered were evaluated using ROC curves.

Results: Out of 191 at-risk individuals, 36 developed clinical arthritis (progressors) within a median of 9 months of follow-up and with a median symptom duration of 31,65 months [IQR=44,25], CRP 5,30 mg/l [IQR=12,21] and DAS28(CRP) 4,62 [IQR=2,18] at the time of manifestation. Progressors included 39% ACPA+, 25% CSA+, and 36% both ACPA+ and CSA+ individuals. For the construction of predictive models, 81 individuals (median age 51 years [IQR=17], 89% females) who have not yet progressed to arthritis (non-progressors) with symptom duration longer than 12 months were included to avoid disqualification of non-progressors limited by CSA definition (symptom duration <12 months). Forty-seven % of them were ACPA+, 36% were CSA+, and 17% were ACPA+ and CSA+, with median symptom duration at baseline being 36 months [IQR=36] and median CRP 1,64 mg/l [IQR=3,28]. No statistically significant differences in lymphocyte subpopulations between ACPA+ and ACPA- or CSA+ and CSA- individuals were found. The resulting predictive model for arthritis development performed in all ARRA individuals based on CD19%, NK%, and anti-CCP IgG U/ml showed AUC=0.732 ($p<0.001$). According to this model, a high percentage of CD19+ B lymphocytes and high anti-CCP IgG levels, and a low percentage of NK cells increase the probability of developing clinical arthritis. When the model with the same set of predictors was applied to ACPA+ individuals, AUC was even higher (AUC=0.804; $p<0.0001$). However, we were not able to construct a well-performing classification model in ACPA- individuals. The CSA definition appears of no predictive value in our at-risk cohort.

Conclusion: We propose a predictive model based on baseline levels of lymphocyte subpopulations and ACPA levels to distinguish individuals with arthralgia who progress to clinical arthritis from non-progressors, especially applicable in ACPA+ individuals. The final model includes B cells and NK cells, which are involved in the pathogenesis of RA. This preliminary model built in the ARRA cohort requires further validation in larger at-risk of RA cohorts.

CLINICAL DISEASE ACTIVITY INDEX REMISSION IN RHEUMATOID ARTHRITIS AT 6 MONTHS IS ASSOCIATED WITH HIGHER FREQUENCY OF TRANSITIONAL B CELLS AT DIAGNOSIS

Keywords: Remission, Adaptive immunity, Rheumatoid arthritis

S. Mcgrath[1], B. Sundbeck[1], C. Jonsson[1], K. Thorarinsdottir[1], A. Camponeschi[1], M. Gatto[1], A. K. H. Ekwall[1], R. Van Vollenhoven[2,3], A. Rudin[1], I. L. Mårtensson[1], I. Gjertsson[1]. of Amsterdam, Department of Experimental Immunology, Amsterdam, Netherlands

Background: Early intervention and implementation of effective treatment is a significant predictor of positive long-term prognosis for rheumatoid arthritis (RA). However, despite major advances in treatment options there are currently no biomarkers to clinically guide treatment selection or to identify individuals who do not respond fully to first line therapy. B cells are known to contribute to RA pathogenesis as exemplified by the success of B cell depleting treatments. It is well known that there are changes in the circulating B cell compartment in both new onset and established RA that include reduced memory B cells and increased naïve and transitional B cells. Among transitional B cells there is a subpopulation described as regulatory B cells (Bregs) that is characterised by markers such as high levels of CD24/CD38, and CD1d as well as PDL1 and production of IL-10. To investigate the predictive potential of the B cell compartment for disease outcome, the different B cell populations must be further divided into specific subset and studied in well characterised cohort followed over time.
Objectives: To identify a B cell subset(s) at clinical onset that predict clinical disease activity index (CDAI) remission 6 months after start of treatment.
Methods: Flow cytometry analysis of peripheral blood B cell subsets was conducted on untreated, early RA patients (ueRA; according to ACR/EULAR 1987/2010 criteria; n=71) and sex matched healthy controls (n=24). PBMCs were stained for the following markers: CD19, CD21, CD27, IgD, CD24, CD38, PD1, PDL1. Patients were then treated with methotrexate and randomised to combination with a) prednisolone; b) certolizumab; c) tocilizumab; or d) abatacept. Patients were grouped based on disease remission status at 6 months (remission n=29; no remission n=42) as defined by a clinical disease activity index (CDAI) <2.8. The predictive value of these population frequencies for remission detection was modelled with receiver operating characteristic (ROC) analysis. Peripheral blood from a second ueRA cohort (n=32) and additional healthy donors (n=11) were analysed by flow cytometry including CD1d, PD1 and PDL1.
Results: Relative to patients who reached CDAI remission, individuals who did not respond to this extent to first line therapy at 6 months had significantly reduced frequencies of transitional ($CD19^+$ $CD24^{++}$ $CD38^{++}$), and $PD1^+$ B cells ($CD19^+$ $PD1^+$ $CD21^-$) at diagnosis (Figure 1), which inversely correlated with CDAI at 6 months (r=–0.355, p=0.002; and r=–0.245, p=0.039 respectively). The predictive value of these subset frequencies for remission was modelled with ROC analysis. Both transitional and $PD1^+$ B cell frequencies had significant predictive capabilities and an AUC of 0.67 and 0.7 respectively (Figure 1). Follow-up analysis in the second RA cohort showed that $CD1d^+$ transitional B cells in ueRA patients (median 14.75%; range 9.4-23.4%; n=32) were significantly increased (p<0.0001, Mann-Whitney) relative to healthy donors (median 8.9%; range 4.4-12.9%; n=11).
Conclusion: A reduced frequency of transitional and $PD1^+$ B cells at diagnosis in ueRA patients was associated with failure to reach CDAI remission within 6 months of treatment. As transitional B cells in ueRA patients express markers closely linked to Bregs, we speculate that the lower transitional B cell frequencies we observed at diagnosis may indicate fewer circulating Bregs and thereby worse conditions for endogenous disease control. Thus, monitoring of transitional B cell frequencies at the point of RA diagnosis may aid in the identification of patients who are less likely to reach remission at 6 months and therefore subjected to additional clinical surveillance.

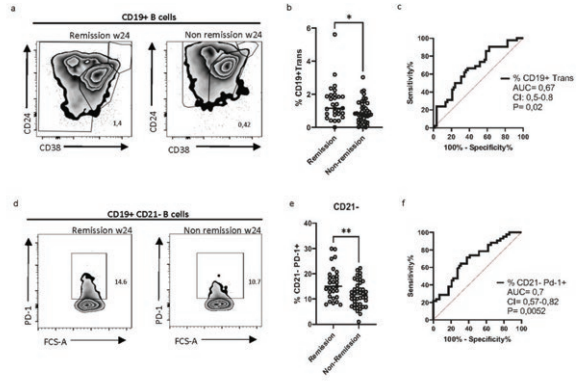

Figure 1. Transitional and PD1+ B cells reduced in treatment refractive RA patients.
a) Patients are subdivided based on 6 month remission status and baseline (samples at diagnosis) peripheral blood B cells analysed by flow cytometry. Transitional cells gated as $CD24^{++}$ $CD38^{++}$ within CD19+ B cells. Representative plots shown for both groups. b) Frequencies of baseline transitional B cells (as a proportion of total B cells) in patients who reach remission and patients who do not reach remission. Mann-whitney U test, * <0.05. c) ROC curve of the frequency of transitional B cells at baseline for prediction of remission by 6 months. d) PD1 gated on CD19+ CD21– B cells. INDIVIDUALS AT RISK FOR RHEUMATOID ARTHRITIS – SELF MONITORING OF SYMPTOMS USING A DIGITAL APPLICATION ENABLES IDENTIFICATION OF HIGH RISK PATIENTS - RESULTS FROM THE PROSPECTIVE REMTORA TRIAL

Keywords: Rheumatoid arthritis, Education, Self-management

N. Pfeuffer[1,2], J. Knitza[1,2], M. Grahammer[3,4], D. Simon[1,2], F. Hartmann[1,2], L. Schuster[1,2], K. Tascilar[1,2], G. Krönke[1,2], G. Schett[1,2], A. Kleyer[1,2]. *[1]Department of Internal Medicine 3, Rheumatology and Immunology, Universitätsklinikum Erlangen and Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany*; *[2]Deutsches Zentrum für Immuntherapie, Universitätsklinikum Erlangen and Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany*; *[3]Abaton GmbH, Abaton, Berlin, Germany*; *[4]Center for Health Services Research, Faculty of Health Siences Brandenburg and Brandenburg Medical School Theodor Fontane, Rüdersdorf bei Berlin, Germany*

Background: Individuals at risk for rheumatoid Arthritis (RA) typically describe diffuse, fluctuating and flare-like symptoms followed by symptom-free periods. In this pre-disease continuum preplanned physical visits reveal only a fraction of symptoms and rudimentarily capture the burden of disease. Implementation of a smartphone-based patient self-monitoring approach could help to characterize the burden of pre-stage disease and enable a timely start of therapy. (1,2)
Objectives: The aim of this study is to evaluate the implementation of a smartphone-based remote patient self-monitoring application in patients in the prodromal phase of RA and to create a predictive tool for the distinction of high-risk and low-risk patients.
Methods: Individuals at risk for RA fulfilling the following inclusion criteria were recruited in a prospective 6-month trial: Proof of anti-citrullinated peptide antibodies (ACPA), no clinically detectable synovial swelling at doctors visit, smartphone ownership. Participants were recruited from a prospective at-risk cohort and provided written consent (ethics-approval: 333_16B and 21_21B). All individuals were presented two standardized, self-produced educational videos about joint self-examination and pre-clinical RA and were informed about the remote monitoring option, using the CE-certified ABATON app. A new adaptive questionnaire-based algorithm “REMOTRA; REMote moniToring in pReclinical Arthritis” was developed including typical RA symptoms such as pain, swelling, morning stiffness and intake of pain medication. The criteria are weighted and added to a quantitative score from 0 to 15 pts. A cut-off value from 10 or more was defined as being highly symptomatic. The total number of questions varies depending on the answers given. Questionnaire frequency was based on shared-decision-making (every 7, 14 or 30 days). App usability and acceptance was measured using the System Usability Scale (SUS) and Net Promoter Score (NPS). Routine clinical visits were scheduled on a regular basis every 3 months.
Results: 79 patients were approached and 43 patients consented to participate (13 male; mean age: 49.3; 7-day/14-day/30-day interval: 3/15/25). Three patients (7%) developed RA during the six months of study follow-up. Patient acceptance of the questionnaire decreased during the trial, from an NPS of 21.8 (47.8% promoters) at 3 months down to 8.3 (45.8% promoters) at six months. The education videos were well accepted with an NPS of 31.6 (joint self-examination; 57.9% promoters) and 54.4 (Pre-RA; 63.6% promoters). Questionnaire usability was continuously rated as high with an average SUS of 88.1/100 (SD: 5,5) at three months and 85.4/100 (SD: 16.0) at six months. The most frequently reported symptoms were joint pain (78.0%, n=32), followed by joint swelling (73.2%, n=30) and morning stiffness (43.9%, n=18). 58.5% (n=24) took analgesics and 29.3% (n=12) took prednisolone at least once. Seven patients (16.3%) reported no symptoms during the six months. None of the patients with a REMOTRA -Score <10 developed RA (negative predictive value: 100%). However, patients with a score of 10 or more were diagnosed with a RA in their next consultation with a probability of 12% (positive predictive value). Monitoring adherence was high with a mean of 4.6 (SD: 2.0) months app usage and 57.1% completing all questionnaires.
Conclusion: Our study shows that individuals at-risk for RA appreciate standardized digital disease education and mostly adhere to a telemedicine monitoring program. Remote self-monitoring sheds light on disease progress of at-risk patients. Further development and testing of this method may be worthwhile for a better informed and efficient utilization of limited in-person visit slots.

Background: Several therapeutic options are currently available to treat rheumatoid arthritis (RA); however, the response to treatment is highly variable, and not all patients achieve clinical remission [1]. Obesity is suggested to lower the chances of remission [2], even though a recent observational study has shown that obesity is not associated with reduced response to conventional synthetic anti-rheumatic drugs in patients with early RA [3].

Objectives: The aim of this study is to determine if obesity affects the response to treatment in participants with early RA.

Methods: This report includes 393 Swedish patients from the NORD-STAR study, which is a multicenter, randomized trial on 812 patients with untreated early RA [4]. The 393 participants have been randomized at baseline into 4 arms of treatment: methotrexate combined with (1) prednisolone, (2) certolizumab, (3) abatacept, or (4) tocilizumab. Scores for disease activity and blood samples were measured and collected before randomization and at 24-week follow-up. Multiple linear regression and binary logistic regression analyses were performed after adjustment for sex, baseline age, anti-citrullinated peptide antibody status, current smoking, disease activity score- C-reactive protein (DAS28-CRP), and treatment randomization. The outcomes for this report were: DAS28-CRP ≤3.2 (DAS28-CRP low disease activity), DAS28-CRP ≤2.6 (DAS28-CRP remission) and clinical disease activity index (CDAI) ≤2.8 (CDAI remission).

Results: In total, 75 (19%) participants had obesity at baseline, defined as body mass index (BMI) ≥30 kg/m^2. The percentage of patients with obesity in each treatment group was (1) 25%, (2) 15%, (3) 19% and (4) 19%. At baseline, there were no differences in terms of disease activity indices and inflammation parameters between patients with BMI <30 vs. ≥30 kg/m^2, except for the number of swollen joints (SJC28), which was slightly lower in those with obesity (mean+SD, 8±5 vs. 9±5, p=0.018). At 24-week follow-up, patients with obesity had higher disease activity indices and inflammation parameters compared to patients with lower BMI (Table 1). Moreover, patients with obesity had a lower chance of achieving response to treatment as measured by DAS28-CRP ≤3.2 (OR 0.5, 95% CI 0.2 - 0.9, p=0.025), DAS28-CRP ≤2.6 (OR 0.4, 95% CI 0.2 - 0.6, p <0.001) and CDAI remission (OR 0.4, 95% CI 0.2 - 0.8, p=0.006), compared to patients with lower BMI (Figure 1). BMI-treatment interaction was not significant for any score of disease activity.

Conclusion: In patients with early RA, obesity was not associated with higher disease activity before treatment initiation. However, 24 weeks after treatment, patients with obesity had higher disease activity and lower chances to respond to therapy compared to patients with lower BMI irrespective of treatment.

Table 1. Disease activity scores and inflammatory parameters at 24 weeks follow-up stratified by baseline BMI

	BMI (kg/m^2)		P-values
	< 30	≥ 30

POS0325 RHEUMATOID ARTHRITIS PATIENTS AND WEATHER PATTERNS: A RHUMADATA™ STUDY OF 14,200 PATIENT-REPORTED OUTCOMES MATCHED WITH METEOROLOGICAL DATA

Keywords: Real-world evidence, Patient reported outcomes, Rheumatoid arthritis

M. Joly-Chevrier[1], L. Coupal[2], L. Choquette Sauvageau[2], D. Choquette[2].
[1]Université de Montréal, Médecine, Montréal, Canada; *[2]Institut de rhumatologie de Montréal, Rhumatologie, Montréal, Canada*

Background: Anecdotally, patients with rheumatoid arthritis (RA) report seasonal changes in their symptoms. Anatomically, atmospheric pressure variations are captured by baroreceptors, which may generate this perception.
Objectives: To correlate seasonal changes with subjective assessment scores.
Methods: Environment Canada provided meteorological data from 2015 to 2020 for Montreal (Dorval). Hourly measurements of temperature, relative humidity, and pressure were available. We matched daily meteorological data with patient-reported pain (PtP), fatigue (PtF), and disease activity (PtGA) assessments from RHUMADATA™ participants. We calculated daily means, minimums, and maximums, as well as changes from the previous day for the winter and summer months. For the years 2015 to 2020, Pearson Correlation Coefficients (PCCs) were computed between Patient Reported Outcomes (PROs) and weather measurements. Optimal regression models (OM) were derived based on Akaike's Information Criteria (AIC).
Results: RA patients' PROs were matched with meteorological data (7411 winter measurements and 6789 summer measurements). At the time of the first PRO assessment, the mean age and disease duration were 60.1(13.5) and 10.5 (10.4), and 74.6% of patients were women. Patients provided an average of 14 PROs. In winter, PtP, PtF and PtGA were 3.48 (2.79), 3.49 (2.96) and 3.42 (2.66), and 3.45 (2.81), 3.46 (2.96) and 3.33 (2.63) in summer. PtGA was statistically higher in winter (p-value=0.0379). PCC and OMs are shown in Table 1. In winter, all correlations are very weak (less than 0.19). PtGA is not correlated with any weather measures in both winter and summer. PtP and PtF correlate with some weather measures in both seasons.
Conclusion: In this study of 14200 wheather-matched PROs, mean PtP, PtF, and PtGA scores are higher in winter among RA patients, but the differences are small. Few meteorological measures are significantly correlated with PROs, and all correlations are very weak. Meteorological variables explain a quite small percentage of the variation in PRO variation (small R-square). No consistent relationship between PROs and meteorological conditions is reported by other smaller studies.

POS0326 POLYGENIC RISK SCORE OF RHEUMATOID ARTHRITIS PREDICTS BONY EROSION

Keywords: Prognostic factors, Rheumatoid arthritis, Genetics/Epigenetics

T. S. Wu[1], Y. J. Chen[1], W. N. Huang[2], Y. H. Chen[2], Y. M. Chen[1,2]. *[1]Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China*; *[2]Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Taichung, Taiwan, Republic of China*

Background: Polygenic risk scores (PRS) are widely used to estimate disease risks and predict clinical outcomes. However, differences exist among PRS derived from genome-wide association study (GWAS) of ethnicities across the globe.
Objectives: We aimed to build up PRS for predicting the development of rheumatoid arthritis (RA) in a Taiwanese population and investigate whether PRS of RA may be associated with bone erosion.
Methods: We constructed PRS using GWAS data from a hospital-based cohort of 2044 RA cases and 7950 non-RA controls participating in the Taiwan Precision Medicine Initiative. LDpred2, PLINK and PRsice2 models were used to evaluate the area under curve (AUC) of RA susceptibility in both training and testing datasets (1022 RA cases and 3975 controls).

[1] PCC=Pearson Correlation Coefficients. [2] γ: 0.001<p≤0.01, δ: 0.01<p≤0.05. [3] The best model was selected by computing Akaike's Information Criteria (AIC) for all possible subsets of multiple regression models for main effects. The model with the smallest AIC value is deemed the "best" model. [4] Difference from the previous day.

Demographic data, seropositivity of rheumatoid factor (RF), anti-citrullinated protein antibody (ACPA), treatment with biological and targeted synthetic disease modifying anti-rheumatic drugs (bDMARDs and tsDMARDs) and bone erosions by either plain x ray or ultrasonography were compared among quantiles of PRS.

Results: PRS of 97,396 single nucleotide polymorphisms derived from LDpred2 exhibited the highest AUC for predicting the development of RA in the overall dataset as compared with the remaining algorithms. Participants with the top RA-PRS quantile have the highest proportion of RF and ACPA positivity (74.8% & 65.0%, respectively), bone erosion (86.4%) and higher chance to receive bDMARDs or tsDMARDs (42.3%) as compared to the counterparts. In addition, RA-PRS quantile was a significant risk for bone erosion in the multivariate regression model with the adjustment of RF, ACPA positivity and therapeutic medication, specifically in the group of age < 60 years.

Conclusion: PRS is associated with seropositivity, erosive bone disease, need for advanced therapy in Taiwanese patients with RA.

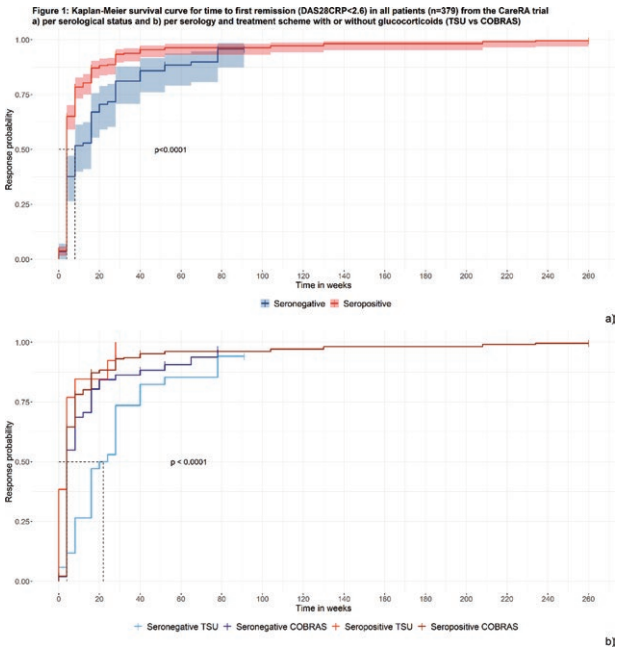
Background: Seronegative rheumatoid arthritis (RA) patients have been historically considered to have a milder disease course.



Objectives: We aimed to compare the disease course in seronegative and seropositive patients from the Care in early RA (CareRA) trial.

Methods: We used data from the 2-year RCT CareRA and its 3-year observational follow-up, CareRA plus. Patients completing the year 2 visit of CareRA were eligible for participation in CareRA plus, in which patients were evaluated every 6 months till year 5. The CareRA trial included patients early RA (≤1 year) and naïve to disease-modifying anti-rheumatic drugs. Patients were stratified in a low- and high-risk group according to prognostic markers and randomized to one of four different treatment schemes: a) MTX and a step-down glucocorticoid (GC) scheme (COBRA Slim) b) this combination with either sulphasalazine (COBRA Classic) or c) leflunomide (COBRA Avant-Garde) in high-risk patients, and d) MTX without GCs (Tight-Step-Up: TSU) or e) COBRA Slim in low-risk patients. Treating-to-target, steering at low disease activity (≤3.2) measured in 28 joints with C-reactive protein (DAS28CRP) was applied while aiming for remission (<2.6) as final outcome. Differences in demographic, clinical and laboratory variables were tested with Wilcoxon rank or Chi-square. Multiple testing was corrected with Holms-Bonferroni. Survival analysis using Kaplan-Meier and Cox regression compared (a) time to first remission (DAS28CRP<2.6), (b) time to first loss of disease-control (DAS28CRP>3.2) in those reaching remission, and all subsequent losses of disease-control as recurrent events between seropositive (ACPA or RF positive) and seronegative (ACPA and RF negative) patients. Survival curves were compared with log rank. To model recurrent events, an extended Cox model with random effect, including the presence of erosions at baseline, disease duration, gender, current smoking, treatment scheme with or without GCs and DAS28CRP at baseline and week 16 was used. Multiple imputation (m=100) was used to handle missing data.

Results: Of the 379 included patients, 83 (23%) were seronegative while 292 (77%) were seropositive. Seronegative patients had a similar median age (54 vs 53 years, p=0.58), BMI (26.5 vs 25.7 kg/m^2, p=1.0), presence of erosions (26% vs 25%, p=1.0) and gender distribution (76% vs 68% females, p=1.0), compared to seropositive patients. However, median disease activity was higher in seronegative patients at baseline: DAS28CRP (5.1 vs 4.7, p<0.01), 28 swollen joint count (8 vs 6, p<0.01) and 28 tender joint count (10 vs 7, p<0.001). DAS28CRP remained significantly higher at week 8 (3.0 vs 2.1, p<0.001), but became comparable by year 1 (2.0 for both p=1.0). There was a significant difference in time to first treatment response between seronegative and seropositive patients as depicted in the inverted Kaplan-Meier plot (Figure 1a). Time to first remission was significantly shorter for seropositive (median 4 weeks IQR 4;8) versus seronegative (8 weeks IQR 4:28) patients (p<0.001). When accounting for the treatment, all COBRA schemes with GCs increased the chance of reaching remission by 58% (HR 1.58; 95%CI 1.10-2.27; p<0.05) compared to TSU (Figure 1b). For the time to first and consecutive losses of disease control after remission, one point higher DAS28CRP at week 16 increased the risk of losing disease control by 59% (HR 1.59; 95%CI 1.38-1.82; p<0.0001), serology status was not significantly predictive of loss of response.

Conclusion: In CareRA, seronegative patients, who have been historically considered to have a milder form of the disease, had a higher initial disease activity, longer time to first treatment response and greatly benefited from an initial treatment scheme that included glucocorticoids. Speed of response during the window of opportunity for RA has been highly advocated. Our findings highlight

that seronegative RA requires an equally intensive initial treat-to-target therapy as seropositive RA to reap the benefits of the window of opportunity.

Lei[1,7,8]. *[1]Central South University, Xiangya Hospital, Department of Orthopaedics, Changsha, China*; *[2]Massachusetts General Hospital, Harvard Medical School, Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Boston, United States of America*; *[3]Massachusetts General Hospital, Harvard Medical School, The Mongan Institute, Times New Roman, United States of America*; *[4]School of Medicine, University of Nottingham, Academic Rheumatology, Nottingham, United Kingdom*; *[5]School of Medicine, University of Nottingham, Pain Centre Versus Arthritis UK, Nottingham, United Kingdom*; *[6]Xiangya Hospital, Central South University, Department of Endocrinology, Endocrinology Research Center, Changsha, China*; *[7]Xiangya Hospital, Central South University, National Clinical Research Center for Geriatric Disorders, Changsha, China*; *[8]Xiangya Hospital, Central South University, Hunan Key Laboratory of Joint Degeneration and Injury, Changsha, China*; *[9]Xiangya Hospital, Central South University, Health Management Center, Changsha, China*; *[10]Xiangya School of Public Health, Central South University, Department of Epidemiology and Health Statistics, Changsha, China*

Background: Hand osteoarthritis is a common heterogeneous joint disorder with differences in aetiology and pathophysiology from the large weight-bearing knee or hip osteoarthritis.[1]-[3] Its pathophysiological mechanism remains largely unexplored, partially because of limited access to clinical sample tissues and lack of animal models.[2] To date, there is no known cure for hand osteoarthritis, indicating an urgent need for better understanding of the underlying mechanisms so that appropriate treatment strategies can be developed to target this disabling disease.

Objectives: We aimed to identify hand joint chondrocyte subpopulations and investigate the molecular mechanism of hand osteoarthritis by performing single-cell RNA sequencing (scRNA-seq) analysis, and verify the findings in two large independent population-based studies.

Methods: We obtained hand interphalangeal joints from five donors who had destructive forearm injury. Using scRNA-seq analysis, we analysed the cellular composition and subpopulation-specific gene expression of hand articular cartilage, and then compared these features between cartilages from joints with macroscopically confirmed osteoarthritis and those without osteoarthritis. To verify the findings, we conducted a Mendelian randomisation study in the UK Biobank and a cross-sectional study using data collected from the Xiangya Osteoarthritis Study. Figure 1 shows the schematic illustration of this study.

Results: Of 105,142 cells we identified 13 subpopulations, including a novel inflammatory chondrocyte subpopulation that specifically expressed genes related to inflammatory and immune response. Fibrocartilage chondrocytes represented a major source of osteoarthritis-related proteases and exhibited an extensive alteration of gene expression patterns in osteoarthritic cartilage compared with non-osteoarthritic cartilage. Both inflammatory chondrocytes and fibrocartilage chondrocytes showed a trend towards increased numbers in osteoarthritic cartilage. In these two subpopulations from osteoarthritic cartilage, the ferroptosis pathway was enriched, in which the expression of iron overload-related genes, eg, *FTH1*, was elevated. These findings are further validated by two independent population-based studies. Among participants (n=332,668) in the UK Biobank, genetic predisposition to higher expression of *FTH1* mRNA significantly increased the risk of hand osteoarthritis (OR=1·07, 95%CI:1·02-1·11). Among participants (n=1,241) from the Xiangya Osteoarthritis Study, high levels of serum ferritin (encoded by *FTH1*), a biomarker of body iron overload, were significantly associated with a high prevalence of hand osteoarthritis (*P*-for-trend=0·037).

Conclusion: Our datasets will be valuable as a rich resource for molecular and cellular exploration and open new possibilities for the research of molecular mechanism, drug development and precise treatment for hand osteoarthritis. Inflammatory and fibrocartilage chondrocytes are key subpopulations and ferroptosis may be a key pathway in hand osteoarthritis. Markers of these chondrocyte subpopulations, as well as ferroptosis inhibitors or iron chelators, could be focus of attention in future studies.

Background: The latest professional guidelines recommend intra-articular (IA) glucocorticoids (GCs) for pain relief in patients with knee osteoarthritis (OA). However, their effect is small-to-moderate and short-term only[1]. There is also concern about the possible risk of cartilage deterioration caused by repeated IA GCs. M1 macrophages and activated synovial fibroblasts (SFs) mutually contribute to the propagation of joint pain and cartilage destruction in OA by constructing a positive feedback loop. To alleviate joint pain more effectively over a longer period without increasing the risk of cartilage deterioration, we developed nano-porous cellular membrane (NM) camouflaged liposome (NM@Lip) for targeted delivery of triamcinolone acetate (TA), one of the IA GCs most commonly used for OA, to both M1 macrophages and activated SFs in the synovium of osteoarthritic joints.

Objectives: To investigate the phenotypic reprogramming effect of TA-loaded NM@Lip (TA-NM@Lip) in M1 macrophages and activated SFs and determine their ability in relieving pain and alleviate OA progression in rodent models.

Methods: TA-NM@Lip was fabricated using the thin-film hydration method. The mRNA and protein levels of pathogenic mediators secreted by M1 macrophages and activated SFs treated with free TA, TA-loaded liposome (TA-Lip) or TA-NM@Lip for 24 h were measured using real-time PCR, RNA sequencing, ELISA and Immunofluorescence staining. To evaluate the joint retention time of NM@Lip, 1,1'-dioctadecyl-3,3,3',3'-tetramethyl indodicarbocyanine, 4-chlorobenzenesulfonate salt (DiD) solution, DiD-loaded Lip or DiD-loaded NM@Lip was injected intra-articularly into the osteoarthritic joints of monosodium iodoacetate (MIA) rats and the fluorescence images were captured by In Vivo Imaging System for 28 days. To study the therapeutic effect of different TA formulations, triamcinolone acetonide injection (TA IR), TA-Lip, TA-NM@Lip, or blank NM@Lip was injected intra-articularly into the osteoarthritic knee of MIA rats at one week after MIA injection or at one week and five weeks after anterior cruciate ligament transection combined with partial medial meniscectomy (ACLT + pMMx) surgery. Mechanical allodynia and hind paw weight distribution were assessed to determine the rats' pain-related behavior. The phenotypic alteration ability and therapeutic efficacy of TA IR, TA-Lip, TA-NM@Lip, and NM@Lip were verified by micro-computed tomography, histological and immunofluorescence staining.

Results: TA-NM@Lip was the most efficient in downregulating the expression of M1-related genes and upregulating M2-related genes compared with other treatment groups. The mRNA and protein levels of pro-inflammatory cytokines, adhesion molecule and proteolytic enzyme secreted by activated SFs were significantly downregulated by TA-NM@Lip. NM@Lip was retained in the joint for up to 28 days and selectively distributed into both M1 macrophages and activated SFs in synovium with low distribution in cartilage. In MIA-induced model, a single IA injection of TA-NM@Lip attenuated synovitis and achieved complete pain relief without inducing adverse effects. In ACLT + pMMx-induced model, repeated TA-NM@Lip did not cause apoptosis of chondrocytes or damage cartilage and attenuated cartilage degeneration.

Conclusion: TA-NM@Lip exhibited extended joint-retention time and selectively remodeled the phenotype of synovial M1 macrophages and activated SFs in OA joints. This dual-targeting scaffold effectively attenuated synovitis, decreased cartilage degeneration, and achieved complete relief of joint pain in two distinct rodent models of OA.

POS0331 MOLECULAR MECHANISMS OF CHONDROPROTECTION INDUCED BY ROR2 BLOCKADE

Keywords: Osteoarthritis, Cell biology

A. S. Thorup[1], J. Wilson[1], M. Deniz[1], F. Dell'accio[1]. *[1]The William Harvey Research Institute, Experimental Medicine and Rheumatology, London, United Kingdom*

Background: We previously reported that ROR2 blockade (ROR2i) induces chondrogenesis *in vitro* and *in vivo*, improving pain and cartilage integrity following joint destabilization in mice (Thorup *et al.*, 2020). Downregulation of YAP signalling was required for chondrogenesis induced by ROR2i, but *per se* not sufficient. Overexpression of constitutively active YAP negated ROR2i-induced chondrogenesis, but the YAP inhibitor Verteporfin was unable to induce chondrogenesis. This means that something else must take place in addition to YAP inhibition for ROR2i to induce chondrogenesis.

Objectives: In this study, we used a phosphoproteomic approach to detail downstream ROR2 signalling in chondrogenic cells.

Methods: Cartilage differentiation was assessed in C3H10T1/2 cells cultured in micromass using Alcian Blue staining and the expression of mRNA encoding chondrogenic markers. Osteogenesis was assessed by molecular marker analysis, alkaline phosphatase activity and alizarin red staining. Phosphoproteomics screening was performed by precipitation of phosphoproteins on TiO2 columns followed by mass spectroscopy. Ror2-/- C3H10T1/2 cells using CRISPR/Cas9.

Results: In keeping with the delayed endochondral ossification and chondrocyte hypertrophy observed in Ror2-/- mice (DeChiara *et al.*, 2000), Ror2-/- C3H10T1/2 cells failed to undergo osteogenesis when exposed to osteogenic medium as assessed by alkaline phosphatase activity, extracellular matrix calcification and expression of hypertrophy/osteogenic markers. We established suitable time points for ROR-2 mediated phosphorylation events based on ERK (early) and JNK (late) phosphorylation following stimulation with WNT5A. Phosphoproteomics analysis using a label-free approach, revealed 1109 early (5 min) phosphorylation events that were ROR2 dependent (taking place in the wild type but

not in the Ror2-/- CRISPR cells) and 708 at 15 minutes. In keeping with the requirement of YAP for ROR2i-dependent chondrogenesis (Thorup *et al.*, 2020), several phosphorylation events of molecules within the YAP pathway occurred including YAP and LATS1/2. In keeping with this, YAP dependent transcription was modulated by WNT5A in a ROR2-dependent manner in a reporter assay. Several phosphorylation sites were non-conventional, suggesting a complex, non-canonical, regulation of YAP by ROR2. Other signalling pathways, previously known to be involved in chondrogenesis, were involved including insulin, autophagy and focal adhesion. Many phosphorylation events were previously poorly characterised.

Conclusion: ROR2i induces modulation of several signalling pathway in addition to YAP. The hierarchy of these phosphorylation events needs to be resolved to identify the detailed molecular mechanism underpinning the efficacy of ROR2i in osteoarthritis.

POS0332 **WITHDRAWN**

POS0333 **NLRP12 EXACERBATES OSTEOARTHRITIS BY PROMOTING DEGRADATION OF NOD2 IN SYNOVIAL MACROPHAGES**

Keywords: Synovium, Innate immunity, Osteoarthritis

C. LI[1], S. Lin[1], Z. Ouyang[1], T. Liu[1], Z. Zheng[1], J. Xu[1], Y. Ding[1]. [1]*Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Orthopaedic Surgery, Guangzhou, China*

Background: Osteoarthritis is the most common degenerative bone and joint disease. Hypothesis has been widely accepted that osteoarthritis (OA) starts from cartilage injury and loss, while emerging evidences suggest that synovial inflammation precedes cartilage loss during the progression of OA [1]. Activation of macrophages plays a crucial part in synovial inflammation in OA [2]. In our previous researches, we have demonstrated NOD2 as an inhibitor of macrophage activation *in vitro*. Besides, bioinformatic analysis suggested a potential link between NLRP12 and NOD2.

Objectives: To investigate the role of NOD2 in OA *in vivo* and explore the potential interaction between NOD2 and NLRP12.

Methods: We established CIOA (Collagenase-induced OA) model with 8-week-old C57BL/6J mice, and injected NOD2 over-expression (oe-NOD2) lentiviral vectors into the knee joint cavity as experimental group (CIOA + oe-NOD2), with the empty vectors as control (CIOA + Mock). 8 weeks later, the knee joints were harvested and stained with Safranin O/fast green. Besides, three-dimensional reconstruction of Micro-CT images were employed to evaluate the pathological changes of OA. In addition, we applied lentiviral transfection, co-immunoprecipitation (Co-IP), and ubiquitination assays to investigate the interaction between NOD2 and NLRP12, as well as its mechanism of action in the regulation of macrophage activation.

Results: *In vivo* over-expression of NOD2 showed significant inhibition of pathological changes (Figure 1A, 1B). Though NLRP12 had no impact on mRNA level of NOD2 in RAW264.7 macrophages (Figure 1C), NOD2 expression at protein level was negatively correlated with NLRP12 (Figure 1D), suggesting that NLRP12 may influence the degradation of NOD2. Co-IP experiments also confirmed the existence of interaction between NLRP12 and NOD2 at protein level, which was influence by MG132, inhibitor of ubiquitin-proteasome pathway (Figure 1E). Besides, NLRP12 over-expression impaired inhibition of macrophage inflammation by NOD2 (Figure 1F). Since HSP90 binds NOD2 to prevent its

proteasomal degradation via poly-ubiquitination (Poly-Ub) [3], we therefore performed Co-IP and Poly-Ub assays. NLRP12 was associated with reduced binding of HSP90 with NOD2, greater scale of K48 Poly-Ub assembling on NOD2, and thus lower level of NOD2 protein. Furthermore, proteasomal degradation of NOD2 was blocked by MG132, though interrupted binding between NOD2 and HSP90, and accumulation of Poly-Ub chains (Figure 1G). These findings suggested sequestration of HSP90 from binding NOD2 by NOD2-NLRP12 interaction, which leaded to assembly of K48 Poly-Ub chains onto NOD2, and its proteasomal degradation (Figure 1H).

Conclusion: NOD2 was demonstrated as an inhibitor of OA *in vivo*, in consistence with our previous *in vitro* data. Besides, NLRP12 interacted with NOD2, and promoted its Poly-Ub and subsequent proteasomal degradation. Our findings highlighted the impressive potential of NLRP12 to be a preventative and therapeutic target in OA, though more in-depth investigations are indispensable before further conclusion is reached.

Background: Pathologic calcification (PC) is the deposition of calcium-containing crystals in soft tissues. PC of cartilage is a hallmark of osteoarthritis (OA), a degenerative joint disease characterized by cartilage degradation. The interplay between calcification- and extracellular matrix (ECM) formation, maturation and degradation in cartilage is not fully understood.

Objectives: We aim to reveal the role of lysyl oxidases (LOX(L)), a family of extracellular enzymes that catalyze collagen crosslinking, in OA cartilage calcification.

Methods: We induced *in vitro* chondrocytes calcification with calcifying medium (CM = BGJb +10% FBS+ 20mM β-glycerophosphate + 50μg/ml ascorbic acid) or control (Nt = DMEM high glucose + 10% FBS), and treated or not with 500μM β-aminoproprionitrile (BAPN). Gene expression was analyzed by qRT-PCR, Il-6 in cell supernantants by ELISA, mitochondrial and cytoplasmic reactive oxygen species (ROS) by use of the kits MitoSOX and DHE (Life Technologies). We induced i*n vivo* murine knee calcifications using the menisectomy (MNX) mode, where medial meniscus is removed in the right knee, while the left knee is sham operated. During two months, mice were injected with PBS or BAPN 50mg/Kg twice per week, and given 1mg/ml BAPN in drinking water. New calcific formation in knees were analyzed by microCT. Bioinformatics analysis was performed with an online tool at www.systems-genetics.org/mmad, using the Modules by Module section in GeneBridge. Manhattan plots were generated by correlating collagen fibril organization module (GO:0030199, representing LOX/L family of enzymes, and calcification-, chondrocyte hypertrophy- and catabolic enzymes-associated modules.

Results: Our findings revealed that CM and calcium-containing crystals induced lox(l) activity in murine chondrocytes *in vitro*. Conversely, treatment with the lox(l) pan-inhibitor BAPN, decreased crystal production in vitro, while decreasing calcification gene expression of *Anx5*, *PC1*, *Pit-1/2* and Alp activity. Intriguingly, we identified that the pro-calcifying effects of LOX/L were mediated via their classical cross-linking activity, as diminished cross-links in pre-formed extracellular matrix reduced in parallel chondrocyte calcification, with specific suppression of *Anx5* and *Pit-1/2* genes. Additionally, BAPN reverted the hypertrophic phenotype of calcifying chondrocytes, reducing expression of *Runx2* and *Col10* and increasing that of early differentiation *Sox9* and *Col2*. In the same conditions, LOX/L inhibition downregulated *Col1* and *Col3*, whose uncontrolled production can lead to ECM fibrosis and calcification. BAPN also inhibited the expression and release of pro-calcifying cytokine Il-6, while also reducing mitochondrial and cytoplasmic ROS, known to be associated with PC. Additionally, we revealed in calcifying chondrocytes that BAPN inhibition decreased cartilage catabolic enzymes genes (*Mmp3*, *Mmp13* and *Adamts5*). In line, treatment with BAPN in an *in vivo* murine OA model based on meniscectomy, led to decreased knee joints calcifications, while not affecting the bone mineral density of the knee. We also confirmed the role of lox/l in human OA cartilage calcification. Indeed. LOX(L) inhibition by BAPN led to reduced crystal production in primary human OA chondrocytes. Finally, a bioinformatics transcript analysis of available human and murine databases obtained from tissues potentially undergoing PC, further confirmed a positive association between LOX(L)/collagen fibril organization module and calcification-, chondrocyte hypertrophy- and catabolic enzymes-associated modules.

Conclusion: Collectively, our results revealed for the first time a pro-calcifying effect of LOX(L) in chondrocytes, through classical (cross-linking of extracellular matrix) and non-classical pathways (i.e. chondrocyte hypertrophy, increased matrix synthesis and degradation, and exacerbated IL-6 and ROS production). In conclusion, LOX(L) provide a novel target for future therapies aimed at treating pathologic cartilage calcification.

POS0335 EXOSOMES TRANSMIT DAMAGE SIGNALS FROM INFRAPATELLAR FAT PAD AND EXACERBATE CHONDROCYTE SENESCENCE IN OSTEOARTHRITIS

Keywords: Osteoarthritis, Treat to target

Y. Cao[1], J. Ruan[1], J. Kang[1], X. Nie[1], G. Ruan[1], Z. Zhu[1], W. Han[1], S. Tang[1], C. Ding[1]. [1]*Zhujiang Hospital, Southern Medical University, Clinical Research Centre, Guangzhou, China*

Background: Infrapatellar fat pad (IPFP) is closely associated with the development and progression of knee osteoarthritis (OA)[1-5], but the underlying mechanism remains unclear.

Objectives: This study aims to investigate the role and regulatory mechanisms of osteoarthritic infrapatellar fat pad (IPFP) tissue-derived exosomes (IPFP-Exos) in chondrocytes senescence and osteoarthritis (OA) progression.
Methods: The IPFP were collected from late-stage OA patients with knee arthroplasty. The role of endogenous osteoarthritic IPFP-Exos was measured in human IPFP explants coculturing with chondrocytes and mice post-traumatic OA models induced by destabilization of the medial meniscus (DMM) surgery with GW4869 or vehicle treatment. Extraction of IPFP tissue exosomes was performed by ultracentrifugation. Chondrocytes degradation and cellular senescence were assessed by qRT-PCR, western blotting, alcian blue and toluidine blue staining, immunofluorescence and senescence-associated beta-galactosidase staining, respectively. MiRNA sequencing was employed in IPFP-Exos to explore its cargoes. Luciferase reporter assay was used to reveal the interaction between exosomal miRNAs and their downstream mRNA target.
Results: Osteoarthritic IPFP tissue could secret exosomes and delivery them into articular chondrocytes. Inhibition of endogenous osteoarthritic IPFP-Exos significantly alleviated cartilage distruction. Functional assays *in vitro* demonstrated that IPFP-Exos significantly promoted chondrocyte extracellular matrix (ECM) catabolism and cellular senescence. Moreover, further experiments demonstrated that IPFP-Exos induced ECM degradation in human and mice cartilage explants and aggravated the progression of experimental OA mice model. Mechanistically, highly enriched let-7b-5p and let-7c-5p in IPFP tissue-derived exosomes were essential to mediate detrimental effects by directly decreasing senescence negative regulator, lamin B receptor (LBR). Notably, intra-articular injection of antagomirs inhibiting let-7b-5p and let-7c-5p in mice increased LBR expression, suppressed chondrocyte senescence and ameliorated the progression of experimental OA model.
Conclusion: This study highlights the function and mechanism of the IPFP-Exos in the progression of OA. Targeting IPFP-Exos cargoes of let-7b-5p and let-7c-5p provide a potential prevention strategy for OA.

