Methods: Data from RISE, a national registry that includes electronic health records from one-third of U.S. rheumatology practices, was used. All bio-originator or biosimilar infliximab administrations (of any dose) between April 2016 and March 2022 were analyzed. We included patients 18 years or older who had at least one visit with a rheumatologist; all infliximab bio-originator or biosimilar users, regardless of diagnosis, were included. To assess the uptake of biosimilar infliximab, we examined the proportion of patients using each formulation (infliximab, infliximab-dybb, infliximab-abda and infliximab-axxq) in 2-month intervals during the study period. Patients were included in multiple time windows if they received different products during the study period. Next, we examined practice-level uptake of biosimilars among practices with ≥ 20 new infliximab users after 2019. Finally, we examined the characteristics of patients who were prescribed biosimilars. For this analysis, we calculated standardized mean differences (SMDs) to permit comparisons of the characteristics of users of bio-originator infliximab and each biosimilar. In cases where more than one infliximab product was prescribed, patients were classified based on their most recent infliximab prescription.

Results: During the study period, 32,916 individuals used bio-originator infliximab, 3,999 used infliximab-dybb, 1,369 used infliximab-abda, and 1,099 used infliximab-axxq. **Figure 1** demonstrates that uptake of biosimilar infliximab formulations remained below 20% and rose only minimally with the introduction of new biosimilar formulations in 2017 and 2020. Among 102 rheumatology practices with ≥ 20 new infliximab users, we observed significant variability in biosimilar use. 16.6% of practices had no patients on biosimilars, 27.4% had between one and ten percent of patients on biosimilars; only 15.6% had more than half of patients on biosimilars. SMDs for age, sex, race and ethnicity, insurance, region, and rheumatic disease diagnosis were all ≤0.5, indicating only small differences in patient characteristics across different formulation groups when comparing bio-originator infliximab to biosimilar versions.

Conclusion: Uptake of biosimilar infliximab drugs has been slow and minimally impacted by the introduction of additional biosimilar formulations in the U.S over the last six years. Only a small percentage of rheumatology practices use biosimilars for most patients, and a substantial proportion do not use biosimilars at all. We noted only small differences in patient characteristics between bio-originator and biosimilar infliximab users, suggesting that patient demographic characteristics, geographical region, diagnosis and insurance are not major drivers of prescribing differences. These findings suggest that in the absence of mandatory switching policies or other incentives, the U.S. has largely failed to achieve a robust biosimilars market, stymieing efforts to increase competition and reduce cost.

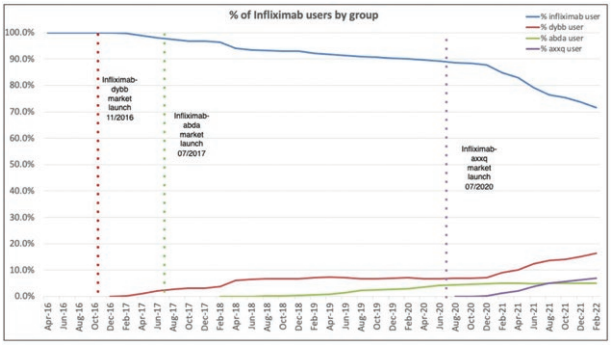

Figure 1. Proportion of patients in the RISE registry using infliximab bio-originator or biosimilars between 2016 and 2022.

Background: FIL is a Janus kinase (JAK) 1 preferential inhibitor for the treatment of RA. Data from the ORAL Surveillance post-marketing study (NCT02092467) suggest that in patients with active RA aged ≥50 years with ≥1 CV risk factor, the risks of cancer and major adverse cardiovascular events (MACE) are higher with the pan-JAK inhibitor tofacitinib vs tumor necrosis factor inhibitors, with higher rates in those aged ≥65 vs <65 years.[1]

Objectives: To assess the incidence of malignancies excluding non-melanoma skin cancer (NMSC), NMSC, MACE and venous thromboembolism (VTE) in patients treated with FIL 200 mg (FIL200) and FIL 100 mg (FIL100) in RA clinical trials.

Methods: Data were pooled from patients treated with FIL200 or FIL100 from DARWIN 1–3 (NCT01888874, NCT01894516, NCT02065700) and FINCH 1–4 (NCT02889796, NCT02873936, NCT02886728, NCT03025308). Data cuts used for the ongoing DARWIN 3 and FINCH 4 studies were May 2, 2022, and May 6, 2022, respectively. Exposure-adjusted incidence rates (EAIRs) per 100 patient-years of exposure (PYE) were calculated for MACE, VTEs, malignancies

excluding NMSC, NMSC and treatment-emergent adverse events (TEAEs) leading to death, according to FIL dose (200 vs 100 mg) and age (<65 vs ≥65 years); no statistical testing was performed, so all differences are numerical. MACE and VTE were adjudicated by an independent committee; the cutoff for adjudication was April 3, 2022.

Results: Overall, 3691 patients were treated with FIL for a total of 12,541 PYEs. Median (max) PYE was 3.8 (8.3) years for FIL200 and 3.3 (7.8) years for FIL100. Baseline characteristics are shown in the **Table 1**. A greater proportion of those aged ≥65 years vs <65 years had a CV medical history in both the FIL200 (75.7% vs 36.1%) and FIL100 (71.8% vs 40.9%) groups. Overall EAIRs (95% confidence interval [CI]) were 0.40 (0.3, 0.5) for MACE, 0.19 (0.1, 0.3) for VTEs, 0.69 (0.6, 0.9) for malignancy excluding NMSC, 0.29 (0.2, 0.4) for NMSC and 0.65 (0.5, 0.8) for TEAEs leading to death. EAIRs of MACE and VTE were higher in patients aged ≥65 vs <65 years but were generally similar for FIL200 and FIL100 within each age group (**Figure 1**). EAIRs of malignancies, NMSC and TEAEs leading to death were also higher in the ≥65- vs <65-year group. Within the ≥65-year group, EAIRs (95% CI) of these events were numerically higher in the FIL200 vs FIL100 group: 2.0 (1.3, 2.9) vs 0.99 (0.5, 1.9) for malignancies, 1.38 (0.8, 2.2) vs 0.44 (0.1, 1.1) for NMSC, and 1.59 (1.0, 2.5) vs 1.20 (0.6, 2.2) for TEAEs leading to death, respectively.

Conclusion: Rates of MACE and VTE in FIL-treated patients were low and similar for FIL200 and FIL100. There was a higher proportion of patients aged ≥65 years vs <65 years with a CV medical history. In patients aged ≥65 years, EAIRs of malignancies, NMSC and TEAEs leading to death were higher with FIL200 vs FIL100, although CIs overlapped.

Background: Concerns regarding the risk of cancer with janus kinase inhibitor (JAKi) use in patients with rheumatoid arthritis (RA) escalated after the release of results from Pfizer's clinical trial, *ORAL Surveillance*.[1] The trial showed increased risks of major adverse cardiovascular events and cancer in tofacitinib compared with tumour necrosis factor inhibitor recipients. Precautionary considerations on JAKi use in high-risk subsets of patients with RA have since been issued by the European Medicines Agency.

Objectives: We aimed to investigate the risk of first primary cancer in patients with RA treated JAKi (tofacitinib and baricitinib) compared with those who received biologic disease-modifying anti-rheumatic drugs (bDMARDs) in a real-world setting.
Methods: We performed an observational cohort study using the nationwide registers in Denmark. Patients with RA aged 18+ years, without a previous cancer diagnosis, and who initiated treatment with JAKi or bDMARDs from 1 January 2017 to 31 December 2020 were identified in the Danish Rheumatology Quality Register (DANBIO) and followed for any cancer (except non-melanoma skin cancer). We applied inverse probability of treatment weighting (IPTW) to account for covariate differences between treatment groups. IPTW-generated weights were used with cause-specific Cox (CSC) models to calculate hazard ratios (HRs) for cancer incidence in JAKi-treated compared with bDMARD-treated patients with RA. Multiple subgroup and sensitivity analyses were performed.
Results: We identified 875 and 4247 RA patients treated with JAKi and bDMARDs, respectively. The JAKi group contributed with 1315 person years (PYRS) and 19 cancers, while the bDMARD group contributed with 8597 PYRS and 111 cancers. The corresponding crude incidence rates per 1000 PYRS for cancer were 14.4 (JAKi) and 12.9 (bDMARD). Comparing the two groups using weighted CSC models, a HR of 1.41 (95%CI 0.76 to 2.37, 95% confidence intervals) was seen for JAKi- versus bDMARD-treated patients with RA.
Conclusion: JAKi treatment in real-world patients with RA was not associated with a statistically significant increased risk of first primary cancer compared with those who received bDMARDs. However, risk estimates were elevated in many analyses, and an excess risk of cancer with JAKi treatment cannot be ruled out. More studies investigating JAKi and cancer risk in patients with RA are highly warranted.

Background: Upadacitinib (UPA) is an oral JAK inhibitor that has demonstrated safety and efficacy in patients (pts) with moderate-to-severe active RA in the phase 3 SELECT clinical program.[1–6]
Objectives: To describe the long-term integrated safety profile of UPA relative to active comparators in pts with RA from the SELECT clinical program through the cutoff date of 15 August 2022.
Methods: Pooled safety data were analyzed from 6 randomized controlled trials evaluating UPA in RA.[1–6] Treatment-emergent adverse events (TEAEs) and AEs of special interest were summarized for the following groups: pooled UPA 15 mg once daily (QD; UPA15, 6 trials), MTX (1 trial), and adalimumab (ADA) 40 mg every other week (EOW; 1 trial). TEAEs were defined as AEs with an onset after the first dose and ≤ 30 days (UPA and MTX) or ≤ 70 days (ADA) after the last dose of study drug and reported as exposure-adjusted event rates (EAERs) per 100 patient-years (PY; E/100 PY). The standardized mortality ratio (SMR) was estimated for the general population using World Health Organization country-age-gender specific mortality rates through 2016.
Results: 3209 pts received ≥ 1 dose of UPA15 with 10 782.7 PY of exposure. EAERs of AEs, serious AEs (SAEs), and AEs leading to discontinuation on UPA15 were comparable to MTX and ADA (**Table 1**). COVID-19 pneumonia was the most common SAE with UPA15 (0.7 E/100 PY). Rates of serious infections were similar between UPA15 and ADA but higher compared with MTX (**Figure 1**). Herpes zoster (HZ) rates were higher with UPA15 vs MTX and ADA. Most HZ cases with UPA15 were non-serious (95%) and affected a single dermatome (75%) or unilateral multiple dermatomes (16%); 8% of cases were reported as disseminated and none involved the central nervous system. Creatine phosphokinase elevations were transient and more common with UPA15 than MTX or ADA. Anemia and neutropenia rates were similar between UPA15 and ADA. Most hepatic disorders were mild or moderate transaminase elevations. Treatment discontinuation due to these lab events was rare (≤ 0.1 E/100 PY). Similar rates of adjudicated MACE, adjudicated VTE, and malignancy (excluding non-melanoma skin cancer [NMSC]) were observed across treatment groups. The rate of NMSC was numerically higher with UPA15 vs ADA; no cases occurred with MTX. SMR analysis indicated that the mortality rate among pts with RA treated with UPA15 was not higher than what would be expected among the general population (SMR [95% CI]: 0.67 [0.52, 0.86] including COVID-19 deaths; 0.41 [0.29, 0.56] excluding COVID-19 deaths).
Conclusion: The integrated safety profile of UPA in pts with RA remained consistent with previous findings,[7] with no new safety risks identified up to 6.5 years of exposure. Similar rates of AEs of special interest were observed for UPA15 and ADA, except for higher rates of HZ, CPK elevations, and NMSC with UPA.

Deaths[a]	0.8 (0.7, 1.0)	1.0 (0.5, 1.6)	0.9 (0.4, 1.8)

ADA, adalimumab; E/100 PY, exposure-adjusted event rates per 100 patient-years; QD, once daily; SAE, serious AE; UPA, upadacitinib.[a]Includes treatment-emergent, non-treatment-emergent, and COVID-related deaths.

Figure. Treatment-emergent Adverse Events of Special Interest in Patients Treated with UPA, ADA, and MTX[a]

ADA, adalimumab; CI, confidence interval; CPK, creatine phosphokinase; E/100 PY, exposure-adjusted event rates per 100 patient-years; EOW, every other week; GI, gastrointestinal; NMSC, non-melanoma skin cancer; QD, once daily; TB, tuberculosis; UPA, upadacitinib.
MTX: n = 314, PY = 865.1; ADA 40 mg EOW: n = 579, PY = 1573.2; UPA 15 mg pooled: n = 3209, PY = 10 782.7.
[a]Patients who switched from placebo, ADA, or MTX to UPA were included in the UPA 15 mg QD group from the start of UPA, while those who switched from UPA to ADA were included in the ADA group from the start of ADA and were censored at the time of switch. MTX monotherapy was censored at the time of rescue to combination therapy (addition of UPA).
[b]Opportunistic infections excluding TB and herpes zoster.
[c]MACE was defined as cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke.
[d]VTE was defined as deep vein thrombosis and pulmonary embolism.

Rubbert-Roth[9]. *[1]Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Department of Internal Medicine, Dallas, TX, United States of America*; *[2]University of Munich, Division of Rheumatology and Clinical Immunology, Department of Internal Medicine IV, Munich, Germany*; *[3]University of Western Ontario, Department of Rheumatology, London, ON, Canada*; *[4]Pfizer Inc, Inflammation and Immunology, Kirkland, QC, Canada*; *[5]Pfizer Inc, Clinical Affairs, City of Makati, NCR, Philippines*; *[6]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; *[7]Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America*; *[8]Pfizer Ltd, Safety Surveillance and Risk Management, Tadworth, Surrey, United Kingdom*; *[9]Kantonsspital St Gallen, Klinik für Rheumatologie, St Gallen, Switzerland*

Background: Switching or discontinuing therapy may occur in patients (pts) with rheumatoid arthritis (RA) with an inadequate response/intolerance to treatment. In ORAL Surveillance, a post-authorisation safety study of tofacitinib vs tumour necrosis factor inhibitors (TNFi) in pts with RA despite methotrexate aged ≥50 years with ≥1 additional cardiovascular risk factor,[1] pts could discontinue the assigned study drug and switch to local standard of care (SOC) treatment and, in contrast to previous randomised controlled trials, were encouraged to remain in the study.
Objectives: To assess efficacy/safety in the SOC period in pts who discontinued study drug and started SOC treatment.
Methods: This post hoc analysis included randomised pts from ORAL Surveillance (NCT02092467) who received ≥1 dose of study drug (tofacitinib 5 or 10 mg twice daily [BID], or TNFi) and initiated SOC treatment per-protocol after discontinuing study drug. SOC treatment could include disease-modifying antirheumatic drugs (DMARDs; biologic, targeted synthetic, or conventional synthetic [cs]), or glucocorticoids. Efficacy outcomes included mean observed and change from randomisation/SOC baseline (BL; Δ) in Simplified Disease Activity Index (SDAI) over time. Adverse events (AEs) and serious AEs (SAEs) were reported; incidence rates (IRs; pts with events/100 pt-years [PY]) were estimated for AEs of

special interest (AESI). Data were analysed for the periods in which pts who discontinued study drug received 1) tofacitinib or TNFi (randomised period) and 2) SOC treatment (SOC period). Pts were analysed in their original treatment group (ex-tofacitinib 5/10 mg BID, or ex-TNFi). Analyses were descriptive.

Results: Of 4362 randomised and treated pts, 718 (16.5%) stopped study drug (50.7, 59.3 and 47.8% due to AEs; 15.1, 5.8 and 21.9% due to insufficient clinical response for tofacitinib 5 mg BID, 10 mg BID and TNFi, respectively); most received csDMARDs only in the SOC period (73.1–79.6% across groups). In general, BL characteristics in pts who switched to SOC treatment were numerically similar across groups. Mean duration of randomised and SOC periods was 21.9–26.0 and 15.0–18.6 months, respectively. ΔSDAI over time was similar across groups in the randomised period (data not shown) with modest improvements in the SOC period (Figure 1) and with SDAI score generally reflecting moderate disease activity (data not shown). In general, AE and SAE rates were similar across groups but numerically higher in the randomised vs SOC period (data not shown). AESI rates were generally similar across groups in the SOC period (Table 1).

IMPACT OF ATHEROSCLEROTIC CARDIOVASCULAR DISEASE RISK IN PATIENTS TREATED WITH UPADACITINIB VERSUS COMPARATORS: POST HOC ANALYSIS OF THE SELECT RHEUMATOID ARTHRITIS PROGRAM

Keywords: Safety, Targeted synthetic drugs, Cardiovascular disease

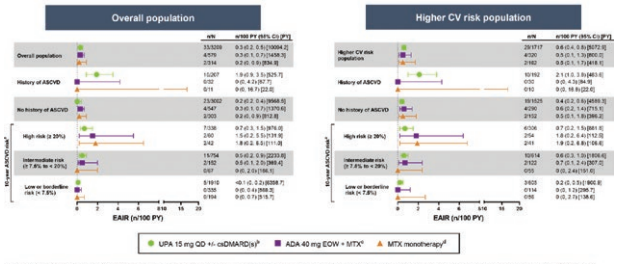
C. Charles-Schoeman[1], M. H. Buch[2], G. R. Burmester[3], J. Liu[4], D. Dilley[4], H. Palac[4], S. Strengholt[4], J. Curtis[5]. *[1]University of California Los Angeles, Department of Medicine, Division of Rheumatology, Los Angeles, CA, United States of America*; *[2]University of Manchester and NIHR Manchester Biomedical Research Centre, Centre for Musculoskeletal Research, Faculty of Biology, Medicine and Health, Manchester, United Kingdom*; *[3]Charité-Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[4]AbbVie, Immunology, North Chicago, IL, United States of America*; *[5]The University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, United States of America*

Background: In ORAL Surveillance, a post-approval safety study conducted in RA patients aged ≥50 years with ≥1 cardiovascular (CV) risk factor, non-inferiority was not shown for MACE and malignancy (excluding nonmelanoma skin cancer) for tofacitinib versus TNF inhibitor (TNFi) therapy.[1] A post hoc analysis of the ORAL Surveillance data suggested that patients with a history of atherosclerotic cardiovascular disease (ASCVD) were most at risk relative to TNFi.[2] Whether these findings are characteristic of the entire JAK inhibitor class is unclear.

Objectives: To evaluate the impact of baseline ASCVD risk on the incidence of MACE with upadacitinib (UPA) versus TNFi and MTX in an RA population similar to ORAL Surveillance from the SELECT RA clinical program.

Methods: Post hoc analysis of adjudicated MACE was performed in two patient populations pooled across six SELECT phase 3 studies: the overall population and the higher CV risk subset (patients aged ≥50 years with ≥1 CV risk factor). Patients received UPA 15 mg once daily (with or without conventional synthetic DMARDs), adalimumab (ADA) 40 mg in combination with MTX, or MTX monotherapy. CV risk factors used to identify the higher-risk patients included prior CV event, hypertension, diabetes mellitus, current or former tobacco/nicotine use, and baseline HDL-C levels <40 mg/dL. Patients were further stratified based on medical history of ASCVD, which included coronary artery disease and other relevant events (e.g., arteriosclerosis, ischemic stroke, and carotid artery disease). In patients without a history of ASCVD, 10-year ASCVD risk categories were calculated with a 1.5 multiplier applied.[3] Exposure-adjusted incidence rates (EAIRs) per 100 patient-years were summarized based on the treatment received; 95% CIs were determined based on the exact method for the Poisson mean.

Results: Of 4102 enrolled patients (UPA 15 mg, n=3209; ADA, n=579; MTX monotherapy, n=314), approximately half were aged ≥50 years with ≥1 CV risk factor (n=2199 total; UPA 15 mg, n=1717; ADA, n=320; MTX monotherapy, n=162). In the overall SELECT population, EAIRs of adjudicated MACE were 0.3, 0.3, and 0.2 n/100 PY for UPA, ADA, and MTX groups, respectively (**Figure 1**). Rates of MACE were higher in UPA-treated patients with a history of ASCVD (1.9 n/100 PY) compared to those without a history of ASCVD (0.2 n/100 PY) in the overall population; no occurrences of MACE were reported with ADA or MTX in patients with a medical history of ASCVD, possibly due to the limited patient numbers in these groups. Among patients with no history of ASCVD in the overall population, higher rates of MACE were observed for patients in the high or intermediate 10-year ASCVD risk categories versus the low or borderline risk category, irrespective of treatment. In the higher CV risk subset of the SELECT population, rates of MACE were numerically higher than the overall population but were similar between treatment groups (0.6, 0.5, and 0.5 n/100 PY for UPA, ADA, and MTX groups, respectively). Consistent with the overall population, the incidence of MACE was higher among UPA-treated patients with a history of ASCVD relative to those without a history of ASCVD. The rates of MACE in the higher-risk population were also generally similar across treatment groups for patients within each of the different 10-year ASCVD risk groups.



Conclusion: In this post hoc analysis, higher rates of MACE were observed in UPA-treated patients with a history of ASCVD versus those with no history of ASCVD. In both the overall SELECT population and the higher CV risk subset, rates of MACE were generally comparable between UPA and ADA in the

different ASCVD risk categories. However, given the low sample size and limited patient-years of exposure in ADA and MTX treatment groups, results should be interpreted with caution.

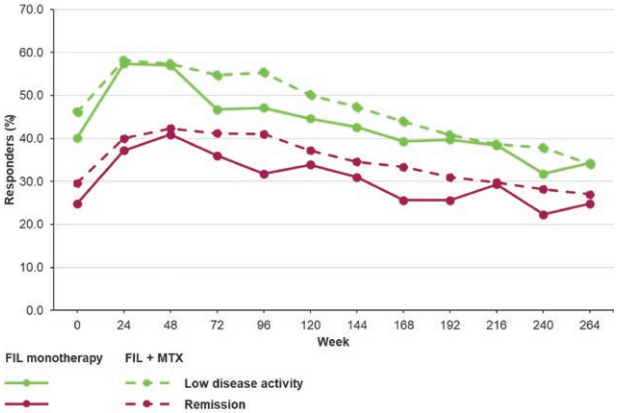
Background: DARWIN 3 (NCT02065700) is a long-term extension (LTE) study assessing the safety and efficacy of filgotinib (FIL) in patients with rheumatoid arthritis (RA) and an inadequate response to methotrexate (MTX).[1] In the DARWIN 1 (NCT01888874) and DARWIN 2 (NCT01894516) parent studies, patients received FIL in combination with MTX or FIL monotherapy, respectively.

Objectives: To provide an update on the safety and efficacy of FIL 200 mg (FIL200) in patients with RA, with or without MTX, with a maximum of 8.2 years of exposure.

Methods: Patients completing the DARWIN 1 (FIL + MTX) and DARWIN 2 (FIL monotherapy) phase 2 studies could enter DARWIN 3, receiving FIL200. The proportion of patients experiencing treatment-emergent adverse events (TEAEs) were reported using the safety analysis set, comprising data from both the parent and LTE studies. Efficacy was assessed from LTE baseline using the American College of Rheumatology (ACR) 20/50/70 improvement criteria and Disease Activity Score in 28 joints–C-reactive protein (DAS28-CRP), up to 264 weeks. Low disease activity and remission were defined as DAS28-CRP ≤3.2 and <2.6, respectively.



Results: In total, 739 patients were enrolled in DARWIN 3. Mean (standard deviation; SD) FIL exposure was 4.89 (2.72) years in the FIL + MTX group and 4.78 (2.79) years in the FIL monotherapy group. In the FIL + MTX vs FIL monotherapy groups, TEAEs were reported for 90.9% and 92.1% of patients, respectively (**Table 1**). The most common TEAE was infection. In both treatment groups, 8 patients had a TEAE leading to death (1.6% and 3.3%, respectively). Exposure-adjusted incidence rates, censored at time of first event for major adverse cardiovascular event, venous thromboembolism, herpes zoster, infections, serious infections, non-melanoma skin cancer (NMSC), malignancies excluding NMSC, gastrointestinal perforations and TEAEs leading to death, will be reported. Through 5 years, ACR20/50/70 responses were maintained in 86.3%/66.7%/50.7% of the FIL + MTX group and 90.8%/74.8%/51.4% of the FIL monotherapy group, respectively (observed data). DAS28-CRP low disease activity and remission rates (non-responder imputation) at DARWIN 3 baseline were 46.1%/40.1% (FIL + MTX) and 29.6%/24.8% (FIL monotherapy) (**Figure 1**). At Week 264, the proportion of patients achieving low disease activity and remission were 34.0%/34.3% (FIL + MTX) and 27.0%/24.8% (FIL monotherapy).

Conclusion: With a maximum of 8.2 years of exposure in patients with RA, the FIL safety profile is similar between the background MTX and monotherapy treatment arms. Both arms show sustained efficacy over time.

POS0830 BARICITINIB VERSUS TNF-INHIBITORS IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND AN INADEQUATE RESPONSE TO CSDMARDS: 12 WEEKS RESULTS OF A PRAGMATIC, MULTICENTER, OPEN LABEL, NONINFERIORITY TRIAL

Keywords: Randomized control trial, Targeted synthetic drugs, Real-world evidence

M. O. Voshaar[1], P. Ten Klooster[2], D. Tedjo[3], C. Van de Laar[4], M. Van de Laar5. [1]*University of Twente, Medical Cell BioPhysics & TechMed Center, Enschede, Netherlands*; [2]*University of Twente, Department Psychology, Health and Technology, Enschede, Netherlands*; [3]*Transparency in Healthcare, -, Hengelo, Netherlands*; [4]*Erasmus University Rotterdam, Erasmus School of Health Policy and Management, Rotterdam, Netherlands*; [2]*University of Twente, Department Psychology, Health and Technology, Enschede, Netherlands*

Background: The EULAR guidelines for RA recommend that treatment should be aimed at reaching a predefined disease activity target (T2T). If this treatment target is not achieved with csDMARD, adding a TNFi or a JAK-inhibitor are advised options in patients with poor prognostic factor, obviously considering contraindications. While randomized clinical trials have provided relevant data on the relative efficacy and safety of TNFi and JAKi under ideal conditions, the extent to which such results can be generalized to real-life clinical practice conditions remains unclear.

Objectives: To demonstrate non-inferiority (NI) and, in case NI could be shown, subsequent superiority of a T2T strategy in which csDMARDs refractory RA patients are subsequently treated with baricitinib versus TNFi.

Methods: Biologic or targeted synthetic DMARD-naïve RA patients failing to respond to csDMARDs were eligible if they were pretreated according to T2T principles, had a disease duration <5 years and no contraindications to b/tsDMARD. All included patients were treated open label at the discretion of their attending rheumatologist with either TNFi (any type) or baricitinib. Patients were seen at baseline and 12-weekly until final follow-up (48 weeks). Full clinical assessment was performed at each visit. Self-report questionnaires, including PROMs, were collected as well. The primary endpoint was defined as NI of baricitinib versus TNFi in the proportion of patients achieving ACR50 response at week 12, with subsequent superiority testing in case non-inferiority was shown. For the primary efficacy analysis, the proportion of patients achieving ACR50 response were compared, using 95% confidence intervals calculated using the Wilson score method. The non-inferiority margin for baricitinib was set at -12%.

Results: 199 patients who received a first dose of either TNFi (102) or baricitinib (97) were included. Baseline characteristics were comparable between both groups (see Table 1). At 12 weeks, the lower bound of the 95% confidence interval for the difference in proportions of patients meeting the ACR50 response is to the right of zero in both the per-protocol and intention-to-treat analysis (see Figure 1). Hence, baricitinib was found to be non-inferior and statistically superior to TNFi in the analysis of the primary endpoint. Moreover, DAS28 remission (DAS28-CRP <0.6) was achieved in 74% of baricitinib patients compared with 46% of TNFi patients (p<0.001) at 12 weeks.

Conclusion: Baricitinib was found to be non-inferior and superior to TNFi in terms of ACR50 response at 12 weeks in real-world csDMARD refractory RA patients. Analysis of secondary endpoints, disease activity across other measurement points, PROMs, radiology, safety and costs is currently ongoing.

POS0831 MALIGNANCIES RISK IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOFACITINIB OR TNF INHIBITORS, A NATIONAL STUDY: RELATION STUDY

Keywords: Targeted synthetic drugs, Rheumatoid arthritis

J. E. Gottenberg[1], M. Kessouri[2], J. Rudant[2], N. Assi[3], F. Raguideau[4], J. Kirchgesner[5]. [1]*Hautepierre Hospital, Rheumatology, Strasbourg, France*; [2]*Pfizer, Medical, Paris, France*; [3]*Heva, Statistique, Lyon, France*; [4]*Heva, RWD, Lyon, France*; [5]*Saint-Antoine Hospital, Gastro-enterology, Paris, France*

Background: Patients with IMID, and notably patients with rheumatoid arthritis RA, are at increased risk of cancer compared with the general population [1,2]. It is hence paramount to assess the impact of biological or targeted DMARD (e.g.., tofacitinib and TNFi) on the risk of cancer outcome in patients already at-risk, particularly in the context of ORAL Surveillance which showed a higher risk for malignancies (excluding nonmelanoma skin cancer, NMSC) with tofacitinib, in comparison with TNFI, in RA patients [3].
Objectives: To assess the impact of tofacitinib and TNFi on the risk of malignancies in patients with RA treated in real-world clinical practice.
Methods: The RELATION study is a retrospective observational cohort study using the French nationwide healthcare database (SNDS). Patients aged 18 years or older, affiliated to the national health insurance with a diagnosis of RA and initiating tofacitinib after November 1, 2017 or TNFi after January 1, 2010 (including adalimumab, etanercept, or other TNFi, without previous exposure to tofacitinib) were followed from treatment initiation to December 31, 2020. Patients with a previous history of a malignancy (excluding NMSC) in the 4 years preceding cohort entry were excluded. All malignancies events were defined by the first hospitalization for malignancy during follow-up. Comorbidities and traditional cardiovascular (CV) risk factors were identified using hospitalizations, procedures, or medication dispensing in the 4 years prior cohort entry. The unadjusted incidence rate (IR) of malignancies (excluding NMSC) was assessed in patients initiating either tofacitinib or a TNFi (with associated 95% confidence intervals (95% CI)). A 1:3 PS matching was conducted to balance the baseline characteristics of patients initiating tofacitinib and TNFi. Cox proportional hazards regression models were used to compare the risk of malignancy with tofacitinib vs TNFi during the follow-up period.
Results: Between 2010 and 2020, a total of 39,578 patients with RA were included in the study. Among these, 2,811 initiated tofacitinib and 36,767 initiated a TNFi (adalimumab: 10,621, etanercept: 16,512, other TNFi: 9,634). Patients had a mean age of 53 years at cohort entry, and 72% to 81% were women. Around 61% of the cohort had at least one CV risk factor (66.3%for tofacitinib compared to 60.9% for TNFi). The two major co-medications at treatment initiation in the two groups were methotrexate (60.9%) and corticosteroids (50.8%).
After PS matching, the tofacitinib cohort included 2,628 patients, and the TNFi cohort included 7,884 patients. Over a median follow-up period of 11.31 months (tofacitinib: 8.56 months, TNFi: 12.52 months), 15 incident malignancy events occurred in the tofacitinib group (IR: 5.89 (3.55–9.77) per 1,000 patient-year (PY)) and 135 occurred in the TNFi group (8.03 (6.78–9.50)). The risk of malignancies was similar with tofacitinib vs TNFi (adjusted HR 0.76 [95%CI 0.44, 1.32]; p=0.3347). Similar results were found for other (other than breast, melanoma, colorectal, lung cancer or lymphoma) active cancers (HR 0.97 [95% CI 0.50, 1.89]; p=0.9382). For other specific cancer types (cited above), the number of events was too low to perform these analyses.
Conclusion: In this large population-based study, tofacitinib was not associated with an increased risk of malignancies (excluding NMSC) in comparison with TNFI in patients with RA treated in real-world settings. Studies with longer follow-up durations may be necessary to understand the long-term implications of tofacitinib vs TNFi on the risk of malignancies.

POS0834 LONG-TERM EXTENSION STUDY OF THE SAFETY AND EFFICACY OF NEUROIMMUNE MODULATION USING A VAGUS NERVE STIMULATION DEVICE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Non-pharmacological interventions, Rheumatoid arthritis, Randomized control trial

N. Gaylis[1], D. Sikes[2], A. Kivitz[3], D. M. Horowitz[4], M. Evangelista[5], Y. Levine[6], D. Chernoff[6], M. C. Genovese[7]. *[1]Arthritis and Rheumatic Disease Specialties, Rheumatology, Aventura, United States of America*; *[2]Florida Medical Clinic, Rheumatology, Zephyrhills, United States of America*; *[3]Altoona Center for Clinical Research, Clinical Research, Duncansville, United States of America*; *[4]Northwell Health, Rheumatology, Great Neck, United States of America*; *[5]SetPoint Medical, Clinical Research, Valencia, United States of America*; *[6]SetPoint Medical, Research and Development, Valencia, United States of America*; *[7]Stanford University, Rheumatology, Palo Alto, United States of America*

Background: The inflammatory reflex is a centrally integrated physiological mechanism whereby vagus nerve signaling regulates the production of proinflammatory cytokines that mediate systemic inflammation. The safety and efficacy of a neuroimmune modulation device were assessed in a first-in-human, double-blind pilot study in subjects with multi-drug refractory rheumatoid arthritis (RA). Previously reported data showed that vagus nerve stimulation (VNS) for 12 weeks using the neuroimmune modulation device, a miniature, leadless neurostimulator that is surgically implanted in the neck on the left vagus nerve, improved clinical outcomes, was safe and well-tolerated.[1] We now report 36-month long-term data from this pilot study.
Objectives: Determine the long-term safety and efficacy of neuroimmune modulation using a novel neuroimmune modulation device.
Methods: Subjects (N=14) with active RA and prior insufficient response to ≥2 biological or targeted synthetic (b/ts) DMARDs with ≥2 modes of action were implanted with the neuroimmune modulation device.[1] All subjects who completed Week 12 (N=14) were enrolled in an open-label, long-term extension study where subjects continued or if assigned to the sham group, began to receive treatment. Of these subjects, 11 completed 36 months of treatment as follows: VNS for 1 minute either once per day (QD, N=4) or four times per day (QID, N=3); subjects randomized to sham treatment during the first 12 weeks were crossed over to active VNS for 1 minute, randomized to either QD (N=3) or QID (N=1). The addition of a concomitant b/tsDMARD to study treatment was allowed at the discretion of the investigator and the subject. The safety and clinical effectiveness of VNS using the Clinical Disease Activity Index (CDAI) were evaluated.
Results: The 11 subjects completing the Month 36 visit had previously failed, on average, five different agents, with 73% (8/11) having failed a tsDMARD. The average CDAI change from baseline (i.e., initiation of stimulation) for the 11 subjects completing Month 36 was -17.8 (SD 16.3). At Month 36, 64% (7/11) of subjects achieved a CDAI MCID response from baseline (by the 12pt/6pt/1pt criteria[1]), of whom two (2) were treated with VNS monotherapy and five (5) were on continuous VNS with concomitant b/tsDMARD. The number of subjects in low disease activity (LDA) increased from 9% (1/11) at baseline to 45% (5/11) at Month 36, while the number of subjects in high disease activity (HDA) decreased from 64% (7/11) at baseline to 36% (4/11) at Month 36. Through Month 36, 81% (9/11) subjects elected to combine VNS with a b/tsDMARD, with 8/11 continuing concomitant b/tsDMARD at Month 36. Two adverse events related to VNS therapy occurred during the long-term follow-up period. These events were non-serious, anticipated, and reported by the same subject. One event was a mild sore throat, and the other was moderate tenderness near the implant site. Both events resolved without sequelae following a reduction in stimulation strength. There were no related infections, surgical revisions, or device explantations.
Conclusion: Despite small numbers, data demonstrate long term use of VNS was safe and effective treatment for RA to maintain or lower disease activity including when added to a b/tsDMARD.

Background: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Abatacept and rituximab are the recommended drugs **[1-2].** JAK inhibitors (JAKi) have demonstrated efficacy in RA. However, in clinical trials patients with active ILD were usually excluded. Moreover, a warning on ILD toxicity is included in SmPC (Summary of Product Characteristics) with tofacitinib (TOFA). Nonetheless, evidence on efficacy of JAKi in RA-ILD is growing **[3].**

Objectives: to assess **a)** the effectiveness and **b)** the safety of JAKi in AR-ILD patients.

Methods: National multicenter study of 57 RA-ILD patients on treatment with JAKi. We analyzed from baseline the following outcomes: **a)** forced vital capacity (FVC), **b)** diffusing capacity of the lungs for carbon monoxide (DLCO), **c)** chest high resolution computed tomography (HRCT), **d)** dyspnea (modified Medical Research Council scale), **e)** arthritis activity (DAS28-ESR or clinical records), and **f)** sparing corticosteroids effect.

Results: We studied 57 patients (37 women/ 20 men; mean age 66 ±10 years) from clinical practice on treatment with JAKi [baricitinib (BARI)= 42 (74%), TOFA= 6 (11%), upadacitinib (UPA)= 8 (14%), filgotinib (FILGO)= 1 (2%)]. Baseline demographic and clinical characteristics are shown in **Table 1**. All patients had received disease-modifying antirheumatic drugs (DMARDs) before JAKi [Methotrexate (49,86%), Leflunomide (37, 65%), Sulfasalazine (14, 25%), Hydroxychloroquine (13, 23%), Abatacept (32, 56%), Tocilizumab (14, 25%) and Rituximab (10, 18%)]. Since most patients were on BARI we focused on this group (n=42). Median [IQR] ILD duration up to BARI initiation was of 42 [13-62] months. Mean baseline values of FVC and DLCO (% predicted) were 87±22 and 71±21, respectively. Patients were followed-up for a mean of 37 ±37 months. The evolution of FVC and DLCO remained stable during the first 12 months (**Figure 1).** At the end of the follow-up, available chest HRCT images improved/ stabilized in 82% of patients. Stabilization or improvement of dyspnea was found in 87% of patients. Most patients showed articular remission or low activity. BARI was withdrawn in 12 (29%) patients due to articular inefficacy (n=11) and development of hypersensitivity pneumonitis (n=1).

Conclusion: JAKi, especially BARI, may be useful and safe in controlling the course of both pulmonary and joint disease in RA-ILD patients, even in refractory cases.

POS0836 RISK OF INFECTIONS BETWEEN JAK INHIBITORS AND TNF INHIBITORS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Safety, Rheumatoid arthritis, Disease-modifying drugs (DMARDs)

S. R. Choi[1], A. Shin[1], Y. J. Ha[1], Y. J. Lee[1], E. B. Lee[2], E. H. Kang[1]. *[1]Seoul National University Bundang Hospital, Division of Rheumatology, Department of Internal Medicine, Seongnam, Korea, Rep. of (South Korea)*; *[2]Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: With the increasing number of treatment options for rheumatoid arthritis (RA), safety is one of the important consideration for decision-making.
Objectives: To compare infectious risk between JAK inhibitors (JAKi) versus TNF inhibitors (TNFi) among patients with RA in Korea.
Methods: Using 2009-2019 Korea National Health Insurance Service database, we conducted a cohort study on RA patients initiating JAKi or TNFi. The outcomes of interest were 1) serious bacterial, 2) opportunistic, and 3) herpes zoster infections. Propensity-score fine-stratification (PSS) based weighting was applied to adjust for >60 baseline covariates. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using Cox proportional hazard models comparing JAKi versus TNFi users.
Results: Among 2,967 JAKi initiators and 13,152 TNFi initiators, 2,963 JAKi initiators PSS-weighted on 5,169 TNFi initiators were included. During a mean follow-up of 1.16 years, the most frequent type of infections was herpes zoster with an incidence rate (IR) per 100 person-years of 11.54 and 4.88 in JAKi and TNFi users, respectively, followed by serious bacterial infections with an IR of 1.39 and 1.32, respectively. The opportunistic infection was rare with a majority being tuberculosis, and showed an IR of 0.12 and 0.49 in JAKi and TNFi users, respectively. The PSS-weighted HR [95% CI] for individual types of infections was 2.37 [2.00-2.80] for herpes zoster, 1.04 [0.71-1.52] for serious bacterial infections, and 0.25 [0.09-0.73] for opportunistic infections, comparing JAKi to TNFi initiators. The risk of hospitalized herpes zoster was even higher among JAKi than TNFi initiators with a HR of 7.43 [3.91-14.11].
Conclusion: In this nationally-representative cohort study on RA patients, we found an exceptionally high IR of herpes zoster among JAKi initiators in Korea, showing a doubled risk compared to that in TNFi initiators. Although the risk of serious bacterial infections was comparable between the two treatment groups, the risk of opportunistic infections, particularly tuberculosis, was less among JAKi than TNFi initiators.

POS0837 IMPACT OF JAKI, TOFACITINIB, ON CV RISK IN RHEUMATOID ARTHRITIS: JAKI CV RISK IMPACT STUDY

Keywords: Targeted synthetic drugs, Rheumatoid arthritis, Cardiovascular disease

A. Syngle[1,2], I. Verma[3], N. Garg[4], K. Chauhan5, S. Patyal5, V. Syngle[6]. *[1]Healing Touch City Clinic, Internal Medicine & Rheumatology, Chandigarh, India*; *[2]Fortis Hospital Mohali, Internal Medicine & Rheumatology, Sahibzada Ajit Singh Nagar, India*; *[3]MM College of Pharmacy, MMU, Pharmacy Practice, Mullana, India*; *[4]Chitkara University, Pharmacy Practice, Rajpura, India*; *[1]Healing Touch City Clinic, Internal Medicine & Rheumatology, Chandigarh, India*; *[6]Healing Touch City Clinic, Internal Medicine, Chandigarh, India*

Background: Cardiovascular disease, that includes CAD & Stroke, is the leading cause of premature mortality and sudden death in RA. Classical CV risk & disease specific risk factors all contribute to the enhanced CV risk in RA. Endothelial dysfunction (ED), the " sine qua non" for atherosclerosis appearance, is the key promoter of CVD. ED is a barometer for CV health and a seminal target for reducing cardiovascular (CV) risk in RA. Given the magnitude of the problem, therapeutic armamentarium for CV risk reduction in RA is limited.
Objectives: To prospectively investigate the impact of Tofacitinib (TOFA) on CV risk in active RA.
Methods: 81 consecutive RA patients (Table 1) meeting 2010 Rheumatoid Arthritis Classification Criteria median age 54 years, 81% female, disease duration 14 years, moderate to high activity (DAS28-5.3) who were non-responders to MTX at least 15 mg/week and/or other synthetic DMARDs free of clinical overt cardiovascular disease were randomized 1:1 to receive TOFA 5 mg bid (n=41) or placebo (n=41) for 12 weeks as an adjunct to existing stable antirheumatic drugs. Primary endpoints included endothelial dysfunction assessed by Flow Mediated Dilatation (FMD), using Angiodefender, at baseline and after 12 weeks of treatment and occurrence of MACE and VTE throughout the study. The secondary end points included: DAS28, ESR, CRP, HAQ-DI.

Table 1. Demographic, clinical and biochemical characteristics of 81 rheumatoid arthritis patients

Clinical Parameters	**Tofacitinib (n=41)**	**Placebo (n=40)**	**P value**
Age (years)	56.13± 7.95	54.8 ± 8.4	0.34
Gender: M/F (n)	06/35	06/34	0.84
BMI (kg/m^2)	26.71 ± 3.23	25.08 ± 4.17	0.79
Disease Duration (yrs)	14.28 ± 6.85	13.7 ± 6.6	0.48
RF Positive	29 (48.33%)	30 (50.84%)	--
Anti CCP	15 (25%)	13 (22%)	--
Systolic Blood Pressure (mm Hg)	124.3± 7.52	122.2 ± 6.89	0.47
Diastolic Blood Pressure (mm Hg)	78.38 ± 5.16	76.84 ± 4.52	0.56
ESR (mm 1sthr)	38.84 ± 16.03	39.2 ± 17.14	0.56
CRP (mg/dl)	20.15± 20.82	18.16 ± 12.25	0.33
DAS-28	5.4 ± 2.18	5.48 ± 2.3	0.88
HAQ-DI	0.52 ±0.54	0.59 ± 0.70	0.32

Values presented as mean ± SD, except gender which is expressed as a number of female and male. F: female, M: male, SBP: systolic blood pressure, DBP: diastolic blood pressure, ESR: erythrocyte sedimentation rate, CRP: C-reactive protein, DAS-28: disease activity score in 28 joints, HAQ-DI

Results: At baseline, endothelial function was impaired and levels of inflammatory measures were elevated and HAQ-DI was impaired in both groups. After treatment, FMD improved significantly in the tofacitinib group from (6.64 ± 2.13 to 8.17 ± 2.69, p=0.0001) as compared to placebo (6.36 ± 3.01% to 6.84 ± 2.95%, p=0.68) (Figure 1A). DAS28 (Figure 1B), ESR and CRP levels improved significantly in tofacitinib group as compared to placebo (p≤0.05). TOFA significantly decreased HAQ-DI (Figure 1C) values as compared to placebo. There was no MACE or VTE event during the study period in either group. After 12 weeks of treatment, FMD increased by 23.04% where as DAS28, ESR and CRP decreased by 31.23%, 29% and 60% respectively in the TOFA group (Figure 1D). Significant negative correlation was observed between FMD and CRP (0.32, p≤0.05) before and after (r= -0.34, p≤0.05) treatment with TOFA whereas no such correlations were found in placebo group.

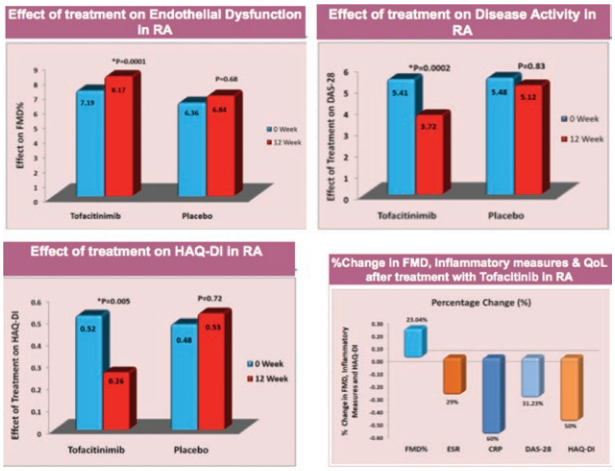

Fig 1. Effect of Tofacitinib treatment on (A) Endothelial dysfunction (B) Disease activity (C) HAQ-DI and (D) % Change

Conclusion: TOFA, apart from its anti-inflammatory activity, improves endothelial dysfunction and cardiovascular risk in active RA without clinical overt cardiovascular disease. Thus, JAK inhibition with TOFA has vasculoprotective and cardioprotective effect mediated through anti-inflammatory and probably other mechanisms.

POS0838 AGOMELATINE IDENTIFIED FROM THE FDA-APPROVED DRUG LIBRARY IS THERAPEUTIC AGAINST COLLAGEN INDUCED ARTHRITIS

Keywords: Rheumatoid arthritis, Cytokines and chemokines

Y. Chen[1,2], Y. Tian[1], H. Liu[1,2], Q. LI[1], Z. Luo[1], G. Yin[1], Q. Xie[1]. *[1]West China Hospital, Sichuan University, Department of Rheumatology and Immunology, Chengdu, China*; *[2]West China Hospital, Department of Rheumatology and Immunology, Chengdu, China*

Background: Treatment effect of tumor necrosis factor α (TNFα) inhibitors is still low in patients with rheumatoid arthritis (RA), around 50%-70%. Thus more drugs by targeting proliferation of synovial fibroblasts (FLS) and TNFα induced inflammatory cytokine production are needed. Repurposed use of drugs that have been used in clinic is a quick and cost-effective way to find new drugs.

Objectives: This study aims to screen drugs that could inhibit the proliferation and inflammation induced by TNFα in FLS from FDA approved on market drug library, then to assess the treatment effect of the identified drugs on collagen-induced arthritis (CIA) mouse model.

Methods: CCK8 assay was performed to screen the drugs that could inhibit FLS proliferation, followed by qRT-PCR and ELISA to select the drugs that could suppress TNFα induced inflammatory cytokine production. Then, treatment effects of the identified drugs were assessed in CIA mouse model.

Results: The first and second round drug librabry screening aimed to select out the drugs that could inhibit the proliferation of FLS. Results showed, from 1815 drugs, 372 drugs were indentified at the initial screening (Figure 1A) and 121 drugs were identified from the second screening (Figure 1B). The third round screening was performed to screen the drugs that could inhibit TNFα-induced inflammation, and results showed that a total of 77 drugs could inhibit mRNA expression levels of both IL-6 and IL-8 by over 50%, and 64 drugs could suppress secretion levels of both IL-6 and IL-8 for more than 20% (Figure 1C-F). Then a total of 14 drugs that were not anti-cancer drugs were used to further confirm the inhibitory effect on the TNFα induced inflammation, and results showed only Agomelatine (AOM), Cinacalcet (CCC), Amlodipine (ALM), Simvastatin (SV), and Pindolol (PDL) could suppress mRNA expression and secretion levels of IL-6, IL-8 (Figure 1G-J). As highly proliferated FLS and inflammatory cytokines play a critical role in the pathology of rheumatoid arthritis (RA), we tested the treatment effect of AOM, CCC, ALM, SV, and PDL in the CIA mose model. Results showed ALM (5mg/kg), CCC (10mg/kg), and PDL (10mg/kg) had a trend to reduce the clinical score but did not reach statistical meaning while SV (10mg/kg) did not show any treatment effect. Whereas, AOM (10mg/kg) could effectively alleviate the swelling of the the joint, which was as effective as the positive control drug methotrexate (MTX) (Figure 1K). ALM, AOM, as well as MTX could reduce the pathological score of inflammation and bone erosion at both the knee and the anke while PDL could only reduce the inflammation and relieve bone erosion at the knee(Figure 1L-N).

Conclusion: Agomelatine indentified from the FDA approved drug library could inhibit FLS proliferation and TNFα induced inflammation, and was therapeutic against CIA mouse model.

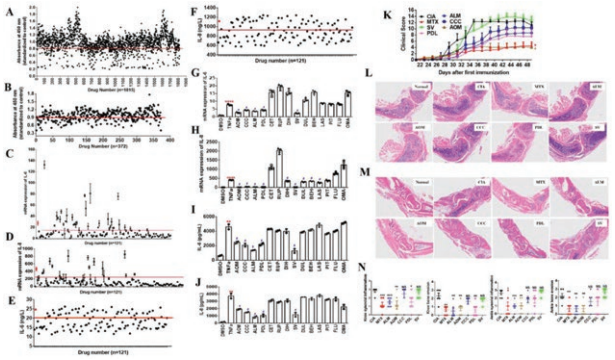

Figure 1. Agomelatine identified from the FDA-approved drug library is therapeutic against collagen induced arthritis. (A) The first round screening by CCK8 assay. The drugs could inhibit more than 20% absorbance at 450nm, under the red lines, were the target ones, n=372. (B) The second round screening. The drugs could inhibit more than 10% absorbance at 450nm, under the red lines, were the target ones, n=121. (C-F) The third round screening. (C-D) mRNA expression levels of IL-6 and IL-8. (E-F) the secretion levels of IL-6 and IL-8. (G-J) The confirmation of drugs' inhibitory effect on the inflammation cytokine production. Red asterisk indicated the conparison between TNFα group and DMSO group and blue pound signs suggested the conparison between drugs and TNFα group. (G-H) the mRNA expression levels of IL-6 and IL-8. (I-J) the secretion levels of IL-6 and IL-8. CIA mouse model was established to test the treatment effect of SV (10mg/kg), PDL (10mg/kg), ALM (5mg/kg), CCC (10mg/kg), and AOM (10mg/kg), and MTX (2mg/kg) was set as the positive control. (K) clinical score of joint swelling (L) H&E staining of knee joint (M) H&E staining of ankle joint (N) pathological scoring of H&E staining for joint inflammation and bone erosion.

POS0839 THE COMPARISON OF MALIGNANCY RISK BETWEEN JAK INHIBITORS AND TNF INHIBITORS IN MULTI-CENTER COHORT STUDY

Keywords: Targeted synthetic drugs, Rheumatoid arthritis, Safety

T. Uchida[1,2], N. Iwamoto[2], S. Fukui[2,3], S. Morimoto[4], T. Aramaki[5], F. Shomura[1], K. Aratake[1], K. Eguchi[5], Y. Ueki[5], A. Kawakami[2]. *[1]Ureshino Medical Center, Rheumatology, Ureshino, Japan*; *[2]Nagasaki University Graduate School of Biomedical Science, Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan*; *[3]Nagasaki University Graduate School of Biomedical Sciences, General Medicine, Nagasaki, Japan*; *[4]Nagasaki University Hospital, Clinical Research Center, Nagasaki, Japan*; *[5]Hakujujikai Sasebo Chuo Hospital, Rheumatology, Nagasaki, Japan*

Background: Ytterberg et al. demonstrated the concern about the incidence of malignancy during treatment with tofacitinib [1]. However, there is few published data of such adverse events in clinical settings.

Objectives: We aimed to compare the incidence of malignancies in RA patients treated with JAK inhibitors and TNF inhibitors in real-world settings.

Methods: We enrolled 499 RA patients treated with JAK inhibitors (tofacitinib, n=192 or baricitinib, n=104) or TNF inhibitors (adalimumab, n=88 or etanercept, n=115). The standardized incidence ratio (SIR) of malignancies were determined using the general Japanese population. After adjusting the clinical characteristic imbalance by propensity score weighting, we compared the risk of malignancy between JAK inhibitors and TNF inhibitors using Cox proportional hazard models.

Results: Observational period was 961.9 patient-years (PY), and median observational period was 1.3 years. We identified 11 cases (3.7%) of malignancies in JAK inhibitors and 4 cases (2.0%) in TNF inhibitors. The SIR for overall malignancies in TNF inhibitors was comparable with general population (0.94, 95%CI: 0.26–2.41), and the SIR in JAK inhibitors was higher than the general population but no significant difference (1.61/100PY, 95%CI: 0.80-2.88). The adjusted hazard ratio was 0.38 (95%CI: 0.09-1.55) between JAK inhibitors and TNF inhibitors in the risk of malignancies (Figure 1).

Conclusion: We demonstrated that the incidence of malignancy in JAK inhibitors was numerically high but not significant compared with general population and TNF inhibitors.

POS0840 THE DIFFERENCE IN CREATINE KINASE ELEVATION CAUSED BY JAK INHIBITORS AND IL-6 INHIBITORS IN RHEUMATOID ARTHRITIS

Keywords: Comorbidities, Rheumatoid arthritis

M. Tada[1], T. Okano[2], K. Mamoto[2], Y. Yamada[3], K. Orita[4], K. Mandai[5], S. Anno[4], T. Iida[6], K. Inui[5], T. Koike[6]. *[1]Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan*; *[2]Osaka Metropolitan University Graduate School of Medicine, Orthopaedic Surgery, Osaka, Japan*; *[3]Osaka Social Medical Center Hospital, Orthopaedic Surgery, Osaka, Japan*; *[4]Yodogawa Christian Hospital, Orthopaedic Surgery, Osaka, Japan*; *[5]Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan*; *[6]Koryokai Hospital, Orthopaedic Surgery, Osaka, Japan*

Background: Cases of creatine kinase (CK) elevation caused by Janus kinase inhibitor (JAKi) treatment for rheumatoid arthritis (RA) have been reported in clinical trials[1]. IL-6 signals via the JAK-STAT pathway. However, it is not known whether the CK elevation is due to JAKi alone or to IL-6 inhibitor (IL-6i) as well.
Objectives: The objective was to examine whether the CK elevation is specific to JAKi therapy or similar to IL-6i therapy by propensity score (PS)-matching.
Methods: A multicenter database of JAKi (n=168) and IL-6i (n=113) treatment was used. All cases were followed-up at 24 weeks, and their CK levels were evaluated. A total of 71 cases in each group were extracted by the PS-matching method (using age, sex, BMI, and CK at 0 weeks (W)). The percentage abnormal from the standard titer was compared for the JAKi and IL-6i groups. The factors related to an elevated CK at 24 weeks were investigated using patients' background characteristics at the time of starting treatment by univariate analysis.
Results: The patients' median age was 66 years, CK at 0W was 57I U/L, and mean BMI was 22.5 kg/m^2. There were no significant differences between the groups at the time of starting treatment (Table 1). The changes in CK by JAKi and IL-6i treatments are shown in the Figure 1. The CK at 4W with JAKi treatment was significantly higher than that with IL-6i treatment (83 vs 72 IU/L; P=0.018). The same tendency was seen at 12W and 24W. The outlier rate (Grade 1: 1 < titer < 2.5 times) with JAKi treatment increased significantly over time (0W: 4.2%, 4W: 18.1%, 12W: 21.7%, 24W: 18.3%, P=0.015), whereas that with IL-6i treatment increased slightly (0W: 5.6%, 4W: 9.2%, 12W: 8.6%, 24W: 8.5%, P=0.745), with a significant difference between the groups (P=0.035). Of all the patients, only three showed Grade 2 (2.5 < titer < 5 times). No RA patients discontinued treatment due to myalgia or renal dysfunction. The factors significantly positively related to elevated CK at 24W were male and creatine, and those significantly negatively related were stage, class, mHAQ, eGFR, and PSL dosage.
Conclusion: CK elevation was greater with JAKi treatment at 4W and maintained until 24W than with IL-6i treatment in RA patients with adjustment for background characteristics. The CK elevation might be specific to JAKi treatment. The mechanism needs to be clarified in the future.

POS0841 EFFECTIVENESS AND SAFETY OF UPADACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PRIOR TNF-THERAPY IN GERMANY. FINAL RESULTS FROM A POST-MARKETING OBSERVATIONAL STUDY

Keywords: Targeted synthetic drugs, Real-world evidence, Rheumatoid arthritis

T. Witte[1], U. Kiltz[2], F. Haas[3], E. Riechers[1], D. Adolf[4], U. Prothmann[5], U. Soppa[6], A. Roessler[6], K. Götz[6], B. Fritz[7], K. Krueger[8]. *[1]Medizinische Hochschule Hannover, Department for Rheumatology and Immunology, Hannover, Germany*; *[2]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*; *[3]Internistisch-Rheumatologische Facharztpraxis, Rheumatologie, Tübingen, Germany*; *[4]StatConsult GmbH, Statistics, Magdeburg, Germany*; *[5]Knappschaftsklinikum Saar, Rheumatologie, Püttlingen, Germany*; *[6]AbbVie Germany GmbH & Co. KG, Rheumatology, Wiesbaden, Germany*; *[7]AbbVie Germany GmbH & Co. KG, Medical Affairs, Wiesbaden, Germany*; *[8]Praxiszentrum St. Bonifatius, Rheumatologie, München, Germany*

Background: The efficacy and safety of Upadacitinib (UPA), a selective Janus kinase inhibitor, have been evaluated in the SELECT clinical trial program [1-6]. The UPwArds study was designed to further elucidate UPA's real-world effectiveness in daily clinical practice.
Objectives: To assess UPA effectiveness and safety after a treatment period of 12 months in three different RA patient groups: i) the total patient population, ii) patients with previous failure of TNFi (prior TNFi), and iii) patients naïve to targeted-synthetic or biological disease-modifying anti-rheumatic drugs (ts/bDMARDs naïve).
Methods: UPwArds is a prospective, open-label, multicenter, post-marketing observational study including adult patients with moderate-to-severe RA and an inadequate response or intolerance to at least one previous disease-modifying anti-rheumatic drug. At month 12 of the observational period, improvement of the DAS28(CRP), CDAI and the 0-10 numerical rating scale for overall pain (NRS pain) were assessed for the different patient populations specified above. In addition, the three patient population groups were evaluated regarding safety data concerning adverse events that were collected over the study period. Respective comparisons are presented as number of events per 100 patient-years, including

confidence intervals. Data analysis was conducted as observed without imputation of missing values.

Results: From all initially enrolled patients (n_{total} = 533, $n_{prior\ TNFi}$ =262, $n_{ts/bDMARDs\text{-}naïve}$ = 209), 371 completed the study (70%), of whom 175 and 148 were prior TNFi or ts/bDMARDs-naïve patients, respectively. At month 12, the proportion of patients achieving DAS28 < 2.6, DAS28 ≤ 3.2, CDAI ≤ 2.8, CDAI ≤ 10, and NRS pain reduction ≥ 50% reflected comparable outcomes in all three patient groups (Figure 1). Although the number of any AE per 100 patient years was higher in prior TNFi patients, no significant differences were found in any particular AE category, including serious AEs or other AEs of particular interest (Table 1).

Conclusion: In a real-world setting, UPA demonstrated comparable effectiveness and safety in prior TNFi patients, ts/bDMARDs-naïve patients and the overall patient population.

GLUCOCORTICOID USAGE AFTER JANUS KINASE INHIBITOR (JAKI) AND OTHER BIOLOGIC DMARDS INITIATION AND IMPACT OF COMEDICATION OF CONVENTIONAL DMARDS ON TREATMENT PERSISTENCE IN RHEUMATOID ARTHRITIS PATIENTS: RETROSPECTIVE STUDY IN THE AUSTRALIAN POPULATION

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Epidemiology

L. Scheepers[1], Y. Yang[2], Y. Chen[2], G. Jones[1]. [1]*Menzies Institute for Medical Research, Musculoskeletal Health and Disease, Hobart, Australia*; [2]*Prospection, Data engineering, Haymarket, Australia*

Background: Janus Kinase inhibitors (JAKi) and biologic disease modifying anti-rheumatic drugs (bDMARDs) are routinely used in the management of rheumatoid arthritis (RA) patients for whom conventional (c)DMARDs have failed. The usage of glucocorticoids after DMARD initiation and the influence of comedication on treatment persistence, used as a surrogate for treatment effectiveness, remains unkown.

Objectives: To assess glucocorticoids usage after treatment initiation and to compare the impact of comedication on the persistence of JAKi and bDMARDs in Australian RA patients.

Methods: A retrospective observational study was conducted among 4,521 RA patients in the Australian Medicare Database (from 2011 to 2022), aged ≥18 and for whom a JAKi or bDMARDs were dispensed. A deidentified 10% sample of the database was taken as a random representation of RA patients in Australia. Kaplan-Meier analysis was used to calculate drug persistence rates, defined as the time from treatment initiation until the date of the last dose when there had not been a script dispensed for 6 months. Wilcoxon Singed Rank test was used to compare glucocorticoid dose changes from 1-year prior to 1 and 1 – 2 years after initiation of the DMARDs. Only patients who had persisted on DMARDs for 2 years were included for analysis. Log-rank test was used to compare time on a particular DMARDs treatment between the following sub-groups: (a) monotherapy; (b) combination MTX; and (c) combination cDMARDs.

Results: A total of 634 met the inclusion criteria for the glucocorticoids analyses, average dose of glucocorticoids decreased from 4.1mg/day at 1 year prior to initiation of DMARD, to 2.9mg/day and 2.0mg/ day at 1- and 1–2-years post-initiation, respectively (**Figure 1**). Daily dose changes were statistically significant for all RA DMARDs combined, tofacitinib and baricitinib combined (1–2 years post initiation only), TNFi, abatacept, and tocilizumab. The proportion of patients with a decrease in glucocorticoids dose from 1 year prior to 1 and 1–2 years after DMARD initiation was 62% and 70% for 'all DMARDs' (*n*=634), 35% and 52% for baricitinib (*n*=23), 58% and 63% for tofacitinib, 59% and 61% for abatacept (*n*=87), 65% and 78% for tocilizumab (*n*=148), and 62% and 70% for TNFi (*n*=387), respectively. For each drug individually, treatment persistence rates were higher in combination with MTX and in combination with other cDMARDs, compared to monotherapy (**Table 1**). Statistical significance was only reached when comparing baricitinib combined with cDMARD to monotherapy baricitinib (65% [*p*=0.04] *vs* 52%), tofacitinib combined with MTX and combined with other cDMARDs to monotherapy tofacitinib (56% [*p*=<0.01] and 55% [*p*=<0.01] vs. 45%); and TNFi combined with MTX and combined with other cDMARDs to monotherapy TNFi (63% [*p*=<0.0001] and 65% [*p*=<0.0001] vs. 43%).

Conclusion: This real-world data showed that among Australian RA patients glucocorticoids dosage decreased with JAKi and bDMARD use. When treatment was combined with MTX or other cDMARDs persistence rates were not sig. different when comparing upadacitinib, baricitinib and TNFi. Tofacitinib had similar persistence rates to TNFi.

Average daily glucocorticoids usage.

DISTINCT TREATMENT RESPONSES IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING FILGOTINIB 200 MG OVER 12 MONTHS: A POST HOC ANALYSIS OF FINCH 1

Keywords: Remission, Rheumatoid arthritis

P. C. Taylor[1], Y. Tanaka[2], E. Aiello[3], T. Debray[4], C. Watson[5], K. Harris[6], G. R. Burmester[7]. *[1]Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom*; *[2]University of Occupational and Environmental Health, Department of Internal Medicine, Kitakyushu, Japan*; *[3]Cytel, Real-world Analytics, Toronto, Ontario, Canada*; *[4]Galapagos NV, Biostatistics, Mechelen, Belgium*; *[5]Galapagos Biotech Ltd, Medical Affairs, Cambridge, United Kingdom*; *[6]Galapagos NV, Medical Affairs, Mechelen, Belgium*; *[7]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: FINCH 1 (NCT02889796) was a Phase 3 randomized controlled trial evaluating filgotinib (FIL) in patients with rheumatoid arthritis and an inadequate response to methotrexate (MTX).[1] Patients received background MTX and were randomized 3:3:2:3 to FIL 200 mg (FIL200), FIL 100 mg, adalimumab or placebo.
Objectives: To identify patterns of response trajectory over 12 months in patients from FINCH 1 receiving FIL200.
Methods: Group-based trajectory modeling is a statistical method which groups individuals based on similar patterns of change in an outcome over time.[2] A group-based trajectory modeling approach was applied to identify five distinct phenotypic groups in terms of observed clinical disease activity index (CDAI) outcomes (and components) over a 12-month period (**Figure 1**). Responders were recorded as either low disease activity (LDA) or remission, defined as CDAI between 2.9 and 10, or ≤2.8, respectively, at 6 or 12 months.
Results: Mean age, the proportion of females and disease duration were similar across all groups. Improvements in efficacy outcome measures were seen for all groups. Baseline (median interquartile range [IQR]) CDAI was highest (worst) in Group 5 (52 [48, 60]), followed by Group 1 (48 [44, 55]). Groups 1 and 3 showed a rapid reduction in CDAI in the first 6 months and sustained response over 12 months. Groups 2, 4 and 5 demonstrated slower response trajectories, with continued improvements in the proportion of CDAI responders between 6 and 12 months; of note, Group 5 constituted 16.8% (80/475) of the total analysis population. **Table 1** shows that despite substantial and comparable improvements in CDAI components across all 5 groups over 12 months, Group 5 demonstrated some residual disease activity.
Conclusion: A group-based multivariate trajectory model identified 5 distinct CDAI disease activity trajectories in patients from FINCH 1 receiving FIL200. Patients in all groups demonstrated either fast and sustained response or slower and continued improvements, with no or low numbers of swollen or tender joints at Month 12. The current analysis suggests that patients who do not achieve CDAI LDA within 6-months may still benefit from treatment continuation and informs a range of expectations for times to clinical response. Future work will assess biomarker profiles that may be used to predict the observed clinical response patterns.

Burmester[12]. *[1]Oregon Health and Science University, School of Medicine, Portland, United States of America*; *[2]Medical University of Vienna, Department of Medicine III (Division of Rheumatology), Vienna, Austria*; *[3]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*; *[4]ASST Gaetano Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy*; *[5]University of Occupational and Environmental Health, Department of Internal Medicine, Kitakyushu, Japan*; *[6]Keio University, Department of Internal Medicine, Tokyo, Japan*; *[7]Galapagos NV, Medical Safety, Mechelen, Belgium*; *[8]Galapagos NV, Biostatistics, Mechelen, Belgium*; *[9]Galapagos NV, Clinical Research, Mechelen, Belgium*; *[10]Galapagos NV, Medical Affairs, Mechelen, Belgium*; *[11]Strasbourg University Hospital, Rheumatology Department, Strasbourg, France*; *[12]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Filgotinib (FIL) is an oral Janus kinase 1 preferential inhibitor, approved for the treatment of moderate to severe active rheumatoid arthritis (RA). In previous analyses, comparable incidence of selected adverse events (AEs) occurred in FIL 200 mg (FIL200) and 100 mg (FIL100) dose groups, except for herpes zoster.[1]

Objectives: To provide an update on FIL selected AEs up to a median (max) exposure of 3.8 (8.3) years.

Methods: Integrated FIL RA data from 7 clinical trials are reported: phase 2 (NCT01888874, NCT01894516), phase 3 (NCT02889796, NCT02873936, NCT02886728), and the long-term extension studies DARWIN 3 phase 2 (NCT02065700) and FINCH 4 phase 3 (NCT03025308). Exposure-adjusted incidence rates (EAIRs)/100 patient-years of exposure (PYE), censored at time of first event, were determined for major adverse cardiovascular event (MACE), venous thromboembolism (VTE), arterial systemic thromboembolism, non-melanoma skin cancer (NMSC), malignancies excluding NMSC, herpes zoster, serious infections and deaths. Data were as of May 2, 2022 (DARWIN 3) and May 6, 2022 (FINCH 4). MACE and VTE only include positively adjudicated events with a data cutoff of April 3, 2022.

Results: The as-treated population included 3691 patients with 12,541 PYE. Median (max) exposure was 3.8 (8.3) in the pooled FIL group; 3.8 (8.3) years for FIL200 and 3.3 (7.8) years for FIL100. Baseline demographics and disease characteristics were balanced between groups.[2] Small numerical differences were observed between FIL doses for EAIRs of selected AEs. Numerically higher incidences of NMSC, herpes zoster and all-cause mortality were reported with FIL200 vs FIL100; incidences of MACE and serious infections were numerically lower with FIL200 vs FIL100, with overlapping confidence intervals (**Table 1**). Over 240 weeks, the risks of MACE and VTE were comparable for FIL100 vs FIL200; low event numbers make interpretation difficult. The risk of herpes zoster was higher with FIL200 vs FIL100, and generally similar for serious infection or all-cause mortality (**Figure 1**).

Conclusion: Over a maximum of 8.3 years, FIL200 and FIL100 continued to show small numerical differences in EAIRs of selected AEs between dose groups in the overall RA population. Slightly higher incidence rates for NMSC, herpes zoster and all-cause mortality were reported in the FIL200 than FIL100 group, with a higher incidence of MACE and serious infections with the lower dose; confidence intervals overlapped between the dose groups.

Figure. Event probability of serious infection and herpes zoster

Solid lines show data for serious infection, dashed lines show data for herpes zoster. Time to event was calculated as (onset date of first event – first dose date) + 1. The population was as-treated, including patients who received ≥1 dose of any study drug. A patient may contribute to ≥1 treatment group summary if the patient received ≥1 treatment of interest. Number of patients at risk = number of patients at risk at the given time point. ADA, adalimumab; BL, baseline; QD, once daily.

Background: Data from the randomised placebo-controlled INBUILD trial in subjects with progressive fibrosing interstitial lung diseases (ILDs) other than idiopathic pulmonary fibrosis suggested that nintedanib may have effects on circulating levels of biomarkers of epithelial injury, inflammation and extracellular matrix (ECM) turnover.

Objectives: We investigated the effects of nintedanib on circulating biomarkers in subjects in the INBUILD trial who had pulmonary fibrosis due to autoimmune disease.

Methods: Subjects in the INBUILD trial had diffuse fibrosing ILD of >10% extent on HRCT and met criteria for progression of ILD within the prior 24 months, despite management in clinical practice. Subjects were randomised to receive nintedanib or placebo, stratified by fibrotic pattern on HRCT (usual interstitial pneumonia-like fibrotic pattern or other fibrotic patterns). Blood samples were taken at baseline and at weeks 12, 24, 36 and 52. Fold changes in adjusted mean levels of biomarkers were analysed using a linear mixed model for repeated measures. Data were log10 transformed before analysis and estimates of change from baseline were back-transformed.

Results: Of 663 subjects, 170 had autoimmune disease-related ILDs; 82 of these subjects received nintedanib and 88 received placebo. Over 52 weeks, there were treatment-related decreases in fold changes from baseline in levels of Krebs von den Lungen-6 (KL-6), surfactant protein D (SP-D), CA-125 (markers of epithelial injury) in subjects who received nintedanib versus placebo (Figure 1). The most pronounced difference between nintedanib and placebo was in CA-125. The effect of nintedanib on CA-125 was observed as early as week 12. Small decreases in fold changes from baseline in soluble intercellular adhesion molecule (s-ICAM) (a marker of inflammation) and in C3M and pro-C6 (markers of ECM turnover) were observed in subjects who received nintedanib versus placebo (Figure). No notable trends were observed for the other biomarkers assessed.

Conclusion: In subjects with progressive fibrosing autoimmune disease-related ILDs, nintedanib reduced circulating levels of markers of epithelial injury, with the most pronounced effect observed on CA-125. The treatment-related decreases in these markers in subjects with autoimmune disease-related ILDs were similar to those observed in subjects with other ILDs.

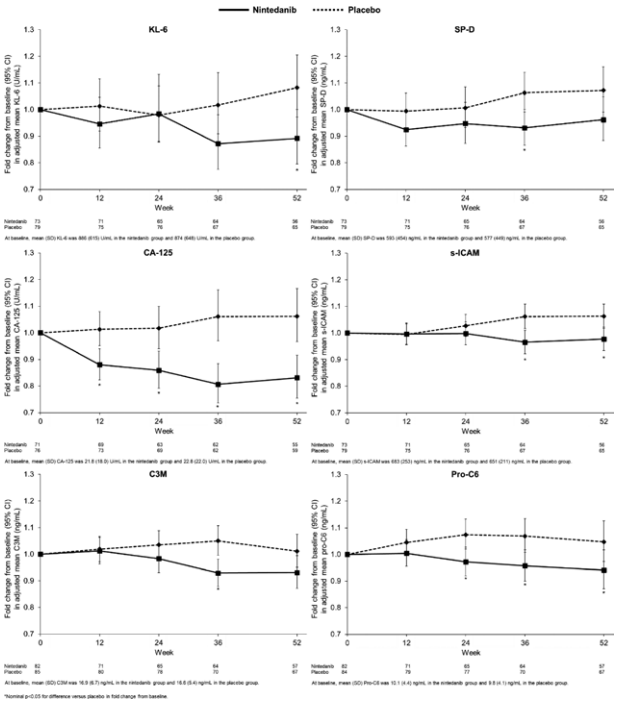

Figure 1. Fold changes from baseline in circulating biomarkers over 52 weeks in subjects with progressive fibrosing autoimmune disease-related ILDs in the INBUILD trial.

Acknowledgements: The INBUILD trial was funded by Boehringer Ingelheim. Martin Kolb was a member of the INBUILD Steering Committee.

POS0846 EFFICACY, SAFETY, AND RECURRENCE OF IGURATIMOD COMBINED WITH CSDMARDS TREATMENT IN RHEUMATOID ARTHRITIS: A PROSPECTIVE REAL-WORLD STUDY

Keywords: Disease-modifying drugs (DMARDs), Clinical trials, Rheumatoid arthritis

Q. Che[1,2], X. Liu[3], X. Qi[1,2], Y. Li[4], X. Zhang[1,2], H. Wang[5], Q. Shu[1,2]. *[1]Qilu Hospital, Cheeloo College of Medicine, Shandong University, Department of Rheumatology, Jinan, China*; *[2]Shandong Provincial Clinical Research Center for Immune Diseases and Gout, Department of Rheumatology, Qilu Hospital, Jinan, China*; *[3]Tianjin Medical University General Hospital, Department of Rheumatology, Tianjin, China*; *[4]Yantaishan Hospital, Department of Rheumatology and Immunology, Yantai, China*; *[5]Jiangsu Simcere Pharmaceutical Co., Ltd., Department of Marketing Management, Nanjing, China*

Background: Iguratimod (IGU) is widely used in the treatment of rheumatoid arthritis (RA) and has been considered the first-line treatment option in many countries. The efficacy and safety of IGU combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) therapy have been

confirmed by many studies [1]. Only a few studies focused on the long-term efficacy and safety of IGU treatment, and the maintenance strategy after short-term remission (REM) still needs to be explored.

Objectives: To observe the long-term efficacy, safety, and recurrence of IGU combination with csDMARDs in the treatment of active RA and the characteristic of patients who obtain the most benefit from IGU.

Methods: The study was conducted in China (ClinicalTrials.gov ID: NCT03855007). Patients who matched the 2010 ACR/EULAR RA criteria or the 2014 early rheumatoid arthritis (ERA) criteria [2] were recruited. According to patientsicalTrials.gov ID: NCT03855007). Patients who matched the 2010 ACR/EULAR RA criteria or the 2014 early rheumatoid arthritis (ERA) criteria enefit from IGU.on with conventiond follow-up from baseline to week 96 regularly. We divided them into three groups according to whether and when to reduce the drugs: maintained (MA), reducing the dose of IGU, MTX, and LEF after (AF) or before (BF) low disease activity (LDA), or REM was achieved. The proportion of LDA or REM of DAS28-ESR achieved at week 96, the ratio of ACR20, ACR50, ACR70, the recurrence (loss of LDA status and the increase of DAS28-ESR ≥ 0.6 [3]), and the occurrence of adverse events (AE) were investigated. The chi-square test or long-rank test analyzed the corresponding statistical differences.

Results: A total of 246 patients were enrolled in this study, and 131 (53.3%) participants completed the 96-week follow-up. Efficacy analysis found that the proportion of achieving ACR20 reached a plateau after 24 weeks, while there was a sustained increase in the LDA and REM ratio of DAS28-ESR (week 24: 57.25% vs. week 96: 68.70%, p = 0.06), ACR50 (66.41% vs. 77.86%, p = 0.01) and ACR70 (22.90% vs. 41.98%, p < 0.01) (**Figure 1 A, B**). Further subgroup analysis revealed the expected effects of age, gender, and disease duration on whether achieved the LDA or REM at 96 weeks. Moreover, the time of IGU, MTX, and LEF reduction also played an essential role in long-term treatment. There was no difference in the improvement of DAS28-ESR between the MA (n=15) and reduction (AF+BE) groups. We found that patients in the AF group (n=73) were able to achieve and maintain LDA or REM and ACR50 responses better than the BE group (n=43) (**Figure 1 C**). There was no statistical difference in the incidence of AE between BE and AF groups (p = 0.44). During the follow-up period, 48 patients had a relapse of the disease in the AF and BE groups. The subgroup analysis found that drug reduction after REM was more recommended in patients with a diagnosis of RA (vs. ERA), disease duration ≥ 2 years, age < 45 years, and morning stiffness <1 hour (**Figure 1 D**) for maintaining long-term LDA or REM (p < 0.05).

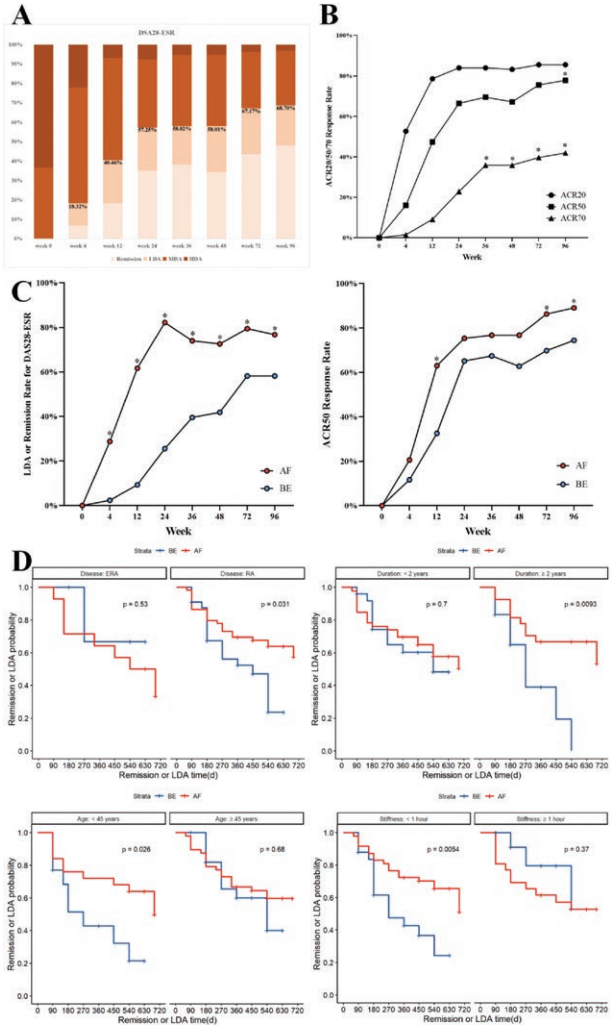

Figure 1. The efficacy and recurrence of IGU combination treatment for patients who completed the 96-week follow-up. (A) The rate of achieving LDA or REM of DAS28-ESR; (B) The rate of achieving ACR20, ACR50, and ACR70, * p < 0.05, compared to week 24; (C) The rate of achieving LDA or REM of DAS28-ESR, ACR50 in AF and BE groups, * p < 0.05, compared to the BE group; (D) The Kaplan-Meier curves of AF and BE subgroup analysis according to the disease stage, duration, age and morning stiffness.

Conclusion: The RA patients could achieve deeper REM and sustained after long-term treatment of IGU combination with csDMARDs. LDA or REM should be achieved before reducing the dose of IGU and csDMARDs, especially for the long-course, younger, with shorter morning stiffness RA patients.

POS0847

UPADACITINIB AS MONOTHERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PRIOR INADEQUATE RESPONSE TO METHOTREXATE: RESULTS AT 260 WEEKS FROM THE SELECT-MONOTHERAPY STUDY

Keywords: Rheumatoid arthritis, Targeted synthetic drugs, Safety

J. S. Smolen[1], P. Emery[2], W. Rigby[3], Y. Tanaka[4], J. Ignacio Vargas[5], N. Damjanov[6], M. Jain[7], K. Kato[8], K. Carter[8], N. Khan[8], H. Camp[8], S. B. Cohen[9].

Background: Upadacitinib (UPA), an oral JAK inhibitor, was shown to be safe and effective in improving the signs and symptoms of moderate-to-severe RA through 84 weeks (wks) when administered as monotherapy in patients (pts) with a prior inadequate response to MTX in the phase 3 SELECT-MONOTHERAPY trial (NCT02706951).[1]

Objectives: To evaluate the efficacy and safety of UPA monotherapy up to wk 260 from the long-term extension (LTE) of SELECT-MONOTHERAPY.

Methods: Pts with active RA on stable MTX were randomly assigned to either continue MTX (cMTX) or switch to UPA monotherapy at 15 mg (UPA15) or 30 mg (UPA30) once daily (QD) during the 14-wk randomized, double-blind treatment period. From wk 14, the start of the LTE, pts receiving cMTX were switched to UPA15 or 30 per pre-specified assignment at baseline; pts randomly assigned to UPA15 or 30 continued their initial treatment assignment. After the study protocol was amended (13 December 2019), all pts treated with UPA30 were eventually switched to UPA15 (approved dose). Efficacy outcomes through wk 260 are presented by randomized treatment group and reported as observed and using non-responder imputation. Safety results are presented based on actual treatment received with treatment-emergent adverse events (TEAEs) summarized per 100 pt years (PY) of exposure through a cut-off date of 10 August 2022, when all pts completed wk 260.

Results: Of 648 pts randomized, 299 (46%) discontinued the study drug by wk 260 primarily due to AEs (16%), consent withdrawal (12%), or other reasons (11%). At wk 260, pts on UPA maintained or further demonstrated clinical improvement across various endpoints; similar efficacy outcomes were also observed among pts who switched from cMTX to UPA15 or 30 (**Table 1**). As observed, over three-quarters of pts achieved low disease activity based on CDAI and DAS28(CRP) at wk 260. Total PY of exposure were 1111.0 for UPA15, 812.5 for UPA30, and 300.2 for UPA15

switched from UPA30. The most frequently reported TEAEs were urinary tract infection, creatine phosphokinase (CPK) elevation, upper respiratory tract infection, nasopharyngitis, bronchitis, and RA worsening/flare. COVID-19 pneumonia was the most common serious AE. Pts on UPA30 had higher rates of herpes zoster (HZ), hepatic disorder, neutropenia, lymphopenia, and CPK elevation than pts on UPA15; rates of serious infection and malignancy excluding non-melanoma skin cancer (NMSC) were similar between UPA doses (**Figure 1**). Most HZ events affected 1–2 dermatomes with 2 ophthalmic (UPA15; 0.2 E/100 PY) and 1 disseminated (UPA30; 0.1 E/100 PY) cases reported. Eleven adjudicated MACE (UPA15: 0.5 E/100 PY; UPA30: 0.7 E/100 PY) and 10 adjudicated VTE (UPA15: 0.6 E/100 PY; UPA30: 0.4 E/100 PY; UPA15 switched from UPA30: 0.3 E/100 PY) all occurred in pts with ≥ 1 cardiovascular risk factor. Through wk 260, 16 deaths were reported (10 treatment-emergent) with 5 related to COVID-19 infection.

Conclusion: UPA monotherapy continued to be effective in treating RA signs and symptoms through wk 260. No new safety signals were identified with longer-term exposure to UPA, consistent with prior findings[1–3] and the established safety profile of UPA across indications.

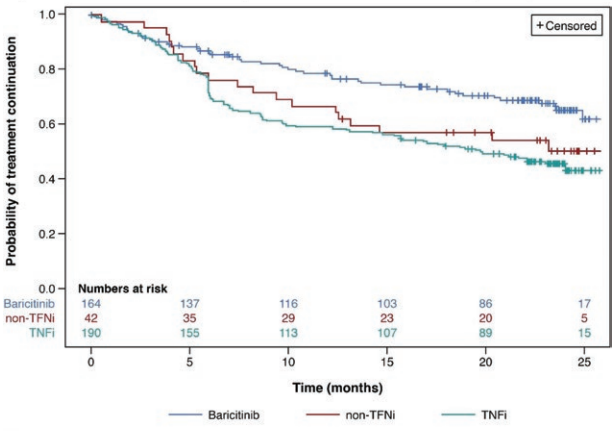
Background: Baricitinib (BARI), an oral selective JAK1/2 inhibitor, is approved for treating adults with moderate to severe active rheumatoid arthritis (RA). RA-BE-REAL is an ongoing 3-year, multinational, prospective, observational study of adult patients with RA starting BARI or any biologic or other targeted synthetic disease-modifying antirheumatic drug (b/tsDMARD).



Objectives: To report treatment discontinuation and effectiveness in patients with RA receiving BARI or b/tsDMARD, based on prior b/tsDMARD use (experienced/naïve) and age <65 years versus ≥65 years, in Europe.

Methods: Patients with RA initiating treatment with BARI 2 or 4 mg (cohort A) or any b/tsDMARD (cohort B) for the first time were included. The primary outcome is time to discontinuation (TTD) for any cause (excluding sustained response) at 2 years; TTD at 6 months has been published [1]. Discontinuation (Kaplan-Meier analyses and rates) and effectiveness (Clinical Disease Activity Index [CDAI] low disease activity [LDA] and remission rates) of treatment to 2 years, based on prior b/tsDMARD status (experienced/naïve) and age (<65/≥65 years) were analysed post-hoc and descriptively for cohort A and subgroups of cohort B.
Results: Key baseline characteristics of 1008 RA patients and effectiveness at 2 years for the subgroups in this analysis are shown in the Table 1. Numerically more BARI-treated patients were receiving monotherapy (Table 1). By 2 years, 31.1%, 54.7% and 47.6% of b/tsDMARD-naïve patients aged <65 years receiving BARI, tumour necrosis factor inhibitors (TNFi) and non-TNFi, respectively, had discontinued treatment; corresponding discontinuation rates for b/tsDMARD-naïve patients aged ≥65 years were 28.4%, 65.6% and 44.0%, b/tsDMARD experienced patients aged <65 years were 47.9%, 59.0% and 65.5% and b/tsDMARD experienced patients aged ≥65 years were 42.0%, 78.3% and 66.7%. An example of TTD is presented in the Figure 1. Consistent CDAI LDA and remission rates were observed with BARI regardless of age and prior treatment (Table 1).
Conclusion: Two-year discontinuation rates and effectiveness with BARI in a real-world setting were consistent irrespective of previous treatment or patient age.

LONG-TERM SAFETY AND EFFICACY OF UPADACITINIB OR ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS: 5-YEAR DATA FROM THE SELECT-COMPARE STUDY

Keywords: Safety, Rheumatoid arthritis, Targeted synthetic drugs

R. M. Fleischmann[1], J. Swierkot[2], S. Penn[3], P. Durez[4], L. Bessette[5], X. Bu[3], N. Khan[3], Y. LI[3], C. Peterfy[6], Y. Tanaka[7], E. Mysler[8]. *[1]Metroplex Clinical Research Center, MD Clinical Professor of Medicine, Dallas, United States of America*; *[2]Wroclaw Medical University, Department of Rheumatology and Internal Medicine, Wrocław, Poland*; *[3]AbbVie, Inc, Immunology, North Chicago, United States of America*; *[4]UCLouvain, Institut de Recherche Expérimentale et Clinique, Ottignies-Louvain-la-Neuve, Belgium*; *[5]Laval University, Rheumatology, Québec, Canada*; *[6]Spire Sciences Inc., Founder & Chief Executive Officer, Boca Raton, United States of America*; *[7]Hospital of University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan*; *[8]Organización Médica de Investigación, Rheumatology, Buenos Aires, Argentina*

Background: Upadacitinib (UPA) is an oral reversible Janus kinase inhibitor. In patients (pts) with RA, UPA 15 mg once daily (QD) demonstrated better clinical responses at 12 weeks (wks) vs adalimumab (ADA) 40 mg every other week (EOW) in the phase 3 SELECT-COMPARE study; these were maintained through 3 years (yrs) in the ongoing long-term extension (LTE), along with an acceptable safety profile.[1,2]
Objectives: To assess the safety and efficacy of UPA vs ADA through 5 yrs in the SELECT-COMPARE LTE.
Methods: Pts receiving background methotrexate were randomized 2:2:1 to UPA 15 mg QD, placebo (PBO), or ADA 40 mg EOW. Rescue (PBO to UPA, UPA to ADA, or ADA to UPA) was mandated for lack of response (<20% improvement in tender or swollen joint counts at wks 14, 18, or 22), or failure to achieve Clinical Disease Activity Index (CDAI) low disease activity (LDA) at wk 26. All remaining PBO pts switched to UPA at wk 26. Pts who completed the 48-wk double-blind period could continue to receive open-label UPA or ADA in the LTE for up to 10 yrs total. Rates of treatment-emergent adverse events (TEAEs) and AEs of special interest were calculated per 100 pt-yrs through 5 yrs for all pts receiving UPA or ADA. Efficacy assessments at 5 yrs were performed by original randomized group for CDAI LDA (≤10) and remission (≤2.8), and disease activity score for 28-joints C-reactive protein (DAS28[CRP]) ≤3.2 and <2.6. Radiographic progression (change from baseline in modified total Sharp score [mTSS]) and proportion of pts with no radiographic progression (change from baseline in mTSS ≤0) were assessed at 192 wks (latest available timepoint; data collected at wks 96/192/520 only) by treatment sequence. No formal statistical comparisons were performed.

Table 1. Baseline data and effectiveness of treatment at 2 years in subgroups based on b/tsDMARD-naïve and -experienced patients aged <65 and ≥65 years[a]

			Age, years[b]	Female[c]	Duration of RA, years[b]	Monotherapy[c]	Baseline CDAI[b]	2-year CDAI remission[d]	2-year CDAI LDA[d]
Naïve <65 years	Cohort A (N=164)	BARI	50.8±9.5	120 (73.2)	5.8±6.4	66 (40.2)	23.0±11.0	20/86 (23.3)	42/86 (48.8)
	Cohort B (N=251)[e]	TNFi (N=192)	49.5±11.0	142 (74.0)	4.9±6.1	48 (25.0)	24.8±13.3	34/130 (26.2)	47/130 (36.2)

[a] Effectiveness data were not available for all patients[b] Mean±standard deviation[c] n (%)[d] n/N (%)[e] An additional 65 patients in total received other tsDMARDs (7–23 per group); data for these patients are not shown because of the small numbers

Results: Through 5 yrs, 1417 pts were exposed to UPA (4497 pt-yrs) and 579 to ADA (1472 pt-yrs). UPA was generally well tolerated, with similar rates of TEAEs, serious TEAEs, TEAEs leading to discontinuation of study drug, and COVID-related TEAEs vs ADA (**Figure 1**). Rates of most AEs of special interest with UPA were similar vs ADA, except for numerically higher rates of herpes zoster, creatine phosphokinase elevation, lymphopenia, and hepatic disorder (mainly transaminase elevations) with UPA. In the 651 and 327 pts originally randomized to UPA and ADA, respectively, greater proportions of pts achieved CDAI LDA and remission, and DAS28(CRP) scores ≤3.2 and <2.6, with UPA vs ADA (**Table 1**). Through 192 wks, similar proportions of pts treated with UPA vs ADA had no radiographic progression; mean changes from baseline in mTSS were similar, except for a numerically smaller change with continuous UPA (**Table 1**).

Conclusion: The safety profile of UPA over 5 yrs was consistent with the 3-yr results and the integrated phase 3 safety analysis.[1,2] Consistent with the 3-yr analyses,[2] UPA continued to show numerically better clinical responses than ADA at 5 yrs. Radiographic progression remained similarly low through 192 wks with UPA and ADA.

REAL-WORLD EXPERIENCE WITH FILGOTINIB (FIL) FOR RHEUMATOID ARTHRITIS (RA) IN GERMANY: A RETROSPECTIVE CHART REVIEW

Keywords: Rheumatoid arthritis, Real-world evidence, Targeted synthetic drugs

O. Schultz[1], C. Fiehn[2], C. Kneitz[3], N. Picker[4], D. Kromer[4], M. Zignani[5], F. De Leonardis[5], H. D. Orzechowski[6], M. Gurrath[6], K. Krueger[7]. *[1]ACURA Kliniken Baden-Baden/Rheumazentrum, Department of Rheumatology, Baden-Baden, Germany*; *[2]Medical Center Baden-Baden, Department of Rheumatology and Clinical Immunology, Baden-Baden, Germany*; *[3]Rheumatologische Schwerpunktpraxis Schwerin, Department of Rheumatology, Schwerin, Germany*; *[4]Ingress-Health HWM GmbH - A Cytel Company, Real World and Advanced Analytics, Wismar, Germany*; *[5]Galapagos GmbH, Medical Affairs, Basel, Switzerland*; *[6]Galapagos Biopharma Germany GmbH, Medical Affairs, Munich, Germany*; *[7]Rheumatologisches Praxiszentrum St. Bonifatius, Department of Rheumatology, Munich, Germany*

Background: Randomized controlled trials have demonstrated the efficacy and safety of FIL for moderate to severe RA;[1–3] however, real-world evidence is lacking.
Objectives: To evaluate the rationale for starting FIL in patients (pts) with moderate to severe RA in Germany. Secondary objectives were to describe pt characteristics, concomitant use of glucocorticoids (GCs) and/or methotrexate (MTX), and prior treatment with disease-modifying antirheumatic drugs (DMARDs). Disease activity was an exploratory objective.
Methods: This multicenter retrospective chart review included pts aged ≥18 years with confirmed moderate to severe RA, who initiated FIL before 1 December 2021, with medical records available for ≥6 months prior to initiating FIL (index date) or since initial diagnosis. Data were collected using electronic case report forms; collection was completed on 2 May 2022. Reasons for starting FIL were recorded at index, based on pre-set response categories. Disease activity was assessed in pts with available data using the Clinical Disease Activity Index and Disease Activity Score for 28 joints with C-reactive protein, 3 and 6 months after the index date. Discontinuation of FIL (including reasons) was assessed during the available follow-up of 12 months.
Results: This study included 301 pts with RA from 20 practices across Germany. Selected baseline pt characteristics and comorbidities are summarized (**Table 1**). Overall, pts had previously been treated with conventional synthetic (cs) DMARDs (n=282, 93.7%), GCs (n=241, 80.1%), biologic (b) DMARDs (n=199, 66.1%), and targeted synthetic (ts) DMARDs (n=113, 37.6%). One, two, and ≥3 prior advanced DMARDs were received by 87 (28.9%), 51 (16.9%), and 90 (29.9%) pts, respectively; 73 pts (24.3%) were advanced DMARD-naïve. Last treatments before initiating FIL included csDMARDs (n=120, 43.0%), bDMARDs (n=97, 34.8%), GCs (n=88, 31.5%), and tsDMARDS (n=63, 22.6%). Most pts received FIL as monotherapy (n=220, 73.1%); pts received FIL + GCs (n=32, 10.6%), FIL + MTX (n=26, 8.6%), and FIL + MTX + GCs (n=23, 7.6%). Reasons for initiating FIL included oral administration (n=236, 78.4%), fast onset of action (n=201, 66.8%), administration as monotherapy (n=197, 65.4%), good controllability (n=176, 58.5%), good benefit/risk ratio (n=155, 51.5%), low potential for drug-drug interactions (n=97, 32.2%), dosage adjustment in elderly pts (n=35, 11.6%), lower risk of herpes zoster (n=45, 15.0%), and inefficacy of previous therapies (n=10, 3.3%). Disease activity during the follow-up is shown (**Figure 1**). In total, 43 pts (14.3%) discontinued FIL during the follow-up because of: lack of efficacy (n=26, 8.6%), intolerance or adverse drug reaction (n=12, 4.0%), lack of drug adherence (n=4, 1.3%), and remission (n=1, 0.3%).
Conclusion: In this real-world setting in Germany, reasons for initiating FIL were related to general Janus kinase inhibitor, as well as FIL-specific, attributes. Most pts received FIL as monotherapy. FIL was effective and generally well tolerated; however, longer-term data are needed.

Background: In the age of targeted-synthetic disease-modifying antirheumatic drugs (tsDMARDs), filgotinib represents the last JAK inhibitor available in Europe for rheumatoid arthritis (RA). Filgotinib is characterized by predominantly inhibition of JAK1 and its efficacy and safety have been highlighted by phase 2/3 studies, but no real-life data in RA are currently available.

Objectives: The aim of this study was to evaluate the effectiveness and safety profile of filgotinib in real-life setting in RA patients included in Italian GISEA (Group for the Study of Early Arthritis) registry.

Methods: For this study, data from RA patients treated with filgotinib recorded in Italian GISEA registry were analysed. Disease activity scores and patients reported outcomes (PROs) were compared at baseline and six months follow-up using paired t-tests. The retention rate was estimated by the Kaplan-Meier method, while a cox regression model was used to search for possible factors influencing drug survival.

Results: One hundred and seventy-nine patients (female 89.4%, age 57.8±12 years, FR/ACPA+ 64.3%, current/former smoker 31.8%) included in GISEA registry started filgotinib for active RA. Most patients were taking filgotinib as second (23.5%) or further (43%) b/tsDMARDs line of treatment. Filgotinib was used in monotherapy in 66.5% of patients, while 52% were not on treatment with glucocorticoids (GCs) at baseline. All demographic and clinical data are reported in Table 1. A follow-up visit was available for 122 patients (mean time of first follow-up visit: 4±2 months). As shown in table 1, we observed a decrease of all disease activity scores and PROs. At first follow-up visit, 67.8% of patients were in remission/low disease activity according to CDAI and 65.4% according to SDAI. Kaplan-Meyer analysis highlighted that drug persistence was similar either in monotherapy or combination therapy (Figure 1a), and irrespective of GCs at

baseline (Figure 1b). However, a better persistence was observed in RA patients on first line treatment with filgotinib (Figure 1c). Thirty-five patients stopped filgotinib during follow-up, 10 for lack of efficacy, 4 for loss of efficacy, 4 for adverse events, while for the remaining cases the cause of drug discontinuation was unknown. No major cardiovascular events were reported. Finally, univariate Cox-regression model showed that b/tsDMARD naïve patients had a lower risk of drug discontinuation (naïve vs other lines: HR 0.37, 95%CI 0.20-0.86).
Conclusion: In Italian real-life setting, filgotinib confirms a good effectiveness and safety profile.

Background: In the treatment of RA, JAK inhibitors are a valuable option to meet remission or low disease activity (LDA) treatment targets following an inadequate response (IR) or intolerance to ≥1 conventional synthetic disease-modifying antirheumatic drug (DMARD). FIL is a JAK1 preferential inhibitor available in two doses for the treatment of moderate to severe RA.
Objectives: To evaluate long-term efficacy of two doses of FIL in clinically relevant pt populations.
Methods: In this interim analysis, efficacy (non-responder imputation) of FIL 200 mg (FIL200) and 100 mg (FIL100) was assessed from LTE baseline (BL) to W156 in pts with an IR to methotrexate (MTX-IR) and biologics (bDMARD-IR), enrolled from FINCH 1 (NCT02889796) and 2 (NCT02873936) parent studies (PS), respectively, receiving ≥1 FIL dose in FINCH 4 (NCT03025308).
Results: Study design, BL characteristics and W48 outcomes for MTX-IR[1] and bDMARD-IR[2] pts were reported previously. For MTX-IR and bDMARD-IR pts who received FIL200 or FIL100 in the PS, W156 remission rates using Boolean 1.0 criteria were 20.5% and 15.8%, and 18.2% and 8.9%, respectively. Adopting the Boolean 2.0 criteria slightly increased remission rates for FIL200 and FIL100 at W156: +4.2% and +4.9% for MTX-IR pts, and +1.5% and +2.4% for bDMARD-IR pts, respectively. For pts rerandomized to FIL on entering the LTE, Boolean 2.0 criteria also increased remission rates vs Boolean 1.0. Both MTX-IR (**Figure 1**) and bDMARD-IR pts maintained long-term Boolean remission through W156 with FIL200 and FIL100, irrespective of prior FIL. Results for Disease Activity Score 28 with C-reactive protein (DAS28-CRP) <2.6, Clinical Disease Activity Index (CDAI) ≤2.8, and Simplified Disease Activity Index (SDAI) ≤3.3, and mean change from PS BL in Health Assessment Questionnaire–Disability Index (HAQ-DI) and pain are shown (**Table 1**). Similar trends in efficacy were seen for LDA and ACR response criteria.
Conclusion: In FINCH 4, both FIL200 and FIL100 showed sustained efficacy up to W156 in clinically relevant pt populations. Boolean 2.0 criteria classified more pts in remission, in line with the range reported in the validation study.[3]

DRUG RETENTION OF BIOLOGIC AND TARGETED SYNTHETIC DMARDS IN KOREAN SEROPOSITIVE RHEUMATOID ARTHRITIS (RA) PATIENTS: A REAL-WORLD SINGLE-CENTER RETROSPECTIVE STUDY

Keywords: Rheumatoid arthritis, Targeted synthetic drugs, bDMARD

B. W. Lee[1], J. J. Lee[1], W. U. Kim[1]. [1]*Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Despite the approval of the new janus kinase inhibitors (JAKi) for rheumatoid arthritis (RA) treatment, the real world data on the drug effectiveness of biologic DMARDs (bDMARDs) and targeted synthetic DMARDs (tsDMARDs) including recently approved JAKi is scarce, especially in Asia.

Objectives: The purpose of this single center, retrospective study was to compare the short and long-term retention rates of b/tsDMARDs including recently approved JAKi in Korean seropositive RA patients.

Methods: This study was conducted with total 1,538 treatment courses of 1063 seropositive RA patients who started b/tsDMARDs between 2008 and 2020 at Seoul St. Mary's Hospital [adalimumab (ADA; n = 332), etanercept (ETN; n = 369), infliximab (IFX; n = 146), abatacept (ABT; n = 152), tocilizumab (TCZ; n = 299), tofacitinib (TOF; n = 136), and baricitinib (BAR; n = 104)]. Discontinuation after 1 year and 3 years from the first prescription of each drug was investigated. Kaplan–Meier estimates of time to discontinuation were conducted to compare the difference in drug retention rate for each drug in b/tsDMARDs-naïve and experienced group, respectively. Patient-level predictors for drug discontinuation were evaluated by a Cox proportional hazard model.

Results: Overall 1-year drug retention rate was as follows: from 60.1% of ADA to 90.0% of TOF in the b/tsDMARDs-naïve group & from 55.2% of IFX to 84.8% of TOF in the b/tsDMARDs-experienced group. And 3-year drug retention rate was as follows: from 36.9% of IFX to 86.5% of TOF in the b/tsDMARDs-naïve group & from 31.0% of IFX to 65.4% of TCZ in the b/tsDMARDs-experienced group. The drug discontinuation seems to be affected by several factors including previous treatment history, starting year, and specific type of b/tsDMARDs, and baseline level of erythrocyte sedimentation rate.

Conclusion: Compared to before 2015, the overall drug retention rate of b/tsDMARDs increased in Korean seropositive RA patients. TCZ and JAKi are as widely used as tumor necrosis factor-alpha inhibitors, and they were less often discontinued at 1 year and 3 years from the first prescription. Especially, drug with the highest 3-year retention rate was TOF in b/tsDMARDs-naïve group, and TCZ in b/tsDMARDs-experienced group.

EVOLUTION OF RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE IN PATIENTS TREATED WITH JAK INHIBITORS: A MULTICENTER RETROSPECTIVE STUDY

Keywords: Safety

V. Venerito[1], A. Manfredi[2], A. Carletto[3], S. Gentileschi[4], F. Atzeni[5], S. Guiducci[6], M. Lavista[1], L. La Corte[5], E. Pedrollo[3], A. Scardapane[7], C. Tomassini[2], B. Frediani[4], C. Salvarani[2], F. Iannone[1], M. Sebastiani[2]. *[1]Rheumatology Unit, University of Bari "Aldo Moro", Bari, IT, Department of Precision and Regenerative Medicine – Ionian Area, Bari, Italy; [2]Rheumatology Unit, University of Modena and Reggio Emilia, Modena, IT, Azienda Ospedaliera Policlinico di Modena, Modena, Italy; [3]Rheumatology Unit, Verona IT, University of Verona, Verona, Italy; [4]Rheumatology Unit, Università degli studi di Siena, Siena IT, Azienda Ospedaliero-Universitaria Senese, Siena, Italy; [5]Rheumatology Unit, Messina, IT, University of Messina, Messina, Italy; [6]Rheumatology Unit, Firenze, IT, University of Florence, Firenze, Italy; [7]Radiology Unit, Bari, IT, University of Bari Aldo Moro, Bari, Italy*

Background: The treatment to adopt when (Interstitial Lung Disease)ILD is detected in Rheumatoid Arthritis (RA) patients has always been a matter of debate. The management and treatment of RA-ILD is challenging because there is still little information available on this topic, and the main literature comes from observational studies. No clinical trials have been dedicated to this topic, however its consideration is increasing in guidelines. There is relatively limited data on the use of JAKi in patients with RA-associated ILD.
Objectives: The aim of this multicenter retrospective study was to investigate the effectiveness and safety of the available JAKi in patients with RA-ILD.
Methods: We retrospectively analyzed patients with classified RA and RA-ILD undergoing JAKi in 6 Italian tertiary centres from April 2018 to June 2022. We included patients with at least 6 months of active therapy and one high-resolution chest tomography (HRCT) carried out within 3 months before the start of JAKi treatment. The HRCT was then compared to the most recent one carried out within 3 months before the last available follow-up appointment. We also kept track of the pulmonary function tests.
Results: We included 43 patients with RA-ILD, 23 males (53.48%) with median age (interquartile range, IQR) of 68.87 (61.46-75.78) treated with JAKi. Clinical and disease characteristics have been reported in Table 1. The median follow-up was 19.1 months (11.03–34.43). The forced vital capacity remained stable in 22/28 (78.57%) patients, improved in 3/28 (10.71%) and worsened in 3/28 (10.71%). The diffusing Capacity of Lung for Carbon Monoxide showed a similar trend, remaining stable in 18/25 (72%) patients, improving in 2/25 (8%) and worsening in 5/25 (20%). The HRCT remained stable in 37/43 (86.05) cases, worsened in 4/43 (9.30%) and improved in the last 2 (4.65%) (Figure 1).

Table 1. Patient characteristics at Treatment Baseline

	Av Obs.	Baseline
Age, years, median (IQR)	43	68.87 (61.46-75.78)
Male, n (%)	43	23 (53.48)
Disease Duration, years, median (IQR)	43	12.66 (7.61)
ILD duration, years, median (IQR)	43	5.55 (5.13)
Follow-up, months, median (IQR)	43	19.1 (14.92)
Rheumatoid factor positivity, n (%)	43	38 (88.37)
ACPA positivity, n (%)	43	35 (81.40)
HRCT pattern, n (%)	43	
UIP		25 (58.14)
NSIP		5 (11.62)
LIP		2 (4.65)
CPFE		1 (2.33)
Indeterminate		10 (23.26)
Baseline DLCO, mean (SD)	27	65.81 (16.92)
Baseline FVC, mean (SD)	30	88.76 (24.03)
Prescribed JAKi, n/%)	43	
Baricitinib		28 (65.12)
Filgotinib		3 (6.98)
Tofacitinib		9 (20.93)
Upadacitinib		3 (6.98)
Use of DMARD before JAKi, n (%)	43	
Methotrexate		32 (74.41)
Leflunomide		3 (6.97)
TNFalpha inhibitors		19 (44.19)
Rituximab		12 (27.91)
Abatacept		16 (38.10)
Tocilizumab		13 (30.23)
JAKi + Methotrexate, n (%)	43	16 (37.21)
Glucorticoids n(%)	43	26 (60.47)

Conclusion: This study seems to confirm that JAKi therapy might be a safe therapeutic option for patients with RA-ILD.

MONOTHERAPY AND FIRST LINE USE ARE ASSOCIATED WITH HIGHER JAK-INHIBITOR RETENTION RATES IN PATIENTS IN BOTH RHEUMATOID AND PSORIATIC ARTHRITIS: A RETROSPECTIVE REAL-WORLD STUDY

Keywords: Psoriatic arthritis, Rheumatoid arthritis, Targeted synthetic drugs

N. Luciano[1], E. Barone[2], E. Brunetta[2], M. De Santis[2], A. Ceribelli[2], M. Caprioli[1], G. M. Guidelli[1], A. Sonaglia[1], D. Renna[1], N. Isailovic[2], C. Selmi[2]. *[1]IRCCS Humanitas Research Hospital, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy*; *[2]IRCCS Humanitas Research Hospital and Humanitas University, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy*

Background: Janus kinase inhibitors (JAKi) have been licensed for the treatment of rheumatoid (RA) and psoriatic arthritis (PsA) and currently there is limited evidence of differences among the four available molecules while real-world data are needed for safety and efficacy.
Objectives: To investigate the efficacy and safety of approved JAKi and analyze the relationship between the patients' baseline characteristics and drug survival.
Methods: This is a retrospective study on patients treated in 2021-2022 with tofacitinib, baricitinib, upadacitinib, or filgotinib for RA or with tofacitinib, baricitinib or upadacitinib for PsA as first or subsequent line of therapy after the failure of one or more conventional DMARD. We collected demographic and clinical data including clinimetric indices and registered the presence of comorbidities, smoking, and previous DMARDs.
Results: The study included 205 patients (81% women) who started or continued a JAKi for RA or PsA between January 2021 and October 2022 (**Table 1**) and were followed until the cutoff on October 31, 2022 for a median of 24 (interquartile range 12-40) months for a total observation of 431 patients-years. One hundred-two (50%) patients received the JAKi as first-line treatment and 108 (53%) as monotherapy. At the last available observation, 144 (72%) patients were still on JAKi, with 27% of patients (54/205) reporting a temporary discontinuation of the therapy, in 69% of cases due to bacterial or viral infections of the upper respiratory tract. Forty-one (20%) patients stopped the JAKi for inefficacy, in 18 (44%) being a primary failure. Eighteen serious adverse events were observed; e.g. 12 major infections, mainly pneumonia, 2 venous thrombotic events, 3 ischemic cardiovascular events and one rhabdomyolysis. Among the 5 patients reporting thrombosis or myocardial infarction, 4 were older than 65 and all had at least one cardiovascular risk factor, mostly obesity and arterial hypertension. Non-disseminated Herpes zoster reactivation was registered in 19 patients but none required the discontinuation of the JAKi. Better retention rates were registered at univariate analysis in bio-naïve patients (p=0.002) and in patients on JAKi monotherapy (p=0.026), while no significant correlation was found with disease duration, comorbidities, and smoking habits. The multivariate analysis confirmed that receiving JAKi as monotherapy (p=0.04, odds ratio 2.01, 95% confidence interval 1.03-3.94) is associated with a longer treatment duration, opposite to having failed one bDMARD before receiving a JAKi (p=0.001, odds ratio 0.29, 95% confidence interval 0.14-0.6), irrespective of gender, age, and disease duration. Having RA or PsA did not impact the treatment duration.

Table 1.

	Total (n=205)	RA (n=187)	PsA (n=18)
Age (years) (median; IQR)	62 (53-71)	61.9 (54-72)	56.6 (48.7-62.0)
Female gender [n (%)]	166 (81%)	152 (81%)	14 (77%)
Rheumatoid Factor positive [n (%)]	117 (57%)	117 (63%)	0 (0%)
ACPA positive [n (%)]	121 (59%)	121 (65%)	0 (0%)
Therapies			
Duration of JAKi therapy (median; IQR)	24 (12-40)	28 (13-41)	8.6 (4-14.5)
bDMARDs naive [n (%)]	102 (50%)	97 (52%)	11 (61%)
JAKi monotherapy [n (%)]	108 (53%)	99 (53%)	3 (17%)
Baricitinib [n (%)]	123 (60%)	122 (65%)	1 (6%)
Upadacitinib [n (%)]	46 (22%)	16 (9%)	2 (11%)
Tofacitinib [n (%)]	18 (9%)	31 (17%)	15 (83%)
Filgotinib [n (%)]	18 (9%)	18 (10%)	0 (0%)
Comorbidities			
Previous or current smoker [n (%)]	61 (30%)	58 (31%)	3 (17%)
Obesity [n (%)]	45 (22%)	37 (20%)	8 (44%)
Hypertension [n (%)]	69 (34%)	65 (35%)	4 (22%)
Diabetes [n (%)]	13 (6%)	13 (7%)	0 (0%)
Previous Venous Thromboembolism [n (%)]	5 (2%)	4 (2%)	1 (6%)
Coronary Arthery Disease [n (%)]	19 (9%)	18 (10%)	1 (6%)

Conclusion: Irrespective of the diagnosis of RA or PsA, JAKi cumulatively have the best treatment duration when are used as monotherapy or as first line before a bDMARD. The safety and efficacy profiles did not differ significantly between RA and PsA, albeit a limited number of patients were included in the latter group.

Background: Nowadays, rheumatoid arthritis (RA) patients can benefit from several drugs classified as biologic (b) or JAK inhibitors (JAKi). Four JAKi are now available, whose two JAKi, with predominantly JAK1 selectivity (JAK1i), came onto the market in 2020.
Objectives: The aim of this study was to compare the effectiveness among RA patients included in BIOPURE registry on treatment on TNF inhibitors (TNFi) JAK1i, other JAKi (oJAKi), and other mechanisms of action (oMOA) bDMARD.
Methods: Data of RA patients who started a new line of treatment with a b/tsDMARD were prospectively collected from October 2020, when JAK1i was first prescribed, to May 2022. Demographics and disease characteristics were evaluated using standard descriptive statistics. Patients were divided in four groups: patients on TNFi therapy, patients on JAK1i (upadacitinib and filgotinib), patients on oJAKi (tofacitinib and baricitinib) and patients on oMOA (abatacept, tocilizumab and sarilumab). The drug survival was evaluated by Kaplan– Meier analysis. Estimated hazard ratios (HRs) of discontinuing therapy were assessed by multivariate regression models.
Results: Since October 2020, 580 RA patients started a new line treatment with b/tsDMARDs (171 TNFi, 192 oMOA, 88 oJAKi and 120 JAK1i). Overall cohort characteristics are reported in Table 1. As expected, monotherapy was more used in patients treated with JAK1i (73.6%), oJAKi (63.6%) and oMOA (54.7%) compared to TNFi (30.4%). Patients treated with JAK1i and oJAKi were more likely to be refractory to previous b/tsDMARDs, 76% of JAK1i and 76.2% of oJAKi had received prior treatment with ≥2 bDMARDs or other tsDMARDs. Patients treated with JAK1i presented higher disease activity compared to other b/tsDMARD and higher grade of disability at baseline compared to TNFi. Drug survival was similar between the four groups, being 66.7% for TNFi, 71.9% for oMOA, 64.8% for oJAKi and 69.8% for JAK1i (log-rank test:4.69, p=0.19) (Figure 1a). Multivariate cox regression model and K-M analysis (Figure 1b) showed that the main predictor of b/tsDMARDs discontinuation was a previous treatment with >2 b/tsDMARDs (HR: 1.85, 95% CI 1.21-2.85) Finally, a comparable number of adverse events causing drug discontinuation was observed: 10 (5.8%) in TNFi, 12 (6.3%) in oMOA, 9 (10.2%) in oJAKi and 10 (8.3%) in JAK1i.

Figure 1. a: drug persistence of RA patients according to different b/tsDMARDs. B: drug persistence of RA patients according to different lines of treatment

Conclusion: Our study highlighted good effectiveness and safety of new and old b/tsDMARDs in Apulian cohort of RA patients included in BIOPURE registry. Of note, despite more than half patients starting JAK1i or oJAKi were multi-failure, they showed a similar drug survival compared to those on TNFi who were predominantly biologic-naïve.

Background: The efficacy of Janus Kinase inhibitors (JAKis) in Rheumatoid Arthritis (RA) has been established in the last years through numerous randomized clinical trials. Recently, the safety profile of this drug class has come under the spotlight, questioning the actual use in clinical practice and making real-life data even more crucial.

Objectives: The purpose of this study is to evaluate the long-term retention rate of JAKis and to estimate the influence of baseline population characteristics on treatment persistence.

Methods: Data of all RA patients who started a JAKi were prospectively collected in the Italian multicentric GISEA registry. The 3-year retention rate of JAKis was calculated by the Kaplan-Meier method and compared by a log-rank test after stratification according to different baseline population characteristics. A descriptive analysis of reasons for discontinuation was performed.

Results: The study population included 1361 patients (females 83.5%, mean age [±SD] 57.3 [±12.3] years, over 65 years 30%, mean disease duration 12.7 [±9.7] years, mean baseline SDAI 20.6 [±11.7], ACPA positive 68%, RF positive 66%, current smokers 19%, past smokers 13%) who received a JAKi (baricitinib=763, tofacitinib=321, upadacitinib=151, filgotinib=126) as first (n=491) or subsequent line (n=870) targeted drug. The overall 3-year retention rate was 46%. Drug survival was significantly higher in ACPA positive compared with negative patients (51.6 vs 41.8%, p=0.0051) (Figure 1A) and in first-line versus second or further lines of therapy (50.6 vs 43.3%, p=0.0013) (Figure 1B). No difference was found according to age (< or ≥65 years), concomitant methotrexate, smoke, history of diabetes, or at least one cardiovascular comorbidity (hypertension, stroke, or heart failure). Therapy was discontinued in a total of 523 patients because of ineffectiveness (67.5%), adverse events (25.8%), or compliance/other reasons (0.3%). Of relevance, adverse events included cancer (0.7%), major adverse cardiovascular events (MACE) (0.4%), deep vein thrombosis (DVT) (0.6%), and herpes zoster virus (HZV) infections (1.5%).

Conclusion: Our data confirmed in a real-life setting a favorable 3-year retention rate of JAKis in RA. ACPA positivity and use as first-line targeted drug significantly improved persistence of JAKis. Discontinuations of JAKis because of adverse events (including MACE, DVT, HZV, and malignancy) were very uncommon, suggesting an overall favorable safety profile.

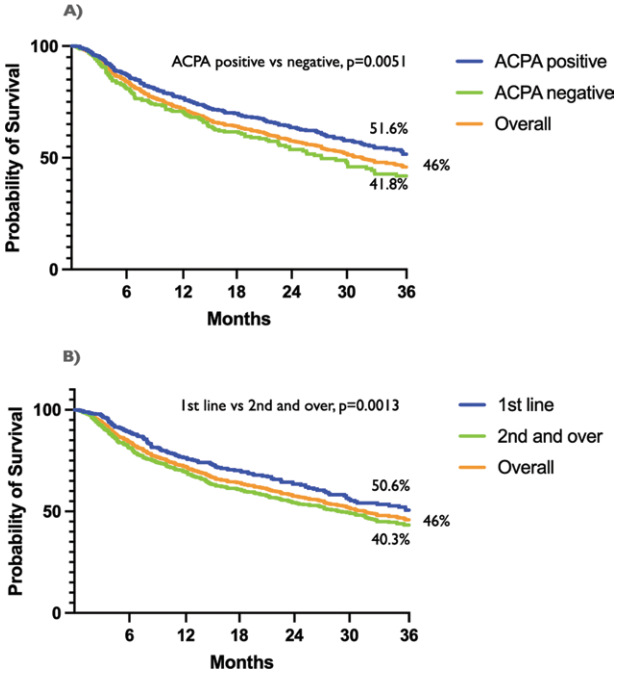

Figure 1. A) Retention rate in ACPA positive versus ACPA negative patients. B) Retention rate in first-line versus second or further lines of therapy.

POS0859 VENOUS AND ARTERIAL THROMBOEMBOLIC RISK OF JAK INHIBITORS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Systematic review, Safety, Randomized control trial

F. Campanaro[1], A. Batticciotto[1], A. Zaffaroni[2], M. P. Donadini[3], A. Squizzato[3,4], A. Cappelli[1]. [1]*ASST Sette Laghi, SSD Reumatologia - Ospedale di Circolo e Foundatione Macchi Varese, Varese, Italy*; [2]*University of Insubria, University of Insubria, Varese, Italy*; [3]*University of Insubria, Research Center on Thromboembolic Diseases and Antithrombotic Therapies,Department of Medicine and Surgery, Varese, Italy*; [4]*Sant'Anna Hospital, ASST Lariana, Internal Medicine Unit, San Fermo della Battaglia (Como), Italy*

Background: JAK inhibitors (JAKi) are a new class of drugs developed for the treatment of different immune-mediated inflammatory diseases (IMIDs). Thrombotic events have been reported in some long-term extension studies as adverse effects. As a consequence, in 2017 the Food and Drug Administration (FDA) inserted a black box warning in the Summary of Product Characteristics (SPC) for Baricitinib, stating that it should be used with caution in patients at increased risk of thrombosis [1]. A similar warning was issued by the European Medicines Agency (EMA) in 2019 for Tofacitinib 10 mg [2].
Objectives: To perform a systematic review of randomized controlled trials (RCTs) with the aim to estimate the risk of venous and arterial thromboembolic (TE) events in patients with IMIDs treated with JAKi.
Methods: RCTs on the efficacy and safety of JAKi in IMIDs patients were identified by electronic search of the MEDLINE and EMBASE database until October 2021. Risk of bias was assessed according to Cochrane criteria. All JAKi and all IMIDs were included in the main analysis. Venous and arterial TE events (deep vein thrombosis, pulmonary embolism, unusual site thrombosis, superficial venous thrombosis, stroke, transient ischemic attack, coronary ischaemic events and peripheral artery ischaemia) and major adverse cardiovascular events (MACE) were extracted from the reported safety analysis of the different RCTs. Studies which did not report any information on the cardiovascular safety profile in the paper or supplementary materials were excluded. Differences in thrombotic outcomes among groups were expressed as pooled odds ratio (OR) and corresponding 95% confidence interval (CI), using both a fixed-effects and a random-effects model. Statistical heterogeneity was evaluated using the I^2 statistic.
Results: One phase I, 21 phase II, 3 phase II-III and 36 phase III RCTs on Rheumatoid Arthritis (32.8%), Atopic Dermatitis (22.9%), Psoriasis (11.5%), Inflammatory Bowel Disease (11.5%), Psoriatic Arthritis (9.8%), Ankylosing Spondylitis (6.6%) and Lupus Erytheratosus (4.9%) were included, for a total of 19443 patients in the JAKi group (Abrocitinib, Baricitinib, Brepocitinib Deucravacitinib, Filgotinib, Ivarmacitinib, Peficitinib, Tofacitinib and Upadacitinib) and 9073 in the placebo group. Thirty-one (unweighted rate 0.16%) TE events were reported in the JAKi group and 20 (unweighted rate 0.22%) in the control group in an unweighted mean follow-up of 16.8 weeks. IMIDs patients treated with JAKi had not an increased TE risk compared to IMIDs patients treated with placebo (OR 0.69 [95% CI, 0.44–1.10, I^2 0%] at fixed-effect model) (Figure 1). No clinically relevant results were seen among different IMIDs and drugs. The ORs of venous and arterial TE events were respectively 0.61 (95% CI, 0.32–1.15, I^2 0%) and 0.78 (95% CI, 0.41–1.48, I^2 0%) at fixed-effect model. The incidence of MACE was similar among the groups (OR 0.82 [95% CI, 0.48–1.40, I^2 0%] at fixed-effect model).
Conclusion: Despite our study has some limits like the short duration of the RCTs, the different inclusion criterias, permitted concomitant therapies, mean age and mean disease activity, we did not find any evidence that JAKi increase the risk of venous and arterial TE events and MACE. The performed sub-analysis did not find any correlation between the use of any JAKi and TE events in any considered IMID, even if the meta-analysis is likely underpowered (i.e. β error) to highlight statistically significant differences of the incidence of TE events between different diseases and different JAKi. JAKi do not increase TE risk compared to placebo in IMIDs patients enrolled in phase I/II/III RCTs.

POS0860 COMPARING THE EFFICACY OF THE BDMARD SWITCHER GROUP AND JAK CYCLER GROUP IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH FAILURE TO THE JAK INHIBITORS

Keywords: Targeted synthetic drugs

M. Yamasaki[1]. [1]*Shin-yokohama Arthritis and Rheumatology Clinic, Rheumatology, Yokohama, Japan*

Background: Patients benefiting from the advent of JAK inhibitors has increased in the treatment of rheumatoid arthritis(RA). However, it is also known that there are RA cases that do not respond sufficiently to JAK inhibitors(JAKi). In order not to increase the number of refractory rheumatoid arthritis cases, it is necessary to establish the following treatment methods for JAKi-resistant cases.
Objectives: We analyzed the efficacy of the bDMARD switcher group and the JAKi cycler group as the next treatment for JAKi- refractory cases.
Methods: Cases were recruited to SHin-yokohama Arthritis REgister (SHARE) between 2015 and 2022 (n=4,056). 347 Patients were diagnosed according to ACR/EULAR 2010 classification criteria and treated with JAKi. Efficacy analysis was evaluated by continuation rate and CDAI improvement rate.

Results: JAKi were administered to 347 patients for an average of 64.5 weeks. There were 75 cases (21.6%) who discontinued the JAKi due to insufficient effect. Of the cases in which JAKi were discontinued, 45 (60.0%) were in the bDMARD switcher group, 22 (29.3%) were in the JAK cycler group, and 8 (10.7%) were switched to csDMARD alone. The continuation rate of the next treatment in the bDMARD switcher group and the JAK cycler group was 77.8% and 89.0% at week 12, respectively, with no significant difference (Log-rank p=0.2806). The CDAI improvement rates in switcher group and the JAK cycler group were 43.5% and 46.2%, respectively, at week 12, with no significant difference (Wilcoxon p=0.6397). There was no significant difference in the CDAI improvement rate according to the treatment class and the number of b/tsDMARDs between the two groups (p>0.05). CDAI improvement rate with each of following b/tsDMARs were TNFi=48.2%, IL-6i=30.0%, abatacept=42.4%, JAKi=49.9%. Especially for IL-6 inhibitors, 50.2% CDAI improvement rate was obtained when sarilumab was selected as the following DMARD.

Conclusion: JAK cycler, as well as bDMARD switcher, may be useful as the next treatment for patients who discontinue JAKi.

POS0861 EFFECT OF JAK1 INHIBITION ON EROSION REPAIR IN RHEUMATOID ARTHRITIS: A PILOT HR-PQCT STUDY

Keywords: Targeted synthetic drugs

H. So[1], I. T. Cheng[1], M. LI[1], C. K. Wong[2], L. S. Tam[1]. [1]*The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*; [2]*The Chinese University of Hong Kong, Chemical Pathology, Hong Kong, Hong Kong (SAR)*

Background: Blockade of JAK, preferably JAK1, by upadacitinib is a feasible approach to achieve erosion repair as it 1) is approved for the treatment of rheumatoid arthritis (RA), 2) effectively controls the inflammation and 3) targets pathogenic pathways that influence local bone homeostasis in the joint.

Objectives: To evaluate whether inhibition of JAK1 could lead to erosion repair on high-resolution peripheral quantitative computer tomography (HR-pQCT) in patients with active RA.

Methods: This was a 24-week, single-centered, prospective, non-randomized pilot study. We enrolled 20 adult patients with active RA (Disease activity score 28-C-reactive protein [DAS28-CRP] > 3.2) and ≥1 bone erosion on HR-pQCT. They were given upadacitinib 15mg once daily for 6 months. HR-pQCT of the 2-4 metacarpophalangeal (MCP) head was done at baseline and 6 months. The serum inflammatory cytokine profile and bone-cartilage interface biomarkers were also checked before and after treatment. The primary outcome was the change of erosion volume on HR-pQCT. Secondary outcomes included change in RA disease activity and serum biomarkers, as well as predictors of response to treatment. Erosion regression was defined as decrease in volume exceeding the smallest detectable change.

Results: The baseline clinical characteristics of the recruited patients were shown in **Table 1**. Of the 20 patients, 11 (55%) patients failed to respond to 3 or more csDMARDs. At 24-week, there was significant improvement in mean DAS28 (-1.75, p<0.001). Erosion regression was seen in 8 (40%) patients on HR-pQCT. Although no significant change in overall median erosion volume before and after upadacintinib (0.07 [-0.90-0.76mm3] mm3, p=0.904) was noted, the deterioration was less obvious compared to a historic cohort of 20 patients with similar age and disease activity on csDMARDs (median erosion volume change in 6 months: 0.67 mm3). There was significant reduction in the serum level of bone resorption marker C1M before and after treatment, which was not seen in the historic cohort. Significant reduction in various inflammatory cytokines (e.g. TNF-α, IL-6) was also noted after treatment. When patients were stratified according to whether or not they had failed multiple csDMARDs, significantly high proportion of patients in the non-multiple-DMARDs failure group had volume regression in at least one erosion compared to those in the failure group (75% vs 25%, p=0.04). There was improvement in mean total erosion volume in the non-failure group (-0.33±1.33 mm3), whereas mean erosion volume in the failure group worsened (2.09±7.62 mm3). One patient developed chest infection requiring hospitalization and withdrew from the study. No other serious adverse event was noted.

Conclusion: The results of the study suggested upadacitinib was clinically efficacious in refractory RA disease and could retard erosion progression. Regression of erosion was possible, particularly in those with limited csDMARDs exposure. Whether earlier JAK1 inhibition could lead to better structural outcome warrants further investigations.

Background: Since 2018, JAK inhibitors became available in Italy for the treatment of adult patients with moderately to severely active Rheumatoid Arthritis (RA) and an inadequate response to methotrexate (MTX).

Objectives: This analysis aimed to characterize the prescription pattern of JAK inhibitors in patients with RA over the last 5 years.

Methods: Patient demographics, disease characteristics and medication history were collected. Patients starting treatment either with biological Disease Modifying Anti-Rheumatic Drugs (bDMARDs) or targeted synthetic (ts)DMARDs (baricitinib, tofacitinib, upadacitinib and filgotinib) were included in the analysis. Data were extracted from the GISEA (Gruppo Italiano di Studio sull'Early Arthritis) registry.
Results: From January 2018 to December2022 overall 4424 patients with RA were included in the GISEA registry (3622 F: 802 M, mean age 57.9±12.8 years, mean disease duration 12.9±9.9 years). Overall, the number of patients starting bDMARDs and tsDMARDs in 2018, 2019, 2020, 2021 and 2022 was 729, 784, 1204, 794 and 913, respectively; 306 (42%), 319 (40,7%), 278 (23%), 291 (36.6%) and 335 (36.7%) started a JAK inhibitor. Figure 1 summarizes the prescription pattern of bDMARDs and tsDMARDs during the 5 years of observation (A) and the percentage of patients starting each JAK inhibitor (B). The prescription of JAK inhibitors was stable from 2018 to 2022 with the only exception of 2020 (coinciding with the beginning of the pandemic) when we recorded a significant decrease in JAK inhibitors prescribed (p<0.00001 vs 2019) and a significant increase in the number of patients treated with abatacept (from 12.1% to 17.1%, p=0.0024) and anti-IL-6R (from 16.3% to 23.7%, p=0.000067). Conversely, in 2021 the number of patients who started JAK inhibitors significantly increased (0<0.00001 vs 2020) and those starting anti-IL-6R significantly decreased (from 23.7% to 13.4%). From 2018 to 2022 the percentage of bDMARD-naıve patients increased, without reaching a statistical significance, from 30.7%, 36%, 43.5%, 44.4%, 40.3% of patients starting a JAK inhibitor after MTX-failure (Figure 1C).
Conclusion: The use of JAK inhibitors for treating RA of patients in Italy is stable from 2018 onward with a shift towards an earlier line of treatment and a significant change in the prescription pattern within the class over time.

Figure. Prescription pattern of bDMARDs and tsDMARDs during the 5 years of observation (A),and prescription patterns of the four available JAK inhibitors in the same period (B). Prescription of JAK inhibitors according to treatment line (C)

POS0863 BARISUR STUDY: DESCRIPTIVE STUDY OF BARICITINIB SAFETY IN SPANISH PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Safety, Rheumatoid arthritis, Descriptive studies

E. Rubio Romero[1], A. Gallego[2], M. Llanes[3], E. Delgado Vidal[4]. [1]*SevilleHospital Universitario Virgen del Rocio, Rheumatology, Seville, Spain*; [2]*Hospital Universitario Badajoz, Rheumatology, Badajoz, Spain*; [3]*Hospital Universitario Juan Ramón Jiménez, Rheumatology, Huelva, Spain*; [4]*Seville, Rheumatology, Seville, Spain*

Background: Baricitinib (BCT) and tofacitinib (TFC) are the most widely used JAK inhibitors worldwide and both were approved in Spain in 2017. Data from Oral Surveillance study showed in 2021 an increased risk of malignancies and major adverse cardiovascular events (MACEs) in patients treated with TFC versus anti-TNF drugs. However, there is no clear position among rheumatologists regarding the risk of MACE, thromboembolic events (TEE) or other safety concerns of JAK inhibitors. Although JAK inhibitors have a common mechanism of action, each drug has specificities such as selective affinity to different targets, pharmacodynamics, metabolism and dosing, conferring differences between drugs. Therefore, it is to be expected that the safety profile may be different.
Objectives: The aim of this study is to collect real world data from Spanish patients to analyze efficacy trends, daily use patterns and a descriptive analysis of the safety profile of rheumatoid arthritis treatments in southern Spain.
Methods: A multicenter, observational, retrospective study was conducted, collecting data from patients with rheumatoid arthritis previously treated with methotrexate (MTX) and other prior biologic therapies.
Results: Data from 270 patients were analyzed, 73% were female, the mean age was 58 years (SD: 12,7) and the mean age at diagnosis was 47 years (SD:14,33). Of the population, 95,1% had some risk factor for MACE or TEE; specifically 7,5% had previous cardiac events, 2,6% and 9,4% had previous TEE and malignancies, respectively. The distribution of baseline treatment is shown in the Table 1. Median use of prior disease-modifying treatments (DMT) was 1 for the total population, but 2 for BCT patients. BCT patients had 10,5 (SD: 9,0) mean years of disease progression and initiated treatment at 57 (SD: 12,25) years mean age. After the first 12 months of follow-up, there was a trend towards reduce the use of NSAIDs (28,9% to 24,2%), prednisone 85% to 58,4%) and MTX (46,2% to 36,6%). Simultaneously, Disease Activity Score 28 (DAS28), VSG and PCR also decreased during the period from 4,92 (SD:0,84), 24,41 (SD: 15,78) mm/h and 11,89 (SD: 9,69) mg/l to 3,06 (SD: 1,13), 20,79 (SD: 13,31) mm/h, and 8,21 (SD: 9,14) mg/l respectively. BCT safety profile was well tolerated, with 33 adverse events at 6 months of follow-up and 3 serious adverse events (TEE, pneumonia and stroke) during the period. Of BCT population, 57,6% stopped treatment due to toxicity or lack of efficacy.
Conclusion: Taking into account the heterogenicity and the age of our population, these preliminary results showed low risk of MACE and cancers with BCT for the Spanish cohort. Future analysis is guarantee in order to understand the safety profile in the long term.

Background: Interstitial lung disease (ILD) is a severe complication of rheumatoid arthritis (RA). Abatacept and rituximab are the preferred disease-modifying antirheumatic drugs (DMARDs) for RA-ILD **[1-4]**. However, progression of ILD despite its use is not uncommon. A subgroup analysis of the INBUILD trial has shown a slower decline in forced vital capacity (FVC) in patients with progressive fibrosing autoimmune disease-related ILDs with the antifibrotic nintedanib (NINTE) **[5]**.

Objectives: A) To assess the efficacy of antifibrotic drugs, NINTE and pirfenidone (PIRFE), in Spanish RA-ILD patients with a progressive phenotype in clinical practice. **B)** To compare the profile of clinical practice RA-ILD patients with the RA-ILD patients included in the INBUILD trial **[5]**.

Methods: National multicenter study of RA-ILD patients to whom NINTE or PIRFE were added due to progressive fibrosing ILD. Demographic and clinical variables were collected from all patients. These features were compared with those of RA-ILD patients included in the INBUILD trial (n=89, 42 treated with NINTE and 47 with placebo). Forced vital capacity (FVC) evolution was the primary endpoint. Results are expressed as percentage, mean±SD or median [IQR].

Results: A total of 50 patients (19 women/31 men) from clinical practice were collected (NINTE=45, PIRFE=5), mean age 70±8 years. Median ILD duration up to antifibrotic initiation was of 45 [19-72] months. Mean FVC one year before antifibrotic start was 81±20 (% pred.), whilst mean baseline FVC was 72±23 (% pred.). Comparison of baseline characteristics of RA-ILD patients treated with NINTE in clinical practice (n=45) and RA-ILD patients of the INBUILD trial is shown in **Table 1**. The evolution of FVC and DLCO in our patients from the previous year of antifibrotic initiation is shown in **Figure 1.** After a median follow-up of 16 [5-24] months, no decline in mean FVC and DLCO values was observed. Stabilization or improvement of dyspnea was found in 83% of patients. NINTE was withdrawn in 8 patients due to: gastrointestinal adverse events (GAE) (n=6), death (n=1) or hemorrhage risk (n=1). PIRFE was withdrawn in 2 patients due to GAE.

Conclusion: Antifibrotics, specially NINTE, seem to slow ILD progression in patients with RA-ILD. In clinical practice, patients are treated later in the evolution of the disease, but results are satisfactory. Combination of antifibrotics and DMARDs in RA-ILD is possible and safe.

POS0865 THE CORRELATION BETWEEN FOUR ADHERENCE MEASUREMENTS METHODS IN PATIENTS WITH RHEUMATOID ARTHRITIS USING METHOTREXATE

Keywords: Rheumatoid arthritis, Disease-modifying drugs (DMARDs)

R. Hebing[1,2], N. Elhendy[1], E. Van Geel[1], M. Van Heuckelum[3], M. T. Nurmohamed[1,2], B. Van den Bemt[3,4]. *[1]Amsterdam Rheumatology and Immunology Center, Reade, Amsterdam, Netherlands*; *[2]Amsterdam Rheumatology and Immunology Center, Amsterdam UMC location VUmc, Amsterdam, Netherlands*; *[3]Sint Maartenskliniek, Department of Pharmacy, Nijmegen, Netherlands*; *[4]Radboudumc, Department of Pharmacy, Nijmegen, Netherlands*

Background: Methotrexate (MTX) is the cornerstone in the pharmacological treatment of rheumatoid arthritis (RA) patients. However, medication adherence to MTX is not ideal, which might lead to suboptimal treatment outcomes. Consequently instruments to assess medication non-adherence are warranted to detect and intervene on non-adherence. To date there is no consensus on the best method to determine adherence to MTX.

Objectives: The aim of this study was to assess the correlation between compliance measured with MEMS (gold standard) versus pill count, MTX-polyglutamate (PG) concentration and Compliance Questionnaire Rheumatology (CQR) in patients with established RA. Second, correlations between these methods and the Disease Activity Scores of 28 joints (DAS28) were examined.

Methods: Adult patients with established RA treated with MTX were included. Multivariable linear and logistic regression were used, with taking compliance assessed with MEMS as dependent variable versus pill count, MTX-PG concentrations, CQR, as independent variables, and DAS28 score versus each of the 4 adherence measurements methods. Comedication, age and use of corticosteroids and NSAIDs were included as covariates in the analysis.

Results: 190 consecutive RA patients were included. Median follow-up time was 4.9 months (IQR 3.6 – 6.2). Pill count correlated with taking compliance assessed with MEMS (linear regression, β =.690, p = <.001), whereas MTX-PG concentrations and CQR were not. Logistic regression only confirmed the correlation between dichotomized taking compliance MEMS and pill count (β = 5.64,

p =.001). No other correlations were found. Between adherence outcomes and DAS28 scores no correlations were seen.

Conclusion: Taking compliance measured with MEMS was correlated with pill count, whereas other methods were not correlated with MEMS, nor with DAS28. Pill count can be used to estimate adherence to MTX therapy, when MEMS is not feasible.

Table 1. Results of multiple imputation linear regression analyses (pooled).

Dependent variable: MEMS		β	p	95% confidence interval forβ	
				Lower bound	Upper bound
IV	Pill count	0.690	<0.001*	0.377	1.004
	MTX-PG concentration	0.000	0.341	0.000	0.001
	CQR	0.035	0.399	-0.046	0.116
Dependent variable: DAS28					
IV	MEMS	0.001	0.748	-0.003	0.004
	Pill count	-0.180	0.544	-0.761	0.402
	MTX-PG concentration	0.000	0.262	0.000	0.001
	CQR	0.118	0.087	-0.017	0.253

Missing data was imputed with 50 imputations. MEMS: Medication Event Monitoring System, LN transformed; CQR: Compliance Questionnaire Rheumatology; IV: independent variable; beta: unstandardized coefficient; * Significance at 0.05. For MEMS, the following covariates were included in the final model: age, treatment centre, amount of other medication, corticosteroid-use, and the use of NSAIDs or COX-2 inhibitors. For DAS28, included covariates were: age, way of living status (e.g., alone, with a partner), educational level, biological-use, corticosteroid-use, other comedication and baseline DAS28.

POS0866 OLIVE OIL AND NUTS IN RHEUMATOID ARTHRITIS DISEASE ACTIVITY

Keywords: Rheumatoid arthritis, Diet and nutrition

S. Cavalli[1,2], V. Edefonti[3], M. Ferraroni[3], R. De Vito[4], F. Fiori[5], M. Parpinel[6], F. Ingegnoli[1,2], R. Caporali[1,2]. [1]*University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*; [2]*ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy*; [3]*University of Milan, Branch of Medical Statistics, Biometry, and Epidemiology "G.A. Maccacaro", Department of Clinical Sciences and Community Health, Milan, Italy*; [4]*Brown University, Department of Biostatistics and Data Science Initiative, Providence, Rhode Island, United States of America*; [5]*University of Udine, Department of Medicine—DAME, Udine, Italy*; [6]*University of Udine, Department of Medicine—DAME, Udine, Italy*

Background: Rheumatoid arthritis (RA) is a chronic, autoimmune arthropathy affecting around 1% of the general population. Though the availability of many synthetic and biologic DMARDs (disease modifying anti-rheumatic drugs), a non-negligible portion of patients still does not reach the remission. Increasing interest is raising about dietary interventions, in order to optimize disease control: scientific literature suggests that Mediterranean diet could exert an anti-inflammatory role in many rheumatologic conditions, including RA.

Objectives: In this cross-sectional analysis of RA patients from Italy, where extra virgin olive oil is traditionally used, we aim to assess if consumption of two food groups, one including olive oil and olives, and the other considering six types of nuts, might improve RA disease activity, through the related higher intake of vegetable-source fatty acids.

Methods: Within a recent Italian cross-sectional study (365 patients, median age: 58.46 years, 78.63% females), we focused on two food groups, olive oil and nuts, representing vegetable sources of fatty acids. Disease activity was measured with Disease Activity Score on 28 joints (DAS28-CRP) and the Simplified Disease Activity Index (SDAI). Robust linear and logistic regression models included tertile-based consumption categories of each food group and several confounders. Stratified analyses were performed by disease severity or duration.

Results: Higher consumption of both food groups exerted a beneficial effect on disease activity, significant only for olive oil (Beta: -0.33, p-value: 0.03) in the linear regression on the overall sample. This effect was stronger in the more severe or long-standing forms of RA (p-value for heterogeneity<0.05, especially for disease severity). Significant ORs were as low as ~0.30 for both food groups, strata, and disease activity. Mean DAS28 significantly decreased by ~0.70 for olive oil and ~0.55 for nuts in the two strata; mean SDAI significantly decreased by 3.30 or more for olive oil in the two strata.

Conclusion: In this cross-sectional study on Italian RA patients, higher consumption of olive oil and nuts generally led to an improvement of disease activity, but, in most cases, in the absence of statistical significance. The beneficial effect was, however, stronger for those patients with a more severe RA form or a long-standing RA activity, in the presence of significant heterogeneity across strata, especially for disease severity.

Background: Psoriatic Arthritis (PsA) has been historically considered as a T-cell driven disease, with the role of B-cells generally under investigated since common seronegativity. However, over the years new insights have come to light on B-cells in PsA, focusing on the presence of ectopic lymphoid structures as well as on the presence of specific anti-carbamylated/citrullinated cathelicidin LL37 antibodies in psoriatic SF and plasma.
Objectives: The aim of the study was to examine the frequencies of distinct peripheral blood (PB) B-cell subsets in across different disease phases, evaluating their potential correlation with synovial tissue (ST) heterogeneity in terms of inflammatory degree and microanatomical organization.
Methods: 150 patients fulfilling the CASPAR criteria for PsA were recruited (81 naive to cDMARDs or bDMARDs, 45 c- and/or b-DMARDs resistant and 24 in clinical and US sustained remission, respectively) and underwent US-guided ST biopsy and PB withdrawal. 22 patients with psoriasis (PsO) and arthralgia were included as comparison group. All ST FFPE specimens were routinely processed and stained with H&E and classified by a pathologist, blinded to clinical characteristics, using a H&E based semiquantitive score (KSS) integrated with the presence/absence of lymphocytes, plasmacells, granulocytes and myxoid degeneration, respectively. [1] Frequencies of PB B-cell subpopulations were determined by FACS using the CD27/IgD classification as follows: naïve B-cells ($CD27^{neg}IgD^{pos}$), IgM memory ($CD27^{pos}IgD^{pos}$), switched memory ($CD27^{pos}IgD^{neg}$), late memory ($CD27^{neg}IgD^{neg}$), plasmablasts ($CD27^{pos}CD38^{pos}$) and plasmacells ($CD138^{pos}$).
Results: In PsA cohort, the distribution of synovitis score was significantly different among patients with distinct disease phases (ANOVA p<0.001). In particular, KSS was contingent on disease phase being significantly lower in PsA in remission (2.04 ± 1.39) compared to naive (3.20 ± 1.77, p=0.02) and resistant PsA (3.78 ± 2.22, p<0.001), while there was no significant difference between remission PsA and at risk PsO group in terms of synovial hyperplasia, stromal density, and lymphocyte infiltrate respectively. ST of c- and/or b-DMARDs resistant PsA was enriched of plasmacells than remission PsA (p=0.03). Considering B-cell subpopulations, PB of c- and/or b-DMARDs resistant PsA was enriched of plasmablasts and plasmacells compared to PsO at risk of PsA development (p=0.01 for plasmablasts and p=0.001 for plasmacells, respectively). Conversely, c- and/or b-DMARDs resistant PsA showed, at PB level, lower rates of switched memory and naïve B-cells compared to PsO at risk of PsA development (p= 0.02 for switched memory and p=0.039 for naive, respectively). Finally, stratifying PsA based on KSS category, remission PsA with persistent high grade synovitis (KSS ≥ 5) showed lower rates of PB plasmablasts compared to remission PsA with low grade or without residual synovial inflammation (p=0.045).
Conclusion: Disease state across PsA course significantly impacts PB B-cell subsets distribution mirroring ST residual inflammation at the time of sustained disease remission and supporting the tight dynamic connection between PB and ST environments.

NOT ALL SYNDESMOPHYTES ARE EQUAL: THE IMPACT OF BODY MASS INDEX ON THE PRESENCE, LOCATION AND TYPE OF SYNDESMOPHYTES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Comorbidities, Imaging

S. B. Acikgoz[1], U. Gazel[1], S. Bakırcı[1], G. Ayan[1], D. Solmaz[1], E. Hepworth[1], S. Aydin[1]. [1]*University of Ottawa, Rheumatology, Ottawa, Canada*

Background: New bone formation is a hallmark of Axial spondyloarthritis (axSpA). Body mass index (BMI) is associated with the presence of syndesmophytes, especially in males. To date, it is not clear whether obesity impacts the axSpA through adipokines or biomechanical forces.
Objectives: We aimed to investigate the relation between BMI and the presence and types of syndesmophytes at different spine levels, to better understand the impact of biomechanical forces in AxSpA.
Methods: AxSpA patients who had cervical and lumbar spine x-rays as their standard of care were included (n=144). The cervical and lumbar spine xrays were scored separately, for the presence and type (thin vs bulky) of syndesmophytes. The factors associated with syndesmophytes were investigated, using a multivariate logistic regression.
Results: The mean±SD age of the patients was 45.2±14.0. Syndesmophytes were seen in 48 (33.3%) patients of the cervical and 43 (29.9%) of the lumbar spine. Older and male patients had more frequent syndesmophytes on both levels. While the BMIs of patients with lumbar syndesmophytes were higher than those without (28.4 (8.2) vs 26.8 (7.0), p=0.015), patients with and without cervical syndesmophytes had similar BMIs (27.1 (8.3) vs 28.2 (7.5), p=0.177). Patients with cervical syndesmophytes had higher frequency of uveitis (47.9% vs 20.8%, p=0.001) than those without, which could not be detected for lumbar syndesmophytes. In regression analysis, age and male gender were associated with syndesmophytes in both the cervical and lumbar spine, whereas uveitis was associated only with syndesmophytes in the cervical spine (Table 1). BMI was associated only with syndesmophytes in lumbar spine, but not the cervical spine. The only factor that was found to be associated with bulky (vs thin) syndesmophytes was BMI for the lumbar spine, but not for the cervical spine (Table 1). Presence of PsA was not linked to the bulky type syndesmophytes.
Conclusion: Higher BMI increases the risk of syndesmophytes in the lumbar spine as well as impacting its shape; but not in the cervical spine. Abdominal obesity (apple-shaped) is more common among men in general. We hypothesize that the obesity may be increasing the risk of lumbar syndesmophytes as well as bulkiness in males due to the mechanical forces, which may not be seen in generally "pear-shaped" women, where the fat tissue and mechanical forces spare the lumbar spine.

POS0869 **WITHDRAWN**

POS0870 **PROTEIN BIOMARKERS ASSOCIATED WITH ENTHESITIS IN PSORIATIC ARTHRITIS**

Keywords: Psoriatic arthritis, Enthesitis, Biomarkers

A. Elliott[1], J. Waddington[2], R. Zhou[2], B. Wundervald[2], G. Wright[3], A. Pendleton[3], O. Fitzgerald[4], S. Pennington[2], M. Rooney[1]. [1]*Queen's University Belfast, Centre for Experimental Medicine Queens University Belfast, Belfast, United Kingdom*; [2]*Atturos Ltd., University College Dublin, Dublin, Ireland*; [3]*Musgrave Park Hospital, Rheumatology, Belfast, United Kingdom*; [4]*UCD Conway Institute, University College Dublin, University College Dublin, Dublin, Ireland*

Background: The presence of enthesitis in PsA may provide clues to disease pathogenesis, aid diagnosis and contribute to poor prognosis. Ultrasound is an invaluable tool in assessing entheseal disease, but it requires training and is time consuming. We investigated whether enthesitis may be measured by changes in serum proteins and as such allow us to better understand, diagnose and treat the condition.
Objectives: To use mass spectrometry (MS) based proteomics to identify protein biomarkers that may be associated with those PsA patients who suffer from enthesitis.
Methods: Serum was collected as part of a prospective observational study from PsA patients who fulfilled the CASPAR criteria and were ≥ 18 yrs. All patients were biologic naive and due to commence biologic treatment. We utilised the MAdrid Sonographic Enthesitis Index (MASEI) to assess US confirmed enthesitis with a score of ≥ 18 suggesting significant enthesitis and <18 determined to be non-significant. The samples were analysed using targeted MS multiple reaction monitoring (MRM) analysis with > 200 candidate proteins. The MRM data was analysed in 3 ways: 1) Raw with no normalisation 2) Normalisation to 7 stable isotopically labelled peptide spike-ins (SIL7) correcting for fluctuations in sample injections/mass spectrometry loading; and, 3) Normalisation to a set of endogenous peptides that represent total serum protein abundance (TSPA) correcting for different amounts of total serum across samples. Univariate analyses and multivariate machine learning Random Forest (RF) modelling were performed.
Results: 80 samples were analysed. 29 patients had a MASEI score of < 18 [36.25%] and 51 had a score > 18 [63.75%]. We identified 35 candidate proteins from all data sets that are included in Figure 1. RF multivariate analysis of all data revealed a set of peptide signatures with the ability to differentiate between MASEI scores < 18 vs ≥ 18. RF models generated from the peptide data had a testing and training AUC of 0.789 [95% CI 0.65, 0.93] 0.953 [95% CI 0.92, 0.98] (Raw), 0.83 [CI 0.74, 0.94], 0.972 [95% CI 0.96, 0.99] (TSPA7) and 0.845 [95% CI 0.72, 0.97]0.966 [95% CI 0.94, 0.99] (SIL7) respectively.
Conclusion: We have identified serum proteins, within this small cohort, which are associated with enthesitis in PsA. Verification of these findings in a larger, independent dataset is the next required step. Proteins related to peptide sequences for univariate + multivariate analysis. ROLE OF INFLAMMATORY BURDEN AND TREATMENT ON JOINT SPACE WIDTH IN PSORIATIC ARTHRITIS-A HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY STUDY

Keywords: Outcome measures, Psoriatic arthritis

Y. Jin[1,2], I. T. Cheng[1], H. So[1], D. Wu[1], J. F. Griffith[3], V. W. Hung[4], L. Qin[4], C. C. Szeto[1,2], A. W. Chan[1], L. S. Tam[1]. [1]*The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, China*; [2]*The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences (LiHS), Hong Kong, China*; [3]*The Chinese University of Hong Kong, Department of Imaging and Interventional Radiology, Hong Kong, China*; [4]*The Chinese University of Hong Kong, Department of Orthopaedics and Traumatology, Hong Kong, China*

Background: Psoriatic Arthritis (PsA) is associated with enthesitis and synovitis which lead to bone erosions, cartilage loss, and new bone formation. High-resolution peripheral quantitative computed tomography (HR-pQCT) enables the quantitative 3D assessment of joint space width (JSW) with superior resolution compared to radiography. Whether disease-specific parameters are associated with JSW on HR-pQCT in PsA remains uncertain.

Objectives: To assess HR-pQCT joint space outcomes by comparison with radiographs and investigate the relationship between disease-related variables and JSW on HR-pQCT in PsA patients.

Methods: PsA patients who underwent HR-pQCT examination (XtremeCT I, SCANCO Medical AG, Brüttisellen, Switzerland) of the second to fourth metacarpophalangeal joint (MCPJ 2-4) were recruited in this cross-sectional study. The joint space metrics included joint space volume (JSV), mean, minimum (Min) and maximum (Max) JSW, JSW asymmetry (Asymm) and distribution (SD). Volumetric joint space was quantified using an algorithm developed by consensus from the Study group for eXtreme Computed Tomography in Rheumatoid Arthritis (SPECTRA). The joint space domain on standard radiography was scored using the Sharp/van der Heijde (SvdH) joint space score. A generalized estimating equation (GEE) was used to estimate the ability of HR-pQCT to predict SvdH scores. Linear regression models were used to determine the association between disease-related variables and JSW.

Results: 67 patients [47 (55.2%) males; median age: 57.0 (53.0, 63.0); median disease duration: 21 (16, 28) years] were included in this analysis. Most had mild disease activity [Disease Activity index for PsA (DAPSA): 10.1 ± 6.6]. 56/67 (84%) were on conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) while 27/67 (40%) were on biologic DMARDs (bDMARDs). 11 MCPJ 2, 9 MCPJ 3 and 7 MCPJ 4 were excluded due to poor image quality. Individual MCP joint space parameters were presented in Table 1. Subluxations were detected more frequently by HR-pQCT than radiographs. SvdH score was negatively associated with a lower mean, Max and Min JSW; and higher JSW SD and Asymm (all p<0.05). Multivariable linear regression analysis showed that males had larger JSV (MCPJ 2-4), mean (MCPJ 4) and Max JSW (MCPJ 3). Longer disease duration (MCPJ 2-3) and higher ESR level (MCPJ 3) were negatively associated with mean and Max JSW, while higher damage joint count was negatively associated with mean and Min JSW (MCPJ 2) (Figure 1). Use of csDMARDs was negatively associated with Min JSW (MCPJ 3); while use of bDMARDs was positively associated with Min JSW (MCPJ 2).

Conclusion: HR-pQCT could be widely used for assessing joint damage prior to evidence of radiographic joint damage in PsA patients. Higher inflammatory burden as reflected by longer disease duration, higher ESR levels, and damage joint count was negatively associated with mean, Max, and Min JSW, while suppression of inflammation using bDMARDs seems to prevent a decline in JSW.

Table 1. Joint space analysis in PsA patients

JS parameters	MCPJ 2	MCPJ 3	MCPJ 4
JS volume (mm^3)	87.1 ± 18.8	94.1 ± 22.7	66.1 ± 15.0
Mean JSW (mm)	1.8 ± 0.2	1.7 ± 0.2	1.6 ± 0.2
JSW SD (mm)	0.3 (0.3, 0.3)	0.3±0.0	0.3±0.1
Max JSW (mm)	2.9 (2.7, 2.9)	2.7 (2.5, 2.9)	2.6 (2.5, 2.7)
Min JSW (mm)	1.1 (0.8, 1.4)	1.1 (0.2, 1.3)	1.0 (0.9, 1.2)
JSW Asym	2.4 (2.1, 3.2)	2.5 (2.2, 15.8)	2.4 (2.1, 3.0)

PsA, psoriatic arthritis; MCPJ, metacarpophalangeal joint; JS, joint space; JSW, joint space width; SD, standard deviation; Max JSW, maximum JSW; Min JSW, minimum JSW; Asym, joint asymmetry.

POS0872 CHARACTERIZATION AND RISK FACTORS FOR LUNG INVOLVEMENT IN PSORIATIC ARTHRITIS: DATA FROM A SINGLE RHEUMATOLOGIC CENTRE

Keywords: Prognostic factors, Lungs, Psoriatic arthritis

B. Monosi[1], I. Cristiano[1], E. Capparelli[1], P. Triggianese[1], E. Greco[1], P. Conigliaro[1], B. Kroegler[1], M. Fatica[1], A. Bergamini[1], M. S. Chimenti[1].
[1]Rheumatology, Allergology and Clinical Immunology, Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy

Background: Psoriatic arthritis (PsA) is a chronic inflammatory systemic disease associated with several comorbidities. Few data are available concerning the association between psoriasis (PsO) and lung disease (LD), such as chronic obstructive pulmonary disease (COPD)[1] and interstitial lung disease (ILD)[2]. This association has also been hypothesized in PsA. Therefore, evaluating distinct lung manifestations in PsA could be an important driver to improve patients' management.
Objectives: To assess the prevalence and clinical features of PsA, to examine the co-occurrence of different LDs patterns and to evaluate their impact on clinical outcomes.
Methods: We performed a cross sectional observational study including patients with diagnosis of moderate to severe PsA and at least one chest imaging (as CT scan) performed at the beginning of bDMARD therapy, referred to our Rheumatologic Unit. Demographic, clinical data and concomitant comorbidities were collected. We used Chi-square test for categorical variables and Student's T test for continuous variables.
Results: 288 PsA patients were evaluated. Patients' characteristics are shown in *Table 1.* We observed 28 patients affected by COPD (9.7%) and 7 by ILD (2.4%). About 20% of patients had radiological abnormalities without a distinct clinical diagnosis. In particular, 27 patients presented aspecific nodules (9.4%), 19 signs of bronchitis or emphysema (6.6%) and 17 interstitial thickening (5.9%). Notably, smoke (HR 2.2, p 0.04), higher age at PsA diagnosis (53.8 ± 8.5, p<0.001), higher BMI (28.6 ± 5.6, p 0.05) and recurrent infections (HR 12.3, p<0.001) were associated to COPD. Among comorbidities, cardiovascular diseases (HR 3.8, p 0.005), dyslipidaemia (HR 3.6, p 0.007) and diabetes (HR 4.1, p 0.001) were associated to COPD. Both COPD patients (HR 3.3, p 0.01) and patients with other LDs (HR 2.9; p 0.002) had a history of bDMARDs failure of at least >3 bDMARDs underwent, significantly more than patients without LD. Even in ILD patients, we observed an older age at PsA diagnosis (58 ± 12.2, p 0.01) and a higher prevalence of diabetes (HR 4.1, p <0.001) compared to patients without LD. Furthermore, nail psoriasis (HR 4.7, p 0.05) and malignancy (HR 7.1, p 0.01) were related to ILD.
Conclusion: Our results confirm the prevalence of COPD in PsA[3] and add evidence about the co-occurrence of other LDs in PsA. Risk factors associated with the presence of LD emerged from our analysis, highlightening an occult unmet need in PsA patients. Moreover, we observed as LDs could influence bDMARDs failure. Otherwise, focusing on pulmonary comorbidities could improve therapeutic response and clinical outcomes.

POS0873 SYNOVIAL TISSUE FEATURES ASSOCIATED WITH POOR PROGNOSIS IN INFLAMMATORY ARTHRITIS

Keywords: Rheumatoid arthritis, Synovium, Psoriatic arthritis

A. B. Azuaga-Piñango[1], J. Ramirez[1], R. Celis[1], A. Cuervo[2], B. Frade-Sosa[1], J. C. Sarmiento-Monroy[1], J. A. Gómez-Puerta[1], R. Sanmartí[1], J. D. D. Cañete[1].
[1]Hospital Clinic, Rheumatology, Barcelona, Spain; *[2]Hospital General Granollers, Rheumatology, Granollers, Spain*

Background: Rheumatoid arthritis (RA), Psoriatic arthritis (PsA), and undifferentiated arthritis (UA) are chronic immune-mediated inflammatory diseases characterized by joint inflammation. However, the prognosis related to progression to chronic and erosive disease or to an autolimited outcome could be different between those clinical phenotypes. Synovial lymphoid neogenesis (LN) has been previously studied as a prognostic factor in RA but results were conflicting between studies [1,2].
Objectives: To evaluate the potential association of inflammatory cell infiltrates and the expression of ectopic LN structures in synovial tissue (ST) with poor prognosis factors (PPF) in patients with RA, PsA, and UA.
Methods: This is a retrospective study including patients with active RA, PsA, and UA who had ST obtained by rheumatological arthroscopy in our department. We evaluated clinical data and synovial LN and the cellular infiltrate by immunohistochemistry, as previously detailed [1]. Patients who were on Biologic Disease-modifying Antirheumatic Drug (bDMARDs) at the time of arthroscopy were excluded. PPF in patients with RA and UA were defined by anti-cyclic citrullinated peptide/protein antibodies (ACPA) and/or rheumatoid factor (RF), development of erosive disease or the initiation of bDMARDs during the follow-up. PPF in patients with PsA were defined by high levels of acute phase reactants (ESR and/or CRP), dactylitis or nail involvement at the time of arthroscopy and/or the initiation of bDMARDs. Statistical analysis was done with SPSS Statistics 27 program. For the analysis of LN and PPF, we performed x^2, T-test to compare PPF with the cellular density and Spearman's rank correlation coefficient for cellular density and disease activity score 28 (DAS28).
Results: A total of 87 patients were included: 26 RA, 32 PsA and 29 UA. Demographic characteristics are detailed in Table 1. Seventeen out of 26 (65.38%) RA patients had LN and 14 (53.84%) had PPF. Twelve patients (46%) had LN and PPF. LN was associated with PPF (p 0.038). In PsA group, we found LN in 16 out of 32 (50%) and PPF in 42.4%. Polyarticular PsA (58.5%) was the most frequent phenotype and 15.2% of patients had onychopathy. Nevertheless, LN was not associated with PPF. Patients with PPF had a higher CD15+ polymorphonuclear cell density (477.63 [SD 410.68] vs 99.63 [SD 93.23] cells/cm2 in patients without PPF, p 0.031). Thirteen out of 29 (44.82%) UA patients had LN and 55.17% had PPF. The final diagnosis for these patients were: 12 RA; 4 PsA; 8 peripheral SpA and 5 remained as UA. LN was not associated with PPF. Synovial CD68+ macrophages cells density (lining, sublining and total) was negatively correlated with DAS28 CRP (r= -0.27, p 0.024).

Table 1.

	RA	PsA	UA
N	26	32	29
Female, n (%)	20 (76.9)	14 (42.4)	18 (41.4)
Smoker, n (%)	5 (19.2)	3 (9.1)	5 (17.2)
Age, mean years (SD)	53.19 (14.4)	51.40 (13.7)	47.24 (16.5)
Disease duration, mean months (SD)	83.30 (113.2)	60.70 (70.9)	29.50 (50.8)
Anti-CCP positive, n (%)	19 (73.7)	-	8 (27.6)
RF positive, n (%)	16 (61.5)	-	8 (27.6)
HLAB27 positive, n (%)	-	9 (27.3)	6 (20.7)
DAS28 CRP, mean (SD)	3.44 (1.1)	2.65 (0.6)	3.00 (0.92)
DAS28 ESR, mean (SD)	4.37 (1.5)	3.46 (1)	4.34 (1.2)
Initiation bDMARd, n (%)	13 (50)	10 (30.3)	12 (41.4)

Conclusion: Synovial LN was associated with PPF only in patients with RA, suggesting the specific pathogenic role that these well-compartmentalized lymphoid aggregated play in RA. However, in PsA, PPF was associated with synovial CD15+ neutrophils density, probably related to the pathogenic relevance of myeloid cells in this disease. Finally, synovial CD68+ macrophages negatively correlated with disease activity in UA patients, probably reflecting the heterogeneity of pathogenic mechanisms occurring in this group. Although this study is retrospective and with relatively small cohorts, the findings suggest a great heterogeneity of the ST features and its pathogenic implications in the subtypes of inflammatory arthritis studied.

POS0874 DO PATIENTS WITH PSORIATIC ARTHRITIS EXPERIENCE MORE FEELINGS OF SHAME AND GUILT THAN PATIENTS WITH RHEUMATOID ARTHRITIS?

