Bass[1,2]. *[1]Hospital for Special Surgery, Department of Medicine, Division of Rheumatology, New York City, United States of America*; *[2]Weill Cornell Medical College, Department of Medicine, New York City, United States of America*; *[3]Memorial Sloan Kettering Cancer Center, Melanoma Service, New York City, United States of America*; *[4]Johns Hopkins School of Medicine, Department of Pathology, Division of Immunology, Baltimore, United States of America*

Background: Immune checkpoint inhibitor (ICI) therapy has greatly improved the prognosis of advanced cancers but is often complicated by immune-related adverse events (irAEs). Biomarkers of ICI safety and efficacy are needed.
Objectives: To identify autoantibodies (AAbs) associated with irAEs and cancer outcomes in ICI-treated patients.
Methods: This analysis used clinical data and biospecimens from a prospective trial of 60 patients with advanced melanoma who received 2-4 doses of combination ICI (anti-PD1 + anti-CTLA4) followed by anti-PD1 monotherapy. [1] Patients were followed for three years for irAE development, cancer progression, and death. Plasma was collected at baseline and six weeks after ICI initiation and assayed for AAbs using PhIP-Seq with a human peptide library spanning the entire human proteome. Baseline levels of AAbs with a ≥2 fold-change in ≥10 patients at follow-up (n = 833 AAbs) were concurrently included in a bootstrapped LASSO Cox proportional hazards model (1000 replications; $\alpha = 0.5$; λ chosen by cross-validation for each replication) that was separately run for each outcome: ≥1 severe irAE (CTCAE grade ≥ 3), progression-free survival (PFS), and overall survival (OS). The proportion of times each AAb was replicated was reported as its "validation frequency."[2] Hazard ratio confidence intervals were reported after individually calculating bias-corrected and accelerated (BCa) bootstrap intervals (1000 replications) for each AAb. The AAbs with the highest validation frequencies were used for Partial Least Squares Discriminant Analysis (PLS-DA) clustering.
Results: Among the 60 patients, 47% developed a severe irAE, 25% progressed, and 23% died. **Table 1** shows the six AAbs with the highest validation frequencies for severe irAE, PFS, and OS. PLS-DA was able to cluster patients by the development of severe irAEs using only six AAbs with a 10-fold cross-validated AUROC of 0.86 ± 0.01 (p <.001) (**Figure 1**). PLS-DA performed similarly well for PFS and OS. **Table 1** reflects that higher levels of the identified AAbs at baseline were associated with worse PFS and OS (HR > 1); this pattern remained true across the 25 AAbs with the highest validation frequencies for PFS (21/25, 84%) and OS (23/25, 92%). Conversely, amongst the top AAbs linked to severe irAEs, lower levels in the majority (15/25, 60%) of the identified AAbs were associated with this outcome (HR < 1). Most of the identified top AAbs were unique to each outcome, but there was some overlap: PFS and OS shared seven AAbs (28%), PFS and severe irAEs shared two AAbs (8%), and OS and severe irAEs shared one AAb (4%). No AAbs overlapped between more than two outcomes.
Conclusion: These results suggest that specific autoantibodies may be useful biomarkers for predicting outcomes in melanoma patients receiving ICI therapy. However, these results require validation.

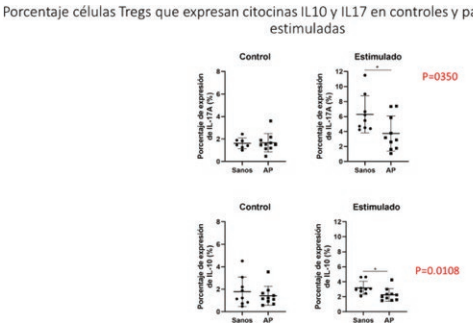
AB0020 CYTOCHEMICAL ASSESSMENT IN TREG CELLS OF PSORIASIC ARTHROPATHY BY INHIBITION OF IL23 (IN REAL LIFE) AND ITS CORRELATION WITH CLINICAL REMISSION



Keywords: Psoriatic arthritis, Cytokines and chemokines

F. J. Navarro Blasco[1], S. Pascual[2]. [1]*University General Hospital of Elche. Spain., Rheumatology, Elche, Spain*; [2]*Universidad de Alicante, Biotecnology and Inmunology, San Vicente del raspeig, Spain*

Background: Psoriatic arthropathy (PsA) is a heterogeneous chronic entity with multiple clinical domains that evolves to irreversible damage both organic and psychological. Therapeutic recommendation guidelines advise differentiated therapies according to the dominant clinical domain (e.g., peripheral arthritis, dactylitis, enthesitis, spondylitis, cutaneous or nail psoriasis). Moderate-severe involvement requires the use of targeted biological or synthetic medication. Primary and secondary failures or intolerances often force the change of therapeutic target in order to achieve greater efficiency. The interrelation of cytokines (mainly IL23, IL17, and IL10) in their pathogenesis at the "in vitro" level seem proven, but their modification "in vivo" and correlation with the clinic are little studied.
Objectives: To identify the cytokine profile of IL -10 and IL -17 in CD4+FoxP3+ cells of patients with PsA, (ii) to identify the degree of expression of CD152 in CD4+FoxP3+ cells of patients with PsA and (iii) to correlate the expression of these molecules and the state of Minimal Activity of the disease (MDA).
Methods: The present study involved 9 healthy volunteers and 10 patients with Psoriatic Arthritis (CASPAR criteria) in treatment for at least 6 months with anti-IL23 and in clinical remission (MDA). To analyze the production of IL-17A and IL-10 by regulatory T cells under basal culture and stimulated conditions (1 µg/ml Ionomycin (Fisher Scientific, EU) and 25 ng/ml forbol-12-myristate-13-acetate (PMA) (MP Biomedicals, EU)., monoclonal antibodies were used: anti-CD4-FITC, anti-CD25-PECy5, anti-FoxP3-PE, anti-IL-10-PECy7 and anti-IL-17A-APC (eBioscience, EU), were processed by flow cytometry (FACS Canto, BD Bioscience, EU).
Results: Percentage of Tregs expressing IL-10 in control condition Healthy: 1.787% BP: 1.418% P value = 0.7354. Percentage of Tregs expressing IL-10 in Healthy stimulated condition: 3.178% PA: 2.256% P value = 0.0108. Percentage of Tregs expressing IL-17A in control condition Healthy: 1.617% AP: 1.665% P value = 0.8923. Percentage of Tregs expressing IL-17A in Healthy stimulated condition: 6.298% PA: 3.742% P value = 0.0350
Conclusion: Although the controls and PsA patients in remission expressed a similar percentage of Tregs cells of both IL10 and IL17 at baseline, the same does not occur after stimulation in culture, showing an increase in both populations of Tregs (IL10-IL17) of the controls that did not occur in ArP patients in remission. This differs from RA patients in remission in which Tregs expressing IL10 is increased, as an expression of the different immunological mechanisms in both pathologies. Likewise, the Treg phenotype has been described with double marker RORγt/ FOXP3 and IL17 production. The plasticity of the T-cell compartment allows the immune response to adapt to the local environment. This is further emphasized by the recent recognition that Tregs themselves can differentiate into IL-17-producing cells, particularly when exogenous IL-1β, IL-23, or IL-21. In patients with psoriatic arthritis, IL-10 levels are increased. The inhibition of IL23 would be suppressing this production hence the double lack of response (Il10-IL17) of ArP patients in remission.

Background: Recurrent pericarditis (RP) affects up to 30% of patients after a first episode of acute pericarditis. The effectiveness of anakinra, an IL-1 recombinant receptor antagonist (IL-1r), has been established in recent clinical trials and multicenter studies[1,2] Currently the treatment with anakinra is usually prescribed as a third-line option in patients with RP and corticosteroid dependence not responsive to colchicine[3]. However, guidance for addressing optimal tapering strategies and discontinuation of biological treatment in RP is limited.
Objectives: To explore key factors for successful anakinra tapering and discontinuation and to investigate potential predictors of disease relapse after complete biologic treatment suspension.
Methods: An international, multicenter, retrospective registry including 18 recruiting centers from five countries (Italy, Greece, Slovenia, Canada, United States) was designed to investigate the disease characteristics of patients with recurrent pericarditis undergoing complete discontinuation of the anti-IL1r therapy anakinra.
Results: A total of 149 patients who had fully discontinued anakinra (59.6% female, median age 51.7 years) were included in the present registry. Most patients had idiopathic aetiology (109; 73.2%) while a first episode of pericarditis after post-cardiac injury syndrome (PCIS) or related to systemic inflammatory diseases was established in 30 and 10 cases (20.1% and 6.7%), respectively, with a median of 3 prior recurrences (interquartile range 2-4). Patients started anakinra treatment after a median time of 12 months (IQR 5-24) after a first episode of acute pericarditis, followed by a period at anakinra full-dosage with a median duration of 6 months (IQR 3–12). Among patients who experienced a recurrence (54 cases; 36.2%), 39 were female (72.2%, $p = 0.019$). Moreover, we observed a significant reduction in the recurrence of flares after an early introduction of anti-IL-1r treatment from first pericarditis episode (mean median time 10 months; IQR 4-18 vs 14 months; IQR 14-29; $p = 0.004$).
Conclusion: The main preliminary findings of this global registry suggest that an early introduction of anakinra in patients with RP, corticosteroid-dependent and not responding to colchicine, significantly reduces the recurrence of flares after discontinuation.

AB0022 IL-23 POSITIVE NEUTROPHIL IS THE MAIN CELL SUBTYPE IDENTIFIED FROM SYNOVIAL FLUID OF PSORIATIC ARTHRITIS WITH THE POTENTIATION OF NEUTROPHIL EXTRACELLULAR TRAPS FORMATION

Keywords: Psoriatic arthritis

Y. P. Tsao[1,2], S. T. Chen[2]. [1]*Taipei Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Medicine, Taipei, Taiwan, Republic of China*; [2]*National Yang Ming Chiao Tung University, Institutes of Clinical Medicine, Taipei, Taiwan, Republic of China*

Background: Psoriatic arthritis (PsA) is a systemic autoimmune disease. Interleukin-23 (IL-23) and IL-17 are two main cytokines involving in the pathogenesis of psoriasis (PsO) and PsA. The origin and maintenance of IL-23 is the stakeholder of disease progression in PsA and should be carefully evaluated.
Objectives: To validate the role of neutrophils in maintaining the inflammation in PsA joint.
Methods: Synovial fluid from PsA was obtained from swelling knee joints, and the immune cells were classified by flowcytometry. The IL-23 positive cells were evaluated with marker of CD66b, CD14, and CD16. Neutrophils from healthy donor were collected and treated with interferon-α (IFN-α) and proteoglycan (PGN) for mimicking the neutrophils activation in PsO/PsA patients. Subsequent evaluation neutrophil extracellular traps (NETs) formation was conducted.
Results: 10 PsA joints fluid was collected. Among active and chronic PsA synovial fluid, neutrophil is the most abundant cell type identified among IL-23 positive cells (ranging from 65-90%). The t-SNE plot for mapping the repertoire of IL-23 containing cells confirmed the majority cell subtype with CD66b+ positive neutrophils. After stimulating neutrophils from healthy donor with IFN-α and PGN revealed increasing IL-23p19 expression after 16 hours stimulation. The NETs formation is profound and IL-23p19 containing NETs material could be identified.
Conclusion: IL-23 containing CD66b+ neutrophil is the main cell type in synovial fluid of PsA, which might be activated by inflammatory factors and release IL-23 with NETs material to promote type 17 T cell differentiation in joints.

AB0023 GLUCOCORTICOIDS AND TNF INHIBITOR EXERT NOVEL REGULATORY MECHANISM THROUGH LAG-3 MODULATION IN SYNOVIAL CELLS

Keywords: Disease-modifying drugs (DMARDs), bDMARD, Synovium

S. Gertel[1], V. Furer[1], A. Polachek[1], O. Elkayam[1]. [1]Department of Rheumatology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, Affiliated to the Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel., Rheumatology, Tel Aviv-Yafo, Israel

Background: Intra-articular (IA) injections of glucocorticoids (GCs) are clinically effective for the treatment of synovial inflammation in patients with persistent arthritis. TNF inhibitors (TNFi) utilization for IA injections was also reported with a varying efficacy [1, 2]. The mechanism of action of GCs and TNFi on regulatory mediators in the synovium is not fully understood. LAG-3 is a regulatory molecule that promotes suppressive immune response. LAG-3 expression could be regulated through multiple mechanisms, including modulation by different drugs.
Objectives: To investigate whether the regulatory mechanism of GCs and other anti-rheumatic drugs is mediated through change in LAG-3 expression in synovial cells derived from psoriatic arthritis (PsA) patients ex-vivo.
Methods: Synovial fluid mononuclear cells (SFMCs) derived from nine PsA patients were cultured ex-vivo with GCs ((betamethasone (BET) and methylprednisolone acetate (MPA)), Methotrexate (MTX), TNF, IL-17A, IL-12/23, and IL-1 receptor inhibitors namely: (Infliximab (IFX), Secukinumab, (SEC), Ustekinumab, (UST), and Anakinra (ANK), respectively) or with medium alone. After 5 incubation days, %$CD45^+LAG\text{-}3^+$ expressing cells was analyzed. We further assessed if the drugs' effect on SFMCs cell numbers in culture was accompanied with LAG-3 modulation. LAG-3 distribution on CD45, CD3, and CD14 cells was analyzed by flow cytometry (FACS).
Results: SFMCs treated with GCs showed a significant increase in %$CD45^+LAG\text{-}3^+$ cells (BET 1µg/ml, 6.8±1.3; BET 10µg/ml, 7.1±1.4; MPA 1µg/

ml, 6.7±1.3; and MPA 10µg/ml, 9.4±2.0, $p< 0.002$, respectively), while IFX showed only a small increase of these cells' population (2.0±0.3, $p= 0.08$) compared to the medium (1.0±0.3). Other treatments, including SEC, UST, ANK and MTX had no effect on %CD45$^+$LAG-3$^+$ cells compared to the medium, (1.0±0.2, 0.8±0.2, 0.8±0.2 and 0.9±0.2, respectively) (Figure 1A). After 5 days in culture, GCs (MPA) and IFX reduced SFMCs cell counts but this change was statistically significant only for GCs (21±5.1X10^5/well, $p< 0.01$ and 41±5.1X10^5/well, respectively), while MTX had no effect compared to the medium (49±4.8X10^5/well and 51±5.1X10^5/well, respectively) (Figure 1B). In this culture setting, GCs significantly increased the %LAG-3$^+$CD14$^+$ cells (12.8±2.1, $p< 0.001$) compared to the medium (0.9±0.4) but not the %LAG-3$^+$CD3$^+$ cells (Figure 1C and D).

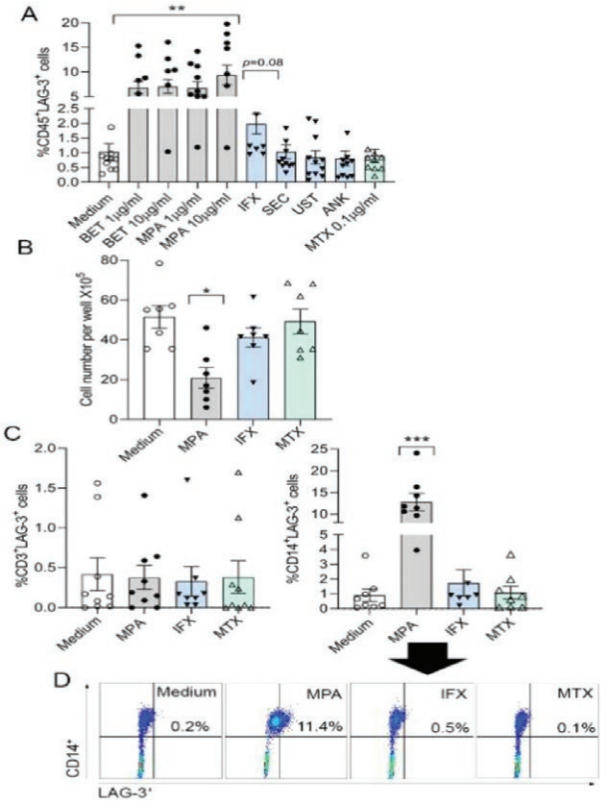

Figure 1. GCs and to a lesser extent infliximab up-regulate LAG-3 in SFMCs (A) PsA patients (n=9) SFMCs were cultured with BET, MPA, IFX, SEC, UST, ANK and MTX and analyzed by FACS for %CD45$^+$LAG-3$^+$ cells (B) SFMCs cell count analysis was performed after 5 days in culture with: MPA, IFX, MTX or medium (C) Cultures were then analysed for %CD3$^+$LAG-3$^+$ and %CD14$^+$LAG-3$^+$ cells by FACS (D) Representative PsA patient SFMCs FACS plots showing CD14 and LAG-3 expression after 5 days in culture with medium or the drugs indicated. Positive staining is presented in each plot right upper quadrant with the % indicated, *$p < 0.01$, **$p < 0.002$, ***$p < 0.0001$.

Conclusion: Our data shows that GCs immunosuppressive activity is mediated through LAG-3 up-regulation in SFMCs. Within the drugs tested, this activity was exclusively mediated by GCs and to a lesser extent by a TNF inhibitor. GCs reduced the SFMCs cell numbers and concomitantly up-regulated LAG-3 expressing cells, mainly in monocytes. This emphasizes that monocytes seem to be the main mediators of the GCs immunosuppressive effect.

GENE EXPRESSION OF ABCG2, ALPK1, SLC22A12 AND IL-1B IN PERIPHERAL BLOOD LEUKOCYTES OF GOUT PATIENTS WERE CORRELATED WITH THEIR COMORBIDITIES AND HYPERURICEMIA

Keywords: Innate immunity, Gout, Crystal arthritis

A. López Macay[1], K. Martinez Flores[2], J. Fernández-Torres[2], Y. Zamudio[2], F. Sanchez Muñoz[3], D. Clavijo-Cornejo[4]. [1]*Instituto Nacional de Rehabilitación LGII, Líquido Sinovial, Mexico City, Mexico*; [2]*Instituto Nacional de Rehabilitación LGII, Líquido Sinovial, Mexico, Mexico*; [3]*Instituto Nacional de Cardiología, Inmunología, Mexico city, Mexico*; [4]*Instituto Nacional de Rehabilitación LGII, Reumatología, Mexico, Mexico*

Background: Genes ABCG2, SLC22A12 (URAT1), and ALPK1 have been strongly associated with dysfunction of urate metabolism in patients with gout [1], but it is unknown how these transporters are expressed in patients with acute or chronic gout. Studies in murine and in vitro models have suggested that the enzyme ALPK1 kinase and the urate transporters ABCG2 and URAT1 may be involved in urate dysregulation and inflammation due to the presence of monosodium urate crystals [2-3]. It is important to know if the patient with acute or chronic gout can differentially express these genes in different tissues. Likewise, it is necessary to know if the patient's comorbidities may be associated with the expression of these transporters or pro-inflammatory molecules such as ALPK1 or IL-1β.

Objectives: To analyze the expression of urate transporters ABCG2, SLC22A12 and inflammation molecules ALPK1 and IL-1β in peripheral blood leukocytes from gout patients and to compare them with their metabolic profile and with the gene expression of people without gout and without hyperuricemia.

Methods: A total of 36 chronic and acute patients and 52 controls were recruited, ABCG2, SLC22A12, IL-1β and ALPK1 gene expression was evaluated by quantitative real-time PCR. Correlations of gene expression with clinical and laboratory parameters of patients were also analyzed.

Results: IL-1β was significantly increased in Peripheric blood monocytes cells (PBMCs) of patients when compared with their polymorphnuclear leukocytes

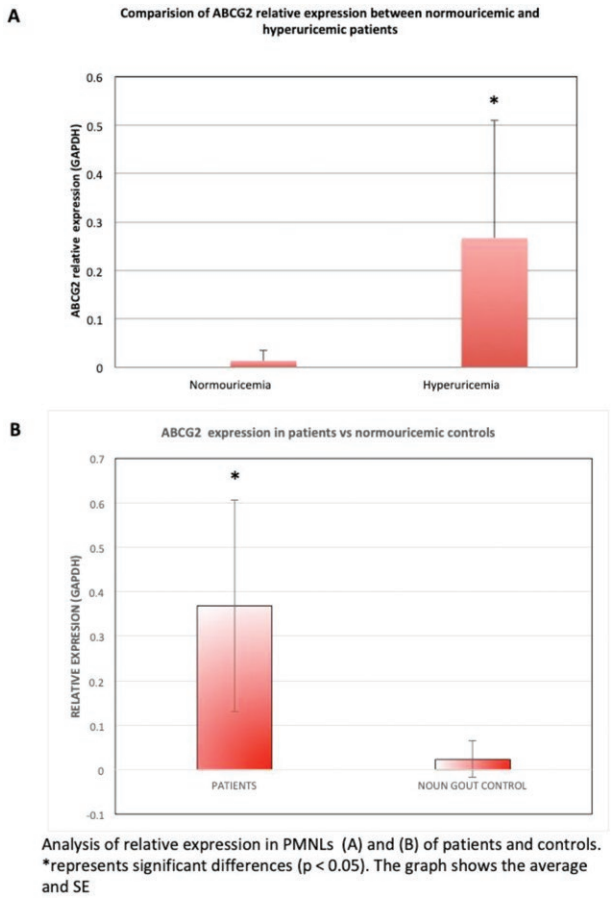

Figure 1.

(PMNLs) ($p<0.05$). A significant increase in ABCG2 were found in PMNLs from patients compared to controls ($p<0.05$) and in hyperuricemic patients compared to normouricemic patients ($p<0.05$) (see Figure 1). Correlations of gene expression in patients were related to levels of serum uric acid (sUA), serum creatinine, CRP, triglycerides, BMI, kidney disease, hypertension, and metabolic syndrome.
Conclusion: Our data suggest that the leukocyte cells of the patients respond to the presence hyperuricemia and comorbidities expressing ABCG2 gene differentially compared to normouricemic and non disease state. Hyperuricemia, dyslipidemias and obesity should stimulate the differential gene expression of peripheral blood leukocytes (neutrophils and monocytes) even in an asymptomatic stat.e.

AB0025 LOW-DENSITY GRANULOCYTES AND NEUTROPHIL EXTRACELLULAR TRAPS IN INCOMPLETE SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Innate immunity, Systemic lupus erythematosus, Biomarkers

S. Henning[1], T. Reimers[1], B. Doornbos- van der Meer[1], H. Bootsma[1], K. De Leeuw[1], J. Westra[1]. [1]University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with a complex and only partly understood pathophysiology, while incomplete SLE (iSLE) defines a group of patients with symptoms typical of SLE but not meeting sufficient criteria required for the classification of SLE. Up to 55% of patients with iSLE will eventually develop SLE, but it is unclear which patients are at risk of progression. [1] Neutrophil dysfunction, among which aberrant neutrophil extracellular trap (NET) formation driven by low density granulocytes (LDGs), has been implicated in SLE pathogenesis. [2] However, the role of neutrophil dysfunction in early forms of SLE is still unclear.
Objectives: The aim of this study was to investigate whether LDGs are elevated in the peripheral blood mononuclear cell (PBMC) fraction of iSLE patients, compared to healthy controls (HCs) and SLE patients with quiescent disease (SLEDAI<4). Next to that, we investigated presence of circulating NETs in plasma of iSLE as well as SLE patients and HCs.
Methods: Circulating plasma NETs were measured cross sectionally in 38 iSLE patients, 30 SLE patients with quiescent disease and 12 HCs while LDGs were measured in 18 iSLE patients, 13 SLE patients and 14 HCs. SLE patients were classified according to the Systemic Lupus International Collaborating Clinics (SLICC) criteria. Patients with iSLE had to meet at least one clinical and one immunological criterion but less than four SLICC criteria in total. LDGs ($CD14^{low}CD15^{+}$) were measured in freshly isolated PBMCs with flow cytometry as previously described [3] and were expressed as percentage of total PBMCs. Circulating plasma NETs were measured by using a previously validated sandwich enzyme linked immunosorbent assay [4] using a plate coated with an anti-myeloperoxidase antibody. Kruskal-Wallis tests were used to compare LDGs and NETs between groups. In case of significance, Mann-Whitney tests were used for pairwise comparison. A two tailed p-value of ≤ 0.05 was considered statistically significant.
Results: Proportions of LDGs and NET-levels were significantly increased in iSLE patients compared to HCs, as shown in Figure 1. The proportion of LDGs and circulating plasma NETs was similar between SLE and iSLE patients.
Conclusion: Our data shows significantly higher amounts of LDGs and circulating NETs in the iSLE and SLE cohort compared to healthy controls, suggesting that aberrant NET formation and clearance is present in early stages of the disease. In future studies, we aim to investigate the correlation between LDGs, circulating NETs and other immunological parameters, such as complement C3 and C4, and anti-dsDNA levels.

AB0026 mtDNA OXIDATIVE DAMAGE IS PROINTERFEROGENIC AND PRONETOTIC, AND RELATES TO ANTIPHOSPHOLIPID ANTIBODY POSITIVITY IN SLE

Keywords: Systemic lupus erythematosus, Innate immunity, Autoantibodies

S. Giaglis[1,2], D. Kyburz[1,2], N. Venhoff[3,4], U. Walker[1,2]. [1]*University of Basel, Laboratory for Experimental Rheumatology, Department of Biomedicine, Basel, Switzerland*; [2]*University Hospital Basel, Division of Rheumatology, Basel, Switzerland*; [3]*University Medical Center Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg im Breisgau, Germany*; [4]*University Medical Center Freiburg, Centre of Chronic Immunodeficiency, Freiburg im Breisgau, Germany*

Background: Mitochondria are essential eucaryotic cell organelles with several bacterial features such as a circular genome with hypomethylated CpG areas, and a double cardiolipin membrane [1]. A fundamental role of mitochondria in systemic lupus erythematosus (SLE) was recently shown; mitochondrial ROS participate in neutrophil extracellular traps (NETs) formation [2], while extrusion of cell-free mitochondria and highly oxidised interferogenic mitochondrial DNA (ox-mtDNA) causes disease in an SLE animal model [3, 4]. Moreover, plasma mtDNA is a sensitive biomarker for SLE diagnosis and the clinical monitoring of SLE activity [5].
Objectives: The present study aimed to explore the cellular mechanisms controlling the inflammatory responses triggered by mtDNA in SLE.
Methods: Total DNA was isolated from healthy individuals' (HC) and SLE patients' plasma. Copy numbers were analysed by qPCR for mtDNA (ATP-6) and nuclear DNA (GAPDH). mtDNA was isolated from HC and SLE patients' platelets. Neutrophils were isolated from EDTA blood by negative selection; cells were incubated with SLE patients' plasma, and NET formation was assessed by Sytox-Green staining. Tofacitinib, a JAK1-JAK3 inhibitor, was utilised to assess the JAK-STAT pathway activation. DNA oxidation was assessed by MitoSOX Red staining *in vitro* and 8-hydroxy-diguanosine (8-OHdG) ELISA of plasma. Plasma IFN type 1 was measured by ELISA. Anti-phospholipid antibodies (aPL Abs) comprising of anti-cardiolipin (aCL) and anti-β2GPI, were analysed by ELISA and the lupus anticoagulant (LAC) test was performed.

Results: Neutrophils from healthy donors exhibit enhanced NET formation when incubated with from SLE patients' plasma (P=0.001), compared to HC plasma. Their NETs are decorated with ox-mtDNA (P=0.01). SLE patients' mtDNA elicits increased NETs (P=0.001) decorated with ox-mtDNA (P=0.001), which are both not entirely abolished after DNase1 treatment. Formation of NETs and ox-mtDNA extrusion seems to be partially regulated through the type I IFN pathway; JAK inhibition with tofacitinib diminishes, however not entirely, NET formation and ox-mtDNA release (56% and 60% decrease, respectively). mtDNA amounts correlate with 8-OHdG (R^2=0.87; P<0.0001) and type I IFN levels (R^2=0.60; P=0.001) in SLE patients' plasma. aPL Ab-positive SLE patients were characterised by higher plasma levels of mtDNA (P=0.004), but not nDNA, compared to aPL Ab-negative SLE patients. Interestingly, aPL Ab-positive and aCL Ab-positive SLE patients' plasma demonstrated a higher proNETotic capacity.
Conclusion: Oxidative damage of mtDNA promotes the formation of NETs, is particularly interferogenic, and NETs relate to the antiphospholipid antibody positivity in SLE patients' circulation. Circulatory ox-mtDNA might promote endothelial damage and vasculitis in SLE. A significant link between aPL, namely aCL IgG, and circulating mtDNA in SLE patients was evident, potentially aggravating the inflammatory state linked to disease severity and promoting thrombotic events.

AB0027

ANTI-INFLAMMATORY EFFECTS OF TNF INHIBITOR AND METHOTREXATE ON IMMUNE CELLS FROM PERIPHERY AND SYNOVIAL FLUID: EX-VIVO STUDY

Keywords: Disease-modifying drugs (DMARDs), bDMARD

S. Gertel[1], V. Furer[1], A. Polachek[1], O. Elkayam[1]. [1]*From the Department of Rheumatology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, Affiliated to the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel., Rheumatology, Tel Aviv-Yafo, Israel*

Background: Methotrexate (MTX) and TNF inhibitors (TNFi) are pivotal treatments for inflammatory arthropathies. Even to date, the mode of action of these drugs on diverse inflammatory cell populations is not well characterized.
Objectives: To study the impact of MTX and TNFi on the proliferation of peripheral blood mononuclear cells (PBMCs) and the intermediate monocytes ($CD14^+CD16^+$) frequency in synovial fluid mononuclear cells (SFMCs). The study focused on monocytes expressing the $CD16^+$ as these cells promote synovial inflammation producing pro-inflammatory cytokines, including: TNF, IL-1β, and IL-6.
Methods: In this pilot exploratory study, we analyzed ex-vivo healthy donors PBMCs (n=19) proliferation without or with phytohemagglutinin (PHA) and PHA in presence of MTX and/or TNFi. Next, the effect of these drugs on $\%CD14^+CD16^+$ cells derived from psoriatic arthritis (PsA) patients SFMCs (n=11) was determined. Both assays were analysed by flow cytometry.
Results: Healthy donors PBMCs proliferation was inhibited by MTX (0.01 µg/ml and 0.1 µg/ml; 41.9±2.3 and 86.3±1.8, respectively) and to a lower extent by TNFi (infliximab, IFX) (1 µg/ml and 10 µg/ml; 43.1±2.5 and 49.4±2.5, respectively), whereas the combination of IFX 10 µg/ml and MTX 0.1 µg/ml led to the highest inhibition (91.0±2.0) (Figure 1 A and B). In PsA patients derived SFMCs, IFX 10 µg/ml significantly reduced ($p < 0.01$) the $\%CD14^+CD16^+$ cells (5.5±1.3) as compared to medium control (10.9±12.4), whereas MTX 0.1 µg/ml had only modest effect on this cell population (10.2±1.4). The combination of IFX 10 µg/ml and MTX 0.1 µg/ml resulted in the greatest reduction of $\%CD14^+CD16^+$ cells (5.1±1.1) (Figure 1 C and D).

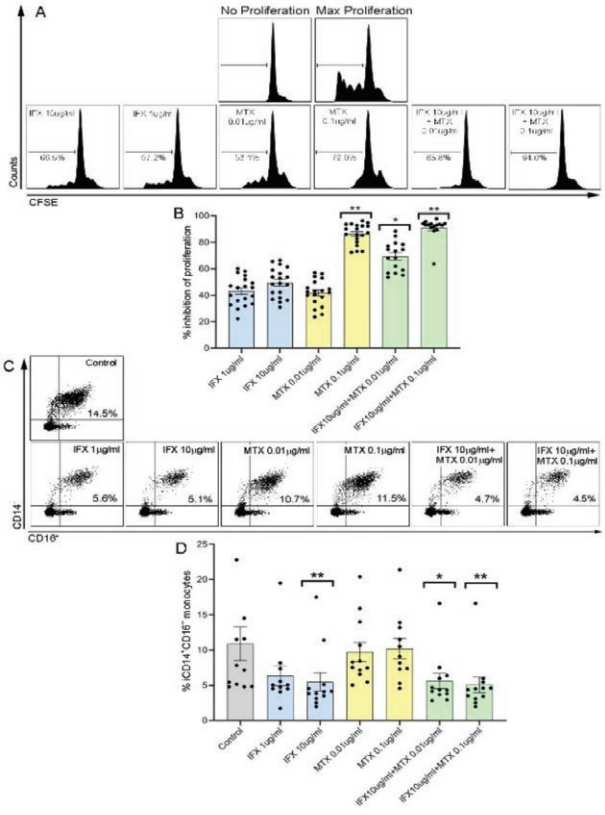

Figure 1. Ex-vivo effects of TNFi and MTX on proliferation inhibition and synovial $CD14^+CD16^+$ monocytes. CFSE-labeled healthy donors PBMCs (n=19) were incubated 5 days without PHA or with PHA alone (5µg/ml), or PHA in the presence of the drugs. (A) Representative plots showing CFSE-labeled healthy subject PBMCs. In the **upper panel**: Proliferation was measured either without PHA (no proliferation) or with PHA alone (maximal proliferation). Proliferation extent is shown in the left side of each plot. **Lower panel**: PHA with different drugs. Each image indicates %proliferation inhibition exerted by each drug. (B) Graph shows mean %proliferation inhibition, $*p < 0.05$, $**p < 0.01$.

SFMCs from PsA patients (n=11) were co-cultured for 7 days with the drugs or with medium alone. (C) Representative PsA patient SFMCs image gated for CD14 and CD16. Positive staining is presented in the right upper quadrant of each plot with $\%CD14^+CD16^+$ monocytes indicated. (D) Graph shows comparison between the groups. Statistical analysis was performed by the non-parametric one-way ANOVA Kruskal-Wallis test followed by Dunn's multiple comparison test, data are shown as mean ± SEM, $*p < 0.05$, $**p < 0.01$.
Conclusion: The immunomodulatory effects induced by TNFi and MTX provide indications for their anti-proliferative activity on PBMCs and on reduction of intermediate synovial monocytes, both involved in perpetuation of arthritis. While both TNFi and MTX inhibited PBMCs proliferation, only TNFi reduced the intermediate synovial monocytes, suggesting that different immune reactions could be controlled by specific drugs targeting distinct immune populations.

LEUCOCYTE ABNORMALITIES IN SYNOVIAL FLUID OF DEGENERATIVE AND INFLAMMATORY ARTHROPATHIES

Keywords: Inflammatory arthritides, Cytokines and chemokines

C. Baggio[1], R. Luisetto[2], C. Boscaro[3], A. Scanu[4], R. Ramonda[1], M. Albiero[3], P. Sfriso[1], F. Oliviero[1]. [1]*University of Padova, Rheumatology Unit - Department of Medicine, Padova, Italy*; [2]*University of Padova, Department of Surgery, Oncology and Gastroenterology-DISCOG, Padova, Italy*; [3]*University of Padova, Department of Medicine; Veneto Institute of Molecular Medicine, Padova, Italy*; [4]*University of Padova, Department of Woman's and Child's Health, Padova, Italy*

Background: Genome damage has been related to the induction of autoimmune processes, chronic inflammation, and apoptosis. Recent studies suggest that some rheumatological disease are associated with overall genomic instability in the T cell compartment [1,2]. However, no data regarding leucocytes abnormalities in synovial fluid (SF) and their relationship with inflammation are available.
Objectives: The aim of this study was to investigate cellular phenotypes in SF collected from patients with different inflammatory arthropathies, including rheumatoid arthritis (RA), psoriatic arthritis (PsA), crystal-induced arthritis (CIA) and non-inflammatory arthropathies such as osteoarthritis (OA).
Methods: SFs were collected by arthrocentesis from swollen knees of untreated adult patients with RA (n = 6), PsA (n = 12), CIA (n = 10), and OA (n = 7). Total white blood cell (WBC) count was performed using a Bürker counting chamber. Differential leucocyte count was performed by microscopic examination of 300 cells on May Grunwald Giemsa-stained preparations (MGG). Crystal search was performed using compensated polarized light microscopy. MGG staining was used for studying cellular morphology and to perform a cytogenic evaluation of leucocytes. All slides were examined for micronuclei (MN) and nuclear abnormality (NA) included binucleated cells, and karyolitic, karyorrhectic, and pyknotic cells. The following cytokines, chemokines and growth factors were measured in SFs using commercially available ELISA kits: interleukin (IL)-1β, IL-6, IL-8, IL-10, TGFβ, and TNFα. The expression levels of factors involved in apoptosis such as BCL-2, BAK, BID, BAD and BAX were measured by real-time quantitative PCR (qPCR). Caspase-3 activity was determined using commercially available colorimetric assay kit.
Results: We found high percentage of MN in SF from CIA and RA compared to the OA group ($p<0.05$) and a high frequency of pyknotic cell in RA ($p<0.05$) and CIA patients ($p<0.01$). The percentage of karyorrhectic and karyolitic cells were higher in RA patients with respect to OA and PsA patients ($p<0.05$). A correlation between pyknosis and immature polymorphonuclear cells with local inflammatory indices was observed. A strong positive correlation between local inflammatory cellular indices including WBC and PMN and the cytokines IL-1β, IL-6, IL-8, IL-10 was found. The study of apoptosis process revealed an increased BAX expression in CIA ($p<0.05$) and RA ($p<0.08$) compared to OA and PsA, while Bcl-2 was higher in CIA ($p<0.05$). Caspase-3 activity was increased in SF from RA patients compared to OA and PsA ($p<0.05$) and correlates with inflammatory and anti-inflammatory cytokines (IL-1β, IL-8, IL-10).
Conclusion: Our results showed that inflammatory SF are associated with genomic instability and abnormal cell subsets. A deeper knowledge of different abnormal cell subsets and their function could lead to a better understanding of the mechanisms underlying in the resolution of inflammation in these diseases.

AB0029 DISBALANCE OF SYNOVIAL FLUID CYTOKINES IN CHRONIC KNEE SYNOVITIS

Keywords: Synovium, Cytokines and chemokines

M. Karimov[1], T. Nuriakhmetova[2], A. Nuriakhmetov[3], I. Akhtiamov[4]. *[1]Tashkent Medical Academy, Traumatology, Orthopedic and Military Surgery, Tashkent, Uzbekistan*; *[2]Kazan State Medical University, Hospital therapy, Kazan, Russian Federation*; *[3]Republican Clinical Hospital, Orthopedics No. 2, Kazan, Russian Federation*; *[4]Kazan State Medical University, Traumatology, Orthopedic and Military Surgery, Kazan, Russian Federation*

Background: One of the most important issues of orthopedics remain long-standing synovitis despite the treatment after traumas and arthroscopy even after removal of mechanical irritating factor (meniscal resection, chondroplasty). In the long term prolonged treatment of arthritis may lead to irreversible joint damage progression. Current generally accepted strategy is to start the treatment as early as possible which affects the following disease course. Due to this, the study of pathogenetic features of posttraumatic synovitis is of interest as based on them, the choice of the most specific and effective treatment may be made.
Objectives: To study the features of cytokine level changes in synovial fluid in knee synovitis.
Methods: The prospective study of patients with long-standing knee synovitis included knee arthroscopy and outcome registration, measurement of cytokines in aspirated prior to surgery synovial fluid using flow fluorometry.
Results: The study included 41 patients (31.7% males and 68.3% females) with an average age 51.3±12.5 years. Trauma was present in 48.8% of patients. The duration of synovitis below 1 years was observed in 68.3% of patients, 56.1% of them had it for less than 6 months. Osteoarthritis stage 1 was observed in 24.4% of patients, stage 2 – in 22%, stage 3 – in 39%, stage 4 – in 14.6% of patients. The average VAS score on inclusion prior to arthroscopy was 3.56±0.72. Improvement immediately after the surgery was observed in 28 patients (68.3%). Other patients (31.7%) had long-standing synovitis (for over 2 weeks after the intervention), and 7 of them (17%) – for over 2 months. In the synovial fluid the level of IL-10 and TNFα decreased with increasing age (rs=-0,637, p=0,014 и rs=-0,481, p=0,044, respectively). The level of IL-10 positively correlated with synovitis duration (rs=0,830, p=0,011). Besides, in patients with synovitis duration more than a year, the level of IL-4 (r=0,578, p=0,024) and IL-10 (r=0,769, p=0,022) was higher. IL-4 was also higher with higher intensity of pain according to VAS score (rs=0,799, p=0,041). Also, there was a correlation of IL-6 level and presence of trauma in past medical history (p=0.05).
Conclusion: Proinflammatory TNFα and anti-inflammatory IL-10 positively correlated with the age. If synovitis was present for over a year, patients had higher levels of IL-4 and IL-10, which could be explained by proliferation processes in osteoarthritis. High pain intensity was associated with higher levels of IL-4. Trauma was associated with increased levels of IL-6 in synovial fluid, which may probably be the trigger factor of inflammation.

Background: Osteoarthritis (OA) is associated with metabolic and structural changes in all joint tissues. Subchondral bone sclerosis, cartilage degradation, and synovial inflammation are the main hallmarks of OA [1–3]. OMD is a keratan sulfate proteoglycan, a member of the small leucine-rich proteoglycan (SLRP) family. OMD was first identified in bone where it is involved in the mineralization process [4,5]. Our previous work demonstrated that in the secretome of osteoblasts, OMD was one of the most differentiating factors between osteoblasts originating from the sclerotic and non-sclerotic zone of OA subchondral bone [3]. OMD levels were lower in the supernatant of osteoblasts coming from the sclerotic area.
Objectives: The present work examined if OMD is involved in bone and cartilage changes occurring during skeletal development and in OA.
Methods: We used *Omd* knock-out (KO) or overexpressing male mice and mutant zebrafish to study *in vivo* the impact of OMD on skeletal development and aging. We investigated the influence of OMD on the severity of cartilage and bone damage induced by destabilization of the medial meniscus in these mice. We also analyzed the animals' gait using the CatWalk XT system. The effect of OMD on gene expression by human trabecular osteoblasts in monolayer culture was analyzed by RNA sequencing method. Finally, OMD binding to RANKL was assessed using a solid phase binding assay.
Results: In wild-type mice, we identified OMD mainly in bone and calcified cartilage. Tibial growth plate significantly decreased in all genotypes with age but to a lesser extent in the KO mice than in other genotypes. In KO mice, the calcified cartilage layer was thinner in the medial tibial plateau and thicker in the tibial lateral plateau than in the wild-type, while total cartilage thickness was not different between genotypes. We also demonstrated that *Omd* deficiency led to thicker and less porous bone and subchondral bone sclerosis. *Omd* knock-out mice spontaneously developed more severe OA cartilage lesions in the medial

tibial plateau than the wild-type during aging. In contrast, OMD production did not influence cartilage and bone changes induced by median meniscus destabilization. The gait pattern of mice was abnormal in KO compared to the wild-type genotype with a shorter swing and a smaller paw contact intensity. *omd*$^{-/-}$ zebrafish developed more severe cartilage lesions than wild-type. In osteoblasts culture, OMD down-regulated some genes involved in the extracellular matrix organization and up-regulated other genes responsible for the collagen network degradation. Finally, OMD bound to RANKL and inhibited osteoclastogenesis.

Conclusion: Alterations of the OMD expression modify bone and cartilage metabolism and structure. OMD helps to preserve bone and cartilage integrity and a local decrease in its production leads to the development of OA mainly by increasing subchondral bone sclerosis and thinning the calcified cartilage.

AB0031 ASSOCIATION BETWEEN OMEGA-3/6 FATTY ACIDS AND OSTEOARTHRITIS: A TWO-SAMPLE MENDELIAN RANDOMIZATION STUDY

Keywords: Osteoarthritis, Validation, Biomarkers

S. Wei[1,2,3], Y. Lu[1,2,3], S. Song[1,2,3], J. Qiao[1,2,3], S. X. Zhang[1,2,3], X. Li[1,2,3]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; [3]*Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China*

Background: Osteoarthritis (OA) is the most common degenerative joint disorder worldwide. Accumulating evidence has demonstrated the associations of omega-3 and omega-6 PUFAs with the disease activity and inflammatory mediators of OA, omega-3 polyunsaturated fatty acids (PUFAs) are recognized for their anti-inflammatory properties[1], while omega-6 FAs are inflammatory mediators that are increased in joints with OA[2]. However, the evidence of causal links of omega-3 and omega-6 PUFAs on the risk for OA remains inconclusive.

Objectives: This study was conducted to evaluate the causal relationships between omega-3/6 and OA by performing the two-sample Mendelian randomization (MR) analysis.

Methods: The data set of this study was from the publicly available genome-wide association study (GWAS). The genetic instrumental variables for omega-3/6 were derived from the UK Biobank (UKB) and included 114,999 participants. Summary statistic data for OA originated from a meta-analysis of GWAS with an overall 50 508 subjects of European ancestry. In the MR Approach, the IV analysis is based on three strict assumptions, namely that IV should be strongly correlated with exposure, independent of confounding factors associated with direction and outcome, and influence outcome solely through exposure. We screened SNPs with genome-wide significance ($P < 5 \times 10^{-8}$). To ensuring that the SNPs were valid and independent, we removed the linkage disequilibrium (LD) between the SNPs at $r^2 < 0.001$, and <10,000 kb in size. Furthermore, the secondary phenotype of each SNP was retrieved to ensure that it was not associated with OA. The F statistic > 10 indicated a relatively strong estimated effect of IVs. Subsequently, two-sample Mendelian randomization analyses were conducted with inverse variance weighted (IVW), MR-Egger regression and weighted median methods. Sensitivity analyses were then conducted to assess the robustness of our results.

Results: The inverse-variance weighted (IVW) method revealed that higher omega-6 levels were correlated inversely with the risk of OA (β = -0.08, 95% CI [-0.16 to -0.02], P = 0.01), but no causal effect of omega-3 on the risk OA was observed (β = -0.04, 95% CI [-0.10 to -0.02], P = 0.15). The causal estimates from MR-Egger and weighted median methods revealed completely concurring effect directions ($\beta < 0$, $p < 0.05$). Cochran's Q of IVW analysis showed that there was heterogeneity among SNPs ($P < 0.05$), it does not affect the results of IVW, which shown the reliability of our results. MR-Egger regression analysis demonstrated that SNPs could have no-horizontal pleiotropy between omega-6 fatty acids and risk of OA ($P > 0.05$). Moreover, Results of the leave-one-out method suggested that MR results were not influenced by individual SNPs.

Conclusion: This study revealed that the high level of omega-6 predicted by genes can reduce the risk of OA. This implies that supplementing omega-6 fatty acids in our diet may be a potential nutritional modality for the prevention of OA.

AB0032 LOCAL EXPRESSION OF miRNAS IN OSTEOARTHRITIS PATIENTS

Keywords: Osteoarthritis, Biomarkers

R. Shumnalieva[1], D. Kachakova[2], R. Kaneva[2], Z. Kolarov[1], S. Monov[1]. [1]*Medical University-Sofia, Department of Rheumatology, Clinic of Rheumatology, Sofia, Bulgaria*; [2]*Medical University – Sofia, Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria*

Background: Microribonucleic acids (miRNAs) comprise a class of small non-coding RNAs that negatively regulate the gene expression on posttranscriptional level. Altered expression of miRNAs has been described systemically as well as locally in the inflamed joints of patients with osteoarthritis (OA) [1-3].

Objectives: The aim of our study was to evaluate the synovial fluid (SF) expression of miRNA-146a (miR-146a), miR-155, miR-193 in OA patients and to determine their role as potential diagnostic biomarkers for this disease.

Methods: 16 OA patients were included in the analysis. Expression levels of miR-146a, miR-155 and miR-193b in SF samples were determined by qPCR (SybrGreen technology) and compared to healthy controls (HCs). Relative changes of gene expression levels of the studied miRNAs were calculated by $2^{-\Delta\Delta Ct}$ method. SPSS v20 was used for statistical analysis.

Results: OA SF showed statistically significant overexpression of miR-146a (in 75.00%), of miR-155 (in 68.75%) and of miR-193b (in 75.00%) when compared to HCs and these miRNAs could be used to differentiate OA from HCs ($p=5.9x10^{-3}$, p=0.043 and $p=5.5x10^{-3}$, respectively). Receiver operating characteristic (ROC) curve analysis was constructed in order to evaluate the diagnostic accuracy of the studied miRNAs in SF to distinguish OA from HCs by using relative expression (RQ) values. Area under the curve (AUC) for miR-146a was 0.830 (95%CI=0.674÷0.985, with 75.00% sensitivity and 72.70% specificity, p=0.004), AUC for miR-155 was 0.767 (95% CI=0.582÷0.952, with 75.00% sensitivity and 54.50% specificity, p=0.020) and AUC for miR-193b was 0.801 (95% CI =0.622÷0.981, with 87.50% sensitivity and 63.60% specificity, p=0.009). There was a correlation between the SF expression levels of miR-146a and miR-193b and the radiographic stage of the disease (p=0.0071 and p=0.0105, respectively). SF levels of miR-146a and miR-155 correlated with the SF cell count ($p=5.16x10^{-3}$ and p=0.0188, respectively).

Conclusion: We found an altered SF expression of miR-146a, miR-155 and miR-193b in OA patients when compared to HCs and these miRNAs could serve as potential diagnostic biomarker for inflammatory OA. Larger sets are needed to confirm the diagnostic accuracy of the studied miRNAs in OA.

AB0033 JANUS KINASE INHIBITOR CAN SUPPRESS STAT3 ACTIVATION IN THE SYNOVIAL TISSUES FROM THE HIP JOINT IN THE EARLY STAGE OF RAPIDLY PROGRESSIVE OSTEOARTHRITIS OF THE HIP

Keywords: Osteoarthritis, Synovium, Targeted synthetic drugs

T. Yasuda[1], S. Mitsuzawa[1], S. Yamashita[1], Y. Tsukamoto[1], H. Takeuchi[1], S. Ota[1], E. Onishi[1]. [1]*Kobe City Medical Center General Hospital, Department of Orthopedic Surgery, Kobe, Japan*

Background: Rapidly progressive osteoarthritis of the hip (RPOH) is an unusual subset of hip osteoarthritis (OA). RPOH with femoral head destruction within 12 months after the onset is associated with increased serum levels of matrix metalloproteinase-3 (MMP-3). Interleukin-6 (IL-6) signaling activates STAT3, resulting in MMP-3 production in OA synovial fibroblasts in culture. The IL-6/gp130-associated Janus kinases/STAT3 axis plays a critical role in mediating inflammatory signals. No information is currently available on STAT3 activation in the synovial tissues in the early stage of RPOH. Recently, tofacitinib and meloxicam have been shown to inhibit STAT3 activation.
Objectives: This study aimed to investigate suppression of phosphorylated STAT3 in the synovial tissues from the hip joint with RPOH after incubation with the potential STAT3 inhibitors.
Methods: Synovial tissues near the acetabular notch of the hip joint were obtained from four RPOH patients with femoral head destruction at the time of total hip replacement. Whereas the initial radiograph showed no typical feature of OA such as joint space narrowing, formation of osteophytes or bone cysts, each patient developed chondrolysis with bone destruction. Duration between the disease onset and operation were 5-7 months. The serum concentration of MMP-3 was determined within two weeks before operation. The tissue samples were incubated for 1 hour with or without tofacitinib or meloxicam. Immunohistochemical examination was performed using anti-human CD3 antibody, anti-human CD68 antibody and anti-human phospho-STAT3 antibody. The number of phospho-STAT3-positive cells was counted in the three different areas of the synovium at a magnification of X 400. A mean percentage was calculated as phospho-STAT3-positive cells in all cell counts out of the three high-power fields in each of the four patients.
Results: The serum concentration of MMP-3 in each RPOH patient were above the reference intervals. RPOH synovial tissues demonstrated the synovial lining hyperplasia with an increase of CD68-positive macrophages and CD3-positive T lymphocytes. STAT3 activation was found in the synovial tissues by immunohistochemistry. The majority of phospho-STAT3-positive cells were the synovial lining cells and showed negative expression of CD68 or CD3. Treatment with tofacitinib resulted in a decrease in phospho-STAT3-positive cells. Immunohistochemical intensity of phospho-STAT3 staining in the nucleus were further classified as high or low, and phospho-STAT3-positive cell numbers were counted separately as high and low intensities. Tofacitinib decreased the percentage of phospho-STAT3-positive cells with high intensity with no alteration in the percentage of low intensity. In contrast, meloxicam showed no inhibition of STAT3 activation.
Conclusion: This study is the first report to show that Janus kinase inhibitor tofacitinib can suppress STAT3 activation in the synovial tissues in the hip joint with RPOH, mainly in synovial fibroblasts. STAT3 may be a potential therapeutic target for prevention of joint structural damage in RPOH. Currently, no non-operative treatment modality is available for RPOH. Based on the present results, tofacitinib may be an effective intervention before the occurrence of significant joint destruction by RPOH.

AB0034 NEXT GENERATION SEQUENCING AND SHIKONIN EFFECTS ON HUMAN PRIMARY ARTICULAR OSTEOARTHRITIS CHONDROCYTES

Keywords: Osteoarthritis

B. Lohberger[1], P. Sadoghi[1], A. Leithner[1], N. Kretschmer[2], B. Steinecker-Frohnwieser[3]. [1]*Medical University Graz, Department of Orthopedics and Trauma, Graz, Austria*; [2]*University of Graz, Department of Pharmacognosy, Graz, Austria*; [3]*Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Saalfelden, Austria*

Background: Osteoarthritis (OA) is one of the most common joint disorders, leading to functional disability, especially in people aged over 50 years, causing loss to the economy and affecting social development [1]. Drugs addressing the underlying biological causes of OA are not currently available [2].
Objectives: Naturally occurring naphthoquinone derivatives, such as shikonin and derivatives thereof, were shown to inhibit inflammatory processes and chondrocyte apoptosis by regulating the PI3K/AKT pathway in a rat model of OA [3]. The corresponding regulatory mechanisms in human OA chondrocytes and their influence by shikonin have not yet been investigated. To develop new therapeutic approaches, we investigated the effect of shikonin derivatives on inflammation, MMP expression, the regulation of MAPK signalling, and the gene expression patterns of DNA repair metabolism and the cell cycle in human healthy (HC) and OA chondrocytes (pCH-OA).
Methods: Viability was analyzed using the CellTiter-Glo® Assay. Inflammatory processes were investigated using a proteome profiler™ assay. Furthermore, we analyzed the effects of the shikonin derivatives by protein expression analysis of the phosphorylation pattern and the corresponding downstream gene regulation using RT-qPCR. Using next generation sequencing (NGS), we have analysed more than 70 key genes of the DNA damage metabolism and cell cycle.
Results: Both HC and pCH-OA showed a dose-dependent decrease in viability after treatment. The strongest effects were found for shikonin with IC50 values of 1.2 ± 0.1 µM. Shikonin counteracts the inflammatory response by massively reducing the expression of the pro-inflammatory mediators. The phosphorylation level of ERK changed slightly. pJNK and pp38 showed a significant increase, and the downstream targets c/EBPs and MEF2c may play a role in the cartilage homeostasis. STAT3 phosphorylation decreased significantly and has a chondroprotective function through the regulation of cyclin D1 and Sox9. NGS data showed a highly significant difference in gene expression under the influence of shikonin.
Conclusion: Our results demonstrate for the first time that shikonin derivatives have extensive effects on the inflammatory processes, MAPKs, the IL6/STAT3 downstream regulation and the DNA repair gene expression pattern in healthy and OA chondrocytes.

AB0035 CHEMOKINES (IL-8 & GRO-A) AND CXCR1/2 PATHWAY INDUCES SENESCENCE INDUCTION IN CHONDROCYTES

Keywords: Cytokines and chemokines, Cartilage, Osteoarthritis

A. K. Anuja[1], A. K. Srivastav[2], M. K. Rai[2], L. Gupta[2,3,4,5], D. P. Misra[2], V. Agarwal[2]. [1]*Sanjay Gandhi Post Graduate Institute of Medical Sciences (SGPGIMS), Clinical Immunology & Rheumatology, Lucknow, India*; [2]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology & Rheumatology, Lucknow, India*; [3]*Royal Wolverhampton Hospital NHS Trust, Department of Rheumatology, Wolverhampton, United Kingdom*; [4]*City Hospital, Sandwell and West Birmingham Hospitals, Department of Rheumatology, Birmingham, United Kingdom*; [5]*The University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Centre for Musculoskeletal Research, Manchester, United Kingdom*

Background: Tumor Necrosis Factor-α(TNF- α) and Interleukin(IL-1) are well-known in the induction of senescence in chondrocytes and play an important role in the pathogenesis of Osteoarthritis (OA). However, targeting these pathways has not yielded promising results. The chemokines IL-8(CXCL8) and Gro-α(CXCL1), as well as the CXCR1/2 pathways, are known to mediate inflammation and apoptosis. However, the precise role of these chemokines in the

pathogenesis of OA is unknown. We hypothesize that the CXCR1/2 signaling pathway is involved in the induction of senescence in chondrocytes.

Objectives: To evaluate the role of chemokines and CXCR1/2 pathway in induction of senescence in chondrocytes derived from patients with OA and healthy chondrocytes cell.

Methods: Healthy primary chondrocytes(HPC) cell lines and human primary chondrocyte cells derived from patients diagnosed with OA cultured and expanded up to passage 5. Cells were induced with IL-8 and GRO–a followed by determining the senescence marker via β -galactosidase(β-GAL, histochemical staining) and UPAR and P16NKa using qRT-PCR. Apoptosis in both HPCs and OPCs were done via Annexin V and Proprium iodide (PI) using Flow-cytometry. Statistical analysis was performed using un-paired t test and One-way-Anova.

Results: This study showed that the % of β-GAL in the HPC were almost negligible. However, showed significantly higher % in OPC(*p<0.001*). Moreover, when stimulated with IL-8, exhibited markedly increase in the positive blue cells in both HPCs and OPCs in a time dependent manner (p<*0.001*)(at 24 hrs., 48 hrs., 72 hrs. & 96 hrs.). In line with results of HPC and OPC stimulated with IL-8, OPC also showed higher % of senescence when induced with Gro- α (p<*0.001*)(at 24 hrs., 48 hrs.,72 hrs. & 96 hrs **{Figure 1(A)(B)(C)}.** Since TNF-α and IL1-β reported to have role in induction of senescence in chondrocytes, we have examined the β-GAL in HPC and OPC treated with TNF-α and IL1-β and found significant higher no. of blue stained in the OPC**(Table 1)**. These results were further validated by fold change expression of senescence induced genes *P16NKa* and *UPAR* at time dependent manner. We observed higher fold change expression of *P16NKa* in IL-8 induced OPC at 24 hrs. (*p=0.01*); at 48 hrs. (*p<0.001*); at 72 hrs. (*p=0.03*) and at 96 hrs. (*p<0.001*) with that of IL-8 induced HPC. However, stimulation with Gro-α showed increase in the expression of *P16NKa* in a time dependent manner(at 24 hrs., 48hrs., 72hrs. and 96 hrs.) in both OPCs and HPCs. Similarly, the expression of *UPAR in* IL-8 induced OPCs at 24 hrs.(*p=0.69*); at 48 hrs.(*p=0.05*); at 72 hrs. (*p<0.0001*) and at 96 hrs. (*p=0.01*) with that of Gro–α induced HPC. While the expression of *UPAR* in Gro–α induced OPCs and HPCs showed increase in a time dependent manner(at 24 hrs., 48 hrs., 72 hrs. and 96 hrs.). Flow-cytometric analysis revealed that induced cells were negative expression for apoptotic markers viz., Annexin V and PI.

Conclusion: Overall, this study highlights that IL-8 and Gro- α induce senescence in chondrocytes, a key event in the pathogenesis of OA. However, CXCR2 pathway may be explored further for therapeutic potential.

AB0036 HIGH THROUGHPUT SIRNA EFFICACY SCREENING USING FLUORESCENCE SYSTEM

Keywords: Cartilage, Osteoarthritis, Genetics/Epigenetics

M. Deniz[1], L. Hakimi Pour[1], A. S. Thorup[1], F. Dell'accio[1]. [1]*The William Harvey Research Institute, Experimental Medicine and Rheumatology, London, United Kingdom*

Background: Osteoarthritis (OA) is characterized by loss of articular cartilage, bone remodelling and pain. It is a leading cause of disability in the elderly population. Currently, there are no disease modifying drugs to stop progression of OA. One bottleneck in clinical translation is that the cartilage extracellular matrix is avascular and impenetrable for large macromolecules. siRNA induces highly specific gene silencing and can be used for targets that are "undruggable". A novel therapeutic target that has been identified for treatment of OA include using siRNA to silence receptor tyrosine kinase–like orphan receptor 2 (ROR2) which offers great potential in improving pain outcomes and structural integrity in OA mice (Thorup et al., 2020). However, efficacy of "naked" siRNA is limited as it is instantly targeted for degradation by nucleases. To improve utility of siRNA as a therapeutic modality, chemical modifications can be introduced to the siRNA backbone, and it can be coupled with carrier molecules.

Objectives: To identify RNA backbone modifications to achieve long-term silencing in joint tissues following intra-articular injection.

Methods: Cos7 cells transduced with a lentivirus encoding EGFP and one specific clone was selected and expanded for downstream experiments (Eldridge *et al.*, 2016). Transfections were performed using JetPrime. Modified siRNA was generated by Integrated DNA Technologies.

Results: As a screening system, we optimized a microtitre plate system coupled with live fluorescent detection to measure GFP expression in cell monolayers. The fluorescence system uses a 96-well plate and allows for repeat measurements over time, without the need to harvest samples at each timepoint. Using this system, we compared 5 different modifications were compared. The best modification allowed to silence GFP in GFP-expressing cells for at least 10 days. The best modification was coupled with atelocollagen and administered via intra-articular injections into mice expressing GFP ubiquitously. After 3 weeks, GFP was efficiently silenced in the full thickness of the cartilage.

Conclusion: Chemical modifications of the RNA backbone and coupling with atelocollagen affords stable gene silencing in cartilage for at least 3 weeks. This technology enables fast, dose-dependent loss of function experiments in animal models of osteoarthritis. This methodology could be developed in the future to therapeutically target pathogenic molecules that are out of reach of traditional biologics such as transcription factors.

AB0037 GENETIC EVIDENCE REVEALS A CAUSAL ROLE OF WHITE BLOOD CELL COUNT IN OSTEOARTHRITIS

Keywords: Genetics/Epigenetics, Osteoarthritis

Q. Wang[1,2], X. Ma[1,2], Y. Niu[1,2], Q. Yu[3], P. F. He[3], X. Li[1,2,4], S. X. Zhang[1,2,4]. [1]*Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; [2]*Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China*; [3]*Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*; [4]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: Osteoarthritis (OA) is increasingly recognized as a disease with a significant inflammatory component[1]. Signs of inflammation such as synovitis can be identified in OA patients using magnetic resonance imaging (MRI) and ultrasonographic imaging. The white blood cell count in synovial tissue has been considered useful in the assessment and diagnosis of arthritis. However, the causal relationship between the white blood cell count and OA has yet to be well.

Objectives: To investigate associations between white blood cell count and OA.
Methods: Mendelian randomized analysis (MR) was performed using white blood cell count as exposure data and OA as outcome data. This study included 173,480 individuals of European ancestry for exposure traits from three extensive UK studies[2]. The random effects inverse variance weighting (IVW) method was used for the primary analysis, and the weighted median and MR-Egger methods were supplemented for analysis. Then, we performed Cochran's Q test, MR pleiotropy residual sum and outlier (MR-PRESSO), to test for heterogeneity and horizontal multiplicity. The sensitivity analysis was also performed to verify the robustness of the primary results of the MR analysis.
Results: IVW method showed that knee or hip (OR=0.942, 95% CI:0.895-0.990, P =0.019), knee (OR=0.944, 95% CI:0.886-1.007, P=0.041) and hip (OR=0.929, 95% CI:0.868-0.995, P=0.035)had a protective effect on white blood cell count. After removing the confounding factors, we identified a significant causal association between white blood cell count and OA by IVW using residual single nucleotide polymorphisms (157 remaining in knee, 159 remaining in hip, and 159 remaining in knee or hip). P values of IVW were less than 0.05, indicating a significant causal relationship. Further sensitivity analyses validated the robustness of the MR results.(Figure 1)
Conclusion: There was a significant causal relationship between white blood cell count and OA. This is meaningful for the prevention and treatment of OA in the future.

AB0038 HINDLIMB SUSPENSION INDUCES KNEE MALALIGNMENTS WITH PATELLOFEMORAL OSTEOARTHRITIS IN GROWING RATS

Keywords: Cartilage, Physical therapy/Physiotherapy

J. Ozawa[1], A. Ikeda[2,3], M. Kanehara[2], A. Kaneguchi[1], H. Moriyama[4]. [1]*Hiroshima International University, Department of Rehabilitation, Higashi-hiroshima,*; [2]*Hiroshima International University, Graduate school of Medical Technology and Health Welfare Sciences, Higashi-hiroshima, Japan*; [3]*Takarazuka University of Medical and Health Care, Department of Judo therapy, Takarazuka, Japan*; [4]*Kobe University, Life and Medical Sciences Area, Kobe, Japan*

Background: Patellofemoral instability is a common disease in pediatrics and patients with Down's syndrome. Reduced weight bearing during growth in the rat hindlimb suspension (HS) model leads to abnormal morphologies of distal femur, which are associated with patellofemoral instability[1]. However, no study has examined whether reduced weight bearing can induce knee joint instability.
Objectives: The aim of this study was to test whether hindlimb suspension in skeletally immature rats affects knee joint alignments and patellofemoral joint pathology. We hypothesized that reduced weight bearing results in knee malalignments such as externally translocation of patella and lateral tibial rotation. Furthermore, lateral patellar dislocation occurs with arthritic changes in the patellofemoral joint.
Methods: Four-week-old female rats were used in this study. In HS groups, rats were applied hindlimb suspension for up to 8 weeks using a tail suspension method. Age-matched untreated rats were used as controls. Knee joints (tibia-femur complex) were isolated and three-dimensional reconstructed images were obtained using X-ray computed tomography. Tibial tubercle-trochlear groove (TT-TG), patellar tilt angle, and bisect offset were measured as indexes of femorotibial or patellofemoral joint malalignment. Histological analysis was also performed to evaluate the osteoarthritic changes in the patellofemoral joints. In addition, gene expression profiles of medial patellofemoral ligament (MPFL), which plays as a stabilizer of the medial aspect of the patella, were analyzed with microarrays in both groups at week 4.
Results: Knee alignment data are shown in Table 1. At week 8, TT-TG, patella tilt angle, and bisect offset in HS group were larger than those in age-matched control, respectively (all $P < 0.05$). These results indicated that tibial external rotation, patellar tilt outward, and external displacement of patella, respectively. In addition, lateral patellar dislocation appeared frequently after 8 weeks of HS (5/8 knee joint, Fisher's exact test, $P < 0.05$). Articular cartilage in the trochlear grooves decreased or disappeared at 8 weeks of HS, especially in the dislocated patellofemoral joint. Modified Mankin's histological score supported these osteoarthritic changes. Synovial hypertrophy was observed at 4 weeks and progressed at 8 weeks of HS. The findings were supported by OARSI synovitis score. Microarray analysis of MPFL revealed that the gene expression of matrix metalloproteinase (MMP)-2, -3, enzymes of collagen degradation, were higher in HS than control (log2 ratio: 1.24 and 3.09, respectively), and tissue inhibitor of metalloproteinase (TIMP)-3, -4, MMPs inhibitor, were lower in HS than control (log2 ratio: -1.79 and -2.84, respectively).
Conclusion: Reduced joint loading during growth resulted in knee malalignments such as external rotation of tibia, lateral tilt, and translocation of patella. In addition, high incidence of lateral patellar dislocation with concomitant patellofemoral OA was found after HS for 8 weeks. Patellofemoral instability may be involved in dysfunction of MPFL via degradation of collagens.

AB0039 EXPRESSION OF INFLAMMATORY MARKERS IN PATIENTS WITH PAINFUL KNEE OSTEOARTHRITIS: A MULTIVARIATE ANALYSIS OF PRESURGICAL SERUM SAMPLES

Keywords: Pain, Biomarkers, -omics

R. Giordano[1], K. Kjær Petersen[2], B. Ghafouri[3], L. Arendt-Nielsen[4]. [1]*Aalborg University, School of Medicine, CNAP/SMI, Gistrup, Denmark*; [2]*Aalborg University, School of Medicine, CMNAP/SMI, Gistrup, Denmark*; [3]*Linköping University, Pain and Rehabilitation Centre, and Department of Health, Medicine and Caring Science, Linköping, Sweden*; [4]*School of Medicine, Aalborg Universiity, CNAP/SMI, Gistrup, Denmark*

Background: Knee osteoarthritis (KOA) is a pathological condition prevalent in the general population. Exercise and pharmaceutical approaches are first-line treatments and the end-stage treatment is total knee replacement (TKR).

Interestingly, around 20% of patients experience chronic postoperative pain and the reason for this is not fully understood. Pain in OA is multifactorial and low-grade chronic inflammation has been indicated as a potential cause. Pre-clinical evidence suggests that pro-inflammatory mediators, such as interleukin 6, can sensitize the peripheral and central nerves and these molecules might be associated to clinical pain. Clinical evidence has demonstrated differences in pro-inflammatory mediators when comparing patients with OA and healthy individuals. A recent study has linked these profiles to chronic postoperative pain after TKR but an in-depth analysis, as seen for neuropathic and widespread pain is needed to advance the field. Currently, no specific biomarkers have been identified, despite initiatives on focused molecular inflammatory mediators. In an attempt to advance the field, a comprehensive analysis of an extensive network of cytokines, chemokines, and growth factors could identify the role of low-grade inflammation in patients with OA and potentially stratify patients more prone to experiencing pain.

Objectives: This study aimed 1) to evaluate preoperative serum levels of 92 inflammatory biomarkers in KOA patients compared to healthy controls, 2) to investigate preoperative differences of inflammatory biomarkers within different subgroups of patients with KOA and link these subgroups to clinical pain before and after TKR surgery.

Methods: Blood samples from preoperative patients with KOA scheduled for TKR (n=200) and healthy participants (n=39) were collected. After centrifugation of the serum was frozen at -80C until analysis. Serum samples were analyzed for inflammatory markers using the OLINK inflammation panel, which included 92 protein markers. Clinical pain was assessed using a Visual Analog Scale (VAS). Moreover, patients completed the Knee injury and Osteoarthritis Outcome Score (KOOS) questionnaire before and 12 months after TKR. Multivariate data analysis was performed to identify differences between patients and controls. Hierarchical cluster analysis (HCA) and Orthogonal Partial least squares discriminant analysis (OPLS-DA) was used for comparing groups (patients vs controls) and to identify subgroups within patients. T-tests were used to evaluate difference within the KOA cohort in terms of VAS and KOOS scores before and 12 months after TKR.

Results: Multivariate analysis showed that 12 proteins were differentially expressed between patients and controls (P<0.05). Hierarchical cluster and OPLS-DA analysis identified two patient subgroups (pat-1, n = 46; pat-2, n= 72) and 23 proteins were dysregulated comparing these two groups (p<0.01). Post-operative VAS and KOOS assessments were significantly different between the two subgroups (p-<0.05).

Conclusion: The present study suggest a low-grade inflammation in patients with KOA when compared to healthy pain free subjects. Additionally, this study suggests that a high inflammatory subgroup for patients with KOA exist and this group is likely to have more clinical and worst function 12-months after TKR.

AB0040 DIFFERENCIALLY EXPRESSED GENES IN PATIENTS WITH OSTEOARTHRITIS

Keywords: Biomarkers, -omics, Osteoarthritis

R. Martinez[1], C. Elizondo Solis[1], A. Montoya Rosales[2], M. Salinas Carmona[1], N. Macias-Segura[1]. [1]*Servicio y Departamento de Inmunología, Service and Department of Immunology, Monterrey, Mexico*; [2]*UANL - CIDICS, Immunomodulators Laboratory, Monterrey, Mexico*

Background: Osteoarthritis (OA) is a chronic degenerative disease that affects the joints, causing symptoms of arthralgias, swelling, loss of flexibility, etc. It is the most common rheumatic disease with an estimate of 27 million patients in the US [2]. Its pathophysiology is not yet well understood, as it is thought to be a result of multiple factors that induce metalloproteases, synovial angiogenesis and inflammatory cytokines that leads to inflammation and cartilage destruction [3]. To better understand the molecular mechanisms underlying this disease, we performed a meta-analysis with integrative bioinformatics.

Objectives: We aimed to obtain and assess overlapped differentially expressed genes (DEGs) in datasets of patients with OA through functional enrichment and protein-protein interactions (PPI).

Methods: We designed a search strategy in the Gene Expression Omnibus platform to identify datasets of gene expression profiling by array of patients with osteoarthritis. The inclusion criteria were: 1) Presence of healthy controls in the datasets, and 2) Analysis of data with GEO2R. The exclusion criteria were: 1) Incomplete information in the datasets, 2) Failure to identify case and controls, and 3) Gene expression by RNAseq. DEGs were selected when $p < 0.05$ and Logfold change > 2. We assessed the genes with DAVID database, and PPI through String and Cytoscape; and performed a prediction analysis of possible therapeutic targets.

Results: 6 datasets fulfilled the inclusion criteria, and 128 overlapped DEGs were identified. DAVID database yielded the top 3 Biological Processes involving those genes (Table 1). Cytoscape detected 3 clusters in which those genes interact, and iRegulon proposed CHD1 gene as a possible therapeutic target to regulate the entire cluster (Figure 1).

Table 1. Top 3 biological processes involving overlapped DEGs among the datasets.

Biological Processes		
Term	**Gene Count**	***p*-value**
Positive Regulation of B-cell activation	9	3,7E-7
Complement activation, classical pathway	9	2,0E-6
Phagocytosis, recognition	8	5,3E-6

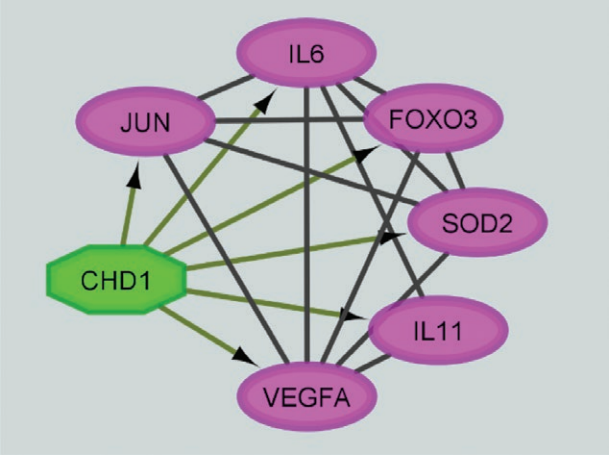

Figure 1. This cluster shows the genes with the strongest interactions. Cytoscape yielded other 2 clusters with a lower punctuation.

Conclusion: We aimed to identify and assess DEGs involved Osteoarthritis pathophysiology, as well as predict a possible therapeutic target. Our results suggest that immune processes involving B-cell activation and phagocytosis, as well as complement activation underlie OA pathophysiology. Validation of these results in patients with OA is needed since they can serve as possible diagnostic biomarkers. Further research is necessary to analyze the other clusters, and CHD1 characterization as a possible therapeutic target.

AB0041 IDENTIFICATION AND PROPERTIES OF EXOSOMES (EX) OF SYNOVIAL FLUID (SF) WITH GONARTROSIS (GA)

Keywords: Osteoarthritis, Synovium

E. De La Poza Plaza[1], V. Shishkin[2], V. V. Shishkin[2], G. V. Kudryavtseva[2], S. Barykin[3]. [1]*Universitat Politècnica de València, Faculty of Business Administration and Management, Valencia, Spain*; [2]*Saint-Petersburg State University, Diagnistic of Functional Systems, Saint-Petersburg, Russian Federation*; [3]*Peter the Great St. Petersburg Polytechnic University, Graduate School of Service and Trade, Saint-Petersburg, Russian Federation*

Background: EX - poorly studied extracellular vesicles, 30-150 nm in diameter, found in various biological fluids and have high functional activity, including immunomodulatory effects.
Objectives: The participation of EX in the development of complex connective tissue immunopathology requires further study. The aim of the work was to study EX of SF in GA.
Methods: SF of knee joints of 12 patients with GA with active synovitis and 7 conditional donors postmortem (D) were researched. EX was isolated by ultrafiltration and double ultracentrifugation (105 g).EX was identified by transmission electron microscopy and flow cytometry. Electrokinetic mobility (EM) determined by the automatic microscope. Registration of the active forms of oxygen (AFO2) was carried out by EPR. The activity of Cu-Zn superoxidismutase (Cu-Zn SOD), as well as DNA and RNA levels, was estimated by employing classical biochemistry methods.
Results: The EX population undergoes significant morphofunctional changes in GA: EX become smaller, their diameter decreases by an average of 2.5 times, and the value of the negative surface charge changes to 45.5%. EM EX at GA increases by 2.4 times. Against the background of the intensification of free radical processes in EX with GA, a decrease in the activity (on average by 1.7 times) of the pathogenic protein Cu-Zn-SOD is observed. The pronounced secretion of EX in GA is accompanied by an enhanced synthesis of information molecules, especially DNA, the amount of which increases by an average of 2 orders of magnitude (Table 1). At the same time, the floating density of EX in the sucrose gradient (g/ml) is normally 1.24 ± 0.09, and at GA 2.52 ± 0.14*.

Table 1. Some Characteristics of Synovial Fluid EX Populations in Normal (D) and in GA

EX	Diameter range, nm	Range charge, mV	DNA, µg/ml	RNA, µg/ml	Cu-Zn SOD, units/mg of protein	AFO2, units/mg of protein	EM, m/v sec
D	80 -120 (100)	-15,3; -13,4 (-14,4)	0,014 ± 0,003	0,085 ± 0,017	17,8 – 23,6 (20,7)	21,7 ± 3,7	0,84 ◆ 10-8
GA	30 – 50 (40)**	-10,2; -7,1 (-8,7)*	1,43 ± 0,32***	1,31 ± 0,2***	9,4 - 14,7 (12,1)*	48,4 ± 3,5 **	1,97 ◆ 10-8 **

* - p <0.05; ** - p <0.01; *** - p <0.001

Conclusion: The molecular mechanisms of GA progression are associated with the ability of EX to influence intercellular communication, epigenetically reprogram various target cells, activate protein biosynthesis, and be carriers of a number of mediators. Violation of exosomal immune intercellular communications, apparently, underlies the development of a variety of pathologies, including systemic connective tissue diseases.

AB0042 AUTOPHAGY IS DECREASED IN BONE FROM OSTEOPOROTIC PATIENTS

Keywords: Osteoporosis, Bone diseases, Cell biology

M. C. Trojani[1,2], C. Arnaud[3], B. Isabelle[4], R. Bernard De Dompsure[5], J. F. Gonzalez[5], C. Trojani[6], S. Santucci[1], G. F. Carle[1], V. Pierrefite-Carle[1], V. Breuil[1,2]. *[1]UMR E4320 UCA/CEA, MATOs Team, Nice, Nice CEDEX 2, France*; *[2]Nice University Hospital, Rheumatology Department, Nice, Nice, France*; *[3]Saint George Clinic, Orthopedic Department, Nice, Nice, France*; *[4]Cimiez Hospital, Geriatric Department, Nice, Nice, France*; *[5]Nice University Hospital, Orthopedic Department, Nice, France*; *[6]Clinique Kantys, Institut de Chirurgie réparatrice, Nice, Nice, France*

Background: Osteoporosis (OP) is a diffuse skeletal pathology characterized by major bone fragility that affects one out of 3 women after menopause. In addition to estrogen loss, an increase in oxidative stress is now recognized as a central mechanism in this pathology. Autophagy is an intracellular process allowing the removal and recycling of damaged proteins and organelles. Thanks to the elimination of damaged mitochondria, which are the main sources of reactive oxygen species, autophagy plays a major role in reducing oxidative stress. An age-related autophagy decline, associated with various experimental arguments in animal models, suggests autophagy implication in OP. However, a definitive proof in humans remains to be obtained.
Objectives: Our objective was to show for the first time that there is a defect in autophagy in the bone of osteoporotic patients.
Methods: We have analyzed autophagy by Western Blot in bone samples from 14 postmenopausal women with OP fracture compared to 30 controls undergoing total hip replacement for osteoarthritis.
Results: Our results indicate that the expression level of the autophagosome marker LC3-II is significantly decreased in OP patients compared to the age-matched controls. We also observed a tendency for the accumulation of the SQSTM1/p62 protein, which is an autophagy substrate, thus supporting the previous results. Finally, we also demonstrate a significant decrease in the hormonally up-regulated neu-associated kinase (HUNK) in bone samples from OP patients compared to the control group. This kinase, whose expression is upregulated by female hormones, promotes autophagy by inhibiting the autophagy inhibitor Rubicon through phosphorylation.
Conclusion: Taken together, these data demonstrate for the first time that OP patients have a deficit in osteocytes autophagy and suggest the involvement of the HUNK kinase in OP pathogenesis. This study should contribute to better understand the role of autophagy in OP pathophysiology and could lead to the design of new therapeutics targeting autophagy for the management of pathological aging.

AB0043 SERIAL ADMINISTRATION OF RECOMBINANT HUMAN BONE MORPHOGENETIC PROTEIN-2 AND OSTEOPROTEGERIN-FC ENHANCES THE DIFFERENTIATION OF OSTEOBLASTS

Keywords: Bone diseases, Osteoporosis

C. N. Son[1], H. J. Choi[1,2], J. M. Kim[1], S. H. Kim[1]. *[1]Keimyung University School of Medicine, Internal Medicine, Daegu, Korea, Rep. of (South Korea)*; *[2]Gyeongbuk Provincial College, Emergency Medical Technology, Gyeongbuk, Korea, Rep. of (South Korea)*

Background: Osteoprotegerin (OPG) is an intrinsic antagonist of the RANKL. A recent study reported that RANKL reverse signaling in osteoblasts may prepare osteoblasts for further maturation and that vesicular RANK stimulates osteoblast differentiation. Hence, OPG is expected to accelerate osteoblastogenesis by affecting RANKL reverse signaling.
Objectives: We compared the level of differentiation from preosteoblasts to osteoblasts by serially administrating recombinant human bone morphogenetic protein-2 (rhBMP-2), involved in bone formation and regeneration, and osteoprotegerin-immunoglobulin Fc segment complex (OPG-Fc), an osteoclast inhibitor.
Methods: The MC3T3-E1 preosteoblast cell line was differentiated for one, three, and seven days with a treatment of OPG-Fc in 10–200 ng/mL concentration and the cell viability was evaluated by Cell Counting Kit-8 analysis. The level of differentiation from MC3T3-E1 cells to osteoblasts was determined by alkaline phosphatase activity. The level of runt domain-containing transcription factor 2 (Runx2) and osteopontin (OPN) manifestation, involved in osteoblast differentiation, was examined by real-time polymerase chain reaction and western blotting.
Results: During MC3T3-E1 cell differentiation, the differentiation level was high with one-day treatment using 100 ng/mL OPG-Fc. The treatment with 50 ng/mL rhBMP-2 for seven days, followed by one-day treatment with 100 ng/mL OPG-Fc produced the highest differentiation level, which was approximately 5.3 times that of the control group ($P < 0.05$). The expression of Runx2 mRNA significantly increased, reaching 2.5 times the level of the control group under the condition of seven-day treatment with rhBMP-2 and one-day treatment with OPG-Fc ($P < 0.001$). The expression of Runx2 protein significantly increased to approximately 5.7 times that of the control group under the condition of seven-day treatment with rhBMP-2, followed by one-day treatment with OPG-Fc ($P < 0.01$). The expression of OPN protein showed no change from that of the control group under various conditions of rhBMP-2 and OPG-Fc combinations.
Conclusion: Differentiation ability of preosteoblasts to osteoblasts was strong with serial treatment and rhBMP-2, followed by OPG-Fc. Runx2 and OPN mRNA levels and Runx2 protein levels increased. These results imply that the combination of OPG-Fc and rhBMP-2 increased osteoblast differentiation efficacy.

Rheumatoid arthritis - aetiology, pathogenesis and animal models

AB0044 **INTERLEUKIN-18 BINDING PROTEIN REGULATES THE APOPTOSIS AND NECROPTOSIS OF FIBROBLAST-LIKE SYNOVIOCYTES AND CHONDROCYTES IN RHEUMATOID ARTHRITIS**

Keywords: Adaptive immunity, Rheumatoid arthritis, Cartilage

S. H. Lee[1], H. K. Min[2], H. R. Kim[1]. [1]*Konkuk University School of Medicine, Rheumatology, Seould, Korea, Rep. of (South Korea)*; [2]*Konkuk University Medical Center, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Interleukin (IL)-18 plays a pro-inflammatory role in rheumatoid arthritis (RA), and its decoy receptor IL-18 binding protein (IL-18BP) has a potential therapeutic role.
Objectives: We investigated the role of IL-18BP on the joint destruction process of RA by accessing the effects of IL-18BP on fibroblast-like synoviocytes (FLSs) and chondrocytes.
Methods: Peripheral blood mononuclear cells (PBMCs) from patients with RA and healthy controls were cultured under T cell proliferative conditions with 10, 50, or 100 ng/mL of IL-18BP. After three days of culture, flow cytometry for CD4+ T cells was performed using various IL-18BP concentrations. The apoptosis and necroptosis of FLSs and chondrocytes were measured by flow cytometry using annexin V and propidium iodide (PI) and western blot under TNF-α stimulation with IL-18BP (10, 50, and 100 ng/mL).
Results: Differentiation of CD4+ IL-17A+ and CD4+ IL-4+ cells decreased and that of CD4+ CD25high Foxp3+ and CD4+ interferon (IFN)-γ+ cells increased on addition of IL-18BP to cultured RA patient-driven PBMCs. RA-FLS migration ability was not suppressed by IL-18BP after 12 or 24 h. IL-18BP increased annexin V+ FLS level and reduced annexin V+ chondrocyte level in a dose-dependent manner, whereas PI+ annexin V- FLS and chondrocyte levels were suppressed by 50, 100 ng/mL IL-18BP in culture.
Conclusion: The administration of IL-18BP regulated the type 17 helper T cell/ regulatory T cell imbalance and attenuated the production of pro-inflammatory cytokines. IL-18BP further increased FLS apoptosis and decreased the necroptosis of FLS/chondrocytes and apoptosis of chondrocytes suggesting the joint preservative potential of IL-18BP.

AB0045 **CXCL14 IN EARLY AND ESTABLISHED RHEUMATOID ARTHRITIS**

Keywords: Cytokines and chemokines, Biomarkers, Rheumatoid arthritis

S. Lomholt[1], L. Hunskjær[1], S. R. Greisen[1,2], T. W. Kragstrup[1,2,3]. [1]*Department of Biomedicine, Aarhus University, Department of Biomedicine, Aarhus, Denmark*; [2]*Aarhus Universitetshospital, Department of Rheumatology, Aarhus, Denmark*; [3]*Silkeborg Regional Hospital, Diagnostic Center, Silkeborg, Denmark*

Background: Single cell sequencings studies have identified a CXCL14+ synovial fibroblast cluster in synovial tissue. This CXCL14+ cluster express CD34 and correlate to lower DAS28 and swollen joint count, while being similar between genders, age or sero status [1]. The biological role of CXCL14 in rheumatoid arthritis (RA) is unknown, but CXCL14+ synovial fibroblasts have been shown to express abundant GAS6, which regulate remission functions in MerTK+CD206+ synovial tissue macrophages [2]. This may suggest an anti-inflammatory or pro-remission role of the CXCL14+ synovial fibroblast cluster in specific RA pathotypes [1].
Objectives: Our study aimed to investigate soluble CXCL14 in plasma and synovial fluid and its potential connection to long term joint deterioration and disease activity in RA.
Methods: We used optimized commercial CXCL14 ELISA kits to investigate CXCL14 levels in 3 cohorts. 1) Plasma samples from patients with early RA (eRA) from the methotrexate arm of the CIMESTRA trial (N=80) [3]. 2) Plasma and synovial fluid from patients with established RA included at time of therapeutic arthrocentesis (the INART cohort) (N=41). 3) Plasma from matched healthy controls (HC) (N=44).
Results: Plasma CXCL14 was significantly higher compared to synovial fluid, median 2.3 ng/ml. CXCL14 levels in the two compartments corelate. Plasma and synovial fluid CXCL14 were not influenced by gender, ACPA, smoking status, disease duration or time since sampling. Age and rheumatoid factor status may affect plasma CXCL14 levels, but this was not consistent in both RA cohorts. Analysis showed a significant higher amount of plasma CXCL14 in patients with RA from the INART cohort, median 6.9 ng/ml, compared to eRA, median 4.8 ng/ml and HC, median 4.3 ng/ml. Plasma CXCL14 did not change significantly in patients with eRA after 1 year of treatment. Baseline plasma CXCL14 in patients with eRA significantly correlated to baseline tender joint count, but not DSA28, swollen joint count or total sharp score. Baseline plasma CXCL14 correlated to DAS28 after 5 years of treatment. Evaluating DAS28 after 11 years of treatment we observed a difference between patients in remission (DAS<2.6) and patients with active disease (DAS28 ≥ 2.6). For patients in remission, baseline CXCL14 correlated inversely with DAS28, whereas this correlation was positive in patients with active disease (Figure1). No associations were present between CXCL14 and change in total sharp score over a 11-year period.
Conclusion: Soluble CXCL14 can be measured in both plasma and synovial fluid from patients with RA. Plasma CXCL14 levels are higher compared to synovial fluid but a significant correlation is present between to two compartments. This suggests plasma CXCL14 as a potential proxy for CXCL14 activity in the joint and joint fluid. CXCL14 was not affected by gender, disease duration, smoking or 1 year of cDMARD treatment. Baseline CXCL14 correlated to higher DAS28 in the CIMESTRA cohort after 5 years and in patients with active disease after 11 years. Interestingly, we noticed that baseline CXCL14 may associate to lower DAS28 in patients in remission after 11 years. Together, this may support previous studies associating CXCL14 to an active anti-inflammatory (positive CXCL14/DAS28 correlation in active disease group) and pro-remission (negative CXCL14/DAS28 in remission group) role in RA.

Background: Epoxy fatty acids (EpFA), cytochrome P450(CYP)-mediated metabolites of polyunsaturated fatty acids (PUFA), have anti-inflammatory effects[1]. However, EpFA is quickly converted to an inactive form by the soluble epoxide hydrolase(sEH). In recent years, the efficacy of sEH inhibitors (sEHi) has been reported in a variety of diseases[2-4]. However, compared to ω-6 epoxides, such as epoxyeicosatirienioic acids (EET) derived from arachidonic acid (AA), there are few reports on ω-3 epoxides, epoxyeicosapentaenoic acid (EEQ) from eicosapentaenoic acid (EPA) and epoxydocosapentaenoic acids (EDP) from docosapentaenoic acid (DHA)5), and their effects on arthritis are not well understood.

Objectives: To investigate and compare the effects of ω-6 and ω-3 epoxides on inflammatory arthritis.

Methods: Collagen induced arthritis (CIA) were treated with three different diets (ω-6 PUFA rich, ω-3 PUFA rich, and Control) and two types of drinking solution, one containing sEHi and the other containing only polyethylene glycol as solvent control (total 6 groups, 8 mice each). Arthritis and pathological scores were evaluated, and feces were collected before the onset of arthritis (day 25) for intergroup comparative analysis of bacterial flora.

Results: In all the dietary groups, there was a tendency for arthritis scores to decrease with sEHi administration, but the incidence of arthritis, arthritis scores, and pathological scores decreased dramatically in the group fed with the ω-3 rich diet and sEHi combination. The groups fed the ω-6 rich diet and Control diet showed almost similar results. In the ω-3 rich diet and sEHi combination group, showed an increase in a certain specific bacterial strain.

Conclusion: ω-3 epoxides were found to be more effective in reducing arthritis, and changes in intestinal bacteria may have influenced this pathological change.

AB0047 **THERAPEUTIC POTENTIAL OF COLLAGEN-DERIVED PEPTIDE P90578 IN THE TREATMENT OF RHEUMATOID ARTHRITIS**

Keywords: Autoantibodies, Rheumatoid arthritis, Vaccination/Immunization

Y. L. Cho[1], C. Wenhart[1], S. Göbel[1], A. Reiman[1], Z. Li[1], M. Neuhaus[1], U. Finger[1], J. Kieselbach[1], G. Münch[1]. [1]*Advancecor, R&D Division, Martinsried, Germany*

Background: Antigen-specific peptide immunotherapy is a booming treatment strategy for autoimmune diseases and designs to restore immune tolerance against self-antigens. Published research findings and our previous study using peptides derived from type II collagen with chemical modification such as glycosylation and fructosylation as therapeutics showed promising outcomes in the reduction of arthritis progression[1,2]. However, the optimal choice of peptide doses in the rheumatoid arthritis (RA) murine model and its therapeutic effect on human samples still awaits to be investigated.

Objectives: The present study further investigated the optimal dose and therapeutic potential of our novel collagen-derived peptide P90578 in the arthritis murine model and RA patient serum samples.

Methods: Male 8-week-old DBA/1 mice were immunized s.c. at the base of the tail with 0.1 mg bovine collagen II and s.c. at the left flank with 0.2 mg human fibrinogen, each of which was separately emulsified in a 1:1 ratio with complete Freund´s adjuvant. On day 21 after the immunization, mice were boosted with 0.2 mg human fibrinogen in incomplete Freund´s Adjuvant s.c. at the left flank. Peptide P90578 or NaCl was intraperitoneally administered three times weekly at 3-day intervals starting on days 7, 24, and 42. Hind paws of the mice were examined for macro-anatomical pathology. Right hind paws of the mice were prepared post mortem and fixed in 4% paraformaldehyde, and embedded in OCT compound. Sagittal sections of 7 µm were cut with an interval of 500 µm and stained with H&E using standard protocols. A histological score was determined based on microscopically pathologic changes of the ankle and tarsal joints. Antibody level against assayed peptides was measured in the serum collected on days 0, 14, 35 and 56 by ELISA assay. Competitive ELISA assays were done by pre-incubation of 10 mg peptide P90578 with sera from RA diseased mice (day 56) and RA patients. Then, the mixture of peptide P90578 and sera was cultured in the plates coated with each of the assayed peptides.

Results: We administered peptide P90578 at a concentration of 1mg/kg, 3mg/kg or 5mg/kg to the arthritic mice. Among the three test groups, the dose of 5mg/kg P90578 revealed the most optimal outcome on arthritis treatment with a reduced severity of tarsal and carpal joint swelling and a lower mean arthritis score compared to the NaCl control (Figure 1A). Hence, we applied the dose of 5mg/kg P90578 in our following experiments. In order to confirm the observation of our findings, we then performed a detailed microscopic examination on the right hind paws. The NaCl-treated mice showed signs of inflammatory cell infiltration, cartilage & bone erosion and typical pannus formation. In contrast, the mice receiving peptide P90578 had structural intact cartilage and minimal infiltration of lymphocytes in the subchondral bone. P90578-treated mice also showed a lower histological score of the joint sections (Figure 1B). Autoantibody levels in all three measurements represented a consistent trend toward decreased antibody titers in the serum of mice treated with peptide P90578 (Figure 1C). Considering the diversity of autoantigens in RA, the cross-reactivity of peptide P90578 binding to each epitope-specific autoantibodies was determined by competitive ELISA. The recognition of autoantibodies against the measured peptide epitopes was reduced by the peptide P90578 about an average of 20% in the RA diseased mice and by approximately 10% in the sera of RA patients, in some cases even exceeding 30% (Figure 1D).

Conclusion: Our study provides evidence showing this novel therapeutic peptide P90578 (5mg/kg) alleviated arthritic burden in the arthritis murine model. Also, autoantibody levels against CCP and peptides derived from collagen and fibrinogen were also reduced after peptide P90578 treatment. Moreover, peptide P90578 can effectively block the binding of autoantibodies in the serum from RA diseased mice and RA patients to the autoantigens.

IL-37 ALLEVIATES TNF-Α-INDUCED PYROPTOSIS OF RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES BY INHIBITING THE NF-ΚB/GSDMD SIGNALING PATHWAY

Keywords: Rheumatoid arthritis, Cytokines and chemokines, Animal models

C. Ren[1,2], Q. Shu[3], J. Chen[3], Q. Che[3], L. Shujie[4]. [1]*Qilu Hospital, Cheeloo College of Medicine, Shandong University, Department of Rheumatology, Shandong, China*; [2]*Jining NO.1 People's Hospital, Department of Rheumatology and Immunology, Shandong, China*; [3]*Qilu Hospital, Cheeloo College of Medicine, Shandong University, Department of Rheumatology, Jinan, China*; [4]*Jining No.1 People's Hospital, Department of Rheumatology and Immunology, Jining, China*

Background: Pyroptosis is crucial to rheumatoid arthritis (RA) by inducing and aggravating inflammation. TNF-α is abundant in fibroblast-like synoviocytes of RA (RA-FLSs) and plays a key role in pyroptosis by inducing nuclear factor (NF)-κB activation. Additionally, interleukin (IL)-37 is involved in autoimmune diseases as an anti-inflammatory cytokine and innate and acquired immune response inhibitor. However, the effect of IL-37 on pyroptosis in RA-FLSs remains unclear.
Objectives: To investigate the effects and mechanism of IL-37 on RA-FLS pyroptosis induced by TNF-α and the effect in collagen-induced arthritis (CIA)+TNF model.
Methods: In this study, the serum cytokines in patients with RA and healthy controls were detected using ELISA. The RA-FLSs were then cultured with TNF-α, with or without various IL-37 concentrations, to test the cytokine levels in the cell supernatant. 5-Ethynyl-2′-Deoxyuridine (EdU) assay assessed the effects of IL-37 on RA FLS proliferation. RA-FLS apoptosis was assessed using flow cytometry and mitochondrial membrane potential (MMP) measurement. In addition, transmission electron microscopy (TEM) was used to examine cell pyroptosis. We selected the optimal concentration for the following experiments and detected the signal pathway of IL-37 on pyroptosis of RA FLSs by quantitative reverse-transcription polymerase chain reaction (qRT-PCR) and Western blotting. Finally, we validated the therapeutic effects of IL-37 on CIA rat model in vivo.
Results: IL-37 inhibited inflammation in vitro and in vivo and reduced pyroptosis-related protein expression in RA FLSs. Furthermore, we determined that nuclear factor κB (NF-κB) signaling is required for GSDMD-mediated pyroptosis in RA FLSs.
Conclusion: IL-37 alleviates TNF-α-induced pyroptosis of RA FLSs by inhibiting NF-κB/GSDMD signaling. Additionally, our data revealed a novel mechanism for IL-37 in RA FLSs, suggesting a new potential therapy for IL-37 to treat RA.

AB0049

A RAPID HEMAGGLUTINATION ASSAY FOR ACPA DETECTION IN PATIENT BLOOD

Keywords: Rheumatoid arthritis, Autoantibodies, Diagnostic tests

I. Kruis[1], A. Van der Heijden[1], M. Salden[2], G. Pruijn[1]. [1]*Radboud University - Institute for Molecules and Materials, Biomolecular Chemistry, Nijmegen, Netherlands*; [2]*Novio Catalpa BV, R&D, Nijmegen, Netherlands*

Background: Anti-citrullinated protein antibodies (ACPA) are the most specific serological marker of rheumatoid arthritis (RA) and are produced by about 75% of RA patients. The presence of ACPA early in the disease, even before onset of clinical symptoms, facilitates early diagnosis and ACPA is among the most prominent classification criteria for RA.[1] Importantly, early diagnosis and immediate start of treatment is strongly correlated with improved outcomes. Several ACPA-detection assays are available for clinical use, which nearly all are based on the same principle: ELISA or related assays with cyclic citrullinated peptides or citrullinated proteins.[2] While these methods can be automated in modern diagnostic laboratories, they are ill-suited for low volume laboratories or resource-poor environments.
Objectives: The aim of this study was to develop a rapid and easy to perform assay for ACPA detection. The assay is based on ACPA-dependent agglutination of erythrocytes and can be executed with whole blood.
Methods: An agglutination mediator was developed by protein engineering. Addition of this mediator to (diluted) blood samples results in hemagglutination when ACPA are present. After optimization of the assay with RA serum-spiked blood samples, the applicability was assessed by the analysis of fresh blood samples from 100 RA patients and from 100 psoriatic arthritis (PsA) patients as a control group. Anti-CCP2 and RF levels in these patient samples were determined by standardized ELISAs.

Results: The agglutination mediator that was generated is based on a single-chain antibody fragment that binds to glycophorin A,[3] one of the major surface proteins of erythrocytes. It is conjugated to a citrullinated peptide that is efficiently recognized by ACPA. In the presence of erythrocytes and ACPA the mediator induces agglutination of the erythrocytes, which can be detected by the naked eye. The addition of the mediator resulted in detectable agglutination in 64% percent of the RA patient samples. Agglutination correlated well with the results obtained with a commercial anti-CCP2 ELISA for ACPA detection. Efficient agglutination was observed with only 7% of the PsA samples. No correlation with rheumatoid factor levels was observed.

Conclusion: An ACPA-dependent hemagglutination mediator was generated. This agglutination mediator allows the rapid and efficient detection of ACPA by hemagglutination in human blood samples.

AB0050 EVALUATION OF THE ASSOCIATION BETWEEN CIRCULATING NON-CODING RNA CIRC_0005567 AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ITS BIOLOGICAL FUNCTION IN THE CELL LINE MODEL

Keywords: Genetics/Epigenetics, Biomarkers, Rheumatoid arthritis

M. Ciesla[1], K. Kwasniak2, B. Kolarz[3]. *[1]University of Rzeszów, Centre for Innovative Reaserch in Medical and Natural Sciences, Rzeszów, Poland*; *[1]University of Rzeszów, Centre for Innovative Reaserch in Medical and Natural Sciences, Rzeszów, Poland*; *[3]University of Rzeszów, Department of Rheumatology, Rzeszów, Poland*

Background: Rheumatoid arthritis (RA) is a chronic, autoimmune disease that leads to chronic inflammation of synovial tissue, ultimately causing joint damage, disability and premature mortality. Disease affects about 1% of the global population. Circular RNAs (circRNAs) are non-coding molecules and are generated through back splicing, during which the 5 ‘ and 3′ ends are covalently joined. Consequently, the lack of free ends makes them stable and resistant to exonucleases, and they become more suitable biomarkers compared with linear RNAs such as microRNAs (miRs) or long non-coding RNAs. CircRNAs are still poorly understood molecules in relation to RA pathogenesis.

Objectives: The aim of the study was to find an association between circ_0005567 plasma levels and disease activity in RA patients and to evaluate its molecular function.

Methods: A total of 66 individuals, 39 RA patients, and 27 healthy controls. RA patients were selected based on disease activity and RA patients with high disease activity (DAS28 >5,1) and remission (≤2,6) were included. RNA was extracted from plasma and quantitative real-time PCR was used to analyze concentration of circ_0005567. The SW982 cell line was cultured in Dulbecco’s Modified Eagle’s Medium and supplemented with 10% fetal bovine serum. The cell line was grown at 37 °C, in a humidified atmosphere, with 5% CO2. The circ_0005567 silencing was performed by designed small interfered RNAs (siRNAs). Bioinformatic analysis was applied to select the miRs and mRNAs that may interact with circ_0005567. The expression levels of microRNAs were evaluated, subsequently the expression levels of selected mRNAs were performed. The expression levels of miRs and mRNA were evaluated at three time points: after 24h, 48h, and 72h.

Results: The expression level for circ_0005567 in RA patients was elevated compared to the control group (mean±SD; 173.6±123.8 vs 108.9±81.03, p=0.017). The molecule also showed significant differences in disease activity. Patients with high disease activity had about 70% higher concentration of circ_0005567 than the control group (186.99 vs 108.9, p=0.015). In the cell line model we found an association between silencing circ_0005567 and elevated miR-194 concentration and elevated concentration of three mRNAs: *KPNA1, HBEGF, TLN2.*

Conclusion: The expression of circ_0005567 was related to genes that are significant for the pathogenesis of RA. For example, *HBEGF* gene expression in fibroblasts plays a role in the remission of rheumatoid arthritis, and *KPNA1* was reported as seed gene related to RA. Due to the fact that circRNAs are stable and resistant to degradation, plasma concentration of circRNAs may be a new potential epigenetic markers of RA and disease activity.

AB0051 DESCRIPTION OF PULMONARY INVOLVEMENT IN THE RAT ADJUVANT-INDUCED ARTHRITIS MODEL

Keywords: Rheumatoid arthritis, Animal models, Lungs

E. Dalix[1], C. Paret[1], M. Maalouf[1], S. Peyroche[1], A. Vanden-Bossche[1], H. Marotte[1,2]. *[1]University of Jean Monnet, INSERM, U1059-SAINBIOSE, Saint-Etienne, France*; *[2]University Hospital Saint-Etienne, Department of Rheumatology, Saint-Etienne, France*

Background: Interstitial lung disease (ILD) is detected until 60% of patients with rheumatoid arthritis (RA), but is clinically significant in around 10% of cases. It is one of the leading causes of disease and death in RA patients. High levels of anti-cyclic citrullinated peptide (CCP) autoantibodies are associated with co-occurrence of pulmonary disease and RA [1]. Moreover, the pulmonary fibrosis marker mucine (MUC-1) was described to be a predictive indicator for ILD [2]. The adjuvant-induced arthritis (AIA) model is commonly used to investigate arthritic diseases due to some pathophysiological similarities to human arthritis [3].

Objectives: The first objective of this study was to investigate the pulmonary involvement occurring in the rat AIA model. The second objective was to investigate the presence of potential biomarkers such as CCP and MUC-1.

Methods: This study was performed from lungs from 64 AIA rats and 6 control rats without arthritis. Lungs were collected to perform histological and immunological analyses. Pulmonary disease was measured with a score based on the percentage of lung damage and the thickness of the alveolar walls (0: absent, 1: mild, 2: moderate, or 3: severe). CCP and MUC-1 immunostaining was also performed.

Results: A nonspecific interstitial lung disease was detected in the lungs of 80% of AIA rats, whereas only half control rats developed it. A heterogeneous percentage of lung damage was observed, which correlated with the thickness of the alveolar walls but not with arthritis severity. Granulomas were observed in the most affected lung tissues, with a slight fibrosis at their periphery. The number of CCP markings correlated positively with the percentage of lung damage in AIA rats. MUC-1 was found homogeneously in the lung tissue of control and AIA rats, but more prominently in the periphery of granulomas in AIA rats.

Conclusion: We have described the pulmonary involvement in the AIA rat model, which developed the extra-articular complication similar to RA-ILD. We identified CCP and MUC-1 as potential biomarkers of this pulmonary involvement. Thus, the lung may be a site of initiation of CCP immunity. The AIA model will then allow a better understanding of RA-ILD, which may lead to earlier diagnosis and the potential development of new targeted therapies.

AB0052 GENETIC EVIDENCE REVEALS CAUSAL LINK BETWEEN RHEUMATOID ARTHRITIS AND MTOR PROTEINS : A MENDELIAN RANDOMIZATION STUDY

Keywords: Genetics/Epigenetics, Rheumatoid arthritis

Z. J. Yuan[1,2], R. Zhao[1,2,3], J. Y. Li[1,2], M. K. Yao[1,2], S. Y. Liu Yue[1,2], S. X. Zhang[1,2,3], X. Li[1,2,3], C. Wang[1,2,3]. [1]*Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; [2]*Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China*; [3]*The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease with hyperplasia of joint tissue and synovial inflammation1. And the mammalian target of rapamycin (mTOR) is a serine/threonine protein kinase, which relates with cellular metabolism, promotes cell growth and inflammatory process2. Some studies show that some downstream proteins of mTOR are associated with RA, but having no directly genetic evidence.
Objectives: We conducted Mendelian randomization (MR) study to discover the genetically and statistically casual association between mTOR and RA.
Methods: A two-sample MR study was applied to investigate the association. Firstly, the GWAS data of 14 downstream proteins of mTOR, including plasma RP-S6K, EIF-4EBP2 and so on was obtain from the 3,301 European samples. And a summary statistic involved 14,361 cases and 43,923 controls was also acquired from the IEU OpenGWAS database. Meanwhile, we extracted Single-nucleotide polymorphisms (SNPs) which were related with mTOR ($P < 1.0\times10\text{-}5$) and satisfied the three assumptions for MR analysis as instrumental variables (IVs). Then, Inverse variance weighting (IVW), weighted median (WM), and MR-Egger regression were performed for MR statistical analysis by R Studio with packages "TwoSampleMR." Additionally, MR Pleiotropy RESidual Sum and Outlier (MR-PRESSO) analysis was conducted to detect outlier instrument and remove pleiotropy. A leave-one-out analysis was conducted to avoid bias caused by a single SNP.
Results: Our study showed that no indication supporting the fact that the 14 downstream proteins of mTOR were causally associated with RA risk. The 15 SNPs of RP-S6K, 12 SNPs of EIF-4EBP2 and so on were selected as IVs for each 14 proteins. MR results showed that there was no causal relationship between RP-S6K and RA (OR = 1.03, CI: 0.89 - 1.20, P = 0.68). The results were same for EIF-4EBP2 (OR = 0.89, CI: 0.74 - 1.06, P = 0.18) and the other 12 proteins. No single SNP significantly biased the causal effect of mTOR and RA. No significant directional horizontal pleiotropy between each 14 downstream proteins and RA was presented.
Conclusion: Our study showed that a cause–effect connection did not appear to exist between mTOR proteins and RA, the findings of this study increased our understanding of the genetic associations, and may provide novel insights into the functional mechanism underlying the associations between SNPs and mTOR and RA.

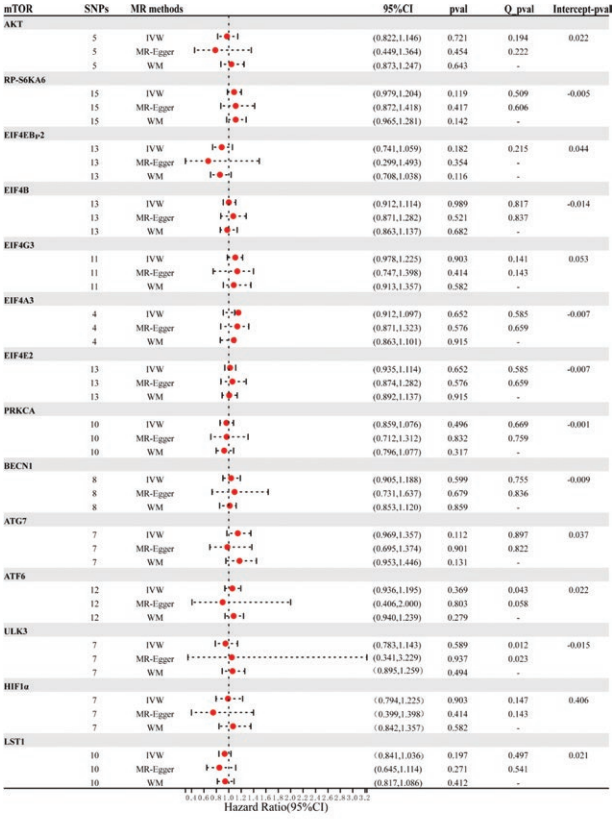

Figure1: Forest plot of MR results by IVW, MR-Egger and WM methods.Odds ratio (OR) and 95% confidence interval (CI) represent the change in the odds ratio of RA 's disease per 1-SD increase in the protein level.

Background: Patients with rheumatoid arthritis (RA) present increased risk of cardiovascular (CV) disease compared to the general population. Moreover, CV risk factors that have causal relationship with atherosclerosis do not seem to fully explain the accelerated process that they exhibit[1]. Over the years, several serum growth factors have been associated with atherosclerosis and some of them have been targeted as potential immunotherapy targets for the treatment of CV disease[2,3]. However, very few studies have studied these associations in RA patients.
Objectives: We evaluated the association of 8 plasmatic growth factors (angiopoietin-2, EGF, HB-EGF, PLGF, TGF-α, VEGFa, VEGFc, VEGFd) with surrogate markers of subclinical arteriosclerosis (carotid intima media thickness (cIMT), carotid plaque presence (cPP) and pulse wave velocity (PWV)) in a cohort of RA patients.
Methods: A total of 199 patients with RA were included. Subclinical markers of arteriosclerosis, (cIMT, cPP and PWV) were measured with the My Lab 50 X-Vision sonogram. The different plasmatic growth factors were measured with Bio-Plex Pro Human Cancer Biomarker Panel 2, from BIO-RAD. Multivariate models and Partial Least Square Discriminant Analysis (PLS-DA) were used for analysis. Analyses were performed in the overall cohort and stratified by sex.
Results: The multivariate models showed that angiopoietin-2 was significantly associated with cPP and PWV in the overall cohort. Moreover, VEGFc was also associated with PWV. Stratified analyses showed that VEGFa, VEGFd, EGF, PLGF, HB-EGF were associated with cPP in men patients. In this direction, PLS-DA analysis showed that the mentioned growth factors properly classified patients with and without cPP (Figure 1). Furthermore, angiopoietin-2, EGF, VEGFc, VEGFa, HB-EGF were associated with PWV. Regarding women, angiopoietin-2 was associated with PWV. Result from the lineal and logistic regressions are summarized in Table 1.
Conclusion: Plasmatic growth factors, especially in men, are highly associated with subclinical arteriosclerosis surrogate markers and could be potential predictors of CV disease in patients with RA.

AB0054 BIOMARKERS OF BONE ACTIVITY IN RHEUMATOID ARTHRITIS SYNOVIAL TISSUE AND THEIR RELATIONSHIP WITH CLINICAL OUTCOME

Keywords: Bone diseases, Rheumatoid arthritis, Biomarkers

B. Le[1], A. Small[1], K. Lowe[1], H. Weedon[1], S. Proudman[2,3], M. Smith[1], J. Walker[1,4], M. Wechalekar[1,4]. [1]*Flinders University, Rheumatology, Adelaide, Australia*; [2]*Royal Adelaide Hospital, Rheumatology, Adelaide, Australia*; [3]*University of Adelaide, Medicine, Adelaide, Australia*; [4]*Flinders Medical Centre, Rheumatology, Adelaide, Australia*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease which can involve bone joint degradation. The Wnt-β/catenin signalling pathway is a major promoter of bone formation. Following triple-DMARD treatment of rheumatoid arthritis patients, systemic levels of sclerostin are increased, correlating with improved patient response. This lies in contrast with the established role of sclerostin as a Wnt-antagonist, which would inhibit bone formation and suggests a protective role for sclerostin against bone loss. However, it is not known if this change is reflected in synovial tissues, the site of inflammation in RA.
Objectives: This study characterised the expression of sclerostin and other biomarkers associated with bone metabolism in synovial tissue biopsy samples in relation to patient erosive status (Sharpe/van der Heijde method), the presence of TNF (as judged by immunohistochemistry (IHC)) and response to treatment (European League Against Rheumatism (EULAR) scores).
Methods: Arthroscopic synovial tissue biopsies from patients with early rheumatoid arthritis, before and after treatment with adalimumab or abatacept were examined for sclerostin and LRP5/6, by immunohistochemistry (IHC), immunofluorescence staining, flow cytometry and bulk RNA sequencing, in addition to other biomarkers associated with bone metabolism. Total RNA libraries were produced using the Tecan Universal Plus Total RNA library preparation kit. Samples were sequenced on 3 x S4 lanes of the NovaSeq using paired end 100 bp reads (Illumina).
Results: No significant changes were observed for both sclerostin and LRP5/6 between erosive and non-erosive patients and at 6-month post-treatment. However, the expression of sclerostin in IHC stains of synovial tissues was significantly increased in TNF-non-dominant patients compared to those who were TNF-dominant. Sclerostin and LRP5/6 expression was localised to different cell populations in synovial tissue.
Conclusion: Bulk assessment of sclerostin and other bone biomarkers within synovial tissue does not currently demonstrate a relationship with clinical outcome. However, further assessment of sclerostin and other biomarkers of bone activity in specific cell types, within synovial tissue, can provide further insights into the role of sclerostin and Wnt pathway molecules in bone homeostasis in the context of RA and may provide biomarkers of erosive disease progression.

AB0055 THE ROLES OF OX40L AND TNF BISPECIFIC ANTIBODY IN OSTEOCLASTOGENESIS

Keywords: Osteoarthritis, Rheumatoid arthritis, Adaptive immunity

H. S. Kwon[1], J. Y. Kim[2], S. U. Kim[2], J. S. Lee[3], H. R. Kang[4,5], S. Ban[1], E. Y. Lee[2]. [1]*Seoul National University, Department of Cancer Biology, Seoul, Korea, Rep. of (South Korea)*; [2]*Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; [3]*Korea Advanced Institute of Science and Technology, Graduate School of Medical Science and Engineering, Daejeon, Korea, Rep. of (South Korea)*; [4]*Seoul National University, Interdisciplinary Program in Cancer Biology, Seoul, Korea, Rep. of (South Korea)*; [5]*Seoul National University, Integrated Major in Innovative Medical Science, Seoul, Korea, Rep. of (South Korea)*

Background: Rheumatoid arthritis (RA) is a chronic, inflammatory disease that leads to progressive cartilage and bone destruction. OX40 ligand (OX40L) is expressed predominantly on antigen-presenting cells and highly associated with joint inflammation in RA[1]. Yet, the role of OX40L in osteoclastogenesis is unclear.
Objectives: In this study, we investigated the effects of dual blocking of TNF and OX40L by bispecific antibody (IMB-101) on RANKL-induced osteoclastogenesis.
Methods: CD14+ monocytes were isolated from peripheral blood mononuclear cells (PBMCs) of healthy donors (n=6). CD14+ monocytes were cultured with M-CSF (20ng/ml) and RANKL (40ng/ml) for 6 to 7 days in the presence of TNF antibody, OX40L antibody, or bispecific antibody. TRAP-positive multinucleated giant cells (>3 nuclei/cell) were counted as osteoclast. PU.1, RANK and NFATc1, markers of osteoclast differentiation were assessed by the quantitative reverse

transcription PCR (RT-qPCR). The expression of OX40L was analyzed in the presence of RANKL or TNF at the early and late stage of osteoclast differentiation.
Results: The expression of OX40L was increased by RANKL and TNF at the early stage of osteoclast differentiation (day 3) in a TNF dose-dependent manner. IMB-101 decreased RANKL-induced osteoclastogenesis via downregulating NFATc1 expression (Figure 1). IMB-101 further reduced PU.1, RANK and NFATc1 expression during early stage of osteoclast differentiation (day 3) compared to TNF inhibitor or TNF inhibitor and OX40L inhibitor (n=3).
Conclusion: Our data suggested that IMB-101 might have a beneficial effect on imbalance of the bone resorption in RA especially by suppressing osteoclast differentiation.

AB0056 CYTOKINE-DIRECTED CELLULAR CROSSTALK IMPRINTS SYNOVIAL PATHOTYPES IN RHEUMATOID ARTHRITIS

Keywords: Synovium, Cytokines and chemokines, Rheumatoid arthritis

M. Kugler[1], M. Dellinger[1], F. Kartnig[1,2], L. Müller[1], T. Preglej[1], L. Heinz[1], E. Simader[1], L. Göschl[1], S. Puchner[3], S. Weiss[4], G. Superi-Furga[2], J. S. Smolen[1], G. Steiner[1], D. Aletaha[1], H. Kiener[1], A. Tosevska[1], T. M. Karonitsch[1], M. Bonelli[1]. *[1]Medical University of Vienna, Department of Rheumatology, Vienna, Austria*; *[2]Austrian Academy of Sciences, Center for Molecular Medicine (CeMM), Vienna, Austria*; *[3]Medical University of Vienna, Department of Orthopaedic Surgery, Vienna, Austria*; *[4]Medical University of Vienna, Department of Pathology, Vienna, Austria*

Background: The chronic inflammatory disease Rheumatoid Arthritis (RA) is characterized by synovial inflammation promoting cartilage and bone degradation when left untreated. Interaction between infiltrating immune cells, such as CD4+ T cells and activated fibroblast-like synoviocytes (FLS) might contribute to joint inflammation ultimately amplifying progressive joint destruction.
Objectives: To elucidate the interaction of stimulated FLS and CD4+ T cells within an inflammatory environment and to define its impact on synovial inflammation.
Methods: To define the effect of inflammatory mediators, FLS were stimulated with different pro- and anti-inflammatory cytokines. Transcriptomic changes were measured using RNA sequencing (RNA-seq). Co-cultures of cytokine pre-treated FLS and fluorescence activated cell sorting (FACS)-purified naïve CD4+ T cells were established. Using high-content fluorescence microscopy combined with bioinformatic image analysis, cell-cell interactions were visualized and quantified. The consequence of FLS co-culturing on CD4+ T-cell development was addressed by flow cytometry of re-isolated CD4+ T-cells.
Results: RNA-seq on cytokine-stimulated FLS revealed cytokine-specific gene expression profiles. In line, we observed cytokine-specific patterns of interaction with CD4+ T-cells which could be further observed in flow cytometry data of T cell activation, proliferation and differentiation. Cytokine-stimulated FLS signatures could be detected in transcriptomic data of RA patient synovial tissue samples.
Conclusion: In this study, we highlight the role of FLS in orchestrating inflammation-associated synovial tissue remodeling and how cytokine induced CD4+ T cells – FLS interactions impact on T-cell development.

AB0057 ESTABLISHMENT OF NOVEL 3D SPHEROID-BASED MODEL OF RHEUMATOID ARTHRITIS SYNOVIAL TISSUE TO INVESTIGATE THE INTERACTION BETWEEN DIFFERENT CELL TYPES

Keywords: Rheumatoid arthritis, Synovium

E. Philippon[1], J. P. Van Hamburg[1], F. Khodadustvaskasi[2], L. Van Rooijen[1], C. J. Van der Laken[2], S. Tas[1]. *[1]Amsterdam UMC, locatie AMC, Department of Rheumatology and Clinical Immunology/Experimental Immunology, Amsterdam, Netherlands*; *[2]Amsterdam UMC, locatie VUmc, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands*

Background: Rheumatoid Arthritis (RA) is a progressive and systemic autoimmune disorder associated with chronic and destructive inflammation of the joints. The hallmarks of RA are synovial cell proliferation, extensive neoangiogenesis and infiltration of numerous immune cells into the synovial tissue. *In vitro* approaches simulating RA synovial tissue are crucial in preclinical and translational research to expand our knowledge on RA human pathophysiology and to test new diagnostic and therapeutic applications.
Objectives: Here, we present the engineering of a spheroid-based model of RA synovial tissue which mimics the close interaction between cells and key pro-inflammatory mediators present in the inflamed synovium.
Methods: Following differentiation in 20 ng/ml GM-CSF for 6-7 days, monocyte-derived macrophages were cultured with RA fibroblast-like-synoviocytes (RA-FLSs) and endothelial cells (ECs) for 24 hours to allow for spheroid formation. Three RA-FLS/EC/macrophage ratios were tested: (1:2:0.4), (1:2:0.8) and (1:2:1.6). Then, the spheroids were placed in a collagen-based matrix for 40 hours to study spheroid outgrowth in 3 dimensions. The spheroids were left unstimulated, or cultured in the presence of growth factors VEGF/bFGF or RA synovial fluid. Sprout formation and cell migration were quantified for all conditions using confocal microscopy and digital image analysis.
Results: Addition of macrophages to the previously established 3D model of RA angiogenesis consisting of ECs and RA-FLSs resulted in close interaction of macrophages with RA-FLSs and ECs within the spheroid structure. The optimal ratio between RA-FLSs, ECs and macrophages in our system was established as 1:2:0.8, based on the proportions of macrophages that remained within the core and migrated throughout the matrix as well as the effect of stimuli on sprout formation. Addition of growth factors (VEGF/bFGF) significantly promoted spheroid outgrowth compared to the unstimulated condition in the new model *($p<0.01$)*.

Representative confocal pictures of the 3D spheroid-based model of synovial tissue including **RA-FLSs (magenta), HUVECs (cyan)** and **macrophages (MΦ) (yellow)** (1:2:0.8) in basal medium (unstimulated), stimulated with VEGF/bFGF (10 ng/ml) or RASF (20%).

Figure 1.

Conclusion: We present a novel 3D-spheroid based model consisting of RA-FLSs, ECs and macrophages that mimics the RA synovial tissue microenvironment. This model is useful to dissect the role of specific cell types in inflammatory responses in RA, to study specific signaling pathways involved in the disease pathogenesis and examine the potential of novel diagnostic (molecular imaging) and therapeutic compounds, including small molecule inhibitors and biologics.

AB0058

NOVEL BIOMARKERS FROM THE S100 PROTEIN FAMILY OF RHEUMATOID ARTHRITIS PROGRESSION WHICH CAN BE REGULATED BY EPIGENETIC DRUGS

Keywords: Genetics/Epigenetics, Rheumatoid arthritis, Biomarkers

L. Roszkowski[1], B. Jaszczyk[1], M. Ciechomska[2]. [1]*National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Outpatient Clinics, Warsaw, Poland*; [2]*National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Pathophysiology and Immunology, Warsaw, Poland*

Background: Monocytes are key players in initiating and maintaining inflammation by producing proinflammatory cytokines and S100 proteins in rheumatoid arthritis (RA). Several studies demonstrated that epigenetic drugs affecting DNA methylation can modulate the production of proinflammatory mediators.

Objectives: This study aimed to test specific DNA methylation inhibitor (RG108) and activator (budesonide) in the regulation of proinflammatory cytokines and S100 proteins in RA monocytes. Our study also looked for new and better biomarkers of high disease activity in RA patients.

Methods: RNA sequencing (RNA-seq) analysis of healthy controls (HC) and RA monocytes was performed. Cell viability was determined in THP-1 monocytic cell line following RG108 and budesonide treatment. Pro- and anti-inflammatory genes such as the S100 family, TNF, IL-8 were validated by qRT-PCR following DNA methylation-targeted drug treatment. The concentrations of proteins from the S100 family in serum and synovial fluid were tested with ELISA assays and their correlation with clinical parameters was carried out.

Results: Based on the RNA-seq analysis, RA monocytes had significantly increased levels of S100A8 (2,2-fold, p=0,024), S100A9 (1,9-fold, p=0,017), S100A11 (1,2-fold, p=0,007), S100A12 (1,6-fold, p=0,007), MYD88 (1,2-fold, p=0,008), JAK3 (1,8-fold, p=0,009), IQGAP1 (1,4-fold, p=0,02), and decreased level of IL10RA (0,7-fold, p=0,011), TGIF1 (0,3-fold, p=0,046) transcripts. In addition, stimulation of THP-1 cells with budesonide (DNA methylation activator) statistically reduced expression of S100A8 (3,0-fold, p= 0,0390), S100A9 (4,4-fold, p= 0,0317), S100A12 (3,3-fold, p= 0,0260), IL-8 (6,8-fold, p= 0,0286) and TNF (7,5-fold, p= 0,0260) genes. In contrast, THP-1 monocytic cell line treated with RG108 (DNA methylation inhibitor) had an increased level of S100 family (S100A8, -A9, -A11, -A12) and TNF genes. ELISAs analysis also revealed significant increased levels of S100A8 (p = 0.0116), S100A11 (p = 0.0138), and S100A12 (p = 0.0296) proteins in RA patients compared to HC sera, similar in early RA sera compared to HC S100A8 (p = 0.0024), S100A11 (p = 0.0020) and S100A12 (p = 0.0059). Moreover, protein levels of S100A8 (p=0.0005), S100A11 (p=0.0007) and S100A12 (p=0.0005) in the synovial fluid of advanced RA patients compared to HC serum were significantly elevated. All these data suggest that a protein of the S100 family may be a promising biomarker of RA progression. In ROC analyses, serum levels of S100A8 and S100A12 proteins were more specific {area under the curve (AUC)=0.78, p=0.006 and AUC=0.87, p=0.0006} respectively in RA patients than CRP levels. In addition, results indicate that S100A8 and S100A12 can serve as a better biomarker of high disease activity than CRP levels.

Conclusion: We have demonstrated that S100 family proteins are increased in RA monocytes (transcriptomics) similar to enhanced S100 production in sera and synovial fluids (ELISA) in RA patients. Our data suggest that the proteins S100A8 and S100A12 in particular are strongly increased during ongoing inflammation, so they could be used as a better biomarker of disease activity than CRP. Interestingly, S100 proteins can be regulated by epigenetic drugs, suggesting their potential use in the targeting of RA inflammation.

THE POTENTIAL ROLE OF THE T2 FAMILY OF EXTRACELLULAR RIBONUCLEASES (RNASET2) AS CIRCULATING BIOMARKER IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Biomarkers

F. Angeli[1], S. Piantoni[1], M. Passari[2], S. Scutera[3], V. Salvi[2], T. Schioppa[2], R. Sparti[3], F. Sozio[2], L. Tiberio[2], D. Bosisio[2], F. Acquati[4], S. Sozzani[5], T. Musso[3], A. Del Prete[2], L. Andreoli[1]. [1]*ASST Spedali Civili of Brescia and University of Brescia, Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, Brescia, Italy*; [2]*University of Brescia, Department of Molecular and Translational Medicine, Brescia, Italy*; [3]*University of Turin, Department of Public Health and Pediatric Sciences, Turin, Italy*; [4]*University of Insubria, Department of Biotechnologies and Life Sciences, Varese, Italy*; [5]*Sapienza University of Rome, Laboratory Affiliated to Istituto Pasteur Italia-Fondazione Cenci Bolognetti, Department of Molecular Medicine, Rome, Italy*

Background: Circulating biomarkers with diagnostic and prognostic value in early Rheumatoid Arthritis (RA) are still an unmet need, especially for the subgroup of seronegative RA [e.g., negative for anti-citrullinated peptides autoantibodies (ACPA) and/or rheumatoid factors (RF)]. In a recent gene-based genome-wide association analysis (GWAS) study, RNASET2 was identified as a potential susceptibility gene [1-3]. Furthermore, the extracellular ribonuclease RNASET2 was demonstrated to be involved in the regulation of several immune processes [4].

Objectives: The aim of this study was to analyse RNASET2 serum levels in a cohort of RA patients upon their disease activity, in comparison with healthy controls (HC).

Methods: Forty consecutive patients with RA (75% female, 55% seropositive) with a median age (25^{th}-75^{th} percentile) of 55 years (45-68) and a CRP-DAS28 index of 3.09 (2.50-3.70), and 25 sex and age-matched HC were enrolled in the study. RNASET2 serum levels were assessed through a commercial hELISA test (WuHan Fine Biotech Co., China).

Results: Serum levels of RNASET2 were higher in RA patients than in HC [29.42 (17.73 – 69.82) vs 18.15 (12.15 – 28.35) ng/mL; p= 0.001]. Among patients with RA, there were no differences between RNASET2 levels in seropositive or seronegative ones [33.14 (16.79 – 74.89) vs 29.01 (17.83 – 39.85) ng/mL; p=0.308]. Furthermore, there were no differences in RNASET2 serum levels between patients in treatment with corticosteroids or not [42.09 (18.11 – 78.78) vs 23.42 (18.29 – 43.87) ng/mL; p=0.239]. RNASET2 serum levels were significantly different across 3 groups of RA patients identified upon the CRP-DAS28 score (high plus moderate disease activity –group A-; low disease activity –group B-; remission –group C-) (p= 0.024). RNaseT2 levels were higher in both group A and B as compared to group C [56.73 (30.22 – 79.67) - 83.72 (52.68 – 113.89) vs 25.43 (20.15 – 39.85) ng/mL; p= 0.005 & p= 0.007]. No difference was found between group A & B. When combining groups A & B, RNASET2 levels were significantly higher than in group C [67.14 (36.07 – 86.68) vs 25.43 (20.15 – 39.85) ng/mL; p= 0.013]. No significant correlation was found between RNASET2 serum levels and CRP-DAS28 (r= 0.36; p= 0.055).

Conclusion: This is the first description of circulating serum levels of RNASET2 as a potential diagnostic biomarker in RA. Higher levels of RNASET2 clustered in RA patients as compared to HC. Low levels of RNASET2 seem to characterize the remission phase of RA. These preliminary results deserve to be expanded in larger cohorts of RA patients, patients with other form of chronic arthritis and other pathological and healthy controls.

AB0060 ANALYSIS OF THE HUMAN GUT MICROBIOME AND NUTRITION PATTERNS IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Diet and nutrition, Gastrointestinal tract

J. Schirmer[1,2], K. Schlicht[2,3], C. Knappe[3], K. Türk[3,4], D. Schulte[2,3,4], K. Hartmann[3,4], U. Settgast[3,4], A. Franke[2,5], S. Schreiber[2,4,5], B. Hoyer[1,2], M. Laudes[2,3,4]. *[1]University Medical Center Schleswig-Holstein, Internal Medicine I, Rheumatology, Kiel, Germany*; *[2]Cluster of Excellence, Precision Medicine in Chronic Inflammation, Kiel, Germany*; *[3]University Medical Center Schleswig-Holstein, Institute of Diabetes and Clinical Metabolic Research, Kiel, Germany*; *[4]University Medical Center Schleswig-Holstein, Internal Medicine I, Kiel, Germany*; *[5]Christian-Albrechts-University, Institute for Clinical Molecular Biology, Kiel, Germany*

Background: The association of the gut microbiome with obesity and metabolic diseases as type 2 diabetes (T2D) as well as the influence of environmental factors like nutrition on its composition is well established. In addition, recent studies[1] described the composition of gut microbiota to be altered in inflammatory rheumatic diseases highlighting a pathogenetic link between the microbiome and autoimmune joint diseases.
Objectives: The aim of this study was to analyze food intake and the composition of the gut microbiota in rheumatoid arthritis (RA) in comparison to healthy controls (adjusted for metabolic conditions known to influence the gut microbiota composition).
Methods: A subset of the FoCus (Food chain plus) cohort (a cross-sectional survey of the general population in northern Germany) with RA and matched controls without RA (matched for age, gender, body mass index and diagnosis of Type 2 Diabetes mellitus [T2D]) was investigated regarding their nutrition patterns and gut microbiome in a case-control analysis. Nutrition patterns were derived from Food Frequency Questionaires (FFQ) and analyzed by hierarchical cluster analysis. The gut microbiota composition was analyzed by 16S rRNA gene sequence data clustered into operational taxonomic units (OTUs). Microbiome composition was analyzed by alpha- (phylodiversity, Shannon index, Chao index) and beta-diversity measures (Bray-Curtis distance, Jaccard index) and by hurdle-models.
Results: We identified n = 94 individuals with RA and n = 94 matched controls (mean age 57 years, SD 12.9; mean BMI 31.1, SD 8.9). Interleukin 6 was significantly higher in the RA group compared with controls (p=0.012), while no differences were observed between groups for HOMA-Index, CRP, lipoprotein (a) or triglycerides. Nutrition data from FFQs was used in a hierarchical cluster analysis, resulting in two main clusters (the second one defined by a significantly higher intake of vegetables, fruit and dairy products). Nutrition clusters did not differ significantly between RA cases and controls (p=0.228). When comparing the composition of the intestinal microbiota between RA patients and controls (adjusted for nutrition cluster and IL-6), significant differences in the beta-diversity were detected using Bray-Curtis distance (p=1.82e-9) and Jaccard index (p=1.82e-9). Hurdle model analysis of the core measurable microbiome identified three candidate species OTUs (Flavonifractor and 2x Blautia). No significant differences in alpha diversity was observed when analyzed by species richness (p=0.9), Shannon (p=0.3) and Chao index (p=0.6).
Conclusion: Participants suffering from RA had significant differences in the composition of the gut microbiome compared to controls matched for age, BMI, gender and T2D after adjusting for nutrition patterns and IL-6. Investigating differences in the functional capacity of the altered gut microbiome in RA may better characterize a possible link of gut microbes to the development of RA.

González-Gay[6,7]. *[1]IDIVAL, HUMV, Research Group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and in Metabolic Bone Diseases of the Musculoskeletal System, Santander, Spain*; *[2]HUMV, Department of Rheumatology, Santander, Spain*; *[3]HUMV, Department of Pneumology, Santander, Spain*; *[4]Hospital Universitario de Canarias, Department of Rheumatology, Santa Cruz de Tenerife, Spain*; *[5]UC, Faculty of Medicine, Santander, Spain*; *[6]IDIVAL, UC, Department of Medicine and Psychiatry, School of Medicine, Santander, Spain*; *[7]IIS-Fundación Jiménez Díaz, Department of Rheumatology, Madrid, Spain*

Background: Interstitial lung disease (ILD) is one of the main causes of death in patients with rheumatoid arthritis (RA), constituting its **e**arly diagnosis in these patients a challenge for the clinicians [1]. In this sense, pulmonary endothelial activation is one of the essential steps to the development of lung lesions [2,3]. In this regard, endothelin-1 (ET-1), the most potent endogenous vasoconstrictor, has been described as a profibrotic molecule [3]. Accordingly, it is plausible to think that ET-1 is involved in the pathophysiology of RA-ILD$^+$.
Objectives: To explore the role of ET-1 as a biomarker of pulmonary fibrosis in RA-ILD$^+$.
Methods: Peripheral venous blood was collected from 21 RA-ILD$^+$ patients and two comparative groups: 25 RA-ILD$^-$ patients and 21 idiopathic pulmonary fibrosis (IPF) patients. All the subjects were recruited from the Rheumatology and Pneumology departments of Hospital Universitario Marqués de Valdecilla, Santander, Spain. Serum levels of ET-1 were determined by ELISA.
Results: RA-ILD$^+$ patients showed increased levels of ET-1 compared to those with RA-ILD$^-$ ($p<0.01$, **Figure 1A**). Interestingly, the ability of serum ET-1 levels to discriminate patients with RA-ILD$^+$ from those with RA-ILD$^-$ was further confirmed by receiver operating characteristic curves (area under the curve: 0.77, $p<0.01$, **Figure 1B**). The optimal cutoff value for ET-1 showing the best sensitivity and specificity was 1.02 pg/mL. Moreover, patients with RA-ILD$^+$ presented similar levels of ET-1 than those with IPF (p=0.50, **Figure 1A**). Additionally, a negative correlation between ET-1 serum levels and both forced vital capacity and forced expiratory volumen at first second was disclosed in patients with RA-ILD$^+$ (r=-0.56, p=0.04 and r=-0.65, p=0.01, respectively).
Conclusion: Our study suggests that ET-1 levels are linked to lung injury and worse lung function, supporting its role as a potential blood biomarker of ILD in RA patients.

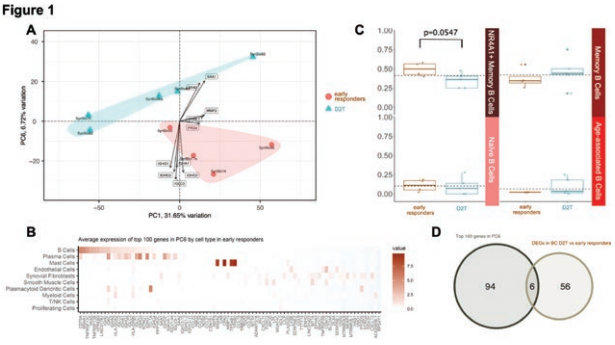
ABUNDANCE AND ACTIVATION OF MEMORY B-CELLS CHARACTERIZE SYNOVITIS IN RHEUMATOID ARTHRITIS PATIENTS WITH EARLY TREATMENT RESPONSE

Keywords: Rheumatoid arthritis, Synovium, Biomarkers



A. Khmelevskaya[1], M. Houtman[1], K. Buerki[1], C. Pauli[2], F. Rivellese[3], E. Prediletto[3], C. Pitzalis[3], O. Distler[1], A. Ciurea[1], C. Ospelt[1], R. Micheroli[1]. *[1]University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland*; *[2]University Hospital Zurich, University of Zurich, Department of Pathology, Zurich, Switzerland*; *[3]William Harvey Research Institute, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, Centre for Experimental Medicine and Rheumatology, London, United Kingdom*

Background: A relevant percentage of patients with rheumatoid arthritis (RA) do not respond to individual (40%) or all available disease modifying anti-rheumatic drugs DMARDs (5-20%). A recent study using synovial bulk RNAseq from a phase 4 trial has shown that humoral immune response gene signatures are associated with response to rituximab and tocilizumab [1]. Other biomarkers that can predict early response to alternative DMARDs are still lacking.
Objectives: This study, performed in a real-life clinical care setting, aimed at characterizing synovitis of RA patients with an early drug response on a single-cell level to identify potential biomarkers and molecular signatures.
Methods: Synovial tissue was obtained by ultrasound-guided synovial biopsy from inflamed joints. Four patients were defined as early responders not meeting the D2T EULAR definition criteria (median (IQR) number of treatments 1.5 (1.25)) [2], but meeting 2022 ACR/EULAR remission within 3 months on the DMARD started after the synovial biopsy. Five patients met the D2T EULAR definition criteria (median (IQR) number of treatments 7 (1)). Two out of five from the D2T group went into ACR/EULAR remission 3 months after the biopsy following DMARD initiation (abatacept (n=1) and upadacitinib (n=1)). Both groups fulfilled the ACR/EULAR classification criteria for RA. 6000 cells were targeted for single-cell encapsulation (10X Genomics workflow v3.1). Libraries were sequenced on NovaSeq6000. The following R packages were used: Cell Ranger, Seurat, Harmony, PCAtools.
Results: Clinical characteristics (sex, age, swollen joint count, C-reactive protein, body mass index, smoking status) were comparable between the two groups, except for the presence of autoantibodies (all D2T compared to only one early responder patient were seropositive). The patients in the early responder group received the following drugs after the biopsy: methotrexate plus certolizumab (n=1), methotrexate alone (n=1) or abatacept (n=2). Patients in the D2T group had received a median of seven treatments before the biopsy. 29,408 cells were integrated for scRNA-seq analysis (mean of 3,267 cells after quality control filtering per patient). Unsupervised dimensionality reduction analysis showed 8 principal components (PCs) explaining all variations in gene expression between samples. PC6 was significantly associated with the early responder/D2T categorization, accounting for 6.72% of the sample variation. Immunoglobulin genes (IgH-, IgL-), Prostaglandin D2 Synthase (PTGDS) and B-cell antigen receptor complex-associated protein alpha chain (CD79A) were among the top 100 genes associated with early response to treatment (PC6) (Figure 1A). Analysis of the average expression of these genes in the early responder and D2T group revealed expression mostly in B cells and plasma cells (Figure 1B). Comparing the proportions of cell populations using graph-based clustering showed no significant differences between early responder and D2T patients. Further clustering of the primary cell populations also did not show changes in proportions except for B cells: the proportions of NR4A1+ memory B cells (B cells recently receiving antigen stimulation) were higher in early responder compared to D2T patients (mean 48%±10 vs 36%±10, p-value = 0.0547) (Figure 1C). Analysis of differentially expressed genes in B cells between early responder and D2T patients revealed 62 genes differentially expressed (p-value<0.05, average fold change > or < 0.3). Still, only six of these genes were among the top 100 genes associated with PC6 (Figure 1D).
Conclusion: Synovitis in rheumatoid arthritis patients with early treatment response was associated with activation of B cells and an abundance of NR4A1+ memory B cells. This finding in a real-life cohort is in concordance with previous results showing an association of humoral immune activation and response [1] and sets the path for future biomarkers predicting early response in RA.

OSTEOCLASTS DIFFERENTIATED FROM DENDRITIC CELLS POSSESS THE INFLAMMATORY OSTEOCLAST PHENOTYPE

Keywords: Synovium, Rheumatoid arthritis

T. Mizuno[1], Y. Matsueda[1], K. Yamaoka[1]. *[1]Kitasato University School of Medicine, Department of Rheumatology and Infectious Diseases, Sagamihara, Japan*

Background: Osteoclasts (OCs) can differentiate from monocytes (MoOC) and dendritic cells (DCOC) in in vitro. On the other hand, there are two OC subsets in in vivo. One is involved in normal bone remodeling, and the other originating

from arthirits-associated osteoclastogenic macrophages (AtoM), characterized by CX3CR1 and FOXM1 expression. However, the relationship between MoOC and DCOC with AtoM is unknown[1].

Objectives: To investigate the phenotype of oteoclasts differentiated from dendritic cells.

Methods: Bone marrow cells or bone marrow derived dendritic cells were cultured with RANKL+M-CSF for 6 days to generate MoOC or DCOC.(2) Osteoclast differentiation was assessed by TRAP staining. NFATc1, CX3CR1 and FOXM1 mRNA expression was evaluated with whole cultured cells, OC or undifferentiated cells residing by OC collected by laser microdissection. Fluorescent immunostaining of cultured cells was used to analyze protein expression, and IL-6 or TNFα was added during OC differentiation to assess effects on OC differentiation, CX3CR1 and FOXM1 expression.

Results: MoOCs and DCOCs differentiation was confirmed by TRAP staining and NFATc1 mRNA expression in whole cultured cells on day 6 of RANKL+M-CSF culture. The expression of CX3CR1 mRNA was significantly higher in DCOC than in MoOC. In DCOCs recovered by microdissection on day 4, confirmed significantly higher expression of CX3CR1 mRNA compared to MoOCs. Comparison of CX3CR1 mRNA expression with residing undifferentiated cells resulted in significantly higher expression in DCOCs, but not in MoOCs. Immunostaining on day 6 showed nuclear translocation of FOXM1 in both DCOCs and MoOCs. IL-6 or TNFα stimulation decreased viable cells in a concentration-dependent manner, with TNFα promoting MoOC differentiation and IL-6 promoting DCOC differentiation.

Conclusion: Compared to MoOCs, DCOCs expressed significantly higher CX3CR1 and FOXM1 from early stage of development specific to progenitor of inflammatory osteoclasts in in vivo. In addition nuclear translocation of FOXM1 suggested its role in gene regulation during OC differentiation. In addition, enhancement of DCOC differentiation by IL-6 is suggesting the usefulness of IL-6 inhibition for the pathophysiology of joint destruction in rheumatoid arthritis.

AB0064 DISCOVERY OF NOVEL LONG-NONCODING RNAS IMPLICATED IN RHEUMATOID ARTHRITIS

Keywords: Genetics/Epigenetics, Rheumatoid arthritis

J. M. Kim[1], C. N. Son[1], K. Hur[2]. *[1]Keimyung University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Daegu, Korea, Rep. of (South Korea); [2]School of Medicine, Kyungpook National University, Department of Biochemistry and Cell Biology, Daegu, Korea, Rep. of (South Korea)*

Background: Rheumatoid arthritis (RA) is a representative systemic autoimmune disease characterized by synovial inflammation and proliferation accompanied by joint destruction. Fibroblast-like synoviocytes (FLS) are a key constituent of the synovium and paly an important role in the pathogenesis of RA. Although accumulating evidence has implicated the role of long non-coding RNAs (lncRNAs) in autoimmune diseases, the role of lncRNAs in the pathogenesis of RA remains unknown.

Objectives: In this study, we aim to investigate the expression profile of lncRNAs in the FLS from the patients with RA (RA FLS) and discover promising candidates involved in the pathogenesis of RA.

Methods: The next-generation sequencing (NGS) data were analyzed to identify differential expressed lncRNAs in RA FLS compared with FLS from the patients with osteoarthritis (OA FLS). NGS data were also analyzed to reveal differentially expressed lncRNAs between unstimulated RA FLS and IL-1-stimulated RA FLS. And then, the intersection of two analysis results was obtained. Data obtained by intersection was validated by RT-qPCR using RA FLS and OA FLS. Changes in lncRNA expression induced by pro-inflammatory cytokines were investigated by RT-qPCR.

Results: According to NGS analysis, among the lncRNAs whose expression was increased in RA FLS compared to OA FLS, there were 4 lncRNAs whose expression was also increased by IL-1 stimulation in RA FLS. On the other hand, among the lncRNAs whose expression was decreased in RA FLS compared to OA FLS, there were 6 lncRNAs whose expression was also decreased by IL-1 stimulation. Of the 4 upregulated and 6 downregulated lncRNAs, we validated the top 3 of each when listed in order of fold change. As a result, it was confirmed that the expression of only one (NR_030732) was increased in RA FLS. The expression level of NR_030732 was more enhanced after treating with IL-1, IL-6, or TNF-α in RA FLS. Although not confirmed in validation, the expression of the top 3 downregulated lncRNAs (NR_034107, NR_046240, NR_121608) derived from NGS analysis was also decreased after the treatment with IL-1, IL-6, or TNF-α in RA FLS.

Conclusion: Our study found that NR_030732 was prominently expressed in RA FLS, and confirmed that the expression of NR_030732 was also increased by pro-inflammatory cytokines. Thus, our data suggest that the lncRNA NR_030732 might be a candidate lncRNA involved in the pathogenesis of RA.

AB0065 COMPARISON OF HISTOLOGICAL AND MOLECULAR FEATURES IN PATIENTS WITH AN ACTIVE RHEUMATOID ARTHRITIS AND PATIENTS IN REMISSION

Keywords: Rheumatoid arthritis, Synovium, Remission

S. Ohl[1], K. Frommer[1], M. Rickert[2], S. Rehart[3], U. Müller-Ladner[1], E. Neumann[1]. *[1]Justus Liebig University Gießen, Campus Kerckhoff, Department of Rheumatology and Clinical Immunology, Bad Nauheim, Germany; [2]University Hospital Giessen and Marburg, Giessen, Department of Orthopaedics and Orthopaedic Surgery, Giessen, Germany; [3]Agaplesion Markus Hospital, Frankfurt, Department of Orthopaedics and Trauma Surgery, Frankfurt, Germany*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease. The disease is manifested by inflamed synovium and destruction of cartilage and bone. So far, the disease cannot be cured, which is why remission is considered as the therapeutic goal. Although the number of patients in remission is increasing, patients still have different prognostic outcomes, which is why a better understanding of remission is needed.

Objectives: Characterization of remission in RA by comparison of histological and molecular features in the synovium of active RA patients compared to patients in remission.

Methods: After joint replacement surgery, RA patients between 43 and 81 years were clinically classified into either remission or active RA. Clinical classification was based on laboratory (e.g. ESR, CRP, leucocytes) and clinical parameters (e.g. painful joint, pain degree, medication). Subsequently, the Krenn Score was applied to characterize synovitis in the synovial tissue. To investigate remission on RNA level, RA synovial fibroblasts (RASF) from both patient groups were either stimulated with IL-1 or left unstimulated for 24h. RNA was isolated and analysed by RNA sequencing. Evaluation included analysis of differentially expressed genes (DEG) based on a combination of absolute expression, divergence and significance as well as gene set enrichment analysis of DEGs to identify the enriched gene sets or pathways.

Results: A total of 39 patients were included in the Krenn Score, of whom 20 were active and 19 in remission. Patients in remission showed a generally lower synovitis score for all parameters. In particular, a reduced synovial hyperplasia of the lining layer (P=0.021) and the total Krenn score (P=0.022) was observed. Sub-analyses regarding medication (biologics, DMARDs, NSAIDs, glucocorticoids) also showed a decreased hyperplasia for patients in remission, especially for patients who received biologics (4.2 fold decrease). Regarding the RASF, RNA sequencing showed a general homogeneity of the expressed genes and the underlying pathways between patients in remission and active RA patients. This observation was evident in both, the unstimulated approach and the stimulated RASF. However, RNAseq identified several DEGs including IL-36B (-7.14 fold) and the IL-36 receptor antagonist (-11.49 fold), cathepsin K (-1.66 fold) and folliculin (-1.54 fold), which were downregulated in patients in remission.

Conclusion: The histological analysis illustrates that patients in remission, especially patients receiving biologics, show a lower degree of inflammation and hyperplasia. RNAseq identified several genes showing altered gene expressions related to the diminished pro-inflammatory and destructive processes during RA. Of note, pro-inflammatory IL-36 family members were predominantly downregulated, which could be used as biomarker for remission.

AB0066 ACCELERATED MONOCYTE DIFFERENTIATION AND HIGH EXPRESSION OF MACROPHAGE COLONY-STIMULATING FACTOR RECEPTOR IN THE MONOCYTES MAY BE INVOLVED IN ACCELERATED OSTEOCLASTOGENESIS IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

M. Murakami[1,2], N. Nishimoto[1,2]. [1]*Osaka Rheumatology Clinic, Department of Rheumatology, Osaka, Japan*; [2]*Tokyo Medical University, Department of Molecular Regulation for Intractable Diseases, Institute of Medical Science, Osaka, Japan*

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by chronic proliferation of synovial cells and destructive polyarthritis. Various kinds of cells are involved in the pathogenesis of RA, including myeloid cells, lymphocytes, and synovial fibroblasts. It has been reported that there are abnormal myeloid cells in bone marrow of RA patients (Ochi, *et al.*, Arthritis Res. Ther., 2007). In addition, myeloid cells differentiate into monocytes/macrophages, which can thereafter differentiate into osteoclasts that mediate bone destruction in RA. In fact, we have previously reported CD14+ monocytes differentiated from induced pluripotent stem cells (iPSCs) derived from RA patients expressed more mRNA of receptor activator of nuclear factor-kappa B (RANK) than those from a healthy donor, non-onset family member (NOF), resulting in the accelerated osteoclastogenesis (Ito, *et al.*, The 36th annual meeting of the Japanese society of inflammation and regeneration, 2015). However, the question remains if distinct monocyte differentiation besides high RANK expression may also be involved in the accelerated osteoclastogenesis in RA.
Objectives: To investigate whether there is distinct monocyte differentiation between a RA patient and NOF.
Methods: iPSCs have been established from skin fibroblasts from a RA patient. For the controls, NOF of the patient are recruited as a donor in order to adjust hereditary background as much as possible. Monocytes were induced from each iPS clone culture on feeder-free conditions using a previously reported method (Cui, *et al.*, Front. Cell Dev. Biol., 2021). Floating cells were sequentially collected on days 10, 14, 18 and 22 during induction of monocytes from iPSCs. Surface phenotypes and the expression of differentiation markers of monocytes were analyzed with flow cytometry using the corresponding antibodies.
Results: RA-iPSCs differentiated into CD43+ (hematopoietic marker) cells earlier than NOF-iPSCs did (the data shown in Table 1). In addition, the proportion of CD45+ in CD43+cells (myeloid progenitors) was achieved in 93.0±4.8% (RA) and 51.0±21.3% (NOF) on day 18 (*p=0.029*) (the data shown in Table 1). The proportion of CD11b+CD45+ cells (monocytes and granulocytes) derived from RA-iPSCs was not significantly different from that from NOF-iPSCs. However, the proportion of $CD45^{high}$ in CD11b+CD45+ cells (monocytes) derived from RA-iPSCs was significantly higher than that from NOF-iPSCs on day 18 and 22 (the data shown in Table 1). $CD45^{high}$ in CD11b+CD45+ cells were mostly CD14+ cells. The proportion of CD115+, macrophage colony-stimulating factor receptor (MCSF-R), in CD14+ cells induced from RA-iPSCs tended to increase compared with NOF-iPSCs as the days of differentiation progressed (the data shown in Table 1).
Conclusion: Hematopoietic stem cells differentiate into myeloid progenitors in monocyte differentiation in RA earlier than those in NOF. Moreover, they differentiate into more CD14+CD11b+$CD45^{high}$ monocytes which are likely to express more MCSF-R as compared with those in NOF. We speculate that these distinct monocyte differentiation may play in accelerated osteoclastogenesis in RA.

Background: Rheumatoid arthritis (RA) is a chronic systemic inflammatory autoimmune disease which primarily affects the joints [1]. Numerous agents are currently used to modify the natural course of the disease, however, several RA patients still do not reach clinical remission[2]. A recently developed quinoxaline analogue named Rabeximod (RBM) showed clinical benefits comparable to TNF-α blockers in a mouse model of collagen antibody-induced arthritis[3]. Moreover, in a phase IIa clinical trial a significantly higher clinical efficacy of RBM + Methotrexate versus Methotrexate alone has also been confirmed.
Objectives: Since RBM's exact biologic target has not been entirely established yet, our objective is to investigate its mode of action at the cellular and molecular level.
Methods: Two *in vitro* models were developed: i) Toll-like receptor (TLR)-4 and TLR-2–stimulated peripheral blood mononuclear cells (PBMCs) cultured for 24-hours and ii) Monocytes derived-macrophages (MDMs), cultured for 96-hours in persisting inflammation conditions mimicking the different phases of ACPA-positive rheumatoid synovial inflammation: recruitment, initiation, development, and persistence of the inflammatory process. PBMCs-transcriptomic analysis was performed using a NanoString nCounter SPRING Profiler (customised panel). Cytokine production was measured by ELISA.
Results: RBM induced dose-dependent cell mortality. Among PBMCs, monocyte viability was preferentially affected compared to lymphocytes. RBM treatment reduced IL-6 and TNF-α production both in TLR4/TLR2-stimulated PBMCs and MDMs supernatants at 24h (PBMCs) and 10-, 24-, 48- and 72-hour time-points (MDMs). RBM-induced down-regulation of IL-6 and TNF-α in PBMCs was also obtained when PBMCs were pre-incubated for 7 hours prior to TLR activation (without additional RBM), suggesting an internalisation process. After 24h, RBM induced the downregulation of several pro-inflammatory genes in TLR-4 and-2 stimulated PBMCs, including IL-6, TNF-α, CSF1, FCN1, and SPP1. Finally, after 24 hours, MDMs treated with RBM developed an altered morphology independently of the frequency of treatment exposure and the stage of inflammation.
Conclusion: Overall, our data suggest that RBM acts predominantly on monocytes/macrophages and can inhibit the production of pro-inflammatory molecules playing a crucial role in RA.

Kim4. *[1]Gyeongsang National University Hospital, Division of Rheumatology, Department of Internal Medicine, Jinju, Korea, Rep. of (South Korea)*; *[2]Gyeongsang National University Changwon Hospital, Department of Radiation Oncology, Changwon, Korea, Rep. of (South Korea)*; *[3]University of Minnesota, Lillehei Heart Institute, Minneapolis, United States of America*; *[1]Gyeongsang National University Hospital, Division of Rheumatology, Department of Internal Medicine, Jinju, Korea, Rep. of (South Korea)*; *[5]Gyeongsang National University, Department of Internal Medicine, Jinju, Korea, Rep. of (South Korea)*; *[6]Gyeongsang National University, Department of Radiation Oncology, Jinju, Korea, Rep. of (South Korea)*

Background: Disease-Modifying Anti-Rheumatic Drugs (DMARDs) have therapeutic effects on rheumatoid arthritis (RA) through the modulating immune responses of systemic and synoviums. However, DMARDs be used for an extended period, drug-related adverse effects can be a severe problem. Therefore, it is necessary to develop a treatment strategy to minimize the adverse effects of DMARDs, such as infection, abnormal liver function tests, and hematological abnormalities.
Objectives: Radiation therapy is one of the crucial therapeutic strategies for cancers. Low-Dose Radiotherapy (LDRT), the total dose may be given in fewer treatments or over a shorter period, has been tried to treat various inflammatory diseases, but its theoretical basis is poor. Therefore, this research aims to elucidate the mechanism and standardization of LDRT for RA.
Methods: The CIA (collagen-induced arthritis) and K/BxN mice used an experimental arthritic model representing RA. At the point of the highest arthritis symptoms, CIA and K/BxN mice were treated with LDRT. Then, the clinical score of the fore or hind paws was measured twice a week for 30 days. After 30 days of LDRT, the mice were sacrificed. Splenocytes, popliteal and inguinal lymphoid cells were analyzed by flow cytometry to measure the level of activation, proliferation, inflammatory-cytokines, and apoptosis of immune cells. To evaluate whether LDRT is effective on human immune cells, RA patients' PBMC were treated with LDRT and analyzed by flow cytometry.
Results: LDRT did not affect the lymphocyte activation, proliferation, differentiation, and inflammatory cytokine secretion. However, LDRT enhanced lymphocyte apoptosis and decreased immune cell numbers and clinical scores in CIA and K/BxN mice. In addition, the degree of cartilage destruction was reduced by treating with LDRT in K/BxN mice. Likewise, the proportion of apoptotic lymphocytes was increased by LDRT in PBMC of a patient with RA, not fibroblast-like synoviocytes (FLS).
Conclusion: We uncovered that LDRT diminished experimental arthritis such as CIA and K/Bx models via augmented lymphocyte apoptosis in draining lymph nodes. Thus, these findings suggest that LDRT can be a new therapeutic strategy with minimal adverse effects for RA.

AB0069 MEASUREMENT OF IL-33/ST2 AXIS IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND ITS ASSOCIATION WITH OTHER CYTOKINES IN SW982 AND U937 CELL LINES

Keywords: Cytokines and chemokines, Rheumatoid arthritis, Cell biology

M. Pai[1], V. Pai[2], P. Kumar[3], G. Badoni[1], S. Saha[3], P. Gupta[1]. *[1]All India Institute of Medical Sciences Rishikesh, Microbiology, Rishikesh, India*; *[2]All India Institute of Medical Sciences Rishikesh, Medicine, Rishikesh, India*; *[3]All India Institute of Medical Sciences Rishikesh, Biochemistry, Rishikesh, India*

Background: An inflammatory maelstrom is a characteristic feature of autoimmune diseases including Rheumatoid Arthritis (RA). IL-33, a member of IL-1 cytokine family has been studied in animal models with induced RA and a few studies in RA patients. These studies have shown the exacerbation of IL-33, however little is known about its pathogenesis and association with other cytokines in vivo and in vitro.
Objectives: This study evaluated the expression of IL33 and ST2 in serum and Peripheral blood mononuclear cells (PBMC's) of active RA patients, in addition to other cytokines (IL-13, IL-5, IL-17) and biochemical parameters. TNF-alpha stimulated and synovial fluid (SF) conditioned growth medias were used to grow cell lines (SW982, U937) so as to have ambient physio-pathological microenvironment during experiments, typically of RA and then the levels of IL-33 were evaluated. Association of IL-33 with expression of LTB4 was also studied.
Methods: PBMC's and sera from 50 active RA patients and 50 healthy individuals were obtained. IL-33 and ST2 were measured using Real Time PCR with specific primers including internal controls. Sandwich ELISA was done for studying protein expressions. Cell lines were grown RPMI-1649 + 10%FBS for U937 and DMEM + Glutamine + 10% FBS for SW982 cells at 5% CO_2.
Results: IL-33 and ST2 mRNA expression was significantly higher in patients with active RA, with estimated fold change of 3.533($\Delta\Delta$Ct = -1.82121) and 4.172 ($\Delta\Delta$Ct = -2.15229) respectively, as compared to controls. ELISA results revealed mean value of IL-33 to be significantly higher in RA patients than in controls (119.32±63.49 and 22.835±12.24 respectively). An increase in serum protein of ST2 was also observed in RA patients as compared to healthy controls (2434.328±834.60 and 705.22±310.05). Out of the total (n^{RA} =50), 35 RA patients showed a hike in serum and mRNA expression of IL-33 which also showed correlation with other disease biomarkers like anti-CCP, CRP, DAS-28 CRP and HAQ-DI. Significant increase in serum protein of IL-17 (1542.112±120.21) and IL-5 (624.21±78.09) were observed. SF stimulated SW982 cells showed a 1.8 fold increase in levels of IL-33 as compared to cells which were stimulated with TNF alpha alone. Further monocytic cell line was treated with recombinantanti human IL-33 antibody and showed direct association with levels of Leukotriene B4 (LTB4) expression.
Conclusion: Elevated IL-33 and ST2 in both serum and PBMC's of RA patients showed correlation with the disease activity. Therefore, IL-33/ST2L signalling represents to be involved in the pathogenesis of RA and also indicates it to be a promising biomarker. Synovial fluid gives a natural microenvironment to cells in in-vitro studies showing increased expression of cytokines. This is the first study that shows a direct relation with IL-33 and LTB4 expression, thus proving the chemoattractive role of LTB4.

AB0070 PIM KYNASES AS POSSIBLE THERAPEUTIC TARGETS IN INFLAMMARORY ARTHRITIDES

Keywords: Biomarkers, Cell biology, Inflammatory arthritides

E. Assirelli[1], J. Ciaffi[1], S. Naldi[1], V. Scorcu[1], L. Mancarella[1], V. Brusi[1], L. Lisi[1], F. Ursini[1,2], S. Neri[1]. *[1]IRCCS Istituo Ortopedico Rizzoli, Medicine and Rheumaology Unit, Bologna, Italy*; *[2]University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy*

Background: Proviral integration site for Moloney murine leukemia virus (PIM) 1 kinase and its family members (PIM2 and PIM3) regulate several cellular functions including survival, proliferation and apoptosis. These proteins have been extensively studied in tumorigenesis, whereas their role in autoimmune and chronic inflammatory diseases remain unclear. PIM kinases are involved in T-cell amplification and differentiation in inflammatory Th1 and Th17 effector T cells subsets. Recent studies suggest that the expression of PIM1 is upregulated in fibroblast-like synoviocytes and CD4+ T cells from patients with rheumatoid arthritis (RA). However, data are

lacking regarding the potential role of PIM kinases in spondyloarthritis (SpA) such as psoriatic arthritis (PsA) and axial spondyloarthritis (AxSpA).
Objectives: To explore the potential role of PIM kinases in inflammatory arthritides, we evaluated PIM kinases expression at gene and protein level in patients with RA, PsA, and AxSpA compared to healthy controls (CTR).
Methods: PIMs expression was analysed in 26 (11 RA, 7 AxSpA, and 8 PsA) biologic DMARDs (bDMARDs)-naive arthritis patients and 13 controls. PIMs mRNA levels were determined in total RNA extracted from freshly isolated peripheral blood mononuclear cells (PBMC) by real-time semi-quantitative PCR. Protein levels were quantified in serum by ELISA test. Data were analysed by Kruskal Wallis test followed by Dunn's correction for multiple comparisons.
Results: All the samples showed expression of PIM1, 2, and 3 kinases both at gene and protein level, with PIM 3 being the less expressed protein. A trend towards lower expression of PIM1 was appreciated in AxSpA samples compared to other groups, reaching statistical significance only for serum protein levels compared to controls ($p < 0.05$). No significant differences were found in PIM2 and PIM3 expression, although all arthritis patients showed a trend towards higher serum levels compared to controls, not mirrored at gene expression levels.
Conclusion: PIM 1 mRNA expression in PBMCs seems to mirror PIM1 protein expression in the serum in all groups, supporting this molecule as a candidate biomarker. Controls, RA and PsA patients displayed similar levels, whereas AxSpA patients showed a trend towards reduced PIM1 levels deserving further investigation. Conversely, serum PIM2 and PIM3 levels did not mirror PIM2 and PIM3 gene expression in resting PBMC. Unlike PIM1, the expression of PIM2 and PIM3 have never been studied in PsA and AS, and additional data are required to explore the potential relevance of PIM2 and PIM3 in SpA pathophysiology. Further studies are also required to evaluate PIM kinases modulation after in vitro cell stimulation, the differential expression in PBMC subpopulations, and the impact of disease activity and concurrent disease-modifying medications.

AB0071 PRE-CLINICAL EVALUATION OF ANTI-ANGIOGENIC EFFECTS OF CANDIDATE AGENTS FOR MOLECULAR DIAGNOSTIC IMAGING AND THERAPY IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Synovium, Imaging

F. Khodadustvaskasi[1], E. Philippon[2,3], E. Mantel[1], J. P. Van Hamburg[2,3], J. Van Beijnum[4], A. D. Windhorst[5], G. Jansen[1], S. Tas[2,3], C. J. Van der Laken[1]. [1]*Amsterdam UMC, locatie VUmc, Department of Rheumatology & Clinical Immunology, Amsterdam, Netherlands*; [2]*Amsterdam UMC, locatie AMC, Department of Experimental Immunology, Amsterdam, Netherlands*; [3]*Amsterdam UMC, locatie AMC, Department of Rheumatology & Clinical Immunology, Amsterdam, Netherlands*; [4]*Amsterdam UMC, locatie VUmc, Angiogenesis Laboratory, Department of Medical Oncology, Amsterdam, Netherlands*; [5]*Amsterdam UMC, locatie VUmc, Department of Radiology & Nuclear Medicine, Amsterdam, Netherlands*

Background: The role of pathological angiogenesis is widely recognized in cancer and various inflammatory diseases, including rheumatoid arthritis (RA). In RA, angiogenesis and inflammation are mutually dependent and play a cooperative role in the disease progression. Angiogenesis mainly relies on the interaction of vascular endothelial cells (ECs), fibroblasts, macrophages, and the extracellular matrix. This phenomenon promotes the infiltration of inflammatory cells into the joints, resulting in more synovial inflammation and structural damage. In this process, a number of soluble and cell surface-bound angiogenic mediators are involved providing candidate targets for diagnosis and therapy [1, 2]. Anti-angiogenesis strategy has been widely used in tumor treatment and its potential value in RA as a single or in combination therapy need to be further explored.
Objectives: To assess potential anti-angiogenic effects of selected compounds with different mechanisms of action in preclinical models of angiogenesis for exploitation as candidate agents for molecular imaging and/or therapeutics purposes.
Methods: Two *in vitro* models of angiogenesis were employed in this study: (i) a scratch assay assessing the closure rate of scratches made in human microvascular endothelial cells (HMEC-1) [3] in the presence of drugs for 24 hr, and (ii) 3D-spheroid model of angiogenesis composed of ECs and fibroblasts, assessing the impact of drugs on EC sprout formation after 40 hr of incubation. Sprout quantification was performed via confocal microscopy and digital image analysis [2]. Candidate anti-angiogenic compounds examined in this study included: sunitinib (pan-kinase inhibitor), a small molecule NF-κB-inducing kinase inhibitor (NIKi), tofacitinib (selective JAK1/3 inhibitor) and fluciclatide (RGD-peptide targeting $\alpha_V\beta_3$ and $\alpha_V\beta_5$ integrins) and tested in concentration range of 0-10 μM. An MTT-proliferation inhibition assay was used to monitor any drug-induced cytotoxicity.
Results: In scratch assays, sunitinib exhibited irreversible inhibition (max 75% at 10 μM after 24 hr incubation) compared to NIKi which had a transient inhibitory effect (max 59% at 10 μM after 8 hr incubation). No apparent effects were observed for tofacitinib up to concentrations of 10 μM. Interestingly, fluciclatide, induced morphological changes at concentration of 0.1 μM, impairing scratch closures. Next, the anti-angiogenic effects of the compounds were verified in the 3D-spheroid model that more closely mimics the *in vivo* situation. Here, marked blockade of sprout formation was noted at 0.1 μM for sunitinib, and 1-2.5 μM for NIKi, tofacitinib and fluciclatide. MTT assays indicated that none of the observed drug-effects were due to induction of cytotoxicity at the indicated concentrations.
Conclusion: This study identified various compounds (sunitinib, NIKi, tofacitinib and fluciclatide) exhibiting potential anti-angiogenic properties *in vitro,* encouraging their further evaluation as radionuclide imaging and therapeutic agents for diagnosis and therapeutics in vivo.

AB0072 THE METABOLITES WERE ALTERED IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Rheumatoid arthritis

R. Wu[1], J. An[2], C. Wang[1]. [1]*the Second Hospital of Shanxi Medical University, the Department of Rheumatology, Taiyuan, China*; [2]*the Fifth Hospital of Datong, the Department of Rheumatology, Datong, China*

Background: Rheumatoid arthritis (RA) is characterized by persistent synovitis and abnormal antibodies production[1].The discovery of follicular helper T cells (Tfh) and follicular regulatory T cells (Tfr) has added a new understanding of the mechanisms of antibody production in RA such as anti-cyclic peptide containing citrulline (anti-CCP) [2]. The gut microbiota-derived metabolites are also important in regulating immune system to balance disease and health. And the altered gut microbiota-derived metabolites had been found in RA patients[3]. However, the relationship between gut microbiota-derived metabolites and Tfr/Tfh cells has not been comprehensively evaluated in RA patients to date, which is the focus of our study.
Objectives: We detected the gut microbiota-derived metabolites and the expression of Tfr and Tfh cells in new-onset RA patients, and then analyzed the relationship between gut microbiota-derived metabolites and Tfr/Tfh cells.
Methods: 17 patients with new-onset RA from the Second Hospital of Shanxi Medical University were recruited. And 13 sex- and age-match healthy controls

(HCs) were enrolled. Fecal samples were collected to determine the gut microbiota-derived metabolites by LC-MS/MS-based nontargeted metabolomic. And blood samples were collected to detect the expression of circulating Tfr and Tfh cells by flow cytometry.

Results: The fecal metabolite profiles between RA and HC groups were different (Figure 1A, B). There were 61 differential annotated metabolites in RA including 34 metabolites upregulated and 27 metabolites downregulated compared to HCs (Figure 1C, D). The KEGG pathway enrichment analysis of the differentially abundant metabolites showed that there were only four pathways were the main pathways related to RA including biosynthesis of unsaturated fatty acids, arginine biosynthesis, tryptophan metabolism as well as alanine, aspartate and glutamate metabolism (Figure 1E). And eleven differentially abundant metabolites were involved in the four mainly altered pathways. The correlation heatmap of the association of the eleven differentially abundant metabolites with indicators of RA was shown in Figure 2A. It showed that the increased arachidonic acid was positively correlated with DAS28, ESR and anti-CCP. We identified the potential biomarker value of RA by performing receiver operating characteristic (ROC) curve analysis, which showed that arachidonic acid yielded the area under curve (AUC) of 0.724 [95% CI = 0.539-0.909, *P*=0.038]. It suggested that arachidonic acid was the potential biomarker of RA (Figure 2B). And arachidonic acid was negatively associated with the number of Tfr cells (r=-0.645, *P*=0.006) and the c-Tfr/c-Tfh ratio (r=-0.623, *P*=0.009).

Conclusion: There was an obvious difference in the fecal metabolite profiles between RA and HCs. Arachidonic acid was identified as the potential biomarker of RA, and the increased arachidonic acid was negatively associated with Tfr cells to affect the disease activity and the production of anti-CCP in RA.

ANTI-ARTHRITIC ACTIVITIES OF THE ELEUTHEROCOCCUS SENTICOSUS, ACHYRANTHES JAPONICA, AND ATRACTYLODES JAPONICA MIXED EXTRACT FERMENTED WITH NURUK IN A TYPE II COLLAGEN-INDUCED ARTHRITIS MOUSE MODEL

Keywords: Rheumatoid arthritis, Animal models, Inflammatory arthritides

C. H. Lee[1], C. H. Chung[1], W. H. Yoo[2], Y. Choi[2], M. S. Lee[1]. [1]*Wonkwang University Medical School, Internal Medicine, Iksan, Korea, Rep. of (South Korea)*; [2]*Jeonbuk National University Medical School, Internal Medicine, Jeonju, Korea, Rep. of (South Korea)*

Background: Rheumatoid arthritis (RA) is an autoimmune disease that is accompanied by chronic synovitis, progressive cartilage, and bone destruction and is affected by inflammatory-associated factors. Vigeo is a mixture of fermented extracts of *Eleutherococcus senticosus* Maxim (ESM), *Achyranthes japonica* (Miq.) Nakai (AJN), and *Atractylodes japonica* Koidzumi (AJK) manufactured using the traditional Korean nuruk fermentation method. Although the bioactive effects of ESM, AJN, and AJK have already been reported, the pharmacological effects of Vigeo have not been proven.

Objectives: In this study, we investigated whether Vigeo had inhibitory effects on RA and its intracellular mechanisms using a type II collagen-induced arthritis (CIA) mouse model.

Methods: CIA was induced in DBA/1 mice by immunization with bovine type II collagen. The mice were administered orally with Vigeo (200 and 500 mg/kg/day, i.g.) from days 21 to 42 after immunization. The clinical scores, hind paw swelling, and histopathological finding were evaluated in the paw of CIA mice. The levels of tumor necrosis factor α (TNF-α), interleukin (IL)-6, and IL-1β in the serum were measured by enzyme-linked immunosorbent assay.

Results: The results showed that Vigeo 500 mg/kg treatment significantly alleviated the severity of the disease, based on the reduced hind paw swelling and clinical scores, compared with untreated CIA mice. Comparing with untreated CIA mice, Vigeo 500 mg/kg treatment inhibited the levels of TNF-α, IL-6, and IL-1β in the serum.

Conclusion: Our results suggest that anti-inflammatory effects of Vigeo against collagen-induced arthritis in mice may be due to its ability to inhibit pro-inflammatory mediators. Vigeo may be a promising potential therapeutic reagent for arthritis treatment.

Background: Patients with rheumatoid arthritis (RA) have a high risk of suffering cardiovascular disease. The cardiovascular and cardiometabolic proteome analysis in RA patients may provide disease biomarkers and insights into the biological pathways that contribute to cardiovascular risk.
Objectives: 1) To evaluate the changes in the cardiometabolic and cardiovascular serum proteome in two cohorts of active RA patients: newly diagnosed (naïve-treated) and well-established disease and its relationship with the clinical characteristics and 2) to analyze the modulation of the levels of these proteins by methotrexate and tofacitinib.
Methods: 1) Cross-sectional study in two cohorts of RA: patients at diagnosis (n=25) and patients with established disease (evolution time>25 years, n=25), age and sex-matched with healthy donors (n=25). 2) Longitudinal study was performed on 25 RA patients treated with methotrexate and 25 RA patients treated with Tofacitinib combined with DMARDs for 6 months. Clinical and analytical variables were recorded. Proteomic profiling of 184 proteins (cardiometabolic and cardiovascular II panels) was performed in the serum using Olink Proteomics technology.
Results: There were no statistical differences between the RA at diagnosis and RA-established disease groups in age and DAS28. The evolution time average in the RA-established disease group was 37.48±11.79 years. One hundred and seven proteins were significantly increased in the serum of RA patients at diagnosis, among these 47 proteins were elevated in RA patients with established disease. The PCA analysis showed that the alteration of these proteins could discriminate between RA patients and healthy donors. The molecules that more significantly increased in the RA at diagnosis group were SAA4, ST6GAL1, CCL18, TNC, IGLC2, IL6, SORT1, TNFRSF10A, AGRP, and CD4. In addition, the top ten molecules significantly elevated in RA patients with the established disease were SAA4, CCL18, ST6GAL1, CRTAC1, ANGPTL3, TNFRSF10A, LEP, Gal-9, SORT1, and TRAIL-R2. The increase of these proteins was associated with the inflammation shown by the correlation with C reactive protein (CRP) levels and DAS28. The elevated levels of SAA4 (serum amyloid A protein-4) discriminated between RA patients and healthy donors with high sensitivity and specificity (AUC=0.95). Treatment with methotrexate in RA patients at diagnosis reduced the levels of 64 proteins (50% of the altered proteins) while tofacitinib modulated the expression of 30 proteins (50% of the altered proteins) in RA patients with established disease after 6 months. These reductions were associated with a decrease in CRP and DAS28 levels.
Conclusion: 1)The cardiovascular and cardiometabolic serum proteome is altered in RA patients at diagnosis and after a long time of the disease evolution and chronic treatments, 2) SAA4 may represent a biomarker for the diagnosis of RA with high sensitivity and specificity, 3) Methotrexate and tofacitinib specifically modulate the alteration on the serum proteome after six months of treatment alongside the reduction of clinical inflammatory and disease activity markers.

AB0075 PRESENCE AND EFFECT OF MUSCLE GDF-8 AND GDF-11 IN THE SYNOVIUM OF PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Synovium

M. L. Gasparini Vieira[1,2], R. T. Pedo[1], J. Miranda de Souza Silva[1], M. Farinon[1,2], S. Dalmolin[1], M. Piccoli[1], M. Dos Santos[1], B. Bartikoski[1], R. Cavalheiro Do Espírito Santo[1,2], V. Hax[3], R. Xavier[1,2]. [1]*Hospital de Clínicas de Porto Alegre, Laboratório de Doenças Autoimunes, Serviço de Reumatologia, Porto Alegre, Brazil*; [2]*Universidade Federal do Rio Grande do Sul, Programa de Pós-Graduação em Medicina: Ciências Médicas, Porto Alegre, Brazil*; [3]*Hospital de Clínicas de Porto Alegre, Serviço de Reumatologia, Porto Alegre, Brazil*

Background: Myokines, such as the growth differentiation factor (GDF) 8 and 11, have the function of regulating autocrine and paracrine activities on muscle tissue metabolism. In Rheumatoid Arthritis (RA), there is increased expression of GDF-8 in the synovial membrane compared to osteoarthritis (OA) patients, more specifically by fibroblast-like synoviocytes (FLS). On the other hand, the GDF-11 treatment appears to have a protective effect against the development of experimental arthritis. Therefore, more studies evaluating the serum and synovial membrane levels of the GDF-8 and GDF-11 in RA patients are needed to better define their possible roles in this disease.
Objectives: To evaluate the GDF-8 and GDF-11 in serum and synovial membrane levels in RA patients and to assess their *in vitro* effect on FLS.
Methods: Patients diagnosed with RA and patients with knee OA with the indication of knee arthrocentesis were included in the study. Disease activity was assessed by Clinical Disease Activity Index (CDAI). The evaluation of serum and synovial fluid levels of GDF-8 and GDF-11 was performed by ELISA. FLS were isolated from the synovial fluid of RA patients, and cell viability was determined in the presence and absence of GDF-8 and GDF-11 (10nM; 20nM and 50nM) for 24h and 48h by the MTT assay. Kolmogorov–Smirnov, Mann-Whitney U and Spearman's correlation tests were performed using SPSS version 20.0 (accepted at $p \leq 0.05$).
Results: As preliminary data, samples from 11 patients with RA and 5 patients with knee OA were evaluated. GDF-8 synovial fluid levels were lower than serum levels in RA patients (p=0.007) and were negatively correlated with disease duration (r=-0.684, p=0.02). GDF-11 levels in synovial fluid were also lower than in serum in RA (p=0.018) and were higher in RA patients than in the OA group (p= 0.052). Furthermore, treatment with different concentrations of GDF-8 and GDF-11 did not affect FLS viability.