POS0336 **PERIPHERAL IMMUNOME DYSREGULATIONS REFLECT OSTEOARTHRITIS (OA) JOINT DISEASE SEVERITY**

Keywords: -omics, Osteoarthritis

A. Chia[1,2], A. M. Lajam[1], G. Ang[1], M. Wasser[1], P. Kumar[1], K. Leung[3,4], S. Albani[1,2,5]. [1]*Translational Immunology Institute, SingHealth Duke-NUS Academic Medical Centre,Translational Immunology Institute, Singapore, Singapore*; [2]*Duke-NUS Medical School, Cancer and Stem Cell Biology (CSCB), Singapore, Singapore*; [3]*Duke-NUS Medical School, Duke-NUS, Singapore, Singapore*; [4]*Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore*; [5]*KK Women's and Children's Hospital, Rheumatology and Immunology Service, Department of Paediatric Subspecialties, Singapore, Singapore*

Background: Osteoarthritis (OA) is a prevalent condition that is especially common among people of advanced ages. It is due to cartilage degeneration which leads to loss of mobility and chronic pain. Currently, there is no disease-modifying drugs to treat OA and the standard of care is pain management, and eventual joint replacement for end-stage disease. It is recognized that OA pathogenesis involves a complex interplay of joint damage, poor cartilage regeneration, and inflammation. However, much is unknown how the peripheral immunome architecture is perturbed by the local joint inflammation.
Objectives: To investigate how the peripheral immunome is dysregulated by local joint inflammation as a result of knee OA, and whether different immune subsets are dysregulated at different stages of OA severity.
Methods: We employed the use of mass cytometry time-of-flight (CyTOF) to investigate peripheral blood mononuclear cells (PBMCs) obtained from patients with OA and healthy controls (HCs). 64 patients with different severity of OA, based on radiographic Kellgren-Lawrence scores, and 37 age, sex, and race-matched HCs were enrolled in this study. To broadly capture the dysregulations in the different immune subsets, we designed two CyTOF marker panels that cover major innate and adaptive immune cell lineages to interrogate these samples. To investigate possible relationships between the peripheral and joint immunome dysregulations, digital deconvolution of RNA-sequencing data obtained from OA synovial samples to estimate immune subset frequency changes in the joint was also conducted.
Results: We observed dysregulations in both the innate and adaptive compartments of the OA peripheral immunome as compared to HCs, and different immune subsets were dysregulated at different OA severity. In early OA, there is an involvement of inflammatory immune subsets, namely natural killer (NK) and gamma-delta T cells, suggesting the possibility of these subsets infiltrating the joint to initiate and perpetuate joint inflammation in OA. As the disease progresses to late OA, we discovered further involvement of CD45RO+ and CTLA-4+/PD-1+ T cell subsets suggesting memory formation and immune exhaustion. Furthermore, we also observed an involvement of regulatory subsets in late OA suggesting the homeostatic attempts to temper the chronic inflammation at the OA joint. Comparing with our analysis of the digital deconvolution of RNA-seq data of OA synovia, NK cells, monocytes, gamma-delta T cells, and resting memory T cell subsets were found to be dysregulated in both the peripheral and joint immunomes, suggesting possible trafficking dynamics and functional relationship between the two immunomes.

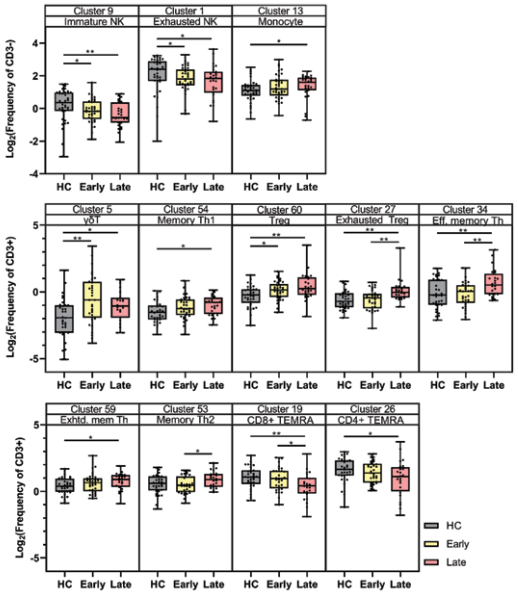

Figure 1.

Conclusion: Our study revealed dynamic peripheral immunome changes that provide insights to the immunopathogenesis of OA. By uncovering these underlying peripheral immunome disruptions in OA, we provide further evidence that the immune system plays an important role in OA disease process.

POS0337 CHARACTERIZATION OF CIRCULATING CHONDROPROGENITOR CELLS IN PATIENTS AFFECTED BY OSTEOARTHRITIS

Keywords: Osteoarthritis, Non-pharmacological interventions, Cartilage

G. Buoncuore[1], C. Barbati[1], E. Balbinot[1], C. Ciancarella[1], A. I. Celia[1], F. M. Ucci[1], G. Sciarra[1], S. Truglia[1], C. Alessandri[1], F. Conti[1]. [1],*Sapienza University of Rome, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rome, Italy*

Background: Osteoarthritis (OA) is a common chronic degenerative disease caused by progressive cartilage degradation [1]. In OA, regenerative medicine based on mesenchymal stem cells (MSCs) is considered the most promising method for restoring articular cartilage [2]. However, the high heterogeneity of MSCs together with invasive and painful procedures for stem cell isolation represent the main challenges of tissue engineering technology (3)[4]. In this regard, a homogeneous population of MSCs, the chondroprogenitor cells (CPs), have been recently discovered in human bone [5].

Objectives: In the light of these considerations, the purpose of this study was to identify CPs in OA. In addition, we aimed to differentiate circulating MSCs into chondrocytes for their in vitro characterization.

Methods: For this study, 10 patients affected by widespread OA [10F; median age 62 years, IQR 9; median disease duration 19 years, IQR 4] related and 10 healthy donors (HD) matched by sex and age were enrolled. A blood sample was collected from each participant to the study for the characterization of three CP populations [5]. In summary, after the isolation of CD45- cells from 500 µl of whole blood using anti-CD45+ magnetic beads, samples were labeled with anti-CD146-PE, anti-CD73-APC, anti-CD164 – FITC and PDPN PerCP/Cyanine5.5 antibodies. The acquisition was performed on a FACSCalibur cytometer. Data was analyzed using the Cell Quest Pro software. For in vitro culture of circulating MSCs, peripheral blood mononuclear cells (PBMCs) were isolated by Ficoll-gradient protocol and were cultured in DMEM supplemented with 20% FBS and 1% antibiotic–antimycotic. At 60–80% of confluence, the adherent cells were cultured in Complete Chondrogenesis Differentiation Medium for 7 days. At the end of in vitro chondrogenesis, morphological analysis was performed by bright-field microscopy. After in vitro differentiation, samples were labeled with anti-CD44-PerCP, anti-CD151-APC and anti-CD49c-PE antibodies, for the analysis of chondrogenic capacity. In addition, cell apoptosis was analyzed using AV-FITC and PI apoptosis detection kit.

Results: Flow Cytometry analysis identified CPs in peripheral blood. Interestingly, the two populations CD45-, PDPN +, CD146-, CD73 +, CD164+ and CD45-, PDPN +, CD146-, CD73-, CD164 + were significantly decreased in OA patients compared to HD (0.82% ± 0.46 vs 4.13% ± 1.92, 0.65% ± 0.22 vs 3.74% ± 1.10, p = 0.0065 and p = 0.0022, respectively) (Figure 1a). During in vitro expansion, MSCs of OA patients were numerically lower than HD (Figure 1b). Moreover, after in vitro chondrogenesis, OA chondrocytes showed a more rounded shape and a volumetric enlargement, which are features typical of chondrocyte hypertrophy (Figure 1c). Flow cytometry results showed that chondrogenic superficial markers, i.e CD44, CD151, and CD49c, were significantly lower in OA chondrocytes to HD (p=0.0009, p=0.0042 and p=0.0002, respectively) (Figure 1d). Lastly, apoptosis was significantly higher in OA chondrocytes than in HD (p=0.004) (Figure 1e).

Conclusion: The results of this study demonstrated a lower percentage of circulating CPs in patients affected by OA compared to HD. Furthermore, OA circulating MSCs showed a reduced chondrogenic capacity supported by a high number of hypertrophic chondrocytes and an increase in apoptosis levels. Further studies are need to clarify the possible application of circulating CPs in cartilage regenerative therapy.

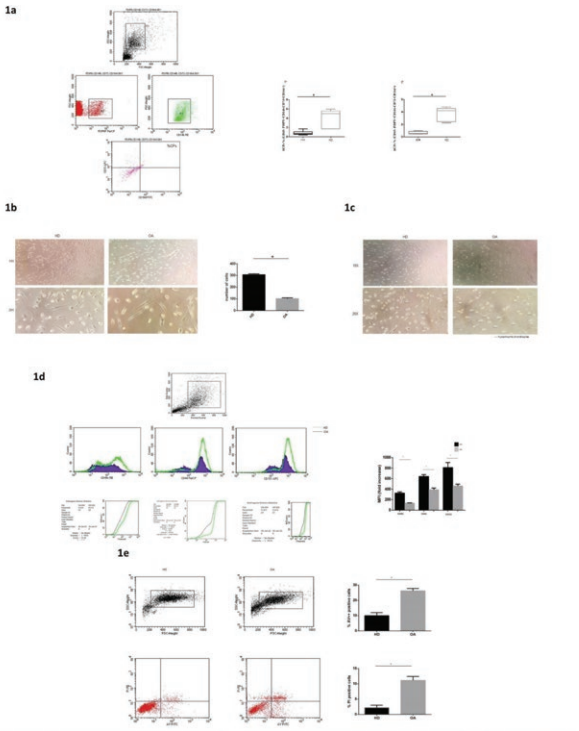

Figure 1a. Flow cytometry strategy for the analysis and characterization of circulating CPs. The upper left panel represented the morphology of CPs cells (CD45-). Within the R1 region, PDPN+ cells (R2) were identified; CD146- (R3) cells were identified within the R2 region; three CPs were identified within the R3 region: CD73+/CD164+, CD73+/CD164-, CD73-/CD164+. Box plots showed the percentage of CPs in OA and HD.
Figure 1b. Circulating MSCs morphology. Panels showed the morphology of circulating MSCs from HD and OA at 20x and 10x magnification. The histogram displayed the number of MSCs in HD and OA.
Figure 1c. Chondrocytes morphology. Panels showed the morphology of chondrocytes from HD and OA at 20x and 10x magnification. Blue bar indicated the chondrocyte size.
Figure 1d. Flow cytometry analysis of chondrogenic capacity. The upper left panel represented the morphology of chondrocytes. The lower panels showed the expression of the surface antigens CD49c, CD44 and CD151 in HD (grey line) and in OA patients (purple). The histogram displayed the expression of surface molecules in HD and OA.
Figure 1e. Flow cytometry analysis of chondrocytes apoptosis. The upper left panel represented the morphology of chondrocytes. The lower panels showed the percentage of annexin V (AV) and PI-positive cells by flow cytometry in chondrocytes from HD and OA. Histograms represented the percentage of apoptotic/necrotic cells in HD and OA.

DEVELOPMENT AND VALIDATION OF RANKED COMPOSITE IMPORTANT DIFFERENCE (RCID) SCORE IN DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS

Keywords: Randomized control trial, Patient-led research, Systemic sclerosis

F. Del Galdo[1,2], L. A. Bissell3, S. Huang[4], P. Hansen[5], S. Johnson[6], D. Furst[7], D. Khanna8. *[1]University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[2]Leeds Teaching Hospital Trust, Biomedical Research Centre, Leeds, United Kingdom*; *[2]Leeds Teaching Hospital Trust, Biomedical Research Centre, Leeds, United Kingdom*; *[4]University of Michigan, Scleroderma Program, Ann Arbor, United States of America*; *[5]1000minds, 1000minds, otago, New Zealand*; *[6]University of Toronto, Scleroderma Program, Toronto, Canada*; *[7]Los Angeles, Pacific Arthritis, Los Angeles, United States of America*; *[4]University of Michigan, Scleroderma Program, Ann Arbor, United States of America*

Background: The revised Combined Response Index in diffuse cutaneous Systemic Sclerosis (dcSSc) (rCRISS) is a composite outcome measure relying on 6 core set variables including Organ Failure, Forced Vital Capacity (FVC), HAQ-DI and modified Rodnan skin score (mRSS), together with patient and clinician global assessments of disease activity [1]. rCRISS is calculated in patients not experiencing any organ failure and reported as proportion of patients who improve a given % (20,30,40 etc) in at least 3 domains. rCRISS discriminated treatment vs placebo in 3 randomised, placebo-controlled trials on early diffuse SSc [1]. Notwithstanding, it is not clear what is the minimal rCRISS score that captures an overall improvement in disease. Further, being developed as a response index, patients that do not experience a predefined organ failure but do worsen in their disease cannot be scored or discriminated from patients that simply do not improve.

Objectives: To improve the clinical interpretation of the rCRISS by creating a continuous ranked score of clinician and patient meaningful changes in its individual measures.

Methods: Following OmerACT guidelines, 100 physicians with experience in dcSSc and 100 patients with dcSSc who have participated in a dcSSc trial were identified in 5 continents. An adaptive survey was developed, based on 1000Minds conjoint analysis software. Patients and doctors were asked to choose, on successive pairs of two hypothetical patients, who had better or worse outcome according to presence of organ failure and Minimally Clinical Important Differences (MCID) in two domains among FVC, HAQ-DI and mRSS. Pairwise comparisons of choices were analysed utilising PAPRIKA methodology [2] to rank and weight the MCIDs against each other. The resulting score was tested in the same cohort utilised for rCRISS development. Briefly, 354 SSc patients data from three randomized, placebo-controlled trials (Asset, Foccussced and Fasscinate) were randomised in 10 development (2/3 pts) and validation (1/3 pts) sets, stratified by study and treatment group. Mean scores of the replicate datasets were calculated for active and placebo treatments. Bootstrapping was employed to determine 95% Confidence Intervals. Kappa statistics were used to analyse concordance.

Results: 160 of the 200 participants completed the survey. Discrete choices conjoint analysis defined ranks and relative weights of the 4 domains in the improved and worsened outcomes groups. A continuous composite ranked score reflecting the relative weighting of the individual outcome measures (Ranked Composite Important Difference, RCID) was developed. The score ranges from -1 (worst possible outcome) to 1 (best possible outcome), with patients who experience no organ failure and do not meet any MCID in any of the 3 domains scoring 0. Positive RCID scores showed a strong correlation with ACR CRISS >0.6 with kappa statistics in development and validation sets of 0.71 (CI 0.64,0.73) and 0.71 (0.66,0.84), respectively. 73.1% of subjects with positive RCIDs (74% in the validation set) met revised CRISS10, with 63.7 and 51.3 meeting rCRISS 20% and 30%, respectively. rCRISS scores between 20 and 30 were associated with only positive RCIDs. Additionally, 32% (C.I 29.7,34.3) of subjects on active treatment showed a positive RCID (>0) vs 25.8 (CI: 23.3,26.6) in the placebo group. Data were confirmed in the validation set (31.7 vs 27.1). Conversely, 12.3% (10.7,14) of subjects on treatment arms showed negative RCID (Any worsening, <0) vs 21.1 (19.2,23.3) in the placebo groups.

Conclusion: Our process adopted a robust methodology with a large patient representation in outcome measure development, to develop a patient and physician derived anchor (RCID) to other composite scores, such as ACR CRISS and revised CRISS. RCID provides a clinician and patient meaningful score that can be used as a dichotomous variable with a positive (improved) or negative (worsened) outcome.

HIGH-GRADE SYNOVITIS ASSOCIATES WITH CLINICAL MARKERS AND RESPONSE TO DMARDS THERAPY IN CHRONIC INFLAMMATORY ARTHRITIS: POST HOC ANALYSIS OF A PROSPECTIVE STUDY

Keywords: Psoriatic arthritis, Synovium, Rheumatoid arthritis

C. Garaffoni[1], I. Calciolari[1], M. Tamussin[1], M. S. Ciliento[1,2], G. Lanza[3], A. Bortoluzzi[1], M. Govoni[1], C. A. Scirè[4], E. Silvagni[1]. *[1]Rheumatology Unit, University of Ferrara and Azienda Ospedaliera-Universitaria S. Anna, Department of Medical Sciences, Ferrara, Italy*; *[2]University della Campania L. Vanvitelli, Department of Precision Medicine, Naples, Italy*; *[3]University of Ferrara, Department of Translational Medicine, Ferrara, Italy*; *[4]University of Milano-Bicocca, School of Medicine and Surgery, Milan, Italy*

Background: Inflammatory arthritis (IA), such as rheumatoid arthritis (RA) and psoriatic arthritis (PsA), are characterized by the presence of chronic synovitis. The Krenn synovitis score (KSS), a semi-quantitative histopathological score, allows the discrimination between high-grade and low-grade synovitis [1]. Although KSS could be potential useful for profiling patients with IA, its associations with clinical and treatment features are not yet thoroughly described.

Objectives: The aim of this post hoc analysis was to identify clinical and instrumental correlates of KSS and to evaluate the association between high-grade synovitis and treatment response in a prospective cohort of IA including both RA and PsA patients.

Methods: Clinical, laboratory and ultrasound (US) data were retrieved from RA and PsA patients recruited in MATRIX cohort. Inclusion criteria were age ≥18 years, RA (ACR/EULAR 2010) or PsA (CASPAR criteria) diagnosis, presence of active disease with eligibility to start/modify new DMARDs therapy. Patients underwent US-guided synovial biopsy of one of the most involved joint (knee or wrist) before starting/modifying DMARDs treatment according to treat-to-target strategy. The samples were analysed by an expert pathologist and KSS was calculated. Univariate and multivariate logistic regression analyses were performed to evaluate the relation between KSS and baseline variables. The association between KSS and treatment response, defined by ACR20, DAS28 remission and the newest ACR/EULAR remission criteria (2) at 6 months of follow-up, was investigated in univariate logistic regression analysis.

Results: 50 patients, 31 RA and 19 PsA, completed 6 months of follow-up after synovial biopsy. Baseline characteristics did not differ between RA e PsA patients except for F/M ratio (77% vs 32%, p=0.001). Four patients (8%) were treatment-naïve and, within the refractory patients (46/50, 92%), 19 (38%) were previously treated with b/tsDMARDs. GCs exposure was reported for 17/31 (55%) RA and 8/19 (42%) PSA patients. KSS was available for 47 patients and the median value was 6.00 (IQR 4.00-7.00) in RA samples and 4.00 (IQR 3.00-5.75) in PsA. Inflammatory infiltrates score was significantly higher in RA than in PsA patients (median 3.00 vs 2.00, p=0.034)(Figure 11A). At univariate analysis, the presence of C reactive protein (CRP)≥0.5 mg/dl, erythrocyte sedimentation rate (ESR)≥30 mm, DAS28-ESR, joint stiffness in the biopsied joint (VAS≥60 mm), moderate to high synovial effusion and moderate to high power Doppler signal detected by US at baseline evaluation in the biopsied joint all associated with increased risk of high-grade synovitis. Fibromyalgia, instead, associated with a reduced risk of high-grade synovitis. At multivariate analysis, US effusion (OR 7.18, 95%CI 1.49, 47.98), CRP (OR 5.66, 95%CI 1.23, 33.22) and joint stiffness (OR 7.67, 95%CI 1.31, 73.51) significantly associated with high-grade KSS (Figure 1B). After 24 weeks (33/50 new b/tsDMARDs, 6/50 new csDMARDs

initiated), 24/48 patients achieved DAS28 remission, 18/48 ACR/EULAR remission and 26/50 ACR20. Univariate analysis revealed increased OR of remission/response for patients with high-grade synovitis (ACR20 OR 4.57, 95%CI 1.36, 17.01, p=0.017; DAS28 remission OR 5.85, 95%CI 1.60, 25.48, p=0.011; ACR/EULAR OR 7.50, 95%CI 1.69, 53.49, p=0.017) (Figure 1C). The interaction between KSS and diagnosis had no significant impact on the outcome.

Conclusion: KSS is a simple and feasible tool for disease stratification of patients with IA, recommended in synovial biopsy research. In our study, high CRP, joint stiffness and US presence of synovial effusion correlated with the presence of high-grade synovitis. High grade synovitis was associated with increased probability of achieving remission 6 months after therapy upgrade in active IA patients independently from diagnosis.

POS0340 PROGNOSTIC FACTORS OF INTERSTITIAL LUNG DISEASE: A 10-YEAR LONGITUDINAL COHORT ANALYSIS

Keywords: Prognostic factors, Imaging, Lungs

K. Nakamura[1], S. Shimoyama[1], N. Abe[1], T. Horita[1]. [1]*Tomakomai City Hospital, Internal Medicine, Tomakomai, Japan*

Background: Interstitial lung disease (ILD), defined as interstitial pneumonia (IP) and pulmonary fibrosis, has a variety of backgrounds. Connective tissue diseases (CTD) is one of the leading causes of ILD, and the concept of "IP with an autoimmune feature (IPAF)" has been established [1]. It has been reported that CTD-related ILD (CTD-ILD) and IPAF have a better prognosis than idiopathic pulmonary fibrosis [2]. However, prognostic differences and factors among CTD-ILD, IPAF, and other ILDs (OILD) remain unknown.

Objectives: This study aimed to analyze the prognosis and its factors in patients with CTD-ILD and IPAF compared to those with OILD.

Methods: We retrospectively collected data from 642 patients diagnosed as "IP" or "pulmonary fibrosis" between 2010 and 2021 at Tomakomai City Hospital. ILD diagnosis was performed by CT scan with 2 rheumatologists. We classified ILD into 3 groups of CTD-ILD, IPAF, and OILD. Mortality and prognostic factors were assessed using Kaplan-Meier methods and Cox proportional hazards models. In addition, we analyzed hospitalization free survival using Kaplan-Meier methods.

Results: Clinical characteristics of the patients are shown in Table 1. The CTD-ILD and IPAF patients were younger, and less frequently complicated by coronary artery disease and chronic heart failure. In addition, more patients in the IPAF and CTD-ILD groups showed a Non-specific interstitial pneumonia (NSIP) pattern on initial CT, while OILD group showed a usual interstitial pneumonia (UIP) and diffuse alveolar damage (DAD) pattern. C-reactive protein (CRP) levels were lower in the IPAF and CTD-ILD group.

The prognosis of CTD-ILD and IPAF group was better than OILD group (Figure1, adjusted p<0.001, <0.01, respectively), but that of CTD-ILD and IPAF was similar (adjusted p=1.0). Multivariate analysis revealed the ILD classification was not independent prognostic factor (p=0.11, Hazard ratio (HR) 0.85, [0.70-1.04]). However, age (p<0.001, HR1.03, [1.02-1.05]), sex (p<0.001, HR 2.08, [1.51-2.87]), initial CT patterns as UIP (p<0.01, HR 2.68, [1.27-5.67]) and DAD (p<0.001, HR 7.99, [3.85-16.60]) were independent prognostic factors. The leading causes of death (CTD-ILD vs. IPAF vs. OILD) were IP (48.2% vs. 55.6% vs. 44.7%, p=0.05), infection (10.8% vs. 22.2% vs. 18.4%, p = 0.07), and malignancy (24.1% vs. 5.6% vs. 7.9%, p = 0.03). In the analysis of event free survival, there was no difference among three groups (p =0.80), and the most common cause was the infection in the CTD-ILD group (36.1%) and primary disease in the OILD and IPAF groups (29.0%, 36.4%, respectively).

Table 1. patient's background

	OILD	IPAF	CTD-ILD	*p* value
N	388	81	173	
Male (%)	271 (69.8)	39 (48.1)	56 (32.4)	<0.001
Age (mean (SD))	74.0 (11.7)	70.2 (12.3)	67.1 (12.9)	<0.001
CT pattern				
NSIP (%)	138 (35.6)	48 (59.3)	114 (65.9)	<0.001
UIP (%)	175 (45.1)	26 (32.1)	45 (26.0)	<0.001
OP (%)	28 (7.2)	3 (3.7)	8 (4.6)	0.3
DAD (%)	47 (12.1)	4 (4.9)	6 (3.5)	0.002
Comorbidity				
DM (%)	132 (34.0)	29 (35.8)	43 (24.9)	0.07
Coronary artery disease (%)	65 (16.8)	8 (9.9)	3 (1.7)	<0.001

POS0341 PERFORMANCE ANALYSIS OF A DEEP LEARNING ALGORITHM TO DETECT POSITIVE SIJ MRI ACCORDING TO THE ASAS DEFINITION IN AXSPA PATIENTS

Keywords: Spondyloarthritis, Artificial Intelligence, Imaging

J. Nicolaes[1,2], E. Tselenti[3], T. Aouad[4], C. López-Medina[5,6,7], A. Feydy[6,8], H. Talbot[4], B. Hoepken[9], N. De Peyrecave[2], M. Dougados[5,6]. *[1]KU Leuven, Department of Electrical Engineering (ESAT), Center for Processing Speech and Images, Leuven, Belgium*; *[2]UCB Pharma, N/A, Brussels, Belgium*; *[3]Veramed, N/A, London, United Kingdom*; *[4]Universite Paris-Saclay, CentraleSup´elec, Inria. Gif-sur-Yvette, France*; *[5]Cochin Hospital, Rheumatology Department, Paris, France*; *[6]University of Paris, INSERM (U1153): Clinical Epidemiology and Biostatistics, Paris, France*; *[7]Reina Sofia Hospital, Cordoba/ IMIBIC/ University of Cordoba, Rheumatology Department, Cordoba, Spain*; *[8]Cochin Hospital, Radiology Department, Paris, France*; *[9]UCB Pharma, N/A, Monheim am Rhein, Germany*

Background: Magnetic resonance imaging (MRI) of the sacroiliac joints (SIJ) is an essential tool in the evaluation of patients with axial spondyloarthritis (axSpA). In-depth knowledge of characteristic MRI lesions and their definitions, as well as reliability of identification and scoring, varies amongst general radiologists and rheumatologists.[1] A deep learning algorithm was developed to detect the presence of inflammation in SIJ MRI (MRI+) scans with promising results.[2]

Objectives: The aim of this diagnostic performance study was to assess the ability of a deep learning algorithm to identify MRI+ scans in a study cohort of axSpA patients.

Methods: 731 baseline SIJ MRI scans were collected from two prospective randomised controlled trial cohorts in patients with non-radiographic (nr-) and radiographic (r-) axSpA (RAPID-axSpA [NCT01087762] and C-OPTIMISE [NCT02505542])[3,4] and were centrally evaluated by two expert readers (and adjudicator in case of disagreement) for the presence of inflammation by the 2009 Assessment in SpondyloArthritis international Society (ASAS) definition.[5] The MRI scans were processed by the previously trained deep learning algorithm,[2] blinded to clinical information and central expert readings.

Performance evaluation included sensitivity, specificity, positive and negative predictive values (PPV and NPV), Cohen's Kappa and the absolute agreement to assess the agreement between the deep learning algorithm and the human readers for the classification of MRI-SIJ scans. Bootstrapping was used to construct the 95% confidence interval (CI).

Results: Pooling the patients from RAPID-axSpA (n=152) and C-OPTIMISE (n=579) yielded a validation set of 731 patients (mean age: 34.2 years, SD: 8.6; 69.1% male) of which 44.6% were patients with nr-axSpA and 59.6% were MRI+ as per central readings.

Comparing the trained algorithm with the human central readings for the classification of MRI+/MRI– on the pooled validation set yielded a sensitivity of 70% (95% CI: 66–73%), specificity of 81% (95% CI: 78–84%), PPV of 84% (95% CI: 82–87%), NPV of 64% (95% CI: 61–68%), Cohen's kappa of 0.49 (95% CI: 0.43–0.55), and absolute agreement of 74% (95% CI: 72–77%; **Table 1**).

Conclusion: A previously trained deep learning algorithm enabled acceptable detection of the presence of inflammation according to the 2009 ASAS MRI definition in axSpA patients from two clinical trials. This suggests that an MRI+ detection algorithm has the potential to support clinicians in identifying axSpA patients.

Background: There is a high unmet need for disease-modifying antifibrotic therapies in diffuse cutaneous systemic sclerosis (dcSSc) which could improve the outcome of this severe disease. Patient reported outcome measures (PROMs) are important and mandatory for randomized clinical trials (RCTs). The EULAR-endorsed ScleroID is the first comprehensive PROM specifically developed by SSc patients and experts to reflect the disease impact of SSc and showed a good performance in the clinical validation study [1]. However, most RCTs focus on dcSSc patients, hence a validated PROM to reflect the disease burden experienced by patients with dcSSc is needed and a detailed analysis of ScleroID in this subset of patients is lacking.

Objectives: To investigate the performance of the EULAR ScleroID in patients with dcSSc as a prerequisite for its use as a PROM in RCTs testing potentially disease-modifying drugs.

Methods: This is a subanalysis of all patients with dcSSc from the large, multicentric, ScleroID validation cohort [1]. As comparators, SSc-HAQ, EQ-5D, SF-36 were included. The study had a longitudinal arm with a reliability visit at 7+/- 3 days and a 12-month follow-up visit [1]. The performance of ScleroID in dcSSc was assessed according to the OMERACT filter [1].

Results: 152 dcSSc patients with a baseline visit were analyzed (44, 28.9% male, median age 54 years, median disease duration 7 years). ScleroID performed well as a PROM reflecting the disease impact of dcSSc: it showed a good construct validity with high Spearman's correlation coefficients with comparators (SSc-HAQ, 0.79, 95%CI [0.69, 0.86]; HAQ-DI, 0.72 95%CI [0.60, 0.80]; SF-36 physical score, -0.69 95%CI [-0.77, -0.60]). Furthermore, the internal consistency was strong:

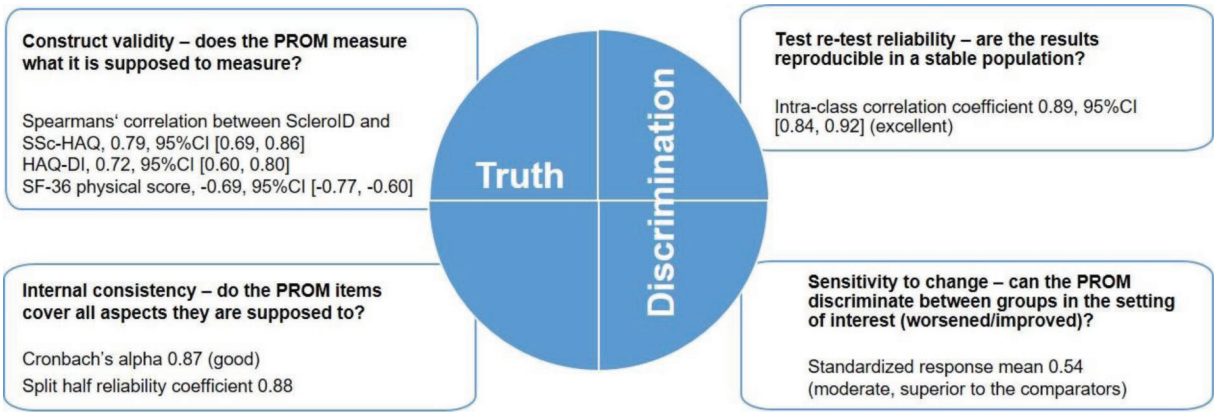

Figure 1. Performance of ScleroID in dcSSc by the OMERACT filter for truth and discrimination.

Cronbach's alpha was 0.87 and the split half reliability coefficient was 0.88. In the longitudinal arm, 44 patients had a test-retest reliability visit and 113 a follow-up visit, of whom 19/113 (16.8%) reported a significant change at 12 months follow-up (11 improved, 8 worsened). ScleroID showed a good consistency and discrimination ability with excellent test-retest reliability (intra-class correlation coefficient 0.89, 95%CI [0.84, 0.92]) and moderate sensitivity to change (standardized response mean 0.54), superior to the comparators (SSc-HAQ, 0.01; HAQ-DI, -0.07; SF-36 physical score, -0.43). The results are summarized in Figure 1.

Conclusion: The EULAR ScleroID, which is a novel, brief, disease specific, patient-derived, disease impact PROM, performs well for patients with dcSSc. This supports the inclusion and further analysis of ScleroID as a PROM to reflect patients' perspective in RCTs.

STATINS INFLUENCE THE RELATIONSHIP BETWEEN ATP-BINDING CASSETTE TRANSPORTER A1 (ABCA1)-MEDIATED CHOLESTEROL EFFLUX AND CORONARY ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS

Keywords: Cardiovascular disease, Biomarkers, Rheumatoid arthritis

G. Karpouzas[1,2], B. Papotti[3], S. Ormseth[2], M. Palumbo[3], E. Hernandez[2], M. P. Adorni[3], F. Zimetti[3], M. Budoff[4,5], N. Ronda[3]. *[1]Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America*; *[2]The Lundquist Institute, Rheumatology, Torrance, United States of America*; *[3]University of Parma - Parco Area delle Scienze, Internal Medicine, Parma, Italy*; *[4]Harbor-UCLA Medical Center, Cardiology, Torrance, United States of America*; *[5]The Lundquist Institute, Cardiology, Torrance, United States of America*

Background: High-density lipoprotein (HDL) mediated cholesterol efflux capacity (CEC) is facilitated by various membrane transporters based on the maturity of the acceptor HDL particles. ATP-binding-cassette membrane transporter A1 (ABCA1) exports cholesterol to immature discoidal HDL particles triggering their maturation to spherical HDL, which in turn serve as cholesterol acceptors for antiatherogenic ABCG1 mediated export. In the context of active RA, increasing ABCA1 CEC may result from reduced HDL particle maturation due to impairment of lecithin-cholesterol acyltransferase, leading to decreased ABCG1 CEC, cholesterol transfer from discoidal HDL to low-density lipoprotein (LDL) and its reloading on macrophages, as well as increased triglycerides favoring a proatherogenic phenotype. Beyond lowering LDL levels, statins have various pleiotropic effects including anti-inflammatory activities, but it is unknown whether they modulate the impact of HDL CEC on atherosclerosis in RA.

Objectives: We here explored associations between ABCA1 CEC, coronary atherosclerosis and cardiovascular risk in RA and the influence of statins on those relationships.

Methods: Coronary atherosclerosis (noncalcified, partially or fully calcified, low attenuation plaques and coronary artery calcium [CAC] score) was evaluated with computed tomography angiography in 140 patients without cardiovascular disease and reassessed in 99 after 6.9±0.4 years. ABCA1 CEC and ABCG1 CEC were measured in J774 macrophages and Chinese hamster ovary cells as previously described. Cox regression evaluated the association between ABCA1 and cardiovascular risk. Multivariable negative binomial and robust logistic regression tested associations of ABCA1 CEC and its interactions with statin therapy on various plaque numbers at baseline, follow-up and CAC progression.

Results: ABCA1 CEC inversely correlated with ABCG1 CEC (Pearson r = -0.167, p=0.049) and directly correlated with triglyceride levels (Pearson r = 0.239, p=0.004), reflecting its association with a proatherogenic phenotype. ABCA1 CEC (per 1 SD increment) associated with long-term cardiovascular risk after adjustments for cardiovascular risk score and baseline plaque burden [HR 2.05 (95% CI 1.20-3.48), Figure 1A]. ABCA1 CEC had no main effect on baseline plaque burden or progression. Instead, its impact on the respective outcomes was influenced by baseline statin use and daily average dose of statin correspondingly. ABCA1 CEC inversely associated with stenotic plaque severity in statin users but not in nonusers (p for interaction = 0.011, Figure 1B). Higher ABCA1 CEC further associated with fewer noncalcified plaques (Figure 1C) and lower noncalcified plaque stenotic severity (Figure 1D) in statin users but not nonusers (p for interaction = 0.024 and 0.023 respectively). Higher ABCA1 CEC associated with fewer low attenuation plaques in statin users but more in nonusers (p for interaction ≤0.001, Figure 1E) and statin users displayed fewer low attenuation plaques compared to nonusers at high (≥+1 SD) but not low (≤-1 SD) ABCA1 CEC. Moreover, ABCA1 CEC inversely associated with CAC progression in patients using high daily atorvastatin equivalent dose (+1 SD) but not nonusers (p for interaction = 0.008, Figure 1F).

Conclusion: In a proatherogenic milieu typical of active RA, including a block in HDL maturation, increased triglycerides and LDL oxidation, increasing ABCA1 activity as the predominant CEC pathway is insufficient to counterbalance and may in fact associate with vascular damage and plaque vulnerability. Statin use, by decreasing triglycerides, LDL levels and oxidation, may reduce cell cholesterol overload, thus unmasking the atheroprotective effects of ABCA1 CEC.

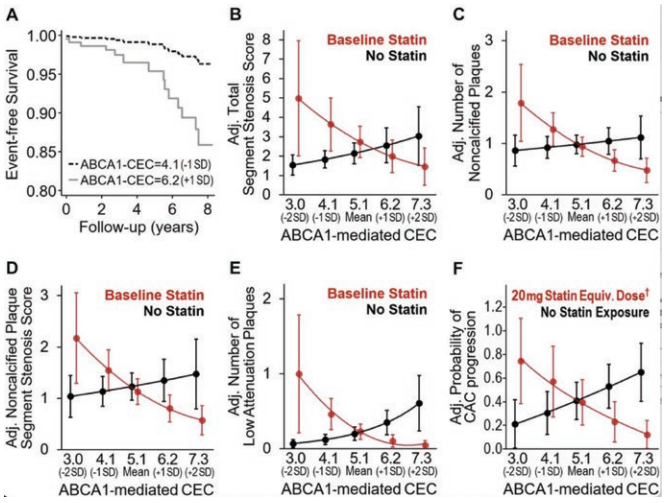

Figure 1. Associations of ABCA1 with cardiovascular risk (A) and influence of statins on the relationships between ABCA1, baseline plaque burden (B-E) and CAC progression (F)

Background: The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is often used for classifying patients according to disease activity states. BASDAI values of 2, 4 and 6 have been applied as cut-offs for inactive disease (ID), between low disease activity (LDA) and high disease activity (HDA) and for very high disease activity (VHDA), respectively, although these cut-off values have not been validated.

Objectives: We aimed to (i) identify BASDAI cut-offs for disease activity states corresponding to the Ankylosing Spondylitis Disease Activity Score (ASDAS) cut-offs, and (ii) investigate the impact of gender on the BASDAI cut-offs.

Methods: Prospectively collected real-world data from axSpA patients receiving tumour necrosis factor inhibitors (TNFi) from countries participating in the European Spondyloarthritis (EuroSpA) Research Collaboration Network were analysed [1]. We chose the ASDAS version based on erythrocyte sedimentation rate (ASDAS-ESR) for which the cut-offs were first developed [2]. Hence, data from 10 registries in EuroSpA with available BASDAI and ASDAS-ESR were included. Analyses were restricted to patients' first TNFi series with available data. To have the best representation of the disease activity states, follow-up data (6, 12 or 24 months) were used to select the cut-offs for ID and between LDA and HDA, while baseline data were used to select the cut-off for VHDA. We performed receiver operating characteristic (ROC) analyses to determine the optimal BASDAI values corresponding to ASDAS-ESR cut-offs using the Youden index (=sensitivity+specificity-1). Furthermore, we carried out separate ROC analyses to identify gender-specific BASDAI cut-offs. Finally, the level of agreement between the new BASDAI cut-offs and the ASDAS-ESR cut-offs was assessed.

Results: We included 4,672 axSpA patients (2,775 (59%) men) with a registration of both BASDAI and ASDAS-ESR at baseline and at least one follow-up visit. Mean (SD) BASDAI and ASDAS-ESR were 5.7 (2.1) and 3.3 (1.0) at baseline, and 3.0 (2.3) and 1.9 (1.0) at follow-up, respectively. The optimal BASDAI values corresponding to ASDAS-ESR 1.3, 2.1 and 3.5 were 2.1, 3.3 and 6.3, respectively (Figure 1). When comparing the BASDAI and ASDAS-ESR cut-offs, the level of agreement was lower for the VHDA cut-off compared to the other disease activity states (Table 1). The gender-specific BASDAI cut-offs corresponding to ASDAS-ESR cut-offs (i.e., 1.3, 2.1 and 3.5) were 2.1, 3.1 and 6.2 for men and 2.1, 3.3 and 6.4 for women, respectively (Figure 1). We also observed that fewer women met the ID and LDA cut-offs of <1.3 and <2.1 than men (Table 1).

Conclusion: The BASDAI cut-offs corresponding to ASDAS-ESR 1.3, 2.1 and 3.5 were 2.1, 3.3 and 6.3, respectively. There was no evidence of a clinically relevant difference in BASDAI cut-offs between men and women.

ADALIMUMAB SERUM DRUG LEVELS AND ANTI-DRUG ANTIBODIES: ASSOCIATION TO DISEASE ACTIVITY AND DRUG SURVIVAL IN INFLAMMATORY ARTHRITIS PATIENTS

Keywords: Inflammatory arthritides, bDMARD

I. Jyssum[1,2], J. E. Gehin[3], E. Kristianslund[1], J. Sexton[1], D. Worren[3], Y. Hu[4], T. K. Kvien[1], E. A. Haavardsholm[1,2], N. Bolstad[3], S. W. Syversen[1], G. L. Goll[1]. *[1]Diakonhjemmet Hospital, Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*; *[2]University of Oslo, Institute of Clinical Medicine, Oslo, Norway*; *[3]Norwegian Radium Hospital, Department of Medical Biochemistry, Oslo, Norway*; *[4]Lillehammer Hospital, Department of Rheumatology, Lillehammer, Norway*

Background: Lack of response to TNF-inhibitors (TNFi) can be caused by subtherapeutic drug levels and anti-drug antibodies (ADAb). Therapeutic-drug-monitoring (TDM) can help clinicians tailor treatment and may improve effectiveness, safety and cost-effectiveness of TNFi. For TDM to be validated as a clinical tool, therapeutic ranges must be identified.

Objectives: To explore the association between adalimumab serum drug level, treatment response and drug survival in patients with inflammatory arthritis, with the intention to identify a therapeutic range. In addition, to assess frequency and clinical implications of ADAb formation.

Methods: Patients with a clinical diagnosis of rheumatoid arthritis (RA), spondyloarthritis (SpA) or psoriatic arthritis (PsA) starting treatment with adalimumab and enrolled in the observational NOR-DMARD study were included. Treatment response at 3 months was defined as EULAR good or moderate response in RA/PsA and ASDAS Major or Clinically Important Improvement in SpA. Serum drug levels and ADAb at 3 months were measured using an in-house fluorescence method, with ADAb measured in patients with serum drug levels < 3mg/L. Comparisons of serum drug level and ADAb formation between diagnosis groups was done by Mann-Whitney U and $\chi 2$ test, respectively. Multivariate logistic regression analyses were used to assess serum drug level and treatment response and Cox proportional hazard regression analyses were used to assess drug survival and serum drug level, ADAb formation and methotrexate use, all analyses adjusted for age, sex and previous use of bDMARDs.

Results: A total of 343 patients (98 RA, 70 PsA, 177 SpA) were included (median age 46.0 years [SD 14.1], 182 [53%] female). 123/340 (36%) patients used methotrexate as co-medication. The median serum drug level at 3 months was 7.3 mg/L (IQR 3.7-10.3) and 34 (10 %) patients developed ADAb, these findings were comparable across diagnoses, (Figure 1A). Serum drug levels at 3 months were higher in responders (7.8 mg/L [IQR 5.4-10.5]) than in non-responders (6 mg/L [IQR 2.6-9.6]), p=0.0014. Percent distribution of responders at 3 months stratified by serum adalimumab levels by percentile distribution suggested that the therapeutic ranges were 6 -12 mg/L for RA/PsA and >1.4 mg/L SpA, with no upper cut-off detected in SpA, (Figure 1B and C). RA and PsA patients with serum adalimumab > 6 mg/L had higher odds for response to therapy at 3 months (Odds Ratio [OR] 2.2 [95% CI 1.1 – 4.5], p=0.026), and lower treatment discontinuation rate (Hazard Ratio [HR] 0.43 [95% CI 0.27-0.80], p= 0.006). No additional benefit was found with serum drug levels >12 mg/L. SpA patients with serum adalimumab level >1.4 mg/L had higher odds for response (OR 4.7 [95% CI 1.4-15], p=0.01) Further, in these patients treatment discontinuation was seen at a lower rate (HR 0.35 [95% CI 0.17-0.73], p= 0.005). Patients with ADAb at 3 months discontinued treatment at a higher rate (HR 3.4 [95% CI 2.1-5.3], p=<0.001). In RA/PsA patients, co-medication with methotrexate was associated with higher serum drug levels (8.4 mg/L [IQR 5.3-10.9] vs 5.8 mg/L [IQR 1.2-8.7], p=0.0003), lower rate of ADAb (6% vs 22 %, p<0.0001) and better drug survival (HR for drug discontinuation 0.50 [95% CI 0.29-0.87] p= 0.013).

Conclusion: This study is the first to explore associations between adalimumab serum levels and clinical outcomes across all inflammatory arthritides. Higher adalimumab drug levels were associated with clinical response at 3 months and long-term drug survival. This study suggests 6 - and 1.4 mg/L as lower target adalimumab levels for RA/PsA and SpA respectively and contributes to the development of TDM algorithms for adalimumab in arthritis patients.

POS0346 DEVELOPMENT AND VALIDATION OF PROGNOSTIC MODELS FOR THE INCIDENCE OF RADIOGRAPHIC KNEE OSTEOARTHRITIS BASED ON NOVEL PROTEIN BIOMARKERS

Keywords: Biomarkers, Prognostic factors, Osteoarthritis

R. Paz González[1], V. Balboa-Barreiro[1], L. Lourido[1], V. Calamia[1], P. Fernández Puente[2], P. Quaranta Díaz[1], N. Oreiro[1], C. Ruiz-Romero[1,3], F. J. Blanco[1,2]. *[1]INIBIC-Hospital Universitario A Coruña, SERGAS, Rheumatology Research Group (GIR), Proteomics Unit, A Coruña, Spain*; *[2]Centro de investigaciones Avanzadas (CICA), Universidad de A Coruña, Rheumatology and Health Group, Department of Physiotherapy and Medicine, A Coruña, Spain*; *[3]Centro de Investigación Biomédica en Red, Bioingeniería, Biomateriales y Nanomedicina (CIBER-BBN), Madrid, Spain*

Background: Knee Osteoarthritis (KOA) is one of the most prevalent and disabling rheumatic diseases. The inability to detect early disease stages and the lack of effective treatments leave KOA patients without non-surgical clinical options. The early diagnosis of KOA at asymptomatic stages is crucial to improve the prompt management of the patients, in order to prevent or slow the course of the disease. Major research interest is focused on discovering prognostic markers useful to identify individuals at high risk of developing KOA before joint damage appears.
Objectives: To develop a prognostic model useful to predict the incidence of radiographic knee osteoarthritis (rKOA).
Methods: This study involved subjects without established KOA according to the Kellgren and Lawrence classification scale (KL=0-1), who were enrolled in the Osteoarthritis Initiative (OAI) cohort and the Prospective Cohort of A Coruña (PROCOAC). We developed two predictive models for rKOA incidence within 96 months of follow-up among participants in the OAI cohort. The protein biomarker candidates APOA1, APOA4, ZA2G and A2AP were quantified in serum using a custom-made multiplex protein microarray. The prospective association of the protein levels with rKOA incidence, defined as progressing to KL≥2 during 96-months follow-up, was evaluated to develop the models based on the protein biomarkers, sociodemographic, anthropometric and non-radiographic clinical measurements. Their predictive capacity was assessed using the area under the curve (AUC). The performance of the models was externally validated in the PROCOAC cohort.
Results: We included 602 participants from the OAI cohort in the development dataset, which had a KL ≤1 at baseline. From these, 390 did not present any radiographic signs of KOA (KL=0) in both knees. The model built exclusively with demographic and clinical data (age, sex, BMI and the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain score) from patients with KL ≤1 (early KOA) at baseline showed an AUC=0,719 to predict rKOA incidence during the follow-up. The inclusion of ZA2G, A2AP and APOA1 significantly improved its predictive performance, yielding an AUC= 0,793. When only subjects with KL=0 in both knees at baseline were included, the clinical model predicts the future development of rKOA with an AUC=0,724 and achieved a significantly higher AUC=0,798 with the addition of the 4 biomarkers (Figure 1). No differences were found in the predictive performance for the proposed models between the development and validation cohorts (Table 1).
Conclusion: Two prognostic models have been developed to predict rKOA incidence based on the measurement of four novel protein biomarkers.