Keywords: Psoriatic arthritis, Quality of life, Mental health

H. Boussaa[1], E. Hannech[1], A. Fazaa[1], S. Miladi[1], M. Yasmine[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology Department, Tunis, Tunisia*

Background: Patients with rheumatoid arthritis (RA) may experience feelings of guilt and shame related to the impact of the disease on their quality of life. However, patients with psoriatic arthritis (PsA) face an aesthetic problem in addition to the functional disability.
Objectives: The purpose of this study was to determine whether patients with PsA experience more feelings of shame and guilt than patients with RA.
Methods: We conducted a cross sectional study including patients with RA (ACR/EULAR criteria) and PsA (CASPAR criteria). Feelings of guilt and shame were assessed using the Experience of Shame Scale (ESS) [1] and the Test of Self Conscious Affect- Version 3 (TOSCA-3S) [2]. ESS is a self-report scale assessing 3 areas: (1) characterological shame (2) behavioral shame and (3) bodily shame. Each item was rated in a 4-point Likert scale. Higher scores indicate higher levels of shame. TOSCA-3S is composed of 11 scenarios, each followed by 4 possible responses. Each item was rated in a 5-point Likert scale. This score measures shame-proneness, guilt-proneness, detachment and externalization (blaming others). Only the shame and guilt subscales of the TOSCA-3S were used for the statistical analysis. A $p<0.05$ was considered significant.
Results: A total of 40 RA patients (36 women, 4 men) and 30 PsA patients (12 women and 18 men) were included. The mean age was 54 years [25-75] and 51 years [21-80], respectively. The mean disease duration was 12 years [3-33] in RA patients and 13 years [2-20] in PsA patients. Illiteracy was noted in 22% of RA patients and in 5% of PsA patients. Regarding the professional status, 42% of RA patients and 50% of PsA patients were employed. High disease activity was noted in 42% of RA patients and in 13% of PsA patients. The mean total score of ESS was 45 [27-80] in RA and 65 [31-98] in PsA. There was a significant difference between the groups ($p<0.001$). The mean subscale scores were significantly higher among PsA patients: the characterological shame (29 vs 19, $p=0.05$), the behavioral shame (25 vs 18, $p=0.001$), and the bodily shame (10 vs 7, $p<0.001$). For the TOSCA-3S, the mean "shame self-talk Total" score was higher in PsA patients, but the difference was not significant (35 vs 33, $p=0.453$). The mean "guilt self-talk Total" score was 48 in RA and 47 in PsA ($p=0.341$).
Conclusion: Feelings of guilt and shame are experienced by both PsA and RA patients. However, PsA may have a higher psychosocial impact. Therefore, effective management of the dermatological and psychological aspects is necessary.

POS0875 AUTOANTIBODIES DIRECTED TO G-PROTEIN COUPLED RECEPTORS CORRELATE WITH DISEASE ACTIVITY SCORES IN PATIENTS WITH PSORIATIC ARTHRITIS

Keywords: Comorbidities, Autoantibodies

H. Grasshoff[1], S. Comduehr[1], J. Ohmes[1], D. Thaçi[2], K. Schulze-Forster[3], H. Heidecke[3], P. Lamprecht[1], G. Riemekasten[1]. [1]*Lübeck, Department of Rheumatology and Clinical Immunology, Lübeck, Germany*; [2]*UKSH Lübeck, Institute and Comprehensive Center for Inflammation Medicine, Lübeck, Germany*; [3]*Luckenwalde, CellTrend GmbH, Luckenwalde, Germany*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease that affects the skin, nails, tendons and joints. In addition, several comorbidities have been identified with PsA. In particular, a frequent occurrence of fatigue and mental disorders such as depression have been described in patients with PsA. Key cellular players in pathophysiology of PsA are T cells. However, in recent years, various autoantibodies such as anti-LL37 and anti-Pso-p27 have been identified in PsA as well [1]. Autoantibodies targeting G protein-coupled receptors (GPCRs) have been identified in several diseases and are involved in disease pathophysiology [2]. Many of these autoantibodies are agonists that enhance the effect of the natural ligand at the receptor [3].
Objectives: The aim of this study was to investigate the association between autoantibodies directed to distinct GPCRs and disease activity as well as comorbidities in PsA.
Methods: In a prospective observational study forty-five patients with an active PsA according to CASPAR criteria and 24 healthy controls (HCs) matched according to age and sex were included in this study. The serum-concentrations of 20 autoantibodies directed to GPCRs involved in the renin-angiotensin-aldosterone system, the sympathetic and parasympathetic nervous system as well as chemokine, complement and scavenger receptors, were measured by the company CellTrend GmbH (Luckenwalde, Germany). Autoantibodies measured in patient's sera at baseline were transformed and adjusted for age as confounder for further analyses. To compare autoantibody concentrations between PsA and HCs we applied Two-Way-ANOVA. Correlation analyses were performed using Pearson correlation. Autoantibody concentrations between patients with and without depression were analyzed by Student's T test and binary logistic regression.
Results: Patients were equally distributed according to sex (male 51.1%, female 48.9%) and of a mean age of 47.5 ± 13.2 years. Mean arthritic disease manifestation assessed by DAPSA was 44.4 ± 21.2. Patients displayed a disease activity with a mean PASI of 6.19 ± 6.33, and high impact on patient reported outcomes with a mean DLQI of 10.3 ± 7.4 and a mean HAQ of 1.0 ± 0.8. Autoantibody concentrations did not differ significantly between patients with PsA and HCs. Further analysis revealed significant correlations between autoantibody levels, disease activity scores and treatment response of cutaneous disease manifestation after 16 weeks of treatment (Δ PASI), **Figure 1**. Moreover, the levels autoantibodies directed to the MAS receptor, CXCR3, PAR1 and stabilin were significantly higher in patients with PsA suffering from depression compared to patients without depression (MASR: $p=0.035$; CXCR3: $p=0.011$; PAR1: $p=0.047$; stabilin: $p=0.035$), although binary logistic regression did not prove any predictive value for these four antibodies.
Conclusion: Autoantibodies directed to GPCRs correlated with disease activity scores in patients with PsA. Further larger analyses regarding the functional role of these autoantibodies in PsA are required.

POS0876 ASYMPTOMATIC HELL ENTHESITIS IN PSORIASIS PATIENTS: AN ULTRASOUND STUDY

Keywords: Enthesitis, Ultrasound, Psoriatic arthritis

R. Ben Aissa[1], S. Boussaid[1], S. Rekik[1], S. Rahmouni[1], S. Jemmali[1], K. Zouaoui[1], H. Srairi Sahli[1], M. Elleuch[1]. [1]*Rabta Hospital, Department of Rheumatology, Tunis, Tunisia*

Background: Enthesitis is a common clinical feature of psoriatic arthritis (PsA) especially in lower limb. Clinical screening for enthesitis in patients with psoriasis before developing PsA may be non-specific. Ultrasound has shown its value in the study of entheses.

Objectives: To asses heel entheses of asymptomatic psoriasis patients and healthy control using ultrasound.

Methods: We conducted a cross-sectional case-control study including psoriasis patients with no rheumatic symptoms and sex and age-matched healthy controls. We assessed the affected skin surface (SC) and the psoriasis severity score (PASI). Ultrasound evaluation of the calcaneal enthesis (CE) and the plantar fascia enthesis (PFE) was performed. Ultrasound abnormalities sought were: hypoechogenicity, enthesis thickening, bursitis, cortical erosion, calcification, enthesophyte, and presence of Doppler signal.

Results: A total of 76 patients (38 cases and 38 controls) were recruited with a mean age of 51.9±15 [19-76] years and male predominance (60%). On clinical examination, pressing pain was present at the CE and PFE in, respectively, 17.5% and 12.5% of psoriasis patients but with no significant difference comparing to controls (10% EC; 10% PFE respectively) (p=0.777; p=0.259 respectively). On ultrasound, 60% of psoriasis patients had at least one ultrasound abnormality at the CE versus 17.5% of controls (p<0.001). The most observed ultrasound abnormalities at the CE were: enthesophyte (n=17), enthesis thickening (n=15), erosions (n=11) and hypoechogenicity (n=5). The PFE was less affected on ultrasound, presenting abnormalities in 42.5% of psoriasis patients versus 12.5% of controls (p=0.410). Erosions (n=13) and enthesis thickening (n=12) were the most observed abnormalities. The presence of ultrasound abnormalities at the PFE in psoriasis patients was correlated with age (p=0.012) and disease duration (p=0.015). Psoriasis severity according to SC and PASI was not associated with the presence of ultrasound abnormalities at CE (p=0.860; p=0.417 respectively) and PFE (p=0.399, p=0.156 respectively).

Conclusion: Our study showed that psoriasis patients could have asymptomatic heel enthesitis with greater involvement of the CE. Psoriasis patients need regular monitoring and screening for early symptoms of PsA.

POS0877 A COMPARISON OF PSA AND RA PATIENT PROFILES REQUIRING ADVANCED THERAPIES: PSA PATIENTS ACCESS TO THE ADVANCED THERAPIES EARLIER THAN RA

Keywords: bDMARD, Psoriatic arthritis, Rheumatoid arthritis

S. B. Acikgoz[1], U. Gazel[1], R. Chowdhury[1], C. Ivory[1], A. Zahrai[2], E. Hepworth[1], S. Aydin[1]. [1]*University of Ottawa, Rheumatology, Ottawa, Canada*; [2]*The Ottawa Hospital Research Institute, Rheumatology, Ottawa, Canada*

Background: International guidelines recommend switching to advanced therapy (AT) in patients with Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA), when conventional synthetic disease modifying antirheumatic drugs (csDMARD) fail. There are several factors playing a role in that decision, including patients' comorbidities and choices as well as the availability of the treatments.

Objectives: Here we present the results of a comparison of PsA and RA patient profiles requiring advanced therapies, from our pilot biologics clinic. Better patient outcomes in one disease may help us to recognize what can be improved in the other.

Methods: Biologics clinic is a new initiative at Ottawa Hospital aiming to improve the long-term outcomes. Patients who are about to start or switch advance therapy are evaluated at the biologics clinic. Extensive data regarding disease history, medication exposure and disease activity are collected in a standardized fashion; the comorbidity burden is documented. A protocoled ultrasound (US) is conducted at baseline and three-month intervals, until reaching remission. The data presented here represent a pilot exploratory comparative analysis.

Results: PsA (n=18) and RA(n=42) patients had similar demographic features, other than RA patients being older (table 1). The majority of the comorbidities were similar in both groups, although PsA patients had more frequent liver disease numerically (5 (27.8 %) vs 5 (11.9%), p= 0.149) and less alcohol use (19 (38.9%) vs 7 (45.2%), p= 0.649). PsA patients had more frequent moderate/severe depression using the PHQ (61.1% of PsA vs 26.2% of RA; p=0.01). For disease activity, PsA patients tend to have higher disease activity based on the TJC, HAQ and physician global; in addition to significantly longer morning stiffness then RA (Table 1). Conversely, the disease activity within the joints based on the US scores of RA patients were higher. Disease duration at the time of initiation of the first advanced therapy was significantly shorter in PsA (median (IQR) 1.0 (7.75) years) compared to RA (6 (12.5), p=0.005) and PsA patients were treated with less numbers of csDMARD.

Conclusion: According to our preliminary data, PsA patients access to advanced therapy earlier than the RA. This may be due to the heterogeneity of PsA, such as manifestations other than the joint inflammation (enthesitis and axial disease) determining treatment decisions. PsA patients also had more frequent liver disease, which also may have prevented initiation of csDMARD and led to expediated initiation of the advance therapy- as early as at diagnosis. Whether earlier access leads to better patient outcomes in PsA, will be investigated with long-term follow up. PsA patients having more tender joints despite less severe US scores may be due to the proximity of the enthesis to the joints and difficulties to differentiate entheseal pain from joint involvement by the physical exam. The use of US may improve the assessment of the domains in PsA leading to choosing the right treatments.

Background: Psoriatic arthritis (PsA) is an inflammatory musculoskeletal disease characterized by different domains.[1] Interest is growing towards early diagnosis of axial PsA (AxPsA), to allow better disease characterization and well-timed targeted therapeutic strategies.

Objectives: In this study, we report preliminary results of a rheumatological screening strategy settled in a dermatological centre. Primary objective is to validate the screening tool in a cohort of Italian patients affected by psoriasis, improving early diagnosis of AxPsA. Secondary objectives are: 1. classification and characterization of axial involvement; 2. profiling of patients' characteristics and comorbidities.

Methods: Patients were enrolled in the ATTRACT study (**A**xial psoria**T**ic ar**T**hritis sc**R**eening **A**n**C**ona i**T**aly) according to the following inclusion criteria: **1.** age > 18 years; **2.** diagnosis of psoriasis (Pso) by a dermatologist; **3.** capacity to understand and sign the informed consent. Patients who assumed any DMARD 12 weeks prior to screening were excluded. Study design is shown in Figure 1. The Dermatologic-Centred Screening (DCS) tool[2], recently validated for early identification of AxPsA, was translated in Italian and administered to outpatients in the dermatological clinic. Patients were divided in the following groups based on answers to the Inflammatory Back Pain (IBP) related questions of the DCS: **A.** no affirmative answers (low AxPsA probability); **B.** all affirmative answers (high probability); **C.** only two affirmative answers (intermediate probability). Group B & C patients underwent complete rheumatological examination comprehensive of clinimetric, laboratoristic and genetic data; Xray and MRI imaging of the whole spine and pelvis were performed in all of them classifying in: **a.** confirmed AxPsA; **b.** peripheral PsA involvement only; **c.** PsA excluded.

Results: N.366 patients were screened; n.101 met exclusion criteria. N.91 (34.3%) were classified as group A, n.125 (47.2%) as group B, n.49 (18.5%) as group C. Following characteristics were notable: a. female sex more represented in group B; b. mean age higher in group C; c. onichopathy more represented in group A & C. List of patients' clinical characteristics is shown in Table 1 Among group B patients, n.28 (22.4% - B1) were classified as PsA excluded; n.22 (17.6% - B2) as isolated per-PsA (according to CASPAR criteria), n.39 (31.2% - B3) as AxPsA (n.34 fulfilling ASAS criteria, n.31 with concomitant per-PsA). Among group C, n.15 (30.6% - C1) as PsA excluded; n.3 (6.1% - C2) as isolated per-PsA, n.5 (10.2% - C3) as AxPsA (n.4 fulfilling ASAS, n.5 with concomitant per-PsA). N.13 patients are still awaiting results of imaging; n.49 (n.24 group B, n.25 group C) refused to undergo imaging and were considered lost at follow-up.

Conclusion: The DCS tool may be useful for PsA screening in a real-life cohort of Pso patients, an Inflammatory Back Pain was reported by about half of the screened Pso patients. This tool helped to identify a substantial number of naïve patients not only affected by AxPsA but also by peripheral PsA in a purely dermatological setting.

Background: The impact of delay in diagnosis on the disease severity and functional loss has been shown previously In Psoriatic arthritis (PsA) patients.

Objectives: This study aimed to evaluate the impact of 6 month-delay in diagnosis on patients` clinical outcomes and functional outcomes in the PsA patients under bDMARD therapy using a national database.

Methods: TReasure is a national, multicentre, longitudinal, and observational database, initiated in Turkey in 2017 and now includes 17 centres [1]. PsA patients with/out more than 6 months from the onset of symptoms to diagnosis were evaluated. Demographic characteristics of the patients (age, gender, delay in diagnosis), smoking (ever), BMI, and CCI score were calculated. PsA and associated disease characteristics; dactylitis, enthesitis, uveitis, IBD, sacroiliitis by mNY, disease activity at bDMARD initiation; SJC (66 joints), TJC (68 joints), ASDAS-CRP, ASDAS-ESR, BASDAI, ESR, CRP, VAS (physician global, patient global), function and quality of life; BASFI (>40 mm), HAQ-DI (<0.5, 0.5-1.0, >1.0), EQ5D, were assessed and compared between two groups.

Results: In TReasure database, the time between symptom to diagnosis was known in 865/911 (94.9%) of PsA patients. More than 6 months of delay in diagnosis was present in 627/865 (72.4%) patients. In delayed-diagnosis group time from symptom onset to initiation of bDMARD was longer (6.1 (3.3-6.1) vs 2.4 (0.8-7.1) years, p<0.001). Patients with delay in diagnosis of PsA had more sacroiliitis (57.3% vs 46.2%, p=0.014) according to mNY criteria. However, dactylitis was more common in patients with less than 6 months of delay in diagnosis (31.2% vs 19.1%, p<0.001).Patients' ASDAS-CRP and VAS-Physician Global score were slightly higher, while other activity parameters were similar; (ASDAS-ESR, BASDAI, BASMI, VAS patient global, SJC and TJC) (Table 1). There was no difference between the median (IQR) BASFI and HAQ-DI scores in delayed-diagnosis group, whereas BASFI and HAQ-DI categories showed worse function and quality of life. EQ5D showed similar result with slightly worse scores in delayed-diagnosis group.

Conclusion: Approximately three-quarters of PsA patients using bDMARDs have a delay of at least 6 months in diagnosis. Delay in diagnosis significantly prolongs the time until bDMARD initiation. The most important clinical finding in earlier diagnosis group is dactylitis. Axial involvement may be a reason, perhaps the result, of the delay in diagnosis. Since the delay in diagnosis is related to poor function and quality of life, efforts should be made for early diagnosis at every stage.

Background: Rheumatoid arthritis (RA) and spondyloarthritis, including either Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS), are some of the most diagnosed autoimmune rheumatic diseases (AIRDs) in rheumatologists' routine clinical practice [1]. Understanding patients' health and functional status is crucial to provide personalized management strategies to optimize disease control and enhance the quality of life.

Objectives: We aimed to compare disease burden in patients with RA, PsA or AS by assessing Patient-Reported Outcome Measurement Information System (PROMIS) Physical Health, Global Mental Health, Physical Function and Fatigue 4a together with VAS Pain.

Methods: Data were obtained in the international COVID vaccination in autoimmune rheumatic diseases study second e-survey (COVAD study). Demographics, AIRD diagnosis, disease activity, PROMIS Global Physical health, PROMIS Global Mental Health, PROMIS Physical Function SF10 and PROMIS Fatigue 4a score were extracted from the COVAD study database. For this study, we only included patients with self-reported RA or spondyloarthritis (either PsA or AS) undergoing active treatment with conventional synthetic disease-modifying drugs (DMARDs) and/or biologic DMARDs, who answered all the survey questions. Active disease was defined as the patient's perception of their disease as active in the four weeks before their first COVID-19 vaccine shot. Analysis of Variance with Bartlett's and Tukey's test was used to compare continuous variables between groups.

Results: From January to June 2022, n.1907 patients with RA, female 87.62% (1671/1907), with mean age (±SD) 50.95 ±13.67, n.311 patients with PsA, female 67.20% (209/311), with a mean age of 50.42 ±12.70, and n.336 patients with AS, male 51.31% (209/311), with a mean age of 43.13 ±12.75 years, responded to the COVAD e-survey. In those with active disease, neither physical health, global mental health, physical function, fatigue, nor pain were different among groups

(Table 1, Figure 1). Patients with inactive AS had higher mean global physical health scores than RA patients (13.13 ±2.93 VS RA 12.48 ±2.90, p=0.01, Table 1). Those with inactive RA or PsA showed more severe fatigue (PsA 10.58 ±2.22, RA 10.45 ±4.08 VS 9.4 ±4.13, p =0.01 for both). Patients with inactive RA also reported poorer physical function and more residual pain than those with AS (37.79 ±8.86 VS 41.13 ±7.79, p<0.001; 3.87 ±2.45 VS 3.34 ±2.39, p=0.01, respectively). Similarly, residual pain was perceived as higher in patients with inactive PsA than those with AS (4.04 ±2.50 VS 3.34 ±2.39, p=0.01)

Conclusion: Disease burden is roughly comparable in patients with active RA, PsA or AS. Patients with inactive RA and PsA suffer higher disease burden than those with inactive AS.

SPECIFIC AI-GENERATED PATTERN OF TENDER JOINTS AND TENDERNESS AT ENTHESIAL SITES ARE PREDICTIVE FOR OBJECTIVE DETECTION OF MUSCULOSKELETAL INFLAMMATION IN PSORIASIS PATIENTS

Keywords: Artificial intelligence, Psoriatic arthritis

M. Köhm[1,2,3], A. Pick[3,4], H. Kratz[2,3], L. Zerweck[2,3], S. Kugler[3,4], S. Mackay[3,4], D. Antweiler[3,4], S. Rüping[3,4], F. Behrens[1,2,3]. [1]*Frankfurt University Hospital, Rheumatology, Frankfurt am Main, Germany*; [2]*Fraunhofer ITMP - Translational Medicine and Pharmacology, Clinical Research, Frankfurt, Germany*; [3]*Fraunhofer Cluster of Excellence Immune Mediated Diseases CIMD, Clinical Research, Frankfurt, Germany*; [4]*Fraunhofer-Institut für Intelligente Analyse- und Informationssysteme IAIS, Healthcare Analytics, Sankt Augustin, Germany*

Background: Psoriasis (Pso) is one of the most common chronic inflammatory skin diseases in Europe. Psoriatic arthritis (PsA) is closely associated to Pso. Up to 30% of the Pso patients will develop PsA during skin disease course. Defined and validated approaches for early detection are still missing. Beside biomarkers from blood or imaging, clinical characteristics of the patients may be of value to detect PsA patients in the transition state early.

Objectives: To perform an AI-based cluster analysis in a cohort of Pso patients at-risk for development of PsA to assess clinical characteristics as markers for early PsA.

Methods: Clinical data sets from the recently published XCITING study [1] were used to perform an AI based analysis using the attributes “tenderness of joints

(68 TJC)" "tenderness at entheses (LEI)" to detect clinical profiles for early detection of inflammatory musculoskeletal (MSK) processes defined as positive findings in clinical examination (SJC, PsA diagnosis), MSUS or fluorescence optical imaging. Main criteria for inclusion into XCITING as at-risk study were Pso without PsA diagnosis, nail involvement and/or MSK complaints within the last 6 months. For clustering the patients, the AI-based analysis contained three steps: (1) Reducing random noise by performing Non-Negative Matrix Factorization, (2) embedding into 2D using t-SNE and (3) clustering using DBSCAN.

Results: Characteristics of the XCITING cohort were described previously [1]. After performance of the cluster analysis, seven different cluster types were identified (cluster 0-6) according to the clinical data sets of the cohort by use of the attributes and tested for their significance to predict the presence or absence of MSK inflammation in Pso (swollen joints, positive MSUS or positive FOI). Three "tenderness clusters" out of 7 were identified with significant correlation: while as expected cluster 2 (no major findings in LEI and TJC) is associated with no inflammation, "feet- type" involvement (cluster 4) and dominance at PIP and DIP joints (cluster 6) (Figure 1, Table 1) are associated with MSK inflammation at the hands.

Conclusion: Markers for early detection of Pso patients who will develop PsA are missing. Within this analysis we show, that by use of clinical data sets only, risk profiles developed from finding of tenderness at different anatomical regions might be helpful for detection of inflammatory MSK processes. Interestingly, the feet tenderness can also predict MSK inflammation at the hands. A combination of both, clinical data sets and liquid/imaging biomarkers may be identified on base of this observation to increase the potential to detect Pso patients with high-risk profiles for PsA early.

Background: Diagnostic delay in psoriatic arthritis (PsA) is associated with poorer outcomes, and early screening/ referral strategies are important to reduce the delay. Implementation of early screening approaches demands cooperation between rheumatologists, dermatologists and primary care providers (PCPs).

Objectives: To explore the experiences of dermatologists and rheumatologists in the early recognition of PsA and suggest improvements to the current shared-care model.

Methods: A 24-question survey addressing referral strategies was constructed within GRAPPA (Group for Research and Assessment of Psoriasis and Psoriatic Arthritis) and sent to all members (n=927). Questions addressed the use of screening tools, interspecialty involvement in therapeutic decision making, and suggestions for earlier recognition.

Results: Surveys were completed by 113 rheumatologists from 37 countries (across six continents) and 26 dermatologists from 16 countries (across 4 continents), with a mean of 21.7 ± 10.7 and 18 ± 12.3 years experience, respectively. Of dermatologists, 81% use PsA-specific screening instruments. Conversely, rheumatologists reported that only 27% of patients referred to them from all sources had been assessed with screening tools. Across both specialties, "PEST" was reported to be the most used tool. Whilst dermatologists reported that 67% ± 28% of their suspected PsA cases were confirmed, rheumatologists felt ~48% ± 24% of suspected PsA cases were confirmed. Both specialties (n=137) reported similar views regarding optimisation of the diagnostic process: 78% believed that the best approach involved combining patient-reported and physician-confirmed findings (see Figure 1A). Moreover, the education of PCPs was seen as the greatest priority to improve screening with 76% raising this as an unmet need (Figure 1B).

Conclusion: The survey indicated the current unmet needs in the early recognition of PsA. Accordingly, important areas to address include improving the use of validated screening instruments, increasing the education of community-based dermatologists and PCPs, and utilising a combination of patient-reported and physician-confirmed findings to identify patients with a high probability of PsA among those with psoriasis.

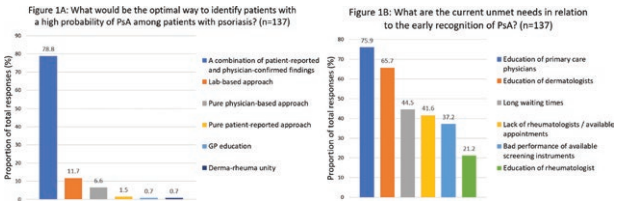

Figure 1. Clinicians' views on optimising early PsA recognition.

POS0883 PREDICTORS OF PATIENT-REPORTED TREATMENT SUCCESS IN PATIENTS WITH PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis

C. Samuel[1], A. Grace-Finney[2], T. Grader-Beck[1], U. Haque[1], J. Miller[1], S. Grieb[1], L. Prichett[2], A. M. Orbai[1]. [1]*The Johns Hopkins University School of Medicine, Rheumatology, Baltimore, United States of America*; [2]*The Johns Hopkins University School of Medicine, Biostatistics, Epidemiology, and Data Management (BEAD) Core, Baltimore, United States of America*

Background: Determinants of patient-reported treatment success in psoriatic arthritis (PsA) have not been defined.

Objectives: To determine predictors of patient-reported treatment success in PsA.

Methods: Rheumatologist-diagnosed PsA patients, who met the CASPAR classification, were recruited from a single center. PsA outcome measures included 68/66 joint counts, enthesitis, dactylitis, psoriasis body surface area (BSA), patient reported outcomes including PROMIS CAT. The study primary outcome was patient-reported treatment success: "Today, considering the level of control of your psoriatic arthritis and psoriasis, do you consider your treatment has been successful?" with response options Yes/No. Multivariate logistic regression analyses were performed to determine

predictors of patient-reported treatment success in PsA. We hypothesized that disease activity measures, including arthritis, psoriasis, enthesitis, and dactylitis, symptoms, and treatment type would contribute to patient-reported treatment success. We did not include multiple patient-reported outcomes in a model due to collinearity.
Results: A total of 178 participants had a baseline visit. Mean (SD) CASPAR score was 3.7 (0.9) age 51.7 (13.5) years, BMI 31.3 (7.2), while 52.2% were women, and 86.0% Caucasian. Treatment success was reported by 116 patients (65%). Overall, 105 participants had complete data for all the variables included in the logistic regression models. The total joint swelling 66, total joint tenderness 68, PROMIS pain interference, and PROMIS fatigue were significantly negatively associated with treatment success while controlling for age, race, gender, and BMI. Each additional swollen joint was associated with a 23% decreased odds of treatment success, each tender joint was associated with 17% decreased odds of success, each additional point on the PROMIS fatigue and on the PROMIS pain interference was associated with 6% and 15% decreased odds of success, respectively (Table 1). Patients receiving a tumor necrosis factor inhibitor (TNFi) had approximately 11-13 times increased odds of reporting treatment success compared to patients on a classical synthetic DMARD alone, while controlling for age, race, gender, and BMI.
Conclusion: Patient-reported treatment success was independently associated with control of tender and swollen joints, pain, fatigue, and with receiving a TNF-inhibitor medication. This supports the use of biological treatments as standard of care in PsA.

Background: Psoriatic Arthritis (PsA) is an immune-mediated disease that additionally to the predominant skin and musculoskeletal features, comorbidities such as metabolic syndrome are common. This type of comorbidities increases significantly the burden of the disease, reduces quality of life, and affects negatively the clinical response to the treatment. Ageing adds another variable to this composite as there appears to be evidence of clinical, genetic, and histopathological differences between early and late-onset PsA.
Objectives: To compare the socio-demographics and clinical data in PsA patients with a younger-onset (YOPsA) and late-onset (LOPsA) of disease and to evaluate disease activity and function at presentation and during a follow-up of two years.
Methods: A multicenter cohort study including adult PsA patients with peripheral involvement registered in the Rheumatic Diseases Portuguese Register (Reuma.pt) up to December 2022 was performed. Patients were divided into 2 groups according to the onset age of PsA: YOPsA (<50 years) and LOPsA (≥50 years). Univariate analysis was performed followed by multivariate analysis.
Results: A total of 543 [YOPsA, 301 (55.4%); LOPsO, 242 (44.6%)] patients with peripheral PsA were included. Demographic and clinical data is represented in Table 1. Compared to patients with LOPsA, PsA patients with early onset showed more frequently dactylitis and nail involvement (p<0.001). Regarding the comorbidities, there was a higher frequency of arterial hypertension, dyslipidemia, diabetes mellitus and hyperuricemia in LOPsA patients (p<0.05). After 2 years of follow-up, LOPsA patients had a worse Disease Activity Score-28 with Erythrocyte Sedimentation Rate (DAS-ESR) (2.8 vs 2.5, p=0.006), higher Patient Global Assessment (PGA) (40.5 vs 35, p=0.05), higher levels of C -Reactive Protein (CRP) (0.9 vs 0.7, p=0.038) and ESR (18.9 vs 14.2, p=0.001) and higher Health Assessment Questionnaire (HAQ) (0.7 vs 0.5, p=0.005). LOPsA patients were treated with more biologic DMARDs (p<0.0001). Adjusting for age, the late onset of PsA was associated with the presence of traditional cardiovascular risk factors.

POS0885 CARDIAC INVOLVEMENT IN SYSTEMIC SCLEROSIS - THE ADDED VALUE OF CARDIAC MAGNETIC RESONANCE

Keywords: Systemic sclerosis, Imaging, Heart

Z. Gogulska[1], Ż. Smoleńska[1], A. Wojteczek[1], A. Viti[2], D. Kulawiak-Gałąska[3], Z. Zdrojewski[1], K. Dorniak[4]. *[1]Medical University of Gdansk, Department of Rheumatology, Clinical Immunology, Geriatrics and Internal Medicine, Gdańsk, Poland*; *[2]University of Naples Federico II, -, Naples, Italy*; *[3]Medical University of Gdansk, Department of Radiology, Gdańsk, Poland*; *[4]Medical University of Gdansk, Department of Noninvasive Cardiac Diagnostics, Gdańsk, Poland*

Background: Cardiac complications of systemic sclerosis (SSc) are frequently subclinical or insidious and may affect up to 80% of patients [1], remaining one of the leading causes of death in, usually in the mechanism of life-threating arrythmia, heart failure or sudden cardiac arrest [2]. Diagnostic tools that can be used for heart involvement in SSc include ECG, echocardiography, serum markers (troponin, CK-MB, BNP, NT-proBNP) and, recently, magnetic resonance imaging. Cardiac magnetic resonance (CMR) with advanced tissue characterization techniques (including parametric mapping of T1 and T2 relaxation times as well as extracellular volume [ECV] fraction of the myocardium) can provide unique non-invasive insight into early (inflammation, oedema) and late (fibrosis, necrosis) stages of heart involvement in those patients [3].
Objectives: To assess cardiac involvement in unselected systemic sclerosis patients in both diffuse (DSSc) and localized (LSSc) clinical subgroups, using contemporary cardiac magnetic resonance imaging techniques.
Methods: In this prospective single-centre study, we included 20 consecutive systemic sclerosis patients (51+/- 14 years, 14 [70%] female) in whom CMR was performed between 2013 and 2022. Their baseline CMR results, clinical presentation of SSc, medical history, laboratory tests, lung function tests, and follow-up were analyzed with special attention to CMR features of heart involvement in the course of SSc in both clinical subgroups. Moreover, CMR findings were compared to a group of healthy controls (N= 37).
Results: Systemic sclerosis patients had significantly lower LVEF (56,6% vs 61,6%, p<0,002), higher LVESVI (38,9 ml/m2 vs 31,6 ml/m2, p=0,002), longer T1 and T2 relaxation times (1029,3 ms vs 993 ms and 48,1 ms vs 44 ms, respectively; p<0,001), and higher ECV (27,9% vs 26,0%, p<0,05) as compared to healthy controls. Overall, 13 (65%) patients had at least one abnormal finding in CMR, of which in 7 (35%) baseline ECG and echocardiogram were normal or borderline normal. Additionally, heart involvement was more frequent among DSSc patients (11/13), with more severe manifestations including greater extent of dysfunction and more pronounced tissue alterations than in LSSc patients (2/7). Of note, CMR allowed for detection of subtle tissue abnormalities in 3 (15%) of patients with normal ECG and normal echocardiogram, as well as added new tissue information (edema/abnormal T1/T2/ECV and/or non-ischemic fibrosis) in 4 (20%) others, in whom borderline unspecific echo abnormalities were detected. During a median follow up of 3,4 (1,9-5,5) years, three patients (15%) died (heart failure - 1, gastrointestinal complications - 1 and breast cancer - 1). Treatment escalation and deescalation were required in 8 and 5 patients, respectively. Two patients had their treatment changed over the follow up period, in 5 the treatment remained unchanged.
Conclusion: SSc patients frequently present heart involvement, especially in DSSc type. This complication is often late diagnosed or misdiagnosed by conventional methods. Cardiac magnetic resonance with modern tissue characterization techniques, provides detailed insight in heart involvement in systemic sclerosis. Modern quantitative techniques allow for early diagnosis, thus prompting closer follow up and/or treatment decisions in a proportion of patients in whom other diagnostic tests were inconclusive.

POS0886 18F-FDG PET-CT OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH EARLY SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Lungs, Imaging

B. Broens[1], G. C. J. Zwezerijnen[2], E. Nossent[3,4], L. Meijboom[2,4], M. Yaqub[2], J. Spierings[5], J. De Vries-Bouwstra[6], J. M. Van Laar[5], C. J. Van der Laken[1], A. Voskuyl[1]. *[1]Amsterdam UMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[2]Amsterdam UMC, Radiology and Nuclear Medicine, Amsterdam, Netherlands*; *[3]Amsterdam UMC, Pulmonary Medicine, Amsterdam, Netherlands*; *[4]Amsterdam Cardiovascular Sciences Research Institute, Amsterdam UMC, Amsterdam, Netherlands*; *[5]UMC Utrecht, Rheumatology and Clinical Immunology, Utrecht, Netherlands*; *[6]LUMC Leiden, Rheumatology, Leiden, Netherlands*

Background: Patients with systemic sclerosis associated interstitial lung disease (SSc-ILD) have a highly variable disease course, which makes clinical management challenging [1]. Hence, there is a clinical need for new tools to improve patient monitoring and stratification. ^{18}F-Fluorodeoxyglucose (FDG) PET-CT of the lungs has previously shown promising results in patients with SSc-ILD by reflecting ILD activity and contributing to the prediction of lung function decline [2,3]. However, as most studies have been performed in patients with longstanding and severe ILD, there is limited information concerning the value of ^{18}F-FDG PET-CT in the first two years after SSc diagnosis and the recognition of early ILD.
Objectives: To prospectively investigate the presence and severity of ILD as detected by ^{18}F-FDG PET-CT in patients with early SSc.
Methods: Included patients fulfilled the 2013 ACR-EULAR classification criteria for SSc, had a disease duration ≤ 2 years (from onset of first non-Raynaud's symptoms) and diffuse cutaneous disease. All patients underwent a high-resolution CT scan of the lungs to evaluate the presence of ILD, as part of routine clinical care, as well as pulmonary function tests. ^{18}F-FDG PET-CT was performed in 13 patients (ILD n=9; no ILD n=4). For quantitative analysis, six volumes of interest (VOIS) of 2cm were placed in pre-specified dorsobasal lung areas, as described previously [3]. The six standardized uptake values (SUV) were processed and averaged to obtain a total SUV for the dorsobasal lung fields. To correct for inter-individual differences, all uptake values were corrected for ^{18}F-FDG uptake in the mediastinal blood pool [3]. Statistical analysis was performed using a Mann-Whitney U test to compare for between-group differences.
Results: In the ILD group, 7/9 (78%) of the patients were male with an average age of 53.2 years. In the non-ILD group 2/4 patients were male (50%), with an average age of 41.3 years. All patients received immunosuppressive treatment with either Mycophenolate Mophetil (ILD 100%; no ILD 50%) or Methotrexate (ILD 0%; no ILD 50%) before inclusion. Quantitative analysis of ^{18}F-FDG PET-CT revealed that SUVmax corrected in the dorsobasal lung fields was higher in the patients with ILD (median [range] 0.90 [0.65]) than in patients without ILD (median [range] 0.63 [0.15]; p=0.03). The higher ^{18}F-FDG uptake in patients with ILD compared to those without ILD is visually illustrated in Figure 1. The relationship between the uptake of ^{18}F-FDG, high-resolution CT scan of the lungs and pulmonary function tests at baseline is currently under analysis (and will be presented during the meeting).
Conclusion: Our results suggest that in early disease stages, within two years of SSc diagnosis, ^{18}F-FDG uptake in the dorsobasal lung fields is higher in patients with ILD compared to patients without ILD. Further analysis is warranted to investigate ^{18}F-FDG uptake in other lung regions, its relationship to conventional tools and with regard to treatment outcomes. As such, we will investigate repeated ^{18}F-FDG PET-CT and clinical outcomes after 1 year of follow-up in patients with SSc-ILD.

POS0887 INFLUENCE OF CONTEXTUAL FACTORS AND RELIABILITY OF ULTRASOUND SKIN MEASURES IN PERSONS WITH SYSTEMIC SCLEROSIS AND HEALTHY CONTROLS

Keywords: Systemic sclerosis

T. Santiago[1], M. Santiago[1], S. Moreira[2], L. Santos[2], M. J. Salvador[1], J. A. P. Da Silva[1]. [1]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; [2]*Centro Hospitalar e Universitário de Coimbra, Internal Medicine, Coimbra, Portugal*

Background: Skin involvement is a cardinal feature for the diagnosis and prognosis of systemic sclerosis (SSc) and is associated with worse functional ability and quality of life.[1] Gender and age have been found to influence ultrasound dermal thickness and skin stiffness, and preliminary normal reference percentile curves for these ultrasound measures have been proposed.[2] The possibility that contextual factors, like room temperature, may influence these measurement is of crucial importance, but it has been very scarcely addressed.[3]
Objectives: To examine the influence of contextual factors upon the evaluation of skin thickness and stiffness by ultrasound and to assess the reliability of these parameters.
Methods: Ultrasound dermal thickness (by B-mode, 18MHz) and skin stiffness (by shear-wave elastography, 9MHz) were assessed in persons with systemic sclerosis (SSc) and in healthy controls. The influence of contextual factors upon repeated measures was evaluated: (i) room temperature (16-17°C *vs* 22-24°C); (ii) time of day (morning *vs* afternoon), and (iii) menstrual cycle phase (menstrual *vs* ovulatory). Differences were analyzed using the related-samples Wilcoxon signed-rank test. Inter- and intra-rater reliability of ultrasound skin thickness and stiffness were evaluated in the 17 skin Rodnan sites of 20 persons with SSc and 20 healthy controls, under stable contextual conditions.
Results: A significant increase in dermal thickness values was observed between the morning and afternoon evaluations, at the leg 6.96% (SD3.39), p=0.007, and 7.39% (8.42), p=0.018, in SSc patients and in controls, respectively (Table 1).No significant changes were observed in association with room temperature and menstrual cycle. Intra- and inter-rater-reliability was good to excellent for ultrasound dermal thickness and stiffness, both in SSc and healthy controls.
Conclusion: The timing of the ultrasound procedure within each day seems to influence the ultrasound measures at the legs and feet, and this aspect should deserve attention when designing and reporting future trials. Our study corroborates that ultrasound dermal thickness and skin stiffness are reliable domains to quantify skin involvement in SSc.

POS0888 NORMAL PERCENTILE REFERENCE CURVES FOR SKIN ULTRASOUND THICKNESS AND STIFFNESS AT RODNAN SITES

Keywords: Systemic sclerosis

T. Santiago[1], E. Santos[2], M. Luis[1], C. Gaspar[3], J. Lima[3], F. Caramelo[3], J. A. P. Da Silva[1]. [1]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; [2]*Nursing School of Coimbra (ESEnfC), Health Sciences Research Unit: Nursing (UICISA: E), Coimbra, Portugal*; [3]*University of Coimbra, Faculty of Medicine, Coimbra, Portugal*

Background: Skin involvement is a hallmark of systemic sclerosis and an important marker of disease activity, severity and prognosis.[1] The modified Rodnan skin score (mRSS), the current gold standard for the evaluation of the skin in SSc, both in clinical trials and in practice, has several limitations.[2] This highlights the need for more sensitive and objective measures of skin involvement, not only support the evaluation and development of new treatments, but also to facilitate the earlier diagnosis of SSc. Normal reference curves for skin ultrasound parameters, considering relevant influential factors seem of pivotal importance to fully exploit the potential of these new techniques as reliable tools for diagnostic and follow-up purposes.
Objectives: Our primary objective was to establish preliminary normal reference curves for ultrasound dermal thickness and skin stiffness, in the 17 Rodnan skin sites, considering the effect of gender and age on these measures. As an exploratory objective, we investigated the effect of body mass index and the menopause on skin ultrasound measures.
Methods: A cross-sectional study was conducted involving 140 healthy volunteers, aged 20-79 years. Recruitment was stratified for age (10-year categories) and gender to guarantee a balanced distribution of these factors in the sample. participants were excluded if they had any of the following conditions: (1) diagnosis of any skin or connective tissue or rheumatic inflamma- tory disease, (2) history of insulin treated diabetes, (3) history of anticancer chemo/radiotherapy treat- ments, (4) exposure to organic solvents, (5) past glucocorticoid treatment for more than 4 months or (6) recent (<4 weeks) treatment with glucocorticoids, regardless of dose, clinical indication and timing. Ultrasound dermal thickness and skin stiffness were assessed by high-frequency ultrasound (18MHz) and shear-wave elastography (9MHz), respectively, at the 17 Rodnan skin sites. All ultrasound measures were performed in the morning (between 9:00 and 13:00 hours) in the same room and at stable temperature. Outcomes were evaluated through a mixed linear model, univariate, and multivariate regressions. Normal reference curves were derived for both ultrasound measures in each Rodnan skin site, for females

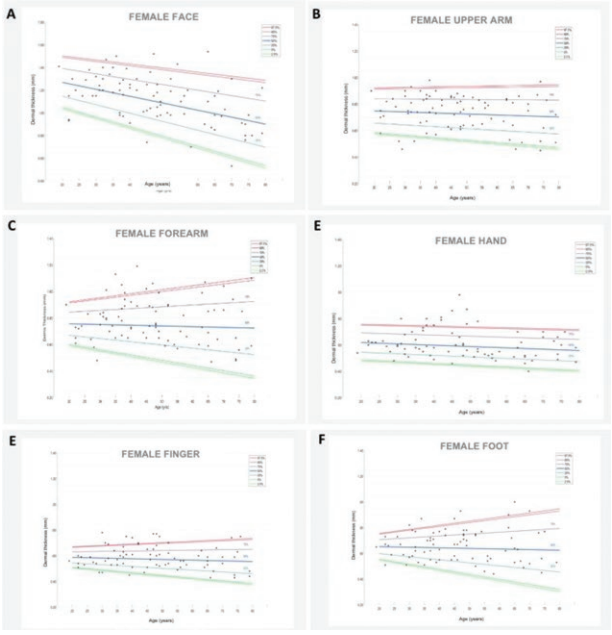

Figure 1. Ultrasound dermal thickness in females: percentile curves. (A) Face; (B) Upper arm; (C) Forearm; (D) Hand; (E) Finger; (F) Foot.

and males (Example in Figure 1). An online calculator of the percentiles of skin ultrasound measures was also developed. A radar chart showing these values and the percentile for each site is automatically drawn, allowing the clinician to export the results obtained.

Results: A total of 140 caucasian participants, i.e., 80 females, mean (SD) age of 47.2 (16.0) years; and, 60 males, 49.5 (17.3) years were included. Ultrasound dermal thickness and stiffness measures were higher in males than females, in all Rodnan skin sites (except in chest for ultrasound-dermal thickness). Age had also a significant impact in both ultrasound measures, but only in some skin sites. Gender and age percentile curves (97.5th, 95th, 75th, 50th, 25th, 5th, 2.5th) were plotted for each of the measures in each skin site.

Conclusion: Gender and age are strongly associated with skin ultrasound parameters, imposing the need for gender- and age-specific reference values. Normal reference percentile curves for skin ultrasound measures are promising tools to support earlier diagnosis and refine sensitivity to time- or drug-induced changes. These reference percentile curves are provided as a basis for future cooperative work to strengthen its evidence-basis, representativeness and refinement regarding potentially influential factors.

POS0889 ASSESSMENT OF MYOSITIS-RELATED INTERSTITIAL LUNG DISEASE BY ^{68}GA-DATA.SA.FAPI PET-CT

Keywords: Lungs, Myositis, Imaging

K. Kastrati[1], T. Nakuz[2], I. Gessl[1], E. Simader[1], D. Mrak[1], M. Bonelli[1], H. Kiener[1], F. Prayer[3], D. Aletaha[1], M. Hacker[2], W. Langsteger[2], T. Traub-Weidinger[2], H. Radner[1], P. Mandl[1]. [1]*Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria*; [2]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-Guided Therapy, Medical University of Vienna, Vienna, Austria*; [3]*Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria*

Background: Idiopathic inflammatory myopathies (IIM) are a group of heterogeneous autoimmune disorders marked by skeletal muscle inflammation and extra-muscular complications including pulmonary involvement. Interstitial lung disease (ILD) is a common manifestation affecting up to 78% in IIM patients. Methods and means for in-vivo visualization of ongoing tissue remodeling in affected organs are scarce.

Objectives: To quantify and compare fibroblast activation in the lungs between IIM-patients and control subjects using ^{68}Ga-labelled inhibitor of Fibroblast-Activation-Protein based positronic emission tomography-computed tomography (^{68}Ga-DATA.SA.FAPI PET-CT) imaging.

Methods: Patients with IIM recruited prospectively from the rheumatology outpatient clinic, and control subjects without rheumatic conditions or ILD recruited from the cardiology outpatient clinic underwent ^{68}Ga-FAPI PET-CT imaging. Pulmonary FAPI accumulation was assessed by measuring the maximal standardized uptake value (SUVmax) and mean SUV (SUVmean) over the whole lung (wl), respectively. Values of SUV were compared across IIM patients with and without ILD and controls using analysis of variance (ANOVA) test and displayed as mean ±standard deviation (SD).

Results: The clinical characteristics of patients with IIM (15 patients with ILD confirmed by CT and 4 non-ILD patients with primary muscular affection) and control subjects (n=17) are displayed in the Table 1. Subtypes of IIM included antisynthetase syndrome (57.9%), dermatomyositis (15.8%), overlap myositis (15.8%), and immune-mediated-necrotizing-myositis (10.5%). In individuals with IIM-related ILD, whole-lung ^{68}Ga-DATA.SA.FAPi uptake was significantly increased as compared to both, the non-ILD IIM patients and the control group: wlSUVmax (6.63 [±2.05] vs. 3.74 [±0.71] and 4.74 [±1.24] respectively, both p<0.001) (Figure 1A) and wlSUVmean (1.50 [±0.48] vs. 0.94 [±0.22] and 1.11 [±0.34] respectively, both p<0.05) (Figure 1B). No differences of wlSUVmax or wlSUVmean were observed between non-ILD IIM patients and the control group.

Conclusion: This study demonstrates enhanced tracer uptake in ^{68}Ga-DATA.SA.FAPi PET-CT in patients with IIM. Thus, FAPi PET-CT may provide a useful tool for the assessment of lung disease in IIM. Further discriminatory and diagnostic testing approaches are needed to integrate this novel imaging method into clinical decision making.

Table 1. Demographic and clinical characteristics of participants at baseline.

POS0890 USING POLYGENIC RISK SCORES TO AID DIAGNOSIS OF PATIENTS WITH EARLY INFLAMMATORY ARTHRITIS: RESULTS FROM THE NORFOLK ARTHRITIS REGISTER

Keywords: Epidemiology, Inflammatory arthritides, Genetics/epigenetics

R. M. Hum[1], S. Sharma[1], M. Stadler[1], S. Viatte[1], P. Ho[1], N. Nair[1], C. Shi[1], C. F. Yap[1], M. Soomro[1], D. Plant[1], J. Humphreys[2], A. Macgregor[3], M. Yates[3], S. Verstappen[2], J. Bowes[1], A. Barton[1]. [1]*The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom*; [2]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [3]*University of East Anglia, Norwich Epidemiology Centre, Norwich, United Kingdom*

Background: There is growing evidence that genetic information can offer valuable information to a clinician in a diagnostic setting, and that it is feasible that

genetic data would be of benefit to the rheumatology outpatient setting by aiding early diagnosis. A genetic probability tool (G-PROB) has recently been developed to aid diagnosis using existing knowledge of disease-associated genetic variants but has only been tested in a limited capacity.

Objectives: Our aim was to assess whether G-PROB could aid diagnosis in the rheumatology outpatient setting using data from the Norfolk Arthritis Register (NOAR), a large prospective observational cohort of patients presenting with early inflammatory arthritis where diagnosis at baseline is unclear.

Methods: Genotypes and follow-up clinician diagnoses were obtained from patients from NOAR. Six G-probabilities (0-100%) were created for each patient based on known disease-associated odds ratios (ORs) of published genetic risk variants, each corresponding to one disease of rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), psoriatic arthritis (PsA), spondyloarthropathy (SpA), gout or "other rheumatological diseases". Performance of the G-probabilities compared with the final (follow-up) clinician diagnosis was assessed.

Results: G-PROB was tested on 972 patients from NOAR. Calibration of G-probabilities with clinician diagnosis was high, with regression coefficients of 1·03, where 1·00 represents perfect calibration. G-probabilities discriminated clinician diagnosis with pooled areas under the curve (95% CI) of 0·84 (0·81 to 0·86). G-probabilities <5% corresponded to a negative predictive value (NPV) of 96% where it was possible to suggest at least one unlikely diagnosis for 99·9% of patients, two or more diseases for 94% of patients, and three or more diseases for 54% of patients. G-probabilities >50% corresponded to a positive predictive value (PPV) of 74%. In 57% of patients, the disease with the highest G-probability corresponded to clinician diagnosis.

Conclusion: G-PROB successfully converts complex genetic information into meaningful, and interpretable conditional probabilities which may be especially helpful at suggesting unlikely diagnoses in the rheumatology outpatient setting.

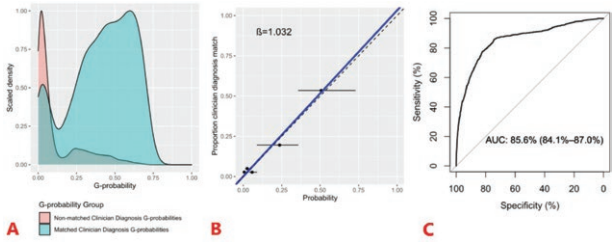

Figure 1. (A) Distribution of G-probabilities which match and those which do not match clinician diagnosis. Ideally the correct diagnosis should have higher probabilities, and the distribution should be skewed to the right, with incorrect diagnoses having lower probabilities with a distribution skewed to the left. (B) Linear regression without intercept showing concordance of G-probabilities with clinician diagnosis match, where x-axis shows G-probabilities, and y-axis shows binary outcome of concordance with clinician diagnosis (y=1) and non-concordance (y=0). A β of one indicating exact calibration is shown as a dashed black line. For visualisation, G-probabilities were placed into five equally sized bins and plotted the proportion of instances where predicted disease is concordant with clinician diagnosis. (C) ROC analysis of correspondence of G-probabilities with clinician diagnosis, where AUC shows pooled data for all diseases (microAUC).

Table 1. Performance of G-probabilities in suggesting likely and unlikely diagnoses at different thresholds

G-probability threshold	# of patients with at least one G-probability at the given threshold (n=972) (%)	# of G-probabilities at the given threshold (n=5,832) (%)	NPV or PPV at the given threshold in %
A) Thresholds suggesting unlikely diagnoses			
<5%	971 (100)	2410 (41)	NPV 96
<20%	972 (100)	3857 (66)	NPV 96
B) Thresholds suggesting likely diagnosis			
>20%	972 (100)	1975 (34)	PPV 41
>50%	470 (48)	470 (8)	PPV 74

POS0891 AUTOMATIC COMPUTATION OF KNEE OSTEOARTHRITIS SEVERITY USING KNEE X-RAYS AND CONVOLUTIONAL NEURAL NETWORKS

Keywords: Imaging, Artificial intelligence, Osteoarthritis

T. Ait Si Selmi[1], F. Muller-Fouarge[2], T. Estienne[2], S. Bekadar[2], Y. Carrillon[3], C. Pouchy[2], M. Bonnin[1]. [1]*Santy Orthopedic Center, Lower Limb Surgery/ Orthopaedic, Lyon, France*; [2]*Deemea, Research and Development, Paris, France*; [3]*Santy Orthopedic Center, Radiology department, Lyon, France*

Background: Knee osteoarthritis is a heterogeneous and complex degenerative pathology, characterized by a progressive deterioration of bone cartilage and structural modifications of the joint [1]. The precision of the diagnosis and the rating of the severity are major criteria for the therapeutic management and its follow-up. They are based on three criteria: the assessment of the pain, of the functional impairment and of the structural modifications. For this last criterion, the standard protocol in routine care remains the interpretation of X-ray images using standardized scales. The Kellgren-Lawrence (KL) score, which assesses both the joint space and the presence of osteophytes, allows a classification of the stages of osteoarthritis, but it relies on subjective manual interpretation and is time consuming for practitioners [2].

Objectives: In this study, we have developed artificial intelligence algorithms to automatically measure the tibia-femur joint spacing (or joint space width JSW) and determine the Kellgren-Lawrence (KL) score.

Methods: We constituted a retrospective cohort of 19,560 patients. Using all their images, we trained different neural networks in order to select just knee AP X-rays without prosthesis nor artifacts. Our work explores two approaches: the prediction of the stage of osteoarthritis according to the KL scale and the measurement of the JSW. For the prediction of the KL score, 2,081 X-rays annotated by 3 radiologists were used to train a convolutional neural network (CNN). The measurement of the JSW required the realization of 3 different annotations: the positioning of the joint, of the two condyles (medial and lateral) and the contouring of tibia and femur. Three neural networks were optimized to reproduce these annotations before calculating the JSW for each condyle. For each individual task, we decomposed the datasets into training, validation, and test sets, used different data augmentation techniques, and researched the best possible architecture.

Results: The Kellgren-Lawrence score prediction obtained the following performances: an accuracy of 0.92, a sensitivity of 0.84 and an average area under the ROC curve (AuC) of 0.97. To evaluate the measurement of the JSW, we calculated the correlation between the area measured by the annotators and the area predicted by the algorithms, obtaining a Pearson correlation of 0.84.

Conclusion: This study highlights the relevance of the use of artificial neural networks for the assessment of osteoarthritis. Their performance opens the way to a tool assisting in the precise and standardized gradation of the severity of joint degradation.

POS0892 AN END-TO-END MACHINE LEARNING PIPELINE FOR THE AUTOMATED DETECTION OF RADIOGRAPHIC HAND OSTEOARTHRITIS: A NO-CODING PLATFORM EXPERIENCE

Keywords: Osteoarthritis, Artificial intelligence, Imaging

L. Caratsch[1], C. Lechtenboehmer[2], M. Caorsi[3], K. Oung[4], F. Zanchi[4], Y. Aleman[4], P. Omoumi[4], T. Hügle[1]. [1]*University Hospital Lausanne (CHUV), Department of Rheumatology, Lausanne, Switzerland*; [2]*University Hospital Basel, Department of Radiology, Basel, Switzerland*; [3]*L2F, EPFL Innovation Park, Lausanne, Switzerland*; [4]*University Hospital Lausanne (CHUV), Department of Radiology, Lausanne, Switzerland*

Background: Machine learning's performances in the field of radiology have been constantly increasing in recent years such that nowadays many algorithms equals human performances and are FDA approved.[1,2] Non-coding platforms have recently emerged and allow healthcare professionals with no programming experience to play an active role in the development of machine learning (ML) algorithms according to existing or emerging clinical needs.

Objectives: We aimed to evaluate the feasibility of ML algorithm generation using a no-coding platform by clinicians without ML experience. By using such a platform, we developed a model for automated recognition and grading of radiographic distal interphalangeal osteoarthritis (DIP-OA) with subsequent user experience (UX) testing of the algorithm.
Methods: 13690 hands x-rays from 2863 patients within the Swiss Cohort of Quality Management (SCQM) and an external control dataset of 346 non-SCQM patients were collected and scored for DIP-OA by the modified Kellgren and Lawrence Score (K/L). 48892 DIP joints were extracted and classified according to the K/L score. GIOTTO (L2F, Lausanne) was used as a no-coding platform for training of 2 convolutional neural networks, the first one for segmentation of hand joints and subsequent DIP-joints extraction, and the second one for classification of KL scores according to the presence of osteophytes and joint space narrowing on the previously extracted DIP-joints. The classification model's performance was tested by an internal test set (SCQM database) and an external test set (non-SCQM). User experience (UX) of a web app developed from the platform as a provisory user interface (UI) was investigated in rheumatologists and radiologists. The usability of heat maps was also investigated.
Results: The sensitivity and specificity of this model for detecting DIP-OA, was 79% and 86%, respectively. The accuracy for grading the K/L score was 75% with a kappa score of 0.76. A similar sensitivity (79%) and specificity (80%) for detecting DIP-OA was found in an independent external test set. The accuracy per DIP-OA class differed with 79% for no OA (defined as K/L 0 and 1), 65% for K/L2, 40% for K/L3, and 70% for K/L4. On the external test set overall accuracy was 66% and the kappa score 0.75. The platform was intuitive and easy to use, but support from data scientists was still required for upload of the data set exceeding the drag and drop process, DIP-joints extraction, heatmap generation and episodic debugging of the platform. UX testing of the web app revealed a moderate demand by rheumatologists (notably for differential diagnosis and evolution over time) and a low demand by radiologists for the automated scoring of DIP-OA. Conversely, adding heat maps to the UI was considered of high added value.
Conclusion: No-coding platforms are an opportunity to develop end-to-end AI-prototypes for further testing. Their use by clinicians without experience in programming and machine learning is possible. Here, automated radiographic DIP-OA detection is both feasible and usable, whereas grading between individual KL scores, e.g. for clinical trials, remains challenging, partly because of the inter-observer variability inherent to the scoring method.

POS0893

SIGNIFICANT OVERLAP OF INFLAMMATORY AND DEGENERATIVE FEATURES ON SPINAL IMAGING AMONG PATIENTS WITH DEGENERATIVE SPINAL DISEASE, DIFFUSE IDIOPATHIC SKELETAL HYPEROSTOSIS AND RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

Keywords: Imaging, Bone diseases

N. Ziade[1], N. Kougkas[2], M. Udod[3], S. Tsiami[3], X. Baraliakos[3]. [1]*Hotel-Dieu De France, Beirut, Saint Joseph University, Beirut, Beirut, Lebanon*; [2]*Fourth Department of Internal Medicine, Medical School, Hippokration University Hospital, Thessaloniki, Aristotle University of Thessaloniki, Thessaloniki, Greece*; [3]*Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany*

Background: Degenerative changes of the spine (DC), diffuse idiopathic skeletal hyperostosis (DISH) and radiographic axial Spondyloarthritis (r-axSpA) may present with overlapping inflammatory and degenerative findings on imaging, which, next to the general symptom of chronic back pain might, represent a challenge for an accurate diagnosis.
Objectives: To evaluate the distribution of spinal imaging features in a real-life cohort of patients with chronic back pain referred to a tertiary university rheumatology center and identify those associated with DC, DISH or r-axSpA.
Methods: In a cross-sectional analysis of patients with chronic low back pain, demographic and disease data were collected. Imaging of the spine (thoracic or lumbar) and sacroiliac joints was performed per the clinical indication. All images were evaluated by two independent trained readers including erosions, sclerosis, squaring, osteophytes and syndesmophytes on conventional radiographs (CR) and bone marrow edema (BME) or degenerative changes on magnetic resonance imaging (MRI). The final diagnosis made by the rheumatologist at discharge was the gold standard. Data were presented descriptively and compared among the three diagnosis groups (DC, DISH and axSpA).
Results: Among 136 referred patients, 71 had DC, 38 DISH, and 27 r-axSpA. Mean age was 63.2±11.4 (p=0.135 among the three groups), and 86 (63.2%) were males (88.9% in axSpA, p=0.003). Patients had high levels of comorbidities: 91 (72.8%) had hypertension (higher in the DC group, 52 (82.8%), p=0.04), 37 (27.6%) had diabetes (higher in DISH, 39.5%, p=0.012) and 31 (23.3%) were current smokers (higher in axSpA, 53.8%, p<0.001). Although axSpA-related spinal changes on CR were expectedly more prevalent in the axSpA group (thoracic 14.1%, p=0.024; lumbar 93.9%, p=0.034), they were also present in DISH (27.8% and 21.9%) and DC (7.6% and 22.6%, respectively). DC were present in the three groups in 93.0% in the thoracic and in 93.9% in the lumbar spine, without a statistically significant differences (Table 1). Similarly, on thoracic and lumbar spine MRI, BME was present in DISH in 33.3% and 41.7% and in DC in 20.4% and 32.7% lumbar spines, respectively.
Conclusion: A significant overlap of inflammatory and degenerative features on spinal imaging among patients with DC, DISH or axSpA was found in this older group of patients. Particularly, r-axSpA-related spinal CR features were found in a fourth of patients with DISH, while MRI BME was found in a third of them.

Table 1. Thoracic and Lumbar Spinal Imaging features in a cohort of 136 patients referred for low back pain.

	DISH	DEGENERATIVE	AS	All	p-value

POS0894 DIFFERENTIAL DIAGNOSIS BETWEEN HAND OSTEOARTHRITIS AND PSORIATIC ARTHRITIS USING INDOCYANINE GREEN-BASED FLUORESCENCE OPTICAL IMAGING

Keywords: Imaging, Osteoarthritis, Psoriatic arthritis

B. Drude[1], Ø. Maugesten[2], S. G. Werner[3], J. Berger[4], J. Klotsche[5], G. R. Burmester[1], I. K. Haugen[2], S. Ohrndorf[1]. *[1]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[2]Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*; *[3]RHIO (Rheumatology, Immunology, Osteology) Düsseldorf, RHIO Research Institute, Düsseldorf, Germany*; *[4]Xiralite GmbH, Research and Development, Berlin, Germany*; *[5]Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), Epidemiologic Unit, Berlin, Germany*

Background: Fluorescence optical imaging (FOI) provides a measure of inflammation in finger joints and wrists [1,2]. Recognizing specific joint signals and morphologic patterns in FOI may be helpful in differential diagnosis of hand osteoarthritis (OA) and psoriatic arthritis (PsA).
Objectives: To analyze the diagnostic value of the established FOI Activity Score (FOIAS) and predefined morphologic patterns in the differentiation between hand OA and PsA.
Methods: FOIAS has been validated for inter- and intra-reader reliability[3]. FOI sequences were examined by one trained reader (BD). Cases with physician-based diagnosis of hand OA (n=47) and PsA (n=54) were randomly mixed and the reader was blinded to diagnosis. In total, 16 joints (wrist, thumb base, MCP1-5, (P)IP1-5, DIP2-5) in each hand were evaluated on a semiquantitative 0-3 scale in five images during the FOI sequence (composite image PrimaVista Mode (PVM), phase 1, phase 2 (first and middle image), and phase 3). Additionally, predefined morphologic patterns were observed ('streaky signals'[2], 'green/blue nail sign'[4], 'Werner sign'[1,5] and 'bishop's crozier sign'[3]). A collection of example images for joint signals and morphologic findings was previously compiled into an atlas for reference and training[3]. Based on joint signals and morphologic findings, the reader matched each case to diagnosis OA or PsA. Agreement on diagnosis was calculated using Cohen's kappa (κ). Mean sum signals for different joint groups were compared by T test for independent samples. Morphologic pattern distribution was assessed with Pearson Chi-Square.
Results: 78.2% of cases (79/101) were diagnosed correctly by reading FOI, showing moderate agreement (κ=0.57, p<0,001). For PIP2-5, we found overall statistically significantly higher mean joint sum scores in OA cases (39.0 in OA vs. 20.0 in PsA, p<0.001) as well as for each of the 5 phases (PVM, phase 1, phase 2 first and middle, phase 3). DIP2-5 displayed overall statistically significantly higher mean joint sum scores in OA (16.5 in OA vs. 8.4 in PsA, p<0.001) as well as in PVM, phase 2 first and middle images. Other joint groups (MCP1-5, wrist) did not present any statistically significant differences between OA and PsA. Regarding morphologic patterns, the 'Werner sign' was presented significantly more often in PsA patients (55.6% in PsA vs. 21.3% in OA, p<0.001).
Conclusion: There was moderate agreement between the physician-based diagnosis of OA and PsA and the diagnosis that was proposed based on FOI findings. OA cases presented more pronounced signal enhancement in PIP and DIP joints when compared to PsA cases. Additional morphologic criteria and pattern recognition might be needed to expand the diagnostic capability of FOI.

POS0895 ANKLE RETINACULA ABNORMALITIES AS FEATURES OF PSORIATIC ARTHRITIS: AN ULTRASOUND STUDY

Keywords: Psoriatic arthritis, Ultrasound

M. Forien[1], E. Ebstein[1], B. Leger[1], L. Benattar[1], P. Dieudé[1], S. Ottaviani[1]. *[1]Bichat Hospital, Rheumatology, DMU Locomotion, Paris, France*

Background: Ankles are frequently involved in rheumatoid arthritis (RA) and psoriatic arthritis (PsA) and can be observed in both diseases. The detection of enthesitis may support the diagnosis for PsA and help to distinguish theses 2 rheumatic diseases. At ankle level, retinacula can be analyzed with ultrasonography (US) and their insertions into bones can be considered as enthesitis.
Objectives: The aim of the present study was to compare the US assessment of the retinacula of ankles in a population of RA and PsA patients with painful ankle.
Methods: This was an observational cross-sectional study. We analyzed consecutive RA or PsA patients with ankle pain. We also analyzed healthy controls (HC), without rheumatic disorders nor ankle pain. The following US features were assessed: presence of synovitis of tibiotalar or talonavicular joints, presence of tenosynovitis of peroneal or posterior tibial tendons. Two retinacula: the superior peroneal retinaculum (SPR) and the flexor retinaculum (FR) were also evaluated in mode B (thickness, echogenicity and presence of malleolar periostosis) and the vascularization at their insertion into bone by using power Doppler (PD).
Results: We analyzed data for 80 consecutive patients (60% women; median age 56 years). Among these patients, 37 (46%), 23 (29%) and 20 (25%) were RA, PsA and HC patients, respectively. A total of 160 ankles were assessed. The evaluation of SPR did not show difference between the two diseases. Regarding the FR, we observed that FR was thicker in PsA patients than in RA (0.96mm ± 0.39 vs. 0.64mm ± 0.15, P<0.001) and HC (0.96mm ± 0.39 vs. 0.56mm ± 0.12, P<0.001) without difference between RA patients and HC. The following US features were more frequently found in PsA than in RA ankles: hypoechogenicity (46% vs 7%, P<0.001), positivity of PD (43% vs 8%, P<0.001) and malleolar periostosis (43% vs 8%, P<0.001). By using ROC curve analysis, we determined that a cut-off of 1mm of FR thickness provided a sensitivity of 49% and specificity of 97% for the diagnosis of PsA. The association of a thickness ≥1mm with hypervascularization of the malleolar insertion of FR, named as "retinaculitis", was observed in 39% and 3% of ankles in PsA and RA, respectively. The proportion of retinaculitis of SPR was not different between the two diseases.
Conclusion: US abnormalities of FR were more frequently observed in PsA than in RA patients and appear to be specific for PsA. Thus, US assessment of FR might be useful to distinguish RA and PsA in patients with painful ankles.

POS0896 ANALYSIS OF THE PERFORMANCE OF AN ARTIFICIAL INTELLIGENCE ALGORITHM FOR THE DETECTION OF RADIOGRAPHIC SACROILIITIS IN AN INDEPENDENT COHORT OF AXSPA PATIENTS INCLUDING BOTH NR-AXSPA AND R-AXSPA

Keywords: Artificial intelligence, Imaging, Spondyloarthritis

F. Proft[1], J. L. Vahldiek[2], J. Nicolaes[3], R. Tham[4], B. Hoepken[5], B. Ufuktepe[6], K. K. Bressem[2], D. Poddubnyy[1]. *[1]Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany, Berlin, Germany*; *[2]Charité – Universitätsmedizin Berlin, Radiology, Berlin, Germany*; *[3]UCB Pharma, -, Anderlecht, Belgium*; *[4]UCB Pharma, -, Slough, United Kingdom*; *[5]UCB Pharma, -, Monheim, Germany*; *[6]UCB Pharma A.S., -, Istanbul, Turkey*

Background: Conventional radiography of the sacroiliac joints is the first imaging method if axial spondyloarthritis (axSpA) is suspected. The presence of definite radiographic sacroiliitis is needed to classify as radiographic (r-axSpA) based on the modified New York Criteria (mNYc). However, the reliability of radiographic sacroiliitis assessment is low, especially if performed locally. Expert central reading for classification purposes in clinical trials is time-consuming and still has high inter-reader variability. A possible solution to detect radiographic sacroiliitis with consistent reproducibility, could be the use of an artificial intelligence analysis of radiographs. Recently an artificial neural network showed an expert-level performance for classification and diagnostic settings[1,2].
Objectives: The aim of this study was to evaluate the performance of this previously trained artificial network in a completely new cohort of patients previously evaluated as r-axSpA or nr-axSpA by central readers.

Methods: Baseline radiographs of sacroiliac joints from RAPID-axSpA (NCT01087762, N=277) were evaluated by 3 central reader experts and the majority decision of fulfillment the mNYc was used as a reference. None of the patients nor any of the central readers participated in the studies used to pre-train the artificial network. For performance evaluation of the neural network, the area under the receiver operating characteristic curve (AUROC) was calculated. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) for the prediction cut-offs were calculated along with their 95% Confidence Intervals (CI) using accelerated bootstrapping. Cohen's Kappa and the absolute agreement were used to assess the agreement between the neural network and the human readers.

Results: Baseline characteristics are presented in Table 1. Sensitivity and specificity for the cut-off weighting both measurements were 0.82 (95% CI: 0.78, 0.86) and 0.81 (95% CI: 0.75, 0.87). The Cohen's kappa between the neural network and the reference judgements was 0.61 (95% CI: 0.51, 0.70), and the absolute agreement on the classification yielded 82% (95% CI: 0.78, 0.85). The neural network achieved an 0.89 (95% CI: 0.86, 0.93) PPV and a 0.70 (95% CI: 0.64, 0.77) NPV in recognition of definite radiographic sacroiliitis with AUROC of 0.88 (Figure 1).

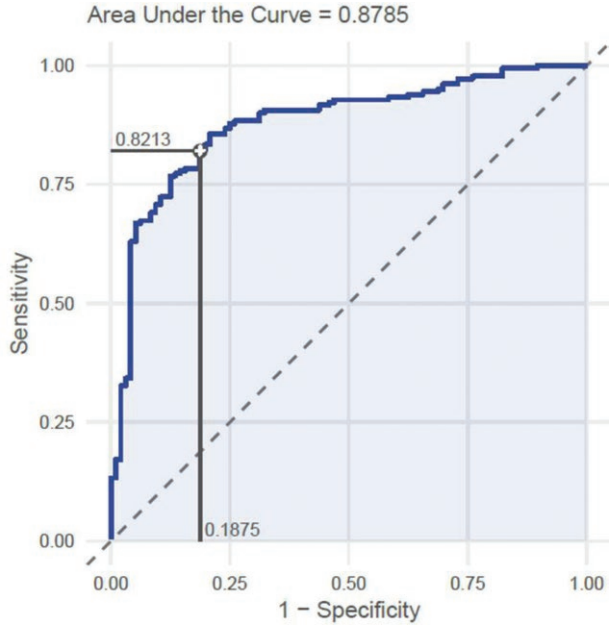

Figure 1. Area Under the Receiver Operating Characteristic Curve for Evaluating Performance of the Neural Network to Detect Radiographic Sacroiliitis

Conclusion: A pre-trained artificial neural network can enable the accurate detection of definite radiographic sacroiliitis relevant for the diagnosis and classification of axSpA close to expert performance. In the present study, the previously trained network showed an excellent ability to generalize data that was completely new to the network. Our results show the potential for classification purposes in multi-center axSpA trials in the future, providing a reproducible and cost-effective tool without unnecessary time delays.

POS0897

THE PERFORMANCE OF COMBINING EYE SIGN AND FUNCTIONAL MAGNETIC RESONANCE IMAGING IN DIAGNOSING PATIENTS WITH NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Diagnostic tests, Systemic lupus erythematosus, Imaging

J. L. H. Shi[1]. [1]*The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China*

Background: The diagnosis of NPSLE becomes challenging for rheumatologists, both at a diagnostic and therapeutic level. The 1999 ACR criteria had a high sensitivity (91%), but a low specificity (46%) [1].

Objectives: To investigate the alterations of eye sign and functional magnetic resonance imaging (fMRI) in patients with neuropsychiatric systemic lupus erythematosus (NPSLE) and to explore the performance of combining eye sign and MRI in diagnosing NPSLE.

Methods: In phase 1, SLE patients were consecutively recruited Sep 2017 to Sep 2018 including NPSLE patients and non-NPSLE patients. Eye sign examination for bulbar conjunctival microvascular were performed for all SLE patients and fMRI scanning for NPSLE patients. Demographic and clinical data were compared between two groups and to identify potential predictors for NPSLE by using multivariable logistic regression analysis. In phase 2, NPSLE patients in phase 1 were enrolled, and a new diagnostic algorithm including predictors and changed fMRI parameters was designed with the 1999 NPSLE ACR classification as comparison. Expert opinion was considered as golden standard. Double-blind clinical diagnosis from expert were recorded using new algorithm and 1999 ACR classification, respectively. Area under the curve (AUC) under receiver operating characteristic (ROC) curve, sensitivity and specificity were calculated and compared between these two diagnostic methods.

Results: 120 SLE patients were recruited (32.99±1.03 years) including 45 NPSLE and 90 non-NPSLE. NPSLE had higher disease activity (reflected as SLEDAI and ESR). Compared with Non-NPSLE group, fMRI showed changed fALFF and ReHo in brain regions relevant to cognition and emotion ($p<0.01$). Eye sign examination showed NPSLE group had significantly higher scores of ramified loops, vascular tone, microangioma, wound point and had higher total scores than non-NPSLE group ($p<.001$). In multivariable logistic analysis, SLEDAI, ramified loop, microangioma, wound point and presence of antiphospholipid antibodies were predictors of NPSLE (Table 1). the AUC of the ACR classification under ROC curve was 0.775, sensitivity was 75.0%, specificity was 80.0% ($p=0.002$), the AUC of new algorithm under ROC curve was 0.815, sensitivity was 75.0%, specificity was 88.0% ($p<.001$) (Figure 1).

Conclusion: This proposed new algorithm showed not to be inferior to the 1999 ACR classification and need to be confirmed in further studies.

POS0898

EARLY DETECTION OF ANTI-TNF INDUCED CHANGES IN NEW BONE FORMATION IN PSORIATIC ARTHRITIS PATIENTS BY ^{18}F-FLUORIDE PET-CT

Keywords: Imaging, Psoriatic arthritis

J. De Jongh[1], G. C. J. Zwezerijnen[2], R. Hemke[3], M. Yaqub[2], M. G. H. Van de Sande[4], A. Van Kuijk[5], A. Voskuyl[1], C. J. Van der Laken[1]. *[1]Amsterdam UMC, Location VUmc, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[2]Amsterdam UMC, Location VUmc, Department of Radiology and Nuclear Medicine, Amsterdam, Netherlands*; *[3]Amsterdam UMC, Location AMC, Department of Radiology and Nuclear Medicine, Amsterdam, Netherlands*; *[4]Amsterdam UMC, Location AMC, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[5]Reade, Department of Rheumatology, Amsterdam, Netherlands*

Background: New bone formation in psoriatic arthritis (PsA) can be observed in all musculoskeletal disease domains and can lead to disability due to ankylosis and bridging syndesmophytes [1, 2]. The positive effect of anti-tumor necrosis (anti-TNF) therapy on radiographic damage (e.g. erosion and joint space narrowing) is well known, but there are contradictory findings on its effects on new bone formation [3, 4]. Imaging of new bone formation in PsA is pivotal in order to ascertain the extent and potential therapeutic effects on structural changes at an early stage of treatment. Our group recently demonstrated that molecular new bone formation can be observed in all PsA disease domains, using ^{18}F-Fluoride PET-CT scans. Moreover, the ability of this imaging technique to detect early therapeutic effects in ankylosing spondylitis patients was also demonstrated by our group [5].
Objectives: To investigate whether ^{18}F-Fluoride PET-CT scans can detect a change in ^{18}F-Fluoride uptake, reflecting a change in new bone formation, after 12 weeks of anti-TNF therapy in clinically active PsA patients.
Methods: Nine patients (male 4/9, median age 47 (IQR 19)) with PsA fulfilling CASPAR criteria or a clinical diagnosis according to the treating rheumatologist and clinically active disease including ≥1 clinically active enthesitis site were included. In each patient, a whole body ^{18}F-Fluoride PET-CT scan was performed prior to and 12 weeks after starting anti-TNF therapy. Scans were independently assessed for PET-positive lesions (dichotomous) by two readers (blinded for clinical data). Fixed sized volumes of interest were drawn on top of visual PET positive lesions as well as on locations where visual PET positive lesions appeared or disappeared before or after treatment. Standardized uptake values corrected for individual integrated whole blood activity concentration (SUV_{AUC}) were used for quantitative analysis. CT was used for anatomical reference.
Results: Combining all PET-positive lesions of all patients, a total of 153 lesions were observed at baseline (89, 30 and 34 in peripheral joints, entheses and spine, respectively). At week 12, a total of 119 PET-positive lesions were observed (69, 13 and 37 in peripheral joints, entheses and the spine, respectively). Grouping all lesions of all patients, there was a decrease in the mean SUV_{AUC} between baseline (1.578, SD 0.99) and week 12 of anti-TNF treatment (1.230, SD 0.85) (Figure 1A). Similar results were observed when grouping all lesions of all patients for separate disease domains. Mean SUV_{AUC} changes between baseline and 12 weeks were -0.294 (SD 0.88), -0.357 (SD 0.69) and -0.300 (SD 0.67) for respectively peripheral joints (Figure 1B), entheses (Figure 1C) and the spine (Figure 1D).
Conclusion: ^{18}F-Fluoride PET-CT detected a change in new bone formation in PsA domains during anti-TNF therapy as early as 12 weeks post-treatment. The data point at a mean decrease of new bone formation in peripheral joints, entheses and axial skeleton.

POS0899 SPECIFICITY OF SALIVARY GLAND ULTRASOUND IN THE DISCRIMINATION OF PRIMARY SJOGREN'S SYNDROME FROM UNDIFFERENTIATED CONNECTIVE TISSUE DISEASES

Keywords: Imaging

M. Djennane[1], T. Arezki[1], S. Slimani[2], H. Imene[1], A. Ifticene[1]. [1]*University Mouloud Mammeri, Department of Medicine, Tizi Ouzou, Algeria*; [2]*University of Batna, Department of Medicine, Batna, Algeria*

Background: Recently, compelling data have been published on the value of salivary gland ultrasound (SGUS) in differentiating between primary Sjögren's Syndrome (SS) from nonimmune-mediated sicca syndrome. Limited data are available regarding the diagnostic accuracy of SGUS to distinguish SS from undifferentiated connective tissue diseases associated with sicca syndrome.
Objectives: The aim of this study was to evaluate the power of SGUS to distinguish patients with SS from those with xerostomia and/or xerophthalmia and suffering from undifferentiated connective tissue diseases.
Methods: Our cross-sectional study consecutively recruited 95 patients with either SS (according to the American European Consensus Group criteria) or undifferentiated connective tissue diseases associated with sicca syndrome. Immunological assessment and salivary gland biopsies were performed in all patients. Ultrasonography of the parotid and submandibular glands on both sides were assessed for size, parenchymal echogenicity, and inhomogeneity, by the same blinded rheumatologist. A second ultrasound reading was performed blinded by another rheumatologist, with inter-observer Kappa calculation. Ultrasound abnormalities of the salivary glands were graded according to the OMERACT score ranging from 0 to 3 (threshold ≥2).
Results: The study included 95 patients; 51 with SS and 44 with undifferentiated connective tissue disease. Patients with SS showed a higher SGUS score compared with those with rheumatism with sicca syndrome [mean 1.69 (SD=1.17) versus 0.18 (SD= 0.44), P < 0.0001]. The SGUS threshold showed a sensitivity of 60%, a specificity of 98%, a positive predictive value of 97% and a negative predictive value of 67% for the diagnosis of SG. A significant correlation was also found between the SGUS score and the minor salivary gland biopsy/focus score (r=0.64, P<0.0001). Finally, the inter-observer Kappa coefficient ranged from 0.61 to 0.70.
Conclusion: Our study confirmed the good sensitivity and high specificity of SGUS in differentiating SS from other undifferentiated connective tissue diseases with sicca syndrome.

Background: Rheumatoid Arthritis (RA) Magnetic Resonance Imaging (MRI) scoring system (RAMRIS) [1] is used to manually assess severity of disease activity and monitor treatment response, but it is dependent on observer variability and is time-consuming. Deep learning techniques have the potential to improve the reproducibility and efficiency of RAMRIS scoring by automating the analysis of hand MRI scans, however, there are limited data on an automated assessment approach.
Objectives: To investigate whether a deep neural network (DNN) can be trained to automatically detect erosion, synovitis, and oedema in RA patients using hand MRI scans and RAMRIS.
Methods: We used 1,5 Tesla hand MRI (Siemens Magnetom Vida and Aera) from the BARE BONE trial, a prospective, single-arm, interventional, open-label, phase 4 trial (EUDRACT 2018-001164-32) in which RA patients were treated with baricitinib (4 mg/day) for 48 weeks. One of the objectives of BARE BONE was to assess the effect of baricitinib on joint damage and synovial inflammation. Participants of BARE BONE received hand MRI at week 0, 24, 48 following a standardized scanning protocol [2]. All images were scored according to RAMRIS. DNNs were applied on coronal T1 (pre/post contrast enhancement) and T2 MR images. 3-D landmarks for each location for RAMRIS scoring were identified and a region of interest (ROI) around each landmark was extracted to train a DNN. Three separate DNNs were trained, one for each of the RAMRIS subcomponents (erosion, synovitis, oedema). Each DNN is based on a ResNet-3D [3] architecture that was pretrained on a video classification task [4]. The networks were trained to predict the severity scores of each disease characteristic into three classes ranging from 0 (no pathological change) to 2 (high disease burden). The performance of the DNNs was evaluated using the area under the receiver operating characteristic curve (AUROC) and the area under the precision-recall curve (PR-AUC). Three-fold cross-validation were used and the network performance on a hold-out test set was evaluated.
Results: In total, we obtained 212 coronal MR images with both T1 and T2 weighting from 30 RA patients (24 woman/6 men, age 53.5±12.6 years, disease duration 4.3±4.4 years). The overall RAMRIS score decreased from 20.6 (CI95% 14.4 to 27.8) to 18.3 (CI95% 11.5 to 26.5) at week 48. For the evaluation of erosions and oedema, 23 landmarks respectively were used per hand, and 7 landmarks for synovitis. In total 4608 landmarks for erosion and oedema were available, and for synovitis 1152 landmarks. The AUROC for predicting erosions was 86±2% with a PR-AUC of 83±4%. For the prediction of oedema the AUROC was 78±14% and PR-AUC was 83%±10%. Despite a low number of ROI for synovitis scoring, the respective AUROC was 60±4% and PR-AUC was of 69±3%.
Conclusion: This proof-of-concept study demonstrated that fully automated extraction of synovitis, bone oedema, and erosion is feasible. In the future, our deep neural network approach may help to automatically assess MRI data of the hand in routine clinical practice and trials with high accuracy while keeping costs and human resources manageable.

POS0901 CAN B-MODE OCULAR ULTRASOUND ASSESS VITRITIS IN PATIENTS WITH AXIALSPONDYLOARTHRITIS AND PSORIASIC ARTHRITIS?

Keywords: Ultrasound, Inflammatory arthritides, Uveitis

J. A. Mendonça[1], L. Eduardo Pedri[2], F. Andrade[2], L. Biselli[3], L. B. Nucci[4].
[1]Pontifical Catholic University of Campinas, Postgraduate Program in Health Sciences and Rheumatology/Ultrasonography Service, Sumaré, Brazil; *[2]Pontifical Catholic University of Campinas, Postgraduate Program in Health Sciences and Rheumatology/Ultrasonography Service, Campinas, Brazil*; *[3]Pontifical Catholic University of Campinas, Ophthalmology Service, Campinas, Brazil*; *[4]Pontifical Catholic University of Campinas, Postgraduate Program in Health Sciences/ Statistics Service, Campinas, Brazil*

Background: Vitritis is the presence of cellular infiltration in the vitreous body, resulting from inflammation of the vitreous cavity itself or from the extension of the anterior chamber inflammatory process[**1**]. Uveitis is the most frequent extra-articular manifestation of axial spondyloarthritis and psoriatic arthritis, and may occur in any uveal topography[**2**]. B-mode ultrasound can useful for confirming uveitis, especially in those conditions in which there is opacification of the light-conducting medium and the vitreous cavity and the rest of the globe cannot be visualized by ophthalmological examination[**3**]. In the case of vitritis, the vitreous appears on the ultrasound screen in the form of thin, confluent and mobile images[**4**].
Objectives: To detect the presence of vitritis in patients with axial spondyloarthritis and psoriatic arthritis using a B-mode ocular ultrasound and comparing it with the slit lamp ophthalmologic examination.
Methods: Observational and cross-sectional study with 6 patients with non-radiographic axial spondyloarthritis according to the ASAS criteria; 24 with radiographic axial spondyloarthritis according to the modified New York criteria and 34 with psoriatic arthritis according to the CASPAR criteria, selected for convenience between the months of August and December 2021, from the Rheumatology outpatient clinic of the Pontifical Catholic University of Campinas Hospital. One hundred and twenty-six eyes were evaluated by an ophthalmologistby slit lamp biomicroscopy. B-mode ocular ultrasound machine (EsaoteSpA, São Paulo, Brazil) was performed with a high frequency linear probe of 12MHz. A total of 127 eyes were evaluated, categorizing vitritis semi-quantitatively through the intensity of echovitreous in grades 0 (absent), 1 (mild), 2 (moderate) and 3 (severe) **(Figure 1)**. Sensitivity, specificity, negative (NPV) and positive (PPV) predictive values and the ROC curve were calculated for B-mode ultrasound in relation to the ophthalmological evaluation.
Results: The mean age of patients with axial spondyloarthritis was 46.3±13 years, with a BASDAI of 4.10±2.84. The mean age among patients with psoriatic arthritis was 55.2±12.5 years, with a DAPSA of 24.27±22.15. Ophthalmic examination detected vitritis in 3.33% of the eyes. B-mode ultrasound identified grade 0 echovitreous in 39.37% of the eyes, **grade 1** in 25.98%, **grade 2** in 29.92%, and **grade 3** in 4.73% of the eyes. Sensitivity, specificity, NPV and PPV are described in **Table 1**. The ROC curve: area under the curve of **0.58 (95% CI: 0.41-0.74)**.
Conclusion: B-mode ocular ultrasound showed an excellent negative predictive value for detecting vitritis, constituting an important complementary tool in the evaluation of uveitis in patients with axial spondyloarthritis and psoriatic arthritis.

Background: Anti-SSA autoantibodies can be differentiated according to their antigenic target proteins as anti-Ro60 (60 kDa) or anti-Ro52 (52 kDa). Anti-SSA(Ro60) are clearly associated with Connective Tissue Diseases (CTD), but the clinical significance of anti-SSA(Ro52) remains unclear.

Objectives: To analyze the disease phenotype of patients with anti-Ro52 and/or anti-Ro60.

Methods: Multicenter, cross-sectional study of anti-Ro52 and/or Ro60 positive patients followed at 10 Rheumatology centers from January 2018 until December 2021. Patients were categorised into 3 groups: group 1 (Ro52+/Ro60-); group 2 (Ro52-/Ro60+); group 3 (Ro52+/Ro60+). Antinuclear antibodies were evaluated by indirect immunofluorescence assay and further screened for anti-extractable nuclear antigen (ENA) antibodies. Demographics and clinical data were compared between the 3 groups, by patients' medical chart review. Univariate analysis was performed using chi-square, Fisher's exact or Kruskall-Wallis test. Subsequently, the Bonferroni test was used to identify intergroup differences (level of significance: p<0.0167). Univariate logistic regression was used to calculate the odds ratio with a 95% confidence interval (CI).

Results: We included 776 patients [female: 83.1%; median age: 59 (46-71) years]. Groups 1, 2 and 3 comprised 31.1%, 32.6%, and 36.3% of the patients, respectively. Characteristics of the groups are presented in Table 1. Anti-Ro52 alone is more frequently associated with non-rheumatic diseases, older age, and men (p<0.05). Among patients with CTD, the diagnosis of systemic lupus erythematosus is 3 and 2 times more prevalent in groups 2 and 3, respectively, than in group 1 [OR 2.8 (95% CI 1.60, 4.97),p=<0.001; OR 2.2 (95% CI 1.28, 3.86), p=0.007]. In group 2, the diagnosis of undifferentiated connective tissue disease is more frequent than in the other groups. The presence of isolated Ro52+ is more frequently associated with inflammatory myositis than in group 2 [OR 0.09 (95% CI 0.01, 0.33), p=<0.001] or group 3 [OR 0.08 (95% CI 0.01, 0.29), p=<0.001]. Group 1 was also more frequently associated with arthritis (p=0.006), interstitial lung disease (p=0.002), and myositis (p=0.009).

Table 1. Characteristics of the study population according to the groups of anti-SSA(Ro) positivity.

	Group 1 (n=241)	Group 2 (n=253)	Group 3 (n=282)	*p*

DIFFUSE GENERALIZED VENULITIS AS THE PRIMARY PATHOLOGY OF BEHÇET'S DISEASE: A COMPREHENSIVE MAGNETIC RESONANCE VENOGRAPHY STUDY

Keywords: Behcet's disease

H. Karadeniz[1], M. Uçar[2], T. Mammadov[2], A. Avanoglu Guler[1], D. Yildirim[1], H. Küçük[1], B. Goker[1], M. A. Ozturk[1], A. Tufan[1,3]. *[1]Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey*; *[2]Gazi University Faculty of Medicine, Department of Radiology, Ankara, Turkey*; *[3]National Human Genome Research Institute/NIH, Inflammatory Disease, Maryland, United States of America*

Background: Behçet's Disease (BD) is a chronic multisystem vasculitis that manifests with recurrent oral/genital ulcerations and destructive inflammation affecting eyes, central nervous system, and blood vessels. Venous thrombosis is observed in up to 40% of patients, however pathology of vein involvement in BD is poorly characterized [**1].** Recently, demonstration of wall thickening in posterior wall of common femoral vein with an ultrasound (US) was reported to be a reliable auxiliary diagnostic tool in BD. Magnetic resonance (MR) venography may give more comprehensive information about deep veins and adjacent tissues.

Objectives: In this study, we aimed to characterize vein involvement in BD and evaluate diagnostic utility of MR venography.

Methods: Sixty-five BD patients who fulfilled the International Study Group (ISG) criteria and 20 healthy control subjects were enrolled. BD patients were separated into two groups based on previous history of vascular involvement. Inferior vena cava (IVC), common iliac veins (CIV), external (EIV) and internal iliac veins (IVV), common femoral veins (CFV), femoral veins (FV), and greater saphenous veins (GSV) of BH patients and healthy controls were evaluated with MR venography and ultrasonography for the presence pathologic features, luminal thrombi, vessel wall changes and perivascular abnormalities.

Results: 33 vascular and 32 non-vascular BD patients (mean age 39.3±11.3 years and 48 [73.8%] male) were enrolled. MR venography revealed diffuse concentric thickening of the walls of IVC, CIV, EIV, IIV, CFV, FV and GSV in BD (healthy controls vs BD p<0.05 for all the vein segments). **(Table 1).** There was no significant difference between vascular and non-vascular BD groups in terms of vein diameter and wall thicknesses, while both groups had significantly thicker veins than healthy controls (p<0.05). US examination revealed similar results. MR venography provided additional information about veins and perivascular tissues like contrast enhancement, enlarged lymph nodes and seminal vesicle vascularization which were significantly more frequent in vascular BD than non-vascular BD and healthy controls.

Conclusion: The results of our study suggest that the involvement of the venous system is diffuse and generalized in BD, and demonstration of venulitis might help diagnose the disease. Further studies are needed to elucidate prognostic role of wall thickening, venulitis, in terms of anticipation of future thrombosis and treatment response.

Background: Ultrasound (US)-guided minimally invasive technique has improved the availability of soft tissue specimens, as synovial tissue (ST), to be used for basic and translational studies. However, to date, there is a lack of standardized programs to systematically train rheumatologists in its performance on joints in different disease stages of inflammation.
Objectives: (i) to develop an intensive training program for US-guided ST biopsy on large and small joints across inflammatory arthritis phases; (ii) to assess the learning curve, sample quality and trainees' expectations and perceptions.
Methods: Rheumatoid arthritis (RA) patients with active disease or in sustained remission were included in the study. Eight trainees in rheumatology with basic skills on musculoskeletal US joined the training program consisting of 4 sequential phases: (i) observation of the procedure performed by the trainer, (ii) performance of guided step-by-step phases of the procedure, (iii) execution of the whole procedure on small and large joints in parallel with the trainer as reference (each one carried out on paired joints with comparable US-defined joint inflammation on the same patient) and (iv) performance of the complete procedure autonomously. ST specimens were processed for histology (H&E) to assess sample quality in terms of anatomical representativity given by lining and sublining layers presence, required for the semiquantitative assessment of synovitis degree using Krenn score. Before and after the program, trainees' expectations and perceptions were collected using a questionnaire.
Results: 236 ST biopsy procedures were included in the analysis. After completing the observational and guided step-by-step phases, trainees conducted complete procedures (n=44) in parallel with the trainer performing the procedure on the contralateral joint [n=36 knees (n=24 inflamed and n=12 in remission) and n=8 inflamed wrists] showing comparable rate of informative samples recovered by trainees on knees in terms of lining (91.4% and 83.3% for active and remission knees, respectively) and sublining (100% for both) presence, compared to the trainer's procedures ($p>0.05$). Conversely, the rate of informative samples retrieved from active wrists by trainees was lower in terms of lining layer (62.5%), but not sublining layer (100%) presence, compared to the trainers (100% for both, $p=0.05$). Then, trainees performed n=148 procedures without the trainer guidance (n=74 on active and n=43 remission knees respectively, and n=31 on active wrists) achieving an excellent rate of informative samples of 93.3% and 90.3% on active knees and wrists respectively but lower (72.1%, $p=0.0017$) on remission knees, always due to the lack of lining layer retrieval. After the training completion, the trainees' expectation about the invasiveness and pain infliction related to the procedure decreased ($p=0.0625$ and $p=0.0156$, respectively). However, after the training program, trainees' perception of the difficulty of executing the procedure decreased only for large joints regardless to the inflammatory status ($p=0.0312$) remaining unchanged for small joints ($p=0.0625$).
Conclusion: This intensive multi-step program is an effective training system for developing advanced skills in the performance of US-guided ST biopsy on large and small joints, providing high quality specimens to be used for basic and translational studies on chronic inflammatory joint diseases as RA. The intensity and the timing of the training needed to reach acceptable success rates, might be adjusted according to the inflammatory status and the location of the procedure.

POS0905 AXILLARY ARTERIES ULTRASOUND IN THE DIAGNOSIS OF GIANT CELL ARTERITIS WITH PREDOMINANTLY CRANIAL SYMPTOMS

Keywords: Diagnostic tests, Imaging, Vasculitis

J. Martinho[1,2], M. J. Sousa Bandeira[1,2], L. James[3], A. Verdiyeva[3], T. Fontes[1,2,4], A. R. Lopes[1,2], N. Khmelinskii[1,2], R. Luqmani[3], C. Ponte[1,2]. [1]*Centro Hospitalar e Universitário de Lisboa Norte, Centro Académico de Medicina de Lisboa, Rheumatolgy Department, Lisbon, Portugal*; [2]*Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Unidade de Investigação em Reumatologia, Lisbon, Portugal*; [3]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; [4]*Hospital Divino Espírito Santo, Rheumatology Department, Açores, Portugal*

Background: Giant cell arteritis (GCA) is the most common form of primary systemic vasculitis in patients aged >50 years. It predominantly affects the cranial arteries; however, extra-cranial disease involving the aorta and its major branches can also be present. According to the 2018 EULAR recommendations, the ultrasound of temporal arteries (TAs), with or without axillary arteries (AXs), should be the first imaging modality performed in patients with suspected predominantly cranial GCA [1]. This recommendation reflects that the value of the AXs ultrasound in GCA diagnosis is still questionable, especially in patients who present with cranial symptoms of the disease.
Objectives: To assess the value of AXs ultrasound in the ultrasonographic diagnosis of GCA, particularly in patients with predominantly cranial symptoms of GCA.
Methods: Observational retrospective study involving the Rheumatology Departments of Centro Hospitalar Universitário Lisboa Norte (CHULN), Lisbon-Portugal, and the Nuffield Orthopaedic Centre (NOC), Oxford-UK. We included patients with a clinical diagnosis of GCA and a positive ultrasound for GCA at diagnosis, i.e., the presence of a non-compressible halo sign in the TAs or AXs. Information regarding the demographics, clinical manifestations at disease presentation, and therapeutics were collected. Cranial symptoms included headache, temporary or permanent loss of vision, diplopia, blurred vision, jaw or tongue claudication, scalp tenderness or paraesthesia, stroke, or transient ischaemic attack (TIA).
Results: We included 230 patients, 139 (60.4%) from the NOC and 91 (39.6%) from CHULN. One hundred and thirty-six (59.1%) patients were females, and the mean ± standard deviation age at diagnosis was 75.3 ± 8.5 years. The ultrasound was performed after ten days of treatment with prednisolone ≥30mg/day in 70/230 (30.4%) patients. The presence of halo sign in the TAs was found in 207/230 (90.0%) patients and in the AXs in 57/230 (24.8%) patients. According to the ultrasound pattern presented, 173/230 (75.2%) patients had positive TAs and negative AXs ultrasound, 23/230 (10.0%) had negative TAs and positive AXs ultrasound, and 34/230 (14.8%) had both positive TAs and AXs ultrasound. Cranial symptoms were reported in 207/230 (90.0%) patients, in whom AXs involvement on ultrasound was detected in 43/207 (20.8%) of cases. Concerning only the patients with negative TAs and positive AXs ultrasound, 13/23 (56.5%) reported cranial symptoms. Headache was reported in 10/23 (43.5%), visual symptoms in 6/23 (26.1%), jaw or tongue claudication in 4/23 (17.4%), scalp tenderness or paraesthesia in 4/23 (17.4%), and stroke or TIA in 1/23 (4.3%) patients. Constitutional symptoms were present in 13/23 (56.5%), polymyalgia rheumatica in 9/23 (39.1%), and limb claudication in 1/23 (4.3%) patients. A total of 10/23 (43.5%) patients were on glucocorticoid treatment at the time of the diagnosis, but only 4/23 (17.4%) were on prednisolone ≥30mg/day for at least ten days.
Conclusion: Axillary involvement in GCA is frequent, affecting around 1/4 of the patients at diagnosis. The additional assessment of the AXs improved the ultrasound diagnostic sensitivity by 10% compared to only assessing the TAs. Patients with AXs involvement were reported to have cranial symptoms in 43/57 (75.4%) of cases. More than half of the patients with negative TAs and positive AXs ultrasound presented with cranial symptoms. Our results support the need to assess the AXs in patients with suspected GCA, regardless of the presence or absence of cranial symptoms.

POS0906 ULTRASONOGRAPHY AND FDG-PET/CT FOR SUSPECTED POLYMYALGIA RHEUMATICA: DIAGNOSTIC PERFORMANCE IN TREATMENT-NAÏVE VERSUS ALREADY TREATED PATIENTS

Keywords: Diagnostic tests, Ultrasound, Imaging

K. Van der Geest[1], K. Bouwman[1], M. Sandovici[1], R. Slart[2,3], E. Brouwer[1]. [1]*University of Groningen, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; [2]*University of Groningen,*

University Medical Center Groningen, Nuclear Medicine and Molecular Imaging, Medical Imaging Center, Groningen, Netherlands; [3]*University of Twente, Faculty of Science and Technology, Department of Biomedical Photonic Imaging, Enschede, Netherlands*

Background: Polymyalgia rheumatica (PMR) is a common rheumatic, inflammatory disease in the elderly. Traditionally, the diagnosis is based on clinical and laboratory findings, which are not specific for PMR. Although most patients initially respond well to glucocorticoid (GC) treatment, a refractory or relapsing disease course is not uncommon and may cause doubt about the initial diagnosis. This usually prompts additional diagnostic evaluation for PMR with imaging tools such as ultrasonography and FDG-PET/CT, usually after GC tapering. However, it is unclear whether these tests perform equally well in patients already treated under the presumed diagnosis of relapsing or refractory PMR, when compared to treatment-naïve patients, suspected of new PMR.
Objectives: To compare the diagnostic accuracy of ultrasonography and FDG-PET/CT for PMR in treatment-naïve and already treated patients
Methods: Retrospective study including 144 consecutive patients that were referred to the Rheumatology and Clinical Immunology department for suspected PMR, including 63 treatment-naïve patients, and 81 already treated patients with or without still ongoing treatment. Patients were referred by general practitioners (n=107) or other medical specialist. Bilateral ultrasonographic evaluation of the shoulders and hips was performed in 135 patients. The presence of biceps tenosynovitis, subacromial bursitis, glenohumeral synovitis, hip synovitis and trochanteric bursitis was assessed. A sum score of the latter abnormalities was constructed (score range 0-10), and termed total ultrasound score. FDG-PET/CT from skull to upper legs was performed in 72 patients. FDG uptake was visually scored at 12 key sites in order to calculate the Leuven PMR-PET score (score range 0-24) [1,2]. The final clinical diagnosis at 6 months was the reference standard.
Results: A clinical diagnosis of PMR was made in 94/144 (65%) patients. The provisional ACR/EULAR criteria for PMR were fulfilled in 67/94 (71%) patients with PMR and in 19/50 (38%) patients without PMR. More specifically, PMR was diagnosed in 42/63 (67%) treatment-naïve patients and 52/81 (64%) already treated patients. Among the already treated patients, 24 patients were still on GC treatment during the ultrasound scan (median prednisolone dose 6.25 mg daily, range 1.25-30), while 2 patients were taking methotrexate (n=1) or leflunomide (n=1). Only 2 patients were on GC treatment during the FDG-PET/CT scan (prednisolone dose 1 and 2.5 mg), while 1 patient was treated with leflunomide. The total ultrasound score and Leuven PMR-PET score showed good diagnostic accuracy in treatment-naïve patients as indicated by the AUC in the ROC analysis (Table 1). The diagnostic accuracy of the total ultrasound score was poor in patients that had already been treated, even when GC treatment had been fully tapered. In contrast, the diagnostic accuracy of FDG-PET/CT remained good in already treated patients.
Conclusion: FDG-PET/CT shows equal diagnostic accuracy for already treated PMR as for treatment-naïve PMR, if GC therapy is fully tapered. However, ultrasonography for suspected PMR is best performed before initiation of treatment. A simple sum score of inflammatory lesions in the shoulders and hips aids the interpretation of ultrasonography in PMR.

POS0907 ULTRA-HIGH FREQUENCY ULTRASOUND TO ASSESS SKIN INVOLVEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS: PRELIMINARY DATA FROM A MONOCENTRIC COHORT

Keywords: Skin, Ultrasound, Systemic lupus erythematosus

C. Cardelli[1,2], V. Signorini[1], G. Granieri[3], C. Stagnaro[1], L. Carli[1], F. Ferro[1], E. Elefante[1], D. Zucchi[1,2], F. Trentin[1], G. Monaco[1], C. Tani[1], V. Dini[3], M. Romanelli[3], M. Mosca[1]. [1]*University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*; [2]*University of Siena, Department of Medical Biotechnologies, Siena, Italy*; [3]*University of Pisa, Dermatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: The assessment of cutaneous involvement in Systemic Lupus Erythematosus (SLE), particularly the differential diagnosis between active lesions and damage, might be a challenge for the clinicians. Ultra-high frequency ultrasound (UHFUS), with a sub-millimeter resolution, is a promising tool in the evaluation of superficial structures. In recent years its use has grown in the field of dermatology, where UHFUS finds application in the study of normal anatomy, differentiation of cutaneous lesions (bullous and inflammatory disease), diagnosis of skin malignancies and pre-surgical mapping, increasing diagnostic sensitivity and accuracy in guiding medical and surgical therapies.
Objectives: The aim of the study was to explore a possible role of UHFUS assessment in the evaluation of skin involvement in a monocentric cohort of SLE patients and to evaluate the relationship with patients' perception of their skin disease.
Methods: Consecutive adult SLE patients (1997 ACR criteria) regularly followed at our Lupus Clinic were prospectively enrolled during a scheduled outpatient visit in presence of skin lesions. Demographical, clinical, laboratory and treatment data were collected at enrolment. Disease activity and organ damage were evaluated with the SELENA-2K and SLICC-DI, respectively. Clinical assessment of skin lesions was done by an experienced rheumatologist using the Cutaneous LE Disease Area and Severity Index (CLASI); at the same time, UHFUS evaluation of skin lesions was performed with a 70 MHz probe by an experienced dermatologist. The Skindex-16 questionnaire was used to assess the impact of the skin involvement on patients' quality of life.
Results: We included 70 assessments in 55 SLE patients with skin lesions (5/55 evaluated twice, 5/55 three times). Cutaneous disease subtypes were distributed as follows: acute 37.5%, subacute 12.5%, chronic 50.0%. The characteristics of the cohort are shown in Table 1. The most frequent UHFUS alteration was the presence of power Doppler (51/70, 72.9%), followed by dermal oedema (37/70, 52.9%), dermal inhomogeneity (33/70, 47.1%), follicular plugging (32/70, 45.7%), vascular ectasia (27/70, 38.6%) and thinning of the epidermis (10/70, 14.3%). The CLASI activity score was significantly higher in cutaneous areas with power Doppler signal (p=0.032). Dermal oedema was also found to be associated with

Table 1. Characteristics of the cohort

N° of patients	55
Female	49 (89.1%)
Age[1] [years]	45 (35-55)
Disease duration[1] [years]	11 (7-19)
Ethnicity: Caucasian/ Asian/ African-American	51 (92.7%)/ 3 (5.5%)/ 1 (1.8%)
Organ involvement *[cumulative/ ongoing]*	
Mucocutaneous	55 (100%)/ 55 (100%)
Haematological	20 (36.4%)/ 6 (10.9%)
Renal	7 (12.7%)/ 2 (3.6%)
Articular	33 (60.0%)/ 8 (14.5%)
Serositis	2 (3.6%)/ 0

SLICC-DI[1]*	0 (0-1)
CLASI activity[1]* *[global/ UHFUS area]*	5 (3-8)/ 2 (1-3)
CLASI damage[1]* *[global/ UHFUS area]*	1 (0-5)/ 0 (0-2)
Skindex-16 global[1]*	53.9 (31.3-83.3)
Skindex-16 symptoms[1]*	50.0 (25.0-85.7)
Skindex-16 emotions[1]*	61.9 (28.6-97.6)
Skindex-16 functioning[1]*	33.3 (13.3-86.7)

[1] Median (IQR)* data on 70 assessments

higher CLASI activity scores, considered both globally (p<0.001) and at the level of the US-evaluated region (p=0.002), and with higher damage scores of the evaluated area (p=0.034), while vascular ectasia was only associated with higher damage scores of the evaluated area (p=0.036). Skindex-16 symptoms subscale scores were significantly higher in patients with thinning of the epidermis (p=0.01) and dermal inhomogeneity (p=0.049). Regarding the subtype of cutaneous involvement, vascular ectasia was significantly more frequent in chronic cutaneous LE (p=0.029), while no other UHFUS alterations were found to differ between the three groups.

Conclusion: Although preliminary, our data seem to suggest UHFUS as a promising tool not only for assessing skin involvement in SLE, but also for monitoring disease activity over time with a view to optimising the management of these patients.

POS0908 NAILFOLD CAPILLAROSCOPY FINDINGS OF INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES (IPAF)

Keywords: Lungs, Imaging

S. H. Lee[1], H. K. Min[2], H. R. Kim[1]. [1]*Konkuk University School of Medicine, Rheumatology, Seoul, Korea, Rep. of (South Korea)*; [2]*Konkuk University Medical Center, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Objectives: We evaluated nailfold capillaroscopy (NFC) of interstitial pneumonia with autoimmune features (IPAF) and compared it with that of patients with CTD-ILD and idiopathic interstitial pneumonia (IIP).

Methods: Patients with newly diagnosed as ILD were evaluated using NFC. Baseline demographic, clinical, serological, and high-resolution CT findings were collected. NFC was semi-quantitatively scored with six domains ranging from 0 to 18. In addition, the overall patterns (scleroderma/non-scleroderma patterns) were determined.

Results: A total of 81 patients (31 with CTD-ILD, 18 with IPAF, and 32 with IIP) were included. The non-specific interstitial pneumonia pattern was the most common ILD pattern in the CTD-ILD and IPAF groups, whereas the usual interstitial pneumonia pattern was the most common in the IIP group. The semi-quantitative score of the CTD-ILD group was higher than that of the IPAF or IIP groups (5.8 vs 4.2 vs 3.0, p < 0.001, respectively). Giant capillaries and haemorrhages were more frequently present in the CTD-ILD and IPAF groups than in the IIP group. A scleroderma pattern was present in 27.8% of the IPAF group, whereas none of the IIP patients showed a scleroderma pattern.

Conclusion: NFC findings may be useful in classifying patients with ILD into CTD-ILD/IPAF/IIP.

POS0909 IS IT NECESSARY TO STOP NOVEL ORAL ANTICOAGULANT THERAPY PRIOR TO MUSCULOSKELETAL ULTRASOUND GUIDED INTERVENTIONAL MANEUVERS?

Keywords: Comorbidities, Ultrasound, Inflammatory arthritides

M. Micu[1], A. Duțu[2], A. Micu[3]. [1]*Rehabilitation Clinical Hospital Cluj Napoca, Rheumatology Division, Cluj Napoca, Romania*; [2]*"Iuliu Haţieganu" University of Medicine and Pharmacy Cluj-Napoca, Romania, Department of Medical Biochemistry, Cluj Napoca, Romania*; [3]*"Iuliu Haţieganu" University of Medicine and Pharmacy Cluj-Napoca,"Iuliu Haţieganu" University of Medicine and Pharmacy Cluj-Napoca, Cluj Napoca, Romania*

Background: Anticoagulation is common in patients undergoing arthrocentesis or joint/ periarticular injections. Previous retrospective studies have established the safety of continuing anticoagulation with Novel Oral Anticoagulant Therapy (NOAC) when performing such kind of interventional maneuvers [1]. Indeed, ultrasound guided interventional maneuvers have shown a superior safety profile compared to blind anatomical maneuvers [2].

Objectives: To evaluate the post-procedural bleeding complications in patients diagnosed with inflammatory/ degenerative rheumatologic pathology.

Methods: Consecutive patients diagnosed with inflammatory/ degenerative rheumatologic pathology requiring interventional articular/ periarticular maneuvers were prospectively recruited. Patients were divided in two groups – Group 1 treated with NOACs and Group 2 (control group) without anticoagulation. NOAC therapy was administered in a continuous regimen prior to the interventional maneuver, in therapeutic regimens dictated by the underlying anticoagulation indication. Demographics, laboratory analysis, systemic medication, local administered medication (corticosteroids/ viscosupplementation), interventional maneuver location, type of needle, the occurrence/ absence of bleeding accidents in the anatomic structures submitted to needle penetration were recorded. The written informed consent was obtained. Post-procedural control was performed at 30 minutes, 48 hours and 7 days.

Results: Results are presented in Table 1. No articular/ intra- tendon sheath/ bursa or muscular bleeding event occurred in patients treated with NOAC regardless of their type and dosage, local medication administration/ needle size/location and number of interventions per individual. Several patients in both groups developed small superficial ecchymoses at injection site.

Table 1. Demographics, laboratory analysis, systemic medication, interventional maneuver location, type of needle, the occurrence/ absence of bleeding accidents.

Parameter	Group with NOAC	Group with No NOAC
Number patients	79	156
with 2 interventions	25	40
Age (median +/- IQR)	65 ± 11.4	69 ± 12.3
Gender (number F/M)	44/35	99/57
GFR (median ± IQR)	79 (50-99)	74 (66-103)
NOAC type		
Apixaban (5mg/day)	40	0
Rivaroxaban (15-20 mg/day)	38	0
Dabigatran (75mg/day)	1	0
Vitamine K antagonists	0	0
Aspirine 100mg/d	12	10
Injection number	104	196
Ultrasound guided injections (%)	100	100
Needle size (Gauge)	15	43
G18 (for viscosupplementation)	70	123
G21	19	30
G24		
Injection site		
Knee joint	55	70
Shoulder (SASDb)*	28	69
Hip joint	2	27
Tendon sheath	9	19
Paravertebral	10	11
Bleeding events in the targeted anatomic structure	0	0

*SASDb = subacromial subdeltoid bursa, GFR-glomerular filtration rate

Conclusion: Our results suggest that NOACs are safe to be used in a continuous regimen prior to joint/periarticular ultrasound guided injections, even in combination therapy with aspirin. The use of lower gauge needles, chosen for viscosupplementation therapy, was not burdened with adverse effects on the procedural outcome.

POS0910 A MULTIPLEX RT-QPCR KIT FOR EXPRESSION ANALYSIS OF INTERFERON-STIMULATED GENES AS A USEFUL TOOL FOR MOLECULAR STRATIFICATION IN LUPUS AND OTHER AUTOIMMUNE DISEASES

Keywords: Validation, Diagnostic tests, Systemic lupus erythematosus

J. Qian[1], L. Lu[1], Z. Cao[2], Q. Fu[1]. [1]*Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Department of Rheumatology, Shanghai, China*; [2]*Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Institute of Molecular Medicine, Shanghai, China*

Background: It is recognized that the expression of interferon (IFN)-stimulated genes (IFN signature) plays a significant role in several autoimmune diseases (AIDs) [1], such as systemic erythematosus lupus (SLE), idiopathic inflammatory

myopathies (IIM) and rheumatoid arthritis (RA). A quick and ready-to-use method to differentiate IFN activation state is clinically needed.

Objectives: This study aimed to conduct analytical validation of the Multiplex ISGs RT-qPCR Kit in clinical practice

Methods: We designed a multiplex RT-qPCR method to provide IFN score covering both type I IFN and type II IFN by simultaneously detecting the expression of 3 IFN stimulated genes (ISGs), IFI44, MX1(type I ISGs), and IRF1(type II ISG), relative to one housekeeping gene (HPRT1). Measurements were performed on mRNA extracted from the peripheral blood cells of patients with multiple AIDs. The relative expression of each target gene (T/R) was calculated via 2^-ΔCT. The T/R of each target gene was then normalized as the following: $T/R_{subject}$ - Mean $_{HC}$/ SD_{HC}. IFN score was calculated as the mean of the normalized T/R of three target genes. Scores higher than the mean of HC plus two SD were designated IFN score high; otherwise, IFN score low. Analytical validation was performed to assess compliance rate, accuracy and method detection limit.

Results: Significantly elevated IFN scores were found in SLE(n=116), IIM(n=118), and RA(n=17) compared to other AIDs and HC. Four distinct subpopulations of SLE patients were observed: Thirty-five percent of SLE patients exhibited elevation of all three genes, indicating both type I and type II IFN pathways were activated. 44% of SLE patients had elevated expression of type I ISGs but no change in the type II ISG suggesting only type I IFN pathway was activated. 15% SLE patients presented no elevated expression of ISG gene. And 6% SLE patients only showed increased expression of IRF1 without overexpression of other 2 Type I ISGs, suggesting they probably only had type II IFN pathway activated. We repeated the tests. The compliance rate was 100% and accuracy was 100% with a CV of 0.36%. The method detection limit was 0.61 ng/μL.

Conclusion: Using the Multiplex® ISGs RT-qPCR Kit, we assessed the IFN score in multiple AIDs. The analytical validation of the kit reveals that it is a reliable, reproducible diagnostic tool that will be useful in clinical practice but may require confirmation in larger-scale trials.

POS0911 **ULTRASOUND-DETECTED SYNOVITIS AMONG INDIVIDUALS AT RISK OF RHEUMATOID ARTHRITIS INCREASES THE RISK OF DEVELOPING CLINICAL ARTHRITIS IN THE FUTURE**

Keywords: Rheumatoid arthritis

P. Hanova[1], K. Prajzlerová[1,2], N. Petrovská[1,2], M. Gregová[1,2], H. Mann[1,2], K. Pavelka[1,2], J. Vencovský[1,2], L. Šenolt[1,2], M. Filková[1,2]. *[1]Institute of Rheumatology, Rheumatology, Prague, Czech Republic*; *[2]First Medical Faculty, Charles University, Department of Rheumatology, Prague, Czech Republic*

Background: During the transition to rheumatoid arthritis (RA) patients pass through several phases. In the preclinical phase, the presence of anti-citrullinated protein antibodies (ACPA) can be detected [1]. A set of clinical characteristics for patients with arthralgia who are at risk of progression to RA was established (clinically suspected arthralgia; CSA) [2]. Ultrasound (US) is more sensitive diagnostic tool in detecting synovitis than clinical assessment and was recommended to use in diagnostics of RA.

Objectives: To test if ultrasound-detected synovitis among patients at risk of progression to RA increases the risk of developing clinical arthritis (CA) in the future.

Methods: ACPA+ individuals with arthralgia and/or those fulfilling CSA criteria were enrolled into the study and were assessed in 3 months interval (routine clinical investigation with laboratory tests, 68-joint count, US assessment). Tender and swollen joint counts were provided by an independent investigator. Sonographer was blinded to all clinical and laboratory data. CA was defined as clinically swollen and tender joint. All US assessments were provided by a single experienced investigator. Thirty joints US score was assessed bilaterally in wrist, MCP I-V, PIP II-V (dorsal and palmar approach), MTP II-V (dorsal approach), ankle (dorsal, medial and lateral approach). US synovitis was defined according the EULAR-OMERACT and scored separately in grey-scale (GS; 0-3) and Power Doppler (PD; 0-3), and combined GS+PD score GLOESS (Global OMERACT-EULAR Score System) was used. For the statistical analysis, we used GraphPad Prism 8.0.0 software (Wilcoxon-Mann-Whitney test), and relative risk ratio (RR).

Results: 159 patients were enrolled into the study (93% female). 95 individuals were ACPA+ (38% fulfilled the CSA criteria additionally), 64 individuals fulfilled the CSA criteria and were ACPA-. At baseline, GS≥1 was detected in 109 patients (67%), PD≥1 was found in 30 individuals (19 %). Single erosion was found by US only in 4 patients (3%) at baseline. 33 patients (21%) developed CA during follow up (mean 13 months after enrolment into the study). No statistical difference in US synovitis score was found between ACPA+ vs. ACPA- and CSA+ vs. CSA- groups at baseline. RR to develop CA at the patient level in patients with GS≥2 at baseline was 1.58 (95% CI 1.16- 2.18; p<0.01), in PD≥1 the RR was 3,14 (95% CI 1.74-5,7; p<0.001), in PD≥2 RR was 7,64 (95% CI 3,1-18,82; p<0.0001). GLOESS score>5 showed RR 3,82 (95% CI 1,74-8,4; p<0,001). US-detected synovitis preceded clinical finding of arthritis by 3 months (SD 1,2).

Conclusion: US-detected synovitis in patients at risk of RA further increases the risk of developing clinical arthritis in a larger prospective study. US detected synovitis in joints appears about 3 months prior synovitis detected by routine clinical assessment.

POS0912 **SARCOPENIA IN SPONDYLOARTHRITIS. ULTRASOUND EVALUATION**

Keywords: Spondyloarthritis, Ultrasound, Sarcopenia

C. Soto[1], C. A. Lozada Perez[1], A. Angeles-Acuna[1], S. Y. Solorzano Flores[1], F. Carranza-Enriquez[1], C. Vega[1], C. Pineda[1]. [1]*Instituto Nacional de Rehabilitación, Departamento de Reumatología, Mexico city, Mexico*

Background: Spondyloarthritis are a group of chronic inflammatory rheumatic diseases that share clinical and imaging characteristics. Sarcopenia is characterized by loss of muscle mass and function associated with impairment of quality of life and adverse outcomes such as fractures and death. Patients with Spondyloarthritis had a prevalence of up to 25.7% of sarcopenia. The available imaging techniques for the detection of low muscle quantity and quality are: dual-energy X-ray absorptiometry (DXA), bioelectrical impedance analysis (BIA), and recently muscular ultrasound (US). Ultrasound estimate muscle quantity using prediction equations based on muscle thickness that have shown to be highly reliable in healthy population. Among the models used, the following equations are applicable in different ethnicities to predict muscle mass Abe 2018, Barbosa Silva 2021, Tang 2022.

Objectives: To evaluate the prevalence of sarcopenia in Spondyloarthritis and to determine which of the three ultrasonographic predictive models correlates best with BIA and DXA in our population.

Methods: Observational, cross-sectional study. We included 42 patients with spondyloarthritis (according to ASAS criteria for ankylosing spondylitis or CASPAR criteria for psoriatic arthritis). Appendicular skeletal muscle mass (ASMM) was evaluated by DXA and predicted by BIA and US. We performed a US examination with a GE LOGIQ^{TM}e, equipped with a broadband linear probe to measure muscle thickness (MT) at seven sites. Based on ultrasound prediction models, we use age, sex, height, and MT to estimate ASMM (Abe-2018, Barbosa-2021, and Tang-2022). A bivariate analysis was performed to assess the differences between patients with and without decreased ASMM. Pearson´s correlation coefficient was calculated to evaluate the correlation of the ultrasonographic predictive models with DXA and BIA. Finally, a ROC curve analysis was performed to determine the area under the curve of the models.

Results: We included 42 patients, composed mainly of men (24/42, 57.1%), with ankylosing spondylitis (AS) in 35 (83.3%) and psoriatic arthritis in 7 (16.7%). The prevalence of sarcopenia was about 33% (10/14 sarcopenia y 4/14 severe sarcopenia). When comparing patients with and without decreased ASMM, differences were only found in ultrasonography measurements of the quadriceps and anterior tibial muscles (p=0.003 y 0.00). On the other hand, the ultrasound prediction models had a moderate to strong correlation with DXA and BIA (0.80, 0.87, 0.53 and 0.88, 0.74, 0.66 for Abe-2018, Barbosa-2021, and Tang-2022). Nevertheless, in the ROC curve, the ABE-2018 model expresses a better diagnostic performance (AUC 0.80 p=0.002).

Conclusion: Results indicated a low ASMM in 30% of the patients with Spondyloarthritis (sarcopenia 24.4%, severe sarcopenia 9.8%). This study supports the use of ultrasound and shows a good correlation with DXA and BIA for ASMM evaluation in Spondyloarthritis, particularly with the Abe-2018 predictive model.

POS0913 **LOW ADDITIVE VALUE OF A REPEAT MRI EXAMINATION OF THE SACROILIAC JOINTS WHEN THE FIRST MRI IS INCONCLUSIVE**

Keywords: Imaging, Inflammatory arthritides, Spondyloarthritis

I. Eshed[1], T. Goitein[1], M. Lidar[2]. [1]*Sheba Medical Center, Diagnostic Imaging, Ramat Gan, Israel*; [2]*Sheba Medical Center, Rheumatology Unit, Ramat Gan, Israel*

Background: Diagnosing sacroiliitis on MRI of the sacroiliac joints (SIJ) is not always straightforward. It is common practice in inconclusive cases to repeat the MRI after a variable period of time with an expectation that more conclusive acute/structural lesions will develop and allow for an irrefutable diagnosis of sacroiliitis.

Objectives: To evaluate the diagnostic utility of a repeat SIJ MRI following an initial inconclusive MRI examination.

Methods: Subjects with >1 SIJ MRI examinations, where the index scan was inconclusive for sacroiliitis and ≥ 6 months' interval has elapsed between scans, were included. Repeat scans were evaluated for the presence of structural/acute SIJ lesions and were accordingly diagnosed with either sacroiliitis or another applicable diagnosis. Clinical data was extracted from the patients' clinical files and by a telephone questionnaire. Diagnoses and scores were compared between index and follow-up examinations (t test).

Results: 71 subjects were included in the study; 77.4% females, mean age 41.0±15 years. Mean time interval between exams 30.4 ± 25.24 months. 12 subjects performed >2 scans. Clinical information was available in 63 subjects (86%) and is summarized in Table 1. In only two subjects (2.81%), both females, MRI diagnosis changed from inconclusive to definite sacroiliitis on the follow-up scan; a 41-year-old patient that had inflammatory back pain for two years prior to the index MRI, had peripheral arthritis but no family history of SpA and a 39-year-old patient with inflammatory back pain since the age of 23 years and an elevated CRP but no family history of SpA or other clinical rheumatic involvement. Final diagnosis after the 2nd MRI was osteitis condensans illi in 29 patients, DISH in 3 patients, degenerative changes in 6 patients (two accompanied by enthesitis) and enthesitis in 1 patient. In 10 patients (14.1%) diagnosis was still inconclusive after the 2nd MRI examination. No major abnormality was found in the follow-up MRI examination in 20 subjects. None of the subjects with >2 scans, had evidence of sacroiliitis in any of the following MRI examinations.

Conclusion: Repeating SIJ MRI examination when index MRI is inconclusive is of minimal additive value. When MRI findings are inconclusive, decision making should be based on clinical data.

POS0914

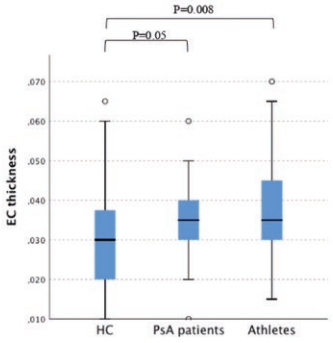
ULTRASONOGRAPHIC EVALUATION OF ENTHESEAL FIBROCARTILAGE IN PATIENTS WITH PSORIATIC ARTHRITIS, HEALTHY CONTROLS AND ATHLETES: A COMPARISON STUDY

Keywords: Enthesitis, Psoriatic arthritis

F. M. Perrotta[1], S. Scriffignano[1], M. Ronga[2], E. Lubrano[1]. [1]*Università degli Studi del Molise, Medicina e Scienze della Salute, Campobasso, Italy*; [2]*University of Piemonte Orientale, Health Sciences, Novara, Italy*

Background: Enthesitis is the hallmark Psoriatic Arthritis (PsA), with the enthesseal fibrocartilage (EF) found to be the possible target tissue of inflammation [1]. With the development of feasible and more accurate imaging modalities, the *in vivo* study of this important tissue has become more precise.

Objectives: The aim of this study was: 1) to evaluate the EF at Achilles tendon insertion by using power Doppler ultrasound (PDUS) in PsA 2) to assess the intra and inter-reader reliability in the evaluation of EF thickness 3) to compare EF thickness of healthy controls (HC) and athletes; 4) to evaluate the association of EF abnormalities with other entheseal abnormalities and disease activity and functional indices in PsA.



Methods: Consecutive PsA patients attending our unit with age < 50 years were asked to participate. HC and agonist athletes (basketball and soccer players with a minimum of 10 hours training per week) were enrolled as control group. Bilateral PDUS evaluation of Achilles tendons was performed in order to evaluate the EF in all patients and controls. EF was defined as the thickness of the anechoic layer just above the cortical bone and was measured at its thickest point in the longitudinal scan, as previously described [2]. All PsA patients underwent a complete clinical examination.

Results: 30 PsA patients, 20 HC and 40 athletes were enrolled. Female/male ratio was balanced among the three group. Median age (IQR) was higher in PsA patient (49; 41-54) than HC (26; 21-29) and athletes (24; 21-27). Four (13.3%). No patients had clinical heel enthesitis. Median (IQR) EF thickness between PsA, athletes and HC was 0.035 (0.03-0.04) cm, 0.035 (0.03-0.04) cm and 0.03 (0.02-0.04) cm respectively (p=0.05 between PsA and HC; Kruskall-Wallis analysis, see Figure 1). The intra-reader reliability was excellent [intraclass correlation coefficient-ICC (95% confidence interval-CI) of 0.91 (0.88-0.95)] and the inter-reader reliability good [ICC (95% CI) of 0.80 (0.71-0.86)]. At PDUS, no statistically significant differences were found in entheseal abnormalities. However, 3 PsA patients showed erosions at entheseal site in respect to HC and athletes which did not show erosive changes. We did not find correlations between EF thickness and BMI, age, disease duration, disease activity (assessed by DAPSA), LEI and impact of disease (assessed by PsAID) and duration of sport activities in athletes. A trend toward a correlation between EF thickness and body weigh was found (Table 1). Assessment of EF was feasible with a mean time of 2 minutes.

Figure 1. Comparison of the median EF thickness among the three groups (Kruskal-Wallis Test)

Independent-Samples Kruskal-Wallis Test Summary

Total number 180; p= 0.025

*HC: healthy controls; PsA: Psoriatic arthritis

Table 1. Spearman's rho correlations (by site) between EF thickness and clinical characteristics in Psoriatic arthritis (PsA) patients, healthy controls (HC) and athletes.

EF thickness (right)		
	rho	P value
All (PsA+ HC+ Althletes)		
Age	-0.144	0.177
Weight	0.193	0.072
BMI	0.117	0.277
PsA patients		
DAPSA	0.194	0.364
Disease duration (months)	-0.171	0.375
LEI	0.109	0.545
PsAID	0.232	0.234
EF thickness (left)		
	rho	P value
All (PsA+ HC+ Althletes)		
Age	-0.091	0.398
Weight	0.156	0.148
BMI	0.149	0.165
PsA patients		
DAPSA	0.036	0.868
Disease duration (months)	-0.094	0.635
LEI	0.129	0.455
PsAID	0.034	0.643

BMI: body mass index; DAPSA: disease activity index for psoriatic arthritis; LEI: Leeds enthesitis index; PsAID: psoriatic arthritis impact of disease

Conclusion: The assessment of EF is a feasible and reproducible test. Furthermore, our data suggest an increased thickness of EF in PsA patients in respect to HC with similar values in respect to agonist athletes and may open the way to further large studies on this peculiar aspect.

POS0915

ATP-BINDING CASSETTE G1 MEMBRANE TRANSPORTER-MEDIATED CHOLESTEROL EFFLUX CAPACITY INFLUENCES CORONARY ATHEROSCLEROSIS AND CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS

Keywords: Cardiovascular disease, Rheumatoid arthritis

G. Karpouzas[1,2], B. Papotti[3], S. Ormseth[2], M. Palumbo[3], E. Hernandez[2], M. P. Adorni[3], F. Zimetti[3], M. Budoff[4,5], N. Ronda[3]. *[1]Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America*; *[2]The Lundquist Institute, Rheumatology, Torrance, United States of America*; *[3]University of Parma - Parco Area delle Scienze, Internal Medicine, Parma, Italy*; *[4]Harbor-UCLA Medical Center, Cardiology, Torrance, United States of America*; *[5]The Lundquist Institute, Cardiology, Torrance, United States of America*

Background: Cholesterol efflux capacity CEC measures the ability of high-density lipoprotein (HDL) to remove cholesterol from arterial wall macrophages upon interaction with membrane transporter proteins and reduce the lipid content of atherosclerotic plaques. CEC inversely associated with cardiovascular risk in general patients independently of HDL levels. CEC through the ATP-binding-cassette G1 (ABCG1) membrane transporter is impaired in RA, yet, its relationship to atherosclerosis and cardiovascular risk is unknown.
Objectives: We here evaluated associations of ABCG1-mediated CEC with coronary atherosclerosis burden, plaque progression and incident cardiovascular event risk in RA.
Methods: Coronary atherosclerosis was evaluated with computed tomography angiography in 140 patients without cardiovascular disease and reassessed in 99 after 83.6±4.0 months. ABCG1-mediated CEC was measured in Chinese hamster ovary cells, not transfected or transfected with ABCG1 gene, as percentage of effluxed cholesterol over total intracellular cholesterol content. Logistic and negative binomial regression tested associations of ABCG1 with binary and count plaque outcomes respectively. Cox regression evaluated the association of ABCG1 with long-term cardiovascular event risk.
Results: Mean (standard deviation [SD]) of ABCG1 was 4.71 (0.92)%. At baseline, ABCG1 inversely associated with likelihood of extensive atherosclerosis (≥5 plaques) (odds ratio 0.50 [95% CI 0.28-0.88]) and numbers of partially-calcified (rate ratio [RR] 0.71 [95% CI 0.53-0.94]) and low-attenuation plaques (RR 0.63 [95% CI 0.43-0.91]) independently of ASCVD score and statin use. There were no main effects of ABCG1-CEC in adjusted plaque progression models. However, higher ABCG1-CEC predicted decreased noncalcified and calcified plaque progression exclusively in patients with higher time-weighted mean prednisone dose (Figure 1A,B). Furthermore, ABCG1-CEC inversely associated with progression of partially-calcified plaque at lower time-averaged CRP levels (Figure 1C). ABCG1-CEC did not have a main effect on cardiovascular event risk after adjusting for ASCVD score. However, higher ABCG1 associated with lower risk in patients with any versus no prednisone exposure during follow-up (Figure 1D,G), ≥1 versus no noncalcified plaques (Figure 1E,H), and low (<median) versus higher baseline CRP (Figure 1F,I) after adjustments including for ASCVD score (p-for-interaction=0.008, 0.021 and 0.033 respectively)
Conclusion: ABCG1-mediated CEC inversely associated with coronary plaque burden and number of high-risk plaques at baseline. It further predicted decreased plaque progression conditionally on cumulative inflammation and prednisone dose. Notably, ABCG1-mediated CEC inversely associated with cardiovascular risk specifically in prednisone users, patients with noncalcified plaques at baseline and those with lower inflammation.

THE CURRENT SITUATION OF MUSCULOSKELETAL ULTRASOUND EDUCATION - A SYSTEMATIC LITERATURE REVIEW

Keywords: Ultrasound, Education

R. Neubauer[1], F. Recker[2], C. J. Bauer[1], P. Brossart[1], V. Schäfer[1]. *[1]Clinic of Internal Medicine III, University Hospital of Bonn, Department of Oncology, Haematology, Rheumatology and Clinical Immunology, Bonn, Germany*; *[2]University Hospital Bonn, Department of Obstetrics and Prenatal Medicine, Bonn, Germany*

Background: The use of musculoskeletal ultrasound improves patient care by increasing diagnostic and therapeutic safety. With its growing application and increasing evidence of its value, the demand for standardized training in musculoskeletal ultrasonography (MSUS) rises rapidly.
Objectives: In this systematic literature review, we aim to provide a general overview of the various aspects of musculoskeletal ultrasound education worldwide, including target groups, teaching staff, didactic methods, and course formats, as well as to reflect on existing problems and future opportunities. No restrictions were made regarding the educational level of the course recipients nor the specialization of the course instructors.
Methods: In our methodological approach, we followed the PRISMA statement for reporting systematic reviews and meta-analyses of studies[1]. In January 2022, the databases Embase, PubMed, and Google Scholar were considered with all publications to date and were filtered for relevant publications using previously defined keywords. Title and abstract were then screened independently by two authors for inclusion using relevant study characteristics determined in advance according to the PICO scheme[1]. Finally relevant information was filtered from the full text version of the sixty-seven included publications.
Results: The range of training programs has increased greatly in recent years, primarily aiming at residents in rheumatology, radiology and physical medicine and rehabilitation. However, MSUS is also receiving more attention as a training tool for medical students. Due to the COVID pandemic, didactic approaches using distance learning via simulators and handheld devices have gained additional importance. Given the existing lack of sufficient equipment and trained teaching staff, those approaches should continue to be explored post-pandemic. Another still existing problem is the low international comparability of MSUS training and competency assessment. Therefore, several international institutions, including the European League Against Rheumatism (EULAR) and the Pan-American League of Associations for Rheumatology (PANLAR) have proposed guidelines for training curricula to promote standardized ultrasound training.
Conclusion: There is a broad consensus that the development of standardized curricula improves training and facilitates the implementation of new training centers. The development of alternative teaching methods incorporating e-learning, peer teaching, and distance learning on mobile ultrasound devices and the determination of international guidelines could facilitate overcoming the remaining major obstacles still to be passed.

POS0917 **ULTRASOUND GUIDED SACROILIAC JOINT INJECTIONS IN MANAGEMENT OF ACTIVE SACROILIITIS: ONE YEAR DATA**

Keywords: Spondyloarthritis, Ultrasound, Imaging

S. G. Al Khayyat[1], P. Falsetti[1], G. Fogliame[1], E. Conticini[1], S. Barbagli[1], S. Gentileschi[1], M. Bardelli[1], C. Baldi[1], A. Vitale[1], S. M. Stella[2], A. Del Chiaro[3,4], A. Saponara[5], L. Cantarini[1], B. Frediani[1]. [1]*Siena, Rheumatology Unit, Siena, Italy*; [2]*Santa Chiara University Hospital, Advanced Musculoskeletal Ultrasound, Department of Clinical and Experimental Medicine, SIUMB School of Pisa, Pisa, Italy*; [3]*Lucca Hospital, Orthopedic and Traumatology Operating Unit, Lucca, Italy*; [4]*SIUMB School of Pisa, Advanced Musculoskeletal Ultrasound, Pisa, Italy*; [5]*SIUMB School of San Giovanni Rotondo, Advanced Musculoskeletal Ultrasound, Foggia, Italy*

Background: Active sacroiliitis represent the radiological hallmark of Ankylosing Spondylitis (Ax-SPA) and manifest as low back pain accompanied by morning stiffness (MS). The pain at rest as well as MS represent the main symptoms that impair patients' quality of life. The treatment of Ax-SPA rely on non steroidal anti-inflammatory drugs (NSAIDs), monoclonal antibodies as Anti-TNF-α, anti interluekine-17/23 and, recently, on Janus Kinase Inhibitors; such compounds modify the disease natural history and reduce inflammation, thus restoring patient's well being and quality of life. However, despite a full treatment regimen, sometimes it is not possible to reach a low disease activity or remission.

Objectives: In rheumatological practice, corticosteroids (GCs) injections are successfully exploited in the every-day scenario to treat oligo-articular inflammatory disorders. In this context, we decided to evaluate the long-term efficacy of ultrasound-guided sacroiliac joint injections (US-SIJIs) of GCs in the treatment of active sacroiliitis and to understand whether local therapy has a role in the management of active sacroiliitis.

Methods: We enrolled patients affected by Ax-SPA with active sacroiliitis from our outpatient clinic. Some were treated with an US-SIJI when starting a biological disease modifying rheumatic drug (bDMARD) while others were treated with conventional therapy (bDMARD + NSAIDs) and used as controls. Variables such as age, gender, disease duration, type of bDmard, visuo-analogic pain scale (VAS) and MS were collected at baseline. VAS and MS were collected at each follow up visit that were scheduled at 24 and 48 hours, then after 7 days, 14 days, 1, 3, 6, 9 and 12 months. Each patient treated with SIJI received an explanation of the technique and informed written consent was obtained; subsequently, each patient was invited to lay pronated on a medical bed while a musculoskeletal sonographer individuated sacroiliac joints (SIJ) with a convex probe and demarcated the needle entry site with a dermographic pen. A sterile hood was put on the probe, the skin was accurately disinfected, then a 2,5 mL syringe was loaded with 40 mg of triamcinolone acetonide and a spinal needle of 22 gauge was used to reach SIJ. Each SIJI involved crossing the posterior sacroiliac ligament and each injection was carried out following real time the needle trajectory. All of the US-SIJI patients received a bilateral SIJI. The statistical analysis exploited descriptive statistics to define baseline anthropometric variables, ANOVA test and Test U of Mann were used to compare the means between groups. The $p<0,05$ was considered significant. The present study was conducted in accordance to the Declaration of Helsinki and was approved by the local ethical committee.

Results: We enrolled 33 subjects: 12 received an US SIJI and 21 were treated with a standard therapy according the most up-to-date recommendations. Both groups were comparable for age and VAS pain at baseline. In US-SIJI group after 24 h was documented a significant reduction of VAS pain that lasted up to 1 year displaying always a persistent significant lower value compared to baseline; in SIJIs group the higher VAS pain reduction from baseline was documented after 7 days (- 71%); in the control group VAS pain reduction reached significance after 3 months from baseline and the higher VAS pain reduction was documented at end of study (-32 %). In the US-SIJI group MS dropped significantly after two weeks from SIJI while in the controls after 3 months from baseline. At the end of study the patients treated with US-SIJI displayed a higher VAS pain (-50 % in SIJIs vs. -32 %, $p<0,05$) as well as MS reduction compared to controls (- 71 % in SIJIs vs – 42%, $p<0,05$). Any serious adverse event was recorded.

Conclusion: The US-SIJIs represent a safe and useful tool to control the symptoms of an active sacroiliitis and they should be performed concomitantly to the beginning of a bDMARD therapy to guarantee a rapid restoration of patients' quality of life.

Background: Radiographic assessment of the sacroiliac joints (SIJ) according to the modified New York (mNY) criteria is essential in the classification of ankylosing spondylitis, but low to moderate inter-reader agreement and limited improvement by calibration have been reported [1]. A web-based real-time iterative calibration (RETIC) module for scoring SIJ radiographs according to the mNY criteria has been developed by experienced readers to allow remote standardized calibration.
Objectives: To test the performance of this online RETIC calibration module in enhancing scoring proficiency with an expert reader as gold standard reference.
Methods: This RETIC module consisted of 50 cases with radiographs of the SIJ at one timepoint with an integrated scoring interface with real time feedback to the reader's grading compared to the expert readers' grading. The mNY grade (0-4) was assessed for each joint. Reliability for fulfilling versus not fulfilling the mNY criteria was assessed in real-time by kappa data being provided every 10 cases, until proficiency targets (kappa > 0.5) were achieved. In this study, 19 readers from the EuroSpA Imaging project were randomized to one of two reader calibration strategies (groups A and B) that comprised of 3 calibration steps, each followed by a reading exercise (Exercises 1-3; 25 patients per exercise). Calibration steps were as follows: Group A; 1. Review of original manuscripts describing the mNY method. 2. Review of PowerPoint summary of mNY method and video with grading examples PLUS completion of mNY_{RETIC} module. 3. Re-review of PowerPoint summary and video. Group B; same 3-step strategy as group A except that the mNY_{RETIC} module was completed at step 3, i.e. immediately before Exercise 3. The reliability of scoring was compared to an expert radiologist (RL) using kappa statistics for positivity of mNY criteria and intraclass correlation coefficients (ICCs) for the grades of the mNY criteria.
Results: The mean agreement for all readers on fulfillment of the mNY criteria with kappa was 0.69 in exercise 1, 0.72 in exercise 2 and 0.83 in exercise 3. Corresponding ICCs for mNY scoring 0-4 were 0.77, 0.77 and 0.82 in exercises 1, 2 and 3, respectively, see Table 1 and Figure 1. For Reader Group A, kappas for exercises 1-3 were 0.65, 0.76 and 0.83, respectively and ICCs 0.71, 0.82 and 0.81 (exercise 3). Interestingly, the main increase in agreement occurred between Exercises 1 and 2, i.e. after the RETIC module was performed. For Reader group B, corresponding kappas were 0.71, 0.77 and 0.83 and ICCs 0.80, 0.72 and 0.80, for exercises 1-3, respectively. Similarly, agreements predominantly improved directly after the RETIC module was performed.
Conclusion: Agreement on scoring radiographs of the SIJ according to the mNY criteria was noticeably improved when using a systematic online calibration module and in general readers achieved very good agreement with experts implying that systematic calibration of readers before scoring of images can enhance scoring proficiency.

POS0919 [18F] POSITRON EMISSION COMPUTED TOMOGRAPHY ([18F] FDG PET/CT) IS ABLE TO PREDICT ULTRASOUND-DEFINED REMISSION IN RHEUMATOID ARTHRITIS

Keywords: Inflammatory arthritides

C. Rinkin[1], C. Florane[1], C. Gérard[1], L. Seidel[1], C. Lamaye[2], R. Hustinx[2], M. Malaise[1], C. Ribbens[1], O. Malaise[1]. *[1]University Hospital of Liège, Rheumatology Department, Liège, Belgium*; *[2]University Hospital of Liège, Nuclear Medicine Department, Liège, Belgium*

Background: Assessing joint inflammation in rheumatoid arthritis (RA) is of high importance because associated with structural damage. In addition to clinical examination and ultrasound (US), joint inflammation can also be quantified by [18F] positron emission computed tomography ([18F] FDG PET/CT). Nowadays, PET/CT is widely used for cancer evaluation and systemic inflammation work-up and it can be used for opportunistic joint evaluation in RA patients. In addition, PET/CT allows a whole-body articular evaluation in one examination. We, and others, have previously demonstrated that PET/CT is significantly correlated with US parameters, but with a weak correlation coefficient.
Objectives: We investigated the ability of PET/CT to predict US-defined remission at the joint level and at the patient level.
Methods: 61 RA patients were included and underwent [18F] FDG PET/CT and US evaluations. For PET/CT, standardized uptake value (SUV) was determined on 22 joints (wrists, PIP and MCP of both hands). At the patient level, the maximum SUV (SUVmax), the number of PET positive joints (SUV>0) and the sum of all SUVs (cumulative SUV) were evaluated. US evaluation included gray-scale and Power Doppler imaging, according to OMERACT.
Results: At the joint level, PET/CT activity (SUV) was significantly different when the joint was under US remission or not (OR 0.411, p<0.0001 with remission defined as "no synovitis grade ≥ 2 with no PDI "). ROC-curves identified SUV thresholds to define joint remission with a high predictive positive value (95.2; confidence interval (CI): 93.8-96.4), but with low negative predictive value (28.9; CI: 21.7-36.8). When wrists, MCP and PIP were evaluated separately, AUC was higher for wrists. Predictive positive value was high for each sub-type (93.4, 94.2, 96.3% respectively). Negative predictive value was low for MCP and PIP (34.0 and 22.2%) but better for wrist (71.4%). At the patient level, SUVmax was significantly different when the patient was under US remission or not (p=0.0023 with remission defined as "no synovitis grade ≥ 2, no PDI, no tenosynovitis"). Cumulative SUV was also different (p=0.045) while there was no difference for the number of PET-positive joints. SUVmax threshold was determined with ROC-curves and demonstrated a high negative predictive value for determining US remission (92.9, CI: 66.1-99.2), while the positive predictive value was lower (67.4, CI: 52.0-80.5). For cumulative SUV threshold, negative and predictive value for determining US-defined remission were 73.1 and 73.5 respectively.
Conclusion: PET/CT is able to predict US-defined remission in RA patients. In addition to its well-known role in cancer evaluation and systemic inflammation work-up, PET/CT is also a promising tool in RA metrology. When considering US remission at the joint level, the predictive positive value is high, while the predictive negative value is better when predicting US remission at the patient level. Among PET/CT parameters, the maximum SUV (SUVmax) and the cumulative SUV exhibit the highest performances to predict US remission.

POS0920 QUANTIFICATION OF TENOSYNOVITIS IN RA FROM WRIST MRIS, BASED ON DEEP LEARNING

Keywords: Artificial intelligence, Rheumatoid arthritis, Imaging

D. Shamonin[1], Y. LI[1], T. Hassanzadeh[1], M. E. Bakker[1], M. Reijnierse[2], A. Van der Helm – van Mil[3], B. Stoel[1]. *[1]Leiden University Medical Center, Division of Image Processing, Department of Radiology, Leiden, Netherlands*; *[2]Leiden University Medical Center, Department of Radiology, Leiden, Netherlands*; *[3]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*

Background: To assess tenosynovitis in wrist MRI scans from patients suspected of developing rheumatoid arthritis (RA), visual scoring (RAMRIS) is usually applied. As this time-consuming and requires rigorous training, we propose a method for the wrist that is based on Deep Learning (DL) combined with post-processing. This method detects all structures (a process called 'segmentation'), including all tendons, and measures inflammation around each tendon (group).
Objectives: To develop a method that automatically segments tendons together with all other anatomical structures of the wrist, and perform automatic tenosynovitis quantification as an alternative to the RAMRIS score.
Methods: Post-contrast axial MR scans of the wrist of 1216 patients with early-onset synovitis from the early arthritis clinic (EAC) cohort were used. From 28 EAC patients, ground truth manual segmentations were obtained as atlases. This dataset contains 33 labels: 14 flexor/extensor tendon groups; 10 carpal, 5 metacarpal bones; 1 label for all main vessels; 2 labels for skin and remaining tissue; and 1 air label. We normalized each input image using the Z-score. For segmentation of the wrist (see Figure 1a), our method utilizes a U-Net. For data augmentations we used intensity scaling (0.8-1.25) and added normally distributed noise (μ= 0, σ=0.06). We used softmax cross-entropy as a loss function, Adam optimization for 200 epochs, with a constant learning rate of 0.001. After 1-fold cross-validation evaluation, we trained on all 28 atlases. For validation we compared the automated tenosynovitis score against the manual RAMRIS score for tenosynovitis. From 10 RAMRIS tenosynovitis scores defined by two clinicians, we computed the mean score (Tμ). To define starting and end MRI slices for the scoring area we followed the RAMRIS definition. Starting from the slice where radius and ulna are closest to each other, ending with the hook of the hamate. The scoring areas were computed 3 mm around tendons, using a Euclidean distance transform, while excluding bones and vessels. Subsequently we computed histograms of the image intensities in the blood vessels and used the 25th percentile point as threshold to define inflamed areas within the scoring area (see Figure 1b). The final tenosynovitis quantification (Tq) was defined as the ratio between the number of 'inflamed pixels' and the total scoring area.

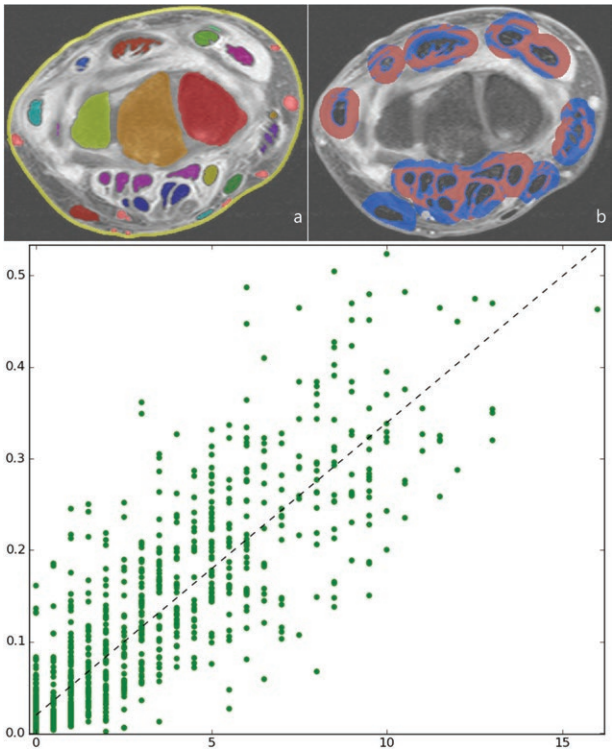

Figure 1. The upper left image shows the result of the segmentations using the U-net, 33 labels for each structure. The upper right image shows the scoring area at 3 mm (in blue), and detected inflamed areas (in pink). The tenosynovitis mean score was Tμ=11.5, the computed quantification value Tq=0.46. The tenosynovitis scores from RAMRIS were: expert 1 (VI:2, V:1, IV:1, III:1, II:2, I:1, 1:0, 2:2, 3:1, 4:1); expert 2 (VI:2, V:1, IV:0, III:1, II:2, I:1, 1:0, 2:2, 3:1, 4:1).

Bottom image: Scatter plot of total quantitative measurements of tenosynovitis versus total visual scores for 1216 patients. Pearson correlation r=0.87, p<0.001. The dashed line represents linear regression fit.

Results: In this work, we presented an alternative automatic quantification of tenosynovitis on MRI of the wrist. The results provide sufficient quantitative measurements compared to RAMRIS visual scores. The quantitative measurement was computed for 1216 patients, with Pearson correlation coefficient r = 0.87 and p < 0.001 (see the scatter plot in Figure 1).

Conclusion: Our DL-method provides a way to automate the quantification of tenosynovitis with MRI. It is very fast (~10 sec per patient) as compared to manual visual scoring. We illustrate the cumulative measurement of all synovial areas, while computing per tendon is also feasible. The accomplished results provide a solid basis for automatic tenosynovitis quantification.

INFLUENCE OF HLA-B27 STATUS ON MR IMAGING FINDINGS IN PATIENTS WITH LOW BACK PAIN

Keywords: Imaging, Gender/diversity issues, Spondyloarthritis

S. T. Ulas[1,2], F. Proft[3], T. Diekhoff[1,2], V. Rios Rodriguez[3], J. Rademacher[2,3], M. Protopopov[3], D. Poddubnyy[3], K. Ziegeler[1]. *[1]Charité - Universitätsmedizin Berlin, Department of Radiology, Charité Campus Mitte, Berlin, Germany*; *[2]Charité - Universitätsmedizin Berlin, Berlin Institute of Health, Berlin, Germany*; *[3]Charité - Universitätsmedizin Berlin, Department of Gastroenterology, Infectious Diseases and Rheumatology, Charité Campus Benjamin Franklin, Berlin, Germany*

Background: The knowledge of factors influencing the susceptibility to and extent of changes at the sacroiliac joints (SIJs) are of great importance in the understanding of pathophysiological processes in axial spondyloarthritis (axSpA)[1]. Recent studies showed that previous delivery and the HLA-B27 status have a special role in the expression of bone marrow edema at the SIJs in the general population. Furthermore, the influence of HLA-B27 differed in men and women[1 2].

Objectives: The aim of this study was to investigate the sex-specific influence of the HLA-B27 status on the SIJ lesions such as ankylosis, erosion, fat metaplasia and bone marrow edema and its distribution and extent in patients with low back pain of non-inflammatory origin.

Methods: In this post-hoc analysis, 139 patients (90 women and 49 men) with low back pain of mechanical/ non-inflammatory origin (after exclusion of axSpA) were included. The MR images of the sacroiliac joints were scored by two trained readers separately for the presence of axSpA features: ankylosis, erosions, sclerosis, fat metaplasia and bone marrow edema. The scoring was performed for the three SIJ regions (ventral/middle/dorsal) differentiated for the sacral and iliac sides. Frequencies of lesions per joint region were compared between HLA-B27 positive and negative individuals using Chi-squared tests. Extent of lesions, expressed as sum scores were compared using T-tests. All analyses were carried out for the entire group and for men and women separately.

Results: A total of 90 women and 49 men were included in this post-hoc-analysis. HLA-B27 was positive in 33/90 women (36.7%), while this was the case in 23/49 men (46.9%) (further clinical data is given in Table 1). There was no difference in frequency of overall occurrence of erosion (22.9% vs. 16.1%; p = 0.392), sclerosis (48.2% vs. 48.2%; p > 0.999), fat metaplasia (12.0% vs. 7.1%; p = 0.403), bone marrow edema (28.9% vs. 32.1%; p = 0.710) and ankylosis (2.4% vs. 3.6%; p > 0.999) between HLA-B27 negative and positive individuals, respectively. A detailed graphical representation of spatial distribution of lesion within the joint is given in Figure 1.

Conclusion: In our cohort of pre-selected patients with chronic low back pain and after exclusion of axSpA, the HLA-B27 status did not determine extent or pattern of imaging lesions in either men or women. These results somewhat contradict previously published data on healthy volunteers. This indicates that further studies are needed especially in the investigation of the sex-specific influence of HLA-B27 status on imaging lesions.

DIFFERENTIAL DIAGNOSIS OF FOCAL IMMUNOGLOBULIN G4-RELATED SIALADENITIS AND BENIGN SALIVARY MASSES: THE VALUE OF CONTRAST-ENHANCED ULTRASOUND

Keywords: Diagnostic tests, Ultrasound

Y. Xin[1], S. Zhang[1], F. Liu[1], J. Zhu[1]. [1]*Peking University People' s Hospital, Department of Ultrasound, Beijing, China*

Background: Immunoglobulin G4 related disease (IgG4-RD) is a newly recognized immune-mediated fibroinflammatory disease characterized by involvement of multiple organs, among which salivary gland is one of the most commonly involved sites. Immunoglobulin G4-related Sialadenitis (IgG4-RS) presents itself as focal or diffuse lesions, of which focal lesions are difficult to differentiate from salivary gland masses [1], especially benign masses with a high clinical incidence. Differential diagnosis of both sets of disorders has significant clinical implications due to different treatment modalities.

Objectives: The aim of this study was to clarify the effectiveness of contrast-enhanced ultrasound (CEUS) in differential diagnosis of focal IgG4-RS and benign salivary masses.

Methods: We retrospectively included 13 patients with diagnosis of focal IgG4-RS according to the Comprehensive Diagnostic Criteria for IgG4-RD (20 foci) and 32 patients with pathologically confirmed benign salivary masses (32 foci). Ultrasonography [grey scale (GS), color Doppler flow imaging (CDFI) and CEUS] of the bilateral parotid and submandibular glands were performed by two experienced radiologists in all patients. We compared the characteristics of ultrasonography and determined the diagnostic value for differentiating between focal IgG4-RS and benign salivary masses.

Results: Of the 13 focal IgG4-RS patients, 7 were female and mean age was 57.46 (± 9.90) years, which was older than that of patients with benign salivary masses (41.03 ± 13.52 years) ($p < 0.001$). Focal IgG4-RS patients were more frequently presented with gland enlargement and elevated serum levels of IgG4 and IgE ($p < 0.001$). These two groups of patients showed localized hypoechoic masses on gray-scale ultrasound, with homogeneous or heterogeneous internal echo, while focal IgG4-RS may have unclear boundaries. CDFI revealed more abundant blood flow signals of patients with IgG4-RS, mostly grade II-III. Compared with benign salivary masses, patients with focal IgG4-RS more often showed iso-enhancement, blurred enhancement margins, whereas unenhanced area was less frequently present. The detail ultrasonography characteristics of patients were compared in Table 1. The AUC of CEUS and conventional ultrasound for differentiating focal IgG4-RS and benign salivary masses were 0.973 and 0.891, respectively, of which CEUS is superior to conventional ultrasound ($p < 0.05$).

Conclusion: CEUS was remarkably effective in differentiating focal IgG4-RS and benign salivary masses, its discriminatory value was superior to conventional ultrasound. The diagnostic accuracy can be more improved by effectively combing clinical data and laboratory findings.

Background: Both active and chronic lesions can be seen on sacroiliac MRI.
Objectives: Aim was to compare the demohraphic and disease characteristics of patients with active and structural lesions on sacroiliac MRI in a bDMARD cohort of Spondyloarthritis (SpA) patients.
Methods: TReasure is a national, multicentre, longitudinal, and observational database, initiated in Turkey in 2017 and now includes 17 centres [1]. 1230/7015 (17.5%) patients with SpA [including Psoriatic arthritis (PsA)] had findings consistent with sacroiliitis on MRI that was recorded by the radiologist at each center for the presence of active and structural lesions. Demographic characteristics of the patients, SpA associated characteristics; dactylitis, enthesitis, uveitis, IBD, SpA family history, hip involvement, hip replacement, sacroiliitis by mNY, syndesmophyte. disease activity during bDMARD initiation; ASDAS-CRP, ASDAS-ESR, BASDAI, ESR, CRP, VAS (physician global, patient global), function and quality of life; BASFI (>40 mm), HAQ-DI (<0.5, 0.5-1.0, >1.0), EQ5D, were assessed and compared between groups with active/ active and structural/structural lesions.
Results: Of 1230 patients with sacroiliac MRI, 548 (44.5%) had only active lesions, 418 (33.9%) had both active and structural lesions, and 264 (21.5%) had only structural lesions. The diagnoses of the patients were r-SpA 833 (67.7%), peripheral SpA 329 (26.7%), nr-SpA 321 (26.1%), enteropathic SpA 79 (6.4%), PsA 64 (5.2%). From `only active lesion` to `only structural lesion` on MRI, age was older, disease duration was longer, meeting mNY criteria and hip involvement was more common, HLA-B27 positivity was more common, syndesmophyte was more common, uveitis was more common, and metrological indices (BASMI and Schober`s test) was worse (Table 1). Multivariate analysis showed factors associated with the development of structural lesions from active lesions, disease duration with OR 1.09 (CI 95% 1.04-1.14), mNY positive sacroiliitis with OR 3.36 (95% CI 1.52-7.40) and uveitis with 3.80 (95% 1.23-11.8).
Conclusion: Transition from active lesions to structural lesions in sacroiliac MRI may be time-related, and chronicity develops in approximately 5 years. As expected, when structural lesions develop on MRI, the rate of meeting the mNY criteria increases around 3 times. There is a relationship between uveitis and the development of structural damage. The relationship of metrological indices with structural damage should also be considered. However, the lack of central reading in MR is a limitation in this assessment.

USEFULNESS OF LOW-DOSE CT IN PSORIASIS AND PSORIATIC ARTHRITIS PATIENTS WITH NON-SPECIFIC AXIAL SYMPTOMS

Keywords: Imaging, Psoriatic arthritis

S. A. Germe[1], G. Ayan[1], S. Dogan[2], B. Yalici-Armagan[2], L. Kılıç[1], U. Kalyoncu[1]. *[1]Hacettepe University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[2]Hacettepe University, Department of Dermatology and Venereology, Ankara, Turkey*

Background: Low-dose CT (ldCT) has been shown advantegous over conventional radiography (CR) in showing spinal structural changes in Axial Spondyloarthritis (AxSpA) [1,2]. There is no data on the value of ldCT in psoriatic arthritis (PsA) patients.
Objectives: The aim of this study is to determine the contribution of spinal ldCT to the diagnosis and disease severity in patients with psoriasis (PsO) and PsA with non-spesific axial symptoms.
Methods: 143 PsO patients referred from the Dermatology Outpatient Clinic in the last 9 months were evaluated; patients with any axial symptoms (116) were included. 47 of 116 patients (40.5%) had ldCT. Patients were evaluated with pelvis CR, lumbar/cervical CR and whole spinal ldCT. Age, gender, PsO and PsA disease duration were recorded. Patients were divided into four groups according to CR findings; 1. Modified New York criteria (mNY) not met, 2. Only sacroiliitis (SI) according to mNY, 3. SI and syndesmophyte (SIN) present, 4. Only SIN (according to the consensus of two rheumatologists UK and LK). All spinal CTs (coronal and sagittal planes) were evaluated by two rheumatologists. Syndesmophytes were determined between C2-S1 and it was also noted if bridging was present (according to the consensus of two rheumatologists UK and GA). The contribution of spinal ldCT to axial involvement was evaluated.
Results: 47 patients (n=15 (32%) with inflammatory, n=32 (68%) non-specific axial symptoms) were evaluated in this study. The mean age of the patients (68.1% female, 31.9% male) was 47.4 years. Median duration of PsO was 15 years. Median disease duration of 10 patients with a previous diagnosis of PsA was 4.5 years. 12 (25.5%) patients had only PsO and 35 (74.5%) patients had PsA. 25/35 (71%) of those with PsA had axial involvement (SI and/or SIN) according to CR, CR was normal in 10/35 (29%) patients (Figure 1). When the whole spinal ldCT was evaluated, SIN was detected in 8/12 (66.7%) of patients with only PsO (8 thoracic, 4 lumbar, 2 cervical). On the other hand, 30/35 (85.7%) of PsA patients had SIN (Figure 1). The distribution of SIN in ldCT is shown in Table

1. Bridging SIN and Andersson lesion were detected in 1/12 (8.3%) and 2/12 (16.7%) of PsO patients versus 17/35 (48.6%) and 8/35 (22.9%) of PsA patients, respectively. In 15/22 (68%) of those with normal CR, 7/9 (77.7%) of those with only SI in CR, 5/5 (100%) of those with SI and SIN in CR, 11/11 (100%) of those with only SIN in CR were found to have syndesmophyte on ldCT. Accordingly, 38/47 (80.8%) patients had at least one syndesmophyte on ldCT (Table 1).

Conclusion: When PsO and PsA patients with non-specific axial symptoms were evaluated with spinal ldCT, new syndesmophytes were found in a significant proportion of patients (2/3 of patients with only PsO), additionally an increased distribution of syndesmophytes was observed. The thoracic vertebra is one of the most frequently involved area in psoriatic disease similar with SpA. Comparative studies with a healthy control group are needed to determine the potential role of ldCT.

POS0925 AUTOMATIC SCORING OF ULTRASOUND SYNOVIAL HYPERTROPHY IN RHEUMATOID ARTHRITIS THROUGH INTEGRATING MULTIPLE CONVOLUTIONAL NEURAL NETWORK MODELS

Keywords: Rheumatoid arthritis, Artificial intelligence, Ultrasound

C. C. Huang[1], P. Huang[1], K. J. Yeo[1], C. J. Chang[2], K. C. Wu[2], W. J. Hong[1], S. H. Chang[1], J. L. Lan[1], D. Y. Chen[1], C. H. Kao[2]. [1]*China Medical University Hospital, Rheumatology and Immunology Center, Taichung, Taiwan, Republic of China*; [2]*China Medical University Hospital, Center of Augmented Intelligence in Healthcare, Taichung, Taiwan, Republic of China*

Background: The OMERACT-EULAR Synovitis Scoring (OESS) system is worldwide used to evaluate arthritis severity on ultrasound (US) images. Because of inter-observer and intra-observer variability, deep learning (DL) has been applied in high-quality image interpretation and analysis. Previous studies mostly focused on Doppler US (DUS) classification by convolutional neural network (CNN), which could provide objective assessment. However, the reports of DL intervention in grey scale (GS) US image automatic measurements are limited.

Objectives: The aim of this study was to develop an integrated multiple CNN model in precise scoring GS US images from rheumatoid arthritis (RA) patients.

Methods: The standard US images from patients of RA were retrospectively selected by three 10-years US experienced rheumatologist together and were graded according to the OESS system. Six different joints data were taken, including proximal interphalangeal, metacarpophalangeal, wrist, elbow, knee and ankle joints. We conducted the DL model integrating three binary CNNs to predict four-class GS US scoring (Figure 1). The accuracy of the trained model was tested by an independent test data.