Table 1. Clinical features of study population

Characteristics	RA (n=11)	OA (n=5)
Age in years (mean ± SD)	65.3 ± 9.26	66.6 ± 5.22
Women, n (%)	10 (90.9)	3 (60)
Disease duration in years (mean ± SD)	16 ± 12.41	
CDAI (mean ± SD)	12.8± 5.68	
Synovial fluid		
GDF-8 (pg/ml) (median (IQR))	31.30 (31.30-181.80)	232.10 (106.15- 855.50)
GDF-11 (pg/ml) (median (IQR))	31.30 (31.30- 88.13)	31.30 (31.30- 31.30)
Serum		
GDF-8 (pg/ml) (median (IQR))	817.20 (334.30- 994.70)	761.70 (440.55- 1312.05)
GDF-11 (pg/ml) (median (IQR))	347.50 (31.30- 1818.00)	31.30 (31.30- 31.30)

RA, rheumatoid arthritis; OA, osteoarthritis; SD, standard deviation; CDAI, clinical disease activity index; IQR, interquartile range.

Conclusion: In this preliminary research, we found lower GDF-8 and GDF-11 synovial fluid levels than in serum in RA patients and higher GDF-11 serum levels in the RA group compared to the OA group. This result could be related to local compensatory mechanisms against the inflammatory state. *In vitro*, both GDF-8 and GDF-11 did not induce proliferation or death of FLS, and more studies are undergoing to analyze their impact on the FLS phenotype. Our results contribute to the knowledge about the participation of myokines in the pathogenesis of RA.

THE THERAPEUTIC POTENTIAL OF CIRCULATING AUTOLOGOUS TISSUE HOMING EXTRACELLULAR VESICLES FOR THE MANAGEMENT OF RHEUMATOID ARTHRITIS PATIENTS

Keywords: Animal models, Rheumatoid arthritis, bDMARD

G. Halpert[1], O. Moskovitch[1], A. Anaki[2], T. Caller[3,4], O. Gendelman[1,5,6], A. Watad[1,5,6], R. Shai[7], R. Popovtzer[2], H. Amital[1,5,6]. [1]*Sheba Medical Center, Center for Autoimmune Disease, Ramat-Gan, Israel*; [2]*Bar-Ilan University, Bar-Ilan Institute for Nanotechnology and Advanced Materials (BINA), Ramat-Gan, Israel*; [3]*Tel Aviv University, Faculty of Medicine, Neufeld Cardiovascular Research Institutes, Tel Aviv, Israel*; [4]*Sheba Medical Center, Tamman Cardiovascular Research Institutes, Ramat-Gan, Israel*; [5]*Tel Aviv University, Sackler Faculty of Medicine, Tel-Aviv, Israel*; [6]*Sheba Medical Center, Department of Medicine 'B', Ramat-Gan, Israel*; [7]*Sheba Medical Center, Pediatric Hematooncology, Ramat-Gan, Israel*

Background: Progress has been achieved with the introduction of biologics for the management of inflammatory/autoimmune diseases such as rheumatoid arthritis (RA), however such medications induce immune suppression, which is nonselective to the pathogenesis of the disease, resulting in higher rates of infections. Therefore, there are unmet medical needs in the treatment of such diseases, which should be addressed by novel approaches. Accumulating evidence suggests that extracellular vesicles (EVs) play a role in the establishment, maintenance and modulation of autoimmune processes.
Objectives: In the current study, we hypothesized that isolation of circulating autologous tissue-specific homing EVs from RA patients - may improve the delivery of current FDA-approved anti-inflammatory drugs, which will be encapsulated into these EVs. The drug-loaded EVs will be injected back to the diseased subjects and will naturally find their way to the inflamed tissue.
Results: Indeed, we found that autologous labeled EVs, expressing joint/synovia-specific homing receptors (e.g. αVβ3 integrin), derived from blood of diseased arthritic mice (Collagen antibody-induced arthritis model), can migrate toward the inflamed synovia, using *in vivo* imaging system (IVIS). Moreover, we show that these EVs strongly expresses glucose transporter 1 (mGLUT1) which in turn, improve their therapeutic potential to be loaded with anti-inflammatory drugs using glucose-coated gold nanoparticles (GNPs). Finally, we show that EVs derived from plasma of RA patients overexpresses αVβ3 integrin and taken up by LPS/TNFα-induced activated human synovial cell line *in vitro*.
Conclusion: Overall, we show the potential of autologous circulating EVs of RA patients to serves as natural nano-carrier for current FDA-approved drugs. We believe that this strategy will increase the specificity and efficiency of current treatment, therefore it will reduce side effects and will improve the quality of life of RA patients and potentially other autoimmune disease patients.

SEMAPHORIN4B IS UPREGULATED IN RHEUMATOID ARTHRITIS PATIENTS AND INDUCES EXPRESSION OF INFLAMMATORY MEDIATORS BY MACROPHAGES AND FIBROBLAST-LIKE SYNOVIOCYTES

Keywords: Rheumatoid arthritis, Cytokines and chemokines, Synovium

S. Martínez-Ramos[1], C. Rafael Vidal[1], B. Malvar Fernández[1], N. Perez-Gomez[1], C. Mouriño Rodríguez[1], F. J. Maceiras-Pan[1], I. Altabás González[1], J. M. Pego-Reigosa[1], S. García[1]. [1]*Galicia Sur Health Research Institute (IIS Galicia Sur), SERGAS-UVIGO, Rheumatology & Immuno-mediated Diseases Research Group (IRIDIS), Vigo, Spain*

Background: Several studies have shown that different semaphorin family members are involved in the pathogenesis of rheumatoid arthritis (RA). On one hand, our group has demonstrated that (Sema)phorin 3B and Sema3F are reduced in RA patients and play a protective role. On the other hand, Sema4A and Sema4D are increased in RA patients and are associated with inflammatory processes (Garcia, 2019; Igea, 2022).
Objectives: The aim of this study is to determine the role of Sema4B in the pathogenesis of RA.
Methods: Gene expression of Sema4B was obtained from the gene expression array available in Gene Expression Omnibus-NCBI (GSE77298). Fibroblasts-like synoviocytes from RA patients (RA-FLS) (n=8) were stimulated 4 and 24 h with Sema4B (200ng/mL), TNF (10 ng/mL) or the combination of both. Peripheral blood monocytes from RA patients (n=12) were differentiated into M1 macrophages by culturing in the presence of IFN-γ (10 ng/mL) for 6 days. Afterwards, macrophages were stimulated 24 h with Sema4B (200ng/mL), LPS (10 ng/mL) or the combination of both. The expression of inflammatory mediators was determined by quantitative PCR (qPCR) and ELISA. Viability and migration of FLS were determined using calcein assays and wound closure assays, respectively.
Results: Sema4B expression was significantly higher in the synovial tissue and FLS of RA patients compared to healthy controls (HC) and osteoarthritis patients (OA), respectively. A significantly higher expression of *SEMA4B* in the synovium and FLS of RA patients compared to, respectively, was found. Interestingly, TNF stimulation induced the expression of *SEMA4B* by RA-FLS. Functional studies showed that Sema4B did not affect the viability of FLS but increased their migratory capacity. Moreover, Sema4B alone did not induce the expression of inflammatory mediators (data non shown), but significantly enhanced the TNF-induced expression of *IL6, IL8, TNF, CCL2* and *MMP3* (Figure 1A) and the secretion of TNF. Finally, Sema4B alone did not modulate the expression of inflammatory mediators in macrophages, but significantly enhanced the LPS-mediated expression of *TNF*, *CCL2*, and *MMP1* (Figure 1B), as well as the TNF protein secretion.

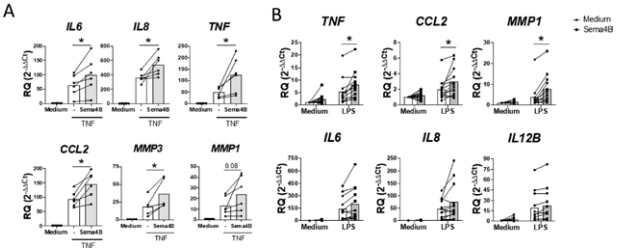

Figure 1. Sema4B enhances pro-inflammatory activity in FLS (n=6) and macrophages (n=10) of RA patients. (A) Significative increment of the genetic expression of pro-inflammatory mediators in RA-FLS stimulated with Sema4B (200 ng/ml), TNF (10 ng/mL) and their combination for 24 hours. (B) Significative increase of the genetic expression of pro-inflammatory mediators in M1 macrophages. Macrophages differentiated from monocytes of RA patients during 6 days (IFN-γ 10 ng/mL) and stimulated with Sema4B (200 ng/ml), LPS (10 ng/mL) and their combination for 24 hours. Symbols represent individual patients; bars show the mean ± SEM. *P < 0.05.

Conclusion: Our data demonstrate that, in an inflammatory context, Sema4B induces FLS migration and the production of inflammatory mediators by FLS and macrophages. These results suggest that Sema4B is involved in inflammatory processes observed in the RA synovium and might be a potential therapeutic target in the treatment of RA.

EARLY ARTHRITIS: IS JAK-STAT SIGNALING KEY TO DISEASE PROGRESSION?

Keywords: Innate immunity, Targeted synthetic drugs, Inflammatory arthritides

R. L. Teixeira[1,2,3], C. Tomé[2], A. R. Faísca[2], V. C. Romão[1], J. E. Fonseca[1,2], I. Alcobia[3], R. A. Moura[2]. [1]*Centro Hospitalar Universitário de Lisboa Norte, Hospital de Santa Maria, Centro Académico de Medicina de Lisboa, Rheumatology Department, Lisboa, Portugal*; [2]*Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Rheumatology Research Unit, Lisboa, Portugal*; [3]*Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Instituto de Histologia e Biologia do Desenvolvimento, Lisboa, Portugal*

Background: Janus kinase inhibitors (JAKi) are a new therapeutic class approved for the treatment of chronic arthritis. JAKi suppress the activity of STAT tyrosine kinases, interfering with the signaling pathway which is critical for immune cell proliferation, survival and differentiation. Our group has demonstrated that early treatment with a JAKi, in animal models, abrogates disease and prevent bone damage. We hypothesize that JAK-STAT pathway is key to chronic arthritis onset and its early inhibition might have a major effect on disease control.

Objectives: The main goal of this study is to characterize the JAK-STAT signaling pathway activation in untreated early arthritis patients.
Methods: Peripheral blood mononuclear cells were isolated from blood samples collected from untreated early arthritis patients (<12 months of disease duration). Frequency, phenotype and STAT phosphorylation (by mean fluorescence intensity, MFI) levels were evaluated on T and B cells, monocytes and dendritic cells (DC) by flow cytometry. A group of age and sex-matched healthy individuals was included for comparison.
Results: The frequency of total CD19+ B cells was similar between patients and controls, although patients presented a significantly decreased level of pre-switch memory B cells when compared to controls. No significant differences were observed in naïve, post-switch memory, double negative B cells, transitional B cells and plasmablasts. The frequency of total CD3+ T cells, CD14+ monocytes and DCs was similar, however patients had significantly decreased levels of plasmacytoid DCs. In addition, we found that STAT3 phosphorylation levels were significantly increased in B cells and DCs in early arthritis patients. The STAT1, STAT5 and STAT6 phosphorylation levels were similar in T and B cells, monocytes and DCs, when compared with the control group.
Conclusion: Alterations in the frequencies of circulating memory B cell subsets and pDCs, but not in T cells and monocytes, are found in untreated early arthritis patients when compared to healthy controls. Changes in STAT3 phosphorylation MFI levels observed in B cells and DCs from early arthritis patients in comparison to controls support an early activation of JAK-STAT pathway in the initial phase of arthritis and a role of these cells in disease pathogenesis.

AB0079 THEAFLAVIN ALLEVIATES COLLAGEN-INDUCED ARTHRITIS IN MICE BY DECREASING REACTIVE OXYGEN SPECIES AND PRO-INFLAMMATORY CYTOKINES

Keywords: Rheumatoid arthritis

W. N. Huang[1,2,3,4], C. C. Lin[5,6,7,8]. [1]*National Chung Hsing University, College of Medicine, Taichung, Taiwan, Republic of China*; [2]*Ling-Tung University, Department of Business Administration, Taichung, Taiwan, Republic of China*; [3]*National Yang Ming Chiao Tung University, School of Medicine, Taipei, Taiwan, Republic of China*; [4]*Taichung Veterans General Hospital, Division of Allergy, Immunology and Rhematology, Taichung, Taiwan, Republic of China*; [5]*National Chung Hsing University, Institute of Biomedical Science, Taichung, Taiwan, Republic of China*; [6]*Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China*; [7]*National Chung Hsing University, Rong Hsing Research Center for Translational Medicine, Taichung, Taiwan, Republic of China*; [8]*National Chung Hsing University, Ph.D. Program in Translational Medicine, Taichung, Taiwan, Republic of China*

Background: An autoimmune disease that causes inflammation and bone and cartilage deterioration is rheumatoid arthritis (RA). In the pathogenesis of RA, oxidative stress and pro-inflammatory cytokines are important factors. The main polyphenol in black tea, theaflavins (TFs), has been used medically to treat a variety of inflammatory illnesses by reducing inflammation and reactive oxygen species (ROS)
Objectives: The medications available to treat RA have a variety of side effects. The current study was designed to assess the anti-arthritic properties of theaflavin in a mouse collagen-induced arthritis model.
Methods: In order to induce arthritis in DBA/1 mice, type II collagen was administered intradermally. From days 21 through days 42, different doses of theaflavin (50 and 100 mg/kg/day) were orally administered. To determine the effect of theaflavin on collagen-induced arthritis, histological analyses were conducted. In addition, the generation of reactive oxygen species (ROS), nitric oxide, and the activities of enzymatic antioxidants (superoxide dismutase, glutathione peroxidase, catalase, and glutathione reductase) in the joint homogenate of mice were examined. The levels of TNF-, IL-6, and IL-1β were also measured by ELISA to detect inflammation.
Results: Our results showed anti-oxidant and anti-inflammatory effects of theaflavin in arthritic mice. Histopathological studies corroborated the anti-arthritic properties of theaflavin. The compound was found to be effective in lowering ROS and nitric oxide levels while increasing enzymatic antioxidant levels. Theaflavin therapy also reduced TNF-, IL-6, and IL-1β levels.
Conclusion: In mice with arthritis, theaflavin was successful in reducing inflammation and oxidative stress. These results suggest that theaflavin may be used in conjunction with other treatments to manage RA.

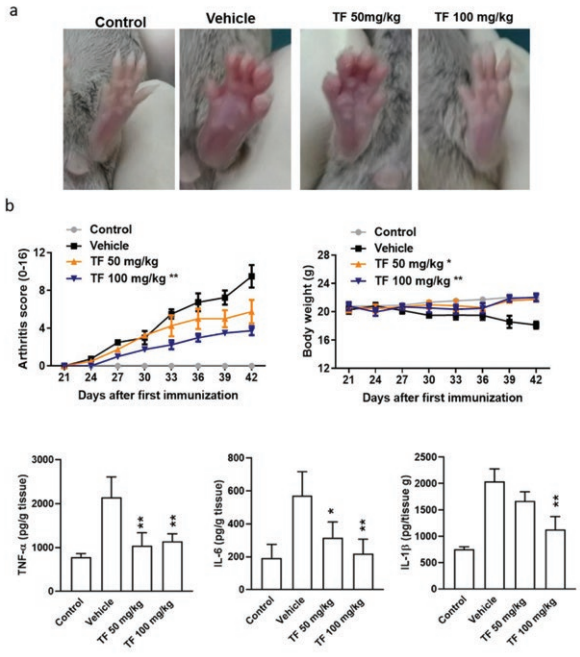

Figure 1. TF ameliorated the severity of arthritis in CIA mouse models. (a) Representative photographs depicted the swollen and reddened rear paws of four animal groups 42 days following the initial vaccination. (b) Accumulated clinical arthritis scores in each leg ranged from 0 to 4 and were evaluated every three days using a visual scoring system. The changes in body weight of normal control or CIA mice treated with or without TF or vehicle were recorded every three days till day 42. (c) TNF-, IL-6, and IL-1 inflammatory cytokine protein levels in arthritic mouse hind paw tissues. On day 42, CIA in DBA/1 mice hind paw homogenates were taken from the normal control, vehicle-treated, or TF-treated (50 or 100 mg/kg) groups of mice. The cytokine profiles were measured using ELISA according to the techniques given. ** $p < 0.01$ and * $p < 0.05$ showed statistically significant differences in two-way ANOVA compared with the vehicle-treated CIA group

AB0080 IMBALANCE OF MONOCYTE/MACROPHAGE POLARIZATION IN PERIPHERAL BLOOD AND SYNOVIAL FLUID OF RHEUMATOID ARTHRITIS PATIENTS

Keywords: Innate immunity, Rheumatoid arthritis

S. Soldano[1], E. Gotelli[1], P. Montagna[1], R. Campitiello[1], A. Sulli[1], V. Smith[2,3], M. Cutolo[1]. [1]*University of Genova, IRCCS Polyclinic San Martino Hospital, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, Genoa, Italy*; [2]*Ghent University Hospital, Department of Rheumatology, Ghent, Belgium*; [3]*Ghent University, Department of Internal Medicine, Ghent, Belgium*

Background: Macrophages strongly contribute to the pathogenesis of rheumatoid arthritis (RA), initiating the inflammatory response, the join damage, but also may promote the resolution of inflammation and the restoration of tissue immune-homeostasis [1,2]. This seems to be related to an unbalanced immunological response mediated by macrophages through their polarization into "classically" and "alternatively" activated phenotypes (M1 or M2) [3,4]. However, little is known about the M1 and M2 phenotype of their circulating precursors (monocytes) in the peripheral blood (PB) and the synovial fluid (SF) of RA patients.
Objectives: To characterise the polarization status (M1 and M2) of PB and SF monocytes of RA patients together with their distribution in the monocyte subsets by flow cytometry (FC).
Methods: Nineteen RA patients not yet treated with biological DMARDs (mean age 62±14 years), who fulfilled the 2010 ACR/EULAR classification criteria for RA and treated in accordance with EULAR recommendation, as well as 19 age-matched healthy subjects (HSs) were enrolled after signed informed consent.

PB and SF cells were collected from each RA patient, whereas only PB cells were collected from HSs. The expression of CD14 and CD16 surface markers allowed to identify the monocyte population and the monocyte subsets: "classical"(CD14++CD16-), "intermediate"(CD14++CD16+), and "non-classical"(CD14-CD16+). The M1 phenotype (M1 monocytes) was identified by the evaluation of CD80, CD86, TLR2 and TLR4, whereas the M2 phenotype (M2 monocytes) was identified evaluating CD204, CD163 and CD206 surface markers. Results were expressed as percentage of positive cells over total leukocytes from PB and SF. Statistical analysis was carried out by Mann-Whitney non-parametric test.

Results: In RA patients, the percentage of CD14++CD16+monocytes was significantly higher in PB compared to that in HS ($p<0.001$), and it was higher in SF compared to PB ($p<0.05$). The percentage of CD14-CD16+monocytes was significantly increased in RA-PB compared to HS-PB and RA-SF ($p<0.01$; $p<0.05$). RA patients were characterized by an increased percentage of M1 monocytes ($CD80^+CD86^+TLR2^+TLR4^+CD204^-CD163^-CD206^-$cells) in PB compared to HSs and compared to RA-SF. The percentage of M2 monocytes ($CD204^+CD163^+CD206^+CD80^-CD86^-TLR2^-TLR4^-$cells) was also increased in RA-PB compared to HS-PB and to RA-SF, but this increase was lower and not significant than that observed for M1 monocytes. Moreover, the M1-M2 monocyte ratio was 8:1in RA-PB. Therefore, in RA patients, circulating M1 monocytes belonged to the "non-classical" subset, whereas M2 monocytes belonged to the "classical" subset. The percentage of circulating mixed M1/M2 monocytes ($CD80^+CD86^+TLR2^+TLR4^+CD204^+CD163^+CD206^+$cells) was higher in RA patients compared to HSs. Moreover, in RA patients, the percentage of these cells was higher in SF than in PB and they primarily belonged to the "intermediate" monocyte subset. Interestingly, the highest percentage of M2 and mixed M1/M2 monocytes was observed in PB and SF of RA patients receiving a higher daily (25mg) and cumulative glucocorticoid dosages.

Conclusion: The results confirm that RA is an immune-inflammatory disease mainly mediated by both M1 monocytes and macrophages, as demonstrated by the increase in the percentage of circulating M1 monocytes. Glucocorticoids might contribute to the M1 to M2 transition, which characterizes RA patients under remission by increasing mixed M1/M2 and M2 monocyte percentage.

AB0081 GLUTATHIONE PEROXIDASE 3 IS A NOVEL CLINICAL DIAGNOSTIC BIOMARKER AND POTENTIAL THERAPEUTIC TARGET FOR NEUTROPHILS IN RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Rheumatoid arthritis

T. Chen[1], Y. Zhao[1,1]. [1]*West China Hospital, Department of Rheumatology and Immunology, Chengdu, China*

Background: Neutrophils have a critical role in the pathogenesis of rheumatoid arthritis (RA) with immune system dysfunction. However, the molecular mechanisms of this process mediated by neutrophils still remain elusive.

Objectives: The purpose of the present study is to identify hub genes in neutrophils for diagnosis and treatment of RA utilizing publicly available datasets.

Methods: Gene expression profiles were downloaded from the Gene Expression Omnibus and batch-corrected and normalized expression data were obtained using the ComBat package. Gene Ontology and Kyoto Encyclopedia of Genes and Genomes enrichment analysis were used to conduct significantly functional analysis and crucial pathways. The resulting co-expression genes modules and hub genes were generated based on the weighted gene co-expression network analysis and visualization by Cytoscape. Flow cytometry was conducted to detect reactive oxygen species (ROS) levels in neutrophils.

Results: Neutrophils underwent transcriptional changes in synovial fluid (SF) of RA patients, different from peripheral blood of healthy controls or patients with RA. Especially, glycolysis, HIF-1 signaling, NADH metabolism, and oxidative stress were affected. These hub genes were strongly linked with classical glycolysis-related genes (ENO1, GAPDH, and PKM) responsible for ROS production. The antioxidant enzyme glutathione peroxidase 3 (GPX3), a ROS scavenger, was first identified as a hub gene in RA neutrophils. Neutrophils from patients with autoimmune diseases had markedly enhanced ROS levels, most notably in RA SF.

Conclusion: This research recognized hub genes and explored the characteristics of neutrophils in RA. Our findings suggest that the novel hub gene GPX3 is involved in the neutrophil-driven oxidative stress-mediated pathogenesis of RA. It has the potency to be a target for neutrophil-directed RA therapy.

AB0082 AGE-RELATED GENES USP2 AND ARG2 ARE INVOLVED IN THE REDUCTION OF IMMUNE CELL INFILTRATION IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Rheumatoid arthritis, -omics

Q. Cheng[1], Y. Du[1], H. Wu[1]. [1]*The Second Affiliated Hospital of Zhejiang University School of Medicine, Rheumatology, Hangzhou, China*

Background: As the prevalence of rheumatoid arthritis (RA) in the elderly is increasing, rheumatologists are increasingly concerned about this group of patients. There is a large gap between the clinical manifestations and biological markers of elderly patients with RA (EPRA, age > 60) and younger patients with RA (YPRA, age ≤ 60), in part from the differences in the immune system in different age groups. The current understanding of EPRA remains insufficient.

Objectives: For better understanding of the mechanism of RA disease progression and subsequent treatment options, here we focused on the changes of immune cell infiltration in YPRA and EPRA.

Methods: R package "ssGSEA" and "GSEA" were used to identify the changes in immune cell infiltration and immune-related pathways. R package "WGCNA" and "DEseq2" were used to screening and verifying age-related differentially expressed genes (DEGs). Hub genes were identified by Cytoscape and cytoHubba. ROC (receiver operator characteristic) analysis was performed to determine the prediction and value of biomarkers. Spearman correlation analysis was conducted to evaluate the correlation between hub age-related genes and immune cells.

Results: In early RA patients (defined as within 12 months of onset of symptoms), there were no differences in the infiltration of 28 types of immune cells between younger and older patients. However, in established RA patients, several immune cells were markedly decreased in older patients, including activated B cells, immature B cells, natural killer cells, CD56dim natural killer cells, MDSCs, monocytes, effector memory CD8+T cells, regulatory T cells, type 1 T helper cells, type 17 T helper cells and T follicular helper cells. Moreover, 78 age-related DEGs related to amino acid and glycosphingolipid synthesis and metabolism were identified by WGCNA analysis and DEG screening. AGMAT, ARG2, OMG, USP2, IL4I1, and ISG15 were obtained by construction of molecular interaction regulatory networks. After verification by GEO validation set and our own RA synovial samples, only two genes, USP2 and ARG2, were still upregulated in EPRA after verification (Figure 1) and ARG2 and USP2 could effectively distinguish YPRA and EPRA and had potential as biomarkers.

Conclusion: In conclusion, this study is the first to systematically analyze changes in immune cell infiltration between younger and older RA patients and obtain hub age-related genes, which may provide the basis for illuminating the pathogenesis of RA and informing treatment strategies.

AB0083 CD14+CD90+ CELLS IN PERIVASCULAR AREAS OF RHEUMATOID ARTHRITIS SYNOVIAL TISSUES HAVE POTENTIAL TO DIFFERENTIATE INTO DENDRITIC CELLS

Keywords: Rheumatoid arthritis, Synovium

R. Kurose[1], T. Satoh[2], A. Kurose[3], Y. Ishibashi[1], Y. Wakai[4], T. Sasaki[4], K. Ishida[2], K. Ogasawara[2], T. Sawai[5]. *[1]Hirosaki University Graduate School of Medicine, Orthopaedic Surgery, Hirosaki, Japan*; *[2]Iwate Medical University School of Medicine, Pathology, Morioka, Japan*; *[3]Hirosaki University Graduate School of Medicine, Pathology, Hirosaki, Japan*; *[4]Hirosaki Memorial Hospital, Orthopaedic Surgery, Hirosaki, Japan*; *[5]Tohoku University, Pathology, Sendai, Japan*

Background: We have previously reported that CD14+ dendritic-shaped cells show a dendritic morphology under the electron microscopy and engage in a pseudoemperipolesis phenomenon with lymphocytes. CD14+ dendritic-shaped cells express CD90 in the perivascular areas of RA synovial tissues.
Objectives: To examine the differentiation potential of CD14+CD90+ cells into dendritic cells and their relationship to chronic inflammation in RA.
Methods: RA synovial tissues harvested at the time of joint surgeries were used after obtaining informed consent. The harvested tissues were cultured in vitro, and CD14+CD90+ cells were sorted using flow cytometry. Subsequently, the cells were divided into CD14+CD90+ and non-CD14+CD90+ cell groups and cultured in dendritic cell differentiation medium. The populations of cells expressing CD83 and HLA-DR were examined by flow cytometry to determine their differentiation potential into dendritic cells.
Results: At day 7 after dendritic cell differentiation culture, the group of CD14+CD90+ cells had a higher percentage of cells expressing CD83 and HLA-DR than the group of non-CD14+CD90+ cells.
Conclusion: CD14+ dendritic-shaped cells detected in RA synovial tissues are considered to be derived from CD14+CD90+ cells in the perivascular areas, which may be involved in RA inflammation as dendritic cells.

AB0084 EVALUATING THE IMPACT OF METFORMIN TARGETS ON THE RISK OF RHEUMATOID ARTHRITIS: A MENDELIAN RANDOMIZATION STUDY

Keywords: Rheumatoid arthritis

Q. Wang[1,2], Y. Gao[1,2], T. Yang[1,2], J. Qiao[1,2], S. X. Zhang[1,2], C. Wang[1,2], X. Li[1,2]. *[1]Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; *[2]Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taiyuan, China*

Background: Metformin is a first-line therapeutic agent for the treatment of type 2 diabetes, and despite its widespread long-term use in type 2 diabetes, the A variety of specific mechanisms of action of metformin are still being elucidated. Metformin is able to regulate cellular metabolism, proliferation, growth and autophagy, so it may have disease-modifying effects under a variety of other conditions. Metformin has been reported to improve a number of autoimmune diseases. Metformin has anti-inflammatory effects through a variety of mechanisms, including inhibition of tumour necrosis α (TNF-α)- induced synovial cell inflammation and angiogenesis[1]. Previously, observational studies have demonstrated the ability of metformin to ameliorate the pathogenesis of rheumatoid arthritis (RA). However, the causality from metformin related targets on the risk of RA remains unknown.
Objectives: The aim of this study was to assess the causal effect of metformin related targets (AMPK, MCI, MG3, GDF15 and GLP1/GCG) on the risk of RA using a two-sample Mendelian randomization (MR) study.
Methods: Genetic proxies for the effects of metformin drug targets were identified as variants in the gene for the corresponding target that associated with HbA1c level. we selected genetic variants within 1 megabase pairs downstream and upstream of the genes encoding the five targets, and low-linkage disequilibrium ($r^2 < 0.3$) variants associated with HbA1c at a nominal level of statistical significance ($p \leq 0.05$) in the Meta-Analyses of Glucose and Insulin-related traits Consortium (MAGIC) , restricted to people of European ancestry to minimise population stratification (n = 88355). Data on RA have been obtained from the NHGRI-EBI Catalog of human genome-wide association studies (14361 cases and 42923 healthy controls)[2]. Two-sample Mendelian randomization (MR) study was conducted to examine the association of metformin related targets and the risk of RA, including the inverse-variance weighted (IVW) method, MR-Egger, and Weighted median (WM), which was followed by sensitivity analyses. In addition, we also performed Cochran's Q test, MR pleiotropy residual sum and outlier (MR-PRESSO), leave-one-out sensitivity test to test for heterogeneity, horizontal multiplicity and stability of results.
Results: Genetically predicted 5 targets were not associated with RA with odds ratio (AMPK [OR=1.21, 95% CI=0.61, 2.39, p = 0.58], MCI [OR=1.16, 95% CI=0.92,1.48, p = 0.20], MG3[OR=1.76, 95% CI=0.49, 6.31, p = 0.14], GDF15 [OR=0.63, 95% CI=0.19, 2.05, p = 0.31], GLP1/GCG [OR=0.97, 95% CI=0.80, 1.16, p = 0.78])(Figure1). In addition, no apparent heterogeneity and no horizontal pleiotropy were observed in the sensitivity analysis.
Conclusion: Our study using MR herein indicated that the metformin related targets is not causally associated with the risk of RA. Future studies shall further systematically explore other potential pathways that metformin may affect to explore the association.

AB0085 CYTOKINE DRIVEN ECM PRODUCTION IS HIGHLY DEPENDENT ON DISEASE DRIVERS IN FIBROBLAST-LIKE SYNOVIOCYTES

Keywords: Biomarkers, Synovium, Cell biology

S. F. Madsen[1,2], D. Sinkeviciute[2], M. Karsdal[2], A. C. Bay-Jensen[2], C. Thudium[2]. *[1]University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark*; *[2]Nordic Bioscience, ImmunoScience, Herlev, Denmark*

Background: Fibrosis is a significant component in arthritis diseases that involves the joint. It can lead to joint swelling, stiffness and ultimately to pain. It is the synovial fibroblasts which secrete the extracellular matrix (ECM) components, and upon activation the production increases. The healthy synovial membrane consists of multiple ECM components, including type I, III and VI collagen[1]. The ECM composition of the fibrotic and fibro-inflamed membrane is unclear. We have previously shown that TGF-β increases the formation of type I, III and VI collagens in osteoarthritis (OA) fibroblasts-like synoviocytes (FLS)[2]. Both IL-1 and TNFα receptors have been found in the synovium of rheumatoid arthritis (RA) patients[1]. We hypothesize that both fibrosis and inflammation are likely to be present in arthritis diseases at the same time. And that the interplay between different disease drivers is crucial for the structural manifestation. Therefore, the combination of both growth factors and cytokines may be directing the composition of the synovial ECM in the joint.
Objectives: The objective of this study was to characterize the effect of inflammation on the fibrotic response of OA FLS using biomarkers of collagen formation.
Methods: Primary human FLS were isolated from synovial membranes, from OA patients undergoing total knee replacement (n=4) and cultured in the Scar-in-a-Jar model. Briefly, the fibroblasts were cultured in 0.4% fetal bovine serum DMEM, ficoll (to create a crowded environment) and ascorbic acid for 12 days. The fibroblasts were stimulated with TGF-β1 [1 nM], IL-1β [0.5 nM] or TNF-α [0.5 nM], either alone or in combination from day 0 and the treatments changed twice a week. Non-stimulated fibroblasts were used as control. Biomarkers of type I, III, and VI collagen formation (PRO-C1, PRO-C3 and PRO-C6, respectively), were measured in the culture supernatants at days 0, 4, 8 and 12 using validated ELISAs.
Results: Treatment with IL-1β or TNF-α alone did not affect PRO-C1, PRO-C3 or PRO-C6, compared control (Figure 1.A). TGF-β1 increased the total release of PRO-C1 and PRO-C6, compared to control ($p<0.001$, Figure 1.A). The total release of PRO-C3 did not increase, while at day 12 the PRO-C3 level was higher compared to control ($p<0.05$; data not shown). Both IL-1β and TNF-α in combination with TGF-β1 decreased PRO-C1 ($p<0.01$, Figure 1.A; decrease of 32-53%, Figure 1.B) and PRO-C6 compared to of TGF-β1 alone ($p<0.001$, Figure 1.A; decrease of 56-78%, Figure 1.B). TNF-α in combination with TGF-β1, increased the release of PRO-C3 ($p<0.01$, Figure 1.A; increase of 172-264%, Figure 1.B), while the combination with IL-1β did not seem to affect the PRO-C3 response compared to TGF-β1 alone (Figure 1.A; increase of 48% to decrease of 39%, Figure 1.B).
Conclusion: The combination of inflammatory cytokines and TGF-β1 leads to a differential effect on formation of ECM components such as type III collagen. These findings suggest that the presence of an inflammatory component, may be important for the development of a fibrotic component in joint diseases. Consequently, this also underlines the need for a better understanding of the molecular mechanisms driving the joints diseases.

AB0086 PLASMA EXPRESSION OF CAROTID PLAQUE PRESENCE-RELATED MIRNA-24, MIRNA-146 AND MIRNA-LET7A IS ASSOCIATED WITH INFLAMMATORY VARIABLES (DAS28 AND ESR) IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Cardiovascular disease, Rheumatoid arthritis

S. Paredes[1,2], D. Llop[2], D. Ibarretxe[2,3], D. Taverner[1], R. Rosales[2], N. Plana[2,3], L. Masana[2,3], J. C. Vallve[2]. *[1]Hospital Universitari Sant Joan, Rheumatolgy, Reus, Spain*; *[2]Universitat Rovira i Virgili., Medicine, Reus, Spain*; *[3]Hospital Universitari Sant Joan, Internal Medicine, Reus, Spain*

Background: Rheumatoid arthritis (RA) causes problems beyond the joints such as cardiovascular (CV) disease. It is estimated that the risk of developing CV disease in RA patients is approximately 50% higher than that in the general population[1]. The formation of atherosclerotic plaques is the main mechanism of the development of CV disease in RA patients[2]. The pathogenesis of atherosclerotic plaques is multifactorial and includes vascular, metabolic and inflammatory components[3]. In this regard, miRNA-24, 146 and Let7a have previously been associated with the presence of carotid plaques in RA patients[4].
Objectives: Given that there is a strong relationship between the chronic inflammatory state of RA and arteriosclerosis, we evaluated, individually and globally, whether miRNA-24, 146 and Let7a were involved in the inflammatory state of RA and could link inflammation and arteriosclerosis.
Methods: A total of 199 patients with RA were included. Inflammatory variables such as disease activity score 28 (DAS28) and erythrocyte sedimentation rate (ESR) were quantified. MicroRNAs were extracted from plasma and quantified with qPCR. Multivariate models were used for analysis. An expression score was created to evaluate all the miRNAs conjunctively.
Results: The multivariate models showed that miRNA-146 was significantly associated with DAS28 ($\beta = -0.15$), and miRNAs 24, 146 and Let7a were significantly associated with ESR ($\beta = -5.17$, $\beta = -5.29$ and $\beta = -6.47$, respectively) in the overall cohort. When miRNAs were evaluated globally, they were also significantly associated with DAS28 and ESR in the overall cohort ($\beta = 0.41$ and $\beta = 14.23$, respectively). Sex-stratified analyses also showed different associations of these miRNAs with the inflammatory variables (Table 1).
Conclusion: Plasmatic expressions of miRNA-24, 146 and Let7a were associated with inflammatory markers of RA. These miRNAs are associated with both

inflammation and atherosclerosis, which could link these processes, and are potential therapeutic targets for RA.

THE SYNOVIAL EXPRESSION OF PSTAT1-3-5 IN PATIENTS WITH KNEE TREATMENT-RESISTANT MONOARTHRITIS IN THE COURSE OF RHEUMATOID AND PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Synovium, Rheumatoid arthritis

C. Garufi[1], F. R. Spinelli[1], M. Leopizzi[2], V. DI Maio[2], V. Andreozzi[3], E. Monaco[3], F. Conti[1]. [1]*Sapienza University of Rome, Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Rheumatology Unit, Rome, Italy*; [2]*Sapienza University of Rome, Dipartimento di scienze e biotecnologie medico-chirurgiche, Rome, Italy*; [3]*Sapienza University of Rome, Dipartimento di Ortopedia, Rome, Italy*

Background: Rheumatoid and Psoriatic Arthritis are both chronic inflammatory diseases of the joints characterized by synovial proliferation [1]. The JAK/STAT signalling pathway is critical in the pathogenesis of both diseases, and among them STAT3 is activated by numerous cytokines, growth factors, and interferons [1]. Hypoxia is also an important stimulus for STAT3 activation and the consequent production and accumulation of HIF-1α, leading to neovascularization [2].

Objectives: The aim of the present study was to analyse the phosphorylation pattern of pSTAT1, pSTAT3 and pSTAT5 and the inflammatory score of synovial tissue from RA and PsA patients with knee treatment resistant monoarthritis.

Methods: The diagnosis of RA and PsA was based on the 2010 American College of Rheumatology/European League Against Rheumatism [3] and Classification Criteria for Psoriatic Arthritis [4], respectively. All patients presented knee treatment-resistant monoarthritis and underwent In Office Needle Arthroscopy (IONA) of the knee with a maximum of 3 samples of synovial tissue taken during each procedure. Synovial tissue specimens were examined histologically using the Krenn scoring system [5]; immunohistochemistry (IHC) was used to assess the phosphorylation of STAT1, STAT3 and STAT5 and the expression of activated STATs was assessed semi-quantitatively with a score ranging from 0 to 3.

Results: The present study evaluated 12 patients with RA (n = 6) or PsA (n = 6). Patients demographic and clinical characteristics are reported in Table 1. According to the pathologic analysis, Krenn median score was 2 (IQR 4). Seven patients showed a synovitis score≤3, the other 5 cases showed a median Krenn score of 6. The IHC analysis did not demonstrate a clear association between the synovitis score and pSTAT expression. The phosphorylated form of STAT1 showed a weak expression in all samples. Conversely, pSTAT3 showed a more intense expression in synovial fibroblasts in those samples with higher synovitis score; moreover, pSTAT3 was expressed in endothelial cells in those patients presenting higher cellularity and stronger stromal infiltration. Finally, pSTAT5 was scarcely expressed in the synovial tissue from RA and PsA patients.

Conclusion: Inflammatory synovial infiltration in course of RA and PsA is associated with the production of VEGF and endothelial proliferation. The phosphorylation of STAT3 – which is associated to the signalling of IL-6 and other gp130 ligands as well as other pro-inflammatory cytokines - could be a marker of hypercellularity and hypoxic metabolism in the synovial tissue, in the context of treatment-resistant monoarthritis.

Spondyloarthritis - aetiology, pathogenesis and animal models

AB0088 GENETICALLY DETERMINED GUT MICROBIOME AND THE RISK OF ANKYLOSING SPONDYLOARTHRITIS

Keywords: Genetics/Epigenetics, Bone diseases

Q. Wang[1,2], J. Hu[1,2], K. Fan[1,2], Q. Yu[3], P. F. He[3], X. Li[1,2,4], S. X. Zhang[1,2,4]. *[1]Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China; [2]Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China; [3]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China; [4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: Ankylosing spondyloarthritis (AS) is a common chronic inflammatory autoimmune disease affecting the sacroiliac joint and spine, with or without systemic symptoms such as peripheral arthritis[1]. The etiology of AS is still unclear, which is affected by genetic risk factors and the environment, especially microorganisms. In addition, growing evidence suggests that the influence of the microbiota extends beyond the gut and affects the systemic immune system[2]. The observational association between the gut microbiome and AS has been well documented. However, the causal relationship between the gut microbiome and AS has yet to be well studied.

Objectives: This study aimed to evaluate the causal relationship between the gut microbiome and AS using a two-sample Mendelian randomization (MR) study.

Methods: Gut microbiome genome-wide association study (GWAS) data were extracted by the MR-base platform. Data on AS have been obtained from genome-wide association data collected by the UK Biobank (968 cases and 336,191 healthy controls). First, we identified SNPs associated with the gut microbiome by genome-wide significance level ($p < 1 \times 10^{-5}$), and Removal of linkage disequilibrium (LD) by conducting a clumping process (R^2<0.001, window size=10,000 kb). Then, a two-sample MR study was conducted to examine the association of gut microbiome and AS, including the inverse-variance weighted (IVW) method, MR-Egger, and Weighted median (WM). In addition, we also performed Cochran's Q test, MR pleiotropy residual sum and outlier (MR-PRESSO), and leave-one-out sensitivity test to test for heterogeneity, horizontal multiplicity, and stability of results.

Results: *Ruminococcaceae* was positively associated with the risk of AS(OR=0.998, 95%CI =0.997, 0.999, p =0.037). *Butyricicoccus*(OR=1.001, 95%CI =1.000, 1.003, p = 0.042, *Coprococcus3*(OR=1.001, 95%CI =1.000, 1.003, P = 0.042), and *Defluviitaleaceae* (OR=1.001, 95%CI =1.000, 1.002, p = 0.004 were negatively correlated with the risk of AS. (Figure 1) In addition, no apparent heterogeneity or horizontal pleiotropy were observed in the sensitivity analysis.

Conclusion: This study supports a causal relationship between gut microbial composition and risk for AS, thus providing novel insights into the gut microbiota-mediated development mechanism of AS.

AB0089 MENDELIAN RANDOMIZATION REVEALS CAUSATIVE GUT BACTERIA FOR ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis

S. Chen[1], X. Wu[1], Z. Chen[1], M. Xiao[1], J. Wu[1], J. Gu[1]. *[1]The Third affiliated Hospital of Sun Yat-sen University, Rheumatology and Immunology, Guangzhou, China*

Background: Genetic, clinical and experimental evidence has mounted to suggest the implication of gut dysbiosis in the pathogenesis of ankylosing spondylitis (AS) through the gut-joint axis of inflammation[1]. A series of cross-sectional studies have unraveled the alterations of gut microbiome composition in patients with AS using metagenome sequencing. However, such observational associations might be limited to the small sample sizes and the influences from confounders. Furthermore, whether gut dysbiosis is a cause or a consequence of AS remains elusive. Mendelian randomization (MR) is an epidemiologic approach for causal inference using genetic variants as instrument variables.

Objectives: To assess the causal relationship between gut bacteria taxa and risk of AS using two-sample MR.

Methods: To select instrument variables for gut bacteria taxa, we filtered genome-wide significant (p ≤ 5 x 10-8) and independent (r 2 < 0.01 within the window size of 500kb) variants for 211 taxa from a large-scale genome-wide association study (GWAS) on gut microbiota which included 18,340 individuals from 24 cohorts[2]. The summary statistics on AS from the UK Biobank (UKB) and the FinnGen consortium were utilized for the discovery and replication analyses, respectively[3]. Under the framework of two-sample MR, the inverse variance weighted method or the Wald ratio method was used to assess the causal effect of gut microbial taxa on risk of AS. In addition, multiple sensitivity analyses and reverse MR analyses were conducted to validate the robustness of results and evaluate reverse causation, respectively.

Results: Despite no taxa passing the multiple-testing correction, six known taxa were identified to have causal effects on the onset of AS in the UKB cohort at the nominal significance level ($p < 0.05$). In the FinnGen cohort, only one bacterial genus, *Anaerotruncus* was replicated (UKB: β_{IVW} = -0.0016, p = 0.04; FinnGen: β_{IVW} = -0.3990, p = 0.04). Sensitivity analyses led no support to the presence of heterogeneity ($Q_p > 0.05$) and pleiotropy (Intercept_$p > 0.05$). Reverse MR analysis found no reverse causality from AS to *Anaerotruncus*.

Conclusion: Despite no current evidence supporting the association between *Anaerotruncus* and AS, this study provides the first genetic evidence for the protective effect of this short-chain fatty acid (SCFA)-producer against AS. Intriguingly, several studies have suggested a relationship between *Anaerotruncus* and immune-mediated diseases including rheumatoid arthritis and inflammatory bowel diseases[4]. These MR findings shed light on the causative microbiota and microbiome-modulating strategies for AS.

AB0090 IN VITRO EFFECTS OF METHOTREXATE, ANTI-PDE-4, AND ANTI-JAK TREATMENTS ON HEPATOCYTES STIMULATED BY PSORIATIC ARTHRITIS SERUM

Keywords: Biomarkers, Psoriatic arthritis

I. Arias de la Rosa[1], L. Cuesta López[2], M. Ruiz-Ponce[1], M. D. López Montilla[1], C. López-Medina[2], C. Perez-Sanchez[3], M. D. Gahete[3], N. Herman-Sanchez[3], C. Lopez-Pedrera[1], A. Escudero Contreras[1], E. Collantes Estevez[2], N. Barbarroja Puerto[2]. *[1]IMIBIC/Reina Sofia Hospital/University of Cordoba, Rheumatology Service, Cordoba, Spain*; *[2]IMIBIC/University of Cordoba/Reina Sofia Hospital, Medical and Surgical Sciences, Cordoba, Spain*; *[3]IMIBIC/University of Cordoba/Reina Sofia Hospital, Cell Biology, Physiology and Immunology, Cordoba, Spain*

Background: In recent years, the increased prevalence of liver abnormalities in Psoriatic Arthritis (PsA) has acquired relevance. The liver dysfunction in PsA might be induced by inflammatory components in parallel with the presence of metabolic complications or due to the potential hepatotoxicity of the treatments administered.
Objectives: 1) to analyze the impact of PsA serum on hepatocytes and 2) to investigate the effect of methotrexate, anti-PDE-4, and tofacitinib on hepatocytes treated with PsA serum.
Methods: serum from 12 healthy donors (HDs) and 20 age and sex-matched PsA patients were collected to perform *in vitro* experiments with the hepatocyte cell line (HEPG2). Cells were treated with HDs serum or PsA serum alone or combined with methotrexate (50μM), roflumilast (1nM), or tofacitinib (250nM) for 24 hours. The expression of genes related to inflammation, immune response, apoptosis, and liver dysfunction was analyzed by RT-PCR. Cell stress protein array was performed. The levels of 92 inflammatory proteins were determined on the treated hepatocytes using PEA technology (Olink Target 96 Inflammation panel, Cobiomic Biosciences). STRING platform (version 11.5) was used to determine the functional protein association networks.
Results: PsA patients showed a mean disease activity in PsA (DAPSA) of 27.10 ±12.52 (moderate-high disease activity) and significantly elevated levels of c-reactive protein and erythrocyte sedimentation rate with respect to HDs. In hepatocytes, the treatment with PsA serum induced the mRNA expression of ADAM-17, CHUK, CTSD, FAF-1, GDF-15, IFGR-1, IL-6, IL-8, MMP-1, STAT-3, TGF-β and TFPI compared to HDs serum, genes directly associated with biological processes which might impact liver function, such as inflammatory response, immune system, apoptotic process and even directly associated with non-alcoholic fatty liver disease. In addition, PsA serum promoted the expression of 22 proteins mainly involved in cell stress in hepatocytes compared to HDs serum treatment. These proteins are also associated with lipids and atherosclerosis, apoptosis, regulation of inflammatory response, hepatic diseases, and regulation of the extracellular matrix. Surprisingly, 33 out of 92 inflammatory-related proteins were significantly increased in hepatocytes treated with PsA serum compared to HDs serum (36% of proteins). On the other hand, the treatment with anti-PDE-4 promoted the reduction of 11 out of 33 proteins altered by the treatment with PsA serum, proteins mainly involved in leukocyte migration and the immune system. The treatment with anti-JAK reduced levels of 20 out of 33 proteins altered by the treatment with PsA serum. However, the treatment with methotrexate significantly increased the expression of 5 out of 33 proteins altered by the treatment with PsA serum.
Conclusion: 1) PsA serum characterized by the presence of inflammatory components profoundly impacts the hepatocyte function promoting the alteration in proteins and genes involved in the inflammatory response, immune system, and the apoptotic and fibrotic process; 2) the treatment with anti-PDE-4 or anti-JAK is able to partially reverse the deleterious inflammatory effect of PsA serum produced in the hepatocytes. AB0091 IMPACT OF COMORBIDITY BURDEN AS SCORED USING THE RHEUMATIC DISEASE COMORBIDITY INDEX (RDCI) ON RESPONSE TO TREATMENT WITH THE FIRST BDMARD AMONG PSORIATIC ARTHRITIS PATIENTS

Keywords: Comorbidities, bDMARD, Psoriatic arthritis

R. Nicolau[1,2], A. Martins[2,3], D. Santos Oliveira[2,3,4], M. Bernardes[2,3], L. Costa[3]. *[1]Centro Hospitalar Tondela Viseu, Rheumatology Unit, Viseu, Portugal*; *[2]Faculty of Medicine, University of Porto, Medicine, PORTO, Portugal*; *[3]São João Universitary Hospital Center, Rheumatology, PORTO, Portugal*; *[4]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), PORTO, Portugal*

Background: In addition to the impact of Psoriatic Arthritis (PsA) on risk of death and increased morbidity, other factors, such as comorbidity burden (CB), have also an important role[1]. Identifying comorbidities and estimating their impact on the disease course are critical to safely and effectively treating a patient with PsA, as these comorbidities have often implications on therapy selection.
Objectives: To measure the impact of CB on PsA patients treated with a first-line Biologic Disease Modifying AntiRheumatic Drug (bDMARD) using the Rheumatic Disease Comorbidity Index (RDCI).
Methods: Retrospective observational cohort-study of patients with diagnosis of PsA, fulfilling the CASPAR criteria and treated with a first bDMARD, using data from the Reuma.pt database. Patients were divided in 2 groups according the RDCI (RDCI=0 and RDCI≥1) for evaluating its role in clinical response and disease activity at baseline and follow up (6 and 12 months). An univariate analysis was performed followed by a multivariate analysis.
Results: A total of 115 patients were included. 53% (n=61) were females, mean age was 47(±10.7) years old and the median disease duration 10.5 years [1.4-44.1]. At baseline, most of patients exhibited a very high or high disease activity (median DAS284V 4.44, ASDAS-CRP 3.98, BASDAI 6.69) and 68% were concomitantly treated with other DMARD and/or corticosteroids. 43% of patients had at least one comorbidity and the median RDCI score was 1.1 [0.0-6.0]. The most frequently reported comorbidities were cardiovascular disorders (37.7%), depression (13.2%) and pulmonary disease (6.1%). When comparing baseline demographic and clinical characteristics of the 2 subgroups, stratified according RDCI score, we found statistically significant differences in age, age at diagnosis, disease duration, BMI and smoking status. RDCI was poorly correlated with CRP (r=0.162, p<0.01), DAS284V (r=0.263, p=0.008), ASDAS CRP (r=0.284, p<0.001) at 12 months. We also found moderate correlations in RDCI with BASFI (r=0.370, p<0.001) and HAQ-DI (r=0.351, p<0.01). Patients with higher RDCI had lower chance to obtain low disease activity (OR 0.69 (95%CI, 0.61–0.79); $p < 0.001$). EULAR response rate at 12 months was lower in PsA patients with comorbidities (69.7%vs90.5%, p=0.02).
Conclusion: To conclude, our study demonstrates that baseline CB is an independent predictor for insufficient 12 months response to the first bDMARD. This confirmed the hypothesis that comorbidity should be treated to improve the long-term prognosis in PsA patients.

ANTIBODIES OF THE IMMUNOGLOBULIN G AND A ISOTYPE TO NOVEL PEPTIDES IN EARLY AXIAL SPONDYLOARTHRITIS PATIENTS

Keywords: Biomarkers, Spondyloarthritis, Autoantibodies

P. Ruytinx[1], P. Vandormael[1], D. Quaden[1], E. Luyten[1], P. Geusens[2,3], J. Vanhoof[2], A. Agten[4], F. Vandenabeele[4], K. De Vlam[5,6], V. Somers[1]. *[1]UHasselt, Biomedical Research Institute, Department of Immunology and Infection, Diepenbeek, Belgium*; *[2]Department of Rheumatology, ReumaClinic, Genk, Belgium*; *[3]University Maastricht, Department of Rheumatology, Maastricht, Netherlands*; *[4]UHasselt, Faculty of Rehabilitation Sciences, REVAL - Rehabilitation Research Center, Diepenbeek, Belgium*; *[5]University Hospitals Leuven, Department of Rheumatology, Leuven, Belgium*; *[6]KULeuven, Skeletal Biology and Engineering Research Center (SBE), Dept Development and Regeneration, Leuven, Belgium*

Background: There is an unmet need for biomarkers to identify patients with axial spondyloarthritis (axSpA), as clinical manifestations often overlap with other disorders. Previously, we identified immunoglobulin G (IgG) antibodies to 3 Hasselt University (UH)-axSpA peptides which could provide a novel tool for diagnosis of a subset of axSpA patients [1].
Objectives: The aim of this study was to identify novel IgA antibodies in early axSpA patients and to determine their diagnostic potential in combination with previously determined IgG antibodies against UH-axSpA-IgG antigens.
Methods: An axSpA cDNA phage display library constructed from axSpA hip synovium, was used to screen for novel IgA antibodies in plasma from early axSpA patients. The diagnostic value of these antibodies against novel UH-axSpA-IgA and previously identified UH-axSpA-IgG antigens was determined in two independent axSpA cohorts [UH cohort and the Leuven spondyloarthritis biologics cohort (BIOSPAR)], in healthy controls and in patients with chronic low back pain (CLBP) using ELISA.
Results: We identified antibodies to 7 novel UH-axSpA-IgA antigens, of which 6 correspond to non-physiological peptides and 1 to the human histone deacetylase 3 (HDAC3) protein. IgA antibodies against 2 of these 7 novel UH-axSpA-IgA antigens and IgG antibodies against 2 of 3 the previously identified antigens were significantly more present in axSpA patients from the UH cohort (18/70, 25.7%) and the (Bio)SPAR cohort (26/164, 15.9%), compared to controls with CLBP (2/66, 3%). Antibodies to this panel of 4 antigens were present in 21.1 % (30/142) of patients with early axSpA from the UH and (Bio)SPAR cohorts. The positive likelihood ratio for confirming early axSpA using antibodies to these 4 UH-axSpA antigens was 7.0. So far, no clinical correlation between the novel identified IgA antibodies and inflammatory bowel disease could be identified.
Conclusion: Screening an axSpA cDNA phage display library for IgA reactivity resulted in the identification of 7 novel UH-axSpA-IgA antigens, of which 2 show promising biomarker potential for the diagnosis of a subset of axSpA patients, in combination with previously identified UH-axSpA-IgG antigens.

COMPLEMENT IN THE DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS (AXSPA). INVESTIGATIONS IN A CROSS-SECTIONAL COHORT (OPTIREF) OF PATIENTS SUSPECTED OF AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Innate immunity

C. E. Mistegaard[1,2,3], A. Troldborg[1,2,3], A. G. Loft[1,3], S. Thiel[2], L. Spiller[4], V. Rios Rodriguez[4], B. Muche[4], J. Rademacher[4], A. K. Weber[4], S. Lueders[4], J. Sieper[4], D. Poddubnyy[4], F. Proft[4]. *[1]Aarhus Universitetshospital, Department of Rheumatology, Aarhus, Denmark*; *[2]Aarhus University, Department of Biomedicin, Aarhus, Denmark*; *[3]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark*; *[4]Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany*

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease without specific diagnostic biomarkers. However, recent evidence suggests an involvement of the innate immune system in the pathogenesis of axSpA [1]. The lectin pathway of complement activation serves essential functions in the innate immune system, regulates homeostasis and development. We have previously shown the lectin pathway proteins (LPPs) L-ficolin and M-ficolin to be elevated in axSpA-patients compared with clinically relevant controls with unspecific low back pain (uLBP).
Objectives: To investigate the diagnostic potential of LPP levels in patients recruited from a well-defined cross-sectional prospective cohort (OptiRef), including newly diagnosed axSpA-patients and uLBP-patients.
Methods: Serum samples were obtained from 515 individuals from the OptiRef cohort; 151 newly diagnosed axSpA-patients and 364 uLBP-patients [2]. All patients were assessed according to a standardized protocol, incl. clinical information as demographics, SpA features, symptom duration, and disease activity. Routine lab tests (HLA-B27 and CRP) were performed. Imaging (x-ray and MRI) was performed if deemed clinically relevant. Serum levels of all 10 LPPs (MBL, CL-L1, M-ficolin, H-ficolin, L-ficolin, MASP-1, MASP-2, MASP-3, MAp19, and MAp44) and the complement activation product C3dg were measured by immunoassays.
Results: Patient characteristics are shown in Table 1. L-ficolin, MASP-2, and C3dg serum levels were increased in axSpA-patients compared with uLBP-patients, whereas CL-L1 and MASP-3 serum levels were decreased (Figure 1). After adjustments for CRP, C3dg serum levels remained significantly increased in axSpA-patients, whereas M-ficolin and MASP-3 serum levels were decreased in axSpA-patients. The diagnostic potential of combining either L-ficolin, MASP-3, and C3dg with HLA-B27 increased specificity to 93-95% compared with HLA-B27 alone (77%) but decreased sensitivity to 29-33% compared with HLA-B27 alone (83%). In a univariate logistic regression analysis, CL-L1, MASP-2, MASP-3, and C3dg were associated with an axSpA-diagnosis, and C3dg and MASP-3 remained significant in a multivariate logistic regression analysis.
Conclusion: In this study, serum levels of C3dg, MASP-3, and CL-L1 differed significantly between axSpA-patients and uLBP-patients after adjustment for CRP. Although combining HLA-B27 with measurements of L-ficolin, MASP-3, and C3dg increased diagnostic specificity for axSpA, it seems unjustified due to the concomitant loss of sensitivity. However, both C3dg and MASP-3 were associated with the axSpA-diagnosis in multivariate logistic regression, indicating the complement system's involvement in axSpA-pathogenesis. This should be further investigated.

Background: Liver abnormalities, particularly non-alcoholic fatty liver disease (NAFLD) are strongly associated with psoriatic arthritis (PsA). In the last decades, the possible hepatotoxic effects of methotrexate in PsA have been studied, however, up to date, the results are controversial.
Objectives: 1) to evaluate the liver damage risk in PsA patients and its relationship with clinical features of the disease; 2) to determine the influence of cumulative doses of methotrexate by *in vivo* and *in vitro* approaches.
Methods: a cross-sectional study was performed on 326 subjects: 155 PsA patients, 87 NAFLD non-PsA patients, and 84 healthy donors (HDs). Clinical and laboratory parameters, liver disease biomarkers, and several indexes to evaluate the risk of suffering hepatic steatosis or fibrosis were evaluated. Cumulative doses of methotrexate were calculated retrospectively. Mechanistic studies were carried out on hepatocytes (HEPG2 cell line) treated with cumulative doses of methotrexate for up to 72 hours and 150μM. The changes in the levels of 92 inflammatory proteins on the hepatocytes were analyzed using PEA technology (Olink Target 96 Inflammation panel, Cobiomic Biosciences).
Results: using a NAFLD non-PsA BMI, age and sex-matched cohort, a cut-off value of hepatic steatosis index (HSI) (35.68; AUC=0.865 $p<0.0001$) was calculated to distinguish NAFLD patients from HDs. Taking this value into account, PsA patients showed a significantly high risk of suffering NAFLD *vs* HDs, 65% respect to 22%. In addition, PsA patients with a high risk for steatosis displayed a significant prevalence of insulin resistance, obesity, type 2 diabetes mellitus, and arterial hypertension compared to PsA patients without that risk. Interestingly, these PsA patients also showed significantly elevated levels of triglycerides, complement component 3, DAPSA, c-reactive protein, and erythrocyte sedimentation rate. Next, PsA patients were divided into two groups depending on mean cumulative doses of methotrexate (<1.5 gr for no hepatotoxic risk group and >1.5 gr for the hepatotoxic risk group). Patients with more than 1.5gr of methotrexate cumulative dose showed significantly lower levels of acute phase reactants and no significant differences in metabolic profile or liver disease biomarkers. However, fibrosis-4 score (FIB-4) was significantly elevated in the group of hepatotoxic risk and positively correlated with cumulative doses. Although, this association was influenced by the age variable and not due to the levels of transaminases or platelets. On the other hand, *in vitro* treatment of hepatocytes with methotrexate for 24 h induced the expression of 19 inflammatory proteins out of 92. These changes were not significantly altered after 72 hours of treatment with methotrexate added each 24h.
Conclusion: 1) PsA patients with a high risk of liver disease show elevated rates of cardiometabolic comorbidities, inflammatory clinical markers and disease activity suggesting the link between metabolic alterations and the clinical features of PsA with the development of NAFLD, 2) PsA patients with high cumulative doses of methotrexate had no alteration of hepatic enzymes and indexes and 3) High cumulative doses of methotrexate *in vitro* did not show a significant impact on hepatocyte cells compared to low doses. Blanco[5]. *[1]Hospital General Universitario Gregorio Marañon, Rheumatology Department, Madrid, Spain*; *[2]Complexo Hospitalario Universitario de A Coruña, Department of Rheumatology, A Coruña, Spain*; *[3]Complexo Hospitalario Universitario de A Coruña, INIBIC, A Coruña, Spain*; *[4]Complexo Hospitalario Universitario de A Coruña, Universidade de A Coruña, Department of Rheumatology, A Coruña, Spain*; *[5]Complexo Hospitalario Universitario de A Coruña, Universidade de A Coruña, Department of Rheumatology-INIBIC, A Coruña, Spain*

Background: PsA diagnosis and treatment delayed is commonly leading to progressive articular damage, and research has aimed to improve PsA diagnosis and prognosis by identifying novel disease biomarkers.
Objectives: The present research aimed to analyze cytokines regarding inflammation and bone destruction/regeneration in patients with psoriatic arthritis (PsA), rheumatoid arthritis (RA), osteoarthritis (OA), and ankylosing spondylitis (AS) as possible biomarkers.
Methods: The patients underwent knee arthroscopy between 2009 and 2013 because they clinically presented with knee joint swelling and tenderness that did not improve with the medical treatment indicated for their diagnosed disease. So, samples were obtained from the swollen knee of patients who had been referred for undergoing arthroscopies and the synovial membrane was processed for pathological description, and protein IHC quantification (% Expressed in Ratio_Area-Intensity) for TGF-β1, IL-23, IL-6, IL-17A, IL-22, Dkk1, Sclerostin, BMP2, BMP4, Wnt1, and Wnt5a was done. All these data were analyzed and compared with the demographic, clinical, analytical, and radiological characteristics of the patients, and their predictive abilities using receiver operating characteristic (ROC) curves.
Results: Synovial membrane samples were obtained from 44 patients (PsA n=13, RA n=9, OA n=18, AS=4) for IHC quantification analysis. At baseline, 9 patients were being treated with csDMARDs, and no one of them was previosly treated with biologics. After 5 years, 4 of 13 with PsA and 2 of 9 the RA patients were treated with biologics. In general, early IHC reactivity for TGF-β1 in the synovial tissue was higher in patients with psoriatic arthritis (p=0.024) and was positively correlated with IL-17A (r = 0.355, p = 0.024), and Dkk1 (r = 0.444, p = 0.004). Early IHC reactivity for TGF-β1 in the synovial tissue was higher in PsA patients treated after with biologics (p = 0.015). Patients with PsA and RA treated with biologics had higher IHC reactivity for IL-17A in the synovial tissue (p = 0.004), for Dkk1 (p = 0.02), and for BMP2 (p = 0.045). There were no differences found regarding gender (p = 0.944), age (p = 0.947), or the Kellgren-Lawrence scale in the knee target (p = 0.608) for TGF-β1 but IL-17A IHC expression was higher in men (p = 0.02). In the logistic regression analysis, these differences seem to be independent of age, gender, or csDMARD use at the basal moment, for TGF-β1 (p=0.014), IL-17A (p=0.009), and Dkk1 (p=0.015). ROC curve analysis of IHC reactivity for TGF-β1 and IL-17A in the synovial seems to predict future treatment with biologics in the next 10 years with the areas under the curve (AUC) of 0.835 (95% CI: 0.695-0.976; p < 0.006), and 0.853 (95% CI: 0.725-0.980; p < 0.004), respectively.

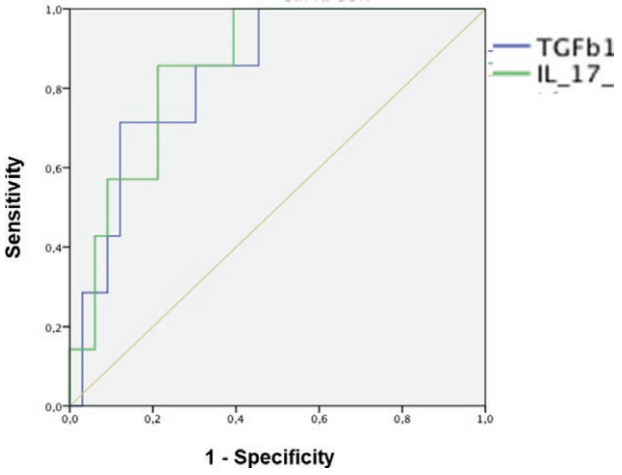

Figure 1.

Conclusion: It was observed that IHC reactivity for TGF-β1 and IL17A was higher in patients who needed biologics after 5 years of following. Early increased synovial immunohistochemistry reactivity of IL17A and TGF-β1 in psoriatic arthritis and rheumatoid arthritis patients could predict the need to use biologics.

AB0096 INVESTIGATION OF THE EFFECTS OF KYNURENIC ACID ANALOG IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS

Keywords: Spondyloarthritis, Cytokines and chemokines

B. Varga[1], F. Fülöp[2], G. Toldi[3], L. Vécsei[4], Y. Mándi[5], A. Balog[1]. [1]*University of Szeged, Department of Rheumatology and Immunology, Szeged, Hungary*; [2]*University of Szeged, Institute of Pharmaceutical Chemistry and Research Group for Stereochemistry, Szeged, Hungary*; [3]*Semmelweis University, Department of Laboratory Medicine, Budapest, Hungary*; [4]*University of Szeged, Department of Neurology, Szeged, Hungary*; [5]*University of Szeged, Department of Medical Microbiology and Immunobiology, Szeged, Hungary*

Background: The anti-inflammatory and immunosuppressive functions of kynurenic acid (KYNA) is in the center of attention. Previously, we demonstrated the effects of KYNA analog on the blood samples of rheumatoid arthritis patients *in vitro*. The results showed the suppression of tumor necrosis factor-α (TNF-α), S100A12 (EN-RAGE), S100A8/9 (calprotectin) and α-defensin production, with the increase of tumor necrosis factor-stimulated gene-6 protein (TSG-6) levels.
Objectives: In the present study, we compared the effects of the previously used newly synthetized KYNA analog on the TNF-α, S100A8/9, S100A12 alarmins, α-defensin and interleukin-17 (IL-17) production, correlation with the effects on the TSG-6 expression in ankylosing spondylitis (AS) and psoriatic arthritis (PsA).
Methods: 38 PsA and 54 AS patients were involved and divided in subgroups based on disease activity. Heat inactivated *Staphylococcus aureus* (SA1) were used as cytokine inducers on peripheral blood mononuclear cells (PBMC) isolated from blood samples of healthy controls, and patients. In parallel *in vitro* experiments, the SA1 induced PBMCs were pretreated with the KYNA analog. The concentrations of the above mentioned inflammatory mediators in the supernatants were quantified by ELISA.
Results: The SA1 induced the TNF-α, TSG-6, calprotectin and α-defensin production while only a modest increase could be seen in the concentration of EN-RAGE, and had no effect on the IL-17 levels. KYNA analog attenuated the SA1 induced TNF-α, calprotectin and α-defensin production, and increased the TSG-6 production. Addition of KYNA analog had no effect on the EN-RAGE and IL-17-levels. The cytokine inducer effect of SA-1 was the mildest in the blood samples of patients with csDMARD or NSAID therapy. The TNF-α inhibitory effect of the KYNA analog correlated inversely with the TSG-6 stimulatory effect.
Conclusion: TSG-6 expression could participate in the suppression of inflammatory cytokines, such as TNF-α, calprotectin and α-defensin in spondylarthropathies. The elevation of the TSG-6 production by KYNA analog is a possible mechanism behind the antiinflammatory effect of KYNA, marking it a potential target for therapeutic application in the treatment of immune mediated diseases such as AS, PsA or RA.

AB0097 DISSOCIATION OF SERUM IL-23 AND IL-17 LEVELS IN PATIENTS WITH SPONDYLOARTHRITIS ACCORDING TO RADIOGRAPHIC STAGE

Keywords: Spondyloarthritis, Cytokines and chemokines

J. Yeo[1], H. Y. Lee[1], M. R. Seo[1], H. J. Choi[1], H. J. Baek[1]. [1]*Gachon University Gil Medical Center, Department of Internal Medicine, Division of Rheumatology, Incheon, Korea, Rep. of (South Korea)*

Background: Spondyloarthritis (SpA) is a chronic inflammatory disease with a pathogenesis which has not been fully understood. In recent years, interleukin (IL)-23/IL-17 axis has been widely proposed, but clinical trials of IL-23 inhibitors have failed in the treatment of SpA.
Objectives: This study aimed to evaluate serum IL-23 and IL-17 levels in SpA patients compared with control subjects according to radiographically different stage and disease activity scores.
Methods: The analysis were included 61 subjects with SpA, fulfilling the Assessment of SpondyloArthritis International Society (ASAS) classification criteria for SpA and 10 controls (8 with osteoarthritis and 2 with healthy controls). IL-17 (pg/ml) and IL-23 (pg/ml) in serum from all subjects and in synovial fluid from additional 9 subjects (4 with SpA and 5 with osteoarthritis) were measured by enzyme-linked immunosorbent assay. At the same time, all SpA patients were examined with the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Ankylosing Spondylitis Disease Activity Score (ASDAS) using clinical and laboratory data.
Results: Among 61 SpA subjects, 83.6% were men, mean [SD] age was 43.2 [12.3] years and mean disease duration was 13.8 [9.1] years. Mean BASDAI was 2.6 [2.0] and mean ASDAS-CRP was 1.6 [1.1]. While median [IQR] serum IL-17 was similar in both SpA and control groups (1.3 [0.6-5.5] pg/ml in SpA vs 1.1 [0.6-5.2] pg/ml in controls, p=ns), serum IL-23 level was significantly higher in controls compared with SpA patients (9.7 [8.0-16.9] pg/ml in SpA vs 20.9 [10.5-66.8] pg/ml in control, p=0.016). Higher level of synovial IL-17 and IL-23 were observed in additional 4 SpA patients (12.3 [0.9-30.6] pg/ml for IL-17 and 82.6 [33.5-112.1] pg/ml for IL-23) than 5 controls (0.4 [0.3-6.4] pg/ml for IL-17 and 57.7 [50.5-108.6] pg/ml for IL-23), albeit not significant (p=ns). Interestingly, significantly higher serum IL-23 was observed in patients with non-radiographic axial SpA (nrAxSpA) (n=20, 13.1 [8.7-49.4] pg/ml) than advanced ankylosing spondylitis (AS) (n=41, 9.1 [7.9-12.6] pg/ml) (p=0.039), but not with IL-17 (1.3 [0.8-3.7] pg/ml in nrAxSpA vs. 1.3 [0.5-6.8] pg/ml in AS, p=ns). Nevertheless, no significant difference regarding serum IL-17 and IL-23 levels was found between patients with less active SpA (ASDAS-CRP ≤2.1, n=44) and more active SpA (ASDAS-CRP >2.1, n=13). No associations of serum IL-17 and IL-23 levels with other clinical parameters including disease duration, syndesmophyte, tumor necrosis factor inhibitors uses were found.
Conclusion: Peripheral blood IL-23/IL-17 concentrations did not show the association with inflammatory burden of the disease. However, the level of serum IL-23 was higher in patients with nrAxSpA than in those with advanced AS. IL-23 might dissociate from IL-17 in advanced AS and play an important role only at early stage of axSpA.

AB0098 THE CAUSAL RELATIONSHIP BETWEEN MULTIPLE SCLEROSIS AND PSORIASIS: A TWO-SAMPLE MENDELIAN RANDOMIZED STUDY

Keywords: Psoriatic arthritis, Randomized control trial

Y. Xu[1,2,3], Z. Duan[1,2,3], J. Wang[1,2,3], S. Song[1,2,3], J. Qiao[1,2,3], S. X. Zhang[1,2,3], X. Li[1,2,3]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; [3]*Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China*

Background: Psoriasis is an immune-related, chronic inflammatory skin disease.The disease often presents with clearly delineated areas of erythematous patches on the skin covered with silvery scales[1].As the research progresses, more and more evidence suggests that multiple sclerosis may help reduce the occurrence of psoriasis.
Objectives: To explore whether there is a causal relationship between having multiple sclerosis and obtaining psoriasis.
Methods: We used a 2-sample Mendelian randomization (MR) method to evaluate the causal effect of multiple sclerosis on psoriasis. Multiple sclerosis (MS) and psoriasis (Ps) Ps summary data from IEU database (http://gwas.mrcieu.ac.uk/).The multiple sclerosis cohort consisted of 9,722 samples and 17,376 controls.The psoriasis cohort consisted of 4510 samples and 212242 controls. To reduce bias due to race-related confounding factors, the genetic background of the study population was limited to European ancestry.In the MR Approach, the IV analysis is based on three strict assumptions, namely that IV should be strongly correlated with exposure, independent of confounding factors associated with direction and outcome, and influence outcome solely through exposure[2]. We screened for significant (p<5× 10-06) and approximately independent (r 2 < 0.01) genome-wide single nucleotide polymorphisms (SNPS) and retained only SNPS with scores over 10 that were considered sufficiently strongly associated. To estimate the causal relationship between exposure and outcome, inverse variance weighting (IVW), MR-Egger regression, and weighted median methods were used. Mendelian random multivariate residuals and outliers, Cochran Q test and MR-Egger regression were used for sensitivity analysis.
Results: MR Statistics showed that genetic prediction of multiple sclerosis was associated with a reduced risk of psoriasis (IVW: OR=0.698,95%CI= 0.5788-0.843 P= 2.098-e-2), which we found to be statistically significant as the weighted

median method (OR=0.827; 95%CI= 0.760- 0.898p =4.476e-06), MR-Egger also showed a similar effect (OR=0.668; 95%CI= 0.482-0.926 P = 2.184e-02). Cochran's s Q test (Q=322.585; p=9.057e-51) found potential heterogeneity. MR-egger regression (P=0.164, intercept=0.043) was used to test the nonexistent horizontal multi-directivity. Similarly, we examined the level of pleiotropy again with MR-PRESSO's global test, and the results showed no evidence of horizontal pleiotropy. In addition, no SNP was found to be a significant factor affecting the association in the residual analysis.

Conclusion: Our results provide causal evidence for the effect of multiple sclerosis on psoriasis risk. This Mendelian randomization study showed a causal relationship between multiple sclerosis and the risk of psoriasis. Multiple sclerosis may help reduce the burden of psoriasis.

AB0099 CLONORCHIS SINENSIS-EXCRETORY/SECRETORY PROTEIN AMELIORATES INFLAMMATION IN ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Animal models

Y. J. Lee[1,2], M. J. Kim[3], H. I. Lee[1], S. C. Shim[4], E. J. Won[3], T. J. Kim[1].
[1]Chonnam National University Medical School and Hospital, Department of Rheumatology, Gwangju, Korea, Rep. of (South Korea); [2]Graduate School of Chonnam National University, Department of Biomedical Sciences, Gwangju, Korea, Rep. of (South Korea); [3]Chonnam National University Medical School and Hospital, Department of Parasitology and Tropical Medicine, Gwangju, Korea, Rep. of (South Korea); [4]Daejeon Rheumatoid & Degenerative Arthritis Center, Chungnam National University Hospital, Department of Rheumatology, Daejeon, Korea, Rep. of (South Korea)

Background: Ankylosing spondylitis (AS) is a sort of inflammatory arthritis that affects axial skeleton, peripheral joints, and certain extra-articular organs, including the eyes, skin, and gut. Recently, many attempts have been made to use parasite administration (e.g., ingestion of eggs of the nematode Trichuris suis) as a new modality for treating inflammatory disorders. Our group published that Clonorchis sinensis protein attenuated inflammation in AS.

Objectives: Thus, this study aimed to assess the therapeutic potential of Clonorchis sinensis-Excretory/Secretory protein (Cs-ESP) for AS.

Methods: Cytotoxicity of Cs-ESP at different doses was assessed by MTS and flow cytometry before performing experiments. Peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) were obtained from AS patients. Inflammatory cytokine-producing cells were analyzed using flow cytometry. The levels of INF-g, IL-17A, TNF-a, and IL-6 were measured by enzyme-linked immunosorbent assay (ELISA). SKG mice were treated with Cs-ESP or vehicles. Inflammation was evaluated using immunohistochemistry.

Results: Treatment with Cs-ESP resulted in no reduced cell viability of PBMCs or SFMCs. In experiments culturing PBMCs and SFMCs, the frequencies of IFN-g and IL-17A producing cells were significantly reduced after Cs-ESP treatment. In the SKG mouse model, Cs-ESP treatment significantly suppressed arthritis and enthesitis.

Conclusion: We provide the evidence demonstrating that Cs-ESP can ameliorate clinical signs and cytokine derangements in AS.

AB0100 TO STUDY THE T CELL AND CYTOKINE PROFILE IN ANKYLOSING SPONDYLITIS WITH EFFECTS OF TACROLIMUS AND TADALAFIL ON THE CYTOKINES IN-VITRO

Keywords: Adaptive immunity, Spondyloarthritis

P. Mehta[1], K. Singh[2], M. K. Rai[2], D. P. Misra[2], V. Agarwal[2]. *[1]King George's Medical University, Clinical Immunology and Rheumatology, Lucknow, India; [2]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India*

Background: Most studies have shown mixed results of Interleukin (IL)17 and IL-23 levels in patients with Ankylosing Spondylitis (AS) compared to controls; with animal studies showing a good correlation between activation of IL 23-IL

27 pathway and radiologic progression. Targeting this pathway in humans has yielded benefits with reduced inflammation and radiologic progression in AS. Controlling inflammation and fibrosis is the key to prevent osteoproliferation. Tacrolimus and tadalafil have shown to inhibit the Th17 pathway and profibrotic pathways respectively.

Objectives: To study the T cell (Th17, PD1, CD25+ CD4 T cells) and cytokine profile (IL-17, IL-23, TGF- β) in AS with influence of disease duration and activity on the above profile. To also study the effect of tacrolimus and tadalafil in ex-vivo peripheral blood monocyte (PBMC) cultures to study their anti-inflammatory and anti-fibrotic potential.

Methods: Patients with AS (ASAS classification criteria) without peripheral disease and not on biologic therapy were recruited and their demographic, clinical profile, disease activity and radiologic indices were recorded. Age and sex matched healthy controls (HC, n=21) were also recruited. Peripheral blood was drawn and sera stored; PBMCs were isolated and cultured. Serum and PBMC culture supernatant (CS) were measured for IL-17, IL-23 and TGF-β. These cytokines were measured at baseline, after stimulation with anti-CD3CD28 antibodies, and after treatment with tacrolimus(10mM/ml), tadalafil(10mM/ml) and both the drugs combined by ELISA(R&D systems, USA). The T cell profile was characterized by flow cytometry (CD4 Th17, CD4 PD1, CD4 Th17 PD1 and CD4 CD25). Statistical analysis was done using GraphPad prism v9.

Results: Twenty-five patients [28(24-36),M:F, 7.3:1] were enrolled with 90% HLA-B27 positivity. The majority had moderate-high disease activity as per ASDAS CRP and were on NSAIDs(24), complementary medications (7) and two each on methotrexate and sulfasalazine. Serum IL-17 and TGF-β, CS TGF- β were significantly elevated in AS compared to controls. All the measures cell populations were significantly elevated in AS compared to HC. When stratified by duration of disease, clinical parameters, disease activity indices, cytokine and T-cell profile was similar across the two groups. ASDAS CRP showed a significant correlation with CD4Th17+ cells (r=0.7, p=0.009) and CD4 PD1/T reg (r=-0.6, p=0.03). A positive association as observed with some cells but not with the cytokines on generalized linear modeling (Table 1). No significant correlation was observed between cytokines or T cell profiling with Modified Stokes Ankylosing Spondylitis Score. There was a significant decline in TGF- β levels in the culture supernatant with tacrolimus and tadalafil combined, however, no such difference was observed with IL-17 or IL-23. (Figure 1)

Conclusion: Serum IL-17 and TGF- β were elevated in the peripheral blood in AS. There was no difference in the cytokine and T-cell profile across early and late disease. A significant decline in TGF- β levels was seen with combined tacrolimus and tadalafil. This needs further exploration in a larger sample size with subgroup characterization as well as testing on synovial fluid and joint tissue samples.

Table 1. Association of disease activity and T cell/cytokine profile

AB0101 ABNORMAL KYNURENINE LEVEL CONTRIBUTES TO THE PATHOLOGICAL BONE FEATURES OF ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis

C. Jeon[1], S. H. Lee[1], S. Weon[1], S. H. Choi[2], T. H. Kim[3], I. H. Sung[2], S. Jo[1]. *[1]Hanyang University, Hanyang University Institute for Rheumatology Research, Seoul, Korea, Rep. of (South Korea); [2]Hanyang University Hospital, Orthopedic Surgery, Seoul, Korea, Rep. of (South Korea); [3]Hanyang University Hospital for Rheumatic Diseases, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Ankylosing spondylitis (AS) exhibits paradoxical bone features typically characterized by new bone formation and systemic bone loss.

Objectives: Although abnormal kynurenine (Kyn), a tryptophan metabolite, has been closely linked to the disease activity of AS, the distinct role of its pathological bone features remains unknown.

Methods: Kynurenine sera level was collected from healthy control (n = 22) and AS (n = 87) patients and measured by ELISA. In the AS group, we analyzed and compared the Kyn level based on mSASSS scores, MMP13, and OCN. Under osteoblast differentiation, the effect of Kyn in AS-osteoprogenitors resulted in cell proliferation, alkaline phosphatase activity, bone mineralization-related alizarin red s (ARS), von kossa (VON), hydroxyapatite (HA) staining, and mRNA expression markers (ALP, RUNX2, OCN, and OPG) for bone formation. TRAP staining was used for osteoclast formation in RANKL-mediated RAW264.7 cells.

Results: Kyn sera level was significantly elevated in the AS group compared to the healthy control group. In addition, Kyn sera level was correlated with mSASSS score (r = 0.03888, p = 0.067), MMP13 (r = 0.0327, p = 0.093), and OCN (r = 0.0436, p = 0.052). During osteoblast differentiation, treatment with Kyn exhibited no difference in cell proliferation and alkaline phosphate (ALP) activity for bone matrix maturation but promoted ARS, VON, and HA staining for bone mineralization. Interestingly, osteoprotegerin (OPG) and OCN expression was augmented in the presence of Kyn treatment during differentiation. In growth medium, Kyn treatment of osteoprogenitors resulted in induction of OPG mRNA, protein expression, and AhR response genes (AhRR, CYP1b1, and TIPARP). Secreted OPG proteins were observed in the supernatant of osteoprogenitors treated with Kyn. Notably, the supernatant addition to osteoclastogenesis interrupted the TRAP-positive osteoclast formation of RANKL-mediated RAW264.7 cells and reduced osteoclast differentiation markers.

Conclusion: Our results revealed that elevated Kyn level increased the bone mineralization of osteoblast differentiation in AS and decreased RANKL-mediated osteoclast differentiation by inducing OPG expression, suggesting a potential therapeutic target where abnormal Kyn level could be involved in pathological bone features of AS.

AB0102 POTENTIAL BIOMARKERS TO PREDICT TNF INHIBITORS OUTCOME IN PSORIATIC ARTHRITIS

Keywords: bDMARD, Psoriatic arthritis, Biomarkers

A. Makos[1], J. H. Kuiper[2], R. Amarasena[3], O. Kehoe[1]. *[1]Keele University School of Medicine at the RJAH Orthopaedic Hospital, Centre for Regenerative Medicine, Keele, United Kingdom; [2]Keele University School of Pharmacy and Bioengineering at the RJAH Orthopaedic Hospital, Centre for Regenerative Medicine, Keele, United Kingdom; [3]The Robert Jones and Agnes Hunt Orthopaedic Hospital NHS Foundation Trust, Rheumatology, Gobowen, United Kingdom*

Background: Psoriatic Arthritis (PsA) is a chronic immune-mediated inflammatory disease characterized by axial and peripheral arthritis, dactylitis, nail changes and most of the time, is associated with psoriasis. Patients are initially treated with conventional synthetic Disease-Modifying Anti-Rheumatic Drugs (csDMARDs), but if they do not respond to these, they are treated with biologics, particularly TNF inhibitors (TNFi) which are common first-line biologics. However, about 40% of patients do not or only partially respond to TNFi. Blood biomarkers predicting response to TNFi would allow patients to be treated earlier with a more appropriate drug [1].

Objectives: We studied pro- and anti-inflammatory cytokines and adaptive immune cells that could be used as biomarkers for TNFi outcome. Predicting responses to TNFi will help clinicians to choose a more appropriate treatment for patients.

Methods: Blood from patients with PsA (n = 8) was analysed before starting TNFi and compared with blood from patients with rheumatoid arthritis (RA) (n = 8). PsA patients were characterised as 'psoriasis positive' and 'psoriasis negative'. Patients were followed at 3 and 6 months after treatment (n = 6). Leukocytes were isolated with Lymphoprep and their phenotype was characterised by

CD45, CD3, CD4, CXCR3, CCR6, HLA-DR, CD38, CD25 and CD127. Levels of 12 cytokines in plasma were measured using a cytokine kit (MACSPlex Cytokine 12 Kit, human, Miltenyi Biotec Ltd, UK). Clinical data from patients were collected to determine treatment outcome.

Results: Mean level of TNFα was higher in our RA patients (6.2 pg/ml) compared to our PsA patients (4.6 pg/ml). Initial analysis of clinical data suggested that our PsA patients without psoriasis (n = 2) responded better to TNFi than those with active psoriasis (n = 4) at 3 months and 6 months after treatment, with a clear reduction in the number of tender joints ('psoriasis positive': 6.65 vs 1.67; 'psoriasis negative': 11.5 vs 0.67) and swollen joints ('psoriasis positive': 2 vs 0.67; 'psoriasis negative': 3.50 vs 0). The mean proportion of activated Th17 cells was higher in our patients with active psoriasis (5.1% of Th17 cells) than those without psoriasis (3.6% of Th17 cells). The mean level of IL-12 and INFγ was higher in the 'psoriasis positive' group (respectively 129.2 pg/ml and 266.1 pg/ml) than the 'psoriasis negative' group (respectively 52.7 pg/ml and 115 pg/ml).

Conclusion: We hypothesize that PsA patients have a lower level of TNFα because of other pro-inflammatory cytokines potentially involved in the inflammatory process. IL-12 can induce IFNγ production by Th1 cells and is involved in the IL12/IL23 axis in psoriasis pathogenesis. IFNγ can induce Th1 and Th17 cells expansion through myeloid dendritic cells activation. In PsA, the high levels of IL-12 and IFNγ involved in psoriasis pathogenesis might be one of the reasons for a poor response to treatment, but larger sample sizes are needed to find a biomarker that could be used routinely by clinicians, and to determine if the same biomarker can also be used for other types of arthritis such as rheumatoid arthritis.

AB0103 THE CAUSAL ASSOCIATION BETWEEN MTOR-DEPENDENT CIRCULATING PROTEINS AND PSORIATIC ARTHRITIS: A MENDELIAN RANDOMIZATION STUDY

Keywords: Spondyloarthritis, Enthesitis, Inflammatory arthritides

Z. Zhao[1,2,3], F. Liu[1,2,3], Z. Wang[1,2,3], S. Song[1,2,3], J. Qiao[1,2,3], S. X. Zhang[1,2,3], X. Li[1,2,3]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; [3]*Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China*

Background: Psoriatic arthritis (PsA) is a chronic, immune-mediated arthropathy mainly affecting the peripheral joints, spine, and sacroiliac joints[1] The key pathologic outcomes of PsA are 'uncontrolled proliferation' of synovial fibroblasts (FLS), along with the proliferation of endothelial cells (EC) and T cells. Growing evidence found that the proliferation of these cells of psoriatic arthritis are dependent on the PI3K-AKT-mTOR kinase system.[2]

Objectives: This study aimed to investigate the causality between key mTOR kinase cascade proteins and psoriatic arthritis.

Methods: We used a 2-sample Mendelian randomization (MR) method to evaluate the causal effect of five mTOR-dependent circulating proteins on psoriatic arthritis. Data about mTOR-related gene exposure (eIF4A3, eIF4E2, eIF4E-BP2, eIF4G3, RP-S6KA) in plasma were obtained from the publicly available proteomics-GWAS INTEVAL study (https://www.phpc.cam.ac.uk/ceu/proteins/), which included 3,622 plasma protein assays from 3,301 participants. PsA relative single nucleotide polymorphisms (SNPs) were obtained from the FinnGen study(https://r5.finngen.fi/). 1637 cases and 212242 controls of European descent were included in our study. Effect estimates were evaluated using inverse-variance weighted method. There are also other MR analyses, including MR-Egger regression, and the weighted median methods. Mendelian Randomization Pleiotropy RESidual Sum and Outlier (MR-PRESSO) test, Cochran's Q test, and MR-Egger regression were performed in sensitivity analyses. All statistical analyses were performed in R (version 4.0.3).

Results: Five proteins were extracted from the downstream target of mTOR, which were eIF4A3 eIF4E2, eIF4E-BP2, eIF4G3 and RP-S6KA. Subsequently, 15, 9, 10, 16, and 18 IVs with mTOR significantly associated with psoriatic arthritis were extracted from genome-wide association studies ($P<5x10^{-6}$). F statistics of all the selected IVs are greater than 10, indicating that all IVs were strongly correlated with exposure. After the removal of SNPs with high linkage disequilibrium and palindrome, the final 8,13,10,7, and 13 SNPs were used as final instrument variables for them, respectively. Evidence for an effect of eIF4E2 on PsA risk was found in inverse-variance weighted method (OR=0.844; 95%CI,0.735,0.969; p=0.016) and weighted median (OR=0.819; 95%CI,0.687,0.977 P=0.026) using 13 single nucleotide polymorphisms (SNPs) as the instruments. For the other four common mTOR related targets, we have not found a causal relationship between them and PsA including eIF4A3 (IVW: OR = 0.912;95% CI,0.749,1.111; p = 0.359), eIF4E-BP2 (IVW: OR = 0.842; 95% CI,0.788,1.031; p = 0.075), eIF4G3 (IVW: OR = 0.768;95% CI,0.709,1.135; p = 0.366) and RP-S6KA (IVW: OR = 0.893; 95% CI, 0.767,1.040; p = 0.146). To verify the robustness of our model, we performed sensitivity analysis. No potential heterogeneity was found by Cochran's Q test (Q=6.311; p=0.852). MR-Egger regression (P=0.425, intercept=0.038) found no horizontal pleiotropy. Similarly, the result of MR-PRESSO test found no evidence of horizontal pleiotropy. In addition, no SNP was identified as an obvious factor affecting the association in the leave-one-out analysis. (Figure 1)

Conclusion: In summary, this 2-sample mendelian randomization study found a causal protective association of eIF4E2 with psoriatic arthritis. This novel result provides the scope to develop new therapeutics targeting PI3K/Akt/mTOR signaling pathway in psoriatic arthritis.

AB0104 THE CAUSAL EFFECT OF LIPID METABOLISM ON THE RISK OF PSORIATIC ARTHRITIS: A MENDELIAN RANDOMIZATION STUDY

Keywords: Genetics/Epigenetics, Psoriatic arthritis

Y. Jin[1], J. Zhu[2], H. So[1], P. Wong[1], L. S. Tam[1], D. Wu[2]. [1]*The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, China*; [2]*Sichuan Provincial People's Hospital, Department of Rheumatology and Immunology, Sichuan, China*

Background: Psoriatic disease, including psoriatic arthritis (PsA) and psoriasis, is driven by a combination of genetic, biomechanical, metabolic, and microbial factors which promote an aberrant immune response and the consequent development of chronic disease.(1) Genetic evidence has indicated that body mass index and glycemic control are associated with an increased risk of psoriasis and PsA, and also with an increased risk of cardiovascular disease.(2) However, the causal relationship between serum lipids and risk of incident PsA remains unclear.

Objectives: To investigate whether lipid metabolites are causally associated with incident psoriatic arthritis (PsA), in comparison with rheumatoid arthritis (RA) and ankylosing spondylitis (AS).

Methods: The publicly available summary-level findings from two genome-wide association studies (GWAS) were used to identify loci influencing circulating metabolites as exposure and a GWAS for PsA (n=1,637, control=212,242), RA (n=6,236, control=147,221), AS (n=1,462, control=164,682) as the outcome. Bi-directional Mendelian randomization (MR) analysis and multivariable MR analysis were used in main and validation analysis.

Results: In the main analysis, pooled data suggested a causal association of PsA risk with total cholesterol (P=0.005), cholesterol esters (P=0.003), free cholesterol (P=0.009), total lipids (P=0.004), phospholipids (P=0.010), and concentration of particles (P=0.005) in large low-density lipoprotein (LDL); total cholesterol (P=0.009), cholesterol esters (P=0.006), total lipids (P=0.009), phospholipids (P=0.002), and concentration of particles (P=0.009) in medium LDL; total cholesterol (P=0.001), total lipids (P=0.001), concentration of particles (P<0.001) in small LDL (Figure 1). Multivariable MR analysis identified cholesterol esters in large LDL as the strongest causal risk factor for PsA (P=0.017) (Table 1). In validation analysis, genetically predicted cholesterol (P=0.004), cholesteryl esters (P=0.001), and total lipids (P=0.003) in LDL; cholesteryl esters in large LDL (P=0.006); phospholipids (P=0.007) and concentration of particles

(P=0.006) in medium LDL; and total lipids in small LDL (P=0.008) were also causally associated with PsA. However, there is no causal association of lipid metabolites with RA and AS.
Conclusion: The present findings supported causal relationships between LDLs and an increased risk of PsA, especially for cholesterol esters in large LDL.

CAUSAL ASSOCIATION BETWEEN IL-7 LEVELS AND ANKYLOSING SPONDYLITIS: A TWO-SAMPLE MENDELIAN RANDOMIZATION STUDY

Keywords: Biomarkers, Genetics/Epigenetics, Inflammatory arthritides

C. Wang[1,2], Y. X. Chen[2,3], Z. J. Li[3], Y. Li[1], T. Huang[3], D. Y. Xue[3], S. X. Zhang[2,4], Q. Yu[1]. [1]*Shanxi Medical University, School of Management, Taiyuan, China*; [2]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [3]*Shanxi Medical University, School of Basic Medical Sciences, Taiyuan, China*; [4]*Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*

Background: Ankylosing spondylitis (AS) is an immune-mediated inflammatory arthritis that affects the axial skeleton. Currently, the cause of AS is still not known, so there is no way to prevent AS. Interleukin-7 (IL-7) is a restrictive and non repetitive cytokine, mainly produced by epithelial and stromal cells. The relationship between IL-7 and some inflammatory cytokines such as AS has been discussed in recent advances in the pathogenesis of AS, but a direct effect of IL-7 on AS has not been demonstrated[1].
Objectives: Study to investigate the casual association between IL-7 and AS.
Methods: We evaluated the causal relationship between IL-7 levels and AS using a Mendelian randomization approach. The GWAS summary statistics of IL-7 (N = 3409) and AS (Ncase = 968, Ncontrol = 336,191) were downloaded from the IEU GWAS database in the study. Instrumental variables (IVs) were constructed using single nucleotide polymorphisms (SNPs). To assess the causal relation of IL-7 and AS, we used three analytical methods: MR-Egger mode, Weighted median mode, and Inverse variance weighted (IVW). In addition, we also conducted sensitivity tests, including the heterogeneity test, the pleiotropy test, the funnel plot, leave-one-out approach and MR-PRESSO.
Results: When selecting SNPs associated with IL-7, in the situation of the genome-wide significant threshold of P < 5×10-6 and LD r2 = 0.001, we finally obtained 9 IVs that could be used in the subsequent steps. Based on the IVW mode with high statistical power, a prudent and credible causal relationship was demonstrated between IL-7 and AS [IVW: P=0.025, OR(95%CI)=0.999(0.999, 1.000)]. As the level of IL-7 increased, the risk of developing AS also decreased, proving that IL-7 was a protective factor for this disease (Figure 1a). The Cochrane Q test (Q test p = 0.99) showed a good homogeneity among studies. The results of a leave-one-out sensitivity analysis suggested that causal associations were not strongly influenced by any of the selected IVs (Figure 1b). Funnel plot results (Figure 1c) and the intercept of the MR-Egger regression (Figure 1d) further showed that pleiotropy did not bias the causal effect in this study.
Conclusion: Our research results show that IL-7 is causally associated with the pathogenesis of AS. which enables the early detection of AS, this findings have great clinical value.

CAUSAL RELATIONSHIP BETWEEN IL-17 FAMILY MEMBERS AND THEIR RECEPTORS AND ANKYLOSING SPONDYLITIS: A TWO-SAMPLE MENDELIAN RANDOMIZATION STUDY

Keywords: Spondyloarthritis, Cytokines and chemokines, -omics

Y. X. Chen[1,2], X. Y. Guo[1,2], C. Wang[2,3], J. Q. Bai[1,2], J. Qiao[2,4], S. X. Zhang[2,4], P. F. He[5], Q. Yu[3]. [1]*Shanxi Medical University, School of Basic Medical Sciences, Taiyuan, China*; [2]*Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [3]*Shanxi Medical University, School of Management, Taiyuan, China*; [4]*Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China*; [5]*Shanxi Medical University, Medical Data Sciences, Taiyuan, China*

Background: Ankylosing spondylitis (AS) is an axial rheumatic and spinal disease based on autoimmune and genetic susceptibility that affects the sacroiliac joints and the spine[1]. Interleukin 17 (IL-17) as an inflammatory cytokine positively correlated with disease activity in AS patients[2]. However, the causal relationship between the IL-17 family and its receptors and AS is inconclusive.
Objectives: The aim of this study was to discover the casual association between the IL-17 family members with their receptors and AS.
Methods: To clarify the causal relationship between the IL-17 family members (and their receptors) and AS, we used two-sample Mendelian randomization (MR).

We selected single-nucleotide polymorphisms (SNPs) from genome-wide association studies (GWAS) which included IL-17 family members and their receptors (N = 3301) and AS (Ncase = 968, Ncontrol = 336,191). Confounding factors were excluded, heterozygosity and lateral polymorphisms were examined and corrected.
Results: We found that IL-17RB level was significantly causally associated with AS (IVW OR=1.0007, 95%CI 1.0002~1.0011, P= 0.0020, Figure 1a). Sensitivity analysis also confirmed the absence of horizontal polymorphism (MR-Egger intercept = 6.5989×10^{-5}, P = 0.5158, Figure 1b) and heterogeneity (IVW Q = 10.7388, Q_pval = 0.5514) that biased the causality. The leave-one-out sensitivity test showed that no single SNP strongly affected the causal relationship between IL-17RB and AS (Figure 1c). Furthermore, funnel plot symmetry suggests that our study fits the IV hypothesis(Figure 1d). However, our results show no significant causal relationship between AS and other IL-17 family members and their receptors.
Conclusion: Our results show that IL-17RB is a protective factor for AS. We offer a new insight into the drug targets of AS.

B.; Xu, S.; Pan, F., Elevated circulating IL-17 level is associated with inflammatory arthritis and disease activity: A meta-analysis. *Clin Chim Acta* **2019,** *496*, 76-83. doi:10.1016/j.cca.2019.06.026

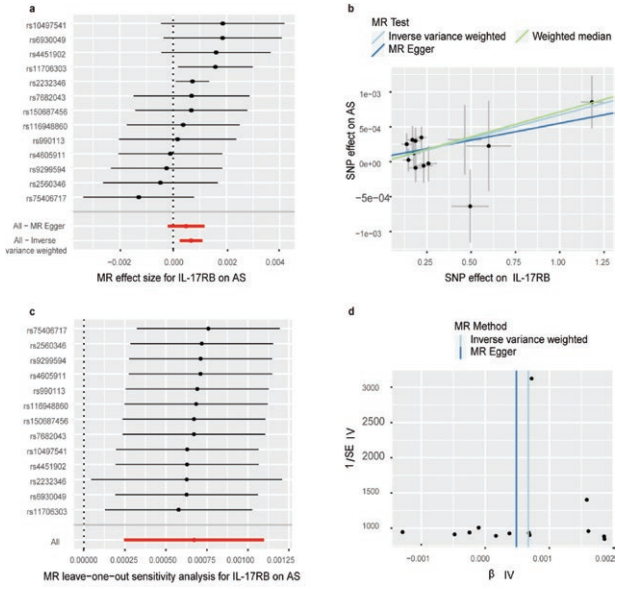

Fig 1. (a) Forest plot. Each horizontal solid line reflects the results estimated by a single SNP using the Wald ratio method: some are complete to the left of 0, indicating that the result calculated by this SNP is that increased exposure reduces the risk of outcome; some are complete to the right of 0, indicating that the result estimated by this SNP is that increased exposure increases the risk of the outcome, and those over 0 are not significant. Looking at the effects of a particular SNP alone may be problematic; only when the results are put together can we see that good results can be obtained. The solid red line reflects that the elevated IL-17RB under IVW and MR-Egger methods will increase the risk of AS. IL17RB is a risk factor for AS. **(b)** Scatter diagram. Each point on the graph represents an IV, the line on each point reflects the 95% confidence interval, the abscissa is the effect of SNP on exposure (IL-17RB level), and the ordinate is the effect of SNP on the outcome (AS), the colored lines represent the MR fit result. As the level of IL-17RB increases, the risk of developing AS also increases. **(c)** Leave-one-out sensitivity test. All the lines are on the right side of 0, indicating that either SNP was removed would not fundamentally affect the results, indicating that the MR was robust in our study. **(d)** Funnel plot. Dashed lines perpendicular to the horizontal axis indicate the combined effect sizes. The studies should be evenly distributed on both sides in a symmetric inverted funnel shape in an ideal state. Our analysis of the individual SNP in the funnel plot is roughly symmetric, suggesting almost no bias in the study.

Background: Ankylosing spondylitis (AS) is a chronic inflammatory immune response disease mainly presenting with fibrosis of the sacroiliac joint and calcification [1]. Interleukin-10 (IL-10) is a factor that suppresses Th17 cell activity and induced Treg cells to achieve immunosuppression. Observational studies show that IL-10 may be one of the important contributing sources of important inflammatory cytokines for AS [2], but the causal relationship between them is not clear.
Objectives: The objective was to investigate the casual association between AS and IL-10.
Methods: The GWAS summary statistics of IL-10 and AS (Ncase = 968, Ncontrol = 336,191) were downloaded from the IEU GWAS database in the study. After a series of screens, SNPs strongly associated with exposure were included as instrumental variables(IVs). The results are from using robust analyses with three two-sample different assumptions (Inverse variance weighting (IVW), Weighted median (WM) and MR-Egger). Meanwhile, we used MR-Egger intercept test, Cochran'sQ test and leave-one-out sensitivity analysis for assessment to avoid the biasing effects of potential genetic variation, horizontal pleiotropy and heterogeneity. MR-PRESSO outlier test was used to identify and eliminate horizontal pleiotropy.
Results: Our result showed that the level of IL-10 has a causal relationship with the risk of developing AS (IVW: OR=0.9992, 95% confidence interval (CI) 0.9985-0.9999, P = 0.03, Figure 1a, 1b). Increasing the IL-10 level can reduce the risk of AS disease. MR-Egger intercept test (MR-Egger intercept = -1.5705×10^{-5}, P = 0.5158, Figure 1b), Cochran's Q test (IVW Q = 4.3071, Q_pval = 0.8284), leave-one-out sensitivity analysis (Figure 1c) and the funnel plot (Figure 1d) suggest almost no bias in the study, indicating that the MR was robust.
Conclusion: Our results indicate a protective role for IL-10 in AS, suggesting that elevated IL-10 levels may be able to alleviate the inflammatory response in AS, providing new insights into AS treatment.

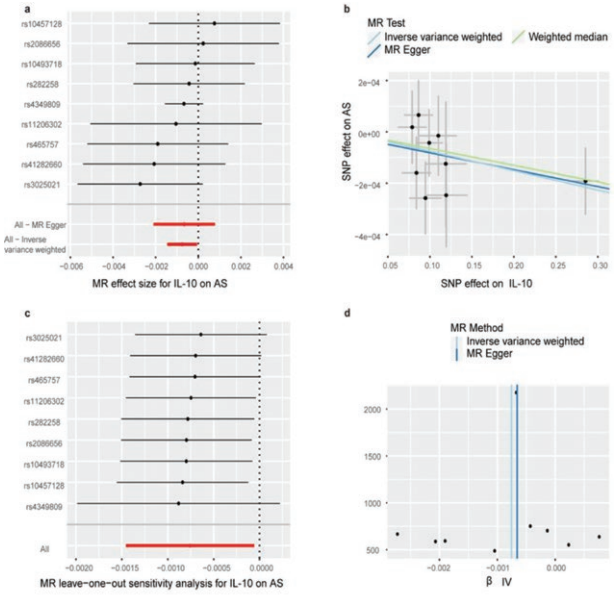

Fig 1. (a) Forest plot. The solid red line reflects that the elevated IL-10 under IVW will decrease the risk of AS. IL-10 is a protective factor for AS. (b) Scatter diagram. Each point on the graph represents an IV, the line on each point reflects the 95% confidence interval, the abscissa is the effect of SNP on exposure (IL-10 level), and the ordinate is the effect of SNP on the outcome (AS), the colored lines represent the MR fit result. As the level of IL-10 increases, the risk of developing AS decreases. (c) Leave-one-out sensitivity test. All the points are on the right side of 0, indicating that either SNP was removed would not fundamentally affect the results, indicating that the MR was robust in our study. (d) Funnel plot. The studies should be evenly distributed on both sides in a symmetric inverted funnel shape in an ideal state. Our analysis of the individual SNP in the funnel plot is roughly symmetric, suggesting almost no bias in the study.

A Coruña, Universidade de A Coruña, Department of Rheumatology, A Coruña, Spain; [5]*Complexo Hospitalario Universitario de A Coruña, Universidade de A Coruña, Department of Rheumatology-INIBIC, A Coruña, Spain*

Background: Interleukin-22 (IL-22) is produced by T helper type 1, type 17, type 22 cells, and type 3 ILC, being probably a marker of osteogenic differentiation and new bone formation. Diagnosis and treatment are commonly delayed due to different clinical presentations that lead the patient to progressive articular damage. In recent studies, it seems that the serum levels of IL-22 are elevated in axial spondyloarthritis (AxSpA) and do not allow differentiation between AxSpA and other joint inflammatory disorders.
Objectives: The present research aimed to analyze serum cytokines as possible biomarkers regarding inflammation and bone destruction/regeneration in four rheumatic diseases.
Methods: Serum samples were acquired from patients with psoriatic arthritis (PsA), rheumatoid arthritis (RA), osteoarthritis (OA), and AxSpA. Serum levels of TGF-β1, IL-23, IL-6, IL-17A, IL-22, Dkk1, Sclerostin, BMP2, BMP4, Wnt1, and Wnt5a were measured by enzyme-linked immunosorbent assay (ELISA). All these data were analyzed and compared with the demographic, clinical, analytical, and radiological characteristics of the patients. Statistical analysis was performed using the SPSS version 23 program (IBM SPSS Statistics). Values of $p < 0.05$ were considered statistically significant.
Results: The serum samples were obtained from 35 patients (PsA n=11, RA n=7, OA n=13, AxSpA=4). All these patients were previously treated with NSAIDs and corticosteroids (oral/intraarticular); 4 were treated with csDMARDs, but no none of them was previously treated with biologics. IL-22 levels were higher in AxSpA patients ($p = 0.046$), although serum IL-22 levels did not correlate with modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) ($p = 0.154$) or C-reactive protein ($p = 0.208$). The sensitivity and specificity of the serum IL-22 for the AxSpA diagnosis were 75% and 81% respectively, for the cut-off value of 58 ng/mL, with AUC 0.798 (95% CI 0.634-0.962

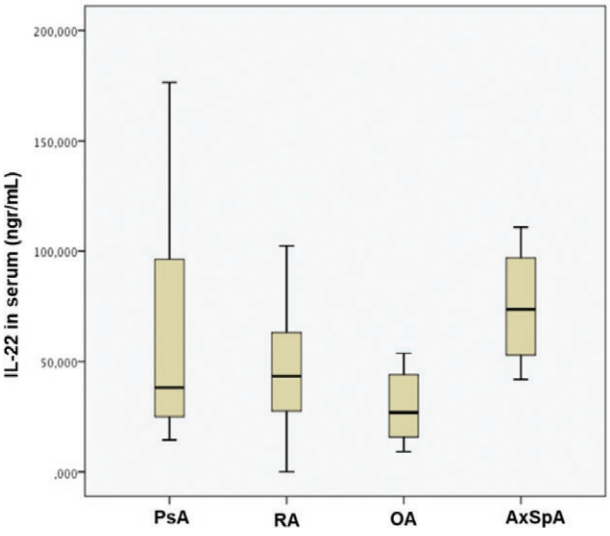

Figure 1.

Conclusion: Serum levels of IL-22 are elevated in patients with clinical diagnoses of AxSpA and could be an independent serum biomarker of this disease.

ASSESSING PREVALENCE OF SPONDYLOARTHRITIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: AN ANALYSIS OF RETROSPECTIVE DATA FROM A NOVEL COMBINED RHEUMATOLOGY AND GASTROENTEROLOGY CLINIC

Keywords: Spondyloarthritis, Disease-modifying Drugs (DMARDs), Gastrointestinal tract

U. Dhamrah[1], S. M. Lao[1], A. Bhattacharya[2], B. Moghaddam[1]. [1]*Icahn School of Medicine at Mount Sinai, Rheumatology, New York, United States of America*; [2]*Icahn School of Medicine at Mount Sinai, Gastroenterology, New York, United States of America*

Background: Spondyloarthritis (SpA) associated with inflammatory bowel diseases (IBD) is a subtype of SpA affecting the axial spine (AxSpA) and peripheral musculoskeletal system causing arthritis, enthesitis and dactylitis (peripheral SpA) in patients with Crohn's Disease (CD) or Ulcerative Colitis (UC). The prevalence of SpA in IBD is variable but reported to range from 5-15% for axial SpA and 30-45% for peripheral SpA. Detection of SpA in IBD patients requires a multidisciplinary approach to ensure early diagnosis and tailored treatment. This highlights the need for combined assessment by rheumatology and gastroenterology to prevent disability and loss of function.
Objectives: We aimed to assess the prevalence of SpA in IBD patients evaluated for arthralgia in a combined gastroenterology and rheumatology clinic (IB-DART), in a large tertiary care center in New York City.
Methods: We conducted a retrospective chart review of patients with IBD and arthralgia who were evaluated by physicians of both specialties in the IB-DART clinic. Patients over the age of 21 with a diagnosis of IBD and symptoms of joint pain were included. A multidisciplinary approach was taken for both diagnosis and treatment. Prevalence of axial SpA, peripheral SpA, HLA B27 positivity were calculated. Descriptive statistics were used.
Results: 63 patients (61.9% females) were seen in the IB-DART clinic, the average age was 48.5. There were 10 (15.8%) patients with non-inflammatory arthritis and 53 (84.1%) patients with axial or peripheral SpA. Of the 53 patients, 7 (13.2%) had AxSpA, 32 (60.3%) had peripheral SpA, and 14 (26.4%) had both axial and peripheral SpA. SpA was seen in 90.9% of the 44 CD patients, 68.7% of the 16 UC patients, 66.6% of the 3 undifferentiated IBD patients. 9 (42.8%) patients with AxSpA were found to have x-ray and MRI evidence of sacroiliitis. 1 had MRI findings of enthesitis. HLA B27 was only positive in 3 of the 39 tested patients and did not correlate with axial or peripheral involvement. In patients with SpA, 23 were on TNF inhibitor therapy, 10 on JAK inhibitors, 13 on interleukin-12/23 inhibition, and 6 on conventional DMARDs (ie Methotrexate, 6MP, hydroxychloroquine) and prednisone. (Table 1)

Table 1. Patient characteristics

SpA	53 patients
Axial	7/53 (13.2%)
Crohn's DIsease	6/7
Ulcerative Colitis	1/7
Peripheral	32/53 (60.3%)
Crohn's DIsease	21/32
Ulcerative Colitis	9/32
Undifferentiated IBD	2/32
Both axial and peripheral	14/53 (26.4%)
Crohn's DIsease	13/14
Ulcerative Colitis	1/14
Radiographic evidence of sacroiliitis in AxSpA	9/21 (42.8%)
HLA B27	
Positive	3/39 (7.69%)
Negative	36/39 (92.3%)

Conclusion: We report a high prevalence of IBD associated SpA in patients presenting for evaluation of arthralgia to a multidisciplinary clinic. Diagnosis and management of SpA in the context of IBD can be challenging and warrants a multidisciplinary approach to timely diagnosis and management. Combined efforts to make treatment changes to induce and maintain disease remission can lead to improvement in morbidity in these patients. This study highlights the characteristics of patients with IBD associated SpA and demonstrates the value of integrated management in clinical practice.

AB0110 FEASIBILITY OF AN IL-17A ASSAY IN PATIENTS WITH ACTIVE AXIAL SPONDYLOARTHRITIS

Keywords: Prognostic factors, Spondyloarthritis, bDMARD

C. Roux[1,2], E. Delannoy[1], M. Cremoni[3], M. C. Trojani[1], L. Evenor[1], D. Graca[3], J. Genovese[1], V. Breuil[1], B. Seitz-Polski[3]. *[1]UNiversité Cote d'Azur, Rheumatology, Nice, France*; *[2]Université Côte d'Azur, CNRS, Inserm, iBV, France., Rheumatology, Nice, France*; *[3]UNiversité Cote d'Azur, Immunology, Nice, France*

Background: In Spondyloarthritis (SpA), the method of determination of IL-17 is questionable. Indeed, studies measuring plasma levels of IL-17A without stimulation have shown discordant results.
Objectives: The objective of our study is to show the validity of an IL17 assay method using both innate and acquired immunity stimulation.
Methods: We included volunteer SpAs presenting for consultation between February 2021 and March 2022 in the study. They were axial SpA meeting the ASAS criteria, naïve to any biological treatment, having failed at least two NSAIDs and in need of biological treatment. The control population was issued from a previews cohort of healthy subjects recruited between January 2020 and February 2021. Serum levels of 11 cytokines (IL-17A, IL-6, IL-1β, IFN-γ, IL-12p70, TNF-α, IL-10, IL-5, IL-4, IL-13, and GM-CSF) were measured with and without stimulation by immune ligands (anti-CD3 as a T-cell stimulant, R848 as TLR 7/8 agonist). Clinical evaluation was performed at 3 months after initiation of biological treatment at the discretion of the investigator (anti-TNFα (TNFi) or anti-IL17). The primary outcome was a BASDAI50 response.
Results: A total of 45 patients with SpA (25 males and 20 females; median age, 41 ± 11 years) were included in the study, along with 27 controls (11 males and 16 females; median age 50.5 ± 28 years). Without stimulation levels of the pro-inflammatory cytokines TNF-α, IL-8, IL-6, and IL-1β were significantly increased in the patients with SpA group in comparison to controls and IL-4, IL-5, IL-12p70, and IL-17A levels in all patients with SpA were below the detection threshold (<2,1 pg/mL for IL-17A). After stimulation, Th17 cytokine IL-17A was significantly increased in the patient group with SpA in comparison to controls (IL-17A 317 pg/mL IQR [59–441] versus 59,9 pg/mL IQR [21,2–127], p = 0,0002). On the other hand, the concentration of Th1 cytokines (IFN-γ, IL-12p70 and TNF-α, IL-1β) were lower in the patient group with SpA than in the controls and the cytokines of the Th2 pathway (IL-4, IL-5) were higher in patients with SpA than in controls. Twenty-eight patients were treated with TNFi, and 14 patients with IL-17i. At three months, 55% of the treated patients had a BASDAI decrease of at least 50% (57.1% of the patients treated with TNFi and 64.3% treated with IL17). In SpA, patients, responders had higher baseline IL17A concentration (383 pg/mL IQR [109–887,2] vs. 30 pg/mL IQR [9–133] p = 0.049). A 145 np/mL threshold was defined to distinguish the patients (responders and non-responders). Positive IL-17A activity was determined using receiver operating characteristic analysis, with a sensitivity of 75% and specificity of 88% (Area Under the receiver operating characteristic Curve = 0,88 p = 0,0415). There was no difference in TNF-α levels without or after stimulation between patients who responded to TNFi treatment and those who did not.
Conclusion: Our study shows the feasibility of a cytokine stimulation method that allows the determination of IL-17A in current practice in axial SpA. The potential interest in guiding the practitioner in their therapeutic choice (IL-17i or TNFi) should be confirmed in future studies.

Background: The chemokine C-X-C Motif Chemokine Ligand 10 (CXCL10) has been found to be elevated in those patients with psoriasis (PsO) who will develop psoriatic arthritis (PsA), thus being proposed as a predictor of joint involvement [1]. CXC10 progressively declines in these PsO patients until the diagnosis of PsA and further, in parallel with the duration of the disease [2]. In contrast, CXCL10 remains invariable on time in the rest of PsO patients. Subclinical ultrasound synovitis may be considered a pre-disease state of PsA [3]. CXCL10 serum levels in patients with preclinical PsA are still unknown.
Objectives: To better characterize the preclinical phase of PsA and to assess the relationship of CXCL10 levels with subclinical joint involvement in PsO patients.
Methods: 62 patients with PsO without PsA were included, all of them naïve to biological therapy. Ultrasonography (US) was performed on the wrist and metacarpophalangeal 1–5 joints (MCP), proximal interphalangeal 1–5 joints (PIP), and distal interphalangeal 2–5 joints (DIP) bilaterally, and grey scale (GS) synovitis were scored semiquantitatively (0–3) using the OMERACT scoring system. Serum CXCL10 levels were also determined by ELISA in all the patients.
Results: 31 men and 31 women were recruited. GS synovitis ≥1 was present in 30 patients, 10 men and 20 women, while only 7 patients exhibited GS synovitis ≥2, 4 men and 3 women. The mean logCXCL10 was inferior in patients showing any grade of GS, both in the whole group and after stratifying by sex (Table 1), although the difference was only statistically significant for grade 1 of GS in men (p=0.02) and grade 2 of GS in women (p=0.02).
Conclusion: PsO patients with subclinical synovitis show lower serum levels of CXCL-10 than patients without it, as occurs in patients with established PsA. This finding confirms a close relationship between this biomarker and joint involvement in PsO and supports its potential use as a predictor marker in the preclinical phase of PsA.

SLE, Sjön's and APS - aetiology, pathogenesis and animal models

AB0112 IT IS SAFE AND EFFECTIVE TO USE HUMAN CXCL5 TO TREAT MURINE LUPUS

Keywords: Systemic lupus erythematosus, Cytokines and chemokines, Animal models

D. Guo[1], F. Lim[1], C. T. Ng[2,3], A. Low[2,3], X. Fan[1,3]. [1]*Singapore General Hospital, Clinical Translational Research, Singapore, Singapore*; [2]*Singapore General Hospital, Rheumatology and Immunology, Singapore, Singapore*; [3]*Duke-NUS Medical School, SingHealth Duke-NUS Medicine ACP, Singapore, Singapore*

Background: As a novel myeloid/neutrophil-targeting therapy for systemic lupus erythematosus (SLE), the therapeutic efficacy of administering mouse (*m*) CXCL5 to lupus-prone mice have been demonstrated by our group recently[1,2].
Objectives: The aim of this study is to examine the pre-clinical safety and establish the pharmacokinetic (PK) response of human (*h*)CXCL5 to ease the commercialization and bring our discovery from bench to bedside.
Methods: Immediate and accumulative liver and kidney toxicity were determined by alanine transaminase and aspartate transaminase activity and urinary albumin-to-creatinine ratio (ACR). *m*CXCL5 expression in major internal organs (e.g., kidneys, lungs, liver, heart, brain and spleen) was determined by immunofluorescent staining on snap-frozen sections. Whether administering *h*CXCL5 promoted cancer cell growth was examined in both *in vitro* and *in vivo* renal cell carcinoma models. Haematological toxicity and circulating immunity, cell counts for white blood cells, red blood cells, monocytes, neutrophils, T cells and B cells, were evaluated in both Institute of Cancer Research (ICR) healthy and MRL/lpr (Fas^{lpr}) lupus-prone mice. PK study of *h*CXCL5 was performed in both ICR healthy and Fas^{lpr} lupus-prone mice intravenously.
Results: Our study showed that it was safe to administer CXCL5. There was no liver or kidney toxicity or cancer inducing effects. There was no further inflammation caused by *h*CXCL5 administration. Major components of the immune system were also not compromised. PK study showed that blood endogenous *m*CXCL5 levels were not altered by exogenous *h*CXCL5 administration in ICR healthy mice, but increased in Fas^{lpr} lupus-prone mice. Blood exogenous *h*CXCL5 was only detectable within 24 hours post-administration and the peak levels were positively correlated with the administration dosage. Mice survival was improved and reversely correlated with administration dosage.
Conclusion: It is safe and effective to use *h*CXCL5 to treat murine lupus.

AB0113 CHRONIC STIMULATION WITH SARS-COV-2 SPIKE PROTEIN DOES NOT TRIGGER AUTOIMMUNITY

Keywords: COVID, Autoantibodies, Animal models

M. Scherlinger[1,2], J. Sibilia[1], G. Tsokos[2], J. E. Gottenberg[1]. [1]*Strasbourg University Hospital, Rheumatology, Strasbourg, France*; [2]*Beth Israel Deaconess Medical Center, Rheumatology, Boston, United States of America*

Background: Systemic autoimmunity is a complex and multifactorial process for which underlying mechanism are unclear. Several theories have been formulated to explain the development of autoimmunity, including excessive self-immunosurveillance, danger, and antigen discontinuity. The antigen discontinuity and the self-criticality theories presume that repetitive antigen exposure leads to a dysregulated immune response. Supporting these theories, Tsumiyama and Shiozawa have shown that repetitive immunization of BALB/c mice with ovalbumin induces auto-antibodies production and a glomerulonephritis with immune deposit resembling lupus nephritis [1]. These data prompted us to consider the potential impact of repetitive SARS-CoV-2 infection in the onset of autoimmune diseases in human. Indeed, since 2020, a large majority of the population has encountered SARS-CoV-2 antigens multiples times, either through vaccination or through infection/reinfection. Hence, we hypothesized that repetitive exposure to the SARS-CoV-2 spike antigen may induce autoimmunity in healthy individuals.
Objectives: Evaluate whether repetitive exposure to SARS-CoV-2 spike protein induces autoimmunity in mice.
Methods: We immunized intraperitoneally C57Bl/6 mice (n = 5/group) with recombinant SARS-CoV-2 spike protein (1µg per injection) or vehicle (phosphate buffered saline [PBS]); **Figure 1A**). The first injection was mixed with Alum as an adjuvant, and the other injections were diluted in PBS, administered intraperitoneally every 5 days, 16 times in total. Five days after the final injection, the mice were sacrificed to retrieve serum. We measured anti-spike and anti-dsDNA IgG using ELISA. The serum from 5 34-week-old C57Bl/6.lpr autoimmune mice were used as positive control. Briefly, 96-well plate were coated overnight with either spike protein (0.2µg/mL) or calf thymus DNA (0.1mg/mL; after precoating with poly-L-lysin 0.05mg/mL). After blocking with PBS-BSA, the diluted serum samples were incubated on the plate for 2 hours at room temperature. Plate-bound IgG were revealed using an alkaline phosphatase-conjugated anti-mouse IgG (1:5000). For anti-dsDNA IgG measurement, the serum of an autoimmune mice was used as a reference standard and the result expressed in unit per mL.
Results: After immunization, the phenotype of control and spike-immunized mice was clinically similar. All the immunized mice were exempt of proteinuria (**Figure 1B**). Only the mice which were injected with spike protein developed measurable amounts of anti-spike IgG as determined by ELISA, while those injected with PBS and the C57Bl/6.*lpr* mice did not (**Figure 1C**). None of the mice in the immunization group developed measurable anti-dsDNA IgG (**Figure 1D**).
Conclusion: In our study, the repetitive exposure of C57Bl/6 mice to the SARS-CoV-2 spike antigen did not lead to autoimmunity. Although these results are reassuring, large scale epidemiological studies are needed to evaluate the incidence of autoimmune diseases in individuals with multiple exposure to SARS-CoV-2 antigens.

AB0114 INCREASED EXPRESSION OF SEMAPHORIN 4A IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS ASSOCIATION WITH THE ACTIVITY OF LUPUS NEPHRITIS

Keywords: Systemic lupus erythematosus, Biomarkers, Animal models

Y. Choi[1], E. K. Lee[2], K. M. Kim[3], M. S. Lee[4], C. H. Lee[4], C. H. Chung[4], W. H. Yoo[1]. [1]*Jeonbuk National University Medical School, Internal Medicine, Jeonju, Korea, Rep. of (South Korea)*; [2]*Jeonbuk National University, Medical Science, Jeonju, Korea, Rep. of (South Korea)*; [3]*Jeonbuk National University Medical School, Pathology, Jeonju, Korea, Rep. of (South Korea)*; [4]*Wonkwang University Hospital, Internal Medicine, Iksan, Korea, Rep. of (South Korea)*

Background: Semaphorin (SEMA), initially identified as a neural guidance molecule, has been recently highlighted for its role in regulating the immune response.

Among seven categories of SEMA, Class 4A SEMA (SEMA4A) involves the T cell-mediated immune responses through the expression of itself in dendritic cells.
Objectives: This study aimed to investigate the expression of SEMA4A in systemic lupus erythematosus (SLE) and the association between the expression of SEMA4A and the activity of lupus in the lupus mouse model and patients with SLE.
Methods: The expression of SEMA4A was measured from peripheral blood mononuclear cells (PBMCs) in healthy controls and patients with SLE by polymerase chain reaction. Bone marrow-derived dendritic cells (BMDCs) and renal tissues from control mice and Toll-like receptor (TLR)-7 agonist (R848)-induced lupus mice were investigated for the expression of SEMA4A using western blotting and immunofluorescence assay. Immunohistochemistry was performed to examine the expression of SEMA4A in the kidney of the patients with SLE and they were analyzed according to the activity index of lupus nephritis.
Results: The expression of SEMA4A of PBMCs was elevated in the patients with SLE (n=20, 3.86±0.80) compared to those of healthy control (n=20, 1.0±0.37). SEMA4A is constitutively expressed by dendritic cells, so we analyzed the expression of SEMA4A in BMDCs of TLR-7 agonist (R848)-induced lupus murine group and control group. The SEMA4A was highly expressed in the BMDCs of the lupus group (2.06±1.67) compared to the control group (1.0±0.29). The immunocytochemistry also showed enhanced fluorescence intensity of SEMA4A in BMDCs of the lupus mouse group (19.57±1.37) compared to the control group (10.43±1.87). The kidneys, one of the main target organs of SLE, were analyzed for the protein level of SEMA4A in the murine lupus group and control group. The western blotting of the whole kidney and isolated glomeruli showed a marked expression of SEMA4A in the lupus group compared to the control group. The mean fluorescence intensity of SEMA4A in the kidneys of lupus mice was significantly enhanced compared to the control group (8.51±0.47 Vs. 3.75 ±0.13). In the analysis of immunohistochemistry of SEMA4A in the kidneys of the patients with SLE, the positivity of SEMA4A staining was markedly higher in lupus nephritis with higher activity score (≥10) (80%) compared to those of lupus nephritis with lower activity score (<10) (0%).
Conclusion: The expression of SEMA4A is significantly increased in the dendritic cells and kidneys of the lupus murine group and the patients with SLE compared to the control group. The expression of SEMA4A in the kidneys in the patients with SLE correlates with the severity of lupus nephritis. These results indicate the possible contribution of SEMA4A in the pathogenesis of SLE and the potential of targeting SEMA4A for the treatment of SLE.

AB0115 CD14+ MYELOID CELLS EXPRESS THE PDC MARKERS BDCA-2, BDCA-4, CD123 UPON DIFFERENTIATION IN BOTH HEALTHY INDIVIDUALS AND SLE PATIENTS

Keywords: Systemic lupus erythematosus, Innate immunity, Cell biology

A. Psarras[1,2], Z. Wigston[2], E. Vital[2,3]. [1]*University of Oxford, Kennedy Institute of Rheumatology, Oxford, United Kingdom*; [2]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [3]*Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Plasmacytoid dendritic cells (pDCs) are crucial mediators of the immune system linking innate and adaptive immune responses [1]. pDCs exhibit high expression of the IL-3 receptor (CD123) as well as other receptors such as BDCA-2 (CD303) and BDCA-4 (CD304). These molecules are used to identify pDCs in mechanistic studies and for therapeutic targeting. A recent clinical trial showed a reduction in interferon-stimulated gene expression and improvement in skin and joint inflammation in lupus patients who received treatment targeting BDCA-2 [2,3]. However, extensive functional and single-cell transcriptomic data have previously shown that pDCs are immunologically inert, not contributing to the type I IFN production seen in patients with systemic lupus erythematosus (SLE) [4,5].
Objectives: To investigate whether the markers BDCA-2, BDCA-4, CD123 are expressed by myeloid cells other than pDCs.
Methods: Peripheral blood mononuclear cells (PBMCs) were obtained from healthy individuals and patients with SLE. PBMCs were analysed fresh or after 24-hour in vitro culture using flow cytometry for the pDC markers. $CD14^+$ monocytes were purified from freshly isolated PBMCs by negative selection. For M1 differentiation, monocytes were cultured for 6 days in the presence of GM-CSF; IFN-γ and LPS were added on day 6 and the cells were incubated for additional 24 hours. For M2 differentiation, monocytes were cultured for 6 days in the presence of M-CSF; IL-4 and IL-13 were added on day 6 and the cells were incubated for an additional 24 hours. After a 7-day culture, M1 and M2 cells were collected, stained for flow cytometry, and analysed using CytExpert (Beckman Coulter) software.
Results: On freshly analysed PBMCs, the expression of BDCA-2 and BDCA-4 was unique to pDCs in healthy controls. CD123 expression was also seen in a subset of $CD14^+$ monocytes as well as in $CD3^-CD19^-CD14^-CD11c^-HLA\text{-}DR^-$ cells. In some SLE patients, $CD14^+$ cells presented positive expression of BDCA-2, although at a lower level compared to pDCs ($CD3^-CD19^-CD14^-CD11c^-HLA\text{-}DR^+CD123^{high}$). After 24-hour in vitro culture, $CD14^+$ cells from both healthy and SLE patients presented strong expression of BDCA-2, BDCA-4, and CD123. After purification of $CD14^+$ cells and differentiation to either M1 ($CD14^+CD16^+CD206^+CD80^{high}CD163^{low}$) or M2 ($CD14^+CD16^+CD206^+CD80^{low}CD163^{high}$) phenotype, positive expression of these markers was seen. M1 macrophages showed high expression of BDCA-2 and BDCA-4 and almost universal expression of CD123. In contrast, M2 macrophages showed a meagre expression of BDCA-2 but universal expression of BDCA-4 and CD123.
Conclusion: We show that the BDCA-2, BDCA-4, CD123 markers -previously thought to be expressed exclusively by pDCs- are also expressed by differentiated $CD14^+$ myeloid cells in both healthy controls and patients with SLE. These findings can limit the significance of those markers to identify pDCs in tissue samples by simple immunohistochemistry. Finally, as monocytes have been shown to be the primary contributor to the interferon signature in blood, these data may explain how therapeutic targeting of BDCA-2 and related markers can impact disease activity and interferon activity in SLE patients.

AB0116 EVALUATING THE IMPACT OF METFORMIN TARGETS ON THE RISK OF SYSTEMIC LUPUS ERYTHEMATOSUS: A MENDELIAN RANDOMIZATION STUDY

Keywords: Systemic lupus erythematosus, Genetics/Epigenetics

L. L. Zheng[1,2], Y. X. Chen[1,2], C. Wang[2,3], M. J. Chang[2,3], S. X. Zhang[1,2], Q. Yu[4], P. F. He[5]. Background: Metformin is a biguanide oral hypoglycemic agent that is widely used as a first-line drug treatment for type II diabetes. In addition, metformin is also used in the treatment of certain autoimmune diseases, such as systemic lupus erythematosus (SLE). It plays a key role in the pathogenesis of SLE through pathways such as inhibiting type 1 IFN, regulating T effector cells and proinflammatory cytokines[1]. However, the causal relationship of the metformin-related targets on the risk of SLE is still unclear.
Objectives: The purpose of this study was to assess the causal effect of metformin targets (AMPK, MCI, MG3, GDF 15 and GLP 1/ GCG) on the risk of SLE using Mendelian randomization (MR).
Methods: Genetic variants including downstream and 100 kb upstream of encoding five genes were selected as candidate tool variants. The SNP was further screened as in low linkage disequilibrium ($r2 < 0.3$) and associated with HbA 1 c ($P \leq 0.05$). The Genome-wide association study (GWAS) of HbA 1 c comes from the Meta-Analyses of Glucose and Insulin-related traits Consortium (MAGIC) (n = 88,355)[2]. The SLE data (ncase = 5,201, ncontrol = 9,066) are pooled from publicly available GWAS. Two-sample MR was performed using inverse variance weighted (IVW), MR-Egger, and weighted median (WM) to obtain causal estimates of metformin-related targets and risk of SLE. In addition, sensitivity analysis, outlier (MR-PRESSO) and leave-one-out analysis were conducted to test the heterogeneity and level pleiotropy of the results.
Results: Genetically predicted increase in HbA1c instrumented by GDF 15 variants was associated with increased risk of SLE (GDF 15[p = 0.028]). However, genetically predicted AMPK, MG3, MCI, and GLP 1/ GCG were not associated with SLE risk (AMPK [p = 0.122], MG3 [p = 0.105], MCI [p = 0.762], GLP 1/ GCG [p = 0.361]) (Figure 1). No outlier between GDF 15 and the risk of SLE was identified via the MR-PRESSO test. The leave-one-out analysis verified the robustness of the outcomes.
Conclusion: This study suggests that the GDF 15 gene may be a plausible mechanism of action to reduce the risk of SLE and provides critical evidence to guide future clinical trials of metformin.

AB0117 **ASSOCIATION OF AUTOANTIBODIES WITH THE IFN SIGNATURE AND NETOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

Keywords: Autoantibodies, Systemic lupus erythematosus, Innate immunity

E. Kaan[1,2,3], T. Brunekreef[2], J. Drylewicz[1], L. Van den Hoogen[1,2], H. Leavis[1,2], J. M. Van Laar[2], M. Van der Vlist[1,3], H. Otten[1], M. Limper[2]. [1]*University Medical Center Utrecht, Center for Translational Immunology, Utrecht, Netherlands*; [2]*University Medical Center Utrecht, Department of Rheumatology & Clinical Immunology, Utrecht, Netherlands*; [3]*Oncode Institute, Oncode Institute, Utrecht, Netherlands*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by a variety of disease symptoms and an unpredictable clinical course. SLE can lead to premature death as the result of disease activity or because of treatment side effects. This underlines the urgency to identify patients at risk for a complicated disease course, and the need to tailor therapy. Stratification based on immunological manifestations such as autoantibodies, upregulation of type I interferon (IFN) regulated genes (IFN signature) and neutrophil extracellular trap (NET) formation via NETosis can help to improve treatment outcome in SLE.
Objectives: Here we study the association between SLE-related autoantibodies, the IFN signature and NET formation in patients with SLE, which could lead to improved tools for patient stratification and more targeted treatment options.
Methods: We studied the association between the IFN signature and plasma induced NET formation with 57 autoantibodies in 25 patients with SLE. The presence of an IFN signature was determined using the sum of standardized mRNA expression of IFI44L, IFITM1, SERPING1, and LY6E in monocytes from SLE patients. Plasma induced NET formation was studied with quantitative live imaging. The threshold for the presence of an IFN signature or NET formation were both set at 2 SD above the mean of a group of healthy controls. With principal component analysis (PCA) and hierarchical clustering we associated autoantibody concentrations with the IFN signature and NET formation. This study was a separate analysis from larger cohorts, of which results have been previously published.[1,2]
Results: We observed two distinct clusters with the PCA: one cluster contained mostly patients with an IFN signature, and another cluster contained a mix of patients with (IFN) and without (noIFN) an IFN signature. Patients with (NET) and without (noNET) plasma induced NET formation were equally distributed between the clusters. PC1 explains 22.7% of total variability, and is mainly driven by antibodies against histones, RibP2, RibP0, EphB2, RibP1, PCNA, dsDNA, and nucleosome. Hierarchical cluster analysis confirmed the two clusters (Figure 1). In addition, we found a trend towards increased concentrations of autoantibodies against EphB2, RibP1, and RNP70 in patients with an IFN signature. We found a negative correlation of NET formation with anti-FcER and anti-PmScl100.
Conclusion: We identified a subgroup of patients with an IFN signature who express increased concentrations of antibodies against DNA and RNA-associated proteins. We did not find positive associations between autoantibodies and plasma induced NET formation. Our study further strengthens the evidence of a correlation between RNA-binding autoantibodies and the IFN signature. As the IFN signature currently is not part of the standard follow-up for patients, partially due to its associated costs, a profile of DNA and RNA-binding autoantibodies might be used for patient stratification, especially related to anti-IFN treatment.

[2]*University Hospital La Princesa, Rheumatology Deparment, Madrid, Spain*;
[3]*University Hospital La Princesa, Pulmonology Deparment, Madrid, Spain*

Background: Rheumatic diseases are generally diagnosed in advanced stages. Systemic lupus erythematosus (SLE) are systemic inflammatory autoimmune disease characterized by presence of autoantibodies against DNA and nuclear proteins and a wide variety of clinical symptoms **(Fava 2019, Wang 2019)**. Actually, it has not curative treatment **(Mathias 2020)**. Therefore, the search for biomarkers for SLE diagnosis in earlier stages and its derived complications is mandatory **(Thanou 2021, Wan 2018)**. Adhesion molecules are crucial to leukocytes infiltration to inflammation sites **(Ponthieux 2004, Ivetic 2019, Tinoco 2017)**, thus they play an important role in autoimmune diseases and have been suggested as a useful markers of diagnosis and prognosis in rheumatic disease **(Gonzalez-Tajuelo 2017, Skeoch 2014, da Rosa Franchi 2018)**.
Objectives: To study the possible involvement of adhesion molecules in the development of disease, we have analysed the pattern of PSGL-1 serum levels together with its main ligands P- E- and L-selectins and ADAM8 in SLE patients.
Methods: Serum samples from 52 SLE patients, 36 inactive (iSLE) and 16 active (aSLE) and 55 healthy donors (HD) sex and age matched per group were collected and proteins levels were measured by available ELISA kits: Human PSGL-1/CD162 kit (Novus Biologicals, Colorado, USA), Human Selectins/CD62 kits CD62E, CD62L and CD62P (Diaclone, France), and Human ADAM8 (A Disintegrin And Metalloprotease 8) Kit (Elabscience, Texas, USA).
Results: SLE patients showed a statistically significant increase of PSGL-1, E-Selectin and ADAM8 and decrease of L-Selectin serum levels with respect to HD. No difference were observed between inactive and active SLE patients. Patients with anti-dsDNA and/or anti-SSA autoantibodies showed lower serum level of PSGL-1 and higher level of L-Selectin and ADAM8 compared to patients with absence of these autoantibodies. Importantly, the expression profile study of these proteins revealed that L-Selectin/ADAM8 ratio in SLE patients is a good predicted marker in a multivariable binary logistic regression model (OR=1,701, CI:1,188-2,450, p<0.005). Receiver operating characteristic (ROC) curve presented an area under curve (AUC) of 0.80 and the optimal cut off value maximizing sensitivity (98%) and specificity (48%) jointly corresponded to ratio<2,06. In this model the 97% of patients were correctly grouped.
Conclusion: SLE patients show significantly different serum levels of PSGL-1, E-Selectin, L-Selectin and ADAM8 with respect to healthy controls. This specific profile of serum protein levels could be a potentially valuable tool for the early diagnosis of SLE.

EVALUATION OF P-GP AND MRP-1 EXPRESSION ON PLASMA CELLS AND TH17 LYMPHOCYTES IN PERIPHERAL BLOOD AND BONE MARROW OF LUPUS NEPHRITIS

Keywords: Adaptive immunity, Systemic lupus erythematosus, Kidneys

K. Singh[1], D. P. Misra[1], S. Katiyar[2], V. Agarwal[1]. [1]*Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Clinical Immunology and Rheumatology, Lucknow, India*; [2]*Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Hematology, Lucknow, India*

Background: P-glycoprotein (p-gp) and multidrug resistance protein 1 (MRP-1) contribute towards resistance to glucocorticoids and/or immunosuppressive drugs in lupus nephritis (LN). Long-lived plasma cells (PCs) persistently produce antibodies and are resistant to most immunosuppressive therapies including B-cell depletion. Elevated T helper 17 lymphocytes (Th17) are associated with resistant LN phenotypes. We hypothesize the overexpression of p-gp and MRP-1 on these two cell types which might eventually contribute towards drug-resistant phenotype in LN.
OBJECTIVES:
1.To evaluate the frequency of peripheral blood PCs and Th17 cells expressing p-gp and MRP-1 in LN compared with healthy controls (HCs).
2.To evaluate the frequency of PCs expressing p-gp in bone marrow of LN.
Methods: Patients with LN fulfilling the 2019 ACR/EULAR classification criteria and HCs were recruited after written informed consent. p-gp and MRP-1 expression on peripheral PCs (CD45+ CD138+), p-gp expression on Th17 (CD4+ IL-17+ p-gp), Th1 (CD4+IFN-γ), Th2 (CD4+ IL-4) and regulatory T lymphocytes (Tregs, CD4+ CD25+ FoxP3+) were determined using flowcytometry (BD FACS Canto II). Proportions of T lymphocytes were normalized to Tregs. Frequencies of P-gp+ PCs were enumerated in bone marrow aspirate of two patients and one control. Results were expressed as median (interquartile range, IQR). Intergroup comparisons were performed with Mann-Whitney U test. p-value were corrected for multiple testing using Bonferroni-Sidak method. Statistical significance was set at p<0.05.
Results: Twenty-one LN [17 females, median (interquartile range – IQR) age 26 (23.25-35) years] and 10 controls [7 females, median (IQR) age 28 (27–31) years] were recruited. Of 21 LN, 13 had active disease (66% had low complements, 59% had elevated anti-dsDNA). Median SLEDAI-2K score of LN patients was 12 (2-21). In peripheral blood, overall PCs as well as PCs expressing P-gp or MRP-1 were increased in LN than in HC. Th17/Tregs ratio, p-gp-expressing Th17 lymphocytes and MRP-1-expressing Th17 lymphocytes were significantly increased in LN compared to HC (Table 1). p-gp expressing Th17 lymphocytes and PCs were significantly increased in active LN than in inactive LN (Table 1). As an exploratory analysis, p-gp-expressing PCs were more prevalent in bone marrow aspirate of LN than non-lupus controls (Figure 1).
Conclusion: We observed for the first time an increased frequency of P-gp and MRP-1-expressing PCs and Th17 lymphocytes in the peripheral blood of LN, which were also associated with disease activity. Whether these cell populations contribute to refractory LN requires evaluation.

Table 1. Peripheral blood cell populations in LN and HC

DIFFERENT PATTERNS OF LONGITUDINAL CHANGES IN ANTINUCLEAR ANTIBODIES TITRES IN CHILDREN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Autoantibodies

P. Morán Álvarez[1], C. Bracaglia[1], V. Messia[1], L. Giovannelli[2], I. Caiello[1], F. De Benedetti[1], E. Marasco[1]. [1]*Ospedale Pediatrico Bambino Gesù, Pediatric Rheumatology, Rome, Italy*; [2]*Ospedale Pediatrico Bambino Gesù, Immunological Laboratory, Rome, Italy*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by the presence of antinuclear antibodies (ANA). Monitoring of anti-DNA antibody levels may reflect disease activity, by contrast a single anti-RBP antibody determination is thought to suffice for clinical purposes. Recent data suggests that ANA levels may decrease over time secondary to the natural history or to treatments.
Objectives: To investigate the trend of ANA and anti-dsDNA titers over time in children with a diagnosis of SLE.
Methods: We enrolled 15 children with SLE. ANA and anti-dsDNA testing were carried out in all patients from diagnosis every 3-4 months for 2 years. ANA were defined as negative for titers < 1:80. Laboratory parameters, clinical and demographic data was retrieved and analyzed. Interferon Gene Signature (IGS was assessed by the expression of 6 interferon-induced genes (IFI27, IFI44L, IFIT1, ISG15, RSAD2, SIGLEC1) in whole blood RNA. Statistical analysis was performed with SW R_v. 4.0.3.
Results: Following 2 years of follow-up, all patients had ANA titers significantly lower than at time of the onset (MWW, p=0.0002) (Figure 1A). After two years of follow-up, 11 patients (73%) remained ANA positive (group 1), while 4 patients (26%) became negative (group 0). At time of diagnosis no significant differences in ANA titers (MWW, p=0.74) nor in disease activity, measured by SLEDAI, (MWW, p=0.88) were observed (table 1; Figure 1E). No significant differences in organ involvement were observed (Table 1). Assessing the change over time in ANA titers, the 2 groups of patients showed 2 different patterns: in group 0, ANA titers quickly declined and disappeared in the first 6 months after diagnosis; in group 1, ANA titers declined more slowly, remaining positive at 2 years (Figure 1C). ANA pattern (by IFA) was also evaluated, changes from homogenous pattern to speckled was observed during follow up (Figure 1B). Both C3 and C4 increased, with no different patterns between the 2 groups (Figure 1D). Similarly, anti-dsDNA antibodies titers declined over time with no clear different patterns between the groups (Figure 1C). We also analyzed the levels of IGS at last of follow-up, observing significant differences between the groups (MWW, p=0.018) with higher levels of IGS in ANA+ patients (Figure 1F).
Conclusion: Our analysis showed 2 different patterns in the reduction of ANA titers over time in children with SLE, with 26% of them becoming ANA negative after 6 months from diagnosis and remaining persistently negative during follow-up. Our data have important implications, specifically for the recruitment of patients into clinical trials, where the latest classification criteria of SLE require ANA positivity as entry criterion. A seronegative state may represent a different subcategory of patients with SLE with specific pathogenetic pathways, possibly independently from autoantibodies. Therefore, further studies are needed to confirm our data.

MULTI-OMICS ANALYSIS REVEALS COX5A AS A BIOMARKER OF DISEASE ACTIVITY AND ORGAN DAMAGE OF LUPUS

Keywords: Systemic lupus erythematosus, Biomarkers

M. Cai[1], Y. Qin[1], Z. Chen[1]. [1]*The First Affiliated Hospital of USTC, Department of Rheumatology and Immunology, Hefei, China*

Background: Systemic Lupus Erythematosus (SLE) is a heterogeneous systemic autoimmune disease with protean clinical manifestations[1]. Although the long-term outcome of patients with SLE has been greatly improved, increased organ damage is associated with poor prognosis in a number of patients. The type I interferon signature, a hallmark of SLE, is not an ideal treatment target or outcome predictor[2, 3], suggesting other critical immunological pathways might contribute to disease pathogenesis.
Objectives: To explore key immunological pathways and gene markers in SLE more precisely, we performed a systematic analysis of transcriptional data from 27 immune cells in the blood and from single cells in the skin and kidney.
Methods: We included a large RNA-seq data from a total of 64 SLE and 62 control with 27 immune cells. Integrated analyses were conducted to find key pathways and driver genes in SLE pathogenesis. The expression of COX5A between SLE phenotypes was compared in two independent cohorts. Single-cell RNA sequencing(scRNA-seq) data from skin and kidney were used to further determine the association of COX5A expression with organ damage.
Results: We found that lymphocytes in SLE showed an overall active immuno-metabolic state when compared to healthy controls, and oxidative phosphorylation (OXPHOS) is the most significant metabolic pathway that differs between SLE and HC, especially for effector T cells. Besides, the OXPHOS enrichment score was significantly correlated with IFN response molecular signature across various T cell subtypes. Particularly, we identified an OXPHOS hub gene, COX5A, as a key driver in SLE T cells. COX5A expression was significantly higher in effector T cells than those in naïve T cells and showed associations with SLE clinical phenotypes including disease activity index, flare, and organ damage. Furthermore, we revealed that high expression of COX5A in T cells contributes to skin and kidney involvement of SLE through scRNA-seq analysis.
Conclusion: Our results identified OXPHOS signature is a prominent feature in SLE T cells. The key gene of OXPHOS, COX5A, showed associations with IFN response molecular signature, severity, skin, and kidney involvement of SLE, which supported that COX5A as a potential candidate biomarker of severity and organ damage of SLE.

ANTI-HISTONE AND ANTI-NUCLEOSOME ANTIBODIES, RATHER THAN ANTI-DSDNA ANTIBODIES ARE ASSOCIATED WITH INTERFERON-INDUCED BIOMARKERS IN SUDANESE AND SWEDISH SLE PATIENTS

Keywords: Cytokines and chemokines, Autoantibodies, Systemic lupus erythematosus

S. Elbagir[1], N. A. Mohammed[2], V. Oke[3], A. Zickert[3], A. Larsson[4], J. Nilsson[5], A. Elshafie[1], A. Svanqvist[1], C. Westerberg[1], E. M. Elagib[6], M. A. M. Nur[7], I. Gunnarsson[3], E. Svenungsson[3], J. Rönnelid[1]. Background: Antibodies against double stranded DNA (anti-dsDNA) can induce production of interferon-alpha and other cytokines after forming immune complexes. In SLE, anti-dsDNA often exists together with autoantibodies against other chromatin components, like histones and nucleosomes. These antibodies are known to characterize a SLE subgroup with early disease onset and increased occurrence of nephritis.
Objectives: We investigated how anti-nuclear autoantibody (ANA) specificities associate with pro-inflammatory cytokines in two ethnically different cohorts of SLE patients, from Sudan and Sweden.
Methods: We included 93 Sudanese and 480 Swedish SLE patients. Serum levels of autoantibodies against dsDNA, Sm, the Sm/U1RNP complex, U1RNP, SSA/Ro52, SSA/Ro60, SSB/La, ribosomal P, PCNA and histones were quantified with a bead-based multiplex immunoassay; with positive reactions determined as above the 98th percentile among respective national controls. In the Swedish cohort another bead-based multiplexed immunoassay including anti-nucleosome antibodies was also used. Relative levels of 73 plasma biomarkers were determined with Proximity Extension Assay technique except for Interferon gamma-induced protein (IP-10) in the Swedish cohort that was quantified by ELISA. Adjusted p values were considered significant when <0.05.
Results: Among Sudanese patients, levels of 5/73 biomarkers showed significant associations to ANA-associated antibodies. Anti-histone antibodies showed the strongest positive correlations with interferon-inducible factors (monocyte chemoattractant protein [MCP-1] and IP-10), monocyte chemoattractant protein-3 (MCP-3) and S100 calcium-binding protein A12 (S100A12), and negative correlation with stem cell factor (SCF); R^2(P values) were 0.15(0.04), 0.18(0.008), 25(0.0001), 0.13(0.04) and 0.31(<0.0001) respectively. Biomarker associations remained significant for anti-histone antibody after adjustment for age and sex. Also, anti-dsDNA antibodies associated with MCP-3 (0.13(0.04)), IP-10 (0.13(0.03)) and S100A12 (0.13(0.04)), but when combining with anti-histone in the same regression model, anti-dsDNA associations were lost while anti-histone antibodies remained. Positive associations with lower R^2 values were found also for anti-ribosomal P antibodies with MCP-1, MCP-2 and C-C motif ligand 19 (CCL-19), and for anti-Sm with IP-10. Validation analysis among Swedish patients for MCP-1, IP-10, SA100A12 also demonstrated significantly stronger associations to anti-histone and anti-nucleosome antibodies compared to anti-dsDNA and other ANA specificities, and in combined regression models, anti-dsDNA either became non-significant or considerably less significant than anti-histone/nucleosome antibodies. When excluding anti-histone or anti-nucleosome positive patients, the associations between interferon-inducible factors MCP-1/IP-10 and anti-dsDNA were lost. In contrary, when excluding anti-dsDNA positive patients, associations with anti-histone and anti-nucleosome remained significant. SA100A12 associations with anti-dsDNA antibodies remained significant after exclusion of anti-histone positive patients, but were lost when excluding anti-nucleosome positive patients.
Conclusion: Using uni- and multi-variate analyses as well as patient stratification, levels of mainly IFN-induced inflammatory biomarkers correlate strongest with anti-histone and anti-nucleosome antibodies compared to other ANA specificities including anti-dsDNA. Our results, from two lupus cohorts with different ethnicities, suggest that autoantibodies against DNA-complexes or DNA-associated proteins rather than anti-dsDNA antibodies per se may drive the induction of the interferon signature in SLE.

ENTEROCOCCUS GALLINARUM IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS.

Keywords: Descriptive studies, Outcome measures, Systemic lupus erythematosus

L. F. Vega Sevilla[1], O. E. Alvarez-González[1], J. C. Riega-Torres[1], D. C. Rubio Torres[1], C. M. Skinner Taylor[1], L. Vera Cabrera[2], J. A. Cardenas-de la Garza[1], M. A. Aguilera Valenciano[2], W. Escalante[2], H. Guerra[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*; [2]*Hospital Universitario "Dr. José Eleuterio González", Dermatology, Monterrey, Mexico*

Background: Systemic Lupus Erythematosus (SLE) is associated with epithelial defects and disrupted intestinal barrier, risking bacterial translocation and promoting systemic inflammation, known as dysbiosis, which is associated with increased disease activity [1]. *Enterococcus gallinarum* has been previously linked to gastrointestinal autoimmune diseases, like autoimmune hepatitis and primary sclerosing cholangitis. [2] However, little is known about *E. gallinarum* prevalence in SLE.
Objectives: To describe the prevalence of *E. gallinarum* in SLE stool samples, as well as clinical and laboratory characteristics.
Methods: A cross-sectional, descriptive study was conducted at the University Hospital ¨Dr. José Eleuterio González¨, in northern Mexico. We included adult patients who met current criteria for SLE and had recent (<3 months) paraclinical routine tests, including acute phase reactants. Patients with other autoimmune

diseases, chronic infections, pregnancy, cancer, abdominal surgery or gastrointestinal bleeding were excluded. Demographic, clinical data, as well as Anti-nuclear antibodies and complement were obtained from records. No participant received antibiotics, probiotics or synbiotics 3 months prior to the study. DNA was extracted with the DNeasy PowerLyzer PowerSoil DNeasy kit, Qiagen (Hilden, Germany) according to the manufacturer's specifications. *E. gallinarum* was detected by endpoint polymerase chain reaction essay.

Results: Sixty patients were included, where most subjects were women (51, 85%). Mean age was 41.79 (± 16.6) and time of diagnosis 107.03 months (± 95.46). *E. gallinarum* and *Enterococcus spp* were found in 7 (11.6%) cases. The most frequent MEX-SLEDAI parameter was arthritis in 34 (56.6%) cases, followed by acute cutaneous lupus in 23 (38.3%). Clinical manifestations and paraclinical findings are shown in Table 1. We found a significant difference in *E. gallinarum* positive patients in creatinine levels (0.98 vs 0.72, *p* 0.032), ESR (11.14 vs 19.49, *p* 0.031) and frequency of serositis (57.14% vs 7.54%, *p* 0.001). When analyzing ESR by age-adjusted upper limit, significance was lost (*p* 0.4)

Conclusion: Prevalence of *E. gallinarum* in SLE stool samples was 11.7%. Serositis, higher mean creatinine and lower mean ESR was more common in *E. gallinarum* positive subjects. Further research is needed to better understand *E. gallinarum* dysbiosis in SLE.

DIMETHYL FUMARATE MODULATES T CELL METABOLISM AND FUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENT SAMPLES

Keywords: Systemic lupus erythematosus

L. Kell[1], S. Taylor[1], K. Shah[1], R. De Maeyer[1], D. Isenberg[1,2], M. Castelino[1,2], G. Cambridge[1], D. Sen[1,2], M. J. Leandro[1,2], A. Akbar[1], V. Reddy[1,2]. [1]*University College London, Rheumatology, London, United Kingdom*; [2]*University College Hospital, Rheumatology, London, United Kingdom*

Background: Activated T cells make a significant contribution to inflammation in systemic lupus erythematosus (SLE). Their ability to secrete proinflammatory cytokines and express activating NK receptors allows them to mediate inflammation. We know that cellular metabolism regulates the activation of T cells. A phase II study has reported on efficacy of DMF in cutaneous lupus [1]. Evidence from patients with multiple sclerosis indicates that dimethyl fumarate (DMF), an electrophile, targets cellular metabolism to modulate T cell activation and function [2]. However, the potential of DMF to modulate T cell metabolism and activation in SLE is not known.

Objectives: We investigated whether DMF modulates T cell metabolism, activation and function in samples from patients with SLE in a series of in vitro experiments.

Methods: All experiments were performed using isolated T cells from freshly drawn whole blood samples from patients with SLE. T cells were isolated using negative selection using Stem cell or Miltenyei magnetic bead separation kit. Isolated T cells were activated with anti-CD3 and IL-2 and incubated with either DMF at 25μM concentration or DMSO alone for three or seven days at 37°C and 5% CO2 before harvesting and analysing on BD FACS flow cytometer. Analysis of cytokines in supernatants was performed using cytometric bead arrays. Flow jo software was used to analyse flow cytometry files. Graph Pad Prism software was used to perform statistical analysis.

Results: In Seahorse experiments, after three days of incubation dimethyl fumarate (DMF) inhibited the oxygen consumption rate (OCR) and extra cellular acidification rate (ECAR) in isolated T cells when compared with samples incubated with vehicle, dimethyl sulfoxide (DMSO). Our results revealed that DMF significantly inhibited: 1) aerobic glycolysis and oxidative phosphorylation in activated CD4+T cells from patients with SLE (n=4), in vitro; 2) T cell activation and proliferation as assessed by a reduction in the frequency of CD69 (n=4) and Ki67 (n=2) positivity, respectively. Collectively, these results suggest that DMF inhibits T cell activation and proliferation in samples from patients with SLE. After 7 days of incubation, DMF significantly inhibited the expression of activating NK receptors CD158a and NKG2D on CD4+T cells whereas DMF seemed to have a trend toward enhancing the expression of inhibitory NK receptors NKG2A and CD158b (n=6). After 7 days of incubation, DMF significantly reduced CD4+T cell intracellular expression of IFN-γ, TNF-α, IL-17 and secretion of pro-inflammatory cytokines IFN-γ and TNF-α in supernatants (n=6).

Conclusion: Our data indicated that DMF modulates metabolic programming, both glycolysis and oxidative phosphorylation, to inhibit activation, proliferation, and secretion of proinflammatory cytokines from CD4+T cells from patients with SLE. These results provide strong mechanistic rationale for considering dimethyl fumarate as a novel therapeutic agent to treat systemic lupus erythematosus.

SPECIFIC AUTOANTIBODY CONTENT OF CIRCULATING IMMUNE COMPLEXES IN SLE – PHENOTYPIC CHARACTERIZATION AND CLINICAL ASSOCIATIONS

Keywords: Biomarkers, Autoantibodies, Systemic lupus erythematosus

E. Fuzzi[1], A. Svanqvist[2], C. Westerberg[2], A. Zickert[1], I. Gunnarsson[1], J. Rönnelid[2], E. Svenungsson[1]. [1]*Karolinska Institutet, Division of Rheumatology, Department of Medicine, Solna, Sweden*; [2]*Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, Sweden*

Background: Systemic Lupus Erythematosus (SLE) is characterised by autoantibody production and immune complex (IC) formation. The relative abundance of different autoantibodies within circulating ICs as compared to serum in SLE is hitherto unclear; moreover, the clinical relevance of the IC-carried fraction of SLE-specific and associated autoantibodies is mostly unknown.

Table 1.

	Anti-Ro52 IC + %	Anti-Ro60 IC + %	Anti-SSB IC + %	Anti-Sm IC + %	Anti-U1RNP IC + %	Anti-dsDNA IC + %	Anti-Histone IC + %
Anti-Ro52+ sera n= 139	**84.9%**	90.6%	56.8%	17.9%	23.7%	12.2%	16.5%

Anti-Histone+ sera n=160	32.5%	42.5%	23.8%	19.4%	30.6%	21.9%	**38.1%**

Objectives: To investigate cross-sectionally the IC-derived fraction of SLE specific and associated antibodies, together with the total circulating C1q-binding immune complex (CIC) levels, in a large well-characterized SLE cohort.
Methods: We studied n=530 consecutive SLE patients (≥ 4 ACR 1982 revised criteria for SLE) who received care at a tertiary referral center for SLE. All participants gave written informed consent for inclusion. The control population consisted of region of residence, age and sex-matched controls (n=192) and n=200 local experimental controls. ACR criteria (at study inclusion), SLEDAI scores, clinical and laboratory variables were obtained at inclusion and through medical file review. At inclusion, fasting blood was drawn from an antecubital vein and was processed to serum, which was stored at -80°C. To obtain IC-derived antibodies, a novel validated method, described in detail elsewhere[1], was employed. Briefly, sera were incubated with C1q-coated beads; the C1q-bound ICs were then eluted through two sequential washes with an acidic and alkaline solution respectively, yielding disassembled IC eluates with conserved antibody specificity. Antibody levels of Anti-dsDNA, Anti-Histone, Anti-Sm, Anti-U1RNP, Anti-Ro52, Anti-Ro60, Anti-SSB were measured in IC eluates and in serum with a bead-based multiplex assay. CIC levels were measured with a commercial ELISA according to the manufacturer's instructions. Parallel analyses of autoantibody levels in serum and in IC eluates were performed on the same day. The results were reported on a standard curve; the 98th percentile of the standard curve values of control sera were set as the threshold for positivity for binary analyses.
Results: CIC levels were higher and more widely dispersed in SLE patients than controls (p<0.0001). A higher CIC load was associated with nephritis, arthritis and SLEDAI > 6 (p<0.0001). Among autoantibody specificities, Anti-dsDNA in serum was independently associated with a high CIC load (OR 4.8, 95% CI 2.5-9.5, p<0.0001, see also Figure 1). Concordance between serum and IC-eluate positivity varied strongly among autoantibody specificities, being highest for Anti-SSA/SSB, and lowest for Anti-dsDNA (Table 1). Among serum Anti-dsDNA+ patients, carriers of Anti-dsDNA from ICs displayed higher Anti-dsDNA titers, lower complement levels, and higher SLEDAI scores (p<0.01 for all).
Conclusion: Different autoantibodies are differentially represented in circulating ICs in SLE. Anti-dsDNA in serum is an independent marker of a higher CIC load, carrying facets of a more IC-mediated disease. Patients with elevated Anti-dsDNA in IC eluates, compared to anti-dsDNA only in serum, are a more clinically and biologically active subset, showing promise of IC-derived Anti-dsDNA as a potential SLE biomarker.

EXPRESSION OF B2 MICROGLOBULIN IN SALIVARY GLAND EPITHELIAL CELLS OF PATIENTS WITH SJOGREN SYNDROME

Keywords: Sjögren syndrome, Biomarkers

E. Simoncelli[1], S. Colafrancesco[1], C. Barbati[1], G. Buoncuore[1], R. Izzo[1], C. Alessandri[1], F. Conti[1], R. Priori[1,2]. [1]*Sapienza University of Rome, Rheumatology Unit, Department of Clinical Internal, Anaesthesiologic and Cardiovascular Sciences, Rome, Italy*; [2]*Unicamillus, Saint Camillus International University of Health and Medical Science, Rome, Italy*

Background: Salivary glands epithelial cells (SGECs) activation and loss of homeostasis play a key role in primary Sjogren Syndrome (pSS) [1]. High serum and saliva levels of β2-mycroglobulin (β2-M) have been described [2] in pSS, however, the exact origin of this molecule is still unclear. Our preliminary data from single cell analysis on pSS salivary glands treated with immunosuppressors show a downregulation of this protein in SGECs following treatment.
Objectives: Aim of this study is to evaluate the expression of β2-M in pSS SGECs and to dissect its modulation in inflammatory conditions.
Methods: To mimic the inflammatory microenvironment of pSS, a human salivary gland (HSG) cell line was treated (48h) with 1) Poly-I:C (40 µg/ml), 2) LPS (50 µg/ml), 3) culture medium (untreated). The HSG expression of β2-M (Ab anti-β2-M) was evaluated by flow cytometry along with the expression of apoptotic [(annexin V (MBL)] and activation [ICAM-1 (Ab anti-CD54)] molecules. Ex vivo expression of β2-M was then assessed in SGECs deriving from both pSS patients (n=3) and sicca (controls) (n=3).
Results: In the HSG cell line treated with both Poly I:C and LPS a significant increase in β2-M was documented [mean fluorescence index (MFI): untreated=1 (1-1), Poly-I:C=2.46 (1.5-3.9), LPS=1.3 (1-1.3); p=0.003]. The increased expression of β2-M was paralleled by an increase in ICAM-1 (MFI: untreated=1 (1-1), Poly-I:C=1.61 (1-2.5), LPS=1.26 (1-1.2); p=0.06) and annexin V (mean%: untreated=7.6% (5-9), Poly-I:C=14.3% (9-18), LPS=8% (6-11); p=0.003). In SGECs from pSS a higher expression of β2-M was detected as compared to controls (MFI: pSS=2.5 (2-3) vs sicca=1 (0.5–1.5) (Figure 1).
Conclusion: Our preliminary data suggest that β2-M is actively expressed by SGECs in pSS and that its exposure is driven by the local inflammatory milieu. Such expression is particularly interesting in view of the already demonstrated capacity of β2-M to activate pro-inflammatory pathways and to influence cellular viability and autoantigens exposure [3]. Functional studies are currently ongoing to dissect the potential pathogenic role of β2-M in pSS.

ANTIGENIC ASSESSMENT FOR THE B2GPIOX-PF4 COMPLEX IN A MONOCENTRIC COHORT OF PATIENTS WITH APS, THROMBOSIS DURING SARS-COV-2 INFECTION AND VITT

Keywords: Autoantibodies, Vaccination/Immunization, Anti-phospholipid syndrome

F. M. Ucci[1], F. Villani[2], A. Capozzi[3], M. De Michele[4], S. Truglia[1], S. Mancuso[1], L. Rapino[1], G. Tripodi[1], V. Manganelli[3], G. Riitano[3], R. Misasi[3], M. Sorice[3], F. Conti[1], C. Alessandri[1]. Background: Platelet factor 4 (PF4) is a protein with a pro-clotting function expressed by activated platelets with a high affinity for anionic glycosaminoglycans present on the platelet surface. It has been shown that the positively charged surface of PF4 tetramer interacts with the negatively charged regions of β2glycoprotein I (β2GPI) domains, stabilising the link between the antigen and the phospholipid surface, thus increasing the possibility of binding with the respective antibodies. In particular, a tetramer of PF4 selectively binds two molecules of β2GPI, favouring the dimerization of the same, which is crucial in platelet activation and therefore in thrombotic manifestations of antiphospholipid syndrome (aPS). PF4 may be a common denominator in syndromes such as aPS and heparin-induced thrombocytopenia (HIT), which share similar clinical manifestations as thrombocytopenia and thrombosis. Other syndromes, which share the same clinical and laboratory features of HIT despite not having previously received heparin, appear to be associated with the presence of anti-PF4 antibodies. Such pathologies could only be explained by HIT antibodies with heparin-independent platelet-activating properties. One of these could be vaccine-induced Immune thrombotic thrombocytopenia (VITT) post-somministration of ChAdOx1 nCoV-19 vaccine. Recent studies have shown structural similarities between heparin and β2GPI, which may be responsible for thrombotic events in those infected with SARS-Cov-2 and VITT, who never had heparin. In particular, oxidised-β2GPI (β2GPIox) may mimic heparin by structural analogy and link to PF4. Considering the structural similarities between heparin and β2GPIox, and demonstrating the immunogenicity of the hypothesised complex in APS, the alternative molecule could be represented by β2GPIox itself, thus explaining the thrombotic events following vaccination in subjects who have never received heparin.
Objectives: The aim of the study is to test the potential immunogenicity of the β2GPIox-PF4 complex and the presence of antibodies against this complex in patients with aPS, thrombosis during infection with SARS-CoV-2 or VITT.
Methods: 34 patients with proven diagnosis of APS, 17 patients with thrombosis related to infection SARS CoV-2 and 3 patients with VITT were enrolled. Only one aPS patient received heparin prior to testing. Antibodies to the β2GPIox-PF4 complex were evaluated by home made ELISA immunoenzyme testing. Competitive inhibition (homologous) experiments of the bond of PF4 with β2GPIox in the fluid phase were conducted in order to verify the binding specificity.
Results: Anti-β2GPIox-PF4 antibodies were detected in 11 of 34 aPS patients (32%) and all VITT patients (100%), while none of covid-19 patients tested positive. In addition, Anti-β2GPIox-PF4 antibodies positivity significantly correlated with the presence of anti-β2GPI antibodies (p=0.0259) and with a triple positive antibody profile (p=0.0017) (Figure 1). There was no significant association between anti-β2GPIox-PF4 antibodies' title and clinical features of aPS patients.
Conclusion: The results of this study show a new antibody positivity in aPS and VITT. In particular we have identified a high prevalence of anti-β2GPIox-PF4 antibodies which may be involved in the pathophysiology of both aPS and VITT. In addition the absence of anti-β2GPIox-PF4 antibodies in covid-19 patients suggest that the thrombotic mechanism that underlies VITT is different from covid-19 and, on the contrary, could resemble aPS.

DIFFERENTIAL EXPRESSION OF PROTEINS IN PATIENTS WITH SUSPECTED SJÖGREN'S SYNDROME

Keywords: Biomarkers, Cytokines and chemokines, Sjögren syndrome

M. J. Santos-Bornez[1], M. Fernandez Castro[1], C. Merino Argumánez[1], J. Sanz[1], J. Campos Esteban[1], N. De la Torre Rubio[1], P. Navarro Palomo[1], M. Pavía Pascual[1], M. Machattou[1], M. C. Sánchez Fernández[1], P. D. Briongos Díaz[1], H. Godoy[1], B. Garcia-Magallon[1], C. Barbadillo Mateos[1], L. F. De Villa[1], C. Isasi Zaragoza[1], J. L. Andréu Sánchez[1], A. Sánchez[1]. [1]*Hospital Universitario Puerta de Hierro Majadahonda, IDIPHISA, Rheumatology, Majadahonda (Madrid), Spain*

Background: Sjögren's Syndrome (SS) is a chronic systemic autoimmune disease characterized by involvement of the exocrine glands in addition to a wide spectrum of systemic manifestations. At present, conventional biomarkers do not respond to unresolved needs regarding diagnosis, stratification of phenotypes and appropriate effective therapies[1]. SS is an orphan disease and new biomarkers could constitute potential future therapeutic targets[2].
Objectives: The purpose of this study was to carry out an exploratory analysis in six serum and saliva samples from suspected SS patients to identify protein biomarkers to distinguish SS patients who were diagnosed with SS from those who were not.
Methods: We selected six patients from a cohort of 199 consecutive patients attended the rheumatology department for suspected SS: 3 patients who met SS classification criteria from 2002 and/or 2016 who were diagnosed with SS by a rheumatologist and 3 patients who did not meet SS classification criteria who were not finally diagnosed. Serum samples were collected and centrifuged at 1800g, divided into aliquots and stored at -80ºC. Saliva samples were cold collected to prevent degradation of proteins, centrifuged at 1800g at 4ºC and stored at -80ºC. A semiquantitative analysis of protein expression was performed using the "Proteome Profiler Human XL Cytokine Array Kit" arrays from R&D system that detects 105 proteins containing interleukins, chemokines, inflammatory factors and other soluble proteins. Analytes optical densities were quantified using Image J software. The content of the analytes was compared between SS patients and non-SS patients using an unpaired Student´s t test and a measure of the odds of an analyte happening in one group compared to the odds of the same analyte happening in another group (OR: odds ratio) is shown. Statistical analysis were performed using Microsoft Excel software. *P* values ≤0.05 were defined as significant and values of 0.1<*P*> 0.05 were considered as borderline.
Results: We found increased serum levels of CD14 (OR:1.21; *P*=0.033), EGF (OR:1.18; *P*=0.050), IP-10 (OR: 1.23; *P*=0.090) Pentraxin 3 (OR:1.32; *P*=0.095) and VEGF (OR:1.41; *P*=0.091) in patients diagnosed with SS who met SS classification criteria, compared with patients who did not meet SS classification criteria who were not diagnosed, although only in the case of CD14 and EGF, statistical significance was reached. In saliva samples, we found significantly increased values of ICAM1 (OR: 1.67; *P*=0.019), IL-6 (OR:1.20; *P*=0.042) and IL-19 (OR:1.51; *P*=0.039) in patient who did not meet SS classification criteria. compared with patients who did.
Conclusion: Sjögren's syndrome patients presented significantly higher levels of CD14 and EGF in serum, as well as significantly decreased levels of ICAM1, IL-6, and IL-19 in saliva, when compared to patients who did not meet SS classification criteria. It is necessary to confirm these results in a larger cohort of patients.

EXPLORING LONG NON-CODING RNA GAS5 IN SLE PATIENTS AND ITS RELATION TO INTERFERON SIGNATURE

Keywords: Genetics/Epigenetics, Systemic lupus erythematosus

G. Maghraby[1], M. Elmeniawy[1], H. Mostafa[1], O. Shaker[2], M. Habib[3], R. Elgohary[1]. [1]*Faculty of Medicine Kasr Al-Ainy, Cairo University, Internal Medicine, Cairo, Egypt*; [2]*Faculty of Medicine Kasr Al-Ainy, Cairo University, Biochemistry and Molecular Biology, Cairo, Egypt*; [3]*Faculty of Medicine Kasr Al-Ainy, Cairo University, Ophthalmology, Cairo, Egypt*

Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease with diverse pathogenesis. Excessive apoptosis and impaired clearance of apoptotic cells are the primary drivers of Interferon I (IFN) signaling pathways. Upregulation of the long noncoding RNA Growth arrest-specific 5 (GAS5) was found to be associated with apoptosis [1]. Oncological studies discovered that GAS5 is regulated by IFN signaling pathways and acts as a positive feedback loop on IFN response [2,3]. In a mouse model, GAS5 was linked to SLE susceptibility [4]. However, the exact mechanism is still unknown. Furthermore, GAS5 has been proposed to act by interfering with glucocorticoid action, with a key role in regulating glucocorticoid resistance and sensitivity [5].
Objectives: To evaluate the expression levels of GAS5 in serum of SLE patients in comparison with healthy controls, assess their relation to SLE Disease Activity Index 2000 (SLEDAI-2K) and Systemic Lupus International Collaborating Clinics/ American College of Rheumatology Damage Index (SDI), and explore their association with each of the 3 IFN stimulatory genes (MX1, IFI44L, IFIT1) as well as IFN signature to elucidate how GAS5 shares in the pathogenesis of SLE.
Methods: 30 adult SLE patients and 20 age and sex-matched healthy controls were enrolled. SLE disease activity and damage were assessed by SLEDAI-2K and SDI respectively. The expression levels of GAS5 as well as 3 IFN stimulatory genes (MX1, IFI44L, IFIT1) were measured by quantitative real-time PCR. IFN signature score was calculated as described in a previous study [6].
Results: GAS5 expression levels were insignificantly upregulated in SLE patients compared to control (p-value 0.11). At cut-off value 1.3-fold change, GAS5 could discriminate SLE from control (AUC 0.63) with high specificity 100 % and modest sensitivity 63%. Their expression levels were not associated with SLEDAI-2K or SDI scores. GAS5 levels were positively correlated with the cumulative dose of steroids in the last 6 months. However, it was not statistically significant. GAS5 was significantly correlated with IFIT1 gene expression (p-value <0.001) and IFN signature score (p-value 0.005) in SLE patients (Figure1), these findings were not previously reported.
Conclusion: GAS5 may be considered a diagnostic biomarker for SLE, but it is not a reliable biomarker for disease activity or damage. GAS5 is suggested to be incorporated into the IFN signaling pathway in SLE raising possible contribution in SLE pathogenesis.

AB0130 KYNURENINE PATHWAY CAN BE A POTENTIAL BIOMARKER OF FATIGUE IN PRIMARY SJOGREN'S SYNDROME

Keywords: Biomarkers, Sjögren syndrome

H. W. Park[1], Y. Park[1], J. Lee[1], J. H. Koh[2], M. J. Kim[3], S. H. Park[1,3], S. K. Kwok[1,3].
[1]The Catholic University of Korea Seoul St. Mary's Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); [2]Uijeongbu St. Mary's Hospital,The Catholic University, Department of Internal Medicine, Euijeongbu, Korea, Rep. of (South Korea); [3]The Catholic University of Korea Songeui Campus, Catholic Research Institute of Medical Science, Seoul, Korea, Rep. of (South Korea)

Background: Primary Sjogren's syndrome (pSS) is a chronic autoimmune disease with low quality of life caused by various constitutional symptoms and glandular dysfunction. Although fatigue is one of the most frequent symptoms in pSS, its etiology or biomarkers are poorly elucidated.
Objectives: We investigated potential relationship between severity of fatigue and the kynurenine pathway in pSS.
Methods: Clinical data and blood samples of 81 patients were obtained from a prospective cohort for pSS and compared with age- and sex-matched healthy controls (HC). Severity of fatigue was defined according to the fatigue domain scores in the ESSPRI. Potential biomarkers related to the kynurenine pathway were determined using ELISA.
Results: Of the total, 44 patients were defined as the "severe fatigue (ESSPRI fatigue ≥ 5)" group, whereas 37 as the "less fatigue (ESSPRI fatigue < 5)". Serum tryptophan levels in the severe fatigue group were significantly lower while those of kynurenine were higher. Serum interferon gamma, IDO1, and quinolinic acid levels were mostly higher in the less fatigue group. Kynurenine/tryptophan ratios were distinctly higher in the severe fatigue group than both HC and the less fatigue group ($p < 0.001$). This ratio showed a strong degree of positive correlation ($r = 0.624$, $p < 0.001$) with severity of fatigue in pSS while the other markers showed fair degrees of correlation.
Conclusion: Serum markers related to the kynurenine pathway, especially the kynurenine/tryptophan ratio, may be associated with severity of fatigue in pSS. These results can provide guidance for further investigations on fatigue in pSS.