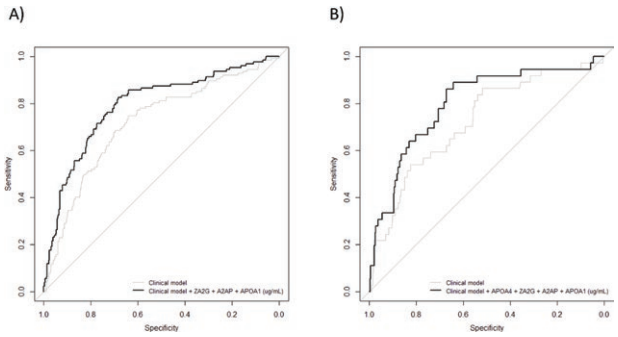

Figure 1. Overlapping of the AUCs obtained from the clinical models (grey line) and the clinical models with the biomarkers (black line) to predict the incidence of radiographic KOA during the follow-up period in the development cohort (OAI). A) Clinical model (AUC= 0,719) and the clinical model with the 4-biomarkers (AUC=0,793) in patients with KL≤1 at baseline; B) Clinical model (AUC= 0,724) and the clinical model with the 4-biomarkers (AUC=0,798) in patients with KL=0 at baseline.

Table 1. Comparison of the performance of the proposed models in the development (OAI) and validation (PROCOAC) cohorts.

Clinical model + biomarkers	AUC (95%CI) Development cohort	AUC (95%CI) Validation cohort	p-value
KL ≤1	0,793 (0,746-0,839)	0,677 (0,564-0,791)	0,224
KL=0	0,798 (0,718-0,879)	0,761 (0,626-0,896)	0,640

POS0347 DETERMINANTS OF PATIENT AND PHYSICIAN GLOBAL ASSESSMENT OF DISEASE ACTIVITY IN SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Pain, Psoriatic arthritis

C. Dantas Soares[1], S. Azevedo[1], F. Guimarães[1], H. Parente[1], M. Pontes-Ferreira[1], J. Tavares-Costa[1], D. Peixoto[1], C. Afonso[1], D. Santos-Faria[1]. *[1]Ponte de lima, Rheumatology Department, Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal*

Background: Patient's and Physician's Global Assessment of Disease Activity (PtGA and PhGA) are important measures in Spondyloarthritis (SpA), but often provide discordant results. Some data show that patient-physician discordance can result in patient poor adherence to treatment and healthcare costs in SpA.[1]
Objectives: We intended to assess the principal determinants of both PtGA and PhGA in SpA patients under biologic treatment.
Methods: We performed a cross-sectional study, including patients with SpA under biologic treatment registered in the Rheumatic Diseases Portuguese Register (Reuma.pt), consecutively evaluated in a tertiary hospital center. Sociodemographic and clinical data were collected. PtGA and PhGA were measured on a Visual Analogue Scale of 0-100. To identify determinants of PtGA and PhGA, we performed firstly a univariate analysis with the independent variables and subsequently a multiple linear regression. SPSS v.24 was used for statistical analysis.
Results: We evaluated 186 patients with SpA according to ASAS criteria, under biologic treatment. Most patients were male (53.20%) with a mean age of 52.15 (SD=12.9) years-old at the time of last medical appointment. PtGA and PhGA were significantly different. Clinical and laboratory characteristics of patients are shown in table 1. There was a positive correlation between higher PtGA and older age, unemployment, number of tender joints, HAQ, HADS, BASDAI, number of comorbidities and daily medication. There was also an association with the concomitant presence of osteoarthrosis, fibromyalgia, C reactive protein

(CRP), erythrocyte sedimentation rate (ESR) and daily prednisolone intake. On the other side, we found a negative correlation with SF-36, FACIT and EQ5D. The multiple linear regression shows that the SF-36 (p=0.001), BASDAI (p<0.001) and being unemployed (p=0.042) were the most preponderant determinants in PtGA explaining 85% of the variability noted in PtGA (R^2 = 0.846; R^2_a= 0.828). Regarding PhGA we found a positive correlation between the number of tender and swollen joints, CRP and daily prednisolone intake. In multivariable analyses the main determinants of PhGA were the number of swollen joints and higher CRP (R^2 = 0.867; R^2_a= 0.829).

Table 1. Clinical and laboratory characteristics of patients with spondyloarthritis.

Age (years), mean ± SD	52.2 ± 12.9
Gender – male, %(n/N)	53.2% (99/186)
Patient Global VAS, mean ± SD	34.4 ± 27.2
Patient pain VAS, mean ± SD	31.9 ± 26.3
Patient back pain VAS, mean ± SD	25.0 ± 26.9
Physician Global VAS, mean ± SD	7.4 ± 12.7
Patient-physician discordance mean ± SD	27.8 ± 24.0
HAQ, median (IQR)	0.8 (1.1)
BASDAI, median (IQR)	2.5 (3.7)
BASFI, median (IQR)	2.4 (4.4)
Short Form (36) Health Survey (SF-36), mean ± SD	455.7 ± 167.2
FACIT, mean ± SD	35.6 ± 11.4
HADS, median (IQR)	Anxiety: 6 (8.0) Depression: 5 (8.0)
EQ5D, median (IQR)	0.4824 ± 0.4058
Daily medication, median (IQR	3 (3)

BASDAI: Ankylosing Spondylitis Disease Activity Index; BASFI: Bath Ankylosing Spondylitis Functional Index; EQ5D: EuroQol-5 dimension; FACIT: Functional Assessment of Chronic Illness Therapy; HADS: Hospital Anxiety and Depression scales; HAQ: Health Assessment Questionnaire; VAS: Visual Analogue Scale

Conclusion: We have demonstrated that comorbidities, employment status, and other factors not directly related to the disease are also determinants in PtGA. On the other hand, more objective data such as swollen joints and increased CRP were predominant in PhGA construct.

Olson[2,3], D. Feith[2,3], T. Loughran[2,3], D. Kimpel[4]. *[1]University of Virginia School of Medicine, Department of Pathology, Charlottesville, United States of America*; *[2]University of Virginia School of Medicine, Department of Medicine, Division of Hematology/Oncology, Charlottesville, United States of America*; *[3]University of Virginia School of Medicine, Cancer Center, Charlottesville, United States of America*; *[4]University of Virginia School of Medicine, Department of Medicine, Division of Rheumatology, Charlottesville, United States of America*; *[5]University of Virginia School of Medicine, Department of Public Health Sciences, Charlottesville, United States of America*; *[6]University of Virginia School of Medicine, Medical Scientist Training Program, Charlottesville, United States of America*; *[7]The Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, United States of America*

Background: Rheumatoid arthritis (RA) is a chronic systemic autoimmune disease that leads to inflammation and bone erosion of synovial joints. Serological markers such as rheumatoid factor (RF) and anti-CCP antibodies are commonly elevated, and cytotoxic CD8+ T-cell expansions have been implicated in disease pathogenesis. Large granular lymphocyte (LGL) leukemia is a rare hematologic malignancy characterized by clonal expansion of CD8+ cytotoxic T-cells. A major hallmark of all LGL leukemia is increased *STAT3* activation. About 50% of patients have somatic activating mutations in *STAT3*, the most common being Y640F and D661Y. Additionally, *STAT3* mutations correlate with numerous clinical features in LGL leukemia. LGL leukemia patients with *STAT3* mutations are more likely to respond to methotrexate treatment, tend to have low neutrophil counts, and clinical features can differ between mutation types (e.g. Y640F vs D661Y). Approximately one third of LGL leukemia patients also suffer from RA, and those with *STAT3* mutations are more likely to exhibit concomitant RA. Those patients with both diseases also tend to have increased positivity for serological markers like RF and anti-CCP antibodies than patients with either disease alone[1].

Objectives: Based on disease overlap between LGL leukemia and RA, and a putative role for CD8+ T-cells in RA, we hypothesized that *STAT3* mutations may be detected in the CD8+ T cells of RA patients without LGL leukemia and correlate with RA clinical characteristics.

Methods: Blood samples, clinical parameters, and demographic data were collected from RA patients (n=96), many of whom were on immunosuppressives such as methotrexate, and healthy controls (n=9). CD8+ cell DNA was isolated and analyzed via droplet digital (dd)PCR to detect common *STAT3* mutations in LGL leukemia: Y640F, D661Y, and mutations in the S614 to G618 region. RA samples were divided into wild-type (WT) vs. *STAT3*-mutant groups using a variant allele frequency (VAF) cutoff of 0.05%, and clinical parameters were correlated to mutation status.

Results: Overall, RA patients had statistically different levels of STAT3 mutations compared to controls (D661Y p=0.0005, Y640F p=0.0185). In particular, many more low level (0.005-0.05% VAF) mutations were detected in the RA population (43/96 Y640F, 59/96 D661Y) vs. healthy controls (0/9 Y640F, 0/9 D661Y). Additionally, 3/96 RA samples had a *STAT3* mutation at a VAF (>5%) large enough to be indicative of CD8+ T cell clonality compared to 0/96 controls (Table 1). Multiple serological RA markers were more frequently positive in *STAT3* mutant (80%-91%) relative to WT RA samples (44%-55%) (RF p=0.0005, anti-CCP p=0.018, double positivity p=0.006), with overall RF levels also significantly elevated (p=0.008) in *STAT3* mutant RA samples (Figure 1). Anti-CCP positivity was more common in Y640F patients (9/9) than D661Y (7/12).

Table 1. *STAT3* mutations were detected by ddPCR analysis of CD8+ T-cell DNA

Healthy Control Samples	<0.005%	0.005%-0.05%	0.05%-5%	5%

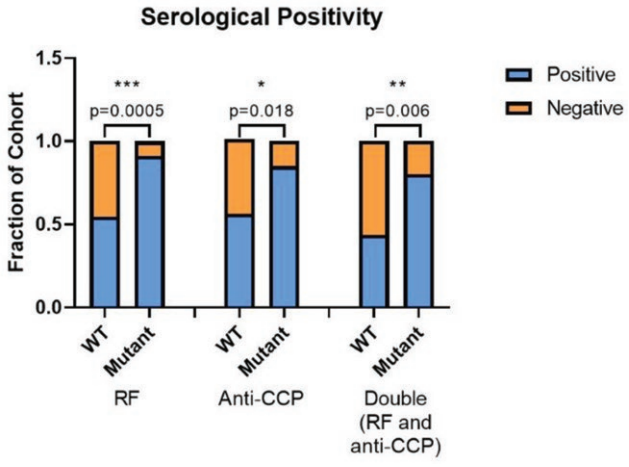

Figure 1. Presence of *STAT3* mutation correlates to increased serological positivity in RA patients

Conclusion: Taken together, the presence of *STAT3* activating mutations in CD8+ T-cells and the association of mutations with sero-positivity suggest that *STAT3* activating mutations may play a role in the pathogenesis and clinical features in a subset of patients with RA. Further study will determine the impacts of *STAT3* mutation presence on disease severity, prognosis, and selection of treatment options/potential treatment responses.

POS0349 ABSENCE OF ASSOCIATION OF COMPLEMENT C4 GENETIC DIVERSITY WITH SERUM COMPLEMENTS, AUTOANTIBODIES AND DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Innate immunity, Systemic lupus erythematosus, Genetics/ Epigenetics

C. Mariaselvam[1,2], G. Seth[1], C. Kavadichanda[1], M. Thabah[1], K. Rajagopal[2], R. Tamouza[2], V. Negi[1]. *[1]Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Clinical Immunology, Puducherry, India*; *[2]Univ Paris Est Creteil, INSERM UMR 955, IMRB, AP-HP, DMU IMPACT, FHU ADAPT, Translational Neuropsychiatry, Créteil, France*

Background: Systemic Lupus Erythematosus (SLE) is characterized by low levels of serum C3 and C4. Low complements in SLE may either be due to increased consumption or decreased synthesis, the exact mechanisms of which is unknown. *C4* gene has copy number variations and exists as two functionally distinct but genetically homologous isoforms, *C4A* (0-8 copies) and *C4B* (0-3 copies). The genes are either long (L) or short (S) based on a 6.4kb Human Endogenous Retrovirus K (*HERV-K*) insertion. Low copy numbers of complement C4 genes in systemic autoimmune disorders and its link with autoantibodies, disease subgroups have been reported.

Objectives: To characterize *C4* and *C4-HERV* genetic diversity in SLE and its relationship with serum complement levels, autoantibodies, disease activity, clinical subgroups and HLA.

Methods: Genomic DNA from 70 SLE and 90 controls were used to characterize the copy numbers of *C4A* and *C4B* genes and the frequency of HERV insertion (*C4AL, C4BL*) using droplet digital polymerase chain reaction. High resolution typing of 8 HLA genes was done using next generation sequencing. Chi-square test was used to compare the frequencies of *C4*, *C4-HERV* structural elements and HLA between groups. Correlation with complement levels, number of autoantibodies present, SLEDAI and clinical subgroups was done using Spearman's nonparametric test.

Results: In this cohort, total *C4* gene copies ranged from 2-6 with two copies of *C4A* and *C4B* genes being frequent; there were no C4 null alleles, and a negative correlation was noted between C4A and C4B copy numbers (r=-0.3713; p<0.001; Figure 1). Compared to controls, presence of two or less copies of *C4A* gene was associated with SLE risk while C4B frequency was comparable between the groups. Significantly increased frequency of *HERV* insertion in C4A than in C4B gene was observed. Of the 34 different *C4-HERV* genotypes observed, 7 were at a frequency greater than 5%. Though the frequency of *AL-AL-BL-BS* genotype was overrepresented in SLE, the difference was not statistically significant. The *AL-AL-AL-BS* genotype was significantly higher in controls than SLE (9% vs 1%, p=0.04; Table 1). HLA-DPA1*02 and DPB1*13 were more frequent in subjects with C4B >2 copies than in those with C4B ≤2 copies (33% vs 61%; Pc=0.04 & 5% vs 28%; Pc=0.04). There was no correlation between the *C4* as well as *C4-HERV* gene copy numbers and serum levels of complement, autoantibodies, SLEDAI and SLE clinical subgroups (Figure 1)

Conclusion: Our data show that, although the *C4A* and *C4B* gene diversity is different between cases and controls, it does not correlate with serum complement levels, autoantibodies, disease activity and clinical subgroups in SLE. Low *C4A* copy number and increased insertion of HERV in *C4A* may be a risk for SLE. Our findings in this small cohort need further validation in a larger homogenous SLE cohort.

López Montilla[2], M. Á. Puche Larrubia[2], E. Collantes Estevez[4], A. Escudero Contreras[4], C. Lopez-Pedrera[5], N. Barbarroja Puerto[4]. *[1]IMIBIC/ University of Cordoba/Reina Sofia Hospital, Cell Biology, Physiology and Immunology, Cordoba, Spain*; *[2]IMIBIC/University of Cordoba/Reina Sofia Hospital, Rheumatology Service, Cordoba, Spain*; *[3]IMIBIC/University of Cordoba/Reina Sofia Hospital, Nephrology, Cordoba, Spain*; *[4]IMIBIC/University of Cordoba/Reina Sofia Hospital, Medical and Surgical Sciences, Cordoba, Spain*; *[5]IMIBIC/Reina Sofia Hospital/University of Cordoba, Rheumatology Service, Cordoba, Spain*

Background: Rheumatic diseases such as systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), systemic sclerosis (SSc), axial spondyloarthritis (axSpA), and psoriatic arthritis (PsA) are characterized by a complex clinical and molecular heterogeneity. Novel and disruptive technologies might shed light on their pathogenesis and clinical management.

Objectives: To evaluate the potential of the innovative proteomic technology "proximity extension assay" (PEA) to identify useful biomarkers, subgroups of patients, and novel insight into rheumatic diseases.

Methods: 533 consecutive patients with rheumatic diseases (141 SLE, 120 RA, 72 SSc, 100 axSpA and 100 PsA) and 50 healthy donors (HDs) were included in

the study where serum samples and clinical data were obtained. A signature of 368 proteins divided into 4 panels of 92 biomarkers associated with Inflammation (SLE, RA, SpA, and HDs), Organ Damage (SLE, SSc, and HDs), cardiovascular disease (RA, SpA, PsA, and HDs), and cardiometabolism (RA and HDs) was analysed by using PEA technology from Olink through its corelab Cobiomic Bioscience SL. PEA technology, already endorsed by more than 1000 peer-reviewed publications, recognizes proteins using antibody-pairs containing unique DNA sequences which are amplified by real-time PCR. Data analysis included t-test, unsupervised clustering analysis, ROC curves, and PCA among others.

Results: In SLE patients, the unsupervised cluster analysis using the circulating proteome identified 2 clusters with distinctive clinical features mainly differentiating disease activity and the presence of renal damage. Several proteins were also identified as novel non-invasive biomarkers of lupus nephropathy. Similarly, in SSc, a panel of proteins related to organ damage identified a subgroup of patients characterized by multiple organ involvement including lung and skin fibrosis and oesophageal dysmotility, along with a preponderance of anti-scl70 antibodies positivity. In axSpA patients, the levels of several proteins related to inflammation and cardiovascular disease (CVD) were altered compared with HDs and associated with key clinical features.

In RA, a specific signature of chemokines before therapy identified non-responders patients to anti-TNF therapy and Methotrexate after 3 months of treatment, pointing out its role as a predictor of therapy response. Moreover, several proteins associated with CVD and metabolism were modulated by the effect of Methotrexate and Tofacitinib, which also underlined their role as biomarkers for treatment monitoring. In PsA patients, numerous proteins related to CVD were up-regulated in relation to HDs and associated with clinical markers of CVD risk. Various circulating proteins also distinguished the presence of insulin resistance, high activity, and poor therapeutic outcome to Methotrexate and Apremilast. Furthermore, the PEA analysis of the inflammatory proteome in PsA synovial fluid revealed novel biomarkers of disease and potential therapeutic targets.

Conclusion: PEA technology might boost the future of precision medicine in rheumatic diseases through the identification of novel biomarkers of disease and therapy response and the stratification of patients with key clinical and molecular features.

POS0351 MULTI-OMICS ANALYSIS IDENTIFIES DIFFERENTIAL LIPID REGULATION AS A POTENTIAL MECHANISM UNDERPINNING METHOTREXATE RESPONSE IN RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Rheumatoid arthritis, -omics

C. F. Yap[1], N. Nair[1], S. Verstappen[1], K. Hyrich[1], A. Barton[1], D. Plant[1]. [1]*The University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease that causes inflammation and joint damage, leading to disability and reduced quality of life. Methotrexate (MTX) is a widely used disease-modifying anti-rheumatic drug that is initially prescribed to reduce inflammation and slowing disease progression in RA; however, approximately 40% of treated patients do not experience a satisfactory response to this drug. Identifying reliable surrogate biomarkers of MTX response would facilitate precision medicine strategies and improve patient outcomes.

Objectives: To identify blood-based transcriptomic and metabolomic biomarkers of MTX response in patients with RA.

Methods: Whole blood samples were taken from patients taking part in the Rheumatoid Arthritis Medication Study (RAMS), an observational longitudinal cohort of early RA patients starting MTX for the first time in the UK. RNA-seq data was generated using the Illumina NovaSeq 6000 platform of patients before and after 4 weeks MTX treatment. Treatment response was determined after 6 months on drug and patients were classified as good or non-responders using established EULAR response criteria. Differential gene expression analysis was performed using glmmSeq [1], which uses generalized linear mixed model with negative binomial distribution. Models were parameterized with size factor and dispersion estimated using DESeq2 [2]. The regression model included patient ID as a random effect and an interaction term was included between time-point and response category. Two-hundred and fifty targeted metabolites were quantified in serum samples from the same patients as above using nuclear magnetic resonance (NMR) based technology. Metabolomics data were normalised using probabilistic quotient normalization and scaled with pareto-scaling. Partial least-square regression (PLSR) and linear mixed effects models (constructed as above) were used to identify differentially expressed metabolites. All linear mixed models were adjusted for baseline disease activity (DAS28). Enrichment analysis for differentially expressed genes was performed using Metascape [3].

Results: In total, 100 patients were analysed (69 good-responders and 31 non-responders). Following quality control, 17,298 genes were tested for differential expression, 25 were significantly associated with response (fold change ≥ 1.5 at baseline, adjusted p-value < 0.05). Of these, 4 were enriched in monocarboxylic acid (which includes fatty acid) metabolism. Differential regulation of this biological process was also observed in the metabolomics profile where low-density lipoprotein cholesterol and triglycerides were associated with MTX treatment response; this was observed using both PLSR (AUC: 0.75) and linear mixed effects models (p-value < 0.05).

Conclusion: Whole blood multi-omics analysis has the potential to identify biomarkers and biological processes underpinning MTX response in RA. Further research is needed to understand and confirm the relationship between monocarboxylic acid metabolism and MTX response in this disease.

POS0352 GENETIC DETERMINANTS OF RESPONSE TO ABATACEPT IN PATIENTS WITH IGG4-RELATED DISEASE

Keywords: Adaptive immunity, Disease-modifying Drugs (DMARDs), Rare/orphan diseases

J. Mahajne[1], C. Minici[1], M. Lanzillotta[1], V. Batani[1], L. Dagna[1], E. Della Torre[1]. [1]*San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy*

Background: IgG4-related disease (IgG4RD) is a fibro-inflammatory disorder of unknown etiology. Emerging evidence indicates that chronic inflammation in IgG4RD is sustained by persistent mutual activation of antigen-specific B and T lymphocytes. Targeting B-T cell co-stimulation represents, therefore, a rationale therapeutic approach for IgG4RD.

Objectives: Threefold aim of the present work was (i) to assess the efficacy of abatacept (a selective inhibitor of B-T cell co-stimulation based on a replica of CTLA4) for the treatment of IgG4RD; (ii) to study T cell activation in IgG4RD patients; and (iii) to identify functional and genetic predictors of response to abatacept in IgG4RD patients.

Methods: Three patients with active IgG4RD (Pt1-3) were treated with monthly intravenous infusions of abatacept (750mg) for 6 months without concomitant glucocorticoids. All patients underwent 18F-FDG PET scan before treatment and after 6 infusions to assess disease response. To identify functional and genetic predictors of response to abatacept we used multicolour flow-cytometry and Whole Exome Sequencing (WES). Flow-cytometry using CD3, CD19, CD4, CD25, and CTLA4 antibodies was performed to assess CD4+ T cell activation upon exposure to recombinant humanized CD3/CD28 after 120 hours in vitro colture. Results were compared to 10 healthy controls and 10 patients with rheumatoid arthritis (RA). WES was performed to screen for mutations of a panel of 452 genes related to known monogenic immune mediated diseases.

Results: Pt 1 was a 47 years old male with bilateral submandibular gland involvement (Figure - A - *arrow*; B - *arrows*) and subcutaneous lesions (B - *circle*). Pt2 was a 78 years old woman with right orbital pseudotumor (Figure - A – *arrow*; B - arrow), sinonasal involvement (B - *arrowhead*), and skin lesions (B - *asterisk*). Pt3 was a 68 years old woman with left lacrimal and parotid glands involvement (Figure - A - *arrows*; B - *arrows*). Abatacept led to a marked decrease of the dimension and 18-F FDG uptake of IgG4RD lesions in Pt1 and Pt2. Pt3 showed increased pathological 18F-FDG uptake of her orbital pseudotumor with minimal morphologic changes at magnetic resonance, consistent with metabolic

progression. In vitro, there was no difference in CTLA4 expression at baseline between IgG4RD patients and controls (p>0.05). Yet, upon activation, IgG4RD patients displayed a premature decrease of CTLA4 expression on T cells compared to healthy donors (p<0.01), suggesting a defective T cell inhibition. Similar results were observed in patients with RA. Accordingly, IgG4RD patients showed expansion of activated CD25+ T cells compared to healthy controls (p<0.05). WES of the three IgG4RD patients treated with abatacept found eterozigous germline mutations of LRBA gene (p.Arg2646His (c.7937G>A)) (Pt1), CTLA4 gene (p.Gly109Glu (c.326G>A)) (Pt2), and DOCK8 gene (p.Gln1550Leu (c.4649A>T)) (Pt3). None of these mutations has been previously reported in the medical literature and remains of uncertain significance but all had a CADD score > 20, thus predicting deleterious impact on protein structure. Of note, mutations in LRBA, CTLA4, and DOCK8 genes are all associated with systemic autoimmunity, lymphoproliferation, and immune deficiency. In particular, as opposed to DOCK8 gene, LRBA and CTLA4 genes encode for functionally related proteins as LRBA regulates the reclycing of CTLA4 on T cell membrane upon antigen engagement to inhibit T cell activation.

Conclusion: In the present work we demonstrate that CD4+ T cells from IgG4RD patients show aberrant activation associated with a reduced expression of the inhibitory molecule CTLA4. Yet, not all patients respond to abatacept suggesting that IgG4RD is sustained by additional pathological mechanisms in at least a proportion of patients. Patients responding to abatacept display, indeed, germline mutations of uncertain significance in CTLA4 pathway and may represent ideal candidates for treatment with abatacept.

DNA METHYLOME ALTERATIONS AS POTENTIAL DIAGNOSTIC AND PROGNOSTIC BIOMARKERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Genetics/Epigenetics, Rheumatoid arthritis, Biomarkers

G. M. Martín-Núlez[1], A. Mucientes[2], J. M. Lisbona[1,2], P. Ruiz-Limon[3], R. Redondo[2], S. Manrique Arija[2], I. Ureña[2], L. Cano Garcia[2], I. Moreno-Indias[3], N. Mena-Vázquez[2], A. Fernandez-Nebro[1,2]. [1]*Universidad de Málaga, Departamento de Medicina y Dermatología, Malaga, Spain*; [2]*Instituto de Investigación Biomedica de Málaga (IBIMA)-Plataforma Bionand, Reumatología, Malaga, Spain*; [3]*Instituto de Investigación Biomedica de Málaga (IBIMA)-Plataforma Bionand, Endocrinología y Nutrición, Malaga, Spain*

Background: The etiology of rheumatoid arthritis (RA) is not entirely known. Epigenetic modifications could be the link between genetic and environmental factors related to the appearance and evolution of RA.

Objectives: To identify differential DNA methylation patterns throughout the entire genome in patients with RA versus healthy controls, as well as epigenetic changes that may predict greater disease severity.

Methods: Cross-sectional study of a prospective cohort, in which 64 subjects were studied: 16 severe RA, 16 non-severe RA and 32 healthy controls. The severity phenotype was defined according to an average of moderate-high inflammatory activity defined by an accumulated Disease activity score (DAS28-ESR) ≥3.2, positivity for rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA), as well as higher *Collinsela aerofaciens* levels (OTU ≥0.15) [1,2]. DNA methylation was determined using *Infinium Methylation EPIC BeadChip* (Illumina, San Diego, CA, USA). The methylation level of each cytosine was expressed as β-value. ANOVA and bivariate analysis were performed to compare between groups of subjects. Multivariate logistic regression models were performed to identify factors associated with RA and severe RA phenotype.

Results: The majority (75%) were female with a mean age of 57.6 ± 9.4 years. The patients with RA, in comparison with the controls, had higher smoking habits (62.5% *vs.* 40.7%; p=0.015) and obesity (53.1% *vs.* 28.1%; p=0.012). Among patients, subjects with severe RA compared with non-severe had a higher mean DAS28-ESR (3.9 ± 0.6 vs. 3.3 ± 0.2 mg/l, p=0.001), and higher abundance in *Collinsela* (median (IQR), 0.3 (0.1-1.7) vs. 0.1 (0.0-0.4), p=0.003); as well as a higher frequency of erosions (93.8% *vs.* 50.0%; p=0.006), elevated ACPA (68.8% *vs.* 31.1%; p=0.034) and treatment with biological therapy (56.3% *vs.* 12.5%, p=0.009). Regarding the methylation analysis, those CpGs related to genes or pseudogenes, with a minimum β value change of ± 0.10 between groups and p value ≤ 0.01 were selected (Figure 1). The described CpG sites located in differentially methylated regions, together with other CpGs, were proposed as possible biomarkers (Table 1). In addition, cg06166490 was also considered, since it is located in a differentially methylated region with an adjusted p-value <0.00001. Of these CpGs, 5 CpG sites were associated with the presence of RA, and 2 CpG sites were associated with disease severity (Table 1).

Conclusion: DNA methylation level at specific CpG sites is associated with RA patients. The present study identified epigenome marks related to RA and possible disease severity, which warrant further investigation and could be useful in the diagnosis and management of the disease.

IDENTIFICATION OF SOMATIC MUTATIONS IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

Keywords: Vasculitis, Genetics/Epigenetics

T. Iwasaki[1,2], K. Ohmura[3], C. Endo[1], M. Shirakashi[1], R. Hiwa[1], H. Tsuji[1], K. Kitagori[1], S. Akizuki[1], R. Nakashima[1], H. Yoshifuji[1], A. Morinobu[1], F. Matsuda[2], Y. Kamatani[4]. *[1]Graduate School of Medicine, Kyoto University, Department of Rheumatology and Clinical Immunology, Kyoto, Japan*; *[2]Graduate School of Medicine, Kyoto University, Center for Genomic Medicine, Kyoto, Japan*; *[3]Kobe City Medical Center General Hospital, Department of Rheumatology, Kobe, Japan*; *[4]The University of Tokyo, Laboratory of Complex Trait Genomics, Department of Computational Biology and Medical Sciences, Tokyo, Japan*

Background: Growing evidence reveals a pathological role of somatic mutations in various autoimmune diseases, such as the mutation in *UBA1* in VEXAS syndrome, *CARD11* and *KLHL6* in cryoglobulinemic vasculitis, or *STAT3* in Felty's syndrome[1]. Somatic mutations might also be involved in the pathogenesis of ANCA-associated vasculitis (AAV), which typically manifests in middle-aged and elderly individuals.
Objectives: We aimed to identify somatic mutations in patients with AAV.
Methods: We collected whole blood and obtained peripheral blood mononuclear cells (PBMCs) and neutrophils from patients with AAV in active-disease status (n=16), as well as from patients with other autoimmune diseases (n=8) as disease controls, and healthy subjects (n=10). In addition, we collected these specimens from 12 out of the 16 patients with AAV after remission induction. We performed RNA sequencing (RNA-seq) on the obtained cells and whole genome sequencing (WGS) on DNA extracted from the whole blood. Somatic mutations were detected by comparing the RNA and DNA sequences[2].
Results: After stringent quality control, we identified 108 somatic mutations across 16 patients in active-disease status. The mean coverage of RNA-Seq at the mutation site was 100.9 ± 367.8 ×, and that of WGS was 14.4 ± 4.3 ×, while the mean allele fraction was 22.9 ± 20.5%. One or more mutations were detected in each of the 15 (93.8%) patients. The median mutation count of each patient was 4.0, which was not significantly different from disease controls or samples after remission induction. We mapped one gene to each of the 108 mutations, resulting in 95 genes in total. Mutations for six of the 95 genes were observed in two or more patients, and two of them were related to the ubiquitin system. Of the 108 mutations, 37 were missense, and 20 were predicted to be deleterious (combined annotation-dependent depletion Phred score > 20). Among the 20 mutations, the *HIST2H2AC* mutation (NM_003517: p.L86P) in neutrophils was observed in two patients. To evaluate the functional outcome of the 20 mutations, we analysed the data on knocking out the corresponding genes using CRISPR in K562 cells[3]. The results showed that the expression of genes related to antigen presentation was increased in *HEATR1* and *RPL18* knockouts. When we followed up with 12 of the 16 patients after remission induction, 81.4% of the somatic mutations were no longer detected. Additionally, 91.7% of the deleterious mutations disappeared.
Conclusion: We found somatic mutations with potential pathological effects in some patients with AAV exhibiting active-disease status. Notably, the majority of these mutations were not detected after remission induction.

Background: Behçet's disease is a complex inflammatory vasculitis with a broad spectrum of clinical manifestations.
Objectives: The purpose of this study was to investigate the genetics underlying specific clinical features of Behçet's disease in a group of patients with > 5 years of follow up.
Methods: A total of 436 patients with Behçet's disease from Turkey were studied. Genotyping was performed using the Infinium ImmunoArray-24 BeadChip. After imputation and quality control measures, logistic regressions adjusting for sex and the first five principal components were performed for each clinical trait using a case-case genetic analysis approach. A weighted genetic risk score was calculated for each clinical feature.
Results: Genetic association analyses of previously identified susceptibility loci in Behçet's disease revealed a genetic association between ocular lesions and *HLA-B/MICA* (rs116799036: OR=1.85, 95% CI=1.35-2.52, p-value=$1.1x10^{-4}$). The genetic risk score was significantly higher in Behçet's disease patients with ocular lesions compared with those without ocular involvement, and is explained by the genetic variation in the HLA region. New genetic loci predisposing to specific clinical features in Behçet's disease were suggested when genome-wide variants were evaluated. The most significant associations were observed in ocular involvement with *SLCO4A* (rs6062789: OR=0.41 (95% CI=0.30-0.58), p-value=$1.92x10^{-7}$), and neurological involvement with *DDX60L* (rs62334264: OR= 4.12 (95% CI 2.34 to 7.24), p-value = $8.85x10^{-7}$).
Conclusion: Our results emphasize the role of genetic factors in predisposing to specific clinical manifestations in Behçet's disease, and might shed additional light into disease heterogeneity, pathogenesis, and variability of Behçet's disease presentation across populations.

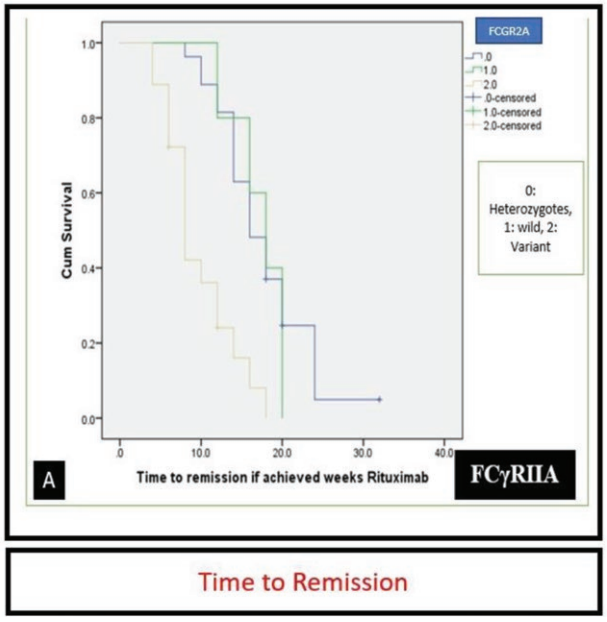
EVALUATION OF FC GAMMA RECEPTOR (FCΓR/ FCGR) & CYP GENETIC POLYMORPHISM AND ITS PHARMACOGENOMIC CORRELATION WITH RITUXIMAB AND CYCLOPHOSPHAMIDE RESPONSE IN ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY ASSOCIATED VASCULITIS

Keywords: Remission, Vasculitis, Genetics/Epigenetics

P. Deo[1], A. Sharma[1], G. Naidu[1], P. Bhatia[2], M. Singh[2], D. Das[1], R. Minz[3], S. Jain[1]. *[1]PGIMER HOSPITAL CHANDIGARH, Department of Internal Medicine - Rheumatology Wing, Chandigarh, India*; *[2]PGI HOSPITAL CHANDIGARH, Department of Pediatrics, Chandigarh, India*; *[3]PGI HOSPITAL CHANDIGARH, Department of Immunopathology, Chandigarh, India*

Background: The antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) are three discrete entities – Granulomatosis with polyangiitis (GPA), Microscopic polyangiitis (MPA), and Eosinophilic granulomatosis with polyangiitis (EGPA). They present with a plethora of signs and symptoms resulting in significant burden of mortality and morbidity. There is huge lacuna in the knowledge of relationship between various genes affecting pharmacogenetics of AAV and its implications in context of therapeutic complications. We thus intend to evaluate genotypic polymorphism in FcγR family & CYP genes affecting pharmaco-biological response of Rituximab and Cyclophosphamide respectively in AAV patients undergoing induction treatment.
Objectives: To study the single nucleotide polymorphism (SNP) of the FcγR family (FcγRIIIA, FcγRIIA, FcγRIIB) in patients receiving Rituximab (RTX) and the SNPs of CYP2C19*2 (rs4244285), CYP2B6 (rs321137) polymorphisms in patients receiving Cyclophosphamide (CYC) using polymerase chain reaction. Additionally, to correlate the genetic polymorphism of AAV patients with Rituximab and Cyclophosphamide treatment response.
Methods: This study was a prospective cohort study in which AAV patients undergoing induction treatment were enrolled from Jan 2021 to Dec 2022 in Clinical Rheumatology Department at PGIMER Chandigarh, India. Functional SNPs for FcγR(FcγRIIb 695T>C, FcγRIIIa 559T>G and FcγRIIa 519G>A) and



CYP enzymes (CYP2C19 681G>A, CYP2B6 1459C>T) were assesed by Sanger sequencing of PCR amplified genomic DNA. The end points were to detect associations between the tested SNPs and status of remission at six months and complete remission at end of the study.

Results: In this study we recruited ninty seven patients of AAV in Indian population. Table 1 summarises the baseline clinical characterisitics of the study population. FcγRIIA variant (v) allele frequency was more than wild allele (W) frequency in the study population. The time to achieve remission was significantly lower (mean:9.22 weeks) in FcγRIIA variant genotype polymorphism (FcγRIIa 519AA) in comparison to wild and heterozygotes variants (mean: 17.25 weeks) of FcγRIIA at site 131 (519G>A), as shown in Figure1. There were no significant difference observed in CYP polymorphism and cyclophosphamide response.

Table 1. Clinical and demographic characteristics of 97 AAV patients

Characteristic	N (%) or mean
Sex	
Male	38 (39%)
Female	59 (61%)
Male: Female Ratio	1:1.55
Mean age at diagnosis (years) ±SD	42.10 ± 15.57
Patient profile	
Newly diagnosed	31
Follow-up	66
AAV Subtypes	
GPA	82
MPA	8
EGPA	7
Signs and symptoms, n(%)	
Constitutional	76 (78.3%)

Skin	20 (20.6%)
CNS	23 (23.7%)
PNS	24 (24.7%)
Eyes	42 (43.2%)
Outcomes characteristics	
Number of patients achieving Remission (at 6 months of induction)	88
Number of patients achieving Complete Remission (at time of analysis)	40

Figure 1: Effect of SNP of FcγR2A at site 131 (519G>A); 0: heterozygotes(519 GA), 1: wild (519GG), 2: variant(519 AA)

Conclusion: This study is one of the first to evaluate the pharmacogenomic profile of AAV in Indian population. We observed highly significant association of SNPs of FcγRIIa 131 site variant/519AA genotype with early remission and complete remission after induction treatment with rituximab. This data could further help in tailored treatment of AAV patients and may also serve as a prognostic marker.

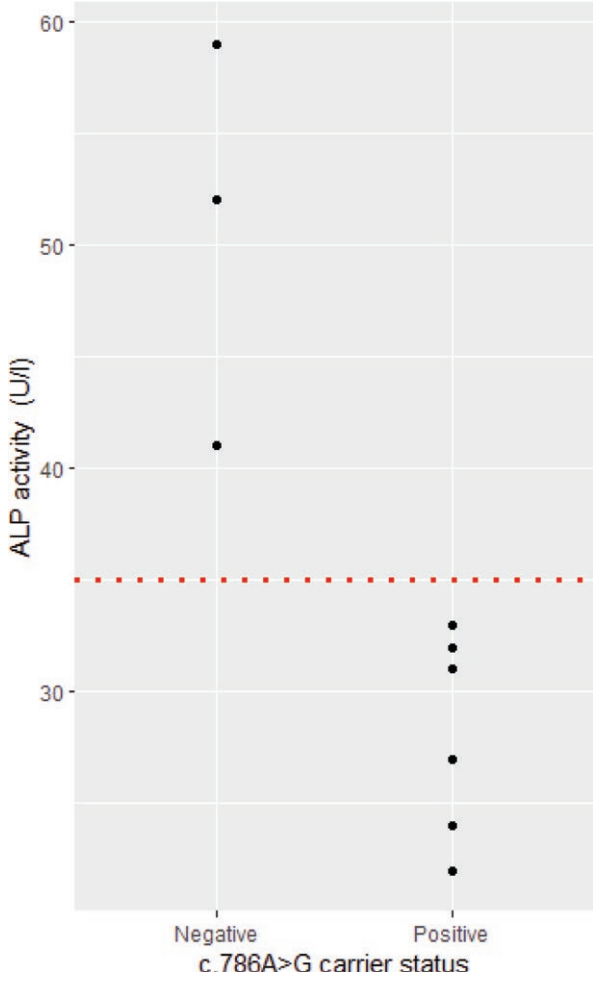
A NOVEL MUTATION IN ALPL GENE CAUSING ADULT AUTOSOMAL DOMINANT HYPOPHOSPHATASIA IN A FAMILY OF SOUTHERN SPAIN: PHENOTYPE CHARACTERIZATION

Keywords: Genetics/Epigenetics, Rare/orphan diseases, Bone diseases

S. Leal Rodriguez[1], N. Roldan Ruiz[2], L. Mayordomo[2], J. Bobillo-Lobato[3]. *[1]La Fe University and Polytechnic Hospital, Rheumatology, València, Spain; [2]Hospital Universitario Nuestra Señora de Valme, Rheumatology, Sevilla, Spain; [3]Hospital Universitario Nuestra Señora de Valme, Clinical Analysis Laboratory, Sevilla, Spain*

Background: Tissue non-specific alkaline phosphatase (TNSALP) is essential for bone and tooth extracellular matrix mineralization. The gene encoding TNSALP (ALPL) is located on the long arm of chromosome 2. More than 400 ALPL variants exist. Low enzymatic activity of serum alkaline phosphatase (ALP) due to gene mutations leads to hypophosphatasia (HPP), a heterogeneous clinical condition ranging from asymptomatic or mild adult forms to severe perinatal disease. Adult's HPP most typical features are stress fractures and early loss of dentition.

Objectives: To describe the clinical phenotype and laboratory features in a family suffering from HPP in which a new gene variant was detected.



Methods: A descriptive observational study of a family belonging to the Virgen de Valme Hospital area (Seville) was conducted through a primary identification of an index case with low level of ALP in whom a novel ALPL gene mutation was found. Members from three family generations were screened for low level of ALP to select patients meeting laboratory criteria for HPP. To assess family segregation, phenotype and clinical relevance of this mutation, genetic analysis of those with confirmed low ALP and a selection of members with normal ALP levels was done. Epidemiological, clinical, laboratory and genetic study variables were collected. A descriptive quantitative analysis of the data was performed.

Results: We studied 16 members corresponding to three generations of the same family suspected to have familial hypophosphatasia. The index case was a 57-year-old male with chronic pain, problems with dentition and previous history of fractures. ALP screening found 8/16 (50%) patients with low level. Genetic testing was performed for 7/16 patients and 3/16 with low and normal ALP levels, respectively. A familial carrier variant c.786A>G heterozygotic single-nucleotide polymorphism (SNP) in the ALPL gene was found in all patients with low ALP (Graph 1). Clinical and laboratory features for the seven positive carriers are shown in Table 1. Most fractures were due to non-minor trauma. Chronic arthralgia was the main articular complaint. All laboratory values were within normal range, ruling out secondary causes of HPP. Only one patient presented with high pyridoxal-5'-phosphate (PLP).

Conclusion: We present a new autosomal dominant inheritance mutation in the ALPL gene that causes HPP. Variable clinical expressivity is observed. Dentition problems and recurrent fractures predominate, associated with chronic pain. Early diagnosis and genetic counselling may be important, although further studies and a larger population are required to establish the definitive pathologic relevance of this variant.

Table 1. Epidemiological, clinical and laboratory characteristics of positive mutation carriers (n = 7). ALP: alkaline phosphatase; PLP: pyridoxal-5'- phosphate; 25-OH-VitD: 25-hydroxy-vitamin D; PTH: parathyroid hormone; TSH: thyroid stimulating hormone.