Results: Total 678 images from 447 patients of RA were used in this study. These images were divided into training (n=611) and testing (n=67) sets. The integrated multiple CNNs model could achieve a four-class accuracy of 77.6%. The individual accuracy of grades 0, 1, 2 and 3 were 68.4%, 77.3%, 73.3% and 100%, respectively (Table 1). Furthermore, we found that adding on anatomic site parameters or labeling areas of interest would establish a better average area under curve (AUC) with 92.6% and 89.0%.

Conclusion: Our study suggests the possibility of using the integrated multiple CNNs model in grading synovial hypertrophy of RA, which is critical in RA healthcare. External validation would be required to confirm the predictive ability of this model.

POS0926 OPTICAL SPECTRAL TRANSMISSION IN THE DIAGNOSIS OF HAND OSTEOARTHRITIS: CLINICAL ASSOCIATIONS AND EVALUATION OF A NEW DIAGNOSTIC ALGORITHM INCLUDING ALL FINGER JOINTS

Keywords: Osteoarthritis, Imaging

K. Triantafyllias[1,2], K. Altamimi[2], S. Gauch[2], A. Schwarting[1]. [1]*Rheumatology Center Rhineland-Palatinate, Rheumatology, Bad Kreuznach, Germany*; [2]*Johannes Gutenberg University Medical Center, Rheumatology and Clinical Immunology, Mainz, Germany*

Background: Optical spectral transmission (OST) is a modern diagnostic technology able to quantify joint inflammation in a non-invasive, rapid and examiner-independent manner [1-3]. The vast majority of studies on OST have been performed in patients with rheumatoid arthritis (RA) [1-3]. No sufficient data on the diagnostic value of OST regarding other arthropathies have been published. However, our study group and others could show that concomitant to RA joint pathologies, such as primary or secondary (post-arthritic) osteoarthritis (OA) could have an influencing effect on OST results [1,4].

Objectives: Aim of this study was therefore to investigate the performance of OST in the diagnosis of OA and to evaluate its ability to identify activated OA changes.

Methods: Patients from two large Rheumatology departments with diagnosed finger and/or wrist OA and without any inflammatory joint disease, as well as healthy controls, were recruited in the context of this study. All study subjects were evaluated via clinical (counts of tender and swollen joints) and OST examinations. Moreover, OA-patients underwent laboratory (C-reactive protein, erythrocyte sedimentation rate) and X-ray examinations of both hands and the extent of osteoarthritic changes was evaluated by an established radiographic score [Kellgren-Lawrence (KL) score]. To evaluate OA activity, joint ultrasound (US) examinations [Grey-scale (GSUS), power Doppler (PDUS) scores] were performed in a subset of patients. Moreover, a new diagnostic algorithm including the distal interphalangeal joints (DIP) was examined next to the established algorithm concerning only wrists, MCP and PIP joints.
Results: *2,134* joints of OA patients [n=97; 80.4%♀; 68 years (58-76, IQR)] and *2,200* joints of healthy controls [n=100; 80%♀; 49 years (33.5-56, IQR)] were examined via OST. OA patients showed statistically significantly higher OST scores compared to control subjects [13.73 (11.19-16.51, IQR) vs. 10.19 (8.05-14.31, IQR); p<0.001] during the evaluation of the algorithm including wrist, MCP and PIP joints. This difference remained significant also after adjusting for age and sex (p=0.033). The novel diagnostic algorithm including additionally DIP joints (next to MCP, PIP and wrists) showed also a statistically significant difference between patients and controls (p<0.001, after adjustment p=0.021). Interestingly, receiver operating characteristics revealed an improved diagnostic performance when including DIP joints in the algorithm [Area under the curve (AUC) 0.718; 95%CI (0.645-0.792) (with DIP) vs AUC 0.698; 95%CI (0.625-0.771) (without DIP)]. OST did not correlate with GSUS/PDUS or KL-Score (all; p>0.05). However, it did correlate moderately-significantly with patient hand-size (without DIPs: rho=0.337; p<0.001; with DIPs: rho=0.363; p< 0.001).
Conclusion: Hereby we could show that presence of OA can indeed influence OST values and that OA changes should be taken into account when interpreting OST results. Moreover, we found that inclusion of DIP joints can lead to an improvement of diagnostic performance of OST. To our knowledge, this the largest study examining the diagnostic value of OST in OA and the first external exploration of this specific DIP-associated algorithm. Value of OST in the follow up examinations of OA patients should be investigated in studies with longitudinal design.

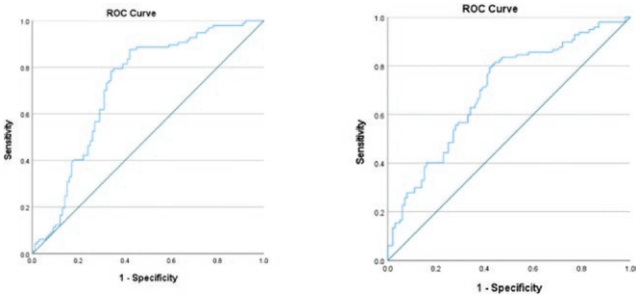

Figure 1. Receiver operating characteristics (patients vs. controls) of two different algorithms: **A.** with DIP joints **B.** without DIP joints.

POS0927 COMBINED BRAIN/HEART MAGNETIC RESONANCE IMAGING REVEALS SUBCLINICAL BRAIN LESIONS IN PATIENTS WITH INFLAMMATORY ARTHRITIDES AND CARDIAC SYMPTOMS

Keywords: Imaging, Inflammatory arthritides, Diagnostic tests

G. Markousis-Mavrogenis[1], A. I. Venetsanopoulou[2], A. Pieta[2], I. Ntalas[3], C. Naka[3], I. Pagounis[3], D. Toliopoulos[3], G. Mouka[3], P. Voulgari[2], S. I. Mavrogeni[1,4,5]. *[1]Onassis Cardiac Surgery Center, Department of Cardiology, Athens, Greece*; *[2]School of Health Sciences, Faculty of Medicine, University of Ioannina, Department of Rheumatology, Ioannina, Greece*; *[3]Iano Epirus, Imaging center, Ioannina, Greece*; *[4]University Research Institute of Maternal and Child Health and Precision Medicine, Medical School, National and Kapodistrian University of Athens, Aghia Sophia Children's Hospital, Athens, Greece*; *[5]Center for Adolescent Medicine and UNESCO Chair in Adolescent Health Care, Medical School, National and Kapodistrian University of Athens, Aghia Sophia Children's Hospital, Athens, Greece*

Background: Inflammatory arthritides (IA) can affect diverse body tissues beyond joints, including the heart [1,2]. Particularly in chronic inflammatory states, circulating immune mediators can also induce central nervous system inflammation [3]. Nevertheless, little is currently known about the consequences of cardiac inflammation on the occurrence of brain lesions in these patients.
Objectives: We hypothesized that patients with IA and cardiac symptoms would show evidence of brain lesions, and that the presence of cardiac inflammation would be associated with the presence of brain lesions. We thus investigated patients with IA and compared them to a cohort of disease-controls using combined brain/heart magnetic resonance imaging (MRI).
Methods: Patients with IA and shortness of breath, chest pain and/or palpitations (n=25) were compared to age-matched disease-controls with non-autoimmune cardiovascular disease (CVD) (n=30) using a 1.5T MRI system. The presence of white matter hyperintensities (WMHs) was investigated in subcortical/deep/periventricular white matter, the basal ganglia, pons, brainstem, or mesial temporal lobe. Cardiac function and inflammation were investigated using standard protocols. Patients with IA were diagnosed with rheumatoid arthritis [14 (56%)], ankylosing spondylitis [5 (20%)], juvenile rheumatoid arthritis [3 (12%)], mixed connective tissue disease [2 (8%)] or enteropathic arthritis [1 (4%)]. Disease controls had various CVDs including coronary artery disease [5 (17%)], myocarditis [5 (17%)], hypertension [3 (10%)], Duchenne muscular dystrophy [3 (10%)], and others.
Results: Patients with IA and disease-controls respectively had a median (IQR) age of 45 (39, 51) vs. 53 (40, 57) years (p=0.269), and 16 (64%) vs. 7 (23%) were women (p=0.002). WMHs were detected in ≥1 brain area in 15 (60%) patients with IA and 15 (54%) disease-controls (p=0.620). The majority of participants had WMHs in subcortical [29 (53%)], periventricular [5 (9%)], or deep WM [11 (20%)]. Some also had cortical lesions [5 (9%)], while basal nuclear, brainstem and mesial temporal lesions were rare [1 (2%) for all]. Amongst subjects with WMHs, the median (IQR) number of brain lesions in patients with IA and disease-controls was 1 (1, 2) for both groups (p=0.635). There were no significant differences in the distribution of brain lesions between groups. Amongst patients with IA, each 0.1-unit increase in cardiac T2-ratio was associated with an increased probability of WMH occurrence [odds ratio (95%): 1.29 (1.05-1.59), p=0.016] and higher cardiac T2-ratio (per 0.1-unit change) and extracellular volume fraction (ECV) were associated with a higher WMH lesion burden in linear regression analysis [Beta (95% confidence interval): 0.08 (0.01-0.15), p=0.021 and 0.22 (0.03-0.41), p=0.027, respectively]. MRI-derived left/right-ventricular ejection fraction, early/late-gadolinium enhancement and T1/T2 mapping were not associated with the presence of WMHs.
Conclusion: In patients with IA and cardiac symptoms, 60% showed evidence of subclinical brain lesions, which was on average as prevalent as in age-matched disease-controls with non-autoimmune CVD. Higher myocardial T2-ratio, an MRI-derived surrogate of myocardial edema, was associated with the presence of WMHs, and higher T2-ratio as well as myocardial ECV values were predictive of higher WMH burden. Further research is required to determine the clinical relevance of these findings.

POS0928 DEEP LEARNING BASED ASSESSMENT OF SALIVARY GLAND ULTRASONOGRAPHY IMAGES FOR SUPPORTING THE DIAGNOSIS OF PRIMARY SJOGREN'S SYNDROME

Keywords: Artificial intelligence, Sjögren syndrome, Ultrasound

Y. Geng[1,1,1,1], X. Zhang[2,2,2,2], Z. Zhang[1,1,2]. *[1]Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China*; *[2]Peking University First Hospital, Department of Radiology, Beijing, China*

Background: Salivary gland ultrasound (SGUS) has proven to be a promising tool for diagnosing primary Sjögren's syndrome (pSS). However, the widespread use of it as standardized diagnostic tools is limited by inter/intra operator variability.

Objectives: The aim of this study was to evaluate the utility of deep learning-based SGUS image assessment in the diagnosis of pSS.
Methods: Between Sep 2021 and Oct 2022, 1133 SGUS images of 137 patients from one center were included in this retrospective study. Among them, 61 patients with 480 images were diagnosed as pSS and 76 patients with 653 images were non-SS. All the SGUS image data were randomly divided into training dataset (50%), validation dataset (20%) and testing dataset (30%). The SGUS automatic classification model was developed by using a deep residual convolutional network architecture (RESNET). The predictive performance was validated by sensitivity, specifcity and area under reciver operating characteristic curve (ROC).
Results: When applying deep learning-based SGUS image assessment, it showed better performance than operator based SGUS score system by improving the specifcity (86.9% vs. 80.1%), while similar sensitivity (59.4% vs. 61.4%). The area under the ROC were comparable between them (0.800 vs 0.775).
Conclusion: Deep learning-based SGUS image assessment maybe an objective and promising tool compared to expert-based scoring of SGUS in the diagnosis of pSS. This may support SGUS as an effective and prospective diagnostic tool to supplement current diagnostic methods.

POS0929 VALUE OF LUNG ULTRASOUND FOR THE DETECTION OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Lungs, Ultrasound

R. Tanten[1], J. Marin2, J. Zacariaz2, J. Maritano[3], M. Fullana4, R. N. Alvarado5, J. Rosa5. [1]*Hospital Italiano de Buenos Aires, Sección Reumatologia, Buenos Aires, Argentina*; [1]*Hospital Italiano de Buenos Aires, Sección Reumatologia, Buenos Aires, Argentina*; [3]*Hospital Italiano de Buenos Aires, Sección Neumonología, Buenos Aires, Argentina*; [3]*Hospital Italiano de Buenos Aires, Sección Neumonología, Buenos Aires, Argentina*; [1]*Hospital Italiano de Buenos Aires, Sección Reumatologia, Buenos Aires, Argentina*

Background: Interstitial lung disease (ILD) is an extra-articular manifestation of rheumatoid arthritis (RA) associated with increased morbidity and mortality. High-resolution computed tomography (HRCT) is the gold standard for ILD diagnosis, but it has high cost and risk of ionizing radiation. Lung Ultrasound (LUS) is a non-invasive, low-cost, non-ionizing and easily performed diagnostic tool.
Objectives: To establish the diagnostic value of LUS in ILD in patients with RA, using chest HRCT as the gold standard.
Methods: A cross-sectional study was performed at the Hospital Italiano de Buenos Aires, Argentina. Consecutive patients with RA (ACR/EULAR-2010 criteria), who had a chest HRCT performed at least 12 months previous to inclusion.Demographic, clinical, laboratory and therapeutic data were recorded. Each patient underwent a LUS with a simplified examination (14 bilateral lung intercostal spaces -LIS-), with assessment of B-lines (BL) and pleural irregularities (PI). Additionally, a 6MWT was performed on each patient. For the diagnosis of ILD, HRCT was the gold-standard, taking as a threshold an extension of interstitial involvement ≥10%, scored by an expert lung specialist. ROC curves were made to test the ability of LUS findings (BL and PI), and 6 MWT, to discriminate patients with ILD.
Results: A total of 104 RA patients were included, 21,8 % with ILD, 82.7% (95% CI 74.0-89.4) were women, with a median age at diagnosis of RA of 57.5 years (IQR 47.3 -67.2) and a median disease duration of 8.7 years (IQR 3.3-15.8). 96.2% of patients (95% CI 90.5-98.9) were seropositive for rheumatoid factor (RF) and/or anti-citrullinated protein antibodies (ACPA), and median DAS28-ESR was 3.19 (IQR 2.6-4.6). Methotrexate had been used at some point of the disease in 94.2% patients (95% CI 87.9-97.8), and 46.2% (95% CI 36.3-56.2) were under bDMARD or tsDMARD treatment at inclusion. Patients with ILD were older at the time of RA diagnosis (64 vs 54 years, p=0.002) and had higher erythrocyte sedimentation rate (ERS) and C-reactive protein (CRP) (48 vs 29 mm/h and 5.9 vs 3 g/L p=0.002) than patients without ILD. In LUS, patients with ILD had more BL (median 26 vs. 1, p <0.001), (Figure 1) and PI (median 12 vs. 4, p <0.001) than patients without ILD.The diagnostic accuracy in ROC curves was: AUC 0.88 - 95% CI 0.78-0.93 for BL and AUC 0.82 - 95% CI 0.74-0.89 for PI (Figure 3 and 4). The best cut-off point for ILD detection was 8 BL and 7 PI.The performance of LUS was more sensitive than 6 MWT (Table 1).
Conclusion: The presence of 8 BL and/or 7 PI in the LUS showed an adequate diagnostic performance for ILD, with a good negative prognostic value.

Table 1. Diagnostic performance of LUS and 6MWT for the detection of ILD

Test	Sensitivity	Specificity	LLR positive	LLR negative	Positive Prognostic Value	Negative Prognostic Value	AUC
	80,95%	79,52%	3,95	0,24	50	94,30	0,88 (0,78-0,93)
Pleural irregularities (≥7 spaces)	80,95%	75,90%	3,36	0,25	45,95	94,03	0,82 (0,74-0,89)
6MWT	36,84%	92,31%	4,70	0,68	53,85	85,71	-

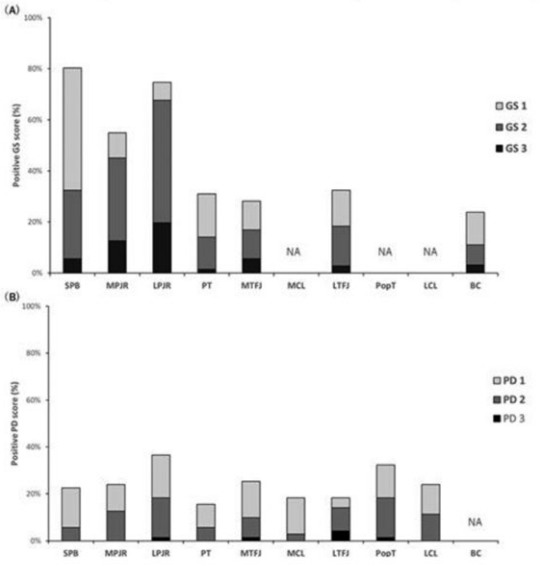
POS0930 SUBCLINICAL SYNOVITIS OF THE KNEE REMAINED IN ONE-THIRD OF CASES IN PATIENTS WITH RHEUMATOID ARTHRITIS AFTER TOTAL KNEE ARTHROPLASTY: MUSCULOSKELETAL ULTRASONOGRAPHY STUDY

Keywords: Rheumatoid arthritis, Ultrasound



Y. Miyoshi[1], E. Takamasu[1], R. Takada[2], Y. Nagase[2]. [1]*Tokyo Metropolitan Tama Medical Center, Department of Rheumatic Diseases, Tokyo, Japan*; [2]*Tokyo Metropolitan Tama Medical Center, Department of Rheumatic Surgery, Tokyo, Japan*

Background: There is no report investigating the prevalence, sites, and risk factors of knee synovitis in patients with rheumatoid arthritis (RA) after total knee arthroplasty (TKA).
Objectives: This study aimed to clarify the prevalence, anatomical distribution, and risk factors of knee synovitis in RA patients after TKA.
Methods: This study was a retrospective cross-sectional study. Subjects were patients who met the 2010 ACR/EULAR RA classification criteria and underwent TKA at Tokyo Metropolitan Tama General Medical Center. Knee joints on surgically treated sides were assessed by musculoskeletal ultrasonography (MSUS) from April 1, 2020, to March 31, 2022. Knee US-synovitis was defined as the presence of PD 2 or higher at joint synovium (suprapatellar bursa, medial/lateral parapatellar joint recess, medial/lateral tibiofemoral joint space).
Results: Forty-five patients with RA after TKA underwent MSUS, with a total of 71 knee joints (38 right, 33 left). Patient background: age (years) 74.4±10.0, female(%) 84%, disease duration (years) 20.6±10.4, TKA postoperative period (years) 5.7±4.0, ACPA positivity 77%, RF positivity 79%, DAS28(ESR) 3.17±1.03, mHAQ 0.8±0.8, PSL users 44%, MTX users 64%, csDMARDs users 87%, BioDMARDs users 44%, tsDMARDs users 0%, Knee injury and Osteoarthritis Outcome Score-pain (KOOS-P) 82.5±17.2. The number of joints with GS 2 or higher

was more prevalent than that with PD 2 or higher (Figure 1). The number of post-TKA knee joints with PD 2 or higher was 18 (25.3%) out of 71. The knee joints assessed within one year from TKA were more likely to have joint synovitis detected by MSUS than those over one year (5 joints (62.5%) vs 13 (20.6%)). Fifteen (33.3%) patients had US-synovitis at post-TKA knee joints. There was no difference in disease activity scores (DAS28-CRP, DAS28-ESR, SDAI, CDAI), patient pain Visual Analogue Scale, or KOOS-P in patients with knee US-synovitis (n=15) compared with those without knee US-synovitis (n=30). There was no significant correlation between PD grades and KOOS-P (p=0.73).

Conclusion: Subclinical US-synovitis of the knee still remained in one-third of cases in patients with RA after TKA. US-synovitis at post-TKA knee joints did not correlate with knee pain scores. The knee prosthesis would have a protective effect on synovitis-induced pain at post-TKA knee joints in RA.

Fig.1 Prevalence of positive US scores at each site on the post-TKA knee joint of RA patients.

Shown are the frequencies of positive GS scores (A) and power Doppler scores (B) at each site on the post-TKA knee joint of RA patients. SPB: suprapatellar bursa; MPJR: medial parapatellar joint recess; LPJR: lateral parapatellar joint recess; PT: patellar tendon; MTFJ: medial tibiofemoral joint space; MCL: medial collateral ligament; LTFJ: lateral tibiofemoral joint space; PopT: popliteal tendon; LCL: lateral collateral ligament; BC: Baker's cyst, NA; not applicable.

POS0931 USEFULNESS OF MUSCULOSKELETAL ULTRASOUND IN CLINICAL DECISION-MAKING IN RHEUMATOLOGY CLINICAL PRACTICE

Keywords: Ultrasound, Descriptive studies, Work-related issues

M. Serrano Warleta[1], A. Palomeque Vargas[1], R. Manzo[1], C. Guillén-Astete[1].
[1]Ramon y Cajal University Hospital, Rheumatology, Madrid, Spain

Background: Ultrasound (US) has proven to be a useful technique in the routine clinical practice of rheumatologists. Due to its low cost, accessibility, and the large amount of information it provides us, more and more ultrasound studies tend to be carried out. However, we wonder about the real clinical-ultrasound correlation and whether, after a given result, the clinician made decisions based on said result.

Objectives: To describe the reason for request of the sonographic studies in our department and the effect of its result in the decision-making in the clinical practice.

Methods: Cross-sectional, observational analytical study. We enrolled all the patients that were cited in the ultrasonography agenda from march to august 2022. Variables for identification of request-exploration-review management times, motivation for the request, topography of the exploration performed, correlation with clinical suspicion and effect on decision-making were collected. Data extraction was performed by four different observers. Quality control was performed by a fifth observer.

Results: Records of 462 medical actions were included in the US agenda over 6 months. Including double requests (211 were bilateral scans), the results of 673 US scans performed were reviewed. Of the requests made, 118 (25.5%) were from patients with known diagnoses of inflammatory diseases. The attached Table 1 summarizes the reasons for the request and topography of the exploration of the studies carried out. The waiting time and standard deviation (SD) until the test was performed from its request was 85.4 SD 54.3 days (0;574) and until the reassessment in the office was 37.5 SD 43.4 days (0;217). The diagnostic correlation of US and clinical suspicion was confirmed in 277 studies (59.2%), it was not demonstrated in 161 (34.4%) and did not apply in the rest. The frequency of bilateral studies whose result could have been obtained with a unilateral exploration was 37/211 (17.5%). In 72 studies we could not determine to what extent US examination changed clinical decision (review query not available or not applicable). In 132 studies (33.8%) the clinician intensified the treatment, in 40 (10.2%) the clinician de-intensified the treatment, and in 63 (16.1%) the clinician indicated the discharge of the patient. Among those cases in which US modified the clinical decision, the time between test-requesting and decision-making was 120.1 SD 64.3 days, while in cases in which there was no effect on the clinical decision it was 160.9 SD 61.3. (p=.0031). Evaluating only the US scans indicated in inflammatory pathology, the times were 66.5 DE 32.5 and 84.3 DE 29.5 days, respectively (p=.0012).

Conclusion: Our study is limited to identifying bivariate associations between decision making and the result of a complementary test. The authors recognize that clinical decisions are made considering all available information, including those from specific complementary test. US proves to be a useful test in clinical decision-making and presumably more so the less time elapses between its request and its interpretation. In addition, performing bilateral US scans seems justified as less than a fifth of the requests would have given the same result with a unilateral scan.

Table 1. Topography of the explorations and reason of the ultrasound request

Topography	Bilaterality	Reason of the ultrasound request				
		Diagnostic uncertainty	Activity assessment	Ultrasound-guided procedure	Diagnostic + Procedure	Activity assessment + Procedure
Hand (50%)	Unilateral	45	15	9	24	8
	Bilateral	75	48	-	8	2

POS0932 ULTRASOUND-DEFINED GRADE I SYNOVITIS IN PATIENTS WITH INFLAMMATORY-SUSPECTED ARTHRALGIA AND ITS ROLE IN DIAGNOSIS A YEAR LATER

Keywords: Ultrasound, Inflammatory arthritides, Diagnostic tests

A. M. Ruiz Bejerano[1], A. Corral Bote[1], J. Arroyo Palomo[1], B. A. Blanco Cáceres[1]. *[1]Hospital Universitario Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: Musculoeskeletal ultrasound is frequently used in several rheumatology units to detect subclinical inflammation in patients with joint symptoms suspected for progression to inflammatory arthritis.

Objectives: The main goal is to investigate the correlation between synovitis grade I (EULAR-OMERACT combined score) and the diagnosis of established inflammatory arthropathy that is carried out after a follow-up period of one year since the first ultrasound findings. The assessment is done in an ultrasound-specialized unit of a Rheumatology Department

Methods: We conducted a descriptive, retrospective and unicentric study where 135 patients were selected from the ultrasound-specialized unit of our rheumatology department from July 2018 to December 2021. Patients that presented synovitis grade 0,2 and/or 3 on combined score were excluded. Collected baseline data included age, sex, immunological profile, acute phase reactants and physical examination previous to the ultrasound findings, as well as the

diagnosis made by the rheumatologist a year after said findings. To achieve that, the patients are divided into two groups: those who were diagnosed with inflammatory arthropathy and those who were not. In addition, non-parametric statistical tests for comparing means were used.

Results: The mean age was 55 years and 75% of the patients were females. At the beginning, clinical examination revealed a median of one tender joints and none swollen. Previous diagnosis of psoriasis was present in 18 (13,3%) patients while inflammatory bowel disease was present in 6 patients (4,4%). Of the 135 patients, after a year follow-up, 46 (34,1%) received the diagnosis of inflammatory arthropaty after a follow-up of one year: 15 (32,6%) psoriatic arthritis, 8 (17,4%) rheumatoid arthritis, 8 (17,4%) undifferentiated arthritis, 4 (8,7%) spondyloarthritis, 4 (8,7%) calcium pyrophosphate dehydrate crystal-related joint disease, 3 (6,5%) reactive arthritis, 2 (4,3%) systemic sclerosis, 1 (2,2%) Sjögren syndrome and 1 (2,2%) polymyalgia rheumatica. Non-inflammatory arthropathies were also found 89 (65,9%), of which 64 (71,9%) were osteoarthritis, 20 (22,5%) Carpal tunnel syndrome and 5 (5,6%) had other soft tissue disease. In the group of patients who did not developed an autoimmune arthropathy, 3 were Rheumatoid factor-positive and 10 were AAN-positive, none of them were aCCP- positive; The HLA B-27 and Cw6 test resulted in 5 patients testing positive in HLA-B27 and none in Cw6. Among the group of patients that developed an inflammatory arthropathy the median of joints with ultrasound involvement was 2. Grade I power Doppler signal was detected in one case. 7 (15,2%) patients were RF- positive, and 6 (13%) aCCP-positive. AANs were positive in 13 cases (28,3%). There were no significant differences for clinical variables and acute phase reactants (Age, sex, SJC, TJC, RCP, ESR) between both groups. Comparing the immunological profile through a Fisher's exact test, we obtained a statistically significant association for RF (p=0,033), aCCP (p=0,001) and AAN (p=0,014) in the group who finally received the diagnosis of inflammatory arthropathy. No other significant differences were found (Total joints GSUS, total joints PDUS, HLA B27 and HLA Cw6)

Conclusion: Despite the limitations and possible statistical bias that might appear in a retrospective study, there are a remarkable number of patients with ultrasound-defined grade I synovitis who develop inflammatory arthropaty a year later. Rheumatoid factor, aCCP and AAN positivity were the only factors statistically associated with progression.

POS0933 NAILFOLD VIDEOCAPILLAROSCOPY AS A POSSIBLE BIOMARKER TO DETECT ABERRANT PLACENTAL MICROCIRCULATION IN PREGNANT WOMEN: A PILOT STUDY

Keywords: Pregnancy and reproduction, Biomarkers, Imaging

C. Schenone[1], G. Pacini[1], E. Hysa[1], S. Sammori[1], C. Pizzorni[1], S. Paolino[1], A. Sulli[1], I. Schiavetti[2], A. Ferraiolo[3], V. G. Vellone[4], V. Smith[5], M. Cutolo[1].

[1]Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties, University of Genova, IRCCS San Martino Polyclinic Hospital, Genova, Italy; *[2]Biostatistics Unit, Department of Health Sciences, University of Genova, Genova, Italy*; *[3]Unit of Obstetrics and Gynaecology, IRCCS Ospedale Policlinico San Martino, Genova, Italy*; *[4]Unit of Pathological Anatomy, Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) Istituto Giannina Gaslini, Genova, Italy*; *[5]Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Centre (IRC), Department of Internal Medicine, Ghent University, Department of Rheumatology, Ghent University Hospital, Ghent, Belgium*

Background: During pregnancy, exchanges between mother and fetus are provided by the placenta. Defects in the early stages of placentation prevent the creation of a high-flow, low-resistance circle resulting in an impaired maternal-fetal exchange. The development of aberrant microcirculation leads to placental abnormalities, detectable by placental histologic examination [1].

Objectives: To assess whether nailfold videocapillaroscopy (NVC), in combination with umbilical artery doppler ultrasound (UA-dU), can detect microvascular status during pregnancy [2]; and to evaluate if NVC follow-up during pregnancy might operate as a red flag biomarker of placental microcirculation abnormalities.

Methods: We conducted a longitudinal observational exploratory study on 54 healthy pregnant women (age range 26-46 y) within the 16th gestational week, excluding those with cardiovascular comorbidities. We performed clinical, UA-dU and NVC evaluation with an optical probe (200x magnification) at each trimester of pregnancy and post-partum [3]. We performed an after-birth placenta histology (abPH) in a subgroup of 20 women (among the 54 women) who developed complications during pregnancy (e.g., gestational hypertension) evaluated through optical microscopic technique, according to Amsterdam criteria [4].

Results: We noticed over time, in the whole cohort, a statistically significant increase in neo-angiogenesis ($p<0.05$), considering the absolute count of microvessel ramifications (abnormal shapes) (**Figure 1a**). Conversely, we did not observe any statistically significant variation in capillary density (n/linear mm), microhaemorrhages or dilated capillaries over time. Besides, a statistically significant difference in the absolute number of capillaries in the first trimester between subjects with and without areas of placental dysmaturity (aberrant placental microcirculation) was detected at abPH (7.0/mm ± 0.82 vs 8.2/mm ± 0.62; $p=0.030$), (**Figure 1b**). A receiver operating characteristic curve was drawn for calculating the Area Under the Curve (AUC: 0.87; 95%CI: 0.66–1.00), identifying the optimal discriminatory cut-off value for prediction of placental dysmaturity areas (≤7.50/mm capillaries, sensitivity: 88.9%; specificity: 75.0%). Of note, a similar difference was confirmed at the third trimester, although not reaching statistical significance ($p=0.06$). Not any significant association was found between UA-dU and any of the assessed NVC parameters.

Conclusion: This study confirms, in a large cohort of pregnant women, the NVC detection of increased neoangiogenesis over time, even during post-partum. In addition, this is the first report suggesting the possible role of NVC (capillary density) for the early detection of aberrant placental microcirculation noticeable at abPH. A study in pregnant patients affected by autoimmune connective tissue diseases has already started, using those findings as reference parameters.

Epidemiology, risk factors for disease or disease progression

POS0934

PREVALENCE AND TRENDS OF PULMONARY HYPERTENSION IN AUTOIMMUNE DISEASES

Keywords: Lungs, Comorbidities, Epidemiology

P. Khandwala[1], D. Desai[2], M. Sen[1]. [1]*Einstein Medical Center Philadelphia, Rheumatology, Philadelphia, United States of America*; [2]*Einstein Medical Center Philadelphia, Hospice and Palliative Medicine, Philadelphia, United States of America*

Background: Pulmonary hypertension (PHTN) is a known complication of connective tissue diseases such as Systemic lupus erythematosus (SLE), Scleroderma (Scl), and Mixed connective tissue disease (MCTD).[1] The underlying mechanism for development of PHTN is remodeling and vasoconstriction of pulmonary arteries and arterioles.[2] There have been cases of severe PHTN in SLE patients that have shown improvement with immunosuppressive therapy, hence accentuating the role of inflammation in pathogenesis.[3] The Prevalence of PHTN is not well studied, and there are no large cohort studies available. This study was undertaken to capture the trend in the prevalence of PHTN in the aforementioned diseases.

Objectives: To determine the prevalence of PHTN in SLE, Scl, and MCTD, analyze the trend over a 15-year period as well as identify racial predisposition, length of stay (LOS), and cost of hospitalization in these patients.

Methods: We used the Nationwide Inpatient Sample database (years 2003-2018) and extracted patients with PHTN using validated International Classification of Disease (ICD) codes. Data from 2015 was excluded from the study considering the transition of the coding system from version 9 to 10. We identified cases having the diagnosis of SLE, Scl, and MCTD. Prevalence, as well as demographics, cost of hospitalization, and length of stay (LOS), were analyzed and charted. Data were analyzed using statistical analysis system 9.4 software.

Results: Over the period of 15 years, we identified 2,155,750 cases of PHTN. As seen in the graph, patients with SLE had the highest prevalence of PHTN. The prevalence rate of SLE in PHTN cases in 2003 was 0.92% which significantly increased to 1.05% in 2018, with a peak of 1.15% seen in 2014 (p <0.0001). Prevalence rate of Scl in PHTN decreased from 1.07% in 2003 to 0.80% in 2018 (p< 0.0001). It was seen that the prevalence rate of MCTD in cases with PHTN significantly increased from 0.06% in 2003 to 0.23% in 2018, (p<0.0001). It was observed that the average age of PHTN cases was significantly younger in SLE (55.60 vs 70.80 years, p <0.0001), Scl (62.94 vs 70.72 years, p < 0.0001), and MCTD (58.49 vs 70.66 years, p <0.0001). On examining the racial distribution, African Americans, Hispanics, and Native Americans were more likely to have underlying SLE, Scl, and MCTD, respectively. PHTN was more prevalent in females in all 3 diseases. The average cost of hospitalization was significantly higher in PHTN cases with MCTD ($76,696.7 vs $65,643.3, p<0.0001) and SLE ($69,106.5 vs $65,620.6, p<0.0001), while it was not significantly lower in PHTN cases with Scl ($65,272.9 vs $65,659.9, p = 0.65). Average LOS was significantly longer in PHTN with MCTD (7.02 vs 6.64 days, p = 0.0119). Though not significant, average LOS was longer in PHTN with SLE (6.73 vs 6.64 days, p = 0.0812) and shorter in PHTN with Scl (6.62 vs 6.64 days, p = 0.7917).

Conclusion: Improved survival, seen secondary to increased awareness, better diagnostic testing, multidisciplinary team approach, and newer treatment modalities has led to an increase in the prevalence of patients living with PHTN. Interestingly, our study shows that the prevalence of PHTN in SLE and MCTD is increasing while decreasing for Scl. Racial predisposition becomes evident, which demands a higher index of suspicion for the early diagnosis of PHTN in the respective races. There is a higher socioeconomic burden for patients with PHTN and autoimmune disease, as reflected by the increased LOS and cost of hospitalization.

THE COURSE OF CYTOKINE AND CHEMOKINE GENE EXPRESSION IN CLINICALLY SUSPECT ARTHRALGIA PATIENTS DURING PROGRESSION TO INFLAMMATORY ARTHRITIS

Keywords: Rheumatoid arthritis, Cytokines and chemokines

J. Heutz[1], C. Rogier[1], E. Niemantsverdriet[2], S. Van den Eeden[3], P. De Jong[1], E. Lubberts[1], A. Geluk[3], A. Van der Helm – van Mil[1,2]. [1]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*; [2]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [3]*Leiden University Medical Center (LUMC), Infectious Diseases, Leiden, Netherlands*

Background: Autoantibody-responses rise years before onset of inflammatory arthritis (IA) and are stable during transitioning from clinically suspect arthralgia (CSA) to IA. Cytokine and chemokine levels also rise years before IA-onset. However, the course in the at-risk stage of CSA during progression to disease or non-progression is unknown.

Objectives: To increase the understanding of processes mediating disease development, we studied the course of cytokine, chemokine and related receptors gene expression in CSA-patients during progression to IA, and in CSA-patients who ultimately did not develop IA.

Methods: Whole-blood RNA-expression of 37 inflammatory cytokines/chemokines/related receptors was determined by dual-colour reverse-transcription multiplex ligation-dependent probe amplification, in paired samples of CSA-patients at CSA-onset and either at IA-development or after 24-months without IA-development. ACPA-positive and ACPA-negative CSA-patients developing IA were compared at CSA-onset and during progression to IA. GEE-models tested changes over time. A false discovery rate approach was applied.

Results: None of the cytokines/chemokine genes significantly changed in expression between CSA-onset and IA-development (Figure 1A). In CSA-patients without IA-development, G-CSF expression decreased (p=0.001), whereas CCR6 and TNIP expression increased (p<0.001 and p=0.002, respectively) over a 2-year period (Figure 1B). Expression levels in ACPA-positive and ACPA-negative CSA-patients who developed IA were similar.

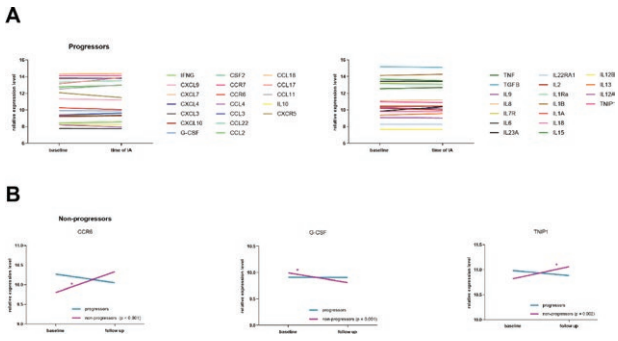

Figure 1. (A) Modelled course of gene expression of 37 cytokines/chemokines/related receptors in CSA-patients that progressed to IA. Cytokines, chemokines and related receptors were measured at baseline and at time of IA-development and for reasons of clarity presented in two plots. No statistically significant changes were observed during follow-up. (B) Modelled course of gene expression of CCR6, G-CSF and TNIP1 in CSA-patients that did not progress to IA. Cytokines, chemokines and related receptors were measured in paired samples from each patient with 2-year intervals. For comparison, the course of patients that progressed to IA was included, here the 2nd samples was collected at IA-development. CSA, clinically suspect arthralgia; IA, inflammatory arthritis.

Conclusion: Whole-blood gene expression of assessed cytokines/chemokines/related receptors did not change significantly from CSA to IA-development. This suggests that changes in expression of these molecules may not be related to the final process of developing chronicity and may have occurred preceding CSA-onset. Changes in gene expression in CSA-patients without IA-development may provide clues for processes related to resolution.

POS0936 TUMOUR NECROSIS FACTOR INHIBITORS USE AND DISCONTINUATION AMONG PREGNANT WOMEN WITH CHRONIC INFLAMMATORY DISEASES

Keywords: Pregnancy and reproduction, bDMARD, Descriptive studies

L. K. Flatman[1,2], S. Bernatsky[1,2,3,4], I. Malhamé[2,3,5], Y. St-Pierre[2], O. Basso[1,6], A. Berard[7,8,9], E. Vinet[1,2,3,4]. Background: Previous guidelines (2006) recommended that tumour necrosis factor inhibitors (TNFi) be discontinued during pregnancy. Despite new guidelines (2016 & 2020) now recommending against this, the choice to stop TNFi pre-conception is patient- and provider-dependent. Observational studies have evaluated use of disease-modifying anti-rheumatic drugs (DMARDs) during pregnancy, but few have specifically assessed TNFi discontinuation pre-conception. Understanding trends and predictors of TNFi discontinuation pre-conception may help inform initiatives to improve care and optimize maternal and fetal outcomes.

Objectives: We examined trends in TNFi discontinuation pre-conception over time, and evaluated the characteristics of pregnant women with chronic inflammatory diseases who stopped using TNFi pre-conception (without resuming in pregnancy) compared with those who used TNFi at any time during pregnancy.

Methods: We created a cohort of pregnant women with rheumatoid arthritis (RA), ankylosing spondylitis, psoriatic arthritis (PsA), psoriasis (PsO), and/or inflammatory bowel diseases (IBD) who delivered between 2011 and 2019, using the MarketScan commercial database. TNFi use was defined as at least 1 filled prescription or infusion procedure claim, categorized according to the timing of the filled prescription or infusion procedure date in relation to the gestational period: 1) TNFi pre-conception only (i.e. at least 1 prescription filled or infusion procedure claim in the 12 weeks preceding the gestational period but none within the gestational period) or 2) TNFi use at any time during pregnancy (i.e. any prescription filled or infusion procedure claim during the gestational period, including restarts, new starts, and those continuing from pre-conception).

Results: We identified 3,372 pregnancies; 13% discontinued TNFi in the 12 weeks before conception and did not restart, and 86% were exposed to TNFi during pregnancy. Pregnancies in IBD patients accounted for 47% of all pregnancies. Nearly all pregnancies with IBD were exposed to TNFi during pregnancy (95%). Compared to those with IBD, more patients with RA (difference of 18%, 95% CI 15-21%) and PsA/PsO (20%, 95% CI 16-24%) discontinued their TNFi. Corticosteroid use was similar in both TNFi exposure groups, while patients who took TNFi during pregnancy were more likely to use non-biologic DMARDs concomitantly. Over time, a lower proportion of patients stopped TNFi pre-conception (2011-2013 19% vs 2014-2016 13% vs 2017-2019 10%; p-value for trend <0.0001).

Conclusion: In our sample, 13% discontinued TNFi in the 12 weeks before conception and did not restart. The proportion of patients stopping TNFi pre-conception between 2017-2019 decreased compared to earlier years, possibly reflecting updated guidelines. Further research on TNFi discontinuation in the years after the 2020 ACR guidelines is warranted.

Table 1. Characteristics of pregnant women with chronic inflammatory diseases who stopped TNFi pre-conception and those who took TNFi at any time during gestation (n=3,372).

POS0937 FACTORS ASSOCIATED WITH HOSPITAL ADMISSIONS DUE TO OPIOID-RELATED HARMS IN PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES

Keywords: Osteoarthritis, Fibromyalgia, Prognostic factors

C. Ramirez Medina[1], D. Jenkins[2], N. Peek[2,3], B. Birlie Yimer[1], J. Y. T. Huang[1], M. Lunt[1], W. Dixon[1,3], M. Jani[1,3]. [1]*University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom*; [2]*The University of Manchester, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom*; [3]*NIHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom*

Background: Hospital admissions due to opioid-related toxicity have doubled in the United Kingdom over the last decade. Rheumatic and musculoskeletal diseases (RMDs) are some of the most common indications for prescribing opioids in primary care. Little is known about what individual factors are associated with serious opioid-related harms in this population. A better understanding of these risks is imperative for safe prescribing of opioids in patients with RMDs.

Objectives: To assess patient factors associated with opioid-related hospitalisations in new opioid users with the following RMDs: rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA), systemic lupus erythematosus (SLE), osteoarthritis (OA), and fibromyalgia.

Methods: This retrospective cohort study evaluated new adult opioid users without cancer between 01-Jan-2006 and 31-Aug-2021 using data from the Clinical Practice Research Datalink Aurum diagnosed with one or more of the six RMDs. Patient-level data were linked to Hospital Episodes Statistics (HES). The main outcome of opioid-related hospitalisations within five years of first opioid prescription, were defined using ICD-10 codes from HES. Logistic regression and random forest classification were used to assess patient characteristics associated with opioid-related hospitalisations. To identify the most relevant variables we used "Boruta" feature selection, a wrapper algorithm built around the random forest classifier that compares the importance of the real predictor variables with those of permuted copies of the original features using statistical testing and several iterations of random forests. Feature importance is ranked by the Boruta algorithm using mean Z-scores (the number of standard deviations from the mean a data point

is). The higher the Boruta importance score, the stronger the impact the particular input variable has on the outcome variable.
Results: The cohort comprised 1,329,698 new opioid users (801,533 women [60.3%]; 992,542 White patients [88.2%]), with a mean age of 60 years [SD 17]. The proportion patients with different RMDs in order of frequency were OA: 1,246,574 (93.7%); RA, 50,000 (3.8%)], fibromyalgia [47,708, 3.6%], PsA [11,181 (0.8%)], SLE [6,757 (0.5%)] and AS [6,560 (0.5%). Of our study population, 4,016 individuals (0.3%) experienced a hospitalization for opioid-related harms within our follow-up period of five years after first prescription date. Logistic regression and random forest models showed consistent results when ranking the most important variables associated to opioid-related hospital admissions. The main risk factor identified consistently across both methods was history of alcohol excess, with an odds ratio (OR) of 10.7, 95% confidence interval (95% CI): 8.1–14.2 and Boruta Importance (Imp) of 93.6. Other main risk factors included history of attempted suicide and self-harm (OR 7.5, 95% CI: 5.6–9.9, Imp: 80.3), major depression (OR 2.0, 95% CI: 1.7–2.3, Imp: 39.7) and lower socioeconomic status (OR: 10.4, 95% CI: 4.6–23.4, Imp: 34.0).
Conclusion: Patients with a documented history of alcohol excess, severe psychological problems and those most socioeconomically deprived were found to have a higher risk of opioid-related hospitalisations. Medical providers should be made aware of psychosocial factors associated with opioid hospital admissions when prescribing opioids to patients with RMDs. By determining patient subgroups most vulnerable to opioid-related harms and further analysing patient risk factors, we hope to contribute to the development of targeted interventions for safer future clinical care.

POS0938

PROLONGED PHYSICAL STRAIN AT WORK CONFERS RISK FOR DEVELOPMENT OF RHEUMATOID ARTHRITIS IN PATIENTS WITH CLINICALLY SUSPECT ARTHRALGIA: CUES FOR MECHANICAL FACTORS AS FINAL PATHOPHYSIOLOGICAL HIT

Keywords: Rheumatoid arthritis, Epidemiology, Work-related issues

B. Van Dijk[1], A. M. P. Boeren[1,2], S. Khidir[1], N. Den Hollander[1], A. Van der Helm – van Mil[1,2]. [1]*Leiden University Medical Centre (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Erasmus Medical Centre (EMC), Rheumatology, Rotterdam, Netherlands*

Background: Some case-control studies have identified physical workload as a risk-factor for rheumatoid arthritis (RA).
Objectives: To better understand its influence on the pathophysiological trajectory of RA-development, we studied the relation of work-related physical strain with MRI-detected joint-inflammation in clinically suspect arthralgia (CSA) and the general population, and with progression from CSA to clinical arthritis.
Methods: 501 consecutively presenting CSA-patients and 155 symptom-free persons filled out questionnaires on their occupation. Physical strain was determined using the International Standard Classification of Occupations (ISCO) per subject-reported occupation. Contrast-enhanced hand-MRIs were evaluated for synovitis/tenosynovitis/osteitis (summed as joint-inflammation) using the RAMRIS-method. CSA-patients were followed on clinical arthritis development (median follow-up 25 months). Analyses included interaction with age as proxy for prolonged physical strain.
Results: In CSA-patients, the degree of physical strain was associated with the severity of subclinical joint-inflammation, independent of BMI/smoking/education-level: there was a positive interaction between age and physical strain; p=0.007. Plotting the age-dependent effects showed a positive relation in CSA-patients aged ≥50 years (Figure 1A), suggesting the effect relates to prolonged physical strain. Especially tenosynovitis was increased in relation to higher physical strain. Prolonged physical strain in symptom-free persons was not associated with MRI-detected joint-inflammation. Older (≥ 50 years) CSA-patients with higher physical strain developed clinical arthritis more often (Figure 1B; HR 1.17 (95%CI 1.00–1.35) per 10 percentage-points physical strain increase; p=0.043). This was partially mediated by subclinical joint-inflammation. Moreover, physical strain partially mediated the known association between low educational attainment and clinical arthritis development.
Conclusion: Prolonged work-related physical strain increases the risk of developing RA in CSA-patients, which is partially mediated by an effect on increased subclinical joint-inflammation. This points to mechanical factors as a final hit in the pathophysiology of RA-development.

POS0939

PLEUROPARENCHYMAL FIBROELASTOSIS: A SPECIAL CLINICAL SITUATION IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH CONNECTIVE TISSUE DISEASES. DESCRIPTIVE STUDY FROM A REFERRAL CENTRE

Keywords: Comorbidities, Lungs

B. Atienza-Mateo[1], S. Remuzgo Martinez[2], V. Pulito-Cueto[2], D. Ferrer[3], G. Blanco[4], S. Izquierdo[3], V. M. Mora-Cuesta[3], D. Iturbe Fernández[3], R. López-Mejías[2], R. Blanco[1], J. M. Cifrián-Martínez[3], M. A. González-Gay[5,6]. [1]*Hospital Universitario Marqués de Valdecilla, IDIVAL, Rheumatology, Santander, Spain*; [2]*IDIVAL, HUMV, Research Group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and in Metabolic Bone Diseases of the Musculoskeletal System, Santander, Spain*; [3]*Hospital Universitario Marqués de Valdecilla, IDIVAL, Pneumology, Santander, Spain*; [4]*Hospital Universitario Marqués de Valdecilla, IDIVAL, Radiology, Santander, Spain*; [5]*IDIVAL, UC, Department of Medicine and Psychiatry, School of Medicine, Santander, Spain*; [6]*IIS-Fundación Jiménez Díaz, Rheumatology, Madrid, Spain*

Background: Pleuroparenchymal fibroelastosis (PPFE) is a rare interstitial lung disease (ILD) that can be idiopathic or associated with a variety of different conditions, including connective tissue diseases (CTD) **[1-2]**. In this regard, the presence of PPFE has been reported as an independent predictor of worse

prognosis in CTD-ILD patients **[3]**. Approximately one third of the patients with ILD meet criteria for a CTD **[4]**.

Objectives: A) To determine the prevalence of PPFE in a cohort of Spanish patients with CTD-ILD, and **B)** to compare the characteristics between CTD-ILD patients with and without PPFE.

Methods: A total of 99 patients with CTD-ILD (31 rheumatoid arthritis (RA), 31 systemic sclerosis (SSc), 21 idiopathic inflammatory myositis (IIM), 6 primary Sjögren's syndrome (SS), 4 systemic lupus erythematosus (SLE) and 6 with other CTDs) from the Hospital Universitario Marqués de Valdecilla (Santander, Spain) were included in this study. The presence of PPFE was confirmed by experienced radiologists evaluating chest high-resolution computed tomography images from all patients. In addition, demographic, clinical and radiological characteristics were collected.

Results: The presence of PPFE was found in 9 (9.1%) of the 99 CTD-ILD patients, whereas the remaining 90.9% had no signs of PPFE. In particular, it was confirmed in 4 patients with RA (12.9%), 2 with SSc (6.5%), 1 with IIM (4.8%), 1 with primary SS (16.7%) and 1 with SLE (25.0%) (**Figure 1**). The prevalence of bronchial dilation was statistically higher in CTD-ILD patients with PPFE compared to those without PPFE (44.4% *versus* 6.74%, respectively, p=0.006, **Table 1**). There were no significant differences in age at CTD or ILD diagnosis, sex, smoking history, body mass index and pulmonary function tests at ILD diagnosis between both groups (**Table 1**).

Conclusion: We provide the prevalence and clinical data of PPFE in patients with CTD-ILD from a national referral centre. Approximately 1 out of 10 of our patients presented associated PPFE, closely correlated to bronchial dilation. The identification of this condition in CTD-ILD patients should be considered routinely since it may worsen their prognosis.

POS0940 CHRONIC PAIN IN MULTIPLE SITES AND WIDESPREAD PAIN IS ASSOCIATED WITH VASCULAR AND HEART FUNCTION: A PROSPECTIVE COHORT STUDY

Keywords: Cardiovascular disease, Heart, Pain

J. Tian[1], G. Jones[1], F. Pan[1]. [1]*University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*

Background: Chronic pain is highly prevalent in the general population and has been considered a disease entity in itself. Recent studies including our own have shown that chronic pain in multiple sites was associated with a higher risk of cardiovascular disease (CVD) and the relationship may be causal. Early changes in vasculature and heart function such as arterial stiffness, carotid intima thickness (CIMT), cardiac index (CI) and ventricular ejection fraction (LVEF), have been strong and independent predictors of CVD risk; however, whether chronic pain is associated with early signs of vasculature and heart function changes has not been investigated.

Objectives: To examine the associations of chronic pain in multiple sites and widespread pain with arterial stiffness index (ASI), CIMT, CI and LVEF.

Methods: This study utlised data from the UK biobank study which is a prospective cohort study with over 500,000 participants aged 40–69 years recruited at baseline, and some participants attending the subsquent three followups including two imaging visits. Pain sites (including hip, knee, back, neck/shoulder or 'all over the body') and duration were measured via a questionnaire at each visit. Chronic pain was defined if pain had lasted for ≥3 months. Participants were categorised into six groups: no chronic pain, chronic pain in 1, 2, 3 and 4-site and 'all over the body'. ASI (in m/s) was measured by using finger photoplethysmography at each visit. CIMT, CI and LVEF were assessed at the two imaging visits. CIMT (in micrometres) was measured using ultrasound. CI (in litres/min/m2) and LVEF (in percentage) were obtained from heart MRI. Linear mixed-effects model was used for the analyses.

Results: A total of 97,774, 12,213, 28,326, and 2,903 participants who had complete data were included in the ASI analysis over a median follow-up of 11.4 years (interquartile range [IQR]: 10.6–12.3), while 22,851 and 607 participants were included for CIMT and heart function analyses over a median follow-up of 2.3 years (IQR: 2.2–2.5) (Figure 1). At baseline, the participants were 56.5 [8.1] years (Mean [SD] age) and 51% were females. Greater number of chronic pain sites was associated with a higher ASI and lower LVEF in a dose-response relationship (both P for trends <0.05) after adjustment for all covariates. Participants with chronic pain 'all over the body' had the highest ASI (β=0.24, 95%CI 0.06–0.43) and lowest LVEF (β=-1.21, 95%CI -2.21—0.22). No statistically significant association was found for CIMT and CI. No significant interaction between chronic pain and follow-up time with all outcomes was observed, indicating that the effect of chronic pain on vasculature and heart function did not change over time.

Conclusion: This study found a dose-response relationship between number of chronic pain sites and ASI and LVEF, with participants with chronic widespread pain having the highest ASI and lowest LVEF. These findings suggest that chronic pain may have a detrimental effect on vasculature and heart function.

POS0941 SYSTEMIC SCLEROSIS IS A RISK FACTOR OF INCIDENT PSORIASIS: RESULTS FROM A NATIONWIDE COHORT STUDY

Keywords: Epidemiology, Systemic sclerosis, Real-world evidence

O. C. Kwon[1], K. D. Han[2], M. C. Park[1]. [1]*Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea)*

Background: Co-existing psoriasis (PsO) in patients with systemic sclerosis (SSc) has been reported. However, it is unclear whether SSc contributes as a risk factor for development of PsO.
Objectives: We aimed to assess whether SSc is associated with the risk of incident PsO.
Methods: From the Korean National Health Insurance Service database, 4,933 patients with SSc and 24,665 age- and sex-matched controls were selected. Hazard ratios (HRs) and 95% confidence intervals (CIs) for incident PsO were estimated using multivariable Cox proportional hazard models adjusted for known risk factors of PsO. Further, we selected individuals whose health check-up data were available (2,355 patients with SSc and 11,775 age- and sex-matched controls). In this population, we further adjusted for additional risk factors of PsO using the health check-up data.
Results: In the analysis of 4,933 patients with SSc and 24,665 age- and sex-matched controls, incidence rates of PsO in patients with SSc and controls were 10.26 and 3.20 per 1,000 person-years, respectively. After adjusting for risk factors of PsO, patients with SSc had a significantly higher risk of incident PsO (adjusted HR: 3.055 [95% CI: 2.597, 3.594]). Moreover, in the analysis of individuals who had health check-up data, additional risk factors of PsO were further adjusted; the result also showed that patients with SSc have a significantly higher risk of incident PsO (adjusted HR: 2.820 [95% CI: 2.207, 3.603]).
Conclusion: In this large cohort study, SSc was associated with a 3-fold higher risk of incident PsO than controls, independent of known risk factors of PsO. This observation advances our knowledge by showing that a risk relationship exists between SSc and PsO, beyond a simple co-existence between the two conditions.

Table 1. Comparison of risk of incident psoriasis between patients with systemic sclerosis and controls.

	N	Incident PsO	Duration, pyrs	Incidence rate /1,000 pyrs	Unadjusted HR (95% CI)	Adjusted HR (95% CI)

POS0942 THE SIGNIFICANCE OF PRE-SCREENING OF SUBCLINICAL MALIGNANCIES BEFORE THE TREATMENT OF BIOLOGIC AGENTS OR JAK INHIBITORS TO CONNECTIVE TISSUE DISEASE PATIENTS

Keywords: Targeted synthetic drugs, bDMARD, Malignancy

K. Misaki[1,2], Y. Mako[1,2], T. Okada[1,2], Y. Tarutani[1,2], M. Yabe[1,2], K. Inoue[1,2], N. Dobashi[1,2], Y. Imaizumi[2]. *[1]Kita-Harima Medical Center, Rheumatology, Ono, Japan*; *[2]Kita-Harima Medical Center, Rheumatology Center, Ono, Japan*

Background: Malignancies under the treatment of biologic agents (Bio) or JAK inhibitors (JAKi) are attracting public attention[1] [2]. It is important to administer Bio or JAKi safely to the patients, it seems to be absolutely necessary of the screening of cancer. Intensive pre-screening examinations for malignancies before the treatment of Bio or JAKi has been performed in our department since 2016.
Objectives: To elucidate the utility of the intensive pre-screening examination and the prevalence of malignancies prior to the therapy of Bio or JAKi to the patients of connective tissue diseases (CTD).
Methods: Three hundred thirty-six CTD patients (RA:254, SLE:27, SpA:25, Vasculitis:13, Overlap syndrome:6, others:11) before the administration of Bio or JAKi were enrolled from April 2016 to September 2021. Upper gastric intestinal endoscope, fecal occult blood test (twice), thyroid and abdominal ultrasound, chest and abdominal non-contrast enhanced CT, serum prostate-specific antigen (only for male) and screening for the cancer of the cervix and mammography (only for female) were performed to all patients above as an intensive pre-screening examination. Herein, we retrospectively analyzed the prevalence of both benign and malignant tumors including species before the therapy of Bio or JAKi, and the patient-treatment outcomes with cancers.
Results: The patient characteristics were as follows: Median age: 68 yr.(n=336). (RA:69 yr., SLE:48yr., SpA:63yr., Vasculitis:73yr., Overlap syndrome:70yr., others:57yr.). The prevalence of benign tumors and malignant tumors were 24.7% (n=83, median age:68yr.) and 5.1% (n=17, median age:74yr.<Max:89yr. Min:50yr.>), respectively. The details of the malignancies were prostate cancer (n=6, 35.3%), uterus or ovarian cancer (n=3, 17.6%), gastric cancer (n=3, 17.6%), colon cancer (n=2, 11.8%), breast cancer (n=1,5.9%), lung cancer (n=1, 5.9%) and thyroid cancer (n=1, 5.9%). Most of the age complicated with cancers was 80yr (median) except for those of uterus or ovarian cancer:50yr(median). Eleven patients (64.7%) among cancer bearing patients (n=17) successfully administered Bio or JAKi after radical operation such as endoscopic or surgical resection and all of the 11 patients achieved clinical remission.
Conclusion: Subclinical malignancies were detected by means of intensive pre-screening examinations. The most common cancer was prostate cancer, subsequently uterus or ovarian cancer and gastric cancer. It is important to perform pre-screening examinations before an aggressive therapy such as Bio or JAKi to CTD patients.

POS0943 A GENETIC STUDY ABOUT POTENTIAL CAUSAL RELATIONSHIP BETWEEN SEDENTARY ACTIVITY AND PSORIASIS

Keywords: Genetics/epigenetics, Psoriatic arthritis

J. Y. Chen[1,2], Q. Feng[1,2], G. Zhen[1,2], Y. Feng[1,2], Q. Yu[3], P. F. He[3], X. Li[1,2,4], S. X. Zhang[1,2,4]. *[1]Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; *[2]Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, China*; *[3]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*; *[4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: Psoriasis is a common, chronic, immune-mediated skin disorder, which is characterized by clearly demarcated areas of erythematous plaques with overlying silvery scales appearing on the skin [1]. Previous studies have shown that plenty of psoriasis patients are engaged in less physical activity (PA), however, the genetic causal association between PA and psoriasis is of scarce evidence [2].
Objectives: In this study, we aimed to evaluate the causal association between PA and psoriasis.
Methods: We used genome-wide association study (GWAS) data to conduct a Two-Sample Mendelian randomization (MR). MR utilizes single nucleotide polymorphisms (SNPs) as instrumental variables (IVs) to examine the causality of an observed association between exposure and outcome [3]. SNPs that were independent ($r2 < 0.001$) and without linkage disequilibrium and strongly related to PA ($p < 1e\text{-}08$, F>10), were selected as IVs. PA was divided into two parts including sedentary and physically active activities. Physically active behaviors include accelerometer-based physical activity, vigorous physical activity, moderate to vigorous physical activity, moderate physical activity 10+ minutes, and vigorous physical activity 10+ minutes. GWAS summary data of four types of sedentary behavior and five types of physically active behaviors were acquired from the UK biobank. The GWAS data of sedentary behavior includes watching TV (N=437,88), using computer(N=360,895), mobile phone use (N=310,555), and driving(N=456,972). The FinnGen collaboration provides summary statistics for psoriasis, which included 216,752 European individuals (4,510 cases and 212,242 non-cases). Inverse-variance weighted (IVW), MR-Egger, and the weighted median were used to assess causality. IVW was a key method to estimate. Cochran's Q test and egger-intercept analysis were used as auxiliary analyses to assess pleiotropy and heterogeneity.
Results: There were strong genetic causal relationships between psoriasis and TV watching. Watching TV was identified as the risk factor of psoriasis by

IVW (OR =2.11; 95% CI, 1.35-3.30, P=1.02E-03), identical to MR-Egger and the weighted median analysis. Pleiotropy and heterogeneity were not found by Cochran's Q (P =0.140)and egger-intercept (P=0.43), suggesting these findings were reliable. In contrast, there was no causal relationship between the other activities and psoriasis (P > 0.05).

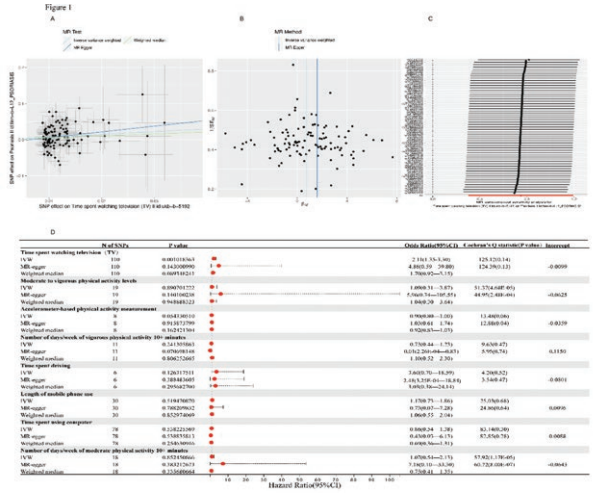

Figure 1: Mendelian randomization results for gene-level causality between physical activity (PA) and psoriasis were evaluated by the odds ratio (OR) values of IVW, MR Egger, and Weighted median. Scatter plots (A), funnel plots (B), leave-one-out analysis (C), and forest plot (D) present TV watching as a risk factor for psoriasis. IVW, inverse-variance weighted; CI, confidence interval; SNP, single nucleotide polymorphisms.

Figure 1. Mendelian randomization results for gene-level causality between physical activity (PA) and psoriasis were evaluated by the odds ratio (OR) values of IVW, MR Egger, and Weighted median. Scatter plots (A), funnel plots (B), leave-one-out analysis (C), and forest plot (D) present TV watching as a risk factor for psoriasis. IVW, inverse-variance weighted; CI, confidence interval; SNP, single nucleotide polymorphisms.

Conclusion: Our findings reveal that TV watching is an apparent risk factor for psoriasis. It provides psoriasis patients with a piece of advice that they should lessen extended sedentary time and boost physical activity.

POS0944 DIETARY PATTERNS AND FOOD GROUPS IN RELATION TO DISEASE ACTIVITY AND FATIGUE IN PATIENTS WITH INFLAMMATORY ARTHRITIS

Keywords: Inflammatory arthritides, Diet and nutrition

D. Fedkov[1], C. Peine[2], F. Lang[3]. [1]*Bogomolets National Medical University, Internal Medicine #3, Kyiv, Ukraine*; [2]*Midaia GmbH, Research and Development, Heidelberg, Germany*; [3]*Midaia GmbH, Product Development, Heidelberg, Germany*

Background: Recently, diet and nutrients have received considerable attention as potential precipitating factors and exacerbation triggers of inflammatory arthritis.

Objectives: To evaluate the associations of diet with disease activity and fatigue in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA, including psoriatic arthritis [PsA]).

Methods: Data of German patients with RA, SpA/ PsA were prospectively collected by the Mida Rheuma App (CE-certified mobile application, Midaia GmbH, Germany) from Jan 2022 to Dec 2022. Anonymized data of patients were extracted for retrospective analysis. We assessed demographic parameters, major dietary patterns, and food groups by each patient's consumption intensity. Consumption of dairy products, fruits, vegetables, sausages, meat, oily fish, white fish, sugar, and alcohol was collected. For each group, participants were asked how often, on average, they had consumed the foods and beverages, with four or five responses ranging from "never" to '4–5 times per day/per week or every day'. The presence of lactose, gluten, and fructose intolerance was also assessed. Disease activity was measured by Patient's Global Assessment of Disease Activity (PtGADA, scored from 0 to 100 mm) and Patient's Global Assessment of Pain Intensity (PPAIN, scored from 0 to 100 mm). Fatigue was assessed by The Brief Fatigue Inventory (BFI, scored from 0 to 10 points). Patients were divided into subgroups to evaluate associations depending on the food group, and the high-consumption group (HCG) was compared with the low-consumption group (LCG). Patients on a specific diet were compared with the 'eat all group' (EAG). The differences in the data sets were examined for their significance using t-test, p-value ≤ 0.05 was considered statistically significant.

Results: Of 1564 extracted patients, 774 completed diet questionnaires. These were included in the analysis (480 RA, SpA: 180 axSpA, 61 PsA, 53 - combination of two arthritis). 79.8% of patients were female, 19.5% - male, and 0.7% - another gender; the mean age was 42.8±12.6 years. The mean PtGADA, PPAIN, and BFI were 55.7±26.7, 52.6 ±26.5, and 5,17±1,98. According to dietary patterns, 432 (55.8%) patients were included in EAG, 21.6% were on a vegan/vegetarian diet (4.8%/16.8%), 15,5% - Mediterranean, and 7.1% - low-carb diet; 8.4% had lactose, gluten, fructose intolerance or their combinations. The Mediterranean diet group had statistically significant lower PtGADA and PPAIN (by 8.98%, p=00.4 and 14.3%, p=0.007 respectively), compared with EAG. Vegan/vegetarian and low-carb diet groups demonstrated only positive trends for PtGADA, PPAIN, and BFI vs. EAG. At the same time, fruit and vegetable HCGs showed negative trends for all outcomes compared with LCGs. Negative trends were also found for dairy products, meat, and sugar, with the most substantial difference for sugar (10.1%, 7.92% and 8.67% for PtGADA, PPAIN and BFI, respectively). Statistically significant higher PtGADA, PPAIN and BFI were in sausage HCG vs. LCG: 16.4%, p=0.01, 15.6%, p=0.02, and 11.8%, p=0.03 for PtGADA, PPAIN and BFI respectively. Statistically significant lower PtGADA and PPAIN were in oily fish HCG vs. LCG (18.1%, p=0.01, and 17.1%, p=0.03, respectively). However, for white fish, this difference was not demonstrated.

Conclusion: According to the presented data high processed meat consumption is potentially associated with higher disease activity and fatigue, while the Mediterranean diet and high oily fish consumption – with low disease activity. These findings highlight the importance of future research and the potential of dietary interventions in patients with inflammatory arthritis.

POS0945 ILD PROGRESSION ON STANDARD OF CARE VARIES IN PATIENTS WITH CONNECTIVE TISSUE DISEASE

Keywords: Prognostic factors, Organ damage, Lungs

E. Langballe[1,2], P. P. Diep[2,3], H. Andersson[1], C. Bruni[4,5], H. Fretheim[1], T. Garen[1], R. Gunnarsson[1], Ø. Midtvedt[1], Ø. Molberg[1,2], Ø. Palm[1], S. Reiseter[6], T. M. Aaløkken[7], O. Distler[5], A. M. Hoffmann-Vold[1,5]. [1]*Oslo University Hospital, Rheumatology, Oslo, Norway*; [2]*University of Oslo, Faculty of Medicine, Oslo, Norway*; [3]*Oslo University Hospital, Respiratory Medicine, Oslo, Norway*; [4]*Careggi University Hospital, Department of Experimental Medicine, Division of Rheumatology, Firenze, Italy*; [5]*University Hospital of Zürich, Rheumatology, Zürich, Switzerland*; [6]*Martina Hansens Hospital, Rheumatology, Gjettum, Norway*; [7]*Oslo University Hospital, Radiology, Oslo, Norway*

Background: A subset of patients with connective tissue disease associated interstitial lung disease (CTD-ILD) progresses. These patients have been included in clinical ILD trials as a group despite their different underlying diseases. It has not been studied whether this basket approach of pooling different CTD-ILDs is valid, e.g., if the disease course of the ILDs depends on the underlying CTD. In addition, the impact of immunosuppressive treatment, which CTD-ILD patients receive for ILD or other organ manifestations as a standard of care, is not fully understood.

Objectives: To assess ILD progression in patients with CTD-ILDs on standard of care treatment.

Methods: CTD-ILD patients (N=504) from a Norwegian and Swiss cohort fulfilling the respective classification criteria of the underlying CTD with ILD diagnosed on HRCT were included. Data were extracted from prospectively collected local registries. Additional data were extracted from electronic patient records. Change in absolute FVC% predicted over 12 months was calculated. In addition, ILD progression was assessed over 12 months on standard of care treatment, defined as:

(I) Absolute decline of FVC (% predicted) ≥10%
(II) 2022 ATS/ERS/JRS/ALAT guideline criteria including 2/3 of (1) worsening of respiratory symptoms; (2) absolute decline in FVC ≥ 5% or in DLCO ≥ 10% and (3) disease progression on HRCT over 12 months

Multivariable logistic regression and descriptive statistics were applied. Analyses were adjusted for underlying CTD and immunosuppressive treatment (including corticosteroids any dose, csDMARDs, mycophenolate, cyclophosphamide, CD-20/TNF/ JAK/IL6-inhibitors).

Results: The total CTD-ILD cohort of 504 patients included 231 (46%) systemic sclerosis (SSc)-ILD, 91 (19%) anti-synthetase syndrome (ASS)-ILD, 82 (16%) rheumatoid arthritis (RA)-ILD, 57 (11%) primary Sjögren syndrome (pSS)-ILD and 43 (9%) mixed connective tissue disease (MCTD)-ILD patients (Table 1). Mean absolute change in FVC% over 12 months was for the entire cohort -0,74% (range -34 to +42%), 57 (13,7%) had an FVC decline ≥10% and 47 (12%) fulfilled the guideline criteria. ILD progression varied between the diagnoses, with SSc-ILD and pSS-ILD showing the strongest absolute FVC decline over 12 months and the highest percentage of progressive patients defined by the 2022 guideline. Additionally, patients with SSc-ILD and MCTD-ILD had more frequent FVC ≥10% events (Table 1). Overall, 240 (62,8%) patients were treated with immunosuppressives (table 1). There was no difference between patients treated and not treated in absolute FVC decline (OR 1.00, 95%CI 0.98-1.02, p= 0.705), and in the percentage of progressive patients according to the guideline criteria (OR 1.00, 95%CI 0.54-1.86, p= 0.995). However, there was less FVC decline ≥10% (OR 0.51, 95% CI 0.28-0.90, p= 0.022) in patients treated with immunosuppressives. Patients with SSc-ILD (11% vs 20%, p=0.059) and pSS-ILD (8% vs 19%, p=0.329) showed numerically less FVC decline ≥10%. The different CTD diagnoses had different patterns of treatment with immunosuppressives, with the majority of RA and ASS-ILD being treated (Table 1).

Table 1.

	pSS (N = 57)	ASS (N= 91)	SSc (N = 231)	RA (N = 82)	MCTD (N = 43)
Male sex, n (%)	10 (18)	29 (32)	55 (24)	37 (45)	14 (33)
Age at diagnosis, yrs (SD)	52 (14,9)	49 (15,4)	48 (15,0)	54 (15,3)	39 (17,4)
Disease duration, yrs (SD)	9,8 (8,7)	10,1 (8,2)	10,4 (12,4)	11,3 (13,2)	13,3 (9,7)
Immunosuppression, n (n with valid data) (%)	28 (46) (60,9)	62 (69) (89,9)	86 (228) (37,7)	47 (50) (94)	17 (23) (73,9)
Baseline FVC% (SD)	91,5 (17,8)	79,6 (23,1)	88,6 (20,0)	73,0 (19,1)	85,5 (18,2)
Δ FVC% (SD) after 12 months	- 2,39 (9,2)	-0,37 (10,3)	-1,18 (9,3)	1,67 (9,0)	-0,64 (11,9)
FVC decline ≥ 10 %, n (%)	5 (13)	7 (11)	38 (17)	3 (5)	4 (18)
Guideline criteria, n (%)	5 (12,8)	5 (8,1)	34 (14,9)	2 (4,5)	1 (5,3)

Conclusion: In this CTD-ILD cohort, both underlying CTD and immunosuppressive treatment seemed to be associated with different patterns of ILD progression over a 12-month period. This has implications for the enrichment for progressive disease and inclusion of CTD-ILD patients into clinical trials.

POS0946

ASSOCIATION BETWEEN PARENTAL AUTOIMMUNE DISEASE AND ATOPIC DERMATITIS IN THEIR OFFSPRING VARIED BY SEX: A NATIONWIDE CASE–CONTROL STUDY

Keywords: Pregnancy and reproduction, Epidemiology

J. Wei[1]. [1]*Chung Shan Medical University Hospital, Division of Allergy, Immunology and Rheumatology, Taichung, Taiwan, Republic of China*

Background: Association of parental autoimmune diseases and offspring atopy is unknown.

Objectives: Our study explored the association between paternal and maternal autoimmune diseases and occurrence of atopic dermatitis in their children in Taiwan.

Methods: The birth data between 2006 and 2012 from National Birth Registry was linked with National Health Insurance Research Database (2003-2017) in this study. We enrolled 312,329 mother-parent linkages when the children were diagnosed with atopic dermatitis before 5 years old, and compared them with 862,612 control parent-child linkages. Conditional logistic regression was utilized to calculate adjusted odds ratio (aOR) and 95% confidence interval (CI) when investigating the association between parental diseases and AD in their offspring.

Results: After adjusting for infant's characteristics, perinatal factors, and other parental illnesses, the odds ratio of developing AD was 2.269 (95% CI 1.333-3.861) with parental rheumatoid arthritis and 1.610 (95% CI,1.094-2.369) with parental psoriasis. Parental allergic diseases such as AD (aOR 2.071, 95% CI 1.952-2.198) and asthma (aOR 1.494, 95% CI 1.400-1.594) were also significant predictors for childhood AD before 5 years old. Thus, parental autoimmune diseases could be one of the risk factors for subsequent AD development in their offspring. The subgroup analysis presented the different odds ratios of parental autoimmune diseases between children's sex. Parental rheumatoid arthritis showed aOR of 3.070(95% CI, 1.532-6.154) in boys with AD, while parental psoriasis showed1.945(95% CI, 1.129-3.350) in girls with AD.

Conclusion: Parental autoimmune diseases were found to induce subsequent atopic dermatitis in their children before 5 years old, and there were different risk factors for atopic dermatitis between boys and girls.

POS0947 SUBCLINICAL SYNOVITIS IN ANTI-CCP POSITIVE INDIVIDUALS AT-RISK OF RA: HOW LIKELY IS IT TO RESOLVE?

Keywords: Prognostic factors, Rheumatoid arthritis, Ultrasound

L. Garcia-Montoya[1], L. Duquenne[1], J. Nam[1], A. DI Matteo[1], K. Harnden[1], R. Chowdhury[1], K. Mankia[1], P. Emery[1]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds Biomedical Research Unit, Leeds, United Kingdom*

Background: Subclinical synovitis is a relatively common ultrasound (US) finding in individuals at-risk of rheumatoid arthritis (RA) (33%) [1]. It is associated with the development of inflammatory arthritis (IA); which often results in physicians prescribing disease modifying anti-rheumatic drugs (DMARDs) in the absence of clinical inflammation. Prediction of resolution of these changes may prevent overtreatment in a number of these patients.

OBJECTIVES:

1) To assess reversibility of subclinical synovitis in individuals at risk of RA, within 12 months' time.
2) To investigate factors associated with resolution of subclinical synovitis.

Methods: A single centre, prospective, observational study recruited anti-cyclic citrullinated peptide (anti-CCP) antibody positive at-risk individuals with a new musculoskeletal complaint, but no clinical synovitis. US scans of wrists, metacarpophalangeal joints, proximal interphalangeal joints and metatarsophalangeal joints were performed at baseline. Those with subclinical synovitis [grey scale (GS) ≥1 and power doppler (PD) ≥1] in at least one joint were then selected. The following variables were collected: gender, age, smoking exposure, anti-CCP titre, the presence of rheumatoid factor, antinuclear antibodies (ANA) and shared epitope, levels of CRP (mg/dL) and ESR (mm/h), minutes of early morning stiffness (EMS), number of tender joints, number of painful joints reported by the patient, number of joints with subclinical synovitis and number of bone erosions. Another US scan was performed after 12 months. If participants had been diagnosed with an IA by then, they were considered to have persistent synovitis and the US scan was not repeated. Univariate analysis was used to identify relevant factors for resolution of subclinical synovitis. Multivariable binary logistic regression and ROC curves were performed to identify the best prediction model.

Results: A total of 91 individuals presented with subclinical synovitis on US. This resolved in 47.3% (43/91) of cases, whereas US changes persisted in 52.7% (48/91) of participants [out of which 62.5% (30/48) developed an IA within 12 months]. Univariate analysis showed that a low anti-CCP titre [<3x upper limit of normality (ULN)], a negative rheumatoid factor, no smoking exposure, age ≤55, ESR≤13, absence of bone erosions and <2 joints with subclinical synovitis at baseline were associated with resolution of subclinical synovitis within 12 months (p<0.05). ROC curves were performed to identify the best cut-offs for continuous variables. Statistically significant factors were included in a multivariate binary logistic regression analysis, which was also adjusted for confounders (age, smoking status and gender). The ROC curve (Figure 1) of the final multivariate prediction model showed AUC=0.819 (p<0.001), with anti-CCP low titre having an odds ratio (OR) of 3.43 for resolution of subclinical synovitis [95%CI (1.07-11.05); p=0.039] and ESR≤13 having OR=3.41 [95%CI (1.22-9.56) p=0.019].

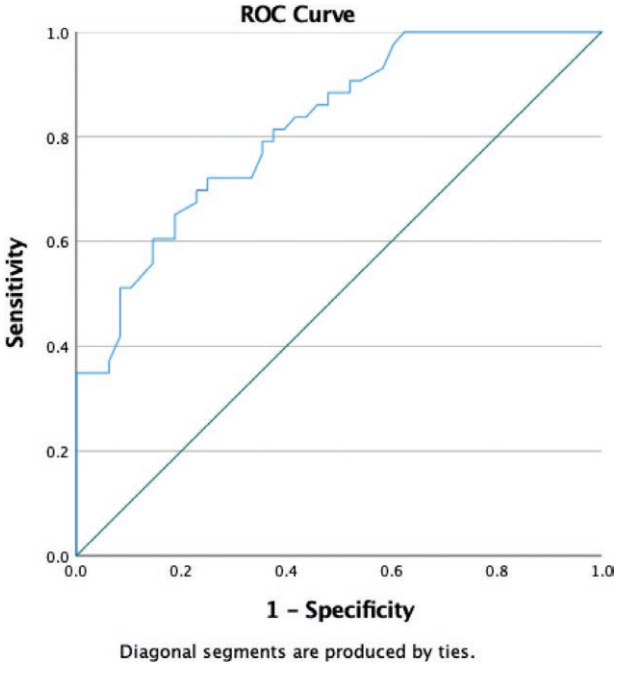

Figure 1. ROC curve of the multivariate predictive model.

Conclusion: Subclinical synovitis is a common finding in anti-CCP positive at-risk individuals, which has shown association with progression to IA. However, by 12 months' time, these US changes disappear in approximately half of the patients, with ESR≤13 and a low anti-CCP titre being the most significant predictors of resolution. Considering the risks associated with immunosuppressants, these data may prevent unnecessary treatment in these patients.

Background: Interstitial lung disease (ILD) is a severe complication of systemic sclerosis (SSc) that may lead to irreversible loss of lung function and increased mortality. Patterns of disease progression (PODs) in SSc-ILD are poorly characterized.

Objectives: To define PODs in SSc-ILD patients that may have clinical implications for patient stratification and clinical trial design.

Methods: Patients with SSc at risk for ILD were recruited in 6 tertiary referral centers. Inclusion criteria were: a) Disease duration < 5 years at the time of the first pulmonary function test (PFT); b) absence of anti-centromere antibodies; c1) diffuse cutaneous subset (dcSSc) OR c2) limited cutaneous subset (lcSSc) with either presence of anti-topoisomerase (Topo I) antibodies or evidence of ILD at high-resolution computed tomography (HRCT). Analyses were restricted to those with ILD at HRCT. PODs at 5 years, defined by absolute changes in forced vital capacity (FVC) % of predictd values, were explored by latent class mixed models (LCMM). Survival analysis (lung-related events) was also conducted on evolution data.

Results: 473 patients at risk for SSc-ILD were identified, of those 424 (89.6%) had evidence of ILD at HRCT and were selected for in-depth analyses. Baseline demographic and clinical characteristics are reported in the Table 1. Multivariable Cox regression showed that FVC values (HR = 0.953, CI95 = 0.956 – 0.982, p < 0.001) as well as the yearly change in FVC (HR = 0.961, CI95 = 0.932 - 0.992, p < 0.05) were predictive of 10-years mortality. LCMM analysis discovered 5 PODs (Figure 1); the majority of patients showed a stable FVC or slow decline in lung function. Patients with sharp improvement had higher age and shorter disease duration compared to patients with sharp deterioration (55 ± 10.5 vs 47 ± 15.3 and 0.88 ± 1.1 vs 1.03 ± 1.5 years, both p < 0.05) and a lower exposure to immunosuppressants (68.4% vs 85.3%); no other difference in clinical or demographic variables was observed among classes. Ten-years survival estimates were lower in patents with sharp (75.1%) or slowly-declining lung function (79.8%) compared to the other groups (>90%) with no event in the sharp improvement class (log-rank p = 8*10-4). The predictive capability of LCMM classes was 0.766 ± 0.03 as measured by Harrel's C-index.

Table 1. Baseline characteristics

Variable	SSc-ILD (n = 424)
dcSSc, n (%)	229 (54%)
F, n (%)	354 (83.5%)
Scl70, n (%)	331 (78.1%)
SSA, n (%)	93 (21.9%)
Deaths 10 yrs	32 (7.5%)
FVC, % pred	88.8 ± 18.8
DLco, % pred	64.4 ± 19.9
Age at first PFR, yrs	49.5 ± 13
Disease duration at first PFR, years	0.91 (0.19 - 2.26)
Patients exposed to immunosuppressants, n (%)	291 (68.6%)
Number of visits	5713
Exposure to CYC, n visits (%)	441 (7.7%)
Exposure to MMF, n visits (%)	729 (12.8%)
Exposure to AZA, n visits (%)	533 (9.3%)
Exposure to TCZ, n visits (%)	26 (0.5%)
Exposure to RTX, n visits (%)	134 (2.3%)
Exposure to csDMARDs, n visits (%)	1703 (29.8%)
Exposure to bDMARDs, n visits (%)	160 (2.8%)

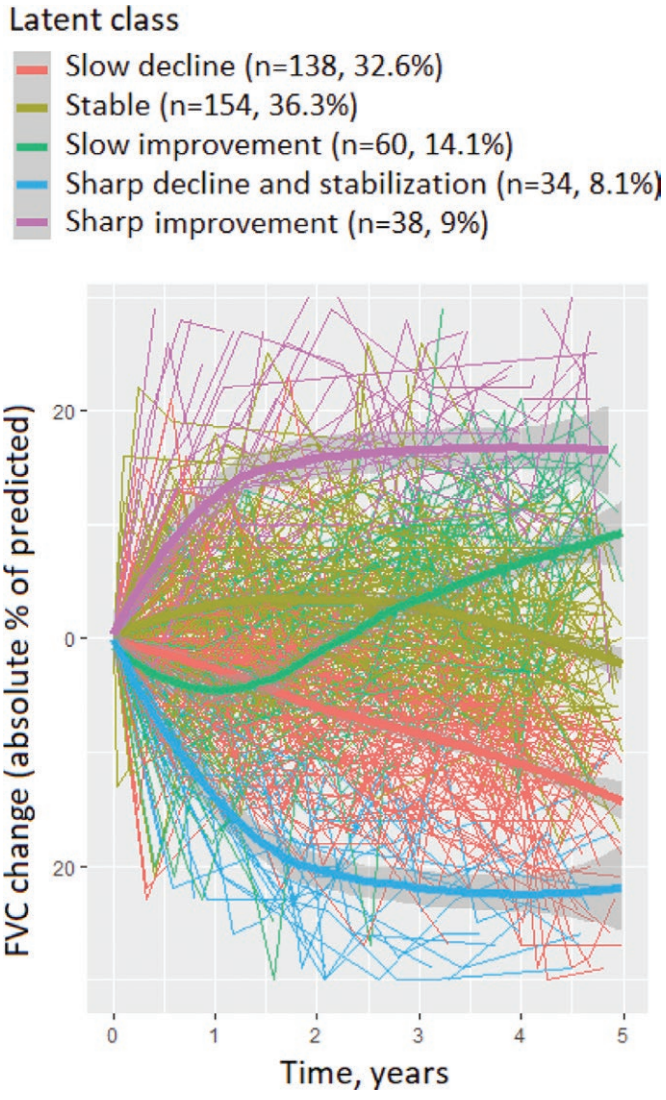

Figure 1. Latent classes of disease progression

Conclusion: PODs in SSc-ILD are associated with mortality with an increased risk for those with a sharply or slowly declining lung function. The use of PODs for patients' stratification may be useful for prognostication and patient counselling as well as for clinical trial design.

CLINICAL FACTORS ASSOCIATED WITH PNEUMOCYSTIS PNEUMONIA DESPITE ITS PRIMARY PROPHYLAXIS: A CASE-CONTROL STUDY

Keywords: Infection-related RMDs

J. Y. Kim[1], J. I. Jung[1], E. B. Lee[1], J. W. Park[1]. [1]*Seoul National University Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Previous studies have suggested that primary prophylaxis against pneumocystis pneumonia (PCP) using trimethoprim-sulfamethoxazole (TMP-SMX) is beneficial in patients with rheumatologic diseases receiving immunosuppressive drugs[1]. However, there is little evidence for an optimal prophylaxis duration or a time point of prophylaxis withdrawal.

Objectives: This study aims to investigate the risk factors that are associated with PCP occurrence despite its primary prophylaxis, and, ultimately, to provide evidence regarding the ideal schedule for primary PCP prophylaxis.

Methods: This case-control study included treatment episodes of patients with rheumatic diseases who received prophylactic TMP-SMX with immunosuppressive treatment between 2010 and 2022 in a tertiary referral center in South Korea. The index date was defined as the date of starting the prophylactic dose of TMP-SMX. We captured PCP cases that occurred within 1 year from the index date based on the review of the medical record by two independent expert investigators. The effect of clinical factors, such as demographics, underlying disease, immunosuppressive treatment, and pattern of prophylaxis on the PCP occurrence was examined using binary logistic regression.

Results: A total of 1,379 treatment episodes were analyzed, and eleven cases of PCP occurred during the observation—a one-year PCP incidence of 0.80 (95% CI=0.40-1.43) per 100 person-years. In 10 cases (90.9%), PCP occurred after discontinuation of TMP-SMX prophylaxis, with a mean (SD) interval of 185.6 (90.9) days. The mean (SD) duration of prophylaxis in the PCP group was 108.5 (132.3) days. The main reasons for prophylaxis withdrawal in the PCP group were adverse events (5 cases) and treating physicians' decisions (5 cases). The dose of glucocorticoid at the time of prophylaxis cessation was the most critical risk factor for PCP. Patients who were receiving glucocorticoid more than 15 mg/day of prednisone equivalent at the time of TMP-SMX discontinuation showed a significantly higher odds of developing PCP (OR=15.06; 95% CI=1.92-117.94). The prophylaxis duration and presence of structural lung disease were not associated with PCP. This result was consistent in the multivariable analysis adjusted for age, underlying disease, rituximab treatment, azotemia, and lymphopenia (adjusted OR=12.21; 95% CI=1.52-98.24) (Table 1).

Conclusion: Discontinuation of TMP-SMX during glucocorticoid treatment greater than 15 mg of prednisone equivalent significantly increases the risk of PCP, which suggests that a time when glucocorticoids are tapered to less than 15mg/day of prednisone dosage equivalent may be a reasonable time to consider withdrawing PCP prophylaxis.

POS0950 THE BURDEN OF TEMPOROMANDIBULAR DISORDERS AMONG IMMUNE-MEDIATED RHEUMATIC DISEASES OF THE ADULT: A SYSTEMATIC REVIEW

Keywords: Patient reported outcomes, Pain, Systematic review

E. Hysa[1], A. Lercara[1], A. Cere[1], E. Gotelli[1], C. Schenone[1], V. Gerli[1], P. F. Bica[1], S. Paolino[1], E. Alessandri[1], C. Pizzorni[1], A. Sulli[1], V. Smith[2], M. Cutolo[1].
[1]*Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties, University of Genova, IRCCS San Martino Polyclinic Hospital, Genova, Italy, Genova, Italy*; [2]*Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Department of Internal Medicine, Ghent University, Department of Rheumatology, Ghent University Hospital;, Ghent, Belgium*

Background: The temporomandibular disorders (TMDs) encompass a heterogenous group of inflammatory and degenerative diseases which impair the masticatory function causing local pain and dysfunctional consequences of the temporomandibular joint (TMJ) [1].
Objectives: To systematically review the literature concerning TMDs in immune-mediated rheumatic diseases (IMRDs) of the adult and synthetize their burden in multiple domains of clinical interest: patient-reported outcomes (PROs), frequencies of signs on physical examination, imaging features, histological findings, and risk factors for their development in patients with IMRDs.
Methods: A literature search on PubMed Central, Embase and Cochrane Library databases was performed, until June 2022, for studies including TMJ outcomes in IMRDs patients compared with healthy controls, other rheumatic diseases or in the assessed IMRDs patients after follow-up and treatment. Among the IMRDs of the adult, original articles investigating TMJ involvement in inflammatory polyarthritides and/or autoimmune connective tissue diseases were considered. The TMJ outcomes used in clinical studies, the prevalence of TMDs in IMRDs and the risk factors for their development were qualitatively synthetized.
The quality of the studies was scored using the Newcastle-Ottawa scale (NOS).
Results: Of the 3259 screened abstracts, 56 papers were included in the systematic review. All of them were evaluated as of fair quality, at least. Most of the papers (77%) investigated TMDs in rheumatoid arthritis (RA) with a prevalence of signs and symptoms varying from 8% to 70% **(Table 1).** The risk factors for TMDs development in RA were female sex, younger age, anti-citrulline peptide antibodies (ACPA) positivity, higher disease activity, cervical spine involvement, cardiovascular and neuropsychiatric comorbidities **(Figure 1).** Ten papers (18 %) evaluated TMDs in spondylarthritides (SpA) reporting a prevalence of symptoms and signs in 12%-80% of patients with higher TMDs prevalence in patients with radiographic spine involvement, skin psoriasis and HLADRB1*01 positivity. Among autoimmune connective tissue diseases (CTDs), systemic sclerosis (SSc) displayed the highest evidence of TMDs PROs and clinical findings (20-93%), followed by systemic lupus erythematosus (SLE) in 18-85%, mixed connective tissue disease (MCTD) in 31-63%, primary Sjögren's syndrome (pSS) in 24-54% and idiopathic inflammatory myopathies (IIMs) in 4-26%. In SSc and SLE, TMDs were more frequent in patients with higher disease activity and duration, correlating with the extent of skin fibrosis in SSc and with renal involvement in SLE.
Conclusion: TMDs in IMRDs display a significant relevance in the rheumatological clinical practice even if they are often overlooked. This burden is epidemiologically important in terms of PROs and clinical findings which correlate with disease activity in RA, SpA, SSc and SLE. The early recognition and multidisciplinary management of TMDs is warranted and should be aimed at hindering the TMJ structural damage maximizing the quality of life of patients.

Table 1. Prevalence of TMJ findings across multiple clinical domains in different IMRDs.

IMRD Domains of TMJ involvement	RA	SpA	SSc	SLE	pSS	MCTD	IIMs
Number of studies investigating TMJ involvement	43/56 (77%)	10/56 (18%)	5/56 (9%)	4/56 (7%)	4/56 (7%)	3/56 (5%)	1/56 (2%)
Prevalence of TMJ PROs	8-70%	12-80%	20-93%	31-66%	24-54%	31%	17-26%
Prevalence of TMJ signs on physical examination (i.e., reduced mouth opening)	30-54%	17-68%	44-71%	41-85%	24-44%	50-63%	4-13%
Imaging findings on X-ray of TMJ	50-66%	30-38%	NA	22%	NA	19%	NA
Imaging findings on computerized tomography of TMJ	61-76%	NA	NA	NA	NA	NA	NA
Imaging findings on magnetic resonance imaging of TMJ	11-95%	6-67%	67-94%	NA	NA	13-93%	NA
Histological findings of TMJ	Synovitis and degenerative changes	NA	NA	NA	NA	NA	NA

POS0951 BASELINE PREDICTORS OF SEVERE OUTCOMES IN IMMUNE CHECKPOINT INHIBITOR-INDUCED INFLAMMATORY ARTHRITIS

Keywords: Malignancy, Inflammatory arthritides

L. Cappelli[1], O. Kamal[1], C. Bingham[1], A. Shah[1]. [1]*Johns Hopkins School of Medicine, Rheumatology, Baltimore, United States of America*

Background: Immune checkpoint inhibitor-induced inflammatory arthritis (ICI-IA) is the most common rheumatic adverse effect of cancer immunotherapy. Patients have dramatically different trajectories; some have a mild self-limited course, while others have severe IA requiring immunosuppression[1]. Additionally, some patients may have persistent IA beyond ICI cessation[1]. Risk factors for severe disease are unknown.
Objectives: To determine which clinical features at baseline rheumatology visit predict severe outcomes such as requirement of immunosuppression in ICI-IA.
Methods: Participants were drawn from a prospective longitudinal study of rheumatic immune related adverse events and had rheumatologist diagnosed ICI-IA. Demographics, cancer history and prior treatment, clinical (e.g.synovitis, tenosynovitis, inflammatory back pain determined by clinician) and laboratory features of arthritis and outcomes were collected at clinic visits. Descriptive statistics were calculated for demographic and clinical features of the whole cohort and for the two groups by primary outcome. The primary binary outcome was requirement of either csDMARDs and/or bDMARDs (determined by failure to wean to < 10 mg prednisone/day); other outcomes were persistence of IA at least 6 months after ICI cessation and requirement of corticosteroids. T-tests or Wilcoxon rank sum tests and Fisher's exact tests were used to compare clinical characteristics by outcome categories. Logistic regression models evaluated univariate associations between clinical features and primary and secondary outcomes. Next, multivariable logistic regression was used to further evaluate these associations, adjusting for potential confounders.
Results: 126 patients with ICI-IA were included. The average age was 60; the majority were female (N=70 56%). The most common cancers were melanoma and lung cancer. Patients were primarily treated with anti-PD-(L)1 agents (N=78 62%) or combination anti-CTLA-4/PD-1 therapy (N=28 22%). Average clinical disease activity index (CDAI) was 17. Of the 126 patients, 53 (42%) required a csDMARD or bDMARD. In univariate logistic regression, higher baseline CDAI (OR 1.05 p=0.01) and presence of tenosynovitis (OR 4 p=0.005) were significantly associated with a higher likelihood of requiring DMARDs; there was a trend toward those treated with prior chemotherapy for cancer being less likely to need DMARDs for IA (OR 0.52 p=0.09). When adjusted for age, gender,

and prior steroid use, tenosynovitis and higher CDAI remained associated with requiring DMARDs and prior chemotherapy was associated with lower likelihood of DMARDs (Table 1). Higher CDAI was also associated with higher likelihood of requiring corticosteroids (1.11 p=0.012). Those positive for rheumatoid factor had a lower likelihood of requiring steroids (0.168 p=0.013). Combination anti-CTLA-4/PD-1 (5.07 p=0.036) therapy and being on steroids at baseline (5.28 p=0.031) were associated with a higher likelihood of persistent IA; there were trends for higher CDAI and tenosynovitis associating with persistence.

Conclusion: Higher levels of disease activity and having tenosynovitis were associated with a higher likelihood requiring immunosuppression beyond corticosteroids for ICI-IA while those treated previously with chemotherapy were less likely to require additional immunosuppression. The presence of risk factors for severe disease at baseline may indicate higher initial steroid dose or earlier adoption of immunosuppression to improve outcomes.

POS0952 ASSOCIATION BETWEEN SARCOPENIA AND RISK OF MAJOR ADVERSE CARDIAC AND CEREBROVASCULAR EVENTS IN A POPULATION FROM THE UK BIOBANK DATABASE

Keywords: Sarcopenia, Prognostic factors, Comorbidities

C. Jauffret[1], R. Périchon[2], A. Lamer[2], M. Courtalin[1], B. Cortet[1], E. Chazard[2], J. Paccou[1]. *[1]Univ. Lille, CHU Lille, ULR 4490 - MABLab, Rheumatology Department, Lille, France*; *[2]Univ. Lille, CHU Lille, ULR 2694 - METRICS, CERIM, Public Health Department, Lille, France*

Background: Few studies on the risk of incident major adverse cardiac and cerebrovascular events in presarcopenic and sarcopenic patients have been reported, with contradictory results [1].

Objectives: The objective was to assess the association between presarcopenia and sarcopenia, and higher risk of major adverse cardiac and cerebrovascular events.

Methods: It was a retrospective analysis of the UK Biobank prospective cohort, using data collected between 2006 and 2021. Community-dwelling Caucasian participants aged 37 to 73 years were included if values for Handgrip Strength and Skeletal Muscle Index were available, and if no history of a major adverse cardiac and cerebrovascular event was reported. Exposure was assessed using the European Working Group on Sarcopenia in Older People 2 (EWGSOP2) criteria [2]. Muscle strength was measured using Handgrip Strength, and muscle mass using the Skeletal Muscle Index (from bioimpedance data). Presarcopenia was defined as low Handgrip Strength with normal Skeletal Muscle Index, whereas sarcopenia was defined as low Handgrip Strength with low Skeletal Muscle Index. Participants with presarcopenia and sarcopenia were merged to form a single group (PreSarc) and were compared against a group of non-sarcopenic participants (NonSarc). To determine whether sarcopenia and/or presarcopenia were predictors of major adverse cardiac and cerebrovascular events (composite events: acute myocardial infarction, angina pectoris, ischemic or hemorrhagic stroke, and transient ischemic attack, whether fatal or non-fatal).

Results: A total of 406,411 participants (women: 55.7%; median age: 58.0 (IQR: [50.0; 63.0]) years) were included. At baseline, 18,612 participants (4.6%) were allocated to the PreSarc group. Over a median follow-up of 12.1 years (IQR: [11.4; 12.8]), 28,300 participants (7.0%) were diagnosed with at least one event. Compared to NonSarc, PreSarc was significantly associated with a higher risk of major adverse cardiac and cerebrovascular events (fully adjusted HR=1.25, 95%CI=[1.20; 1.31]). When presarcopenia and sarcopenia were considered independently, they were still associated with a higher risk of all major adverse cardiac and cerebrovascular events (fully adjusted HR=1.24, 95%CI=[1.18; 1.30]) and HR=1.58, 95%CI=[1.31; 1.90], respectively).

Conclusion: In a community-dwelling population, the risk of major adverse cardiac and cerebrovascular events was higher in both presarcopenic and sarcopenic participants.

POS0953 PROGRESSIVE PULMONARY FIBROSIS IN CONNECTIVE TISSUE DISEASE ASSOCIATED INTERSTITIAL LUNG DISEASES

Keywords: Lungs, Outcome measures

Y. H. Chiu[1,2], M. Koops[1], M. Voortman[3], H. W. Van Es[4], L. Langezaal[4], P. Welsing[1], A. Jamnitski[5], A. Wind[6], J. M. Van Laar[1], J. C. Grutters[3,6], J. Spierings[1]. *[1]University Medical Center Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands*; *[2]Tri-Service General Hospital, National Defense Medical Center, Division of Rheumatology/Immunology/Allergy, Taipei, Taiwan, Republic of China*; *[3]University Medical Center Utrecht, Department of Pulmonology, Utrecht, Netherlands*; *[4]St. Antonius Hospital, Department of Radiology, Nieuwegei, Netherlands*; *[5]St. Antonius Hospital, Department of Rheumatology, Nieuwegein, Netherlands*; *[6]St. Antonius Hospital, Department of Pulmonology, ILD Center of Excellence, Nieuwegein, Netherlands*

Background: Progressive pulmonary fibrosis (PPF) is characterized by deterioration of respiratory symptoms, lung function decline and progressive fibrosis on high-resolution computed tomography (HRCT). It is associated with poor prognosis. Patients with connective tissue disease-related interstitial lung disease (CTD-ILD) may also develop PPF and need intensified clinical management. However, different criteria for PPF are used in trials (i.e. INBUILD and RELIEF) and the ATS/ERS/JRS/ALAT 2022 guideline.[1-3] This variety in criteria complicates study comparison and clinical implication.

Objectives: To explore the prognostic relevance for mortality of different PPF criteria in patients with CTD-ILD.

Methods: This is a single center retrospective cohort study in patients with CTD-ILD or interstitial pneumonia with autoimmune features between 2005 and 2021. The prognostic relevance was compared between the INBUILD criteria[1], the ATS/ERS/JRS/ALAT 2022 criteria[3], and the simplified progressive fibrosing (simplified PF) criteria used in a previous cohort (≥10% relative decline in FVC, ≥15% relative decline in DLCO, or progression of fibrosis on HRCT within two years)[4] in the time-dependent receiver operator characteristic model.

Results: The cohort consisted of 230 patients. The median age was 63 years (IQR 54—69), and 122 (53%) were female. The most prevalent CTD was rheumatoid arthritis (n=77, 33%), followed by 38 (17%) patients with idiopathic inflammatory myopathies and 33 (14%) with primary Sjögren's syndrome. Various HRCT patterns were observed at baseline: UIP in 63 (27%) patients, fibrotic NSIP in 21 (9%), cellular NSIP in 25 (11%), mixed NSIP in 79 (34%), OP in 34 (15%), two (1%) mixed NSIP/OP, and other patterns in six. The median follow-up period was 6 (3—9) years. Mortality risk was independently associated with age (adjusted HR 1.07, $p < 0.001$), smoking history (adjusted HR 1.90, $p = 0.045$), extent of fibrosis on HRCT at baseline (adjusted HR 1.05, $p = 0.018$) and baseline DLCO % of predicted (adjusted HR 0.97, $p = 0.013$). PPF was observed in 61 (27%) patients meeting INBUILD criteria, 53 (23%) meeting ATS/ERS/JRS/ALAT 2022 criteria, 136 (59%) meeting simplified PF criteria and 125 (54%) when using simplified PF criteria with a threshold for HRCT ≥ 5% increase in the extent of fibrosis. The prognostic relevance for mortality did not differ between simplified PF criteria, INBUILD and ATS/ERS/JRS/ALAT 2022 criteria; the prognostic relevance improved when the simplified PF criteria defined HRCT progression with a ≥5% increase in fibrosis. (Figure 1)

Conclusion: Higher age, smoking, increased extent of fibrosis and low baseline DLCO were associated with poor prognosis. The prognostic value was similar between the different PPF criteria and increased during the first three years and achieved a plateau thereafter.

Background: Autoimmune and inflammatory diseases (AID) are associated with myeloid malignancies[1], and include both organ-specific diseases and systemic inflammatory disorders. While the occurrence of associated AID reaches up to 15-20% in myelodysplastic neoplasms (MDS) patients[2,3], its prevalence in the context of myeloproliferative neoplasm (MPN) remains unknown. In patients with a history of AID, the risk of developing MPN was increased[4], suggesting a correlative link between the two disorders, but data regarding the characterization of AID in MPN patients remain scarce and the lack of studies prevents from identifying potential risk traits that may underline a common physiopathology.
Objectives: We conducted a single center retrospective study to describe the prevalence, clinical and biological features of AID in MPN patients. We also reported the mutational landscape of MPN with associated AID, along with its prognostic impact.
Methods: All patients with a diagnosis of Philadelphia-negative MPN according to the World Health Organization's criteria, followed between January 2011 and January 2021 in our center were included. Clinical and biological characteristics at the time of diagnosis and follow-up were collected. Next-generation targeted sequencing was performed targeting a panel of 36 genes involved in myeloid malignancies. AID diagnosis was based on recommended international criteria specific to each AID. Patients with interferon-alpha-induced AID were excluded from this study.
Results: A total of 1541 MPN patients were included, including 95 (6%) patients with AID who were compared to the remaining 1446 (94%) patients without AID. Median age was 51.6 [6.6; 98.3] years at MPN diagnosis in the whole cohort. Female patients were predominant within the AID group (62 (65%) versus 773 (54%), p=0.03). Within the AID cohort, a total of 103 diagnoses of AID were reported in 95 patients, including 48 organ-specific AID (47%) (autoimmune hypothyroidism (n=33), inflammatory bowel diseases (IBD, n=7), neuroinflammatory disorders (n=4), autoimmune cytopenia (n=2), glomerulonephritis (n=1) and pernicious anemia (n=1)), 13 inflammatory arthritis (13%), 9 connective tissue diseases (9%), 9 dermatosis (9%), 6 systemic vasculitis (6%) and 18 unclassified AID (17%). Molecular sequencing was performed in 998/1541 (65%) patients and the prevalence of driver and additional mutations did not differ between the MPN with or without AID. The prevalence of *TET2* mutations was higher in the AID cohort (21/65, 32% versus 208/993, 22%), although not reaching statistical significance (p=0.08). After a median follow-up of 8.3 $_{IQR}$[3.7-14.3] years, the association with AID did not impact overall survival (p= 0.67), MDS/AML transformation free survival (p=0.37) or secondary myelofibrosis-free survival (p=0.91).
Conclusion: Our data suggest that the prevalence of AID is similar in MPN patients to that of the general population, and that the distribution and presentation of AID in MPN patients is also similar. *TET2* mutations are highly prevalent in MPN patients with AID suggesting a shared physiopathology. Additional mechanistic studies are needed to further decipher a potential TET2-mediated common physiopathology. The association with AID did not impact MPN patients' outcome.

POS0955 PREGNANCY IN CONNECTIVE TISSUE DISEASES: A 30 YEAR FOLLOW-UP STUDY OF 465 PREGNANCIES FROM A SPANISH MONOCENTRIC REGISTRY

Keywords: Pregnancy and reproduction, Sjögren syndrome, Systemic lupus erythematosus

C. Sieiro Santos[1], P. Pérez-García[1], J. Ordas Martínez[1], C. Moriano[1], C. Álvarez Castro[1], M. Martín Martín[1], E. Diez Alvarez[1]. [1]*Complejo Asistencial Universitario de León, Rheumatology, León, Spain*

Background: Pregnancy in patients with connective tissue diseases are known to be at high risk for the occurrence of adverse pregnancy outcomes.
Objectives: To evaluate the pregnancy outcomes in patients with systemic autoimmune diseases, including systemic lupus erythematosus (SLE), systemic sclerosis (SSc), primary Sjögren's syndrome (pSS) and undifferentiated connective tissue disease (UCTD).
Methods: A retrospective and descriptive study was conducted from 1990 to 2020. All data were collected from the medical records of childbearing age women with SLE, SSc, SS and UTCD enrolled in our clinic at the time of their pregnancy and childbirth. The obstetric, maternal and fetal outcomes were collected and compared regarding diagnosis and adverse outcomes.
Results: The study group included 295 patients, 125 patients (42%) with SLE, 50 patients (17%) with SSc, 80 patients (27%) with Sjogren's, 40 patients (14%) with UCTD. A total of 465 pregnancies were registered. The maternal and fetal outcomes are detailed in Table 1 and Figure 1. The mean age at delivery was 31.5±8.5 years and the mean duration of disease was 7.2±5.6 years. Pregnancy loss occurred in 21% of patients, live births in 66% of pregnancies, preterm delivery in 8%, postpartum haemorrhage in 6%, preeclampsia in 5%, placental abnormalities in 4%, ectopic pregnancy in 3%, premature rupture of membranes in 2%. Treatment with HCQ was received in 115 pregnancies in SLE (59%), 21 pregnancies in SSc (24%) 62 pregnancies in pSS (52%) and 32 pregnancies in UCTD (49%). Exposure to corticosteroids and biologics during pregnancy was 23 (18.4%), 6 (12%), 15 (19%) and 3 (7.5%), respectively. Patients with SLE had a higher risk of fetal morbidity, including abortion (p=0.03), mean abortion rate (p=0.03), preeclampsia (p=0.04), ectopic pregnancy (p=0.03), preterm delivery (p=0.02) and postpartum haemorrhage (p=0.01) than patients without SLE. The multivariate model adjusted for age, nulliparity, active disease activity during pregnancy, smoking and exposure to biologics, HCQ and corticosteroids found an association between unfavourable pregnancy outcomes and disease activity (OR 2.4 95% CI (1.3-7.2), p 0.003), whilst HCQ during pregnancy (OR 0.23 95% CI (0.03-0.82) had a protective effect.
Conclusion: 66% of pregnancies in patients with autoimmune diseases resulted in live births. Patients with SLE had higher rates of fetal and maternal morbidity than SSc, pSS and UCTD. Disease activity was associated with unfavourable pregnancy outcomes. Exposure to HCQ had a protective effect during pregnancy. Pregnancy planning and counselling prior to conception of patients with connective tissue diseases leads to a reduction in maternal and perinatal complications.

Table 1. Fetal and maternal morbidity outcomes in SLE, SSc, pSS and UCTD

	SLE	SSc	pSS	UCTD	P value
Total of pregnancies	192	88	120	65	
Age at pregnancy	32.4±4.5	29.5±7.2	30.4±3.5	33.5±2.7	0.45
Smokers	32 (26%)	17 (34%)	25 (31%)	12 (30%)	0.27
Birth	103 (67%)	68 (77%)	90 (75%)	47 (72%)	0.28
Abortion	57 (37%)	12 (14%)	18 (15%)	10 (15%)	**0.03**
Mean abortion number	2.7±0.7	1.1±0.6	2.4±0.3	0.9±0.5	**0.03**
Preeclampsia	15 (9.8%)	3 (3%)	2 (2%)	2 (3%)	**0.04**
Ectopic pregnancy	10 (6.5%)	0	1 (1%)	1 (2%)	**0.03**

POS0956 **WITHDRAWN**

POS0957 **EPIDEMIOLOGY OF NEUROSARCOIDOSIS DISEASE IN NORTHERN SPAIN 1999-2019: A POPULATION-BASED STUDY**

Keywords: Registries, Lungs, Epidemiology

A. Herrero-Morant[1], L. Sanchez-Bilbao[1], I. Gonzalez-Mazon[1], D. Martínez-López[2], C. Álvarez-Reguera[1], J. L. Martín-Varillas[3], R. Fernández-Ramón[1], R. Blanco[1]. *[1]Marqués de Valdecilla University Hospital, Rheumatology and Ophthalmology, Santander, Spain*; *[2]Sierrallana Hospital, Rheumatology, Torrelavega, Spain*; *[3]Hospital Comarcal de Laredo, Rheumatology, Laredo, Spain*

Background: Neurosarcoidosis (NS) is a serious and relative uncommon complication of sarcoidosis [**1**]**.** Data on incidence is scarce and varies worldwide.
Objectives: To estimate NS epidemiology in Northern Spain.
Methods: Patients diagnosed with sarcoidosis at a University hospital in Northern Spain, between January 1999 and December 2019 were assessed. Sarcoidosis diagnosis was established according to ATS/ERS/WASOG criteria as follows: compatible clinical and radiological presentation, histopathologic confirmation, and exclusion of other granulomatous diseases. NS was diagnosed according to the NS Consortium Consensus Group [**2**]**.** Demographic and clinical data were collected. The incidence of sarcoidosis between 1999-2019 was estimated by gender, age, and year of diagnosis.
Results: NS was observed in 30 of 234 (12.8%) (19 women/ 11 men) (mean age: 55.0±15.8 years) patients with sarcoidosis. The underlying neurological manifestations were chronic headache (n=13, 43.4%), peripheral neuropathy (n=6, 20.0%), cranial neuropathy (n=5, 16.7%), spinal cord abnormalities (n=3, 10.0%) and aseptic meningitis (n=3, 10.0%). A comparison between different geographical areas is summarized in **Table 1**. There are wide variations in frequency (US:4.8% to France:33.9%), gender predominance and age at diagnosis (31 to 55 years) depending on the geographical area. Nevertheless, most of the patients were diagnosed in the 5th decade of life. Annual incidence of NS in our population area in the 1999-2019 period was 0.11 per 100,000 people, 95% (CI:0.11-0.26); 0.08 (0.07-0.24) in men, 0.13 (0.09-0.24) in women. There were variations in annual incidences, ranging from a minimum value of 0.08 in 2013-2014 to a maximum of 0.19/100,000 people in 1999-2000. A downward trend in annual incidence over time was observed. Nevertheless, the correlation was weak (r^2=0.1135) (**Figure 1**).
Conclusion: The epidemiological characteristics of NS is very different in frequency. Frequency estimated in this study was similar to that of other countries.

POS0958

PREVALENCE AND RISK FACTORS OF OSTEONECROSIS OF THE FEMORAL HEAD IN PATIENTS WITH ADULT-ONSET STILL'S DISEASE

Keywords: Inflammatory arthritides, Quality of life, Epidemiology

S. Kasai[1], Y. Kondo[1], Y. Sakai[1], S. Kojima[1], H. Tamai[1], J. Kikuchi[1], K. Matsumoto[1], Y. Kaneko[1]. [1]*Keio University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Tokyo, Japan*

Background: Adult-onset Still's disease (AOSD) is a rare systemic autoinflammatory disease, characterized by symptoms such as spiking fever, arthralgia, sore throat, and skin rashes. The detailed pathogenesis of AOSD is not yet understood, hence the management often involves the use of corticosteroids. Among glucocorticoid-associated complications, osteonecrosis of the femoral head (ONFH) is rare and not immediately life threatening, however, delayed diagnosis can lead to a significant reduction in patients' quality of life and often requires surgical treatment. Although it is of great importance for rheumatologists to understand ONFH, little is known about ONFH in patients with AOSD because most studies on ONFH in adult have focused on systemic lupus erythematosus (SLE) despite AOSD being heavily glucocorticoid-exposable similar to SLE.
Objectives: To investigate the prevalence of ONFH complications among AOSD patients and explore its risk factors.
Methods: We reviewed all consecutive patients with AOSD who have visited the Keio University Hospital from 2012 to 2022 retrospectively. We investigated the development of ONFH after treatment and assessed relevant clinical features and laboratory data. To compare the frequency of ONFH in patients with AOSD with that in those with other rheumatic diseases, we also investigated prevalence of OFNH in patients with other rheumatic musculoskeletal diseases including SLE, idiopathic inflammatory myopathy (IIM), and vasculitis who had a history of treatment with high-dose (0.8 – 1mg/kg) glucocorticoid. All statistical analyses were performed using JMP 15 (SAS Institute Inc., Cary, NC, USA).
Results: We included 108 AOSD patients in the analysis and collected information from their charts. The mean age of onset was 44 years old, and 77% of the patients were female. Out of 108 patients, 9 (8.3%) developed OFNH throughout the mean observation period of 12.8 years. All 9 patients with OFNH had a history of high-dose corticosteroid therapy, and 8 of 9 (88.9%) received glucocorticoid pulse therapy. Univariate analysis revealed that male and complication of serositis or remarkable leukocytosis (>15000/μL) were associated with development of ONFH in AOSD patients, in addition to the history of treatment with high-dose glucocorticoid and pulse therapy (Table 1.) Next, we compared the frequency of ONFH development among 60 AOSD patients with high-dose corticosteroid treatment history with that of patients with other rheumatic diseases including SLE (n=312), IIM (n=84), small-vessel vasculitis (n=123), and large-vessel vasculitis (n=59). We identified that AOSD patients were second most likely to develop ONFH, following SLE; ONFH prevalence was 15.0% in AOSD, 20.5% in SLE 6.0% in idiopathic inflammatory myopathy, 1.6% in small-vessel vasculitis, and 1.6% in large-vessel vasculitis (Figure 1).
Conclusion: The complication of ONFH is frequent in patients with AOSD, the second highest after SLE in rheumatic musculoskeletal diseases. Glucocorticoid pulse therapy, high-dose glucocorticoid therapy, male sex, and remarkable leukocytosis and serositis are risk factors for developing ONFH.

POS0959 **WITHDRAWN**

POS0960 **INCREASED INCIDENCE OF SJÖGREN'S SYNDROME IN THE FEMALE PATIENTS WITH HASHIMOTO THYROIDITIS: A LARGE PROPENSITY SCORE-MATCHED COHORT STUDY**

Keywords: Epidemiology, Sjögren syndrome, Comorbidities

Y. Du[1], Q. Tong[1], R. Cui[1], Q. Wang[1], S. I. Wang[2], J. Wei[3], S. M. Dai[1]. *[1]Shanghai Sixth People's Hospital, Shanghai Jiao Tong University School of Medicine, Department of Rheumatology and Immunology, Shanghai, China*; *[2]Chung Shan Medical University Hospital, Center for Health Data Science, Taichung, China*; *[3]Chung Shan Medical University Hospital, Department of Allergy, Immunology and Rheumatology, Taichung, China*

Background: In clinical practice, we notice that **S**jögren's syndrome (SS) usually coexists with Hashimoto thyroiditis (HT). There were a lot of case reports regarding the coexistence of SS and HT.
Objectives: To determine whether Hashimoto thyroiditis (HT) is a risk factor of Sjögren's syndrome (SS) longitudinally in a very large cohort.
Methods: We conducted a cohort study using TriNetX (Cambridge, MA, USA), a global federated health research network that provides real-time electronic medical record datasets. The diagnosis of HT or SS was based on ICD10 codes. We analyzed the incidence of newly diagnosed SS in the female patients with HT within ten years. Propensity score matching including 38 factors was performed to adjust for demographic variables, comorbidities, and medication use. Kaplan-Meier analysis was used to estimate the probability of the outcome of interest. The hazard ratio (HR) and associated confidence intervals (CI) were calculated along with the proportionality test using R's Survival Package v3.2-3.
Results: We identified 101,590 female patients aged 20-64 years with HT among 54,801,179 patients in the database with ≥ 2 visits between 2012/01/01~2021/12/31. Of these patients, 100,027 were included after exclusion those diagnosed with SS before index date. The control cohort was selected from those females without thyroid disorders or related therapy. After 1:1 propensity score matching, 100,027 patients in either HT or control cohort were analyzed for comparison. After one-year follow-up, the incidence (0.51%) of new cases of SS in the HT cohort was higher than that (0.098%) in the control cohort (HR 4.324, 95% CI 3.483-5.368). During the study period, higher incidence of SS in the HT cohort (1.16%) than in the control cohort (0.36%) was found (HR 3.557, 95% CI 3.151-4.016). Increased incidences of SS in HT cohort were also confirmed in the subgroups of different ages, races and smoking status, and subgroups with or without diabetes mellitus, overweight/obesity, sleep disorder, depression, hypertension and asthma (Figure 1).
Conclusion: This study underlines that HT is a risk factor for developing SS, which implies that SS and HT are 2 autoimmune diseases closely related, and may share some underlying pathophysiological mechanisms.

POS0961

ASSOCIATION BETWEEN AIR POLLUTANTS AND INITIATION OF BIOLOGICAL THERAPY IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A NATIONWIDE, POPULATION-BASED CASE-CONTROL STUDY

Keywords: Epidemiology, bDMARD, Spondyloarthritis

C. M. Kao[1], H. H. Chen[1,2]. [1]*Taichung Veterans General Hospital, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Taichung City, Taiwan, Republic of China*; [2]*Taichung Veterans General Hospital, Division of General Internal Medicine, Department of Internal Medicine, Taichung City, Taiwan, Republic of China*

Background: Ankylosing spondylitis (AS) is a systemic inflammatory disease and the first-line pharmacological therapy includes non-steroidal anti-inflammatory drugs (NSAIDs) for spinal and peripheral joint involvement and immunosuppressants including methotrexate (MTX) and sulfasalazine (SSZ) for peripheral arthritis[1]. Biological therapy under National Health Insurance (NHI) reimbursement is indicated for AS patients without adequate response to first-line therapy in Taiwan. Initiation of biologics such as tumor necrosis factor inhibitors and interleukin-17 inhibitors may act as a proxy for high disease activity. Outdoor air pollution has been found to trigger a systemic inflammatory response[2]. Therefore, we hypothesized that air pollutants may be associated with biologics use in AS patients.
Objectives: To investigate the association between air pollutants and initiation of NHI-reimbursed biologics indicated for high disease activity in patients with AS.
Methods: We conducted a nationwide case-control study using the Taiwan National Health Insurance Research Database, and incidental AS patients from 2003 to 2013 were identified. We excluded those with visits with a diagnosis of rheumatoid arthritis, those treated with biologics including etanercept, adalimumab, and golimumab before the first date of visit with AS diagnosis, and those without outpatient visits after 2009. We identified all AS patients initiating biologics for active AS as biologics cases, and non-biologics controls for those who didn't. Index date was designated as the date of initiation of first biologics for cases and the date of first outpatient department visits each year for controls. We matched both groups at a 1:4 ratio for gender, age at first biologic initiation (± 3 years), year of first AS diagnosis, and disease duration (± 0.3 year), and finally included 584 biologics cases and 2336 matched controls. With aid of a spatio-temporal model built by a deep-learning approach, we used the hourly concentrations of ambient air pollutants from 60 air quality censoring stations to estimate the mean exposed levels of air pollutants, including PM2.5, PM10, NO2, CO, SO2, and O3, at 374 residential locations in Taiwan within one year before index date. We examined the association of biologics initiation and air pollutants using conditional logistic regression analyses shown as adjusted odds ratio (aOR) with 95% confidence intervals (CIs) adjusting for potential confounders within one year before index date including disease duration, urbanisation level, monthly income, Charlson comorbidity index (CCI), extra-articular manifestations (i.e., uveitis, psoriasis, and inflammatory bowel disease), and use of medications for AS.
Results: The initiation of NHI-reimbursed biologics was associated with disease duration (aOR, 8.97; 95% CI, 5.99–13.46), CCI (aOR, 1.31; 95% CI, 1.12–1.53), psoriasis (aOR, 25.06; 95% CI, 9.47–66.35), use of NSAIDs (aOR, 23.66; 95% CI, 8.96–62.46), MTX (aOR, 4.53; 95% CI, 2.93–7.00) and SSZ (aOR, 12.15; 95% CI, 8.98–15.45), prednisolone equivalent dose (mg/day) (aOR, 1.11; 95% CI, 1.05-1.18). After adjusting for potential confounders, it was associated with exposure to CO (per 1 ppm) (aOR, 8.58; 95% CI, 2.02–36.35), and NO2 (per 10 ppb) (aOR, 0.23; 95% CI, 0.11–0.50).
Conclusion: Use of NHI-reimbursed biologics, a proxy for high disease activity, in AS patients was positively associated with CO level, but negatively associated with NO2 level. Further studies are warranted to confirm our findings and elucidate the mechanisms.

POS0962

DIFFERENCE IN CLINICAL AND SEROLOGICAL CHARACTERISTICS OF ADULT ONSET STILL'S DISEASE BETWEEN ELDERLY-ONSET AND YOUNG-ONSET PATIENTS

Keywords: Rare/orphan diseases, Epidemiology

Y. Sakai[1], Y. Kondo2, S. Kasai2, S. Kojima2, H. Tamai2, Y. Kaneko2. [1]*Keio University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Tokyo, Japan*; [1]*Keio University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Tokyo, Japan*

Background: Adult-Onset Still's Disease (AOSD) is a systemic autoinflammatory disease of unknown etiology characterized by fever, skin rash, and arthritis. AOSD generally develops in young adults, with the mean age at onset in the 30 to 40 years old and female dominant. However, the distribution of age at diagnosis has recently shifted towards older in patients with AOSD, as well as other rheumatic musculoskeletal diseases. The clinical manifestations of patients with elderly-onset AOSD have not been characterized yet, and understanding the characteristics of patients with elderly onset AOSD is essential for appropriate management.
Objectives: To clarify the clinical manifestations of patients with elderly onset AOSD.
Methods: We reviewed consecutive patients with AOSD who had visited Keio University Hospital from 2012 to 2022 retrospectively. We divided them into two groups according to the onset age. The age for elderly-onset AOSD was defined as ≥ 65 years. We compared their clinical characteristics, laboratory findings, and image examination data. All statistical analyses were performed using JMP 15 (SAS Institute Inc, Cary, NC, USA).
Results: We included 103 patients with AOSD in the analysis. Among them, 20 (19%) developed AOSD at age 65 or older and were categorized as elderly-onset. The median age of the elderly-onset and young-onset patients was 78 and 47 years, and female proportion was 75% and 82%, respectively. The proportion of elderly-onset AOSD patients significantly increased from 2000s, with the highest of 30% after 2010s (Figure 1). In the elderly-onset group, the frequency of serositis, interstitial lung disease, and median Pouchot Score were significantly higher than the young–onset group (70% vs 8%, p<0.001; 26% vs 6%, p=0.009; 7 vs 6, p=0.014, respectively). On another front, typical rash, sore throat, and splenomegaly were less frequent (40% vs 74%, p=0.039; 40% vs. 67%, p=0.026; 21% vs 50%, p=0.025, respectively, Table 1). The duration of hospitalization was longer (48 vs 30 days, p=0.03), and the yearly incidence of hospitalization was significantly higher in the elderly-onset group (0.86/year vs 0.24/year, p<0.001). Hospitalization for AOSD flare or recurrence was comparable between the groups (44% vs 50%, p=0.632), while hospitalization due to infectious complications was more frequently observed in the elderly-onset group.

Table 1. Clinical characteristics of young and elderly-onset AOSD

	Younger-onset AOSD (n=83)	Elderly-onset AOSD (n=20)	p Value
Age at diagnosis (years)	**47**	**78**	**<0.001***
Sex (Female %)	62(75%)	14(82%)	0.501
Death (n (%))	4(4.8%)	2(10.0%)	0.330
Observation period (year)	**7.8(3.4-14.7)**	**3.5(1.9-5.8)**	**0.008***
Length of Hospitalization (Day)	**27(0, 56)**	**79(36.5, 169.5)**	**<0.001**
Clinical Characteristics			
High fever (>39℃)	46(92%)	17(85%)	0.399
Pharyngalgia	**53(67%)**	**8(40%)**	**0.026***
Typical rash	**57(74%)**	**8(40%)**	**0.004***
Myalgia	30(65%)	8(44%)	0.128
Arthralgia	72(87%)	19(95%)	0.302

White blood cell (/μL)	15450 (11700-19335)	16250 (10978-19958)	0.838
CRP (mg/dL)	15.8(7.9-19.7)	14.1(7.1-24.0)	0.620
Ferritin (ng/mL)	3373 (990-9020)	4565 (1306-13640)	0.747
Pouchot score	**6(4-6)**	**7(5-7.8)**	**0.013***

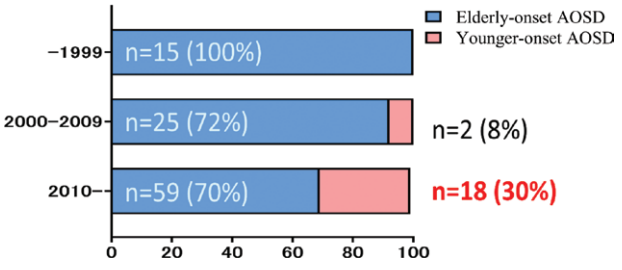

Figure 1. Trends in the proportion of young and elderly-onset AOSD

Conclusion: The frequency of patients with elderly-onset AOSD has been increasing in recent years. Patients with elderly-onset AOSD had significantly characteristic clinical features in comparison with those with young-onset AOSD. Attention should be made for infectious complications as well as AOSD flare in patients with elderly-onset AOSD.

POS0963 PERINATAL DEATHS IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

Keywords: Mental health, Pregnancy and reproduction

M. E. Corral Trujillo[1], R. A. Cerda González[1], H. G. Martínez Sandoval[1], A. Carrazco Chapa[1], F. R. Arevalo Nieto[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], D. Á. Galarza-Delgado[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*

Background: The grief over the death of a baby around the date of birth registers becomes a traumatic event and generates emotional distress, changes in sleep and eating patterns, vulnerability to illness and an increased risk of maternal mortality up to two years following the loss [1]. In México during 2021, 23,000 fetal deaths were registered: 83.5% were before birth, 15.3% during birth and 1.2% was not specified [2]. Women with autoimmune rheumatic diseases (ARDs) have greater risk of perinatal loss, the correct psychological approach is fundamental in the grieving process when these events occur.

Objectives: Describe the frequency and characteristics of the perinatal loss (PL) in women with ARDs.

Methods: A descriptive, observational, cross-sectional study was conducted; we selected patients with history of PL from 2017 to date. Clinical records from the Pregnancy and Rheumatic Diseases Clinic (CEER) from the Hospital University "Dr. José Eleuterio González" in México were revised to obtained ARDs, obstetric clinical history, socioeconomic studies and the Edinburgh Postnatal Depression Scale (EPDS) scores.

Results: From the 79 patients that have been admitted to the clinic, 16 (20%) had PL. The ARDs more frequent was Rheumatoid Arthritis (RA) with 7 (43.8%) patients, Systemic Lupus Erythematosus (SLE) with 6 (37.5%) and other diagnosis (Dermatomyositis, Antiphospholipid Syndrome and UCTD) with 3 (18.9%), other characteristics are displayed in **table 1**. Twelve of these patients have their ARDs active during their pregnancy, 4 of them didn't continue with their rheumatic treatment after the event. Regarding the PL; 6 (37.5%) experienced the loss during the first trimester, 3 (18.7%) in the second trimester and 1 (6.2%) in the third trimester and 6 (37.5%) were neonatal losses. From all the pregnancies, 9 were not planned and 13 were desired. Grieving counseling was offered to the patients, only 5 (31.2%) get the counseling for an unspecified period of time. All the patients were asked to respond the EPDS; only 11 (69%) of them answered it and 3(27%) got a score greater than 13 (need for follow up of possible depressive symptoms). Of this deaths, one was in the second trimester and two were after birth. Scores greater than 13 were correlated with education, marital status, total number of PL and agreeing to the grieving counseling. No statistically significant correlation was found.

Conclusion: We have a 20% loss rate in our population. Women with ARDs that experienced one or more perinatal deaths could have greater risk to develop physical and emotional complications after the event. It's necessary to develop a proper guideline to treat our patients and prevent physical and emotional struggles.

Table 1. Clinical characterization

	Loss during pregnancy (n=10)*	Neonatal loss(n=6)*
Age(mean)	33.7	24.33
Years of education, n(%)		
<9 years	5(50%)	1(17%)
High School	5(50%)	5(83%)

POS0964 RELATIONSHIP BETWEEN PM2.5 PARTICLE FROM HOUSEHOLD AIR POLLUTION AND INFLAMMATORY AND EPIGENETIC MARKERS IN RHEUMATIC PATIENTS FROM AN INDIGENOUS COMMUNITY IN CHIAPAS: BASELINE STUDY

Keywords: Cytokines and chemokines, Genetics/epigenetics, Lifestyles

J. L. Montiel Hernández[1], I. Peláez-Ballestas[2], J. A. Alegria-Torres[3], C. A. Celia[4], D. L. Gomez-Galicia[1], M. A. Garza Elizondo[5], A. Gastelum-Strozzi[6]. *[1]Universidad Autónoma del Estado de Morelos - UAEM, Pharmacy, Cuernavaca, Mexico*; *[2]General Hospital of Mexico Dr. Eduardo Liceaga, Rheumatology, Ciudad de México, Mexico*; *[3]Universidad de Guanajuato, Pharmacy, Guanajuato, Mexico*; *[4]National Autonomous University of Mexico, Biomedical Devices Group ICAT, Mexico City, Mexico*; *[5]Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*; *[6]Universidad Nacional Autónoma de México, Technological Research and Development Unit, Ciudad de México, Mexico*

Background: Chronic exposure to household air pollution (HAP) from cooking by biomass leads to noncommunicable diseases as chronic obstructive pulmonary disease or lung cancer (1), but it is less well known if it could promote epigenetic or proteomic changes leading to autoimmune susceptibility. HAP remains a serious health problem for poor and marginalized indigenous communities. Recent studies have shown a high prevalence of rheumatic disease in Latino American indigenous people (2), but it is unknown if HAP and the PM2.5 particles, could be a risk factor for the pathogenesis of rheumatic diseases.

Objectives: To evaluate the relationship between the levels of PM2.5 derived from HAP and levels of inflammatory and epigenetic markers in rheumatic patients from an indigenous community in Chiapas, México.

Methods: Cross-sectional study nested in a cohort of patients with rheumatic disease in a Tzotzil indigenous community in Chiapas (Southern Mexico). Following the COPCORD methodology and employing an instrument adapted and translated into the local language, people with chronic pain were identified from the adult inhabitants of the community. Rheumatic disease diagnosis was made by a certified rheumatologist. Baseline blood samples were collected from rheumatic patients and controls without rheumatic disease. PM2.5 particle ($\mu g/m^3$) were measured in house indoor air continuously for 37 hours and the mean and accumulated levels calculated. Blood levels of cytokines IL-6, IL-8 and MCP-1 and epigenetic markers (H3K18ac and 5-methylcitosine%) were determined by ELISA. Comparisons between groups were analyzed using the Mann-Whitney U tests. Spearman correlation testing was employed to correlate PM2.5 particle and baseline markers levels. Statistical significance was set at 0.05%.

Results: The indigenous community is made up of 123 adults who live in 53 houses, with an average age of 38.3±16.2 years, where 61.2% are women and 43% only speak local language. Of a total of adult inhabitants, 69 people with chronic pain and 14 patients with different rheumatic diseases (11.4%) were identified. Additionally, 25 biological samples were collected from volunteers without rheumatic disease. When comparing the inflammatory levels and epigenetic markers in the baseline blood samples between these two groups, no significant differences were found. The mean PM2.5 particle inside the houses was 114.5±140.1 $\mu g/m^3$ (8.23-462.9), while for control measurements outside it was 9.1±5.5 $\mu g/m^3$ (4-14.9). However, when comparing PM2.5 levels at homes of patients and controls, no significant differences were found (40.99 vs. 65.19 $\mu g/m^3$). Likewise, no significant correlation was observed between inflammatory markers or epigenetic markers, either when evaluating as group or as a whole. It is necessary to complete the baseline study by evaluating citrullination levels in sputum and blood samples, as well as perform a deeper analysis of exposure time to high levels of the PM2.5 particle.

Conclusion: We found no relationship between PM2.5 levels and the levels of inflammatory or epigenetic markers, suggesting that HAP could have a more complex pathogenesis than expected on rheumatic health.

POS0965 SEVERITY AND PROGRESSION OF RADIOGRAPHIC HAND OA IS NOT ASSOCIATED WITH PROGRESSION OF RADIOGRAPHIC KNEE OA: THE IMI-APPROACH COHORT

Keywords: Prognostic factors, Bone diseases, Osteoarthritis

S. Terpstra[1,2], L. A. Van de Stadt[1], F. Berenbaum[3], F. Blanco[4], I. K. Haugen[5], F. Lafeber[6], H. Weinans[7], F. Rosendaal8, M. Kloppenburg8,9. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[2]Leiden University Medical Center (LUMC), Clinical Epidemiology, Leiden, Netherlands*; *[3]Sorbonne Université, Rheumatology, Paris, France*; *[4]University Hospital of A Coruña, Rheumatology, A Coruña, Spain*; *[5]Diakonhjemmet Hospital, Rheumatology, Oslo, Norway*; *[6]UMC Utrecht, Rheumatology & Clinical Immunology, Utrecht, Netherlands*; *[7]UMC Utrecht, Orthopedics, Utrecht, Netherlands*; *[2]Leiden University Medical Center (LUMC), Clinical Epidemiology, Leiden, Netherlands*; *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: Osteoarthritis (OA) frequently affects multiple joints including the knees and hands. Currently, it is unknown which patients with knee OA have the highest risk to progress, and how these patients can be identified.

Objectives: To investigate the association of radiographic hand OA and its progression with radiographic knee OA progression over two years of follow-up.

Methods: We used baseline and two-year follow-up data from the Applied Public-Private Research enabling OA Clinical Headway (IMI-APPROACH) cohort. This cohort consists of participants fulfilling the American College of Rheumatology clinical knee OA classification criteria who were likely to have radiographic joint space width loss and/or knee pain progression based on machine learning. Participants and OA characteristics were collected using validated questionnaires and tests. Radiographs of both knees and both hands were scored paired in known time order. Joints were scored according to Kellgren and Lawrence (KL) assessing both knees and both hands (DIPJs, PIPJs, IPJs, MCPJs and CMC1Js (range 0-4 for each joint)). Osteophytes and joint space narrowing (JSN) were scored on 0-3 scales in the bilateral DIPs, PIPs and CMC1s and as absent/present in the IPJs and STTs according to the OARSI atlas, bilateral medial and lateral femoral and tibial osteophytes were scored (0-3 scale), as well as medial and lateral tibiofemoral JSN (0-3 scale). Radiographic knee and hand OA progression were defined as a difference larger than the minimal detectable difference (MDD; based on repeated scoring of 30 radiographs) for the concerning score. Participants that had a knee replacement during follow-up (n=22) were considered as progressors. Logistic regression analyses were used to assess the association of the severity (sum score) or progression of hand OA with knee OA progression for osteophytes, JSN and KL score separately, adjusted for potential confounders (age, sex, BMI and radiographic hand and knee baseline scores).

Results: There were 222 participants with radiographic data on both knees and both hands at baseline and two years (mean baseline age 66 (standard deviation (SD) 7), 171 (77%) women, mean BMI 27.7 (SD 5.0)). Any radiographic abnormality at baseline (osteophyte, JSN or KL score >0) was present in 195 participants (88%) in any knee and for 217 (98%) in any hand. Baseline and two-year radiographic outcomes are shown in **Table 1**. Radiographic hand OA features at baseline were not associated with knee OA progression of the same features (adjusted odds ratio (95% confidence interval (OR (95% CI)) for osteophytes 0.98 (0.95;1.01), for JSN 1.01 (0.98;1.04) and for KL score 1.00 (0.97;1.02)). Osteophyte and KL score progression in the hands were not associated with knee progression of the same features (adjusted ORs 0.62 (95%CI 0.30;1.23) and 0.94 (95%CI 0.42; 2.00), respectively). Those with hand JSN progression had a crude OR of 2.45 (95%CI 1.01;5.70) for knee JSN progression (adjusted: 2.24 (0.88;5.42)).

Conclusion: Radiographic hand OA severity and progression was not associated with a higher risk of progression of radiographic knee OA. These data indicate that radiographic hand OA does not add to identify radiographic knee OA progressors, and suggest different underlying pathogenetic mechanisms playing a role in these two phenotypes.

Table 1. Radiographic hand and knee osteoarthritis scores (n=222)

Score (range)	Baseline (median, interquartile range)	Two years (median, interquartile range)	Minimal detectable difference	Number of participants with progression (%)
Knees				
Osteophyte sum score (0;24)	4 (1;7)	5 (2;9)	1.1	81 (38%)
JSN sum score (0;12)	1 (0;3)	2 (1;4)	1.24	32 (15%)
KL sum score (0;8)	3 (1;4)	3 (2;5)	0.65	53 (25%)
Hands				
Osteophyte sum score (0;58)	10 (5;27)	10.5 (6;19)	1.7	60 (28%)
JSN sum score (0;58)	4 (1;9)	5 (1;11)	1.98	39 (18%)
KL sum score (0;120)	16 (9;27)	17 (10;29)	1.73	55 (26%)

Progression was defined as a change larger than minimal detectable difference. Abbreviations: JSN = joint space narrowing, KL = Kellgren and Lawrence.

POS0966 THE RISK OF INFLUENZA IN PATIENTS WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES-FOCUS ON PRIMARY SJOGREN'S SYNDROME, POLYMYOSITIS/DERMATOMYOSITIS AND SYSTEMIC SCLEROSIS

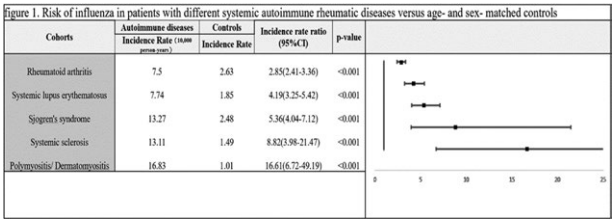
Keywords: Sjögren syndrome, Systemic sclerosis, Myositis

I. P. Lee[1], F. Y. Wu[1], C. F. Su[1], S. H. Lin[1], Y. S. Chang[1,2]. *[1]Shuang Ho Hospital, Taipei Medical University, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, New Taipei City, Taiwan, Republic of China*; *[2]School of Medicine, College of Medicine, Taipei Medical University, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China*

Background: Influenza vaccine is recommended in patients with most systemic autoimmune rheumatic diseases (SARDs). However, the risk of influenza was less studied in the SARDs other than rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE).

Objectives: This study aimed to investigate the risks of influenza-related hospitalization in patients with SARDs, including primary Sjogren's syndrome (pSS), polymyositis/dermatomyositis (PM/DM), systemic sclerosis (SSc), RA and SLE.

Methods: This is a nationwide population-based cohort study analyzing the National Health Insurance Database in Taiwan. Patients with catastrophic certification of each SARD were identified. The risks of influenza-related hospitalization in patients with each SARD were compared with their age- and sex-matched non-AIIRD cohort (1:2). Incidence rates (IR) with incidence rate ratios (IRR) in various AIIRDs were analyzed.



Results: Totally, 48,905 patients with RA, 24,143 patients with SLE, 16,891 patients with pSS, 2,633 patients with SSc and 2561 patients with PM/DM were identified, with basic characteristics shown in table 1. The IR of hospitalization due to influenza was highest in patients with PM/DM (Figure 1) followed by pSS, SSc, SLE and RA. In comparison with their age- and sex-matched controls,

the risk was highest in patients with PM/DM with an IRR of 16.83, followed by patients with SSc, pSS, SLE and RA.

Conclusion: Patients with PM/DM, SSc, pSS, RA and SLE had significant increased risk of influenza-related hospitalization. In comparison with each matched controls, PM/DM, SSc and pSS cohorts had even higher IRR than that of the SLE and RA cohorts, whose risks of influenza and the benefit of vaccination were well-known. Considering the risk, patients with these SARDs should follow the recommendations to have influenza vaccine every year and further study about the benefit of vaccine in patients with DM/PM, SSc and pSS are needed.

Table 1. Clinical characteristics of systemic autoimmune rheumatic diseases and the age- and sex-matched cohorts

Variables	Patients with autoimmune diseases	Age- and sex-matched controls	*p* value
Rheumatoid arthritis	**n =48905**	**n =97810**	
Mean age (SD), years	52.50(15.61)	52.52(16.61)	0.813
Female, n (%)	37659(77.0%))	75318(77.0%)	1
Influenza, n (%)	291(0.60%)	297(0.30%)	<0.001
Systemic lupus erythematosus	**n =24143**	**n =48286**	
Mean age (SD), years	35.56(15.84)	35.56(15.84)	0.952
Female, n (%)	21308(88.3%)	42616(88.3%)	1
Influenza, n (%)	170(0.70%)	99(0.21%)	<0.001
Systemic sclerosis	**n =2633**	**n =5266**	
Mean age (SD), years	50.04(49.44)	50.02(49.60)	0.965
Female, n (%)	1979(75.2%)	3958(75.2%)	1
Influenza, n (%)	25(0.95%)	9(0.17%)	<0.001

POS0967

MORTALITY-RELATED HEALTH METRICS IN RHEUMATIC AND MUSCULOSKELETAL DISEASES AN EPIDEMIOLOGICAL ANALYSIS OF A NATIONWIDE REGISTER-BASED COHORT

Keywords: Geographical differences, Registries, Epidemiology

M. Li[1], C. Wu[1], P. Yin[2], M. Zhou[2], M. Li[1], X. Zeng[1]. *[1]Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China*; *[2]Chinese Center for Disease Control and Prevention, National Center for Chronic and Noncommunicable Disease Control and Prevention, Beijing, China*

Background: Rheumatic and musculoskeletal diseases (RMDs) have become leading causes of death (CODs)[1,2]. However, few study has provide an integrated overview of mortality burdens, leaving a care gap between regions[3]. Therefore, estimates on mortality burdens of RMDs and their relationships with socioeconomic factors are essential for prioritizing health policies, especially in low-to-middle income countries (LMICs).

Objectives:

- To provide an integrated atlas of mortality-related health metrics of 9 RMDs, including RA, SpA, SLE, SS, IIM, SSc, BD, TAK, and AAV.
- To illustrate the associations between disease burdens of RMDs and development indicators from multiple aspects.

Methods: A nationwide multicentre cohort was linked to Nation Mortality Surveillance System. RMD ascertainment was based on classification criteria, death case ascertainment was following ICD-10 codes. Data collection was conducted, followed by a 3-phase imputation and sensitivity analyses. CODs, SMRs, and life expectancies were estimated. A composite indicator, human development index (HDI), and indicators in economy, healthcare, and education were adopted as area-level socioeconomic status indicators. Mixed-effects meta-regression models were established to explore impacts of socioeconomic indicators.

Results: Between 2008 and 2021, 175 846 individuals were included (Figure 1). AAV, IIM, and SSc ranked top 3 diseases with the highest fatality rates over 10% and lowest survival rates within 10 years after the first diagnosis of RMDs. Principal immediate CODs in patients with RMDs are shown in Figure 1. Adjusted SMR was highest for TAK, followed by IIM, SSc, SLE, AAV, BD, and SS (Figure 1). The mortality risk of patients with RA was generally comparable with overall population. Early disease-onset is a risk factor of excess death in both male and female patients with CTDs. Higher HDI was associated with significant increases in mortality risks in both RA and SLE (SMR ratio 12.24 and 5.15 for 1-unit increase in HDI, p<0.001 and p=0.080) patients compared with region-specific general population. More medical institutions (SMR ratio 0.95 for 1 more medical institution per 10 000 resident population, p=0.005) and hospital beds (SMR ratio 0.35 for 1 more hospital bed per 100 resident population, p=0.131) were protect factors of excess mortality in SLE. In overall patients, SS, SLE and AAV, IIM and SSc, had mild, moderate, and strong associations with the loss in life expectancy, respectively (Figure 1).

Conclusion: This study relied on the biggest nationwide register-based cohort of more than 170 000 patients with RMDs confirmed by rheumatologists. We observed that mortality risk (up to 4.5 times) and loss of life years (up to 25 years at the age of 10) in patients with RMDs can be in substantial excess versus general population. Additionally, our study provides the first systematic account that the mortality burdens of RMDs have a complicate relationship with the level of regional deprivation. Increasing mortality burdens associated with RMDs implied the relative insufficiency of capacity building of diagnosis and treatment in RMDs in LMICs.

POS0968

ANCA-ASSOCIATED VASCULITIS INCIDENCE IN A NORTHERN SPANISH HEALTH REGION, 1994-2022: A POPULATION-BASED STUDY

Keywords: Descriptive studies, Vasculitis, Epidemiology

S. Al Fazazi[1], A. Herrero-Morant[2], V. Calvo-Río[2], M. Renuncio García[3], C. Escagedo Cagigas[4], M. Rodriguez Vidriales[4], R. Blanco[2]. *[1]Hospital Universitario Puerta del Mar, Rheumatology, Cádiz, Spain*; *[2]Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; *[3]Marqués de Valdecilla University Hospital, Immunology, Santander, Spain*; *[4]Marqués de Valdecilla University Hospital, Nephrology, Santander, Spain*

Background: Anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) includes granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA) or microscopic polyarteritis (MPA). Precise estimation of the incidence of AAV has been difficult due to the absence of reliable diagnostic criteria.
Objectives: To estimate the incidence in a Northern Spanish population-based cohort.
Methods: Population-based study of 132 patients diagnosed with small vessel vasculitis between 1994 and 2022 in a tertiary hospital. Finally, 98 patients were included as AAV according to ACR/EULAR 2022 criteria [1]. Incidence was estimated by gender, age, and year of diagnosis.
Results: AAV was diagnosed in 98 (49 women/ 49 men) patients: GPA (n=47, 48%) MPA (n=37,37.8%) and EGPA (n=14, 14.3%). Annual incidences were estimated in AAV (Figure 1). GPA annual incidence in our population area in the 1994-2022 period was 2.81 per 1,000,000 people, 95% CI: 3.77-1.85 (2.82 [4.35-1.29] in males and 2.80 [4.50-1.09] in females). An upward trend in annual incidence over time was observed with rates ranging from 1.88 in 1994 to 6.84 in 2022 (weak correlation; r 2=0.2729). On the other hand, MPA annual incidence was 2.23 per 1,000,000 people (1.92 [3.55-0.27] in males and 2.46 [4.07-0.85] in females). Rates ranged from 1.88 in 1994 to 1.71 in 2022 with an upward trend over time (very weak correlation; r 2=0.0746). In the case of GEPA, annual incidence was 0.83 per 1,000,000 people, 95% CI: 1.72-0.06 (1.22 [2.74-0.30] in males and 0.46 [2.29-1.37] in females). As in the other types of AAV, there was an upward trend over time with variations of from 1.88 in 1999 to 3.42 in 2022 (weak correlation; r 2=0.3335). A comparison between different geographical areas is summarized in Table 1. Wide varia-tions in annual incidence per million were observed in all AAV (GPA 2.1-34; MPA 2.23-10.4; EGPA 0.64-2.7). The highest annual incidence of all AAV was observed in nordic countries and central Europe while the lowest in Southern Europe.
Conclusion: There seems to be a progressive increase in incidence of AAV over the years in the studied population. Annual incidence in our population was similar to that of other south-ern European countries.

Background: The main treatment of polymyalgia rheumatica (PMR) are glucocorticoids (GC) with a 6-month decrease target, but 45% of patients have an unfavourable evolution with relapses or glucocorticoids dependence. Poor prognostic factors in PMR are understudied and controversial.
Objectives: The aim of this work was to identify predictive factors of favourable evolution in GC-dependent PMR patients to optimize its management.
Methods: This work used data from the phase III study SEMAPHORE, which compared tocilizumab with placebo in combination with a standardized decrease in oral GC in patients with GC-dependent PMR. Response to treatment was assessed at week 24 after 6 administrations of tocilizumab 8 mg/kg or placebo. The favourable outcome criterion was a PMR-AS < 10 with a dose of glucocorticoids ≤ 5 mg/day of prednisone equivalent or a dose reduction of ≥ 10 mg/day between inclusion and week 24. The prediction of a favourable outcome based on the inclusion parameters was evaluated in univariate and then multivariate analysis for the variables with a p <0.2 in univariate in the whole of the population and in both treatment arms (tocilizumab and placebo).
Results: At week 24, 49% of the 100 patients included had fulfilled the favourable outcome criterion. In the whole population, being treated with tocilizumab was the main predictor of favourable evolution (OR: 6.28 (2.49-17.27), p=0.0002). In the tocilizumab group, the absence of anemia, the absence of renal impairment and a low HAQ-DI at inclusion were predictive of favourable evolution (OR: 13.2

Present study, 2023	Northern Spain.	1999-2022	2.81	2.23	0.83

(1.62-166.5613.2), 8.78 (1.19-91.23) and 10.16 (2.03-78.66) respectively). No variable was related to favourable outcome in the placebo group.
Conclusion: In patients with an active disease despite GC, a favourable outcome was predict by tocilizumab treatment. In the population treated by tocilizumab, the absence of comorbidities such as anemia or renal impairment and a better functional activity with a low HAQ-DI were associated with favourable outcome. No predictive factors were identified in patients trated with GC only.

POS0970 PSYCHO-COGNITIVE FACTORS AND ADHERENCE IN AXIAL SPONDYLOARTHRITIS: A MULTICENTER CROSS-SECTIONAL STUDY

Keywords: Spondyloarthritis, bDMARD, Descriptive studies

M. Vandersmissen[1], T. Barnetche[2], A. Charlotte[3], J. Bernard[4], D. Jerome[5], J. Landrin[2], C. Lukas[3], A. Ruyssen-Witrand[5], A. Tournadre[4], P. Vergne-Salle[1]. *[1]Chu Dupuytren 2, Department of Rheumatology, Limoges, France*; *[2]Hospital Center University De Bordeaux, Department of Rheumatology, Bordeaux, France*; *[3]Hospital Center University De Montpellier, Department of Rheumatology, Montpellier, France*; *[4]CHU Gabriel-Montpied, Department of Rheumatology, Clermont-Ferrand, France*; *[5]Hospital Pierre Paul Riquet Toulouse, Department of Rheumatology, Toulouse, France*

Background: There is a lack of data on adherence in axial Spondyloarthritis (axSpA). It is estimated between 28.2 et 70.6% by the largest study currently available [1]. Many factors may influence adherence, among them psychological factors.
Objectives: The objectives were to assess the adherence to biological disease-modifying anti-rheumatic drug (bDMARDs) and the impact of catastrophizing, fibromyalgia, anxiety, and depression in a cohort of patients with axSpA.
Methods: A multicenter cross-sectional study was conducted in five departments of Rheumatology in France. Inclusion criteria were axSpA according to the ASAS criteria, and treatment by bDMARDs. Patients completed an anonymous self-questionnaire including demographic data, disease activity scores, Girerd score (GS) measuring adherence, and psycho-cognitive scores such as the Fibromyalgia Rapid Screening Tool (FIRST), Hospital Anxiety and Depression Scale (HAD) and the Pain Catastrophizing Scale (PCS). Rheumatologists completed an independent medical questionnaire collecting the disease-related data.
Results: 500 patients with axSpa were enrolled into the study between June 2021 and June 2022. Patients had a mean age of 49.5 ±13.8 and 53.2% were male. They were treated by anti-TNF, anti-IL 17 or anti-IL 12-23 in 85.8%, 13.2% and 1% of cases, respectively. Forty-nine point two percent were adherent (GS=0) and 50.8% were non-adherent (GS ≥1). The prevalence of catastrophizing, fibromyalgia, anxiety and depression in our study was 17.2%, 21.4%, 25.6% and 11.0%, respectively. Patients with best adherence were older (mean age: 53.26 ± 13.3 with GS=0 vs 45.85 ± 13.4 with GS ≥1; p<0.0001), pensioners (26.4 % with GS=0 vs 12.6% with GS ≥1; p<0.001) and had a lower education level (OR 1.84; 95% CI 1.23-2.75; p=0.03). Patients with anxiety and catastrophizing had a lower adherence (OR 1.53; 95% CI 1.02-2.30; p=0.04 and OR 1.61; 95% CI 1.00-2.58; p=0.05, respectively). Adherence was not different between male and female patients, although female patients with axSpA had more catastrophizing (OR 1.84; 95% CI 1.15-2.95; p=0.015), fibromyalgia (OR 3.27; 95% CI 2.07-5.16; p<0.0001) or anxiety (OR 2.26; 95% CI 1.50-3.41; p<0.0001). In multivariate analysis, lower adherence was associated with younger age (OR 0,96; 95 CI 0,95-0,98; p<0,001) and anxiety (OR 1,72; 95% CI 1,05-2,81; p=0,03).
Conclusion: Half of axSpA patients were non-adherent to bDMARDs, especially among young people, catastrophizers and patients with anxiety. We recommend that practitioners screen for these psycho-cognitive factors and manage them very carefully.

Background: Idiopathic inflammatory myopathies (IIM) are a group of systemic autoimmune conditions with predominant skeletal muscle involvement. Major subsets of disease recognised by the EULAR/ACR Classification Criteria include dermatomyositis (DM), amyotrophic dermatomyositis (ADM), inclusion body myositis (IBM) and polymyositis (PM) and immune mediated necrotising myositis (IMNM). Myositis-specific antibodies (MSA) more so than myositis-associated antibodies (MAA) are associated with distinct clinical phenotypes of disease and can aid in predicting the risk for extra-muscular manifestations, such as interstitial lung disease (ILD). Racial differences in autoantibody profile and clinical phenotypes have been described, though pooled intergroup comparisons are limited.
Objectives: We characterised the autoantibody profiles in IIM patients of different racial groups and identified relationships with IIM subsets and select extra-muscular manifestations.
Methods: Pooled data for adult IIM patients who had been tested for MSA and MAA was analysed. IIM subtypes were diagnosed by histology and/or EULAR/ACR criteria. Demographic, autoantibodies, clinical data, and mortality data, where available, was collected and analysed retrospectively in STATA. MSA includes autoantibodies directed against Jo1, PL-7, PL-12, EJ, OJ, Mi-2, SRP, NXP-2, TIF1-gamma, MDA5 and anti-HMGCR. MAA include autoantibodies against PM-Scl, Ku, U1RNP, and Ro52. Using multivariate logistic regression, we analysed the relationship of racial groups and autoantibodies, with (i) IIM subtypes, (ii) ILD and(iii) mortality.
Results: 787 (Australia (n=243), India (n=241), Japan (n=134), Malaysia (n=99), Singapore (n=51), Thailand (n= 19)) patients with IIM were analysed; 543 (67%) patients were female. The median age of diagnosis was 52 years (IQR 39, 64) with the following racial distribution: 26.7% identified as Caucasian, 37.2% East and Southeast Asian (SEA), 33.4% South Asian, and 3% other. The most frequent disease subsets were DM (n = 259) and PM/ IMNM (n = 264). MSA or MAA were detected in 351/787 patients (44.6%); of these 54.7% (192/351) were positive for MSA, 33.9% (119/351) were positive for MAA, and 11.4% were positive for both (40/351). DM was most frequently diagnosed in the East and SEA and South Asian racial groups. Controlling for demographics and autoantibodies, IIM patients of East and SEA descent were five times more likely to be diagnosed with DM (OR 5.52, 95% CI 3.19, 9.56) compared with Caucasians; South Asians were nine times more likely to be diagnosed with DM (OR 8.89, 95% CI 4.83, 16.36). Conversely in PM/IMNM, East and SEA (OR 0.20, 95% CI 0.12, 0.33) and South Asian (OR 0.34, 95% CI 0.20, 0.58) groups were much less likely to be diagnosed compared with Caucasians. Specific MSA and MAA were infrequently associated with racial groups. However, anti-SRP antibodies were 3 times more likely to be detected in the East and SEA groups (OR 2.84, 95% OR 1.04, 7.74) compared with Caucasians. Patients with anti-HMGCR antibodies were four times more likely to be diagnosed with PM and IMNM (OR 4.24, 95% CI 2.16, 8.33). MSA (OR 6.66, 95% CI 4.25, 10.43) and MAA (OR 3.06, 95% CI 1.76, 5.35) were more likely to be detected in

patients with ILD; no gender difference was evident. Compared with Caucasians, East and SEA (OR 5.14, 95% CI 2.59, 10.21) patients were up to 10 times more likely to be diagnosed with ILD. Controlling for racial groups, age and gender, IIM patients with ILD had significantly higher odds of mortality (OR 1.84, 95% CI, 1.02, 3.32), though the odds were significantly lower in the South Asian racial group (OR 0.37, 95% CI 0.14, 0.92) compared with Caucasians.

Conclusion: Our study is the first of its kind to demonstrate an association between racial groups, clinical profiles, autoantibodies, and the subtypes of IIM. There is heterogeneity in MSA and MAA positivity among racial groups. Importantly, we show that race appears to have a possible role in the predilection for IIM subtypes and ILD.

POS0972 INCREASED RISK FOR STROKE IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER, RESULTS FROM A LARGE POPULATION-BASED STUDY

Keywords: Rare/orphan diseases, Real-world evidence, Innate immunity

N. Ben-Shabat[1], O. Gendelman[1], L. Fisher[1], U. Shani[1], Y. S. Patt[1], D. Mcgonagle[2], A. Watad[1,2], H. Amital[1]. [1]*Sheba Medical Center, Internal Medicine B, Ramat-Gan, Israel*; [2]*Leeds Institute of Molecular Medicine, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom*

Background: The association between chronic inflammatory conditions and cardiovascular disease is well established. Considering Familial-Mediterranean-Fever (FMF), few studies exist investigating the risk of ischemic heart disease, and none address the risk of stroke.

Objectives: To evaluate the incidence and risk for stroke in FMF patients compared to the general population.

Methods: A retrospective cohort study using the electronic database of Clalit Health Services (CHS), the largest health organization in Israel. All FMF patients diagnosed between 2000-2016 were included and matched with control according to age, gender, and place of residence. Follow-up continued until the first diagnosis of stroke or death. The incidence of stroke was compared between the groups using univariate and multivariate models adjusting for cardiovascular risk-factors.

Table 1. Comparison of rates and risk for stroke in FMF patients compared to controls

Group	Variables	FMF	Controls
FMF (n=9,769 ¥)	Stroke events, n	208	148

† Including amyloidosis, chronic renal failure, dialysis, and kidney transplant.¶ Adjusted for age, sex, and cardiovascular baseline risk factors.¥ Compared to a similar number of matched controls.

Results: 9,769 FMF patients and a similar number of controls were followed up for a median period of 12.5 years. The mean age at the beginning of the follow-up was 25.7 years. 208 FMF patients were diagnosed with stroke compared to 148 controls, resulting in an incidence rate (per 10,000 persons-years) of 19.8 (95%CI 17.2-22.7), and 13.9 (95%CI 11.8 to 16.4) respectively, and a crude HR of 1.42 (95% CI 1.15 to 1.76; p<0.001). In a multivariate analysis, FMF patients who developed amyloidosis with related or non-related renal failure demonstrated significant stroke risk (HR=2.16; 95%CI 1.38 to 3.38; P<0.001), as well as for those who did not develop these complications (HR=1.32; 95%CI 1.04 to 1.67; P<0.05).

Conclusion: FMF patients are at increased risk for stroke regardless of known complications.

POS0973 EFFECT OF RENAL AND EXTRARENAL FLARES ON DEVELOPMENT OF CKD AND EXTRARENAL ORGAN DAMAGE IN PATIENT WITH LUPUS NEPHRITIS

Keywords: Organ damage, Systemic lupus erythematosus, Kidneys

C. Cruciani[1], M. Gatto[1], G. Frontini[2], M. Calatroni[3,4], F. Reggiani[3,4], B. Trezzi[5], L. Iaccarino[1], R. A. Sinico[4], A. Doria[1], G. Moroni[3,4]. Background: Systemic Lupus Erythematosus (SLE) is a systemic autoimmune disease with a plethora of manifestations potentially affecting every organ system. Lupus nephritis (LN) is recognized as one of the most common and fearsome manifestations presenting in up to 35-60% of SLE patients, usually during the first 5 years from disease onset[1]. LN and LN flares are associated with nephron loss and chronic kidney disease (CKD)[1,2,3], which on its own is a major risk factor for overall morbidity and mortality[1,4]. However, the association between extrarenal disease flares and CKD and the contribution of LN and extrarenal flares to overall damage accrual are less investigated.

Objectives: To assess the impact of disease flares on development of CKD and extrarenal organ damage in lupus nephritis.

Methods: We performed a multicentric retrospective cohort study on biopsy-proven LN patients in whom we evaluated the impact of disease flares on CKD development and damage accrual. Disease flares were divided into renal (doubling of serum creatinine or persistent increase in proteinuria with normal GFR) and extra-renal (cSLEDAI>0 across extrarenal domains). Renal-extrarenal clinical remission was defined as serum creatinine <1mg/dl, eGFR>60ml/min/1.73m2, proteinuria <0.5g/24h and cSLEDAI=0 lasting for at least one year.

CKD as serum creatinine >1.0mg/dl with eGFR <60ml/min/1.73 m2 and inactive urinary sediment, confirmed by at least three determinations for at least 3 months, and damage was measured by the SLICC damage index (SDI). Non-parametric tests were used for comparisons.

Results: 303 LN patients were included (females 86.5%, mean follow-up 14.8 (9.8-22.0) years). 257 patients (84.8%) achieved remission after a median of 1.44 (0.69-3.58) years from initial treatment, which persisted throughout follow-up in 115 patients. Among 142 patients who had their remission interrupted, 39 (27.5%) did so due to extrarenal flares, while 103 (72.5%) experienced renal flares (creatinine or proteinuria). Loss of remission due to extrarenal flares was less frequently associated with CKD development than remission lost to renal flares (5.1% vs. 28.2%, respectively; OR95%CI 0.14 (0.031-0.61), p=0.003), while the ultimate median annual SDI increase was comparable between patients experiencing either renal or non–renal flares (renal vs. extrarenal flares: +0.05 (0-0.1) vs. +0.06 (0-0.14), p=0.8).

Conclusion: Patients experiencing renal flares are at greater risk of CKD, yet more than 5% of patients undergoing extrarenal flares develop CKD. Renal and extrarenal flares both contribute comparably to damage accrual across other organ domains. Extra-renal flares deserve attention and should not be regarded as mild by definition.

Background: Major Cardiovascular Adverse Events (MCAE) are a concern in autoimmune diseases. Rheumatoid Arthritis (RA) and psoriasis arthritis (PsA) are diseases where inflammation plays a vital role in developing the disease and producing short- and long-term damage.

The TNF alpha plays a significant role in inflammation. The JAK/STAT signaling pathway is an essential regulatory signaling cascade of intracellular processes used in treating these conditions. It is crucial to evaluate the effect of these treatments on long-term comorbidities associated with these diseases.

Objectives: This study aims to provide real-world evidence on the influence of Anti-JAK, Anti-TNFa, and cs-DMARDs therapy on cardiovascular events in RA and PsA.

Methods: Data from the BIOBADASAR 3.0 registry of patients diagnosed with RA and PsA (ACR-EULAR 2010/ CASPAR 2006) from June 2010 to May 2022. This data was recollected from patients treated with cs-DMARDs (control group), Anti-TNF alpha, and JAK inhibitors. The history of specific comorbidities and the appearance of AE were recorded. Kaplan Meier curves evaluated event-free survival time, and the comparison between the different treatments was performed by Log Rank analysis. Additionally, to account for alternative explanations, a propensity score (PS) was estimated, which assigned a value to each observation according to the probability of incorporating all the information available to estimate this probability and making the groups associating similar patients more comparable.

Results: Of 6,209 patients, 4,817 (77.6%) with RA and 510 (8.2%) with PsA were studied. The overall frequency of MCAE was 48 (2.2%) in the Anti-TNFa group, 5 (2.37%) in the Anti-JAK group, and 38 (1.84%) in the control group (p=0.6). MCAE-free survival was a median in years of 3.02 for the Anti-TNFa group (HR 1.3 95%CI 0.8-384), 5.1 for the control group (HR 1.5 95%CI 0.32-651), and 1.8 for the group with JAK inhibitors (HR 3.02 95% CI 0.2-0.8), The results of the regression model adjusted by PS to present MCAE were for the Anti-TNFa group HR 1.28 IC95% 0.77-2.13 p 0.34, for the non-exposed group HR 1.48 IC95% 0.82-2.67 and the JAK inhibitor group 3.12 IC95% 1.48-6.6 p < 0.001.