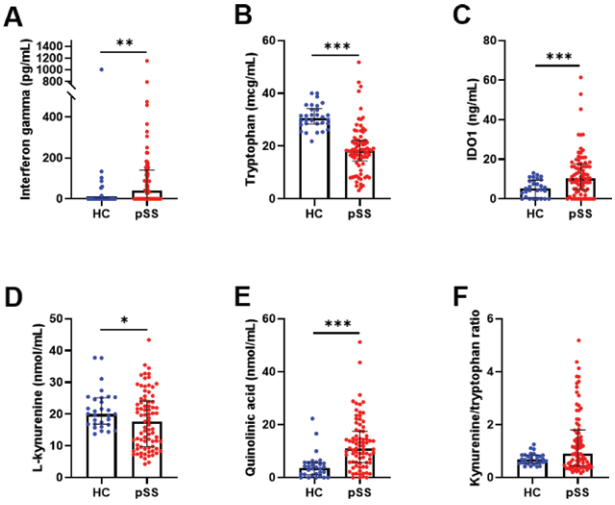

Figure 1. Serum levels of tryptophan, its metabolites, and related enzymatic activities in patients with primary Sjogren's syndrome (pSS) and healthy controls (HC). (A) Interferon gamma; (B) tryptophan; (C) indoleamine-2,3-dioxygenase 1 (IDO1); (D) L-kynurenine; (E) quinolinic acid; (F) ratio of L-kynurenine to tryptophan. All data were measured using enzyme-linked immunosorbent assay. The bars indicate the median and interquartile range. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

ASSOCIATION OF CYTOKINE AND CLINICAL EVALUATION BASED ON ULTRASOUND OF SALIVARY GLAND GRADE CLASSIFICATION IN PATIENTS WITH EARLY PRIMARY SJÖGREN'S SYNDROME

Keywords: Imaging, Sjögren syndrome, Cytokines and chemokines

Y. F. Chen[1], Y. F. Fang[1]. *[1]Chang Gung Memorial Hospital, Rheumatology, Allergy and Immunology, Taoyuan city, Taiwan, Republic of China*

Background: Primary Sjögren's syndrome (pSS) is a chronic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands, the presence of anti-SSA/Ro, anti-SSB/La antibody and hypergammaglobulinemia.
Objectives: To investigate the clinical manifestations in patients with early primary Sjögren's syndrome (pSS), and cytokine difference based on the severity score under salivary gland ultrasonography.
Methods: Forty-six newly diagnosed patients with early pSS were enrolled and divided into mild (score 0-1) and severe (score 2-3) groups according to the salivary gland ultrasonography grade (SGUS) scores at baseline. Clinical evaluation, ESSPRI and ESSDAI index values, sicca symptoms of mouth, salivary capacity, and serum autoantibody and cytokines were investigated.
Results: Mean age of pSS patients at diagnosis were 50.02 ± 12.4 years and the mean duration of sicca symptoms were 1.4 years. ESSPRI (EULAR Sjögren's syndrome patient report index) and ESSDAI (EULAR Sjögren's syndrome disease index) scores were 5.71 and 5.37, respectively. The higher prevalence of rheumatoid factor (p=0.04), antinuclear antibody (p=0.009) and elevation of total IgG (p=0.08) were found in severe group than in mild group. In addition, elevated titer of IL-18, IL-31 and IL-33 were detected in patients with pSS than in healthy subjects, but there were shown no statistical significance between mild and severe groups.
Conclusion: Salivary gland ultrasonography grade (SGUS) scans may help physician diagnose pSS. Clinical manifestation including the low production of saliva and autoantibody production such antinuclear antibodies, rheumatoid factor, and anti-SSA antibody were found. The elevated titer of IL-18, IL-31 and IL-33 in patients may be implicated in the pathogenesis of pSS.

AFIMETORAN (BMS-986256), AN EQUIPOTENT TLR7/8 ANTAGONIST, DEMONSTRATES STEROID-SPARING EFFECTS IN A LUPUS MOUSE MODEL

Keywords: Systemic lupus erythematosus, Animal models

S. Dudhgaonkar[1], P. Chopra[2], A. Rudra[2], S. Subramani[2], S. Palachandra[2], N. Bhatt[2], V. Pabbala[2], S. Ranade[2], D. S. P. Ega[2], A. Dyckman[3], Q. Zhao[4]. *[1]Bristol Myers Squibb, Discovery Biology, Bangalore, India*; *[2]Biocon Bristol Myers Squibb Research Center, Discovery Biology, Bangalore, India*; *[3]Bristol Myers Squibb, Medicinal Chemistry, Lawrenceville, United States of America*; *[4]Bristol Myers Squibb, Discovery Biology, Lawrenceville, United States of America*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with extensive heterogeneity in disease presentation due to an underlying molecular diversity of dysregulated pathways. Glucocorticoids, like prednisolone, are part of the standard-of-care treatment for SLE. However, over time, patients develop resistance to glucocorticoid therapies, and steroid resistance is an important unmet need for patients with SLE. Furthermore, patients can experience side effects, which make long-term use undesirable. Toll-like receptors (TLR) 7 and 8 are endosomal receptors that play a key role in innate immunity. TLR7 and 8 are expressed in various immune cells where they recognize single-stranded RNA and initiate downstream signaling via the Nuclear Factor kappa B (NFkB) and interferon regulatory factor pathways. Activation of the NFkB pathway contributes to the resistance to steroids, and its activation via TLR7 and 8 pathways, along with inhibition of plasmacytoid dendritic cell (pDC) apoptosis via TLR7, could be a driving factor leading to steroid resistance.
Objectives: To evaluate the steroid-sparing potential of afimetoran, an equipotent, dual antagonist of TLR7 and TLR8, currently in clinical development for SLE and cutaneous lupus erythematosus.
Methods: NZB/W mice with moderate disease (proteinuria of 60–100 mg/dL) were treated therapeutically once daily with vehicle or selected doses of afimetoran and/or prednisolone. Survival, kidney injury, splenomegaly, age-associated B-cells (ABCs, measured by CD19, T-bet, and CD11c positivity), serum auto-antibody titers (anti-double stranded DNA antibodies, anti-nuclear antibodies [anti-Smith, anti-ribonucleoprotein, anti–Sjögren's-syndrome-related antigen A autoantibodies]), and plasma interleukin-12p40 (IL-12p40) were assessed in all treatment groups. To assess the impact of afimetoran on the effect of steroids on TLR7 activation in vitro, C57 wild-type mouse bone marrow cells (BMCs) were challenged with the TLR7 agonist gardiquimod and treated with prednisolone alone, or in combination with afimetoran. Both for C57 wild-type BMCs treated in vitro and NZB/W BMCs from mice dosed orally, B-cell and pDC apoptosis was evaluated by annexin V staining using flow cytometry.
Results: In the NZB/W mouse model, afimetoran improved survival when used alone or in combination with prednisolone. It also significantly and dose-dependently suppressed kidney injury markers such as proteinuria, neutrophil gelatinase-associated lipocalin (NGAL), and tissue inhibitor of metalloproteinases 1 (TIMP1). Splenomegaly and suppression of ABCs were improved, particularly when afimetoran was combined with prednisolone. Significant and dose-dependent suppression of plasma IL-12p40 and serum auto-antibody titers was also observed in all active treatment groups, demonstrating the potential of afimetoran in this mouse model of SLE. An improved steroid response was

seen in gardiquimod-stimulated mouse BMCs collected from C57BL/6 mice and exposed in vitro to afimetoran, which showed a significant increase in prednisolone-induced apoptosis of pDCs and B cells compared to baseline control or prednisolone alone. A similar trend was seen in vivo for BMCs collected from NZB/W mice dosed with combinations of afimetoran and prednisolone.

Conclusion: Afimetoran, either alone or in combination with prednisolone, showed efficacy in NZB/W mice with moderate disease. It also reversed the resistance of bone marrow pDCs and B cells to prednisolone-induced apoptosis. These data confirm that afimetoran, an equipotent TLR7/8 antagonist, has the clinical potential to be steroid-sparing.

AB0133 DYSAUTONOMIA IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A CROSS-SECTIONAL STUDY

Keywords: Cardiovascular disease, Systemic lupus erythematosus, Diagnostic tests

S. Barak Lanciano[1], U. Nussinovitch[2], Y. Levy[3]. [1]*Tel Aviv University, Sackler Faculty of Medicine, TEL AVIV, Israel*; [2]*Wolfson Medical Center, Cardiovascular Division, Holon, Israel*; [3]*Meir Medical Center, Internal Medicine Department, Kfar Saba, Israel*

Background: Systemic lupus erythematosus (SLE) is a chronic, inflammatory, autoimmune disease associated with increased cardiovascular risk. Impaired autonomic nervous system (ANS) function (dysautonomia) is one of the causes and a marker of increased cardiovascular risk. Heart rate variability (HRV) is an accepted method of ANS evaluation. Pupillary light reflex (PLR) test is indicative of ANS dysfunction in healthy adults. The efficiency of PLR test for ANS evaluation among SLE patients has yet to be reported.

Objectives: To evaluate ANS function among SLE patients using PLR and HRV testing. The secondary objective was to assess the correlation between PLR and HRV tests among patients with SLE and to evaluate whether they are correlated.

Methods: A cross-sectional study was conducted. Forty-nine SLE patients and a matched group of 87 healthy volunteers were recruited. The participants were questioned about risk factors and other conditions that affect the ANS. Autonomic functions was evaluated by HRV and PLR testing. Strength of correlations were also evaluated.

Results: Maximum pupil diameters (PDmax) and maximal constriction velocity (MCV) was significantly lower in the SLE group (4.80±0.13 mm vs. 5.59±0.15 mm, p<0.01 and 4.01±0.44 mm/s vs. 5.94±0.51 mm/s, p<0.01, respectively). Compared with controls, the SLE patients had significantly lower values of NN50 (number of successive RR intervals that differ by more than 50ms, 12.78±3.78 vs. 25.08±2.84, p = 0.031), pNN50 (percentage of pNN50, 4.03±1.30 % vs. 8.84±0.98 %, p<0.01), SDNN (standard deviation of interbeat intervals, 38.44±3.19 ms vs. 50.19±2.39 ms, p<0.01) and HRV triangular index after 5 minutes standing (11.19±0.63 vs. 14.27±0.47, p<0.01).

Conclusion: Patients with SLE have excessive parasympathetic activity, manifested as decreased HRV parameters and indices reflective of heart rate response to autonomic maneuvers. Similar results demonstrated by pupillary autonomic function. PLR test may be used as an alternative to HRV testing due to its simplicity and reproducibility.

Background: Monocytes -key regulators of the innate immune response- are actively involved in the pathogenesis of systemic lupus erythematosus (SLE). Monocytes and macrophages constitute a major cellular compartment derived from hematopoietic myeloid precursors. Monocyte-macrophage lineage cells exhibit versatile immunoregulatory, inflammatory and tissue repairing capabilities and play an instrumental role in the development of systemic lupus erythematosus (SLE). Abnormal activation of autoreactive T and B cells in SLE could also be caused by dysregulated cytokine production by monocytes. Monocytes in SLE display excess production of the B-lymphocyte stimulator (BLyS) which promotes the survival and proliferation of B cells.

Objectives: We sought to identify novel compounds that might serve as monocyte-directed targeted therapies in SLE.

Methods: We performed mRNA sequencing in monocytes from 15 patients with active SLE and 10 healthy individuals. Disease activity was assessed with the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K). Leveraging the drug repurposing platforms iLINCS, CLUE and L1000CDS[2], we identified perturbagens capable of reversing the SLE monocyte signature. We identified transcription factors and microRNAs (miRNAs) that regulate the transcriptome of SLE monocytes, using the TRRUST and miRWalk databases, respectively. A gene regulatory network, integrating implicated transcription factors and miRNAs was constructed, and drugs targeting central components of the network were retrieved from the DGIDb database, in order to build a final drug-protein interaction network.

Results: Inhibitors of the NF-κB pathway, compounds targeting the heat shock protein 90 (HSP90), as well as a small molecule disrupting the Pim-1/NFATc1/NLRP3 signaling axis were predicted to efficiently counteract the aberrant monocyte gene signature in SLE. Based on our network-based drug repurposing approach, an IL-12/23 inhibitor, an EGFR inhibitor and the proteasome inhibitor bortezomib may represent potential drug candidates in SLE.

Conclusion: Application of two independent - a transcriptome-reversal and a network-based -drug repurposing strategies uncovered novel agents that might remedy transcriptional disturbances of monocytes in SLE.

AB0135 ASSOCIATION OF STAT1, STAT4 AND JAK2 IMMUNOEXPRESSION WITH THE GRADE OF MONONUCLEAR CELL INFILTRATION IN MINOR SALIVARY GLAND BIOPSIES IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME

Keywords: Sjögren syndrome, Prognostic factors

M. Maślińska[1], M. Grabowska[2], A. Wajda[3], K. Kostyra-Grabczak[1], A. Paradowska-Gorycka[3]. *[1]National Institute of Geriatric, Rheumatology and Rehabilitation, Early Arthritis Clinic, Warsaw, Poland*; *[2]Pomeranian University, Department of Histology and Developmental Biology, Szczecin, Poland*; *[3]National Institute of Geriatric, Rheumatology and Rehabilitation, Department of Molecular Biology, Warszawa, Poland*

Background: Signal transducer and activator of transcription 4 (STAT4) is an important for Interferon-γ induction (type 2 IFN signaling). Whereas type 1 IFN signaling pathway depends on signal transducer and activator of transcription 1 (STAT1) and Janus kinase 2 (JAK2). JAK2 is a non-receptor tyrosine kinase that plays a role in signal transduction via others type II receptors including IFN-α, IFN-ß, IFN-γ. The IFN signature in Sjogren's syndrome and overexpression of IFN-1 and IFN-2 in minor salivary glands biopsies (MSGBs) were described.
Objectives: The aim of the study was to analyze the immunoexpression of STAT4, STAT1 and JAK2 in biopsies of MSG depending on the severity of mononuclear cell infiltration (focus score, FS) in patients with primary Sjogren's syndrome(pSS).
Methods: The study group consisted of 64 patients with pSS aged 48.25±16.47. 89% of the subjects were women. MSGBs were routinely stained with HE for conventional histopathological examination with determination of FS. Monoclonal antibodies were used to determine the immunoexpression of the STAT1, STAT4, and JAK2,Quantitative Computer Image Analysis of Immunoexpression (ScanScope AT2 scanner) has been conducted. The percentage of positive immunostaining for each protein was determined in 20 HPF in each group of patients according to FS. Results were analyzed using TIBCO Statistica v. 13.3 Obtained values failed normal distribution assumption, therefore the non-parametric Kruskal–Wallis test with Dunn's multiple comparison test for post hoc analysis was used to assess the differences between the groups. $p < 0.05$ were considered to be statistically significant.
Results: 33% pSS patients were characterized by FS=1; 30%-FS= 3; FS=0 - 9%; 3% and 2% of patients revealed FS=5 and FS=6, respectively. In MSGBs JAK2-, STAT1-, and STAT4-immunopositive cells were observed. The various nuclear and cytoplasmic immunoexpression of JAK2, STAT1 and STAT4 in acinar and ductal cells and also in lesions displaying immune-cell infiltration were observed. However the immunoexpression of STAT4 in the nucleus was relatively rarely found. The percentage of JAK2-, STAT1- and STAT4-positive cells in FS = 0 was significantly lower in comparison with FS equal or greater than 3. However for STAT4, already in FS=2 there was a stronger signal compared to FS=0. The percentage of JAK2- and STAT1-positive cells in MSG in FS = 0 was statistically insignificant in comparison with FS = 1 and 2. There was no statistical significance in the percentage of STAT4- positive cells in patients with FS = 0 in comparison with FS = 1 (Figure 1). mRNA level of *STAT4* in whole blood in patients with pSS revealed the opposite trend. The increase of FS was correlated with the decreased mRNA level of *STAT4*.

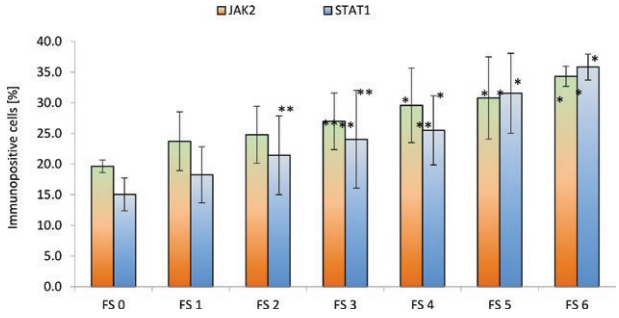

Figure 1. The percentage of JAK2-, STAT1- and STAT4-immunopositive cells in the human labial salivary glands according to the focus score (FS 0, FS 1, FS2, FS 3, FS 4, FS 5, FS 6) in the patients with pSS ** $p < 0.05$ vs. F0 group; * $p < 0.001$ vs. F0 group

Conclusion: Notably, in the case of STAT4 immunoexpression increased with increasing FS. Interestingly, mRNA level of *STAT4* determined in the whole blood decreased with increasing FS (data not shown).
The question remains why the immunoexpression of STAT4 in nucleus was relatively rarely found, and what is the impact of the dynamics of STAT4-dependent gene expression on the pathogenesis of pSS. In studied patients STAT4 activity dominates in MSG infiltrates which confirms the role of this factor in the pathogenesis of pSS.

AB0136 INTERFERON STIMULATED GENES IN CD4 T CELLS ARE ASSOCIATED WITH PYROPTOSIS PATHWAYS IN PATIENTS WITH LUPUS

Keywords: Systemic lupus erythematosus, -omics

S. J. Lee[1], B. A. Kim[1]. *[1]Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, Internal Medicine, Daegu, Korea, Rep. of (South Korea)*

Background: Single cell RNA sequencing (scRNA-seq) of kidney tissues in patients with lupus has led to landscape of complete cellular composition and states for immune and non-immune cells. These studies suggested type I interferon (IFN) signatures prime inflammatory responses. However, there is a lack of knowledge regarding the characteristics of subsets of IFN stimulating genes (ISG) high expressed cells.
Objectives: Here we investigated immune cell compositions between peripheral blood mononuclear cells (PBMCs), skin and kidney tissues in patients with lupus using scRNA-seq. We characterized a subset of ISG high CD4 T cells, which are commonly expressed across PBMCs, skins and kidneys of lupus but not skins of healthy.
Methods: scRNA-seq dataset of PBMCs, skin and kidney tissues in patients with lupus were collected. We integrated and analyzed immune cell compositions from this scRNA-seq dataset. We focused on subset of ISG high expressed CD4 T cells and characterized top 200 genes of this subset.

Results: There is one subset of ISG high expressed CD4 T cells in the lupus PBMCs, kidneys, and skins but not in the healthy skins. This ISG high expressed CD4 T cells have the greatest number of type I interferon signatures and gasdermin D gene, which is related to pyroptosis of cells, among top 200 genes. We further investigated pyroptosis pathway genes in the subsets of CD3 T cells. Interestingly, the subset of ISG high expressed CD4 T cells have most increased pyroptosis related upstream regulating genes including IRF1, GBP1, CASP4 and CASP1. Furthermore, this subset highly expressed inflammasome gene such as NLRC5 not NLRP3

Conclusion: There are ISG high expressed CD4 T cells across tissues of lupus. Those cells highly expressed pyroptosis pathway related genes. Further investigation is needed to characterize association between ISG and pyroptosis.

Background: Within the still poorly understood pathogenesis of systemic lupus erythematosus (SLE) granulocyte neutrophils have been shown to play a key role. In our research on mouse models, we found that important functions of neutrophils are regulated by the hydrogen voltage-gated channel 1 (HVCN1), whose deficiency causes an SLE-like autoimmune disorder in old mice [1]. Among other effects, HVCN1 regulates the secretion of myeloperoxidase (MPO) and the release of neutrophil extracellular traps (NETs) in mice, thereby controlling inflammation. Based on this knowledge and a previous gene array analysis of CD16+ peripheral blood cells from SLE patients that showed reduced HVCN1 mRNA expression in neutrophils [2], we hypothesize that reduced HVCN1 expression leading to increased MPO and NET release might be a pathomechanism observable in humans that could contribute significantly to the pathogenesis and disease activity in SLE.

Objectives: This first-in-human trial prospectively assesses HVCN1 protein expression of leukocytes and plasma levels of MPO and 8-OHdG in correlation with clinical disease activity in SLE patients and matched healthy controls, in order to gain deeper understanding of SLE pathogenesis.

Methods: In this prospective study (ethical approval obtained under Institutional Review Board #112/22), 50 patients with SLE and 50 healthy controls are investigated for HVCN1 expression in peripheral blood leukocytes and plasma levels of myeloperoxidase (MPO) and oxidized DNA (8-OHdG), accompanied by application of the SLEDAI-2K assessment for clinical disease activity and recording of further clinical (demographics, patient and treatment history) and laboratory data (autoimmune, urine and routine serum diagnostics). HVCN1 protein expression is quantified by flow cytometry (BD FACS Symphony A5) via targeted HVCN1 staining (Alomone labs anti-HVCN1 rabbit IgG and Invitrogen anti-rabbit IgG Alexa Fluor 488). Previous processing steps include leukocyte staining (CD45, CD14, CD15 and CD16), cell fixation and permeabilization. Reference quantification of HVCN1 protein expression via Western Blot and further mRNA and DNA measurements are planned. MPO and 8-OHdG levels will be quantified by ELISA and mass spectrometry.

Results: The preliminary analysis of 18 SLE patients revealed a statistically significant positive correlation between SLEDAI-2k scores and HVCN1 protein expression (Pearson correlation coefficient: 0.563; p=0.015). Also, within the typical SLEDAI-2k disease activity categories, there was a clear tendency towards ascending HVCN1 protein quantities expressed with every severity category step-up [see Figure 1]. Further analysis is ongoing.

Conclusion: Unlike previous studies, our preliminary SLEOx trial data suggests a positive correlation of HVCN1 protein expression and SLE activity. General HVCN1 upregulation following leukocyte activation in response to disease activity (among other factors) could be one explanation. Validation in a larger study cohort is currently underway.

AB0138 CHARACTERIZATION OF SERUM CYTOKINE PROFILE IN PATIENTS WITH ACTIVE LUPUS NEPHRITIS

Keywords: Cytokines and chemokines, Systemic lupus erythematosus

Z. Rahme[1], M. Gatto[1], A. Ghirardello[1], C. Cruciani[1], F. Pettorossi[1], A. Zaramella[2,3], C. Franco[1], A. Doria[1]. [1]*University of Padova, Department of Medicine, Rheumatology Unit, Padova, Italy*; [2]*University of Padova, Department of Surgery, Oncology and Gastroenterology (DISCOG), Padova, Italy*; [3]*Veneto Institute of Oncology IOV-IRCCS, Gastroenterology Unit, Padova, Italy*

Background: Cytokines (CKs) are known to play a role in the pathogenesis of lupus nephritis (LN), yet their role as biomarkers is still debated.

Objectives: To describe the CKs picture in patients with active LN and to assess possible clinical correlates in LN course.

Methods: A prospective cohort study including patients with active biopsy-proven LN was performed. Serum CKs were assessed at the time of diagnosis and at 3 subsequent time points (3, 6 and 12 months) during follow-up. Clinical and serological data were collected for further analysis. BLyS (B Lymphocyte stimulator) and interleukin (IL)-37 were measured by ELISA assays (Quantikine BAFF, R&D, USA, detection limit DL 0.02 ng/mL; IL37 ELISA kit, Adipogen, Swizerland, DL 0.001 ng/mL), IL-2, IL-10, IL-17A and IL-18 (pg/mL) by Luminex multiplex assay (Millipore, USA, DL 0.6 pg/mL for all), according to the manufacturers' instructions. Measurements for IL-37 and BLyS were matched with sera of sex- and age-matched healthy subjects (HC). Mann-Whitney test was used for comparisons between two independent groups, Wilcoxon log-rank test for paired comparisons at different time points, Spearman's correlation coefficient for associations between CK and between CK and clinical features.

Results: Twenty-seven patients with active LN (mean±SD age 41.75±14.74, 78.8% women) were included for initial CK analysis at the time of LN activity. At baseline (T0), BLyS levels were significantly increased in LN compared with HC (median [range], 1.107 [0.326-4.00] vs. 0.563 [0.265-1.409]; p<0.0001); IL-37 was significantly reduced in LN compared with HC (median [range] 0.016 [0.001-0.251] vs. 0.056 [0.001-1.147]; p = 0.0185). At T0, median (range) levels of IL-2, IL-10, IL-17A and IL-18 were: IL-2 0.640 (0-37.82), IL-10 2.60 (0-106.86), IL-17A 2.10 (0-138.20), IL-18 243.10 (28.20-950.30). The longitudinal association study between CK levels of the entire cohort revealed a trend of inverse correlation between IL-37 and BLyS (r=-0.281, p=0.06) and a direct correlation between BLyS and IL-18 (r=0.330, p=0.04) and between IL-2 and IL-17A (r=0.470, p<0.001) (Figure 1). A subset of 17 patients (70.6% F, mean age at renal flare 34.3±18.6y, mean duration of disease at the time of renal flare 4.99±8.94y, caucasian ethnicity n=14, 82.3%), was followed-up prospectively: 7 (41.18%) had biopsy-proven (III-IV class) proliferative glomerulonephritis. Proteinuria at T0 was 2.19±1.35 g/24h. All patients were treated with pulsed glucocorticoids (GCS, 750-2500 mg) followed by oral GCS (0.3-0.5mg/kg/day prednisone equivalent) and immunosuppression1. Higher titres of IL-18 were present in the sera

of patients with proliferative forms of LN (p=0.053) and with a higher SLEDAI-2K score at T0 (p=0.0759). A significant correlation was found between IL-2, and to a lesser extent of IL-17, with anti-dsDNA antibodies (IL2: r=0.6098, p=0.0094; IL17: r=0.4591, p=0.0638). High levels of IL-17 correlated with lower C3 at T0 (r=-0.5085, p=0.0372). No significant longitudinal changes in CKs levels nor correlation with clinical features were observed.

Conclusion: Patients with proliferative LN and higher SLEDAI-2K scores displayed higher levels of IL-18, thus supporting IL-18 likely role in the pathogenesis of LN. We documented a correlation between IL2 and higher titres of anti-dsDNA antibodies and an inverse correlation between IL-17 and C3 at baseline, suggesting a contribution of CKs to LN onset. Our study was limited by the small sample size, limiting retrieval of significant data on CK levels and clinical-laboratoristic changes at different time points, demanding further studies.

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune rheumatic disease with a complex pathogenesis. The etiology of SLE is multifactorial, and includes contributions from genetic, epigenetic, environmental, hormonal, and immune regulatory factors. The hereditary pattern of the disease is polygenic in most patients. A polygenic risk scoring (PRS) model has been used to estimate the genetic risk of SLE in individuals. This approach assumes independent and additive contribution of genetic variants to disease development. The Taiwan Precision Medicine Project (TPMI) in our hospital invited patients with various diseases to participate in the research project. We had collected and analyzed clinical data from electric medical records. We had also established SLE-PRS risk analysis for our TPMI cohort.

Objectives: To validate the clinical utility of PRS in Asian SLE.

Methods: To understand the clinical characteristics of individuals with high SLE-PRS, we recruited female individuals, aged 20-50, from the top 5% subjects with the highest SLE-PRS from TPMI cohort. Pre-existing diagnosis of SLE was excluded (Figure 1). Questionnaire was assessed with self-reported symptom. Autoantibodies and serum complement levels were also assessed.

Results: Among 442 patients had high SLE-PRS, we included 131 patients in our study. Antinuclear antibody detection rate was 37.3%. 16.8% of recruited individuals had either low serum complements level or defected complement function (Table 1). Overall, 20.37% of individuals with high SLE-PRS had two immunological abnormalities by SLICC criteria, while 5.56% of individuals had more than three immunological abnormalities.

Conclusion: High SLE-PRS may be helpful for early lupus detection.

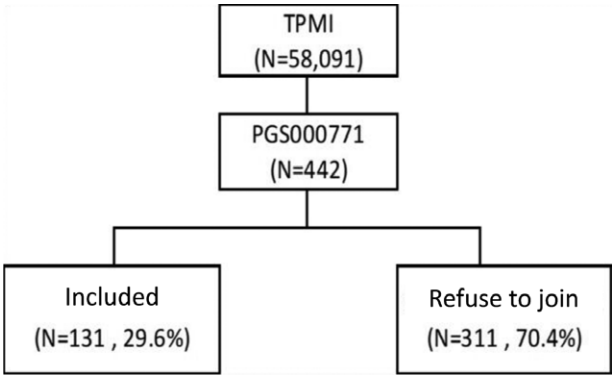

Figure 1. Study flow of SLE-PRS

Table 1. Proportion of SLE related immunologic abnormality in high SLE-PRS individuals

	SLE immunologic criteria	Positive

UTILITY OF MONOCYTES, THEIR SUBSET ANALYSIS, CIRCULATING IMMUNE COMPLEXES AND CYTOKINES IN ASSESSMENT OF SLE DISEASE ACTIVITY

Keywords: Innate immunity, Biomarkers, Systemic lupus erythematosus

A. Jha[1], J. Joseph[1], S. Prabhu[2], A. Chaudhary[2], J. Mathew[1], B. Yadav[3].
[1]christian Medical College, Clinical Immunology and Rheumatology, Vellore, India; *[2]christian Medical College, Wellcome Trust Lab, Vellore, India*; *[3]christian Medical College, Department of Biostatistics, Vellore, India*

Background: Systemic lupus erythematosus (SLE) is a heterogeneous disease with interaction of innate and adaptive immunity in pathogenesis and clinical activity. Monocyte and its subset role in SLE disease activity is not well defined. Complement levels and dsDNA levels are used for monitoring but are less than perfect and there is a need for newer prognostic markers in SLE management.

Objectives: To assess the prognostic utility of monocyte subsets,circulating immune complex (CIC) against C1q, cytokines like Tumour necrosis factor-alpha (TNF-a), Transforming growth factor-beta (TGF-b), interleukin-6 (IL-6) in lupus.

Methods: We conducted a prospective observational study in patients with SLE and no flare (as per SELENA-SLEDAI score =>4). A single visit interview of patients along with routine laboratory reports was used to select samples. A voluntary written consent was obtained and a blood sample (10ml) was collected to separate peripheral blood mononuclear cells (PBMC) and Serum. Cell analysis for monocyte subtypes was done using antibodies against cell surface markers using Fluorescence-activated cell sorting (FACS). Monocyte was sorted as classical and non-classical by CD14 and CD16 expression. Serum cytokines levels of IL-6, TNF-α, TGF-β and circulating immune complexes (CIC) were measured using ELISA kits.

Results: Among the 42 patients of SLE, 22 had active disease and 15 were newly diagnosed cases. The median age was 31 years (IQR 22.75 to 39.25) and the disease duration was 22 months (IQR 0-70.5). Musculoskeletal (76.2%), mucocutaneous (69%), renal (52.4%) and neuropsychiatric involvements (26.2%) were the common organ system involvements. Total monocytes were significantly reduced in active disease and Intermediate monocyte subset was numerically increased but not statistically different in active group(p=0.09). Mean fluorescence intensity (MFI) of CD 163 was significantly elevated in active disease(p=0.006).TNF alpha levels was elevated in active disease(p=0.042) but

other cytokines didn't correlate with disease status. CIC levels significantly differentiated active from inactive disease ($p<0.001$).

Conclusion: CIC along with TNF alpha levels might be a novel valuable predictors of disease activity whereas other serum cytokine levels did not correlate with SLEDAI-based activity. Intermediate subset of monocytes was increased numerically. CD 163 MFI was significantly increased in active SLE and should be evaluated in further studies.

AB0141 GUT MICROBIOTA DYSBIOSIS IN KOREAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus

J. W. Kim[1], J. Y. Jung[1], H. A. Kim[1], C. H. Suh[1]. [1]Ajou University School of Medicine, Rheumatology, Suwon-si, Gyeonggi-do, Korea, Rep. of (South Korea)

Background: In the development of various illnesses including autoimmune diseases, many studies proving the crucial role of gut microbes are gradually being reported. Alterations of gut microbiota can lead to abnormalities in the host immune system, causing autoimmune, which can ac as pathogenesis of systemic lupus erythematosus (SLE).

Objectives: The purpose of this study was to analyze the diversity and taxonomic composition of the gut microbiotas affecting SLE and to investigate their association with disease activities.

Methods: Fecal samples of 38 patients with SLE in Ajou Lupus Cohort and 52 age and sex-matched healthy volunteers were provided by the same protocol. We analysed the components of the gut microbiota in feces via 16S rRNA next-generation sequencing, and evaluated alpha and beta diversities. Demographic, laboratory, and medication data of SLE patients were obtained through medical records, and Pearson correlation analysis was performed to analyse the association between disease activity and gut microbiota.

Results: We observed a significant decrease in species richness in the beta diversity analysis by NMDS plots compared to controls in the SLE group. Compared with SLE and healthy controls (HCs), significant differences were found at phylum, genus, species levels in the taxonomic composition. At the species level, there were 7 species with a significantly higher relative abundance and 7 species with a lower relative abundance in the SLE group compared to the HCs, of which the reduction of *Faecalibacterium prausnitzii* and *Prevotella copri* ($p = 0.001$ and $p = 0.001$, respectively) played an important role in SLE. Pearson correlation analysis suggested that *Faecalibacterium prausnitzii was* positively correlated with complement 3 and complement 4 ($r = 0.44$ and $r = 0.49$, respectively), and *Prevotella copri* was positively correlated with total lymphocytes ($r = 0.45$).

Conclusion: There was a significant difference in the composition and diversity of gut microbiota between SLE patients and healthy controls in Korean population. In particular, *Faecalibacterium prausnitzii* and *Prevotella copri,* which are greatly reduced in patients with SLE, are expected to provide potential targets for new treatment.

AB0142 AVAILABLE EVIDENCE ON RENAL FIBROSIS SERUM BIOMARKERS

Keywords: Organ damage, Biomarkers, Kidneys

A. Barinotti[1], M. Radin[1], I. Cecchi[1], S. G. Foddai[1], E. Rubini[1], S. Sciascia[1], D. Roccatello[1]. [1]*University of Turin, Department of Clinical and Biological Sciences, Turin, Italy*

Background: Renal fibrosis is the main biological mechanism underlying chronic kidney disease (CKD), representing a point of no return of tissue damage and dysfunction. The best tool clinicians can use to address the extent of renal fibrosis at any level (glomeruli, tubule-interstitium, vasculature) is kidney biopsy that, despite its overall safety, remains an invasive procedure showing some shortcomings. The identification of novel non-invasive biomarkers would be of fundamental importance to improve patients' diagnosis, management and responsiveness to therapy.

Objectives: To investigate the recent evidence supporting the use of available serologic biomarkers to evaluate the degree of kidney fibrosis.

Methods: We systematically reviewed the available evidence on serological biomarkers associated with renal fibrosis evaluated in patients suffering from CKD. Inclusion criteria were as follow: a) studies including at least 25 patients; b) published in the last five years; c) presenting clinical related data (not just *in vitro* analysis).

Results: The literature search identified 29 eligible studies according to the inclusion criteria. A total of 65 different biomarkers were evaluated in patients' serum and a statistically significant association has been found between 42 of them and/or other fibrotic biomarkers/histopathological findings. Among these, the most frequently tested were: MCP-1 (4/29=13.8%), KIM-1 (3/29=10.3%), MMP-7 (3/29=10.3%), Pro-C3 (3/29=10.3%), Pro-C6 (3/29=10.3%), TNFR-1 (3/29=10.3%), and TNFR-2 (3/29=10.3%). 14 studies out of 29 (48.3%) compared the circulating biomarkers of interest to findings from kidney biopsy (Table 1), while 15/29 (51.7%) compared them to other biomarkers presumed to have a role in CKD and fibrosis according to the literature. When focusing on the first group, the following biomarkers were associated with fibrosis: MMP-7, C3M, Pro-C6, Klotho, HE4, miR-181, PTX-2, LOX, CDH11, SMOC2, PEDF, RelB, ETP, NGAL, cystatin C, TGF-β1, TGF-β2, TGF-β3, BMP-7, uromodulin, and DKK-3. Interestingly, among those biomarkers associated with fibrosis in the overall cohort of patients included, only MMP-7 and Pro-C6 maintained this association with biopsy-proven renal fibrosis.

Conclusion: The current evidence on potential novel biomarkers to assess kidney fibrosis is still very scattered. Probably, the idea of a panel combining different biomarkers, rather than the employment of a single one, could be the best path to follow in order to capture the high complexity characterizing renal fibrotic process, deeply impacting on clinical practice by improving prevention, diagnosis, and management.

Biomarkers Tested	Significant Biomarkers	Fibrosis grade assessment
MMP-7	MMP-7	MEST-C (Oxford classification)
C3M, Pro-C3, C4M, C5M, Pro-C6, C6M	C3M, Pro-C6	Not specified
Klotho	Klotho	% of glomeruli affected by segmental or global glomerulosclerosis • Degree of foot process effacement assessed based on the % of evaluated areas • IFTA evaluated semi-quantitatively according to the proportion of the cortical area involved • Intimal thickening assessed as the % of narrowing lumen of most severely affected blood vessel
HE4	HE4	Banff classification
miR-181	miR-181	Not specified
PTX-2	PTX-2	Not specified
LOX	LOX	Not specified
CDH11, SMOC2, PEDF, MGP, TSP2	CDH11, SMOC2, PEDF	IFTA was graded as involvement of <10%, 11%–25%, 26%–50% or>50% of total cortical volume.
RelB, HE4	RelB, HE4	Not specified
ETP	ETP	MEST-C (Oxford classification)[66], Banff classification
Pro-C3, Pro-C6	Pro-C6	• % of interstitial fibrosis • % of tubular atrophy • Interstitial mononuclear cell infiltration
NGAL, cystatin C, TGF-β1, TGF-β2, TGF-β3, BMP-7	NGAL, cystatin C, TGF-β1, TGF-β2, TGF-β3, BMP-7	Not specified
Uromodulin	Uromodulin	Areas with fibrosis were determined at 5% level for each visual field and 1% level for averaged values.
DKK-3	DKK-3	ISN/RPS

AB0143 **VORINOSTAT IMPROVES THE PATHOGENESIS OF SLE MODEL MICE BY SUPPRESSING IFN-I AND TLR7/8 SIGNALS**

Keywords: Systemic lupus erythematosus

T. Hirayama[1,2], H. Konaka[1,3], Y. Kato[1,2], H. Takamatsu[1,2], A. Kumanogoh[1,2,4]. *[1]Graduate School of Medicine, Osaka University, Department of Respiratory Medicine and Clinical Immunology, Suita city, Japan*; *[2]Immunology Frontier Research Center (iFReC), Department of Immunopathology, Suita, Japan*; *[3]Nippon life Hospital, Department of Internal Medicine, Osaka, Japan*; *[4]Institute for Open and Transdisciplinary Research Initiatives, Integrated Frontier Research for Medical Science Division, Suita, Japan*

Background: SLE is a systemic autoimmune disease caused by impaired innate and acquired immune tolerance, resulting in increased Type I IFN (IFN-I) and aberrant B cell development, in which cGAS and TLR 7/8 signaling play critical roles. TLR7/8 and cGAS signal is activated due to the overresponse to nucleic acid derived from impaired clearance of apoptotic cells, which leads to increased IFN-I production. Activation of TLR7/8 signaling also leads to the development of abnormal B cell populations, including short-lived plasma blasts, double negative B cells (DNB), and active native B (NAB). It suggests that signaling pathway via TLR7/8 and cGAS would be a good therapeutic target for SLE. Therefore, we screened agents that inhibit the induction of interferon-stimulated genes (ISGs) by LPS, R848 or cGAMP stimulation using an approved drug library and found that vorinostat inhibits ISG induction upon cGAMP and LPS stimulation.
Objectives: The purpose of this study is to elucidate the mechanism by which vorinostat suppresses IFN-I production and to demonstrate that vorinostat improves the severity of the disease phenotype in SLE-prone mice.
Methods: We investigated the effect of vorinostat on the expression and phosphorylation of TBK1, IRF3, IRF5, and IRF7, upon LPS or cGAMP stimulation, as well as on the in vitro differentiation of human B cells into plasma cells by a culture medium containing R848. Additionally, the effect of Vorinostat on the severity of SLE-prone mice, such as NZB/W F1 mice and SAVI mice with point mutations in STING, was also investigated.
Results: Vorinostat inhibited TBK1 phosphorylation and subsequent nuclear translocation of IRF3 and expression of IRF5 and IRF7. Consequently, the expression of IFN-β and ISGs were suppressed. Additionally, differentiation of human B cells cultured in R848-containing medium into plasma cells was inhibited in the presence of vorinostat. Furthermore, vorinostat improved the disease severity of NZB/W F1 mice, including survival, proteinuria, and glomerulonephritis, and decreased autoantibody titer and TLR7 expression. Vorinostat also ameliorated the lung inflammation and fibrosis, and interstitial nephritis in SAVI mice by inhibiting the ISG expression.
Conclusion: We found vorinostat ameliorates the disease severity of SLE prone mice by inhibiting IFN-I production and pathogenic B cell development via suppressing the downstream signal of TLR7/8 and cGAS. This finding represents a new therapeutic candidate for SLE.

Lagoutte[3], A. Van de Water[4], L. Perret[3], S. Alves[3], D. Amantini[3], S. Van der Plas[4], R. Galien[3]. *[1]University of Pittsburgh, Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America*; *[2]Monash University, Centre for Inflammatory Disease, Melbourne, Australia*; *[3]Galapagos SASU, -, Romainville, France*; *[4]Galapagos NV, -, Mechelen, Belgium*

Background: Tyrosine kinase 2 (TYK2) is an intracellular kinase that transduces signalling from type 1 interferons (IFN), interleukin (IL)-12/ IL-23 and the IL-10 family of cytokines. Genetic analyses show an association of TYK2 variants with risk of inflammatory and autoimmune diseases. In addition, clinical data obtained with deucravacitinib (a TYK2 selective inhibitor) in SLE patients suggest that inhibition of TYK2 could be beneficial to patients with diseases driven by type I IFN such as systemic lupus erythematosus (SLE) and dermatomyositis (DM).
Objectives: We describe here GLPG3667, a TYK2 inhibitor in development for treatment of DM and SLE.
Methods: Potency and selectivity of GLPG3667 on TYK2 was assessed using radioactive, luminescent and fluorescent biochemical assays. Peripheral blood mononuclear cells (PBMC) and human whole blood assays for various Janus kinases (JAK)-dependent pathways were performed to assess GLPG3667 potency and selectivity, using flow cytometry or ELISA. GLPG3667 pharmacological activity was investigated in a psoriasis mouse model driven by IL-23. In healthy human volunteers (NCT04097938), pharmacodynamic activity of GLPG3667 was evaluated by measuring signal transducer and activator of transcription (STAT) phosphorylation using flow cytometry. Selectivity was assessed by analysing the impact of GLPG3667 on IFNα, IL-2 and granulocyte-macrophage colony-stimulating factor (GM-CSF) pathways. Biological effects of orally administered GLPG3667 in humans were assessed using transcriptomic analysis of blood cells after in vivo IFNα (1 million IU of Intron-A) challenge in healthy volunteers.
Results: Biochemical assays showed that GLPG3667 displayed a nanomolar potency on TYK2 with a >3-fold selectivity over the other JAK kinases. In human PBMC activated with phorbol m12-myristate 13-acetate and ionomycin calcium salt, GLPG3667 showed comparable potency (around 50 nM) on the IFNα and IL-23 pathways. Potency of GLPG3667 was >14-fold and >19-fold higher in the IFNα pathway vs the IL-2 and GMCSF pathways in human PBMC and whole blood, respectively. In mice, dermal ear inflammation driven by IL-23 was prevented by GLPG3667 with a minimal effective dose of 3 mg/kg given orally once daily. This effect was associated with a decrease in neutrophil infiltration and STAT3 phosphorylation at sites of inflammation. In human healthy volunteers, GLPG3667 completely inhibited IFNα-induced STAT1 and STAT3 phosphorylation but did not impact IL-2- or GM-CSF-induced STAT5 phosphorylation. GLPG3667 strongly inhibited the expression of IFN-response genes induced by in vivo IFNα challenge in healthy human subjects.
Conclusion: GLPG3667 demonstrated selectivity for TYK2 relative to the three other JAK family members in biochemical and cellular assays, and in human whole blood assays ex vivo and in vivo during a phase 1 study in healthy human volunteers. Pharmacological effects of GLPG3667 were demonstrated in a mouse model of psoriasis driven by IL-23 and in human healthy volunteers challenged with IFNα. These data support the development of GLPG3667 in autoimmune diseases driven by type I IFN such as DM and SLE.

AB0145 GENETIC EVIDENCE REVEALS A CAUSAL ROLE OF BLOOD LEUKOCYTE COUNTS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus

Y. Zhang[1,2], K. Fan[1,2], Z. Han[1,2], Q. Yu[3], P. F. He[3], X. Li[4], S. X. Zhang[4]. [1]*Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, Shanxi Province, China*; [2]*Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, Shanxi Province, China*; [3]*Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, Shanxi Province, China*; [4]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China*

Background: Blood leukocyte counts are important biomarkers for the onset of systemic lupus erythematosus (SLE)[1-3]. However, the causal relationship is unclear.
Objectives: We implement a two-sample Mendelian Randomization (MR) analysis to investigate the potential association.
Methods: The summary statistics of blood leukocyte counts were available from public databases (n=172435)[4]. The SNPs related to SLE risk were extracted from a large SLE GWAS with 5201 cases and 9066 controls of European ancestry[5]. All genetic variants significantly associated with blood leukocyte counts ($p<5\times10^{-8}$) were used as instrumental variables (IVs). Then, the linkage disequilibrium (LD) was excluded (distance threshold = 10,000 kb, r^2 = 0.001). In this study, the inverse variance weighted (IVW) method, the MR-Egger method, and the weighted median (WM) were used to estimate the causal effect of the blood leukocyte counts and SLE. In addition, Cochran's Q test, MR pleiotropy residual sum and outlier (MR-PRESSO), and leave-one-out analysis were implemented as sensitivity tests.
Results: We selected 119 independent SNPs as IVs in the MR analysis of total WBC. Higher blood leukocyte counts were associated with a lower risk of SLE (OR:0.629, 95% CI: 0.436-0.907, P: 0.013) by IVW method (Figure 1). However, the results of Cochrane Q statistics showed heterogeneity ($p<0.05$). Therefore, we used the random-effects model[6].
Conclusion: Our study predicted genetically that individuals with lower blood leukocyte counts face a higher risk of SLE, which was consistent with the previous observational studies.

AB0146 A SINGLE-CELL AND SPATIALLY RESOLVED ATLAS OF LUPUS NEPHRITIS

Keywords: Systemic lupus erythematosus, Kidneys, -omics

J. Wang[1], Z. Chen[1], X. Li[1], G. Wang[1], Q. Kun[1], C. Guo[1]. [1]*Department of Rheumatology and Immunology, The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, Hefei, China*

Background: Systemic lupus erythematosus is a typical autoimmune disease with multiple clinical complications. Lupus nephritis (LN) affects half of the patients and is the leading cause of both death and morbidity[1]. Although previous studies have reported that a variety of cell types are locally present in the kidneys of patients with lupus nephritis[2,3], the specific mechanism of pathogenesis, especially considering the spatial content in LN, remains unknown.
Objectives: To investigate the pathways and gene expression changes in the kidneys of patients with lupus nephritis in a spatial context, we conducted an in-depth study of kidney tissues using multi-omics and spatial transcriptomics.
Methods: We included multi-omics and spatial transcriptome samples from ten patients and five controls. The integrative analysis identifies key pathways and potential disease-associated driver genes in the pathogenesis of lupus nephritis. Finally, heritability enrichment identifies genetic associations of endothelial and fibroblast alterations.
Results: Multimodal data integration enabled us to assess the composition of renal cell types at higher resolution and gain insight into changes in the nephritis transcriptome and epigenome by identifying injury, inflammation, and fibrotic changes in different histoarchitectural disease states. We identified and validated disease-specific fibroblast and endothelial cell states of major cell types and analyzed the disease-associated alterations in their spatial context. Finally, genetic association analysis identified heritability enrichment and specific transcription factor alterations in fibroblasts, endothelial cells, and immune cells.
Conclusion: Our data elucidate key pathways and genetic alterations in human kidney tissue following the onset of lupus nephritis and correlate such alterations with genetics, provide a comprehensive molecular map of lupus nephritis, and present guidance for advanced mechanistic and therapeutic studies.

Systemic sclerosis, myositis and related syndromes - aetiology, pathogenesis and animal models

AB0147 ANTI-FIBROTIC EFFECTS OF MT-5562, A NOVEL POTENT SELECTIVE AUTOTAXIN INHIBITOR, IN PRECLINICAL STUDIES: CLUES TO TREAT SKIN AND LUNG FIBROSIS IN SYSTEMIC SCLEROSIS

Keywords: Animal models, Systemic sclerosis

H. Matsuura[1], M. Kondo[1], R. Ohno[1], A. Ishii[1], M. Piruzyan[1], K. Funayama[1], Y. Ono[1], A. Iwamura[2], T. Endou[2], T. Akashi[2], T. Tomari[3], N. Uchiyama[3], G. Kania[4], P. Blyszczuk[4], O. Distler[4]. *[1]Mitsubishi Tanabe Pharma Corporation, Research Unit/Immunology & Inflammation, Yokohama, Japan*; *[2]Mitsubishi Tanabe Pharma Corporation, DMPK Research Laboratories, Yokohama, Japan*; *[3]Mitsubishi Tanabe Pharma Corporation, Safety Research Laboratories, Fujisawa, Japan*; *[4]University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland*

Background: Autotaxin (ATX) is the lysophosphatidic acid (LPA)-producing enzyme. Targeted small-molecule therapies to ATX have been shown to be potentially effective in systemic sclerosis (SSc) treatment, but the clinical benefit and safety of selective inhibition remains unclear.

Objectives: To explore the potential of MT-5562, a novel oral selective inhibitor of ATX, as a therapeutic agent for SSc by evaluating its efficacy and toxicity in preclinical models.

Methods: MT-5562 and a free form of MT-5562 (MT-5562F) were evaluated, and other ATX inhibitors (ziritaxestat and cudetaxestat) were used as comparators in the present study. In vitro ATX activity was measured by choline assay using fluorescent substrate Amplex UltraRed. The effects of MT-5562F on IL-6 and connective tissue growth factor (CTGF) production in TGF-beta stimulated dermal fibroblasts from healthy donors and lung fibroblasts from idiopathic pulmonary fibrosis patients were evaluated in vitro. Cell toxicity was evaluated in human pulmonary alveolar epithelial cells (HPAEpiC), human lung fibroblasts from idiopathic pulmonary fibrosis patients (DHLF-IPF) and lung microvascular endothelial cells (HMVEC-L) by live cell counting. The plasma concentration of MT-5562F and LPA production were evaluated in C57BL/6 mice. The effects of MT-5562F on skin and lung fibrosis were evaluated in murine SSc models induced by bleomycin (BLM).

Results: MT-5562F, ziritaxestat, and cudetaxestat inhibited the enzyme activity of human ATX with IC50s of 0.45, 49.3, and 2.77 nmol/L, respectively. MT-5562F and ziritaxestat inhibited the enzyme activity of mouse ATX with IC50s of 0.15 and 10.9 nmol/L, respectively. MT-5562F concentration-dependently inhibited TGF-beta-induced IL-6 and CTGF production in human dermal fibroblasts from healthy donors and lung fibroblasts from IPF patients. MT-5562 showed minimal effects on cell viability using lung structural cells such as alveolar epithelial cells (HPAEpiC), pulmonary fibroblasts (DHLF-IPF) and endothelial cells (HMVEC-L) even at the maximum dissolved concentration (60 µmol/L). On the other hand, ziritaxestat showed more cytotoxic effects than MT-5562 on cell viability in vitro. MT-5562 didn't show any specific off-target inhibition on receptor binding and kinase profiling assays. In vivo, MT-5562F and ziritaxestat (10, 30 mg/kg) dose-dependently reduced plasma LPA concentration in mice according to the plasma drug exposure and mouse ATX inhibitory activity, and MT-5562F showed more sustained effects compared with ziritaxestat. Therapeutic treatment with MT-5562F (30, 60 mg/kg, once daily) significantly suppressed skin thickening and the numbers of myofibroblasts in pre-established subcutaneous BLM-induced skin fibrosis model. Therapeutic treatment with MT-5562F (30, 60 mg/kg, twice daily) and ziritaxestat (30 mg/kg, twice daily) showed significant reduction of the average Ashcroft score and collagen severity score in the BLM-induced lung fibrosis model together with the reduction of the biomarker LPA. All doses of MT-5562F significantly reduced the expression of inflammatory and fibrotic mediators such as C-reactive protein, IL-6R-alpha, epidermal growth factor receptor (EGFR) and periostin in bronchoalveolar lavage fluid.

Conclusion: Our results suggest that MT-5562 is a selective and potent ATX inhibitor. It is expected to be a safer compound comparing other ATX inhibitors under development, and it may offer a good option to treat lung and skin fibrosis in SSc.

Background: A group of patients with chronic interstitial pneumonia (IP) have an underlying autoimmune disease -typically a connective tissue disorder (CTD)-. In turn, autoimmune-related IP (AIP) processes are highly heterogenous as regards to their clinical presentation, extra-pulmonary features and risk of fibrotic progression. A better understanding of clinically-relevant disease phenotypes is needed in order to tailor therapeutics.

Objectives: MicroRNA are short non-coding RNAs which orchestrate multiple biological processes by regulating mRNAs via cleavage or translational repression. Circulating levels of miRNA molecules provide excellent information about pathogenic processes in complex diseases, help identify specific disease subgroups and therapeutic targets.

Methods: We have conducted NGS of small-noncoding RNA in patients with AIP enrolled in the NEREA register of AIP and being followed at any of the Special Multidisciplinary Clinics from the participating Centers. The study population comprised 29 subjects (24 cases, 5 controls; 93% women, 87% newly diagnosed patients). Sixty seven % of the patients were diagnosed with interstitial pneumonia with autoimmune features (IPAF) and all patients had a pulmonary dominant disease at the time of blood sampling. QIAGEN genomic services and a NextSeq (Illumina Inc.) instrument were used. For statistical comparisons, the sample was further segregated according to clinical diagnosis, radiographic pattern, evidence of fibrosis in HRCT, relative levels of Krebs von den Lungen (KL-)6 and type of autoantibodies (classified into those potentially-associated to vasculopathy, the ones typically associated to rheumatoid arthritis, and non-specific ANA). The association was considered true for a p level < 0.02 and a low false discovery

rate (FDR), p < 0.1. DIANA tools including the Tarbase v8.0 were used to assess functional pathways with GO and KEGG analysis.
Results: As compared to the healthy controls, patients with IP showed higher levels of let-7i-5p (1.9-fold, p <0.01), miR-483-5p (3.5-fold, p <0.0005) and the miR-320 family. Fibrotic disease was associated to an up-regulation of the let-7 cluster, miR-151a-5p (2.04-fold, p < 0.01), miR-185-5p (2.4-fold, p 0.011), miR-320a-3p (2-fold, p 0.016), miR-320e (2-fold, p 0.016) and miR-423-5p (1.9-fold, p < 0.01). Besides, there was an up-regulation of both of let-7e-5pb levels (3.55-fold, <p 0.005) and miR-483-5p (4.78-fold, p <0.005) in patients with high KL6. On the other hand, patients with vasculopathy-related autoantibodies had a characteristic microRNA signature, with an up-regulation of the miR-10 and miR-30 families as well as levels of miR-320b (2.77-fold, p <0.005), miR-320c (3.71-fold, p < 0.005) and miR-320d (3.84-fold, p <0.005), in addition to miR-483-5p (4.2-fold, p < 0.005), miR-675-5p (7.74-fold, p < 0.005) and miR-1283 (7.40-fold, p < 0.005). The cluster dendogram showed association between miR-10a, miR-10b, miR320c and miR320d regulated processes, with an enrichment in the Hippo signalling, the TFGβ pathway and the fatty acid biosynthesis.
Conclusion: Or data suggests a common miRNA signature in patients with AIP, which includes 2 miRNA molecules, miR-483-5p and miR-320a, which have already been identified in in patients with CTD and IP. In addition, a specific microRNA pattern was found in those patients with a "SSc-like" autoantibodies, pointing to the existence of particular driving processes in this subtype of disease. Confirmation of these findings and validation of targets in a larger sample is warranted in order to advance to a pathophysiologic classification of AIP.

AB0149 THE EXPRESSION AND REGULATION OF NOX4 IN DAMAGED MYOBLASTS IN INFLAMMATORY MYOPATHY

Keywords: Myositis, Adaptive immunity

H. R. Kang[1,2], J. Y. Kim[3], S. U. Kim[3], E. Y. Lee[3], H. S. Kwon[4], S. Ban[4]. *[1]Seoul National University Graduate School, Interdisciplinary Program in Cancer Biology Major, Seoul, Korea, Rep. of (South Korea)*; *[2]Seoul National University Graduate School, Integrated Major in Innovative Medical Science, Seoul, Korea, Rep. of (South Korea)*; *[3]Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[4]Seoul National University, Department of Cancer biology, Graduate School of College of Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Idiopathic inflammatory myopathy (IIM) is a rare autoimmune disease characterized by proximal muscle weakness, elevated muscle enzymes, inflammation in the muscle. If the muscle is already damaged in IIM, it may not regain full strength even after treatment. Also the mechanisms that contribute to muscle weakness in myositis are currently unknown. Nox is the main source of ROS production in various cells types, and is also the source of mitochondria ROS. Excessive expression of Nox4 is characteristic of sclerosis, fibrosis, and cardiac related diseases, and it had been reported that knock down of Nox4 lowers the production of superoxide and hydrogen peroxide. However, the effect of Nox4 in myositis has not been reported.
Objectives: We investigated the expression and role of Nox4 in damaged myoblasts of myositis.
Methods: Myoblasts were isolated from IIM patients who underwent muscle biopsy in Seoul National University Hospital between February 2019 and February 2021. Skeletal muscle cell(SMC) was purchased. Myoblasts and SMCs were treated with cytokine mixture {interferon gamma(IFN-γ), interleukin(IL)-6, IL-15} or PBS for 30 minutes. The expression of Nox4, MyoD and myosin heavy chain(MYH) in myoblast and myotube was analysed by Western blot. For inhibition of Nox4, GKT137831(inhibitor of Nox4) was treated before the cytokine stimulation.
Results: Myoblasts from IIM patients did not differentiate into myotubes like healthy myoblasts suggesting impaired muscle regeneration. Myoblasts from IIM patients express higher level of Nox4 compared to healthy myoblasts. When treated with cytokine mixture(IFN-r, IL-6, IL-15), healthy myoblasts or SMC mimicked inflammatory myositis and showed increased expression of Nox4 and decreased expression of MYH similar to myositis phenotype. Nox4 inhibitor suppressed Nox4 expression and MyoD overexpression in inflammatory myoblasts.
Conclusion: We showed that Nox4 expression is increased in myoblasts from IIM patients and is associated with impaired muscle regeneration. Nox4 inhibition attenuated Nox4 and MyoD overexpression in inflamed myoblasts.

AB0150 ISOLATION AND PHENOTYPIC CHARACTERIZATION OF CIRCULATING EXTRACELLULAR VESICLES IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Myositis, Cell biology

F. Pettorossi[1], C. Franco[1], A. Ghirardello[1], L. Bertazza[2], M. Gasparotto[1], A. Doria[1], M. Gatto[1]. *[1]University of Padova, Unit of Rheumatology, Department of Medicine, Padova, Italy*; *[2]University of Padova, Unit of Endocrinology, Department of Medicine (DIMED), Padova, Italy*

Background: Idiopathic Inflammatory myopathies (IIM) encompass a group of heterogeneous systemic autoimmune diseases for which biomarkers are needed. Extracellular vesicles (EVs) are cell-derived nanoparticles regulating several biological functions[1] and likely involved in the pathogenesis of autoimmune diseases[2], yet their role in IIM was not investigated thoroughly.
Objectives: 1) to develop an effective and reproducible laboratory method to isolate EVs from venous blood; 2) to trace any prominent EVs cellular origin; 3) to perform a quantitative and comparative evaluation of EVs between IIM patients and healthy donors (HD) and across distinct IIM subsets.
Methods: We enrolled adult (≥18 years) consecutive IIM patients (EULAR 2017 criteria) and sex- and age-matched HD. Clinical evaluation of IIM patients was performed by an expert rheumatologist. A venous blood sample (5 mL) was collected from each participant and processed through size exclusion chromatography (SEC) and subsequent ultra-filtration (UF). Particles morphology was observed via transmission electron microscopy (TEM). Nanoparticle tracking analysis (NTA) was performed to evaluate the concentration of EV. The characterization of EV surface markers was conducted through imaging flow cytometry (IFC). Comparisons were carried out using Student's t-test or one-way ANOVA with multiple comparisons.
Results: Sixty-five consecutive IIM patients (dermatomyositis (DM) n=19; polymyositis (PM) n=8; inclusion body myositis (IBM) n=2; anti-synthetase syndrome (ASyS) n=17; cancer-associated myositis (CAM) n=16; unspecified n=3) and 65 HDs were included. Isolated EVs concentration values reached 10^{10}EV/mL. IFC showed surface expression of EVs tetraspanins CD63, CD81, CD9, and integrin CD11c and highlighted a predominance of CD19+ EVs vs. CD3+ EVs in both IIM and HDs (p<0.0001 for both). TEM images showed intact small particles with the typical EVs-"cup-shape" morphology. NTA showed a significantly higher mean concentration of circulating EVs in IIM vs. HD (mean [EVs/mL] ± SD $1.71x10^{10}$ ± $1.29x10^{10}$ vs. $1.31x10^{10}$ ± $7.17x10^{9}$, p=0.031). Across IIM subsets, the highest EVs levels were found in CAM vs. HD ($2.35x10^{10}$ ± $2.20x10^{10}$ vs. $1.31x10^{10}$ ± $7.17x10^{9}$, p=0.0026) and vs. no-CAM patients ($2.35x10^{10}$ ± $2.20x10^{10}$ vs. $1.51x10^{10}$ ± $7.51x10^{9}$, p=0.0206). Patients in clinical remission (n=26, 40%) displayed higher EVs levels than active patients ($2.13x10^{10}$ ± $1.60x10^{10}$ vs. $1.46x10^{10}$ ± $1.02x10^{10}$, p=0.0452) (**Figure 1)**. Concerning treatment, patients on glucocorticoids (GC) alone (n=20, 30.7%) displayed higher EVs levels than patients receiving GC plus immunosuppressants (IS) ($2.23x10^{10}$ ± $1.99x10^{10}$ vs. $1.49x10^{10}$ ± $7.25x10^{9}$, p=0.0341). EVs concentration was significantly decreased in patients receiving rituximab (RTX) vs. other IS ($9.63x10^{9}$ ± $3.26x10^{9}$ vs. $1.96x10^{10}$ ± $1.46x10^{10}$, p<0.001).
Conclusion: The combination of SEC and UF is a reliable approach to obtain intact EVs with preserved morphology and good purity from blood, as confirmed by diverse characterization techniques. The prevalence of CD19+ circulating EVs might indicate B cells as their main origin. Different EVs concentrations discriminate IIM from HD and may provide distinction among specific IIM subsets and treatment response.

DYSFERLIN AS A POTENTIAL ANTI-FIBROTIC PROTEIN INVOLVED IN TGF-B/FOSL-2/AUTOPHAGY CROSSTALKING IN CARDIAC FIBROBLASTS UNDER IMMUNOFIBROTIC CONDITIONS

Keywords: Heart, Cell biology, Cardiovascular disease

I. Kocherova[1], E. Pachera[1], D. Nurzynska[2], F. Di Meglio[2], O. Distler[1], P. Blyszczuk[1], G. Kania[1]. [1]*University of Zurich, University Hospital Zurich, Department of Rheumatology, Center of Experimental Rheumatology, Zurich, Switzerland*; [2]*University of Naples Federico II, Department of Public Health, Naples, Italy*

Background: Myocardial fibrosis, ultimately leading to heart failure (HF), represents a point of convergence for most cardiac disorders. Heart involvement is a common finding in autoimmune rheumatic patients. The TGF-β-FOSL-2-autophagy axis controls cardiac fibroblast differentiation, driving the progression of profibrotic changes [1]. Limited evidence suggests the pro-regenerative potential of adult cardiac fibroblasts directed to restrain the excessive profibrotic response and support tissue regeneration following myocardial injury.
Objectives: To identify the molecular basis of fibroblast-mediated compensatory response to myocardial fibrosis in adult heart.
Methods: Adult cardiac fibroblasts were isolated from the left atria of patients undergoing heart transplantation due to end-stage HF caused by inflammatory dilated cardiomyopathy (n=5) and from unaffected myocardium of brain-dead donors (Ctrl, n=5). Protein quantification was performed using liquid chromatography tandem-mass spectrometry (LC–MS/MS), and the data analysis was conducted with MaxQuant v1.6.2.3 software. The Enrichr tool was used for pathway enrichment analysis [2]. Selected gene knockdown was achieved through Lipofectamine 2000-mediated siRNA transfection of human foetal cardiac fibroblasts (HCFs, Sigma), untreated or stimulated with TGF-β (10 ng/mL, 48-72h). Chosen gene and protein expression was evaluated by RT-qPCR and Western Blot, respectively. Cell viability was determined with PrestoBlue HS reagent, and ATP levels were measured with CellTiter-Glo assay 48h after transfection.
Results: Quantitative proteomic analysis of adult cardiac fibroblasts revealed 14 differentially expressed proteins (adj. p<0.05) in HF compared to Ctrl. The identified proteins belong to biological pathways mainly involved in ECM remodeling and associated with several pathologies, such as atherosclerosis, muscular dystrophy and myocardial ischemia. The most upregulated protein in HF fibroblasts was dysferlin (DYSF, log2FC=5.78, adj. p<0.005), which is known to promote sarcolemma repair in skeletal muscle fibres and cardiomyocytes. Further *in vitro* study showed that TGF-β stimulation significantly upregulates DYSF gene (n=4, p<0.001) and protein (n=3, p<0.001) expression in cultured HCFs. *DYSF* silencing upregulated *COL1A1* expression in untreated (n=4, p<0.05) and TGF-β-stimulated (48h, n=4, p<0.05) HCFs. On the protein level, *DYSF* knockdown upregulated the profibrotic transcription factor FOSL-2 in untreated HCFs (n=9, p=0.004) and following 72h of TGF-β stimulation (n=9, p<0.001). In turn, *FOSL-2* silencing in HCFs significantly upregulated DYSF protein level (n=5, p<0.0001) after 72h of TGF-β stimulation, suggesting a mutual regulation between DYSF and FOSL-2. Further analysis of autophagy-related proteins revealed that *DYSF* silencing increases LC3BII expression (n=6, p<0.05) and downregulates P62 (n=6, p=0.01) in TGF-β-stimulated HCFs. Finally, we observed reduced viability of cells subjected to *DYSF* knockdown in both untreated (n=4, p<0.01) and TGF-β-stimulated (n=4, p<0.05) conditions. *DYSF* silencing was also associated with decreased ATP production in TGF-β-treated HCFs (n=6, p=0.05).
Conclusion: Proteomic profiling of human cardiac fibroblasts supported by *in vitro* analysis identified DYSF as an anti-fibrotic protein compensatory upregulated under immunofibrotic conditions and involved in TGF-β-FOSL-2-autophagy axis regulation. This newly proposed candidate may serve as a potential therapeutic target for stimulating fibroblast-induced myocardial regeneration.

URIC ACID IN SYSTEMIC SCLEROSIS-RELATED PULMONARY ARTERIAL HYPERTENSION:INNOCENT BYSTANDER OR COVERT ACCOMPLICE?

Keywords: Systemic sclerosis, Cardiovascular disease, Cytokines and chemokines

A. Van Caam[1], J. Lemmers[1], M. Vonk[1], S. Van Leuven[1]. [1]*Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*

Background: When uric acid levels increase to reach the supersaturation level (>70 μg/ml), it transforms into its crystalline form and binds to surface lipids on immune cells. Phagocytes ingest this cellular debris and thereby receive a 'danger signal' from uric acid and are stimulated to mature and become immunostimulatory [1,2].
Objectives: Considering uric acid helps to predict the development of pulmonary arterial hypertension (PAH) in systemic sclerosis (SSc) (3), we aim to establish whether uric acid induces a pro-inflammatory response in SSc in general and in SSc-PAH in particular.
Methods: Peripheral blood mononuclear cells (PBMCs) were harvested from 16 SSc-PAH patients. PMBCs were isolated from 32 age- and sex-matched SSc-nonPAH patients with similar skin distribution and autoantibodies. Finally, PMBCs from 5 idiopathic PAH (iPAH) patients and 16 age- and sex- matched healthy controls were collected. Cells were treated with or without uric acid in

soluble form for 24 hours, and subsequently cytokine production was measured by Luminex, and mRNA levels were assessed using qPCR.

Results: Baseline expression of interleukin (IL)-1β and IL-6 was similar in SSc-PAH, SSc-nonPAH, iPAH and healthy controls. On mRNA level, urid acid stimulated IL-1 and IL-6 expression in all PBMCs but IL-1 and IL-6 expression was most potently upregulated in SSc patients compared to healthy controls (a 2-fold versus an 8-fold increase respectively). However, induction of IL-1 and IL-6 expression by urid acid-stimulated PBMCs was similar in SSc-PAH and SSc-nonPAH patients. Similarly, on protein level, production of IL-1β, IL-6 and TNF-α was increased in PBMCs from SSc patients compared to iPAH patients and healthy controls. Interestingly, we observed that urid-acid stimulated PBMCs from SSc-PAH patients produced significantly more IL-1β, IL-6 and TNF-α compared to SSc-nonPAH patients.

Conclusion: In this study we demonstrate that soluble uric orchestrates an excessive inflammatory response by facilitating more enhanced IL-1β, IL-6 and TNF-α production in SSc-PAH compared to SSc-nonPAH, iPAH and healthy controls. These findings suggest that uric acid not only has a role in prediction of SSc-PAH but also contributes to the development of SSc-PAH.

AB0153 GENETIC EVIDENCE SUPPORTS CAUSAL EFFECT OF GUT MICROBIOTA AND DERMATOMYOSITIS

Keywords: Genetics/epigenetics, Myositis

L. Liu[1,2], Y. Zhang[1,2], X. Geng[1,2], Q. Yu[3], P. F. He[3], X. Li[1,2,4], S. X. Zhang[1,2,4]. *[1]Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; *[2]Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan,*; *[3]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*; *[4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: Recent observational research has documented that dermatomyositis (DM) has lower gut microbial diversity and a distinct taxonomic composition[1]. However, the underlying causality remains unclear.

Objectives: To explore the potential causal associations between gut microbial genera and DM, a two-sample Mendelian randomization (MR) analysis was conducted.

Methods: We selected genetic variants associated with gut microbiota traits (n = 14,306) [2]and DM (n=213,353) from genome-wide association studies (GWAS). Two-sample MR analysis was conducted to identify potential causal gut microbial genera for DM using the inverse-variance weighted (IVW) method, weighted-median, and MR-Egger regression. The sensitivity analysis was also performed to verify the robustness of the primary results of the MR analysis. Cochran's Q statistics were used to quantify the heterogeneity of instrumental variables[3].

Results: Three bacterial genera were associated with the risk of DM in the IVW method. *Ruminococcaceae* genus(id.11360) was positively associated with DM [odds ratio(OR):2.44, 95%CI:1.17-5.07], as well as for *Sutterella* genus (id.2896, OR:3.39, 95%CI:1.30-8.84). In addition, results indicated a negative association for the *Anaerotruncus* genus (id.2054, OR:0.31, 95%CI:0.11-0.88) with DM (Table 1). Moreover, the sensitive analysis excluded the influence of heterogeneity and horizontal pleiotropy. Leave-one-out analysis also suggested the results were robust.

Conclusion: This study demonstrates that the *Ruminococcaceae*, *Sutterella*, and *Anaerotruncus* are causally related to DM, providing novel insights into the gut microbiota-mediated development mechanism of DM to access more therapeutic methods.

AB0154 MENDELIAN RANDOMIZATION STUDY IMPLIES CAUSAL LINKAGE BETWEEN POLYMYOSITIS AND PHYSICAL ACTIVITY

Keywords: Myositis, Genetics/epigenetics, Self-management

J. Y. Chen[1,2], B. Song[1,2], Q. Feng[1,2], Y. Feng[1,2], Q. Yu[3], P. F. He[3], X. Li[1,2,4], S. X. Zhang[1,2,4]. *[1]Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Shanxi Medical University, Taiyuan, Shanxi Province, China*; *[2]Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, Shanxi Province, China*; *[3]Shanxi Key Laboratory of Big Data for Clinical Decision Research, Shanxi Medical University, Taiyuan, Shanxi Province, China*; *[4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China*

Background: Polymyositis (PM) is autoimmune myopathy characterized clinically by proximal muscle weakness, muscle inflammation, extra-muscular manifestations, and frequently, the presence of autoantibodies[1].The causal relationship between physical activity (PA) and PM remains uncertain.

Objectives: This study aimed to determine the effect of physical activity on PM.

Methods: The instrumental variables proposed SNP at the genome-wide significance threshold ($p < 5\times10^{-8}$).To mitigate collinearity between the contained SNPs, we excluded SNPs in the linkage disequilibrium (LD) (pairwise $r^2 > 0.01$). F-Statistics, above the threshold of 10, showed the result's sensitivity. Summary statistics of PM were obtained from a genome-wide association study (GWAS) meta-analysis

of the descent, including 16,380,451 cases and 213,145 controls[2].The data of PA, including accelerometer-based physical activity(APA), vigorous physical activity(VPA),moderate to vigorous physical activity (MVPA),moderate physical activity 10+ minutes(MPA10+), vigorous physical activity 10+ minutes(VPA10+) and sedentary behavior (Time spent watching television (TV), Time spent using computer and Time spent driving) were available from UK Biobank dataset. To evaluate the causal association between PA and PM, the inverse variance weighted (IVW) was conducted as the primary method. In sensitivity analyses, we used the MR-Egger method to evaluate the potential pleiotropy effects. Moreover, we also applied weighted median and MR-PRESSO to assess the presence of pleiotropy. Meanwhile, leave-one-out analysis was performed to test the influence of outlying values.
Results: We selected 313 SNPs (10 SNPs for APA,2 SNPs for VPA, 23 SNPs for MVPA, 19 SNPs for MPA10+, 13 SNPs for VPA10+, and 246 SNPs for sedentary). APA was positively associated with the risk of PM (OR 1.53 95%CI 0.03-0.82 P=0.036). MR-Egger, MR-PRESSO, and leave-one-out analysis did not indicate horizontal pleiotropy. Based on the result of IVW method, there was little evidence of causal associations of the remaining seven exposures with the risk of PM. (p > 0.05)(Figure1).

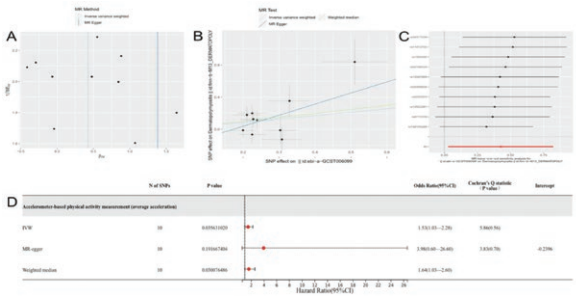

Figure 1. Mendelian randomization analysis for gene-level causality between PA, sedentary behaviors, and PM were evaluated by the odds ratio (OR) values of IVW, MR Egger, and Weighted median. Funnel plot (A), scatter plot (B), leave-one-out analysis (C), and forest plot (D) assessed that APA increases the risk of PM. MR, mendelian randomization; IVW, inverse-variance weighted method; MR-Egger, Mendelian randomization-Egger; SNP, single nucleotide polymorphisms; CI, confidence interval.

Conclusion: APA was causally associated with the risk of PM.

AB0155 POTENTIAL DIAGNOSTIC AND PROGNOSTIC SIGNIFICANCE OF ANTI-CARBAMYLATED PROTEIN ANTIBODIES IN THE SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Biomarkers, Autoantibodies

E. Favoino[1], E. Grapsi[1], M. Prete[1], V. Racanelli[1], F. Perosa[1]. [1]*University of Bari Medical School, Department of Interdisciplinary Medicine, Bari, Italy*

Background: Spondyloarthritis (SpA) include a group of inflammatory rheumatic diseases with different clinical manifestations. The diagnosis of SpA is still a challenge in clinical practice, in that specific serological markers are still missing. Recently, anti-carbamylated protein antibodies (anti-CarP Ab) have been detected in patients with psoriatic arthritis (PsA) and their levels appear to be associated to disease activity [1].
Objectives: The aim of this esplorative study was to evaluate the potential role of anti-CarP Ab in the diagnosis and prognosis of peripheral enthesitis or arthritis (E/A).
Methods: Serum samples and clinical data from 91 patients with peripheral E/A, of which 43 with PsA, 8 patients with uSpa and 40 with E/A responding to disease-modifying antirheumatic drugs (DMARDs) not fulfilling ASAS classification criteria ($ASAS^-$), were collected. Anti-CarP Ab were detected by indirect ELISA. Serum anti-CarP were also determined in 35 healthy donors (HD).
Results: Anti-CarP were detected in both PsA (14%) and E/A $ASAS^-$ (5.2%) patients, being their prevalence significantly higher in PsA patients than in HD (*chi-square* p=0.019). No anti-CarP Ab were detected in uSpA. Kendall's correlation analysis showed that in the whole E/A population, anti-CarP Ab levels directly correlated with disease activity (p=0.047), plantar fasciitis (p=0.037) and family history of psoriasis (p=0.012). Anti-CarP Ab levels were also directly correlated with the presence of autoimmune thyroiditis in PsA subgroup (p=0.02), and with family history of psoriasis in E/A $ASAS^-$ subgroup (p=0.016).
Conclusion: This study suggests an association of anti-CarP Ab levels and disease activity in peripheral E/A. Whether the presence of anti-CarP Ab in E/A $ASAS^-$ may predict evolution in PsA remains to be assessed.

AB0156 MECHANOTRANSDUCTION VIA MYOSIN II ISOFORMS IN DEVELOPMENT OF SKIN FIBROSIS WITHIN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Cytokines and chemokines, Skin

B. Russo[1], M. Shutova[1], G. Romanescu[1], N. Brembilla[1], W. H. Boehncke[2]. [1]*University of Geneva, Pathology and Immunology, Geneva, Switzerland*; [2]*Hôpitaux Universitaires de Genève (HUG), Dermatology and Venereology, Genève, Switzerland*

Background: Skin fibrosis, the hallmark of systemic sclerosis (SSc), is a complex inflammatory process leading to excessive extracellular matrix (ECM) deposition and increased stiffness in the dermis [1]. The mechanical properties of the extracellular environment can be sensed by the cells and transformed into intracellular signalling and gene expression regulation in the process of mechanotransduction. The upregulation of mechanotransduction has been linked to the progression of fibrosis in SSc, particularly through the Rho-ROCK-dependent myosin II pathway, which activates intracellular contractility [2]. Nonmuscle myosin II itself is expressed as three isoforms (NMIIA, NMIIB, NMIIC) with common and unique functions. However, the specific role of Rho activation and distinct NMII isoforms in SSc pathogenesis is unknown.
Objectives: To investigate the role of NMII isoform regulation in the development of skin fibrosis in SSc.
Methods: The expression of NMIIA and NMIIB, as well as their activation through phosphorylation of Myosin Light Chain (MLC) were evaluated by immunofluorescence in primary fibroblasts from four SSc and four healthy donor (HD), which were stimulated with rhTGFβ. The NMII contractility was inhibited with Y-27632, a small molecule inhibitor of ROCK that phosphorylate MLC, or blebbistatin, a small molecule that inhibit NMII. The production of IL-6 and type-I collagen by fibroblasts was assessed by ELISA.
Results: We have observed a re-distribution of NMII isoforms within the intracellular contractile system and increased MLC phosphorylation in cultured SSc fibroblasts compared to HD. A similar phenotype was observed in HD fibroblasts primed with TGFβ. Treatment of TGFβ-primed HD fibroblasts with Y-27632 or blebbistatin substantially reduced IL-6 and collagen I production.
Conclusion: Our data point to an altered actomyosin cytoskeleton dynamics and force distribution in SSc fibroblasts and indicate that NMII isoforms are required for the TGFβ-dependent secretion of inflammatory cytokines and collagen deposition by fibroblasts.

AB0157 SYNERGISTIC EFFECT OF AT1R-AUTOANTIBODIES AND EXTRACELLULAR VESICLES IN SSC PATHOGENESIS

Keywords: Systemic sclerosis, Innate immunity, Autoantibodies

A. Hackel[1], R. Akbarzadeh[1], M. Leiber[1], A. Müller[1], G. Riemekasten[1]. [1]*University Clinic Schleswig-Holstein, Lübeck, Germany, Clinic of Rheumatology and Clinical Immunology, Lübeck, Germany*

Background: Systemic sclerosis, a rare chronic inflammatory disease, are characterized by immune system activation, vasculopathy, and fibrosis of the body organs. Emerging evidence have so far indicated that autoantibodies (abs) directed against G protein-coupled receptors (GPCRs) particularly contribute to the SSc pathogenesis and inducethe release of inflammatory and profibrotic proteins by immune cells such as monocytes [1-3]. Increased levels of autoantibodies against the angiotensin II type 1 receptor (AT1R abs) have been found in SSc patients [4-5], which are associated with increased secretion of extracellular vesicles (EVs) [6]. Interestingly, upregulated CCL18 levels could be associated with AT1R-EVs in SSc patients [8]. EVs play an important role in the pathogenesis of diseases by packing and transfer of AT1R to different tissues and immune cells, exemplary shown by activated cardiomyocytes leading to higher responsiveness to angiotensin II of recipient cells and vessels [9]. Taken together, the importance of studying anti-GPCR-abs together with GPCR-EVs in the pathogenesis of SSc becomes evident [10].
Objectives: Here we decipher the immune response of peripheral blood monocytes mediated by anti-AT1R-abs and EVs, in the pathogenesis of SSc.
Methods: Monoclonal AT1R ab (AT1R mab) has been generated by hybridoma technique, sequenced and recombinantly expressed in HEK cells. Human peripheral blood monocytes and monocytic cell lines were stimulated by the recombinant monoclonal anti-human AT1R ab and, in comparison, in the presence or absence of EVs precipitated from sera of SSc patients versus sera of HD. The response of the monocytes was measured via CCL18 secretion by ELISA.
Results: We compared CCL18 release, a profibrotic cytokine, of monocytic cells upon stimulation for 24 h with the AT1R mab in presence or absence of sera EVs (SSc vs. HD). The recombinant monoclonal anti-human AT1R antibody induced secretion of CCL18 by monocytes. Our data indicate that EVs together with AT1R mab have an effect on monocyte activation and CCL18 secretion. Remarkably, combination of SSc-EVs, but not of HD-EVs, with the recombinant AT1R mab showed an additive effect on monocyte activation and CCL18 response (Figure 1).

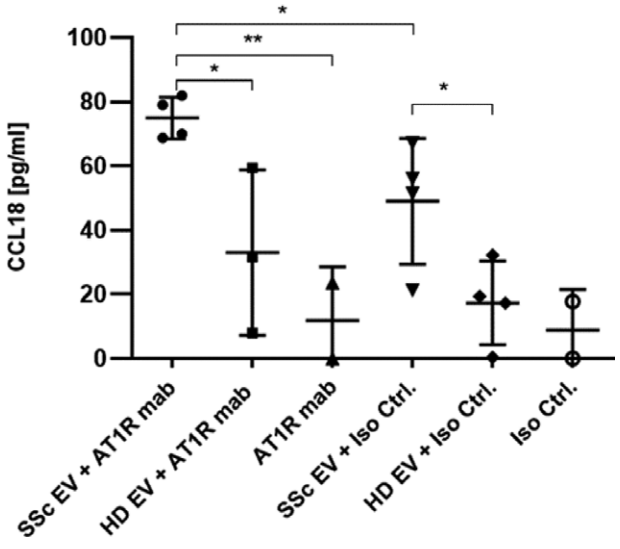

Figure 1. CCL18 levels released by monocytic cells after stimulation with EVs and AT1R mab or isotype.

Stimulation with SSc EV + AT1R mab (n=4), HD EV + AT1R mab (n=3), AT1R mab control, SSc EV + isotype (n=4), HD EV + isotype (n=3) and isotype control. One-way ANOVA was used to test for statistical significance (*p<0.05, **p<0.01, ***p<0.001).
Conclusion: The secretion of pro-fibrotic CCL18 by human monocytes in response to a monoclonal AT1R antibody as well as to SSc IgG indicates that anti-AT1R abs are involved in the SSc pathogenesis. Further, this effect could also be due to SSc-EVs potentially presenting anti-GPCR abs to their receptors on immune cells.

GENETIC EVIDENCE OF CASUAL ASSOCIATION BETWEEN POLYMYOSITIS AND RISK OF INTERSTITIAL LUNG DISEASE: A MENDELIAN RANDOMIZATION STUDY

Keywords: Lungs, Myositis

Z. J. Yuan[1,2], R. Zhao[1,2,3], M. K. Yao[1,2], J. Y. Li[1,2], S. Y. Liu Yue[1,2], S. X. Zhang[1,2,3], X. Li[1,2,3], C. Wang[1,2,3]. *[1]Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; *[2]Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China*; *[3]The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China*

Background: Polymyositis (PM) is an immunologically abnormal inflammatory myopathy, which is one of the common types of idiopathic inflammatory myopathy[1]. A global prevalence of approximately 41% of Interstitial lung disease (ILD) in PM patients has been estimated, which causes significant morbidity and mortality[2]. There have been a number of studies shown that PM and ILD may have similar pathogenesis, which focus on PM may induce ILD cellular immune system components[3]. While the two diseases may occur at the same time, but there is no directly evidence that the two diseases are causally related.
Objectives: Our study aimed to discover the casual association between PM and ILD, and determine the impact of PM on ILD.
Methods: We retrieved two large European genome-wide association study (GWAS) summary data of PM and ILD from MRC IEU OpenGWAS, which included 213,264 and 218,072 individuals, respectively. Single-nucleotide polymorphisms (SNPs) linked with disease were selected as instrumental variables (IVs) using genome-wide significance levels ($P < 1.0 \times 10^{-5}$). And the interference of confounding factors, including smoking, drinking and BMI were eliminated. The two-sample Mendelian randomization (MR) method was applied to estimate the casual relationship of PM on ILD. The random-effects inverse variance weighted method (IVW) was mainly used to the MR analysis. Additionally, the horizontal pleiotropy effect was analyzed by MR-Egger and weighted median method sensitivity test. A leave-one-out analysis was conducted to avoid bias caused by a single SNP.
Results: Our study discovered that PM was considered as a risk factor of ILD. 15 SNPs strongly associated with PM were extracted from GWAS. The existence of PM may increase the risk of ILD by 1% (OR = 1.008, 95% CI: 1.001 - 1.016, p = 0.002) No single SNP significantly biased the causal effect of PM on ILD (Q = 0.18). No significant directional horizontal pleiotropy between PM and ILD was presented in the MR-Egger regression analysis.
Conclusion: This study provides evidence of an adverse effect of PM on ILD. And these may be meaningful for the prevention and intervention of PM and ILD. Meanwhile, our work also provides genetic statistical evidence for the study of the causal relationship of PM and ILD.

AB0159 THE POSITIVE EFFECT OF VITAMIN D3 AND Α-TOCOPHEROL ACETATE ON PULMONARY ARCHITECTONICS IN AN EXPERIMENTAL MODEL OF SYSTEMIC SCLEROSIS

Keywords: Animal models, Lungs, Systemic sclerosis

B. Doskaliuk[1], L. Zaiats[1], R. Yatsyshyn[2]. [1]*Ivano-Frankivsk National Medical University, Pathophysiology, Ivano-Frankivsk, Ukraine*; [2]*Ivano-Frankivsk National Medical University, Internal Medicine #1 Clinical Immunology and Allergology, Ivano-Frankivsk, Ukraine*

Background: Systemic scleroderma (SSc) is an autoimmune disease characterized by a wide range of clinical manifestations. One of the main targets of this pathology is the pulmonary system. In turn, SSc-associated damage of lung structures is characterized by a significant negative impact on the survival and quality of life of patients.
Objectives: Therefore, we aimed to assess the possible favorable influence of vitamin D3 (VD3) and α-tocopherol acetate (ATA) on the morphological structure of lungs' parenchyma in the experimentally induced SSc.
Methods: We assembled our experimental animals into three groups: a control group (CG) (20 animals), an experimental group (EG) #1 (25 animals), and #2 (25 animals). Experimental animals were mature laboratory rats, belonged to the Wistar line, and were 180-220 g of weight. Animals in EG #1 were injected with sodium hypochlorite (NaClO) according to the reported previously schedule [1] for SSc modeling purposes. Laboratory animals of the CG were receiving isotonic solution according to the same scheme. In EG #2, rats were subjected to intramuscular injections of ATA solution 10 mg/ 100 g of body weight, and of a VD3 solution 1000 IU/ 100 g of body weight for 3 weeks (second half of the experiment performance). All three groups of animals were removed from the experiment 8 weeks after its beginning. The lung tissue specimens were examined using light (Leica DM750, x200 magnification) microscopy. Data distribution was evaluated with descriptive statistics, and a $p<0.05$ was considered statistically significant. Statistical analysis was carried out using IBM SPSS version 26.
Results: The lung parenchyma samples obtained from CG did not show significant deviations from the normal histological picture. (Figure 1A). The histological analyses of lung specimens of experimental animals reviled non-specific interstitial pneumonia (NSIP) which is the most common type of SSc-associated interstitial lung disease (ILD) (Figure 1B). There were productive and sclerotic modifications of the interalveolar septum, their infiltration by the lymphoid and plasma cells with significant disfigurement of alveolar structure. (White arrow – alveolar wall thickening; black arrow – thickening of basal membrane of microvessels). After using VD3 and ATA animals demonstrated a distinct decrease in the intensity of lymphoid and plasma cells infiltration of interalveolar spaces (Figure 1C). Furthermore, the sclerotic alteration of the alveolar-capillary barrier was less prominent compared to EG #1 specimens. The Ashcroft score was significantly higher in EG#1 (3.7±0.6) compared to EG#2 (1.8±0.3) ($p<0,05$) and CG (0.6±0.1) ($p<0,05$).
Conclusion: This study confirms positive effect of vitamins D3 and α-tocopherol acetate on morphological structure of pulmonary parenchyma in the preclinical model of SSc.

Background: There is growing evidence supporting an association between gut microbiota and the risk of systemic sclerosis (SSc)[1]. However, the causal relationship between gut microbiota and SSc remains ambiguous.
Objectives: A two-sample Mendelian randomization (MR) analysis was performed to reveal the causal relationship between gut microbiota and SSc.
Methods: We obtained data on intestinal flora from the MR-base website [2] and 218,499 samples for systemic sclerosis from the IEU database for a two-sample MR analysis. Inverse variance weighting, MR-Egger, and weighted median were used to examine the causal relationship between gut flora and SSc. Then a series of sensitivity analyses were performed to verify the robustness of the results. Finally, the bacteria which appeared causality with SSc were subjected to reverse MR analysis to assess the possibility of reverse causality.
Results: Inverse variance-weighted estimates indicated that genus *Collinsella* (odds ratio(OR) = 8.982, 95% confidence interval(CI): 1.571-51.366 , P = 0.014), phylum *Actinobacteria* (OR = 5.746, 95% CI: 1.247-26.491 , P = 0.025), genus *Ruminococcaceae* (OR = 5.500, 95% CI: 1.477-20.477 , P = 0.011) had a risk effect on SSc (**Table 1**). According to the results of the reverse MR analysis, SSc had no significant causal effect on intestinal flora. No significant heterogeneity or horizontal pleiotropy of instrumental variables was found.
Conclusion: The present study revealed a causal relationship between three gut microflora genera and SSc, providing new insights into the mechanisms of gut microbiota-mediated scleroderma development.

EARLY INITIATION OF QUADRUPLE THERAPY IN PATIENTS WITH ANTI-MELANOMA DIFFERENTIATION-ASSOCIATED 5 GENE ANTIBODY-POSITIVE (MDA5) DERMATOMYOSITIS (DM) WITH RAPIDLY PROGRESSIVE INTERSTITIAL LUNG DISEASE (RP-ILD) – A RETROSPECTIVE CASE SERIES

Keywords: Disease-modifying drugs (DMARDs), Lungs, Myositis

K. M. Chong[1], M. MA[2,3], F. Teo[3,4], P. Cheung[2,3]. [1]*National University Hospital, Department of Medicine, Singapore, Singapore*; [2]*National University Hospital, Division of Rheumatology, Department of Medicine, Singapore, Singapore*; [3]*National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore*; [4]*National University Hospital, Division of Respiratory and Critical Care Medicine, Department of Medicine, Singapore, Singapore*

Background: MDA5 autoantibodies have been associated with an amyopathic form of dermatomyositis, with a subset developing RP-ILD with high mortality of 50%, despite intensive immunosuppressive therapies like high dose prednisolone, cyclophosphamide and calcineurin inhibitors.[1] Tofacitinib and rituximab have also been used as single agents, mainly as salvage therapy. [2]
Objectives: We aimed to investigate the role of early use of quadruple therapy (high dose steroids, one dose of cyclophosphamide, tofacitinib, rituximab) in patients with anti-MDA5 Ab-positive DM with RP-ILD.
Methods: This is a retrospective case series involving 4 patients with anti-MDA5 Ab-positive DM with RP-ILD from 2019 to 2021. They were treated with quadruple therapy. Their clinical outcomes including survival and adverse events were evaluated.
Results: At initial diagnosis of RP-ILD, all patients were given pulsed methylprednisolone and 1 dose of cyclophosphamide. Tofacitinib was started within 2 weeks, followed by rituximab. 3 patients achieved clinical and biochemical improvement over time, with reduction of glucocorticoids by 6 months. Of the 4 patients, 1 required ICU stay and died. Severe adverse events were observed, most of which were infective complications.

Graph 1. Trend of ferritin and LDH during clinical course over 6 months

Conclusion: We report a general improvement of survival in anti-MDA5 Ab-positive DM with RP-ILD when treated early with quadruple therapy.

Vasculitis - aetiology, pathogenesis and animal models

AB0162 RELATIONSHIPS BETWEEN THE SIGNALING PATHWAY OF BAFF/APRIL AND CIRCULATING B CELLS IN ANTINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

Keywords: Vasculitis, Cytokines and chemokines

Y. Shimojima[1], D. Kishida[1], T. Ichikawa[1], R. Takamatsu[1], S. Nomura[1], Y. Sekijima[1]. *[1]Shinshu University School of Medicine, Department of Medicine (Neurology and Rheumatology), Matsumoto, Japan*

Background: Increased production of B-cell activation factor of the TNF family (BAFF) and a proliferation-inducing ligand (APRIL) have been identified in antineutrophil cytoplasmic antibody-associated vasculitis (AAV). BAFF and APRIL exhibit biological activities by binding to three different types of receptors; BAFF receptor (BAFF-R), transmembrane activator and calcium modulator and cyclophilin ligand interactor (TACI), and B-cell maturation antigen (BCMA). Meanwhile, it is uncertain how these three receptors could express or be altered depending on disease activity in AAV.
Objectives: We investigated the characteristics of circulating B cells, serum levels of BAFF, and APRIL, as well as the expression of their binding receptors on B cells, and analyzed the relationships among them in patients with AAV.
Methods: This study used peripheral blood samples from 24 patients with active AAV (a-AAV), 13 with inactive AAV (i-AAV), and 19 healthy controls (HC). The proportion of B-cell subsets, including CD19+ cells, CD19+CD27-CD38+ (immature B) cells, CD19+CD27+CD38- (memory B) cells, and CD19+CD27+CD38+ cells (plasmablasts/plasma cells: PB/PC), and their expressing BAFF-R, TACI, and BCMA were analyzed using flow cytometry. Serum levels of BAFF, APRIL, and interleukin (IL)-6 were also evaluated using an enzyme-linked immunosorbent assay. The relationships among these experimental results were statistically analyzed using univariate regression analyses.
Results: The proportion of PB/PC was significantly higher in a-AAV than in HC ($p < 0.0001$). Higher serum levels of BAFF, APRIL, and IL-6 were significantly observed in a-AAV than in HC ($p < 0.0001$), while serum levels of BAFF and APRIL were significantly higher in i-AAV than in HC ($p = 0.0003$ and $p = 0.005$, respectively). BAFF-R expression on memory B cells was significantly lower in the patients with a-AAV and i-AAV than in the HC ($p = 0.017$ and $p = 0.016$) but not significantly different between patients with a-AAV and i-AAV. Expression of TACI was significantly higher in a-AAV and i-AAV than in HC on CD19+ cells ($p = 0.011$ and $p = 0.028$, respectively), immature B cells ($p = 0.014$ and $p = 0.002$, respectively), and PB/PC ($p = 0.013$ and $p = 0.011$, respectively), despite not being significantly different between the patients with a-AAV and i-AAV. The regression analyses demonstrated that the population of memory B cells was positively associated with serum APRIL levels (coefficient 0.071, 95% confidence interval [CI] 0.035 to 0.106, $p = 0.0004$) and BAFF-R expression (coefficient 0.0001, 95% CI 0.00006 to 0.0002, $p = 0.002$).
Conclusion: Decreased expression of BAFF-R on memory B cells and increased expression of TACI on CD19+ cells, immature B cells, and PB/PC, as well as increased serum levels of BAFF and APRIL, were significantly demonstrated even in patients with remission AAV. Our results suggested that the signaling of BAFF/APRIL and their receptors was pivotally implicated in the generation of B cells. Furthermore, persistently activated signaling of BAFF/APRIL may lead to disease relapse.

Background: The pathophysiology of Takayasu arteritis (TAK) is incompletely understood. Gene expression profile of peripheral blood mononuclear cells (PBMCs) in TAK has been scarcely studied and may provide new insights into its pathogenesis.
Objectives: To identify and functionally annotate differentially expressed genes (DEGs) in immunosuppressive-naïve TAK compared with healthy controls (HCs).
Methods: Fifteen immunosuppressive-naïve TAK [10 Females, mean (SD) age 34.13(13.28) years] and 10 healthy controls (HC) [8 females, mean (SD) age 31.8(4.57) years] were recruited after obtaining written informed consent. After isolating PBMCs, RNA was extracted using Trizol method. RNA quality was checked using Nanodrop™ (260/280~2, 260/230≥2). Whole gene transcriptome signature was assessed using Affymetrix Clariom™ D human microarray. Using Transcriptome analysis console (version 4.0.3.1.4), signal output from raw CEL files was normalized (group-averages with standard deviations and gene-level limma) to generate CHP files which were analysed for DEGs (up- & down-regulated), filtered on fold-change in TAK versus HC (≥2 or ≤-2) and p value < 0.05.Thereafter, functional annotation of up- and down-regulated genes was performed using Database for Annotation, Visualization, and Integrated Discovery (DAVID) to evaluate Gene Ontology (GO) clusters and processes.
Results: Of 135750 genes, 558 genes passed filter criteria [up-regulated 185 - Coding 33 (17.84%), micro RNA 1 (0.54%), multiple complexes 93 (50.27%), non-coding 23 (12.43%); down-regulated 373 - Coding 53 (14.21%), micro RNA 61 (16.35%), multiple complexes 35 (9.38%), non-coding 190 (50.94%)] (Volcano plot in Figure 1). After functional annotation for 111 up-regulated genes identified on DAVID, two clusters were generated. Cluster 1 (enrichment score 2.20) comprised hemoglobin complex, oxygen transport activity, heme binding, and oxygen binding pathways. Cluster 2 (enrichment score 0.70) comprised JNK cascade, protein kinase activity, and protein phosphorylation. Sixty-seven up-regulated processes were identified (Table 1). Functional annotation for 14 down-regulated genes identified on DAVID identified one cluster (enrichment score 0.76) comprising extracellular exosomes, cytoplasm, nucleoplasm, cytosol and protein binding pathways. Four down-regulated processes were identified (Table 1).
Conclusion: We identified an up-regulation of processes related to protein-specific domain binding, serine/threonine kinase activity, magnesium ion binding, oxygen transporter activity, and various cellular components in TAK than in HC.

Down-regulated processes in TAK than in controls related to protein translation and generation of exosomes. A detailed pathway analysis of these processes may provide novel pathophysiological insights into TAK.

Background: Behçet's syndrome (BS) is a rare systemic vasculitis hallmarked by oral, genital and ocular involvement, often accompanied by articular, cutaneous, vascular, neurological, and gastrointestinal manifestations [1, 2]. Articular involvement is present in up to 80% of BS patients [3], and, from a clinical point of view, it may resemble seronegative arthritis, particularly psoriatic arthritis (PsA), with which an overlap has also been described [4-6]. To this date, no specific instrumental or laboratory biomarker is available to help the differential diagnosis between BS and PsA, which currently relies only on clinical assessment and might be particularly challenging. On these bases, there is a growing interest on the identification of new laboratory biomarkers which might assist in the diagnostic process. Among them, interleukin (IL)-36 belongs to the IL-1 family and is involved in skin and joint-related inflammatory conditions [7, 8]. Increased serum levels of IL-36, especially IL-36α, have been described in PsA at synovial level [9], while no study investigated its levels in BS.
Objectives: This study aimed to assess the ability of serum IL-36α to differentiate BS from PsA patients.
Methods: A cross-sectional study was performed on a cohort of 90 adult patients with BS followed at two referral centres for BS (Behçet Center of the Careggi University Hospital of Florence, and University Hospital of Siena, Italy), 80 patients with PsA from the University Hospital Erlangen (Germany), and 80 healthy controls (HCs). Serum IL-36α concentrations were measured in blood samples using human IL-36α enzyme-linked immunosorbent assay (ELISA) kits (MyBioSource, San Diego, Ca), and compared in the three groups.
Results: Serum IL-36α concentrations were significantly higher among BS patients [median level of 201.7 (112.7 – 320.2) pg/mL] as compared to HC [16.9 (13.7-22.2); p<0.001]. Conversely, BS patients displayed significantly lower IL-36α levels as compared to the PsA group (544 (296-759); p<0.001) (**Figure 1**). When we investigated the ability of IL-36α to discriminate BS patients from PsA patients, an empirical optimal cut-off of 420.6 pg/ml displayed a specificity of 0.93, with a sensitivity of 0.70 (AUC 0.82) in discriminating PsA from BS. This cut-off displayed a good diagnostic performance also in BS patients with mucosal and ocular manifestations, i.e., the two BS involvement associated with the highest IL-36α levels, as well as in those lacking major organ involvement, who represent a challenging group from a diagnostic point of view.
Conclusion: Serum IL-36α is remarkably increased in patients with PsA as well as in BS, although to a lesser extent. Serum IL-36α could be a candidate biomarker for the differential diagnosis between these two conditions.

AB0165 **BIOMARKERS ASSOCIATED WITH GIANT CELL ARTERITIS IN PATIENTS WITH POLYMYALGIA RHEUMATICA FEATURES**

Keywords: Vasculitis, Biomarkers

A. Ramon[1,2], H. Greigert[2,3,4], C. Cladière[2], M. Ciudad[2], P. Ornetti[1], J. F. Maillefert[1], B. Bonnotte[2,3], M. Samson[2,3]. *[1]Dijon University Hospital, Rheumatology Department, Dijon, France*; *[2]INSERM, EFS BFC, UMR 1098, RIGHT Graft-Host-Tumor Interactions/Cellular and Genetic Engineering, INSERM, Dijon, France*; *[3]Dijon University Hospital, Internal Medicine and Clinical Immunology Department, Dijon, France*; *[4]Dijon University Hospital, Vascular Medicine Department, Dijon, France*

Background: Polymyalgia Rheumatica (PMR) is a frequent inflammatory rheumatism associated with giant cell arteritis (GCA) in 16-21% of cases. GCA is characterised by large vessel vasculitis which is absent in isolated PMR [1]. The identification of serum biomarkers reflecting vascular involvement could allow the selection of PMR patients in whom further investigations are indicated to confirm or rule out GCA.
Objectives: This study aimed to identify serum biomarkers associated with GCA in a population of patients with PMR features.
Methods: Patients were prospectively enrolled in Dijon University Hospital, France. At inclusion, no patient had yet received glucocorticoids or immunosuppressive treatment. All PMR patients fulfilled 2012 ACR/EULAR classification criteria [2] and GCA was ruled out by at least an exam evaluating temporal arteries (biopsy and/or color doppler ultrasound) and another evaluating large vessels (angio-CT or FDG-PET/CT). All GCA patients fulfilled the 2022 ACR/EULAR classification criteria [3]. Usual clinical, biological, and therapeutic data were recorded at diagnosis. Several serum biomarkers were measured by Luminex assays: CD141, CD146, CD31, ICAM-1, VCAM-1, ANGPTL-4, ANGPTL-6, and C3L1. Student t test or Mann-Whitney test were performed to compare data, as appropriate. The significance threshold was set at P<0.05 (two-tailed). Analyses were performed with Graphpad PRISM software.
Results: Fifty patients with PMR without GCA (isolated PMR) and 33 patients with PMR and GCA overlap were included. In PMR/GCA overlap patients, 14 (42.4%) had aortitis. Serum level of CD141 was significantly higher in the PMR/GCA overlap group in comparison to isolated PMR group (mean = 6854 pg/mL *vs.* 5558 pg/mL, p = 0.003). The area under cover (AUC) was 0.68 (CI95%: 0.56; 0.80). No differences were found regarding serum levels of ANGPTL-4 (p = 0.39), ANGPTL-6 (p = 0.22), CD31 (p = 0.74), CD146 (p = 0.35), C3L1 (p = 0.75), ICAM-1 (p = 0.94) and VCAM-1 (p = 0.52) between PMR without GCA and PMR/GCA overlap. Likewise, no significant differences were found for the usual markers of inflammation between both groups: ESR (p = 0.22), CRP (p = 0.39) or fibrinogen (p = 0.92). Comparison between PMR without GCA and PMR/GCA overlap with aortitis found higher level of ANGPTL-4 and ANGPTL-6 in isolated PMR patients (median = 160.7 ng/mL *vs.* 128.9 ng/mL [p = 0.04] and 4.3 ng/mL *vs.* 3.1 ng/mL [p = 0.02], respectively). CD141 was positively correlated with CD146 (r =0.48; p < 0.001) and VCAM-1 (r = 0.34; p = 0.001). VCAM-1 was positively correlated with CD141 (r = 0.34; p = 0.001), C3L1 (r = 0.35; p = 0.001) and ANGPTL-4 (r = 0.47; p < 0.001)
Conclusion: This study found lower serum concentrations of CD141 in PMR patients without GCA *versus* those having PMR and GCA overlap. However, the diagnostic performance of CD141 does not appear to be sufficiently discriminative to rule out GCA in PMR patients. ANGPTL-4 and ANGPTL-6 could be interesting serum biomarkers to detect aortitis in patients with PMR features. The study of other biomarkers reflecting endothelial aggression during GCA is needed with larger patients' cohorts.

Background: IgA vasculitis (IgAV) and IgA nephropathy (IgAN) are inflammatory conditions that share pathophysiological mechanisms, being B-cells crucial players in both diseases [1]. In this regard, some authors have suggested that IgAV and IgAN may represent different outcomes of a continuous spectrum of a disease [2]. In addition, *CD40, BLK* and *BANK1* are relevant genes involved in the development and signalling of B-cells and are also identified as susceptibility *loci* for several immune-mediated diseases [3-6].
Objectives: To determine whether IgAV and IgAN may be different outcomes of a single disease, by assessing the *CD40, BLK* and *BANK1* genetic pattern.
Methods: Three genetic variants within *CD40* (rs1883832, rs1535045, rs4813003), three genetic polymorphisms within *BLK* (rs2254546, rs2736340, rs2618476) as well as two *BANK1* genetic variants (rs10516487, rs3733197) were genotyped in 380 Caucasian patients diagnosed with IgAV, 90 patients diagnosed with IgAN and 1,012 ethnically matched healthy controls. The eight polymorphisms selected were previously associated with several inflammatory diseases [3-6].
Results: Similar genotype and allele frequencies were observed in IgAV patients when compared to those with IgAN, when *CD40, BLK* and *BANK1* variants were analyzed independently (**Table 1**). In addition, no statistically significant differences were observed between patients with IgAV and healthy controls as well as between patients with IgAN and healthy controls, when *CD40, BLK* and *BANK1* genetic variants were analyzed independently (**Table 1**). Similar results were disclosed when haplotype frequencies of *CD40, BLK* and *BANK1* were compared between patients with IgAV and those with IgAN, as well as between patients with IgAV and healthy controls and between IgAN and healthy controls.
Conclusion: Our results reveal a similar *CD40, BLK* and *BANK1* genetic distribution in IgAV and IgAN, supporting that IgAV and IgAN may represent different outcomes of a single disease.

SINGLE-CELL SPATIAL TRANSCRIPTOME ANALYSIS IDENTIFIES DISEASE-SPECIFIC FIBROBLASTS IN RHEUMATOID VASCULITIS

Keywords: Vasculitis, Rheumatoid arthritis, Biomarkers

A. Tsujii[1], Y. Hoshida[2], T. Tamada[3], D. Kim[1], K. Yamamoto[1], A. Nakabayashi[1], M. Yoshimura[1], K. Isoda[4], S. Ohshima[3]. *[1]National Hospital Organization Osaka Minami Medical Center, Department of Rheumatology, Kawachinagano, Japan*; *[2]National Hospital Organization Osaka Minami Medical Center, Department of Pathology, Kawachinagano City, Japan*; *[3]National Hospital Organization Osaka Minami Medical Center, Department of Clinical Research, Kawachinagano, Japan*; *[4]National Hospital Organization Osaka Minami Medical Center, Department of Clinical Research/Rheumatology, Kawachinagano, Japan*

Background: Spatial transcriptome analysis is an advanced technique that adds spatial information to gene expression analyses to identify differences in gene expression based on the location in specimen tissues. It can also provide disease-specific gene expression data in individual cells. This method has the potential to identify important gene expression related to disease pathogenesis, which cannot be obtained through conventional bulk analysis. CosMx™ Spatial Molecular Imaging (SMI) is a platform for spatial transcriptome analysis of formalin-fixed paraffin-embedded tissue samples at subcellular resolution (NanoString® Technologies, Seattle, WA, USA). The use of high-plex in situ hybridization followed by cyclic hybridization of immunofluorescent detection reagents and imaging enables the localization and identification of approximately 1,000 RNA targets in situ, and antibody-based, machine learning-augmented cell segmentation with nuclear and membrane markers localizes these targets to individual cells[1]. Cutaneous vasculitis is characterized by vasculitis of small-sized vessels of the skin and causes skin lesions, such as purpura or ulcers, resulting in a low quality of life. A variety of autoimmune diseases can cause cutaneous vasculitis, but its pathogenesis is unknown. In particular, cutaneous vasculitis associated with rheumatoid arthritis (RA) (referred to as rheumatoid vasculitis) is often difficult to treat and is associated with high rates of premature mortality[2]. Histologically, cutaneous vasculitis associated with autoimmune diseases is characterized by fibrinoid degeneration or neutrophilic

Table 1. Genotype and allele frequencies of *CD40, BLK* and *BANK1* in patients with IgAV, patients with IgAN and healthy controls.

	Change		Genotypes, % (n)			Alleles, % (n)

vasculitis; however, these findings are nonspecific and do not lead to a precise diagnosis.

Objectives: In the present study, we aimed to identify disease-specific cell types and gene expression via single-cell spatial transcriptome analysis of skin tissues from patients with autoimmune disease-associated cutaneous vasculitis. This can lead to improved diagnosis, pathogenesis understanding, and treatment.

Methods: Single-cell spatial transcriptome analysis was performed using NanoString's CosMx™ SMI on tissues from vasculitis associated with five autoimmune diseases, including rheumatoid vasculitis, and a case with toxic rashes as controls. Following data collection, NanoString's data processing pipeline[1] was used to identify transcripts, define cell locations and boundaries, and count the number of transcripts per cell to determine the expression profiles for each cell. Cell types were inferred from these expression data using InSituType[3] and a reference Human Cell Atlas skin dataset. Immunostaining was performed to validate the identified gene markers.

Results: A total of 35,503 cells and 4,530,981 transcripts were analyzed. Clustering of cells based on gene expression levels revealed cells with a high expression of several specific genes, including MMP1, in rheumatoid vasculitis. CosMx™ SMI analysis revealed that these cells were primarily located in the perivascular area (Figure 1A). Immunostaining with anti-MMP1 antibody (1:100; ab52631, Abcam) revealed that the cells were histologically fibroblasts (Figure 1B). These findings revealed that fibroblasts expressing MMP1 are specific to rheumatoid vasculitis. MMP1 is highly expressed in synovial fibroblasts in RA and plays a substantial role in disease pathogenesis[4]. Our results suggest that disease-specific fibroblasts expressing MMP-1 are involved in the pathogenesis of rheumatoid vasculitis. The pathological roles of MMP1 and other markers merit further investigation.

Conclusion: Single-cell spatial transcriptome analysis revealed fibroblasts specific to rheumatoid vasculitis. The result of this study might contribute to understanding of etiology and treatment of rheumatoid vasculitis.

AB0168 **IMBALANCE IN THE TAXONOMIC COMPOSITION OF GUT MICROBIOTA IN TAKAYASU ARTERITIS**

Keywords: Gastrointestinal tract, Vasculitis

T. Shirai[1], S. Watanabe[2], N. Shinozaki[2], K. Baba[2], H. Yamasaki[2], T. Ishii[1], H. Fujii[1]. [1]*Tohoku University Hospital, Rheumatology, Sendai, Japan*; [2]*Cykinso, Inc., Research Project Office, Tokyo, Japan*

Background: Takayasu arteritis (TAK) is one form of the large vessel vasculitis and predominantly affects young female. TAK sometimes coexists with other inflammatory diseases which include ulcerative colitis (UC) and spondyloarthropathy. Recent evidences revealed close genetic background between TAK and these diseases, and we found the common autoantibodies against endothelial protein C receptor among TAK and UC. These evidences suggest the common underlying pathophysiology among these diseases. UC and spondyloarthropathy are known to be associated with dysbiosis. Therefore, the involvement of dysbiosis in the pathogenicity of TAK is possible. However, little is known regarding the composition of gut microbiota in TAK.

Objectives: This study aimed to investigate whether there existed the imbalance in the taxonomic composition of gut microbiota in TAK.

Methods: 31 patients with TAK who satisfied the classification criteria of American College of Rheumatology 1990 and 31 background-matched healthy controls (HC) were included in this study. Feces were collected from each individual, and fecal microbial DNA was isolated. 16S rRNA gene amplicon sequencing was performed to analyze the microbiota. Microbial richness and β-diversity were compared among HC and TAK, and the differences in the abundant taxa were analyzed by the LEfSe algorithm.

Results: The clinical background of each group was as follows; the mean age, 41 years; female, 87%. The disease activity of TAK was assessed using the Indian Takayasu arteritis score (ITAS)-A, and 17% were in an active disease status when they collected feces. Then, 16S rRNA gene amplicon sequencing was successfully performed using microbial DNA extracted from the collected feces. Microbial richness was compared between HC and TAK using the Shannon index, which revealed significant decrease of microbial richness in TAK patients (P=0.02). β-diversity between HC and TAK was next investigated, and approximately half of the patients with TAK were clearly separated from the clusters of HC. Therefore, the presence of dysbiosis in TAK was confirmed even in the condition in which most of patients with TAK were in inactive status. Analysis of composition of microbiomes (ANCOM) showed abundance of eight and 10 genera in TAK and HC, respectively with the cut-off of centered log ratio as 1. Cladograms showed changes in the microbiota, in which each level of phylum, class, order, family, and genus were related. Differential microbiota at the genus level were observed at a linear discriminant analysis threshold of >2.0. Altered microbial genera in our study included enrichment of Streptococcus, Lactobacillus, Veillonella, Enterococcus, Dialister, Actinomyces, Sardovia, Sellimonas, Rothia, and Campylobacter. More numbers of genera were depleted in TAK, which included Bacteroides, Phascolarctobacterium, Dorea, Parasutterella, Barnesiella, and Acidaminococcus. Importantly, enrichment of oral bacteria species was documented in most of the patients with TAK. Among them, two cases were complicated with infectious endocarditis during the treatments with tocilizumab, suggesting the contribution of dysbiosis for such complication in TAK.

Conclusion: Significant imbalance of gut microbiota was observed in TAK. The diversity of fecal microbiota was reduced in TAK, and altered genera were relevant for the exacerbation of inflammation. Dysbiosis could be related to the exacerbation of inflammation and the complications in TAK.

Background: Neutrophils play a key role in ANCA-associated vasculitis, where they are both targets of autoimmunity and facilitators of vascular damage.
Objectives: This study analyzed the production of reactive oxygen species (ROS) in neutrophils from patients with granulomatosis with polyangiitis (GPA) and investigated its associations with IL-1–related cytokines and proteinase 3 (PR3).
Methods: Thirty-eight GPA patients with a disease flare were included in the NEUTROVASC prospective clinical study. ROS production was evaluated in peripheral blood neutrophils of patients with active GPA and compared to the same patients after 12 months of immunosuppressive treatment in remission as well as to healthy controls. Associations between ROS production, membrane expression of PR3 on neutrophils and serum levels of IL-1–related cytokines were analyzed.
Results: Under basal conditions, neutrophils from patients with active GPA produced less ROS compared to neutrophils from healthy controls. While there was no intrinsic defect in ROS production when using a pharmacological trigger, there was a robust defect in ROS production in response to physiologic mediators combined with TNF in GPA neutrophils compared with healthy control neutrophils. Serum levels of IL-1-related cytokines were significantly increased in GPA patients, particularly in those with kidney involvement, and levels of these cytokines returned to normal in remission. There was a positive correlation between membrane PR3 expression and ROS production in GPA patients, but not in healthy controls. Similarly, there was a positive correlation between PR3 expression and the serum levels of IL-1-related cytokines in GPA patients.
Conclusion: Our data suggest that membrane expression of PR3 links ROS production and regulation of inflammation in patients with GPA and may be a potential therapeutic target.

AB0170 ACTIVATED SENESCENCE PATHWAYS IN THE TEMPORAL ARTERIES OF PATIENTS WITH GIANT CELL ARTERITIS

Keywords: Vasculitis

W. F. Jiemy[1], Y. Van Sleen[1], J. C. Graver[1], S. A. Pringle[1], E. Brouwer[1], K. Van der Geest[1], D. Cornec[2], A. Boots[1], M. Sandovici[1]. [1]*University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands*; [2]*Université de Bretagne Occidentale, Service de Rhumatologie, Brest, France*

Background: Giant cell arteritis (GCA) is an inflammatory disease marked by granulomatous inflammation of the large- and medium-vessels. GCA exclusively affects older patients above 50 years old, suggesting a role of senescence in the pathobiology of GCA. IL-6 receptor blocking therapy has been shown to be effective treatment for GCA.(1) More recently, a phase two randomized control trial has shown the efficacy of GM-CSF receptor blocking therapy for the treatment of GCA.(2) Both IL-6 and GM-CSF are senescence-associated secretory phenotype (SASP) cytokines,(3) implicating the roles of cellular senescence and SASP in the immunopathology of GCA.
Objectives: We seek to find clues of senescent and SASP in the inflamed arteries of GCA patients.
Methods: Immunohistochemical stainings of the senescence markers p21 WAF1/CIP1 and p16/INK4A as well as SAPS cytokines IL-6 and GM-CSF were performed on temporal artery biopsies (TABs; n=8) from patients with giant cell arteritis. Non-inflamed arteries from age-matched controls were included (n=14). Stainings were scored quantitatively by using QuPath software. Opal based multiplex fluorescent stainings were performed to confirm the colocalization of p21 WAF1/CIP1 and p16/INK4A with IL-6 and GM-CSF.
Results: All four markers were detected in the inflamed GCA temporal arteries, most notably by giant cells surrounding the intimal lamina elastica although expression by other cells was also detected throughout the vessels. The expression of all four markers were significantly lower in control arteries. Cells positive for p21 WAF1/CIP1 and p16/INK4A that co-express IL-6 and GM-CSF were detected throughout the vessels.
Conclusion: Our data suggest the presence of activated senescence pathways at the site of vascular inflammation in GCA and support further research into the role of senescence in GCA.

AB0171 MENDELIAN RANDOMIZATION ANALYSIS REVEALS CAUSAL EFFECTS OF GUT MICROBIOTA ABUNDANCE ON GIANT CELL ARTERITIS RISK

Keywords: Vasculitis, Gout, Genetics/epigenetics

Z. Han[1,2], J. Hu[1,2], Z. Zhang[1,2], Q. Yu[3], P. F. He[3], X. Li[1,2,4], S. X. Zhang[1,2,4]. Background: Gut microbiota (GM) abundance is associated with giant cell arteritis, but their causality remains unclear[1].
Objectives: In order to comprehensively investigate the causal relationship between gut microbiota abundance and giant cell arteritis risk and to identify specific beneficial or pathogenic microbe taxa, we performed a two-sample Mendelian randomized (MR) analysis.
Methods: MR analysis was conducted on genome-wide association study (GWAS) summary statistics of gut microbiota abundance and giant cell arteritis. Specifically, the microbiome GWAS in 14,306 individuals from the MiBioGen consortium was used as exposure[2], while the GWAS (n = 213,604) for giant cell arteritis was used as the outcome. At the suggestive significance level ($p = 1\times10^{-5}$), SNPs associated with bacteria abundance were utilized as instrumental variables. Inverse variance weighted (IVW) was the primary method for analyzing causality, and Cochran's Q statistic was used to quantify the heterogeneity of instrumental variables.
Results: Inverse variance weighted estimates suggested that genus Eubacterium rectale group (odds ratio = 0.38, 95% confidence interval: 0.16-0.93, P = 0.03), class bacteroidia (odds ratio = 0.44, 95% confidence interval: 0.21-0.93, P = 0.03), order Bacteroidales (odds ratio = 0.44, 95% confidence interval: 0.21-0.93, P = 0.03), family Lachnospiraceae (odds ratio = 0.32, 95% confidence interval: 0.16-0.63, P = 0.001) and genus Lactobacillus (odds ratio = 0.6, 95% confidence interval: 0.37-0.97, P = 0.04) had a protective effect on Giant cell arteritis. In addition, the relative abundance of class Betaproteobacteria (odds ratio = 2.53, 95% confidence interval: 1.03-6.19, P = 0.04) and relative abundance of genus Ruminococcaceae (odds ratio = 1.7, 95% confidence interval: 1.04-2.8, P = 0.04) were negative significant correlated with Giant cell arteritis risk (Figure 1). Further sensitivity analyses validated the robustness of the MR results.
Conclusion: The study suggested that gut microbiota abundance was causally associated with the risk of giant cell arteritis, which may provide novel insights into the prevention and diagnosis of giant cell arteritis.

AB0172 ANTI-MITOFUSIN-1 AND THROMBOSPONDIN-1 AS POTENTIAL MARKERS FOR POLYMYALGIA RHEUMATICA

Keywords: Vasculitis, Biomarkers

L. Johansson[1], D. Michailidou[2], S. Rantapää Dahlqvist[1], C. Lood[2]. [1]*Umeå University, Department of Public Health and Clinical Medicine, Umeå, Sweden*; [2]*University of Washington, Division of Rheumatology, Seattle, United States of America*

Background: Polymyalgia rheumatica (PMR) is a chronic, inflammatory disorder characterized by aching and stiffness in the proximal regions of the extremities and elevated markers of inflammation. PMR and giant cell arteritis (GCA) are two conditions frequently coexisting [1,2], with increased incidence of large vessel vasculitis and aneurysm development found at long term follow-up. Furthermore, PMR can be one of the manifestations of GCA in 20-40% of cases [3]. The etiology of the diseases are still largely unknown, and specific serological markers, including to monitor arterial disease, are lacking. Recent studies have shown that mitochondrial dysfunction may play a central role in immune activation and could act as a potential source of antigens, including mitofusin-1 (MFN1), in autoimmune diseases [4,5,6].
Objectives: To determine whether patients with PMR, with or without overlapping GCA, have elevated levels of markers of platelet activation (e.g. thrombospondin-1; TSP-1), and mitochondrial autoantibodies (e.g. anti-MFN1).
Methods: Plasma levels of anti-MFN-1 IgG and TSP-1 were measured in healthy controls (HC) (n=30) and patients with PMR (n=60), before and after treatment with glucocorticoids using in-house and commercial ELISAs, respectively.
Results: Plasma levels of anti-MFN-1 IgG and TSP-1 were elevated in patients with PMR, compared with HC, both before and after treatment with corticosteroids ($p<0.001$). The highest levels of anti-MFN-1 and TSP-1 were found before treatment of corticosteroids ($p<0.001$). Co-existence of GCA did not affect levels of either anti-MFN1 or TSP-1, nor treatment response to corticosteroids. Elevated levels of TSP-1 were found to be significantly elevated in patients with symptoms from hips/glutes (n=39) as compared to patients without these symptoms (n=13), median (P25-P75) 27.11 ug/mL (22.5-35.0) vs 19.6 ug/mL (14.1-27.9), p=0.046. Lower concentration of anti-MFN1 IgG was found in patients with symptoms from the spine (n=31) in comparison with those without symptoms from the spine (n=21), median (P25-P75) 0.37 U/mL (0.27-0.57) vs 0.54 U/mL (0.47-0.96), p=0.043.
Conclusion: Increased levels of anti-MFN-1 IgG and TSP-1 were found in PMR patients and decreased significantly after treatment with corticosteroids, although still significantly higher than HC. The highest concentration of TSP-1 was found in individuals with symptoms from hips/glutes. Increased concentrations of anti-MFN-1 and TSP-1 are suggested as novel biomarkers for PMR and further, could serve as potential biomarkers for treatment response.

Background: Several mucosal immune defence polymorphisms have an impact on IgA production by plasma cells in the mucosa [1]. In this regard, these genetic variants have been previously reported as susceptibility *loci* for IgA nephropathy [1]. Given the pathophysiological similarities described between IgA nephropathy and Immunoglobulin-A vasculitis (IgAV) [2, 3], mucosal immune defence polymorphisms may also be implicated in the pathogenesis of IgAV.

Objectives: To determine whether mucosal immune defence polymorphisms represent novel genetic risk factors for the pathogenesis of IgAV.

Methods: 6 mucosal immune defence polymorphisms previously described as susceptibility *loci* for IgA nephropathy (*ITGAM-ITGAX* rs11150612, *VAV3* rs17019602, *CARD9* rs4077515, *CFHR3.1-del* rs6677604, *DEFA* rs2738048 and *HORMAD2* rs2412971) were selected. These 6 genetic variants were genotyped in 300 unrelated Caucasian patients with IgAV (the largest series of Caucasian IgAV patients assessed for genetic studies) and 1,012 matched healthy controls. 36.1% of the IgAV patients developed renal manifestations.

Results: No statistically significant differences were observed in the genotype and allele frequencies of mucosal immune defence polymorphisms when IgAV patients and healthy controls were compared (**Table 1**). Moreover, no statistically significant differences were disclosed in the genotype and allele frequencies of the 6 polymorphisms selected when patients with IgAV were stratified according to the presence/absence of renal manifestations (**Table 1**). Likewise, similar genotype and allele frequencies of these polymorphisms were disclosed in patients with IgAV stratified according to the age at disease onset and to the presence/absence of gastrointestinal manifestations.

Conclusion: Our results reveal that mucosal immune defence polymorphisms do not contribute to the genetic background of IgAV.

AB0174 EXPLORING A POTENTIAL ANTI-TUMOR IMMUNE MICROENVIRONMENT IN GIANT CELL ARTERITIS

Keywords: Cytokines and chemokines, Vasculitis

S. Albano-Aluquin[1], J. Malysz[2], M. Savjani[3], V. Aluquin[4], M. Ratnam[5], N. Olsen[1]. [1]*Penn State Hershey, Medicine, Hershey, United States of America*; [2]*Penn State Hershey, Pathology, Hershey, United States of America*; [3]*Houston Methodist, Medicine/Rheumatology, Houston, United States of America*; [4]*Penn State Hershey, Pediatrics, Hershey, United States of America*; [5]*Wayne State University, Karmanos Cancer Institute, Detroit, United States of America*

Background: The diagnosis of giant cell arteritis (GCA) is confirmed by temporal artery (TA) biopsy findings of internal elastic lamina disruption, activated macrophages and T-lymphocytes infiltrating the arterial layers. The immune microenvironment in GCA becomes T helper-1 polarized after steroid therapy and consists of potential anti-tumor cytokines including interferon-gamma (IFG) and interleukin-12 (IL-12) which can be protective against the development of cancer. We have previously identified folate receptor beta positive macrophages in GCA, which can serve as a target for hacking this immune microenvironment.

Objectives: To compare the tumor outcomes in our cohort of GCA vs controls who had TA biopsies. To select a line-up of CD3, IFG, IL12 and FRB as potential anti-tumor proteins and compare their expression in GCA+ TA tissue that did not develop tumors versus GCA -negative tissues that developed tumors. To assess the persistence of this line-up over time.
Methods: We performed a retrospective chart review of GCA subjects and controls to assess development of tumors over long-term follow up. Formalin-fixed paraffin embedded tissue sections were obtained from both groups and immunohistochemical stains were performed using CD3, IFG, IL12 and FRB antibodies.
Results: 40 GCA and 40 controls demonstrated similar follow-up durations (76.9 vs 70.1 years; NS), time-to-incident cancer (21 vs 62 mos; NS) and deaths from cancer (5% vs 17.5%;NS). GCA subjects were older than controls (77.2 vs 69.7 years; p= 0.004). Cancer incidence is lower in GCA than controls (25% vs.47.5%; p=0.036). The incident cancers in GCA include 8 basal or squamous cell skin cancer(BCC/SCC) and 1 each of chronic lymphocytic leukemia, thyroid, esophageal and angiosarcoma. The controls had 6 BCC/SCC, 2 each of breast, skin melanoma and lymphoma, and 1 each of tonsil, parotid, colon, lung, renal, prostate, myelodysplastic syndrome and metastatic disease of unknown primary. Histopathology/IHC Findings: FRB was selectively expressed in macrophages and correlated with IFG, IL12 and CD3 expression. FRB, IFG, IL12 and CD3 expression were higher in GCA without incident cancer compared to controls with cancer: FRB (14 vs 2.3;p=0.006), IFG (3 vs 1;p=0.005), IL12 (1.5 vs 0;p=0.003), CD3 (79 vs 0;p=0.004). This multi- protein expression persisted for years in 3 repeat biopsies.
Conclusion: GCA has a lower risk of cancer which was associated with a chronic FRB+-macrophage and Th1-polarized anti-tumor autoimmunity.

AB0175 EVALUATION OF THE STATE OF ACTIVATION OF PERIPHERAL BLOOD MONONUCLEAR CELLS IN PATIENTS WITH POLYMYALGIA RHEUMATICA

Keywords: Cytokines and chemokines, Innate immunity

C. Castellani[1], S. Colafrancesco[1], C. Barbati[1], S. Truglia[1], G. Buoncuore[1], R. Priori[1,2], A. Sili Scavalli[1], E. Molteni[1], G. Sciarra[1], L. Di Sanzo[1], G. Bevignani[1], F. Conti[1], R. Scrivo[1]. *[1]Sapienza University of Rome, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, Roma, Italy*; *[2]Università UniCamillus | Saint Camillus International University of Health Sciences, Saint Camillus International University of Health Science, Roma, Italy*

Background: Polymyalgia rheumatica (PMR) is a chronic inflammatory disease that affects individuals of 50 or more years of age. It is characterised by shoulder and pelvic girdle pain, morning stiffness, functional limitation, and an increase in inflammatory indexes. Glucocorticoids (GC) represent the cornerstone of treatment. The pathogenesis is still not completely understood, although many shreds of evidence show the role of innate immunity.
Objectives: To evaluate whether peripheral blood mononuclear cells (PBMCs) of patients with newly diagnosed PMR and not yet treated with GC show a baseline activation that is affected by treatment with GC.
Methods: We carried out an observational study, enrolling patients with PMR (2012 EULAR/ACR criteria) not yet treated with GC and controls. Blood samples were obtained from patients at baseline (T0) and after 4 months since the beginning of GC (T4), and from controls. An ultrasound (US) of shoulder and pelvic girdles was performed in PMR patients at T0 and T4. Demographic, clinical and US results were recorded in an electronic database. Patients with a personal history of rheumatic, inflammatory or oncologic diseases or subjects that received such a diagnosis during the study were excluded. PBMCs were isolated by density gradient centrifugation and analyzed in triplicates, among which one was stimulated with lipopolysaccharide (LPS). Then, the supernatant was collected and ELISA was performed for the determination of IL-1β, TNF, and IL-6 levels. The same cytokines were searched in the sera of PMR patients at T0 and at T4 and in the controls.
Results: We consecutively enrolled 8 patients with a new diagnosis of PMR (F/M 6/2; median age/IQR 73/9.75 years; median disease duration 2/2.75 months) and 8 individuals without PMR matched for gender, age, and comorbidities with PMR patients (F/M 6/2; median age/IQR 69/10.5 years). We found higher concentrations of IL-1β and IL-6 in the unstimulated supernatant of PMR patients at T0 compared to T4 (p=0.0313 for both) (Figure 1A-B). Higher TNF levels were found in the unstimulated supernatant of PMR patients at baseline compared to controls (p=0.0127). Surprisingly, IL-6 levels in the stimulated supernatant of PMR patients at T0 were lower than those of controls (p=0.0426). No significant differences were found in the serum levels of IL-1β and TNF, while IL-6 levels in the sera of PMR patients at baseline were higher compared to those of the control group (p=0.0123).
Conclusion: PBMCs of PMR patients seem to be activated at baseline compared to controls. Our data indicate a possible role of immunosenescence or an "exhaustion" of PMBCs, that could be constitutively activated and not prone to responding to further stimuli, such as LPS. Moreover, we observed higher serum levels of IL-6 in PMR patients. More studies are needed to confirm the role of PBMCs and inflammatory cytokines in the pathogenesis of PMR.

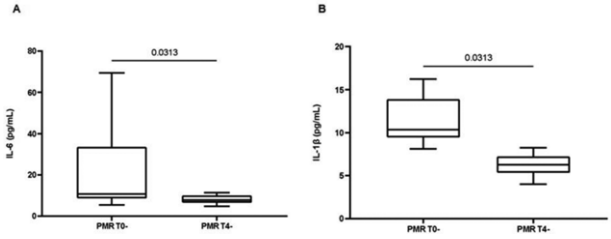

Figure 1. - IL-6 (A) and IL-β (B) levels in the unstimulated supernatant of PMR patients at baseline (PMR T0-) and after 4 months of GC therapy (PMR T4-)Data are shown as Tukey boxplots; lines represent the median level with the 25th-75th percentile.

AB0176 GENETIC EVIDENCE REVEALED A CAUSAL ROLE OF GUT MICROBIOTA IN POLYMYALGIA RHEUMATICA

Keywords: Genetics/epigenetics, Fibromyalgia

Y. Zhang[1,2], Z. Zhang[1,2], J. Hou[1,2], L. Liu[1,2], Q. Yu[3], P. F. He[3], X. Li[4], S. X. Zhang[4]. *[1]Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, Shanxi Province, China*; *[2]Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, Shanxi Province, China*; *[3]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, Shanxi Province, China*; *[4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China*

Background: Polymyalgia rheumatica (PMR) is an inflammatory disease characterized by bilateral pain involving and less commonly the neck and the pelvic girdle[1]. However, no definitive evidence supports that gut microbiota is associated with PMR.
Objectives: In this study, we conducted Mendelian randomization (MR) to assess the associations of genera of gut microbiota with PMR.
Methods: The data of gut microbiota were derived from the Integrated Epidemiology Unit (IEU) GWAS database, which included 1523 PMR cases and 213145 healthy controls[2]. A series of results were calculated to analyze the causal effects between gut microbiota and PMR. Inverse variance weighted is the primary and we did several analyses to prove MR result, weighted-median, MR Egger regression, and MR-presso. Cochran's Q statistics were used to quantify the heterogeneity of instrumental variables[3].
Results: The MR results for the causal effect of gut microbiota on PMR showed that genus Erysipelatoclostridium(odds ratio (OR)=0.910, 95% confidence interval (CI) =0.307-2.39, p =0.867) and genus Ruminococcaceae(OR=0.394, 95% CI =0.124-1.250, p =0.145) are protective factors for PMR. And genus Butyricimonas(OR=2.837, 95% CI=0.861-9.346, p=0.114), genus Eisenbergiella(OR=1.5818551, 95% CI =0.251-9.945,p=0.631), genus Coprobacter(OR=1.359, 95% CI =0.470-3.925, p =0.586)were correlated with the risk of PMR. In the meantime, heterogeneity(P>0.05) and pleiotropy (P>0.05) analysis confirmed the reliability of MR results.(Figure 1)

Conclusion: These findings provided that partial gut microbiota have an obvious causal relationship with PMR. Further trials are needed to clarify the protective effect of gut microbiota.

ESTIMATING CAUSALITY FOR POLYARTERITIS NODOSA WITH IL-1, AND IL-10: MENDELIAN RANDOMISATION ANALYSES

Keywords: Cytokines and chemokines, Vasculitis

Y. Zhang[1,2], R. Zhao[1,2,3], H. Zhang[1,2], Y. Hou[1,2], S. X. Zhang[1,2,3], X. Li[1,2,3], C. Wang[1,2,3]. [1]*Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; [2]*Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taiyuan, China*; [3]*Department of Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China*

Background: Polyarteritis nodosa (PAN) is a primary form of vasculitis characterized by inflammation of primarily medium-sized arteries[1]. Although the etiology of vasculitis is not fully understood, it has been suggested that cytokines(including interleukin-1 (IL-1) and interleukin-10(IL-10)) are significantly associated with a high susceptibility to vasculitis[2, 3]. However, there is no relevant research to explore the causality and direction of this association between interleukin and PAN.

Objectives: In this study, we intended to detect the casual association between PAN and interleukin using two-sample Mendelian randomization (MR) analysis.

Methods: The summary statistics of PAN were obtained from the FinnGen consortium release data (82 cases and 213145 controls). We also selected genetic instruments associated with il-1 and il-10 from the study of Sun et al. (3301 sample size). Initially, SNPs associated with interleukin at the genome-wide significance threshold ($p<1\times10^{-5}$) were extracted. Afterwards, We used a two-sample mendelian randomization analysis to explore the causal associations between PAN with IL-1, and IL-10. The inverse variance weighted (IVW) was the primary approach to calculating the effect estimates. To increase the IVW estimates, we also used other MR methods, such as MR-Egger and weighted median. Additionally, Sensitivity analyses of evaluating the influence of outliers and pleiotropy effects were performed by a variety of MR methods. All Statistical analyses were performed using R (version 4.2.1).

Results: Using single-nucleotide polymorphisms (SNPs) of genome-wide significance as instrumental variables, we did not find a significant association of IL-1α(odds ratio[OR] = 1.044, 95% confidence interval [CI]: 0.551 to 1.981, p = 0.895), IL-1β (odds ratio[OR] = 0.986, 95% confidence interval [CI]: 0.557 to 1.745, p = 0.962), and IL-10 (odds ratio[OR] = 1.066, 95% confidence interval [CI]: 0.621 to 1.832, p = 0.815) on PAN. Likewise, Comparable results were obtained using MR-Egger regression, and weighted median. We did not find evidence to support a causal association between IL-1α, IL-1β, IL-10, and PAN.

Conclusion: The results of this study based on genetic data did not support a causal relationship between PAN and Il-1, IL-10.

POSTURAL DEFECTS IN CHILDREN AT EARLY SCHOOL AGE - CROSS-SECTIONAL STUDY

Keywords: Physical therapy/physiotherapy, Lifestyles

A. Baranowska[1], M. Sierakowska[1], A. Owczarczuk[2], B. Olejnik[3], A. Lankau[1]. [1]*Medical University of Białystok, Department of Integrated Medical Care, Faculty of Health Sciences, Białystok, Poland*; [2]*Medical University of Białystok, Faculty of Health Sciences, Białystok, Poland*; [3]*Medical University of Białystok, Department of Developmental Age Medicine and Pediatric Nursing, Białystok, Poland*

Background: The physical posture of a person is a movement habit which is formed on a morphological and functional basis, associated with everyday activity. During a person's life, body posture changes, especially during growth. The first critical period for physical posture is the age of 7-10 years. It is associated with a change in the current lifestyle, with the transition from a large freedom of movement to staying in a sitting position at school for several hours [1-3].

Due to the prevalence of the problem and the possibility of effective prevention, it is important to detect posture defects early and identify risk factors in order to identify a group of children potentially at risk of posture defects.

OBJECTIVES:

1.Assessment of the occurrence of posture defects viewed from the back and side in the study group of school-aged children.
2.Identification of factors related to the formation of posture abnormalities in the study group.

Methods: The study was covered among 141 children aged 7-10 attending grades 1-3 of the primary school in Bialystok, north-eastern Poland. The criterion for inclusion in the study was the child's age and parental consent.

The study consisted of:

1.Measuring the child's height using a standard centimeter measure and the child's weight using an electronic scale.
2.Evaluation of body posture using the Kasperczyk scoring method.
3.Interview with the parents of the examined children using a self-designed questionnaire.

Results: Among the examined children (n=141), only one had not been diagnosed with any postural abnormalities, both from the back and from the side. Irregularities most often concerned: shoulders 73% (projected forward), feet 71% (lowered longitudinal), arch 49%, valgus heels 22%, flat feet 19%, shape of the spine (hyperlordosis 24%, flat back 18%), scoliotic posture 28% and pelvis (anterior tilt 43%). Gender differentiated only the occurrence of abnormalities in the waist triangles (p=0.0489) and knees (p=0.038) in boys. On the other hand, age differentiated the incidence of defects in the position of the shoulder blades (p=0.0037) and shoulders (p=0.0129) with a negative tendency with age. In 67% of the examined children, the BMI index was normal and did not differentiate the occurrence of posture defects. There was also no statistically significant correlation between the weight of the school bag and the number of posture defects. Looking for factors further, the parents of the surveyed children were asked about their lifestyle. Almost half of the children (47%) were transported to school by car. Most had a separate room (67%), their own desk (81%) and an adjustable chair (70%). Most children participated in physical education classes (96%), they also participated in extracurricular activities (77%) up to 2-3 times a week (43%). The eating habits of the majority of children were also correct, and the majority (92%) spend their free time in the yard.

Conclusion: Factors related to BMI, children's physical activity and nutrition were not related to the occurrence of posture defects. Despite this, almost all of the examined children had postural defects of varying severity, and mostly several defects. The posture that is revealed on the basis of research is a closed posture with the head pushed forward, with extended, retracted shoulders, hyperlordosis and anteversion. It seems that the research should be deepened and the causes of such a large number of posture defects among children should be found, for the purpose of early prevention.

PAIN SENSITISATION IN FIBROMYALGIA. THE CROSS-SECTIONAL ASSOCIATIONS BETWEEN MEASURES OF QUANTITATIVE SENSORY TESTING AND FIBROMYALGIA SEVERITY

Keywords: Fibromyalgia, Patient reported outcomes, Biomarkers

P. Steen Pettersen[1], T. Haugmark[1], I. J. Berg[1], T. Neogi[2], H. B. Hammer[1], H. A. Zangi[1,3], I. K. Haugen[1], S. Aarrestad Provan[1,4]. [1]*Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*; [2]*Boston University School of Medicine, Section of Rheumatology, Boston, United States of America*; [3]*VID University College in Oslo, Faculty of Health, Oslo, Norway*; [4]*Inland Norway University of Applied Sciences, Public Health, Elverum, Norway*

Background: Whether patient's experience of fibromyalgia severity is related to measures of pain sensitisation assessed by quantitative sensory testing is not clear. How disease duration effects the relationship between disease severity and pain sensitisation changes is also unknown.

Objectives: To examine the associations between pain sensitisation and fibromyalgia disease severity, as measured by the Polysymptomatic Distress scale (PDS) and Fibromyalgia Impact Questionnaire (FIQ). Secondly, to examine the impact of disease duration on the associations.

Methods: Participants were recruited from referrals to a hospital clinic and the diagnosis verified by a specialist rheumatologist. Patients self-reported PDS and FIQ. Quantitative sensory testing included assessments of pressure pain threshold (PPT), temporal summation (TS) and conditioned pain modulation (CPM) were performed. PPT was tested 3 times at 5 predefined sites (a non-painful interphalangeal joint, dorsal radio-ulnar joint, lateral epicondyle of the elbow, middle surface of the trapezius muscle, and tibialis anterior muscle) using an algometer (FPIX 25). The pressure at which the patient first reported a slight pain was recorded, and the mean PPT values at each site and for all measurements (aggregated mean) were calculated. Lower PPTs indicate more pain sensitization. TS was estimated using probes of increasing weight that were tapped against the radioulnar joint. Pain was recorded on a numeric rating scale for the 1st, 5th, and 10th tap of the probe that elicited a pain ≥ 4 on a 0-10 scale. The maximum difference in pain between the 1st and either 5th or 10th tap was calculated, and an increase in pain during repetitive stimuli indicate TS. PPT was also tested before and after a conditioning stimulus with a blood pressure cuff around the contra-lateral arm, and the ratio of the PPTs (post:pre) was calculated. A positive ratio indicates adequate CPM. Cut-offs of pain sensitization were defined as PPT < median, TS ≥ 2 and CPM <1. Disease duration was dichotomized at ≤ 5 vs. > 5 years. The associations between quantitative sensory testing and disease severity were explored in linear regression models adjusted for age, sex and body mass index and interactions with disease duration were explored.

Results: A total of 78 patients (90% women, mean age 40.9 years (SD 7.3)) were recruited. In linear regression models, aggregated mean PPT was weakly associated with the PDS score, the FIQ total score and the pain, fatigue and depression components (Table 1). The mean PPTs from the trapezius and tibialis anterior muscles were also weakly but significantly associated with several components of the PDS and FIQ. TS was weakly associated with the anxiety and depression components of FIQ while there was no association between CPM and PDS or FIQ (Table 1). We found no evidence of disease duration being an effect modifier for the associations.

Conclusion: In this cohort of patients with clinically verified fibromyalgia, pain sensitisation was weakly associated with self- reported disease severity. Disease duration did not impact on the relationship. Our results point to the multifactorial nature of the fibromyalgia symptom burden.

Table The cross-sectional associations between measures of quantitative sensory testing and fibromyalgia severity

	Measures of quantitative sensory testing (Independent variables) (β (95% CI))		
(Dependent variables)	PPT<vs.>=median	TS ≥ 2 vs. <2	CPM < 1vs. ≥ 1

Graven-Nielsen[2]. *[1]Instituto de Saúde Pública da Universidade do Porto (ISPUP), EPIUnit, Porto, Portugal*; *[2]Aalborg University, Centre for Neuroplasticity and Pain, Aalborg, Denmark*; *[3]Faculdade de Medicina da Universidade do Porto - FMUP, CISPFEM, Porto, Portugal*

Background: Prolonged exposure to pain may induce sensitisation through neuroplastic processes, resulting in gain/loss of function and alteration of signal processing, and probably playing an important role in the experience and chronification of pain. Quantitative sensory testing (QST) assesses responses to standardised stimuli, allowing for an estimation of the effects of health conditions on somatosensory function [1]. Sensitized pain mechanisms are often reported in adults with musculoskeletal pain conditions, but population-based pediatric studies are lacking.

Objectives: To investigate the association between reported musculoskeletal pain history (based on complementary criteria) and pain sensitisation measures at age 13 years in a population-based cohort. We hypothesised that adolescents reporting more adverse musculoskeletal pain experiences would have higher pain sensitivity, impaired anti-nociceptive and/or facilitated pro-nociceptive mechanisms.

Methods: We analyzed data from 1496 adolescents of the population-based Generation XXI birth cohort study in Porto, Portugal. Pain history was collected using the Luebeck Pain Questionnaire (self-reported at 13 years, parent-reported at 7 and 10 years). Musculoskeletal pain was considered present if reported in the back, neck, shoulders, upper/lower limbs, hips, or widespread musculoskeletal. Three case definitions for adverse musculoskeletal pain history were used: 1) chronic (3+ months) musculoskeletal pain at age 13; 2) musculoskeletal pain with an impact on daily living (school and/or hobbies) at age 13; and 3) musculoskeletal pain at age 13 together with previous musculoskeletal pain reports at ages 7 and/or 10 (reported in previous data collection waves). Lower limb cuff pressure algometry was conducted at age 13 using a computerized system coupled with a visual analogue scale for pain intensity rating. We extracted pain sensitivity (pain detection and tolerance thresholds), conditioned pain modulation (CPM, changes in thresholds in the presence of a distant painful conditioning) and temporal pain summation (TSP, changes in pain intensity to ten phasic painful cuff stimulations). Non-parametric tests were used to compare QST parameter distributions.

Results: Adolescents with musculoskeletal pain at age 13 who had a history of musculoskeletal pain at ages 7 and/or 10 had lower pain tolerance threshold compared to the remaining sample (mean 40.2 vs. 49.0 kPa, p=0.020) and lower pain detection threshold point estimate (14.5 vs. 18.2, p=0.072). Slightly lowered pain tolerance was also found in adolescents with musculoskeletal pain with an impact on daily living at age 13 (42.4 vs. 49.0, p=0.091). No differences were found for pain sensitivity measures according to the presence of pain lasting 3+ months at age 13. No differences were found for CPM-effects and TSP-effects according to pain history regardless of the case definition used.

Conclusion: Repeated musculoskeletal pain up to age 13 years may contribute to lower pain tolerance in the general adolescent population. This does not seem to be the case when reported pain experiences are recent or when the outcomes are temporal pain summation or conditioned pain modulation. In this community-based sample the vast majority showed no sign of altered central pain processing but a small fraction with longer pain experiences may reveal some pain sensitization at 13 years of age.

AB0182 **CONDITIONED MEDIA FROM PRIMARY OA CHONDROCYTES AFFECT THE BEHAVIOUR OF PHEOCHROMOCYTOMA PC 12 CELLS**

Keywords: Pain, Cartilage, Osteoarthritis

B. Steinecker-Frohnwieser[1], S. Toegel[2], V. Glanz[3], L. Weigl[3]. *[1]Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Department for Rehabilitation, Saalfelden, Austria*; *[2]Department of Orthopedics and Trauma-Surgery, Medical University of Vienna, Department of Orthopedics and Trauma-Surgery, Vienna, Austria*; *[3]Department of Special Anesthesia & Pain Therapy, Medical University of Vienna, Department of Special Anesthesia & Pain Therapy, Vienna, Austria*

Background: Osteoarthritis (OA) is the most common joint disease characterized by progressive degradation of articular cartilage, synovial hyperplasia, bone remodeling and angiogenesis [1]. Symptomatic painful OA leads to psychological distress and significant restrictions in daily living. Shortening of work life accompanied by an exponential rise in healthcare costs causes OA to become a major socio-economic burden [2]. Although, OA induced pain represents the most frequent cause of chronic pain, its mechanisms are poorly understood and treatments are not satisfactory [3].

Objectives: It is of great interest to investigate whether OA-induced changes in chondrocyte metabolism can affect neurons. Neurons with increased expression of neurogenic markers could contribute to enhanced pain perception. An investigation of the influence of conditioned media from primary OA chondrocytes on PC12 cells may serve to elucidate interactions.

Methods: PC12 cells, have been treated with conditioned media from primary OA chondrocytes (pCH-OA) and tested for changes in expression by RNA sequencing. Expression of neurogenic markers nestin, microtubule-associated protein 2 (Map2) and tyrosine hydroxylase (TH) from PC12 cells after treatment were analyzed by qPCR. Screening of the conditioned media for relevant factors was performed by using a cytokine proteome profiler array. Electrophysiological measurements were performed by the patch clamp method on rat dorsal root ganglia neurons (DRGs) treated with specific cytokines.

Results: RNA sequencing of treated PC12 cells showed changes in expression profile when cells were treated with conditioned media from pCH-OA and HC control chondrocytes compared with standard differentiation and growth media, respectively. Specific qPCR for the neuronal differentiation markers nestin, Map2, and Th showed an increase in expression in PC12 cells induced by most of the conditioned media from pCH-OA cells tested. In particular, Map2 and TH were increased by treatment in almost all conditioned media (n=14). Results of a cytokine proteome profiler array showed high levels of IL6, IL8, and MCP1 in conditioned media from pCH-OA cells of different patients. Treatment of DRGs with an interleukin cocktail altered the electrophysiological behavior tested by the patch-clamp technique and provided the first evidence that chondrocytes might secrete neuromodulatory substances.

Conclusion: Changes in the electrophysiological behavior of neurons caused by OA and the identification of the responsible metabolites should help to shed more light on the process of neuronal sensitization and pain generation in the development of OA in more detail and at the molecular level. In addition, the results also suggest that there are individual responses in individual patients. This information lays the groundwork for explaining why differences in pain perception may vary among OA patients and why there are different pain phenotypes in OA.

AB0183

DEVELOPMENT AND VALIDATION OF THE PLACEBO SENSITIVITY QUESTIONNAIRE (PSQ): CAN THE PSQ PREDICT PLACEBO ANALGESIA RESPONSIVENESS?

Keywords: Treat to target, Pain, Prognostic factors

E. Camerone[1], G. Tosi[2], M. Di Magro[1], D. Romano[1]. *[1]Università degli Studi di Milano-Bicocca, Department of Psychology, Milan, Italy*; *[2]Università del Salento, Department of Human and Social Sciences, Lecce, Italy*

Background: People respond to placebo to different degrees, and some do not respond at all (Frisaldi et al., 2018). Several studies investigated whether there are psychological aspects that predict these differences, but the results remain heterogeneous (Horing et al., 2014; Kern et al., 2020)
Objectives: Here, we develop and validate the Placebo Sensitivity Questionnaire (PSQ), an instrument that measures behaviors potentially related to placebo responsiveness. The idea is to treat placebo as a personality trait, with its own dimensions and its set of marker behaviours, instead of a phenomenon determined by multiple personality traits as it has been done up to now.
Methods: 330 individuals completed the initial version of the PSQ along with 9 additional scales measuring psychological traits associated with placebo responsiveness. These data were used to reduce the dimension of the PSQ, identifying a shorter set of predictive items, and to bring evidence of construct validity. A second experiment, currently ongoing, tests the predictive validity of the PSQ using a classic placebo analgesia experimental paradigm. Here, healthy volunteers are administered a placebo cream, presented as a potent analgesic, and receive noxious stimulations by means of thermal stimulation.
Results: Principal component analysis revealed a 3-factor structure – Symptoms Exaggeration, Seek for Support, Alternative Medicine Beliefs - and the number of items was reduced from 40 to 19. Construct validity indicated that the PSQ correlates with most of the scales previously associated with placebo responsiveness. For the predictive validity study, which is in due course at the time of this abstract submission, we hypothesise that the PSQ will be successful in discriminating a priori placebo sensitivity and non-responders.
Conclusion: The PSQ has the potential to become an important tool for researchers and clinicians working with pain, moving us a step forward toward personalised pain management.

SENSORY PROFILING IN CLASSICAL EHLERS-DANLOS SYNDROME: EVIDENCE FROM A CASE-CONTROL STUDY REVEALS PAIN CHARACTERISTICS, SENSORY CHANGES AND IMPAIRED PAIN MODULATION

Keywords: Pain, Genetics/epigenetics

M. Colman[1,2], D. Wille[1,2], I. De Wandele[2], L. Rombaut[2], A. M. Malfait[3], M. Meeus[4], J. Van Oosterwijck[4], D. Syx[1,2], F. Malfait[1,2]. *[1]Ghent University, Biomolecular Medicine, Ghent, Belgium*; *[2]Ghent University Hospital, Center for Medical Genetics Ghent, Ghent, Belgium*; *[3]Rush University Medical Center, Division of Rheumatology, Chicago, United States of America*; *[4]Ghent University, Rehabilitation Sciences, Ghent, Belgium*

Background: The Ehlers-Danlos syndromes (EDS) are a paradigm group of rare heritable connective tissue disorders caused by pathogenic defects in genes involved in biosynthesis, fibrillogenesis, and/or supramolecular organization of collagen fibrils in the extracellular matrix (ECM). Joint hypermobility, skin hyperextensibility, abnormal wound healing and easy bruising are among the cardinal clinical features. The classical EDS type, caused by caused by defects in type V or rarely type I collagen, is the most prevalent genetically elucidated EDS type [1]. (Chronic) pain is highly prevalent in individuals with EDS and is one of the foremost reasons these individuals seek medical attention. There is a high use of analgesics, surgery, and physical therapy but these treatment modalities often bring only modest relief at best, and some are associated with unwanted side effects. Few studies, almost exclusively conducted in the molecularly unexplained hypermobile EDS type, have brought limited evidence for neuropathic pain and decreased intra-epidermal nerve fiber density. Interestingly, functional and structural abnormalities of the nervous system and associated pain-related behaviors have also been described in mouse models of EDS [2]. Comprehensive human studies on pain prevalence and pain mechanisms in molecularly solved EDS types are however currently not available, thereby representing a major gap in the study of pain in EDS.
Objectives: The primary aim of this cross-sectional study was to identify the sensory profile of individuals with cEDS. Secondly, we aimed to identify the pain characteristics and the emotional-cognitive burden in cEDS.
Methods: Nineteen individuals with molecularly confirmed cEDS and 19 healthy matched control were recruited. Sensory profiling included sensitivity to innocuous and noxious stimuli of multiple modalities (electrical, thermal, vibration, touch, pressure) and a parallel and sequential conditioned pain modulation protocol. Moreover, pain characteristics and emotional-cognitive factors that are known to influence pain processing were studied using a set of validated questionnaires (PD-Q, DN4, HADS, HAQ, SF-36, CSI, PVAQ, TAMPA scale).
RESULTS:

Table 1.

cEDS cohort compared to control group	
Pain	+
Emotional burden	(+)
Detection thresholds	
Electrical	=
Thermal	=
Vibration	+
Touch	=
Paradoxical thermal sensations	+
Pain thresholds	
Electrical	=
Cold	-
Heat	=
Pressure	-
Conditioned pain modulation	-

+/-: statistically significant differences; = non-significant

The cEDS cohort showed an altered sensory profile. Higher (p=0.04) detection thresholds for vibration stimuli at the lower limb were found indicating the presence of hypoesthesia. Reduced/altered thermal sensitivity was found with significantly more (p<0.001) paradoxical thermal sensations at the lower limb (usually to heat). Lower pain thresholds were found to mechanical (p<0.001) stimuli at both the upper and lower limbs and to cold (p=0.005) stimulation at the lower limb indicating hyperalgesia. Using a parallel conditioned pain paradigm, significantly (p=0.005 and p=0.046) smaller antinociceptive responses were shown in cEDS suggestive of impaired central pain inhibition.
Conclusion: This study represents the first systematic investigation of pain in a genetically defined EDS type. With evidence for sensory changes and impaired pain modulation in cEDS, we provide new insights on the possible role of the ECM in the development and persistence of pain.

INVESTIGATION OF THE RELATIONSHIP BETWEEN PATIENTS WITH ARTHROPLASTY AND PATIENTS WITHOUT ARTHROPLASTY FOR LOWER EXTREMITY OSTEOARTHRITIS IN TERMS OF PAIN COPING STRATEGIES, FUNCTIONAL STATUS AND QUALITY OF LIFE.

Keywords: Quality of life, Osteoarthritis, Pain

B. Malkoco[1], N. Elibol[2], V. Karatosun[3]. *[1]Ege University, Department of Physiotherapy and Rehabilitation, Institute of Health Sciences, Izmir, Turkey*; *[2]Ege University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Izmir, Turkey*; *[3]Dokuz Eylul University, Department of Orthopedics and Traumatology, School of Medicine, Izmir, Turkey*

Background: Osteoarthritis (OA) is the most common joint disease worldwide and a major source of pain, disability, and socioeconomic cost [1]. Most of the pain or functional disability induced by these diseases can be improved by the surgery. Arthroplasty currently is considered the international gold standard of treatment the knee and hip joints osteoarthritis [2]. In the literature it was defined that pain can be exacerbated and inhibited by the psychological variable. Except the surgical trauma and social factors, the psychological factors have huge influence on the occurrence of the pain [3]. Pain coping strategies are the person's responses to manage pain and they are generally classified as active and passive strategies. While active strategies identify as controlling the pain or functioning despite the pain, passive strategies identify as withdrawing and surrendering control over the pain [4]. Pain is very effective factor on the patients' outcomes after arthroplasty. Some psychological coping strategies have been introduced to minimize the effects of pain, but there are no guidelines to follow to reduce pain, because the psychological interventions are different based on the surgery types, technique mechanism and pain specific information [5].
Objectives: This study aims to investigate the relationship between patients with arthroplasty and patients without arthroplasty for lower extremity osteoarthritis in terms of coping with pain, functional status and quality of life.
Methods: Twenty patients with bilateral arthroplasty (mean age 62,75±12,22) and thirty-two patients with OA (mean age 58,87±9,22) were included in the study. The Pain Coping Inventory (PCI), Timed Up and Go Test (TUG), 5 Times Sit to Stand Test (FTSST), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Short Form (SF)-12 Quality Life Questionnaire administered to the patients.
Results: Demographics were statistically similar in both the lower extremity arthroplasty group (LEAG) and osteoarthritis group (OAG). PCI passive total score, PCI passive worrying, PCI passive retreating, PCI passive resting, PCI active total, PCI active distraction and PCI active reducing demands scores were similar in the groups. PCI active pain transformation score was significantly lower in the OAG. TUG and FTSST were similar in groups. WOMAC pain, WOMAC stiffness, WOMAC physical function and WOMAC total scores were significantly higher in the OAG. SF12 PCS and SF12 total scores were significantly higher in the LEAG than in the OAG. SF12 MCS score was similar between the groups.
Conclusion: This study demonstrated that LEAG have better pain transformation, pain intensity, stiffness, patient reported function and physical component of quality of life compared to OAG. Surgery has been effective in improving function and reducing pain according to the results. The difference in active pain transformation in PCI between groups is thought to be related to this. However, it was determined that psychosocial approaches should be included in pain management in the rehabilitation program of patients with OA and arthroplasty.

AB0186

THE EFFECT OF KNEE JOINT LOSS ON PROSTHESIS AWARENESS IN LOWER LIMB AMPUTEES

Keywords: Patient reported outcomes, Physical therapy/physiotherapy, Quality of life

G. Karakaş[1], S. Topuz[1]. *[1]Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey*

Background: In knee disarticulation, transfemoral and hip disarticulation amputations, unlike transtibial amputations, the anatomical knee joint is replaced by a prosthetic knee joint. In amputations where the natural knee joint is not preserved, compared to transtibial amputations; It has been stated that it is difficult to reach the normal functional level and more energy is spent [1]. The closer the amputation level is to the proximal, the more restrictions the amputee has in activities of daily living [2].
Objectives: In this study, we compared the ability of forgetting the prosthesis, which is an indicator of adaptation with the prosthesis, of amputees with and without an anatomical knee joint in daily life activities. The aim of this study is to examine the effect of loss of the knee joint on the ability to forget the prosthesis in daily life in amputees.
Methods: Lower limb amputees aged 18-65 years, who used prosthesis for at least 6 months were included in this study. Prosthesis awareness was evaluated with the Forgotten Joint Score-12 (FJS-12) amputee version [3]. The FJS-12 amputee version consists of 12 questions about awareness of the artificial limb during daily living activities. The raw scores are transformed to range from 0 to 100 points, with high scores indicating as a percentage (%) the extent to which the patient can forget the artificial limb, that is, adapt them to their lives. Amputees were divided into two groups as with and without knee joint loss. The prosthetic awareness scores of the two groups were compared. Independent sample t-test was used to compare the data.
Results: 29 transtibial amputees (mean age: 37.17 ± 11.05 years; Body Mass Index: 25.21 ± 3.02 kg/m2) were included in the knee joint group. A total of 26 amputees (mean age: 35.07 ± 10.29 years; Body Mass Index: 23.77 ± 3.59 kg/m2) were included in the group without knee joint, including 5 knee disarticulations, 18 transfemoral and 3 hip disarticulations. The groups were similar in terms of mean age, body mass index, and years of prosthesis use (respectively p=0.470;p= 0.143; p=0.980) When the FJS-12 total score means of the groups with and without knee joint were compared, there was a statistically significant difference between the two groups (p=0.017; Z=-2.337).
Conclusion: This study showed that loss of the knee joint affects the way amputees perceive their prosthesis. In the absence of a anatomical knee joint, amputees' attention to their prosthesis is increasing. Amputees with a knee joints focus less on their prostheses in daily life activities. Our study revealed that the knee joint, which is frequently used in activities of daily living, is also a determining factor in the adaptation of amputees to the prosthesis.

Rheumatoid arthritis - prognosis, predictors and outcome

AB0187 **CONSIDERATIONS OF REALISTIC TREATMENT GOALS BASED ON PREDICTORS OF FRAILTY PROGRESSION IN PRE-FRAIL PATIENTS WITH RHEUMATOID ARTHRITIS: A MULTICENTER RETROSPECTIVE OBSERVATIONAL STUDY.**

Keywords: Real-world evidence, Prognostic factors, Rheumatoid arthritis

Y. Ohashi[1], N. Takahashi[2], Y. Sobue[3], M. Suzuki[1], R. Sato[1], M. Maeda[1], D. Kihira[1], K. Kishimoto[1], K. Terabe[1], S. Asai[1], S. Imagama[1]. [1]*Nagoya University Hospital, Orthopaedic Surgery, Nagoya, Japan*; [2]*Aichi Medical University Hospital, Orthopaedic Surgery, Nagakute, Japan*; [3]*Japanese Red Cross Nagoya Daiichi Hospital, Orthopaedic Surgery, Nagoya, Japan*

Background: Frailty is a common geriatric syndrome that involves an elevated risk of catastrophic declines in health and function [1]. Rheumatoid arthritis (RA) is an autoimmune disease that causes synovitis in the joints, resulting in a high prevalence of joint deformity (0.5–1.0% in Japan) [2]. Japan is one of the world's most rapidly aging societies [3]. Many older adults in Japan are in the pre-frailty category (4), and older RA patients are generally at a greater risk of frailty than the general population. Against this backdrop, the present study aimed to examine predictors of frailty progression in RA patients. Pre-frailty patients with RA were focused on because, in the short term, they are more prone to frailty than robust patients.

Objectives: To examines the predictors of frailty progression in pre-frail patients with RA.

Methods: A total of 287 RA patients who were pre-frailty in 2020 were evaluated on the basis of our observational study data. Of the patients, 55 were robust, 186 were pre-frailty, and 46 were frailty in 2021 and were assigned to the Better, Stable, and Worse groups, respectively. After comparing the characteristics of the patients in the three groups at baseline, the two-year change was assessed with respect to the use of DAS28-ESR, HAQ-DI, and methotrexate (MTX); biological and targeted synthetic disease-modifying antirheumatic drugs (b/ts-DMARDs); and steroids. The Better and Stable groups were compared to clarify the difference between the two groups. The Stable and Worse groups were compared by univariate analysis. The predictors of transitioning to the Worse group were assessed by logistic regression analysis.

Results: At baseline, mean DAS28-ESR for all groups exhibited low disease activity levels, but only the Worse group deteriorated, eventually reaching moderate disease activity levels. The Better and Stable groups maintained sub-low disease activity over two years (Figure 1A). HAQ-DI in the Worse group was significantly higher than in the other two groups. However, comparing HAQ-DI in the Stable and Better groups, the Stable group was substantially worse (Figure 1B), although there were no differences in the other factors, suggesting an irreversible gap between the two groups. There were no differences in MTX and steroid use among the groups, although the rate of steroid use in the Worse group was slightly higher than in the other two groups over two years (Figure 1C, 1D). On the other hand, b/ts-DMARDs in the Stable group were higher than in the other two groups (Figure 1E). This suggested that most patients in the Stable group required a combination of MTX and b/ts-DMARDs to maintain treat-to-target strategy, unlike the Better group. In comparing the Stable and Worse groups, age, DAS28-ESR, and non-use of b/ts-DMARDs were predictors of frailty progression (Table 1).

Conclusion: DAS28-ESR and non-use of b/ts-DMARDs were predictors of frailty progression over two years in pre-frail patients with RA. The ideal treatment goal is to improve from pre-frailty to robust, but a realistic goal is not to worsen from pre-frailty to frailty by using a combination of MTX and b/ts-DMARDs.

AB0188 **A BIOINFORMATIC APPROACH TO IDENTIFYING SENSITIZING THERAPEUTICS FOR RHEUMATOID ARTHRITIS**

Keywords: Rheumatoid arthritis, -omics

J. Rajan[1], D. Gibson[1], S. D. Zhang[1], A. Bjourson[1]. [1]*Ulster University, Life and Health Sciences, Londonderry, United Kingdom*

Background: Rheumatoid Arthritis (RA) is a systemic and chronic autoimmune disorder that has significant impact on quality of life and work capacity for the patient. Treatment and management of RA is aimed at gaining control of inflammation and alleviating pain, however, achieving remission and low disease activity with minimal toxicity is frequently not possible with the current suite of drugs. Additionally with escalating de novo drug development costs, alternate bioinformatic approaches which scope the potential to repurpose already licenced compounds and their ability to work synergistically have become attractive.

OBJECTIVES:

1)Develop, test and refine a bespoke connectivity mapping based bioinformatic pipeline, DrugExpress, with capability of mining treatment response gene signatures using public RNAseq and microarray datasets.

2)Verify treatment response signatures and prioritise novel drugs to generate a list of robust sensitising drugs.

Methods: Public RNAseq (GSE198529) and microarray datasets (GSE93777 and GSE24742) were mined based on the presence of DAS score, clinical features, sample size and technological platform. R/Bioconductor packages and Perseus software were used to pre-process and carry out differential expression (DE) analysis to obtain a list of differentially expressed genes (DEGs), based on the cut off criteria of padj < 0.05 and a minimal 2-fold change of expression, and derive gene signatures characteristic of treatment response. DEGs from multiple datasets were combined to create a master gene list consisting of 21 DEGs. Gene Ontology (GO) enrichment analysis was performed on the genes in the master list to identify the top biological pathways. A list of inferred genes involved in each of these pathways was compiled to determine the overall direction of expression with response to treatment. DEGs in the master list were extracted and mapped to Affymetrix probeset IDs to create treatment response gene signatures to be entered into a sscMap search for candidate drugs. Connectivity mapping (CMap) analysis was used to establish networks between DEGs in the gene signature and FDA approved drugs. P-value and connection score of each reference drug in the CMap was obtained and used to determine statistical significance and perturbation stability.

Results: GO enrichment analysis performed on the master gene list identified the top 3 pathways: transport of connexons to the plasma membrane, oligomerization of connexins into connexons, and gap junction assembly. CMap analysis identified a total of 36 statistically significant compounds with a perturbation stability score of 1. Candidate compounds were selected based on whether they enhanced a theoretical response phenotype. The top 3 ranked compounds (by p value) which would induce theoretical reduction in disease activity were: ciclosporin (p-value = 0.0001), demecarium bromide (p-value = 0.0002) and 2-aminobenzenesulfonamide (p-value = 0.0002).

Conclusion: The analysis using the DrugExpress pipeline illustrates the process of treatment response DEG extraction from public expression datasets.

These response signatures can be used for CMap analysis to predict new compounds for treatment refractive patients and can potentially simulate the effective changes observed in responders. Next step in the pipeline would be to implement *in silico* toxicity screening methods to identify any contraindications with existing treatments.

AB0189 THE BEST CARDIOVASCULAR RISK ALGORITHM FOR PREDICTING THE PRESENCE OF CAROTID PLAQUE IN WOMEN WITH RHEUMATOID ARTHRITIS

Keywords: Gender/diversity issues, Rheumatoid arthritis, Cardiovascular disease

I. J. Colunga-Pedraza[1], J. R. Azpiri-López[2], D. Á. Galarza-Delgado[1], V. Gonzalez-Gonzalez[1], V. M. Beltran-Aguilar[1], A. G. Arias Peralta[2], N. De Avila Gonzalez[1], J. A. Cardenas-de la Garza[1], G. García-Arellano[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico*

Background: Atherosclerotic cardiovascular disease is the leading cause of death in patients with rheumatoid arthritis (RA). Chronic inflammation increases cardiovascular risk (CVR) in these patients [1]. Heart disease remains the most likely cause of death for women, and a higher risk is established than for men [2].

Objectives: To compare six CVR algorithms with carotid ultrasound findings in women with RA and to identify the algorithm with the cutoff point with the best sensitivity for carotid plaque (CP) detection.

Methods: Cross-sectional, and descriptive study. Patients aged 40 to 75 years who met the ACR/EULAR 2010 classification criteria for the diagnosis of RA. Patients with a history of cardiovascular disease were excluded. CVR was calculated using 6 algorithms: ACC/AHA 2013, FRS-Lipids, FRS-BMI, RRS, QRISK3 and SCORE2. Carotid ultrasound was performed on all study participants, and the presence of CP, defined as diffuse carotid intima-media thickness (cIMT) ≥1.2 mm or focal thickness ≥0.5 mm, was assessed. Subclinical atherosclerosis was defined as the presence of CP or a cIMT ≥0.8mm. An ROC curve analysis was performed and the cutoff points for each algorithm were determined using the Youden index. Area under the curve (AUC) sensitivity, specificity, and likelihood ratios (LR) were calculated. A value of $p \leq 0.05$ was considered statistically significant.

Results: A total of 158 women with a diagnosis of RA were included. The prevalence of CP was 32.3%. Results are shown in Figure 1.

Conclusion: The FRS-Lipids algorithm was one of the best algorithms for the detection of CP in women, with the best sensitivity compared to the other algorithms, however, in the low-risk group none of the algorithms proved to be sufficiently effective in predicting CVR. Therefore, we suggest to consider carotid ultrasound as part of the evaluation in women with RA.

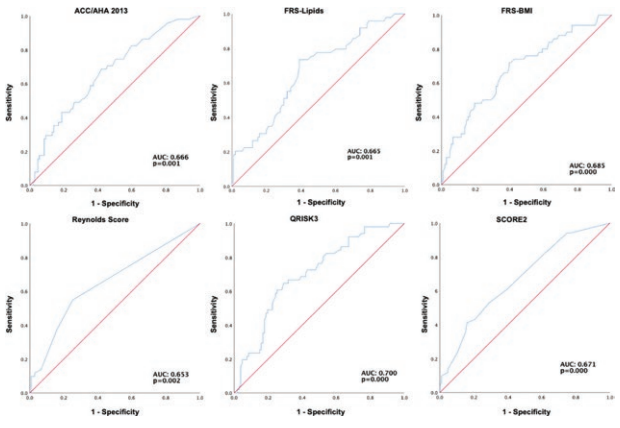

Figure 1. ROC curves of the cardiovascular risk algorithms.

AB0190 GENDER DIFFERENCES IN OSTEOPOROSIS RISK FACTORS IN PATIENTS WITH RHEUMATOID ARTHRITIS REFERRED FOR BONE DENSITY ESTIMATION – AN OBSERVATIONAL STUDY

Keywords: Osteoporosis, Epidemiology, Rheumatoid arthritis

M. D. Bokobza de la Rosa[1], Z. Sultan[2], M. Bukhari[3,4]. [1]*Lancaster University, Medical School, Bailrigg, United Kingdom*; [2]*University Hospitals of Morecambe Bay Trust, Rheumatology, Lancaster, United Kingdom*; [3]*Lancaster University, Lancaster Medical School, Lancaster, United Kingdom*; [4]*University Hospitals of Morecambe Trust, Rheumatology, Lancaster, United Kingdom*

Background: Rheumatoid arthritis (RA) is associated with a loss of bone density and fragility fractures [1]. There are few studies that compare bone loss by gender.

Objectives: This study aims to explore the bone loss by gender in a large RA cohort referred for bone mineral density (BMD) estimation.

Methods: RA patients referred to a district BMD scanner in the northwest of England between 2004 and 2019 were included. The cohort was divided by gender and the prevalence of fracture, and risk factors for fractures modelled. Initially, traditional risk factors as defined by FRAX(tm) were compared between men and women and subsequently the ability of those risks to predict fractures were modelled. For the characteristic of secondary osteoporosis, only coeliac disease was included. Comparison was made using Chi-squared test for categorical variables and T-test for continuous variables. Predictors of fracture were modelled using logistic regression.

Results: 2072 patients, mean age 66.97 years (s.d. 11.34) were included, of whom 1628 (78.6%) were females. The mean age was significantly higher in Males at 68.02yrs compared to Females at 66.69yrs (p=0.0284). Height (171.62cm) and Weight (80.97) was higher in males and History of fractures was higher in females (33.11% vs 23.42% - p<0.001). Excess alcohol (6.08% vs 2.58% - p<0.001) and Steroid therapy (46.4% vs 28.62% - p<0.001) were higher in men. All other characteristics had no significant difference except lumbar spine BMD which was higher in men (-0.24 vs -0.82 - p<0.001). A summary of the differences is shown in Table 1.

Table 1. Results of logistic regression on fracture risk in men and women in the cohort

	Male OR	Male 95% CI	Female OR	Female 95% CI
Age	0.997	0.976-1.018	1.028	1.019-1.038
Height	1.017	0.986-1.049	0.969	0.955-0.984
Weight	1.005	0.991-1.018	0.992	0.986-0.999
FHx of fracture	1.101	0.479-2.530	1.371	1.038-1.810
Smoker current	1.801	1.011-3.210	0.969	0.722-1.300
Steroid therapy	0.761	0.488-1.186	0.785	0.622-0.991
Excess Alcohol	1.158	0.476-2.821	0.904	0.466-1.754
R NOF BMD	0.640	0.511-0.803	0.719	0.652-0.793
L NOF BMD	0.646	0.512-0.814	0.735	0.667-0.810
Lumbar spine BMD	0.957	0.922-0.992	0.956	0.940-0.973
Malabsorption – Secondary osteoporosis	2.410	0.748-7.748	2.235	1.321-3.781

Yellow – Statistically significant with P<0.05

Conclusion: The study identifies gender differences in the risk factors for fractures in rheumatoid arthritis patients. This will have implications when assessing fracture risk using FRAX(tm) underestimating fracture risk in this population. FHx of fractures was only significant in fractured RA females. Steroid therapy had an idiosyncratic effect and was seen as protective; this was previously described in this cohort [3]. Being a current smoker was only a significant risk factor in males. Finally, Left and Right NOF and lumbar spine BMD were significantly smaller in both fractured genders making a reduced BMD on these sites an important risk factor to consider in any patient with RA. The strength of this study was the large cohort of rheumatoid arthritis patients included while it was limited by lack of detail on disease activity, treatment and duration. A variety of significant data was found, but further work is required

to find accurate differences between the risk factors associated with fractures in both genders with RA.

AB0191 SAFETY OUTCOMES IN PATIENTS (PTS) WITH RHEUMATOID ARTHRITIS (RA) TREATED WITH FILGOTINIB (FIL) IN FILOSOPHY: INTERIM RESULTS FROM A PROSPECTIVE OBSERVATIONAL STUDY

Keywords: Real-world evidence, Safety, Rheumatoid arthritis

P. Verschueren[1], J. Avouac[2], K. Bevers[3], S. Romero-Yuste[4], R. Caporali[5,6], T. Debray[7], F. De Leonardis[8], J. Galloway[9], M. Zignani[8], G. R. Burmester[10]. *[1]University Hospital Leuven and KU Leuven, Department of Rheumatology, Leuven, Belgium*; *[2]Hôpital Cochin, AP-HP Centre - Université Paris Cité, Rheumatology A Department, Paris, France*; *[3]Sint Maartenskliniek, Department of Rheumatology, Nijmegen, Netherlands*; *[4]University Hospital Complex of Pontevedra, Department of Rheumatology, Pontevedra, Spain*; *[5]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*; *[6]ASST Gaetano Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy*; *[7]Galapagos NV, Biostatistics, Mechelen, Belgium*; *[8]Galapagos GmbH, Medical Affairs, Basel, Switzerland*; *[9]King's College London, Centre for Rheumatic Diseases, London, United Kingdom*; *[10]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Consideration is needed when using Janus kinase (JAK) inhibitors to treat RA in pts aged ≥65 years or those with cardiovascular (CV) risk factors. The JAK1 preferential inhibitor FIL was generally well tolerated in clinical trials[1]; safety has not been determined in a real-world setting.

Objectives: To report baseline characteristics and up to 6-month safety data from the first 480 pts treated with FIL in the FILOSOPHY study (NCT04871919), and in two mutually exclusive subgroups based on age and CV risk.

Methods: FILOSOPHY is an ongoing, phase 4, non-interventional, European study of pts with RA who have been prescribed FIL for the first time and in accordance with the product label in daily practice. Baseline characteristics and the incidence of select adverse events (AEs) are assessed in pts aged ≥65 years and/or with ≥1 CV risk factor (**Table 1**), and in those aged <65 years with no CV risk factors.