Baseline characteristics (n = 7)			
Sex	Male	3 (42.8%)

JAK2 MUTATION, TNF-A AND IL 6 PREDICT RESPONSE TO JAK INHIBITOR IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Rheumatoid arthritis, Prognostic factors

Y. Adel Abdelsalam Hussein[1], Y. Sadeq[2]. [1]*Mansoura University Hospital, Rheumatology, Mansoura, Egypt*; [2]*Mansoura University Hospital, Clinical Pathology, Mansoura, Egypt*

Background: STAT4 is activated by the JAK family members Tyk2 and JAK2 in response to IL and TNF, with subsequent down-stream signaling to promote Th1 mediated autoimmunity [1]. JAK inhibitors [2] are type of medication that function by inhibiting activity of one or more of the Janus kinase family of enzymes. These inhibitors have therapeutic application in the treatment of cancer and inflammatory diseases such as rheumatoid arthritis [3].
Objectives: Study impact of JAK2 mutation, TNF-α and IL 6 levels on response to JAK inhibitors and ACR response criteria.
Methods: The study included 120 newly diagnosed rheumatoid arthritis patients and 80 matched controls. All patients started therapy with csDMARDs. 70 patients failed to achieve adequate response so, they were shifted to Baricitinib. JAK2 mutation assessed by PCR in blood samples, TNF-α and IL 6 were measured by ELISA in serum of patients at diagnosis, before and after Baricitinib treatment.
Results: 102 females (85%) and 18 males (15%) with age mean ± SD (years); (47.7±7.5). Pretreatment JAK2 mutation, TNF-α and IL 6 were significantly high in patients than control. JAK2 mutation were more presented in young age patients (mean ± SD; 47.1 ±3.2 vs 51.4 ± 7.9 in mutant vs non-mutant JAK2 patients, respectively with *P* 0.03). Mutant JAK2 was significantly linked to severity of disease by DAS28; 70% of patients with DAS28 (≤ 2.6) were non-mutant JAK2 vs 30% patients mutant JAK2 while 73.1% of patients with DAS28 (> 5.1) were mutant JAK2 vs 26.9% patients non-mutant JAK2 (P 0.04). 70 patients were csDMARD incomplete responders. Jak2 mutation was significantly presented in these group comparing to patients achieved response to csDMARDs (P 0.002) associated with significant high serum TNF-α (P 0.03) and IL 6 (P 0.001). These refractory patients allowed to receive Baricitinib (single or with other antirheumatic). ACR20 response criteria was significantly better in patients with JAK2 mutation compared with those non mutant after Baricitinib therapy at week 12 (65 versus 31 percent, P 0.04). Also, Baricitinib responders were significantly have high serum TNF-α (P 0.002) and marginal significance high serum IL 6 (P 0.06).
Conclusion: JAK2 mutation in RA patients associated with high disease activity score and inadequate response to csDMARDs. Pretreatment detection of JAK2 mutation in RA patients with high serum level of TNF-α and IL 6 predict a good response to JAK inhibitors with better ACR response criteria.

SEX-RELATED INEQUITY IN RANDOMIZED CONTROLLED TRIALS IN PSORIATIC ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

Keywords: Psoriatic arthritis, Spondyloarthritis, Clinical Trials

L. Eder[1,2], S. Mylvaganam[3], J. Pardo Pardo[4], J. Petkovic[5], V. Strand[6], P. J. Mease[7,8], K. Colaco[1,9]. [1]*Women's College Hospital, Rheumatology, Toronto, Canada*; [2]*University of Toronto, Medicine, Toronto, Canada*; [3]*University of Toronto, Biochemistry, Toronto, Canada*; [4]*University of Ottawa, Cochrane Musculoskeletal, Ottawa, Canada*; [5]*University of Ottawa, Cochrane Equity Methods Group, Ottawa, Canada*; [6]*Stanford University, Medicine, Stanford, United States of America*; [7]*University of Washington, Medicine, Seattle, United States of America*; [8]*Swedish Medical Center, Rheumatology, Seattle, United States of America*; [9]*University of Toronto, Health and Society, Toronto, Canada*

Background: Sex is an important determinant of health including response to therapy. Limited information exists on representation and reporting of results by sex in randomized controlled trials (RCTs) in patients with psoriatic arthritis (PsA).
Objectives: Through a systematic literature review and meta-analysis of RCTs in PsA, we aimed to assess potential health inequities in sex-related dimensions by describing the proportion of trials reporting sex-disaggregated data and by comparing the efficacy of advanced therapies between male and female participants.
Methods: We performed a systematic literature search of Medline, Embase and Central databases, and conference abstract archives from January 1, 2000 to June 30, 2022. We included RCTs that reported sex-disaggregated results and assessed the efficacy of an advanced therapy (biologic or targeted synthetic) in adult participants with PsA. Efficacy end points included the proportion of participants achieving minimal disease activity (MDA) or meeting the American College of Rheumatology 20 (ACR20) and ACR50 response criteria at the primary endpoint of the trial. We used random-effect models to calculate pooled effects for responses in males vs. females for the different classes of advanced therapies (Odds Ratio (OR) and 95% Confidence interval (CI)).
Results: We included a total of 52 RCTs, accounting for 21,769 participants, in the review. An equal participation of male and female patients was found (50.1% male participants). Only 9 trials (17.3%, 5,604 participants) reported sex-disaggregated baseline characteristics, 16 trials (30.7%, 9,028 participants) reported sex-disaggregated efficacy endpoints and 2 trials (3.8%, 1,005 participants) reported sex-disaggregated safety endpoints. Female patients had significantly higher baseline tender joint count, Health Assessment Questionnaire Disability Index, physician and patient global assessment of disease activity and pain scores. Male patients had significantly higher baseline psoriasis area and severity index (PASI) and CRP. Differences in pooled estimates of efficacy endpoints were evident for male and female patients across the different classes of advanced therapies. The probability of achieving ACR20 responses was significantly higher in male vs. female patients for IL-17 inhibitors (i) (OR 1.76, 95% CI 1.33, 2.34), IL-23i (OR 1.46, 95% CI 1.20, 1.78), IL-12/23i (OR 2.66, 95% CI 1.39, 5.09) and TNFi (OR 1.67, 95% CI 1.20, 2.34), but not for JAKi (OR 1.10, 95% CI 0.87, 1.38). [**Figure 1A**] Similarly, the probability of achieving ACR50 responses was significantly higher in males vs. females with all advanced therapies, except JAKi (OR 1.09, 95% CI 0.73, 1.62) **[Figure 1B]**. The probability of achieving MDA was higher in males across all classes of advanced therapies, including IL-17i (OR 1.99, 95% CI 1.50, 2.63), IL-23i (OR 1.79, 95% CI 1.29, 2.50), TNFi (OR 2.62, 95% CI 1.54, 4.44) and JAKi (OR 1.77, 95% CI 1.15, 2.73) and IL-12/23i (OR 1.82, 95% CI 0.97, 3.40). Male and female patients had similar probabilities for achieving ACR20 responses when using placebo (OR 1.04, 95% CI 0.86, 1.27).
Conclusion: Based on the reported results, female patients participating in RCTs are less likely to achieve efficacy end points for most classes of advanced therapies. Some differences in responses were found across classes of advanced therapies. RCTs should report sex-disaggregated results to identify sex-related differences in efficacy and safety outcomes which will inform patient-centered therapeutic strategies.

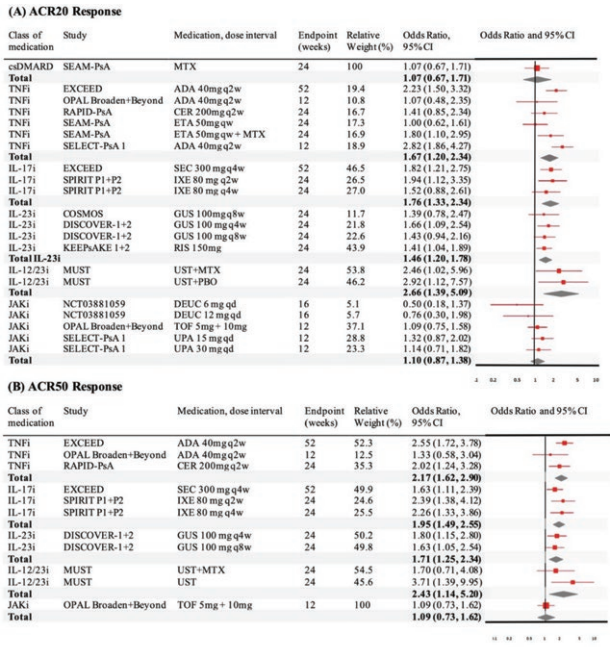

Figure 1. Random-effects meta-analysis of the efficacy of advanced therapies, by (A) ACR20, (B) ACR50 response between male and female patients with psoriatic arthritis. POS0360

X-CHROMOSOME DOSAGE, RATHER THAN THE GONADAL SEX ITSELF, MAJORLY CONTRIBUTES TO SEX BIAS IN AUTOIMMUNITY IN HUMANS

Keywords: Autoantibodies, Gender/diversity issues

R. Singh[1], E. Yen[1], I. Valera[1]. [1]*UCLA, Medicine, Los Angeles, United States of America*

Background: Most autoimmune diseases exhibit a profound female sex bias. Mechanisms underlying this sexual dimorphism remain unclear. We previously reported that the XX sex chromosome complement, as compared to XY, imparts greater susceptibility to autoimmune diseases such as lupus in experimental models (Smith-Bouvier D, et al, J Exp Med 2008). Gonadectomized XX female

mice had more anti-DNA antibodies, autoimmune pathology, and mortality than XY female (Sry^{ko}) mice. Similarly, gonadectomized XX male (Sry^{Tg}) mice had more severe autoimmune disease than XY male ($Sry^{ko}Sry^{Tg}$). To begin to translate these murine findings onto humans, we asked if sex chromosome dosage plays a role in predisposition to autoimmunity.

Objectives: To test the hypothesis that X chromosome dosage, rather than the female sex itself, imparts susceptibility to autoimmunity in humans.

Methods: We administered autoimmune disease and connective tissue disease questionnaires and analyzed serum autoantibody levels in males and females with sex chromosome aneuploidy including males with two X chromosomes (XX males, including Klinefelter's syndrome) and females with one X chromosome (X0 females, including Turner's syndrome) and their respective male and female controls with normal sex chromosome numbers.

Results: Levels of IgG anti-chromatin, anti-nucleosome and anti-histone (H2A, H2B and H3) autoantibodies were significantly higher in XX males (47,XXY; 48,XXYY, and mosaics) compared to 46,XY men. XX males, however, did not have non-specific B cell hyper-reactivity, as the levels of anti-thyroid peroxidase antibody that is associated with autoimmune thyroiditis were similar between the two groups and antibodies against intrinsic factor which are present in patients with autoimmune gastritis/pernicious anemia were reduced in XX males than in XY males. In contrast to the increased frequency of autoantibodies against systemic autoantigens in XX males vs. XY males, such autoantibodies were reduced in X0 females as compared to XX females. However, autoantibodies against organ-specific autoantigens such as thyroid and gliadin were higher in X0 females than in XX females. A preliminary analysis of clinical questionnaire revealed an increase in autoimmune conditions in XX males when compared with known population prevalence of these diseases. Preliminary immune phenotyping of peripheral blood cells conducted thus far show altered frequency and/or function of natural killer T-cells, CD8+ T cells or IL-4/IL-17 producing cells in individuals with sex chromosome aneuploidy compared to their respective controls.

Conclusion: These data suggest that humans with two X chromosomes as compared to those with one X chromosome, regardless of their gonadal sex, exhibit increased susceptibility to systemic autoimmunity. Preliminary evidence also suggests a differential regulation of systemic versus organ-specific autoimmunity in persons with sex chromosome aneuploidy.

COMPREHENSIVE TRANSCRIPTOMIC CHARACTERIZATION REVEALS CORE GENES AND MODULES ASSOCIATED WITH SEX-DEPENDENT MOLECULAR PAIN MECHANISMS IN OSTEOARTHRITIS

Keywords: Pain, Gender/diversity issues, Osteoarthritis

Z. Wang[1,2], V. Batchelor[3], J. Miotla-Zarebska[3], B. Gerritsen[4], N. Eijkelkamp[4], T. Vincent[3], C. Svensson[1]. [1]*Karolinska Institute, Department of Physiology and Pharmacology, Stockholm, Sweden*; [2]*Tongji Hospital, Tongji Medical College, HUST, Department of Orthopedics, Wuhan, China*; [3]*University of Oxford, Kennedy Institute of Rheumatology, london, United Kingdom*; [4]*Utrecht University, Centre of Translational Immunology, Utrecht, Netherlands*

Background: Female sex is identified as a key nonmodifiable risk factor in the development of OA, particularly after the age of 55. Additionally, women appear to have a lower threshold for pain and present with more chronic pain conditions than men. Our previous studies demonstrated that female mice develop pain at the same time as male mice despite having reduced levels of joint damage, indicating the existence of sex-dependent mechanisms for the induction of pain. In non-arthritis murine pain models, different immune cells in the dorsal root ganglia (DRG) appear to contribute to sex-dependent differences in sensitization. Furthermore, we have recently uncovered cellular and molecular differences between immune cells and inflammatory profiles in the DRGs and joints of male and female mice with collagen antibody-induced arthritis.

Objectives: Search for putative pain pathways and associated temporal patterns in male and female mice subjected to surgically induced OA.

Methods: C57BL/6 male and female mice (10-week-old, n=5 per group, i.e., surgery, sex, and timepoint) were randomized subjected to either sham surgery or partial meniscectomy (PMX). Static weight bearing measurements were performed using a Linton Incapacitance Tester. Mice underwent a 2-week acclimatization post-surgery, followed by weekly measurement between week 5 to 12. L3-L4 DRGs were harvested for RNA sequencing at week 6, 10 and 12 post-surgery. The Weighted Gene Co-expression Network Analysis (WGCNA) package in R was used to construct a signed co-expression network from the expression data.

Results: Considering all groups, a tendency to pain-related behavior was observed at week 10 post-surgery, and a statistically significant difference in weight bearing found at week 12 when the PMX group was compared with sham group. We performed WGCNA to identify modules that were related to surgery and sex using 6-, 10-, and 12-week samples, respectively. For the 6-week network, 14 modules were identified. Only associations with sex were observed, with 3 modules positively related with male and 1 module positively related with female. For the 10-week network, 14 modules were identified. 6 modules were related by single trait, 3 of which were positively related with male, 2 of which were positively related with PMX, and 1 of which weas negatively related with PMX. In addition, 1 module was related with both surgery and sex, whereby it was negatively related with PMX and positively with being female. For the 12-week network, 19 modules were identified. Most significant associations were observed only with PMX, where 5 modules showed positive associations and 3 modules showed negative associations. Furthermore, greenyellow module was related with both surgery and sex, positively related with PMX and being female. As a result, this module was chosen to investigate further. According to the threshold (MM > 0.8 and GS > 0.2), 102 candidate hub genes were obtained in this module. When PPI analysis was performed, 14 candidate hub genes (top 5%, ranked by the MCC scoring method) were obtained. In total, 9 overlapping genes (Npy, Tac1, Calca, Gap43, Bdnf, Shc1, Ngfr, Casp3 and Jun) were identified as hub genes. The enriched biological process was 'neurotrophin TRK receptor signaling pathway'. And the enriched KEGG pathway were 'neurotrophin signaling pathway' and 'MAPK signaling pathway'.

Conclusion: This study reveals sex, disease and time-dependent changes in the DRG transcriptome during the development of painful OA. Importantly, our findings highlight a distinct TrkA and neurotrophin signaling signature that is evident at 12 weeks post-surgery only in OA-induced pain-related behaviors in female mice.

POS0362 SEX-RELATED DIFFERENCES IN CHARACTERISTICS AND MORTALITY OF PATIENTS WITH RHEUMATOID ARTHRITIS AND CONCOMITANT HEART FAILURE

Keywords: Outcome measures, Rheumatoid arthritis, Heart

T. Rudi[1], V. Zietemann[1], Y. Meissner[1], M. Schneider[2], M. Worsch[3], A. Strangfeld[1,4]. [1]*German Rheumatism Research Centre, Epidemiology and Health Services Research, Berlin, Germany*; [2]*Universitätsklinikum Düsseldorf, Rheumatology, Düsseldorf, Germany*; [3]*Rheumatologist, Private Practice, Mühlhausen, Germany*; [4]*Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: Heart failure (HF) is a common co-morbidity of rheumatoid arthritis (RA) with a high mortality risk [1]. In the general population, significant sex-related differences in HF including aetiology, pathophysiological mechanisms and age are observed, emphasizing the importance to stratify analyses by sex [2] and there is increasing evidence that mortality rates of females are lower, which cannot be explained by comorbidities, HF characteristics or HF medical treatment [3].
Objectives: To investigate sex specific differences in patient characteristics and their association with mortality in RA patients with concomitant HF.
Methods: RA-patients enrolled and observed in the German biologics register RABBIT between 01/2007 and 04/2022 were selected for the analysis if they presented HF either at enrolment or during follow-up. Observation started at the time of HF reporting (=baseline) and ended at death, dropout or end of follow-up, whichever came first. Baseline patient characteristics were stratified by sex. Cox proportional hazard regression with sex as exposure of interest was applied, adjusted for age (model 1) and further adjusted for comorbidities and RA specific characteristics (model 2). Missing values were imputed once.
Results: Out of 15,917 cohort participants (11,835 females, 74%), 718 patients were identified as prevalent HF cases (473 females, 66%). Females with HF were on average 1.7 years older, had worse physical function and longer RA disease duration compared to males. Females were more likely to have osteoporosis and less likely to have ischemic heart disease (Table 1). 25% of the females and 34% of the males died after a mean follow-up time of 39 and 36 months, respectively. Females had a significant lower risk of death compared to males regardless of adjustment (model 1: HR=0.57 [0.43-0.76]; model 2: HR=0.51 [0.37-0.71], Figure 1).
Conclusion: Our findings demonstrate a longer survival for females compared to males in a cohort of patients with RA and concomitant HF. The difference could not be explained by age, comorbidities and RA-related characteristics at baseline. The observed differences in the clinical profile and mortality highlight the need for research stratifying by sex when investigating cardiac events.

Background: There is increasing evidence revealing sex differences in the manifestations of axial spondyloarthritis (axSpA). However, the results in this regard are heterogeneous and studies that analyze the influence of sex on cardiovascular (CV) risk are lacking.
Objectives: To assess the CV profile of male and female axSpA patients and to determine the potential impact of sex-specific disease-related characteristics on atherosclerosis in these patients.

Methods: This is a cross-sectional study of the AtheSpAin cohort, a Spanish multicenter cohort to study atherosclerosis in axSpA. Data on clinical and subclinical atherosclerosis, as well as CV and disease-related characteristics were collected in 912 patients.

Results: 611 men and 301 women were recruited for this study. Smoking habit (p=0.033), hypertension (p=0.009), and dyslipidemia (p=0.015) were less prevalent in women, who also showed less severe atherosclerosis measured by the presence of carotid plaques (p=0.001), carotid intima-media thickness (IMT) values (p<0.001), and CV events (p=0.008). After adjustment for traditional CV risk factors only the results regarding carotid IMT remained statistically significant. Regarding disease-related features, radiographic axSpA (r-axSpA) was more common in men (p<0.001). Women with axSpA showed a shorter disease duration (p<0.001), a lower prevalence of psoriasis (p=0.008), higher ESR levels at diagnosis (p=0.038) and more active disease measured by ASDAS (p=0.012) and BASDAI (p<0.001). However, they had less structural damage (mSASSS, p<0.001) and mobility limitation (BASMI, p=0.033). These differences that remained statistically significant after adjustment for r-axSpA/nr-axSpA, disease duration or smoking. Remarkably, many of these sex-related differentiating characteristics were associated with subclinical atherosclerosis (table 1). To clarify if this finding could lead to sex differences in the atherosclerotic burden, we compared the prevalence of carotid plaques in men and women with the same level of CV risk stratified according to the SCORE. Within the category of low-moderate SCORE, men showed more severe atherosclerosis than women (p=0.050), which could be related to a longer disease duration (p=0.004), higher mSASSS (p=0.001) and BASMI (p=0.071) values. However, in patients with high-very high SCORE, carotid plaques were more commonly observed in the female group (p=0.025), which was characterized by a higher inflammatory burden (ESR at diagnosis, p=0.007) and worse BASFI (p=0.011) compared with men, with no differences regarding disease duration, mSASSS or BASMI.

Conclusion: Although the burden of traditional CV risk factors leading to more severe atherosclerotic disease is greater in men with axSpA, potential sex-related proatherogenic features of axSpA also appear to have an impact on CV risk. This may be especially applicable to women at high CV risk, who have a greater inflammatory response, worse functional impairment, and more severe subclinical atherosclerosis than males, suggesting a closer interaction between atherosclerosis and disease burden in women with axSpA.

SEX DIFFERENTIAL IMPACT OF CO-MORBIDITIES ON DISEASE ACTIVITY IN SPONDYLOARTHRITIS: DATA FROM COMOSPA STUDY

Keywords: Spondyloarthritis, Registries

M. Llop Vilaltella[1], J. Gratacos-Masmitja[2], M. Moreno[1], M. Arévalo[2], A. Berenguer-Llergo[3], J. Calvet[1], M. Dougados[4], A. Moltó[4], C. López-Medina[4]. [1]*Parc Tauli Hospital Universitari, Rheumatology, Sabadell, Spain*; [2]*Parc Tauli Hospital Universitari, Rheumatology, SABADELL, Spain*; [3]*Institut d'Investigació i Innovació Parc Taulí I3PT, Fundació Parc Taulí-Institut Universitari UAB, SABADELL, Spain*; [4]*Hôpital Cochin, Rheumatology, Paris, France*

Background: Previous studies have examined the distinct phenotypes and the factors linked to disease activity and response to treatment in spondyloarthritis (SpA), some reporting several differences between men and women. However, there is still scarce literature on sex differences in SpA co-morbidities such as cardiovascular (CV) risk factors, osteoporosis, neoplasms or infections, or exploring sex differential impacts of these co-morbidities in the disease activity of SpA patients.

Objectives: To characterize differences in SpA associated co-morbidities between male and female patients and to evaluate the existence of a differential impact of these comorbidities on the disease activity between SpA gender.

Methods: This is a post-hoc analysis of the COMOSPA study which included 3982 patients with SpA, 2588 male patients and 1394 female patients. Differences in co-morbidities regarding sex were assessed using logistic regression models. Co-morbidities were evaluated for their impact on disease activity indexes with linear models, which included sex and the comorbidity as explanatory variables, as well as their interaction. Age and treatment with bDMARDS were included as confounders. We retrieved odds ratios (OR) and group differences from these models to measure the magnitude of the effects and determined statistical significance at a level of p<0.05 using Wald tests.

Results: After statistical control for age and bDMARDS, our analysis found that men had a higher prevalence of several cardiovascular comorbidities such as hypertension (OR, 95%CI) (1.47, 1.23 - 1.77), dyslipidemia (1.29, 1.07 - 1.56), ischemic heart disease (2.77, 1.72 - 4.65) and renal deficiency (2.36, 1.46 - 4.01). Additionally, a greater proportion of men had a history of tuberculosis (1.59, 1.45 - 3.95), and a lower prevalence of fibromyalgia (0.47, 0.39 - 0.57). However, we did not find differences between men and women in terms of prevalence of neoplasms, osteoporosis, gastrointestinal disease, or severe infection (Table 1). Several co-morbidities were associated with disease activity equally in both sex, including CV conditions, severe infection, osteoporosis, chronic obstructive pulmonary disease, gastrointestinal disease and fibromyalgia. When comparing men and women patients, gastrointestinal ulcer and fibromyalgia associates with ASDAS and BASDAI and have a differential impact depending on sex. Specifically, fibromyalgia has a higher impact in men (ASDAS: 1.367 vs 1.612; BASDAI: 4.28 vs 4.70) (Figure 1).

Conclusion: Our data show that co-morbidities occur similarly in men and female SpA patients, except for a higher frequency of CV co-morbidities in men and a higher prevalence of fibromyalgia in women. Moreover, fibromyalgia and gastro-intestinal ulcer evidenced a sex-specific association with disease activity among all the co-morbidities studied.

POS0365 SEX DIFFERENCES CONCERNING EXPERIENCED PAIN IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Pain, Spondyloarthritis, Gender/diversity issues

Y. Van der Kraan[1], D. Paap[1,2], H. Timmerman[3], F. Wink[4], S. Arends[1], M. Reneman[5], A. Spoorenberg[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]Saxion University of Applied Sciences, Physiotherapy, Enschede, Netherlands*; *[3]University Medical Center Groningen, Anaesthesiology, Groningen, Netherlands*; *[4]Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands*; *[5]University Medical Center Groningen, Rehabilitation Medicine, Groningen, Netherlands*

Background: Research shows that there are significant sex differences in experienced pain. Contributing factors are neuroanatomical, hormonal, neuro-immunological, psychological, social, cultural, and comorbidities. Women have more and different expression of nociceptors, and a stronger proinflammatory response to tissue damage than men. Women also use different coping styles regarding to pain and tend to engage more in pain catastrophizing. Therefore, women may experiencing more severe pain than men. Also in axial spondyloarthritis (axSpA), higher pain scores are observed in women compared to men with axSpA.[1] Sex differences in experienced pain within axSpA is not well studied. It is unclear if differences are related to the involvement of altered pain processing of the central nervous system (CNS) including central sensitization (CS) and/or psycho-social aspects.
Objectives: To explore sex differences in pain perception, coping with pain, pain catastrophizing and altered pain processing of the CNS in patients with axSpA.
Methods: A cross-sectional study of consecutive outpatients from the Groningen Leeuwarden axSpA (GLAS) cohort, fulfilling the ASAS classification criteria. Participants filled out the Central Sensitization Inventory (CSI), Pain Catastrophizing Scale (PCS) Coping with Rheumatic Stressors (CORS), and underwent Quantitative Sensory Testing (QST) according to a standardized protocol, including Pain Threshold Testing (PTT) at 11 sites, Temporal Summation (TS) at 3 sites and Conditioned Pain Modulation (CPM). Widespread low PPTs, high TS (both pain facilitation) and positive CPM (impaired pain inhibition) are indicators of CS. Independent Samples T Test and Mann-Whitney U Test were used for normally- and non-normally distributed data resp.. Bonferroni correction was applied for multiple significance testing and P-value was determined at 0.004.
Results: 201 patients were included, 128 men and 73 women with no significant differences in the patient characteristics; median age (50.8 vs 51.6 years), median symptom duration (22.0 vs 21.0 years) and median CRP (1.8 vs 2.5). Significant differences between men and women were observed for the classification radiographic axSpA (71.9% vs 50.7%), HLA-B27 status (84.1% vs 67.1%), mean BMI (27.2 ± 4.9 vs 29.0 ± 6.9), mean $ASDAS_{CRP}$ (2.1 ± 0.8 vs 2.5 ± 0.9) and mean BASDAI (3.4 ± 2.1 vs 4.7 ± 2.1). Women scored significantly higher on the CSI and used the coping styles comforting cognitions, decreased activities and diverted attention more often (CORS). Concerning the involvement of altered pain processing of the CNS, women had significantly lower PPTs. TS and CPM were comparable in men and women (Table 1).
Conclusion: In patients with axSpA, significant sex differences in pain coping styles, CSI score and PPTs were observed. Therefore, sex differences should be taken into account in the management of pain in daily clinical practice and in pain research in these patients.

POS0366 SEXUAL DYSFUNCTION IN SPONDYLOARTHRITIS PATIENTS: DIFFERENCES BETWEEN MALES AND FEMALES PATIENTS IN A REAL-WORLD SETTING

Keywords: Gender/diversity issues

I. Pantano[1], D. Mauro[1], L. Napolitano[2], M. S. Ciliento3, M. Visconti3, F. Ciccia3. *[1]University of Campania L. Vanvitelli, Rheumatology Unit, Precision Medicine, Naples, Italy*; *[2]University Federico Second, Urology Unit, Neuroscience department, Naples, Italy*; *[1]University of Campania L. Vanvitelli, Rheumatology Unit, Precision Medicine, Naples, Italy*

Background: In the field of rheumatology in general and in the context of spondylarthritis (SpA) more specifically, gender medicine is gaining more recognition and relevance. Available data suggest female patients feature higher diagnostic deladelayspared to males. Furthermore, female SpA patients experience higher disease activity, lower response rates to treatment and, less probability to achieve remission. Sexual dysfunctions are an aspect little investigated in SpA. Disease features and disease activity are known to influence sexual health. Conversely, little is known about the difference existing in sexual satisfaction in males and females affected by SpA.
Objectives: To investigate the sexual function and satisfaction in female and male patients affected by SpA and identify gender-specific features.
Methods: We conducted a cross-sectional study enrolling consecutive SpA patients satisfying ASAS criteria attending the SpA clinic of a tertiary university rheumatology clinic. Demographic and clinical characteristics were collected alongside with validated gender-specific questionnaire for the evaluation of sexual function. For male assessment, we used the international index of erectile function (IIEF) and the Premature Ejaculation Diagnostic Tool (PEDT); whereas in women we used The Female Sexual Function Index (FSFI) that explores domains such as desire, arousal, lubrification, orgasm, satisfaction, and pain. To evaluate the correlation between the presence of sexual dysfunction and disease characteristics or therapies we used the Spearman test and the univariate and multivariate tests.
Results: 73 males and 64 females were recruited, and the two groups were comparable with similar mean age, BMI, and disease duration (patients' characteristics are shown in table 1). PEDT test showed that 9.5% (5 male patients) had probable premature ejaculation and 15% (8 male patients) had premature ejaculation. According to IIEF sexual dysfunction was present in 19.4% of cases as mild dysfunction in 15.5% as moderate dysfunction and in 5.4% as severe dysfunction. Univariate and multivariate analysis showed a correlation between sexual dysfunction and mood disorders and premature ejaculation in men (p=0.02). The prevalence of premature ejaculation was not influenced by disease characteristics or activity or therapies. Sexual dysfunction in males was associated only with the use of NSAID (p=0.04). Evaluating the female group, FSFI showed that 85% (54 female patients) had sexual dysfunction. In the univariate and multivariate analysis, we found correlations between age (p=0.07), mood disorders (p=0.04), dyslipidemia (p=0.006), and BASDAI (p=0.04). Fibromyalgia was detected only in women.
Conclusion: This data demonstrates that sexual function is impaired in an extremely high percentage of female SpA patients, which contributes to the higher burden of SpA on women. Sexuality is still a little explored topic in SpA, despite is a relevant aspect of quality of life and determinant of psychological health. Therefore, it is necessary to thoroughly investigate the impact that the disease and comorbidities have on the sexual life of these patients with a particular focus on females.

FILLING GAPS IN FEMALE GOUT: A CROSS-SECTIONAL STUDY OF 192,000 PATIENTS HOSPITALIZED WITH GOUT FROM 2005 TO 2015

Keywords: Gender/diversity issues, Comorbidities, Gout

E. Rodríguez-Sosa[1], E. De Miguel[2], F. Borrás[3], M. Andrés[1,4,5]. *[1]Miguel Hernandez University, Clinical Medicine, San Juan de Alicante, Spain*; *[2]La Paz Hospital, Rheumatology, Madrid, Spain*; *[3]Miguel Hernandez University, Statistics, Mathematics and Informatics, San Juan de Alicante, Spain*; *[4]Dr. Balmis General University Hospital, Rheumatology, Alicante, Spain*; *[5]Alicante Institute for Health and Biomedical Research (ISABIAL), Research Group on Rheumatic and Autoimmune Diseases, Alicante, Spain*

Background: Patients with gout show several comorbidities, especially cardiovascular, renal and metabolic diseases. The odds of developing new comorbidities increase progressively since the first flare, with a higher risk than general population. Female gout has received little attention in the published literature, although clinical experience and some studies suggest different clinical picture with higher mortality.
Objectives: To compare the distribution of comorbidities by sex in hospitalized patients with gout in Spain.
Methods: Retrospective, nation-based cohort study. The Minimal Basic Data Set from all Spanish hospitalizations including gout as either primary or secondary diagnosis (ICD-9 coding) from 2005 to 2015 was collected. The comorbidities of interest were obesity, dyslipidemia, chronic kidney disease, diabetes mellitus, coronary heart disease, chronic heart failure, peripheral vascular disease, arrhythmia, venous thromboembolism, cerebrovascular disease, dementia, urinary tract infection, pneumonia, sepsis, obstructive pulmonary disease, liver disease and rheumatological disease. Arterial hypertension and urinary lithiasis were not analyzed since they were underrepresented in the dataset. Comparative analyses were performed by sex. Later, stratification by age was performed and the population was divided by sextets (≤70years; 71-80years; 81-85years; 86-90years; 91-95years; >95years). A multiple logistic regression model was built to discern the strength of association of comorbidities with each sex, for the entire population and stratifying by age (≤60years and >60years). Additionally, a decision tree was constructed to have sex predicting algorithms based on the presence of comorbidities.
Results: 192,037 admissions were analyzed, 5.47% (n=10,512) with gout as primary diagnosis. 158,646 cases occurred in men (82.6%), significantly younger than women (64.0±14.4 vs 73.9±13.7 years; p<0.001). Female predominant comorbidities were obesity (16.3% vs 10.8%), dyslipidemia (31.8% vs 30.7%), chronic kidney disease (33.8% vs 25.1%), diabetes (36.2% vs 25.9%), heart failure (31.8% vs 16.6%), dementia (2.1% vs 1.2%), urinary tract infection (12.0% vs 5.4%) and concurrent rheumatic disease (2.6% vs 1.4%). Otherwise, male predominant comorbidities were coronary heart disease (21.8% vs 16.9%), peripheral artery disease (3.8% vs 1.2%), liver disease (2.2% vs 1.3%), pneumonia (4.5% vs 3.8%) and obstructive pulmonary disease (8.9% vs 2.3%). No differences were seen for others. After age stratification, differences in dementia were no longer significant. Multiple logistic regression, with an accuracy score of 68.5%, confirmed a differential comorbidity profile between men and women (**Figure 1**). After age stratification, for <60years renal and rheumatic diseases were closely linked to women with gout, whilst in >60years heart failure was the leading. For men, coronary heart disease and obstructive pulmonary disease were the chief associations. A decision tree algorithm was built [1], with an accuracy of 74.4%.

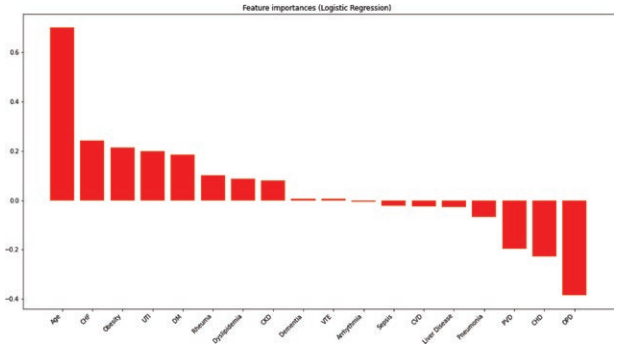

Figure 1. CHF: chronic heart failure; UTI: urinary tract infection; DM: diabetes mellitus; Rheuma: rheumatological disease; CKD: chronic kidney disease; VTE: venous thromboembolism; CVD: cerebrovascular disease; PVD: peripheral vascular disease; CHD: coronary heart disease; OPD: obstructive pulmonary disease. Positive coefficients associate with women with gout, negative ones otherwise.

Conclusion: A nation-wide analysis of 11years of hospitalizations with gout confirm a different comorbidity profile between men and women. Women with gout were significantly older and more likely to suffer from heart failure, obesity, urinary infection and diabetes. Association between sex and certain comorbidities is intense enough for sex prediction by an algorithm with considerable accuracy. A different approach for female gout is thus needed, to reduce gender blindness.

POS0368 PERSISTENT PREMATURE MORTALITY IN GOUT: NATIONWIDE PROSPECTIVE COHORT STUDY

Keywords: Gender/diversity issues, Epidemiology, Gout

N. Mccormick[1,2,3], C. Yokose[1,2], K. Lin[4], L. Lu[3], A. Joshi[4], H. Choi[1,2,3].
[1]Massachusetts General Hospital, Clinical Epidemiology Program, Boston, United States of America; *[2]Harvard Medical School, Medicine, Boston, United States of America*; *[3]Arthritis Research Canada, n/a, Vancouver, Canada*; *[4]Brigham and Women's Hospital, Channing Division of Network Medicine, Boston, United States of America*

Background: A recent UK study reported a higher cardiovascular event risk after gout flare episodes,[1] which may translate to premature mortality for gout patients over the long term. Prior studies reported premature mortality in gout, but did not compare demographic subgroups, and it is unknown whether the excess risk has improved over recent years at a national level.
Objectives: We prospectively evaluated the association between gout and the risk of all-cause and cardiovascular mortality in the latest US general population data and compared with the prior data.
Methods: Using nationally representative samples of US adults in the National Health and Nutrition Examination Survey (NHANES), linked prospectively with vital statistics data, we examined the association between gout and mortality and compared Early (NHANES III: 1988-1994) and Late cohorts (2007-2016), as well as key demographic subgroups defined by age, sex, and self-reported race/ethnicity (Black vs. White). Hazard ratios (HRs) were calculated over 10 years adjusting for atherosclerotic cardiovascular disease (ASCVD) risk factors, cardiometabolic comorbidities, kidney function, and relevant medications.
Results: Adjusted HR for all-cause mortality comparing US adults with and without gout in aggregate was 1.19 (95% CI, 1.08–1.32), with the same HR in the Early and Late cohorts (1.19; 1.02–1.38 and 1.19, 1.03–1.37, respectively) (**Figure 1**). HR was larger among those < 60 years (1.62; 95% CI, 1.19–2.19; p-interaction < 0.001 vs. age **>=** 60 years) and among women (1.33; 95% CI, 1.11–1.60, p-interaction=0.03 vs. men) (**Table 1**), and was also prominent among Black individuals (HR, 1.40; 95% CI, 1.12–1.74). Corresponding HR for cardiovascular mortality in the late cohort was 1.39 (95% CI, 1.09–1.78). All associations remained similar when adjusting for serum urate levels.
Conclusion: This representative cohort study illustrates premature mortality in gout at a national level, even after accounting for serum urate levels, which has not improved over past decades. Excess mortality was higher among women and younger adults, and was more prominent among Black individuals; the latter group already experiences an excess *prevalence* of gout at the US national level, compared to White individuals (age- and sex-adjusted odds ratio for gout=1.5 (1.2 to 1.7)).[2] These data are suggestive of continued shortcomings in current gout care practices and a compelling need to understand and mitigate the premature mortality risk in gout, especially for women and Black individuals.

POS0369 TREATMENT RELATED COST SAVINGS DUE TO EARLY IDENTIFICATION OF RHEUMATOID ARTHRITIS

Keywords: Epidemiology, bDMARD, Rheumatoid arthritis

E. Van Mulligen[1,2], A. Van der Helm – van Mil[1,2]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[2]Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands*

Background: EULAR guidelines advocate early detection and treatment of rheumatoid arthritis (RA) to induce a milder disease course. It was shown that early detection and treatment prevents erosive disease and maintains functional capabilities. Despite of that, the effect of early detection of RA on treatment related costs has never been investigated. Due to rising health care costs, it is important for society to keep health care affordable.
Objectives: Our objective was to investigate whether early identification and treatment of RA patients (within 12 weeks after symptom onset) results in a reduction of treatment related costs when compared to a patient group that was seen after 12 weeks after symptom onset, stratified for ACPA status.
Methods: Patients were obtained from the Leiden Early Arthritis Clinic (EAC), an inception cohort consisting of patients presenting with recent onset arthritis with a symptom duration ≤ 2 years. All consecutive RA patients fulfilling the 1987 and/or 2010 criteria, and who started a DMARD, included between May 2011 and December 2017 were evaluated, allowing a follow-up of 5 years. In this inclusion period, referral strategies were optimized for early recognition of RA. Early treatment start was defined as within 12 weeks after symptom onset. Information on medication use was obtained from prescription data from electronic patient records. Prices were used from both 2012 (at time of prescription) and 2022 (current). ACPA-positive and ACPA-negative RA were studied separately. Inverse probability weighting accounted for differences in patient characteristics between the early and late groups. The weighted average difference in medication costs was estimated with a generalized linear model with a log link and gamma distribution.
Results: In total, 196 RA patients were ACPA-positive and 235 patients were ACPA-negative. Median (IQR) symptom duration was 5.5 (3-9) weeks in the early group, and 29.7 (19-53) weeks for the late group for ACPA-positive patients, and 6.4 (4-9) weeks and 26 (17-50) weeks in the ACPA-negative patients. At diagnosis, the early group of both ACPA-negative and ACPA-positive patients had more severe inflammation compared to the late group. After 5 years, 6% of ACPA-negative patients and 20% of ACPA-positive patients had used ≥1 biological. The average number of biologics within these patients was 1 in the early ACPA-negative group, 1.4 in the ACPA-negative late group, and 1.9 and 2 in ACPA-positive early and late groups. When using current price levels (2022), mean (sd) cost of treatment over 5 years was €11250 (25774) for ACPA-positive patients, and €3526 (11556) for ACPA-negative patients, while treatment costs among biological users was €44788 (36360) for ACPA-positive and 40896 (25123) for ACPA-negative RA. After weighting, within ACPA-negative RA costs were lower in the early compared to the late group (€2877 versus €4213, respectively), β=1.46 (95%CI 0.32 – 3.4),

indicating 46% higher costs in the late group. For ACPA-positive patients, costs were more similar (€11631 and €10988 respectively for the early and late group, β=0.96, 95%CI 0.52 – 1.8)(figure 1A). When 2012 prices were used, costs were in general higher: €14482 (29101) and €5158 (17897) for ACPA-positive and ACPA-negative patients, respectively. Comparing late and early groups using 2012 prices provided similar results in ACPA-negative RA (β=1.34 (95%CI 0.54 – 3.3), and a larger difference in costs for ACPA-positive RA (β=0.77 (95%CI 0.44 – 1.35)).

Conclusion: Treatment-related costs of ACPA-positive RA are higher compared to ACPA-negative RA. However, early detection and treatment has the greatest impact on reducing treatment costs in ACPA-negative RA.

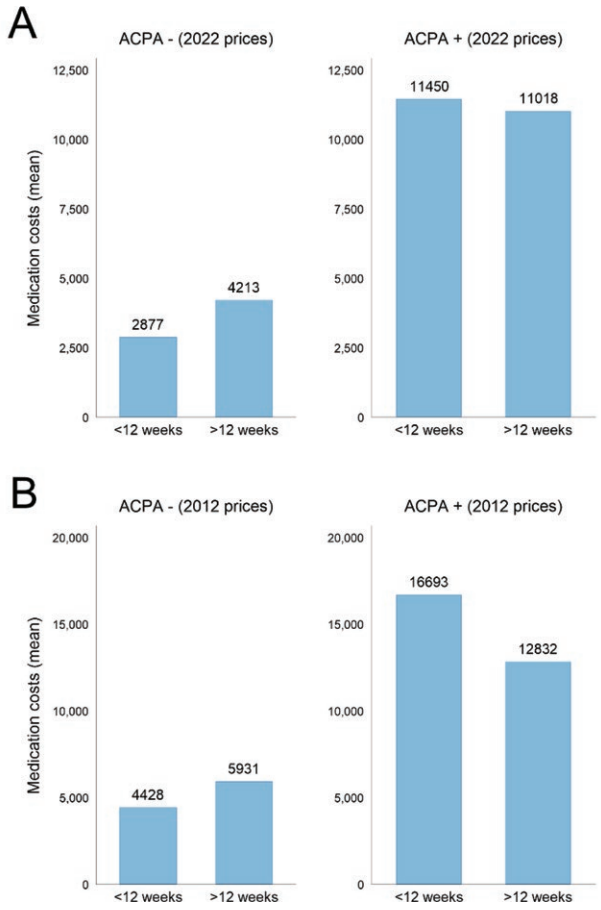

Figure 1. (A) Medication costs over 5 years indicated for ACPA-positive and ACPA-negative RA using current prices (2022), comparing early (<12 weeks after symptom onset) and later referral (>12 weeks after symptom onset). (B) Medication costs in euros over 5 years using prices at time of prescription (2012). ACPA: anti-citrullinated protein antibody

Background: Fatigue is prevalent in people with inflammatory rheumatic and musculoskeletal diseases (I-RMDs) and recognised as one of the most challenging symptoms to manage [1]. The existence of multiple factors associated with fatigue, the lack of clarity around underlying pathophysiological mechanisms and the limited evidence about what helps have led to a multifaceted and often fragmented approach to symptom management. However, there are no recommendations for fatigue management in people with I-RMDs, and this lack of guidance has been challenging for those living with fatigue as well as for healthcare professionals delivering clinical care.

Objectives: To develop EULAR recommendations for the management of fatigue in people with I-RMDs.

Methods: A multi-disciplinary taskforce comprising 26 members from 14 European countries was convened and two systematic reviews were conducted. The taskforce developed recommendations based on evidence from the systematic reviews and taskforce members' personal and professional experience of fatigue in I-RMDs.

Table 1. EULAR overarching principles and recommendations for the management of fatigue in people with I-RMDs.

Overarching principles		
1. Health professionals should be aware that fatigue encompasses multiple and mutually interacting biological, psychological and social factors. 2. In people with I-RMDs, fatigue should be monitored, and management options should be offered as part of their clinical care. 3. Management of fatigue should be a shared decision between the person with an I-RMD and healthcare and well-being professionals. 4. Management of fatigue should be based on the needs and preferences of people with I-RMDs, as well as their clinical disease activity, comorbidities and other individual psychosocial and/or contextual factors.		
Recommendations	**LoE**	**GoR**
1. Healthcare professionals should incorporate regular assessment of fatigue severity, impact and coping strategies into clinical consultations.	5	D
2. As part of their clinical care, people with I-RMDs and fatigue should be offered access to tailored physical activity interventions and encouraged to engage in long-term physical activity.	1a	A
3. As part of their clinical care, people with I-RMDs and fatigue should be offered access to structured and tailored psychoeducational interventions.	1a	A
4. The presence or worsening of fatigue should trigger evaluation of inflammatory disease activity status and consideration of immunomodulatory treatment initiation or change, if clinically indicated.	1a	A

I-RMDs, inflammatory rheumatic and musculoskeletal diseases; GoR, Grade of recommendation; LoE, Level of Evidence. GoR and LoE as per 2011 Oxford Centre for Evidence Based Medicine Levels of Evidence.

Results: Four overarching principles and four recommendations were developed (Table 1), including health professionals' awareness that fatigue should be monitored and assessed and that people with I-RMDs should be offered management options. Shared decisions about fatigue management should consider the needs and preferences of individuals, their clinical disease activity, comorbidities and other psychosocial and contextual factors (**Table 1**).

Conclusion: These 2023 EULAR recommendations provide consensus and up-to-date guidance on the management of fatigue in people with I-RMDs.

Background: Efficient pandemic planning is a key for providing a timely response to any developing disease outbreak. For example, at the beginning of the current Coronavirus disease 2019 (COVID-19) pandemic, the UK's Scientific Committee issued extreme social distancing measures, termed 'shielding', that were aimed at a subset of the UK population who were deemed especially vulnerable to infection. In April 2020 the British Society for Rheumatology (BSR) issued a risk stratification guide to identify patients at the highest risk of COVID-19 requiring shielding. This guidance was based on patients' age, comorbidities, and immunosuppressive therapies, including biologics that are not captured in primary care records. This meant rheumatologists needed to manually review outpatient letters to score patients' risk. The process required considerable clinician time, with shielding decisions not always transparently communicated.