Conclusion: In conclusion, we found no statistically significant difference between the RA and APS groups appearance of adverse events of interest. In this study, we observed a higher MCAE-free survival time in the not exposed group than in the Anti-TNFa group and considerably low in the Anti-JAK group with a statistically significant difference. These differences persist in the multivariate model adjusted by propensity score.

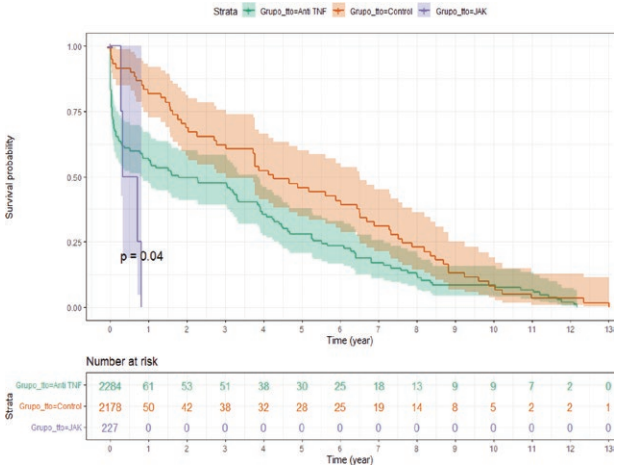

Figure 1. MCAE free-survival time according to treatment.

Validation of outcome measures and biomarkers

POS0975

VALIDATION OF INTERFERON STIMULATED GENE SCORES, PREVIOUSLY DEVELOPED IN PERIPHERAL BLOOD MONONUCLEAR CELLS, IN WHOLE BLOOD SAMPLES

Keywords: Rheumatoid arthritis, Cytokines and chemokines, Systemic lupus erythematosus

M. Wilson[1], Z. Wigston[1], A. Burska[1], A. Alase[1], D. Plant[2], E. Hensor[1], E. Vital[1]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*; [2]*Manchester, Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom*

Background: A recent EULAR Task force identified critical variability in interferon (IFN) assay methods and defined a research agenda to improve and harmonise assays. IFN scores A and B, developed using IFN stimulated genes (ISG) measured in peripheral blood mononuclear cells (PBMC) differentiate between clinical subsets of patients with autoimmune disease [1]. Whole blood (WB) samples are more commonly used in clinical practice and trials. Regardless of sample type, real time polymerase chain reaction (RT-PCR) experiments require a suitable reference gene (RG) which is uniformly expressed across different experimental conditions in order to normalise target gene expression quantities [2].
Objectives: (i) To determine whether sample type affects the previously defined IFN scores; (ii) if so, to develop revised IFN scores in WB; (iii) to identify the best RG for future RT-PCR experiments.
Methods: Samples were collected from participants enrolled in 5 studies; DEFINITION, CONVAS, USEFUL, MASTERPLANs and BRAGGSS. PBMCs were separated from blood using leucosep tubes and WB was collected using Tempus™ Blood RNA Tubes. Undetected delta Ct values were singly imputed. IFN scores A and B were calculated in paired WB and PBMC samples and agreement between the sample types was assessed via the Bland-Altman (BA) method. New IFN scores for WB were derived via exploratory factor analysis (EFA) of 31 ISG as per the original work [1]. Separation of clinical subgroups was visualized using violin plots and effect sizes calculated using Hedges' g. RG identification from 16 candidates used online software.
Results: We used samples from 342 participants with systemic lupus erythematosus (SLE), 6 ANA positive at risk progressors, 7 at risk non-progressors, 30 with rheumatoid arthritis (RA) and 10 healthy controls (HC). Subsets were used for sample comparison (n=45) and RG work (n=22). Comparing score A in PBMC versus WB matched samples resulted in bias of -1.44, limits of agreement (LOA 0.08, -2.96), the spread of data on BA plot showed a systematic difference. The same comparison in score B gave bias of -1.23 (LOA 0.26, 2.73), data on BA plot suggested differences were not systematic. EFA in WB produced a two-factor solution which explained 97% of the variation. The first (score C) contained 3 ISG and the second (score D) contained 4 (Table 1), compared with score A (12 ISG) and score B (14 ISG) [1]. Both scores showed potential to differentiate between HC and those with SLE or RA, but neither separated SLE from RA as the original PBMC scores A and B had done (Figure 1). YWHAZ, PGK1 and GUSB were the most stable RG. Others such as ACTB performed poorly as RG.
Conclusion: PBMC and WB may be used interchangeably to calculate IFN score A, but not score B. This suggests an influence of neutrophils, including the demethylation of neutrophil ISG cytosine-guanine sites, on Score B genes [3]. In WB we derived a further two scores which differentiated SLE or RA from HC, although neither score distinguished between SLE and RA. Further work is needed to assess the performance of scores A-D in WB samples. The Minimum Information for Publication of Quantitative Real-Time PCR Experiments recommend using ≥3 RG to avoid bias[4]; we found that YWHAZ, PGK1 and GUSB were the most stable genes across a range of experimental conditions.

HAND FUNCTION IS ALREADY REDUCED BEFORE RA-DEVELOPMENT AND REFLECTS SUBCLINICAL TENOSYNOVITIS

Keywords: Imaging, Rheumatoid arthritis, Motor function

D. Krijbolder[1], S. Khidir[1], X. Matthijssen[1], R. Ten Brinck[1], J. Van Aken[2], I. Speyer[3], F. Van der Giesen[1], E. Van Mulligen[1,4], A. Van der Helm – van Mil[1,4]. Background: Clinically suspect arthralgia (CSA) is characterized by arthralgia of small joints and considered a risk stage for development of rheumatoid arthritis (RA). However, it remains unknown if the function of the hands is already affected and what mechanisms underlie impaired hand function in CSA.
Objectives: We aimed to study to what extent the function of the hands is affected in CSA-patients, whether that would reflect underlying subclinical inflammation, and if it can be of value in clinical practice.
Methods: We studied various measures of hand function in two CSA-populations. CSA-patients in the TREAT-EARLIER-trial (n=236) were evaluated at baseline for: grip strength on a dynamometer, patient-reported difficulties in the grip-domain of the HAQ-questionnaire and incomplete fist-closure at physical examination. Contrast-enhanced MRI of the hands measured synovitis/tenosynovitis/osteitis (summed as subclinical inflammation). Findings were validated in an independent CSA-cohort (n=600) where hand-function was measured as: grip strength evaluated by squeezing the examiner's fingers, grip-domain of the HAQ-questionnaire, and fist-closure.
Results: Grip strength (on a dynamometer) was reduced in 75% compared to reference-values in healthy-controls (1), 60% reported grip-difficulties and 13% had incomplete fist-closure. Reduced grip strength was associated with subclinical inflammation (-0.38 kg per point inflammation, 95%CI -0.68;-0.08). Studying separate MRI-features, grip strength reduction was independently associated with tenosynovitis, decreasing with -2.63kg (-2.26; -0.33) per point tenosynovitis (range of observed tenosynovitis scores: 0-20). Similar relations with tenosynovitis were seen for patient-reported grip-difficulties (OR 1.12 per point, 1.07;1.42) and incomplete fist-closure (OR 1.36 per point, 1.03;1.79). In the validation-cohort, 36% had decreased examiner-assessed GS, 51%

reported grip-difficulties, and 14% incomplete fist-closure: all were associated with tenosynovitis. Decreased dynamometer-measured grip strength was most sensitive for detecting tenosynovitis (75%), while incomplete fist-closure was most specific (88-90%).

Conclusion: Hand function is already often affected before RA-development, reflecting subclinical inflammation. In practice, testing hand-function in CSA-patients could conveniently objectify functional limitations and reveal subclinical tenosynovitis.

POS0978 EXPLORING SMARTPHONE-BASED DIGITAL ENDPOINTS FOR RHEUMATIC CONDITIONS

Keywords: Outcome measures, Telemedicine, Validation

R. Araújo[1], P. Matias[1], P. Studenic[2,3], M. Valada[4], R. Graca[1], N. Nakhost Lotfi[2], D. Belo[1], F. Nunes[1]. [1]*Fraunhofer Portugal AICOS, Research Center for Assistive Information and Communication Solutions, Porto, Portugal*; [2]*Medical University of Vienna, Internal Medicine 3, Division of Rheumatology, Wien, Austria*; [3]*Karolinska Institute, Medicine (Solna), Division of Rheumatology, Stockholm, Sweden*; [4]*Nova Medical School, EpiDoC Unit, CHRC, Lisbon, Portugal*

Background: The care of rheumatic diseases is currently episodic, based on visits every 3-6 months at the rheumatologist, which may fail to characterize the condition state. To address this issue, the research community is investigating ways to use smartphones and sensors to monitor conditions passively.

Objectives: Explore associations between smartphone-generated data, standardized functional tests, and Patient Reported Outcome Measures (PROMS) to support the creation of digital endpoints.

Methods: Participants from Portugal and Austria participated in a Data Collection that included: (i) physical activities, such as walking with a smartphone in the pocket; (ii) hand dexterity exercises, such as copying text sentences with the smartphone keyboard; (iii) downloading and processing sociability data from the participants' smartphone; (iv) performing functional tests, such as Moberg Pickup Test (Moberg) and Timed Up-and-Go (TUG); and (v) answering validated PROMS, such as MD-HAQ, EQ-5D-5L, and visual analogue scale (VAS) for pain, fatigue, and disease activity. Statistical analysis focused on the correlation between smartphone-collected data and functional tests or PROMs, and independent t-test for between-group comparison.

Results: We collected data from 59 participants (76% female, 24% male). From this set, 31 were patients diagnosed with osteoarthritis (45%), rheumatoid arthritis (26%), or psoriatic arthritis (29%). The remaining 28 were age-matched healthy controls. In terms of age, 17% of participants were under 41 years old, 52% were between 41 and 60, and 31% were 61 or older. Most patients reported stiffness or pain in the upper (90%) and lower (83%) parts of the body. Subjective health status was high (M=77.95, SD= 16.31) in the VAS of EQ-5D-5L. Independent t-tests (Table 1) showed significant differences between patient and control groups regarding Mobility (M= 1.90, SD= 0.77), Pain/Well-Being (M= 2.48, SD= 0.81), and Mental Health (M= 1.68, SD=0.83) with higher difficulty levels reported by rheumatic patients compared to controls. Rheumatic patients also rated worse in HADS anxiety (M= 5.90, SD= 3.74) but not depression. We found significant differences between patients and controls in the variability of key pressing time (ms), with less variability among patients than controls (M= 30.71, SD= 11.99). The inter-key typing time was lower in participants below 50 years than above. A moderate correlation was found between the number of character deletions and the Moberg test (r= 0.44, p = 0.02) in patients with hand joint pain. Regarding Mobility associations, TUG total time (s) was positively correlated with the number of total steps (r=0.81, p <.001), the average duration (s) of each step (r= 0.35, p <.001), the average speed (m/s) of walking (r= -0.92, p <.001), as well as the standing up (r= 0.59, p <.001) and sitting down (r=0.55, p <.001) times (s).

Table 1. – Group comparison through independent t-test applied to some of the collected variables.

Dimension	Variable	Significance	Effect Size (*d*)	Patient Group (mean±SD)	Control Group (mean±SD)
Functional and disease assessment (EQ-5D-5L)	Mobility	0.018	-0.63	1.90±0.77	1.32±0.77
	Self-Care	0.981	-	1.39±0.76	1.39±1.10
	Daily Activities	0.116	-	1.71±0.78	1.36±0.91
	Pain/Well-Being	<.001	-1.02	2.48±0.81	1.68±0.82
	Mental Health	0.014	0.39	1.68±0.83	1.25±0.59
	Subject H. Status	0.200	-	75.10±16.31	81.22±19.67
Mental health (HADS)	Anxiety	0.005	-0.68	5.903±3.744	3.75±2.40
	Depression	0.124	-	3.83±3.10	2.43±3.75
TUG	Standing time (s)	0.001	-0.72	1.26±0.364	0.98±0.24
	Sitting time (s)	0.045	-0.53	2.215±0.922	1.80±0.58
	Avg. number of steps in curves	0.035	-0.56	3.419±0.847	2.93±.90
Moberg	Dominant hand time (s)	0.004	-7.20	19.813±6.21	15.856±4.58
Transcriptions	Key pressing time variability (ms)	0.005	0.78	30.71±11.99	22.996±7.71

Conclusion: Data collection with smartphone appears to have face, construct and discriminative validity, able to support future trials in patients with rheumatic diseases, to validate smartphone-based data vs objective measures of disease activity and quality of life over time.

POS0979 THE GLUCOCORTICOID TOXICITY INDEX-METABOLIC DOMAINS: AN ABRIDGED VERSION OF THE GLUCOCORTICOID TOXICITY INDEX

Keywords: Outcome measures

N. Patel[1], D. Jayne[2], P. A. Merkel[3], P. Bekker[4], Y. Zhang[1], M. Stone[5], H. Yue[6], J. H. Stone[1]. [1]*Massachusetts General Hospital, Rheumatology Unit, Boston, United States of America*; [2]*University of Cambridge, Medicine, Cambridge, United Kingdom*; [3]*Hospital of the University of Pennsylvania, Rheumatology Unit, Philadelphia, United States of America*; [4]*ChemoCentryx, Inc., Clinical Development, San Carlos, United States of America*; [5]*Steritas, LLC, Clinical Outcomes Assessments, Concord, United States of America*; [6]*Amgen, Inc, Clinical Development, Thousand Oaks, United States of America*

Background: Measurement of glucocorticoid (GC) toxicity is critical to efforts to reduce it. In clinical trials, the Glucocorticoid Toxicity Index (GTI)[1] measures toxicity effectively using two scores, the Cumulative Worsening Score (CWS) and the Aggregate Improvement Score (AIS). In clinical practice, high patient volumes limit time available to perform the full GTI. An abbreviated GTI version – the GTI-Metabolic Domains (GTI-MD) – may address this issue by including only data that are collected routinely at clinic visits, requiring no additional physician time. The GTI-MD includes four domains: Body Mass Index, Glucose Tolerance, Blood Pressure, and Lipid Metabolism.

Objectives: We evaluated the correlations between the GTI-MD, overall GTI scores, and the remaining GTI domains to determine if the GTI-MD differentiates patients effectively according to GC toxicity.

Methods: We used data from ADVOCATE[2], a phase 3 trial in which avacopan replaced a standard GC taper in ANCA-associated vasculitis, to test the correlation of the GTI-MD with overall GTI scores. We evaluated the ability of the GTI-MD to differentiate the treatment groups by GC toxicity, comparing GTI-MD scores between groups at weeks 13 and 26.

Results: The abilities of the full GTI domains to differentiate the treatment groups according to GC toxicity have been reported[3]. The Spearman rank correlation coefficient for the GTI-MD CWS with GTI CWS was 0.78 (p<0.0001). The corresponding correlation for the AIS was 0.73 (p<0.0001). The GTI-MD distinguished the two groups by GC toxicity at both 13 and 26 weeks (**Table 1**). The mean GTI-MD CWS was lower in the avacopan group, consistent with less toxicity (15.9 versus 23.0 at 13 weeks [p=0.001]; 26.7 versus 31.7 at 26 weeks [p=0.009]). The GTI-MD AIS values were also consistent with less toxicity in the avacopan group (2.5 versus 13.0 at 13 weeks [p=0.0003], 4.4 versus 10.1 at 26 weeks [p=0.03]). Contributions of the four GTI-MD domains were balanced (**Figure 1**). A GTI-MD score of zero correlated with low toxicity in other domains.

Table 1. Differentiation of the two treatment groups in ADVOCATE by glucocorticoid toxicity, as measured by the Glucocorticoid Toxicity Index-Metabolic Domains.

GTI-MD Score	Week	Treatment Group	N	Mean Score	Standard Deviation	P-value
AIS	13	Avacopan	160	2.5	23.4	0.0003
		Prednisone	161	13.0	27.3	
	26	Avacopan	154	4.4	25.7	0.03
		Prednisone	153	10.1	26.1	
CWS	13	Avacopan	160	15.9	15.7	0.001
		Prednisone	161	23.0	19.2	
	26	Avacopan	154	26.7	20.1	0.009
		Prednisone	153	31.7	20.3	

GC, glucocorticoid; GTI-MD, Glucocorticoid Toxicity Index-Metabolic Domains; AIS, Aggregate Improvement Score; CWS; Cumulative Worsening Score

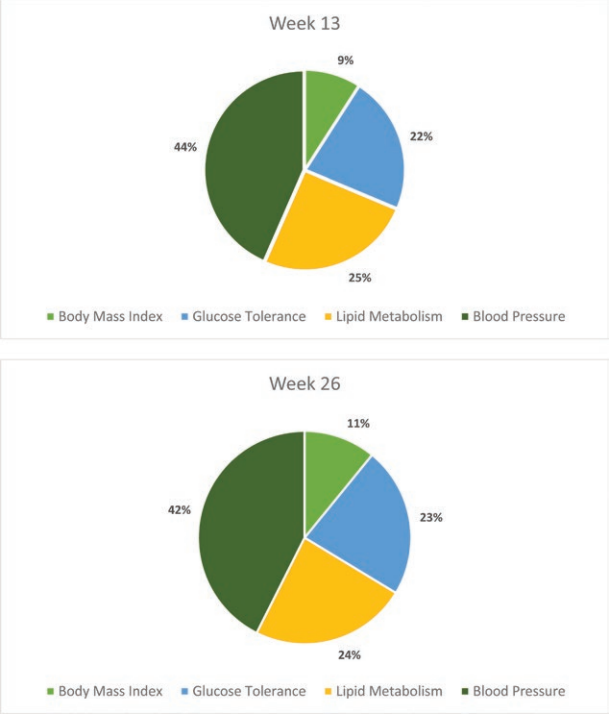

Figure 1. Percentage of the Glucocorticoid Toxicity Index-Metabolic Domains score contributed by each domain at 13 and 26 weeks, as reflected by the Aggregate Improvement Score values adjusted for weight.

Conclusion: The GTI-MD correlated well with the full GTI in ADVOCATE and may be incorporated readily into routine clinic workflows. Additional studies will be required to determine how effectively the GTI-MD predicts certain long-term GC toxicities such as osteonecrosis, bone fractures, infection, and death, and to understand how the instrument performs in other types of settings and study designs. Utilization of the GTI-MD may help clinicians monitor GC toxicity longitudinally, with the goals of preventing the burden of chronic, treatment-related morbidity, and reducing long-term costs to health systems.

WHICH ACR RESPONSE DEFINITION SHOULD BE USED FOR DISEASE ACTIVITY CLAIMS IN APPROVAL STUDIES OF RHEUMATOID ARTHRITIS? A SYSTEMATIC EVALUATION

Keywords: Outcome measures, Validation, Rheumatoid arthritis

V. Konzett[1], A. Kerschbaumer[1], J. S. Smolen[1], D. Aletaha[1]. [1]*Medical University of Vienna, Department of Internal Medicine III, Division of Rheumatology, Vienna, Austria*

Background: An accurate evaluation of efficacy is key in any trial of novel pharmaceutical compounds. For rheumatoid arthritis (RA), the American College of Rheumatology 20, 50 and 70 response criteria (ACR20/50/70) were reported in all major clinical trials since 1995. Although clinically irrelevant, the ACR20 response still remains the primary endpoint required by the European Medicines Agency (EMA) and the US Food and Drug Administration (FDA).

Objectives: In this analysis we explored how the stringency of the ACR response definitions (20%, 50% or 70%) differs with respect to their observed frequency and timing to inform potential future trial designs and regulatory decisions on required claims during the drug approval process in RA.

Methods: We conducted a systematic literature search in EMBASE, Medline and the Cochrane Library for multi-national, multi-center, phase 3 randomized drug trials (RCTs) investigating biological and targeted synthetic disease modifying anti-rheumatic drugs (bDMARDs/tsDMARDs) in adult RA patients. We included full articles published in English and reporting ACR responses for ≥3 time points over a 24-week study period. Baseline characteristics as well as ACR responses were extracted. For direct comparison of the response dynamics over time, we visualized ACR response rates on scales normalized to their maximum numerical responses observed during the respective trial (for details see legend). Calculation of p-values per outcome and timepoint for each treatment arm against placebo (Fisher's Exact test; α=0.05) allowed us to compare the discriminative capacity of the ACR responses between active treatment and placebo across all timepoints. Statistical analyses were done using R (V4.2.1, 2022, Vienna, Austria).

Results: We screened 12.457 articles (AK and VK) and selected 313 articles for full-text reading; we included 44 articles in the final analysis, which allowed for comparison of 95 treatment arms against placebo, investigating 8 different modes of action in DMARD-naïve patients as well as csDMARD and bDMARD insufficient responders (IR). The discriminative capacity of the ACR20 was highest across all timepoints analyzed (week 1 to 24), on average reaching 70% of the maximum response rate in the trial as early as by week 2 ('normalized' ACR response, Figure 1, Panel A). In contrast, ACR50 and 70 responses reached rates comparable to the ACR20 close to or at week 24, thus exhibiting slower response dynamics (Figure 1,

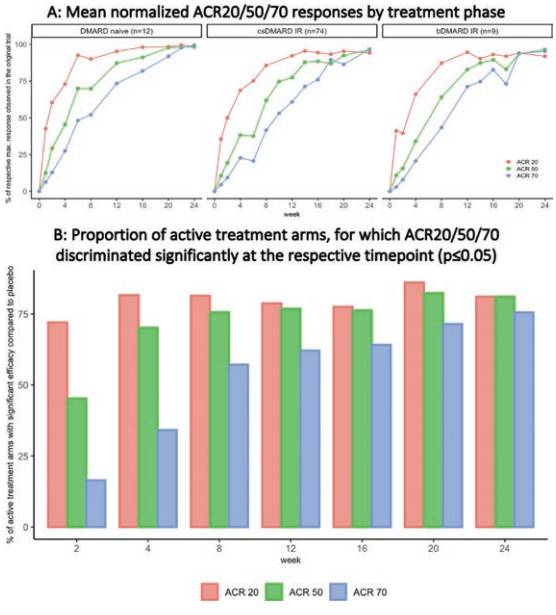

Figure 1. Mean normalized ACR responses. ACR responses were normalized to the respective maximum response achieved during the course of the trial; for example, if the maximum ACR20 response rate was observed at week 16 and amounted to 76% responders, then this was the normative 100% in the respective trial; and if the maximum ACR70 response rate was observed at week 20 and amounted to 28%, then this was taken as 100% for the ACR70 response. These data are summarized in panel A for DMARD naïve patients (n=12), csDMARD IR (n=74) and bDMARD IR (n=9) (n=number of treatment arms); Panel B: Percentage of treatment arms (n=95) from 44 different trials with significant (p≤0.05) ACR20, 50 and 70 response (active treatment vs. placebo) per timepoint (week 0-24).

Panel B). This effect was seen across all treatment arms (N=95) and independent of the mode of action, but slower for trials including treatment-IR patients compared with those assessing DMARD-naïve patients (Figure 1, Panel A).
Conclusion: The ACR20 response definition continues to be the most powerful discriminator between active treatment and placebo at early timepoints during trials; however, the discriminative capacity of the ACR50 and 70 definitions increases over the course of time. Our findings therefore support the use of these clinically more relevant response definitions at later but not early timepoints.

PRECISION MEDICINE IN RHEUMATOID ARTHRITIS. EVALUATION OF TWO NOVEL TESTS TO PREDICT CLINICAL RESPONSE TO METHOTREXATE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Biomarkers

A. Escudero Contreras[1], F. J. Blanco[2], M. Alperi-López[3], A. I. Turrión[4], C. Lopez-Pedrera[1], T. Yebra[5], G. Cordero[5], T. Diez[5], I. Portero[5]. *[1]Hospital Reina Sofía de Córdoba, Rheumatology, Córdoba, Spain*; *[2]Complejo Hospitalario Universitario de A Coruña (CHUAC), Rheumatology, La Coruña, Spain*; *[3]Hospital Central de Asturias, Rheumatology, Oviedo, Spain*; *[4]Hospital Universitario de Salamanca, Rheumatology, Salamanca, Spain*; *[5]Biohope Scientific Solutions for Human Health, Medical, Tres Cantos, Madrid, Spain*

Background: The main goal of treatment in patients with early Rheumatoid Arthritis (RA) is to achieve a clinical remission. Methotrexate (MTX) should be the first treatment strategy in naïve patients, but about one third will not respond to this therapy. There is a lack of tools to predict the individual response to MTX. Pre-treatment number of circulating monocytes may predict clinical response to MTX (1) and ROS production may be related to the pharmacological action of MTX (2, 3).
Objectives: To evaluate the feasibility of 2 novel tests (ROS and Monocytes Tests) to measure in vitro the sensitivity to MTX in patients with new-onset RA and the association of MTX response with clinical remission at 6 months.
Methods: This is an observational, longitudinal Proof-of-Concept with a follow-up of 6 months. 33 adult patients with early RA according EULAR criteria and with a DAS28 ≥2.6 were included before treatment with a disease-modifying antirheumatic drugs disease (DMARD). 26 patients had a valid sample for tests performance. At baseline a patient blood sample was collected, where PBMCs were isolated and frozen. After 3 weeks, PBMCS were defrost, placed in a plate p96, activated with phytohemagglutinin, and exposed to MTX. In the ROS test, Reactive Oxygen Species were measured by means of a specific vital probe with fluorimetry. In the Monocytes test, monocytes metabolic activity was determined with resazurin and measured with fluorimetry. Clinical and analytical variables were registered along patients´ follow-up and DAS28<2.6 was used as criteria for clinical remission. Results of both tests were compared in patients with and without clinical remission at 6 months.
Results: ROS levels as determined with the ROS test showed to be increased in patients with clinical remission when compared with patients without remission (p<0.001) (Figure 1). Monocytes number determined with the Monocytes test was decreased in the patients with clinical remission vs patients without remission (p<0.05) (Figure 1). The predictive capacity of these models was analyzed with the area under the operating characteristics curve (ROC), showing for ROS Test an AUC of 0.919 (CI95% 0.813- 1.025) (p<0.0001) and for Monocytes test 0.826 (CI95% 0.664-0.989) (p<0.0001).

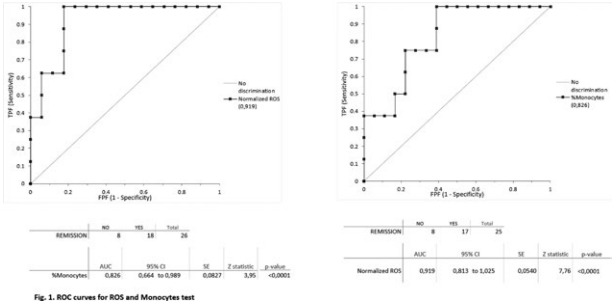

Figure 1.

Conclusion: In naïve patients with new-onset RA, the pharmacological response to MTX can be measured in vitro by the quantification of total monocytes and ROS production from PBMCs. Low monocyte percentages and high levels of ROS production are associated with patients´ clinical remission at 6 months.

Clinical cases

POS0982

UNUSUAL PRESENTATION OF LEWIS-SUMNER SYNDROME IN ELDERLY SIMULATING POLYMYOSITIS AND POLYMYALGIA RHEUMATICA

Keywords: Rare/orphan diseases

M. Brahem[1], R. Sarraj[1], O. Jomaa[1], B. Jebali[1], S. Abdellatif[1], H. Hachfi[1], Y. Mohamed[1]. *[1]Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia*

Background: Lewis-Sumner syndrome (LSS) or multifocal acquired demyelinating sensory and motor neuropathy (MADSAM) is an atypical form of chronic inflammatory demyelinating polyneuropathy (CIDP). This rare disease is characterized by a predominantly distal, asymmetric weakness mostly affecting the upper limbs and motor dysfunction with adult onset. Diagnosis can be difficult to establish if the clinical presentation is atypical and frequently simulates inflammatory myopathy.
OBJECTIVES:
Methods: We report a rare case of LSS in an old patient with unusual clinical aspects.
Results: A 70-year-old female patient with a history of atrial fibrillation complicated by pulmonary embolism, presented with myalgia and muscle weakness of the shoulders, upper arms, hips and thighs. This involvement was bilateral, symmetrical and evolving since 3 months, causing difficulties in climbing stairs, standing or walking. Physical examination showed a proximal muscle deficiency affecting proximal muscles of the upper and lower limbs. In this stage we suspected a poly yositis or polymyalgia rheumatica. We completed by biological assessment that showed a biological inflammatory syndrome (ESR at 90 mm at first hour; CRP at 80 mg/L) and elevated lactate dehydrogenase level at 490 IU/L. The immunoblot polymyositis profile (anti-Mi2, anti-Ku, anti Pm/SCL, anti-Jo1, anti-PL12, anti-PI7, anti-SSA 52kDa, anti-EJ, anti-OJ and anti-SRP) was negative. The MRI of lower limbs revealed a signal abnormality in the gluteus medius muscles on both sides with inflammatory appearance. The Electromyography revealed sensorimotor neuropathy affecting the four extremities with motor nerve conduction blocks. This aspect was in favor of LSS, so we completed by a cerebrospinal fluid study which revealed a proteinorachia at 0.4g/l with normal glycorachia and normal cell counts. These results confirmed the diagnosis of LSS. The patient was treated by corticosteroids at dose of 1 mg/ kg/ day during 2 months, with a progressive decrease of treatment. The evolution was marked by a spectacular clinical and biological response.
Conclusion: LSS is a very rare disease that can simulate inflammatory myopathy and polymyalgia rheumatica in elderly. So, it should be suspected in old patients suffered from proximal muscle deficiency.

POS0983

TET2 MOSAICISM IN HUMAN IS ASSOCIATED WITH A COMPLEX PHENOTYPE INCLUDING LYMPHOPROLIFERATION, AUTOIMMUNITY, IMMUNODEFICIENCY, AND HEMATOLOGIC MALIGNANCY

Keywords: Autoantibodies, Genetics/epigenetics, Malignancy

R. Lorenzetti[1], J. Staniek[1], M. Rizzi[1], R. Voll[1], N. Venhoff[1], J. Thiel[1,2]. *[1]Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Faculty of Medicine, Albert-Ludwigs-University of Freiburg,*

Freiburg, Germany; [2]*Division of Rheumatology and Immunology, Department of Internal Medicine, Medical University of Graz, Graz, Austria*

Background: The TET2 gene encodes ten-eleven translocation methylcytosine dioxygenase 2 (TET2). TET2 is an epigenetic regulator that converts 5-methylcytosine to 5-hydroxymethylcytosine and also interacts with histone-modifying enzymes and transcription factors. Somatic mutations in TET2 are early events in clonal expansion and are found in association with myeloid and lymphoid haematological diseases. Germline mutations in TET2 have only been described in 3 children of consanguineous parents. These mutations led to immunodeficiency and lymphoma and early mortality in childhood.
Objectives: To assess the clinical and immunological consequences of a combination of a germline and a somatic mutation in *TET2*.
Methods: Genetic analysis was done by whole exome sequencing. An in-depth immunological analysis was performed.
Results: Clinical phenotype: The patient of non-consanguineous parents presented at the age of 38 with axial spondyloarthritis. Apart from trace homogeneous fluorescence on the HEp2 cell his immunologic work-up was unremarkable. After start of a TNF-inhibitor he developed persisting fever, serositis, interstitial lung disease, peripheral arthritis and a pronounced lymphadenopathy/splenomegaly. His condition improved after the TNF-inhibitor was changed to an IL-17-inhibitor combined with prednisone (up to 40 mg/d), but lymphadenopathy persisted and the patient recurrently suffered from fevers, fatigue and pleurisy. Lymphnode biopsies showed no signs of malignancy. The patient had recurrent episodes of pancytopenia that spontaneously improved and he developed two episodes of pneumonia. Furthermore, he suffered from recurrent episodes of herpes zoster.
Immunological results: On immunologic work-up the patient had a polyclonal hypergammaglobulinemia and autoantibody testing revealed a homogenous ANA (1:1600), and positive anti-nucleosomen-, anti-PM-Scl75-, anti-SRP-, anti-PL-12-, anti-phospholipid-, anti-dsDNA- and anti-MPO-autoantibodies. Despite of increased amounts of immunoglobulins the patient developed a progressive and persistent loss of B cells (Figure 1), with an increased expression of CD80/86 on the remaining memory B cells. Within the T cell compartment double-negative T cells were increased.
Results of whole exome sequencing: Whole exome sequencing revealed a germline mutation in TET2 with the variant c3641G>A; pArg1214Gln in the heterozygous state (NAF 0.53; NM_001127208.3). This mutation affects a phylogenetically conserved amino acid and is classified as predominantly pathogenic in the in silico prediction. Another variant identified is the mutation c.1864C>T; p.Gln622, which leads to the emergence of a stop codon (NAF 0.41). This variant was only detectable as a low-grade mosaic (5-10%) in the buccal mucosa in the control, possibly as a result of lymphocytic infiltration into the buccal mucosa. In leukocytes, this mutation was detectable in 83% of cells in the heterozygous state. Both mutations have a low frequency in the population (1-2/125000-150000; gnomAD).
Hematogical malignancy: 5 years after the progessive loss of B cells had started, the patient was diagnosed with a follicular B cell lymphoma and shortly after with AML with myelodysplasia-associated changes (AML-MRC). A familial-allogeneic peripheral blood stem cell transplantation was performed. During the now 6 months follow-up no relapse occurred.
Conclusion: Combined heterozygous germline and somatic mutations in TET2 are associated with a very complex phenotype combining autoimmunity, lymphoproliferation and hematological malignancy, may present in adulthood and thus clinically differ from combined heterozygous germline mutations with early onset in childhood.

POS0984 DARATUMUMAB RESCUE THERAPY IN A PATIENT WITH ANTI-MDA5 ASSOCIATED ARDS

Keywords: Myositis, Lungs, Autoantibodies

L. Ostendorf[1,2], F. Münch[1], L. Thormählen[3], J. Nee[1], U. Schneider[4]. [1]*Charité – Universitätsmedizin Berlin, Department of Nephrology and Medical Intensive Care, Berlin, Germany*; [2]*Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Autoimmunity, Berlin, Germany*; [3]*Charité – Universitätsmedizin Berlin, Department of Cardiology, Angiology and Intensive Care Medicine, Berlin, Germany*; [4]*Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: MDA5-associated dermatomyositis is often associated with rapid progressive interstitial lung disease resulting in acute respiratory distress syndrome (ARDS). Patients that progress to require mechanical ventilation or extracorporeal membrane oxygenation (ECMO) generally have a high mortality despite intensive combined immunosuppressive treatment. (1) Daratumumab, an anti-CD38 monoclonal antibody has been successfully used in the treatment of refractory autoantibody-associated diseases with the intention of targeting autoantibody-producing CD38+ plasma cells. (2)
Objectives: Rescue treatment of anti-MDA5 antibody associated ARDS with Daratumumab combination therapy.
Methods: We treated an ECMO-dependent patient with refractory anti-MDA5 dermato-pulmonary syndrome with a combination treatment of four weekly doses of 1800mg daratumumab s.c. as well as tofacitinib, ciclosporin and prednisolone.
Results: A 55-year-old patient was transferred to our hospital with ARDS of unknown origin combined with a short history of oligoarthritis and Gottron's papules. She required mechanical ventilation and ECMO. Autoantibodies showed strong positivity for anti-MDA5 and -Ro52, so she was diagnosed with MDA5+ dermatopulmonary syndrome. She initially received treatment with cyclophosphamide, tofacitinib, ciclosporin, intravenous immunoglobulins and high-dose steroids. However, her interstitial lung disease showed no improvement. We escalated the immunosuppressive therapy with daratumumab. The pulmonary function improved approximately four weeks after daratumumab initiation and the patient was consequently weaned from ECMO and respirator. The clinical course was complicated by an ischemic stroke and a blood stream infection with enterococci which would have made a lung transplantation impossible. We were able to discharge the patient to rehabilitative care with only low-flow supplemental oxygen.
Conclusion: Rescue immunosuppressive therapy of MDA5-antibody associated ARDS with daratumumab in addition to tofacitinib, ciclosporin and prednisolone was associated with remarkable clinical improvement in this case. More clinical data and long-term follow-up are needed to investigate safety and efficacy of this treatment regimen in MDA5-antibody-associated disease.

Psychosocial support

POS0985-PARE FACTORS ASSOCIATED WITH FEELINGS OF GUILT AND SHAME IN PATIENTS WITH PSORIATIC ARTHRITIS

Keywords: Mental health, Skin, Psoriatic arthritis

E. Hannech[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], M. Yasmine[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology Department, Tunis, Tunisia*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease that can have a major impact on patients' quality of life with functional and psychological impairment.
Objectives: We aimed to investigate feelings of shame and guilt among patients with PsA and to determine its associated factors.
Methods: We conducted a cross-sectional study including patients with peripheral PsA according to the CASPAR criteria. Sociodemographic data, clinical, and therapeutic modalities were collected. Patients were asked to respond to the Experience of Shame Scale (ESS) [1] and to the Test of Self Conscious Affect- Version 3 (TOSCA-3S) [2]. ESS is a self-report scale assessing 3 areas: (1) characterological shame (2) behavioral shame and (3) bodily shame. Each item was rated in a 4-point Likert scale. Higher scores indicate higher levels of shame. TOSCA-3S is composed of 11 scenarios, each followed by 4 possible responses. Each item was rated in a 5-point Likert scale. This score measures shame-proneness, guilt-proneness, detachment and externalization (blaming others). Only the shame and guilt subscales of the TOSCA-3S were used for the statistical analysis. A $p<0.05$ was considered significant.
Results: We included 30 patients with PsA: 12 females (40%) and 18 males (60%). The mean age was 51±14years [21-80]. Five percent of patients were illiterate and 95% of them had an educational level. Twenty seven percent of patients were unemployed, 50% were employed, and 23% were retired. Seventy seven percent of patients were married. The mean disease duration was 13±5 years [2-20]. The mean DAS28 ESR and DAS28 CRP were 5.34±1.84 and 4.75±2.06, respectively. The mean Psoriatic area severity index (PASI) was 10.2 [0-70]. For the ESS, the mean total score was 63 [31-98] with mean subscale scores of: 28 [14-45] for characterological shame, 25 [12-35] for behavioral shame and 9 [5-20] for bodily shame. For the TOSCA-3S, the mean "shame self-talk Total" score was 33 [17-44], and the mean "guilt self-talk Total" score was 47 [37-55]. A significant correlation was found between guilt self-talk Total score and disease activity: DAS 28 ESR ($p=0.028$) and DAS28 CRP ($p=0.039$). The guilt self-talk Total score was significantly higher in women (49 vs 46, $p=0.025$) and among unemployed patients ($p=0.08$). The shame self-guilt Total score was associated with educational level ($p=0.027$). The Bodily shame subscale was associated with the educational level ($p=0.028$). A significant positive correlation was noted between the PASI and the bodily shame score ($p<0.001$, $r=0.673$).
Conclusion: Feelings of guilt and shame were frequent among PsA patients. Associated factors were mainly disease activity, PASI, and sociodemographic parameters.

Best practice campaigning

POS0986-PARE **IMPACT OF EDUCATIONAL CAMPAIGNS ON RMD IN SOCIAL NETWORKS**

Keywords: Education, Self-management, Quality of life

E. Pinzon[1], L. Higuera[2]. [1]*FUNARP, Education, Panama, Panama*; [2]*FUNARP, Education, Panama, Panama*

Background: Panama's prevalence of rheumatoid arthritis lies within the global range (.24 to 1%). To improve the quality of life of RMD patients in the country, FUNARP was created over 18 years ago to educate and support patients, caregivers, and civil. FUNARP decided to focus its efforts on digital campaigns since 2020 taking advantage of its coverage, low costs, and ease of usage. Further, the mobile penetration of Panama is 136% of its population [1] making social media the best distribution channel for this purpose.
Objectives: To expand educational coverage, especially for those with limited mobility or living in hard-to-reach areas. Another objective is to measure the effectiveness of digital media campaigns (paid vs organic growth), as well as to identify the most effective social network for these purposes.
Methods: Social media campaigns complement FUNARP's annual education plan which consists of monthly onsite and virtual lectures/seminars. The educational approach is based on the physician's perspective and the patient's experience. The campaigns consist of a mixed scheme: selected ad investment and in-house content creation; and full-fledged campaigns with professional content development and paid ads. In 2022, a total of five campaigns were launched following this process: a) selection of the campaign theme, b) professional advice on content, c) sponsorship, d) hiring of the marketing agency, e) approval of design and publications, and f) analysis of results to the board of directors and sponsors.
Results: "*Early Diagnosis and Motivation to Consult a Rheumatology Specialist*" was the most successful campaign - developed by a marketing agency with videos supporting the message, and paid ads on both Instagram and Facebook, see Figure 1. Salient results: 110,488 accounts reached and 25,975 interactions, see Table 1.

Figure 1. Best performing campaign.
Campaigns with professional content creation and paid ads in social media ads had more than 50% reach and 90% interaction than the ones without them. Videos have a higher acceptance vs. static images, see Table 1:

Table 1. Salient KPI of social media campaigns in 2022 (reach vs. engagement)

	Campaign	Facebook	Instagram	Images	Videos	Paid Ads	Non-paid Ads
Reach (110,488 accounts)	Arthritis remission, is it possible?	9%	91%	81%	19%	24%	76%
	Self-care in rheumatic diseases	37%	63%	74%	26%	0%	100%
	Prepare your visit to the rheumatologist	68%	33%	94%	6%	93%	7%
	Myths around rheumatic diseases	21%	79%	87%	13%	20%	80%
	Early diagnosis and motivation to consult a rheumatology specialist	18%	82%	13%	87%	87%	13%
Interactions (25,975)	Arthritis remission, is it possible?	9%	91%	88%	12%	31%	69%
	Self-care in rheumatic diseases	37%	63%	76%	24%	0%	100%
	Prepare your visit to the rheumatologist	68%	33%	92%	8%	91%	9%
	Myths around rheumatic diseases	21%	79%	98%	2%	29%	71%
	Early diagnosis and motivation to consult a rheumatology specialist	18%	82%	2%	98%	89%	11%

Qualitative results have been observed by rheumatologists who have indicated that patients who have had access to information from our foundation are more informed and involved in their treatment. They perceive that these patients have a better quality of life compared to those who do not have access to information about their pathology.
Conclusion: Working with marketing companies, and rheumatologists, as well as investing in advertising directly influences the effectiveness of health awareness and literacy campaigns. Publications where real patients appear as protagonists had higher acceptance vs. those with stack images and videos, or models. Instagram appears to have a better impact than Facebook. The early diagnosis campaign managed to overcrowd first-time consultations with rheumatologists in the public health system (less than 20 rheumatologists for a 4.2 MM population in Panama). FUNARP observed an increase in requests for information and orientation in the navigability of the system to obtain care with rheumatologists and advice on various health issues from the community through social media messaging services.

FUNARP will continue to conduct digital campaigns to expand the educational coverage of the Panamanian population. It is recommended to have advertising investments of more than U.S.$100.00 per publication of each campaign and to have content generated by specialists and advertising agencies. In addition, sponsorship will continue to be sought to increase literacy in patients with RMD. For the next campaigns, the WhatsApp button will be made available to easily address requests and questions from the community. A marketing and advertising commission has been created within FUNARP to keep more detailed metrics and measure other variables in the campaigns that have not been measured so far.

POS0987-PARE **SPONDYREPORT: A REPORT SENT TO ALL GPS IN NORWAY, TO PROVIDE KNOWLEDGE ABOUT THE DIFFERENT SPONDYLOARTHRITIS DIAGNOSES**

Keywords: Spondyloarthritis

L. Wermskog[1], L. M. Eidet[2], K. Lilleby[3], H. Pettersen[4]. [1]*Spondyloarthritis Association Norway, None, Oslo, Norway*; [2]*Spondyloarthritis Association Norway, N/A, Oslo, Norway*; [3]*Novartis, Oslo, Oslo, Norway*; [4]*UCB Pharma, Oslo, Oslo, Norway*

Background: The report provides brief and precise knowledge of spondyloarthritis diagnoses, axial spondyloarthritis, psoriatic arthritis, IBD associated arthritis and juvenile spondyloarthritis.

Objectives: The aim of sending this report to all GPs in Norway is to give knowledge gaps around the different spondyloarthritis diagnoses. To give knowledge gap in this report, we want to reduce the diagnostic delay of SpA.

Methods: Information about the diagnoses axial spondyloarthritis, psoriatic arthritis, IBD arthritis and juvenile spondyloarthritis, is written and quality assured by rheumatologists. This report provides information on what the referral should contain when sent to a rheumatologist if suspected spondyloarthritis. It provides information that MRI is the most important tool for setting axSpA diagnosis and ASAS criteria for SpA. It provides information where both healthcare professionals and patients can turn to when planning pregnancy and rheumatic diseases. Provides information about physical activity, where patients can get help for this. These patients have several health challenges in addition to their Spondyloarthritis diagnosis, this report gives knowledge about heart disease, dry eyes and exhaustion fatigue. In addition, we have included patients' stories about their experiences with their GP, both what help they get and don't get from their GP.

Results: The spondyreport has been physically sent to all (5071) GPs in Norway in January 2023. In order to reach as many GPs as possible, it was decided to send it out physically to all GPs. This report is a pilot project, where the goal is to send it yearly to GPs and other relevant physicians.

Conclusion: By sending this report to all GPs in Norway, it provides knowledge about symptoms and referrals to rheumatologists, to make this work easier for the GP and at the same time provide knowledge to a patient group who lives a lifetime with burden of their diseases.

Acknowledgements: The report is supported by Novartis, AbbVie, UCB Pharma, Pfizer.

Background: Systemic sclerosis (SSc) is a multi-organ disease and patient-reported outcome measures (PROMs) are important to better understand the complexity and impact of the disease. This heterogeneous disease has a wide specter of symptoms, and there are several different PROMs in use for this disease-group to assess all possible symptoms. Recently, a SSc-specific patient-derived questionnaire The Systemic Sclerosis Impact of Disease (ScleroID) has been developed and validated. Longitudinally, the questionnaire performed better than other comparators with regard to change over time. The ScleroID has so far not been used in a clinical study, nor been compared with the Scleroderma Clinical Trials Consortium Gastrointestinal Scale (UCLA GIT score) 2.0.

Objectives:

i: To estimate the sensitivity to change in ScleroID with the UCLA GIT score as comparator.

ii: To assess association between upper and lower GI in ScleroID and the UCLA GIT score.

Methods: We assessed the ScleroID and the UCLA GIT score in a 20 weeks randomized clinical trial, including patients with predominantly lower GI symptoms and without severe cardiopulmonary complications. The ScleroID includes questions about the severity of Raynaud`s phenomenon, hand function, upper and lower GI symptoms, life choice and mobility. It is scored using a 10 points Likert scale, with scores ranging from 0 (no impairment) to 10 (extreme impairment). The UCLA GIT score is a seven –item scale asking for frequency of experienced reflux, distention/bloating, diarrhea, fecal soilage, constipation, emotional well-being and social functioning, where all scales are scored from 0 (none of the days) to 3 (5-7 days a week). Changes in the scores from baseline to week 20 were analyzed by Paired- Samples T test. The Standardized response mean (SRM) was computed and interpreted according to Cohen's effect size index, in which 0.2 refers to a small difference, 0.5 to a moderate difference, and 0.8 or more to a large difference. Correlation were determined by the Spearman correlation coefficient at baseline.

Results: The study cohort included 67 SSc patients with mean age of 61 years and mean disease duration of 10 years (table 1). After week 20, the ScleroID and UCLA GIT total score showed low sensitivity to change, with SRM 0,42 (95% CI 0,10-0,68) and 0,45 (95%CI 0,18-0,77), respectively (Figure 1). Upper GI score of the ScleroID showed a strong correlation with UCLA reflux (r=0.799, p< 0.001). Lower GI of the ScleroID correlated moderately with UCLA reflux (r=0.399, p=0.008), constipation (r=0.306, p=0.031) and distention/bloating (r=0.444, p<0.001). In total, 54% of the patients reported an improvement in upper GI symptoms and 51% in lower GI symptoms of ScleroID. For the UCLA GIT score 56% reported improvement in reflux, 59% in bloating/distention and 33% in diarrhea.

Conclusion: The ScleroID and UCLA GIT score showed a low sensitivity to change after 20 week in a lower GI predominant SSc-cohort without severe organ involvement. The majority of the patients reported improvement in upper and lower GI symptoms in both questionnaires.

POS0989-HPR REAL-WORLD INDUCTION DMARD THERAPY IN RHEUMATOID ARTHRITIS; INSIGHTS IN THE DUTCH SANTEON BENCHMARK FRAMEWORK TO IMPROVE PATIENT CARE

Keywords: Real-world evidence, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

A. Van Groenestijn[1], A. B. G. Kwast[2], S. Van Lint[3], L. Van Lier[1], C. Storck[2], I. Fransen[3], A. Jamnitski[4], M. Ghiti Moghadam[5], A. Weel[6,7]. *[1]Maasstad Ziekenhuis, Quality and Safety, Rotterdam, Netherlands*; *[2]Medisch Spectrum Twente, Quality and Safety, Enschede, Netherlands*; *[3]St. Antonius Hospital, Quality and Safety, Nieuwegein, Netherlands*; *[4]St. Antonius Hospital, Rheumatology, Nieuwegein, Netherlands*; *[5]Medisch Spectrum Twente, Rheumatology, Enschede, Netherlands*; *[6]Maasstad Ziekenhuis, Rheumatology, Rotterdam, Netherlands*; *[7]Erasmus University, ESHPM, Rotterdam, Netherlands*

Background: Methotrexate (MTX) is the cornerstone therapy for rheumatoid arthritis (RA) patients, with well-established safety and efficacy profiles and support in international guidelines. Guidelines state that the maximal effect of MTX in a dose around 25 mg/wk can be seen after 3-6 months of therapy. However, older studies showed that the maximum dosage usually is up to 15 mg/wk and <40% had started treatment with MTX within 3–6 months from the diagnosis.[1,2,3] Santeon hospitals showed by analysis that disease activity score (DAS 28 CRP) of newly diagnosed RA patients was comparable after 6 months of treatment. However, initial treatment protocols showed large variation leading to difference in MTX dosage, mono and/or combination csDMARD therapy[4]. This suggests that under and/or overtreatment might be the fact.
Objectives: To get insight in the actual induction DMARD treatment strategies in newly diagnosed RA patients based on real world data.
Methods: We used data of the Santeon RA program[4] Maasstad Hospital, Medisch Spectrum Twente, St. Antonius Hospital treat over 4,500 RA patients/year. Although there are no (inter)national protocols for induction dose of MTX, all hospitals had a protocol but they varied between the hospital.[4] We included all newly diagnosed RA patients during Jan 2016 – June 2021. For analysis we assessed the initial conventional DMARD therapy and MTX dose at baseline, at 3 months and 6 months.
Results: In total 1238 new RA patients (714 Maasstad, 284 MST, 240 Antonius) were diagnosed during a 5.5 year period. A large variation in initial MTX dosages was seen (Figure 1). Data shown are of all Santeon hospitals combined, but differences within hospitals varied even more (data not shown). In 551 of 1238 patients (44%) does not start with MTX within 3 weeks after diagnosis. 931 (74%) started MTX treatment within 3 months after the diagnosis. Of those 921 MTX users, 253 (27%) started with a dose of 15mg/week. At three months the MTX dosages differed between the hospitals: in two of the three hospitals the most patients used 25 mg/week while in the other 15 mg/week (data not shown). Overall at 6 months 29% (361/1238) Santeon RA patients were on a dose of 25mg MTX. Of all 258 patients that did not start with MTX during 6 months, 216 (84%) started with other csDMARD where hydroxychloroquine (HCQ) was most frequent. The prescription of HCQ in combination with MTX varied strongly between the centers (69% vs 33% and13% per center) 3.3% of all new RA patients no csDMARD was started. The top 3 was 1. missing data (n= 19) 2. patients decision (n=7) and 3. unclear diagnosis (n=3).
Conclusion: We can conclude from real-world benchmark data from Dutch Santeon hospitals that a large variance in MTX dose was observed within and between hospitals. Moreover a large group of new RA patients did not start with MTX, within 3 months but with other csDMARD like HCQ. Our findings rise the urgency of an international induction protocol since the DAS28 did not vary after 3 and 6 months. Moreover this raises the urgency for precision treatment based on patients characteristics (gender, rheumafactor, anti CCP) can achieve similar outcomes (low disease activity) using a lower dose of MTX. To identify these characteristic is topic for further analysis.

POS0990-HPR COMPARISON BETWEEN THE CLINIMETRY MEASUREMENTS MADE BY THE PATIENTS AND BY THE RHEUMATOLOGIST UNDER DIFFERENT EDUCATIONAL CONTEXTS

Keywords: Outcome measures, Patient reported outcomes

G. S. Rodríguez-Vargas[1], N. Pinto-Florez[2], Z. Castaño[2], F. Rodriguez[3], J. A. Rubio-Rubio[4], P. Rodríguez-Linares[1], A. Rojas-Villarraga[4], P. Santos-Moreno[1]. *[1]BIOMAB, Scientific Direction, Bogotá, Colombia*; *[2]UniversitAR, Expert Patient, Bogotá, Colombia*; *[3]BIOMAB, Patients Education, Bogotá, Colombia*; *[4]Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia*

Background: Rheumatoid arthritis (RA) is a chronic disease that affects different spheres of the patient, compromising their quality of life. Patient education for self-knowledge and active participation in follow-up is essential. Through the present study, the clinimetry performed by the rheumatologist (RC) was compared with that performed by the patient (PC) when educated through different strategies.
Objectives: Compare the clinimetry measurements made by the patients with the rheumatologist measurements under different educational contexts.
Methods: A Cross-sectional study was designed. Inclusion criteria: Patients older than 18 years with RA, in follow-up under treatment of a T2T (Treat to target) strategy and access to digital tools. Three groups were included: Group 1 education under an RA program with thematic deepening in three levels and duration of 12-14 months, Group 2 with short education carried out in digital format through original video, duration of 75 minutes, in Spanish containing 7 talks (10 - 20 minutes each one). Group 3 without any educational intervention. The three groups performed the PC by means of a digital form and a maximum of one week later they were evaluated by the rheumatologist who developed the RC in a blind manner. Disease activity scales, functional class and quality of life were measured. Univariate and bivariate analyzes (Chi-square and Wilcoxon for paired data) were performed to compare the RC and PC measurements in the three groups. The project was approved by the ethics committee.

[a] Median (Interquartile range) [b].Signifficant differences in the total group [c] Wilcoxon test for paired samples. RC: Rheumatologist Clinimetry. PC: Patient Clinimetry.

Results: 28 patients were included in Group 1, 26 in Group 2, and 37 in Group 3. 100% were women. 51.6% presented erosivity, 81.3% positivity for rheumatoid factor and 79.1% for anti-citrulline antibodies. 46.2% had secondary level studies (higher proportion in Group 1). In group 1, there were no significant differences between the RC variables and those PC, except for fatigue (Table 1). In group 2, significant differences were found in 4 variables, as in Group 3. The RAPID 3 and PAS variables did not have significant differences when analyzing the total group or when analyzing by intervention subgroups.

Conclusion: When the clinimetry performed by the rheumatologist is compared with that performed by the patient, no differences are found in the group of patients who have in-depth educational training; while when the education is short, differences are found between the measurements of the rheumatologist and the patient, in a similar way to when there is no such education. These results deserve to be corroborated in other contexts.

Background: The Mediterranean diet (MedDiet) has been shown to have protective effects against the development and activity of Rheumatoid Arthritis (RA). It is hypothesized that changes in lifestyle which include diet may lead to the reduction of RA activity and progression. Dietary manipulations are commonly used to minimize RA symptoms by lowering inflammation.

Objectives: The aim of the present study was to assess the adherence of adult patients with RA from Kuwait to the MedDiet and its association with RA activity.

Methods: Adult patients who satisfied the American College of Rheumatology (ACR) classification criteria for RA from major hospitals in Kuwait were evaluated. A cross-sectional study conducted on 187 RA patients aged (35-82) years. DAS-28 scores were obtained in those patients. A validated 14-item Questionnaire (paper-based or web-based) given to the patients to measure adherence to MedDiet. Multivariate and univariate statistical techniques were utilized to analyze data. Statistical comparison and correlation were made in terms of MedDiet levels and RA disease activity by multivariant logistic regression.

Results: A total of 187 patients were included (median age 54 years; 140 males) with a median DAS-28 of 2.616. Out of 187 RA patients, 103 (55.1%) had lower MedDiet scores (MedDiet ≤ 5). Based on the logistic regression function, we found that The multivariable-adjusted odds ratio of RA patients with high adherence to the MedDiet (MedDiet ≥ 6) had lower DAS-28 scores (OR 5.34, 95% CI 1.176 - 24.230, P-value = 0.030) and improved lipid profiles compared to patients with low adherence.

Conclusion: Higher adherence to the MedDiet among Kuwaiti adults with RA may lead to improved DAS-28 scores. Lifestyle and dietary manipulations may be one of the non-pharmacological methods to control RA activity scores.

Acknowledgements: I would like to acknowledge Kuwait Registry for Rheumatic Diseases (KRRD), for providing us the needed data.

Gemelli IRCCS, Roma, Italy*

Background: Patients with RA experience a decline in health-related quality of life, which is associated with increased illness severity and impairment of work abilities. Central sensitization (CS) emerges as an accurate predictor and correlate of poor pain experience.

Objectives: The purpose of this cross-sectional, multicentric study is to investigate the mediating role of CS in unfavorable relationships with disease activity levels, CS and work productivity loss due to presenteeism in women with RA, with the goal of identifying potential new targets for preventive interventions.

Methods: The study used a cross-sectional design and included 101 female workers with RA classified according to 2010American College of Rheumatology (ACR)/Europenan League Against Rhumatisms (EULAR) classification criteria. All patients filled out the italian version of the RAID, an assessment and evaluation tool that measures RA patient disease activity, progress, and outcomes. The Central sensitization Inventory (CSI) was used to measure CS, and the Work Productivity and Activity Impairment questionnaire-RA (WPAI-RA) was used to evaluate patients' employment status. RA patients were grouped into categories, based on their RAID total score. Multiple regression analysis was used to find out which factors were most likely to presenteeism.

Results: The patients' age ranged from 25 to 65 years, with a disease duration of 5.4 (SD 6.1) years. The CSI score was ≥ 40 in 39/101 patients (38.6%). 70 patients (69.3%) worked full-time, while 31 (30.7%) worked part-time. The

majority of respondents (64.5%) reported a high degree of presenteeism with an average level of 31.8%. On the other hand, absenteeism was uncommon, with just 7.3% of respondents reporting it. %. Presenteeism was associated with higher CSI score (0.049), increased disease activity (0.0007), disease duration (0.0072) and age (0.0019) (Table 1).

Conclusion: CS disease activity and age were the factor most significantly associated with presenteeism-related productivity loss in RA patients. our findings have implications for health policy and emphasize the significance of identifying high-risk RA patients by monitoring CS as an indicator of presenteeism and severe disease activity.

POS0993-HPR NAILFOLD VIDEOCAPILLAROSCOPIC CHANGES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHROPATHY ON ANTI-TNF-ALPHA THERAPY

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Psoriatic arthritis

D. Anghel[1], O. G. Petrache[1], D. Opris-Belinski[2], V. Bojinca[3], L. Groseanu[2], M. M. Negru[3], A. Mihai[4], C. F. Pleșa[5], F. Ioniță-Radu[6]. *[1]Central Military Emergency University Hospital, Rheumatology, Bucharest, Romania*; *[2]'Sf. Maria' Clinical Hospital, Rheumatology, Bucharest, Romania*; *[3]'Sf. Maria' Clinical Hospital, Internal Medicine, Bucharest, Romania*; *[4]Central Military Emergency University Hospital, Internal Medicine, Bucharest, Romania*; *[5]Central Military Emergency University Hospital, Neurology, Bucharest, Romania*; *[6]Central Military Emergency University Hospital, Gastroenterology, Bucharest, Romania*

Background: It is known that systemic inflammation in rheumatic diseases was associated with microvascular involvement that can determine the severity and prognosis of the disease [1]. Videocapillaroscopy is an easy and non-invasive method with high sensitivity and specificity, that allows the study "in vivo" of nailfold capillaries.

Objectives: To assess the changes in capillary morphology in rheumatoid arthritis and psoriatic arthritis patients after anti-TNF-alpha treatment using nailfold videocapillaroscopy.

Methods: We performed a retrospective study on 80 patients (rheumatoid arthritis (RA) – 30 patients, psoriatic arthritis (PsA) – 31 patients and a control lot – 19 healthy subjects). Inclusion criteria: patients with high disease activity with RA (who met the EULAR/ACR 2010 criteria), and patients with PsA (who met CASPAR criteria). Exclusion criteria: age under 18 years old, Raynaud's syndrome, history of smoking or alcoholism, patients with history of biological treatment. Patients received anti-TNF-alpha therapy (Infliximab – 33.3% of RA patients and 25.8% PsA patients, Adalimumab - 36.7 % of RA patients and 38.7% of PsA patients, Etanercept- 33.3% of RA patients and 35.5% of PsA patients). In the RA group, 86% of the patients were females, and the mean age of the group was 42 ± 12. In the PsA group, 57% of the patients were females and the mean age of the group was 46 ± 19. We used a videocapillaroscope (VideoCap 3.0) with a magnification of 200x before (T0) and after 6 months of anti-TNF-alpha treatment (T1). We analyzed the capillaroscopic abnormalities such as bushy, tortuous capillaries, dilated capillaries, megacapillaries, hemorrhages, angiogenesis and avascular areas.

Results: We observed a significant correlation between the use of anti-TNF agents and improved. capillary density in RA patients (p=0.00001) and PsA patients (p=0.00002). Moreover, significant correlation was observed between the improvement of avascular areas and Adalimumab use in both groups (p=0.001). We also observed a significant correlation between the lack of angiogenesis and six months use of anti-TNF agents in RA group (p=0.00001) and PsA group (0.00003). A significant correlation was observed between the use of Infliximab and the lack of dilated capillaries (p=0.00005) in the RA group and the use of Etanercept (p=0.00001) and Infliximab (p=0.00001) in the PsA group. Also, strong correlation was observed between the lack of giant capillaries at 6 months and the use of TNF-alpha inhibitors in RA group (p=0.00003) and PsA group (p=0.00001). Significant correlation was found between the lack of hemorrhages and the use of 6 months of Adalimumab and Etanercept in the RA (p=0.00003) and the use of Adalimumab, Etanercept and Infliximab in the PsA (p=0.00001). No significant correlations were observed between videocapillaroscopic changes and age and sex. Also, no significant correlations were observed between the use of TNF-alpha inhibitors and elongated, tortuous and ramified capillaries in both groups.

Conclusion: According to our findings, after six months of anti-TNF treatment we observed a decrease in the incidence of dilated/giant capillaries, angiogenesis, hemorrhages and avascular areas in RA and PsA patients. Nailfold capillaroscopy could be useful in monitoring the efficacy of the biological treatment in patients with inflammatory arthritis.

POS0994-HPR CONVERGENT VALIDITY OF SIX MINUTE STEPPER TEST TO EVALUATE FUNCTIONAL EXERCISE CAPACITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Physical therapy/physiotherapy, Validation

S. Bayram[1], N. G. Tore[1], G. G. Pala[1], I. Vasi[2], A. Tufan[3], D. Oskay[1]. *[1]Gazi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey*; *[2]Gazi University, Faculty of Medicine, Department of Internal Medicine-Rheumatology, Ankara, Turkey*; *[3]National Human Genome Research Institute, Inflamatuar Disease Section, Rockville Pike, United States of America*

Background: Exercise capacity is impaired in systemic sclerosis (Ssc) patients due to respiratory and cardiovascular involvements, muscle weakness, arthritis/arthralgia, and joint contractures. Various tests are employed to assess submaximal and maximal exercise capacity in Ssc. Maximal exercise tests, the gold standard for assessing exercise capacity, are challenging since they require expensive equipment and qualified personnel. The 6-minute walk test (6MWT) is a commonly used submaximal field exercise test to assess functional exercise capacity and is shown to be associated with the prognosis in SSc patients. The 6-minute stepper test (6MST) is a low-cost, space-friendly submaximal field test that has been demonstrated to be valid, reliable, and sensitive in assessing exercise capacity in various diseases.

Objectives: No research hasn't been done on the validity of 6MST in Ssc patients. Given that it mimics stair climbing, the 6MST may be more helpful in evaluating lower extremity functions in Ssc. Therefore, the aims of this study were (1) to assess the convergent validity of the 6MST in Ssc; and (2) to compare physiological responses, dyspnea and fatigue perception obtained in 6MST and 6MWT.

Methods: Thirty female patients with Ssc (52.13 + 11.83 years) were enrolled. Demographic and clinical characteristics were recorded. 6MST was performed twice (6MST-1 and 6MST-2) to eliminate learning effect and because the hydraulic jacks become more flexible after they have warmed up. The 6MST-2 was performed after a resting time of at least 20 minutes after 6MST-1. The 6MWT was carried out three hours after the 6MST-2 to minimize fatigue on outcomes. To test the convergent validity of the 6MST, correlation between the 6MWT and 6MST-2 was assessed. In addition, the association between 6MST and the level of physical activity, dyspnea and fatigue severity in Ssc patients was investigated. International Physical Activity Questionnaire (IPAQ), modified British Medical Research

Council Questionnaire (mMRC) dyspnea scale, Fatigue Severity Scale (FSS) were used to assess physical activity, dyspnea and fatigue severity, respectively. The heart rate (HR), peripheral oxygen saturation (SpO_2), blood pressure (BP), modified Borg scale score for dyspnea, general and leg fatigue were recorded before and after 6MWT and 6MST. Changes between their final and initial values (Δ) for HR, SpO_2, BP, and modified Borg score were calculated.

Results: The number of steps in 6MST-2 was significantly higher than 6MST-1 ($p<0.001$). The number of steps in the 6MST-2 was significantly correlated with the distance walked in the 6MWT ($r=0.616$, $p<0.0001$). Additionally, significant correlations were observed between 6MST-2 and mMRC dyspnea scale score ($r=-0.733$, $p<0.0001$), FSS score ($r=-0.575$, $p\leq0.001$), IPAQ score ($r=0.330$, $p<0.05$). ΔBP, Δdyspnea, Δgeneral and Δleg fatigue perception were higher in the 6MST-2 than the 6MWT ($p<0.0001$). ΔHR and ΔSpO_2 were similar in 6MST and 6MWT ($p<0.05$).

Conclusion: The 6MST is a valid test to evaluate functional exercise capacity in Ssc patients. The 6MST might be more appropriate for evaluating perceived exertion, functioning, and lower extremity capacity. To assess the exercise capacity in Ssc patients, 6MST can be done with ease in all settings, including primary care to hospital settings with limited space and home-based telerehabilitation.

POS0995-HPR SLE-DAS AS AN ALTERNATIVE TOOL TO MEASURE ACTIVITY OF SYSTEMIC LUPUS ERYTHEMATOSUS: COMPARISON WITH SLEDAI-2K, IN A POPULATION FROM THE DOMINICAN REPUBLIC. PILOT STUDY

Keywords: Systemic lupus erythematosus

L. Perez Rodriguez[1], R. A. Alvarez Santana[1], D. Garcia[1], T. Polanco Mora[1], L. Concepción Sanchez[1], I. Paulino[1], I. Mercedes[1], E. Rodriguez Bautista[1], T. Valdez[1], A. Feriz[1], R. Muñoz Louis[1]. *[1]Hospital Padre Billini, Rheumatology, Santo Domingo, Dominican Republic*

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease that mainly affects women. Efforts are currently being made to validate the Systemic Lupus Erythematosus Disease Activity Score (SLE-DAS), since it allows quantifying the magnitude of the findings as opposed to an arbitrary value of present or absent in the renal, joint, hematological and serological spheres. [2]

Objectives: To evaluate the activity of Systemic Lupus Erythematosus with the SLE-DAS tool, comparing it with SLEDAI2-K.

Methods: Descriptive, observational, transversal. Patients from the Rheumatology Service of the Padre Billini Teaching Hospital were evaluated between October-December 2022. Inclusion criteria: > 18 years, SLE according to the EULAR/ACR 2019 classification criteria. Exclusion criteria: diagnosis of another autoimmune disease, patients with cognitive deficits. SLE-DAS tool: Inactive ≤2.08, mild 2.08 - 7.64, moderate/severe >7.64, SLEDAI: Inactive: <3, Mild to moderate: 3/12, severe >12. Descriptive analysis and Spearman's rho (ρ) correlation using SPSSv23.

Results: 92 patients met inclusion criteria. 95.7% (88) female, mean age 41.5 ± 12 years, mean SLE 8.2 years. AHT 29.3% (27), DM 7.6% [7], lupus nephritis 35.8% (33), Obesity 7.6% [7], musculoskeletal 20.6% (19), Vasculitis 6.5% [6], Neuro Lupus 4.3% [4], antimalarials 96.7% (89), glucocorticoids 39.1% (36), Mycophenolate Mofetil 40.2% (37), Rituximab 7.6% [7], Methotrexate 5.4% [5], Azathioprine 4.3% [4], Tacrolimus 2.1% (2), Cyclophosphamide 1.1% [1]. SLE-DAS inactive: 81.5% (75) vs SLEDAI inactive: 88% (81), SLE-DAS inactive: 81.5% (75) vs SLEDAI inactive: 88% (81) (Spearman's rho (ρ)= -0.11), a gradient difference of 6.5% [6].

Conclusion: Our study demonstrated a significant inverse correlation in the correlation between SLE-DAS vs. SLEDAI in inactive patients, supporting that the use of the SLE-DAS may be more sensitive to assess activity or changes in the clinical course of patients with SLE. More studies are needed to validate this tool and standardize it for our population.

HPR Epidemiology and public health (including prevention)

POS0996-HPR THE PREVALENCE OF PULMONARY ARTERIAL HYPERTENSION IN PATIENTS WITH MIXED CONNECTIVE TISSUE DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Epidemiology, Systematic review, Mixed connective tissue disease

A. Al-Bakri[1,2], R. Hozayen[3], Z. Mustafa[4], I. E. Lundberg[5,6], H. Jahrami[7,8]. *[1]King Abdullah Medical City (KAMC), Medicine, Manama, Bahrain*; *[2]College of Medicine and Medical Sciences, Arabian Gulf University (AGU), Kingdom of Bahrain, Internal Medicine, Manama, Bahrain*; *[3]College of Medicine and Medical Sciences, Arabian Gulf University (AGU), Kingdom of Bahrain, Medicine, Manama, Bahrain*; *[4]Salmanyia Medical Complex (SMC), Medicine, Manama, Bahrain*; *[5]Karolinska Institutet, Stockholm, Sweden, Division of Rheumatology, Department of Medicine, Solna, Stockholm, Sweden*; *[6]Karolinska University Hospital, Stockholm, Sweden, Department of Gastro, Dermatology, Rheumatology, Stockholm, Sweden*; *[7]Arabian Gulf University, Internal Medicine, Manama, Bahrain*; *[8]Ministry of Health, Kingdom of Bahrain., Psychatric, Manama, Bahrain*

Background: The prevalence and outcome of mixed connective tissue disease-associated pulmonary arterial hypertension (MCTD-PAH) has not been well understood.

Objectives: Our aim was to review the current knowledge on the prevalence, severity, and mortality of MCTD-PAH. We also aimed to examine the trend of the prevalence of MCTD-PAH over the years.

Methods: PubMed/Medline, Embase, Scopus and Web of Science electronic databases were searched for the published randomized controlled clinical trials (RCTs) and observational/original studies on PAH in patients with MCTD from January 1972 – December 2020.

Results: The results were pooled using random-effects meta-analysis based on the DerSimonian and Laird method. A total of 983 patients from eight studies were included in the meta-analysis (K=8, N=983). Pooled prevalence of PAH in MCTD patients was 12.53% [95% CI 8.30%-18.48%] with significant level statistical heterogeneity tau2=0.30, tau=0.55, I2 83.3%, H=2.13 Q(df,7) =31.90, P=0.001. There was no association between PAH and female gender or age. The percentage of deaths in MCTD patients due to PAH varied and reached up to 81.8%.

Conclusion: This is the first systematic review and meta-analysis investigating the prevalence of PAH in patients with MCTD and it revealed an overall prevalence of PAH in patients with MCTD of 12.53%. Our results showed trends of reduced prevalence of MCTD-PAH over the years, reconfirmed the lower prevalence rate in the recent studies, but revealed increased mortality rate. We also determined the low impact of the age, gender, and interstitial lung disease on MCTD-PA.H.

POS0997-HPR LUPUS MORTALITY IN RELATION TO THE OVERALL ENVIRONMENTAL QUALITY INDEX AND ITS FIVE DOMAINS

Keywords: Geographical differences, Prognostic factors

R. Sharma[1], E. Yen[2], L. Chen[3], M. Sim[3], R. Singh[2]. *[1]California University of Science and Medicine, Medical Student, Colton, United States of America*; *[2]University of California Los Angeles, Rheumatology, Los Angeles, United States of America*; *[3]University of California Los Angeles, Statistics, Los Angeles, United States of America*

Background: Growing evidence suggests a role of exposure to chemicals and industrial pollutants, such as hydrocarbons, silica, mercury, organochlorines and trichloroethylene, particulate air pollution, UV radiation, infectious agents, living in certain geographic regions, and sociodemographic factors in increasing the risk and/or affecting the outcome of systemic lupus erythematosus (SLE). We utilized the environmental quality index (EQI) developed by the U.S. Environmental

Protection Agency (EPA) to represent environmental quality to better understand the association between environmental factors and lupus deaths. Five domains including air, water, land, built and sociodemographic comprised the EQI.
Objectives: Here, we summarize the descriptive statistics between environmental exposures and lupus death and compared them to accidental deaths, heart disease and malignant neoplasm.
Methods: The study population comprises all individual U.S. deaths from 2006 to 2011. We describe mean/median EQI in lupus deaths versus those who died of other leading causes of death, namely accident, heart disease, and malignant neoplasm. Cause-specific death counts were obtained using ICD 10 codes: lupus (M321, M328, M329), accident (V, W, X0-5, Y85-86), heart disease (I0, I11, I13, I2-4, I50-51), and malignant neoplasm (C0-8, C90-97).
Results: There were 5,430 lupus deaths and 398,382 accidental deaths in the US from 2006 to 2011. The total EQI was significantly worse in lupus decedents than in accidental deaths ($p<0.001$), but not when compared to deaths attributed to heart disease and malignant neoplasm. Of the five EQI domains, air and built, but not the other three domains, were higher in lupus decedents than in accident ($p<0.001$), heart disease ($p <0.05$), and malignant neoplasm ($p<0.05$) decedents.
Conclusion: Total environmental quality as well as its air and built domains were worse in lupus decedents than in accidental deaths, suggesting a possible role of environmental exposure in contributing to lupus outcome. Further analysis is needed to identify the specific environmental determinants, which are potentially modifiable to improve lupus outcome.

POS0998-HPR THE EPIDEMIOLOGY OF PRIMARY SJOGREN'S SYNDROME: IS IT A RARE DISEASE?

Keywords: Sjögren syndrome, Real-world evidence, Epidemiology

S. Parisi[1], L. Lo Sardo[2], M. C. Ditto[1], R. Gnavi[3], M. Dalmasso[3], A. Migliardi[3], L. Brussino[2], E. Fusaro[1]. [1]*Azienda Ospedaliero Unviersitaria Città della Salute e della Scienza di Torino, Rheumatology Unit, Turin, Italy*; [2]*Azienda Ospedaliera Ordine Mauriziano di Torino, Immunology and Allergolgy Unit, Turin, Italy*; [3]*Azienda Sanitalira Locale Torino 3, Servizio Sovrazonale di Epidemiologia, Turin, Italy*

Background: Sjogren's syndrome (SSj) is a systemic disease with autoimmune pathogenesis, with prevalent involvement of the lacrimal and salivary exocrine glands, classified as primary or secondary on the basis of the association with other rheumatic diseases.
The epidemiological data in the literature are variable due to the heterogeneity of the populations examined and the different classification criteria used.
In a recent systematic review by Baodon Qin et al. In a recent systematic review by Baodon Qin et al. the average incidence rate was 7 cases every 100,000 people/year (range 5-9) with higher values in the Caucasian and Asian populations, with a women/men ratio of 9.3 (95% CI 3.35 to 13.18), while the prevalence rate was 61 cases per 100,000 inhabitants (range 10-90) with a female/male ratio of 10.7 (95% CI 7.35-15.62).
Objectives: The aim of the study was to estimate the prevalence rate of primary SSj in real-life, through analysis of administrative data.
Methods: An epidemiological research was carried out as at 31 December 2020, through the analysis of all adult patients residing in Piedmont (northwest of Italy) with exemption code (EC) for SSj (code 030) and any association with other ECs for rheumatological pathologies or for pathologies considered according to the 2016 EULAR/ACR classification criteria; specifically, the EC were considered for rheumatoid arthritis, ulcerative colitis and Crohn's disease, chronic hepatitis (active), HIV infection, affected subjects from malignant neoplastic pathologies, tumors of uncertain behavior, systemic lupus erythematosus, Hashimoto's thyroiditis, undifferentiated connective tissue disease; mixed cryoglobulinemia, antiphospholipid antibody syndrome (primary form), primary and familial amyloidosis, hereditary/familial autoinflammatory syndromes, microscopic polyangiitis, polyarteritis nodosa, sarcoidosis, dermatomyositis, polymyositis, mixed connective tissue disease, progressive systemic sclerosis.
Results: There were 3889 patients with EC for SSj as at 31 December 2020, of which 2611 with active EC. The number of assisted people alive with the aforementioned exemption was 2601, while those with other exemptions in the list were 1020. Of these patients, 1581 had only the exemption from code 030 as at 31 December 2020; the distribution of the other pathologies analyzed is shown in the tables below (Table 1). Of the total number of patients with active exemption, 2442 were female, while 159 were male, with a female/male ratio of 15.3; the distribution by gender is shown in Figure 1. Considering that the Piedmont population on 31 December 2020 was 4 274 945 inhabitants (ref: National Institute of Statistics), the estimated prevalence rate was 4.7 cases per 10 000 inhabitants.

Table 1. Distribution of EC in patients residing in Piedmont as at 31/12/2020

Diseases with EC	N of patients
Rheumatoid Arthritis	250
Ulcerative colitis and Crohn's disease	18
chronic hepatitis	52
HIV infection	2
Systemic Lupus Erythematosus	122
Subjects affected by malignant neoplastic pathologies	330
Hashimoto's thyroiditis	280
Undifferentiated Connective Tissue Sisease	86
Mixed Cryoglobulinemia	6
Antiphospholipid Antibody Syndrome	8
Primary And Familial Amyloidosis	3
Hereditary/Familial Autoinflammatory Syndromes	1
Microscopic Polyangiitis	2
Polyarteritis Nodosa	1
Sarcoidosis	5
Dermatomyositis	2
Polymyositis	5
Mixed connective tissue disease	25
Progressive systemic sclerosis	56

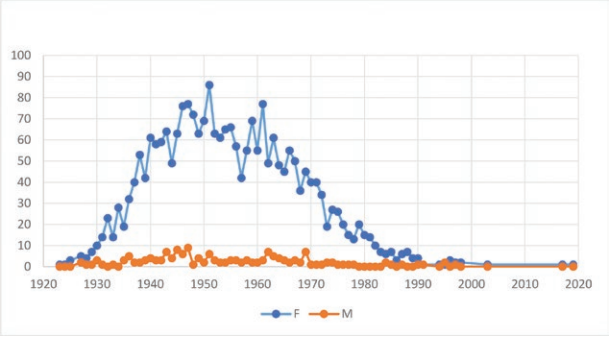

Figure 1. Distribution by gender of patients residing in Piedmont with exemption for Sjogren's Syndrome. F: Female; M: Male

Conclusion: This research has some limitations, including the retrospective design and the use of administrative data which may be affected by the aforementioned difficulty of classification as well as incorrect attributions of exemption, both for SSj and for associated pathologies. Our research highlights a number of patients with primary SSj lower than the prevalence figure that defines a rare disease, i.e. a prevalence of less than 5 cases per 10,000 inhabitants. Further studies are needed to confirm these preliminary data.

POS0999-HPR THE IMPACT OF THE COVID-19 PANDEMIC ON REFERRALS TO MUSCULOSKELETAL SERVICES FROM PRIMARY CARE AND SUBSEQUENT INCIDENCE OF INFLAMMATORY RHEUMATIC MUSCULOSKELETAL DISEASE: AN OBSERVATIONAL STUDY

Keywords: Rheumatoid arthritis, Epidemiology, COVID

R. Bajpai[1], C. Burton[1], K. Mason[1], J. Bailey[1], M. Frisher[2], K. Jordan[1], C. Mallen[1], V. Welsh[1]. [1]*Keele University, School of Medicine, Keele, United Kingdom*; [2]*Keele University, School of Pharmacy and Bioengineering, Newcastle-under-Lyme, United Kingdom*

Background: Inflammatory rheumatic and musculoskeletal diseases (iRMDs), including rheumatoid arthritis (RA) and juveneille inflammatory arthritsi (JIA), are common and cause a high disease burden globally. Early diagnosis of iRMDs and subsequent timely access to disease modifying therapies is associated with improved health and socio-economic outcomes. However, the COVID-19 pandemic meant that the way healthcare was delivered changed abruptly as all consultations were 'remote by default' was widely implemented, replacing traditional 'face-to-face' healthcare.
Objectives: To describe the impact of the COVID-19 pandemic upon referral patterns and incident diagnosis of iRMDs.

Methods: Data from the Clinical Practice Research Datalink Aurum were analysed from 01/04/17 to 01/10/2021 to describe episodes of care for patients with musculoskeletal (MSK) conditions, in a primary care setting, for pre-COVID-19 (01/04/2017–31/03/2020), early-COVID-19 (01/04/2020–31/07/2021), and late-COVID-19 pandemic (01/08/2020–31/10/2021) periods. Prevalent and incident MSK consultations were determined. Referrals were matched to these consultations. Trends in referrals to MSK services and further incident diagnoses of iRMDs were described using Joinpoint regression and comparisons made between time-periods. Negative binomial regression was used to compare incident rates between time-periods: first MSK consultation to RA/JIA/iRMD diagnosis; first MSK consultation to first referral; first referral to RA/JIA/iRMD diagnosis. The number of consultations between first MSK consultation and referral/diagnosis were described. Results were adjusted for age and sex and further stratified by geographical region and deprivation.
Results: The incidence of RA and JIA reduced by -13.3% (from 32.0 to 17.2 per 100,000) and -17.4% (from 1.8 to 0.97 per 1,000,000) per month respectively between January 2020 and April 2020, and then increased by 1.9% (from 17.2 to 25.2 per 100,000) and 3.7% (from 0.97 to 1.3 per 1,000,000) per month respectively between April 2020 and October 2021. The incidence of all diagnosed iRMDs was stable until October 2021. Referral incidence decreased between February 2020 and May 2020 by -16.8% (from 4.8 to 2.4 per 100) per month in patients presenting with a MSK condition. After May 2020, referrals increased significantly (16.8% per month from 2.4 to 4.5 per 100) to July 2020. Time from first MSK consultation to RA diagnosis, and referral to RA diagnosis increased in the early-pandemic period (rate ratio (RR) 1.11, 95% confidence interval (CI) 1.07-1.15; RR 1.23, 95%CI 1.17-1.30) and remained consistently higher in the late-pandemic (RR 1.13, 95%CI 1.11-1.16; RR 1.27, 95%CI 1.23-1.32) periods respectively, compared to the pre-COVID-19 period.
Conclusion: Patients with underlying RA/JIA that developed during the pandemic may be yet to present, or in the process of being referred and/or diagnosed. Primary care clinicians should remain alert to this possibility and consider the use of fast-track referral pathways where indicated. It is apparent that patients developing incident episodes of inflammatory arthropathies may display a prodrome of other MSK symptoms and conditions, which alone may not warrant referral but in combination require further investigation. Commissioners should be alert to these findings to allow for the appropriate planning and commissioning of services.

Background: It is considered that unhealthy diet and unhealthy lifestyle has a possible role in inflammation of patients with Rheumatoid arthritis (RA), Spondyloarthritis (SpA) and Psoriatic arthritis (PsA).
Objectives: We set out to find out the role of unhealthy diet and unhealthy lifestyle in the regulation of inflammation after treatment in our patients with autoimmune arthritides such as RA, SPA, PSA.
Methods: A retrospective analysis was carried out using a questionnaire on diet and lifestyle for our defined study population. Our source data was analyzed for inflammatory markers such as CRP, ESR and RAPID 3 scores post-treatment for the patients who filled the questionnaire. A total of 56 patients participated who visited our clinic. After obtaining informed consent, data was gathered through interview method and was further correlated with ESR, CRP and RAPID 3 scores post treatment. Based on consensus, unhealthy diet was defined as consuming red meat anytime, having more than two teaspoons of sugar per day, smoking any amount or in any frequency, and daily alcohol consumption beyond the usual acceptable standard daily limits. Unhealthy lifestyle was defined as spending more than 6 hours per day sitting without taking any break and never engaging in any physical exercises. All the parametric measures were represented as mean ± SEM, and categorical variables were represented in contingency tables as number of incidences/occurrences. The continuous variables were compared by One-way Anova, categorical variables were analyzed by Chi-square test (non-parametric test) and correlation analysis was performed using Pearson's correlation test. The $p<0.05$ was considered as statistically significant.
Results: Average age of our study group of 56 patients was 48 years, 64% were female, 50% were homemakers, mean duration of treatment was 51 months, predominance of RA (42%), PsA patients (25%), SPA (31%) and a few overlaps. Mean weight was 67.6kg and mean height was 158.76cms. 77% were on combination of CS DMARDS + TS DMARDS. 46% reported they consumed red meat any time, 68% consumed sugar more than 2 teaspoons per day, 9% were smokers while 21 % consumed alcohol daily above the usual defined daily limits. 34% of study population were sedentary, 17% sitting for long hours without break, while 38% with minimal or no exercise. We observed no statistically significant (p 0.5798) correlation between unhealthy diet and RAPID 3 scores post treatment. Similarly, there was no statistically significant correlation between unhealthy diet and ESR (P 0.09) and CRP (p 0.7). There was again no statistically significant correlation between unhealthy lifestyle and CRP (p 0.539), ESR (p 0.164) and RAPID 3 scores (p 0.7) post treatment. However when we analyzed the unhealthy lifestyle parameter sitting for more than 6 hours without break separately we found the correlation of sitting for more than 6 hours without break and RAPID 3 scores to be statistically significant in our study population (p 0.04).
Conclusion: In our study group with limited number of patients we found no statistically significant correlation of unhealthy diet or unhealthy life style in regulation of inflammation post treatment in patients with inflammatory arthritides (RA, SpA and PsA). However, we found that sitting for 6 hours without break and RAPID 3 scores statistically correlated well. This possibly indicates that those patients with inflammatory arthritides (RA, SpA, PsA) who did not move from one place beyond 6 hours in a day had persisting poor quality of life even after treatment suggesting that "Sitting beyond 6 hours without a break could be deemed as the new smoking". But, more patient numbers would be required to retest the same hypothesis at a later stage.
Unhealthy Lifestyle vs Rapid 3 scores Correlation.
Criteria: Sitting for More than 6 Hours.
p value 0.04

POS1001-HPR THE IMPACT OF FRAILTY ON FEAR OF FALLING, QUADRICEPS MUSCLE STRENGTH AND FUNCTIONAL PERFORMANCE IN OLDER ADULTS WITH TOTAL KNEE ARTHROPLASTY DUE TO KNEE OSTEOARTHRITIS

Keywords: Osteoarthritis, Outcome measures

Ö. Öztürk[1], O. Aydoğdu[2], H. Bombacı[3], B. Başalan[4], Z. Sarı[2]. [1]*Acıbadem Mehmet Ali Aydınlar University, Physiotherapy and Rehabilitation, Istanbul, Turkey*; [2]*Marmara University, Physiotherapy and Rehabilitation, Istanbul, Turkey*; [3]*Yeditepe University, Orthopedics and Traumatology, Istanbul, Turkey*; [4]*Haydarpasa Numune Research and Training Hospital, Orthopedics and Traumatology, Istanbul, Turkey*

Background: Frailty has been linked with poor quality of life, mortality, and readmission to the hospital. Also, frailty may have an impact on patients' capacity to enhance their functional ability which may be revealed by impaired muscle strength and increased fear or risk of falling. The presence of frailty is generally investigated before the arthroplasty surgery, however, patients may be at risk of future adverse health outcomes during the post-surgical period.
Objectives: To investigate the impact of frailty on fear of falling, quadriceps femoris muscle strength, and functional performance among older adults who had undergone total knee arthroplasty due to knee osteoarthritis.
Methods: A total of 70 patients were evaluated aged between 60 to 90 years, had undergone total knee arthroplasty surgery at least one year before the study. Patients were categorized according to their frailty status based on the FRAIL scale. The FRAIL scale includes 5 items as fatigue, resistance, ambulation, illness, and loss of weight (scoring: ≥3/5 criteria as frail, 1-2/5 as pre-frail, and 0/5 as robust). The Falls Efficacy Scale (FES) was utilized to determine the fear of falling. Bilateral isokinetic quadriceps femoris muscle strength was evaluated at 180 deg/sec. The Timed Up and Go (TUG) test was used to assess functional performance. A between-group comparison with post hoc analysis was performed to reveal the effects of frailty on outcome measures.
Results: The mean age of patients was 71.04±6.43 years with 87.1 % being female. According to the FRAIL scale, 30.0 % of the patients were frail, 44.3 % were pre-frail, and 25.7 % were robust. The frail group had higher fear of falling and lower functional performance compared to pre-frail and robust individuals ($p<0.05$). The peak torque of the quadriceps femoris muscle at 180 deg/sec was lower in the frail group compared to pre-frail and robust patients ($p<0.05$). No differences were detected between robust and pre-frail patients ($p>0.05$).
Conclusion: Our findings indicate that frailty status should be considered during the routine assessment of patients who had undergone total knee arthroplasty. Concomitant frailty during the post-surgical period may decrease functional performance, increase fear of falling, and deteriorate muscle strength which may result in increased fall risk and adverse health outcomes. Patients may need a multimodal intervention including muscle strengthening and postural balance exercises to reverse the effects of frailty.

POS1002-HPR PREDICTIVE FACTORS FOR MAJOR ADVERSE CARDIOVASCULAR EVENTS IN SERBIAN ANTIPHOSPHOLIPID SYNDROME PATIENTS– A 10-YEAR FOLLOW-UP STUDY

Keywords: Anti-phospholipid syndrome, Cardiovascular disease

A. Djokovic[1,2], L. Stojanovich[3,4], N. Stanisavljevic[5,6], S. Djokic[7], I. Soldatovic[8], P. Matic[9,10]. *[1]University of Belgrade - Faculty of Medicine, Cardiology, Beograd, Serbia*; *[2]University Hospital Medical Center Bezanijska Kosa, Cardiology, Belgrade, Serbia*; *[3]University of Belgrade - Faculty of Medicine, Rheumatology, Beograd, Serbia*; *[4]Dr Žutić, Rheumatology, Belgrade, Serbia*; *[5]University of Belgrade - Faculty of Medicine, Hematology, Beograd, Serbia*; *[6]University Hospital Medical Center Bezanijska Kosa, Hematology, Belgrade, Serbia*; *[7]University Clinical Centre of Serbia, Pulmonology, Belgrade, Serbia*; *[8]University of Belgrade - Faculty of Medicine, Institute for Medical Statistics and Informatics, Beograd, Serbia*; *[9]University of Belgrade - Faculty of Medicine, Surgery, Beograd, Serbia*; *[10]Institute for Cardiovascular Diseases Dedinje, Vascular Surgery, Beograd, Serbia*

Background: Non-valvular cardiac disease in antiphospholipid syndrome (APS) has been modestly evaluated.
Objectives: We wanted to assess the prevalence and evolution of major adverse cardiovascular events (MACE) in a cohort of APS patients.
Methods: From a large cohort of 181 APS patients included in a study from 2011-2012.year at University Clinical Hospital Center Bezanijska kosa, Belgrade, Serbia, data for the occurrence of MACE in 10 years of follow-up were evaluated in 82 patients (86.6% females, 62.2% with primary (PAPS), and 37.8% patients with APS associated with systemic lupus erythematosus (SLE) (sAPS)). At the inclusion in all patients, a transthoracic echocardiography study for the assessment of dimensions and functionality of the left and right heart along with valvular functions and morphology has been performed along with color doppler scan of carotid arteries for the intima-media thickness and presence of plaques, and flow-mediated dilatation of the brachial artery (FMD) as markers of subclinical atherosclerosis. Standard atherosclerotic risk factors prevalence was analyzed. Antiphospholipid antibodies (aPL) analysis included the detection of aCL (IgG/IgM), ß2GPI (IgG/IgM), and LA, and all patients were treated according to the valid guidelines by the rheumatologist. Data regarding the occurrence of new myocardial infarction (MI), cerebrovascular events (CVI), arterial and/or venous thrombosis, heart failure (HF), and cardiovascular death (considered as MACE) have been collected 10 years after inclusion.
Results: The prevalence of standard atherosclerotic risk factors was less than 40% in both study groups. Left ventricle ejection fraction (LVEF) was over 45% in more than 90% of patients in both groups (p=0.246) with valvular dysfunction present in 49% of PAPS and 58.1% of sAPS patients (p=0.426). FMD was lowered in 29.4% of PAPS and 29% of sAPS (p=0.971) and carotid atherosclerotic plaques were present in 41.2% of PAPS and 64.5% of sAPS patients (p=0.040). 9.8% PAPS and 12.9% sAPS had coronary artery disease (CAD) (p=0.724) and HF was present in 7.8% PAPS and 3.2% sAPS (p=0.645). MACE occurred in 17.6% of PAPS and 22.6% of sAPS (p=0.585). The new MI occurred in 9.8% of PAPS and 9.7% of sAPS (p=1.000), CVI in 5.9% of PAPS and 3.2% of sAPS (p=1.000), HF in 5.9% of PAPS and 3.2% of sAPS (p=1.000) and cardiovascular death in 9.8% of PAPS and 12.9% of sAPS (p=0.724). New thrombotic events (arterial and/or venous) occurred in 15.7% of PAPS and 17.2% of sAPS (p=1.000). During the follow-up period, 66.7% of PAPS and 55.2% of SAPS (p=0.313) were treated with aspirin, 25.5% of PAPS and 25.0% of sAPS with warfarin, and chloroquine was administered in 46.8% of PAPS and 53.6% of sAPS (p=0.571). Age (p=0.008), gender (p=0.034), thrombotic APS (p=0.033), hypertension (p=0.003), diabetes mellitus (p=0.043), and cardiovascular manifestations present at the time of APS diagnosis (p=0.035), namely CAD (p=0.001) and HF (p=0.005) were significantly associated with 10y MACE. In our cohort, aPL type and category were not associated with 10y MACE. In a multivariate logistic model, age. hypertension, and HF were independent predictors for 10y MACE (p=0.012, OR 8.406, p=0.032, OR 4.588, p=0.019, OR 20.377, respectively for CI 95%).
Conclusion: APS patients develop new cardiovascular events despite optimal medical therapy. Cardiovascular evaluation at the time of diagnosis and proper cardiologist follow-up with the rigorous treatment of standard atherosclerotic risk factors is of utmost importance.

HPR Interventions (educational, physical, social and psychological)

POS1003-HPR EFFECTS OF VIRTUAL REALITY IN PATIENTS WITH CHRONIC REFRACTORY PAIN SYNDROMES UNDERGOING A MULTIMODAL PAIN PROGRAM

Keywords: Health services research, Fibromyalgia, Pain

T. Pretat[1], T. Hügle[1], P. Ming Azevedo[1]. *[1]University Hospital Lausanne (CHUV), Rheumatology, Lausanne, Switzerland*

Background: Virtual reality (VR) has shown efficacy and safety in reducing pain in various indications. Our department has been using virtual reality applications for several years in the multimodal pain program, where patients also undergo a detailed physical and psychological evaluation, allowing for distinct phenotyping.
Objectives: The aim of this study was to investigate the quantitative and qualitative analgetic and anxiolytic effect of a virtual reality (VR) procedure, and to identify patient clusters with a positive response to virtual reality.
Methods: 201 patients with refractory chronic pain syndromes (mainly back pain, primary or secondary fibromyalgia) who participated in a two-week multimodal treatment were included. Of those, 43 performed VR sessions under supervision. Pain (0-10) and anxiety (0-10) were assessed before and directly after a 10-minute VR session (Healthy Mind, France). Multivariate analysis with clinical variables and unsupervised machine learning for clustering analyses by hierarchical agglomerative clustering using the Ward variance minimization algorithm was performed (Python 3.10). In 40 patients, we performed qualitative user experience (UX) assessment of VR by telephone interviews.

Results: Overall, 51% patients experienced a reduction of pain (mean -1.03, baseline 6.15) and 49% a reduction of anxiety (mean -1.36, baseline 4.25) directly after the VR intervention. In 14% pain reduction was ≥3 points (25% for anxiety). Pain increased after the intervention in 15% and anxiety in 7% of the patients. The overall experience with VR was rated as positive in 76%, neutral in 9%, and negative in 14%. Qualitative assessment revealed that several of the non-responders expect a positive outcome in case of a more frequent application of VR. Unsupervised learning indicated the highest positive response in 2/5 clusters. One cluster was characterized by peri-menopausal women with moderate depression and systemic low-grade inflammation. The second cluster was mainly young to middle-aged men with low BMI, hypermobility, anxiety and somatoform pain. Other clusters characterized by failed-back surgery or post-traumatic stress disorders responded less to VR.

Conclusion: Overall, VR was well tolerated and showed a positive short-term response on pain and anxiety. Machine learning algorithms trained in larger cohorts may confirm the prediction of VR response in specific patient subgroups.

Acknowledgements: We thank Chris Lovejoy for the cluster analysis.

POS1004-HPR INVESTIGATING THE EFFECTS OF COGNITIVE EXERCISE THERAPY APPROACH ON FUNCTIONING, ANXIETY, DEPRESSION AND BIOPSYCHOSOCIAL STATUS OF INDIVIDUALS DIAGNOSED WITH SYSTEMIC SCLEROSIS: A CONTROLLED PILOT STUDY

Keywords: Systemic sclerosis, Physical therapy/physiotherapy, Rehabilitation

M. O. Tüfekçi[1], A. Akdoğan[2], E. Ünal[3]. *[1]Hacettepe University Institute of Health Sciences, Department of Basic Physiotherapy and Rehabilitation, Ankara, Turkey*; *[2]Hacettepe Universiy Faculty of Medicine, Department of Rheumatology, Ankara, Turkey*; *[3]Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey*

Background: Systemic Sclerosis (SSc) with heterogeneous involvement limits the functionality of individuals. Anxiety-depression and biopsychosocial effects are observed due to these functional limitations. Therefore, a biopsychosocial approach is recommended in the disease management of individuals with SSc [1, 2]. The Cognitive Exercise Therapy Approach (BETY) developed on individuals with rheumatism has been presented to the literature as a biopsychosocial-based exercise approach [3].

Objectives: The aim of this study was to investigate the effects of BETY on functionality, anxiety-depression and biopsychosocial status of individuals diagnosed with SSc.

Methods: 24 individuals diagnosed with SSc, 12 of who participated in BETY exercise sessions (Group 1) and 12 in the control group (Group 2) were included in the study. BETY exercise sessions were applied as group exercises 3 days a week for 12 weeks. At the beginning of the sessions and at the end of 12 weeks, functionality was evaluated with the Scleroderma Health Assessment Questionnaire (SHAQ) [4], anxiety-depression status with the Hospital Anxiety Depression Scale (HADS) (2) and biopsychosocial status with the BETY-Biopsychosocial Questionnaire (BETY-BQ) [3].

Results: The mean age of the individuals in the exercise group (44.50 ± 10.16 years) and the control group (47.75 ± 13.63 years), other demographic information and first evaluation parameters were similar (p>0.05). Individuals who participated in all BETY exercise sessions showed a significant improvement in all parameters (p<0.05). In the control group, depression score worsened (p<0.001) while other parameters did not change (p>0.05) (Table 1).

Table 1. Within and between group changes of individuals with SSc

		Pre-treatment (n=12)	Post-treatment (n=12)	Wilcoxon Signed Ranks Test	Mann-Whitney U Test
		Median (Min-Max)	Median (Min-Max)	p value	p value
SHAQ-Global (0-3)	Grup 1	0,54 (0-2,2)	0,2 (0-1,5)	0,019	0,006
	Grup 2	0,84 (0,1-1,7)	1,2 (0,3-2)	0,117	
HADS-Anxiety (0-21)	Grup 1	6,5 (0-18)	4,5 (0-16)	0,003	<0,001
	Grup 2	10 (5-15)	12 (5-18)	0,065	
HADS-Depression (0-21)	Grup 1	5 (0-12)	1 (0-12)	0,011	<0,001
	Grup 2	7 (2-12)	10 (3-19)	0,014	
BETY-BQ (0-120)	Grup 1	43 (8-93)	24 (3-68)	0,003	0,003
	Grup 2	56 (27-87)	61 (13-95)	0,875	

Conclusion: Individuals with SSc who participated in BETY exercise sessions showed improvements in functionality, anxiety-depression and biopsychosocial features which were not seen in the control group. The results obtained from the study were interpreted as an example that BETY, an innovative exercise method on the basis of the biopsychosocial model, can meet this need in the disease management of individuals with SSc, where the importance of biopsychosocial approach is emphasized. It was aimed to investigate the contribution of BETY to the literature by evaluating it on more individuals with SSc and with objective measurement parameters as well as scales.

POS1005-HPR RELIABILITY AND VALIDITY OF THE CONE EVASION WALK TEST IN KNEE OSTEOARTHRITIS

Keywords: Cartilage, Comorbidities, Clinical trials

B. Unver[1], K. S. Kacmaz[2], V. Karatosun[3]. *[1]Dokuz Eylul University, Physical Therapy and Rehabilitation, Izmir, Turkey*; *[2]Izmir Katip Celebi University, Physical Therapy and Rehabilitation, Izmir, Turkey*; *[3]Dokuz Eylul University, Orthopedics and Traumatology, Izmir, Turkey*

Background: Knee osteoarthritis (OA) can cause a variety of dysfunctions leading to limitations in mobility, gait, and balance that predisposes them to increased fall risk [1,2]. Falls are the leading cause of injury and fracture [3], putting a significant financial burden on the healthcare system. The fall risk is even higher in people with knee OA with a prevalence between 23 and 63% [4]. Another study reported that almost 50% of patients with knee OA experienced falls [5]. Therefore, the identification of fall predictors is essential to minimize fall incidence [6]. The Cone Evasion Walk Test (CEW) evaluates fall risk by the ability to evade obstacles and walking, which provides a versatile assessment including attentional, perceptual, seeing, and several neuromusculoskeletal and movement-related functions and can be performed with or without a walking aid [7].

Objectives: The study aimed to investigate the reliability, validity, and minimal clinically important difference (MCID) of the CEW in people with knee OA.

Methods: Thirty-three patients with knee OA were included. Patients performed trials for the CEW and the Timed up and Go Test on the same day. Between the trials, patients waited for an hour in a sitting position to prevent fatigue.

Results: The CEW was shown to have excellent test-retest reliability and moderate validity (p<0.001). The relative (ICC coefficient) and absolute (SEM and SRD95) reliability of the CEW were 0.97, 0.73, and 2.02 respectively. The Pearson correlation coefficient between the CEW and the TUG was 0.72.

Conclusion: The measurements support the use of the CEW to evaluate dynamic balance and obstacle avoidance of knee OA patients. The analysis demonstrated excellent reliability and moderate validity. The low MCID value (2.02) indicated that it is a responsive test to identicate small changes in a patient's status. The CEW can be used for a global evaluation of the function and mobility of knee OA patients with little space and equipment, easily and quickly.

HPR Patients' perspectives, functioning and health (descriptive: qualitative or quantitative)

POS1006-HPR DOES FIBROMYALGIA AFFECT OCCUPATIONAL PRODUCTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS?

Keywords: Work-related issues, Fibromyalgia, Rheumatoid arthritis

O. Hamdi[1], H. Boussaa[1], S. Miladi[1], B. A. Hiba[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], F. Alia[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia*

Background: Rheumatoid arthritis (RA) may have a negative impact on patients' autonomy, quality of life and work productivity. Associated fibromyalgia may further accentuate this issue.
Objectives: We aimed to assess the impact of RA-associated fibromyalgia on occupational productivity.
Methods: We conducted a cross-sectional study including RA patients (2010 ACR/EULAR criteria). Patients were divided into two groups: group 1 (G1) including patients with fibromyalgia associated to RA, and group 2 (G2) including patients with RA. Fibromyalgia screening was based on the Fibromyalgia Rapid Screening Tool (FIRST). All patients completed the following questionnaires: Workplace Activity Limitations Scale (WALS) which is composed of 11 items (total score varying between 0 and 33), Work Productivity and Activity Impairment (WPAI) and Euro-Qol (EQ-5D). We compared the two groups of patients using the Student's t-test. The significance threshold was set at a p value of 0.05.
Results: Our study included 80 patients (G1: N=40 and G2: N=40) with an average age of 59±9 years [42-77] for G1, and 53 ±10 years for G2 [37-74]. The gender-ratio was 0.05. All the patients in G1 and 80% of patients in G2 held a job. The mean RA duration was 11.29±6.24 years. RA was erosive and ACPA/RF positive in 90% and 85% of cases, respectively. The mean delay between fibromyalgia and RA diagnosis was 49±7 months. The mean Disease Activity Score 28 (DAS_{28} ESR) was 5 in G1, and 3.97 in G2. The reduction of work activity was greater in G1 compared to G2: the mean WALS in G1 was 18±2.7 vs 10.2±1.5 in G2; p= 0.01. The WPAI showed that the mean number of work hours missed due to RA was significantly higher in G1 compared to G2: 10.2±8 hours vs 4.3±0.8 hours (p< 0.01). The mean absenteeism rate was higher in G1 compared to G2: 17.5 ±1.9% in G1 vs 10.2 ±0.5% in G2 (p= 0.02). The percentage of overall impairment of health related-activity was higher in G1 compared to G2: 50±8.6% in G1 vs 30±4.4% in G2 (p= 0.01). The mean self-rated health status using the EQ-5D VAS was 72.08 ±7% in G1 and 48 ±3.5% in G2 (p=0.05). The most affected dimensions in the EQ-5D for both groups were in the first place pain and discomfort, and secondly mobility. Loss of autonomy was found in 7 patients (37.5%) in G1 and 3 patients (7.5%) in G2. Depression and/or anxiety occurred in 45% of cases in G1, and 22.5% of cases in G2, respectively.
Conclusion: Our study showed that RA-associated fibromyalgia has a negative impact on work performance and productivity. This association also seems to alter the quality of life.

POS1007-HPR EXPERIENCES OF PARTICIPATION IN GOAL SETTING PRIOR TO RHEUMATIC TEAM REHABILITATION – A JOINT VENTURE

Keywords: Qualitative research methods, Rehabilitation

L. Skovly Nielsen[1,2,3], J. Primdahl[1,2,4], B. Clausen[3], A. Bremander[1,2,5,6]. [1]*Danish Hospital for Rheumatic Diseases, The Research Unit, Sønderborg, Denmark*; [2]*University of Southern Denmark, Department of Regional Health Research, Odense, Denmark*; [3]*Sano Denmark, Sano Middelfart, Middelfart, Denmark*; [4]*Hospital of Southern Jutland, University Hospital of Southern Denmark, Aabenraa, Denmark*; [5]*Lund University, Department of Clinical Sciences Lund, Section of Rheumatology, Lund, Sweden*; [6]*Spenshult Research and Development Centre, Spenshult, Halmstad, Sweden*

Background: Patient involvement in the goalsetting process and use of shared decisions increases adherence to rehabilitation and support patients' motivation to achieve the goals (1). However, the shared decisions that are essential for goal setting during a rehabilitation process may be compromised by patients' lack of ability to participate actively in setting goals, inadequate skills among health professionals (HPs) to facilitate goal setting and poor organizational conditions such as insufficient time [2]. This study focuses on a Danish multi-professional team rehabilitation context where, over several years, work has been done to improve the prerequisites for goal setting, both by organizational changes and by educating and preparing HPs as well as patients for the goal setting process.
Objectives: To understand how patients with rheumatic musculoskeletal diseases (RMDs) perceive participation in the goal setting process prior to multi-professional team rehabilitation.
Methods: Individual semi-structured interviews were performed with 22 patients (median 49 years, 17 female), who were to be admitted to multi-professional team rehabilitation for patients with RMDs at one of two Danish rehabilitation centres. We applied qualitative content analysis with an inductive approach. All participants had received information about goal setting prior to admission and the team used supportive tools and motivational interviewing to facilitate the goal setting process.
Results: The analysis derived one overarching theme, goal setting was viewed as a *joint venture* between the patients and the team, where capacities and resources were shared in order to formulate one or more goals. Three subthemes emerged from the analysis (Table 1): 1) *Responsibility during goal setting* was experienced as a shared responsibility between the patient and the team, where active involvement in the goal setting process added to patients' feeling of responsibility. For others, goal setting was perceived as a responsibility that solely rested with the team of HPs, who were considered to be the experts. 2) *Being dressed for goal setting* reflected whether patients felt prepared to take part in goal setting. Written and oral information prior to rehabilitation evoked thoughts on potential goals and previous experiences with rehabilitation made patients feel more qualified for setting goals. Others perceived goal setting as very difficult, partly because it felt like a huge commitment or due to lack of information.3) *Being an equal member of the team* referred to the interaction with the HPs. Patients felt they were seen as whole persons, and they felt acknowledged and respected. On the other hand, some felt as outsiders and considered HPs as authorities, causing a feeling of nervousness and insecurity related to the validity of the patients' wishes and expectations.
Conclusion: Despite a clinical practice where key areas of importance to successful patient-centred goal setting has been implemented, goal setting is still perceived as a challenge for some patients with RMDs. Future studies should uncover whether the level of health literacy among patients with RMDs bears importance for shared decisions and goal setting prior to rehabilitation.

Adaptive immunity (T cells and B cells) in rheumatic diseases

POS1008 INVESTIGATING ANTIGEN SPECIFIC T CELLS AND THEIR CITRULLINATED PROTEIN TARGETS IN SYNOVIAL TISSUE

Keywords: Adaptive immunity, Rheumatoid arthritis, Synovium

E. A. James[1], C. Rims2, S. Posso2, J. Carlin[3], W. Kwok2, S. E. Ong[4], J. Buckner2. *[1]Benaroya Research Institute, Center for Translational Immunology, Seattle, United States of America*; *[1]Benaroya Research Institute, Center for Translational Immunology, Seattle, United States of America*; *[3]Benaroya Research Institute, Clinical Member, Seattle, United States of America*; *[4]University of Washington, Pharmacology, Seattle, United States of America*

Background: Rheumatoid arthritis (RA) is a T cell mediated autoimmune disease in which citrullinated self-antigens are recognized by anti-citrullinated protein antibodies (ACPA) and T cells. To date, the majority of T cell studies have been performed using peripheral blood and have focused on well-documented ACPA targets. Studies of disease-affected tissue are needed to confirm and extend observations that have been made through study of peripheral blood T cells.
Objectives: T cell subsets and targets that have not been observed in peripheral blood are likely to comprise an important (but as yet, understudied) component of the antigen specific responses that underlie RA. We sought to generate novel insights about T cell phenotypes and antigenic targets by performing multicolor flow cytometry analysis and HLA peptidomics studies of synovial tissue samples from subjects with RA.
Methods: Synovial tissue was obtained from 7 subjects with seropositive RA, 4 subjects with seronegative RA, and 8 subjects with osteoarthritis, all of whom had undergone arthroplasty procedures. Synovial cell suspensions were obtained from tissue through mincing, digestion in collagenase I, and filtration. These were subjected to multicolor flow cytometry analysis to gain insights about the lymphocyte and non-lymphocyte cell subsets present. After confirming leukocyte antigen (HLA) protein expression by flow cytometry, additional tissue was solubilized in lysis buffer and HLA class I and HLA-DR complexes were captured (separately) on affinity columns. HLA-bound peptides were eluted, concentrated, and peptide spectra were identified by LC-MS/MS analysis. The resulting datasets were assigned sequences by searching against a human protein database. Mass shifts associated with each assigned sequence were utilized to identify post-translational modifications – most notably citrullination of native arginine residues. Comprehensive libraries of the HLA-Class I- and HLA-DR-bound peptides from each individual were imported into a custom database, which was then used to catalogue the most prevalent self-proteins for each patient type. T cell assays were then performed to demonstrate the immunogenicity of novel targets and probe T cell antigen specificity in tissue.
Results: Flow cytometry analysis of synovial tissue derived cells demonstrated that fibroblasts (including fibroblast-like synoviocytes), monocytes, and B cells were all present in tissue. In particular, fibroblasts and monocytes showed evidence of inflammation, including upregulated levels of HLA-DR expression. Similar numbers of CD4+ and CD8+ T cells were present in tissue, with phenotypes that included various memory subsets but essentially no naïve cells. In comparison with peripheral blood, T cells from synovial tissue showed evidence of recent activation, expressing higher levels of CD95, CD71, PD-1, ICOS, and CD69. The most prevalent self-proteins in the HLA-DR-bound peptidome from the synovial tissue of RA subjects included expected targets such as vimentin, alpha-enolase, fibrinogen, collagen, histones, and BIP but also contained novel targets such as fibronectin, gelsolin, and proteoglycan 4. Prevalent self-proteins in the HLA-Class I-bound peptidome included well-studied CD4+ T cell targets such as vimentin, alpha-enolase, and collagen but also contained more novel targets such as caspase-14, stromelysin-1, and filamin-A. T cell assays supported the immunogenicity of expected targets and the new candidate antigen gelsolin. In particular, a comparatively robust population of aggrecan specific T cells was present in tissue.
Conclusion: Our findings demonstrate that flow cytometry and HLA peptidomic analysis of synovial tissue can provide novel insights about the phenotype and antigen specificity of T cells in RA. Further characterization of T cell response in tissue, including those that recognize novel antigens, has the potential to provide important new insights about the character of antigen specific T cell responses that promote the development of RA.

Innate immunity in rheumatic diseases

POS1009 RADIOGRAPHIC AIRWAY ABNORMALITIES IN UNTREATED EARLY RHEUMATOID ARTHRITIS ARE ASSOCIATED WITH PERIPHERAL NEUTROPHIL ACTIVATION

Keywords: Lungs, Innate immunity, Rheumatoid arthritis

C. Kärrman Mårdh[1,2], T. Selldén[1], M. Joelsson[1,2], J. Vikgren[3], Å. Johnsson[3], G. Larsson[1], D. Glinatsi[4], K. Stubendorff[4], K. Svensson[4], I. Gjertsson[1,2], A. Rudin[1,2], A. C. Lundell[1], A. K. H. Ekwall[1,2]. *[1]Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; *[2]Sahlgrenska University Hospital, Department of Rheumatology, Gothenburg, Sweden*; *[3]Institute for Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Department of Radiology, Gothenburg, Sweden*; *[4]Skaraborg Hospital, Skövde, Sweden, Department of Rheumatology, Skövde, Sweden*

Background: The role of the lung for the initiation and progression of rheumatoid arthritis (RA) is still unclear [1]. Up to 10% of RA patients develop severe treatment resistant lung disease [2]. Understanding early disease mechanisms is of great importance. Neutrophils are key players in RA pathogenesis and are recruited to the lungs early in the disease [3]. In RA, circulating neutrophils display an activated phenotype and neutrophil activation markers predict joint destruction and development of extra-articular nodules [4]. Neutrophil activation status has not been studied in relation to pulmonary abnormalities (PA) in early untreated RA (ueRA).
Objectives: To determine whether there is an association between peripheral neutrophil phenotypes and presence of PA on chest high-resolution computed tomography (HRCT) in ueRA.
Methods: Clinical data and blood were collected, and HRCT performed at diagnosis on 30 consecutive anti-citrullinated protein antibody (ACPA) and/or rheumatoid factor (RF) positive ueRA patients. HRCTs were evaluated for the presence and extent of RA-associated parenchymal, airway and/or pleural abnormalities. Expression of phenotype markers on neutrophils separated by density was determined by flow cytometry. Levels of calprotectin, ACPA and RF were measured using immunoassays. An initial principal component analysis was used to visualize the relationships of the multidimensional data followed by univariate analysis of the strongest associations.
Results: The median patient-reported symptom duration was 6 months, 20 % of the patients were current smokers and the mean disease activity was moderate in this seropositive ueRA cohort. The frequency of having any PA detected by HRCT was 60 %. Airway abnormalities were present in 50%, nodules in 43 % and interstitial lung abnormalities (ILA) in 10 %. Unsupervised multivariate factor analysis showed clustering of "any PA" with neutrophil activation, parameters of inflammation and RF titres (Figure 1A). Univariate analysis confirmed a significantly increased CD11b and decreased CD62L expression on neutrophils indicating activation in patients with PA as compared to no PA. Titres of RF, but not ACPA, correlated with expression of the neutrophil activation marker CD11b. A stratified analysis demonstrated that airway involvement was the PA subtype with the strongest association with neutrophil activation (CD11b 1.3-fold, p=0.014 and CD62L 0.6-fold, p=0.003 in patients with airway abnormalities as compared to no PA) and with RF IgM titres (8.8-fold, p=0.0002) (Figure B-E).
Conclusion: We report a significant association between radiographic airway findings and activation of circulating neutrophils in early RA supporting a role of innate immunity and the lung in disease onset. Our results also indicate different contributions of RF and ACPA in the RA pathogenesis. Parts of this abstract was presented 15 September 2022 on a national rheumatology meeting in Gothenburg, Sweden.

POS1010 MACROPHAGE EXTRACELLULAR TRAPS PROMOTE FIBROBLAST-LIKE SYNOVIOCYTES PROLIFERATION AND PROINFLAMMATORY CYTOKINE IN RHEUMATOID ARTHRITIS

Keywords: Innate immunity, Synovium, Rheumatoid arthritis

W. Weng[1], Y. Jiang[1], S. Zhong[1], Y. Liang[1], Y. Pan[1]. *[1]Third Affiliated Hospital of Sun Yat-Sen University, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Macrophage Extracellular Traps (METs) play an important role in the promotion of tissue injury, inflammation progression and autoimmune diseases.
Objectives: This study aims to investigate the effects of METs on the proliferation and expression of proinflammatory cytokines in fibroblast-like synoviocytes (FLS) in patients with rheumatoid arthritis (RA).
Methods: Synovial tissues of RA patients and traumatic controls undergoing joint replacement in our hospital were collected, and FLS of RA patients were cultured in vitro. Peripheral blood mononuclear cells (PBMC) were isolated from RA patients and differentiated into macrophages by M-CSF. The macrophages were co-cultured with serum of RA patients and healthy controls. SYTOX green, which stained the DNA released from cells and was a common method for detecting ETs, was added to observe the formation of METs. The expressions of CD68 and CitH3 in synovium were detected by immunofluorescence. METs were isolated and purified from THP-1 derived macrophages and co-incubated with FLS. The RNA expressions of proinflammatory cytokines TNF-a and IL-1β of RA-FLSs were detected by qPCR. The proliferation ability of RA-FLSs was detected by CCK-8 assay.
Results: We found the enrichment of macrophages labeled with CD68 and CitH3 in RA synovial tissues but not in traumatic controls. Immunofluorescence co-localization assay displayed that most CitH3 were distributed around CD68, suggesting that macrophages may be the main source of ETs (Figure 1A). PBMC induced macrophages co-incubated with serum from RA patients showed the formation of strip-like METs, while no obvious METs were observed with serum from healthy controls (Figure 1B). Purified METs were isolated and co-incubated with RA-FLSs for 48h. TNF-a and IL-1β were significantly overexpressed, and the proliferation of RA-FLSs was promoted (Figure 1C-D).
Conclusion: METs were detected in RA synovium but not in traumatic controls. The autoantibodies or inflammatory cytokines presented in the serum or RA patients may be associated with the increased METs formation in RA. In vitro experiments, METs could promote the proliferation and proinflammatory cytokines expression of RA-FLSs, suggesting that clearing or blocking the formation of METs may be a new therapeutic target for RA.

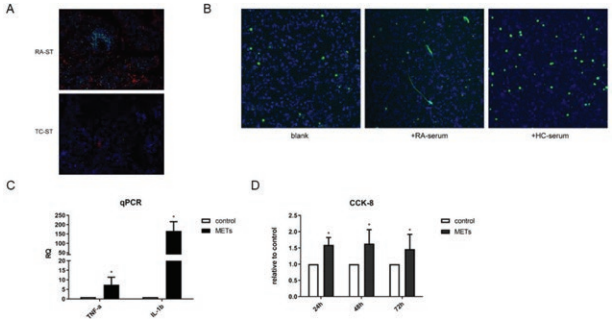

Figure 1. A, Immunofluorescence of synovium in RA and traumatic controls. Immunofluorescence showed the areas stained with anti-CD68 (red), anti-CitH3 (green) and DAPI (blue). RA: rheumatoid arthritis, ST: synovial tissue, TC: traumatic controls. B Formation of METs in human monocyte-derived macrophages with serum SYTOX green showed the formation of METs in macrophage with RA-serum. SYTOX green (green) and Hoechst 33342 (blue). C-D The promotion of METs in biologic behaviors of RA-FLSs. METs could promote the proliferation (C) and proinflammatory cytokines expression (D) of RA-FLSs.

POS1011 DIFFERENT SYNOVIAL MACROPHAGE AND FIBROBLAST SUBSETS, EXPRESSION PROFILES AND CELL-CELL INTERACTIONS CHARACTERISE SEX DIFFERENCES IN CHRONIC INFLAMMATORY JOINT DISEASES

Keywords: Synovium, Inflammatory arthritides, -omics

R. Micheroli[1], A. Khmelevskaya[1], C. Pauli[2], E. Vallejo-Yagüe[3], M. Elhai[1], K. Buerki[1], O. Distler[1], A. Ciurea[1], C. Ospelt[1]. *[1]University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland*; *[2]University Hospital Zurich, University of Zurich, Department of Pathology, Zurich, Switzerland*; *[3]ETH Zurich, Institute of Pharmaceutical Sciences, Department of Chemistry and Applied Biosciences, Zurich, Switzerland*

Background: Chronic inflammatory joint diseases differ between males and females in terms of disease manifestation, treatment response and radiographic progression. A molecular basis that could explain these differences has yet to be identified.
Objectives: The study aimed to find differences in synovitis at histology and transcriptome level between males and females with chronic inflammatory joint diseases.
Methods: Synovial tissue was obtained by ultrasound-guided biopsy from inflamed joints from 5 males and 5 age- and disease-matched females. Histological analysis included Krenn score and synovial pathotype. Single-cell RNA-sequencing (scRNA-seq) libraries were prepared with 10X Genomics and sequenced with NovaSeq 6000. We performed additional histological analyses (Krenn score and CD68 staining) on synovial tissue samples obtained from joint replacement surgery in 13 males and 13 age- and synovial pathotype-matched females with rheumatoid arthritis. The following R packages were used for bioinformatic analysis: Cell Ranger, Seurat, Harmony and CellChat. KEGG gene set enrichment analysis was performed with ClusterProfiler.
Results: We included 4 psoriatic arthritis, 2 rheumatoid arthritis, 2 undifferentiated arthritis and 2 peripheral spondyloarthritis patients. Females and males did not significantly differ in baseline characteristics: mean age was 46.2 years in females, 46.8 years in males; 2 knees and 3 wrists were biopsied per sex; mean swollen joint count was 6.8 in females and 8.2 in males. Histological analysis between the sexes showed no significant differences: synovitis was moderate in both sexes (mean Krenn total score 4.0) and pathotypes were balanced in males (1 diffuse-myeloid, 2 lympho-myeloid, 2 pauci-immune) and females (1 diffuse-myeloid, 1 lympho-myeloid, 1 pauci-immune, 2 ungradable). 41,014 cells were integrated for scRNA-seq analysis (female 21,636 and male 19,378 cells). Pseudobulk variance analysis showed a significant correlation of sex with principal component (PC) 3, accounting for 12.6% of the sample variation (Figure 1A). In addition to the sex-specific genes XIST and PRS4Y1, the following genes were main drivers of the PC3 variation: H19, CXCL9 and CXCL10. Diagnosis was not significantly associated with any PC. Comparison of the individual cell cluster proportions showed that LYVE1^{pos} macrophages (MC) were significantly more prevalent in females (4.9% in males versus 13.7% in females, p = 0.03) (Figure 1B). In confirmatory histological analysis, consistent with the known location of LYVE1^{pos} MC in the lining layer, both Krenn lining score (mean (SD) score in males 1.85 (0.69) and 2.08 (0.76) in females) and CD68 lining score (mean (SD) score in males 1.77 (1.17) and 2.08 (0.95) in females) were higher in females but did not reach statistical significance. Differential gene expression analysis showed that mainly in synovial fibroblasts (SF) genes were differentially expressed between males and females (n = 1944). In SF, upregulated genes in males led to a significant enrichment of proinflammatory pathways (TNF pathway, NF-kappa B pathway, IL-17 pathway). In contrast, upregulated genes in females were significantly associated with ECM-receptor interaction, focal adhesion, protein digestion and absorption pathways (Figure 1C). In cell-cell interaction analyses, most outgoing signaling was observed in SF while MC represented most receiving cells; IL6 and CXCL signaling pathways were significantly enriched in males, and COLLAGEN and THY1 signaling pathways in females (Figure 1 D/E).
Conclusion: Our study shows potential important differences in synovitis between males and females with chronic inflammatory joint diseases. In females, synovitis was characterized by abundance of LYVE1^{pos} MC and SF expressing

extracellular matrix-associated genes. In contrast, male SF showed a proinflammatory transcriptional profile. These sex-specific differences should be considered in research studying synovitis and may warrant sex-specific therapeutic approaches.

Rheumatoid arthritis - aetiology, pathogenesis and animal models

POS1012

SINGLE CELL RNA SEQUENCING REVEALS DISTINCT B CELL CHARACTERISTICS IN ANTI-CCP POSITIVE AT-RISK INDIVIDUALS WITH IMMINENT RHEUMATOID ARTHRITIS

Keywords: -omics, Genetics/epigenetics, Rheumatoid arthritis

W. Ye[1,2], O. Tong[1,2], D. Corscadden[3], K. Mbara[3], P. Emery[3,4], B. Fairfax[1,2], K. Mankia[3,4]. *[1]MRC Weatherall Institute of Molecular Medicine, Department of Oncology, Oxford, United Kingdom*; *[2]University of Oxford, Department of Oncology, Oxford, United Kingdom*; *[3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Division of Musculoskeletal Disease, Leeds, United Kingdom*; *[4]Leeds Biomedical Research Centre, Department of Rheumatology, Leeds, United Kingdom*

Background: Anti-cyclic citrullinated peptide (CCP) antibody positive individuals with musculoskeletal (MSK) symptoms but no clinical synovitis are at elevated risk of developing rheumatoid arthritis (RA) [1]. Whilst risk stratification is possible, specific immunological changes underpinning the transition from pre-RA to clinical arthritis remain unclear.

Objectives: We aimed to define markers of rapid progression across immune-cell subsets to enable early differentiation of those who will progress to arthritis in 'high-risk' anti-CCP positive individuals.

Methods: Peripheral blood mononuclear cells (PBMCs) were collected from anti-CCP positive individuals with MSK symptoms but no clinical synovitis (CCP+ at-risk). We performed single cell RNA sequencing (scRNAseq) of PBMCs from 10 CCP+ at-risk individuals (6 CCP+ progressors, 4 CCP+ non-progressors) collected at baseline and follow-up time points (i.e. progression to arthritis in the CCP+ progressors). All subjects had high positive anti-CCP levels (>3x ULN) and were HLA-DR shared epitope positive with median time to progression in progressors being 4 months. Analysis was performed in R using SingleR for subset annotation and Seurat for differential gene expression analysis between progressors and non-progressors and across time points.

Results: Examining all subsets, we noted a generalised increased Type 1 interferon response in non-progressors, with B cells (n=8,659) showing the most prominent divergence between groups. Within B cells we observed 334 differentially expressed genes (DEG) in CCP+ progressors versus non-progressors at baseline and 143 DEG at follow up (padj<0.05), with 77 DEG consistent across timepoints. At baseline, CCP+ progressors demonstrated upregulation of genes associated with B cell antigen-presentation, including Class II MHC molecules, CD83 and CD74. Conversely, interferon stimulated genes (ISG) were enriched in the CCP+ non-progressor DEG. Notably, this ISG signature ceased at follow-up (median 14 months). Examining the DEG per B cell subset, we noted that upregulation of genes associated with B cell antigen-presentation is found across naïve, unswitched memory and switched memory B cells in CCP+ progressors at baseline. In contrast, ISG upregulation is specific to a separate subset of interferon-responsive B cells. At baseline, these cells form a significantly greater proportion of all B cells in the CCP+ non-progressor group versus the progressor group (17.8% versus 2.6%, p<10-5). At follow-up, the proportions are comparable between the two groups (2.5% in non-progressor versus 3.4% in progressor, p=0.08), reflecting the transient nature of ISG upregulation.

Conclusion: CCP+ at risk individuals with imminent arthritis demonstrate a distinct B cell gene expression profile. Imminent progression is associated with markers of B cell mediated antigen presentation across multiple subsets whereas non-progressors demonstrate transient over-expression of ISGs driven by expansion of a subset of interferon-responsive B cells. These data reveal mechanistic insights into the early divergence between these groups and the development of RA.

POS1013

EARLY LOW DOSE IL-2 REDUCED THE INITIATION OF COLLAGEN-INDUCED ARTHRITIS THROUGH RESTORING TFH/TFR BALANCE

Keywords: Rheumatoid arthritis, Adaptive immunity, Animal models

R. Su[1], B. C. LI[1], C. Wang[1,1,1,1]. *[1]The Second Hospital of Shanxi Medical University, Rheumatoogy, Taiyuan, China*

Background: To date,there are also exploratory studies of partial prevention of RA, including dexamethasone,methotrexate, hydroxychloroquine, abatacept and so on[1].But no interventions have been proven to prevent the clinical onset of RA, and only some drugs may delay the appearance of clinical symptoms. Early restoration of immune tolerance and interruption an autoimmune response that is not yet well established may help prevent the occurrence of RA or achieve drug-free remission.Low-dose IL-2 is a new therapeutic strategy for many autoimmune diseases, including RA.However, no studies have focused on its preventive effect in Pre-RA.

Objectives: The aim of this study was to observe the preventive effect of low-dose IL-2 in collagen-induced arthritis, and to characterize the cellular mechanism underlying such an effect.

Methods: CIA is induced by primary immunization of bovine type II collagen (CII) and complete Freund's adjuvan and a booster injection of CII in incomplete Freund's adjuvant (day 21)in DBA/1 mice. CIA mice were intraperitoneally injected with 30000 IU rhIL-2 every other day at 0, 7, 14 and 21 days after primary immunization, lasted for 28 days.In addition CIA control, healthy control and Control-IL-2 were set up.Arthritis index was assessed after booster immunization.At the end of the experiment(d56 after the initial immunization), splenic mononuclear detected by flow cytometry.

Results: (1)The results showed that incidence rate of arthritis of the 0d-IL-2 group was lower than the 7d, 14d, 21d and CIA model groups (p=0.0012, p=0.0003, p<0.0001,p=0.0013). The arthritis index(AI) of 0d-IL-2 group was lower than that of 14d, 21d and CIA groups (p=0.0224, 0.0389, 0.0498), showing a trend of delayed arthritis.The AI of the 21d-IL-2 group had a decreased tendency compared with CIA group, but there was no significant difference. (2)At the end of the experiment, Flow cytometry was used to evaluate the proportions of Tfh($CD4^+CXCR5^+$) and Tfr($CD4^+CXCR5^+CD25^+Foxp3^+$) cells in spleen.The Tfh had no significant changes among all groups. The 14d-IL-2 group showed an increased trend of Tfh compared with other groups, but there was no statistical difference.The proportion of Tfr cells in both 0d-IL-2 and 14d-IL-2 group was significantly increased than that of CIA and healthy control group.By comparing the proportion of Tfh/Tfr in each

group, the proportion of Tfh/Tfr in CIA group was significantly higher than healthy control group. Compared with CIA model group,Tfh/Tfr in all intervention groups (0d,7d,14d,21d-IL-2) were significantly lower.

Conclusion: Early administration of low-dose IL-2 may help reduce the incidence of arthritis and disease activity in CIA by restoring Tfh/Tfr balance,but it has time heterogeneity.

Background: Despite of recent developments in therapeutic agents for rheumatoid arthritis (RA) patients[1], it is reported that half of the patients are unable to achieve remission even with existing drugs[2]. Therefore, there is an urgent need to gain mechanistic insight into treatment resistance. Nowadays, single-cell RNA sequencing (scRNA-seq) technology have dramatically improved our understanding of the heterogeneity in synovial cells. However, it has not been fully elucidated how the cell clusters are related to treatment response, especially in Asian races[3].

Objectives: We intend to analyze the RA synovium from Japanese patients based on single-cell transcriptomics to explore the pathological key players related to treatment resistance.

Methods: Synovial specimens were collected from 31 RA patients using an ultrasound-guided needle biopsy. The proportion of 5 immune cell subsets ($CD4^+$ T cells, $CD8^+$ T cells, B cells, NK cells, monocytes) and mesenchymal cells (synovial fibroblasts (SF), endothelial cells, mural cells) were analyzed by flow cytometry. $CD45^+$ and $CD45^-$ live cells were isolated, and scRNA-seq libraries were prepared using the 10x chromium system.

Results: We classified the patients into the following three groups based on treatment status at the time of biopsy; treatment-naïve, inadequate response to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs-IR), or biological DMARDs (bDMARDs-IR). The proportion of $CD8^+$ T cells, especially *GZMB*$^+$ *GZMK*$^+$ $CD8^+$ T cells, was significantly lower in csDMARDs-IR patients compared to treatment-naïve patients. This population was characterized by enhanced expression of *IFNG* and *GZMK*, the cooperative inducers of IL-6 production from SF. Meanwhile, an increased proportion of SF, especially *THY1*^{low} sublining and *CD34*$^+$ sublining, was observed in csDMARDs-IR and bDMARDs-IR patients. Intriguingly, by integrating gene set variation analysis (GSVA) with transcriptomic data of cytokine-stimulated SF *in vitro*[4], *THY1*^{low} sublining was indicated to be activated independently of the effects of inflammatory cytokines (e.g., TNF-α, IL-1β, IFNs) (Figure 1). Collectively, this SF subpopulation was inferred to be less susceptible to cytokine-blocking agents such as IL-6 receptor or TNF-α inhibitors.

Conclusion: The synovial analysis has the potential to be useful in parsing the mechanism of treatment resistance in Japanese RA patients, and gaining insights into novel therapeutic targets.

Background: At present, specific immune targeted therapeutics including biologics and kinase inhibitors has made significant progress in Rheumatoid arthritis (RA). However, the irresponse to targeted therapies in some refractory RA patients suggests more attention should be paid on cell death pathways, such as pyroptosis. TNF-α is a proinflammatory cytokine that plays a fundamental role in the pathogenesis of RA, which could induce pyroptosis in monocytes and macrophages and cause the destruction of bone and cartilage. Iguratimod (IGU) has been confirmed as a highly efficacious and safe conventional synthetic disease-modifying

anti-rheumatic drug for RA in Asia. Whether the combination of IGU and Tofacitinib (TOF), the Janus kinase inhibitor, would be better partner need to be elucidated.
Objectives: To evaluate the therapeutic effect of IGU and TOF on active RA and secondary osteoporosis in collagen-induced arthritis (CIA)+TNF model.
Methods: In this study, hematoxylin and eosin (HE) staining were used to evaluate the pathological changes in ankle joints of CIA+TNF model. Immunohistochemistry (IHC) were used to evaluate the level of pyroptosis related proteins in synovial tissue. We performed Micro-computed tomography (Micro-CT), HE staining and IHC to analyze the trabecular bone changes in distal femoral metaphyses to investigate the destruction of knee joint.
Results: After 6 weeks treatment of IGU and/or TOF, the diameter of ankle joint and the level of interleukin (IL)-18, IL-1 of CIA+TNF model. Immunohistochemistry (IHC) were used to evaluate the level of pyroptosis related proteins in synovial tissue. We performed M group. HE staining showed that only a small amount of inflammatory cell infiltration and less pannus were seen in synovial tissue of both monotherapy and combination group, when compared with the CIA+TNF group. Of importance, the pyroptosis related proteins, such as gasdermin D (GSDMD), nucleotide-binding domain (NOD)-like receptor protein 3 (NLRP3), caspase-1, and IL-1β were significantly less expression in synovial tissue of combination group compared with the CIA+TNF group. Both the osteoblast bone formation and osteoclast bone absorption were sharply ruined in CIA+TNF model. However the bone destruction was significantly alleviated and bone turnover rate was remarkably increased in combination group, detected by Micro-CT, HE staining and IHC.
Conclusion: The TOF-IGU combination synergistically alleviated the disease severity of the CIA model, including relieving joint inflammation and bone erosion, with suppressing the activation of the NLRP3 inflammasome and reducing GSDMD-mediated pyroptosis. The combined application of TOF and IGU may have a stronger therapeutic effect on RA and secondary osteoporosis bone remodeling.

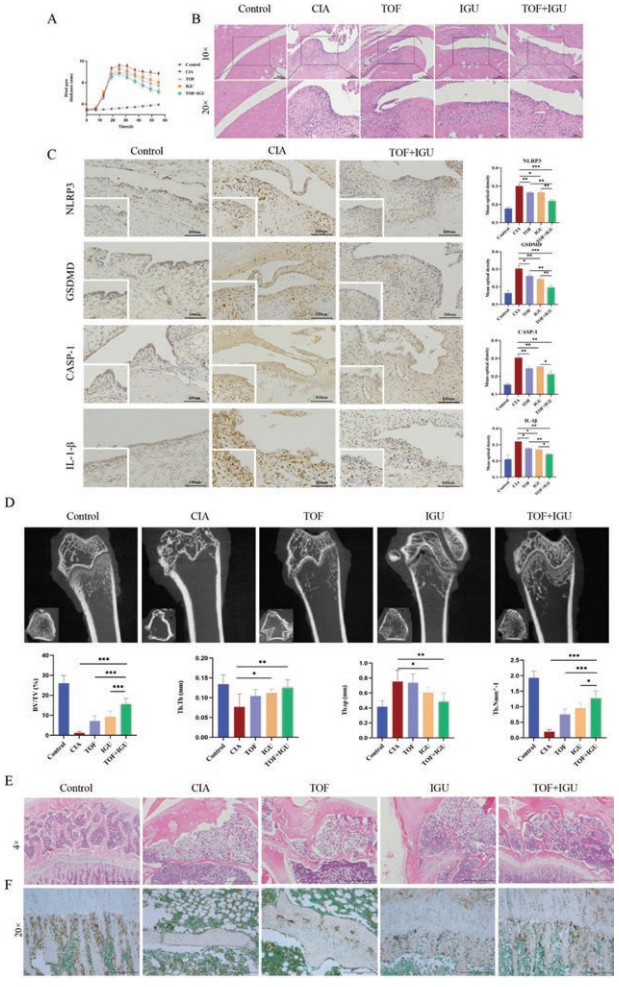

Figure 1. Therapeutic effects of TOF and IGU on the disease severity in CIA+TNF model. Background: The gut microbiota has been related to rheumatoid arthritis (RA), inflammation, and its severity. Interstitial lung disease (ILD) causes high morbidity and mortality in RA patients. However, the association between gut microbiota and RA- associated ILD (RA-ILD) is still unknown.
Objectives: -To analyze the gut microbiota and gut permeability in RA-ILD patients. -To evaluate the association between gut microbiota and permeability, and the pulmonary progression.
Methods: Nested case-cohort study of 2 prospective cohorts of patients with RA with and without ILD. The cohorts were matched for age, sex, and time of RA evolution. All cases systematically underwent high-resolution computed tomography (HRCT) and pulmonary function testing (PFT) on the diagnosis of ILD. The ILD was defined according to the lung biopsy or HRCT based on the standard criteria of the American Thoracic Society/European Respiratory Society, the progression was defined as the worsening of the FVC > 10% or DLCO > 15%. The gut microbiota was measured by the 16S rRNA gene and the sequences were processed using the Quantitative Insights into Microbial Ecology (QIIME2). Serum lipopolysaccharide-binding protein (LBP) and lipopolysaccharide (LPS) were measured as markers of gut permeability. Demographic, clinical, laboratory, and treatment-related data were recorded. The disease activity was measured by Disease Activity Score-28 with Erythrocyte Sedimentation Rate (DAS28-ESR), and the function using the Health Assessment Questionnaire (HAQ). We performed a descriptive analysis and Cox regression analysis to identify prognostic factors for the time to progression of RA-ILD.
Results: Thirty-five RA-ILD and 35 RA without ILD were included. Table 1 shows the baseline characteristics. After a median (SD) period of 66,1 (47,2) months, pulmonary progression criteria had observed in 13 patients (37.1%). Compared with controls, RA-ILD had greater values of DAS28-ESR (p=0.032) and higher HAQ scores (p=0.003). They also had higher levels of serum LPS (p = 0.007) and more abundance of *Streptococcus* genus (p = 0.087), as well as a lower abundance of *Slackia* (p = 0.022) and *Paraprevotella* genera (p = 0.082). The RA-ILD with progression had a higher abundance of *Streptococcus* genus (p = 0.090) and a lower abundance of *Slackia* genus. In Cox regression analysis, the moderate-high activity of DAS28-ESR (HR [IC 95%], 3.53 [1.20-6.98]; p=0.017), LPS (HR [IC 95%], 1.12 [1.02-1.23]; p=0.018) and the *Slackia* genus (HR [IC 95%], 0.98 [0.97-0.99]; p=0.010) were associated with RA-ILD.
Conclusion: RA-ILD patients showed increased gut permeability and also displayed a different pattern of gut microbiota associated with ILD diagnosis and prognosis. These findings may enable the discovery of potential RA-ILD biomarkers.

Table 1. Clinical and demographic characteristics

VARIABLE	RA-ILD n=35	RA without ILD n=35	P-value
Age in years, mean (SD)	69.7 (9.3)	66.6 (7.0)	0.130

POS1018 **ROLE OF THE SIGNALING LYMPHOCYTE ACTIVATION MOLECULE FAMILY IN RHEUMATOID ARTHRITIS COMPLICATED WITH INTERSTITIAL LUNG DISEASE**

Keywords: Rheumatoid arthritis, Cytokines and chemokines, Lungs

Q. Che[1,2], J. Chen[1,2], Y. Zhang[3,4], C. Ren[1,2], X. Zhang[1,2], W. Hongxing[3,4], Q. Shu[1,2]. *[1]Qilu Hospital, Cheeloo College of Medicine, Shandong University, Department of Rheumatology, Jinan, China*; *[2]Shandong Provincial Clinical Research Center for Immune Diseases and Gout, Department of Rheumatology, Qilu Hospital, Jinan, China*; *[3]Qilu Hospital, Cheeloo College of Medicine, Shandong University, Department of Clinical Laboratory, Jinan, China*; *[4]Shandong Engineering Research Center of Biomarker and Artificial Intelligence Application, Department of Clinical Laboratory, Jinan, China*

Background: Interstitial lung disease (ILD) is the most common extra-articular complication of rheumatoid arthritis (RA). The prevalence of RA with ILD is approximately 20% and the risk of ILD is significantly higher in RA patients than in healthy controls [1]. The pathogenesis of RA-ILD has not been elucidated, although various genetic, immunological, and environmental factors have been suggested to be involved in its development and progression [2]. Therefore, it is crucial to explore new targets and predictors of RA-ILD pathogenesis.
Objectives: To explore the possible mechanisms involved in the initiation and progression of RA-ILD.
Methods: Synovial samples of RA (GSE55235), lung samples of ILD (GSE53845 and GSE81292) were extracted from the Gene Expression Omnibus (GEO) database. Differentially expressed genes (DEGs) analysis, weight gene co-expression network analysis (WGCNA) and Consensus Cluster were implemented with R language. Enrichment analysis and shared hub gene analysis were then performed. The function of selected gene signatures and hub genes were validated in external datasets (synovial tissues of RA (GSE55457) and RA-associated usual interstitial pneumonia (RA-UIP) (GSE199152)), in terms of single cells level, RA-ILD patients and our collagen-induced arthritis (CIA) relative ILD animal model.
Results: The ILD relative gene signatures which contained 90 shared genes was obtained (Figure 1 A). KEGG pathway enrichment analysis identified cytokine-cytokine receptor interactions and chemokine signaling pathways (Figure 1 B). CytoHubba selected 17 hub genes as shown Figure 1 C. Validated the 17 hub genes in lung tissue samples from three RA-UIP patients and four non-UIP controls with the external database (Figure 1 D). In single cell port, the surface molecules of B cells, CD19, CD27, CD38, CD79A, SLAMF1, SLAMF2 and SLAMF7 can be detected in RA synovial tissues and lung samples of ILD (Figure 1 E). The SLAMF1, SLAMF2 and SLAMF7 in PBMCs of RA-ILD patients were highly expressed (Figure 1 F). Furthermore, we constructed the CIA+TNF animal model , whose lung pathology showed ILD-like manifestations (Figure 1 G), together with an increased infiltration of B cells, especially those expressing SLAMF1, SLAMF2 and SLAMF7 in both synovial and pulmonary tissues (Figure 1 H).
Conclusion: Our study explored the common pathogenic mechanisms of RA and ILD, identified the shared 17 hub genes of RA-ILD. Especially the SLAMF1, SLAMF2 and SLAMF7 expressing B cells can migrate to pulmonary and take part in the development of fibrosis and ILD, with the guide of chemokines. This indicated a joint-lung axis hypothesis might play important roles in the development and progression of RA-ILD.

POS1019 DIPYRIDAMOLE, A COMPOUND THAT INCREASES EXTRACELLULAR ADENOSINE LEVELS, AS A THERAPEUTIC AGENT FOR RHEUMATOID SARCOPENIA

Keywords: Rheumatoid arthritis, Animal models, Sarcopenia

M. Marco-Bonilla[1], M. Fresnadillo[1], I. Sanchez[1], R. Largo[1], G. Herrero-Beaumont[1], A. Mediero[1]. [1]*IIS-Fundación Jiménez Diaz, Bone and Joint Metabolism, Madrid, Spain*

Background: In addition to joint damage, rheumatoid arthritis (RA) confers a higher risk of several comorbidities, including changes in body composition with reduced muscle mass and strenght (sarcopenia) with stable or increased fat mass. Adenosine and ATP are responsible for the maintenance of energy balance and activate cell signaling through selective receptors. Adenosine A2A receptor activation regulates bone turnover, targetting bone destruction in inflammatory diseases like RA. The use of dipyridamole (blocks adenosine uptaken by the cells increasing extracellular adenosine levels activating adenosine receptors) modulates the intracellular and extracellular levels of adenosine and ATP in murine C2C12 myoblasts, via activation of the adenosine A2B receptor, cAMP and AMPK pathways, counteracting deleterious effects on skeletal muscle differentiation.
Objectives: To determine if dipyridamole prevents sarcopenia in arthritis murine model.
Methods: 12-wk-old C57BL/6 male mice were injected with pooled K/BxN serum (100 µl, ip) on day 0 and 2. Dipyridamole 25mg/Kg was administered daily starting after the first serum injection. Clinical signs (joint swelling and thickness) were measured daily. DXA analysis and motor activity tests were performed prior to serum inoculation and at day 13. Mice were euthanized on day 16. Inflammatory cytokines and C-reactive protein (CPR) were measured in serum. Gastronemius was collected for protein and RNA extraction. Tibialis was frozen and embedded in OCT for histology.
Results: Serum transfer (RA mice) induced an increase in joint inflammation that was maximal 2wk after injection. Dipyridamole decreased the appearance of inflammation in the joints (clinical score of 5±3 vs 14±1 RA mice, p<0.005, n=7), and counteracted weight loss (p<0.01). Moreover, dipyridamole modulates the systemic inflammation found in RA mice promoting an signifficant increase on anti-inflammatory cytokines such as IL-10, and a signifficant reduction on pro-inflammatory citokines such as INFγ, IL1β, TNFα and IL6, with a non signifficant decrease in CRP. In motor tests, the RAmice had a reduced distance traveled when compared to healthy mice (sham) (830±37cm vs 1393±187cm Sham, p<0.001, n=4-7), as well as a reduce strength (22.4±7g vs 44.4±3g Sham, p<0.05, n=4-7) and endurance, while the rotarod test showed a loss of motor coordination with increase of latency to fall(43.3±5.4sec vs 75.9±3.3sec Sham, p<0.05, n=4-7). Dipyridamole treatment resulted in a revertion of physical development induced by serum transfer. Furthermore, RA mice had decreased lean mass, BMD and BMC, as well as an increased fat percentage, that were reverted in the presence of dipyridamole. RA mice muscle weights decreased when compared to sham mice, whereas dipyridamole reversed this effect. MHC protein expression was decreased in RA mice when compared to sham mice (60±7% vs 100% Sham, p<0.005, n=4-7) and reverted by dipyridamole (184±6%vs 60±7%RA mice, p<0.005,n=6-7), meanwhile PAX7 expression was enhanced by dipyridamole (274±11%dipyridamole,151±13% RA mice vs. 100%, p<0.005, n=6-7). AMPK activation decreased in RA mice (53±7% decreased vs Sham, p<0.05, n=4-7), whereas dipyridamole reversed this loss (152±5% dipyridamole vs 53±7% RA mice, p<0.001,n=6-7). Adenosine A2A and A2B receptors protein expression were decreased in RA mice (71±3% for A2A and 35±9% for A2B vs 100% Sham, p<0.005,n=4-7), been reverted by dipyridamole. Senescence markers p21and p16 were increased in RA mice (221±38% for p21 and 392±25% for p16 vs 100% Sham, p<0.001,n=4-7) and dipyridamole reduced their expression.
Conclusion: Arthritic mice developed sarcopenia accompanied by a loss of motor activity, strong systemic inflammation and an increased muscle senescence. Dipyridamole counteracted both systemic and joint inflammation as well as muscle loss, enhancing muscle regeneration. This indicate that the use of agents that increase extracellular adenosine levels might be interesting as a therapeutically approach forinflammatory sarcopenia.

Background: A consistent connection between rheumatoid arthritis (RA) and type 2 diabetes (T2D) has been recently reported highlighting interleukin-1β (IL-1β) as shared pathogenic pathway and therapeutic target [1]. In a clinical trial

enrolling patient with RA and T2D, we demonstrated that IL-1 inhibition led to a marked reduction of glycated haemoglobin together with a decrease of RA disease activity [2].

Objectives: To evaluate the synovial expression of IL-1 related genes and the relationship to the ubiquitin-proteasome system in the synovial tissues of RA patients with and without T2D. To assess the effects of high concentration of insulin in vitro, mimicking the hyperinsulinism of the early phases of T2D, on ubiquitinated proteins in fibroblast-like synoviocytes (FLSs).

Methods: Early (<1 year) treatment-naïve RA patients with T2D (RA/T2D n=16) were compared with age- and gender-matched RA patients without T2D (n=16) enrolled in the Pathobiology of Early Arthritis Cohort (PEAC) [3]. Synovial tissue biopsies obtained under ultrasound guidance underwent RNA-sequencing as previously described [3], and we compared IL-1 pathway genes in patients without and with T2D. The synovial expression of ubiquitin in macrophages and synovial lining fibroblasts was assessed by immunohistochemistry/immunofluorescence and correlated with synovial pathotypes [4]. Finally, FLSs from RA patients (n=5) were isolated and treated with human insulin (200 and 500 nM) and ubiquitinated proteins were assessed by western blot.

Results: Synovial RNA-sequencing showed that one third of IL-1 pathway genes (41/138) were significantly different in RA/T2D patients compared to RA patients without T2D. In parallel, synovial tissues of RA/T2D patients were characterised by a consistent reduced expression of ubiquitin-proteasome genes. More specifically, ubiquitin genes (*UBB*, *UBC*, and *UBA52)* were significantly lower in T2D/RA patients. Furthermore, 22 genes codifying proteasome subunits were significantly lower in RA/T2D patients (*PSMA2*, *PSMA6*, *PSMA7*, *PSMB1, PSMB3, PSMB4, PSMB6, PSMB7, PSMB8, PSMB9, PSMB10*, *PSMC1, PSMC3, PSMC5, PSMC13*, *PSMD4, PSMD7, PSMD8, PSMD9*, *PSME1, PSME2*, and *PSMF1)*. Additionally, several genes regulating ubiquitin and proteasome system were significantly different in the synovial tissue of RA/T2D patients. Specifically, *APP*, *BAG4*, and *BTRC* were upregulated in RA/T2D patients. Conversely, *RACK1*, *RBX1*, *RPS27A*, *SEM1*, *SHARPIN*, and *SIGIRR* were significantly downregulated in RA/T2D patients. Immunohistochemistry showed a significant reduction of the percentage of ubiquitin-positive cells in synovial tissues of RA/T2D patients. The percentage of ubiquitin-positive cells was also increased in patients with a lympho-myeloid pathotype compared to diffuse myeloid or pauci-immune-fibroid. Despite its widespread expression in synovia, immunofluorescence showed that ubiquitin mainly colocalized with synovial macrophages and lining fibroblasts. Finally, *in vitro* experiments showed a reduction of ubiquitinated proteins in RA-FLSs treated with a high concentration of insulin (500 nM).

Conclusion: Increased IL-1 gene expression was observed in the synovial tissues of RA/T2D patients linked with decreased ubiquitin-proteasome system. These findings may provide a mechanistic explanation of the observed clinical benefits of IL-1 inhibition in patients with RA and concomitant comorbid T2D, as the reduction of the ubiquitin-proteasome system may enhance the levels of precursor IL-1β and the production of bioactive IL-1β.

HIGH THROUGHPUT MULTIPLEX PROTEOMICS IDENTIFIES BIOMARKERS AND NETWORKS ASSOCIATED WITH THE RHEUMATOID ARTHRITIS-CARDIOVASCULAR DISEASE (RA-CVD) MULTIMORBID AXIS

Keywords: Rheumatoid arthritis, Cardiovascular disease, Biomarkers

R. Shukla[1,2], N. Black[2,3], B. Erhayiem[4], G. Fent[4], C. Miller[2,3,5], S. Plein[4], D. Plant[1,2], M. H. Buch[1,2,6]. [1]*University of Manchester, Centre for Musculoskeletal Research, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom*; [2]*Manchester University NHS Foundation Trust, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom*; [3]*University of Manchester, Division of Cardiovascular Sciences, Manchester, United Kingdom*; [4]*University of Leeds, Multidisciplinary Cardiovascular Research Centre (MCRC) and Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom*; [5]*University of Manchester, Wellcome Centre for Cell Matrix Research, Manchester, United Kingdom*; [6]*University of Leeds, Leeds Institute of Rheumatic & Musculoskeletal Medicine, Faculty of Medicine & Health, Leeds, United Kingdom*

Background: Rheumatoid arthritis (RA) patients have higher mortality rates compared to the general population, primarily due to excess cardiovascular (CV) disease (CVD). We have shown the earliest stages of RA are associated with CV abnormalities but blood biomarkers to identify CVD in early RA are lacking.

Objectives: In a treatment-naïve new-onset RA trial cohort, to identify (i) blood-based protein biomarkers that associate with cardiovascular magnetic resonance imaging (CMR) abnormalities, (ii) whether these biomarkers are sensitive to change; (iii) the predominant inflammatory and metabolic pathways implicated.

Methods: CADERA (Coronary Artery Disease in Early RA)[1] was an add-on study to a parent RCT of an early RA inception cohort where 81 patients underwent CMR at baseline and year 1. Proximity extension immunoassay (Olink) was used to measure normalised protein expression (NPX) across inflammation, CV II/III and cardiometabolic panels at time of CMR. Bayesian linear mixed effects regression was used to identify proteins associated with CMR parameters of myocardial oedema/fibrosis [MO/MF = native T1, myocardial extracellular volume (ECV) and late gadolinium enhancement (LGE)] and vascular stiffness [VS = aortic distensibility and stiffness index] at baseline, year 1 and those sensitive to change over time. An expanded protein interaction (PPI) network using baseline proteins was created using an induced network approach (String-DB) and clusters identified using k-means that were then subjected to Gene ontology (GO) and KEGG enrichment analysis.

Results: Of 340 proteins analysed using Olink, 108 proteins were associated with CMR markers of MO/MF (64 proteins; 28 positively, 36 negatively) and VS (44 proteins; 13 positively, 38negatively) at baseline. 46/108 proteins identified at baseline were sensitive to change over time and of these, 15 remained associated with CMR parameters at Year 1 (see Figure 1A & B). No overlapping proteins were identified that associated with focal (LGE) and diffuse fibrosis (ECV). Table 1 reports posterior estimates and 95% credible intervals for two top proteins. Figure 1C displays change in predicted NPX for 2 time-sensitive proteins associated longitudinally with CMR parameters. K-means clustering of the expanded baseline PPI network (enrichment $p < 0.0001$) identified 4 clusters (Figure 1D) with roles in IL27 receptor binding and NF-kB signalling pathway (red), vascular endothelial growth factor receptor binding and JAK-STAT signalling pathway (green); Macrophage CSF receptor binding and ErbB signalling pathway (blue); and IL10 receptor activity and complement and coagulation cascades (yellow).

Conclusion: This is the first study to identify sensitive protein biomarkers that may help with early diagnosis and monitoring of RA-CVD and inform on possible therapeutic targets. Treatment group differences and subgroup analyses with responders are ongoing. Further validation of these candidate biomarkers is needed in an independent cohort.

Table 1. Top proteins sensitive to change and longitudinally associated with CMR detected subclinical myocardial oedema(MO)/fibrosis(MF) and vascular stiffness (VS). PE = posterior estimate, CrI = credible intervals.

	Proteins	Role	Baseline PE(95%CrI)	Year 1 PE(95%CrI)
MO/MF	*Protein A	Lipid metabolism	-4.33(-8.07 to -0.6)	-52.18 (-97.4 to -6.8)
VS	*Protein G	Growth factor, heparin binding	0.84(0.12 to 1.58)	1.31(0.2 to 2.4)

*Proteins, clusters subject to intellectual property discussions via Innovation Factory, University of Manchester.

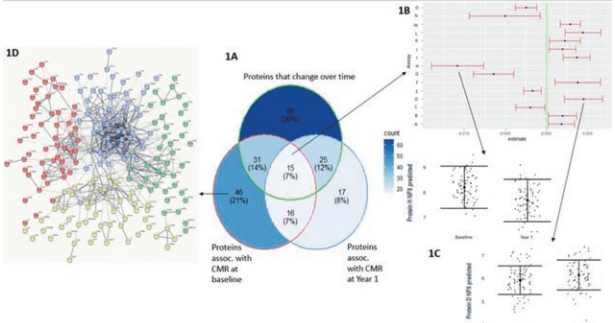

Figure 1. A(middle):Overlap of proteins associated with CMR parameters at baseline, year 1 and those sensitive to change. B(top right): Posterior estimate of 15 proteins from the intersect of figure 1A. C(bottom right): Predicted normalised protein expression of protein D(bottom) and H (top)at baseline and Year 1. D(left): Baseline PPI network analysis identifies 4 clusters.

POS1022 A NEWLY DEVELOPED SMALL MOLECULE CD38 INHIBITOR EXERTS THERAPEUTIC EFFECTS IN A COLLAGEN-INDUCED ARTHRITIS MOUSE MODEL

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Animal models

R. Perrone[1,2], P. Vadhana Ashok Kumaar[1], K. Gore[3], J. Favret[4], E. Verdin[1], S. Felstead[2]. [1]*Buck Institute For Research On Aging, -, Novato CA, United States of America*; [2]*Napa Therapeutics Ltd, -, Tortola, Virgin Islands, British*; [3]*KDL Gore Solutions Ltd, -, Hertfordshire, United Kingdom*; [4]*Inotiv, -, West Lafayette IN, United States of America*

Background: CD38 is a NAD+ consuming enzyme ubiquitously expressed on immune cells and its expression increases in several pathological conditions, including Rheumatoid Arthritis (RA) [1, 2]. Pre-clinical studies in CD38 *knock-out* models have demonstrated that CD38 deficient animals develop an attenuated form of Collagen-Induced-Arthritis (CIA) characterized by reduced inflammation and damage at the joint level suggesting a causal role of CD38 in the pathogenesis of CIA and, potentially, RA [3-5].
Objectives: This study investigated the efficacy of NTX-748, a newly developed, potent and orally available small molecule inhibiting the enzymatic activity of CD38, in reducing the inflammation, cartilage destruction, pannus formation, and bone resorption associated with developing CIA in mice, a well-established animal model for the study of RA.
Methods: Mice were injected intradermally (ID) with Freund's complete adjuvant (CFA) containing bovine type II collagen to induce arthritis on study days 0 and 21. Beginning on study day 18, the animals were dosed twice daily (BID) by the oral route (PO) with vehicle or NTX-748 (3, 10, or 30 mg/kg), or dosed PO once daily (QD) with Methotrexate (1 mg/kg) (n=12/group) for 18 days. One group served as a naïve control group (n=4). Efficacy evaluation was based on animal body weights, clinical arthritis scores (CAS) based on daily clinical scores of the paws (right front, left front, right rear, left rear) expressed as area under the curve (AUC), summed histopathology scores based on histopathologic evaluation performed on fore paws, hind paws, and knees, analysis of NTX-748 plasma concentrations and tissue metabolomic profile. The primary endpoint was day 36 CAS.
Results: Treatment with NTX-748 at 10 and 30mg/kg showed a statistically significant dose-dependent beneficial effect reducing day 36 CAS by 37% and 50% respectively relative to vehicle (p=0.13 and p=0.047), without showing any toxicity, including body and spleen weights. Histopathology analysis of joints, paws and knees confirmed NTX-748 efficacy. Strikingly, NTX-748 reduces incidence of CAS up to 50% in a dose-dependent manner (p = 0.0015). Plasma concentrations of NTX-748 increased approximately in proportion to dose. Mass Spectrometry-based tissue metabolomic analysis (liver and spleen) confirmed target engagement with dose dependent increases of NAD+ levels, the main substrate of CD38-mediated NAD+ hydrolysis, and decreases of NAM and ADPR, both products of the same enzymatic reaction. Methotrexate 1mg/kg also demonstrated efficacy (98% reduction in CAS) however significant splenomegaly (3-fold increase) indicated toxicity at this dose.
Conclusion: Our results demonstrated that NTX-748, a small molecule inhibiting the NADase enzymatic activity of CD38, is efficacious in the mouse CIA model, and thus potentially RA. These data confirm the potential of CD38 as druggable target in the treatment of inflammation-driven autoimmune diseases such as RA.

POS1023 CHARACTERIZATION OF TRYPTOPHAN METABOLISM ALTERATION IN RHEUMATOID ARTHRITIS AND EVIDENCE FOR A THERAPEUTIC POTENTIAL OF AADAT ADMINISTRATION IN MICE

Keywords: Rheumatoid arthritis

D. Moulin[1], M. Taieb[2], C. Michaudel[3], A. Aucouturier[3], L. Bermudez-Humaran[3], P. Langella[3], D. Mulleman[4], X. Mariette[5], P. Dieudé[6], J. Y. Jouzeau[2], P. Emond[7], J. Sellam[8], H. Sokol[3]. Background: Tryptophan metabolism alterations have been reported in inflammatory diseases, including rheumatoid arthritis. However, understanding whether these alterations participate RA development and can therefore be considered as putative therapeutic targets remain undetermined.
Objectives: In this study, we combined quantitative Tryptophan metabolomics in the serum of RA patients and corrective administration of a recombinant enzyme in experimental arthritis to address the question.
Methods: Targeted quantitative metabolomics was performed on the serum of 574 treatment naïve early untreated RA patients from the ESPOIR cohort and on 98 healthy subjects. Dosages were also conducted in serum of collagen-induced arthritis mice and controls. A proof-of-concept study evaluating the therapeutic potency of targeting the kynurenine pathway was performed in the collagen-antibody induced arthritis model.
Results: Differential analysis revealed drastic changes in Trp metabolites levels in RA patients compared to healthy controls. Amongst them, decreased levels of kynurenic (KYNA), xanthurenic (XANA) acids and indoles derivatives as well as an increased level of quinolinic acid in the serum of RA were positively correlated to disease severity (assessed by both circulating biomarkers and disease activity scores) and negatively correlated to quality-of-Life scores. Similar alterations of metabolites of the kynurenine pathway were observed in collagen-induced arthritis. Finally, the administration of the recombinant enzyme Aminoadipate Aminotransferase (AADAT), which is responsible for the generation of XANA and KYNA, was protective in collagen-antibody induced arthritis model.
Conclusion: Altogether, our clinical and experimental data indicate that Trp metabolism alterations play an active role in RA pathogenesis and might be considered as new therapeutic avenue.

POS1024 TOFACITINIB TREATMENT AMELIORATES MUSCLE LOSS IN COLLAGEN-INDUCED ARTHRITIS MODEL

Keywords: Targeted synthetic drugs, Animal models, Sarcopenia

R. Cavalheiro Do Espírito Santo[1], T. Hein Da Rosa[1], B. Bartikoski[1], M. Farinon[1], R. T. Pedo[1], M. L. Gasparini Vieira[1], T. Karnopp[1], G. Chapacais[1], A. DI Domenico[1], S. Loch[1], M. Dos Santos[1], L. Santos[1], J. Miranda de Souza Silva[1], R. Xavier[1]. [1]*Universidade Federal do Rio Grande do Sul, Faculdade de Medicina, Porto Alegre, Brazil*

Background: Sarcopenia is a muscle disease characterized by reduction of muscle strength and muscle mass. In RA, 25.9 to 43.3% of the patients present sarcopenia [1]. The loss of muscle mass observed in RA patients occurs either by activation of catabolic pathways or by inhibition of anabolic pathways [2]. Despite having a list of drugs capable of treating RA inflammation, the effect of these therapeutic interventions on muscle are not elucidated [3].