Results: As of the end of June 2022, 480 pts had been treated: 441 received FIL 200 mg and 39 received FIL 100 mg. Of the 480 pts, 148 (30.8%) were aged ≥65 years; 332 (69.2%) were aged <65 years. In total, 86 (17.9%) were former smokers, 81 (16.9%) were current smokers and 203 (42.3%) were non-smokers (data were missing for 110 pts [22.9%]). In addition to smoking, the most frequent CV risk factors included a history of hypertension (32.3%), a history of dyslipidemia (10.2%) and a family history of myocardial infarction (8.5%; **Table 1**). 23 pts (4.8%) discontinued treatment due to AEs. Of the 354 pts aged ≥65 years or with ≥1 CV risk factor, infections affected 64 pts (18.1%), 34 (9.6%) had COVID-19, 2 (0.6%) had herpes zoster, and cardiac disorders (angina pectoris, atrial fibrillation, palpitations and tachycardia) affected 5 pts (1.4%); no cases of malignancies were observed. In the subgroup aged <65 years and with no CV risk factors (n=126), infections occurred in 18 pts (14.3%) (9 [7.1%] had COVID-19; 3 [2.4%] had herpes zoster) and malignancies (myeloproliferative neoplasm) affected 1 pt (0.8%); no pts had cardiac disorders. There were no cases of deep vein thrombosis or pulmonary embolism in either subgroup.

Conclusion: In this interim analysis of FILOSOPHY, no unexpected safety signals emerged at up to 6 months. Although infections and cardiac disorders affected a numerically greater proportion of pts aged ≥65 years or with ≥1 CV risk vs those aged <65 years with no CV risk, longer follow-up on a broader cohort is necessary to further characterize the safety of FIL in different groups of pts with RA.

AB0192 ANALYSIS OF ULTRASOUND FINDINGS IN PATIENTS WITH DIFFICULT TO TREAT RHEUMATOID ARTHRITIS

Keywords: Ultrasound, bDMARD, Rheumatoid arthritis

T. Okano[1], K. Mamoto[1], Y. Yamada[1], S. Anno[2], A. Yagami[3], Y. Domae[3], S. Washida[3], Y. Yoshida[3], T. Koike[4,5], H. Nakamura[1]. *[1]Osaka Metropolitan University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka, Japan*; *[2]Yodogawa Christian Hospital, Department of Orthopedic Surgery, Osaka, Japan*; *[3]Osaka Metropolitan University Hospital, Central Clinical Laboratory, Osaka, Japan*; *[4]Osaka Metropolitan University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan*; *[5]Shirahama Hamayu Hospital, Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan*

Background: In recent years, the concept of D2TRA (difficult-to-treat rheumatoid arthritis) has become widespread, and D2TRA patients are defined as a state in which activity cannot be controlled even with the use of various molecular-targeted drugs. In this study, we investigated the ultrasound synovial findings in D2TRA patients. However, ultrasound findings in D2TRA patients are unknown.

Objectives: In this study, we investigated the ultrasound findings of D2TRA patients.

Methods: A total of 750 RA patients who underwent ultrasound examination were included. Ultrasond examination was performed at the of bilateral first to fifth metacarpophalangeal (MCP) joints, first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) joints, wrist joints (three part of radial, medial and

ulnar) and first to fifth metatarsophalangeal (MTP) joints. Of all 750 RA patients, 517 RA patients (68.9%) who treated bDMARDs/JAKi were included and devided in D2TRA patients and non-D2TRA patients. The patients' characteristics, total gray scale (GS) and power Doppler (PD) score (GSUS/ PDUS) were compared between D2TRA patients and non-D2TRA patients.

Results: There were 40 D2TRA patients and 477 non-D2TRA patients. Mean age was 61.2 vs. 65.0 years (p=0.133), mean disease duration of RA was 17.6 vs. 14.9 years (p=0.199), CDAI was 12.6 vs. 9.8 (0.166), and CRP level was 0.79 vs. 0.28 mg/dL (p=0.233), MMP-3 level was 295.6 vs 10.8ng/mL (p=0.057), respectively. In the D2TRA group, concomitant use ratio of MTX was low (50.0 vs 70.9 %, p=0.011), but there was no difference in the average dose of MTX (8.9 vs 9.2 mg/w, p=0.581). The concomitant use ratio of glucocorticoid (32.5 vs 12.6 %, p=0.002) and the average dose of glucocorticoid (7.7 vs 3.1 mg/d, p=0.003) were higher in D2TRA group. Regarding ultrasound findings, GSUS score (16.2 vs 9.5, p=0.011) and PDUS score (11.0 vs 6.4, p=0.034) were significantly higher in the D2TRA group.

Table 1.

	D2TRA (n=40)	non D2TRA (n=477)	p value
Age (years)	61.2±17.3	65.0±14.1	0.113
Female, %	77.5	82.1	0.390
BMI (kg/m^2)	22.5±4.9	22.3±3.4	0.750
Disease duration (years)	17.6±9.6	14.9±12.7	0.199
RF+, %	95.0	89.9	0.410
RF titer (mg/dL)	754.3±1284.7	301.2±423.4	0.032
CCP+, %	94.8	85.2	0.144
CCP titer (U/mL)	227.0±183.2	134.0±165.6	0.001
MTX use, %	50.0	70.9	0.011
MTX dose (mg/week)	8.9±2.6	9.2±3.6	0.581
Glucocorticoid use, %	32.5	12.6	0.002
Glucocorticoid dose (mg/day)	7.7±4.4	3.1±1.8	0.003
DAS28 ESR	3.2±1.9	3.0±1.4	0.668
DAS28 CRP	2.8±1.4	2.7±1.2	0.438
SDAI	13.4±12.6	10.1±9.5	0.120
CDAI	12.6±12.0	9.8±9.3	0.166
HAQ	0.90±0.98	0.66±0.74	0.137
ESR (mm/h)	26.2±30.2	17.6±20.6	0.085
CRP (mg/dL)	0.79±2.67	0.28±0.77	0.233
MMP-3 (ng/mL)	295.6±611.9	105.8±157.2	0.057
GSUS	16.2±15.7	9.5±9.5	0.011
PDUS	11.0±13.0	6.4±7.7	0.034

Conclusion: The definition of D2TRA is resistant to multiple mode of bDMARDs/ JAKi. Although, disease activity and inflammatory markers tended to be worse in the D2TRA group, there was no statistically significant difference in this study. However, ultrasound findings were significantly worse in D2TRA. Suppression of synovitis might be important to prevent D2TRA.

AB0193 PATIENT-PHYSICIAN DISCORDANCE IN GLOBAL ASSESSMENTS AMONGST SOUTH AFRICANS WITH RA

Keywords: Patient reported outcomes, Rheumatoid arthritis, Outcome measures

S. A. Didi[1], B. Hodkinson[1]. [1]*University of CapeTown, Rheumatology Division, Department of Medicine, Observatory, Cape Town, South Africa*

Background: Discordance between the patient global assessment (PGA) and physician global assessment (PhGA) is well reported in rheumatoid arthritis (RA) and can lead to suboptimal care[1]. There are no published studies on discordance in South African (SA) patients.

Objectives: To measure and explore patient-physician discordance amongst RA patients attending a tertiary SA hospital.

Methods: Consenting adults (≥18 years) with RA completed demographic, clinical and patient-reported outcome measures including Health Assessment Questionnaire-Disability Index (HAQ-DI),FACIT fatigue scale, Hospital Anxiety and Depression Scale (HADs), Brief Pain Questionnaire-short form (BPI-SF), and EuroQOL five dimensions questionnaire (EQ5D). Poor socio-economic status (SES) was defined using a pooled index. The Clinical Disease Activity Index (CDAI) was calculated based on the swollen and tender joint counts (SJC and TJC), PGA and PhGA visual analogue scale. Patients were categorized into high, moderate or low disease activity (HDA, MDA and LDA) states. Discordance was calculated by subtracting the PhGA score from the PGA and positive discordance was defined as a difference of > 2.5 points. Determinants of PGA and PhGA were also analyzed.

Results: Of 550 patients (467 females), the mean (SD) age and disease duration were 55.8 (12.9) and 10.5 (9.7) years, most were in LDA (47.8%), and 371 (67.4%) had poor SES. Positive discordance was seen in 136 patients (24.7%). Fifteen patients with negative discordance (PGA- PhGA < - 2.5) were excluded from this analysis. Comparing concordant and positive discordant patients, there were no significant differences in age, sex, disease duration, SES, RA therapy or number of comorbidities, nor in fatigue, HAD-DI, or HADs. The discordant group had significantly lower SJC, TJC and PhGA. More patients in the discordant group were in LDA (58.1% vs. 45.4%), with fewer in MDA (32.4 % vs. 29.1 %) and HDA (9.6% vs. 25.6%), p = 0.001. In addition, the discordant group included more fibromyalgia (FMS) patients, reported higher pain severity score and a higher EQ5D level sum score, with problems with usual activities being the only statistically significant domain (p<0.001). In logistic regression analysis, pain severity score and problems with usual activities on EQ5D were predictors of positive discordance. Pain was the main determinant of PGA (R^2 0.24, p<0.001) and SJC was the main determinant of PhGA (R^2 0.44, p<0.001).

Table 1. Factors influencing Discordance

Variables	No discordance n=399	Positive discordance n= 136	p-value
Age (years)	55.7(13.3)	55.8(11.6)	ns
Poor SES	260(65.2%)	96(70.6%)	ns
Duration of RA (years)	10 (5-16)	9 (5-15)	ns
Comorbidities ≥3	67 (16.8 %)	29 (21.3%)	ns
Fibromyalgia	22 (5.5%)	17(12.5%)	0.007
HAQ-DI	1.49(0.72)	1.54 (0.71)	ns
EQ5D-3L- Level Sum Score	9(8-11)	10(9-11)	0.04
Pain severity score	4.6(2.1)	5.2(1.8)	0.005
Pain interference score	4.4(2.5)	4.8(2.2)	0.06
HADS-Anxiety Score	8.2(4.7)	8.9(4.8)	ns
HADS-Depression Score	8.9(6.0)	9.7(6.2)	ns
FACIT-F scale	28.6(13.5)	27.9(12.5)	ns
Tender joint count	2(0-5)	1(1-3)	0.005
Swollen joint count	2(1-5)	0(0-1.75)	<0.001
Physician Global Assessment	3.8(2.8)	1.7(1.7)	0.001
Patient global assessment	4.4 (2.7)	6.6 (1.9)	<0.001

ns not significant; categorical data reported as n (%); continuous data reported as mean (standard deviation (SD), median (Interquartile rang, IQR)

Conclusion: In this cohort of indigent SA RA patients, patient-physician discordance was found in a quarter of participants, and was noted in the LDA states, FMS and in patients with high pain scores and those who have problems with usual activities. We have shown, similar to studies elsewhere, that patients and clinicians focus on different aspects of disease when making their global assessments. Studies to understand the impact of discordance and the role of interventions, including pain management and occupational therapy are planned.

AB0194 PROGRESSION OF RHEUMATOID PULMONARY NODULES: WHAT ARE THE PREDICTIVE FACTORS?

Keywords: Prognostic factors, Rheumatoid arthritis, Lungs

G. Sandal Uzun[1], Y. Sarıkaya[2], E. B. Ata[3], M. Ekici[1], S. Arslan[2], E. Bilgin[1], G. Durhan[2], L. Kılıç[1], U. Kalyoncu[1], M. Arıyürek[2]. [1]*Hacettepe University Faculty of Medicine, Department of Internal Medicine Division of Rheumatology, Hacettepe University Medical Faculty, Ankara, Turkey, Ankara, Turkey*; [2]*Hacettepe University Faculty of Medicine, Department of Radiology, Hacettepe University, Faculty of Medicine, Ankara, Turkey*; [3]*Hacettepe University Faculty of Medicine, Department of Internal Medicine, Hacettepe University Medical Faculty, Ankara, Turkey, Ankara, Turkey*

Background: Pulmonary rheumatoid nodule(RPN) is an serious extraarticular manifestation of rheumatoid arthritis (RA). The clinical features and activity of the RA, used DMARDs and the characteristics of the nodule may affect the progression of the RPN. [1]

Objectives: To identify the characteristics of the PRN and factors affecting its progression.
Methods: In this study, 4117 patients with RA according to the ICD-10 code from the hospital database and who had at least one computed tomography (CT) were identified. The RA diagnosis of the patients were confirmed by examining the medical files (history, physical examination, radiography and laboratory evaluations). Then, chest CTs of the patients with confirmed RA diagnosis were examined by an experienced radiologist. To classify pulmonary nodules as ''pulmonary rheumatoid nodule'', following inclusion and exclusion criteria were used; For inclusion: 1) nodules with changing dimension on follow-up, 2) At least two nodules with different dimensions, 3) Cavitary nodule at any chest CT. For exclusion: 1) Solitary nodules OR all nodules ≤ 5mm and without follow-up OR no change on follow-up. Biggest nodule was named as dominant nodule. Then, patients were grouped according to status of progression. Progression was defined as growth or new nodule formation.
Results: Of 680 RA patients who had pulmonary nodule in chest CT, 208 (30.6%) patients were classified as having PRN. Of these patients, 135 had at least one control chest CT for PRN follow-up and were included in the study. The median disease duration from diagnosis of RA to baseline CT with PRN was 6.74(0.1-33.9) years. Before the baseline CT, 59 (43.7%) patients were recieving methotrexate and it was discontinued in 22 (37.2%) patients after RPN detection. 39 (28.9%) patients had PRN progression on their final chest CT compared to baseline. The median duration between baseline and final CT was 1.58(0.04-33.81) years. Anti-CCP positivitiy(OR 3.39, %95 CI 1.15-9.94), usage of bDMARDs between baseline and last CT (OR 2.48, %95 CI 1.1-5.5), cavitation (OR 3.31, %95 CI 1.5-7.4) and diameter of dominant nodules at baseline CT (OR 1.03, CI %95 1.00-1.07) were significantly assosiated factors with progression in RPN.

Table 1.

	PRN Progressed (n=39)	PRN Non-progressed, n=96	p

Anti-CCP: Anti- Cyclic citrullinated peptide, RF: Rheumatoid Factor, ILD: interstitial lung disease, csDMARDs: conventional synthetic Disease Modifying Anti-Rheumatic Drugs)

Conclusion: Our study shows that there are multiple factors that predict RPN progression. Especially the presence of cavitary nodules and seropositivity is important.Although clinicians tend to discontinue MTX when RPN is detected, MTX is not associated with RA nodule progression.

AB0195 **GENETIC ASSOCIATION BETWEEN INTERLEUKIN-17 AND SUSCEPTIBILITY TO RHEUMATOID ARTHRITIS**

Keywords: Cytokines and chemokines, Rheumatoid arthritis, Genetics/epigenetics

Y. W. Zhang[1,2], R. Zhao[1,2,3], J. Y. Yao[1,2], J. C. Guo[1,2], S. X. Zhang[1,2,3], X. Li[1,2,3], C. Wang[1,2,3]. [1]*Shanxi Medical University, Ministry of Education Key Laboratory of Cellular Physiology, Taiyuan, China*; [2]*Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; [3]*Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: The pathogenesis of rheumatoid arthritis (RA) is immune imbalance, in which various inflammatory immune cells and pro-inflammatory factors are involved[1]. In particular, interleukin-17 (IL-17) is a potent pro-inflammatory cytokine[2], but the causal relationship between the expression level of IL-17 or IL-17 receptor (IL-17R) and rheumatoid arthritis remained unknown at genetic.
Objectives: In this study, two-sample Mendelian randomization (MR) was used to investigate the causal relationship between IL-17 and RA.
Methods: Summary statistics for RA (14,361 RA cases and 43,923 healthy controls (HCs)) and IL-17 (3,301 samples) were obtained from an available meta-analysis of published genome-wide association studies (GWAS). Relevant single nucleotide polymorphisms (SNPs) were selected by executing quality control steps ($p < 1.0 \times 10^{-5}$) from the GWAS summary results. Mendelian randomization (MR) analyses progressed mainly using inverse variance weighted (IVW), weighted median (WM), and MR-Egger regression methods. For assessing the robustness of the results, we also carried out sensitivity analysis to assess heterogeneity and pleiotropy, such as MR-Egger, leave-one-out and MR pleiotropy residual sum and outlier (MR-PRESSO).
Results: MR Methods were applied to the genetic instrumental variables (IVs) of IL-17A/IL-17 RA, IL-17C/IL-17 RC and IL-17D/IL-17RD and RA. The result of MR analysis indicated that the higher level of IL-17RA (95%CI = 1.006-1.231, p = 0.038) was associated with a significantly higher risk of RA, while remaining exposure IVs did not show a causal relationship with RA, including IL-17A(95%CI = 0.990-1.210, p = 0.078), IL-17C(95%CI = 0.890-1.139, p = 0.910), IL-17RC(95%CI = 0.904-1.119, p = 0.913), IL-17D(95%CI = 0.843-1.137, p = 0.778), IL-17RD(95%CI = 0.876-1.104, p = 0.773). More importantly, sensitivity analysis showed no heterogeneity or pleiotropy in any of the above results.
Conclusion: MR analysis supported a potential causal relationship between IL-17RA and the risk of RA, prompting that doctors should pay close attention to the level of IL-17RA during the examination of RA patients. Furthermore, it will promote future studies on reducing the risk of RA by developing drugs that limitation IL-17A.

AB0196

IMPACT OF ANTIRHEUMATIC TREATMENTS ON THE INDIVIDUAL COMPONENTS OF THE ACR COMPOSITE SCORE IN PATIENTS WITH RA: REAL-WORLD DATA FROM TWO REGISTRIES

Keywords: Rheumatoid arthritis, Outcome measures, bDMARD

L. Bessette[1], M. Movahedi[2,3], D. Choquette[4], L. Coupal[4], C. Bombardier[2,3,5], E. Keystone[5]. [1]*Laval University, Rheumatology, Quebec City, Canada*; [2]*Toronto General Hospital Research Institute, Ontario Best Practice Initiative, Toronto, Canada*; [3]*University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada*; [4]*Institut de Rhumatologie de Montréal, Rhumadata, Montreal, Canada*; [5]*University of Toronto, Medicine, Toronto, Canada*

Background: Standard criteria for measuring treatment efficacy in patients with RA include ACR response rates, which require meeting a threshold of ≥ 20/50/70% improvement in several physician- and patient-reported measures, including tender and swollen joint counts (TJC and SJC, respectively; primary criteria) and at least 3 of 5 secondary criteria (Physician (Ph) global assessment (GA), Patient (Pt) GA, Pain, HAQ-DI, and CRP).
Objectives: The purpose of the analysis was to evaluate the impact of csDMARDs, TNF inhibitors (TNFi), and tofacitinib (TOFA) on each ACR score component in real-life practice.
Methods: Clinical data of RA patients with a CDAI >10 at the time they started a csDMARDs (all biologic naïve), TNFi or TOFA were pooled from two registries: Ontario Best Practices Research Initiative (OBRI) and RHUMADATA. Endpoints summarized descriptively included proportions of pts achieving: ACR20/50/70 responses, ≥ 20/50/70% improvements and mean percent improvement in individual ACR components (TJC, SJC, PhGA, PtGA, Pain, HAQ-DI, and CRP) at Month (M6).
Results: A total of 669 pts were included (csDMARD, n=157, TNFi, n=252; TOFA, n=260). At baseline, patients starting TOFA had longer disease duration, failed more bDMARDs and used more corticosteroids than csDMARDs and TNFi. The CDAI was similar between the 3 groups. ACR50 response rates were numerically lower for the TOFA group (Table 1). The ACR70 response was similar in the 3 groups. An overall higher proportion of patients in all three-medication groups achieved ≥20/50/70% improvement in primary ACR components vs secondary components. Among secondary components, ≥20/50/70% improvement rates were numerically highest for PhGA and lowest for HAQ-DI and pain. The improvement in the SJC and TJC were numerically similar between all groups (Table 1). Among ACR20/50/70 responders for all medications, mean percent improvement was more than 80% for primary components, and ranged from 30% to 80% for secondary components (Figure 1).
Conclusion: In this real-world practice analysis, physician-reported measures (TJC, SJC, and PhGA) contribute slightly more to overall ACR20/50/70 responses, compared with Pt-reported outcomes (PROs; PtGA, Pain and HAQ-DI). In the ACR20 response group, a lower-level outcome, the improvement of the SJC and TJC, exceeded 80%. Pain was the most important factor in achieving an ACR50 for pts treated with TOFA, possibly reflecting the different effects of JAKi on pain.

Table 1. Percentage of patients treated with csDMARD, TNFi, and TOFA who reported an ACR50 response and ≥ 50% improvement at month 6

	csDMARD (N=157)	TNFi (N=252)	TOFA (N=260)
ACR50 response and ≥ 50% improvement in each component of the ACR50 score, n (%)			
ACR50 response	27.4%	25.3%	19.4%
TJC	62.1%	63.8%	68.5%
SJC	64.9%	67.8%	67.2%
PhGA	58.3%	51.7%	50.3%
PtGA	44.9%	38.8%	32.7%
Pain	27.6%	23.7%	26.7%
HAQ-DI	23.6%	17.3%	17.7%
CRP	40.9%	41.4%	35.6%

The analysis is based on observed case data (without imputation) of patients with all 7 components assessed ACR50/70: American College of Rheumatology ≥ 50/70% response rates; CRP: C-reactive protein; csDMARD: conventional synthetic disease-modifying antirheumatic drug; HAQ-DI: Health Assessment Questionnaire–Disability Index; Pain: patient-reported pain (visual analog scale); PhGA: physician global assessment; PtGA: patient global assessment of disease activity; SJC: swollen joint count; TJC: tender joint count; TNFi: tumour necrosis factor inhibitors; TOFA: tofacitinib.

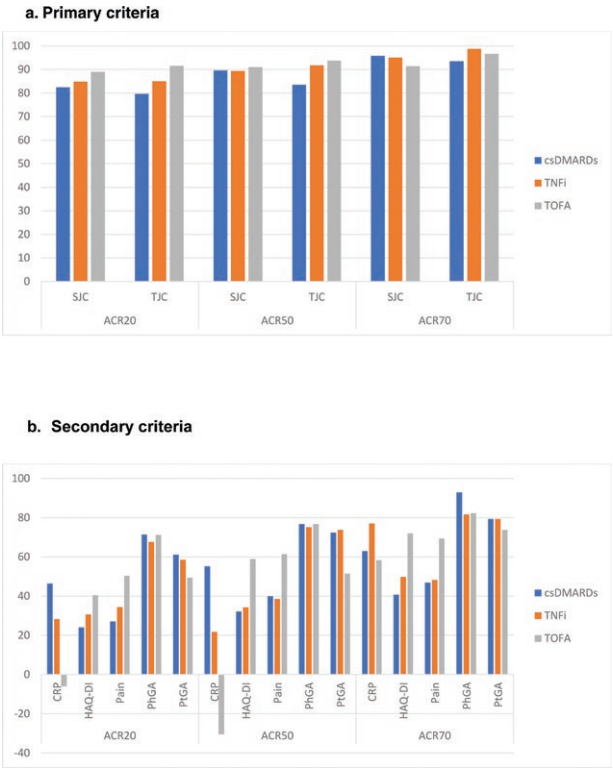

Figure 1. Mean percent improvement in ACR components in those patients who achieved an ACR20/50/70 at month 6
Analysis is based on observed case data (without imputation) of patients with all 7 components assessedACR20/50/70: American College of Rheumatology ≥ 20/50/70% response rates.

Background: Rheumatoid Arthritis (RA) is often associated with autonomic dysfunction, which is presumably playing a role in the pathogenesis of the disease and may contribute to disease activity [1,2]. Accordingly, patients with RA show reduced heart rate variability (HRV) [3].
Objectives: The aim of this prospective pilot study was to examine a possible connection between disease activity and activity of the autonomic nerve system in patients with RA.
Methods: In the non-randomized prospective exploratory study, patients with active RA and an upcoming change in treatment were included. Assessments were performed at baseline before treatment initiation (T0) and after 3 months (T1), including the Disease Activity Score 28 (DAS28-CRP), HRV measurement, and the physician and patient global assessment (PGA, PtGA). HRV was measured through a 5-minute ECG with finger electrodes, using Kardia App®. Total variability was measured by the variance of RR intervals over the temporal segment (Total Power) as well as by standard deviation of the average RR intervals (SDRR). Root Mean Square of successive differences (RMSSD) and percentage of number of pairs of adjacent RR intervals differing by more than 50 milliseconds (pRR50) were used for estimating parasympathetic activity. In addition, blood concentrations of Neuropeptide Y (NPY), vasoactive intestinal peptide (VIP) were measured as surrogate parameters for activity of the sympathetic (NPY) and parasympathetic (VIP) nervous system. Statistical analysis was performed using linear regression analysis.
Results: A total of 40 patients was included. Our results showed an overall improvement in both disease activity measured by DAS28-CRP (p= <0,001; SMD= 1.393) and HRV (Total Power p= 0.014; SDRR p= 0.0023) between visits (Table 1). DAS28-CRP was inversely associated with parasympathetic activity (pRR50, p= 0.0494). PtGA also correlated inversely with pRR50 (p= 0.0049). RMSSD as another parasympathetic indicator was negatively predictive for percentage change of PGA (p= 0.0109). Patients with lower parasympathetic activity at baseline had a higher change in disease activity than patients with higher parasympathetic activity at baseline.

Table 1. HRV parameters and disease activity at T0 and T1 (*all parameters at T0 and T1as mean values*)

Parameter	T0	T1	p-Wert	SMD
SDRR (ms)	36,23	64,06	0,007	0,621
RMSSD	37,61	76,64	0,013	0,565
PtGA	6,55	4,47	0,001	0,780
PGA	5,42	3,02	< 0,001	1,064
DAS28	4,25	2,76	< 0,001	1,393
SDAI	26,95	13,70	< 0,001	1,216
Remission (n)	0	16	< 0,001	1,376

DAS28 disease activity score 28, HRV heart rate variability, ms milliseconds, PGA physician global assessment, PtGA patient global assessment, RMSSD Mean Square of successive differences, SDAI Simple Disease Activity Index, SDRR standard deviation of the average RR intervals, SMD standardized mean difference

Conclusion: The results of our prospective study underline the importance of the autonomic nerve system regarding disease activity and prognosis in RA. Higher parasympathetic activity was associated with lower disease activity. Patients with initially lower parasympathetic profile and higher disease activity benefited to a greater extend from initiation or change of therapy. In our study, the specific blood parameters NPY and VIP showed no relevant association with disease activity and treatment response.

THRESHOLDS OF PRESENTEEISM MEASUREMENT INSTRUMENTS FOR UNACCEPTABLE WORK PARTICIPATION AND FUTURE ADVERSE WORK OUTCOMES IN RA

Keywords: Rheumatoid arthritis, Patient reported outcomes, Work-related issues

D. Capelusnik[1,2], S. Ramiro[3], E. Nikiphorou[4,5], W. P. Maksymowych[6], M. Magrey[7], H. Marzo-Ortega[8], A. Boonen[1,9]. Background: Presenteeism is associated with lower work satisfaction and increased risk of future sick leave in rheumatic diseases. Presenteeism is generally measured on a continuous scale; however, despite a lower precision, identifying persons with a meaningful level of presenteeism can improve interpretation in clinical studies and might be useful in routine practice. Recently, thresholds of meaning for presenteeism instruments were established for axial spondyloarthritis (axSpA).
OBJECTIVES:
1)To identify thresholds for presenteeism instruments that reflect unacceptable work status in patients with RA and whether those thresholds could predict future adverse work outcomes (AWO);
2)To assess in patients with RA the performance of presenteeism thresholds previously established in axSpA for the same instruments.
Methods: We used data from the 1-year multinational prospective study on Patient-Reported Outcomes in Employment Study in Rheumatoid Arthritis (RA-PROSE). Thresholds to determine when patients consider themselves in 'unacceptable work status' were calculated at baseline for 4 presenteeism instruments (Work Productivity and Activity Impairment questionnaire -WPAI-, Quality and Quantity method -QQ-, Workplace Activity Limitations Scale -WALS- and Work Limitations Questionnaire -WLQ 25-) and for a patient global assessment of pain. We created receiver operating characteristic (ROC) using as external criterion a Patient Acceptable Work State question, addressing one's ability to perform their current job satisfactorily. We used different approaches (75th percentile, Youden index, Liu method, nearest to 0.1) to determine the optimal cut-off, while balancing over-under diagnosis. Accuracy of thresholds to predict "future adverse work outcome" throughout 12 months (defined as sick leave or long-term disability) was assessed. The recently developed presenteeism thresholds for axSpA were also tested.
Results: A total of 105 employed patients were included: 77% females, mean age 48 (SD 9), with a mean symptom duration of 9.8 (8.7) years. 15% of the patients considered themselves in an unacceptable work status and 7 (8%) had at least one AWO during 12 months. All instruments (presenteeism and pain) showed good performance vs the external criterion (AUC >0.75) except for the QQ method (AUC 0.62). The Table 1 shows the optimal thresholds for each instrument and their performance to correctly identify an unacceptable work status and AWO during 12 months for the RA-specific threshold (1st row) and the available axSpA threshold (2nd row). Interestingly, the axSpA thresholds performed better to classify work status as 'unacceptable' and to predict AWO. For adverse work outcome over 12 months, pain and WPAI performed better specially in predicting AWO.
Conclusion: Thresholds for presenteeism and pain representing unacceptable work status have been established for RA. Previously developed thresholds for axSpA showed an even better performance and are therefore the preferred to be used. WPAI performed the best and can be used to identify patients requiring more tailored care in order to avoid future AWO.

Table 1. Optimal thresholds for presenteeism measures and patients correctly classified for unacceptable work status and adverse work outcome during 12 months.

	Optimal threshold (SE/SP)	Correctly classified for unacceptable work status n (%)	Correctly classified for AWO during 12 months n (%)
WPAI presenteeism (0-100)	**≥30 (89/70)**	66 (73)	57 (69)
	≥40 (78/82)	77 (82)	62 (75)
QQ method (0-10)	**≥2 (67/55)**	53 (56)	49 (59)
	≥3 (56/64)	59 (63)	57 (69)
WALS (0-3)	**≥0.61 (89/59)**	51 (62)	44 (61)
	≥0.75 (67/68)	56 (68)	49 (68)
WLQ 25 (0-100)	**≥27 (89/77)**	53 (57)	45 (55)
	≥29 (77/80)	57 (61)	46 (56)
Pain (0-10)	**≥4 (67/68)**	64 (68)	61 (73)

The final thresholds are colored in green and correspond to the one's derived from axSpA. For pain measurement there was no axSpA derived threshold.

THE PROGNOSTIC VALUE OF IGA ANTI-CITRULLINATED PROTEIN ANTIBODY AND RHEUMATOID FACTOR IN AN EARLY ARTHRITIS COHORT WITH A TREAT-TO-TARGET APPROACH

Keywords: Prognostic factors, Rheumatoid arthritis, Autoantibodies

J. Heutz[1], M. W. Schreurs[2], A. Van der Helm – van Mil[3], P. De Jong[1]. [1]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*; [2]*Erasmus MC, Immunology, Rotterdam, Netherlands*; [3]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: The EULAR research agenda states that new biomarkers are needed to stratify patients and to predict therapeutic response or lack of response in rheumatoid arthritis. Currently, IgG anti-citrullinated protein antibody (ACPA) and IgM rheumatoid factor (RF) are used as poor prognostic factors for treatment decisions in RA. The mucosal origin hypothesis of RA renewed the interest in the role of IgA isotype autoantibodies for disease pathogenesis. However, the value of IgA ACPA and RF for prognostication of treatment response under a treat-to-target approach is not clear to date.

Objectives: To evaluate the prognostic value of IgA ACPA and RF by considering 'quick-attained and persistent remission', DMARD-free remission (DFR) and biological use in an early (rheumatoid) arthritis population.

Methods: All patients from the treatment in the Rotterdam Early Arthritis Cohort (tREACH) trial with available baseline sera were included. The tREACH trial is a multicentre, stratified, single-blinded trial with a treat-to-target approach. IgA ACPA and RF isotypes were measured by automated fluorescence enzyme-immuno assay (FEIA) in baseline sera. The prognostic value of positivity for IgA ACPA and RF was evaluated for three outcome measures: (1) quick-attained (at 6 months) and persistent (to 2 years) remission, analysed with logistic regression analysis; (2) achievement of DFR for at least 6 months over a 2 year follow-up period, analysed with survival analysis; and (3) incident biological use over 2 years, analysed with mixed effects logistic regression analysis. Results were stratified for IgG ACPA, since it is known that IgG ACPA is related to lower (DMARD-free) remission rates and more biological use.

Results: IgA isotypes of ACPA and RF were measured in baseline sera of 480 tREACH patients. 66% was female, mean age was 53 years, median symptom duration 21 weeks, and median swollen joint count 5. A positive IgA ACPA titre was present in 109 (23%) patients and most of them also had a IgG ACPA result above the cut-off value for positivity (n=102, overlap of 94%). Positive IgA RF on the other hand was present in 172 (36%) of patients, which overlapped with IgM RF for 90% (n=154). Double positivity for IgA and IgG ACPA (n=102) revealed lower DFR rates after 2 years compared to IgG ACPA positivity alone (6% and 11%, respectively, Figure 1A), although this finding was not significant (p=0.09). No differences were observed in 'quick-attained and persistent remission' and biological use for both IgA ACPA and RF, after stratification for IgG ACPA.

Conclusion: IgA isotypes of ACPA and RF almost completely overlap with the commonly measured isotypes (IgG ACPA and IgM RF, respectively). In addition, both an IgA ACPA and IgA RF response do not predict persistent remission, DFR and biological use in this treat-to-target population. Based on these results, there is no rationale for measuring these isotypes in newly diagnosed (rheumatoid) arthritis patients in daily clinical practice.

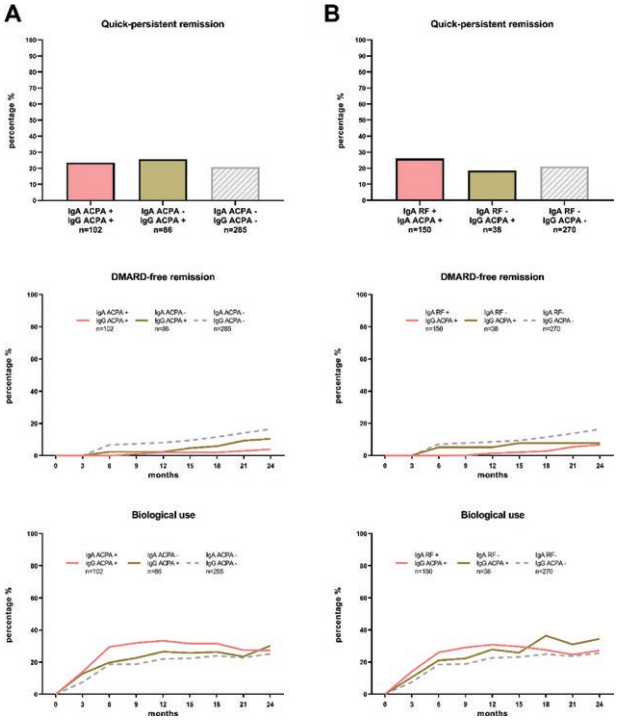

Figure 1. Quick-persistent (6-24 months) remission, DMARD-free remission and biological use over 2 years in (A) IgA/IgG ACPA positive patients vs. IgG ACPA positive patients, with IgA/IgG ACPA negative patients as a reference group; and in (B) IgA RF/IgG ACPA positive

patients vs. IgA RF negative/IgG ACPA positive patients, with IgA RF/IgG ACPA negative patients as a reference group.

IMPROVEMENT OF SLEEP IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS ACHIEVING REMISSION OR PAIN RELIEVE WITH UPADACITINIB: RESULTS FROM THE POST-MARKETING OBSERVATIONAL SLEERA STUDY

Keywords: Rheumatoid arthritis, Quality of life, Real-world evidence

T. Hügle[1], H. Prillwitz[2], B. Moeller[3], D. Kyburz[4], J. Dudler[5], K. Schmiedeberg[6], M. Harrer Kuster[7], P. Roulin[7], A. Rubbert-Roth[6]. *[1]Lausanne University Hospital, Department of Rheumatology, Lausanne, Switzerland*; *[2]Rheumatologisches Versorgungszentrum Weinfelden, Rheumatology, Weinfelden, Switzerland*; *[3]Inselspital, Department of Rheumatology, Immunology and Allergology, Bern, Switzerland*; *[4]University Hospital of Basel, Department of Rheumatology, Basel, Switzerland*; *[5]HFR Fribourg, Department of Rheumatology, Fribourg, Switzerland*; *[6]Cantonal Clinic St Gallen, Division of Rheumatology, St Gallen, Switzerland*; *[7]AbbVie AG, Immunology, Cham, Switzerland*

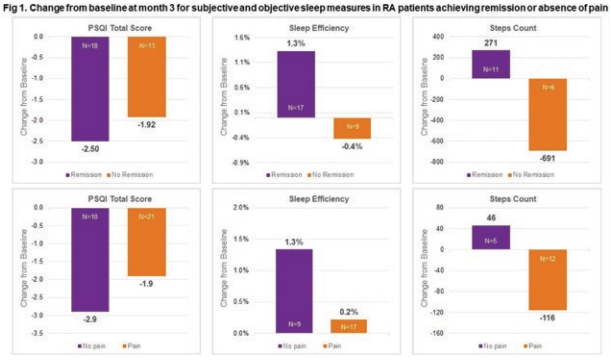
Background: Sleep impairment is a common clinical condition in the rheumatoid arthritis (RA) population, which has been reported in over 60% of patients[1]. Although few longitudinal studies demonstrated change from baseline on sleep quality with advanced therapies[2,3], none of them described the clinical meaningfulness of these changes by subjective and objective measures.

Objectives: The SLEERA study aims to investigate the impact of upadacitinib (UPA), a selective and reversible JAK inhibitor, on sleep quality in a real-world RA population in Switzerland, by using a validated patient-reported measure, the Pittsburgh Sleep Quality Index (PSQI)[4], and an actigraphy-based objective measure with the GT9x wearable.

Methods: SLEERA is a sub-study of UPHOLD, an international, multicenter, prospective, non-interventional, open-label, observational cohort study (NCT04497597) that assesses sleep quality in a real-world population of adult Swiss patients with moderate-to-severe active RA, initiating treatment with UPA 15 mg once daily according to the product label and with the treatment decision made prior to study participation. This primary interim analysis reports data for all enrolled patients up to 3 months after treatment start. Results are presented for the total sample using descriptive measures reflecting sample size (N), average values (standard deviation) for each visit and average change scores (standard deviation) for follow-up visit at month 3. All data were analyzed as observed, with no imputation of missing data.

Results: Of the 39 patients (87% female) included in this study, 35 completed the follow-up visit at month 3. The mean age and disease duration were 59.5 (13.9) years and 7.0 (8.3) years, respectively. The mean initial DAS28-CRP was 4.1 (1.0). At baseline, 76% of patients showed subjective sleep impairment (defined by PSQI >5) and 51% had objective poor sleep efficiency (defined by actigraphy sleep efficiency <85%) (Table 1). At month 3, upadacitinib showed significant improvement in the PSQI total score with a decrease of 2.26 (2.92, p value <0.001), as well as other subjective outcomes. The proportion of objective poor sleepers decreased to 38%, while sleep efficiency and physical activity outcomes in total remained unchanged. However, patients achieving DAS28-CRP remission or absence of pain after 3 months of treatment showed higher improvements in both subjective and objective measures compared to those who did not achieve DAS28-CRP remission or have residual pain (Figure 1).

Table 1.



PSQI	BL Visit N = 37	Visit at Month 3 N = 33	Change from BL N = 31
Sleep impairment (PSQI >5), n (%)	28 (76%)	18 (55%)	
PSQI total score	7.84 (3.12)	6.06 (4.26)	-2.26 (2.92)
PSQI sleep efficiency (%)	78.5% (18.5%)	84.2% (16.0%)	5.0% (17.7%)
PSQI sleep duration (hours)	6.8 (1.0)	6.9 (1.2)	0.2 (0.9)
Actigraphy	**N = 39**	**N = 26**	**N = 26**
Poor sleep efficiency (SE <85%), n (%)	20 (51%)	10 (38%)	
Sleep efficiency (%)	84.2% (6.8%)	84.5% (7.9%)	0.5% (3.9%)
Total sleep time (hours)	6.7 (0.9)	6.8 (1.0)	-0.1 (1.4)
Total awake time (minutes)	74 (37)	73 (49)	-7 (36)
Physical Activity	**N = 32**	**N = 17**	**N = 17**
Steps count	4,272 (2,270)	4,509 (2721)	-68 (1157)
MVPA (minutes)	177 (98)	181 (95)	-2 (37)

Conclusion: In this Swiss cohort, a high proportion of RA patients exhibited sleep impairment as shown by subjective and objective measures. Patients treated with upadacitinib significantly improved their subjective sleep quality after 3 months. Higher improvements for both subjective and objective sleep measures were observed in patients achieving remission or absence of pain. This research provides evidence of sleep impairment in RA patients which can be improved following a treatment, and further supports the importance of remission when assessing disease treatment goals.

"IT SURPRISED ME A LOT THAT THERE IS A LINK": A QUALITATIVE STUDY OF THE ACCEPTABILITY OF PREVENTIVE PERIODONTAL TREATMENT FOR INDIVIDUALS AT-RISK OF RHEUMATOID ARTHRITIS

Keywords: Qualitative research methods, Rheumatoid arthritis, Patient information and education

L. Chapman[1], K. Vinall-Collier[2], H. J. Siddle3, Z. Mustufvi[2], K. Mankia[3,4], S. Serban[2]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[2]University of Leeds, School of Dentistry, Leeds, United Kingdom*; *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[4]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Current evidence suggests that periodontitis could be a causal risk factor for rheumatoid arthritis (RA) onset and progression, and periodontal treatment may improve disease activity in patients with established RA [1, 2]. Earlier periodontal intervention in individuals at-risk of RA could provide a unique opportunity to delay progression or prevent RA entirely.

Objectives: To explore the acceptability of preventive periodontal treatment among individuals at-risk of RA and healthcare professionals from dental and medical backgrounds.

Methods: This was a qualitative study using a phenomenological approach. Anti-CCP positive at-risk individuals with musculoskeletal symptoms but no synovitis were recruited from the Leeds CCP cohort, and healthcare professionals were recruited through dental and rheumatology professional networks. Individual semi-structured interviews were conducted via video or telephone. Interviews were audio-recorded and transcribed verbatim. Data were analysed thematically.
Results: Nineteen at-risk participants (ten women; age range 35-70) and 11 healthcare professionals (rheumatology clinicians, dentists, general practitioners, commissioners) participated. Three themes (six subthemes) were identified as important to understand factors that may influence participants' acceptance of preventative periodontal treatment to reduce the risk of RA: i) understanding risk (knowledge of shared risk factors; information and communication); ii) oral health perceptions and experiences (personal challenges for dental intervention and oral health maintenance; external barriers); iii) oral health treatment and maintenance (making oral health changes to prevent RA; acceptability of participation in periodontal research to prevent RA). The majority of at-risk participants lacked awareness of the association between oral health and the risk of developing RA, and perceived a lack of knowledge of this link among dentists. Healthcare professionals highlighted disjoin between dentistry and medicine due to commissioning and financial barriers, and inadequate training. Preference for information provision relating to oral health as a risk factor varied extensively among all participants. At-risk participants discussed oral health issues, but oral health was less of a priority when compared to comorbidities that had a bigger impact on daily life, e.g. irritable bowel syndrome. Both groups of participants perceived that dental anxiety, the cost of dental treatment, and difficulty in accessing NHS dentists were barriers to seeking dental care. Participation in a clinical trial involving preventive periodontal treatment was perceived to be acceptable for most at-risk participants. Comparatively, taking medication to prevent RA was perceived to be less acceptable. Facilitators to trial participation included reducing risk, access to a dentist, and not having to pay for treatment. At-risk participants with dental anxiety indicated that seeing the same dentist at every visit was important.
Conclusion: The impact of poor oral health may not be well understood by individuals at-risk of RA. Information relating to this risk factor should be tailored to the individual and is a key first step before clinical trial involvement. Whilst periodontal disease is common in individuals at-risk of RA, both at-risk participants and healthcare professionals identified that seeking dental treatment can be hindered by dental anxiety, treatment costs and a shortage of dentists. Future trials involving preventive periodontal treatment should take into account what has been identified as important by this group of individuals at-risk of RA.

Background: In the last decade there have been multiple attempts to characterize patients with refractory rheumatoid arthritis (RA). In 2020, EULAR proposed a definition for difficult-to-treat RA (D2T-RA) to standardize this population. The mechanisms leading to D2T RA are varied and not fully understood. A better understanding of clinical profile of this specific population may be helpful to support rheumatologists in their clinical decisions.
Objectives: To determine the prevalence of D2T-RA in a multicenter national registry (BIOBADASER) and to investigate the influence of the initial successive lines of treatment (LoT) in the development of D2TRA.
Methods: Longitudinal and prospective cohort study of patients with RA from BIOBADASER (a multicenter national registry of adverse events of biologics and targeted therapies in rheumatic diseases). Patients were classified as refractory if failure to at least 2 biologics or targeted synthetic disease modifying antirheumatic drugs (b/tsDMARDs) with different mechanisms of action (MoA) and as D2TRA if refractory RA who presented moderate to high disease activity according to DAS 28-ESR at their last visit. The comparator group included patients with refractory RA but low disease activity/remission. The therapeutics groups were stablished as TNF inhibitors (TNFi), JAK-inhibitors (JAKi) and other biological therapies non-TNFi bDMARD. Demographic, clinical and therapeutical data on the 1st and 2nd LoT were compared between groups.
Results: A total of 3852 patients with RA with at least one year follow up were included in the analysis, 1612 (42%) had refractory RA and 348 (9%) D2TRA. Patient and therapeutic characteristics are shown in Table 1. No differences were found between D2TRA and non-D2TRA in clinical variables except for age, being patients with D2TRA significantly older. The use of JAKi as their first or second LoT was more frequent in patients with non-D2TRA, although no statistical significance was reached.
Conclusion: Around 40% of patients were classified as refractory RA in our registry but only 9% as D2T-RA. Earlier treatment with JAKi was more frequent in the non-D2TRA group. Further research should analyse the influence of LoT on the development of D2TRA.

Table 1. Demographic, clinical and therapeutic characteristics in the refractory RA, D2TRA and non-D2TRA population

	Refractory RA (n= 892)	D2TRA (n=348)	Non-D2TRA (n=544)	p-value

AB0203 REAL WORLD EXPERIENCE OF MODERATE DISEASE ACTIVITY STATE (MDAS) RA PATIENTS OVER 4-YEAR FOLLOW-UP

Keywords: Inflammatory arthritides, Pain, Fibromyalgia

M. Gibson[1], N. Ladha Hassan[1], L. B. Kirkham[1]. [1]*Guy's Hospital, Department of Rheumatology, London, United Kingdom*

Background: In recent years despite improved therapies for RA, there is an increased awareness of persistent pain in people with RA. Before the pandemic we assessed a large group of patients with RA with comprehensive joint ultrasound (US) and for presence of fibromyalgia (FM) meeting 2010 ACR diagnostic criteria. When combinations of synovitis and/or FM were made we noted 4 groups

Table 1.

of patients. As well as some with only FM, we also noted a group we believe had peripheral non-inflammatory pain, a new concept in RA. Here we investigate if these different groups change over time in our T2T routine care pathway.

Objectives: To assess the progress and outcomes patients with RA with different well defined pain states during 4 years of follow up including the COVID19 pandemic.

Methods: The TITRATE-ULTRASOUND patient cohort categorised patients with RA into 4 groups depending on the presence or absence FM and the presence or absence of power doppler synovitis (PD, defined as positive PD signal in ≥2 joints in a 44 joint US). We identified 72 patients with active RA (DAS28 3.2 – 5.1) from this cohort with sufficient clinical data during the study period and collected the following data on each follow up encounter: visit type, treatment changes and disease activity measures. In the COVID19 pandemic follow up visits were largely virtual without the ability to collect physician assessed disease activity scores. Progress assessment was performed as to whether the patient had improved, no change or worse with a numerical value of +1, 0 and -1 at each visit to calculate a score tracking patient progress during the pandemic. Statistical analysis was performed using 1-way ANOVA to assess for difference between the 4 groups.

Results: 72 patients with were assigned into the following categories: FM-PD-, 12 (peripheral pain group); FM-PD+,18; FM+PD-, 29; FM+PD+, 13. Table 1 shows baseline characteristics of the 4 groups and reveals no significant difference by ANOVA between the 4 groups in total visits, face to face visits, telephone visits, tender joint count, treatment escalations, steroid prescriptions, csDMARD prescriptions, and progress score. Biologic prescriptions did vary significantly between the groups (p = 0.009).

Conclusion: Over the follow-up period we show the management of RA patients without active power doppler synovitis or fibromyalgia did not differ significantly from other categories of patients. Similar numbers of visits, treatment escalations, csDMARDs and corticosteroid prescriptions were observed. This illustrates how it can be difficult to define the specific causes of disease activity without access to US. Despite similar management strategies, FM-PD- patients tended towards worse progress scores, suggesting a potential unmet need in such patients.

GENETICALLY PREDICTED EOSINOPHIL COUNT IS ASSOCIATED WITH INCREASED RHEUMATOID ARTHRITIS SUSCEPTIBILITY

Keywords: -omics, Rheumatoid arthritis

T. Chong[1], R. Gopalarathinam[2], D. Hughes[3], S. S. Zhao[4]. [1]*University of Manchester, School of Biological Sciences, Faculty of Biological Medicine and Health, Manchester, United Kingdom*; [2]*Southport and Formby District General hospital, Division of Rheumatology, Southport, United Kingdom*; [3]*University of Liverpool, Department of Health Data Science, Liverpool, United Kingdom*; [4]*University of Manchester, Centre for Epidemiology Versus Arthritis, Division of Musculoskeletal and Dermatological Science, School of Biological Sciences, Faculty of Biological Medicine and Health, Manchester, United Kingdom*

Background: Increasing evidence shows that eosinophils – white blood cells typically linked to atopic and parasitic diseases – are involved in regulating adaptive immune responses. Baseline eosinophilia has been associated with poor prognosis in early arthritis patients, while synovial regulatory eosinophils are associated with rheumatoid arthritis (RA) remission [1,2]. However, the role of eosinophils for RA susceptibility is unclear. Traditional observational designs are limited by reverse causation, that is, RA onset or prodrome may influence eosinophil count and/or function. Using genetic variants in instrumental variable analysis can reduces such biases.

Objectives: To investigate the association between genetically predicted circulating eosinophil count and RA risk using genetic instrumental variable analysis.

Methods: We selected uncorrelated (r^2<0.001) and significant (p-value <$5x10^{-8}$) single nucleotide polymorphisms (SNP) as genetic instruments for circulating eosinophil count from a genome wide association study of 563,085 individuals. Genetic association data for RA was obtained from 22,350 cases and 74,823 controls. We included psoriatic arthritis (PsA; 3,609 cases, 9,192 controls) and osteoarthritis (OA; 177,517 cases, 649,173 controls) as negative control outcomes, and asthma (56,167 cases, 352,255 controls) and atopic eczema (10,788 cases, 30,047 controls) as positive controls. We used the ratio method and meta-analysed estimates from each SNP using the inverse-variance weighted method. We used weighted median, mode and the Egger method to test for horizontal pleiotropy (i.e., violation of the model assumption that genetic instruments only affect the outcome through the exposure).

Results: Circulating eosinophil count was instrumented using 448 SNPs that explained 11% of variance, with a mean F statistic of 157 suggesting adequate instrument strength. For each standard deviation increase in eosinophil count, risk of RA was increased (OR 1.60; 95% CI 1.35, 1.89; p-value=$6.9x10^{-8}$). Genetically predicted eosinophil count was not associated with risk of PsA and OA negative controls, but were associated with increased risk of asthma and eczema positive controls (Figure 1). Pleiotropy robust sensitivity analyses showed consistent estimates.

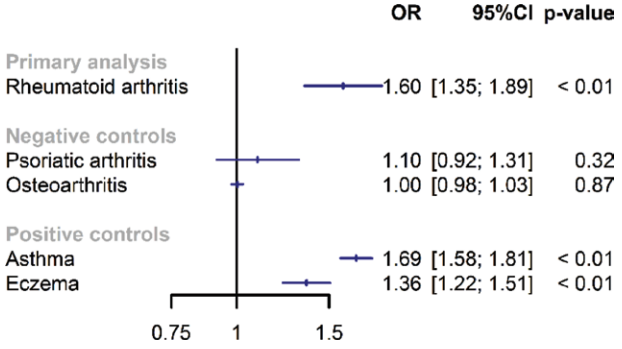

Figure 1. Association between genetically predicted circulating eosinophil count and risk of rheumatoid arthritis and control outcomes.

Conclusion: This study provides genetic data to support a causal relationship between circulating eosinophil count and RA susceptibility. Eosinophils may play a causal role in RA aetiology and, if these results are replicated in future studies, may represent a novel predictor of RA onset and potential modifiable factor for RA prevention.

RA TREATMENT EFFECTS IN WRIST MRIS, DETERMINED BY DEEP LEARNING

Keywords: Artificial intelligence, Rheumatoid arthritis, Imaging

T. Hassanzadeh[1], D. Shamonin[1], Y. Li[1], M. Reijnierse[2], A. Van der Helm – van Mil[3], B. Stoel[1]. *[1]Leiden University Medical Center, Division of Image Processing, Department of Radiology, Leiden, Netherlands*; *[2]Leiden University Medical Center, Department of Radiology, Leiden, Netherlands*; *[3]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*

Background: Determining the response to early treatment of Rheumatoid Arthritis (RA) or the at-risk stages for RA from MRI scans requires sensitive and specific measurements of imaging biomarkers of inflammation. Employing artificial intelligence (AI), especially deep learning, can be an option to measure RA treatment effects.
Objectives: We aimed to assess the ability of deep learning to determine treatment response by distinguishing MRIs of the wrist between treatment and placebo arms (as proxy for treatment effects) from the TREAT-EARLIER trial.
Methods: Wrist MRIs (contrast enhanced T1-weighted TSE fat suppressed sequences) were collected from 236 patients with clinically suspect arthralgia at four time points (baseline, with 4, 12 and 24 months follow-up) to determine the response to treatment by intramuscular methylprednisolone followed by methotrexate during one year [1]. 3D wrist MRI data were reconstructed in super-resolution from axial and coronal images. Since a statistically significant treatment effect was determined previously y RAMRIS [1], we used these 3D wrist MRI data from baseline and after 4 months to classify patients into treatment arms by a 3D convolutional neural network. Five different inputs were explored for training the model: 1) a difference image (baseline image simply subtracted from follow-up); 2) the combination of baseline and follow-up image; 3) the combination of baseline and difference image; 4) change maps (AI-based maps containing changes between two time points); and 5) the combination of baseline and change maps (see bottom panel in Figure 1). To evaluate the proposed model, 10-fold cross-validation was repeated five times with five different splits, and the area under the receiver operator curve (AUC) was reported.
Results: The mean (±SD) AUCs are presented in Table 1. As shown, the combination of different MRIs obtained promising results. Specifically, the combination of baseline images and AI-based extracted change maps could improve the accuracy. Compared to a setting where follow-up and baseline scans were simply 'subtracted', this improved the prediction of treatment from 0.72 to 0.76.

Table 1. Obtained AUC using Wrist MRI. (BL: baseline MRI; FU: Follow-up MRI; Diff: Difference image; and CM: Change Map)

Input	AUC (mean ± SD)
Diff (= BL-FU)	0.71 ± 0.027
BL and FU	0.70 ± 0.032
BL and Diff	0.72 ± 0.017
CM	0.73 ± 0.009
BL and CM	**0.76 ± 0.008**

Conclusion: The results show that deep learning models using baseline and follow-up MRI specifically AI-extracted change maps can accurately determine treatment response in CSA patients.

DIFFICULT TO TREAT RHEUMATOID ARTHRITIS (D2T-RA) IN THE REAL LIFE SETTING IS INDEPENDENT OF AUTOANTIBODY STATUS OR GENDER BUT IS ASSOCIATED WITH OBESITY, FIBROMYALGIA, AND EROSIONS AT DIAGNOSIS.

Keywords: Rheumatoid arthritis, Prognostic factors, Comorbidities

N. Luciano[1], E. Barone[2], E. Brunetta[1], M. De Santis[2], A. Ceribelli[2], M. Caprioli[1], G. M. Guidelli[1], A. Sonaglia[1], D. Renna[1], N. Isailovic[2], C. Selmi[2]. *[1]IRCCS Humanitas Research Hospital, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy*; *[2]IRCCS Humanitas Research Hospital and Humanitas University, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy*

Background: Despite the growing number of available drugs for Rheumatoid Arthritis (RA) and the significant improvement in disease management, numerous patients continue to fail multiple lines of DMARDs. The EULAR definition of Difficult to Treat Rheumatoid Arthritis (D2T-RA) is based on 3 criteria: the failure of 2 or more b/tsDMARDs with different mechanism of action, the persistence of signs of active/progressive disease despite treatments, and the clinician or patients' perception of a "problematic" management. There is limited evidence on the prevalence of D2T-RA in real life and the factors associated with this entity.
Objectives: To characterize D2R-RA cases in a real-life cohort of patients.
Methods: We retrospectively collected data of patients with RA fulfilling the ACR/EULAR 2010 classification criteria who attended our outpatient clinics between January 2019 and November 2022. The comparison between D2T-RA and other patients was performed using T-, Mann-Whitney and Chi-Square tests while logistic regression models analyzed the impact of principal clinical features and comorbidities on outcome variable, adjusted for confounders.
Results: Eighty-seven/400 (21%) patients enrolled met the DT2-RA criteria. No significant differences were found in median age (no-D2T 62±12 vs. D2T 64±15, p= 0.6), median disease duration (no-D2T 8±9 vs. D2T 12±10 years, p=0.9) and gender (female 77%, p=0.9). D2T-RA had similar autoantibody profile, prevalence of interstitial lung disease, C-reactive protein levels at diagnosis, number of tender and swollen joints at diagnosis) and major comorbidities (hypertension, dyslipidemia, COPD, depression, autoimmune thyroiditis). At univariate D2T-RA correlated, without reaching statistical significance, with diabetes (p=0.055), a previous history of major cardiovascular events (p=0.071), previous or current history of smoking (p=0.081) and GERD (p=0.079). Of note, D2T-RA significantly correlated with fibromyalgia (p=0.004), previous surgical intervention to treat RA (p=0.01), peripheral arteriopathy (p=0.035), obesity (p=0.023) and evidence of erosions at diagnosis (p=0.045). The multivariate analysis confirmed the correlations between D2T-RA and baseline erosions (p=0.034, OR 2.23 IC 1.06-4.69), obesity (p=0.041, OR 2.05 IC 1.03-4.09) and fibromyalgia (p=0.004, OR 3.28 IC 1.47-7.32) regardless of age and gender or, in the case of fibromyalgia, obesity.
Conclusion: Our data support the importance of comorbidities to determine D2T-RA which is not influenced by the autoantibody profile. In particular, fibromyalgia and obesity likely increase the probability of a DMARDs multi-failure. Data on baseline erosions and a previous history of surgery possibly suggest that a better timing of intervention with earlier treatments may reduce the risk of D2T-RA.

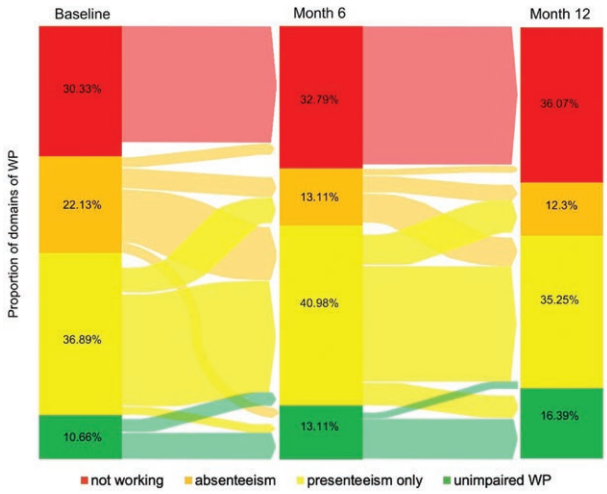
VOLATILITY OF WORK PARTICIPATION DOMAINS AFTER A FLARE OF RHEUMATOID ARTHRITIS UNDER TREAT-TO-TARGET THERAPY

Keywords: Rheumatoid arthritis, Work-related issues, Treat to target

S. E. Meyer[1], J. R. Hoeper[2], B. L. Haegermann[1], I. Iliadis[3], T. Witte[1], K. Kahl[3], K. Hoeper[1], D. Meyer-Olson[4]. [1]*Medizinische Hochschule Hannover, Clinic for Rheumatology and Immunology, Hannover, Germany*; [2]*Leibniz Universität Hannover, Center for Health Economics Research Hannover, Hannover, Germany*; [3]*Medizinische Hochschule Hannover, Department of Psychiatry, Social Psychiatry and Psychotherapy, Hannover, Germany*; [4]*m&i Fachklinik Bad Pyrmont, Medizinisches Forschungszentrum Weserbergland, Bad Pyrmont, Germany*



Background: Rheumatoid arthritis (RA) is one of the most common diseases worldwide with a need for rehabilitation despite recent advantages in pharmacological treatment options. Furthermore, data show a numerical increase in years of life with disability in RA patients in Germany from 1990 to 2017. Limitations in work participation (WP) also remain highly prevalent.
Objectives: We investigate the development of different domains of WP (unimpaired WP, presenteeism, absenteeism, and no employment) at the patient level under drug therapy over 12 months to understand the impact of pharmacological treatment.
Methods: The multicenter ERFASS study prospectively enrolled seropositive RA patients with an active flare of disease initiating treat-to-target (T2T) drug therapy over 12 months [1]. Patients were enrolled between 01/2018 and 12/2019. We examine the different domains of WP in working-age patients (18-65 years) excluding students and old-age pensioners using the WPAI of patients with a complete dataset at all three measurement time points (month 0, 6 and 12). Disease activity was measured using the DAS28.
Results: A total of 122 patients (73.0% female) with a mean age of 52.8 years (SD: 8.5) were included. Disease activity according to DAS28-CRP decreased significantly over the course of the study from 4.2 at baseline to 2.5 at month 12 (p<.001). The proportion of non-working patients increased numerically over the course of the study from 30.3% to 36.1% (p=0.085). The proportion of patients with absenteeism decreased significantly from 22.1% at baseline to 12.3% at month 12 (p=0.033). There were small changes in presenteeism (month 12: 35.2%; p=0.086). The proportion of patients with unrestricted WP increased significantly from 10.7% at baseline to 16.4% at month 12 (p<0.001) (Table 1). Graph 1 shows the quantitatively relevant changes in WP over the course of the study in a sankey diagram. The group of not working patients mainly gains growth from the group of patients with absenteeism. Patients with unimpaired WP proportionally become more because patients with presenteeism or absenteeism at baseline improve their WP to unimpaired WP. However, we detected a substantial proportion of patients with initially unimpaired WP facing impairments as most likely presenteeism during T2T. At all measure points we see the most substantial fluctuations in patients with presenteeism and absenteeism.
Conclusion: Besides good therapy response in terms of disease activity, we demonstrate that the majority of unemployed patients during an acute disease flare does not find their way back into the work force within twelve months of T2T pharmaceutical treatment. The greatest improvements in WP were observed in patients with absenteeism at baseline. Although the proportion of patients without limitations in WP increased significantly, it remained at a low level at the end of the study. Our data provide an understanding of the development of the different domains of WP in patients after a flare of RA which helps to tailor occupational rehabilitation concepts.

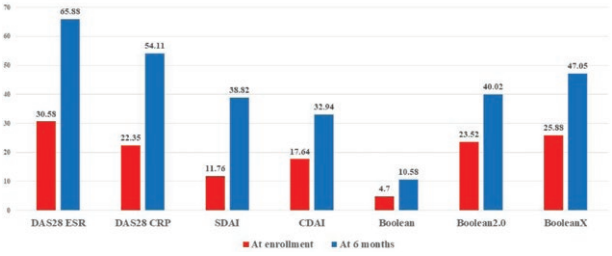
COMPARISON OF PERFORMANCE OF ACR EULAR 2022 REMISSION CRITERIA IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM INDIA

Keywords: Remission, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

S. B[1], A. Kumar P H[1], M. Gopalakrishnan[1], M. K. Garg[1]. [1]*All India Institute of Medical Sciences, Internal Medicine, Jodhpur, India*

Background: Remission is a state, not change or transition with absence of disease activity in rheumatoid arthritis (RA) [1]. Remission at 6 months has been shown to predict future good outcomes such as arresting radiographic progression and better functional status at 12 and 24 months [2]. ACR EULAR have endorsed Boolean2.0 in the revised remission criteria in 2022 [3]. None of these participants were recruited from India. In this ongoing study, we compare the various remission criteria in patients with RA in our setting.
Objectives: To compare the performance of various remission criteria (Disease Activity Score 28 (DAS28 ESR), Disease activity Score 28 CRP (DAS28 CRP), Simple Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI), Boolean, Boolean2.0, and BooleanX) in patients with RA presenting to our rheumatology clinic, at Jodhpur, India.
Methods: A longitudinal study was initiated in July 2021 after Ethics Committee approval. Demographic and treatment details were collected after written informed consent. Remission criteria were calculated at 6 months follow up. We analysed agreement between the Boolean- and index-based criteria SDAI, CDAI, DAS28 ESR and DAS28 CRP. The study is an ongoing study, with a calculated sample size of 165.
Results: Follow-up data of 85 participants of which 85.9% female with median age of 47 (12) years with RA diagnosed by ACR EULAR 2010 were collected. At enrolment, 10.6% (n = 9) were on biologicals, 35.3% (n = 30) on methotrexate alone and 54.1% (n = 46) on combination Disease-modifying Antirheumatic Drugs (DMARDs) therapy and at 6 months, 5.9% (n = 5) were on biologicals, 61.17% (n = 52) on methotrexate alone and 32.9% (n = 28) on combination DMARDs therapy. The proportion of patients in remission at 6 months using DAS28 ESR was 65.9% (n = 56), DAS28 CRP was 54.1% (n = 46), SDAI was 38.8% (n = 33), CDAI was 32.9% (n = 28), Boolean was 10.6% (n = 9), Boolean2.0 was 40% (n = 34) and BooleanX was 47.1% (n = 40) (Figure 1). DAS28 CRP showed substantial agreement with Boolean2.0 (kappa 0.63) at enrolment and moderate



agreement (kappa 0.49) at 6 months, however, SDAI had only slight agreement with modified Boolean based indices (Table 1).

Table 1. Agreement between modified Boolean indices and disease activity

Kappa	SDAI at enrolment (CI)	SDAI at 6 months (CI)	DAS28 CRP at enrolment (CI)	DAS28 CRP at 6 months (CI)
Boolean	0.23 (0.00-0.08)	0.09 (0.20-0.38)	0.10 (0.09-0.23)	0.15 (0.00-0.03)
Boolean2.0	0.13 (0.13-0.29)	0.08 (0.27-0.45)	0.63 (0.00-0.03)	0.49 (0.00-0.03)
BooleanX	0.03 (0.97-1.00)	0.06 (0.39-0.59)	0.71(0.00-0.03)	0.39 (0.00-0.03)

Conclusion: This study provides evidence of external validation of the newly proposed modification of the Boolean ACR/EULAR remission criteria; however, we found that the Boolean2.0 criteria did not exhibit agreement with index-based remission definitions in the Indian population from our centre. Our results replicate the findings that a Boolean definition using 2 cm as threshold for patient global assessment of disease activity (Boolean2.0) yields better agreement than Boolean [2]. With the validation Boolean2.0 in our settings, our data support the revised ACR/EULAR remission criteria as a target in clinical practice.

Fig 1: Comparison of different ACR/EULAR remission criteria and Boolean indices at enrollment and at 6 months after treatment initiation

VALIDATION OF REVISED 2022 ACR/EULAR REMISSION CRITERIA FOR RHEUMATOID ARTHRITIS IN ASIAN INDIAN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Outcome measures, Rheumatoid arthritis

C. B. Prasad[1], V. Dhir[1], G. Naidu[1], S. K. Sharma[1], A. Sharma[1], S. Jain[1]. [1]*Post Graduate Institute of Medical Education and Research, Clinical Immunology and Rheumatology Unit, Department of Internal Medicine, Chandigarh, India*

Background: Remission has become a key target in the management of rheumatoid arthritis (RA) patients[1]. In 2022, American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) has revised the Boolean based remission criteria in RA by increasing the patient global assessment of disease activity (PtGA) threshold to ≤2cm (range 0–10 cm). This has not been validated in an Asian Indian cohort of RA patients[2,3].

Objectives: To validate ACR/EULAR remission criteria for RA: 2022 revision in Asian Indian RA patients by using data of an ongoing clinical trial.

Methods: For the purpose of validating the remission criteria, data generated at our center from an ongoing clinical trial (SMART study) which enrolled patients with active seropositive RA, who were 18-60 years old with disease duration ≤5 years was used. This is a 24-week multicenter, open-label RCT to compare efficacy of split versus non-split doses of methotrexate (MTX). For this analysis, data from both groups was analyzed together. Patients are started on oral MTX 15 mg/week which was escalated every two weeks by 5 mg, to reach a maximum dose of 25 mg/week by 4 weeks. At the end of 16 weeks, if Disease Activity Score 28 (DAS28) >3.2 another DMARD can be added. Disease activity was measured using the DAS28, Simplified Disease Activity Index (SDAI) and Clinical Disease Activity Index (CDAI) at 24 weeks. Proportion of patients achieving remission with index-based (SDAI≤3.3 & CDAI≤2.8) and ACR/EULAR Boolean-based criteria was compared. The proposed PtGA threshold of 2 cm (Boolean2.0) (range 0–10 cm) was compared with the original threshold of 1 cm (Boolean1.0) as well as with 1.5 cm, 2.5 cm and no PtGA (Boolean X) for remission. Agreement (Cohen's kappa) was assessed between Boolean-based and index-based criteria. #Trial registration number: **CTRI/2021/02/031361**.

Results: This study included 125 patients, majority being females (105 (84%)), with mean (±SD) age of 42.8 (±10.8) years and mean (±SD) disease duration of 2 (±1.5) years. At 24-weeks, using the index based (SDAI and CDAI) criteria, remission was achieved in 24.8% and 24% of patients respectively. Among the various Boolean criteria, remission occurred in only 21.6% using the original Boolean1.0. This increased with Boolean2.0 to 23.2%, and further increased with Boolean2.5 and Boolean X [Figure 1]. The highest agreement between SDAI or CDAI-defined remission was found to occur with Boolean2.0-defined remission rather than Boolean1.0 (or 1.5, 2.5 or X) defined remission [Table 1]. Also, there was strong agreement (0.89 (95% CI 0.79-0.99)) between SDAI and CDAI-defined remission criteria.

Conclusion: We validated the performance of revised 2022 ACR/EULAR remission criteria for RA in Asian Indian RA patients and found the higher agreement of Boolean2.0 (rather than Boolean1.0) with index-based remission cutoffs.

AB0210 CAN RHEUMATOID ARTHRITIS IMPACT OF DISEASE (RAID) SCORE BE USED AS A PATIENT REPORTED OUTCOME BASED TARGET IN A TREAT-TO-TARGET APPROACH: A PROSPECTIVE STUDY FROM INDIA

Keywords: Patient reported outcomes, Rheumatoid arthritis, Treat to target

P. S Kumar[1], A. Kumar P H[1], M. K. Garg[1], M. Gopalakrishnan[1]. [1]*All India Institute of Medical Sciences, Internal Medicine, Jodhpur, India*

Background: Rheumatoid arthritis impact of disease (RAID) is a well validated patient reported outcome (PRO) in patients with Rheumatoid Arthritis (RA) [1]. RAID score involves the active participation of patients and can be easily calculated at the comfort of home with minimal training and assistance or while the patient is waiting to see the doctor in the outpatient department. It is helpful in giving an idea of the overall well-being of the patient and takes into account sleep and depression which are the unmet needs in RA treatment. However, the effectiveness of RAID as a patient reported outcome and the optimal RAID score which can be used as a target for treat-to-target approach has not been studied in the Indian population.
Objectives: To determine if the RAID score can be used as a PRO target along with a clinician reported disease activity score for managing patients with RA under a treat-to-target approach. To establish an acceptable cut-off for the RAID score which can be used as a target in patients with RA and validate it against disease activity indices.
Methods: We prospectively enrolled patients with RA diagnosed using ACR/EULAR 2010 criteria in our tertiary care institute, at Jodhpur, India from March 2021 to May 2022 and followed them over 6 months after their written informed consent and Ethics Committee approval (AIIMS/IEC/2021/3370). DAS28, patient assessment of global disease activity (PtGA), Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI), RAID score and modified Boolean indices (2) were calculated at enrolment and 6 months. Binary logistic regression analysis was used to determine if RAID could reliably predict DAS28 <3.2 and Boolean remission indices at enrolment and 6 months. DAS28 <3.2, CDAI ≤10 and SDAI ≤11 were considered as the target as per EULAR recommendations, with remission and low disease activity as acceptable goals to achieve while treating patients with RA.
Results: We included 156 patients with a mean age of 47.0±12.3 years, 86.5% were females. Among them, 23.4% patients had DAS28 <3.2, 11.7% had SDAI ≤11, 13.6% had CDAI ≤10 while only 0.6% were in Boolean and Boolean2.0 remission. At 6 months, 110 patients were followed up and among them, 78.6% had achieved DAS28 <3.2, 66.0% had achieved SDAI ≤11, 68.9% had achieved CDAI ≤10 while only 1.9% had achieved remission according to Boolean remission criteria. However, Boolean2.0 criteria showed that 20.9% were in remission. RAID score could reliably and independently predict DAS28, SDAI, CDAI, PtGA and Boolean2.0 criteria. We constructed multiple Receiver Operating Characteristic (ROC) curves to determine the optimal cut-off of RAID for defining low disease activity and remission using SDAI, CDAI, DAS28 and Boolean2.0 remission criteria (Figure 1). We noted that the RAID score of 2.32 had 85.7% sensitivity and 76.1% specificity in predicting SDAI ≤11 and 87.5% sensitivity and 74.3% specificity in predicting CDAI ≤10. Further, RAID score of 2.32 had a sensitivity of 86.4% and specificity of 72.5% in predicting DAS28 <3.2 and a sensitivity of 55.9% and specificity of 81.2% in predicting remission as per Boolean2.0 criteria.
Conclusion: RAID score can be used as a reliable and validated PRO in patients with RA. We also propose a cut-off of a composite RAID score of 2.32 as an additional target to achieve while treating patients with RA in the Indian population.

Fig 1: ROC curves of RAID with SDAI, CDAI, DAS28, and Boolean2.0 to predict remission and low disease activity

AB0211 ASSESSMENT OF STIGMATIZATION IN RHEUMATOID ARTHRITIS USING THE STIGMA SCALE FOR CHRONIC ILLNESSES-SHORT FORM (SSCI-8)

Keywords: Rheumatoid arthritis, Cognitive function, Mental health

L. Rouached[1], E. Hannech2, S. Bouden[1], A. Ben Tekaya[1], R. Tekaya[1], I. Mahmoud[1], O. Saidane[1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia*; [1]*Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease that occurs among productive patients. It often causes functional disability that can be permanent, with both physical and mental impact.
Objectives: We aimed to assess the degree of stigmatization and associated factors in patients with RA.
Methods: This was a cross-sectional study including patients with RA. Sociodemographic, clinical, paraclinical, and therapeutic data were collected. Stigma was assessed using the Stigma Scale for Chronic Illnesses-Short Form (SSCI-8) [1]. This scale is composed of 8 items. Responses for each item are made as follows: 1 = never, 2 = rarely, 3 = sometimes, 4 = often, and 5 = always. The range of raw scores assigned for the SSCI-8 was 8 to 40. The closer the score was to the upper value, the greater the degree of stigma.
Results: These were 100 RA patients: 81 women (81%) and 19 men (19%). The mean age was 55.33±10.08 years [25-76]. The mean disease duration was 14.21±10.10 years [1-46]. RA was immunopositive in 50% of patients. It was erosive in 75% of cases. Coxitis was present in 6 patients. The mean disease activity measured by DAS28-CRP was 3.81±1.56 [0.12-6.90]. The mean value of functional impairment assessed by HAQ was 0.91±0.64 [0-2.4]. Regarding the SSCI-8 score, the mean value was 17.85±6.02 [8-32]. The stigma score was not correlated with patient age (r=-0.184, p=0.075), nor with age at diagnosis (r=-0.001, p=0.993). It was not statistically different by gender (p=0.648). This score was positively correlated with DAS28 (CRP) (r=0.244, p=0.034). It was not correlated with HAQ (r=0.037, p=0.754). The presence of coxitis and the erosive nature of RA had no influence on stigma (p=0.923, p= 0.895 respectively).
Conclusion: According to our study, stigma was associated with disease activity during RA. The degree of stigma was not very high in our population, which can be explained by a moderately active disease.

AB0212 FUNCTION AND PAIN IN KNEE JOINTS IN PATIENTS WITH RHEUMATOID ARTHRITIS AFTER TOTAL KNEE ARTHROPLASTY

Keywords: Osteoarthritis, Rheumatoid arthritis

M. Karimov[1], S. Lapshina[2], T. Nuriakhmetova[2], I. Gilmutdinov[3], A. Nuriakhmetov[3], S. Ardashev[3], I. Akhtiamov[4]. [1]*Tashkent Medical Academy, Traumatology, Orthopedics and Military Surgery, Tashkent, Uzbekistan*; [2]*Kazan*

Background: Total knee arthroplasty (TKA) in patients with rheumatoid arthritis (RA) is considered the most effective intervention reducing knee pain and improving physical function. However, higher risk of late complication and worse surgery outcomes may be observed in patients with active disease.[1]
Objectives: To study the knee joint function and pain before and after the TKA in patient with rheumatoid arthritis.
Methods: 69 RA patients (10 (14,5%) males and 59 (85,5%) females) with an average age of 59 [52; 64] years were included into the study group. 81 osteoarthritis (OA) patients (38 males (46,9%) and 43(53,1%) females) aged 66 [61; 73] years, were included into the control group. 23,2% of RA patients had a highly active disease at the moment of intervention. All patients underwent cemented TKA and completed Oxford Knee score (OKS) before the surgery, after discharge and 3 and 12 months after the surgery. Knee pain was assessed using VAS score also before intervention, straight after and 3 and 12 months after the surgery. All analyses were performed using SPSS version 23.0 (IBM Corp., Armonk, NY, USA). A p value of less than 0.05 was considered statistically significant.
Results: Patients in RA group had significantly lower preoperative OKS results, than OA patients (25.0 [23.5; 27.0] versus 29.0 [26.5: 30.0], p=0.00, Mann-Whitney) as well as lower postoperative OKS results before the discharge (34.0 [34; 38] versus 40.0 [35; 40] p=0.00, Mann-Whitney). 3 months after the intervention OKS scores were comparable within the two groups (43.0 [42; 44] versus 43.0 [42; 44], p=0.557; Mann-Whitney). The same was found for OKS scores 12 months after the surgery (44.0 [44; 47] versus 44.0 [44; 47], p=0.328, Mann-Whitney). Pain intensity in RA patients varied from 60 to 90 mm according to VAS prior to surgery and was lower than among OA patients (80.0 [80; 90] versus 90.0 [80; 100], p=0.00, Mann-Whitney) which can be explained by patients' higher pain tolerance due to "usual" pain in RA. The same tendency was observed immediately after the intervention (55.0 [50; 60] versus 65.0 [50; 65], p=0.00, Mann-Whitney). 3 months after the surgery pain intensity was similar in both groups (30.0 [30; 35], p=0.349, Mann-Whitney). 1 year after the intervention RA patients reported higher VAS scores probably due to RA activity (20.0 [20; 20] versus 10.0 [10; 15], p=0.00, Mann-Whitney).
Conclusion: The effectiveness of TKA for pain reduction and improvement of knee function in patients with RA was comparable to that among patients with OA. OKS scores were lower in RA group prior to surgery, however, 3 and 12 months after the intervention they did not differ between the patients with RA and OA.

AB0213 EQ5D SCORES ARE NOT AFFECTED BY AGING

Keywords: Outcome measures, Rheumatoid arthritis, Patient reported outcomes

I. Yoshii[1]. [1]*Yoshii Clinic, Mueculoskeletal Medicine, Shimanto City, Japan*

Background: Estimating cost-effectiveness in the treatment of rheumatoid arthritis (RA) has received increasing attention in recent years as a large number of new drugs have been developed and generated through huge development costs and soaring drug costs.
Objectives: EuroQol-5th dimension score (EQ5D) is a most popular index for measuring the quality of life in patients with rheumatoid arthritis (RA). In this study, an association between EQ5D and aging using retrospective cohort data.
Methods: RA patients who had been followed up for more than 3 years were picked up. Patients' simplified disease activity index score (SDAI), HAQ, pain score using a visual analog scale (PS), Sharp/van der Heijde score (SHS), and EQ5D were monitored since the start of treatment (baseline: BL). Patients were divided into 3 groups; G-YY who began treatment before age 65 and continued until age 65; G-YY who began treatment before age 65 and continued until age 65 or older; G-OO who began treatment at age 65 or older. The crude model and SHS or HAQ matched models were used to compare the mean EQ5D during treatment of G-YY and G-OO statistically using Mann-Whitney U test. We also statistically compared the EQ5D of each subject under age and over age 65 in the G-YO group using repeated T-test measurements.
Results: There were 143 G-YY, 88 G-YO and 307 G-OO, for a total of 538. The means for each group were 49.9, 61.2 and 76.9 for ages G-YY, G-YO and G-OO, 12.5, 12.1 and 13.0 for SDAI, 0.281, 0.353 and 0.627 for HAQ, 29.7, 55.4 and 56.3 for SHS, 35.5, 31.1 and 36.6 for PS and 0.807, 0.761 and 0.724 for EQ5D, respectively. The mean EQ5D score of G-YY was significantly higher than that of G-OO using crude data, but there was no significant difference between the two groups after adjusting for SHS or HAQ. Comparing the mean EQ5D scores of G-YO before age 65 and after age 65 also showed no difference between the two periods. Using data from all patients, HAQ scores were significantly correlated with age.
Conclusion: HAQ scores were significantly correlated with aging, and EQ5D scores were significantly correlated with HAQ scores, but EQ5D scores were not correlated with aging. This explains why EQ5D scores are independent of aging. This may be useful in calculating cost-benefit assessments for older RA patients.

AB0214 VALIDATION OF JOINT INDEX VECTOR FOR PATIENT WITH RHEUMATOID ARTHRITIS

Keywords: Validation, Outcome measures, Rheumatoid arthritis

I. Yoshii[1], S. Nishiyama[2]. [1]*Yoshii Clinic, Mucsuloskeletal Medicine, Shimanto City, Japan*; [2]*Kurashiki Medical Center, Rheumatology, Kurashiki, Japan*

Background: There are only few indices that can estimate joint involvement in both of upper and lower extremities in patients with rheumatoid arthritis (RA).
Objectives: One indicator can measure involvement on both upper and lower joint and large and small joint. The index developed by Nishiyama is called "Joint Index Vector," which can represent the affected state of upper and lower joints as well as large and small joints by using three-dimensional coordinates. The aim of this study is to validate the efficacy and availability in clinical practice using monitoring data from RA patients.
Methods: Patients who started treatment for RA after January 2016 and whose Simplified Disease Activity Index (SDAI), Health Assessment Questionnaire Disability Index (HAQ-DI), Pain Score with Visual Analog Scale (PS-VAS), and EuroQol 5th dimension (EQ5D) were monitored at each visit and Sharp/van der Heijde score (SHS) was monitored annually were included in the study. The JIV represents the joint prevalence of the upper limb in X coordinates (Vx), the joint prevalence of the lower limb in Y coordinates (Vy), and the difference in joint prevalence between large and small joints in Z coordinates (Vz) [1]. The relationship between each clinical parameter and three elements of the JIV was evaluated statistically. Each parameter was defined as the dependent factor, and the three elements of the JIV were defined as the independent factor, and correlation was examined using linear regression analysis. These procedures were performed at the first visit (BL), 1 year after the first visit (1Y), and at te last visit (LT). Additionally, the change in the HAQ score and SHS at 1Y (dHAQ and dSHS) were defined as the dependent variant, and the other parameters including the three coordinates of JIV were defined as the independent variant. Then, correlation between these parameters were statistically examined also using linear regression analysis.
Results: A total of 419 patients in whom 113 were male and 306 were female, were recruited in the study. Mean age at baseline was 68.1 and mean follow-up period was 65.3 months. Vx, Vy, and Vz significantly correlated with SDAI at all periods of BL,1Y, and LT. Vy significantly correlated with HAQ-DI at all periods, whereas Vx and Vy significantly correlated with PS-VAS at all periods. Vy significantly correlated with SHS at 1Y and LT. Vz significantly correlated with EQ5D at 1Y and LT. Mean dHAQ significantly correlated with age, SHS, PS-VAS, and Vz. Mean dSHS significantly correlated with Vx, Vy and annual change of Vx.
Conclusion: These results demonstrated that Vx, Vy, and Vz suggested significant correlation with other clinical parameters, especially Vy which represents affected joints in the lower extremities significantly correlates with important patient related outcomes.

AB0215 MAGNITUDE OF THE INFLUENCE BY JOINT INVOLVEMENT ON HEALTH ASSESSMENT QUESTIONNAIRE DISABILITY INDEX SCORE

Keywords: Rheumatoid arthritis, Outcome measures, Validation

I. Yoshii[1], S. Nishiyama[2]. [1]*Yoshii Clinic, Musculoskeletal Medicine, Shimanto City, Japan*; [2]*Kurashiki Medical Center, Rheumatology, Kurashiki, Japan*

Background: The Health Assessment Questionnaire Disability Index (HAQ-DI) is the best-known index for measuring functional capacity in patients with rheumatoid arthritis (RA). This index is well known to be influenced by disease activity, aging, joint deformities and pain. However, these parameters are related to each other and it remains unclear how joint involvement affects HAQ-DI in RA patients.

Objectives: The aim of this study is to determine how joint involvement affects HAQ-DI in RA patients using a retrospective cohort study.

Methods: Patients with RA who have been monitored since the first visit for tenderness and swelling of the whole body and limb joints, patient's global assessment (PGA), evaluator's global assessment (EGA), pain score using a visual analog scale (PS), and HAQ-DI at every visit were included in the study. The patient's mean age, HAQ score, PGA, EGA, C-reactive protein (CRP), and Sharp/van der Heijde score (SHS) were collected. Joint Index Vector (JIV) was used as an index of joint lesions. JIV represents the joint prevalence of the upper limb in X coordinates (Vx), the joint prevalence of the lower limb in Y coordinates (Vy), and the difference in joint prevalence between large and small joints in Z coordinates (Vz) [1]. The average value of the triaxial coordinates of the JIV was also collected. As a preliminary study, the correlation between the mean HAQ score of all cases collected and other parameters such as patient gender and serum albumin level (ALB) was evaluated using multivariate linear regression analysis. Statistical significance was set as less than $1.0*10^{-10}$. Next, the association of the HAQ score with other parameters at baseline, the association of the HAQ score after 1 year at baseline with other parameters at baseline and the change from baseline to 1 year, and the annual change in the HAQ score and other parameters at baseline and the annual change in these parameters were statistically evaluated using multivariate linear regression analysis. Statistical significance was set as less than 5.0%.

Results: A total of 601 patients in these 166 males and 435 females data were used in the study. The HAQ score positively correlated with male gender, older age, higher SHS, higher PGA, lower EGA, higher PS, higher Vy, and higher Vz with beta values of 0.09, 0.22, 0.17, 0.19, -0.12, 0.17, 0.07, and 0.11, respectively. The HAQ score at baseline positively correlated with older age, higher PGA, higher CRP, higher PS, higher SHS, and higher Vy at baseline with beta values of 0.26, 0.13, 0.21, 0.14, 0.14, and 0.10, respectively. The HAQ score at one year after the baseline positively correlated with older age, higher PS, and higher SHS at the baseline, and higher annual change of the PS with beta values of 0.26, 0.25, 0.22, and 0.15, respectively. The annual change of the HAQ score positively correlated with higher SHS and higher Vy at the baseline, and higher annual change of PS, Vx, Vy, and Vz with beta values of 0.04, 0.11, 0.04, 0.67, 0.43, and 0.09, respectively.

Conclusion: These results indicate that there is a close association between HAQ scores and aging, degree of pain, and joint deformities, and in addition, joint involvement also influences HAQ scores. In particular, changes in HAQ scores are governed by joint involvement. The effect of disease activity on HAQ scores will be largely governed by joint involvement.

AB0216 INHIBITION OF RADIOGRAPHIC JOINT DAMAGE BY JAK INHIBITORS IN PATIENTS WITH DESTRUCTIVE RHEUMATOID ARTHRITIS WITH EXTENSIVE BONE MARROW EDEMA IN HAND

Keywords: Prognostic factors, Imaging, Rheumatoid arthritis

K. Katayama[1], K. Tanaka[2], T. Kawahata[2], M. Yuichi[3], T. Okubo[4], T. Sato[1], S. Abe[5], H. Ito[5]. [1]*Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan*; [2]*Asahikawa Medical University, Division of Metabolism and Biosystemic Science, Gastroenterology, Hematology/Oncology, Department of Medicine, Asahikawa, Japan*; [3]*Asahikawa Medical University Hospital, Department of Medicine, Division of Rheumatology, Asahikawa, Japan*; [4]*Katayama Orthopedic Rheumatology Clinic, Radiology, Asahikawa, Japan*; [5]*Asahikawa Medical University, Department of Orthopedic Surgery, Asahikawa, Japan*

Background: Rapid radiographic progression (RRP) is considered to be one of the factors in difficult to treat rheumatoid arthritis (RA). MRI bone marrow edema has been reported to be a risk factor for RRP. We reported that extensive bone marrow edema (BE) determined by hand MRI is a prognostic indicator for rapid radiographic progression in MTX inadequate response to early RA treated with MTX+ Adalimumab combination therapy (1) and we reported biologics were more effective for radiological damage compared with MTX +csDMARDs enhanced therapy for RA inadequate response to MTX accompanying with extensive BE in hand[2].

Objectives: To investigate the radiographic joint damage by usage of JAK inhibitors (JAKi) in RA patients inadequate response to MTX/ Biologics/ other JAKi with or without BE in clinical practice.

Methods: Twenty-four RA patients (pts) with extensive BE by hand MRI (BE group) and 30 pts without BE (non-BE group) despite treatment with MTX/biologics/JAKi were retrospectively recruited from JAK inhibitor treated pts (total:130 pts; two JAK1,3 selective inhibitor-Toficitinib(TOF):34 pts; Peficitinib(PEF):33 pts and two JAK1 selective inhibitor- Upadacitinib(UPA):35 pts; Filgotinib(FIL):28 pts). Baseline demography of patients in BE and non-BE group were shown in Table 1. Significant difference of baseline factors between BE(+) group and BE(-) group were only observed in mTSS/y (6.76 vs 3.21,P = 0.0000582, t test). Bone destruction expressed as yearly progression of mTSS (ΔmTSS/y) was determined before and after treatment by modified total Sharp scoring (mTSS) using conventional radiography. BE score measured by RAMRIS method using T1 or STIR image of hand MRI (CANON, 1.5T). Based on our previous data, extensive BE in hand was defined designated as BE score≥15[1].

Results: DAS28-ESR values from baseline to 1 year was significantly reduced from 4.82 to 3.39(P<0.01) in the BE group and from 4.83 to 3.45(P<0.01) in the non-BE groups. After 1 year treatment by JAKi, RRP(ΔmTSS/y≥5) was more observed in 5 pts in the BE group, however RRP were not observed in the non-BE group (Figure 1). Significant differences betwwen JAK1 inhibitors and JAK1/3 inhibitors were not observed. Yearly radiographic progression observed from 6.39 to 1.59 (P=0.000003)in the BE group and from 3.21 to 0.16 (P= 0.000545) in the non-BE group.

Conclusion: Results of this study in the baseline and 1 year treatment indicated that BE may be a predictor of RRP not only in the MTX, biologics treatment, but in the JAKi treatment. A further prospective, randomized study may be required to clarify this.

Rheumatoid arthritis - prognosis, predictors and outcome

AB0217 MANAGEMENT OF RHEUMATOID ARTHRITIS THERAPIES IN TELECONSULTATION

Keywords: Rheumatoid arthritis, Telemedicine

J. Avouac[1], A. Moltó[1], C. Frantz[1], O. Fogel[1], Y. Allanore[1]. [1]*Cochin Hospital, Rheumatology, Paris, France*

Background: Therapeutic adjustment is of major importance in the treat to target strategy proposed for rheumatoid arthritis (RA). This aspect can be challenged in teleconsultation given the multiplicity of treatments, efficacy/ safety issues of RA therapies and the absence of clinical examination. These could lead the physician to prefer modifying the treatment in face-to-face visit rather than in teleconsultation.
Objectives: To evaluate how clinicians adapted RA therapies in teleconsultation.
Methods: Retrospective monocentric routine care cross-sectional study conducted in the Rheumatology department of Cochin Hospital. We reviewed electronic medical report (EMR) to identify all teleconsultations performed by telephone or video consultation in a 2-year period and extract data of interest. We compared treatment adaptation performed in teleconsultation to treatment adaptation that requested a face-to-face visit following teleconsultation. Treatment adaptation was defined by the introduction of a new treatment, modification of treatment dose and/or route or discontinuation of the treatment. This treatment adaptation may be motivated by efficacy or safety issues. Different treatment classes were considered: corticosteroids, methotrexate and targeted biologic/ synthetic therapies (b/tsDMARDs).
Results: We included 187 patients (150 females, 80%) who had a teleconsultation performed, with a mean age of 56±16 years and a disease duration of 13±11 years. Positive rheumatoid factor and positive anti-CCP pantibodies were detected in 125 (67%) and 139 (74%) patients respectively. 96 patients (51%) had erosive disease. A total of 56 therapeutic adaptations were collected: 34 were performed in teleconsultation and 22 requested face-to-face visits (**Table 1**). Demographics and RA disease characteristics did not differ between patients who had therapeutic adaptations performed during teleconsultation or during face-to-face visits. Corticosteroid and methotrexate were more likely to be adapted in teleconsultation compared to face-to-face visits (16/34, 47% vs 2/22, 9%, p=0.003 and 15/34, 44% vs 1/22, 5% p=0.002, repectively). Interestingly, methotrexate was adapted in teleconsultation for both efficacy and safety issues, leading do dose increase/reduction, switch from oral to subcutanous route, or drug discontinuation. In the other hand, targeted therapies were preferentially initiated or modified during face-to-face visits which all included clinical examination, lab tests and power doppler ultrasounds (19/22, 86% vs. 3/34, 9%, p<0.001).
Conclusion: Corticosteroids and methotrexate were mainly adaptated in teleconsultation without requesting a face-to-face visit, supporting their flexibility in teleconsultation and clinician's confidence in their use, even at a distance from the patient. In the other hand, b/tsDMARDs were preferentialy adapted in face to face consultation, highlighting the need of a careful evaluation of disease activity by clinical examination before modifying this class.

Table 1. Therapeutic adaptations performed in teleconsultation or in face-to-face visits

	Adapted therapy	Adaptation	Cause
Teleconsultation (n=34)	Corticosteroids (n=16)	Introduction (n=3)	Disease flare
		Dose increase (n=7)	Disease flare
		Dose reduction (n=6)	Low disease activity or remission
	Methotrexate (n=15)	Introduction (n=3)	Active disease
		Dose increase (n=2)	Active disease
		Swith from oral to SC (n=3)	Active disease (n=2), nausea (n=1)
		Dose reduction (n=2)	Increased liver enzymes
		Discontinuation (n=5)	(n=1) and asthenia (n=1) Asthenia (n=3), nausea (n=2)
	b/tsDMARDs (n=3)	Introduction of JAKi (n=1)	Active disease
		JAKi dose reduction (n=2)	Age (n=1) and CV risk factors (n=1)
Face-to-face visits (n=22)	Corticosteroids (n=2)	Corticosteroid infusion (n=2)	Active disease
	Methotrexate (n=1)	Swith from oral to SC (n=1)	Active disease
	b/tsDMARDs (n=19)	Introduction (n=3)	Active disease
		Swith to a new b/tsDMARD (n=16)	Active disease

AB0218 RHEUMATOID ARTHRITIS OUTCOMES: A MULTICENTRE CROSS-SECTIONAL STUDY OF PATIENTS IN IRELAND (CONTEXT-RA)

Keywords: Remission, Patient reported outcomes, Quality of life

G. Murphy[1], D. Kane[2], K. O'rourke[3], C. Sheehy[4], F. B. O'shea[5], R. Conway[5], D. Veale[6], A. Camon[7], D. Moran[8]. [1]*Cork University Hospital, Rheumatology, Cork, Ireland*; [2]*Tallaght University Hospital, Rheumatology, Dublin, Ireland*; [3]*Midland Regional Hospital Tullamore, Rehumatology, Dublin, Ireland*; [4]*University Hospital Waterford, Rheumatology, Waterford, Ireland*; [5]*St James's Hospital, Rheumatology, Dublin, Ireland*; [6]*St. Vincent's University Hospital, Rheumatology, Dublin, Ireland*; [7]*Midland Regional Hospital Tullamore, Rheumatology, Tullamore, Ireland*; [8]*AbbVie, Medical Affairs, Dublin, Ireland*

Background: Despite increasing treatment options for RA, many patients still do not appear to achieve remission, especially in more established disease.[1]
Objectives: To evaluate disease outcomes and quality of life (QoL) of DMARD treated patients with RA in clinical remission (CR) in routine Irish rheumatology clinics vs those with residual disease activity.
Methods: A multicentre, cross-sectional study with a 9-month recruitment period (Mar-Nov 2021). Demographics, disease activity, patient reported outcomes, comorbidities, workability & healthcare resource utilisation (HRU) data were collected. Patients on a stable dose of any DMARD (> 3 months) were classified according to disease activity state as follows:

- Responder group 1 (RG1) CR (CDAI≤2.8)
- Responder group 2 (RG2) CR/ Low Disease Activity (LDA) (CDAI>2.8 -10) &
- Non-responders (NR) moderate/high disease activity (CDAI>10)

Results: 130 RA patients were recruited (Table 1). 69% were female, mean age of 60.1 yrs and disease duration of 11.5 yrs. There was no significant difference in seropositivity between responder and non-responder groups (~75% RF+, ~69% ACPA+), 69% were treated with advanced therapy (biologic/targeted synthetic DMARDs), primarily TNFi's.

- 26% of patients were in CR, 32% in LDA & 42% NR. Significant differences in QoL-primary endpoint were noted between CR/LDA patients vs NR group. The difference in QoL index score (EQ5D-5L) for patients in CR and LDA vs those in remission alone, suggest QoL is considerably higher in patients in CR compared even to those in LDA.
- Joint pain (VAS), fatigue (FACIT-F) and function (HAQ-DI) scores all yielded strong negative correlations, indicating that CR/LDA patients had significantly better outcomes than those with MDA/HDA (Figure 1). A similar pattern was seen amongst patients in CR vs LDA, although significance was not achieved.
- In addition, more impaired productivity was noted in NR vs CR/LDA regarding ability to work and perform regular 'non-work' activities.
- Comorbidities were common, affecting over 90% of the non-responder group and 74% of patients in CR. The NR group had higher proportions of patients with cardiac, gastrointestinal, psychiatric and vascular disorders vs patients in CR/LDA.
- With respect to HRU, more patients in the NR group required medical visits for both RA and non-RA reasons vs patients in CR/LDA.
- Of the 54 patients in MDA/HDA, the study found there was a plan to add or switch DMARD, for only 32% of patients.

Table 1. Patient Characteristics

	RG1 1 N=34	RG 2 N=76	NR N=54
Age Mean (SD), yrs	57.1 (12.91)	57.6 (13.13)	63.7 (13.00)
Female, mean N (%)	23 (67.6)	51 (67.1)	38 (70.4)
Duration of disease, yrs, mean (SD)	12.1 (10.5)	11.2 (11.4)	11.3 (11.02)
Comorbidities, n (%)	25 (73.5)	36 (85.7)	49 (90.7)
Employed^, n (%)	19 (55.8)	37 (48.6)	11 (20.3)
Employment sick leaves due to RA^*, mean (SD)	0.3 (0.58)	0.3 (0.57)	0.6 (1.21)
Smoking status: Never smoked, n (%)	17 (50.0)	35 (46.1)	18 (33.3)
Alcohol Units, mean (SD)	4.0 (5.98)	3.3 (6.31)	3.8 (6.05)
Disease Activity (CDAI score)	1.21 (0.883)	4.06 (3.088)	19.46 (11.162)

^ Patients in either full or part time employment *Sick leave in the past 6 months

Figure 1. Patient reported outcomes across pain, fatigue and function

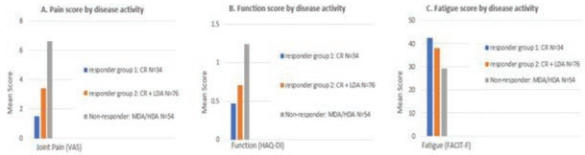

Figure 1a-c. Patient reported outcomes per disease activity state. **A.** Patients assessment of worst joint pain measured by VAS. 0 means no joint pain and 10 means worst possible joint pain. **B.** Function scores as measured by HAQ-DI. HAQ-DI is the sum of scores in the 8 categories divided by 8. Scores are adjusted for the use of aids/devices and/or help. The higher the score, the worse the patients functioning. **C.** Fatigue scores (FACIT-F). FACIT F score is the sum of individual item scores multiplied by 13 & divided by number of items answered. The higher the score the lower the level of reported fatigue.
Responder group 1 CDAIs≤2.8. Responder group 2 CDAI <10. Non responder group CDAI>10.

CDAI: clinical disease activity; CR: clinical remission, HDA: high disease activity, LDA low disease activity; MDA moderate disease activity

Conclusion: Overall, these data support the treat-to-target approach of striving for remission in RA, with important differences reported between non-responder & responder groups 1 & 2 but additionally between patients achieving CR vs LDA. The relatively low % of non-responder patients with a documented 'action plan', suggests improved approaches to shared decision making are warranted for patients not yet at the agreed target.

LONG-TERM OUTCOMES OF METHOTREXATE IN ELDERLY-ONSET RA IMPLEMENTING THE TREAT-TO-TARGET STRATEGY

Keywords: Outcome measures, Rheumatoid arthritis, Disease-modifying drugs (DMARDs)

H. Baba[1,2], T. Sugihara[2,3,4,5], T. Ishizaki[5], M. Nomura[1], T. Hosoya[1,2], M. Kamiya[1,2], T. Matsumoto[1,2], K. Kubo[2], F. Hirano[1,2], N. Miyasaka[1], M. Kojima[6], S. Yasuda[1], M. Harigai[7]. *[1]Tokyo Medical and Dental University (TMDU), Department of Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo, Japan*; *[2]Tokyo Metropolitan Institute for Geriatrics and Gerontology, Department of Medicine and Rheumatology, Tokyo, Japan*; *[3]Tokyo Medical and Dental University (TMDU), Department of Lifetime Clinical Immunology, Graduate School of Medical and Dental Sciences, Tokyo, Japan*; *[4]St. Marianna University School of Medicine, Department of Internal Medicine, Division of Rheumatology and Allergy, Kawasaki, Japan*; *[5]Tokyo Metropolitan Institute of Gerontology, Human Care Research Team, Tokyo, Japan*; *[6]National Center for Geriatrics and Gerontology, Department of Frailty Research, Center for Gerontology and Social Science, Aichi, Japan*; *[7]Tokyo Women's Medical University School of Medicine, Department of Rheumatology, Tokyo, Japan*

Background: Continuation of methotrexate (MTX) treatment is recommended in both MTX responder and non-responder elderly-onset RA (EORA) patients. However, there are insufficient data on its effectiveness and long-term safety, although we have previously reported that a treat-to-target (T2T) strategy targeting low disease activity (LDA) is safe and effective in the prospective CRANE cohort study of MTX-naïve EORA patients [1, 2].

Objectives: To identify factors predicting failure to achieve LDA by month 6 in EORA patients starting MTX, and effectiveness and safety of MTX over 5 years in MTX responders and non-responders.

Methods: MTX-naïve patients (mean age 73.8 years, n=163) from the CRANE cohort [2] had started MTX with moderate-to-high disease activity. Maximum dose of MTX was 0.19±0.06 mg/week/kg with folate supplementation. Treatment was adjusted to target LDA. Treatment intensification using biological disease-modifying antirheumatic drugs (bDMARDs) for EULAR-unresponsive patients by month 3 and moderate-high disease activity at month 6 was applied. MTX non-responsiveness was defined as no LDA and/or initiation of bDMARDs by month 6. Primary outcomes were achievement of Simplified disease activity index (SDAI) LDA and discontinuation of MTX due to adverse events (AEs). Secondly outcomes were achievement of remission and Health Assessment Questionnaire Disability Index (HAQ-DI) ≤0.5, and incidence of serious AEs.

Results: At week 24, 77 (47.2%) patients achieved LDA without bDMARDs (MTX responders), and of the remaining 86 (MTX non-responders), 35 (21.5%) had started bDMARDs by month 6 and 51 (31.3%) had moderate-to-high disease activity on MTX at week 24. At baseline, MTX non-responders had longer disease duration, higher SDAI and HAQ-DI, higher prevalence of erosion score ≥2 (modified total sharp score) and chronic lung disease (CLD), but baseline glucocorticoid use was similar. Multivariable analysis identified CLD as a predictor of MTX non-responsiveness. Regarding long-term outcomes, 14 (18.2%) of the 77 MTX responders and 55 (64%) of the 86 MTX non-responders received intensified treatment with bDMARDs within 5 years. MTX was continued in 65 (94.2%) of the 69 patients at the start of bDMARDs. The Cumulative rate of MTX discontinuation due to AEs was similar in MTX responders and non-responders (34.0% and 33.1%) as was the time to discontinuation of MTX due to AEs. The time to discontinuation of MTX for any reason was also similar. SDAI LDA and HAQ-DI ≤0.5 achievement by year 5 applying the last observation carried forward (LOCF) method was 92.2% and 74.0% respectively for MTX responders and 77.9% and 53.5% for MTX non-responders, respectively (p=0.011 for SDAI LDA and 0.007 for HAQ-DI). SDAI remission at year 5 by LOCF was similar (62.6% and 52.3% in MTX responders-vs-non responders). The time to serious AEs was also similar, as was the cumulative incidence of serious AEs over the 5 years was 32.6% and 44.3% in MTX responders-vs-non-responders.

Conclusion: CLD was a predictive factor of non-achievement of LDA by month 6 in EORA patients starting MTX, and early application of bDMARDs may be adequate for treating EORA with CLD at baseline. The 5-year long-term outcome for MTX responders was excellent, and continuation of MTX was tolerable even in MTX non-responders. Treatment intensification on MTX could be an optimal T2T strategy for EORA.

AB0220 THE ASSOCIATION BETWEEN LAUGHTER AND FRAILTY IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM THE FAIRY STUDY

Keywords: Rheumatoid arthritis, Patient reported outcomes

M. Suzuki[1], T. Kojima[2], Y. Ohashi[1], R. Sato[1], D. Kihira[1], M. Maeda[1], K. Kishimoto[1], K. Terabe[1], S. Asai[1], S. Imagama[1]. *[1]Nagoya University Graduate School of Medicine, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan*; *[2]Nagoya Medical Center, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan*

Background: In the treatment of rheumatoid arthritis (RA), advances in drug therapy have led to better control of disease activity. However, RA is a systemic chronic inflammatory disease that causes frailty, a fragile state of mind and body. It is important for RA patients, who are prone to physical anxiety due to poor disease control and frailty, to be able to smile and live their lives. While there is anxiety about the disease, daily laughter may be helpful in resolving anxiety and preventing frailty. Although there have been reports on laughter and health, there are no reports on RA and laughter, so we decided to conduct a new study on laughter.

Objectives: The purpose of this study was to investigate the association between disease activity, laughter, and frailty in RA patients.

Methods: Data were obtained from participants in the Fairy study (The prospective cohort study of frailty in patients with rheumatoid arthritis to extend healthy life expectancy), a prospective cohort study of frailty in RA patients at Nagoya University Hospital. A frailty questionnaire was administered to 243 RA patients from February 2021 to January 2022. Patients' subjective assessments of Kihon checklist for frailty (KCL), the 25-question Geriatric Locomotive Function Scale (GLFS-25), Health Assessment Questionnaire Disability Index (HAQ-DI), Beck Depression Inventory-II (BDI-II), and frequency of laughter were investigated using a self-administered questionnaire. The frequency of laughter was divided into four levels: " "Almost every day", "1-5 days per week", "1-3 days per month" and "Never or almost never" [2], and the association with each item was analyzed by analysis of variance. The frequency of laughter was divided into two groups: "Almost every day, 1-5 days per week" and "1-3 days per month, never or almost never", and multivariate logistic analysis was conducted to examine factors affecting laughter.

Results: Mean age (± standard deviation) was 64.5±10.4 years at baseline, 85.6% were female, duration of disease was 13.1±9.9 years, disease activity score (DAS28)-CRP was 1.92±0.84, KCL was 4.7±3.7, GLFS-25 was 15.1±13.6, HAQ-DI was 0.37±0.51, and BDI-II was 10.7±8.0. Regarding drug therapy, 67.9% of the patients used Methotrexate and 23.0% used glucocorticoid. The frequency of laughter was "Almost every day" (43%), "1-5 days per week" (40%), "1-3 days per month" (11%), and "Never or almost never" (6%). The DAS28-CRP was 1.89/1.87/2.15/1.81 (P=0.487), KCL score was 3.5/4.6/7.3/8.1 (P<0.001), GLFS-25 was 13/15/22/21 (P=0.003), HAQ-DI 0.30/0.38/0.55/0.48 (P=0.105), and BDI-II 8.4/10.9/15.1/16.5 (P<0.001) for "Almost every day", "1-5 days per week", "1-3 days per month", and "Never or almost never", respectively. Multivariate analysis showed that KCL score (Odds Ratio [OR]: 0.81, 95% confidence interval [CI]: 0.73-0.90), GLFS-25 (OR: 0.97, 95% CI: 0.94-0.99) and BDI-II (OR: 0.91, 95% CI: 0.86-0.95) were independently associated with laughter frequency (Table 1).

Conclusion: We found that frailty was associated with laughter in RA patients with controlled disease activity. Evaluation of laughter as a patient-reported outcome (PRO) may be novel as a positive indicator for patients themselves. Interventions not only for disease activity but also for frailty may lead to a life with laughter.

AB0221 A STUDY OF REVERSIBILITY OF FRAILTY IN RHEUMATOID ARTHRITIS FROM THE T-FLAG STUDY

Keywords: Patient reported outcomes, Rheumatoid arthritis

M. Suzuki[1,2], Y. Sobue[3], Y. Ohashi[1,4], R. Sato[1], D. Kihira[1], M. Maeda[1], K. Kishimoto[1], K. Terabe[1], S. Asai[1], S. Imagama[1]. *[1]Nagoya University Graduate School of Medicine, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan*; *[2]Jcho Kani Tono Hospital, Department of Orthopedic Surgery, Kani, Japan*; *[3]Japanese Red Cross Nagoya Daiichi Hospital, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan*; *[4]Yokkaichi Municipal Hospital, Department of Orthopedic Surgery, Yokkaichi, Japan*

Background: Rheumatoid arthritis (RA) is a systemic chronic inflammatory disease that causes joint symptoms due to inflammation in bones and joints, leading to physical dysfunction such as loss of activities of daily living. With advances in the treatment of RA, it has become possible to achieve the goal of treatment to a state in which joint destruction causes little deformity and no physical disability. However, RA is a disease that causes not only physical dysfunction but also generalized fatigue due to chronic inflammation. Therefore, there is a decrease in patient satisfaction due to pain and physical fatigue, which may lead to a decline in daily life. Frailty, a state of physical and mental frailty due to decreased physical and mental function and social connectedness, is a condition that can easily lead to functional disability in daily living and the outcome of requiring long-term care [1]. RA is known to cause pain and limited range of motion of joints as the disease activity worsens, which may contribute to frailty. Since frailty is reversible and patients can return to a healthy state with appropriate interventions [2], it is expected that appropriate interventions will help maintain and improve the functions of daily living.

Objectives: The purpose of this study was to investigate factors associated with improvement from frailty in RA patients.

Methods: Of 460 RA patients (a observational study, T-FLAG study) who completed a questionnaire on frailty including the Kihon Checklist (KCL) from June 2020 to August 2022, 321 patients who were Frailty/Pre-frailty at baseline were included. After 2 years, patients who had improved from frailty to pre-frailty/robust or pre-frailty to robust were included in the improvement group, and the other patients were included in the non-improvement group. Multivariate analysis was used to examine the factors associated with improvement at 2 years. The cutoff values of the factors related to improvement were calculated by ROC analysis.

Results: Mean age (± standard deviation) was 67±13 years at baseline, 76% were female, duration of disease was 12±10 years, and BMI was 22.1±4.0. There were 83 patients (25.9%) in the improvement group. There were significant differences in age at baseline (63 vs. 68 years), DAS28-ESR (2.57 vs. 3.06), HAQ-DI (0.19 vs. 0.65), and KCL score (7.0 vs. 8.7) in the improvement group vs. the non-improvement group. There was no significant difference in gender (76% vs. 77%), disease duration (10 vs. 12 years) and BMI (21.8 vs. 22.3 years). Multivariate analysis revealed that age (OR: 0.97, 95% CI: 0.95-0.99) and HAQ-DI (OR: 0.19, 95% CI: 0.08-0.42) were independent factors associated with improvement (Table 1). The age and HAQ-DI cutoff values related to improvement were 72 years (sensitivity 73.5%, specificity 44.1%) and 0.25 points (sensitivity 78.3%,

specificity 58.9%). The cutoff value of HAQ-DI was used to examine the rate of improvement group in the two groups. In the HAQ-DI≤0.25 group, 40.1% of patients were in the improvement group, while only 11.5% were in the improvement group in the HAQ-DI>0.25 group, indicating a significant difference between the two groups (P<0.001).

Conclusion: Age and HAQ-DI were found to be indices for improvement in RA patients. Since frailty is a state in which physical and mental vitality declines with age, it is important to know age, which is a reversible state of frailty. In addition, among the multifactorial components of frailty, a low HAQ-DI, an assessment of physical function, may indicate the possibility of improving from a frailty state with appropriate intervention.

AB0222 PICTORIAL REPRESENTATION OF ILLNESS AND SELF-MEASURE (PRISM): A VISUAL TOOL TO ASSESS THE BURDEN OF RHEUMATOID ARTHRITIS

Keywords: Patient reported outcomes, Rheumatoid arthritis, Quality of life

A. Lotesoriere[1], M. Rizzo[1], B. Maranini[1], C. Garaffoni[1], F. Cirilli[1], M. Govoni[1].
[1]*University of Ferrara, Rheumatology, Ferrara, Italy*

Background: Rheumatoid arthritis (RA) has a negative impact on patients' quality of life, with both physical and psychosocial impact. Treatment recommendations advocate a treat-to-target (T2T) approach with the ideal goal of remission. Composite clinimetric scores are available to assess and monitor disease activity; however, although now widely recognized as an important aspect, the patients' perceived burden of disease still remains not regularly checked during medical consultation in daily practice. Pictorial Representation of Illness and Self Measure (PRISM) was developed to measure this global suffering but, to our knowledge, not yet used in RA patients.

Objectives: To understand the relationships and correspondences between common clinimetric indexes and patients' perception of RA impact on daily life measured by PRISM.

Methods: The present single-center explorative study included 86 RA patients, consecutively evaluated between July and December 2022 at our Rheumatoid Arthritis Clinic. During routinely scheduled follow up visits, disease activity, organ damage, treatment changes, and a number of clinimetric indices were regularly recorded. Patients were also asked to complete the basic PRISM. The physician showed patients a blank sheet with a yellow circle in a corner and they were asked to imagine the sheet as their "life" at the moment, while the yellow circle as "themselves." Next, patients were asked to imagine another smaller as RA and were asked the question: "Where would you place the RA-red circle in your life now?" The distance between both circles (SIS) reflects the patient's burden of suffering. A higher SIS indicates a lower burden. A blue circle has been used as an example before testing. Statistical tests produced regression R2 values and Pearson correlation coefficients.

Results: PRISM proved to correlate very well particularly with the Rheumatoid Arthritis Impact of Disease (RAID) score (p = -0,6), patient's global assessment (PtGA) (p = -0,59), patient's pain (p = -0,52) and global health (p = -0,52) but no correlation was observed with swollen joint count or tender joint count. PRISM also correlates to composite clinimetric indexes exploring disease activity but to a lesser extent, while it revealed no correlation with inflammatory indexes such as C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR).

Conclusion: Our investigation showed significant correlation with subjective patient reported outcome (PRO) tool, not counting inflammatory indexes nor joint count. To a lesser extent, it correlates also with physician's global assessment (PhGA). PRISM strongly correlates with RAID questionnaire, which is one of the most valid tool to measure the impact of RA in different domains (pain, function, fatigue, sleep disturbance, emotional well-being, physical well-being and coping). PRISM may therefore represent a reliable new, easy, more intuitive and friendly approach to quantify each individual perceived burden of disease. It may serve as complementary to common disease activity measures in setting agreed personalized therapeutic targets. Patients who were asked for a degree of approval with the test showed satisfaction with the possibility of visually showing the degree of suffering caused by their disease. To the best of our knowledge, this is the larger cohort of RA patients described in literature tested with PRISM. A prospective validation study in RA is now ongoing.

AB0223 ADHERENCE TO TREAT-TO-TARGET APPROACH IN A RHEUMATOID ARTHRITIS COHORT: RETROSPECTIVE ANALYSIS FROM 3 YEARS OF REAL-LIFE EXPERIENCE IN A REFRACTORY CLINIC

Keywords: Treat to target, Rheumatoid arthritis, bDMARD

B. Maranini[1], E. Silvagni[1], V. Venturelli[1], A. Piovani[2], E. Zagnoni[1], M. Govoni[1].
[1]*University of Ferrara, Department of Medical Sciences, Ferrara, Italy*;
[2]*University of Bologna, Department of Physics "Augusto Righi", Bologna, Italy*

Background: The European Alliance of Associations for Rheumatology (EULAR) advocates a "treat-to-target" (T2T) strategy for rheumatoid arthritis (RA) management, consisting in adjusting therapy if target is not achieved at 6 months. However, patients with moderate disease activity (MDA) currently constitute the most

common RA patient subset in clinical practice, possibly leading to refractory RA, defined as resistance to multiple drugs with different mechanisms of action and persistence of physical symptoms and/or high disease activity (HDA). Real-life studies examining the impact of switching/swapping versus not switching/swapping therapies in RA active patients are still limited.

Objectives: To evaluate predictors of therapy switch/swap in a population of patients with refractory RA who already failed ≥ 1 biological/targeted synthetic disease-modifying antirheumatic drug (b/tsDMARD), not reaching predefined target at 6-months after starting subsequent lines of DMARDs.

Methods: This single-center study retrospectively included 117 patients evaluated at our Clinic from 2019 to 2022. During subsequent 3- and 6-months T2T visits, disease activity through 28-joint disease activity score (DAS28), organ damage, treatment changes and composite disease activity indices were recorded. Chi square and Fisher's exact test was used for comparison of dichotomous variables and oneway analysis of variance (ANOVA) for continuous variables. Threshold of statistical significance was defined as a p-value < 0.05.

Results: 66 patients (56.4%) did not achieve remission or low-disease activity target 6 months after starting b/tsDMARD; among them, 47/66 (71.2%) were in MDA, 11/66 (16.6%) in HDA and 8/66 (12.1%) were lost at follow up. 24/66 patients (36.4%) switched/swapped therapy at 6-months follow up. Longer disease duration correlated with treatment continuation (p=0.04). HDA at 6-months was a strong predictor of treatment change (p=0.009), as well as drug suspension for all reasons (e.g., safety issues, lack of therapeutic efficacy reported in medical records; p < 0.001). Major results from ANOVA are summarized in Figure 1: Evaluator's Global Assessment (EGA) at 6-months significantly correlated with treatment switch (p=0.007), while patients taking drugs from more time tend to be switched less frequently (p=0.01). Remarkably, we did not find any correlation between the variations of DAS28, Global Health (GH), swollen joint count (SJC), tender joint count (TJC), Health Assessment Questionnaire (HAQ), Visual Analogue Scale (VAS) for Pain, steroid dependence. Similarly, baseline erosions, seropositivity, or number of prior DMARDs did not influence the outcome.

Conclusion: In our retrospective cohort study, drug switching seems not linked to a more severe disease. Examining disease activity indexes, neither baseline data nor PROs, but only 6-months EGA, appears statistically significant. While a number of explanations might be offered, including limitations of the current RA measurement tools, such as DAS28, and the limited sample size, our findings are concerning, suggesting that probably, in real-practice, a sort of physician "general impression" rather than objective findings of disease activity still guide therapeutic switching.

CORONARY CALCIUM, CAROTID SUBCLINICAL ATHEROSCLEROSIS AND CAROTID STIFFNESS AS PREDICTORS OF ALL-CAUSE MORTALITY AND CARDIOVASCULAR EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A 10-YEAR PROSPECTIVE FOLLOW-UP STUDY.

Keywords: Cardiovascular disease, Rheumatoid arthritis, Prognostic factors

C. Corrales-Selaya[1], N. Vegas-Revenga[2], J. A. Parra Blanco[3], V. Portilla[4], R. Blanco[1], M. A. González-Gay[5], I. Ferraz-Amaro[6], A. Corrales[1]. Background: The risk of mortality is increased in patients with RA compared to the general population. Different non-invasive surrogate markers of atherosclerosis have been implemented to identify RA patients who are at high risk of cardiovascular (CV) disease.

Objectives: In the present study, we aimed to establish the predictive capacity of the following surrogate markers: Coronary calcium (CAC), carotid ultrasonography (US), and pulse wave velocity (PWV) to predict CV events and all-cause mortality in a cohort of RA patients prospectively followed.

Methods: We conducted a prospective longitudinal study that included 126 patients with RA. The patients were recruited in 2011 and followed-up for 10 years. All patients had undergone baseline CAC score, evaluation of subclinical carotid atherosclerosis by US, and PWV. Multivariate Cox regression analysis was performed to identify the predictive ability of these surrogate markers for CV events and all-cause mortality.

Results: After a follow-up of 14.479 person (p)/months (m), 15 deaths (incidence rate -IR- 0.001 p/m) and 24 CV events (IR 0.001 p/m) in 18 RA patients were recorded. The causes of mortality in decreasing order of frequency were infections 7 (47%, IR 0.012 p/m), malignancies 5 (33%, IR 0.011 p/m) and others 3 (20%). To our surprise, none of the recorded deaths was from CV causes. The main results of the study are summarized in **Table 1**. After multivariate analysis, CAC score was associated with a significantly increased risk of CV events. When the CAC score was stratified into different categories, CAC>400 showed an increased risk of CV events on univariate analysis. However, this association was lost after adjustment. Carotid plaque and intima media thickness and PWV did not show a significant association with CV events. Regarding any-cause of death, CAC score, carotid plaque and PWV showed an association with higher risk of mortality. However, they were lost after adjustment for traditional CV risk factors.

Conclusion: Infections and malignancies were the most common cause of mortality in RA after a 10-year prospective follow-up study. CAC score, but neither carotid plaque nor PW, was significantly associated with increased risk of CV events at 10 years.

AB0225 WHAT FACTORS INFLUENCE RA PRESENTATION AT DIAGNOSIS?

Keywords: Rheumatoid arthritis, Prognostic factors, Epidemiology

D. Di Giuseppe[1], J. Askling[1], H. Westerlind[1]. [1]*Karolinska Institute, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden*

Background: Researchers have mostly focused in understanding which factors influence the risk of rheumatoid arthritis (RA) and its progression. However, little is known on the determinants of disease presentation at diagnosis. This is a fundamental prerequisite for studies focusing in understanding disease progression.
Objectives: To estimate the association between demographic and disease related factors and high disease activity (HDA) of RA at diagnosis by a rheumatologist.
Methods: Data from newly diagnosed RA patients between October 2004 and May 2018 from the Epidemiological Investigation of RA study (EIRA) will be included in these analyses. The outcome of interest is high disease activity, defined as having either DAS28 ESR >5.1 or DAS28 CRP>4.6. Patients without an HDA evaluation at baseline (defined as recorded in a visit between 40 days before and 75 days after EIRA inclusion) have been excluded from the analyses. Odds ratios (ORs) and their 95% confidence intervals (CIs) of HDA were estimated through a mixed model with region as random intercept, to account for between regions variations. The association between each of the factors and HDA was first evaluated with a univariate model. Then, only factors with a significant association were included in the multivariable model. Missing values were excluded in the univariate analyses, but included as separated category in the multivariable analysis.
Results: A total of 1665 patients were included in this study, of which 995 (60%) had HDA at diagnosis. In the univariate analyses, young age at diagnosis (50-59 years: OR=0.76 (0.59-1.00)), longer symptoms duration (>365 days: OR= 0.51 (0.37-0.7)), and diagnosis in more recent years (≥2015: OR= 0.66 (0.48-0.9)) were inversely associated with HDA, while being underweight (BMI <18.5: OR= 2.17 (1.04-4.51)), low education (≤9 years: OR= 1.41 (1.09-1.82)), living alone (OR= 1.42 (1.13-1.78)) and being seronegative (OR=1.78 (1.39-2.28)) had higher odds of HDA. Sex, shared epitope, and cigarette smoking were not associated with HDA at diagnosis. In the multivariable analyses, age and education were no longer associated with HDA.
Conclusion: In this study we observed that sex, symptoms duration, calendar time, living alone, serostatus were associated with high disease activity at diagnosis, while age, sex, education, shared epitope, and cigarette smoking were not.

AB0226 PREDICTORS OF RESPONSE AFTER CESSATION OF JAKI THERAPY IN PATIENTS WITH RA

Keywords: bDMARD, Rheumatoid arthritis, Remission

D. C. Diederik[1], P. Durez[2,3], J. Lenaerts[4], R. Westhovens[5], P. Verschueren[5,6]. [1]*Vrije Universiteit Brussel, Biostatistics and Medical Informatics Research Group, Department of Public Health, Brussels, Belgium*; [2]*Université Catholique de Louvain, Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium*; [3]*Cliniques Universitaires Saint-Luc, Department of Rheumatology, Brussels, Belgium*; [4]*Reuma-Instituut Hasselt, Department of Rheumatology, Brussels, Belgium*; [5]*University Hospitals Leuven, Department of Rheumatology, Leuven, Belgium*; [6]*KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium*

Background: In a previous study based on data from the Belgian register "Tool for Administrative Reimbursement Drug Information Sharing" (TARDIS)[1], IL6 inhibitors showed a better clinical response after JAKi cessation compared to other b/tsDMARDs. However, considerable baseline differences in demographic and clinical variables, and previous exposure to advanced therapies were found between treatment groups, which could have influenced our results.
Objectives: We aimed to find predictors of short-term response after cessation of JAKi therapy in patients with RA.
Methods: Patients were selected from TARDIS for this analysis if they had stopped JAKi therapy and initiated a subsequent therapy between register inception and December 2021. Patients were grouped per subsequent therapy: TNFi, Abatacept, IL6 inhibition or JAKi. Rituximab was excluded as patients are reimbursed on RA flare in Belgium. Linear and logistic regression models were constructed to establish predictors of clinical response. DAS28 change between baseline and first follow-up, DAS28 remission (DAS28<2.6) and DAS28 low disease activity (LDA, DAS28≤3.2) at first follow-up were taken as dependent variables. Following variables were inserted in the models: age, disease duration, b/tsDMARD naive, treatment group and baseline values for HAQ, swollen/tender joint count, PGA, ESR, and CRP. Final models included only variables reaching statistical significance of 0.05 (by backwards elimination).
Results: In total, 193 RA patients, who had stopped JAKi therapy and had complete baseline and follow-up data, could be included. Table 1 shows baseline demographic and clinical characteristics. TNFi, Abatacept, IL6 inhibition or JAKi therapy was initiated in 33% (63/193), 11% (20/193), 18% (34/193) and 39% (76/193) of patients respectively. Remission and LDA were reached in 42% (81/193) and 63% (122/193) of patients respectively. Common predictors for achieving remission and LDA were baseline HAQ and not receiving abatacept (Figure 1). Variables positively associated with a higher DAS28 change were baseline PGA (Relative Risk (RR) 0.02 (0.01, 0.03)), TJC (0.06 (0.01, 0.12), SJC (RR 0.10 (0.03, 0.16)) and CRP (RR 0.02(0.01, 0.03)), while baseline HAQ (RR -0.60 (-0.88, -0.31) and not receiving abatacept (RR -0.70 (-1.25, -0.15)) were negatively correlated with DAS28 change in the adjusted multivariate linear regression model.

Table 1. Patient characteristics at the start of next treatment after failing the first JAKi therapy

	Total population
Number	193
Age (mean ±SD, years)	57 ±13
Disease duration (mean ±SD, years)	10 ±8
ESR (mean ±SD, mm/hour)	24 ±18
CRP (mean ±SD, mg/L)	11 ±18
SJC28 (mean ±SD)	6 ±5
TJC28 (mean ±SD)	8 ±5
DAS28 (mean ±SD, years)	4.6 ±1.1
HAQ-DI (mean ±SD, 0-3)*	1.3 ±0.7
PGA (mean ±SD, 0-100)	64 ±20
Used JAKi as first line advanced therapy	76/193 (39%)

Legend: Number given are mean ± SD or number, proportion. TNFi = tumour necrosis factor inhibitor, JAKi = Janus Kinase inhibitor, HAQ= health assessment questionnaire, PGA= Patient Global assessment; CRP= C-reactive protein; ESR= erythrocyte sedimentation rate; TJC= tender joint count; SJC= Swollen joint Count; DAS28 = disease activity score based on the 28joints. *Missing HAQ(0-3) scores were imputed by regression using age and HAQ(0-60) scores, the sum of the scores (0-3) on all (20) individual HAQ questions.

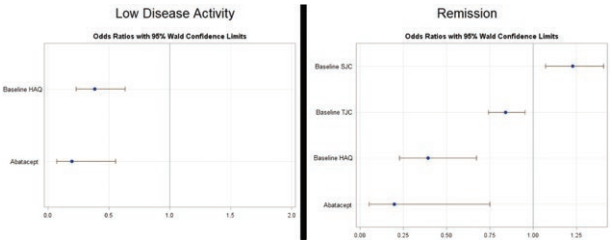

Figure 1. Predictors of remission or LDA

Conclusion: This explorative analysis reveals that after adjustment, patients who have worse functionality and receive abatacept compared to other b/ts DMARD show worse clinical outcomes in the short-term. This treatment effect should be further explored, but caution is warranted as the sample size was relatively small and indication bias cannot be excluded.

AB0227 EARLY RHEUMATOID ARTHRITIS DIAGNOSIS: PRIMARY CARE PHYSICIAN'S PERSPECTIVE AND NEEDS

Keywords: Education, Rheumatoid arthritis

C. Bourgeois Avella[1], M. Sánchez Lucas[1], J. Molina Collada[1], J. Martínez-Barrio[1], J. M. Alvaro Gracia[1], J. Rivera[1], J. Olmedo[2], G. Fernandez Plana[3], I. Castrejon[1]. [1]*Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain*; [2]*Centro Salud Ibiza, Primary Care, Madrid, Spain*; [3]*Centro de Salud Dr. Cirajas, Primary Care, Madrid, Spain*

Background: Primary care physicians (PCPs) play a crucial role in early recognition and rapid referral of patients with inflammatory arthritis to improve early management and patient outcomes. However, there is limited information on perceived barriers for referral and areas of improvement [1]. The purpose of this study is to explore the perspective and needs of PCPs to guide a specialist's referral program.

Objectives: To explore the perspective and needs of primary care physicians (PCPs) to guide a specialist's referral program at an academic rheumatology center in Madrid and to identify areas of improvement to facilitate early referral for early rheumatoid arthritis.

Methods: A PCPs-rheumatology early referral program (REUCARE) has been initiated at our area in January 2022 with 257 PCPs participating. Up to May 2022, 88 patients have been referred, however only 24 (27%) fulfil inclusion criteria. In order to improve the referral strategy, a survey has been developed in collaboration with primary care investigators to explore areas of improvement. The survey included 5 domains covering: PCPs demographics, previous knowledge about RA, level of confidence, factors and potential barriers influencing referral and interest on rheumatological training. Data were captured using four-point Likert scales, yes/no question or free text, and were analyzed descriptively.

Results: E-mail invitations were sent to 257 PCPs through their primary care center coordinator and completed by 26 (10% response rate). More respondents were women (76%) in practice for over more than 20 years who reported having 30-40 patients per day and only 1-5 patients diagnosed of RA in the last year. The majority (83%) reported additional rheumatological training besides medical school, however they were no familiar with the incidence and prevalence of the disease. Around 67% were aware of the importance of early diagnosis and treatment, however they felt not very confident making the initial diagnostic (61% "somehow confident" and 35% "not confident"). Main reasons for referral were clinical presentation (65%), positive rheumatoid factor (46%) and elevation of acute phase reactants (46%). Most PCPs considered the waiting time for rheumatology prolonged (65%) and very prolonged (22%) and reported insufficient feedback information from rheumatologists (60%). Main reasons for delay from PCPs perspective were nonspecific initial symptoms of the disease (48%) followed by rheumatology long waiting list (39%) (Figure 1).

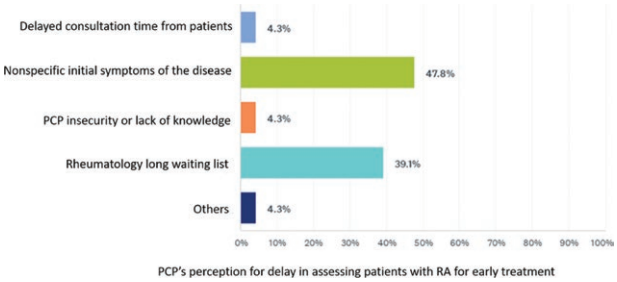

Figure 1.

Although 77% indicated using additional resources to improve their knowledge in RA, all participants stated that they would be interested in receiving more information on early diagnosis, being the preferred resources a specific e-consult (87%), updated mini guidelines (78%) and face-to face meetings with rheumatologists.

Conclusion: Most PCPs are aware of the importance of early diagnosis and management of RA but feel uncomfortable making the initial diagnosis. Non-specific initial symptoms and long waiting lists for rheumatology are the main reasons for delay from PCPs perspective. Resources to improve referral, including e-consult and specific guidelines, are in need as part of the actual referral program.

Background: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Previously, we stratified the patients with rheumatoid arthritis-associated interstitial lung disease (RA-ILD) into four distinctive groups according to their change of percent predicted forced vital capacity using trajectory analysis: persistently improving, stable, slowly declining, and rapidly declining.[1] Till October 2020, a total of twelve patients died, of which eight patients died even though they belonged to either stable or slowly declining groups. Therefore, it advantages additional biomarkers benefits to anticipate poor prognosis.

Objectives: To analyze whether serum Kreb von den Lungen 6 (KL-6) predicts mortality among patients with stable or slowly declining % FVC pred. trajectory group.

Methods: The Korean RA-ILD (KORAIL) cohort is the prospective observational cohort. Patients diagnosed with RA based on either 1987 or 2020 ACR criteria and with ILD based on CT scans had been recruited from six tertiary medical hospitals in Korea from January 2015 to July 2018 and followed for 3 years. Pulmonary function tests and chest CT scans were conducted annually. Serum KL-6 level at enrollment was measured by Nanopia KL-6 assay (SEKISUI, Japan). The cut-off value of KL-6 was referenced in the previous report.[2] Kaplan-Meier Log-rank tests and Cox proportional hazard analysis were conducted using SPSS statistics 21.0.

Results: Among patients with stable (n=68) and slowly declining (n=54) lung function groups, three and five patients died, respectively. The mean age of the stable disease group was statistically significantly higher than that of the slowly declining group (64.9±7.7 vs 67.9±6.8-year-old, p=0.03). There was no significant difference between groups in the proportion of males (n=21 vs 19, p=0.70) or ever-smokers (76.1% vs 66.7%, p=0.31), and the mean duration of RA or ILD (RA duration 8.6±8.8 vs 6.7±7.1 years, p=0.21; ILD duration 3.2±3.6 years vs 2.5±2.9 years, p=0.25). Serum KL-6 levels at baseline were comparable between groups (636.3±454.6 U/mL vs 590.6±547.3 U/mL, p=0.62). The hazard ratio for death in the KL-6>1000 U/mL compared with the KL-6 group≤1000U/mL was 3.77 (95% confidence interval, 0.90-15.8, p=0.07) in an unadjusted model and 4.05 (95% CI, 0.68-24.2, p=0.13) in a model adjusted for age, sex, history of smoking (Figure 1).

Conclusion: In RA-ILD, patients with serum KL-6 levels>1000U/mL at baseline tend to have 3.8 times as high mortality as those with serum KL-6 levels≤1000U/mL, although not statistically significant. The current study result implies that serum KL-6 level can be a useful tool to predict poor prognosis even in the case when the lung function of patients is stable or slowly declining.

Bonfiglioli[10], C. Brenol[11], L. Mota[3], G. Da Rocha Castelar Pinheiro[2]. *[1]Hospital do Servidor Público Estadual de São Paulo, Rheumatology, São Paulo, Brazil*; *[2]Universidade do Estado do Rio de Janeiro, Rheumatology, Rio de Janeiro, Brazil*; *[3]Universidade de Brasília, Rheumatology, Distrito Federal, Brazil*; *[4]Universidade Federal do Paraná, Rheumatology, Curitiba, Brazil*; *[5]Universidade Federal de Santa Catarina, Rheumatology, Florianópolis, Brazil*; *[6]Universidade Federal de Minas Gerais, Rheumatology, Belo Horizonte, Brazil*; *[7]UniversidadeEstadual de Campinas, Rheumatology, Campinas, Brazil*; *[8]Universidade de São Paulo, Rheumatology, Ribeirão Preto, Brazil*; *[9]Universidade Federal do Pará, Rheumatology, Belém, Brazil*; *[10]Universidade de São Paulo, Rheumatology, São Paulo, Brazil*; *[11]Universidade Federal do Rio Grande do Sul, Rheumatology, Porto Alegre, Brazil*

Background: Rheumatoid arthritis (RA) is defined as a systemic autoimmune pathology associated with a chronic inflammatory process, which can damage joints and extra-articular organs. The target of therapy is to obtain remission and to reduce side effects [1].

Objectives: Analyze racial differences in the context of RA, from an epidemiological, disease activity, diagnosis and treatment standpoint.

Methods: This work is part of a Brazilian multicentric study called REAL-Rheumatoid Arthritis in Real Life in Brazil, which is a prospective observational cohort study of patients with RA from 11 public healthcare centers in different geographic regions of Brazil that are specialized in RA management. For the present article, a cross-sectional cohort was analyzed (2), which included 754 patients who classified themselves as caucasian or Afro-Latin Americans. Others ethnicities were excluded.

Results: We enrolled 754 patients, 83.8% were caucasians and 16.2% were Afro-Latin Americans. In the caucasians group 88.4% were female and in the Afro-Latin Americans group 92.6% were female. The mean age was 63.4 years in the caucasians group versus 61.7 years in the Afro-Latin Americans (p = 0.137). The mean years of schooling was 8.28 among caucasians and 7.87 among Afro-Latin Americans (p = 0.341). There was no statistically significative difference in relation to social class between the groups (p = 0.266). 55.5% among the caucasians and 56.7% among the Afro-Latin Americans had erosive disease (p = 0.822). The average time between beginning of symptoms and diagnosis in the caucasians group were 28.1 months and in the Afro-Latin Americans were 33.3 months (p = 0.123), the average time between beginning of symptoms and beginning of treatment were 33.1 months among the caucasians and 42.2 months among the Afro-Latin Americans (p = 0.115). The CDAI mean in the caucasians group was 11.8 and in the Afro-Latin Americans group was 13.7 (p = 0.179). The following tests were applied: SF-12 (Medical Outcomes Study Short Form 12), presenting an average in the physical component of 36.7 among the caucasians and of 36 among the Afro-Latin Americans (p=0.253) and in the mental component of 44.4 and 48.4 respectively (p< 0.001); SF-6D (Short-Form 6 Dimensions – Brazil), that verified a mean of 0.373 between the caucasians and 0.357 between the Afro-Latin Americans (p=0.292). Current medications in use were described in Table 1.

Conclusion: Health disparity has multiple consequences and represent differences in health outcomes between different ethnicities, for example. Working toward health equity in society is fundamental to provide excelente care for all groups, as demonstrated in our study, which did not evidenced statisticallt significant diferences in most of the characteristics of RA between caucasians and Afro-Latin Americans, this may demonstrate that there is no difference between diagnosis, indications and disease control betwee races. It is important to highlight that Brazil is a country with a racial multiplicity that can be a limiting factor for this type of analysis and the lack of undestanding of the epidemiology of RA by race and ethinicity limits our understanding about the disease.

AB0230 **IS IT POSSIBLE TO STOP TAKING GLUCOCORTICOIDS IN RHEUMATOID ARTHRITIS WHILE USING THE SYNTHETIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS?**

Keywords: Rheumatoid arthritis

G. Mykytenko[1], O. Iaremenko[2]. [1]*Bogomolets National University, Internal Medicine 3, Kyiv, Ukraine*; [2]*Bogomolets National University, Internal Medicine 3, Kyiv, Ukraine*

Objectives: to investigate the possibility of withdrawing glucocorticoids (GC) or reducing their dose to the target (<7.5 mg/d in terms of prednisone) when using traditional synthetic disease-modifying antirheumatic drugs (DMARD) in patients (pts) with rheumatoid arthritis (RA); to study independent prognostic factors that affect the continuation of taking GC.
Methods: 270 patients with RA (women - 86.6%) aged 51.2 ± 0.71 years, with a disease duration of 50.2 ± 3.82 months were examined. Rheumatoid factor (RF) was found in 64.8% of individuals, antibodies to cyclic citrullinated peptide (ACCP) - in 66.6%. DMARD therapy included methotrexate (n = 91), leflunomide (n = 95), sulfasalazine (n = 51), hydroxychloroquine (n = 3) or its combination (n = 126). Statistical analysis was performed using program SPSS 22.0. Certainty disagreements average values were estimated using non-parametric of the Mann-Whitney criterion for quantitative signs and criteria χ^2 for frequency indicators. To identify prognostic markers that affect the possibility of canceling GC, the method of logistic regression analysis was used with the calculation of the risk ratio (RR) and 95% confidence interval (95%CI). In order to identify the decisive factor affecting the possibility of achieving the target dose of GC, a stepwise logistic regression analysis of multivariate models was performed. The difference was considered probable at p<0.05.
Results: During 3 years of study, GC was canceled in 33% of pts in the period from 3 to 30 months (mostly in the first 6 mth). Among those who continued to take GC, the target dose (<7.5 mg/d) was achieved only in 32.6% of pts. Among pts continuously receiving GC, compared with pts who discontinued GC, there were probably more women (89.5% vs. 80.8%, p<0.05), ACCP-positive pts (88.4% vs. 55.0%, p<0.01), with higher DAS (ESR) values (5.29 ± 0.1 vs 4.84 ± 0.15, p<0.05) and more pronounced structural changes on the SHS scale (43.4 ± 2.42 vs 32.4 ± 2.71, p<0.05). According to the logistic regression analysis, the risk of continuing GC treatment was probably associated with female gender (RR 2.39 (1,09–4,97)), elderly pts (RR 1.02 (1,001–1,04)), ACCP-positivity (RR 3.73 (1,26–11,0)), disease activity by DAS (ESR) (RR 1,19 (1,0–1,43)) and structural joint changes (RR 1,01 (1,005–1,02)). Only the initial dose of GC ≥ 7.5 mg/d was associated with the inability to reach the target dose of GC during the entire follow-up period (RR 6.32 (2,0–19,5)).
Conclusion: Despite of the treatment with traditional synthetic DMARD, only a third of RA pts can cancel GC, mainly in the first 6 months. For the pts who continue taking GC, the target dose can be achieved in 33% of them. Independent predictors of the impossibility of GC discontinuation are female gender, old age, ACCP-positivity, higher RA activity according to DAS (ESR) and more pronounced joint destruction at the initial stage. A negative prognostic factor in achieving the target dose of GC is their initial dose ≥ 7.5 mg/d.

AB0231 **COMPARISON OF THE CLINICAL IMPLICATIONS AMONG SIX DIFFERENT NUTRITIONAL AND INFLAMMATORY INDICES IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Keywords: Rheumatoid arthritis

A. Gümüştepe[1], İ. Sunar[1], A. Kahveci[1], C. Baysan[2], Ş. Ataman[1]. [1]*Ankara University School of Medicine, Rheumatology, Ankara, Turkey*; [2]*Izmir Democracy University School of Medicine, Public Health, Izmir, Turkey*

Background: The most commonly used disease activity index in rheumatoid arthritis (RA) is Disease Activity Score 28 (DAS28). However, the need for objective disease activity indices retains. The nutritional and inflammatory indices were recently evaluated in many rheumatologic and non-rheumatic conditions as predictors of disease activity.
Objectives: We aimed to evaluate the association of six different nutritional and inflammatory indices with disease activity and patient reported outcomes (PROs) in patients with RA.
Methods: In this cross-sectional study, we recruited RA patients who fulfilled the 2010 ACR/EULAR classification criteria. Participants' demographic features, disease duration, current medication, disease activity indices [DAS28 with erythrocyte sedimentation rate (DAS28-ESR), simplified disease activity index (SDAI), clinical disease activity index (CDAI)], PROs [Health Assessment Questionnaire-Disability Index (HAQ-DI), Rheumatoid arthritis Impact of Disease (RAID)], Multimorbidity Index (MMI), hand and foot erosions, deformities, extra-articular manifestations of RA, nutritional and inflammatory status [prognostic nutritional index (PNI), controlling nutritional status (CONUT) score, neutrophil/lymphocyte ratio (NLR), monocyte/lymphocyte ratio (MLR), platelet/lymphocyte ratio (PLR), systemic inflammation response index (SIRI), Mini Nutritional Assessment-Short Form (MNA-SF), body mass index (BMI), waist and hip circumference] were noted. Patients were divided into 2 groups (remission and low disease activity vs. moderate and high disease activity) according to their DAS28-ESR scores.
Results: A total of 183 RA patients were analyzed. The mean age was 29.5±5.7 years, the median time of disease duration was 120 (60-238) months, 83.1% (n=152) were female, 69.9% were RF positive (n=128), 59% (n=108) were anti-CCP positive, 79.1% (n=145) were on conventional synthetic disease-modifying antirheumatic drugs (csDMARD), 5.5% (n=10) used targeted synthetic DMARD (tsDMARD), 16.4% (n=30) were used biologic DMARD (bDMARD). Median PNI values were lower in patients with extra-articular involvement (p<0.001). Mean PNI values were lower in patients with hematologic involvement, anemia, and thrombocytopenia (p<0.001, p=0.026, p=0.033), those with erosion on the foot X-ray (p=0.005), and CCP positive ones (p=0.028). NLR and SIRI were positively correlated with physician's global assessment (PGA) score (r=0.270, p<0.001; r=0.227, p=0.002), SDAI (r=0.219, p=0.003; r=0.199, p=0.007), CDAI (r=0.192, p=0.009; r=0.154, p=0.037), DAS28-ESH (r=0.232, p=0.002; r=0.186, p=0.012), ESR (r=0.233, p=0.001; r=0.218, p=0.003) and c-reactive protein (r=0.324, p<0.001; r=0.380, p<0.001). MNA-SF was negatively correlated with HAQ-DI (r=-0.199, p=0.007), RAID (r=-0.179, p=0.015), PGA score (r=-0.280, p<0.001), SDAI (r=-0.205, p=0.005), CDAI (r=-0.224, p=0.002), and DAS28-ESH (r=-0.186, p=0.012). PNI was not correlated with disease activity scores and PROs.
Conclusion: In this study where we aimed to determine the role of a variety of nutritional inflammatory indices in disease activity ascertainment of RA patients, while NLR, MNA-SF, and SIRI had significant associations with other composite disease activity indices, PNI failed to establish such a relationship. However, PNI was significantly higher in CCP-positive RA patients and ones with extraarticular involvement. Prospective longitudinal studies on larger samples are needed to elucidate the role of nutritional inflammatory indices in determining RA disease activity.

AB0232 **COMPARATIVE FUNCTIONAL ABILITY OF PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS AFTER TOTAL KNEE ARTHROPLASTY**

Keywords: Osteoarthritis, Rheumatoid arthritis

M. Karimov[1], S. Lapshina[2], T. Nuriakhmetova[2], I. Gilmutdinov[3], A. Nuriakhmetov[3], S. Ardashev[3], I. Akhtiamov[4]. [1]*Tashkent Medical Academy, Traumatology, Orthopedic and Military Surgery, Tashkent, Uzbekistan*; [2]*Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation*; [3]*Republican Clinical Hospital, Orthopedics No. 2, Kazan, Russian Federation*; [4]*Kazan State Medical University, Traumatology, Orthopedic and Military Surgery, Kazan, Russian Federation*

Background: Patients with rheumatoid arthritis (RA) often require adequate disease control prior to total knee arthroplasty (TKA). At the same time, they may have worse outcomes and late complications compared to osteoarthritis (OA) patients.
Objectives: To study the functional abilities of RA patients undergoing TKA compared to OA patients using the KSS scoring system.
Methods: The study included 150 patients: 69 patients (46%) with RA and 81 patients (54%) with OA. 32% of them were males and 68% were females. Th average age of patients with RA was 59.0 [52; 64] years, while in OA group – 66.0 [61; 73] years. Among patients with RA, 60.9% had moderately active diseases and 23.2% had highly active disease prior to intervention. All patients underwent cemented TKA. All of them also completed KSS score prior to surgery, immediately after that and 3 and 12 months after the discharge. Statistical analysis was performed using SPSS version 23.0 (IBM Corp., Armonk, NY, USA). A p value of less than 0.05 was considered statistically significant.
Results: Prior to intervention patients with RA had significantly lower KSS scores compared to OA patients (45.0 [40; 55] versus 60.0 [50; 60], p=0.00, Mann-Whitney). After the surgery KSS became comparable between the two groups (83.0 [74; 84] versus 82.0 [80.5; 85], p=0.754, Mann-Whitney). 3 months

after the intervention RA patients had significantly higher KSS scores than prior to surgery (Mdn=88.0, n=69 versus Mdn=40.0, n=69, z=-7.23, p=0.00) or at discharge (Mdn=88.0, n=69 versus Mdn=83.0, n=69, z=-7.25, p=0.00, Wilcoxon test). The same trend was observed for KSS completed 12 months after the surgery (Mdn=93.0, n=69 versus Mdn=88.0 in KSS 3 months after the surgery, n=69, z=-7.26, p=0.00). At the same time, the results of KSS were comparable between RA and OA groups 3 and 12 months after the intervention (88.0 [88; 88] in RA group versus 88.0 [87; 89] in OA group, p=0.772, Mann-Whitney; 94.0 [93; 95] in RA group versus 94.0 [93;95] in OA group, p=0.702, Mann-Whitney, respectively).

Conclusion: The functional abilities of patient with RA after TKA did not differ from those among OA patients regardless of diseases activity despite, despite the fact that among RA patients KSS scores were significantly lower prior to surgery. KSS scores of RA patients improved 3 and 12 months after the intervention and were comparable to OA group.

Background: Rheumatoid arthritis (RA) is the most common autoimmune disease. Clinical remission is the main therapeutic target for patients with RA, with low disease activity (LDA) as a best possible alternative[1].

Objectives: Evaluate clinical response of patients with RA treated with biologic (bDMARDs) and the associated factors for remission and low activity disease at the first year of treatment.

Methods: BIOBADAMEX is a Mexican ongoing cohort of patients using bDMARDs since 2016. In this analysis we included all patients with diagnosis of RA with at least two assessments, baseline and at one year of follow up. Clinical response was measured by DAS-28 score and factors associated with having a remission or low disease activity vs moderate/high activity were estimated using univariable and multivariable logistic regression analysis adjusting by potential confounders, such as age, gender, disease duration.

Results: A total of 336 RA patients were included in this analysis. At baseline 68 (20%) and after one year of follow 171 (50.1%) were in remission or low activity disease. Mean baseline disease duration was 8.8 years. Table 1 shows baseline characteristics by groups. Baseline steroid treatment and previous biologic treatment were the only factors associated with less probability of being in remission/low disease activity at one year in our cohort. In multivariable analysis adjusted by age, gender, disease duration, these two factors were no longer associated with remission/low disease activity (p=0.055 and p=0.14, respectively).

Conclusion: In our registry baseline steroid treatment and previous biologic treatment were the only factors associated with less probability of being in remission/low disease activity at one year on biologic treatment, however these factors did not remain significant associated after adjusted analysis. Follow up and inclusion of more participants is going on and will allow us to perform further analyses.

AB0234 PROGNOSTIC POTENTIAL OF EXOSOMES (EX) AS IMMUNOMODULATORS IN SYNOVIAL FLUID (SF) IN RHEUMATOID ARTHRITIS (RA)

Keywords: Synovium, Rheumatoid arthritis

E. De La Poza Plaza[1], S. Barykin[2], V. Shishkin[3], V. V. Shishkin[3], G. V. Kudryavtseva[3]. *[1]Universitat Politècnica de València, Faculty of Business Administration and Management, Valencia, Spain*; *[2]Peter the Great St. Petersburg Polytechnic University, Graduate School of Service and Trade, Saint-Petersburg, Russian Federation*; *[3]Saint-Petersburg State University, Diagnistic of Functional Systems, Saint-Petersburg, Russian Federation*

Background: Secretory EX various biological fluids, including synovial, – key mediators of intercellular communication, regulating the body's immune responses, information transfer, vesicular transport, etc. Penetrating into cells, EX can cause a cascade of changes in them at the genomic and epigenomic levels.

Table 1. The level of some endonucleases, tetraspanins and chaperones in normal (D) and in RA SF

EX	DNA-ase (acid)	DNA-ase (alk.)	RNA-ase (acid)	RNA-ase (alk.)	CD9	CD81	Hsp70	Hsp90
D	0,08± 0,01	0,45±0,03	0,18 ±0,04	0,89±0,21	935±97	697±68	9,8±2,3	6,4±1,5
RA	4,4± 0,7***	0,17± 0,02*	5,4 ±0,3***	0,47 ±0,08*	2987 ± 237**	893±76*	21,3± 3,7**	8,9±2,3*

* - p <0.05; ** - p <0.01; *** - p <0.001

Objectives: The aim of the study was to assess the degree of expression of exosomal membrane proteins and endonucleases from SF in RA.
Methods: SF of knee joints of 10 patients with RA with active synovitis and 7 conditional donors postmortem (D) were researched. EX was isolated by ultrafiltration and double ultracentrifugation (105 g).EX was identified by transmission electron microscopy and flow cytometry. The expression level of tetraspanins (CD9, CD81) and chaperones (Hsp70, Hsp90) was determined (conv. units) by flow cytofluorimetry and by immunoblotting, respectively. The activity of endonucleases of EX (units/ml) was carried out spectrophotometrically.
Results: In RA, there is a pronounced expression of transmembrane markers of exosomes: tetraspanins CD9 and CD81 (on the surface of exosomes) and chaperones Hsp70 and Hsp90 (obligate internal components). The levels of major tetraspanins CD9 and Hsp70 were significantly increased (by 3.2 and 2.2 times, respectively). Functional groups of proteins such as acidic and alkaline endonucleases show multidirectional changes in EX with RA: a sharp increase in the activity of acidic DNA-as and RNA-as (by 55-30 times) and a 2-3-fold decrease in the activity of alkaline analogues (Table 1). It is obvious that the shift of the pH of SF at RA (on average, from 7.75 units in normal to 7.21 – at RA) noted by many authors, affects the implementation of exosomal secretion of proteins and nucleic acids, which disrupts the immunomodulatory intercellular signaling.
Conclusion: EX-secretion of proteins and nucleic acids in RA can be not only a fundamental way of intercellular communication, but also an immunomodulatory factor of etiopathogenetic significance. EX obtained from SF have potential prognostic value in the study of immunocomplex pathologies.

Background: Great advances have been made in the treatment of rheumatoid arthritis (RA), and remission has become a viable target. However, some patients complain of fatigue even in remission.
Objectives: The purpose of this study was to investigate whether RA patients are more likely to experience fatigue than the general population, and to clarify the factors involved in the formation of fatigue.
Methods: We analyzed data from the TOMORROW study (UMIN000003876) study, which is a 10-years prospective cohort consisting of age and sex matched RA patients (n=208) and volunteers (Vo) (n=205). We conducted a QOL survey using SF-36 in 2019. Fatigue was assessed using the vitality component (VT) of the SF-36. First, each scale of SF-36 was compared between RA patients and Vo, and the effects of RA on fatigue and QOL were evaluated by multiple liner regression analysis. Next, we limited the target to RA patients and tried to identify the factors involved in fatigue. We included anthropometric measurements parameters, disease activity score 28-erythrocyte sedimentation rate (DAS28-ESR), RA medication (methotrexate (MTX) dose, prednisolone dose, use of biologic disease modifying anti-rheumatic-drugs (bDMARDs)), tender joint count, swelling joint count, VAS and modified Health Assessment Questionnaire (mHAQ) as candidate factors.
Results: Subjects were 186 Vo and 167 RA patients in 2019. In RA, average age was 65.8 ± 12.7 year, 143 patients (85.6%) were female, average disease duration was 13.8 ± 11.8 year and DAS28-ESR was 3.10 ± 1.45. Compared with Vo, Physical Component Summary (PCS) (Vo 46.9 ± 12.2, RA 34.1 ± 18.0: p<0.01), Mental Component Summary (MCS) (Vo 52.2 ± 9.5, RA 49.4 ± 9.5: p<0.01) and VT (Vo 50.5 ± 10.1, RA 44.0 ± 10.8: p<0.01) were significantly lower in RA patients. In multiple liner regression analysis, RA was a significant decreasing factor of PCS (β -12.8, 95%CI -15.7 - -9.89: p<0.01), MCS (β -2.75, 95%CI -4.68 - -0.82: p<0.01) and VT (β -3.01, 95%CI -4.57- -1.45: p<0.01). In RA patients, multiple liner regression analysis shows that VAS (β -0.06, 95%CI -0.12 - -0.00: p=0.03), ESR (β -0.09, 95%CI -0.16 - -0.02: p=0.02), and mental health component of the SF-36(MH) (β 0.55, 95%CI 0.42 – 0.68: p<0.01), were significant affecting factor for VT. (Table 1)
Conclusion: In this study, RA was a significant QOL declining factor. High VAS score, high ESR values and low mental health score were associated with fatigue in patients with RA.

Table 1. Summary of multiple liner regression analysis for fatigue (vitality score of SF-36) in patients with rheumatoid arthritis.

AB0236 THE HAPTOGLOBIN 2-2 GENOTYPE IS ASSOCIATED WITH INCREASED RISK OF CARDIOVASCULAR DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS: A CASE-CONTROL STUDY

Keywords: Rheumatoid arthritis, Cardiovascular disease

C. Xu[1], L. W. Khin[2], H. Z. Tam[2], E. T. Koh[1], R. Dalan[3], K. P. Leong[1]. [1]*Tan Tock Seng Hospital, Rheumatology, Allergy and Immunology, Singapore, Singapore*; [2]*Tan Tock Seng Hospital, Clinical Research & Innovation Office, Singapore, Singapore*; [3]*Tan Tock Seng Hospital, Endocrinology, Singapore, Singapore*

Background: Traditional risk factors do not fully explain the increased risk of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA). [1] The Hp2-2 genotype is known to confer a lower anti-oxidant and higher inflammation effect when compared to the non Hp2-2 genotype. [2]
Objectives: This study aims to investigate the association of Hp genotype with CVD in patients with RA.
Methods: Sixty-nine with CVD cases and 207 gender and ethnicity matched control (without CVD) with allocation of 1:3, were retrieved from the Tan Tock Seng Hospital RA registry from 1 Jan 2000 to 31 Dec 2020. Hp genotype was determined using TaqMan-based real-time polymerase chain reaction (PCR). CVD was examined against demographics, clinical and laboratory variables in univariate models. Associations between Hp genotypes and CVD were analyzed using conditional logistic regression. All analysis was done using Stata version 16.1.
Results: The prevalence of Hp2-2 genotype was: Group 1 (CVD group): Chinese: 29/57, 50.9%, Indian: 5/5, 100%, and Malay 2/7, 28.6%; Group 2 (Control group): Chinese 80/171, 46.8%, Indian: 10/15, 66.7%, and Malay 11/21, 52.4%). CVD was significantly associated with age, disease duration, disease activity score 28 (DAS28), diabetes, hypertension, hyperlipidemia, Hp 2-2 allele, rheumatoid factor, cyclic citrullinated peptide (CCP), cumulative dose of prednisolone and methotrexate. Hp 2-2 genotype significantly associated with CVD outcomes in the logistic regression model adjusting for age, smoking status, DAS28, diabetes, hypertension, hyperlipidemia, and CCP (adjusted matched odds ratio: 1.13 (95% CI: 1.01 – 1.27); p = 0.033).
Conclusion: The Hp 2-2 genotype is associated with an increased risk of CVD in patients with RA in the Singapore multi-ethnic Asian cohort. Further epidemiological and mechanistic studies are warranted to understand the role of the Hp-genotype in rheumatoid arthritis.

AB0237 EFFECTS OF ONE-YEAR TOFACITINIB THERAPY ON ANGIOGENIC BIOMARKERS IN RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Rheumatoid arthritis, Targeted synthetic drugs

G. Kerekes[1], M. Bodoki[2], A. Hamar[2], A. Pusztai[2], G. Tajti[3], M. Katkó[1], E. Végh[2], Z. Pethö[2], N. Bodnár[2], Á. Horváth[2], B. Soós[2], S. Szamosi[2], Z. Hascsi[4], M. Harangi[1], G. Panyi[3], G. Szücs[2], Z. Szekanecz[2]. *[1]University of Debrecen, Internal Medicine, Debrecen, Hungary*; *[2]University of Debrecen, Rheumatology, Debrecen, Hungary*; *[3]University of Debrecen, Biophysics and Cell Biology, Debrecen, Hungary*; *[4]University of Debrecen, Nuclear Medicine Unit, Debrecen, Hungary*

Background: Rheumatoid arthritis (RA) has been associated with increased angiogenesis and the production of angiogenic factors. Targeted therapies may attenuate angiogenic molecule production.
Objectives: We wished to determine how the Janus kinase (JAK) inhibitor tofacitinib influences the production of various angiogenic mediators including growth factors, cytokines, chemokines, adhesion molecules and others. We correlated these biomarkers with ultrasound-based vascular pathophysiology and ^{18}F-FDG-PET-CT.
Methods: Thirty RA patients with active disease were treated with either 5 mg bid or 10 mg bid tofacitinib and evaluated at baseline and after 6 and 12 months. We assessed numerous angiogenic mediators including VEGF, bFGF, EGF, PIGF, TNF-α, IL-6, cathepsin K (cathK), angiopoetins (Ang1, Ang2), PECAM-1 (CD31), CXCL8/IL-8, galectin 3 and NT-proBNP. For comparisons, we determined DAS28, CRP, IgM rheumatoid factor (RF) and anti-cyclic citrullinated peptide (aCCP) levels. We assessed brachial artery flow-mediated vasodilation (FMD), carotid intima-media thickness (IMT) and pulse-wave velocity (PWV) by ultrasound. We also performed simultaneous PET-CT assessment of joints and vessels.
Results: Twenty-six patients completed the study. Tofacitinib treatment significantly decreased VEGF (p=0.019), PIGF (p=0.019), IL-6 (p=0.001), cathK (p=0.04) and galectin 3 levels (p=0.013) after 12 months of treatment. Seropositive patients had increased bFGF, PIGF and NT-proBNP levels (p<0.05). Uni- and multivariable regression analysis indicated variable correlations of baseline and 12-month TNF-α, IL-6, bFGF, PIGF, NT-proBNP and PECAM-1 with IMT, as well as synovial and vascular inflammation as determined by PET-CT (p<0.005).
Conclusion: Tofacitinib suppressed the production of multiple angiogenic biomarkers. Number of these biomarkers are involved in carotid atherosclerosis, as well as synovial and vascular inflammation.

AB0238 USEFULNESS OF RAPID3 IN ASSESSING UNMET NEEDS OF RHEUMATOID ARTHRITIS PATIENTS FROM THE T-FLAG STUDY

Keywords: Patient reported outcomes, Rheumatoid arthritis

M. Suzuki[1,2], N. Takahashi[3], Y. Sobue[4], Y. Ohashi[1,5], R. Sato[1], M. Maeda[1], D. Kihira[1], K. Kishimoto[1], K. Terabe[1], S. Asai[1], S. Imagama[1]. *[1]Nagoya University Graduate School of Medicine, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan*; *[2]Jcho Kani Tono Hospital, Department of Orthopedic Surgery, Kani, Japan*; *[3]Aichi Medical University Hospital, Department of Orthopedic Surgery, Nagakute, Japan*; *[4]Japanese Red Cross Nagoya Daiichi Hospital, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan*; *[5]Japanese Red Cross Nagoya Daiichi Hospital, Department of Orthopedic Surgery, Nagoya, Japan*

Background: Routine Assessment of Patient Index Data 3 (RAPID3) is a patient-reported outcome (PRO) that can be used to assess the condition of rheumatoid arthritis (RA) patients using only a questionnaire that can be completed in a short time. It is useful as a simple method for assessing disease activity. In previous reports, RAPID3 could be used as an assessment similar to Disease Activity Score 28 (DAS28), a common disease activity assessment [1]. However, in the treatment of RA, there are unmet needs in which patients have low satisfaction with treatment, even though they are in remission according to disease activity assessments such as DAS28. To investigate the cause of this discrepancy, we decided to conduct a study using RAPID3 as a subjective patient assessment and DAS28 as a general disease activity measure.
Objectives: The purpose of this study was to investigate the association between disease activity and RAPID3 in RA patients.
Methods: The data for this study were obtained from the Tsurumai-Frailty and Locomotive Syndrome of Rheumatoid Arthritis for Globalization (T-FLAG), a observational study involving three centers. A PRO questionnaire was administered to 467 RA patients between June 1 and August 31, 2020. Disease activity was assessed using the RAPID3, DAS28-CRP, DAS28-ESR, Clinical Disease Activity Index (CDAI), and Simplified disease activity index (SDAI). the RAPID3 (30 points total) consists of three domains: physical function (0-10), pain (Visual Analogue Scale 0-10), and Patient global assessment (PtGA) of disease activity (0-10). It consists of three domains, divided into disease activity categories (remission: ≤3, low disease activity: 3.1-6, moderate disease activity: 6.1-12, high disease activity: >12). PRO assessment was performed using PtGA, Health Assessment Questionnaire Disability Index (HAQ-DI), Kihon checklist (KCL),

and the 25-question Geriatric Locomotive Function Scale (GLFS-25). We compared the disease activity categories using DAS28-CRP and RAPID3.

Results: The mean age (± standard deviation) was 66±13, female was 73%, disease duration was 11±10, RAPID3 was 5.6±5.7, DAS28-CRP was 2.19±1.03, HAQ-DI was 0.46±0.66, and KCL was 6.6±4.4. RAPID3 and DAS28-CRP showed a strong correlation with a correlation coefficient of 0.743, and CDAI and SDAI as other disease activity assessment methods also showed a strong correlation (CDAI: r=0.883, SDAI: r=0.880). On the other hand, the HAQ-DI and GLFS-25, which are PRO assessments of physical function, showed strong correlations, but the KCL, which includes psycho-social assessments along with physical function assessments, showed a slightly weaker correlation (r=0.507). Morning stiffness was not correlated with RAPID3 (r=0.206). In the disease activity category, 59.5% of patients had RAPID3 and DAS28-CRP in the same category (RAPID3 = DAS28-CRP). In addition, RAPID3 belonged to the worse category than DAS28 in 31.3% of cases (RAPID3 > DAS28-CRP). The group with RAPID3 > DAS28-CRP (31.3%) vs. the group with RAPID3 = DAS28-CRP (59.5%) showed no significant differences in age, gender, and tender/swollen joint count (Table 1). On the other hand, there were significant differences between the two groups in disease duration (14 vs. 11 years), PtGA (36 vs. 14mm), HAQ-DI (0.84 vs. 0.29), KCL (8.5 vs. 5.8), and GLFS-25 (28 vs. 13).

Conclusion: In this study, we showed that the correlation between RAPID3 and disease activity assessment was quite strong. In the disease activity category, approximately 60% of all patients had similar DAS28-CRP and RAPID3. However, the discrepancy between DAS28-CRP and RAPID3 may be caused by physical dysfunction and frailty. Therefore, it is important to achieve clinical remission and improve PRO in RA treatment as an intervention to address unmet needs.

AB0239 THE REDUCTION OF CIRCULATING LEVELS OF SERUM CALPROTECTIN IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ABATACEPT

Keywords: Biomarkers, bDMARD, Rheumatoid arthritis

S. E. L. Della Pina[1], S. Piantoni[1], E. Garrafa[2,3], M. Vezzoli[3], A. Caproli[1], L. Franzoni[3], I. Cavazzana[1], P. Airò[1], F. Franceschini[1]. [1]*Rheumatology and Clinical Immunology Unit, ASST Spedali Civili and University of Brescia, Brescia, Italy, Department of Clinical and Experimental Sciences, Brescia, Italy*; [2]*ASST Spedali Civili, Brescia, Italy, Department of Laboratory Diagnostics, Brescia, Italy*; [3]*University of Brescia, Italy, Department of Molecular and Translational Medicine, Brescia, Italy*

Background: The research of new biomarkers is still an unmet need in the field of rheumatoid arthritis (RA), especially for patients (pts) without rheumatoid factor and/or anti-citrullinated peptides positivity (seronegative RA), and for those without the elevation of inflammatory markers, such as the C-reactive protein (CRP) [1]. Calprotectin (CLP) is a heterodimeric complex of two calcium binding proteins which is expressed in granulocytes and monocytes. It mediates cell differentiation, activation, migration, apoptosis and the production of pro-inflammatory factors [2]. Recent studies showed that CLP synovial fluid levels are higher in RA pts and that its serum levels might directly reflect the synovitis severity [3]. Abatacept (ABA) was demonstrated to interfere with the migration of monocytes to the joint, reducing the expression of adhesion molecules via hampering actin dynamics [4]. No studies are available on the potential value of CLP as a biomarker of ABA treatment response in pts with RA.

Objectives: To analyse CLP levels in ABA treated RA pts.

Methods: Forty-three consecutive ABA treated RA pts [84% female, median age (1^{st}-3^{rd} quartile)=61 (52-68) years, 81% seropositive, DAS28-CRP=4.57 (3.95-5.27)] were enrolled. EULAR criteria were used to evaluate the response to the treatment after 6 months (T6). CLP serum levels (μg/ml) were measured at baseline (T0) and at T6, by a commercial kit (Quanta Flash Calprotectin assay, Werfen; cut-off value=4).

Results: At T0, RA pts showed increased CLP serum levels (65%) irrespective of their seropositivity (p=0.50) or the presence of elevated CRP (p=0.23). T0 CLP was not different comparing pts according to their response [good+moderate, 67% vs non-responders, 33%: 4.44 (2.68-7.64) vs 6.66 (4.80-8.71); p=0.33], even in pts with T0 normal CRP levels [5.8 (3.27-6.36) vs 4.54 (3.61-7.47); p=0.86]. CLP decreased after treatment with ABA (T0 vs T6) (4.98 (3.04-7.88) vs 3.24 (2.20-5.72); p=0.0049), both in responders [4.44 (2.68-7.64) vs 3.24 (1.90-5.64); p=0.034], and in non-responders (6.66 (4.80-8.71) vs 2.95 (2.18-4.30); p=0.039). CLP was not significantly correlated with CRP at T0 or at T6, nor with DAS28-CRP at T0, whereas a significant correlation was observed with DAS28-CRP at T6 (r=0.34; p=0.034). The T6-T0 variations of CLP and DAS28-CRP were not correlated (r=0.06; p=0.6919), even evaluating separately pts according to their response.

Conclusion: CLP serum levels are increased in RA pts, without differences in groups separated on the basis of their seropositive status or their CRP levels, confirming the potential role of CLP as a biomarker of RA [3, 5]. The correlation between CLP levels and the composite index at T6, but not with CRP levels, suggests a possible clinical value, independent from CRP [6]. Circulating levels of CLP, a myeloid-related protein, did not have a predictive value for the response to ABA, an agent mainly targeting lymphocytes [4].

AB0240 RHEUMATOID ARTHRITIS CLINICAL ACTIVITY IS NOT ASSOCIATED TO CARDIOVASCULAR RISK AS MEASURED BY TRADITIONAL RISK SCALES

Keywords: Cardiovascular disease, Rheumatoid arthritis

J. R. Azpiri-López[1], I. J. Colunga-Pedraza[2], D. Á. Galarza-Delgado[2], V. M. Beltran-Aguilar[2], V. Gonzalez-Gonzalez[2], A. G. Arias Peralta[1], N. De Avila Gonzalez[2], J. A. Cardenas-de la Garza[2], G. García-Arellano[2]. [1]*Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*

Background: Rheumatoid arthritis (RA) patients have a higher cardiovascular risk (CVR) than the general population, being atherosclerotic cardiovascular disease the main cause of mortality [1]. Such increased could be explained by traditional CVR factors and chronic inflammatory state of disease. Clinical activity of disease, which is evaluated by DAS-28, is a parameter that denotes the current inflammatory status. [2]

Objectives: To compare CVR, by six scales: ACC/AHA ASCVD 2013, Framingham lipids and BMI, SCORE2, QRISK3 and Reynolds risk score, according to clinical activity of RA patients using DAS-28 CRP.

Methods: Descriptive, comparative and cross-sectional study. We enrolled RA patients between 40 and 75 years old who fulfilled ACR/EULAR 2010 classification criteria and recruited in the Rheumatology service from a tertiary care hospital, in Monterrey, Mexico. Patients were divided by time of disease evolution

Table 1. Demographic characteristics (n= 377)

Variable	Remisión (n= 121)	Low activity (n=51)	Moderate activity (n=156)	High activity (n=49)	p
Duration of disease, years. median (p25-p75)	7.0 (3.0-14.0)	7.9 (2.7-14.9)	7.0 (3.0-15.4)	5.1 (1.6-12.9)	NS
Women, (n)%	103 (85)	47 (92)	149 (95)	49 (100)	0.002
Age, years. median (p25-p75)	57 (49-62)	53 (48-63)	54 (48-59)	55 (45-58)	NS
BMI, kg/m2. median (p25-p75)	27.2 (25.0-30.4)	26.7 (24.7-30.8)	28.0 (24.6-31.8)	28.4 (24.7-32.3)	NS
Laboratory tests, median (p25-p75)

SCORE 2	6	4.5	4.5	4.5	NS
Q-RISK III	6.1	5.3	4.5	5.7	NS
RRS	1.5	1.5	1.5	1.5	NS

This table shows demographic and clinical characteristics. BMI Body Mass Index; CRP C Reactive Protein; ESR Erythrocyte Sedimentation Rate; ACPA Anti–Citrullinated Protein Antibody; RF Rheumatoid Factor; ASCVD Atheroesclerotic Cardiovascular Disease; FRS Framingham Risk Score; RRS Reynolds Risk Score; SCORE 2 Systematic Coronary Risk Evaluation 2.

into quartiles. CVR results from scales were multiplied by 1.5 factor according to EULAR 2016 recommendation. Normality was assesed by Kolmogorov-Smirnov test. Variables with a non-normal distribution were described by median and interquartile range (p25-p75). Differences between groups was analyzed by Kruskal-Wallis test or Chi-squared, accordingly.

Results: A total of 377 RA patients were included. Demographic characteristic are shown in Table 1. An increased in acute phase reactants, CRP (p= 0.000) and ESR (p= 0.003) was found, as severity of clinical activity increased, meanwhile CVR did not show significative changes, regardless of which of scales it was measured by.

Conclusion: CVR did not increase according to clinical activity of RA, which suggests that such severity can not explain by itself the increased in risk showed in this population.

Background: Rheumatoid Arthritis (RA) represents a huge burden for patients' quality of life and there are still relevant unmet needs in its management due to uncovered patients' needs even once sustained remission is achieved.

Objectives: This study aimed to investigate disease burden, treatment priorities and preferences across disease phases comparing patients' and physicians' perspectives.

Methods: Consultants or residents in rheumatology (across Academic and non-academic hospitals) and patients with RA both aged ≤40 years were reached by an anonymous online survey between November 2021 and November 2022, designed by the SIRyoung commission. For each included RA patient, demographic and clinical parameters (RA diagnosis timing, current and previous treatments) were collected. For each included physician demographic, education and professional profile details were collected.

Results: Two-hundred seventy-four consultants or residents in rheumatology and 90 RA patients, both aged ≤40 years, completed the online survey. All Italian regions were equally represented for both physicians' and patients' subgroups. Considering the patients' disease referral status, 26(28.9%) received RA diagnosis at the very early stage (≤3 months), 33(36.7%) at early stage (3-12 months) and 31(34.4%) after 12 months from symptoms' onset. When asked for the priority in RA treatment objectives, the survey revealed a different priority among the subgroups with a higher importance given to fatigue resolution (p<0.0001) and morning stiffness reduction (p<0.0001) by patients and to radiological damage prevention (p=0.01) and disability reduction (p=0.0108) by physicians, while comparable priority was given by the 2 groups to pain relief, physical function restoration and work-ability recover (p>0.05 for all). When asked about the factors that could improve RA management, the survey revealed higher agreement scores for patients compared to physicians in educational need (p<0.0001), increase of outpatient visits and access to treatment (both p<0.0001) and use of digital apps (p<0.0001). Stratifying patients based on self-perceived disease control, 30(33.3%) were well controlled, 52(57.8%) moderately controlled and 8(8.9%) very poorly controlled. When questioned about their will to treatment modification once sustained remission status is achieved, patients showed a higher agreement of maintaining the treatment unchanged (p=0.0002) and a higher fear of modification consequences (p<0.0001) compared to physicians, mostly if not guided by the treating rheumatologist or out of established decisional algorithms.

Conclusion: Young patients with RA and young rheumatologists have variable agreements on treatment aims and priority. In particular, when dealing with the sustained remission status, a shared decisional algorithm between physicians and patients is needed to reduce patients fear and improve their empowerment.

IMPACT OF DISEASE ACTIVITY ON SLEEP DISORDERS IN RHEUMATHOID ARTHRITIS: A CROSS SECTIONAL STUDY ABOUT 100 PATIENTS

Keywords: Rheumatoid arthritis, Lifestyles

M. Brahem[1], B. Jebali[1], S. Abdellatif[1], R. Sarraj[1], O. Jomaa[1], H. Hachfi[1], Y. Mohamed[1]. *[1]Hôpital Universitaire Tahar Sfar, Service Rhumatologie, Mahdia, Tunisia*

Background: Rheumatoid arthritis (RA) is an inflammatory autoimmune disease, characterized by joint pain, joint swelling in period of active disease and poor sleep.
Objectives: The present study aims to evaluate the sleep disorders in RA patients and to determine their relationship with disease activity.
Methods: This is a cross sectional study including RA patients followed in the rheumatology department at TAHER SFAR university hospital in Mahdia. All patients were diagnosed with RA based on 2010ACR/EULAR criteria. For each patient, we evaluated the Epworth sleepiness scale (ESS) [0-24] and Pitsburg sleep score [0-21] with its 7components.
Results: We included 100 participants with a mean age of 53,2 ±11,2 years [21-76 years] in which most of them (89%) were female. The average duration of diseases was 11,1±8,9 years [1- 40 years]. The assessment of the RA activity showed a mean DAS28(ESR) and DAS28(CRP) of 3.88±1.19 [1-6.15] and 4.6 ±1.19 [1-6.15] respectively. Highly active RA (DAS 28 ≥ 5.1) was found in 34 patients. The mean Epworth score was 7,9±5,6 [0-24], 28 patients (28% of cases) had signs of daytime sleepiness (ESS ≥ 11 points). The mean Pittsburgh global score was 6.9± 5.1 [0-19]. 51 patients (51% of cases) had disturbed sleep (PSQI >5.5 points). Over half of participants (65.7%) rated the quality of sleep as very good or fairly good. 47.5 % of them were scored 0 for sleep duration; however, 17,2 % were sleeping fewer than five hours a night. 26 participants had long sleep latency (>1 hour). The average sleep efficiency score was 0.92 ±1.25 [0-3]; only 21 reported such complaints. The mean score for sleep disturbance was 1.19±0.86 [0-3] and for daytime dysfunction was 0.79 ± 1.05 [0-3]; however, half of them (55%) presented this complaint. 86,9% of patients have not used a sleeping medication. Statistical analysis showed that the Pittsburg score was associated with a severe activity stage(p=0.045). Furthermore, we did not found any relationship between ESS and the disease activity.
Conclusion: Sleep disorders are common among RA patients and were frequently associated with severe disease activity.