Objectives: Our aim was to develop an automated shielding algorithm by text-mining outpatient letter diagnoses and medications, reducing the need for future manual review.

Methods: Rheumatology outpatient letters from Salford Royal Hospital, a large UK tertiary hospital, were retrieved between 2013-2020. The two most recent letters for each patient were extracted, created before 01.04.2020 when BSR guidance was published. Free-text diagnoses were processed using Intelligent Medical Objects software1 (Concept Tagger), which utilised interface terminology for each condition mapped to a SNOMED-CT code. We developed the Medication Concept Recognition tool (MedCore Named Entity Recognition) to retrieve medications type, dose, duration and status (active/past) at the time of the letter. The medication status was established based on the heading where they appeared (e.g. past medications, current medications), but incorporated additional information such as medication stop dates. The age, diagnosis and medication variables were then combined to output the BSR shielding score. The algorithm's performance was calculated using clinical review as the gold standard.

Results: To allow for the comparison with manual decisions, we focused on all 895 patients who were reviewed clinically. 64 patients (7.1%) had not consented for their data to be used for research as part of the national opt-out scheme. After removing duplicates, 803 patients were used to run the algorithm. 5,942 free-text diagnoses were extracted and mapped to SNOMED CT, with 13,665 free-text medications. The automated algorithm demonstrated a sensitivity of 80.3% (95% CI: 74.7, 85.2%) and specificity of 92.2% (95% CI: 89.7, 94.2%). Positive likelihood ratio was 10.3 (95% CI: 7.7, 13.7), negative likelihood ratio was 0.21 (95% CI: 0.16, 0.28), F1 score was 0.81. False positive rate was 7.9%, whilst false negative rate was 19.7%. Further evaluation of false positives/negatives revealed clinician interpretation of BSR guidance and misclassification of medications status were important contributing factors.

Conclusion: An automated algorithm for risk stratification has several advantages including reducing clinician time for manual review to allow more time for direct care, improving efficiency and transparently communicating decisions based on individual risk. With further development, it has the potential to be adapted for future public health initiatives that requires prompt automated review of hospital outpatient letters.

POS0372 GROUP-BASED TRAJECTORIES OF ADHERENCE TO ANTI-TUMOUR NECROSIS FACTOR (TNF) AGENTS: A POPULATION-BASED LONGITUDINAL STUDY

Keywords: Health Services Research, Inflammatory arthritides, bDMARD

M. De Vera[1,2], E. C. Sayre[2], N. Rebić[1,2]. [1]*University of British Columbia, Faculty of Pharmaceutical Sciences, Vancouver, Canada*; [2]*Arthritis Research Canada, Vancouver, Canada*

Background: Studies of adherence to biologic disease modifying anti-rheumatic drugs (bDMARDs), namely anti-TNFs, have been largely limited to short durations or used traditional methods that do not capture the dynamic nature of medication taking.

Objectives: Our objective was to characterize long-term trajectories of adherence to anti-TNFs and evaluate associated factors.

Methods: We linked population-based health data on all physician visits, hospital admissions, and all dispensed medications, regardless of payer in British Columbia from 01/01/1996 to 3/31/2021. We identified prescriptions for anti-TNFs (including infliximab, etanercept, adalimumab) using drug identification numbers among indicated individuals (e.g., rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis) with at ≥6 years of continuous data following initiation. We used group-based trajectory models (GBTMs), a semi-parametric application of finite mixture modeling which detects longitudinal patterns in a repeatedly measured outcome, to identify and group individuals with similar patterns of bDMARD use (i.e., 'adherence trajectory group') over 6 years of follow-up. We then evaluated factors associated with each adherence trajectory group using multinomial logistic regression.

Results: We identified 1,593 patients prescribed anti-TNFs, of which 59.7% were female with a mean age of 45.2 ± 13.2 years. Group-based trajectory modeling identified 4 distinct adherence trajectories for anti-TNFs overall (**Figure 1a**): "moderate then high adherence" (Group 1; n = 814, 51.1% of the cohort), "moderate then low adherence" (Group 2; n = 314, 19.7%), "low adherence, declining to discontinuation" (Group 3; n = 291, 18.3%), and "low then high adherence" (Group 4; n = 174, 10.9%). Specific group-based trajectories for adalimumab, etanercept, and infliximab are presented in **Figure 1b-d**. Among anti-TNFs, number of prior hospitalizations was significantly associated with initial low adherence increasing to high adherence (Group 4) compared to initial moderate adherence increasing to high adherence (Group 1)(odds ratio 1.41; 95% confidence interval: 1.19, 1.68).

Conclusion: This population-based study demonstrates the heterogeneity in real-world patterns of anti-TNFs use. Findings also suggest the inadequacy of clinical and demographic characteristics in predicting patients' adherence trajectories.

POS0373

A SYSTEMATIC LITERATURE REVIEW OF RANDOMISED CONTROLLED TRIALS EVALUATING COLCHICINE FOR CARDIOVASCULAR PREVENTION: THERE IS AN ELEPHANT IN THE ROOM

Keywords: Systematic review, Cardiovascular disease

A. Alunno[1], C. Martini[1], V. Moronti[1], J. Santilli[1], F. Carubbi[1], J. Schoones[2], C. Ferri[1]. [1]*University of L'Aquila and Internal Medicine and Nephrology Division, ASL 1 Avezzano-Sulmona-L'Aquila, San Salvatore Hospital, Department of Life, Health and Environmental Sciences, L'Aquila, Italy*; [2]*Leiden University Medical Center, Directorate of Research Policy, Leiden, Netherlands*

Background: Colchicine (COL) is widely used in rheumatology for treatment and prophylaxis of acute gout flares, other crystal diseases, and autoinflammatory diseases. In recent years evidence on the efficacy of COL for the prevention and treatment of cardiovascular diseases (CVD) has accrued. Since patients with gout and other inflammatory RMDs have a higher CV risk, COL may be a useful resource for CV prevention in rheumatology.
Objectives: To review the randomised controlled trials (RCT) investigating the use of COL for CV prevention from a rheumatology perspective.
Methods: A systematic literature review (SLR) of 7 databases was conducted following the PICO framework. Three researchers independently screened abstracts and titles and then full texts were reviewed to determine eligibility (RCTs enrolling adult subjects with or w/o history of CVD treated with COL for CV prevention). Data from eligible articles were extracted and risk of bias (RoB) was assessed with validated tools.
Results: A total of 3867 articles were retrieved and screened, 174 articles were read in full and 20 of them were eligible for inclusion. Of 19440 enrolled patients, 9655 were randomised to receive COL at a dose varying between 0.5mg/day and 2mg/day and for a period ranging between 10 days and several months (covering in part or in full the study follow-up period). Main inclusion criteria were recent acute coronary syndrome or planned cardiac surgery. In two studies, patients with stable chronic heart failure or stable coronary disease were recruited. The primary outcome varied across studies, being for example new-onset CV events, need of hospital admission, CV death, a composite index including all of these, or serum concentrations of high-sensitivity C-reactive protein. Median follow up time was largely different across studies allowing to stratify them in short term (<1 month, 2 studies), medium term (1-3 months, 7 studies), long term (4-6 months, 4 studies), very long term (>6 months, 4 studies) studies. The remaining studies assessed in-hospital events. In 7 out of 20 RCTs previous or ongoing COL use for any indication was as exclusion criterion. However, no further details about the reason for taking COL was provided. Male gender was predominant in all studies (between 65 and 96%) whereas mean age ranged between 59 and 69 years. A thorough CV history was collected at recruitment, however there was no mention to uric acid levels or a previous diagnosis of gout. Furthermore, 3 RCTs excluded patients with known autoimmune/inflammatory disease (in 2 of them ongoing immunosuppressive or steroid therapy was an additional exclusion criterion) however the other RCTs did not mention coexisting autoimmune/inflammatory diseases. The primary endpoint was met by 0/2 (0%) short term studies, 4/7 (57%) medium term studies, 2/4 (50%) long term studies and 2/4 (50%) very long-term studies. Neither of the studies assessing in-hospital events met the primary endpoint.
Conclusion: Our SLR of RCTs showed that COL may be useful in preventing new CV events/CV death in the general population when administrated for at least on month. However, the overall lack of information about coexisting gout/other inflammatory RMDs does not allow to derive meaningful data to be applied in rheumatology practice. Future RCTs should consider this aspect when defining the eligibility criteria and describing the patient cohorts since COL may be even more effective in patients that display a higher CV risk due to an underlying inflammatory disease. This may ultimately increase the likelihood to achieve the study primary endpoints.

HOW WELL DO EULAR/ASAS-EULAR AND NATIONAL TREATMENT RECOMMENDATIONS FOR PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHRITIS ALIGN? IS IT TIME FOR AN UPDATE OF NATIONAL TREATMENT RECOMMENDATIONS?

Keywords: Psoriatic arthritis, Health Services Research, Spondyloarthritis

B. Michelsen[1], M. J. Nissen[1], A. Ciurea[1], B. Moeller[1], L. Midtbøll Ørnbjerg[1], J. Zavada[1], B. Glintborg[1], A. Macdonald[1], K. Laas[1], D. Nordström[1], B. Gudbjornsson[1], F. Iannone[1], P. Hellamand[1], T. K. Kvien[1], A. M. Rodrigues[1], C. Codreanu[1], Z. Rotar[1], I. Castrejon[1], J. K. Wallman[1], J. Vencovský[1], A. G. Loft[1], M. Heddle[1], S. Vorobjov[1], A. M. Hokkanen[1], G. Gröndal[1], M. Sebastiani[1], M. G. H. Van de Sande[1], E. Kristianslund[1], M. J. Santos[1], C. Mogosan[1], M. Tomsic[1], F. Diaz-Gonzalez[1], D. DI Giuseppe[1], M. Østergaard[1], M. L. Hetland[1]. [1]*European Spondyloarthritis Research Collaboration Network (EuroSpA RCN), on behalf of ATTRA, DANBIO, ESRBTR, ROB-FIN, ICEBIO, GISEA, ARC, NOR-DMARD, Reuma.pt, RRBR, biorx.si, BIOBADASER, SRQ, SCQM and BSRBR-AS, Copenhagen, Denmark*

Background: National treatment recommendations are often used to optimize patient care and may differ from international recommendations. Although such potential heterogeneity may affect outcomes, mapping of these differences across European countries was last performed more than a decade ago for axial spondyloarthritis (axSpA) and has never been undertaken in psoriatic arthritis (PsA).[1]
Objectives: To assess differences and similarities between the EULAR and ASAS-EULAR recommendations for the treatment of patients with PsA and axSpA, respectively, versus national PsA and axSpA treatment recommendations across Europe.
Methods: Rheumatologists from 15 European countries (Czech Republic, Denmark, Estonia, Finland, Iceland, Italy, Netherlands, Norway, Portugal, Romania, Slovenia, Spain, Sweden, Switzerland, and the United Kingdom) compared the most recent national treatment recommendations for PsA and axSpA with the "EULAR recommendations for the management of PsA with pharmacological therapies: 2019 update"[2] and the "2016 update of the ASAS-EULAR recommendations for axSpA"[3], in an online survey conducted between October 2021 and April 2022. The study was an initiative of the European Spondyloarthritis Research Collaboration Network (EuroSpA RCN).[4]
Results: Three countries (Czech Republic, Netherlands, and Spain) followed all EULAR recommendations for treating patients with PsA and four countries (Czech Republic, Italy, Spain, and Switzerland) all ASAS-EULAR recommendations for axSpA. A total of 4/15 countries had no national treatment recommendations for PsA or axSpA, but had other rules or regulations to follow, for which the comparisons in this study were then performed. The Netherlands had national treatment recommendations for axSpA, but not yet for PsA, for which EULAR recommendations were followed. In six countries, the national treatment recommendations for PsA predated the 2019 EULAR recommendations and in one country the national treatment recommendations for axSpA predated the 2016 ASAS-EULAR recommendations. More differences were seen between the EULAR and the national treatment recommendations for PsA than between the ASAS-EULAR and the national treatment recommendations for axSpA (Figure 1). Discrepancies between international and national treatment recommendations included: Entry criteria for start of a biologic/targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARD) varied and were the most stringent in Romania, where DAPSA>28 for PsA and BASDAI>6 and ASDAS≥2.5 for axSpA were required for the start of a bDMARD. Regarding PsA, in two countries (Finland and Switzerland) a conventional synthetic DMARD should be initiated before a b/tsDMARD including in patients with predominantly enthesal or axial disease. In several countries, no preference for IL17 inhibitors was given for PsA patients with significant skin involvement. The positioning of Janus Kinase inhibitors (JAKi) differed across countries, e.g. in Estonia JAKi were indicated after failure of two tumor necrosis factor inhibitors and in Romania JAKi were positioned at the same level as bDMARDs. Phosphodiesterase-4 inhibitors were not in use or not reimbursed

in most countries. Analgesics were not specifically mentioned in several of the national treatment recommendations.

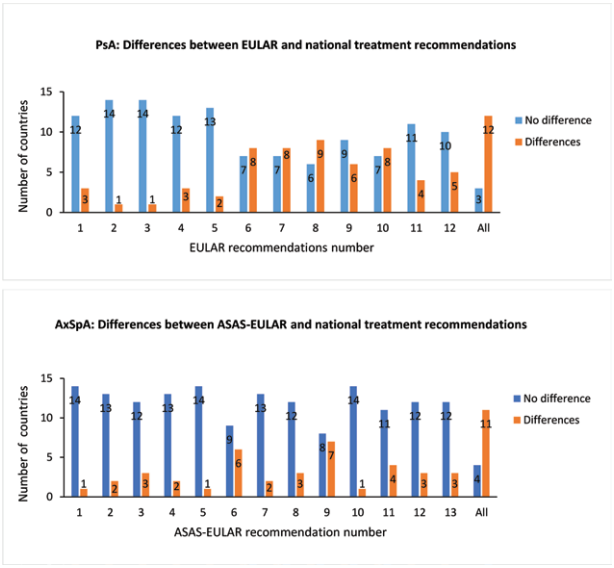

Figure 1.

Conclusion: Only a few European countries incorporated all EULAR and ASAS/EULAR treatment recommendations in their national recommendations. The potential impact of this on access to b/tsDMARD treatments needs to be further explored.

POS0375 CONVENTIONAL-DOSE VERSUS HALF-DOSE OF SULFAMETHOXAZOLE–TRIMETHOPRIM IN THE PROPHYLAXIS FOR PNEUMOCYSTIS PNEUMONIA: A 52-WEEK, RANDOMIZED, OPEN-LABEL, TWO-ARM, PARALLEL-GROUP, MULTICENTER CONTROLLED TRIAL

Keywords: Comorbidities, Safety

Y. Abe[1], A. Makiyama[1], M. Kogami[1], T. Ando[1], K. Tada[1], K. Yamaji[1], N. Tamura[1].
[1]*Juntendo University, Department of Internal Medicine and Rheumatology, Tokyo, Japan*

Background: Pneumocystis pneumonia (PCP) is a potentially life-threatening opportunistic infection. Sulfamethoxazole–trimethoprim (SMX/TMP) is effective in preventing pneumocystis pneumonia in patients with systemic rheumatic disease. However, the frequency of adverse events (AEs) due to SMX/TMP in rheumatic disease patients is higher than in the general population. The EULAR recommendation 2022 was described as "Of note, there is some evidence that reduced doses (eg, half-strength, daily) may also be effective and associated with fewer adverse events" [1].

Objectives: This study aimed to identify the optimal dose of SMX/TMP for the prophylaxis of PCP in patients with systemic rheumatic disease.

Methods: Our protocols of this study were described previously [2]. This study was a 52-week, randomized, open-label, two-arm, parallel-group, multicenter controlled trial. We compared a full-dose group (SMX/TMP at 400/80 mg daily) with a half-dose group (SMX/TMP at 200/40 mg daily). Inclusion criteria were follows: aged over 20 years; admission to our hospitals for diagnosis and/or treatment of new-onset or relapsed systemic rheumatic diseases from April 1, 2018, to March 31, 2021; current treatment with at least 0.6 mg/kg/day of oral prednisolone or equivalent doses of corticosteroids with or without any immunosuppressant; no prior treatment with SMX/TMP, pentamidine isethionate, dapsone, or atovaquone; Serum creatinine levels within the institution's normal range; Able and willing to provide written informed consent. Exclusion criteria were follows: contraindications to SMX/TMP; past history of PCP; prior treatment with biologic agents; currently uncontrollable complications; body weight below 40 kg; currently pregnant or nursing; unable to begin SMX/TMP within 14 days of starting prednisolone; unable to provide informed consent. The Mann–Whitney U test was used for non-normally distributed variables. Categorical variables were compared using Fisher's exact test. The discontinuation rate of SMP/TMP in each group was compared by plotting Kaplan–Meier survival curves and evaluating them with the log-rank test.

Results: Forty-two patients in full-dose group and 43 patients in half-dose group were analyzed. Since all patients were not developed with PCP while taking SMX/TMP, the results of the primary outcome measure of current as the number of patients in each treatment arm who were diagnosed with PCP were both 0. The discontinuation rates were 38% in full-dose group vs 16% in half-dose group (p value = 0.028).

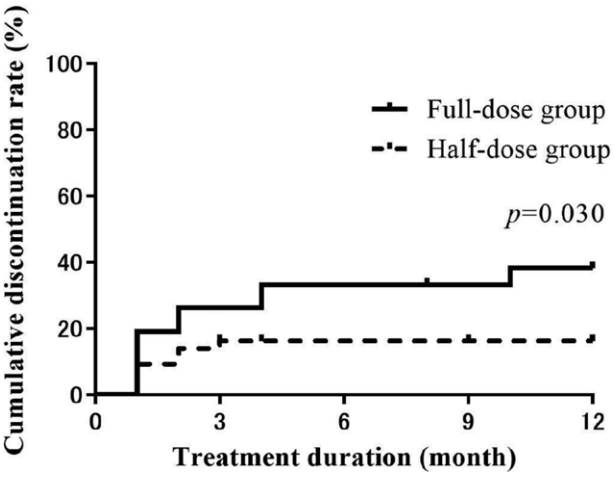

Figure 1.

Conclusion: Half-dose regimen of TMP/SMX may be better to reduce AEs than full-dose regimen in prophylaxis for PCP in patients with systemic rheumatic disease.

POS0376

DOES A MANDATORY SWITCH FROM ORIGINATOR ADALIMUMAB TO BIOSIMILAR GP2017 OR SB5 LEAD TO INCREASED HOSPITAL COSTS? A DANBIO STUDY OF >1,300 PATIENTS WITH INFLAMMATORY ARTHRITIS

Keywords: Real-world evidence, bDMARD, Health Services Research

H. Nabi[1,2], R. Ibsen[3], M. Ibsen[3], J. Kjellberg[4], M. L. Hetland[1,2], B. Glintborg[1,2].
[1]DANBIO and Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Copenhagen University Hospital Rigshospitalet, Glostrup, Denmark; *[2]Faculty of Health and Medical Sciences, University of Copenhagen, Department of Clinical medicine, Copenhagen, Denmark*; *[3]i2minds, i2minds, Aarhus, Denmark*; *[4]VIVE, The Danish Centre for Social Science Research, Copenhagen, Denmark*

Background: In 2018, Danish national guidelines dictated a mandatory switch from originator to biosimilar adalimumab based on geographical residence, i.e., GP2017 in Eastern regions and SB5 in Western regions of Denmark[1]. The switch was motivated by cost savings (approx. 34-49%). Concerns were raised if hospitals would encounter additional costs as a result of increased numbers of outpatient visits/contacts (due to patient concerns, education, treatment monitoring).

Objectives: To investigate if the switch from originator to either of the adalimumab biosimilars led to increased hospital costs, defined as all in- and outpatient contacts.

Methods: Observational cohort study with surrogate cluster (i.e. geographical) pseudo-randomization. Patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloartritis (AxSpA), who performed an adalimumab biosimilar switch were identified in the rheumatology registry, DANBIO. Hospital contacts were identified through linkage to the National Patient Registry. Hospital costs (based on DRG tariffs) were reported 9 months pre- and post-switch. In addition, the difference between pre- and postswitch costs was estimated by a generalized estimation equations (GEE) model. Medication costs of adalimumab originator and biosimilars were not available, and thus not included in the model.

Results: 1,318 patients were included (51% male, mean disease duration 16 years) and switched to either GP2017 (n=621) or SB5 (n=695). Baseline characteristics for both treatment groups stratified by diagnosis are given in **Table 1.** Monthly hospital costs 9 months pre- and post-switch were largely similar or decreased post-switch (**Figure 1**). No increase was found in the adjusted analyses (GEE); hospital costs decreased post-switch (by approximately 15%) for GP2017 switchers, especially PsA (estimate 0.83; 95% CI 0.75-0.92) and AxSpA patients (estimate 0.85;0.77-0.93), whereas no significant changes were found for SB5 switchers (**Table 1**).

Conclusion: In this study of >1,300 patient with inflammatory arthritis, we found no sign of increased healthcare hospital costs 9 months following a nationwide mandatory adalimumab originator to biosimilar switch. Our findings were strengthened by similar results regardless of whether patients switched to GP2017 or SB5.

Background: Inflammatory rheumatic diseases (IRD) are often diagnosed too late due to non-specific symptoms and the lack of specialists in rheumatology. Digital diagnostic decision support systems (DDSS) promise to accelerate diagnosis and decrease the overall healthcare burden.
Objectives: To assess the ability of an artificial intelligence (AI)-based symptom checker (Ada) and an online self-referral tool (Rheport) to diagnose inflammatory rheumatic diseases (IRD).
Methods: In a prospective, multicenter open-label controlled randomized cross-over trial patients newly presenting to a rheumatology center were randomly assigned in a 1:1 ratio to complete a symptom assessment with Ada or Rheport followed by a crossover to the other respective diagnostic decision support system (DDSS). The primary outcome was correct identification of a patient with IRD by the DDSS, defined as the presence of any IRD in the list of suggested diagnoses with Ada or a pre-specified threshold score with Rheport. Physicians' diagnosis was the gold standard.
Results: In total, 600 patients were included and 214 (36%) patients were eventually diagnosed with an IRD by a physician. Rheport showed a sensitivity of 62% and specificity of 47% for IRDs. Ada's top 1 (D1) and top 5 disease suggestions (D5) showed a sensitivity of 52% and 66% and a specificity of 68% and 54% concerning IRDs, respectively. Ada, in comparison to Rheport, was more likely to correctly identify patients with an IRD when used as the first DDSS (OR: 1.09, 95% CI: 1.01 to 1.18) however this finding was not consistent after cross-over (OR: 0.97, 95% CI: 0.90 to 1.05).
Conclusion: The diagnostic capability of both DDSS for IRDs was not promising in this high-prevalence patient population referred for subspecialty evaluation. Although the overall numbers suggest that AI-based Ada demonstrated a slightly higher specificity and sensitivity compared to the questionnaire-based Rheport, Ada was not consistently better than Rheport in correctly identifying patients with an IRD when the use sequence of the apps was taken into account. Our results indicate that, strict regulation and drastic improvement is necessary to ensure safety and effectiveness of DDSS.

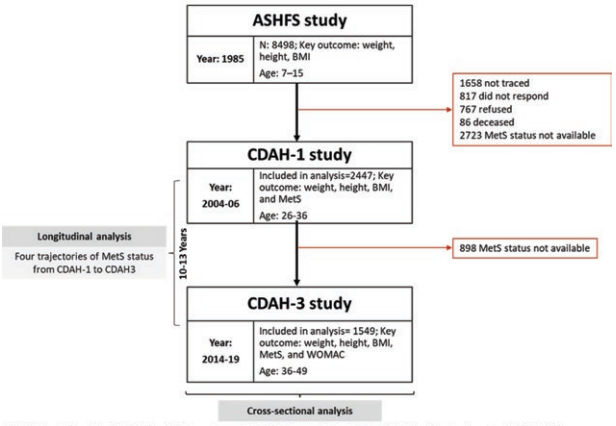
Touring the landscape of epidemiology

POS0378



ASSOCIATION BETWEEN METABOLIC SYNDROME AND KNEE PAIN IN MIDDLE-AGED ADULTS OVER 10-13 YEARS

Keywords: Pain, Osteoarthritis, Epidemiology

A. Singh[1], B. Fraser[1], A. Venn[1], L. Blizzard[1], G. Jones[1], C. Ding[1], B. Antony[1]. *[1]University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*

Background: Metabolic syndrome (MetS) is characterized by an increased waist circumference, dyslipidaemia (elevated triglycerides and reduced high-density lipoprotein (HDL)), hypertension and hyperglycaemia. MetS has been suggested as having a role in osteoarthritis (OA) pathogenesis. Few studies have described the association of MetS with joint pain in older adults with OA; however, none has described the association between MetS and knee pain in a middle-aged adult population.
Objectives: We aimed to describe the association of MetS and trajectories of MetS over 10-13 years with knee symptoms in general population-based middle-aged adults.
Methods: Fasting blood biochemistry, waist circumference and blood pressure measures collected during the Childhood Determinants of Adult Health (CDAH)-1 study (year:2004-6; n = 2447) and at 10-13 year follow-up at CDAH-3 (n = 1549) were used to define MetS using the International Diabetes Federation (IDF) definition. Knee symptoms were assessed using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) scale at the CDAH-3 follow-up (mid-adulthood). Univariable and multivariable (adjusted for age, sex, and body mass index (BMI)) zero-inflated Poisson (ZIP) regression models were used for analysis.

Figure 1: Participant flowchart

ASHFS: Australian Schools Health and Fitness Survey; BMI: body mass index; CDAH: Childhood Determinants of Adult Health; MetS: Metabolic syndrome; WOMAC: Western Ontario and McMaster University Osteoarthritis Index

Results: Overall, the prevalence of MetS increased from 8% (mean age:31.48±2.60; female:52.06%) to 13% (mean age: 44±2.90; female: 53.78%) over 10-13 years. Four MetS trajectories were identified—'No MetS' (85.01%); 'Improved MetS' (2.14%), 'Incident MetS' (8.81%), and 'Persistent MetS, (4.04%). The presence of MetS at any point, compared to no MetS, was significantly associated with worse knee symptoms at follow-up. Notably, 'Incident MetS' was most strongly associated with knee symptoms [RoM: 1.56;95%CI: 1.48,1.65] and pain [RoM:1.52;95%CI:1.37,1.70] at follow-up (**Table 1**).

POS0379 WHEN SHOULD WE USE MARGINAL STRUCTURAL MODELS FOR DRUG STUDIES IN RHEUMATOLOGY? THE EXAMPLE OF CORTICOSTEROIDS AND INFECTIONS IN RHEUMATOID ARTHRITIS

Keywords: Education, Real-world evidence, Epidemiology

A. Barbulescu[1], A. Sjölander[2], B. Delcoigne[1], J. Askling[1,3], T. Frisell[1].
[1]*Karolinska Institutet, Medicin Solna, Solna, Sweden*; [2]*Karolinska Institutet, Medical epidemiology and Biostatistics, Solna, Sweden*; [3]*Karolinska University Hospital, Rheumatology,Theme Inflammation and Ageing, Stockholm, Sweden*

Background: The use and dosing of pharmacotherapy for chronic inflammatory disease is commonly changed over time, adapting to previous treatment response, current disease activity, tolerability, and onset of adverse events. This makes evaluating the treatments difficult, as the treatment received over time becomes entangled with time-varying confounding factors, even if the initial treatment choice was randomized. To naïvely adjust for these time-varying factors in regression models have long been recognized by epidemiologists to introduce bias in most realistic settings, and marginal structural models (MSM) has been proposed as a less biased alternative. Despite this, MSMs are used very sparingly in drug studies in rheumatology.

Objectives: The objective of this work is to explain the rationale for why MSMs are recommended in the context of time-varying drug use and confounding factors, and what may go wrong if they are not used. The method will be demonstrated by comparing the incidence of serious infections between different oral glucocorticoid (GC) dose patterns over the first three years after first RA diagnosis, adjusting for time-varying confounders in MSM or through conventional regression models.

Methods: For the demonstration study, we followed 9654 recently diagnosed RA patients for three years from their first rheumatology visit in the Swedish rheumatology register (SRQ), 2007 to 2018. Follow-up was divided into 3-month periods. An average oral prednisone daily-dose was calculated for each period and categorized into "no use," "low" (≤10mg/day) and "high" (>10mg/day) doses. The MSM was implemented through sequential inverse probability of treatment weighting across time periods, accounting for demographic factors, current DAS28 and HAQ, co-medication and history of comorbidity. The incidence of serious infections (hospitalization for infection identified through the Swedish National Patient Register) was modelled by pooled logistic regression allowing separate effects for recent and past GC. We compared confounding adjustment via conventional regression versus MSM.

Results: An increased incidence of serious infections was associated with higher compared to lower doses and with more recent compared to past GC. Although in theory less biased by confounding factors, the results from MSMs were similar to those from conventional regression. Compared to no glucocorticoids, exposure to low doses during the first year added 1.9 infection cases per 100 patients (95%CI 0.9-2.9) at three years, while exposure to high doses added 4.1 (2.5-5.9) cases.

Conclusion: Our results broadly agree with previous observational studies showing a dose dependent increased risk of infection associated with (recent) use of oral glucocorticoids. Although theoretically the MSM has the potential to be less biased than ordinary regression models, the results from the two models were almost indistinguishable in this realistic example, and the implementation of the MSM led to limitations in the study design (including the categorization of exposure), and was very time consuming both in programming and computation time compared to the more widely used option. This similarity in results is not guaranteed however, and the biases that MSMs were designed to avoid should be kept in mind in all studies of drugs were the use may change over time in response to possibly confounding factors.

POS0380 PERFORMANCE OF EYE SIGN IN DIAGNOSING PATIENTS WITH NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Diagnostic Tests, Systemic lupus erythematosus, Prognostic factors

J. L. H. Shi[1]. [1]*The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China*

Background: The featured alterations of eye sign has been reported (1) in patients with neuropsychiatric systemic lupus erythematosus (NPSLE). Whether eye sign can predict NPSLE remains unknown.

Objectives: To investigate the performances of potential predictors and predictive models utilizing eye sign in classifying NPSLE.

Methods: Patients (>18 years) fulfilled the SLE diagnosis (2) were consecutively enrolled from 30 September 2016 to 30 September 2017. The diagnosis of NPSLE was evaluated and based on the consensus from rheumatologist, neurologist, radiologist and psychiatrist. Bulbar conjunctival microvascular changes in eye sign were performed and scored for all SLE patients by rheumatologist using our criteria. NP assessments were evaluating in all SLE patients by psychiatrist, including the mini-mental state examination (MMSE), self-rating anxiety scale (SAS), self-rating depression scale (SDS). Demographic and clinical data were compared between two groups and to identify potential predictors for NPSLE by using multivariable logistic regression analysis. The receiver operating characteristic (ROC) curve was plotted and the area under the curve (AUC) was used to evaluate the performance of the models in the prediction of NPSLE.

Results: 120 SLE patients were recruited (30 [24-41] years) including 30 NPSLE and 90 non-NPSLE. Totally 39 NP events were recorded in these NPSLE patients. NPSLE had higher disease activity (reflected as SLEDAI and ESR), more prevalence of positive antiphospholipid antibody (aPL), poorer NP assessments than non-NPSLE group. Eye sign examination showed NPSLE group had significantly changes of ramified loops, microangloma, wound spot, worse vascular tone and

higher total score than non-NPSLE group. In multivariable logistic analysis, model 1 showed total score of eye sign was the only predictor for NPSLE; while in model 2, except for SLEDAI, specific items of ramified loops, microangloma and wound spot were predictors for NPSLE (Table 1). Predictive model 1 utilizing total score as predictor showed AUC of 0.933 with sensitivity of 83.3%, specificity of 93.3%; model 2 including SLEDAI, ramified loops, microangloma and wound spot demonstrated an AUC of 0.960 with sensitivity of 86.7%, specificity of 95.6% (Figure 1).
Conclusion: In conclusion, ramified loops, microangioma and wound spot in eye sign were independent predictors in addition to SLEDAI for patients with NPSLE.

FACTORS ASSOCIATED WITH PREGNANCY-RELATED CONCERNS IN WOMEN WITH INFLAMMATORY RHEUMATIC DISEASES – AN ANALYSIS OF A NATIONWIDE PREGNANCY COHORT

Keywords: Patient reported outcomes, Registries, Pregnancy and reproduction

Y. Meissner[1], B. Eickhoff[1], C. Glaser[2], J. Henes[3], J. Richter[4], S. Spaethling-Mestekemper[5], C. Specker[6], R. Fischer-Betz[4], A. Strangfeld[1,7]. Background: Pregnancies in women with chronic diseases are often accompanied by concerns about possible complications during pregnancy and about the health of the child [1]. In women with inflammatory rheumatic diseases (IRD) this can lead to a reduced number of offspring [2]. To date, surveys and interviews, but no data quantifying these worries and factors influencing them, have been published.
Objectives: To investigate and quantify pregnancy concerns in women with various underlying IRD, and to identify factors that have an impact on these sorrows.
Methods: The German registry Rhekiss is a nationwide, multicentre, web-based longitudinal cohort study, which was initiated in 2015 to investigate pregnancies and related issues in women with various IRD. Women can either be enrolled if they are planning a pregnancy (cohort 1) or if they are already pregnant prior to gestational week 20 (cohort 2). Rheumatologist- and patient-reported data are captured at regular, pre-defined follow-up visits. For this analysis, women who had answered the question regarding their concerns about their pregnancy and child's health due to the IRD were included. Categorical answers as well as patient characteristics were analysed descriptively. The impact of different factors associated with patients' anxieties was estimated by multivariable ordinal logistic regression using the proportional odds model and combining the two cohorts. Missing values were replaced by single imputation.
Results: Between 09/2015 and 10/2022, a total of 2,240 patients were enrolled, including 708 in cohort 1 and 1,532 in cohort 2. Out of those, n=455 and n=784, respectively, were eligible for the analysis. Women of both cohorts were on average 32-34 years old and had a mean disease duration of 8-9 years (table 1). A total of 31% of women in cohort 1 and 22% in cohort 2 stated that they are concerned "a lot" (figure 1). Answers of patients varied between the IRD diagnoses. A significant association with higher levels of worry was found in patients with a greater disease impact, measured by the patient-reported RAID score, an established seven-item composite index for assessing the disease burden in rheumatic diseases [3, 4], (Odds ratio 1.35 [95% confidence interval 1.27; 1.43]). A similar association was found with nulligravidity (1.29 [1.01; 1.65]) and with recent treatment changes (1.26 [1.00; 1.60]). Higher age was related with a lower level of concern (0.96 [0.94; 0.99]). No significant relationship was found for the number of underlying comorbidities (1.13 [0.98; 1.29]). Furthermore, patients who were already pregnant at enrolment were less worried than patients planning a pregnancy (0.74 [0.60; 0.93]).
Conclusion: At least one in five women with IRD is "very concerned" about pregnancy and infant health due to the underlying rheumatic disease. A higher RAID score, nulligravidity, treatment changes and younger age were associated with higher levels of concern. Therefore, patient concerns should be an essential part of individual counselling for women with IRD who want to become pregnant or are already pregnant.

POS0383 **FATIGUE IS FREQUENT IN INFLAMMATORY RHEUMATIC DISEASES: DESCRIPTIVE DATA FROM THE NATIONAL DATABASE OF THE GERMAN COLLABORATIVE ARTHRITIS CENTRES**

Keywords: Health Services Research, Quality of life, Epidemiology

C. Duesing[1,2], K. Thiele[3], K. Albrecht[3], S. Wassenberg[4], J. Callhoff[3,5], J. Richter[1,2]. *[1]University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Department of Rheumatology, Duesseldorf, Germany*; *[2]University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Hiller Research Center, Duesseldorf, Germany*; *[3]German Rheumatism Research Center Berlin (DRFZ), Epidemiology and Health Services Research, Berlin, Germany*; *[4]Rheumazentrum Ratingen, Rheumatology community practice, Ratingen, Germany*; *[5]Charité – Universitätsmedizin Berlin, Institute for Social Medicine, Epidemiology and Health Economics, Berlin, Germany*

Background: Fatigue is a major symptom in patients with inflammatory rheumatic diseases (IRD) that often severely affects quality of life and participation. While improved treatment strategies have reduced radiologic progression, fatigue often persists [1].
Objectives: To explore the frequency of fatigue and its relationship to physician- and other patient-reported outcomes in patients with IRD.

Methods: In 2020, 7637 patients with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), psoriatic arthritis (PsA) or systemic lupus erythematosus (SLE) reported fatigue in the National Database of the German Collaborative Arthritis Centres [2]. Fatigue, pain, physician (PhGl) and patient global (PtGl) disease activity, PtGl health status (all on numeric rating scales, 0-10) were categorized into three groups (mild (0-3), moderate (4-6), severe [7-10]. Depressive symptoms assessed by WHO-5 well-being (0-100) were categorized to no (>50), mild (29-50) and moderate to severe (<29). The frequency and severity of fatigue was compared in terms of the rheumatic diseases, age, sex, disease duration and sociodemographics. Violin plots show the relationship between fatigue and the other outcomes.

Results: A total of 4900 patients (84%) reported fatigue. Higher mean values were observed in patients with axSpA (4.3) compared to PsA (3.9), RA (3.8) and SLE (3.7) (table 1). Female and elderly patients, singles, and patients with little education years reported more fatigue. No difference in fatigue severity was found between patients with initial diagnosis and those with long-term disease. More fatigue was related to a poorer global health status, higher PhGl and PtGl disease activity, higher levels of pain, and more severe depressive symptoms (figure 1). Patients with concomitant fibromyalgia or depression reported worse fatigue compared to those with no or other comorbidities.

Table 1. Patient characteristics

	RA	axSpA	PsA	SLE
Number of cases	4863	777	1223	774
Female (%)	75	35	52	88

PtGl disease activity (mean±SD)	3.5±2.4	3.8±2.4	3.6±2.4	2.7±2.4
PhGl disease activity (mean±SD)	1.5±1.7	1.8±1.9	1.7±1.8	1.5±1.5
WHO-5 (mean±SD)	54±27	50±25	55±27	54±27

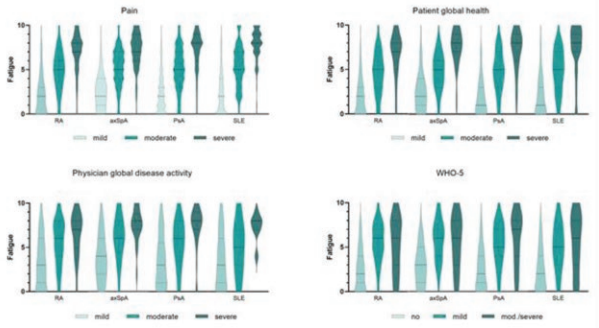

Figure 1. Relationship between fatigue and pain, global health, disease activity and depressive symptoms

Conclusion: Fatigue is a frequent symptom across various inflammatory rheumatic diseases. A strong relationship to global health, disease activity, pain and depressive symptoms needs to be considered in the (individual) therapeutic management of the diseases that relies on a shared decision making.

POS0384

THE PREVALENCE AND INCIDENCE OF PSORIASIS AND PSORIATIC ARTHRITIS IN ENGLAND FROM 2009-2019: AN OBSERVATIONAL STUDY USING PRIMARY CARE DATA

Keywords: Psoriatic arthritis, Epidemiology, Real-world evidence

A. Vivekanantham[1], E. Burn[1], M. Pineda-Moncusí[1], S. Khalid[1], D. Prieto-Alhambra[1], L. Coates[1]. [1]*University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: Psoriasis (PsO) and psoriatic arthritis (PsA) can greatly impact quality of life and result in substantial personal and societal costs. Complete and up to date data on the prevalence and incidence of these conditions and whether these change over time and vary by age is important for healthcare service planning so that specialist care and funding can be appropriately allocated.

Objectives: To determine the prevalence and incidence of PsO and PsA in males and females from 2009-2019 across all age groups in England.

Methods: We used Clinical Practice Research Datalink AURUM, a primary care electronic health record database, including 20% of the English population. The codes used to identify patients with PsO and PsA were selected by rheumatologists and dermatologists and cross-checked with published code lists from other studies to ensure inclusion of all relevant codes. All included patients must have data for at least 1 year before their diagnosis. The annual incidence and point prevalence were calculated from 2009-2019 and stratified by age/sex. The study period ended in 2019 to avoid COVID-19 pandemic affecting results.

Results: The prevalence of PsO and PsA in males and females increased annually, peaking in 2019 (PsO males 2.41% [95% confidence interval (CI) 2.40, 2.42]; PsO females 2.60% [95% CI 2.59-2.61]; PsA males 0.20% [95% CI 0.20-0.20]; PsA females 0.21% [95% CI 0.21- 0.22]), as illustrated in Table 1. In 2019, the prevalence of PsO and PsA was highest in the over 65 years age group; PsO 4.25% [95% CI 4.22-4.28] and PsA 0.38% [95% CI 0.37-0.38]. The annual incidence (per 100,000 person years) of PsO has gradually decreased in males (from 168 (164-171) in 2009 to 148 (145-151) in 2019) but in females it has been stable with a slight annual decrease (from 180 (177-184) in 2009 to 173 (170-176) in 2019). The annual incidence for PsA has increased in both males and females (13 (12-14) in 2009 and 15 (14-16) in 2019 for males and 12 (11-13) in 2009 and 18 (17-19) in 2019 for females).

Table 1. Prevalence of PsO and PsA from 2009-2019 in England

POS0385 SQUASH VERSUS ACTIHEART-MEASURED PHYSICAL ACTIVITY IN THE MIDDLE-AGED GENERAL POPULATION: THE NEO STUDY

Keywords: Patient reported outcomes, Lifestyles, Epidemiology

S. Terpstra[1,2], L. Hoogervorst[3], J. Van de Velde[2], R. De Mutsert[2], L. A. Van de Stadt[1], F. Rosendaal[2], M. Kloppenburg[1,2]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Leiden University Medical Center, Clinical epidemiology, Leiden, Netherlands*; [3]*Leiden University Medical Center (LUMC), Orthopedics, Leiden, Netherlands*

Background: Adequate physical activity levels have been associated with wide-ranging beneficial health outcomes. It is therefore important to adequately measure physical activity. This is often done by the SQUASH (Short Questionnaire to Assess Health-enhancing physical activity), a patient-assessed instrument. However, this is a subjective method of which data on validity in large, middle-aged population groups are lacking.

Objectives: To assess 1) the construct validity of the SQUASH, and 2) participant characteristics associated with difference between SQUASH and ActiHeart outcome.

Methods: Cross-sectional data from the population-based Netherlands Epidemiology of Obesity (NEO) study were used, of which participants were 45 to 65 years of age. Physical activity (in Metabolic Equivalent of Task (MET) hours) was assessed using the SQUASH on one week and in a random subset using the ActiHeart accelerometer for approximately 96 hours continuously, extrapolated to one week. Convergent validity of the SQUASH was assessed by calculating Spearman's rank correlation between the SQUASH and the ActiHeart. Extreme group validity was assessed based on the difference in SQUASH activity between 1) 25% of participants with highest and lowest activity according to ActiHeart 2) participants with and without any comorbidity, and 3) participants with BMI< 25 kg/m2 versus participants with BMI> 30 kg/m2. Discriminative validity was assessed by a lack of Spearman's rank correlation between SQUASH physical activity and participant height (correlation <0.10). Participant characteristics associated with the difference between SQUASH and ActiHeart outcome were assessed by comparing quintiles of SQUASH minus ActiHeart outcome with a reference quintile (=quintile with lowest difference between SQUASH and ActiHeart).

Results: SQUASH data were available for 6,550 participants (mean age 56 years, 56% women, 24% having any comorbidity) of which 875 had ActiHeart data. Median (interquartile range) physical activity was 118 (76;154) MET hours/week according to the SQUASH and 75 (58;99) according to the ActiHeart (mean difference 47 (standard deviation 63)). The Bland-Altman plot of the difference between SQUASH and ActiHeart measurement per patient is shown in figure 1. Convergent validity was weak (ρ = 0.20, p < 0.01). Participants with the 25% highest ActiHeart scores had 38 MET hours/week more SQUASH activity (95% confidence interval (95%CI) 27;50) than the lowest 25%. Participants with any comorbidity had -13 (95%CI -17;-9) MET hours per week of SQUASH compared with those without any comorbidity, participants with BMI > 30 had -13 (-17;-9) MET hours per week compared with BMI< 25 kg/m2. Discriminative validity was present (ρ = 0.01, p = 0.41). Cut-offs of the quintiles of participants according to SQUASH minus ActiHeart physical activity (range: -61 to 411) were: -6, 27, 61 and 91 MET hours/week (reference quintile: -6;27). Men were overrepresented in the lowest quintile of SQUASH minus ActiHeart activity (-161 to 6 MET hours/week, odds ratio (OR) for being male compared with the reference quintile: 2.35 (95%CI 1.52;3.64)). Men were also overrepresented in the second-highest quintile (61 to 91 MET hours/week, OR 1.89 (95%CI 1.23;2.94)) and highest quintile (91 to 411 MET hours/week, OR 2.47 (95%CI 1.61;3.84)).

Conclusion: In this study to investigate the convergent validity of the SQUASH, there were differences between MET hours assessed by SQUASH and ActiHeart, with weak correlation between these instruments; SQUASH activity was on average higher than ActiHeart. However, discriminative and extreme group validity of the SQUASH was present. Men appeared more prone for a difference between SQUASH and ActiHeart outcome than women. These results indicate that construct validity of the SQUASH is sub ideal, although an alternative explanation could be that SQUASH and ActiHeart measure different domains or have different underlying methods. This underscores the importance of further study on adequate physical activity measurement.