Objectives: To evaluate the effect of tofacitinib on muscle mass of collagen-induced arthritis (CIA) mice.
Methods: CIA was induced in male DBA/1J mice. Animals were randomized into 3 groups: I) CIA + tofacitinib (CIA-TOF; n=10); II) CIA + vehicle (CIA-VEH; n=10); III) healthy controls (CO; n=9). Vehicle (PBS) or tofacitinib 15mg/kg were administered twice a day, between days 18 and 45 after the disease induction. Clinical score, edema and body weight were evaluated during the experimental period. After euthanasia, tibio-tarsal joints were collected for assessment of disease histopathological score, and tibialis anterior (TA) and gastrocnemius (GA) muscles were weighed to assess muscle mass. Muscle atrophy was evaluated by measurement of TA myofiber cross-sectional area (CSA). Expression of proteins related to muscle regeneration or catabolism (Pax7, MyoD, myogenin and Murf-1) were evaluated by western blot in GA homogenates. Serum inflammatory markers (TNF and IL-6) were evaluated by ELISA. Statistical analysis included ANOVA followed by Tukey's or with Kruskal-Wallis. The statistical difference was assumed for $p<0.05$.
Results: As expected, tofacitinib treatment decreased arthritis severity by reducing clinical score ($p=0.03$) and hind paw edema ($p=0.04$) in comparison with CIA-VEH group. CIA-TOF showed weight gain ($p=0.02$), higher TA ($p=0.009$) and GA ($p=0.02$) weights, and increased CSA compared to CIA-VEH group ($p=0.01$). On day 45, CIA-TOF presented increased muscle strength compared to CIA-VEH group ($p=0.006$), however, no difference was found in the fatigue parameter among groups ($p>0.05$). The expression of Pax7 was unchanged ($p=0.07$), while MyoD expression showed an increase trend, and myogenin expression was significantly increased in CIA-TOF compared to CIA-VEH ($p=0.04$) and CO groups ($p=0.02$). The treatment did not significantly modify Murf-1 expression. Compared to CIA-VEH group, CIA-TOF mice showed decreased serum levels of TNF ($p=0.04$), and no difference in IL-6 serum levels ($p=0.08$).
Conclusion: Tofacitinib attenuated muscle loss in arthritic mice, as increased muscle weight and muscle CSA were detected in treated mice. Additionally, an increased activation of satellite cells regeneration, based on the expression of myogenin, is a potential mechanism involved in tofacitinib-protection against muscle loss.

POS1025 COMBINATION OF BULK AND SINGLE CELL RNASEQ ANALYSES TO REVEAL MECHANISMS OF ABT-317 (JAK INHIBITOR) ON SYNOVIAL FIBROBLASTS

Keywords: Rheumatoid arthritis, -omics, Disease-modifying drugs (DMARDs)

Y. Son[1], D. Korenfeld[2], B. Harvey[1], J. Wang[2], A. Suarez-Fueyo[2], D. Chang[2], T. Radstake[2], M. Ruzek[1]. *[1]AbbVie, Bioresearch Center, Worcester, United States of America*; *[2]AbbVie, Cambridge Research Center, Cambridge, United States of America*

Background: Janus Kinase (JAK) inhibitors, including upadacitinib, are approved for clinical use, and show good therapeutic responses in Rheumatoid arthritis (RA) patients. In addition to impacts on cytokine signaling in immune cells, fibroblast-like synoviocytes (FLS) are also emerging as key cellular participants that contribute to the JAK- Signal transducer and activator of transcription (STAT) pathway guided cytokine-mediated interactions between FLS and immune cells. Despite the important role of FLS in RA pathogenesis, the mechanism of action of JAK inhibitors on FLS has not been extensively studied.
Objectives: The aim of this study is to characterize the molecular effects of a tool JAK1 selective inhibitor (ABT-317) on RA-FLS by performing bulk RNA-seq and single cell RNA seq (scRNA-seq) analysis on cell cultures following exposure to Staphylococcus enterotoxin B (SEB)-conditioned PBMC medium (CM) to mimic the RA inflammatory milieu +/- ABT-317.
Methods: RA-FLS cultures from 6 (Bulk RNA-seq) or 4 (ScRNA-seq) donors were pre-treated with various concentrations (0.1 and 1 μM) of ABT-317 with/without exposure to 30% SEB-conditioned PBMC medium. Total 36 Bulk RNA-seq library was prepared using NEB kit. EdgeR was used for differential expression gene (DEG) analysis, and DEGs (defined as padj < 0.1) were evaluated using Ingenuity Pathway Analysis (IPA). Total 24 ScRNA-seq libraries were prepared by 10x Genomics, and 87,108 cells were recovered. The data was analyzed with Cell Ranger, IPA, Seurat, and Harmony R packages. Gene Expression Omnibus (GEO) repository data sets (GSE12021 and GSE55457) from RA synovial tissue studies were used to compare with this study.
Results: The addition of ABT-317 to CM-stimulated FLS resulted in a downregulation of the same genes upregulated to the greatest degree by CM indicating that ABT-317 reverses a major portion of gene expression induced. IPA analysis demonstrated the expected impact of Jak inhibition on JAK/STAT and interferon signaling pathways that drive inflammation. Interestingly however, pathways unrelated to JAK signaling, such as the regulation of cell adhesion, complement activation and cytosolic DNA-sensing were also downregulated by ABT-317, suggesting that additional pathogenic mechanisms in synovial fibroblasts are also impacted by JAK inhibition. To determine whether specific fibroblast sub-populations are impacted by Jak inhibition, scRNA-seq was used to segregate FLS cells into distinctive clusters with and without CM and ABT-317 (1uM). We found that the pseudobulk data from scRNA-seq was highly correlated to the bulk RNA-seq data demonstrating consistency between our single cell and bulk datasets. We identified 9 clusters that only emerged following treatment of FLS with CM and upon addition of ABT-317 in a dose-dependent manner. ABT-317 reversed the elevated expression of cell migration related genes like ITGB8 after CM treatment in a specific cluster which suggests a potential for differential Jak responsiveness within subpopulations of fibroblasts. To establish the relevance of this in vitro data to patients, the relationship of FLS cultures stimulated with CM with public synovial tissue datasets from RA patients was explored. DE genes from the datasets (RA vs. OA) were positively correlated with the bulk and pseudobulk from the FLS culture scRNAseq (CM vs. UT), suggesting many of the same pathways are activated in vitro compared to patient synovial tissue.
Conclusion: We find that Jak inhibition is effective in downregulating several proinflammatory pathways induced by conditioned media stimulation in FLS cultures as well as additional mechanisms that could impact fibroblast pathogenesis in RA. These studies advance our understanding of Jak1 inhibitors and how they may contribute to clinical efficacy.

POS1026 FUNCTIONALLY SELECTIVE IMMUNOMODULATOR SHOWS ROBUST EFFICACY IN A MURINE COLLAGEN-INDUCED-ARTHRITIS MODEL

Keywords: Rheumatoid arthritis, Innate immunity, Animal models

H. Asnagli[1], S. Tessier[1], M. Foster[2], S. Denies[3], E. Hoeben[4], J. P. Herbeuval[5], J. Crouzet[1], A. Van der Aa[1]. *[1]Ermium Therapeutics, R&D, Paris, France*; *[2]Experimental Pathology Consultancy, 45 Hope Road, Benfleet, Essex, United Kingdom*; *[3]SD Analytics, Statistics, Bellem, Belgium*; *[4]2-Bridge, Pharmacokinetics, Zoersel, Belgium*; *[5]"Chemistry & Biology, Modeling & Immunology for Therapy" (CBMIT), CNRS UMR 8601, Faculté Biomédicale des Saints-Pères, Université Paris Cité, Paris, France*

Background: Activated monocytes play a key role in the initiation and progression of inflammatory synovitis in rheumatoid arthritis (RA), leading to cartilage destruction and, via invasive pannus development, loss of peri-articular bone.

ER000145 is a functionally selective immunomodulator derived from IT1t, a CXCR4 antagonist demonstrated to exert immunomodulating properties[1]. As an immunomodulating model compound, ER000145 previously showed increased potency by downmodulating several key pro-inflammatory cytokines in Toll-like receptor (TLR)7/8 stimulated immune cells and low/no CXCR4 antagonism *in vitro* as well as strong efficacy in a murine pristane-induced lupus model[2].

Objectives: The aim of the present study is to evaluate the potency of the functionally selective immunomodulator ER000145, both *in vitro* on murine and human immune cells as well as *in vivo* in a murine collagen-induced arthritis (mCIA) model.

Methods: *In vitro* immunomodulating potency of ER000145 was evaluated in fresh murine splenocytes and isolated primary monocytes from healthy volunteers (HV). After 1-hour incubation with ER000145 and 24-hour stimulation with TLR7/8 agonists (R848 or R837, 5 or 1 µg/mL respectively), supernatant was collected. Pro-inflammatory cytokines were detected by flow cytometry (LegendPlex). For the mCIA model, male DBA-1 mice (n=8 per group) were immunized with bovine collagen type 2 on Day 1 in Complete Freund Adjuvant (FA) and on Day 21 with Incomplete FA. Mice were randomized and dosed once daily (QD) intraperitoneally (IP) with either PBS (vehicle control), ER000145 at 3, 10 or 30 mg/kg, or IT1t at 30 mg/kg as of Day 28, for a duration of 14 days. As a positive control, mice received 10 mg/kg prednisolone QD orally. Blood samples were collected after single (Day 28) and 14-days of repeated dosing to evaluate exposure of ER000145. During the study, disease activity was monitored based on the extent of edema and erythema in each paw, and paw thickness was measured using a digital caliper. At study termination, all paws from the vehicle-treated and 30 mg/kg ER000145-treated mice were collected and prepared for histopathological scoring using hematoxylin and eosin (H&E) staining.

Results: ER00145 inhibited key pro-inflammatory cytokines (TNF-α/IL-6/IL-1β) in TLR7/8 agonist-stimulated HV primary monocytes as well as murine splenocytes. Daily IP administration of ER000145 in a mCIA model reduced significantly clinical scores in a dose-dependent manner: a dose of 3 mg/kg was not efficacious in contrast to both the 10 and 30 mg/kg QD doses. At efficacious doses, the average concentration (C_{avg}) of ER000145 in blood ranged between 14 and 33 ng/mL. In addition, no body weight loss was observed. Histologically, administration of 30 mg/kg of ER000145 QD was associated with significant suppression of the severity of articular pathology (synovitis, pannus infiltration and bone resorption) and reactive inflammatory responses (stromal cell reactions and bonne marrow cellularity).

Conclusion: The immunomodulator ER000145 showed significant *in vitro* potency by downmodulation of key proinflammatory cytokines in both human and murine cellular assays after stimulation. *In vivo* potency was further demonstrated in a therapeutic mCIA model where both 10 and 30 mg/kg daily IP doses prevented significant disease progression. Based on these promising efficacy data with ER000145, orally available immunomodulators are currently being developed as a potentially novel treatment option for chronic inflammatory autoimmune diseases like rheumatoid arthritis.

POS1027 THE LIPOPROTEIN AND LIPID PROFILE CAN PREDICT THE DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Rheumatoid arthritis, -omics

K. Tsezou[1], M. Ghorasaini[2], A. Verhoeven[2], D. Benaki[3], A. Iliou[3], A. Tzioufas[1], E. Mikros[3], P. Vlachoyiannopoulos[1]. Background: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic and systemic synovial inflammation, cartilage erosion and subsequent joint destruction. Despite the existence of many targeted therapies, RA remains a disease with high morbidity, requiring monitoring with prognostic biomarkers. RA presents with abnormal lipoprotein levels, a phenomenon known as the "lipid paradox," which requires comprehensive characterization with -omics techniques [1].

Objectives: The purpose of this study is to describe the distinct lipoprotein and lipidomic profile in active and remission RA populations, in an effort to globally map the effect of inflammation and disease activity on the metabolome and obtain biomarkers with predictive capacity.

Methods: Plasma samples of 161 RA patients were collected under fasting conditions. Patients were classified based on their DAS28 as High (>5.1), Moderate (3.2-5.1), Low (2.6-3.2) and Remission (<2.6). Lipoproteins and their subclasses were detected and quantified using 1H NMR spectroscopy with the B.I.LISA method (Bruker), while lipid spieces detection was achieved with mass spectrometry (DMS-MS) using the Lipidyzer method (Sciex). Glycoproteins signals were acquired from 1H NMR led spectra. High Disease Activity (n=21) and Remission (n=33) were analysed pairwise with Multivariate models (OPLS-DA) and univariate t-test (boxplots). The correlation coefficient was calculated for the entire lipoprotein and lipid profiles with DAS28 for each experimental group.

Results: Patients with high disease activity showed relatively increased levels of VLDL (VLPN), IDL (IDPN), total Triglyceride (TPTG), Free fatty acids (FFA(18:1), FFA(16:0)) and Phosphatidylcholines (PC(16:0/20:4), PC(18:0/20:4)) compared to those in remission. RA patients in remission were characterized by high levels of LDL (LDPN, L4PN), HDL Apolipoprotein A1 (HDA1, H4A1), Cholesterol Esters (CE(18:2), CE(18:1)) and Phosphatidylcholines (PC(16:0/18:2), PC(18:0/18:2)). The entire lipoprotein and lipid profiles were correlated with DAS28 in Remission (R2=0.24; R2=0.40) and High disease activity (R2=0.26; R2=0.47) groups, indicating that the lipid profile is more predictive of the disease activity in both groups. Univariate analysis highlighted relatively higher concentration of large density HDL-4 subclasses (HDL-4 -Cholesterol (p=0.0003), ApoA1 (p=0.0003), ApoA2 (p=0.0018) and Phospholipids (p=0.0024)), Sphingomyelin (SM(24:0); p=0.0012), Hexosylceramide (HCER(22:0); p=0.0057), and Cholesterol Esters (CE(18:0); p=0.0025, CE(18:2); p=0.0121), but lower Glycoprotein A and B (p=0.0003; 0.0007) levels in Remission.

Conclusion: In summary, comprehensive lipoprotein and lipid analysis identifies markers that characterize RA in exacerbation and remission. Large density HDL-4 Apolipoprotein A1 and Cholesterol Esters are indicative of Remission, while VLDL, Triglycerides and Free fatty acids describe High disease activity in RA. The above markers will be evaluated in comparison with those already existing in clinical laboratory application.

POS1028 SUCCESSFUL TREATMENT OF MURINE RHEUMATOID ARTHRITIS MODELS WITH CENERIMOD, A SELECTIVE S1P1 RECEPTOR MODULATOR, HIGHLIGHTS THE BENEFIT OF S1P IMMUNOMODULATION IN RHEUMATIC DISEASES

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Animal models

T. Hoyler[1], M. Bulle[1], J. Scherer[1], C. Wyss[1], S. Froidevaux[1], M. Martinic[1]. [1]*Idorsia Pharmaceuticals Ltd., Pharmacology Immunology, Allschwil, Switzerland*

Background: Since the discovery of the sphingosine-1-phosphate (S1P) pathway and its potentially beneficial role of inducing lymphocyte retention and subsequent immunomodulation [1], several small molecule S1P receptor modulators have been approved for the treatment of diverse autoimmune diseases such as multiple sclerosis and ulcerative colitis. Cenerimod, a selective $S1P_1$ receptor modulator, has shown efficacy in preclinical models of systemic lupus erythematosus (SLE), systemic sclerosis and Sjögren's syndrome [2-4] and is now entering a Phase III clinical trial (OPUS; NCT05648500) in patients with moderate to severe SLE.

Objectives: We investigated the efficacy of cenerimod in modulating disease progression in preclinical models of rheumatoid arthritis (RA).

Methods: We analyzed the efficacy of cenerimod in several models of RA in mice and rats. Disease-relevant biomarkers such as autoantibody development and chemokine secretion were measured to gain a deeper understanding of the mode of action of $S1P_1$ receptor modulation in these RA models.

Results: In mouse RA models, prophylactic treatment with cenerimod inhibited the acute inflammatory response post antigen challenge and prevented autoantibody formation, thus completely preventing the initiation of disease. Cenerimod treatment at disease onset further showed a strong reduction of joint inflammation and significantly delayed clinical symptoms and the secretion of several pro-inflammatory chemokines. Although corticosteroid treatment is frequently administered as an adjunct treatment for interventional disease management in RA, its systemic toxic effects do not permit long-term usage to control disease activity in patients with rheumatic diseases [5]. In rats, cenerimod treatment prevented disease development dose-dependently when given directly at initiation of disease, while treatment at disease onset stopped further inflammation of the joints. Further, treatment with low-dose cenerimod limited joint inflammation to the same extent as low-dose corticosteroid treatment while not having a similar negative impact on body weight over the duration of the experiment.

Conclusion: S1P receptor immunomodulation is a highly effective treatment option for murine models of RA with translational value for rheumatological indications. Combined with the published data on rheumatic diseases, we believe that $S1P_1$ receptor modulation by cenerimod will benefit patients suffering from RA who are underserved by the current treatment landscape.

POS1029 MACROPHAGE MARKERS FOLATE RECEPTOR BETA AND CD206 ARE DIFFERENTIALLY EXPRESSED IN SYNOVIAL TISSUE OF RA PATIENTS WITH A DIFFUSE-MYELOID, LYMPHO-MYELOID AND FIBROID-PAUCI IMMUNOPATHOTYPE

Keywords: Rheumatoid arthritis, Prognostic factors, Imaging

M. Steinz[1], J. Van der Krogt[2], J. P. Van Hamburg[2], G. Jansen[1], S. Tas[2], C. J. Van der Laken[1]. [1]*AmsterdamUMC- Location VUmc, Clinical Immunology & Rheumatology, Amsterdam, Netherlands*; [2]*AmsterdamUMC- Location AMC, Clinical Immunology & Rheumatology, Amsterdam, Netherlands*

Background: Three different synovial immunopathotypes of rheumatoid arthritis (RA) have been identified: Fibroid-Pauci immune (FP, fibroblast-rich), Diffuse-Myeloid (DM, macrophage-rich) and Lympho-Myeloid (LM, lymphocyte- and macrophage-rich), and have been associated with treatment outcome to biologicals [1]. Therefore, identification of the synovial immunopathotypes before the start of therapy could be supportive for development of individualized treatment strategies. However, this currently requires invasive synovial tissue sampling. Novel whole-body molecular imaging with positron emission tomography (PET) and the use of specific PET tracers can non-invasively detect and quantify the presence of immune cells in RA inflamed synovium. Folate-receptor beta (FRβ) is a cell surface receptor on macrophages, shown clinical exploitation for high specificity PET imaging of arthritis [2]. However, it remains to be elucidated whether FRβ is a suitable marker for RA immunopathotype stratification. Furthermore, it is unclear whether FRβ is expressed on macrophages with a pro-inflammatory (M1) or homeostatic (M2) phenotype in the 3 immunopathotypes.

OBJECTIVES:

(1) Investigate FRβ expression across the three distinct RA immunopathotypes.
(2) Investigate FRβ expression in relation to the general macrophage marker CD68 and the mannose receptor CD206 (which is associated with M2-type macrophages [3]).

Methods: Synovial biopsies of the RA-affected ankle or knee (N=28) were retrieved from RA patients with clinically active disease defined by ACR RA criteria [4]. Subsequently, biopsy sections were immunohistologically stained in order to stratify each patient into one of three RA-immunopathotypes. Confocal microscopy was used to determine CD68, FRβ and CD206 expression (integrated density), and co-expression (comparing fold-change average expression) for all patients within each immunopathotype (N=8-10/ group).

Results: Out of 28 RA synovial biopsies 10 could be classified as FP, 9 DM and 9 LM immunopathotype. Average expression of CD68, FRβ and CD206 was significantly increased in the DM and LM compared to the FP immunopathotype (## $p<0.01$). Quantitative CD68, FRβ and CD206 expression was highest in the DM immunopathotype. FRβ expression correlated significantly with CD206 expression in all three pathotypes (Spearman $R_{FP}= 0.67$; $R_{DM}= 0.76$; $R_{LM}= 0.49$). On the contrary FRβ expression did not correlate with CD68 expression except in the DM pathotype (Spearman $R_{DM}= 0.46$).

Conclusion: The results of this study put forward that FRβ is a potential target for delineation of RA immunopathotypes, to be explored for non-invasive molecular imaging stratification. Furthermore, investigation of FRβ expression has an additive value over CD68 since it can be used to distinguish the presence of M2 macrophages in the RA synovium specifically.

Background: Rheumatoid Arthritis-associated Interstitial Lung Disease (RA-ILD) is an extraarticular manifestation with clear clinical relevance because it impairs quality of life and survival. Despite this, RA-ILD etiology and pathogenesis are only partially understood. However, we know that fibrosis and collagen deposition, aging and telomere shortening, the expression of the mucin MUC5B gene, the RA autoantibodies and smoking are contributing elements. A better knowledge of RA-ILD pathogenesis will lead to improved outcomes for the patients.

Objectives: This study aims to identify CpG sites that are differentially methylated in the blood of RA-ILD patients compared to matched RA patients without ILD. These findings will point to genes and pathways of specific relevance to RA-ILD pathogenesis.

Methods: We compared two matched groups of 32 patients with RA: RA patients diagnosed with ILD less than one year before sample collection; RA patients without ILD. The two groups were assessed by High-Resolution Computed Tomography (HRCT) and matched by sex, age, smoking (ever/never), and anti-CCP status. Blood samples were used for DNA extraction. Methylation of 850000 CpG was measured with the Infinium Methylation Epic BeadChip (Illumina). Identification of the differentially methylated positions (DMP) and differentially methylated regions (DMR) was performed using the R application ShinyÉPICO [1]. Gene set enrichment analysis (GSEA) was done with the R package methylGSA [2].

Results: A total of 6679 DMP with ≥ 2 % difference and FDR < 0.05 were identified in the autosomal chromosomes. In addition, 119 DMR (72 in gene bodies, 32 in promoters, and 15 in CpG Islands) were discovered. Some of these DMP y DMR are associated with genes of known relevance (Figure 1): genes of mucins (*MUC6, MUC13*) and collagens (*COL9A3, COL21A1*), genes involved in telomere maintenance (*TERF, TERT1, POT1*), and some genes related to immunological processes (*HLA-DRA, VCAM1, TGFBR2…*). A systematic analysis of the associated genes with GSEA showed significant enrichment of 62 gene ontology (GO) terms and 49 Reactome pathways. Several of the top enriched GO terms referred to the detection of chemical stimuli involved in sensory perception, either by smell or taste. This finding was replicated in the enriched pathways. Other top GO terms identified chromosome changes during mitosis: centromeric duplication, chromosome segregation, and others. They corresponded to top-enriched pathways involved in the M phase of mitosis and cell cycle checkpoints. Another group of GO terms referred to post-translational modifications of proteins: deacylation of proteins, which coincided with top pathways involved in chromatin modifications, including acetylation and deacetylation of histones; and ubiquitination of proteins, also reflected in several top enriched pathways. Besides, enriched GO terms that referred to the catabolic process of nuclear-transcribed mRNA correlated with top pathways of mRNA metabolism. In addition, there were other significantly enriched gene sets, such as the involved in the transport of intracellular vesicles and the location in the cell of proteins, mitochondria, RNA, and chromosomes, the host interaction with viral infections, gene silencing by small RNA, SUMOylation, and the RHO GTPase cycle.

Conclusion: We observed significant differences in blood DNA methylation between matched RA-ILD and RA-control patients. Some of these differences were related to potentially interesting genes (mucins, collagen, telomere maintenance), and biological processes and pathways (detection of chemical stimuli, post-translational modifications of proteins, chromosome and intracellular vesicle localization, and transport) that will help us to better understand RA-ILD pathogenesis.

THERAPEUTIC EFFECTS OF GINGIVAL MESENCHYMAL STEM CELLS AND THEIR EXOSOMES IN A CHIMERIC MODEL OF RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Animal models

S. Bruckner[1], V. Capria[2], B. Zeno[1], W. Willis[3], L. Ganesan[3], W. Jarjour[3], B. Hanaoka[4]. [1]*The Ohio State University Wexner Medical Center, Immunology and Rheumatology, Columbus, United States of America*; [2]*The Ohio State University, University Laboratory Animal Resources, Columbus, United States of America*; [1]*The Ohio State University Wexner Medical Center, Immunology and Rheumatology, Columbus, United States of America;* [4]*The Ohio State University, Rheumatology, Columbus, United States of America*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease that leads to progressive joint destruction involving multiple joints. There is a large body of evidence that suggests a crucial role for activated synovial fibroblasts (RASF) in mediating both direct tissue injury and perpetuation of the complex disease process in RA [1]. RASF from RA patients are able to attach to articular cartilage and deeply invade and degrade the cartilage matrix [2] and have been shown to migrate to secondary joint locations *in vivo* and invade and degrade cartilage similarly to the primary site [3]. Human gingival-derived mesenchymal stem cells (GMSC) are promising therapeutic cell treatments for autoimmune diseases due to their immunomodulatory capacity [4]. Others have demonstrated the ability of GMSC, and exosomes derived from GMSCs (GMSCExo) to suppress the deleterious *in vivo* effects of the collagen induced arthritis model in mice [5].
Objectives: Our aim was to test whether the destructive invasive effects of RASF in an *in vivo* chimeric mouse model of RA could be modulated by the presence of GMSC or GMSCExo. In addition, we analyzed the effects of both GMSC and GMSCExo on the ability of RASF to migrate to secondary locations. Mechanistic studies were done to understand how the GMSC were inhibiting the invasiveness of the RASF.
Methods: A chimeric human/mouse model of synovitis was created by surgically implanting SCID mice with a small piece of human articular cartilage surrounded by RASF. Each mouse received two implants; the primary implant on the right flank of the mouse contained RASF, the secondary implant contained no RASF. Mice were retro-orbitally injected once with either GMSC or GMSCExo at 5-7 days post-implantation. The implants were removed after 60 days for evaluation. Histology and IHC were used to assess RASF invasion of the cartilage. Flow cytometry was used to understand the homing ability of GMSC *in vivo,* the incidence of apoptosis of RASF and the exchange of exosomes *in vitro.*
Results: We demonstrate that both GMSC and GMSCExo are potent inhibitors of the deleterious effects of RASF. Both treatments were effective in inhibiting the invasive destructive properties of RASF as well as the potential of these cells to migrate to secondary locations and attack the cartilage there. We also present evidence that GMSC home to the site of the implant and induce programmed cell death of the RASF through the direct transfer of exosomes.
Conclusion: Our results indicate that both GMSC and GMSCExo can block the pathological effects of RASF in this chimeric model of RA. A single dose of either GMSC or GMSCExo can inhibit the deleterious effects of RASF. These treatments can also block the invasive migration of the RASF, suggesting that they can inhibit the spread of RA to other joints. Because the gingival tissue is harvested with little difficulty, relatively small amounts of tissue are required to expand the cells, the fairly simple *in vitro* expansion process, and the increasing technological advances in the production of therapeutic exosomes, we believe that GMSCExo are excellent candidates as a potential therapeutic for RA.

Background: Rheumatoid arthritis (RA) is the most prevalent autoimmune mediated joint disease. A complex dysfunction of the immune response is considered central for its pathogenesis as well as a dysregulated crosstalk between fibroblast-like synoviocytes (FLS) and monocytes.
Objectives: This project aims to examine and validate the anti-inflammatory effects of the natural glucose metabolite itaconate-derivative 4-octyl itaconate (4-OI) on stromal and immune cells from patients with active RA and evaluate the downstream effector molecule Heme-Oxygenase 1 (HO-1) as a potential biomarker.
Methods: Synovial fluid mononuclear cells (SFMC) from patients with chronic RA (cRA) were used to harvest RA FLS. Monocultures of synovial fluid derived FLS (SF-FLS) and autologous co-cultures of SF-FLS and peripheral blood mononuclear cells (PBMC) were cultured with and without 4-OI, corticosteroids, and anti-TNF (n=7). Subsequently, analyses by flow cytometry, Western Blotting, MTT assay, and ELISA were performed. The 4-OI target protein Nrf2 was knocked out in immortalized FLS (FLS-KO) generated by Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR). Furthermore, we measured HO-1 by ELISA in plasma samples from newly diagnosed, active and treatment-naïve early RA (eRA) patients at baseline and after 6 months of intensive treatment (the OPERA trial, n=80)[1] with a follow-up period of 24 months and plasma and in synovial fluid samples from patients with active, chronic RA (cRA, n=20) during disease activity flares. Plasma samples from age approximated and gender matched healthy controls (HC) (n=35) were also included.
Results: *In vitro* 4-OI significantly inhibited MCP-1 secretion in cultured SFMC, THP-1 (monocyte cell line), and FLS and resulted in a concomitant increased HO-1 production. 4-OI reduced the MCP-1 secretion by 84%, anti-TNF by 41% and corticosteroids by 54% (all $p<0.01$) in co-cultures consisting of autologous RA SF-FLS and PBMCs. In FLS we observed a linear decrease in pro-inflammatory cytokine production. 4-OI did not decrease collagen production, even in dosage of 500 µn FLS we observed a linear decrease in pro-inflammatory cytokine production. 4-OI did not decrease collagen production, even in dosage of 500 1 production. 4-OI reduced the MCP. In eRA plasma levels of HO-1 was significantly increased at baseline (2039 pg/mL, 95% CI [1619, 2460]) vs HC (1209 pg/mL, 95% CI [1047, 1370]). Treatment with MTX or MTX + anti-TNF, lowered levels of HO-1 (1704 pg/mL, 95% CI [1377, 2031]) after 6 months irrespective addition of anti-TNF treatment, reducing the difference to a no longer significantly different level from HCs. HO-1 was associated with number of swollen joints ($r=0.25$, $p<0.02$), tender joints ($r=0.24$, $p<0.02$) and Clinical Disease Activity Index ($r=0.23$, $p<0.02$). Baseline HO-1 predicted radiographic joint damage progression (change in Total Sharp-van der Heijde score (Δn eRA plasma levels of HO-1 was significantly increased at baseline (2039 pg/mL, 95% CI [1619, 2460]) vs HC (1209 pg/mL, 95% CI [1047, 1370]). Treatment with MTX or MTX + anti-TNF, lowered levels of HO-1 (1704 pg/mL, 95% CI [1377, 2031]) after 6 months irund ($r=0.75$, $p<0.001$). High levels of HO-1 in SF from inflamed joints were associated with CRP ($r=0.52$, $p<0.05$) during flares in cRA.
Conclusion: *In vitro* 4-OI decreased MCP-1 secretion and increased the HO-1 expression in cultures of monocytes and in RA FLS and PBMC without decrease in collagen production or cell growth. In total, 4-OI decreased MCP-1 in both immune and stromal dominated RA pathobiology. In eRA patients, pre-treatment-plasma HO-1 levels were increased and correlated with parameters for disease activity, treatment-effect after 6 months, and predicted radiographic progression after 24-month.

Background: Rheumatoid arthritis (RA) results from a gene-environment interaction and is characterized by a preclinical, or asymptomatic, phase during which autoantibodies appear, in particular anti-citrullinated protein antibodies (ACPA) [1].This gene-environment interaction, occurs many years before the diagnosis of RA, possibly during childhood. Only smoking, in genetically predisposed patients (carriers of the shared HLA-DRB1 epitope), has been shown to be a reproducible risk factor for developing seropositive RA [2,3]. Other inhaled substances may play a role as many non-smokers develop RA, inducing inflammation of the lung mucosa and a systemic immune response, such as occupational exposure to silica, possibly pesticides and air pollution [4]. Early life exposures may play a major role in the pathophysiology of RA. All these elements lead us to study the impact of exposure to environmental factors in childhood on the risk of RA in adulthood, mainly airborne exposure.
Objectives: To assess the relationships between exposure to a rural lifestyle during childhood and the risk of RA in women involved in the E3N cohort.
Methods: E3N is an ongoing French prospective cohort that included 98,995 women aged 40-65 years. Women completed, every 2-3 years, mailed questionnaires on their lifestyle and health-related information. In 2002 a questionnaire on their childhood environment was assessed, including passive smoking, educational level, smoking during pregnancy and World War II deprivation scores, exposures to cats and dogs at home, whether women had lived on a farm for at least 3 successive months during childhood, and if so, the type of animals they were exposed to and their age at first pet or farm animal exposure. Hazard ratios (HRs) and 95% confidence intervals (CIs) for the risk of incident RA were estimated using multi-adjusted Cox proportional hazards regression models with age as the time scale.
Results: A total of 698 incident RA cases, among whom 77,754 non RA women were ascertained. Farming lifestyle was not associated with the risk of RA. In contrast, in a multivariable-adjusted Cox regression model including known risk factors of RA (age, active and/or passive smoking during adulthood, BMI, educational level), exposure to cats and/or dog between 1 and 2 years old was associated with a decrease risk of incident RA compared to children without pets: HR = 0.55 (95% CI 0.3-0.9), p= 0.031). Furthermore, as previously described, passive smoking in childhood [HR=1.24 (1.0-1.5) p=0.044] and high educational level ([HR=0.78 (0.6-0.9) p=0.037]; [HR=0.772 (0.6-0.9) p=0.0426] for up to 2 years and ≥3 years of university education, respectively versus no education) were shown to be associated with RA in the multi-adjusted model.
Conclusion: More than farming lifestyle or the type of pet, the very early exposition to cats and/or dog (1-2 years) seems to reduce the incidence of RA while passive smoking in childhood increases it. This supports the idea that the lung and thus airborne exposures in early childhood play an important role in the genesis of RA occurring in adulthood.

Background: Rheumatoid arthritis (RA) patients are heterogeneity in their clinical phenotype and in response to molecular targeted therapies. To date, only limited number of studies addressed the immunological changes that lie behind the clinical heterogeneity.
Objectives: To identify immunological correlates of clinical phenotypes and predictors of treatment response, we performed peripheral blood multi-omics profiling of patients initiating abatacept treatment.
Methods: In the PREDICTABA study, we have recruited 104 RA patients starting abatacept treatment at six hospitals in Japan (Figure 1A). Peripheral blood mass cytometry analysis was performed in discovery and validation cohorts (n=79 and 22). In total, 10 million T and B cells were clustered by cell surface protein expression (Figure 1B, 1C). After accounting for the effects of age, sex, CDAI disease activity, anti-CCP antibody titer, and donor batch effects, immune cell clusters were tested for their association with baseline treatment and future abatacept treatment response (CDAI improvement at 6 months) using mixed-effects modeling of association of single cells [1]. Peripheral blood RNA-seq identified immune cell signatures and immune pathway signatures.
Results: At baseline, median age was 73 years. 80% were female and 80% were seropositive. Median CDAI improved from 17 to 5 after 6 months of abatacept treatment. RNA-seq immune cell gene signatures validated mass cytometry immune cell cluster frequencies. Naive CD8 T cells were negatively associated with age (odds ratio (OR) 0.57 and 0.32, P-values<0.001). Naive B cells were negatively associated with baseline prednisolone use (OR 0.53 and 0.25, P-values<0.001). Plasmablasts were negatively associated with baseline methotrexate use (OR 0.59 and P-value<0.001, Figure 1B, 1D, 1E), and with IL6_JAK_STAT3 signaling gene signature (Rho=-0.36, P-value<0.001). Finally, CD8+CD25+ T cells showed suggestive association with CDAI improvement after abatacept treatment (OR 1.4 and 1.6, P-values 0.01 and 0.07, Figure 1C, 1F, 1G).
Conclusion: Through immunophenotyping analysis of RA patients, we have revealed that B cell subsets are associated with conventional RA treatments. Abundance of CD8+CD25+ T cells may be predicative of good abatacept response.

POS1035 FOCAL ADHESION PROTEINS KINDLIN-1, -2 AND TALIN-1 ARE REGULATED IN IL-1B-STIMULATED RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

Keywords: Synovium, Cytokines and chemokines, Rheumatoid arthritis

Hoehe, Germany*; [4]*University Hospital of Giessen-Marburg, Dept. of Trauma, Hand and Reconstructive Surgery, Giessen, Germany*

Background: Rheumatoid arthritis (RA) is a progressive chronic inflammatory autoimmune disease characterized by synovial hyperplasia, articular inflammation and excessive joint and bone erosion. Activated RA synovial fibroblasts (SF) are key players of cartilage erosion by attaching and invading into cartilage. The kindlin family of focal adhesion proteins consists of three members, whose function is to activate integrins and thereby enable focal adhesion. Integrins play a central role in regulating cell-matrix and cell-cell adhesion. The effects of integrin activation are cell adhesion and migration, which are known to be pathologically increased in RASF. It is well described that dysfunction of integrins and kindlins and their co-factor talin-1 are involved in the pathogenesis of certain diseases characterized by inflammation and malignant transformation. However, the role of kindlins and talin-1 in RA, and specifically RASF, remain unclear.
Objectives: To investigate the compartmental and cellular localisation of kindlin-1, -2, -3 and talin-1 in RA synovial tissue and RASF, and the impact of pro-inflammatory activation on their expression on mRNA and protein level.
Methods: Synovial fibroblasts were isolated from synovial tissue after joint replacement surgery (RA, osteoarthritis (OA)) or synovectomy of hand joints (non-arthritic controls). RASF were stimulated with 10 ng/ml IL-1β for 6, 17, 24 and 48 h. In a second approach, RASF were repetitively stimulated three times with 0.05 ng/ml IL-1β every 24 h. RNA was isolated, reverse-transcribed and qPCR performed for kindlin-1, -2, -3 and talin-1. Whole RNA sequencing was performed for the repetitive stimulation approach and evaluated using matrix combining pairwise contrasts (DESeq2 and DESeq) normalized counts and thresholds for significance of differential expression per contrast. Immunocytochemistry on RASF seeded on chamber slides was performed. Immunohistochemistry on synovial tissue was performed on 5 µm acetone-fixed cryosections. Biological replicates and Kruskal-Wallis-test with Dunn's multiple comparison were used for statistics.
Results: In RA synovial tissues, kindlin-2 and talin-1 protein were detectable adjacent to blood vessels, in the synovial lining layer and in the sublining. Kindlin-2 and talin-1 could be detected in cultured RASF with a consistent signal of the cell body without a nuclear signal. Kindlin-1 and -3 were neither detectable in synovial tissue nor in synovial fibroblasts. Relative mRNA levels (arbitrary units) of kindlins and talin-1 in RASF differed, with the strongest signal for talin-1 (663 ± 186), followed by kindlin-2 (88 ± 23), kindlin-1 (2.15 ± 2.06) and kindlin-3 (0.12 ± 0.08). In comparison to unstimulated controls, stimulation of RASF with IL-1β led to a temporary downregulation of kindlin-2 (-4.1-fold, p=0.0456) and talin-1 (-1.6-fold) after 17 h and returned to the baseline levels after 48 h. This time-dependent effect could also be observed by immunocytochemistry of IL-1β-stimulated RASF. Kindlin-1 mRNA expression was significantly upregulated after 6 h (2.9-fold, p=0.0178) of stimulation and downregulated after 17 h (-1.5-fold, p<0.0001), 24 h (-0.7-fold, p=0.0004) and 48 h (-1.2-fold, p<0.0001) compared to 6 h. After repetitive activation of RASF, kindlins and talin-1 were constantly regulated compared to the first stimulation (kindlin-1: 1.03-fold; kindlin-2: -1.06-fold; talin-1: 1.00-fold). In contrast, IL-6 showed an inflammatory adjustment to IL-1β leading to lower induction of IL-6 (49.1%) after repetitive IL-1β exposure.
Conclusion: Focal adhesion proteins kindlin-2 and talin-1, factors involved in integrin activation of cells, are present on RA synovial tissue and in RASF. As a time-dependent regulation of kindlin-2 and talin-1 after stimulation was observed, this effect may lead to a temporary and repetitive reproducible activation of RASF and activation of integrins, subsequently contributing to altered adhesion and migration of RASF under inflammatory arthritic conditions.

POS1036 NF-ΚB SIGNALLING IS CRITICALLY IMPORTANT FOR FUNCTIONAL RESPONSES OF ACPA-PRODUCING B CELL CLONES FROM PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Cell biology

G. Frazzei[1,2], Y. Kan[1,2], J. P. Van Hamburg[1,2], R. Van Vollenhoven[1], S. Tas[1,2]. [1]*Amsterdam Rheumatology and Immunology Center, Amsterdam University Medical Centers, University of Amsterdam, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; [2]*Amsterdam University Medical Centers, University of Amsterdam, Department of Experimental Immunology, Amsterdam, Netherlands*

Background: Anti-citrullinated protein antibodies (ACPA) play a role in rheumatoid arthritis (RA) pathogenesis, and their presence is associated with disease severity. Moreover, high serum levels of ACPA in the preclinical phase are one of the major risk factors for RA progression. Consequently, detailed analysis of ACPA^{pos} B cells is required to disentangle the role of these cells in RA. Multiple intracellular signalling pathways are involved in functional B cell responses. NF-κB signalling is one of the prime regulators of B cell proliferation, differentiation and (auto)antibody production. Moreover, NF-κB activation leads to pro-inflammatory cytokine and chemokine production. JAK-STAT signalling is induced after activation of the B cell receptor (BCR) and is also involved in B cell proliferation and maturation. Targeting NF-κB or JAK-STAT signalling may advance our understanding of the mechanisms involved in the activation of ACPA-producing B cells. We make use of ACPA^{pos} B cell clones, since peripheral ACPA^{pos} cells are present at low frequencies in the peripheral blood.
Objectives: To identify whether NF-κB or JAK-STAT signalling inhibition using small molecule inhibitors (SMIs) is effective in targeting functional responses of ACPA^{pos} B cell clones from RA patients, including survival, proliferation, differentiation, and antibody production.
Methods: Previously generated ACPA^{pos} and ACPA^{neg} B cell clones [1] (see Figure 1A for method) were expanded and cultured with anti-CD40 and IL-21. Canonical and non-canonical NF-κB signalling were targeted by validated SMIs of Inhibitor of κB kinase β (IKKβi, canonical NF-κB signalling) and NF-κB inducing kinase (NIKi, non-canonical NF-κB signalling), respectively. Tofacitinib (a JAK1/JAK3 specific small molecule inhibitor) was used to target JAK-STAT signalling. Cell viability, proliferation and differentiation were evaluated by flow cytometry. Antibody production was measured by ELISA.
Results: We observed a dose-dependent reduction in proliferation in ACPA-producing B cell clones treated with either IKKβi (12.5 µM IKKβi: 39.12±9.86% decrease, 25 µM IKKβi: 56.55±1.84% decrease, 50 µM IKKβi: 65.65±3.1% decrease; data normalised on DMSO) or NIKi (12.5 µM NIKi: 12.13±19.42% decrease, 25 µM NIKi: 26.63±17.37% decrease, 50 µM NIKi: 41.69±2.00% decrease; data normalised on DMSO) upon T cell-dependent stimulation with 2.25 µg/ml anti-CD40 and 1.0 ng/ml IL-21 (Figure 1B). Similarly, we observed a dose-dependent reduction in IgG production (Figure 1C). IKKβi treatment seemed to have a stronger effect than NIKi treatment on ACPA^{pos} B cell clones, while we did not observe a clear difference between IKKβi and NIKi in ACPA^{neg} B cells (12.5 µM IKKβi: 6.90±5.38% decrease, 25 µM IKKβi: 33.32±2.15% decrease, 50 µM IKKβi: 50.11±3.15% decrease; 12.5 µM NIKi: 6.09±3.61% decrease, 25 µM NIKi: 17.83±6.53% decrease, 50 µM NIKi: 54.67±20.37% decrease; data normalised on DMSO). These effects were not caused by cytotoxic effects as cell viability was not affected by IKKβi or NIKi treatment. In contrast to the effects of IKKβi and NIKi treatment, tofacitinib only had limited effects on ACPA^{pos} and ACPA^{neg} B cell proliferation and IgG production. At present these results are being corroborated in freshly isolated ACPA^{pos} B lineage cells of RA patients.
Conclusion: Our data point towards a critical role of the NF-κB signalling pathways in the functional responses of ACPA-producing B cells, whereas a limited role of JAK-STAT signalling was observed. Consequently, targeting NF-κB signalling may have beneficial effects in limiting (autoreactive) B cell responses in RA.

Kim[4]. *[1]Uijeongbu St. Mary's Hospital,The Catholic University of Korea, Internal Medicine, Division of Rheumatology, Uijeongbu-Si, Korea, Rep. of (South Korea)*; *[2]KIST Gangneung Institute of Natural Products, Natural Product Informatics Research Center, Gangneung-si, Korea, Rep. of (South Korea)*; *[3]Seoul National University Medical Research Center, Institute of Endemic Diseases, Seoul, Korea, Rep. of (South Korea)*; *[4]The Catholic University of Korea Seoul St. Mary's Hospital, Department of Internal Medicine, Division of Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: The gut microbiota has been proposed to be an important environmental factor in the development of rheumatoid arthritis (RA). However, changes in the gut microbiome of RA patients who were already treated with disease-modifying anti-rheumatic drugs (DMARDs) have not been studied well.
Objectives: We aimed to investigate the gut microbiota of patients with established rheumatoid arthritis (RA) who have been managed with DMARDs for a long time. We focused on factors that might affect composition of the gut microbiota. Furthermore, we investigated whether gut microbiota composition predicts future clinical responses to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) in patients with an insufficient response to initial therapy.
Methods: We recruited 94 patients with RA and 30 healthy participants. Fecal samples were collected, and the gut microbiome was analyzed by 16S rRNA amplificon sequencing. Calypso online software was used to compare microbial composition between groups. For RA patients with moderate-to-high disease activity, treatment was changed after stool collection, and responses were observed 6 months later.
Results: The composition of the gut microbiota in patients with established RA was different from that of healthy participants. Young RA patients (< 45 years) had reduced richness, evenness, and distinct gut microbial compositions when compared with older RA patients and healthy individuals. Disease activity and rheumatoid factor levels were not associated with microbiome composition. Overall, biological DMARDs and csDMARDs, except sulfasalazine and TNF inhibitors, respectively, were not associated with the gut microbial composition in patients with established RA. However, the combination of *Subdoligranulum* and *Fusicatenibacter* genera was associated with a future good response to second-line csDMARDs in patients who showed an insufficient response to first-line csDMARDs.
Conclusion: Gut microbial composition in patients with established RA is different from that in healthy individuals. Thus, the gut microbiome has the potential to predict responses of some RA patients to csDMARDs.

POS1038 NAD+ BOOSTERS AS A NOVEL ANTI-INFLAMMATORY TOOL IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Rheumatoid arthritis

C. Perez-Sanchez[1], A. Escudero Contreras[2], T. Cerdó[2], L. Muñoz-Barrera[2], I. Arias de la Rosa[2], I. Sanchez-Pareja[2], L. Marina Mendoza[3], N. Barbarroja Puerto[2], M. C. Background:
Objectives: 1- To analyze the levels of NAD^+ and genes involved in its metabolism in Rheumatoid Arthritis (RA) patients. 2- To evaluate the effect of anti-TNF therapy in the NAD^+ metabolism. 3- To explore mechanistically the anti-inflammatory effects of NAD^+ boosters in leukocytes from RA patients.
Methods: Plasma and PBMCs were purified from 100 RA patients and 50 healthy donors (HDs). NAD+ levels were determined by using the NAD/NADH-Glo Assay. Gene expression analysis of markers related to the synthesis (NAMPT, NMNATs, etc), transport (Cx43), and consumption of NAD^+ (PARPs, SIRTs, CD38, etc) were performed in PBMCs by RT-PCR. Public datasets from GEO repository were used to validate the analyses. A panel of 92 inflammatory mediators was also analyzed in the RA serum using Olink platform. In a second cohort of 50 RA patients treated with anti-TNF therapy, NAD+ levels were analyzed before and after 6 months of treatment. PBMCs from a third cohort of 10 active RA patients were treated *ex vivo* with 1 mM of NAD^+ boosters including nicotinamide (NAM) and nicotinamide riboside (NR) in the presence of inhibitors of NAMPT (FK866) and Cx43 (GAP19). After 24 hours, the Olink inflammatory panel was used to evaluated anti-inflammatory effects.
Results: NAD+ levels were significantly reduced in the plasma of RA patients and the expression of genes involved in the consumption (PARPs, SIRTs, CD38, CD157) and biosynthesis (NMNATs) of NAD^+ were increased and reduced respectively in RA PBMCs. NAMPT and Cx43 were also upregulated in those patients. The results were validated in an independent dataset. Unsupervised clustering analysis of the inflammatory proteome identified 3 cluster of patients, where cluster 1 was characterised by higher levels of inflammatory mediators and disease activity (DAS28) and lower levels of NAD^+, and cluster 3 by lower levels of inflammatory mediators and DAS28 and higher levels of NAD^+. Cluster 2 showed intermediate profiles. Anti-TNF therapy restored the altered NAD^+ levels in RA patients towards those exhibited by HD. Moreover, changes in DAS28 and NAD^+ levels were correlated. In vitro, NAD^+ boosters promoted a significant increase in NAD^+ levels of RA PBMCs. The FK866 treatment highlighted the key role of NAMPT in the generation of NAD^+ promoted by NAM. The inhibition of the extracellular transport of NAD^+ with GAP19 further increased the intracellular NAD^+ content in the presence of NAM and NR. Both boosters reduced the levels of numerous secreted inflammatory mediators in the supernatant, which was enhanced by effect of GAP19. In parallel, the gene expression of key inflammatory mediators was deeply reduced along with markers of oxidative stress and apoptosis.
Conclusion: 1- The NAD^+ levels and its metabolism is altered in RA patients and directly linked to their inflammatory profile and disease activity. 2- Anti-TNF therapy restore NAD+ altered levels in line with the clinical response. 3- NR and NAM increase the NAD^+ levels in PBMCs from active RA patients, through a mechanism mediated in part by NAMPT, promoting an extensive anti-inflammatory effect which is enhanced by Cx43 inhibition. NAD^+ boosters might be considered as novel therapeutic approach to reduce inflammation in RA.

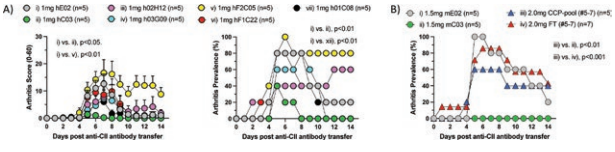
Middleton Memorial Veterans Hospital, Madison, United States of America*



Background: Why the adaptive immune system turns against citrullinated antigens in rheumatoid arthritis (RA) and whether anti-citrullinated protein antibodies (ACPAs) contribute to pathogenesis are questions that have triggered intense research but still are not fully answered. Neutrophils may be crucial in this context, as sources of citrullinated antigens and also as targets of ACPAs.
Objectives: To better understand how ACPAs and neutrophils contribute to RA pathogenesis, we studied the reactivity of a broad spectrum of RA patient-derived ACPA clones to activated or resting neutrophils, and we also compared neutrophil binding using CCP2 captured polyclonal ACPAs from different patients.
Methods: Human neutrophils were isolated from the peripheral blood of healthy volunteers, individuals at risk for RA [1] and patients with established RA. The cells were activated using a Ca^{2+} ionophore, phorbol 12-myristate 13-acetate (PMA), nigericin, zymosan or IL-8. The binding of different monoclonal or polyclonal ACPA preparations to the cells was studied using flow cytometry and confocal microscopy. Neutrophil extracellular trap formation (NETosis) was analyzed using IncuCyteZOOM™. The role of protein arginine deiminase (PAD)2 and PAD4 was studied using neutrophils obtained from PAD-deficient mice or PAD4 inhibitors. Osteoclast cultures were established from human peripheral blood monocytes in the presence of M-CSF and RANK-L.
Results: ACPAs targeted NET-like structures in all tested conditions but did not bind to the surface of intact cells or influence NETosis. We observed a prominent clonal diversity in the capacity of ACPAs to bind to neutrophil-derived antigens. PAD2 was dispensable but the majority of the clones required PAD4 for neutrophil binding. When using polyclonal ACPA preparations from different patients, we observed high patient-to-patient variability in targeting neutrophil-derived antigens. Similar inter-individual variability was observed in another cellular effect of ACPAs: the stimulation of osteoclast differentiation.
Conclusion: Neutrophils can be important sources of citrullinated antigens under conditions that lead to PAD4 activation, NETosis and the extrusion of intracellular material. A substantial clonal diversity in targeting neutrophils and a high variability among individuals in both neutrophil binding and osteoclast stimulation suggest that ACPAs may influence RA-related symptoms with high patient-to-patient variability.

Background: Anti-citrullinated protein autoantibodies (ACPA) are known to associate with strong risk factors for rheumatoid arthritis (RA), as well as worse clinical prognosis[1]. Due to their high specificity in RA, ACPA are part of the classification criteria and regarded as being essential in the identification of individuals at risk of developing RA. However, not every ACPA-positive at-risk individual progresses to a clinical diagnosis[2], suggesting that the presence of ACPA per se does not dictate the clinical outcome. We have recently shown that ACPA are in fact predominantly anti-inflammatory and present different biological effects in a murine model of arthritis[3]. Having a wide diversity of ACPA clones isolated from different tissues of RA patients at our disposal, we have continued to analyze different monoclonal as well as polyclonal ACPA in their capacity to affect inflammatory processes in vivo.
Objectives: To determine whether ACPA with pathogenic features, i.e. capable of increasing or sustaining joint inflammation, can be found among different isolated ACPA clones from patients with established RA.
Methods: Immunoglobulin from single B cells from RA patients were sequenced and recombinantly expressed as monoclonal human (h)IgG1 in Expi293F cells, followed by validation of citrulline reactivity. Here, we tested 5 new monoclonal ACPA isolated based on anti-citrullinated tetramer staining of B cells[4]. Polyclonal ACPA IgG from 34 RA patients were enriched via a CCP2 affinity column. The unbound IgG fraction was used as the flow-through control. Arthritis was induced in BALB/c mice by i.v. transfer of 1.5mg of an arthritogenic cocktail of anti-type II collagen (CII) antibodies (Chondrex, USA) followed by administration of 25ug of LPS (*E. coli* strain O55:B5) 3 days later. Individually, 1mg of purified ACPA monomers, 2mg of ACPA-pool or 2mg flow-through IgG were transferred i.v. together with the arthritogenic antibody cocktail. An isotype control antibody and a previously identified anti-inflammatory ACPA clone (hE02 and hC03, respectively)[3] were used as experimental reference conditions. Arthritis development was monitored daily by a quantitative scoring system of inflamed joints – toes, knuckles, and wrist/ankle of front/hind paws. Statistical analysis was performed with repetitive-measure one-way ANOVA with Geisser-Greenhouse correction and Holm-Šidák's multiple comparisons test.
Results: Adding to our previous data with 8 monoclonal ACPA[3], where 3 of them did not alter the disease course, and 4 displayed strong anti-inflammatory properties, we observed an additional 4 newly tested ACPA clones that did not influence arthritis development. Furthermore, we identified one novel monoclonal ACPA (hF2C05) that displays a pro-arthritogenic effect ($p<0.01$). When assessing a polyclonal ACPA sample, we observed a dominant anti-inflammatory effect of the ACPA-pool in comparison to its non-ACPA flow-through IgG fraction, displayed by a significantly reduced disease prevalence ($p<0.001$).
Conclusion: Our preliminary data focusing on distinct monoclonal ACPA, as well as a new set of patient-derived polyclonal ACPA-pool, strengthens the notion that ACPA clones differ significantly between them, and within the same individual. Although we were able to identify an ACPA clone with arthritogenic potential, the majority of ACPA display no aptitude to affect joint inflammation or are anti-inflammatory. Together, this diversity of inflammatory effects calls for a re-evaluation of the proposed role of ACPA in RA, where their heterogeneity must be considered.

Background: Since lipid metabolism impact immune cell plasticity regulating cell activation, differentiation and function, the extensive analysis of the lipidomic profile using novel high-throughput metabolomic techniques in chronic inflammatory diseases such as Rheumatoid Arthritis (RA) might contribute to better characterise the pathogenesis of the disease.
Objectives: To analyse the whole lipidomic profile in the serum of RA patients, its association with the disease activity and its modulation by biological and targeted synthetic therapies.
Methods: Two hundred and fifty consecutive RA patients were included in this study. Serum samples and clinical data (disease activity, acute phase reactants, autoimmune profile, etc) were obtained from all subjects. The lipidomic profile was analysed by using nuclear magnetic resonance (NMR) spectroscopy from Nightingale LTD technology which included more than 200 lipid markers. In parallel, active RA patients from this cohort were prospectively followed up after 6 months of therapy with biologics [anti-TNF (n=50), anti-IL6R (n=15)], and JAK inhibitors (JAKi, n=20) and serum samples were obtained before and after those therapies where changes in the lipid and clinical profile were also evaluated.
Results: RA patients were stratified according to high (68), moderate (117) and low (65) disease activity and approximately 100 lipid markers were significantly altered in the serum of patients from these groups. Interestingly, most of the lipid markers were found reduced in the group of patients with high disease activity including apolipoproteins, cholesterol (free and in lipoproteins), fatty acids [saturated fatty acids (SFA), monounsaturated fatty acids (MUFA), polyunsaturated fatty acids (PUFA), Omega 3 and 6, Linoleic acid (LA), Docosahexaenoic acid (DHA)], triglycerides (alone and in lipoproteins), cholines, phospholipids, lipoproteins [high-density lipoproteins (HDL), low-density lipoproteins (LDL), very low-density lipoproteins (VLDL)], and the total lipid content present in those lipoproteins. These alterations of the lipidomic profile might be associated with an abnormal liver function linked to an exacerbated inflammatory status. Furthermore, multiple correlations were also found among those lipids markers and inflammatory [C-reactive protein (CRP) and erythrocyte sedimentation rate CRP (ESR)] and autoimmune parameters [anti-citrullinated protein antibodies (ACPAS) and rheumatoid factor (RF)]. Interestingly, after six months of therapy, in parallel to the improvement in clinical and analytical profiles of RA patients, a significant upregulation of lipid markers was observed, including common and distinctive molecules reversed by each drug.
Conclusion: The circulating lipidomic profile of active RA patients is deeply reduced and directly linked to the activity of the disease, its inflammatory and autoimmune profile. In parallel to the clinical improvement of the disease, biological therapies and JAKi re-establish the altered lipid metabolism.

POS1042 JANUS KINASE INHIBITOR SUPPRESSES THE DIFFERENTIATION AND FUNCTION OF TUMOR NECROSIS FACTOR-ALPHA AND INTERLEUKIN-6-INDUCED OSTEOCLASTS IN PERIPHERAL BLOOD MONOCYTES FROM PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Cytokines and chemokines, Disease-modifying drug (DMARDs)

K. Yokota[1], Y. Aizaki[1], H. Kajiyama[1], Y. Araki[1], H. Yazawa[1], Y. Akiyama[1], T. Mimura[1]. *[1]Saitama Medical University, Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama, Japan*

Background: We have previously reported that stimulation of mouse bone marrow–derived macrophages with tumor necrosis factor-α (TNF-α) and interleukin-6 (IL-6) induces differentiation of osteoclast-like cells having bone resorption ability[1]. Recently, we have shown that the combination of TNF-α and IL-6 can induce osteoclasts (OCs) from human peripheral blood mononuclear cells (PBMCs) via receptor activator of nuclear factor kappa-B ligand (RANKL)-independent pathways, and that there are functional differences between TNF-α and IL-6-induced OCs and RANKL-induced OCs. In particular, the number of TNF-α and IL-6-induced OCs differentiated from PBMCs in patients with rheumatoid arthritis (RA) positively correlated with the modified total Sharp score (mTSS). On the other hands, no such correlation was observed between the number of RANKL-induced OCs from RA PBMCs and mTSS[2].
Objectives: We undertook this study to clarify whether Janus kinase (JAK) inhibitors, a new class of disease modifying anti-rheumatic drugs, could inhibit the differentiation and function of TNF-α and IL-6-induced OCs using peripheral blood monocytes (PBMs) derived from patients with RA.
Methods: PBMs derived from RA patients and healthy donors were stimulated by TNF-α and IL-6 or RANKL with or without 10-1000 nM filgotinib, a JAK inhibitor. The number of tartrate-resistant acid phosphatase-positive multinucleated cells induced by TNF-α and IL-6 or RANKL and bone resorption activity using a pit formation assay were assessed. The examination was the number of TNF-α and IL-6-induced or RANKL-induced OCs differentiated from PBMs in RA patients before and 6 months after treatment with filgotinib.
Results: The number of TNF-α and IL-6–induced OCs and RANKL-induced OCs derived from PBMs in patients with RA was significantly increased compared to that derived from PBMCs in healthy donors (n = 5 each). Addition of filgotinib *in vitro* significantly inhibited the differentiation of TNF-α and IL-6-induced OCs derived from PBMs of RA patients in a dose-dependent manner. The same concentrations of filgotinib did not inhibit osteoclastogenesis induce by RANKL. Stimulation of RA PBMs by TNF-α and IL-6 in the presence of filgotinib significantly inhibited generation of resorption pits on dentin slices compared to findings in those PBMs in the absence of filgotinib. In contrast, stimulation of RA PBMs by RANKL with filgotinib showed generation of resorption pits in a manner similar to those generated by RANKL without filgotinib. Six months after treatment with filgotinib, the number of TNF-α and IL-6-induced OCs differentiated from PBMs was significantly decreased compared with those of before the treatment, whereas no significant change in the number of RANKL-induced OCs was observed in the same patients (Figure 1).
Conclusion: Our results suggest that the prevention effect of progressive bone destruction by JAK inhibitor in RA patients may involve inhibition of TNF-α and IL-6-induced OC differentiation, as well as suppression of osteoclastic bone resorption activity.

POS1043 SKELETAL MUSCLE PGC1A1 PREVENTS ARTHRITIS-INDUCED CAPILLARY RAREFACTION AND IMPAIRED GLUCOSE UPTAKE

Keywords: Sarcopenia, Comorbidities, Rheumatoid arthritis

B. Jude[1], A. Chibalin[1], S. Ducommun[1], J. Zierath[2], F. Von Walden[3], J. Ruas[1], A. Krook[1], J. Lanner[1]. [1]*Karolinska Institutet, Physiology & Pharmacology, Stockholm, Sweden*; [2]*Karolinska Institutet, Molecular Medicine and Surgery, Stockholm, Sweden*; [3]*Karolinska Institutet, Women's and Children's Health, Stockholm, Sweden*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease with prevalent musculoskeletal complications (Steinz et al., 2019; Steinz, Santos-Alves, & Lanner, 2020), including metabolic disturbances. Patients with RA have a higher risk of developing type 2 diabetes (T2D) than the general population, however, the causality between RA and T2D is unknown. Skeletal muscle is essential for locomotor activity and the primary site for postprandial glucose disposal.
Objectives: Here we utilized a mouse model of arthritis and mice with chronic elevated expression of the transcriptional co-activator PGC1α1 to elucidate metabolic and functional alterations in skeletal muscle induced by chronic inflammation.
Methods: Arthritis was induced by complete Freund's adjuvant (CFA, ankle injection) in female wildtype or muscle-specific PGC-1α1 transgenic (MCK-PGC1α1) mice. Glucose uptake (*in vivo* and ex *vivo*), immunofluorescence staining, and immunoblotting were assessed 14 days post-CFA injection. Gene expression was analyzed 3 days after CFA induction.
Results: *In vivo* glucose uptake was reduced by 50-80% in limb muscle (extensor digitorum longus, tibialis anterior, soleus) of mice with arthritis as compared with control mice. Despite this, GLUT4 abundance and membrane translocation were enhanced by ~160% and ~70%, respectively, in limb muscle afflicted by CFA as compared with control. However, no difference was observed in *ex vivo* glucose uptake between the two groups, suggesting the reduction in glucose uptake was due to an alteration in muscle blood perfusion. Expression of angiogenesis-associated genes, including PGC1α (total and α1 isoforms), VEGF (A and B), and ERR (α and γ) was decreased by 50-70% in muscles afflicted by CFA, which was accompanied by a 25% reduction in muscle capillary density (capillary rarefaction). Muscle specific chronic elevation of PGC1α1 prevented the increase in GLUT4 abundance and capillary rarefaction induced by arthritis.
Conclusion: Induction of arthritis leads to reduced muscle capillary rarefaction and glucose uptake, which can advance the risk of developing metabolic disease. Strikingly, this pathophysiological development can be corrected by PGC-1α1.

Background: Single cell transcriptional profiling has previously been used to identify gene signatures associated with rheumatoid arthritis (RA) pathophysiology, as well as characterize cell subpopulations. However previous studies have not adequately addressed potential comparison bias such as age and sex, or included patients from different ethnic backgrounds.
Objectives: This study leverages single cell sequencing of peripheral blood mononuclear cells (PBMCs) from patients with RA and matched healthy controls to identify disease relevant cell subsets and cell type specific signatures of disease in the periphery across a diverse cohort of patients.
Methods: PBMC samples from 18 RA patients and 18 healthy controls matched on age, sex, and ethnicity were sequenced at a single cell resolution using 10X Chromium protocols. Samples were processed using standard CellRanger and Scanpy pipelines, with HarmonyPy for batch correction. Differential gene expression was computed using DESeq2 and pathway analysis was carried out with GSEA. Cell proportion analyses were carried out within cell subsets using Mann-Whitney analysis between matched RA and control and in RA remission and low activity (DAS28 CRP < 3.2) versus moderate and high (DAS28 CRP ≥ 3.2).
Results: The final dataset consisted of 22,159 genes across 125,698 cells. The cohort was composed of 66.7% of females with a mean age of 54 years old, and was multi-ethnic with 11.1% of asian-american, 83.5 % of caucasian-american and 5.6 % of hispanic american, the mean DAS28-CRP for patients with RA was 3.33, 61.1 % had positive rheumatoid factor and 83.3 % had anti-citrullinated protein antibodies, 38.9 % were treated by DMARDs, only one patient had a biological. We identified 18 peripheral blood mononuclear cells (PBMC) subsets, including 5 CD4+ T cell subsets, 3 CD8+ T cell subsets, 2 Natural Killer (NK) cell subsets, 3 B cell subsets, and 5 monocyte subsets (Figure 1A). 70 genes were found to be significantly differentially expressed between RA and control CD4+ T cells, 98 genes in monocytes, 11 in B cells, 97 in CD8+ T cells, and 23 in NK cells (FDR ≤ 0.05) with some overlapping across cell types (Figure 1B). Enrichment analysis of genes significantly upregulated in RA-derived classical monocytes identified pathways associated with type 1 interferon signaling and cytokine production (p<0.001). Density plots revealed shifts in proportions of cell subsets between patients with high and moderate activity (DAS28 CRP ≥ 3.2;n=7), patients in low disease activity and remission (DAS28 CRP < 3.2; n=9), and healthy controls (n=18, Figure 1C). Non classical monocytes were significantly decreased in patients with low disease activity compared to control and high disease activity (p = 0.015 and 0.022). CD4 T central memory cells were also decreased in patients with high disease activity (p = 0.034) compared with controls.
Conclusion: Here we describe a dataset of single cell RNA sequenced PBMCs from a diverse population of patients with RA and matched healthy controls. We identified differentially expressed genes and new cell subsets linked to RA but also disease activity, providing potential new insight in non-remission mechanisms and pathophysiology in a diverse RA cohort.

Gemelli IRCCS - Università Cattolica del Sacro Cuore, Division of Rheumatology, Rome, Italy*

Background: Subclinical tenosynovitis arose as a primary sign of inflammation already in the pre-clinical phases of Rheumatoid Arthritis (RA) and tenosynovitis is a common feature of active state and might persist although sustained remission is achieved.
Objectives: To assess the histological features of (teno)synovium from the extensor digitorum tendons of the hand across RA trajectory and to compare it with paired synovial tissue samples.
Methods: Thirty-seven patients underwent minimally invasive ultrasound (US)-guided biopsy of the tenosynovium of extensor digitorum tendons [n=16 with clinically suspected arthralgia (CSA), n=19 with RA (n=4 naïve, n=6 resistant to csDMARDS, n=8 to bDMARDs, and n=1 in sustained remission respectively)]. Twenty-three out of 37 patients presenting CSA or clinically evident synovitis in a peripheral joint (whether anatomically adjacent or not to the tendon of interest) underwent US-guided synovial tissue (ST) biopsy also in that location. The Krenn synovitis score (KSS) and the inflammatory infiltrate using CD68/CD21/CD3/CD20 immunohistochemical (IHC) analysis were assessed for each sample.
Results: Tenosynovium belonging to the extensor digitorum compartment of the wrist was successfully collected using a minimally invasive US-guided technique that enabled to retrieve representative samples in terms of lining and sublining layers presence in 86.5% and 100% of cases, respectively. Considering the pre-arthritis subgroup, KSS was similar in ACPA/RF^{pos} vs ACPA/RF^{neg} CSA (p=0.5814) and KSS was contingent with RA activity, being significantly higher in naïve or resistant RA (ANOVA p<0.001) compared to CSA. Moreover, the comparison between (teno)synovial and synovial tissue paired samples from two adjacent anatomical locations revealed a similar KSS value (p>0.999) and IHC showed comparable enrichment in terms of lining and sublining CD68^{pos}, sublining CD20^{pos} and CD3^{pos} cells (for all comparisons p>0.05) between the two sites, in naive and c- or b-DMARDs resistant RA patients. The procedure was well tolerated, and no tendon injury occurred within 10 months follow-up. One patient developed local hematoma that recovered after topic treatment.
Conclusion: (Teno)synovium is a retrievable tissue through a minimally invasive procedure across RA trajectory and its inflammation is directly related to the disease state. Semiquantitative analysis showed comparable inflammatory degree and inflammatory cellular composition in adjacent anatomical sites of the same person.

IN ANTI-CCP POSITIVE AT RISK INDIVIDUALS, WHICH BIOMARKERS CHANGE PRIOR TO PROGRESSION TO INFLAMMATORY ARTHRITIS?

Keywords: Descriptive studies, Autoantibodies, Rheumatoid arthritis

L. Duquenne[1], K. Harnden[1], L. Garcia-Montoya[1], A. DI Matteo[1], R. Chowdhury[1], J. Nam[1], N. Sidhu[1], K. Mankia[1], P. Emery[1]. *[1]Leeds Musculoskeletal Biomedical Research Unit, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: The pre-clinical phase of inflammatory arthritis (IA) can be prolonged. Although many baseline biomarkers have shown predictive value for progression to IA, their evolution during the disease continuum remains unclear.
Objectives: To investigate which biomarkers change before progression to IA and assess their predictive value in the next 6 months.
Methods: In a single centre prospective cohort, 472 at-risk individuals were recruited with a positive anti-cyclic citrullinated peptide antibody (anti-CCP Ab) and a new musculoskeletal symptom, but without clinical arthritis. They were followed prospectively until IA occurred. Sequential data on early morning stiffness (EMS) duration, erythrocyte sedimentation rate (ESR), anti-CCP2 Ab value, rheumatoid factor (RF) value, number of small joints tender on examination, number of joints with power Doppler grade ≥1 (PD≥1), health assessment questionnaire (HAQ), visual analog scale for general health (VAS GH), global pain (VAS GP), and fatigue (VAS fatigue) were analysed. Three time-intervals were investigated within the progression (P) group: less than 6 months (P≤6M), 6 to 12 months (P 6-12M), and over 12 months before progression to IA (P>12M). Paired analysis (Wilcoxon signed rank and Mc-Nemar tests) were used to compare P≤6M and P >12M **(Pα)**, P≤6M and P6-12M **(Pβ)** within the P group. Independent analyses (Mann Whitney U and Fisher's tests) were used to compare the non-progression (NP) and P groups. Time-intervals for NP visits were adjusted to P visits by time elapsed since first visit. Multivariate predictive analysis of change in biomarkers were done using random effects panel data using robust standard errors, adjusted for age and gender. Significant difference was defined by p<0.05.
Results: Paired analysis within P group showed significant increase in **Pα** for RF, EMS, ESR, number of small joints tender, HAQ, and VAS GP, and in **Pß** for EMS and VAS GP (Figure 1). After dichotomisation, significant increases were also found for EMS ≥30min, ≥1 joint PD≥1, VAS GP ≥50mm, ESR positive, and ≥1 small joint tender. Analysis between P and NP groups showed significant differences in anti-CCP2 Ab, RF, ESR, number of joints PD≥1, number of small joints tender on examination, and HAQ at multiple time-intervals (Figure 1). EMS and VAS GP were only different at P≤6M. Multivariate panel data analysis showed predictive value in the change of anti-CCP2 Ab ≥3x upper limit of normal (ULN) (OR 51, p=0.041), positive RF (OR 7, p=0.002), EMS ≥30min (OR 9 p=0.004), and abnormal ESR (OR 7, p=0.046) for progression to IA within 6 months.
Conclusion: In anti-CCP2 Ab+ at-risk individuals, a change in predictive biomarkers occurs in the 6 months prior to IA development. Whilst EMS and VAS GP only show a late increase, multivariate panel data analysis suggest that anti-CCP2Ab ≥3xULN, positive RF, EMS ≥30min and positive ESR predict IA development within the next 6 months. These observations may be of value for monitoring at-risk individuals.

Table 1. Biomarkers characteristics

	NP group (N=330)	P group (N=142)	
		P >6M before IA	P ≤6M before IA
Anti-CCP2 Ab value ≥3xULN [A]	412/783 (53%)	170/206 (83%)	67/73 (92%)
RF positive [A]	183/778 (24%)	120/189 (63%)	53/68 (78%)
EMS minutes [B]	5 (0-30)	10 (0-30)	30 (3-67)
ESR abnormal [A]	435/1307 (33%)	150/330 (45%)	67/115 (58%)
Nb of small joint tender [B]	0 (0-2)	0 (0-2)	1.5 (0-5)
Nb of joint PD≥1 [B]	0 (0-0)	0 (0-1)	0 (0-1)

RNA-SEQUENCING OF CLASSICAL MONOCYTES FROM RHEUMATOID ARTHRITIS PATIENTS WITH AND WITHOUT BONE EROSION

Keywords: Genetics/epigenetics, Inflammatory arthritides, Rheumatoid arthritis

L. Peixoto Sales[1], B. Hounkpe[1], M. Perez[1], V. Caparbo[1], D. S. Domiciano[1], E. Borba[1], C. Figueiredo[1], R. M. Pereira[1]. [1]*Hospital das Clínicas HCFMUSP, Faculdade de Medicina, Universidade de São Paulo, Rheumatology Division, São Paulo, Brazil*

Background: Rheumatoid arthritis (RA) is an inflammatory autoimmune disease characterized by systemic and localized bone impairment. Bone erosions, the hallmark lesions of RA, are an important predictor of disability, disease severity, and mortality. The arising of bone erosions is triggered by chronic inflammation, mediated mainly by immune cells. Under inflammatory conditions, classical (CD14++CD16-) monocytes are the main source of osteoclasts precursors, the accountable cells responsible for bone resorption process. Although previous transcriptomic studies have shown that CD14++CD16- monocytes have high expression of genes involved in inflammation and in extracellular matrix degradation process, there is no data regarding the impact of CD14++CD16- monocytes on bone destruction in RA.

Objectives: To analyze CD14++CD16- monocytes transcriptomic profile from RA patients presenting bone erosions evaluated by high-resolution peripheral quantitative computed tomography (HR-pQCT), comparing with RA patients without bone erosions and healthy controls.

Methods: Thirty-nine premenopausal RA women were included in this study. Based on bone erosion identification on metacarpophalangeal and proximal interphalangeal joints of the dominant hand assessed by HR-pQCT, RA patients were classified into two groups according to the presence or absence of bone erosions. Twenty age- and body mass index-matched healthy subjects were enrolled in the control group. CD14++CD16- monocytes were indirectly isolated using the CD16 MicroBeads, and RNA-Sequencing was performed. Transcriptome analysis of CD14++CD16- monocytes from control group were used to account for background expression. The differentially expressed genes (DEGs) were identified and the analysis of the biological pathways was performed using bioinformatics tools.

Results: RNA-seq analysis revealed 1140 DEGs in RA patients with erosion, of which 89 were up-regulated and 1051 down-regulated compared to the group of patients without erosion. A top ranked genes suggested that the up-regulated genes were highly associated with immune response and cytokine activation. Interestingly, the down-regulated genes were associated with bone formation and wound healing (Table 1). Enriched pathways in patients with erosion were associated with substantial activation of immunity and inflammation. Pathways associated with osteoblast differentiation and the regulation of Wnt signaling were less activated in RA patients with erosion. Interesting, while the activity of immune pathways was positively correlated with the number of bone erosions, a negative correlation was observed between the number of erosions with osteoblast differentiation and regulation of cell matrix adhesion.

Table 1. Top differentially expressed genes identified in RA patients with bone erosion.

Genes	Ave FC	FDR	Main biological process
Up-regulated genes			
HSPA1B	9.26	0.0001	Ubiquitin-proteasome pathway
HLA-DQA2	6.35	0.0095	Adaptive immunity
KLF14	4.60	0.0416	Innate and adaptative immunity
IL18RAP	3.90	0.0317	Cytokine activity
CMTM1	3.83	0.0439	Chemokine activity.
Down-regulated genes			
LARP6	0.0026	0.0001	Collagen biosynthetic
PRRX1	0.0029	0.0004	Regulation of transcription by RNA polymerase II
RAB3B	0.0061	0.0001	Regulation of ion transport
AHNAK2	0.0065	0.0001	Wound healing
PAPPA	0.0072	0.0001	Bone formation

FC: Fold-change; Ave FC: average FC; FDR: False Discovery Rate.

Conclusion: These findings suggest that increasing of immuno-inflammatory activation and impairment of bone formation processes might potentially be a key driver of bone erosion in RA pathogenesis.

SEMAPHORIN3B PROMOTES A RESOLVING-INFLAMMATION PHENOTYPE IN MACROPHAGES FROM RHEUMATOID ARTHRITIS PATIENTS

Keywords: Genetics/epigenetics, Rheumatoid arthritis, Cytokines and chemokines

S. Martínez-Ramos[1], C. Rafael Vidal[1], B. Malvar Fernández[1], N. Perez-Gomez[1], C. Mouriño Rodríguez[1], F. J. Maceiras-Pan[1], I. Altabás González[1], J. M. Pego-Reigosa[1], S. García[1]. [1]*Galicia Sur Health Research Institute (IIS Galicia Sur), SERGAS-UVIGO, Rheumatology & Immuno-Mediated Diseases Research Group (IRIDIS), Vigo, Spain*

Background: Our group have recently shown that (Sema)phorin3B is reduced in RA patients and plays a protective role in an arthritis mouse model, through the reduction of inflammatory mediators and the synovial fibroblast invasiveness and was associated with a reduction of CD68 positive synovial macrophages (Igea, 2022). On the other hand, MerTK is a receptor protein kinase involved in the resolution of inflammation and plays a protective role in arthritis mice models (Waterborg, 2018). A recent study has shown that a population of synovial tissue macrophages characterized by the expression of MerTK are associated with remission maintenance and with an anti-inflammatory phenotype of RA FLS (Alivernini, 2020).
Objectives: The aim of this study is to determine the role of Sema3B in the phenotypic characteristics of RA macrophages and the implication of MerTK.
Methods: Peripheral blood monocytes from RA patients (n=10) were differentiated into macrophages by culturing in the presence of IFN-γ (10 ng/mL) for 6 days. Afterwards, macrophages were stimulated for 24 h with LPS (10 ng/mL), Sema3B (200 ng/mL) or the combination of both mediators. The expression of pro- and anti-inflammatory mediators was determined by quantitative PCR (qPCR) and ELISA. The expression of MerTK and macrophage surface markers was measured by flow cytometry.
Results: Sema3B did not modulate the macrophage expression of pro-inflammatory mediators *IL1B, IL6, IL12B, IL23, TNF, CCL2, CXCL10* and *CD86*, but significantly reduced the LPS-induced expression of these mediators (Figure 1A), as well as the protein secretion of IL6, IL12p70 and TNF. In addition, Sema3B alone, but not in combination with LPS, significantly induced the gene and protein expression of MerTK and the secretion of Resolvin D1, a MerTK-mediated lipid involved in resolution of inflammation (Figure 1B). Moreover, Sema3B reduced the expression of the M1 marker CD64, while induced the expression of the M2 marker CD163.

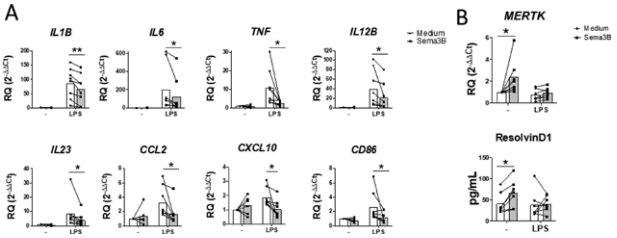

Figure 1. Sema3B enhances anti-inflammatory activity in macrophages of RA patients (n=6). (A) Significative reduction of the genetic expression of pro-inflammatory mediators. (B) Significative increase of *MERTK* and ResolvinD1. Macrophages differentiated from monocytes of RA patients during 6 days (IFN-γ 10 ng/mL) and stimulated with Sema3B (200 ng/ml), LPS (10 ng/mL) and their combination for 24 hours. Symbols represent individual patients; bars show the mean ± SEM. *P < 0.05 and **P < 0.01.

Conclusion: Our data demonstrate that Sema3B modulates the macrophage phenotype of RA macrophages, inducing a skewing towards an anti-inflammatory/pro-resolving phenotype, likely in a MerTK-dependent manner. Therefore, here we identified a new mechanism involved in the protective role of Sema3B in RA pathogenesis.

INTERLEUKIN 40 IS INCREASED IN THE SERUM OF INDIVIDUALS AT RISK OF RHEUMATOID ARTHRITIS AND STIMULATES AN INFLAMMATORY RESPONSE IN MONONUCLEAR CELLS VIA NFKB

Keywords: Cytokines and chemokines, Biomarkers, Rheumatoid arthritis

A. Navrátilová[1,2], K. Prajzlerová[1], N. Petrovská[1,2], K. Pavelka[1,2], J. Vencovský[1,2], L. Šenolt[1,2], M. Filková[1,2], L. Andres Cerezo[1,2]. [1]*Institute of Rheumatology, Prague, Czech Republic, Department of Rheumatology, Prague, Czech Republic*; [2]*1st Faculty of Medicine, Charles University, Prague, Czech Republic, Department of Rheumatology, Prague, Czech Republic*

Background: Interleukin 40 (IL-40) is a new cytokine implicated in the pathogenesis of several autoimmune disorders including rheumatoid arthritis (RA). Recently, we found an association of IL-40 with the early stages of RA and demonstrated the pro-inflammatory potential of IL-40 on neutrophils.
Objectives: As the period preceding clinically apparent RA has not yet been fully described with respect to clinical biomarkers, we aimed to investigate IL-40 in individuals who are at risk of RA and to assess its functional mechanism in immune regulation in peripheral blood mononuclear cells (PBMCs).
Methods: IL-40 was determined in the serum of individuals at risk of RA (defined as patients with arthralgia with no clinical arthritis at baseline who are either carriers of anti-citrullinated protein antibodies, ACPA, or meeting the EULAR definition of clinically suspect arthralgia) at baseline (n=179) and at the time of arthritis manifestation in patients who progressed to clinical arthritis (n=25). IL-40 was also analysed in the serum of age and sex-matched healthy controls (n=60). *In vitro* experiments were performed on PBMCs from at-risk individuals (n=10). PBMCs were exposed to recombinant IL-40 (10, 50, 100, and 250 ng/ml) and LPS. For inhibition studies, cells were pretreated with NFkB inhibitor prior to incubation with IL-40. Levels of IL-40 and IL-6 were measured by commercially available ELISA kits.
Results: Serum IL-40 was significantly up-regulated in at-risk individuals compared to healthy individuals (4.8 ± 0.2 vs. 1.5 ± 0.09 ng/ml, p<0.0001). Moreover, the levels of IL-40 were significantly higher in the serum of double-positive ($ACPA^+$/rheumatoid factor, RF^+) compared to double-negative at-risk individuals (6.4 ± 0.7 vs. 4.5 ± 0.5 ng/ml; p<0.05). Out of 175 at-risk individuals, only 25 developed clinical arthritis (within a median of 8,17 months of follow-up); however, we have not found a significant difference in the levels of IL-40 at baseline, and at the time of arthritis manifestation. To evaluate the pro-inflammatory effect of systemically elevated IL-40 in at-risk individuals, their PBMCs were exposed to recombinant IL-40 *in vitro*. We showed that IL-40 strongly enhances the secretion of IL-6 by PBMCs in a dose-dependent manner when compared to unstimulated cells (10 ng/ml of IL-40: p<0.05; 50, 100, 250 ng/ml of IL-40: p<0.01). Furthermore, the application of NFkB inhibitor to the PBMCs prior to the exposure to IL-40 significantly reduced the secretion of IL-6 when compared to IL-40 treated cells without NFkB inhibition (p=0.004).

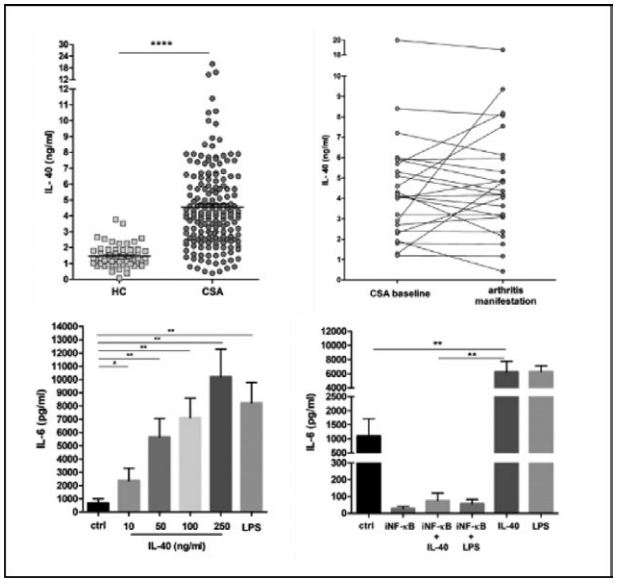

Figure 1.

Conclusion: This is the first study to demonstrate the up-regulation of IL-40 in the serum of individuals at risk of RA. Moreover, we showed that IL-40 induces the pro-inflammatory response in PBMCs at-risk individuals via NFκB dependent pathway.

INCIDENCE RATES OF INTERSTITIAL LUNG DISEASE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ABATACEPT: A POST HOC POOLED ANALYSIS FROM A COMPENDIUM OF CLINICAL TRIALS

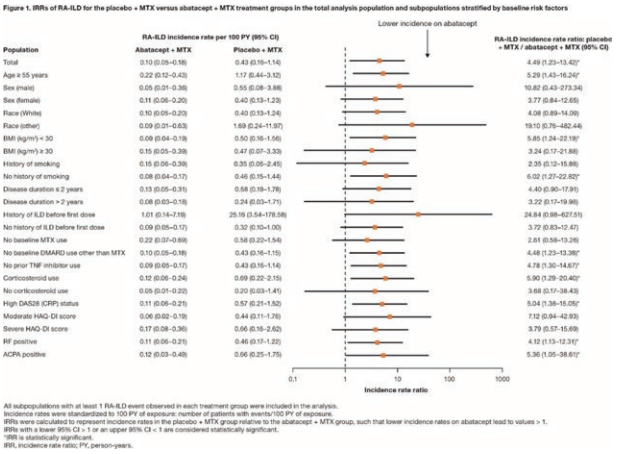
Keywords: Rheumatoid arthritis, Lungs, Disease-modifying drug (DMARDs)

P. Dieudé[1], J. Sparks[2], A. Fischer[3], L. Chen[4], K. Lozenski[5], S. Dahan[6], M. Chaballa[7], W. Little[8]. [1]*Paris Cité University, Bichat Hospital, APHP, Department of Rheumatology, Paris, France*; [2]*Brigham and Women's Hospital, Harvard Medical School, Division of Rheumatology, Inflammation and Immunity, Boston, United States of America*; [3]*Bristol Myers Squibb, Lung Fibrosis, Lawrenceville, United States of America*; [4]*Syneos Health, Biostatistics and Statistical Programming, Richmond, Canada*; [5]*Bristol Myers Squibb, Rheumatology Pipeline and Early Assets, Lawrenceville, United States of America*; [6]*Bristol Myers Squibb, Worldwide Medical, Lawrenceville, United States of America*; [7]*Bristol Myers Squibb, US Medical, Immunology and Fibrosis, Lawrenceville, United States of America*; [8]*Bristol Myers Squibb, Worldwide Rheumatology, Lawrenceville, United States of America*

Background: Interstitial lung disease (ILD) is a recognized complication of RA. Prior studies have suggested stabilization or improvement of ILD in patients with RA (RA-ILD) treated with abatacept.[1,2] Few studies have evaluated the background incidence rate of RA-ILD.

Objectives: To determine the incidence rate of clinically significant ILD in a cohort of patients with RA receiving abatacept + MTX versus placebo + MTX from multiple clinical trials.

Methods: This retrospective analysis examined pooled safety data from ten phase 3 clinical trials of patients with RA treated with background MTX in combination with abatacept or placebo. The term 'interstitial lung' was used to identify incidences of ILD reported as AEs in the safety data. The exposure period for each patient was censored at first incidence of clinically significant ILD, 56 days after last study drug administration, or 1 day prior to commencement of another study drug, whichever occurred first. Poisson regression models were used to estimate crude incidence rates per 100 person-years for baseline risk factors within treatment groups, and to estimate incidence rate ratios for the placebo + MTX versus abatacept + MTX treatment groups. Disease activity parameters, DAS28 (CRP) and HAQ-DI, were estimated from baseline to the time of ILD diagnosis (as reported by AEs).



Results: In total, 3,708 patients (10,521 person-years) treated with abatacept + MTX and 999 patients (938 person-years) treated with placebo + MTX were included. Patients treated with placebo + MTX had a higher incidence rate of ILD per 100 person-years (95% CI) versus those treated with abatacept + MTX (0.43 [0.16–1.14] vs 0.10 [0.05–0.18], respectively; Figure 1). The incidence rate ratio of placebo + MTX versus abatacept + MTX treatment groups for the total population was 4.49 (95% CI, 1.23–13.42). For all subpopulations stratified by baseline risk factors (where ≥ 1 patient in each treatment group had an ILD event), incidence rate ratios were > 2. Patients with RA aged ≥ 55 years, BMI < 30 kg/m^2, no history of smoking, no baseline DMARD use other than MTX, no prior TNF inhibitor use, corticosteroid use, high DAS28 (CRP) status, and RF or anti-citrullinated protein antibody (ACPA) positivity were all significantly less likely to develop ILD if treated with abatacept + MTX versus placebo + MTX (Figure 1).

Conclusion: Incidence rates of ILD among patients with RA were significantly lower in those treated with abatacept + MTX than placebo + MTX, both in the total analysis population and subpopulations stratified by baseline risk factors. This suggests a possible protective benefit of abatacept on the incidence rate of RA-ILD. Limitations of this post hoc analysis include the different observation period lengths of the 2 treatment arms due to the original study designs, and the low number of patients with ILD events overall. However, the low incidence rate of ILD observed here is consistent with previously reported studies.[3]

Figure 1. IRRs of RA-ILD for the placebo + MTX versus abatacept + MTX treatment groups in the total analysis population and subpopulations stratified by baseline risk factors

All subpopulations with at least 1 RA-ILD event observed in each treatment group were included in the analysis.
Incidence rates were standardized to 100 PY of exposure; number of patients with events/100 PY of exposure.
IRRs were calculated to represent incidence rates in the placebo + MTX group relative to the abatacept + MTX group, such that lower incidence rates on abatacept lead to values > 1.
IRRs with a lower 95% CI > 1 or an upper 95% CI < 1 are considered statistically significant.
*IRR is statistically significant.
IRR, incidence rate ratio; PY, person-years.

Background: Lung involvement is a prevalent extraarticular manifestation of rheumatoid arthritis (RA) that remains a significant clinical challenge. Few studies have comprehensively quantified lung abnormalities of RA patients using artificial intelligence-based (AI) technology.

Objectives: The aim of this study was to quantify lung lesions in RA patients and classify them based on their lung parameters.

Methods: An AI-based quantitative computed tomography (CT) image analysis software (AIQCT) was applied to high-resolution CT scans of RA patients in a cross-sectional manner. AIQCT automatically classified and quantified 10 types of parenchymal image patterns, expressing the volumes as percentages of total lung volume [1]. Hierarchical Ward's linkage clustering based on these patterns identified five clusters. Visual assessments (ILD, and airway lesions) of HRCT and clinical phenotypes were assessed.

Results: A total of 408 RA patients were included in the study. The lung profiles of the five clusters were as follows: Cluster I (68.6%), characterized by nearly normal lungs; Cluster II (23.5%), characterized by slight lung lesions with honeycombs or ground-glass opacities (GGOs); Cluster III (5.6%), characterized by the

predominance of GGOs; Cluster IV (1.0%), characterized by a predominant hyperlucent area; and Cluster V (1.2%), characterized by extensive lung abnormalities (Figure 1, Table 1). The number of patients in each cluster with ILD and airway lesions, based on visual assessments, were as follows: [ILD] Cluster I, 11/280 (3.9%), Cluster II, 19/96 (19.8%), Cluster III, 5/23 (21.7%), Cluster IV, 0/4 (0%), and Cluster V, 5/5 (100%) ($p < 0.001$): [airway lesions] Cluster I, 31/280 (11.1%), Cluster II, 29/96 (30.2%), Cluster III, 6/23 (26.1%), Cluster IV, 0/4 (0%), and Cluster V, 1/5 (20%) ($p < 0.001$). Clinical characteristics of each cluster were described in Table 1. The disease activity of RA in each cluster were as follows: [DAS28ESR, mean (SD)] Cluster I, 2.4 (1.0), Cluster II, 3.0 (1.2), Cluster III, 2.8 (1.0), Cluster IV, 2.2 (0.7), and Cluster V, 3.0 (0.8) ($p < 0.001$); [HAQ, mean (SD)] Cluster I, 0.4 (0.6), Cluster II, 0.9 (0.9), Cluster III, 1.1 (0.9), Cluster IV, 0.3 (0.3), and Cluster V, 0.8 (0.9) ($p < 0.001$).

Conclusion: This study is the first to classify lung lesions in comprehensive RA patients using quantitative data derived from novel AI technology. The AIQCT-derived clustering of RA patients appears to be associated with their clinical backgrounds and characteristics.

Background: Interstitial lung disease (ILD) is a spectrum of inflammatory and fibrotic lung diseases, and can be associated with RA (RA-ILD). The reported prevalence ranges from 1.8 to 58 percent, depending on the definition and diagnostics.

Objectives: To investigate the incidence and prevalence of RA-ILD in different countries worldwide.

Methods: Patients of 5 countries from 2 observational databases were studied. Patients from India, Mexico, South Africa (two clinics) and Colombia with a physician-based RA diagnosis were selected from the observational METEOR database. From the Leiden EAC in the Netherlands, patients with early RA (1987 ACR/ 2010 ACR/EULAR criteria) were included. A clinical diagnosis of RA-ILD was based on chest X-ray or CT. X-ray was performed at the first visit in India, South Africa and the Netherlands and on clinical indication in all countries. Prevalence of RA-ILD at the end of follow-up was calculated for each country. Incidence rates (IR) were calculated in patients with newly diagnosed RA and an available baseline visit. Patient characteristics were described, comparing patients with and without RA-ILD using appropriate statistical tests.

Results: Within the five countries 16,667 patients with RA, both newly diagnosed and with longer RA disease duration, were evaluated. Prevalence and incidence of RA-ILD differed per country. The prevalence of RA-ILD at the end of follow-up was 0.7% (84/11,733) in India (mean follow-up 12±20 months), 2.1% (9/427) in Mexico (mean follow-up 17±27 months), 2.0% (21/1,077) in the Netherlands (mean follow-up 83±71 months), 3.0% (19/629) in South Africa (mean follow-up 20±21 months) and 0.7% (18/2,747) in Colombia (mean follow-up 14±12 months). The IR of RA-ILD in newly diagnosed RA patients in India was 1.6 (95% CI 1.0-2.5) per 1000 person years. In the Netherlands the IR was 3.8 (95% CI 1.6-9.1) per 1000 person years. In South Africa the IR was 6.6 (95% CI 2.5-17.5) per 1000 person years. For Mexico and Colombia, no IR could be calculated. Patient characteristics are described in Table 1. In India and Mexico, patients with RA-ILD were older. In 4 of 5 countries RA-ILD patients were more often male. Higher inflammatory markers and more RF positivity were seen in RA-ILD patients in India and the Netherlands. In South Africa, patients with RA-ILD more often had a history of smoking. ACPA positivity was more frequent in RA-ILD patients from India, but less frequent in RA-ILD patients from South Africa.

Conclusion: Prevalence and incidence of RA-ILD varied between the four countries with the highest prevalence and incidence in South Africa. These differences might be partially explained by differences in diagnostic approaches, and potentially in patient populations, used therapies and comorbidity.

Background: Interstitial lung disease (ILD) related to rheumatoid arthritis (RA) significantly impacts on quality of life and survival of the patients. Data about prevalence and natural history of RA-ILD are only partially known and mainly based on retrospective studies. The recent introduction of antifibrotic drugs have allowed for the first time the opportunity to treat ILD in RA patients; in fact, INBUILD study demonstrated the efficacy of nintedanib in the treatment of progressive fibrosing ILD different than idiopathic pulmonary fibrosis (IPF), including RA-ILD, but the prevalence of RA-ILD patients that may potentially benefit from nintedanib therapy remain unknown.

Objectives: Aim of the present multicenter Italian study was to investigate the prevalence of fibrosing progressive patterns in a cross-sectional cohort of non-selected RA-ILD patients.

Methods: We enrolled in the study all RA patients according to 2010 EULAR/ACR classification criteria, with an ILD confirmed at high resolution computed tomography (HRCT) and with a follow-up of at least 24 months. According to the current indication of nintedanib, patients were defined as having a progressive fibrosing ILD in case of a relative decline in forced vital capacity (FVC) ≥10% predicted and/or an increased extent of fibrotic changes on chest imaging in a 24 month-period. Respiratory symptoms were excluded to reduce possible bias due to the retrospective interpretation of cough and dyspnoea.

Results: One hundred and thirty-four RA-ILD patients were enrolled in the study (males/females 54/80, mean age 72±9.5 years, mean RA and ILD duration 13.1±9.5 and 4.6±4.1 years, respectively. Anticitrullinated peptides antibodies (ACPA) and rheumatoid factor (RF) were recorded in 76.2% and 87.6% of cases, respectively. According to radiologic features, ILD was classified as probable or definite usual interstitial pneumonia (UIP) in 50.7% of patients, NSIP in 19.4% and other patterns in 29.8%. A fibrosing pattern was reported in 73.9% of cases (all patients with UIP pattern, 57.7% of patients with NSIP and 40% with other pattern). A relative decline of 6.8% of forced vital capacity (FVC) was recorded during the follow-up, without significant difference between fibrosing and non-fibrosing ILD (6.3%±13.8 vs 5.9%±21.3, respectively). A relative FVC decline ≥ 10% and/or a progression of radiologic fibrotic involvement was observed in 38.8% of patients. As expected, a significant difference in relative decline of FVC was recorded between progressive and non-progressive ILD (15.7%±16.4 vs -1.3%±8.3, respectively). Globally, a fibrosing progressive pattern was recorded in 35.8% of patients (48/134, 48.5% of patients with fibrosing pattern). Of interest, also 11.4% of patients with a non-fibrosing pattern showed a progressive behavior of disease (see Figure 1).

Conclusion: The recent introduction of nintedanib for the treatment of fibrosing progressive ILD different by IPF has potentially changed the paradigm for the treatment of RA-ILD. In fact, for the first time, rheumatologist has a therapy available with efficacy on RA related lung involvement. This study shows some limitations. The retrospective design and the need of serial HRCT and FVC could induce an overestimation of progressive disease (pulmonary function could not have been properly evaluated in asymptomatic patients). On the other hand, the exclusion of symptoms, such as a worsening of dyspnea and cough, might underestimate the prevalence of progressive lung disease. Finally, some patients were already treated with antifibrotic drugs, possibly influencing the evolution of lung disease in the last 2 years. In conclusion, about a third of RA-ILD patients shows a fibrosing progressive pattern of ILD and might benefit of antifibrotic treatment, alone or in combination with anti-rheumatic drugs. For RA patients with progressive non-fibrosing ILD, we need more studies to establish the best therapeutic approach.

Background: Interstitial lung disease (ILD) can have a significant impact on the long-term outcome in patients with rheumatoid arthritis (RA) but international screening guidelines for early diagnosis of RA-ILD are lacking. It is unknown to date how RA patients are screened for ILD in clinical practice. An analysis of patients' experiences and perspectives will help identify current practice and guide future directions to optimize screening, management and patients care.

Objectives: To identify patients' experiences and unmet clinical needs regarding screening for RA-ILD.

Methods: An international multidisciplinary panel of 18 ILD experts developed and distributed an online-based survey in 12 languages for RA patients with and without ILD from August to December 2022 to receive self-reported data. User representatives of relevant patient associations and RA patients with and without ILD refined and piloted the survey questions. The survey covered management strategies, including information and awareness of ILD, screening for ILD and patient' perspectives on future directions. The study was approved by the Ethics committee of the University Clinic Heidelberg, Germany, and patients consented before starting the online survey.

Results: In total, 1132 RA patients from 11 countries answered the survey. Mean age was 57 (SD13.6) years, 129 (12%) were males, 690 (75%) had seropositive RA with a disease duration of 9.9 (SD7.9) years (Table 1). Of all, 434 (39%) were informed about the possibility of ILD development and 387 (35%) were screened for ILD, of which 75% by x-ray, 49% by high-resolution computed tomography (HRCT), 49% with pulmonary function test (PFT), 23% with respiratory symptoms, 40% with auscultation and 194/387 (59%) were screened with several modalities. Older age, male sex, presence of other lung comorbidities and treatment with Rituximab or Abatacept were associated with screening assessed by multivariable logistic regression (Figure 1). Of all RA patients, 138 (12.4%) were diagnosed with ILD. Screening was significantly associated with an ILD diagnosis (OR 8.87, 95%CI 5.61-14.03, p<0.001) driven by screening for symptoms (OR 1.77 (95% CI 1.06-2.94, p=0.028), PFT (OR 3.42, 95%CI 2.11-5.36, p<0.001) and HRCT (OR 7.17, 95%CI 4.16-12.34, p<0.001). Screening by auscultation or x-ray was not associated with a diagnosis of ILD. Of all RA patients, 89% sought more information about the risk of lung involvement in RA, 95% asked for better information about respiratory symptoms, 71% would prefer that increased attention be paid to potential lung involvement by their treating physician and 98% wanted more research in RA-ILD.

Conclusion: Based on this self-reported patient survey, information about ILD provided to RA patients is frequently limited. Only one third are screened for ILD. The majority of patients stated a clear need for more information on RA-ILD, increasing awareness of lung involvement in RA should be a priority in clinical practice and research.

Table 1. Disease characteristics of all RA patients, and patients screened and not screened for ILD

Background: Quantitative computed tomography (QCT) methods have been developed to automatically quantify parenchymal lung features on chest CT imaging. There have been limited investigations of QCT in RA participants and non-RA comparators or studies of the mortality impact of QCT features in RA.
Objectives: Determine the association and mortality impact of QCT features in RA and non-RA participants.
Methods: We analyzed associations between RA and QCT features in COPDGene, a multicenter cohort study of current or former smokers that excluded participants with known interstitial lung disease or bronchiectasis. We identified participants with and without RA using RA self-report and DMARD use. We assessed the lung parenchyma in each scan by categorizing regions of interest into normal lung, interstitial changes, or emphysema using the local tissue density and distance from the pleural surface. Interstitial changes were subclassified into reticular, subpleural line, linear scar, honeycombing, centrilobular nodule, nodular, and ground glass. Each feature was summed and standardized to total lung volume. We examined associations between QCT features and RA using multivariable linear regression. We dichotomized participants using the 75th percentile for each QCT feature among non-RA participants and investigated mortality associations by RA status and QCT features using Cox regression. We examined multiplicative interactions between RA and continuous interstitial and emphysema percentages and additive interactions between RA status and >75th percentile of QCT features using multiplicative interaction terms and attributable proportion.
Results: We identified 82 RA cases and 8820 non-RA comparators. RA was associated with a lower percentage of normal lung (85.8% vs. 91.0% p=0.0001), increased interstitial changes (7.0% vs. 4.8%, p<0.0001), and no statistical difference in emphysema (2.6% vs. 1.9%, p=0.09) compared to non-RA comparators. In linear regression analyses adjusted for age, sex, smoking status, pack-years, and body mass index, RA was associated with increased interstitial changes (β=1.7±0.5, p=0.0008) but not emphysema (β=1.3±1.7, p=0.44). The combination of RA and >75th percentile of emphysema had significantly higher mortality compared to both non-RA participants (HR 5.86, 95%CI 3.75-9.13) and RA participants (HR 5.56, 95%CI 2.71-11.38) with <75th percentile of emphysema. There were statistically significant interactions between RA and emphysema for mortality (multiplicative: p=0.014; additive: attributable proportion 0.53, 95%CI 0.30-0.70, p<0.0001).
Conclusion: Using machine learning-derived QCT data in a cohort of smokers, we found that RA was associated with increased interstitial changes, even after adjustment for smoking and other lifestyle factors. The combination of RA and emphysema conferred greater than 5-fold increased mortality.

Table 1. Quantitative CT features and multivariable linear regression by RA status in COPDGene (n=8902)

Feature (% of lung volume, median, IQR)	RA cases (n=82)	Non-RA comparators (n=8820)	Unadjusted p-value	Adjusted* β±SE (RA vs. non-RA)	Adjusted p-value
Normal lung	85.8 (77.3-92.4)	91.0 (82.7-94.7)	0.0001	-3.0±1.7	0.08

POS1056 CYTOKINE ANALYSIS IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH RHEUMATOID ARTHRITIS

Keywords: Comorbidities, Cytokines and chemokines, Biomarkers

J. M. Lisbona[1,2,3], A. Mucientes[1,2], B. Oliver-Martos[1,3,4], G. Diaz-Cordobes[1,2], I. Ureña[1,2], R. Redondo[1,2], S. Manrique Arija[1,2,3], A. Fernandez-Nebro[1,2,3], N. Mena-Vázquez[1,2]. *[1]Instituto de Investigación Biomédica de Málaga (IBIMA)-Plataforma Bionand, Enfermedades Inflamatorias y Autoinmunes, Málaga, Spain*; *[2]Hospital Regional Universitario de Málaga, UGC de Reumatología, Málaga, Spain*; *[3]Universidad de Málaga, Departamento de Medicina y Dermatología, Málaga, Spain*; *[4]Hospital Regional Universitario de Málaga, UGC de Neurociencia, Málaga, Spain*

Background: Interstitial lung disease (ILD) is the most frequent non-pleural pulmonary manifestation in rheumatoid arthritis (RA) and causes high morbidity and mortality [1-3]. Currently, there are no clinically useful serum markers for the diagnosis and prognosis of RA associated ILD (RA-ILD) [4].

Objectives: To identify soluble cytokines that work as biomarkers for diagnosis and prognosis in RA-ILD and explore whether there is an association between those and pulmonary progression.

Methods: Observational case-control study nested in a prospective cohort of cases of patients with RA (ACR/EULAR 2010) [5] with and without ILD, paired by sex, age, and time of RA evolution. All subjects underwent pulmonary function tests (PFTs) and high-resolution computed tomography (HRCT) on the inclusion date (protocol date) and, in cases of RA-ILD, also on diagnosis of ILD. The primary variable ILD was defined according to lung biopsy or HRCT according to the American Thoracic Society/European Respiratory Criteria [6], and pulmonary progression was defined as worsening FVC >10% or DLCO >15% [4]. Inflammation variables included inflammatory activity data measured by DAS28-ESR and a cytokine multiplex including Th1/Th2 function, inflammatory cytokines, and chemokines. Other clinical, RA severity and therapeutic variables were also studied: rheumatoid factors (RF), anti-cyclic citrullinated peptide antibodies (ACPA), radiological erosions, and Health Assessment Questionnaire (HAQ) values. A descriptive analysis and two Cox regression models were performed to identify factors associated with ILD and ILD progression in RA, adjusting for time to development of ILD-RA and to ILD progression, respectively.

Results: A total of 70 subjects were included, 35 RA-ILD cases and 35 RA controls without ILD (Table 1). A higher percentage of patients with RA-ILD, compared to the rest, presented elevated RF (p=0.089) and ACPA levels (p=0.031), higher DAS28-ESR values (p=0.032), number of swollen joints (p=0.040) and worse quality of life measured by HAQ (p=0.003). The variables that were independently associated with RA-ILD in the Cox regression adjusted for time of evolution of RA (Figure 1) were DAS28-ESR of moderate-high activity (OR [95% CI], 2,474 [1,173-5,220]; p= 0.017), elevated ACPA levels (OR [95% CI], 2.905 [1.244-6.786]; p=0.014), IL-18 (OR [95% CI], 1.063 [1.002-1.127]; p=0.044), MCP1CCL2 (OR [95% CI], 1.031 [1.001-1.064]; p=0.049) and SDF1 (OR [95% CI], 1.001 [1.001-1.002]; p=0.010). In the other COX regression model adjusted for time to ILD progression, the only variable associated with progression was IL18 (OR [95% CI], 1.254 [1.074-1.465]; p=0.004).

Table 1. Baseline characteristics of the study population

VARIABLE	RA-ILD n=35	RA without ILD n=35	*P*-value
RF+ (>10), n (%)	33 (94.3)	31 (88.6)	0.393
High RF (>60)	24 (68.6)	17 (48.6)	**0.089**
ACPA+ (>20), n (%)	32 (91.4)	31 (88.6)	0.690
High ACPA (>340), n (%)	22 (63.0)	14 (40.0)	**0.039**
Erosions, n (%)	21 (60.0)	19 (55.6)	0.705
DAS28-ESR, mean (SD)	3.1 (0.9)	2.6 (0.9)	**0.032**
Remission/low activity, n (%)	19 (54.3)	27 (77.1)	**0.044**
Moderate/high activity, n (%)	16 (45.7)	8 (22.9)	**0.044**
Number of swollen joints, median (IQR)	0.0 (0.0-1.0)	0.0 (0.0-0.0)	**0.040**
HAQ, mean (SD)	1.2 (0.6)	0.8 (0.6)	**0.003**

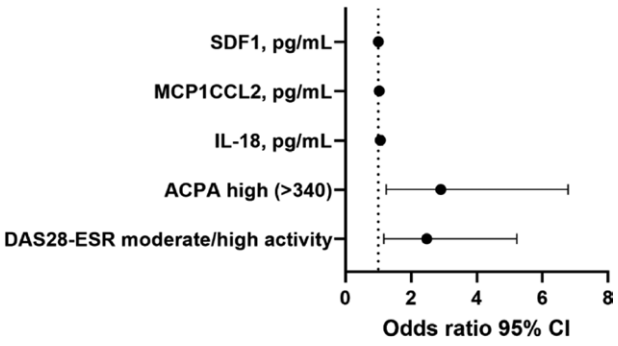

Figure 1. Cox regression analysis adjusted for time of evolution of RA

Conclusion: Patients with RA-ILD show higher inflammatory activity than RA patients without ILD. Some cytokines are associated both with diagnosis and with a worse prognosis in patients with RA-ILD, so they could be potential biomarkers for this entity. Future studies are needed to validate these data and confirm the findings.

POS1057 LUNG ULTRASONOGRAPHY AS A SCREENING TOOL FOR INTERSTITIAL LUNG DISEASE IN RHEUMATOID ARTHRITIS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

Keywords: Ultrasound, Rheumatoid arthritis, Systematic review

A. Alunno[1], S. Bellando Randone[2], E. Pintus[2], N. Piccini[2], J. Schoones[3], M. Matucci-Cerinic[2,4]. *[1]Internal Medicine and Nephrology Unit, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy*; *[2]Division of Rheumatology, AOUC, Dept. Experimental and Clinical Medicine, University of Florence, Florence, Italy*; *[3]Leiden University Medical Center, Directorate of Research Policy (formerly Walaeus Library), Leiden, Netherlands*; *[4]IRCCS San Raffaele Hospital, UnIRAR, Milan, Italy*

Background: In rheumatoid arthritis (RA), interstitial lung disease (ILD) is a frequent pulmonary manifestation which is responsible for a high morbidity and mortality. Chest high resolution computed tomography (HRCT) is the imaging gold standard for the diagnosis and characterisation of ILD. Recently, the use of lung ultrasonography (US) has been suggested as a valid, less invasive and radiation-free tool in the pulmonary screening process.

Objectives: To review the reliability of lung US as a screening tool for the diagnosis of ILD in RA patients.

Methods: A systematic literature search in several databases was conducted following the PICO framework on July 2022. Two researchers independently screened abstracts and titles, and full texts were subsequently reviewed to determine eligibility (original research articles enrolling adult RA patients undergoing lung US and HRCT). Data from eligible articles were extracted and risk of bias (RoB) was assessed with validated tools. Owing to extensive interstudy heterogeneity, narrative summaries had to be used to present the data.

Results: Out of 690 retrieved papers, only 7 were eligible and only 5 of them enrolled a control group (Table 1). All studies had a cross-sectional design and no follow-up data were available. Although all studies relied on the US identification of B-lines, the number of intercostal spaces assessed as well as the threshold/score to classify the findings as ILD or no-ILD varied across studies. Furthermore, some studies also focused on the irregularities of the pleural line. The sensitivity of lung US ranged between 62.2 and 97.1% while specificity ranged between 89 and 100%. However, the studies' heterogeneity did not allow any comparison. In RA patients with neither respiratory symptoms nor previous ILD diagnosis, the concordance in identifying pathological findings between US and HRCT ranged between 90 and 100%.

Conclusion: Our Systematic Literature Review shows that lung US may have a role as screening tool for ILD in RA and also in asymptomatic patients. The implementation of the routine use of lung US in RA might allow an early identification and a prompt treatment of RA-ILD patients as well. However, the harmonization of US findings is required to allow either for the comparison of research studies and for a broad implementation of lung US in clinical practice.

Table 1. Characteristics and main findings of studies with a control group

	Patients N, type	Controls N, type	Comparator	US Se%	US Sp%	Thresholds for Se and Sp calculation

Background: Some studies have shown that Krebs von den Lungen-6 (KL-6) may be a valuable biomarker for diagnosis and stratifying prognosis in Rheumatoid Arthritis-Associated Interstitial Lung Disease (RA-ILD). Citrullination and carbamylation are responsible for generating Anti-Modified Protein/Peptide Antibodies (AMPAs) and are associated with RA-ILD.
Objectives: To evaluate the correlation between serum KL-6 and AMPAs in patients with RA.
Methods: We conducted a cross-sectional study that included patients with RA (ACR/EULAR 2010 criteria) with available KL-6 and AMPAs data measured in blood serum at study enrolment. ILD was diagnosed by high-resolution computed tomography and confirmed by a multidisciplinary committee. Serum KL-6 levels were measured by Lumipulse G KL-6 Kit (Fujirebio, Japan), using Chemiluminescent enzyme immunoassay (CLEIA). The reference value for KL-6 in healthy subjects was 118-627 U/mL. The inter-assay variation coefficient of the reagent was ≤ 4.4%. AMPAs repertoire tested included ACPA, anti-carbamylated protein antibodies (anti-CarP), and autoantibodies to malondialdehyde–acetaldehyde (anti-MAA). ACPA, anti-CarP, and anti-MAA were determined by homemade ELISA tests. Antigens, cut-off values, and isotypes tested are depicted in Figure 1. Spearman's rank correlation coefficient was used to analyze the correlation between serological markers.
Results: A total of 128 patients were included (24 RA-ILD and 104 RA-non-ILD). Patient characteristics were as follows: female 73%, mean age 60.3 ± 12.4 years, mean disease duration 6.5 ± 4.7 years, RF positive 68%, anti-CCP positive 83.6%, erosive disease 54.7%, and mean DAS28 2.94. Most patients received treatment with methotrexate 84 (65.6%), glucocorticoids 72 (56.3%), and biological DMARDs 23 (18.0%). Among RA-ILD patients, the median FVC and DLco (% predicted value) were 79 (IQR 74.7–88.7) and 62.9 (IQR 53.1–70.6), respectively. Usual interstitial pneumonia (UIP) was found in 11/24 (45.8%) patients. The mean KL-6 level was 476.4 ± 400.9 U/mL. KL-6 levels were elevated in 22 patients (17.2%). Serum levels of KL-6 in the RA-ILD group were significantly higher than those in the RA-non-ILD group (756.0 ± 673.4 U/mL vs. 411.9 ± 273.0 U/mL; p<0.001). Serum KL-6 had a moderate positive correlation with HSA-MAA IgA (*r*=0.56; p=0.048) in patients with non-UIP pattern (**Figure 1**). Anti-CarP (Fib IgG: 81.8% vs. 54.7; p=0.019) and anti-MAA antibodies (HSA-MAA IgA: 36.4% vs. 10.4; p=0.018) were significantly associated with elevated KL-6 values (**Table 1**).
Conclusion: Serum KL-6 is a surrogate biomarker of ILD, elevated in a subgroup of patients with RA-ILD. KL-6 elevation correlated with some AMPAs, such as anti-CarP and anti-MAA. Whether AMPAs are potential biomarkers for RA-ILD requires further analysis.

Antigens and cut-off values are specified in Figure

ILD: Interstitial Lung Disease; KL-6: Krebs von den Lungen-6; RA: Rheumatoid arthritis; RF: Rheumatoid factor; UIP: Usual interstitial pneumonia. **ACPA** was assessed by anti-CCP3 chemiluminescent immunoassay (QUANTA Flash CCP3, Inova Diagnostics), and citrullinated synthetic peptide (CFFCP1 IgG). The cut-offs for positive values were 20 chemiluminescence units, and 177.5 AU/mL, respectively. Three **carbamylated (CarP)** antigens, namely fetal calf serum (FCS IgG/IgA), fibrinogen (Fib IgG), and synthetic chimeric fibrin/filaggrin homocitrullinated peptide (CFFHP IgG), were used. A positive cut-off value was defined as ≥173.5 AU/mL, ≥257.0 AU/mL, ≥166.9 AU/mL, and ≥146.5 AU/mL for anti-FCS IgG, anti-FCS IgA, anti-Fib IgG, and CFFHP IgG, respectively. Three modified **malondialdehyde–acetaldehyde (MAA)** antigens, namely Human Serum Albumin (HSA-MAA IgG/IgM/IgA), fibrinogen (Fib-MAA IgG), and fibrin/filaggrin chimeric peptide (CFFCMaP IgG) were tested. A positive cut-off value was defined as ≥3.22 ng/mL, ≥1.49 ng/mL, ≥1.18 ng/mL, ≥1.11 ng/mL, and 15.05 ng/mL for HSA-MAA IgG, HSA-MAA IgM, HSA-MAA IgA, Fib-MAA IgG, and CFFCMaP IgG, respectively.

ASSOCIATION OF THE MULTI-BIOMARKER DISEASE ACTIVITY SCORE WITH ARTERIAL INFLAMMATION, ASSESSED WITH ^{18}F-FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY, IN RHEUMATOID ARTHRITIS

Keywords: Cardiovascular disease, Biomarkers

J. Giles[1], D. Solomon[2], K. Liao[2], P. Rist[2], L. Santacroce[2], Z. Fayad[3], A. Tawakol[4], J. Bathon[1]. [1]*Columbia University, Department of Medicine, New York, United States of America*; [2]*Brigham & Women's Hospital, Department of Medicine, Boston, United States of America*; [3]*Mount Sinai Medical Center, Translational and Molecular Imaging Institute, New York, United States of America*; [4]*Massachusetts General Hospital, Department of Medicine, Boston, United States of America*

Background: Rheumatoid arthritis (RA) and atherosclerosis share many common inflammatory pathways. Reducing the activity of inflammatory pathways with immunomodulators may lessen the risk of cardiovascular disease in RA. As such, a multi-biomarker of RA disease activity (MBDA; AKA the Vectra Score) could serve as an indicator of treatment-associated improvements in atherosclerotic plaque inflammation.
Objectives: To prospectively evaluate the association of an MBDA score and its components with the change in arterial inflammation in RA patients enrolled in a clinical trial of two different RA treatment strategies.
Methods: In the TARGET Trial, patients with active RA despite methotrexate were randomly assigned to the addition of either a TNF inhibitor (TNFi) or sulfasalazine+hydroxychloroquine (triple therapy). Baseline and 24-week follow-up 18F-flourodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) scans were assessed for change in arterial inflammation measured as the maximal arterial target-to-blood background ratio (TBR) of FDG uptake in the most diseased segment (MDS) of either the carotid arteries or aorta (TBRmax MDS). The MBDA score, measured at baseline and weeks 6, 18, and 24, was assessed for its association with the change in arterial inflammation. The MBDA score was categorized as low, moderate, and high disease activity (LDA, MDA, and HDA; LDA<30, MDA 30-44, HDA>44 units).
Results: Among the 150 randomized TARGET participants, 112 had an interpretable TBR at baseline and trial conclusion (24 weeks) (mean age=60 years; 71% female; RA duration=1.4 years; baseline DAS28-CRP=4.8). The MBDA score at week 24 was significantly correlated with the change in TBRmax MDS (Spearman's rho=0.239; p=0.011), while the baseline and interim MBDA scores were less strongly and not significantly correlated with the change in TBRmax MDS. The week 24 MBDA score remained significantly associated after adjustment for relevant confounders. Neither the baseline, follow-up, or change in DAS28-CRP nor CRP significantly predicted the change in TBRmax MDS. There was no significant difference in the association of the MBDA score with the change in arterial inflammation between the two randomized treatment groups. Those achieving MBDA LDA at week 24 had a statistically significant adjusted reduction in TBRmax MDS of 0.35 TBR units, while no significant reductions in TBRmax MDS over time were observed in those remaining in MBDA MDA or HDA(Figure 1A). The component of the MBDA score with the strongest association with change in TBRmax MDS was serum amyloid A (SAA) (Figure 1B), with the largest reduction in TBRmax MDS occurring in those in the lowest tertile of SAA week 24 who also achieved DAS28-CRP LDA (-0.450 TBR units) vs. those in the highest tertile of SAA who had also achieved articular LDA (-0.019 TBR units; Figure 1C).
Conclusion: Achieving low disease activity by the MBDA at 24 weeks was associated with a clinically meaningful reduction in arterial inflammation, similar to high-intensity statins, in a way not predicted using other RA disease activity measures, suggesting that treatment-associated improvements in arterial inflammation may be indicated by specific biomarkers that overlap those used to track articular disease activity.

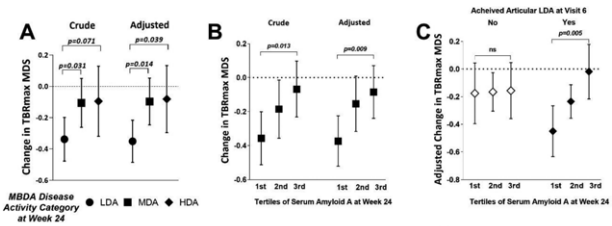

Figure. Associations of the MBDA Score at Week 24 with the Change in ^{18}F-FDG PET Detected Arterial Inflammation (Maximal Target-to-Background Ratio of the Most Diseased Arterial Segment; TBR_{max} MDS). Crude and adjusted means and 95% CIs presented. Adjusted for age, current and former smoking, and methotrexate dose.
MBDA=multi-biomarker disease activity score; FDG=fluorodeoxyglucose; PET=positron emission tomography; LDA=low disease activity; MDA=moderate disease activity; HDA=high disease activity; ns=non-significant

HUMORAL RESPONSES AGAINST HDL ARE LINKED TO LIPOPROTEIN TRAITS, ATHEROSCLEROSIS, INFLAMMATION AND PROTEOMIC PATHOGENIC PATHWAYS DURING EARLY ARTHRITIS STAGES

Keywords: -omics, Cardiovascular disease, Autoantibodies

J. Rodríguez-Carrio[1,2], M. Alperi-López[2,3], P. López[1,2], Á. Pérez-Álvarez[2], G. Robinson[4], S. Alonso Castro[3], N. Amigó[5,6], F. Atzeni[7], A. Suárez[1,2]. Background: cardiovascular (CV) risk excess in rheumatoid arthritis (RA) cannot be solely attributed to traditional CV risk factors. Chronic inflammation and immune dysregulation are crucial mechanisms for atherosclerosis development in RA. Recent evidence suggests a link via humoral responses against high-density lipoproteins (HDL) and its components. However, their exact specificity, clinical relevance and emergence along disease course are unknown, especially during the earliest phases of arthritis.
Objectives: to characterize the specificity and clinical relevance as predictors of anti-HDL responses along during the earliest phases of arthritis.
Methods: IgG and IgM serum levels of antibodies against HDL (anti-HDL) and Apolipoprotein A1 (anti-ApoA1) were measured in 82 early RA patients (EULAR/ACR classification criteria), 14 arthralgia individuals (EULAR definition) and 96 controls. Established RA patients (n=42) were included for validation. Atherosclerosis occurrence and vascular stiffness were measured by Doppler-ultrasound. Lipoprotein content, particle numbers and size were measured by H-NMR. Cytokines were measured by immunoassays. A cardiometabolic-related protein panel was evaluated using high-throughput targeted proteomics.
Results: IgG and IgM anti-HDL and anti-ApoA1 responses were increased in early RA compared to controls (both p<0.001) and were comparable to established disease. Only IgG anti-ApoA1 antibodies were increased in arthralgia compared to controls (p<0.050). IgG anti-HDL and anti-ApoA1 were associated with unfavourable lipoprotein traits (particle content, number and size distribution) in RA and arthralgia, respectively. A similar picture was observed for positive correlations with inflammatory mediators (IFNa, MIP-1a, IL-6, IL-8 and IFNg). No associations with clinical features or traditional risk factors were found. IgG anti-HDL were independently associated with atherosclerosis occurrence (p=0.012) and extension (r=0.274, p=0.016) in early RA. This association remained after adjusting for traditional CV risk factors in multivariate models (OR 1.001 [95% CI: 1.000 – 1.002], p=0.004). The addition to IgG anti-HDL to the mSCORE chart improved patient classification and outperformed patient stratification over mSCORE alone (Table 1). The addition of IgG anti-ApoA1 levels resulted in low-to-milder improvements (Table 1). IgG anti-HDL antibodies correlated with serum proteomic signatures involved in immune activation, remodelling, and lipid metabolism pathways in early RA (Figure 1).

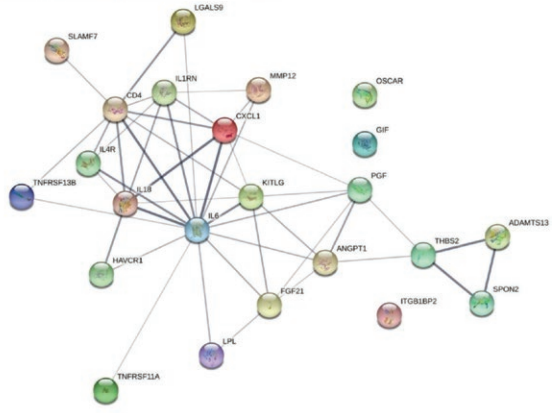

Table 1.

	mSCORE	mSCORE + IgG anti-HDL	mSCORE + IgG anti-ApoA1
AUC ROC (95% CI)	0.636 (0.514 – 0.759)	0.826 (0.731 – 0.922)	0.740 (0.627 – 0.852)
p-value	p=0.044	p<0.0001	p=0.0003
Mathews' Correlation Coefficient	0.319 p=0.003	0.514 p<0.0001	0.431 p<0.001
Hosmer-Lemeshow test	p=0.002	p=0.207	p<0.001
R2	0.173	0.510	0.297
OR (95% CI)	13.12 (1.62 – 106.00)	36.80 (7.67 – 176.93)	10.500 (3.14 – 35.05)
% Patients Correctly Classified	57.14 (45.37 – 68.19)	80.52 (69.60 – 88.34)	71.43 (59.83 – 80.86)
Likelihood Ratio (95% CI)	9.43 (1.31 – 68.13)	11.12 (2.87 – 43.01)	4.72 (1.84 – 12.12)
Sensitivity	30.43 (18.20 – 45.92)	71.74 (56.32 – 83.54)	60.87 (45.39 – 74.54)
Specificity	96.77 (81.49 – 99.83)	93.55 (77.16 – 98.87)	87.10 (69.52 – 95.92)
Positive Predictive Value	93.33 (66.03 – 99.65)	94.29 (79.48 – 99.00)	87.50 (70.07 – 95.92)
Negative Predictive Value	48.39 (35.66 – 61.32)	69.05 (52.76 – 81.69)	60.00 (44.37 – 73.94)
Youden Index (value)	0.632 (2.25)	0.685 (4.75)	0.634 (2.75)
NRI		0.381	0.207

Conclusion: humoral responses against HDL particles are an early event along arthritis course, although quantitative and qualitative differences can be noticed among stages. These differences informed distinct capacities as biomarkers (incremental value) and underlying pathogenic circuits. Anti-HDL but not anti-ApoA1 were robust predictors of lipoprotein features, inflammatory milieu and subclinical CV burden in early RA.

RISK OF ACUTE MYOCARDIAL INFARCTION AND STROKE ASSOCIATED WITH ANTI-RHEUMATIC DRUGS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A NATIONWIDE POPULATION-BASED STUDY

Keywords: Disease-modifying drug (DMARDs), Cardiovascular disease, Rheumatoid arthritis

S. M. Ahn[1], Y. J. Lee[1], S. Hong[1], C. K. Lee[1], B. Yoo[1], J. S. Oh[1,2], Y. G. Kim[1].

Background: The risk of acute cardiovascular events including acute myocardial infarction (AMI) and ischemic stroke in patients with rheumatoid arthritis (RA) is increased compared with the general population and is the leading cause of death in these patients.
Objectives: The present study aimed to investigate the risk of new-onset AMI/stroke following the initiation of different anti-rheumatic drugs for RA using a nationwide database.
Methods: This nested case–control study with a cohort of 35,133 AMI/stroke-naïve patients with RA was conducted using the Korean Health Insurance Review and Assessment (HIRA) database from 2011 to 2020. Cases with incident AMI/stroke were identified and individually matched to randomly selected controls (1:4). Anti-rheumatic drug use was measured for one year before the index date and stratified by exposure duration. The association of each anti-rheumatic drug with AMI/stroke risk was estimated using conditional logistic regression adjusted for comorbidities and concomitant drug use.
Results: Approximately 5.3% of patients (n=1,870) were newly diagnosed with AMI (n=484) or ischemic stroke (n=1,386). In total, 1,868 (excluding unmatched control [n=2]) AMI/stroke cases and 7,423 controls with newly diagnosed RA were included for analysis. In a multivariable-adjusted analysis, recent use (within three months) of leflunomide (adjusted odds ratio [aOR]=1.21, 95% confidence interval [CI]=1.06–1.37), glucocorticoids (aOR 1.84, 95% CI 1.61-2.11) and tocilizumab (aOR=2.04, 95% CI=1.11–3.75) were associated with increased AMI/stroke risk. The recent use of anti-TNF-alpha agents (aOR=0.72, 95% CI=0.52–0.99), sulfasalazine (aOR=0.79, 95% CI=0.66–0.93), and hydroxychloroquine (aOR=0.83, 95% CI=0.74–0.94) were associated with a significantly decreased AMI/stroke risk.
Conclusion: Anti-TNF-alpha agents, hydroxychloroquine, and sulfasalazine used to treat RA decreased the risk of AMI/stroke, whereas leflunomide, glucocorticoids, and tocilizumab increased this risk.

THE USE OF EXPANDED RISK SCORE IN RA (ERS-RA) FOR THE DEFINITION OF RISK FOR MAJOR CARDIOVASCULAR EVENTS IN PATIENTS CANDIDATES TO RECEIVE JANUS KINASES INHIBITORS FOR THE TREATMENT OF RHEUMATOID ARTHRITIS

Keywords: Cardiovascular disease, Rheumatoid arthritis, Targeted synthetic drugs

E. G. Favalli[1,2], G. Cincinelli[1,2], F. Orsini[1,2], M. Manara[2], S. Germinario[1,2], M. Biggioggero[2], R. DI Taranto[1,2], M. Ferrito[1,2], R. Caporali[1,2]. [1]*University of Milan, Department of Clinical Sciences and Community Health, Milano, Italy*; [2]*ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy*

Background: The observation in the ORAL SURVEILLANCE trial[1] of an increased rate of major cardiovascular (CV) events (MACE) in patients with rheumatoid arthritis (RA) treated with Janus kinase inhibitors (JAKis) recently prompted the EMA's Pharmacovigilance Risk Assessment Committee (PRAC) to suggest significant restrictions on the use of this class of drugs in order to minimize CV risk.
Objectives: Assessing the performance of a CV risk chart developed and validated for RA (Expanded Risk Score in RA [ERS-RA[2,3]) in quantifying the risk for MACE in comparison with the PRAC recommendation in a real-life cohort of RA patients treated with JAKis.
Methods: A retrospective analysis on all RA patients treated with a JAKi in a tertiary care academic hospital was conducted. According to PRAC recommendation, the study population was stratified into patients at increased (>65 years old; current or former long-term smokers; patients carrying increased risk of MACE, defined according to ORAL SURVEILLANCE trial[1] inclusion criteria [>50 years old and having at least one CV risk factor]) or not CV risk. The same stratification was also calculated with the ERS-RA[2,3], using a 10% increase in 10-year risk of MACE as a cut-off for the definition of increased CV risk. The incidence of MACE was calculated over a mean follow-up period of 3 years and was correlated with the two different definitions of CV risk considered.
Results: The study population included 194 RA patients exposed to JAKis for a total of 337 patient/years. The baseline characteristics of enrolled population has been fully described in **Table 1**. According to PRAC definition, CV risk was considered increased in 80 (41.2%) patients (n=27 [33.8%] >65 years old; n=25 [31.2%] smokers). Calculated with the ERS-RA, the CV risk was found to be increased in 36 (18.6%) patients. Over the follow-up period, we observed only one MACE (a non-fatal stroke) in a patient who met the definition of increased CV risk according to both criteria. The specificity of ERS-RA score was 0.82 (positive predictive value 0.03), whereas the specificity of PRAC criteria was 0.59 (positive predictive value 0.01).
Conclusion: Our study shows that in a real-life setting the use of a validated score chart as ERS-RA allows CV risk to be calculated more accurately in RA patients undergoing JAKis than the strict application of the PRAC recommendation. Further prospective observational studies on larger populations are advocated to better define CV risk assessment in this scenario.

CARDIOVASCULAR AND THROMBOEMBOLIC EVENTS IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS PATIENTS OVER 3 YEARS BEFORE AND 3 YEARS AFTER INITIATION OF A FIRST ADVANCED THERAPY. DATA FROM THE UNIVERSITY OF SHERBROOKE REGISTRY OF ADVANCED THERAPIES (USRAT)

Keywords: Disease-modifying drug (DMARDs), Rheumatoid arthritis, Cardiovascular disease

G. Boire[1], N. Carrier[2], S. Roux3, H. Allard-Chamard3. [1]*University of Sherbrooke, Medicine - Rheumatology, Sherbrooke, Canada*; [2]*CIUSSS de l'Estrie - CHUS, Medicine - Rheumatology, Sherbrooke, Canada*; [1]*University of Sherbrooke, Medicine - Rheumatology, Sherbrooke, Canada*

Background: Uncontrolled inflammation increases the risk for cardiovascular (CV) and venous thromboembolic (TE) events. Reducing inflammation using advanced therapies (AT) is expected to reduce these risks. Clinical registries are best for precise observations on diagnosis, reasons for drug withdrawal, and disease activity. Administrative databases are more comprehensive for comorbidities and outcomes.
Objectives: To compare the incidence of CV and TE events before and after AT initiation in the same rheumatoid arthritis (RA) patients, to explore specific toxicities or poorer protection of some ATs.
Methods: USRAT Registry combines administrative and clinical data. Our team is the single one treating rheumatology patients among over 500,000 people. All their inpatient episodes are recorded in the administrative system of one single multisite hospital. Since 2003, we developed a registry of 1800+ patients treated with AT. Episodes of inpatient care for these patients were extracted from our hospital's database from 1995 up to the end of 2021. Clinical charts were revised to confirm diagnosis and disease activity over time. We report severe CV and TE events occurring over the 3 years before and the 3 years after initiation of a first AT in patients for which chart revision is currently completed. We analyzed data according to initial AT, identifying a large subset remaining on first AT (First Persistent), a small subset who stopped first AT but did not switch (First-Stop), and others who switched AT over the period (Switch)
Results: RA was confirmed in 596 (66.3% women; mean age 59.1). Mean disease duration at first AT initiation (anti-TNF in 61%) was 7.3 years. First Stop patients trended to be men (47.6%) vs 34.8% (First Persistent) and 30.1% (Switch) (p = 0.074). Switch patients were younger (57.9 yo vs 59.8 First Persistent and 60.8 First Stop) (p = 0.04). Mean duration of first AT treatment was similar in Switch and First-Stop (0.94 vs 0.93 y), versus 5.3 in First Persistent.
Incidences of CV (1.57/100 person-years (py)) and TE (0.34/100 py) events before first AT were similar across First-Persistent, Switch and First-Stop subsets (Table 1). Over the 3 years after first AT initiation, we noted a numerical (non-significant) increase in new CV (2.35/100 py) and TE (0.67/100 py) events. CV incidence post-AT was significantly higher in the First-Stop subset, and not significantly different between First Persistent and Switch patients.
After initiation of a first AT, TE events were numerically higher in Switch (1.05/100 pt-y) and First Stop (2.33/100 pt-y) than First Persistent (0.26/100 pt-y) patients.
Conclusion: Prescribing an AT to patients with active RA appears insufficient to bring their 3-year risk for CV and TE events below their pre-AT levels. The worst CV and TE outcomes were seen in patients who stopped their first AT and did not switch (First-Stop) over the observation period, compatible with persistent poorly controlled inflammation. Numerically higher TE but not CV events were seen in Switch relative to First-Persistence patients. First-Stop patients did not have more CV or TE events before AT initiation; other characteristics of the more at risk First-Stop patients are to be defined.

Table 1. Incidence of events over the 3 years preceding and the 3 years following the initiation of a first advanced therapy in 596 RA patients

	Before		After	
	Events (n)	Incidence per 100 py	Events (n)	Incidence per 100 py
Cardiovascular (CV)	28	1,57	35	2,35
First-Persistent (n=305)	11	1,20	16	2,06

POS1064 PRE-DIABETES INCREASED THE RISK OF MAJOR CARDIOVASCULAR EVENTS IN PATIENTS WITH INFLAMMATORY ARTHRITIS: A POPULATION-BASED COHORT STUDY

Keywords: Inflammatory arthritides, Cardiovascular disease, Comorbidities

H. Meng[1], H. So[1], S. H. M. Lam[1], L. S. Tam[1]. [1]*The Prince of Wales Hospital, The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*

Background: Pre-diabetes was associated with an increased risk of all-cause mortality and cardiovascular disease (CVD) in the general population. However, data exploring the effect of pre-diabetes on the risk of CVD in patients with inflammatory arthritis (IA), including rheumatoid arthritis (RA) and psoriatic arthritis (PsA), were limited.

Objectives: To evaluate the effect of pre-diabetes on the risk of major cardiovascular events (MACE) in patients with IA.

Methods: A population-based cohort of IA patients was identified in the city-wide platform (The Hospital Authority Data Collaboration Lab) of the Hong Kong Hospital Authority. IA patients recruited from 2006 to 2015 were followed until the end of 2018. Time-varying Cox proportional hazard models with time-varying fasting glucose (FG) levels were analyzed to identify the risk of having MACE in IA patients.

Results: A total of 13,905 (12,233 RA and 1,672 PsA) patients with IA were recruited. After a total of 119,571 patient-years of follow-up, 934 (7.0 %) patients developed a first MACE. At baseline, the mean age of the entire cohort was 56.9±14.4 (RA: 57.7±14.4 vs. PsA: 51.0±12.8, p<0.001), mean disease duration was 0.6±1.5 (RA: 0.7±1.5 vs. PsA: 0.3±1.0, p<0.001) and the proportion of patients with diabetes was 3.6% (RA: 3.4 vs. PsA: 5.4, p<0.001). Using multivariable Cox regression analysis, in IA patients who were not on any anti-diabetic medications, the time-varying FG level of a prediabetic state (5.6-6.9 mmol/L) was found to be independently associated with a higher risk of MACE (HR 2.54, 95%CI 1.50-7.71, p<0.001 in the ESR model; HR 2.43, 95%CI 1.97-2.99, p<0.001 in the CRP model) (Table 1), after adjusting for age, sex, and baseline cardiovascular comorbidities and treatment. On the other hand, in patients already on anti-diabetic treatments, MACE risks were similar between patients with FG levels <5.6 mmol/L and prediabetes.

Conclusion: Pre-diabetes, as reflected by FG level at 5.6-6.9 mmol/L over time, was independently associated with an increased risk of MACE.

POS1065 DAS28-GGT FOR THE PREDICTION OF MAJOR CARDIOVASCULAR EVENTS IN RHEUMATOID ARTHRITIS: RESULTS FROM THE ESPOIR COHORT

Keywords: Rheumatoid arthritis, Biomarkers, Cardiovascular disease

A. Dupont[1], A. Constantin[2], M. Soubrier[3], N. Rincheval[4], J. Avouac[1]. [1]*Cochin Hospital, Rheumatology, Paris, France*; [2]*Toulouse University Hospital, Rheumatology, Toulouse, France*; [3]*CHU Gabriel Montpied, Rhumatologie, Clermont-Ferrand, France*; [4]*Institut de recherche Clinique EA2415, Département de Statistiques, Montpellier, France*

Background: Patients with rheumatoid arthritis (RA) experience premature mortality that is largely due to cardiovascular disease (CVD). Ample evidence suggests that elevated γGT activity is associated with increased risk of CVD. We have previously showed that replacing ESR by γGT in DAS28 calculation (DAS28-γGT) allowed a combined evaluation of cardiovascular risk in patients with RA, in addition to joint disease activity [1].

Objectives: To validate the predictive value of the DAS28-γGT for the occurrence of major cardiovascular events (MACE) in the ESPOIR cohort.

Methods: We conducted a prospective observational study including patients with RA from the ESPOIR cohort fulfilling the 2010 ACR/EULAR criteria. Patients were recruited between 2002 and 2005 and were followed up to 10 years. Patients with a history of cardiovascular disease and not followed up to 1 year were excluded from the analysis. DAS28-γGT was calculated at baseline using the following formula: $0.56*\sqrt{TJ\text{-}28}+0.28*\sqrt{SJ\text{-}28}+2*ln(\gamma GT)+0.014*GH$. Our primary outcome was the occurrence of MACE during the observation period.

Results: 720 RA patients (77% females) were considered with a mean age of 48±13 years and a mean disease duration of 93±185 days. Disease activity was high, with a mean DAS28 of 5.1±1.3. At baseline, the DAS28-γGT correlated with age (r=0.26, p<0.001) and the Framingham risk score (r=0.31, p<0.001). The DAS28-γGT was also significantly increased in males (10.3±1.8 vs. 9.4±1.9, p<0.001) and in patients presenting the following conditions: high alcohol consumption (11.2±1.8 vs. 9.5±1.9, p<0.001), active smoking (9.72±1.93 vs. 9.44±1.86, p=0.036), blood hypertension (10.2±2.01 vs. 9.44±1.85, p<0.001), diabetes mellitus (10.67±2.20 vs. 9.53±1.87, p=0.001), hypercholesterolemia (9.95±1.97 vs.

9.50±1.88, p=0.017) and obesity (BMI > 30 kg/m^2) (10.01±1.90 vs. 9.26±1.83, p<0.001). No association was observed between DAS28-γGT and treatment with NSAIDs or corticosteroids. The DAS28-γGT steadily increased according to cardiovascular risk (**Figure 1A**) and was significantly increased in patients with at least 2 cardiovascular risk factors (**Figure 1B**). A total of 35 MACE was recorded during the observation period, with a mean time to event of 70±44 months. ROC curve analysis indicated that DAS28-γGT>9.4 had the best sensitivity (74%) and specificity (62%) for the diagnosis of MACE during the observation period. Increased DAS28-γGT (>9.4) was predictive of the occurrence of MACE, with a hazard ratio (HR) of 3.05 (95% confidence interval, CI 1.44-5.43) (**Figure 1C**). Multivariate Cox analyses confirmed increased DAS28-γGT together with age and diabetes mellitus as independent predictors of MACE (**Table 1**). The DAS28 was not predictive of the occurrence of MACE in this cohort.

Conclusion: The DAS28-γGT was identified in this large prospective cohort as an independent predictor of MACE in patients with RA. In addition to the assessment of disease activity, the DAS28-γGT is a simple and useful tool to evaluate CV risk in routine and warn the clinician about the CV risk burden in patients with RA.

POS1066 WHERE HAVE ALL THE RHEUMATOID NODULES GONE?

Keywords: Rheumatoid arthritis, Epidemiology, Skin

B. Kimbrough[1], H. Langenfeld[2], C. S. Crowson[1], J. M. Davis III[1], E. Matteson[1], E. Myasoedova[1]. [1]*Mayo Clinic, Rheumatology, Rochester, United States of America*; [2]*Mayo Clinic, Quantitative Health Sciences Division of Clinical Trials and Biostatistics, Rochester, United States of America*

Background: The most common extraarticular manifestation of rheumatoid arthritis (RA) is the rheumatoid nodule, which is reported to affect about 30% of patients with RA.[1] The development of rheumatoid nodules has been associated most strongly with high disease activity, seropositive status, and more rapid progression of joint destruction. Despite significant changes in RA treatment and decreasing incidence of seropositive RA, no recent population-based studies have assessed the epidemiology of rheumatoid nodules.

Objectives: We aim to investigate changes in rheumatoid nodule incidence over time.

Methods: This study evaluated rheumatoid nodule incidence trends using an inception cohort that included all adult patients from a geographically well-defined area who met the 1987 American College of Rheumatology criteria for RA between 1/1/1985 and 12/31/2014. Patients were followed until the earlier of death, migration from the region, or 12/31/2000 (for patients with incident RA in 1985-1994) or 12/31/2008 (for 1995-2007 patients) or 10/15/2022 (for 2008-2014 patients). Patients were divided into two cohorts based on the incidence date of RA, an early cohort from 1985-1999 and a later cohort from 2000-2014. Medical records were reviewed manually, and the incidence date of rheumatoid nodules was recorded if determined to be present either by clinical judgment and/or histopathology. The 10-year cumulative incidence of rheumatoid nodules was estimated in each cohort. Cox proportional hazard models adjusted for age, sex and calendar year were used to determine associations between specific demographic and RA disease data with rheumatoid nodules.

Results: 907 patients were included in this study, 296 (67% female) in the 1985-1999 cohort and 611 (70% female) in the 2000-2014 cohort. The mean follow-up period between these cohorts, respectively, was 9.1 and 7.4 years. Baseline characteristics (earlier cohort, latter cohort) included rheumatoid factor (RF) positive (70%, 59%), joint erosions in the first year of RA (24%, 29%), and ever smoker (57%, 47%). The 10-year cumulative incidence of rheumatoid nodules was 31% in the 1985-1999 cohort and 16% in the 2000-2014 cohort (hazard ratio [HR] 0.52, 95% confidence interval [CI] 0.39-0.70). Identified risk factors for the development of rheumatoid nodules included RF positivity (HR 4.38, 95%CI 2.37-8.09), erosions (HR 2.53, 95%CI 1.64-3.91), current smoker (HR 2.09, 95%CI 1.30-3.37), male sex (HR 1.77, 95%CI 1.14-2.73), methotrexate use (HR 1.77, 95%CI 1.09-2.86) and other DMARDs (HR 2.07, 95%CI 1.14-3.74) (Table 1).

Conclusion: The incidence of rheumatoid nodules has decreased substantially over time. More research is needed to understand the drivers of this improvement and implications on RA disease outcomes.

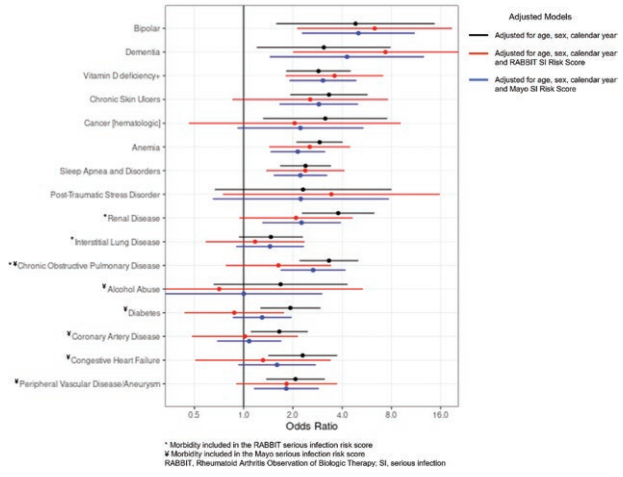
POS1067 MORBIDITIES ASSOCIATED WITH SERIOUS INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Epidemiology



B. Kimbrough[1], C. S. Crowson[1], R. Lennon[2], J. M. Davis III[1], A. Strangfeld[3], E. Myasoedova[1]. [1]*Mayo Clinic, Rheumatology, Rochester, United States of America*; [2]*Mayo Clinic, Quantitative Health Sciences Division of Clinical Trials and Biostatistics, Rochester, United States of America*; [3]*German Rheumatism Research Centre (DRFZ) Berlin and Charite University Medicine, Epidemiology and Health Services Research, Berlin, Germany*

Background: Patients with rheumatoid arthritis (RA) are at increased risk for serious infections (SI) and have a higher prevalence of multimorbidity. The increased risk for SI has led to the creation of multiple infection risk models over the last decade for patients with RA. These models often include combinations of patient demographics, medications, and a limited list of morbidities. However, the limited number of morbidities included in these models are not fully reflective of the morbidity burden seen in real-world practice. Thus, some morbidities that contribute to SI risk may be absent from the existing models.

Objectives: We aim to examine associations between a comprehensive list of morbidities and SI in patients with RA.
Methods: This population-based cohort study evaluated morbidities as risk factors for SI by including all adult patients from a geographically well-defined area from 1/1/1999 through 12/31/2013 who met the 1987 American College of Rheumatology criteria for RA. Patients were followed until the earlier of: death, migration from the region, or 12/31/2021. Fifty-five morbidities were evaluated as risk factors for SI and were ascertained from medical records using international classification of disease (ICD)-9 and ICD-10 codes, requiring 2 separate codes at least 30 days apart for inclusion. Serious infections were defined as infections requiring hospitalization and were identified using previously validated ICD-9 and ICD-10 codes where the primary diagnosis for hospitalization was infection. Conditional frailty models (a variation of Cox model that accounts for multiple events per patient) were used to analyze the association between each morbidity and SI. The first model adjusted for age, sex, and calendar year; the second model adjusted for age, sex, calendar year, and factors included in the Rheumatoid Arthritis Observation of Biologic Therapy (RABBIT) SI risk score;[1] the third model adjusted for age, sex, calendar year, and for factors included in the Mayo SI risk score.[2]
Results: 911 patients (70% female, mean age 56 years, 66% seropositive) were included. The most common morbidities (% of patients; % person-years) included hypertension (53.6%; 40.9%), hyperlipidemia (54.6%; 37.4%), and osteoarthritis (55.2%; 32.6%). There were 293 SI among 155 patients (17%), which corresponded to an incidence of 3.9 SI per 100 person-years. Nineteen SI were fatal. Risk of SI was significantly increased in 26 of 55 morbidities in the initial model adjusted only for age, sex, and calendar year. In the RABBIT and Mayo SI risk score adjusted models, 12 and 23 morbidities were associated with increased risk, respectively. Morbidities conferring high risk among the three adjusted models are included Figure 1. Specific morbidities included in the RABBIT and Mayo SI risk scores continued to have large and/or significant effect sizes despite adjustment (Figure 1). The number of morbidities was also associated with SI risk, leading to a 16% (initial), 11% (RABBIT), and 13% (Mayo) increase in SI risk per morbidity.
Conclusion: Several morbidities are associated with increased risk of SI in patients with RA, and this risk is not completely accounted for in two SI risk scores. Morbidity burden is an important clinical characteristic that may influence SI prevention strategies and treatment approaches in patients with RA.

Background: To prevent infections, EULAR recommends to vaccinate RA patients against streptococcal pneumoniae. It is recommended to vaccine with the conjugate vaccine (PCV13) followed by a dose of PPSV23 at least 8 weeks later. PCV13 is a T- cell dependent vaccine whereas PPSV23 induces a T-independent humoral response. Abatacept is a biological DMARD that inhibits T cell activation.
Objectives: We hypothesized that the humoral response may be more affected under abatacept after PCV13 vaccination than after PPSV23. To adress this question, we compared the humoral response four weeks after vaccination with PCV13 or PPSV23 in RA patients treated with abatacept.
Methods: We conducted a prospective, multicenter, randomized, open-label study in patients with RA according to ACR/EULAR 2010 criteria, and starting abatacept because of inadequate response to MTX or leflunomide (DAS28>3,2). Patients were randomized in 2 groups: the first group (G1) was vaccinated with the PPSV23 and the second group (G2) with PCV13 and PPSV23 8 weeks later. Abatacept was to be started on the same day as the first vaccine (PCV13 or PPSV23). Patients having been treated previously with rituximab within the last year were excluded. A patient was considered as responder if there was a two-fold increase in the antibodies titer measured by ELISA for at least 3 of 5 serotypes of interest (1, 3, 14, 7F, 19A) which are the most frequently involved in pneumococcal infections. For the primary endpoint, we compared the rate of responders at one month in G1 and G2 using a Chi-Square test. Sample size calculation based on alpha risk 5% and 80% power requirements resulted in 80 patients. Tolerance of the vaccines were collected within the first week and later in a patient booklet. Adverse events were also collected at 1, 2, 6 and 12 months.
Results: Eighty patients were included and randomized in the two groups: 40 in G1 and 40 in G2 (1 patient withdrew his consent before any treatment in G2). Characteristics of patients are described in Table 1. Female were more represented in G1 (82.5%) compared to G2 (64.1%). Lymphocyte count were significantly higher in G1 compared to G2: 1841/uL (+/-887) vs 1603/uL (+/-580). In the mITT, the rate of responders was 47.5% in in G1 and 38.46% in G2 (p=0.42) with a RR of 1.23 (IC95%: 0.73-2,06; when comparing responders in PPSV23 vs PCV13 groups. This absence of difference was confirmed with a per protocol analysis (p=1) and after adjusting for gender and lymphocytes count with a logistic regression test (RR=1.6 IC95% 0.6-4.2). 17 infections were reported in G1 and 28 in G2 with 3 severe infections but no pneumococcal infection.
Conclusion: In RA patients treated with abatacept combined with sDMARDs (MTX or LEF), the rate of responders is similar 28 days following vaccination with PCV13 or PPSV23. Although PCV13 is a T cell dependent vaccine, immunogenicity to PCV13 under abatacept is similar to PPSV23. There were no unexpected side effects after pneumococcal vaccines.

Table 1. Characteristics of patients at inclusion

Variable	Modality	All population N=79	Group1 PPSV23 N=40	Group 2 PCV 13 N=39
Age (years)	Mean (±SD)	59.61 (± 12.59)	58.08 (± 13.74)	61.18 (± 11.24)
Gender	Women	58 (73.42)	33 (82.50)	25 (64.10)
BMI (kg/m²)	Mean (±SD)	26.03 (± 5.09)	26.76 (± 6.17)	25.29 (± 3.62)
Previous pneumocccal vaccine	Yes/ (%)	17 (21.52)	10 (25.00)	7 (17.95)
DAS28 CRP	Mean (±SD)	4.33 (± 0.90)	4.20 (± 0.79)	4.46 (± 1.00)
RF positive	Yes/ (%)	55 (70.51)	30 (75.00)	25 (64.10)
ACPA positive	Yes/ (%)	55 (70.51)	31 (77.50)	24 (61.54)
Erosive RA	Yes/ (%)	47 (61.04)	24 (60.00)	23 (58.97)
Lymphocytes count n/uL	Mean (±SD)	1822.31 (± 778.25)	2029.73 (± 886.68)	1603.97 (± 579.90)
MTX	Yes/ (%)	63 (79.75)	32 (80.00)	31 (79.49)
MTX dose (mg/w)	Mean (±SD)	15.67 (± 4.52)	15.63 (± 5.12)	15.73 (± 3.88)
Leflunomide	Yes/ (%)	8 (10.13)	4 (10.00)	4 (10.26)
Steroids	Yes/ (%)	33 (41.77)	16 (40.00)	17 (43.59)
Steroid dose (mg/d)	Mean (±SD)	7.77 (± 2.42)	7.50 (± 2.58)	8.03 (± 2.30)

Background: Potential associations between targeted therapies in patients with an inflammatory arthritis (IA)
and malignancy are a frequent concern in daily rheumatology practice. No specific framework has been proposed to evaluate the benefit/risk balance of initiating or reinitiating a targeted therapy (bDMARDs/tsDMARDs) in patients with IA and a history of cancer.
Objectives: To perform a systematic literature review (SLR) to inform the task force formulating.
the EULAR Points to Consider on the initiation of targeted therapies in patients. with IA and a history of cancer.
Methods: Specific research points were defined with the task force before formulating. the research questions with a librarian under supervision of two methodologists. The task force agreed to focus the SLR on clinical data in patients treated with any targeted therapy for an inflammatory or autoimmune rheumatic or skin or bowel disease. All studies up to. the 15th July 2022 were searched through Pubmed and Embase. Inclusion criteria required studies reporting on the initiation of a targeted therapy in patients with history of cancer, a control group. of patients treated with a conventional DMARDs or healthy controls, and report of a relative risk measure (e.g. Hazard Ratio (HR)) of cancer recurrence between groups. Two reviewers independently performed standardized article selection, data extraction, synthesis, and risk of bias assessment. The quality of the studies was graded according to the Newcastle-Ottawa quality assessment scale.
Results: A total of 1555 publications were identified of which 79 articles fulfilled inclusion criteria, including. 13 published articles and 1 EULAR abstract. All studies were high quality observational data from cohorts or registries, representing 4522 patients (13030 patient-years). Most of the patients included were treated for rheumatoid arthritis. The previous cancer was a solid cancer for more than 90% of the patients. The targeted therapy evaluated was a TNF inhibitor in all the studies, and 4 studies evaluated rituximab as well. The overall HR of cancer recurrence was 1.02 (0.83-1.26) in patients treated with a targeted therapy compared to those treated with a conventional DMARD (Figure 1). In patients treated with. a TNF-inhibitor, the HR was 1.01 (0.86-1.18). In patients treated with rituximab, the HR. was 1.10 (0.72-1.67). In subgroup analyses, no difference in cancer recurrence was observed if. the targeted therapy was initiated before or after 5 years since the diagnosis of the initial cancer; no difference in cancer recurrence was observed depending on the initial cancer type.
Conclusion: The SLR informing EULAR PTC show that overall, the targeted therapies and clinical context covered by the included studies were not associated with an increased risk of cancer recurrence when compared with conventional synthetic DMARDs. This SLR also shows the lack of data for other targeted therapies, for other clinical contexts, and for other conditions than RA.

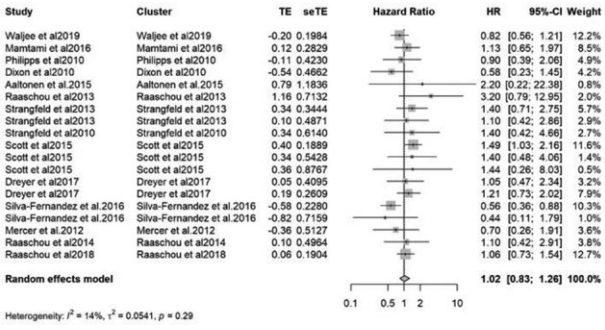

Figure 1. Relative risk of cancer between targeted therapies and csDMARDs in patients with a history of cancer

SLIGHTLY INCREASED INFECTION RISK FOR JAK INHIBITORS TOFACITINIB AND BARICITINIB COMPARED TO BDMARDS: A REAL-WORLD EVIDENCE STUDY

Keywords: bDMARD, Rheumatoid arthritis, Targeted synthetic drugs

M. Opdam[1,2], N. Den Broeder[1], B. Van den Bemt[3,4], K. Mulder[5], K. M. Van de Wiel[5], H. Van Ballegooijen[5], R. Van Crevel[6], A. Den Broeder[1,7]. *[1]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands*; *[2]Radboud University Medical Center, Radboud Institute for Health Sciences, Nijmegen, Netherlands*; *[3]Sint Maartenskliniek, Pharmacy, Ubbergen, Netherlands*; *[4]Radboud University Medical Center, Pharmacy, Nijmegen, Netherlands*; *[5]IQVIA Nederland, IQVIA Solutions, Amsterdam, Netherlands*; *[6]Radboud University Medical Center, Infectious Diseases, Nijmegen, Netherlands*; *[7]Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*

Background: Rheumatoid arthritis (RA) is treated with disease modifying anti-rheumatic drugs (DMARDs), including biological DMARDs (bDMARDs) and more recently, Janus kinase inhibitors (JAKi). Both JAKi and bDMARDs are safe and effective, however infection risk remains a concern. Recently, the ORAL Surveillance trial showed an increased risk of infections and especially herpes zoster (HZ) in JAKi compared to TNF-inhibitors (a type of bDMARDs).[1] However, clinical trials do not fully reflect the real-world population as they usually include younger and healthier patients and have a short follow-up time. Therefore, larger long-term observational studies also including more frail and older adults as seen in clinical practice are needed.

Objectives: The objective of this study was to compare infection risk between bDMARDs and JAKi in RA patients, with a special focus on HZ and older adults.

Methods: From a nationally representative prescription database, all adult RA patients starting a new JAKi or bDMARD between August 1st 2018 and January 31st 2021 were included. This database covers ~63% of all outpatient prescriptions dispensed in the Netherlands and contains coded prescription records including patient characteristics, medication and prescriber information. Prescriptions of antibiotic, antiviral or antifungal medication were used as proxy for infections. Infection incidence rates (IR) were compared between JAKi and bDMARDs and infection risks using multilevel Poisson regression adjusted for follow-up time and potential confounders and stratified for age < 65 and ≥ 65 years.

Results: In total, 14,989 patients were included, with 20,050 treatment episodes with either JAKi or bDMARDs. Most patients were female (72%) and median age was 61 years (IQR 52-70). Infection IRs were higher in JAKi (48/100 patient years) compared to bDMARDs (35/100 patient years, adjusted incidence rate ratio (IRR) 1.22, 95% CI 1.12-1.33). More HZ infections were seen in JAKi compared to bDMARDs (adjusted IRR 3.03, 95% CI 2.26-4.07) (Table 1). No significant differences in infection IRs were found between JAKi baricitinib and tofacitinib. In older patients, absolute infection IRs were higher (overall infection IR 42/100 patient years for age ≥ 65 versus 31/100 patient years for age < 65). However, comparing JAKi to bDMARDs, IRRs were similar for all ages (adjusted IRR for age ≥ 65 1.31 (95% CI 1.15-1.49), adjusted IRR for age < 65 1.17 (95% CI 1.05-1.30)).

Conclusion: JAKi are - compared to bDMARDs - associated with a slightly higher infection risk and a higher risk of HZ specifically. In older patients, absolute infection IRs are higher but relative infection risks for JAKi versus bDMARDs are similar in all age groups. No differences in infection risk between tofacitinib and baricitinib were found.

THE IMPACT OF COMORBIDITIES ON THE EFFICACY OF IL-6 INHIBITOR OLOKIZUMAB COMPARED TO ADALIMUMAB

Keywords: bDMARD, Comorbidities, Rheumatoid arthritis

E. Feist[1], M. E. Luggen[2], E. Nasonov[3], S. Yakushin[4], D. Bukhanova[5], A. Egorova[5], S. Grishin[5], M. Samsonov[5], J. S. Smolen[6]. *[1]Helios Fachklinik Vogelsang-Gommern, Helios Clinic, Rheumatology, Vogelsang-Gommern, Germany*; *[2]University of Cincinnati College of Medicine, Division of Rheumatology, Allergy, and Immunology, Cincinnati, United States of America*; *[3]Nasonova Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*; *[4]Ryazan State Medical University named after academician I.P. Pavlov, Rheumatology, Ryazan, Russian Federation*; *[5]R-Pharm, Medical, Moscow, Russian Federation*; *[6]Medical University of Vienna, Rheumatology, Vienna, Austria*

Background: Comorbid conditions may affect efficacy of treatment in patients with rheumatoid arthritis (RA).

Objectives: The aim of this analysis was to evaluate the impact of comorbidity burden on the efficacy of IL-6 inhibitor olokizumab (OKZ) and TNF-α inhibitor adalimumab (ADA) in the CREDO-2 clinical trial cohort of patients with active rheumatoid arthritis (RA).

Methods: Patients in the double-blind RCT (NCT02760407) who received OKZ 64 mg once every 2 weeks (q2w) or 4 weeks (q4w), or ADA 40mg q2w for 24 weeks were included. To assess the impact of comorbid conditions on efficacy, outcomes were stratified by patients with Low Charlson Comorbidity Index (CCI = 1; RA only) vs High (CCI ≥ 2; RA and at least 1 comorbidity). Age points in CCI were excluded from the analysis. The comparison of outcomes between the Low and the High CCI groups was performed using $\chi 2$-test in unadjusted analysis, and logistic regression in adjusted analysis. Baseline characteristics with an absolute standardized difference > 0.1 were identified as covariates for adjusted comparison. The impact of comorbidity was investigated separately for OKZ and ADA.

Results: A total of 1402 patients with RA were included in the analysis: 940 patients treated with OKZ 64 mg q2w or q4w and 462 patients treated with ADA 40mg q2w. All patients received background MTX therapy. The results are presented in the Table 1. There was no difference in efficacy results between the OKZ-treated groups with and without comorbid conditions during the study, except the achievement of SDAI ≤ 3.3 at Week 24, which was observed more frequently in the Low CCI group. However, the presence of comorbid conditions affected the efficacy of ADA therapy. In the group of High CCI, the proportions of patients who achieved ACR 20 response at Week 12, ACR 50 response (Weeks 12 and 24), SDAI ≤ 3.3 (Weeks 12 and 24) and CDAI ≤ 2.8 (Week 24) and CDAI ≤ 10 (Week 24) were significantly lower in comparison with the group of Low CCI.

Conclusion: High CCI (or presence of at least one comorbid disease) does not affect OKZ treatment efficacy in RA patients. In the same study, high CCI significantly reduces the efficacy of ADA treatment, including LDA and remission achievement.

Table 1. Impact of comorbidities on the efficacy parameters in the OKZ and ADA-treated patients

POS1072 INSULIN INHIBITS ACTIVITY OF CD4+ T CELLS IN RHEUMATOID ARTHRITIS

Keywords: Adaptive immunity, Comorbidities, Rheumatoid arthritis

M. Erlandsson[1,2], M. Tuameh[1], L. Nilsson[1], E. Malmhäll-Bah[1], S. Silfverswärd[1], T. Zverkova Sandstrom[1], K. M. Andersson[1], M. Dehlin[1,2], R. Pullerits[1,2,3], M. I. Bokarewa[1,2]. [1]*Gothenburg University, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; [2]*Sahlgrenska University Hospital, Rheumatology clinic, Gothenburg, Sweden*; [3]*Sahlgrenska University Hospital, Department of Clinical Immunology and Transfusion Medicine, Göteborg, Sweden*

Background: Rheumatoid arthritis (RA) and diabetes mellitus (DM) have common genetic risk factors, while molecular mechanisms behind this commonality have not been studied.

Objectives: To study non-metabolic effects of insulin in CD4+ T cells of RA patients.

Methods: Incidental DM was studied in a consecutive cohort of 330 (256 female, 74 male) RA patients and 1011 (798 female, 213 male) gout patients matched to RA by age and gender (1 to 3) retrieved from the Health Care Register of Western Sweden during 10 years of follow-up. Insulin was measured at baseline and analyzed in relation to clinical and serological disease parameters. Transcriptomics by RNAseq was done on $CD4^+$T cells of 57 RA patients. Differentially expressed genes (DEG, nominal p<0.05) in patients with hyperinsulinemia (n=11, median 344 pmol/L) were identified using DESEq2 (R studio, Bioconductor) and analyzed for enrichment of biological processes and transcription factor (TF) families using GSEA (Broad Institute). To study direct effect of insulin on $CD4^+$T cell function, *in vitro* culture experiments were performed. Analysis of $CD4^+$Tcell phenotype for senescence, exhaustion and apoptosis was done by flow cytometry, transcriptomics and cytokine measurement.