AB0243 ASSOCIATION BETWEEN THE GERIATRIC NUTRITIONAL RISK INDEX (GNRI) AND THE DISEASE ACTIVITY IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Diet and nutrition, Rheumatoid arthritis, Prognostic factors

M. Ardhaoui[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1].
[1]Fattouma Bourguiba Hospital, Rheumatology, Monastir,Tunisia

Background: The Geriatric Nutritional Risk Index (GNRI) is a tool that assesses the risk of malnutrition-related complications in elderly patients. Some recent publications have suggested that the GNRI could predict disease activity in people followed for rheumatoid arthritis (RA) [1].
Objectives: Our aim was to evaluate the correlation between the GNRI and the disease activity in elderly RA patient.s.
Methods: This is a cross-sectional study including patients followed for RA and aged at least 65 years. The GNRI was calculated for all patients: *GNRI = [1.489*albumin (g/L)] + [41.7 *(weight/WLo)]*, where WLo means ideal weight and was calculated from the **Lorentz** equations: for men: H-100-[(H-150)/4]; for women: H-100-[(H-150)/2.5](H: height).
Results: We included 63 patients (52 women and 11 men). The mean age was 68.17±4.35 years. The median duration of disease progression was 11 years with an IQR of [4-16]. The mean DAS28 was 3.72±1.48. The mean HAQ was 1.6±0.58. The median value of GNRI was 116.47 with an IQR of [106.6-125.12] and extremes ranging from 70.06 to 145.02. According to the GNRI, 58 patients (92.1%) had a GNRI > 98 indicating no nutritional risk, 2 patients (3.2%) were low risk with GNRI between 92 and 98, no patient had a GNRI between 82 and 92 indicating moderate risk and 3 patients (4.8%) had a GNRI < 82 indicating a high risk of malnutrition-related complications. After statistical analysis, we found significant association between GNRI and DAS28 score (p=0.05). We also found a significant association between GNRI and higher ESR (p=0.03), CRP (p<0.001) and higher daily doses of corticosteroids (p=0.024). However, we did not found significant association between the GNRI and advanced age (0.11), duration of RA progression (p=0.07), VAS of pain (p=0.2) or with HAQ score (p=0.06).
Conclusion: Our results showed that the GNRI is associated with DAS28, inflammatory biomarkers and higher corticosteroid doses. The GNRI could be used as a simple and reliable tool to assess both nutritional status and disease activity in RA elderly patients.

AB0244 ROLE OF FATIGUE IN DIFFICULT TO TREAT RHEUMATOID ARTHRITIS PATIENTS OUTCOME

Keywords: Rheumatoid arthritis, Quality of life, Mental health

J. P. Otazu Moudelle[1], D. Freites[1], M. Rodríguez Laguna[1], C. Hormigos[1], M. P. Álvarez Hernandez[1], A. Madrid García[2], L. Abasolo[2], L. León[2]. *[1]Hospital Clínico San Carlos, Rheumatology, Madrid, Spain*; *[2]Instituto de Investigación Sanitaria San Carlos (IdISSC), Rheumatology, Madrid, Spain*

Background: In difficult to treat rheumatoid arthritis patients (D2T RA), a wide spectrum of factors may contribute to the persistence of signs and/or symptoms, although these are not always directly related to inflammation (eg, functional disability, pain and fatigue). Of these, fatigue is still the least evaluated and taken into account.
Objectives: To identify the role of fatigue in D2T RA.
Methods: Cross-sectional study. 143 patients patients followed up in the rheumatology outpatient clinic of Hospital Clínico San Carlos, Madrid, Spain were included. Data were collected between July 2018 and November 2022. All patients met the ACR/EULAR 2010 criteria and they were in treatment with Biological agents (anti-TNF and Non anti-TNF) or Targeted Synthetic DMARDs (jakinibs). D2T RA was defined based on EULAR criteria (treatment failure, signs suggestive of currently active/progressive disease, and management being perceived as problematic by the rheumatologist and/or patient). Main variable: Fatigue was assessed by the Bristol Rheumatoid Arthritis Fatigue Multidimensional Questionnaire (BRAF-MDQ). Covariables: Sociodemographic and disease-related variables. Statistical analysis. A descriptive and comparative analysis was carried out for the different variables. To identify factors independently associated to D2T RA a multivariable logistic regression was applied. Results were expressed as OR with their corresponding 95% CI. A value of $p < 0.05$ was consider as statistically significant.
Results: The study population comprised 143 patients and 22 (15.38%%) developed D2T RA. The D2T RA group were older, with a higher DAS28 and disability. Sociodemographic, clinical, disease-related variables, and the fatigue scores used in the study are shown in Table 1. In our final logistic regression model, age (OR: 1.05; p=0.017) and fatigue were independently associated with D2T RA (OR: 1.04; p=0.011).
Conclusion: Despite the absence of an explicit mention of fatigue in the definition of AR D2T, it appear to be a main factor explaining the D2T RA outcome. The evaluation and management of fatigue should be one of the objectives in the treatment of patients with RA.

Table 1. Characteristics of the sample

Variable	D2T RA (n=22)	Non D2T RA (n=121)	p
Age (years), mean (SD)	62.82 (13.45)	56.19 (11.89)	0.019
Women, n (%)	11 (50)	73 (60.83)	0.34
Disease duration, mean (SD), years	17.76 (8.47)	13.41(8.74)	0.03

AB0245 IMPACT OF EXTRA-ARTICULAR RHEUMATOID ARTHRITIS MANIFESTATIONS ON ATLANTOAXIAL SUBLUXATION

Keywords: Prognostic factors, Osteoporosis, Rheumatoid arthritis

H. Ferjani[1], H. Bettaieb[1], D. Ben Nessib[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]. *[1]Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Rheumatology, Mannouba, Tunisia*

Background: The cervical spine is frequently affected during RA. It's the third joint location after the hands and feet [1].

Objectives: The objective of our work was to investigate the association between atlanto-axial subluxation (AAS) and the presence of extra-articular manifestations (EAM).

Methods: This is a cross-sectional comparative, single-center and hospital-based study of 102 RA patients (ACR/ EULAR 2010). Population was divided into two groups: Group 1 (study group) including 51 patients with AAS and Group 0 (control group) including 51 RA patients without AAS. AAS was defined as: the presence of an anterior C1C2 diastasis on the cervical spine radiograph in hyperflexion and/or by the presence of anterior, posterior, lateral or rotational C1C2 dislocation on MRI with/or without inflammatory signal.

Results: The study group (G1) consisted of 37 women and 14 men (M/F sex ratio = 0.37). The control group (G0) consisted of 40 women and 11 men (M/F sex ratio =0.28). The mean age was 60.3 ± 14.1 and 59 ± 11.3 years in G1 and G0, respectively. Median disease duration was 144 [6-480] and [5-216] months in G1 and G0 respectively. In G1, the median time to onset of AAS was 48 months [0-492]. At AAS diagnosis, EAM were present in 49% of G1 patients: dry ocular and/or mouth syndrome (60%), pulmonary involvement (16%) (3 cases of usual interstitial pneumonia and one case of constrictive bronchitis) and rheumatoid subcutaneous nodules (24%). Furthermore, 30 patients of G1 had bone densitometry. Osteoporosis and osteopenia were found respectively in 66% and 26% of cases. In the control group, only 3.9% of G0 patients had EAM. It was dry ocular syndrome in 2 patients. Bone densitometry, performed in 34 patients, was normal in 26.5% of cases. Osteoporosis and osteopenia were found respectively in 35.3% and 38.2% of patients. In analytical study, patients of G1 had higher prevalence of EAM (p<0.001) and osteoporosis (p=0.012). Though, no association was found between the presence of AAS and osteopenia (p=0.79).

Conclusion: In this work, patients with AAS had significantly more EAM and osteoporosis. A regular monitoring of cervical spine radiographic assessment in these patients is highly recommended to prevent such complication.

AB0246 IMPACT OF RHEUMATOID ARTHRITIS DISEASE ACTIVITY ON PATIENT'S NUTRITIONAL STATUS

Keywords: Quality of life, Diet and nutrition, Rheumatoid arthritis

H. Boussaa[1], D. Souissi[2], S. Miladi[2], A. Fazaa[2], M. Yasmine[2], L. Souabni[2], K. Ouenniche[2], S. Kassab[2], S. Chekili[2], K. Ben Abdelghani[2], A. Laatar[2]. *[1]Mongi Slim University Hospital, Rheumatology, Tunis, Tunisia*; *[2]Mongi Slim University Hospital, Rheumatology, Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is a potentially destructive chronic inflammatory disease that can be responsible for a deterioration of quality of life. Deformities, loss of autonomy and depression can lead to malnutrition in these patients.

Objectives: The aim of this study was to evaluate the impact of RA disease activity on the patient's nutritional status.

Methods: We conducted a cross-sectional study including RA patients according to the ACR/EULAR 2010 criteria. Sociodemographic data and disease parameters were collected. RA activity was assessed using the Disease Activity Score (DAS28), Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). Nutritional status was assessed by the Mini-Nutritional Assessment (MNA). Then, the patients were divided into two groups: Group 1: no risk of malnutrition if the MNA score was >23.5 and Group 2: risk of malnutrition (if the MNA score was between 17 and 23.5) or poor nutritional status (if the MNA score was <17). The significance value "p" was set at 0.05.

Results: A total of 30 patients were included. The gender ratio was 0.43 with a female predominance. The mean age was 57.8±13.8 years [25-79]. The most frequent comorbidities were arterial hypertension (43.3%), diabetes (20%) and gastritis (16.7%). RA was immunopositive and erosive in 80% of cases. The mean duration of the disease was 14.4 years [13-23]. More than half of the patients (55.2%) were on corticosteroids, 48.3% were on methotrexate, 27.6% were on biotherapy, 13.8% were on sulphasalazine and 6.9% were on hydroxychloroquine. The mean value of the visual analogue pain scale was 4.7 [0-9] and the mean value of the patient's global assessment was 5 [2-9]. The mean ESR and CRP values were 50.6mm [3.9-131] and 22.2mg/l [0.9-77], respectively. The mean DAS-28ESR was 4.2± 1.3[1.1-6.9] reflecting moderate activity. The mean body mass index was 25.1±4.45kg/m² [16.8-39] and the mean brachial muscle circumference was estimated at 26.1±3.6cm [20-31]. The mean DAS28 ESR score was higher in G2, but the difference was not statistically significant. A significant association was noted between RA activity level and patient nutritional status (p=0.017). In patients with high activity, 71.3% were at risk of malnutrition and one patient was in poor nutritional status. Among patients with moderate activity, 42.9% were at risk of malnutrition and 50% had normal nutritional status. Among patients with low activity, the majority (60%) had normal nutritional status.

Conclusion: Our study shows an impact of RA disease activity on the patient's nutritional status. The higher the disease activity, the higher the patient's risk of malnutrition.

Rheumatoid arthritis - prognosis, predictors and outcome

AB0247 WHICH PARAMETERS INFLUENCE DOMESTIC AND OCCUPATIONAL PRODUCTIVITY IN RHEUMATOID ARTHRITIS

Keywords: Quality of life, Work-related issues, Rheumatoid arthritis

S. Miladi[1], W. Belhaj[1], F. Alia[1], H. Boussaa[1], M. Yasmine[1], K. Ouanniche[1], S. Leila[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia*

Background: Rheumatoid arthritis (RA) is a chronic rheumatism that mainly affects young adults. It has an impact on the patient's quality of life and professional abilities.
Objectives: The aim of this study was to evaluate the influence of RA activity, its impact, and its functional impact on patients' domestic and professional productivity.
Methods: We conducted a cross-sectional study over an 8-month period. Seventy adult patients diagnosed with RA for more than a year and receiving an antirheumatic therapy were interviewed. We assessed disease activity by the Disease Activity Score (DAS28), the impact of RA by the Rheumatoid Arthritis Impact of Disease (RAID) and functional impairment by the Health Assessment Questionnaire (HAQ). The impact of RA on domestic and professional productivity over the last month was assessed by the Rheumatoid Arthritis Specific Work Productivity Survey (WPS-RA).
Results: We noted a female predominance (63 women and 7 men) with an average age of 57.8 ±10.6 years [29-81]. At the time of the study, 13 (19%) patients were employed, 4 (6%) were unable to work because of RA while the rest were either unemployed or retired. The mean DAS28 was 3.31 ±1.13 [1.14-5.92]. The DAS28 was positively correlated with the degree of interference of RA on domestic work (p=0.001), professional work (p=0.005), and the decrease of domestic productivity (p=0.012) and professional productivity (p=0.021). Absenteeism was not influenced by RA activity (p=0.109). The average RAID score was 4.72 ±2.11 [0.6-9.48]. The RAID score was positively correlated with the degree of interference of RA on domestic work ($p < 0.001$) and professional work ($p = 0.013$). No correlation was noted between the impact of RA and the decrease of domestic productivity (p=0.511), professional productivity ($p = 0.109$) or the absenteeism ($p = 0.248$). The mean value of HAQ score was 1.04 ±0.61 [0-2.60]. We noted a positive correlation between the HAQ score and the degree of interference of RA at domestic work ($p < 0.001$) as well as the interference of RA at professional work ($p = 0.012$). The decrease of domestic productivity (p=0.133) and professional productivity (p=0.128) as well as the absenteeism (0.125) were not correlated with the functional impairment of RA.
Conclusion: According to these results, RA activity, impact, and functional impairment influenced mainly the degree of RA interference at work and domestic work. Productivity was essentially correlated with RA activity. Absenteeism was not influenced by any of the parameters studied previously.

AB0248 USEFULNESS OF THE C-REACTIVE PROTEIN TO ALBUMIN RATIO IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Biomarkers

M. Ardhaoui[1], M. Ghali[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia*

Background: C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are commonly used to assess rheumatoid arthritis (RA) activity. New biomarkers have been developed, such as the CRP to albumin ratio (CAR), which has been proposed as a new inflammatory marker for monitoring disease activity in RA [1].
Objectives: The aim of our study was to evaluate the relationship between the CAR and RA parameters in a population of elderly patients.
Methods: We conducted a cross-sectional study including patients followed up for RA and aged 65 years or older. CRP, albumin, ESR, orosomucoid and haptoglobin levels were dosed. We calculated the CAR for each patient.
Results: Sixty-three patients (11 men and 52 women) were included. The mean age was 68.17±4.35 years. The median duration of disease progression was 11 years with an IQR of [4-16]. The median CRP was 8.33 mg/L. Mean albumin level was 41.43±4.58 g/L. The median ESR was 47 mm at 1 hour. The mean orosomucoid level was 1.29±0.46 g/L. The mean haptoglobin value was 2.07±0.97 g/L. The mean CAR value was 0.51±0.81 [0.01-3.72]. After statistic analysis, we found a significant association between the CAR and the DAS28 (p=0.03). In addition, CAR was positively correlated with ESR, CRP and Orosomucoid (p<0.001, p=0.01 and p=0.002, respectively). In addition, this ratio was significantly associated with HAQ score (p=0.01), and was higher in patients with major functional impairment (HAQ>2) (p=0.002). However, we did not found significant association between CAR and age, duration of evolution, VAS of pain, seropositivity, structural damage or with the use of corticosteroids.
Conclusion: Our study showed the association of the CAR with DAS28, inflammatory biomarkers and functional impairment among elderly RA patients. This suggests that this ratio could be a reliable tool as a prognostic index to assess disease activity and inflammation in this population.

AB0249 RHEUMETRIC QUANTITATIVE 0-10 PHYSICIAN ESTIMATES OF INFLAMMATION, DAMAGE, AND DISTRESS IN RHEUMATOID ARTHRITIS: VALIDATION AGAINST REFERENCE MEASURES

Keywords: Rheumatoid arthritis, Fibromyalgia, Outcome measures

N. Rodwell[1,2,3], G. Hassett[1,2], P. Bird[3], T. Pincus[4], J. Descallar[2,3]. [1]*Liverpool Hospital, Rheumatology, Liverpool, Australia*; [2]*Ingham Institute for Applied Medical Research, Rheumatology, Liverpool, Australia*; [3]*UNSW Sydney, Medicine and Health, Sydney, Australia*; [4]*RUSH University Medical Center, Rheumatology, Chicago, United States of America*

Background: A physician global assessment (DOCGL) distinguishes active from control treatments in rheumatoid arthritis (RA) effectively in clinical trials. However, RA trials select for patients who have high inflammatory activity, generally only 5-30% of all RA patients. In routine care, DOCGL, and all clinical RA measures and indices, may be elevated not only by inflammatory activity but also by joint damage and/or patient distress, complicating interpretation of RA indices and clinical decisions. A RheuMetric checklist provides feasible physician 0-10 subscale estimates of inflammation (DOCINF), damage (DOCDAM), and distress (DOCSTR), in addition to DOCGL.
Objectives: To analyze criterion validity and specificity of 0-10 RheuMetric physician estimates for inflammation, damage, and distress, by comparing these estimates to reference RA core data set measures, as well as joint deformity/limited motion (DJC), radiographic scores and indices for FM and DEP.
Methods: A cross-sectional assessment was performed at one routine care visit in Liverpool, Australia. Rheumatologists recorded RheuMetric, with 4 0-10 scales for DOCGL, DOCINF, DOCDAM, DOCSTR, and 28 joint counts for swelling (SJC), tenderness (TJC), and limited motion/deformity (DJC), laboratory tests, and radiographic scores. Patients completed a multi-dimensional health assessment questionnaire (MDHAQ), which includes RAPID3 (routine assessment of patient index data), FAST4 (fibromyalgia assessment screening tool) and MDS2 (MDHAQ depression screen). RheuMetric estimates of inflammation, damage and distress were compared to reference and other measures using correlations and linear regressions.
Results: In 173 RA patients, variation in RheuMetric DOCINF was explained significantly by SJC and inversely by disease duration, DOCDAM by DJC, radiographic scores, and physical function, and DOCSTR by fibromyalgia and depression.
Conclusion: RheuMetric DOCINF, DOCDAM, and DOCSTR estimates were correlated significantly and specifically with reference measures of inflammation, damage, and distress, documenting criterion validity.

Table 1.

Significant Variables	Multivariable analyses

AB0250 PATIENT BELIEFS AND FEARS IN RHEUMATOID ARTHRITIS ASSESSED BY QUESTIONNAIRE FOR ARTHRITIS DIALOGUE

Keywords: Rheumatoid arthritis, Quality of care

R. Sarraj[1], M. Brahem[1], O. Jomaa[1], A. Ben Salem[1], B. Jebali[1], S. Abdellatif[1], H. Hachfi[1], Y. Mohamed[1]. [1]*Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia*

Background: Misinterpretation of patient beliefs can complicate shared decision making in rheumatoid arthritis (RA) leading to inadequate treatment adherence.
Objectives: The aim of this study was to determine patients' beliefs and fears about their disease and its treatment.
Methods: This is a cross sectional study conducted among patients diagnosed with RA based on ACR/EULAR criteria. All patients completed the Arthritis Dialogue Questionnaire (QuAD) which included 21 opinion statements that they scored from 0 (totally disagree) to 10 (totally agree). A score of more than 7 was interpreted to mean that the person significantly agreed with the opinion. The beliefs in this questionnaire include those that are supported by scientific evidence and those that are inconsistent with current medical opinion.
Results: A total of 56 RA patients were included in this study. There were 53 females (94.6% of cases) and 3 males (5.4%). The mean age of participants was 51.5 ± 11.7 years [21-74 years]. The average duration of disease was 11.5 ± 8.6 years [1-40 years]. The mean of DAS 28 ESR and DAS 28 CRP were respectively 4 ± 1.5 and 3.4 ± 1.5. The socio-economic status was low in 14 patients (25% of cases). 19.6% of patients were illiterate and 50% of patients had no education beyond primary level. Twenty-four patients (42.8%) believed that the onset of RA and its flare-ups were due to physical overload. As a result of these false beliefs, these same patients did not believe that doing sport or a physical activity can reduce flare-ups. Sixteen patients (28.5%) believed that RA was triggered by an emotional shock and 10 (17.8%) patients considered that flare-ups of the disease are triggered by psychological factors. The belief that the disease has a genetic cause was reported by 11 patients (19.6%). Uncertainty about disease progression was reported by 31 patients (55.3%) and 19 patients (33.9%) thought that all treatments have negative effects in the long term. The relationship between change in the weather and disease flare-ups was reported by 10 patients (17.8%).
Conclusion: The most widely held beliefs were related in our study to uncertainty about disease progression, physical and psychological factors that may trigger the disease, and fears about side effects of treatments. It is important to understand patients' beliefs about RA in order to optimize the adherence to treatment and to encourage patients to take up healthy lifestyles and habits that are beneficial for their disease management.

AB0251 RELATIONSHIP BETWEEN ANXIETY, DEPRESSION AND FUNCTIONAL DISABILITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Quality of life, Rheumatoid arthritis

M. Brahem[1], R. Sarraj[1], O. Jomaa[1], S. Abdellatif[1], B. Jebali[1], H. Hachfi[1], Y. Mohamed[1]. [1]*Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia*

Background: The management of rheumatoid arthritis (RA) must be multidisciplinary in order to relieve pain, prevent functional disability and improve quality of life.
Objectives: The objective of this study was to evaluate the impact of functional status on the psychological state in patients with RA.
Methods: This is a cross sectional study conducted among patients diagnosed with RA based on ACR/EULAR criteria. We assessed them for anxiety and depression symptoms using the Hospital Anxiety and Depression scale (HADS). The functional status was assessed by the Health Assessment Questionnaire (HAQ).
Results: A total of 100 RA patients were included in this study. There were 89 females (89% of cases) and 11 males (11%). The mean age of participants was 53.2 years [21-76 years]. The average duration of disease was 11.1 years [1-40 years]. Very active RA disease (DAS 28 greater than 5.1) was observed in 34 patients. The mean HAQ value was 1.28 [0-2.87]. 25% of our patients had high functional disability (HAQ >2). Nearly half of the study population (54% of cases) suffered from depression and/or anxiety symptoms. The mean HADS-D score was 8.39 [0-16] and thirty patients (30% of cases) had certain depressive symptoms (HADS-D ≥11). The mean HADS-A score was 7.79 [0-15] and 24 of our patients (24% of cases) presented certain symptoms of anxiety (HADS-A≥11). In statistical analysis, the HAD-A scale was associated with higher HAQ level (p<0,01). In addition, depressive patients (HADS-D ≥11) had higher HAQ level than patients without signs of depression with significant difference (p<0.01).
Conclusion: Our study showed that more than quart of RA patients suffers from anxiety and/or depression, and these troubles were related to functional disability. This suggests that treatment should focus also on improving physical function, detection and management of depression or anxiety.

AB0252 IMPACT OF ADHERENCE TO THE MEDITERRANEAN DIET ON DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Disease-modifying drugs (DMARDs), Diet and nutrition

S. Rekik[1], S. Nouicer[1], S. Boussaid[1], S. Rahmouni[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. [1]*Rabta, Rheumatology, Tunis, Tunisia*

Background: The Mediterranean diet (MD), mainly consists of olive oil, cereal products, fresh or dried fruit and vegetables, nuts, a moderate amount of dairy and meat, and many condiments and spices, has been suggested to have a beneficial effect on mortality and cardiovascular diseases. However, there is limited evidence regarding its impact on rheumatoid arthritis (RA) disease activity.
Objectives: The aim of this study was to assess association between adherence to MD and disease activity in RA patients.
Methods: In this cross-sectional study, we included patients with RA in remission or low disease activity. Patients with intestinal disease and smorkers were not included. Socio demographic data (age, sexe, educational level and living area) were recorded. Tender and Swollen Joint Count (T/SJC), Disease Activty Score (DAS28), Clinical Disease Activity Index (CDAI) and Score Disease Activity Index (SDAI) were used to access disease activity. Levels of C-reactive protein (CRP) and hemoglobine (Hb) were determined. Medication (paracetamol, Non Steroidal Anti-inflammatory Arugs (NSAIDs) and Disease-modifying antirheumatic drugs (DMARDs)) were recorded. We assessed MD adherence through a 14-item questionnaire in RA patient. The MD adherence score was classified as follows: good adherence (≥ 10 points) and low and medium adherence (≤ 9 points). We divided patients into two groups: G1: good adherence and G2: low and medium adherence to MD. We compared parameters of G1 and G2 using the Mann-Whitney U test.
Results: We enrolled 39 patients (34 female) with mean age of 52.74 ± 11.31 [20-74] years. Most of patients lived in rural area (61.5%). Half of patients (53.8%) had primary school level. The mean disease duration was 8.68 ± 6.6 years. The mean CRP and Hb levels were respectively 2.9 ± 9.67 [0-21] and 11.72 ± 1.4 [10-14]. The mean DAS28, CDAI and SDAI were respectively: 2.06 ± 0.71 [1-3.1], 5.46 ± 3.4 [1-10] and 8.26 ± 5.62 [2-28]. The most of patients were on paracetamol (53.9%) and conventional synthetic DMARDs (82.1%). NSAID were used by 35.9% of patients. The mean MD score was 9.1 ± 2.67 [4-12]. G1 enrolled 20 patients and G2 19. No significant differences emerged in the distribution of sexe, age, living area and educational level between two groups. G1 had significant lower disease activity in comparison to G2: (median [extrema]) TJC (0 [0-1] vs 1 [0-2], p=0.02), DAS28 (1.7 [1 - 3.1] vs 2.2 [1.7-3.1], p=0.001), CDAI (2 [1-7] vs 9 [3 - 11] p<0.001) and SDAI (4 [2 - 9] vs 11 [5 - 30], p<0.001). No significant differences was observed in SJC and CRP level, p=0.11 and p=0.22 respectively. However, Hb levels were higher in G1 (13 [13-14]) than in G2 (10 [10-13]), p<0.001. G2 had higher paracetamol and NSAID consumption with 84.3% and 57.9% vs 57.9% and 84.3 % respectively. Less use of biological DMARD were observed in G1 since all patients were on conventional synthetic DMARDs.

Conclusion: In our study, higher adherence to a MD was associated with reduced RA activity, symptomatic treatement consumption and more remission and low disease activity with conventional synthetic DMARD. Therefore, nutritional therapy could be a promising adjunct to pharmacological therapy in RA. Further studies are needed to confirm these findings.

AB0253 IDENTIFICATION OF FACTORS ASSOCIATED WITH A WORSE OUTCOME -EXITUS- IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SEVERE INFECTION

Keywords: Prognostic factors, Rheumatoid arthritis

P. Vela Casasempere[1,2,3], L. Vegara Vicea[1], S. Gomez-Sabater[3], R. Caño-Alameda[3]. [1]*Universidad Miguel Hernández (UMH), Medicina, San Juan de Alicante, Spain*; [2]*General University Hospital of Alicante, Reumatologia, Alacant, Spain*; [3]*Instituto de Investigación Sanitaria y Biomédica de Alicante (ISABIAL), GRUPO 16, Alicante, Spain*

Background: Infections constitute an important and frequent cause of morbidity and mortality in patients with chronic inflammatory and systemic autoimmune rheumatic diseases. In rheumatoid arthritis (RA), this increased risk has been related to the immune system alterations inherent to the disease, the drugs used to control it (corticosteroids, DMARDs and immunosuppressants) and associated comorbidities. Most studies focus on the search for factors associated with the development of infections but do not explore the worst outcome: patient failure.

Objectives: To identify factors that help to predict an unfavorable outcome (exitus) after a severe infection in patients with rheumatoid arthritis.

Methods: This study was a retrospective case-control study at a single institution over a 10-year period. Patients with a diagnosis of rheumatoid arthritis with hospital admission for infection from January 1, 2010, to December 31, 2019 (pre-pandemic SARS-COV-2) were selected. The main variable was exitus due to the infectious episode. We collected: age, sex, time of evolution of RA, previous treatment and at the time of admission, number of admissions for infection, location of the infection, comorbidities, and other associated serious diseases. The statistics included a descriptive analysis of the different variables (expressed as median and interquartile range -IR- for quantitative variables and percentages for qualitative variables), and the association study using the $\chi 2$ test or Fisher's exact test for qualitative variables, and t-student or Mann-Whitney U and Kruskal Wallis for quantitative variables.

Results: We obtained 152 patients (71.7% female, 28.3% male), with a total of 214 episodes of admission for infection (115 patients with 1 episode (75.7%), 25 (16.4%) with 2 episodes, 6 being the maximum number of episodes recorded). The median age at admission was 77 years, and the median time of RA evolution was 8 years (IR 4-16). The location of the infection responsible for admission was mainly respiratory and urinary. Forty-eight patients died in the episode (31.6% of the sample, 15 males and 33 females, median age 81.5 years (IR 69.5-86.5)). Comparing the patients with unfavorable outcomes (exitus) with the rest, we only found a statistically significant difference in the number of previous admissions (p=0.011), and in the coexistence of some other serious disease (exitus 85.4%, rest 61.5% p=0.003). There were no differences by sex, age, time of RA evolution, drugs, location of the infection, or comorbidities.

Conclusion: A history of hospital admission due to infection, and having another serious disease, are factors associated with an unfavorable outcome (exitus) in patients with RA admitted for an infectious process.

AB0254 ACCEPTABILITY OF A SMARTPHONE APPLICATION AMONG TUNISIAN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Rheumatoid arthritis, Self-management, Quality of care

M. Yasmine[1], E. Hannech[1], S. Miladi[1], A. Fazaa[1], H. Boussaa[1], K. Ouenniche[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology Department, Tunis, Tunisia*

Background: Nowadays, the utility of smartphone application for patients with rheumatic diseases, especially rheumatoid arthritis (RA) is well established and codified [1]. Indeed, patient-centered smartphone applications have the potential to assist with the adoption and maintenance of self-management behaviors [2].

Objectives: The purpose of our study was to investigate the willingness of RA patients to use smartphone applications for managing their disease.

Methods: This was a cross-sectional survey conducted in our rheumatology department including patients with RA, fulfilling the ACR/EULAR 2010 criteria. Sociodemographic data were initially collected. Patients were invited to answer a questionnaire regarding their willingness to accept smartphone application as part of their management strategies. We evaluated their points of view and suitability by inquiring about their experience with smartphones, as well as the previous applications used. Moreover, additional questions probed the patients' willingness to pay for this monitoring app.

Results: The study included 40 RA patients. There was a female predominance with a sex ratio of 0.11. The mean age was of 52.25±14.4 years [21-78]. The mean disease duration was of 11.97±6.69 years [1-29]. Regarding the educational level, 10 patients (25%) were illiterate, 14 (35%) had primary education, 11 (27%) had secondary education, and 5 patients (13%) were university graduates. Most of them (60%) were unemployed, and 13% were retired. As for marital status, 37 patients (92%) were married, and 1 was divorced. According to the patients, the two main reported mobile phone utility concerned the ability to communication with other individuals (48%) and internet navigation (52%). None of them had uploaded a healthcare application before and only 4 patients had previously contacted their doctor via text messages or e-mail. Overall, 67% of the respondents agreed on the usefulness of a patient-centered smartphone app and 65% were willing to accept this alternative as a model of care. Similarly, most of the patients refused to pay for the app (63%). The adherence to the smart app was significantly higher among females compared to males (p=0.011). Moreover, willingness to accept these applications was associated with a higher level of education without reaching a statistically significant correlation (p=0.07). There was no association between the marital, profession, age or disease duration and the acceptability of the smartphone app (p=0.418, p=0.246, p=0.382 and p=0.527 respectively).

Conclusion: Findings from this study showed that RA patients were not as reluctant to accept a health-related smart phone application. The willingness to adopt these applications was higher among female patients. Further steps are needed for a better implementation of this utility in clinical practice.

AB0255 CORRELATION BETWEEN PATIENT GLOBAL ASSESSMENT AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: ANY CHANGE OVER TIME?

Keywords: Outcome measures, Patient reported outcomes, Rheumatoid arthritis

A. Fazaa[1], H. Boussaa[1], K. Ouenniche[1], S. Miladi[1], M. Yasmine[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim University Hospital, Rheumatology, Tunis, Tunisia*

Background: Patient-reported outcomes (PROs) such as the Patient Global Assessment (PGA) are included in the definition of disease activity in rheumatoid arthritis (RA). Major determinants of the PGA are pain severity, functional limitations and fatigue. In contrast, the correlation with more objective measures of inflammation is weaker. In the early stages of the disease, the PGA might in theory more strictly reflect the patient's perception of inflammation.

Objectives: The aim of this study was to investigate the correlations between the PGA and disease parameters in patients with RA over time.

Methods: We conducted a prospective study including patients with RA (ACR/EULAR 2010). Demographic data and the following disease parameters were collected at inclusion and at 12 months follow-up: PGA, pain Visual Analog Scale (VAS), tender joint count (TJC), swollen joint count (SJC), Erythrocyte Sedimentation Rate (ESR), C Protein Reactive (CRP), Disease Activity Score 28 (DAS28), and Health

Assessment Questionnaire (HAQ). Fatigue was assessed using the Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) which is a short 13-item questionnaire validated in RA. The score FACIT-F ranges between 0 and 52. Fatigue was considered mild if the FACIT-F score was ≥40, moderate if 20≤FACIT-F<40 and severe if 0≤FACIT-F<20. A *p* value inferior to 0.05 was considered significant.

Results: We included 100 RA patients (84 women and 16 men) with a mean age of 49.5±10 years old [18-65]. The mean disease duration was 87.3 months [1-360]. Rheumatoid Factor (RF) and Anti-Citrullinated Protein Antibodies (ACPA) were positive in 75% and 72.6%, respectively. At inclusion, the mean PGA was 47.8 cm [0-100] and the mean pain VAS was 49 cm [0-100]. The mean TJC and SJC were 5.3 [0-36] and 1 [0-9], respectively. The mean levels of ESR and CRP were 38.1 mm [10-120] and 10.8 mg/l [2-61], respectively. The mean DAS28 ESR was 3.68 [1.90-8.33] and the mean HAQ score was 0.9 [0-2.75]. The mean FACIT-F score was 27.1 [0-51] in RA patients versus 46.2 [0-52] in healthy controls (p<0.001). Among RA patients, 57% had moderate fatigue and 26% had severe fatigue. A significant positive correlation was noted between PGA and, TJC (r=0.508, p<0.001), SJC (r=0.331, p=0.001), pain VAS (r=0.763, p<0.001), ESR (r=0.364, p<0.001), DAS28 ESR (p=0.743, p<0.001) and HAQ (r=0.660, p<0.001). A significant negative correlation was noted between GPA and FACIT-F score (r=-0.658, p<0.001). At 12 months follow-up, the correlations became stronger between PGA and, TJC (r=0.664, p<0.001), SJC (r=0.673, p<0.001), pain VAS (r=0.893, p<0.001), ESR (r=0.536, p<0.001), DAS28 ESR (p=0.867, p<0.001), HAQ (r=0.686, p<0.001), and FACIT-F score (r=-0,792, p<0.001). A positive correlation was also noted between PGA and disease duration (r=0.205, p=0.045).

Conclusion: Disease activity, functional limitation, pain and fatigue directly correlate with PGA. This relation seems to strengthen over time as RA patients gain the ability to better understand and assess their illness.

AB0256 ARE CRP/ALBUMINE, PLATELET/LYMPHOCYTE, NEUTROPHIL/LYMPHOCYTE RATIO INDICATORS OF SPONDYLARTHRITIS ACTIVITY?

Keywords: Biomarkers, Cell biology, Spondyloarthritis

Z. Ammor[1], N. Akasbi[2], H. Bourkhime[3], T. Harzy[2]. [1]*Medicine Faculty of Fez, Rheumatology, Fez, Morocco*; [2]*University Hospital Center of Fez, Rheumatology, Fes, Morocco*; [3]*Faculty of Medicine of Fez, Epidemiology, Fez, Morocco*

Background: Spondylitis is a chronic inflammatory rheumatism that most often affects young adult males. In recent studies it has been reported that the platelet ratio (PLR) and neutrophil lymphocyte ratio (NLR) are important in demonstrating systemic systemic inflammation, the CRP albumin ratio (CAR) has been reported as a marker of of inflammation.

Objectives: Our objective is to study the relationship between the value of CAR, PLR, NLR, and the BASDAI score.

Methods: A cross-sectional study including patients with spondyloarthritis according to ASAS 2009 criteria. For each patient CAR, PLR, NLR and BASDAI score were calculated.

Results: 112 patients were included in this study. The average age was 46.9 (+/- 12.7) years, the sex ratio M/F is 1.29, the mean duration of the disease is 7.8 years, 68.8% of the axial spondyloarthritis are severe, 70.5% of spondyloarthritis are radiographic, the average EVA pain is 61.6, 54.5% of patients have a BASDAI >=4, the average CRP is 30.16, the average SR(sedimentation rate) is 32.77, 41.7% of patientsnhave stage III sacroiliitis, 93.9% have bilateral sacroiliitis. The average CAR is 0.88 (+/-1.84), the mean PLR is 157.6, the mean NLR is 3.32, the mean CAR is of 0.88. In the bivariate analysis, the CAR ratio was significantly associated with BASDAI (p=0.038), CRP is also significantly associated with BASDAI score (p= 0.028).

Conclusion: The CAR can be a practical measurement method in the follow-up of patients with axial spondyloarthritis axial spondyloarthritis because it can be used quickly under routine ambulatory conditions,in correlation with the BASDAI.

AB0257 GENETIC EVIDENCE REVEALS A CAUSAL ROLE BETWEEN LEUKOCYTE COUNTS AND THE RISK OF RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

Y. Zhang[1,2], Q. Qiu[1,2], J. Hu[1,2], J. Hou[1,2], Q. Yu[3], P. F. He[3], X. Li[4], S. X. Zhang[4]. [1]*Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, Shanxi Province, China*; [2]*Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, Shanxi Province, China*; [3]*Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, Shanxi Province, China*; [4]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China*

Background: Accumulating inflammatory leukocytes in articular tissues is the hallmark feature of rheumatoid arthritis (RA). However, no relevant study indicates whether there is insidious causation between leukocyte count (LC) and the risk of RA. Traditional observational studies were susceptible to bias from confounding and reverse causation. It was necessary to estimate an exact correlation between LC and the risk of RA.

Objectives: This study aimed at evaluating the correlation between LC and the risk of RA by performing two-sample Mendelian Randomization(MR).

Methods: This study selected single nucleotide polymorphism (SNPs) associated($p<5e^{-8}$) with exposure (LC) from a genome-wide association study (GWAS), which included 171846 European ancestry participants and wiped off confounding factors. The association estimates of these SNPs with the risk of RA were obtained from another GWAS, including 14361 RA cases and 42923 controls. Upon SNPs were compared with SNPs related to the risk of RA and performed harmonization analysis to wipe off the irrelevant or inconsistent site SNPs. Ultimately, the remaining SNPs were selected as instrument variables(IVs). Then, we utilized two-sample Mendelian randomization (MR) to evaluate whether LC was causally associated with the risk of RA. Furthermore, Cochran's Q test, MR pleiotropy residual sum and outlier (MR-presso), and leave-one-out analysis were performed as a sensitivity test.

Results: A total of 70 independent SNPs were selected as IVs in the MR analysis of total WBC. Higher leukocyte counts were associated with a higher risk of RA (OR=1.025,95% CI: 0.998-1.053,p-value=0.038) by the IVW method (**Figure 1**). The MR-Egger regression test did not reveal any evidence of directional pleiotropy (intercept = -0.0002, stand error (SE) = 0.008, p = 0.981). In addition, leave-one-out sensitivity analysis showed similar findings, which further emphasized the effectiveness and stability of the causation. However, in the Cochrane's Q test, it turned out [Cochrane's Q statistic= 69, p-value=$3.472e^{-20}$], suggesting heterogeneity exists. For this reason, the processed steps were rechecked, and finally got, the conclusion that heterogeneity is produced from sysmaticness.

Conclusion: This study indicated the insidious causation between LC and the risk of RA. Further studies are warranted to determine how related pathways may contribute to the unnormal LC to promote the comprehension of the pathology of the happening of RA and access more therapeutic methods.

AB0258 PREPULSE INHIBITION OF THE BLINK REFLEX -A PUTATIVE MARKER OF "FIBROMYALGIANESS" - IS ALTERED IN PTS WITH RHEUMATOID ARTHRITIS COMPARED TO HEALTHY CONTROLS, BUT NOT PREDICTIVE FOR PAIN LEVEL OR THERAPEUTIC RESPONSE TO BDMARDS

Keywords: bDMARD, Fibromyalgia, Rheumatoid arthritis

J. Zavada[1], Z. Forejtová[2], L. Nováková[2], T. Serranová[2]. [1]*Institute of Rheumatology, Rheumatology, Praha 2, Czech Republic*; [2]*First Faculty of Medicine, Charles University and General University Hospital, Department of Neurology and Centre of Clinical Neuroscience, Prague, Czech Republic*

Background: Concomitant fibromyalgia (FM) is highly prevalent in pts with RA. In FM patients, altered abnormalities in processing of sensory stimuli including abnormal subcortical sensorimotor integration measured using prepulse inhibition (PPI) have been described [1]. PPI is a robust neurophysiological phenomenon in which a weak sensory event leads to reduction in magnitude of the reflex response that would be otherwise elicited by a reflex-eliciting stimulus presented 30-500 ms later. Its physiological purpose is to protect salient from irrelevant information at the subcortical level, thereby preventing undesired motor reactions. In RA patients, abnormal processing of sensory information may affect subjective aspects of disease activity indices, and thus influence treatment decisions.
Objectives: We aimed to investigate, whether PPI may serve as a predictive marker of FM in pts with RA starting their first targeted therapy.
Methods: PPI was measured in 15 patients with RA before initiation of treatment with bDMARDs, and 50 healthy controls (HC). We examined the effect of a weak electrical stimulus to the index finger (prepulse) on the blink reflex magnitude induced by electrical stimuli delivered to the supraorbital nerve at interstimulus interval 100 ms. To analyze the degree to which PPI affects baseline actual pain (VAS-NRS), patient global assessment PGA, discordance between PGA and EGA (expert global assessment) calculated as PGA minus EGA we performed univariate linear regression analyses using VAS-NRS, PGA, and PGA minus EGA as dependent variables. We selected the following predictive variables: age; sex; BMI; disease duration; erosive disease; SJC; TJC; pain VAS, ESR; mHAQ; ACPA. We used standardised β to compare the strengths of the relationships. We also analyzed the contribution of PPI to therapeutic response in month 3 and 6.
Results: As compared to HC, patients with RA were older, reported higher pain levels, and their mean PPI scores were significantly lower (Table 1). In RA pts PPI was neither predictive for baseline VAS-NRS, PGA, PGA-EGA, nor for ΔDAS28, ΔHAQ or ΔVAS in month 3 or 6. The trajectory of mean DAS28 according to ordinal level of PPI is shown in Figure 1.
Conclusion: Lower PPI in RA patients may reflect abnormal filtering of afferent information flow to the brain. Together with previous findings in FM, our results suggest abnormal subcortical sensory information may be involved in nociplastic pain in RA patients. However, PPI was neither predictive for baseline level of pain, PGA, or EGA-PGA, nor for therapeutic response in pts with RA.

AB0259

PREDICTIVE VALUE OF C-REACTIVE PROTEIN/ ALBUMIN RATIO(CAR) FOR THE DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE COHORT STUDY

Keywords: Rheumatoid arthritis

N. Öz[1], M. T. Duruöz[1]. [1]*Marmara University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Division of Rheumatology, İstanbul, Turkey*

Background: Rheumatoid arthritis (RA) is a chronic, systemic and disabling autoimmune disease with inflammatory synovitis. Many biochemical factors are used as diagnostic, activation and prognostic markers in certain diseases. The C-reactive protein/albumin ratio(CAR) is an inflammatory marker that is considered to have prognostic value in many disease. The CAR has shown high value in colorectal cancer, inflammatory bowel disease and ANCA-associated vasculitis activity.
Objectives: In this study, we aimed to evaluate the predictive value of CAR for disease activity in RA patients.
Methods: This prospective study included 144 RA patients who fulfilled the 2010 revised criteria of the American College of Rheumatology (ACR) for RA. The demographic characteristics of the patients, duration of the disease and clinic characteristics of the patients such as the 28-joint Disease Activity Score based on the erythrocyte sedimentation rate (DAS28-ESR), Visual Analogue Scale, Health Assessment Questionnaire-Disability Index were collected. Labotaruvary finding such as erythrocyte sedimentation rate, CRP, albumin were noted. The CAR ratio was obtained by dividing the CRP level with albumin level. Based on the DAS28-ESR level, the included patients were categorized into two groups, namely, inactive to mild active RA (n=69; DAS28-ESR level <3.2) and moderate to highly active RA (n=75; DAS28-ESR level ≥3.2). These group were compared with the parameters described above.
Results: One hundred ten patients (76.4% female) with mean age 52.3 SD 11.8 years were recruited into the study. Age and disease therapy duration of the patients were similar in both groups. Female gender was significantly higher in the DAS28-ESR ≥3.2 group. Patients who DAS28-ESR ≥3.2 had a significantly higher CAR compared to those who did not (0,11 SD 0,09 *vs*. 0,20 SD 0,16, *p*<0.001) (Table 1). Multivariate logistic regression analyses revealed that CAR was an independent predictor of moderate to highly active RA (OR: 2.180, 95%CI: 1.307–3.637; *p*=0.003). A receiver operating characteristic curves analysis yielded that the optimal cut-off value of CAR for moderate to highly active RA was 0.126 with sensitivity 64.0% and specificity 66.2% (AUC: 0.683, 95%CI: 0.597-0.769, p<0.001) (Figure 1).
Conclusion: Based on the study findings, we were able to show that simple and easily obtained CAR could be an independent predictor of disease activity in rheumatoid arthritis patients.

AB0260 **DISABILITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: RELATIONSHIP WITH ALEXITHYMIA.**

Keywords: Quality of life, Rheumatoid arthritis

Y. Shalkovskyi[1], Y. Shkarivskyi[1], M. Stanislavchuk[1]. [1]*National Pirogov Memorial Medical University, Vinnytsya, Department of Internal Medicine №1, Vinnytsya, Ukraine*

Background: Rheumatoid arthritis (RA) is the chronic, destructive, immune-mediated inflammatory process that has a gradient course and causes disability of approximately 50% over the next 5 years of the disease. Acute pain syndrome, which is accompanied by RA, often leads to a violation of the psycho-emotional sphere with manifestations in the form of depression, anxiety and alexithymia. Alexithymia defined as a personal emotional disorder that characterized by difficulty in identifying and describing subjective feelings. As there are insufficient data on disability in patients with RA in combination with alexithymia, we screened patients with RA, investigated the level of disability and found a connection with alexithymia.
Objectives: To investigate the level of disability in patients with rheumatoid arthritis and clarify a probable connection with alexithymia.
Methods: RA patients diagnosed according to the ACR/EULAR 2010 classification criteria (Daniel Aletaha et al., 2010). The presence of alexithymia was determined by TAS-20 – «Toronto Alexithymia Scale» questionnaire (Graeme J. Taylor, D. Ryan, R. Michael Bagby, 1994). Disability was determined by a questionnaire DRI - «The Disability Rating Index» (Bo A. Salen, Erik V. Spangfort, Ake L. Nygren and Rolf Nordemar, 1994).[1] RA activity was assessed with the Disease Activity Score (DAS28), Simplified disease activity index (SDAI), Clinical disease activity index (CDAI), functional status with the Health Assessment Questionnaire (HAQ), pain intensity was determined by the Visual Analogue Scale (VAS). Statistical analyses were performed using IBM Statistics SPSS 20. Results are presented as mean with standard deviation (M ± SD).
Results: The study included 146 patients with RA (90.7% of women). The average age of the patients was 50.1 ± 12 years, and the duration of the disease ranged from 1 to 21 years (7.4 ± 4.7). Among 146 examined, alexithymia (TAS-20 ≥ 61) was detected in 36 people (24.7%). All patients had different level of disability detected by the DRI questionnaire, with scores ranging from 5.4 to 79.8; and the average value was - 31.1 ± 17.1. In patients without alexithymia, the disability was 26.8 ± 14.8, in patients with alexithymia – 44.5 ± 16.8. Functional ability in individuals with RA without alexithymia according to the HAQ was 0.9 ± 0.6, in contrast to the group of patients with RA and alexithymia - 1.7 ± 0.6. The significance of the differences between groups depending on the presence of alexithymia according to functional ability and intensity of pain was at the level of $p < 0.05$; and disability - at the level of $p < 0.01$. A direct strong correlation was established between alexithymia and disability, functional ability and VAS: DRI ($r = 0.514$; $p < 0.01$); HAQ ($r = 0.450$; $p < 0.01$); VAS ($r = 0.457$; $p < 0.01$). We found that the presence of alexithymia in patients with RA was associated with an increased risk of functional disability. Odds ratios are used to identify the risk of functional disorders in patients with alexithymia. RA patients with TAS-20 score ≥ 61 had an odds ratio of 7.57 [95% CI: 2.13 – 26.98] ($p < 0.002$) for moderate functional disability and 21.47 [95% CI: 4.82 – 95.61] ($p < 0.0001$) for severe functional disability by HAQ, and 14.98 [95% CI: 4.48 – 50.13] ($p < 0.0001$) by DRI.
Conclusion: The alexithymia in patients with rheumatoid arthritis is associated with a bigger disability, as well as with impaired functional ability and severity of pain syndrome. We concluded that alexithymia may be consider as a risk factor of the disability in patients with RA.

AB0261 **PREVALENCE OF HEART VALVULAR REGURGITATION ACCORDING TO THE TIME OF DISEASE EVOLUTION IN RHEUMATOID ARTHRITIS PATIENTS**

Keywords: Heart, Rheumatoid arthritis, Imaging

D. Á. Galarza-Delgado[1], I. J. Colunga-Pedraza[1], J. R. Azpiri-López[2], V. M. Beltran-Aguilar[1], V. Gonzalez-Gonzalez[1], A. G. Arias Peralta[2], N. De Avila Gonzalez[1], J. A. Cardenas-de la Garza[1], G. García-Arellano[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico*

Background: Rheumatoid arthritis (RA) patients are at higher risk of developing cardiovascular (CV) diseases, both ischemic and non-ischemic, than the general population [1]. Inflammatory status and fibrotic changes at cardiac valves in these patients predispose them to a higher risk of valve diseases, which could be detected by echocardiography [2].
Objectives: To determine the prevalence of valvular regurgitation, according to the time of disease evolution in RA patients.
Methods: Descriptive, comparative, and cross-sectional study. We enrolled RA patients between 40 and 75 years old who fulfilled ACR/EULAR 2010 classification criteria and recruited in the Rheumatology service from tertiary care hospital. Patients were divided by time of disease evolution into quartiles. A transthoracic echocardiogram performed by a certified cardiologist blinded to clinical data. Normality was assesed by Kolmogorov-Smirnov test. Variables with normal and non-normal distribution were described by media and standard deviation, such as median and interquartile range (p25-p75), respectively. Differences between groups was analyzed by ANOVA, Kruskal-Wallis test or Chi-squared, accordingly.
Results: We included 151 RA patients. Demographic characteristics are in Table 1. Overweight/obesity was found between 62-87% of patients, hypertension between 26-34%, and Type 2 Diabetes mellitus between 8-26%. The tricuspid valve was the most affected (73-84%). There was no differences in prevalence of valvular regurgitation.
Conclusion: RA patients have a high prevalence of valvular regurgitation, which could predispose them to develop heart failure, therefore it is important to consider echocardiography in the approach of this population, despite not showing an increase.

AB0262 **FATIGUE PATTERNS IN DIFFICULT TO TREAT RHEUMATOID ARTHRITIS PATIENTS**

Keywords: Quality of life, Rheumatoid arthritis, Mental health

J. P. Otazu Moudelle[1], D. Freites[1], M. Rodríguez Laguna[1], C. Hormigos[1], M. P. Álvarez Hernandez[1], A. Madrid García[2], L. Abasolo[2], L. León[2]. [1]*Hospital Clínico San Carlos, Rheumatology, Madrid, Spain*; [2]*Instituto de Investigación Sanitaria San Carlos (IdISSC), Rheumatology, Madrid, Spain*

Background: Fatigue study is scarce in D2T RA. The experience of fatigue is multidimensional, implying complex, multicausal pathways.
Objectives: to identify the factors associated with fatigue on its different subscales (Physical, Living, Cognitive and Emotional).
Methods: Cross-sectional study. 22 patients with D2T RA were included; patients were being followed up in the rheumatology outpatient clinic of Hospital Clínico San Carlos, Madrid, Spain. Data were collected between July 2018 and November 2022. All patients met the ACR/EULAR 2010 criteria and they were in

treatment with Biological agents (anti-TNF and Non anti-TNF) or Targeted Synthetic DMARDs (jakinibs). Outcome: Difficult to treat Rheumatoid Arthritis Patients (fulfillment of EULAR criteria). Main variable: Fatigue was assessed by the Bristol Rheumatoid Arthritis Fatigue Multidimensional Questionnaire (BRAF-MDQ) and the Bristol Rheumatoid Arthritis Fatigue Numerical Rating Scale (BRAF-NRS). Covariables: Sociodemographic and disease-related variables. Statistical analysis: A descriptive analysis was carried out for the different variables. To identify factors independently associated to BRAF-MDQ and its subscales, multivariable linear regression was applied. Results were expressed as coef with their corresponding 95% CI. A value of $p < 0.05$ was consider as statistically significant.

Results: A total of 22 (15.38%) patients were found D2T RA, comprising of 11 females (50%) with a mean age of 62.82±13.45 years and mean disease duration of 17.76±8.47 years. RF was positive in 59% of patients. Regarding comorbidities, 32% had dyslipidemia, 28% hypertension, 10% vascular disease, 27% hypothyroidism and 23% depression. The DAS28-ESR mean score of the patients were 4.10 ± 0.67. The factors affecting the global fatigue and its different subscales was evaluated in multivariate analyze **Table 1.** Our results shows a different correlation structure between disease and treatment factors and the different dimensions of the BRAF-MDQ. Patients who reported high disability scores had more global fatigue, while those with a poor patient global health assessment perceived more physical fatigue. In addition, an association was observed between depression and cognitive fatigue. Male sex and positive RF was associated with less living fatigue.

Conclusion: It is important to evaluate fatigue in a multidimensional perspective, each of the different subscales could be modulated by different factors. The results of our study indicated that disability predicts global fatigue, however, other factors can configure different patterns of fatigue in D2T RA patients, and identify them is key to the approach of this complex symptom.

AB0263 FAT AND LEAN MASS DISTRIBUTION USING DUAL ENERGY X-RAY ABSORPTIOMETRY (DEXA) IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ITS RELATIONSHIP TO DISEASE SEVERITY

Keywords: Sarcopenia, Rheumatoid arthritis, Quality of life

M. Malik[1], P. S Kumar[1], A. Kumar P H[1], M. Gopalakrishnan[1], R. Shukla[1], M. K. Garg[1]. [1]*All India Institute of Medical Sciences, Internal Medicine, Jodhpur, India*

Background: Obesity and sarcopenia have been associated with higher disease activity, poor response to disease modifying agents and lower remission achievement in rheumatoid arthritis (RA) patients [1, 2]. Weight loss has been associated with increased chances of remission [1]. The prevalence of obesity in the Asian population is 64% but the relationship between fat distribution and disease activity is not explored in the Indian population [3].

Objectives: To describe fat mass, lean mass, fat mass index, lean mass index, fat mass percentage, fat-to-lean mass ratio, android-gynoid ratio and trunk-leg fat ratio measured using dual energy x-ray absorptiometry (DEXA) in patients with rheumatoid arthritis and assess their relationship with DAS28, patient global assessment of disease activity (PtGA), and Indian health assessment questionnaire (IHAQ) disability index.

Methods: A hospital based cross-sectional study was initiated after Ethics Committee approval in patients with RA at our rheumatology clinic from March 2022 onwards, at Jodhpur, India. Demographic, clinical, anthropometric and treatment details of the patients were collected after informed written consent. Whole body DEXA was done using a DEXA scanner Hologic Corp, model no - Horizon A S/N 303237M). Correlation of fat mass, lean mass, fat mass index, lean mass index, fat mass percentage, fat-to-lean mass ratio, android-gynoid ratio and trunk-leg fat ratio with DAS28, PtGA, and IHAQ was determined using Spearman correlation. Multivariable logistic regression was done to see if fat distribution indices could predict disease activity and IHAQ disability index. This is an ongoing study, with a calculated sample size of 104.

Results: Sixty patients have been enrolled so far with a mean age of 46 ± 11 years, 78.3% were females. Mean body mass index was 23.7 ± 5.1 kg/m^2 and 51.7% (n = 31) patients were overweight. Mean waist-hip ratio was 0.88 ± 0.07 among females and 0.98 ± 0.08 among males. The mean fat mass percentage, lean mass index, fat lean mass index, android-gynoid ratio and fat trunk-leg ratio were 39.87 ± 6.13%, 14.46 ± 2.31 kg/m^2, 67.19 ± 19.26, 0.92 ± 0.14 and 0.81 ± 0.12 respectively. The median fat mass, lean mass and fat mass index in the study population were 22.98 ± 10.42 kg, 33.53 ± 10.42 kg and 10.05 ± 4.19 kg/m^2 respectively (Table 1). The fat mass percentage had significant correlation with previous history of steroid use for more than 21 days ($r = 0.347$, $p = 0.008$). None of the fat distribution indices evaluated could reliably predict DAS28, PtGA, and IHAQ disability index using multivariable logistic regression models.

Conclusion: The proportion of patients who were overweight was less in our patients with RA compared to the general population [3]. In this ongoing study, body fat composition and distribution did not exhibit any relationship with disease severity, or disability. However, prolonged steroid use increased fat mass percentage. Further studies are needed to evaluate the changes in fat and lean mass distribution and their relationship to disease activity.

AB0264 PREDICTION OF FLARE FOLLOWING GLUCOCORTICOIDS WITHDRAWAL IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING CSDMARDS: A REAL-LIFE STUDY

Keywords: Outcome measures, Rheumatoid arthritis, Real-world evidence

W. Xie[1], Z. Zhang[1]. [1]*Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: In patients with rheumatoid arthritis (RA), glucocorticoids (GC) should be firstly discontinued before considering tapering conventional synthetic disease-modifying anti-rheumatic drugs (csDMARD) or other biological agents.

Objectives: We aim to determine risk factors for flare after GC withdrawal in RA patients undergoing csDMARDs.

Methods: Electronic database searches of PubMed, EMBASE and Cochrane Library were performed. Observational studies that assessed the association of dementia with DMARDs in RA were included. Pooled risk ratios (RRs) with 95% confidence intervals (CIs) were used as summary statistic, with either fixed-effects or random-effects model. The certainty of evidence using the GRADE system.

Results: In total, 115 RA patients discounted GC in the context of csDMARDs (methotrexate: 80%; hydroxychloroquine: 61%; csDMARDs combination: 79%). Of these, twenty-four patients experienced flare after GC discontinuation. Compared with relapse-free patients, flare patients were more likely to have established RA (75% vs. 49%, p=0.025), higher median cumulative prednisolone dosages (3.3g vs. 2.2g, p=0.004), and higher proportion of dissatisfied RA control during GC usage (66% vs. 33%, p=0.038). In multivariate analysis,

significantly increased flare risk was predicted by established RA (OR 2.93 [1.02-8.43]), cumulative prednisolone doses>2.5g (OR 3.69 [1.34-10.19]) and dissatisfied RA control (OR 3.00 [1.09-8.30]).
Conclusion: Flare following GC withdrawal is not common in RA patient undergoing csDMARDs therapy. Established RA, higher cumulative GC doses and dissatisfied RA control before GC discontinuation are important factors associated with flare after GC withdrawal.

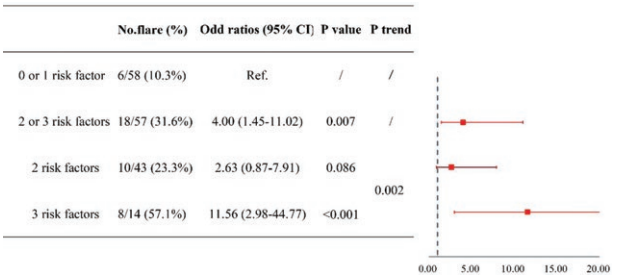

Figure 1. Flare risk following GC withdrawal in RA patients with different number of risk factors.

AB0265

SLEEP QUALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SINGLE CENTER EXPERIENCE FROM JODHPUR, INDIA

Keywords: Patient reported outcomes, Mental health, Quality of life

N. K[1], A. Kumar P H[1], R. Sivaprasad[1], S. Nandagopal[2], A. Garg[1], M. K. Garg[1], M. Gopalakrishnan[1]. [1]*All India Institute of Medical Sciences, Internal Medicine, Jodhpur, India*; [2]*All India Institute of Medical Sciences, Biochemistry, Jodhpur, India*

Background: Sleep disorders are prevalent in rheumatoid arthritis (RA). Sleep is closely related to disease activity, depression, stress, fatigue and pain [1]. Community prevalence of sleep disorders in India varies from 6.2% to 36.3% [2,3]. Studies assessing sleep quality in the Indian population with RA are limited.
Objectives: To assess the prevalence of impaired sleep quality using Pittsburgh Sleep Quality Index (PSQI) and determine factors predicting impaired sleep quality in patients with RA.
Methods: A cross-sectional study was conducted in patients with RA presenting to our rheumatology clinic after informed consent and Ethics Committee approval from January 2021. Sleep quality was assessed by PSQI, depression by Patient Health Questionnaire (PHQ-9) and Quality of life by Indian Health Assessment Questionnaire (IHAQ). Disease activity was assessed using Disease Activity Index (DAS28 CRP) and Clinical Disease Activity Index (CDAI). Serum samples for interleukin-1 (IL-1), interleukin-6 (IL-6), and tumor necrosis factor alpha (TNF-α) were collected and stored at -80^0 C. Relationship of fatigue was examined with age, serum TNF-α, IL-1, IL-6, CDAI, DAS28 CRP and patient global assessment (PtGA) using Spearman correlation coefficient. Linear regression analysis was performed to determine the predictors of impaired sleep quality in patients with RA.
Results: One hundred and fifty-four patients were enrolled, 133 were females (86.3%). Median pain VAS score was 6[2]. Mean DAS was 4.35 ± 1.31, mean CDAI: 19.75 ± 7.91 and median IHAQ was 9.5[8]. The prevalence of depression (PHQ-9 >10) was 5.8% (n = 9) with a median PHQ-9 of 2[3]. One patient was on tofacitinib, 20 were on methotrexate monotherapy and others were on combination of conventional DMARDs. The prevalence of impaired sleep (PSQI >5) was 8.4% (n = 13) with a median PSQI of 2[2]. PSQI had significant correlation with PHQ-9 (r = 0.471, p<0.0001), IHAQ (r = 0.288, p<0.0001), DAS28 (r = 0.197, p = 0.015) and CDAI (r = 0.235 p = 0.003). Age, pain VAS, serum TNF-α, IL-1 and IL-6 had no correlation with PSQI. Among individual components of DAS, PtGA (r = 0.296 p <0.0001) alone correlated with PSQI. PHQ-9, IHAQ and PtGA were significant predictors of impaired sleep quality (Table 1).
Conclusion: Compared to other studies within India, our patients had very low prevalence of impaired sleep quality. Sleep quality significantly influences disease activity likely by affecting PtGA. Risk factors for poor sleep quality are presence of depression, poor quality of life and patient global assessment of disease activity. Hence a holistic management of RA must involve addressing these risk factors.

Table 1. Predictors of impaired sleep quality

Predictors	β (95% CI)	P value
PtGA	0.176(0.023 - 0.412)	0.004
Depression (PHQ-9)	0.282 (0.101 - 0.342)	<0.0001
IHAQ	0.230 (0.025 -.129)	0.004

THE INFLUENCE OF HEREDITY ON RHEUMATOID ARTHRITIS: EXAMINING THE DISTINCT CHARACTERISTICS IN PATIENTS WITH A FAMILY HISTORY

Keywords: Prognostic factors, Rheumatoid arthritis

H. EL-Kasmi1, N. Akasbi[1], I. El Mezouar[1], M. Omari[2], T. Harzy[1]. [1]*الروماتولوجيا الاستشفائي الجامعي الحسن الثاني, Rheumatology, Fes, Morocco*; [2]*مختبر الاستشفائي الجامعي الحسن الثاني, Laboratory of Epidemiology, Clinical Research and Community Health, Faculty of Medicine and Pharmacy, Sidi Mohammed Ben Abdellah University, Fes, Morocco*

BACKGROUND: NIL.
Objectives: The aim of this study was to describe the particularities of patients diagnosed with rheumatoid arthritis (RA) who have a family history of the disease.
Methods: In this retrospective study, a total of patients diagnosed with RA between the years 2011 and 2022 were included. The primary aim of the study was to investigate the relationship between different parameters such as age of disease onset, Disease Activity Score using C-reactive protein(DAS CRP), serological profile, erosive character,extra-articular manifestations, and use of biotherapy. Data were collected from the medical records of the patients, and analyzed using statistical test such chi-squared, Fisher's exact test and t-test.the level of significance was set at p=0.05.the study design included a thorough data cleaning process.
RESULTS:

Table 1.

	RA with Family History (n=21)	RA without Family History (n=386)	(p)
Sex-Ratio	6	6.12	1.00
Young onset RA (%)	66.7	55.3	0.30
Extra-articular manifestations (%)	66.7	46.3	**0.05**
Serological profile (%)	85.7	87.5	0.73
C-reactive protein (mg/L)	22.25 ± 37.23	27.87 ± 25.11	0.487
DAS CRP*	5.3 ± 1.63	5.4± 2.5	0.90
Erosions (%)	81	87	0.50
The use of biological treatment (%)	38.1	39.2	0.91

DAS CRP: Disease Activity Score using C-reactive protein*

The study included 407 patients with a mean age of 58.86 years ± 12.441, and a sex ratio of 6 (F/M). The median duration of the disease was 14 ± 7.523 years. Erosions were found in 87.2% of patients. Rheumatoid factor (RF) was positive in 85% of patients and anti-citrullinated protein antibodies (ACPA) were positive in 64.9% of patients. The mean DAS 28 score was 5.409± 2.52, the mean CRP was 33.84±35.19, and extra-articular manifestations were found in 46.4% of patients and 39.1% of patients were receiving biological treatment. 21 patients (5.17%) reported a family history of RA. In bivariate analysis, RA patients with a family history had more extra-articular manifestations compared to patients without a family history of the disease (66.7%) versus (46.3%) (p =0.05). No association was found for the other parameters.
Conclusion: The results of this study suggest that a family history of RA may be a predictive factor for extra-articular manifestations in patients with the disease. These findings highlight the importance of considering family history when

evaluating and treating patients with RA. Further research is needed to confirm these results and to better understand the underlying mechanisms.

Background: Anaemia is a multifactorial, pervasive, extra-articular manifestation that is a significant burden in RA. The most common types of anaemia in RA are chronic anaemia and iron-deficiency anaemia. A number of existing studies observed anaemia in 24.0%–70.6% of RA patients.
Objectives: The primary objective of this study was to examine the association between haemoglobin (Hb) levels and disease activity in patients with rheumatoid arthritis (RA).
Methods: This retrospective study obtained data from adult RA patients with Hb reports from the Kuwait Registry for Rheumatic Diseases (KRRD). Patients were recruited from four public hospitals in Kuwait between February 2013 and February 2022. The cohort was stratified into two groups: low Hb (anaemic, ≤ 110 g/L) and high Hb (non-anaemic, > 110 g/L). Demographic, treatment, clinical, and laboratory characteristics were used to compare the two Hb cohorts. Multivariate and univariate statistical analyses were used to analyse the data.
Results: The total number of patients visited (N_v) was 11393 and consecutive patients with RA diagnoses and Hb data (N_p) was 1584. Both N_v and N_p were included in the study. Of these, 72.5% (n = 8260) had high Hb levels and 27.5% had low Hb levels (n = 3133). The average age of the cohort was 55.9±12.5 years. Logistic regression analysis revealed that a greater number of non-Kuwaiti patients had anaemia than Kuwaiti patients [adjusted odds ratio (aOR), 1.34; 95% confidence interval (CI):1.16-1.56; *P* <0.001). Patients who received biologic treatment were more likely to be non-anaemic [aOR, 1.33; 95% CI:1.23-1.45; *P* <0.001). Additionally, the study demonstrated that patients with anaemia had greater odds of acquiring Disease Activity Score 28-joint count (DAS-28) ≥ 3.2 as opposed to DAS-28 < 3.2 [aOR, 0.74; 95% CI:0.61-0.90; *P* =0.002].
Conclusion: Lower haemoglobin levels in RA are independent predictors of disease activity.
Acknowledgements: I would like to acknowledge Kuwait Registry for Rheumatic Diseases (KRRD), for providing us the needed data.

AB0268 IS THERE A CORRELATION BETWEEN PLATELET/ LYMPHOCYTE RATIO AND NEUTROPHIL/ LYMPHOCYTE RATIO AND RHEUMATOID ARTHRITIS ACTIVITY?

Keywords: Biomarkers, Rheumatoid arthritis, Prognostic factors

H. Arabi[1], Z. Baba[1], F. E. Chekkouri[1], A. Mougui[1], I. El Bouchti[1]. [1]*Centre Hospitalo-Universitaire Mohammed Vi Marrakech, Department of Rheumatology, Marrakech, Morocco, Rheumatology, Marrakesh, Morocco*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease, the evaluation of its activity is based on several scores, including the DAS28, which is the most frequently used. In recent years, platelet to lymphocyte ratio (PLR) and neutrophil to lymphocyte ratio (NLR) have become markers of systemic inflammation.
Objectives: Evaluate the correlation of RPL and RNL with disease activity in patients followed for RA.
Methods: Retrospective study conducted in the rheumatology department between 2007-2021, including patients followed for RA. Demographic, clinical, biological data and RA activity indices were collected from patient records. The RNL and the RPL were obtained by dividing the neutrophil and platelet levels respectively by the lymphocyte level.
Results: Were included 260 patients followed for RA, the average age was 49.91 ± 12.96 years, with a female predominance of 86.9%. Structural damage was noted in 84.8% of patients. RA was seropositive for ACPA in 82.9% of cases and 77.5% for rheumatoid factor. The mean RPL and RNL were 163.32 and 2.88 respectively. The mean DAS28-CRP was 5.26 ±1.42. A highly significant correlation was found between RPL and CRP and sedimentation rate (p<0.0001, P<0.001 respectively). RNL was also correlated with ESR (P: 0.005) and CRP (p=0.0001). RPL was significantly correlated with DAS28-CRP (p=0.032), unlike RNL (p=0.36). No correlation was noted between these two ratios and age, sex, BMI and comorbidities.
Conclusion: In recent years, RNL and RPL have emerged as markers of systemic inflammation. Our results are consistent with data from the literature.

AB0269 RHUMATOID FACTORS ISOTYPES DIAGNOSTIC SENSITIVITY AND SPECIFICITY IN RHUMATOID ARTHRITIS PATIENTS IN TUNISIA

Keywords: Rheumatoid arthritis, Biomarkers, Diagnostic tests

R. Ben Tekaya[1], J. Mahbouba[1], M. Elghali[2], N. Hafdhouni[1], A. Saad[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Sakly[2], N. Bergaoui[1]. [1]*Hospital University Fattouma Bourguiba, Rheumatology Department, Monastir, Tunisia*; [2]*Hospital University Fattouma Bourguiba, Immunology Department, Monastir, Tunisia*

Background: Rheumatoid factor (RF) is a well-established marker for the diagnosis and classification of rheumatoid arthritis (RA). Most studies have evaluated IgM RF or isotype-nonspecific total RF tests.
Objectives: We evaluated the importance of rheumatoid factor isotype in this study.
Methods: An international cohort consisting of samples from 52 RA patients and 57 patients suffer from other rheumatologic deseases were tested for IgA, IgM and IgG RF. Clinical and biological data were collected.
Results: IgM, IgA, and IgG were positive in RA patients 96,15%, 88,46% and 17,3% respectively. The sensitivity of IgG RF for the diagnosis of RA was the lowest 16,7%, IgA RF sensitivity was lower than IgM RF (87,8% vs 95,9%). The specificity of IgM, IgA and IgG RF for the diagnosis of RA were (29,8 %vs 61,4 %vs 89,4% respectively). Double positivity for RF IgM and RF IgA had a higher specificity for RA than RF IgM or RF IgA (92.6% vs. 29,8% vs 89,4%). However, combined positivity for IgA RF, IgM RF, and IgG ACPA had higher specificity and lower sensitivity for RA classification than positivity for either antibody.
Conclusion: IgA RF showed lower sensitivity than IgM RF. The combination of IgA RF with IgM RF and ACPA did not improve the sensitivity of RA classification. Combined positivity (IgA-RF/IgM-RF/ACPA) increased specificity.

KG, Global Biostatistics and Data Sciences, Ingelheim am Rhein, Germany*; [9]*Boehringer Ingelheim International GmbH, TA Inflammation Medicine, Ingelheim am Rhein, Germany*; [9]*Boehringer Ingelheim International GmbH, TA Inflammation Medicine, Ingelheim am Rhein, Germany*; [11]*Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*; [12]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

Background: ILD is a significant complication of RA, but diagnosis of RA-ILD is often delayed as respiratory symptoms do not develop until the disease is advanced. Several risk factors for the development of ILD in patients with RA have been identified. Screening tools are required to facilitate earlier detection of RA-ILD in clinical practice.
Objectives: The aim of this prospective cross-sectional study is to develop and validate a multivariable prediction model for RA-ILD screening based on risk factors.
Methods: Investigators will enrol consecutive patients diagnosed with RA who have ≥2 of the following risk factors for ILD: male; current or previous smoker; age ≥60 years at RA onset; high-positive rheumatoid factor and/or anti-cyclic citrullinated peptide (titre >3 x upper limit of normal); high RA disease activity score (based on DAS-28, SDAI, CDAI, RAPID-3, PAS, or PAS-II) ≤12 months prior to screening; presence or history of extra-articular manifestations of RA (vasculitis, Felty's syndrome, secondary Sjögren's syndrome, cutaneous rheumatoid nodules, serositis, and/or scleritis/uveitis). Patients previously identified as having ILD, or who have had a high-resolution computed tomography (HRCT) scan in the prior 2 years, will not be eligible. Patients will undergo an HRCT scan, which will be assessed centrally by two thoracic radiologists. Data will be collected on demographic and RA-related characteristics, patient-reported outcomes, comorbidities and pulmonary function. It is planned that up to 1200 patients will be enrolled at approximately 30 sites in the USA, UK, Germany, France, Italy, Spain.
Results: The results of this study will elucidate the prevalence of RA-ILD, and of features of RA-ILD on HRCT, in the study population and enable development of a probability score for RA-ILD based on a multivariable model incorporating risk factors. The performance, area under the receiver operating characteristic (ROC) curve, sensitivity, specificity and predictive value of the model for predicting the presence of RA-ILD on HRCT (yes/no) will be reported.
Conclusion: The results of this prospective multi-national cross-sectional study will enable development of a screening tool for RA-ILD, guided by risk factors, to identify patients with RA who should be screened for ILD using HRCT.

AB0271 PREDICTIVE FACTORS OF CARDIAC IMPAIRMENT IN RHEUMATOID ARTHRITIS

Keywords: Imaging, Heart, Comorbidities

M. Brahem[1], R. Sarraj[1], H. Ibn Hadj Amor[2], A. Ben Salem[1], S. Kraiem[2], R. Rouabhia[2], E. Hmaier[2], H. Hachfi[1], Y. Mohamed[1]. [1]*Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia*; [2]*Taher Sfar University Hospital, Cardiology, Mahdia, Tunisia*

Background: In view of the insidious and serious nature of cardiac involvement in rheumatoid arthritis (RA), systematic screening for these diseases and the identification of risk factors is of paramount importance in order to preserve and improve patients' quality of life and life expectancy.
Objectives: The objective of our study is to determine the predictors of cardiac involvement.
Methods: We performed a cross-sectional study conducted in Taher Sfar Hospital, Mahdia, Tunisia. Each patient underwent a transthoracic echocardiography (TTE) coupled with Strain technique. The comparison between a quantitative variable and a qualitative variable was made by the "Student's t" test if the quantitative variable follows the normal law, if not, the "Mann-Whitney" test was used. The multivariate study was done by binary logistic regression. A p value <0.05 was considered statistically significant.
Results: Seventy-two patients with RA were included in our study. There was a clear female predominance with a sex ratio of 0.07. The mean age of RA patients was 52.9 ± 11.72 years [21-75 years]. The mean duration of disease progression was 12.4 ± 9.9 years [6 months-40 years]. The means of DAS 28 (CRP), DAS 28 (ESR) and HAQ score were respectively 3.4 ± 1.4 [1.2-6.7]; 3.9 ± 1.4 [1.4-7.4] and 0.9 ± 0.7 [0-2.5]. 51.4% of patients had an increased ESR and 37.5% of cases had an increased CRP (CRP>6). Corticosteroid therapy was used in 94.4% of patients with a mean duration of 5.9 ± 5.2 years [1-20 years], methotrexate (MTX) in 98.6% of patients with a mean duration of 8.1 ± 6.9 years [1-40 years] and biotherapy in 19.4% of cases. Rheumatoid factor was positive in 51.7% of cases and ACPAs were positive in 73.3% of cases. TTE revealed abnormalities in 58 patients (80.6% of cases). Echocardiographic impairments were dominated by valvular involvement (45.8%), followed by subclinical left ventricular myocardial damage assessed by the Global Longitudinal Strain (GLS) method (37.5%), Left ventricular diastolic dysfunction (36.1%), Left ventricular hypertrophy (22.2%), pericardial effusion and pulmonary arterial hypertension (2,8%). The bivariate analysis found a statistically significant relationship between echocardiographic damage and disease activity ($p<0.01$), the number of painful joints ($p<0.01$), the functional impact of the disease (HAQ) ($p=0.01$), the importance of the CRP level ($p<0.01$) and the use and dose of corticosteroid therapy ($p=0.02$; $p=0.01$). The multivariate study showed only one significant association between echocardiographic involvement and disease activity ($p = 0.03$; OR = 1.8; CI [1.04-3.3]).
Conclusion: Our study proved an association between cardiac involvement and disease activity. Therefore, early and appropriate management of RA may decrease the risk of cardiac impairment.

AB0272 INSUFFICIENCY OF VITAMIN D AS A PREDICTOR OF RHEUMATOID ARTHRITIS SEVERITY

Keywords: Prognostic factors, Vitamin D, Rheumatoid arthritis

M. Osipyan[1], M. Efraimidou[1], A. Antikyan[2], K. Ginosyan[1]. [1]*1st University Hospital Complex After M. Heratsi, Rheumatology, Yerevan, Armenia*; [2]*Gyumri Medical Center, Rheumatology, Gyumri, Armenia*

Background: The main function of VitD was historically linked with Ca/P03 metabolism and bone homeostasis, but recent research data have shown its major role in modulating the immune system. Taking into consideration the expression of the vitamin D receptor (VDR) and 1a-hydroxy- lase on dendritic cells, monocytes, macrophages, neutrophils, natural killer cells and B and T cells, VitD regulates both innate and adaptive immunity. It has been proposed, that VitD suppresses autoimmunity by different mechanisms and there is a growing interest in the role of VitD deficiency in the etiopathogenesis of RA and worst prognosis. With all this mentioned above in mind, it is clear that deficit of VitD has the potential to contribute to severity and progression of RA.
Objectives: The aim of this study is to evaluate VitD levels among patients with RA, investigate corelations between VitD levels and RA activity.
Methods: 47 patients with mean age of 52±9,8 were included in this study. All patients fulfilled EULAR/ACR 2010 classification criteria for rheumatoid arthritis.

Disease activity was measured with help of DAS28. All patients were examined using the same protocol, ESR, CRP and VitD level were assessed. 51 healthy patients with the same statistical data were included in the control group.

Results: 68,085% of examined patient were female and 31,91%- male. Duration of the RA at the moment of the study was 5,2±8,1 years and mean DAS28 score was 4,8±1,02. According to our study significant negative correlation between levels of VitD and DAS28 score was found (p=0,02), correlations between CRP, ESR were also found, but the results were not significant. The mean VitD level in patient group was 13,3± 8,5 ng/mL and in control group 38,4±2,6 ng/mL. The difference of VitD levels between groups was significant (p<0,05).

Conclusion: According to our data, levels of VitD are lower among patients with RA, especially among patients with high activity. Taking that into consideration, the levels of VitD should be assessed in patients with RA and insufficiency of VitD should be corrected in the course of Ra treatment.

AB0273 INTERSTITIAL MATRIX DESTRUCTION IS A CENTRAL PATHOLOGICAL FEATURE OF RHEUMATOID ARTHRITIS

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Biomarkers

A. C. Bay-Jensen[1], S. Holm Nielsen[1], C. Thudium[1], M. Karsdal[2]. [1]*Nordic Bioscience, ImmunoScience, Herlev, Denmark*; [2]*Nordic Bioscience, Fibrosis Biology, Herlev, Denmark*

Background: The interstitial matrix is the ground substance of all connective tissues, such as bone, skin, tendons, internal organs, and ligaments[1]. Type I collagen (COL1) is not only the most abundant protein, but also crucial for tissue integrity and stability as it act as the skeletal network of most organs. COL1 is organized in fibrils and connecting other extracellular matrix proteins to form a dynamic tissue. In bone, COL1 is 80% of the total protein amount and 95% of the total collagen amount, and thereby bone is by far the most COL1 rich tissue[1]. Matrix metalloproteinase (MMP) driven COL1 degradation is a central feature of in the pathogenesis of rheumatoid arthritis (RA) resulting in the release of C1M into the circulation. The common soluble biomarkers in RA are measures of inflammatory factors such as CRP, thus there is room for blood-based biomarkers reflecting tissue destruction.

Objectives: MMP-mediated tissue destruction may be a central part of inflammatory disorders, albeit overlooked. The biomarker C1M was developed more than a decade ago[2]. C1M originates from soft tissue turnover (from the action of MMP-2, -9, and -13[2]), not bone, thus very different from the bone degradation biomarker CTX-I. The aim was to review the literature to provide an overview on the potential context of use of assessing MMP-mediate COL1 degradation in RA, according to the FDA BEST guidelines[3].

Methods: PubMed and google scholar were searched for full-text original articles in English using the keywords C1M, biomarker, and rheumatoid arthritis. The search period was set to 2011 to 2022, included. Also, we limited the included articles to those assessing blood levels of C1M in clinical RA samples and animal models, thus excluding articles assessing the biomarker assessed in cell cultures or in silico models.

Results: 396 titles were identified of which 14 were full text, English written articles. The figure provides the main conclusions of the 14 articles. C1M was 2-4 times elevated in patients with RA compared to healthy donors or to patients with undifferentiated arthritis (UA) and is increased in a rat model of RA (orange box). C1M release is inhibited by biologics, such as anti-IL6 receptor, anti-TNFs, and Jak inhibitors, and was shown to be associated with disease activity (blue box). C1M was predictive of treatment response (purple box) and associated with disease progression (green box).

Conclusion: MMP-mediated COL1 degradation was more than 100% elevated in RA, suggesting that tissue destruction is actively ongoing in these patients. Tissue destruction was prognostic for further joint damage. Only those treatments that strongly inhibited this tissue destruction was efficacious. In alignment, changes in tissue destruction were predictive for efficacy.

AB0274 EFFECT OF RHEUMATOID ARTHRITIS ON BONE MINERAL DENSITY AND ITS RELATIONSHIP WITH INFLAMMATORY MILIEU IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Osteoporosis, Rheumatoid arthritis

R. Sivaprasad[1], M. Gopalakrishnan[1], S. Khichar[1], R. Shukla[2], K. Shukla[3], M. K. Garg[1]. [1]*All India Institute of Medical Sciences, Internal Medicine, Jodhpur, India*; [2]*All India Institute of Medical Sciences, Endocrinology, Jodhpur, India*; [3]*All India Institute of Medical Sciences, Biochemistry, Jodhpur, India*

Background: Rheumatoid arthritis (RA) is an inflammatory disorder, associated with significant systemic and local bone loss. Factors determining bone mineral (BM) loss in rheumatoid arthritis (RA) are important. This study aimed to determine the occurrence and predictors of low bone mineral density (BMD) in patients with RA.

Objectives: To estimate Bone Mineral Density in patients with Rheumatoid arthritis. To determine the frequency and risk factors for osteopenia/osteoporosis in patients with Rheumatoid arthritis.

Methods: We studied 102 RA patients diagnosed using ACR/EULAR 2010 at our Rheumatology clinic in Jodhpur, India from January 2021 to August 2021 after written informed consent and Ethical Committee approval. We collected the clinical, demographic, treatment history and calculated disease severity with Disease Activity Score (DAS28 CRP) and Clinical Disease Activity Index (CDAI). BMD was assessed (Dual-energy X-ray absorptiometry scanner-Hologic Corp, model no-Horizon A S/N 303237M). Serum samples for Interleukin-1 (IL-1) and Interleukin 6 (IL-6) were collected and stored at -80^{0}C and analysed by ELISA.
Results: In the study population, with mean age of 46.7±12.3 years, median disease duration of 48±36 months, mean DAS28 CRP score of 4.5±1.2, mean CDAI value of 18.6±8.58 prevalence of osteopenia and osteoporosis calculated using T score were found to be 43.1% and 15.7% at left hip, 42.2% and 16.7% at lumbar spine, 18.6% and 17.6% at left forearm respectively(Table 1, Figure 1). There was significant variation in BMD across various age categories at lumbar spine (P value-0.031) and left forearm (P value < 0.0001). There was statistically significant reduction in BMD with higher disease activity at hip (p value-0.019), however significance was not observed at lumbar spine and forearm. There was no significant association between BMD and CDAI. There was statistically significant difference in the lumbar spine BMD across the DAS 28 CRP <3.2 and DAS 28 CRP >3.2 subgroup. Lower values of BMD were observed in female patients, RF positive patients and established RA patients but these were not statistically significant. There was no association between Serum vitamin D3 levels, cumulative steroid dose, Interleukin-1 levels, Interleukin-6 levels, IL-17 levels, TNF α levels, Serum Osteoprotegerin (OPG) levels, Serum Receptor activator of nuclear factor kappa-B ligand (RANKL) levels and BMD.
Conclusion: Prevalence of osteopenia and osteoporosis and magnitude of bone mineral loss is significantly higher in our population compared to previous Indian studies including Sharma et al [1]. This lower BMD may be partially attributed to lower remission rates and low BMI in our study population. Hip joint appears to be particularly vulnerable to bone loss in those with higher disease activity suggesting that local effects maybe more important in bone loss. This observation is also supported by the finding that serum inflammatory markers or bone loss markers did not have a significant relationship to bone mineral density in our population.

SERUM LEVELS OF HOMOCYSTEINE, LEPTIN AND NEOPTERIN AS MARKERS OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

Keywords: Biomarkers, Rheumatoid arthritis

M. Gamal[1,2], Y. Gazar[2], M. Ghait[2]. [1]*Dubai Hospital, Rheumatology, Dubai, United Arab Emirates*; [2]*Al-Azhar University, Rheumatology, Cairo, Egypt*

Background: Rheumatoid arthritis (RA) is a chronic, systemic disorder characterized by the presence of many proinflammatory cytokines that have been involved in the pathogenesis, comorbidity, and premature mortality, due to increased atherosclerotic heart disease[1]. homocysteinemia is an independent risk factor for coronary heart disease, stroke, and an independent predictor for cardiovascular mortality in atherosclerotic patients.[2] leptin is a component of cytokines that mediates immune response and plays an important role in the T-cell related inflammatory process.[3] Neopterin is a pteridine derivative produced by monocytes and macrophages primarily as a response to interferon-gamma stimulation induced by the activation of the cellular immune system.(4)
Objectives: To investig the relationship between serum levels of homocysteine, leptin and neopterin and clinical & laboratory parameters of disease activity in patientes with rheumatoid arthritis.
Methods: This study included 80 RA patients and age& sex-matched 80 healthy controls. RA patients were divided into two groups (A&B) depending on the presence or absence of Extra-articular manifestations. There was 40 with Extra-articular manifestations (9 patients with Cutaneous vasculitis, 7 with Nodules, 6 with Neuropathy, 5 with Reynaud's phenomenon,7 with secondary sjogren, 2 with Fealty's syndrome, 2 with Interstitial nephritis, 2 with Interstitial lung disease).
Results: In the RA group (A+B), mean serum homocysteine, leptin and neopterin levels were (11.79 + 8.72 µmol/L), (22.43 ± 7.37 ng/ml) & (3.83±1.84 nmol/L) respectively with No statistically significant difference was found between RA and control groups regarding serum Leptin (p=0.674). While a significant difference was found between RA and control groups regarding serum Neopetrin (< 0.001) & homocysteine. (< 0.001). Also, In RA groups (A, B) there was a statistically significant difference regarding serum Neopterin (p< 0.03) and DAS 28 ESR (p< 0.05). there was a Positive significant correlation between serum (neopterin - Hcy) and ESR, TNF-α, IL-6, and DAS-28 (p < 0.05) while no significant correlation was found between serum (neopterin- homocysteine) and CRP (p > 0.05).
Conclusion: Serum leptin cannot be considered of value as an marker of disease activity in RA patients. Serum neopterin can be used as a sensitive marker for assaying inflammation and disease activity in RA patients while serum homocysteine can be used as a predictor of RA extra articular complications.

NAILFOLD VIDEO CAPILLAROSCOPY SUPPORT THE DIAGNOSIS OF OVERLAP CONNECTIVE TISSUE DISEASE: A PILOT STUDY IN A SAMPLE OF RHEUMATOID ARTHRITIS PATIENTS

Keywords: Diagnostic tests, Rheumatoid arthritis

T. Vojinovic[1], R. Campitiello[1], V. Gerli[1], S. Sammorì[1], A. Pinelli[1], C. Schenone[1], E. Gotelli[1], C. Pizzorni[1], A. Sulli[1], V. Smith[2], M. Cutolo[1]. *[1]University of Genoa, IRCCS San Martino Polyclinic, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, Genoa, Italy*; *[2]Ghent University (Hospital), VIB Inflammation Research Centre, Department of Internal Medicine and Department of Rheumatology, Unit for Molecular Immunology and Inflammation, Ghent, Belgium*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease characterized by arthritis and a range of extra-articular organ involvement. Altered microcirculation is an important contributor to the inflammatory reaction characterizing RA and is involved in synovitis and systemic organ manifestations[1]. Nailfold video capillaroscopy (NVC) is a reliable, safe and highly sensitive method for evaluating the morphology of microcirculation and detailed alterations[2].

Objectives: The objective of the study was to evaluate the microcirculation in adult RA patients by using NVC and to identify morphological and quantifiable NVC parameters with possible correlations with clinical and laboratory findings.

Methods: NVC was performed at baseline on 8 fingers of both hands of 25 RA patients (EULAR/ACR 2010 criteria) (mean age 68.57±13.47 years, mean disease duration 14.6±8.6 years)[3]. Different NVC parameters indicating microvascular damage were detected and analyzed, such as microvascular architecture, capillary morphology and loss of capillaries (linear/mm). The results were categorized into "non-scleroderma" pattern, such as "normal" and "non-specific alterations", as well as "scleroderma" and "scleroderma-like" pattern. The RA patients were treated (at the time of the analysis) with low dose glucocorticoids, NSAIDs and cDMARDs (see Table 1). Statistical analysis was performed by non-parametric tests.

Results: The patient's mean age at the time of NVC was 62.68±12.68 years and they consisted mostly of women (84%). The caucasian cohort was composed of 56% seropositive RA patients, all of which were RF positive (100%) and 71.43% also presented anti-CCP positivity. Nine patients (36%) were affected by Raynaud phenomenon. Eighty-four percent of RA patients (84%) presented together with normal capillaries a varying degree of microvascular nonspecific findings, like tortuosity, capillary crossing as well as some abnormal shapes (ramified capillaries). Interestingly, "Early" scleroderma NVC pattern was observed in 1 patient (4%), showing giant capillaries and microhaemorrhages. "Scleroderma-like" capillaroscopic pattern was found in 2 patients (8%) with the following features: dilatations, giant capillaries, microhaemorrhages, abnormal capillary shape with ramifications and reduced mean capillary number per linear mm. NVC observation of "Early" scleroderma pattern and "Scleroderma-like" pattern in 3 patients (12%), suggested the coexistence of an overlap syndrome (most likely MCTD), also supported by clinical and autoantibodies specificities. No specific RA NVC pattern was detectable. No statistically significant correlations were found between different NVC parameters and autoantibodies or specific RA clinical features.

Conclusion: The results of present study confirm in sample size that a specific NVC pattern is not detectable in RA, even in early RA patients. The presence of specific patterns, like "Early" scleroderma NCV pattern and "scleroderma-like" pattern, suggest in those "RA patients" the presence of an overlap syndrome. The inclusion of the NVC analysis in patients affected by autoimmune connective tissue diseases (like RA) may contribute to a better definition of the diagnosis, especially in presence of complex clinical symptomatology (overlap syndromes).

AB0277 WHAT IS THE LINK BETWEEN LUNG INVOLVEMENT AND ANTI-CCP ANTIBODIES IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE STUDY

Keywords: Rheumatoid arthritis, Lungs

H. EL-Kasmi[1], N. Akasbi[1], I. El Mezouar[1], M. Omari[2], T. Harzy[1]. *[1]الروماتولوجيا, Rheumatology, Fes, Morocco*; *[2]لابورطوار الابيدميولوجيا والصحة الجماعية والطب الاجتماعي, Laboratory of Epidemiology, Clinical Research and Community Health, Faculty of Medicine and Pharmacy, Sidi Mohammed Ben Abdellah University, Fes, Morocco*

Background: Rheumatoid arthritis (RA) is chronic inflammatory rheumatism responsible for joint destruction and also a systemic disease. Pulmonary involvement is one of the most common extra-articular manifestations of RA and it is associated with a poor prognosis. Several studies have demonstrated an association between the occurrence of RA and the positivity of anti-cyclic citrullinated peptide antibodies (anti-CCP), an immunological biomarker that is used to evaluate the disease activity in RA patients.

Objectives: The objective of this study was to investigate the link between anti-CCP and lung damage in patients with RA.

Methods: The study was a retrospective analysis that included 407 patients who were followed for RA between January 2011 and March 2022. Data were collected from the medical records of the patients, and analyzed using statistical test such chi-squared, Fisher's exact test and t-test. The level of significance was set at p=0.05.The study design included a thorough data cleaning process.

Results: The mean age of patients (n=407) was 58.86 years ± 12.441 with a sex ratio of 6 (F/M). The median duration of evolution was 14 ± 7.523 years, 16% of patients were hypertensive and 19.5% were diabetic RA was erosive in 87.2% of patients, rheumatoid factor (RF) was positive in 85% of patients, and anti-CCP was positive in 64.9% of patients. The mean RF level was 165.8982 ± 278.49, and the mean anti-CCP level was 224.26 ± 440.18. Pulmonary involvement was present in 14.5% of patients, with a restrictive pattern seen on pulmonary function tests in 40.4% of cases, and rheumatoid nodules, diffuse interstitial lung disease lesions, and bronchiectasis seen on thorax CT scan in 67.2%, 31.6%, and 25.9% of cases respectively. The study found that anti-CCP was positive in 96.6% of patients with lung involvement, compared to those without lung involvement, with a statistically significant difference (p<0.001). This suggests that a high anti-CCP level may be a risk factor for pulmonary involvement in RA patients.

Conclusion: The study demonstrated the positive association between anti-CCP and the existence of pulmonary involvement in RA, which is consistent with data from the literature. It's important to note that this study is a retrospective one and further studies with larger population and different design are needed to validate the findings.

AB0278 PERIPHERAL MICROANGIOPATHY ASSESSED WITH VIDEO-CAPILLAROSCOPY IS ASSOCIATED WITH SURROGATE MARKERS OF ACCELERATED ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

E. Angeloudi[1], E. Pagkopoulou[2], E. Bekiari[1], P. Anyfanti[1], M. Doumas[3], A. Garyfallos[2], T. Dimitroulas[2]. *[1]Geniko Nosokomeio Thessalonikis "Ippokrateio", Second Department of Internal Medicine, Thessaloniki, Greece*; *[2]Geniko Nosokomeio Thessalonikis "IPPOKRATEIO", Fourth Department of Internal Medicine, Thessaloniki, Greece*; *[3]Geniko Nosokomeio Thessalonikis "Ippokrateio", Second Propedeutic Department of Internal Medicine, Thessaloniki, Greece*

Background: Rheumatoid Arthritis (RA) is characterized by increased risk for cardiovascular disease [1]. Microvascular dysfunction often coexists with or even precedes macrovascular disease, possibly due to common mechanisms of vascular damage, such as inflammatory processes and oxidative stress [1, 2].

Objectives: To investigate the correlation between microcirculatory changes and markers of atherosclerosis in patients with RA.

Methods: The study evaluated the structural capillaroscopic parameters using video-capillaroscopy (NVC). Applying the tonometry method, the augmentation index (Aix) was calculated, as well as its adjustment to a heart rate of 75 (Aix75). Additionally, pulse wave velocity (PWV), and mean intima-media thickness (cIMT) of the two common carotids, as well as central systolic and diastolic blood pressure (cSBP, cDBP), were calculated in each patient.
Results: A total of 32 patients with a mean age of 63.06±11.05 years were studied. At the same time, the existence of ramified capillaries was significantly correlated with PWV (r=0.38, p=0.032), while the existence of crossed capillaries was inversely correlated with cSBP (r=-0.43, p=0.014). Based on the measurements performed in each capillary, a significant correlation was found between the internal capillary diameter and cSBP (r=0.36, p=0.043). In 16 patients the subpapillary venous plexus was visible and this finding was significantly correlated with the mean value of left cIMT (p=0.005).
Conclusion: The findings of this small study indicate an association between NVC alterations and markers of atherosclerosis in patients with RA.

AB0279 FACTORS AFFECTING QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Quality of life

M. Brahem[1], R. Sarraj[1], B. Jebali[1], O. Jomaa[1], M. Hassayoun[1], S. Abdellatif[1], H. Hachfi[1], Y. Mohamed[1]. [1]*Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia*

Background: Rheumatoid Arthritis (RA) has an important impact on patients 'quality of life (QoL), affecting both physical and mental domains of well-being.
Objectives: This study aims to assess the QoL of RA patients based on the Short Form Health Survey-36 (SF-36) questionnaire and to evaluate the associated factors.
Methods: This is a cross-sectional study including patients with RA disease. Each patient answered to the SF-36 Questionnaire assessing quality of life, which evaluates 8 domains: physical functioning (PF), bodily pain (BP), role limitations due to physical health problems (RP), role limitations due to personal or emotional problems (RE), mental health (MH), social functioning (SF), energy/fatigue or vitality (VT), and general health perceptions (GH).
Results: We included 78 patients with a mean age of 52.9±11.3 years and a female preponderance (88.5%). The mean duration of disease progression was 11.1±9.5 years. The average of patient global health, numbers of swollen and tender joints were respectively 51.4 ± 2.2, 3.7± 3.2 and 8.6 ± 7.6. Two thirds of patients had moderate to severe disease activity (DAS 28 >3.2). The mean Health Assessment Questionnaire (HAQ) was 1.3 ± 0.8. Hospital Anxiety and Depression Scale (HADS) showed that 16.7% of patients had anxiety and 18% had depression. The SF-36 global score was 52.3 ± 24.8 [15.5-92.8] with an impaired QoL (SF-36 <66.7) in 51 (65.4%) patients. Among the eight domains, the most affected domain was the "role limitations due to physical health problems" (RP) with a mean of 45.4±20.3. Impaired QoL was associated with disease activity parameters: number of swollen joints (p<0.01), number of tender joints (p<0.01), patient global health (p=0.02) and DAS 28 score (p<0.01). Patients with high functional disability (HAQ ≥ 1), high scores of depression and anxiety had poor quality of life (p<0.01). No significant associations were found between QoL and age, gender or duration of disease activity.
Conclusion: RA has a significant physical, psychological and social impact on affected patients. This impairment of QoL was associated with disease activity, functional impact and psychological disorders. Therefore, it is necessary to improve these parameters for a better management of the disease.

AB0280 PREGNANCY, BIRTH OUTCOMES, AND BREASTFEEDING IN CHRONIC RHEUMATIC DISEASES WOMEN

Keywords: Pregnancy and reproduction

K. Maatallah[1], L. Kharrat[1], H. Ferjani[1], D. Ben Nessib[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Orthopedics Institute, Ksar Saïd, Rheumatology, Tunis, Tunisia*

Background: Parenthood is usually challenging in chronic rheumatic diseases, such as rheumatoid arthritis (RA) and spondyloarthritis (SpA). It seems to be affected by the disease state and pharmacological therapies [1,2].
Objectives: We aimed to assess pregnancy, birth, and breastfeeding outcomes in patients with RA and SpA.
Methods: We conducted a cross-sectional study including patients followed for RA or SpA. We collected the following data: age, disease duration, erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) levels, disease activity was assessed using DAS28 score for patients with RA and ASDAS-CRP scores for patients with SpA. We asked patients about their pregnancies, birth outcomes, and breastfeeding. Statistical analysis was performed using SPSS software.
Results: Forty-six women were included. They were 23 RA patients and 23 SpA patients. The mean age was 50.2 ± 13.1 years. The mean disease duration was 9.64 ± 8.27 years. The mean ESR and CRP levels were 40.45 ± 33.12mm and 15.22 ± 24.21 mg/L. The mean DAS28-ESR and ASDAS-CRP were 5.25 + 1.21 and 2.7 + 0.6, respectively. Forty-one women were married, 3 were divorced and 2 were widows. The mean age at the marriage was 24.9 + 6.66 years. Half of the patients had suffered from infertility (n=23). Eight of them never had kids (17%). The mean numbers of gestation and parity were 3 + 2 [0-7] and 2+ 1 [0-6], respectively. Seven patients discontinued their treatment to get pregnant without discussing it with their rheumatologists (15%). Only 6 patients had complications during their pregnancies (16%). Complications were abortion in 5 cases and preeclampsia with premature birth in one case. Twenty-five patients gave natural vaginal birth (66%), 7 patients gave birth by C-section (18%), and 6 patients needed obstetrical forceps to give birth (16%). Two patients had a post-partum hemorrhage. The mean term birth was 39.18 ± 1.44 weeks of amenorrhea. Thirty-four patients had breastfed the children (74%). The mean breastfeeding duration was 13.76 ± 8.8 months. Eight patients reported impairment of breastfeeding due to their diseases (21%). Birth with cesarean section was associated with a younger age at the onset of the disease (32.75 ± 5.73 vs 43.16 ± 10.3 years, p=0.031). DAS28-ESR and ASDAS-CRP were higher in patients who had cesarean section but the difference was not significant (DAS28: 5.12 ± 0.45 vs 4.34 ± 0.79, p=0.08; ASDAS: 3.04 ± 0.9 vs 2.59 ± 0.6, p=0.3). Furthermore, younger age was associated with impaired breastfeeding (39.4 ± 9.23 vs 56.11 ± 11.27 years, p=0.01). Discontinuing the treatment was associated with infertility (p=0.003), a younger age of the patient (40.8 ± 7.82 vs 51.33 ± 14.47 years, p=0.002), older age at the marriage (34 ± 6 vs 23.21 ± 5.02 years, p=0.042), and higher CRP (22.08 ± 27.58 vs 8.18 ± 8.36 mg/L, p=0.04).
Conclusion: Our results are consistent with other studies [2], caesarean section rates seem to be high in RA and SpA patients [3]. Strikingly, our youngest patients were the ones that discontinued their treatment to get pregnant. This highlights the importance of informing and discussing pregnancy with patients with chronic inflammatory diseases.

AB0281 THE ALBUMIN LEVEL AND THE ACTIVITY OF RHEUMATOID ARTHRITIS, WHAT CORRELATION?

Keywords: Rheumatoid arthritis, Descriptive studies

F. E. Chekkouri[1], A. Mougui[1], I. El Bouchti[1]. [1]*centre Hospitalo-Universitaire Mohammed Vi Marrakech, Rheumatology, Marrakech, Morocco*

Background: Inflammation during rheumatoid arthritis (RA) can cause changes in the serum levels of certain proteins, including albumin. Our study aims to find a link between albumin level and disease activity.
Objectives: The objective of our study was to study the correlation between the albumin level and the indices of RA activity.
Methods: Descriptive and comparative study including patients with RA between 2007 and 2021.
Statistical data analysis was performed using SPSS version 20 software.
The correlation between albumin level and RA activity indices was assessed using Pearson's correlation coefficients (p-values).
Results: 260 patients were included. The average age was 49.91 years, with a female predominance in 86.9% of cases. The average duration of evolution was 4.64 years. Chronic polyarthritis was the most frequent mode of revelation (74.2%), it was deforming in 64.1% of cases. Structural damage was present in 84.8% of patients, RA was seropositive for ACPA in 82.9% and seropositive for RF in 77.5% of cases. The mean ESR and CRP levels were 44.08 mm/h and 32.68 mg/l respectively. Hypoalbuminemia was found in 41.1% of patients with an average albuminemia of 36.5 ± 6.78 g/l. The mean DAS28-CRP was 5.26 and the mean CDAI was 35.75. Patients with severe activity had more frequent hypoalbuminemia than those with moderate and low activity (67% vs 22% and 7%). A significant negative correlation was found between the albumin level and the DAS28 - CRP (r= -0.24, p=0.003), on the other hand the CDAI score was not correlated with the albumin level (r= -0.22, p=0.16). There is a significant correlation between albumin level, CRP level and ESR (r=-0.27,p=0.001, r=-0.27, p=0.001).
Conclusion: These results suggest that the albumin level could provide additional information on the intensity of inflammation in RA.

AB0282 NEW INFLAMMATORY MARKER IN RHEUMATOID ARTHRITIS: NEUTROPHIL/LYMPHOCYTE RATIO (NLR)

Keywords: Rheumatoid arthritis, Biomarkers

H. Hachfi[1], R. Sarraj[1], M. Brahem[1], O. Jomaa[1], N. E. H. Othman[1], S. Abdellatif[1], B. Jebali[1], Y. Mohamed[1]. [1]*Taher Sfar University Hospital, Rheumatology, Mahdia,Tunisia*

Background: Although neutrophils and lymphocytes play well-established roles in the pathogenesis of Rheumatoid arthritis (RA), their count is most often ignored by clinicians. However, the neutrophil/lymphocyte ratio (NLR) seems to be of great value in the evaluation of disease activity.
Objectives: Our objective is to determine the interest of this ratio and to study its relationship with the other parameters of RA activity.
Methods: Cross-sectional study of 70 patients followed for RA. We performed a biological check-up including a complete blood count (CBC), an ESR and CRP level. A NLR was calculated for each patient.
Results: There were 58 women (82.9%) and 12 men (17.1%) with a mean age of 54.7 ± 13.6 years [19-82]. The mean duration of the disease was 10.1± 9.9 years. Sixteen patients (22.8%) had recent RA (<2 years). The mean DAS 28 ESR was 5.38± 1.48. Thirty-nine patients (55.7%) had high disease activity. The average of ESR and CRP were 59 mmH1± 35 [12-150] and 30.3 mg/l ± 28.6 [0-159], respectively. Anemia of inflammation was observed in 43.3% of cases. Lymphopenia was found in 28.6% of cases, neutropenia in 1.4% and neutrophilic polynucleosis in 17% of cases. The mean of neutrophil/lymphocyte ratio was 3.62±2.68 [0.48-13.26]. It was 3.7 in patients with severe activity and 3.5 in those with low to moderate activity. Statistical analysis found a significant association between this ratio (NLR) and anemia (p=0.003), ESR (p=0.005), CRP (p=0.038) and disease activity assessed by DAS 28 ESR (p=0.04).
Conclusion: Despite the fact that in RA there are few studies evaluating the interest of the NLR, our study concludes that this ratio is considered as an alternative inflammatory biomarker that could be used to assess the disease activity.

AB0283 THE IMPACT OF POLLUTION ON DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS: A 112 PATIENT GROUP STUDY

Keywords: Rheumatoid arthritis, Prognostic factors, Geographical differences

H. Tebaa[1], A. Rafi[1], H. Arabi[1], A. Mougui[1], I. El Bouchti[1]. [1]*Centre Hospitalo-Universitaire Mohammed Vi Marrakech, Rhumatology, Marrakech, Morocco*

Background: Air pollution is incriminated in a large number of respiratory and cardiovascular pathologies. More recently, the role of particulate matter from pollution has been studied in autoimmune diseases and in particular in rheumatoid arthritis (RA).
Objectives: The objective of our study is to evaluate the impact of air pollution measured by the air quality index (AQI) on different disease parameters during rheumatoid arthritis.
Methods: We included in this study 112 patients with seropositive rheumatoid arthritis, residing in different regions of southern Morocco. Inclusion criteria were: established rheumatoid arthritis, duration of residence exceeding one year in the same region. Exclusion criteria were: specific professional exposure to industrial pollutants and passive and active smoking. The air quality was evaluated by the new ATMO index which classifies the air quality in five levels: Good, average, degraded, bad, very bad and extremely bad according to the concentration of the four air pollutants. The following parameters were collected: duration of disease progression, age, number of exacerbations per year, the mean DAS 28 CRP during the last year, the mean CRP during the last year, the use of analgesics, the number of hospitalizations, an univariate and multivariate analysis evaluating the association and the correlation with the different parameters was carried out by the SPSS 2021.
Results: 112 patients were included. The female sex represents 66%. The different regions included in the study were: Marrakech in 68 cases with an AQI of 47, Safi in 9 cases with an AQI of 21, Beni Mellal in 6 cases with an AQI of 29, Sidi Rehal in 1 case with an AQI of 1, Demnate in 2 cases with an AQI of 29, Ouarzazate in 4 cases with an AQI of 25, Azilal in 10 cases with an AQI of 34, Zagora in 4 cases with an AQI of 21, Youssoufia in 1 case with an AQI of 9, Guelmim in 7 cases with an AQI of 17, Semara in 1 case with an AQI of 46. The average DAS 28 was 3.11. The mean CRP was 23.1 mg/l. The average number of hospitalizations during the last year was 2.5. The average number of exacerbations in the last year was 5.6. The use of level 1 analgesic was noted in 22%, level 2 in 13%. A positive correlation was found between the number of exacerbations and AQI (p 0.001, rs 0.67), CRP and AQI (p 0.013, rs 0.71).
Conclusion: The associations between rheumatoid arthritis and air pollution seem complex, it can be considered as a risk factor aggravating rheumatoid arthritis, and these hypotheses have to be demonstrated on a larger sample.

AB0284 EVALUATION OF THE RELATIONSHIP BETWEEN SERUM NETRIN-1 LEVEL AND PATIENT CHARACTERISTICS IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

G. Ozan[1], S. Erten[2], S. C. Güven[3], A. Kor[2], F. Eren[4], P. Akyüz Dağlı[3], Y. Maraş[5], I. Dogan[2], K. Gok[3], O. Küçükşahin[2], B. Armagan[3], S. Neşelioğlu[6], S. Başer[1],

O. Erel[6]. [1]*Ankara Yıldırım Beyazıt University, Internal Medicine, Ankara, Turkey*; [2]*Ankara Yıldırım Beyazıt University, Rheumatology, Ankara, Turkey*; [3]*Ankara City Hospital, Rheumatology, Ankara, Turkey*; [4]*Ankara City Hospital, Clinic of Biochemistry, Ankara, Turkey*; [5]*University of Health Sciences, Rheumatology, Ankara, Turkey*; [6]*Ankara Yıldırım Beyazıt University, Clinic of Biochemistry, Ankara, Turkey*

Background: Although many predictors have been proposed to predict rheumatoid arthritis (RA) disease activity, most of these markers are not specific to RA and their levels can be affected by many other factors. The need for ideal markers to predict disease activity in RA continues. The association of netrin-1 with RA disease activity has not been evaluated before.

Objectives: This study aimed to investigate the plasma levels of the netrin-1 molecule in RA patients and its relationship with RA disease activity.

Methods: Sixty RA patients and 41 age and sex-matched healthy volunteers were included in this study. An ELISA kit (Elabscience, Texas, USA; catalog number: E-EL-H2328; lot number: GZWTKZ5SWK) analyzed by quantitative sandwich enzyme immunoassay method was used to calculate netrin-1 values. Disease Activity Score-28 (DAS-28) and Clinical Disease Activity Index (CDAI) were calculated to measure disease activity, and Rheumatoid Arthritis Disease Impact (RAID) score was calculated to measure disease-related deterioration in the quality of life.

Results: Netrin-1 serum levels were similar in RA and healthy controls (respectively, 64.4 [35.8-551.4] and 65 [35.8-436.6], p:786). No significant correlation was found between levels of Netrin-1 and DAS-28-CRP, DAS-28-ESR, CDAI, and RAID scores (p>0.05).

Conclusion: Netrin-1 is not elevated in RA patient serum and its levels are not correlated with RA disease activation scores.

AB0285 MANAGEMENT OF ATLANTO-AXIAL SUBLUXATION IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Rheumatoid arthritis, Prognostic factors, Disease-modifying drugs (DMARDs)

S. Miladi[1], S. Bouzid[1], A. Fazaa[1], H. Boussaa[1], M. Yasmine[1], K. Ouenniche[1], S. Kassab[1], C. Selma[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Recent studies have shown that around 86% of Rheumatoid Arthritis (RA) have cervical spine involvement [1]. The synovial inflammation in the upper cervical spine causes instability. Atlanto-axial subluxation (AAS) is the most frequent injury of the cervical spine in RA.

Objectives: Our study aimed to assess the medical management of AAS in our RA patients.

Methods: We conducted a retrospective, monocentric study, including patients fulfilling the ACR/EULAR 2010 criteria for RA. All patients had a confirmed AAS on MRI of the cervical spine findings. Disease activity was assessed using the disease activity score 28 (DAS-28). Treatment received by each patient, before and after the occurrence of AAS, was noted.

Results: We included 19 patients with a confirmed AAS. The mean age was 62±14.91 years. Male to female ratio was 0.5. The mean disease duration was 19.27±8.04 years. RA was erosive in all patients and immunopositive in 87% (n=13). When AAS occurred, twelve patients were on csDMARDS. The mean DAS28 ESR was 5.25±1.1. According to DAS28ESR, high disease activity was noted in 10 patients (66.7%). Methotrexate was the most frequent treatment used (n=9, 60%). An association of Methotrexate and sulfasalazine was prescribed in 5 cases (33%). Two patients were using leflunomide. Three patients were on bDMARDS. Nine patients (60%) received bolus steroid therapy. These patients had a vascularized synovial pannus on MRI findings. Four patients remained on the same DMARDs. An association of sulfasalazine to methotrexate was performed in 6 patients. A change from csDMARDs to bDAMRDs was undergone in only two patients (from sulfasalazine to rituximab, and from leflunomide to etanercept). A switch of bDMARDs was performed in three patients: from infliximab to rituximab in one case, and from rituximab to tocilizumab in two others. Surgical treatment was indicated in three patients for neurological complications, but the patients did not agree to proceed with the surgery.

Conclusion: AAS is a potentially lethal complication of RA. The use of bolus steroid therapy can be handy to reduce acute inflammation. However, adjustment of DMARDs is needed to better control RA activity and to slow its progression.

Rheumatoid arthritis - comorbidity and clinical aspects

AB0286 **RETENTION RATE OF BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH DECREASED KIDNEY FUNCTION: RESULTS FROM THE IORRA COHORT**

Keywords: Disease-modifying drugs (DMARDs), Safety, Rheumatoid arthritis

T. Higuchi[1,2], E. Tanaka[1], E. Inoue[1,3], M. Abe[1], K. Saka[1], E. Sugano[1], N. Sugitani[1], H. Yoko[1], M. Ochiai[1], R. Yamaguchi[1], K. Ikari[2,4], Y. Hisashi[1,5], M. Harigai[1]. [1]*Tokyo Women's Medical University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*; [2]*Tokyo Women's Medical University School of Medicine, Division of Multidisciplinary Management of Rheumatic Diseases, Department of Internal medicine, Tokyo, Japan*; [3]*Showa University, Showa University Research Administration Center, Tokyo, Japan*; [4]*Tokyo Women's Medical University School of Medicine, Department of Orthopedic Surgery, Tokyo, Japan*; [5]*Sanno Medical Center, Rheumatology, Tokyo, Japan*

Background: We previously reported that rheumatoid arthritis (RA) patients with chronic kidney disease (CKD) were at increased risk of failure to achieve remission and of occurrence of hospitalized infections [1]. Although biologic disease-modifying anti-rheumatic drugs (bDMARDs) are a promising treatment option, their effectiveness and safety for this population have not been fully evaluated to date.

Objectives: To determine the optimal bDMARD selection for treatment of RA patients with decreased kidney function, we compared the retention rates of patients receiving tumor necrosis factor inhibitor (TNFi), interleukin-6 inhibitor (IL-6i), and abatacept (ABT) in RA patients using data from the IORRA cohort, the real-world data registry of Japanese RA patients.

Methods: Renal function was calculated using the Japanese versions of the equations for estimated glomerular filtration ratio (eGFRcr). Deceased renal function was defined as $eGFR_{Cr}$ <60 mL/min/1.73m^2. Among RA patients enrolled in the IORRA cohort between 2003 and 2020, data from patients with decreased kidney function who started bDMARDs were extracted. Renal function and use of bDMARDs by the extracted patients were identified in their medical records. Reasons for discontinuation were classified as ineffectiveness, adverse events caused by bDMARDs, or other reasons. Retention rates due to ineffectiveness or adverse events caused by TNFi (adalimumab or adalimumab biosimilar [ADA], certolizumab pegol [CZP], etanercept or etanercept biosimilar [ETN], golimumab [GLM], infliximab or infliximab biosimilar [IFX]), IL-6i (tocilizumab [TCZ], sarilumab [SAR]) and ABT spanning 36 months were calculated using the Kaplan-Meier method, and adjusted hazard ratio [aHR] of discontinuation of each bDMARD was calculated using the Cox proportional hazard model, with adjustments for age, sex, disease duration, clinical disease activity index (CDAI), methotrexate (MTX)/ prednisolone (PSL) use, and previous bDMARD use at baseline.

Results: A total of 238 treatment courses administered to 191 patients with decreased renal function were included. Median $eGFR_{Cr}$ was 52.5 mL/min/1.73m^2 (interquartile range: 43.3–57.4). The numbers of bDMARD users were as follows: TNFi, 143 (ADA, 15; CZP, 5; ETN, 67; GLM, 30; IFX, 26); IL-6i, 59 (all were TCZ); and ABT, 36, respectively. ABT users were older than IL-6i users, and TNFi users had higher $eGFR_{Cr}$ and a higher proportion of MTX and previous DMARD use than the other groups. Sex, seropositivity, CDAI, health assessment questionnaire, and the proportion of PSL use were similar between groups. The retention rates at 36 months were 59.9%, 72.9%, and 61.7% for TNFi, IL-6i, and ABT, respectively. aHR of discontinuation when TNFi served as reference was 0.60 (95% confidence interval: 0.32–1.10) for IL-6i, and 0.85 (95% confidence interval: 0.44–1.64) for ABT.

Conclusion: Because the retention rate of IL-6i was numerically high compared with TNFi and ABT in this study, IL-6i may offer a treatment advantage in RA patients with decreased renal function.

RHEUMATOID ARTHRITIS PATIENTS WITH INTERSTITIAL PNEUMONIA NEED APPROPRIATE TREATMENT ENHANCEMENT TO RECOVER FROM FRAILTY: A MULTICENTER RETROSPECTIVE OBSERVATIONAL STUDY

Keywords: Rheumatoid arthritis, Comorbidities, Lungs

Y. Ohashi[1], N. Takahashi[2], M. Suzuki[1], Y. Sobue[3], R. Sato[1], M. Maeda[1], D. Kihira[4], K. Kishimoto[1], K. Terabe[1], S. Asai[1], S. Imagama[1]. *[1]Nagoya University Hospital, Orthopaedic Surgery, Nagoya, Japan*; *[2]Aichi Medical University Hospital, Orthopaedic Surgery, Nagakute, Japan*; *[3]Japanese Red Cross Nagoya Daiichi Hospital, Orthopaedic Surgery, Nagoya, Japan*; *[4]Nagoya University Hospital, Orthopaedic Surgery, Nagya, Japan*

Background: Frailty is a common geriatric syndrome that embodies an elevated risk of catastrophic health and physical function declines among older adults [1]. Rheumatoid arthritis (RA) is an autoimmune disease that causes synovitis in the joints, resulting in joint deformity with a high prevalence (0.5-1.0% in Japan) [2]. Japan is one of the world's most rapidly aging societies [3], and older RA patients are generally at a greater risk of frailty than the general population. Most patients with comorbidities such as pulmonary, renal, and liver dysfunction are more prone to become frailty in the short term than healthy people [4], as well as poor control of disease activity in RA patients [5]. Against this background, the present study aimed to investigate factors associated with frailty in RA patients, including their comorbidities.

Objectives: This study investigates factors associated with frailty in RA patients.

Methods: 656 RA patients were evaluated from our observational study data in 2022. Of the patients, 152 were frailty, and 504 were not frailty assigned to the frailty group and the non-frailty group, respectively. Both patient characteristics were compared in univariate analysis. The factors associated with frailty were assessed by logistic regression analysis. As a sub-analysis, patients who have Interstitial pneumonia (IP) history and patients who do not were assigned to the IP (n =102) and non-IP (n =554) groups, respectively, to clarify differences between both groups.

Results: The frailty group was older (mean: 73.6 vs. 66.8 years) and had a higher DAS28-ESR (mean: 3.67 vs. 2.66) than the non-frailty group. DAS28-ESR (OR: 1.85, P<0.001) and IP history (1.74, P =0.043) were associated with frailty (Table 1). The IP group was older (mean: 73.3 vs. 67.5 years), had a higher DAS28-ESR (mean: 3.30 vs. 2.80) (Figure 1 A), a higher HAQ-DI (mean: 0.32 vs. 1.19) (Figure 1 B), lower use of methotrexate (MTX) (26,5 vs. 62.9%), and higher use of steroid (44.1 vs. 26.8%) than the non-IP group. There was no difference in the use of biological and targeted synthetic disease-modifying antirheumatic drugs (b/ts-DMARDs) between both groups (38.3 vs. 37.3%) (Figure 1 C). The IP group had a higher frailty proportion than the non-IP group (20.6 vs. 37.3%) (Figure 1 D).

Conclusion: DAS28-ESR and IP history were associated with frailty in RA patients. Most RA patients with IP had frailty with insufficient treatments, i.e., low use of MTX, high use of steroid, and low use of b/ts-DMARDs. They might recover from frailty through appropriate control of disease activity using b/ts-DMARDs, which are easy to use for patients with comorbidities.

COMORBIDITY CLUSTERS IN PATIENTS WITH RHEUMATOID ARTHRITIS ARE ASSOCIATED WITH DISEASE ACTIVITY AND PREDICT SURVIVAL PROGNOSIS

Keywords: Prognostic factors, Rheumatoid arthritis, Comorbidities

C. S. Crowson[1], E. Atkinson[1], E. Myasoedova[2], V. Kronzer[2], B. Kimbrough[2], C. Kodishala[2], E. Lovering[2], R. Kumar[2], J. M. Davis III[2]. *[1]Mayo Clinic, Quantitative Health Sciences, Rochester, United States of America*; *[2]Mayo Clinic, Rheumatology, Rochester, United States of America*

Background: Comorbidities are common in patients with rheumatoid arthritis (RA), but there is little information regarding distinct comorbidity patterns in patients with RA and how these patterns impact disease activity and mortality.

Objectives: To examine clusters of patients with RA based on comorbidities, the association between these clusters and RA disease activity, and their impact on mortality.

Methods: In this retrospective, population-based study, residents of a geographically well-defined area with prevalent RA on 1-1-2015 were identified. Patients were followed for vital status until death, last contact or 12-31-2021. Clinical Disease Activity Index (CDAI) was obtained from the medical visit closest to the prevalence date (±1 year). Diagnostic codes were retrieved for 5 years prior to the prevalence date. Using 2 codes ≥30 days apart, 55 comorbidities were defined. Latent class analysis (LCA) was used to cluster patients based on comorbidity patterns with the optimal number of clusters determined by Bayesian Information Criteria. Standardized mortality ratios (SMR) were used to assess differences in mortality across the clusters.

Results: A total of 1643 patients with prevalent RA (72% female; 94% white; median age 64 years, median RA duration 7 years) were studied. Comorbidities were present in 1548 (94%) of the subjects with 5+ comorbidities present in 980 (59%) subjects. LCA identified 4 clusters of patients. Although only comorbidities were used in the LCA, the clusters differed by age, sex, number of comorbidities, smoking status, body mass index (BMI) and RF/ anti-CCP positivity (Table 1). Cluster 1 (n=686) included younger patients who were less likely to smoke and had fewer comorbidities compared to other clusters. In contrast, cluster 4 (n=134) included older patients with 6+ comorbidities who were more likely to have smoked. Cluster 2 (n=200) included younger patients with 6+ comorbidities and high prevalences of depression and obesity, while cluster 3 (n=623) included the remaining patients with 3+ comorbidities consisting mainly of hypertension, hyperlipidemia and back pain). Cluster 1 had no increased mortality based on US lifetables (SMR 0.8; 95% confidence interval [CI: 0.55-1.1). Cluster 4 had the worst survival (SMR 3.5; 95% CI 2.8-4.4). Cluster 2 also had poor survival (SMR 1.6; 95% CI 1.03-2.2), while the poor survival in cluster 3 was less pronounced (SMR 1.2; 95% CI 0.99-1.4). Data on CDAI were available on 725 patients who were mostly like those without CDAI except they were slightly younger (mean age 62 vs 64 years), fewer ever smoked (51% vs 58%) and more were seropositive (71% vs 63%) compared to those without CDAI. CDAI differed across the clusters (p<0.001) with the highest proportion of remission in Cluster 1 and the lowest proportion of remission and the largest proportion of high disease activity in Cluster 2.

Conclusion: Clustering of patients with RA based on comorbidity profiles identified distinct groups exhibiting different prognosis. This demonstrates comorbidities congregate in some patients, leading to poor prognosis, while others

experience fewer comorbidities and better survival than people without RA. The cluster with both better survival and more remission despite a high proportion of seropositivity is intriguing.

Table 1. Characteristics of four clusters of patients with RA

Characteristic	C1 (N=686)	C2 (N=200)	C3 (N=623)	C4 (N=134)	p value
Age, years	55 (46, 63)	60 (51, 68)	72 (63, 78)	77 (71, 82)	< 0.001
Female sex	75%	86%	64%	66%	< 0.001
RF/anti-CCP positive	70%	62%	64%	65%	0.073
RA duration, years	6 (3, 12)	5 (3, 11)	8 (3, 17)	9 (4, 21)	< 0.001
BMI, kg/m^2	27 (24, 33)	31 (27, 35)	29 (25, 34)	28 (25, 34)	< 0.001
Ever smoker	50%	60%	57%	62%	0.005
Number of comorbidities					< 0.001
0-2	43%	0%	0%	0%	
3-5	43%	0%	29%	0%	
6+	4%	100%	71%	100%	
Disease activity	N=327	N=94	N=260	N=44	
CDAI	4 (1, 13)	11 (6, 20)	8 (3,13)	7 (4, 13)	<0.001
Remission (≤2.8)	40%	11%	26%	25%	
Low (>2.8 to 10.0)	29%	36%	38%	39%	
Moderate (>10.0 to 22.0)	19%	31%	23%	20%	
High (>22.0)	12%	22%	13%	16%	

Values in the table are median (25th, 75th %ile) or %

AB0289 FACTORS ASSOCIATED WITH DEVELOPMENT OF MENTAL ILLNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING BIOLOGICAL AND TARGETED SYNTHETIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS: A POPULATION-BASED STUDY

Keywords: Targeted synthetic drugs, bDMARD, Mental health

H. H. Chen[1,2], W. C. Chao[1,3]. [1]*National Chung Hsing University, Department of Post-Baccalaureate Medicine, Taichung, Taiwan, Republic of China*; [2]*Taichung Veterans General Hospital, Department of Internal Medicine, Taichung, Taiwan, Republic of China*; [3]*Taichung Veterans General Hospital, Department of Critical Care Medicine, Taichung, Taiwan, Republic of China*

Background: Rheumatoid arthritis (RA) is a leading chronic inflammatory systemic disease worldwide, and increasing evidence have shown under-recognised impacts on mental health. However, the assessment and management of mental health is somehow not included in the T2T despite increasing evidence have shown that mental illnesses, particularly depression and anxiety, were not only highly prevalent in patients with RA but also associated with control of disease activity. In the present study, we used a population-based database with 10,852 patients with RA who had initiated biollogical or targeted synthetic disease modifying antirheumatic drugs (b/tsDMARDs) thereapy to address the incidence of mental illness and to investigate risk factors for mental illness.

Objectives: This population-based study aim to address the incidence and risk factors of mental illness among patients with RA starting b/tsDMARDs therapy.

Methods: We used the 2001–2020 Taiwanese National Health Insurance Research Database to identify patients with RA receiving b/tsDMARDs. The primary outcome was newly developed mental illness, including anxiety and mood disorders, among spouses. We performed a Cox regression analysis to determine factors associated with mental illness. The results were presented as hazard ratios (HR) with 95% confidence interval (CI).

Results: We enrolled 10,852 patients with RA and had received b/tsDMARDs. Of them, 7,854 patients received tumor necrosis factors inhibitors (etanercept n=3,322; adalimumab n=2,689; golimumab n=1,346; certolizumab n=490; infliximab n=7), 1,693 patients received non-TNFi bDMARDs (tocilizumab n=856; abatacept n=837), and 1,305 patients were treated with tsDMARD (tofacitinib n=1,192; barticitinib n=113). We found that 13.62% of enrolled patients developed mental illness, with the incidence was 4,054 per 100,000 person-year. Those receiving tocilizumab (aHR 0.65, 95%CI 0.51–0.82), Abatacept (aHR 0.69, 95%CI 0.55–0.87) and tsDMARDs (aHR 0.59, 95%CI 0.47–0.73) had a lower risk of mental illness compared with receiving TNFi. We also found that old age (aHR 1.02, 95%CI 1.01–1.02), low income (aHR: 1.16, 95% CI: 1.04–1.29), use of cyclosporine (aHR: 1.20, 95% CI: 1.05–1.38), and use of steroid higher than 5 mg/day (aHR: 1.23, 95% CI: 1.02–1.48) correlated with incident mental illness.

Conclusion: This population-based study investigated the incidence and risk factors of mental illness among the patients with RA receiving b/tsDMARDs. Our findings highlight the need for vigilance of mental illness in patients with RA.

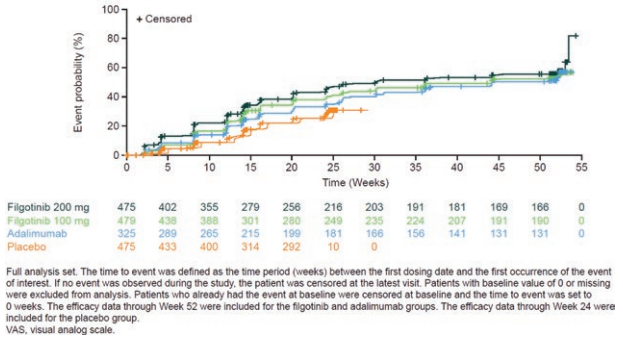
Background: Patients (pts) with rheumatoid arthritis (RA) often experience substantial pain despite treatment, and pain control is considered an important treatment outcome. The FINCH 1–3 studies demonstrated the efficacy and acceptable safety of the preferential Janus kinase (JAK) 1 inhibitor filgotinib (FIL) in pts living with RA.

Objectives: This *post-hoc* analysis of the FINCH studies assessed specific effects of FIL on pain.

Methods: FINCH 1–3 (NCT02889796, NCT02873936, NCT02886728) were Phase 3, randomized, double-blind trials of FIL 100 mg and 200 mg (FIL100/200). In FINCH 1, pts with an inadequate response (IR) to methotrexate (MTX) received FIL, adalimumab (ADA) or placebo (PBO) + MTX for 52 weeks. In FINCH 2, pts with an IR to biologic disease-modifying anti-rheumatic drugs (DMARDs) received FIL or PBO + conventional synthetic DMARDs for 24 weeks. In FINCH 3, MTX-naïve pts received FIL ± MTX or MTX for 52 weeks. For each treatment group, pts reported pain on a 100-mm visual analog scale (VAS). Scores of ≤10 mm reflected limited to no pain; scores of ≤20 mm indicated health status was not negatively affected by pain.[1] Time to first VAS score of ≤10 mm was assessed. The proportion of pts who achieved remission (as per Disease Activity Score 28 with C-reactive protein [DAS28-CRP] <2.6 or Clinical Disease Activity Index [CDAI] ≤2.8) at Week 24 was evaluated. Of pts who achieved DAS28-CRP or CDAI remission, the proportion who also reported VAS pain scores of ≤10 mm or ≤20 mm was determined.

Results: In FINCH 1, there was a higher probability of achieving a VAS pain score of ≤10 mm with FIL200, vs ADA + MTX or PBO + MTX; responses were better or comparable with FIL100 vs other treatment arms (**Figure 1**). Similar findings were observed in FINCH 2 and 3 for FIL vs PBO and MTX, respectively. In FINCH 1, the proportion of pts achieving DAS28-CRP remission was greater with FIL200 + MTX (48.4%) and comparable for the FIL100 + MTX (35.2%) vs ADA + MTX arms (35.7%; **Table 1**). Further, the proportion of pts who achieved VAS pain scores of ≤10 mm and ≤20 mm in addition to DAS28-CRP remission was 26.3% and 35.8%, respectively, in the FIL200 + MTX group, compared with 17.2% and 24.6% in the ADA + MTX group (**Table 1**). In FINCH 2 and 3, a



greater proportion of pts in the FIL groups achieved remission vs the PBO or MTX arms, respectively. A greater proportion of pts achieved pain responses in addition to DAS28-CRP remission in the FIL groups of FINCH 2 and FINCH 3 compared with PBO or MTX, respectively. Findings were similar when CDAI remission was assessed.

Conclusion: FIL positively affected pain parameters across the FINCH studies as early as Week 2, with responses sustained over time (up to Week 52 [FINCH 1 and 3] and Week 24 [FINCH 2]). In FINCH 1, FIL200 had a particularly favorable impact when pain response and remission were assessed together. Similar findings were seen with FIL compared with PBO and MTX in FINCH 2 and 3, respectively. These findings suggest that JAK inhibition may offer potential added value with respect to patient-reported pain outcomes when treat-to-target goals are met.

Figure. Cumulative incidence of time to first VAS pain score ≤10 mm in FINCH 1

Full analysis set. The time to event was defined as the time period (weeks) between the first dosing date and the first occurrence of the event of interest. If no event was observed during the study, the patient was censored at the latest visit. Patients with baseline value of 0 or missing were excluded from analysis. Patients who already had the event at baseline were censored at baseline and the time to event was set to 0 weeks. The efficacy data through Week 52 were included for the filgotinib and adalimumab groups. The efficacy data through Week 24 were included for the placebo group.
VAS, visual analog scale.

AB0291

QUICK ATTAINMENT OF LOW DISEASE ACTIVITY LESSENS THE DISEASE BURDEN OF RHEUMATOID ARTHRITIS IN THE LONG TERM, EVEN WHEN A TREAT-TO-TARGET APPROACH IS APPLIED

Keywords: Patient reported outcomes, Rheumatoid arthritis, Treat to target

S. Snoeck Henkemans[1], M. Vis[1], A. Van der Helm – van Mil[1,2], P. De Jong[1].
[1]Erasmus MC, Rheumatology, Rotterdam, Netherlands; *[2]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: Treat-to-target (T2T) strategies in early rheumatoid arthritis (RA) are aimed at achieving sustained remission or low disease activity. Remission and low disease activity are both associated with improved clinical outcomes and patient-reported outcomes (PROs). However, it is currently unknown if achieving sustained remission in the first year improves long-term PROs in RA.

Objectives: To examine associations between functional ability, health-related quality of life, pain and depression over 1-3 years in RA patients who have (1) sustained remission, (2) low disease activity or (3) active disease in the first year after the diagnosis is made.

Methods: We included all RA patients, according to 2010 or 1987 criteria, from the tREACH trial. The tREACH is a multicenter, stratified single blinded trial with a T2T approach, aiming for low disease activity (DAS44 <2.4). Included patients were categorized in 3 groups depending on their DAS44/ESR-3 items (DAS), thus not including general health, in the first year:

- **Sustained remission**, includes patients who were in remission (DAS <1.6) at the 6, 9 and 12 month visit;
- **Low disease activity**, includes patients who had low disease activity (DAS ≤2.4) at 6, 9 and 12 months and did not fit in the sustained remission group;
- **Active disease**, includes patients who had an active disease (DAS >2.4) at least at 6 and 9 months, 6 and 12 months or 9 and 12 months.

Functional ability was measured with the Health-Assessment Questionnaire – Disability Index (HAQ-DI). Health-related quality of life (HRQoL) was measured with the Short form-36 (SF-36). Pain was measured with a 10-point Likert scale and depression was measured with the Hospital Anxiety and Depression Scale (HADS). Linear mixed models from 1-3 years, with gender, initial treatment, DAS and baseline PRO score as covariates, were used to compare PROs over time.

Results: We included 304 RA patients (61% female) of whom 90 (30%) had sustained remission, 148 (49%) low disease activity and 66 (22%) active disease. RA patients with active disease were, compared to the low disease activity and remission groups, more often female (79% vs 65% vs 42%) and had more tender joints (median 14 (IQR 9-21) vs 8 (IQR 5-14) vs 5 (IQR 2-10)) and a higher baseline DAS (mean 3.6 (sd 0.8) vs 3.1 (sd 0.8) vs 2.8 (sd 0.9)). After 15 months all 3 groups had a mean DAS <2.4 (Figure 1A). Nevertheless, RA patients in the active disease group continued to have more functional limitations and pain during 1-3 years of follow-up compared to the other groups, respectively low disease activity (β -0.35 (95% CI -0.47, -0.23), p<0.001 for HAQ-DI and β -0.91 (95% CI -1.42, -0.39), p=0.001) for pain) and remission (β -0.42 (95%CI -0.57, -0.28), p<0.001 for HAQ-DI and β -1.26 (95% CI -1.86, -0.66), p<0.001) for pain) (Figure 1B-C). No differences were seen in depression scores and mental health items over time. However, at baseline, a higher proportion of RA patients in the active disease group (26%) had a score suggestive of the presence of depression (HADS >7) compared to the low disease activity (18%) and sustained remission (13%) groups (Figure 1D). HRQoL was comparable to the general Dutch population after 1 and 3 years of follow-up, except for patients with an active disease (Figure 1E-F).

Conclusion: Failure to achieve remission or low disease activity in the first year after RA diagnosis is associated with persistent functional impairment and pain, despite the T2T approach that aims for low disease activity.

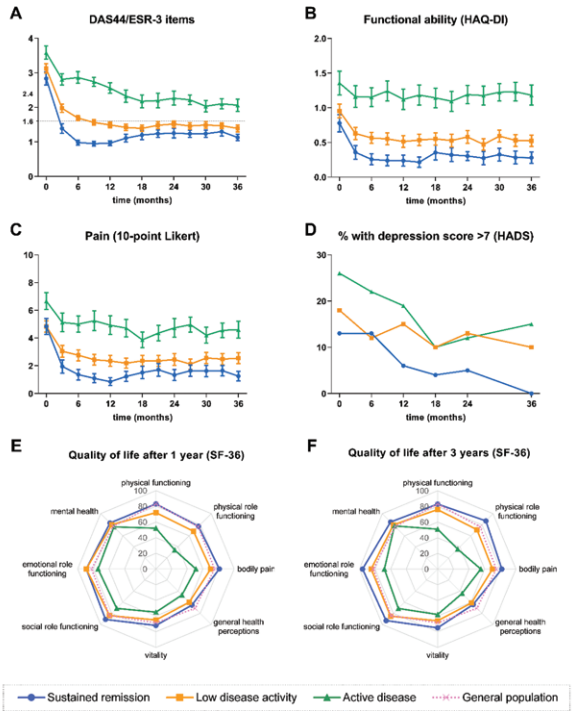

Figure 1. (A) DAS-44 3-items, **(B)** Functional ability and **(C)** Pain scores over 3 years per group, **(D)** Percentage of patients who have depression scores >7 per group, **(E)** 1 year and **(F)** 3 year HRQoL scores, measured with the SF-36 domains, for disease activity groups and compared with the general Dutch population norms

AB0292 A CROSS-SECTIONAL STUDY OF THE CENTRAL SENSITIVITY SYNDROME USING THE CENTRAL SENSITIZATION INVENTORY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Pain

K. Seki[1], T. Imagama[1], T. Seki[1], T. Okazaki[1], K. Uehara[1], T. Sakai[1]. [1]*Yamaguchi University Graduate School of Medicine, Department of Orthopedic Surgery, Ube, Japan*

Background: Despite having low levels of inflammation, 47.3% of patients with rheumatoid arthritis (RA) continued to report moderate-to-high pain and fatigue [1], indicating that chronic pain can interfere with disease activity assessment. And chronic pain have linked to central sensitization syndromes (CSSs) of pain [2]. The central sensitization inventory (CSI) is a valid and reliable tool for detecting CSS, its severity, and associated syndromes [3]. However, there have been few reports of CSS in patients with RA being analysed with CSI.
Objectives: This study aims to conduct a cross-sectional analysis of CSS in RA patients using the CSI and investigate the relationship with disease activity.
Methods: We performed a retrospective, cross-sectional study on 269 consecutive RA patients (70 males and 196 females; mean ± SD = 69.9 ± 12.2 years, range: 27–92 years; mean ± SD, disease duration: 12.9 ± 10.4 years, range: 0–55 years; mean ± SD DAS28CRP: 1.89 ± 0.78; range: 0.99–4.88). Patients were evaluated by the CSI; clinical and laboratory examinations were performed on all patients on the same day. SJC, TJC, CRP, ESR, PtVAS, pain VAS, DAS28CRP, DAS28ESR, HAQ-DI, and CDAI were compared in the "CSS group (CSI ≧ 40)" and the "non-CSS group (CSI < 40)" [4]. Furthermore, the relationship between each parameter and the CSI was also investigated.
Results: CSI had a mean ± SD of 18.4 ± 14.6. CSI ≥ 40 was found in 9.6% (26 patients). The number of PtGA, pain VAS, CDAI, and HAQ-DI were all significantly higher in the "CSS group" than in the "non-CSS group" (Table 1). PtGA ($r = 0.352$, $p < 0.001$), pain VAS ($r = 0.369$, $p < 0.001$), CDAI ($r = 0.253$, $p < 0.001$), and HAQ-DI ($r = 0.477$, $p < 0.001$) were all found to have significant correlations with CSI.

Table 1. Compared with CSS group and non-CSS group

	CSS group(n=26) Mean±SD, %	non-CSS group (n=243) Mean±SD, %	*p* value
Disease duration (years)	15.4±11.3	12.6±10.3	0.202
Steinbrocker stage 1 2/3 4(%)	26.9/73.1	45.9/54.1	0.064
Tender joint count (0-28)	0.7±0.9	0.4±0.9	0.054
Swollen joint count (0-28)	0.2±0.5	0.4±1.0	0.389
CRP (mg/dl)	0.38±0.67	0.47±1.02	0.874
ESR (mm)	15.4±16.9	18.0±18.3	0.636
PtGA (VAS/100mm)	37.3±24.2	20.2±23.7	<0.001*
DAS28CRP	2.14±0.80	1.85±0.77	0.068
CDAI	5.23±28.4	3.46±3.82	<0.01*
Pain VAS/100mm	42.1±28.4	19.4±23.2	<0.001*
HAQ-DI	1.41±0.97	0.40±0.64	<0.001*

*significant

Conclusion: In RA patients, CSI was not associated with inflammation (CRP or ESR) but was related to subjective assessment (PtGA or pain VAS), functional impairment, and disease activity (CDAI). CSS may influence disease activity assessment, and CSS treatment may improve functional impairment.

AB0293 RISK FACTORS ASSOCIATED WITH VENOUS THROMBOEMBOLISM IN RHEUMATOID ARTHRITIS IN CLINICAL PRACTICE

Keywords: Comorbidities, Rheumatoid arthritis

F. Oudart[1], M. Thomas[1], A. Combier[1], A. Moltó[1], Y. Allanore[1], J. Avouac[1]. [1]*Cochin Hopital, Rheumatology, Paris, France*

Background: Increased risk of venous thromboembolism (VTE) has been reported in rheumatoid arthritis (RA) compared to the general population [1]. However, factors associated with the risk of VTE have been barely studied in RA.
Objectives: To identify classical or disease-related risk factors of VTE in RA patients in clinical practice.
Methods: Retrospective observational study performed on all RA patients fulfilling the 2010 ACR/EULAR clarification criteria attending the one-day hospitalization program of the Rheumatology department, Cochin hospital, in 2021. We used the electronic medical report to identify the occurrence of VTE in 2021 and collect RA disease characteristics and risk factors for VTE. Multivariate analysis by logistic regression was performed to determine the factors independently associated with VTE.
Results: We included 317 RA patients (263 females, 83%), with a mean age of 59±14 years and a mean disease duration of 16±14 years. Positive rheumatoid factor and positive anti-CCP antibodies were detected in 255 (80%) and 271 (85%) patients respectively. 190 patients (60%) had erosive disease. The mean DAS28 was 3.5±1.4 and the mean CRP level was 6.8±15.9 mg/L; 161 patients (51%) received corticosteroids (mean dose 3.0±3.5 mg/L), 195 (62%) methotrexate, and 151 (48%) targeted biologic or synthetic DMARDs (b/tsDMARDs), including 60 on TNF-α inhibitors, 34 on rituximab and 27 on JAK inhibitors (10 baricitinib, 7 tofacitinib and 10 upadacitinib). We identified 12 (4%) venous thromboembolic events that occurred in 2021, including 9 PVT and 6 PE (incidence of 3.8 for 100 patient/year). The mean duration between the occurrence and VTE and the visit was 3.6±4.8 months. Among these 12 VTE patients, 9 were women (75%, vs. 97% in patient without VTE, p<0.001), with a mean age of 65±12 years (vs. 59±15, p=0.14). Age >65 years was more frequent in patient with VTE (58%

vs. 33%, p=0.064); 7 (58%) patients with VTE had a history of previous VTE (vs. 3%, p<0.001), 6 (50%) were hospitalized up to 6 months before the event (vs. 6%, p<0.001), 3 (25%) experienced surgery up to 3 months bfore the event (vs. 2%, p<0.001) and 4 (33%) had a history of fracture (vs. 3%, p<0.001). No difference was oberved regarding body mass index, the frequency of smoking, neoplasia, recent travel (up to 3 months) and estrogen/antidepressant therapies. No patient had thrombophilia. Regarding RA characteristics, patients with VTE were more likely to present extra-articular manifestations (67% vs. 33%, p=0.015) and higher CRP levels (20±40 mg/L vs. 6.4±14.5 mg/L, p=0.006). They also received more frequently corticosteroids (83% vs. 50%, p=0.025) and JAKi (25% vs. 8%, p=0.041). Disease duration, autoantibody status, frequency of erosions, DA28 and treatment with methotrexate or bDMARDs did not differ between these 2 groups. Logitic regression analysis identified the following risk factors independently associated with the occurrence of VTE: history of previous VTE, hospitalization up to 3 months before the occurrence of VTE, surgery up to 6 months before the occurrence of VTE and treatment with JAKi (**Table 1**).

Conclusion: History of VTE was identified as the strongest risk factor of the occurrence of VTE. Our results suggest a specific warning on recent hospitalization and surgery as precipitating events to VTE. As recommended by the PRAC JAKi should be used with caution in patients with risk factors for VTE.

INFLAMMATION AND IMMUNOMODULATORY THERAPIES INFLUENCE THE RELATIONSHIP BETWEEN ATP-BINDING CASSETTE TRANSPORTER A1 (ABCA1)-MEDIATED CHOLESTEROL EFFLUX AND CORONARY ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Imaging, Cardiovascular disease

G. Karpouzas[1,2], B. Papotti[3], S. Ormseth[2], M. Palumbo[3], E. Hernandez[2], M. P. Adorni[3], F. Zimetti[3], M. Budoff[4,5], N. Ronda[3]. [1]*Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America*; [2]*The Lundquist Institute, Rheumatology, Torrance, United States of America*; [3]*University of Parma - Parco Area delle Scienze, Internal Medicine, Parma, Italy*; [4]*Harbor-UCLA Medical Center, Cardiology, Torrance, United States of America*; [5]*The Lundquist Institute, Cardiology, Torrance, United States of America*

Background: Cholesterol efflux capacity (CEC) measures the ability of high-density lipoprotein (HDL) to remove cholesterol from atherosclerotic plaques. It is mediated by various membrane transporters exporting cholesterol to HDL particles based on their maturation. It is unclear whether CEC associates with coronary atherosclerosis independently of HDL-C levels in RA or whether CEC itself or its impact on atherogenesis are influenced by inflammation or RA-specific therapies. Conventional and biologic DMARDs are atheroprotective while corticosteroids are proatherogenic. ATP-binding-cassette membrane transporter A1 (ABCA1) exports cholesterol to apo A1 or lipid-poor HDL particles.

Objectives: We here explored associations between ABCA1 CEC and coronary atherosclerosis and whether inflammation and disease-specific therapies influence this relationship.

Methods: Coronary atherosclerosis (noncalcified, partially or fully calcified plaque and coronary artery calcium [CAC] score) was evaluated with computed tomography angiography in 140 patients without cardiovascular disease and reassessed in 99 after 6.9±0.4 years. ABCA1 CEC was measured in J774 macrophages as previously described. Multivariable negative binomial regression evaluated associations of ABCA1 CEC with plaque numbers at baseline and follow-up. Robust logistic regression tested the association of ABCA1 CEC with CAC progression (>2.5 U difference in square root CAC scores).

Results: ABCA1 CEC was not associated with baseline atherosclerosis. Inflammation, prednisone, methotrexate or bDMARD use did not influence the relationship between ABCA1 CEC and baseline plaque. However, both baseline and cumulative inflammation modulated the relationship between ABCA1 CEC and plaque progression. Each standard deviation (SD) increase in ABCA1-CEC associated with 41% fewer new plaques in patients with low (<median) baseline ESR but 67% more new plaques in those with high (>median) ESR (p for interaction = 0.015, Figure 1). Likewise, each SD increase in ABCA1 CEC associated with 53% fewer new calcified plaques in patients with low (<median) but not high (>median) time-averaged CRP (p for interaction = 0.028). Higher ABCA1 CEC (per SD) associated with 37% fewer new calcified plaques in baseline prednisone nonusers but not users (p for interaction = 0.021). For time-weighted mean daily prednisone dose, each SD increase in ABCA1 associated with 31% fewer new plaques in unexposed patients (p for interaction vs. high exposure group = 0.034), as well as 53% fewer and 2.4 times more new calcified plaques in the unexposed and high exposure groups respectively (p for interaction unexposed vs. high exposure = 0.004). Higher ABCA1 CEC (per SD) was linked to 2.2 times higher adjusted likelihood of CAC progression in methotrexate nonusers but not in users (p for interaction = 0.018). Likewise, each SD increase in ABCA1 CEC associated with 2.7 times more new plaques in baseline bDMARD nonusers and 35% fewer new plaques in users (p for interaction ≤ 0.001).

Conclusion: ABCA1 CEC attenuated plaque progression exclusively in patients with low baseline and cumulative inflammation as well as in baseline methotrexate and bDMARD recipients. In contrast, ABCA1 CEC associated with plaque progression in baseline corticosteroid recipients and those receiving high time-weighted daily average prednisone dose during follow-up. In uncontrolled or inadequately treated disease ABCA1 CEC fails to counteract and may in fact contribute to the proatherogenic state promoted by inflammation and oxidation. The latter also occurs during treatment with prednisone, known to promote intracellular cholesterol accumulation. When RA is sufficiently treated and controlled, ABCA CEC effectively performs its atheroprotective function.

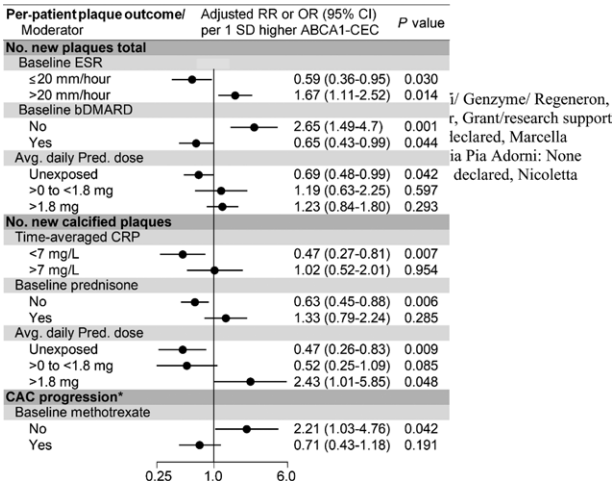

Figure 1. Influence of inflammation and RA therapies on associations of ABCA1 CEC with coronary atherosclerosis progression

Background: Patients with rheumatoid arthritis (RA) have increased morbidity and mortality due to cardiovascular (CV) comorbidities.
Objectives: The association of CV diseases (CVD) and traditional CV risk factors have been debated, depending on patient and RA characteristics. This study aimed to find the prevalence of CVD and CV risk factors in patients with RA.
Methods: A multi-center cross-sectional study was performed on RA patients using the BioSTAR (Biological and Targeted Synthetic Disease-Modifying Antirheumatic Drugs Registry). Socio-demographic, clinical, and follow-up data were collected. Patients with and without major adverse cardiovascular events (MACE) were grouped as Group 1 and Group 2. Prevalence rates of CVD and traditional CV risk factors were the primary outcomes. Secondary outcomes were the differences in the clinical characteristics between patients with and without CVD.
Results: We analyzed 724 RA patients with a mean age of 55.1 ±12.8 years. There was a female preponderance (79.6%). The prevalence rate of CVD was 4.6% (n=33). The frequencies of the diseases in the MACE category were ischemic heart disease in 27, congestive heart failure in 5, peripheral vascular disorders in 3, and cerebrovascular events in 3 patients. The patients with CVD (Group 1) were significantly male, older, and had higher BMI (p=0.027, p<0.001, and p=0.041). Obesity (33.4%) and hypertension (27.2%) were the two CV risk factors most frequently. Male sex (HR=0.085, 95% CI:0.028-0.257, p<0.001) and hypertension (HR=4.63, 95% CI:1.251-17.134, p=0.022) were the independent risk factors for CVD.
Conclusion: The prevalence of CVD in RA patients was 4.6%. Some common risk factors for CVD in the general population, including male sex, older age, and hypertension, were evident in RA patients. sex and hypertension were the independent risk factors for developing CVD in patients with RA.

THE REAL IMPACT OF DEPRESSION AND ANXIETY ON RHEUMATOID ARTHRITIS PATIENTS: A COHORT STUDY

Keywords: Patient reported outcomes, Quality of care, Health services research

R. Nicolau[1,2], A. Martins[2,3], D. Santos Oliveira[3,4], M. Bernardes[2,3], L. Costa[3]. *[1]Centro Hospitalar Tondela Viseu, Rheumatology Unit, Viseu, Portugal*; *[2]Faculty of Medicine, University of Porto, Medicine, Porto, Portugal*; *[3]São João Universitary Hospital Center, Rheumatology, Porto, Portugal*; *[4]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*

Background: Rheumatoid Arthritis (RA) patients are more prone to have depression and anxiety compared to the general healthy population. Although it's been increasingly recognised that mental health conditions are associated with higher disease activity and worse disease outcomes, depression and anxiety are not widely considered in routine care of arthritis patients.
Objectives: This study aims to estimate, in a large cohort of Portuguese patients with RA, the prevalence of depression and anxiety and to explore associations with demographic characteristics and disease-related measures.
Methods: We performed a retrospective analysis including patients diagnosed with RA, according to the 2010 ACR/EULAR criteria, who started their first biological Disease Modifying Antirheumatic Drug (bDMARD). Demographic, clinical and laboratory data were obtained by consulting Rheumatic Diseases Portuguese Register (Reuma.pt). Associations with demographic characteristics and disease-related measures were examined at baseline, 6, 12, 18 and 24 months. Statistical analyses were performed using SPSS statistical software, version 23.0.
Results: A total of 357 patients with RA were included. Eighty-two per cent were females (82%). The mean age was 54 ± 11.01 years and the median disease duration was 10 years [min 0.5, max 45]. Rheumatoid Factor (RF) was positive in 75% of patients and Antibodies to Citrullinated Peptides (anti-CCP) in 82%. The prevalence of depression and anxiety were 34.7% and 23.5%, respectively. Both groups (RA depressed/anxiety) had statistically significant differences concerning gender. Patients with RA and depression/anxiety were significantly more likely to be women and had a lower disease duration. Depressed patients showed a younger RA onset. Unemployed patients were more likely to be depressed. Other factors such as education, smoking or alcohol consumption were not significantly associated. Baseline depression/anxiety was associated with increased patient's global assessment and number of painful joints but not with levels of acute phase reactants. Treatment with conventional synthetic DMARD and/or glucocorticoids did not have any significant association with either depression or anxiety. The proportion of patients achieving disease

remission and good/moderate EULAR response was overall lower in patients with depression/anxiety during the follow-up.
Conclusion: The presence of depression and anxiety among patients with RA was associated with worse response to the first bDMARD. Screening and recognition of such psychosocial disorders may help patients achieve optimal disease control and a good outcome.

AB0297 FOOT AND ANKLE INVOLVEMENT IN RHEUMATOID ARTHRITIS IS ASSOCIATED WITH DISEASE ACTIVITY AND LESS INTENSIVE TREATMENT

Keywords: Outcome measures, Pain, bDMARD

A. Giollo[1], F. Frizzera[1], M. Salvato[1], F. Arru[1], F. Vesentini[1], M. Zen[1], A. Doria[1].
[1]*University of Padova, Rheumatology Unit, Padova, Italy*

Background: Foot and ankle involvement is not encompassed in joint counts routinely used for the management of rheumatoid arthritis (RA). For this reason, RA patients with foot and ankle involvement are at risk of undertreatment.
Objectives: To assess the prevalence of foot and ankle involvement in people with RA, and disease severity and RA-related comorbidities in this group.
Methods: This cross-sectional cohort study included all patients with established RA treated with biological and targeted synthetic disease-modifying anti-rheumatic drugs (b/tsDMARDs) at our Unit between 11/2014 and 12/2021. The following variables were recorded systematically: demographics, RA characteristics and joints involved, glucocorticoid therapy and dose, DMARDs, disease activity score in 28 joints with C-reactive protein (DAS28), and extra-articular manifestations (RA-related lung diseases, rheumatoid vasculitis, rheumatoid nodules, neuropathy, skin diseases, systemic symptoms including Felty's syndrome, and secondary Sjogren's syndrome). We also assessed comorbidities as recommended by EULAR (cardiovascular disease, gastrointestinal disease, depression, osteoporosis, malignancy and infections). We performed crude comparisons between patients with and without foot and ankle involvement by chi-squared test of association and independent T-tests. We used logistic regression to determine the odds ratio (OR) of the association between foot and ankle involvement and b/tsDMARDs, adjusting for DAS28, use of hydroxychloroquine (HCQ), and cardiovascular and lung disease.
Results: Among 1192 RA patients included in this study, foot or ankle involvement was reported in 469 (39%), equally distributed for age (mean±SD 61±13 years) and sex (females 82%). Age at onset, disease duration, erosions, seropositivity, use and dose of glucocorticoid therapy and methotrexate were similar between groups. DAS28 was significantly higher (4.3±1.2 vs 3.7±1.4, p<0.0001) in RA patients with foot and ankle involvement, consistently with a significantly higher patient global assessment (55±22 vs 47±25 mm, p<0.001), and number of tender joints (7±5 vs 5±5, p<0.001) and swollen joints (4±4 vs 3±9, p<0.001); the distribution of RA patients according to categories of disease activity was also significantly different between groups (p<0.001; **Figure 1**). Nevertheless, the use of b/tsDMARDs was less intense in this group, as significantly fewer patients had received ≥2 b/tsDMARDs (28 vs 47%, p<0.0001) despite similar disease duration. They also received more frequently hydroxychloroquine (55.2 vs 46.5%, p=0.003). These patients had significantly more cardiovascular (20.3 vs 15.8%, p=0.046) and lung disease (6.0 vs 2.9%, p=0.008). The body mass index was also significantly higher (25.6±6.5 vs 24.7±8.2 kg/m^2, p=0.048), yet the proportion of patients with obesity was similar between groups (11.3% and 9.3%, respectively). Logistic regression confirmed the significant associations of foot and ankle involvement with a less intensive b/tsDMARDs use and higher disease activity (**Table 1**).

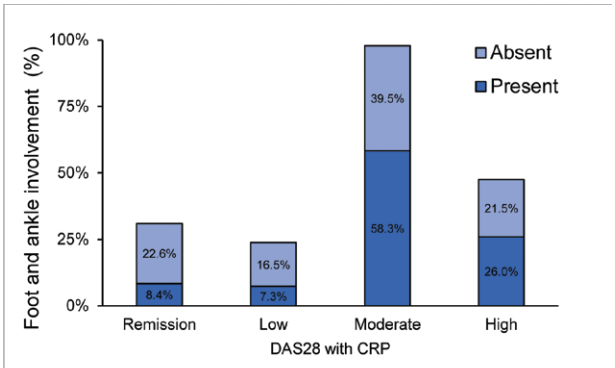

Figure 1. Foot and ankle involvement in 1192 RA patients according to disease activity

Table 1. Factors associated with foot and ankle involvement

	P-value	Odds ratio	95% C.I. Lower	95% C.I. Upper
b/tsDMARDs (vs none)				
1 b/tsDMARDs	0.784	1.05	0.73	1.51
≥2 b/tsDMARDs	0.009	0.59	0.39	0.88
Hydroxychloroquine	0.002	1.46	1.15	1.86
Cardiovascular disease	0.619	1.08	0.79	1.49
Lung disease	0.091	1.69	0.92	3.11
DAS28	<0.0001	1.25	1.13	1.38

Conclusion: Nearly 40% of RA patients have foot and ankle involvement that associates with higher disease activity in other joints. However, we noticed low use of b/tsDMARDs in this group, a finding only partially explained by a substantially increased burden of RA-related cardiovascular and lung comorbidities.

AB0298 SAFETY OF THE JAK INHIBITORS IN COMPARISON WITH THE TNF INHIBITORS IN RHEUMATOID ARTHRITIS: REAL WORLD DATA FROM THE HONG KONG BIOLOGICS REGISTRY

Keywords: Targeted synthetic drugs, bDMARD, Rheumatoid arthritis

C. C. Mok[1], H. So[2], C. Ho[3]. [1]*Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; [2]*Prince of Wales Hospital, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*; [3]*Queen Mary Hospital, Medicine, Hong Kong, Hong Kong (SAR)*

Background: The recent Oral Surveillance study has raised concerns about major cardiovascular events and malignancies related to tofacitinib in older rheumatoid arthritis (RA) patients with cardiovascular risk factors.
Objectives: To compare the incidence of major adverse cardiovascular events (MACEs), cancer and infective complications in RA patients using the JAK (JAKis) and TNF inhibitors (TNFis).

Methods: A retrospective analyses of data retrieved from the Hong Kong Biologics Registry from 2008 to 2021 were performed. Patients with RA (fulfilling the EULAR/ACR criteria) who had ever been treated with the JAK or TNF inhibitors were included. Withdrawal rates due to inefficacy or serious adverse events (SAEs) were compared between the two groups, along with the incidence of MACEs, cancer, infective complications and all-cause mortality. The hazard ratios (HRs) of these outcomes were calculated for the JAKis with reference to the TNFis and adjusted for confounding factors in regression models.
Results: A total of 2471 courses of JAKis (n=551) and TNFis (N=1920) were used in 1732 RA patients (83.7% women, age 53.8±12.5 years; follow-up 6431 patient-years). The most frequent JAKi and TNFi prescribed were tofacitinib (81%) and etanercept (37%). Users of the JAKis, compared to the TNFis, had significantly longer RA duration, older age and were more likely to have atherosclerotic risk factors (diabetes mellitus, hypertension, hyperlipidemia, previous coronary heart disease) and a past history of malignancy. The withdrawal rate of the JAKis was significantly lower than the TNFis due to clinical inefficacy or occurrence of SAEs (p<0.001 by survival analyses). A total of 15 and 40 MACEs developed in the JAKi and TNFi group of patients, respectively (incidence 1.34 vs 0.75 per 100 patient-years; p=0.22, adjusted for age, sex and follow-up duration). Moreover, there was no significant difference in the incidence of new cancers between the two groups (0.81 [JAKi] vs 0.85 [TNFi] per 100 patient-years; p=0.25). The adjusted HRs of MACE and cancer in the JAKi users were 1.36[0.62-2.96] (p=0.44) and 0.87[0.39-1.95] (p=0.74), respectively. Rates of infections were significantly higher in the JAKi than TNFi users (16.3 vs 9.9 per 100 patient-years; p=0.02), particularly herpes zoster (3.49 vs 0.94 per 100 patient-years; p<0.001) reactivation. The incidence of tuberculosis infection was similar between the two groups (0.45 [JAKi] vs 0.60 [TNFi]; p=0.21). All-cause mortality occurred in 8 patients in the JAKi group and 25 in the TNFi group and the difference was not statistically significant (0.72 vs 0.47 per 100 patient-years; p=0.54).
Conclusion: In a real-life setting, the JAKis have a better retention rate than the TNFis in patients with RA. There is no increase in the incidence of MACEs, cancers and all-cause mortality observed with the JAKis in comparison to the TNFis, adjusted for age, sex and other confounding factors. However, infective complications, particularly herpes zoster, are more common in the JAKi users.

AB0299 THE RISK OF ATHEROSCLEROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS IS COMPARABLE TO THE GENERAL POPULATION IN THE TREAT-TO-TARGET ERA

Keywords: Treat to target, Rheumatoid arthritis, Comorbidities

W. Bian[1], Y. Hao[1], H. Huang[1], W. Xie[1], Y. Wang[1], X. Deng[1], Y. Geng[1], L. Ji[1], X. Zhang[1], J. Zhao[1], Z. Zhang[1]. [1]*Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Patients with rheumatoid arthritis (RA) suffer form an increased cardiovascular disease (CVD) risk compared with the general population. This is due to the fact that systemic inflammation not only accelerates the progress of RA but also promotes the development of atherosclerotic plaque.[1] Intima-media thickness of the carotid artery (cIMT) is considered as a reliable marker of the presence and the burden of atherosclerosis.[2] Since the treat-to-target (T2T) strategy was first introduced into RA management in 2010, it has been widely proved that patients treated with an underlying T2T strategy could obtain clinical remission more rapidly and achieve higher clinical remission rates[3]. However, what's the effect of a better controlled disease on the development of atherosclerosis?
Objectives: To compare the prevalence and incidence of carotid atherosclerosis monitored by ultrasound between patients with RA treated guided by a T2T strategy and age, gender-matched healthy controls, as well as identify risk factors of atherosclerosis aggravation among RA patients.
Methods: We used data from a longitudinal prospective cohort of RA patients and a community-based atherosclerosis cohort in the general population. Age and gender-matched participants were picked up by propensity score matching to be compared in their clinical characteristics and the process of atherosclerosis. And then a comparison was made according to the traditional CVD risk factors and RA-related factors between RA patients with carotid atherosclerosis progress (CAP) and without. A Cox proportional hazards regression model was operated to find out the risk factors of carotid atherosclerosis progress in the patients with RA.
Results: A total of 182 patients with RA were included. After a median 28 months of follow-up, 91.76% of patients reached remission or low disease activity target. The mean (or median) cIMT in RA patients was increased significantly after the follow-up, and 39 participants were recognized as CAP. Age at entry (HR 1.095, 95% CI 1.043, 1.149, P<0.001) and time adjusted body mass index (HR 1.127, 95% CI 1.011, 1.257, P=0.030) were identified by the multivariate Cox regression hazard model as the independent risk factor of carotid atherosclerosis progress for this group of RA patients. The prevalence of carotid atherosclerosis between 80 RA patients and 400 age, gender-matched controls, was compared, and no significant difference was found, no matter at the baseline (52.50% vs 49.67%, P=0.652)(Figure 1A) or the endpoint of the follow-up (53.75% vs 54.75%, P=0.870)(Figure 1B). The incidence of carotid atherosclerosis during the follow-up between 50 RA patients and 50 age, gender, and BMI- matched controls was also comparableb(28.00% vs 28.00%, P=1.0)(Figure 1C).
Conclusion: Compared with the general population, the patients with RA treated adhering to a T2T strategy presented with a similar incidence and prevalence of atherosclerosis. Among disease well-controlled RA patients, RA-related factors have little impact on the carotid atherosclerosis progress.

AB0300 GENETIC EVIDENCE REVEALS A CAUSAL RELATIONSHIP BETWEEN RHEUMATOID ARTHRITIS AND INTERSTITIAL LUNG DISEASE

Keywords: Comorbidities, Rheumatoid arthritis, Genetics/Epigenetics

Y. W. Zhang[1,2], R. Zhao[1,2,3], J. C. Guo[1,2], J. Y. Yao[1,2], S. X. Zhang[1,2,3], X. Li[1,2,3], C. Wang[1,2,3]. [1]*Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; [2]*Shanxi Medical University, Ministry of Education Key Laboratory of Cellular Physiology, Taiyuan, China*; [3]*Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: The most common extra-articular manifestation of rheumatoid arthritis (RA) is interstitial lung disease (ILD)[1] which in severe cases can lead to a range of complications and is one of the leading causes of death in patients with RA[2]. Many genetic studies found that patients with RA demonstrated an excess of mutations in genes that have been previously linked to ILD like TERT and RTEL1 et al. However, there is no directly evidence that the two diseases are causally related.

Objectives: In this paper, bidirectional two-sample Mendelian method was used to focus on the genetic factors related to ILD and RA, and to explore the causal relationship between ILD and RA in the pathogenesis.
Methods: A two-sample bi-directional Mendelian randomization (MR) approach was conducted to investigate the causal relationships between RA and ILD. Summary statistics for RA (14,361 RA cases and 43,923 healthy controls (HCs)) and ILD (1,969 cases and 196,986 HCs) were obtained from an available meta-analysis of published genome-wide association studies (GWAS). Relevant single nucleotide polymorphisms (SNPs) were selected by executing quality control steps ($p < 1.0 \times 10^{-5}$) from the GWAS summary results. MR analyses progressed mainly using inverse variance weighted (IVW), weighted median (WM), and MR-Egger regression methods. For assessing the robustness of the results, we also carried out sensitivity analysis to assess heterogeneity and pleiotropy, such as MR-Egger, leave-one-out and MR pleiotropy residual sum and outlier (MR-PRESSO).
Results: Our study discovered a bidirectional causal effect between RA and ILD. The presence of ILD may increase the risk of RA by 12.8% (OR: 1.128, 95%CI: 1.013-1.256, P = 0.029). Similarly, the existence of RA may increase the risk of ILD by 9.4% In addition, reverse MR analysis found that RA also influenced the risk of ILD significantly (OR: 1.094, 95%CI: 1.023-1.171, P = 0.009). Sensitivity analysis showed no pleiotropy but have heterogeneity (Q = 0.030) in reverse MR analysis.
Conclusion: MR analysis supported a potential causal relationship between RA and ILD. In RA and ILD, no matter which disease the patient has, it will greatly increase the risk of another disease. This study increases the emphasis on therapeutic or defensive interventions for patients with RA or ILD in the future to reduce severe complication and mortality.

AUTOIMMUNE POLYENDOCRINOPATHY SYNDROMES IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SINGLE-CENTER STUDY ON 2166 PATIENTS

Keywords: Epidemiology, Comorbidities, Rheumatoid arthritis

G. I. Gozzoli[1], E. Piovani[1], P. Bizioli[1], M. Taglietti[1], M. Fredi[1], C. Cappelli[2], F. Franceschini[1]. *[1]Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, ASST Spedali Civili and University of Brescia, Brescia, Italy, Department of Clinical and Experimental Sciences, Brescia, Italy; [2]Endocrinology and Metabolism Unit, Department of Clinical and Experimental Sciences, ASST Spedali Civili and University of Brescia, Brescia, Italy, Department of Clinical and Experimental Sciences, Brescia, Italy*

Background: Autoimmune polyendocrinopathy syndromes (APS) include heterogeneous clinical conditions characterized by functional alterations of at least one endocrine gland associated with other autoimmune diseases. APS-1 is a rare disease due to gene AIRE mutation and characterized by at least two of the following manifestations: chronic mucocutaneous candidiasis, hypoparathyroidism and Addison's Disease (AD). APS-2 is characterized by the presence of AD associated with at least one between Diabetes Mellitus Type 1 (DM1) and autoimmune thyroid disease (Hashimoto's Thyroiditis (TH) or Graves-Basedow Disease (GD)). APS-3 includes the association of autoimmune thyroiditis and other autoimmune manifestations, excluding hypoparathyroidism and AD. APS-4 is characterized by autoimmune activity against an endocrine organ in combination with at least one more autoimmune disease not included in previous definitions. As of today, there is very little data in literature about the prevalence of APS. Scarce data are available on the association between rheumatologic diseases and endocrine disorders.
Objectives: This paper aims to describe the prevalence of APS in our cohort of rheumatoid arthritis (RA) patients and to assess the possible association between autoimmune endocrine diseases, RA and gender.
Methods: This retrospective observational study collected medical history, biochemical and immunological data and risk factors about 2166 RA patients older than 18 years of age examined by our Department of Rheumatology from January 1, 2020 to August 1, 2022. Patients included presented at least one additional non-rheumatologic organic autoimmune disease. The prevalence of autoimmune diseases in our cohort were compared with those reported in the literature.
Results: This study included 2166 RA patients (534 men, 1632 women, M/F ratio 1:3). We found 352 patients (16%) having at least one autoimmune disease other than RA. The cohort consisted of 307 (87%) women, 45 (13%) men, M/F ratio 1:7, with mean age 63 ± 17 years at the time of examination. Among our patients, 300 (85%) presented with one additional non-rheumatologic autoimmune disease, 43 (12%) two non-rheumatologic autoimmune diseases, and 9 (3%) three non-rheumatologic autoimmune diseases. Figure 1 shows the autoimmune disorders collected. No cases of AD, chronic mucocutaneous candidiasis, hypoparathyroidism, myasthenia and AIRE mutation were found. In our cohort, no patient satisfied diagnostic criteria for APS 1 and 2; 212 (61%) patients presented with APS-3, 7 (2%) patients had APS-4 (all with RA and DM1 association). The diagnosis of APS occurred more frequently in female than in male patients, 199/1632 (12%) vs 20/534 (4%) (p< 0,001, OR 3,56, CI 2,29-5,71). Moreover differences related to gender were also evaluated for all the non-rheumatologic autoimmune disease, and a significant association between RA female patients and HT was found: 179/1632 (11%) vs 18/534 (3%) (p<0,001, OR 2,30, CI 1,22-4,33). Finally, comparing the prevalence of these autoimmune diseases in our cohort with those of the general population, we found higher prevalence for HT (9% vs 5%), autoimmune urticaria (0,7% vs 0,1%), DM1 (0,5% vs 0,3%), inflammatory bowel disease (0,5 vs 0,3%), alopecia (0,5% vs 0,1%), primary biliary cirrhosis (0,1% vs 0,03%), autoimmune hepatitis (0,09% vs 0,01%), autoimmune thrombocytopenia (0,05% vs 0,01%) and pemphigoid (0,05% vs 0,025%). Concerning risk factors, 78 (22%) patients had family history of autoimmune disease, 93 (26%) smoked, 23 (7%) had BMI>30.
Conclusion: The presence of at least one non-rheumatologic autoimmune disease was a nor rare event in our cohort of RA patients, with HT as the most frequent endocrine disease in our cohort. Among these cases, the diagnosis of APS was present in 62% of cases, mostly APS-3 and is more frequently found in female RA patients. Finally, we observed how the frequency of non-rheumatologic autoimmune diseases seems to be higher in RA patients than in general population.

Background: The recent EULAR recommendations [1,2] suggest using JAK-inhibitors (JAKis) for treating RA patients. These drugs include both selective (upadactinib and filgotinib) and unselective (tofacitinib and baricitinib) JAKis.
Objectives: To describe JAKis' discontinuation rate and to determine predictors of JAKIs' discontinuation in a real life setting.
Methods: All patients with RA treated with JAKis were prospectively followed up for at least 12 months in this multicentric study carried out on 23 Italian centres. For each patient, the following variables were collected: sex, age, disease duration, smoking, BMI, comorbidities (diabetes, hypertension, hypercholesterolemia, cancer, major cardiovascular events), positive RF/ACPA, cDMARDs at baseline, prednisone at baseline, previous use of JAKis, discontinuation, time to discontinuation, JAKis line of treatment, DAS28-ESR at baseline, 6 and 12 months. Statistical analyses were performed using R (2022.12.0).
Results: 864 patients were included (**Table 1**). 487 (55.2%) received baricitinib, 213 (24.6%) tofacitinib, 111 (12.8%) upadacitinib and 62 (7.2%) filgotinib. 192 (22.2%) patients discontinued JAKis after a median time of 334 days (IQR 154.5-879.5). Among them, a statistical difference was found between selective-JAKis and other JAKis (p=0.03, 14.6% of selective JAKis vs 85.4% of other JAKis); finally unselective JAKis were discontinued later than selective JAKis (p<0.001, median 401.5 days, IQR 197.5-976 for unselective JAKis vs median 74 days, IQR 129-212 for selective JAKis). Discontinuation's causes are reported in **Figure 1**. Notably, VZV infection determined JAKis withdrawal in 4 patients and pulmonary embolism/deep venous thrombosis in 6 patients (both with baricitinib). Regarding discontinuations' causes, no differences between selective JAKis and other JAKis were found with factor logistic regression model. At multivariate analysis, predictors of discontinuation were prednisone at baseline (OR 1.48, p=0.03), treatment with unselective JAKis (OR 1.79, p=0.01), and line of treatment (OR 1.29 p<0.001).
Conclusion: Our study showed that only a minority of patients discontinued JAKis. Among discontinuation's causes, no differences between selective JAKis and other JAKis were found. Predictors of JAKis discontinuation were prednisone at baseline, treatment with unselective JAKis and line of treatment (with more advanced lines of treatment associated with a higher risk of discontinuation).

AB0303 ASSESSMENT OF SEXUAL DISORDERS IN TUNISIAN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Quality of life

J. Mahbouba[1], M. Ardhaoui[1], M. Ghali[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia*

Background: Sexual dysfunction is common in patients with rheumatoid arthritis (RA), but is often under-estimated.
Objectives: The aim of this study was to assess the sexual function and to identify the associated factors of sexual disorders in Tunisian RA patients.
Methods: This is a cross-sectional study conducted in the Rheumatology department of Monastir in Tunisia including patients followed for RA. Functional impact was assessed by the Health Assessment Questionnaire (HAQ) and Rheumatoid Arthritis Quality of Life (RAQoL). Disease activity was evaluated using the DAS28 score. Sexual function was assessed for women by a self-assessment questionnaire: the Female Sexual Function Index (FSFI) including several parameters: desire, arousal, lubrication, orgasm, satisfaction and pain. For men, it was evaluated by the Sexual Health Inventory (SHIM) assessing erectile dysfunction.
Results: One hundred patients were included. There were 85 women and 15 men. The mean age was 55.88 ± 10.5 years. Sixty out of 85 women were sexually active. Thirty-five women (58.3%) had sexual dysfunction (FSFI ≤ 26.55). Lack of arousal and loss of desire were the most reported disorders with mean scores of 2.33 and 2.58 respectively. Among the 15 men, nine were sexually active. Only one men had normal sexual activity. Erectile dysfunction was the most common disorder with a mean score of 11. After statistical anlysis, significant association was found between sexual dysfunction assessed by FSFI and SHIM total scores and increased age (p=0.01 and p=0.005, respectively). More intense pain (visual analog scale) was significantly associated with sexual disability in women and men (p=0.01 and p=0.05, respectively). A significant correlation was found between lower FSFI score and higher disease activity by the DAS28 (p=0.001). Concerning the relationship with RA functional impact: we noted that among women, the alteration of arousal and satisfaction domains of the FSFI were correlated with higher HAQ (p=0.05 and p=0.004, respectively). In men, there was a significant association of lower SHIM score with HAQ and RAQoL (p=0.015 and p=0.001, respectively). However, there was no significant association between sexual dysfunction and the duration of RA progression, biological inflammatory syndrome, joint deformities, sturtural damage or the used treatments.
Conclusion: Our study showed that sexual dysfunction is frequent in women and men with RA, and that these disorders can affect their quality of life. Therefore, the sexual life of RA patients should be considered as one of the important therapeutic targets in the global management of this disease.