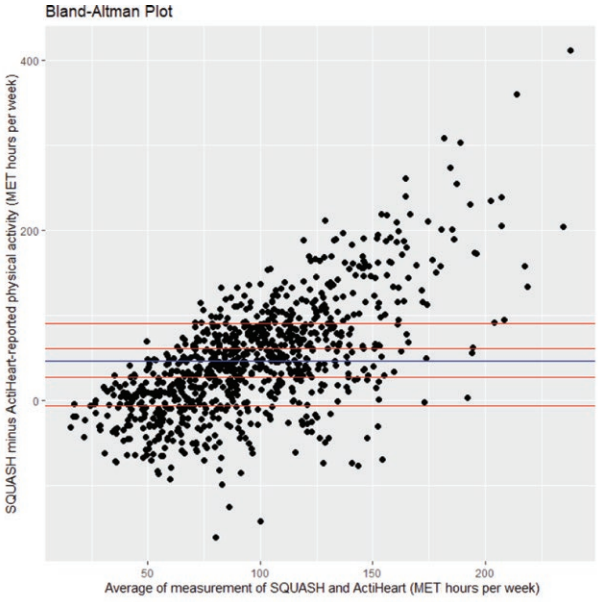

Figure 1. Bland Altman plot of SQUASH and ActiHeart physical activity (n=875). The blue line signifies the mean difference between these two instruments, and the red lines signify quintiles of difference between SQUASH and Actiheart.

POS0386 IMMUNE CHECKPOINT INHIBITORS: FAIL TO KEEP A CHECK ON AUTOIMMUNE DISEASES

Keywords: Epidemiology, Malignancy, Targeted synthetic drugs

D. Desai[1], P. Khandwala[2], I. Tan[2]. [1]*Einstein Medical Center Philadelphia, Hospice and Palliative Medicine, Philadelphia, United States of America*; [2]*Einstein Medical Center Philadelphia, Rheumatology, Philadelphia, United States of America*

Background: The introduction of immune checkpoint inhibitors (ICIs) has revolutionized cancer treatment. ICIs augment antitumor activity by blocking the binding of checkpoint proteins with their partner proteins. This inhibition is a negative regulator on T cell cytotoxicity causing the unrestraint killing of tumor cells, a loss of self-tolerance, and increased risk of inducing autoimmunity.[1][1]

Objectives: The study was undertaken to establish correlation between the use of ICIs and autoimmune conditions (ACs), and to study trends in incidence and prevalence of ACs in patients treated with ICIs.

Methods: TrinetX, a global federated research network that provides a dataset of electronic medical records from different healthcare organizations (HCOs) was utilized. Initial query was made to isolate patients who had a diagnosis of "Neoplasm" (International Classification of Diseases, 10th version (ICD-10) Code C00 - D49). Two cohorts were made, on basis of ICIs use. Propensity score matching was carried out to match age, race and gender. Compare outcome analytic function was utilized to map the co-relation with ACs. ACs included were Systemic Connective Tissue Disorders (ICD-10:M30-M36), Rheumatoid Arthritis (ICD-10:M05, M06), Arthropathic Psoriasis (ICD10 L40.5). 9 FDA-approved checkpoint inhibitors were included in our study: Atezolizumab, Avelumab, Cemiplimab, Dostarlimab, Durvalumab, Ipilimumab, Nivolumab, Pembrolizumab, and Relatlimab.[2]

Results: A total of 12,009,334 patients had a diagnosis of neoplasm out of which 72,865 (0.61%) patients were taking ICIs. Patients in ICIs group were older as compared to patients in non-ICIs group (68 ±12.6 years vs 62.7±17.7 years). Males were predominant in ICIs group (58% vs 42%) while they were in minority in the non ICIs group (43% vs 57%). Caucasians were the predominant race followed by unknown race and then African Americans (76% vs 13% vs 9% in

ICI group, and 63% vs 25% vs 10% in non-ICI group). 5.16% of patients in the ICIs group had ACs while only 4.17% of patients in non ICIs group had ACs (p<0.0001). The hazard ratio (HR) of having ACs was higher in ICIs group as compared to non ICIs group (HR = 1.96, 95% confidence interval (CI), 1.898-2.024, p<0.0001). After propensity score matching, both groups had 72,865 patients. 5.16% patients in the ICIs group had ACs, while only 4.46% of patients in the non ICIs group had ACs. HR was 1.925 (95% CI, 1.831-2.025, p<0.0001). As shown in the graph below, the incidence of autoimmune conditions increased from 0.79% in 2015 to 2.16% in 2021 in ICIs group. Similarly, prevalence also increased from 2.97% in 2015 to 8.06% in 2021.

Conclusion: Although ICIs transformed the cancer management landscape, it is important to be aware of its effects on autoimmune disorders. Incidence and prevalence of ACs have increased in patients with neoplasm treated with ICI over the years. It can also be seen that HR of having outcome of ACs is higher in ICI group. There is a need for a prospective study to correlate the causality of development of AC with use of ICI.

POS0387

IMPACT OF RHEUMATIC DISEASE SUB-TYPES ON MATERNAL AND NEONATAL OUTCOMES: A POPULATION LEVEL ANALYSIS

Keywords: Pregnancy and reproduction, Rheumatoid arthritis, Systemic lupus erythematosus

S. Keeling[1], A. Savu[2], P. Kaul[2]. [1]*University of Alberta, Medicine, Edmonton, Canada*; [2]*Canadian Vigour Centre, University of Alberta, Edmonton, Canada*

Background: There are limited data on the differing effect of rheumatic diseases (RD), including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA) and systemic lupus erythematosus (SLE), on maternal and neonatal outcomes.

Objectives: We evaluated the impact of four rheumatic diseases (RA, SpA, PsA and SLE) on maternal and neonatal outcomes at a population level. We also examined medication use during pregnancy across these four groups.

Methods: A contemporary pregnancy cohort of 452,273 singleton live birth events of 307,590 women was assembled for the province of Alberta, Canada. We identified 5 groups: (1) no rheumatic disease (no RD, n=449,933 pregnancies), (2) RA (n=1214), (3) PsA (n=177), (4) SpA (n=445) and SLE (n=504). We compared maternal and neonatal outcomes, comorbidity burden, and medication use among the 5 groups.

Results: Across all groups, mothers were predominantly ethnically Caucasian (>90%), residing in urban residences (>75%), and multiparous (> 58%). Maternal comorbidities including renal, vascular diseases and hypertension were most prevalent in SLE mothers. Rates of preclampsia, caesarean section and induction were highest in mothers with SLE. Pregnant women with SLE were the most likely to have preterm delivery (18.3%) and NICU admission at birth (21.8%) followed by RA (preterm delivery 11.3%, NICU admission at birth 12.8%) compared to those with PsA, SpA or no RD (Figure 1). Prednisone use for at least 28 days or any duration during pregnancy was highest amongst mothers with SLE (8.9%) followed by RA (7%) (Table 1). Antimalarial use for at least 28 days or any duration during pregnancy was highest in SLE mothers (32.7%) followed by RA mothers (18.5%) while biologic medications were used mostly in mothers with RA (10.5%).

Conclusion: Women with SLE had the worst maternal and neonatal outcomes and highest medication use followed by RA, with varying degrees for those with PsA and SpA compared to controls. The extent to which these outcomes are related to differing medication use, such as higher rates of prednisone and lower rates of antimalarials in mothers with SLE, and lower use of biologics in RA mothers, requires further exploration.

Osteoporosis

POS0388

IMPACT OF GLUCOCORTICOIDS AND ANTI-OSTEOPOROTIC TREATMENT ON BONE HEALTH IN PATIENTS WITH INFLAMMATORY RHEUMATIC MUSCULOSKELETAL DISEASES (IRMD): A LONGITUDINAL STUDY

Keywords: Real-world evidence, Osteoporosis, Inflammatory arthritides

G. Adami[1], A. Fassio[1], C. Benini[1], O. Viapiana[1], D. Gatti[1], D. Bertelle[1], M. Rossini[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*

Background: The negative effects of glucocorticoids (GCs) on the bone depend on dose and treatment duration. However, it is unclear whether a safe dose exists, especially for patients with inflammatory rheumatic musculoskeletal diseases (iRMDs).

Objectives: The primary objective of the present study was to determine, in a real-life setting, the risk of fragility fracture associated with the dose of glucocorticoids in iRMD.

Methods: We conducted a longitudinal cohort study on women with iRMD. Data were extracted from the DeFRA database (2012-2020). DeFRA is a fracture risk assessment tool similar to FRAX. Bone mineral density and fractures were assessed prospectively and compared to a matched cohort (propensity score matching, PSM with age, T-score and the % 10-year fracture risk estimated with DeFRA fracture risk assessment tool). Kaplan-Meier curves with log-rank test were made for iRMD (stratified for glucocorticoid use and dosage) and matched cohort respectively.
Results: 884 women with iRMD and 1,766 controls (age, T-score, and 10-year fracture risk matched) were included in the study and followed for up to 6 years. BMD levels decreased significantly in all GCs users not receiving anti-osteoporosis treatment (-4.26% p 0.0011, -4.23% p 0.0422, -2.66% p 0.0006 for ≥5mg/day, 2.5mg to 5mg and 0 to 2.5mg/day of prednisolone, respectively). As regards patients receiving anti-osteoporosis medications, BMD levels decreased significantly only in patients receiving ≥5mg/day of pred eq (-3.01%, p 0.0012), whereas in patients receiving 2.5mg to 5mg and 0 to 2.5mg/day, concomitantly treated with anti-osteoporotic drugs, BMD did not decrease significantly (+3.10% p NS, +1.12% p NS, respectively). **figure 1A**. Fracture incidence was greater in patients with iRMD compared to controls but only GC doses above 5mg/day were associated with significantly higher risk of fracture **figure 1B**. 21, 12 and 29 fractures were reported for patients receiving ≥5mg/day, 2.5mg to 5mg and 0 to 2.5mg/day respectively, corresponding to a crude fracture rate of 4.8 fractures per 100 person-year, 2.8 fractures per 100 person-year and 2.5 fractures per 100 person-year respectively. 103 fractures were registered in the PSM cohort (crude fracture rate of 2.2 fractures per 100 person-year). We also explored the effects of GC on serum C-terminal telopeptide of type 1 collagen (CTX) in a subset of patients with available data (n=335). We found that the proportion of patients with low bone turnover (<400ng/L) was numerically greater in patients receiving ≥5mg/day compared to other doses and controls (p NS)
Conclusion: GC doses as low as 2.5mg/day were associated with BMD loss in iRMD but this effect was preventable. BMD loss in patients taking ≥5 mg/day was not totally prevented by anti-osteoporotic medications currently used in clinical practice, resulting in higher risk of fracture.

POS0389

THE PREVALENCE OF GLUCOCORTICOID PRESCRIPTIONS IN ICELAND OVER 17 YEARS AND ACTIVE OSTEOPOROSIS PREVENTION FOR LONG-TERM USERS

Keywords: Osteoporosis, Quality of care, Registries

H. H. Bjornsdottir[1], O. Einarsson[2], G. Gröndal[3,4], B. Gudbjornsson[4,5].
[1]Landspitali University Hospital, Department of Medicine, Reykjavik, Iceland; *[2]Icelandic Directorate of Health,The Icelandic Prescription Medicines Register, Reykjavik, Iceland*; *[3]Landspitali University Hospital, Department of Rheumatology, Reykjavik, Iceland*; *[4]Landspitali University Hospital, Faculty of Medicine, Reykjavik, Iceland*; *[5]Landspitali University Hospital, Centre for Rheumatology Research, Reykjavik, Iceland*

Background: Glucocorticoid steroids (GCS) are frequently prescribed, and side effects are well-known, such as corticosteroid-induced osteoporosis (CIOP).
Objectives: To estimate the nationwide trend in the prevalence of glucocorticoid prescription over 17 years and to elucidate the proportion of patients on long-term GCS therapy who receive active bone protective therapy.
Methods: This retrospective observational registry study extended over 17 years (2003-2020). Data were retrieved from the Icelandic Prescription Medicine Register (IPMR) on all delivered GCS (ACT: H02AB) for oral use. Long-term users were defined as those who annually received ≥90 defined daily doses of GCS. We defined an individual on active bone protective therapy if, within ±45 days of receiving a prescription for GCS, they also filled a prescription of a bone protective agent.
Results: Annually, 3.8% of the Icelandic population received oral GCS, from 3.3% in 2006 to 4.3% in 2017. There was a significant increase in prescriptions over the study period (p<0.00001). Prednisolone was most frequently prescribed (Figure 1). Females dispatched GCS prescriptions more often than males (55.8%). Males and females reached their peak prevalence between the ages of 60 and 70. Prescription rates of GCS were stable for all age groups except for the 90+ age group, where prescription rates increased significantly (p<0.00001). Family medicine practitioners prescribed the highest amount of GCS, followed by physicians in specialist training, rheumatologists, oncologists, and internists (Table I). Of those who received prescriptions of GCS, 12.2% - 18.1% were classified as long-term users, representing 0.5% - 0.7% of the population. In the first years of the study there was an increase in the percentage of patients on long-term GCS therapy who received active bone protective therapy and the percentage remained stable around 22.5% until 2013. Since then, a declining number of patients have been receiving bone-protective therapy. Only 13.0% of chronic users received bone protective therapy in 2020.
Conclusion: Use of GCS has increased during the last two decades despite improvements in biological therapies for inflammatory disorders. The percentage of long-term users has remained stable. Meanwhile, the use of bone-protective therapy is declining. Thus, improvements in prophylaxis for corticosteroid-induced osteoporosis are urgently needed for patients who require long-term treatment with GCS.

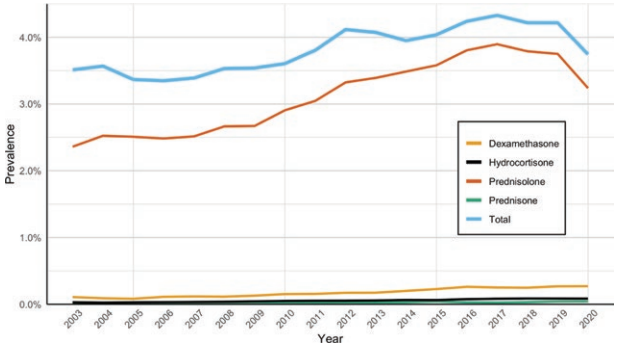

Figure 1. The prevalence of prescriptions of different oral GCS medications per year as well as the total prescription prevalence of all GCS in Iceland from 2003 to 2020 (light blue line).

POS0390 PRIOR ANTIRESORPTIVE TREATMENT REDUCES LUMBAR SPINE BMD RESPONSE TO ROMOSOZUMAB IN CAUCASIAN POSTMENOPAUSAL WOMEN WITH SEVERE OSTEOPOROSIS

Keywords: Osteoporosis, Real-world evidence, Bone diseases

P. Ravji[1], M. Mcrorie[2], K. Berg[2], S. Ralston[1,2], B. Hauser[1,2]. *[1]NHS Lothian, Rheumatology Department, Edinburgh, United Kingdom*; *[2]Centre for Genomic and Experimental Medicine, Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom*

Background: Romosozumab, a monoclonal antibody against sclerostin, is a newly licensed dual-acting osteoporosis (OP) treatment for patients at very high fracture risk. Most patients included in the pivotal trials (ARCH[1] and FRAME [2]) were treatment naïve. However, many patients in day-to-day clinical practice who are eligible for anabolic therapy have been pre-treated with antiresorptive medications.
Objectives: Our aim was to analyse bone mineral density (BMD) treatment response to Romosozumab in patients with severe osteoporosis who are attending the osteoporosis clinic. A further objective was to analyse whether pre-treatment with antiresorptive osteoporosis medication (OPTx) influences the BMD treatment response at any BMD site.
Methods: Retrospective single-centre analysis of patients who have completed a 12-month course of monthly sc Romosozumab treatment (210mg) between February 2021 and November 2022. Local guidance recommends the use of Romosozumab in patients with severe spinal OP with at least two moderate vertebral fractures and OP at the hip as defined by DXA. BMD assessment was usually performed with DXA at baseline and after treatment completion.
Results: Out of 56 patients offered Romosozumab, 52 agreed to start treatment and 47 patients completed the full course of therapy. All patients were postmenopausal women with an average age of 73.1± 9.7 years and BMI of 24.4 ±7.1 kg/m^2. The baseline 10% major osteoporotic fracture risk as calculated by FRAX was 32.2 ±13.5. Mean baseline BMD lumbar spine (LS) T-score was -3.8 ±1.0 and total hip (TH) T-score was -3.0 ±0.7. The vast majority (95%) of patients had a history of vertebral fractures and half of the patients (50%) had a history of an additional non-vertebral fracture. 31 (66%) patients were treatment naïve or had recent antiresorptive treatment for less than 6 months, the remainder of patients received recently mostly oral or parenteral bisphosphonate treatment. After 12 months the overall mean % change BMD at the LS was 14.1 ±9.4 and 5.7 ± 5.6 at the TH site. Spine BMD increase was significantly higher in treatment naïve patients than in patients who had previous OPTx over 6 months (17.3 ±9.0 vs 7.6 ±6.9; p<0.01). Prior OPTx however did not seem to influence TH BMD response to Romosozumab (5.1 ±6.3 vs 6.1 ±5.1 in OPTxnaive patients) as shown in Figure1. Age (*r =-.37 p <.05; Spearman's rho)* and prior OPTx (r= -.49 *p<0.01)* are inversely related to LS BMD increase. Multivariate regression analysis including age, baseline spine BMD and prior OPTx identified prior OPTx as independent predictor (beta$_{St}$= 0.422; p<0.05) of spine BMD response to Romosozumab treatment.
Conclusion: The overall BMD response at LS and TH site after 12 months Romosozumab treatment in real world is similar to that reported in the ARCH trial. Pre-treatment with antiresorptive treatment seems to significantly dampen the BMD response at the lumbar spine, which highlights the importance of the choice of OPTx sequence.

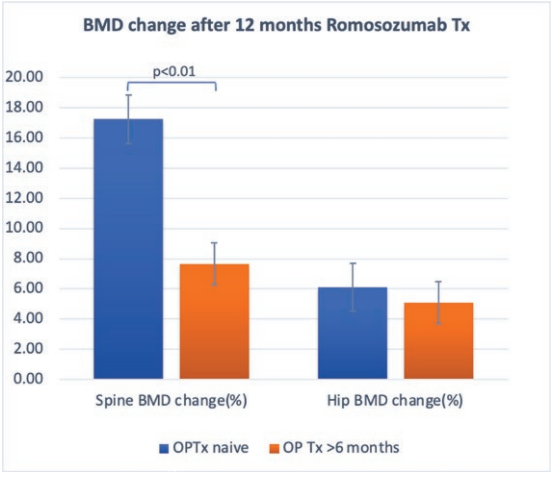

Figure 1. Bone mineral density (BMD) change (%) after 1 year treatment with Romosozumab; OP Tx = treatment with antiresorptive osteoporosis medication; OPTx naïve= no previous osteoporosis treatment or treatment for less than 6 months

POS0391 INCREASED RISK OF OSTEOPOROSIS AND HEAD OF FEMUR FRACTURES IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER - A LARGE RETROSPECTIVE COHORT STUDY

Keywords: Epidemiology, Osteoporosis

Y. S. Patt[1], N. Ben-Shabat[1], L. Fisher[1], K. Sharif[1,2], S. Lassman[1], A. Watad[1,3], H. Amital[1]. *[1]Sheba Medical Center,Tel-Hashomer, Department of Internal Medicine B & Zabludowicz Center for Autoimmune Diseases, Ramat Gan, Israel*; *[2]Sheba Medical Center,Tel-Hashomer, Department of Gastroenterology, Ramat Gan, Israel*; *[3]Leeds Institute of Molecular Medicine, University of Leeds, Chapel Allerton Hospital, Leeds, UK, Section of Musculoskeletal Disease, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom*

Background: Chronic inflammatory conditions are characterized by an inflammatory milieu and increased exposure to glucocorticoids both resulting in increased risk of osteoporosis and subsequently bone fractures. Familial-Mediterranean-Fever (FMF) is a prototypical autoinflammatory disorder not treated with steroids. FMF association with osteoporosis and risk for femur fractures is not well evaluated.
Objectives: To evaluate the incidence of osteoporosis and head of femur fractures in FMF patients compared to the general population.
Methods: A retrospective cohort study using the electronic database of Clalit Health Services (CHS), the largest health organization in Israel. All FMF patients diagnosed between 2000-2016 were included with age-, sex- matched controls in 1:1 ratio. Follow-up continued until the first diagnosis of osteoporosis or femur fracture. The incidence of these conditions was compared between the groups using univariate and multivariate models adjusting for cardiovascular risk-factors.
Results: 9,769 FMF patients were followed for a median period of 12.5 years. 304 FMF patients were diagnosed with osteoporosis compared to 191 controls, resulting in an incidence rate (per 10,000 persons-years) of 28.8 (95%CI 15.7-32.5), and 17.8 (95%CI 15.4-20.6) respectively, and a crude HR of 1.62 (95% CI 1.35-1.93;p<0.001). Patients were diagnosed with osteoporosis at a considerably younger age than controls (60.1±12.4 vs 62.5±11.0 years; p=0.028).

Table 1. Incidence of osteoporosis and head of femur fracture in FMF patients compared to controls, time to event analysis.

Group	Variables	FMF	Controls
Osteoporosis	Events, n	304	191
	Age at osteoporosis, mean ±SD	60.1 ± 12.4*	62.5 ±11.0
	Follow-up time, person-years	105,480	107,068
	Follow-up time, median (IQR)	12.5 (6.8-14.6)	12.6 (7.1-14.7)
	Incidence rate per 10,000 person-years, (95%CI)	28.8 (25.7 to 32.5)	17.8 (15.4 to 20.6)
	Unadjusted HR (95%CI)	1.62 (1.35 to 1.93) **	reference
	Age-and-sex adjusted HR (95%CI)	1.80 (1.50 to 2.15) **	reference
	Multivariate¶ HR (95%CI)	1.73 (1.43 to 2.10) **	reference
Head of Femur Fracture	Events, n	56	35
	Age at femur fractures, mean ±SD	69.8 ± 13.1	65.1 ±19.9
	Follow-up time, person-years	105,718	105,813
	Follow-up time, median (IQR)	12.5 (7.2-14.4)	12.5 (7.2-14.4)
	Incidence rate per 10,000 person-years, (95%CI)	5.3 (4.0 to 6.9)	3.3 (2.3 to 4.6)
	Unadjusted HR (95%CI)	1.60 (1.05 to 2.44) *	reference
	Age-and-sex adjusted HR (95%CI)	1.61 (1.06 to 2.46) *	reference
	Multivariate¶ HR (95%CI)	1.58 (1.02 to 2.44) *	reference

¶ Adjusted for age, sex, ethnicity, socioeconomic status, obesity, smoking, diabetes, alcohol abuse, lupus, rheumatoid arthritis, sarcoidosis, thyroid dysfunction, parathyroid dysfunction, chronic renal failure, and amyloidosis.* P-value< 0.05. ** P-value<0.001.Abbreviations: CI, confidence interval, HR, hazard ratio, IQR, interquartile-range; FMF, familial-Mediterranean-fever.

Regarding femur fractures, 56 FMF patients were diagnosed with the condition compared to 35 controls, resulting in an incidence rate (per 10,000 persons-years) of 5.3 (95%CI 4.0-6.9), and 3.3 (95%CI 2.3-4.6) respectively, and a crude HR of 1.60 (95% CI 1.05 to 2.44;p<0.05). Predictors of osteoporosis or femur fractures among FMF patients included older age, Arab ethnicity, as well as North African origin. In contrast, obesity was considered a protective factor, while colchicine treatment did not significantly affect the risk of these outcomes.

Conclusion: FMF patients are at increased risk for osteoporosis and consequently femur fractures.

Chan School of Public Health, Cambridge, United States of America*

Background: Osteoporotic hip fracture causes a high level of dependency in older adults, as their functional status suddenly decreases greatly. In addition, the high level of pain and the fear of falling that they frequently experience maintain this decrease in functional status for a longer period. Digital health, the promotion of health through the use of Information and Communication Technologies, emerges as an option for the rehabilitation of older adults with hip fracture.

Objectives: To test the effectiveness of the co-created ActiveHip+ mHealth system on the recovery of the functional status and the decrease of the pain and fear of falling in older adults with hip fracture.

Methods: A total of 110 older adults with hip fracture and their family caregivers were recruited from hospitals in southern Spain. Participants were randomly assigned to an intervention group (n = 55), in which rehabilitation was performed through ActiveHip+, or to a control group (n = 55), in which they received standard rehabilitation for a hip fracture from the Andalusian Public Health System. Participants were assessed during the hospital stay and 3 months after surgery. Feasibility assessment was done through adoption (participation proportion), usage (access to the app), satisfaction with the app (Net Promoter Score) and user perception of the quality of the app (Mobile App Rating Scale). Clinical assessment was conducted through patient-reported outcomes, such as the Functional Independence Measure and the New Mobility Score Spanish version for functional status, the Numerical Rating Scale for pain and the Short Falls Efficacy Scale-International for fear of falling.

Results: We obtained positive results in terms of feasibility as we observed 88% adoption, 82% usage, 8.35/10 in satisfaction with the app and 4.3/5 in perceived quality of the app.The functional status of patients allocated to the intervention group (those using ActiveHip+) had a statistically significant greater recovery than participants of the control group at 3-months (medium effect size: 0.70 Cohen's d; p = 0.02) and (medium effect size: 0.62 Cohen's d; p = 0.03) respectively. In addition, the level of pain was statistically significant lower in participants of the intervention group than those in the control group (medium effect size: 0.45; Cohen's d p = 0.03). Regarding the fear of falling, there was no statistically significant difference (medium effect size: 0.32 Cohen's d; p = 0.17).

Conclusion: The ActiveHip+ mHealth system is effective in the recovery of the functional status and the decrease of pain in older adults with hip fracture. However, it was not effective on the decrease of the fear of falling.

Table 1. Baseline characteristics and pre-interventions raw of sample divided by groups.

POS0393 DEFINING THE KEY ATTRIBUTES OF A CLINICIAN WITH COMPETENCE IN BONE HEALTH MANAGEMENT

Keywords: Descriptive Studies, Osteoporosis

L. Jackson[1], S. Johnson[2], E. Mcneeley[1], K. Saag[1], M. Danila[1,3]. [1]*University of Alabama at Birmingham, Medicine, Birmingham, United States of America*; [2]*University of Toronto, Medicine, Toronto, Canada*; [3]*Birmingham VA Health Care System, Geriatric Research, Education, and Clinical Center, Birmingham, United States of America*

Background: Osteoporosis and fragility fractures are managed by clinicians across a variety of specialties and there is no specific certification in osteoporosis diagnosis and management. These clinicians are an integral part of interventions aimed to improve bone health care (e.g., fracture liaison service [FLS]). Yet, the key skills and attributes of a clinician with competence in bone health management have not been established in a systematic fashion.
Objectives: We conducted a Delphi exercise and a discrete choice experiment (DCE) to generate a decision rule aiming to define the minimal attributes of a clinician best poised to assess and treat people with osteoporosis and serve as a referral source for post-fracture management.
Methods: In part 1, we used a modification of the Delphi method with two rounds. Clinicians with experience in treating osteoporosis and representatives of patient advocacy groups were purposively sampled to participate. Participants asynchronously generated a list of desirable characteristics/skills of a "clinician with competence in bone health". Characteristics were coded and organized into non-overlapping themes or "attributes" with sub-themes or "levels" within each attribute. Participants prioritized and ranked levels in order of perceived importance for inclusion in the definition for a bone health clinician. Levels within attributes associated with the highest median scores were included in the final list of criteria. In part 2, participants ranked 20 hypothetical clinicians defined by various levels of attributes from highest to lowest likelihood of being a bone health clinician to identify the minimal threshold for defining competence in managing bone health. Consistency amongst rankings was evaluated using intraclass correlation coefficients (ICC). In part 3, we conducted a DCE to generate a weighted importance score for each independent and mutually exclusive attribute and level such that the sum of weights across the highest level within each attribute would equal 100%. The threshold for competence was the total weighted score at which ≥70% of participants agreed a clinician had bone health competence.
Results: Part 1 included 13 participants, and 11 completed the DCE survey. Those who completed part 1 included 3 endocrinologists, 3 rheumatologists, 1 orthopedist, 3 general internists, and 3 representatives of patient advocacy groups. The Delphi exercise generated a list of N=108 characteristics, which were coded and grouped into common themes/attributes. Through an iterative process with 2 rounds of piloting, the attribute categories were reduced to 8 broad categories with a total of 20 levels. The participants' rankings of the relative probability that each of the 20 hypothetical clinician cases represented a clinician with adequate competence in bone health is plotted in **Figure 1**. The ICC for agreement across participants was 0.90 (95% confidence interval [CI]: 0.83, 0.95). The maximum possible score in the final criteria was 25. A threshold score of ≥12 classified a clinician as having adequate competence in bone health. For example, a clinician that prescribes all osteoporosis drugs, performs osteoporosis workup/ treatment monitoring, and leads or participates in an FLS would receive 5, 3.5, and 3.5 points, respectively, that summed would reach the threshold.
Conclusion: We developed a numeric additive decision rule to classify clinicians across multiple specialties with competence in evaluating and treating patients with osteoporosis. Our data provides the critical definition of a "clinician with competence in bone health" that may be useful for identifying and qualifying the skill of clinicians who may be included in interventional studies or clinical activities that aim improve bone health care.

Background: The FRAX™ risk assessment tool is utilised to predict fracture risk in patients with poor bone health. It uses the bone mineral density (BMD) at the non-dominant femoral neck. The performance of the tool in predicting fractures with worsening BMD has not been examined.
Objectives: The aim of this study was to investigate whether different factors within the FRAX™ tool are more predictive of severe osteoporosis; defined by a T score of -3.5 and below, compared to patients with a t score of -2.5 to -3.49.
Methods: Two patient cohorts were identified from patients referred for routine DEXA scans between 2004 and 2019, in the Northwest of England. The first cohort (group A) consisted of patients with a T score between -2.5 and -3.5 and the second cohort (group B) consisted of patients with a T score of -3.5 and below. The FRAX risk factors and the BMD data were analysed, using a Student's T test for continuous variables and a Chi Squared test for categorical variables. Univariate and multivariate logistic regression models were also fitted examining the differences in the FRAX™ risk factors and severe osteoporosis prediction. The sites measured included an average of L1-L4, right and left femoral neck in which their BMD mean and both their respective BMD totals were analysed. FRAX™ risk factors included age, weight, height, BMI, sex, previous fracture, parent fractured hip, smoking, steroid use, rheumatoid arthritis, alcohol consumption and coeliac disease/malabsorption.
Results: 31,547 patients were included in the analysis, with a mean age of 64.9 years (SD = 12.9). The number of individuals in group A were 4,714 (81.54%) and 1,067 (18.46%) in group B. Table one depicts the differences in the FRAX™ risk factors between the two groups and the odds ratios. Age, weight, height, BMI and current smoking were statistically significant in predicting severe osteoporosis. Lower weight, height and BMI was associated with group B. In addition, increased age and current smoking was also associated with group B. There was no significant difference between group A and B in regard to sex, previous fracture, parent fractured hip, steroid use, rheumatoid arthritis, alcohol consumption or coeliac disease/malabsorption.
Conclusion: The results of this study indicate that certain risk factors used in the FRAX™ scoring are more predictive of a severe osteoporosis than others. In addition, research providing insight into utilising FRAX™ variables in fracture prediction in patients with severe osteoporosis will provide valuable insight.

Table 1. The differences in the FRAX™ characteristics between group A and B, the corresponding odds ratio and confidence interval

Characteristic	Group A	Group B	Odds ratio and confidence interval
Average age in years (SD)	72.52 (10.80)	75.52 (11.18)	1.10* [1.02,1.04]
Average weight in kilograms (SD)	63.27 (13.27)	55.94 (14.02)	0.95* [0.95,0.96]
Average height in centimetres (SD)	158.96 (8.44)	155.89 (10.48)	0.96* [0.95,0.97]
Average BMI in kg/m^2 (SD)	25.02 (4.82)	24.16 (26.62)	0.91* [0.90,0.92]
Sex	Female - 3,844 (81.54%) Male – 870 (18.46%)	Female – 854 (80.04%) Male – 213 (19.96%)	1.10 [0.93,1.30]
Previous fracture	2 (0.04%)	1 (0.09%)	2.21 [0.20, 24.4]
Parent fractured hip	65 (1.38%)	9 (0.84%)	0.61 [0.30,1.23]
Current smoking	1,792 (38%)	445 (41.71%)	1.17* [1.01,1.34]
Steroids (current)	1,165 (24.71%)	271 (25.4%)	1.04 [0.89,1.21]
Rheumatoid arthritis	362 (7.68%)	88 (8.25%)	1.08 [0.85,1.38]
Alcohol consumption	284 (6.02%)	68 (6.37%)	1.06 [0.81,1.40]
Coeliac disease/ malabsorption	183 (3.88%)	50 (4.69%)	1.22 [0.88,1.67]

POS0396

DISEASE SEVERITY IS ASSOCIATED WITH LOW BONE MINERAL DENSITY AND OSTEOPOROSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Epidemiology, Systemic lupus erythematosus, Osteoporosis

E. Wiebe[1], E. C. Schilling[1], D. Huscher[2], A. Palmowski[1,3], Z. Boyadzhieva[1], S. Hermann[1], B. Muche[1], T. Alexander[1], F. Hiepe[1], F. Buttgereit[1]. *[1]Charité Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[2]Berlin Institute of Health, Charité – Universitätsmedizin Berlin, Institute of Biometry and Clinical Epidemiology, Berlin, Germany*; *[3]Bispebjerg and Frederiksberg Hospital, Section for Biostatistics and Evidence-Based Research, the Parker Institute, Copenhagen, Denmark*

Background: Patients with systemic lupus erythematosus (SLE) are at an increased risk for osteoporosis and fragility fractures.[1] This risk is mediated by a variety of factors such as chronic inflammation, treatment with glucocorticoids (GC), vitamin D deficiency, and others.[2] The role of disease-specific factors of SLE has not been fully elucidated.
Objectives: We aimed to identify factors associated with bone mineral density and osteoporosis including fragility fractures to better understand the interplay between disease-specific factors and general risk factors that drive bone loss in this patient population.
Methods: Rh-GIOP is a prospective observational cohort study investigating bone health in consecutive patients ≥18 years with inflammatory rheumatic diseases and current or prior GC treatment. This cross-sectional analysis assessed the baseline visits of all patients with SLE fulfilling the EULAR/ACR 2019 SLE classification criteria. Multivariable linear regressions models were fitted to identify factors associated with bone mineral density (BMD). As a second outcome, we investigated factors associated with clinical osteoporosis (defined by either a T-Score of ≤ -2,5, anti-osteoporotic treatment and/or fragility fractures) by multivariable logistic regression analysis.
Results: Baseline data from 110 patients with SLE were analyzed. The mean age was 48.1±14.5 years, mean disease duration 16.3±9.9 years, and 41% of the cohort was identified as having osteoporosis (OP). Lupus nephritis was present in 35% of the SLE patients, of whom 55% had active nephritic disease at baseline osteoporosis screening visit. Class IV and V accounted for most nephritis cases (61%). In multivariable linear regression analysis, lupus nephritis class IV and V (reg. coefficient (95%CI): -0.745 (-1.395;-0.095)), the presence of U1-RNP antibodies (-0.750 (-1.314;-0,187)) as well as C-reactive protein (CRP, -0.015 (-0.026;-0.003)) and longer disease duration (-0.037 (-0.056;-0.018)) were significantly associated with low BMD. Conversely, clinical remission (defined as SLEDAI-2K=0 and GC dosage ≤5 mg prednisone equivalent per day) was positively associated with BMD (0.447 (0.037;0.857)), as were Siglec-1 levels on monocytes as surrogate for Type-I interferon activity (0.558 (0.150;0.967)), BMI (0.045 (0.014;0.076)), and health assessment questionnaire (HAQ, 0.307 (0.078;0.536)). In multivariable logistic regression analysis, active lupus nephritis (OR (95%CI): 7.42 (1.256;43.868)) was strongly associated with OP in patients with SLE. Additionally, age (1.06 (1.020;1.100)), HAQ (0.29 (0.120;0.682)) and complement factor 3 (1.27 (1.002;1.601)) were found to be significantly related to the presence of OP. Neither current GC use, cumulative GC dose nor GC duration were significantly associated with BMD or clinical OP.
Conclusion: In patients with SLE, indicators of disease severity, expressed by (active) lupus nephritis, high CRP, U1-RNP antibodies, and long disease duration, are related to poor bone health in addition to commonly known risk factors

such as low BMI and higher age. The knowledge of these disease-specific factors helps to identify patients with SLE at particular high risk for OP and fragility fractures.

POS0397 SHORT-TERM (2 YEARS) FRACTURE RISK PREDICTION: A MACHINE LEARNING APPROACH

Keywords: Real-world evidence, Osteoporosis, Bone diseases

G. Adami[1], M. D'souza[2], S. Vijayakumar[2], E. Grisan[2], A. Fassio[1], O. Viapiana[1], D. Gatti[1], M. Rossini[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*; [2]*London South Bank University, School of Engineering, London, United Kingdom*

Background: Osteoporotic fractures continue to be a major cause of global health concerns around the world. The most common risk scores (FRAX, DeFRA) are evaluating this risk within a 10-yearstime window, which might not be suitable for evaluating shorter term risk, or quickly progressing patients.

Objectives: The objective of the present analysis is to develop 2-year fracture risk scoring models using Machine Learning (ML) techniques and compare their performance with the DeFRA tool.

Methods: Data were obtained from web-based fracture risk assessment tool (DeFRA) used in Italy. This tool is a derived version of the FRAX and can be accessed through a website (https://defra-osteoporosi.it/). 33 clinical and densitometric variables were used to compute the DeFRA risk score, with variable degree of completeness for each patient. After eliminating the attributes with a large number of missing values, and eliminating the patient with large outlier values for any of the attributes, the dataset was reduced to 2516 patients (with follow-up visits) and 15 attributes (Age, Weight, Height, BMI, Smoking, Alcohol, Familial Fractures/Osteoporosis, Previous femur or vertebra fractures, Previous other fractures, Comorbidities, Prednisone mg equivalent per day, T-score femoral-neck, T-score spine, Serum CTX levels, Anti-osteoporotic therapy prescribed). For the development of the machine-learning prediction, the dataset has been randomly divided into a train-set and a test-set, and the train-set has been synthetically balanced using Synthetic Minority Oversampling Technique (SMOTE). A Logistic Regression (LR) model and a Random Forest (RF) model have been optimized on the train-set for predicting the patients who incurred either a hip fracture, or any major osteoporotic fracture, or both in the 2 years following the baseline visit. DeFRA risk score is used as a benchmark for the prediction of either hip fracture or of any major fracture within 2-years.

Results: The DeFRA score, when used to predict the patients incurring a hip fracture within 2 years, has an Area Under the Receiver-Operating Curve(AUROC) of 0.52, compared to 0.76 for Random Forest and 0.81 for Logistic Regression. When looking at other major osteoporotic fractures, the AUROC is 0.59 for DeFRA, 0.77 for LR and 0.80 for RF, and when looking at any fracture the values are 0.58, 0.78, 0.80 for DeFRA, LR and RF respectively. Performance metrics including accuracy, sensitivity, and specificity are summarized in Table 1.

Table 1.

Table I: Performance of DeFRA and machine learning classifier in predicting patients incurring an osteoporotic fracture within 2 years

	Hip fracture			Major osteoporotic fracture			Any fracture		
	DeFRA	LR	RF	DeFRA	LR	RF	DeFRA	LR	RF
AUROC	0.52	0.81	0.76	0.59	0.77	0.80	0.58	0.78	0.80
Accuracy	0.62	0.63	0.92	0.68	0.69	0.89	0.61	0.71	0.90
Sensitivity	0.40	0.76	0.29	0.49	0.76	0.34	0.54	0.79	0.34
Specificity	0.63	0.62	0.95	0.69	0.69	0.93	0.61	0.70	0.95

Conclusion: Currently usedrisk scores for osteoporotic fractures are developed within a 10-years time window, which might be toolong to stratify the most at risk-patients or those that are showing a fast-progressing disease. This isreflected by the poor predictive performance of DeFRA when looking at a 2-years time window. Machine-learning (either logistic regression or random forest) could greatly improve the predictive performance ofa scoring system to identify the patients most likely to incur an osteoporotic fracture in the short term,thus requiring shorter follow-ups.

Background: Patients hospitalized for severe osteoporotic fractures are at increased risk of morbidity and mortality. It is recommended to improve their medical management by Fracture Liaisons Services (FLS) organization.

Objectives: Our aim was to assess the determinants of mortality and imminent refracture in those patients followed in FLS.

Methods: The CROSS study is a national, prospective, observational, multicenter study conducted in 12 centers with Fracture Liaison Services (FLS). Patients included were men and women above 60 years, hospitalized for a recent (less than 3 months) severe fragility fracture (hip, pelvis, humerus or vertebrae) that occurred after a low-energy trauma. Patients with either a non-severe fracture, a pathological fracture, a high trauma fracture or a per-prosthetic fracture were not included. At baseline and 2 years we have collected sociodemographic data, fracture event, bone risk factors, factors of falling, FRAX items, history of treatments, comorbidities, Charlson score and DXA measurement. To assess the risk factors for new severe fracture or death, a multivariate Cox proportional hazard multivariate analysis was performed.

Results: 895 patients were included in the cohort with the following fracture location distribution: clinical vertebrae 43.3%, hip 37.5%, pelvis 10.3%, and humerus 11.1%. Most patients were women (79%) with a median age of 81 years (71-85). 40% had a previous history of fragility fracture after 40 years. Only 17.7% received an anti-osteoporotic treatment in the 5 years prior baseline whereas 21.4% received a calcium supplementation and 43.6% received a vitamin D supplementation. At baseline 48% of patients had densitometric osteoporosis. Over the 2 years of follow-up (data completed for 95% of population), 116 severe fractures in 110 patients (12.9%) and 80 deaths (8.9%) occurred. 49.1% of patients were prescribed an antiosteoporotic treatment after the fracture (75% of bisphosphonates), that was initiated within the 3 months following fracture event in 63 % of the cases. Multivariate analysis showed that reduced spinal BMD (OR=24.6 CI 95% 2.84-247, p=0.027), recurrent falls (OR= 2.80 (1.11-6.65), p=0.023), antiosteoporotic treatment initiation (OR= 2.17, CI 95% 1.19-4.08, p=0.013) and increased age (OR=1,04 CI 95% 1,01-1.08, p=0.027) were significantly associated with the risk of a new severe fracture. Use of walking aids (RR=2.71 (CI 95% 1.15-6.39), p=0.02), diabetes (RR=3.70 (CI 95% 1.04 to 13.2), p=0.044), metastatic cancer (RR=15,5 (CI 95% 1.08 to 221), p=0.043) were positively associated with risk of death whereas antiosteoporotic initiation was negatively associated with this risk (OR=0.19 (CI 95% 0.07 to 0.49), p<0.001).

Conclusion: In patients hospitalized for severe osteoporotic fractures and managed in a FLS setting, initiation of an anti-osteoporotic treatment is associated with a decreased risk of mortality. In this population, a low BMD was a strong determinant of an imminent fracture risk.

L. Wang[1], Y. Wei[2], R. Ma[3], C. Cang[2], X. Li[1]. *[1]The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, Anhui，China, Department of Rheumatology and Immunology，The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, Anhui，China, Hefei, Anhui, China; [2]Hefei National Laboratory for Physical Sciences at Microscale, the CAS Key Laboratory of Innate Immunity and Chronic Disease, School of Basic Medical Sciences, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei National Laboratory for Physical Sciences at Microscale, the CAS Key Laboratory of Innate Immunity and Chronic Disease, School of Basic Medical Sciences, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, Anhui, China; [3]Department of Orthopaedics，The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Department of Orthopaedics，The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, Anhui, China*

Background: Osteoarthritis (OA) is the leading cause of disability for bone and joint diseases. Cartilage injury is its pathological basis. There is a lack of therapeutic drugs with clear cartilage protection in clinic. Iguratimod (IGU) has cartilage protection effect in the treatment of rheumatoid arthritis, but it is not clear whether it also has cartilage protection effect on OA.
Objectives: To investigated the efficacy and mechanism of Iguratimod (IGU) on cartilage protection effect on knee osteoarthritis (OA).
Methods: Type VII collagenase was injected into the knee joint cavity of C57BL6/N rats to establish a model of CIOA (Collagenase-induced Osteoarthritis), to establish the model of osteoarthritis, followed by IGU given by intragastrium at 10mg/kg. μCT and Immunohistochemistry (IHC) were used to evaluate the structural changes of OA knee joint, the degree of destruction of knee cartilage layer and subchondral bone. IHC and qPCR were used to evaluated the expression of TPRV4 in chondrocytes of OA rats. Chondrocytes were processed by IGU at the cellular level, and the concentration of glycosaminoglycan secreted and the expression of chondrogenic differentiation factor in cells were further detected. TRPV4 ion channel inhibitor and interfering RNA technology were used to verify whether TRPV4 was involved in the effect of IGU on cartilage.
Results: It was found that IGU could change the pain sensitivity of OA model rats and effectively reduce the pain of OA rats. μCT showed that IGU could effectively inhibit the subchondral bone injury of knee joint in OA rats; Toluidine blue staining and Safranin O-Fast Green staining of rats knee joint also showed that IGU treatment could delay the degeneration of knee cartilage of rats with OA. At the cellular level, it was found by qPCR that IGU could effectively promote the expression of mRNA levels of Sox9 and Col2a, markers of chondrogenesis, in chondrocytes. Alcian blue staining also showed that IGU promoted chondrocyte secretion of glycosaminoglycan; Moreover, the results of scratch experiment also showed that IGU promoted the migration of chondrocytes. The results addressed above all indicated that IGU could promote the differentiation of chondrocytes. The expression of transient receptor point vanillin 4 (TRPV4) in OA rats chondrocytes in the treatment group of IGU was increased. We used ion channel inhibitors and interfering RNA technology to show that IGU played a role in delaying cartilage damage, promoting cartilage differentiation and migration by regulating the function of TRPV4.
Conclusion: IGU can effectively alleviate the pain of OA model rats, and exert cartilage protection by regulating TRPV4. The results offer new treatment options for osteoarthritis.