Results: In total, 102 new cases of DM were registered, significantly less often in RA patients compared to gout patients (p=3.2e-4, OR=0.34 [0.18-0.64]). The new DM were more prevalent in men (p=0.012) with no difference between RA and gout patients (9.8 vs 7.5%, OR=1.34 [0.46-3.52] p=0.55). In females, RA patients developed significantly fewer cases of DM than gout patients (2.1 vs 9.4%, OR=0.21 [0.07; 0.47], p=3.2e-5). In RA patients, the insulin levels correlated positively to inflammation measured by serum levels of IL6, VEGF and IL8 followed by IFNγ total, 102 new cases of DM were registered, significantly less often in RA patients compared to gout patients (p=3.2e-4, OR=0.34 [0.18-0.64]). The new DM were more prevalent in men (p=0.012) with no difference between RA and gout patients (9.ol/L). Transcription profile of $CD4^+$T cells revealed 688 (131 upregulated, 557 downregulated) protein-coding DEG in patients with hyperinsulinemia. The down-regulated DEG showed enrichment for T cell activation (GO:0042110, FDR 2.6e-26) and inflammatory response (GO:0006954, FDR 2.9e-21). Analysis for TF families showed that the down-regulated DEG were controlled by TFs HMGB1, NFAT and NFκB (all FDR<e-6), which were significantly enriched for Th1 T cell markers including TBX21, EOMES, CXCR3 and IL2. The upregulated DEG were controlled by TFs MORC2, which regulates response to DNA damage, and ZBTB7B essential for differentiation and commitment of $CD4^+$T cells. DEG included GART gene controlling the folate biosynthesis and the transcription regulating proteins MRPL3 and DAP3. Patients with hyperinsulinemia had significantly higher serum levels of IL6, IL8 and VEGF (all p<0.05), suggesting an inflammatory environment. However, they were not different in DAS28, CRP, WBC and platelet counts. Stimulation of $CD4^+$T cell cultures with insulin (n=12) resulted in a significant suppression of IFNγ cell cultures with insulin (n=12) resulted in a significant suppression of IFNscription regulating proteins MRPL3 and DAP3. Patients with hyperinsulinemia had significantly higher serum levels of IL6, IL8 and VEGF (all p<0.05), suggesting an inflammatoryrichment for DNA ($7AAD^+$ cells) in flow cytometry, which does not support induction of senescence by insulin in $CD4^+$ cells. In contrast, $CD4^+$ cells of hyperinsulinemic RA patients expressed lower levels of CCL chemokines, IL2, and TNF, which suggests that insulin induced exhaustion of $CD4^+$T cells.

Conclusion: This study shows that hyperinsulinemia has non-metabolic functions under conditions of chronic inflammation. It could indicate residual RA activity. Insulin controls overactivation of adaptive immunity and causes exhaustion of pro-inflammatory Th1 cells in RA patients.

Background: Patients with Rheumatoid Arthritis (RA) have a higher prevalence of comorbidities, compared to the general population. The presence of such comorbidities has been directly associated with an increased disease activity. However, little is known about the impact of comorbidities in the therapeutic response and in the retention rate.
Objectives: a) To evaluate the effect of comorbidities on the first biologic disease-modifying antirheumatic drug (bDMARD) effectiveness in patients with RA after 2 years of follow-up, and b) to determine the influence of such comorbidities on the first bDMARD retention rate.
Methods: The study population consisted of patients with a diagnosis of RA and exposed to a first bDMARDs, included in BIOBADASER. BIOBADASER is a prospective, large national drug safety registry of patients with rheumatic diseases exposed to b- or tsDMARDs. Patients were classified in two groups at baseline according to the Charlson Comorbidity index (CCI) score: <3 and ≥3. Patients achieving remission (DAS28<2.6) at 1 and 2-years timepoints after the anti-TNF initiation were compared between the two groups using chi-square test. The absolute DAS28 score over time was compared between both groups of patients using a linear regression model adjusted for sex and age, and considering the follow-up visit as covariate. Finally, the first bDMARD retention rate was compared between patients <3 and ≥3 using Log-Rank test and Kaplan-Meier curve.
Results: A total of 1253 patients initiating bDMARD were included (76.6% female and mean age 56 years at the beginning of therapy). Overall, 107 (9%) patients had a CCI ≥3, being diabetes the most frequent comorbidity (5.0%). No differences were found in DAS28<2.6 between patients with CCI<3 and CCI≥3 after 1 year of follow-up (48.2% vs. 44.2%, p-value=0.457), nor after 2 years (50.8% vs. 40.7%, p-value=0.135). The linear regression model showed significant higher scores in DAS28 over the two years in patients with a CCI ≥3 after adjusting for age and sex (beta coefficient 0.27, 95%CI: 0.02-0.51; p-value=0.034). Finally, no differences in the bDMARD retention rate were found between both groups (median 2.6 years [IQR: 1.5-4.1] in CCI<3 vs. 2.1 years [IQR: 0.6-3.7] in CCI≥3; log rank test p-value 0.467) (Figure 1).
Conclusion: These data suggest that a higher CCI in patients with RA is associated with greater DAS28 scores during the first two years after bDMARD initiation, although no differences in remission status were found. In addition, a slightly shorter retention rate was found in patients with CCI≥3, although the difference was non-significant. These results suggest a lower probability of disease activity control in patients with comorbidities after the initiation of bDMARD.

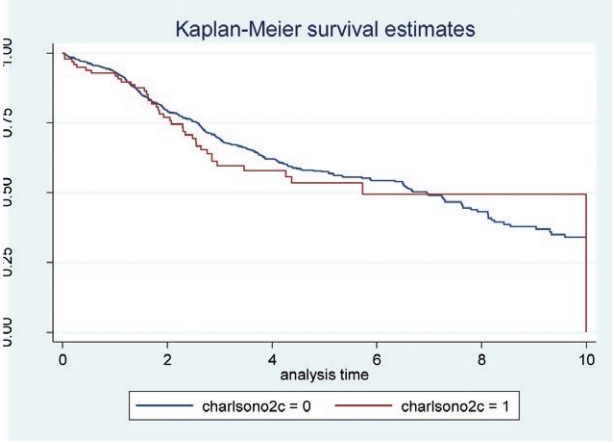

Figure 1. Kaplan Meier curve comparing the first bDMARD retention rate between the two groups.

COMORBIDITIES AND EXTRA-ARTICULAR INVOLVEMENT IN PERSISTENT INFLAMMATORY AND NON-INFLAMMATORY DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS AND CONTROLS

Keywords: Rheumatoid arthritis, Cardiovascular disease, Comorbidities

M. Salvato[1], A. Giollo[1], M. Zen[1], M. Larosa[2], F. Frizzera[1], F. Arru[1], F. Vesentini[1], G. Bianchi[2], A. Doria[1]. [1]*University of Padova, Rheumatology Unit, Padova, Italy*; [2]*SC Reumatologia, Dipartimento Apparato Locomotore, ASL3 - Azienda Sanitaria Genovese, Genova, Italy*

Background: Comorbidities are prevalent among people with rheumatoid arthritis (RA). Some authors have postulated that there is a tight relationship between comorbidities and refractoriness to treatments and a status of difficult-to-treat (DT2) RA. Nevertheless, strong evidence for this association is lacking.
Objectives: We compared the frequencies and type of comorbidities and extra-articular RA manifestations in a cohort of patients previously assessed for D2TRA.
Methods: This was a cross-sectional study in a multicentre cohort of patients diagnosed with RA between 2000 and 2019 and with a disease duration of more than two years (established disease). Participants were stratified according to their fulfillment of the EULAR definition of DT2RA. We analyzed comorbidities according to EULAR domains (cardiovascular diseases, malignancies, depression, osteoporosis, gastrointestinal diseases, and serious infections) plus the following not included in EULAR domains: fibromyalgia, thyroiditis, osteoarthritis, chronic kidney disease (CKD), and obesity. We compared the frequencies of each comorbidity by Chi-squared test between three groups: non-D2TRA, DT2RA 'persistent-inflammatory refractory RA' (PIRRA[1]) and DT2RA 'non-inflammatory refractory RA' (NIRRA[1]). DT2RA-PIRRA and DT2RA-NIRRA were defined according to the presence (PIRRA) or absence (NIRRA) of active inflammation as detected by raised inflammatory markers, clinical or ultrasound-proven synovitis. We also assessed extra-articular manifestations of RA (serositis, secondary Sjogren's syndrome, inflammatory eye diseases, neuropathy, interstitial lung disease, vasculitis, and rheumatoid nodules). Correlations were assessed by the Spearman test. P-values were not corrected for multiplicity due to the exploratory nature of this analysis.
Results: This cohort included 211 RA patients: D2TRA-PIRRA (n=32), DT2RA-NIRRA (n=34), non-D2TRA (n=145). At least one EULAR comorbidity was present in 46% of patients (range 0 to 4). The most represented EULAR comorbidities were cardiovascular diseases (29.5%), osteoporosis (19.5%) and gastrointestinal diseases (8.0%). The number of EULAR comorbidities was similar across groups (p=0.581 by Kruskal-Wallis test), and it was moderately correlated with age at RA onset (r=0.439, p<0.0001). When separately analyzing each comorbidity, there were no significant differences yet a numerical increase in the prevalence of gastrointestinal diseases (15.6% vs 7.3% vs 0.0%, p=0.162) and serious infections (12.5% vs 6.0% vs 5.9%, p=0.328) in D2TRA-PIRRA compared to D2TRA-NIRRA and non-D2TRA patients (Figure 1A). With regard to comorbidities not encompassed in the EULAR domains, fibromyalgia was highly prevalent among D2TRA-NIRRA (23.5%) compared to DT2-RAPIRRA (3.1%) and non-D2TRA (2.7%) patients (p<0.0001; Figure 1A). Extra-articular manifestations were recorded in 27.2% of non-DT2RA, 25.0% of DT2RA-PIRRA and 17.62% of DT2RA-NIRRA (p=0.787), without significant differences in single manifestations. DT2RA-PIRRA patients had numerically more serositis, inflammatory eye disease, and interstitial lung disease than non-D2TRA, while D2TRA-NIRRA patients only showed features of serositis and Sjogren's syndrome (Figure 1B).

Conclusion: Fibromyalgia was associated with D2TRA-NIRRA. Otherwise, we did not find a strong association between comorbidities or extra-articular manifestations and D2TRA. There were trends for more serious infections, gastrointestinal diseases and extra-articular manifestations in D2TRA-PIRRA. Our results suggest that the current definition of D2TRA may not adequately identify DT2RA patients with a substantial burden of comorbidities.

Background: An increased number of elderly patients with rheumatoid arthritis (RA) has been observed in the last years mainly due to the increase of life expectancy. In this group it is possible to include two different categories: patients with onset of RA in advanced age (60-65 years old), and patients with an early occurrence of RA aged with the disease. For all elderly patients many factors such as: comorbidities and polytherapy, extra-articular manifestations of RA, and the process of immune-senescence can increase frailty and difficulties for rheumatologist in management of RA. Although patients with late onset of RA frequently show more aggressive articular involvement and systemic manifestations, literature data suggest that rheumatologists tend to treat elderly patients less aggressively. Moreover, they delay treat to target approach with less frequent use of biologic drugs and prolonged use of steroids or NSAIDsThe improvement of knowledge about persistence of different drugs and associated patients' profiles could suggest more specific treatment strategies encouraging the correct management of RA elderly patients in clinical practice.

Objectives: Aim of the study was to evaluate the retention rate at two years of treatment with biologic or targeted synthetic (ts) DMARDs, namely TNF inhibitors, anti-IL6, anti-CD20, Abatacept and Janus kinases inhibitors (JAKis), in patients with RA who received a targeted therapy over 65 years of age.

Methods: Data were extracted from the GISEA registry (Gruppo Italiano Studio Early Arthritis), selecting RA patients in which biologic- or ts-DMARDs were prescribed over 65 years of age.

Global persistence in therapy and 2-year retention rate were evaluated by mean of Cox regression. Then, a multivariate analysis was performed to evaluate factors associated to the discontinuation of the treatment.

Results: We analysed data of 1221 patients (F/M ratio 966/255). Therapies prescribed were: TNFis in 362 pts (29.6%), anti-IL6 in 199 pts (16.3%), JAKi in 304 pts (24.9%), anti-CD20 in 53 pts (4.3%), abatacept in 303 pts (24.8%). Median time of persistence in therapy was 181 weeks (confidence interval 95% 158-205), with a significant difference among different classes of drugs (abatacept 254 weeks, CI95% 219-289; anti-CD20 221, 104-337; TNFis 184, 151-217; JAKis 139, 115-164; and anti-IL6 136, 105-167; p<0.001). Retention rate at two years was 66.3%± 3.8 for abatacept, 59.7%± 8.8 for anti-CD20, 54.9%± 3.7 for TNFis, 49.2%±0.5 for anti-IL6, 52.7%±3.7 for JAKis (Figure 1). A multivariate analysis including age, gender, class of drug, line of treatment, disease activity index on 28 joints (DAS28) was performed. Anti-citrullinated peptides antibodies, rheumatoid factor, combination therapy with glucocorticoids or methotrexate were excluded from the model, since not significant at univariate analysis. Multivariate analysis revealed that treatment with TNFis (HR 1.63 CI 1.01-2,63, p=0.044), treatment with anti-IL6 (HR 1.43 CI 1.11-1.85, p=0.006), an increase of 1 point of DAS28 (HR 1.21 CI 1.08-1.35, p=0.001) correlated with lower retention rate at two years. Among 1220 pts considered, 33.5% discontinued therapy. The most frequent cause of discontinuation for all drugs was a secondary loss of efficacy in 49.3% of cases.

Conclusion: In our study abatacept resulted the drug with the highest retention rate among drugs prescribed in elderly patients. On the other side, anti-IL6 showed the lowest persistence. Disease activity and the therapeutic choice may influence the retention rate. Our results on a very large population represent interesting points to consider for the choice of treatment for elderly RA patients. Prospective studies should be advisable to confirm these data.

POS1076 ARE DISEASE-MODIFYING ANTIRHEUMATIC DRUGS FOR RHEUMATOID ARTHRITIS ASSOCIATED WITH A LOWER RISK OF DEMENTIA? A SYSTEMATIC REVIEW WITH META-ANALYSIS

Keywords: Comorbidities, Rheumatoid arthritis, bDMARD

W. Xie[1], Z. Zhang[1]. [1]*Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Dysregulation of several inflammatory cytokines including tumor necrosis factor (TNF) in dementia patients has also been identified as a key factor in the pathogenesis of rheumatoid arthritis (RA). Existing epidemiologic evidence suggests an increased risk of incident dementia associated with RA. Modulating systemic inflammation with disease-modifying anti-rheumatic drugs (DMARDs) is hypothesized to attenuate the development of dementia.

Objectives: We aimed to investigate the association of DMARDs therapy for RA with risk of incident dementia.

Methods: Electronic database searches of PubMed, EMBASE and Cochrane Library were performed. Observational studies that assessed the association of dementia with DMARDs in RA were included. Pooled risk ratios (RRs) with 95%

confidence intervals (CIs) were used as summary statistic, with either fixed-effects or random-effects model. The certainty of evidence using the GRADE system.
Results: A total of 14 studies involving 940,442 patients with RA were finally included. Compared with conventional synthetic DMARDs, a 24% reduction in dementia risk was found with biological DMARDs overall (RR 0.76, 95% CI 0.72-0.80, n=9 studies), with 24% for TNF inhibitors (RR 0.76, 95% CI 0.71-0.82), 24% for non-TNF biologics (RR 0.76, 95% CI 0.70-0.83). There was a significant subgroup effect among different types of TNF inhibitors (RR 0.58, 0.65, 0.80 for etanercept, adalimumab, infliximab, respectively; P-value between groups=0.002). However, compared with nonusers of investigative treatment, no significant effect on dementia incidence was observed in those receiving conventional synthetic DMARDs overall (RR 0.84, 95% CI 0.59-1.20), methotrexate (RR 0.78, 95% CI 0.54-1.12), hydroxychloroquine (RR 0.95, 95% CI 0.63-1.44), except for sulfasalazine with its seemingly detrimental effect (RR 1.27, 95% CI 1.06-1.50).
Conclusion: Biological DMARDs for RA are associated with decreased risk of dementia, while the protective effect is not observed in conventional synthetic DMARDs. Future interventional studies may be worth considering.

Invetigative treatment	No. study	Risk ratio (95% CI)	I^2	Egger	Begg
Biological DMARDs	9	0.76 (0.72, 0.80)	14.4%	0.754	0.371

POS1077

TIME TREND OF SEROPOSITIVITY IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS BETWEEN 2000 AND 2021: DATA FROM THE IORRA COHORT

Keywords: Rheumatoid arthritis, Real-world evidence

T. Higuchi[1,2], E. Tanaka[2], E. Inoue[2,3], M. Abe[2], K. Saka[2], E. Sugano[2], N. Sugitani[2], M. Ochiai[2], R. Yamaguchi[2], K. Ikari[2,4], Y. Hisashi[2,5], M. Harigai[2].
[1]Tokyo Women's Medical University School of Medicine, Division of Multidisciplinary Management of Rheumatic Diseases, Department of Internal Medicine, Tokyo, Japan; *[2]Tokyo Women's Medical University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*; *[3]Showa University, Showa University Research Administration Center, Tokyo, Japan*; *[4]Tokyo Women's Medical University School of Medicine, Department of Orthopedic Surgery, Tokyo, Japan*; *[5]Sanno Medical Center, Rheumatology, Tokyo, Japan*

Background: It has been reported that patients with rheumatoid arthritis (RA) differ in disease progression and responsiveness to treatment depending on their serological status. Examining time trends in serological status may lead to the recognition of changes in the phenotype of RA. Recent reports revealed that the incidence of rheumatoid factor (RF)-positive RA had been decreasing[1,2]. This needs to be further investigated in other registries and races; however, data from a large observational study of Japanese are lacking.
Objectives: We aimed to investigate the time trend of seropositivity in Japanese RA patients.
Methods: This is a retrospective study using data from the Institute of Rheumatology Rheumatoid Arthritis (IORRA) cohort. Among patients enrolled in the IORRA cohort between 2000 and 2021, patients with a disease duration of <3 years at enrolment were included. Seropositive status was defined as positive for rheumatoid factor (RF) (cut-off: 15 IU/mL) and/or anti-cyclic citrullinated peptide (CCP) antibody (second generation; cut-off: 4.5 U/mL). Patients with one negative and one unmeasured or both unmeasured were excluded. The time period was divided into 2000–2010 and 2011–2021. The effect of the time period on seropositivity was analyzed using multivariable analysis after adjusting for age, sex, smoking, and body mass index (BMI) at enrollment.
Results: Of 6,514 patients enrolled, 5,289 (81.2%) patients were female, and the median age was 54.9 (interquartile range: 44.0–64.5). 5,142 (88.2%) were seropositive, and the proportion of serological status differed between 2000–2010 (n=4,261) and 2011–2021 (n=2,004) (Figure 1). The proportion of seropositive patients was 90.2% in 2000–2010 and 84.0% in 2011–2021. The positivity for RF and anti-CCP antibody was decreased over time: 74.9% and 78.1% in 2000–2010 and 70.0% and 74.3% in 2011–2021, respectively. The time period (2011–2021) was associated with seronegativity (adjusted odds ratio [OR]: 1.51, 95% confidence interval [CI]: 1.24–1.83). Additionally, the time period (2011–2021) was also associated with RF negativity (adjusted OR: 1.44, 95% CI: 1.23–1.68) and anti-CCP negativity (adjusted OR: 1.30, 95% CI: 1.10–1.52).
Conclusion: Analysis of the IORRA cohort data revealed a decrease in seropositivity in Japanese patients with RA. The phenotype of RA in the clinical setting may have been changing over time.

Background: High-dose glucocorticoids (GCs) can cause weight gain and hypertension. It is unclear whether GCs at ≤7.5mg/d prednisone equivalent ("low dose"), administered for rheumatoid arthritis (RA), do as well. Prior studies could not definitively answer this research question: Observational studies are confounded by indication, and individual randomized trials (RCTs) are usually underpowered for small safety signals.

Objectives: To assess the effects of long-term treatment with low dose GCs in RA on body weight and blood pressure by pooling individual patient data from RCTs.

Methods: Data from five RCTs with two-year interventions were pooled.[1-5] All trials originated in Europe and allowed concomitant treatment with DMARDs. Intervention groups received GCs at a dose of ≤7.5mg/d prednisone equivalent, control groups received placebo or nothing. Co-primary outcomes were the difference in change from baseline in a) body weight (kg) and b) mean arterial blood pressure (MAP; mmHg). A secondary outcome was difference in the change of number of administered antihypertensive drugs. Several sensitivity and subgroup analyses were conducted. All analyses were based on analyses of covariance, trial ID was included as a random effects factor to account for clustering of patients within trials. Multiple imputation was used to account for missing data under the intention-to-treat approach. No imputations were performed for trials with no data collected or available for the given outcome. A detailed prespecified protocol (dx.doi.org/10.17504/protocols.io.x54v9y4d1g3e/v1) with a hierarchical statistical testing procedure was followed.

Results: 1,112 participants were included (mean ± SD age 61 ± 15 years; 68% female). A mean DAS28 of 4.87 ± 1.16 indicated moderate disease activity at baseline; disability was moderate to severe with a median (interquartile range) health assessment questionnaire score of 1.38 (0.80; 2.25). Median disease duration was 1 year (0.42; 7). Baseline values for weight and MAP were 73kg ± 14 and 98mmHg ± 12; median number of antihypertensive drugs was 0 (0; 1). After two years, patients on GCs gained mean 1.1kg (95%CI 0.5 to 1.8; p < 0.001; **Table 1**) more weight than patients in the control groups. Both groups increased MAP by 2-3mmHg, without difference between the groups (–0.4; 95% CI –3.0 to 2.2 mm Hg; p = 0.19; **Table 1**). The change in number of antihypertensive drugs was low and similar in both groups (**Table 1**). Results were consistent across sensitivity and subgroup analyses focusing on overweight or hypertensive patients, and when comparing GCs at 5mg/d with 7.5mg/d (data not shown).

Conclusion: We present robust evidence that low dose GCs, taken over two years for the treatment of RA, lead to about one additional kg of weight gain but do not cause changes in blood pressure.

Table 1. Changes in weight and mean arterial blood pressure in GC and control groups over two years.

	n	GC group n		Control group	Contrast	P value
Weight, kg	547	1.9 (0.8)	565	0.7 (0.8)	1.1 (0.5 to 1.8)	<0.001
Mean arterial blood pressure, mmHg	429	2.3 (1.3)	433	2.7 (1.4)	–0.4 (–3.0 to 2.2)	0.19
Number of antihypertensive drugs*	276	0 (0;0)	282	0 (0;0)	0 (0 to 0)	**

Values are least squares mean changes (SE), and differences in least squares mean changes (95% confidence intervals), unless otherwise stated.* Non-normal distribution: the group estimates are median changes (inner quartiles), and effect estimate is the median of differences between the two groups with corresponding 95% CIs, with no imputation for missing data and ignoring the grouping within studies. Analysis on the studies separately, and separate analyses on each imputed dataset showed similar results.** In line with the study protocol, no significance test was performed for this secondary outcome.

POS1079 COMPARISON OF CHOLESTEROL PROFILE CHANGES AFTER TREATMENT WITH BIOLOGICS OR JANUS KINASE INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, bDMARD, Comorbidities

J. H. Koh[1], B. W. Lee[2], W. U. Kim[2]. *[1]Uijeongbu St. Mary's Hospital, The Catholic University, Division of Rheumatology, Department of Internal medicine, Euijeongbu, Korea, Rep. of (South Korea)*; *[2]The Catholic University of Korea Seoul St. Mary's Hospital, Division of Rheumatology, Department of Internal medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Janus kinase inhibitor (JAKi) and tumor necrosis factor inhibitor (TNFi) both effectively reduce inflammation, and both increases serum lipid levels. However, in the recent phase 3b-4 trial, major adverse cardiovascular events were higher with tofacitinib than TNFi. Cholesterol is still primary to the development of atherosclerosis, which collaborates with inflammation. Even in the young population, mildly abnormal lipid levels were associated with an increased future risk of atherosclerotic cardiovascular disease events.

Objectives: To assess the effects of biological and targeted synthetic disease-modifying anti-rheumatic drugs (DMARDs) on lipid profiles in patients with moderate-to-severe rheumatoid arthritis (RA).

Methods: This retrospective single-center observational study included patients with RA who initiated and maintained tumor necrosis factor-α inhibitor (TNFi), abatacept, tocilizumab, and Janus kinase inhibitor (JAKi) for at least 6 months. Changes in lipid profile were assessed at months 3 and 6, and associations with clinical efficacy, concomitant medications, and co-morbidities were evaluated.

Results: This study included 114 patients treated with TNFi, 81 patients with abatacept, 103 patients with tocilizumab, and 89 patients with JAKi. Median percent change from baseline to 6 months in total cholesterol, low-density lipoprotein-cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), and non-HDL-C levels were higher in tocilizumab and JAKi versus TNFi and abatacept recipients (16% and 15% vs 6% and 3%, 19% and 24% vs 8% and 3%, 5% and 9% vs 3% and 0%, 19% and 19% vs 7% and 8%, respectively). The significant change in non-HDL-C was associated with JAKi (versus TNFi, OR, 2.671; 95% CI, 1.44–4.956), tocilizumab (versus TNFi, OR, 1.996; 95% CI, 1.087–3.665), concomitant glucocorticoids (OR, 2.802, 95% CI 1.344–5.843), and statin (OR, 0.419; 95% CI 0.230–0.765), and presence of rheumatoid factor (OR, 3.252, 95% CI, 1.029–10.276). However, the change in disease activity in 28 joints was not associated with a significant non-HDL-C change.

Conclusion: Regardless of disease activity changes, tocilizumab and JAKi-associated increases in serum non-HDL-C levels were observed. Combination with glucocorticoids may induce elevations in non-HDL-C, whereas statins may decrease in non-HDL-C.

POS1080

THE IMPACT OF SYNOVITIS OF INDIVIDUAL FINGER JOINTS ON GRIP FORCE OVER THE FIRST FIVE YEARS IN EARLY RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

M. Rydholm[1], A. Sharma[2], L. T. H. Jacobsson[3], C. Turesson[2]. *[1]Skåne University Hospital, Department of Rheumatology, Malmö, Sweden; [2]Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden; [3]Sahlgrenska Academy at Gothenburg University, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*

Background: Rheumatoid arthritis (RA) has a major impact on hand function in many patients. Information on the contribution of individual joints to impaired grip strength may be helpful for guiding individualized management.
Objectives: The objective of this study was to investigate the relation between swelling and tenderness of individual finger joints and grip force over time in patients with early RA.
Methods: An inception cohort of patients with early RA (symptom duration ≤12 months), recruited in 1995-2005, was investigated and followed in a structured program, with follow-up evaluations after 1 and 5 years. All patients were examined by the same rheumatologist according to a structured protocol. Grip force (Newton) was measured using the electronic instrument Grippit (AB Detektor, Gothenburg, Sweden). Average grip force values of each hand were evaluated and compared to the expected, based on age- and sex-specific reference values from the literature [1]. Grip force was expressed as % of expected values. Generalized estimating equations were used to assess the relation between finger joint synovitis and grip force over time. With repeated measures of grip force as the dependent variable, we investigated whether time-varying synovitis of individual metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints were associated with reduced grip force over time. As wrist involvement, high erythrocyte sedimentation rate (ESR) and severe patient reported pain have been independently associated with reduced grip force in early RA (2), the analyses were adjusted for these parameters as time-varying covariates.
Results: A total of 215 patients with early RA (71 % women; mean age 60 years) were investigated. The median symptom duration at inclusion was 7 months; interquartile range 5-10. Clinical synovitis was most frequently observed in MCP I and MCP II (>60% at inclusion in both hands), and less in MCP IV and V (12-13% at baseline). Swelling of individual PIP joints was observed in 16-34% of patients at inclusion. Swollen joint counts (of 28 joints) decreased over time (median 7, interquartile range (IQR) 5-11 at diagnosis; median 4, IQR 4-7 after 5 years), and there was a parallel increase in grip force (mean 39% of expected for both hands at inclusion, 56% for the right hand and 55% for the left hand after 5 years). Synovitis of MCP I and MCP IV was significantly associated with reduced grip over time in both hands, with a similar finding for MCP V in the left hand only (Table 1). PIP synovitis had a lower impact on grip force (Table 1).

Table 1. Relation between synovitis of individual MCP and PIP joints and grip force (% of expected) over the first five years after diagnosis of RA; β (95 % CI), adjusted for wrist synovitis, ESR and VAS pain

	Right hand	Left hand
Synovitis		
MCP I	**-5.0 (-8.3 to -1.7)**	**-3.7 (-6.6 to -0.8)**
MCP II	-1.7 (-4.9 to 1.5)	-1.7 (-4.8 to 1.4)
MCP III	-1.2 (-4.4 to 2.0)	-0.4 (-3.3 to 2.4)
MCP IV	**-4.7 (-9.3 to -0.2)**	**-6.1 (-10.9 to -1.4)**
MCP V	-3.0 (-7.7 to 1.7)	**-6.0 (-10.2 to -1.8)**
PIP I	0.8 (-4.5 to 6.1)	-2.4 (-6.7 to 1.9)
PIP II	0.3 (-3.3 to 3.9)	-1.8 (-5.6 to 1.9)
PIP III	0.7 (-2.6 to 4.0)	-0.6 (-4.4 to 3.3)
PIP IV	-0.3 (-4.4 to 3.9)	0.1 (-4.2 to 4.3)
PIP V	-3.0 (-8.1 to 2.2)	1.1 (-4.6 to 6.9)

MCP: Metacarpophalangeal joint
PIP: Proximal interphalangeal joint

Conclusion: MCP synovitis of the thumb is common in early RA, and a major contributor to reduced grip force over the first 5 years. Although less frequent, involvement of MCP IV and MCP V may also have a significant impact on hand function. Despite improvement, grip force was still impaired 5 years after RA diagnosis. This underlines the importance of both efficient treatment of synovitis and structured hand training in early RA.

POS1081

SERONEGATIVE RHEUMATOID ARTHRITIS (RA) – IS IT REALLY RA?

Keywords: Rheumatoid arthritis

E. Birgersson Wettersand[1], K. Chatzidionysiou[1]. *[1]Karolinska Institute, Rheumatology Division, Department of Medicine Solna, Stockholm, Sweden, Sweden*

Background: The 2010 rheumatoid arthritis (RA) classification criteria are intended for research purposes and classification of the disease and not for diagnostic purposes. It is however a tool which clinicians commonly use in everyday practice when evaluating patients with arthritis. It is clearly stated in the criteria that the synovitis should not be better explained by another disease. However, some patients who are classified as seronegative RA might still have an alternative diagnosis, such as psoriatic arthritis, chronic gout or pseudogout, polymyalgia rheumatica etc. Misclassification has direct impact on treatment, prognosis and follow up of patients, but also on research projects. Increased attention and constant re-evaluation should be embraced in this group of patients to avoid misclassification and promote optimal treatment.
Objectives: To assess the frequency of patients classified as seronegative RA that have a potential alternative diagnosis that could better explain the arthritis.
Methods: This is an observational cohort study including adult patients classified as rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP) negative RA (symptom duration < 1 year), based on ICD-10-SE (M06.0, M06.0M), and without typical RA radiographical changes, between 2015-2019 at Karolinska University hospital. Patients were identified from the Swedish Quality Rheumatology register (SRQ) and had a minimum of 2 years follow-up after RA diagnosis. Additional medical information was collected from the medical charts retrospectively. Patients were re-classified in 6 different groups: G1: presence of symptoms and signs typical for crystal arthritis (gout or pseudogout), and/or hyperuricemia and/or typical ultrasound and/or x-ray changes; G2: symptoms typical for PMR – fulfilment of PMR criteria at the time of RA diagnosis or before; G3: diagnosis of systemic inflammatory disease after RA diagnosis (SLE, myositis, systemic sclerosis, etc); G4: cancer diagnosis one year before or after RA diagnosis; G5: signs of seronegative spondylarthritis (i.e. diagnosis of psoriasis before or after RA diagnosis, development of inflammatory back pain, presence of dactylitis +/- enthesitis); G6: no other diagnosis than seronegative RA which can better explain the polyarthritis.
Results: A total of 229 patients received a diagnosis of RA and fulfilled the criteria (double-seronegativity and absence of radiographical changes) during 2015-2019 and were included in the study. Approximately 85% of the patients had at least 3 years and 50% at least 5 years of follow-up time. The percentage of patients who were re-classified in the 6 subgroups as described above were: G1 = 6.6%, G2 = 6.5%, G3 =3.1%, G4 =7.4%, G5 = 4.4% and G6 =72%.
Conclusion: In this observational study almost one third of patients who received a diagnosis of seronegative RA have an alternative diagnosis than RA that can explain the arthritis, with paramalignant phenomenon, PMR and crystal arthritis being the most common. Increased vigilance in the subgroup of seronegative, non-erosive RA patients is important and constant consideration of differential diagnoses is warrantied.

JOINT INVOLVEMENT IN RA STARTS PREDOMINANTLY IN THE HANDS: FUNCTIONAL, CLINICAL AND IMAGING STUDIES IN CLINICALLY SUSPECT ARTHRALGIA AND DURING PROGRESSION TO RA

Keywords: Rheumatoid arthritis

S. Khidir[1], B. Van Dijk[1], D. Krijbolder[1], M. Verstappen[1], E. Van Mulligen[1,2], A. Van der Helm – van Mil[1,2]. *[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; *[2]Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands*

Background: At time of Rheumatoid arthritis (RA) diagnosis, patients typically present with clinical arthritis of hand and foot-joints. It is unknown whether RA starts in hands or feet.
Objectives: To investigate this, we performed functional, clinical and imaging studies during progression from clinically suspect arthralgia (CSA) to RA. We also studied whether functional disabilities of hands/feet in CSA contribute to predicting RA-development.
Methods: 600 CSA-patients were followed for development of clinical inflammatory arthritis (IA) during a median follow-up of 25 months, of whom 99 developed IA. Functional disabilities were measured at baseline/4/12/24 months with the Health Assessment Questionnaire Disability-Index (HAQ); HAQ-items assessing hand- and foot-disabilities were selected. The course of disabilities towards IA-development (here considered as t=0) was depicted by increasing incidences and analysed using linear mixed models. To evaluate robustness of findings, tender hand/foot joints and subclinical joint-inflammation (measured with CE-1.5TMRI of hand/foot) were additionally studied. Associations between disabilities at CSA-presentation (here t=0) and future IA-development were studied using Cox-regression in the total CSA-population.
Results: During IA-development, hand-disabilities occurred earlier and more frequently than foot-disabilities. Despite both hand- and foot-disabilities rose significantly towards IA-development, hand-disabilities were more severe during this course (mean difference over time: 0.41 units,95%CI=0.28-0.55,p<0.001, on a range 0-3). Similar to functional disabilities, tender joints and subclinical joint-inflammation occurred earlier in the hands than feet (Figure 1). In the total CSA-population, a single HAQ-question on difficulties with dressing (hand-functioning) was independently predictive for IA-development: HR=2.2,95%CI=1.4-3.5,p=0.001.
Conclusion: Evaluation of functional disabilities, supported by clinical and imaging findings, revealed that joint involvement starts predominantly in the hands during RA-development. Additionally, a single question on dressing-difficulties adds value to risk stratification in CSA-patients and is easy to use in clinical practice.

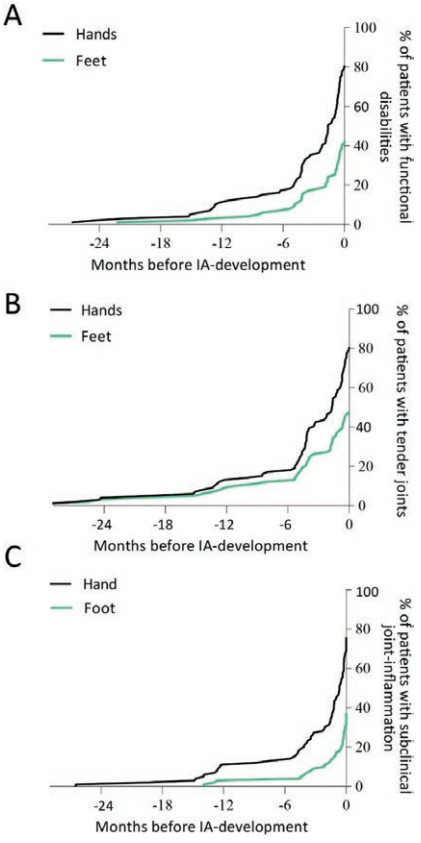

Figure 1. Functional disabilities (A), tender joints (B) and subclinical joint-inflammation (C) towards IA-development occur earlier and more frequently in the hands than in the feet lines depict the increasing incidence of functional disabilities (HAQ), tender joints (physical examination) and subclinical joint-inflammation (MRI-detected) in the hands and feet prior to development of inflammatory arthritis.Abbreviations: HAQ= Health Assessment Questionnaire; IA= inflammatory arthritis.

Background: Management of difficult to treat (D2T) inflammatory arthritis requires meticulous evaluation for the presence or absence of inflammation to support pharmacological and non-pharmacological management strategies. The challenge arises from the finding that D2T has been linked to a variety of characteristics. The EULAR Task Force has recently defined D2T rheumatoid arthritis as patients having persistency of symptoms and/or signs despite failure of at least two biological or targeted synthetic disease modifying anti-rheumatic drugs with different mechanisms of action. However, the proposed EULAR Task Force definition of D2T was based on just one assessment at one moment of time, during which flare up of the disease may not be reflective of the actual disease activity status.
Objectives: To address the unmet needs and derive a comprehensive, yet precise, approach to define the inflammatory arthritis patients who are "Difficult-to-Treat".
Methods: Five key clinical questions including 20 domains were identified by core scientific committee. Literature Review team performed a systematic review to summarize evidence advocating the D2T definition, assessment and management, as well as benefits and harms of available pharmacologic and non-pharmacologic therapies. Subsequently, recommendations were formulated. The level of evidence was determined for each section using the Oxford Centre for Evidence-based Medicine (CEBM) system. A 3-round Delphi process was conducted. All rounds were conducted online. Consensus, consequently, to become a recommendation, would be achieved if at least 80% of participants reached agreement (score 7-9). A consensus was achieved on the direction and the strength of the recommendations.
Results: The work proposed an inclusive definition of D2T in inflammatory arthritis based on 4 pillars: "persistent inflammation that continues to cause significant burden despite standard treatment as perceived by the treating rheumatologist and/or the patient". Two extra factors have been suggested to be added to the EULAR definition. These are "disease burden" and "timeframe" for the assessment of the disease activity status. "Continuous disease burden" has been defined as having difficulties in: Achieving treatment target, controlling disease progression, sustained elevation of the acute phase response over 3 months period attributed to the inflammatory joint disease, lack of functional restoration and poor quality of life despite good

symptomatic control, and treatment compliance due to: unacceptable tolerability or non-adherence or rejection of the treatment option. Time frame has been identified as: persistent joint inflammation (active/progressive disease") has been documented according to validated composite measures including joint counts in 2-readings, 3-months apart. Level of agreement was high and in the range of 8.17-8.83).

Conclusion: this study revealed a consensus that time factor is vital to consider inflammatory arthritis as persistent, hence meet the difficult to treat definition. Adding the "continuous disease burden has added another dimension to the management of D2T, advocating a more holistic approach toward the patient rather than observing a patient through the prism of the index disease.

POS1084 EFFECT OF RHEUMATOID ARTHRITIS ON TOTAL KNEE ARTHROPLASTY

Keywords: Rheumatoid arthritis

W. Jeong[1], J. Kim[1]. *[1]Jeju National University Hospital, Internal Medicine, Jeju, Korea, Rep. of (South Korea)*

Background: According to the results of previous studies, it has been reported that rheumatoid arthritis (RA) patients receive total knee arthroplasty (TKA) at a younger age than osteoarthritis (OA) patients. However, studies on the effect of RA on TKA are still insufficient.

Objectives: We conducted this study to find out how RA affects primary TKA and revision arthroplasty.

Methods: The data of OA and RA patients who underwent primary TKA and revision at Jeju National University Hospital between March 2003 and December 2022 were retrospectively analyzed. To exclude the effect of other connective tissue diseases, patients with SLE, Sjogren's syndrome, polymyalgia rheumatica, mixed connective tissue disease, undifferentiated connective tissue disease, Behcet's disease, systemic sclerosis, and vasculitis were excluded.

Results: A total of 5245 TKAs were performed, and the average age at primary TKA was 72.4 ± 6.4 years, and 2292 (85.7%) were female. When they were divided into OA group and RA group, RA knees were 159 (3.1%). The age at primary TKA in the RA group was significantly smaller (69.6 ± 6.8 vs 72.5 ± 6.4, p<0.001), and the female ratio was higher (91.9% vs 85.5%, P=0.031). Although the rate of revision surgery was not statistically significant, the RA group had more (5.6% vs 3.1%, p=0.111), and the period to revision tended to be shorter in the RA group (33.8 ± 49.2 months vs 67.7 ± 56.1 months). month, p=0.078). The cause of reoperation was not significantly different between the two groups, but the rate of infection was higher in the RA group (55.6% vs 43.7), and reoperation due to loosening was more common in the OA group (46.2% vs 22.2%). There was no difference in other test values at the time of surgery, but in the RA group, ESR (43.8 ± 31.7 mm/h vs. 26.6 ± 22.6 mm/h, P<0.001), CRP (1.8 ± 2.3 mg/dL vs. 0.8 ± 2.1 mg/dL, p<0.001) was significantly higher. The incidence of TKA was higher in the RA patients than OA patients (1436.2 per 100,000 Person-Years vs 1379.7 per 100,000 Person-Years). When comparing the risk of patients undergoing primary TKA during their lifetime by adjusting for gender, it was found that RA patients started receiving primary TKA at a younger age and had a significantly higher risk of undergoing TKA (HR 1.48, 95% CI 1.263–1.733, P<0.001). As a result of logistic regression analysis, the increase in ESR (OR 10.2, 95% CI 1.01-1.03, P=0.001) and CRP (OR 1.09, 95% CI 1.01-1.17, P=0.021) at the time of primary TKA increase risk of revision arthroplasty, but RA did not.

Conclusion: Patients with RA have a higher risk of primary TKA and start primary TKA at a younger age, and the increased inflammation level at the time of primary TKA increase risk of revision arthroplasty, so it is recommended to perform primary TKA after inflammation is controlled.

POS1085 INITIATION OF A JANUS KINASE INHIBITOR BEFORE AND AFTER THE SAFETY WARNINGS: CHANGES IN CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Registries, Comorbidities, Disease-modifying drug (DMARDs)

D. Huschek[1], P. Herzer[2], A. Zink[3], M. Feuchtenberger[4], A. Strangfeld[1,5]. *[1]German Rheumatism Research Center Berlin, Epidemiology and Health Services Research, Berlin, Germany*; *[2]Rheumatologist, Private Practice, München, Germany*; *[3]Scientific Advisory Board, RABBIT, Berlin, Germany*; *[4]Rheumatologist, Innklinikum, Burghausen Altötting, Germany*; *[5]Charité, Universitätsmedizin, Berlin, Germany*

Background: In 2019, 2020 and 2021, the European and US-American regulatory agencies issued warnings about venous thromboembolism, major cardiovascular events and malignancy risks associated with the Janus kinase inhibitor (JAKi) tofacitinib and required changes in labelling.

Objectives: To investigate whether characteristics of patients with rheumatoid arthritis receiving a JAKi versus biologic therapy differed before and after the safety warnings.

Methods: Data from patients who started with any JAKi or biologics treatment in the German biologics register RABBIT between 01/2017 and 04/2022 were included. Multivariate logistic regression analyses were used to understand differences in characteristics of patients starting a JAKi treatment versus a biologic treatment in three annual cohorts: 2017 the year JAKis became available in Germany, 2019 before the EMA safety warnings and 2021. In each year, only the first treatment episodes of each JAKi, TNF inhibitor, interleukin-6 inhibitor or B/T-cell targeted therapy were considered. Prior treatment episodes were possible. The logistic regressions were corrected for clustering at the patient level. In 2017, we included 549 JAKi versus 2510 bDMARD treatment episodes, in 2019 674 versus 2233 and in 2021 700 versus 1296 episodes.

Results: Patient characteristics at treatment start have changed over time. In 2017, compared to patients receiving a biologic, patients starting a JAKi had been treated with a higher number of therapies, had a higher (worse) physician reported heath and were more likely to have comorbidities such as hypertension, coronary heart disease, diabetes, hyperlipoproteinaemia, thrombosis, malignancy or lymphoma. In 2019, patients initiating a JAKi therapy compared to a biologic were less likely to be women, had a worse physician reported health and were more likely to receive a dose of less than 10mg glucocorticoids than none. In 2021, after the safety warnings, compared to patients receiving a biologic, those who started a JAKi were older, had a worse physician reported health, had received a higher number of previous therapies, had poorer self-reported health and were less likely to receive a high dose of glucocorticoids. Although not significant, patients with comorbidities were less likely to receive a JAKi.

Conclusion: The analyses show that after the launch of JAKi treatment in 2017, comorbidities increased the likelihood to receive JAKis as a new treatment option. In 2021, patients with a high disease burden and with many other previous therapies were more likely to receive JAKis, but not those with comorbidities. This development shows that rheumatologists in Germany follow the safety recommendations and consider the patients' disease burden and risk factors when prescribing JAKis.

EFFICACY OF PHARMACOLOGICAL INTERVENTIONS: A SYSTEMATIC REVIEW INFORMING THE 2023 EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF FATIGUE IN PEOPLE WITH INFLAMMATORY RHEUMATIC AND MUSCULOSKELETAL DISEASES

Keywords: Patient reported outcomes, Systematic review, bDMARD

B. Farisogullari[1], E. Santos[2], E. Dures[3,4], P. Machado[5,6,7]. *[1]Faculty of Medicine, Hacettepe University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[2]Nursing School of Coimbra (ESEnfC), Health Sciences Research Unit: Nursing (UICISA: E), Coimbra, Portugal*; *[3]Bristol Royal Infirmary, Academic Rheumatology, Bristol, United Kingdom*; *[4]University of the West of England, Faculty of Health and Applied Sciences, Bristol, United Kingdom*; *[5]University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom*; *[6]University College London Hospitals NHS Foundation Trust, National Institute for Health Research (NIHR) University College London Hospitals Biomedical Research Centre, London, United Kingdom*; *[7]Northwick Park Hospital, London North West University Healthcare NHS Trust, Department of Rheumatology, London, United Kingdom*

Background: There is evidence that pharmacological interventions, including biologic therapies, can improve inflammation, disease activity and function in inflammatory rheumatic and musculoskeletal diseases (I-RMDs), and fatigue has increasingly been included as a secondary outcome of I-RMDs clinical trials. However, no systematic review (SR) has established the evidence for the pharmacological management of fatigue in people with I-RMD [1,2].
Objectives: To identify the best evidence on the efficacy of pharmacological interventions in reducing fatigue in people with I-RMDs and to summarise their safety in the identified studies to inform EULAR recommendations for the management of fatigue in people with I-RMD.
Methods: Systematic review of adults with I-RMD conducted according to the Cochrane Handbook. Search strategy ran in Medline, Embase, Cochrane Library, CINAHL Complete, PEDro, OTseeker and PsycINFO. Assessment of risk of bias, data extraction, and synthesis performed by two reviewers independently. Data pooled in statistical meta-analyses.
Results: From a total of 4,150 records, 454 were selected for full-text review, 105 fulfilled the inclusion criteria, and 19 RCTs were included in meta-analyses. Adalimumab was superior to placebo in reducing fatigue at 52 and 12 weeks (wk) in rheumatoid arthritis (RA) (mean difference [MD]=-2.25, p=0.03; MD=-3.03, p<0.001; respectively) and psoriatic arthritis (MD=-3.16, p=0.26). Golimumab (24wk: MD=-5.27, p<0.001), baricitinib (24wk: MD=-4.06, p<0.001), sarilumab (24wk: MD=-3.15, p<0.001), tocilizumab (24wk: MD=-3.69, p<0.001) and tofacitinib (12wk: MD=-4.44, p<0.001) were also superior to placebo in reducing fatigue in RA. A dose/effect relationship was observed for sarilumab, tocilizumab and tofacitinib. In spondyloarthritis, secukinumab was superior to placebo in reducing fatigue at 16wk (MD=-4.15, p<0.001), with a dose/effect relationship also observed (**Figure 1**). The narrative results of the RCTs not included in the meta-analysis indicated that several other pharmacological interventions were efficacious in reducing fatigue, with reassuring safety results.
Conclusion: Pharmacological interventions are efficacious and safe for the management of fatigue in people with I-RMD.

THE PATIENT-PERSPECTIVE AND FEASIBILITY OF HOME FINGER PRICK TESTING TO COMPLEMENT AND FACILITATE LARGE SCALE DIGITAL DATA COLLECTION

Keywords: Health services research, Inflammatory arthritides, Patient reported outcomes

Y. Besten[1], L. Boekel[1], M. Steenhuis[2], F. Hooijberg[1], M. Leeuw[1], S. Atiqi[1], E. Vogelzang[3], J. Keijser[2], O. Cristianawati[2], S. Keijzer[2], F. Loeff[2], M. Gerritsen[1], S. Tas[4], M. Nurmohamed[1,5], T. Rispens[2], G. Wolbink[1,2]. *[1]Reade, Locatie Dr. Jan Van Breemenstraat, Rheumatology, Amsterdam, Netherlands*; *[2]Sanquin Research and Landsteiner Laboratory, Immunopathology, Amsterdam, Netherlands*; *[3]Amsterdam UMC, locatie AMC, Medical Microbiology and Infection Control, Amsterdam, Netherlands*; *[4]Amsterdam UMC, locatie AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[5]Amsterdam UMC, locatie VUmc, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*

Background: Previous studies have shown that using a finger prick as the primary method for blood withdrawal is an efficient way to collect blood samples remotely, and data on blood levels from a finger prick are directly comparable to that obtained by a venepuncture. During the COVID-19 pandemic, we therefore complemented our large digital research platform with serum collection via a home finger prick testing in order to collect samples without the need of visits to a hospital. This repeatedly enabled us to rapidly answer new and relevant clinical research questions about COVID-19, thereby showing the potential of the finger prick for research purposes. However, the use of finger pricks in a research or clinical practice setting is still uncommon, and not yet tested on a large scale. In addition, there is limited data on peoples' willingness and ability to successfully use the finger prick at home, especially in patients with inflammatory rheumatic diseases (iRD) who may have impaired hand function.
Objectives: To investigate the feasibility of finger prick testing in combination with a digital research platform by evaluating the success rate and patients' perspective towards the use of the finger prick.
Methods: Data were collected from an ongoing prospective cohort study including patients with iRD from the Amsterdam Rheumatology & immunology Center and healthy controls. Serum samples were collected up to eight times during follow-up via blood withdrawal by venepuncture at the local research institute or via a finger prick that could be performed at home. For the latter option, participants were instructed to collect three drops of blood, which would yield approximately 40-80 µL of serum after clotting. All study participants were questioned about their preference for a particular sampling method for individual healthcare and for scientific research. Participants who received a finger prick test before June 26, 2021, were asked to complete a digital evaluation questionnaire of the finger prick after their attempt. The finger prick was defined as failed when less than 10 µL of serum could be recovered from the collection device, or if no sample was returned to the laboratory and participants indicated in the questionnaires that they did not succeed in collecting the required amount of serum.
Results: A total of 3080 patients with iRD and 1102 healthy controls were included in the study. Of these, 2135 (69%) patients and 899 (82%) controls attempted to execute at least one finger prick, and 1439 (67%) patients and 712 (21%) controls executed multiple finger pricks. The first finger prick was successfully done by 92% (CI 90 – 93) of iRD patients, 94% (CI 92 – 95) of healthy controls, 93% (CI: 92 – 94) of all participants aged 70 years or younger, and 89% (CI 86 – 92) of all participants aged above 70 years (Table 1). Sex did not impact

these success rates. Repeated failure occurred in 11 of 1439 (0.8%) patients and 4 of 712 (0.6%) controls. The two most common reasons for perceived failure of the finger prick were related to insufficient blood yield when applying the finger prick. Finally, both patients and controls were less willing to perform a finger prick for individual healthcare compared to scientific research; 31% of patients and 61% of controls were willing to perform a finger prick for scientific research compared to 19% of patients and 39% of controls for healthcare. The most important reason for this was lower confidence in the execution and laboratory measurements when blood was drawn via a venepuncture compared to a finger prick.

Conclusion: In this study, we demonstrated that the vast majority of participants, among which elderly and patients of whom hand function may be impaired by an underlying rheumatic disease, were able to successfully draw the required amount of blood for serological analyses. This shows that the finger prick testing is suitable for a high-throughput implementation to monitor patients remotely, which will likely contribute to improving the efficiency and cost-effectiveness of both healthcare and scientific research.

PSYCHOLOGICAL DISTRESS OVER 12 MONTHS POST-DIAGNOSIS IN A NATIONAL EARLY INFLAMMATORY ARTHRITIS COHORT

Keywords: Mental health, Inflammatory arthritides, Patient reported outcomes

L. Zhao[1], J. Galloway[2], J. Ledingham[3], S. Gallagher[4], N. Garnavos[4], P. Amlani-Hatcher[4], N. Wilson[2], L. Carpenter[5], K. Bannister[6], S. Norton[2,5]. *[1]King's College London, Institute of Psychiatry, Psychology, and Neuroscience, London, United Kingdom*; *[2]King's College London, Center for Rheumatic Diseases, London, United Kingdom*; *[3]Portsmouth Hospitals University NHS Trust, Rheumatology Department, Portsmouth, United Kingdom*; *[4]British Society for Rheumatology, National Early Inflammatory Arthritis Audit (NEIAA), London, United Kingdom*; *[5]King's College London, Department of Psychology, London, United Kingdom*; *[6]King's College London, Wolfson Centre for Age-Related Diseases, London, United Kingdom*

Background: In inflammatory arthritis patients, the concomitant decline of their mental wellbeing is an increasing concern[1,2]. It is important to not only describe the trajectory of psychological distress in early disease stages, but also understand which clinical outcome measures are most associated with these changes.

Objectives: Using data from the National Early Inflammatory Arthritis Audit (NEIAA), we assessed trends in psychological wellbeing over 12 months after initial diagnosis and mapped these against clinical outcomes to identify significant associations.

Methods: NEIAA collects data from patients referred with suspected early inflammatory arthritis in rheumatology services in England and Wales. We used data provided by 20,472 patients eligible for follow-up (diagnosis of inflammatory arthritis) between May 1st, 2018, and April 1st, 2022. Data items included baseline demographics e.g., age and gender, and clinical variables e.g., rheumatic disease comorbidity index (RDCI), DAS28, and patient reported outcomes. Psychological distress was measured by the sum score of Patient Health Questionnaire Anxiety and Depression Screener (PHQ4ADS). Using mixed effects regression models, we analysed the co-variability of PHQ4ADS with demographic factors and clinical outcomes over 12 months. Time was included as a dummy-coded covariant.

Results: The analysis included 36% of patients (7,378 out of 20,472) who completed the baseline patient outcome survey. In this cohort, PHQ4ADS scores decreased from a baseline average of 4.7 (CI: [4.6, 4.8]) to 2.62 (CI: [2.5, 2.8]) at 12 months post-diagnosis. The proportion of patients screening positive decreased from 50.0% (CI: [48.9, 51.1]) at baseline to 23.8% (CI: [21.8, 25.9]) at 12 months. At baseline, psychological distress correlated significantly with age, gender, ethnicity, RDCI, prior depression diagnosis, and baseline DAS28 (Figure 1). No significant correlations were found between psychological distress and working diagnosis, seropositivity, or the assessment being recorded after the start of the COVID-19 pandemic. Younger ages were nonlinearly associated with higher distress levels (coefficient per decade: -0.006; p<0.001; CI: [-0.009, -0.003]) (Figure 1a). Distress levels in females were higher than that of males (coefficient: 0.5; p<0.001; CI: [0.4, 0.7]) (Figure 1b). White patients reported lower PHQ4ADS scores compared to non-white patients (coefficient: -0.7; p<0.001; CI: [-1.0, -0.4]) (Figure 1c). Higher distress levels were also associated with higher RDCI (coefficient: 0.2; p<0.001; CI: [0.1, 0.3]) and prior diagnosis of depression (coefficient: 1.8; p<0.001; CI: [1.5, 2.2]) (Figure 1d, 1e). Furthermore, higher baseline DAS28 scores correlated with more severe psychological distress (coefficient: 0.8; p<0.001; CI: [0.7, 0.8]) (Figure 1f). By 12-months, psychological distress decreased significantly overall, which correlated significantly with ethnicity (coefficient: 0.8; p=0.005; CI: [0.3, 1.4]) and baseline DAS28 (coefficient: -0.5; p<0.001; CI: [-0.6, -0.4]). Compared to white patients, the reduction was significantly greater for non-white patients, but the level of distress was no longer different at 12 months (Figure 1c). While those with higher baseline DAS28 showed a greater reduction in psychological distress, the distress levels remained higher at 12 months (Figure 1f).

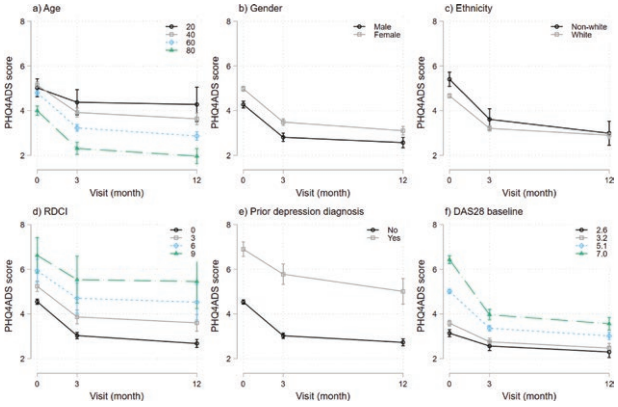

Figure 1. Changes in psychological distress correlated with age, gender, ethnicity, RDCI, prior depression diagnosis, and baseline DAS28.

Conclusion: In this early inflammatory arthritis cohort, mental health burden was high. Age, gender, ethnicity, RDCI, prior depression diagnosis and baseline DAS28 significantly correlated with psychological distress at baseline. Supporting mental health should be a focus of clinical care for this population and it may be beneficial to use an approach that is culturally valid for non-white patients and accounts for multimorbidity.

Background: Despite the establishment of national and international recommendations for the management of patients with rheumatoid arthritis (RA), remediable deficits in the quality of care (QoC) still exist. On behalf of the German Society for Rheumatology, with participation of the patient organization Deutsche Rheuma-Liga, eight Quality standards (QS) have been developed to improve the QoC in Germany. The QS can be used to determine and quantitative gaps in QoC in respect to time to diagnosis, use of glucocorticoids, rates of remission and impairments in physical function [1].

Objectives: To quantify gaps in QoC based on five QS in patients with RA for whom data from the National Database of the German Collaborative Arthritis Centres (NDB) exists.

Methods: In 2020, 4863 patients with RA from 12 Rheumatology centres were followed in the NDB. Five QS were reviewed: (QS1) How often was RA diagnosed within 8 weeks of symptom onset? (QS2) How many patients are in remission? (QS3) How many patients are in glucocorticoid-free remission? (QS4) How many patients who were not in remission had their medication adjusted? (QS5) How many patients with impairments in physical function received physiotherapy, functional training, and/or rehabilitation? Remission was investigated both by DAS28 and by CDAI cut-offs. Impairments in physical function were assessed with the FFbH (≤70% of full function). Switches, additions, or dose increases of disease-modifying antirheumatic drug (DMARD) were considered adjustment of medication. Individual components of the DAS28 are reported to determine reasons for not achieving remission.

Results: Fulfillment of QS (Figure 1) was investigated in 4863 patients (Table 1). In 2020, 76 patients had their first contact to rheumatologist and 30 were seen by a rheumatologist within 8 weeks (39%). Of 61 patients with available diagnosis date, 25 (41%) were diagnosed within 8 weeks. 1523 of 3410 patients with available DAS28 were in DAS28 remission (45%) and 933 of 4023 patients with available CDAI were in CDAI remission (23%). 1155 of 1520 patients in DAS28 remission and 789 of 930 RA patients in CDAI remission were glucocorticoid-free (76%/85%). 373 of 1676 patients who were not in DAS28 remission had adjustment of medication (22%). Patients without therapy adjustment had fewer clinical signs of inflammatory activity (SJC 1.3 vs. 2.6, TJC 2.6 vs. 3.7, ESR 25.7 vs. 27.4, Physician global 1.8 vs. 2.8, Patient disease activity 4.1 vs. 4.8) compared to patients with adjustment of medication. 68 of 149 patients with high disease activity (DAS28>5.1) had adjustment of medication (46%). 377 of 772 patients with impairments in physical function and information on physiotherapy received physiotherapy (49%), 32 of 767 patients with data on functional training received functional training (4%) and 117 of 1175 patients with data on rehabilitation received rehabilitation (10%).

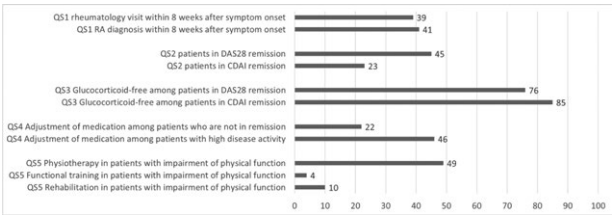

Figure 1. Fulfillment of quality standards (%)

Conclusion: With the new QS, QoC of patients with RA can be measured in a standardized form. While some results reflect high quality of care, other QSs point to opportunities for improvement. The implementation of the QS enables both a comparative evaluation at facility level and a general rheumatology health care outcome. This will help to optimize the QoC for patients with RA in Germany.

POS1091

INFLAMMATION IS MORE PROMINENT THAN JOINT DAMAGE AT INITIAL VISITS OF PATIENTS WITH INFLAMMATORY ARTHRITIDES, BUT ORGAN DAMAGE AND PATIENT DISTRESS ARE AS PROMINENT IN OVERALL RHEUMATOLOGY CARE: DATA FROM A FEASIBLE PHYSICIAN RHEUMATIC CHECKLIST

Keywords: Inflammatory arthritides, Treat to target, Comorbidities

T. Pincus[1,1,1,1], T. LI[2], J. Schmukler[1]. [1]*RUSH University Medical Center, Medicine/Rheumatology, Chicago, United States of America*; [2]*Georgetown University, Biostatistics, Bioinformatics & Biomathematics, Washington, United States of America*

Background: Patients consult rheumatologists for symptoms which may result from inflammatory activity (INF), joint or other organ damage (DAM) and/or distress (STR), e.g., fibromyalgia, depression. However, quantitative assessment in routine rheumatology care is directed primarily (often exclusively) to INF, e.g., DAS28, CDAI, SLEDAI, ASDAS, and DAPSA. DAM and STR are recognized in many patients, but generally recorded only as narrative descriptions, rather than as quantitative data. INF indices function effectively in clinical trials, but measures and indices designed to assess INF may be elevated in many unselected routine care patients by comorbid DAM and/or STR, often despite little or no INF. A RheuMetric checklist includes 4 0-10 visual numeric scales (VNS) for physician global assessment (DOCGL), DOCINF, DOCDAM, and DOCSTR, and estimates of the % of DOCGL attributed to INF, DAM, and STR.

Objectives: To analyze RheuMetric scores in unselected routine care patients with all diagnoses at initial or return visits to an academic rheumatology setting.

Methods: A retrospective cross-sectional study was performed of RheuMetric checklist 0-10 VNS estimates for DOCGL and estimates of %INF, %DAM, and %STR (total=100%) completed in routine care by the treating rheumatologist. Mean levels of these estimates were analyzed according to primary diagnosis, classified as INF (RA, SLE, SpA, vasculitis and gout), osteoarthritis (OA), primary fibromyalgia (FM), and "other," at initial or return visits, using descriptive and chi-square statistics.

Results: Highest DOCINF was in inflammatory diseases, DOCDAM in OA, and DOCSTR in primary FM (Table 1). The % of DOCGL attributed to INF, DAM, and STR was highest in INF diseases, OA, and primary FM, respectively

Table 1. Cross sectional analyses of mean (standard deviation) for 0-10 physician global estimate (DOCGL) and % of DOCGL attributed to inflammation (%INF), damage (%DAM), and patient distress (%STR) (Total=100%) at 244 first visits compared to 319 return visits

	Initial visits					Return visits				
Primary rheumatic physician ICD-10 diagnosis	N (%)	DOC GL	Mean (SD) % of DOCGL attributed to…			N(%)	DOC GL	Mean (SD) % of DOCGL attributed to…		
		DOC GL	% INF	% DAM	% STR		DOC GL	% INF	% DAM	% STR
Inflammatory diseases (RA, SLE, SpA, Vasc, Gout)	67 (27%)	4.3 (2.5)	62%Δ (33%)	24% (24%)	14% (24%)	127 (40%)	3.7 (2.6)	33%Δ (31%)	49% (35%)	18%* (27%)
Osteoarthritis	45 (18%)	4.4 (2.0)	14% (19%)	72%Δ (28%)	14% (18%)	69 (22%)	5.0 (2.2)	7% (14%)	69%Δ (30%)	24% (28%)
Fibromyalgia	32 (13%)	4.9 (2.6)	14% (22%)	12% (16%)	74%Δ (28%)	36 (11%)	5.0 (2.0)	12% (21%)	20% (21%)	68%Δ (26%)
Other diagnosis	100 (41%)	3.0 (2.1)	37% (33%)	35% (31%)	29% (33%)	87 (27%)	3.5 (2.4)	26% (29%)	52% (35%)	22% (30%)
TOTAL	244 (100%)	3.9 (2.4)	36% (35%)	36% (33%)	28% (34%)	319 (100%)	4.1 (2.5)	22% (28%)	51% (35%)	28%◊ (32%)

Δ32%)35%))nosisseases (RA, SLE, SpA, Vasc, Gout) at 244 first visits compared to 319 return visits

(p<0.001) (Table 1). At initial visits of patients with INF, mean DOCGL was 4.3, attributed 62% to INF, 24% to DAM and 14% to STR, respectively; at return visits, DOCGL was 3.7, attributed 33% to INF, 49% to DAM and 18% to STR (Table 1). In patients with all diagnoses, 36%, 36%, and 28% of DOCGL were attributed to INF, DAM, and STR, respectively, at first visits, vs 22%, 51%, and 28% at return visits (Table 1). RheuMetric estimates required 15-20 seconds to complete.

Conclusion: RheuMetric physician estimates for INF, DAM, and STR are feasibly assessed in routine care, with face validity documented by significantly higher INF in inflammatory diseases, DAM in OA, and STR in FM. DOCINF was higher at first vs return visits, reflecting highly effective anti-inflammatory treatments at this time, while %DOCDAM rose. At return visits, INF accounted for 22% of DOCGL vs 50% for DAM and 28% for STR, indicating that control of inflammation is not the primary activity in overall rheumatology care after the first visit.

PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOR IN PATIENT WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES: A CASE CONTROL STUDY

Keywords: Lifestyles, Rehabilitation, Inflammatory arthritides

A. Adnine[1], F. Z. Taik[1], N. Takhrifa[1], N. Soba[2], F. Z. Aharrane[1], M. Fourtassi[2], F. E. Abourazzak[1]. [1]*Abdelmalek Essaidi University, Faculty of Medecine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco*; [2]*Abdelmalek Essaidi University, Faculty of Medecine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco*

Background: Engaging in regular physical activity (PA) is important in maintaining health and increasing the overall quality of life of patient living with chronic inflammatory rheumatic diseases (CIRD). Its is assumed that patients with CIRD reports low levels of physical activity. In the era of evidence-based medicine few studies compare PA levels and its predictors between patient with CIRD and healthy control.

Objectives: we aim to investigate PA levels of patients with CIRD, to examine predictors of PA and furthermore compare findings to healthy control.

Methods: A cross-sectional study was performed among patients with CIRD Aged between 18 and 65 years old who visited the outpatient clinic between April 2022 and October 2022. The diagnosis of spondyloarthritis was based on ASAS criteria and the diagnosis of rheumatoid arthritis was based on ACR/EULAR 2010 criteria. Healthy controls were recruited in a specialized consultation. Socio-demographic findings were collected. Patients were assessed for pain and disease activity using visual analogic scale (VAS), DAS28 CRP and ASDAS CRP. Physical activity levels were assessed using the international physical activity questionnaire (IPAQ-SF). Furthermore, all participants underwent screening for anxiety and depressive disorders using Patient health questionnaire (PHQ-9) and General anxiety disorder (GAD-7) respectively.

Results: The final study simple was made up of 172 patients (92 RA, 65 SpA and 15 Undifferentiated CIRD) and 159 healthy controls.

Table 1. socio-demographic informations, clinical findings and physical activity levels of patients with CIRD and healthy controls.

	Patients with CRID N= 172	Healthy controls N= 159	p Value
Age (Mean ±SD)	45,97 ± 12,063	45,53 ± 12,244	P= 0.787
Sexe (female pourcentage)	72,7%	70,3%	P= 0.654
BMI (Median percentiles)	25 [20.93, 28.08]	26.39 [23.63, 29.75]	P=0.033
Socioeconomic status:	Low: 50.6 %(n=87) Medium: 28.5 %(n=49) High: 1.7 % (n=3) Don't Know: 19,2 %(n=33)	Low: 28.9 % (n=46) Medium: 40.3 % (n=64) High: 11.3 % (n=18) Don't Know: 19,5 % (n=31)	P=0.007
IPAQ-SF: Met/min/week (Median percentiles)	936 [231, 4282]	1546 [864, 3612]	P= 0.001
IPAQ-SF: category	Low PA: 38.4% (n=63) Moderate PA: 32.9%(n=54) High PA: 28.7% (n=47)	Low PA: 17% (n=27) Moderate PA: 31.4% (n=50) High PA:51.6% (n=82)	P=0.000
Sedentary behavior: Min/day (IPAQ-SF)	120 [60, 240]	120 [60, 180]	P= 0.015
Depression PHQ-9 scale	8 [5, 14]	4 [1, 9]	P=0.000
Anxiety GAD-7 scale	8 [4.75, 12]	6 [3, 10]	P=0.001
Disease duration year	8 [3, 17]	N/A	N/A
Disease activity	Remission: 39 %(n=67) Low disease activity: 11.6% (n=20) Moderate disease activity: 24.4%(n=42) High disease activity: 25%(n=43)	N/A	N/A

In patients with CIRD uni and multivariate analysis showed no association between PA levels and disease related variables: Disease activity(OR (95%CI) = -0.032 (-0.160, 0.095); p=0.61), disease duration(OR (95%CI) = -0.013 (-0.028, 0.003); p=0.111) and comorbidities(OR (95%CI) = -0.013 (-0.109, 0.083); p=0.794) on the contrary PA levels were negatively associated with depression (OR (95%CI) = -0.011(-0.021,- 0.002); p=021)In healthy controls uni and multivariate analysis showed that PA levels were negatively associated with age (OR (95%CI) =-0.013 (-0.004, -0.023; p=0.007)), BMI (OR (95%CI) = -0.029 (-0.051, - 0.006; p=0.013)) and depression (OR (95%CI) =-0.029 (-0.049, - 0.009; p=0.004)).

Conclusion: Our study shows that patients with CIRD reports significantly low levels of PA and high level of SB compare to healthy controls. The unexpected finding in our study is that low levels of PA in patients with CRDI were not associated with disease activity nor disease duration. Depressive disorders are an important predictor of physical inactivity and sedentary behavior regardless of the presence of CRID. Depressive disorders are common among patients with CRID. Screening for depression and treating in time is essential to help overcome sedentary behavior in our patient and community.

POS1093

WHO ARE THE PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASE IN NEED TO SPECIALISED MULTIDISCIPLINARY REHABILITATION?

Keywords: Rehabilitation, Non-pharmacological interventions

E. Besada[1,2,3]. [1]*Fysikalskmedisinsk avdeling, UNN Tromsø, Tromsø, Norway*; [2]*Medisinsk avdeling Kirkenes, Finnmarkssykehuset, Kirkenes, Norway*; [3]*Institutt for klinisk medisin, UiT Norges arktiske universitet, Tromsø, Norway*

Background: Patients with inflammatory rheumatic disease, while receiving highly effective disease-modifying antirheumatic drugs, are still referred to multidisciplinary rehabilitation in specialised centres. Although multidisciplinary rehabilitation only have small and short-term improvements in patients' outcome, it could benefit patients with specific disability and rehabilitation needs, indicating a more complicated disease [1].
Objectives: In order to identify the specific rehabilitation needs of patients with inflammatory rheumatic disease, it is of paramount importance to describe their clinical characteristics. The present study includes all patients with inflammatory rheumatic disease who were referred to multidisciplinary rehabilitation in Northern Norway between 2018 and 2021.
Methods: In Norway, the cost of multidisciplinary rehabilitation in specialised centres is covered by the national welfare system. However patients must be referred by a physician and the referral approved by the regional assessment office (rehabilitation regional vurderingsenhet) at the University Hospital of North Norway. All patients referred to multidisciplinary rehabilitation were included in this longitudinal study; the study was retrospective from January 1st 2018 to 31st December 2018 and afterwards prospective to June 10th 2021. Data were extracted from referrals and hospital discharge summaries. Age, gender, diagnosis, county and municipality, referring physicians were collected in all patients. Major symptoms and associated diseases were later included in the study.
Results: 786 patients out of 1028 referrals were referred to multidisciplinary rehabilitation during the study period. The referral rate was 0.39 and 0.56/1000 persons/year for respectively the counties of Nordland and Troms-Finnmark. Patients´ mean age was 54 and 76 % were women. 43 % of all patients were first time referral. 56 % had spondyloarthritis, 23 % rheumatoid arthritis, 15 % connective tissue disease and 3.3 % vasculitis including polymyalgia rheumatica. The most common associated diseases were osteoarthritis and obesity, respectively in 36 and 31 % (Table 1). 41 % complained of fatigue and 38 % had diffuse pain.
Conclusion: In Northern Norway, the referral rate to multidisciplinary rehabilitation is 0.47/1000 persons/year. The prototypical patient referred to multidisciplinary rehabilitation is a woman in her sixth decade with spondyloarthritis, often complaining of fatigue and diffuse pain. Although these patients have seldom major physical disability, they are mostly in need for coping strategies regarding fatigue and chronic pain.

THE EULAR TOOL IS SUPERIOR TO A GENERIC TOOL IN THE ASSESSMENT OF MUSCULOSKELETAL ULTRASOUND COMPETENCE: A VALIDITY STUDY

Keywords: Ultrasound, Education

S. M. D. Carstensen[1,2], S. A. Just[3], M. Pfeiffer-Jensen[1], M. Østergaard[1,2], L. Konge[2,4], L. Terslev[1,2]. *[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre for Head and Orthopaedics, University Hospital of Copenhagen, Rigshospitalet, Glostrup, Denmark*; *[2]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*; *[3]Section of Rheumatology, Department of Medicine, Svendborg Hospital, Odense University Hospital, Odense, Denmark*; *[4]Copenhagen Academy for Medical Education and Simulation,The Capital Region of Denmark, Copenhagen, Denmark*

Background: Musculoskeletal ultrasound (MSUS) is a widely implemented tool in rheumatological routine care. It has been established which competencies are relevant for rheumatologists[1], and competency levels have already been developed within European League Against Rheumatism (EULAR)[2] and European Federation of Societies for Ultrasound in Medicine and Biology (EFSUMB)[3]. Furthermore, the content and conduct of MSUS courses have been published [2]. Thus, the only component missing is an objective assessment tool supported by a contemporary validity framework to determine when residents have acquired the competencies relevant for independent practice[1]. A generic assessment tool for the assessment of ultrasound competence, The Objective Structured Assessment of Ultrasound skills (OSAUS)[4], has been developed and is already used in clinical practice in several other medical fields[5,6]. EULAR has developed another assessment tool specific for MSUS. Although both OSAUS and the EULAR tool are consensus-based, the tools' reliability and their discriminatory ability have not been explored.
Objectives: To explore the validity of the generic OSAUS tool and the EULAR tool for the assessment of MSUS operator performance. Moreover, to examine the optimal number of cases and raters needed to ensure a reliable assessment of residents.
Methods: We included 30 physicians, representing MSUS novices, intermediates, and experts. Validity evidence was gathered using the gold standard contemporary framework of Messick[8] All participants performed MSUS examinations of four joint areas: the wrist, fingers, ankle, and shoulder on the same patient with rheumatoid arthritis. All performances were video recorded and subsequently assessed in completely random order by two blinded raters using first the OSAUS assessment tool and then one month after, followed by new randomization of the videos, the EULAR tool.
Results: A total of 120 videos were assessed twice by two assessors. The inter-rater reliability was high for both tools: 0.807 (OSAUS) versus 0.848 (EULAR), and both tools demonstrated excellent inter-case reliability of 0.970 (OSAUS) versus 0.964 (EULAR). The ability to discriminate between different experience levels and MSUS performance was significant (p <0.001) for both the OSAUS and the EULAR tool. Moreover, by conducting a series of Decision-studies, we estimated the optimal number of cases and raters needed to ensure a reliable assessment (generalizability coefficient >0.8). A reliable assessment could be reached by using either one rater and three cases or two raters and one case (OSAUS), whereas the EULAR assessment tool only needed one rater assessing two cases or two raters assessing one case (Figure 1).

Figure 1: Number of raters and cases needed to make a reliable assessment of MSUS competences

The red-dotted lines illustrate the acceptance limit of 0.8 for normal supervision and examinations and the high-stake limit of 0.9 (e.g., obtaining final medical degree or postgraduate medical exams).

Conclusion: MSUS operator competences can be assessed in a reliable and valid way using either the OSAUS or the EULAR assessment tool, thereby allowing a uniform competency-based MSUS education in the future. Although both tools demonstrated high inter-rater reliability, the EULAR tool was superior to OSAUS. Using the EULAR tool in clinical practice will allow a single assessor to provide a reliable MSUS assessment of the trainee by observing only two different MSUS examinations.

POS1095 E-LEARNING AND PRACTICAL PERFORMANCE IN MUSCULOSKELETAL ULTRASOUND - A MULTICENTER RANDOMIZED STUDY

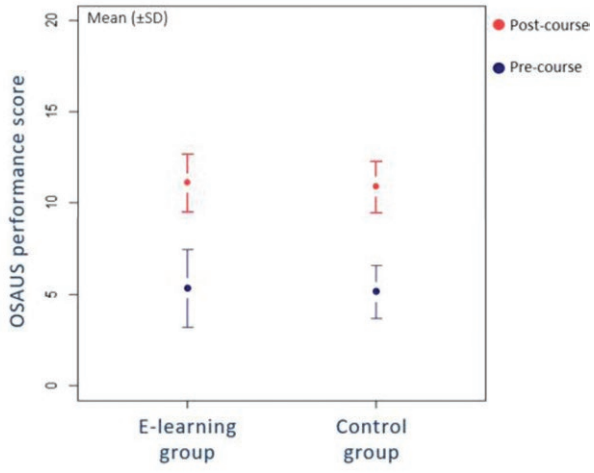
Keywords: Education, Ultrasound, Randomized control trial

S. M. D. Carstensen[1,2], S. A. Just[3], M. Velander[3], L. Konge[2,4], M. Slusarczyk Hubel[5], T. R. Savarimuthu[5], M. Pfeiffer-Jensen[1], M. Østergaard[1,2], L. Terslev[1,2]. *[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre for Head and Orthopaedics, University Hospital of Copenhagen, Rigshospitalet, Glostrup, Denmark*; *[2]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*; *[3]Section of Rheumatology, Department of Medicine, Svendborg Hospital, Odense University Hospital, Svendborg, Denmark*; *[4]Copenhagen Academy for Medical Education and Simulation, The Capital Region of Denmark, Copenhagen, Denmark*; *[5]SDU Robotics, The Maersk Mc Kinney Moller Institute, University of Southern Denmark, Odense, Denmark*

Background: The COVID-19 pandemic has forced a change in the teaching approach when educating physicians. Several training programs have been digitally transformed, including complex procedures such as ultrasound [1]. Recent studies have suggested the possibilities for practicing theoretical and practical ultrasound skills using online platforms, e.g., e-learning [2]. Even though the effect of e-learning on theoretical knowledge is unquestionable, the impact on practical skills is unknown. Thus, it is essential to examine the effect of e-learning on the development of practical skills.

Objectives: To examine the effect of pre-course e-learning on residents' practical performance in musculoskeletal ultrasound (MSUS). Moreover, to examine the effect of pre-course e-learning on residents' satisfaction with the following face-to-face MSUS course.

Methods: We designed a multi-center randomized controlled study following the CONSORT statement. Residents with no or little MSUS experience were randomized to either an e-learning group or a traditional group. One week before a 2-day face-to-face MSUS course, the e-learning group received access to an interactive platform consisting of online lectures, assignments, and practical instruction videos aligned with the content of the following course. The traditional group only received standard pre-course information (program, venue, and time). All participants performed a pre- and post-course practical MSUS examination and were assessed by two individual raters, blinded to the group allocation, using the validated Objective Structured Assessment of Ultrasound skills (OSAUS) tool. Finally, the participants filled out a subjective satisfaction questionnaire, the Intrinsic Motivation Inventory (IMI).



Results: Twenty-eight participants completed the study. There were no statistically significant differences in the pre- or post-course practical MSUS performance between the e-learning group and the traditional group; the mean pre-course OSAUS score (±SD) in the e-learning group was 5.4±3.7 compared to 5.2±2.4 in the traditional group, p=0.8, whereas the post-course OSAUS score in the e-learning group was 11.1±2.8 compared to 10.9±2.4 in the traditional group, p=0.8 (Figure 1). There was a significant difference between the mean pre- and post-course scores (p<0.001) for both groups. The OSAUS assessment tool demonstrated excellent inter-rater reliability (ICC=0.84). There were no significant differences between the groups regarding their subjective satisfaction with the course measured by the IMI score.

Conclusion: We found no significant impact of pre-course e-learning on novices' acquisition of practical MSUS skills or on trainees' satisfaction with the course. Hands-on training is of utmost importance and improves MSUS performance significantly. The OSAUS assessment tool is an applicable tool for the assessment of trainees' MSUS competences and demonstrated excellent interrater reliability.

POS1096 ASSESSMENT OF PERCEPTION OF BENEFITS AND BARRIERS TO EXERCISE PARTICIPATION AMONG PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES AND HEALTHY INDIVIDUALS: A CASE CONTROL STUDY

Keywords: Inflammatory arthritides, Education, Rehabilitation

A. Adnine[1], F. Z. Taik[1], N. Takhrifa[1], F. Z. Aharrane[1], N. Soba[2], M. Fourtassi[2], F. E. Abourazzak[1]. *[1]Abdelmalek Essaidi University, Faculty of Medecine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, TANGIER, Morocco*; *[2]Abdelmalek Essaidi University, Faculty of Medecine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco*

Background: Benefits of regular physical activity (PA) are well known and well publicized. Despite the many benefits of PA, patients with chronic inflammatory rheumatic diseases (CIRD) report low levels of PA and engage more in sedentary behavior.

Objectives: We aim to assess the perception levels of benefits and barriers to exercise participation among patients with CIRD and healthy individuals and examine the predictors of poor perception levels.

Methods: A cross-sectional study was performed among patients with CIRD Aged between 18 and 65 years old who visited the outpatient clinic. Healthy controls were recruited in a specialized consultation. Socio-demographic and clinical findings were collected. Physical activity levels were assessed using (IPAQ). Perceived benefits and barriers to exercise scale (PBBS) was used to assess the perception of patients and healthy controls toward exercise. Furthermore, all participants underwent screening for anxiety and depressive disorders using (PHQ-9) and (GAD-7) respectively.

Results: 172 patients were enrolled in the study (92 RA, 65 SpA and 15 Undifferentiated CIRD) and 159 healthy controls.

Table 1. Sociodemographic and clinical findings, PA levels and perception toward PA among patients and healthy individuals.

	Patients with CRID N= 172	Healthy controls N= 159	p Value
Age (Mean ±SD)	45,97 ± 12,063	45,53 ± 12,244	p= 0.787
Gender (female)	72,7%	70,3%	p= 0.654
Disease duration year	8 [3, 17]	N/A	N/A
Disease activity	Remission: 39 % LDA: 11.6% MDA: 24.4% HDA: 25%	N/A	N/A
IPAQ:	Low PA: 38.4% Moderate PA: 32.9% High PA: 28.7%	Low PA: 17% (n=27) Moderate PA: 31.4% (n=50) High PA:51.6% (n=82)	**p=0.000**
Top three Perceived benefits to exercise (Mean ±SD).	**1-**Exercise decreases feelings of stress and tension for me (3.49 ± 0.77) **2-**Exercise improve my mental health (3.48 ± 0.87) **3-** My disposition is improved with exercise (3.46 ± 0.79)	**1-**Exercising increases my level of physical fitness (3.69 ± 0.61). **2-**Exercise improves overall body functioning for me (3.65 ± 0.57) **3-** My disposition is improved with exercise (3.65 ± 0.678)	N/A
Top three Perceived barriers to exercise (Mean ±SD).	**1-** I'm fatigued by exercise (2.38 ± 1.19) **2-** Exercise tires me (2.21 ± 1.15) **3-** Places for me to exercise are too far away (2.13 ± 1.23)	**1-** Exercise tires me (1.97 ± 1.02) **2-** I'm fatigued by exercise (1.94 ± 1.06) **3-** Places for me to exercise are too far away (1.91 ± 1.19)	N/A
PBBS Total (Mean ±SD).	138.81 ± 23.36	147.87 ± 18.83	**p= 0.000**
PBBS of perceived Benefits (Mean ±SD).	94.30 ± 20.09	101.01 ± 15.27	**p= 0.001**
PBBS of perceived Barriers (Mean ±SD).	25.49 ± 7.46	23.14 ± 7.92	**p= 0.006**
Depression PHQ-9	8 [5, 14]	4 [1, 9]	**P=0.000**

In patients with CIRD, multivariate analysis showed a positive association between the PBBS scale and Socio-economic status:(OR (95%CI) = 4.960 (1.901, 8.019); **p=0.002**), and level of education (OR (95%CI) = 3.789 (0.833, 6.745); **p=0.012**).Poor perception of benefits towards exercise participation was associated with high levels of depression in both groups: - In patients with CIRD (OR (95%CI) = -0.792 (-1.395, -0.189); **p=0.010**) and in healthy controls (OR (95%CI) = -0.520 (-1.046, -0.001; **p=0.050**)).

Conclusion: We found that patients with CIRD perceive significantly less benefits and more barriers to exercise participation than healthy individuals. Barriers to physical activity in both groups are related to physical exertion, thus we highlight the role of adapted PA especially in patients with CRID. Depressive disorders is known to alter perception of reality in a negative way [1]. Education about the diagnosis and treatment of depressive disorders is essential to promote PA [2].

POS1097 IMPROVED REFERRALS FROM PRIMARY CARE AND MANAGEMENT OF INFLAMMATORY ARTHRITIS THROUGH AN INTEGRATED COLLABORATIVE ACADEMY AND NETWORK USING BLENDED LEARNING, MENTORING AND ACTION LEARNING SETS

Keywords: Education, Inflammatory arthritides, Quality of care

A. Chan[1], K. Rigler[1], J. Kitchen[1], L. Van Rossen[2], G. Macdonald[1], A. Mcdougall[1], J. Mcnally[1], S. Melath[1], A. Mistry[1]. [1]*Royal Berkshire NHS Foundation Trust, Department of Rheumatology, Reading, United Kingdom*; [2]*East Kent Hospitals NHS Trust, Rheumatology, Canterbury, United Kingdom*

Background: Improving the delay to diagnosis in inflammatory arthritis remains an important challenge in rheumatology. The National Early Inflammatory Arthritis Audit (NEIAA) in the UK aims to reduce the time to diagnosis through early referral from primary care. In order to achieve this as well as improve the quality of referrals, we have created an integrated Rheumatology Academy and Collaborative Network (RheumACaN) for clinicians in primary care.

Objectives: RheumACaN aims to build confidence in primary care to refer and manage patients with inflammatory arthritis (RA, PsA, AxSpA) as well as other rheumatic diseases. Through integration of pathways from primary to secondary care, RheumACaN aims to reduce delays to diagnosis, improve referral from primary care and enhance management of patients.

Methods: RheumACaN was a 1 year rolling programme with face to face discovery day meetings sharing best practice, teaching and discussion on local referral pathways, guidelines and investigations. In between the face to face sessions there was active learning through virtual mentoring. Participants completed action learning sets, case discussion and the course workbook. The outcome was measured through metrics in the NEIAA, referral patterns and feedback from participants.

Results: RheumACaN was attended by 80 participants over 2 cohorts in 2021-2022 including general practitioners (GPs), community musculoskeletal (MSK) physiotherapists and first contact practitioners (FCPs). Prior to RheumACaN, the number and percentage of patients with suspected early inflammatory arthritis (EIA) referred to a specialist clinic within three working days which is a measure of primary care performance was 109/312 (32%) in 2018/19, 190/334 (57%) in 2019/20, 45/86 (52%) in 2020/21. Post RheumACaN, this increased to 140/201 (70%) in 2021/22. The national average for this metric was 47% in 2019/20 and 54% in 2021/22. Feedback from 2 cohorts was 100% scored 5/5 (excellent) for how well the purpose of the programme was communicated, 100% scored 5/5 for how organised and easy to follow the programme was, 98% scored 5/5 for how engaged the presenters were. All participants responded that they had learned from the programme and this would change their practice. Narrative feedback included: "Very interesting - diagnosis and management, and when to refer onwards, very clear", "Really helpful for future referrals, good tips what to look out for", "Clear criteria and management (onward referral)", "Enjoy discussing the cases and getting feedback, useful to hear other cases", "Great having group discussion, learned so much", "Fantastic afternoon, energising, positive, lots of new ideas/approaches."

Conclusion: We created RheumACaN, a knowledge-sharing model to bring together clinicians from primary and secondary care for a robust, holistic approach to manage rheumatic diseases. Similar models such as project ECHO with the hub and spoke model of 'moving knowledge not people' have been used[1]. Our collective understanding of how to disseminate and implement best practices across diverse disciplines resulted in the rapid increase of early referrals of inflammatory arthritis from primary care in our centre which is now above the national average in the UK. New referral quality and outcomes are continuously reviewed with an annual audit to assess impact in line with the NEIAA. RheumACaN has also a train the trainer ethos with participants in Cohort 1 coming back to share and teach Cohort 2. Cohort 1 graduates have also been doing peer to peer teaching sessions to help spread and ensure sustainability. This continuous loop of learning, mentoring and peer support makes this a unique programme, with a long-lasting impact far beyond that of a webinar, e-learning course or seminar, with knowledge which is tested and refined through a local lens.

Background: Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, met all primary/secondary endpoints at Week (Wk) 16 in patients (pts) with active non-radiographic axial spondyloarthritis (nr-axSpA) and radiographic axSpA (r-axSpA; i.e., ankylosing spondylitis), in the parallel phase 3 BE MOBILE 1 and 2 studies, respectively.[1,2]
Objectives: To assess efficacy and safety of BKZ in these pts up to Wk 52.
Methods: BE MOBILE 1 (NCT03928704) and 2 (NCT03928743) both involved a 16-wk placebo (PBO)-controlled and 36-wk maintenance period.[1,2] Pts were randomised to subcutaneous BKZ 160 mg Q4W (BKZ) or to PBO then BKZ from Wk 16 (PBO/BKZ).
Results: 220/254 (86.6%) randomised pts with nr-axSpA and 298/332 (89.8%) with r-axSpA completed Wk 52. Efficacy was sustained to Wk 52 in both studies (**Table 1**). ASAS40 responses in BKZ-randomised pts increased from Wk 16 (nr-axSpA: 47.7%; r-axSpA: 44.8%; non-responder imputation [NRI]) to Wk 52 (60.9%; 58.4%; NRI) with high levels of efficacy across TNFi-naïve and TNFi-IR populations (**Table 1**). At Wk 52, ASDAS <2.1 was achieved by 61.6% and 57.1%, and ASDAS <1.3 by 25.2% and 23.4%, of BKZ-randomised pts with nr-axSpA and r-axSpA, respectively (**Figure 1**). Wk 16 reductions from baseline in objective signs of inflammation (MRI, hs-CRP), and improvements in function (BASFI) and ASQoL, were maintained through 52 wks. Efficacy at Wk 52 was similar in PBO/BKZ-treated and BKZ-randomised pts (**Table 1**). At Wk 52, 75.0% (183/244) of pts with nr-axSpA and 75.5% (249/330) of pts with r-axSpA had ≥1 treatment-emergent adverse event (TEAE) on BKZ; the most frequent (% pts) TEAEs by preferred term (MedDRA v19.0) were nasopharyngitis (nr-axSpa: 12.3%; r-axSpA 9.1%) and upper respiratory tract infection (9.4%; 6.4%); few COVID-19 infections were reported (7.0%; 2.1%). Incidence (pts/100 pt years) of serious TEAEs were low (4.4; 7.1); no major adverse cardiovascular events, active tuberculosis cases, serious COVID-19 infections, or deaths were reported. Most incidences of fungal infection (19.6; 14.9; none serious or systemic) were *Candida* (12.8; 8.3) and mild to moderate; two pts in both studies discontinued the study due to *Candida* infections. Incidence of IBD (1.0; 1.0) and uveitis (1.5; 2.4) were low.
Conclusion: Across the axSpA spectrum, BKZ resulted in sustained efficacy to Wk 52. No new safety signals were observed, consistent with the Wk 24 safety profile.[1,2]

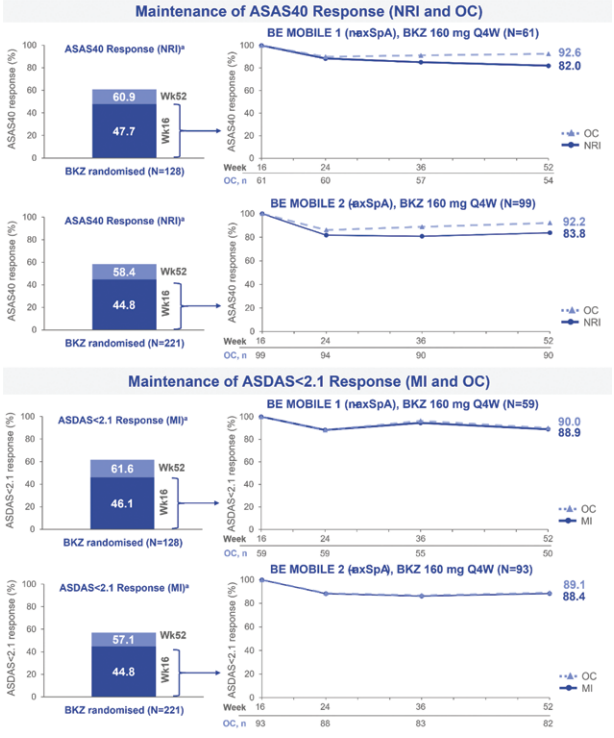
Background: Axial spondyloarthritis (axSpA) is a chronic rheumatic disease which requires optimal management and disease control. Assessment of SpondyloArthritis international Society ≥40% improvement (ASAS40) is a stringent efficacy outcome in clinical trials, while in clinical practice the focus is on the achievement of sustained remission or low disease activity (LDA) according to Ankylosing Spondylitis Disease Activity Score (ASDAS). Patients (pts) can



experience loss of response in the long term and maintenance of response is an internationally recommended treatment target.[1] Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A. BKZ has demonstrated consistent and sustained clinical efficacy to Week (Wk) 52 in pts across the full spectrum of axSpA in the phase 3 studies BE MOBILE 1 and 2.[2]

Objectives: To report the maintenance of stringent clinical responses through one year of treatment with BKZ in pts with non-radiographic axSpA (nr-axSpA) and radiographic-axSpA (r-axSpA, i.e., ankylosing spondylitis)[3] in phase 3 studies.

Methods: In BE MOBILE 1 (NCT03928704; nr-axSpA; pts met ASAS criteria for axSpA) and BE MOBILE 2 (NCT03928743; r-axSpA; pts fulfilled ASAS and modified New York criteria for r-axSpA), pts were randomised to receive subcutaneous BKZ 160 mg every 4 wks (Q4W) or placebo (PBO) to Wk 16. From Wks 16–52, all pts received BKZ 160 mg Q4W.[4,5] ASAS40 and ASDAS <2.1 (LDA) or <1.3 (inactive disease [ID]) responses to Wk 52 were assessed among BKZ-randomised pts who responded at Wk 16. Missing ASAS40 data were imputed using non-responder imputation (NRI), and multiple imputation (MI) was used for missing ASDAS data. MI was based on Markov Chain Monte Carlo (for intermittent missing data) followed by monotone regression (for monotone missing data). Observed case (OC) data are also reported. Wk 16 and Wk 52 responder rates for all BKZ-randomised pts are included for context (NRI or MI). The number of treatment-emergent adverse events (TEAEs) to Wk 52 are reported for pts who received ≥1 dose of BKZ, including pts who switched from PBO to BKZ at Wk 16.

Results: A total of 128 and 221 pts were randomised to BKZ 160 mg Q4W in BE MOBILE 1 and 2, respectively. At Wk 16, 47.7% and 44.8% of these pts achieved the primary endpoint, ASAS40, and this increased to 60.9% and 58.4% at Wk 52 (NRI, **Figure 1**). Of pts that achieved ASAS40 at Wk 16, 82.0% and 83.8% maintained this response at Wk 52 (NRI, **Figure 1**). ASDAS LDA was achieved by 46.1% and 44.8% of BKZ-randomised pts at Wk 16 of BE MOBILE 1 and 2, respectively; this increased to 61.6% and 57.1% at Wk 52 (MI, **Figure 1**). Of pts that achieved ASDAS LDA at Wk 16, 88.9% and 88.4% maintained this response at Wk 52 (MI, **Figure 1**). At Wk 16 of BE MOBILE 1 and 2, ASDAS ID was achieved by 18.8% and 16.4% of BKZ-randomised pts, respectively; and this increased to 25.2% and 23.4% at Wk 52 (MI). Among Wk 16 ASDAS ID responders, ASDAS ID was maintained by 79.2% and 75.1% at Wk 24, 85.3% and 71.7% at Wk 36, and 88.0% and 58.7% at Wk 52 (MI). To Wk 52 of BE MOBILE 1 and 2, 183/244 (75.0%) and 249/330 (75.5%) pts reported ≥1 TEAE whilst receiving BKZ, respectively; 9 (3.7%) and 20 (6.1%) reported serious TEAEs.

Figure. Maintenance of ASAS40 and ASDAS LDA (ASDAS <2.1) through 52 wks of BKZ 160 mg Q4W among Wk 16 ASAS40 and ASDAS LDA responders, respectively, from BE MOBILE 1 and 2

[a]Response at Wk 16 and Wk 52 in pts randomised to BKZ 160 mg Q4W at baseline.
Abbreviations: ASAS40: Assessment of SpondyloArthritis international Society 40%; ASDAS<2.1: Ankylosing Spondylitis Disease Activity Score <2.1; axSpA: axial spondyloarthritis; BKZ: bimekizumab; LDA: low disease activity; MI: multiple imputation; nr-axSpA: non-radiographic axSpA; NRI: non-responder imputation; OC: observed case; pts: patients; Q4W: every four weeks; r-axSpA: radiographic axSpA; wk: week.

Conclusion: Dual inhibition of IL-17F and IL-17A with BKZ provided robust maintenance of stringent clinical responses from Wk 16 to Wk 52 across the full axSpA disease spectrum. This is consistent with previously reported observations of BKZ treatment over three years in pts with r-axSpA in the phase 2b study BE AGILE and its open-label extension.[6]

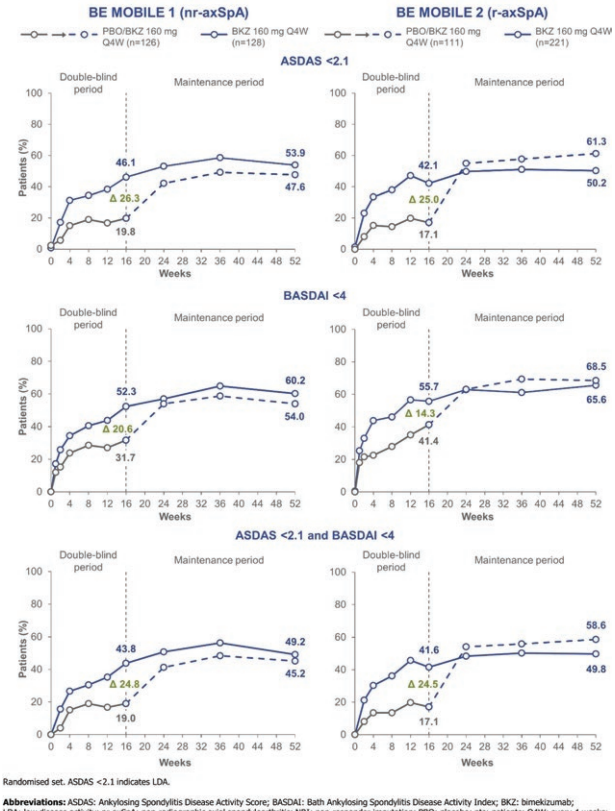
Background: Ankylosing Spondylitis (AS) Disease Activity Score (ASDAS) is the recommended instrument to assess disease activity in axial spondyloarthritis (axSpA).[1] However, the Bath AS Disease Activity Index (BASDAI) remains commonly used in clinical practice. The recommended treatment target for axSpA is remission or low disease activity (LDA) according to ASDAS levels,[1] while limited data exist to validate cut-offs for BASDAI.[2,3] However, remission is difficult to achieve for many patients (pts), especially in established disease. Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A. BKZ has demonstrated consistent and sustained efficacy up to Week (Wk) 52 in the BE MOBILE 1 and 2 phase 3 studies, including achievement of LDA according to ASDAS by >50% of pts with non-radiographic (nr-)axSpA and radiographic (r-)axSpA (i.e. AS).[4,5]

Objectives: To report achievement of LDA, as assessed by either ASDAS <2.1, BASDAI <4, or both, to Wk 52 with BKZ across the spectrum of axSpA in two phase 3 studies.



Methods: BE MOBILE 1 (NCT03928704) and BE MOBILE 2 (NCT03928743) each comprised a 16-wk placebo (PBO)-controlled and 36-wk maintenance period.[5] Pts with nr-axSpA in BE MOBILE 1 met Assessment of SpondyloArthritis international Society (ASAS) classification criteria and had objective inflammation as assessed by MRI and/or elevated C-reactive protein. Pts with r-axSpA included in BE MOBILE 2 met modified New York criteria and also fulfilled ASAS classification criteria. All pts had active disease (BASDAI ≥4 and spinal pain ≥4 as per BASDAI item 2) at baseline. Pts were randomised to subcutaneous BKZ 160 mg every 4 wks (Q4W) or PBO; all pts received BKZ 160 mg Q4W from Wk 16 onwards.[5] The PBO arm is therefore referred to as PBO up to Wk 16, and PBO/BKZ at later timepoints. Here, we present the proportion of pts achieving LDA to Wk 52, as defined by either ASDAS <2.1, BASDAI <4, or both, using non-responder imputation.

Results: A total of 254 pts with nr-axSpA (BKZ: 128, PBO: 126) and 332 with r-axSpA (BKZ: 221, PBO: 111) were randomised. Most pts had high (ASDAS ≥2.1–≤3.5) or very high (ASDAS >3.5) disease activity at baseline (nr-axSpA: BKZ: 99.2%, PBO: 97.6%; r-axSpA: BKZ: 98.6%, PBO: 100%). In pts with nr-axSpA, a greater proportion of BKZ vs PBO-treated pts achieved LDA at Wk 16 according to ASDAS <2.1 (BKZ: 46.1%, PBO: 19.8%), BASDAI <4 (BKZ: 52.3%, PBO: 31.7%), and both (BKZ: 43.8%, PBO: 19.0%). Separation from PBO was apparent from first post-baseline assessment for ASDAS <2.1 and both ASDAS <2.1 and BASDAI <4 (**Figure 1**). Results were similar for pts with r-axSpA (**Figure 1**). Across continuous BKZ-treated pts and PBO/BKZ switchers, achievement of LDA, according to ASDAS <2.1, BASDAI <4, and both, was sustained or improved in both studies to Wk 52 (**Figure 1**). Proportion of pts achieving BASDAI <4 was consistently higher compared with achievement of ASDAS <2.1, regardless of treatment arm.

Conclusion: Across the full axSpA disease spectrum, dual inhibition of IL-17A and IL-17F with BKZ resulted in rapid achievement of LDA vs PBO to Wk 16, as assessed by ASDAS <2.1, BASDAI <4, or both. Proportion of pts achieving LDA increased to Wk 52. These data suggest that ASDAS <2.1 is a more stringent criteria for LDA than BASDAI <4, and the majority of pts who achieved ASDAS <2.1 also achieved BASDAI <4. This is relevant for the consideration of BKZ in the context of a potential treat-to-target approach for pts with axSpA in daily practice.

Background: In patients (pts) with axial spondyloarthritis (axSpA), tumour necrosis factor inhibitors (TNFi) are the usual first line biologic treatment, yet many pts may experience loss of response over time, and some are intolerant to TNFis.[1] Typically, response to second line biologics is limited in TNFi-inadequate responders (IR). Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A. In the phase 3 BE MOBILE 1 and 2 studies, BKZ treatment resulted in rapid and sustained improvements in efficacy outcomes through 52 weeks (wks) in pts with active non-radiographic (nr-)axSpA and r-axSpA (i.e., ankylosing spondylitis [AS]).[2,3] In studies of BKZ in psoriatic arthritis, similar efficacy between TNFi-naïve and TNFi-IR pts were observed.[4]

Objectives: To assess the efficacy of BKZ in TNFi-naïve or -IR pts with active nr-axSpA and r-axSpA through Wk 52 across multiple key endpoints.

Methods: In BE MOBILE 1 (nr-axSpA; NCT03928704) pts met Assessment of SpondyloArthritis international Society (ASAS) classification criteria and in BE MOBILE 2 (r-axSpA; NCT03928743) pts fulfilled modified New York and ASAS criteria. Pts were randomised to receive subcutaneous BKZ 160 mg every 4 wks (Q4W) or placebo (PBO) then BKZ 160 mg Q4W from Wk 16. This post hoc analysis reports pooled mean efficacy data, including disease activity, MRI inflammation, physical function, and quality of life (QoL), through Wk 52 of BE MOBILE 1 and 2, stratified by TNFi status (naïve/IR). TNFi-IR pts are defined as those who experienced intolerance, or IR, to prior treatment given at an approved dose for ≥12 wks.

Results: This pooled analysis included 505 TNFi-naïve and 81 TNFi-IR pts. 302/505 (59.8%) TNFi-naïve and 47/81 (58.0%) TNFi-IR pts were randomised to BKZ. At Wk 16, the proportion of pts achieving ASAS40 and AS Disease Activity Score (ASDAS)<2.1 (low disease activity) were higher in BKZ-randomised TNFi-naïve/-IR pts vs PBO. In both TNFi-naïve/-IR continuous BKZ-treated pts, responses were similar and increased to Wk 52 (**Figure 1**). Similar substantial reductions from baseline in ASDAS-CRP and MRI inflammation by Wk 16 were also achieved with BKZ vs PBO in both TNFi-naïve and IR pts; in continuous BKZ-treated pts this was sustained or further improved through 52 wks. Comparable improvements in physical function, nocturnal spinal pain and ASQoL were observed through 52 wks with BKZ in TNFi-naïve/-IR pts (**Table 1**).

Conclusion: Across the full axSpA disease spectrum, BKZ treatment resulted in clinically relevant improvements in key efficacy outcomes vs PBO, including suppression of inflammation and improvements in physical function and QoL, regardless of prior TNFi exposure. The improvements with BKZ at Wk 16 were sustained to Wk 52.

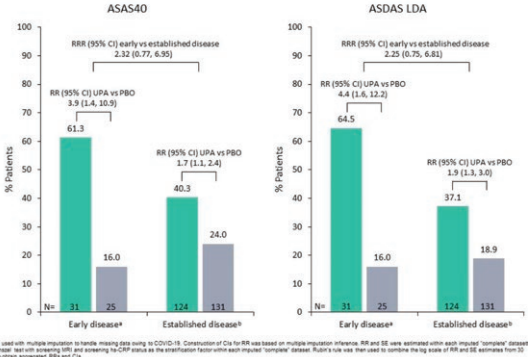
POS1108 EFFICACY OF UPADACITINIB IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN EARLY VERSUS ESTABLISHED DISEASE

Keywords: Spondyloarthritis

V. Navarro-Compán[1], F. Van den Bosch[2], P. D. Sampaio-Barros[3], F. Ganz[4], A. Biljan[5], Y. Duan[5], K. D'silva[5], P. Wung[5], A. Ostor[6], S. Ramiro[7]. [1]*Hospital Universitario La Paz, Department of Rheumatology, Madrid, Spain*; [2]*Ghent University Hospital, Department of Internal Medicine and Pediatrics, Gent, Belgium*; [3]*Hospital das Clínicas da Universidade de São Paulo, Division of Rheumatology, Sao Paulo, Brazil*; [4]*AbbVie, Global Development, Baar, Switzerland*; [5]*AbbVie, Department of Immunology, North Chicago, United States of America*; [6]*Cabrini Hospital, Monash University & Emeritus Research, Melbourne, Australia*; [7]*Leiden University Medical Center (LUMC), Department of Rheumatology, Leiden, Netherlands*

Background: The phase 3 SELECT-AXIS 2 trial (NCT04169373) assessed the efficacy and safety of upadacitinib (UPA) in patients with non-radiographic axial spondyloarthritis (nr-axSpA). This subgroup analysis investigated the efficacy of UPA in early versus established disease.



Objectives: This post hoc analysis evaluated the rates of achievement of ≥40% improvement in ASAS score (ASAS40 response) and Ankylosing Spondylitis Disease Activity Score (ASDAS) low disease activity (LDA; <2.1) at week 14 in early versus established disease (defined as symptom duration <2 versus ≥2 years).

Methods: In SELECT-AXIS 2[1], adult patients with or without prior biologic DMARD (bDMARD) exposure, with a clinical diagnosis of axSpA, fulfilling the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for nr-axSpA, and with objective signs of active inflammation on MRI of SI joints and/or high-sensitivity (hs)-CRP exceeding the upper limit of normal (2.87 mg/L) at screening, were randomized 1:1 to UPA 15 mg once daily or placebo (PBO) for 52 weeks. Response rate, relative risk (RR; UPA versus PBO), and RR ratio (RRR; early versus established disease) are reported. When interpreting RRRs, a 95% confidence interval (CI) that crosses 1 indicates no statistically significant difference between the groups being compared.

Results: Baseline characteristics were similar in patients with early versus established disease, although the proportion of females, mean age, and rates of prior bDMARD exposure were higher in established versus early disease **(Table 1)**. Mean symptom duration was 1.0 versus 10.9 years in patients with early versus established disease. ASAS40 and ASDAS LDA response rates at week 14 were significantly increased with UPA versus PBO in both early and established disease (ASAS40: 61.3% versus 16.0% and 40.3% versus 24.0%; ASDAS LDA: 64.5% versus 16.0% and 37.1% versus 18.9%; respectively) **(Figure 1)**. For ASAS40 and ASDAS LDA, the RR of response for UPA versus PBO was greater in early versus established disease (3.9 versus 1.7 and 4.4 versus 1.9, respectively). RRRs for ASAS40 and ASDAS LDA for early versus established disease were 2.3 (95% CI: 0.77, 6.95) and 2.3 (95% CI: 0.75, 6.81), respectively, reflecting no statistically significant difference in treatment response between early and established disease.

Conclusion: UPA 15 mg is more efficacious than PBO in reducing signs and symptoms of nr-axSpA, regardless of symptom duration. Although treatment responses were numerically higher in early disease, the differences versus established disease were not statistically significant.

Figure. Rates of Achievement of ASAS40 Response and ASDAS LDA at Week 14 (NRI-MI)

Non-responder imputation was used with multiple imputation to handle missing data owing to COVID-19. Construction of CIs for RR was based on multiple imputation inference. RR and SE were estimated within each imputed "complete" dataset using the Cochran-Mantel-Haenszel test with screening (vIR) and screening hs-CRP status as the stratification factor within each imputed "complete" dataset. Rubin's rule was then used to combine the log scale of RR and SE estimates from 30 imputed "complete" datasets to obtain aggregated RRs and CIs

[a]Defined as symptom duration <2 years. [b]Defined as symptom duration ≥2 years.

ASAS40, ≥40% improvement in Assessment of SpondyloArthritis international Society score; ASDAS LDA, Ankylosing Spondylitis Disease Activity Score low disease activity; CI, confidence interval; hs-CRP, high-sensitivity CRP; NRI-MI, non-responder imputation with multiple imputation; PBO, placebo; RR, relative risk; RRR, RR ratio; SE, standard error; UPA, upadacitinib

PUTATIVE ROLE OF THE HISTIDINE AND TRYPTOPHAN BIOCHEMICAL PATHWAYS IN THE MODE OF ACTION OF UPADACITINIB IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: -omics, Spondyloarthritis, Clinical trials

T. Sornasse[1], L. LI[2], S. Zhao[2], X. Wang[2], F. Cai[1], Y. Bi[3], I. H. Song[4], S. Wichuk[5], R. Lambert[5], W. P. Maksymowych[5]. Background: Upadacitinib (UPA) 15 mg QD is efficacious in patients with active ankylosing spondylitis (AS) exhibiting inadequate responses to nonsteroidal anti-inflammatory drugs (NSAIDs-IR).[1]

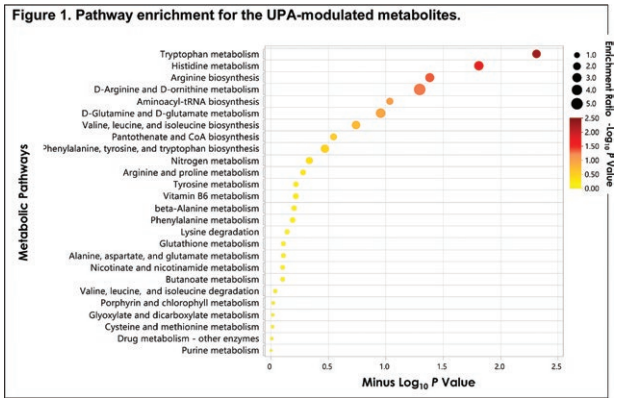
Objectives: We determined the impact of UPA on the global metabolome in these patients.

Methods: Baseline (BL), weeks 4, and 14 serum samples were obtained from a subset of patients enrolled in SELECT-AXIS1 (PBO, n = 59 out of 94; UPA, n = 59 out of 93). Patients met the modified New York AS criteria and had active disease at BL. Samples were processed using dansyl-^{12}C-labeling kits or DmPA-^{12}C-labeling kits for each chemical-group channel and analyzed by LC-MS–based metabolomics. Data analysis was performed using a commercial software and metabolite identification was done using a commercial reference database.[2] Tier 1 and 2 metabolites matched single compounds from a labeled metabolite library and a linked identity library, respectively. Tier 3 metabolites matched more than 1 compound. Differentially modulated metabolites (DMM) were identified using a mixed linear model measuring change from BL for each treatment group (selection criteria, absolute Log10 fold change ≥ 0.079, and false discovery rate ≤ 0.1). Pathway enrichment analyses were conducted using a dedicated software.[3] Relationships between metabolite level changes, and clinical changes were assessed by Pearson's correlation.



Results: We detected a total of 8020 distinct metabolites (ie, ≥ 80% detectability across timepoints within each treatment group) across the global metabolome. From these 8020 metabolites, we identified 289 and 221 DMM at weeks 4 and 14 in the UPA group vs 32 and 89 in the PBO group, respectively. Most DMM in the UPA group (187 and 144 at weeks 4 and 14, respectively) belonged to the Tier 3 identification category, and 51 and 40 at weeks 4 and 14, respectively, belonged to the Tier 1 and 2 categories. Pathway enrichment suggests UPA affects the histidine and tryptophan biochemical pathways (**Figure 1)**, consistent with increases in metabolites observed in the UPA group. Increases in histidine and tryptophan levels were significantly associated with an improvement in CRP levels and Ankylosing Spondylitis Disease Activity Score-CRP scores ($P \leq .05$). Increases in histidine levels were also associated with the improvement in MRI Spondyloarthritis Research Consortium of Canada Spine indices.

Conclusion: This is the first comprehensive metabolome analysis of serum samples collected from patients with AS treated with UPA. Data highlight the promise of advanced metabolomics to elucidate therapeutic agent's mode of action in AS. The putative effect of UPA on the tryptophan biochemical pathway is of particular interest because the tryptophan/kynurenine pathway is associated with chronic pain[4] and is perturbed toward the degradation of tryptophan in patients with AS.[5] We hypothesize that the increase in tryptophan and histidine may be related to the mode of action of UPA in NSAID-IR patients with AS.

PATIENT CLUSTERS IDENTIFIED BY MACHINE LEARNING: DATA FROM A POOLED ANALYSIS OF PHASE-3 TRIALS OF SECUKINUMAB IN PSORIATIC ARTHRITIS, ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS WITH AXIAL MANIFESTATIONS

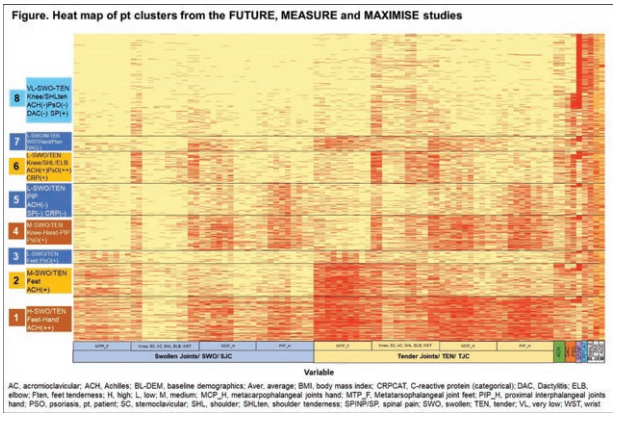
Keywords: bDMARD, Spondyloarthritis

X. Baraliakos[1], E. Pournara[2], D. D. Gladman[3], P. J. Mease[4], S. Jahandideh[2], L. Coates[5]. [1]*Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Rheumatology, Bochum, Germany*; [2]*Novartis Pharma AG, Rheumatology, Basel, Switzerland*; [3]*Toronto Western Hospital, Rheumatology, Toronto, Ontario, Canada*; [4]*Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, Washington, United States of America*; [5]*University of Oxford, Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: Universally acceptable criteria to define axial psoriatic arthritis (PsA) are lacking. Machine learning (ML) algorithms can detect patterns from large clinical datasets and identify clusters with potential therapeutic or prognostic significance in PsA patients (pts) with axial manifestations.[1]

Objectives: To identify pt clusters based on baseline (BL) demographics and clinical indicators to support characterisation of the axial PsA phenotype within the spondyloarthritis (SpA) spectrum.

Methods: Pooled BL demographics and clinical data of secukinumab (SEC)-treated pts from 10 Phase-3 studies: FUTURE 1–5 (PsA), MEASURE 1–4 (ankylosing spondylitis, AS) and MAXIMISE (PsA with axial manifestations) were analysed to identify pt clusters by ML.[2] Finite mixture model methodology was applied to the pooled dataset. Longitudinal responses of SEC 300 mg vs 150 mg were explored across the identified clusters and clinical indicators tender joint counts (TJC), swollen joint counts (SJC) and enthesitis.



Results: Eight distinct clusters were identified (n=3907, **Figure 1 and Table 1**). Pts with PsA with axial manifestations (MAXIMISE) were overrepresented in clusters 6–8. Pts in cluster 6 (mean age 48 yrs; 46% male) were overweight with pronounced psoriasis (PsO), and high articular burden in large joints. Pts in cluster 7 (mean age 47 yrs; 53% male) were less overweight with lower polyarticular joint counts (mean 11 joints) and tenderness focused on the feet, wrists and hands. Pts in cluster 8 were mostly pts with AS (mean age 43 yrs; 64% male), less overweight with oligoarthritis and high prevalence of spinal pain. Pts with PsA (FUTURE) were overrepresented in clusters 1–5. Longitudinal analysis showed significant improvements with SEC 300 mg vs 150 mg in clusters 6 and 8 for TJC, and cluster 7 for SJC.

Conclusion: PsA clusters obtained by ML in the pooled dataset indicate phenotypical heterogeneity of pts with PsA with axial manifestations and overlapping features across the SpA spectrum.

TREATMENT WITH UPADACITINIB RESULTS IN THE INHIBITION OF A BROAD RANGE OF POTENTIALLY PATHOGENIC PATHWAYS IN NR-AXSPA AND BDMARD-IR AS PATIENTS: PROTEOMIC ANALYSIS FROM THE SELECT-AXIS 2 PHASE 3 STUDIES

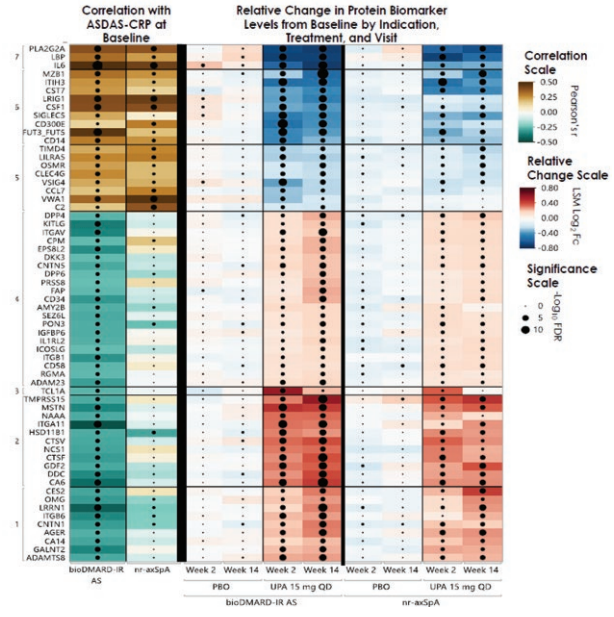
Keywords: Clinical trials, Biomarkers, Spondyloarthritis

T. Sornasse[1], I. H. Song[2], P. Wung[2], Y. Bi[3], B. Ravishankar[1], H. A. Hu[4], W. P. Maksymowych[5]. [1]*AbbVie, Precision Medicine Immunology, South San Francisco, United States of America*; [2]*AbbVie, Immunology Clinical Development, North Chicago, United States of America*; [3]*AbbVie, Data Science and Statistics, Worcester, United States of America*; [4]*AbbVie, Genome Research Center, North Chicago, United States of America*; [5]*University of Alberta, Department of Medicine Division of Rheumatology, Edmonton, Canada*

Background: Upadacitinib (UPA) 15 mg QD, an oral Janus kinase inhibitor, demonstrated efficacy in patients with non-radiographic axial spondyloarthritis (nr-axSpA) and patients with ankylosing spondylitis (AS) with an inadequate response (IR) to biological disease-modifying antirheumatic drugs (bDMARD) in SELECT-AXIS 2[1,2] (NCT04169373).

Objectives: To identify biological pathways modulated by UPA in nr-axSpA and bDMARD-IR AS patients based on an extensive proteomic profiling, emphasizing those associated with disease activity at baseline.

Methods: A subgroup of patients from the SELECT-AXIS 2 program, with available biomarker samples, were selected for analysis (nr-axSpA PBO: n = 82; nr-axSpA UPA: n = 82; bDMARD-IR AS PBO: n = 111; bDMARD-IR AS UPA: n = 112). In addition, samples from 24 age- and gender-matched healthy volunteers (HVs) were included in the analysis. The levels of 1463 unique protein biomarkers (pBMs) were analyzed using proximity extension assay technology. Differences in pBMs levels between patients and HVs and their changes from baseline upon treatment were expressed as Log2 Fold Changes (Log2 FC). Relationships between pBMs levels and the Ankylosing Spondylitis Disease Activity Score using C-reactive protein (ASDAS-CRP) were derived using Pearson's correlation. A repeated measure mixed linear model identified pBMs differentially modulated by UPA. All tests were corrected for multiple testing using the Benjamini-Hochberg method. Significance threshold was defined as FDR ≤ 0.05. We used a commercially available software application for pathway analysis.



Results: At baseline, we identified 174 (nr-axSpA) and 178 (bDMARD-IR AS) pBMs that were significantly differentially expressed in patients compared to HVs. Only 24 out of 1463 pBMs tested were differentially expressed between the two patient populations. Notably, interleukin-6, matrix metalloproteinase-1, metalloproteinase-3, and interleukin 17 receptor A were significantly more elevated in bDMARD-IR AS patients than in nr-axSpA patients. The pathway enrichment analysis on the differential pBMs pointed to a dysregulation of the adaptive and innate immune systems, increase in endothelial activation, and damage to connective tissue in both patient groups, although more pronounced in bDMARD-IR AS patients. Baseline levels of 49 (4 negatives and 45 positives) and 178 (130 negatives and 48 positives) pBMs correlated with baseline ASDAS-CRP in the nr-axSpA and bDMARD-IR AS patients, respectively. Treatment with UPA resulted in a broad modulation of pBMs at weeks 2 and 14 in both patient groups, with a larger effect in bDMARD-IR AS patients than in nr-axSpA patients. Based on pathway prediction analysis, the effects of UPA on pBMs were consistent with the inhibition of the adaptive (T cell activation and migration, and antigen presenting cell activation) and innate (phagocyte and granulocyte migration and activation) immune pathways. The effects of UPA treatment on pBM correlating with ASDAS-CRP at baseline were consistent with UPA's broad activity on potential pathogenic pathways in both nr-axSpA and bDMARD-IR AS patients (**Figure 1**).

Conclusion: While presenting different degrees of axial skeletal involvement, nr-axSpA and bDMARD-IR AS patients share common pathogenic pathways, with a more pronounced dysregulation observed in the latter group as observed from our data. Treatment with UPA inhibited multiple potentially pathogenic pathways associated with disease activity at baseline in nr-axSpA and bDMARD-IR AS patients. These observations are consistent with prior analyses in bDMARD-naïve AS patients[3]. We propose that the clinical efficacy of UPA in these 2 patient populations may result, at least in part, from its broad biological activity observed at the protein level.

Background: Combined biological or targeted therapy (CBTT) is rarely considered in clinical practice due to not being recommended in clinical guidelines, potential safety concerns and high costs. Successful experiences have been found with CBTT in refractory patients with inflammatory bowel disease (IBD). Previous early data in selected refractory spondyloarthritis (SpA) have shown encouraging results[1].

Objectives: Our aim was to assess real-world effectiveness and safety of CBTT in a wider SpA population.

Methods: This is a retrospective multicenter study. We identified patients with SpA and simultaneous combined use of two biological or targeted (excluding apremilast) agents with different therapeutic targets since 2017. All patients fulfilled axial or peripheral SpA ASAS criteria and signed written informed consent. Demographics, clinical, laboratory, and safety data were collected from electronic medical records. Cut-offs for remission/low activity criteria for axial-peripheral disease were ASDAS-CRP <1.3/<2.1 or DAS-28-CRP<2.6/<3.2 or DAPSA<4/<14, respectively. Major clinical improvement (MCI) was defined as a change in ASDAS-CRP>2 and DAS-28-CRP>1.2 units and improvement of >85% in DAPSA.

Results: A total of 39 CBTT courses were identified in 35 SpA patients (Table 1). The main indication for CBTT was active musculoskeletal disease (Table 2). Three patients presented remission or low SpA activity at baseline and were excluded in the efficacy SpA analysis. Most patients (89.7%) had previously failed at least one of the two therapies used in CBTT. The most common combination was TNF inhibitor plus IL12/23 inhibitor agent (n=20; 51.2%). Median exposure to CBTT was 16 months (IQR 11-24). At last follow-up, we observed a significant mean reduction in ASDAS-CRP (2.07; 95% CI: 1.31-2.83; p=0.001). Remission/low activity rates were 52.7%, and 61.1% (n=22) reached MCI. In a bivariate analysis, patients who reached MCI had a lower baseline ASDAS-CRP than those who did not (4.33 vs 6.20, p=0.052). Nine patients discontinued CBTT due to inefficacy, seven of them because of IBD activity. In 39 CBTT courses, 4 serious AE were identified in only 3 patients: non-infectious pulmonary infiltrates, a staphylococcal bacteremia and a patient with cytomegalovirus colitis and esophageal candidiasis.

Conclusion: Our preliminary results suggest that CBTT might be a feasible alternative in selected refractory multidomain SpA patients, with acceptable effectiveness/safety ratio. Prospective wider studies are warranted to confirm these data.

PROFILING OF SYSTEMIC IMMUNE RESPONSES IN AXIAL SPONDYLOARTHRITIS PATIENTS REVEALS STRIKINGLY DISTINCT CELLULAR AND MOLECULAR MECHANISMS OF ACTION OF IL-17A INHIBITORS AND TNF-BLOCKERS

Keywords: bDMARD, Spondyloarthritis

Miceli Richard[1,6], L. Rogge[1]. *[1]Institut Pasteur, Université Paris Cité, Immunoregulation Unit, Department of Immunology, Paris, France*; *[2]Université Paris Diderot, Sorbonne Paris Cité, Paris, France*; *[3]Institut Pasteur, Université Paris Cité, Bioinformatics and Biostatistics Hub –, Département de Biologie Computationelle, USR 3756 IP CNRS, Paris, France*; *[4]Sorbonne Université, Hôpital Saint-Antoine, Service de Rhumatologie, AP-HP, Paris, France*; *[5]Centre de Recherche Saint-Antoine, INSERM UMR_S 938, Paris, France, Paris, France*; *[6]Université Paris Cité, Hôpital Cochin Port Royal, AP-HP, Service de Rhumatologie, Paris, France*

Background: IL-17A inhibitors (IL-17i) and TNF-inhibitors (TNFi) are currently the only biologic drugs available as first line treatment in axial spondyloarthritis (axSpA). While several studies have provided mechanistic insights into TNFi action, much less is known how IL-17i affect immune responses in patients.
Objectives: We have compared the effects of IL-17i and TNFi on immune cell frequencies and induced immune responses to obtain information about the mechanisms of action of these two drugs in axSpA patients *in vivo*.
Methods: Induced immune responses to microbial and pathway-specific stimuli were analyzed in peripheral blood samples from 40 axSpA patients before and after IL-17i or TNFi treatment, using highly standardized whole-blood stimulation assays. Changes in gene expression were determined by RNA sequencing and secreted molecules were measured using proximity ligation assays.
Results: IL-17A-blockade had very limited effects on systemic immune responses with no significant gene expression changes detectable in stimulated whole-blood cultures when comparing samples before and 16 weeks after treatment initiation. In contrast, anti-TNF therapy induced profound changes in patients' immune responses affecting the expression of more than 4000 genes. Pathways analysis revealed major effects of TNFi on the expression of genes involved in protection from bacterial (Tuberculosis, Legionellosis), viral (EBV, Influenza) and parasitic (Leishmaniasis, Toxoplasmosis) infections (Figure 1). Analysis of secreted inflammatory cytokines and chemokines showed that TNF-blockade also strongly affected innate and adaptive immune cell signaling, while only minor changes were observed in stimulation cultures from IL-17i-treated axSpA patients. Furthermore, we noted major effects of TNFi, but not of IL-17i, on neutrophil and monocyte counts in the circulation of treated patients.
Conclusion: We show that the two currently used biotherapies of axSpA act by strikingly distinct cellular and molecular mechanisms. While anti-TNF therapy has major effects on systemic immune responses with potential implications for increased susceptibility to infectious microorganisms, IL-17 inhibitors had a lesser impact on systemic immune responses compared to TNFi, suggesting that may rather act on non-immune cells and/or in inflamed tissues.

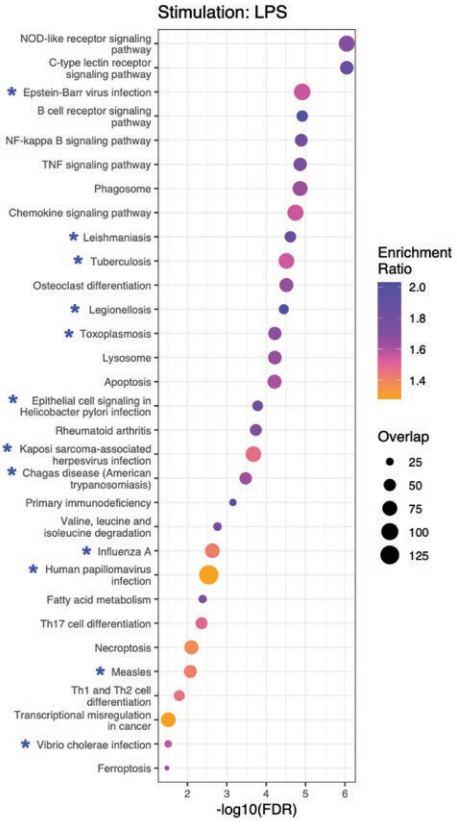

Figure 1: TNF-blockade affects multiple pathways associated with protection to infectious microorganisms. Pathway over-representation analysis (ORA) of differentially expressed genes from RNA-seq data generated from whole-blood stimulation (TruCulture) assays (LPS stimulus) performed before and 12 weeks after initiation of anti-TNF therapy. Pathway analysis was performed with the WEB-based gene set analysis toolkit (WebGestalt). Bubble plot representation of significant pathways with False Discovery Rate (FDR < 0.05, x-axis), enrichment ratio and gene counts (colors and bubble size, respectively). Blue asterisks mark infectious disease pathways.

CHARACTERISTICS OF DIFFICULT TO TREAT AXIAL SPONDYLOARTHRITIS: A COMPARATIVE ANALYSIS

Keywords: Spondyloarthritis, Real-world evidence, Disease-modifying drug (DMARDs)

T. Delepine[1], E. Cailliau[2], P. Philippe[1], X. Deprez[3], N. Taisne[3], E. Houvenagel[4], T. Pascart[4], R. M. Flipo[1,5], J. G. Letarouilly[1,5]. *[1]Hospital Center University De Lille, Rheumatology, Lille, France*; *[2]Hospital Center University De Lille, Statistics, Economic Evaluation, Data-management Unit, Lille, France*; *[3]Hospital Center De Valenciennes, Rheumatology, Valenciennes, France*; *[4]Hôpital Saint Philibert, Rheumatology, Lille, France*; *[5]Université de Lille - Pôle Recherche de la Faculté de Médecine, FHU Precise, Lille, France*

Background: The concept of difficult-to-treat rheumatoid arthritis (D2T RA) has recently emerged. It is defined by the persistence of disease activity and the failure of at least 2 b/tsDMARDs of 2 different mechanisms of action (MoA) [1]. In this definition, the period during which the treatments have failed is not included. The D2T concept has not yet been applied with consensus in axial spondyloarthritis (axSpA).
Objectives: To study the characteristics of patients with D2T axSpA to better identify the potential causes of treatment failure. The second objective was to study a sub-group of D2T axSpA patients with a predefined time criteria.
Methods: A multicentric retrospective longitudinal study was performed in secondary and tertiary centers. axSpA diagnosis was based on ASAS criteria. Patients were followed up from January 2016 to December 2021. Patients starting a b/tsDMARDs with a minimum of 2-year follow-up were included. D2T axSpA patients were defined as patients who received more than 2 b/tsDMARDs with different MoA among b/tsDMARD available. These patients were compared to non-difficult-to-treat axSpA patients (nD2T axSpA) using statistical tests. Very D2T axSpA patients were defined as patients who received at least 2 b/tsDMARDs in less than 2 years during the time of follow-up.
Results: 311 patients were included, 88 were D2T axSpA and 223 nD2T axSpA. Baseline characteristics are presented in the Table 1. No statistical difference was found between the 2 groups regarding main comorbidities, including fibromyalgia and depression. Among the D2T patients, 76 (86%) had presented a primary or secondary inefficacy from 2 drugs with different MoA and 12 (14%) presented a contraindication to TNFinhibitor or IL17 inhibitor (multiple sclerosis, inflammatory bowel diseases, recurrent uveitis, solid cancer less than 5 years old). Seven patients were categorized as very D2T axSpA. When compared to the rest of the D2T axSpA group, no significant difference was observed.
Conclusion: Significant differences were found between the characteristics of patients D2T axSpA and nD2T axSpA, which were the smoking status, axSpA duration, presence of arthritis, history of uveitis and baseline BASDAI. Limitations exist about applying the EULAR D2T RA definition to axSpA. The inclusion of a time should also be considered.

Background: SURPASS, a phase IIIb randomised controlled study in patients (pts) with radiographic axial spondyloarthritis (r-axSpA), found low spinal radiographic progression over 2 years with no significant difference between the secukinumab (SEC) and adalimumab biosimilar (SDZ-ADL) arms.[1,2] Baseline (BSL) radiographic damage (presence of syndesmophytes) and elevated C-reactive protein (CRP) levels have been identified as predictors of radiographic progression in r-axSpA.[3]
Objectives: To evaluate the effect of SEC and SDZ-ADL on spinal radiographic progression in subgroups of pts based on the presence of syndesmophytes and elevated high-sensitivity CRP (hsCRP) levels at BSL, from the SURPASS study.
Methods: Biologic-naïve pts with active r-axSpA and with hsCRP ≥5 mg/L and/or ≥1 syndesmophyte(s) on spinal radiographs were randomised (1:1:1) to SEC (150 or 300 mg; dose-blinded) or SDZ-ADL (40 mg; open label). Pts were categorised into the following subgroups at BSL: hsCRP ≥5 mg/L (CRP+), hsCRP <5 mg/L (CRP–), presence of syndesmophyte(s) (Synd+), absence of syndesmophyte(s) (Synd–), and CRP+Synd+. The proportion of pts with no radiographic progression (change from baseline in modified Stoke Ankylosing Spondylitis Spinal Score [mSASSS] ≤0.5), mean change from BSL in mSASSS, and proportion of pts with no new syndesmophytes(s) in each subgroup at week 104 (all as observed) are reported.
Results: Of the 859 pts, 653 (76%) were CRP+, 627 (73%) were Synd+, and 466 (54%) were CRP+Synd+ at BSL. Demographic and BSL disease characteristics were largely balanced across subgroups and treatment arms, except for the Synd– group in which mean age, proportion of male pts, and mean time since diagnosis were lower than in other subgroups (**Table 1**).
All radiographic outcomes at week 104 were similar across treatment arms; however, differences were observed between subgroups irrespective of the treatment arm. The Synd– subgroup followed by the CRP– subgroup showed the least progression in all radiographic outcomes (as indicated by the higher proportion of pts with no radiographic progression and no new syndesmophytes, and lower mean change from BSL in mSASSS), across treatment arms (**Figure 1**). The CRP+Synd+ subgroup followed by the Synd+ subgroup and the CRP+ subgroup had higher radiographic progression compared with the Synd– and CRP– subgroups (**Figure 1**).
Conclusion: Spinal radiographic progression over 2 years was low with no notable difference between SEC and SDZ-ADL arms regardless of the presence or absence of specific predictive factors for progression (syndesmophytes/elevated CRP). Expectedly, pts from subgroups without predictive factors (especially Synd–, followed by CRP–) had lower rates of radiographic progression.

POS1116

TIME TO IMPROVEMENT OF PAIN, MORNING STIFFNESS AND DISEASE ACTIVITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH TOFACITINIB

Keywords: Pain, Patient reported outcomes, Spondyloarthritis

V. Navarro-Compán[1], A. Deodhar[2], R. Bahiri[3], A. G. Bushmakin[4], J. C. Cappelleri[4], C. Kinch[5], J. Rammaoui[6]. *[1]La Paz University Hospital, IdiPaz, Department of Rheumatology, Madrid, Spain*; *[2]Oregon Health & Science University, Division of Arthritis and Rheumatic Disease, Portland, OR, United States of America*; *[3]El Ayachi Hospital Medical University, Department of Rheumatology, Rabat, Rabat-Salé-Kénitra, Morocco*; *[4]Pfizer Inc, Statistical Research and Data Science Center, Groton, CT, United States of America*; *[5]Pfizer Canada ULC, Inflammation and Immunology, Kirkland, QC, Canada*; *[6]Pfizer Inc, Innovative Medicines/Emerging, Casablanca, Morocco*

Background: Pain, morning stiffness and disease activity are core domains of ankylosing spondylitis (AS), relevant to patients (pts) and physicians. AS treatment guidelines recommend using the AS Disease Activity Score C-reactive protein ($ASDAS_{CRP}$) to assess disease activity. Greater improvements in pain, morning stiffness and disease activity were previously shown with tofacitinib vs placebo (PBO) in pts with AS.[1] There are limited data on time to improvement in these core domains in pts with AS receiving tofacitinib.

Objectives: To estimate the median time to improvement of pain, morning stiffness and disease activity in tofacitinib-treated pts with AS.

Methods: This post hoc analysis used data from a Phase 3 trial (NCT03502616)[1] in pts with AS receiving tofacitinib 5 mg twice daily (BID) or PBO to Week (W)16. After W16, all pts received open-label tofacitinib 5 mg BID to W48. Outcomes included nocturnal pain (numerical rating scale 0–10), morning stiffness (mean of Bath AS Disease Activity Index [BASDAI] Questions 5 and 6), BASDAI total score and $ASDAS_{CRP}$. Median time (weeks) to initial improvement events was estimated using non-parametric Kaplan-Meier models. Initial improvement event was defined as time to first post-baseline observation with an improvement of ≥30% (nocturnal pain ["much improved"][2]), ≥50% (nocturnal pain ["very much improved"],[2] morning stiffness and BASDAI total score) or $ASDAS_{CRP}$ ≥1.1 (clinically important improvement)/≥2.0 (major improvement) points.

Results: Overall, 269 pts (tofacitinib: n=133; PBO→tofacitinib: n=136) were assessed. Median times to initial improvement events were shorter with tofacitinib vs PBO→tofacitinib (p<0.05 [Table 1]). Median times to initial ≥30% and ≥50% improvement in nocturnal pain for tofacitinib were 4 and 8 weeks, respectively, and 24 weeks (8 weeks since switch to tofacitinib) for both thresholds for PBO→tofacitinib. Median time to initial ≥50% improvement in morning stiffness and BASDAI total score for tofacitinib was 12 weeks, and 32 weeks (16 weeks since switch to tofacitinib) for PBO→tofacitinib. Median time to $ASDAS_{CRP}$ improvement ≥1.1 for tofacitinib was 4 weeks, and 24 weeks for PBO→tofacitinib (not estimable [NE] for $ASDAS_{CRP}$ improvement ≥2.0 [both treatment arms]). Limitations: this was a post hoc analysis, there was no active treatment comparator, trial pt population may not reflect routine care pt population and comparisons with PBO were only possible to W16.

Table 1. Median times (weeks) to initial improvement events (Kaplan-Meier analysis)

	Median time (interquartile range)		
Improvement threshold	**Tofacitinib 5 mg BID (N=133)**	**PBO→tofacitinib[a] (N=136)**	**p value**
≥30% improvement			
Nocturnal pain	4 (2–24)	24 (8–32)	0.0003
≥50% improvement			
Nocturnal pain	8 (4–40)	24 (16–NE)	<0.0001
Morning stiffness	12 (4–NE)	32 (24–NE)	0.0091
BASDAI total score	12 (4–NE)	32 (16–NE)	0.0002
Improvement in $ASDAS_{CRP}$			
≥1.1 points	4 (2–20)	24 (12–40)	<0.0001
≥2.0 points	NE	NE	0.0361

p values are based on log-rank tests for differences in survival curves for tofacitinib vs PBO→tofacitinib[a]Switched to open-label tofacitinib at W16

Conclusion: In pts with AS, during the first month of tofacitinib treatment, it is expected that half of pts will experience ≥30% improvement in nocturnal pain ("much improved") and a clinically important improvement in $ASDAS_{CRP}$. During the first 2 and 3 months of tofacitinib treatment, it is expected that half of pts will experience ≥50% improvement in nocturnal pain ("very much improved") and morning stiffness, respectively. Improvements in pain, morning stiffness and disease activity occurred more rapidly with tofacitinib vs PBO→tofacitinib. This study informs physicians and pts receiving tofacitinib of when improvement in these core domains in AS may be anticipated.

POS1117 DOWNSTREAM EFFECTS ON CYTOKINE EXPRESSION PROFILE OF SIX DIFFERENT JAK INHIBITORS IN AN IN VITRO MODEL OF IMMUNE MEDIATED INFLAMMATORY ARTHRITIS

Keywords: Cytokines and chemokines, Targeted synthetic drugs

M. B. Kristensen[1], T. W. Kragstrup[1,2,3]. *[1]Aarhus University, Department of Biomedicine, Aarhus, Denmark*; *[2]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark*; *[3]Silkeborg Regional Hospital, Diagnostic Center, Silkeborg, Denmark*

Background: Janus kinase inhibitors (JAKis) are a group of disease modifying antirheumatic drugs (DMARDs) used for the treatment of several immune mediated inflammatory arthritides (IMIAs) including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA). There are several JAK inhibitors (JAKis) with different selectivity already approved or in clinical and preclinical development[1]. Thus, tofacitinib is a JAK1/3 inhibitor, baricitinib is an JAK2/3 inhibitor, filgotinib and upadacitinib are selective JAK1 inhibitors, decernotinib is a selective JAK3 inhibitor[2] and deucravacitinib is a selective tyrosine kinase 2 (TYK2) inhibitor[3]. The downstream effects on cytokine expression profile of JAKis with different selectivity is not fully understood.

Objectives: Here we investigate whether JAKis with different selectivity show differences in downstream cytokine expression in an in vitro model of IMIA.

Methods: Synovial fluid mononuclear cells (SFMCs) from patients with peripheral SpA (n=3), PsA (n=3), juvenile idiopathic arthritis (n=4), and unspecified inflammatory arthritis (n=1). Synovial fluid was collected after therapeutic arthrocentesis. SFMCs from each patient were cultured for 48 hours with the JAKis priorly listed. Culture medium and DMSO were used as negative controls. In vitro drug response was assessed by MesoScale V-PLEX Proinflammatory Panel 1 Human Kit measuring interferon γ (IFN- γ), interleukin 1β (IL-1β), IL-2, IL-4, IL-6, IL-10, IL-12p70, IL-13 and TNFα.

Results: First, we tested whether JAKis with a similar selectivity had comparable effects on the secretion of cytokines. Indeed, JAKis with selectivity towards JAK1 and JAK3 clustered together in the hierarchical analysis. Then, we examined whether there was a difference between the six JAKis on mean cytokine expression merging all cytokines (mean merged cytokine expression). All JAKis with a JAK1 selectivity decreased the cytokine secretion more than the JAK2/3 inhibitor baricitinib (filgotinib vs. baricitinib, p<0.005; upadacitinib vs. baricitinib, p<0.05; tofacitinib vs. baricitinib, p<0.05). There was no difference between the JAKis with JAK1 selectivity and decernotinib (JAK3) or deucravacitinib (TYK2). After correcting for multiple comparisons using Tukey's test, there was also no difference in mean merged cytokine expression between JAKis with JAK1 selectivity and baricitinib. Finally, we studied differences between individual patients. Interestingly, JAKis with different selectivity were better at decreasing certain cytokine secretions compared to other JAKis on an individual level. E.g., SFMCs from patient H had a generally higher decrease in cytokine secretion after filgotinib treatment.

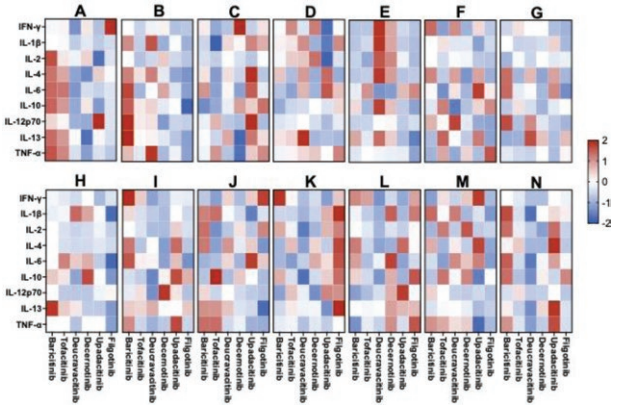

Figure 1. Cytokine secretion for each JAKi treatment relative to DMSO control for each patient (n=14). Data are z-normalized for each patient relative to each cytokine's level of secretion.

Conclusion: Similarities in mode of action for the six JAKis were reflected in drug response measured by multiple cytokine secretions. Generally, JAKis with JAK1 and JAK3 selectivity decreased total cytokine secretion the most. In selected patients, specific JAKis decreased total cytokine secretion considerably more than the remaining JAKis, while most patients had an equal response to all six JAKis.

POS1118 DISCRIMINATING CAPACITY OF THE ASAS HEALTH INDEX IN PATIENTS TREATED WITH IXEKIZUMAB IN THE COAST PROGRAMME

Keywords: Spondyloarthritis, bDMARD, Clinical trials

U. Kiltz[1], A. Moltó[2], D. Van der Heijde[3], L. Bessette[4], A. Boonen[5], R. Bolce[6], C. Sapin[6], T. Hunter[6], B. Janos[6], A. Kronbergs[6], S. Liu Leage[6], J. Braun[7,8]. *[1]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Rheumatology, Herne, Germany*; *[2]Université de Paris, Hôpital Cochin, Assistance Publique-Hôpitaux de Paris, Department of Rheumatology, Paris, France*; *[3]Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; *[4]Laval University, Department of Medicine, Quebec, Canada*; *[5]Maastricht University Medical Centre, 6Department of Internal Medicine, Division of Rheumatology, Maastricht, Netherlands*; *[6]Eli Lilly and Company, Indianapolis, United States of America*; *[7]Rheumazentrum Ruhrgebiet, Herne, Germany*; *[8]Ruhr University Bochum, Bochum, Germany*

Background: The Assessment of SpondyloArthritis international Society Health Index (ASAS HI) is a validated health outcome measure used to assess functioning and health in patients (pts) with axial spondyloarthritis (axSpA) [1]. Two thresholds for clinical improvement have been recently proposed: improvement ≥3 points and a 30% improvement from baseline [1,2]. However, an exploration of the optimal threshold in an independent cohort has not been carried out to date.

Objectives: Using data from the COAST trials, this analysis aimed to test the discriminatory capacity of the ASAS HI at different thresholds of improvement.

Methods: This *post hoc* analysis included patients treated with either ixekizumab (IXE) 80 mg every 4 weeks (Q4W) or placebo (PBO) from the intent-to-treat populations of COAST-V (NCT02696785) and COAST-W (NCT02696798) for radiographic (r)-axSpA, and COAST-X (NCT02757352) for non-radiographic (nr)-axSpA over 16 weeks. To assess the discriminatory capacity of the ASAS HI, response rates at Week 16 were compared between IXE Q4W and PBO using Fisher's exact test. Phi coefficients (ranging from -1 to +1) were calculated to compare the degree of association between the level of improvement and treatment allocation. Missing data were handled using non-responder imputation.

Results: ASAS HI data at Week 16 were available for pts with r-axSpA from COAST-V (IXE Q4W, N=81; PBO, N=87) and COAST-W (IXE Q4W, N=114; PBO, N=104) and pts with nr-axSpA from COAST-X (IXE Q4W, N=96; PBO, N=105). Percentages of pts reaching improvement scores for different study arms are shown in Figure 1. Differences in response rates by the various absolute or

relative thresholds for improvement are shown in Table 1. Data demonstrated an inconsistent picture of the best performing threshold between the different COAST studies. While for COAST-V discriminatory capacity were demonstrated for higher values this was opposite to COAST-W, and there was no clear discriminating threshold in COAST-X (Table 1, Figure 1). The majority of Phi coefficients were below 0.2, suggestive of low discriminatory capacity.

Conclusion: In this post hoc analysis of pts from the COAST trials at Week 16, several thresholds of improvement of the ASAS HI seem to have discriminating capacity. However, there were some differences between the COAST trials and no single threshold worked best in the r-axSpA (bDMARD-naïve and experienced) and nr-axSpA populations.

Background: Data on the extent to which internationally agreed treat-to-target (T2T) recommendations were applied in clinical practice in patients with spondyloarthritis (SpA) across the Asia-Pacific region is lacking. The APLAR SpA Registry is a multi-centre study aiming to assess the utility of early diagnosis and intensive protocolized treatment to patients with SpA on the long-term outcome.

Objectives: This analysis aimed to evaluate the extent of T2T achievement after 1-year intensive treatment in patients with SpA.

Methods: Patients who fulfilled the CASPAR 2006 classification criteria for psoriatic arthritis (PsA), and 2009 ASAS classification for axial spondylitis (AxSpA) were recruited. The current analysis included the first 99 patients reaching the 1-year timepoint across 6 Asia-Pacific regions.

Results: 49 patients with PsA (age: 52±11 years, 27(55%) male, disease duration: 6.0±7.9 years) and 50 patients with AxSpA (age: 40±14 years, 36(72%) male, disease duration: 5.9±7.6 years) were included. All of them were Asian. After 1-year treatment, there were significant improvements in disease activity (Disease Activity in Psoriatic Arthritis (DAPSA): 15.3±11.6 at baseline vs 10.1±11.2 at 1-year, p=0.002; Ankylosing Spondylitis Disease Activity Score (ASDAS): 2.4±1.0 at baseline vs 1.9±0.9 at 1-year, p=0.003). Other characteristics are shown in Table 1. Concerning medication use, there was an increase in the number of PsA patients receiving conventional synthetic disease-modifying drugs (csDMARDS, 65% at baseline to 72% at 1-year) and biologic DMARDS (bDMARDS, 24% at baseline to 43% at 1-year). For AxSpA, the prevalence of csDMARDs use decreased (30% at baseline to 18% at 1-year) while the prevalence of bDMARDs use increased (32% at baseline and 54% at 1-year). Patients in both groups required less NSAIDs (Figure 1). Regarding T2T, 63% and 51% of PsA patient achieved DAPSA-low disease activity (DAPSA-LDA) and minimal disease activity (MDA) respectively, while 66% of patients with Axial SpA achieved ASDAS-LDA. The MDA and ASDAS-LDA achievement rate was slightly higher than that of the tight control arm of TICOPA (41%)[1] and TICOSPA cohort (60%)[2] respectively. The bDMARDs use in TICOPA cohort was 37% and that in TICOSPA was 57%, both comparable to our APLAR SpA cohort (Figure 1). There was no significant difference in baseline demographics and clinical features between patients who could or could not achieve treatment target, except a lower patients' pain and global assessment, and lower functional disability in patients who achieved DAPSA-LDA at 1-year.

Conclusion: Implementing the T2T strategy in a patient with SpA is feasible in the selected sites of the APLAR SpA registry. We expect more long-term outcome data in the following years regarding other outcomes.

IMPACT OF BASELINE CRP LEVEL ON SECUKINUMAB (SEC) RETENTION IN AXIAL SPONDYLOARTHRITIS (AXSPA): RESULTS OF THE FRENCH RETROSPECTIVE STUDY FORSYA

Keywords: Spondyloarthritis, Prognostic factors, Real-world evidence

P. Goupille[1], M. Dougados[2], A. Lardy-Cléaud[3], E. Desfleurs[4], P. Claudepierre[5], A. Ruyssen-Witrand[6], A. Saraux[7], A. Tournadre[8], C. Lukas[9], D. Wendling[10].
[1]University Hospital of Tours, Department of Rheumatology, Tours, France; [2]Hôpital Cochin. Assistance Publique - Hôpitaux de Paris, Department of Rheumatology, Paris, France; [3]RCTs Clinical Research Organization, Biostatistics, Lyon, France; [4]Novartis, Medical Affairs, Rueil Malmaison, France; [5]Hôpital Henri Mondor, Assistance Publique - Hôpitaux de Paris, Department of Rheumatology, Créteil, France; [6]University Hospital of Toulouse, Rheumatology center, Toulouse, France; [7]University Hospital of Brest, Department of Rheumatology, Brest, France; [8]University Hospital of Clermont-Ferrand, Department of Rheumatology, Clermont-Ferrand, France; [9]University Hospital Montpellier, Department of Rheumatology, Montpellier, France; [10]University Hospital of Besançon, Department of Rheumatology, Besançon, France

Background: While data on real-life SEC retention rate in patients (pts) with axSpA is accumulating, there are few data on predictive factors for this retention. Presence of objective sign of inflammation (OSI), especially increased baseline CRP level, is known to be predictive of efficacy of anti-TNFs and their retention in axSpA.

Objectives: To assess whether OSI, especially increased baseline CRP level, were predictive of SEC retention at 1 year in axSpA.

Methods: French retrospective study collecting between October 2019 and September 2020 data from axSpA pts a) having initiated and received at least one dose of SEC between August 11th 2016 and August 31st 2018, b) with at least a one-year follow-up period. Retention rate of SEC at 1 year was estimated by the Kaplan Meier (KM) method. OSI were defined by at least one of the following: CRP ≥5 mg/l or ESR ≥28 mm/h if CRP not available (CRP+) within the 3 months before initiation of SEC and MRI inflammation at the sacroiliac or spine level (MRI+) at any time. *The a priori selected potential predictive factors of the SECU 1 year retention* (CRP+, MRI+, age, sex, BMI, smoking, HLA B27, non-radiographic vs radiographic axSpA, past or present uveitis/Inflammatory Bowel Disease/psoriasis/arthritis or synovitis, diagnostic delay, disease duration, SEC line of biologic therapy, SEC maintenance dose, concomitant csDMARD/oral corticosteroids/proton pomp inhibitor at SEC initiation, history of depression/fibromyalgia) were analyzed by cox model regression. Only variables with <20% missing data were included in the model after imputation and stepwise selection (significance level for entering variables =20%; significance level for removing variables =10%), except for CRP and MRI which were forced into the model whatever their significance level or rate of missing data.

Results: In total, 906 pts from 47 centers (male: 42.2%, mean age: 46.2 ± 11.7 years, mean disease duration: 9.3 ± 9.1 years) were included in the analysis. The mean baseline CRP (± SD) was 11.1 ± 17.5 mg/L. At initiation of SEC, 86.3% of pts had ≥ 1 OSI (41.3% CRP+, and 69.4% MRI+) and respectively 8.0%, 14.9% and 77.1% were in 1st, 2nd and ≥ 3rd line (L) of biologic/targeted synthetic DMARD. The 1-year retention rate for SEC was 59% [95%CI: 55%-62%]. This retention at one year was 62.4% vs 59.1% and 57.4% vs 66% in patients with CRP+ vs CRP- and MRI+ vs MRI- respectively. In univariate cox regression, CRP+ was not predictive of SEC discontinuation at 1 year (HR = 0.90 [0.71-1.16]; p=0.422 nor was MRI+ (HR=1.29 [0.99; 1.68]; p=0.063). In multivariate cox analysis, after adjustment, these results were confirmed for CRP+ but MRI+ was identified as predictive of a worst SEC retention at 1 year (Table 1). In multivariate analysis lack of prior exposure to anti-TNF inhibitors, absence of IBD and absence of history of depression were also associated with a better SEC retention at 1 year (at 10%).

Conclusion: The overall retention of SEC at 1 year in daily practice in France was 59% for axSpA patients, independently of CRP level at SEC initiation.

POS1121

IMPACT OF SUBCLINICAL ANKLE AFFECTION ON THE FUNCTIONAL STATUS OF RHEUMATOID ARTHRITIS PATIENTS: AN ULTRASOUND-BASED STUDY

Keywords: Ultrasound, Quality of life, Rheumatoid arthritis

M. G. Abdelzaher[1,2], S. Finzel[2], A. Abdelsalam[1], A. Enein[1], N. Abdelsalam[1].
[1]Faculty of Medicine, Mansoura University, Rheumatology and Immunology Unit, Internal Medicine Department, Mansoura, Egypt; *[2]University Medical Center Freiburg, Rheumatology and Clinical Immunology Department, Freiburg, Germany*

Background: Subclinical involvement of the ankles is common in rheumatoid arthritis (RA) and occurs even in patients in clinical remission[1]. Assessing the characteristics of ankle inflammation and its effect on the functional status will enable the clinician to target treatment interventions[2]. Ankle joint is underrepresented in many clinical, sonographic RA-scores, and there is little information available in the literature about ultrasound (US) evaluation of asymptomatic ankle pathologies in RA patients.

Objectives: To assess the impact of US diagnosed subclinical ankle pathologies on the functional status of RA patients.

Methods: The study included 52 RA patients without ankle pain and 52 healthy age, gender matched controls. Ankle joints were examined clinically then by US using gray scale (GS) and Power Doppler (PD) including tibiotalar (TTJ), subtalar (STJ), talonavicular (TNJ), calcaneo-cuboid joints. In addition, tibialis anterior (TA), extensor hallucis longus (EHL), extensor digitorum longus (EDL), tibialis posterior (TP), flexor digitorum longus (FDL), flexor hallucis longus (FHL), peroneus longus, brevis and achilles tendons (AT), retrocalcaneal bursa (RCB) and plantar fascia (PF) were assessed. Functional capacity was measured using Health Assessment Questionnaire (HAQ) and Foot Function Index (FFI)

Results: Data showed significantly more GSUS pathologies in the asymptomatic RA group than in the control group in TP (27.9% vs 3.8%) (P=0.043), FDL (3.8% vs 0%) (P=0.043), and peroneal tenosynovitis (26% vs 0%) (P<0.001), TTJ (23.1% vs 5.8%) (0.024) and TNJ synovitis (23.1% vs 3.8%) (P=0.024), AT tendinitis (19.2% vs 4.8%) (P=0.01), RCB bursitis (13.5% vs 1.9%) (P=0.002), STJ (13.5% vs 0%) (P=0.024), and calcaneo-cuboid joint synovitis (4.8% vs 0%) (P=0.024). Pathologies; see Figure 1. There was a trend to statistical significance of PDUS in TTJ and peroneal tendons in RA patients. Impaired functional activity as represented by higher HAQ and FFI scores was highly significantly associated to pathologies in TTJ, STJ, TNJ, AT, RCB, and PF; see Table 1.

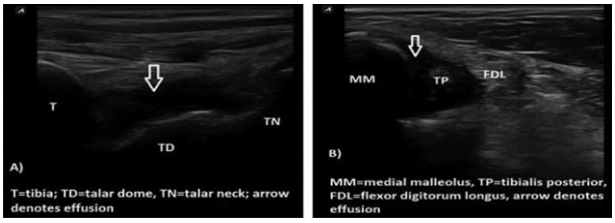

Figure 1. Asymptomatic ankle pathologies in RA by US. a) Tibiotalar synovitis, b) Tibialis posterior tenosynovitis)

Table 1. Impact of subclinical ankle pathologies on functional status of RA patients

Ultrasound pathology	Health assessment questionnaire				Foot function index			
	Low	Moderate	High	P	Low	Moderate	High	P

EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS AND AN INADEQUATE RESPONSE TO BIOLOGIC DMARD THERAPY: ONE-YEAR RESULTS FROM A PHASE 3 STUDY

Keywords: Spondyloarthritis, Targeted synthetic drugs, Clinical trials

X. Baraliakos[1], D. Van der Heijde[2], J. Sieper[3], R. Inman[4], H. Kameda[5], Y. Li[6], X. Bu[6], A. Shmagel[6], P. Wung[6], I. H. Song[6], A. Deodhar[7].
[1]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Professor of Internal Medicine and Rheumatology, Herne, Germany; *[2]Leiden University*

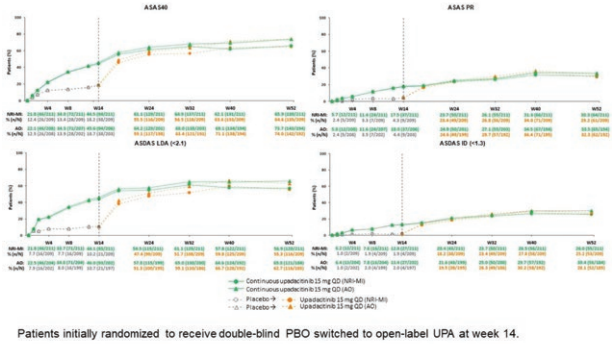
Medical Center (LUMC), Rheumatology, Leiden, Netherlands; [3]*Charité – Universitätsmedizin Berlin, Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*; [4]*Schroeder Arthritis Institute, University Health Network, and University of Toronto, Toronto, Canada*; [5]*Toho University Ohashi Medical Center, Internal Medicine, Meguro City, Japan*; [6]*AbbVie, Inc, Immunology, North Chicago, United States of America*; [7]*Oregon Health & Science University, Division of Arthritis & Rheumatic Diseases, Portland, United States of America*

Background: Upadacitinib (UPA), a Janus kinase inhibitor, has demonstrated efficacy and an acceptable safety profile in patients (pts) with ankylosing spondylitis (AS) in the phase 3 SELECT-AXIS 1 and 2 program, including pts with an inadequate response or intolerance to biologic disease-modifying antirheumatic drugs (bDMARD-IR).[1,2]

Objectives: To assess the 1-year efficacy and safety of UPA 15 mg once daily (QD) in bDMARD-IR pts with active AS in SELECT-AXIS 2.

Methods: The design of the SELECT-AXIS 2 AS bDMARD-IR study has been described previously.[1] Pts who completed the 14-wk placebo (PBO)-controlled period were eligible to enter an ongoing long-term extension and receive open-label UPA 15 mg QD for up to 90 wks. This analysis evaluated efficacy over 52 wks in pts who received continuous UPA, and those who switched from PBO to UPA at wk 14. Efficacy endpoints included proportion of pts achieving Assessment of SpondyloArthritis international Society 40 response (ASAS40), ASAS partial remission (PR), ASDAS (AS Disease Activity Score with C-reactive protein [CRP]) low disease activity (LDA; <2.1), ASDAS inactive disease (ID; <1.3), and changes from baseline in ASDAS and high-sensitivity CRP (hsCRP). As-observed (AO) and non-responder imputation with multiple imputation (NRI-MI) analyses are presented for binary endpoints and mixed model for repeated measures (MMRM) analyses for continuous endpoints. Safety was assessed through the cut-off date of May 19, 2022 in all pts who received ≥1 dose of UPA. Treatment-emergent adverse events (TEAEs) and TEAEs of special interest are presented as exposure-adjusted event rates (events/100 pt-years [E/100 PY]).

Results: A total of 420 pts were randomized and received study drug (PBO to UPA: n=209; continuous UPA: n=211). Response rates were maintained from wk 14 to wk 52 in the continuous UPA group, and responses were similar in the PBO to UPA group at wk 52. NRI-MI response rates at wk 52 for the PBO to UPA and continuous UPA groups, respectively, were: ASAS40 (64.6% and 65.9%), ASAS PR (29.2% and 30.3%), ASDAS LDA (55.3% and 56.9%), and ASDAS ID (25.2% and 26.0%) (**Figure 1**). Changes from baseline in ASDAS and hsCRP were also similar between groups (-1.9 and -2.0, and -10.6 and -10.0 for the PBO to UPA and continuous UPA groups, respectively). Safety was assessed in 414 pts (534.4 PY of exposure) who received ≥1 dose of UPA (**Table 1**). Rates of serious TEAEs and TEAEs leading to study drug discontinuation were 9.9 and 3.0 E/100 PY, respectively. Rates of malignancy, major adverse cardiovascular events, and venous thromboembolic events were low (0.2, 0.2, and 0.4 E/100 PY, respectively).