AB0304 PATIENTS WITH RHEUMATOID ARTHRITIS PRESENTING WITH MONO- OR OLIGO-ARTHRITIS AND HIGH PATIENT GLOBAL ASSESSMENT REMAIN MOST FATIGUED DURING 5-YEARS FOLLOW-UP

Keywords: Rheumatoid arthritis, Patient reported outcomes

A. M. P. Boeren[1,2], M. Verstappen[2], A. Looijen[1], P. De Jong[1], A. Van der Helm – van Mil[1,2]. [1]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*; [2]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: The severity of fatigue in rheumatoid arthritis (RA) has hardly improved in recent decades, leaving a large unmet need. Fortunately, not all RA-patients suffer from persistent fatigue, but the subgroup of patients who suffer the most is insufficiently recognizable at diagnosis. As disease activity is partly coupled to fatigue, Disease-Activity-Score (DAS)-components may associate with the course of fatigue.
Objectives: We aimed to identify the RA-patients who remain fatigued by studying DAS-components at diagnosis in relation to the course of fatigue over a 5-year follow-up period in two independent early RA-cohorts.
Methods: 1560 consecutive RA-patients included in the Leiden Early-Arthritis Cohort and 415 RA-patients included in the tREACH-Cohort were studied. Swollen Joint Count (SJC), Tender Joint Count (TJC), Erytrocyte Sedimentation Rate (ESR) and Patient Global Assessment (PGA) (Visual Analogue Scale(VAS),0-100mm) were studied in relation to fatigue (VAS, 0-100mm) during 5-years using linear mixed models.
Results: Higher TJC and PGA at diagnosis were associated with a more severe course of fatigue. The SJC, in contrast, showed an inverse association; patients with mono- or oligo-arthritis at diagnosis remained more fatigued. The combination of aforementioned characteristics revealed that patients presenting with a mono- or oligo-arthritis and PGA≥50 remained the most fatigued over time(+20mm versus polyarthritis with PGA<50), whilst the DAS-course over time was not different. This subgroup comprised 14% of the early RA-population. Data from the tREACH-cohort showed similar findings.
Conclusion: RA-patients who remain the most fatigued are characterized by mono- or oligo-arthritis and high PGA(VAS≥50) at diagnosis. This understanding may enable early-intervention with non-pharmacological approaches in dedicated patient groups.

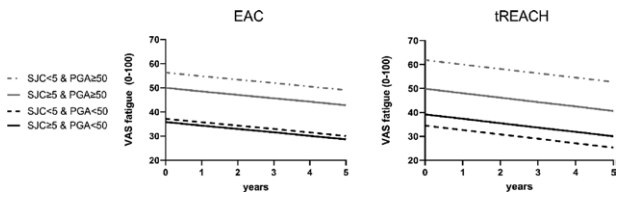

Figure 1. Fatigue trajectories stratified for combined DAS-characteristics at diagnosisLegend: Depicted are mean effect sizes from linear mixed models of fatigue scores stratified for different subgroups. The subgroups are based on two combined DAS-characteristics, SJC and PGA, at diagnosis.

AB0305 HOW DOES PSYCHOLOGICAL TRAUMA AFFECT THE COURSE OF RHEUMATOID ARTHRITIS?

Keywords: Rheumatoid arthritis

A. Nurmamedov[1], S. Lezhenina[2], N. Shuvalova[3], E. Guryanova[2]. *[1]Mary Central Clinic, Department rheumatology, Mary,Turkmenistan; [2]Chuvash State University by I. N. Ulianov, Departament of Healthcare Management and Economics, Cheboksary, Russian Federation; [3]I.Ya.Yakovlev Chuvash Pedagogical State University, Department of Theoretical Foundations of Physical Education, Cheboksary, Russian Federation*

Background: Psychological trauma is a short-term or long-term stressful event associated with a sense of extreme threat or catastrophe. Psychological trauma predisposes to the development of a systemic inflammatory process. Dysregulation of the immune response occurs, which leads to an increase in the rate of aging of immune cells and changes in gene expression in immune cells, contributing to the development of autoimmune aggression [1]. The effect of psychic trauma on the decrease in IL-6 promoter methylation in patients with rheumatoid arthritis was revealed [2].

Objectives: The purpose of the study: to evaluate the impact of psychological mental trauma on the course of rheumatoid arthritis.

Methods: The study was conducted from September 2021 to September 2022. 80 patients with RA of varying severity were examined. Inclusion criterion was a European Antirheumatic League diagnosis of RA (EULAR/ACR 2010). The age of the patients ranged from 20 to 69 years. (Mean age of patients was 48 +/- 6.24). Most of the examined women - 85%. The study was carried out in two stages. The first stage is (screening). All patients admitted to the hospital were determined the level of situational and personal anxiety according to the Spielberger questionnaire modified by Yu.L. Khanina. The results obtained were interpreted: up to 30 points - a low level of anxiety, 31-45 points corresponded to the average level, over 45 points - a high level of anxiety. At the second stage (39 patients with medium and high levels of situational and/or personal anxiety), a survey was conducted, consisting of two blocks. The first block revealed the psychotraumatic factor by groups. 1. Shock injuries (a situation that threatens a person's life, various types of violence). 2. Injuries of loss (loss of a loved one, job, property). 3. Relationship trauma (betrayal, family relationship discomfort). 4. Others. The second set of questions assessed the relationship between the course of RA and psychic trauma, especially the onset of the disease. Statistical processing of the results was carried out in MS Office Excel programs.

Results: Almost half of 39 (48.7%) patients entered the second stage of the study, i.e. they had an average or high level of situational and/or personal anxiety. Shock injury was observed in 3 (3.75%) patients, loss trauma in 5 (6.72%) patients, relationship trauma in 29 (36.25%) patients, other causes indicated in 2 (2.5%) patients Acute trauma was detected in 5 (6.25%) patients, chronic trauma in 32 (40%) patients, 2 (2.5%) patients found it difficult to answer. In the analysis of the second block of questions of the questionnaire, 31 (38.75%) patients note the relationship between PT and worsening of the course of RA. Deterioration in the form of increased pain syndrome was noted by 37 (46.25%) patients, an increase in edema of the affected joints was noted by 30 (37.5%) patients, a decrease in mobility in the joints was noted by 26 (32.5%) patients. Most of the 36 patients note that about 2 months passed from the moment of PT to the worsening of the course of RA. In 2.5% of patients, the onset of RA disease with a history of acute PT was observed.

Conclusion: Psychological trauma worsens the course of RA. This deterioration manifests itself in the form of an increase in pain, an increase in swelling of the affected joints, and a decrease in joint mobility. In the treatment of patients with RA, it is necessary to use a multidisciplinary approach involving psychologists and psychotherapists in order to timely identify and treat psychological trauma.

AB0306 IMPACT OF TOFACITINIB ON LIPID METABOLISM IN PATIENTS WITH RHEUMATOID ARTHRITIS: A REAL-WORLD STUDY

Keywords: Real-world evidence, Rheumatoid arthritis

H. Huang[1], Y. Geng[1], Y. Fan[1], Z. Zhang[1]. *[1]Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Tofacitinib is the first Janus Kinase (JAK) inhibitor available in China, and it has significantly improved the efficacy of treatment of rheumatoid arthritis (RA). Previous clinical trials found that tofacitinib can affect lipid metabolism in patients.

Objectives: Whether lipid and lipoprotein concentrations can recover by themselves and whether lipid-lowering drugs intervention is required, are currently inconclusive, and there is a lack of real-world experience.

Methods: Patients from the CENTRA (Collaboratively intENsive Treat-to-target in RA) cohort, a prospective follow-up cohort for RA in the Department of Rheumatology and Clinical Immunology, Peking University First Hospital were enrolled, and those who used lipid-lowering drugs were excluded. Patients were divided into tofacitinib exposure group and non-exposure group according to whether patients were prescribed with or without tofacitinib. Disease activity scores, TG, TCHO, HDL and LDL at baseline and during follow-up were calculated, and the ratios of TCHO/HDL to HDL/LDL was also calculated. Changes in lipid and lipoprotein concentrations after use of tofacitinib during follow-up were analyzed. Age, gender, disease duration, and the Simplified Disease Activity Index (SDAI) at baseline as covariates for propensity score matching was performed on patients with and without tofacitinib, and the lipid and lipoprotein profiles of the two groups were compared.

Results: A total of 304 patients were included, with 88 prescribed with tofacitinib and 216 without tofacitinib. (1) In patients with tofacitinib, the median TG and TCHO were 0.95 mmol/L and 4.45 mmol/L, respectively, the mean HDL and LDL were 1.32 mmol/L and 2.63 mmol/L at baseline, and the median TCHO/HDL and HDL/LDL ratios were 3.62 and 2.24, respectively. After 4 weeks of use of tofacitinib, the levels of TCHO, HDL and LDL increased compared with baseline by 16.6%, 12.9% and 14.4%, respectively. At week 12, LDL increased by 12.9% compared with baseline, indicating the returning to baseline levels, while the levels of TCHO and HDL were still significantly elevated. At week 48, TCHO also returned to baseline levels (increased by 2.9%). HDL levels remained elevated during follow-up. There were no significant increases in TG, TCHO/HDL and LDL/HDL ratios throughout the follow-up. In addition, there was no significant difference in lipid and lipoprotein changes between tofacitinib monotherapy (43 patients) and tofacitinib combined with csDMARDs (45 patients) during follow-up. (2) After 1:1 matched by propensity score matching, there were 83 patients prescribed with tofacitinib exposure and 83 without. In the 4 weeks of follow-up, there was no significant difference in the increase of lipid and lipoprotein between the two groups. At week 12, week 24, and week 48, the increase of TCHO in patients with tofacitinib was significantly higher than those without (0.47 vs. -0.1, $p<0.001$; 0.33 vs.-0.06, $p=0.001$; 0.22 vs.-0.1, $p=0.017$). The LDL elevation in patient with tofacitinib was higher than that in patients without at week 12 and continued to week 24 (0.17 vs.-0.07, $p=0.002$; 0.18 vs.-0.09, $p=0.001$), but at week 48, there was no significant difference between the two groups compared with baseline. At week 12, patients in the tofacitinib-exposure group had higher HDL elevations (0.22 vs. 0.02, $p < 0.001$), but there was no significant difference between the two groups form week 24 to week 48. Elevation in TG, THCO/HDL or LDL/HDL was not significantly different between the two groups throughout the follow-up.

Conclusion: After 4 weeks of using tofacitinib, TCHO, HDL and LDL levels increased in RA patients. LDL and TCHO returned to the baseline level at the week 12 and week 48, respectively, while HDL continued to increase. There was no significant change in TG, THCO/HDL or LDL/HDL throughout the follow-up. The elevation in lipid and lipoprotein profiles in RA patients prescribed with tofacitinib was significantly higher than those without.

JAK INHIBITORS DO NOT WORSEN RA-ILD; COMPARISON OF CHANGES IN CT IMAGES AND KL-6/SP-D LEVELS BETWEEN PERIODS WITH BIOLOGICS AND WITH JAK INHIBITORS IN THE SAME INDIVIDUALS

Keywords: Rheumatoid arthritis, Targeted synthetic drugs, Lungs

A. Tanaka[1], R. Koike[1], R. Sato[1], A. Kikuchi[1], S. Komatsu[1], A. Hasegawa[1], T. Hiyama[1], E. Fukasawa[1], T. Miyao[1], S. Arai[1], T. Owada[2], R. Maezawa[1], M. Arima[1], K. Kurasawa[1]. [1]*Dokkyo Medical University, Rhumatology, Tochigi, Japan*; [2]*Dokkyo Medical University Saitama Medical Center, Respiratory Medicine and Clinical Immunology, Saitama, Japan*

Background: Interstitial lung disease (ILD) is a serious organ involvement that influences the prognosis of RA patients and limits RA therapy. The association between RA activity and ILD progression has been suggested. However, the effects of biologics (Bio) on ILD are controversial; several studies showed that Bio increased ILD-related death, whereas others reported that Bio stabled the progression of ILD. Moreover, the effects of JAK inhibitors (Jaki) on ILD are largely unknown.
Objectives: To clarify the effects of Jaki on RA-ILD by comparing the changes in CT images and KL-6/SP-D levels between periods with biologics and with JAK inhibitors in the same individuals.
Methods: Participants were consecutive RA patients who received Jaki from June 2014 to April 2022. Among them, patients who received Bio prior to Jaki therapy underwent analysis of changes in CT images and serum KL-6/ SP-D levels in the same individuals. Change in CT images of pulmonary abnormalities, such as reticular pattern, was assessed by CT score: the extent of lesions of 6 lung fields was scored as follows; score 0 (absent), 1 (-25 %), 2 (25–50 %), and 3 (50 %-). The CT scan score for each patient was obtained by adding the score for each field (max 18).
Results: Patients included in the analysis were 79 RA patients, M/F; 34/45. When they started Bio, their mean age was 59.3 years old, disease duration was 7.7 years, positive for anti-CCP antibody in 82.9%, and positive for RF in 83.5%. They received 3.7 (average) different Bios for 4.6 years (average) prior to JAKi therapy for 2.8 years. Serum KL-6 levels increased by 91.2±416.0 U/ml (average+sd) during Bio treatment but decreased by 82.1±383.3 mg/dl during JAKi therapy. Similarly, serum SP-D levels increased by 10.1±60.3ng/ml during Bio but decreased by 23.7±83.1 ng/dl during JAKi therapy. However, no differences were found in KL-6/SP-D levels between periods with Bio and JAKi in the same individuals. ILD was found in 22 out of 79 RA patients. GGO was found in 2 cases. Reticular opacities were found in 18 cases, and 3 of them developed during Bio. Honey-combing occurred in 9 cases; 3 and 1 developed during Bio and JAKi, respectively. CT score of reticular opacities was increased in 9 cases (50%) during Bio but in 3 cases (16%) in JAKi (Figure 1) (p=0.04). The CT score change was significantly greater in the period with Bio than with JAKi in between-group comparisons and the same individuals (Figure 1).
Conclusion: The frequencies and severities of worsening in the CT imaging, particularly reticular opacities, were less in patients with JAKi than in Bio. JAKi did not worsen ILD but rather may stable it.

QUANTIFICATION OF SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS BY MEASURING THE CROSS-SECTIONAL AREA OF THE THIGH MUSCLES WITH MAGNETIC RESONANCE IMAGING

Keywords: Comorbidities, Imaging, Rheumatoid arthritis

F. Salaffi[1], M. Carotti[2], A. C. Poliseno[2], L. Ceccarelli[3], S. Farah[1], M. Di Carlo[1], A. Giovagnoni[2]. [1]*Università Politecnica delle Marche, Rheumatology Clinic, Jesi (Ancona), Italy*; [2]*Università Politecnica delle Marche, Radiology Clinic, Ancona, Italy*; [3]*IRCSS Ospedale Sant'Orsola-Malpighi, Radiology Clinic, Bologna, Italy*

Background: Sarcopenia is a prevalent condition in patients suffering from rheumatoid arthritis (RA), estimated to affect 31% of them. Magnetic resonance imaging (MRI) allows the measurement of cross-sectional area (CSA) and volume of a muscle and the visualization of its morphological features and their distribution. Quality deterioration of the muscle, characterised by the presence of adipose tissue (defined as myosteatosis) and of fibrous connective tissue (defined as myofibrosis), is best diagnosed with MRI.
Objectives: To determine the utility of CSA measurements on MRI, at the level of the thigh muscles, to estimate muscle mass in discriminating RA patients with sarcopenia from those without.
Methods: Consecutive female RA patients were enrolled for this cross-sectional study. Patients were assessed for disease activity, radiological damage, handgrip strength, physical performance and for the presence of sarcopenia, identified in accordance with the EWGSOP2 criteria. A 1.5T MRI machine was used to scan the thigh muscles. A dimensional region growth algorithm (Horos™) was used to semiautomatically segment the muscles cross-sectional areas (CSAs, in cm^2) on MR images located 25 cm above the knee joint (MRI-CSA-25) (Figure 1). The MRI-CSA-25 was obtained by summing the areas of the individual muscles. MRI-CSA-25 was correlated (Pearson's r) with the other variables, and its optimal cut-off point (Youden index) for sarcopenia diagnosis was identified in relation to the EWGSOP2 criteria.
Results: 32 RA female patients were studied, 34.4% diagnosed as sarcopenic. The mean MRI-CSA-25 was 151.00 cm^2 for patient with sarcopenia, 275.57 cm^2 for patient without sarcopenia ($p < 0.001$). MRI-CSA-25 correlated significantly with measures of physical performance, and disease activity, but not with radiological damage or age. The MRI-CSA-25 optimal cut-off point in discriminating sarcopenic patients was identified at 182 cm^2 (AUC-ROC = 0.894).
Conclusion: MRI-CSA-25 can differentiate sarcopenic versus non-sarcopenic RA patients, representing an imaging biomarker of this condition.

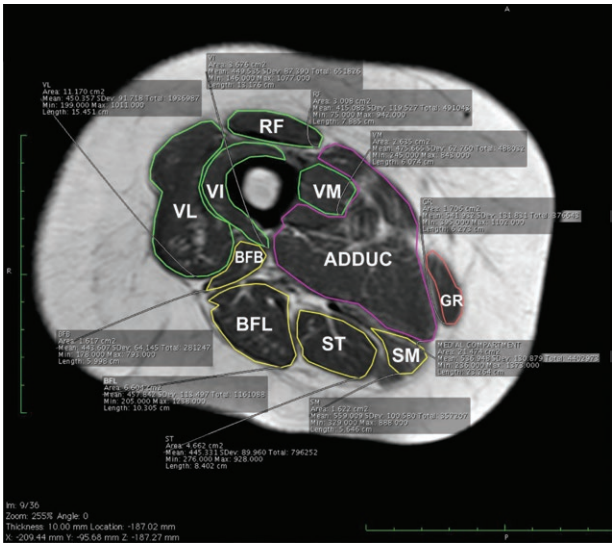

Figure. 1 Illustrative magnetic resonance image of a segmented muscle region of the thigh at a 25 cm above the knee joint (MRI-CSA-25) of a 50-year-old female patient, acquired as axial T1-weighted gradient-echo. Group muscles are color-coded: rectus femoris (RF), vastus lateralis (VL), vastus intermedius (VI), and vastus medialis (VM), the four muscles composing the hamstrings muscles (HAMST) [biceps femoris short head (BFB), biceps femoris long head (BFL), semitendinosus (ST) and semimembranosus (SM), and adductors (ADDUC) [adductor longus, brevis, magnus, pectineus, sartorius and gracilis (GR)]. Because the delineations between adductors muscles were not so obvious at proximal part, all adductors' muscles were segmented together, except for the gracilis which was easily recognizable. Note the exclusion of non-muscular elements (blood vessels, nerves) in the manual segmentation.

AB0309 **CLINICAL EFFICACY AND SAFETY OF TOFACITINIB COMBINED WITH IGURATIMOD FOR RHEUMATOID ARTHRITIS-ASSOCIATED USUAL INTERSTITIAL PNEUMONIA**

Keywords: Rheumatoid arthritis, Comorbidities

W. Xie[1], S. Wang[1], Y. Li[1], Y. Tang[2]. [1]*Qingdao University Medical College Affiliated Yantai Yuhuangding Hospital, Rheumatology, Qingdao, China*; [2]*Qingdao University Medical College Affiliated Yantai Yuhuangding Hospital, Rheumatology, Qingdao, China*

Background: Research has found that iguratimod(IGU) could be an effective therapeutic strategy for pulmonary fibrosis[1-3].The results of the Vitro and in vivo studies indicated that tofacitinib(TOF),slowing the progression of ILD associated with connective tissue diseases,is a potential therapeutic option for rheumatoid arthritis with usual interstitial pneumonia(RA-UIP)[4-7]
Objectives: This study aimed to investigate the efficacy and safety of TOF plus IGU in RA-UIP.
Methods: This was a prospective observational cohort,single-center study. Data were analyzed from 52 RA-UIP patients.24 were treated with TOF(5mg twice daily) plus IGU.28 were treated with Methotrexate(MTX)/Leflunomide(LEF) plus conventional synthetic disease-modifying anti-rheumatic drugs(csDMARDs).A clinically relevant response was defined as a decrease in disease activity score 28-joint count CRP(DAS28-CRP) score and high-resolution computed tomography(HRCT) scores from baseline.Deterioration and regression were respectively defined by an increase or decrease of at least 10% of the overall disease extent according to HRCT,whereas changes of less than 10% defined stability.Clinical indicators were compared between the two groups to evaluate the efficacy.
Results: A total of 24 RA-UIP patients treated with TOF plus IGU and 28 treated with MTX/LEF plus csDMARDs were enrolled and followed up for 6 months.The DAS28-CRP of the TOF plus IGU group was significantly lower than baseline(4.8±1.6vs.3.8±1.9),but there was no significant difference compared with the MTX/LEF plus csDMARD group(P=0.762). The FVC% was significantly improved after 6 months of TOF plus IGU treatment;the change from baseline was more significant than the MTX/LEF plus csDMARD group(-1.89±2.33,P=0.031).TOF plus IGU group had a significantly HRCT fibrosis scores improvement(-0.17±2.52)than the MTX/LEF plus csDMARD group(1.36±2.42,P=0.038)(**Table 1**).In the TOF plus IGU group,8 patients(8/24,33.3%) showed RA-UIP deterioration,6 patients(6/24,25.0%) were considered stable,and 10 patients(10/24,41.7%) demonstrated regression.In the MTX/LEF plus csDMARD group,18 patients(18/28,64.3%) showed deterioration,6 patients(6/28,21.4%) were stable,and 4 patients(4/28,14.3%) demonstrated RA-UIP regression.TOF plus IGU-treated group had a significantly higher response(regression + stability) than MTX/LEF plus csDMARD-treated group,66.7%(16/24) vs.33.5%(10/28)(P=0.008),respectively.
Conclusion: Our results indicated that TOF plus IGU could simultaneously relieve RA and RA-UIP,and be better than the MTX/LEF plus csDMARDs with a higher response rate in RA-UIP,which may be a potential choice for dual treat-to-target.

AB0310 **CARDIOVASCULAR RISK STRATIFICATION IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Keywords: Cardiovascular disease, Rheumatoid arthritis

P. Pusineri[1], S. Cabrera-Villalba[1], G. Avila[1], E. Leiva[1], V. Valinotti[2], L. Roman[2], A. Pineda[2], I. Acosta-Colman[1], M. Martínez[3], P. DE Abreu Trigueros[2], O. Centurion[1]. [1]*Hospital de Clinicas, FCM-UNA, Rheumatology, San Lorenzo, Paraguay*; [2]*Sociedad Paraguaya de Reumatología, Rheumatology, Asunción, Paraguay*; [3]*Laboratorios Curie, Bioquímica, Asunción, Paraguay*

Background: Patients with Rheumatoid Arthritis show an increased mortality population due predominantly to cardiovascular complications, which represent up to 50% of deaths. There are CVR scales that include RA as an independent risk factor. Even with constantly revised and updated assessment tools such as Qrisk III and SCOREm, there is still a tendency to underestimate the cardiovascular risk evidenced by asymptomatic atherosclerosis on ultrasound of the carotid vessels in patients previously classified in intermediate or low risk strata.
Objectives: To determine the cardiovascular risk stratum in adult patients with rheumatoid arthritis to stratify them according to the 2008 Framingham Risk Score, ScoreM and Qrisk III scales and to identify those high-risk patients who developed carotid lesions in ultrasonographic studies.
Methods: Descriptive, prospective, cross-sectional study, in a Paraguayan cohort of patients with RA meeting ACR/EULAR2010 criteria. A standardized questionnaire according to the variables included in the Cardiovascular Risk project (PINV15-0346), from the National Sciences and Technology Council (CONACYT), physical examination was made, and carotid ultrasound evaluation

by a trained specialist, to evaluate subclinical atherosclerosis. Subclinical atherosclerosis was defined as carotid intima-media thickness (CIMT) >0,9mm and/or presence of carotid plaques. The 2008 Framingham score, QRisk III and modified mSCORE were used for CV risk stratification. Quantitative variables were presented as means and qualitative as frequencies. Chi square test was performed for comparisons between dichotomous variables and t Student for continuous, and $p \leq 0.05$ for statistical significance. Kappa coefficient was performed between scales, interpreted as: ≤ 0 as no agreement and 0.01–0.20 as none to slight, 0.21–0.40 as fair, 0.41– 0.60 as moderate, 0.61–0.80 as substantial, and 0.81–1.00 as almost perfect agreement. All patients signed informed consent.

Results: 100 were included, 87% were women, with a mean age of 51±11.3 years and mean disease duration 130.9±102.64 month. 9 (9%), 13 (13%) and 5 (5%) were classified as high risk according to the QriskIII, Framingham 2008 and ScoreM scales respectively. 27.14% of patients had subclinical atherosclerosis, exceeding by 14% the high-risk patients according to the Framingham classification, while mSCORE and QriskIII underestimated cardiovascular risk in 22 and 18 individuals, respectively. The kappa coefficient for agreement of high-risk patients according to QRiskIII was 0.593 (moderate concordance) relative to Framingham 2008 while ScoreM had a Kappa coefficient of 0.401 (fair concordance) relative to Framingham 2008.

Conclusion: In contrast to the estimation scales frequently used in clinical practice, which have a tendency to underestimate the risk in patients with rheumatoid arthritis, these results show that the cardiovascular risk demonstrated through ultrasonography of the carotid vessels more effectively characterizes high-risk patients.

ANALYSIS OF THE MALIGNANCY-RELATED SAFETY OF ABATACEPT FOR RHEUMATOID ARTHRITIS IN CLINICAL PRACTICE

Keywords: Malignancy, bDMARD, Rheumatoid arthritis

Y. Kunishita[1], K. Harita[1], C. Honda[1], Y. Uzawa[1], M. Mitsuhashi[1], S. Ohta[1], T. Igarashi[1], S. Nagaoka[1]. [1]*Yokohama Minami Kyosai Hospital, Department of Rheumatology, Yokohama, Japan*

Background: In 2019, a study based on post-marketing surveillance data in Japan reported that ABT was as effective and safe in elderly patients with rheumatoid arthritis (RA) as non-elderly[1]. However, there were inconsistent reports on the impact of ABT on malignancies which are more common in the elderly and strongly related to prognosis[2-4], and there are still unanswered questions.

Objectives: To evaluate the incidence of malignancy and the efficacy and safety of previous malignancy in RA patients using ABT in our clinical practice. In addition, to explore the predictive risk factors of developing or relapsing malignancy during ABT use.

Methods: Patients who received ABT for RA at our department from October 2010 to May 2022 were included in the study. Patient background, prior malignancy at starting ABT, disease activity from starting ABT up to 60 months, continuation rates of ABT, and safety, including onset or recurrence of malignancy during ABT use, were retrospectively collected from electronic medical records. The patients were divided into two groups according to the absence or presence of previous malignancy (No previous malignancy: NP group, previous malignancy: PM group), and the collected parameters were compared between the groups.

Results: A total of 276 patients were included, of which 61 had previous malignancies when starting ABT. The age of starting ABT was significantly higher in the PM group (72.5 ± 10.6 vs. 68.5 ± 13.0years-old, $p = 0.025$), and the rate of methotrexate use was significantly lower in the PM group (29.5 vs. 51.2%, $p = 0.0028$), although there were no significant differences in other patient backgrounds between the groups (Table 1). The disease activity improved significantly at three months after starting ABT in both groups, and DAS28-CRP remission was maintained after that. There was no significant difference in disease activity between the groups from starting ABT to 60 months after. There were no significant differences in the continuation rates for 1-year and 5-year of ABT between the groups (86.3 vs. 86.6%, and 70.5 vs. 65.7%, respectively, Figure 1). There were 14 cases of occurrence and recurrence or progression of malignancy during the observation period. The incidence of malignancy was 1324.6 per 100,000 person-years, and there were no differences in the risk of malignancy in a Japanese national survey of similar age. Despite the significantly older patient population in the PM group, the 5-years incidence rate of malignancy was no significant difference between the groups. Binomial logistic analysis was performed using factors such as age, disease duration, history of previous malignancy, concomitant disease and medications, and disease activity at starting ABT. However, no predictive risk factors were found to be associated with the development or relapse of malignancy during ABT use in this study.

Conclusion: In our clinical practice, ABT was effective and safe in both patients with and without previous malignancy.

ASSOCIATION BETWEEN DISEASE ACTIVITY AND CHANGES IN FIBROSIS-4 INDEX LEVEL IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH METHOTREXATE FOR A SHORT PERIOD

Keywords: Rheumatoid arthritis, Descriptive Studies, Comorbidities

N. Namura[1], K. Kamada[2], T. Hagiwara[2], K. Takahashi[3], K. Matsui[1]. *[1]Hyogo Medical University, Division of Allergology and Rheumatology, Department of Internal Medicine, Nishinomiya, Japan*; *[2]Takarazuka City Hospital, Rheumatology, Takarazuka, Japan*; *[3]Hyogo Medical University, Department of Medical Statistics, Nishinomiya, Japan*

Background: Liver fibrosis and liver damage are major concerns associated with long-term side effects in patients with rheumatoid arthritis (RA) treated with methotrexate (MTX). Recently, fibrosis-4 index (FIB-4) has often been used as an indicator of liver fibrosis. However, most studies examining the association between MTX and liver fibrosis, including FIB-4, have involved patients with RA treated with MTX for an extended period. To the best of our knowledge, no study has reported associations between FIB-4 and disease activity in patients with RA after using MTX for a short period.
Objectives: We focused on FIB-4 as an indicator of liver fibrosis in patients with RA treated with MTX in phase I and aimed to evaluate the changes in FIB-4 level in these patients for a short period.
Methods: Patients diagnosed with RA at our hospital and who had not received MTX before diagnosis (using the 2010 ACR/EULAR criteria) were included. Patients with hepatitis virus infection, alcoholism, or severe obesity were excluded from the study. Patients unable to continue using MTX for more than 12 months and those who used a maximum dose of MTX of 10 mg/week or less during the observation period were excluded. Patients' clinical and functional data were recorded at baseline and at all subsequent visits (6 and 12 months). We used the Mann–Whitney U test to compare aspartate transaminase (AST), alanine aminotransferase (ALT), and FIB-4 levels between the baseline and each observation period. Multiple regression analysis was performed to examine the effect of the cumulative MTX dose on the changes in FIB-4 levels from baseline to 6 and 12 months, after adjusting for factors involved in RA.
Results: A total of 144 patients were examined. The median FIB-4 levels increased from baseline to 6 and 12 months ($p < .001$). Multiple regression analysis revealed that the cumulative MTX dose was not a factor independently influencing the changes in FIB-4 levels. Therefore, to identify predictors other than the cumulative MTX dose for changes in FIB-4 levels from baseline, we performed multiple linear regression analysis, after adjusting for sex, body mass index (BMI), CRP, MMP-3, mHAQ, RF, ACPA, DAS28ESR, and FIB-4 level at baseline, defining the changes in FIB-4 level from baseline as the dependent variable. The factors independently influencing the changes in FIB-4 level were DAS28ESR ($\beta = 0.107$) at 6 months and DAS28ESR ($\beta = 0.086$) at 12 months. DAS28ESR at baseline affected the changes in FIB-4 level from baseline to both observation periods. There was also a significant correlation between the change in FIB-4 from baseline to each period and the DAS28ESR ($p < .001$). Further, a mediation analysis was performed for the association between DAS28ESR and the changes in FIB-4 level, considering the cumulative MTX dose as a mediator. The results indicated that the cumulative MTX dose did not mediate the relationship between DAS28ESR at baseline and the changes in FIB-4 level at either observation period.
Conclusion: The cumulative MTX dose did not affect the changes in FIB-4 level over a short period. In contrast, disease activity in patients with RA before MTX administration showed an effect on the changes in FIB-4 level. Clinicians should be more careful regarding liver fibrosis after MTX administration when treating patients with higher disease activity before treatment.

UNDERSTANDING DISEASE PREVALENCE AND COMORBIDITY PROFILES AMONG SEROPOSITIVE AND SERONEGATIVE RHEUMATOID ARTHRITIS PATIENTS IN PUERTO RICO

Keywords: Rheumatoid arthritis, Comorbidities, Autoantibodies

F. Arenal-Cruz[1], G. Jobson[2], E. Villanueva[3], J. Zhu[4]. *[1]Bristol Myers Squibb, Health Economics and Outcome Research, Guaynabo, Puerto Rico*; *[2]Mu Sigma, Offshore delivery, Bangalore, India*; *[3]Bristol Myers Squibb, Medical Affairs, Guaynabo, Puerto Rico*; *[4]Bristol Myers Squibb, Center for Observational Research and Data Science, Princeton, United States of America*

Background: Prevalence of rheumatoid factor (RF) and/or anti-cyclic citrullinated peptide antibody (ACPA) positivity in US patients with rheumatoid arthritis (RA) is around 70% [1]. Seropositive RA status, defined by positivity for RF and/or ACPA, is associated with poor disease prognosis [2]. Little is known about the prevalence of RA, percentages of seropositive RA versus seronegative RA, and the comorbidity profile and infections of these patients in Puerto Rico (PR).
Objectives: To estimate the prevalence of seropositive and seronegative RA in PR and to understand the demographic and clinical characteristics among Puerto Ricans with seropositive versus seronegative RA.
Methods: This was a descriptive retrospective observational cohort study using Merative™ MarketScan® claims database. To examine RA prevalence, eligible Puerto Rican adults were required to have ≥6 months of continuous enrolment (CE) from October 1, 2016, through April 30, 2021 (index period), have ≥3 visits with RA diagnose codes (ICD-10-CM M05 or M06, ignoring M06.1 and M06.4, with ≥2 claims with RA diagnoses occurring between 7 and 365 days of one another). Those patients with ≥1 M05 diagnosis code during the index period were categorized into the seropositive cohort (SP), the index date is the date of the first M05 diagnosis during the index period; otherwise, they were classified into the seronegative cohort (SN), the index date was the date of first an M06 (excluding M06.1 and M06.4), Patients with RA diagnosis in the baseline period were excluded. To assess comorbidity profile and infections, the eligible patients were also required to have ≥12 months CE prior to index date. The demographics, clinical characteristics, and infections were assessed during 12 months prior to the index date (baseline period), and standardized differences were estimated. The crude incidence rate (total new cases/100 person-year) of comorbid conditions and infections were estimated during the follow-up period.
Results: The prevalence of RA among Puerto Ricans was 1.03%. Of 141 patients with RA, 56.7% of them were seropositive. Within eligible seropositive (n=53) and seronegative (n=42) RA patients for the evaluation of comorbidities and infections, the mean (SD) of age were 50.75±12.93 and 49.36±11.22 years (d = 0.11), respectively. Most patients were females (79.25% for SP vs 71.43% for SN, d=0.18) and had commercial insurance (92.45% for SP vs 97.62% for SN, d=0.24). The mean (SD) of Charlson Comorbidity Index scores were 0.79±1.17 vs 0.64±1.01(d=0.14) for seropositive and seronegative respectively. For both seropositive and seronegative cohorts, the most prevalent comorbidities were hyperlipidemia (37.74% vs 30.95%, d=0.14), hypertension (33.96% vs 66.67%, d=0.69) and Type II diabetes (24.53% vs 21.43%, d=0.07) respectively. The most frequent infections were those happening in the urinary tract (18.87% for SP vs 14.29% for SN, d=0.12). In the follow-up period, the crude IR/100-person year were 79.34 and 33.45 for hyperlipidemia; 42.74 and 32.46 for T2DM; 27.47 vs 29.46 for hypertension, and 19.53 vs 25.00 for urinary tract infection for seropositive and seronegative RA cohorts, respectively.
Conclusion: This study found that the prevalence of RA among Puerto Ricans was similar to that reported in US mainland, with most (56.7%) presenting seropositive RA. We also observed a substantial burden of comorbidities among both seropositive and seronegative RA patients. Future studies with a large sample size are warranted.

DMARD INITIATION IN OLDER ADULTS WITH NEW DIAGNOSIS OF LATE-ONSET RHEUMATOID ARTHRITIS

Keywords: Real-world evidence, Rheumatoid arthritis, Disease-modifying Drugs (DMARDs)

J. Lee[1], N. Singh[2], R. Yung[1], U. Makris[3,4], J. Bynum[1]. *[1]University of Michigan Hospital, Internal Medicine, Ann Arbor, United States of America*; *[2]University of Washington, Internal Medicine, Seattle, United States of America*; *[3]University of Texas Southwestern Medical Center: Library, Internal Medicine, Dallas, United States of America*; *[4]VAMC Dallas, Internal Medicine, Dallas, United States of America*

Background: The number of older adults living with rheumatoid arthritis (RA) is growing as the world population is aging. Older adults with RA are less likely to receive disease modifying anti-rheumatic drug (DMARD) despite these medications being effective and generally well tolerated in older adults. Up to one-third of the older RA population are diagnosed after the age of 65 and have late-onset RA (LORA). Older adults with LORA experience more symptomatic and progressive disease, and yet, their treatment in usual care is not well understood.
Objectives: To evaluate initiation of DMARDs in older adults with new diagnosis of LORA.
Methods: In this retrospective observational study, using 20% Medicare data from 2009-2017, we identified adults 66 years of age or older with new diagnosis of LORA without any DMARD use during the 12 months prior to cohort entry. Information on baseline patient characteristics and DMARD initiation during the first 12 months after LORA diagnosis were collected. We also assessed concomitant use of glucocorticoids (GCs) and opioids that are not disease modifying but can improve symptoms of RA.
Results: We identified 25,139 older adults with new diagnosis of LORA in continuous fee-for-service Medicare. Average age at LORA diagnosis was 76.9 (SD 7.6), 76.4% were female, 76.7% were non-Hispanic white, 37.2% had low-income subsidy, and 63.1% had three or more comorbid conditions. Less than one third were initiated on some form of DMARD (28.8%) during the first 12 months after LORA diagnosis. Among those on any DMARDs (N=7252), 87.7% were initiated conventional synthetic DMARD only, 2.2% on biologic DMARD only, and 10.1% on both classes of DMARDs. Concomitant long-term (≥3 months) GC use was greater among those on any DMARD (44.7%) compared to those without DMARD (15.0%). Opioid use was common and observed in 50.4% and 46.9% of those on any DMARD and those without DMARD, respectively. In multivariable analyses, DMARD initiation was associated with younger age, fewer comorbidities, and absence of low-income subsidy status (Table 1).
Conclusion: DMARD use in older adults with new diagnosis of LORA is low despite current clinical practice guidelines recommending early aggressive initiation of treatment. Long-term GC use is common among those on any DMARDs, raising concern for suboptimal DMARD use. Further studies are needed to understand drivers of DMARD use in older adults with LORA.

ESTABLISHED RHEUMATOID ARTHRITIS PATIENTS APPEAR TO HAVE IMPAIRED QUADRICEPS MUSCLE MORPHOLOGY ASSESSED BY ULTRASOUND AND MUSCLE STRENGTH IMPAIRED OVER TIME: A COHORT STUDY

Keywords: Rheumatoid arthritis, Ultrasound

L. Santos[1,2], R. Cavalheiro Do Espírito Santo[1,2], E. Pena[1,2], L. Denardi Dória[1,2], A. L. Mallmann[1,2], S. Pilotti[1,2], D. Moraes[1], M. Antunes[1,2], V. Hax[1,2], C. Brenol[1,2], O. Monticielo[1,2], R. Chakr[1,2], R. Xavier[1,2]. [1]*Hospital de Clínicas de Porto Alegre, Laboratório de Doenças Autoimunes, Serviço de Reumatologia, Porto Alegre/RS, Brazil*; [2]*Universidade Federal do Rio Grande do Sul (UFRGS), Postgraduate Program in Medical Science, Porto Alegre/RS, Brazil*

Background: Rheumatoid arthritis (RA) patients usually present extra-articular manifestations [1], which affect muscle strength, muscle mass and physical functional [2]. There are several methods to assess muscle mass and, among these methods, muscle ultrasound (MU) has been suggested as an alternative to assess muscle morphology [3].
Objectives: [1] To assess the MU of the quadriceps muscle and verify changes over time (1-year) in muscle thickness and pennation angle in RA patients; and [2] to verify the of changes in clinical features, muscle strength, physical functional in over time in RA patients.
Methods: RA patients, age ≥18years and who met 2010 American College of Rheumatology criteria were included. Morphological parameters in quadriceps muscle consisted of the muscle thickness and pennation angle of rectus femoris (RF), vastus intermedius (VI) and vastus lateralis (VL). RA activity was measured by 28-joint disease activity score (DAS28) assessed by C-reactive protein (CRP), muscle strength by handgrip, and physical functional by health assessment questionnaire (HAQ) and timed-up-and-go (TUG) test. The paired samples Wilcoxon test was used to compare variables between the baseline and 1-year assessments. The significance level was set at $p \leq 0.05$ for all analyzes.
Results: At baseline, 155 patients with median of age 60.00 (52.00-65.00) years old, disease duration 11.00 (6.00-20.00) years and DAS28-CRP 2.77 (2.02-3.76) were included. Until moment, twenty-two patients completed the 1-year follow-up. Among these re-evaluated patients, there was a decrease in the VL (-11%) and VI (-13%) pennation angles of quadriceps muscle, and decrease in muscle strength assessed by handgrip test (-36%) after 1-year. On the other hand, no changes were observed in muscle thickness, RF pennation angle, DAS28-CRP, HAQ, and TUG test in over time ($p>0.05$; table 1).
Conclusion: These preliminary observations indicate that established RA patients have impaired muscle quality (pennation angles) and impaired muscle strength over time. However, it is necessary to complete the remainder of the reassessments to confirm these findings, besides verifying the associations with clinical parameters.

Rheumatoid arthritis - comorbidity and clinical aspects

AB0316 CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS AND THE PRESENCE OF PORPHYROMONAS GINGIVALIS IN THE ORAL FLORA

Keywords: Rheumatoid arthritis, Descriptive Studies, Comorbidities

M. Sanchez-Wonenburger[1], I. González Fernández[1], P. Castro-Santamaria[1], J. L. Puga Guzmán[1], A. Mata Ojeros[1], I. Alvarez Losada[1], V. Busto[1], R. Dos-Santos[1], E. Perez-Pampín[1,2], J. R. Maneiro[1], A. Mera Varela[1,2,3], J. Ruiz[1]. [1]*Complejo Hospitalario Universitario De Santiago de Compostela, Reumatología, Santiago de Compostela, Spain*; [2]*Facultade de Medicina de Santiago de Compostela, Reumatología, Santiago de Compostela, Spain*; [3]*Instituto de Investigacion de Santiago de Compostela (IDIS), Reumatología, Santiago de Compostela, Spain*

Background: It has been shown that periodontal disease, together with the presence of other germs, may play an important role in the development and maintenance of rheumatoid arthritis (RA). In particular, Porphyromonas gingivalis (Pg), a large anaerobic gram-negative bacteria, produces the extracellular proteases arginine-gingipain and petidyl-arginine deiminase, which contribute to oral periodontal destruction but also promote peptide citrullination, inducing the synthesis of anti-citrullinated peptide antibodies that have been linked to the onset of rheumatoid disease, its severity and its perpetuation[1,2].
Objectives: The purpose of the present work is to characterize patients with RA who are carriers of Pg in the oral cavity.
Methods: Oral flora has been analyzed by semiquantitative PCR for 5 germs involved in periodontal disease, which includes Pg (Peiropoc-Genspeed biotect) in 236 RA patients and 84 healthy controls, obtained from an outpatient clinic of non-inflammatory conditions: 172 women and 63 men, mean age 57.69 years. Correspondence analyses were performed with Pearson's test for different non-parametric variables and Mann-Whitney test for continuous variables.
Results: Presence of Pg was detected in 80 patients with RA(34%) and in 28 controls (33.7%). The mean age of the carriers was slightly higher (62.04; p>0.05) and the majority were women (72.5%). 22.5% of the smokers were carriers of Pg, while 10.8% were in the control group (p= 0.16). The mean activity, measured by DAS28 was 2.05 in carriers and 2.66 in non-carriers, with no significant differences (p=0.84). The mean CRP in carriers was 0.47 and in the overall RA of 1.08 (p=0.61) and the mean ESR was 13.37 in carriers and 16.83 in noncarriers (p=0.11). Anti-CCP were found in 55% of Pg carriers and in 72% of noncarriers (p=0.009). The functional capacity measured by HAQ was 0.245 in carriers vs 0.442 in non-carriers (p>0,05). Interestingly, in all the cases where Pg was identified, other bacteria capable of causing periodontal disease were also detected, especially Tanerella forsythia.
Conclusion: The presence of Prophyromonas gingivalis is more frequent in older and smoker patients with RA. Pg in the oral flora of patients with RA does not seem to contribute to a greater severity of the disease, in terms of functional capacity or activity, as well as in its measurement parameters. It should be noted that whenever Pg has been detected there is co-infection with other germs involved in periodontal disease.

AB0317 PLASMA NETS LEVELS IN ESTABLISHED RHEUMATOID ARTHRITIS PATIENTS RECEIVING BIOLOGICAL OR JAK INHIBITOR THERAPY AND ASSOCIATION WITH DISEASE ACTIVITY

Keywords: bDMARD, Outcome measures, Rheumatoid arthritis

B. Frade-Sosa[1], A. Ponce Fernandez[1], E. Ruiz-Ortiz[2], O. Viñas[2], J. Yagüe[2], J. M. Auge[3], A. Azuaga[1], J. C. Sarmiento-Monroy[1], R. Morlà[1], V. Ruiz[1], J. Ramírez[1], P. Corzo Garcia[1], S. M. Farietta Varela[1], N. Sapena[1], J. D. D. Cañete[1], J. A. Gómez-Puerta[1], R. Sanmartí[1]. Background: Neutrophil extracellular traps (NETs) may play a pathogenic role in rheumatoid arthritis (RA)[1]. Elevated circulating NETs have been found in RA plasma, but their relationship with synovial inflammation and antirheumatic therapy including biologics and JAK inhibitors (JAKi) is unclear.
Objectives: To evaluate whether plasma levels of NETs remnants in patients with established RA are associated with disease activity or type of antirheumatic therapy (biologics or JAKi).
Methods: Observational cross-sectional study. RA patients (ACR/EULAR 2010) receiving treatment with IL6 inhibitors (IL6i), JAKi, or TNF inhibitors (antiTNF) were consecutively included regardless of disease activity and previous therapy. Controls were RA patients with high disease activity (≥ 4 swollen joints), regardless of treatment, as was a second control group of healthy blood donors. Clinical disease activity indexes (DAS28, SDAI, CDAI) and laboratory parameters of inflammation, including high-sensitive CRP (hsCRP) and calprotectin were evaluated. Plasma levels of elastase-DNA (EN-DNA) and histone-DNA complex (H_3-DNA) (NETs remnants) were examined by ELISA. We analysed NETs remnant levels and clinical variables using Spearman's correlation test.
Results: 111 patients (90.1% female, 85.6% seropositive (RF and/or ACPA), mean age 56.45 years and mean RA duration 15.9 years) were included: 83 received biologics (53 IL6i and 30 antiTNF) and 28 JAKi (19 baricitinib and 9 tofacitinib). Mean DAS28 and CDAI were 3.00 and 10.5, respectively. Controls were 18 active RA patients (mean DAS28 5.72 and CDAI of 34.9), 11 without biological or JAKi treatment [Table 1]. 30 healthy blood donors were also analysed. NETs levels of patients under biologic or JAKi therapy showed no significant differences with healthy controls. No significant differences were observed in NETs values according to the type of therapy. In the control group of patients with high disease activity, plasma NETs were higher than in the main group (treated with JAKi or biologics), but only with statistically significant in H3-DNA levels (EN-DNA 2.96 (sd 5.42) vs 1.25 (sd 1.03) p=0.03; H3-DNA 2.67 (sd 4.52) vs 1.36 (sd 1.15) p >0.05). The two NETs were strongly correlated (ρ=0.97; p<0.001). A weak correlation between NETs and clinical disease activity (DAS28, CDAI, SDAI) was found, but not with laboratory parameters of inflammation including calprotectin.
Conclusion: NETs are elevated in active RA patients but weakly correlated with clinical disease activity. Patients with established RA under biologic or JAKi

AB0318 DAS28 WITH THREE VARIABLES PERFORMANCE IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS WITH AND WITHOUT CONCOMITANT FIBROMYALGIA

Keywords: Rheumatoid arthritis, Fibromyalgia

S. Miladi[1], B. A. Hiba[1], F. Alia[1], S. Ben Yaacoub[1], H. Bousaa[1], M. Yasmine[1], K. Ouenniche[1], K. Selma[1], C. Selma[1], K. Ben Abdelghani[1], L. Ahmad[1]. [1]*Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia*

Background: Several studies have shown that rheumatoid arthritis (RA) patients with concomitant fibromyalgia (FM) can cause an overestimation of the disease. activity assessed by the 28 disease activity score (DAS28) by inflating the patient reported components. DAS28 V3 is calculated based on only three variables: swollen and tender joint counts and CRP.

Objectives: The aim of this study was to evaluate the performance of the DAS28 V3 in a cohort of RA patients with and without concomitant FM.

Methods: Cross-sectional observational study that included consecutive patients with diagnosis of RA (ACR/EULAR 2010 criteria) with and without concomitant FM (ACR 2016). Demographic and RA characteristics were collected. All patients underwent a clinico-biological and an ultrasound (US) assessment of RA activity. US examination included the assessment of synovial/tenosynovial hypertrophy in grey scale and in Power Doppler (PD). P<0.5 was accepted for significance.

Results: Eighty patients distributed into 40 patients in each group were recruited. Epidemiological and RA characteristics were comparable between groups. Subjective. activity parameters were higher in RA with FM group (p ≤0.05). No significant difference was observed between the groups in regards to mean DAS28, DAS28 V3, SDAI and CDAI (p=0.12, p=0.14, p=0.2 and p=0.5 respectively). DAS28 was significantly greater than DAS28 V3 in RA with FM group (p=0.000). However, no difference between DAS28 and DAS28 V3 was not significant in the PR without FM group. Multivariate analysis in RA with FM group showed that DAS28 V3 was significantly positively associated with the presence of US synovial hypertrophy (r=0.494, p=0.001) and the presence of US PD synovitis (r=0.155, p=0.032), while Patient Global Activity expressed a significant negative association (r=-0.392, p=0.049 and r=-0.642, p=0.005 respectively).

Conclusion: Our study confirms that DAS28 V3 score would represent a better alternative for the clinical assessment of disease activity in RA patients with concomitant FM.

AB0319 HIGH PREVALENCE OF HYPOALBUMINEMIA IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Diet and Nutrition

P. W. Jia[1], J. Pan[1], Y. W. Zou[1], H. W. Zheng[1], J. D. MA[1], Z. M. Ouyang[1], Q. Zhang[1], T. Wu[1], Y. Lu[1], L. Dai[1]. [1]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Hypoalbuminemia is associated with worse medical conditions in chronic diseases and surgery outcomes. The concentration of serum albumin in patients with rheumatoid arthritis (RA) has been reported to decline. However, less is known about the prevalence and severity of hypoalbuminemia in RA patients and its association with RA disease.

Objectives: To investigate the association of hypoalbuminemia with RA disease characteristics and its potential mechanism in RA.

Methods: This cross-sectional study collected clinical data from a Chinese RA cohort, including disease activity, physical function, and radiographic assessment. Serum levels of albumin and inflammatory cytokines including soluble interleukin 2 receptor (sIL-2R), IL-6, IL-10, TNF-α, IL-8, and IL-1β were detected. According to the level of serum albumin, RA patients were divided into four groups as normal albumin (≥ 35.0 g/L), mild hypoalbuminemia (30.0 - 34.9 g/L), moderate hypoalbuminemia (25.0 - 29.9 g/L) and severe hypoalbuminemia (< 25 g/L).

Results: ①Among 1510 RA patients recruited in the cohort, 890 RA patients were eligible for analysis. Their mean age was 53.5 years old and 77.2% were female. There were 87.9% patients with active RA (CDAI > 2.8). ② The prevalence of hypoalbuminemia was 48.2% (429/890) in all RA patients and 50.9% (398/782) in active RA. The prevalence of hypoalbuminemia increased with age, disease activity, but decreased with BMI (all *P* trend < 0.05, Figure 1). ③ Compared with those with normal albumin, RA patients with hypoalbuminemia were older, had lower BMI, higher levels of ESR and CRP, higher disease activity, and higher HAQ-DI. ④ RA patients with hypoalbuminemia had higher levels of serum inflammatory cytokines, including sIL-2R, IL-6, TNF-α and IL-10 than those without, regardless the severity of hypoalbuminemia. Moreover, the level of albumin was negatively correlated with all six inflammatory cytokines (*r* range from -0.124 to -0.334, all *P* < 0.001). ⑤ Multivariate ordinal logistic regression analysis showed that BMI [adjusted odd ratio (AOR) = 0.889) and IL-10 (AOR = 0.971) were negatively, age, ESR, CRP, previous treatment with glucocorticoids, sIL-2R, IL-6, and IL-8 were positively associated with hypoalbuminemia in RA patients (AOR range from 1.001 to 1.671, all *P* < 0.05).

Conclusion: Our data show high prevalence of hypoalbuminemia in patients with active RA which is associated with high inflammation. These data imply the importance of the control of inflammation and nutrition supply. Further prospective study is needed in future.

AB0320 SACROILIITIS AND ACPA POSITIVE: IS THIS AN ASSOCIATION OF RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS? ABOUT 16 CASES

Keywords: Psoriatic arthritis, Spondyloarthritis, Rheumatoid arthritis

H. Arabi[1], H. Tebaa[1], A. Mougui[1], I. El Bouchti[1]. [1]*CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Department of Rheumatology, Marrakech, Morocco, Rheumatology, Marrakesh, Morocco*

Background: Rheumatoid arthritis (RA) and spondyloarthritis (SpA) in particular psoriatic arthritis (RP) are two distinct inflammatory rheumatisms having in common destructive peripheral involvement.

Objectives: We report a series of chronic inflammatory rheumatism with features of RA and SpA.

Methods: Descriptive retrospective study including patients with chronic inflammatory rheumatism, collected in the rheumatology department over a period of 10 years (2009-2019).

Results: 16 patients were included. The average age was 45.94 ± 12.10 years [28-71], with a female predominance of 87.5%. The mean age at onset of symptoms was 34.69 ± 12.71 years [14-57]. The disease duration was 11.25 ± 10.44 years. History was dominated by hepatic steatosis in 25%, diabetes in 18.8%, hypertension and smoking in 12.5%. A history of familial rheumatism and cutaneous psoriasis was found in only one patient. The revealing symptomatology was dominated by chronic polyarthritis in 75%, polyarthralgia in 18.8%

and mono-arthritis in one case. Deformities were described in 43.8%. On the immunological assessment, the mean ACPA was 191.25 ± 155.68 [36-500]. Rheumatoid factor and Anti-nuclear antibodies were positive in 50% and 37.5% respectively. HLA B27 was done in 2 patients, 1 of whom was positive. Sjögren's syndrome was present in 37.5% of patients. A biological inflammatory syndrome was found in the majority of patients with an average ESR and CRP of 37.38 and 20.41 respectively. Radiographic sacroiliitis was noted in 56.3%, and the rest were non-radiographic. Syndesmophytes were noted in 3 patients (18.8%). Coxitis was present in 12.6%. Structural damage in 81.3% made of erosions, geodes and pinching with reconstruction images in 4 patients. Patients were treated with corticosteroid therapy in 87.5%, methotrexate in 62.5%, sulfasalazine in 43.8%, and biotherapy in 25% of cases with anti-TNF alpha type.

Conclusion: These associations pose difficulties in diagnosis and management. A more in-depth study of these patients can help with an accurate diagnosis and therefore with optimal management.

AB0321 APPLICATION OF NOVEL REFERENCE VALUES FOR 24-HOUR PROFILE OF CENTRAL SYSTOLIC BLOOD PRESSURE IN RHEUMATOID ARTHRITIS: CORRESPONDENCE WITH PERIPHERAL BLOOD PRESSURE AND CLINICAL ASSOCIATIONS OF HYPERTENSIVE PHENOTYPES

Keywords: Comorbidities, Heart, Cardiovascular disease

R. Rakhmadzhanova[1], G. Farias[2], E. Troitskaya[3], R. Osipyants[3], S. Velmakin[3], Z. Kobalava[3]. *[1]Osh State University, Internal Medicine, Osh, Kyrgyzstan*; *[2]Universidad Tecnica de Manabi, Internal Medicine, Manabi, Ecuador*; *[3]RUDN University, Internal Medicine, Moscow, Russian Federation*

Background: Prognostic significance of 24-h profile of peripheral BP is well-known. The growing insights in the role of arterial stiffening in cardiovascular disease led to the viewpoint that vascular risk must be more closely associated with central than brachial BP. While the upper limits for clinic and ambulatory peripheral BP have been routinely used for a long time and the reference values for clinical central BP have been developed some years ago, the hypertensive threshold for 24-h central BP hasn`t been investigated until 2022.

Objectives: To apply novel reference values of 24-h central SBP (cSBP) in the patients with rheumatoid arthritis and to characterize the hypertensive profile.

Methods: The study group included 85 patients with RA (females 77.6%, age 59.7±14.3 (M±SD) years, HTN 65%, median HTN duration 6.6 years, RA duration – 7 years seropositive RA 65%, mean DAS-28(CRP) 3.7±1.1) and control group (40 patients matched by gender, age and risk factors). All patients with HTN received antihypertensive therapy. Office peripheral BP was measured with a validated oscillometric device, 24-hour ABPM was performed with BPLab Vasotens, arterial stiffness – by applanation tonometry. CV risk was calculated by mSCORE (EULAR recommended modified version). The upper limits for normal central SBP were 125 mmHg for daytime, 115 mmHg for nighttime and 120 mmHg for 24-h BP. P<0.05 was considered significan.t.

Results: Mean central SBP in patients with RA was 123±21 mmHg (108±13 mmHg in normotensive and 132±20 in hypertensive patients, p<0.05). Hypertensive patients with RA vs controls were characterized by significantly higher frequency of elevation of daytime cSBP (44.1% vs 12.5%, p=0.01) and a trend to higher frequency of elevation of nighttime cSBP (58.8% vs 37.5%, p=0,09) and 24-h SBP (47.1% vs 25%, p=0.05). In normotensive RA patients compared to controls cSBP was elevated in 7.1% vs 0% for daytime, 14.3% vs 0% for nighttime and 7.1% vs 0% for 24H BP respectively (p>0.05 or the trend). All patients with normal peripheral ambulatory SBP (daytime, nighttime and 24-h) had normal central ambulatory SBP. 2 patients with elevated 24-h pSBP and 5 patients with elevated nighttime pSBP had normal cSBP while 2 patients with normal daytime pSBP had elevated cSBP. Patterns of diurnal index were similar for peripheral and central SBP (the discordance was observed only in 4 patients who were dippers by peripheral BP and non-dippers by central). Patients with RA and central 24-h BP elevation compared to patients with normal profile had higher ESR, longer RA duration, higher BMI, higher frequency of obesity, HTN, longer duration of HTN, higher cfPWV, central pulse pressure, stiffness gradient (cfPWV/crPWV), CAVI and higher CV risk. There were significant correlations between central 24-h BP elevation and ESR, hypertension-related parameters (PWV, pulse pressure, stiffness gradient, CAVI) and SCORE index.

Conclusion: The first application of novel reference values of ambulatory cSBP in RA showed that cSBP elevation is highly prevalent and in hypertensive individuals the frequency of daytime cSBP elevation is higher than in controls. Not only hypertension related parameters but also high ESR may be the markers of 24-h cSBP elevation.

Background: We have reported that a decrease in phase angle (PhA), an index of cell membrane fragility, nutritional status, and muscle strength, measured by bioelectrical impedance analysis (BIA), is associated with falls in patients with rheumatoid arthritis (RA) [1]. Since a decline in physical balance ability is thought to be related to falls, assessing physical balance ability is important, and in recent years, assessment of physical balance ability has been included in the diagnostic criteria for sarcopenia. The PhA reflects muscle status and may be related to physical balance ability, but the relationship between physical balance ability and the PhA in RA patients is unclear.

Objectives: To examine the relationship between physical balance ability and the PhA in RA patients.

Methods: A cross-sectional analysis of 89 RA patients (78% female, mean age: 66.7±14.3 years) was performed. The PhA was evaluated at 50 kHz on a BIA device (MC-780A; TANITA, Japan). Assessment of physical balance ability was performed with a muscle function analyzer (BM-220; TANITA), which can assess physical balance ability based on changes in load during standing up from a chair. Of the indices obtained by the muscle function analyzer, lateral balance was evaluated by dividing the lateral directional variation value (Vx mm/sec) by the load variation value (Vw kg/sec) (Vx/Vw). The balance score, which is the score of the stability time (stable time) from the point after the maximum load value and Vx/Vw compared to the reference value, was also assessed. The associations of PhA with Vx/Vw being above the median and the z-score of Vx/Vw and of the balance score being above -0.5 were tested by logistic regression analysis, and the association between Vx/Vw and the PhA as continuous variables was tested by multiple regression analysis. The cutoff value of PhA for the balance score z-score of -0.5 was calculated by receiver-operating characteristic (ROC) curve analysis.

Results: Even after adjusting for covariates (sex, age, BMI, ADL, disease activity, and medication status), the PhA was significantly associated with Vx/Vw greater than the median [odds ratio (OR): 0.44, 95% confidence interval (CI): 0.19-0.995)] and z-score > -0.5 (OR: 0.42, 95%CI: 0.19-0.93). Multiple regression analysis adjusted for covariates also showed that the PhA was significantly associated with Vx/Vw (β=-0.22, p=0.023). A balance score z-score ≥ -0.5 was significantly associated with a PhA above the 75th percentile (OR: 9.34, 95%CI: 1.45-60.1). The cutoff value of the PhA for a balance score z-score of -0.5 was 4.87° (AUC = 0.64, p = 0.32) for men and 4.30° (AUC = 0.78, p < 0.001) for women.

Conclusion: The PhA may be associated with physical balance ability.

AB0323 DOES FRAILTY PREDICT METHOTREXATE DISCONTINUATION DUE TO ADVERSE EVENTS IN RHEUMATOID ARTHRITIS PATIENTS?

Keywords: Disease-modifying Drugs (DMARDs)

Y. Sobue[1], S. Asai[2], M. Suzuki[2], Y. Ohashi[2], S. Imagama[2]. *[1]Japanese Red Cross Nagoya Daiichi Hospital, Department of Orthopedic Surgery, Nagoya, Japan*; *[2]Nagoya University Graduate School of Medicine, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan*

Background: Rheumatoid arthritis (RA) patients are more likely to develop frailty than general population [1]. Frailty is defined as the intermediate stages of health and disability in physical and cognitive function, and can lead to various negative health outcomes. On the other hand, Methotrexate (MTX) is an anchor disease-modifying antirheumatic drug. RA treatment has advanced significantly with the introduction of MTX. However, it was reported that 94.3% of MTX-naïve RA patients had adverse events (AEs) (C-OPERA study) [2]. Thus, RA patients on MTX should always be aware of complications and AEs.
Objectives: Since RA patients with frailty have more comorbidities than those with non-frailty, complications of RA or RA drugs are also expected to increase. The purpose of this study was to clarify whether frailty in RA patients influences the occurrence of AEs related to MTX.
Methods: Of 538 RA patients (an observational study, T-FLAG study) who visited us in 2020, 320 used MTX. After 2 years of follow-up, we investigated final follow-up date and AEs leading to MTX discontinuation. Frailty was defined as a score of 8 or more on the Kihon Checklist (KCL). Logistic regression analysis was performed to determine factors associated with MTX discontinuation due to AEs. MTX retention rates were calculated by Kaplan–Meier analysis, and crude retention rates were compared using the log-rank test.
Results: Of the 320 patients (249 females) in this study, 23 patients (7.2%) discontinued MTX due to AEs. AEs included liver disorder (26.1%), MTX pneumonia (21.7%), decreased renal function (13.0%). There were no patients with MTX discontinuation due to inefficacy. Mean age at baseline (standard deviation [SD]) was 68.2 (11.9)/ 64.5 (13.9) years (MTX discontinuation/ MTX continuation), MTX dose was 8.1 (2.8)/ 8.1 (2.9) mg, Clinical Disease Activity Index (CDAI) was 6.1 (6.1)/ 5.6 (7.3), KCL was 9.0 (5.0)/ 5.8 (4.0) point ($p<0.05$), and the proportion of frailty was 56.5%/ 31.3% ($p<0.05$). Logistic regression analysis revealed significant associations of MTX discontinuation with KCL (OR: 1.16, 95%CI: 1.06–1.28), and frailty (OR: 2.77, 95%CI: 1.16–6.61), adjusting for age and sex. The rate of MTX retention (at 1 year, and 2 years) was significantly lower in subjects with frailty (91.2%, and 86.6%) than in those with non-frailty (96.2%, and 95.1%) respectively. Comparing the patient characteristics at baseline in subjects with frailty and non-frailty, mean age, CDAI, KCL, and the proportion of MTX discontinuation due to AEs were significantly higher in subjects with frailty.
Conclusion: Our finding suggest that frailty was the significant factor of MTX discontinuation due to AEs, and the rate of MTX retention was significantly lower in the subjects with frailty compared to non-frailty. Moreover, the subjects with frailty had significantly higher mean age and disease activity, suggesting that frailty comprehensively reflects a bad condition. Frailty is significantly associated with poor physical function, and poorer physical function is reportedly associated with a poorer response to treatment [3]. Poor physical function (physical frailty) may make patients more prone to MTX discontinuation due to AEs. These findings suggest that frailty is a comprehensive index with high predictive power for MTX discontinuation due to AEs. Therefore, the occurrence of MTX AEs should be carefully monitored when using MTX in RA patients with frailty.

DEVELOPMENT OF A MOBILE APP TO SUPPORT SELF-MANAGEMENT IN INDIVIDUALS WITH INFLAMMATORY ARTHRITIS

Keywords: Self-management, Rheumatoid arthritis, Artificial Intelligence

Y. El Miedany[1], B. M. Elnady[2], S. Abd-Elmaksoud[3], O. El Miedany[4], D. Palmer[5], N. Fouda[6], M. H. Abu-Zaid[7], W. Elwakil[8], W. Hassan[2], I. Aabda[9]. *[1]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom; [2]Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Banha, Egypt; [3]Faculty of Medicine Banha University, Psychiatry, Banha, Egypt; [4]University College London, Computer sciences, London, United Kingdom; [5]North Middlesex University Hospital, Rheumatology, London, United Kingdom; [6]Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt; [7]Faculty Of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; [8]Faculty of Medicine Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt; [9]Faculty Of Medicine Kasr Al-Ainy, Cairo University, General Medicine, Cairo, Egypt*

Background: EULAR has recently highlighted the vital role of digital health in standard practice and the possibility to enhance the self-management abilities of the patients. Self-management strategies play an important role in improving clinical outcomes in patients with inflammatory arthritis. Smartphone technology has the potential to engage the patients with their treating health care professionals through suitable self-monitoring and easy access to information. In addition, having a more accurate summary of self-reported fluctuations in symptoms, psychosocial problems and behaviors can help both the patients and the treating health care professionals better understand the patient's condition, identify barriers to self-management, and assess treatment effectiveness and additional health care needs. However, evidence regarding these supporting digital tools, including smartphone apps, is currently very limited. So far there is no comprehensive mobile app developed to facilitate the collaboration between the patients and their treating physicians.
Objectives: 1.To provide basic data on system requirement specifications for a mobile app to self-manage inflammatory arthritis. 2. Identify the target audience, characteristics of the app, and correlations between the system requirements and the established behavior change techniques.
Methods: A participatory action research design was adopted to inform the app developer of the major themes recognized as the main pillars for the app development, implementing artificial intelligence. Qualitative data were collected using multiple methods in several workshops. Participants were 2 Rheumatologists, 1 rheumatology nurse specialist, 1 rheumatoid arthritis patient, 1 psoriatic arthritis patient, 1 patient Ankylosing spondylitis, and an App/ machine learning engineer. A taxonomy was used to determine the degree of correlation between the system requirements and established behavior change techniques.
Results: The app targets the optimization of self-management and provide non-medical management approach. The major themes identified were: 1. collect self-reported patient reported outcomes (disease functional ability, quality of life, motivation), 2. Collect information on patient demographics, comorbidity(ies), disease activity status (self-reported disease activity score), past and current medications, 3. Identify the individual patient's target to be achieved, 4. Develop a patient profile that focuses on the patient's disease activity status, well-being, targets and attitude, 5. Using artificial intelligence, construction of a personalized, evidence-based disease self-management program based on recommendations from medical guidelines, medical standards, and state-of-the-art clinical research; 6. implementation of personalized recommendations into the patient's daily life by providing short daily tasks that accelerate positive behavior change. 7. a calendar feature for goal setting, planning, and recording of (HRQoL) performance and progress, 8. a small community feature for positive feedback, support from peers and support the patient in coping with stress, sadness, depression, fatigue, and further disease-related symptoms, 9. Implementation of cognitive behavioral techniques, meditation and relaxation methods, 10. adapt a reward system to motivate end users for using the app, and, 11. Format the app interface.
Conclusion: These findings highlight the potential of implementing digital therapy to encourage self-management and engagement with health care professional for the management of patients with inflammatory arthritis. The results of this work suggest that using an app-based personalized disease management program may reflect significantly on several measures of patient-reported outcomes and disease activity in patients with RA/PsA/SpA. Future feasibility testing in a prospective study will firmly establish the reliability, efficacy, and cost-effectiveness of such an app intervention for this cohort of patients.

AB0325

DEVELOPMENT OF A MOBILE APP FOR DISEASE-SPECIFIC COGNITIVE BEHAVIOR THERAPY MANAGEMENT IN INDIVIDUALS WITH RHEUMATOID ARTHRITIS

Keywords: Cognitive Function, Self-management, Rheumatoid arthritis

B. M. Elnady[1], S. Abd-Elmaksoud[2], O. El Miedany[3], Y. El Miedany[4]. *[1]Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Banha, Egypt*; *[2]Faculty of Medicine Banha University, Psychiatry, Banha, Egypt*; *[3]University College London, Computer Sciences, London, United Kingdom*; *[4]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom*

Background: EULAR has recently highlighted the vital role of digital health in standard practice and the possibility to enhance the patient's quality of life. Cognitive Behavior Therapy (CBT) plays an important role in improving clinical outcomes in inflammatory arthritis patients. The aim of CBT is to boost patients' self-efficacy for pain management, or their confidence in their ability to control their pain, and lessen the interference that pain causes in their everyday lives. CBT does this by educating patients on how to develop more efficient coping mechanisms to deal with everyday pain sensations and enhance functionality and quality of life. So far, no comprehensive mobile app has been developed to facilitate the collaboration between patients and their CBT therapist, especially with those having monetary and physical constraints related to their disease.
Objectives: 1-To provide basic data on system requirement specifications for a mobile app to provide constructed CBT program for RA patients 2. Identify the target audience, characteristics of the app, and correlations between the system requirements and the established CBT.
Methods: To identify the major themes recognised as the main pillars for app development and inform the app developer/machine learning engineer, a participatory action research design was implemented. Qualitative data were collected using multiple methods in four workshops. Participants were 2 Rheumatologists, 1 rheumatology nurse specialist, 1 Psychiatrist4 rheumatoid arthritis patient, and an App developer. A taxonomy was used to determine the degree of correlation between the system requirements and established cognitive behavioral therapy techniques.
Results: The app targets the optimization of patient-reported outcomes and quality of life to provide a non-medical management approach via modifying Disease-specific dysfunctional beliefs and behaviors using cognitive and/or behavioral exercises in a structured manner. The major themes identified were: 1. collect self-completed patient-reported outcomes (disease functional ability, quality of life, motivation), 2. Collect information on patient demographics, comorbidity(ies), disease activity status (self-reported disease activity score), plus past and current medications, 3. Identify the individual patient's target to be achieved, 4. Develop a patient profile that focuses on the patient's perpetuating factors, 5. construction of a personalized, evidence-based disease management program based on recommendations from medical guidelines, medical standards, and state-of-the-art clinical research; 6. implementation of a personalized CBT program for Effective Coping, Life Goals, Pain Management, Emotional Responses, Managing Change, Self-Esteem, Relationships 7. a calendar feature for goal setting, planning, and recording of physical activity performance and progress, 8. a small community feature for positive feedback, support from peers and support the patient in coping with stress, sadness, depression, pain, fatigue, and further disease-related symptoms, 9. Implementation of relaxation exercises, 10. adapt a reward system to motivate end users for using the app,11. to help the patients learn ways to cope with increased resilience to disease-related episodes.12. Format the app interface.
Conclusion: These findings highlight the potential of implementing digital CBT to encourage RA patients to be able to cope with their disease, change wrong beliefs, allow them to retain jobs, socialize normally, and engage with healthcare professionals. The results of this work suggest that using an app-based personalized disease management program may reflect significantly on several measures of patient-reported outcomes and disease quality of life in RA considering alleviating conventional physical CBT barriers. Future feasibility testing in a prospective study will firmly establish the reliability, efficacy, and cost-effectiveness of such an app intervention for this cohort of RA patients.

IMPACT OF ANTI-CITRULLINATED PROTEIN ANTIBODIES AND RHEUMATOID FACTOR ON BONE MINERAL DENSITY CHANGE IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH DENOSUMAB

Keywords: Autoantibodies, Osteoporosis, Rheumatoid arthritis

S. Anno[1], T. Okano[2], T. Koike[3,4], H. Nakamura[2]. *[1]Yodogawa Christian Hospital, Orthopaedic Surgery, Osaka, Japan*; *[2]Osaka Metropolitan University Hospital, Orthopaedic Surgery, Osaka, Japan*; *[3]Osaka Metropolitan University Hospital, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan*; *[4]Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan*

Background: Osteoporosis is one of the major comorbidity in patients with rheumatoid arthritis (RA). A low bone mineral density (BMD), especially in the femoral neck, was associated with the presence of anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF). However, there are few reports investigated the influence of autoantibody on BMD change in patients with RA after osteoporosis treatment.
Objectives: There are a lot of evidence that denosumab increased BMD in patients with osteoporosis, and improved bone eroison in patients with RA. We evaluated the BMD change in patients with RA treated denosumab, and assessed the effect of autoantibody, such as ACPA and RF.
Methods: This study included 196 RA patients (187 female; mean age, 71.0 ± 9.0 years; mean disease duration, 17.8 ± 15.3 years; mean DAS28-CRP, 2.9 ± 1.2) who fullfilled the criteria of osteoporosis and treated with denosumab. Disease activity of RA was treated according to EULAR recommendation 2022. BMD at the lumbar spine, proximal femoral and femoral neck were evaluated by dual energy X-ray absorptiometry at baseline and 12 months after denosumab treatment. We evaluated the influence of ACPA and RF for BMD change.
Results: Improvement ratio of BMD at the lumbar spine, proximal femoral and femoral neck were 6.4% (p<0.01), 3.4% (p<0.01) and 1.6% (p=0.10) after 12 months treatment. There were no differences in BMD at the lumbar spine, proximal femoral and femoral neck before denosumab treatment between 101 ACPA-positive patients and 30 ACPA-negative patients (0.77 vs 0.77g/cm^2, p=0.68; 0.58 vs 0.61 g/cm^2, p=0.13; 0.48 vs 0.47 g/cm^2, p=0.7), between 128 RF-positive patients and 42 RF-negative patients (0.75 vs 0.76 g/cm^2, p=0.47; 0.59 vs 0.59 g/cm^2, p=0.68; 0.47 vs 0.46 g/cm^2, p=0.12). Improvement ratio of BMD at the lumbar spine, proximal femoral and femoral neck were 6.1% (p<0.01), 3.6% (p<0.01) and -0.18% (p=0.49) in ACPA-positive patients, 5.8% (p<0.01), 2.3% (p=0.01) and 3.7% (p<0.01) in ACPA-negative patients after 12 months treatment. Although there were no differences between ACPA-positive patients and ACPA-negative patients in BMD change at the lumbar spine (p=0.86) and proximal femoral (p=0.72), BMD change at femoral neck in ACPA-positive patients were lower than ACPA-negative patients (p=0.03). Improvement ratio of BMD at the lumbar spine, proximal femoral and femoral neck were 6.6% (p<0.01), 3.5% (p<0.01) and 1.1% (p=0.47) in RF-positive patients, 6.5% (p=0.04), 2.5% (p<0.01) and 2.0% (p=0.06) in RF-negative patients after 12 months treatment. There were no differences between RF-positive patients and RF-negative patients in BMD change at the lumbar spine (p=0.08), proximal femoral (p=0.66) and femoral neck (p=0.45). Multivariate linear regression analysis revealed that low BMD at baseline (β=-0.35, p<0.01) and ACPA positive (β=-0.2, p=0.04) inhibited the improvement of BMD at femoral neck (table 1).

Table 1. Multivariate linear regression analysis of risk factors to inhibit the improvement of BMD at femoral neck in patients with RA.

	β	95% CI	p
Age (years)	-0.054	-0.193, 0.103	0.551
Male (0, male; 1, female)	-0.007	-5.815, 5.367	0.937
ACPA (0, negative; 1, positive)	-0.199	-6.814, -0.233	0.036
RF (0, negative; 1, positive)	0.011	-2.995, 3.364	0.909
BMD of femoral neck at baseline (g/cm^2)	-0.355	-44.361, -14.521	<0.01
Glucocorticoid dose (mg/day)	-0.032	-0.741, 0.500	0.701
b/tsDMARDs use (0, no; 1, yes)	-0.110	-4.219, 0.908	0.204
Preosteoporosis treatment (0, no; 1, yes)	0.029	-2.078, 2.945	0.733

RA, rheumatoid arthritis; BMD, bone mineral density; ACPA, anti-citrullinated protein antibodies; RF, rheumatoid factor; b/tsDMARDs, biological and targeted synthetic disease-modifying antirheumatic drugs.

Conclusion: Denosumab improved BMD at the lumbar spine and proximal femoral in patients with RA independently regardless of ACPA and RF. ACPA-positive patients were difficult to improve BMD at femoral neck despite denosumab treatment.

DEVELOPING A CLINICAL ASSESSMENT TOOL FOR DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW AND FEASIBILITY ASSESSMENT

Keywords: Rheumatoid arthritis, Inflammatory arthritides

R. Singh[1], S. Chambers[1], A. Baranskaya[1], A. Filer[1,2,3], M. Falahee[1], K. Raza[1,2,3,4], A. Croft[2,3,4]. [1]*University of Birmingham, Rheumatology Research Group, Institute of Inflammation and Ageing, Birmingham, United Kingdom*; [2]*NIHR Birmingham Biomedical Research Centre, University Hospitals Birmingham NHS Foundation Trust and University of Birmingham, Birmingham, United Kingdom*; [3]*MRC Versus Arthritis Centre for Musculoskeletal Ageing Research and the Research into Inflammatory Arthritis Centre Versus Arthritis, University of Birmingham, Birmingham, United Kingdom*; [4]*Sandwell and West Birmingham NHS Trust, Department of Rheumatology, Birmingham, United Kingdom*

Background: Management of difficult-to-treat rheumatoid arthritis (D2T-RA) is challenging since poor treatment response also incorporates non-inflammatory symptoms that can mimic or amplify pain and scores on composite disease activity measures. Identification of modifiable non-inflammatory factors is vital to improve health outcomes and minimise harm from inappropriate escalation of drug therapy.
Objectives: To develop and assess feasibility of a systematic, evidence-based clinical assessment tool for the identification of modifiable non-inflammatory factors in D2T-RA.
Methods: A systematic literature search of PubMed, Embase and Web of Science databases for studies pertaining to D2T-/treatment refractory RA was undertaken from database inception to October 2021. Studies were screened against inclusion/exclusion criteria, and further excluded if deemed to have a high risk of bias. Data pertaining to factors associated with treatment non-response were extracted from eligible papers and categorised to inform composition of the clinical assessment tool. Through patient involvement, the proposed tool's components were assessed for their feasibility and ease of capture in an outpatient setting. Eight patients fulfilling EULAR definition of D2T-RA were recruited from a single centre. Clinical data and responses to relevant questionnaires mapped to the clinical tool, including: Patient Health Questionnaire-9 (PHQ-9), Brief Illness Perception Questionnaire (B-IPQ), Beliefs about Medicines Questionnaire-Specific (BMQ-S), Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) and Medication Adherence Report Scale-5 (MARS-5) were collected.
Results: 1154 records were screened, of which eight studies informed the development of a clinical assessment tool. Modifiable factors including raised BMI, smoking status, non-adherence, and co-morbidities, such as fibromyalgia and worse mental health were identified and incorporated into an initial tool. These factors were apparent and readily assessed within a local cohort of D2T-RA patients (Table 1). In summary, data from this cohort revealed a low burden of classified fibromyalgia, mild depression severity, and responses in keeping with a high illness concern. Despite general acceptance of pharmacological treatments, 'ever' non-adherence, classified as a response other than 'never' within the MARS-5 questionnaire was noted in two, five, and three patients regarding steroids, csDMARDs and b/tsDMARDs respectively.

Table 1. Clinical demographics and disease characteristics (n=8)

	Age (years)	59.5 (56.5-64.8)
	Female*	8 (100)
	Disease duration (years)	17 (11-23)
	Anti-CCP positive*	7 (87.5)
	RF positive*	6 (75)
	DAS28-ESR	4.6 (4.0-5.9)
	No. of comorbidities	4 (2-4)
	No. of previous csDMARDs	3 (2-4)
	No. of previous b/tsDMARDs	5 (5-6)
	Ever Smoker*	2 (25)

Depression	PHQ-9	6 (3-9)
'Ever' non-adherence	Steroids*^	2 (33.3)
	csDMARds*	5 (62.5)
	b/tsDMARDs*	3 (37.5)
B-IPQ	B-IPQ (0-80)	42 (30-55)
BMQ-Specific	Necessity-Concerns Differential (-4 to +4)	1.2 (1-1.7)

Results presented as median (IQR); *n (%); ^n=6

Conclusion: Following a systematic review of the literature, we identified several modifiable factors that inform the development of a clinical assessment tool in D2T-RA and can be readily evaluated in an outpatient setting. A holistic approach is required to address both inflammatory and non-inflammatory aspects of D2T-RA. The development of an evidence-based clinical assessment tool is the first step in providing this, by identifying and targeting patient-specific non-inflammatory modifiable factors, in conjunction with pharmacological escalation.

AB0328 EFFECTS OF BIOLOGICAL-DMARDS ON THE SERUM URIC ACID LEVEL IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

Y. Miwa[1], Y. Miwa[2]. [1]*Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Yokohama, Japan*; [2]*Showa University School of Nursing and Rehabilitation Sciences, Department of Nursing, Yokohama, Japan*

Background: Hyperuricemia associated with rheumatoid arthritis (RA) has been reported to be a risk factor for cardiovascular disease. It has been reported that uric acid (UA) levels decrease with the use of leflunomide and increase with tumor necrosis factor (TNF) inhibitor therapy. However, the effects of long-term biological disease-modifying antirheumatic drugs (bDMARDs) therapy and non-TNF inhibitor biologic therapy on UA levels have not been reported.
Objectives: We aimed to investigate the changes in UA levels during TNF and non-TNF inhibitor therapy.
Methods: Patients with RA treated with bDMARDs from 2008 to 2018 were studied based on the All Showa University of RA (ASHURA) database. The association between uric acid level reduction and treatment was evaluated in 629 patients treated with the bDMARDs, and the medical records of 256 patients with available uric acid levels were included. The following background factors were investigated: age; sex; type of bDMARDs; dosage of methotrexate and prednisolone; usage of conventional synthetic DMARDs, dyslipidemia drugs, hyper uremia drugs, and nonsteroidal anti-inflammatory drugs; body mass index; smoking history; HbA1c; presence or absence of hypertension and dyslipidemia; and serum creatinine, C-reactive protein, and matrix metalloproteinase-3 levels. We also used the simplified disease activity index (SDAI) to evaluate RA disease activity. The analysis was performed in two groups, TNF inhibitor-treated group (148 patients) and the non-TNF inhibitor-treated group (108 patients, tocilizumab and abatacept). The primary endpoint was UA levels before and after six months and one year, which was determined using the repeated-measures analysis of variance (ANOVA), and the secondary endpoint was the proportion of patients with hyperuricemia (uric acid level of 7.0 or higher was defined), determined using spearman's correlation coefficient by rank test.
Results: In TNF inhibitor-treated group, the UA levels were not increased from 4.9 ± 1.4 (mg/dl) to 4.9 ± 1.4 and 5.1 ± 1.7 before treatment and after six months and one year, respectively (p=0.50). The number of patients with hyperuricemia increased from 7 to 12 and 16 (p=0.026). The UA levels were not raised in non—TNF inhibitor-treated group from 5.2 ± 1.4 (mg/dl) to 5.2 ± 1.4 and 5.3 ± 1.4 (p=0.78). The number of patients with hyperuricemia increased from 8 to 16 and 12 (p=0.193). There was a difference in the type of drug but no difference in the duration of administration by repeated-measures ANOVA.
Conclusion: Our study suggests that TNF inhibitor therapy may affect an increased percentage of patients with hyperuricemia. On the other hand, non-TNF inhibitor therapy may not affect the increased rate of patients with hyperuricemia, and bDMARD treatment has a mild effect on UA levels in patients with RA.

AB0329 THE IMPACT OF WEIGHT ON FOOT INVOLVEMENT DURING RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

K. Zouaoui[1], S. Boussaid[1], S. Rekik[1], S. Jriri[1], S. Rahmouni[1], H. Ajlani[2], H. Sahli[1], M. Elleuch[1]. [1]*La Rabta Hospital, Tunisia, Rheumatology, Tunis, Tunisia*; [2]*Yasminette Ben Arous Hospital, Rheumatology, Ben Arous, Tunisia*

Background: Overweight and obesity are highly common in patients with Rheumatoid Arthritis (RA), with probable impact on bearing foot joints.
Objectives: The aim of the present study was to explore the associations between Body Mass Index (BMI) and measures of foot health (foot pain, foot-related activity limitation, foot synovitis and deformities) in patients with RA.

Methods: A cross sectional study was conducted on 50 patients with RA consulting a rheumatology departement with different complains. Domains of foot health studied comprised: foot pain (Numeric Rating Scale), foot-related activity limitations (Foot Function Index), foot synovitis (Metatarsophalangeal Joint Count), and foot deformity (Platto Score).
Results: The mean age was 45.68 +/-10.3 years [20-76], most were female (82%), and most patients had moderately long disease duration (12.12 ± 7.67 years). RA was often moderately active (mean DAS28: 3.25 ± 0.98). Sixty six percent of our population were overweight or obese with a mean BMI 29 Kg/m2±5.74. The average foot pain intensity while walking was 6 ± 1.75, the mean FFI pain subscale was 40 ± 15.7 and the mean WOMAC pain subscale was 30 ± 13.2. Seventy percent of our patients had chronic foot pain (> 6 months). The heel was the most symptomatic location (62%). Podoscopic examination showed flat feet in 46% of cases, hollow feet in 20%, a valgus heel and varus heel were noted in 34 % and 12 % of cases respectively. The mean tender foot joint count was 5.5 ± 1.79and of swollen foot joint was 2.2 ± 1.55. The average of the foot structure index (Platto score) was 7.8 ± 2.73. Hallux valgus was the most common deformity (74 %) followed by claw toe in 43.5 % of cases and then subluxation of MTP joints in 26 %. Concerning foot-related activity limitation, the mean FFI score of Disability subscale was 32 ± 14.2 and the mean WOMAC score of physical functioning subscale was 33.8 ± 13.98. Half of our patients suffered from problems fitting their shoes because of claw toe, heel pain and Hallux valgus in 40 %, 36% and 32 % of cases respectively. Our study showed that higher BMI was associated with lower foot health in many of the studied measures. Patients with higher BMI reported significantly more foot pain (p = 0.001), more foot-related activity limitations: for both scales: FFI (p = 0.01; B=21.71) and WOMAC (p<0.001; B=20.64), more foot deformities assessed with Platto score (p= 0.02; B=4.78), more foot synovitis (p<0.001; OR=4.66) and more problems with footwear (p=0.05).However, in our population, higher BMI was significantly associated with less radiological joint damage (p=0.01) and lower feet sharp score (B= -13,9; *P* = 0.06).
Conclusion: Despite our findings of a possible protective effect of obesity on structural damage, obesity is still, as seen in this and many other studies, an important cause of increased pain, increased functional disability and impaired quality of life in patients with RA that requires special interventions.

AB0330 EVALUATION OF THE ASSOCIATION BETWEEN MOOD DISORDERS AND THE REGION OF THE AFFECTED JOINTS IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY

Keywords: Rheumatoid arthritis

K. Tokunaga[1], H. Oshikawa[1], T. Nishino[2], T. Matsui[2], S. Tohma[3]. [1]*Japanese Red Cross Kumamoto Hospital, Department of Rheumatology, Kumamoto, Japan*; [2]*National Hospital Organization Sagamihara National Hospital, Department of Rheumatology Research, Clinical Research Center for Allergy and Rheumatology, Kanagawa, Japan*; [3]*National Hospital Organization Tokyo Hospital, Department of Rheumatology, Tokyo, Japan*

Background: The prevalence of mood disorders, such as anxiety and depression, is higher in patients with rheumatoid arthritis (RA) than the general population. Even in the absence of a formal mood disorder, a significant number of RA patients are reported to have anxiety or depression. Although there have been reports of several factors associated with anxiety and depression in RA patients, few have evaluated associations with specific region of the affected joints.
Objectives: We aimed to evaluate the association between mood disorders and specific regions of the affected joints and compare them with previously reported associated factors.
Methods: We performed an analysis of data from 15,553 RA patients registered in a large database (NinJa: National Database of Rheumatic Diseases in Japan) in 2020. Patients for whom hospital anxiety and depression scale (HADS) data were acquired were included in this study. Presence of anxiety and depression were defined by a HADS score ≥11. We analyzed the data using multivariable logistic regression analyses. The affected joints from 68 joint counts were divided into four regions: upper/large, upper/small, lower/large, and lower/small. We performed the logistic regression analyses with anxiety or depression as dependent variables respect to age, sex, body mass index (BMI), disease duration, smoking history, the Steinbrocker's stage, CRP, regions of affected joints, and use of PSL, MTX, biologics, and JAK inhibitors as independent variables.
Results: In total, 8,982 patients were included in this study; of which; 7,154 were women (79.6 %) with a mean age 67.1 years (standard deviation [SD] = 12.8). The mean disease duration was 14.2 (SD = 11.6) years. In total, 489 (5.5 %) patients had anxiety, and 992 (11.2 %) had depression. The mean HADS-anxiety (A) in the non-anxiety, and anxiety groups, were 3.61 (SD = 2.70) and 13.24 (SD = 2.29), respectively. Moreover, mean HADS-depression (D) in the non-anxiety, and anxiety groups were 5.74 (SD = 3.30) and 10.45 (SD = 3.87), respectively. The mean HADS-A in the non-depression and depression groups were 3.67 (SD = 3.03) and 7.75 (SD = 4.40), respectively. Lastly, mean HADS-D scores in the non-depression and depression groups were 5.15 (SD = 2.62) and 12.73 (SD = 1.90), respectively. In logistic regression analysis, anxiety was associated with lower/large, and small joints, along with female sex, smoking history, and use of PSL. Moreover, depression was associated with upper/small and lower/large joints, along with female sex, lower BMI, disease duration, smoking history, use of PSL, non-use of MTX, and CRP.
Conclusion: Anxiety and depression were associated with the region of the affected joints, but in different patterns. When assessing the patient's mood in RA, the distribution of affected joints should also be noted.

AB0331 CHEST HIGH-RESOLUTION COMPUTED TOMOGRAPHY IN PATIENTS WITH LONG STANDING RHEUMATOID ARTHRITIS: IS THERE ANY BENEFIT?

Keywords: Rheumatoid arthritis, Imaging, Lungs

K. Tahir[1], N. Akasbi[1], I. El Mezouar[1], T. Harzy[1]. [1]*University Hospital Center Hassan II, Rheumatology, Fez, Morocco*

Background: Pulmonary involvement is a frequent and severe extraarticular manifestations of rheumatoid arthritis (RA). Chest high resolution computed tomography (HRCT) have been shown to be of interest in the detection and characterization of morphological changes in the lungs of RA patients.
Objectives: The aim of our study was to investigate the prevalence and types of pulmonary involvement in patients with longstanding RA using chest HRCT.
Methods: A retrospective study was conducted in a single rheumatology hospital in Morocco, including patients diagnosed as having RA according to the ACR/EULAR 2010 criteria from Avril 2018 to Avril 2022. Longstanding RA was defined as disease duration > 2 years. All patients underwent chest X-ray and chest HRCT.
Results: Our study included 148 patients with longstanding RA. The cohort was predominantly female (87,2%) with a mean age of 60,56 ± 11,79 years. 8 patients (5.4%) had a history of smoking. Mean age at RA onset was 44,77 ± 12,82 years and disease duration was 14,75 ±7,55 years. The mean BMI was of 28,19 ± 6.47 Kg/m2. RA was seropositive in 95,3 %, erosive in 91,2% and deforming in 66,2 % of our subjects.

Methotrexate was used in 142 patients (95,9%). 41 patients (27.7%) were complaining of respiratory symptoms: dyspnea (n=20, 13.5%), cough (n=11, 7.4%), and both (n=10, 6.8%). The chest X-ray abnormalities were present in 41 patients (27,7%). Abnormal spirometry was found among 49.4% of subjects. Pulmonary HRCT abnormalities were found in 60,8% of patients and the most common were: subpleural micronodules (25 %), bronchiectasis (23,6%), non-septal linear opacities (16,9 %), pulmonary nodules (11,5%), ground glass opacity (10,8%), reticulation (8.8%) and honeycombing (8,8%). The presence of HRCT pulmonary lesions was associated with smoking history (p=0,020), seropositivity (p=0,010), respiratory symptoms (0,002) and chest X-ray changes (< 0,0001). However, there were no significant association with the other clinical, biological, radiological and therapeutic criteria.

Conclusion: Our study confirms that a large proportion of patients with long-standing RA has abnormal findings in chest HRCT even in those with no chest X-ray findings or respiratory symptoms. RA patients should undergo chest HRCT to detect pulmonary abnormalities as early as possible.

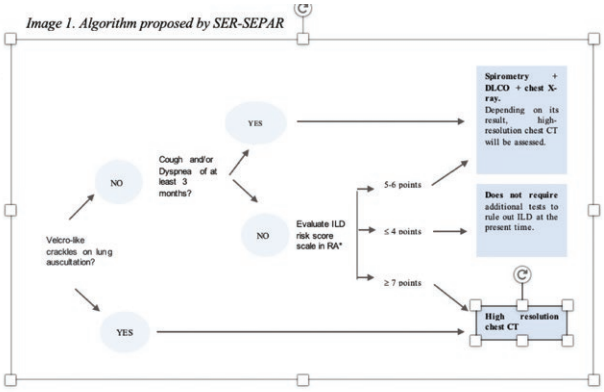
AB0332 APPLICATION IN CLINICAL PRACTICE OF THE SCREENING CRITERIA FOR INTERSTITIAL LUNG DISEASE IN RHEUMATOID ARTHRITIS PROPOSED BY SER-SEPAR IN A COHORT OF RHEUMATOID ARTHRITIS. PRELIMINARY STUDY

Keywords: Rheumatoid arthritis, Diagnostic Tests, Lungs



H. Borrell Paños[1], E. Trallero Araguas[1], X. Michelena[1], A. Pluma Sanjurjo[1], L. Coronel Tarancon[1], D. V. Clofent Alarcon[2], H. F. Avalos Bogado[1], S. Marsal[1], M. Lopez Lasanta[1]. [1]*Vall d'Hebron University Hospital, Rheumatology, Barcelona, Spain*; [2]*Vall d'Hebron University Hospital, Pneumology, Barcelona, Spain*

Background: A screening tool has recently been proposed by two scientific societies (Spanish Society of Rheumatology and Pneumology), combining clinical and serological data to improve the detection of interstitial lung disease (ILD) in rheumatoid arthritis(RA) [1].

Objectives: To apply a new ILD screening tool in a cohort of patients with RA in order to determine its prevalence, and evaluate the burden of complementary exams generated for this purpose derived from its thorough application.

Methods: Observational and single-center cross-sectional study of a cohort of RA patients under active follow-up at the Rheumatology Service of the Vall d'Hebron Hospital. The sample will be all the patients who attend the clinic routinely for 1 year (July 2022- 23) and who have not been previously diagnosed with ILD. To assess the presence of pulmonary involvement, a detailed history and pulmonary auscultation will be performed. Subsequently, the screening tool will be applied to decide the use of complementary exams if necessary (image 1). The orders of High Resolution Chest CT (HRCTs), lung function tests (LFTs) and chest X-rays are carried out routinely in the regular circuit with the radiology and pulmonology services.

Image 1. Algorithm proposed by SER-SEPAR

*Set of variables and score proposal for each of the variables for the global calculation.	Punctuation
Age ≥ 60 years old	2
Male	1
Tobacco use (current or ex-smoker)	
≤ 20 pack-year	2
> 20 pack-year	3
Disease duration > 5 years	1
Moderate-high disease activity (average DAS28-ESR >3.2) from diagnosis of the disease in early RA (<12 months) or for a minimum of 6 months in established RA.	1
Serology (only the criterion with the highest weight is counted for the total score)	
- Positive rheumatoid factor > 3 times the ULN	1
- ACPA positive < 3 times the ULN	2
- ACPA positive > 3 times the ULN	3
ILD family history	1

Results: In 6 months (July-December 2023), 349 patients have been screened. Of these, in 22.3% (78) a HRCT request has been recommended, in 31.2% (109) chest X-rays and LFT and in 46.5% (162) regular follow-up. Of the 78 patients to whom HRCT has been recommended, this has already been carried out in 19 patients (the characteristics of these patients are described in Table 1), in two of whom the diagnosis of ILD has been made (1 Non-Specific Interstitial Pneumonia -NSIP- and 1 Usual Interstitial Pneumonia -UIP-), both in mild degree. Neither of the two patients had symptoms or auscultation abnormalities, and both are awaiting LFTs.

Table 1. Characteristics of patients who have already undergone HRCT according to the recommendation of the algorithm proposed

Female, n(%)	11 (57.9%)
Age, mean±SD, years	65.52±10.95
RA disease duration, median(IQR), years	11(5-21.5)
FR +, n (%)	
<3 ULN	5 (26.3%)
≥ 3 ULN	14(73.7%)
ACPA +, n (%)	
<3ULN	0
≥ 3ULN	17 (89.5%)
ANA	
Positive (>1/160), n (%)	3(15.8%)
Erosive, n (%)	11(57.9%)
Tobacco use, n (%)	
< 20 pack-year	4 (21.1%)
≥ 20 pack-year	13 (68.4%)
≥ 1 cardiovascular risk factors, n (%)	8 (42.1)
Moderate-high disease activity from diagnosis of the disease in early RA or for a minimum of 6 months in established RA.	0
Dry cough and/or dyspnea for more than 3 months, n (%)	2 (10.5%)
Velcro-like crackles, n (%)	1 (5.3%)
ILD family history, n (%)	2 (10.5%)
Chest X-rays, n (%)	
- Made during evolution	16 (84.2%)
- Not available	3 (15.8%)
HRCT compatible with ILD, n (%)	2 (10.5%)
Other HRCT findings, n (%)	
- Emphysema	10 (52.3%)
- Bronchiectasis	13 (68.4%)

Of the 109 patients for whom chest X-rays and LFTs were recommended, in 26 (24%) have been performed, due to usual delay in the pneumology service for LFTs. A restrictive pattern was detected in 4 patients (15.4%), half of whom also presented a decrease in DLCO. HRCT in those patients is still pending. 50% of the LFTs performed were normal and in the rest of the cases alterations compatible with other respiratory pathologies have been observed.

Conclusion: The application of this screening algorithm is allowing to diagnose patients with asymptomatic ILD. However, the costs of performing the various complementary exams and its effect in treatment decisions in this profile of patients must continue to be studied.

AB0333 PERIODONTITIS AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS: A CASE CONTROL STUDY

Keywords: Rheumatoid arthritis

A. Ben Salem[1], M. Brahem[1], C. Baccouche[2], R. Sarraj[1], O. Jomaa[1], H. Hachfi[1], Y. Mohamed[1]. [1]*Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia*; [2]*Taher Sfar University Hospital, Dentistry, Mahdia, Tunisia*

Background: Different studies have estimated a higher risk of dental and periodontal abnormalities in patients with rheumatoid arthritis (RA), but it is often under-diagnosed.

Objectives: In this context, we conducted this study, whose objectives were to evaluate the frequency and the type of oral and periodontal abnormalities in patients with RA compared to control subjects and to determinate the predictive factors of the periodontal disease.

Methods: This is a case control study conducted during the period between July 2020 and June 2022. The oral and osteoarticular examination was performed for each patient. The different dental and periodontal indices were calculated: CAO index, plaque index (PI) and gingival index (GI).

Results: Sixty patients diagnosed with RA according to the ACR/EULAR 2010 classification and 71 control patients were included. The mean age of patients with RA was 51.5 ± 12.4 years [21-78 years] and that of the control group was 47.2 ±12.8 years [22-74 years]. The oral examination showed poor oral hygiene based on the plaque index (PI). The frequency of moderate to abundant plaque

accumulation (PI≥ score 2) was comparable between the two groups with non-significant difference (91.7% versus 94.4%; p=0.5). Regarding dental caries, the median CAO was greater in the RA group than in the control group with a significant difference (5 [1-10] versus 2 [0-5]; p<0.01). The mean numbers of missing and decayed teeth in RA patients were higher than those found in controls (3.3±4.6 versus 2±3.06; 1.9±2.3 versus 1.39±2.2 respectively). Analysis of the superficial periodontal status showed that 88.3% of RA patients had gingivitis compared with 90.1% of controls. The mean gingival index was 1.72±0.8 in RA group versus 1.76±0.7 in control group without a significant difference. As for the alteration of the deep periodontium, 53.3% had periodontal pockets and/or gingival recessions compared to 19.8% of controls with a statistically significant difference (p=0.01). This involvement in RA patients was significantly correlated with disease activity DAS 28 and the importance of the CRP level (p=0.02, p=0.03 respectively). Tooth mobility was experienced by 28.4% of RA patients versus 11.2% of controls with a significant difference between the two groups (p=0.01).

Conclusion: Our study confirmed the frequency of periodontitis and dental caries in RA patients compared to controls and their association with disease activity. Hence the importance of early detection and management of these abnormalities in order to improve the disease activity and the quality of life of our patients.

AB0334 PREVALENCE AND ASSOCIATED FACTORS OF MULTIMORBIDITY IN PATIENTS WITH STABLISHED RHEUMATOID ARTHRITIS. DATA FROM THE CRHREAR REGISTRY

Keywords: Comorbidities, Real-world evidence, Rheumatoid arthritis

M. Rojas-Giménez[1], S. Dans-Caballero[2], M. Parra-Moreno[2], M. Á. Puche Larrubia[1], M. Rico-Muñoz[2], R. Ortega Castro[1], C. López-Medina[1], J. Calvo Gutierrez[1], M. L. Ladehesa Pineda[1], A. Escudero Contreras[1]. *[1]Reina Sofia University Hospital, Rheumatology, Cordoba, Spain. Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), GC05 Group, Cordoba, Spain. University of Cordoba, Medical Surgical Sciences, Cordoba, Spain., Rheumatology Department, Córdoba, Spain*; *[2]Reina Sofia University Hospital, Rheumatology, Cordoba, Spain, Rheumatology Department, Córdoba, Spain*

Background: Patients with Rheumatoid Arthritis have an increased risk of developing comorbidities that contribute to increased worsened quality, disability and mortality. Knowledge of comorbidity is important when attempting to identify the conditions most associated with the greatest morbidity and mortality. However, comorbidities in RA are often underrecognized despite their impact on disease activity and treatment outcomes.

Objectives: To evaluate the prevalence of multimorbidity in a cohort of patients with stablished Rheumatoid Arthritis (RA) and the factors associated with such condition.

Methods: Cross-sectional observational study of a cohort of patients with RA according to the ACR/EULAR 2010 criteria of the CRhreAR registry of the Reina Sofia University Hospital of Córdoba. Multimorbidity was defined, according to the WHO, as the presence of two or more chronic diseases, in addition to RA. Comorbidities included in the Charlson index were collected, in addition to others such as arterial hypertension (HT), dyslipidemia (DL), diabetes mellitus, depression, osteoporosis, interstitial lung disease, and thyroid pathology. Other sociodemographic and disease-related variables were collected. Statistical analysis: descriptive, bivariate analysis and multivariate logistic regression to evaluate variables independently associated with multimorbidity.

Results: A total of 233 patients were included (mean age 63.6 (13.4) years and 70.4% women). More than 70% were ACPA and RF positive. 99.1% had used any csDMARD and 42.1% any bDMARD. The disease duration was 13.7 years (11.6). 192 patients had at least one comorbidity. 151 (64.8%) had multimorbidity, and the mean age-adjusted Charlson index was 2.9 (2.4). The most frequent morbidity was HT (45.1%) and DL (47.6%), followed by osteoporosis (27.5%) and ILD (16.7%). The most frequent comorbidities included in the Charlson index were cardiovascular disease (14.2%) and cancer (11.2%). Table 1 shows the differences between patients with and without multimorbidity. The multivariate analysis showed that the diagnosis delay of RA [OR 1.31; IC95 (1.1-1.7)], age [OR: 1.2; IC95 (1.1-1.23)] and the number of bDMARDs used since the diagnosis [OR: 2.7; IC95 (1.7-4.3)] were independently associated with multimorbidity, adjusted by sex.

Table 1. Differences between patients with multimorbidity and those without multimorbidity.

Variable	Multimorbidity (n= 151)	No multimorbidity (n= 82)	p-value
Age (years), mean (SD)	68.8 (11.5)	53.8 (10.9)	**<0.001**
Sex (female), n (%)	96 (63.6)	68 (82.9)	**0.002**
Ever smoked, n (%)	70 (46.3)	29 (35.4)	0.123
Disease duration (years), mean (SD)	14.5 (9.5)	12.1 (14.6)	0.196
Diagnosis delay (years), mean (SD)	3.4 (11.1)	0.9 (1.4)	**0.013**
Positive Rheumatoid factor, n (%)	112 (74.2)	61 (74.4)	0.971
Rheumatoid factor, mean (SD)	145 (205)	156 (313)	0.805
Positive ACPA, n (%)	110 (72.8)	63 (76.8)	0.558
ACPA, mean (SD)	240 (260)	260 (309)	0.674
Erosions, n (%)	58 (38.4)	32 (39.02)	0.926
Nodules, n (%)	13 (8.6)	11 (13.4)	0.249
DAS28-VSG, mean (SD)	2.7 (1.1)	2.6 (1.1)	0.648
SDAI, mean (SD)	10.5 (10.3)	8.4 (6.9)	0.086
CDAI, mean (SD)	8.7 (7.2)	7.5 (6.3)	0.226
Current csDMARDs, n (%)	99 (65.6)	70 (85.4)	**0.002**
csDMARDs ever, n (%)	147 (98)	82 (100)	0.292
Current bDMARDs, n (%)	66 (97.3)	26 (31.7)	0.006
bDMARDs ever, n (%)	71 (47.01)	27 (32.9)	**0.024**
Charlson index, mean (SD)	1.5 (1.7)	0.3 (0.6)	**<0.001**
Age-adjusted Charlson index, mean (SD)	3.9 (2.3)	1.2 (1.3)	**<0.001**

Conclusion: These results suggest that the presence of multimorbidity in stablished RA was high (64.8%). The most frequent comorbidities were arterial hypertension, dyslipidemia, interstitial lung disease, and osteoporosis. The diagnosis delay of RA, age and the number of bDMARDs used were independently associated with the presence of multimorbidity.

AB0335 INCIDENT CHRONIC KIDNEY DISEASE IN PATIENTS WITH RHEUMATOID AND PSORIATIC ARTHRITIS – A COMPARATIVE ANALYSIS

Keywords: Psoriatic arthritis, Kidneys, Rheumatoid arthritis

T. Harty[1], D. Dahly[2,3], S. Costelloe[4], M. O' Shaughnessy[1,5], S. Harney[1,6]. *[1]University College Cork, School of Medicine, Cork, Ireland*; *[2]University College Cork, School of Public Health, Cork, Ireland*; *[3]University College Cork, HRB Clinical Research Facility, Cork, Ireland*; *[4]Cork University Hospital, Department of Biochemistry, Cork, Ireland*; *[5]Cork University Hospital, Department of Renal Medicine, Cork, Ireland*; *[6]Cork University Hospital, Department of Rheumatology, Cork, Ireland*

Background: Patients with inflammatory joint conditions have a high prevalence of comorbidities including chronic kidney disease (CKD) [1]. The data pertaining to CKD in rheumatoid arthritis (RA) is limited [2], however and its association with psoriatic arthritis (PsA) remains unclear. Renal disease in RA and PsA is clinically important as it can lead to restrictions in the management of the primary disease, and is also associated with increased all-cause morbidity and mortality [3].

Objectives: To determine and compare the rate of incident CKD in patients with rheumatoid and psoriatic arthritis and to determine the rate of estimated glomerular filtration rate (eGFR) change over time.

Methods: Patients with RA and PsA who were first diagnosed between 1st January 2005 and 31st December 2010 were included in this retrospective, longitudinal analysis. All eGFR values, calculated using the Modification of Diet in Renal Disease equation, for each patient were collected from time of diagnosis until 31st December 2020. Demographic details, disease-specific characteristics, the presence of cardiovascular disease at baseline and anti-rheumatic drug use at each appointment were recorded. Generalized additive models (GAMs) were used to smooth the eGFR trajectories for each patient, and mixed-effects models were then used to estimate crude linear trends in eGFR across the period of observation. The primary outcome measure was diagnosis of CKD, defined as patient's eGFR falling below 60ml/min/m 2 for a period of at least 90 days in their smoothed eGFR trajectory.

Results: The patient sample (n = 159) included 114 RA and 45 PSA patients. RA patients were less likely to be male (39 vs 51%, p = 0.2) and older (mean age at baseline 52 vs 46 years, p < 0.001) than PsA patients. They also tended to have moderately lower eGFR upon initial observation (78 vs 83 ml/min/m2, p = 0.07). Baseline comorbidity profiles were broadly similar between the two groups. Treatment profiles were also similar, but with RA patients prescribed DMARDs at 69% of their appointments on average vs 56% in PSA patients (p = 0.003). There were 22 incident cases of CKD in the RA patients (19%), vs 7 in the PSA patients (16%, p = 0.6), and 17 RA patients died during the observation period (15%) vs 2 PSA patients (4.4%, p = 0.07). Results from a sex- and age-adjusted

mixed effects models suggested that eGFR trajectories tended to slowly decline on average in PSA patients (-0.22 ml/min/m2 per year, p vs no trend = 0.14), but increased on average (0.79 ml/min/m2 per year) among RA patients (p for interaction < 0.001).

Conclusion: Incident CKD diagnosis was high in both patient populations. While rate of eGFR decline was greater in patients with PsA, overall rates of CKD diagnosis did not differ significantly. Monitoring of kidney function should be an important part of management of inflammatory joint conditions, as the majority of these patients non-steroidal inflammatory drugs and immunosuppressive therapies which may be contraindicated or require dose adjustment if renal impairment is present.

AB0336 RHEUMATOID ARTHRITIS AND UPPER DIGESTIVE TRACT BLEEDING: ASSOCIATED FACTORS BEYOND THE USE OF NSAIDS AND CORTICOSTEROIDS

Keywords: Safety, Rheumatoid arthritis, Gastrointestinal tract

W. Carvajal-Gutiérrez[1], M. A. Cisneros-Cisneros[1], O. J. Calixto[2,3], E. C. Vera-Parra[2,3], M. A. Meneses-Toro[2,3], M. A. Vega-Baéz[1], D. A. Álvarez-Vargas[1], A. C. Uscategui-Ruíz[1], J. A. Prada Rueda[4], M. C. Romero[2,5], J. M. Bello-Gualtero[2,3]. *[1]Hospital Militar Central, Internal Medicine Department, Bogota, Colombia*; *[2]Universidad Militar Nueva Granada, Medicine School, Clinical Immunology Group, Bogota, Colombia*; *[3]Hospital Militar Central, Rheumatology and Immunology Department, Bogota, Colombia*; *[4]Hospital Militar Central, Gastroenterology Department, Bogota, Colombia*; *[5]Universidad El Bosque, Cellular and Molecular Immunology Group/ INMUBO, Bogota, Colombia*

Background: Rheumatoid arthritis (RA), with a prevalence of 0.52% in Colombia, is an autoimmune disease with erosive joint involvement associated with significant manifestations in other organs and systems. RA has been associated with a greater risk of upper gastrointestinal bleeding (UGIB), highlighting the greater exposure to non-steroidal anti-inflammatory (NSAID) and corticosteroids [1].

Objectives: Describe the safety profile with emphasis on UGIB associated with the use of NSAIDs and corticosteroids in patients with RA treated at the Central Military Hospital.

Methods: Analytical cross-sectional study of patients diagnosed with RA according to EULAR/ACR 2010 classification criteria between 2015-2021, describing the clinical and demographic variables and evaluating the association with UGIB. Patients with variceal UGIB were excluded. A bivariate and multivariate statistical analysis was performed by binary logistic regression. Approved by the institutional ethics committee.

Results: 405 individuals were evaluated, 80.5% were female, UGIB was present in 16 patients (4%). ESR was elevated in 60.9% and CRP in 67.9%. Rheumatoid factor (RF) >20U/mL was positive in 68.6% and anti-CCP in 62.30% of the total population; 100% of the UGIB group were RF+ (p=0.006) and anti-CCP+ (p=0.002). DAS28 presented a median of 3.46 (IQR=2.2-4.9), with higher levels in patients with UGIB -median of 5.1 (IQR=3.7-6.0) p=0.009-. In UGIB group, 6.25% used NSAIDs (p=0.97), while 62.5% used corticosteroids (p=0.44). NSAIDs doses and time of use did not present statistical differences between both groups (p=0.640 and p= 0.80). Neither does the type of NSAIDs (p=0.480). There were no significant differences regarding the type of corticosteroid (p=0.441) or the time of use (p=0.847); however, there were differences in doses used (p=0.036). As a result of logistic regression, the presence of anemia was identified with ORA 12.3 (95%CI 1.4-110.3), HAQ moderate or severe disability with ORA 7.6 (95%CI 1.4-39.9) and DAS28-CRP ORA 0.52 (95% CI 0.29-0.94) as factors associated with UGIB.

Conclusion: Our RA population shows an adequate control of disease activity. Lower use of NSAIDs is reported compared to other populations and the use of corticosteroids and DMARDs was used in a similar proportion to the literature. In patients with RA and UGIB, there were no statistically significant differences regarding NSAIDs and corticosteroid use. The presence of anemia, greater disability, and high levels of activity were associated. The study group presented a lower proportion of UGIB compared to the evidence published to date.

AB0337 MENTAL HEALTH AND RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

S. Baliga[1], R. Samant[2], C. Balakrishnan[3]. *[1]Father Muller Medical College, Rheumatology, Boloor mangalore, India*; *[2]P D Hinduja National Hospital and Research Centre, Mumbai, Rheumatology, Mumbai, India*; *[3]P D Hinduja National Hospital and Research Centre, Mumbai, Rheumatology, Mumbai, India*

Background: Rheumatoid arthritis(RA) is a chronic systemic inflammatory disorder characterised by symmetrical involvement of small and large joints of the body. It has a prevalence of 0.5 – 1% in the world, affecting more commonly women [1].Due to the inflammatory burden of the disease, RA patients develop articular damage of various joints causing disability, reduced quality of life, and reduced life expectancy.[2,3] Patients with long standing or severe disease can also manifest with extraarticular symptoms. These in addition to chronic pain and disability can affect mental status of the patients [4]. Poor quality of sleep, anxiety and depression have been thought to contribute to the disease flare.[5] DMARDs are the best treatment offered to control disease activity in patients with rheumatoid arthritis.However it is important to emphasize that sleep, depression and stress have also an important role to play in the disease management. Treatment of depression, improvement of sleep quality in addition to DMARDS should always be kept in mind.Through this study we attempt to find there is any correlation of mental health with disease activity in RA.

Objectives: To find the prevalence of depression, anxiety, and disturbed sleep in RA patients. To find the correlation of depression, anxiety and quality of sleep with disease activity in RA.

Methods: A cross sectional study was done on RA patients in a tertiary care centre from western India. A questionnaire-based study was conducted among adult RA patients attending Rheumatology clinic at P D Hinduja Hospital Mumbai between March 2020 to July 2021. Depression was assessed using Becks depression scale, anxiety using Becks anxiety scale and sleep quality using sleep quality scale.

Results: A total of 200 RA patients within 5 years of disease were included in the study. Out of 200 patients, majority (84 %) were females.The prevalence of depression, anxiety and disturbed sleep in our RA population was 23.5%, 27.5% and 44.5 % respectively. Using Spearman correlation, we found a positive correlation of depression(Figure1), anxiety and disturbed sleep with disease activity using DAS 28 score. We also found a positive correlation of number of joints involved with pain (PAS) scores, depression with anxiety, anxiety with both depression and disturbed sleep and poor sleep quality with anxiety.

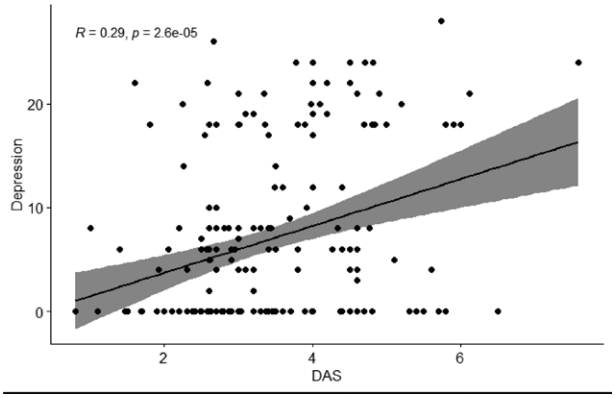

Figure 1: Correlation between Disease activity using DAS Score and Depression Score:- Interpretation: - The p-value of the test is <0.0001.DAS Score and Depression Score are significantly correlated with correlation coefficient 0.29 and P-value <0.0001

Conclusion: Depression, anxiety, and sleep disturbance is significantly higher in patients with early RA. Rheumatologists in addition to assessing disease activity in RA should also include assessment of the mental health. Early evaluation and intervention might result in better outcomes, reduce disease burden and avoid unnecessary immunosuppressive drug escalation.

AB0338 METABOLIC SYNDROME AND ITS COMPONENTS HAVE A DIFFERENT PRESENTATION AND IMPACT ON THE CARDIOVASCULAR RISK PROFILE OF PATIENTS WITH PSORIATIC AND RHEUMATOID ARTHRITIS

Keywords: Comorbidities, Cardiovascular disease, Inflammatory arthritides

F. Atzeni[1], L. La Corte[1], M. Cirillo[1], M. Giallanza[1], J. Rodríguez-Carrio[2,3]. *[1]University of Messina, Rheumatology Unit, Department of Experimental and Internal Medicine, Messina, Italy*; *[2]University of Oviedo, Department of Functional Biology, Oviedo, Spain*; *[3]Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Department of Metabolism, Oviedo, Spain*

Background: Patients with inflammatory arthritidies have a higher cardiovascular (CV) risk than the general population. Traditional CV risk factors are involved, while the impact of the metabolic syndrome (MetS) is less defined. Whether MetS clinical presentation and its components are comparable across conditions is unclear.

Objectives: To compare the prevalence of MetS and their components, and the impact on the CV risk profile, in psoriatic arthritis (PsA) versus rheumatoid arthritis (RA).

Methods: a retrospective analysis with follow-up of real-world PsA (CASPAR criteria) and RA (2010 EULAR/ACR classification criteria) patients referred to a rheumatology clinic was performed. Demographical, clinical data and presence of CV risk factors were evaluated from patient charts using national guidelines, both at baseline and after 12-months of follow-up. MetS was defined according to the American Heart Association (AHA)/National Heart, Lung, and Blood Institute (NHLBI) criteria. Univariate and multivariate models were used to compare the impact of the MetS and its components in patients with PsA versus RA.

Results: PsA patients (n=78) were younger (45.23 (16.99) vs 60.81 (13.19) years, p<0.001), exhibited lower disease duration (18.86 (48.43) vs 176 (169.77) months, p<0.001) and prevalence of autoantibodies (RF: 7.7 vs 58.7%, ACPA: 7.9 vs 57.6%; both p<0.001) than their RA counterparts (n=92). PsA patients were more likely to present with MetS (40(51.3%) vs 25(27.2%), p=0.003) and dyslipidemia (56(71.8%) vs 26(28.3%), p<0.001) compared to RA. No differences were observed for smoking (22(28.2%) vs 26(28.3%), p=0.836), diabetes (26(38.3%) vs 33(35.9%), p=0.823 and hypertension (44(56.4%) vs 51(55.4%), p=0.749). These differences were maintained after adjusting for age. Multivariate analyses revealed that hypertension (OR 11.818 [95% CI: 2.046–58.053, p=0.002) and dyslipidemia (OR 5.190 [95% CI: 1.118–24.092], p=0.035) were predictors of MetS in PsA, and no effect was observed for diabetes (p=0.066) smoking (p=0.367), age (p=0.445) or sex (p=0.445); whereas diabetes (OR 15.58, [95% CI: 2.41–100.45], p=0.004), hypertension (OR 20.44, [95% CI: 2.58–161.05], p=0.004) and dyslipemia (OR 43.29 [95% CI: 6.82–274.75], p<0.001) predicted MetS in RA, and no effect of age (p=0.473), sex (p=0.615) or smoking (p=0.317) was noted. No effect was observed for autoantibodies or treatments received. Despite the history of CV events was similar between disorders (PsA: 22(28.2%) vs RA 24(26.1%), p=0.602), differences in predictors were found. Multivariate analyses revealed that hypertension and MetS predicted CV history in PsA, whereas dyslipidemia was the only factor predicting CV history in RA (Table 1). Associations were stronger in PsA, and total variance explained in each model differed across groups.

Table 1. Multivariate analysis of predictors of history of CV events in RA PsA and RA

	OR	95% CI	p-value
PsA (R^2 = 0.693)			
Smoking	3.88	0.60–25.05	0.154
MetS	22.61	1.32–58.65	**0.031**
Diabetes mellitus	0.27	0.03–2.46	0.250
Hypertension	50.30	2.58–97.66	**0.010**
Sex	0.50	0.08–2.92	0.445
Dyslipidemia	3.22	0.45–22.87	0.241
CRP	0.95	0.79–1.12	0.560
Age	0.98	0.91–1.06	0.740
Disease duration	0.96	0.92–1.01	0.134
RA (R^2 = 0.296)			
Smoking	1.89	0.56–6.23	0.298
MetS	1.35	0.28–6.53	0.702
Diabetes mellitus	1.89	0.56–6.32	0.413
Hypertension	3.00	0.72–12.43	0.129
Sex	0.58	0.17–2.68	0.586
Dyslipidemia	4.50	1.11–16.12	**0.011**
CRP	1.02	0.96–1.08	0.518
Age	1.01	0.96–1.06	0.669
Disease duration	0.99	0.99–1.00	0.329

Finally, follow-up analyses revealed that progression of MetS and its components in PsA and RA were negligible after 12 months of follow-up (Figure 1).

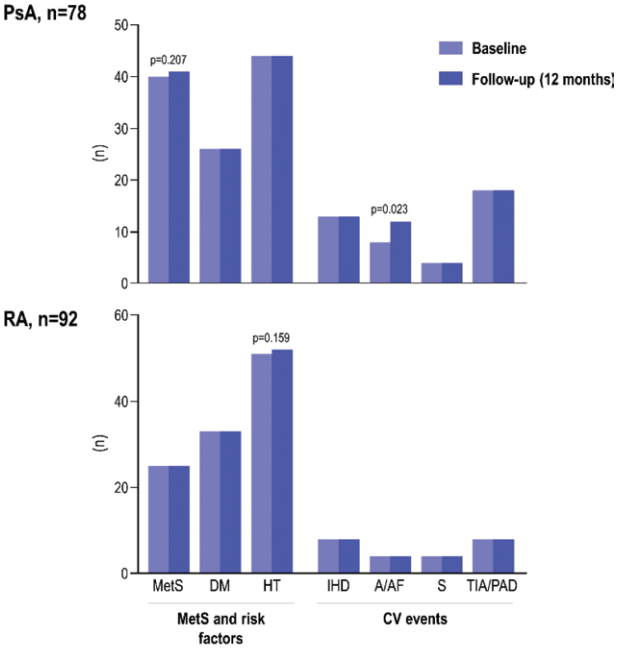

Figure 1

Conclusion: Occurrence and presentation of MetS differed between inflammatory arthritidies. The impact of these risk factors on CV risk profile was stronger in PsA compared to RA, and showed no progression in one year. This suggests the implication of different mechanisms, which may require distinct CV preventive strategies in PsA and RA.

AB0339 DYNAMIC RESPONSE TO INTRAVENOUS IRON, MEASURED BY NOVEL RETICULOCYTE INDICES, AS A PREDICTOR OF COEXISTING IRON DEFICIENCY IN ANAEMIA OF INFLAMMATION

Keywords: Comorbidities, Diagnostic Tests, Biomarkers

P. Singh[1], V. Ingle[1], R. Joshi[1], D. Joshi[2], A. Kotnis[3]. *[1]AIIMS Bhopal, General Medicine, Bhopal, India*; *[2]AIIMS Bhopal, Pathology and Lab Medicine, Bhopal, India*; *[3]AIIMS Bhopal, Biochemistry, Bhopal, India*

Background: Anemia of inflammation (AI) can be referred to as the proverbial “Starvation amidst plenty” as body iron stores are unavailable for

the erythron[1]. Anemia of iron deficiency(AID) is prevalent in developing countries and often coexists with AI [2]. There is no simple, single static iron or red blood cell parameter, which reliably predicts iron deficiency in patients with AI. The erythron is in a state of flux; modulated by physiological demands (e.g., hemoglobin(Hb) levels, tissue hypoxia), metabolic substrates (e.g., iron, Vitamin B12, Folic acid, etc), and pathologic states (e.g., inflammation, malignancies, etc). Therefore, even at the risk of oversimplification, it may be hypothesized that dynamic tests are needed to determine limiting factors for erythron responsiveness.

Objectives: This study aimed to evaluate the performance of novel reticulocyte (Ret) indices Reticulocyte Hemoglobin (RetHb) and Immature Reticulocyte Fraction (IRF) in identifying coexistent iron-deficient states in AI. We correlated the change in RetHb & IRF with an increase in Hb after intravenous iron in AI.

Methods: In this study, we have used intravenous iron in patients with AI (hemoglobin<10gm/dL and serum ferritin <500ng/ml) and employed changes in Ret parameters - RetHb/IRF to predict coexisting iron deficiency "Iron challenge test". All participants received intravenous Iron sucrose after sensitivity testing (100 mg day 1 and 400mg Day 3). An increase in Hb of at least 1gm/dL at one month was considered a positive iron response & diagnostic of coexistent iron deficiency with AI. Change in RetHb/IRF on 3rd day from baseline was compared in Iron responders(AID with AI) vs non-responders (AI only).

Results: Out of 62 patients who were enrolled, 46 patients completed the study protocol & were finally analyzed for the study. The majority of the participants had chronic autoimmune inflammatory disorders (Rheumatoid arthritis-30 Ankylosing Spondylitis-5, Systemic Lupus Erythematosus-4, Sjogren -1, Psoriatic arthritis-1) while the rest were Chronic liver disease/ Chronic heart disease. About 63% of participants were iron responders and therefore, considered to have AID with AI; while the rest were iron non-responders and considered to have predominant AI. There was no significant difference between the change in RetHb/IRF amongst responders and non-responders at 72 hrs (Table 1). Baseline serum iron parameters (Serum iron, Total Iron Binding Capacity, % Saturation, Serum ferritin) and Red blood cell (RBC) indices (Mean corpuscular volume, Mean Corpuscular Hb) were also not statistically different in iron responders vs non-responders.

Conclusion: Diagnosing and treating coexisting iron deficiency in AI is a clinical conundrum. In this study, a significant proportion of AI (37%) didn't respond to intravenous iron at 1 month. Baseline iron parameters like serum ferritin/ % saturation and RBC Mean corpuscular volume didn't predict response to iron in this study. Change in novel automated Ret indices (RetHb and IRF) failed to predict response to iron and therefore, failed to diagnose co-existent iron deficiency in AI. Dynamic studies demonstrating erythron responsiveness to iron therapy using "point of care" automated hematologic parameters may provide a template for further studies.

MULTI-DRUG RESISTANT RA IS ASSOCIATED WITH HIGHER BASELINE DISEASE ACTIVITY, MULTI-MORBIDITY, AND LOWER QUALITY OF LIFE: ANALYSES FROM THE R4RA BIOPSY-DRIVEN CLINICAL TRIAL

Keywords: Comorbidities, Clinical Trials, Rheumatoid arthritis

F. Rivellese[1], D. Currado[1,2], G. Giorli[1], E. Prediletto[1], A. Nerviani[1], A. Khmelevskaya[3], R. Micheroli[3], C. Ospelt[3], M. Lewis[1], M. Bombardieri[1], C. Pitzalis[1]. [1]*Queen Mary University of London, Centre for Experimental Medicine and Rheumatology, London, United Kingdom*; [2]*Campus Bio-Medico University, Rheumatology, Immunology, and Clinical Medicine Research Unit, Rome, Italy*; [3]*University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland*

Background: We have recently described a fibroblast/stromal signature in patients with multi-drug resistant Rheumatoid Arthritis (MDR-RA). However, MDR-RA is known to be extremely heterogeneous, with multiple clinical and pathogenetic factors potentially contributing to multi-drug resistance.

Objectives: Define the association of MDR-RA with clinical and demographic factors.

Methods: Patients with multi-drug resistant RA (MDR-RA), defined as failure of 3x bDMARDs with a different mechanism of action (TNF-inhibitor, tocilizumab and rituximab) were identified from the R4RA clinical trial (n=40) and compared with first-line responders to either rituximab or tocilizumab (n=72) for: disease activity scores, including composite indexes and individual components; baseline demographics, including co-morbidities, and quality of life scores (HAQ and SF-36 domains); synovitis, assessed by ultrasound and immunohistochemistry.

Results: MDR-RA patients did not differ significantly from first-line responders in terms of age, disease duration and ethnicity, as shown in Table 1. MDR-RA patients were treated more often with a csDMARDs combination, while the number of previous anti-TNF did not differ. Baseline disease activity was significantly higher in MDR-RA compared to first-line responders. This difference was mainly driven by tender joints, while there were no significant differences for 28 swollen joints count, pain, and patient/physician global health scores (Table 1). Ultrasound scores and synovial pathotype distribution were not significantly different between MDR-RA and responders, but responders had a numerically higher power doppler score and significantly higher sub-lining macrophages, in line with the known association of synovial macrophages with treatment response. The incidence of individual comorbidities such as diabetes, hypercholesterolemia, hypertension, anxiety/depression, and obesity was non significantly different between MDR-RA and responders; however, the prevalence of multi-morbidities was significantly higher in MDR-RA patients, as 50% had more than 2 comorbidities compared to 22.8% of responders (p=0.0343). Finally, MDR-RA patients had significantly lower FACIT fatigue scores and worse scores for multiple SF-36 domains (physical functioning, emotional well-being, social functioning, and general health). Although the difference in baseline disease activity was mainly driven by tender joints, the longitudinal assessment of disease activity across 48 weeks showed persistently elevated tender and swollen joint counts, pain, and global health scores in MDR-RA patients compared with responders (Figure 1).

Conclusion: MDR-RA, defined as lack of response to 3x biologics with different mechanisms of action, is associated with worse disease activity baseline and multi-morbidity. There were no specific associations with pain scores, but MDR-RA had a huge impact on multiple quality-of-life domains. At follow-up, MDR-RA was associated with persistently elevated disease activity scores, including both higher tender and swollen joints, in keeping with persistently active inflammatory disease.

AB0341 COMPARISON OF CANDIDATE KEY FACTORS FOR INCIDENT FRAGILITY FRACTURE IN POSTMENOPAUSAL FEMALE PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Biomarkers, Osteoporosis

I. Yoshii[1], N. Sawada[2], T. Chijiwa[3], S. Nishiyama[4]. [1]*Yoshii Clinic, Musculoskeletal Medicine, Shimanto City, Japan*; [2]*Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan*; [3]*Kochi Memorial Hospital, Rheumatology, Kochi, Japan*; [4]*Kurashiki Medical Center, Rheumatology, Kurashiki, Japan*

Background: Bone fragility fracture (BFF) in patients with rheumatoid arthritis (RA) is still a significant comorbidity that deteriorates the quality of life after that. Some reports clarified risk factors and the keys to preventing them.
Objectives: The aim of this study is to evaluate the factors statistically and advocate a novel key to preventing the incidence of BFF.
Methods: A retrospective cohort study data was used. Postmenopausal RA patients were picked up. They have been treating RA and measured bone mineral density (BMD) with dual-energy X-ray absorptiometry. The initial target of therapy is the attainment of remission with SDAI within 6 months of initiation. The primary outcome was incident BFF (inc-BFF). Follow-up started at BMD measurement (baseline) and continued until the development of the first fracture or censoring at death, loss to follow-up or end of the study. In these subjects, T-scores and pr-BFF were combined, and T-score < -2.5 in the lumbar spine (LS) or femoral neck (FN), or presence of pr-BFF was evaluated as primary osteoporosis criteria matched (pr-OP). Potential key factors for incident BFF, such as age, disease duration of RA, anti-citrullinated polypeptide antibodies (ACPA), rheumatoid factor (RF), remission rate using clinical disease activity index (CDAIRR), C-reactive protein, Health Assessment Questionnaire Disability Index, pain score using a visual analog scale (PS-VAS), vector value of coordinate on X-axis and Y-axis (Vxy) using Joint Index Vector (JIV), body mass index (BMI), presence of comorbidities such as hyper-fallability (Fall), lifestyle-related diseases (LSD), cognitive impairment (CI), estimated glomerular filtration rate calculated with cystatin C (eGFR_CysC), anti-osteoporotic drug administration and glucocorticoid administration, and serum albumin level (ALB) were chosen as variants. Receptor operation characteristics (ROC) curve was examined for each variant in regard to inc-BFF and the Cut-off index (COI) for each variant was determined. A Cox regression analysis with a multivariate mode in the variants that had statistical significance with the ROC. Kaplan-Meier survival curve (K-M) was examined for each variant in regard to COI. Finally, the K-M study examined the chi-square test by dividing it into positive pr-OP, positive all single significant variants, and positive combined conditions, and simultaneously calculated inc-BFF rates for each subgroup. Differences in BFF rates were compared for each matching pair. Statistical significance was set at less than 5% for all statistical methods.
Results: A total of 239 patients were recruited. The mean age was 73.6 years and the mean follow-up period was 52.4 months. In the ROC study, pr-OP, ACPA, CDAIRR, PS-VAS, Vxy, Fall, LSD, CI, eGFR_CysC, and ALB demonstrated statistical significance with the COI of presence, 0.9 (U/mL), 0.52, 25.0 (mm), 0.012, presence, presence, presence, 50.7 (ml/min/1.41m2), and 4.0 (g/dL), respectively. In these, PS-VAS, Vxy, and ALB had significant risk ratios with values of 1.04, 0.07, and 0.20, respectively. Hazard ratios of each variant in the K-M study were 3.51, 4.56, and 1.81, however, p-values were <0.001, <0.01, and 0.07 for PS-VAS, Vxy, and ALB, respectively. The BFF rate in the pr-OP and PS-VAS ≥ 25.0 subgroups were 4.5%, 12.9%, 14.7%, and 37.9% in the negative/negative, negative/positive, positive/negative, and positive/positive groups, respectively, whereas the BFF rate in the pr-OP and Vxy ≥ 0.012 subgroups were 4.3%, 8.3%, 6.3%, and 32.4% in the negative/negative, negative/positive, positive/negative, and positive/positive group, respectively, When PS-VAS and Vxy were combined to matching either of these, the BFF rate in the subgroups were 5.6%, 12.5%, 12.8%, and 49.0% in the negative/negative, negative/positive, positive/negative, and positive/positive group, respectively.
Conclusion: These results suggest that Vxy > 0.012 and PS-VAS > 25 mm are available risk indicators for inc-BFF. The composite indicator should be more predictable.

AB0342 ASSOCIATION OF GLUCOCORTICOID USE WITH HEALTHCARE UTILIZATION AMONG PERSONS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus

P. Katz[1], S. Pedro[2], J. Choi[3], K. Michaud[4]. [1]*University of California San Francisco, Medicine, San Francisco, United States of America*; [2]*FORWARD, National Databank for Rheumatic Diseases, None, Wichita, United States of America*; [3]*Bristol Myers Squibb, WWHEOR, New York City, United States of America*; [4]*University of Nebraska Medical Center, Medicine, Omaha, United States of America*

Background: Glucocorticoids (GCs) have long been a mainstay of treatment for systemic lupus erythematosus (SLE). While GCs do provide benefit, there are potential side effects which increase with dose and duration. GC-associated adverse events have been linked to significant increased health care costs, although excess healthcare utilization due to GC events has not been examined in SLE.
Objectives: To examine the association of GC use and healthcare utilization.
Methods: Data are from FORWARD, The National Data Bank for Rheumatic Diseases, questionnaires collected from participants with physician-diagnosed SLE and no concomitant RA at 6-month intervals during July 2015 – July 2020. Respondents provided comprehensive health information including GC use and dosage and healthcare use during the prior 6 months. Analyses examined 6-month utilization according to GC use/non-use, as well as by GC dose (0, 1- <5 mg, 5- <10 mg, ≥10 mg). For GC users, data were drawn from the questionnaire in which GCs were first reported during the analysis period. Data for non-users were drawn from the first questionnaire completed during the observation period. Adjusted analyses used double selection LASSO to form the best fitting model considering the

following co-variates: age, sex, race, BMI, comorbidities, education level, smoking, SLE duration, self-reported lupus disease activity, SLE organ damage measured by BILD (Brief Index of Lupus Damage), and other medications. Results of LASSO analyses are reported as incidence rate ratios (IRRs).

Results: 512 participants qualified for the analysis; 46.3% reported GC use in at least one 6-month period. Over 90% of the cohort was male, mean age 58 ±13 years, SLE duration 24 ±12 years. GC users were significantly less likely to be male or white, had more comorbidities, had lupus of greater duration, were more likely to also be taking immunosuppressive medications, and reported more active SLE and greater disease damage (BILD). In bivariate analyses (Table 1), GC users reported significantly more rheumatology and other doctor visits, and more PT/OT visits. They also reported more lung function, blood, and urine tests. There was no difference between GC users and non-users in the occurrence of a hospitalization, but users had significantly longer hospitalizations. The multivariable LASSO regression analyses[1] revealed similar results, with significantly IRRs for GC users for rheumatology and other visits, blood and urine tests, and hospitalizations. In analyses based on GC dosage, IRRs for rheumatology visits, other medical visits and blood tests were significantly elevated for each dosage group compared to the no-GC group; the highest GC dosage group also had significantly elevated IRRs for lung and urine tests and hospitalizations.

Conclusion: GC use is associated with greater healthcare utilization among this cohort with SLE, even after adjusting for a wide range of sociodemographic and disease-related factors. Additional analyses are needed to explore whether greater GC use reflects more severe disease, and/or whether GC use itself leads to increased healthcare utilization.

DEVELOPMENT OF PERSONALISED CARE PACKAGES FOR PEOPLE WITH EARLY RHEUMATOID ARTHRITIS: A MIXED-METHODS STUDY

Keywords: Inflammatory arthritides, Qualitative research methods, Rheumatoid arthritis

M. Dey[1,2], A. Busby[3], H. Lempp[4], E. Nikiphorou[4,5]. *[1]Queen Elizabeth Hospital, Rheumatology, London, United Kingdom*; *[2]University of Liverpool, Institute of Life Course and Medical Science, Liverpool, United Kingdom*; *[3]University of Hertfordshire, Centre for Health Services and Clinical Research, Life and Medical Sciences, Hatfield, United Kingdom*; *[4]King's College London, Centre for Rheumatic Diseases, London, United Kingdom*; *[5]King's College Hospital, Rheumatology, London, United Kingdom*

Background: Disease management in early rheumatoid arthritis (RA) needs careful assessment of various aspects of the patient and their condition. We previously showed a need to address socioeconomic (SE) factors to improve clinical and patient-reported outcomes in RA, and benefits of a syndemics approach to care. We aimed to design a tailored care package which is acceptable, beneficial and relevant to the care of people with early RA.

Objectives: i) Determine aspects of care that people with early RA find beneficial to be included in potential care packages, based on individual needs and disease characteristics; ii) determine factors considered important by patients and healthcare professionals caring for people with RA to be included in care packages.

Methods: This work comprised two stages: i) three workshops involving healthcare professionals caring for people with RA, and patients with RA, using a modified-Delphi approach; ii) online survey informed by outcomes from the workshops, featuring responses from an expanded cohort of participants from the above two groups (Figure 1). Purposive sampling was used to identify potential UK-based participants including patients, rheumatology healthcare professionals, members of national rheumatology charities, and academics with an interest in RA. The online survey was based upon: i) key themes identified by the thematic analysis from the workshops; ii) results from previous findings from quantitative datasets conducted prior to this study, e.g. SE circumstances, clinical factors, and disease outcomes. Views were sought on future 'care packages' for people with early RA relevant to disease progression/ stages.

Results: Thematic analysis from the workshops identified two conceptual care pathways, with distinct MDT care packages, allowing for expansion of the core MDT as needed. The first pathway related to the time prior to RA diagnosis. Attendees considered this an early opportunity to potentially change the disease course, highlighting the importance of exploring risk factors e.g. obesity, smoking, social deprivation and isolation. The second pathway related to individuals with existing RA, with participants emphasising the importance of 'the right MDT member at the right time'. Core care packages were suggested, containing three distinctive components: 1) **early care package** (up to 6 weeks post-diagnosis) with introduction to MDT; 2) **personalised holistic care package** in collaboration with AHPs; 3) **continuity of care package** between primary and secondary providers. Thematic analysis results also informed the survey. We received 41 responses: 17 (43%) rheumatology consultants, 7 (18%) specialist nurses, 6 (15%) rheumatology trainees, 5 (13%) occupational therapists, 3 (8%) physiotherapists, 1 (3%) patient and 1 (3%) dietician. 34 (82.9%) of respondents agreed people with RA need access to the same 'early care package', (a core MDT) at diagnosis. A further 35 (85.4%) approved that the care package for people with early RA can be tailored to individual's clinical, psychological and social needs at subsequent reviews. There was strong consensus for the following two statements: 'A care package with core members of the multidisciplinary rheumatology team need to be available to people newly diagnosed with RA' (mean 9.05, using scale 0-10) and 'Personalised comprehensive care packages, comprising a core plus various additional members of the multidisciplinary team, need to be offered and adapted according to a person's individual disease characteristics and socio-economic circumstances' (mean 9.49). Fleiss' Kappa calculations demonstrated fair level of agreement amongst respondents in the quantitative survey questions.

Conclusion: We identified two care pathways with tailored care packages to optimise management in people with RA. Our results reiterate the benefits of holistic care in early and established disease. This can be further explored using syndemics to focus and better understand the relationships between bio-psycho-social factors influencing RA disease outcomes.

AB0344 **EFFICACY AND SAFETY OF NINTEDANIB IN INTERSTITIAL LUNG DISEASE ASSOCIATED WITH RHEUMATOID ARTHRITIS: A SINGLE CENTER 6 MONTHS OBSERVATIONAL STUDY**

Keywords: Lungs, Rheumatoid arthritis

O. Murata[1], T. Okawara[1], M. Fujimoto[1], T. Naka[1]. [1]*Iwate Medical University School of Medicine, Division of Allergy and Rheumatology, Department of Internal Medicine, Morioka, Japan*

Background: Nintedanib, an intracellular inhibitor of tyrosine kinases, inhibits processes involved in the progression of lung fibrosis [1]. Although the efficacy and safety of nintedanib have been demonstrated for interstitial lung disease (ILD) associated with systemic scleroderma (SSc) [2-4], information of the efficacy and safety of nintedanib in patients with rheumatoid arthritis (RA) is limited [5].
Objectives: The aim of this study was to compare the efficacy and safety of nintedanib in patients with RA-ILD with those in patients with ILD associated with collagen tissue diseases, including SSc-ILD.
Methods: We extracted patients who visited our department and were received nintedanib and had pulmonary function tests performed 6 months after. Then, they were divided into two groups, which were RA group and non-RA group. Clinical and epidemiological parameters, fibrosis pattern on HRCT, pulmonary function at the time of nintedanib administration and 6 months after nintedanib administration and adverse events were compared between the two groups. Those data were collected from medical records and statistically analyzed.
Results: Ten patients were enrolled. RA group had 6 patients and non-RA group had 5 patients. Among the RA and non-RA group, 50% and 60% were women, respectively (*P*=0.74). Age at the time of nintedanib administration was 70.8±5.5 years and 59.0±9.1 years, respectively (*P*=0.035). At the time of nintedanib administration, oral glucocorticoids (GC) were used in 83.3% and 100%, oral GC dose was 8.5±10.9 mg/day and 9.4±1.7 mg/day, and immunosuppressants were used in 83.3% and 100% (*P*=0.27, 0.17, and 0.27, respectively). Usual interstitial pneumonia (UIP) pattern on HRCT was 100% and 40%, and nonspecific interstitial pneumonia pattern on HRCT was 0% and 60%, respectively (*P*=0.013). At the time of nintedanib administration, FVC was -1977±867.2 ml and 1654±507.3 ml, %FVC was 66.9±20.7% and 53.2%±10.9%, and %DLco was 54.8±8.9% and 46.2%±15.9% (*P*=0.58, 0.36, and 0.51, respectively). After 6 months of nintedanib treatment, ΔFVC was -18.3±103.5 ml and -24.0±101.5ml (Figure 1.), Δ%FVC was 0.75±5.03% and -2.4%±1.91%, and Δ%DLco was 0.375±4.02% and -7.27%±6.54% (*P*=0.52, 0.20, and 0.28, respectively). The incidence of adverse events was 50% and 40%, respectively. In the both groups, there was no patients with severe adverse events and acute exacerbations of ILD, and the continuation rate was 100%, respectively.
Conclusion: This observational cohort study revealed that there was no statistically significant difference in the reduction of respiratory function in both FVC, %FVC, and %DLco in the RA group compared to the non-RA group, and the safety was also comparable between the two groups. Although RA-ILD have more UIP pattern on HRCT than SSc-ILD, nintedanib may effective for RA-ILD as same as SSc-ILD.

AB0345 **ACPA TITER IS AN INDEPENDENT DETERMINANT OF SERUM CTX IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS**

Keywords: Prognostic factors, Rheumatoid arthritis, Bone diseases

G. Adami[1], G. Orsolini[1], A. Fassio[1], D. Bertelle[1], C. Benini[1], O. Viapiana[1], D. Gatti[1], M. Rossini[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*

Background: Serum C-terminal telopeptide of type I collagen (CTX - a marker of bone resorption) and ACPA titer have been associated to higher erosive score in rheumatoid arthritis (RA) and lower bone mineral density (BMD), even in patients with pre-arthritis. Prominent inflammatory status cannot totally explain such association. The interplay between ACPA, disease activity, BMD and CTX is still unclear.
Objectives: To investigate the determinants of CTX serum levels in RA patients.
Methods: We conducted a cross-sectional analysis on RA patients with active disease activity failure to first-line cDMARDs candidate to bDMARDs. Clinical, laboratoristic and densitometric and BMD parameters were collected. ACPA, CTX, Procollagen I Intact N-Terminal Peptide (P1NP), Dkk1, Sclerostin (SOST), 25-OH-Vitamin D (VitD), PTH, RANKL, OPG, B-ALP were dosed. Potential predictors of serum were analyzed using hierarchical regressions. Potential predictors were selected based screened via simple regression analyses which included CTX and a single candidate baseline predictor in each model. Any baseline predictor with $p < 0.10$ entered the multivariable model (model 1). We also conducted a multivariable linear regression forcing variables associated with CTX serum levels from the literature (model 2). Results were analyzed using GraphPad Prism version 9.5.0 for Windows, GraphPad Software, San Diego, California USA.
Results: We enrolled 62 RA patients in the study. DAS28-CRP at baseline was 4.17 (SD 1.28). 80.6% of patients were ACPA positive. The factors associated with CTX serum levels in the univariate analysis were: ACPA titer, DAS28-CRP, B-ALP, P1nP and BMD levels (**table 1**). ACPA titer was the only independent factor significantly associated with CTX serum levels in both model 1 and model 2 (**table 1**).
Conclusion: We found that ACPA titer is an independent determinant of serum CTX levels in RA patients with active disease activity.

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease characterized by a persistent immune response leading to arthritis and destruction. Mounting evidence has suggested that dysbiosis of the intestinal microbiome is a vital environmental element that triggers the onset of RA[1]. Unraveling the interactions between the gut microbiome and metabolome could provide new insights to discover novel targets for treating various inflammatory diseases. However, the current understanding of the potential association between intestinal microbiota and RA still needs to be improved.

Objectives: Recent studies have reported that the change in the interaction between the microbiome and the immune system is one of the characteristics of RA. Therefore, we conducted a meta-analysis and Mendelian randomization(MR) to explore the association and causality between RA and intestinal flora.

Methods: The PubMed, Embase, Medline, Web of Science, CNKI, Wanfang, VIP, and CBM databases were searched from the establishment of the databases to January 1, 2023, to retrieve trials about RA and intestinal flora. We performed a meta-analysis to calculate the odds ratio(OR) and 95% confidence intervals (95%CI). In addition, we conducted a bi-directional MR study to explore the causal relationship between RA and intestinal microbial composition. Single nucleotide polymorphisms (SNPs) associated with RA from 22 genome-wide association studies (14,361 cases and 43,923 controls) were selected as instrumental variables (IVs) at a genome-wide significance level. The aggregated statistical data of intestinal microbiota were obtained from a large-scale multiracial GWAS meta-analysis, including 18,340 people from 24 cohorts. The random-effects inverse variance weighted method (IVW) was used to combine the causal effect of IVs. Sensitivity analyses were performed to test the robustness of our findings. All analyses were conducted in R 4.2.1 and STATA 12.0.

Results: We included 17 case-control studies that examined 1,062 RA patients and 921 healthy controls(HCs). Compared with HCs, decreases in α-diversity indices were consistently found in RA[Shannon-Wiener diversity index (SMD=-0.608, 95% CI -0.935 to -0.281, p<0.001); Simpson index-(SMD=-0.558, 95% CI -0.891 to -0.225, p<0.001); ACE index(SMD=-0.414, 95% CI -0.697 to -0.132, p<0.001); Chao1 index(SMD=-1.373, 95% CI -1.980 to -0.766, p<0.001); Eveness index(SMD=-1.863, 95% CI -3.181 to -0.544, p=0.004)]. There was no significant difference in Observed_species between the two groups(SMD=-4.342, 95% CI -9.098 to 0.415, p<0.001). Further, we conducted a bi-directional MR analysis to test the causal relationship between RA and intestinal microorganisms, which included three phyla(*Firmicutes, Proteobacteria, Actinobacteria*), six families(*Bacteroidaceae, Actinomycetaceae, Clostridiales, Lactobacillaceae, Bifidobacteriaceae, Lachnospiraceae*) and seven genera(*Bifidobacterium, Butyricicoccus, Escherichia Shigella, Lachnospiraceae, Lactobacillus, Actinomyces, Bacteroides*). However, no genetic prediction causal relationship was found between them (all p>0.05). These results were robust in a wide range of sensitivity analyses.

Conclusion: This study suggested a significant correlation between RA and lower intestinal microflora abundance. This may provide new insight into the development mechanism of RA mediated by intestinal microbiota and may provide a evidence for regulating intestinal microecology to target the treatment of RA.

AB0347 PREDICTIVE FACTORS OF SLEEP DISORDERS IN RHEUMATOID ARTHRITIS PATIENTS: A CROSS-SECTIONAL STUDY

Keywords: Rheumatoid arthritis, Quality of life

M. Brahem[1], S. Abdellatif[1], B. Jebali[1], R. Sarraj[1], A. Ben Salem[1], O. Joma[1], H. Hachfi[1], Y. Mohamed[1]. [1]*Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia*

Background: Rheumatoid Arthritis (RA) is a chronic inflammatory disease that causes chronic inflammatory joint pain that disturbs the quality of life of patients including sleep disorders.

Objectives: The aim of our study was to evaluate the quality of sleep of RA patients and to determine the predictive factors of sleep disturbance.

Methods: This is a cross-sectional study conducted among patients followed in the rheumatology department for RA. All patients were diagnosed with RA based on ACR/EULAR criteria. We assessed them for sleep disorders using the Pittsburgh Sleep Quality Index (PSQI) and Epworth Sleepiness Scale (ESS) after clear consent.

Results: One hundred patients (11 men (11%) and 89 women (89%)) were included. The average age was 53.2 ±11.21 years. The mean duration of the disease was 11.1 years [1 - 40 years]. 70% of the participants had joint deformities,35% had extra-articular manifestations and 17% were obese. 81% of patients were treated with Methotrexate and 10% received biological treatment. The mean visual analogic scale (VAS) was 5.19/10 [1-9] and the average Swollen joints count (SJC) and Tender joints count (TJC) were consecutively 8.5 et 3,95 [0-24]. The average DAS28(CRP) score was 4.6±1,19 and DAS28(ESR) was 3,8±1,19. The mean ESR and CRP values were 46 mm at the first hour and 14.7 mg/L respectively. The disease was very active (DAS 28 ≥ 5.1) in 34% of patients. The average HAQ (Health Assessment Questionnaire) was 1.28±0.7. The mean Epworth score was 7.9 with extremes ranging from 0 to 24. The majority of our population (72%) had normal daytime sleepiness (ESS≤10) and 28% had excessive daytime sleepiness (ESS ≥11). The mean PSQI score was 6,9 [0-19]. Almost half of our RA patients had sleep disorders with an index of PSQI≥5.5. Statistical analysis found a positive significant correlation between the ESS score and the VAS, TJC, SJC, DAS28, HAQ scales, and female gender. Also, we proved a significant relationship between sleep disorders based on the PSQI scale and higher DAS28 (p<0.01), TJC (<0.01), SJC (<0.01), CRP (p<0.01), VAS (p<0.05), and HAQ (p<0.01).

Based on the multivariate study, a high CRP and SJC were found to be predictive factors to sleep disorders according to the PSQI score. on the other hand, the presence of extra-articular manifestations, female gender, and higher VAS were considered as predictive factors of this disorder in conformity with the Epworth score.
Conclusion: Sleep disorders are common among RA patients and they were essentially related to disease activity and functional disability, so it is important to guarantee the remission or low disease activity to improve sleep quality in these patients.

AB0348 DEPRESSION IN RHEUMATOID ARTHRITIS: PREVALENCE AND PHENOTYPIC CHARACTERISTICS - A SINGLE CENTER EXPERIENCE

Keywords: Rheumatoid arthritis, Mental health

C. E. Ionescu[1], C. Popescu[1], M. Agache[1], G. Dinache[1], C. Codreanu[1].
[1]*Rheumatic Disease Center DR ION STOIA Bucharest, Rheumatology, Bucharest, Romania*

Background: Psychiatric comorbidities are frequent extra-articular manifestations in rheumatoid arthritis (RA) and depression is the most common [1]. A 2013 study estimated that 16.8 % of RA patients suffer from major depressive disorder, being more prevalent than diabetes, Parkinson's disease or cancer [2-3]. Patients with RA have constitutional symptoms, frequently encountered in depression, like fatigue, weight loss, insomnia and lack of appetite. The overlap of depression in inflammatory immune mediated diseases is recognized for some time [4]. Studies show that immune mediated inflammation affects and modulates neurogenesis, neurotransmission, neuroendocrine activity and neuroplasticity [5]. Depression has important effects on RA patients: worse prognosis, pain, fatigue, functional deficit, more comorbidities, higher rate of mortality, increased healthcare resource utilization and lowered quality of life [6].
Objectives: The scope of this article is to highlight the importance of managing depression in RA. The primary objective was to estimate the prevalence of depression in a cohort of RA patients. The secondary objective was to describe the phenotypic characteristics of RA patients with depression.
Methods: RA patients from the Center of Rheumatic Diseases in Bucharest were included in the study if they were at least 18 years-old and if they had two or three follow-ups, after 2019. The protocol included collection of demographical, clinical and biological data. Prevalence of depression is derived from patients' medical history, known depression. Demographical characteristics and RA phenotype were compared between the two groups. Disease activity was estimated with DAS28 and its components, tender joint count, swollen joint count, CRP and were followed over time to compare disease activity between patients with known depression and patients without depression.
Results: We collected data from 203 patients with RA, among whom 37 were known with depression, generating a prevalence of 18.2%. A meta-analysis from 2013 reported that 16.8 % patients with RA suffer from a major depression disorder [1]. Most of the patients with depression were women (87.2%). Female sex is a potential risk factor for depression [7]. The prevalence of active smoking among the depression subgroup was higher (8.1%, 1.8%, p = 0.041). Depression is a known risk factor for negative behaviors like smoking [8]. Patients had a longer disease duration (in median, 13 years compared to 10 years, p = 0.059) and also the seropositivity prevalence was lower. In 2022 a correlation between depression and seronegative RA was found [9]. DAS28 and the components of DAS28 were higher in the depression RA subgroup; DAS28 was higher at all time points (p < 0.001). Higher tender joint count was expected (p < 0.001), but swollen joint count was also higher among depressive RA patients (p < 0.001), as well as CRP (p = 0.009, Figure 1).

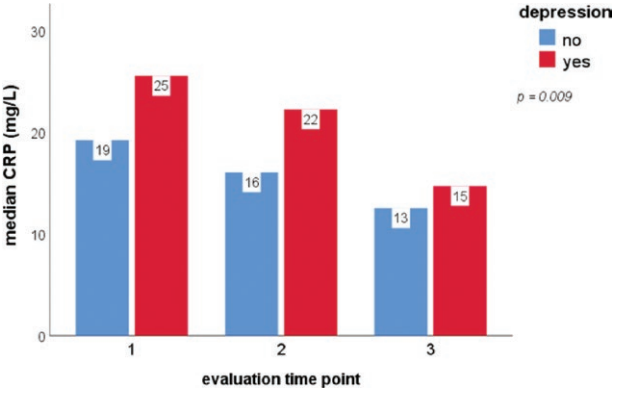

Figure 1. Median CRP levels as three time points among depressive and non-depressive RA patients (ANCOVA)

Conclusion: Depression is prevalent among RA patients and it has an important impact on the quality of life; so depressive symptoms should be addressed in clinical practice. The correlation between the prognosis of rheumatic disease and depression is strong, regardless of the direction of causality. The assessment of depression could be a psychomarker for assessing RA prognosis. DAS28 is used to make therapeutic decisions, so given that depression scores increase DAS28, it follows that they also influence therapeutic decisions.

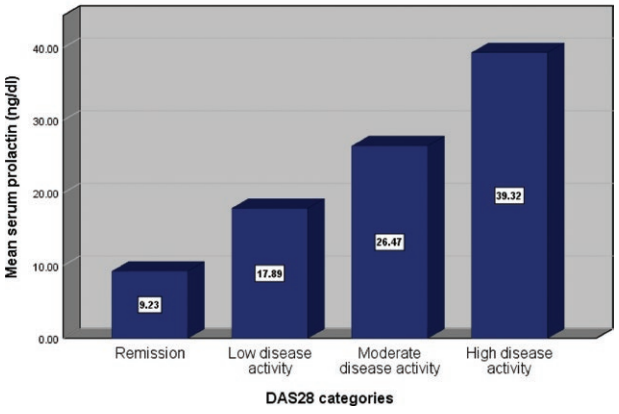
AB0349 ENDOCRINE DYSFUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS AND THEIR RELATIONSHIP TO DISEASE SEVERITY

Keywords: Comorbidities, Rheumatoid arthritis, Descriptive Studies



M. K. Garg[1,2], P. S Kumar[1], S. Nandagopal[3], K. Shukla[3], M. Gopalakrishnan[1]. [1]*All India Institute of Medical Sciences, Internal Medicine, Jodhpur, India*; [2]*All India Institute of Medical Sciences, Endocrinology and Metabolism, Jodhpur, India*; [3]*All India Institute of Medical Sciences, Biochemistry, Jodhpur, India*

Background: Rheumatoid arthritis (RA) is known to be associated with multiple endocrine dysfunctions including hypothyroidism, adrenal insufficiency, hyperprolactinemia, and hypoandrogenism. The link between endocrine system and synovitis in RA is attributed to the presence of functional receptors for glucocorticoids, androgens and estrogen in the synoviocytes which function as an intracrine system [1,2].
Objectives: To describe endocrine dysfunction in patients with RA and to determine its relationship with disease severity and disease duration.
Methods: We studied RA patients diagnosed using ACR/EULAR 2010 at our clinic in Jodhpur, India from January 2021 to August 2021 after written informed consent and Ethical Committee approval. We collected the clinical, demographic, treatment history and calculated disease severity with Disease Activity Score (DAS28) and Simplified Disease Activity Index (SDAI). Serum samples for thyroid profile, prolactin, dehydroepiandrosterone sulphate (DHEAS), testosterone, cortisol, Tumor Necrosis Factor alpha (TNF-α) and Interleukin 6 (IL-6) were collected and stored at -80^{0}C and analysed by chemiluminescent immunoassay (Siemens Advia Centaur© immunoassay system, USA) as per the standard hospital protocol. Spearman's correlation was used to determine the relationship between endocrine dysfunction with disease severity scores and total disease duration.
Results: Among the 160 patients included in the study, 4 were on levothyroxine supplementation for hypothyroidism. Thirteen patients (8.8%) had primary hypothyroidism, 2 patients (1.3%) had subclinical hypothyroidism with no cases of central hypothyroidism and 31 patients (20.9%) had sick euthyroid syndrome (Table 1). Hyperprolactinemia was seen in 24.3% patients and the mean level of serum prolactin increased as the disease severity increased but it was not statistically significant (Figure 1). DHEAS levels were below the accepted age and gender cut-offs in 56.4% patients while 56.6% had low testosterone. Among the 99 patients who had random cortisol values, 36 patients (36.4%) had adrenal insufficiency (random cortisol range<3 µg/dl). Serum cortisol was negatively correlated with serum TNF-α but had no relationship with serum IL-6. None of the endocrine parameters were correlated with disease severity scores (SDAI/DAS) or their individual components.
Conclusion: Considerable percentage of patients with RA have endocrine dysfunction compared to the general population, likely secondary to raised inflammatory cytokines produced at synovial tissues. However, they do not correlate to disease activity or disease duration in RA.

Table 1. Endocrine dysfunction in patients with Rheumatoid arthritis.

Endocrine Abnormality	No of Patients/Total patients (%)
Primary hypothyroidism	13/148 (8.8%)
Subclinical hypothyroidism	2/148 (1.3%)
Sick Euthyroid cases	31/148 (20.9%)
a. low fT3 and low fT4	13/148 (8.7%)
b. low fT3 and normal fT4	14/148 (9.5%)
c. low fT3 with increased fT4	4/148 (2.7%)
Hyperprolactinemia	37/152 (24.3%)
Low DHEAS	88/156 (56.4%)
In males	15/21 (71.4%)
In females	73/135 (54.1%)
Low Testosterone	86/152 (56.6%)
In males	13/21 (61.9%)
In females	73/131 (55.7%)
Primary Adrenal insufficiency	36/99 (36.4%)

DRUG SAFETY AND PREGNANCY OUTCOME IN INDIAN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

Keywords: Safety, Rheumatoid arthritis, Pregnancy and reproduction

P. Aggarwal[1], B. Aggarwal[2], V. Gupta[3], P. Gupta[4]. [1]*Punjab Rheumatology and Immunology Center, Rheumatology, Ludhiana, India*; [2]*Punjab Rheumatology and Immunology Center, Rheumatology & Internal Medicine, Ludhiana, India*; [3]*Dayanand Medical College & Hospital, Rheumatology, Ludhiana, India*; [4]*Dayanand Medical College & Hospital, Medical Student, Ludhiana, India*

Background: Due to ethical issues conducting controlled trials to assess safety, teratogenicity of medicines to treat Rheumatoid Arthritis (RA) is not feasible and pregnant women are excluded from drug trials. Hence data concerning safety of arthritis medicines in RA is limited. To our knowledge no study is available from India regarding pregnancy outcome and drug safety in RA patients.
Objectives: Analyze safety of arthritis medicines and pregnancy outcome in Indian women suffering from RA.
Methods: Retrospective analysis of RA women with pregnancy treated at Punjab Rheumatology Immunology Centre, Ludhiana and DMC, Ludhiana between 2012 to 2022. Patients were classified as RA based on ACR/EULAR 2010 criteria. Compliance to treatment and additional medication usage was self-reported by the patients. Delivery of healthy baby was counted as successful while spontaneous abortion, MTP due to fetal abnormality were counted as adverse pregnancy outcome.
Results: 77 patients (Mean age 31.3 years) and 82 pregnancies were evaluated. 68 were successful. 10 patients had 11 spontaneous abortions out of whom 4 subsequently had successful pregnancy. Anticardiolipin antibodies were negative in 7, not available in 3. Patient with 2 spontaneous abortions had a successful pregnancy following low molecular weight heparin treatment throughout pregnancy despite negative anticardiolipin antibodies. 3 patients underwent MTP due to antenatal fetal defects (Table 1). Most commonly used medicines during pregnancy were Sulfasalazine(SSZ), Hydroxychloroquine(HCQ), Low dose Prednisolone, Azathioprine(AZA) (Table 1). No specific teratogenicity pattern was identified. 3 patients without Methotrexate(MTX) and 1 patient without MTX+Leflunomide washout had successful pregnancy.

Table 1.

Pregnancy Outcome	Successful	Adverse
Number	68	14
Hydroxychloroquine (HCQ) Monotherapy	9	
Sulfasalazine (SSZ) Monotherapy	10	2 (1 spontaneous abortion, 1 MTP due to hydrocephalus)
SSZ + HCQ	28	4 (spontaneous abortions)
SSZ+Prednisolone	1	2 (spontaneous abortions)
HCQ+Prednisolone	1	
SSZ+HCQ+Prednisolone	13	5 (4 spontaneous abortions, 1 MTP due to fetal spine limb developmental defect)
Azathioprine (AZA) +HCQ+Prednisolone	1	1 (MTP due to fetal spine abdominal defect)
Prednisolone	2	
Treatment default	3	

Conclusion: To our knowledge this is the first study evaluating drug safety and pregnancy outcome in Indian RA patients. Most RA patients can have successful pregnancy. SSZ, HCQ, Azathioprine and low dose prednisolone are safe during pregnancy. Limited data indicates patients can have successful pregnancy without observing MTX washout but more data is required.

RELATIONSHIP BETWEEN NUTRITIONAL STATUS AND OSTEOPOROSIS IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Osteoporosis, Diet and Nutrition, Rheumatoid arthritis

M. Ardhaoui[1], M. Ghali[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia*

Background: Malnutrition is a recognised risk factor for osteoporosis. These two conditions are frequent comorbidities in rheumatoid arthritis (RA), especially in elderly patients.
Objectives: The aim of our study was to evaluate the association between malnutrition and osteoporosis among elderly patients followed for RA.
Methods: This is a cross-sectional study including patients followed for RA aged 65 years or older. Nutritional status was assessed by body mass index (BMI) and the Mini-Nutritional Assessment (MNA) questionnaire. Patients were divided into 2 groups according to the MNA: an "impaired nutritional status" group with an MNA score ≤ 23.5 and a "normal nutritional status" group with an MNA ≥ 24. Bone mineral density was assessed by two-photon X-ray absorptiometry.
Results: There were 63 patients (52 women and 11 men). The mean age was 68.17±4.35 years. The median duration of RA was 11 years with a IQR of [4-16]. The mean DAS28-VS was 3.72±1.48. The mean total MNA score was 20.19±4.71 [8-27.5]. According to the MNA, 76.2% of the patients had an «altered nutritional status» and 23.8% of the patients had a «normal nutritional status». The mean BMI was 27.97±5.44 kg/m². Osteoporosis was found in 25 patients (39.7%). In the «impaired nutritional status» group according to the MNA, there were significantly more osteoporotic patients (p=0.05). The mean T-score at the lumbar spine site was significantly lower in patients with MNA indicating «impaired nutritional status» (-2.36±1.17 SD vs -1.53±0.81; p=0.04), as was the mean T-score at the femoral site (-1.89±1.18 SD vs -1.03±0.76; p=0.001). A lower BMI was significantly associated with the T-score at the femoral site (p=0.04) but not at the lumbar spine site (p=0.18).
Conclusion: Our study showed that in elderly patients followed for RA, malnutrition diagnosed with the MNA score was significantly associated with osteoporosis and lumbar and femoral T-scores, and low BMI was associated with the femoral site T-score.

AB0352

FREQUENCY, CLINICAL AND FUNCTIONAL IMPACT OF FOOT INVOLVEMENT IN RHEUMATOID ARTHRITIS

Keywords: Descriptive Studies, Inflammatory arthritides, Rheumatoid arthritis

C. Pinto Oliveira[1], S. F. Azevedo[1], S. P. Silva[1], A. R. Prata[1], A. Barcelos[1]. [1]*Centro Hospitalar do Baixo Vouga, Rheumatology Department, Aveiro, Portugal*

Background: Rheumatoid Arthritis (RA) is a chronic inflammatory disorder affecting the joint synovium. Foot involvement is frequent throughout the disease course[1]. However, definition of foot involvement differs, with some scientific works using patient reported outcomes, especially pain, rather than arthritis detected by clinical examination or ultrasound[2,3].
Objectives: Primary – to study the frequency and pattern of foot involvement in RA's patients. Secondary – to compare patients with or without foot involvement concerning sociodemographic, clinical, radiographic and laboratorial characteristics.
Methods: Single center, retrospective study including patients evaluated in our center with a diagnosis of RA, between June-December, 2022. All patients fulfilled the 2010 ACR/EULAR classification criteria for RA. Patient records were searched for sociodemographic, clinical, laboratorial, and radiographic data. Multimorbidity was defined as the coexistence of 2 or more comorbidities. Patients were divided into two groups, according to the presence/absence of cumulative foot involvement, defined as the presence of clinical arthritis or synovitis in ultrasound. Descriptive analysis used mean, median, standard deviation, and interquartile range for continuous data, as well as frequency counts and percentages for categorical variables. A statistical analysis was performed, with a statistically significant p-value ≤ 0.05. The two groups of patients (with/without foot involvement) were compared using parametric and non-parametric tests for continuous variables, and Chi-squared test for categorical variables.
Results: 110 patients were enrolled, with a mean age of 62.97 ± 13.81 years. 84 patients were women (76.36%). Cumulative foot involvement was found in 71 patients (64.55%). The forefoot was the most frequently affected area (69.01% of the patients with foot involvement, n=49), followed by the tibiotarsal joint (53.52%; n=38), the mid foot (12.68%; n=9) and the hindfoot (11.27%; n=8). Patients with foot involvement were more likely to receive a biologic disease modifying anti-rheumatic drug (p <0.05). We found no statistically significant differences between patients with or without foot involvement regarding gender, age at diagnosis, disease duration, rheumatoid factor or anti-citrullinated protein antibodies positivity, bone erosions, multimorbidity, inflammatory markers levels, number of tender or swollen joints at last evaluation, mean Disease Activity Score (DAS)28-C-reactive protein (CRP) and DAS28-erythrocyte sedimentation rate (ESR) or Health Assessment Questionnaire Disability Index Score (HAQ-DI).
Conclusion: In our study, objective foot involvement in RA was frequent and associated with higher probability of biological therapy. However, it did not correlate with poor prognosis factors[4] such as seropositivity, bone erosions or high disease activity measured by DAS28-CRP and DAS28-ESR. We found no higher levels of disability (as measured by the HAQ-DI) in patients with RA involving the foot. Studies with greater sample sizes are paramount to better comprehend the clinical and functional impact of foot involvement in RA, using clearer definitions of the former.

AB0353 ASSESSMENT OF KIDNEY INVOLVEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Kidneys, Rheumatoid arthritis, Comorbidities

S. Monov[1], T. Todorov[2], D. Monova[3]. [1]*Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria*; [2]*Medical University - Sofia, Department of General and Clinical Pathology, Sofia, Bulgaria*; [3]*Medical Institute, Medical University - Sofia, Department of Internal Medicine, Sofia, Bulgaria*

Background: In rheumatoid arthritis (RA) kidney is commonly affected organ with clinical presentation characterized by proteinuria and microalbuminuria, followed by chronic renal failure. RA is associated with reduced kidney function, possibly due to chronic inflammation or the use of nephrotoxic therapies. Renal diseases occurring in patients with RA may have a variable clinicopathological picture. Little is known about the effects of using the novel biological agents on the risk of kidney diseases.
Objectives: The aim of this study was to determine the relationship between effect of therapy and kidney involvement in patients with RA and evaluated the histopathological findings and associated clinical manifestation.
Methods: In this retrospective study 275 patients with diagnosis of RA were included. In 48 patients renal biopsy was performed. The patients were divided in three groups according to changes in management of RA: 1991-2001, 2002-2011 and 2012-2022 year. Data of demographic characteristics, clinical symptoms and pathological diagnosis were extracted from medical records and pathological reports [1,2,3].
Results: In our study amyloidosis was the most common histologic pattern, followed by chronic glomerulonephritis (GN) and tubulointerstitial nephritis. Renal amyloidosis was diagnosed in 13 patients, membranous GN – in 9, mesangioproliferative GN - in 7 patients, focal segmental necrotizing GN – in 5, focal segmental sclerosis – in 4, minimal change disease – in 3, tubulointerstitial nephritis – in 7 patients. Between 1991 and 2001 year the most common clinical manifestation was nephrotic syndrome and the most common histopathological findings - renal amyloidosis, followed by membranous GN and focal segmental necrotizing GN. The membranous GN was related to the use of gold and its frequency decreased after 2001. The mesangioproliferative GN was the leading cause of kidney disease between 2002 - 2011 years and focal segmental sclerosis – between 2012-2022. In our study 68 patients had a decrease of glomerular filtration rate (GFR) < 60 mL/min/ m2. No kidney biopsies were performed in these cases because no urine abnormalities were detected. We found that age, duration of the disease, arterial hypertension, C-reactive protein were significant risk factors for GFR decline in patients with RA. Patients with RA who are treated with biologic agents are less likely to experience progressive decline in kidney function than those not receiving biologic treatment (hazard ratios {HRs] [95% CI], 0,84 [0,68-1,02]}.
Conclusion: In all patients with RA, renal function should be monitored and in the case of pathologic results, renal biopsy should be performed. In RA patients with renal disorder, suspected causal drug should be removed from the treatment and specific immunosuppressive therapy initiated. Improved pain management associated with biologic treatment may help to reduce the need for potentially nephrotoxic anti-inflammatory agents such as NSAIDs and certain types of non-biologic DMARDs, which could consequently reduce the risk of drug-induced nephrotoxicity and thereby contribute to the lower risk of renal diseases.

AB0354 ORBITAL MYOSITIS ASSOCIATED WITH RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW OF CLINICAL FEATURES AND PARACLINICAL DATA

Keywords: Rheumatoid arthritis, Myositis, Systematic review

J. Mahdavi[1]. [1]*Arak University of Medical Sciences, Students Research Committee, Arak, Iran (Islamic Republic of)*

Background: Orbital myositis (OM) is an inflammatory condition that mainly involves extraocular muscles. The exact etiology of this disease is not known [1]. However, rheumatoid arthritis (RA) has been reported as a possible cause of OM in some cases.
Objectives: The aim of this study was to assess the clinical features and paraclinical data of patients with OM associated with RA.
Methods: This study is a systematic review that followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The search was performed in PubMed, Web of Science, Scopus, and ScienceDirect for English articles published between 1990 and 2022. Google Scholar was also utilized to find more studies. The keywords used were: "orbital myositis", "ocular myositis", and "rheumatoid arthritis". There was no limitation in age, gender, nationality, and severity of disease.
Results: A total of 6 studies, describing 5 females and 1 male with age ranging from 38 to 61 years, were included [2-7]. The time between the diagnosis of RA and OM was different, with a maximum of 34 years. The most common sign/symptom found in the patients was diplopia (5 cases) followed by proptosis (3 cases), headache (2 cases), drooping eyelid, periorbital swelling, pain on eye movement, conjunctival

chemosis, and eye movement limitation (each 1 case). In physical examination, decreased vision and weakness/paralysis of the orbital muscles including medial, lateral, and superior rectus were found. Laboratory data revealed increased thyroxine and mildly raised inflammatory markers including ESR and CRP in 1 case. MRI/CT showed thickening of the involved orbital muscles in all cases and tendon enlargement in 2 cases. Although most of the patients being treated with corticosteroids had good outcomes, paresis of the orbital muscles and mild restriction of horizontal movements due to fibrosis remained as sequels in 2 cases.

Conclusion: Although more research is needed on the relationship between RA and OM, RA should be considered as a rare possible cause of OM, which can lead to nonspecific findings such as headache and elevated inflammatory markers to ocular manifestations like diplopia, proptosis, and drooping eyelid. In addition, in patients with RA and ophthalmological diseases, it is recommended that OM be evaluated as a differential diagnosis to avoid irreversible complications with timely treatment.

AB0355 CURRENT CARDIOVASCULAR RISK (MANAGEMENT) IN NEWLY DIAGNOSED RHEUMATOID ARTHRITIS

Keywords: Cardiovascular disease, Rheumatoid arthritis

R. Raadsen[1,2], R. Hansildaar[1,2], A. Van Kuijk[1], M. T. Nurmohamed[1,2].
[1]Amsterdam Rheumatology Centre, Location Reade, Department of Rheumatology, Amsterdam, Netherlands; *[2]Amsterdam UMC, location VUmc, Department of Rheumatology, Amsterdam, Netherlands*

Background: Patients with rheumatoid arthritis (RA) are at an increased risk for developing cardiovascular diseases. While advice regarding cardiovascular risk screening and management in RA patients has been incorporated in several guidelines in recent years, its implementation and adherence is still poor (1, 2).

Objectives: To assess the cardiovascular disease risk in patients with newly diagnosed RA, and evaluate whether advice to initiate preventive medical treatment of high risk patients was followed.

Methods: All patients with RA, aged 40-70 years, are screened for cardiovascular diseases and risk factors within the first year after diagnosis at the outpatient rheumatology clinic of Reade, as part of standard care. Screening included a physical examination with blood pressure measurement, and laboratory tests with lipid profile tests. All patients and their general practitioner (GP) received an overview with their cardiovascular risk profile and calculated 10-year cardiovascular mortality risk. Risk was defined as low (<1%), intermediate (1-5%), high (5-10%) and very high (>10%).The national pharmacy network was consulted to check whether or not patients started preventive medication after screening.

Results: A total of 125 RA patients were included in this study. The mean age was 56 years and 78% was female. Median RA disease duration at screening was 6 months. 6 patients (5%) indicated to have been screened before, and used antihypertensive medication. During screening, hypertension was found in 46% of patients, with 57% occurring in men and 43% in women. Dyslipidemia was found in 33% of patients, with 36% in male patients and 32% in female patients. 21% of female patients and 46% of male patients currently smoked. Hypertension and dyslipidemia are shown in Table 1. A low 10-year cardiovascular mortality risk was found in 36% of patients, an intermediate risk in 49%, a high risk in 11% and a very high risk in 4% of patients (Figure 1). Only 26% of high and very high risk patients started antihypertensive or statin medication after screening.

Conclusion: An increased cardiovascular disease risk in RA patients, especially male patients, is often present soon after diagnosis, with a large proportion having undiagnosed and untreated hypertension and hypercholesterolemia. Even with structural screening and informing the GP, treatment of cardiovascular risk factors in high risk patients remains insufficient. Obviously, a better collaboration between GPs and rheumatologists is urgently needed to lower the cardiovascular burden of our patients.