POS0400 **A CAUSATIVE ROLE FOR PERIARTICULAR SKELETAL MUSCLE WEAKNESS IN THE PROGRESSION OF JOINT DAMAGE AND PAIN IN OA**

Keywords: Pain, Cartilage, Osteoarthritis

H. A. Kim[1], H. S. Hwang[1], J. R. Kim[1]. *[1]Hallym University Sacred Heart Hospital, Division of Rheumatology, Internal Medicine, Anyang, Korea, Rep. of (South Korea)*

Background: Although OA is regarded as a disease of the articular cartilage, recent research has demonstrated whole-joint pathology, including synovial inflammation, subchondral bone sclerosis, osteophyte formation, and changes in periarticular muscles that surround the affected joint. There is also increasing evidence that the consequences of knee OA are associated with decreased lower limb muscle strength and function. It is unclear whether the change in periarticular muscle is the cause or result of disease progression, however.
Objectives: This study investigated changes in periarticular muscle during the progression of osteoarthritis (OA), as well as the cause-and-effect relationship between muscle weakness and OA, in a mouse model of OA achieved by destabilization of the medial meniscus (DMM).
Methods: Knee OA was induced by DMM in 10-week-old male C57BL/6 mice. Pathological muscle phenotypes in the tibialis anterior (TA) and quadriceps muscles were assessed in both the early and late stages of OA with muscle-fiber cross-sectional area analysis, markers of myogenesis, as well as the proliferation of satellite cells. OA pathology and pain behavior were examined with OARSI grade, von Frey filament threshold and pressure algometer. Periarticular muscle weakness was induced by multiple rounds of barium chloride injections after DMM induction. In addition, myostatin knockout.mice with muscle hypertrophy phenotype was used to evaluate the influence of muscle mass on pain and joint destruction after DMM.
Results: Morphological alterations in the TA and quadriceps in DMM mice included variations in muscle-fiber size, aberrant muscle fibrosis, inflammatory cell infiltration, and decreased muscle mass. Periarticular muscle fibers isolated from DMM mice showed reductions in cell number and myogenic capacity, as well as the proliferation of satellite cells. DMM mice exhibited exacerbated articular cartilage destruction, subchondral bone sclerosis, synovitis and pain after muscle injury compared to the DMM + vehicle group. Myostatin knockout mice were characterized by attenuated OA and the complete abrogation of pain behavior after DMM.
Conclusion: DMM-induced knee OA resulted in morphological changes in periarticular muscle, in a manner that coincided with muscle atrophy. Joint destruction and pain after DMM were aggravated by muscle weakness and alleviated by muscle hypertrophy. Our results suggest a causative role for muscle weakness in the progression of joint damage and pain in OA.

POS0401 OSTEOARTHRITIS SYNOVIAL MACROPHAGES HAVE A TOLERIZED PHENOTYPE AND A VERY WEAK CORTICOSTEROID RESPONSE

Keywords: Osteoarthritis, Innate immunity, Cell biology

C. Wang[1], R. De Francesco[1,2], L. Lamers[1], S. Rinzema[1], S. Frölich[3], P. Van Lent[2], C. Logie[1], M. Van den Bosch[2]. *[1]Radboud University, Department of Molecular Biology, Nijmegen, Netherlands; [2]Radboud University Medical Center, Experimental Rheumatology, Nijmegen, Netherlands; [3]Radboud University, Department of Molecular Developmental Biology, Nijmegen, Netherlands*

Background: The majority of osteoarthritis (OA) patients show synovial inflammation. Intra-articular corticosteroid injections are often given to decrease this inflammation. Whereas these provide relatively short-term alleviation of clinical symptoms, they do not improve long-term disease prognosis. Monocytes/macrophages are key cells in OA synovial inflammation. Whereas past research mainly focused on pro-inflammatory M1-like and anti-inflammatory M2-like macrophages, a second logic related to long-term macrophage polarization is interesting to study; macrophage training versus tolerization that is the result of prior exposure of monocytes/macrophages to different inflammatory cues. This process is also referred to as innate immune memory.

Objectives: Here, we investigated what could underlie the absence of long-term amelioration of OA by corticosteroids. Hereto, we compared global RNA profiles of OA synovium macrophages with well-defined *in vitro* trained and tolerized monocyte-derived macrophage models, all in the presence or absence of corticosteroids.

Methods: Macrophages were obtained from OA synovium (OA-Mf) using tissue digestion followed by CD14+ MACS isolation or differentiated from blood-derived CD14+ monocytes using medium with human pooled serum. Tolerance and training was induced in monocyte-derived macrophages using 5 ng/mL LPS (LPS-Mf), mimicking macrophage paralysis as observed in sepsis, or 10 µg/ml β-glucan (BG-Mf), which mimics non-specific vaccination against an ulterior lethal pathogen exposure by generating macrophages that present robust M1 responses upon TLR receptor stimulation, during the first 24 hours of differentiation respectively. Samples were treated with 1 µM triamcinolone acetonide (TA) or DMSO for 4 hours. The genome-wide transcriptomic response to corticosteroids was determined using RNA sequencing.

Results: TA exposure of trained BG-Mf and tolerized LPS-Mf significantly altered the expression of 201 and 257 RNA transcripts, respectively. In contrast, in OA-Mf only 12 RNA transcripts were significantly regulated, indicating a globally paralyzed TA response. Interestingly, evaluation of the IL1, and C-C motif chemokine ligand (CCL) and CXCL clusters of chemotactic factors showed close resemblance between OA and tolerized but not trained macrophages in terms of basal expression, although only one gene in these clusters (*IL36RN*) was significantly regulated by TA in the OA-Mf. This indicates that OA-Mf have a state that is related to the memory of inflammation as in the LPS-Mf for key pathways involved in OA and further confirms that the OA-Mf have a weak TA response. However, this did not extend to all genes significantly induced by LPS (n= 895), since OA-Mf clustered apart from the LPS-Mf and BG-Mf, indicating a distinct global pro-inflammatory mRNA expression profile when compared with both tolerized and trained monocyte-derived macrophages. Finally, we observed that OA-Mf have a matrix-metalloproteinase (MMP) expression profile that is consistent with a macrophage phenotype, since they express *MMP9*, *MMP14*, and *MMP19*, but furthermore very strongly express *MMP1*, *MMP2*, *MMP3*, and *MMP10* that are not expressed by our monocyte-derived macrophage models, highlighting their unique phenotype. Again, corticosteroid treatment of OA-Mf could not repress MMP expression.

Conclusion: OA synovial macrophages have an inflammatory polarization state that closely resembles the tolerized macrophage state in terms of relevant secreted cytokines and chemokines transcripts. Furthermore, they show a very weak corticosteroid response, which might explain why corticosteroid treatment fails to ameliorate long-term pathology and symptoms in OA patients.

POS0402 LYSYL OXIDASE (LOX) AND LYSYL OXIDASE-LIKE 2 (LOXL2) CONTRIBUTE TO CARTILAGE CALCIFICATION DURING OSTEOARTHRITIS

Keywords: Crystal arthritis, Osteoarthritis, Cartilage

E. Faure[1], I. Bernabei[1], J. Wegrzyn[2], T. Hügle[1], N. Busso[1], S. Nasi[1]. *[1]Lausanne University Hospital, Department of Musculoskeletal Medicine, Lausanne, Switzerland; [2]Lausanne University Hospital, Department of Orthopedic Surgery, Lausanne, Switzerland*

Background: Cartilage pathological calcification is a hallmark of osteoarthritis (OA), a degenerative disease characterized by articular cartilage degradation that leads to joint pain and impaired movement. We previously demonstrated that lysyl oxidase-like enzymes (LOX(L), which include five enzymes, LOX and LOXL1-4), that catalyze the crosslinking of collagen and elastin fibers of the extracellular matrix (ECM), play a crucial role in cartilage calcification (Bernabei et al, in preparation). Indeed, the pan-LOX(L) inhibitor BAPN decreased crystal production in chondrocytes, but the identification of the crucial LOX(L) involved in this process remained to be established.

Objectives: To identify the specific LOX(L) involved in cartilage calcification during OA.

Methods: *In vitro*, murine chondrocytes (primary cells or ATDC5 cells) were cultured in normal medium ((Nt), DMEM high glucose + 10% FBS) or calcifying medium ((CM), BGJb +10% FBS+ 20mM β-glycerophosphate + 50µg/ml ascorbic acid). The expression of Lox was silenced using siRNA at 100nM ((siLox), OriGene). Gene expression was measured by qPCR. Calcium-containing crystals were evidenced by alizarin red staining and quantified by cetylpiridinium dissolution of crystals. *In vivo*, mice were subjected to meniscectomy (MNX) in the right knee or sham operated in the left. *Ex vivo*, cartilage explants from undamaged or damaged cartilage regions were obtained from 7 OA patients undergoing knee replacement surgery. Immunohistochemistry (IHC) was performed on murine knees and human cartilage sections ((anti-LOX or anti-LOXL2 rabbit polyclonal antibodies (Proteintech or Genetex respectively). Calcification was detected by Alizarin red staining on histological sections, and proteoglycan loss by safranin-O staining. Mouse gene expression data from primary articular chondrocytes treated with interleukin-1β (IL-1β) for 24h were obtained from GEO (identifier: GSE104793).

Results: *Lox* expression was increased in murine chondrocytes stimulated with calcification medium (CM), but not *Loxl2*. Similarly, transcriptome data from primary mouse articular chondrocyte treated with IL-1β, revealed that both *Lox* and *Loxl2* were markedly upregulated in treated cells. We then evaluated Lox and Loxl2 modulation by IHC in calcified cartilage in the MNX OA model. Both Lox and Loxl2 were increased in MNX cartilage compared to sham cartilage and at an even higher extent in osteophytes and in newly formed calcified deposits appearing in MNX knees. In human OA cartilage we found massive calcification and proteoglycan loss in damaged areas compared to undamaged. In line with murine data, we revealed increased LOX and LOXL2 expression in damaged human cartilage, both in chondrocytes and in the extracellular matrix in correspondence to calcified regions. Next, we performed *in vitro* Lox RNA silencing using siLox or siControl RNA transfected ATDC5 cells (siLox cells or siCtrl cells). Lox expression was decreased by more than 80% in siLox cells compared to siCtrl cells. Most importantly, in CM, siLox cells calcified less as demonstrated by alizarin red quantification. Furthermore, gene expression data showed inhibition of calcification gene *Annexin 5* by Lox silencing. In agreement, we found an increase of early differentiation genes *Sox9* and *Col2*, along with significant downregulation of hypertrophic marker *Col10*. However, no effect by Lox silencing was found on fibrotic genes (*Col1, Col3*) and on pro-calcifying cytokine interleukin-6 (*Il-6*). Additionally, we revealed a trend towards decreased mitochondrial reactive oxygen species in siLox cells. Finally, Lox silencing decreased gene expression of the ECM catabolic enzyme *Mmp13*.

Conclusion: Our data revealed that LOX and LOXL2 are increased in calcified areas of murine and human cartilage. Additionally, *in vitro* inhibition of Lox prevents at least in part, calcium-crystal deposition, chondrocyte hypertrophy, and *Mmp13* catabolic enzyme expression. Altogether, our results suggest that both LOX and LOXL2 might play a role in cartilage calcification and OA.

SENSITIVITY OF AUTOMATED, U-NET-BASED SEGMENTATION TO LAMINAR CARTILAGE TRANSVERSE RELAXATION TIME (T2) IN KNEES WITH DIFFERENCES IN CONTRALATERAL OSTEOARTHRITIS STATUS – DATA FROM THE THE OA-BIO CONSORTIUM

Keywords: Imaging, Osteoarthritis

F. Eckstein[1,2], A. Wisser[1,2], F. Roemer[3,4], F. Berenbaum[5,6], J. Kemnitz[1,2], G. Duda[7], S. Maschek[1], W. Wirth[1,2]. *[1]Chondrometrics Gmbh, Department of Research, Freilassing, Germany; [2]Paracelsus Medical University, Institute of Anatomy & Cell Biology, Salzburg, Austria; [3]University of Erlangen, Department of Radiology, Erlangen, Germany; [4]Boston Imaging Core Lab, (BICL), Boston, United States of America; [5]4Moving Biotech, Department of Research, Lille, France; [6]Sarbonne University INSERM, AP-HP Saint-Antoine Hospital Paris, Paris, France; [7]BIH at Charite, Universitätsmedizin Berlin, Berlin, Germany*

Background: Radiographically normal knees with contralateral (CL) radiographic joint space narrowing (JSN) are at elevated risk of incident radiographic osteoarthritis (ROA). We previously observed increased superficial femorotibial cartilage layer transverse relaxation time (T2) on magnetic resonance images (MRI) of 39 KLG0 knees (0=normal) with advanced ROA in the contralateral knee (CL JSN), compared with 39 (1:1-matched) KLG0 knees without evidence of CL ROA (bilateral KLG0) [1]. These results suggest that cartilage matrix degeneration occurs in radiographically normal knees with CL JSN, and can be detected in vivo using MRI [1]. Application to larger cohorts, however, will benefit from fully automated image segmentation, as manual segmentation is a labor-intensive process.

Objectives: To evaluate the performance of U-Net-based cartilage segmentation, using an artificial intelligence (AI), i.e. convolutional neuronal network (CNN) approach, combined with fully automated detection of bony landmarks and the specific MRI slices requiring cartilage segmentation. The U-Net results were compared with those from manual segmentation, and the fully automated technology was applied to a larger (extended) control group.

Methods: U-Nets were trained from manual, quality-controlled cartilage segmentations in sagittal MESE images of the Osteoarthritis Initiative healthy reference cohort (n=92; HRC), one on the medial (MFTC) and one on the lateral femorotibial compartment (LFTC). All 7 echos (10-70 ms) were used. A 3rd U-Net was trained from manual, quality-controlled bone segmentations in 60 OAI HRC knees. The latter was used for automated detection of the weight-bearing femoral region of interest. The automated bone segmentation was registered to an atlas comprising both bone and cartilage segmentation, for identifying the slices required for cartilage segmentation. Automated post-processing was employed to correct obvious segmentation errors. This pipeline was first applied to n=39 dataset pairs (KLG0 with CL JSN vs. bilateral KLG0 knees) [1]. Then it was applied to n=642 bilateral KLG0 knees, to extend the limited paired case-control design (n=39) to a much larger control cohort. The agreement of the U-Net-based vs. manual segmentation was evaluated using the Dice Similarity Coefficient (DSC). Actual differences in cartilage T2 between a) 39 case vs. 39 control knees were compared between manual [1] vs. fully automated segmentation, and b) 39 case vs. 642 control knees (U-Net). Cohen's D was used as a measure of effect size.

Results: The DSC for the 2x39 knees with manual segmentations available ranged from 0.83±0.05 to 0.87±0.04 across the medial/lateral tibia and femur. When applied to the 39 pairs of case vs. control knees, fully automated segmentation identified differences in superficial layer T2, with the effect size apparently larger (Cohen's D MFTC/LFTC: 0.62/0.50) than that obtained from manual segmentation (0.46/0.48). Further, the U-Net was more sensitive to deep layer T2 differences (MFTC/LFTC: 0.36/0.50) than manual segmentation (0.25/0.35). When comparing the case knees to 642 control knees, the fully automated segmentation showed similar between-group differences (0.57/0.48 for superficial T2).

Conclusion: Fully automated segmentation of the femorotibial cartilage, in combination with automated detection of the relevant slices and femoral region of interest, showed high agreement with manual segmentation. The pipeline was able to reproduce differences in laminar T2 observed by manual segmentations [1], indicating early superficial cartilage matrix degeneration in radiographically normal knees with advanced contralateral radiographic KOA (JSN). The proposed fully automated analysis pipeline was readily expanded to a much larger cohort and thus represents a promising tool for future clinical studies on early cartilage change.

POS0404

SOLUBLE LOW AFFINITY NERVE GROWTH FACTOR RECEPTOR (LNGFR) MAY REGULATE PAIN IN KNEE OSTEOARTHRITIS

Keywords: Pain, Osteoarthritis, Biomarkers

A. Altaie[1,2], M. Campbell[3,4,5], R. Doyle[6], H. Owston[1], E. Jones[1], R. Feibel[7], S. Westbrook[6], D. Mcgonagle[1]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [2]NIHR, Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom; [3]Elisabeth Bruyère Hospital, Department of Physical Medicine and Rehabilitation, Ottawa, Canada; [4]Ottawa Hospital Research Institute, Bone and Joint Lab, Ottawa, Canada; [5]Ottawa Hospital Research Institute, Ottawa Hospital Research Institute, Ottawa, Canada; [6]Levicept Ltd, Levicept Ltd, Kent, United Kingdom; [7]The Ottawa Hospital, The Ottawa Hospital, Ottawa, Canada*

Background: Osteoarthritis (OA) is a disease of the entire joint. OA causes significant pain that has been linked to increased neurotrophin concentrations, including mature nerve growth factor β-NGF[2]. β-NGF antagonism was efficacious in reducing OA pain in clinical trials but was associated with rapidly progressive OA[1], hampering mainstream delivery of this treatment. β-NGF binds to tropomyosin receptor kinase A (TrkA) and low-affinity NGF receptor (LNGFR), a tumour necrosis factor receptor (TNFR) superfamily member. Given that TNFR superfamily member shedding regulates inflammation and immunity, soluble LNGFR (sLNGFR) shedding might be important in pain regulation[3] and association between these molecules and OA-related knee pain may point to an alternative, less harmful approach to β-NGF antagonism and pain reduction.

Objectives: Therefore, we investigated the association between (synovial fluid) SF levels of soluble LNGFR, TrkA, proNGF and NGF and other relevant neurotrophins with OA-related knee pain. Key cytokines involved in TNFR family receptor shedding were also investigated.

Methods: SF was procured from 42 subjects with severe OA at the time of arthroplasty. VAS pain scores were recorded pre-operatively. In-house developed ELISAs, commercial ELISAs and LEGENDplex™ were used to measure sLNGFR, TrkA, proNGF, β–NGF, other neurotrophins and cytokines including TNF-α. Statistical analysis was implemented using Graphpad Prism software, version 9.0. Data normality was analysed using Kolmogorov-Smirnov and Shapiro-Wilk testing. The Spearman rank correlation test and multivariate linear regression analyses were performed to assess the correlations. Statistical significance was defined as $p<0.05$.

Results: VAS pain score positively correlated with β–NGF ($r=0.34$, $p<0.05$) and TrkA ($r=0.33$, $p<0.05$, $r=0.32$, $p>0.05$). There was a positive association trend with NT-3 and BDNF with a negative trend for ProNGF. sLNGFR. The β–NGF/TrkA ratio showed a strong positive correlation with VAS ($r=0.80$, $p<0.001$). However, there was no correlation between pain and the β–NGF/sLNGFR ratio ($r=-0.08$, $p>0.05$). TNF-α positively correlated with β–NGF ($r= 0.83$, $p<0.001$), NT-3 ($r= 0.66$, $p<0.01$), and BDNF ($r= 0.50$, $p<0.05$) and negatively with ProNGF ($r= -0.74$, $p<0.01$). Additionally, TNF-α positively correlated with TrkA ($r=0.62$, $p>0.05$) and sLNGFR ($r=0.26$, $p>0.05$).

Conclusion: Our results align well with the previously-proposed β–NGF pain molecular pathway and suggest that inflammation-related endogenous cleavage of sLNGFR, but not TrkA may modulate pain *in vivo* in OA as sLNGFR act as sink of the endogenous NGF. These novel findings may provide new avenues for safe and effective pain reduction strategies in OA.

POS0405 TREATMENT WITH INTEGRIN A10B1-SELECTED MESENCHYMAL STEM CELLS ALLEVIATES POST-TRAUMATIC OSTEOARTHRITIS DEVELOPMENT IN AN EQUINE MODEL

Keywords: Osteoarthritis, Disease-modifying drugs (DMARDs), Animal models

C. Andersen[1,2], S. Jacobsen[2], K. Uvebrant[1], J. Griffin IV[3], L. Vonk[1,4], M. Walters[2], L. Berg[2], E. Lundgren-Åkerlund[1], C. Lindegaard[2]. *[1]Xintela AB, Research, Lund, Sweden; [2]University of Copenhagen, Veterinary Clinical Sciences, Faculty of Health and Medical Sciences, Taastrup, Denmark; [3]Texas A&M University, Large Animal Clinical Sciences, College Station, United States of America; [4]University Medical Center Utrecht, Orthopaedics, Utrecht, Netherlands*

Background: Mesenchymal stem cells (MSCs) have gained much attention for their potential to treat osteoarthritis (OA) due to their regenerative and immunomodulatory properties. So far, studies have shown varying results, potentially due to variations in the MSC preparations. Previously it was shown that integrin $\alpha 10\beta 1$-selected equine MSCs (integrin α10-MSCs) decrease cartilage degradation and bone sclerosis in an experimental equine post-traumatic OA model[1], and that integrin $\alpha 10\beta 1$-selected human MSCs could to home to experimental cartilage defects in rabbit knees and directly participate in new cartilage formation[2].
Objectives: This study investigated disease modifying effects of integrin $\alpha 10\beta 1$-selected MSCs in terms of joint function, cartilage structure and immunomodulation in an experimental equine post-traumatic OA model.
Methods: This was a non-randomized and partially blinded experimental study including 17 Standardbred trotters. OA was induced using the carpal osteochondral fragment model. On day 18 after surgery, the treatment-group (n = 8, all females) received $20x10^6$ allogeneic adipose tissue-derived integrin α10-MSCs from a male equine donor. The control group was left untreated (n = 9). From day 14 after surgery and until study termination on day 70, the horses underwent weekly joint and lameness examinations (AAEP score and flexion tests) and synovial fluid collection. After euthanasia, the carpi were evaluated by computed tomography (CT), magnetic resonance imaging (MRI), macroscopic pathology and histology evaluation. MSCs were traced through PCR detection of the Y-chromosome in the cell pellet from the synovial fluid samples and in tissue samples from cartilage, synovial membrane, and subchondral bone from the osteochondral fragment site, collected postmortem.
Results: A significant improvement of lameness scores (p=0.02) and response to flexion (p=0.004) over time was observed in the treatment group, while the untreated group had no change in lameness and a smaller decrease in flexion response (p=0.03). No joint flares were seen after MSC treatment. The integrin α10-MSCs treated horses had significantly less macroscopic cartilage pathology (p=0.019), lower cartilage histology score (p=0.037) and showed a better but not statistically significant (p=0.069) healing of the osteochondral fragment on CT. Prostaglandin E2 (PGE2) and interleukin-10 (IL-10) were significantly increased in the synovial fluid of the treated group on day 21 (p=0.018 and p=0.035, resp) and on day 28 (p=0.0606 and p=0.042, resp) compared to day 18. Interleukin-6 (IL-6) showed a non-significant increase in the treated group on day 21 (p=0.085). MSCs were detected in the synovial fluid of the treated horses on day 21 (n=8), day 28 (n=1) and day 35 (n=2) and in the cartilage/subchondral bone (n=7) at study termination (day 70), which was 52 days after integrin α10-MSC treatment.
Conclusion: Intra-articular injection of integrin α10-MSCs is safe, alleviates the development of pathological changes in the joint and improves joint function in an equine post-traumatic OA model. In addition, integrin α10-MSCs were still present in the joint 52 days after treatment. This suggests that that integrin α10-MSCs hold potential to be a disease modifying treatment of OA.

POS0406 INCREASE OF CARTILAGE REGENERATION BY IFN-Γ IN CARTILAGE INJURY MOUSE MODEL

Keywords: Cartilage

H. A. Kim[1], J. R. Kim[1]. *[1]Hallym University Sacred Heart Hospital, Internal Medicine, Anyang, Korea, Rep. of (South Korea)*

Background: Until now, there was no effective cure for cartilage injury and degeneration commonly occurring in joint injury and OA. The efficiency of cartilage regeneration in young people is generally considered higher than in the elderly.
Objectives: In this study we investigated candidate genes associated with cartilage regeneration in knee joints of young and adult mice using a full-thickness cartilage injury (FTCI) mouse model.
Methods: Young (3 week-old) and adult mice (9 week-old) were subjected to FTCI and cartilage was harvested at 3, 7, and 14 days after FTCI. Cartilage regeneration was evaluated with safranin O staining and immunohistochemistry. For discovery of novel genes associated with cartilage regeneration, RNA-seq analysis was performed. For differentiation into chondrocytes, ATDC5 cells were monolayer and 3D cultured in DMEM containing insulin-transferrin-selenium (ITS) for 7 and 14 days. Chondrocyte specific IFN- γ receptor 1 knock out mice were created to examine the influence of IFN signaling in cartilage repair.
Results: Cartilage regeneration significantly increased in damaged region of FTCI in young mice compared with that of adult mice at 7 and 14 days. Gene expression profiles of cartilage from young and adult mice of 3 day (damaged stage) and 14 day (repair stage) after FTCI were examined by RNA-seq analysis. A total of 1115 (448 up- and 667 down-regulated) and 2294 (726 up- and 1568 down-regulated) differentially expressed genes (DEGs) were identified in young mice compared with adult mice at 3 and 14 days after FTCI, respectively. Gene ontology (GO) analysis revealed that genes responsible for interferon gamma (IFN-γ) and innate immune response, and cell proliferation, cell-substrate adhesion, and wound response were significantly up-regulated in the young mice at 3 and 14 days after FTCI, respectively. In particular, our data using monolayer and micromass culture of ATDC5 cells showed that blockade of IFN-γ signal by small interference RNA (si-IFN-γ receptor) suppressed synthesis of anabolic factors, including ACAN and Col II, along with decreased chondrogenic differentiation of ATDC5 cells, whereas treatment with IFN-γ (20 ng/ml) up-regulated synthesis of anabolic factors and chondrogenic differentiation. Cartilage repair score after FTCI was significantly worse in chondrocyte specific IFN- γ receptor 1 knock out mice compared to WT.

Conclusion: IFN-γ signaling may play a critical role in the process of cartilage regeneration.

POS0407 CHEMICALLY AND MECHANICALLY ACTIVATED PIEZO1 LEADS TO CHANGES IN THE EXPRESSION OF ECM-MODULATING FACTORS THAT DIFFER BETWEEN HEALTHY AND HUMAN OA CHONDROCYTES

Keywords: Cell biology, Cartilage, Osteoarthritis

B. Lohberger[1], B. Steinecker-Frohnwieser[2], V. Glanz[3], S. Toegel[4], L. Weigl[3]. *[1]Department of Orthopaedics and Traumatology, Medical University of Graz, Graz, Austria, Department of Orthopaedics and Traumatology, Graz, Austria; [2]Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Department for Rehabilitation, Saalfelden, Austria; [3]Department of Special Anesthesia & Pain Therapy, Medical University of Vienna, Department of Special Anesthesia & Pain Therapy, Vienna, Austria; [4]Department of Orthopedics and Trauma-Surgery, Medical University of Vienna, Department of Orthopedics and Trauma-Surgery, Vienna, Austria*

Background: Osteoarthritis (OA) is the most common degenerative joint disease that causes functional limitations in addition to pain and has become a major global health problem in recent decades. Meta-analysis of studies on patients with knee OA showed that physical exercise can function as a clinically relevant, effective intervention and non-drug treatment for reducing pain and improving physical activity in patients with OA [1]. In chondrocytes, the perception and transduction of mechanical signals leading to changes in $[Ca^{2+}]_i$ is orchestrated by mechanosensitive ion channels [2].

Objectives: Piezo1 represents a mechanosensitive cation channel (MSC) that allows Ca^{2+} influx in chondrocytes and acts as an important mechanotransducer that senses deleterious mechanical stresses (high strains) [3]. Numerous studies have shown that Ca^{2+} regulation in conjunction with mechanical stimulation is crucial for the behaviour and function of chondrocytes and the balanced assembly of the ECM. The underlying mechanism could influence the expression profile as a consequence of mechanical stimulation. Differences in this regard between primary human chondrocytes isolated from knees of OA patients (pCHOA) and healthy chondrocytes could explain the altered sensitivity to mechanical stimuli in OA.

Methods: Mechanical stimulation of chondrocytes was performed by the use of the flexcell system whereas in parallel cells were chemically activated via different concentrations of the Piezo agonist Yoda1. Changes in expression were analysed by qPCR for metalloproteinases (MMP1, 3,13), inflammatory cytokines (IL6, IL8, IL4) and ECM relevant components (Col-I, Col-II, BMP2). The decreased expression of Yoda1 by siRNA knockdown was used to more clearly map the effect of MSC on ECM under mechanical stimulation.

Results: Chondrocytes responded to flexcell tension stimulation with decreased expression of MMP3 and IL6, whereas application of Yoda1 resulted in an opposite effect. In healthy chondrocytes the MMP expression was more enhanced than in OA chondrocytes whereas in both cell types the same reduction for TIMP-2 through the activation of Piezo1 was detected. Yoda1 increased IL6 and IL8 expression while IL4 was reduced. The knock-out of Piezo1 can partially reverse these effects.

Conclusion: Performing expression studies in the context of mechanical stimulation and targeting Piezo1 in OA and healthy chondrocytes may reveal OA-specific changes in mechanisms of mechanical signal transduction. Furthermore, this may provide further insight into the extent to which OA cells exhibit differential sensitization to mechanical signals.

Background: Aging is a main risk factor of many major human diseases, including Osteoarthritis (OA). Compromised autophagy, a hallmark of aging, is involved in joint aging and OA and its activation protects against joint damage and disease. However, targets underlying this defective mechanism are still unknown.

Objectives: *Here, we aimed to identify targets regulating autophagy* with potential clinical relevance in joint aging and OA.

Methods: We performed a quantitative proteomic analysis of defective autophagy by Atg5 knockdown in human OA chondrocytes by using iTRAQ (isobaric tags for relative and absolute quantitation) labeling coupled LC/MS/MS. Protein identification and quantification were performed using Protein Pilot Software v 4.0. Each MS/MS spectrum was searched in the Uniprot/Swissprot database for *Homo sapiens*. Human cartilage and chondrocytes from healthy, aging and OA subjects were employed to investigate the role of Lamin A/C in aging and disease by western blot, and inmunohistochemistry. To test the relevance of Lamin A/C accumulation in joint tissues, a mutant mice model of accelerated aging by genetic deletion of Zinc Metalloproteinase STE24 (*Zmpste24*$^{-/-}$) was employed. The functional consequences of Lamin A/C accumulation on macroautophagy, inflammation, and senescence were determined in human chondrocytes. To evaluate the therapeutic effect of regulating Lamin A/C in human chondrocytes, Lonafarnib, an FDA approved drug for Progeria Syndrome, acting as Lamin A/C accumulation inhibitor, was employed.

Results: 24 out of 487 proteins were significantly altered ($p<0.05$) in response to defective autophagy. Cytoskeleton organization, collagen catabolism, oxidative stress, and aging pathways were affected. Interestingly, Lamin A/C, a nuclear envelope protein implicated in cell senescence and aging, was found upregulated under defective autophagy. Increased Lamin A/C expression was found in human chondrocytes with reduced macroautophagy. Furthermore, increased Lamin A/C expression is found in aging and OA human cartilage. Importantly, *Zmpste24* KO mice showed bone damage and intervertebral disc degeneration (IDD), suggesting that Lamin A/C accumulation associated to deficient autophagy is correlated with aging and OA phenotype. Human chondrocyte premature aging by genetic knockdown of *Zmpste24*, lead to Lamin A/C accumulation, accompanied by a reduction of macroautophagy by *MAP1LC3B* downregulation, increased inflammation, cartilage degradation and senescence represented by upregulation of *NFKB/RELA, MMP13, CDKN1A and CDKN1A* respectively. Remarkably, inhibition of Lamin A/C accumulation by Lonafarnib upregulates macroautophagy and protects against inflammation, cartilage degradation and chondrocyte senescence.

Conclusion: The results suggest that increased LMNA due to autophagy defects compromises chondrocyte homeostasis and joint integrity, potentially contributing to systemic maladaptation that occurs in aging. Therefore, targeting Lamin A/C might be a promising strategy to develop novel therapeutics for cartilage aging and OA.

POS0409 IMPLICATION OF GLYPICANS AND NOTUM IN BONE MARROW MESENCHYMAL STROMAL CELLS DURING OSTEOGENIC DIFFERENTIATION IN OSTEOARTHRITIC DISEASE

Keywords: Bone diseases, Cell biology, Osteoarthritis

I. González-Guede[1], M. López-Ramos[1], L. Rodriguez Rodriguez[1], L. Abasolo[1], B. Fernandez[1]. *[1]Fundación para la Investigación Biomédica del Hospital Clínico San Carlos (IDISCC), UGC de Reumatología, Madrid, Spain*

Background: Osteoarthritis (OA) is accompanied by an excessive formation of underlying bone caused by homeostatic alterations. It has been described that in OA joints there is an up-regulation of the WNT/β-catenine pathway driving to the differentiation of Mesenchymal Stromal Cells (MSCs) into osteocytes [1]. Glypicans 1-6 act as co-receptors of WNT pathway, improving interactions between molecules [2]. On the other hand, NOTUM plays a role as a negative regulator of the pathway preventing WNT binding to its receptors and favouring the soluble form of Glypicans [3]. All these evidences lead us to think about the importance of Glypicans 1-6 and NOTUM in the osteogenic differentiation of MSCs in OA disease.
Objectives: To determine the differences at gene and protein levels of Glypicans 1-6 and NOTUM in MSCs between OA patients and controls at baseline and during induced *in vitro* osteogenic differentiation.
Methods: Bone Marrow Mesenchymal Stromal Cells (BM-MSCs) from both, 8 OA patients and 8 healthy donors were isolated from BM samples. BM samples were obtained by joint replacement and traumatic fractures. BM-MSCs were cultured during 21 days with normal culture medium and with osteogenic inducing medium. Cells and supernatant were recovered at 1, 7, 14 and 21 days. Protein levels were determined by ELISA in cells supernatant. Extraction and purification of RNA from cells and cDNA synthesis were performed. Glypicans 1-6 and NOTUM gene-expression was analysed by qPCR and normalized with housekeeping genes β-actin and RNA18S. The data were calculated with the method of fold change ($2^{-\Delta\Delta Ct}$). Statical analysis were performed with GraphPad Prism 8.0. For the detection of outliers, the ROUT method (Q=1%) was used. Data were analyzed using t-test.
Results: The mRNA levels of cells with normal culture medium were up-regulated in GPC6 (t=7d; p=0,016) in OA patients. During osteogenic differentiation, was observed a statistically significant up-regulation in levels of OA patients vs controls of GPC2 (t=14d; p=0,034), GPC4 (t=14d, p=0,025; t=21d, p=0,017), GPC5 (t=14d, p=0,007), GPC6 (t=14d, p=0,013) and *NOTUM* (t=14d, p=0,009) and down-regulation of GPC3 (t=7d, p=0,034). In addition, protein levels of NOTUM were lower compared to the control group in OA BM-MSCs (t=1d, p=0,049) and in the differentiation to osteocytes (t=1d, p=0,049; t=7d, p=0,043; t=14d, p=0,016). GPC3 levels were higher OA patients in all the times and in the two conditions (p < 0,0001). In the differentiation, GPC2 were lower (t=7d, p< 0,0001). GPC1, GPC4 and GPC6 were not present in any case.
Conclusion: Our results evidence a dysregulation in the glypicans in BM-MSCs of OA patients and, specially, during osteogenic differentiation. NOTUM, extracellular negative regulator of the WNT/β-catenine signaling pathway, is decreased at protein level in OA patients, despite the fact that gene expression is elevated. Thus, our data confirm the differences in expression in NOTUM and Glypicans between OA patients and healthy controls. Further studies are needed proposing these molecules, specially NOTUM, as an effective treatment of the disease.

Background: Knee osteoarthritis (KOA) is a heterogenous disease, meaning individuals can present with various signs and symptoms related to different biopsychosocial (BPS) factors [1,2]. Several phenotypes can as such be expected. Phenotyping KOA patients, specifically those awaiting total knee arthroplasty (TKA), could be relevant, because a substantial part of patients (20%) reports chronic post-TKA pain [3]. Various preoperative phenotypic factors related to domains of the BPS model have been described, but consensus and a classification of patients based on these factors is still lacking [4–7].
Objectives: The aim of this exploratory study is to identify phenotypes based on BPS related factors in KOA patients awaiting TKA.
Methods: Participants were included if they were diagnosed with KOA and waiting for TKA surgery in one of the four participating hospitals in Belgium and the Netherlands. A cross-sectional latent profile analysis was conducted in MPlus [8] containing the grade of KOA before TKA surgery (structural variable); body mass index and glycated hemoglobin value (metabolic variables); isometric strength of m. Quadriceps and m. Hamstrings of the affected leg, proprioceptive accuracy of the affected leg, and physical function (functional variables); pain intensity scores and symptoms related to altered somatosensory processing (pain-related variables); pain catastrophizing, depression, anxiety symptoms, expectations and satisfaction (psychological variables); and work and education level (social variables). Data were checked for multicollinearity and multivariate outliers. The ideal model was chosen based on qualitative evaluation, goodness of fit and classification uncertainty.
Results: 224 participants were included of which 109 women (65.19 +/- 8.18 years old) and 108 men (66.92 +/- 7.18 years old). A model with 2 phenotypes was found to be most appropriate. Both phenotypes differed in 13 out of 19 continuous variables. Phenotype 1 (72% of all participants) was characterized by scoring better on at least one of all metabolic, functional, psychological and pain-related continuous variables compared to phenotype 2 (28% of all participants), except for glycated hemoglobin value, proprioception, expectations, and widespread temporal summation and conditioned pain modulation (part of somatosensory processing variables). Concerning categorical variables, phenotype 1 (72%) was characterized by having a lower probability to have a Kellgren & Lawrence (K&L) scale 2 compared with patients in phenotype 2 (28%). The probabilities of the other categorical variables did not differ between the two phenotypes.
Conclusion: A model with 2 phenotypes in KOA patients awaiting TKA appeared the most appropriate, which confirmed the existence of a group that experiences disturbed somatosensory processing signs in combination with worse results on psychological (pain catastrophizing, fear and depression), functional (strength and physical function), structural (higher possibility to have a K&L grade 2 compared to the other phenotype) and metabolic factors (body mass index), and a group that does not present this disruption in combination with better results on the aforementioned BPS factors. Further research is necessary and should also investigate if different phenotypes react differently regarding treatment outcome after TKA.

PROFILING THE HISTONE LANDSCAPE IN OSTEOARTHRITIS: ENRICHMENT OF HISTONE VARIANT H3.3 AND ITS ASSOCIATED POST-TRANSLATIONAL MODIFICATIONS

Keywords: Genetics/Epigenetics, Osteoarthritis, Cartilage

C. Núñez Carro[1], V. Calamia[2], P. Fernández Puente[3], M. Blanco-Blanco[1], P. Quaranta Díaz[2], T. Hermida Gómez[3,4], C. Ruiz-Romero[2,4], F. J. Blanco[5], M. C. De Andres[1]. *[1]Instituto de Investigación Biomédica de A Coruña, Unidad de Epigenética - Grupo de Investigación de Reumatología (GIR), A Coruña, Spain; [2]Instituto de Investigación Biomédica de A Coruña, Unidad de Proteómica - Grupo de Investigación de Reumatología (GIR), A Coruña, Spain; [3]Centro de Investigaciones Científicas Avanzadas (CICA), Universidad de A Coruña (UDC), A Coruña, Spain; [4]Centro de Investigación Biomédica en Red de Bioingeniería, Biomateriales y Nanomedicina, CIBER-BBN, Madrid, Spain; [5]Grupo de Investigación de Reumatología y Salud (GIR-S), Departamento de Fisioterapia, Medicina y Ciencias Biomédicas, Facultad de Fisioterapia, Universidade da Coruña (UDC), A Coruña, Spain*

Background: Nucleosomes, the basic structural unit of chromatin, are composed of DNA wrapped around an octameric core of histone proteins. The latter is usually comprised by canonical histones H2A, H2B, H3 and H4[1]. These can be replaced by histone variants, which provide structural and functional changes to the nucleosome[2]. Histones are prone to undergo post-translational modifications (PTMs) that can modify chromatin conformation to induce changes in gene expression[3]. Recent evidence supports that epigenetic mechanisms, such as DNA methylation and non-coding RNA modifications, are involved in the pathogenesis of osteoarthritis (OA). Nevertheless, histone modifications mainly remain an unexplored epigenetic mechanism in OA.
Objectives: The aim of the present study was to identify, characterize and compare the histone profile in human articular cartilage samples from normal (N) and OA patients to provide novel insights into the role of histones in the development of OA.
Methods: Histones were extracted from 3 N and 3 OA cartilage samples following a protocol based on acid extraction previously described by our group. Prior to mass spectrometry (MS) analysis, samples were reduced with dithiothreitol and alkylated with iodoacetamide. After an overnight digestion with trypsin, peptides were desalted via StageTips. Samples were injected on a nanoElute LC coupled to a high-resolution timsTOF (Bruker). Peptides were analyzed in DDA mode with PASEF enabled. Raw data were processed using PEAKS Studio 10.6. software against the Human UniProtKB/Swiss-Prot database. Search parameters were: trypsin digestion, one missed cleavage allowed, 15.0 ppm parent mass tolerance, 0.05 Da fragment mass tolerance and carbamidomethylation as fixed modification. To identify and quantify the most studied biological modifications, "PTM" and "Label-free" modules from PEAKS were employed.
Results: Our histone extraction protocol successfully enriched the samples for subsequent MS analysis. The most detected PTMs are among the most studied, including methylation, acetylation, ubiquitination, phosphorylation, deamidation, biotinylation, citrullination, and ADP-ribosylation. PTMs were found in core histones H2A, H2B, H3, H4 and linker histone H1. Moreover, PTMs were detected in some of their variants. Strikingly, we found that the histone variant H3.3 is significantly increased in OA cartilage compared to N cartilage (2.67×104 ± 9.56×103 vs. 3.11×103 ± 1.71×103) (Figure 1 A). Further H3.3 analysis showed three differentially abundant PTMs between OA and N (Figure 1 B). Acetylation of lysine 18 (K18ac) was more abundant in N cartilage. Monomethylation of K79 (K79me1) was upregulated in OA samples. Likewise, dimethylation of K36 (K36me2) was also more abundant in OA cartilage.
Conclusion: The histone variant H3.3, which associates with decondensed states of chromatin and transcriptionally active sites, is upregulated in human OA cartilage. Furthermore, we identified three H3.3-associated PTMs that are differentially expressed in OA and N cartilage. These data provide new insights into the epigenetic landscape of OA and could contribute to the search for novel therapeutic targets to treat the disease.

INTRA-ARTICULAR INJECTION OF STIGMASTEROL LOADED NANOPARTICLES IS EFFECTIVE IN INHIBITING JOINTS DESTRUCTION IN OSTEOARTHRITIS RAT MODEL

Keywords: Animal models, Osteoarthritis, Cartilage

J. H. Jung[1], B. Y. Kim[2], S. W. Nam[3]. *[1]Korea University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of (South Korea); [2]Gangneung Asan Hospital, Internal Medicine, Gangneung, Korea, Rep. of (South Korea); [3]Yonsei University Wonju College of Medicine, Internal Medicine, Wonju, Korea, Rep. of (South Korea)*

Background: Stigmasterol is the most abundant plant sterols and its chemical structure is very close to cholesterol. Stigmaterol inhibits pro-inflammatory and matrix degradative mediators typically involved in cartilage degradation through inhibition of the nuclear factor kappa-B (NF-κB) pathway and attenuates chondrocyte injury induced by interleukin-1β (IL-1β). Mesoporous silica nanomaterials (MSNs) have been proven to be promising nanoparticles due to their superior loading capability, multitudinous functionalization, and biocompatibility. Since

osteoarthritis (OA) is mainly developed in weight bearing or overused joints, the locally sustained therapy using nanoparticles is effective for targeting inflammatory component of OA.

Objectives: This study aimed to investigate the effects of intra-articular injection of rebamipide loaded MSNs in OA rat model.

Methods: We modified the surface of MSNs using tannic acid and anchor the stigmasterol that allow the sustained release of stigmasterol from nanoparticles. In vitro, lipopolysaccharide induced RAW cell were used to investigate the cytotoxicity and anti-inflammatory effect of stigmasterol-loaded MSNs. In vivo, monosodium iodoacetate (MIA)-induced OA rats were divided into five groups, consisting of healthy control rats and rats injected with MIA alone or in combination with MSNs, stigmasterol (10 μg)/MSNs, stigmasterol (50 μg)/MSNs. The levels of IL-6, matrix metalloproteinase-3 (MMP-3), and tumor necrosis factor- α (TNF-α) measured periodically and the micro-computed tomography (CT) and histological examination was performed at eight week.

Results: In vitro, stigmasterol/MSNs dose-dependently suppressed the levels of pro-inflammatory mediators, including IL-6, MMP-3 and TNF-α. In vivo, the levels of pro-inflammatory components most markedly decreased in the intra-articularly injected stigmasterol (50 μg)/MSNs group compared to other groups. Micro-CT images and histological evaluations showed that the intra-articular injection of stigmasterol/MSNs also inhibited cartilage degeneration dose-dependently.

Conclusion: Using a chemically induced rat model of OA, intra-articular delivery of stigmasterol was associated with decreased local and systemic inflammatory response decreased joint degradation and arthritic progression.

POS0413 SEX DIFFERENCES IN A MURINE MODEL OF OSTEOARTHRITIS

Keywords: Pain, Osteoarthritis, Animal models

S. Bharde[1], S. Caxaria[1], P. Celik[1], S. Sikandar[1]. *[1]William Harvey Research Institute, Experimental Medicine and Rheumatology, London, United Kingdom*

Background: Pain is the leading cause of disability in osteoarthritis (OA), but the correlations between structural changes of the joint and functional changes in pain-related outcomes remains poorly understood. Animal models of OA have poor translational outputs to improve pain management in OA[1,2]. Moreover, several studies demonstrate a higher prevalence of chronic pain in the female OA population[3,4] and sex differences that can give rise to distinct pain mechanisms in male and female rodents with OA[5].

Objectives: We aim to define the translational value of a murine model of surgically-induced OA with meniscal/ligamentous injury (MLI), in terms of the progressive nature of joint degeneration, temporal delay in development of chronic pain following joint damage and potential sex differences.