Conclusion: UPA 15 mg demonstrated sustained efficacy up to wk 52 in bDMARD-IR pts with active AS. Similar efficacy was observed at wk 52 in pts with continuous UPA exposure and those who switched from PBO to UPA. UPA 15 mg was generally well tolerated in this bDMARD-IR population, with no new safety signals identified.

POS1123

IMPACT OF THE TIME OF INITIATION AND LINE OF BIOLOGIC THERAPY ON THE RETENTION RATE OF SECUKINUMAB (SECU) IN AXIAL SPONDYLOARTHRITIS (AXSPA). DATA FROM THE FRENCH MULTICENTER RETROSPECTIVE FORSYA STUDY

Keywords: Prognostic factors, Spondyloarthritis, Real-world evidence

Background: The characteristics of patients receiving a new therapy might differ overtime since its launch (date of its availability in a specific region/country); the differences in these characteristics might impact the efficiency of this treatment.

Objectives: To compare the one year retention rate of SECU in axSpA and its predisposing factors with regard to its time of initiation (e.g. right after its launch or later).

Methods: *Study design*: Retrospective multicenter French study of axSpA patients a) having initiated and received at least one dose of SECU b) with at least a one year follow-up. *Study periods*: Two cohorts were evaluated with regard to the time of initiation of SECU: *Cohort (C1)*: between August 11th, 2016 (time of the launch of SECU in France) and Aug 3st 2018; *Cohort 2 (C2)*: between sept 1st 2018 and Nov 13, 2020 (remotely from the launch). *Statistical analysis*: The one year retention rate of SECU was estimated using the Kaplan Meier technic and Cox models and was used to compare the retention rate performed in C1 and C2. Preselected factors of SECU retention at 1 year (≥1 Objective Sign of Inflammation [CRP> N, MRI-inflammation at the sacroiliac or spine level], age, sex, BMI, smoking, HLA B27, non-radiographic vs radiographic axSpA, past or present uveitis/ Inflammatory Bowel Disease (IBD)/ psoriasis/ arthritis or synovitis, diagnostic delay, disease duration, SEC line of biologic therapy, SECU maintenance dose, concomitant csDMARD/ oral corticosteroids/ proton pomp inhibitor at SECU initiation, history of depression/ fibromyalgia) were analyzed by univariate and multivariate cox model regression. Only variables with <20% missing data were included in the model after multiple imputation and stepwise selection (significance level for entering variables = 20%; for removing variables = 10%).

Results: In total, 906 pts in C1 and 758 pts in C2 from 50 centers were included in the analysis. Pts characteristics (male: 42.8%, mean age: 46.5 ± 11.9 years, mean disease duration: 9.2± 9.4 years) were similar between the 2 cohorts. The 1 year retention rate was better in C2 vs C1 (64% [61-68%] vs 59% [55-62%], Hazard Ratio (HR)=0.84 [0.72-0.98], p = 0.03). Between C1 and C2, the proportion of patients receiving SECU as the 1st or 2nd line of biologic therapy increased from 23% to 40%. In the multivariate analysis, line of biologic therapy was the single predictive factor of the 1 year retention rate of SECU in both cohorts with a better retention rate for the 1st line of biologic therapy (Table 1).

Table 1. Impact of SECU line on SECU retention rate at 1 year with regard of its time of initiation

SECU line (* reference)	Survival probability estimate at 1 year (95% CI)#	$HR_{adjusted}$ [95% CI]$	p vs ref	p type III
Cohort 1†				
1st L (n=68; 8%)*	70% [59%-81%]			0.084
2nd L (n=132, 15%)	62% [54%-70%]	1.53 [0.91; 2.57]	0.107	
≥ 3rd L (n=676, 77%)	57% [53%-61%]	1.67 [1.06; 2.62]	0.028	
Cohort 2†				
1st L (n=93, 13%)*	78% [69%-86%]			0.007
2nd L (n=192, 27%)	63% [56%-70%]	1.92 [1.18; 3.13]	0.009	
≥ 3rd L (n=437, 60%)	62% [57%-66%]	2.11 [1.32; 3.35]	0.002	

† See Methods for explanation# without imputation for missing data$ Adjustment on: C1 (OSI, IBD, History of depression or anti-depressive concomitant treatment); C2 (OSI, History of depression or anti-depressive concomitant treatment, disease duration, corticosteroids)Interpretation HR > 1: the hazard of discontinuation at 1 year is X times higher vs referenceL = Line of biologic therapy

Conclusion: These data showing a better retention rate at 1 year remotely from the launch of SECU, probably explained by its use at an earlier stage of the disease, suggest a change in the behavior of prescribing physicians probably reflecting a better confidence in this treatment. These data also underline the interest of iterative evaluations of treatments used in daily practice.

SLE, Sjön's and APS - treatment

POS1124 LUPUS100.ORG A NEW TOOL FOR DOCTORS TO BUILD PATIENTS LUPUS KNOWLEDGE AND FIGHT POOR QUALITY WEB INFORMATION

Keywords: Education, Systemic lupus erythematosus, Best practices

A. Cornet[1], A. Sluijmers[2], F. Marchiori[2], C. Hjelmeset[2], I. D. Povilaite[2], E. Koskina[2], K. Blomkvist Sporre[2]. [1]*Lupus Europe, HQ, Brussels, Belgium*; [2]*Lupus Europe, PAN, Brussels, Belgium*

Background: Access to quality disease information is one of the cornerstones of therapeutic education and critical to help the doctor-patient dialog and adherence to treatment. Lupus patients and doctors alike lack the time in consultation to address the many questions patients have. As a result, patients often rely on poor quality or unverified information from the web. For non-English speakers, the language barrier is adding yet another obstacle to quality therapeutic education.
Objectives: To provide access to doctor verified SLE quality information on-line, in the mother language of 95%+ of the European population so that doctors can refer patients to quality information sources.
Methods: With the endorsement of ERN ReCONNET reference network, Lupus Europe and doctors from ReCONNET's SLE Working group have developed a multilingual Euro-wide website answering the top 100 questions patients have about lupus. The starting point to build the content has been the French book "lupus en 100 questions" authored by lupus experts from the French FAI2R. Working extensively with patients from Lupus Europe PAN, the list of questions has been adjusted, answers to existing questions have been checked and validated or adjusted for up-to-dateness. New patient questions have been answered by lupus specialised doctors in collaboration with patients. The resulting documents have been translated in English and the translations validated by both patients and doctors. This core English version has then received feedback from ERN ReCONNET SLE WG doctors. Finally, the end result has been translated in more than 15 languages, verified by native lupus doctors and patients prior to being put on line. This exercise is continuing at the time of writing the abstract, with the goal of covering more than 20 languages and 99% of European population by end 2023. The web site is managed and controlled by Lupus Europe, the European Lupus patients organisation. Aside from this "one-shot" effort, a process has been designed to collect questions and comments from patients and doctors. Those will then feed the on-going maintenance of the information. New developments or new questions will be used to systematically review the content and update it using a Delphi process within the ERN ReCONNET SLE Working group.
Results: lupus100.org website provides free of charge quality information on lupus for patients, relatives, doctors or students. Its multilingual character allows all people in Europe to have access to verified information in their own language, with lay terms. This non-commercial tool is available for doctors of all countries to grow their patients education on lupus and hence build a stronger therapeutic alliance, minimising the time lost in fighting wrong information.
Conclusion: A new tool is available for doctors and patients to build lupus education. The challenges are now (a) to maximise its reach by ensuring all patients and doctors are aware of the initiative, and (b) to ensure that currency is maintained medium to long term.

POS1125 HYDROXYCHLOROQUINE USE IN PREGNANT WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND MAJOR CONGENITAL MALFORMATIONS IN THE OFFSPRING

Keywords: Registries, Pregnancy and reproduction, Systemic lupus erythematosus

N. V. Nguyen[1], E. Svenungsson[2], A. Dominicus3, K. Hellgren[1], J. Simard[4], E. Arkema[1]. [1]*Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden*; [2]*Karolinska Institutet, Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden*; [1]*Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden*; [4]*Stanford School of Medicine, Division of Immunology and Rheumatology, Department of Medicine, California, United States of America*

Background: Hydroxychloroquine (HCQ) is currently recommended for all pregnant women with systemic lupus erythematosus (SLE) if tolerated. Some studies have reported an increased risk of malformations associated with HCQ, but others find no increased risk.
Objectives: To assess the risk of major congenital malformations (MCM) associated with exposure to HCQ during the 1st trimester in the offspring of women with SLE.
Methods: We conducted a population-based cohort study of pregnancies with a singleton birth from 2006 to 2020 among women with prevalent SLE in Sweden. Pregnancies were identified from the Medical Birth Register (MBR). Prevalent SLE was defined as having at least two ICD-coded visits in the National Patient Register before pregnancy, with at least one with an SLE specialist. The exposure was defined as filling at least one HCQ prescription during the 1st trimester (Prescribed Drug Register). The unexposed births were required to not have any HCQ dispensations from three months preconception to the end of the 1st trimester. The outcome was any ICD code for MCM in the offspring assessed at birth listed in the MBR, defined according to the European Surveillance of Congenital Anomalies classification. Inverse probability of treatment weighting (IPTW) using propensity score was applied to adjust for confounding. We included maternal characteristics, comorbidities (e.g., diabetes, other autoimmune diseases), and medication use (e.g., corticosteroids, other disease-modifying anti-rheumatic drugs) in the propensity score model as a priori variables. Risk ratios and 95% confidence intervals (RR 95%CI) were estimated using modified Poisson regression models in the weighted population with robust variance estimation.
Results: The study population comprised 407 exposed births and 520 unexposed births. The mothers' mean age at delivery was 32 (standard deviation ± 5). Overall, there were 21 births with at least one MCM, corresponding to an overall risk of 2.3%. The most common type of MCM was ventricular septal defect (n = 6). The unadjusted risks of MCM among the exposed and unexposed were 2.7% and 1.9%, respectively (unadjusted RR 1.42, 95%CI 0.60-3.28). The IPTW-adjusted population achieved a good balance across patient characteristics. The IPTW-adjusted RR was 1.59 (95%CI 0.67-3.75). The adjusted risk difference was 0.01 (95%CI -0.01-0.03). In a sensitivity analysis in which the exposure was defined as having at least one HCQ dispensation from three months preconception to the end of the 1st trimester, the IPTW-adjusted RR was 1.56 (95%CI 0.69-3.54). We could not examine different categories of HCQ daily dose due to very few events in each category.
Conclusion: In this birth cohort, our findings show an increased, but not statistically significant, risk of MCM at birth among births born to women with SLE exposed to HCQ during the 1st trimester compared to those without HCQ exposure. Our findings should be interpreted considering the lack of data on early pregnancy termination or loss induced by MCM. Future studies are warranted to investigate this association further and should utilize a longer follow-up for MCM ascertainment (i.e., within one year of birth). For managing SLE during pregnancy, the benefits of HCQ may still outweigh the risks.

POS1126 THERAPEUTIC RANGE OF HYDROXYCHLOROQUINE BLOOD LEVELS CAN REDUCE ODDS OF HIGH LUPUS DISEASE ACTIVITY

Keywords: Treat to target, Systemic lupus erythematosus, Outcome measures

S. Garg[1], B. Chewning[2], S. Gomez[2], C. Bartels[1]. [1]*University of Wisconsin, School of Medicine & Public Health, Medicine, Rheumatology, Madison, United States of America*; [2]*University of Wisconsin, School of Pharmacy, Pharmacy, Madison, United States of America*

Background: Hydroxychloroquine (HCQ) is the cornerstone of systemic lupus erythematous (SLE or lupus) treatment, yet, the optimal dosing of HCQ in SLE is unknown. Reducing HCQ dose to 5 mg/kg to limit toxicity, as suggested by the American Academy of Ophthalmologists (AAO),(1) also predicts increased flares.(2) One study showed six-fold higher risk of severe SLE flares in patients receiving AAO recommended HCQ dosing.(2) Therefore, establishing effective therapeutic ranges of HCQ blood levels may provide an opportunity to individualize HCQ dosing to maximize efficacy and limit toxicity.

Objectives: The objective of this study was to examine the association of HCQ blood levels with high lupus disease activity (HDA) in a prospective SLE cohort.
Methods: This cross-sectional study measured HCQ blood levels in unique SLE visits using liquid chromatography-tandem mass spectrometry. HCQ blood levels and SLE disease activity index (SLEDAI) scores were measured on the day of the visit for each patient. High lupus disease activity (HDA) was defined as SLEDAI scores of ≥6.(3) To identify significant HCQ blood levels that determined lower odds of HDA, we examined associations between HDA and every 50-100 ng/ml increase in HCQ blood levels starting at 100 ng/ml through 1500 ng/ml. Other factors that can affect HCQ levels, such as patient-reported adherence, kidney function, and HCQ dose and timing, were included in multivariable models.
Results: Among 143 SLE patients in whom HCQ blood levels were measured, 92% were women and 32% were of non-White race or Hispanic ethnicity. HDA was noted in 18% of patients. We noted a 75% reduction in the odds of HDA first at HCQ blood levels of ≥750 ng/ml (Adjusted OR 0.25, 95% CIs 0.066-0.89, p-value = 0.035; Figure 1). This effect peaked with HCQ blood levels ≥1100 ng/ml with 93% lower odds of HDA at this level (Adjusted OR 0.07, 95% CIs 0.005-0.61, p-value = 0.038; Figure 1). Interestingly, levels of 1150 ng/ml or higher did not further reduce the odds of HDA (Figure 1).
Additionally, we noted that female sex was associated with 88% lower odds of HDA (Table 1), while other factors including HCQ dose or timing were not associated with HDA (Table 1).
Conclusion: We report an effective therapeutic range of HCQ blood levels, 750-1100 ng/ml, that significantly correlated with reduced risk of high lupus disease activity (HDA) by 75-93% in patients with SLE. These findings could guide clinicians to individualize HCQ doses to achieve target blood levels within this range to maximize efficacy, while balancing safety.

ZETOMIPZOMIB (KZR-616) TREATMENT RESULTS IN CLINICALLY MEANINGFUL RENAL RESPONSES IN PATIENTS WITH LUPUS NEPHRITIS

Keywords: Kidneys, Clinical trials, Systemic lupus erythematosus

A. Saxena[1], S. Parikh[2], S. Hua[3], R. Leff[4], E. Park[5], N. Henig[6]. *[1]NYU School of Medicine, Rheumatology, New York, United States of America*; *[2]The Ohio State University Wexner Medical Center, Nephrology, Columbus, United States of America*; *[3]Kezar Life Sciences, Biometrics, South San Francisco, United States of America*; *[4]Kezar Life Sciences, Clinical Development, South San Francisco, United States of America*; *[5]Kezar Life Sciences, Medical Affairs, South San Francisco, United States of America*; *[6]Kezar Life Sciences, Chief Medical Officer, South San Francisco, United States of America*

Background: Zetomipzomib, a first-in-class selective inhibitor of the immunoproteasome blocks multiple pathways involved in inflammatory cytokine production and immune effector cell activity – including macrophages, B cells and T cells leading to broad immunomodulation across both the innate and adaptive immune systems[1-3]. The MISSION Phase 1b/2, open-label study (NCT03393013; KZR-616-002) evaluated safety, tolerability, and exploratory efficacy of zetomipzomib in patients with systemic lupus erythematosus (SLE) +/- lupus nephritis (LN). In the Phase 1b portion, zetomipzomib was well-tolerated in patients with active SLE +/- LN and resulted in improvement across disease activity measures as well as biomarkers, including reduced proteinuria and urinary CD163 in 2 of 2 patients with LN[4].
Objectives: Results from the completed Phase 2 portion of the MISSION study are presented here.
Methods: MISSION Phase 2 evaluated zetomipzomib 60 mg SC QW in patients with active LN (Class III or IV ± Class V) with proteinuria, defined as urine protein to creatinine ratio (UPCR) >1 despite stable background therapy of ≥8 weeks. Patients received zetomipzomib for 24 weeks. Safety, tolerability, UPCR, other measures of renal function, SLE disease activity, and biomarkers were measured.
Results: 21 patients received ≥1 dose of zetomipzomib (safety population) and 4 patients discontinued before end of treatment (evaluable population, n=17). 90.5% were women with a mean age of 35.3 years; 52.4% were Hispanic/Latino. Patients had mean LN duration of 5.3 years with mean 24-hour UPCR of 2.6 mg/mg and mean eGFR of 104.7 mL/min/1.73 m^2. Concomitant medications included corticosteroids (100%, mean dose: 20.2 mg/d), MMF or mycophenolic acid (95.2%), HCQ (66.7%), and/or AZA (9.5%). Clinically meaningful renal responses were observed by the end of treatment (EOT) at Week (W) 25 with 11/17 evaluable patients demonstrating ≥50% reduction in UPCR from baseline and 6 of 17 patients achieving a Complete Renal Response*. Furthermore, renal responses were maintained or deepened through the end of study 12-weeks post-treatment at W37. eGFR levels remained stable throughout the study. Reduction of daily steroid dose to 10 mg/day was observed in 14/17 patients as early as W13 and at W25 while other background immunosuppressive doses remained stable throughout the study. Urinary CD163, a marker of inflammation, decreased with zetomipzomib treatment and was shown to be correlated with UPCR. Adverse events were generally mild to moderate (Grade 1/2) without evidence of immunosuppression (no serious/opportunistic infections or immune cell depletion). *Complete Renal Response: UPCR ≤0.5, eGFR ≥60 mL/min/1.73m^2 or no worsening of eGFR from baseline of ≥25%, prednisone (or equivalent) ≤10 mg and no use of prohibited medication.
Conclusion: In the MISSION Phase 2 study, treatment with zetomipzomib 60 mg SC QW for 24 weeks demonstrated strong activity against LN as evidenced by improvement in UPCR and has the potential to be a long-term, steroid-sparing immunomodulatory treatment for LN patients.

Background: Systemic lupus erythematosus (SLE), a chronic autoimmune disease, is characterized by high clinical and molecular heterogeneity and the presence of autoantibodies with various specificities, including those against DNA and RNA. While steroids, such as prednisolone, are a part of the standard-of-care for SLE, alternative treatments that overcome steroid resistance and minimize the risk of numerous short- and long-term side effects associated with their use remain an important unmet need. Toll-like receptors 7 and 8 (TLR7/8), two endosomal receptors expressed in various immune cells, play key roles in innate immunity through recognition of single-stranded RNA and driving downstream signaling via the nuclear factor kappa B (NFkB) and interferon regulatory factor (IRF) pathways. Activation of the NFkB pathway via TLR7/8 along with inhibition of plasmacytoid dendritic cell (pDC) apoptosis via TLR7 are reported to contribute to steroid resistance.
Objectives: *In vitro* determination of the potency and modes of action of afimetoran in whole blood (WB) of healthy volunteers (HVs) and patients with SLE, as well as probing the modes of action for the steroid-sparing potential of afimetoran.
Methods: Afimetoran was evaluated *in vitro* for its ability to inhibit TLR7- and TLR8-mediated interleukin 6 (IL-6) induction in WB. Briefly, WB samples from HVs and patients with SLE were treated with afimetoran for 1 hour before the addition of the TLR7 or TLR8 agonists. Following overnight incubation, supernatants were collected, and IL-6 was quantified by ELISA. The same assay was used to determine the pharmacodynamic activity of afimetoran in WB from HVs in a phase 1 multiple ascending dose study (NCT03634995). The potency of afimetoran to inhibit TLR7 agonist-induced CD69 expression on B cells and TLR8 agonist-induced CD319 expression on monocytes from WB was assessed using flow cytometry. The steroid-sparing potential of afimetoran was evaluated *in vitro* in combination with prednisolone through inhibition of IL-6 induction in WB from HVs and reversal of TLR7 agonist-induced resistance to prednisolone-induced pDC apoptosis, which was measured by flow cytometry staining of annexin V.
Results: Afimetoran equipotently inhibited TLR7- and TLR8-mediated induction of IL-6 in WB from HVs and patients with SLE. Afimetoran also equipotently inhibited surface expression of CD69 on B cells and CD319 on monocytes with single-digit nM IC50 values. Afimetoran robustly and durably inhibited TLR7- or TLR8-mediated induction of IL-6 in HV WB samples from a phase I multiple ascending dose clinical trial. When combined with prednisolone, afimetoran had a synergistic effect in inhibiting TLR7- and TLR8-mediated induction of IL-6 in WB of HVs and reversed TLR7-mediated resistance to prednisolone-induced pDC apoptosis.
Conclusion: WB-based data show that afimetoran is an equipotent TLR7/8-dual antagonist with sub-nM to nM potency in blocking TLR7- and TLR8-mediated functions. WB- and cell-based evidence demonstrates that afimetoran in combination with prednisolone synergistically inhibits induction of IL-6, a NFkB-dependent cytokine, and reverses TLR7-mediated resistance to prednisolone-induced pDC apoptosis, thus supporting the steroid-sparing potential of afimetoran in patients with SLE.

Background: Dysregulated humoral immunity is a hallmark of primary Sjögren's Syndrome (pSS). This dysregulation involves aberrant B-lymphocyte activity resulting in abnormally high immunoglobulin G (IgG) levels and the production of autoantibodies, particularly those reactive with Ro/La ribonuclear complexes. pSS can affect almost any organ system, and current evidence-based therapies only offer some symptom relief, but no licensed therapy has been shown to alter the disease course. Nipocalimab is a high-affinity, fully human monoclonal antibody that reduces circulating IgG levels by selectively blocking the interactions of IgG, including pSS autoantibodies, with the neonatal Fc receptor (FcRn). Nipocalimab has previously induced rapid, safe, and durable serum IgG reductions in healthy volunteers (NCT02828046)[1] and in autoantibody-driven generalized myasthenia gravis (gMG) in adults (Vivacity-MG; NCT03896295)[2], suggesting that nipocalimab may treat a broad range of autoimmune disorders associated with autoantibodies, immune complexes and B-lymphocyte hyperactivity, including pSS.
Objectives: Here, we describe the key data from Vivacity-MG that illustrate the therapeutic potential of nipocalimab in IgG autoantibody-driven conditions and review the design of a phase 2 study evaluating the efficacy and safety of nipocalimab in patients with pSS (NCT04968912).
Methods: Study feasibility assessments involved evaluating results from the phase 2 placebo-controlled trial Vivacity-MG. Of the 68 patients enrolled, 54 patients were randomized 1:1:1:1:1 to 4 treatment groups or a placebo group.
Results: In Vivacity-MG, there were no discontinuations due to treatment-emergent adverse events (TEAEs), severe AEs, or related serious AEs with nipocalimab. The incidence of infections and headaches with nipocalimab were comparable to placebo (**Table 1**). Treatment with nipocalimab resulted in rapid

and dose-dependent reductions in serum total IgG levels and anti-AChR IgG autoantibodies (**Figure 1**), as compared to placebo. The safety and pharmacodynamic data from Vivacity-MG support the hypothesis that nipocalimab has the potential to treat pSS through lowering pathogenic IgGs. As such, we developed a phase 2, multicenter, randomized, placebo-controlled, double-blind study enrolling adults with moderately-to-severely active pSS. The pSS study consists of a ≤6-week screening period, a 24-week double-blind treatment period, and a 6-week follow-up period. Participants are randomized 1:1:1 to treatment every 2 weeks with intravenous nipocalimab (low or high dose), or placebo, through Week 22. The primary efficacy endpoint is change from baseline in Clinical European League Against Rheumatism Sjögren's Syndrome Disease Activity Index (clinESSDAI) score at Week 24. Safety assessments include TEAEs, abnormal vital signs, and laboratory parameters.

Conclusion: Vivacity-MG demonstrated that nipocalimab has the potential to offer an important new and targeted treatment option for patients with IgG-mediated diseases. The ongoing phase 2 study evaluates the safety and efficacy of treatment with nipocalimab in patients with moderately-to-severely active pSS.

POS1131 SECRETAGOGUE EFFECT OF PDE4 INHIBITOR APREMILAST ON HUMAN SALIVARY GLAND ORGANOIDS OBTAINED FROM PRIMARY SJÖGREN'S SYNDROME PATIENTS

Keywords: Disease-modifying drug (DMARDs), Cell biology, Sjögren syndrome

L. Quartuccio[1], V. Manfrè[1], S. Parisi[2], I. Caligiuri[2], E. Pegolo[3], S. De Vita[1], C. DI Loreto[3], F. Rizzolio[2,4]. *[1]Division of Rheumatology, Department of Medicine, University of Udine, Udine, Italy*; *[2]Pathology Unit, Centro di Riferimento Oncologico di Aviano (CRO) IRCCS, Aviano, Italy*; *[3]Institute of Anatomic Pathology, Azienda Sanitaria Universitaria Friuli Centrale c/o University of Udine, Udine, Italy*; *[4]Department of Molecular Sciences and Nanosystems, Ca'Foscari University of Venice, Venezia, Italy*

Background: in primary Sjögren's syndrome (pSS), salivary epithelial cells show an active role in the initiation and reiteration of the immunomediated damage. Epithelial saliva production is regulated by autonomic stimuli, intracellular calcium and cAMP concentration. The latter controls the action of cystic fibrosis transmembrane conductance regulator (CFTR), whose malfunction is postulated in sicca syndrome and pSS pathogenesis. (1) Forskolin is an activator of CFTR used in organoid swelling test in human salivary-gland derived organoid culture systems. Interestingly, also PDE4 is involved in intracellular cAMP deregulation: PDE4 inhibition might thus stimulate salivary function in pSS. (2-3) To the best of our knowledge, no data on the application of human salivary gland organoids specifically for testing drugs effective on xerostomia in pSS are found in literature.

Objectives: to culture vital salivary gland organoids obtained through labial or parotid biopsy of pSS patients; to evaluate the morphological structure and functional capacity of organoids in basal condition and after stimulation with forskolin or PDE4 inhibitor apremilast.

Methods: salivary gland tissues were harvested from 5 pSS patients through labial or parotid biopsy. After tissue processation and vital organoids obtainment, swelling essay and cell proliferation tests were performed after forskolin and apremilast application, compared to DMSO-treated controls. Immunohistochemistry evaluation on original salivary gland tissue and corresponding organoids was performed, by testing: alpha-amylase and AQP5 for acinar differentiation; EMA for ductal differentiation; calponin for myoepithelial differentiation and CK5 for basal differentiation; CK14, cKit and CD34 as markers of progenitor/stem cells.

Results: after application of forskolin or apremilast, we observed organoid swelling after 30 minutes, compatible with positive functional status and enhancement of saliva production. DMSO-treated controls were instead unaffected. In 3 cases apremilast induced proliferation of the organoids (Figure 1). All the cases were positive for CK14, most of the cases for CK5. All the cases were positive for Amylase; its secretion, and thus functional status of organoids, was confirmed by its high concentration in the culture medium. A focal ductal differentiation was found in some cases, highlighted by EMA positivity. The more differentiated EMA positive areas were negative for the staminal marker CK14, showing a sort of "complementary staining".

Conclusion: our data confirm that, from pSS epithelium, differentiated cells that escape senescence and vital and functional organoids that recapitulate the development of original salivary glands can be obtained from different target tissues of pSS. The direct stimulating effect of PDE4 inhibitor apremilast on pSS human salivary organoids is reported, opening new perspectives on targeting oral dryness with drugs that combine secretagogue and immunomodulatory effects.

HYDROXYCHLOROQUINE, WHICH REGULATES IFN, IS HIGHLY EFFECTIVE IN SLE WITH ELEVATED SERUM S100 PROTEIN

Keywords: Systemic lupus erythematosus, Cytokines and chemokines

R. Wakiya[1], H. Shimada[1], K. Ueeda[1], S. Nakashima[1], T. Miyagi[1], Y. Ushio[1], K. Sugihara[1], R. Mino[1], M. Mizusaki[1], K. Chujo[1], T. Kameda[1], H. Dobashi[1]. [1]*Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa, Japan*

Background: Background: Serum S100 protein, a damage-associated molecular pattern factor, has been associated with interferon (IFN) [1]. In a previous study, we found that hydroxychloroquine (HCQ), which regulates IFN activity, modulates serum S100 protein in SLE patients [2].
Objectives: This study determined if the therapeutic effect of HCQ is altered in SLE patients with different serum S100 protein levels.
Methods: This single-center, prospective, exploratory study evaluated patients before HCQ treatment and every 3 months for a year. SELENA-SLEDAI, SLE-DAS, and the Lupus Low Disease Activity State (LLDAS) scale measured disease activity. Serum cytokines (TNF-α, IL-6, IL-8, MCP-1, IL-1ra, VEGF-A, and MIP-1a) were measured by the multiplex Luminex assay, and serum S100A8 and S100A9 protein and adipokines (adiponectin, leptin, and resistin) by ELISA.
Results: Sixty-seven patients (63 females, mean age 41.8 years) were divided into three groups, namely, high, intermediate, and low, according to baseline S100A8 and S100A9 protein levels. The high and low groups were analyzed (Table 1). The S100A8 high group was more likely to have a history of lupus nephritis and active skin lesions. The S100A8 low group had a low serum complement titer (C3) and white blood cell count. The S100A8 high group was more likely to achieve LLDAS after HCQ treatment (high group, 76.9 % vs. low group, 56.3%). SLEDAI and SLE-DAS improved in the S100A8 high group after 3 months of HCQ treatment. There was no significant improvement in SLEDAI and SLE-DAS in the S100A8 low group (Figure 1). The C3 increase was greater in the S100A8 high group after 3 months of HCQ treatment. Regarding serum cytokines and adipokines, serum IL-1ra and resistin levels were significantly higher in the S100A8 high group. Cytokine changes after HCQ treatment were also greater than S100A8 low group. A trend similar to S100A8 was observed in S100A9.
Conclusion: SLE patients with high serum S100 protein levels respond better to HCQ therapy. This finding suggests that serum S100 protein levels may predict the response to IFN inhibitor therapy.

TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH UPADACITINIB RESULTS IN THE COORDINATED INHIBITION OF TYPE 1 IFN-RELATED BIOMARKERS: BIOMARKER ANALYSIS OF THE M19-130 (SLEEK) PHASE 2 STUDY

Keywords: Cytokines and chemokines, Biomarkers, Systemic lupus erythematosus

M. C. Gaudreau[1], J. Fann[1], S. Contrepois[1], A. Friedman[1], T. Sornasse[1], J. T. Merrill[2]. [1]*AbbVie, Rheumatology, North Chicago, United States of America*; [2]*Oklahoma Medical Research Foundation, Arthritis & Clinical Immunology Program, Oklahoma City, United States of America*

Background: Activation of Type I interferons (IFNs) and a wide array of innate and adaptive immune mediators are hallmarks of the pathogenesis of systemic lupus erythematosus (SLE) and activation of IFN pathways correlates with disease activity [1]. In a phase 2 study of SLE patients, upadacitinib (UPA, Janus kinase inhibitor) given alone or in combination with elsubrutinib (ABBV-599, Bruton's tyrosine kinase inhibitor) resulted in significant improvement in disease activity as measured by British Isles Lupus Assessment Group-Based Combined Lupus Assessment (BICLA) and SLE Responder Index-4 (SRI-4) at weeks 24 and 48.

Objectives: To evaluate the impact of UPA and ABBV599 on immunologic pathways associated with SLE pathogenesis.
Methods: SLE patients (n = 205) were randomized to (placebo [PBO]: n = 75; UPA 30 mg QD: n = 62; ABBV599: n = 68). At screening, patients were stratified by their SLE Disease Activity Index 2000 (SLEDAI-2K) score, corticosteroid dose (> 10-mg prednisone or not), immunosuppressant and IFN score. Proteomic analyses were performed on the plasma samples using a commercial proximity-extension immunoassay. A repeated mixed linear model was used to compare changes in biomarkers vs PBO and Pearson's correlation was tested to compare protein biomarkers, IFN score, and SLEDAI-2K score. All analyses were corrected for multiple testing using the Benjamini–Hochberg method. Enrichment analyses were performed to elucidate the biological pathways associated with changes in protein biomarkers.
Results: As expected, elevated IFN gene expression at baseline was associated with higher SLEDAI 2K disease activity scores, increased anti-double stranded DNA titers, and lower levels of complement components. Expression of serum proteins related to the IFN pathway, such as CXCL10, sialic acid binding immunoglobulin-like lectin 1, IFN gamma, and ZBP1, positively correlated with the IFN score. Treatment with UPA monotherapy or the combination ABBV-599 significantly reduced the IFN gene scores compared with PBO at weeks 4 and 24 ($P \leq .0001$). Proteomic analyses revealed 301 protein biomarkers differentially modulated at weeks 2, 12, and 24 compared with PBO, including significant downregulation of Type I IFN pathway proteins. There were additional impacts of UPA and ABBV-599 on T-cell–associated cytokines, B cells, macrophages, and innate response markers. These effects were similar with UPA and ABBV-599, suggesting that the main effect was attributable to activity of UPA.
Conclusion: These results suggest that the clinical benefit demonstrated by UPA in patients with SLE includes the modulation of Type I IFN with impact on several core pathogenic pathways involved in SLE. The main biomarker effects of UPA and ABBV-599 were driven by UPA.

POS1134 NOVEL APPROACH TO TREAT SYSTEMIC LUPUS ERYTHEMATOSUS, BY TARGETING THE "ROOT CAUSE", B CELLS AND PLASMA CELLS, USING BCMA-CD19 COMPOUND CAR

Keywords: Autoantibodies, Systemic lupus erythematosus, Clinical trials

Y. Yuan[1], S. He[2], W. Zhang[3], H. Zhang[3], V. Destefano[4], M. Wada[4], K. Pinz[4], G. Deener[4], Y. MA[5], M. Wang[2], F. LI[1], M. Hong[1], L. Ting[1], C. Zou[2], M. Wang[2], L. Ding[2], Y. Liang[1], Y. MA[4], W. Wang[1]. [1]*Zhongshan People's Hospital, Department of Translational Medicine, Zhongshan, China*; [2]*Zhongshan People's Hospital, Department of Rheumatoid Immunology, Zhongshan, China*; [3]*Peking University Shenzhen Hospital, Department of Hematology, Shenzhen, China*; [4]*iCell Gene Therapeutics Inc., Research & Development Division, Stony Brook, United States of America*; [5]*iCAR Bio Therapeutics Ltd, Research & Development Division, Zhongshan, China*

Background: Systemic lupus erythematosus (SLE) is a heterogenous multi-system autoimmune disease characterized by presence of autoreactive antibodies produced by the "root" cause, B and plasma cells. Autoantibody depletion has been attempted by targeting B cells, however no such treatment addresses both B and plasma cells.
Objectives: We assess the safety and efficacy of dual resetting B and plasma cell populations using our novel BCMA-CD19 cCAR T (cCAR) in an open label phase I clinical trial.
Methods: We constructed a cCAR composed of a complete BCMA-CAR fused to a complete CD19-CAR, separated via self-cleaving P2A peptide. The cCAR functional activity was assessed in co-culture assays with multiple cell lines and mouse models. T cells from peripheral blood obtained via apheresis were transfected to create cCAR. Cessation of steroids and immunosuppressing medications was followed by conditioning. Patients received monthly IgG until B cells recovered. Patients were dosed from $1.5\text{-}3x10^6$ cCAR cells/kg body weight and monitored. P1 and P2: 20-year history of managed SLE and received cCAR as compassionate use for B cell lymphoma. P1 and P2achieved complete remission (CR). After 1-year follow up demonstrated CR of SLE, hospital approved additional SLE/Lupus Nephritis (LN) patients for treatment. Baseline Characteristics: 12 patients received cCAR as of 15 Jan 2023. Patient age range: 20-58. Ten of 12 were female. P1 and P2: SLEDAI-2K score 4, and 8, respectively. Patient 3-12: SLEDAI-2K baseline score mean 11 range 6 to 16. All of patients (3-12) had LN on kidney biopsy between IV to V with failure of standard therapy.
Results: Safety: Overall cCAR has been well tolerated to date. There have been no severe adverse events (SAE) or infections attributed to cCAR, no CRES and no CRS above Grade 1. All patients with >3 weeks follow up had a mild fever (CRS grade 1) which resolved with supportive care. Onset of mild fever occurred between days 3 to 14 and resolved within a week of onset. Efficacy: B cells were entirely depleted in peripheral blood 3-14 days post cCAR. Three patients treated >6 months in CR (SLEDAI-2K = 0, all autoantibodies negative, and normal complement). P1 and P2 maintain drug free CR and with no autoantibodies post-cCAR approximately 40 and 20 months respectively. All B cells recovered within 2-6 months with no indications of relapse. At ≥1-4 months post-treatment 9 patients were negative for, anti-dsDNA autoantibody, anti-nuclear autoantibody, anti-SSA/Ro52 autoantibody, anti-SSA/Ro60 autoantibody, anti-ribosomal P, and anti-U1-snRNP. Among 9 patients rapid improvement within 1 month after cCAR, mean SLEDAI-2K dropped from 8.7 mean at baseline to 2 at 1 month (7 patients no symptoms), and mean drop to 0.88 within 6 months (9 patients no symptoms). All patients achieved 100% response and are maintaining medication free recovery (no immunosuppressives or glucocorticoids). An immune "reset" was confirmed via flow cytometry showing that most of recurring cells are naïve B cells, and further observed in BCR deep sequencing (patients 3-4), whereby IgG and IgA clonotypes are absent and non-class-switched BCR repertoires are greater than 95% IgM heavy chain.
Conclusion: These data on the 12 patients treated with cCAR demonstrate that the intervention is well tolerated. Initial data suggests immune system "reset" with long-term remission is possible as cCAR treats the "root cause" of disease by depleting autoreactive antibodies produced by plasma cells and memory B cells. This approach can be extended to other B and/or plasma cell mediated autoimmune disorders. The full dataset will be updated at the meeting.

POS1135 EFFECT OF IMMUNOMODULATORY THERAPIES ON ANTIPHOSPHOLIPID ANTIBODIES TITERS IN CHILDREN WITH ANTIPHOSPHOLIPID SYNDROME

Keywords: Anti-phospholipid syndrome, Autoantibodies

P. Morán Álvarez[1], E. Marasco[1], V. Messia[1], F. De Benedetti[1], C. Bracaglia[1]. [1]*Ospedale Pediatrico Bambino Gesù, Pediatric Rheumatology, Rome, Italy*

Background: Pediatric Antiphospolipid Syndrome (APS) is an autoimmune disease characterized by venous and/or arterial thrombotic events (TE) associated with 2 consecutive positive determinations (at least 12 weeks apart) of antiphospholipid antibodies (aPL), IgG/IgM anticardiolipin (aCL), IgG/IgM β2-glycoprotein I (aβ2GPI) and/or lupus anticoagulant (LA). Recent data suggests that aPL levels may decrease over time due to the natural history of the disease or to treatments. Therefore, monitoring of aPL levels may represent a strategy to evaluate disease activity and response to therapies.
Objectives: To investigate the trend over time of aPL titers in children with APS, comparing patients under immunomodulatory therapies and those without them.
Methods: A descriptive, observational, cross-sectional study was carried out in children with APS. aPLs testing was carried out in all patients from diagnosis every 3-4 months for 2 years. Interferon Gene Signature (IGS) was assessed as described by Crow[1]. Laboratory parameters, clinical and demographic data was retrieved and analyzed. Statistical analysis was performed with software R_v. 4.0.3.

Results: Sixteen children with a diagnosis of APS were included in this study. The median age at disease onset was 11.5 years (range: 6 months – 17 years) and 62.5% were female; 87.5% Caucasians. Thirteen patients (81.2%) had a diagnosis of primary APS and 3 (18.8%) out of 16 of secondary APS. Regarding clinical manifestations, 11 children developed at least one TE (7 arterial and 5 venous). Cerebral territory was the most frequently involved with 5 thrombosis, followed by 3 deep vein thrombosis, 1 pulmonary thromboembolism and 2 arterial renal thrombosis. Most of the patients received an antiaggregant and/or anticoagulant therapy (13 and 8 patients, respectively). However, 1 patient presented a new TE after the antiaggregant withdrawal. A total of 12 (75%) children developed at least one non-criterion manifestation: 7 patients (44%) cardiac (Libman-Sacks endocarditis or valvular heart disease), 7 patients (44%) neurological (chorea or white matter lesions), 6 patients (37.5%) hematological (thrombocytopenia, hemolytic anemia or Evans syndrome) and 1 patient (3.8%) a renal thrombotic microangiopathy. Related to immunological parameters, 4 (25%) were positive for only 1 aPL, 5 (42%) for 2 aPL subtypes and 7 (44%) for all 3 aPL subtypes, showing the highest rates IgG aβ2GP (87.5%) and IgG aCL (81.25%). Lower rates were identified for LA (44%), IgM aCL (18.7%) and IgM aB2GP (12.5%). Four (25%) had ANA positivity (3 secondary and 1 primary APS). Regarding treatment, 13 children (81.25%) received at least one immunomodulatory drug (13 patients mycophenolate; 4 rituximab) and 3 (18.7%) were not treated with them. During the 2-year-follow-up, 11 patients (68.8%) showed a reduction of aPL titers compared to the onset, with becoming 9 negative (56.3%) at the end of follow-up (Figure 1A). Of those who were negative, 8 children were under immunomodulatory therapies and only 1 did not receive any treatment. Five patients (31.2%) showed stable titers of aPLs during follow-up. Of them, 2 were not treated with immunomodulatory therapies and 2 were under mycophenolate but with poor compliance (reduction of titers with the restart of therapy were observed). We also evaluated the presence of the IGS in 11 patients with APS for whom a whole blood RNA sample was available: the IGS was positive in 9 (81.8%) of 11 children (7 with primary APS and 2 with secondary APS).

Conclusion: Our data suggest the possible effect of immunomodulatory therapies in reducing antibody titers in APS. Therefore, it may represent a strategy to control the disease activity leading to a better prognosis. Further studies are needed to confirm and expand our data.

POS1136 DISEASE-MODIFYING EFFECT AND LONG-TERM SAFETY DATA OF BELIMUMAB IN PATIENTS WITH SLE: A SINGLE CENTRE RETROSPECTIVE ANALYSIS

Keywords: Systemic lupus erythematosus

M. Okada[1], T. Nakai[1]. *[1]St. Luke's International Hospital, Immuno-Rheumatology Center, Tokyo, Japan*

Background: Disease modification is an important concept for minimizing disease activity with the fewest treatment-associated toxicities when managing SLE. Belimumab has been used as a maintenance therapy for SLE; however, data on its disease-modifying effects are scarce.

Objectives: Therefore, we aimed to investigate the disease-modifying effects of belimumab in SLE patients.

Methods: This single-centre retrospective cohort study included SLE patients treated with belimumab at our institution. We analysed the changes in flare-free ratio, lupus low disease activity state (LLDAS) achievement ratio, glucocorticoid dosage, SLICC/ACR damage index (SDI) score, and drug retention rate after belimumab initiation.

Results: Of the 567 patients with SLE followed up in our hospital, 95 used belimumab and to 92 were included in the study. Fifty-two weeks after initiating belimumab, the flare rate decreased (82.6% to 14.1%) ($p<0.01$). At week 52 and day 1,000 after initiation of belimumab, >70% and approximately 90% of the patients achieved LLDAS, respectively. Belimumab administration also significantly decreased glucocorticoid demands, and at the end of the study period, 68.5% of patients achieved prednisolone ≤5 mg/day and 22.8% achieved glucocorticoid discontinuation. Furthermore, most patients were free of SDI progression (week 52, ±95%; end of study period, almost 90%), and belimumab showed a high drug retention rate (week 52, 90%; day 1000 after initiation >80%).

Conclusion: Most patients on belimumab achieved LLDAS, decreased flare rate and glucocorticoid demand, and a stable trend of SDI after its induction. Furthermore, belimumab had a high drug retention rate. Therefore, the introduction of belimumab may be a key element in disease modification.

POS1137 PHARMACOKINETICS AND EXPOSURE-RESPONSE RELATIONSHIPS OF UPADACITINIB OR ELSUBRUTINIB ALONE OR IN COMBINATION (ABBV-599) IN SYSTEMIC LUPUS ERYTHEMATOUS

Keywords: Systemic lupus erythematosus

S. Bhatnagar[1], L. Siovitz[2], A. Friedman[3], W. Liu4, M. E. Mohamed4. *[1]AbbVie, Inc, Clinical Pharmacology, North Chicago, United States of America*; *[2]AbbVie, Clinical Pharmacology, Ludwigshafen am Rhein, Germany*; *[3]AbbVie, Inc, Immunology Clinical Development, North Chicago, United States of America*; *[1]AbbVie, Inc, Clinical Pharmacology, North Chicago, United States of America*

Background: ABBV-599 is a novel combination of upadacitinib (UPA), a reversible JAK inhibitor approved for the treatment of several autoimmune diseases, and elsubrutinib (ELS), a covalent BTK inhibitor being developed for the treatment of immune-mediated inflammatory diseases. The efficacy and safety profile of the monotherapies (UPA and ELS) and combination (ABBV-599) were evaluated in systemic lupus erythematous (SLE) in the global Phase 2 Study SLEek (NCT#03978520).

Objectives: The analyses presented here characterize the pharmacokinetics of UPA and ELS as well as exposure-response relationships for efficacy at Week 24 and Week 48 and safety endpoints through Week 48.

Methods: Phase 2 Study SLEek evaluated UPA 30 mg once-daily (QD), ELS 60 mg QD, ABBV-599 high dose (ELS 60 mg + UPA 30 mg) QD and ABBV-599 low dose (ELS 60 mg + UPA 15 mg) QD in a placebo-controlled manner. Pharmacokinetic, efficacy, and safety data from subjects with moderately to severely active SLE enrolled in the study were used to conduct the analyses (N = 341). UPA pharmacokinetics were described using a previously published population pharmacokinetic model[1] and ELS pharmacokinetics were characterized using Bayesian population pharmacokinetic analyses based on data from the healthy subjects, RA patients, and SLE patients. Exposure-response analyses for efficacy were conducted using logistic regression models to characterize the relationships for the monotherapies and combination average plasma concentration (C_{avg}) and the percentage of patients achieving SLE Responder Index-4 (SRI-4), SRI-4 and steroid dose ≤ 10 mg QD, and British Isles Lupus Assessment Group (BILAG)-Based Combined Lupus Assessment (BICLA) response at Week 24 and Week 48. Exposure-response analyses for safety were conducted using quartile plots and logistic regression modeling at or through Week 48.

Results: The previously developed population pharmacokinetic model for UPA showed that UPA pharmacokinetics were comparable in subjects with SLE and RA. A one-compartment model with a proportional error model best described the pharmacokinetics of ELS. Exposure-response analyses for efficacy based on logistic regression modeling demonstrated that at Week 24 and Week 48, statistically significant relationships were observed between UPA C_{avg} and SRI-4, SRI-4 and steroid dose ≤ 10 mg QD, and BICLA (Figure 1). No exposure-response trends were observed for ELS C_{avg} and the evaluated efficacy endpoints during the Week 24 analysis. Inclusion of ELS C_{avg} in the logistic regression models did not improve the model performance. Simulations based on the logistic regression models showed that UPA 30 mg QD is predicted to provide 8% to 17% higher response rates across the evaluated endpoints compared to UPA 15 mg QD. Exposure-response analyses for safety showed no clear trend for serious infections, lymphopenia, or neutropenia through Week 48. A shallow trend was observed for an increase in the percentage of subjects experiencing herpes zoster and a > 2 g/dL decrease in hemoglobin from Baseline at or through Week 48 with increasing upadacitinib C_{avg}.

Conclusion: Population pharmacokinetic and exposure-response analyses demonstrated that plasma exposures associated with UPA 30 mg QD were efficacious in subjects with SLE, while maintaining an acceptable safety profile. Addition of ELS, as part of ABBV-599, was not estimated to provide any additional efficacy benefit over UPA alone.

SIROLIMUS VERSUS MYCOPHENOLATE MOFETIL FOR THE TREATMENT OF LUPUS NEPHRITIS: RESULTS FROM A REAL-WORLD CSTAR COHORT STUDY

Keywords: Systemic lupus erythematosus, Kidneys

W. Bai[1,1,1], M. LI[1,1,1,1,1]. [1]*Peking Union Medical College Hospital, Rheumatology, Beijing, China*

Background: The effectiveness and safety of sirolimus for the treatment of systemic lupus erythematosus (SLE) and lupus nephritis (LN) have been shown in some studies. However, a comparison of sirolimus with standard of care (SoC) for LN patients has not been reported.

Objectives: To compare the effectiveness and safety of sirolimus versus mycophenolate mofetil (MMF) for LN treatment.

Methods: A real-world cohort study based on the Chinese SLE Treatment and Research (CSTAR) registry was conducted. Excluded patients with LLDAS (lupus low disease activity state) or remission at baseline, LN patients who were prescribed sirolimus or MMF were enrolled. Propensity score matching was used to ensure equivalent disease conditions. SLE and LN disease activity indices, serological parameters, steroid doses, and adverse events were compared between the two groups at 3-month, 6-month, and 12-month visits.

Results: Data from 53 patients in each group were analyzed. The clinical effectiveness of sirolimus, including the proportion of patients with LLDAS/remission, or clinical response (SLEDAI-2K reductiongroups at 3-month, 6-month, and 12-month vSystemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) scores, physician's global assessment (PhGA) scores, the remission of LN, the change of 24 hours urine protein level, and the steroid tapering effect, were equivalent to those of MMF (P≥0.05). Greater improvements in complement levels were observed in the sirolimus group than the MMF group at 3, 6, and 12 months. Ten adverse events in the sirolimus group and one in the MMF group were recorded. None was severe or led to drug discontinuation.

Conclusion: Sirolimus was as effective as MMF in the treatment of LN and glucocorticoid tapering. Sirolimus had better effects on serological improvement. Sirolimus was well tolerated in LN patients.

Background: Toll-like receptors (TLR) 7 and 8 are innate sensors of single stranded RNA (ssRNA). Genetic and *in vivo* evidence suggests that aberrant recognition of RNA-containing autoantigens by TLR7/8 drives autoimmune diseases (Junt and Barchet, 2015). More validation for a pathogenic effect of TLR7 in chronic inflammation comes from recent data showing that a TLR7 gain-of-function mutation is sufficient to drive lupus-like disease (Brown et al., 2022).
Objectives: Here we report on the preclinical characterization of MHV370, a highly selective, orally active TLR7/8 inhibitor for treatment of chronic inflammatory diseases.
Methods: We used a suite of in vitro profiling assays to investigate the effect of MHV370 on TLR responses. This included the stimulation of PBMCs by immune complexes from systemic lupus erythematosus patient sera. Furthermore we characterized MHV370 in different mouse models of acute and chronic TLR7-driven inflammation.
Results: *In vitro,* MHV370 interfered with TLR7/8-dependent production of cytokines in humans and mice, most notably of interferon alpha, a clinically validated driver of autoimmune diseases. MHV370 abrogates B cell, monocyte, and neutrophil responses downstream of TLR7/8. *In vivo*, prophylactic or therapeutic administration of MHV370 suppressed TLR7-dependent cytokines and interferon stimulated genes. In the NZB/W F1 mouse model of lupus, MHV370 prevented halted disease progression and glomerulonephritis. Unlike hydroxychloroquine, MHV370 interfered with cytokine production triggered by immune complexes between systemic lupus erythematosus patient sera and necrotic cell extract, suggesting differentiation from clinical standard of care.
Conclusion: The pharmacological data presented here support further development of MHV370 towards clinical proof of concept trials in man.

SUBTHERAPEUTIC HYDROXYCHLOROQUINE CONCENTRATION IS ASSOCIATED WITH INCREASED DISEASE ACTIVITY AND GREATER ORGAN DAMAGE DURING 5-YEAR FOLLOW-UP IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus

S. S. Lee[1], J. H. Kang[1], S. E. Choi[1], D. J. Park[1]. *[1]Chonnam National University Medical School and Hospital, Rheumatology, Gwangju, Korea, Rep. of (South Korea)*

Background:
Objectives: Hydroxychloroquine (HCQ) is a cornerstone drug in patients with systemic lupus erythematosus (SLE), as it decreases the risk of flares and comorbidities and improves survival. This study investigated the effects of the serum HCQ concentration on clinical manifestations, disease activity, and organ damage in a longitudinal cohort of SLE patients.
Methods: The 338 SLE patients from the Korean Lupus Network registry were assessed with respect to their demographic data, clinical and laboratory findings, PGA score, and adjusted mean SLEDAI-2000 (AMS) and SLICC damage index scores annually for 5 consecutive years. Patients were divided into two groups according to their serum HCQ concentration at baseline: patients with a subtherapeutic level (< 500 ng/mL) and those with a therapeutic level (try were assessed with respect to their demographion the clinical outcomes was evaluated in a longitudinal analysis using a generalized estimating equation (GEE) and a logistic regression analysis.
Results: Of the 338 patients, 287 (84.9%) were in the subtherapeutic group at baseline. This group had a higher incidence of newly developed lupus nephritis (P = 0.036) and had been prescribed higher mean and cumulative doses of prednisolone (P = 0.003 and P = 0.013) than the therapeutic group. In multivariable analyses based on GEE, an association of the subtherapeutic group with both a higher PGA score (β coefficient = 0.328, 95% confidence interval [CI]: 0.215–0.441, P < 0.001) and a higher SLICC damage index score (β coefficient = 0.366, 95% CI: 0.061–0.671, P = 0.019) was determined across all 5 years. In the multivariate logistic regression analysis, subtherapeutic HCQ was significantly associated with the AMS (odds ratio [OR] = 1.142, 95% CI 1.022–1.276, P = 0.019), mean PGA (OR = 3.697, 95% CI 1.767–7.735, P < 0.001), and an annual increase in the SLICC damage index score (OR = 1.529, 95% CI 1.005–2.325, P = 0.047).
Conclusion: A subtherapeutic HCQ concentration may affect the development of new-onset LN, and had the significant association with higher disease activity and cumulative organ damage in these SLE patients over time.

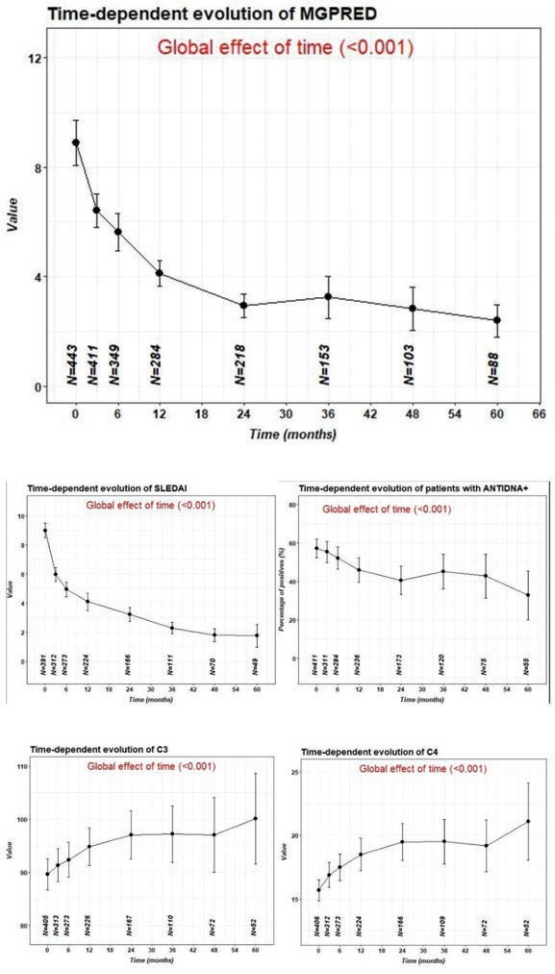
Background: Belimumab (BLM) is a monoclonal antibody that inhibits B-lymphocyte stimulating factor (BlyS) approved as a specific treatment for systemic lupus erythematosus (SLE) in 2011. We present the experience with BLM in a Spanish cohort with more than 460 patients.

Objectives: To describe demographic characteristics, efficacy and safety of BLM in patients with SLE in Spanish population since its approval.

Methods: Descriptive, retrospective, multicenter study in patients diagnosed with SLE according to EULAR/ACR 2019, SLICC and/or ACR 1997 diagnostic criteria. Data regarding SLE patients treated with BLM were collected from medical records (2011-2022). Demographic features, efficacy, laboratory variables, SLEDAI, renal involvement, steroid dose, administration routes and safety were assessed. To see whether a trend in BLM prescription had changed or not over time, two periods of time were analyzed: 2011-2016 (period1) and 2017-2022 (period2).



Results: Baseline characteristics of patients are summarized in Table 1. A total of 462 patients (36 hospitals) were included, 50.9% were on intravenous (IV), 34% on subcutaneous (SC) and 15.1% switched from IV to SC route. The median number of pre-BLM csDMARD use was 2.0 (2.0-3.0), being hydroxychloroquine (HCQ) the most frequently used (94.5%). Fifty-two patients were treated with IV cyclophosphamide with a median of 6 bolus received. At the time of BLM start, 443 patients were on prednisone with a median dose of 6.2 mg (5.0-10.0). Significant decreases in prednisone dose, SLEDAI and anti-DNA antibodies were observed from baseline until the last visit, whereas complement C3 and C4 values raised (Figure 1). A total of 118 patients (27.4%) had renal involvement with a median proteinuria of 1.0 g/day (0.5-2.4). Renal biopsy was done in 102 out of 118 patients, being class IV (33%), class III (21%) and class V (16%) the most frequently reported. After BLM, 73.3% of these patients improved (median proteinuria of 0.2 g/day (0.1-0.7). In period1, 100 patients started BLM compared to 362 in period2. The median time from SLE diagnosis to BLM begin was 7.1 (4.0-13.7) and 6.2 (2.1 -14.4) years in period1 and period2, respectively (p=0.454). We found a trend to use more csDMARD before BLM treatment in period1: 2.5 (2-3) vs. 2 (2-3) (p=0.088). A total of 143 (30.5%) patients discontinued treatment mostly due to inefficacy (55.9%) and infections (11.9%). In fact, 116 patients developed infections, mostly mild; 2 patients died, 16 had COVID-19 and 4 patients developed tumors requiring discontinuation of the drug.

Conclusion: In our cohort of SLE patients in a real-world setting, BLM has been effective, safe and seems to be a good choice to treat renal involvement.

URINARY CD163 PREDICTS COMPLETE RENAL RESPONSE WITH ZETOMIPZOMIB TREATMENT IN THE OPEN-LABEL MISSION PHASE 2 STUDY IN PATIENTS WITH LUPUS NEPHRITIS

Keywords: Biomarkers, Systemic lupus erythematosus, Clinical trials

J. T. Merrill[1], R. Leff[2], A. Fan[3], K. Palaniswamy[4], N. Henig[5], S. Hua[6]. *[1]Oklahoma Medical Research Foundation, Arthritis & Clinical Immunology Research Program, Oklahoma City, United States of America*; *[2]Kezar Life Sciences, Clinical Development, South San Francisco, United States of America*; *[3]Kezar Life Sciences, Biology and Translational Research, South San Francisco, United States of America*; *[4]Kezar Life Sciences, Medical Affairs, South San Francisco, United States of America*; *[5]Kezar Life Sciences, Chief Medical Officer, South San Francisco, United States of America*; *[6]Kezar Life Sciences, Biometrics, South San Francisco, United States of America*

Background: Complete renal response (CRR) defined by ACR/EULAR guidelines is a desirable clinical outcome associated with long-term preservation of kidney function in patients with lupus nephritis (LN) as demonstrated in clinical trials when achieved after 1-2 years. Urinary CD163 (uCD163), a biomarker that correlates with LN histologic inflammation, has been observed to predict clinical response to therapy[1]. Results previously reported on MISSION, a Phase 2 open-label study evaluating the safety and tolerability of zetomipzomib in active, proliferative LN, demonstrated clinically meaningful renal responses along with reductions in uCD163 and strong correlation with UPCR[2]. Decrease in uCD163 at early timepoints and its prediction in proteinuria response may increase probability of achieving a meaningful treatment effect.

Objectives: Data from the MISSION Phase 2 study of zetomipzomib was used to evaluate uCD163 as a potential predictor of complete renal response (CRR) for patients with LN.

Methods: In the MISSON Phase 2 study, patients with active proliferative LN (Class III or IV ± V) received 60 mg of zetomipzomib subcutaneously once weekly (first dose 30 mg) in addition to stable background therapy for 24 weeks. End-of-treatment (EOT) was at Week (W) 25, and end-of-study (EOS) occurred at W37. uCD163 data at W13 and W25 were used to model a predictive association with CRR* at W25 & W37, respectively. A logistic regression model and the Youden Index were used to generate Receiver Operating Characteristics (ROC) curves to help evaluate accuracy and identify optimal cut-off points to differentiate responders and non-responders. *Complete Renal Response: UPCR ≤0.5, eGFR ≥60 mL/min/1.73m^2 or no worsening of eGFR from baseline of ≥25%, prednisone (or equivalent) ≤10 mg and no use of prohibited medication.

Results: Of the 21 patients enrolled in MISSION, 17 reached EOT and EOS. CRR was achieved in 35% and 41% of patients at W25 and W37. Anti-inflammatory potential of zetomipzomib was demonstrated by reduction of uCD163, which was strongly correlated with UPCR improvement at W13, W25 and W37 (Figure 1). For the thirteen patients who consented to urine biomarker analysis, baseline 24-hour UPCR was: mean=2.8 mg/mg, median=1.8 mg/mg, SD=3.3, range 0.93-13.4; uCD163: mean=1.7 mg/mmol, median=0.97 mg/mmol, SD=2.3, range 0.28, 8.9. ROC analysis results from the MISSION study suggests that LN patients with uCD163 values of ≤0.13 at W13 and ≤0.09 at W25 are more likely to achieve a CRR at W25 and W37 following treatment with zetomipzomib (Table 1).

Conclusion: This post-hoc analysis of zetomipzomib data generated from the MISSION Ph2 study suggests that in patients with proliferative LN, uCD163 levels might predict CRR achieved up to 3 months later and could therefore potentially help to guide optimal therapy. Further evidence is needed from larger randomized LN trials with zetomipzomib to confirm the utility and limits of uCD163 as a predictive biomarker.

Background: Belimumab (BLM) is a recombinant human IgG-1λ monoclonal antibody that inhibits B-cell activating factor. It is approved for the treatment of systemic lupus erythematosus (SLE). It is effective in reducing disease activity, flares, damage prevention and also as a steroid-sparing agent. A treat to target (T2T) approach in the care of SLE patients is important in terms of improving short and long-term outcomes.
Objectives: To evaluate belimumab (BLM) effectiveness in SLE patients from a Spanish multicenter registry.
Methods: A longitudinal retrospective multicenter cohort including SLE patients treated with belimumab from 18 Spanish rheumatology departments. Demographic, clinical and serological data were collected at baseline, 6, 12 and in the last visit available. Changes in SLEDAI-2K; LLDAS and DORIS 2021 states and global response according to physician criteria were compared between visits, as well as changes in damage and glucocorticoids used. T-test was used for numerical variables and the Fisher's test for categorical variables.
Results: 324 patients were included: 295 (91%) females with a mean (±SD) age of 42.4 (±12.9) years. Mean follow-up was 3,8 (±2.7) years and mean time with BLM was 2.7 (±2.4) years. At baseline, mean SLEDAI-2K was 10.4 (±5.25), 68.2% had elevated anti-double-stranded DNA (anti-dsDNA) antibodies and 69.8% had complement consumption. BLM was initiated concomitant to other DMARD in 67.9% (n=220) of patients. Mean reduction in SLEDAI-2K score was 5.0 (± 5.1), 6.1 (± 5.5) and 7.13 (± 5.3) points at 6, 12 months and in the last visit, respectively (p<0.05 for all comparisons). Rates of achievement of LLDAS, DORIS and clinical response according to physician criteria, significantly increased from baseline to 6, 12 months, and to the last visit (Table 1). Anti-dsDNA antibodies and inflammatory markers (ESR, CRP), significantly decreased from baseline to 6, 12 months and in the last visit. Complements increased over the follow up but without statistical significance. A total of 107 (45,9%) patients discontinued GC. At 6 months, 58.9% (n=155) of patients reduced the dose of GC with respect to baseline and 72.8% (n=131) of patients did it at the last visit. Mean (±SD) prednisone dose was significantly reduce over the visits: 12.3 (±12.16); 7.42 (±5.36); 5.8 (±4.42) and 4.7 (±3.7) mg/day at baseline, 6 and 12 months and in the last visit, respectively. Median (IQR) SDI score at the end of the observation period did not change from baseline visit: 0 (0-1) and 0 (0-1), respectively (p=0.97). Neither were changes observed in the percentage of patients with damage between the beginning and the end of the observation period: at baseline 47.5% (n=152) patients presented damage and, in the last visit, 45.6% (n=99).

Table 1. Clinical response and changes in GC dose.

Disease activity Mean (±SD) or number (%); n=324	Baseline	6 months	12 months	Last visit
SLEDAI reduction; mean (±SD)	10 (± 5.25)	5.0 (± 5.1) *	6.1 (± 5.5) *	7.13 (± 5.3) *
LLDAS	6 (1.9%)	137(45.8%) *	145 (62%) *	177 (73.1%) *
DORIS	6 (1.9%)	72 (24%) *	85 (36.3%) *	127 (52.5%) *
Response according to physician		212 (65.4%) *	185 (57.1%) *	165 (50.9%) *
Number of swollen joints; mean (±SD)	3.3 (±3.6)	1.2 (±2.8) *	0.69 (±1.95) *	0.55 (±1.82) *
Prednisone dose (mg/day); mean (±SD)	12.3 (± 12.16) *	7.4 (± 5,36) *	5.8 (± 4,42) *	4.75 (±3.74) *

Ongoing	279	250	194

Figure 1. Rates of therapeutic targets attained by patients in treatment with Belimumab.

Conclusion: Real-world data of SLE patients confirm belimumab efficacy in real world, reducing clinical and serological activity in the short and medium-term. Add-on therapy with BLM leads to high rates of LLDAS and DORIS at 6 months, that continue increasing over time. BLM has an important GC sparing effect and prevents organ damage accrual. All these data shows that BLM is useful to achieve the therapeutic goals of a T2T strategy.

POS1145

FACTORS ASSOCIATED WITH SURVIVAL AND DISCONTINUATION OF ANTIMALARIAL AGENTS IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM A SWEDISH LONGITUDINAL REGISTRY

Keywords: Disease-modifying drug (DMARDs), Systemic lupus erythematosus

T. Walhelm[1], L. Wirestam[1], Y. Enman[2], I. Parodis[2,3], C. Sjöwall[1]. *[1]Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection/Rheumatology, Linköping, Sweden*; *[2]Karolinska Institutet and Karolinska University Hospital, Department of Medicine Solna, Division of Rheumatology, Stockholm, Sweden*; *[3]Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden*

Background: Hydroxychloroquine (HCQ) and chloroquine, referred to as antimalarial agents (AMA), are cornerstone drugs in systemic lupus erythematosus (SLE), which inhibit type I interferon release via toll-like receptor binding and increasing the pH in plasmacytoid dendritic cell lysosomes [1]. AMA use has established benefits in SLE, such as improved prognosis and decelerated accrual of organ damage. Use of HCQ is safe for most patients and serious side-effects are uncommon, even during pregnancy. Medical therapy to prevent repeated disease flares is of essential weight in the treatment of SLE. However, it is well-known that non-adherence to prescription of AMA is a considerable problem [2].
Objectives: The aim of this cross-sectional study was to investigate the frequency of AMA prescription, and evaluate factors associated with ongoing use and discontinuation of AMA in a Swedish SLE population.
Methods: We retrieved data from the *Clinical Lupus Register in North-Eastern Gothia* (Swedish acronym: KLURING), a longitudinal research and quality registry, including all prevalent and incident cases of SLE in the Östergötland County from 2008 onwards. All included subjects fulfilled the validated 1982 American College of Rheumatology (ACR) and/or the 2012 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria and had been diagnosed from 1963 onwards. Factors associated with ongoing use and discontinuation of AMA were investigated using logistic regression analysis, Mann-Whitney U test and chi-square test.
Results: A total of 328 subjects were included in the analysis. The mean age at diagnosis was 40.0 years (range: 3–85; standard deviation [SD]: 17.7) and 85.7% were females. The mean SLICC/ACR damage index (SDI) score at last visit was 2.0 (range: 0—11; SD: 2.5). In total, 92.4% had used AMA at some point during their disease course ("ever" users; Table 1). Data from the last available visit indicated that 73.2% were currently prescribed AMA, exclusively HCQ, yielding a

daily mean HCQ dose of 228.0 mg (range: 100—400; SD: 71.0). Among individuals who had discontinued AMA, 25.9% had developed a contraindication, mostly on ophthalmological basis (33.3%). Less common reasons were cardiac conditions (19.0%) and renal failure (9.5%). Subjective side-effects were also common; the most frequently reported were gastrointestinal symptoms (n=20/37). Most common patient-related factor associated with discontinuation was intentional non-adherence (e.g., low motivation; 8/11). Patients who had discontinued AMA showed a higher SDI score at the last visit (mean: 2.9; SD: 2.8; mean follow-up: 20.0 years) compared with patients on AMA (mean: 1.4; SD: 1.8; p=0.001; mean follow-up: 15.3 years). Those who fulfilled the immunological disorder ACR criterion (ACR-10) were more likely to continue on AMA (p=0.003). No significant differences were found regarding gender or smoking status.

Table 1. AMA therapy

	N (%)
AMA, ever user	303 (92.4)
AMA, current use	222 (73.3)
AMA, discontinued user	81 (26.7)
Therapy related factors	58 (71.6)
Related to contraindication	21 (25.9)
Related to adverse events	37 (45.7)
Patient related factors	11 (13.6)
Unknown reason	12 (14.8)

Conclusion: The vast majority of patients in KLURING had been exposed to AMA, and approximately 25% discontinued AMA therapy during follow-up. The main reason for discontinuation were therapy-related factors, such as contraindications and experience of side-effects. Above 50% of the reported side-effects that led to discontinuation were gastrointestinal symptoms. The group of discontinued AMA users accrued more damage over time.

POS1146 LOW MOLECULAR WEIGHT HEPARINS INTERFERE WITH NEUTROPHIL ACTIVATION AND NET GENERATION IN HIGH-RISK PREGNANT PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

Keywords: Cell biology, Pregnancy and reproduction, Innate immunity

P. Rovere-Querini[1], V. Canti[1], A. D'angelo[1], M. T. Castiglioni[1], S. Rosa[1], E. Manfredi[1], B. Frascella[1], V. D'alberti[1], A. Manfredi[1], N. Maugeri[1]. [1]*IRCCS San Raffaele Scientific Institute, Autoimmunity and Vascular Inflammation Unit, Milano, Italy*

Background: Neutrophil activation and the generation of neutrophils extracellular traps (NETs) contribute to vascular damage and thrombosis in antiphospholipid syndrome (aPS). We reported that Low molecular weight heparin (LMWH) prevent neutrophil activation induced by P-selectin expressed by activated platelets [1, 2] and jeopardize in healthy subjects the ability of neutrophils to generate NETs and to mobilize granule contents [3].

Objectives: To investigate whether LMWH, used on empirical bases to in high-risk patients, regulate neutrophil/platelet interaction in pregnant women.

Methods: Here we report preliminary data from a prospective monocentric study in which the activation of platelets and neutrophils was assessed in sixteen pregnant women treated with LMWHs, with or without aPS at 12, 24 and 32 weeks of gestation. Patients were studied again when feasible after pregnancy completion. Sixteen healthy pregnant women, ten healthy women outside pregnancy and ten women with Systemic Lupus Erythematosus outside pregnancy served as controls.

Results: Platelets of pregnant healthy women were activated, as assessed by the increased expression of P-selectin and tissue factor. All patients successfully completed the pregnancy. Abnormalities were evident at the pathological assessment of the placentae despite the treatment with LMWHs. The treatment was associated with significantly reduced: i) platelet/neutrophil interaction, as assessed by heterotypic aggregates; ii) neutrophil expression of tissue factor; iii) platelet expression of the prototypic DAMP, HMGB1; iv) accumulation in the blood of byproducts of NET formation/catabolism, such as myeloperoxidase-DNA complexes. P-selectin expression was, in contrast, unaffected.

Conclusion: The results indicate that neutrophil and platelet activation/interaction, which may reflect detrimental intravascular immune events leading to pregnancy complications, abate in patients treated with LMWHs.

POS1147 EFFICACY OF CENERIMOD IN PATIENTS WITH HIGH IFN-1 GENE EXPRESSION SIGNATURE AND HIGH ANTI-DSDNA ANTIBODY LEVELS: POST-HOC ANALYSIS FROM A PHASE 2 STUDY

Keywords: Clinical trials, Systemic lupus erythematosus

A. Askanase[1], D. D'cruz[2], K. Kalunian[3], J. Merrill[4], S. Navarra[5], C. Cahuzac[6], P. Cornelisse[6], D. Strasser[6], L. Trokan[6], O. Berkani[6]. [1]*Columbia University, Medicine, New York, United States of America*; [2]*Guy's and St. Thomas' Hospital, Rheumatology, London, United Kingdom*; [3]*UCSD, Rheumatology, San Diego, United States of America*; [4]*OMRF, Rheumatology, Oklahoma City, United States of America*; [5]*University of Santo Tomas, Rheumatology, Manilla, Philippines*; [6]*Idorsia Pharmaceuticals, Clinical Development, Allschwil, Switzerland*

Background: Cenerimod is an orally active, selective sphingosine 1-phosphate (S1P) 1 receptor modulator under investigation for the treatment of systemic lupus erythematosus (SLE). The Phase 2 CARE study (NCT03742037) did not meet its primary endpoint after adjustment for multiplicity, but patients treated with cenerimod 4 mg showed reduced disease activity versus placebo after 6 months.[1] Along with prior findings that type-1 interferon (IFN-1) activation is a robust biomarker of SLE disease activity and that an elevated IFN-1 signature associates with autoantibodies and more severe disease, cenerimod reduces plasma levels of IFN-α and leads to decreased circulating B and T cells in patients with SLE, suggesting effects on both innate and acquired immune responses.

Objectives: These post-hoc analyses evaluated the efficacy of cenerimod in subpopulations of patients with SLE.

Methods: CARE randomised 427 patients with SLE to once-daily cenerimod (0.5, 1, 2 or 4 mg) or placebo. At month (M) 6, patients receiving 4 mg cenerimod were re-randomised to placebo or cenerimod 2 mg for the subsequent 6 months, while all other groups continued their initially assigned treatment to M12. The primary endpoint was change from baseline to M6 in SLEDAI-2K score modified to exclude leukopenia (mSLEDAI-2K) due to the mechanism of action of cenerimod. Post-hoc analyses were performed in patients with high IFN-1 gene expression signature or anti-dsDNA levels ≥30 IU/mL. IFN-1 gene expression signature was based on the expression of four genes (*IFI27*, *RSAD2*, *HERC5*, *IFIT1*).

Results: Primary results from the CARE study were presented at ACR 2022.[1] The primary endpoint was not met (nominal P=0.0291 for cenerimod 4 mg vs placebo). At baseline, 207 patients (51%) in CARE had high IFN-1 gene expression signature, including 36 (45%) and 40 (50%) randomised to cenerimod 4 mg and placebo, respectively. Anti-dsDNA antibody levels ≥30 IU/mL were noted in 86 patients (20%), including 21 (25%) and 15 (17%) for cenerimod 4 mg and placebo, respectively. There was an association between high IFN-1 gene expression signature and high anti-dsDNA levels, with more than 75% of patients with anti-dsDNA levels ≥30 IU/mL having high IFN-1 gene expression signature. Reduction in mSLEDAI-2K from baseline to M6 for the cenerimod 4 mg group was greater in patients with high IFN-1 gene expression signature and high anti-dsDNA antibody levels versus the overall population (Figure 1A). Similarly, the proportion of SRI-4 responders at M6 was higher in patients with high versus low IFN-1 gene expression signature

(70% vs 41% for cenerimod 4 mg; 46% vs 43% for placebo). Patients with high IFN-1 gene expression signature treated with 4 mg cenerimod showed reduced IFN-α and anti-dsDNA levels at M6 versus baseline. At M6 resolution of alopecia was reported by more patients with high versus low IFN-1 gene expression signature (38% vs 26% for cenerimod 4 mg; 14% vs 7% for placebo), as were resolution of arthritis (57% vs 28% for cenerimod 4 mg; 38% vs 42% for placebo) and reduction in mucosal ulcers (80% vs 67% for cenerimod 4 mg; 41% vs 41% for placebo) on the mSLEDAI-2K. However, there was no treatment effect observed in rash.

Conclusion: Treatment with cenerimod 4 mg resulted in greater reductions of disease activity versus placebo at M6 in patients with high IFN-1 gene expression signature or high anti-dsDNA antibody levels at baseline. Cenerimod treatment also reduced levels of IFN-α protein and anti-dsDNA antibodies in these patients. Two Phase 3 studies of cenerimod 4 mg in SLE are underway.

POS1148 OPTIMAL CUT-OFF POINT FOR ELECTROCARDIOGRAM IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ON HYDROXYCHLOROQUINE THERAPY

Keywords: Disease-modifying drug (DMARDs), Systemic lupus erythematosus

A. Herrero-Morant[1], J. Zubiaur-Zamacola[1], A. Margarida-de Castro[1], R. Pérez-Barquín[1], R. Blanco[1]. [1]*Marqués de Valdecilla University Hospital, Rheumatology and Cardiology, Santander, Spain*

Background: Hydroxychloroquine (HCQ) is a widely used drug in Systemic Lupus Erythematosus (SLE) that can cause cardiac alterations such as arrhythmic events in the short-term and dose-dependent cardiomyopathy in the medium to long-term. The cardiological implications of HCQ accumulation in these patients in the medium to long-term is unknown.

Objectives: To assess the optimal cut-off point for electrocardiogram (ECG) in patients with SLE on HCQ therapy to prevent arrhythmic complications.

Methods: Single university hospital observational study of all consecutive SLE patients who had an ECG at baseline and at least one ECG at follow-up. New conduction disturbances were assessed by ECG, defined as atrioventricular block, bundle branch block or QT interval prolongation. ECGs were extracted from the medical record and interpreted at baseline and for 15.2 years (95%CI 13.24-17.16) of follow-up. We defined cumulative HCQ (cHCQ) as the total grams of HCQ that had been administered. A Receiver Operating Characteristic (ROC) curve analysis was performed to determine the optimal cut-off point for sensitivity and specificity.

Results: We studied 105 (93 female/12 male) SLE patients with a mean (±SD) age of 61.8±14.9 years. The mean daily dose of HCQ in our sample was 256 mg per day (**Table 1**). The ROC curve showed a moderate diagnostic ability for new conduction disturbances with an area under the curve of 0.69 (95% CI 0.59 - 0.77) (**Figure 1**). The highest efficacy cut-off point was cHCQ: 4097g (Sensitivity 15%; Specificity 100%) and the optimal cut-off point was cHCQ: 901g (Sensitivity 85%; Specificity 52.9%). This cut-off point was reached with a mean HCQ treatment in our sample of 9.7 years. High grade atrio-ventricular block was found in 5 patients. In all of them the cHCQ dose was over 901g.

Conclusion: According to our study, 901g of cHCQ dose is a good cut-off point for performing a protocolized ECG to rule out cardiac conduction disturbances in patients with SLE and chronic HCQ treatment. This is equivalent to 9.7 years of treatment with the mean HCQ dose use in our sample.

COMPARISON OF THE EFFICACY AND SAFETY OF TELITACICEPT VERSUS BELIMUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN REAL CLINICAL PRACTICE: ANALYSES WITH PROPENSITY SCORE-BASED INVERSE PROBABILITY OF TREATMENT WEIGHTING

Keywords: Treat to target, Real-world evidence, Systemic lupus erythematosus

H. Jin[1], Z. Chen[1,2]. [1]*The First Affiliated Hospital of USTC, Department of Rheumatology and Immunology, Hefei, China*; [2]*University of Science and Technology of China, Division of Life Sciences and Medicine, Hefei, China*

Background: Systemic lupus erythematosus (SLE) is a multi-system autoimmune disease characterized by aberrant expansion of B cells. The B cell-stimulating molecules, B cell activating factor/a proliferation-inducing ligand (BAFF/APRIL), are critical factors in promoting the proliferation and differentiation of B cells thus play a prominent role in the pathogenesis of SLE. There are two types of BAFF/APRIL-targeted biological agents being approved as an add-on therapy for patients with active SLE in China, including the BAFF/APRIL dual inhibitor, telitacicept and the BAFF inhibitor, belimumab. However, the differences of efficacy and safety between these two agents in real clinical practice has not been clarified.

Objectives: To compare the differences of efficacy and safety between the two types BAFF/APRIL inhibitors telitacicept and belimumab in the treatment of active patients with SLE.

Methods: Clinical features, laboratory data, SLE Disease Activity Index 2000 (SLEDAI-2K), treatment history, and adverse events (AEs) during the six months follow-up were collected. Propensity score based inverse probability of treatment weighting (IPTW) was used to reduce the selection bias.

Results: Active SLE patients who received telitacicept (N=52) and belimumab (N=77) from 2019 to 2022 at our rheumatology department were retrospectively reviewed. No significant differences were observed in patient characteristics between the two groups after adjustment by IPTW. Patients who received telitacicept have a significantly higher decrease of SLEDAI-2K score and Physician's Global Assessment (PGA) score at 24 weeks ($p<0.05$). Consistently, there was a higher elevation of complement (C) 3 and C4 levels at 4 and 12 weeks in telitacicept group ($p<0.05$). The telitacicept group acquire a higher frequency of primary efficacy renal response (PR) than belimumab at 12 weeks and no obvious differences were observed in complete renal response (CR) at 12 and 24 weeks according to the Belimumab International Lupus Nephritis Study (BLISS-LN) criteria. In addition, the improvement of anemia was better in the telitacicept group ($p<0.05$). Importantly, the telitacicept group had a lower incidence of AEs, including upper respiratory tract infections, diarrhea and leukopenia, than the belimumab group after IPTW ($p<0.05$).

Conclusion: Telitacicept showed a better efficacy and safety than belimumab for active SLE patients in a single center clinical practice. Further investigations in a larger cohort are required to testify these findings.

ULTRASOUND-DETECTED EROSIONS COULD PREDICT THE EFFICACY OF BELIMUMAB IN ARTICULAR SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: bDMARD, Systemic lupus erythematosus, Ultrasound

G. Orsolini[1], R. Bixio[1], F. Mastropaolo[1], A. Piccinelli[1], E. Favaro[1], O. Viapiana[1], G. Adami[1], M. Rossini[1]. [1]*University of Verona - AOUI Verona, Rheumatology Unit, Verona, Italy*

Background: Articular involvement (69-95%) in patients with systemic lupus erythematosus (SLE) is traditionally considered non-erosive. SLE arthritis with radiographic erosions with or without rheumatoid factor (RF) and/or anti-citrullinated peptide antibody (ACPA) positivity is often described as "rhupus" and is considered an overlap between SLE and rheumatoid arthritis (RA). While radiographic erosions are shown in about 5-15% of the patients, ultrasound and magnetic resonance imaging could reveal erosions in up to 40% of patients with SLE.

Objectives: The aim of this study is to assess if the presence of ultrasound-detected erosions can predict the efficacy of belimumab, a B lymphocyte simulator (BlyS) inhibitor, in the treatment of SLE-related articular manifestations.

Methods: We performed a spontaneous, monocentric, retrospective, and observational study. We enrolled patients with a diagnosis of SLE according with the 2019 American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) criteria with articular involvement treated with belimumab. Patients with ACPA- or RF-positivity, Jaccoud's arthropathy, or radiographic erosions were excluded. We collected laboratory and clinical data from the electronic records. Joint disease activity was assessed at baseline, 3- and 6-months follow-ups (FU) using disease activity score on 28 joints based on C-reactive protein (DAS28-CRP). At baseline, all patients underwent an ultrasound examination of the wrist, metacarpophalangeal, proximal interphalangeal, and metatarsal-phalangeal joints. Erosions were defined according with the outcome measures in rheumatology (OMERACT) definition (at least 1 mm). Student's T-test and Mann-Whitney's U-test were used to assess differences between means and Fisher's exact test to assess differences between proportions.

Results: We enrolled 23 patients (baseline characteristics in Table 1). Seven patients (30.4%) had bone erosions at baseline. They were generally older (61±16.1 vs 46.13±10.7 years, p=0.016), more frequently male (42.8 vs 6.2%, p=0.03), with higher CRP levels (10.29±11.6 vs 2.25±3.1 mg/L, p=0.015), and higher C4 (0.19±0.17 vs 0.1±0.04 g/L, p=0.05) than patients without erosions. DAS28-CRP decreased significantly at 6-months FU (2.95±0.89 vs 2.26±0.48, p=0.01) only in patients without erosions, as shown in Figure 1. The majority of patients (73.9%) achieved remission at 6-months FU (DAS28-CRP criteria), with a significant difference between patients with and without erosions (42.8 vs 87.5%, p=0.045).

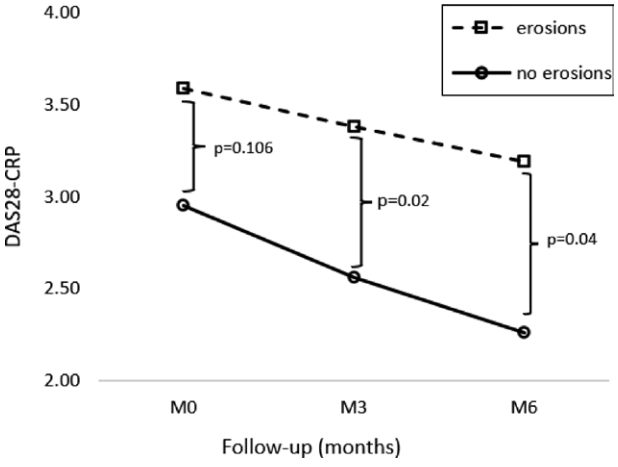

Figure 1. Mean DAS28-CRP levels at baseline and 3- and 6-months FU in patients with and without erosions Legend: DAS28-CRP = Disease Activity Score 28 joints count based on C-reactive protein, FU=follow-up

Table 1. Clinical, laboratoristic, and therapeutic characteristics of the cohort at baseline

Age (years), mean ± SD	50.65 ± 14.1
Female, n (%)	19 (82.6)
Disease duration (years), mean ± SD	12.74 ± 9.7
Smokers, n (%)	6 (26.1)
CRP (mg/L), mean ± SD	4.7 ± 7.6
Concomitant HCQ, n (%)	20 (87)
Glucocorticoid (PDN mg/day), mean ± SD	10.54 ± 10.5
Articular bone erosions, n (%)	7 (30.4)
Number of joints with erosions, mean ± SD	1.04 ± 2
Tender joints, mean ± SD	3.2 ± 2.4
Swollen joints, mean ± SD	1.04 ± 1.5
PGA, mean ± SD	9.2 ±.4
DAS28-CRP, mean ± SD	3.14 ± 0.9
SLEDAI-2K, mean ± SD	6.7 ± 2.8
Clinical SLEDAI-2K, mean ± SD	2.83 ± 2.5
SDI, mean ± SD	1.17 ± 1.3

Conclusion: The presence of ultrasound-detected erosions could be predictive of a decreased efficacy of belimumab in articular SLE. A possible explanation is a rheumatoid-like articular phenotype, despite the lack of ACPA-positivity and radiologic erosions. Our findings could help expand the "rhupus" spectrum and highlight the possible role of different SLE phenotypes in the therapeutic response.

THERAPEUTIC DRUG MONITORING OF AZATHIOPRINE AND TACROLIMUS IN SLE PREGNANCIES: PRELIMINARY RESULTS FROM THE LEGACY COHORT

Keywords: Disease-modifying drug (DMARDs), Pregnancy and reproduction, Systemic lupus erythematosus

R. Farhat[1,2], A. Mendel[2,3,4], I. Malhamé[2,3,5], J. Y. E. Lee[2], L. Ciofani[2], S. Bernatsky[2,3,4], E. Vinet[2,3,4]. *[1]McGill University, Division of Experimental Medicine, Faculty of Medicine and Health Sciences, Montreal, Canada*; *[2]Research Institute of the McGill University Health Centre, Centre for Outcomes Research and Evaluation (CORE), Montreal, Canada*; *[3]McGill University, Department of Medicine, Faculty of Medicine, Montreal, Canada*; *[4]McGill University Health Centre, Division of Rheumatology, Division of Clinical Epidemiology, Department of Medicine, Montreal, Canada*; *[5]MUHC - McGill University Health Centre, Division of General Internal Medicine, Department of Medicine, Montreal, Canada*

Background: Pregnant SLE women still face an unacceptably high risk of maternal and fetal morbidity, particularly when their disease is active. How to personalize SLE therapies to optimize pregnancy outcomes remains unknown. Though guidelines strongly recommend azathioprine (AZA) and tacrolimus (TAC) in specific SLE pregnancy scenarios, evidence to guide drug monitoring in this context is non-existent.

Objectives: In the prospective "Lupus prEGnAnCY (LEGACY)" cohort we evaluated AZA and TAC levels at the first pregnancy (baseline) visit.

Methods: LEGACY is a prospective cohort enrolling unselected SLE pregnancies ≤16 6/7 gestational weeks at 7 Systemic Lupus International Collaborating Clinics. We record demographics, disease activity, and drugs. In addition, whole blood samples are collected at baseline to determine AZA metabolites (e.g., erythrocyte-free 6-thioguanine, 6-TG) and trough TAC levels if applicable. The present study included Montreal LEGACY participants prescribed either AZA or TAC ≥3 months prior to their first pregnancy visit. We characterized AZA metabolite and TAC levels as continuous and categorical variables (i.e., non-adherent, sub-therapeutic, therapeutic, and supra-therapeutic, using established cut-offs in non-pregnant populations). We defined patients as non-adherent if they had undetectable or barely detectable levels despite appropriate dosing.

Results: Of 64 LEGACY pregnancies enrolled in Montreal, 23 (36%) and 6 (9%) were prescribed AZA and TAC, respectively. Among those prescribed AZA, only 9% had therapeutic levels, while 91% were sub-therapeutic or non-adherent. Compared to those with therapeutic levels, pregnancies with sub-therapeutic or non-adherent AZA levels were more likely to occur in women of non-Caucasian ethnicity/race, on steroids, with longer SLE duration, and with prior lupus nephritis (Table 1). Among those prescribed TAC, 50% (3/6) had therapeutic levels, while 33% (2/6) and 17% (1/6) were sub-therapeutic and supra-therapeutic, respectively. No patient on TAC were identified as non-adherent. Less than half (43%) of pregnancies non-adherent to AZA were in Lupus Low Disease Activity State (LLDAS) at baseline as opposed to 71% of those with higher AZA levels (i.e., sub-therapeutic or therapeutic). Of the pregnancies with sub-therapeutic TAC levels, 50% (1/2) were not in LLDAS, while all (4/4) pregnancies with therapeutic or supra-therapeutic TAC levels were in LLDAS at baseline.

Conclusion: We observed that most SLE pregnancies prescribed AZA had sub-therapeutic levels, with nearly a third identified as non-adherent. Pregnancies with lower AZA and TAC levels may be less likely to achieve LLDAS. Despite low numbers, our preliminary results suggest the value of personalized drug monitoring as a novel approach to precision medicine in pregnant SLE women, that might improve efficacy, safety, and adherence in a high-risk population.

Background: The approval of two new drugs, belimumab and voclosporin, in lupus nephritis (LN) over the last years has raised questions regarding their place in the therapeutic algorithm of LN. Their use in initial regimens or in refractory/relapsed disease depends on disease outcomes with current standard of care (SoC) therapies.

Objectives: To calculate EULAR/ERA-EDTA renal response rates with SoC therapies at 3, 6 and 12 months, as well as rates of successful tapering to the recommended glucocorticoid use at 6 months in real-life clinical settings.

Methods: Combined retrospective and prospective (2015-today) cohort study of patients with histologically confirmed LN. Demographic, clinical, and laboratory data, as well as treatment administered at baseline and respective changes every 3 months, were collected. Renal response rates according to EULAR/ERA-EDTA goals of treatment were calculated: (at 3 months: proteinuria reduction by 25%, 6 months: 50% reduction to subnephrotic level, 12 months: proteinuria< 500-700mg/24h, all with stabilization or improvement in kidney function). The percentage of patients who received IV methylprednisolone (total recommended dose 500-2500mg), as well as mean prednisone dose per day at baseline (recommended dose 0.3-0.5mg/kg in class III and class IV and 20mg in class V) and thereafter (<7.5mg/day at 6 months in class III and class IV and <5mg/day at 3 months in class V). We also calculated the percentage of patients who had tapered prednisone to the recommended daily dose by 6 months.

Results: 110 patients were included, 83 completed a 12month follow up [81.8% female, median (IQR) age 36.5 (23) years]. One third (33.6%) of patients had nephrotic range proteinuria at diagnosis. Histologically, 16.7% had LN class III, 33.3% class IV, 18.5% class V and 27.8% mixed class (III/IV +V). With SoC therapy [initial therapy: 48.1% cyclophosphamide (CYC), 32.4% mycophenolic acid (MPA), followed by maintenance therapy], 76.7%, 82.6% and 71.1% achieved EULAR/ERA-EDTA renal response rates at 3, 6 and 12 months, respectively. No differences between CYC and MPA groups regarding response rates were noted. All patients received IV methylprednisolone at baseline [median (IQR) 2.0 (3.0) gr].

Regarding glucocorticoid use, in proliferative classes (III/IV), median (IQR) prednisone starting dose was 40.0 (20.0) mg/day, corresponding to a mean (SD) dose of 0.63 (0.27) mg/kg/day. At 6 months, median (IQR) daily dose was 10.0 (10.0) mg. In class V LN, median (IQR) daily starting dose was 32.5 (20.0) mg and 15.0 (10.0) mg at 3 months.

Conclusion: Although a significant number of LN patients achieve treatment target between 3-12 months, approximately 25-30% fail. Moreover, prednisone doses used in LN tend to be higher than those recommended by EULAR/ERA-EDTA. Predictive factors associated with suboptimal response can help to shape therapeutic decisions identify patients that may benefit from early use of novel therapies.

Background: In our recently published working definition, we proposed that disease modification in systemic lupus erythematosus (SLE) requires 'minimising disease activity with the fewest treatment-associated toxicities and slowing or preventing organ damage progression'.[1]

Objectives: To apply the proposed non-renal disease modification criteria to SLE treatments.

Methods: Based on a review of a selection of clinical trial (n=31) and observational (n=42) data publications for 16 SLE medications across different treatment classes and, the authors' clinical experience, we evaluated their disease modification potential per the non-renal disease activity and organ damage criteria at three time points (**Table 1**).[1]

Results: Nine of the 16 SLE treatments met at least one disease modification criterion across all time points (**Table 1**). Hydroxychloroquine improved overall survival at >5 years, suggesting long-term disease modification, but with data per specific criteria lacking.[2] Belimumab met two of the three disease modification criteria at the first two time points, but was the only treatment to meet criteria at >5 years based on the current literature. While steroids unambiguously decrease disease activity at early timepoints, at doses higher than 7.5 mg/day the negative impact on damage accrual might hamper their disease modification potential >5 years.

Conclusion: This is the first attempt to determine which of the currently used treatments in patients with SLE fulfil the disease modification criteria at different time points. Belimumab and hydroxychloroquine showed evidence of disease modification up to and beyond 5 years; evidence for many other SLE therapies was incomplete, particularly at >5 years of follow up. The use of multiple agents, differences in study designs, patient populations, and definitions of treatment response pose challenges in categorising treatments as disease modifiers. Future studies will evaluate the minimum number of criteria required to designate disease modification at each of the three time points so that disease modification can be considered in the care of patients with SLE and in SLE trial design.

PRE-TREATMENT DIFFERENTIALLY EXPRESSED METAGENES CHARACTERIZE SYSTEMIC LUPUS PATIENTS WHO SUBSEQUENTLY ACHIEVE CLINICAL RESPONSE TO BELIMUMAB

Keywords: Clinical trials, -omics, Systemic lupus erythematosus

J. T. Merrill[1], M. Smith[1], K. Thomas[1], C. Guthridge[1], N. Dominguez[1], S. Macwana[1], W. Dejager[1], S. Kamp[1], C. Arriens[1], B. Parrish[1], J. A. James[1].
[1]*Oklahoma Medical Research Foundation, Arthritis and Clinical Immunology, Oklahoma City, United States of America*

Background: Belimumab, which targets the B Cell activator and survival factor BLyS, is an approved treatment for systemic lupus (SLE) and has demonstrated efficacy in multiple clinical trials around the world. Nevertheless, like other SLE treatments, belimumab can have disappointing results in a significant proportion of this heterogenous population, a problem further complicated by the unpredictable impact of various combination treatments used with belimumab in trials and clinical practice.

Objectives: Examination of gene expression variables in SLE patients prior to belimumab treatment with limited background medications in order to distinguish those who subsequently respond from those who do not.

Methods: A prospective open-label study of belimumab was conducted in 24 SLE patients with active but non-organ threatening disease, who were required to withdraw other immune suppressants (only antimalarials or low dose steroids allowed). At baseline, patients were given optional steroid injections for temporary relief, then followed for six months on intravenous belimumab (10 mg/kg). The primary endpoint was time to treatment failure compared to historical controls from the BOLD study which followed the same protocol but without treatment after initial steroids[1]. Response was also evaluated at six months by the SLE Responder Index (SRI-4) or the BILAG-based Combined Lupus Assessment (BICLA). Before and during treatment, Pax Gene tubes were collected, and RNA sequenced, using the same methods for healthy control samples. To maximally discriminate clinical responders from non-responders by baseline gene expression patterns in a small, heterogenous population, principal component analysis was conducted with modules (metagenes) comprised of differentially expressed genes (DEGs).

Results: Of 24 patients entering the study, 20 completed 6 months of treatment. The mean survival time without flare, treatment change, or study withdrawal was 18.4 weeks (CI 15.3-21.5) compared to the 41 BOLD participants with mean survival 9.829 weeks (CI 0.999-7.871) ($p<0.001$ by log rank test). At 6 months, 14 patients who received belimumab (58%) and 1 from the BOLD study (2.4%) remained free of flare. The SRI-4 was met by 7 patients in this study (29.2%), the BICLA by 9 (37.5%). SRI-4 response was used as the basis for modeling two metagenes comprised of the 25 most upregulated and 25 most downregulated genes at baseline in belimumab responders as compared to non-responders. There was no overlap between metagene scores of responders' vs non-responders (Figure 1). After 3 months of treatment with belimumab all metagene scores corrected towards levels in healthy controls. The most discriminatory DEGs included protein transcription factors and long non-coding RNA (transcription regulators).

Conclusion: When background immune suppressants are excluded, belimumab still achieves SRI 4 or BICLA response for some patients, and most do not flare for at least six months. A composite metagene model has been identified as a potential predictor of belimumab response. Confirmation studies should be prospectively conducted.

IMPACT OF HYDROXYCHLOROQUINE ON INTERFERON PATHWAY EXPRESSION OF SLE PHENOTYPIC SUBSETS IN THE ABSENCE OF BACKGROUND MEDICATIONS

Keywords: -omics, Systemic lupus erythematosus, Biomarkers

C. Mowery[1,2], M. Smith[1], K. Thomas[1], S. Macwana[1], W. Dejager[1], S. Kamp[1], B. Parrish[1], C. Arriens[1], T. Aberle[1], J. T. Merrill[1], J. Guthridge[1], J. A. James[1].
[1]Oklahoma Medical Research Foundation, Arthritis and Clinical Immunology, Oklahoma City, United States of America; *[2]University of Oklahoma Health Sciences Center, School of Medicine, Oklahoma City, United States of America*

Background: Chronic activation of interferon (IFN) pathways is a key driver of immune dysregulation in SLE. Hydroxychloroquine (HCQ) inhibits toll-like receptors 7 and 9 in plasmacytoid dendritic cells resulting in decreased release of interferon alpha[1]. Studies in SLE are limited by patient heterogeneity and the superimposed complexity of combined medications they receive.
Objectives: This project compared activation of Type I and II interferon (IFN) pathways in SLE patients with discrete immune phenotypes who were taking hydroxychloroquine or not (HCQ vs No Rx) without corticosteroids or any other SLE treatments.
Methods: 133 samples from 85 SLE patients (70 on HCQ, 63 on No Rx) and 37 healthy controls were studied. Characteristic clusters of patients who shared immune activation patterns were identified by Random Forest modeling of soluble mediators and gene co-expression module scores, as previously reported[2,3]. Samples from four of these immunologic clusters (C1, C4, C3, and C6), all with elevated expression of IFN modules (M1.2, M3.4, and M5.12) were examined for impact of HCQ on IFN pathway expression and compared to clusters with lower interferon signals. Dual samples from each of 21 patients when on HCQ vs on No Rx at different timepoints were also examined.
Results: As expected, expression of IFN pathway modules were increased in the overall SLE population vs healthy controls, driven by patient phenotype clusters 1,3,4 and 6. All IFN modules were decreased in SLE patients on HCQ vs. no Rx (M1.2 p=0.035, M3.4 p=0.009, and M5.12 p=0.005), again promulgated by changes in clusters 1,3,4 and 6 (Figure 1). In multilinear regression modeling, HCQ had independent effects on M1.2 (p=0.004), M4.3 ($p < 0.001$), and M5.12 ($p < 0.001$) after adjusting for cluster and race. Age and SLEDAI score had no confounding effects. Of the 21 patients with samples on HCQ vs No Rx, IFN scores were lower when on HCQ by Wilcoxon matched pairs signed rank test with Holm-Sidak correction (M1.2 p=0.0125, M3.4 p=0.0125, M5.12 p=0.0048).
Conclusion: This study confirms previous reports that hydroxychloroquine dampens interferon pathways in SLE patients, while addressing potentially confounding effects of polypharmacy and differing immune activation patterns in these patients. Limitations include inability to include more ill patients who inevitably require more complex treatment regimens and not having HCQ levels to improve data interpretability. These findings support the feasibility of strategies to improve patient selection for HCQ, optimize its dosing, and more rationally select combination treatments.

PREDICTORS OF DE NOVO RENAL FLARES IN SYSTEMIC LUPUS ERYTHEMATOSUS – TIME TO REVISIT BELIMUMAB DOSE FOR EXTRA-RENAL DISEASE? RESULTS FROM FIVE PHASE III CLINICAL TRIALS OF BELIMUMAB

Keywords: Clinical trials, Kidneys, Systemic lupus erythematosus

I. Parodis[1,2], J. Lindblom[1], N. Çetrez[1], L. Palazzo[1], H. Ala[1], F. Houssiau[3], C. Sjowall[4], B. H. Rovin[5]. *[1]Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden*; *[2]Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden*; *[3]Université Catholique de Louvain and Service de Rhumatologie, Cliniques Universitaires Saint-Luc, Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium*; *[4]Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection/Rheumatology, Linköping, Sweden*; *[5]The Ohio State University College of Medicine, Department of Internal Medicine, Columbus, United States of America*

Background: Each lupus nephritis (LN) flare causes nephron loss that equals a decade or more of reduction in renal function lifespan, making prompt initiation of therapy imperative and prevention of flares even more desirable. Identification of readily available signals of imminent flare is therefore expected to improve prognosis.
Objectives: In light of observed cases of *de novo* LN during belimumab treatment (1), we evaluated predictors of *de novo* renal flare occurrence in patients with systemic lupus erythematosus (SLE) and no prior history of renal disease undergoing standard therapy (ST) with or without add-on belimumab in clinical trial settings.
Methods: Data from five clinical trials of belimumab in SLE (BLISS-52 NCT00424476; BLISS-76 NCT00410384; BLISS-NEA NCT01345253; BLISS-SC NCT01484496; EMBRACE NCT01632241) were utilised. The study population comprised 1932 patients with a baseline renal British Isles Lupus Assessment Group (BILAG) score E. *De novo* renal flares were defined as a change from renal BILAG E to A or B within a 52-week follow-up. Comparisons of baseline data were made using the Mann-Whitney *U* test, Pearson's chi-squared (χ^2) test or Fisher's exact test as appropriate. Predictors of renal flare occurrence were investigated using univariable and multivariable Cox regression analysis. *p* values <0.05 were considered statistically significant.
Results: *De novo* renal flares were documented in 146 (7.6%) patients. Among patients who developed at least one renal flare, greater proportions were Asians (30.8% versus 20.2%; $p<0.003$), had positive baseline anti-dsDNA levels (74.0% versus 61.3%; $p=0.003$), and had low baseline levels of C3 (51.4% versus 38.2%; $p=0.002$) and C4 (45.2% versus 35.8%; $p=0.030$) compared with patients who did not flare. In univariable Cox regression analysis, azathioprine use was protective against renal flares (HR: 0.70; 95% CI: 0.49–0.99; $p=0.047$), while anti-Sm positivity at baseline showed a trend towards an association with imminent renal flare (HR: 1.68; 95% CI: 0.99–2.85; $p=0.057$). In multivariable Cox regression analysis adjusting for age, sex, ethnicity, serum creatinine, and variables that differed significantly in univariable analysis, Asian ancestry (HR: 1.60; 95% CI: 1.03–2.49; $p=0.036$), high mean prednisone dose from baseline until renal flare occurrence or throughout the follow-up (HR: 1.03; 95% CI: 1.02–1.05; $p<0.001$), and baseline serum creatinine (HR: 1.02; 95% CI: 1.01–1.03; $p=0.001$) were associated with imminent *de novo* renal flare, while extra-renal clinical SLE Disease Activity Index 2000 (cSLEDAI) showed a negative association (HR: 0.92; 95% CI: 0.86–0.98; $p=0.007$). Notably, use of belimumab 1 mg/kg by intravenous (IV) infusion yielded a nearly 3 times decreased hazard of renal flare (HR: 0.37; 95% CI: 0.20–0.68; $p=0.001$), whereas IV belimumab 10 mg/kg and belimumab 200 mg administered subcutaneously (SC) displayed no clear protection.
Conclusion: Asian patients appeared particularly susceptible to new-onset renal involvement, corroborating the substantial vulnerability of Asian SLE populations to renal affliction. Add-on low-dose IV belimumab on top of ST appeared protective against renal flares in SLE patients with no prior history of nephritis, while addition of the approved 10 mg/kg IV belimumab dose and SC belimumab yielded no clear protection. Discrepant results between low and high/approved belimumab doses warrant in-depth mechanistic exploration of underlying reasons e.g., potential effects of belimumab on B cell subsets that acquire regulatory properties.

POS1157 WARFARIN VS DOACS IN A REAL-WORLD DATA

Keywords: Real-world evidence, Anti-phospholipid syndrome

O. Carmi[1], T. Madjar[2], T. Hornik-Lurie[3]. [1]*Meir Medical Center, Rheumatology, Kfar Saba, Israel*; [2]*Meir Medical Center, Rheumatology, Kfar Saba, Israel*; [3]*Meir Medical Center, Statistics, Kfar Saba, Israel*

Background: Antiphospholipid syndrome (APS) is a syndrome which consists of vascular thrombotic events, arterial or venous, with the presence of persistent circulating antibodies. APS patients have a highly variable risk profile, derived from their different medical risk factors and diverse antiphospholipid antibodies (aPL) profile. The current mainstay for the treatment of APS is anticoagulation with Vitamin K antagonists (VKAs). The primacy of Warfarin has been challenged by the introduction of direct oral anticoagulants (DOACs), stems from DOACs convenience, constant dosing, without the need for blood test monitoring and almost no drug interactions. However, the TRAPS study that compared Rivaroxaban to Warfarin treatment in APS patients was terminated prematurely due to higher incidence of thrombotic events in the Rivaroxaban group [1]. Yet, all patients on the TRAPS trial were triple-aPL positive. Similar conclusions were demonstrated on the ASTRO study that compared Apixaban to Warfarin treatment [2]. Because the risk profile of APS patients is heterogeneous, both clinically and serologically, it is difficult to conclude that treatment with DOACs is generally inferior to VKAs for all APS patients, for instance in the low-risk patient population.
Objectives: We assume that under real-life circumstances, VKAs narrow therapeutic range and the constant need for repeated INR checkups may change the above studies outcomes. Hereby, the aim of this study is to compare real-life outcomes of APS patients treated with DOACs to patients treated with Warfarin from the aspect of thrombotic events reoccurrence on one hand and bleeding events on the other hand. We also checked the outcomes specifically for different APS risk profile subgroups under different treatments with either Warfarin or DOACs.
Methods: 139 non obstetric APS patients from "Meir" medical center were followed up retrospectively for a mean period of 16 years, since diagnosis time until 31/12/2022. We gathered data on patients SLE status, aPL profile and type of thrombotic event at the time of diagnosis. We checked for thrombotic events reoccurrence and bleeding events (including their types) with respect to the specific treatment at the time of each event.
Results: Of 139 followed-up patients, we report a total of 217 thrombotic and 60 bleeding events. From the Warfarin treated group, 178 (82%) thrombotic events were recorded, 130 (74%) of them occurred in the high risk serological profile patients. From the DOACs treated group, 39 (18%) thrombotic event were recorded, 23 (59%) of them occurred in the high risk serological profile patients. 59 (98%) bleeding events were recorded in the Warfarin treated group, 46 (82%) among the high risk profile group. only one bleeding event was recorded in the DOACs group.
Conclusion: According to our single center data gathered retrospectively form a follow up of real- life APS patient's treatment, Warfarin vs DOACs, we found higher incidence of thrombotic events (82%) in the Warfarin group compared to the DOACs group (59%). High risk profile patients had a higher thrombotic incidence in both groups. Moreover, patients taking Warfarin had a dramatically higher incidence of bleeding events comparing to DOACs (98% vs 0.01% respectively). These findings may raise the differences between real-life and controlled researches and may challenge the superiority of Warfarin. More researches are needed in order to answer this question.

Vasculitis - small vessel vasculitis

POS1158

COMPARISON OF THE ACR/EULAR 2022 CLASSIFICATION CRITERIA AND THE EMEA (THE EUROPEAN MEDICINES AGENCY) ALGORITHM IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS (AAV)

Keywords: Validation, Vasculitis

Y. Imai[1], Y. Ota[1], K. Matsumoto[1], M. Akiyama[1], K. Suzuki[1], Y. Kaneko[1]. [1]*Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: The anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAVs) are a group of disorders involving systemic, small-vessel vasculitis. The diseases include granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA). The diagnosis of vasculitis is challenging, due to the heterogeneous nature of these diseases. In 2022, ACR/EULAR proposed new internationally standardized classification criteria for AAV (ANCA-associated vasculitis). However, the performance of the new classification criteria have not been fully verified.
Objectives: To clarify the characteristics of the ACR/EULAR 2022 classification criteria (the 2022 criteria) in patients with AAV, by comparing those of the 2022 criteria with the existing European Medicines Agency (EMEA) algorithm.
Methods: All consecutive patients who had been newly diagnosed with AAV in Keio University Hospital between March 2012 and May 2022 were retrospectively reviewed. We reclassified them according to the EMEA algorithm and the 2022 criteria and identified their difference. We also analysed their clinical characteristics statistically.
Results: We included 114 patients in the analysis. The mean age at diagnosis of AAV was 67.2 ± 14.3, and 70 patients (61.4%) were female. According to the EMEA algorithm, the patients were classified as EGPA in 21 patients, GPA in 43, MPA in 29, and unclassifiable in 21, while according to the 2022 criteria, they were classified as EGPA in 24, GPA in 13, MPA in 62, EGPA-MPA overlap in 1, GPA-MPA overlap in 6, and unclassifiable in 8. All 21 EGPA patients with the EMEA algorithm met the EGPA-2022 criteria. Forty three GPA patients with the EMEA were classified as EGPA in 1, GPA in 11, MPA in 24, GPA-MPA overlap in 6, and unclassifiable in 1 with the 2022 criteria. Patients who were classified as GPA according to both criteria were significantly younger (53.0 ± 18.6 vs 74.5 ± 9.9 years old, respectively, P=0.003), female dominant (54.5% vs 20.8%, P=0.056), c/PR3-ANCA positive (90.9% vs 0%, P<0.001), had frequent epistaxis (45.5% vs 0%, P=0.001), and less with interstitial lung disease (9.1% vs 58.3%, P=0.007) compared to those who were reclassified from GPA to MPA with 2022 criteria. Among the 29 MPA patients with EMEA, 26 patients also met the MPA classification criteria with 2022 criteria, and among the 21 unclassifiable patients with EMEA, 12 patients were classified as MPA. Patients who were reclassified from unclassifiable to MPA with 2022 criteria were significantly older (75.2 ± 8.7 vs 57.7 ± 5.9 years old, P=0.002), had more p/MPO-ANCA (100% vs 11.1%, P<0.001), fewer ENT lesions (0% vs 55.6%, P=0.003), and tended to have more interstitial lung disease (75.0% vs 33.3%, P = 0.056) than 9 patients who did not meet the MPA-2022 criteria. During the average observation period of 3.95 ± 2.91 years, 16 patients deceased. The 16 deceased patients were classified as GPA in 7, MPA in 6, and unclassifiable in 3 with the EMEA algorithm, while they were classified as MPA in 14, GPA-MPA overlap in 1, and unclassifiable in 1 with the 2022 criteria. Overall survival was not significantly different with the EMEA algorithm (P=0.21), whereas it was significantly shorter in patients with MPA according to the 2022 criteria (P=0.023).

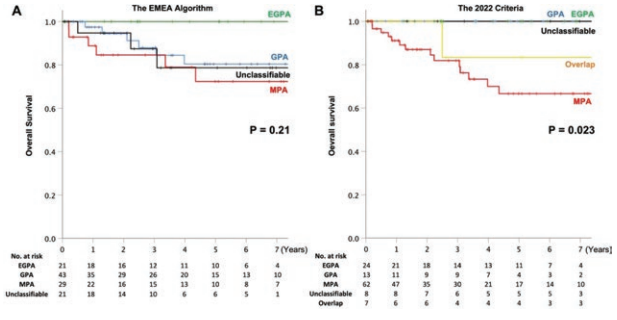

Figure 1. Overall Survival. (A) Based on the EMEA algorithm. (B) Based on the 2022 criteria.

Conclusion: Among the cases classified as GPA or unclassifiable by the EMEA algorithm, older cases with a high rate of p/MPO-ANCA and interstitial lung disease reclassified as MPA by the 2022 criteria were detected. The 2022 criteria is also useful for prognostic prediction compared to the EMEA algorithm.

GLUCOCORTICOID-SPARING EFFECT OF MEPOLIZUMAB: REAL LIFE EXPERIENCE IN A MONOCENTRIC COHORT OF PATIENTS AFFECTED BY EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS

Keywords: Real-world evidence, Vasculitis, Tapering

S. Bertocchi[1,2], F. Regola[1,2], M. Taglietti[1], F. Franceschini[1,2], P. Toniati[1]. [1]*ASST Spedali Civili of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy*; [2]*University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy*

Background: Oral glucocorticoids (GC) are the mainstay of treatment for eosinophilic granulomatosis with polyangiitis (EGPA) but chronic exposure to GC is associated with serious comorbidities. Mepolizumab (MEPO) demonstrated to be an efficacious treatment for EGPA in the randomized controlled MIRRA trial [1]. ACR guidelines suggest treating non-severe EGPA with MEPO associated with GC as first choice and adding MEPO in non-severe relapses occurred while receiving other immunosuppressants. There are insufficient data to support dosages and duration of GC treatment during MEPO treatment, although guidelines suggest prescribing the minimum effective dose to minimize GC toxicity [2].
Objectives: The aim of the study was to evaluate the GC-sparing effect of MEPO in our cohort of patients affected by EGPA.
Methods: We enrolled 26 patients affected by EGPA according to MIRRA criteria and/or ACR criteria [1][3]. We compared cumulative GC dosage prescribed in the 6 months before beginning treatment with MEPO to the cumulative dosage prescribed in the 6 months after starting MEPO. We also analyse MEPO efficacy comparing median number of asthma attacks, BVAS and VDI.
Results: Twenty-six patients (M/F 16/10) affected by EGPA were diagnosed at a median age of 57 years (IQR 47-65) and started therapy with MEPO after a median disease duration of 6 (1.5-10) years. Overall clinical features of patients before MEPO starting, at MEPO starting (T0) and after 6 months of MEPO (T6) are described in Table 1a. At MEPO starting (T0), 24/26 (92.3%) were treated with GC and 13/26 (50%) were on treatment with other immunosuppressants (1 cyclosporine, 2 methotrexate, 3 mycophenolate, 7 azathioprine). The cumulative GC dosage administered to patients in the six months after MEPO starting was significant lower if compared with dosage in the prior six months. After MEPO starting, there was also a significant reduction of asthmatic flares number and BVAS score, with no increasing in VDI score (Table 1b and 1c). Eleven patients were treated with MEPO 300 mg monthly, and 15 with 100 mg monthly, with no statistically significant differences in clinical response.

Table 1.

1a. Clinical features

	Overall before T0 N(%)	T0 N(%)	T6 N(%)
General	12 (46%)	1 (4%)	1 (4%)
Cutaneous	9 (35%)	1 (4%)	0 (0%)
Ear, nose, throat	22 (85%)	9 (35%)	5 (19%)
Pulmonary	25 (96%)	18 (69%)	1 (4%)
Cardiac	6 (23%)	1 (4%)	0 (0%)
Digestive	4 (15%)	1 (4%)	0 (0%)
Neurological	14 (54%)	6 (23%)	2 (8%)
Renal	0 (0%)	0 (0%)	0 (0%)

1b. Disease activity before MEPO starting (T0) and after 6 months (T6)

	T0 N(%)	T6 N(%)	p value
BVAS: median (IQR)	2 (0-2)	0 (0-0)	0.0005*
VDI: median (IQR)	2 (1,25-3)	2 (1,25-3)	0.5716

1c. Comparison of asthma activity and GC therapy between the 6 months before and the 6 months after T0

	In the 6 months before T0	In the 6 months after T0	p value
GC cumulative dose (mg): median (IQR)	1376 (821-2045)	964 (521-1561)	0.0005*
GC daily dose (mg/day): median (IQR)	8 (5-11)	5 (3-9)	0.0007*
Cumulative Number of asthma attacks: median (IQR)	1 (0-1)	0 (0-0)	0.0211*

IQR: interquartile ratio, BVAS: Birmingham vasculitis activity index, VDI: Vasculitis damage index. *Significant p value

Conclusion: In our cohort MEPO had a significant GC-sparing effect and significantly reduced asthma attacks and disease activity.

POS1160 AGE, FRAILTY, AND OUTCOMES IN OLDER ADULTS WITH ANCA-ASSOCIATED VASCULITIS

Keywords: Epidemiology, Real-world evidence, Vasculitis

S. E. Sattui[1], X. Fu[2,3], C. Cook[2,3], S. Srivatsan[2,3], Y. Zhang[2,3], Z. Wallace[2,3].
[1]University of Pittsburgh, Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America; *[2]Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America*; *[3]Massachusetts General Hospital, Clinical Epidemiology Program, Mongan Institute, Boston, United States of America*

Background: Older adults with ANCA-associated vasculitis (AAV) have differences in clinical presentation, as well as increased mortality and risk of infections, when compared to younger adults. Despite a high incidence of AAV in older adults, these individuals are underrepresented in clinical trials. Frailty, a geriatric syndrome associated with increased morbidity and mortality, has not been adequately studied in older adults with AAV. Better characterization of outcomes and risk factors in these patients is needed to inform treatment.

Objectives: To compare the risks of and factors associated with early (within 2 years) end-stage renal disease (ESRD), severe infection, and death in adults with a new diagnosis of AAV who are ≥ 75 years old vs 65-74 years old.

Methods: Patients ≥ 65 years were included from the 2002-2019 Mass General Brigham AAV cohort, a consecutive inception cohort. EGPA patients were excluded. Covariates including demographics, disease characteristics, and comorbidities (Charlson comorbidity index) were assessed at baseline. Disease activity at time of diagnosis was assessed using the Birmingham Vasculitis Activity Score (BVAS/WG). Frailty was measured at baseline using a claims frailty index, and pre-established cut-offs were utilized to define degrees of frailty (robust, pre-frail, mildly frail, and moderately/severely frail).[1] Death and ESRD were ascertained from linkage to national registries and/or medical records. Severe infections were identified utilizing inpatient data and/or death certificates. The cumulative incidence of death, ESRD and severe infections within 2 years were estimated. In univariate analyses, we assessed factors associated with outcomes within 2 years.

Results: 298 individuals were included. Most patients were female (61%), white (86%), MPO-ANCA+ (80%), and had renal involvement (72%). Patients ≥ 75 years old (n=156) had a median age of 81 years, while median age was 69 years in the 65-74 years group. The cumulative incidence at 2 years of the composite outcome of ESRD/death (23.1% [95% CI 16.5, 29.7]) vs 5.6% [95% CI 1.8, 9.4]) and severe infection (34.0% [95% CI 26.5, 41.4] vs 12% [95% CI 6.6, 17.3]) higher in AAV patients ≥ 75 vs 65-74 years old. Age ≥ 75 years was associated with an increased risk of ESRD/death (hazard ratio (HR) 4.42, 95% CI 2.05-9.51); frailty was not (HR 2.71, 95% CI 0.63,11.72) (Table 1). In contrast, frailty (HR 19.39, 95% CI 2.77,135.66) as well as age ≥ 75 years (HR 3.21, 95 CI% 1.87, 5.52), pulmonary involvement (HR 1.98, 95% CI 1.23, 3.18), and higher baseline comorbidity burden (HR 1.13, 95% CI 1.06, 1.20) were associated with severe infection risk.

Conclusion: Compared to AAV patients aged 65-74 years, AAV patients ≥ 75 years had a higher incidence of death/ESRD and severe infections. Older age but not baseline frailty was associated with ESRD/mortality risk whereas frailty was a very strong risk factor for severe infection. These findings highlight the need for innovative considerations beyond age when assessing outcome risks in AAV.

Table 1. Univariate analyses of factors associated with composite outcome and severe infections within 2 years

Factors	Composite outcome (ESRD/Death)	Severe infection
	HR (95% CI)	HR (95% CI)
Age ≥ 75 years (Ref, 65-74 years)	4.42 (2.05, 9.51)	3.21 (1.87, 5.52)
Female sex (Ref, male)	0.75 (0.41, 1.35)	0.70 (0.44, 1.12)
Comorbidities (CCI per 1 unit)	1.07 (0.97, 1.19)	1.13 (1.06, 1.20)
Frailty	REF	REF
Robust	1.85 (0.44, 7.80)	4.01 (0.56, 28.72)
Pre-frail	2.71 (0.63, 11.72)	19.39 (2.77,
Frail		135.66)
BVAS (per 1 unit)	1.14 (0.99, 1.31)	1.05 (0.94, 1.18)
Organ involvement	1.58 (0.76, 3.29)	1.26 (0.74, 2.16)
Renal (Ref, none)	1.75 (0.95, 3.20)	1.98 (1.23, 3.18)
Pulmonary (Ref, none)		
Induction Regimen (CYC-based vs not)	1.45 (0.72, 2.94)	1.07 (0.64, 1.78)

ESRD = end-stage renal disease, HR = hazard ratio, CI = confidence interval, CCI = Charlson Comorbidity Index, BVAS = Birmingham Vasculitis Activity Score, CYC = cyclophosphamide

POS1161 RITUXIMAB VS. COMBINATION OF RITUXIMAB AND CYCLOPHOSPHAMIDE INDUCTION THERAPY FOR ANCA-ASSOCIATED VASCULITIS: A RETROSPECTIVE STUDY

Keywords: Real-world evidence, Quality of care, Vasculitis

K. Von Allwörden[1], S. Klapa[1], S. C. Werth[2], A. Müller[1], G. Riemekasten[1], M. Nitschke[2], D. Thaçi[3], P. Lamprecht[1]. *[1]Universität zu Lübeck, Rheumatologie, Lübeck, Germany*; *[2]Universität zu Lübeck, Nephrologie, Lübeck, Germany*; *[3]Universität zu Lübeck, Entzündungsmedizin, Lübeck, Germany*

Background: In ANCA-associated vasculitis (AAV), the use of rituximab (RTX) according to the RAVE trial [1] or RTX in combination with cyclophosphamide (CYC) according to the RITUXVAS trial [2] showed noninferiority to CYC for the induction of remission. However, there is a lack of comparative real-world data between both therapy regimens.

Objectives: To compare the effectiveness of RTX with combined RTX/CYC for remission induction in AAV.

Methods: In this comparative effectiveness retrospective monocentric study, data of 166 patients with AAV (granulomatosis with polyangiitis [GPA] n=97; microscopic polyangiitis [MPA], n=69) were analyzed. Patients were treated first-line with RTX, RTX/CYC, or CYC between January 2012 and November 2022. The primary outcome was the relapse rate at 24 months. Clinical data (BVAS, therapy) and serologic markers (creatinine, protein excretion, CRP, immunoglobulin levels) were assessed at baseline and every 6 months up to 24 months.

Results: Of the 166 patients, 81 received first-line RTX (RAVE), 23 RTX/CYC (RITUXVAS), and 62 CYC according to CYCLOPS [3]. At baseline, there was no difference between RAVE and RITUXVAS treatment groups with respect to disease activity (BVAS; RAVE vs. RITUXVAS: 12.07±5.69 vs. 16.12±9.85, *P*=0.2083). In AAV, treatment according to RAVE and RITUXVAS was not inferior to treatment according to CYCLOPS (Figure 1). Moreover, RTX was not inferior to RTX/CYC (HR 0.61, P=0.1356, Figure 1). Interestingly, subgroup analysis showed RAVE was slightly superior to RITUXVAS in GPA (HR: 0.48, P=0.0408, Figure 1).

Conclusion: In AAV, RTX and the combination of RTX/CYC were not inferior to CYC. The combination of RTX and CYC was not superior to RTX alone.

POS1162 EVALUATION OF THE 2022 ACR/EULAR CLASSIFICATION CRITERIA FOR GPA AND MPA IN A EUROPEAN ANCA-ASSOCIATED VASCULITIS (AAV) COHORT

Keywords: Vasculitis, Validation

S. Krämer[1], T. Rauen[1], K. Pruin[1], T. Anslinger[1], M. Busch[2], T. Schmitt[2], R. Bergner[3], S. Mosberger[3], T. Neumann[4]. *[1]RWTH, University Hospital Aachen, Department of Nephrology and Rheumatology, Aachen, Germany*; *[2]University Hospital Jena, Friedrich-Schiller University, Department of Internal Medicine III, Jena, Germany*; *[3]Municipal Hospital Ludwigshafen, Department of Internal Medicine A, Nephrology and Rheumatology, Ludwigshafen, Germany*; *[4]Cantonal Hospital St. Gallen, Department of Rheumatology, St. Gallen, Switzerland*

Background: In 2022, the ACR and the EULAR proposed new classification criteria for granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) based on numerical item scoring for different manifestations in ANCA-associated vasculitis (AAV). Recently, a low concordance rate of only 73% in comparison with the 2012 revised International Chapel Hill Consensus Conference Nomenclature and the 2007 European Medicines Agency (EMA) algorithm [1] was reported in a Korean cohort of 65 GPA patients.
Objectives: We performed a retrospective classification according to the new 2022 classification criteria of patients from our multi-centric AAV cohort, using a computational algorithm that involved existing clinical, laboratory and histological entries. These results were compared to prior clinical diagnoses.
Methods: Data of AAV patients from four tertiary referral centers (Germany and Switzerland) were collected between 2000 and 2021. The 2022 ACR/EULAR criteria for GPA and MPA were applied by algorithmically analyzing (1) BVAS entries for organ manifestation, (2) laboratory results for ANCA/ ELISA testing and (3) histological data for detection of granuloma and/or pauci-immune glomerulo-nephritis. Twenty cases with inconclusive ANCA status were excluded from computed analysis. Results were compared to previously reported diagnoses; whereby renal limited disease was considered a distinct entity.
Results: The final dataset included 305 cases, 294 (96.4%) of Caucasian ethnicity, 161 males (52.8%), median age 61 years (IQR 50-70). Based on the 2022 ACR/EULAR criteria, 299 (98%) cases could be unambiguously categorized, 180 patients were classified as GPA and 119 as MPA (**Table 1**). Positive concordance, i.e. patients matching the novel classification criteria and clinical diagnosis, was higher in MPA than in GPA patients (98.8 vs. 90.8%). By contrast, negative concordance, i.e. proportion of cases negative for both clinical and novel classification-based diagnosis, was higher in GPA (97.3 vs. 84.1%). Twenty-seven cases of renal limited disease were mostly reclassified as MPA (92%). Taken together, alignment of matching both, positive and negative cases in relation to all cases was 93.1% in GPA and 88.2% in MPA. Six cases (2%) that were clinically diagnosed as GPA could not be classified due to competing findings of increased eosinophil cell count and anti-proteinase-3 positivity.
Conclusion: In the present multi-centric cohort, our computational algorithm applying the novel 2022 ACR/EULAR criteria based on existing clinical, laboratory and histological data performed well to categorize 98% of all cases. Our findings demonstrated overall positive and negative concordance rates above 88% and suggest a higher specificity for GPA, but higher sensitivity for MPA classification criteria.

UNBIASED PROTEOMIC APPROACH TO IDENTIFY NOVEL BIOMARKERS OF DISEASE ACTIVITY IN ANCA-ASSOCIATED VASCULITIS

Keywords: Vasculitis, Biomarkers, Prognostic factors

N. Atallah[1], V. Panossian[2], X. Fu[1], C. Cook[1], Z. Wallace[1]. [1]*Massachusetts General Hospital, Medicine, Division of Rheumatology, Boston, United States of America*; [2]*American University of Beirut, Medicine, Beirut, Lebanon*

Background: ANCA-associated vasculitis (AAV) carries excessive morbidity and mortality owing to the delay in diagnosis and limited prognostication. Identifying clinically useful biomarkers of disease activity that facilitate accurate prognostication would help personalize management decisions. Biomarkers used in day-to-day practice include PR3- or MPO-ANCA, CRP, and ESR, but these poorly predict future disease activity. Few studies have examined a limited number of circulating proteins as biomarkers, including BCA-1, MMP-3, TIMP-1[1-4]. We previously leveraged a high-throughput, unbiased approach to investigate 92 potential biomarkers for disease prognostication in AAV patients and identified 5 potential biomarkers.

Objectives: To further investigate the association of 5 novel protein biomarkers with AAV disease activity.

Methods: Serum samples from patients in the Mass General Brigham (MGB) AAV cohort were retrieved from the MGB Biobank following IRB approval. We chose a random 78 subjects who had AAV. We classified disease activity as "Active" or "Remission" at sample collection. The O-link high-throughput proteomic assay was used to measure the levels of 5 proteins of interest (MCP3, TNFSF-14, OSM, Flt3L, and SCF). For analysis, protein levels were first normalized. We compared protein levels in active disease vs remission. ESR, CRP, white blood cell (WBC) count and platelet levels were extracted for comparison. Using the mean value of each potential biomarker in the cohort as cut-off values, we determined the odds ratio (OR) and the area under the receiver operating curve (AUC) of the association of elevated biomarkers with active disease.

Results: Of n=78, the mean age was 57.3 +/- 17.6, 55% were female, and 28% had active disease at sample collection. When examining the outcome of active disease vs remission, abnormal levels of OSM, TNF-SF-14, Flt3L, and SCF differentiated disease states: OR of 5.10 (p=0.005), 3.71 (p=0.017), 0.13 (p=0.001), and 0.34 (p=0.040), respectively. AUC analysis indicated that TNF-SF-14 (0.731, CI 0.601-0.862), OSM (0.745, CI 0.622-0.867), and Flt3L (0.757, CI 0.644-0.871) were more strongly associated with active disease than other biomarkers, including WBC (0.703, CI 0.566-0.840), platelets (0.680, CI 0.551-0.809), CRP (0.549, CI 0.376-0.721), and ESR (0.547, CI 0.372-0.722).

Conclusion: Using a high-throughput, unbiased proteomics approach, we further investigated 5 novel candidate markers differentiating active AAV disease from remission. These proteins likely reflect different states of immune activation during active disease and outperform conventional inflammatory markers (e.g., CRP, ESR) as well as WBC and platelets. Our study has certain limitations, including sample size, a cross-sectional study design, and requires validation across diverse, longitudinal cohorts. The potential for biomarkers that accurately identify those individuals in remission compared to active disease may facilitate tailored, personalized therapeutic intervention, which avoids unnecessary exposure to the toxic side effects of immunomodulatory agents.

Table 1. Biomarker mean levels and characteristics for active disease.

Biomarker	Mean level Active vs. Remission	Odds Ratio (mean cutoff, CI, p-value)	AUC (CI)
OSM	7.39 ± 0.83 vs. 6.60 ± 1.01, p=0.002	5.1 (≥ 6.96, 1.64-15.85, p=0.005)	0.745 (0.622-0.867)
TNF-SF-14	7.59 ± 0.90 vs. 6.85 ± 0.91, p=0.001	3.71 (≥ 7.07, 1.26-10.93, p=0.017)	0.731 (0.601-0.862)
Flt3L	9.28 ± 0.48 vs. 9.74 ± 0.49, p=0.001	0.13 (≥ 9.64, 0.04-0.43, p=0.001)	0.757 (0.644-0.871)
MCP-3	3.51 ± 0.78 vs. 2.99 ± 0.73, p=0.008	1.24 (≥ 3.18, 0.46-.3.36, p=0.666)	0.628 (0.485-0.771)
SCF	9.73 ± 0.74 vs. 10.19 ± 0.38, p=0.001	0.34 (≥ 10.13, 0.12-0.95, p=0.04)	0.700 (0.570-0.830)

POS1166

IDENTIFICATION OF KEY GENES AND IMBALANCE OF IMMUNE CELL INFILTRATION IN IMMUNOGLOBULIN A ASSOCIATED VASCULITIS NEPHRITIS BY INTEGRATED BIOINFORMATIC ANALYSIS

Keywords: Cell biology, Vasculitis, Genetics/epigenetics

X. MA[1], X. Jia[1], H. Zhu[1], R. Wang[1], Y. Shan[2]. [1]*The First Hospital of China Medical University, Department of Pediatrics, Shenyang, China*; [2]*University of Occupational and Environmental Health, Japan,The First Depatment of Internal Medicine, Kitakyushu, Japan*

Background: Immunoglobulin A associated vasculitis (IgAV), also known as Henoch-Schonlein purpura, is a common systemic vascular inflammatory disease that chiefly manifests as skin purpura, arthritis, abdominal pain, gastrointestinal bleeding, and kidney involvement [1]. It is characterized by immunoglobulin A-dominant immune deposition in small blood vessels, and the excessive production of various inflammatory molecules [2]. Although the etiology and pathogenesis of IgAV are not fully understood, there is increasing evidence that infection, genetic susceptibility, and immune response disorders are closely related to the development and progression of IgAV [3,4]. Meawhile, abnormal expression of immune factors and imbalance of immune cell differentiation in general circulation may play crucial roles in the pathogenesis of IgAV [5]. Therefore, it is necessary to identify key pathways and immune cells in vasculitis, and to assess the significance of the immune microenvironment in the pathogenesis of IgAV.
Objectives: This study attempted to identify differentially expressed genes (DEGs) and find dysregulated immune cell types in IgAV to find the underlying pathogenesis for IgAV to the effective prediction of therapeutic targets in the future.
Methods: GSE102114 datasets were obtained from the Gene Expression Omnibus (GEO) database to identify DEGs. Then, the protein-protein interaction (PPI) network of the DEGs was constructed using the STRING database. And key hub genes were identified by cytoHubba plug-in, performed functional enrichment analyses and followed by verification using PCR based on patient samples. Finally, the abundance of 24 immune cells were detected by Immune Cell Abundance Identifier (ImmuCellAI) to estimate the proportions and dysregulation of immune cell types within IgAV.
Results: A total of 4200 DEGs were screened in IgAV patients compared to Health Donor, including 2004 upregulated and 2196 downregulated genes. Of the top 10 hub genes from PPI network, *STAT1*, *TLR4*, *PTEN*, *UBB*, *HSPA8*, *ATP5B*, *UBA52*, and *CDC42* were verified significantly upregulated in more patients. Enrichment analyses indicated that hub genes were primarily enriched in Toll-like receptor (TLR) signaling pathway, nucleotide oligomerization domain (NOD)-like receptor signaling pathway, and Th17 signaling pathways. Moreover, we found a diversity of immune cells in IgAV, consisting mainly of T cells. Finally, this study suggests that the overdifferentiation of Th2 cells, Th17 cells and Tfh cells may be involved in the occurrence and development of IgAV.
Conclusion: We screened out the key genes, pathways and maladjusted immune cells and associated with the pathogenesis of IgAV. The unique characteristics of IgAV-infiltrating immune cell subsets were confirmed, providing new insights for future molecular targeted therapy and a direction for immunological research on IgAV.

POS1167

SHORT-TERM OUTCOME OF ADULTS WITH IGA VASCULITIS – A SINGLE CENTER EXPERIENCE

Keywords: Vasculitis, Prognostic factors

A. Hočevar[1], J. Ostrovrsnik[1], M. Tomsic[1], Z. Rotar[1]. [1]*University Medical Center Ljubljana, Department of Rheumatology, Ljubljana, Slovenia*

Background: Follow-up data on IgA vasculitis (IgAV) in adults are scarce compared to paediatric population.
Objectives: The aim of our study was to investigate the short-term outcome in a well-defined adult IgAV cohort.
Methods: We analyzed medical records of histologically proven adult IgAV cases diagnosed between January 2010 and July 2022, and followed at our rheumatology center for more than 3 months. The frequency and type of relapses were studied. In addition the information on renal function (creatinine, estimated glomerular filtration rate (eGFR)) and urine analysis was recorded. Persistent abnormal urinalysis was defined as persistent haematuria (>10x10^6 red blood cells/L) and/or daily proteinuria >300 mg. A significant worsening of renal function during follow-up was defined as eGFR decline >20% from baseline. Risk factors for relapsing IgAV and persistent abnormal urinalysis were studied using Cox regression analysis.
Results: We identified 362 IgAV patients (59.4% males, median (IQR) age 64.2 (45.4; 76.2) years). Four patients died during the acute IgAV. Of the remaining patients, 265 (73.2%) were followed for a median (IQR; range) 24.1 (12.5, 55.2; range 3.0 to 146.1) months, while 93 patients had either a follow-up time less than 3 months or were lost to follow up. Of 265 patients 38.9%, 29.8% and 44.5% had at baseline articular, gastrointestinal, and renal involvement, respectively; and 28.3% had skin limited IgAV. One hundred and eighty-nine (71.3%) patients received at baseline systemic glucocorticoid, and 32 (12.1%) additional immunomodulatory therapy. One patient transiently required haemodialysis. During the follow-up period 42 (15.8%) patients relapsed. Table 1 shows the frequency and type of relapses. As factors associated with relapses emerged age (HR 0.97 (95% CI 0.95; 0.99)), and the use of systemic glucocorticoid at initial presentation (HR 0.27 (95% CI 0.15; 0.50)). Seventy-four (27.9%) patients had persistent abnormal urinalysis during follow-up, and 12 (16.2%) of them had daily proteinuria >1g. As factors associated with persistent abnormal urinalysis emerged heart failure as comorbidity (HR 2.28 (95% CI 1.20; 4.32), articular involvement (HR 0.42 (95% CI 0.25; 0.70)) and baseline immunomodulatory treatment (HR 2.30 (95%CI 1.29; 4.10)). eGFR decline of >20% from baseline was recorded in 41 (15.5%) patients (in 18/74 (24.3%) patients with persistent abnormal urinalysis, and in 23/191 (12.0%) patients without clear IgAV associated renal pathology; p=0.022). Heart failure (HR 3.06 (95%CI 1.44; 6.52)) and age (HR 1.03 (95CI 1.01; 1.05)) were associated with eGFR decline during follow up. Two patients developed end-stage kidney disease in association with IgAV. Forty-eight (18.1%) patients died during follow-up period, and death of one patient was related to IgAV relapse.

Table 1. Frequency and type of relapses of IgAV

Number of relapses	Number (%) of patients	The type of relapse in 33 patients with up to 3 relapsing episodes *	
1	24 (57.1%)	Skin	23 (52.3%)
2	7 (16.7%)	Skin + kidney	14 (31.8%)
3	2 (4.8%)	Skin + joints	2 (4.53%)
≥4	9 (21.4%)	Skin + joints + GIT	1 (2.3%)
		Kidney	4 (9.1%)

Legend: GIT gastrointestinal tract; *patients with multiple (≥4) relapses had skin relapses.

Conclusion: Fifteen percent of our adults had relapsing IgAV course, with skin relapses being the predominant relapse type. Younger patients with symptomatically managed IgAV were more prone to relapse. Persistent abnormal urinalysis was recorded in a quarter of patients. Concurrent heart failure had an impact on the persistent renal pathology in adult IgAV.

NOMOGRAM FOR IDENTIFYING THE HIGH-RISK PATIENTS OF ORGAN INVOLVEMENT IN EARLY-STAGE ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

Keywords: Vasculitis

R. Wu[1], R. Su[1], C. Wang[1]. [1]*The Second Hospital of Shanxi Medical University, The Department of Rheumatology,Taiyuan, China*

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is characterized by small-vessel vasculitis and systemic autoimmune inflammatory response [1, 2]. Although AAV is rare, the condition of AAV is relatively severe. The clinical manifestations of patients with AAV are different [3], ranging from mild non-specific symptoms to severe life-threatening organ involvement. Therefore, the clinical need to achieve accurate and quick identification for the high-risk groups of organ involvement in early-stage AAV remains strong.
Objectives: There is no study to identify the high-risk patients with organ involvement of early-stage of AAV. We aimed to develop a model to identify those high-risk patients at an early stage.
Methods: The data of the 74 new-onset patients with AAV (61 of whom had definite organ involvement) was collected in our retrospective study. The predictor variables for organ involvement in AAV were assessed by the logistic regression analysis. We developed the risk stratification model by nomogram. And the model was validated by concordance index, calibration curve, and decision curve analysis.

Results: The logistic regression analysis showed that BVAS, IL-17 and Treg cells were the predictor variables for organ involvement in AAV (Figure 1). We constructed a nomogram model consisting of BVAS, Treg cells and IL-17 (Figure 2A). In the nomogram, the value of each predictor was assigned a certain number of points, and the sum of the points for each predictor corresponded to the risk of organ involvement in AAV. Then we evaluated the nomogram model. The calibration curve in 1000 bootstrap replications revealed a good predictive accuracy between the predicted probability and observed probability of the nomogram model with a concordance index (C-index) of 0. 957 (95% CI = 0. 694–0.960) and bias-corrected C-index of 0. 937 (Figure 2B). And the chi-squares of Hosmer–Lemeshow test was 0.37(P = 0.83) indicating a good fitness of the model. Next, the receiver operating characteristic (ROC) curve of the model (Figure 2C) yielded the AUC of the curve was 0.9571 (95%CI =0.9124–1.000) showing it had a great ability for discriminating organ involvement in AAV. The decision curve analysis (DCA) showed a positive net benefit for patients with organ involvement (Figure 2D), which suggested that patients with organ involvement could benefit from interventions. And the clinical impact curve (Figure 2E) showed that the risk of organ involvement predicted by the nomogram model under threshold probability (red curve) was close to the actual value of organ involvement events under each threshold probability (blue curve).

Conclusion: The risk stratification nomogram model was effective to identify the high-risk patients of organ involvement in early-stage AAV, and it was validated with good discrimination, calibration as well as great application value in clinical.

RECOVERY AND LONG-TERM RENAL OUTCOME OF PATIENTS WITH ANCA-ASSOCIATED VASCULITIS WHO ARE ON DIALYSIS AT PRESENTATION

Keywords: Vasculitis

Y. J. Lee[1], S. M. Ahn[1], S. Hong[1], J. S. Oh[2], C. K. Lee[1], B. Yoo[1], Y. G. Kim[1]. [1]*Asan Medical Center, Division of Rheumatology, Department of Internal medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*Asan Medical Center, Department of Information Medicine, Big Data Research Center, Seoul, Korea, Rep. of (South Korea)*

Background: Renal involvement in ANCA-associated vasculitis (AAV) can lead to severe renal dysfunction requiring dialysis at the time of diagnosis. Studies have demonstrated that a significant proportion of patients could discontinue dialysis after treatment, with dialysis recovery-associated factors including kidney pathology such as proportion of normal glomeruli and extent of tubular atrophy or interstitial fibrosis. However, these works focused on short-term outcomes within 6–12 months after AAV diagnosis (1, 2). Research reporting if patients who discontinued dialysis resumed during long-term follow-up are lacking.

Objectives: We assessed the clinical and pathologic characteristics of patients with AAV dependent on dialysis at presentation and the long-term renal outcomes of those who recovered after dialysis.

Methods: This retrospective study analyzed the data of patients diagnosed with AAV who were on dialysis at baseline from July 2005 to May 2021 at a single tertiary center in Korea. Medical records, including renal function and dependence on dialysis, were obtained.

Results: We included 34 patients on dialysis at the time of AAV diagnosis in this study. The median age was 64.5 years, and 61.8% were female. Among all patients, 13 discontinued dialysis and 21 remained dialysis dependent. The proportions of normal glomeruli (p<0.001) and interstitial fibrosis (p=0.024) were significantly different between the two groups. The multivariable analysis revealed that the proportion of normal glomeruli tended to be associated with dialysis discontinuation (OR=1.34, 95% CI 0.88–1.27, p=0.068). Treatment modalities, including plasmapheresis, were not significantly associated with dialysis discontinuation. In the follow-up analysis of 13 patients who had discontinued dialysis for a median of 81 months, 12 did not resume dialysis, and their glomerular filtration rate values had significantly increased at follow-up compared with at dialysis cessation (37.5 [28.5–45.5] vs. 24.0 [18.5–30.0] mL/min/1.73 m², p=0.008).

Conclusion: Approximately 38% of AAV patients discontinued dialysis, and the recovered patients had improved renal function without dialysis. Thus, patients with AAV on dialysis should be considered for dialysis discontinuation and renal recovery, especially those with normal glomeruli in kidney pathology.

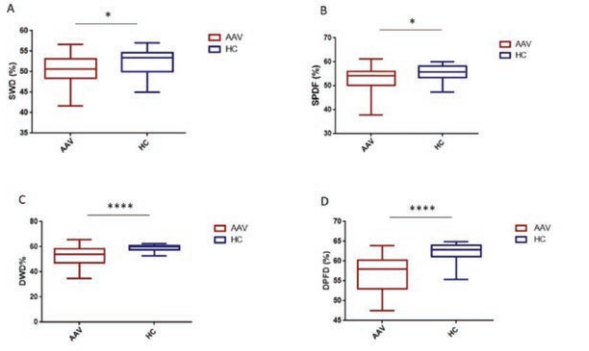
EXPLORING SUBCLINICAL MICROVASCULAR CHANGES IN ANCA-VASCULITIDES: THE OPTICAL COHERENCE TOMOGRAPHY ANGIOGRAPHY AND NAILFOLD CAPILLAROSCOPY IN THE EVALUATION OF DISEASE-RELATED DAMAGE



Keywords: Organ damage, Vasculitis

A. D'antonio[1], P. Triggianese2, C. Nesi[3], B. Kroegler[1], S. Modica[1], E. Greco[1], P. Conigliaro[1], A. Bergamini[1], C. Nucci[3], M. Cesareo[3], M. S. Chimenti[1].
[1]Rheumatology, Allergology and Clinical Immunology, University of Rome Tor Vergata, Rome, Italy; *[1]Rheumatology, Allergology and Clinical Immunology, University of Rome Tor Vergata, Rome, Italy*; *[3]Ophthalmology Unit, University of Rome Tor Vergata, Rome, Italy*

Background: Both cardiovascular and complement-mediated disorders might lead to microvascular damage in anti-neutrophil cytoplasm autoantibodies (ANCA)-associated vasculitides (AAV). No evidence of subclinical microvascular retinal abnormalities neither their potential correlation with capillaroscopy anomalies has been reported in eosinophilic granulomatosis with polyangiitis (EGPA), granulomatosis with polyangiitis (GPA), and microscopic polyangiitis (MPA).
Objectives: We aimed at investigating subclinical microvascular abnormalities by analyzing retinal and nailfold capillary changes in an AAV cohort. Retinal plexi were investigated using optical coherence tomography angiography (OCT-A), while nailfold capillary changes with videocapillaroscopy (NVC). Potential correlations between OCT-A abnormalities and both disease damage and periungual capillaries change were also explored.
Methods: A monocentric observational study was conducted on consecutive AAV. Main inclusion criteria were a defined diagnosis of EGPA/GPA/MPA in accordance with International Criteria, age ≥18 ≤ 75 yrs, intraocular pressure (IOP) <21 mmHg by Goldmann, a best-corrected-visual-acuity (BCVA) ≥ 0,5 logMAR, and no ophthalmological and/or systemic disorders or treatment with known retinal involvement. Disease activity was assessed by Birmingham Vasculitis Activity Score (BVAS), damage by Vasculitis Damage Index (VDI), and poorer prognosis by the Five Factor Score (FFS). Moreover, OSDI and MIDAS questionnaires have been administered. Quantitative analysis of vessel density (VD) was performed by OCT-A in the superficial capillary plexi (SCP) and deep capillary plexi (DCP) for all subjects. For completeness, a structural analysis of retinal thickness was performed by OCT-scans. Figures and detailed analysis from NVC were performed for all AAV patients.
Results: From 47 consecutive AAV patients referring to the Rheumatologic Clinic, 23 consecutive patients who met the inclusion criteria were included and compared with 20 age/sex-matched healthy subjects (HC) (Table 1). In AAV, BVAS correlated directly with VDI (P=0.001) and FFS (P=0.01) while it was inversely related with disease duration (P=0.01). A total of 46 eyes from AAV patients were analyzed. Retinal VD in superficial whole (SWD) and parafoveal (SPFD) plexi were significantly decreased in AAV compared to HC (P=0.02 and P=0.01, respectively, Figure 1A-B). Furthermore, deep whole (DWD) and parafoveal vessel density (DPFD) were strongly reduced in AAV than HC (P ≤0.0001 for both, Figure 1C-D). In AAV patients, significant inverse correlations emerged between VDI and OCTA-VD in both the superficial (parafoveal, P=0.03) and the deep plexi (whole, P=0.003, and parafoveal P=0.02). The retinal thickness measured by OCT-scans was similar between AAV patients and HC. At NVC examination we found non-specific pattern abnormalities in 82% of AAV patients. Common abnormalities were pericapillary edema (73%), tortuosity (65%), while rare cases of ectasias and hemorrhages resulted (0.8%). No meandering capillaries nor empty dermal papillae were observed. Correlations between NVC changes and OCT-A abnormalities were not described.
Conclusion: Subclinical microvascular retinal changes occur in patients with AAV and correlate with the disease-related damage. In this context, the OCT-A can represent a useful tool in the early detection of vascular damage. AAV patients present microvascular abnormalities at NVC, whose clinical relevance requires further studies.

NEW INDEX USING TRIGLYCERIDE-GLUCOSE-BODY MASS INDEX FOR PREDICTING MORTALITY IN PATIENTS WITH ANTINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

Keywords: Vasculitis, Biomarkers, Diet and nutrition

P. G. Park[1], J. Y. Pyo[2], S. S. Ahn[2], J. J. Song[2], Y. Park[2], J. H. Huh[3], S. Lee[2].
[1]National Health Insurance Service Ilsan Hospital, Department of Internal Medicine, Goyang, Korea, Rep. of (South Korea); *[2]Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[3]Hallym University Sacred Heart Hospital, Department of Internal Medicine, Anyang, Korea, Rep. of (South Korea)*

Background: The mortality rate of patients with antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is relatively higher than that of those

with other vasculitides. Various biomarkers are developed to predict outcome of AAV. Recently, a novel index, triglyceride (TG) glucose-body mass index (BMI) (TyG-BMI) was introduced to predict insulin resistance (IR), cardiovascular disease, cerebrovascular accidents in general population. Given that IR and its related diseases such as CVD and CVA are generally major risk factors for all-cause mortality in the general population, it could be assumed that TyG-BMI could be a robust predictor of all-cause mortality in AAV patients.

Objectives: This study aimed to investigated whether TyG-BMI and a new index using TyG-BMI (NITGB) could predict all-cause mortality in nonobese patients with AAV.

Methods: The medical records of 78 nonobese AAV patients (BMI < 23.0 kg/m2 for Asian) were retrospectively reviewed. TyG-BMI was calculated by the equation: Ln [triglyceride × fasting glucose/2] × BMI. To develop NITGB, we assigned a weight of a number close to an 0.1 decimal integer to each variable according to the slopes for independent variables with P-value < 0.1 in the multivariable Cox analysis.

Results: The median age was 54.3 years and five patients died. When nonobese AAV patients were divided into two groups based on TyG-BMI ≥ 187.74, those with TyG-BMI ≥ 187.74 exhibited a significantly higher risk for all-cause mortality than those without (RR 9.450). Since age (HR 1.324), Birmingham vasculitis activity score (BVAS; HR 1.212), and TyG-BMI ≥ 187.74 (HR 12.168) were independently associated with all-cause mortality, NITGB was developed as follow: age + 0.2 × BVAS + 2.5 × TyG-BMI ≥ 187.74. When nonobese AAV patients were divided into two groups based on NITGB ≥ 27.36, those with NITGB ≥ 27.36 showed a significantly higher risk for all-cause mortality than those without (RR 284.000).

Conclusion: Both nonobese AAV patients with TyG-BMI ≥ 187.74 and those with NITGB ≥ 27.36 exhibited significantly higher cumulative rates of all-cause mortality than those without. NITGB along with TyG-BMI could predict all-cause mortality in nonobese AAV patients.

Background: A remarkable variability in the clinical course of Behçet's Syndrome (BS) seems to arise by comparing cohorts from different geographical areas. However, no data are currently available on the possible variability of organ damage burden, although it is currently recognized as a major outcome in BS.

Objectives: To evaluate and compare the extent, characteristics, and associated factors of organ damage in patients from different World areas.

Methods: We analyzed demographic and clinical data of a multicenter cohort of 935 consecutive BS patients from 11 Countries clustered in 5 geographic areas: Europe (EU, n 345), North Africa (NA, n 278), Middle East (ME, n 227), Central Asia (CA, n 44), America (AM, 41). Organ damage was assessed by the BS organ damage index (BODI) [1]. Uni- and multivariate analysis was performed to evaluate the association between the geographical region and organ damage using demographic and clinical data as covariates.

Results: Demographics and clinical features are reported in the Table 1. The prevalence of any damage (BODI≥1) in the EU, ME, NA, CA, and AM areas

Table 1. Demographic and clinical characteristic of the patients form different geographical area.

Europe included patients from Italy. Portugal. Spain. Greece; North Africa: Morocco. Egypt; Middle East: Turkey. Iran; Central Asia: Kazakhstan; America: USA. Brazil. Continuous variables are reported as mean (SD).

was 47.0%. 54.6%. 91.7%. 97.6% and 77.3%, respectively, whereas the mean (SD) total BODI score was 1.1 (1.7), 1.2 (1.7), 3.5 (2.4), 4.5 (2.6), and 1.9 (1.9). The prevalence of different BODI domains is reported in the Table 1. Significant differences were recorded in NA vs. EU and ME cohorts (Figure 1) (CA and AM not included in the statistical analysis for the small sample size). In multivariate analysis, the geographical area was independently associated ($p < 0.001$) with damage (NA vs. EU OR 11.3; ME vs. EU OR 1.5). Male gender (OR 1.5; $p = 0.004$), age (OR 1.03 per year; $p = 0.002$), disease duration (1.03 per year; $p = 0.003$), ocular (OR 2.8; $p < 0.001$), vascular (OR 5.3, $p < 0.001$), and neuropsychiatric (OR 3.8, $P<0.001$) involvement were also associated with BODI≥1.

Conclusion: A variable prevalence of organ damage was observed in BS patients from different World areas. Further research is needed to understand the cause underlying such geographic variability, as it may unveil biological, environmental, or health-system factors driving damage accrual in BS. The BODI effectively captures damage independently from the studied cohort's geographical origin.

POS1173 LONG-TERM ANALYSIS OF RELAPSE RATES IN A EUROPEAN ANCA-ASSOCIATED VASCULITIS (AAV) COHORT FOR GPA AND MPA

Keywords: Registries, Vasculitis

S. Krämer[1], T. Rauen[1], K. Pruin[1], T. Anslinger[1], M. Busch[2], T. Schmitt[2], R. Bergner[3], S. Mosberger[3], T. Neumann[4]. [1]*RWTH, University Hospital Aachen, Department of Nephrology and Rheumatology, Aachen, Germany*; [2]*University Hospital Jena, Friedrich-Schiller University, Department of Internal Medicine III, Jena, Germany*; [3]*Municipal Hospital Ludwigshafen, Department of Internal Medicine A, Nephrology and Rheumatology, Ludwigshafen, Germany*; [4]*Cantonal Hospital St. Gallen, Department of Rheumatology, St. Gallen, Switzerland*

Background: Therapeutic interventions for ANCA-associated vasculitides (AAV) dramatically changed over the last two decades. Especially the introduction of rituximab into the therapeutic portfolio significantly improved outcome data, whereby relapse rates in previous cohorts were mostly reported from only up to two-year periods.

Objectives: With the present study, we thought to retrospectively investigate the overall relapse rates in a large European AAV cohort.

Methods: Data of patients with newly diagnosed GPA and MPA (retrospectively classified on ACR/EULAR 2022 criteria) from four tertiary referral centers in Germany and Switzerland were collected between 2000 and 2021. Events were captured during routine out-patient visits and hospital admissions. A relapse was considered at the time of any increased vasculitis activity, i.e. therapeutic necessity to increase glucocorticoids ≥10 mg prednisolone per day. First relapse occurrence was analyzed as time-to-event analysis and number of cases for each group. Differences were compared by ANOVA- and X^2-test, respectively.

Results: Our data set comprised a total of 338 patients, 46.2% women (mean age of 59.2±14.7 years). Of these, 203 cases (60.1%) were classified as GPA and 135 (39.9%) as MPA. At initial presentation, 74.9% of patients exhibited renal, 50.9% pulmonary and 35.2% ENT involvement. Over a median follow-up period of 58.7 months (IQR 29.4 to 101.7) we observed an overall relapse rate of 35.8% in the entire cohort and median time to first relapse was 32.6 months (IQR 11.9 to 56.9). Following three years after initial diagnosis, we observed a significant difference, yielding 46 relapses (22.7%) in GPA and 19 (14.1%) in MPA patients at that time ($p<0.05$). Over the entire follow-up, 86 patients with GPA experienced at least one relapse (42.4%) whereas in MPA only 35 (25.9%) patients relapsed ($p<0.01$). In addition, log-rank test revealed a significant difference in relapse over time ($p<0.05$, Figure 1). The median time to the first relapse did not differ significantly between GPA and MPA patients (GPA: 27.9 months, IQR 13.6 to 55.9, vs. MPA: 35.1 months, IQR 8.6 to 55.9, $p=0.458$).

Conclusion: In our European AAV cohort, we observed an overall relapse rate of 35.8% for both AAV entities with the first relapse occurring after a median of 32.6 months. GPA patients exhibited consistently higher relapse rates than those with MPA over the entire observational period. We propose that future analyzes of relapse rates should cover a minimum of three years to capture roughly half of all expected events.

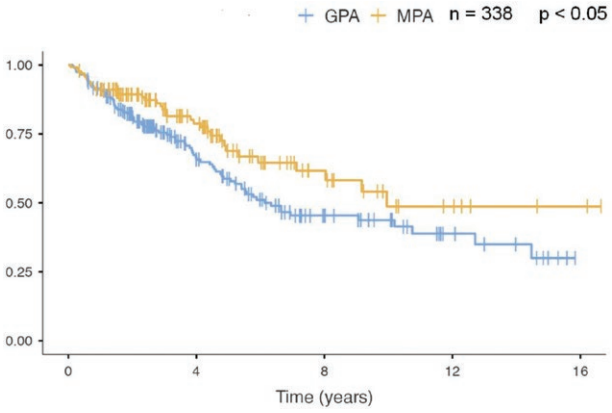

Figure 1. Kaplan Meier curve of relapses.

POS1174 IMPACT OF THE 2022 ACR/EULAR CLASSIFICATION CRITERIA ON CLINICAL DIAGNOSIS OF ANTINEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA) ASSOCIATED VASCULITIS

Keywords: Vasculitis, Real-world evidence

J. Van Leeuwen[1], S. Hafemann[1], Y. K. O. Teng[1]. [1]*Leiden University Medical Center (LUMC), Nephrology Section - Internal Medicine Department, Leiden, Netherlands*

Background: In 2022 the American College of Rheumatology (ACR) and European Alliance of Associations for Rheumatology (EULAR) presented new classification criteria for the three subsets of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV): granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and Eosinophilic Granulomatosis with Polyangiitis (EGPA).[1-3] The purpose of this classification was to ensure homogeneous populations for clinical trials and research. These criteria were developed based on a population of patients with a high certainty of diagnosis.[1-3] As with any novel criteria, these can potentially lead to re-classification of AAV patients which can impact selection of patients in future studies.

Objectives: To assess the impact of the new 2022 ACR/EULAR classification criteria for GPA, MPA and EGPA on re-classification of clinical diagnoses of AAV patients.

Methods: An established cohort of 337 patients of AAV patients at a single center, academic hospital was used to screen patient and disease characteristics and clinical data at the time of diagnosis and matched to the novel 2022 ACR/EULAR classification criteria for GPA, MPA or EGPA. Patients with an unspecified AAV diagnosis and patients with no clinical data or only ANCA serology available for the time of diagnosis were excluded.

Results: In total 249 patients, 160 (64%) and 89 (36%) females, with a median age of 66 (range 12-96) and a AAV diagnosis between 1983 to 2022, were included. 179 patients had a clinical diagnosis of GPA, 43 of MPA and 27 of EGPA. Of the 179 GPA patients, 155 (87%) met the classification criteria for GPA, 15 (8%) for MPA and 10 (6%) remained unclassified. One patient could be classified as both GPA and MPA. Of the 43 MPA patients, 33 (77%) classified as MPA, 8 (19%) as GPA and 3 (7%) patients remained unclassified. Again, one patient could be classified as GPA and MPA. Only 14 of 27 (52%) EGPA patients met the classification criteria for EGPA. Three (11%) EGPA patients classified as GPA, 4 (15%) as MPA and 6 (22%) remained unclassified. These results show a lower sensitivity than observed in the development study (87 vs 93% for GPA, 78 vs 93% for MPA and 52 vs 85% for EGPA).[1-3] When analysing our cohort based on ANCA specificity, from 67 MPO positive patients, 50 (75%) would classify as MPA, 9 (13%) as GPA and 4 (6%) as EGPA. Clinical diagnosis was MPA in only 40 (60%) of patients and GPA in 18 (27%) patients and EGPA in 9 (13%) patients. From 145 PR3 positive patients, 141 (97%) would classify as GPA, none as MPA and 1 (1%) as EGPA, compared to 140 (97%) clinical diagnosis of GPA, 1 (1%) of MPA and 4 (3%) of EGPA.

Conclusion: When comparing the EULAR/ACR classification criteria to real-life clinical diagnosis, 13% of GPA patients, 23% MPA patients and 48% of EGPA patients would not meet the criteria for the corresponding classification. Moreover, because the presence of ANCA auto-antibodies is highly weighted, the percentage of MPO positive GPA patients is diminished. We demonstrate using these new criteria will impact selection of patients in future studies, especially for EGPA studies.

POS1175 ANTI-IL5 THERAPY IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS: DOSAGE, EFFICACY AND OUTCOME IN A LARGE COHORT OF PATIENTS IN REAL LIFE (REVAS STUDY)

Keywords: Targeted synthetic drugs, Descriptive studies, Vasculitis

R. Solans-Laqué[1], A. Noblejas Mozo[2], J. L. Callejas-Rubio[3], E. Fonseca[4], B. Sopeña[5], X. Solanich[6], J. Mestre[1], J. J. Rios[2], C. Ausin[7]. *[1]Vall d'Hebron University Hospital, Internal Medicine, Barcelona, Spain*; *[2]La Paz University Hospital, Internal Medicine, Madrid, Spain*; *[3]San Cecilio University Hospital, Internal Medicine, Granada, Spain*; *[4]Cabueñes Hospital, Internal Medicine, Gijon, Spain*; *[5]Clinic University Hospital Santiago Compostela, Internal Medicine, Santiago de Compstela, Spain*; *[6]Bellvitge University Hospital, Internal Medicine, Barcelona, Spain*; *[7]Gregorio Marañon University Hospital, Internal Medicine, Madrid, Spain*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA), formerly Churg-Strauss syndrome, is a rare type of anti-neutrophil cytoplasm antibody-associated vasculitis, associated with asthma, nasal poliposis and rinosinusitis, in which eosinophils play a key role. Eosinophil targeted therapies alone or associated to conventional treatment with corticosteroids and immunosuppressant drugs may be useful in patients with refractory disease or asthma/ENT manifestations difficult to treat.

Objectives: To describe the indications, dosage, efficacy and safety, of eosinophil targeted therapies in patients with EGPA in a real practice.

Methods: Retrospective study evaluating all patients with EGPA included at REVAS Registry, treated with anti-IL5 therapy, in order to assess the effectiveness and safety of this therapy. Treatment response was evaluated from 3 months to the censoring data. Complete response (CR) was defined as the absence of asthma and/or sinonasal exacerbations with a prednisone dosage of ≤5 mg/day, and partial response (PR) when the prednisone dosage was ≥5 mg/day. Statistical analysis was performed using SSPS 21 package.

Results: Fifty patients (median age 47 years) were evaluated. Forty-five (90%) patients received mepolizumab (38 patients 100 mg every 4 weeks and 7 patients 300 mg every 4 weeks) for a mean period of 31 (1-68) months; 4 (8%) received benralizumab (30 mg every 4 weeks) for a mean of 33 (7-42) months, and 3 (6%) received resilizumab (n=3, 6%) for a mean period of 54,3 (43-67) month. Anti-Il5 therapy was indicated for severe steroid-dependent asthma (94%) and/or persistent sinonasal involvement (80%). 11 (22%) patients also had symptoms of active vasculitis (5 mononeuritis multiplex, 3 miocarditis, 2 infiltrative cutaneous lesions, 1 orbital pseudotumor). ANCA were positive in 27 (54%) cases with MPO specificity. All patients were receiving corticosteroids at the time of anti-IL5 therapy beginning, with a mean dosage of 11,5 mg/day. A total of 11 (22%) patients had previously received omalizumab, that was changed to mepolizumab in 9 cases, reslizumab in 1 and benralizumab in another, due to PR (n=5) or recurrence of asthma and/or sinusitis (n=6) after a long period of treatment (70.5 months). Anti-IL5 therapy was given concomitantly to AZA in 7 cases, MTX in 3, and RTX in 2. 38 (84,4%) patients treated with mepolizumab achieved a CR after 6-18 months of treatment. The median dosage of prednisone 6 months after mepolizumab, benralizumab and reslizumab initiation was 6 (5-15) mg/day, 5.3 (2.5-10) mg/day, and 3.3 (0-5) mg/day, respectively. The median dosage of prednisone 12 months after mepolizumab, benralizumab and reslizumab beginning was 3.5 (0-5) mg/day, 3.1 (0-5) mg/day and 2.5 (0-5) mg/day, respectively. The median number of exacerbations decreased from 2.5 over the 6 months previous to therapy beginning to 1 in the following 12 months. CS were stopped in 12 (24%) patients. All 3 drugs were safe and well tolerated. During the follow-up period, three patients experienced a major relapse of the disease, and were successfully treated with RTX in conjunction with mepolizumab, with no serious adverse events. Mepolizumab dosage was reduced to 100 mg every 6 weeks in 50% of cases. In one case mepolizumab was changed by benralizumab due to PR.