AB0356 EVALUATION OF CARDIOVASCULAR RISK AND OSTEOMETABOLIC ALTERATIONS IN A POPULATION OF PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS: PRELIMINARY RESULTS OF A MULTIDISCIPLINARY PROSPECTIVE STUDY

Keywords: Comorbidities, Rheumatoid arthritis, Real-world evidence

S. Parisi[1], M. C. Ditto[1], C. Lopez[2], G. Beccuti[2], F. Broglio[2], E. Ghigo[2], E. Fusaro[1]. *[1]Azienda Ospedaliero Universitaria Città Della Salute e della Scienza di Torino, Rheumatology Unit, Turin, Italy*; *[2]Azienda Ospedaliero Universitaria Città della Salute e della Scienza di Torino, Endocrinology, Diabetes and Metabolism Unit, Department of Medical Sciences, Turin, Italy*

Background: Rheumatoid Arthritis (RA) is associated with increased cardiovascular (CV) morbidity and mortality and osteometabolic alterations risk, associated with chronic inflammation, the use of glucocorticoids (GC) and the reduced physical exercise.[1]

Objectives: The objective of the study is to cross-sectionally estimate cardiovascular risk and osteometabolic status in patients (pts) with RA and to evaluate the association with some disease parameters such as positivity of autoantibodies, disease activity and steroid therapy.
Methods: At the current time, 61 consecutive pts with diagnosis of RA, admitted to the Rheumatology Unit of the University Hospital of Turin, were prospectively recruited and assessed for cardiometabolic risk by the Endocrinology Unit, by undergoing laboratory and instrumental tests.
Results: The following prevalences were observed: arterial hypertension (52%), type 2 diabetes mellitus (7%), dyslipidemia (56%), osteoporosis (42%), and vertebral fracture (30%). At the univariate analysis, the enrolled pts were divided according to serodiagnosis, GC therapy and disease remission. No statistically significant results were highlighted stratifying population by serodiagnosis. Pts with high disease activity showed lower bone mineral density (BMD) values [BMD femoral trochanter: 0.53± 0.08 vs 0.60 ± 0.08 (g/m^2), p=0.031] and T-score value on bone densitometry [T-score Femoral total: -1.88 ± 0.53 vs -1.07 ± 0.83, p=0.005], higher percentage of osteoporosis [67% vs 27%, p=0.047] and vertebral fractures [60% vs 12%, p=0.001], and higher sarcopenia score [SARC-F: 5 (3-7) vs 2 (2-4), p=0.020], in comparison with pts with remission disease. These differences were not confirmed when the population was divided according to the use of GC therapy. For CV risk factors, disease activity group showed a trend of higher prevalence compared to remission group, but without reaching statistical significance. At the multivariate analysis, advanced age (p=0.001), GC therapy (p=0.021) and copeptin (p=0.002) showed an inverse association and lumbar T-score (p=0.002) a direct one with lumbar trabecular bone score (TBS). Moreover, male gender (p=0.001) revealed a direct and significant association, while copeptin (p=0.086) an inverse and not significant one with percentage of lean mass on total densitometry, correcting for advanced age, duration of disease, GC therapy, and disease activity. In the last model, advanced age (p<0.001) and copeptin (p<0.001) showed a direct and significant association with HeartSCORE, correcting for parameters of disease while serodiagnosis, duration of disease, GC therapy, and disease activity.

Table 1. Multivariate linear regression analysis

Covariates associated with lumbar TBS	B-coefficient	CI 95%	p-value
Age	-0.005	(-0.007- -0.002)	0.001
GC	-0.068	(-0.125- -0.011)	0.021
T-Score	0.049	(0.020-0.079)	0.002
Copeptin	-0.014	(-0.023- -0.006)	0.002
Covariates associated with HeartSCORE cardiovascular risk score	**B-coefficient**	**CI 95%**	**p-value**
Age	0.242	(0.180-0.304)	<0.001
Duration of disease	-0.045	(-0.099-0.008)	0.096
RF and/or ACPA +	-0.224	(-1.855-1.407)	0.782
GC	0.840	(-0.454-2.135)	0.195
Copeptin	0.345	(0.172-0.518)	<0.001
Remission	0.502	(-0.848-1.853)	0.454

Conclusion: At univariate analysis osteometabolic alterations were associated with disease activity, but not with GC therapy and serodiagnosis. At the multivariate analysis, the association of disease activity and TBS values, did not reach the statistical significance, probably for the loss of statistical power. However, GC therapy, as well as advanced age, low lumbar T-score and high value of copeptin, remained independently associated with lower TBS value. Disease parameters were not associated with lower percentage of lean mass at total body densitometry and higher HeartSCORE values, while advanced age and copeptin were associated with bone health and cardiovascular risk.

AB0357 INCREASED SOLUBLE INTERLEUKIN 2 RECEPTOR IS ASSOCIATED WITH UNDERWEIGHT IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

H. W. Zheng[1], J. Pan[1], Y. W. Zou[1], J. D. MA[1], J. Lin[1], Z. M. Ouyang[1], Q. Zhang[1], Q. Y. Song[2], L. W. Su[2], Y. Su[2], L. Dai[1]. [1]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology and Immunology, Guangzhou, China*; [2]*Sun Yat-sen University, Zhongshan School of Medicine, Guangzhou, China*

Background: It have been reported that adipose tissue with proinflammatory properties and obese body mass index (BMI) are involved in rheumatoid arthritis (RA) disease severity. However, less attention was focused on underweight BMI in RA, especially in the early stage.
Objectives: This study aims to investigate the association of underweight with RA disease characteristics and its potential mechanism in early RA.
Methods: This cross-sectional study was carried out retrospectively based on our Chinese RA cohort and controls of general population. Clinical data in RA patients as well as BMI in both RA patients and controls were collected. Early RA patients (disease duration ≤ 12 months) and age- and sex- matched controls were included in this study. Serum levels of inflammatory cytokines including soluble interleukin 2 receptor (sIL-2R), TNF-α, IL-6, IL-1β, IL-8, and IL-10 were detected by chemiluminescent immunoassay.
Results: ① Among 1511 RA patients recruited in the cohort, there were 293 (19.4%) patients with early RA, and 221 early RA patients (mean age 49.4±13.1 years with 69.7% female) and 442 age- and sex- matched (1:2 ratio) controls were eligible for analysis. ② Compared with matched controls, early RA patients had a lower BMI (21.9 ± 3.2 kg/m^2 *vs.* 23.3 ± 2.9 kg/m^2) together with a higher proportion of underweight (16.3% *vs.* 2.0%, both $P < 0.05$). Further compared with matched male controls, male patients with early RA also had a higher proportion of underweight (22.4% *vs.* 0%, $P < 0.001$). Surprisingly, compared with female patients, male patients with early RA had a lower BMI (21.1 ± 2.9 kg/m^2 *vs.* 22.3 ± 3.3 kg/m^2) together with a higher proportion of underweight (22.4% *vs.* 13.6%, both $P < 0.05$). On the contrary to patients, matched male controls had a higher BMI (25.0 ± 2.6 kg/m^2 *vs.* 22.6 ± 2.7 kg/m^2) and less proportion of underweight (0% *vs.* 2.9%, both $P < 0.05$) than female controls. ③ Compared with those without underweight, early RA patients with underweight were younger, more male, more active smoking and lower rate of positive ACPA (all $P < 0.05$). ④ Early RA patients with underweight had a higher level of sIL-2R than those without (median 7.83×10^2 U/ml *vs.* 4.97×10^2 U/ml, $P < 0.001$). Spearman correlation analysis showed that BMI was negatively correlated with sIL-2R (r = -0.393, $P < 0.001$). ⑤ Multivariate logistic regression analysis showed that sIL-2R (OR = 1.127, 95% CI 1.058-1.401) was positively associated with underweight in patients with early RA.
Conclusion: Increased serum sIL-2R was associated with underweight in patients with early RA. The underling mechanism of sIL-2R and underweight in RA need further exploration.

AB0358 PLAIN HAND X-RAY-BASED MACHINE LEARNING MODEL THAT PREDICTS BONE MINERAL DENSITY IN RA PATIENTS

Keywords: Osteoporosis, Rheumatoid arthritis

R. Saito[1,2], T. Fujii[1,3], T. Yoshida[4], K. Murata[1,3], H. Onizawa[3], A. Onishi[3], K. Murakami[5], M. Tanaka[4], K. Omura[6], A. Morinobu[7], S. Matsuda[1]. [1]*Kyoto University, Department of Orthopedics surgery, Kyoto, Japan*; [2]*Kobe City Medical Center General Hospital, Department of Orthopaedic Surgery, Kobe, Japan*; [3]*Kyoto University, Department of Advanced Medicine for Rheumatic Diseases, Kyoto, Japan*; [4]*Kyoto Prefectural University of Medicine, Department of Epidemiology for Community Health and Medicine, Kyoto, Japan*; [5]*Kyoto University, Center for Cancer Immunotherapy and Immunobiology, Kyoto, Japan*; [6]*Kobe City Medical Center General Hospital, Department of Rheumatology, Kobe, Japan*; [7]*Kyoto University, Department of Rheumatology and Clinical Immunology, Kyoto, Japan*

Background: Rheumatoid arthritis(RA) is known as a risk factor for osteoporosis. However, few patients with osteoporotic fractures have measured bone mineral density (BMD) before fracture[1]. Therefore, there is still a need for the development of a simple screening method.
Objectives: The previous studies showed that BMD correlates with the second metacarpal cortical index (2MCI)[2,3,4]. This study aims to build a machine learning model that effectively predicts BMD from plain X-rays to identify high-risk patients for osteoporosis.
Methods: Among the RA patients enrolled in KURAMA cohort between 2012 and 2020, 302 patients received a set of tests, including Dual-energy X-ray absorptiometry(DXA) and bilateral hand X-rays multiple times with a minimal interval of two years. 2MCI was defined as the ratio between the thickness of the cortex and the width of the bone of the second metacarpal(Figure1). We examined the correlation between changes in 2MCI and BMD of the hip and the forearm. Then, we built a machine learning model that predicts BMD using 2MCI and clinical variables. In addition, we evaluated the robustness of the model using an external validation dataset.
Results: The mean age was 62.6 years, and the mean disease duration was 14.1 years. Baseline cross-sectional analysis showed a significant correlation between 2MCI and BMD of the hip and forearm ($p<0.01$). Longitudinal analysis showed a significant correlation between changes in BMD and 2MCI ($p<0.01$). For exploring the best machine learning model, we used Pycaret and found that Bayesian Ridge showed the best performance for predicting BMD of the hip using 2MCI and clinical parameters (MAPE; Mean Absolute Percentage Error = 0.109). Furthermore, model validation using an external dataset revealed good generalized performance (MAPE= 0.145).
Conclusion: Establishing a simple and efficient screening method for osteoporosis is a social issue in an aging society. This study showed that 2MCI significantly correlates not only with BMD at a single time point but also with changes in BMD. Furthermore, a machine learning model built from KURAMA cohort dataset showed good predictive performance when testing on external data. In this study, we proposed a robust model for predicting BMD using a plain hand X-ray in RA patients.

AB0359 SALIVARY ULTRASONOGRAPHY AND HISTOPATHOLOGIC EVALUATION OF SECONDARY SJÖGREN'S SYNDROME IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Ultrasound, Sjögren syndrome, Diagnostic Tests

Y. Park[1], M. Oh[1], B. W. Lee[1], E. J. Kwon[1], Y. S. Lee[2], W. U. Kim[1]. [1]*Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Department of Hospital Pathology, Seoul, Korea, Rep. of (South Korea)*

Background: Novel modalities, such as salivary ultrasonography (SGUS) and shear wave elastography (SWE), have previously been introduced to evaluate Sjögren's syndrome (SS). However, in secondary SS (sSS), the diagnostic performance of SGUS and its relationship with clinicopathological characteristics have not yet been clearly defined.
Objectives: In this study, we aimed to investigate sSS in RA patients using SGUS and SWE and sought to determine its pathological correlations.
Methods: Thirty-one RA patients who presented with sicca symptoms were included to be evaluated on SS, and were compared with 18 primary SS (pSS) patients. All subjects were assessed through SGUS and SWE, as well as conventional diagnostic approaches for SS, including minor salivary gland biopsy (MSGB). In SGUS evaluation, two separate scoring systems, suggested by Hocevar and OMERACT, were used.
Results: Among 31 RA patients with sicca symptoms, 19 (61.2%) were diagnosed as sSS. RA patients with sSS showed significantly lower positivity for anti-Ro/La antibody than did pSS patients. Similar to pSS, SGUS showed good diagnostic performance in differentiating sSS from RA patients with simple sicca symptoms. The sSS and pSS patients exhibited significantly higher lymphoid infiltration areas in MSGB than RA patients without SS. Focus score and lymphoid infiltration areas correlated well with sonographic severity. The severity of fibrosis in MSGB showed better positive correlation with SWE than with SGUS.
Conclusion: sSS is frequent in RA patients and presents with less positivity for anti-Ro/La antibodies than does pSS. Similar to pSS, SGUS and SWE show good diagnostic performance for sSS, reflecting histopathologic severity well in MSGB.

AB0360 IMPACT OF PSYCHOLOGICAL STATUS ON COPING STRATEGIES IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Rheumatoid arthritis, Patient reported outcomes

O. Saidane[1], M. Haddad[1], S. Bouden[1], L. Rouached[1], R. Tekaya[1], I. Mahmoud[1], A. Ben Tekaya[1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia*

Objectives: The aim of our study was to determine whether psychological status has an impact on coping strategies in patients with rheumatoid arthritis (RA).
Methods: We conducted a single-centre cross-sectional study for 6 months from 28 March to 28 September 2021 in which we included patients with RA fulfilling the ACR/EULAR 2010 criteria. Characteristics of RA including disease duration and disease activity by the DAS 28 CRP were recorded. The Brief Cope score was used to assess coping strategies. Five grouped coping strategies were evaluated: problem-focused strategies, cognitive restructuring-based strategies, support-based strategies, avoidance-based strategies, and distraction-based strategies. We assessed anxiety and depression using the Hospital Anxiety and Depression Scale (HAD).
Results: Sixty-five patients were included (89.2% women). Mean age was 58.6 ± 9.9 [24-73 years]. Mean duration of RA was 15 ± 10.6 years. Median DAS28 (CRP) was 3.4 (IQR 25-75: 2.8- 4.6) [1.54-6.67]. Median anxiety score was 6 (IQR 25-75: 1-10). Twelve patients (18.5%) had anxiety. Median depression score was 7 (IQR 25-75: 1-13). Eighteen patients had depression (27.7%). Problem-focused and support-based strategies were the most used among all patients, with respective means of 5.6 and 5.5. The association of grouped coping strategies with anxiety and depression was shown in table I.

Table I: Association of grouped coping strategies with depression and anxiety

	Depression		Anxiety	
	p	β	**p**	β
Problem-focused strategies	0,107	0,202	**0,004**	0,357
Cognitive restructuring-based strategies	**0,000**	-0,434	**0,000**	-0,447
support-based strategies	0,100	-0,206	0,142	-0,184
avoidance-based strategies	**0,001**	0,412	**0,000**	0,470
distraction-based strategies	0,202	-0,160	0,212	0,157

Conclusion: Among our patients, depression and anxiety decreased the use of cognitive restructuring strategies. However, they were associated with an increase in avoidance-based strategies and problem-focused strategies.

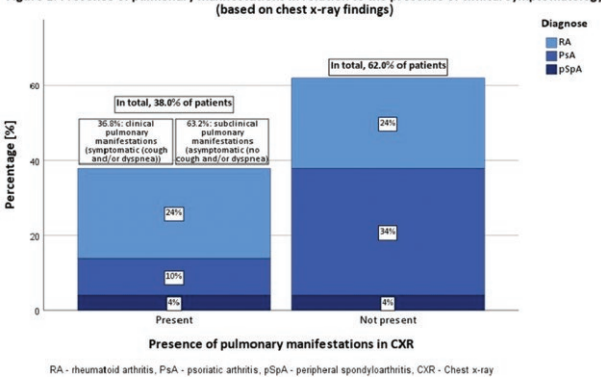
BONN PULSA: PULMONARY SCREENING IN ARTHRITIS - PREVALENCE OF PULMONARY MANIFESTATIONS IN PATIENTS WITH NEWLY DIAGNOSED RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS, AND PERIPHERAL SPONDYLOARTHRITIS



Keywords: Diagnostic Tests, Psoriatic arthritis, Rheumatoid arthritis

L. Winter[1], D. Skowasch[2], M. Weber[3], D. Kütting[4], C. Behning[5], P. Brossart[1], V. Schäfer[1]. [1]*Clinic of Internal Medicine III, University Hospital of Bonn, Department of Oncology, Haematology, Rheumatology, and Clinical Immunology, Bonn, Germany*; [2]*Clinic of Internal Medicine II, University Hospital of Bonn, Department of Pulmonology, Bonn, Germany*; [3]*Clinic of Internal Medicine II, University Hospital of Bonn, Department of Interventional Cardiology and Echocardiography, Bonn, Germany*; [4]*University Hospital of Bonn, Department of Diagnostic and Interventional Radiology, Bonn, Germany*; [5]*University Hospital of Bonn, Department of Medical Biometry, Informatics, and Epidemiology, Bonn, Germany*

Background: Pulmonary impairment in rheumatic diseases is a common, but poorly understood and deficient screened and managed extraarticular manifestation, which causes a huge increase in morbidity and mortality[1]. As previous studies focused on rheumatoid arthritis (RA) and in some intent on psoriatic arthritis (PsA), data for patients with peripheral spondyloarthritis (pSpA) is lacking.
Objectives: To investigate the prevalence of clinical and subclinical pulmonary manifestations in newly diagnosed patients with RA, PsA, and pSpA and to compare different baseline examination results to develop a screening proposal for detecting patients at risk.
Methods: This clinical-prospective, longitudinal cohort study included a diagnostic workup consisting of a questionnaire for patient history, a physical examination, a body plethysmography with CO diffusion capacity (DLCO), a 6-minute walk test, laboratory parameters, and a chest x-ray (CXR) at the time of the initial diagnosis of arthritis disease, and at four additional time points in three-month intervals. This paper focuses on the baseline characteristics.

Results: 54 outpatients (26 RA, 24 PsA, 4 pSpA) and 26 age- and gender-matched controls were examined. Pulmonary impairment, in the sense of a morphologically abnormal CXR, was diagnosed in 19 arthritis patients (38.0%). 36.8% of these suffered from clinical symptoms, such as cough and/or dyspnea. However, 63.2% presented subclinical, asymptomatic pulmonary abnormalities (see Figure 1). The baseline results of several examinations are illustrated in Table 1. An elevation of rheumatoid factor (> 14 IU/ml) showed an association with the manifestation of RA (p=0.002) as well as with the presence of pulmonary affection (p=0.008). In addition, the mean age of patients with pulmonary abnormalities (57.0 ± 12.8 yrs.) was different from that of patients without such abnormalities (43.9 ± 14.3 yrs.), with a p-value of 0.002. The association between the activity of arthritis disease, assessed by Disease Activity Score in 28 joints using CRP (DAS-28CRP), and CXR findings proved to be significant (p=0.011). A DAS28CRP less than 3.2 (remission or low disease activity) indicated non-pathological findings in CXR.
Conclusion: The prevalence of pulmonary manifestations was more than one-third, of which more than two-thirds presented asymptomatic. The large proportion of asymptomatic subjects highlights the need for the implementation of a pulmonary screening at the initial diagnosis of arthritis disease. By alerting physicians, especially in the observed age cohort of 57 years with elevated RF levels, morbidity and mortality could be reduced.

AB0362 PROFESSIONAL COUNTRY-WIDE SURVEY ON CLINICAL DECISION-MAKING IN THE TREATMENT OF RHEUMATOID ARTHRITIS

Keywords: Work-related issues, Disease-modifying Drugs (DMARDs), Best practices

O. Rusinovich[1], E. Calvo-Aranda[2], M. D. C. Uyaguari Morocho[3], A. Pareja Martinez[4], P. Navarro Palomo[5], P. Navarro[1], M. Cantalejo Moreira[1], A. J. Diaz Oca[1], M. Machattou[5], M. Alonso de Francisco[5], C. Navarro Joven[5], M. Fernandez Castro[5], H. Godoy[5], C. Merino Argumánez[5], B. Garcia-Magallon[5], J. Sanz[5], C. Barbadillo Mateos[5], J. Campos Esteban[5], J. L. Andréu Sánchez[5], L. F. De Villa[5], S. Gonzalo Pascua[6]. [1]*Hospital Universitario de Fuenlabrada, Rheumatology, Fuenlabrada, Spain*; [2]*Hospital Universitario Infanta Leonor, Rheumatology, Madrid, Spain*; [3]*La Paz University Hospital, Rheumatology, Madrid, Spain*; [4]*Hospital Universitario del Sureste, Rheumatology, Arganda del Rey, Spain*; [5]*Puerta de Hierro Majadahonda University Hospital, Rheumatology, Majadahonda, Spain*; [6]*Hospital Universitario de Fuenlabrada, Internal Medicine, Fuenlabrada, Spain*

Background: Incorporation of conventional synthetic (cs), biologic (b) and targeted synthetic (ts) disease-modifying drugs (DMARDs) has enriched the therapeutic arsenal, but at the same time has complicated the decision-making process, since it requires considering not only the profile of each patient and the characteristics of each drug, but also the high cost of many of them and diverse administrative limitations.
Objectives: To analyze the way of acting of Spanish rheumatologists in different clinical situations in order to understand the decision-making process in the treatment of rheumatoid arthritis (RA).
Methods: A questionnaire that consisted of 15 questions was sent to several groups of rheumatologists country wide between October 19 and 26, 2022. Descriptive statistical analysis and Pearson's Chi2 test were performed to compare responses to the items by the different groups, significance level 0.05 (p>0.05 N.S.)
Results: A total of 108 questionnaires were collected. Work experience of the respondents is reflected in Table 1. In patients with recent-onset RA associated with poor prognostic factors, in addition to corticosteroids half of the respondents (50%) opt to start treatment with csDMARD + rapid escalation to d/tsDMARD if clinical response is insufficient. The most important factor when choosing the drug is the patient´s profile (47.2%), followed by clinical practice guidelines (34.3%). The most relevant factors when choosing each DMARD were: anti-TNF - cost-effectiveness (47.2%); anti-IL6 - efficacy (72.2%); abatacept - efficacy and safety in patients with RA-associated interstitial lung disease (53.7%); rituximab - its safety in patients that didn´t respond to other treatments (76.9%); and JAK inhibitor - its possibility of use in monotherapy (40.7%). The most important factors that lead to change treatment are the disease activity measures (57.4%) and personal perception of the clinician based on anamnesis and physical examination (31.5%). If there is a good therapeutic response, the majority of respondents first taper the b/tsDMARD (50%). If bDMARD-csDMARD combination therapy is used, 59.3% of respondents try to maintain csDMARD in addition to b/tsDAMRD. Regarding the use of corticosteroids, the vast majority of colleagues (79.6%) prefer to try to discontinue them as soon as possible. In case of pregnancy, more than half of the respondents (59.3%) switch to a safer drug. Incidentally diagnosed cancer is a reason for discontinuation of all b/tsDMARD for 47.2% of respondents, while 29.6% additionally discontinue csDMARD and use corticosteroids for disease control; in this clinical situation, respondents with <30 years of work experience discontinue all DMARDs in higher proportion than those with >30 years of work experience (p<0.05). The majority of respondents (80.6%) consider biosimilar drugs to be equally effective and safe as the origininator.

Table 1. Years of work experience in rheumatology.

Resident	9,3%
0-10 years	43,4%
11-20 years	17,6%
21-30 years	9,3%
>30 years	20,4%

Conclusion: The study revealed a striking heterogeneity in the way of acting in complex clinical situations, which confirms that the decision-making process depends on many factors but also that there is still room for homogenizing clinical practice guidelines in rheumatology. However, there seems to be agreement on the need to minimize systemic exposure to corticosteroids, on the use of disease activity measures to evaluate therapeutic response and on the wide acceptance of biosimilar drugs.

AB0363 UTILITY OF EPITHELIAL CELL BIOMARKERS TO ASSESS SEVERITY AND DISCRIMINATE BETWEEN DIFFERENT PATTERNS OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Biomarkers, Lungs

F. Paulin[1], N. Antoniol[2,3], M. Stolar[1], P. Barrios[1], C. Fernandez[4], F. Ferrero[1], L. Fassola[5], D. Alonso[6], D. Litewka[4], J. L. Presas[1], C. Perandones[2,3], E. Buschiazzo[7]. Ferrer, Radiology, Buenos Aires, Argentina*; [6]*CIAC - Centro Integral de Alta Complejidad, Rheumatology, Salta, Argentina*; [7]*Sr Hospital del Milagro, Rheumatology, Salta, Argentina*

Background: Several biomarkers have been studied in rheumatoid arthritis (RA) interstitial lung disease (ILD), but their clinical application has not been well established yet [1]. Given that usual interstitial pneumonia (UIP) is the most common pattern of ILD in patients with RA, the utilization of biomarkers that give information about the epithelial cell activation could be an interesting approach to assess the severity of lung disease in these patients [2].
Objectives: To know the ability of CA19-9, CA125 and CEA to discriminate different patterns on HRCT and assess the severity of ILD in patients with RA.
Methods: We conducted a cross sectional study. Patients with a diagnosis of RA-ILD who were evaluated in three different rheumatic diseases clinics between December 2021 and January 2023 were consecutively included. The diagnosis of RA was defined according to ACR/EULAR 2010 classification criteria. The diagnosis of ILD was confirmed by an experienced radiologist. We performed HRCT, lung function tests, joint disease evaluation, and blood extraction to determine the values of CA 19-9, CA 125, CEA, rheumatoid factor (RF) and ACPAs. The pattern found on HRCT was classified in UIP pattern, probable UIP, indeterminate for UIP, and suggestive of another diagnosis, as proposed the inter society consensus of 2022 [4]. The score proposed by Goh was calculated to determine the extension of lung opacities (inflammatory, fibrotic, and total extension scores) [5]. The joint disease activity was assessed using the DAS28 score. The values of the biomarkers in serum were measured by electrochemiluminescence. T-test, Mann Whitney test, and Chi square were used for comparisons. The Spearman test was used for correlation analysis.
Results: We included 38 patients, 29 were women (76.3%). The mean (SD) age was of 62.1 (11.5) years. The median (IQR) of DAS28 was 3.3 (2.6-4). Regarding serologic tests, 35/36 (97.2%) and 36/37 (97.3) were positive for ACPAs and RF respectively. In relation to lung disease, the mean (SD) of FVC% was 83.8 (23.4) and the median (IQR) DLCO was 59 (52-81). Eighteen patients (47.3%) showed UIP or probable UIP pattern in the HRCT, while 20 (52.7%) had another pattern. The median (IQR) of Goh score for total lung disease extension was 20 (8-25). Patients with UIP pattern showed significantly higher values of CA19-9 [11.5 (7-35.7) vs 6.5 (2-12.5), p=0.017] and a trend to higher values of CA125 [22 (15-52) vs 14 (11.4-20.7), p=0.06] than those with other patterns. The values of CA19-9 showed a good correlation with total Goh score (r=0.52, p=0.02) and fibrosis Goh score (r=0.65, p=0.03) in patients with UIP pattern. Also, the values of CEA showed an acceptable correlation with total Goh score (r=0.46, p=0.05) and fibrosis Goh score (r=0.43, p=0.07) in patients with UIP pattern.
Conclusion: Patients with RA ILD and UIP pattern showed higher plasmatic values of biomarkers that reflect epithelial cell activation. Also, the values of some of these biomarkers showed good correlation with the extension of the disease on HRCT. Therefore, these biomarkers could be a useful tool to identify a more aggressive clinical behavior in patients with RA ILD.

AB0364 CIGARETTE SMOKING AMONGST RHEUMATOID ARTHRITIS PATIENTS IN A TERTIARY CENTER IN SOUTH AFRICA

Keywords: Patient reported outcomes, Descriptive Studies, Rheumatoid arthritis

S. Le Roux[1], H. Bagula[1], S. A. Didi[2], R. Van Zyl-Smit[3], B. Hodkinson[2]. *[1]Groote Schuur Hospital, Department of Medicine, Cape Town, South Africa*; *[2]Groote Schuur Hospital, Rheumatology, Department of Medicine, Cape Town, South Africa*; *[3]Groote Schuur Hospital, Pulmonology, Department of Medicine, Cape Town, South Africa*

Background: Cigarette smoking is associated with poorer outcomes amongst rheumatoid arthritis (RA) sufferers, with poorer disease control, increased extra-articular complications and more comorbidities[1]. There are currently no data from sub-Saharan Africa.

Objectives: To describe the prevalence of cigarette smoking, and explore disease control, comorbidities, extra-articular disease and attitudes of smokers to their habit amongst RA patients in an outpatient clinic at tertiary level public hospital in South Africa. Further, we asked patients about the impact of prohibition during the COVID pandemic.

Methods: A cross-sectional study of consenting adult outpatients with RA meeting the EULAR/ACR 2010 Classification Criteria. Demographic, clinical and patient-reported outcome measures (PROMs) including the Health Assessment Questionnaire-Disability Index (HAQ-DI), FACIT-fatigue scale, Brief Pain Inventory-short form and Hospital Anxiety and Depression Scale (HADs) together with a questionnaire about smoking and Fagerström test for nicotine dependence were collated.

Results: Of 632 patients (536 females), the mean (SD) age and disease duration were 55.4 (13.0) and 10.1 (9.3) years. A poor socio-economic setting (SES) (defined using a pooled index) was noted in 67.0%. The mean (SD) Clinical Disease Activity Index (CDAI) and HAQ-DI were 14.3 (11.8) and 1.5 (0.7). The cohort included 218 (34,5%) smokers, and 89 (14.1%) ex-smokers, and more males smoked (49/218 vs 47/414, p=0,0002). Compared to non- or ex-smokers, smokers had lower BMI (29.7 vs 32.7 (p= 0.01), higher anxiety scores (8.8 vs 8.0, p=0,048) and incidence of COPD (7.8 % vs 1.0%, p< 0.005). The vast majority (74.1%) had two or more comorbidities, and the commonest comorbidities were hypertension, dyslipidaemia and diabetes. There were no significant differences in age of RA onset, disease duration, SES, number of comorbidities, CDAI nor its individual components, extra-articular diseases nor in HAQ-DI, FACIT, depression or pain scores. Of 160 patients who completed the smoking questionnaire, 83 (51.9%) believed smoking worsened their arthritis, and 119 (74.4%) reported receiving smoking cessation advice at the RA clinic. Participants' most common reasons for smoking were emotional support (32.2%), nicotine craving (21.7%) and pain control (27.3%). Although 50.1% felt that living with RA made quitting difficult, 86.9% had considered quitting, and almost half (45.6%) had previously quit for more than 3 months. The Fagerström score revealed mild, moderate and severe nicotine dependence in 67.5%, 24.4%, and 7.5% respectively. The Fageström score was significantly associated with anxiety (r=0.2, p=0.02) and depression (r=0.28, p<0.005). Smoking prohibition during COVID pandemic resulted in 60.0% (96) patients quitting or reducing cigarette consumption. Patients felt that helpful services from their RA team might include referral to a smoking cessation clinic (48.1%) and availability of more reading material (36.1%).

Conclusion: In this cohort of indigent RA patients, a third of RA patients are smokers, with higher prevalence in males, and associated with lower BMI and higher anxiety scores but with no differences in disease parameters or other PROM's. Smoking is a modifiable risk factor, of great importance given the high prevalence of comorbidities in the cohort. Only half the cohort were aware that smoking worsened their RA disease control. The mild to moderate nicotine dependence in this cohort, together with patients' willingness to quit should encourage both patient and health care providers to positively engage in smoking cessation.

AB0365 PATIENTS WITH RHEUMATOID ARTHRITIS CLASSIFIED AS "HIGH ACTIVITY" ACCORDING TO DAS28 OR CDAI INCLUDE 55% AND 70% WHO SCREEN POSITIVE FOR DEPRESSION AND 67% AND 80% WHO SCREEN POSITIVE FOR FIBROMYALGIA, RESPECTIVELY

Keywords: Rheumatoid arthritis

T. Pincus[1], R. Hunter[1], N. Rodwell[2,3]. *[1]RUSH University Medical Center, Medicine, Division of Rheumatology, Chicago, United States of America*; *[2]Liverpool Hospital, Rheumatology, Liverpool, Australia*; *[3]Ingham Institute for Applied Medical Research, Rheumatology, Liverpool, Australia*

Background: No single measure can serve to assess all patients with rheumatoid arthritis (RA), and indices based on a core data set of 7 measures are used in clinical trials and clinical care. Two prominent RA indices are DAS28 (disease activity score 28) and CDAI (clinical disease activity index), which are classified into 4 categories of high, moderate, low disease activity and remission. It has been reported that comorbid fibromyalgia (FM) and depression (DEP) may elevate DAS28 and CDAI values, but systematic comparison of the proportions of patients in different activity categories who screen positive for these comorbidities has not been reported. Feasible screening for FM and DEP is available using MDHAQ (multiple dimensional health assessment questionnaire) FM and DEP indices, which agree more than 80% with reference standards.

Objectives: To analyze the proportion of routine care RA patients who screen positive for FM and DEP according to the 4 DAS28 and CDAI activity categories.

Methods: The 7 RA core data set measures - SJC, TJC, PaGA, PhGA, ESR, CRP, physical function and pain - were collected in unselected RA patients in a cross-sectional study at a routine care visit to an academic site. The patient measures were all collected on an MDHAQ which is completed by all patients and includes physical function, pain, PaGA, fatigue visual numeric scales (VNS), 0-3.3 DEP query, self-report 0-54 patient RADAI painful joint count, 60-symptom checklist including DEP, medical history queries, and FAST4 and MDS2 indices. FAST4 FM screen is positive if 3/4 of: pain VNS ≥6/10, fatigue VNS ≥6/10, self-reported painful joint count ≥16/54, and/or symptom checklist ≥16/60. MDS2 DEP screen is positive if 0-3.3 DEP response is ≥2.2 OR positive DEP on the symptom checklist. DAS28-ESR and CDAI were computed according to standard methods, and patients were classified into 4 activity categories: high (>5.1/28 and >22/76), moderate (3.2-5.1 and 10.1-22), low (2.6-3.2 and 2.9-10), and remission (≤2.6 and 2.8), for DAS28-ESR and CDAI, respectively. The median SJC, TJC, and proportions of FAST4 and MDS2 patients in each category were compared using chi-square analyses.

Results: Among 122 patients, categories of remission, low, moderate, and high activity, respectively, included 44%, 15% 34%, and 7% by DAS28-ESR, and 13%, 31%, 39% and 16% by CDAI. Median SJC was 0, 0, 2 and 4 for DAS28-ESR and 0, 0, 0 and 4 for CDAI categories. Median TJC was 0, 2, 5 and 5 in DAS28-ESR and 0, 1, 3 and 14 in 4 CDAI categories (Table 1). Positive FM FAST4 FM screen was seen in 13%, 22%, 44% and 67% in 4 DAS28-ESR categories and 0%, 2.6%, 38%, and 80% in 4 CDAI categories. Positive DEP MDS2 was seen in 20%, 44%, 46% and 56% in 4 DAS28-ESR categories, and 6%, 24%, 40% and 70% in 4 CDAI categories.

Conclusion: Among RA patients classified as high DAS28-ESR or CDAI "activity", respectively, 55% and 70% screened positive for DEP, 67% and 80% for FM respectively. These phenomena may affect treat-to-target and other aspects of RA management.

AB0366 RHEUMATOID ARTHRITIS PATIENTS WITH ≥6/28 TENDER JOINTS AND PATIENT AND PHYSICIAN GLOBAL ASSESSMENTS ≥3/10 HAVE SIGNIFICANTLY HIGHER LEVELS OF COMORBIDITIES WHICH MAY NOT BE RELATED TO INFLAMMATORY ACTIVITY, INCLUDING FIBROMYALGIA, DEPRESSION, FATIGUE, NECK PAIN, BACK PAIN, AND DEFORMED JOINTS

Keywords: Rheumatoid arthritis

R. Hunter[1], N. Rodwell[2,3], T. Pincus[1]. [1]*RUSH University Medical Center, Medicine, Division of Rheumatology, Chicago, United States of America*; [2]*Liverpool Hospital, Rheumatology, Liverpool, Australia*; [3]*Ingham Institute for Applied Medical Research, Rheumatology, Liverpool, Australia*

Background: Patients with rheumatoid arthritis (RA) are assessed in clinical trials and clinical care according to a core dataset and derived indices, which include tender (TJC) and swollen (SJC) joint counts, erythrocyte sedimentation rate (ESR), and patient (PaGA) and/or physician global assessments (PhGA). Many clinical trials require TJC and/or SJC ≥6 for enrollment, and improvement criteria require that SJC and TJC are 20%, 50%, or 70% better. It has been reported that TJC, PaGA, and PhGA may be elevated by comorbidities in the presence of little or no (or high) inflammatory activity, associated with high levels of fibromyalgia (FM), depression (DEP), fatigue (FT), back pain (Bpain), neck pain (Npain), and/or joints with deformity/limited motion (DJC). The likelihood and extent of elevations of RA measures associated with these comorbidities has not been extensively analyzed. FM, DEP, BPain, Npain, and FAT can be screened for on a multidimensional health assessment questionnaire (MDHAQ), and DJC can be included on a 28 joint count.

Objectives: To analyze RA patients seen in a routine care academic setting for possible elevations of SJC, TJC, ESR, PaGA and PhGA associated with positive screening for FM, DEP, FT, Bpain, Npain, and DJC.

Methods: A cross-sectional study was conducted at a routine care visit of RA patients to an academic rheumatology setting. All 7 RA core dataset measures were collected, including SJC, TJC, ESR, PaGL, and PhGL. The patient self-report measures were collected on an MDHAQ, completed by all patients in 5-10 minutes at this setting, which includes queries for FT, Npain, Bpain, and indices to screen for FM - FAST4 (fibromyalgia assessment screening tool), and DEP - MDS2 (MDHAQ depression screen). FAST4 and MDS2 agree more than 80% with reference standards but can be feasibly collected in routine care on a single questionnaire. Patients were classified into 2 groups according to clinically relevant cut-points for each possibly non-inflammatory variable, and the number of patients above and below these cut points compared by chi square analyses.

Results: In 125 RA patients with complete data, significant differences (p<0.01) were seen for TJC <6 vs ≥6, PaGA <3 vs ≥3, and PhGA <3 vs ≥3, according to positive FAST4 FM, DEP MDS2, Bpain and Npain, FAT ≥3/10, and DJC ≥6. No significant differences were seen according to ESR <30 vs ≥30 or SJC <6 vs ≥6, other than a difference in SJC <6 vs ≥6 for patients with DJC <6 vs ≥6, (Table 1).

Conclusion: TJC, PaGA, and PhGA, but not ESR or SJC, are associated with positive screening for FM, depression, back pain, neck pain, fatigue, and joints with deformity/limited motion, that may not result from inflammatory activity. These elevations may affect DAS28 and CDAI scores, interpretation for treat-to-target, and general management. It is feasible to screen for these comorbidities in routine care, which may enhance clinical decisions and outcomes.

Number of patients in different categories

AB0367 ANXIETY AND DEPRESSION IN RHEUMATOID ARTHRITIS DISEASE: A CROSS SECTIONAL STUDY AMONG 100 TUNISIAN PATIENTS

Keywords: Quality of life, Rheumatoid arthritis, Mental health

M. Brahem[1], A. Khemiri[1], A. Ben Salem[1], O. Jomaa[1], R. Sarraj[1], H. Hachfi[1], Y. Mohamed[1]. [1]*Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia*

Background: Rheumatoid Arthritis (RA) is a common chronic inflammatory disease, which can lead to structural joint damage and important handicap. RA is associated with pain, fatigue, functional disability and deterioration of emotional state that influence people's lives and may cause psychiatric signs and symptoms, particularly anxiety and depression.

Objectives: The present study aims to Assess the frequency of anxiety and depression in patients with RA and to determine their associated factors.

Methods: This is a cross sectional study conducted among patients followed in the rheumatology department at TAHER SFAR University Hospital in Mahdia. All patients were diagnosed with rheumatoid arthritis based on ACR/EULAR criteria. We included only patients without any previous psychiatric history and assessed them for anxiety and depression symptoms using the Hospital Anxiety and Depression scale (HADS) after a clear consent.

Results: We included in our study 100 patients with a mean age of 53.2 years (±11.21). The average duration of disease was 11.1 ± 8.9 years. The assessment of the RA activity showed a severe activity RA in 34% of participants. After analyzing the questionnaire results, according to HADS, the mean HAD-D score was 8.39 ±3.84 with 30% of definite depressed patients while the mean HAD-A score was 7.79± 3.6 with 24 patients presenting definite anxiety disorder. A significant association was found between the presence of depressive disorder and high disease activity (p<0.01), higher HAQ level (p=0.02), higher NTJ (Number of Tender Joints) (p<0.01), NSJ (Number of Swollen Joints) (p<0.01) and higher VAS (Visual Analogue Scale) (p=0.04). Anxiety was also associated with severe activity stage (p<0.01), higher HAQ level (p<0.01), higher NSJ (p=0.01) and NTJ (p<0.01).

Conclusion: Our study showed that more than quart of RA patients suffers from anxiety and/or depression, and these troubles were related essentially to active disease and functional disability. Screening for these disorders and the management of the RA activity will be necessary during follow up of our patients to ameliorate their quality of life.

AB0368

DIFFERENCES IN THE ASSESSMENT OF COMORBIDITIES (FATIGUE AND DEPRESSION) BETWEEN RA PATIENTS AND PHYSICIANS. DO WE MEASURE THE SAME?

Keywords: Patient reported outcomes, Rheumatoid arthritis, Outcome measures

R. Morlà[1], B. Frade-Sosa[2], N. Sapena[2,3], J. A. Gómez-Puerta[2], R. Sanmartí[2].
[1]*Hospital Clinic de Barcelona, Rheumatology Department, Bareclona, Spain*;
[2]*Hospital Clinic de Barcelona, Rheumatology Department, Barcelona, Spain*;
[3]*Hospital Clinic de Barcelona, Rheumatology Deprtment, Barcelona, Spain*

Background: Differences in physicians' assessment of disease activity and patients' perception of disease activity have been described [1]. Two of the most important disease-related symptoms experienced by patients are fatigue and depression, which are not routinely assessed by physicians [2].
Objectives: To study the differences between patient and physician perspectives on fatigue and depression, as well as on other biological, clinical and self-reported disease variables in a group of patients with established rheumatoid arthritis (RA).
Methods: Patients with RA (ACR/EULAR,2010) followed up by the Arthritis Unit who agreed to participate in this study were included consecutively in the Arthritis Unit for 3 months. They fulfilled 3 questionnaires to evaluate fatigue and depression: 1. MDHAQ, that includes: 0-10 physical function (FN) according to modified HAQ (0-10), visual analogue scale (VAS) 0-10 for pain (PN), VAS 0-10 for fatigue (VAS-Fatigue) (in the question 9, considering high fatigue with >5 cut off) and patient global assessment (PGA) to calculate RAPID3, a review of 60 symptoms (ROS60) and self-assessment 48 joint count (RADAI48). 2. FACIT-(FS)=FACIT-Fatigue, 13 questions (0-4 score) with a global score of 0-52 (lower scores indicate worse fatigue). 3. Patient Health Questionnaire 9= PHQ9, 10 questions with PHQ9>10 screened for depression. Physical articular examination (28TJC, 28SJC), laboratory test (CRP, ESR), composite EULAR disease activity indices (DAS28, DAS28 CRP, CDAI and SDAI), demographic (sex, age, BMI), patient´s disease characteristics and the Physician Global Assessment (PhGA) for the disease were collected. A descriptive analysis of the variables was done, and Pearson´s correlation between PhGA and PGA, and the rest of variables studied was performed.
Results: A total of 75 patients (84% females) with RA were recruited, with a mean age of 62±11.6 years, a mean disease duration of 14.6± 5 years and a mean BMI of 22.8 ± 8.0. 64% were under with bDMARD and 45.3% with glucocorticoids treatment. Depression (PHQ9>10) was observed in 12 patients (16%) and in 31 (41.2%) of patients we observed high fatigue (VAS-fatigue>5/10). Correlation results between PGA and Fatigue (FS) were almost good for VAS-Fatigue (r=0.604, p<0.001) and for PHQ9>10(r=0.616, p<0.001), and almost good for FACIT(FS)(r=-0.517, p<0.001). On the other hand, correlations between PhGA were smaller with fatigue (Fatigue (FS): r=-0.428, p<0.001; VAS-Fatigue: r=0.451 p<0.001) and with depression (PHQ9: r= 0,477 p<0.001). Correlation of the rest of studied variables (DAS28, CDAI, SDAI, 28TJC, 28SJC, CRP, ESR and ROS) were smaller for PhGA than for PGA, except for 28SJC, where the assessment of physician is closer to that the patient (Table 1).
Conclusion: The patient's perception of disease status is better than the physician's perception of these two important comorbidities associated with RA, as well as disease activity indices. Clinicians have to take into account scores on fatigue and depression questionnaires or scales when assessing patients with RA.

Background: Clinical RA-associated ILD (RA-ILD) presents in almost 10% of RA patients but subclinical RA-associated ILD is detected in 20-60%. The course of subclinical RA-ILD is not fully known. Some patients have disease progression to pulmonary symptoms, decreased respiratory function and high levels of morbidity and mortality. It is necessary to improve ways to determinate risk of progression in patients with subclinical RA-ILD.
Objectives: To describe a cohort of patients with clinical and subclinical Rheumatoid Arthritis-associated Interstitial Lung Disease (RA-ILD) and to compare the evolution and progression of both.
Methods: Ambispective observational study of a cohort of patients with RA-ILD confirmed by respiratory function tests (RFT) or high-resolution computed tomography (HRCT). From January 2019 to December 2021, all patients with these diagnoses from RA monographic clinic were included consecutively. Data on the onset of ILD were included retrospectively and data at the end of follow-up prospectively (last review). The % of patients who had subclinical ILD was evaluated, defined as pulmonary involvement due to a requested HRCT without any previous respiratory symptoms. Outcome: evolution of the final ILD: (1) improvement (improvement in FVC ≥10% or DLCO ≥15% and no radiological progression); 2) no progression (stabilization or improvement in FVC ≤10% or DLCO <15% and no radiological progression); 3) progression (>10% worsening of FVC or >15% DLCO and radiological progression); or 4) death. Demographic variables, activity data (DAS28VSG accumulated 24 months prior to the diagnosis of ILD), RF and ACPA levels, RA severity data and treatments. Descriptive analysis, χ^2 or t-Student, and multivariate logistic regression analysis were performed to find predictive variables for the evolution of ILD.
Results: 50 patients with RA-ILD were included, 18 (36%) had subclinical ILD. The reason for requesting HRCT when they were diagnosed was abnormal chest X-ray in 11 patients (61.1%) and crackles in 7 patients (38.8%). The baseline characteristics of both groups at the time of ILD diagnosis and the evolution are shown in Table 1. The disease duration of the clinical ILD was longer than that of the subclinical ILD 5.6 (5.2) vs. 3.5 (2.4) years, p=0.053). At the moment of ILD diagnosis, the treatments were modified in 10 patients with clinical ILD and in 7 with subclinical ILD (p= 0.593): 8 abatacept, 7 rituximab and one antifibrotic drug were started. A total of 13 patients (26%) progressed and 25 (48%) showed a stabilization or improvement. Four patients died because of non-pulmonary causes. The only variable independently associated with the progression of ILD in the complete sample, adjusted for ACPA titres and age at diagnosis of ILD, was UIP pattern [OR = 5.3 (95%CI 1.1-26.2), p = 0.037]

Table 1. Heatmap of correlation between Patient Global Assesment.

RF titers, mean (SD)	247.3 (244)	339.2 (390)	0.338
Positive ACPA, n (%)	32 (100)	16 (88.9)	0.054
ACPA titers, mean (SD)	395.6 (643)	468 (698)	0.740
Erosions, n (%)	10 (31.2)	5 (27.8)	0.797
Rheumatoid nodules, n (%)	6 (18.8)	3 (16.7)	0.854
Secondary S. Sjogren, n (%)	2 (6.2)	0	0.279
Osteoporosis, n (%)	10 (31.2)	3 (16.7)	0.259
Cumulative DAS28-VSG, mean (SD)	3.4 (1.1)	3.3 (1.2)	0.949
Cumulative ESR, n (%)	26.6 (14.7)	19.1 (13.4)	0.097
Cumulative CRP, n (%)	10.4 (8.9)	13.5 (9.8)	0.299
DMARDs, n (%)	23 (71.9)	16 (88.9)	0.163
Methotrexate, n (%)	13 (40.6)	12 (66.7)	0.077
Leflunomide, n (%)	9 (28.1)	5 (27.8)	0.979
Hydroxichloroquine, n (%)	4 (12.5)	6 (33.3)	0.077
Sulfasalazine, n (%)	1 (3.1)	0	0.448
bDMARD, n (%)	9 (28.1)	3 (16.7)	0.362
Rituximab, n (%)	1 (3.1)	0	0.448
Abatacept, n (%)	2 (6.2)	1 (5.6)	0.920
Anti-TNFα, n (%)	6 (18.8)	2 (11.1)	0.478
Glucocorticoids, n (%)	20 (69)	12 (66.7)	0.869
Glucocorticoids dose, mean (SD)	4.6 (2.2)	6.6 (4.3)	0.153
HRCT pattern			0.407
UIP, n (%)	9 (28.1)	4 (22.2)	
UIP Probable, n (%)	8 (25)	1 (5.6)	
Indeterminate UIP, n (%)	9 (28.1)	9 (50)	
NSIP, n (%)	4 (12.5)	3 (16.7)	
Others, n (%)	2 (6.2)	1 (5.6)	
DLCO-SB, mean (SD)	66.1 (17.9)	80.3 (12.7)	**0.013**
FVC, mean (SD)	86.4 (19.3)	90.6 (15.6)	0.461
FVC<80%, n (%)	10 (40)	5 (38.5)	0.926
ILD evolution at the end of the follow-up (total)			
Improvement, n (%)	8 (25)	4 (22.2)	0.896
Stabilization, n (%)	11 (34.4)	8 (44.4)	
Progression, n (%)	10 (31.2)	5 (27.8)	
Death, n (%)	3 (9.4)	1 (5.5)	

Conclusion: In our cohort, the prevalence of subclinical ILD was high (36%). Although RFT at diagnosis of ILD, specifically DLCO levels, were higher in subclinical ILD than in clinical ILD, progression at the end of follow-up was the same in both groups. The UIP pattern was independently associated with progression. Therefore, taking into account that ILD is one of the main causes of mortality in our patients, we must actively search for this condition in order to treat it early and improve the prognosis.

DISORDERS OF PERIPHERAL LYMPHOCYTE SUBSETS IN RHEUMATOID ARTHRITIS PATIENTS COMPLICATED WITH HASHIMOTO'S THYROIDITIS

Keywords: Comorbidities, Rheumatoid arthritis, Descriptive Studies

T. Cheng[1,2,2], S. X. Zhang[1,1,1,2,2,2,2,2,2], H. Zhang[3], X. LI[1,1,2,2]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; [3]*Shanxi Medical University, First School of Clinical Medicine, Taiyuan, China*

Background: Hashimoto's thyroiditis (HT) is an organ-specific autoimmune disease that is not rare in RA. Hypothyroidism caused by HT can affect the prognosis and quality of life in patients with RA [1]. Many studies showed that immune cells play a critical role in HT [2-3]. However, the alterations of lymphocyte subsets in RA patients with HT are unclear.

Objectives: This study aimed to assess the absolute numbers and proportions of peripheral lymphocyte subsets in RA with HT and investigate the clinical significance.

Methods: A total of 1636 RA patients and 54 gender- and age-matched healthy controls (HCs) were enrolled in this study. Patients were divided into RA-non-HT and RA-HT groups according to the thyroid peroxidase antibody (TPOAb) and thyroid globulin antibody (TgAb). Peripheral lymphocyte subsets of all participants were assessed by flow cytometry. All clinical and laboratory data were analyzed by SPSS 23.0.

Results: Among 30 (1.83%) RA-HT patients, there were more female (P=0.005), suggesting female was more susceptible to developing HT (Figure 1A). In addition, there were higher levels of erythrocyte sedimentation rate (ESR) (P=0.045) and C-reactive protein (CRP) (P=0.042) than those in RA-non-HT (Figure 1B-C). Compared with those of HCs and RA-non-HT, the level of circulating Th17 in RA-HT patients was significantly increased (P<0.05), while those of Tregs decreased (P<0.05), leading to a higher ratio of Th17/Treg (P<0.01). Notably, the level of B cells and Th1 cells, as well as the Th1/Th2 ratio, increased in the RA-HT compared with those of the RA-non-HT (P<0.05) (Figure 1D-F).

Conclusion: The occurrence of RA-HT is closely related to female patients with high disease activity. Disorders of lymphocyte subsets, especially Th17/Treg imbalance, may contribute to HT in RA, which deserves more clinical attention.

Rheumatoid arthritis - comorbidity and clinical aspects

AB0371 PREVALENCE OF CACHEXIA IN A POPULATION OF MOROCCAN WOMEN WITH RHEUMATOID ARTHRITIS

Keywords: Diet and Nutrition, Descriptive Studies

H. Elhani[1,2], H. Taoufik[1], A. Majjad[1], L. Taoubane[1], N. El Ouardi[1], A. Bezza[1]. [1]*Mohamed V Military Training Hospital, Rheumatology, Rabat, Morocco*; [2]*Faculty of Medicine and Pharmacy of Rabat, Rheumatology, Rabat, Morocco*

Background: Prevalence of cachexia in a population of Moroccan women with rheumatoid arthritis.
Objectives: The objective of our study is to assess body composition in women with rheumatoid arthritis (RA) compared to healthy controls.
Methods: We conducted a case-control study of 112 female patients with rheumatoid arthritis according to ACR/EULAR 2010 Rheumatoid Arthritis Classification Criteria; and 224 healthy women of the same age. Body composition and bone mineral density (BMD) results were obtained by Dual-Energy X-Ray Absorptiometry (DXA). Rheumatoid cachexia (RC) was defined as a Lean mass index (LMI) below the 10th percentile and a Fat mass index (FMI) above the 25th percentile compared with the control group. We performed a comparison between RA patients and healthy controls and then performed multiple regression looking for factors associated with rheumatoid cachexia.
Results: The prevalence of rheumatoid cachexia was 42.85% while the mean body mass index (BMI) was the same in both groups. RA patients had higher fat mass and lower lean mass compared with healthy controls. In our population, 78.60% of patients were on methotrexate and 12.50% on TNF inhibitor. Comparison between patients with and without CR showed that patients with CR have high disease activity, with the presence of more bone erosions. Regression showed that CR was significantly associated with bone erosions and disease activity (OR at 33.31 (8.42- 131.70) and 8.98 (1.64 - 49.20) respectively) This was independent of age, erythrocyte sedimentation rate, C-reactive protein, duration of disease, cumulative steroid dose, and use of conventional or biologic background therapies.
Conclusion: Our study showed that nearly half of our RA patients have CR even with high BMI. CR in our work is associated with the presence of high disease activity, and the presence of bone erosions.

AB0372 THE IMPACT OF BODY MASS INDEX ON BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

Z. Baba[1], A. Rafi[1], F. E. Chekkouri[1], A. Mougui[1], I. El Bouchti[1]. [1]*Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Rheumatology, Marrakech, Morocco*

Background: It has long been thought that a higher body mass index is protective against osteoporosis. However, recent studies showed an increase in fracture risk in obese individuals.
Objectives: To study the impact of body mass index (BMI) on bone mineral density (BMD) during rheumatoid arthritis (RA).
Methods: Retrospective study including 260 RA patients meeting the ACR/EULAR 2010 criteria. We collected demographic, clinical, biological, and bone densitometric data from patients.
Results: The mean age was 49.91 ± 12.97 years. The sex ratio F/H was 6.6. The mean DAS28-VS was 5.32 ± 1.35. According to the DAS28-VS, 60.7% of the patients were high activity. The mean BMI was 26.26 ± 4.83 Kg/m². 21.9% of patients were obese, 31.5% were overweight and 2.3% were underweight. The mean BMD was 0.856 ± 0.200 g/cm² at the femoral neck and 0.950 ± 0.218 g/cm² at the lumbar spine. The mean T-SCORE was -1.41 ± 1.48 at the femoral neck and -1.90 ± 1.58 at the lumbar spine. Osteoporosis at one of the two sites was found in 38.4% of patients. Eleven patients (4.8%) had a severe fracture and 6 patients (2.6%) a non-severe fracture. A negative correlation was found between BMI and the presence of osteoporosis at one of the two sites (r=-0.138; p=0.04). BMI was also correlated with T-Score and BMD at the lumbar spine (r=0.196; p=0.007 and r=0.278; p=0.001 respectively). No correlation was found between BMI and T-Score and BMD at the femoral neck level as well as fracture occurrence.
Conclusion: In our study, BMI correlated with BMD and T-SCORE at the lumbar spine, and negatively correlated with the presence of osteoporosis.

AB0373 DEPRESSION IN RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY FROM A TERTIARY CARE HOSPITAL IN NORTH INDIA.

Keywords: Rheumatoid arthritis, Descriptive Studies, Mental health

V. Pai[1], S. S[1], V. S. Rawat[2]. [1]*All India Institute of Medical Sciences, Dept of Internal Medicine - Division of Clinical Immunology & Rheumatology, Rishikesh, India*; [2]*All India Institute of Medical Sciences, Dept of Psychiatry, Rishikesh, India*

Background: Rheumatoid arthritis(RA) is a chronic inflammatory polyarthritis, with deformities associated with poor functional outcome. Psychiatric comorbidities are common among them, contributing to poor outcome.
Objectives: This study was aimed at determining prevalence of depression in RA and its association with disease severity.
Methods: This is a cross-sectional study carried out in the OPD/IPD of Rheumatology in a tertiary care hospital in India. This study recruited 272 patients classified as RA, fulfilling 2010 ACR/EULAR criteria, with minimum duration of illness of at least 1 year. Patients with prior psychiatric illness were excluded. Informed consent was taken from all participating patients, after institute ethical clearance. RA disease activity was measured using DAS28 ESR, and these patients were screened for depression with PHQ-2 questionnaire.**[1]** Patients with depression were further assessed with Depression, Anxiety and Stress Scale (DASS) for depression severity.**[2]** The functional status was assessed with Health Assessment Questionnaire –Disability Index(HAQ-DI). Data were interpreted by descriptive statistics, and correlation assessed using Spearman correlation coefficient. Regression analysis was used to find odds of significant variables associated with depression.
Results: Twenty-three percent of these patients had depression according to PHQ-2 screen. Forty-four (69.8%) of these had depression on further assessment using DASS questionnaire. The median DAS-28 in mild, moderate, severe and extremely severe depression groups were 4.6, 4.9, 6.4 and 5.3, respectively. There was a significant difference between the 5 groups in terms of DAS-28 ($X^2 = 42.209$, $p = <0.001$), with the median DAS-28 being highest in severe depression group. It had a strong association with DASS depression score and with significant p value of <0.001. There was a weak positive correlation between DAS-28 and DASS depression score, though this correlation was not statistically significant (rho = 0.18, p = 0.167). With further regression analysis, it was clear that, TJC, SJC, and ESR, were significantly associated with depression. All of these parameters had an odds ratio of >1, indicating that if each of them increased, odds of having depression would significantly increase.
Conclusion: Depression, though very common, is yet an underestimated co-morbidity in RA and contributes to their functional impairment/ morbidity. RA patients with high TJC, SJC, ESR and disease activity were found to have depression of more severity, which favors the inflammatory hypothesis of depression.**[3]** Depression, is indeed an under-estimated yet significant comorbidity in patients with RA. This is often missed or over looked by rheumatologists/ clinicians. Early identification with subsequent referral to concerned specialty will definitely improve functional outcomes.

A STUDY OF MYOSTATIN LEVELS IN A GREEK COHORT OF POST-MENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

Keywords: Osteoporosis, Rheumatoid arthritis

K. Zoupidou[1], M. Krikelis[2], D. Moschou[2], S. Tournis[3], K. Makris[4], S. Gazi5, P. Katsimpri[1], D. Boumpas[1], E. Chronopoulos[3], I. Dontas[3]. *[1]Attikon University Hospital, Athens, Rheumatology and Clinical Immunology Unit, 4th University Clinic of Internal Medicine, Chaidari, Greece*; *[2]KAT General Hospital, Athens, Rheumatology Clinic, Kifisia, Greece*; *[3]National and Kapodistrian University of Athens, Greece, Laboratory of Research of the Musculoskeletal System, Athens, Greece*; *[4]KAT General Hospital, Athens, Laboratory of Biochemistry, Kifisia, Greece*; *[2]KAT General Hospital, Athens, Rheumatology Clinic, Kifisia, Greece*

Background: Myostatin is expressed in skeletal muscles and exerts a negative feedback in myogenesis. Chronic inflammation has been associated with increased serum myostatin levels (Baig MH, Front Physiol. 2022).
Objectives: The calculation of serum myostatin levels in patients with rheumatoid arthritis (RA) and association with disease parameters.
Methods: A cross-sectional study of 30 post-menopausal women with RA, classified according to the 1987 ACR criteria. Blood samples were collected and inflammatory markers (erythrocyte sedimentation rate, ESR, and C-reactive protein, CRP) were calculated. Serum myostatin levels were assessed using the ELISA method. Seropositive disease was defined according to a positive history of antibodies against rheumatoid factor (RF) or against citrullinated proteins (ACPA). Disease activity and patient functionality were expressed by using the DAS28 (ESR) and the HAQ-DI scores respectively.
Results: In our cohort, 47% (n=14) had seropositive disease. Mean values for ESR, CRP, DAS28 (ESR) and HAQ-DI were 29 ± 20 mm, 1.6 ± 2.6 mg/dl, 3.9 ± 1.7 and 0.9 ± 0.6 respectively. The mean serum myostatin levels were 5.9 ± 1.3 μg/ml. According to the DAS28 (ESR) score, 17% (n=5) patients were in disease remission, 20% (n=6) had low disease activity, 40% (n=12) had medium disease activity and 23% (n=8) had high disease activity. Serum myostatin was not associated with disease activity (p=0.32), patient functionality (p=0.08) or the inflammatory burden attributed to active disease (p=0.67 for ESR and p=0.83 for CRP). Seropositive disease did not correlate with serum myostatin levels (p=0.08).
Conclusion: In post-menopausal women with rheumatoid arthritis, serum myostatin levels are independent of disease activity, patient functionality, inflammatory burden, RF or ACPA seropositivity. Except for inflammation per se, other disease parameters associated with RA influence the regulation of myostatin.

DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS (D2T-RA): CLINICAL ISSUES AT EARLY STAGES OF DISEASE

Keywords: Rheumatoid arthritis, Disease-modifying Drugs (DMARDs), Epidemiology

D. Freites Nuñez[1], L. León[2,3], A. Madrid García[2], P. Lopez Viejo[1], I. Garcia Alvaro[4], M. Novella-Navarro[5], Z. Rosales[1], B. Fernandez[1], L. Abasolo[2]. *[1]Hospital Clinico San Carlos, Rheumatology, Madrid, Spain*; *[2]Instituto de Investigación Sanitaria San Carlos (IdISSC), Rheumatology, Madrid, Spain*; *[3]Universidad Camilo Jose Cela, Health Sciences, Madrid, Spain*; *[4]Hospital Universitario La Princesa, Rheumatology, Madrid, Spain*; *[5]Hospital Universitario La Paz, Rheumatology, Madrid, Spain*

Background: Most studies on difficult-to-treat rheumatoid arthritis (D2T RA) have focused on established RA.
Objectives: To analyze whether disease activity in the early stages of RA could influence progression to a D2T RA under real-life conditions. Other clinical and treatment-related factors were also analyzed.
Methods: A longitudinal multicenter study of RA patients was conducted from 2009 to 2018. Patients were followed up until January 2021. D2T RA was defined based on EULAR criteria (treatment failure, signs suggestive of currently active/progressive disease, and management being perceived as problematic by the rheumatologist and/or patient). The main variable was disease activity in the early stages. The covariates were sociodemographic, clinical, and treatment-related factors. We ran a multivariable logistic regression analysis to investigate risk factors associated with progression to D2T RA.
Results: The study population comprised 631 patients and 35 (5.87%) developed D2T RA. At the time of diagnosis, the D2T RA group were younger, with a higher disability, DAS28 score, tender joint count and pain scores. In our final model, DAS28 was not statistically significantly associated with D2T RA. No differences were found between groups for therapy. Disability was independently associated with D2T RA (OR: 1.89; p=0.01).
Conclusion: In this cohort of patients newly diagnosed with RA, our results do not allow us to prove the influence of active disease according to DAS28. However, we did find that younger patients and those with elevated initial disability scores are more likely to develop D2T RA regardless of other factors.

CARDIOVASCULAR RISK STRATIFICATION ACCORDING TO SERUM NON-HDL CHOLESTEROL LEVELS IN PATIENTS WITH RECENTLY DIAGNOSED RHEUMATOID ARTHRITIS.

Keywords: Biomarkers, Comorbidities, Rheumatoid arthritis

F. Bizzarri[1], N. Molina Osorio[1], E. Raya[1], I. Aomar Millan[1], J. Salvatierra[1].
[1]*Hospital Universitario Clínico San Cecilio, Reumatología, Granada, Spain*

Background: It is estimated that rheumatoid arthritis (RA) increases the risk of cardiovascular disease (CVD) by 50% compared to the general population [1,2]. Non-HDL cholesterol (non-HDL CT) has become an innovative marker of cardiovascular risk (CVR). According to the recommendations of the ESC of 2022 [2], patients with RA start from an intermediate CVR and recommend non-HDL TC levels <130mg/dL.
Objectives: To evaluate long-term risk of CVD according to nonHDL CT levels in a cohort of patients with recently diagnosed RA who started biological therapy and describe its characteristics.
Methods: 71 patients with RA under biological treatment were reviewed. Demographic, clinical, and analytical data were obtained at the time of diagnosis. To estimate the risk of CVD in the long term, we applied the model developed by Brunner F. J. et al. [3] -Figure 1-. Based on this, the patients were stratified into 5 CVR groups according to the non-HDL CT and grouped into three age ranges. Statistical analysis was carried out using IBM-SPSS Statistics version 26.
Results: The demographic, clinical, laboratory characteristics and CVR groups are indicated in Table 1. Regarding the mean age according to the CVR group: in the 8 patients of group 1 it was 38.13 ± 15.28 years - 7 with age < 45 years and one > 60 years -, in group 2 it was 42.93 ± 11.76 years - 17 patients < 45 years, 10 between 45 and 59 years and 2 ≥ 60 years -, in the 31 patients of group 3 it was 51.45 ± 11.49 years - 8 < 45 years, 15 between 45-59 years and 8 ≥ 60 years -. In the 2 patients in group 4 it was 52.5 years (45-59) and the patient in group 5 was 36 years old at diagnosis. No significant correlations were found between CRP, ESR, RF, ACPAs levels and presence of radiographic erosions with nonHDL CT values. Significant differences (p value < 0.01) were observed between the youngest individuals (age < 45 years) in groups 1 and 2 with respect to individuals older than 60 years in risk groups 3 or 4. The application of the current model -Figure 1- estimated a mean probability of CVD of 9.7% at 75 years with a reduction to 3.54% after a 50% decrease in non-HDL TC. A single fatal cardiovascular event was recorded in an obese, hypertensive, and diabetic man, classified in risk group 3.
Conclusion: In our cohort of patients with new-onset RA, the majority (46%) were classified as CVR group 3 (nonHDL CT 145-184 mg/dL), despite approximately 50% being <45 years of age. Exposure from an early age to a moderate increase in non-HDL CT induces an increase in long-term CVR, not captured by the 10-year CVR estimate. For all this, emphasis should be placed on the establishment of measures to reduce CVR guided by non-HDL CT levels in patients diagnosed with RA.

CHARACTERISTICS OF BLOOD TEST RESULTS IN D2T RA BEFORE INITIATING DMARDS TREATMENT: HIGHER IFN AND LESS IL-6 INVOLVEMENT WERE PRESUMED BY PROPENSITY SCORE MATCHING ANALYSIS

Keywords: Rheumatoid arthritis, Biomarkers

Y. Nishiura[1,2], Y. Nakai[1], M. Tokunaga[1], Y. Koyama[1]. [1]*Japanese Red Cross Okayama Hospital, Division of Rheumatology, Center for Autoimmune Diseases, Okayama, Japan*; [2]*Okayama University Hospital, Center for Graduate Medical Education, Okayama, Japan*

Background: Difficult-to-treat rheumatoid arthritis (D2T RA) is a new concept of RA patients who do not achieve remission despite several types of treatment. It remains to be elucidated what makes the clinical differences between D2T RA and non-D2T RA.
Objectives: To analyze blood test results of D2T RA patients and non-D2T RA patients before initiating treatment to see if there are differences in their trends and characteristics.
Methods: We conducted a retrospective, observational cohort study using blood tests, including patients diagnosed with RA who attended our institute. The patients were divided into two groups; those who satisfied EULAR definition of D2T were included as D2T-RA, and the others who did not meet the definition after at least 2 years of treatment were included as non-D2T RA patients. To eliminate the influence of treatment on blood test data and disease activity, only patients whose blood test data existed prior to starting treatment with disease modifying antirheumatic drugs (DMARDs) were picked from both groups. The two groups were then matched 1:1 using propensity scores adjusted for gender, age, duration of RA disease, BMI, smoking habits, and DAS28-ESR. Comparisons were made between these two adjusted groups for each blood test item using an independent-samples t-test. SPSS statistical software was used.
Results: Ninety-four RA patients (mean age 60.3±12.6 years, 74% female) were included, 23 (mean age 55.4±13.2 years, 83% female) belonged to D2T RA and 71 (mean age 61.8±12.1 years, 72% female) to non-D2T RA. Of these, 13 cases of D2T RA and 2 cases of non-D2T RA were excluded due to lack of blood test data before starting DMARDs therapy. D2T RA patients were 57.6 ± 11.1 years old (86% female) and non-D2T RA patients were 57.0 ± 10.1 years old (100% female). In D2T RA, mean corpuscular volume (MCV: D2T vs non-D2T = 95.6±3.8 vs 85.6±3.9, p<0.001), mean corpuscular hemoglobin (MCH: 32.0±1.7 vs 28.7±1.7, p=0.003), serum transferrin saturation (TSAT) ratio (Fe*100/TIBC: 32.3±7.2 vs 19.3±9.6, p=0.020) and lactate dehydrogenase (LDH: 203±33U/L vs 164±16U/L, p=0.026) were significantly higher. On the other hand, unbound iron binding capacity (UIBC: 184±42 vs 253±35, p=0.007) was significantly lower in D2T RA. Although it was not reaching statistical significance, lower lymphocyte count (1068±304/μ vs 1816±867/μ, p=0.052), fewer red blood cell (RBC: 4.03±0.34*10^6/μ vs 4.45±0.51*10^6/μL, p=0.096) and higher neutrophil ratio (76.9±8.2% vs 66.5±10.7%, p=0.065) were observed in D2T RA.
Conclusion: In a comparison of blood test results before initiating treatment, the differences between D2T and non-D2T cases were mainly related to iron metabolism and white blood cell differential. Patients with non-D2T RA had significantly lower

TSAT than patients with D2T RA, with a trend toward having a microcytic hypochromic anemia. This reminds us of the involvement of hepcidin and may suggest that Interleukin 6 (IL-6) is involved in the pathogenesis of non-D2T RA but it is less involved in that of D2T RA 1). The hypothesis explains the clinical features of resistance to treatment with IL-6 inhibitors in patients with D2T-RA. Furthermore, a clear lymphocyte count decrease was observed in D2T RA cases, suggesting a strong IFN signature 2). Interestingly, D2T RA cases showed a greater tendency toward anemia than non-D2T RA cases, with a tendency toward macrocytic rather than microcytic anemia. A trend of increased neutrophil ratio was also observed in D2T RA cases. On the other hand, there were no significant differences in immunological background, such as rheumatoid factor (RF) nor anti-citrullinated protein antibodies (ACPA).

AB0378 RELATIONSHIP BETWEEN EGO STATE, DISEASE ACTIVITY, AND ACTIVITY OF DAILY LIVING IN RHEUMATOID ARTHRITIS PATIENTS: USING EGOGRAMS

Keywords: Rheumatoid arthritis

Y. Miwa[1], Y. Miwa[2], H. Tomioka[3], M. Hosaka[4]. *[1]Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Yokohama, Japan*; *[2]Showa University School of Nursing and Rehabilitation Sciences, Department of Nursing, Yokohama, Japan*; *[3]Showa University School of Medicine, Department of Psychiatry, Yokohama, Japan*; *[4]Katsuyama Clinic, Department of Psychosomatic Medicine, Yamanashi, Japan*

Background: Although there have been several previous reports on the personality patterns of rheumatoid arthritis (RA) patients and their habits and tendencies in thinking, feeling, and behaving when interacting with others (ego state), there have been no new research reports in the last ten years. During this period, the treatment outcome of RA has improved, and changes in ego states are expected.
Objectives: This study investigated the relationship between ego state, disease activity, and activity of daily living (ADL) in RA patients.
Methods: A total of 133 RA patients attending outpatient clinics at Showa University Hospital and Showa University Northern Yokohama Hospital who agreed to participate in this study were included. The patient background had age, gender, type of DMARDs, and prednisolone use; the simplified disease activity index (SDAI) was used to assess RA disease activity, and the health assessment questionnaire (HAQ) was to sed determine ADL. The University of Tokyo Egogram (TEG-II) was to sed determine ego status; the TEG-II consists of pattern categories and types from critical parental ego (CP), nurturing parental ego (NP), adult ego (A), free child ego (FC), and submissive child ego (AC). The scores for each item were evaluated, and associations with SDAI, HAQ, and gender were examined.
Results: The AC was the highest (15.0 points), and the CP and A were the lowest (6.0 points each) on the TEG-II for all the subject patients. The pattern classification showed that the AC-dominant type was the most common (45 patients, 33.8%), with no significant difference in HAQ remission (<0.5) and non-remission, low disease activity (SDAI≤11) and SDAI>11, nor in gender.
Conclusion: In previous reports, TEG-II in RA patients was predominantly NP, but in the present study, AC was predominant. The behavioral pattern was inferred to be cooperative, honest, able to listen to other's opinions, and patient, but loose, lax, lack discipline, inconsistent in thought and action, and poor planning. The results may be influenced by the improvement of rheumatoid arthritis performance and the decrease in disease activity.

AB0379 EVALUATION OF BODY COMPOSITION IN RHEUMATOID ARTHRITIS PATIENTS WITH HIGH CUMULATIVE INFLAMMATORY ACTIVITY.

Keywords: Sarcopenia, Comorbidities, Rheumatoid arthritis

A. Garcia Studer[1], F. Ortiz-Márquez[1], R. Redondo[1], C. M. Romero-Barco[2], S. Manrique Arija[1], N. Mena-Vázquez[1]. *[1]Instituto de Investigación Biomédica de Málaga (IBIMA)-Plataforma Bionand, Hospital Regional Universitario de Málaga (HRUM), Unidad de Gestión Clínica de Reumatología, Málaga, Spain*; *[2]Hospital Universitario Virgen de la Victoria, Reumatología, Málaga, Spain*

Background: Previous studies have reported a higher prevalence of sarcopenia in patients with systemic diseases. Thus, it is believed that the inflammation may contribute to the onset of sarcopenia.
Objectives: To study whether there is an association between high sustained inflammatory activity and with a major frequency of sarcopenia and others alterations in body composition in rheumatoid arthritis (RA) patients.
Methods: We conducted a controlled cross-sectional observational study of a prospective cohort of RA patients. The cases were RA patients with mean moderate-high inflammatory activity during the disease course who were selected to start first biologic treatment. The controls were subjects without inflammatory disease, matched for sex and age with cases. All patients were recruited consecutively from a rheumatology clinic. Body composition was measured using dual-energy x-ray absorptiometry. The main variables were sarcopenia (RSMI <5.5 kg/m^2 for women and <7.26 kg/m^2 for men), fat mass (Kg) and body mass index (BMI). Other variables included average inflammatory activity by DAS28-ESR since diagnosis, epidemiological characteristics, lifestyles (physical activity and adherence to the Mediterranean diet), comorbidities and treatment. Statistical analysis included descriptive analysis, bivariate and two models of multivariate analysis.
Results: A total of 62 subjects were included, 32 with RA and 32 healthy controls. Most of them were female (84.4%) with a mean (DS) age of 57.1 (10.8) years. The main baseline characteristics of subjects are shown in Table 1. Compared with controls, RA patients had higher prevalence of sarcopenia (7 [21.9%] vs 2 [6.3%]; p=0.074), a higher mean (DS) of fat mass (31.8 [7.4] vs 27.1 [13.8]; p=0.129) and BMI (28.0 [5.2] vs 26.6 [4.4]; p = 0.278). The RA patients with sarcopenia, compared with the other RA patients, had a higher frequency of erosions (85.7% vs 32.0%; p=0.011), dyslipidemia (71.4% vs 16%; p =0.100), higher mean (DS) of age (64.8 [10.2] vs 55.9 [10.3]; p = 0.021), DAS28-ESR (4.5 [0.7] vs 3.7 [0.8]; p = 0.031), average of DAS28-ESR (1.6 [0.3] vs 1.0 [0.5]; p = 0.024) and ESR (33.0 [18.1] vs 15.8 [10.7]; p = 0.003). The multivariate analysis showed the factors associated independently with sarcopenia in RA patients were age (OR [CI 95%], 1.125 [1.002-1.262]; p=0.045), and the average of DAS28-ESR (OR [CI 95%], 2.761 [1.843-10.430]; p=0.048) (R2= 0.173).
Conclusion: Our preliminary data show a significant trend to a higher prevalence of sarcopenia in RA patients with moderate to high inflammatory activity. In addition, RA patients with sarcopenia have higher mean of age and inflammatory activity, compared to the rest of the patients.

Table 1. Baseline characteristics of 32 RA patients and 32 controls.

VARIABLE	RA N= 32	CONTROL N = 32	P-value
Sex, female, n (%)	27 (84.4)	27 (84.4)	1.000

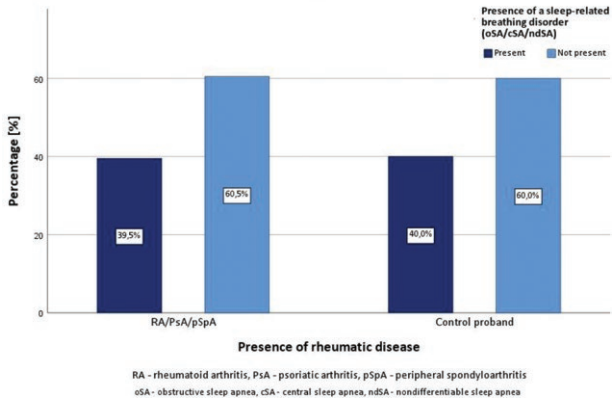
AB0380 PREVALENCE OF SLEEP-RELATED BREATHING DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS, AND PERIPHERAL SPONDYLOARTHRITIS



Keywords: Spondyloarthritis, Rheumatoid arthritis, Psoriatic arthritis

L. Winter[1], D. Skowasch[2], M. Weber[3], D. Kütting[4], C. Behning[5], P. Brossart[1], V. Schäfer[1]. *[1]Clinic of Internal Medicine III, University Hospital of Bonn, Department of Oncology, Hematology, Clinical Immunology, and Rheumatology, Bonn, Germany*; *[2]Clinic of Internal Medicine II, University Hospital of Bonn, Department of Pulmonology, Bonn, Germany*; *[3]Clinic of Internal Medicine II, University Hospital of Bonn, Department of Interventional Cardiology and Echocardiography, Bonn, Germany*; *[4]University Hospital of Bonn, Department of Diagnostic and Interventional Radiology, Bonn, Germany*; *[5]University Hospital of Bonn, Department of Medical Biometry, Informatics, and Epidemiology, Bonn, Germany*

Background: Quality of life in patients suffering from rheumatological diseases is negatively affected by sleep disturbances, a frequently observed phenomenon. In rheumatoid arthritis, the prevalence of sleep disturbances ranges from about 50% to 70% [1]. The non-restorative sleep patterns result in excessive daytime sleepiness, reduced physical and mental performance, depression, and concentration disorders, as well as increased cardiovascular morbidity and risk of accidents [2].
Objectives: To investigate the prevalence of sleep-related breathing disorders (SRBD), including obstructive and central sleep apnea (oSA, cSA), in patients with rheumatoid arthritis, psoriatic arthritis, and peripheral spondyloarthritis and to examine the relation between deterioration in sleep quality and selected clinical parameters.
Methods: This cross-sectional assessment consisted of a diagnostic workup, encompassing a questionnaire regarding sociodemographic characteristics, the assessment of arthritis disease activity using the Disease Activity Score (DAS-28CRP), and the evaluation of daytime sleepiness using the Epworth Sleepiness Scale (ESS). Cardiorespiratory polygraphy (RPG) was performed to detect SRBD.
Results: A total of 54 patients (26 RA, 24 PsA, 4 pSpA) and 28 age- and gender-matched controls were recruited. The prevalence of sleep apnea in this study accounted for 39.7%, with a more than twofold higher presence of oSA than cSA. However, sleep apnea was diagnosed in approximately equal proportions of arthritis patients (39.5%) and controls (40.0%) (Figure 1). Male gender (p=0.013) and an increased age of approximately 55 years (p<0.001) were found to be significant risk factors for the presence of sleep apnea. Furthermore, differences, but without statistical significance, were found between subjects with sleep apnea and subjects without sleep apnea with respect to body mass index (p=0.085), positive smoking status (p=0.191), and arthritis disease activity as assessed by DAS28CRP (p=0.275). 42.3% of subjects affected by oSA or cSA showed excessive daytime sleepiness rated by ESS (p=0.024).
Conclusion: Despite the fact that the prevalence of SRBD in arthritis patients and controls is the same, physicians should be especially cautious of male patients over the age of 55. ESS score assessment helps to estimate the clinical risk. An early diagnosis of sleep apnea in arthritis patients may improve physical and psychological quality of life.

AB0381 **TREATMENT EXPECTATIONS OF PATIENTS WITH RHEUMATOID ARTHRITIS BEFORE STARTING METHOTREXATE**

Keywords: Rheumatoid arthritis

U. Kiltz[1,2], A. Petridou[1,2], N. Timmesfeld[3], W. Rief[4], K. Schmidt[5], D. Krause[3,6], U. Bingel[5], J. Braun[1]. *[1]Ruhr University Bochum Faculty of Medicine, Rheumatology, Bochum, Germany*; *[2]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*; *[3]Ruhr University Bochum Faculty of Medicine, Department of Medical Informatics, Biometry and Epidemiology, Bochum, Germany*; *[4]University of Marburg, Division of Clinical Psychology, Marburg, Germany*; *[5]University Hospital Essen, Department of Neurology, Essen, Germany*; *[6]Rheumatology Practice Gladbeck, Rheumatology, Gladbeck, Germany*

Background: Although the long-term efficacy, tolerability, and safety of methotrexate (MTX) in patients with rheumatoid arthritis (RA) are well documented, the clinical response and incidence of adverse events (AE) vary. Data on adherence to MTX in RA patients vary between retention rate of 35% to 80% in 5 years. In addition to aspects of safety, important determinants for continuing MTX therapy are patient-associated factors including individual treatment preferences and expectations.
Objectives: This study investigated treatment expectations in RA patients who were about to start therapy with MTX, and aim to identify variables associated with discontinuation of MTX.
Methods: Consecutive patients with RA who were about to start MTX were prospectively included after informed consent. Treatment expectations, medication-related beliefs and AE, treatment satisfaction and health–related quality of life were assessed using the generic rating scale for previous experiences, expectations and effects of treatment (G-EEE), the general assessment of side effects (GASE), the beliefs about medicines questionnaire (BMQ), the treatment satisfaction questionnaire for medication (TSQM) and the EuroQol-5 dimensions (EQ-5D) before treatment initiation (T0), and after 3 months (T1). Treatment adherence to MTX was checked at month 6 (T2). Associations treatment expectations and adherence to MTX were explored by regression analyses.
Results: A total of n=100 consecutive RA patients before starting MTX treatment were included (table 1). A history of inadequate response to sulfasalazine was determined in n=6 (6%) and to hydroxychloroquine in n=1 patient, respectively. At T0, patients perceived the need for treatment with MTX as high, and they were only moderately concerned regarding potential adverse events of this therapy. Treatment expectations regarding the decrease of pain levels and development of adverse events did not differ much between T0 and T1, when disease activity had significantly decreased and physical function increased. MTX was withdrawn in 3 out of 59 patients (5.0%) and in 13 out of 64 patients (20.3%) assessed at T1 and T2, respectively, with a mean of 16.0 (5.9) weeks after treatment initiation. The most frequent reason for discontinuation of MTX was the occurrence of adverse events (n=12) followed by infections or malignancies (both n=2). There was no significant relationship between patients' treatment expectations reported at T0 and their adherence to MTX at T2.
Conclusion: In this study, we found no evidence for the assumption that patients' expectations before the start of MTX did substantially influence adherence to treatment.

COMPARISON OF CARDIOVASCULAR RISK SCALES ACCORDING TO TIME OF EVOLUTION IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Cardiovascular disease, Rheumatoid arthritis

I. J. Colunga-Pedraza[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], V. M. Beltran-Aguilar[1], V. Gonzalez-Gonzalez[1], A. G. Arias Peralta[2], N. De Avila Gonzalez[1], J. A. Cardenas-de la Garza[1], G. García-Arellano[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico*

Background: Rheumatoid arthritis (RA) is a chronic, multisystemic and multifactorial disease. RA patients are at increased risk of cardiovascular (CV) morbimortality, with atherosclerotic CV disease being the leading cause of death. The traditional risk factors cannot explain such an increase by themselves. (1) There are many algorithms for CV risk (CVR) prediction, and results obtained by these must be multiplied by 1.5 factor, since the EULAR recommendation from 2016. (2)
Objectives: To compare CVR by six scales: Framingham lipids and BMI, ACC/AHA ASCVD 2013, Reynolds (RRS), SCORE 2 and QRISK III, according to the time of disease evolution in RA patients.
Methods: Descriptive, comparative, and cross-sectional study. We enrolled RA patients between 40 and 75 years old who fulfilled ACR/EULAR 2010 classification criteria and recruited in the Rheumatology service from a tertiary care hospital. Patients were divided by time of disease evolution into quartiles. CVR results from scales were multiplied by 1.5 factor according to EULAR 2016 recommendation. Normality was assessed by Kolmogorov-Smirnov test. Variables with a non-normal distribution were described by median and interquartile range (p25-p75). Differences between groups was analyzed by Kruskal-Wallis test or Chi-squared, accordingly.
Results: Total of 406 RA patients were included. Demographic characteristics are shown in table 1. For longer disease evolution, CV scales showed an increased (except for RRS; p= 0.123), just like anti-citrullinated peptide antibody (p=0.001), rheumatoid factor IgG (p=0.003), IgM (p=0.00) and IgA (p=0.00).
Conclusion: CVR increased according to disease duration. Despite that most of the scales showed such increased, CVR varies between them, which may be attributable to the variables evaluated in each one. More studies are required to define which scale is the best to predict in RA patients.

CARDIAC INVOLVEMENT IN RHEUMATOID ARTHRITIS: A COMPARATIVE TRANSTHORACIC ECHOCARDIOGRAPHY STUDY

Keywords: Comorbidities, Rheumatoid arthritis, Heart

R. Sarraj[1], M. Brahem[1], H. Ibn Hadj Amor[2], O. Jomaa[1], A. Ben Salem[1], B. Jebali[1], S. Kraiem[2], R. Rouabhia[2], H. Hachfi[1], Y. Mohamed[1]. [1]*Taher Sfar University Hospital, Rheumatology, Mahdia, Tunisia*; [2]*Taher Sfar University Hospital, Cardiology, Mahdia, Tunisia*

Background: Cardiac involvement in rheumatoid arthritis (RA) is one of the most frequent and severe extra-articular manifestations, but it is often under-diagnosed.
Objectives: In this context, we conducted this study, whose objective is to determine the prevalence and types of cardiac abnormalities in patients with RA using the transthoracic echocardiography (TTE) and to compare them with control subjects.
Methods: We performed a comparative cross-sectional study conducted in Taher Sfar Hospital, Mahdia, Tunisia. Each patient underwent a TTE coupled with Strain technique.
Results: Seventy-two patients with RA according to the ACR/EULAR 2010 criteria and 72 control subjects (control group) were included. In our study, there was a clear female predominance in both groups with a sex ratio of 0.07 in the RA group and a sex ratio of 0.05 in the control group (p=1). The mean age of RA patients was 52.9 ± 11.72 years [21-75 years] and that of the control group was 49.26 ± 10.74 years [19-76 years] (p=0,06). Abnormalities detected by TTE were more frequent in subjects with RA compared with the control group (80.6% vs 36.1%; p < 0.01) and they were asymptomatic in 65.5% of cases of RA group. Pericardial effusion was more frequent in the RA group compared with the control group but without significant difference. Valvular involvement was significantly more frequent in patients with RA compared to the control group (45.8% vs 1.4%; p<0.01) with predominance of tricuspid involvement (31.9%). Left ventricular diastolic dysfunction was more frequent in RA patients compared with the control group with a significant difference (36.1% vs 13.9%; p<0.01). Regarding the left ventricular systolic dysfunction, left ventricular ejection fraction impairment was absent in both groups, but subclinical left ventricular myocardial damage assessed by the Global Longitudinal Strain (GLS) method was detected in 37.5% of RA patients and 16.6% of control subjects (p<0.01). The mean of GLS in RA patients was -17.8% ± 2.9 [-22 to -10.7%], while it was -19.4% ± 1.9 [-24.7 to -15.7%] in control subjects. Left ventricular hypertrophy was detected on TTE in 22.2% of RA patients and in 6.9% of control group (p<0.01). Pulmonary arterial hypertension was present only in the RA group (2.8% of cases).
Conclusion: Our study showed that cardiac involvement is more frequent in RA than the general population, hence the interest of systematic screening, in order to improve the quality of life and the vital prognosis of patients.

CHANGES IN LEFT VENTRICULAR SYSTOLIC AND DIASTOLIC FUNCTION IN PATIENTS WITH AUTOIMMUNE INFLAMMATORY DISEASES

Keywords: Systemic lupus erythematosus, Rheumatoid arthritis, Heart

J. R. Azpiri-López[1], D. Á. Galarza-Delgado[2], I. J. Colunga-Pedraza[2], A. G. Arias Peralta[1], V. M. Beltran-Aguilar[2], V. Gonzalez-Gonzalez[2], N. De Avila Gonzalez[2], J. A. Cardenas-de la Garza[2]. [1]*Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*

Background: Rheumatological diseases such as rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and psoriatic arthritis (PsA) increase the cardiovascular (CV) risk by the development of a pro-inflammatory state that can affect the ventricular function of the heart. (1)
Objectives: To compare left ventricular (LV) systolic and diastolic function in patients with RA, SLE, and PsA as compared with healthy controls.
Methods: A cross-sectional and comparative study. Patients included in the cohort were between 30–75 years old, who fulfilled 2006 Classification Criteria for PsA; patients between 40-75 years old who fulfilled 2010 ACR/EULAR criteria for RA; Patients older than 18 years old who fulfilled 2019 ACR/EULAR Criteria for SLE, and Controls. A transthoracic echocardiogram was performed by a certified cardiologist blinded to clinical data. Normality was assessed by the Kolmogorov-Smirnov test and the Kruskal-Wallis test for comparison among groups. P value <0.05 was considered significant.
Results: 186 patients were included in the study, divided into groups as its shown in Table 1. Most of them were women (146); the most common comorbidities were hypertension (36%, 20.8%, and 17.5% in the RA, SLE, and Control groups, respectively), and dyslipidemia (73.9% in the PsA group). Echocardiographic findings are shown in Table 1.
Conclusion: LV systolic and diastolic function changes in the rheumatic population, especially RA, SLE, and PsA, are higher in comparison with healthy people and affect the prognosis in these patients, those changes can be detected by echocardiogram, which is a safe tool that may prevent complications and improve the prognosis with early detection and management of this CV involvement.

AB0385

RISK FACTORS AND CARDIOVASCULAR DISEASES AMONG PATIENTS WITH RHEUMATOID ARTHRITIS IN A TERTIARY GOVERNMENT HOSPITAL IN THE PHILIPPINES

Keywords: Rheumatoid arthritis

M. A. Yano[1], E. Salido[1]. [1]*Division of Rheumatology, Department of Medicine, Philippine General Hospital, University of the Philippines Manila, 1000, Philippines*

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by inflammatory arthritis and extra-articular involvement [1] Comorbidities are highly prevalent in patients with RA, [2] in particular cardiovascular disease (CVD), which is responsible for over 50% of premature deaths among these patients.[3] It causes lower life expectancy in 3 to 10 years and higher mortality rate compared to the general population. [4]
Objectives: To describe cardiovascular (CV) diseases and their risk factors among patients with rheumatoid arthritis.
Methods: This is a review of the medical records of patients with rheumatoid arthritis, ambulatory and hospitalized, at the Philippine General Hospital from January 2019-December 2022.
Results: There were 123 patients included in the study, 95.1% were females with a mean age and disease duration of 51.31 and 9.78 years, respectively. Only a few (6.5%) were hospitalized. Disease activity was low in 41.5% and moderate in 35% based on disease activity score (DAS 28) and/or clinical disease activity index (CDAI) scores. Methotrexate (54%) was the most commonly used conventional synthetic disease modifying antirheumatic drug (csDMARD). The use of glucocorticoids was observed in 51.2% while no patients were on biologic (DMARD) at the time of data collection. There were 12 (9.7%) patients with CV diseases, namely myocardial infarction, heart failure, and stroke. There were 87 (70%) patients with at least one CV risk factor and 60 (48%) with multiple risk factors. The risk factors identified were: dyslipidemia (43.1%), hypertension (40.7%), elevated body mass index (35.7%), and diabetes mellitus, (15.4%). However, there were 18 (14.6%) patients without a lipid determination. Five hospitalized patients (4%) died, three from infectious causes, one from malignancy, and one from myocardial infarction.
Conclusion: The majority (70%) in our cohort had at least one CV risk factor and 10% had an identified CV disease. Dyslipidemia was the most common CV risk factor. The high proportion of patients with CV disease and risk factors highlights the need to add the screening and management of CV diseases as a priority among patients with rheumatoid arthritis.

Background: Current and previous EULAR recommendations (1,2) suggest using JAK-inhibitors (JAKis) for treating Rheumatoid Arthritis (RA). However, little is known about differences of patients who are JAK-inhibitors (JAKis) naïve and patients who have already experienced at least one JAKi.

Objectives: To analyse differences between JAK-naïve and JAKis not naive patients in a real life setting.

Methods: All patients with RA on JAKis were prospectively followed up for 12 months in this multicentric study conducted in 23 centres. For each patient, the following variables were recorded: sex, age, disease duration at JAKi prescription, smoking, BMI, comorbidities, positive RF/ACPA, DAS28-ESR at baseline, 6 and 12 months, cDMARDs and prednisone at baseline, JAKis discontinuation, JAK-naïve. Statistics were performed by R (2022.12.0).

Results: 864 patients were included (**Table 1)**. Among them, 731 (84.60%) were JAKis naïve, whereas 122 (14.12%) were not naïve (missing data in 11-1.27%-patients). 473 (55.22%) patients were treated with baricitinib (JAK-naïve were 412, 87.3%), 213 (24.6%) with tofacitinib (JAKis-naïve 187, 87.79%), 111 (12.84%) with upadacitinib (JAKis-naïve 78.37%) and 62 (7.17%) with filgotinib (JAKis-naïve 72.58%). Significant differences between JAKis-naïve and not naïve were found for hypercholesterolemia (p=0.04), hypertension (p=0.02), previous cancer (p<0.001), disease duration (p<0.001), line of treatment (p<0.001). No difference was found for JAKis discontinuation (p=0.13) **(Table 1).**

Conclusion: Our data suggest that line of treatment and disease duration result higher in JAKis not naive compared to naïve ones. Notably, JAKis naïve and not naïve did not differ regarding drug discontinuation, suggesting a similar retention rate irrespective of previous JAKis.

AB0387 PREDICTIVE FACTORS OF DETECTION OF ULTRASOUND SYNOVITIS IN RHEUMATOID ARTHRITIS PATIENTS WITH CONCOMITANT FIBROMYALGIA

Keywords: Rheumatoid arthritis, Fibromyalgia, Ultrasound

S. Miladi[1], B. A. Hiba[1], F. Alia[1], S. Ben Yaacoub[1], M. Yasmine[1], H. Bousaa[1], L. Souabni[1], K. Ouenniche[1], K. Selma[1], C. Selma[1], K. Ben Abdelghani[1], L. Ahmad[1]. [1]*Hôpital Mongi Slim, Rheumatology, Marsa,Tunisia*

Background: Recent studies have shown that ultrasound (US) assessment of disease activity in rheumatoid arthritis (RA) with associated fibromyalgia (FM) before disease-modifying antirheumatic drug (DMARD) escalation is primordial.
Objectives: The purpose of this study was to identify predictive factors of detection of US synovitis and Doppler activity in RA patients with and without concomitant FM.
Methods: Cross-sectional study that included patients with diagnosis of RA (ACR/EULAR. 2010 criteria) with concomitant FM (ACR 2016) and to compare it to RA patients without FM. Demographic and RA characteristics were collected. US examination of 22 joints was blindly. performed by a single physician. US-detected synovitis was defined and scored 0-3 using. the OMERACT scoring system at the joint level for both grey-scale (GS) and Doppler power. (DP). The number of joints with ≥ grade 1 GS synovitis and those with ≥ grade 1 DP were. calculated. Multiple linear regression analysis performed, adjusting for clinical and. demographic variables.
Results: Eighty patients distributed into 40 patients in each group were recruited. Epidemiological and RA characteristics were comparable between groups. No significant. difference was observed between the groups in regards to mean DAS28 and the three- variables (DAS28 V3). Multiple linear regression showed that in RA-FM group US synovitis detection was positively. associated with male gender (B=0.135, p=0.045) and with DAS28 V3 (B=0.454,p=0.004), and negatively associated with the Patient global assessment (PGA) (B=-1.092,p=0.007). In. RA group (witout FM), US synovitis was positively associated with Swollen joints count. (SJC) (B=0.837, p=0.001). In RA-FM group, Doppler activity was positively associated with. the DAS28 V3 (B=0.637,p=0.04) and with Physician global assessment (B=0.873,p=0.023), negatively associated with the PGA (B=-0.642, p=0.005) while it was positively associated. with the DAS28 (β=3.08, p=0.047) in RA group.
Conclusion: Our study shows that a high DAS28 V3 seems to be significantly associated. with active synovitis in US assessment in RA patients with comorbid FM.

AB0388 RHEUMATOID ARTHRITIS WITH CONCOMITANT FIBROMYALGIA: THE ROLE OF ULTRASOUND IN ASSESSING DISEASE ACTIVITY

Keywords: Fibromyalgia, Rheumatoid arthritis, Ultrasound

S. Miladi[1], B. A. Hiba[1], F. Alia[1], H. Bousaa[1], M. Yasmine[1], L. Souabni[1], K. Ouenniche[1], K. Selma[1], C. Selma[1], K. Ben Abdelghani[1], L. Ahmad[1]. [1]*Hôpital Mongi Slim, Rheumatology, Marsa,Tunisia*

Background: Fibromyalgia (FM) is a chronic painful condition frequently associated with rheumatoid. arthritis (RA) which may falsely increase RA activity by modifying the subjective components. of disease activity scores.
Objectives: The aim of our study was to compare clinical scoring and ultrasound (US) assessment in RA patients with concomitant FM to RA patients without FM.
Methods: Cross-sectional study that included patients with diagnosis of RA (ACR/EULAR 2010 criteria) with concomitant FM (ACR 2016) and to compare it to RA patients without FM. Demographic and RA characteristics were collected. US examination of 22 joints was blindly performed by a single physician. US-detected synovitis was defined and scored 0-3 using the OMERACT scoring system at the joint level for both grey-scale (GS) and Doppler power (DP). The number of joints with ≥ grade 1 GS synovitis and those with ≥ grade 1 DP were calculated. Multiple linear regression analysis performed, adjusting for clinical and demographic variables.
Results: Eighty patients distributed into 40 patients in each group were recruited. Epidemiological characteristics and RA characteristics were comparable between groups. Biologic DMARDs prescription was more frequent in RA with FM patients than control group (p=0.04). Subjective activity parameters were higher in RA with FM group (p<0.05). DAS28 was significantly greater than DAS28 V3 in RA with FM group (p=0,000). FM group had significantly less US synovitis (p=0.035) and less Power Doppler (PD) activity (p=0.035). Grey scale (GS) US score (p=0.87) and DP US score (p=0.162) were similar in the two groups. Multivariate analysis in RA with FM group showed that DAS28 V3 and male gender were positively associated with the presence of US synovitis, while Patient Global Activity expressed a negative association.
Conclusion: Our study confirms the overestimation of disease activity by the clinical scores in RA with concomitant FM. DAS28 V3 score and US assessment would represent a better alternative.

AB0389 EXTRA-ARTICULAR MANIFESTATIONS ARE FREQUENT IN SOUTH INDIAN PATIENTS WITH RHEUMATOID ARTHRITIS AND ARE INDEPENDENT OF THE DISEASE ACTIVITY OR SEROPOSITIVE STATUS.

Keywords: Rheumatoid arthritis, Comorbidities, Inflammatory arthritides

H. Gangadharan[1], R. Thomas[2], R. T R[1]. [1]*Government Medical College Kottayam, Department of Internal Medicine, Kottayam, India*; [2]*Government Medical College Kottayam, Department of Community Medicine, Kottayam, India*

Background: Extra-articular manifestations are seen in around 40% of patients with Rheumatoid arthritis (RA) in western studies and increase the mortality in patients with RA [1]. There is a paucity of data from India, especially from South India on the prevalence and associations of extra-articular manifestations in RA.
Objectives: To estimate the frequency of extra-articular manifestations (EAM) and their associations with disease characteristics in patients with Rheumatoid arthritis attending the Rheumatology clinic of a tertiary care teaching hospital in South India.
Methods: A cross-sectional study of 316 consecutive patients fulfilling the 2010 ACR EULAR classification criteria of RA was done at a Rheumatology clinic in South India between October 2020 and December 2022. The various EAM studied were keratoconjunctivitis SICCA, Interstitial lung disease (ILD), pleuritis/ pleural effusion, bronchiectasis, small airway disease, pericarditis/ pericardial effusion, myocarditis, subcutaneous nodules, peripheral neuropathy, anaemia and Rheumatoid vasculitis. The comorbidities studied were diabetes mellitus, systemic hypertension, coronary artery disease, chronic obstructive pulmonary

disease, hypothyroidism, and stroke. Various parameters like age, gender, disease duration, comorbidities, seropositivity, erythrocyte sedimentation rate (ESR), smoking, disease activity score (DAS28 ESR), and methotrexate use were compared between patients with EAM and those without EAM. Comparisons between groups were made with the chi-squared test when testing categorical variables and the Mann-Whitney *U* test or Independent samples' t test for continuous data. A binomial logistic regression analysis was also carried out to find the independent factors associated with EAM.

Results: Among the 316 patients, 272 were female (86.1%). The mean age of the study population was 51.6 ± 11.38 years and the median disease duration was 36 months (84). 141 patients (44.6%) had at least one comorbidity and 23 patients (7.3%) were current or former smokers. 264 patients (84.1%) were Rheumatoid factor (RF) positive and 298 patients (94.6%) were cases of seropositive RA (RF and/or Anti CCP positive) The median ESR was 50 mm/ hour and the median DAS 28 ESR was 4.65. 164 patients (51.9%) were methotrexate naïve. At least one EAM was seen in 134 patients (42.4%) and the most frequently seen EAM was anaemia (48 patients, 15.2%). Keratoconjunctivitis SICCA was seen in 32 patients (10.1%) and symptomatic ILD was seen in 30 patients (9.5%). Rheumatoid vasculitis was seen in 20 patients (6.3%). Age, disease duration, and ESR (table 1) were found to have significant association with extra-articular manifestations by univariate analysis. On binomial logistic regression, disease duration (p=0.002) and ESR (p=0.047) were found to have a significant association with the presence of extra-articular manifestations.

Conclusion: Extra- articular manifestations were seen in a significant proportion of our RA patients irrespective of the seropositivity status, disease activity, or methotrexate use and had a positive association with disease duration and ESR.

AB0390 OVERACTIVATION OF THE RENIN ANGIOTENSIN SYSTEM AS A POSSIBLE CONTRIBUTOR TO THE INCREASED CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS (RA); EVALUATION OF LEUKOCYTE EXPRESSION OF ANGIOTENSIN II RECEPTOR TYPE 1 AND TYPE 2 IN A POPULATION OF RA PATIENTS.

Keywords: Rheumatoid arthritis, Cardiovascular disease

C. Bentivenga[1], N. E. Politi[1], A. Bragagni[1], E. R. Cosentino[1], F. A. G. Cicero[1], M. Reta[2], C. Borghi[1]. *[1]S. Orsola-Malpighi Polyclinic IRCCS, Medicina Interna Cardiovascolare-Borghi, Bologna, Italy*; *[2]S. Orsola-Malpighi Polyclinic IRCCS, Medicina Interna ad indirizzo reumatologico, Bologna, Italy*

Background: rheumatoid arthritis (RA) is a chronic systemic autoinflammatory disease of unknown aetiology characterized by joint inflammation and multiple comorbidities, with a prevalence of approximately 1% of the adult population. It is considered an independent cardiovascular (CV) risk factor, in fact it is associated with significantly increased CV morbidity and mortality. The renin angiotensin system (RAS) is a hormonal cascade with pleiotropic effects. Not only is it crucial in blood pressure regulation but it also plays an important role, among many other effects, in inflammation. High circulating levels of proinflammatory cytokines such as TNF-α and IL-6 are critical in the pathogenesis of RA as well as in determining increased CV morbidity and mortality among these patients. TNF-α and IL-6 activate the systemic and local RAS; in turn, Angiotensin II (Ang II) increases several proinflammatory cytokines among which TNF-α and IL-6. Therefore, a self-perpetuating vicious circle between RAS and cytokines is triggered. Activation of the classical RAS leads to Angiotensin II (Ang II) formation which binds to Ang II receptors type 1 (AT1R) and 2 (AT2R). RAS overactivation is essential in determining vascular inflammation and endothelial dysfunction through its proinflammatory and profibrotic effects.

Objectives: to determine whether RAS activity is higher among RA patients.

Methods: leukocyte AT1R and AT2R mRNA was extracted and measured by real-time polymerase chain reaction analysis (RT-PCR) from 18 RA patients with stable disease and no traditional CV risk factors (mean age 52.17±11.4) and 10 healthy controls (mean age 43.8±8.61). Intergroup comparisons were made using the Mann-Whitney U test.

Results: A significantly higher expression of AT1R was found in RA patients compared to healthy controls (p<0.01). Even though the finding did not reach statistical significance, AT2R expression was also higher in RA patients (p =0.072).

Conclusion: the results suggest AT1R and possibly AT2R upregulation in RA patients, indicating that RAS overactivation could contribute to the increased CV risk observed in RA patients. If such findings are confirmed by further research, they could have important implications in terms of prevention and treatment strategies for RA patients as RA is associated with an elevated CV risk that is often overlooked and underdiagnosed in these populations.

AB0391 THE IMPACT OF OBESITY ON LIPID PROFILE AND ATHEROGENIC INDEXES AMONG RHEUMATOID ARTHRITIS ELDERLY PATIENTS

Keywords: Rheumatoid arthritis, Comorbidities

M. Ardhaoui[1], M. Ghali[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. *[1]Fattouma Bourguiba Hospital, Rheumatology, Monastir,Tunisia*

Background: Obesity and dyslipidemia are two common comorbidities in rheumatoid arthritis (RA). They are considered as important cardiovascular and atherosclerosis risk factors in RA.

Objectives: The aim of our study was to evaluate the impact of obesity on lipid parameters as well as on atherogenic indexes among RA elderly patients.

Methods: A cross-sectional study was conducted including patients followed for RA and aged ≥ 65 years. All patients had lipid measurements of standard (total cholesterol (TC), high-density lipoproteins (HDL), low-density lipoproteins (LDL), and triglycerides (TG)) and specific (Apolipoproteins (Apo) A1 and B) parameters. We calculated the atherogenic indexes TC/HDL and LDL/HDL and apoB/apoA1. Patients were divided according to body mass index (BMI), into 2 groups: G1=obese patients with BMI ≥ 30 Kg/m² and G2 of non obese patients with BMI <30.

Results: We included 63 patients (52 women and 11 men). The mean age was 68.17±4.35 years [65-83]. The median duration of disease was 11 years. The mean BMI was 27.97±5.44 kg/m2 [14.85-43.2]. Twenty-two patients (34.9%) were obese (G1) and 41 patients (65.1%) had a BMI < 30 (G2). Mean levels of Apo A1, Apo B, TC, HDL, LDL and TG were 1.53±0.34 g/L, 1.1±0.29 g/L, 4.91±1.03 mmol/L, 1.09±0.29 mmol/L, 2.96±0.86 mmol/L and 2.02±1.47 mmol/L, respectively. Mean values of the atherogenic indexes TC/HDL, LDL/HDL and ApoB/ApoA1 were 4.77±1.59, 2.96±1.39 and 0.74±0.2 respectively. Comparing the G1 of obese patients with the G2, we found that obese patients had changes in lipid profile with significantly higher levels of Apo B (1.22±0.29 g/L vs. 1.04±0.27; p=0.018), TC (5.6±0.82 mmol/L vs 4.2±1.07; p=0.008) and LDL (3.5±0.84 mmol/L vs 2.54±0.84; p=0.03). A significantly lower ApoA1 level was noted in G1 (1.47±0.3 g/L vs 1.66±0.24; p=0.019). A lower level of HDL was noted in the

G1 (1.06±0.33 mmol/L vs 1.15±0.2), but without significant association (p=0.5). However, there was no significant difference in TG levels (p=0.9) and atherogenic indexes including TC/HDL (p=0.07), LDL/HDL (p=0.1) and ApoB/ApoA1 (p=0.2).
Conclusion: We demonstrated that obesity is associated with alterations in many lipid parameters among RA elderly patients. Obesity actually acts in synergy with the various conventional factors, including dyslipidemia, to increase the cardiovascular risk in this population.

AB0392 RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE: RISK FACTORS

Keywords: Rheumatoid arthritis, Organ damage, Lungs

M. Slouma[1], S. Bouzid[1], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1], B. Louzir[2]. [1]*The Principal Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia*; [2]*The Principal Military Hospital of Instruction of Tunis, Internal medicine, Tunis, Tunisia*

Background: Interstitial lung disease (ILD), a severe extra-articular manifestation of rheumatoid arthritis (RA), contributes to significantly increased morbidity and mortality [1].
Objectives: Our study aimed to determine the risk factors of RA-associated ILD.
Methods: We conducted a retrospective, monocentric study over 4 years (2018-2022). Patients with RA, fulfilling the ACR/EULAR 2010, were included. ILD was defined as the presence of a radiologist-defined pattern consistent with ILD on chest computed tomography. Potential risk factors included age, sex, smoking, obesity, immunopositivity, extra-articular manifestations, disease activity, and medications. A statistical study was carried out using SPSS software.
Results: We included 128 patients with RA. The mean age was 53,03±12,87 years, with a male-to-female ratio of 0,31. The mean disease duration was 8,88±7,33 years. Nineteen patients had a confirmed ILD. Usual interstitial pneumonia was the most frequent subtype of ILD (63%, n=12). Using logistic regression analysis, the significant risk factors of ILD were: age (>60 years) (OR=29,516, IC95% [1,416-615,176], **p=0,029**), the erosive nature of RA (OR=24,302, IC95% [1,185-498,175], **p=0,038**), the presence of cutaneous rheumatoid nodules (OR=52,558, IC95% [1,696-1628,890], **p=0,024**) and ocular involvement (OR=45,377, IC95% [1,825-1128,183], **p=0,020**).
Conclusion: Our study showed that older patients (age>60 years), with an erosive RA, cutaneous rheumatoid nodules, and ocular manifestations are at higher risk of developing ILD. These findings suggest that an early screening of ILD in these patients can be advised.

AB0393 SLEEP DISORDERS IN PATIENTS AFFECTED WITH RHEUMATOID ARTHRITIS: ASSESSMENT AND CORRELATION WITH FLARE-UPS

Keywords: Rheumatoid arthritis, Quality of life, Inflammatory arthritides

M. Ghanmi[1], S. Mtawaa[1], N. El Fani[1], M. Gaddour[2], W. Wanes[2], S. Jemni[2]. [1]*University Hospital Ibn Jazar Kairouan, Physical Medicine and Rehabilitation, Kairouan, Tunisia*; [2]*University Hospital Sahloul, Physical Medicine and Rehabilitation, Sousse, Tunisia*

Background: Patients with rheumatoid arthritis (RA) suffer from augmented inflammatory pain during flare-ups. Their quality of sleep (QOS) is altered, but to the best of our knowledge no local data has been published on the matter.
Objectives: We aim to assess the quality of sleep in Patients with RA and to study its correlation with the disease flare-ups. QOS was altered among patients with RA. Poor sleep quality has been linked to pain, mood, fatigability, stress, and disease activity in the rheumatic disease population [1]. This study established the link between flare-ups and the presence of sleep disorders. We found greater frequence of sleep disturbance in this population [1] which may be explained by the presence of more patients with higher DAS28.
Methods: We conducted a cross sectional study using a self-administered questionnaire. Patients with RA consulting in physical medicine and rehabilitations outpatient clinics were included. Data was collected during the period from September 1, 2020 until the end of Mai 2022. We collected sociodemographic and clinical data. Disease Activity Scale (DAS28) greater than 5.1 was used to define a flare-up. QOS was assessed using the Pittsburg Sleep quality index (PSQI) in its validated Arabic version. Sleep disorder was defined by PSQI greater than 5.
Results: We included 54 patients. Their mean age was 38.6. Mean duration of progression of the disease was 6.9 years. Almost half of the patients were having a flare-up (42.6%). Mean score of PSQI was 9.6. 82.5% of the patients had a sleep disorder. The most common sleep disorder was multiple nocturnal wake ups (94.4%). We found a significant correlation between sleep disorder and a rheumatoid flare. Odds Ratio was 11.8 (p= 0,012).
Conclusion: QOS was altered among patients with RA. Poor sleep quality has been linked to pain, mood, fatigability, stress, and disease activity in the rheumatic disease population [1]. This study established the link between flare-ups and the presence of sleep disorders. Clinicians dealing with patients with patients with RA should have more attention to the QOS especially on flare-ups.

AB0394 DYSLIPIDEMIA IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Comorbidities, Rheumatoid arthritis

I. Klymas[1]. [1]*Shupyk National Healthcare University of Ukraine, Department of Therapy, Family Medicine, Hematology and Transfusiology, Kyiv, Ukraine*

Background: Patients with rheumatic diseases characterized by a pronounced inflammatory process. Systemic chronic inflammation, which is characteristic of patients with rheumatoid arthritis (RA), determines the high risk of developing metabolic disorders. Most often, patients with RA have disorders of lipid metabolism.
Objectives: To investigate the dystipidemia frequency in RA patients and in the control group without autoimmune and inflammatory diseases.
Methods: Were investigated 126 RA patients (102 women and 24 men, average age 43,82±2,8 years) and 30 subjects (control group) without autoimmune and inflammatory diseases (25 women and 5 men, average age 42,4±2,6 years). RA was diagnosed according to ARA criteria (1987); patients with hepatitis, alcohol abuse, >55 years old were not included. Statistical analysis was performed using program Statistica. The reliability of differences was defined at p <0.05.
Results: The evaluated of lipid metabolism in RA patients and control group are presented in Table 1.

Table 1. Characteristics of lipid metabolism in RA patients and in the control group. (M - the average value, m - the standard deviation).

The investigated indicator	RA patients (n=126) M±m	The control group (n=30) M±m	p
Total cholesterol, mmol/ L	5,21±0,84	4,51±0,31	p<0,001
HDL cholesterol, mmol/ L	1,41±0,25	1,52±0,28	p<0,05
LDL cholesterol, mmol/ L	3,10±0,90	2,51±0,42	p<0,001
VLDL cholesterol, mmol/ L	0,70±0,22	0,49±0,14	p<0,001
TG, mmol/ L	1,55±0,48	1,08±0,30	p<0,001
Atherogenicity index	4,21±0,84	2,09±0,74	p<0,001

***** - the difference between groups is significant, p<0.05.

In conduct an analysis of lipid metabolism in RA patients and in the control group, a high level of statistical significance p<0.001 was found in the indicators of lipid metabolism in patients with RA compared with those of the examined control group.
Conclusion: Disorders metabolism of lipids have a high prevalence among patients with RA. For the purpose of timely diagnosis of metabolic disorders of lipid metabolism in patients with RA, it is recommended to carry out a laboratory blood test with the determination of lipidogram indicators at least once a year.

Rheumatoid arthritis - biological DMARDs

AB0395 **IMMUNE-MEDIATED SKIN LESIONS RELATED TO BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS: A 22-YEAR EXPERIENCE OF A TERTIARY CENTER**

Keywords: bDMARD, Skin

A. Martins[1,2], D. Santos Oliveira[1,2,3], F. R. Martins[4], R. Nicolau[5], F. Oliveira Pinheiro[1], M. Rato[1], A. Bernardo[1], S. Pimenta[1,2], M. Bernardes[1,2], L. Costa[1]. *[1]São João Universitary Hospital Center, Rheumatology, Porto, Portugal; [2]Faculdade de Medicina da Universidade do Porto - FMUP, Medicine, Porto, Portugal; [3]Faculdade de Medicina da Universidade do Porto - FMUP, CINTESIS, Porto, Portugal; [4]University Hospital Center of Algarve, Faro, Rheumatology, Faro, Portugal; [5]Centro Hospitalar Tondela - Viseu, Epe, Rheumatology, Viseu, Portugal*

Background: Biological disease-modifying antirheumatic drugs (bDMARDs) have revolutionized the treatment of chronic inflammatory rheumatic diseases. However, the physician and the patient should be aware of possible adverse reactions. Skin is one of the most frequent organs involved in bDMARD adverse reactions and immune-mediated skin lesions (IMSL) have rarely been described before in cohort studies and their incidence is unknown.
Objectives: To explore the cumulative incidence, type of lesions, management and outcomes of IMSL related to bDMARD in a large cohort of patients with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA).
Methods: We conducted a retrospective single-center study including patients with RA, axSpA and PsA followed at a Rheumatology Department from a University Hospital Center between April 2000 and December 2021, treated with at least one bDMARD for at least 6 months. Sociodemographic characteristics, disease duration, age at diagnosis, concomitant immunosuppressive medications, type and duration of the treatment with bDMARD and number of previous bDMARD were collected. For all patients with IMSL, age at onset, disease duration at the time of the IMSL, culprit bDMARD and duration of the treatment, specific management and outcomes were collected. Descriptive statistics for continuous variables were presented with mean and standard deviation and categorical variables were presented with absolute and relative frequencies.
Results: A total of 441 patients with RA, 386 with axSpA and 162 with PsA were included. The majority were female (63.4%), with a mean age of 54.3 ± 12.8 years. An important proportion of patients (47.6%, n=471) were taking csDMARDs and the most prescribed bDMARD was adalimumab (21.8 %), followed by etanercept (16.5%). Twenty-seven (2.7%) patients presented IMSL potentially related to the bDMARD. Regarding the patients with IMSL, 55.6% were females, mean age at the onset of IMSL was 48.4 ± 12.0 years, mean duration of the treatment with bDMARDs was 4.3 ± 4.5 years and mean duration of the treatment with the culprit bDMARD was 2.3 ± 2.1 years. The majority of patients had SpA (n= 14), followed by RA (n=10) and PsA (n=3). Adalimumab was the culprit agent in half of the patients (n=14), followed by etanercept (n=4), golimumab (n=3), infliximab (n=3), rituximab (n=2) and tocilizumab (n=1). Four patients (14.8%) needed hospitalization with the purpose of performing a clinical, laboratorial and histological investigation. In most patients, skin lesions resolved completely with topical (n=12) or systemic (n=6) treatment. IMSL led to withdrawal of bDMARD in 18 patients (66.7%). More information about the type of IMSL was described in table 1.

Table 1. Description of number of cases, age at IMSL onset, disease duration and duration of treatment with the culprit bDMARD for each type of IMSL.

Type of immune-mediated skin lesion	Number of patients, n(%)	Age at skin lesion onset, mean±SD, years	Female, n(%)	Disease duration, mean±SD, years	Duration of treatment with culprit bDMARD, mean±SD, years
Psoriasis	**12**	49.3 ± 14.5	6 (50.0)	19.5 ± 15.3	1.9 ± 1.7
Plaque psoriasis	5 (41.7)				
Palmoplantar pustulosis	4 (33.3)				
Guttate psoriasis	1 (8.3)				
Inverse psoriasis	1 (8.3)				
Undefined	1 (8.3)				
Drug-induced lupus erythematosus	**6**	40.8 ± 2.9	4 (66.7)	15.2 ± 7.8	2.4 ± 1.4
Malar Rash	1 (16.7)				
Alopecia	2 (33.3)				
Chilblains	2 (33.3)				
Subacute cutaneous LE	1 (16.7)				
LE tumidus	1 (16.7)				
Alopecia areata	3	4.4 ± 6.7	1 (33.3)	12.2 ± 627	1.2 ± 0.6
Leukocytoclastic vasculitis	2	60.9 ± 2.8	0 (0)	31.9	2.9 ± 3.6
Urticaria	2	57.3 ± 15.9	2 (100)	27.8 ± 22.1	0.9 ± 1.2
Rosacea	1	48	1 (100)	18.5	9.7
Erythema nodosum	1	60	1 (100)	40.7	2.9

Conclusion: IMSL related to bDMARDs are unusual events with an estimated cumulative incidence of 2.9%, in our sample. The most frequent IMSL were psoriasis and cutaneous manifestations of DILE and the most frequent culprit bDMARD was adalimumab. The majority of patients didn't need hospitalization and presented complete resolution of IMSL. IMSL led to withdrawal of the bDMARD in 2/3 of patients.

AB0396 **DISCONTINUATION AND EFFECTIVENESS OF ORIGINATOR AND BIOSIMILAR TNFI IN PATIENTS WITH RHEUMATOID ARTHRITIS: REAL WORLD DATA FROM A RHEUMATOID ARTHRITIS REGISTRY IN CANADA**

Keywords: Rheumatoid arthritis, Outcome measures, bDMARD

M. Movahedi[1,2], A. Cesta[1], X. LI[1], C. Bombardier[1,2]. *[1]Toronto General Hospital Research Institute, Ontario Best Practice Initiative, Toronto, Canada; [2]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada*

Background: In recent years, biosimilars, highly similar copies of originator biologics, have been available in clinical practice to patients with Rheumatoid Arthritis (RA) in Canada. The Ontario government is expected to implement a policy mandating a switch from originator biologics to biosimilars. We may be able to anticipate the outcomes of implementing such a policy by analyzing the existing data for patients already using biosimilars in Ontario.
Objectives: We aimed to describe discontinuation and disease activity in patients starting an originator or biosimilar TNFi, using real-world data from the Ontario Best Practices Research Initiative (OBRI), Canada.
Methods: Patients with active RA enrolled in the OBRI and initiating an originator or biosimilar TNFi between 1st Jan 2015 and 30st March 2022 were included. We investigated time to discontinuation by using Kaplan-Meier (KM) survival curves in the two groups. Due to a small number of biosimilar users, curves were not statistically compared. Using clinical disease activity index (CDAI), disease status was also described for patients with available data at 12 months after treatment.
Results: A total of 494 patients started an originator TNFi (n=401) or biosimilar TNFi (n=93) with mean (SD) disease duration of 12.0 (9.4) and 9.7 (9.3) years, respectively. In the originator group, 81.5% were female and mean age (SD) was 57.2 (11.9) years. In the biosimilar group, 82.8% were female and mean (SD) age was 59.2 (11.5) years. The originator group was less likely to have prior biologic use (31.9%) compared to the biosimilar group (58.1%). The mean (SD) baseline CDAI was lower in the originator group [17.2 (11.6)] compared to the biosimilar group [22.6 (13.7)]. Over a mean follow-up of 25.9 months, discontinuation was reported in 154 (38.4%) and 21 (22.6%) originator and biosimilar groups, respectively. The mean survival (standard error) in originator group was 49.5 (1.85) months and 56.1 (4.70) months in biosimilar group. The retention rate (95% Confidence Interval) at 12 months was 74.8% (70.1%-78.9%) in the originator group and 84.6% (74.4%-91.0%) in the biosimilar group (Table 1). At 12 months after treatment initiation, disease activity was similar in the two groups (mean of CDAI: 14.0 vs.13.0).
Conclusion: In this real-world data descriptive study, we found that the proprtion of patients who remained on their medication in the biosimilar group was numerically higher than the originator TNFi. We also found that disease activity after 12 months after initiation was numerically similar in both groups. Next steps include, comparing discontinuation and disease activity between the two groups using a statistical regression analysis adjusting for potential confounders.

Table 1. Survival rate over 2 years of follow-up by treatment group

	TNFi Biosimilar N=93	Originator TNFi N=401
Number of discontinuation	21	154
Probability of survival		
6 month (%, (95%CI))	92.9 (84.9-96.8)	88.4 (84.7-91.2)
12 months (%, (95%CI))	84.6 (74.4-91.0)	74.8 (70.1-78.9)
18 months (%, (95%CI))	77.8 (65.9-85.9)	69.8 (64.7-74.2)
24 months (%, (95%CI))	70.9 (57.5-80.8)	65.9 (60.7-70.6)

Background: Rheumatoid arthritis (RA) is associated with a 2-fold higher risk of venous thromboembolism (VTE) compared with the general population [1]. The immune system and hemostatic system are closely linked by a shared origin. Inflammation affects thrombotic responses by upregulating procoagulants and downregulating anticoagulants and fibrinolysis [1]. Tumor necrosis factor (TNF), an important mediator in the inflammatory pathway, induces a disbalance between the coagulation system and fibrinolytic system, resulting in a hypercoagulable state. In addition, several studies have suggested that some Janus kinase-inhibitors (JAKi) might be associated with an increased risk for VTE [2]. However, the underlying pathogenic mechanisms have yet to be elucidated.
Objectives: To compare changes in hemostatic parameters during treatment with TNF-blockers (aTNF) and JAKi in RA.
Methods: Biomarkers for the coagulation system, including D-dimer, fibrinogen, PT, aPTT, F1+2, TAT, F IX and vWF, were prospectively measured in 121 consecutive RA patients: 83 patients treated with aTNF and 38 patients with JAKi. Data were collected at baseline, after 1, 3, and 6 months.
Results: Mean age for all patients was 57 (±14) years, 76% were female. Mean DAS28-CRP at baseline for TNF-inhibitor group was 3.6 (±1.3) and 4.1 (±1.4) for JAKi group, steadily declining in aTNF users, while decreasing in JAKi users with an intermittent peak at 3 months. Baseline coagulation markers levels were comparable between the groups. D-dimer and vWF levels were slightly higher in the JAKi group (p = 0.30 and p = 0.08, respectively), while F IXa levels were lower (p = 0.17). D-dimer and fibrinogen levels steadily declined in the aTNF group, while fluctuating in the JAKi group, with a peak at 3 months with a subsequent decline thereafter (Figure 1). In aTNF users, TAT increased slightly during follow-up. VWF, PT and aPTT remained relatively stable, while F IXa and F 1+2 showed an increase after 3 months of follow-up, after which they returned to baseline. In JAKi users, D-dimer, fibrinogen, VWF and F 1+2 fluctuated, with a peak after 3 months and then a subsequent decline. F IX and PT initially decreased slightly but increased steadily after 6 months, while TAT and aPTT remained stable during follow-up.
Conclusion: The pro-thrombotic tendency in active RA declined during effective treatment with both aTNF as well as JAKi. A gradually decrease in D-dimer and fibrinogen was seen after 6 months of treatment. The transient increase of coagulation activation in JAKi users at three months coincided with increased disease activity. Altogether, our data suggests that an increased VTE risk in the first six months due to either treatment aTNF or JAKi seems unlikely. Whether or not the risk increases beyond this time period remains to be investigated.

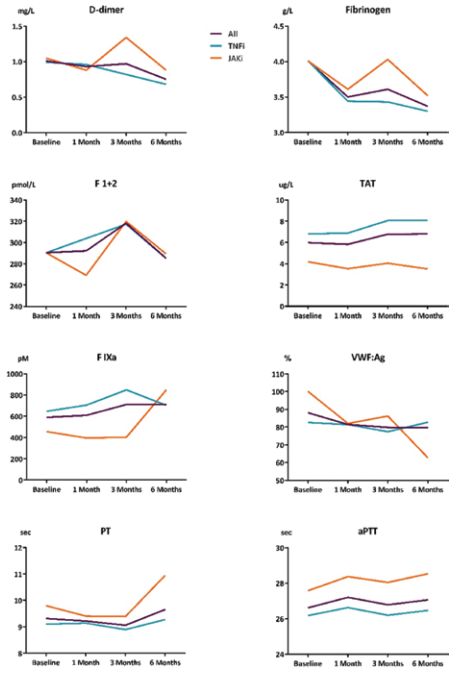

Figure 1. Progression of coagulation markers.

Table 1. Progression of mean coagulation markers.

	Baseline	1 Month	3 Months	6 Months
D-dimer				
TNF	0,99	0,96	0,82	0,68*
JAK	1,05	0,88	1,34	0,88
Fibrinogen				
TNF	4,01	3,44*	3,43*	3,3*
JAK	4,01	3,61	4,03	3,52
F1+2				
TNF	290,46	303,88	317,27	285,21
JAK	290,39	269,24	319,87	289,37
VWF				
TNF	82,56	81,45	77,42	82,74
JAK	100,13	82,00	86,23	62,72
TAT				
TNF	6,81	6,89	8,06	8,06
JAK	4,19	3,54	4,05	3,51
FIX				
TNF	646,86	705,61	848,85	703,32
JAK	456,53	395,40	403,36	848,85
PT				
TNF	9,10	9,14	8,90	9,28
JAK	9,80	9,41	9,39	10,95
aPTT				
TNF	26,17	26,63	16,19	26,47
JAK	27,58	28,37	28,04	28,53

* Significantly different from baseline, p < 0,05. TNF = tumor necrosis factor, JAK = Janus kinase, F1+2= prothrombin fragment 1+2, VWF= von Willebrand factor, TAT= thrombin-antithrombin complex, FIX= Factor 9, PT = prothrombin time, aPTT = activated partial thromboplastin time.

Background: The ORAL-surveillance trial showed a higher risk of major adverse cardiovascular events (MACE) and cancer in patients with rheumatoid arthritis (RA) taking tofacitinib, a Janus kinase inhibitor (JAKi), compared to those taking tumor necrosis factor alpha inhibitors (TNFi's). However, little is known regarding the comparative safety of these two drug classes relative to non-TNFi biologics.
Objectives: To assess the comparative safety of TNFi's, non-TNFi's, and JAKi's in RA patients for the risk of MACE (e.g., myocardial infarction, cardiac arrest, sudden death, stroke, percutaneous coronary intervention, and coronary artery bypass graft), cancer, deep vein thrombosis (DVT), and pulmonary embolism (PE).

Methods: We performed a retrospective cohort study using IBM Watson MarketScan databases (2012-2019) of RA patients 18-64 years of age who initiated treatment with TNFi's, non-TNFi's, or JAKi's on or after January 2012. We used Cox Proportional hazards models to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for developing MACE, cancer, DVT, and PE within 2 years of initiation in patients on non-TNFi's or JAKi's relative to TNFi's, adjusting for multiple confounders, including age, gender, geographic region, year of initiating a biologic, Charlson Comorbidity Index, frailty status, healthcare utilization within 12 months prior to starting treatment (i.e., major infection requiring hospital admissions, general hospital admissions, outpatient visits, and emergency department visits), and RA severity (i.e. disease-modifying antirheumatic drug, nonsteroidal anti-inflammatory drug, glucocorticoid, and opioid fills 3 months prior to starting treatment).

Results: A total of 39,032 drug initiation events met eligibility criteria for our study (73.6% initiation of TNFi's, 18.6% non-TNFi's, and 7.80% JAKi's). The mean age of the patients in each of the groups ranged from 47-49 years old; the majority were female. The mean follow-up time was 349 days for TNFi's, 272 days for non-TNFi's, and 266 days for JAKi's. Non-TNFi's were associated with an increased risk of MACE, cancer, and DVT, though the incidence of adverse health outcomes overall was still quite low (Table 1). In multivariable models, patients who started non-TNFi's had a significantly higher risk of MACE (HR 1.75; 1.34-2.28), incident cancer (HR 2.06; 1.70-2.50), and DVT (HR 1.84; 1.45-2.32) compared to those who initiated TNFi's. Patients who filled JAKi's had a significantly higher risk of developing cancer compared to those who filled TNFi's (HR 1.48; 1.09-2.03).

Conclusion: TNFi's may be safer for RA treatment than non-TNFi's and JAKi's for RA in this generally younger and predominantly female population. However, since most RA patients initiate treatment with TNFi's, results could be confounded by the possibility of more severe or prolonged disease in patients on non-TNFi's and JAKi's. These findings need to be replicated in other study populations. Future steps include looking at the risk conferred by individual non-TNFi's towards these risks. Studies with longer follow-up are needed for better assessment of cancer risk among these drug classes.

Table 1. Incidence per 10,000 person-years of each adverse health outcome* stratified by drug class in RA patients 18-64 years of age.

Adverse Health Outcome	TNFi n = 28,716 (73.6%)**	Non-TNFi n = 7,290 (18.6%)**	JAKi n = 3,026 (7.80%)**
MACE	72.9	162.6	94.8
Cancer	132.9	296.4	192.3
DVT	90.9	216.5	107.7
PE	22.1	43.9	24.6

*Outcomes are not mutually exclusive; each patient could have experienced multiple outcomes.**Number and percentage of drug class initiation events.

Background: Rheumatoid arthritis(RA) is a systemic inflammatory disorder that mainly affects the diarthrodial joint. Abatacept was approved by the US Food and Drug Administration (FDA) in December 2005 for use in RA[1,2].

Objectives: This study aimed to systematically evaluate the efficacy and safety of abatacept therapy in RA.

Methods: Eight databases (PubMed, Web of Science, Embase, Cochrane Library, Web of Knowledge, MEDLINE, Clinical Trials.gov, and FDA.gov) were searched for studies on abatacept treatment of RA published from the date of establishment of the database to January 1, 2022. A random effect model was used to conduct a meta-analysis of the efficacy and safety of abatacept in patients with RA using (Stata 12.0).

Results: The DAS28-CPR of RA receiving abatacept therapy at 24 weeks was significantly decreased compared with the baseline[SMD= -1.624, 95%CI -1.903 - -1.345, P<0.01]. After receiving abatacept therapy for 24 weeks, patients with RA had a significantly decreased in DAS28-ESR [SMD= -1.067 (95% CI: -1.399 - -0.735), P<0.01], SDAI [SMD= -1.484 (95% CI: -2.167 - -0.802) P<0.01], and CDAI [SMD=-1.726 (95% CI: -2.671 - -0.781), P<0.01] compared with the baseline. The incidence of adverse events was 58.7%. The incidence of serious adverse events was 8.7%. General infection is a typical effect of abatacept, occurring in 25.2% of RA. Most of these adverse events were mild and recovered

quickly after discontinuation. Besides, severe infection occurred in 2.3 % of RA (Figure 1).

Conclusion: Abatacept was effective and well-tolerated in RA patients. The incidence of adverse events was high, but most were mild and recovered quickly after discontinuation.

THE PATTERN OF INTERLEUKIN-6 INHIBITORS VERSUS OTHER BIOLOGIC DRUG USE IN PATIENTS WITH RHEUMATOID ARTHRITIS IN WALES, UK: A REAL-WORLD STUDY USING ELECTRONIC HEALTH RECORDS

Keywords: bDMARD, Rheumatoid arthritis, Real-world evidence

R. Cooksey[1], J. Kennedey[2], R. Muhammad[3], S. Brophy[4], E. Choy[5]. *[1]Cardiff University, Medicine, Cardiff, United Kingdom*; *[2]Swansea University, Data Science, Swansea, United Kingdom*; *[3]Cardiff Metropolitan University, Cardiff School of Technologies, Cardiff, United Kingdom*; *[4]Swansea University, Medicine, Swansea, United Kingdom*; *[5]Cardiff University, Medicine, Cardiff, United Kingdom*

Background: Rheumatoid arthritis (RA) guidelines highlight the importance of early treatment to reduce disease activity and prevent long term damage [1-4]. Infection risk must be considered when starting biologic therapy as infections account for significant morbidity and mortality in RA [5]. Tocilizumab and sarilumab are anti-interleukin-6 (IL-6) receptor antibodies also effective in treating RA symptoms and preventing progression of structural damage [6-9]. Risk of infections in RA patients treated with IL-6 inhibitors have also been reported [10]. However, IL-6 inhibitor monotherapy has a superior efficacy than adalimumab [11]. More information is required to assess real-life burden and predict infection risk in RA patients using biologics [12].

Objectives: Examine the treatment pathway, factors associated with drug initiation and treatment discontinuation in patients with RA treated with either IL-6 inhibitors versus non-IL-6 biologic disease modifying anti-rheumatic drugs (bDMARDs).

Methods: A retrospective cohort study of RA patients in the Secure Anonymised Information Linkage databank, including primary care, secondary care and rheumatology clinic records of over 90% of the population in Wales, UK. Patients initiated on first treatment initiation, discontinuation and clinical outcomes including infection and hospitalisation were analysed using cox regression analysis.

Results: Data from 4922 patients with RA were analysed. The majority of patients had taken at least one conventional synthetic disease modifying anti-rheumatic drug (csDMARD) 95.7%, (4,691/4,922) while 29.6% (1,457) went on to take bDMARDs. Of these, 2% (97) biologic-naïve patients were treated with IL-6 inhibitors. Earlier treatment with bDMARDs was associated with increasing disease duration (HR: 1.11, 95% CI: 1.07 to 1.15) while younger age at diagnosis, orthopaedic surgery pre-treatment and kidney disease reduced the likelihood of being treated with biologics. Previous history of infection was associated with increased likelihood of treatment with IL-6 inhibitors rather than non-IL-6 bDMARDs (HR: 1.73, 95% CI: 1.15 to 2.59). The rate of treatment discontinuation was significantly higher in the non-IL-6 bDMARDs-treated patients compared to the IL-6 inhibitor treated individuals (difference: 9.4, 95% CI: 1.1 to 15.7). Treatment failure, orthopaedic surgery pre-treatment and steroid use was associated with non-IL-6 bDMARDs treatment failure (HR: 1.64, 95% CI: 1.00 to 2.68; HR: 1.62, 95% CI: 1.26 to 2.08, respectively). No factors were associated with treatment failure in the IL-6 inhibitor treated patients.

Conclusion: Patients treated with IL-6 inhibitors and other biologics were similar in demographics but had a different comorbidities pre- treatment; there was more orthopaedic surgery in those who went on to be treated with non-IL-6 biologics and more prior history of infections and kidney disease in those treated with IL-6 inhibitors. Treatment failure was higher in the non-IL-6 bDMARDs-treated patients.

EFFICACY OF ABATACEPT FOR SUPPRESSING RADIOGRAPHIC PROGRESSION OF CERVICAL LESIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARISON WITH METHOTREXATE TREATMENT; THREE YEARS OF FOLLOW-UP ~A MULTICENTER REGISTRY STUDY ~

Keywords: Rheumatoid arthritis, bDMARD

Y. Kanayama[1], K. Hattori[1]. [1]*Toyota Kosei Hospital, Orthopedic Surgery and Rheumatology, Toyota, Japan*

Background: Cervical lesions are known to occur at high frequency as a complication of rheumatoid arthritis (RA). Treatment with biological agents are more clinically effective than the DMARDs that were in use previously, in particular, with their efficacy in suppressing joint destruction having been emphasized. We reported the efficacy of infliximab, anti-tumor necrosis factor antibodies for suppressing the radiographic progression of RA cervical lesions at ACR2009, EULAR2010, 11, 12, 13, 14, 16, 18, 19 and 20. However there is still few studies of efficacy of against RA cervical lesions of Abatacept (ABT) that inhibits T cell activation by binding to CD80/86.
Objectives: To evaluate the efficacy of ABT for suppressing the radiographic progression of RA cervical lesions comparison with MTX for 3 years.
Methods: We used ABT or MTX for treating Japanese patients with active RA who fulfilled the ACR criteria in 1987. The final study cohort of each 49 and 75 patients received continuous ABT and MTX treatment for at least 3 years. For evaluation of cervical lesions, the atlanto-dental interval (ADI), the space available for the spinal cord (SAC), and the Ranawat value were measured by plain lateral radiographs in the flexion position, at initiation and Year 1, 2, 3.
Results: In the patients receiving ABT (n=49) and MTX (n =75), the number of female were each 39(80%) and 52(69%) cases(p=0.206). The mean age was 67.1 ± 13.1 and 63.6 ± 11.0 years old (p=0.010); disease duration was 17.3 ± 14.0 and 8.0 ± 9.5 years (p<0.001) and the mean dose of MTX was 8.1 ± 3.5 and 8.2 ± 2.9 mg/w (p=0.970). Clinical findings related to RA were as follows; CRP 2.2± 2.1 and 1.7± 2.3 mg/dl(p=0.010); ESR 44.1 ± 21.1 and 31.9 ± 21.8mm/h(p=0.001); MMP3 273 ± 303 and 223 ± 350ng/ml(p=0.002); the number of RF-positive 48(98%) and 60(80%) cases(p=0.004); DAS28-ESR 5.12 ± 1.03 and 4.30 ± 1.38 (p<0.001); ADI 3.7 ± 2.1 and 2.6 ± 1.6mm(p<0.001); SAC 18.6 ± 2.9 and 20.8 ± 2.5mm(p<0.001) and Ranawat value 14.4 ± 2.0 and 16.0 ± 1.5mm (p<0.001). The respective changes in cervical lesion parameters after 1 year were as follows: ADI: 0.20 ± 0.41 and 0.25 ± 0.45 mm (p = 0.528); SAC: −0.14 ± 0.35 and −0.17 ± 0.38 mm (p = 0.653); and Ranawat value: −0.18 ± 0.39 and −0.13 ± 0.34 mm (p = 0.449). The respective changes in cervical lesion parameters after 2 years were as follows: ADI: 0.35 ± 0.56 and 0.55 ± 0.70 mm (p = 0.126); SAC: −0.27 ± 0.49 and −0.45 ± 0.62 mm (p = 0.087); and Ranawat value: −0.27 ± 0.49 and −0.33 ± 0.55 mm (p = 0.528). The respective changes in cervical lesion parameters after 3 years were as follows: ADI: 0.47 ± 0.77 and 0.71 ± 0.80 mm (p = 0.063); SAC: −0.39 ± 0.73 and −0.63 ± 0.82 mm (p = 0.040); and Ranawat value: −0.41 ± 0.71 and −0.44 ± 0.66 mm (p = 0.606) in the patients receiving ABT and MTX (Figure 1). The numbers of patients who did not showed progression in ADI, SAC and Ranawat value were each 33(67%) and 37(49%) cases(p=0.048); 37(76%) and 40(53%) cases(p=0.013) and 35(71%) and 49(65%) cases(p=0.478) after 3 years. Also the number who was able to suppress progression in all three parameters were each 32 cases (65%) receiving ABT and 37 cases (49%) receiving MTX (p=0.128) after 3 years (Figure 2).
Conclusion: This study suggested that ABT treatment can be used to suppress the progression of RA upper cervical lesions more than MTX treatment.

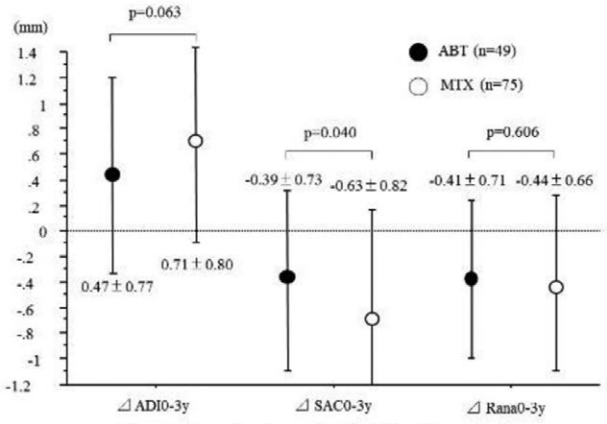

Figure 1 : Respective changes in ADI, SAC and Ranawat value from Year 0 to Year 3 between ABT and MTX patients

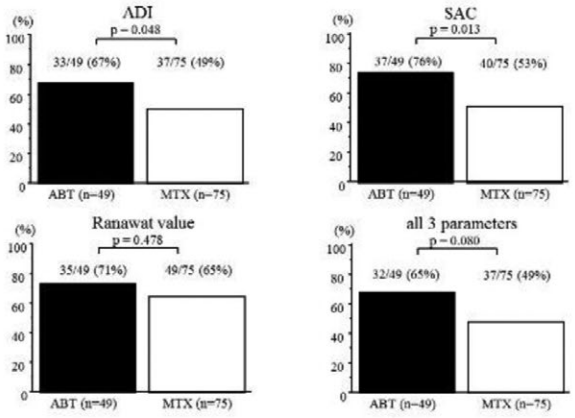

Figure 2 : The rate of patients who did not showed progression in ADI, SAC, Ranawat value and all three parameters after 3 years

Background: CT-P47 is a recombinant humanized monoclonal antibody that was developed as a proposed biosimilar of tocilizumab.
Objectives: The purpose of this study was to compare the pharmacokinetics (PK), safety, and immunogenicity of CT-P47 and EU-approved tocilizumab (EU-tocilizumab) up to 42 days after a single subcutaneous injection of 162 mg of each product in healthy subjects.
Methods: 289 healthy subjects aged 19 to 55 years were randomly assigned 1:1 to receive either CT-P47 or EU-tocilizumab. The primary PK endpoints included area under the serum concentration-time curve (AUC) from time zero to infinity ($AUC_{0\text{-}inf}$), AUC from time zero to the last quantifiable concentration ($AUC_{0\text{-}last}$), and maximum serum concentration (C_{max}). Secondary endpoints were additional PK, safety, and immunogenicity.
Results: Demographics and baseline characteristics were well balanced between groups. The 90% confidence intervals for the geometric least squares mean ratios of each of the primary PK parameters ($AUC_{0\text{-}inf}$, $AUC_{0\text{-}last}$, C_{max}) were within the predefined equivalence margin of 80% to 125% (Table 1). Secondary PK variables (T_{max}, $t_{1/2}$, λ_z, CL/F, V_z/F, $\%AUC_{ext}$) were also comparable between groups. Mean serum concentrations of tocilizumab observed through 42 days post-dose were comparable between groups (Figure 1). Overall, 55 (38.2%) and 72 (51.4%) subjects reported ≥1 treatment-emergent adverse event (TEAE) in the CT-P47 and EU-tocilizumab groups, respectively. Most of TEAEs were grade 1 or 2 in intensity and TEAEs considered to be related to study drug were reported by 47 (32.6%) and 61 (43.6%) subjects, respectively. Neutrophil count decreased was the most commonly reported TEAE overall (14 [9.7%] and 15 [10.7%] subjects, respectively). There were 3 treatment-emergent serious adverse events (2 [1.4%] and 1 [0.7%] subjects, respectively). Of these, only 1 case was considered to be related to study drug (EU-tocilizumab: headache). Overall, 20 (13.9%) and 29 (20.7%) subjects in the CT-P47 and EU-tocilizumab groups, respectively, had ≥1 post-treatment positive result for anti-drug antibodies (ADA) and 17 (11.8%) and 20 (14.3%) subjects, respectively, had ≥1 positive result post-treatment for neutralizing antibody. Primary PK parameters of $AUC_{0\text{-}inf}$, $AUC_{0\text{-}last}$, and C_{max} were slightly lower in subjects with at least 1 ADA positive compared with those subjects with all ADA negative, at post-dose, among groups in the PK set.
Conclusion: This study demonstrated PK equivalence of CT-P47 to EU-approved tocilizumab in healthy subjects. Safety profiles, including immunogenicity, were comparable between groups.

AB0403 LONGITUDINAL ANALYSIS OF CHANGES IN THE FINE ARTICULAR STRUCTURE BY CTLA4-IG USING HR-PQCT IN RHEUMATOID ARTHRITIS

Keywords: Imaging, Rheumatoid arthritis, Real-world evidence

N. Iwamoto[1], K. Chiba[2], S. Sato[3], K. Watanabe[2], K. Shiraishi[2], N. Ohki[4], A. Kawakami[1]. [1]*Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan*; [2]*Nagasaki University Graduate School of Biomedical Sciences, Department of Orthopedic Surgery, Nagasaki, Japan*; [3]*Nagasaki University Hospital, Clinical Research Center, Nagasaki, Japan*; [4]*Nagasaki University Graduate School of Biomedical Sciences, Department of Radiological Sciences, Nagasaki, Japan*

Background: Although the clinical effect of CTLA4-Ig (abatacept: ABT) on rheumatoid arthritis (RA) has been shown by a several kinds of large scale clinical trials and postmarketing surveillances, detail of its effect at a local joint has not been sufficiently analyzed. Recently, it has been shown that CTLA4-Ig has not only inhibition effect on T-cell activation but also has inhibition effect on osteoclast differentiation by directly affecting osteoclast precursors,[1] therefore analysis of the effect on changes in the bone structural at an actual clinical site has been expected. A novel imaging test method of High Resolution peripheral Quantitative CT (HR-pQCT) can detect fine structure of bones that could not have been detected in the past and it can evaluate not only conditions of joint destruction but also periarticular osteoporosis.
Objectives: To compare the changes in fine articular structure including bone erosion and micro-architecture by ABT and csDMARD in patients with RA using HR-pQCT.
Methods: In this open-label, parallel-group study, twenty patients who started newly csDMARD and 15 patients who started ABT were enrolled. Fine articular structure in 2,3 metacarpal head were assessed by HR-pQCT every 6 month for 12 months. Synovitis was assessed by musculoskeletal ultrasound (MSUS) and magnetic resonance imaging (MRI) of wrist and fingers. We also measured

the bone mineral density (BMD) of lumber spine. The estimated difference in adjusted mean and mean (ABT–csDMARD group) and 95% CIs and P-values were calculated using a linear mixed model with treatment group, allocation factor, baseline disease activity, observation time-point, and treatment group × observation time-point as fixed effect, patients as random effect, and baseline value as covariates.

Results: Baseline characteristics including disease activity were similar between the ABT and csDMARD groups. The mean Δdisease activity scores (DAS)28-ESR from baseline to 12 months were −1.61 (ABT) and −1.71 (csDMARDs). The estimated difference of mean changes in erosion volume, depth and width of 2,3 metacarpal head between ABT and cs DMARDs group were -1.86mm^3, -0.02mm and -0.09mm, respectively (Table 1). During observational period (12 months), only one new erosion detected by HR-pQCT appeared, and 14 erosions were repaired in ABT group, whereas, in csDMARD group, 5 new erosions appeared, and 5 erosions were repaired. Regarding synovitis, changes in synovitis score defined by MSUS and the RA-MRI score (RAMLIS) were similar between these two groups. Compared with patients in the csDMARD group, those in ABT group had better bone micro-architectures improvement (Table 1). In the other hand, % change of BMD of lumbar at 12 months were less improved in ABT group as compared csDMARDs group (0.17%, 1.82%, respectively).

Conclusion: Our results indicated that the ABT could repair bone erosions and had better inhibitory effect of bone erosion, improvement periarticular osteoporosis as compared with csDMARD treatment regardless of improvement of disease activity, synovitis and progress of systemic osteoporosis. Thus, CTLA4-Ig treatment might be beneficial not only in terms of inhibition of bone erosion but also improvement of bone micro-architecture.

AB0404 DE-ESCALATION OF ANTI-TNFS IN OLDER ADULTS WITH RHEUMATOID ARTHRITIS

Keywords: bDMARD, Tapering, Rheumatoid arthritis

J. Lee[1], N. Singh[2], R. Yung[1], U. Makris[3,4], J. Bynum[1]. [1]*University of Michigan, Internal Medicine, Ann Arbor, United States of America*; [2]*University of Washington, Internal Medicine, Seattle, United States of America*; [3]*University of Texas Southwestern Medical Center: Library, Internal Medicine, Dallas, United States of America*; [4]*VA Dallas, Internal Medicine, Dallas, United States of America*

Background: Biologic disease modifying anti-rheumatic drugs (bDMARDs) such as anti-TNFs improve clinical and radiographic outcomes in rheumatoid arthritis (RA). However, their use is associated with dose- and age-dependent adverse effects including increased risk of serious infections. In recent years, de-escalation (or deprescribing) has been proposed as an approach to reduce polypharmacy and optimize medication use in older adults more prone to the negative, often additive, adverse effects of medications. Current clinical practice guidelines recommend de-escalating bDMARDs in RA patients with low disease activity or in remission. Whether and how bDMARDs are de-escalated in usual care in older adults with RA is poorly understood.

Objectives: To evaluate prevalence and factors associated with anti-TNF de-escalation in older adults with RA.

Methods: In this retrospective observational study using 20% Medicare data from 2009-2017, we identified adults 66 years of age or older with RA, on anti-TNF therapy within 6 months of cohort entry date with at least 6-7 months duration (proxy for stable use). We evaluated the use of five anti-TNFs: Adalimumab, Etanercept, Certolizumab, Golimumab, and Infliximab. Baseline patient characteristics including comorbidity and concomitant use of glucocorticoid (GC) and other DMARDs were collected. Anti-TNF use was categorized as either continuation or de-escalation, identified by dose reduction, dosing interval increase or cessation of use.

Results: We identified 5720 Medicare beneficiaries who met study inclusion criteria. Average age was 74.0 (SD 5.8), 77.9% were female, 83.3% were non-Hispanic white, 26.4% had low-income subsidy, and average Elixhauser comorbidity count was 2.2 (SD 2.0). At baseline, 65.7% had concomitant conventional synthetic DMARD (csDMARD) use and 30.9% were on long-term (≥90 days) GCs. During the study period, one in five de-escalated anti-TNFs (20.1%), of whom 61.3% either reduced dose or increased dosing interval and 38.7% ceased use. Compared to those with continuation of use, de-escalators had more concomitant csDMARD use (60.0% versus 56.5%) and less long-term GC use (26.6% vs 30.9%). In multivariable analyses, de-escalation was less likely in those with low-income subsidy (HR 0.70, 95% CI 0.60-0.82, p<0.0001), adjusting for patient age, sex, race/ethnicity, and comorbidity as a time-varying variable (Table 1).

Conclusion: Anti-TNFs are de-escalated in one in five older adults with RA in usual care. Further study is needed to evaluate impact of de-escalation on RA outcomes.

*Baseline variables used for propensity score adjustment: age, gender, time between BSRBR-RA registration and drug start, DAS28, disease duration, RF status, smoking history, BMI, current methotrexate, total number of prior csDMARDs, line of therapy (only in analyses of all LoTs), prior use of TNFi (not in analyses of first LoT only), prior use of IL6i (not in analyses of first or second LoT only), current use of steroids, ever use of antiplatelet or anticoagulant drugs; history of: hypertension, dyslipidaemia, diabetes, lung disease, renal disease, depression, cancer, venous thromboembolism, ischemic heart disease (myocardial infarction and angina), stroke

Background: Interleukin 6 inhibitors (IL-6i) can increase LDL cholesterol levels, which raises concerns about the risk of myocardial infarction (MI) in patients with rheumatoid arthritis (RA) receiving this therapy.
Objectives: This study aims to compare the risk of MI between people with RA in the UK clinical setting receiving IL-6i or tumour necrosis factor inhibitors (TNFi) overall or by line of therapy (LoT).
Methods: Patients with RA registered between 01/10/2001 and 30/05/2022 with BSRBR-RA starting IL-6i or TNFi treatments were included. Occurrence of MI was identified from clinical follow-up forms and through cause of death reported by the national UK death register. Only those MIs occurring whilst patient was actively receiving drug were included. The risk of MI in patients receiving IL6i compared to TNFi was compared using Cox regression, adjusted for baseline co-variates using propensity scores (PS, see Table 1). Follow-up commenced at the start of the drug of interest and patients were censored at occurrence of MI, death, discontinuation of therapy or last follow-up visit, whichever came first. Multiple imputation was used for missing data. To account for known differences in LoT use of TNFi and IL6i (with IL6i more likely as a later line bDMARD), overall analyses adjusted for LoT in PS and secondary analyses by LoT were conducted. Direct switches between originator to biosimilars were considered the same treatment.
Results: A total of 30,022 IL6i or TNFi LoTs in 20,898 patients were included (3,278 IL-6i; 26,744 TNFi), representing 119,797 person-years of exposure. Compared to patients receiving TNFi, patients starting IL-6i treatment were older, had longer disease duration, less likely to use methotrexate and steroids, and had more comorbidities. During follow-up, 409 MIs occurred, 30 on IL-6i and 379 on TNFi. After PS adjustment, the risk of MI was not significantly different between the two treatment overall (HR 0.87, 95% CI 0.56-1.37) or when stratified by LoT (Table 1).
Conclusion: This study could not identify any difference in risk of MI between IL-6i and TNFi treatment after patient characteristics and LoT were considered.

AB0406

EFFICACY OF TNF-ALPHA INHIBITORS IN MANAGEMENT OF IMMUNE CHECKPOINT INHIBITOR RELATED ARTHRITIS

Keywords: Malignancy, Inflammatory arthritides, bDMARD

M. Callan[1]. [1]*Chelsea & Westminster Hospital, Rheumatology, London, United Kingdom*

Background: Use of immune checkpoint inhibitors (ICI) has revolutionised management of multiple malignancies but may be complicated by development of immune-related adverse events including inflammatory arthritis. Once triggered, arthritis may persist, with 50% patients having ongoing symptoms even 1 year after stopping ICI treatment. EULAR guidance, based on small retrospective and prospective studies and case reports, recommends treatment with corticosteroids, with escalation to DMARDs particularly where arthritis remains active at doses of prednisolone >10mgs [1]. There is some evidence to support use of biologic DMARDs in management, but a lack of studies using validated rheumatology scoring tools to objectively assess ICI arthritis response to biologic agents [2-4].
Objectives: The aim of this study was to assess efficacy of TNF-alpha inhibitors in ICI arthritis, using change in Clinical Disease Activity Index (CDAI) as an outcome measure. The CDAI was chosen as it is independent of ESR and CRP which may be influenced by other complications of malignancy and its treatment.
Methods: This was a single centre retrospective study of 65 patients referred with musculoskeletal symptoms following use of an ICI. Patients with ICI arthritis treated with a TNF-alpha inhibitor were identified and their notes systematically reviewed for information about malignancy diagnosis, use of ICI, presentation with inflammatory arthritis and its response to treatment, with arthritis activity monitored using the CDAI.
Results: 40 of the 65 patients referred presented with an inflammatory arthritis and 9 were treated with a TNF-alpha inhibitor to manage arthritis. These included 4 male and 5 female patients, with mean age 65 years. 5 patients had melanoma, 2 renal cell cancer, 1 mesothelioma and 1 gall bladder adenocarcinoma. All 9 patients had received treatment with a PD-1/PDL-1 inhibitor, with 5 patients also receiving a CTLA-4 inhibitor. 1 patient had a prior diagnosis of psoriatic arthritis and 1 had a prior diagnosis of rheumatoid arthritis. Both experienced increased arthritis activity following ICI treatment. The remaining 7 patients developed new onset polyarthritis following ICI treatment, with 1 of 7 being anti-CCP and RF positive. Prior to use of a TNF-alpha inhibitor, all 9 patients had received treatment with prednisolone. 4 patients had been treated with methotrexate, of whom 3 had also had sulfasalazine. 6 of 9 patients received adalimumab as a first biologic, with the other 3 receiving infliximab. CDAI prior to use of a TNF-alpha inhibitor ranged from 20 to 62, with a mean of 32.8. 2 patients had moderate disease activity (CDAI>10 and ≤22) and 7 patients had high disease activity (CDAI>22). The CDAI at follow up ranged from 4 to 31 with a mean of 13.2. 5 patients had low disease activity (CDAI≤10), 4 patients had moderate disease activity and 2 patients had high disease activity at this time. Use of a TNF-alpha inhibitor was associated with a clinically meaningful improvement in CDAI in 8 of 9 patients at follow up after a mean of 11 weeks of treatment, including 1 patient who continued with ICI treatment.
Conclusion: This single centre retrospective study suggests efficacy of TNF-alpha inhibitors in management of ICI arthritis. Similar to previous work, this study is small and limited by lack of a control cohort but has the advantage of using a validated rheumatology scoring tool to confirm changes in arthritis activity. TNF-alpha inhibitors have a shorter time to onset of action than csDMARDs and so offer an opportunity for early control of ICI arthritis, with potential for use in parallel with continued ICI treatment if needed for management of the underlying malignancy.

Background: 2022 EULAR recommendation announced that biological disease-modifying antirheumatic drugs (bDMARDs) and janus kinase inhibitors (JAKi) are considered in the phase IItreatment of rheumatoid arthritis (RA). On the other hand, serum rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (ACPA) titer are reported to affect bDMARDs and JAKi efficacy. However, we still lack reliable evidence of the impact of RF and ACPA titer on these agents' retention, which may reflect both effectiveness and safety.

Objectives: The aim of this multicenter (7 university-related hospitals)[1,2], retrospective study was to clarify the impact of RF or ACPA titer on treatment retention of bDMARDs and JAKi in patients with RA, which may be useful for adequate treatment selection in a real-world setting.

Methods: This study assessed 5,343 treatment courses of bDMARDs and JAKi introduced from 2001 to 2022 (TNF inhibitors [TNFi]=2,724, anti-IL-6 receptor antibody [aIL-6R]=1,227, cytotoxic T lymphocyte-associated antigen-4-Ig [CTLA4-Ig]=906, JAKi=486; bDMARDs/JAKi naive cases 50.6%, baseline age 60.0 years, female 83.5%, disease duration 10.3 years, DAS28-ESR 4.3, RF positivity 78.3%, ACAP positivity 82.8%, combined methotrexate [MTX] dose 8.4mg/week [47.8%], and prednisolone [PSL] dose 5.9mg/day [28.2%]). Patients were classified into three groups according to their serum RF (IU/mL) and ACPA (U/mL) titer: negative (RF<15 or ACPA<4.5), low positive (15≦RF<100 or 4.5≦ACPA<100), or high positive (100≦RF or 100≦ACPA), respectively. Reasons for discontinuation were classified into four categories by each attending physician: 1) lack of effectiveness (primary and secondary), 2) toxic adverse events (infection, malignancies, and cardiovascular events, et al.), 3) non-toxic reasons (patient preference and pregnancy, et al.), and 4) remission. Retention rates of each discontinuation reason were estimated at 24 months using the Kaplan-Meier method and adjusted for potential clinical confounders (age, sex, concomitant PSL and MTX, switched number of bDMARDs or JAKi, and prior use of TNFi, aIL-6R, CTLA4-Ig, or JAKi) using Cox proportional hazards modeling.

Results: Adjusted discontinuation rates for each reason were as follows: due to lack of effectiveness was aIL-6R=21.4%, JAKi=27.1%, CTLA4-Ig=30.4%, and TNFi=36.2% (Cox P<0.001 between 4 groups), due to toxic adverse events was CTLA4-Ig=12.1%, aIL-6R=12.5%, TNFi=13.3%, and JAKi=14.6% (Cox P=0.369 between 4 groups). When categorized by RF (Figure 1a), adjusted discontinuation rates due to lack of effectiveness were listed in ascending order as follows, respectively; RF negative (aIL-6R, 16.2%; TNFi, 30.5%; CTLA4-Ig, 33.8%; JAKi, 39.9%; Cox P<0.001), low positive (aIL-6R, 19.6%; JAKi, 21.7%; CTLA4-Ig, 26.6%; TNFi, 29.9%; Cox P<0.001) and high positive (aIL-6R, 25.4%; JAKi, 28.1%; CTLA4-Ig, 31.2%; TNFi, 38.6%; Cox P<0.001). When categorized by ACPA (Figure 1b), discontinuation rates due to lack of effectiveness were listed in ascending order as follows, respectively; ACPA negative (aIL-6R, 20.9%; TNFi, 28.8%; JAKi, 30.7%; CTLA4-Ig, 43.4%; Cox P<0.001), low positive (aIL-6R, 19.2%; JAKi, 26.4%; CTLA4-Ig, 27.3%; TNFi, 33.6%; Cox P<0.001) and high positive (aIL-6R, 23.1%; JAKi, 25.6%; CTLA4-Ig, 29.7%; TNFi, 35.2%; Cox P<0.001).

Conclusion: Considering lack of effectiveness, aIL-6R showed highest continuation rates compared to other agents regardless of RF/ACPA positivity or titer levels. On the other hand, CTLA4-Ig and JAKi showed higher continuation rates, although TNFi showed lower continuation rates in RF/ACPA-positive (low or high titer) cases compared with RF/ACPA-negative cases.

DESCRIPTIVE STUDY ON USE OF BIOSIMILARS IN RHEUMATOID ARTHRITIS IN UNIVERSITY HOSPITALS PLYMOUTH, UNITED KINGDOM

Keywords: Descriptive Studies, Real-world evidence, bDMARD

A. Ediriweera[1], T. Aung[1], O. Savanovic-Abel[1]. [1]*University Hospitals Plymouth, Rheumatology, Plymouth, United Kingdom*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease of unknown etiology marked by a symmetric, peripheral polyarthritis. Treatment of RA should be aimed at reaching a target of sustained remission or Low Disease Activity (LDA) in every patient. [1] Given the heterogenicity of the disease, there are multiple disease modifying anti rheumatoid drugs (DMARDs) available including biologics and biosimilars with different modes of action to achieve disease remission or low disease activity. A biosimilar medicine is a biological medicine manufactured to be similar to an existing licensed "reference" biological medicine, with no meaningful differences from reference medicine in terms of quality, safety or efficacy. However, it has been observed significant number of patients going back on bio-originator drugs complaining either side effects or less efficacy of biosimilar. This study is aimed at looking at real rate of bio-similar (BS) switching back to bio- originator (BO) due to various reasons.

OBJECTIVES:

1)To look for rate of switching back to bio-original and reasons behind
2)Biosimilar persistence rate in RA and side effect profile
3)To look for any association between concurrent use of methotrexate with biosimilar persistence rate.

Methods: Descriptive study was done at department of rheumatology University Hospitals Plymouth (UHP). All patients with the diagnosis of Rheumatoid arthritis, treated with biological DMARDs were screened till October 2019. Data were gathered about switching back to BO from BS and if switched reason for switch, persistence rate of biosimilar, duration of biosimilar, disease activity measured by DAS 28 before and 6 weeks after biosimilar, side effects and concurrent use of methotrexate with biosimilar. Data were analyzed as percentages and chi-square is used to find associations.

Results: Total number of 590 patients with RA on biological DMARDs were screened. Most popular first choice of BS was etanercept (318) followed by rituximab (177), adalimumab (85) and infliximab [9]. Only 19 patients out of 318(5.9%) patients treated with etanercept BS went back to BO due to inefficacy and side effects. 222/318 (69.8%) remained on etanercept. Switching back rate of adalimumab BO was only 9.4% (8/85) while 73% remained on adalimumab BS. (62/85). For rituximab, 9 out of 177 (5.08%) patients went back to original; 6 due to inefficacy and 3 side effects. 147/177(83.05%) remained on BS rituximab. Only one patient out of 9 treated with infliximab went back on original drug due to inefficacy. Commonly observed side effects of BS are infections, allergic reactions, and gastrointestinal disturbances. Average DAS 28 score difference after 6 weeks of commencement of BS was calculated only for adalimumab and etanercept. There was 2.27 reduction of DAS 28 in adalimumab group (from 5.22 to 2.95) while the reduction was 1.67 for etanercept group (from 5.14 to 3.47). Looking at association between persistence rate of BS and concurrent use of methotrexate, only RA etanercept group showed a significant association with a *p value* of 0.000041.

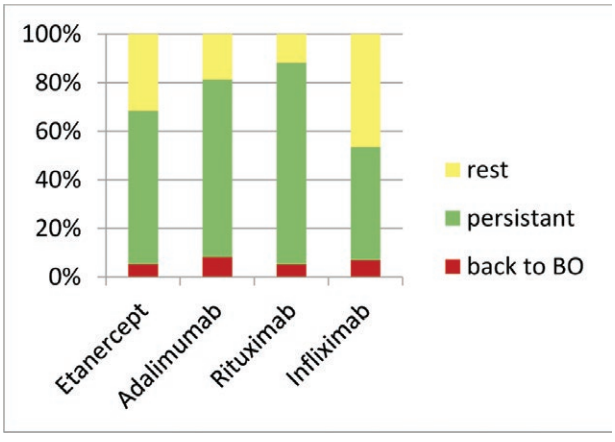

Figure 1.

Conclusion: Significant number of patients with RA are treated with biosimilar in UHP. Re switching to bio-originator is not very commonly seen. Most of the patients could tolerate biosimilar well and persistence rate is impressively high with good response reflected by reduction of average disease activity in studied cohorts. Among side effects infection, allergic reaction and GI side effects are common. Concurrent use of methotrexate showed positive correlation with persistent rate of biosimilar only in one group (RA treated with etanercept) but not others, hence does not give strong ground to the hypothesis that methotrexate minimizes immunogenicity for biosimilar.

TIME TO FIRST REMISSION AND PREVALENCE OF SUSTAINED REMISSION AFTER ETANERCEPT BIOSIMILAR (ETA-B) OR ORIGINATOR (ETA-O) INITIATION IN RHEUMATOID ARTHRITIS (RA)

Keywords: Real-world evidence, bDMARD, Rheumatoid arthritis

C. S Moura[1], D. Choquette[2], G. Boire[3], W. P. Maksymowych[4], L. Lukusa[1], L. Yan[1], M. G. Birck[1], S. Bernatsky[1,5]. [1]*Research Institute of the McGill University Health Centre, Centre for Outcomes Research and Evaluation, Montreal, Canada*; [2]*CHUM - Centre hospitalier de l'Université de Montréal, Institut de Rhumatologie de Montréal, Montréal, Canada*; [3]*Université de Sherbrooke, Faculty of Medicine, Sherbrooke, Canada*; [4]*University of Alberta, Department of Medicine, Division of Rheumatology, Edmonton, Canada*; [5]*McGill University, Epidemiology, Biostatistics and Occupational Health, Faculty of Medicine, Montréal, Canada*

Background: The first biosimilar etanercept (ETA-B) was approved in Canada in 2016, but real-world data comparing the effectiveness of ETA-B versus their equivalent originator (ETA-O) remains scarce.

Objectives: To compare time to remission throughout follow-up and sustained RA remission in the first 12 months.

Methods: We studied etanercept-naïve RA patients starting ETA-B or ETA-O between January 2015 and May 2022 from three prospective research cohorts related to the Early Undifferentiated Polyarthritis (Sherbrooke), RA Pharmacovigilance Program and Outcomes Research in Therapeutics (Edmonton), and RHUMADATA™ (Montreal) registries. We restricted analyses to RA patients with at least one follow-up visit after treatment initiation and with enough data to calculate remission. Remission was defined as Disease Activity Score 28-CRP or -ESR ≤2.6, Simplified Disease Activity Index ≤ 3.3, or Clinical Disease Activity Index ≤ 2.8. We used Cox regression to compare ETA-B versus ETA-O regarding time to first remission during follow-up (among those without remission at baseline) and logistic regression to assess sustained remission (remission in two consecutive visits) in the first 12 months of follow-up. Models were adjusted for sex, age, body mass index (BMI), RA duration, and smoking status at cohort entry. We also adjusted for high/moderate disease activity and the use of corticosteroids, methotrexate (MTX), or hydroxychloroquine (HCQ), all at etanercept initiation.

Results: We studied 150 RA patients initiating etanercept (65% on the biosimilar) between 2015-2022. Sex distribution was similar among ETA-B and ETA-O, but the biosimilar group has a longer disease duration and moderate/higher disease activity at baseline. Among 125 participants without remission at baseline, the median time to first remission was 8.7 months with ETA-B versus 14.5 with ETA-O. In the multivariate analysis (Table 1A), we were unable to detect a clear difference in time to achieve first remission when comparing ETA-B to ETA-O (hazard ratio, HR = 1.43, 95% confidence interval, CI 0.65-3.13). Obesity (BMI>30) was negatively associated with the outcome. Sustained remission in the first 12 months of follow-up was observed in 16.3% of ETA-B initiators versus 17.3% with ETA-O. After multivariate analysis (Table 1B), we were unable to establish any clear difference between ETA-B versus ETA-O (OR 1.16, 95% CI 0.31-4.74). HCQ was positively associated with sustained remission within the first 12 months.

Conclusion: In this pooled analysis of three Canadian RA cohorts, we were unable to detect clear differences in achievement or sustained remission when comparing ETA-B and ETA-O.

Table 1. – Cox proportional hazard ratios (HR) for time to remission and logistic regression model for sustained remission within first 12 months.

Baseline characteristics	Time to remission		Sustained remission (12 months)	
	Unadjusted HR (95% CI)	Adjusted HR (95% CI)[a]	Unadjusted OR (95% CI)	Adjusted OR (95% CI)[a]

AB0410 OBESITY AND ADIPOSE TISSUE CYTOKINES IN RHEUMATOID ARTRHITIS: DOES THE ROUTE OF ADMINISTRATION OF THE IL6 INHIBITORS MATTER?

Keywords: bDMARD, Rheumatoid arthritis, Comorbidities

M. Novella-Navarro[1], F. Genre Romero[2], A. Martínez-Feito[3], V. Pulito-Cueto[2], I. Monjo[1], D. Peiteado[1], M. A. González-Gay[2,4], C. Plasencia[1], A. Balsa[1]. *[1]Hospital Universitario La Paz, Rheumatology, Madrid, Spain*; *[2]IDIVAL, Research Group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and in Metabolic Bone Diseases of the Musculoskeletal System, Santander, Spain*; *[3]Hospital Universitario La Paz, Immunology, Madrid, Spain*; *[4]IIS-Fundación Jiménez Díaz, Rheumatology, Madrid, Spain*

Background: Obesity has been associated with the response to biologic disease modifying anti-rheumatic drugs (bDMARDs). Obese patients have lower response to anti-TNF drugs than to other cytokine-targeted drugs, such as anti-IL6[1]. IL6 receptor inhibition is effective in the treatment of rheumatoid arthritis (RA), and there are two ways of administration: intravenous (IV) weight-adjusted tocilizumab and subcutaneous (SC) fixed-dose tocilizumab or sarilumab. However, evidence regarding the influence of body mass index (BMI) and these different routes of administration is still scarce.

Objectives: To analyze the role of BMI in the clinical response to antiIL6 therapy in its different routes of administration in patients with RA. To perform an in-depth analysis of the pathophysiology of obesity by assessing serum adipokine levels and their potential changes according to treatment.

Methods: This study involved 65 patients with RA starting IV tocilizumab at 8mg/kg every 4 weeks or SC antiIL6: tocilizumab 162mg/week or sarilumab 200mg/14days. Demographic and clinical characteristics before antiIL6 initiation (age, sex, smoking habit, age at diagnosis, concomitant and previous treatments and BMI) were collected. Laboratory parameters such as rheumatoid factor and anti-citrullinated peptide antibody were also assessed. Adipokine serum levels (leptin and adiponectin) were measured at baseline and after 6 months (6M) of treatment. Clinical response to treatment was assessed by Clinical Disease Activity Index (CDAI) 6M after initiation of the bDMARD. Differences between variables were assessed using the X2 test and Mann-Whitney test. Correlations between BMI, adipokines and other quantitative variables were assessed using the Pearson or Spearman coefficients. P-values <0.05 were considered statistically significant.

Results: Forty seven patients started IV antiIL6 (72.3%) and 18 SC (27.7%). Thirty six (55.4%) achieved low disease activity (LDA)/remission by CDAI: 24 patients from the IV group (51.4%) and 12 (66.7%) from the SC group without significant differences (p=0.19). No differences between BMI or serum adipokine levels were associated with the achievement of LDA/remission when patients were stratified according to the route of antiIL6 administration. Leptin levels in both groups (SC and IV) were very similar at baseline and 6M and regarding changes on adipokine profile between baseline and 6M, we observed a decrease in leptin and an increase in adiponectin levels both in SC and IV (Table 1).

	Serum adipokine levels (ng/mL)			
Route of administration		baseline	6 months	p
iv	Leptin	18.6 (10.4-30.9)	16.9 (7.2-29.2)	0.22
	Adiponectin	18310(13250-33890)	20610 (12690-33650)	0.39
sc	Leptin	17.9 (10.1-27.4)	16.3 (7.6-30.7)	0.22
	Adiponectin	28750 (20570-4394)	33350 (24157-49862)	0.35

BMI showed a significant positive correlation with leptin, overall and stratifying by route of administration, both at baseline and 6M. Adiponectin did not show a significant correlation with BMI.

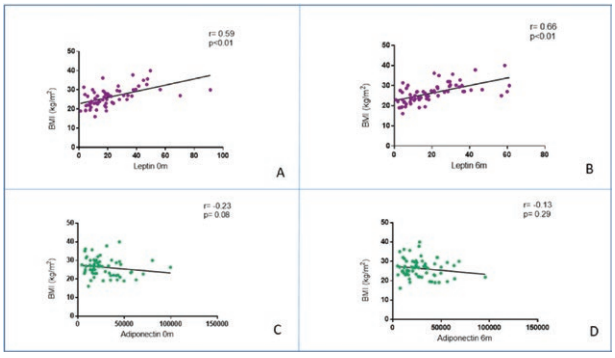

Figure 1.

Conclusion: Obesity and serum adipokines did not show association with the achievement of LDA/remission in patients treated with antiIL6 regardless the route of administration. Furthermore, IV and SC treatments could be used both in obese and normal-weight RA patients expecting the same efficacy.

Background: Little is known about the association between ethnicity and response to TNF inhibitors (TNFi) in people with rheumatoid arthritis (RA).
Objectives: This study examines the association between self-reported ethnicity and DAS28 response after 6 months of treatment in patients starting their first TNFi using data from the British Society for Rheumatology Biologics Register for RA.
Methods: 14133 RA patients with self-reported ethnicity starting their first TNFi were included. Due to a very low proportion of non-white patients, ethnicity was divided into white or non-white for analysis. Outcomes included the change in disease activity using DAS28, the proportion of patients who achieved DAS28 remission and EULAR response at month 6. Adjusted regression models appropriate to outcome were used to compare between the two groups. Multiple imputation was used to account for missing data.
Results: Of 14133 patients starting TNFi with recorded ethnicity, only 607 (4.3%) recorded themselves as non-white (389 Asian, 134 Black, 57 Mixed ethnicity and 27 other) (Table 1). At start of TNFi, non-white patients were younger (non-white vs. white: mean 51 vs. 57 years; p<0.001), with shorter disease duration (median 8 vs. 10 years; p<0.001), higher proportion of females (86% vs. 76%; p<0.001) and fewer current cigarette smokers (9% vs. 20%; p<0.001). Non-white patients had lesser improvement in DAS28 at month 6 (adjusted regression coefficient (95% confidence interval (95%CI)): 0.3 (0.04-0.5)). However, using the white patients as a reference, non-white patients were not associated with the achievement of DAS28 remission (adjusted odds ratio (95%CI): 0.7 (0.5-1.1)) or EULAR response (aOR (95%CI): 0.8 (0.7-1.0)) at month 6.

Odds of DAS remission*	1 [reference]	0.7 [0.5-1.1]	0.1
Good EULAR response (%)	18.2%	16.5%	
Moderate EULAR response (%)	33.7%	33.2%	
Odds of achieving higher EULAR response*	1 [reference]	0.8 [0.7-1.0]	

Data is expressed as mean±SD, median (interquartile range), number (percentage), adjusted regression coefficient [95% confidence interval] or adjusted odds ratio [95% confidence interval].*Adjusted for baseline age, gender, disease duration, concomitant csDMARDs, concomitant steroid, rheumatoid factor status, cigarette smoking status, DAS28 and HAQ

Conclusion: Recruitment to the BSRBR-RA of non-white patients was exceptionally low compared to expected population distribution – the reasons for this are not immediately evident. Among those recruited, there were no significant differences observed in initial treatment response although non-white patients were younger, more likely to be female, had shorter disease duration and less likely to be smokers. Further evaluation into both ways to increase representativeness in our national RA treatment register and influence of ethnic differences on longer term outcomes with biologic therapies is warranted.