Methods: *Model*: OA was induced in 10-week-old C57BL/6J mice under isoflurane anaesthesia with resection of the medial collateral ligament (MCL), meniscotibial ligament and removal of the medial meniscus. *Behaviour*: Sensory thresholds were assessed using the up-down von Frey, hindlimb capacitance, Hargreaves', hotplate and dry ice tests. Affective behaviours were measured using hotplate and open field assay. *In vivo electrophysiology*: Extracellular recordings of L4 dorsal horn neurones was performed in anesthetised mice. Mechanically and thermally evoked action potentials were quantified. *MicroCT*: Bone mineral density was measured along the growth plate and BoneJ was used for microarchitecture analysis to determine 3D geometric parameters. *Histological OA scoring and immunohistochemistry*: Coronal sequential paraffin sections were stained with Safranin-O for OA severity scoring using the Osteoarthritis Research Society International grading system. Additional knee sections were stained for neo-innervation using anti-PGP9.5. *RNASeq:* RNA was extracted from L3-L5 ipsilateral DRGs and differentially expressed transcripts generated by GeneWiz.

Results: We observed progressive development of persistent mechanical and cold hypersensitivity in MLI mice compared to Sham controls. We also observed contralateral hypersensitivity, indicative of nociplastic pain. Female mice expressed an earlier onset and greater extent of hypersensitivity compared to male mice. The temporal delay in the expression of hindlimb hypersensitivity correlates with a loss of cartilage integrity measured by OARSI scoring of the knee joint in both males and females. Affective behaviours are also correlated with changes in sensory thresholds, indicating emotional processing of nociceptive inputs form the injured knee. We observed greater PGP9.5 staining in female MLI mice and key transcriptional changes in DRG neurons.

Conclusion: Our data demonstrates that the MLI model reproduces clinical features of nociplastic pain and cartilage loss in OA. We identify structural changes in the knee joint that correlate with pain behaviour, as well as sex differences in knee innervation, transcriptomic profiles of primary sensory neurons and pain behaviour that is exacerbated in female mice, informing on sex specific pain mechanisms. This establishes the use of MLI surgery as a clinically relevant mouse model for OA pain.

POS0414 ASSOCIATIONS BETWEEN BONE MARROW ADIPOCYTE SIZE, BONE REMODELLING AND BODY MASS INDEX IN PATIENTS WITH BASE OF THE THUMB OSTEOARTHRITIS

Keywords: Bone diseases, Osteoarthritis, Descriptive studies

M. Maniglio[1], L. Loisay[2], T. Hügle[2], J. Geurts[2]. *[1]Lausanne University Hospital, Plastic and Hand Surgery, Lausanne, Switzerland; [2]Lausanne University Hospital, Rheumatology, Lausanne, Switzerland*

Background: Subchondral bone sclerosis, osteophyte formation and bone marrow lesions are radiographic hallmarks of base of the thumb osteoarthritis (CMC-1 OA)[1]. High body mass index (BMI) and obesity are major risk factors for CMC-1 OA [2]. Adipose tissue-derived systemic factors, such as lipids and adipokines, have been proposed as mediators of such increased risk at a non-weight bearing joint. In support of this hypothesis, alterations in systemic lipid levels have been found to partially associate with the severity of hand OA [3]. It

is unknown whether subchondral marrow adipose tissue contributes to development and progression of CMC-1 OA.
Objectives: To determine whether bone marrow adipocyte (BMAd) size, as a surrogate marker of adipocyte lipolysis and (dys)function, differed as a function of the extent of subchondral bone remodelling and BMI in CMC-1 OA.
Methods: Trapezium bone resections were harvested from 14 consecutive CMC-1 OA patients (9 female, 63±11 years, 26±6 kg/m^2) undergoing arthroplasty. BMAd size, osteoblast numbers and OA severity were determined by histomorphometry. Expression of the lipolytic enzyme monoacylglycerol lipase (MGLL) on bone marrow-resident cells was assessed by immunohistochemistry.
Results: Eight out of fourteen specimens displayed regions of increased bone remodelling and osteoblast numbers, which were classified by histology as subchondral sclerosis (n=6) and central osteophyte formation (n=2). BMAd size was significantly reduced (p=0.02) in the remodelling (839±319 µm^2) compared with non-remodelling regions (1438±578 µm^2), independent of OA severity. BMAd size was positively correlated with BMI (r=0.63, p=0.03), but in non-remodelling regions only. MGLL was differentially expressed both in terms of quantity and cell type in non-remodelling and remodelling regions (Figure 1). Surprisingly, MGLL was strongly expressed by osteoblasts and blood vessels rather than mature BMAd in remodelling regions.
Conclusion: Collectively, these data suggest that BMAd properties in the CMC-1 joint may be BMI-dependent. Increased lipolytic activity in subchondral bone marrow adipose tissue may be fueling pathologic bone formation in CMC-1 OA.

POS0415 **ADIPOCYTE-OSTEOBLAST CROSSTALK IN SUBCHONDRAL BONE MARROW: NEW THERAPEUTIC TARGET IN OSTEOARTHRITIS**

Keywords: Bone diseases, Biomarkers, Osteoarthritis

L. Loisay[1], A. Antoniadis[2], T. Hügle[1], J. Geurts[1]. [1]*Lausanne University Hospital, Rheumatology, Lausanne, Switzerland;* [2]*Lausanne University Hospital, Orthopaedics and Traumatology, Lausanne, Switzerland*

Background: Subchondral sclerosis and bone marrow adipose tissue (BMAT) lesions are radiographic hallmarks of knee osteoarthritis (OA). Energy supply through lipolysis of bone marrow adipocytes (BMAd) has recently been established as a crucial mechanism to fuel bone regeneration and maintain bone mass during energy deficits. It is unknown whether subchondral BMAd may contribute to subchondral sclerosis in OA through a similar mechanism.
Objectives: The goal of this study was to determine whether BMAd-derived factors differed as a function of the extent of subchondral sclerosis and to evaluate effects of lipolysis-modulating treatments in a human knee OA explant model.
Methods: Non-sclerotic (NS) and sclerotic (SC) osteochondral tissue chips (n=48 each) were explanted from tibial plateaus and treated with an activator (forskolin) or inhibitor (pioglitazone, metformin) of lipolysis. Secreted free fatty acids (FFA), triglycerides (TGL), adiponectin, IL-6 and ALP activity were measured in supernatants.
Results: Adiponectin (1.6-fold), TGL (1.7-fold) and ALP activity (6.7-fold) levels were increased in SC compared with donor-matched NS tissues (p<0.05). Interestingly, FFA (r=0.60) and adiponectin (r=0.76) were positively correlated with ALP activity (p<0.01) in SC tissues only (Figure 1). Modulation of lipolysis affected secretion of FFA and TGL (p<0.01), but not adiponectin, in NS tissues only. ALP activity remained unaffected by any treatment in NS or SC tissues. Metformin treatment reduced IL-6 secretion 4-fold (p<0.05) in SC tissues.
Conclusion: Collectively these data support the new paradigm that BMAd-derived factors may play a previously unrecognized role in regulating pathological bone remodelling in human OA.

Medicine and Rheumatology, Zürich, Switzerland; [4]Balgrist University Hospital, Department of Radiology, Zurich, Switzerland; [5]Balgrist University Hospital, Department of Orthopedics, Zurich, Switzerland; [6]University of Zurich, Center of Experimental Rheumatology, Zurich, Switzerland; [7]University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland

Background: Modic changes (MC) are painful vertebral bone marrow lesions and are often found in patients with chronic low back pain. The adjacent intervertebral disc (IVD) seems to play an important role: the rapidly degrading disc stands in an inflammatory cross-talk with the MC bone marrow and MC develop almost always simultaneously cranial and caudal to a degenerated IVDs. Few studies have investigated expression of inflammatory cytokines and proteases expressed by IVD cells adjacent to MC, however, how this affects the ECM degeneration has not been determined.
Objectives: The aim of this study was to identify MC-specific mechanisms in degenerated discs. We hypothesize that the 'Modic discs' have a distinct disc matrix degradome.
Methods: Degenerated lumbar IVDs from MC1 (n=26), MC2 (n=20) and non-MC (n=19) levels from gender and age matched patients undergoing spinal fusion surgery were collected. Degradome was measured with N-terminal amine isotopic labeling of substrates (TAILS) liquid chromatography tandem mass spectrometry (LC-MS/MS). TAILS allows to identify degraded proteins by detecting de novo N-terminal peptides. Sequence motifs were calculated using TwoSample Logo web application to identify significantly enriched amino acids around the cleavage site of the top 50 upregulated peptides. Since proteases have preferences for amino acid sequences, different sequence motifs can indicate activity of different proteases. Proteases were matched to cleavage sites of the top 50 enriched MC1 and MC2 peptides using TopFINDer database.
Results: Mean degree of disc degeneration as measured by Pfirrmann grade was not significantly different between all groups (MC1: 3.8 ± 0.9, MC2: 4.2 ± 0.6, non-MC: 3.6 ± 0.8). A total of 487 (MC1), 419 (MC2), and 404 (non-MC) different protein fragments were detected of which 21.0%, 12.2% and 9.4% were unique to MC1, MC2, and non-MC, respectively (Figure 1a). Comparing MC1 to non-MC discs, the degradome was more complex with a variety of ECM fragments enriched (e.g. type II collagen, fibrinogen), while fragments of type I collagen, clusterin, and fibronectin were depleted (Figure 1b). In MC2 discs, mainly fibronectin and clusterin were enriched, while type I collagen was depleted (Figure 1b). Sequence motifs show unique cleavage preferences for each group (Figure 1c) indicating activity of different proteases in MC1 and MC2 discs. TopFinder identified neutrophil elastase as an important protease in all groups targeting cleavage of different proteins. In MC1 and MC2 IVDs kallikrein 3 as well as MMP9 and MMP2 are associated with found cleavage products. Finally, in MC1 TopFINDer uniquely identifies multiple fragments created by MMP2, MMP7, MMP12, MMP13 or cathepsin B.
Conclusion: MC1, MC2 and non-MC discs have different ECM degradomes that may be caused by the activity of different proteases. Differences in disc degeneration mechanisms and in the type and amount of bioactive ECM fragments explain why not all degenerating discs lead to adjacent MCs.

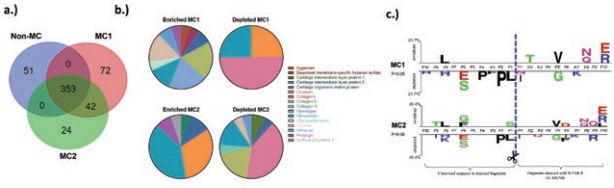

Fig. 1: a.) Number of peptides identified in each group b.) Respective proteins of which the 50 most enriched peptides (left) and 50 most depleted peptides (right) per group derive from. c.) Sequence logos to represent difference in fragmentation pattern of MC1, MC2 and non-MC discs. Unique amino acids significantly ($p<0.05$) enriched around cleavage site P1'/P1 (dotted line) compared to unique non-MC disc peptides.

POS0417 ACTIVATED NEUTROPHILS DEGRADE CARTILAGE ENDPLATES

Keywords: Cartilage, -omics, Innate immunity

I. Heggli[1], M. Habib[2], J. Scheer[3], N. Herger[1], T. Mengis[1], C. Laux[4], F. Wanivenhaus[4], J. M. Spirig[4], M. Betz[4], M. Farshad[4], O. Distler[1], A. Fields[2], S. Dudli[1]. *[1]University of Zurich, Center of Experimental Rheumatology, Balgrist Campus, University Hospital Zurich and Balgrist University Hospital, University of Zurich, Switzerland, Zurich, Switzerland; [2]University of California San Francisco, Department of Orthopaedic Surgery, University of California San Francisco, San Francisco, CA, USA, San Francisco, United States of America; [3]University of California San Francisco, Department of Neurological Surgery, University of California San Francisco, San Francisco, CA, USA, San Francisco, United States of America; [4]University of Zurich, Department of Orthopedics, Balgrist University Hospital, University of Zurich, Switzerland, Zurich, Switzerland*

Background: Modic type 1 changes (MC1) are painful vertebral bone marrow lesions often found in patients with chronic low back pain. Damage of the endplate associates with MC1, is a risk factor for MC1 progression, and associates with pain. Recent evidence suggests a role of MC bone marrow neutrophils in endplate damage.
Objectives: The aim of this study was 1) to show that MC1 bone marrow neutrophils are activated and 2) to show that activated blood neutrophils degrade cartilage endplates (CEPs).
Methods: From MC1 patients undergoing lumbar spinal fusion, MC1 and intra-patient control bone marrow neutrophils ($CD45^+CD66b^+$) were isolated from bone marrow aspirates by cell sorting. Bulk RNA sequencing was performed (n = 5+5), differentially expressed genes (DEGs) were identified, and enrichment analysis was performed. In addition, neutrophil activation was assessed as CD66b expression by flow cytometry (n = 3+3). To assess the effect of activated neutrophils on CEP degradation, a neutrophil-mediated CEP damage model was established. Blood neutrophils were isolated from one donor and exposed to lumbar CEPs. A lumbar CEP was collected from six patients undergoing spinal fusion. From each CEP, three punch biopsies (ø=4-mm) were taken and halved. The six CEP biopsy halves per patient (1A,1B; 2A, 2B; 3A, 3B) were exposed for 18 h at 37 °C to: 1A) 0.75 U/ml collagenase P (positive control) and 1B) Hanks balanced salt solution (negative control); 2A) conditioned medium from 25 mio/ml activated neutrophils (100 nM PMA, 3 h, 37 °C) and 2B) conditioned medium from 25 mio/ml non-activated neutrophils; 3A) conditioned medium from 12.5 mio/ml activated neutrophils (100 nM PMA, 3 h, 37 °C) and 3B) conditioned medium from 12.5 mio/ml non-activated neutrophils. Exposure supernatant and CEP tissues were assayed for sulphated glycosaminoglycans (sGAG) and hydroxyproline (as measure for total collagen). Release of sGAG and hydroxyproline from condition 1A, 2A, and 3A was normalized to condition 1B, 2B and 3B, respectively. Relative release was tested against null hypothesis (μ0 = 100%) using a one sample t-test.
Results: 185 genes were differentially expressed between MC1 and control vertebral bone marrow neutrophils. Enrichment analysis revealed an activated pro-inflammatory transcriptome (**Figure 1a**). Flow cytometric analysis confirmed neutrophil activation on protein level (measured as % of $CD66^{high}$) in MC1 (control: 43.1% ± 15.7%, MC1: 54.1% ± 16.7%, p = 0.018) (**Figure 1b**).
Exposure of CEP tissues to conditioned medium from activated neutrophils significantly increased the release of sGAG from the CEP tissues in a dose-dependent manner (25 mio/ml: 380.1% ± 177%, p = 0.012; 12.5 mio/ml: 123.7% ± 22.3%, p = 0.048, positive control: 545.0 % ± 302.8 %, p = 0.016) (**Figure 1c**) but there was no significant hydroxyproline release (not shown).
Our data shows that neutrophils in MC1 bone marrow are activated and activated blood neutrophils degrade CEPs. Hence, neutrophils in MC1 bone marrow might promote and exacerbate CEP damage. Therefore, MC1 are not just reactive changes but can drive CEP damage that enhances a vicious inflammatory crosstalk with the adjacent disc.

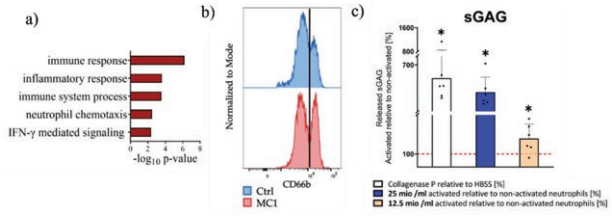

Figure 1. (a) Top 5 upregulated biological processes in MC1 bone marrow neutrophils (b) Representative flow cytometry image c) Relative sGAG released from CEP tissues. * P < 0.05.

Conclusion: We identified neutrophils as a potentially important player in MC1. Therefore, the present findings could have implications for treatment strategies to mitigate CEP damage in MC1.

Background: Bone erosion is a key clinical feature of inflammatory osteolysis. Emerging evidence shows a link between biological lipids and the pathogenesis of bone loss in inflammatory conditions. Osteoclasts are the sole bone resorbing cells and are responsible for bone erosion. Sterol regulatory element binding protein 2 (SREBP2) is a key transcription factor for cholesterol biosynthesis and a sensor for intracellular lipids.
Objectives: We aim to test the role of SREBP2 in physiological and pathological bone resorption.
Methods: Lysozyme M promoter-driven Cre transgene on the C57/BL6 background mice and $Srebp^{flox/flox}$ mice were crossed to generate $Srebp2^{fl/fl}$LysM-Cre (referred to as $SREBP2^{\Delta M}$ mice). Micro-computed tomography (μCT) analysis was performed to analyze bone volume and architecture. Mouse bone marrow-derived macrophages were cultured with receptor activator of nuclear factor-kappa beta ligand (RANKL) and macrophage colony stimulating factor (M-CSF)-containing conditioned media in α-minimum essential medium supplemented with 10% fetal bovine serum for three days to generate osteoclasts.
For the supracalvarial osteolysis model, recombinant human tumor necrosis factor-α (TNFα, 40μg/kg) was injected daily into calvarial periosteum in 12-week-old female control and $SREBP2^{\Delta M}$ mice for five consecutive days.
Results: μCT analysis of the femurs of 12-week-old female mice revealed a significant decrease in trabecular bone mass of $SREBP2^{\Delta M}$ mice relative to control mice. In contrast, cortical parameters, including cortical bone volume/tissue volume (BV/TV) and porosity, were comparable between the two groups. Bone histomorphometric analysis of the femur indicated that the trabecular osteoclast numbers, surface area, and bone resorption activity were significantly higher in $SREBP2^{\Delta M}$ mice than in control mice. However, there was no difference in mineral apposition rate and bone formation rate between $SREBP2^{\Delta M}$ mice and control mice. Consistent with in vivo findings, RANKL-induced in vitro osteoclast differentiation was accelerated in SREBP2-deficient cells compared to control cells, as measured by the formation of TRAP+ multinucleated cells. Moreover, in TNFα and RANKL co-treatment settings, SREBP2 deficiency enhanced TNFα-mediated enhancement of osteoclastogenesis compared to control cells. In the supracalvarial osteolysis model, TNFα administration over calvaria increased bone resorption pit area in $SREBP2^{\Delta M}$ mice compared to littermate control mice. μCT analysis revealed a significant decrease in calvaria bone volume/tissue volume and apparent density of $SREBP2^{\Delta M}$ mice compared to control mice. The histomorphometric analysis demonstrated significant increases in trabecular osteoclast numbers and surface area in $SREBP2^{\Delta M}$ mice relative to littermate control mice, suggesting that inflammatory osteolysis is enhanced under SREBP2 deficiency.
Conclusion: Using the myeloid-specific SREBP2-deficient model, we demonstrated that SREBP2 negatively regulates in vitro and in vivo osteoclastogenesis. SREBP2-deficient mice exhibit an osteoporotic phenotype. SREBP2 deficiency exacerbates TNFα-induced osteolysis in mice, supporting a protective role of SREBP2 in inflammation-associated pathological bone loss.

POS0419 THE ROLE OF OROSOMUCOID 2 IN THE REGULATION OF BONE REMODELING BY INHIBITING OSTEOCLASTOGENESIS AND PROMOTING OSTEOGENESIS

Keywords: Osteoporosis, Biomarkers, Animal models

M. S. Lee[1], C. H. Chung[1], W. H. Yoo[2], Y. Choi[2], C. H. Lee[1]. *[1]Wonkwang University Medical School, Internal Medicine, Iksan, Korea, Rep. of (South Korea); [2]Jeonbuk National University Medical School, Internal Medicine, Jeonju, Korea, Rep. of (South Korea)*

Background: Orosomucoid (ORM) is one of the acute phase reactant protein family and is expressed in hepatocytes and secreted into plasma under stress conditions such as tissue injury, infection, and inflammation. Three types of ORM are known to date (ORM1, 2 and 3), and ORM2 is mainly expressed in bone marrow cells. ORM2 has only some studies on hepatic metabolism, inflammation and immune regulation, and no studies on bone metabolism have been reported.
Objectives: The aim of this study is to reveal the role of ORM2 in the differentiation and function of osteoclasts and osteoblasts.
Methods: To determine the effect of ORM2 on RANKL-induced osteoclast differentiation and function, we performed TRAP staining, F-actin stating, and bone resorbing assay using ORM2 recombinant protein or ORM2 siRNA. Also, the effect of ORM2 on osteogenesis was confirmed by ALP and ARS assay. The intracellular mechanisms responsible for the dual regulation of osteoclastogenesis and osteogenesis of ORM2 were revealed by western blotting and quantitative real-time RT-PCR.
Results: We found that ORM2 is a potential target for osteoporosis therapeutics, as treatment with this agent enhances osteoblast differentiation and bone growth and suppresses osteoclast differentiation and bone resorption by performing gain- and loss-of-function studies. During ORM2-mediated regulation of osteoclastogenesis, phosphorylation of early signal transducers such as p38, JNK, Akt, IκB, PLCγ2, and Btk was affected, which in turn altered the mRNA and protein levels of c-Fos and NFATc1. ORM2 also increased ALP, Alizarin Red-mineralization activity, and the expression of osteoblastogenic gene markers, such as Runx2, osteocalcin (OCN), and ALP in mouse calvarial primary osteoblasts, and activated the p38-Runx2 pathway, which enhanced osteoblast differentiation.
Conclusion: we suggest that ORM2 may be a promising candidate for gene therapy for bone metabolic diseases, and further serve as a potentially important biomarker in the field of bone disease diagnosis.

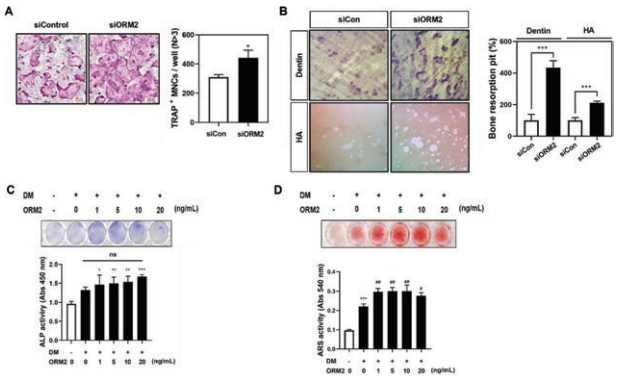

Figure 1. The effect of ORM2 in RANKL-induced osteoclast differentiation and osteoblast differentiation. (A) BMMs transfected with negative control siRNA (siControl) or siRNA against ORM2 (siORM2) were cultured with M-CSF (30 ng/mL) and the indicated concentrations of RANKL for TRAP staining. The TRAP-positive MNCs were counted as mature osteoclasts. $^{*}P < 0.05$ versus siControl group. (B) Mature osteoclasts transfected with siControl and siORM2 were cultured in a hydroxyapatite-coated plate and dentin slice to detect resorption pits. The number of TRAP-positive MNCs and relative resorption areas in the hydroxyapatite-coated plate and dentin slice were quantified. $^{***}P < 0.001$ versus siControl group. (C and D) Osteoblasts treated with the indicated concentration of recombinant protein were cultured for seven days to perform ALP staining and activity assay. The calcium deposits for matrix mineralization were measured by ARS staining after 21 days of culture and the intensity of staining was quantified with CPC.

POS0420 GENERATION OF A HUMAN 3D IN VITRO BONE MODEL THAT MIMICS GLUCOCORTICOID-INDUCED OSTEOPOROSIS

Keywords: Bone diseases, Osteoporosis

M. Pfeiffenberger[1,2], A. Damerau[1,2], T. Gaber[1,2], F. Buttgereit[1,2]. [1]*Charité Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany;* [2]*German Rheumatism Center, Rheumatology, Berlin, Germany*

Background: Osteoporosis is a bone disease characterized by low bone mass and changes in bone architecture, leading to pain and reduced mobility in patients. Glucocorticoid-induced osteoporosis (GIOP) is the best known form of secondary osteoporosis. Glucocorticoids (GC) are commonly used to treat inflammation, such as in rheumatic diseases. However, GC use can have a negative effect on the skeletal system and lead to osteoporosis.
Objectives: (i) Establishing and characterizing a human *in vitro* bone model consisting of osteoblasts and osteoclasts embedded in β-TCP ("healthy" bone model), (ii) treatment with dexamethasone to induce GIOP ("osteoporotic" bone model) and (iii) using this model as a testing platform for the treatment of osteoporosis.
Methods: Our model includes osteoblasts and osteoclasts, which are mainly responsible for bone remodeling. We defined an osteoclast differentiation protocol using low-attachment plates and cultured the cells for 21 days in αMEM medium, 5% FCS, 5% human AB serum, 2 mmol L-glutamine, 25 ng/ml M-CSF, and 50 ng/ml RANKL. To provide the basic scaffold for the structure of the "healthy" bone model, mesenchymal stromal cells (MSCs) were seeded on β-tricalcium phosphate (β-TCP). This bone model, consisting of differentiated osteogenic cells, was fully characterized in our previous work [1].
Results: The multinuclearity, typical ß-actin ring formation, cellular activity by TRAP staining and functionality in resorption assays proved functional osteoclasts. Our protocol allowed us to passage these cells without cell loss or loss of function. To establish the previously "healthy" (i.e., untreated) bone model, we seeded osteoclasts onto a pre-seeded β-TCP construct and cultured the co-culture for 7 days. We then analyzed the supernatant and detected marked secretion of RANKL, MMP-9, and free phosphate. This indicates the functionality of both osteoclasts and osteoblasts in our 3D model. Subsequently, the healthy model will be transferred to the osteoporosis-simulating model where treatment with dexamethasone will be applied. Once established, we plan to use the model we have developed for in vitro preclinical trials to test marketed drugs.
Conclusion: Ultimately, we will obtain an *in vitro* 3D co-culture of osteoblasts/osteoclasts simulating human native bone, which will be treated with dexamethasone to mimic key aspects of GIOP *in vitro*.

POS0421 GLUCOSE TRANSPORTER 1 REGULATES MECHANICAL STRESS-ACTIVATED SUBCHONDRAL BONE FORMATION VIA THE SIGNAL TRANSDUCTION NETWORK OF CELLULAR ENERGY SENSOR, NAD+-DEPENDENT DEACETYLASE (SIRTUIN 1) AND OSTEOGENIC TRANSCRIPTION FACTOR, RUNT-RELATED TRANSCRIPTION FACTOR 2 (RUNX2), IN SUBCHONDRAL BONE TISSUE

Keywords: Cartilage, Cell biology, Osteoarthritis

K. Yudoh[1], S. Somemura[2], R. Karasawa[1]. [1]*St. Marianna University School of Medicine, Department of Frontier Medicine, Kawasaki City, Japan;* [2]*St. Marianna University School of Medicine, Department of Orthopeadic Surgery, Kawasaki City, Japan*

Background: Mechanical stress is an important factor affecting bone and cartilage tissue homeostasis in osteoarthritis (OA). We focused on the interaction among mechanical stress, glucose uptake via glucose transporter 1 (Glut1) and the cellular energy sensor sirtuin 1 (SIRT1) in energy metabolism, since it has been recognized that SIRT1, an NAD+-dependent deacetylase, may function as a master regulator of mechanical stress response as well as cellular energy metabolism Also, it has already been demonstrated that SIRT1 regulates the activity of the osteogenic transcription factor, runt-related transcription factor 2 (Runx2).
Objectives: Purpose of this study was to determine whether mechanical force affects the expression of factors regulating energy metabolism and transcription factors controlling subchondral bone formation and ossification in OA.
Methods: Comparative analyses of the expression of Glut1, SIRT1 and Runx2 in osteoblasts and chondrocytes were performed after mechanical loading of a 3D cell–collagen sponge construct.
Results: Mechanical loading increased osteoblast activity. Mechanical loading significantly increased the expression of Glut1, significantly decreased the expression of SIRT1 and increased the expression of Runx2 in osteoblasts in comparison with non-loaded osteoblasts. Incubation with Glut1 inhibitor blocked mechanical stress-induced changes in SIRT1 and Runx2 in osteoblasts. In contrast to osteoblasts, expressions of Glut1, SIRT1 and Runx2 in chondrocytes were decreased by loading. Over loading reduced chondrocyte activity (production of proteoglycan, type II collagen).
Conclusion: Our present study indicated that mechanical stress induced upregulation of Glut1, downregulation of SIRT1, and upregulation of Runx2 in osteoblasts, but not in chondrocytes. Since SIRT1 is known to negatively regulate Runx2 activity, mechanical stress-induced downregulation of SIRT1 may lead to upregulation of Runx2, resulting in osteoblast differentiation and bone formation. Incubation with Glut1 inhibitor blocked mechanical stress-induced changes in SIRT1 and Runx2 suggesting that Glut1 is necessary to mediate the responses of SIRT1 and Runx2 to mechanical loading. These results suggest that Glut1 regulates mechanical stress-activated subchondral bone formation and ossification via the signal transduction network of cellular energy sensors, sirtuin 1 and Runx2, in OA.

Spondyloarthritis - aetiology, pathogenesis and animal models

POS0422 METABOLOMIC FINGERPRINT TO DISCRIMINATE REMISSION FROM ACTIVE DISEASE AND HEALTHY CONTROLS IN PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Biomarkers, Remission

M. M. Angioni[1], C. Piras[2], A. Floris[1], V. P. Leoni[2], M. Congia[1], E. Chessa[1], M. Piga[1], L. Atzori[2], A. Cauli[1]. *[1]Rheumatology Unit, AOU and University of Cagliari, Department of Medical Sciences and Public Health, Monserrato, CAGLIARI, Italy; [2]University of Cagliari, Clinical Metabolomics Unit, Department of Medical Sciences and Public Health, Monserrato, Cagliari, Italy*

Background: Among the unmet needs in psoriatic arthritis (PsA), the discovery of molecular players and biomarkers of disease activity or clinical remission achievement, remains unsolved. Metabolomics is a valuable technology in identifying biomarkers, by the study of a set of small molecules produced by the catabolism or anabolism of an organism in response to physiological or pathological states, allowing to better understand the disease-related variations downstream of the genome and proteome.

Objectives: In this pilot study, we have compared the serum metabolomics profile of patients with psoriatic arthritis with active or clinically inactive disease state compared with healty controls, using Nuclear Magnetic Resonance Spectroscopy (^{1}H-NMR).

Methods: From a cohort of 300 PsA patients according to CASPAR criteria, we selected 30 PsA with active disease state by DAPSA > 14 score (no bDMARDs ongoing) (A), 38 patients (peripheral arthritis subset) with >1-year remission by antiTNFα assessed by DAPSA ≤ 4 (B) and 32 healthy controls (C) matching for mean age and gender ratio. The sera metabolomics profile of 100 subjects was analyzed with a Varian UNITY INOVA 500 MHz NMR spectrometer, combined with Multivariate statistical Analysis (MVA). Principal Component Analysis (PCA) and Orthogonal Partial Least-Squares Discriminant Analysis (OPLS-DA) were applied. The model's goodness was evaluated using a permutation test (Q2 intercept value <0.005).

Results: The represented OPLS-DA models (Figure 1) exhibited a clear separation between subjects with active disease (red dots) and healthy controls (green dots), and patients with active disease or clinical remission state (blue dots), indicating significant differences in the serum metabolomics profile between all compared conditions. Interestingly, the OPLS-DA model shows how the PsA patients in the remission state have a profile which does not completely overlap with healthy subjects. The validity of the OPLS-DA models was evaluated through a permutation test using 500 times (Table 1) and indicate the great statistical validity of the OPLS-DA reported models.

Conclusion: The metabolomic profile of PsA patients with different disease state and healthy subjects reveal a high grade of dissimilarity between all compared conditions: remarkably, the metabolomic profile of patients with the drug-induced clinical remission appears still different from a healthy condition, perhaps reflecting molecular modifications induced by the great response to TNFalpha inhibition sustaining the clinical remission of PsA disease. Supplementary analysis of single-spectra is ongoing to obtain a list of metabolites differentially expressed in all conditions, and on this field further explorations are needed to validate metabolomics biomarkers that can accurately and reliably measure PsA disease activity or remission achievement, as well as to identify the metabolic fingerprint of antiTNFα-treatment success.

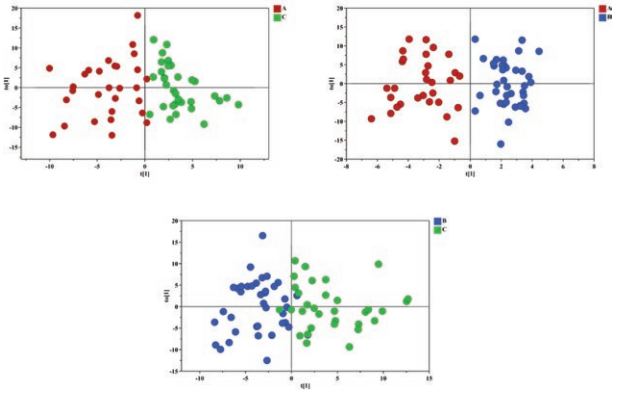

Figure 1. OPLS-DA scores plots of ^{1}H NMR spectra of sera samples. Red dots: (A) active PsA patients; blue dots: (B) remission PsA patients; green dots: (C) healthy controls.

Table 1. Parameters for OPLS-DA models

	OPLS-DA models				Permutation (500 times)*	
active PsA patients *vs* healthy controls	Components[a]	R2Xcum[b]	R2Ycum[c]	Q2cum[d]	R2 intercept	Q2 intercept

Marchesi[3], T. Ellingsen[1,2]. *[1]Odense University Hospital, Department of Rheumatology, Odense, Denmark; [2]University of Southern Denmark, Department of Clinical Research, Odense, Denmark; [3]Imperial College London, Faculty of Medicine, Division of Digestive Diseases, London, United Kingdom; [4]Odense University Hospital, Department of Clinical Immunology, Odense, United Kingdom; [5]University of Copenhagen, Department of Biology, Laboratory of Genomics and Molecular Biomedicine, Copenhagen, Denmark; [6]Odense University Hospital, Department of Medical Gastroenterology, Odense, Denmark*

Background: Metabolite profiling of biofluids has an emergent role in exploring the contribution of host-microbiome interactions to the treatment response of immune-mediated arthritis.[1]

Objectives: As part of the FLORA trial (exploring the impact of gut microbiome manipulation upon response to methotrexate [MTX]),[2] we investigated plasma metabolomic profiles of adults with psoriatic arthritis (PsA) and whether they correlated with the primary trial outcome, which was clinical response to MTX (responder vs failure) following one faecal microbiota transplant (FMT) or sham transplant.

Methods: Thirty-one PsA patients with active peripheral disease, despite at least 3 months of steady-state dose MTX, were included in the 26-week, double-blind, parallel-group, 1:1 randomised, sham-controlled, superiority trial (FLORA trial; NCT03058900).[2] Patients were randomly allocated to receive either one gastroscopic-guided FMT (n = 15) or sham transplant (n = 16). Each FMT product encompassed 50 g of processed faeces obtained from one of four healthy, thoroughly screened donors. Patients continued MTX throughout the trial. The primary trial endpoint was the proportion of treatment failures through 26 weeks, defined as need for treatment escalation (in most cases instigation of TNF inhibitors) due to insufficient improvement of disease activity or disease worsening.[2] Li-Hep plasma samples were collected at baseline, week 4, 12, and 26. The metabolic profiles were measured using ^{1}H Nuclear Magnetic Resonance (NMR). We used a supervised multivariate orthogonal partial least squares-discriminant analysis (OPLS-DA) to model metabolic differences among groups.

Results: Twenty women and eleven men with a mean age of 50.7 years (SD = 13.6) and a mean swollen joint count of 7.1 (SD = 2.8) were included in the trial.[2] We were able to annotate 40 plasma metabolites in the baseline samples. No differences in baseline plasma profiles were observed between patients allocated to FMT and sham (OPLS-DA model; Q2 = -0.452, p = 1). However, the OPLS-DA analysis revealed a significant model for treatment responders (n = 19) vs failures (n = 12) among all patients, Figure 1. Correlations between metabolites and the primary trial outcome with a correlation coefficient (r) ≥0.50 are presented in Table 1. When patients were stratified for intervention type, the models continued to show significant separation (FMT arm: Q2 = 0.383, p < 0.0001; sham arm: Q2 = 0.260, p = 0.002). In both the FMT and the sham models, glucose (r = 0.67 and r = 0.63) correlated positively with treatment failure

while lysine (r = -0.83 and r = -0.65) and phenylacetate (r = -0.66 and r = -0.51) correlated with successful treatment response.

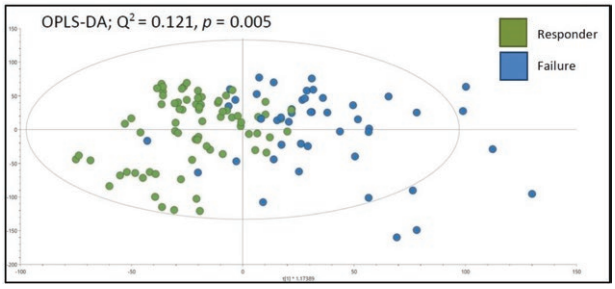

Figure 1. OPLS-DA model that significantly separates treatment responders (n = 19) from failures (n = 12) based on their plasma metabolomic profiles. Plot includes ^{1}H-NMR plasma profile for all patients at all timepoints.

Table 1. Plasma metabolites associated with successful treatment response (green) vs failure (blue) in the Figure 1 model.

Plasma metabolite	Correlation coefficient	Positive correlation with
Lysine	-0.61	Responder
Valine	-0.54	Responder
Serine	-0.50	Responder
Alanine	0.82	Failure
N-acetylglutamine	0.81	Failure
Glucose	0.80	Failure
Lipid CH2CO	0.80	Failure
Citrate	0.78	Failure

Conclusion: In the FLORA trial, plasma metabolomic profiles of patients with active, peripheral PsA significantly discriminated between treatment responders and failures. This discriminatory power was the case for the entire trial population as well as for each of the two treatment arms (FMT vs sham).

POS0424 CHARACTERIZATION OF THE INFLAMMATORY PROTEOME OF SYNOVIAL FLUID FROM PATIENTS WITH PSORIATIC ARTHRITIS: POTENTIAL TREATMENT TARGETS

Keywords: Synovium, Psoriatic arthritis, Biomarkers

N. Barbarroja Puerto[1], M. D. López Montilla[2], L. Cuesta López[1], C. Perez-Sanchez[3], M. Ruiz-Ponce[2], C. López-Medina[2], M. L. Ladehesa Pineda[2], C. Lopez-Pedrera[4], A. Escudero Contreras[1], E. Collantes Estevez[1], I. Arias de la Rosa[2]. *[1]IMIBIC/University of Cordoba/Reina Sofia Hospital, Medical and Surgical Sciences, Cordoba, Spain; [2]IMIBIC/University of Cordoba/Reina Sofia Hospital, Rheumatology Service, Cordoba, Spain; [3]IMIBIC/University of Cordoba/Reina Sofia Hospital, Cell Biology, Physiology and Immunology, Cordoba, Spain; [4]IMIBIC/Reina Sofia Hospital/University of Cordoba, Rheumatology Service, Cordoba, Spain*

Background: Synovial membrane inflammation, driven by effector T-cell activation and altered inflammatory cytokine expression, is a key feature of this psoriatic arthritis. The proximity extension assay (PEA) technique could contribute to identifying novel protein biomarkers associated with PsA and to improving the biological understanding and the future management of PsA, leading to novel intervention targets.

Objectives: 1) To characterize the inflammatory proteome of synovial fluid (SF) from patients with Psoriatic Arthritis (PsA) using a next generation proteomics technique, and 2) to evaluate its potential to stratify patients according to clinical features.

Methods: Inflammatory proteome profile of SF from thirteen PsA patients with active knee arthritis were analysed using PEA technology (Olink Target 96 Inflammation panel, Cobiomic Biosciences). Four patients with OA were included as control group.

Results: Seventy-nine inflammation-related proteins were detected in SF from PsA patients (SF-PsA). Unsupervised analyses of the molecular proteome profile in SF-PsA identified two specific phenotypes characterized by higher or lower levels of inflammation-related proteins. Clinically, SF-PsA with higher levels of inflammatory proteins also showed increased systemic inflammation and altered glucose and lipid metabolisms. Besides, SF from PsA patients showed 39 out of 79 proteins significantly altered compared to SF-OA specifically related to cell migration and inflammatory response. Among these, molecules such as TNFα, IL-17A, IL-6, IL-10, IL-8, ENRAGE, CCL20, TNFSF-14, OSM, IFNγ, MCP-3, CXCL-11, MCP4, CASP-8, CXCL-6, CD-6, ADA, CXCL-10, TNFβ and IL-7 showed the most significantly alteration.

Conclusion: This is the first study that characterizes the inflammatory landscape of synovial fluid of PsA patients by analyzing a panel of 92 inflammatory proteins using PEA technology. Novel SF proteins have been described as potential pathogenic molecules involved in the pathogenesis of PsA. Despite the flare, inflammatory proteome could distinguish two different phenotypes related to systemic inflammation and lipid and glucose alterations.

Background: Single cell technologies (scRNAseq) are increasingly applied in rheumatology to identify key cellular phenotypes that drive disease pathogenesis, enabling to deconvolute cellular heterogeneity within tissues.

Objectives: To investigate ST heterogeneity in terms of myeloid cells enrichment and distribution across different disease phases on ST samples obtained from US-guided biopsies in a bio-samples dataset of patients with Psoriatic Arthritis (PsA).

Methods: 17 patients fulfilling the CASPAR criteria[1] for PsA underwent US-guided ST biopsy and were included. At baseline, patients were categorized based on their disease phase: n=4 naïve to DMARDs; n=3 resistant to c-DMARDs; n=5 resistant to b-DMARDs; n=2 Difficult to treat and n=3 in sustained clinical and US remission or in low disease activity (LDA) state. All ST specimens were processed for phenotyping and sorting. Alive cells were sorted and loaded onto a Chromium Controller (10x Genomics) for single-cell partitioning, followed by library preparation according to the Chromium Next GEM Single Cell 3′ Reagent Kits v3.1 (Dual Index) protocol. Single-cell libraries were sequenced on the Illumina HiSeq 4000 system to a minimum depth of 20,000 reads per cell.

Results: After standard data processing and quality control procedures, we obtained transcriptomic profiles for 16701 synovial tissue-derived cells. For analysis of ST myeloid compartment only, 10194 cells were computationally isolated with the subset function from other cell types based on expression of CD14,MARCO,LYZ,CD11b and CD64. We identified 10 different myeloid subclusters from the scRNA-seq profiles using SCTransform integration: 2 clusters of lining layer and 8 sublining layer macrophage named after main differentially expressed (DE) genes (adjusted P < 0.05 by Bonferroni correction and multiple test correction, multiplied by number of tests) and according to the nomenclature established in Alivernini et al 20202. Each cell type group is present across all disease conditions but differences in relative proportions were detected.Specifically, ST of patients with active PsA resistant to pharmacological treatment was significantly enriched in sublining MerTKnegSPP1pos macrophages. In addition, we observed pro-inflammatory changes in lining layer TREM2pos STMs as compared to patients who achieved Remission/LDA status(p<0.001 for both).

Conclusion: MerTKnegSPP1pos STM macrophage may contribute to synovial pathology of PsA resistant to pharmacological treatment.

POS0426 PKM2 PROMOTES PRO-INFLAMMATORY MACROPHAGE ACTIVATION IN ANKYLOSING SPONDYLITIS

Keywords: Innate immunity, Spondyloarthritis

Y. Jiang[1], W. Weng[1], Y. Liang[1], S. Zhong[1], Y. Pan[1], J. Gu[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Macrophages are vital effector cells in ankylosing spondylitis (AS), leading to autoimmune tissue inflammation through varied effector functions [1]. The pro-inflammation potential of macrophages depends on their metabolic environment. Macrophages also work as principal regulators in T lymphocyte activation. To meet amplified bioenergetic and biosynthetic demands, metabolic pathways are joined to facilitate the proliferation and effector molecule production. A critical question is whether glycolysis and the rate-limiting enzyme, pyruvate kinase isoenzyme M2 (PKM2) could positively influence AS macrophages' inflammatory function.
Objectives: The objectives of the study was to investigate the effect of glycolysis and PKM2 on AS macrophage functions featured by the secretion of inflammatory cytokines and the presentations of co-stimulatory signals.
Methods: Peripheral blood mononuclear cells (PBMC) were isolated from AS patients and differentiated into macrophages by M-CSF. Macrophages were further differentiated into M1 or M2 macrophages by stimulation with IFN-γ and LPS, or IL-4 and of IL-13. For glycolysis inhibition, cells were treated with 10mM of 2-Deoxy-D-glucose (2-DG). For inhibition of *PKM2*, macrophages were treated with 0.25μM of Shikonin. The RNA expressions of proinflammatory cytokines and glycolysis-related genes were detected by qPCR. Immunoblotting, ELISA and confocal miroscopy was applied to examine the expression of *PKM2*. Extracellular acidification rate (ECAR) analysis was performed to assess glycolysis. The expressions of surface molecule CD80, CD86, and HLA-DR were measured using CytoFLEX flow cytometer.
Results: AS macrophages are prone to produce excessive inflammation, including *TNFα*, *IL1β*, and *IL23,* and are at overactive status by exhibiting stronger co-stimulatory signals, such as CD80, CD86, and HLA-DR. Meanwhile, we found that patient-derived M1 macrophages intensified glycolysis, captured as a higher ECAR. Obviously, upregulation of *PKM2* and *GLUT1* has been observed on AS-derived monocytes and macrophages, especially on M1 macrophages, indicating a glucose metabolic alteration in AS macrophages. To investigate how glycolysis impacts macrophage inflammatory ability, 2-DG and Shikonin were applied to AS M1 macrophages, respectively. Consequently, both inhibitors could lessen pro-inflammatory function and reverse overactive status of AS macrophages, potentially favoring disease treatment.
Conclusion: We emphasized hyper-metabolic M1 macrophages of AS and suggested an essential role for PKM2 in inflammatory effector functions of AS macrophages. Targeting PKM2 to inhibit glycolysis in an overactive macrophage may provide novel therapeutic methods for AS inflammation.