Conclusion: Mepolizumab at both 100 mg every 4 weeks and 300 mg every 4 weeks is effective for the treatment of EGPA. Both doses should be compared in the setting of a controlled trial. Benralizumab and reslizumab are also effective. Sequential therapy with anti-IL5 drugs and rituximab was safe and effective in achieving remission in patients with a major relapse of the disease.

Maria delle Croci, Rheumatology, Ravenna, Italy*

Background: Hospitalizations due to relapse or disease complications are major concerns during follow-up of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV).

Objectives: To determine rates of hospitalization in a large cohort of patients with AAV compared with the national general population, and to describe features and associated primary discharge diagnoses.

Methods: Between 2007 and 2018, we examined the hospitalization records of AAV patients from 13 Italian hospitals. Hospitalization dates, features, length of stay, primary discharge diagnoses and patient data were abstracted from charts. Age- and sex-standardized hospitalization rates (SHR) were calculated by an indirect method, per year and for the study period, using the 2007–2018 hospitalization data provided by the Italian Ministry of Health. Multivariable and survival models were used to explore associations between these outcomes, clinical parameters at diagnosis, and pre-existing comorbidities.
Results: A total of 610 hospitalizations occurred in 635 patients with AAV (19.4% microscopic polyangiitis, MPA; 34.6% granulomatosis with polyangiitis, GPA; 46.0% eosinophilic GPA, EGPA) during a 12-year observation; in 19.8% for life-threatening conditions and leading to death in 2.3%. The median time to first hospitalization was 504 days (25-75%IQR, 95-1497), and the median hospitalization length was 8 days (25-75%IQR, 8-14). The 2018 SHR (95%CI) was 1.14 (0.91, 1.43) for all AAV combined, 1.13 (0.68, 1.76) for MPA, 1.48 (1.02, 2.08) for GPA, and 0.90 (0.60, 1.31) for EGPA. These rates tended to a gradual increase from 2007 to 2018 in the whole AAV cohort of patients and in every disease subset (Figure 1A). The main causes of hospitalization in patients with AAV were infectious diseases (18.7%), followed by major relapse and diagnostic re-evaluation (17.2% each), and cardiovascular diseases (10.8%). Among those due to infections, the main site was the respiratory system (44.6%), followed by urinary tract (9.6%) and sepsis (6.3%). Among AAV patients hospitalized during follow-up (47.1%), 55.5% had only 1 hospitalization, 18.7% had 2, and 25.6% had 3 or more hospitalizations. Patients with a diagnosis of GPA or MPA (versus EGPA), higher vasculitis activity (assessed by BVAS), ANCA positivity at diagnosis, and hospitalization at diagnosis (all $p<0.001$), more pre-existing comorbidities and older age (both $p<0.05$), were more likely to be hospitalized during follow-up (Figure 1B).
Conclusion: Patients with AAV have a significant burden of hospitalization during the disease course. Approximately half of the patients is hospitalized during follow-up, with infections, relapses and cardiovascular diseases as the main causes of hospitalizations. Our findings showed the existence of risk profiles of patients more likely to be hospitalized, requiring more active vigilance.

POS1177

ROLE OF INTRATHECAL PRODUCTION OF IL-6 IN THE PATHOGENESIS OF CHRONIC PROGRESSIVE NEURO-BEHCET'S DISEASE

Keywords: Cytokines and chemokines, Behcet's disease

S. Hirohata[1,2], H. Kikuchi[2]. [1]*Nobuhara Hospital, Rheumatology, Tatsuno, Japan*; [2]*Teikyo University School of Medicine, Internal Medicine, Tokyo, Japan*

Background: Behçet's disease (BD) is characterized by recurrent attacks of aphthous stomatitis, uveitis, genital ulcers, and skin lesions, including folliculitis, erythema nodosum like lesions, and superficial thrombophlebitis. Central nervous system (CNS) involvement is one of the most serious complications in BD and is called neuro-Behçet's disease (NB). There has been accumulating evidence that NB can be classified into acute type (ANB) and chronic progressive type (CPNB) based upon differences in the clinical courses as well as in responses to corticosteroid treatment. Thus, ANB responds well to corticosteroids and usually runs a self-limiting course. By contrast, CPNB is characterized by intractable neuro-behavior changes and cerebellar ataxia, which progress in spite of high doses of corticosteroids or immunosuppressive drugs, including azathioprine or cyclophosphamide.
Objectives: Previous studies have demonstrated that cerebrospinal fluid (CSF) IL-6 was elevated in patients with CPNB. However, little is known as to the mechanism of the elevation of CSF IL-6 in CPNB. The present study was designed in order to elucidate the mechanism of the elevation of CSF IL-6 in the pathogenesis in CPNB.
Methods: Paired serum and cerebrospinal fluid (CSF) samples were obtained from 19 patients with CPNB when they presented active neuropsychiatric manifestations and from 19 control patients with non-inflammatory neurological diseases. Among the 19 patients with CPNB, 5 patients received treatment with infliximab and followed up thereafter. The levels of albumin and IL-6 in CSF and sera were measured by ELISA. Blood-brain barrier (BBB) function was evaluated by Q albumin (CSF/serum albumin quotient x 1,000). The intrathecal production of IL-6 was evaluated by CSF IL-6 indices ([CSF IL-6 x serum albumin]/[serum IL-6 x CSF albumin]).
Results: Serum IL-6 and CSF IL-6 were significantly higher in 19 patients with CPNB compared with control patients with non-inflammatory neurological diseases. Among 19 CPNB patients, serum IL-6 levels were not significantly correlated with CSF IL-6 levels (r=0.0938). As for 5 patients with CPNB treated with infliximab, all of CSF IL-6, serum IL-6, Q albumin and CSF IL-6 indices were significantly elevated compared with control patients with non-inflammatory neurological diseases. Treatment of the 5 patients with infliximab dramatically decreased CSF IL-6 in the next day, but neither serum IL-6 nor Q albumin (Figure 1). Of note, CSF IL-6 indices were dramatically decreased on the next day of treatment with infliximab in the 5 patients with CPNB (Figure 1).

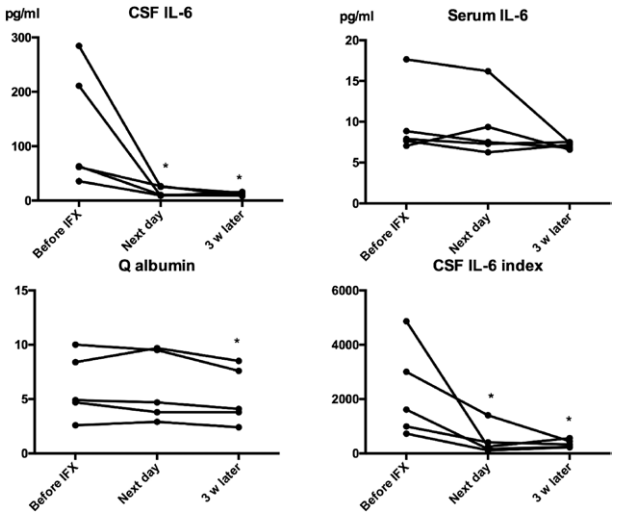

Figure 1.

Conclusion: These results indicate that serum IL-6 as well as CSF IL-6 is involved in the pathogenesis of CPNB. More importantly, the course of treatment of 5 CPNB patients with infliximab clearly indicated that the elevation of CSF IL-6 was not caused by blood-brain barrier breakdown, but by its intrathecal production in CPNB.

POS1178

IDENTIFYING THE NEW DISORDER "IDIOPATHIC HYPOCRYOGLOBULINAEMIA" IN PATIENTS WITH PREVIOUSLY UNIDENTIFIED CLINICAL CONDITIONS

Keywords: Rare/orphan diseases, Vasculitis, Kidneys

D. Roccatello[1], S. Sciascia[1], C. Naretto[1], A. Barreca[2], L. Solfietti[1], L. Battaglia[1], L. Viziello[1], R. Fenoglio[1], D. Rossi[1]. [1]*University of Turin, Clinical and Biological Sciences, Turin, Italy*; [2]*Città della Salute e Della Scienza, Pathology Division, Turin, Italy*

Background: A considerable number of patients with high clinical suspicion for cryoglobulinaemic vasculitis either. show negative results for the detection of cryoglobulins or show only trace amounts which cannot. be characterized for composition.
Objectives: We aimed at establishing whether the failure to detect or the detection of trace amounts of cryoglobulin with conventional methods either identifes a peculiar subset of low level cryoglobulinaemia (from now on hypocryoglobulinaemia) or represents a separate entity.
Methods: Using a modifed precipitation technique in hypo-ionic medium, we prospectively identified between 2008 and 2021 237 patients (median age 60.8 years [22–97], 137 females) having < 0.5% cryocrit and clinical suspicion of autoimmune disorder.
Results: Of these 237 patients, only 54 (22.7%) had a history of HCV infection. One hundred and sixty-nine out of 237 patients (71%) had an established underlying disease, while 68 patients (28.6%) (median age 62.9 years [29–93], 35 females) did not show either laboratory markers or clinical symptoms consonant with an underlying aetiology. These 68 cases with only trace amounts of cryoglobulins were defned as having a putatively idiopathic hypocryoglobulinaemia. Nineteen of these 68 patients (27.9%) had a history of HCV infection. Twentyfour patients out of 68 (35.3%) were positive for rheumatoid factor (RF), while 25 (36.7%) patients had signs of complement consumption (i.e., C4< 15mg/dl and/or C3 < 80mg/dl), and 36 (52.9%) had increased infammatory indexes. Seven patients only had arthralgia and constitutional symptoms while 61 out of 68 (89.7%) presented with at least one of the three cardinal signs of cryoglobulinaemic vasculitis including skin lesions, peripheral nerve involvement, and glomerulonephritis. Seventy-fve percent of the subjects had type III hypocryoglobulins. In patients with hypocryoglobulinaemia the histologic features of glomerulonephritis (also examined by electron microscopy) resembled those of mixed cryoglobulinaemia-associated glomerulonephritis.
Conclusion: In conclusion, hypocryoglobulins are often polyclonal and are mainly unrelated to HCV infection. Patients who present high clinical suspicion for vasculitis, especially glomerulonephritis and yet test negative for cryoglobulinaemia detected by standard techniques, could require deeper investigation even in the absence of HCV infection, RF activity or signs of complement consumption.

POS1179

USING ARTIFICIAL INTELLIGENCE TO IDENTIFY ANTI-NEUTROPHIL CYTOPLASMATIC ANTIBODY (ANCA)-ASSOCIATED VASCULITIS PATIENTS IN ELECTRONIC HEALTH RECORDS

Keywords: Vasculitis, Artificial intelligence

J. Van Leeuwen[1], E. Penne[2], Y. K. O. Teng[1]. [1]*Leiden University Medical Center (LUMC), Nephrology Section - Internal Medicine Department, Leiden, Netherlands*; [2]*Northwest Clinics, Nephrology Section - Internal Medicine Department, Alkmaar, Netherlands*

Background: Anti-neutrophil cytoplasmatic antibody (ANCA) associated vasculitis (AAV) is a rare, life-threatening, systemic auto-immune disease.[1] Due to the low prevalence, multiple treating disciplines and poor registration, including ICD-10 classification, identifying AAV patients for (pre-)clinical studies, research and health care evaluation is challenging.[2, 3] Therefore, there is an urgent need to improve identifying these patients in health care organisations. Employing artificial intelligence (AI) – supported search engines are increasingly suggested to achieve this.

Objectives: Reliably identify AAV patients in electronic health records (EHR) using an AI-based tool that incorporates text mining and Natural Language Processing (NLP).
Methods: The identification method consists of a search strategy combined with NLP-based exclusion. A search strategy to optimally identify AAV patients within a single center EHR system of an academic hospital was developed using an established AAV cohort (n=203) as a gold-standard reference set. Patient records, identified by the search strategy outside of the reference set, underwent manual review to confirm newly-identified AAV patients. Then, improvement in performance by adding NLP to the text-mining search strategy was investigated. Validation was performed on an independent EHR system of a non-academic hospital with an established AAV cohort available for reference (n=84).
Results: The search strategy combined five queries based on disease description, laboratory measurements, medication and relevant specialisms. In the determination EHR, the search strategy identified 608 patients, including 197/203 (97.0%) AAV patients of the reference set and 149 newly-identified AAV cases confirmed by manual review. Employing NLP in the identification method improved the positive predictive value (PPV) from 57% (346/608 patients) to 78% (339/444 patients). These results were validated in an independent EHR system where the search strategy identified 333 patient, including 82/84 (97.6%) AAV patients of the reference set and 112 newly-identified AAV cases upon manual review. NLP improved PPV from 59% (194/333 patients) to 86% (192/223 patients). Negative predictive values and specificities were above 98% in all analyses.
Conclusion: We present an AI based identification method to identify low-prevalent AAV patients in EHR systems. We demonstrated improved performance when adding NLP to the text-mining search strategy. Successful validation in an independent health organisation supports the applicability and transportability of this method which can be an important accelerator for research efforts and health care evaluation in AAV patients.

POS1180 CONCORDANCE IN THE CLASSIFICATION CRITERIA IN A PATIENT COHORT OF ANCA ASSOCIATED VASCULITIS

Keywords: Validation, Vasculitis

O. Iaremenko[1], L. Petelytska2, V. Kravchenko3. *[1]Bogomolets National Medical University,The Department of Internal Medicine #3, Kyiv, Ukraine*; *[1]Bogomolets National Medical University,The Department of Internal Medicine #3, Kyiv, Ukraine*; *[1]Bogomolets National Medical University,The Department of Internal Medicine #3, Kyiv, Ukraine*

Background: Despite existing of different classifications criteria for ANCA-associated vasculitis (AAV), early diagnosing AAV is still challenging. Previous classification criteria do not include some of important diagnostic tests (for example, ANCA) or surrogate clinical markers and had insufficient specificity. According to the Vasculitis Patient-Powered Research Network study, the median time to diagnosis of vasculitis amounts 7 months and 73% of patients are misdiagnosed initially. Recently the American College of Rheumatology (ACR) and European Alliance of Associations for Rheumatology (EULAR) have proposed the new classification criteria for AAV, but they have not yet wildly used in a clinical practice.
Objectives: to evaluate the 2022 ACR/EULAR classification criteria for AAV in a Ukrainian patient cohort and compare it with the ACR 1990 classification criteria/ European Medical Agency (EMA) algorithm.
Methods: The retrospective study included 42 patients diagnosed between 2010 and 2022 with GPA, EGPA, MPA and undifferentiated vasculitis (UN) in two rheumatology centers from Ukraine. All patients have serology conformation (positivity of antibodies against proteinase-3 and/or myeloperoxidase performed using the ELISA test) and surrogate clinical markers of vasculitis. All cases were classified according to the 1990 ACR criteria, the 2007 EMA algorithm and reclassified according to the new ACR/EULAR 2022 criteria. If the patients do not meet the criteria of EGPA, MPA, or GPA, they are classified as UN. Concordance between different classification criteria and diagnosis was performed using Cohen's kappa coefficient with determination of sensitivity and specificity.
Results: Among 42 patients (female: male ratio 1:0.6) with AAV with mean age at the time of diagnosis of 47.19±11.55 years, 25 patients were diagnosed with GPA, 7 patients with EGPA, 7 patients with MPA and UV – 3 patients. According to the classification criteria of ACR 1990 and EMA 2007, 31 patients were diagnosed with GPA, EGPA – 4 patients, MPA – 1 patient, UV – 3 patients. Three patients simultaneously met the criteria for GPA and EGPA. When applying the new classification criteria, 24 patients were diagnosed with GPA, 5 patients with MPA, 5 patients with EGPA, and 4 patients with UV. Four patients simultaneously met the criteria for GPA and MPA. In total, in 28 patients the established diagnosis corresponded to the diagnosis according to the previous and new criteria, in 8 patients the diagnosis corresponded only to the new criteria (6 MPA, 1GPA, 1 UV), in 5 patients the diagnosis corresponded only to the classification criteria of ACR 1990 and the EMA algorithm (3 EGPA, 1 UV, 1 GPA), and one patient has not met any criteria. The new classification criteria compared to the previous ones demonstrated better agreement with the established diagnosis of GPA (k 0.6 vs 0.3, sensitivity 88.0% vs 92.0%, specificity 70.6% vs 35.3 %) and MPA (k 0.5 vs 0.2, sensitivity 71.4% vs 14.3%, specificity 88.6% vs 100%), but worse agreement with the diagnosis of EGPA (k 0.8 vs 1.0, sensitivity 71.4% vs 100%, specificity 100% vs 100%). The observed agreement between the two classification criteria was slight for GPA (k 0.3) and MPA (k 0.2), but substantial for EGPA (k 0.8).
Conclusion: The new ACR/EULAR 2022 classification criteria for ANCA-associated vasculitis demonstrate a high diagnostic value in the Ukrainian patient population (for GPA, sensitivity - 88%, specificity - 71%, for MPA - 71% and 89%, respectively, and for EGPA - 71% and 100%, respectively) and an advantage over the previous classification criteria for GPA and MPA. However, about 10% of the patients are unclassified and the same amount are matched two diagnoses with the new criteria. There is a slight agreement between ACR/EULAR2022 criteria and ACR1990 criteria/EMA algorithm for GPA and MPA.

POS1181 VALIDATION OF THE 2022 - AMERICAN COLLEGE OF RHEUMATOLOGY/EUROPEAN ALLIANCE OF ASSOCIATIONS FOR RHEUMATOLOGY CLASSIFICATION CRITERIA IN INDIAN PATIENTS WITH ANCA ASSOCIATED VASCULITIS

Keywords: Vasculitis

A. Sharma[1], P. Deo[1], G. Naidu[1], J. Samanta[1], S. Mittal[1], K. Sharma[2], R. Nada[3], V. Dhir[1], S. Jain[1], R. Minz[4]. *[1]Post Graduate Institute of Medical Education & Research, Chandigarh, Internal Medicine, Chandigarh, India*; *[2]Post Graduate Institute of Medical Education & Research, Chandigarh, Medical Microbiology, Chandigarh, India*; *[3]Post Graduate Institute of Medical Education & Research, Chandigarh, Histopathology, Chandigarh, India*; *[4]Post Graduate Institute of Medical Education & Research, Chandigarh, Immunopathology, Chandigarh, India*

Background: 2022 American College of Rheumatology/European Alliance of Associations for Rheumatology Classification Criteria for classification of ANCA associated vasculitis need to be validated in different cohorts.
Objectives: The purpose of this study was to validate the recently published 2022 American College of Rheumatology/European Alliance of Associations for Rheumatology Classification Criteria for classification of ANCA associated vasculitis/AAV (Granulomatosis with Polyangiitis [GPA], Eosinophilic Granulomatosis with Polyangiitis [EGPA] and Microscopic Polyangiitis [MPA])
Methods: Patients with a diagnosis of AAV from Indian vasculitis registry (INVAR) cohort were included in the study. The new 2022 ACR classification criteria of AAV[1]–[3], 1990 ACR classification criteria for GPA and EGPA, and the EMA Algorithm were validated in our cohort to assess their performance. The level of agreement was assessed using Cohen's kappa. The clinician's diagnosis was considered as the gold standard.
Results: A total of 302 patients diagnosed AAV with mean age of 42.87 ± 14.7 years were included. 58.7% were female and 42.3 % were male. Figure 1 show the distribution of AAV patients classified according to various classification criteria. The new ACR 2022 criteria for GPA (kappa: 0.961; sensitivity: 99% and specificity: 99%), MPA (kappa: 0.992, sensitivity: 99.9% and specificity: 99.9%), EGPA (kappa:0.961, sensitivity: 92% and 100%) had almost perfect agreement with INVAR cohort. Table 1 shows performance of EMA algorithm and the ACR 1990 criteria compared to the new 2022 classification criteria for AAV in the INVAR

cohort. Furthermore, predominant CNS or ocular GPA (if PR3/MPO negative) were missed by the new ACR classification criteria. EMA Algorithm missed cases of ANCA vasculitis where histology was not possible or ANCA was positive by IIF.
Conclusion: The study showed the new criteria for AAV, had good performance in INVAR registry AAV patients. The new criteria had good sensitivity and specificity for classification of GPA, MPA and EGPA compared to EMA algorithm.

POS1182 **GENDER IMPACT ON BASELINE PRESENTATION AND OUTCOME IN ADULT IGA VASCULITIS**

Keywords: Epidemiology, Gender/diversity issues, Vasculitis

K. L. Baud[1], Y. Ramdani[1], V. Maisons[1], E. Pillebout[2], J. F. Augusto[3], N. Jourde-Chiche[4], S. Faguer[5], N. Ferreira-Maldent[1], F. Maillot[1], B. Terrier[2], A. Audemard[1]. [1]*Chru Hospitals of Tours, Indre et Loire, Tours, France*; [2]*Aphp, Seine, Paris, France*; [3]*Angers University Hospital Center, Maine-et-Loire, Angers, France*; [4]*Assistance Hopitaux De Marseille, Bouches-du-Rhône, Marseille, France*; [5]*Hospital Center University De Toulouse, Haute-Garonne, Toulouse, France*

Background: It has been shown that patient's demographical characteristics may impact presentation and outcome in adult IgA vasculitis (IgAV). Aging was shown to negatively impact disease severity and outcome of adult IgAV. IgAV is also known to be more frequent in male, with a male to female gender ratio of 1.6. However, the potential impact of gender during vasculitis has been overlooked.
Objectives: We aimed to study the impact of gender on presentation and outcome of adult IgAV.
Methods: We retrospectively study the data of the French retrospective multicenter cohort (IGAVAS), including 260 IgAV adult patients. Comparison of presentation and outcome were performed according to gender status (male *vs*. female).
Results: Of the 260 patients included, data from 259 patients were analyzed: 95 female and 164 male (one missing data). Compared to female, baseline disease presentation in male was similar for cutaneous involvement (n=164 (100%) *vs.* n=95 (100%), p= 1.0), joint (n= 99/164 (60%) vs. n= 60/95 (63%), p= 0.7) involvement, gastrointestinal involvement (n= 93/164 (57%) *vs.* 43/95 (45%) p=0.093) and glomerulonephritis (n=120/164 (73%) *vs.* n=61/95 (64%) p=0.16)). However, compared to female, glomerulonephritis in male was more severe at baseline with lower glomerular filtration rate (median (IQR) 90 ml/min/1,73m2 (59-105) *vs.* 97 ml/min/1,73m2 (76-116), p = 0.015)), increased protein level excretion (0.84 g/day vs 0.58 g/day, p = 0.01) and a higher serum IgA level (3.6 g/l (2.5-4.8) *vs.* 3.3 g/l (2.3-4.6) p=0.03). However, among patients who had renal biopsy (n =47 female, n=97 male), no significant difference was observed. Male were more frequently and more aggressively treated than female. Pulses of methylprednisolone were more frequently prescribed in male (n=52/129 (40%) *vs.* n=14/64 (22%), p= 0.015). Immunosuppressants were more frequently given to male, especially cyclophosphamide (n=31/129 (24%) *vs*. n=4/64 (6%), p=0.0025) and azathioprine (10 % *vs* 2%, p = 0.038). Analysis of treatment response showed that male had more frequent refractory disease: lack of response was significantly higher in male compared to female (30 % *vs.* 13%, p = 0.004). Finally, baseline differences did not impact long term outcome such as mortality (7 % in male *vs.* 5 % in female, p = 0.77), neither progression to chronic kidney failure, dialysis transplantation.
Discussion: Interpretation of this study is tricky. There is a discrepancy between renal laboratory and pathological findings making difficult to affirm a greater severity of glomerulonephritis in male. Additionally or renal. data regarding comorbidities influencing renal function has not been gathered. However, in the literature, studies have shown differences between male and female in IgA nephropathy with more rapid progressive disease in male population. Moreover, a Slovenian group recently observed in a prospective cohort of 124 adults IgAV patients, that males had more severe disease than females.
Conclusion: Despite its limits, this study raises the question of a more severe disease in male in terms of glomerulonephritis. This hypothesis is sustained by the fact that male compared to female were strikingly more severely treated and present a poor short outcome whereas the long term outcome do not seem to differ. Altogether, these results raise the question of the gender as a new prognostic factor during the course adult IgAV.

Clinical cases

POS1183 **DIAGNOSTIC CHALLENGES IN A PREGNANT PATIENT WITH SLE AND SYSTEMIC SCLEROSIS OVERLAP – PREECLAMPSIA, ACTIVE LUPUS NEPHRITIS OR RENAL CRISIS?**

Keywords: Systemic lupus erythematosus, Pregnancy and reproduction, Systemic sclerosis

K. Gheorghe[1], K. Hellgren[2], K. Gunnarsson[2]. [1]*Karolinska University Hospital, Rheumatology, Stockholm, Sweden*; [2]*Karolinska Institutet, Department of Medicine Solna, Division of Clinical Epidemiology, Stockholm, Sweden*

Background: Pregnancy is an important issue for young women with inflammatory systemic disease and pose a clinical challenge.
Objectives: The aim of this case report is to underline the challenges to correctly diagnose pregnancy complications versus disease flare in pregnant women with overlap syndrome.
Methods: Clinical information collected from the patient's journal.
Results: A 26 years old woman was referred to Karolinska University Hospital because of Raynaud's phenomenon, sclerodactyly, skin rash, palate ulcerations and recurrent finger ulcerations with necrosis, infections and self-amputation of distal phalanges. Interstitial lung disease was confirmed by high resolution CT and a restrictive pattern on lung function tests. Immunological analyses detected autoantibodies against Scl-70, ribosomal-P, SS-A, SS-B, Ku, as well as dsDNA with immunofluorescence technique with varying titers over the years. Complement activation, anemia and lymphopenia were also present. The patient experienced muscle weakness and peripheral muscle MRI and muscle biopsy confirmed myositis. During follow-up she developed pericardial effusion and myocarditis. The patient was diagnosed with overlap syndrome with clinical and serological features of systemic sclerosis, SLE and myositis. The immunosuppressive treatment over the disease course comprised hydroxychloroquine, methotrexate, azathioprine, rituximab and low dose prednisolone. Later, treatment was switched to mycophenolate mofetil because of flares on the previous regimens. For the digital ulcers, she was treated with nifedipine, sildenafil and iloprost infusions. Despite medical advice on pregnancy risks during active disease, the patient stopped medication with mycophenolate at the age of 35 years and became pregnant. Enalapril, spironolactone and sildenafil were discontinued and she was referred to the specialist maternity care. The pregnancy evolved without complications until week 18 when the blood pressure (BP) began to rise.

In trying to avoid alpha blockers, because of recent finger ulcerations, nitrates and hydralazine were started without sufficient effect on the BP. Soon thereafter, she also developed marked trombocytopenia and hemolytic anemia. The titers of dsDNA antibodies were higher compared to the status before pregnancy and the creatinine and proBNP started to rise. Urine analysis revealed proteinuria and granular casts. Pre-eclampsia was suspected, though SLE flare with active nephritis, hemolysis and trombocytopenia could not be ruled out. Tacrolimus, intravenous immunoglobulin and methylprednisolone were started, as well as labetalol and diuretics. Plasmapheresis was applied twice. The BP remained uncontrolled and kidney function was deteriorating; therefore hemodialysis was started. Since the foetal growth was impaired and the patient's clinical status was not improving, decision was made to stop the pregnancy. The medical abortion with vaginal birth proceeded without complications and minimal hemorrhage. Since hypertension and hemolysis continued post-abortion despite several antihypertensive drugs and the patient developed lung edema, renal crisis was suspected and the patient was started on enalapril. BP, and later on the renal function, improved slowly. Two weeks postpartum dialysis was no longer needed. Renal biopsy revealed thrombotic microangiopathy without signs of nephritis.

Conclusion: We described a patient with overlap syndrome who developed serious pregnancy complications that ended up with pregnancy termination in week 20. This case illustrates the difficulty in differential diagnostics of preeclampsia-induced hypertension with renal and hematological changes versus active SLE and the importance of keeping in mind that renal crisis may complicate the clinical picture in SLE/ scleroderma patients. Also, this case underscores the significance of low disease activity when starting a pregnancy and that every effort should be made for shared decision making.

POS1184 A CASE OF DELAYED DIAGNOSIS OF MUCKLE WELLS SYNDROME- AN EXTREMELY RARE BUT IMPORTANT DIFFERENTIAL OF INFLAMMATORY ARTHRITIS IN A RHEUMATOLOGY CLINIC

Keywords: Rare/orphan diseases, Inflammatory arthritides

A. Anjum[1], R. Davies[1], R. Asif[2]. [1]*Cardiff & Vale University Health Board, Department of Rheumatology, Cardiff, United Kingdom*; [2]*Aneurin Bevan University Health Board, Department of Rheumatology, Newbridge, United Kingdom*

Background: Muckle wells syndrome (MWS) is one of the rare clinical phenotypes of Cyropyrin associated periodic syndromes (CAPS), driven by Interleukin-1 mediated systemic inflammation.[1] A typical presentation includes episodic fever, urticarial rash and arthralgia but can also result in episodic inflammatory arthritis and sensorineural hearing impairment. Secondary amyloidosis is the most feared complication especially in patients with untreated active disease.[2]

Objectives: We present a case of a 32 years old male, with history of episodic pain and swelling of the right knee for 2 years before presentation to rheumatology clinic.

Methods: Over the years, prior to rheumatology review he was seen by multiple specialties for varied unexplained symptoms including ENT for progressive sensorineural hearing impairment, dermatology for intermittent childhood onset eczematous rash and by ophthalmology for episodic idiopathic iritis and uveitis. He was also seen by haematology for an episode of cervical lymphadenopathy with no definite cause identified. There was no history of inflammatory back pain, psoriasis or Inflammatory bowel disease. Of note, his father had severe sensorineural hearing loss and his brother had a diagnosis of undifferentiated inflammatory arthritis at a young age. On initial rheumatology assessment he had a moderate knee right knee effusion and an erythematous non-specific rash over his upper back. A review of previous investigations showed raised inflammatory markers (CRP 93). A prior MRI right knee showed areas of synovial hypertrophy with a moderate knee effusion.

Results: Subsequent investigations were negative for Rheumatoid factor, Anti-CCP Ab, ANA, ENA, ANCA, HLA B27 and HLA B-51. The initial rheumatology impression was of an isolated seronegative inflammatory arthritis of the right knee but given other unexplained symptoms and family history we investigated for autoinflammatory disorders. Subsequent genetic screen was positive for NLRP3 gene confirming Muckle Wells syndrome as the unifying diagnosis. This case was also discussed with the National Autoinflammatory Disease Centre, UCL London and he has recently been commenced on Anakinra.

Conclusion: Targeted IL-1 inhibitors can prevent secondary amyloidosis. Effect on hearing impairment is uncertain but can be reversed in some cases. The heterogeneity of presentation poses a significant diagnostic challenge, however given the clear efficacy of available treatment options, an early diagnosis is extremely important to improve symptoms and prevent serious organ damage from secondary amyloid.

2) Although episodic pyrexia is considered a hallmark of autoinflammatory disorders, its absence does not exclude CAPS, as was the case in our patient.

3) We recommend considering this diagnosis as a differential of seronegative inflammatory arthritis, especially in younger patients with unexplained multi systemic involvement and suspicious family history.

POS1185 WITHDRAWN

HPR Patients' perspectives, functioning and health (descriptive: qualitative or quantitative)

POS1186-HPR INVESTIGATION OF THE RELATIONSHIP BETWEEN ARTIFICIAL JOINT AWARENESS AND EMOTIONAL STATUS IN PATIENTS WITH TOTAL HIP ARTHROPLASTY

Keywords: Cognitive function, Outcome measures, Health services research

A. Özçadırcı[1], O. Caglar[2], G. Coşkun[1]. [1]*Hacettepe University Faculty of Physical Therapy and Rehabilitation, Musculoskeletal Physiotherapy and Rehabilitation, Ankara, Turkey*; [2]*Hacettepe University Faculty of Medicine, Orthopedics and Traumatology, Ankara, Turkey*

Background: Patient-reported outcome measures, including joint-specific parameters of activities of daily living, such as joint awareness, are increasingly recognized as an important part of post-surgical outcome assessment [1].
Objectives: The aim of this study was to examine the relationship between artificial joint awareness and emotional status in patients who have undergone total hip arthroplasty (THA) surgery.
Methods: In this study, volunteer patients aged between 40-65 years who had undergone THA surgery and at least 1, a maximum 3 years after surgery were included. Artificial joint awareness was evaluated with the Forgotten Joint Score-12 (FJS-12) scale. It is a scale that questions awareness of artificial joint during various daily living activities from the patient's perspective in order to determine the ability of patients to forget artificial hip joints after THA surgery [2]. High scores indicate how much (%) the patient can forget the operated side of the patient and adapt to their life. In other words, a high score indicates a high degree of "forgetting" the artificial joint – i.e. a low degree of awareness. A 5-point Likert system is used in the scoring. The emotional status of patients was determined by Hospital Anxiety and Depression Scale (HADS). It includes anxiety (HADS-A) and depression (HADS-D) subscales. It consists of a total of 14 items, 7 of which are about anxiety and 7 of which are investigating symptoms of depression [3]. Pearson correlation analysis was used according to distribution of the data to determine relationship between the variables. The significance level was accepted as $p<0.05$.
Results: Sixty patients with THA, aged 53.46±7.9 years, were included in the study. Mean FJS-12, HADS-A, and HADS-D scores were 32.68±6.54, 7.27±3.2, and 5.27±2.5, respectively. A moderately and statistically significant correlation was found between FJS-12 and HADS-A and HADS-D ($r=0.466$, $p=0.004$; $r=0.483$, $p=0.003$ respectively).
Conclusion: The results of the current study showed that the adaptation of the artificial limb to daily life is poor and was correlated with emotional status. These results may show that worsening of patients' emotional status may contribute to development of artificial joint awareness. Therefore, also take into consideration the emotional state of patients with THA while applying therapeutic approaches aiming to decrease awareness of artificial joint and increase adaptation of artificial limb to daily life may increase the effectiveness of rehabilitation.

POS1187-HPR PARTICIPANTS' VIEW ON THE FEASIBILITY OF INSELMA - A NEW INTERDISCIPLINARY NURSE-COORDINATED SELF-MANAGEMENT INTERVENTION TO PEOPLE WITH INFLAMMATORY ARTHRITIS AND SUBSTANTIAL DISEASE IMPACT - A QUALITATIVE EVALUATION

Keywords: Inflammatory arthritides, Qualitative research methods

N. Blum[1], B. A. Esbensen[1], M. Østergaard[1], A. Bremander[2], O. Hendricks3, L. Lindgren[1], L. Andersen3, K. V. Jensen[1], J. Primdahl3. [1]*Copenhagen University Hospital, The Department of Rheumatology and Spine Diseases - Copenhagen Center for Arthritis Research, Glostrup, Denmark*; [2]*University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark*; [2]*University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark*

Background: Despite continuous improvements in antirheumatic pharmacological treatment, many people with inflammatory arthritis (IA) still report substantial disease impact. Based on the framework for complex interventions [1], we developed a self-management intervention (INSELMA)[2]. Based on shared decision-making, which included an initial assessment and a goal setting process a rheumatology nurse coordinated interdisciplinary support and available offers in primary care to achieve the patients' individual goals. A feasibility test of the six-month intervention encompassed 19 patients with IA and substantial impact of the disease.
Objectives: The objective of this study was to explore the participants' experience of feasibility, acceptability, and potential benefit from participation in the INSELMA intervention.
Methods: Individual semi-structured interviews were conducted with participants in INSELMA. Thematic analysis was applied [3].
Results: Fifteen participants were interviewed (9 women, 6 men, aged 44-75, 17-75 min.). The participants associated the benefits they experienced from the intervention to the impact IA had on their everyday lives.
The analysis derived four overall themes.
1) *A new opportunity*. Participation in INSELMA was experienced as an opportunity to improve, reduce challenges, or change issues they felt they had fought alone until now. Some expressed worries that their situation was too complex to be able to contribute to the study and some participated to contribute to scientific IA evidence.
2) *The importance of person-centred goals*. The individual goals encompassed both physical, social, and emotional life skills. When expectations and goals were aligned, it facilitated a positive outcome. The empathic support and coaching from the nurses, who listened, motivated, and understood their problems were considered especially valuable. Time between consultations to work with goals at home was pointed out as important to experience progress.
3) *A little nudging means everything.* Several participants expressed that the intervention had contributed with new or refreshed knowledge and motivation to change habits. Some would like continued follow-up with the nurse after the end of the study to stay committed. Also some suggested that this type of intervention should be a general offer for all patients with IA. Having access to a physiotherapist and an occupational therapist with rheumatology experience for exercise support adapted to the participants' needs and abilities was especially important for them.
4) *I got more than I wished for*. The intervention was experienced as feasible and meaningful, and the overall impression was positive. Several cried tears of joy and gratitude as they experienced decreased symptom load, improvement in physical strength, mobility, and sleep as well as increased energy and coping. Two had experienced no change, of which one had resumed physical activity after several years. The participants expressed hope for the future as they had new tools and habits to prevent problems and manage symptoms, which resulted in motivation to work towards new goals.
Conclusion: Patients found the INSELMA intervention feasible. They experienced decreased disease impact and increased activity level, facilitated by empathy and self-management support from the health professionals.

POS1188-HPR EXPERIENCES OF TELEMONITORING PULMONARY FUNCTION IN SYSTEMIC SCLEROSIS ASSOCIATED INTERSTITIAL LUNG DISEASE – A QUALITATIVE STUDY

Keywords: Telemedicine, Qualitative research methods, Systemic sclerosis

A. Velauthapillai[1], G. Schepers[1], M. Vonk[1], C. Van den Ende[1]. [1]*Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*

Background: Systemic sclerosis (SSc) is a heterogeneous auto-immune disease with interstitial lung disease (ILD) being the leading cause of mortality [1]. Current practice is to treat patients with severe or progressive ILD with immunosuppression[2]. Therefore tight monitoring of the pulmonary function is of huge importance, which can be improved by telemonitoring.

Objectives: To analyse experiences, facilitators and barriers of telemonitoring the pulmonary function in SSc-ILD patients.
Methods: This study was embedded in a longitudinal study on the validity of detecting progressive ILD with weekly home spirometry in adult SSc patients, fulfilling the ACR-EULAR criteria with a disease-duration ≤ 5 years and a maximum of immunosuppressive treatment of 8 weeks. Using a bluetooth-enabled handheld spirometer, measurements are collected via a mobile application for smart devices with results being visible, as graphs and bar charts, for both physician and patient. The weekly measurements are evaluated by a physician and an extra hospital check-up will be scheduled if results decrease. This system has proven to be feasible in SSc patients in our pilot study [3].
In patients, who used home spirometry for at least 3 months, semi-structured interviews were conducted and audio-records were transcribed. Patients were selected using purposive sampling based on age, treatment for ILD and course of pulmonary function in telemonitoring (>5% decline/stable) till data-saturation was achieved (i.e. no new codes in the last 2 interviews). Interviews were coded by 2 researchers independently using inductive thematic analysis.
Results: In total 13 patients (8 female/5male) were interviewed from whom 3 patients had > 5% decrease in pulmonary function during the observation period. The age ranged from 36-75 with a median of 58 year. Five main themes were extracted: telemonitoring routine, impact of telemonitoring, trust in telemonitoring, contextual factors and implementation in regular healthcare (Figure 1).
Most patients perceived it as reassuring to see stable results weekly, though the moment itself might be tensive. Moreover, the possibility to detect progressive disease earlier was appreciated. One patient, however, preferred disease activity being monitored by the physician instead.
Some patients placed fluctuations of measurement within limits of normal in perspective, while others experienced negative feelings in case of a decreased value. Experienced advantages of telemonitoring were being in the lead, insight in disease course (for some resulting in less confronting hospital visit), increased trust in health, decreased fear of progression, and reduced dependence on hospital visits. Most patients trusted the results of telemonitoring, although some trusted the hospital measurements more, because of external guidance from an analyst (leading to more motivation and unbiased results), and the manner of measurement (during breathing cycle in hospital vs. single breath at home). Understanding the rationale behind telemonitoring is an important facilitator, whereas possible barriers to perform weekly home spirometry are excessive saliva production (as it hinders proper function of the spirometer), confrontation with the disease, and older age. Most patients advocated to implement telemonitoring in healthcare and appreciated an accompanied reduction in hospital visits, although others viewed the regular physical contacts and control of other disease features as important. It was recommended to provide information about limits of normal values or regular feedback.

Figure 1. Overview of general dimension, first-, and second-order themes.

Conclusion: In SSc telemonitoring the pulmonary function can contribute to patient empowerment, however it might not be suitable for every patients, as it might elicit negative feelings.

POS1189-HPR

LUNG AND MYELOPROLIFERATIVE NEOPLASMS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH JANUS KINASE INHIBITORS: A REVIEW OF THE LITERATURE

Keywords: bDMARD, Malignancy, Rheumatoid arthritis

O. Hamdi[1], M. Yasmine[1], S. Miladi[1], F. Alia[1], H. Boussaa[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia*

Background: Janus Kinase inhibitors (JAKi) have been shown to be effective in the therapeutic strategy of rheumatoid arthritis (RA). However, an increased risk of developing malignancy has been reported in previous literature [1].
Objectives: This review aimed to investigate the risk of lung carcinoma and subsequent myeloproliferative neoplasm (MPN) in RA patients treated with JAKi.
Methods: We conducted a literature review in order to identify cases of lung carcinoma and MPN associated to JAKi in RA patients. A comprehensive search was conducted using *PubMed* and *Scopus*. The databases were searched from 2015 until date December 2022. No restrictions were applied in terms of study design, setting, country, or time frame. For *PubMed*, the search was carried out using a strategy employing the combination of synonyms of "pulmonary neoplasm," terms related to "JAK inhibitors," and terms related to "rheumatoid arthritis." For Scopus, the previous terms were searched in the article title, abstract, or key-words. We also did manual research on reference lists of retrieved relevant articles. Articles were eliminated if they had duplicate titles, did not contain the key-words, or included the words "review", "expert's opinion", or "qualitative." In this review, we included prospective or retrospective case reports and case series conducted on JAKi and lung carcinoma or MPN.
Results: The initial search yielded 153 papers. Following duplicate elimination, we screened for 119 papers. Only eight papers were finally selected for analysis and met inclusion criteria. The mean number of RA patients included was 2422 [486-6194]. Standardized incidence ratio of lung carcinoma and MPN ranged from 0.17 to 0.19 and 0.01 to 0.1, respectively. Most papers raised the possibility that RA patients treated with JAKi may have a markedly higher rate of development of lung carcinoma (95% CI [1.51 - 1.79]) or MPN (95% CI [2.05 - 2.96]) compared to patients who did not receive the treatment. The Table 1 exposes the main characteristics of the nine studies retained in this review.

Table 1. Studies assessing malignancy associated to JAKi therapy in RA patients

Authors	Year	Article type	Neoplasm	Number of cases/ SIR*	(95% CI**)
Curtis JR et al.	2015	Retrospective case series	Lung carcinoma	24 out of 5761/ 0.19	(1.39-3.29)
Hisashi Y et al.	2016	Prospective case series	Lung cancer	2 out of 486/ --	--
			Lymphoma	2 out of 486/ --	
Masayoshi H.	2019	Prospective case series	Lung cancer	24 out of 5677/ --	--
			Lymphoma	10 out of 5677/ --	
Taylor CT et al.	2021	Retrospective case series	Lung cancer	26 out of 3770/ 0.17	(0.11-0.25)
			Lymphoma	6 out of 3770/ 0.01	(0.01-0.09)
Eun BL et al.	2014	Prospective study	lymphoma	5 out of 958/ --	--
Curtis JR et al.	2015	Retrospective case series	lymphoma	10 out of 5761/ 0.08	(0.04-0.14)
Mariette X et al.	2018	Prospective study	Lymphoma	19 out of 6194/ 0.1	(0.06-0.15)
Josef S et al.	2019	Retrospective case series	lymphoma	6 out of 3492/ 0.09	(0.03-0.19)

***SIR: Standardized incidence ratio, **CI: confidence interval**

Conclusion: Our study showed that JAKi was associated with an increased risk of development of lung malignancy and lymphoma. Although the risk of malignancy is increased compared with the general population, it is still similar to that seen in the overall RA patients.

POS1190-HPR WHY LUPUS? – PATIENTS' THOUGHTS OF TRIGGERS OF SYSTEMIC LUPUS ERYTHEMATOSUS AND PERCEIVED HEALTH

Keywords: Systemic lupus erythematosus, Patient information and education

S. Pettersson[1,2], S. Möller[2], H. Kling[2], I. Gunnarsson[2,3], E. Svenungsson[2,4]. *[1]Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden*; *[2]Karolinska University Hospital, Rheumatology, Stockholm, Sweden*; *[1]Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden*; *[1]Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden*

Background: It is well known that genetic factors and environmental triggers contribute to the inflammatory process and onset of systemic lupus erythematosus (SLE). Yet, other contributors may still be unknow, and few studies have to date systematically explored patients' views on what caused SLE onset. In a longer perspective, we also need to pay more attention to health literacy, and to patients' understanding of their disease since these aspects are important for treatment compliance, patients' perceptions of health and patient education.

Objectives: To explore patients' thoughts of the cause of SLE and to analyse their reports in relation to perceived health and quality of life.

Methods: Adult patients with SLE (≥ 4 ACR criteria) recruited to a cohort study in tertial care. The participants answered the written question *"Do you have any thoughts of why you got SLE?"* and additional questions of perceived SLE activity during the last three months (score 0-10, 0= no activity), SLE health last week (score 0-100, 0=good SLE health) and current general health (score 0-100, 100=full health). The participants' free written answers were categorized according to the content. We explored if patients' age, educational level, disease duration as well as perceived health differed between the categories.

Results: 375 patients were included. The main question regarding their thoughts of why they got SLE, was commented by 290 patients (77%), mean age 48 years, range 18-87, mean disease duration 15 ±14 years. The replies on the health scales ranged from minimum till maximum. SLE activity was low to moderate (mean 4.2 ±3), perceived SLE health mean 34.7 ±25.9 and current general health mean 63.1 ±21.0. The highest reported level of education was university education for 47% and high school for 36%. Among the patients who answered the main question (n=290), 33% (n=95) answered that they had no idea/thoughts of why they got SLE. Men (p = 0.041) and persons with lower educational level (p = 0.038) were more common in this group, also reporting slightly better general health (p= 0.050) than the group that had explicit thoughts of why they got SLE. Age, disease duration or perceived SLE parameters did not differ between the two groups. The answers of patients' thoughts of why they got SLE were sorted into categories: genetics (n=82), stress/trauma (n=65), infections/immunization (n=36), hormones/treatment (n=28), lifestyle behavior (n=28), treatment/disease other than SLE (=26) and environmental factors (n=5). A majority (n=135, 69%) wrote one potential factor of why they got SLE, two factors were reported by 49 patients (25%), one patient wrote five potential reasons. It was exclusively answers from women that could be categorized as "hormones/treatment" or "treatment/diseases other than SLE", and only one man wrote a statement of stress/trauma" as potential trigger of SLE. Patients in the category "hormones/treatment" had shorter disease duration (p=0.029), higher perceived SLE activity (p=0.011) and worse general health (p= 0.002) compared to those that had no statement that could be sorted into the category. Only five patients reported environmental triggers and these perceived worse SLE health (p= 0.022) and worse general health (p=0.038). Patients who reported stress/trauma as potential triggers of SLE onset had in a lager extent university education (p= 0.027) than those who did not report stress/trauma as a trigger.

Conclusion: Beside genetic factors, a prominent number of patients in this study reported stress/trauma or hormones as important triggers for developing SLE. In these groups perceived health and educational levels had different patterns. Additionally, infections/immunization were perceived as triggers for SLE but without the same difference in perceived health or educational level. Further studies should extend these results and investigate patients' perceptions of triggers for SLE flares, and high disease activity, information which can enhance our understanding of factors that may contribute to important aspects of SLE and patients' perceptions of health.

Acknowledgements: We are grateful to the participating patients contributing with their time and colleagues assisting in the data collection.

POS1191-HPR ULTRASONOGRAPHIC AND FUNCTIONAL CORRELATION OF THE FEET IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Ultrasound, Systemic lupus erythematosus

L. Cano Garcia[1], J. García-Campos[2], F. Ortiz-Márquez[1], A. Reinoso Cobo[3], L. Ramos Petersen[3], J. Marco-Lledó[2]. *[1]Hospital Regional Universitario de Málaga; Instituto de Investigación Biomédica de Málaga (IBIMA), Rheumatology, Málaga, Spain*; *[2]Universidad Miguel Hernández; Instituto de Investigación Sanitaria y Biomédica de Alicante, Podología, Alicante, Spain*; *[3]Universidad de Málaga, Departamento de Podología, Málaga, Spain*

Background: Systemic lupus erythematosus (SLE) is a chronic immune-mediated disease with involvement of various organs[1,2]. El 95% of patients with SLE have musculoskeletal involvement[1], most often in the form of arthralgias or non-erosive arthritis affecting mostly the hands and knees. A subgroup of patients with SLE, which is seen with increasing frequency, late develops a deforming arthropathy as a result of laxity of ligaments and peritendinous apparatus resulting in joint subluxations and tendon ruptures which is part of the accumulated damage of the disease. The foot is a heavily affected structure that may initially go unnoticed, but results in significant disability.

Objectives: To determine the relationship between inflammatory activity measured by ultrasound in metatarsophalangeal (MTF) and questionnaires of foot functionality, hand deformities and SLE activity.

Methods: A cross-sectional study was performed. Thirty-six subjects with a diagnosis of SLE in the Rheumatology Unit were consecutively recruited between March and June 2022. Inclusion criteria were: patients with SLE diagnosis according to EULAR/ACR 2019 criteria, with at least one year of evolution and age equal or older than 18 years. A Rheumatology nurse collected information on socio-demographic data, questionnaires and ultrasound scans. The SLE activity questionnaires completed were: SLEDAI and SLICC, quality of life: EQ-5D, foot function: FFI (Foot Function Index), FAAM (Foot and Ankle Ability Measures Questionnaire), FPI (Foot Posture Index). As for hand malformations collected were: Jaccoud arthropathy, non-reducible arthritis, z-finger, grommet finger, non-reducible arthritis, burst finger and gooseneck finger. A descriptive, bivariate and R-Pearson correlation analysis was performed.

Results: Thirty-six SLE patients (97.2% female) with a mean (SD) age of 49.31 (11.4) years with a range 23-66 years participated. A total of 30 patients (83.3%) showed at least one MTF synovitis, the most frequent being 2nd MTF left (58.8%) and right (44.4%), followed by 1st MTF right and left (41.7%). The number of patients with and without ultrasound synovitis, as well as the degree of synovitis and Doppler signal in each joint are shown in Table 1. A significant direct correlation was observed between inflammatory activity with Doppler in the 1st MTF of the right foot with the SLICC (r=0.439; p=0.007) and SLEDAI (r=0.608; p<0.001) questionnaire; as well as an inverse relationship between synovitis in the 1st toe of the right foot with the FPI questionnaire of the right foot (r=-0.340; p=0.040) (Table 2). Likewise, a significant relationship was observed between deformity in the hands with the synovitis of 5 right (p=0.042) and left (p=0.005) MTFs.

Conclusion: Ultrasound synovitis in MTFs is common in SLE patients and is associated with disease activity, some deformities and functionality.

Table 1. Description of inflammatory activity by ultrasound in metatarsophalangeal joints of 36 patients with SLE.

Variable	Grade 1 Synovitis	Grade 2 Synovitis	Grade 3 Synovitis	Doppler 1	Doppler 2

POS1192-HPR ASSESSMENT OF KNOWLEDGE AND ATTITUDE IN MOROCCAN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Best practices, Patient information and education

R. Honsali[1], T. Latifa[1], S. Farih[1], H. Rkain[1,2], R. Razine[3], S. Elhilali[3], F. El Joumani[1], S. Bahloul[1,2], S. Ez-Zaoui[1], F. Kronbi[1], I. Bensaghir[1], N. Alami[1], F. Allali[1]. *[1]Hospital Al Ayachi, Rheumatology B, Salé, Morocco*; *[2]Faculty of Medicine And Pharmacy of Rabat, Exercise Physiology and Autonomous Nervous System Team, Physiology Laboratory, Rabat, Morocco*; *[3]Faculty of Medicine And Pharmacy of Rabat, Department of Public Health, Rabat, Morocco*

Background: Rheumatoid arthritis (RA) is a chronic, disabling condition that impairs quality of life.

Objectives: The objective of the study was to evaluate the knowledge and attitude of Moroccan patients with rheumatoid arthritis, and to determine the factors associated with them. Thus, it will be possible to set up a targeted education program for a better adherence to treatments.

Methods: This is a descriptive and analytical monocentric study of patients followed up for RA at Al Ayachi University Hospital, Sale, Morocco; and of patients who are members of the Moroccan Association for the fight against Rheumatoid Arthritis (AMP), from December 2021 to July 2022. The consent of the study population was free and informed. The interview questionnaire was developed by the team of rheumatologists and included sociodemographic data, the patients' knowledge about their disease, the treatments and their side effects, the follow-up and the patients' attitude toward self-medication. A score was indicated between 0 and 10 and represents the rate of correct answers per patient.

Results: We recruited 200 patients. The mean age was 55.1 ± 12.0 years, and the majority were women (91%). More than half of the population (57.5%) was illiterate and only 5.5% of the patients had a university education. ¾ of the population was urban (74.5%), and 93% were not working. 64.5% correctly identified the nature of RA as an autoimmune disease, and 26% correctly recognized that RA has a genetic predisposition. 58.5% of patients do not use corticosteroids over the counter against medical advice, 78% do not discontinue corticosteroids abruptly. Whereas 49.4% of patients undergoing biotherapy do not discontinue methotrexate against medical opinion. Moreover, the majority of patients (85%) had a favorable attitude for not accepting paramedic's opinions. Only about a third of patients (30%) knew that pneumopathy could be a possible complication of Methotrexate. 56% did not know what a biomedical drug is, 82.1% did not know that infection is an adverse effect of a biomedical drug, and 98% had no idea what a biosimilar is. The study revealed that 67% of the patients had a total score of correct answers more than 5.0, and the remaining 33% had a score between 2.0 and 4.5.

Conclusion: The level of knowledge of the disease and attitudes among Moroccan patients with RA was globally satisfying. The maintenance and improvement of this level of knowledge and the acquisition of good practices remain fundamental, in particular by diversifying the sources of information: awareness campaign by direct doctor-patient contact, multimedia supports and patients' associations.

POS1193-HPR AN EVALUATION OF PATIENT EXPERIENCE OF THE BELFAST HEALTH AND SOCIAL CARE TRUST RHEUMATOLOGY ETANERCEPT BIOSIMILAR SWITCH PROGRAMME

Keywords: Patient information and education, Best practices, Patient reported outcomes

M. Mcverry[1], P. Mckee[1], J. Thompson[2], S. Jacklin[2]. *[1]Musgrave Park Hospital, Rheumatology, Belfast, United Kingdom*; *[2]Keele University, School of Pharmacy and Bioengineering, Newcastle-Under-Lyme, United Kingdom*

Background: The Belfast Health and Social Care Trust Rheumatology department commenced a biosimilar switch programme in July 2019, switching patients from Etanercept (Enbrel) to biosimilar (Benepali). Patients attended a bespoke switch clinic providing education and training before proceeding with biosimilar switch.

Objectives: To evaluate patients' experience of the Etanercept biosimilar switch programme including understanding of, attitudes towards and satisfaction with the switch process.

Methods: A service evaluation of patients invited to undergo biosimilar switch was undertaken. Ethical approval was not required. Patients' views were surveyed with a web-based questionnaire via text message/QR code or completed via telephone by an evaluator entering responses into the survey-tool.

Results: 182/342 patients responded (53%). Most [171 (94%)] reported discussing biosimilars with a healthcare-professional, received written information [174 (96%)] and felt adequately informed [172 (95%)]. 140 (77%) thought the reason for switching was to save money and 83 (45%) understood biosimilars as "*A highly similar but not identical copy of a biologic medicine*". Most [118 (65%)] reported a shared decision-making process but 52 (28%) thought "*Rheumatology team alone decided*". Most [126 (69%)] had no reservations about biosimilars, but 53 (29%) were concerned about its effectiveness. Mean visual analogue score for confidence in the biosimilar was 7.51 (median 8, 1-10). 168 (92%) reported switching to biosimilar agent. 103/168 (61%) reported no problems afterwards. Switch-back rate was 13% (22/168). 95% (161/168) rated support provided afterwards as adequate or better. Mean visual analogue score for satisfaction was 7.84 (median 8, 1-10).

Conclusion: The Etanercept biosimilar switch programme was successful with high switch rates, high levels of patient confidence and satisfaction. Recommendations for future include improving the process of shared decision-making during consultation to ensure fully informed patient consent.

POS1194-HPR EFFECTS OF RAMADAN INTERMITTENT FASTING ON RHEUMATIC DISEASES

Keywords: Spondyloarthritis, Rheumatoid arthritis

A. Mougui[1], H. Tebaa[1], I. El Bouchti[1]. *[1]Arrazi Hospital, Faculty of Medicine and Pharmacy of Marrakech, Mohammed VI University Hospital, Marrakech, Morocco., Department of Rheumatology, Marrakech, Morocco*

Background: Intermittent fasting (IF) during the month of Ramadan is one of the 5 fundamental pillars of Islam. Many patients report that IF improves or worsens their symptoms during this month, however, few studies had assessed the impact of IF on rheumatic diseases.

Objectives: The present study was conducted to assess the impact of IF during the month of Ramadan on rheumatoid arthritis (RA) and spondyloarthritis (SpA) activity.

Methods: The study included 71 patients with RA or SpA who fasted during Ramadan of 2022. Patients were assessed in 2 visits: 4 months before the month of Ramadan and the second after fasting at least after 15 days.

Results: RA group: 49 patients were included. IF was associated with a significant decrease in VAS (Visual analogue Scale) pain (5.76± 2.16 to 3.14 ±1.47) ($p < 0.001$), duration of morning stiffness (47,76 ± 39,68 minutes to 11,73 ± 11,11 minutes) ($p < 0,001$), number of painful joints (13,35 ± 5,43 to 7,36 ± 0,71) ($p<0.001$), number of synovitis(12,84 ± 6,715 to 3,04 ± 3,6) ($p<0.001$), CDAI (18.29 ± 4.74 to 12.35 ± 3.48) ($p<0.001$), SDAI (20.39 ±4.86 to 10.32± 4.68) ($p < 0.001$), DAS28 ESR (4.003 ± 0.1 to 2.55 ± 1.39) ($p < 0.001$), and DAS 28 CRP (4.06 ± 0.89 to 2.15 ± 0.77) ($p < 0.001$). SpA group: 22 were included. IF was associated with a significant decrease in VAS pain (5,14 ± 1,93 to 3,05 ± 1,70) ($p < 0.001$), number of painful joints (10,91 ± 5,63 to 1,27 ± 4,24) ($p<0.001$), number of synovitis (12,41± 6,71 to 1,73± 1,38) ($p<0.001$), BASDAI (4.92 ± 0.88 to 2.28 ± 0.81) ($p<0.001$), ASDAS CRP (4.44 ± 0.69 to 2.49 ± 1.29) ($p< 0.001$), and ASDAS ESR (4.12± 0.83 to 2.55± 1.39) ($p<0.001$).

Conclusion: IF was associated with significant improvement in RA and SPA activity. It is a promising non-pharmacological therapeutic option for patients with RA and SpA. Larger sample studies with control groups are needed to confirm these findings.

POS1195-HPR REPRODUCTIVE HEALTH IN AUTOIMMUNE RHEUMATIC DISEASES FROM THE PATIENT'S PERSPECTIVE: QUALITATIVE STUDY

Keywords: Pregnancy and reproduction, Descriptive studies, Quality of life

I. Peláez-Ballestas[1], C. M. Skinner Taylor[2], L. Pérez Barbosa[2], A. Y. Lujano Negrete[2], M. E. Corral Trujillo[2], F. R. Arevalo Nieto[2], A. Aguilar-Leal[2], M. C. Rodriguez-Ruiz[2], G. Sandoval[2], M. G. Ríos Medina[2], A. Carrazco Chapa[2], D. Á. Galarza-Delgado[2]. *[1]General Hospital of Mexico Dr. Eduardo Liceaga, Rheumatology, Ciudad de México, Mexico*; *[2]Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*

Background: Reproductive health (RH), family planning (FP), and managing a high-risk pregnancy should be prioritized in the rheumatology consultation to achieve shared and respectful decision-making [1]. Lack of knowledge of reproductive health and poor communication during the consultation may lead to increased pregnancy complications in patients with ARDs.

Objectives: To describe and analyze patients' experiences with ARDs on reproductive health issues at the clinic of pregnancy and reproductive health in rheumatic diseases (CEER) in Mexico.

Methods: A descriptive qualitative study was conducted using semi-structured interviews following an interview guide. Women of childbearing age, suffering from ARD, with different socioeconomic, cultural, disability, and sexual diversity conditions were invited to participate. The face-to-face or virtual interviews were recorded and transcribed. A multidisciplinary team of researchers performed an independent and blinded thematic analysis.

Results: Twenty-one patients participated. The age media was 28 years (yrs.), 38% were married, 28.5% were free union and 28.5% were single; 33.3% were pregnant, 38% were in the preconception stage with the desire of pregnancy and 28.5% women who have already had children. The main rheumatologic diagnoses were rheumatoid arthritis (47.6%), systemic lupus erythematosus (47.6%), and mixed connective tissue disease (4.7%). Three main themes were identified: medications related to pregnancy and lactation, contraceptive methods, and pregnancy planning (Table 1).

Table 1. Themes and narratives of patients with ARDs on reproductive health issues

Theme	Subtheme	Quote
Medications/ Breastfeeding	**Medication**	*But I don't know, uh, which medications to take, no";"… the truth, and I don't remember". (27 yrs., AR, pregnant).*
	Breastfeeding	*"I know that there is much more myth about (breastfeeding), … I feel that there is a lot of misinformation about it and that there are minimal medications that interfere with breastfeeding" (34 yrs., RA, pregnant).*
Contraceptive Methods	**Contraception**	*"I'm not sure, and I don't know which ones do interfere. I've never wondered if arthritis interferes with any method" (23 yrs., RA, pregnant).*
	Factors influencing choice	*"My mom helped me to make the decision"*"She told me, "If you want to use that one, that's fine" (20 yrs., SLE, postpartum).*
Pregnancy planning	**Planning**	*"Because first, you have to check that everything is okay in your health, they have to make sure that your disease is asleep, that nothing is altered, that everything is under control" (22 yrs., SLE/RA, reproductive age).*
	Heredability	*"Well, there is a certain percentage, according to what the geneticist explained when I went to her office. Yes, I knew something about it because my mother has rheumatoid arthritis. … I don't think it is a fact that I will pass it on to my baby". (34 yrs., RA, pregnant).*
	Accompaniment	*"Well, that they have all the information about both arthritis and pregnancy because, for me at least, it gives me a lot of comfort to be in the clinic because I know that I have this communication…y then not being with one doctor and then with another and explaining to one what the other one told me. (23 yrs., RA, pregnant).*

All quotes were extracted from interviews conducted in Spanish. Quotes were further translated to English.

Conclusion: The experiences of patients with rheumatic diseases were diverse, and the amount of biomedical knowledge of RH issues was limited in FP, decision-making, and prenatal or postnatal care. The patients recognized the relevance of a multidisciplinary team led by their rheumatologist to generate confidence in the quality of information and allow better decision-making according to patients' beliefs, preferences, and reproductive rights.

POS1196-HPR WHAT OUTCOMES MATTER TO PATIENTS WITH FOOT AND ANKLE DISORDERS IN RHEUMATIC AND MUSCULOSKELETAL DISEASES? FINDINGS FROM A QUALITATIVE SYNTHESIS AND SCOPING REVIEW OF THE LITERATURE

Keywords: Qualitative research methods, Systematic review, Patient reported outcomes

L. Chapman[1], C. Flurey[2], A. Redmond[1,3], P. Richards[4], C. Hofstetter[5], B. Tapster[6], J. Emmel[7], P. Helliwell[1], H. Menz[8], H. Marian[9], B. Shea[10], H. J. Siddle[1]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[2]University of the West of England, Department of Health and Social Sciences, Faculty of Health and Applied Sciences, Bristol, United Kingdom*; *[3]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*; *[4]OMERACT, Patient Research Partner, Bristol, United Kingdom*; *[5]OMERACT, Patient Research Partner, Toronto, Canada*; *[6]Leeds Teaching Hospitals NHS Trust, Library and Information Service, Leeds, United Kingdom*; *[7]Bradford District Care NHS Foundation Trust, Library Service, Bradford, United Kingdom*; *[8]School of Allied Health, Human Services and Sport, La Trobe University, Melbourne, Australia*; *[9]Harvard Medical School, Department of Epidemiology, Boston, United States of America*; *[10]Ottawa Hospital Research Institute, Clinical Epidemiology Program, Ottawa, Canada*

Background: Foot and ankle involvement is common and debilitating in rheumatic and musculoskeletal diseases (RMDs), but outcomes in research and clinical practice are often inconsistently measured and may not be meaningful to patients. Outcome inconsistency contributes to lack of high-quality evidence to determine the effectiveness of foot and ankle treatments [1].

Objectives: To understand what outcomes are important to patients living with foot and ankle disorders in RMDs through an exploration of symptoms and impact, and to establish how these compare to outcomes measured in existing research studies.

Methods: A qualitative systematic review of interview and focus group studies involving patients with foot and ankle disorders in RMDs (inflammatory arthritis, osteoarthritis, crystal arthropathies, connective tissue diseases and musculoskeletal conditions in the absence of systemic disease) was undertaken. A scoping review of clinical trials and observational studies comparing conservative, pharmacological or surgical interventions for these disorders was also performed. Seven databases (Ovid Embase; Ovid MEDLINE; CINAHL; Psycinfo; Cochrane Database of Systematic Reviews; CENTRAL; PEDro) were searched from inception to March 2022. All data from the results sections of qualitative studies were extracted, coded and synthesised to develop themes, whilst outcomes measured in quantitative studies were extracted and tabulated. Confidence in the qualitative findings was assessed using the GRADE-CERQual (Confidence in the Evidence from Reviews of Qualitative research) approach, incorporating Critical Appraisal Skills Programme quality appraisal [2]. Patient and public involvement contributors were involved throughout both reviews, in the design, analyses and discussions about the findings.

Results: Thirty-four studies were included in the qualitative review, whilst 150 studies (n=83 randomised trials) were included in the scoping review. The majority of studies included patients with foot and ankle disorders in rheumatoid arthritis (n=18 qualitative studies, n=43 quantitative studies) or osteoarthritis (n=5

qualitative, n=96 quantitative). Six themes were generated from the qualitative synthesis: pain, change in appearance, activity limitations, social isolation, work disruption and emotional distress. Themes were closely related; foot/ankle pain and appearance changes (e.g. deformity and subsequent limitations in footwear and clothing) affected emotions and led to restrictions in physical, social and work activities, which caused further distress. Based on grading of the evidence, we had moderate confidence that most of the review findings represented the experiences of patients with foot and ankle disorders in RMDs. Foot/ankle pain (n=117 studies) and foot/ankle function (n=102 studies) were the most commonly measured outcomes identified in the scoping review; social function, occupational function and emotional status were rarely reported.

Conclusion: This is the first study to explore patients' experiences of foot and ankle disorders in RMDs alongside outcomes currently measured by clinicians and researchers. Our findings highlight that these disorders impact on multiple areas of patients' lives, both physically and psychologically. Pain was the predominant symptom experienced by patients and the most commonly measured outcome in existing research, but other outcomes that are important to patients should not be overlooked by clinicians and researchers. Our findings can guide patient-centred care and measurement of outcomes within clinical practice and future research.

POS1197-HPR HEALTH-RELATED MOBILE APPLICATIONS IN RHEUMATOID ARTHRITIS: WHAT ARE THE PATIENTS' EXPECTATIONS?

Keywords: Self-management, Rheumatoid arthritis, Telemedicine

E. Hannech[1], M. Yasmine[1], S. Miladi[1], A. Fazaa[1], H. Boussaa[1], K. Ouenniche[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology Department, Tunis, Tunisia*

Background: The use of mobile phone applications for the management of rheumatic diseases (RD) has grown significantly these past few years [1]. Nevertheless, the success of these applications requires identifying the educational needs and interests of patients with RD.

Objectives: The purpose of our study was to investigate the expectations of rheumatoid arthritis (RA) patients regarding mobile applications in managing their disease.

Methods: We conducted a cross-sectional survey in our rheumatology department including RA patients, fulfilling the ACR/EULAR 2010 criteria. They were invited to respond to a questionnaire related to the utility of a mobile application in managing their disease. We evaluated their point of view on the desired functions of a smartphone app, the required content as well as the preferred design.

Results: The study included 40 RA patients: 36 females (90%) and 4 males (10%). The mean age was 52.25±14.4 years [21-78]. The mean disease duration was 11.97±6.69 years [1-29]. Two items were considered important and concerned the ability to contact the doctor when necessary and discuss their symptoms (72%), as well as the ability to check laboratory results (72%). Other features listed as useful were reminder date of clinic appointments (65%), and reminder of hours' medication intake (60%). Nearly half of the patients expected the app to include educational videos (52%), exercise strategies to feel better (52%), ways to improve lifestyle habits (sports, sleep, professional activity, and dietary habits) (52%) and information about alternative treatments (55%). When asked about "what kind of health-related information should be tracked or monitored using a smartphone application?", the most requested data to monitor concerned disease symptoms tracking (45%) using a validated measures of disease activity (43%), pain and fatigue (52%) using pain and general well-being questionnaires (41%) as well as arthritis-related functional scores (42%). Regarding the design, the application should be simple (68%), quick (63%), with clear font (44%). Moreover, it shouldn't require too much battery power (42%), and include frequent recall notices (42%).

Conclusion: Our study showed that RA patients prioritized information about medications and monitoring their disease. Surprisingly, the availability of lab results was considered an important component of the app. Identifying these needs will be the first step to ensure the success of the mobile phone applications.

POS1198-HPR PREVALENCE OF INFLAMMATORY BACK PAIN IN PRIMARY SJOGREN'S SYNDROME IS INCREASED AND ASSOCIATED WITH ACUTE AND STRUCTURAL CHANGES OF THE SACROILIAC JOINT

Keywords: Sjögren syndrome, Pain, Spondyloarthritis

K. Abacar[1], Ş. Çolakoğlu Özkaya[2], E. Bıyıklı[3], O. Buğdaycı[3], P. Atagündüz[1], Z. D. Selcuk[4]. [1]*Marmara University, School of Medicine, Rheumatology, Istanbul, Turkey*; [2]*Marmara University, Institute of Health Sciences, Department of Medical Biology and Genetics, Istanbul, Turkey*; [3]*Marmara University, Radiology, Istanbul, Turkey*; [4]*Marmara University Faculty of Medicine, Internal Medicine, Istanbul, Turkey*

Background: An increased prevalence of axial articular manifestations has recently been reported in primary Sjögren's syndrome (pSS).[1]Radiologic findings associated with inflammatory back pain (IBP) are not well documented in pSS patients.

Objectives: To assess the prevalence of IBP and its association with magnetic resonance imaging (MRI) detected acute inflammatory and structural changes of sacroiliitis in pSS patients with IBP.

Methods: In this cross-sectional study, consecutive pSS patients fulfilling ACR/EULAR classification criteria and age- and sex-matched healthy controls (HC) were screened for IBP according to the Calin, Rudwaleit and ASAS IBP criteria.[2] Sacroiliac MRI imaging of patients with IBP was performed and SpA features in the ASAS Classification Criteria for Axial Spondyloarthritis (SpA) were questioned. Two radiologists assessed sacroiliac joint MRIs (SIJ/MRI) for the cut-off values for a possible diagnosis of axSpA using ASAS defined lesion definitions. Cut-off values were defined previously by Maksymowych et al.[3]. The First questionnaire was used to evaluate the relationship between fibromyalgia and back pain.[4]

Results: A total of 202 pSS patients meeting the ACR/EULAR classification criteria and 124 healthy controls were included. The mean age [mean (SD)=52.8 (11.9)] and sex distribution in pSS (female/male: 198/4) was similar to HC [51.5 (9.2), (p=0.3) and female/male: 119/122? 5, (p=1), respectively] IBP was more prevalent in pSS (for pSS n(%): 51 (25.2), for HC n(%): 11 (8.8), p<0.001). SIJ/MRI was available in 49 patients with IBP. The mean (SD) age of onset of IBP was 33.6 (5.8). The mean (SD) duration of the IBP of the patients with pSS was 18.9 (10) years. pSS patients with IBP had significantly higher scores of the First questionnaire (patients with IBP mean (SD): 3.9 (1.7), patients without IBP: 2.8 (1.9), p=0.001). A total of 12 (24.5%) patients could meet the an axSpA diagnosis with a PPV of ≥95% as defined by Maxymowych et al. [3] Of these 12 patients, two with edema in the sacroiliac joint, nine with erosions, and four with fat metaplasia could be diagnosed as axSpA based solely on SIJ/MRI findings.

Conclusion: Low back pain meeting the IBP criteria is highly prevalent in pSS, and a quarter of these patients may have a radiologic diagnosis of axSpA. However, axSpA-associated features are absent in most patients, and very few meet the ASAS classification for axSpA. The presence of increased fibromyalgia may lead to an over-interpretation of radiologic features in the majority of these patients.

HPR Service developments, innovation and economics in healthcare

POS1199-HPR **IMPROVING THE UPTAKE OF ELECTRONIC PATIENT REPORTED OUTCOME MEASURES IN A SPECIALISED AXIAL SPONDYLOARTHROPATHY CLINIC**

Keywords: Patient reported outcomes, Spondyloarthritis, Outcome measures

J. Jade[1], Z. Cox[1], E. Fox[1], R. Tattersall[1], L. Dunkley[2]. [1]*Sheffield Teaching Hospitals NHS Foundation Trust, Rheumatology, Sheffield, United Kingdom*; [2]*Sheffield Teaching Hospitals NHS Foundation Trust, Rheumatology, Sheffield, United Kingdom*

Background: Sheffield Teaching Hospitals (STH), UK, has a specialised axial spondyloarthropathy (axSpa) clinic run by a rheumatology consultant and physiotherapist with special interest in this area. BASDAI and BASFI patient reported outcome measures are used to assess disease activity and response to treatment, in line with national guidelines. STH has invested in MyPathway (MP), an electronic patient messaging system used for patient information, appointments and electronic patient reported outcome measures (ePROMs). The data can also be viewed at a system level on a clinician dashboard. Prior to 2020 the uptake of ePROMs was low in the axSpa clinic. The move primarily to telephone consultations in March 2020, due to the COVID-19 pandemic, created an opportunity for increasing the use of MP for ePROMs collection to enable improved remote monitoring of patients with axSpa.
Objectives: This quality improvement project aimed to increase the use of electronic BASDAI and BASFI (ePROMs) in the axSpa clinic.
Methods: A multi-pronged approach has been taken since March 2020 to increase ePROMs completion and improve their use. Each appointment was used as an opportunity to discuss and recruit patients to MP. Clinicians invited each patient to join MP and sent them a link after their appointment. QR codes were then added to all rheumatology patient letters encouraging patients to register. A pathway was set up that automatically sent a prompt to patients registered on MP to complete their BASDAI and BASFI questionnaires prior to clinic appointments. Clinicians began logging into MP to view scores during appointments to provide patients with real-time feedback. A mixed methods approach was used to assess the uptake of ePROMs over time. We tracked MP registration rates and BASDAI completion rates as the key outcome measures, using a run chart to assess special cause variation. We undertook a patient focus group to explore attitudes towards ePROMs, key barriers and opportunities for further improvement.
Results: The total number of axSpa patients seen in the specialised clinic (named LADAS) who have registered with MP has increased from 56 (35.9%) in January 2019 to 200 (58.9%) in September 2022. There has been an improvement in the BASDAI completion rate, with 80% of patients completing more than one BASDAI in 2022, compared to 24% in 2019, as illustrated on a run chart (Figure 1). Patients can complete BASDAI forms sent to them in a previous month, therefore the completion rate some months exceeds 100%. In a dedicated focus group, patients reported that ePROMs were generally more convenient, and provided a useful record to refer back to. This could be further improved by development of a graph function to view scores over-time and the ability for patients to complete a questionnaire between appointments when they feel their disease is more active. A key theme for improving the use of ePROMs was the need for more discussion about their utility and around individual patient's scores. There is concern that the BASDAI and BASFI scores are arbitrary and lack nuance, and that the importance of these scores at an individual patient level is not clear. This may be rectified by more discussion with clinicians in appointments, to add meaning to these scores. There was also concern that sleep and other generic health measures are not covered in the BASDAI or BASFI. The EQ-5D, a generic questionnaire, is also sent to axSpa patients, but there seems to be a lack of patient awareness regarding it. There is an appetite to improve and standardise the amount of patient information accessible on MP, for example disease information and links to patient support groups.
Conclusion: There has been a clear improvement in the completion of ePROMs in the dedicated axSpa clinic at STH, over the last three years. Patient feedback has highlighted key areas for further improvement to maximise the potential of ePROMs, including more discussion around PROM scores to increase understanding and add individual patient meaning and nuance.

POS1200-HPR **IL-17 OR TNF INHIBITORS - REAL WORLD IMPACT OF SHARED DECISION MAKING IN A NURSE LED BIOLOGICS SERVICE**

Keywords: bDMARD, Spondyloarthritis, Real-world evidence

J. Begum[1], M. Nisar[1]. [1]*Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom*

Background: Since the availability of anti TNF biosimilars and the push from reimbursement panels to use them first line, real world data regarding therapeutic choice in biologic naive population is sparse.
Objectives: Evaluate the reasons for nurse led service choosing IL17 antagonists in biologic naïve SpA patients, in a shared decision making model, despite the availability of cheaper anti TNF biosimilar.
Methods: We conducted a retrospective analysis of our electronic register for people with PsA and AS from 1994 up to and including April 2022 at our university teaching hospital. We had access to full patient records including details on co-morbidities, drugs and disease management. All patients were evaluated in biologics service led by clinical specialist nurses.
Results: PsA. 90 patients were prescribed Secukinumab since its availability in the UK. Mean age was 51 yrs (24-80) and 56 (62%) were women. All were prescribed since the adoption of Adalimumab biosimilar. Median duration of therapy was 551 days (62-1284). Mean TJC and SJC were 8.14 (1-64) and 3.15 (1-57) at initiation which improved at six months to 6.28 (1-46) and 2.77 (1-18) respectively. 24 (27%) were biologic naïve; 18 had it for better efficacy (six had axial disease, four with enthesitis and eight with concomitant moderate to severe psoriasis) and six for relative anti TNF contraindications including three with treated solid organ neoplasms, one with BMI>35 and two for concurrent chronic infections including HIV. AS. 47 patients were prescribed Secukinumab. Mean age was 54 (27-79) and half were women. Median duration of therapy was 679 days (51-1154). Mean BASDAI was 3.3 (0-9.2) at initiation which improved to 2.1 (0-7.5). 11 (23%) were biologic naïve; five had it for better efficacy and six for relative anti TNF contraindications including three with treated cancers, two with latent TB and one for MS.
Conclusion: To our knowledge this is the first dedicated retrospective review of a large real world spondyloarthritis cohort evaluating reasons for biologic choice. Nearly a quarter of patients were prescribed Secukinumab prior to cheaper adalimumab biosimilar despite it being commissioned first choice agent in the region. Clinicians including nurse specialists chose it for better efficacy in various SpA domains. Relative contraindication to anti TNF drugs, which would not have been considered significant in the past, was the second reason. Efficacy and safety outcomes were comparable to other biologics. This confirms that shared decision

making process demands flexibility and limiting choice goes against clinical acumen and patient preference. Opting only for lower drug acquisition tariff is unlikely to be cost effective as the disease progresses whilst patients struggle with inappropriate prescription and thus delay biologics which are more likely to be efficacious and retained longer. Hence there is an urgent need to review prescribing guidelines to allow earlier employment of appropriate advanced therapies in the treatment paradigm with significant benefits to both patients and the health economy.

POS1201-HPR ADVANCED PRACTICE RHEUMATOLOGY NURSING FOR PATIENTS WITH GOUT TARGETS URATE, KNOWLEDGE, AND LIFESTYLE TO ENHANCE CHRONIC DISEASE OUTCOME

Keywords: Gout, Patient information and education, Treat to target

M. O'neill[1], D. Veale[2], E. Molloy[2], C. Orr[2], P. Minnock[1]. *[1]Our Lady's Hospice & Care Services, Rheumatology, Dublin 6W, Ireland*; *[2]St Vincent's University Hospital, Rheumatology, Dublin 4, D04 T6F4, Ireland*

Background: Gout is the most common chronic inflammatory arthritis worldwide and the only curable. Yet, gout care remains suboptimal despite evidence of the benefits of a treat-to-target approach to normalise urate levels. The efficacy and cost effectiveness of nurse led care in this treat-to-target strategy has been well recognised (Fuller, 2020)

OBJECTIVES:

- To implement a patient centred treat-to-target urate lowering strategy within a holistic health promotion, secondary prevention model of advanced practice nursing.
- To engage, raise awareness and educate patients about:

i) the short and long-term health implications of hyperuricaemia and
ii) the merits of self-management strategies to improve their health outcome

Methods: With stakeholder agreement a gout clinic was established. The Making Every Contact Count (MECC) framework was used to implement the treat-to-target approach per the EULAR (European Alliance of Associations for Rheumatology) recommendations for the management of gout. Making every contact count, grounded in a behavioural change approach, promotes brief intervention therapy to support lifestyle behaviour change to make each routine contact with patients count in terms of chronic disease healtcare (Meade, 2022: Gwinnutt, 2023). The 12-question Gout Self-Management Knowledge Questionnaire was completed at baseline, followed by a nursing educational intervention through a planned gout programme and repeated at final visit (Fields, 2017).

Results: To date 102 patients have attended the clinic. Baseline and final clinic assessments are available for 42 patients. The number of clinic reviews per patient was 6. Thirty-five (83%) were male; mean age was 61 years (range 29-91); mean disease duration was 9 years (range 1-40). The mean time to diagnosis from symptom onset was 4 years (range 0-29). At baseline, 17 (40%) reported a family history and past experience of a urate-lowering therapy. The reported mean number of flares per-annum was 1-2 (n=20); 3-5 (n=17); >6 (n=5); 20 patients (48%) had podagra; 14 patients (33%) had tophi. Urate levels improved by 76%, falling from a baseline of 397 µmol/L to 301 µmol/L at final visit; an 83% improvement was seen in the Gout Self-Management Knowledge Questionnaire. The subjective numeric global health score (0-10, where 10 represents worst health status) showed a median score of 1.5 at baseline and 1 at final visit.

Conclusion: Findings demonstrated 1) normalisation of urate to target levels, 2) an improvement in patients' insight and 3) a parallel upgrading in patients reported global health score.

Schmalzing[1], G. Schett[2,3], J. Knitza[2,3]. *[1]Department of Internal Medicine II, Rheumatology/Clinical Immunology, Würzburg, Germany*; *[2]Friedrich-Alexander-University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Erlangen, Germany*; *[3]Friedrich-Alexander-University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Deutsches Zentrum für Immuntherapie (DZI), Erlangen, Germany*; *[4]Brandenburg Medical School Theodor Fontane, Center for Health Services Research, Rüdersdorf, Germany*; *[5]Thermo Fisher Scientific, Phadia GmbH, Freiburg im Breisgau, Germany*

Background: Axial Spondyloarthritis (axSpA) has one of the longest diagnostic delays in rheumatology [1]. Telemedical solutions and integration of medical students to support routine care may be promising to overcome current limitations and accelerate axSpA diagnosis and treatment.

Objectives: We aimed to test a novel diagnostic pathway and asynchronous report-based diagnostic assessments for patients with suspected axSpA.

Methods: 40 patients with chronic back pain for more than 3 months completed a pre-appointment visit (T-1) with a medical student prior to their planned actual first visit (gold standard, T0) (Figure 1). Findings were discussed with a rheumatologist to finalize diagnostics and initiate therapy. Patients also completed two digital symptom checkers (SC), started to continuously report ePROs (BASDAI) via an app and received upper-arm self-sampling devices to self-collect capillary blood at home for remote C-reactive protein (CRP) and HLA-B27 analysis. Two additional students and three additional tele-rheumatologists reviewed SC, laboratory and imaging results to investigate an asynchronous telemedical diagnostic approach. Acceptance was measured using the net promoter score (NPS) [2]. For this, patients were asked to rate on an 11-point scale ranging from 0 ('Very unlikely') to 10 ('Very likely') how likely they would recommend the applications to others. To calculate an overall NPS, the percentage of detractors (rating 0-6) was subtracted from the percentage of promoters (rating 9 or 10).

Results: N=36 patients completed the study. AxSpA was confirmed in 17 and ruled out in 19 cases. The student visit helped to complete diagnostic evaluations prior to the actual first visit and the diagnostic delay (T-1,T0) was significantly reduced by about two months (Med (IQR), 55.5 (67.3) days, p <0.0001). The diagnostic accuracy (DA, axSpA yes or no) for the two SC Ada and bechterew-check was 58% and 47%, respectively. The student with patient contact reached a DA of 86%, the mean DA ± SD of the students who did not have patient contact (asynchronous decision) was 75% ± 0%. Results of the three tele-rheumatologists showed a high sensitivity (98% ± 3%) and diagnostic accuracy (89% ± 3%). Imaging results turned out to be an essential part for asynchronous decision making, as they significantly increased the sensitivity of the decision of all three physicians. Unsupervised at-home self-collection of capillary blood was successfully conducted by 80% of the patients. For the first time, accuracy of self-sampled HLA-B27 was demonstrated. Patients expressed high acceptance regarding the pre-appointment student visit, self-sampling and ePRO, with NPS of +62%, +36% and +31%, respectively.

Conclusion: To our knowledge, this is the first study exploring the potential of self-sampling, medical students and asynchronous assessments to accelerate axSpA diagnosis. The investigated elements were well accepted among patients and significantly reduced axSpA diagnostic delay.

POS1203-HPR EVALUATION OF TELENURSING FOLLOW-UP IN A COHORT OF STABLE/LOW DISEASE ACTIVITY PATIENTS WITH INFLAMMATORY ARTHRITIDES: A FEASIBILITY STUDY

Keywords: Telemedicine, Nursing, Inflammatory arthritides

M. R. Melis[1], K. El Aoufy[1], Y. Longobucco[2], S. Bambi[2], S. Guiducci[1], L. Rasero[2], M. Matucci-Cerinic[1]. [1]*Careggi Hospital, Rheumatology, Florence, Italy*; [2]*University of Florence, Health Sciences, Florence, Italy*

Background: Periodic follow-up (FU) is necessary for patients with Rheumatic Diseases (RDs). In the case of a stable clinical condition or low disease activity, FU can be carried out also by rheumatology nurses (RNs). Recent studies focusing on FUs led by RNs either in Rheumatology Clinics and with Telenursing (TN), showed promising results in terms of outcomes, cost reduction and users' satisfaction.

Objectives: To evaluate the feasibility of a Telenursing FU in a Rheumatology Centre in Florence, Italy.

Methods: In this pilot study, patients with stable inflammatory arthritis or low disease activity were contacted, after their first visit, through TN (T0) and then assessed during the following in-person visit (V12) by RNs for treatment adherence, for pain, for mental and physical health, for workability, for perception of disease activity and satisfaction concerning the TN service.

Results: Out of 27 interviewed patients, 59.3% (n=16/27) was affected by Rheumatoid Arthritis (RA), 18.5% (n=5/27) by Spondyloarthritis (AS), 14.8% (n=4/27) by Psoriatic Arthritis (PsA) and 7.4% (n=2/27) by Juvenile Idiopathic Arthritis. The mean age was 57.5±13.1 (M± DS) years and the treatment adherence level was optimal. 11.1% (n=3/27) of patients was referred for medical consultation because of the urgent clinical situation assessed by the RNs according to the clinical multidisciplinary checklist. After specialist consultation, 1 patient was revalued in presence for a transient ischemic attack; 1 patient was contacted by the rheumatologist following independent discontinuation of methotrexate therapy; 1 patient was redirected to urgent dermatology consultation because of a suspected cutaneous drug reaction. During the TN period (12 months), 33.3% (n=9/27) of the patients contracted SARS-CoV-2 infection and 11.1% (n=3/27) contracted urinary or upper respiratory tract infections. RA patients showed a mean Rheumatoid Arthritis Impact of Disease-RAID score of 2.4 at T0 and 2.5 at V12 (Range 0-10); AS patients showed a mean Assessment of Spondyloarthritis International Society-ASAS score of 0.3 in both periods and PsA showed a mean Psoriatic Arthritis Impact of Disease-PSAID score of 0.7 and 0.8 at T0 and V12, respectively. Among RA, AS and PsA patients, as a pain score of 3 was recorded in both periods. In order to attend the in-person FU visit, 68.4% (n=13/19) of the patients took work leave. 37% (n=10/27) of them waited 40.9±18.6 minutes at V12 control. The average distance between the Rheumatology Centre and patients' home was 29.3±25.6 km. 15.4% (n=5/13) of the respondents did not own a car and 23.1% (n=3/13) was accompanied to visit by their caregiver. All the included patients expressed high satisfaction for the TN service, corresponding to 5 point Likert scale.

Conclusion: The data show that TN FU is a valuable model for maintaining an adequate level of therapeutic adherence, reducing the travel time and working day loss, intercepting remotely clinical issues, as well as registering a high level of user acceptance and satisfaction. Further studies on larger samples are needed to confirm our findings.

POS1204-HPR PREVALENCE OF SATISFACTORY REPLACEMENT OF IN-PERSON RHEUMATOLOGY CONSULTATIONS WITH TELECONSULTATIONS IN A BRAZILIAN TELEHEALTH SYSTEM - THE TELESSAÚDERS-UFRGS EXPERIENCE

Keywords: Telemedicine, Quality of care, Health services research

D. Piovesan[1,2], M. Bredemeier[1], F. Carvalho[2,3], D. Rados[3,4], R. Souza Da Silva[3,5], S. Ramos[1], C. Solórzano[1], M. Gonçalves[2,3]. [1]*Hospital Nossa Senhora Conceição, Rheumatology Department, Porto Alegre, Brazil*; [2]*Federal University of Rio Grande do Sul, Epidemiology Postgraduate Program, Porto Alegre, Brazil*; [3]*Núcleo de Telessaúde Técnico Científico do Rio Grande do Sul - TelessaúdeRS-UFRGS, Coordenadoria Técnico-Científica, Porto Alegre, Brazil*; [4]*Federal University of Rio Grande do Sul, Internal Medicine department, Porto Alegre, Brazil*; [5]*Instituto Nacional de Ciência e Tecnologia para Avaliação de tecnologias em Saúde - IATS, Departamento Técnico-Científico, Porto Alegre, Brazil*

Background: TelessaúdeRS-UFRGS is a university-based telemedicine project in Brazil that receives support and resources from Brazil's Ministry of Health, and the State Health Department of Rio Grande do Sul. Since 2013, TelessaúdeRS has provided a synchronous toll-free telephone teleconsulting service that supports primary health care (PHC) physicians across the country. Family medicine, internal medicine, and rheumatology specialists answer clinical inquiries using the best evidence. (1)

Objectives: Describe the prevalence of specific rheumatology topics, recommendations provided in teleconsultations, and the change in the utilization pattern of this service over time.

Methods: In this cross-sectional study, we retrospectively extracted data from the TelessaúdeRS-UFRGS database. Teleconsultations were included from September 21, 2018, to January 25, 2022, addressing rheumatologic topics. Teleconsultations with incomplete data were excluded. Teleconsulting involves the discussion of clinical cases between patients' physicians and a rheumatologist or a trained PHC physician. All teleconsultations are registered in the TelessaúdeRS-UFRGS database. The teleconsultant formulates a diagnostic hypothesis, and a decision (based on referral protocols) is taken: referral to rheumatology, emergency care, stay in PHC or re-evaluation after a treatment course, or diagnostic tests. Criteria for referral to a rheumatologist were: diagnosis or high suspicion of systemic inflammatory disease, diagnosis still in doubt after re-evaluation, or non-inflammatory rheumatic diseases refractory to treatment. Besides the consultant's recommendation, the assistant doctor has the final decision about the referral. Chi-square test was used for statistical analysis.

Results: A total of 7715 teleconsultations were eligible for analysis after excluding 39 cases with incomplete data. The most frequent diagnostic hypotheses generated during teleconsultations were rheumatoid arthritis (RA), non-specific arthralgia/arthritis, and systemic lupus erythematosus (Table 1). Fibromyalgia, gout, and osteoarthritis were other diagnostic hypotheses commonly considered. Almost one-third (n=2219; 29% of total consultations) of the discussions referred to patients already waiting for rheumatology consultation, and teleconsulting replaced the in-person specialist evaluation in 32% (n=722) of these cases. Of the 5496 that were not waitlisted, 1369 (24.9%) were referred after teleconsulting. In total, 54.9% of the teleconsultations decided that the patients could be adequately managed in the PHC. The Figure 1 describes the utilization pattern of the rheumatology teleconsulting service during the time frame of this study. The utilization of the teleconsulting service increased significantly, and the proportion of patients referred to in-person rheumatology consultations reduced over the last years (P<0.001).

Table 1.

Diagnostic hypotheses formulated after teleconsulting, n=7715 (%)	
Rheumatoid arthritis	1665 (21.6%)
Undifferentiated arthralgia/arthritis	1298 (16.8%)
Systemic lupus erythematosus	830 (10.8%)
Fibromyalgia	570 (7.4%)
Laboratory test	547 (7%)
Gout	466 (6%)
Spondylarthritis	432 (5.6%)
Osteoarthritis	326 (4.2%)
Other connective tissue disease	431 (5.6%)
Other soft tissue diseases	396 (4.5%)
Osteoporosis	153 (1.9%)
Others	601 (7,7%)

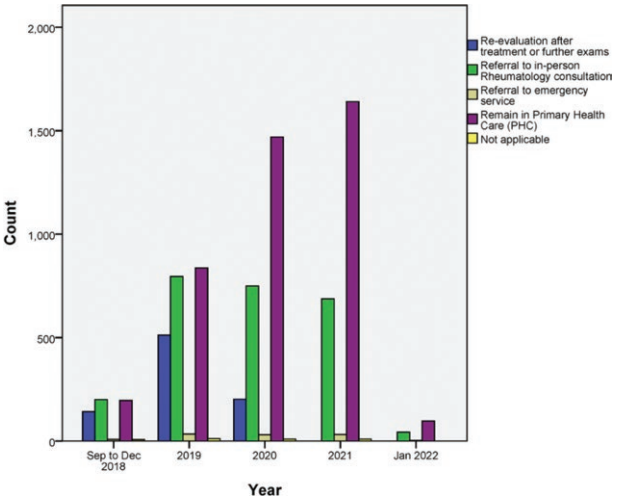

Figure 1.

Conclusion: Prevalent rheumatic diseases, especially RA, are frequent reasons for using teleconsulting support in our country. According to our study, after guidance, the PHC physician was considered able to manage most cases in rheumatology. This reduced the waiting list by approximately one-third. There was a progressive increase in teleconsultations over the years, but the proportion of patients referred to rheumatology reduced over time.

HPR Professional education, training and competencies

POS1205-HPR **PRESCRIBING TRENDS OF METHOTREXATE IN RHEUMATOID ARTHRITIS: A TUNISIAN SURVEY**

Keywords: Disease-modifying drug (DMARDs), Rheumatoid arthritis

F. Alia[1], O. Hamdi[1], S. Miladi[1], M. Yasmine[1], H. Boussaa[1], L. Souebni[1], K. Ouenniche[1], S. Chekili[1], S. Kassab[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia*

Background: Methotrexate (MTX) remains the first line disease modifying antirheumatic drug (DMARD) in the course of treatment for rheumatoid arthritis (RA). There are wide variations in prescribing pattern among rheumatologists.

Objectives: We aimed to determine the prescribing practices of MTX by Tunisian rheumatologists.

Methods: We conducted a cross-sectional study including Tunisian rheumatologists. An online survey composed of 18 questions via Google Drive Forms was designed to analyse the prescription trends of MTX in RA patients.

Results: The online questionnaire was sent to 184 rheumatologists, 66 of whom (35.8%) responded. The majority of rheumatologists initiated MTX at therapeutic doses: 10 mg/week (34.8%) and 15 mg/week (36.3%). Ninety-eight percent of rheumatologists preferred the oral route during the initiation of MTX. Fifty-nine percent of rheumatologists advised their patients to take MTX on an empty stomach. Doctors preferred injectable MTX in case of digestive intolerance (96.9%) or in case of lack of efficacy (48.4%). Regarding the MTX escalation strategy, the majority of rheumatologists followed a conventional strategy with an increase in doses in steps of 2.5 mg (65%) and 5 mg (35%) every 02 (16.6%) to 04 (42.4%) weeks. The optimal dosage of MTX was reached after 08 and 12 weeks in 27.2% and 59% of cases, respectively. Sixty-eight percent of rheumatologists split doses of MTX, 60% of whom from a dose of 15 mg/week. The time interval between the two doses was 06 (27.2%) to 12 hours (27.2%). All rheumatologists systematically associated folic acid with MTX. The average dose of folic acid prescribed was 10 mg/week (72.7%). The doctors questioned advised patients to take acid folic 48 hours after MTX 51.5%. The maximum dose of MTX prescribed by rheumatologists before switching to biological (b) DMARDs was 20 mg/week (60.6%). In case of use of bDMARDs, 63.6% of doctors decreased the dose of MTX to 10 mg/week. Once remission is reached, 34.8% of doctors continued MTX at the same dose while 62% of them gradually reduced the dose (decrease of 2.5mg every 02 weeks in 27.2% of cases and 5 mg every 08 weeks in 34.8% of cases).

Conclusion: Our study showed that the majority of Tunisian rheumatologists prescribe MTX according to international recommendations. Indeed, the current therapeutic strategy for RA encourages powerful and effective treatment early in the course of the disease.

SARCOPENIA IS A MARKER OF MUSCLE DAMAGE ASSOCIATED WITH DISEASE SEVERITY AND DISABILITY IN PATIENTS WITH INFLAMMATORY MYOPATHIES

Keywords: Biomarkers, Myositis, Sarcopenia

M. Giannini[1], A. L. Charles[2], L. Debrut[2], F. Goupilleau[2], J. Blaess[3], R. M. Javier[4], B. Geny[5], A. Meyer[6]. *[1]University of Strasbourg, Service de Physiologie et explorations fonctionnelles, CHU, Strasbourg; Centre de Référence des Maladies Autoimmunes Rares, CHU, Strasbourg; UR3072, Centre de Recherche en Biomédecine, Université de Strasbourg, Strasbourg, France*; *[2]University of Strasbourg, UR3072 Centre de Recherche en Biomédecine, Université de Strasbourg, Strasbourg, France*; *[3]University Hospital of Strasbourg, Service de Physiologie et explorations fonctionnelles, CHU, Strasbourg; Centre de Référence des Maladies Autoimmunes Rares, CHU, Strasbourg, Strasbourg, France*; *[4]University Hospital of Strasbourg, Service de Rhumatologie, Centre de Référence des Maladies Autoimmunes Rares, CHU Strasbourg, Strasbourg, France*; *[5]University of Strasbourg, Service de Physiologie et explorations fonctionnelles, CHU, Strasbourg; UR3072 Centre de Recherche en Biomédecine, Université de Strasbourg, Strasbourg, France*; *[6]University of Strasbourg, Service de Physiologie et explorations fonctionnelles, CHU, Strasbourg; Service de Rhumatologie, Centre de Référence des Maladies Autoimmunes Rares, CHU, Strasbourg; UR3072, Centre de Recherche en Biomédecine, Université de Strasbourg, Strasbourg, France*

Background: Inflammatory myopathies (IM) are autoimmune diseases characterized by muscle inflammation and weakness. Damage is a prognostic factor in IM, but its assessment in daily clinical practice represents an unmet need.
In other settings than IM, a low muscle mass and strength (referred as sarcopenia) have been linked with disability, decreased quality of life and increased mortality. Sarcopenia has never been studied in IM.
Objectives: To determine the prevalence and clinical significance of low muscle mass, strength and sarcopenia in inactive or low-activity IM.
Methods: Adult IM patients according to 2017 ACR/EULAR classification criteria with disease duration ≥12 months, creatine kinase (CK) serum level <500 U/l, >6-month stable medication and Physician Global Activity ≤3/10 were prospectively enrolled. Healthy age and sex-matched volunteers were enrolled as controls. Activity and damage were assessed according to the IMACS scores. Appendicular lean mass (ALM) and strength were measured by dual-energy X-ray absorptiometry (DXA), hand-held dynamometer and manual muscle testing (MMT). Physical performance, disability, respiratory volumes and maximum inspiratory (Pimax) and expiratory pressures (Pemax) were assessed. Sarcopenia was diagnosed according to the EWGSOP consensus[1]. Several myokines were measured in the blood.
Results: Forty IM patients (27 females, 68%) with an average age of 59.9 years (±14) and 30 healthy age and sex-matched volunteers (19 females, 63%) were prospectively enrolled. Eight patients suffered from dermatomyositis (DM), twelve from immune-mediated necrotizing myopathy (IMNM), eleven from anti-synthetase syndrome (ASS), nine from scleromyositis (SM) since 4.6 years (2.9 - 8.4). At the enrolment, MMT-8 was 140/150 (135.3-147), MMT-12 was 213/220 (203.3-216.8), CK were 122 U/l (87.5-195.5). ALM correlated with MMT-8 (r=0.4, p=0.01), MMT-12 (r=0.5, p=0.004), grip strength (r=0.3, p=0.05), 6-minute walking distance (6mWD) (r=0.6, p=0.0002), time to drink a 20 centilitre cup (r=-0.5, p=0.001), vital capacity (r=0.5, p=0.02), Pimax (r=0.6, p=0.03) and Pemax (r=0.6, p=0.04), severity (r=-0.5, p=0.003), extension (r=-0.4, p=0.007) and global (r=-0.6, p=0.0001) damage. Grip strength correlated with MMT-8 (r=0.5, p=0.003), MMT-12 (r=0.4, p=0.005), ALM (r=0.3, p=0.05), 6mWD (r=0.4, p=0.02), global damage (r=-0.4, p=0.008), HAQ score (r=-0.3, p=0.04). Seven out of forty myositis patients (17.5%) were sarcopenic (vs 0% in the control group). They suffered from IMNM (57% vs 24%), DM (29% vs 18%) and SM (14% vs 24%). No patient suffered from ASS (0% vs 33%). Sarcopenic patients had history of severe muscle involvement: loss of walking ability (vs 21%, p=0.0002), higher maximum CK values (5998 U/l (3488-6500) vs 1636 (626-5000), p=0.07), respiratory muscles impairment (29% vs 3%, p=0.02) and myocarditis (43% vs 3%, p=0.001); and they more frequently required intravenous immunoglobulins (86% vs 33%, p=0.03), plasmapheresis (29% vs 3%, p=0.02) and/or unconventional immunosuppressants (57% vs 27% p=0.1). By contrast, extramuscular involvements were less frequent (43% vs 76%, p=0.08). None of sarcopenic patients had inflammatory joint involvement during the follow-up (0% vs 49%, p=0.02). At the time of evaluation, sarcopenic patients had lower MMT-8 (131/150 vs 142/150, p=0.004) and MMT-12: 199/220 vs 215/220, p=0.004), reduced 6mWD (196 (±80) vs 478 (±89) meters, p<0.0001) and HAQ score (2.1 (1.2-2.8) vs 0.6 (0.3-1), p=0.0008).
Irisin and secreted protein acidic and rich in cysteine serum levels were lower in sarcopenic compared to non-sarcopenic patients (respectively p=0.008, p=0.001).
Conclusion: Muscle mass measurement by DXA and muscle strength measurement by hand held dynamometer are simple and relevant tools to assess muscle damage in IM. Sarcopenia is frequent in patients with inactive or low-activity IM. It is associated with important skeletal damage, poor function and disability.

Background: Interferon (IFN) dysregulation is a key feature in the pathogenesis of dermatomyositis (DM). PF-06823859 is a potent, selective, humanised immunoglobulin 1-neutralising monoclonal antibody (mAb) directed against human IFNβ.
Objectives: To examine the efficacy and safety of IFNβ blockade with PF-06823859 in adult patients with muscle-predominant moderate-to-severe DM.
Methods: This DM cohort within the Phase 2 study randomised patients with DM with moderate-to-severe muscle disease activity to PF-06823859 600 mg or placebo (1:1) for 12 weeks. Patients were required to meet one of the following inclusion criteria: (1) Manual Muscle Testing (MMT-8) ≤136/150 and Physician Global Assessment (PhGA) ≥3 cm on a 0–10 cm visual analogue scale (VAS) or (2) the sum of PhGA, Patient Global Assessment (PtGA), extramuscular global assessment ≥10 cm (using 0–10 cm VAS for each), with refractory disease, defined as failure of at least two or more adequate courses of an immunosuppressive or immunomodulatory agent, including intravenous immunoglobulin. Endpoints included clinical efficacy assessments (mean Total Improvement Score [TIS], mean change from baseline [CFB] in MMT-8, and mean CFB in PhGA), patient-reported outcomes (mean CFB in PtGA and mean CFB in Health Assessment Questionnaire Disability Index [HAQ-DI]), muscle enzyme levels (mean CFB in creatine kinase [CK]), mean CFB in extra muscular activity, and safety and tolerability at Week 12.
Results: All 18 randomised patients completed the 12-week treatment. The least squares mean (LSM) TIS showed numerical advantage of PF-06823859 600 mg versus placebo with increasing trends over time (4–12 weeks) and no plateau at Week 12. The LSM (90% confidence interval [CI]) TIS at Week 12 for PF-06823859 600 mg and placebo were 56.4 (41.4, 71.4) and 36.9 (22.0, 52.0), respectively, with a placebo-adjusted difference of 19.4 (-1.8, 40.7). Sensitivity analyses, excluding a single efficacy observation for a placebo recipient who received prohibited concomitant medications, reached nominal statistical significance (p=0.0497). At Week 12, PF-06823859 600 mg had numerically better efficacy scores than placebo across other key muscle function endpoints (estimated mean [90% CI] CFB in MMT-8 21.2 [11.9, 30.6] for PF-06823859 600 mg and 11.7 [2.3, 21.0] for placebo; in PhGA -3.40 [-4.9, -1.9] for PF-06823859 600 mg and -2.05 [-3.56, -0.55] for placebo; in PtGA -4.6 [-5.9, -3.4] for PF-06823859 600 mg and -1.2 [-2.4, 0.1] for placebo; in HAQ-DI -0.54 [-0.87, -0.22] for PF-06823859 600 mg and -0.03 [-0.38, 0.32] for placebo; in CK -185.8 [-273.9, -97.6] for PF-06823859 600 mg and -39.9 [-125.7, 46.0] for placebo; in extra muscular activity -2.81 [-3.87, -1.76] for PF-06823859 600 mg and -1.62 [-2.68, -0.56] for placebo. The mean (90% CI) placebo-adjusted differences in CFB for MMT-8, PtGA and CK were 9.6 (-3.8, 23.0), -34.5 (-52.7, -16.2) and -145.9 (-269.4, -22.4), respectively, with nominal statistical significance for PtGA (p=0.0046) and CK (p=0.0282). Treatment-emergent adverse events (TEAEs) were similar between

the PF-06823859 and placebo groups, and mostly mild in severity. The most common TEAEs were gastrointestinal disorders. There were no cases of herpes zoster or herpes simplex.

Conclusion: Anti-IFNβ mAb PF-06823859 was generally safe and well tolerated, improved clinical parameters (TIS, MMT-8, PhGA), patient-reported outcomes (PtGA, HAQ-DI), extra muscular activity and significantly decreased muscle enzyme levels (CK) in patients with muscle-predominant refractory moderate-to-severe DM.

INCIDENCE, PREVALENCE & MORTALITY IN IDIOPATHIC INFLAMMATORY MYOPATHIES & ASSOCIATED INTERSTITIAL LUNG DISEASE IN ENGLAND: A NATIONAL COHORT USING ROUTINELY COLLECTED ADMINISTRATIVE DATA

Keywords: Lungs, Epidemiology, Myositis

J. Hannah[1,2,3], F. Pearce[3,4,5], M. Odingo[3,4], M. Rutter[3,4,5], J. Aston[3], J. Lai[6], M. Grainge[4], S. Mcphail[6], P. Lanyon[3,4,5], M. Bythell[3], J. Galloway[1,2], P. Gordon[1,2].
[1]King's College Hospitals NHS Trust, Department of Rheumatology, London, United Kingdom; *[2]King's College London, Department of Academic Rheumatology, London, United Kingdom*; *[3]National Disease Registration Service, NHS Digital, National Congenital Anomaly and Rare Disease Registration Service, United Kingdom*; *[4]School of Medicine, University of Nottingham, Department of Lifespan and Population Health, Nottingham, United Kingdom*; *[5]Nottingham University Hospitals NHS Trust, Department of Rheumatology, Nottingham, United Kingdom*; *[6]National Disease Registration Service, NHS Digital, National Cancer Registration and Analysis Service, United Kingdom*

Background: Ethnicity, sex, age & socioeconomic deprivation can all lead to health inequity. Impact of these factors in epidemiology of Idiopathic Inflammatory Myopathies (IIM) has not been widely researched.

Objectives: In collaboration with National Congenital Anomaly & Rare Disease Registration Service (NCARDRS), we described national incidence, prevalence & mortality in IIM and associated Interstitial Lung Disease (IIM-ILD) according to demographics.

Methods: Hospital Episode Statistics (HES) collected at every NHS hospital admission in England, were used to create a national cohort of patients with IIM & IIM-ILD associated ICD-10 codes between 2006-2022. Cases were identified according to pre-validated methods.[1] Age, sex, ethnicity, Index of Multiple Deprivation (IMD) and death certification were collated. Denominator populations were extracted from Office of National Statistics publications. Incidence rates were calculated by multivariate Poisson regression, standardized mortality ratio (SMR) by indirect standardization, and survival analysis by multivariate Cox models. Incidence Rate Ratios (IRR) were mutually adjusted for age, sex & IMD (Ethnicity IRR was not adjusted for IMD due to lack of suitable denominator data). Cox models were adjusted for age, sex, ethnicity, IMD and ILD status.

Results: 14,891 incident IIM cases were identified giving an incidence rate of 1.72/100,000 person-years. Point prevalence was 17.9/100,000 in 2022. Mean age was 59.7 years with incidence peaking at 70-80 years. Multivariate models (Table 1) showed IIM incidence was higher in females IRR 1.30 (95%CI 1.25, 1.34), but mortality was lower (hazard ratio (HR) 0.78 (95%CI 0.74, 0.82)). Incidence was higher in Asian and Black ethnicities than White (IRR 1.56 and 2.77 respectively). Mortality was higher in White ethnicity (Asian HR 0.80 and Black HR 0.78). The most deprived population quintile had similar incidence IRR 1.06 (95%CI 1.02, 1.11), but higher mortality HR 1.34 (95%CI 1.25, 1.44) than less deprived populations. 17.2% of IIM cases had ILD. Incidence of IIM-ILD did not vary largely by socioeconomic deprivation, but incidence was substantially higher in Black, Other and Asian populations compared to White (IRR 5.11, 4.07, 2.48). Mortality of IIM-ILD was also lower in Asian HR 0.76 (95%CI 0.61, 0.95) and Black HR 0.73 (95%CI 0.57, 0.93) patients. SMR was 5.13 for IIM and 7.92 for IIM-ILD. Crude mortality increases with age, but standardized mortality is highest in younger patients with ILD. (Graph). Death certification was available in 7,159 cases. IIM was recognized as a contributory factor in 39%, and ILD in 10.6%. Malignancy was the most reported 'underlying cause of death' (24.7%), then cardiovascular disease (19.9%) and respiratory disease (15.8%). Asian and Black ethnicities were less likely to have malignancy mentioned on death certificates (IRR 0.48 and 0.61 respectively).

Table 1.

	Adjusted IRR (95%CI)		Adjusted mortality HR (95% CI)	
	IIM	IIM-ILD	IIM	IIM-ILD
Male	-	-	-	-
Female	1.30 (1.25, 1.34)	1.73 (1.60, 1.88)	0.78 (0.74, 0.82)	0.79 (0.70, 0.89)
IMD 1 (most deprived)	1.06 (1.02, 1.11)	1.04 (0.94, 1.15)	1.34 (1.25, 1.44)	1.37 (1.17, 1.61)
IMD 2-5	-	-	-	-
White	-	-	-	-
Asian	1.56 (1.47-1.66)	2.48 (2.19, 2.81)	0.80 (0.71, 0.91)	0.76 (0.61, 0.95)
Black	2.77 (2.59-2.96)	5.11 (4.51, 5.79)	0.78 (0.67, 0.90)	0.73 (0.57, 0.93)
Mixed	0.96 (0.82-1.14)	1.28 (0.89, 1.86)	0.81 (0.53, 1.23)	0.95 (0.42, 2.13)
Other	2.97 (2.63-3.35)	4.07 (3.16, 5.25)	0.79 (0.61, 1.02)	0.84 (0.54, 1.30)

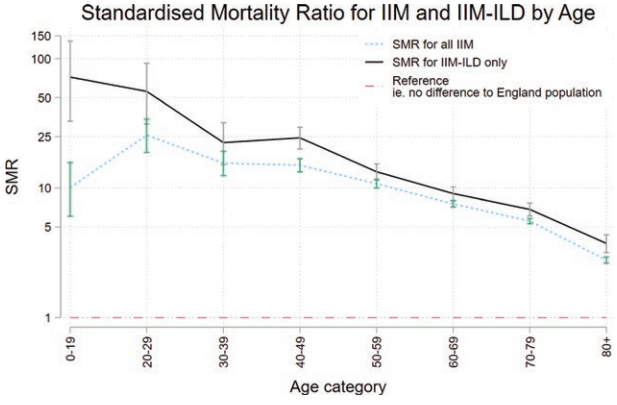

Figure 1.

Conclusion: We have defined national incidence, prevalence and SMR estimates for IIM and IIM-ILD. Incidence is higher in females, Black, Asian and Other ethnicities. Mortality is higher in White ethnicities, increased deprivation and males. Increased mortality in White ethnicities may partially relate to increased malignancy-associated disease.

POS1209 INTERNET-BASED ENROLLMENT OF A MYOSITIS PATIENT COHORT

Keywords: Telemedicine, Myositis

R. Lomanto Silva[1], S. Moghadam-Kia[2], S. Keret[3], C. V. Oddis[2], R. Aggarwal[2]. [1]*UPMC Internal Medicine/Pediatrics Residency Training Program, Internal Medicine, Pittsburgh, United States of America*; [2]*University of Pittsburgh, Rheumatology, Pittsburgh, United States of America*; [3]*Bnai Zion Medical Center /וויצ ינב יאופרה זכרמה, Rheumatology, Haifa, Israel*

Background: Recruitment for myositis clinical research is challenging, due to the rarity of the disease and geographic considerations. Remote enrollment using digital health technologies, social media, and tele-medicine provide researchers with more optimal recruitment options. (1)
Objectives: To assess the effectiveness of various remote recruitment strategies in myositis patients.
Methods: "Myositis Patient Centered Tele-Research" (MyPacer) is an NIH-funded multi-center observational study assessing the feasibility, efficiency and acceptability of virtual research in myositis. Subjects were recruited from anywhere in the United States (U.S.) via online strategies: a) Patient organizations (e.g. The Myositis Association [TMA], Myositis Support and Understanding [MSU], etc.) posted a study link on their website, emailed members, and posted on social media; b) Targeted advertisements were posted on Google, Facebook and Twitter; c) Myositis physicians were emailed with a request to refer patients. Interested subjects reviewed study details, e-consented and enrolled via the study mobile application (app) or website. Adult patients who fulfilled self-reported eligibility criteria were enrolled (after physician verification of polymyositis [PM], necrotizing myositis [NM], or dermatomyositis [DM] and fulfillment of at least 4/6 disease criteria for PM/NM, or 3/6 for DM). Disease criteria included: muscle weakness, elevated CK, compatible EMG or biopsy (muscle or skin), DM rash, or a positive myositis associated auto-antibody. The diagnosis and disease criteria were confirmed by a physician via chart review.
Results: In 6 months, 94 participants were enrolled [71 (75.5%) females, median age of 54 years (SD +/- 13.9), and 76 (80.9%) White, 9 (9.6%) Black, and 3 (3.2%) Asian]. The most common diagnosis was DM (46, 48.9%), then PM (35, 36.2%), NM (7, 7.5%), and unspecified myositis (6, 6.4%). Primary myositis doctors were rheumatologists (80, 85.1%), neurologists (10, 10.6%), or dermatologists (2, 2.1%). We enrolled subjects from 30 states and 5 regions in the U.S., with higher participation from Virginia (n=13; 13.8%), Pennsylvania (n=11; 11.7%), Florida (n=8;8.5%), and California (n=7; 7.4%). Among the main recruitment sources, TMA was responsible for 63 (67%) participants, MSU for 20 (21.3%), and doctor referral for 9 (9.6%). Other recruitment sources (n=53; 56.4%) included 18 (19.1%) via Facebook, 6 (6.4%) via study website, 2 (2.1%) via Twitter, and 1 (1%) via Google advertisements. Participants recruited via Facebook were younger than those recruited via email (mean ages 47.39, SD +/- 10.66 and 56.59, SD +/- 13.63 respectively; 95% CI 2.15-16.25; p=0.01). For enrollment method, 62 (66%) individuals used the study app, and 32 (34%) used the study website. The app was the preferred method throughout the country, except in the Southeast where 51.7% of participants used the study website. The mean age of app and website users was 51.79 (SD +/- 12.43) and 60.12 (SD +/- 14.23) years, respectively (95% CI 2.68-13.98; p=0.004).
Conclusion: Online recruitment is a viable alternative for maximizing potential recruitment in myositis clinical studies. We remotely enrolled patients from every region in the U.S. Patient support organizations were very successful in augmenting recruitment. Moreover, Facebook was responsible for almost 20% of participants, especially within the younger (ages 30 to 66) population. Our study app appeared quite functional with 66% use of the enrolled subjects and a clear favorite in younger individuals compared to website use. We hope these findings will guide future online myositis studies and advance clinical research.

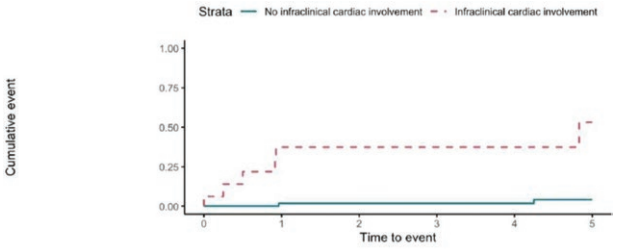
POS1210 PATIENTS WITH SUBCLINICAL HEART INVOLVEMENT AT DIAGNOSIS OF MYOSITIS ARE MORE LIKELY TO PRESENT CARDIOVASCULAR EVENTS THAN PATIENTS WITHOUT CARDIAC INVOLVEMENT IN A MONOCENTRIC RETROSPECTIVE STUDY



Keywords: Heart, Myositis

C. Kasser[1], A. F. Guedon[1], A. Mekinian[1]. [1]*Hospital Saint-Antoine Ap-Hp, Internal Medicine, Paris, France*

Background: Idiopathic inflammatory myositis (IIM) is a group of rare and heterogeneous systemic diseases characterized by clinical muscle weakness and histological inflammation in skeletal muscles. Myositis classification distinguishes dermatomyositis (DM), inclusion body myositis (IBM), immune-mediated necrotizing myopathy (IMNM), anti synthetase syndrome (ASSD) and overlap myositis (OM) [1-2]. Patients with myositis are more likely to die younger than in general population [3]. Cardiovascular events (CVE) are one of the main causes of death during the disease's course [4].
Objectives: To investigate the occurrence of CVE and their link with features of cardiac involvement in a French myositis population.
Methods: We conducted a retrospective observational cohort study of patients with a diagnosis of DM, ASSD, IBM, IMNM or OM, from the department of internal medicine in Saint Antoine's hospital, Paris, France, between 1992 and 2020. Demographic and clinical data were collected at diagnosis, at the last follow up visit, and at the first CVE if one happened. Subclinical heart involvement was defined by electrocardiogram abnormality, transthoracic echocardiography abnormality or cardiac MRI abnormality. CVE were defined by the occurrence during the follow up of heart failure, inflammatory myocarditis or admission in resuscitation department. Descriptive, bivariate and survival analysis were performed.
Results: Among the 78 patients included, 52 (67%) were women. Thirty three patients (42%) had a DM, 18 (23%) an ASSD, 12 (15%) an OM, 11 (14%) an IMNM and 4 patients (5%) an IBM. Mean age at diagnosis was 49 years. Median follow up time was 72 months. Subclinical involvement was present at diagnosis for 17 (22%) patients; and 14 (21%) patients presented a CVE during the follow up period. Patients with subclinical cardiac involvement at diagnosis were more likely to present a CVE than patients without subclinical cardiac involvement. Three years after the diagnosis, 7 CVE occurred in the subclinical cardiac involvement group (event rate 37.5%; 95% CI 4.92-58.92) and only 1 CVE occurred in the no cardiac involvement group (event rate 1.89%; 95% CI 0-5.48). Time to CVE was significantly different between groups (log rank test p < 0,001, Graph 1). This difference remains significant at 5 years after myositis diagnosis.
Conclusion: Patients with subclinical cardiac involvement at myositis diagnosis are more likely to present CVE in the first 5 years of disease than patients without subclinical cardiac involvement. Clinical cardiac involvement is rare at diagnostic, but subclinical cardiac involvement seems to be a more frequent condition. Our results suggest that we should pay more attention to patient with subclinical cardiac involvement at myositis diagnosis, especially in the first years of the disease's course.

POS1211 CHARACTERISTICS OF MYOCARDIAL INVOLVEMENT OF POLYMYOSITIS/DERMATOMYOSITIS EVALUATED BY CARDIAC MAGNETIC RESONANCE: A PILOT STUDY

Keywords: Biomarkers, Imaging, Myositis

S. Asatani[1], M. Tsukamoto[1], A. Yamada[2], H. Kobayashi[1], K. Sugito[1], Y. Okumura[2], H. Nakamura[1], N. Kitamura[1]. *[1]Nihon University School of Medicine, Division of Hematology and Rheumatology, Department of Medicine, Itabashi-ku, Tokyo, Japan*; *[2]Nihon University School of Medicine, Division of Cardiology, Department of Medicine, Itabashi-ku, Tokyo, Japan*

Background: Polymyositis (PM) and dermatomyositis (DM) are autoimmune systemic diseases characterized by muscle weakness and inflammatory cell infiltration into skeletal muscle. Myocardial involvement is a common cause of death in PM/DM. It has been reported that myocardial involvement is observed in 9% to 72% of PM/DM [1], but it is still unclear. Electrocardiogram (ECG) and echocardiography are the most often used tests to evaluate cardiac abnormalities, but early detection of myocardial involvement in PM/DM is difficult. Cardiac magnetic resonance (CMR) is a noninvasive technique that has been efficiently evaluated in early myocarditis [2]. Late gadolinium enhancement (LGE) imaging evaluated at T1 remains one of the most important MRI techniques in the setting of suspected myocarditis [3], and the presence of LGE denotes tissue inflammation, necrosis, and early fibrosis [4,5]. Contrast-enhanced T1 mapping can calculate extracellular volume (ECV) fraction and is used for evaluation of myocardial fibrosis and scar [6]. T2 mapping is used for the evaluation of myocardial edema in association with myocardial inflammation [7]. T1, T2 and ECV are elevated in the setting of myocardial lesions. However, the evaluation of myocardial involvement in PM/DM by CMR still remains unclear and warrants investigation.
Objectives: This study aimed to investigate characteristics of myocardial involvement evaluated by CMR, and identify the clinical markers indicating the presence of cardiac complications in PM/DM.
Methods: PM/DM patients who visited our service between January 2014 to September 2022 were enrolled in this retrospective study. All patients met the 2017 EULAR/ACR classification criteria for idiopathic inflammatory myopathies, and patients with several elevated cardiac markers were included. Patients were excluded if they were complicated with other connective tissue diseases and cardiovascular diseases at the diagnosis of PM/DM. All patients performed ECG, echocardiography and CMR. Clinical and findings of CMR information were collected and statistically analyzed. The findings of CMR, such as T1, T2, LGE and ECV, were also analyzed.
Results: Twelve patients (3 patients with PM and 9 patients with DM) were enrolled in this study. ECG and echocardiography did not detect any abnormalities associated with PM/DM. However, in CMR, abnormalities indicating myocardial involvement were identified in 6 (3 patients with PM and 3 patients with DM) patients: 66.6% of patients had LGE, all patients had elevated ECV, and 33.3% of patients had elevated T2. Serum myoglobin levels were significantly elevated in patients with myocardial involvement (814.5±124.7 ng/mL vs 324.8±151.0 ng/mL, p=0.031). There were no significant differences in other cardiac markers, including serum CK, CK-MB and NT-pro-BNP, between with and without myocardial involvement. The following items were extracted as possible items for the presence of myocardial involvement: being PM (p=0.003) and anti-ARS antibodies positive (p=0.049).
Conclusion: Our results propose that myocardial involvement is more likely to develop in PM/DM patients even if the finding of echocardiography is normal. In addition, CMR should be performed in cases of PM/DM with high myoglobin levels, considering the possibility of myocardial involvement.

POS1212 SERIAL IMAGING CHANGES IN SKELETAL MUSCLE COMPOSITION AND THEIR ASSOCIATION WITH CLINICAL OUTCOMES IN IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Outcome measures, Myositis, Imaging

M. Gorijavolu[1], C. Kavadichanda[1], R. Ananthakrishnan[2], C. Mariaselvam[1], M. M. Thabah[1], V. S. Negi[3]. *[1]Jawaharlal Institute of Postgraduate Medical Education and Research, Clinical Immunology and Rheumatology, Puducherry, India*; *[2]Jawaharlal Institute of Postgraduate Medical Education and Research, Radiology, Puducherry, India*; *[3]All India Institute of Medical Sciences, Executive Director, Bilaspur, India*

Background: Muscle weakness in inflammatory myopathies (IIM) is due to muscle-edema, atrophy and fatty-infiltration among which edema is the predominant cause at baseline. Some IIM pateints donot achieve full muscle power even with immunosupressive treatment which mainly targets edema. Serial changes occuring in skeletal muscles visualized on thigh MRI can help understand the failure of complete recovery. Role of Dual energy X-ray Absorptiometry (DXA) assessed skeletal muscle compositon as outcome measure in IIM was not studied previously.
Objectives: To see the changes in skeletal muscle composition over 6 months in IIM patients using imaging and to assess the agreement of MRI and DXA scores with each other and with clinical outcome measures.
Methods: Patients satisfying 2017 ACR-EULAR classification criteria for IIM were prospectively enrolled. All patients underwent thigh MRI(t-MRI) STIR and T1 weighted sequences (axial and coronal) at baseline, 3 and 6 months and DXA scan at baseline and 6 months. Manual muscle testing-8(MMT-8), Functional index-3(FI-3), 2-minute walk distance (2MWD) were assessed at baseline, 3 and 6 months. t-MRI was scored using a semi-quantitative score for muscle edema, fascial edema, muscle atrophy and fatty infiltration. Friedman test was used to compare variables at baseline, 3 and 6 months and Spearman correlation was done for agreement of MRI and DXA scores with each other and clinical outcome measures.
Results: 17 patients (12 females) were enrolled and all of them completed 3 months follow-up while only 13 completed 6 months follow-up. Median (IQR) age was 38 (27-46) years, disease duration was 6 (2-24). The study group comprised of 10 dermatomyositis, 5 antisynthetase syndrome and 3 immune mediated necrotizing myopathy patients. MRI assessed muscle edema and fascial edema decreased significantly ($p<0.01$) and fatty infiltration increased significantly ($p=0.001$) from baseline to 3 months. Muscle atrophy did not change significantly from baseline to 3 months and 6 months. DXA assessed appendicular lean mass/ht^2($p=0.007$) and total lean mass/ht^2($p=0.021$) improved significantly from baseline to 6 months. Improvement in MMT-8 and 2MWD was significant only from baseline to 3 months($p=0.000$) whereas FI-3 continued to improve till 6 months($p=0.000$) (Table 1). At baseline MMT-8($R=-0.631$; $p<0.01$), FI-3($R=-0.698$; $p<0.01$) and 2MWD ($R=-0.485$; $p<0.05$) negatively correlated with only muscle edema. At 3 months MMT-8 and 2MWD (R1, R2) negatively correlated with muscle edema (R1=-0.673, R2=-0.591), atrophy (R1=-0.732, R2=-0.577) and fatty infiltration (R1=-0.575, R2=-0.743; $p<0.05$). FI-3 negatively correlated with only atrophy ($R=-0.488$; $p<0.05$). MRI fatty infiltration score and atrophy score did not correlate with DXA assessed leg fat percentage and appendicular mass/ht2 respectively at baseline but had significant correlation ($p<0.05$) at 6 months (Figure 1).
Conclusion: In IIM, edema decreased and muscle strength increased significantly in first 3 months but fatty infiltration increased. DXA assessment of fat and lean mass did not agree with MRI atrophy and fatty infiltration at baseline probably due to concomitant muscle edema.

Table 1 : Serial change in t-MRI scores, DXA assessed lean mass and clinical outcome measures

	Baseline	3 months	6 months	P-value
Muscle edema	17.03(7.4-32.4) *	0.37(0.00-11.11) *	0.00(0.00-5.37)	**0.000**
Fascial edema	46.66(15.0-57.7) *	7.77(0.00-25.55) *	4.44(0.00-23.88)	**0.004**
Muscle atrophy	0.00(0.00-1.67)	0.00(0.00-2.22)	0.00(0.00-2.22)	0.670
Fatty infiltration	6.66(0.00-15.00) *	8.88(2.22-21.66) *	8.88(2.22-23.33)	**0.001**
Appendicular lean mass/Ht^2	5.5(3.9-6.2) *	-	5.6(4.8-7.3) *	**0.007**
Lean body mass/Ht^2	12.6(10.7-14.4) *	-	13.4(11.1-15.6) *	**0.021**
Manual Muscle Testing-8	56(51.5-70.5) *	78(71.50-80) *	78(76-80)	**0.000**
Functional Index-3	33.88(9.7-57.2) *	56.6(29.4-77.2) *	72.2(50-83.3) *	**0.000**
2-Minute Walking Distance	122(40-141) *	142(126.5-177) *	150(138-161)	**0.002**

*indicates significant change between 2 time points

RISK OF ATHEROSCLEROSIS-RELATED DISEASES IN ADULTS WITH POLYMYOSITIS AND DERMATOMYOSITIS: A LARGE SCALE POPULATION-BASED STUDY

Keywords: Myositis

L. Fisher[1], N. Ben-Shabat[1], O. Gendelman[1], K. Sharif[1,2], S. Ehrenberg[1], U. Shani[1], Y. S. Patt[1], A. Watad[1,3], H. Amital[1]. *[1]Sheba Medical Center, Tel-Hashomer, Israel. Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel., Department of Internal Medicine B & Zabludowicz Center for Autoimmune Diseases, Ramat gan, Israel*; *[2]Sheba Medical Center, Tel-Hashomer, Department of Gastroenterology, Ramat Gan, Israel*; *[3]Leeds Institute of Molecular Medicine, University of Leeds, Chapel Allerton Hospital, Leeds, UK, Section of Musculoskeletal Disease, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom*

Background: Select systemic autoimmune diseases show a predilection to Atherosclerotic and Cardiovascular Disease (ASCVD) largely attributed to proinflammatory cytokines supporting the role of the inflammatory hypothesis in endothelial dysfunction and subsequent clinical sequala. Dermatomyositis (DM) and polymyositis (PM) are polygenic autoimmune disorders involving mainly skeletal muscles. The association between DM/PM and ASCVD has not been well addressed and explored.
Objectives: To investigate the association between DM/PM and ASCVD events by exploring incidence, mortality, and interaction with respect to disease-modifying agents, autoantibodies, and traditional CVD risk factors in a large, population-based sample.
Methods: A retrospective cohort study using the electronic database of Clalit Health Services (CHS), the largest health organization in Israel. All DM and PM patients diagnosed between 2000-2016 were included with age- and sex-matched controls in a 1:5 ratio. Follow-up continued until the first diagnosis of ASCVD or death. The incidence of ASCVD was compared between the groups using univariate and multivariate models adjusting for baseline cardiovascular risk factors.
Results: The study population included 1,567 DM/PM patients and 7,676 controls. The mean age at the index date was 32.5 years (SD±19 years), and the female proportion was 60.3%, similar for both groups. Traditional cardiovascular risk factors were similar between both groups. Median follow-up time was 8.4 (3.6-12.8) in the PM/DM group compared to 8.6 (3.7-12.9) in the control group. 47 (3.0%) PM/DM patients were diagnosed with IHD compared to 140 (1.8%) controls, yielding an Unadjusted HR of 1.66 (1.19 to 2.30). Unadjusted HR for CVA in the PM/DM group was (95%CI) 2.76 (1.86 to 4.11). Unadjusted HR for ASCVD (95%CI) was 1.88 (1.46 to 2.43). APLA-associated antibody predicted ASCVD among PM/DM groups as compared to non-ASCVD PM and DM patients (OR- 2.33, 95% CI - 1.41 to 3.86, p<0.0001).
Conclusion: Our study demonstrates that PM and DM are both associated with an increased risk of MI and ischemic stroke. Furthermore, PM and DM patients positive for APLA-associated antibodies were associated with excessive rates of ASCVD. Taken together, these findings support the increased need for awareness and surveillance of cardiovascular outcomes in the DM/PM cohort.

PATIENT REPORTED OUTCOME FOR PHYSICAL FUNCTION IN IDIOPATHIC INFLAMMATORY MYOPATHY

Keywords: Patient reported outcomes, Myositis

S. Keret[1], R. Lomanto Silva[2], A. Sharma[3], T. Chandra[4], S. Moghadam-Kia[5], C. V. Oddis[5], R. Aggarwal[5]. *[1]Bnai Zion Medical Center, Rheumatology, Haifa, Israel*; *[2]University of Pittsburgh Medical Center, Internal Medicine, Pittsburgh, United States of America*; *[3]University of Pittsburgh Medical Center Mercy, Internal Medicine, Pittsburgh, United States of America*; *[4]Medstar Georgetown University Hospital, Rheumatology, Washington DC, United States of America*; *[5]University of Pittsburgh Medical Center, Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America*

Background: Patient-reported outcomes (PRO) measures provide direct and valuable information on treatment efficacy and quality of life. However, the commonly-used PRO measures in Idiopathic inflammatory myopathies (IIM) have several psychometric limitations. The Patient-Reported Outcomes Measurement Information System (PROMIS) is an NIH initiative, with several PROs developed and validated in different medical conditions.
Objectives: To (1) investigate the psychometric properties of PROMIS physical function-20 (PF-20) in a large US-wide IIM population, and (2) evaluate the feasibility and compliance of PRO measures administered in a local clinic compared to remote US-wide patients.
Methods: "Myositis Patient Centered Tele-Research" (My PACER) is a multi-center prospective 6-month observational study of U.S. IIM subjects, competitively recruited through traditional in-person clinic visits (Center-Based Cohort [CBC]), and remotely using smartphone technology, wearable devices, and

telemedicine principles (Tele-Research Cohort [TRC]). Data collection included baseline demographic and clinical parameters, PRO and other patient self-assessments at 6 monthly visits, including myositis core set measures (health assessment questionnaire [HAQ-DI], patient global disease activity), PROMIS PF-20, functional tests (six-minute walk, timed up-and-go [TUG] and sit-to-stand [STS] tests], and physical activity monitor. Physician-reported assessments including myositis core set measures (manual muscle testing [MMT], physician global disease activity, extra-muscular global disease activity, creatine kinase [CK]) were obtained at baseline and 6 months.

Results: 141 IIM patients were enrolled (94 TRC/47 CBC). Mean age was 55±13.4 years, female sex 106/141 (75.2%), and 113/141 (80.1%) Caucasians, with similar demographics between the two groups. 116 patients completed the PROMIS-PF form (79 (84%) and 37 (78.7%) in TRC vs. CBC group) with a mean of 6.6±1.7 vs. 6.3±1.5 times per patient (p=0.33) in TRC and CBC group, respectively. The PROMIS PF-20 score was not associated with age, gender or race. There was no difference between the mean PROMIS PF-20 score in the TRC and CBC groups (p=0.84). The mean PROMIS PF-20 score was 43.9 ± 9.5 in the whole cohort, with 26/116 (22.4%) with a mean t-score lower than 35, indicating severe functional limitation, which was similar between TRC and CBC groups. PROMIS PF-20 showed strong test-retest *reliability* with a high correlation when repeated at 1 month (r=0.94,p<0.0001). At baseline, PROMIS PF-20 was significantly associated with all core set measures except extra-muscular global and CK. In addition, PROMIS PF-20 was associated with myositis symptoms as well as functional tests and physical activity **(Table 1),** indicating good *validity.* Finally, absolute changes in the PROMIS-PF t-score (between the baseline and 6-month visit) were significantly associated with absolute changes in some of the core set measures as well as with the STS and physical activity.

Conclusion: PROMIS PF-20 demonstrates favorable psychometric properties in a large cohort of myositis patients, with similar compliance and results in patients recruited traditionally from clinics or remotely using social media and digital health technology.

Background: Viral infections are known triggers of disease flares in idiopathic inflammatory myopathies (IIMs). Reports of post-COVID-19 flares of IIMs have raised suspicion of a possible role of SARS-COV-2 in their onset [1,2]. However, despite rising flare rates in this vulnerable patient group during the pandemic, the risk factors for post-COVID-19 IIMs flares remain unknown [3,4].

Objectives: Disease flares among patients with idiopathic inflammatory myopathies (IIMs) can lead to significant disability, though are poorly explored in the post-COVID-19 period. We analysed risk factors for post-COVID-19 flares in a global sample of IIM patients in a subset analysis as part of the ongoing COVID-19 Vaccination in Autoimmune Diseases (COVAD) study.

Methods: A cross-sectional patient self-reporting survey was circulated by the international COVAD study group (157 collaborators, 106 countries) to patients with autoimmune diseases and healthy controls from February-June 2022. Data was collected on demographics, autoimmune disease details, treatment history, comorbidities, COVID-19 history and course and COVID-19 vaccination details. Patients with IIMs who flared post COVID-19 were compared to those who did not using the χ^2 test, factors found significant in univariate analysis and deemed clinically important, underwent multivariable analysis (binary logistic regression using the Enter method) with adjustment for age, gender, ethnicity, vaccine type, immunosuppression, autoimmune and non-autoimmune comorbidities, COVID-19 antibody status, and clinical symptoms of COVID-19. Statistical analyses were performed using IBM SPSS version 28.0, with statistical significance considered at p<0.05.

Results: 15,165 respondents completed the survey of whom 1,169 contracted COVID-19. Of these, 207 had IIMs [median (IQR) age 57.0 (47.0-67.0), 71% female, 74.4% Caucasian]. We noted with concern that nearly a third of patients with IIMs (63/207, 30.4%) reported experiencing a flare. A past medical history significant for Asthma, (34.9% vs 6.9%, multivariable OR: 7.1; 95%CI: 3.1-16.4, p<0.001) and specific clinical symptoms during COVID-19 including joint pains (multivariable OR: 6.05; 95%CI: 1.60-22.9, p=0.008), and difficulty in breathing (multivariable OR: 3.43; 95%CI: 1.09-10.8, p=0.036) were found to confer conferred a higher risk of flares (Table 1).

Table 1 Patient Reported Flares following COVID-19 infection among IIM patients

	Total IIMs (n=207)	IIMs with flare after COVID-19 (n=63)	IIMs without flare after COVID-19 (n=144)	OR (95%CI)	P
Age (median, IQR) years	57.0 (47.0-67.0)	53.0 (47.0-62.0)	59.0 (47.0-69.0)	-	0.024
Gender	60 (29.0)	7 (11.1)	53 (36.8)	0.2 (0.09-0.5)	<
Male	147 (71.0)	56 (88.9)	91 (63.2)		0.001
Female					
Comorbidities	32 (15.5)	22 (34.9)	10 (6.9)	7.1 (3.1-16.4)	<0.001
Asthma	31 (15.0)	11 (17.5)	20 (13.9)	1.3 (0.5-2.9)	00.508
ILD					
Clinical features in previous COVID-19 infection	134 (64.7)	52 (82.5)	82 (56.9)	3.5 (1.7-7.4)	<0.001
	94 (45.4)	44 (69.8)	50 (34.7)	4.3 (2.3-8.2)	<0.001
Fatigue	56 (27.1)	36 (57.1)	20 (13.9)	8.2 (4.1-16.4)	<0.001
Myalgia	41 (19.8)	27 (42.9)	14 (9.7)	6.9 (3.3-14.6)	<0.001
Arthralgia					
Difficulty in breathing					

Conclusion: We observed a high frequency of patients with IIM experiencing post-COVID-19 disease flares. A past history of Asthma and those with certain acute COVID-19 symptoms were at higher risk.

Background: Prevalence of comorbidities and their impact on health outcomes in Idiopathic inflammatory myopathies (IIMs) is limited.
Objectives: This study aimed to explore the prevalence of multimorbidity in patients with IIMs, other autoimmune rheumatic diseases (AIRDs) and Healthy controls (HCs). We further explore the impact of comorbidities on patients' physical, mental, and social health assessed by the Patient-Reported Outcome Measurement Information System (PROMIS instruments).
Methods: Data for this study were acquired from the COVAD 2 e-survey hosted by a study group consisting of 167 collaborators in 110 countries. Basic multimorbidity (BM) was defined as the co-occurrence of two or more comorbidities in an individual, while complex multimorbidity (CM) signified the co-occurrence of 3 or more chronic conditions affecting 3 or more different organ systems. PROMIS global physical health (PGP), mental health (PGM), fatigue 4a (F4a) and physical function short form (SF10) were analysed using descriptive statistics and linear regression models. Hierarchical Clustering on Principal Components was performed to outline the grouping.
Results: Of 10740 complete respondents, 1558 IIMs, 4591 AIRDs and 3652 HCs were analysed. Individuals with IIMs exhibited high burden of any comorbidity (OR: 1.62 vs AIRDs and 2.95 vs HCs,p<0.01), BM (OR 1.66 vs AIRDs and 3.52 vs HCs,p<0.01), CM (OR: 1.69 vs AIRDs and 6.23 vs HCs,p<0.01), and mental health disorders (MHDs) (OR 1.33 vs AIRDs and 2.63 vs HCs,p<0.01). IIM patients with comorbidities (and MHDs) had worse physical function (low PGP, PGM, SF10 and higher F4a scores, all p<0.001). Worse physical function (PGP) was predicted by age (0.35; 0.030), active disease (-1.51; <0.001), BM (-1.11; <0.001), and MHDs (-1.47; <0.001). PGM was impacted by age (0.51; 0.004), active disease (-1.34, <0.001), BM (-0.75; 0.001) and MHDs (-2.22; <0.001). Determinants of SF10a were age (-3.86; <0.001), active disease (-7.03, <0.001), female (2.85, <0.001), BM (-2.95; <0.001) and MHDs (-2.37; <0.001). Fatigue (F4a) was impacted by age (-0.96, <0.001), active disease (1.45, <0.001), country human development index (0.95; 0.036), BM (1.11; <0.001); and MHDs (2.17; <0.001). Four distinct clusters (Figure 1A, Table 1) were identified i.e., cluster 0: lower burden of comorbidities and good health status; cluster 1: older patients, whit higher burden of comorbidities and poor health status, cluster 2: patients with higher prevalence of MHDs, lower PGP and PGM; and higher F4a scores; and lastly Cluster 3 that comprised older patients with an average burden of comorbidities and overall good health status according to PROMIS scores. Dermatomyositis, anti-synthetase syndrome, necrotizing autoimmune myopathy were similarly represented in all clusters, whilst inclusion body myositis and polymyositis were more predominant in clusters 1 (40.6% and 17.2%) and 3 (32 % and 17.5%), while overlap myositis was more represented in cluster 2 (25.6%) and 0 (32.7%) (Figure 1B).

Table 1. Characteristics of clusters

	Cluster 0 (n. 219)	Cluster 1 (n.564)	Cluster 2 (n. 318)	Cluster 3 (n.422)
Female, n. (%)	189 (86.3)[a]	358 (63.5)[b]	288 (90.6) [a]	258 (61.1) [b]
Age, mean ±SD	44 ±13[a]	66 ±10[b]	45 ±12[a]	66 ±9[b]
BM, n. (%)	10 (4.6)[a]	330 (58.5) [b]	44 (13.8)[c]	156 (37)[d]
CM, n. (%)	4 (1.8)[a]	153 (27.1)[b]	27 (8.5)[c]	31 (7.3)[c]
MHDs, n. (%)	39 (17.8)[a]	241 (42.7)[b]	176 (55.3)[c]	61 (14.5)[a]
PROMIS Global Physical health, mean ±SD	15.8 ±2.1[a]	10.2 ±1.9[b]	10.5 ±2.3)[b]	14.5 ±1.7[c]
PROMIS Global Mental Health, mean ±SD	15.4 ±2.7[a]	11.2 ±2.7[b]	10.8 ±3.0[b]	15.2 ±2.4[a]
PROMIS Physical function SF10a, mean ±SD	45.8 ±4.5[a]	25.6 ±8.5[b]	34.3 ±8.6[c]	36.4 ±9.5[d]
PROMIS Fatigue 4a score, mean ±SD	7.2 ±2.4[a]	13.7 ±3.2[b]	13.8 ±3.3[b]	8.0 ±2.3[c]

Each superscript letter indicates a subset of the 4 groups analyzed for which the means or proportions showed no difference at a significance level of.05.

Figure 1A: Cluster dendrogram representation; Figure 1B: Violin plots of hierarchical cluster analysis in IIM subsets

Conclusion: Patients with IIMs have a higher burden of comorbidities that adversely impact physical and mental health, calling for optimized approaches for holistic patient management.

POS1217 CCL-18 AS A BIOMARKER OF INTERSTITIAL LUNG DISEASE (ILD) AND PROGRESSIVE FIBROSING ILD IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Biomarkers, Myositis, Lungs

E. Zanatta[1], R. Depascale2, A. Gamba[1], M. Tonello2, A. Martini[3], M. Gatto[1], A. Doria2, L. Iaccarino[1]. [1]*Rheumatology Unit, University Hospital of Padova, Department of Medicine, Padova, Italy*; [1]*Rheumatology Unit, University Hospital of Padova, Department of Medicine, Padova, Italy*; [3]*Unit of Internal Medicine and Hepatology, University Hospital of Padova, Department of Medicine, Padova, Italy*

Background: Interstitial lung disease (ILD) is the most frequent organ involvement in patients with idiopathic inflammatory myopathies (IIMs). Some patients with connective tissue diseases including IIMs may develop a progressive fibrosing (PF-)ILD [1]. The chemokine CCL18 is constitutively expressed by dendritic cells and macrophages in lung tissues and may induce collagen synthesis in lung fibroblasts. Circulating CCL18 correlated with fibrosis severity in idiopathic pulmonary fibrosis and it predicts ILD progression in patients with systemic sclerosis (SSc) [2]. OX40 ligand (OX40L) is a glycoprotein expressed on activated antigen-presenting cells and in vivo OX40L blockade prevents inflammation-driven skin, lung, and vessels fibrosis in mouse models of SSc [3].
Objectives: To assess the potential role of CCL-18 and OX40L as biomarkers of ILD and PF-ILD in patients with IIMs.
Methods: Patients affected with IIMs (EULAR/ACR 2017 criteria) followed in our referral center were consecutively enrolled from September 2020 to March 2021. Clinical and serological variables, and organ involvement were recorded. Pulmonary involvement was investigated by high-resolution CT (HRCT) and pulmonary function tests (PFTs). CCL-18 (pg/ml) and OX40L (pg/ml) serum levels were measured by validated ELISA assays (according to the manufacturer's instructions) in patients and in 35 controls (matched for age and sex). Follow-up data including worsening of respiratory symptoms, and repeated PFTs and HRCT were recorded. PF-ILD was defined according to the INBUILD criteria [1].
Results: Ninety-three IIMs patients (64.5% females) with median age 62 (IQR 54.5-71) years and disease duration 3 (IQR 2-9) years were enrolled; ILD was detected in 52 (54.7%) patients. OX40L serum levels were similar between patients and controls, whereas CCL-18 serum levels were higher in IIMs patients than in controls (232.9 [IQR 134.7-399.07] vs. 48.4 [IQR 29.9-147.5], p<0.0001, **Figure 1A**). Among IIMs patients, those with ILD exhibited higher levels of CCL-18 than those without (305.6 [181.6-518] vs. 164.3 [79.6-270.7], p=0.001, **Figure 1B**). No association between CCL-18 values with autoantibodies, PFTs or any other clinical features was detected. During follow-up 16/52 (31%) patients developed a PF-ILD. At baseline, patients who developed PF-ILD had higher CCL-18 serum levels than non-progressors (306.4 [198.9-621.9] vs. 207.8 [102.6-376.8],

p=0.03]. Higher CCL-18 values, Anti-Ro52 and anti-MDA5 positivity, lower Creatine Kinase levels and diffusing capacity for carbon monoxide (DLCO) values were predictors of PF-ILD occurrence at univariate but not at multivariate analysis.

Conclusion: CCL-18 but not OX40L may be a useful biomarker in the assessment of patients with IIMs-ILD.

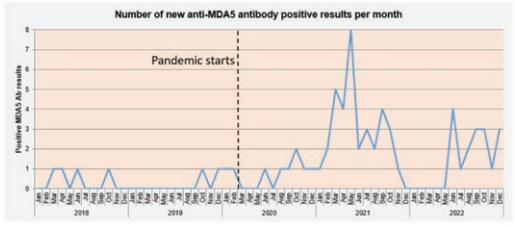
POS1218 A LARGE INCREASE IN ANTI-MELANOMA-DIFFERENTIATION-ASSOCIATED-GENE-5 (MDA5) ANTIBODY POSITIVITY AND ASSOCIATED DISEASE IN YORKSHIRE SINCE 2020

Keywords: Myositis



K. Iqbal[1], G. De Marco[2,3], S. Maisuria[4], G. Arumugakani[4,5], Z. Ash[6], C. Buckley[1], L. Coles[1], C. Hettiarachchi[7], M. Keen[6], C. Lawson[8], J. Mclorinan[1], S. Nizam[7], H. Reddy[9], O. Sharif[10], S. Sultan[9], G. Tran[8], M. Wood[1], S. Wood[1], D. Mcgonagle[2]. [1]*Leeds Teaching Hospitals NHS Trust, Rheumatology, Leeds, United Kingdom*; [2]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [3]*Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*; [4]*Leeds Teaching Hospitals NHS Trust, Pathology, Leeds, United Kingdom*; [5]*University of Leeds, Immunology, Leeds, United Kingdom*; [6]*Bradford Teaching Hospitals NHS Foundation Trust, Rheumatology, Bradford, United Kingdom*; [7]*Mid Yorkshire Hospitals NHS Trust, Rheumatology, Wakefield, United Kingdom*; [8]*Harrogate and District NHS Foundation Trust, Rheumatology, Harrogate, United Kingdom*; [9]*Airedale NHS Foundation Trust, Rheumatology, Steeton with Eastburn, United Kingdom*; [10]*Calderdale and Huddersfield NHS Foundation Trust, Rheumatology, Huddersfield and Halifax, United Kingdom*

Background: Melanoma differentiation-associated protein 5 (MDA5) is an intracellular detector of viral RNA. It is considered that viral infections are involved in the aetiology of autoimmune diseases, including autoimmune myositis. Previously we reported on a post-COVID-19 pandemic cluster of myositis occurring in the Yorkshire region (De Marco, 2022), despite the usually low frequency observed in the UK. More recently, we noticed increased anti-MDA5 positivity rate in myoblot tests.

Objectives: Our aim is to appraise the significance of the observed increased anti-MDA5 positivity recognized at our tertiary centre.

Methods: The Leeds Teaching Hospitals NHS Trust serves as an immunology laboratory reference for the wider Yorkshire region (3.6 million residents). We audited the increased anti-MDA5 positivity in relationship to other muscle-specific autoantibodies (Euroimmun immunoblot©) analysing retrospectively all tests performed between January 2018 and December 2022. Clinical notes review focused on: MDA5+ without disease; patterns of symptomatic MDA5 disease (including degree of ILD); muscle or other organs involvement; response to therapy. We also appraised the temporal associations between recent COVID-19 infection and SARS-CoV-2 vaccination.

Results: Requests for anti-MDA5 were stable between 2018 and 2020, but doubled thereafter. Anti-MDA5 positivity went from 0.6% to 4.9% in that period, dropping to 2.2% at the end of 2022 (Figure 1). Out of 66 individuals testing positive for anti-MDA5, clinical notes were available in 50 cases. Eleven had myositis without ILD (7 had dermatomysitis/"mechanic" hands rash). 18/50 cases developed ILD (12 had also myositis associated pathology, including 5 dermatomyositis rash and 5 "mechanic" hands). No cases of carditis were recorded. After treatment, outcome was stable/improved in 17 cases (6 ILD cases). Yet, 3 cases worsened and 6 died despite therapy (ILD cases). Twenty cases had signs described as within the connective tissues diseases spectrum (without any lung involvement), though no formal diagnosis. A minority of cases were associated with evidence of SARS-CoV-2 infection or vaccination, with 15 cases vaccinated before disease onset and 4 with preceding COVID-19 infection.

Summary per year	2018	2019	2020	2021	2022
Number of requests	364	535	459	812	1011
Number of patients	339	505	425	726	947
Total MDA5 Ab positive	4	3	10	40	22
New MDA5 Ab positive	4	2	9	35	17
Percentage positive (of total requests)	1.1	0.6	2.2	4.9	2.2

Figure 1.

Conclusion: Our data show an increased rate of anti-MDA5 positivity in the latter stages of the COVID-19 pandemic, as previously noted in the UK (Hannah J, ACR 2022). Most cases had MDA5 positivity without confirmed autoimmune disease and despite the MDA5 positivity occurrence in the face of the COVID-19 pandemic further longitudinal observation is needed to ascertain any potential links with either infection, vaccination or both.

POS1219 INCIDENCE, FEATURES AND OUTCOME OF DISEASE RELAPSE AFTER COVID-19 VACCINATION IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: COVID, Myositis, Vaccination/Immunization

T. G. Béldi[1], M. Nagy-Vincze[1], K. Szabó[1], A. Vincze[1], B. Miltényi-Szabó[1], Z. Varga[1], J. Varga[2], Z. Griger[1]. [1]*University of Debrecen, Division of Clinical Immunology, Faculty of Medicine, Debrecen, Hungary*; [2]*University of Debrecen, Department of Medical Imaging, Division of Nuclear Medicine, Debrecen, Hungary*

Background: The approved COVID-19 vaccines showed clear safety and efficacy in reduction of severe SARS-CoV-2 disease. Patients with idiopathic inflammatory myopathies (IIM) were not well represented in these vaccine trials and there are limited data in the literature about development of confirmed disease flare after COVID-19 vaccination.

Objectives: To evaluate frequency, features and outcome of disease relapses in patients with IIM following SARS–CoV-2 vaccination.

Methods: A cohort of 176 IIM patients (mean age:57.6 years, 117 females, 59 males, 106 PM, 70 DM) were interviewed after the 3rd wave of COVID-19 pandemic and prospectively followed. Relapses were determined using the IMACS disease state criteria, outcome of the flares with myositis response criteria, calculating the total improvement score (TIS).

Results: A total of 146 (82.9%) patients received vaccination and 17/146 (11.6%) patients had relapse within 3 months and 13/146 (8.9%) patients within one month. The relapse rate of unvaccinated patients (1/30; 3.3%) was not significantly different (p>0.1). No fatal flare has been observed. Three months after the post-vaccination relapses, 70.6% of the patients (12/17) achieved improvement of disease activity (average TIS score:30±15.81; 7 minor, 5 moderate and 0 major improvement). Six months after flares improvement was detected in 14/16 (87.5%) of relapsed patients (average TIS score: 43±20.17; 3 minimal, 7 moderate and 4 major). Forward stepwise logistic regression analysis revealed that the active state of myositis at time of injection (p<0.0001; OR: 31.2 CI: 9.0 – 108) and the application of BNT162b2 vaccination (p=0.026; OR: 4.06 CI: 1.1 – 14.7) were significantly associated with the occurrence of relapse.

Conclusion: Minority of the vaccinated IIM patients had confirmed disease flare after COVID-19 vaccination and majority of the relapses improved after individualized treatment. Active disease state at the time of vaccination probably contributes to the increased risk of post vaccination myositis flare.

POS1220

TRANSITION IN SYMPTOMS, ORGAN INVOLVEMENT, AND CLINICAL DIAGNOSIS OF PATIENTS POSITIVE FOR ANTI-ARS ANTIBODIES

Keywords: Epidemiology, Myositis

S. Inotani[1], Y. Kondo[2], S. Takanashi[2], S. Ishigaki[2], S. Saito[2], M. Takeshita[2], J. Kikuchi[2], H. Hanaoka[2], K. Suzuki[2], Y. Kaneko[2]. *[1]Keio University Hospital, Kochi University Hospital, Rheumatology,Tokyo, Japan*; *[2]Keio University, Rheumatology,Tokyo, Japan*

Background: Myositis-specific autoantibodies are useful biomarkers to make a diagnosis and predict prognosis of idiopathic inflammatory myopathies. Anti-aminoacyl transfer RNA synthetase antibodies (anti-ARS) is one of the most representative myositis-specific autoantibodies, however, organ involvement in patients positive for anti-ARS is not limited to the muscles but also skin, joints, and lungs, which constructs spectrums of idiopathic inflammatory myopathies called anti-synthetase syndrome. While individual anti-ARS antibodies have been known to form distinct clinical subsets, little is known regarding their chronological clinical presentation patterns and diagnosis during clinical course.
Objectives: To clarify the clinical characteristics of patients positive for anti-ARS and transition in manifestations and diagnosis during their clinical courses.
Methods: We reviewed consecutive patients with anti-ARS who had visited our hospital between 1998 and 2022 retrospectively. Anti-ARS antibodies were detected and categorized with RNA immunoprecipitation assays. We collected patient clinical characteristics and laboratory parameters including transition of diagnosis, manifestations and, organ involvement from their medical records chronologically. All statistical analyses were performed using JMP 15 (SAS Institute Inc., Cary, NC, USA).
Results: We included 97 patients positive for anti-ARS in the analysis. The mean age was 53.2 years old, and 73 (75%) were female. The types of anti-ARS Ab were anti-Jo-1 (37%), anti-EJ (32%), anti-PL-7 (11%), anti-PL-12 (12%), anti-KS (4%), and anti-OJ (3%). Half of the patients had co-existing other autoantibodies such as anti-SS-A/Ro, anti-SS-B/La, anti-dsDNA, anti-RNP, and/or rheumatoid factor, but the combination of antibodies was not different among each anti-ARS. The initial diagnoses of the patients were polymyositis (22%), dermatomyositis (33%), amyopathic dermatomyositis (13%), and interstitial pneumonia with autoimmune features (27%). Raynaud's phenomenon were observed in 25% of the patients; 19% in patients with anti-Jo-1, 36% in anti-EJ, 11% in anti-PL-7, 30% in anti-PL-12, 25% in anti-KS, and 33% in anti-OJ antibodies. Interstitial lung disease was observed in all patients except for three (two with anti-Jo-1 and one with anti-PL-12). Myositis was diagnosed initially in 72% of patients with anti-Jo-1, 50% with anti-EJ, 40% with anti-PL-7, 42% with anti-PL-12, none with anti-KS, and 67% with anti-OJ antibodies, but additional 6%, 4%, 40%, 8%, 0%, and 0% with those individual antibodies, respectively, were diagnosed with myositis during the mean observation period of 9.6 years. Acute or subacute exacerbation of interstitial lung disease requiring immunosuppressive treatment intensification were observed in 28% of patients with anti-Jo-1, 33% with anti-EJ, 40% with anti-PL-7, 8% with anti-PL-12, 33% with anti-KS, and 67% with anti-OJ antibodies.
Conclusion: Almost all patients positive for anti-ARS positive had interstitial lung disease irrelevant of myositis diagnosis. Patients with anti-Jo-1 were suffering from typical myositis complicated with interstitial lung diseases at initial diagnosis, while patients with anti PL-7 tended to have precedent interstitial lung disease followed by development of myositis during clinical courses. The incidence of acute exacerbation of interstitial lung disease was the lowest in patients with anti-PL12.

Background: Up to 28% of patients with anti-synthetase syndrome (AsyS) have dermatomyositis (DM)-type rashes. However, it is not clear whether ASyS patients with DM-type rashes should be treated similarly to patients with DM or classified as DM in a clinical trial setting. Furthermore, it is not known if presence of DM-type rashes confers an increased risk of DM-specific extramuscular manifestations, such as malignancy.
Objectives: To compare clinical characteristics, including the frequency of cutaneous, extramuscular features, and malignancy, between adults with ASyS and DM.
Methods: Using data from the MYONET registry, an adult cohort of DM patients with anti-Mi2/TIF1γ/NXP2/SAE/MDA5 autoantibodies, and an ASyS cohort of patients with anti-tRNA synthetase autoantibodies (anti-Jo1/PL7/PL12/OJ/EJ/KS), were identified. Patients with DM *sine* dermatitis and with dual autoantibody specificities were excluded. Sub-cohorts of ASyS patients with or without skin involvement were defined based on presence of DM-type rashes (heliotrope rash, Gottron's papules, violaceous rash, shawl sign, V sign, erythroderma, and/or periorbital rash).
Results: In total, 737 patients were included (DM, n=251; ASyS, n=486). Within the ASyS cohort, 34% (n=163) had DM-type skin involvement (ASyS-skin). A higher frequency of Raynaud's phenomenon differentiated ASyS-skin from DM (n=72, 44% vs n=34, 14%, p<0.01), whereas higher frequency of any of four DM-type rashes: heliotrope rash (n=155, 62% vs n=73, 45%), V sign (n=69, 28% vs n=22, 14%), periorbital rash (n=53, 21% vs n=27, 17%), and shawl sign (n=89, 36% vs n=15, 9%) differentiated DM from ASyS-skin (all p<0.01). Cancer-associated myositis (CAM) was more frequent in DM (17%) compared to ASyS (3%) and ASyS-skin (3%) cohorts (both p<0.01) (Table 1).
Conclusion: DM-type rashes are frequent in patients defined as having ASyS; however, certain clinical features differentiate these patients from classical DM. Skin involvement in ASyS does not necessitate increased malignancy surveillance or investigation. These findings will help to inform future ASyS-based classification criteria.

POS1222 PROGRESSIVE PULMONARY FIBROSIS IN ANTI-SYNTHETASE SYNDROME: A SINGLE CENTER COHORT

Keywords: Lungs, Myositis

I. Peralta Garcia[1], A. M. Svensson[2], A. S. Galindo-Feria[3,4], A. Notarnicola[3,4], L. Dani[3,4], I. E. Lundberg[3,4], M. Dastmalchi[3,4]. Background: Interstitial lung disease (ILD) is one of the major causes of morbidity and mortality in patients with idiopathic inflammatory myopathies (IIM). [1] Within IIM, ILD is frequently found in patients with anti-synthetase syndrome (ASyS). Current treatment is based on a combination of high doses of glucocorticoids and other immunosuppressors such as cyclophosphamide, with progression of ILD despite the treatment. One anti-fibrotic drug, nintedanib, has recently been approved for patients with progressive fibrotic ILD.

Objectives: To explore if within patients with ASyS there is a group with worsening ILD that fits the definition of progressive pulmonary fibrosis (PPF)[2] and thus would be eligible for anti-fibrotic treatment.[3]

Methods: A single center based retrospective cohort of patients diagnosed with ASyS, ILD involvement, and positivity for specific autoantibodies anti-Jo1, anti-PL7, anti-PL12, anti-EJ and/or anti-OJ (ASyS-AB) was identified using the Swedish Myositis network register. We selected the latest computed tomography (CT) thoracic scans, pulmonary function tests (PFT) and the development of respiratory symptoms according to clinical records. Patients were evaluated based on the INBUILD study criteria[3] and the international thoracic and respiratory clinical practice guideline (CPG)[2] for the presence of PPF. An experienced thoracic radiologist reviewed the CT scans of those who met the criteria to confirm PPF.

Results: We identified 147 individuals positive for ASyS-AB; 66 of them were not included due to either a follow-up period of less than one year, lack of data in the national registry or absence of ILD. Finally, a cohort of 81 patients was included, 67.9% women, with a median (Q1,Q3) age at disease onset of 58 (48,67) years (Table 1). The median time from disease onset until assessment for PPF criteria was of 6 years. The most prevalent CT finding amongst all groups was fibrotic changes (n=28) neither fitting the usual interstitial pneumonia (UIP) (n=9) nor the fibrotic non-specific interstitial pneumonia (NSIP) (n=6) criteria; followed by inflammatory NSIP (n= 18). 14.8 percent or 19.8 percent (INBUILD and CPG, retrospectively) of the individuals with any type of lung fibrotic pattern on CT met the definition of PPF.

Table 1. Baseline characteristics of patients with anti-synthetase syndrome (ASyS) in the cohort

	Total	By antibody				
		PL7, n=8	**PL12**, n=8	**Jo1**, n=58	**EJ**, n=4	**OJ**, n=3
Women, n (%)	55 (67.9)	6 (75)	5 (62.5)	40 (69)	3 (75)	1 (33.3)
Median age at disease onset, years (Q1,Q3)	58 (48,67)	61 (35,68)	61 (48,67)	56 (47,65)	72 (46,76)	61 (55,74)
Time since disease onset at evaluation, years (Q1,Q3)	6 (3,11)	10 (3,22)	4 (2,5)	7 (3,13)	2 (2,15)	4 (1,7)
Patients meeting criteria for progressive fibrosis, n (%)						
INBUILD criteria	12 (14.8)	2 (25)	1 (12.5)	8 (13.8)	0 (0)	1 (33.3)
ATS/ERS/JRS Clinical practice guidelines	14 (17.3)	3 (37.5)	1 (12.5)	10 (17.2)	0 (0)	0 (0)
Time since disease onset at evaluation, years (Q1,Q3)	10 (5,21)	-	-	-	-	-

Conclusion: In this cross-sectional study, 15% of patients with ASyS fulfilled the definition of progressive fibrosis and thus could be eligible for anti-fibrotic treatment. To our knowledge, this is the first cohort to demonstrate a possible real-life target of anti-fibrotics in IIM-ILD.

Background: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of acquired muscle diseases with distinct clinical, pathological and histological features. interstitial lung disease (ILD) is a frequent pulmonary manifestation in IIM (IIM-ILD) and considerably influences morbidity and mortality. Krebs von den Lungen 6 (sKL-6) has been proposed as a potential biomarker reflecting the severity of ILD in connective tissue diseases. Raynaud's phenomenon is very

frequent and the presence of microvascular changes in IIM have been described however, the role of nailfold videocapillaroscopy (NVC) in diagnosis and prognosis in IIM is not clearly established.

Objectives: To determine if there is any association between NVC findings, sKL-6 levels and pulmonary involvement in patients with inflammatory myopathies.