COMPARISON OF THE EFFICACY AND SAFETY OF A PROPOSED BIOSIMILAR MSB11456 WITH TOCILIZUMAB REFERENCE PRODUCT IN MODERATE-TO-SEVERE RHEUMATOID ARTHRITIS: RESULTS OF A RANDOMIZED DOUBLE-BLIND STUDY

Keywords: Rheumatoid arthritis, Randomized control trial, bDMARD

A. Zubrzycka-Sienkiewicz[1], M. Misterska-Skora[2], M. Socik Pojawa[3], K. Klama[4], M. Ullmann[5], C. Petit-Frere[5], A. Illes[5], E. Vincent[5], J. Monnet[5], J. Brzezicki[6]. Dąbrowskiego, Poznań, Poland*; [5]*Fresenius Kabi SwissBioSim, Biosimilars, Eysins, Switzerland*; [6]*Centrum Kliniczno Badawcze, 35-36/A Ulica Studzienna, Elbląg, Poland*

Background: MSB11456 is a biosimilar to currently marketed originator tocilizumab. It has demonstrated pharmacologic, safety and immunogenic similarity to the US-licensed and EU-approved tocilizumab in healthy subjects.
Objectives: To evaluate the efficacy, immunogenicity and safety of MSB11456 versus EU-approved tocilizumab in patients with moderate to severe rheumatoid arthritis (RA) who had experienced inadequate clinical response to ≥1 disease-modifying antirheumatic drug and were receiving a stable dose of methotrexate.
Methods: Patients were randomised to double-blind subcutaneous injections of 162 mg MSB11456 or EU-approved tocilizumab for 24 weeks (W). At W24, patients receiving EU-approved tocilizumab were re-randomized to continue their treatment or to switch to MSB11456 up to W52. Those receiving MSB11456 continued MSB11456 for the 52W. Primary efficacy endpoint - change from baseline in Disease Activity Score-28 Joint Count (DAS28)-erythrocyte sedimentation rate (ESR) at W24 - was analysed using analysis of covariance to determine the least squares mean (LSM) difference between MSB11456 and EU-approved tocilizumab; MSB11456 was considered equivalent to EU-approved tocilizumab if the 95% confidence interval (CI) for this difference was entirely within the equivalence interval -0.6 to 0.6. Secondary endpoints were 20% improvement in American College of Rheumatology core set measures (ACR20) at W24 and DAS28-ESR at W12. Additional endpoints included ACR50/70, change in DAS28-C-reactive protein (CRP), Simplified Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI) at various time points up to W52, and evaluation of immunogenicity and safety. Results up to W24 are presented.
Results: Clinically relevant LSM decreases from baseline in DAS28-ESR were observed at W24 with MSB11456 and EU-approved tocilizumab (Table 1). As the 95% CI for the LSM difference in the change from baseline in DAS28-ESR between treatments was fully included within the predefined equivalence interval, therapeutic equivalence of MSB11456 and EU-approved tocilizumab was demonstrated. All sensitivity and other efficacy endpoint analyses supported

this finding. Immunogenicity results were similar in both treatment groups. Treatment-emergent adverse events (TEAEs) were usually mild or moderate and occurred at similar frequency with both drugs. There were no discernible patterns in terms of the nature, frequency or other characteristics of serious or treatment-related TEAEs to suggest a difference between drugs.

Conclusion: Equivalent efficacy, immunogenicity and safety at W24 of MSB11456 and EU-approved tocilizumab was demonstrated in patients with moderate to severe RA. Pharmacological and clinical similarity of these drugs was supported, therefore MSB11456 can be considered as biosimilar to EU-approved tocilizumab.

AB0413 COMPARISON OF THE EFFECTS OF TOCILIZUMAB AND TNF-A INHIBITORS ON HEMOGLOBIN AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS WITH ANEMIA

Keywords: bDMARD, Rheumatoid arthritis

H. Lee[1], S. K. Kim[1], S. H. Park[1], J. W. Kim[1], S. G. Kwak[2], J. Y. Choe[1]. *[1]Daegu Catholic University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Daegu, Korea, Rep. of (South Korea); [2]Daegu Catholic University School of Medicine, Department of Medical Statistics, Daegu, Korea, Rep. of (South Korea)*

Background: Rheumatoid arthritis is a systemic disease with various extra-articular symptoms. Anemia is common comorbidity of RA.

Objectives: The purpose of this study is to compare the effect of tocilizumab and TNF-α inhibitors on hemoglobin changes and disease activity changes in RA patients. This study aims to determine whether tocilizumab is more effective in controlling hemoglobin elevation and disease activity in patients with anemia.

Methods: The data in this study derived from the Korean College of Rheumatology Biologics (KOBIO) registry. OF the patients registered in KOBIO registry, patients using tocilizumab and TNF-α inhibitors were enrolled in this study. To exclude the effects of previously used biologic DMARDs, patients who started the first biologic DMARDs and have been using one biologic DMARD for more than 1 year were included in this study. Anemia was defined as Hb levels <12.0g/dL in women and <13.0g/dL in men according to the World Health Organization (WHO) criteria at index date.

Results: Among rheumatoid arthritis patients with anemia, there were 126 patients in the tocilizumab group and 248 patients in the TNF-α inhibitor group. Initial and follow-up data collected after 1 year of biologic use were analyzed. After initiation of treatment, Hb and Hct were significantly elevated in tocilizumab group. Mean increases in Hb and Hct were 1.56 and 3.53 in tocilizumab group, 1.02 and 2.64 in TNF-α inhibitor group. DAS28-ESR and RAPID3 decreased significantly in tocilizumab group after using biologics. In tocilizumab group, DAS28-ESR decreased by 3.35 and RAPID3 decreased by 8.31. The changes in SJC, PGA, PhGA, SDAI and CDAI were not different between the two groups. Multivariate analysis was performed using the TNF-α inhibitor group as a control. Tocilizumab was more effective than TNF-α inhibitors in increasing Hb.

Conclusion: In RA patients with anemia, although tocilizumab was more effective than TNF inhibitors in increasing Hb, there was no difference between the two drugs in controlling disease activity. During the course of this research, the results of the DAS28-ESR and other outcome measures did not match. In patients treated tocilizumab, assessment of disease activity using the DAS28-ESR may be overestimated due to its effect on acute phase reactant values.

AB0414 FACTORS PREDICTING THE INITIATION OF BIOLOGIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS FOR RHEUMATOID ARTHRITIS WITHIN THE FIRST THREE YEARS OF DIAGNOSIS

Keywords: bDMARD, Rheumatoid arthritis

M. Hameed[1], S. Exarchou[1], A. Eberhard[1], A. Sharma[1], U. Bergström[1], G. Cagnotto[1], J. T. Einarsson[2], C. Turesson[1]. *[1]Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden; [2]Skåne University Hospital, Department of Rheumatology, Lund, Sweden*

Background: Factors related to the use of biologic disease modifying anti-rheumatic drugs (bDMARDs) in rheumatoid arthritis (RA) have varied in prior studies.

Objectives: This study aims to identify characteristics at the time of diagnosis that may be related to the initiation of treatment with bDMARD within the first three years following diagnosis.

Methods: All patients with early RA diagnosed at the outpatient clinics of Skåne University Hospital in 2012-2016 were identified using the local patient administrative system. Diagnoses were validated in a structured review of the medical records. Patients with a confirmed RA diagnosis, aged ≥18 years with symptom duration <12 months at diagnosis, and who fulfilled the 2010 ACR/

EULAR and/or the 1987 ACR classification criteria for RA, were included. Patients who started their first bDMARD in a clinical trial were excluded. Data on treatment were obtained from a national quality register, and from complementary case record reviews. Data on comorbidities were retrieved from a regional healthcare register, and data on level of formal education, country of origin and family background from national registers. The relation between characteristics at diagnosis and initiation of bDMARD within the first three years following diagnosis was examined in crude, age-adjusted and multivariable logistic regression models.

Results: Lower age, higher values for joint counts and DAS28-CRP3, and birth outside Europe were statistically significant baseline predictors of bDMARD start within the first 3 years after diagnosis in crude and age-adjusted analyses (Table 1). High level of education and absence of major comorbidities were predictive in crude but not in age-adjusted models. In multivariable logistic regression analysis, lower age (odds ratio (OR) 0.61 per SD; 95 % CI 0.46-0.83) and higher tender joint count (OR 1.56 per SD; 95% CI 1.18-2.10) were the only significant predictors of start of bDMARD ≤ 3 years after diagnosis.

Table 1: Predictors at RA diagnosis for a first bDMARD/tsDMARD start in patients with early RA within 3 years after diagnosis.
Logistic regression.

Conclusion: Lower age and higher tender joint count at diagnosis were associated with an increased likelihood of starting bDMARD therapy within the first 3 years in early RA. The impact of age on the subsequent start of bDMARD therapy was not explained by other patient factors.

CAN WE PREDICT THE RISK FACTORS FOR SWITCHING IN THE FIRST YEAR OF THERAPY WITH BDMARD IN PATIENTS WITH RHEUMATOID ARTHRITIS?

Keywords: bDMARD, Rheumatoid arthritis, Real-world evidence

A. Martins[1,2], D. Santos Oliveira[1,2,3], R. Nicolau[2,4], T. Martins-Rocha[1,2], A. Bernardo[1], S. Pimenta[1,2], M. Bernardes[1,2], L. Costa[1]. *[1]São João Universitary Hospital Center, Rheumatology, Porto, Portugal*; *[2]Faculdade de Medicina da Universidade do Porto - FMUP, Medicine, Porto, Portugal*; *[3]Faculdade de Medicina da Universidade do Porto - FMUP, CINTESIS, Porto, Portugal*; *[4]Centro Hospitalar Tondela - Viseu, Epe, Rheumatology, Viseu, Portugal*

Background: Biological Disease-modifying Antirheumatic Drugs (bDMARD) have improved the clinical course and quality of life of patients with rheumatoid arthritis (RA). However, some patients failed to respond or have an insufficient response to bDMARD, early in the course of the treatment, and the reasons why this happens aren't fully understood.

Objectives: To determine the percentage of RA patients who failed to respond to bDMARD and need to switch in the first year of treatment, describe their characteristics, and identify specific baseline features as possible predictors of bDMARD early failure.

Methods: An observational monocentric retrospective cohort study was conducted with RA patients (according to 2010 ACR/EULAR criteria), registered in the national database (Reuma.pt) that started their first bDMARD between June 2000 and December 2021 and had a minimum follow-up of 12 months. Demographic data, disease characteristics, laboratory parameters and treatment at baseline were collected. Disease activity scores (CDAI, SDAI and DAS-28-CRP), functional scores (HAQ) and clinical response to treatment (according to EULAR and ACR response criteria) were collected at 3, 6 and 12 months after the start of bDMARD. The proportion of patients who failed to respond (according to treat-to-target strategies) and who switched to another bDMARD was calculated. Patients who discontinued treatment in the first year due to adverse events were excluded. Chi-square test, t-test and Mann-Whitney U test were conducted (categorical, normally and not normally distributed continuous variables, respectively). Also, a multivariate logistic regression analysis was performed. Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated. A p-value <0.05 was considered statistically significant.

Results: 437 (364 females, 83.3%) patients with RA were included. The mean age was 52.4 ± 11.4 years and the disease duration was 11.8 ± 8.8 years. The majority of these patients started an anti-TNF-α agent as their first bDMARD (n=315, 72.1%). The remaining patients started rituximab (n=66, 15.1%), tocilizumab (n=51, 11.7%) and abatacept (n=5, 1.1%). Forty-eight (11.0%) patients failed to respond to the bDMARD in the first year of treatment (mean duration of bDMARD treatment was 0.75 ± 0.3 years) and needed to switch to another bDMARD. Demographic characteristics were similar in the group of patients that switch due to ineffectiveness and patients that didn't switch in the first year. Disease activity scores (DAS-28-CPR, CDAI, SDAI) and HAQ at baseline were also similar in the two groups. There were significantly more current or former smokers in the group of patients that needed to switch in the first year of therapy (p=0.030). Moreover, depression was significantly more frequent in the switch group (p=0.003). Positivity for rheumatoid factor at baseline was also significantly more frequent in the switch group (p=0.014). Regarding the type of bDMARD, patients in the switch group were more frequently treated with anti-TNF-α agents than patients that didn't switch (p<0.001). In the multivariate analysis, anti-TNF-α agents use (versus non-anti-TNF-α agents) (OR 8.3, 95% CI 2.4-28.8, p=0.001), tobacco exposure (OR 2.3, 95% CI 1.1-4.8, p=0.02) and history of depression (OR 3.1, 95% CI 1.3-7.7) seem to predict the bDMARD early failure and the need to switch in the first year of treatment.

Conclusion: In our study, anti-TNF-α agents were associated with a higher switch rate due to ineffectiveness in the first year of treatment in RA patients, when comparing to non-anti-TNF-α agents. Moreover, current and former smokers, patients with depression and with positive rheumatoid factor had a higher switch rate due to ineffectiveness. This study reinforces the importance of RA patients quit smoking, as tobacco may interfere with clinical response to bDMARD. Furthermore, routine screening for depression should be included in daily clinical practice and a multidisciplinary treatment approach should be offered to these patients.

Background: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Abatacept (ABA) has demonstrated efficacy in RA-ILD **[1-2].** Clinical trials have shown equivalence in subcutaneous (SC) and intravenous (IV) administration of ABA for articular manifestations **[3].** However, it has not been studied in RA-ILD.

Objectives: to compare the effectiveness of ABA in RA-ILD patients according to the route of administration (IV-ABA vs SC-ABA).

Methods: National multicenter study of RA-ILD patients on treatment with ABA. They were divided into 2 groups according to the route of administration: a) IV, and b) SC. We analyzed from baseline the following outcomes in both groups: **a)** forced vital capacity (FVC), **b)** diffusing capacity of the lungs for carbon monoxide (DLCO), **c)** chest high resolution computed tomography (HRCT), **d)** dyspnea (assessed with the modified Medical Research Council scale), **e)** arthritis activity (assessed with DAS28-ESR or described in clinical records), and **f)** sparing corticosteroids effect.

Results: We studied a total of 392 [SC-ABA/IV-AB; 288/91(available data)] patients. Baseline demographic and clinical characteristics are shown in **Table 1**. Patients were followed-up for a median [IQR] of 24 [10-48] months. FVC and DLCO remain stable during the first 24 months in both SC-ABA and IV-ABA **[Figure 1].** Dyspnea stabilized or improved in 85% of patients (89% of IV-ABA; 83% of SC-ABA). ABA was withdrawn in 80 patients: 60 (39%) in SC-ABA group and 20 (22%) in IV-ABA group. ILD worsening and articular inefficacy were the most common reasons of ABA discontinuation.

Conclusion: In RA-ILD, ABA seems equally effective and safe regardless of the route of administration IV or SC.

AB0417 JAK INHIBITORS AND LIVER INVOLVEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS: RISK ASSESSMENT OF NAFLD AND SAFETY PROFILE IN HBV INFECTIONS

Keywords: bDMARD, Rheumatoid arthritis

G. Busto[1], C. Rotondo[1], N. Maruotti[1], F. D'onofrio[1], A. Mele[1], F. P. Cantatore[1], A. Corrado[1]. [1]*Rheumatology Clinic, Department of Medical and Surgical Sciences, University of Foggia, Foggia, Italy*

Background: Janus kinase inhibitors (JAK-i) are increasingly used in the treatment of Rheumatoid Arthritis (AR). Hypertransaminasemia is one of the described side effects of this class of drugs.
Objectives: The aim of the study is to evaluate the possible hepatotoxicity, the risk of NAFLD onset, and the reactivation of HBV and HCV in patients with AR and JAK-i therapy.
Methods: 78 patients with AR (81%F) were enrolled with an average disease duration of 15±7 years, BMI 26±4. The inclusion criteria were age > 18 years, fulfillment of ACR/EULAR 2010 criteria for AR, and stable intake for at least 3 months of JAK-i in monotherapy or combined therapy with methotrexate (MTX) and/or steroid.
Results: The average therapy duration of JAK-i treatment (Baricitinib, Filgotinib, Tofacitinib or Upadacitinib) was of 67±50 weeks. 32% of patients were on combined therapy with MTX and 22% took steroids (mean dose in prednisone equivalents of 5.5±2.5 mg/day). No patients had positivity for HCV antibodies at the beginning of JAK-i therapy, and no one reported alcohol abuse. At the beginning of JAK-i therapy, 9% of patients had hepatic steatosis on abdominal ultrasound and 26% had occult HBV infection. 8% of patients had hypertransaminasemia before starting therapy with JAK-i. During treatment with JAK-i, hypertransaminasemia occurred in 6% of patients; of these 20% had already known hepatic steatosis, 40% were occult HBV carriers and 40% were with combined therapy with MTX. Particularly, hypertransaminasemia was detected in 8% of patients treated with Baricitinib and in 8% of patients with Tofacitinib. No patients treated with Filgotinib and Upadacitinib developed hypertransaminasemia during follow-up. JAK-i treatment was not stopped in any patient with hypertransaminasemia. 14% had NAFLD during treatment with JAK-i, and no patients had hepatic steatosis with hypertransaminasemia above 3 times normal values. Among patients who developed NAFLD after JAK-i treatment, 18% were overweight, 36% were obese, 27% were in therapy with steroids, and 18% were with combined therapy with MTX. NAFLD has been detected in 16% of patients treated with Baricitinib, 8% of patients treated with Tofacitinib, and 15% of patients treated with Upadacitinib, no patients treated with Filgotinib showed onset of NAFLD. Among patients with previous episodes of hypertransaminesia for other reasons, JAK-i treatment didn't cause alterations of bio-humoral indexes of hepatic function. No HBV reactivation occurred in patients with occult HBV infection during treatment with JAK-i.
Conclusion: JAK-i treatment in patients with occult HBV infection or previous NAFLD has a good safety profile. In terms of hypertransaminasemia with or without NAFLD, the risk of liver dysfunction appears to be very low during JAK-i treatment, both in monotherapy or in MTX combination treatment.

AB0418 ELEVATED ANA AS A PREDICTOR OF THERAPEUTIC FAILURE TO BIOLOGICAL ANTI-TNF AGENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: bDMARD, Autoantibodies, Rheumatoid arthritis

F. Liñán Ponce[1], J. Leiva Goicochea[1], C. Leiva[1], D. Sevilla Rodriguez[1], C. Otoya Guzmán[1], D. Corro García[1], J. Rodríguez Baldeón[1], E. Hidalgo Bravo[1], G. Obregón Atanacio[1], I. Loyola Macalapú[1]. [1]*Hospital Victor Lazarte Echegaray, Medicina, Trujillo, Peru*

Background: Currently there is no way to distinguish or predict therapeutic failure of Tumor Necrosis Factor (TNF) inhibitors in patients with autoimmune diseases, especially rheumatoid arthritis (RA). Elevated Antinuclear Antibodies (ANA) have been linked as potential markers of therapeutic failure to iTNF.
Objectives: To analyze a possible relationship between high levels of ANA and the presence of therapeutic failure to infliximab (IFX) and Etanercept (ETN) in patients with RA.
Methods: Retrospective cohort study. Two groups were formed: 135 patients with RA and elevated ANA (> 1/80) and 135 patients with RA and negative ANA (< 1/80). All patients received IFX or ETN therapy. ANA was measured before starting therapy. Each group had 60 patients using IFX and 75 using ETN. The appearance of therapeutic failure was expected (DAS28 > 3.2 after at least 3 months of treatment with iTNF). The number of therapeutic failures in each group was counted and then a logistic regression analysis was used with the variables elevated ANA and existence of iTNF therapeutic failure.
Results: Thirty-two therapeutic failures were counted in the elevated ANA group and 16 in the negative ANA group. A higher percentage of failures was observed in IFX users. A higher percentage of therapeutic failure was also observed at a higher ANA level. No relationship was found between the ANA pattern and the presence of failure. The presence of an elevated ANA multiplies by 2.4 the risk of presenting therapeutic failure to IFX or ETN in patients with RA.
Conclusion: An elevated ANA is a predictor of therapeutic failure to IFX or ETN in patients with RA.

OUTCOMES OF THE SELF-INJECTION ASSESSMENT QUESTIONNAIRE IN RHEUMATOID ARTHRITIS, AXIAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS PATIENTS RECEIVING GP2015 (ETANERCEPT BIOSIMILAR) IN A REAL-WORLD STUDY: FINAL RESULTS FROM COMPACT STUDY

Keywords: Rheumatoid arthritis, Spondyloarthritis, Patient reported outcomes

M. Schmalzing[1], A. Askari[2], T. Sheeran[3], S. Jathanakodi[4], C. Both[4], H. Kellner[5].
[1]University Hospital, Wuerzburg, Rheumatology/Clinical Immunology, Department of Internal Medicine II, Wuerzburg, Germany; *[2]Robert Jones and Agnes Hunt Orthopedic Hospital NHS Foundation Trust, Rheumatology, Oswestry, United Kingdom*; *[3]New Cross and Cannock Chase Hospitals, University of Wolverhampton, Department of Rheumatology, Wolverhampton, United Kingdom*; *[4]Sandoz Hexal AG, Rheumatology, Holzkirchen, Germany*; *[5]Hospital Neuwittelsbach, Center for Rheumatology and Gastroenterology, Munich, Germany*

Background: COMPACT is an international, non-interventional cohort study evaluating the effectiveness, safety and quality of life in patients (pts) with rheumatoid arthritis (RA), axial-spondyloarthritis (axSpA) or psoriatic arthritis (PsA) treated with GP2015, an approved etanercept (ETN) biosimilar, in real-world conditions.
Objectives: To assess patient usage behaviour and feelings of self-administered injection with auto-injector device using the Self-Injection Assessment Questionnaire (SIAQ) in pts with RA, axSpA and PsA receiving GP2015.
Methods: Pts aged ≥18 years from Germany and UK who initiated treatment with GP2015 were enrolled in this study. The SIAQ, a questionnaire developed to assess overall pt experience with subcutaneous self-injection was used to assess the perceived self-confidence on self-injection, potential barriers as well as satisfaction with self-injection via device before the first self-injection (PRE module) and after dosing (POST module).[1] In COMPACT study, the POST module was assessed which comprised of 21 items grouped into 6 hypothetical domains: "feelings about injection", "self-image", "self-confidence", "skin reaction" (injection-site reactions), "ease of use of self-injection device", and "patient satisfaction". Domain scores were rated on a 10-point scale, i.e., 0 (worst experience) to 10 (best experience). Data was analysed from the first collected SIAQ responses during the study and was summarised using descriptive statistics. The final SIAQ scores by domain in pts with RA, PsA and axSpA and by study group in pts with RA are reported here.
Results: A total of 458 pts from Germany (RA: 285, PsA: 79, axSpA: 94) and 273 pts from UK (RA: 174, PsA: 54, axSpA: 45) responded to the questionnaire. Overall, each domain showed high SIAQ scores which were consistent across all indications. The "self-image" and the "skin reaction" domains were scored highest (**Figure 1**). RA pts who had prior experience with biologic or non-ETN targeted medication (Group A + B) had mean scores mostly higher than or equal to those of biologic-naïve pts (Group C + D). RA pts who switched from iETN (reference ETN or biosimilar ETN other than GP2015) to GP2015 treatment (Group A) reported high SIAQ scores in all domains, which can be explained by good patient experience with the device (**Table 1**).
Conclusion: The SIAQ showed high acceptance of the auto-injector device in both countries where the survey was performed across all indications. Most RA pts were satisfied with auto-injector device usability after switching from iETN to GP2015, demonstrating no major concerns after switching.

Table 1. Mean domain SIAQ scores by study group in pts with RA in GP2015 treated pts

Mean domain scores*	Group A (N=177)	Group A + B (N=206)	Group C + D (N=253)
Feelings about injections	9.1	9.0	7.9
Self-image	9.0	9.1	8.8
Self-confidence	7.7	7.5	6.9
Skin reactions	8.5	8.5	8.5
Ease of use	7.7	7.6	7.8
Patient satisfaction	8.0	7.8	7.7

*Scores are rated on a 10-point scale: 0, worst experience; 10, best experience. Study groups are defined as RA pts who were treated with iETN and switched to GP2015 (Group A) or pts who received non-ETN targeted therapies and switched to GP2015 (Group B) or biologic-naïve (Group C) or DMARDs-naïve pts who started GP2015 as a first biologic therapy (Group D). N, total number of responders with non-missing evaluations at visit

Background: While protection against pertussis following maternal tetanus-diphtheria-and-acellular-pertussis (Tdap) vaccination has been demonstrated in term-born infants from healthy mothers[1], no evidence is available on Tdap vaccination in combination with immune-modulating therapy during pregnancy.
Objectives: In this pilot-study, we explored whether treatment with Tumor Necrosis Factor alpha inhibitors (TNFis) in pregnant patients with rheumatic disease interferes with Tdap vaccine responses and/or affects maternal IgG antibody concentrations against the relevant antigens in the newborns.
Methods: Patients included by a rheumatologist during pregnancy received a Tdap vaccination in their late-second or early-third trimester. Blood samples were drawn during the first trimester, three months after delivery and from the umbilical cord. IgG antibody levels against Tdap-included antigens were measured using a bead-based multiplex immunoassay. Findings on patients exposed to TNFis were compared with those from TNFi-unexposed patients and with data from a historical comparator study among healthy Tdap vaccinated mother-infant-pairs (n=53). [2]
Results: 66 patients (46 exposed and 20 unexposed to TNFIs) were enrolled. No differences in IgG antibody levels against Tdap-included antigens were observed between TNFi-exposed and unexposed patients before and after Tdap vaccination (Figure 1). In cord sera however, antibody levels against pertussis toxin were significantly lower after TNFi-treatment (35.94IU/mL, 95%CI 20.68-62.45) compared with no TNFis (94.61IU/mL, 95%CI 48.89-183.07) and with cord blood from the comparison cohort of healthy women-infant-pairs (125.12IU/mL, 95%CI 90.75-172.50). We observed similar differences for filamentous hemagglutinin, pertactin, tetanus toxoid, and diphtheria toxoid.
Conclusion: These preliminary data indicate no reduced IgG antibody response upon maternal Tdap vaccination in pregnant women following immune-modulating treatment, although our findings suggest that TNFis during pregnancy induce lower maternal antibody levels against Tdap-included antigens in newborns.

AB0421 REAL-WORLD EFFECTIVENESS OF UPADACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Real-world evidence

D. C. Diederik[1], P. Durez[2,3], J. Lenaerts[4], R. Westhovens[5,6], P. Verschueren[5,6].
[1]Vrije Universiteit Brussel (VUB), Biostatistics and Medical Informatics Research Group, Department of Public Health, Brussels, Belgium; *[2]Université Catholique de Louvain, Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium*; *[3]Cliniques Universitaires Saint-Luc, Department of Rheumatology, Brussels, Belgium*; *[4]Reuma-Instituut Hasselt, Department of Rheumatology, Hasselt, Belgium*; *[5]University Hospitals Leuven, Division of Rheumatology, Leuven, Belgium*; *[6]KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium*

Background: The Janus Kinase (JAK) inhibitor Upadacitinib (UPA) has shown efficacy in rheumatoid arthritis (RA) in trials, yet real-world evidence is lacking.
Objectives: We aimed to assess short-term effectiveness of UPA for standard of care for RA.
Methods: Data from participants included in the electronic platform "Tool for Administrative Reimbursement Drug Information Sharing" (TARDIS) were analysed. TARDIS collects data from all Belgian RA patients on advanced therapy during submissions of reimbursement requests for drug initiation or prolongation. Patients initiating UPA between 01/11/2020-31/12/2021, ≥18 years and DAS28>3.7 were included. Effectiveness was based on drug retention, proportion of patients achieving remission (DAS-28 <2.6), low disease activity (LDA, DAS-28 ≤3.2), HAQ-DI≤0.25 (HAQ25), HAQ-DI≤0.50 (HAQ50) as well as a clinical meaningful HAQ-DI-decrease (MCID_HAQ) since baseline of 0.22 at the first follow-up moment at 3 months. Sensitivity analyses by 1st, 2nd or 3rd+-line advanced therapy were performed.
Results: From 13 175 patients in TARDIS in the relevant time period, 996 patients on UPA could be included. Table 1 details this population. Of 871 patients with drug information at next follow-up, 783 (90%) continued UPA, and 42 (5%), 22 (3%), and 18 (2%) changed to a TNFi, non-TNFi and other JAKi respectively. In other effectiveness analyses, 705/996 (71%) patients were included. Remission and LDA were reached in 60% (421/705) and 74% (521/705) of patients respectively. HAQ25, HAQ50 and MCID_HAQ were reached in 11% (78/705), 26% (183/705) and 67% (475/705) of patients. Effectiveness slightly decreased with increasing line of therapy (Figure 1).

Table 1. Baseline characteristics of TARDIS patients on UPA

	Total UPA population
Number	996
Age (mean ±SD, years)	57.5 ±12.7
Disease duration (mean ±SD, years)	9.3 ±9.5
ESR (mean ±SD, mm/hour)	24.3 ±19.9
CRP (mean ±SD, mg/L)	13.1 ±15.5
SJC28 (mean ±SD)	6.5 ±4.5
TJC28 (mean ±SD)	9.2 ±5.4
DAS28 (mean ±SD, years)	5.0 ±0.8
HAQ-DI (mean ±SD, 0-3)*	1.3 ±0.8
PGA (mean ±SD, 0-100)	67.5 ±18.3
Advanced treatment naïve (yes)	434/996 (43.6%)
Advanced treatment Experienced (yes)	562/996 (56.4%)
2nd line	247/562 (24.8%)
3th line +	315/562 (31.6%)
Previous advanced treatment type**	
TNFi,	268/562 (48.2%)
Non-TNFi,	177/562 (31.8%)
JAKi	111/562 (20.0%)

Legend: Numbers given are mean ± SD or number, proportion. TNFi = tumour necrosis factor inhibitor, JAKi = Janus Kinase inhibitor, HAQ= health assessment questionnaire, PGA= Patient Global assessment; CRP= C-reactive protein; ESR= erythrocyte sedimentation rate; TJC= tender joint count; SJC= Swollen joint Count; DAS28 = disease activity score based on the 28joints. *Missing HAQ(0-3) scores were imputed by regression using age and HAQ(0-60) scores. **for 6 patients this was undefined.

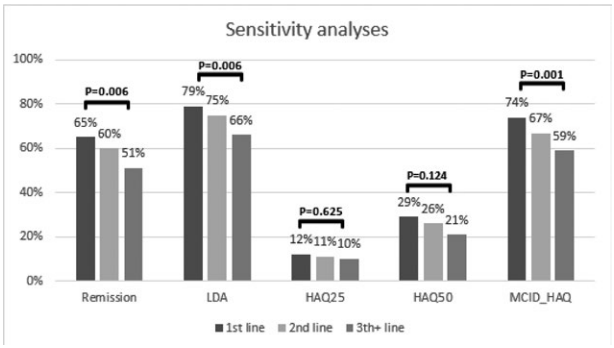

Figure 1. Effectiveness outcomes at 3 months of UPA per treatment line. remission (DAS-28 <2.6), LDA - low disease activity (DAS-28 ≤3.2), HAQ-DI≤0.25 (HAQ25), HAQ-DI≤0.50 (HAQ50) and minimum HAQ-DI-decrease (MCID_HAQ) since baseline of 0.22

Conclusion: Most patients continued UPA treatment. UPA improved clinical outcomes after 3 months in patients with moderately to severely active RA in a real-world setting, even in 3rd line of advanced therapy.

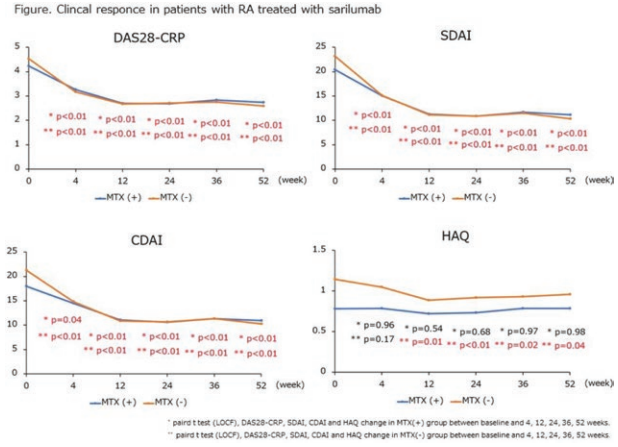
AB0422 THE EFFECTS OF CONCOMITANT USE OF METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SARILUMAB

Keywords: Real-world evidence, Rheumatoid arthritis, bDMARD

S. Anno[1], T. Okano[2], K. Mandai[3], K. Orita[1], Y. Yamada[2], K. Mamoto[2], T. Iida[4,5], M. Tada[6], K. Inui[3], T. Koike[7,8], H. Nakamura[2]. *[1]Yodogawa Christian Hospital, Orthopaedic Surgery, Osaka, Japan*; *[2]Osaka Metropolitan University Hospital, Orthopaedic Surgery, Osaka, Japan*; *[3]Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan*; *[4]Koryokai Hospital, Orthopaedic Surgery, Osaka, Japan*; *[5]Takahiro Clinic, Orthopaedic Surgery, Nishinomiya, Japan*; *[6]Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan*; *[7]Osaka Metropolitan University Hospital, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan*; *[8]Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama, Japan*

Background: Sarilumab was launched the second interleukin 6 receptor inhibitor (IL-6Ri) as a treatment for patients with rheumatoid arthritis (RA) in Japan. Tocilizumab, that was known as first IL-6Ri, showed excellent therapeutic effect without methotrexate (MTX) for RA. However, it was unknown that the effect on concomitant use of MTX in RA patients treated with sarilumab.



Objectives: We evaluated the effect on concomitant use of MTX in RA patients treated with sarilumab.

Methods: This study used a multicenter database included 673 RA patients treated with b/tsDMARDs. We finally analyzed 72 RA patients treated with sarilumab. Thirty-three RA patients were combined with MTX (MTX group) and 39 RA patients were not combined with MTX (non-MTX group). The continuation rate and efficacy at 52 weeks after sarilumab treatment in each group was evaluated.

Results: Non-MTX group was older, longer disease duration, and lower eGFR than MTX group (Table 1). The continuation rate at 52 weeks was not different between MTX group and non-MTX group (56.4 vs 74.4%, p=0.08). DAS28-CRP, SDAI, CDAI were decreased at 4, 12, 24, 36, 52 weeks after sarilumab treatment compared to baseline in both MTX group and non-MTX group (Figure 1). Improvement rate of DAS28-CRP, SDAI and CDAI at 4, 12, 24, 36, 52 weeks after sarilumab treatment were not different between groups (DAS28-CRP: p=0.36, p=0.53, p=0.56, p=0.46, p=0.29; SDAI: p=0.58, p=0.93, p=0.90, p=0.63, p=0.56; CDAI: p=0.65, p=0.98, p=0.99, p=0.61, p=0.47; respectively). HAQ was not improved in MTX group, but improved in non-MTX group during 52 weeks sarilumab treatment (MTX group, p=0.98; non-NTX group, p=0.04). In all patients, 49 RA patients were treated sarilumab as 2nd and more line biological/ targeted synthetic disease-modifying anti rheumatic dugs (b/tsDMARDs). DAS28-CRP, SDAI and CDAI at baseline in RA patients treated with sarilumab as 2nd and more line b/tsDMARDs were 4.1, 18.9, 16.4 in MTX group (n=23), and 4.6, 24.3, 22.6 in non-MTX group (n=26). DAS28-CRP, SDAI and CDAI were decreased at 4, 12, 24, 36, 52 weeks after sarilumab as 2nd and more line treatment compared to baseline in both MTX group (DAS28-CRP: 3.0, 2.5, 2.5, 2.7, 2.7, p<0.01, respectively; SDAI: 12.5, 9.6, 9.3, 10.6, 10.3, p<0.01, respectively; CDAI: 12.2, 9.4, 9.0, 10.2, 10.1, p<0.01, respectively) and non-MTX group (DAS28-CRP: 3.3, 2.8, 2.8, 2.8, 2.6, p<0.01, respectively; SDAI: 15.6, 11.5, 11.4, 11.1, 9.9, p<0.01, respectively; CDAI: 15.2, 11.1, 11.1, 11.0, 9.7, p<0.01, respectively). Improvement rate of DAS28-CRP, SDAI and CDAI at 4, 12, 24, 36, 52 weeks after sarilumab as 2nd and more line treatment were not different between groups (DAS28-CRP: p=0.99, p=0.96, p=0.83, p=0.94, p=0.53; SDAI: p=0.10, p=0.65, p=0.79, p=0.87, p=0.68; CDAI: p=0.95, p=0.72, p=0.76, p=0.74, p=0.53; respectively).

Table 1. Baseline characteristics of RA patients treated with sarilumab

	MTX (+) group (n=33)	MTX (-) group (n=39)	p
Age (years)	61.51 ± 13.68	69.51 ± 13.12	< 0.01
Male/ Female ratio	10/23	8/31	0.5
Disease durations (years)	9.30 ± 10.22	17.39 ± 11.33	< 0.01
RF positive ratio (%)	81.82	79.49	1.0
CCP positive ratio (%)	77.42	82.86	0.85
CRP (mg/dl)	2.44 ± 2.82	1.90 ± 2.06	0.65
MMP-3 (ng/ml)	271.57 ± 314.38	342.34 ± 327.87	0.047
eGFR	79.78 ± 27.50	58.22 ± 27.52	<0.01
DAS28-CRP	4.23 ± 1.31	4.53 ± 1.0	0.26
SDAI	20.41 ± 12.07	23.17 ± 9.66	0.17
CDAI	17.97 ± 10.71	21.27 ± 9.25	0.08
HAQ	0.78 ± 0.78	1.14 ± 0.88	0.02
MTX (mg/week)	8.58 ± 3.58	0 ± 0	<0.01
Glucocorticoid use (%)	18.18 (6/33)	38.46 (15/39)	0.1
Glucocorticoid dose (mg/day)	7.17 ± 3.19	5.83 ± 3.24	0.37
Number of past use of b/tsDMARD			
0 (%)	30.3	33.3	
1 (%)	51.5	33.3	
2 (%)	12.1	15.4	
3(%)	6.1	10.3	
4 (%)	0	5.1	
5 (%)	0	2.6	
Interstitial pneumonia	2/33	7/39	0.17

Conclusion: Sarilumab improved disease activity in patients with RA regardless of concomitant use of MTX.

AB0423 IMPROVEMENT OF ULTRASONOGRAPHIC FINDINGS IN JAK INHIBITOR TREATED JAPANESE RHEUMATOID ARTHRITIS PATIENTS COMPARISON WITH TNF INHIBITOR THERAPY

Keywords: Rheumatoid arthritis, Ultrasound, bDMARD

Y. Kanayama[1], A. Nagata[2], M. Shimotake[2], F. Miyachi[2], K. Fujita[2], M. Koyama[2], S. Uno[2], K. Hattori[1]. *[1]Toyota Kosei Hospital, Orthopedic Surgery and Rheumatology, Toyota, Japan*; *[2]Toyota Kosei Hospital, Clinical Technology, Toyota, Japan*

Background: JAK inhibitor (JAKi) and TNF inhibitor (TNFi) are the important therapeutic agent for the treatment of rheumatoid arthritis (RA). However there is still few studies of improvement of ultrasonographic findings in RA treats comparison with JAKi and TNFi.

Objectives: To evaluate the improvement of ultrasonographic findings in JAKi treated RA patients comparison with TNFi.

Methods: Participants comprised 40 and 43 Japanese RA patients who had recently received each JAKi (BAR26, PEF9, UPA5) and TNFi (CZP30, ADA5, ETN4, GLM4). All patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria. Patients underwent clinical and laboratory assessments every 4 weeks from baseline to 24 weeks, and US assessments at baseline, 4, 12 and 24 weeks. Gray scale (GS) and power doppler (PD) signals were scored using a semi-quantitative scale from 0 to 3 at 26 (0-78) synovial sites (22 joints) in the following joints: bilateral first to fifth metacarpopharangeal (MCP) joints (dorsal recess); first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) (dorsal recess) joints; and the wrists (dorsal radial, median and ulnar). We evaluated the improvement of GS and PD score from baseline to week 24.
Results: In the patients receiving JAKi (n=40) and TNFi (n=43), the mean age was 56.0 vs 54.0 years old (p=0.514), disease duration was 7.3 vs 5.9 years (p=0.343), the rate of MTX use was 70% vs 86% (p=0.076), the mean MTX dose was 10.0 vs 9.9 mg/w (p=0.888), the rate of ACPA positive was 90% vs 79% (p=0.171), the rate of b/ts DMARDs naïve patients was 65% vs 91% (p=0.005), DAS28-ESR was 5.03 vs 4.69 (p=0.102), CDAI was 24.5 vs 19.2 (p=0.038), GS score was 22.1 vs 18.3 (p=0.535) and PD score was 15.1 vs 11.1 (p=0.625). The degree of improvement respective changes in GS and PD score from baseline to 4, 12 and 24 weeks were as follows: GS: -5.7 vs -4.7 (p=0.762) and PD: -6.6 vs -3.1 (p=0.489) after 4 weeks, GS: -9.3 vs -6.7 (p=0.975) and PD: -8.7 vs -4.6 (p=0.340) after 12 weeks, GS: -11.5 vs -9.7 (p=0.732) and PD: -9.5 vs -7.1 (p=0.802) after 24 weeks between JAKi and TNFi (Figure 1, 2). Next, The improvement rate of respective changes in GS and PD score after 4, 12 and 24 weeks were as follows: GS: -16.2% vs -20.7% (p=0.463) and PD: -29.7% vs -20.8% (p=0.414) after 4 weeks, GS: -30.2% vs -27.9% (p=0.884) and PD: -34.0% vs -33.0% (p=0.830) after 12 weeks, GS: -42.4% vs -39.4% (p=0.712) and PD: -41.6% vs -54.0% (p=0.865) after 24 weeks between JAKi and TNFi. Next, we evaluated the improvement of ultrasonographic findings between b/ts DMARDs naïve and switch, with and without MTX in the JAKi-treated patients. The degree of improvement respective changes in GS and PD score from baseline to 24 weeks were as follows: GS: -13.8 vs -7.1 (p=0.313) and PD: -10.8 vs -6.9 (p=0.334) between b/ts DMARDs naïve and switch patients, GS: -11.7 vs -11.0 (p=0.988) and PD: -9.2 vs -10.0 (p=0.658) between with and without MTX patients.
Conclusion: The present study provides evidence supporting the improvement in ultrasonographic findings in RA was similar for both JAKi and TNFi. Also In the JAKi-treated patients, similar improvement in ultrasonographic findings was observed regardless of whether the patients were naive or switch, with and without MTX.

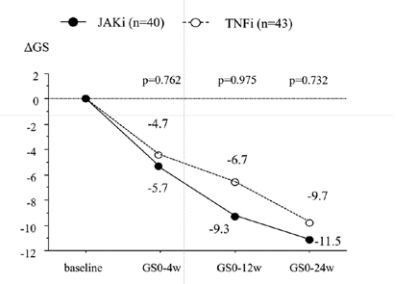

Figure 1 : The degree of improvement respective changesin GS score from baseline to Week 24 between JAKi and TNFi patients

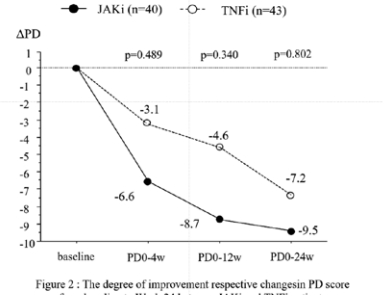

Figure 2 : The degree of improvement respective changesin PD score from baseline to Week 24 between JAKi and TNFi patients

AB0424

IMPACT OF BASELINE RHEUMATOID FACTOR TITERS AND ANTI-TNF MOLECULAR STRUCTURE ON THE RETENTION RATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: bDMARD, Real-world evidence, Rheumatoid arthritis

J. Calvo Gutierrez[1,2,3], R. Ortega Castro[1,2,3], M. C. Ábalos-Aguilera[1,2], F. J. Cepas[1,3], D. Ruiz[1,2], M. Rojas-Giménez[1,2,3], M. L. Ladehesa Pineda[1,2,3], A. Escudero Contreras[1,2,3], C. López-Medina[1,2,3]. *[1]Reina Sofía University Hospital, Rheumatology, Cordoba, Spain*; *[2]Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), GC05 group, Cordoba, Spain*; *[3]University of Cordoba, Medical Surgical Sciences, Cordoba, Spain*

Background: Rheumatoid Factor (RF) is an antibody against the Fc portion of IgG forming immune complexes that contribute to the Rheumatoid Arthritis (RA) process. RF also binds the Fc region of many monoclonal antibodies (mAB), leading to lower drug levels and potential early withdrawal. Conversely, the absence of Fc portion in Certolizumab Pegol (PEG) may lead to a higher retention rate in comparison with other drugs in RA patients with higher RF titers.
Objectives: a) To evaluate the retention rate to any anti-TNF according to the baseline RF titers in patients with RA and b) to compare the retention rate to PEG vs. other anti-TNF in patients with high RF titers.
Methods: Longitudinal, retrospective and unicentre study including patients with a diagnosis of RA and treated with any anti-TNF (mAB (Adalimumab, Golimumab and Infliximab), fusion protein (Etanercept) or PEG (Certolizumab Pegol)) between 2007 and 2022. RF levels before anti-TNF initiation as well as the dates of both initiation and treatment withdrawal were collected. Log-rank test and Kaplan-Meier curves were conducted to evaluate the retention rate to the treatment in RF positive vs. negative, and between RF <110 IU/ml vs RF ≥110 IU/ml (considering the median titre of RF (110 IU/ml) as the cut-off). In addition, the retention rate to each molecular structure were compared in patients with high RF titres (≥110 IU/ml).
Results: A total of 356 patients with RA treated with anti-TNF and with available titres of RF were included. Mean age was 52.0 (11.2) years and 80.1% were female. A total of 254 (71.3%) were RF positive. Retention rate to any anti-TNF was similar in RF- vs RF+ (median 4.30 vs. 3.91 years, p-value 0.580). However, considering the titres of RF, those with baseline RF ≥110 IU/ml showed a shorter retention rate in comparison with RF <110 IU/ml (median 2.78 vs. 6.13 years, p=0.016). In patients with high RF titres (RF ≥110 IU/ml), a longer retention rate was found with PEG in comparison with fusion protein and mAB, although these differences were not significant (median 4.08 in PEG, 2.33 in fusion protein and 1.24 in mAB, respectively; p=0.460).
Conclusion: Higher RF titers before anti-TNF initiation were associated with a shorter retention rate in patients with RA. However, no differences were found between molecular structures, although patients treated with PEG seem to have a longer retention rate. These results confirm the possible effect of the RF in binding the Fc portion of the drug.

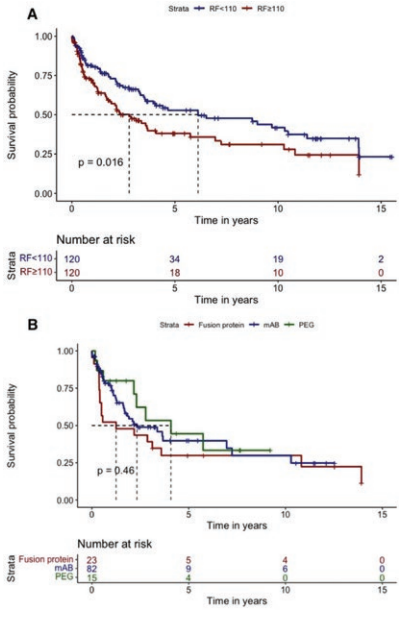

Figure 1. Retention rate to any anti-TNF according to the RF titers (A) and retention rate of each molecular structure in patients with high titers levels (≥110 UI/L) (B).

AB0425 REAL-WORLD EFFECTIVENESS OF FILGOTINIB IN BELGIAN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Real-world evidence, Rheumatoid arthritis, Targeted synthetic drugs

D. C. Diederik[1], P. Durez[2,3], J. Lenaerts[4], R. Westhovens[5], P. Verschueren[5,6]. *[1]Vrije Universiteit Brussel, Biostatistics and Medical Informatics Research Group, Department of Public Health, Brussels, Belgium*; *[2]Université catholique de Louvain, Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium*; *[3]Cliniques Universitaires Saint-Luc, Department of Rheumatology, Brussels, Belgium*; *[4]Reuma-Instituut Hasselt, Department of Rheumatology, Hasselt, Belgium*; *[5]University Hospitals Leuven, Department of Rheumatology, Leuven, Belgium*; *[6]KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium*

Background: Filgotinib (FIL), a preferential Janus Kinase (JAK) inhibitor targeting the JAK1 enzyme, has demonstrated efficacy in rheumatoid arthritis (RA) in clinical trials. FIL is reimbursed in Belgium since August 2021 for adult patients with moderate to severe RA with a DAS28 score >3.7 and inadequate response or intolerance to 2 conventional DMARDs including Methotrexate. Today, limited data exist on the real-world effectiveness of FIL in RA.
Objectives: Our aim was to examine the short-term effectiveness of FIL in a heterogeneous RA population.
Methods: Patients were included from the electronic platform "Tool for Administrative Reimbursement Drug Information Sharing" (TARDIS). Data from all Belgian RA patients on biologic and targeted therapy are collected in this platform during the submission of a request for initiation or prolongation of reimbursement of these drugs. The study population included adult patients ≥18 years starting FIL between August 2021 and November 2022. Baseline characteristics (demographics, clinical characteristics, treatment history) of Belgian RA patients treated with FIL were registered. Effectiveness of FIL was determined by the patient proportion achieving remission (DAS28 <2.6), low disease activity (DAS28 ≤3.2), HAQ-DI≤0.25 (HAQ25) and minimum HAQ-DI-decrease (MCID_HAQ) since baseline of 0.22, at the first follow-up moment, structurally planned in TARDIS after 3 months. Sensitivity analyses were performed in patients starting FIL as 1st, 2nd or 3th+-line advanced therapy.
Results: In total, 405 RA patients on FIL were included, representing all newly initiated FIL patients. Table 1 gives detailed information on the demographics, clinical characteristics and treatment history. Of the 228 patients with information on treatment at the next follow-up moment, 210 (92%) continued FIL, and 6 (3%), 9 (4%), and 3 (1%) changed to a TNFi, non-TNFi and JAKi respectively. In total, 193/405 (48%) patients could be included in the effectiveness analysis. Remission and low disease activity were reached in 61% (117/193) and 81% (156/193) of patients respectively. Baseline mean ±SD DAS28 was 4.9 ±0.8. The DAS28 change was 2.5 ±1.2, resulting in a mean ±SD DAS28 of 2.4 ±1.1 at first follow-up. HAQ25 and MCID_HAQ were reached in 21% (41/193) and 70% (136/193) of patients. FIL efficacy slightly decreased with increasing line of therapy (Figure 1).

Table 1. Baseline characteristics of TARDIS patients on FIL

	Total FIL population
Number	405
Age (mean ±SD, years)	58.3 ±13.7
Disease duration (mean ±SD, years)	10.0 ±9.5
ESR (mean ±SD, mm/hour)	24.9 ±20.9
CRP (mean ±SD, mg/L)	12.4 ±15.7
SJC28 (mean ±SD)	6.5 ±4.2
TJC28 (mean ±SD)	9.0 ±5.6
DAS28 (mean ±SD, years)	4.9 ±0.9
HAQ-DI (mean ±SD, 0-3)*	1.6 ±0.6
PGA (mean ±SD, 0-100)	65.6 ±18.9
Advanced Therapy Naive yes	148/405 (36,5%)
Advanced Therapy Experienced yes	257/405 (63.5%)
2nd line	113/405 (27.9%)
3th line +	144/405 (35.5%)
Previous advanced treatment**	
TNFi,	77/226 (34.0%)
Non-TNFi,	97/226 (42.9%)
JAKi	52/226 (23.0%)

Legend: Number given are mean ± SD or number, proportion. TNFi = tumour necrosis factor inhibitor, JAKi = Janus Kinase inhibitor, HAQ= health assessment questionnaire, PGA= Patient Global assessment; CRP= C-reactive protein; ESR= erythrocyte sedimentation rate; TJC= tender joint count; SJC= Swollen joint Count; DAS28 = disease activity score based on the 28joints. Advanced Therapy naive patients were patients starting FIL as first advanced therapy. *Missing HAQ(0-3) scores were imputed by regression using age and HAQ(0-60) scores. **for 31 of 257 Advanced Therapy Experienced patients this was undefined.

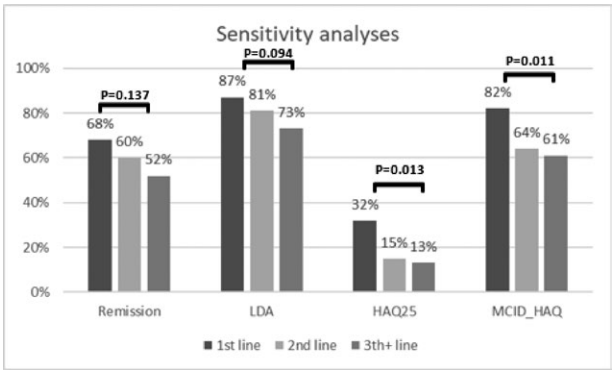

Figure 1. Effectiveness outcomes of FIL per treatment line

Conclusion: FIL treatment offered promising clinical outcomes after 3 months in most patients with moderately to severely active RA in a real-world setting.

AB0426 PROFILE OF REFRACTORY RA PATIENTS FOR TARGETED THERAPIES IN REAL LIFE

Keywords: bDMARD, Rheumatoid arthritis, Targeted synthetic drugs

E. Grau García[1], L. Mas Sanchez[1], P. Muñoz Martinez[1], C. Riesco Barcena[1], A. M. Torrat Noves[1], E. Tovar-Sugrañes[1], E. Vicens Bernabeu[1], H. Charia[1], L. Gonzalez Puig[1], A. V. Huaylla Quispe[1], J. Ivorra Cortés[1], S. Leal Rodriguez[1], I. Martínez Cordellat[1], R. Negueroles Albuixech[1], J. E. Oller Rodríguez[1], F. Ortiz-Sanjuán[1], D. Ramos Castro[1], I. Cánovas Olmos[1], C. Nájera Herranz[1], J. A. Román Ivorra[1]. *[1]HUP La Fe, Rheumatology Department, Valencia, Spain*

Background: A proportion of RA patients fails to respond to their first targeted therapy (TT), and response decreases with increasing TTs exposures. EULAR have defined refractory RA (refRA) patients as a failure of two or more TTs of differing mechanisms of action.
Objectives: We aimed to determine the clinical and therapeutic profile of refRA and describe the patterns of drug sequencing.
Methods: Cross-sectional, observational study with RA patients diagnosed according to ACR/EULAR 2010 criteria, and exposed to TT over the last 20 years was performed. We classified patients in 1) non-refRA (1 or 2 TTs) and 2) refRA (at least 3 TTs). We analyzed the different lines of treatment with TTs, its duration treatment and reasons for discontinuation of treatment.
Results: 544 RA patients undergoing TTs were included, 122 from them were considered as refRA (at least 3 lines of TTs). RefRA patients showed younger age at diagnosis than non-refRA (P<0.001) but there is no differences on time of disease evolution until de 1st TT in both groups. Anti-TNF was the treatment of choice for the 1stline therapy, however is less likely to be administered in non-refRA rather than refRA (P<0.001) (table 1). "Cycling" after the first-line TTs was frequent in refRA (P<0.001), but from the 3rd-line of treatment "switching" is the main choice and different TTs differing mechanisms of action were used. The absence of conventional DMARD treatment is more likely in refRA, as well as a reduction in the treatment duration as increase the number of treatment lines administered. Secondary non-response in 1st and 2nd TTs were the main reason for discontinuing treatment (P<0.001) in refRA, being the adverse event more frequent as cause of discontinuing treatment in non-refRA (P=0.005). Analyzing the reason for discontinuing treatment and excluding the "other reasons", if the cause of discontinuing treatment in refRA is a primary non-response, near of the 30% of patients discontinue in 2nd-line by the same reason; and if the cause for discontinuation in 1st-line is an adverse effect, the 33% of patients discontinue in 2nd-line by the same reason (see image).
Conclusion: RefRA patients showed lower age at diagnosis. Anti-TNF was the most frequent TT both in 1st and 2nd line of treatment; and as from the 3rd-line there is a switching for TTs with mechanisms of action. Despite to secondary non-response is the most common cause of discontinuation in first and second-line in refRA, we observed a tendency to reiterate in the second-line of treatment the reason for discontinuation of the first-line of treatment.

AB0427 ADHERENCE ANALYSIS OF REAL-WORLD EVIDENCE FOR ADALIMUMAB BIOSIMILAR MSB11022 THERAPY IN RHEUMATOLOGIC DISEASES

Keywords: Rheumatoid arthritis, Real-world evidence, bDMARD

S. Cheung[1], D. Truong2. [1]*Fresenius Kabi Canada, Medical Affairs, Toronto, Canada*; [1]*Fresenius Kabi Canada, Medical Affairs, Toronto, Canada*

Background: Phase III clinical trial results demonstrated evidence of safety and efficacy data are similar between MSB11022 (an adalimumab biosimilar) and reference adalimumab in patients with moderate to severe rheumatoid arthritis (RA)[1]. Adherence to biologic treatments is often indicative of disease control and good patient treatment experience. However, evidence on the adherence for MSB11022 in rheumatology diseases is lacking in real-world clinical care setting.
Objectives: The objective of this project was to analyze real-world data collected by Fresenius Kabi patient-support program (PSP, KabiCare) on adherence to MSB11022. Patients with RA, psoriatic arthritis (PsA), and ankylosing spondylitis (AS) were included in this analysis.
Methods: Patients with RA, PsA and AS enrolled in KabiCare and received at least one dose of adalimumab biosimilar, MSB 11022, were follow-up from Feb 2021 to Nov 2022 in Canada. Medication initiation date and stop date, disease types and patient treatment (categorized by naïve to biologic or, switched from other biologics) were recorded in the database. The stop date was the date when KabiCare was informed that medication was discontinued. The patients continuing medication were censored at the maximal follow-up date of analysis, November 9, 2022. Log-rank tests were used for KM (Kaplan-Meier) plot comparison to examine if there were differences in medication adherence among RA, PsA and AS, and between naïve group vs. switch group by disease.
Results: The analysis sample consisted of 2049 patients, 879 of whom had RA, 514 had PsA and 656 had AS. Naïve group included 448 RA, 192 PsA and 256 AS patients. KabiCare followed patients for a median time of 260 days (interquartile range: 169-383 days; maximum: 609 days). At 500 days (approximately 18 months) post initiation of medication, the adherence probability was similar for patients with RA, PsA and AS (At day-500: 75.3%, 82.8% and 81.9%, P=0.096). The adherence probability was higher with switch group compared to naïve group (At day-500: 79.9.8% vs. 70.7%, P=0.027 in RA, 88.1% vs. 72.0%, P=0.0011 in PsA, and 85.8% vs. 74.9%, P=0.0057 in AS).
Conclusion: MSB11022 adherence probability for naïve group ranged between 70%-74.9%; and for switched group ranged from 79.9% - 88.1% for RA, PsA, and AS patients combined at 18 months after initiating MSB11022 biologic therapy. This real-world evidence analysis suggests that patients switching to MSB11022, adalimumab biosimilar, will more likely maintain on therapy when compared to patients initiating MSB11022 therapy. In both cases, inflammatory arthritis patients had high adherence to MSB11022 therapy.

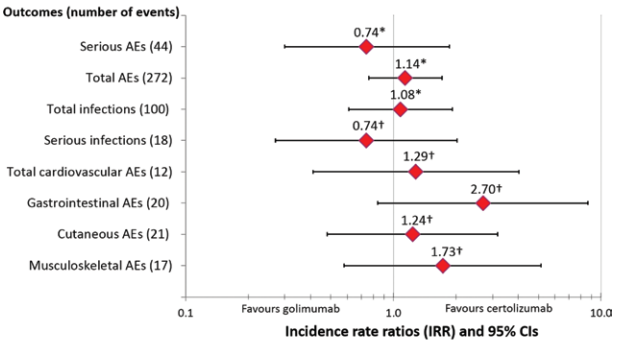
AB0428 SAFETY AND PERSISTENCE OF TREATMENT WITH GOLIMUMAB VERSUS CERTOLIZUMAB IN RHEUMATOID ARTHRITIS: RESULTS FROM BIOBADABRASIL COHORT STUDY.

Keywords: Real-world evidence, Safety, Registries

M. Bredemeier[1], S. Ramos[1], C. Solórzano[1], A. Duarte[1], M. Pinheiro[1], B. Stadler[1], J. C. Macieira[1], R. Ranza[1], J. Miranda[1], V. Valim[1], G. Castro[1], M. Bertolo[1], M. D. F. Sauma[1], V. Fernandes[1], A. C. Medeiros-Ribeiro[1], R. Botelho[1], C. Brenol[1], H. M. Da Silveira De Carvalho[1], S. Studart[1], G. Da Rocha Castelar Pinheiro[1], L. Rocha Jr[1], H. De Leon de Lima[1], I. Pereira[1], M. Ohira Gazzeta[1], A. Kakehasi[1], P. Louzada Jr[1], A. L. S. Hayata[1], F. Pina[1], C. Lupo[1], L. Balarini[1], I. G. Silveira[1], S. Kowalski[1], D. Titton[1], A. Ranzolin[1], R. Xavier[1], I. Laurindo[1], M. Antonio Araujo Da Rocha Loures[1]. [1]*Sociedade Brasileira de Reumatologia, Registros - BiobadaBrasil, Sao Paulo, Brazil*

Background: Golimumab and certolizumab were the last original anti-TNF agents approved in Brazil for the treatment rheumatoid arthritis (RA). Recent studies indicate that certolizumab is associated with higher risk of infections [1] and golimumab with better drug survival compared to the other anti-TNF agents [2], although they have not been compared in head-to-head trials.
Objectives: To evaluate the risk of adverse effects and survival of treatment course in RA patients treated with certolizumab or golimumab.
Methods: BiobadaBrasil is a multicentric registry-based cohort study of Brazilian patients with rheumatic diseases starting their first biologic disease modifying anti-rheumatic drug [3]. The present analysis includes RA patients recruited from Jan 2009 to Oct 2019, followed-up over one or two courses of treatment (latest date, Nov 19, 2019). A treatment course is defined as a period during which the medication scheme does not change. The primary outcome was the incidence of serious adverse events (AEs) and total AEs. System-specific AEs, treatment interruption for any reason, interruption due to AEs and due to inefficacy served as secondary outcomes. Negative binomial regression with generalized estimating equations (to calculate multivariate incidence rate ratios [mIRRs]) and extended (frailty) Cox proportional hazards models were used for statistical analyses (both types of analyses allowing time-fixed and time-varying covariates over multiple courses of treatment).
Results: In total, 227 patients (120 courses, 269.1 patient-years [PY] on treatment with certolizumab and 119 courses, 287.4 PY on golimumab therapy) were enrolled. Patients' features (female: 88.3%; seropositivity: 14.6%; mean age, 52.5 years; mean disease duration, 10.1 years) were comparable between the groups, but start of treatment with certolizumab was on average one year later than golimumab. The



crude incidence of serious AEs was 9.2/100PY for certolizumab and 6.6/100 PY for golimumab. The incidence of any (total) AEs was 37.1/100 PY for certolizumab and 59.8/100 PY for golimumab. The risk of serious and total AEs (primary outcomes) did not differ significantly between the study groups (Figure 1). There was also no significant difference in the risk of infections and other secondary outcomes. Persistence of treatment and reasons for interruption of therapy course also were not significantly different between certolizumab and golimumab (Table 1).

Table 1. Results of univariate and multivariate frailty Cox proportional hazards models estimating the hazard of treatment interruption with golimumab versus certolizumab users (reference). Results are hazard ratios, 95% CIs, and P values.

Cause of interruption (number of events)	Crude analysis	Adjusted for covariates*
Interruption for any reason (111)†	1.58, 0.96 to 2.60, P=0.069	1.45, 0.88 to 2.40, P=0.150
Interruption due to adverse events (24)	1.93, 0.59 to 6.34, P=0.280	1.78, 0.48 to 6.56, P=0.380
Interruption due to inefficacy (65)	0.97, 0.54 to 1.74 P=0.920	0.92, 0.44 to 1.91, P=0.820

*Adjusted for time-fixed covariates (gender, smoking, seropositivity for RF or anti-CCP, history of malignancy, interstitial lung disease, diabetes, hypertension, renal failure, ischemic cardiomyopathy, chronic obstructive pulmonary disease, heart failure, hypercholesterolemia, osteoporosis, and hepatitis B and C; recorded at baseline) and time-varying covariates (age, baseline DAS28, disease duration, starting year, order of treatment, concurrent use of sulfasalazine, methotrexate, leflunomide, cyclosporine and corticosteroids; recorded at the start of each course). †Except for pregnancy or disease remission.

Figure 1. Safety of golimumab versus certolizumab in RA

*Multivariate IRR, adjusted for the same variables described in Table 1.
†Univariate IRR.

Conclusion: In this cohort study of Brazilian RA patients, we did not observe significant differences between certolizumab and golimumab in relation to safety outcomes and persistence of treatment course.

EIGHT-MONTH FOLLOW-UP OF THE NON-MEDICAL SWITCH FROM ETANERCEPT BIO-ORIGINATOR TO GP-2015 OR SB4 ETANERCEPT BIOSIMILARS IN PATIENTS WITH CHRONIC INFLAMMATORY ARTHROPATHIES: A MONOCENTRIC OBSERVATIONAL STUDY

Keywords: bDMARD, Rheumatoid arthritis, Spondyloarthritis

C. Castellani[1], L. Di Sanzo[1], G. Bevignani[1], E. Molteni[1], G. Sciarra[1], M. Di Franco[1], C. Alessandri[1], V. Riccieri[1], R. Priori[1,2], F. Ceccarelli[1], F. R. Spinelli[1], R. Scrivo[1], F. Conti[1]. [1]*Sapienza University of Rome, UOC Reumatologia - Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Roma, Italy*; [2]*Università UniCamillus | Saint Camillus International University of Health Sciences, Saint Camillus International University of Health Science, Roma, Italy*

Background: After the expiration of bio-originators' licenses, the development of less expensive biosimilars has prompted the switch to these drugs. Data on the switch from etanercept (ETA) bio-originators to biosimilars are reassuring [1-2] but still limited.

Objectives: This observational study evaluated the real-life effectiveness of a non-medical switch from ETA bio-originator to GP-2015 or SB4 biosimilars in our cohort of patients with inflammatory chronic arthritis.

Methods: We enrolled consecutive adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS) classified according to standard criteria switched from ETA bio-originator to GP-2015 or SB4 biosimilars for administrative/economic reasons. The date of the switch was the baseline (T0). Patients were reassessed after 4 (T4) and 8 months (T8). At T0, T4, and T8, data on demographic and clinical/laboratory features were registered. Patient-reported outcomes (PROs), such as visual analog scale (VAS 0-10) for pain and global assessment (PGA) and functional status by Health Assessment Questionnaire (HAQ) were used, together with disease-specific scores (DAS28-CRP for RA, DAPSA for PsA, ASDAS-CRP and BASDAI for AS). We assessed the same data at the time of early discontinuation for inefficacy (loss or lack of efficacy – LoE or LaE) or adverse events (AEs).

Results: One hundred and twelve patients switched from ETA bio-originator to GP-2015 [45 RA, F:M=33:12, median age 67 years (IQR 24), median disease duration 214 months (IQR 180), median exposure to bio-originator 126 months (IQR 97); 48 PsA, F:M=18:30, median age 59 years (IQR 18), median disease duration 168 months (IQR 120), median exposure to bio-originator 120 months (IQR 96); 19 AS, F:M=7:12, median age 55 years (IQR 16), median disease duration 162 months (IQR 245), median exposure to bio-originator 132 months (IQR 82)]. No differences were found in the clinical and laboratory parameters compared to T0 in RA and PsA, while AS patients showed an improvement of BASDAI at T8 compared to T4 (p=0.0273). Interestingly, at T8 RA patients experienced a worsening in the HAQ (p=0.0313) with respect to T0 (figure 1A) and PsA patients had a worsening of VAS pain compared to T4 (p=0.0371) (figure 1B). Four (8.8%) RA patients discontinued GP-2015 at T4 due to AEs (1 for recurrent infection of upper airways, 1 for injection site reaction, 1 for skin cancer, 1 for breast cancer). One (2%) PsA patient discontinued GP-2015 at T4 due to AE (oral ulcers). Twenty-eight patients switched from ETA bio-originator to SB4 [14 RA, F:M=13:1, median age 63.5 years (IQR 33), median disease duration 144 months (IQR 206), median exposure to bio-originator 84 months (IQR 96); 11 PsA, F:M=6:5, median age 54 years (IQR 12), median disease duration 205 months (IQR 198), median exposure to bio-originator 177 months (IQR 164); 3 AS, F:M=0:3; median age 56 years, median disease duration 210 months, median exposure to bio-originator 120 months]. An improvement of DAPSA at T4 compared to T0 was observed in PsA patients (p=0.0469). At T8, no differences were found compared to T0. One (9%) PsA patient experienced LoE at T4.

Conclusion: Our data indicate that the switch to GP-2015 or SB4 ETA biosimilars from ETA bio-originator does not bear clinical and laboratory differences in patients with chronic arthropathies. The worse outcome in PROs, which we also observed in the adalimumab bio-originator to biosimilar switch (3), does not reflect a worsening of disease activity indexes and could indicate a possible nocebo response.

MEDICATION ADHERENCE IN PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS TREATED WITH BIOLOGIC OR TARGET SYNTETIC -DMARDS: EVALUATION OF PREDICTIVE FACTORS IN AN ITALIAN MONOCENTRIC COHORT

Keywords: Quality of care, Patient information and education, Rheumatoid arthritis

L. Moschetti[1], C. Bazzani[1], F. Delvecchio[1], F. Franceschini[1]. [1]*Rheumathology and Clinical Immunology Unit, ASST Spedali Civili of Brescia and University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy*

Background: In rheumatoid arthritis(RA), medication non-adherence can be considered one of the primary determinants of therapeutic failure.
Objectives: To evaluate 1)the prevalence of treatment adherence in RA patients(pts) treated with biologic(b) or target synthetic(ts)-DMARDs followed in a tertiary rheumatologic center and 2)the factors associated to a better treatment adherence.
Methods: An observational retrospective single center study was conducted enrolling adult RA pts treated with b/ts-DMARDs, in monotherapy or in combination with methotrexate. Demographic data, clinical characteristics and outcomes measures were collected. To evaluate the comorbidities the Rheumatic Disease Comorbidity Index(RDCI) was used. Treatment adherence was assessed through self-reported adherence rate(SRAR) rated on a visual analogue scale (VAS, 0-100 mm) and 5-item Compliance Questionnaire for Rheumatology(CQR5). Pts were considered adherent if SRAR ≥80/100. All the participants were required to complete: VAS pain questionnaire, Patient Global Assessment(PGA), Health Assessment Questionnaire(HAQ), Depression Anxiety Stress Scales(DASS21), Insomnia Severity Index and self-reported VAS therapy satisfaction scale (0-100 mm, higher values indicate higher satisfaction).
Results: Among the 116 pts (Table 1) evaluated, 57% described themselves as being adherent to their treatment (median SRAR: 80 [60-90]; median satisfaction level: 80 [60-90]). According to CQR5, 97% of the pts presented a high adherence level; 28/116 pts declared a treatment suspension during the previous month; in most cases the withdrawal was reasonable (due to vaccinations, infections, surgery). The comparison between adherent and non-adherent pts is shown in Table 1: a significative association between non-adherence and higher DAS28, HAQ and VAS pain scores was observed; in addition, an association was found between adherence and treatment satisfaction level. No significant differences in demographic features, educational level, work status, comorbidities and therapeutic formulation/plan/type were found. Patient's reported outcomes scores regarding insomnia/anxiety/depression/stress were higher in non-adherent pts but not statistically different.
Conclusion: Treatment adherence is still a complex process difficult to measure. Our data show a discrepancy between SRAR and CQR5 adherence assessment (57% vs 97%). In our cohort of pts, regularly followed-up in a tertiary outpatient clinic, the prevalence of adherence is overall higher as compared with that reported in literature (medication adherence in RA pts: 30-80%)[1]. In this study, treatment adherence seems to be associated with a higher therapy satisfaction level and a lower disease activity, pain perception, and physical disability. However, a cause-effect relationship still remains difficult to analyze.

Background: Treatment with biotechnological anti-interleukin (IL)-1 agents is recommended in patients with Still's disease especially in cases refractory to glucocorticoids and conventional disease modifying anti-rheumatic drugs (cDMARDs), avoiding a long-term glucocorticoids exposure. In cases with refractory arthritis, IL-6 inhibitors have shown to be effective on articular inflammatory involvement.
Objectives: The objective of the present study is to evaluate any difference in the effectiveness of the IL-1β antagonist canakinumab prescribed as first-line biologic agent between the systemic and the chronic-articular Still's disease.

Methods: Data were drawn from the retrospective phase of the AutoInflammatory Disease Alliance (AIDA) international registry dedicated to Still's disease. Patients affected by Still's disease classified according to internationally accepted criteria (Yamaguchi criteria and/or Fautrel criteria) and treated with canakinumab as first-line biologic agent were enrolled.
Results: A total of 26 patients (17 females, 9 males; 18 patients developing Still's disease after the age of 16 years) were enrolled; 16 (61.5%) patients suffered from the systemic pattern of the disease; 10 (38.5%) patients suffered from the chronic-articular type. No differences were observed between the systemic and the chronic-articular Still's disease in the frequency of complete response, of flares after the start of canakinumab (p=0.701) and in the persistence in therapy (p=0.62). No statistical differences were observed between the two groups after 3 months, 12 months and at the last assessment in the decrease of: the systemic activity score (p=0.06, p=0.17, p=0.17, respectively); the disease activity score on 28 joints (p=0.54, p=0.77, p=0.98, respectively); the glucocorticoid dosage (p=0.15, p=0.50, and p=0.50, respectively); the use of concomitant disease modifying anti-rheumatic drugs (p=0.10, p=1.00, and p=1.00, respectively). No statistically significant differences were observed in the decrease of erythrocyte sedimentation rate (p=0.34), C reactive protein (p=0.48), and serum ferritin levels (p=0.34) after the start of canakinumab.
Conclusion: Canakinumab employed for Still's disease has been effective in controlling both clinical and laboratory manifestations disregarding the type of disease course when used as first-line biotechnological agent. These excellent results might have been further improved by the early start of IL-1 inhibition.

AB0432 COMPARISON OF SYMPTOMATIC AND DISEASE-MODIFYING TREATMENT IN RHEUMATOID ARTHRITIS WITH CONCOMITANT FIBROMYALGIA

Keywords: Disease-modifying Drugs (DMARDs), Rheumatoid arthritis, Fibromyalgia

B. A. Hiba[1], S. Miladi[1], F. Alia[1], H. Bousaa[1], M. Yasmine[1], L. Souabni[1], K. Ouenniche[1], K. Selma[1], C. Selma[1], K. Ben Abdelghani[1], L. Ahmad[1]. *[1]Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia*

Background: There is evidence that concomitant fibromyalgia (FM) among rheumatoid arthritis (RA) patients make the management of RA challenging by inflating subjective disease activity parameters.
Objectives: Thus, the aim of this study was to compare symptomatic and disease-modifying treatments in RA patients with and without concomitant FM.
Methods: This was a cross-sectional study including patients with an established RA according to the 2010 ACR/EULAR criteria. All patients were screened for concomitant FM by 2016 ACR criteria. Patients were divided into 2 groups: RA and RA+FM. Demographic and RA characteristics were collected. P<0.05 was accepted for significance. Multiple linear regression analysis performed, adjusting for clinical and demographic variables.
Results: Eighty patients distributed into 40 patients in each group were recruited. Epidemiological characteristics, RA characteristics and disease activity scores were. comparable between groups. Coxitis and atlantoaxial subluxation were significantly more frequent in RA+FM group (p=0.006 and p=0.049 respectively). No significant difference in corticosteroids prescription was found between the groups (p=0.88), nor in non Non-steroidal anti-inflammatory drugs prescription (p=0.48). Of the RA patients with concomitant FM, 52% were treated with biological therapy vs. 18% of RA patients without concomitant FM (p = 0.04). Tumor necrosis factor inhibitors were the most frequently prescripted in the two groups (47.5% of RA patients with FM vs 12.5 in RA patients, p=0.03). No significant difference was noted between the groups regarding conventional Disease-modifying antirheumatic drugs (DMARDs) prescription (p=0.052). Multiple linear regression in RA+FM group showed that FM is an independent factor for biological DMARDs prescription (B=0.284, p=0.018).
Conclusion: Our study showed that concomitant FM in patients with RA was associated with a higher use of biological treatments. This raises the question of whether the more frequent use of biologics in these patients is justified by inflammation, or by persistent pain and other centrally mediated symptoms.

AB0433 BIOLOGICAL THERAPIES SURVIVAL FOR RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS SPONDYLOARTHRITIS AND JUVENILE ONSET ARTHRITIS. A COHORT STUDY FROM BIOBADAGUAY

Keywords: Inflammatory arthritides, bDMARD

G. Avila[1], S. Cabrera-Villalba[1], P. Melgarejo[2], L. Roman[3], Z. Morel[4], R. Rolón[1], M. Zarza[1], M. Soto Estevez[5], E. Leiva[6], A. Amarilla[1], P. Pusineri[6], C. Parodi[6], C. Díaz[7], B. Acevedo[5], A. Fernandez[7], V. Valinotti[1], P. DE Abreu Trigueros[8]. *[1]Hospital Central del Instituto de Previsión Social, Rheumatology, Asunción, Paraguay*; *[2]Hospital de Villarrica, Rheumatology, Villarrica, Paraguay*; *[3]Hospital de Villa Elisa, Rheumatology, Villa Elisa, Paraguay*; *[4]Hospital Central del Instituto de Previsión Social, Reumatología Pediátrica, Asunción, Paraguay*; *[5]Instituto Nacional De reumatología, Rheumatology, Montevideo, Uruguay*; *[6]Hospital de Clinicas de la Universidad Nacional de Asunción, Rheumatology, Asunción, Paraguay*; *[7]COSEM, Rheumatology, Montevideo, Uruguay*; *[8]Sociedad Paraguaya de Reumatología, Rheumatology, a, Paraguay*

Background: BIOBADAGUAY is the Paraguayan/Uruguayan registry of adverse events in patients with inflammatory rheumatic conditions under biologic therapy (BT). The registry includes patients with different diagnosis that share similar biological therapies indication. However, different pathogenesis, patients' characteristics and treatment options can affect the survival of the BT.
Objectives: To analyze survival of biological therapies among patients with chronic inflammatory arthritis in the BIOBADAGUAY registry.
Methods: Patients with chronic inflammatory arthritis (CIA) such us rheumatoid arthritis (RA), spondylarthritis (SpA), psoriatic arthritis (PsA) and juvenile onset arthritis (JIA) enrolled in BIOBADAGUAY where analyzed. Other diseases included in the registry were grouped as others. Drug survival and clinical and epidemiological predictors were studied. Fewer than BT 25 registries were not included in the study. Survival analysis was performed using Kaplan-Meier estimators, and Cox proportional hazard models were used to estimate hazard ratios (HRs).
Results: A total of 1378 treatments (876 RA, 176 SpA, 40 JIA, 88 PsA, 98 others) were included. The mean BT survival according to diagnosis was 300.9 (95%CI, 230.6-444.4) weeks (wks) for RA; 541.6 (95%CI, 409.6-541.6) wks for SpA; 154.1 (95%CI, 125.0-194.7) wks for JIA and 555.3 (95%CI, 282.1-611.6) wks for PsA. In the general analysis, when survival was compared between different diagnosis, it was found that BT survival for SpA patients (p˂0.05; HR=1.23 [95% CI 0.97-1.56]) was higher than other CIA. On the other hand, JIA diagnosis was significantly associated with a lower BT survival (p˂0.05; HR=1.85 [95% CI 1.36–2.52]). In the general analysis, no significant differences between BT were found (p>0.05). When each drug survival was analyzed according to diagnosis, adalimumab showed a significant difference in SpA patients (p˂0,05; HR=0.55 [95% CI, 0.39-0.76]) and JIA patients (p=<0.005; HR=1.8 [95% CI 1.36–2.52]). Etanercept had a significant difference in RA (p <0.005; HR=0.57 [95% CI, 0.40-0.82]) and JIA patients (p=<0.005; HR=2.07 [95% CI, 1.39–3.06]). Following these results we analyzed JIA patients and found that remission was the principal reason of discontinuation in this group of patients (p<0.005, HR=10.700 [95% CI, 5.91–19.36]). Multivariable analysis showed that the number of previous BTs (p=0.01, HR=1.18 [95% CI, 1.03-1.34), corticosteroid treatment (p=0.05; HR=1.18 [95% CI; 0.99–1.40), SpA (p=0.01; HR=0.688 [95% CI 0.51-0.91) and JIA diagnosis (p=0.02; HR=1.4 [95% CI, 1.06-2.02]) where associated with BT survival.
Conclusion: In this study we found different survival profiles according to diagnosis. This could be related to different pathogenesis, discontinuation motives and treatment options in different health systems.

AB0434 RHEUMATOID FACTOR AS PREDICTOR OF RESPONSE TO RITUXIMAB

Keywords: bDMARD, Rheumatoid arthritis

B. Touil[1], N. Akasbi[1], I. El Mezouar[1], T. Harzy[1]. *[1]Sidi Mohammed Ben Abdellah University, Rheumatology Department, FEZ, Morocco*

Background: In Rheumatoid Arthritis (RA), the presence of rheumatoid factor (RF) indicate poor prognosis. Strategies searching biomarkers that predict response to biologic therapies allowing the selection of patients with the highest

chance for response are pertinent. Whether RF is a biomarker of response to RTX is disputed. [1]

Objectives: To investigate whether high rheumatoid factor (3 times normal) is predictive of a good therapeutic response in RA patients treated with Rituximab (RTX).

Methods: We conducted a Retrospective study in a single rheumatology hospital in Morocco. All patients satisfied the ACR-EULAR 2010 RA classification criteria. Socio-demographic data, comorbidities, disease-related variables (duration, characteristics, and drugs) were collected. The endpoint was a decrease in DAS28 greater than 1.2 at 6 month after RTX therapy. Statistical analysis were performed with SPSS 20.

Results: We included 129 patients with a mean age of 58.45 ± 11.99 years. The sex ratio F/M was 8:1. The mean duration of RA was 17.73 ± 8.34 years. The mean age at diagnosis was 44.13 ± 13.91 years, 87% of patients were seropositive. The positivity of rheumatoid factor and ACPA was in 82% and 69% of the patients respectively. RF was highly elevated in 48.4% of patients. In bivariate analysis, strong RF positivity was significantly associated with a good response as assessed by DAS28 (p=0.002), and to a high initial IgM level (p= 0.018).

Conclusion: In our study, RA patients with strong positive rheumatoid factor had a better therapeutic response as assessed by DAS28. These results should be taken into account when making therapeutic choices.

AB0435 ADHERENCE TO BIOLOGIC THERAPIES IN INFLAMMATORY RHEUMATIC DISEASES: INFLUENCE OF ROUTE OF ADMINISTRATION

Keywords: Spondyloarthritis, bDMARD, Rheumatoid arthritis

F. Wertani Ep Amiri[1], I. Mahmoud[1], S. Bouden[1], R. Leila[1], R. Tekaya[1], A. Ben Tekaya[1], H. Sahli[2], O. Saidane[1], L. Abdelmoula[1]. *[1]Tunis, Rheumatology of Charles Nicolle Hospital,Tunis,Tunisia*; *[2]Tunis, Rheumatology of Rabta Hospital, Tunis,Tunisia*

Background: Inflammatory rheumatic diseases are a debilitating disease affecting the joints and periarticular structures and leading, more or less rapidly, to cartilage and bone destruction. It is a major source of chronic pain and physical, psychological, and social disability, it affect approximately 1% of the world's population [1]. For more than 20 years, biotherapies have revolutionized the treatment of these inflammatory diseases and have largely contributed to the improvement of their prognosis [2]. Adherence to biologic therapies conditions the effectiveness of the treatments then the improvement of patients' quality of life [3].

Objectives: To evaluate and compare adherence to biologic disease-modifying antirheumatic drugs (bDMARDs) according to the route of administration and the molecule used (Infliximab, Tocilizumab, Etanercept, Adalimumab, Certolizumab, and Golimumab) in patients with inflammatory rheumatic diseases.

Methods: This is a descriptive cross-sectional study with repeated data collection, bi-centric carried out in the rheumatology departments and outpatient clinics at Charles Nicolle Hospital and Rabta Hospital in Tunis and conducted over a period of 01 year and 02 months between 02/02/2021 and 30/04/2022. 71 adult patients with rheumatoid arthritis, spondyloarthritis or juvenile idiopathic arthritis were recruited, their adherence rate in the last 3 months before inclusion should be ≥80%. The collection of socio-demographic, clinical and therapeutic data was established with the help of a pre-established form, from medical files completed by questioning the patients during a direct interview or through a telephone communication. Adherence rate was calculated by determining the ratio of treatments cures (number of biologic injections taken during a year divided by the number of annual biologic injections prescribed).

Results: Within the study population, adherence was estimated at 85.9%; in the group of patients using intravenous biotherapy was 82.1% (Infliximab 86%, Tocilizumab 75% p=0.04) and in the group of patients using subcutaneous treatment was 89.9% (Golimumab 94%, Etanercept 92%, Certolizumab 89%, Adalimumab 87% p=0.3). Adherence to biologic therapy was significantly higher in the subcutaneous group than in the intravenous group (p=0.01). The causes of poor adherence presented by the patients in this study were: stock-outs of biological treatment and delay in renewal by the national health insurance (CNAM) in thirty-eight cases (54%p<0.001), intercurrent infections in thirty-three cases (46% p=0.005) and the COVID 19 pandemic and its consequences in thirty patients (42%,p=0.28).

Conclusion: Adherence to biologic treatment is influenced by the route of administration, drugs type, intercurrent infections and drugs availability. All this factors must be treated to improve therapeutic adherence then the efficiency of the biologic therapy which conditions the preservation of physical capacities and an improvement in the quality of life.

AB0436 THE IMPROVEMENT OF THE DAS28 SCORE AT THREE MONTHS PREDICTS BIOLOGIC DRUGS TOLERANCE AND SURVIVAL IN RHEUMATOID ARTHRITIS

Keywords: bDMARD

S. Boussaid[1], M. Hassayoun2, S. Rekik[1], S. Rahmouni[1], K. Zouaoui[1], H. Ajlani[1], H. Sahli[1], M. Elleuch[1]. *[1]La Rabta Hospital, Rheumatology Department,Tunis, Tunisia*; *[1]La Rabta hospital, Rheumatology Department,Tunis,Tunisia*

Background: The treat-to-target strategy has been established as a guiding principle for the treatment of rheumatoid arthritis (RA). Nevertheless, data on the degree to which the improvement of the DAS28 score impacts the survival of biologic drugs is rarely studied.

Objectives: Our objective in this study was to assess the influence of the improvement of the DAS28 score at 3 months on biologics tolerance and survival.

Methods: We conducted a cross-sectional and observational study. Files of patients with RA on biologics drugs (archived from the files of patients on the National Health Insurance Fund of Tunis) were studied. Epidemiological characteristics such as age, sex, and comorbidities, were collected. RA activity was assessed by the composite score 'Disease Activity Score 28' (DAS28). Patient follow-up was done at 3 months by the DAS28 disease activity score. We specified the ΔDAS28, between the initiation of biotherapy and the value at 3 months. The therapeutic maintenance rate at 3 months as well as the biologics survival was analyzed using Kaplan-Meier survival curves and compared using the Log-Rank test.

Results: Three hundred and seventy-four files were selected. The average age of our cohort was 55±12.54 years [20-90]. A female predominance was noted with a sex ratio M/F=0.147. The average duration of RA was 11.7±6.76 years [2-41]. The first biotherapy prescribed was certolizumab pegol 13%, adalimumab in 14% of cases, infliximab 6%, tocilizumab 6%, etanercept in 54% of cases, and rituximab in 7% of cases. The average DAS28 at the initiation of the biological treatment was 6.02 ± 0.89. The median was 6 [5.37–6.50]. We noted that the higher the delta DAS28 at 3 months of treatment, the lower the risk of interrupting the biological treatment, as evidenced by the HR = 0.709 (p < 10-3). For patients with a moderate to good response the maintenance rate was 45.35 months [43.06-47.64]; for patients with no response; therapeutic maintenance was 28.55 months [22.41-34.69].

Conclusion: Efficient and rapid management of RA remains the most appropriate strategy to achieve control of the disease. The rapid improvement of DAS28 under biologics would be, according to our results, a factor influencing the survival of these treatments. Larger-scale studies will be needed to confirm these results.

AB0437 IMMUNOGENICITY ANALYSIS FROM THE VOLTAIRE TRIALS IN PATIENTS WITH RHEUMATOID ARTHRITIS, CROHN'S DISEASE, AND CHRONIC PLAQUE PSORIASIS

Keywords: Rheumatoid arthritis, Safety, Disease-modifying Drugs (DMARDs)

V. Strand[1], S. Bender[2], D. Mccabe[3]. [1]*Stanford University School of Medicine, Immunology/Rheumatology, Palo Alto, United States of America*; [2]*Alnylam Pharmaceuticals, Inc., Biostatistics, Cambridge, United States of America*; [3]*Boehringer Ingelheim USA, Immunology/Biosimilars, Ridgefield, United States of America*

Background: The VOLTAIRE trials program compared safety, efficacy, and immunogenicity of biosimilar BI 695501 with adalimumab reference product (RP) for indications including moderate-severely active rheumatoid arthritis (RA), Crohn's disease (CD), and chronic plaque psoriasis (PsO). Details of each active-comparator, randomized controlled trial (RCT) are published. [1,2,3]
Objectives: Here we compare immunogenicity across these indications and by patient sex.
Methods: Immunogenicity was assessed at various timepoints by the proportion of patients with anti-drug antibodies (ADAs) and neutralising antibodies (nAbs), using acid dissociation followed by an electrochemiluminescence assay (ECL; MSD platform; Meso Scale Diagnostics LLC, USA).[4] Assay sensitivity was 50 ng/mL, and drug tolerance ≥30 µg/mL (free drug) at the low positive control level.
Results: Data are presented in **Table 1**.

Table 1. Immunogenicity data

a. Wk 4 = Day 29 in CD trial; b. Median (minimum, maximum); c. Reported by randomisation completed at baseline

Conclusion: Minor differences in immunogenicity (ADAs, ADA titres and nAbs) between BI 695501 and adalimumab RP were observed across these 3 indications. The proportion of ADA- and nAb-positive patients increased from baseline in all 3 RCTs, and were similar in RA and CD RCTs, but rates were higher in PsO RCT. Subgroup analysis by patient sex showed the same trend. These differences may be partially explained by concomitant background therapy (MTX) in RA trial, stable doses of AZA, 6-MP or MTX in 36% of CD patients and the absence of background therapy in PsO RCT. Comparisons are limited by different visit schedules in the trials. Historical comparisons to RP data are complicated by recent differences in regulatory requirements for increased ADA assay sensitivity and stringency for biosimilar products than those originally used for the RP. Acid dissociation followed by the more sensitive ECL assay for detection of ADAs is not dependent on serum drug concentrations. In conclusion, these analyses confirm the biosimilarity of BI 695501 with the adalimumab RP across RA, CD, and PsO.

AB0438 TAPERING BIOLOGICAL DMARD IN RHEUMATOID ARTHRITIS: REAL-WORLD EVIDENCE.

Keywords: bDMARD, Remission, Tapering

W. G. Rojas Zuleta[1], M. Barbosa[1], C. Becerra-Arias[1], O. J. Felipe Díaz[1], J. H. Donado Gómez[1], L. A. González[1], N. Duque Zapata[1]. [1]*Medicarte SAS, Center for Immune-Mediated Diseases, Medellín, Colombia*

Background: biological DMARDs have revolutionized the treatment of rheumatoid arthritis (RA), demonstrating effectiveness in terms of symptom control, improvement in quality of life and radiographic progression. However, their high-cost impacts global health systems. Therefore, tapering strategies are important therapeutic strategies to consider in patients with sustained remission. It is estimated that up to 50% of patients with bDMARDs and sustained response would be successful upon biologic therapy optimization [1].
Objectives: to estimate the relapse rate in patients with RA on tapering bDMARD protocol.
Methods: This is an observational cohort study of established RA patients followed in Medicarte, a Colombian specialized outpatient clinic, between 2014 and 2022. Selection criteria included patients ≥18 years of age, with a diagnosis of RA according to the 2010 EULAR classification criteria, who has been in remission for at least 12 months and agreed to enter the bDMARD reduction strategy either by reducing the dose or increasing the interval between doses. Relapse was defined according to the consensus of the Spanish Society of Rheumatology: mild relapse as an increase in DAS28>0.6 and final DAS28 >3.2, and severe relapse as an increase in DAS28 >1.2 [2]. Quantitative variables are presented as medians (interquartile range, IQR), while the qualitative variables as frequencies (percentages). Kaplan Meier was used to estimate the survival drug, according to tapering medication strategy and incidence density. A p value <0.05 was considered statistically significant.
Results: 167 patients [82.6% women, median (IQR) age of 59 years (52-65), and median (IQR) disease duration of 13.7 years (7.7-20.8)] were included. They have been in the tapering strategy for 2.4 years (IQR: 2-3.7). The median (IQR) of DAS 28 -CRP before start of tapering was 1.2 (0–1.6) and at the end of follow-up was 2.12 (IQR 1.54–2.77). Increasing the interval between doses was used as a tapering strategy in 70.1% of the patients. The most frequently bDMARD used was etanercept [n=57 (34.1%)], followed by tocilizumab 27.5% [n=46, subcutaneous and intravenous (27.5%)], adalimumab [n=27 (16.2%)], abatacept 8.4% [n=14, subcutaneous and intravenous (8.4%)], certolizumab 4.2% [n=7 (4.2%)], subcutaneous golimumab [n=11 (6.6%)], rituximab [(n=4 (2.4%)], and Infliximab [n=1

(0.6%)]. Relapses were observed in 24 (14.4%) patients while on biologic therapy optimization, being more frequent with certolizumab and abatacept. The lowest rates of relapse were observed with infliximab, adalimumab and etanercept, while certolizumab and abatacept had the shorter time to relapse (table 1). Overall, the relapse rate was 5.5 per 100 patient-years with RA at risk (p=0.021) (figure 1).

Conclusion: Tapering bDMARD strategy was effective in our large RA cohort with 85.6% of patients remaining in remission during the follow up. Adalimumab, etanercept and tocilizumab were the bDMARDs with the longest time to relapse. These findings support the use of the tapering strategy in patients with established RA.

ADALIMUMAB AND NUMBER OF PREVIOUS BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS AS PREDICTIVE FACTORS FOR THE DEVELOPMENT OF IMMUNE-MEDIATED SKIN LESIONS

Keywords: Skin, bDMARD

A. Martins[1,2], D. Santos Oliveira[1,2,3], F. R. Martins[4], R. Nicolau[5], F. Oliveira Pinheiro[1], M. Rato[1], A. Bernardo[1], S. Pimenta[1,2], M. Bernardes[1,2], L. Costa[1].
[1]São João Universitary Hospital Center, Rheumatology, Porto, Portugal; [2]Faculdade de Medicina da Universidade do Porto - FMUP, Medicine, Porto, Portugal; [3]Faculdade de Medicina da Universidade do Porto - FMUP, CINTESIS, Porto, Portugal; [4]University Hospital Center of Algarve, Faro, Rheumatology, Faro, Portugal; [5]Centro Hospitalar Tondela - Viseu, Epe, Rheumatology, Viseu, Portugal

Background: Treatment of inflammatory rheumatic diseases has dramatically changed with the introduction of biologic disease modifying anti-rheumatic drugs (bDMARDs). However, these drugs aren't exempt from risks and skin lesions are the most frequent adverse reactions. Among the possible adverse skin reactions, immune-mediated skin lesions (IMSL) may occur. Risk factors associated with the occurrence of IMSL in rheumatic patients under bDMARDs are poorly known and studied.

Objectives: To identify predictive factors for IMSL in patients with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA) under bDMARD therapy.

Methods: A retrospective single-center cohort study including patients with RA, axSpA and PsA followed at the Department of Rheumatology of a University Hospital Center between April 2000 and December 2021, treated with at least one bDMARD for at least 6 months was conducted. Data were collected from a national register of rheumatic patients (Reuma.pt) and medical records. Sociodemographic characteristics, disease duration, age at diagnosis, smoking and drinking habits, concomitant immunosuppressive medications, type and duration of the bDMARD treatment and number of previous bDMARD were collected. IMSL development were also collected. Independent samples t-test for normally distributed continuous data and chi-square tests for categorical variables was performed. Also, a multivariate logistic regression analysis was performed to identify possible predictive factors for the occurrence of IMSL. Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated. Statistical significance was set at a p-value <0.05.

Results: From a total of 441 patients with RA, 386 with axSpA and 162 with PsA, 27 developed IMSL related to bDMARD (2.7%). Comparing the groups with and without IMSL, no differences were found regarding age, gender, BMI, presence of concomitant csDMARD or type of rheumatic disease. Patients with IMSL have a significant younger age at diagnosis (p=0.038), a longer disease duration (p=0.018) and a longer duration of bDMARD treatment (p=0.008). Patients with IMSL also have a higher number of previous bDMARDs (p<0.001) and adalimumab was the bDMARD with the higher risk of IMSL development (p<0.001). Table 1 described the demographic and clinical features of these two groups.

Table 1. Demographic and clinical features in patients with and without IMSL.

	With IMSL (n=27)	Without IMSL (n=962)	p-value
Age, mean ± SD, years	55.5 ± 14.0	52.2 ± 12.7	0.605
Female, n (%)	15 (55.6)	612 (63.6)	0.391
BMI, mean ± SD	25.4 ± 4.8	27.2 ± 7.5	0.227
Current/Former smoker, n (%)	10 (37.0)	327 (34.0)	0.477
Alcohol consumption, n (%)	4 (14.8)	140 (14.6)	0.599
Disease duration, mean ± SD, years	24.4 ± 12.7	19.2 ± 11.1	**0.018**
Duration of bDMARD treatment, mean ± SD, years	9.3 ± 4.4	6.6 ± 5.3	**0.008**
Age at diagnosis, mean ± SD, years	29.4 ± 12.8	35.0 ± 13.2	**0.038**
Number of previous bDMARDs, mean ± SD	1.6 ± 1.1	0.74 ± 0.84	**<0.001**
Presence of concomitant csDMARD, n (%)	10 (37.0)	467 (48.5)	0.238
Adalimumab vs other bDMARD, n (%)	14 (51.9)	211 (21.9)	**<0.001**

In a multivariate regression model, number of previous bDMARDs (OR 2.13, 95% CI 1.47 to 3.10, p<0.001) and treatment with adalimumab (OR 4.60, 95% CI 1.96 to 10.80, p<0.001) were statistically significant predictive factors for IMSL development.

Conclusion: In our cohort, we found that a younger age at diagnosis, longer disease duration, longer duration of bDMARD treatment, higher number of previous bDMARDs and treatment with adalimumab were independently associated with an increased risk of IMSL development. In the multivariate regression model, number of previous bDMARDs and exposure to adalimumab were statistically significant predictive factors for IMSL development. Further research is required to better understand and recognize the risk factors for IMSL.

CHANGES IN BONE BIOCHEMICAL MARKERS DUE TO THE INFLUENCE OF RISK FACTORS FOR OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TUMOR NECROSIS FACTOR INHIBITORS

Keywords: Rheumatoid arthritis, bDMARD, Biomarkers

T. Janković[1], J. Zvekic Svorcan[1], K. Boskovic[1], A. Savic[1], A. Glavčić[1], I. Minaković[2].
[1]Faculty of Medicine, University of Novi Sad, Special Hospital for Rheumatic Diseases, Rheumatology, Novi Sad, Serbia; [2]Faculty of Medicine, University of Novi Sad, Health Center "Novi Sad", Health Center, Novi Sad, Serbia

Background: Rheumatoid arthritis (RA) is an independent risk factor for osteoporosis which influences bone remodeling processes via increased production of proinflammatory cytokines, especially tumor necrosis factor-α (TNF-α), or through hormone-mediated mechanisms. The presence of other classical risk factors for osteoporosis additionally raises the risk of changes in bone tissue. Some of the most commonly used biological drugs in the osteoporosis treatment are those that inhibit TNF-α action. Apart from reducing inflammation, these TNF-inhibitors suppress osteoclast activity.
Objectives: To determine the impact of osteoporosis risk factors on the bone turnover marker levels in RA patients treated with TNF-inhibitors.
Methods: This 12-month-long study included 50 patients with RA who received a drug from the TNF-inhibitor group. In order to enter the study, patients had to fulfill certain inclusion/exclusion criteria considering the RA duration, the RA treatment method, the degree of joint damage, and the presence of other diseases affecting bone tissue. Data regarding traditional risk factors for osteoporosis and fractures were collected, such as menopause length, body mass index (BMI), previous fractures due to minor trauma, family history of osteoporosis and osteoporotic fractures, reduced physical activity, cigarette smoking, and alcohol consumption. Serum levels of the bone synthesis marker procollagen type I N propeptide (P1NP), and the bone resorption marker beta C-terminal telopeptide of type I collagen (b-CTX) were assessed via ECLIA method at the baseline and upon TNF-inhibitor therapy completion.
Results: The mean age in this cohort was 51.6 years. A higher percentage increase in P1NP and b-CTX was recorded in patients aged below 50 years, as well as those of normal weight (BMI = 18.50–24.99 kg/m², P1NP: Wilk's lambda =0.83, F = 9.56, p = 0.003; b-CTKS: Wilk's lambda = 0.77, F = 14.16, p = 0.000). A greater increase in the P1NP and b-CTX levels was also observed in non-smokers (28.70% and 27.50%) relative to smokers (27.50% and 7.75%). Menopause length had a statistically significant effect on both P1NP (Wilk's lambda = 0.84, F = 8.18, p = 0.006) and b-CTX (Wilk's lambda = 0.77, F = 13.31, p = 0.001) concentrations, whereby the highest percentage increase in P1NP (29.85%) was related to menopause duration below 2 years. On the other hand, the greatest b-CTX increase (10.2%) was recorded in patients that had entered menopause 2–3 years ago. Physical activity had a significant effect on changes in P1NP (Wilk's lambda = 0.84, F = 8.57, p = 0.005) as well as b-CTX (Wilk's lambda = 0.78, F = 13.30, p = 0.001) values. Further, P1NP percentage increase was higher in patients without family history of osteoporosis, while the opposite was true for the b-CTX levels. Finally, number of previous fractures was inversely correlated with the P1NP and b-CTX percentage increase.
Conclusion: After 12-month TNF-inhibitor treatment, although a significant increase in both bone turnover markers was achieved, it was greater in the bone synthesis marker P1NP. Younger age, normal body weight, shorter menopause duration, greater physical activity, negative osteoporosis family history, and non-smoking emerged as the most important factors associated with the P1NP percentage increase.

AB0441 JANUS KINASES INHIBITORS THERAPY FOR THE TREATMENT OF RHEUMATOID ARTHRITIS: AN OVERVIEW OF SYSTEMATIC REVIEWS AND META-ANALYSES

Keywords: Rheumatoid arthritis, Qualitative research methods

X. Shen[1,2], X. Guo[3], X. Gao[1,2], J. Zhang[3], X. Hou[2], Z. Feng[1]. [1]*China Three Gorges University, College of Medicine and Health Sciences , China Three Gorges University, Yichang, China*; [2]*China Three Gorges University, Institute of Rheumatology, the First College of Clinical Medical Sciences, China Three Gorges University, Yichang, China*; [3]*China Three Gorges University, Medical College of Basic Sciences, China Three Gorges University, Yichang, China*

Background: Janus kinases (JAK) inhibitors are a family of intracellular tyrosine kinases that act as hubs in the signaling process of many cytokine receptors, mediating inflammation and autoimmune diseases. It was reported that JAK inhibitors played an important role in inhibiting bone destruction by inhibiting the phosphorylation of proteins. In recent years, JAK inhibitors have been widely used to treat Rheumatoid Arthritis(RA).and proved to have an obvious curative effect. However, the efficacy and safety of the clinical use of JAK inhibitors need to be further verified.
Objectives: To access the methodological, reporting and evidence quality of systematic reviews and meta-analyses of JAK inhibitors for RA.
Methods: We comprehensively searched the literature in CNKI, Wanfang Data, VIP, PubMed, Web of Science databases from inception to November 2022. A Measurement Tool to Assess systematic Reviews (AMSTAR-2) tool and the Preferred Reporting Items for Systematic reviews and Meta-analyses (PRISMA) were used to access the methodological and reporting quality. The level of evidence quality was evaluated by employing the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) scale.
Results: The AMSTAR-2 tool showed that half of the included literature had low quality, and the other 6 literatures had a very low quality. The study process lacked certain normativity, which had a certain impact on the implementation of the study and the evaluation of outcomes. The PRISMA statement showed that there were numerous vulnerabilities in the methodology module of each document, which was mainly manifested in the scheme and registration. The GRADE analyses showed that the quality of the evidence for the outcome measures was moderate to low. The results showed that JAK inhibitors had certain advantages in the proportion of patients with ACR20, 50 and 70 after treatment for 3 months or 6 months. In addition, this study found that JAK inhibitors could alleviate adverse reactions. Furthermore, all the included literature had certain deficiencies in randomization, blinding, allocation, etc. There was a risk of bias, which directly reduced the evidence level of RCT trials and showed that the included studies had defects in the design of trial protocols.
Conclusion: The effectiveness of JAK inhibitors for RA has certain advantages compared with placebo, and more studies need to be demonstrated than other drugs. However, the safety is uncertain and need further explored.

AB0442 RETROSPECTIVE ANALYSIS ON JAK INHIBITORS AT SINGLE CENTRE IN THE UK

Keywords: Safety, Rheumatoid arthritis, Targeted synthetic drugs

D. Nagra[1], K. Bechman[1], M. Russell[1], E. Alveyn[1], C. Baldwin[1], G. Bird[1], S. Steer[1], C. Byrne[1], K. Lawan[1], V. Vescovi[1], M. Adas[1], M. Nursoy[1], S. Norton[1], A. Mahto[1], A. Rutherford[1], J. Galloway[1], E. Nikiphorou[1]. [1]*King's College London, Centre for Rheumatic Disease, London, United Kingdom*

Background: There are limited real world data on the use of JAK inhibitors (JAKi). In 2022, the EMA suggested that JAKi should only be used if alternative therapies are not available in patients over 65 years, smokers or in those with cardiovascular or cancer risk factors.
Objectives: We conducted a retrospective study to describe the demographics, duration of therapy and adverse events profile of patients prescribed JAKi.
Methods: Baseline data including age, gender, smoking status, ethnicity, co-morbidities, cardiovascular risk factors, rheumatic diagnosis, concomitant csDMARD use and prior biological therapies was collected. Duration on therapy and reasons for stopping JAKi were identified. A Cox proportional hazard model was used to plot survival of drug therapy, by JAKi drug. Data was analysed on the STATA platform.
Results: In total, 151 patients were prescribed a JAKi since 2017. The average age was 55, with a female predominance, (n=125, 83%), and the majority had rheumatoid arthritis. Baricitinib and Filgotinib represented the most commonly prescribed JAKi. Over ¼ of the cohort were using JAKi monotherapy (28%). For those on combination therapy, methotrexate was the most commonly prescribed (53%). The median number of prior biologics was 1 (IQR 1-2), with TNFi the most frequently prescribed (66%). 48% had cardiovascular risk factors or cardiovascular disease; this was more prevalent in patients prescribed baricitinib or tofacitinib compared to upadacitinib or filgotinib (57%) versus (39%). During JAKi therapy 3 patients developed cancer, 2 had VTEs (both on Baricitinib) and 5

Table 1.

		Total	Baricitinib	Filgotinib	Tofacitinib	Upadacitinib	
		N=151	N=43	N=43	N=32	N=33	P value
Age, (median, SD)		55 (14)	54 (16)	57 (13)	58 (11)	51 (13)	0.10
Gender, female (n,%)		125 (82.8%)	36 (83.7%)	37 (86.0%)	28 (87.5%)	24 (72.7%)	0.36

	Cancer	9 (6.0%)	4 (9.3%)	1 (2.3%)	1 (3.1%)	3 (9.1%)	0.41
	Mental health	33 (21.9%)	7 (16.3%)	11 (25.6%)	8 (25.0%)	7 (21.2%)	0.72
Post JAK new comorbidity	Cholesterol	11 (7.3%)	4 (9.3%)	0	3 (9.4%)	4 (12.1%)	0.17
	Diabetes	3 (2.0%)	2 (4.7%)	0	0	1 (3.0%)	0.35
	IHD	1 (0.7%)	1 (2.3%)	0	0	0	0.47
	VTE	2 (1.3%)	0	0	2 (6.2%)	0	0.06
	Cancer	3 (2.0%)	1 (2.3%)	0	2 (6.2%)	0	0.21
	Mental health	5 (3.3%)	1 (2.3%)	1 (2.3%)	0	3 (9.1%)	0.19
JAKi therapy stopped		56 (37.0%)	25 (58.1%)	3 (6.9%)	20 (62.5%)	8 (24.2%)	<0.001
Reason for stopping	AE	25 (44.6%)	7 (28.0%)	1 (33.3%)	15 (75.0%)	2 (25.0%)	0.028
	Primary failure	14 (25.0%)	7 (28.0%)	1 (33.3%)	2 (10.0%)	4 (50.0%)	
	Secondary failure	12 (21.4%)	8 (32.0%)	0 (0.0%)	2 (10.0%)	2 (25.0%)	
	Death	2 (3.6%)	1 (4.0%)	1 (33.3%)	0 (0.0%)	0 (0.0%)	
	Not documented	3 (5.4%)	2 (8.0%)	0 (0.0%)	1 (5.0%)	0 (0.0%)	

had new mental health diagnoses. The reason for stopping therapy was equally spilt between drug failure (46%) and adverse events (45%). Drug survival over 2 years was numerically higher for Filgotinib and Upadacitinib. Cycling between JAKi occurred in 28 patients. Patients prescribed a second JAKi (n=26) or a third JAKi (n=2) had cycled through more prior biologics than patients prescribed their first JAKi [median number prior biologics 2 (IQR 1-3) versus 1 (IQR 1-2) p=0.007].
Conclusion: Our real world experience of JAKi is broadly similar to expectations from clinical trials. The differences in patient characteristics and drug survival between individual JAKi are likely to reflect drug availability and emergence of safety warnings over time.

AB0443

REAL-WORLD EXPERIENCE OF BIOSIMILAR RITUXIMAB GP2013 IN RHEUMATOID ARTHRITIS PATIENTS NAÏVE TO OR SWITCHED FROM REFERENCE RITUXIMAB

Keywords: bDMARD, Real-world evidence, Outcome measures

K. Łosińska[1], M. Korkosz[1,2], A. H. Pripp[3], G. Haugeberg[4,5]. *[1]University Hospital, Division of Rheumatology and Immunology, Krakow, Poland*; *[2]Jagiellonian University Medical College, Department of Rheumatology and Immunology, Krakow, Poland*; *[3]Oslo University Hospital, Oslo Centre of Biostatistics and Epidemiology, Oslo, Norway*; *[4]Sørlandet Hospital, Division of Rheumatology, Department of Internal Medicine, Kristiansand, Norway*; *[5]NTNU, Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Trondheim, Norway*

Background: Randomized controlled trials showed high comparability of biosimilar rituximab (bs-RTX) GP2013 to biologic originator RTX (bo-RTX) in terms of physicochemical and functional properties, pharmacokinetics, efficacy and safety [1,2]. Data on effectiveness of switching from bo-RTX to bs-RTX, starting therapy with bs-RTX and bs-RTX drug survival in real-world setting is sparse.
Objectives: To explore long-term drug effectiveness and survival of bs-RTX GP2013 in rheumatoid arthritis (RA) patients both naïve to and mandatory switched from bo-RTX in ordinary outpatient clinic.
Methods: Retrospective observational cohort study including adult RA patients treated with bs-RTX between 2018 and 2021 in Norway. Patients were examined and monitored with recommended disease activity measures and patient-reported outcomes (PROs). Drug survival was assessed with Kaplan-Meier survival analysis.
Results: 110 RA patients (71.8% women) treated with bs-RTX were identified (88 mandatory switched from bo-RTX, 22 RTX-naïve), baseline median (IQR) age was 68.0 (59.0-76.0) years, disease duration 13.0 (7.4-18.7) years, 93.6% were RF and 96.3% ACPA positive, 30.0% currently used csDMARDs (26.4% methotrexate). Statistically significant difference between bs-RTX-naïve and bs-RTX-switched patients was found for disease duration (3.0 vs 14.2 years, p<0.01), current steroids use (68.2% vs 35.2%, p=0.01) and first cycle bs-RTX dose: 90.9% bs-RTX-naïve received 2000 mg, while 85.3% bs-RTX-switched 1000 mg or 500 mg. During 2-year follow-up disease activity and PROs measures remained stable in switchers and improved in those starting naïve on RTX (Table 1).

Table 1. Changes in disease activity and PROs, median (IQR)

	Baseline		1 year-period		2 year-period	
	bs-RTX switched n=88	bs-RTX naïve n=22	bs-RTX switched n=88	bs-RTX naïve n=22	bs-RTX switched n=74	bs-RTX naïve n=13

CDAI	2.65 (1.00-5.60)	15.50 (10.00-29.20)	2.65 (0.90-5.50)	6.90 (2.30-10.20)	3.80 (1.60-6.50)	4.53 (3.38-10.20)
PGA, 0-100mm	20.00 (8.00-33.00)	51.00 (40.00-67.00)	20.00 (8.00-37.50)	40.00 (15.50-57.00)	30.00 (12.00-50.00)	35.00 (23.50-46.50)
MHAQ, 0-3	0.32 (0.00-0.75)	0.57 (0.38-0.88)	0.38 (0.00-0.63)	0.25 (0.07-0.50)	0.38 (0.00-0.63)	0.13 (0.00-0.38)

Overall drug survival for bs-RTX was 80.0% (95% CI 71.2-86.3%) after 1 year and 57.7% (95% CI 47.8-66.3%) after 2 years. Drug survival in bs-RTX-switched patients was significantly higher than in bs-RTX-naïve (Figure 1).

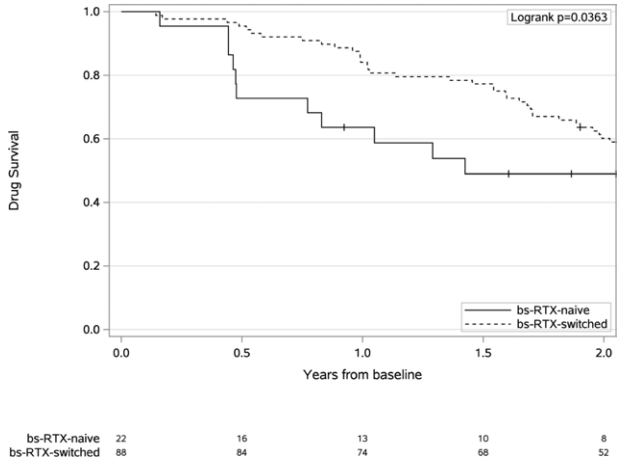

Figure 1. Kaplan-Meier plots of treatment retention rates

Conclusion: For the first time real-life data on drug effectiveness for GP2013 bs-RTX in RA is presented. Non-medical switch to bs-RTX is largely effective, no deterioration in disease activity outcomes was observed. Response in RTX-naïve patients was satisfactory and effect remains stable after 2-year follow-up. Drug survival was similar to published data for originator RTX.

Background: In North African countries, few data are available on the safety of biotherapies.

Objectives: To evaluate safety of biological therapy (excluding infections) in a population with rheumatoid arthritis (RA) followed in the RBSMR (Registry of Biological therapies in rheumatic diseases of the Moroccan Society of Rheumatology).

Methods: This work was based on data from inclusion and 3 years of follow-up. It concerns 223 patients with RA receiving biotherapies, included between May 2017 and December 2018. safety was evaluated at inclusion and every 6 months for 3 years. Serious adverse events were defined as those that are life-threatening, that required hospitalization or permanent stopping of current biological agent.

Results: 223 patients were included in the study, the mean age was 51.8 ± 11.3 years, 87.4% were females, average duration of RA was 20.8 [13.9 - 31.3] months, The median duration of exposure to biotherapy was 3.1 [0 - 18.23] months. Patients were receiving anti-TNFα in 16.6% (37/223) of case, Rituximab (RTX) in 59.6% (133/223) and Tocilizumab (TCZ) in 23.8% (53/223). About 70% (155/223) of patients had an association with a csDMARDs. At inclusion, 19.73% (44/223) of patients had previously developed 59 adverse events (AEs) on current biotherapy. The 44 noninfectious AEs are occurred in 14.8% (33/223) of patients: 19 infusion reactions, 2 liver toxicities, 7 hematological disorders, 7 dyslipidemias and 9 other AEs. The global incidence of AEs was 24.81 per 100 patient-years (PA). The incidence of noninfectious AEs was 11.06 per 100 PA (Table I), The incidence of serious non-infectious AEs was 2.09 per 100 PA (n=14). The occurrence of noninfectious AEs differs depending the biological agent: anti-TNF=27% (10/37), RTX =27.3% (36/133) et TCZ =37.7% (20/53); with no statistically significant difference in frequency between these molecules (p=0,454). In logistic regression, no factors were associated with serious adverse events. The percentage of patients who changed their biological agent was 13.9% (31/223). During the 3 years of follow-up, 8 patients died, 4 of which by non-infectious AEs (lymphoma, heart rhythm disorder, unexplained deterioration of general condition, decompensated cirrhosis). Because of non-infectious AEs, biotherapy was discontinued in 3.58% (8/223) of patients. The percentage of patients lost to follow-up was 9.86% (22/223).

Conclusion: In RA, biological agents have a positive benefit/risk ratio. However, non-infectious side effects are not rare, they are multifactorial and can be potentially serious.

Table I non-infectious adverse events in the RBSMR

Type of adverse events	Incidence per 100 patient-years	Number of adverse events	Biological agents
Infusion reactions	1,19	8	RTX (n=6) TCZ (n=2)
Paradoxical reactions	0,29	2	Uveitis under TCZ (n=1) Paradoxical arthritis under Golimumab (n=1)
Drug-induced lupus	0,14	1	RTX
Cancers	0,44	3	Urothelial carcinoma under TCZ having already received RTX (n=1) Breast carcinoma under TCZ having already received RTX (n=1) Non-Hodgkin's lymphoma under TCZ (n=1)
Liver toxicities	1,79	12	TCZ (n=7) RTX (n=5)
Hematological disorders	3,13	21	TCZ (n=14) RTX (n=5) Anti-TNFα (n=2)
Dyslipidemias	1,94	13	TCZ (n=8) RTX (n=4) Golimumab (n=1)
Severe heart rhythm disorder	0,14	1	TCZ
Phlebitis	0,14	1	Etanercept
Other AEs (injection site reactions, myalgia, depression…)	2,69	16	RTX (n=7) Anti-TNFα (n=5) TCZ (n=4)

AB0445 CHARACTERISTICS OF FIRST-LINE UPADACITINIB INITIATORS AND FACTORS CONTRIBUTING TO PRESCRIBING UPADACITINIB AS FIRST-LINE B/TSDMARD

Keywords: Disease-modifying Drugs (DMARDs), Real-world evidence, Rheumatoid arthritis

W. Krueger[1], L. Harrold[2], A. Sima[3], T. Eckmann[3], R. Kilpatrick[1]. [1]*AbbVie Inc, n/a, North Chicago, United States of America*; [2]*University of Massachusetts, Medical School, Worcester, United States of America*; [3]*CorEvitas, n/a, Waltham, United States of America*

Background: EULAR guidelines recommend switching to or adding a b/tsDMARD in patients with rheumatoid arthritis (RA) who do not respond or have an inadequate response to csDMARDs. Traditionally, TNF inhibitors (TNFi) are prescribed as the first b/tsDMARD. In Dec 2021, the upadacitinib (UPA) label in the US was updated to restrict use to those who have had an inadequate response or intolerance to one or more TNFi.

Objectives: In the period prior to the UPA label change in the US (through Jan 2022), to (1) compare characteristics of patients with RA receiving UPA as first b/tsDMARD with those who initiated TNFi as their first b/tsDMARD, and (2) explore the reasons why UPA was chosen as first-line advanced therapy.

Methods: Using CorEvitas RA registry data from Aug 2019 to Jan 2022, patients who initiated UPA or TNFi at or after enrollment in the registry with no history of prior b/tsDMARD use were evaluated. The patients' providers indicated which factors (they could choose more than one) contributed to prescribing UPA as first-line advanced therapy based on medical record chart review.

Results: Few differences in demographics, comorbidities, and disease activity at initiation were observed between the 815 TNFi initiators and 142 UPA initiators identified. UPA initiators were older (mean [SD] age 58.9 [12.8] vs 56.7 [13.9] yrs), had a higher proportion of White patients (87% vs 83%), and were less likely to be working (44% vs. 53%), and have private insurance (73% vs. 68%). UPA initiators had more frequent history of cardiovascular disease (16% vs 10%), joint deformity (17% vs 12%), and subcutaneous nodules (13% vs 10%), but less frequent history of anxiety/depression (29% vs 34%) than TNFi initiators. UPA initiators had greater disease severity, including mean CDAI (23.7 [14.9] vs 19.0 [13.0]), and tender (8.4 [7.7] vs 6.6 [6.7]) and swollen (6.1 [5.1] vs 4.3 [5.1]) joint counts, self-reported pain (54.5 [28.7] vs 50.3 [28.3]), and proportion with morning stiffness (89% vs 85%). UPA initiators were more likely to have a history of multiple csDMARDs (43% vs 35%), monotherapy b/tsDMARD initiation (32% vs 22%) and use of NSAIDs (53% vs 48%). For 142 patients initiating UPA as first-line, 34 providers (87% response rate) indicated major factors in the choice of prescribing UPA as first-line advanced therapy were the patient's level of disease activity (75%), patient's disease progression (61%), patient preference (51%), and patient's disease profile (43%). These reasons contributed to any part of the prescription decision in 99%, 96%, 77%, and 79% of patients, respectively. Oral delivery was indicated as a contributing factor by almost all (91%) of the 109 patients that were prescribed UPA as first-line therapy and indicated patient preference was a factor in prescribing UPA. Side effects were not a concern when deciding to prescribe UPA in at least 50% of the patients included in this study.

Conclusion: In a real-world cohort of patients with RA initiating a first-line b/tsDMARD, those who received UPA were more likely to have previously failed multiple csDMARDs, to initiate as monotherapy, and to have had greater disease activity based on both physician and patient measures compared to patients who received TNFi. Clinical factors including disease activity, disease progression, and disease profile influenced the prescribing decision by providers as well as patient preference.

Background: BIOBADAGUAY is the Paraguayan/Uruguayan registry of adverse events (AE) in patients with inflammatory rheumatic conditions under biologic therapy (BT).

Objectives: Determine the frequency and severity of AE of patients under BT in the BIOBADAGUAY registry.

Methods: Prospective, observational study of undetermined length to verify the efficacy, safety, and survival of the BT. The methodology applied is available at https://biobadaguay.ser.es. For the present study epidemiological and clinical variables, BT, type, and severity of AE were analyzed. The incidence rate (IR) was calculated as the total number of adverse events per 1000 patients/year and the incidence rate ratio (IRR) was analyzed using the Poisson regression model. (Significance value 0,05)

Results: 1104 patients with TB were analyzed, between 2016 and 2022. 73.28% were women, mean age at treatment initiation was 42±17.1 years. The most frequent diagnosis was rheumatoid arthritis (RA): 686 patients (62.4%). There were 1375 treatment cycles. 1365 AE were observed, 1191 (87.2%) were non-severe, 161 (11.8%) severe and 13 (0.95%) mortal. The IR of AE was 251.75 (238.6-265.8), for severe AE 32.1 (27.5-37.2). Infection was the most frequent AE in 731/1365 (55% of total AA): non-severe 661 (88%), 86 (11.5%) severe and 4 (0.5%) mortal. The IR of infections was 138.4 (126.69-265.47), 32.1 (27.48-37.2%) for severe infections. When analyzing the IR of AE according to diagnosis, it was observed that RA is associated with a higher IR of global AE when compared to other diagnoses (IRR=1.35 [95% CI,1.1-1.7] p=0.0088), and severe AE (IRR=1.72 [95% CI,1.2-2.5] p=0.006). Psoriatic arthritis (PsA) and ankylosing spondylitis (AS) were associated with lower overall IR of global AE: IRR=0.57 [95% CI,0.4-0.9] (p=0.007) and IRR=0.66 [95% CI,0.5-1] (p=0.04), respectively. corticosteroid use was associated with a higher global AE IR (IRR=1.46 [95% CI,1.2-1.8] p=0.0009). When IR was analyzed according to severity, it was observed that the second and subsequent cycles of BT were significantly associated with a higher IR of global and non-severe AE compared to the first cycle of BT (Table 1). Treatment with anti-TNF was significantly associated with lower IR of global and mortal AE compared to non-anti-TNF (Table 1).

INCIDENCE RATE OF ADVERSE EVENTS ACCORDING TO SEVERITY

First Cycle		Follow Cycles		
Adverse Event	Incidence Rate	Incidence Rate	Incidence Rate Ratio	P
Global	233.22 (219.28, 247.80)	339.2 (303.1, 378.3)	1.45 (1.14, 1.85)	**0.0024**
Not Serious	201.27 (188.34, 214.85)	306.50 (272.29, 343,82)	1.52 (1.18, 1.197)	**0.0014**
Serious	30.16 (25.26, 35.69)	27.39 (17.89, 40.13)	0.91 (0.55, 1.51)	0.7101
Mortal	1.79 (0,77, 3.52)	5.27 (1.71, 12,29)	2.95 (0.96-9.56)	0,0588
Non-antiTNF		AntiTNF		
Adverse Event	Incidence Rate	Incidence Rate	IRR	P
Global	306.31 (276.92, 337.98)	234.63 (220.09, 249.88)	0,77 (0.61, 0.97)	0,**0262**
Not Serious	261.56 (234.46, 290.94)	206.54 (192.91, 220.88)	0.79 (0.61, 1.02)	0.0695
Serious	38.58 (28.63, 50.86)	26.88 (22.11, 32.37)	0,70 (0.47, 1.04)	0,0758
Mortal	6.17 (2.66, 12.16)	1.21 (0.39, 2.83)	0.20 (0.06, 2.83)	**0.0043**

Conclusion: AE were in general non-severe, and infections were the most frequent. RA and concomitant treatment corticosteroid presented a higher IRR of global AE, whereas PsA and AS a lower IRR of AE. Second and Subsequent cycles of BT presented a higher IRR of global an AE. The RA diagnosis presented a higher rate of severe AE.

AB0447 MEDICATION BELIEFS DURING THE PRECONCEPTION PERIOD AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Safety, Disease-modifying Drugs (DMARDs), Rheumatoid arthritis

E. Hannech[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], M. Yasmine[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology Department, Tunis, Tunisia*

Background: Treatment maintenance in young women with rheumatoid arthritis (RA) may be influenced by factors such as fears of side effects on fertility and conception.

Objectives: We aimed to assess the therapeutic beliefs of patients with RA during the preconception period and to investigate associated factors.

Methods: We conducted a cross-sectional study including patients diagnosed with RA before menopause. We assessed beliefs about treatment during the preconception period using the French version of Beliefs about Medicines Questionnaire (BMQ). The questionnaire assessing specific beliefs is composed of 10 items: 5 items to assess beliefs regarding the necessity for treatment and 5 items to assess concerns.

Results: We included 31 females (mean age: 49.7±10.4 years). RA was erosive in 93% of cases. Coxitis was noted in 6 patients (19%) and atloido-axial dislocation in 2 patients (6%). The average number of gestation and parity was, respectively, 3 [0-9] and 2 [0-7]. Contraception was used by 20 patients (64%). The contraceptive method was progestin-only pill (10 patients), intrauterine device (6 patients), condoms (2 patients), and calendar method (2 patients). The mean beliefs' score regarding treatment necessity and concerns were 18.8±3.3 [10-23] and 12.3±5.9 [5-23], respectively. The score of therapeutic necessity was higher in patients without desire to conceive, but the difference was not significant (19.1±3.1 vs 17.2±4.8, p=0.246). The presence of erosions had an influence on therapeutic necessity (19±3 vs 16.5±7.7, p=0.03). The therapeutic necessity score was statistically higher in patients with coxitis (20.1±1.6 vs 18.5±3.6, p=0.05). The conception desire had no influence on concerns. The disease duration had a statistically negative correlation with concern score (r=-0.480, p=0.006). Contraception use was not influenced by either therapeutic necessity or concerns (p=0.129 and p=0.140, respectively).

Conclusion: This study showed that beliefs about therapeutic necessity during the preconception period were more important than concerns. We emphasize the importance of therapeutic patient education to fight against negative beliefs.

AB0448 THE IMPACT OF ACPAS ON THE RESPONSE TO BIOLOGICAL THERAPY IN RHEUMATOID ARTHRITIS

Keywords: bDMARD

S. Boussaid[1], M. Hassayoun[1], S. Rekik[1], S. Rahmouni2, K. Zouaoui[1], H. Ajlani[1], H. Sahli[1], M. Elleuch[1]. [1]*La Rabta Hospital, Rheumatology Department, Tunis, Tunisia*; [1]*La Rabta hospital, Rheumatology Department, Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is a chronic, debilitating disease associated with reduced quality of life. It is characterized by the positivity of various antibodies, the most specific being autoantibodies against citrullinated antigens (ACPA). Those antibodies are associated with severe erosive phenotype and higher mortality rate comparisons to seronegative RA. Moreover, ACPA status is known to be associated with a favorable response to biologics drugs.

Objectives: Our objective in this study was to investigate whether ACPA positivity in RA can predict treatment responses to biologic therapies in Tunisian patients with rheumatoid arthritis.

Methods: We conducted a cross-sectional and observational study. Files of patients with RA on biologics drugs (archived from the files of patients on the National Health Insurance Fund of Tunis) were studied. ACPA and rheumatoid factor assays were performed. RA activity was assessed by the composite score 'Disease Activity Score 28' (DAS28). Patient follow-up was done with the DAS28 disease activity score. The therapeutic maintenance rate as well as the biologics survival was analyzed using Kaplan-Meier survival curves and compared using the Log-Rank test.

Results: Three hundred and seventy-four files were selected. Their average age was 55±12.54 years [20-90]. A female predominance was noted with a sex ratio M/F=0.147. The average duration of RA was 11.7±6.76 years [2-41]. Rheumatoid serology specified in 324 patients (86%), was positive in 79% of cases. Anti-citrullinated protein antibodies (ACPA) data were available in the records for 267 patients (71%). These were positive in 72% of patients. Anti-nuclear antibodies (ANA) were only positive in 12% of our population. Native anti DNA and anti Sm were respectively positive in one patient. First biogics prescription was: etanercept 54%, adalimumab 14%, certolizumab pegol 13%, infliximab 6%, tocilizumab 6% and rituximab 7%. In patients with positive rheumatoid factors, survival after 4 years of the first biological treatment was 58.8% versus 35.5% in FR negative patients. Mean therapeutic maintenance was 42.15 months and 34.97 months respectively for the two groups. For ACPA negatives, the 4-year survival was 52.05% versus 49.2% for ACPA positives. These antibodies did not influence the survival of the biotherapy with an HR = 1.004 (p=0.987).

Conclusion: Our study did not reveal any impact of ACPA positivity on the therapeutic response to biologics. These results are inconsistent with most of those in the literature. A larger-scale study is needed to confirm our results.

Rheumatoid arthritis - non biologic treatment and small molecules

AB0449 ASSOCIATION OF OPG, OPN AND OCN PROTEINS WITH THE RISK OF RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Genetics/epigenetics, Biomarkers

J. Hu[1,2], C. LI[1,2], Z. Zhang[1,2], J. Qiao[1,2], S. X. Zhang[1,2], C. Wang[1,2], X. LI[1,2]. *[1]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision, Taiyuan, China; [2]Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterised by joint swelling, joint compression and synovial joint destruction, where inflammation and bone destruction can lead to significant functional impairment. Recently, several studies have reported the identification of new biomarkers of RA, such as osteoprotegerin (OPG), osteocalcin (OCN) and osteopontin (OPN)[1], all three of which play a significant role in regulating bone metabolism and influencing osteoclast synthesis and secretion. Although OPG, OCN and OPN are strongly correlated with RA, it is not clear whether there is a causal relationship between them.
Objectives: The aim of this study was to assess whether OPG, OPN and OCN are causally related to the risk of RA in a Two-Sample Mendelian randomisation(TSMR).
Methods: The genetic instrumental variables (IVs) for OPG, OPN and OCN exposure from a large genome-wide association study (GWAS) meta-analysis including 21,758, 1322 and 3301 participants, respectively. The GWAS data for RA were selected from an independent RA GWAS analysis that included 29,880 RA cases of European ancestry and 73,758 controls.Significant ($P < 5 \times 10\text{-}6$) and independent ($r2 < 0.001$) SNP in genome-wide association studies were selected as IVs for performing MR analyses. The causal relationship between OPN、OPG、OCN and RA risk was assessed by TSMR analysis using inverse variance weighting (IVW) methods as the primary analysis, supplemented by weighted median, MR-Egger. MR-Egger regression, Leave-one-out analysis and Mendelian Randomization Pleiotropy RESidual Sum and Outlier (MR-PRESSO) were used to detect and correct for the effects of horizontal multi-effects[2].
Results: The Eighteen,seven and nine SNPs were selected as IVs for OPN, OPG and OCN respectively. The results of theIVW method (OPN:OR = 1.0191, 95% CI: 0.9800-1.0597, p = 0.3440; OPG: OR = 1.0396, 95% CI: 0.9327- 1.1588, p = 0.4827;OCN: OR = 1.077, 95% CI: 0.990- 1.077, p = 0.812) showed that there was no strong evidence of a relationship between the production of OPN, OPG and OCN in people of European ancestry and RA risk. Further sensitivity analyses verified the robustness of the above associations, with MR-Egger regressions showing no evidence of pleiotropy (OPN:p = 0.8703; OPG:p = 0.7043;OCN:p = 0.6356) and heterogeneity analyses showing no heterogeneity (OPN:p = 0.7880; OPG:p = 0.2451;OCN:p =0.5651). The leave-one-out method analysis indicated that genetically determined PN, OPG and OCN were not driven by any single SNP in association with RA risk.
Conclusion: We did not find any evidence of a causal relationship between OPN, OPG,OCN and RA risk. Further research is needed to elucidate the potential mechanisms underlying the role of OPN, OPG and OCN in the development of RA.

AB0450 REAL-WORLD USE OF JAK INHIBITORS IN RHEUMATOLOGICAL PRACTICE IN SOUTH LONDON

Keywords: Targeted synthetic drugs, Rheumatoid arthritis, Psoriatic arthritis

K. Biddle[1,2], O. Buckeldee[1], A. Latheef[2], I. Al-Shakarchi[1], N. Sofat[2,3]. *[1]Rheumatology, Kingston Hospital NHS Trust, London, United Kingdom; [2]Rheumatology, St George's Hospital NHS Trust, London, United Kingdom; [3]Institute for Infection & Immunity, St George's, University of London, London, United Kingdom*

Background: Janus Kinase inhibitors (JAKi) are targeted synthetic disease modifying anti-rheumatic drugs (tsDMARDs) used in the treatment of inflammatory arthritis. Whilst evidence for their efficacy and side-effect profile is supported by data from randomised control studies, real world data is lacking.
Objectives: The objectives of the study were to evaluate the efficacy and safety of JAKi in real-world clinical rheumatological practice in the South London region.
Methods: Data was collected from two hospitals; St Georges University Hospitals NHS Trust (SGH; a tertiary centre) and Kingston Hospital NHS Foundation Trust (KH; a district general hospital). All rheumatology patients who were prescribed JAKi between January 2017 and June 2022 were included in the analysis. Baseline patient demographic data included age, gender, rheumatological diagnosis and comorbidities. A retrospective analysis evaluated prescribing practice, drug efficacy (measured using the Disease Activity Score (DAS-28)), adverse events and drug discontinuation rates.
Results: A total of 288 patients were included in the analysis; 184 from SGH and 104 from KH. The average age was 55.6 (range 20-82), 87% were female. Baricitinib was the most frequently prescribed JAKi (231 patients), followed by tofacitinib, filgotinib and upadacitinib (49, 7 and 1 patients respectively). Baricitinib was most prescribed for patients with seropositive rheumatoid arthritis (RA) (62%), seronegative RA (17%) and seronegative inflammatory arthritis (10%). 73% on tofacitinib had a diagnosis of psoriatic arthritis, 20% had RA. All patients on filgotinib had RA and the one patient on upadacitinib had overlap RA/systemic lupus erythematosus. In 53% of patients, JAKi was prescribed following biological DMARD (bDMARD) therapy. In these patients; 32%, 13%, 5% and 3% had previously received 1, 2, 3 and 4 bDMARDs respectively. Median DAS-28 scores improved with all JAKi therapy. This is summarised in Figure 1.

The most frequent documented adverse events included bacterial infection (25) hypercholesterolaemia (18), gastrointestinal side effects (18), viral infection (15) and deranged liver function tests (LFTs) [10]. These are summarised in Table 1.

Table 1.

Adverse events	Number of events		
	Baricitinib (n=231)	Tofacitinib (n=49)	Filgotinib (n=7)
Gastrointestinal side effects	**18**	**0**	**0**
Bacterial infection	**19**	**4**	**2**
Lower respiratory tract	10	1	1
Urinary tract	5	1	0
Genitourinary	1	0	0
Skin	1	1	1
Not specified	2	1	0
Viral/fungal infection	**15**	**1**	**1**
Shingles	6	0	1
COVID-19	4	0	0
Upper respiratory tract	2	0	0
Fungal nail infection	2	0	0
Herpes Simplex Virus	1	0	0
Biochemical abnormalities	**22**	**6**	**0**
Hypercholesterolaemia	14	4	0
Deranged Liver functions tests (LFTs)	8	2	0
Neutropenia	**2**	**0**	**0**
Venous thromboembolism (VTE)	**1**	**1**	**0**
Other side effects	**11**	**1**	**0**

10 patients died whilst on JAKi therapy (8 on baricitinib, 2 on tofacitinib). 5 died from COVID-19, 1 from pancreatic cancer and 4 with unknown cause of death. Excluding deceased patients, 77 discontinued JAKi therapy (56 on baricitinib, 19 on tofacitinib, 2 on filogitinib). Mean duration to discontinuation was 9.3 months (baricitinib), 11.7 months (tofacitinib) and 4.5 months (filgotinib). For all JAKis, drug inefficacy was the most commonly reported reason for discontinuation (40 patients). Other reasons included bacterial infection [8], deranged LFTs [6], perceived high risk for VTE [4], shingles [2] and other side effects [8].

Conclusion: JAKi are effective across a range of rheumatological diagnoses in a South London real-world analysis, including patients with bDMARD-naïve and bDMARD-refractory disease. JAKi are generally well tolerated and adverse events in this study were in keeping with the current literature.

AB0451 FRENCH REAL LIFE SAFETY DATA ON THE USE OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS: OBSERVATIONAL STUDY, DEFACTO

Keywords: Safety, Real-world evidence, Targeted synthetic drugs

C. Gaujoux-Viala[1,2], A. Basch[3], S. Lassoued[4], F. Coury-Lucas[5], M. Kessouri[6], Y. Brault[7], T. Lequerre[8], C. Salliot[9]. *[1]Desbrest Institute of Epidemiology and Public Health (IDESP), Univ Montpellier, INSERM, Rheumatology, Montpellier, France; [2]CHU Nîmes Hospital, Rheumatology, Nimes, France; [3]Infirmerie Protestante Clinic, Lyon, Rheumatology, Caluire-et-Cuire, France; [4]Cahors Hospital Centre, Rheumatology, Cahors, France; [5]Lyon Sud Hospital, Rheumatology, Lyon, France; [6]Pfizer, Medical, Paris, France; [7]Pfizer, Statistique, Paris, France; [8]Rouen University Hospital (CHU) & Inserm U905, Rheumatology, Rouen, France; [9]Orléans Regional Hospital Centre (CHR), Rheumatology, Orléans, France*

Background: Tofacitinib, an oral Janus Kinase inhibitor, is indicated for the treatment of adult patients with moderate to severe active rheumatoid arthritis (RA).

Objectives: To describe the safety profile of Tofacitinib in a French prospective observational study DeFacTo.

Methods: The safety profile of tofacitinib was assessed using interim data from a descriptive analysis of patients who took at least one dose of tofacitinib in the DeFacTo study.

Results: Among 314 patients enrolled in the study, 306 received tofacitinib and were included in the safety analysis, including 274 patients with a follow-up ≥ 18 months (POP2) on 03/15/22 date of analysis) with a median exposure duration of 538 [Q1; Q3: 381; 554] days. 113 patients (41.2%) were still on tofacitinib (39 discontinued, 122 missing data regarding prescription). At inclusion, 78.3% of the 306 pts were women with a mean (± standard deviation) age of 59.5 ± 11.5 years, median disease duration of 8.9 years [Q1; Q3: 4.1; 18.9]. There was a history of cardiovascular (CV) disease in 11.9% of cases (including 4.6% myocardial infarction (MI), 5.0% stroke/transient ischemic attack (TIA), 1.7% heart failure, and 1.7% peripheral arterial disease); 5.6% history of cancer, 16.8% history of infection, and 46.6% smoker/former smoker. Tofacitinib was prescribed in combination with a csDMARD in 61.1% of patients and corticosteroids in 56.2% of cases. The results showed that adverse events (AEs) were reported in 54.2% of the 306 patients, 14.4% were considered as serious. Infections were found in 22.2% of patients, no deaths were reported (Table 1).

Table 1. Real-life and age-specific safety data for tofacitinib

N, (%)	< 65 ans (n=193)	≥ 65 ans (n=111)	Total (n=306*)
Adverse events (AEs)	104 (53.9)	62 (55.9)	166 (54.2)
Serious adverse events	21 (10.9)	23 (20.7)	44 (14.4)
Infection	41 (21.2)	27 (24.3)	68 (22.2)
Herpes Zoster	6 (3.1)	6 (5.4)	12 (3.9)
Serious AEs of special interest			
Serious infection	5 (2.6)	4 (3.6)	9 (2.9)
Herpes zoster	1 (0.5)	0 (0.0)	1 (0.3)
Tuberculosis	0 (0.0)	2 (1.8)	2 (0.7)
Cancer	1 (0.5)	1 (0.9)	2 (0.7)
CV event†	1 (0.5)	1 (0.9)	2 (0.7)
VTE‡	0 (0.0)	2 (1.8)	2 (0.7)
Death	0 (0.0)	0 (0.0)	0 (0.0)

*2 patients with missing age but counted in the total. † cardiovascular event (Evt): non-fatal MI and stroke + CV death. ‡ VTE (venous thromboembolic disease): deep vein thrombosis + pulmonary embolism.

Conclusion: These intermediate, descriptive results show a safety profile of tofacitinib in real-life RA similar to the one previously reported in clinical and observational studies. [1-2]

Background: Recently, the new class of drugs, namely targeted synthetic (ts) DMARDs, has broadened the possibilities of treating rheumatoid arthritis (RA). In particular, Janus Kinase inhibitors (JAKi) are used in RA and are currently represented by four drugs: baricitinib, tofacitinib, upadacitinib and filgotinib. One of the first to be used in Italy was baricitinib, a JAKi acting on JAK1 and JAK2.

Objectives: The aim of this study was to evaluate the clinical efficacy of baricitinib in a real-life setting in a cohort of RA patients.
Methods: This multicenter retrospective observational study included patients from 25 rheumatology centers diagnosed with RA and treated with baricitinib. The following were recorded for each patient: gender; age; duration of disease; presence of rheumatoid factor and anti-citrulline antibodies; concomitant treatment with conventional synthetic (cs) DMARDs; previous treatments with biological (b) or ts DMARDs. In order to evaluate the clinical efficacy, the retention rate was evaluated, calculated by means of the Kaplan-Meier method. The variables under examination were reported as frequencies and median with relative interquartile range.
Results: We included 478 patients of which 380 (79.5%) were female. 286 (60.1%) patients tested positive for rheumatoid factor (RF) and 264 (55,2%) for anti-citrulline antibody (ACPA). The parameters analyzed are shown in Table 1. 105 (22.0%) patients were treated with baricitnib as first line (after csDMARD), the remaining patients had failed at least one bDMARD and 9 (1.9%) also failed a tsDMARD. In 34,7% of cases baricitinib was used as monotherapy, the most frequently used csDMARD was methotrexate (29.2%). The median period of therapy was 674 days (298-1087). The survival rate at 6 months was 94.6%, at 12 months it was 87,9%, at 24 months was 81.7% and at 48 months was 53.4% (Figure 1). The main causes that led to the discontinuation of baricitinib therapy were: primary ineffectiveness (7,3%), secondary ineffectiveness (4.2%) and adverse events (3,7% 5 TEP/DVT). The concomitant steroid therapy seems to be a negative prognostic factor (HR 1,65 95% CI 1.03-2.63; p=0.035) as well as the line of therapy (HR 1.35 95% CI 1.15-1.58; p=0.000).

Table 1.

Characteristics		Value
M:F		98:380
Age, median [IQR] yrs		60 [51-70]
Smokers, n (%) (**)	Yes	84 (18,8)
	Former	76 (17,0)
	No	288 (64,2)
Body Mass Index, median [IQR] kg/m^2 (*)		24,8 [23,0-27,0]
Disease Duration, median [IQR], months		78 [32-163]
RF positivity, n (%)		286 (60,1)
ACPA positivity, n (%)		264 (55,2)
SJC, median [IQR]		5 [3-8]
TJC, median [IQR]		8 [4-12]
ESR, median [IQR], mm/h		33 [20-46]
CRP, median [IQR], mg/dl		1,3 [0,5-2,9]
VAS Patient (0-100), median [IQR]		70 [50-80]
DAS28, median [IQR]		5,4 [4,8-6,1]
Line of treatment, [IQR]		2 [2-3]
Concomitant csDMARDs use, n (%)	MTX	140 (29,2)
	LFN	11 (2,3)
	SSZ	3 (0,6)
	HCQ	12 (2,5)
Concomitant steroids use, n (%)		237 (49,6)
Steroids dose (PDN-Eq), median, mg/die		5 [4-5]
Prior bDMARDs use, n (%)	TNFi	164 (34,3)
	IL6i	84 (17,6)
	IL1i	0
	CD20i	8 (1,7)
	CD80i	54 (11,3)
Prior tsDMARDs use, n (%)	Tofacitinib	9 (1,9)
Concomitant relevant disease, n (%)	Diabetes	36 (7,5)
	Hypercholesterolemia	119 (24,9)
	MACE	28 (5,9)
	Arterial Hypertension	179 (37,4)
	Cancer	24 (5,0)

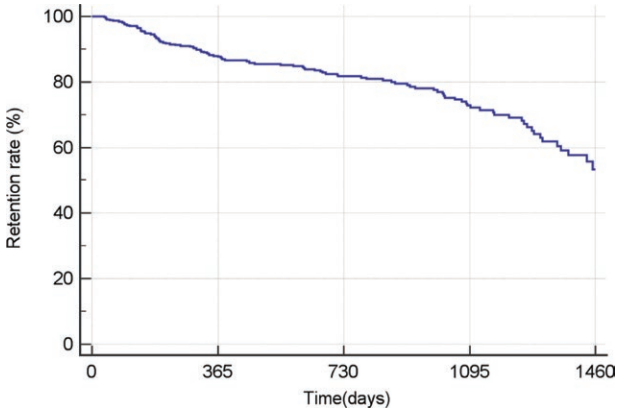

Figure 1. 4 year retention rate of baricitinib

Conclusion: The efficacy of baricitinib in the treatment of RA in a real-life context appears consistent with what was reported by the pivotal studies. Furthermore, from this preliminary experience, seropositivity and combo therapy seems to not correlate with a better retention rate, while concomitant steroid therapy and line of treatment are a negative prognostic factor.

AB0453 ARE WE DOING A CORRECT METHOTREXATE MONITORING?

Keywords: Rheumatoid arthritis, Disease-modifying drugs (DMARDs)

C. Zamora Ramos[1], P. Turiel[1], N. Garvin Grande[1], M. Beladiez Giner[1], M. Alcalde Villar[1], A. C. Valenciano[1]. [1]*Hospital Universitario Servero Ochoa, Rheumatology, Madrid, Spain*

Background: Methotrexate (MTX) is an antimetabolite of folic acid commonly used for the treatment of Rheumatoid Arthritis (RA). Despite its recognized benefit in controlling the activity of the disease, it can cause side effects, such as hepatic and hematologic toxicity. This makes necessary to carry out periodic analytical controls. According to the recommendations of ACR_1 and $EULAR_2$ on the monitoring of MTX toxicity, the most appropriate frequency for analytical controls in patients starting treatment with MTX would be 4-6 weeks, and it could be spaced up to every 3 months when reaching a stable dose. We consider this study in view of the perception in our real clinical practice of a low frequency of analytical abnormalities that lead to modify the treatment with MTX in our patients with RA.
Objectives: To evaluate the frequency of analytical abnormalities in patients with RA who start treatment with Methotrexate and to review the modifications in the treatments carried out based on these analytical abnormalities.
Methods: Retrospective descriptive study on patients with RA who had started treatment with MTX (15 mg per week) between 2001 and 2021. The results of hematological parameters and liver function tests, obtained in the analytical controls carried out, were collected from the beginning of the treatment and during the following two years. These controls were carried out before starting MTX, one month later, at 3 months, and subsequently every 3-4 months; according to the recommendations of the clinical guidelines. The parameters collected were aspartate aminotransferase (AST), alanine aminotransferase (ALT), hemoglobin (Hb), neutrophils, and lymphocytes. Only patients treated with MTX in monotherapy, with or without corticosteroids, were included in the study. The frequency of the analytical abnormalities found was calculated and the therapeutic changes made were reviewed in the medical records.
Results: 97 patients were included, of whom 67% were women and 33% men with a mean age of 55.94 (±12.9) years. Significant new-onset abnormalities in transaminases (>2-fold normal value: 68 U/L) were found in 8 patients (8.2%) during the 2-year monitoring. Of these, the MTX dose was modified in 6 patients (6.1%) and it was stopped in 2 patients (2.1%) due to ALT/AST>3-fold normal (102 U/L). After the suspension, the two patients normalized analytical values. Regarding the hematological parameters, anemia was observed (Hb <13 g/dl in men, <12 g/dl in women) in 10 patients (9.7%). However, none of them presented Hb < 10 g/dl and there was no treatment modification due to this alteration. Lymphopenia (lymphocytes < 0.9 x10^3/µL) was observed in 3 patients (3.1%) and neutropenia (neutrophils < 1.9 x10^3/µL) in 4 patients (4.1%). None of these patients required modifications in the treatment.
Conclusion: The low incidence of analytical abnormalities found in our study makes us reconsider the frequency of analytical controls in monitoring MTX, not only to avoid unnecessary repeated venipuncture, but also the visits to health centers. On the other hand, we must not forget the cost of health and human resources that these procedures entail. Larger studies are required to elucidate the most optimal time interval required to monitor MTX toxicity in the management of patients with RA.

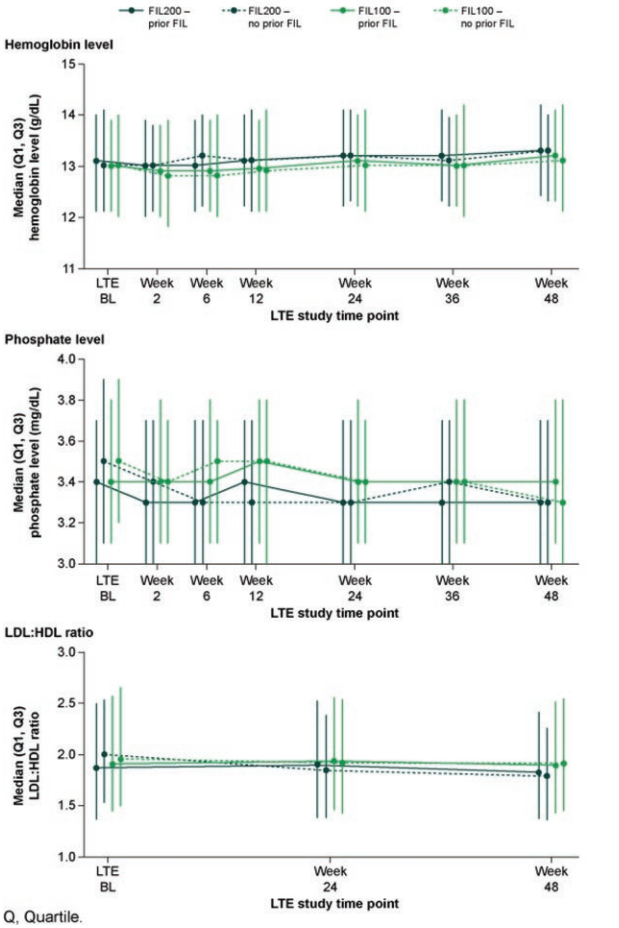
Combe[13]. *[1]ASST Gaetano Pini-CTO, Division of Clinical Rheumatology, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [3]University of Manchester and NIHR Manchester Biomedical Research Centre, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom; [4]King's College London, Centre for Rheumatic Diseases, London, United Kingdom; [5]Toulouse University Hospital and University Toulouse III Paul Sabatier, Rheumatology Department, Toulouse, France; [6]Cliniques Universitaires Saint-Luc, Université Catholique de Louvain (UCLouvain), Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium; [7]Galapagos NV, Medical Safety, Mechelen, Belgium; [8]Galapagos Biotech Ltd, Medical Affairs, Cambridge, United Kingdom; [9]Galapagos NV, Biostatistics, Mechelen, Belgium; [10]Galapagos NV, Clinical Research, Mechelen, Belgium; [11]Galapagos NV, Medical Affairs, Mechelen, Belgium; [12]Keio University, Department of Internal Medicine, Tokyo, Japan; [13]Montpellier University, Department of Rheumatology, Montpellier, France*

Background: Filgotinib (FIL) is a Janus kinase (JAK) 1 preferential inhibitor, approved for treatment of moderate to severe active RA in Europe, the UK, and Japan. Graded laboratory abnormalities from placebo-controlled analyses and long-term data on lymphocytes have been reported previously.

Objectives: Report the effect of FIL on laboratory parameters in the FINCH 4 long-term extension (LTE).

Methods: Safety was assessed from LTE baseline (BL) to data cutoff (1 Jun 2020) in patients (pts) receiving ≥1 FIL dose (FIL 200 mg [FIL200] or 100 mg [FIL100]) in FINCH 4 (NCT03025308). Laboratory abnormalities were graded per Common Terminology Criteria for Adverse Events v4.03. Frequencies and exposure-adjusted incidence rates (EAIRs)/100 pt-years of exposure (PYE) for graded abnormalities are reported. Median laboratory parameters are reported to LTE Week (W) 48.

Results: In FINCH 4, 2729 pts received FIL for 4198.08 PYE (mean 80.3 weeks); exposure was similar between dose groups. Frequency and EAIR of laboratory abnormalities were similar for anemia, decreased platelets, and increased alanine aminotransferase (ALT), aspartate aminotransferase (AST), and serum creatinine, and higher in the FIL200 vs FIL100 group for neutropenia, increased creatinine kinase (CK), hypophosphatemia, and cholesterol (high) (**Table 1**; graded data not shown). No Grade 4 decreased phosphate laboratory abnormalities were observed and hypophosphatemia was not associated with adverse events. Laboratory abnormalities led to discontinuation of FIL in 7 pts: ALT and AST increased, 3 (0.2%, FIL 200); ALT increased, 1 (<0.1%, FIL 100); and neutropenia 3 (0.3%, FIL 100). From LTE BL to W48, hemoglobin, platelets, ALT, and AST were relatively stable, with no clear differences between doses, or between pts with or without prior FIL. Neutrophil count was relatively stable from LTE BL to W48. Neutrophils decreased for the FIL200 group with no prior FIL exposure, remaining stable from W24. CK and serum creatinine were relatively stable from LTE BL to W48 in pts with prior FIL exposure; in pts with no prior FIL, initial increases plateaued by W6 and W12, respectively, remaining stable. Changes in phosphate levels from LTE BL were small, remaining within normal range (2.2–5.1 mg/dL). Triglycerides were stable over time with no differences between groups. Total cholesterol, high-density lipoprotein (HDL), and low-density lipoprotein (LDL) levels were stable in pts with prior FIL exposure. In pts with no prior FIL exposure, small increases in total cholesterol, HDL, and LDL plateaued by W24, remaining stable. The LDL:HDL ratio was stable, with no differences between groups (**Figure 1**).



Conclusion: Laboratory abnormalities were generally mild to moderate, similar to previous observations. Frequency and EAIR were higher in the FIL200 vs FIL100 group for neutropenia, increased CK, hypophosphatemia, and high cholesterol.

Table 1. Treatment-emergent laboratory abnormalities* (any Grade ≥1; safety analysis set†)

n/N (%); EAIR (95% confidence interval)	FIL200 (n=1530; PYE=2346.0)	FIL100 (n=1199; PYE=1852.1)
Anemia	264/1526 (17.3); 11.3 (10.0, 12.7)	227/1193 (19.0); 12.3 (10.8, 14.0)
Platelets (decreased)	44/1525 (2.9); 1.9 (1.4, 2.5)	24/1189 (2.0); 1.3 (0.9, 1.9)

BARICITINIB IN THE TREATMENT OF PATIENTS WITH MODERATE TO SEVERE ACTIVE RHEUMATOID ARTHRITIS IN CHINA: 24-WEEK RESULTS OF POST-MARKETING SAFETY STUDY

Keywords: Real-world evidence, Safety, Rheumatoid arthritis

C. Y. Wu[1], Q. Wang[1], J. Shi[2], X. Zhang[3], R. Du[4], J. Gu[5], Q. H. Liu[6], J. Yu[7], J. W. Xu[7], Y. J. Zhang[7], H. Zhu[7], M. Li[1], X. Zeng[1]. *[1]Peking Union Medical College Hospital (PUMCH), Chinese Academy of Medical Sciences & Peking Union Medical College, Department of Rheumatology and Clinical Immunology, Beijing, China; [2]Yiyang Central Hospital, Department of Rheumatology and Clinical Immunology, Yiyang, China; [3]Zibo Central Hospital, Department of Rheumatology and Clinical Immunology, Zibo, China; [4]Wuhan Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Rheumatology and Clinical Immunology, Wuhan, China; [5]The Third Affiliated Hospital, Sun Yat-Sen University, Department of Rheumatology and Clinical Immunology, Guangzhou, China; [6]Sinopharm Dongfeng General Hospital , Hubei University of Medicine, Department of Rheumatology and Clinical Immunology, Shiyan, China; [7]Eli Lilly and Company, LCDDMAC, Shanghai, China*

Background: Baricitinib, an orally selective inhibitor of JAK1 and JAK2, was approved for adult patients with moderate-to-severe rheumatoid arthritis (RA) in China. The recommended dose is 2mg once daily and 4mg once daily in patients who have inadequately responded to baricitinib 2mg once daily (for 3 months) or TNF inhibitors. A single-arm, prospective, non-interventional post-marketing safety study (PMSS) was conducted in Chinese RA patients to describe the safety and effectiveness of baricitinib at 24 weeks.
Objectives: To describe the safety and effectiveness of baricitinib in real-world setting of treating patients with moderate to severe active RA.
Methods: This PMSS (starting July 2020) included 667 patients with RA treated with baricitinib (2 mg or/and 4mg/day) and followed up for 24 weeks. Safety and effectiveness (disease activity) were assessed for 24 weeks. All statistical analyses are descriptive.
Results: Safety analyses included 667 patients (females=82.3%, mean age=53.3 years, mean RA duration 86.9 months). 106 (15.9%) were ≥65 and <75years and 19 (2.8%) were ≥75 years. 29 (4.3%) had previously received biologic therapy. Baricitinib dose regimen was as follows: 2 mg/day, n = 580 (87.0%); 4 mg/day, n = 53 (7.9%); 2/4 mg, n = 34 (5.1%). Concomitant use of MTX and leflunomide occurred in 54.3% and 35.5%, respectively. The overall exposure of baricitinib was 262.1 patient-years; 197 (29.5%) patients withdrew from the study, mostly for patient's decision (n = 101). Adverse events (AEs) occurred in 250 (37.5%) patients [serious: 28 (4.2%)]. Two patients (0.3%) died: one of pneumonia and one with no cause reported. The incidence of serious infection, herpes zoster and hepatotoxicity was 0.6%, 1.0%, and 3.4%, respectively. No case met laboratory criteria for potential Hy's Law (ALT/AST ≥3 x ULN and TBL ≥2 x ULN). Malignancy occurred in one patient (thyroid cancer). No venous thromboembolism (VTE) or major adverse cardiovascular event (MACE) were reported during the study observation period (**Table 1**). In the effectiveness analysis at Week 24, the proportions of patients achieving remission/ low disease activity were 66.6% (235/353) for DAS28-CRP, 64.6% (228/353) for SDAI, and 63.5% (242/381) for CDAI (**Figure 1**).
Conclusion: In conclusion, the safety and effectiveness profile of baricitinib in this Chinese PMSS was generally similar to that in the global RA population with no VTEs or MACE reported and no new safety signals.

Abbreviations: AE= adverse event; AESI= adverse event with special interest; EAIR= exposure-adjusted incidence rate; MACE= major adverse cardiovascular events; N= number of patients in the safety analysis set; n= number of patients in the specified category; PYE= patient-years of exposure; RA= rheumatoid arthritis; SAE= serious adverse event; VTE= venous thromboembolismUsed EAIR per 100 PYE (patient exposure censored at the event).AESI was based on the judgement of investigator recorded in eCRF (electronic case report form)MACE included myocardial infarction, cardiovascular death, and stroke.

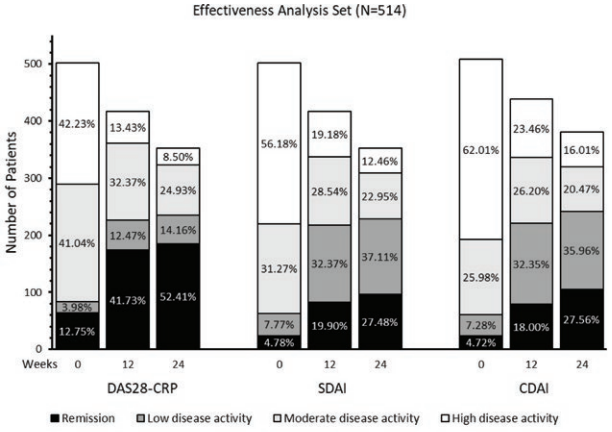

Figure1. The number of patients with known remission (black), low disease activity (dark grey), moderate disease activity (light grey), and high disease activity (white) based on DAS28-CRP, SDAI, and CDAI at each time point is plotted. The percentage of patients in each category, using the total number of applicable patients for each measure at each time point as the denominator, is shown within the columns. Patients with unknown effectiveness scores are not included in the analysis.

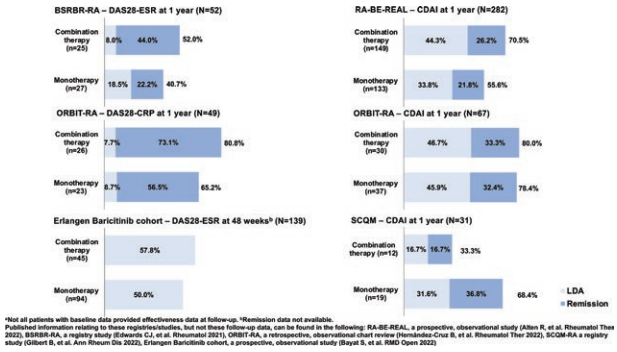
BARICITINIB AS MONOTHERAPY FOR TREATMENT OF RHEUMATOID ARTHRITIS: SUMMARY OF DATA FROM FIVE REAL-WORLD DATA SOURCES

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Real-world evidence

C. J. Edwards[1], A. Finckh[2], T. Takeuchi[3], A. Kleyer[4], E. Haladyj[5], C. Laedermann[5], J. Gerwien[5], T. Treuer[5], L. Zaremba-Pechmann[6], J. S. Smolen[7]. *[1]University Hospital Southampton, NIHR Southampton Clinical Research Facility, Southampton, United Kingdom; [2]University of Geneva, Geneva University Hospitals & Faculty of Medicine, Geneva, Switzerland; [3]Tokyo and Saitama Medical University, Keio University School of Medicine, Saitama, Japan; [4]University Hospital Erlangen, Department of Internal Medicine 3, Rheumatology and Immunology, Erlangen, Germany; [5]Eli Lilly and Company, Rheumatology, Indianapolis, United States of America; [6]HaaPACS GmbH, Biostatistics, Schriesheim, Germany; [7]Medical University of Vienna, Division of Rheumatology, Department of Medicine 3, Vienna, Austria*

Background: EULAR recommendations suggest that use of interleukin-6 inhibitors and Janus kinase (JAK) inhibitors are preferred in rheumatoid arthritis (RA) when combination therapy with conventional synthetic disease modifying antirheumatic drugs (csDMARDs) is not indicated due to intolerance of csDMARDs. Monotherapy data for the JAK1/JAK2 inhibitor baricitinib (BARI) in patients with inadequate response to csDMARDs or biologic DMARDS (bDMARDs) are limited.

Objectives: To present an overview of baseline characteristics and effectiveness outcomes for patients with moderate-to-severe RA receiving BARI as monotherapy and combination therapy for up to 1 year in real world European settings.



Methods: BARI-related real-world data from available European registries, long-term observational studies and retrospective chart review, obtained from published sources or investigators, were reviewed. Baseline and effectiveness data, separately from each source, were reviewed for patients who received BARI as monotherapy and for those receiving BARI in combination with csDMARDs with findings presented descriptively as mean ± standard deviation (SD) or number (%) of patients. No statistical modelling was applied. Disease activity score for 28-joint count (DAS-28) low disease activity (LDA) and remission data were collected in ORBIT-RA, BSRBR-RA and the Erlangen Baricitinib cohort; and Clinical Disease Activity Index (CDAI) LDA and remission data were collected in RA-BE-REAL, ORBIT-RA and SCQM-RA.

Results: In BARI cohorts, monotherapy was used by 51.0% of patients in RA-BE-REAL, 61.5% in ORBIT-RA, 60.1% in SCQM-RA, 39.4% in BSRBR-RA and 67.6% in the Erlangen Baricitinib cohort. Across all databases, most patients were female, and in general, patients who received BARI as monotherapy appeared to be older, with a longer disease duration and numerically larger likelihood of previous treatment with a bDMARD than those who received the drug in combination (Table 1). Available LDA and remission rates from patients with data in the different databases are shown in the Figure 1; 40.7–78.4% of patients receiving BARI monotherapy and 33.3–80.8% receiving BARI in combination achieved either LDA or remission states at 1 year.

Conclusion: Approximately 40–78% of patients achieved LDA or remission after up to 1 year of monotherapy across the different data sources and populations with RA, although the numbers of patients with data to up to 1 year were small for most registries. These findings suggest that BARI monotherapy is a suitable treatment option for patients with RA.

JAK INHIBITORS IN REFRACTORY AND AT-RISK COMORBID PATIENTS WITH RHEUMATOID ARTHRITIS IN CLINICAL PRACTICE

Keywords: Rheumatoid arthritis, Real-world evidence, Comorbidities

O. Al Tabaa[1], S. Hecquet[1], M. Thomas[1], S. Carvès[1], A. Combier[1], C. Miceli Richard[1], O. Fogel[1], A. Moltó[1], Y. Allanore[1], J. Avouac[1]. [1]*Cochin Hospital, Rheumatology, Paris, France*

Background: The use of JAK inhibitors (JAKi) may be challenged in rheumatoid arthritis (RA) by the multiplicity of previous treatment lines and the presence of comorbidities that may trigger the occurrence of potentially severe side effects.
Objectives: To assess the efficacy and safety profile of JAKi in active RA patients with refractory disease and/or risk factors for JAKi.
Methods: Retrospective routine care study carried out between 2018 and 2022 in the Rheumatology department of Cochin Hospital. We selected from our electronic medical report database RA patients initiating a JAKi between 2018 and 2021 who presented active disease (i.e. by a DAS28 >3.2) and at least one of the following criteria: age ≥65 years, presence of comorbidities (cardiovascular risk factors including active smoking, obesity, atherosclerotic cardiovascular (CV) disease, history of venous thromboembolism (VTE), previous malignancy, severe infection including herpes zoster), failure to at least two targeted biological therapies and inability to taper corticosteroids below 7.5 mg/day. Efficacy was assessed at the first visit following the initiation of treatment and at the last available visit up to December 2022. The number and causes of treatment discontinuations were collected during the exposition period.
Results: We included 83 RA (68 females, 82%) initiating a JAKi, with a mean age of 58±14 years and a mean disease duration of 16±13 years. Patients had a mean DAS28 of 4.60±1.42, they had received 3±2 previous lines of biologics, 63% belonged to the group "age ≥65 years and/or presence of at least one CV risk factor" and 20% received corticosteroids ≥7.5 mg/day. The first treatment visit was scheduled 3 or 6 months following JAKi initiation, and the last visit occurred 15±10 months after the baseline visit. The DAS28 and other parameters assessing disease activity were markedly reduced at the first and the last available visit compared to the baseline visit (**Table 1**). Low disease activity (DAS28 <3.2) was reached in 51% of patients at the first visit and 47% at the last visit. No difference of efficacy was observed according to the treatment line. A total of 35 patients (42%) discontinued the JAKi during a mean observation period of 20±10 months (**Figure 1**). The mean time to discontinuation was 10±8 months. Treatment retention was 70% at 12 months and 58% at the last visit. Discontinuations were related to inefficacy (n=21, 25%), side effects (n=11, 13%) and desire for pregnancy (n=3, 4%). The side effects leading to discontinuation were: VTE (n=2), myocardial infarction (n=2) (these 4 events occurred in the group of patients aged ≥65 years with or without presence of at least one CV risk factor), non-severe infections (n=2), allergy (n=2), gastrointestinal symptoms (n=2) and headache (n=1). No cancer was recorded during the observation period.
Conclusion: In a population o RA enriched with refractory and at-risk comorbid patients, JAKi demonstrated potent efficacy with a safety profile consistent with this population. Our results support the statement from the PRAC to use with caution JAKi in patients aged ≥65 years and/or with at least one CV risk factor.

STEROIDS IN RHEUMATOID ARTHRITIS - TIME FOR REPREAVAL

Keywords: Cardiovascular disease, Tapering, Rheumatoid arthritis

N. Prabu[1], V. Petciappan[2], G. Anand[1], A. Kumar[1], S. Ram[1]. [1]*Sakthi Rheumatology Centre Pvt. Ltd, Rheumatology, Coimbatore, India;* [2]*PSG Hospitals, Internal Medicine, Coimbatore, India*

Background: The usage of steroids in the management of Rheumatoid Arthritis (RA) has been questioned after the ACR-2021 guidelines while short-term steroid use has been advocated by EULAR-2022.In usual clinical practices steroid has a major role in the management. The adverse events associated with the steroid use is a major limiting factor.
Objectives: To assess the steroid use in routine clinical practice and review the occurrence of Diabetes(T2DM), Hypertension(HTN),Osteoporosis,CoronaryArteryDisease(CAD),Avascular necrosis (AVN), Cataract, Infections.
Methods: All patients diagnosed with RA from 2014 to 2019 with regular follow up of minimum one year duration were taken for analysis. Demographics, weight recordings, steroid prescribed and baseline characteristics were noted.The presence of complications like DM, HTN, cataract, osteoporosis, CAD, AVN,infections before and after steroids were noted.
Results: A total of 967 patients were included in the analysis,826(85.4%) were given steroids and 141 (14.6%) were managed without steroids. The mean age was 53.58 (10.94) yrs the mean disease duration was 4.73 (5.21) for patient with steroids and 6.104 (6.05%) yrs for patients without steroids Patients who were given steroids had increased occurrence of HTN(8.7%), Infections(6%), cataract(5.3%), diabetes(3.6%), osteoporosis(1.2%), AVN(0.8%), CAD(0.7%). In non-steroids group this was 1.4% each in diabetes and infection, 0.7% HTN while 0% in other categories(**Table 1**).In the 826 patients steroids were stopped in 567 (58.6%) but the risk of HTN(8.2%), Infections(5.46%), cataract(4.9%), DM(4.05%),Osteoporosis(0.8%),AVN(0.7%)and CAD (0.8%) still remained high.
Conclusion: RA patients treated with Steroids have a increased chance of developing HTN, Infection followed by cataract, diabetes, with minimal increase in osteoporosis, CAD and AVN and this persists even after stopping steroids.

AB0459 RELATIONSHIP BETWEEN FISH CONSUMPTION AND RESPONSE TO TREATMENT WITH MOLECULAR TARGETED THERAPIES IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Remission, Non-pharmacological interventions, Rheumatoid arthritis

M. Tarumi[1], O. Amengual[1], M. Navidad Fuentes[2], M. Yasuda[1], Y. Kosumi[1], S. Takeyama[1], M. Yoshimura[1], K. Ninagawa[1], K. Aso[1], R. Hisada[1], M. Kono[1], Y. Fujieda[1], M. Kato[1], R. Cáliz Cáliz[2], T. Atsumi[1]. *[1]Hokkaido University, Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Sapporo, Japan; [2]Hospital Virgen de las Nieves, Department of Rheumatology, Granada, Spain*

Background: The use of molecular targeted therapies has improved the clinical course and quality of life of patients with rheumatoid arthritis (RA); however, a percentage of patients experience treatment failure (non-responders), which is a particular challenge for clinicians. Diet and nutrients are potential environmental factors that are likely to influence the course and the response to pharmacological therapies in RA. The Mediterranean diet or omega-3 polyunsaturated fatty acids (n-3 PUFAs) supplementation have been shown to have a favorable effect on the reduction of RA symptom. A higher intake of fish, the main source of PUFAs, was associated with lower disease activity in RA patients. Several factors have been identified that may affect treatment response in RA; however, the effect of fish consumption on treatment response in RA patients has not been clarified.
Objectives: To explore the relationship between fish consumption and response to targeted therapies in RA patients with two dietary patterns characterized by high fish consumption.
Methods: The study is a collaborative international cross-sectional retrospective study involving RA patients on treatment with biologics or Janus kinase inhibitors (JAKi) attending Hokkaido University Hospital (Japan) or Hospital Virgen de las Nieves (Spain). Patients complete a brief-type self-administered diet history questionnaire (BDHQ) and a detailed food frequency questionnaire (DFFQ) to assess fish consumption in the previous month. At study entry, qualified rheumatologists assessed RA disease activity. Demographic, clinical/laboratory data were collected retrospectively from the medical records. Descriptive analysis was performed in each cohort.
Results: One-hundred-twenty-four Japanese RA patients, 100 females, median age at entry 66 yrs [IQR 54-72], median disease duration 12 yrs [IQR 7-20] were included. One-hundred-seven (86%) patients were on biologics and 17 (14%) on JAKi, median treatment duration of 4 yrs [IQR 1-7]. Concomitant treatment with conventional synthetic disease modifying anti rheumatic drugs (csDMARDs) and glucocorticoids were reported in 84% and 53% of patients, respectively. Ninety-six (77%) patients were responders to treatment defined as disease activity score 28 (DAS28)-ESR <3.2 and DAS28-CRP <2.7. All patients had fish consumption in the last month and 82% reported intake of n-3 PUFA rich fish (fatty fish) (<1 time/week 33%, ≧1 time/week 49%). A higher estimated daily intake of n-3 PUFAs from fish was found in the responder group compared to the non-responder group [median grams, 1.01 (IQR 0.47-1.44) vs 0.51 (IQR 0.34-1.14), p=0.044]. The Spanish cohort comprised of 62 RA patients, 47 females, median age at entry 58 yrs [IQR 49-66], median disease duration 12 yrs [IQR 5-21]. Fifty-nine (95%) patients were on biologic therapies and three (5%) on JAKi, median treatment duration of 3 yrs [IQR 1-8]. Concomitant treatment with csDMARDs and glucocorticoids were reported in 38% and 42% of patients, respectively. Thirty-four (55%) patients were responders to treatment. All patients had consumption of fish in the last month and 77% had consumed fatty fish (<1 time/week 31%, ≧1 time/week 46%). No difference in estimated intake of n-3 PUFAs from fish was observed in this cohort.
Conclusion: Fish consumption may have a positive effect on the response to treatment of Japanese RA patients receiving targeted therapy.

AB0460 JAK INHIBITOR DISCONTINUATION RATES: RETROSPECTIVE REAL-WORLD DATA FROM A TERTIARY CENTRE

Keywords: Real-world evidence, Targeted synthetic drugs, Inflammatory arthritides

K. Bland[1], S. Ganguly[2], A. Jubber[2], A. Moorthy[2,3]. *[1]University of Leicester, Leicester Medical School, Leicester, United Kingdom; [2]Leicester Royal Infirmary, Rheumatology, Leicester, United Kingdom; [3]University of Leicester, College of Life Sciences, Leicester, United Kingdom*

Background: JAK inhibitor uptake has increased in recent years, and recent NICE (National Institute for Health and Care Excellence) approval of certain JAK inhibitors for moderate rheumatoid arthritis disease activity will likely increase this further. The EULAR guidance on the management of rheumatoid arthritis recommends JAK inhibitors as part of the treat-to-target strategy, provided certain risk factors are considered [1]. However, there remains limited data on discontinuation rates for this drug class.
Objectives: This retrospective study aimed to measure the discontinuation rates of the four UK approved JAK inhibitors in a multi-ethnic population at a UK tertiary centre, thereby providing real-world data on the durability of the different JAK inhibitors.
Methods: All patients ever prescribed a JAK inhibitor at University Hospitals of Leicester were identified on a drug monitoring database. Discontinuation rates were calculated for each JAK inhibitor, as well as the median duration of time on each drug prior to discontinuation. The baseline characteristics of the patients who discontinued a JAK inhibitor were documented, as well as reason for discontinuation. These were categorized as either primary inefficacy, secondary inefficacy, toxic adverse events, non-toxic reasons, and disease remission.
Results: In total, 375 patients had been prescribed a JAK inhibitor since 2018. Discontinuation rates and duration of time prior to discontinuation for each drug are shown in Table 1.

Table 1. JAK inhibitor discontinuation rates and duration of use.

			Duration prior to discontinuation (weeks)							
Drug	Number of patients	Proportion discontinued	Median	Minimum	Q1	Q3	Maximum	Mean	Standard deviation	Standard error of mean
Baricitinib	233	51/233 (21.89%)	35.00	0.86	18.43	68.14	230.10	49.55	48.68	6.82
Tofacitinib	61	33/61 (54.09%)	70.29	5.29	37.86	96.93	161.10	72.35	43.29	7.54
Filgotinib	51	4/51 (7.84%)	13.50	4.71	6.54	15.86	16.14	11.96	5.14	2.57
Upadacitinib	30	0/30 (0%)	n/a	n/a	n/a	n/a	n/a	n/a	n/a	n/a

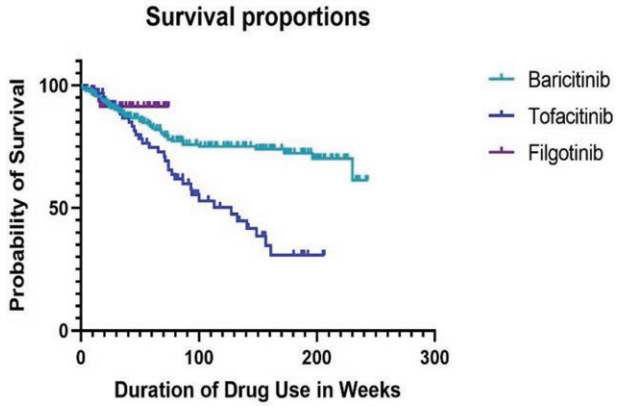

Figure 1. JAK inhibitor survival proportions.

Of the 88 patients who discontinued a JAK inhibitor, 86% were female and 14% male. Median age was 60 years (IQR 53-70 years), and median duration of drug intake was 45.60 weeks (IQR 19.29-74.07). Of these 88 patients, 77% were Caucasian, 20% from the Indian subcontinent, and the remaining patients mixed race, Asian other, and not stated. Furthermore, 65.9% of patients were on concomitant DMARDs, 71.6% had received a previous biologic drug (median number of previous biologics was 1 [0-2]). Diagnosis was seropositive RA (rheumatoid arthritis) in 59.1%, seronegative RA in 27.3%, PsA (psoriatic arthritis) in 11.4%, and 2.2% in RA/PsA overlap. Of the 88 patients where the JAK inhibitor was discontinued, reasons included primary inefficacy 37.5%, toxic adverse events 35.23%, non-toxic reasons 17.05%, secondary inefficacy 5.68%, disease remission 1.14%, and not stated 3.41%. Adverse events of interest included viral infections 6.81%, non-viral infections 4.54%, malignancy 2.27%, and MHRA alerts 9.09%. In this multi-ethnic population, there were no discontinuations for venous thromboembolism, or major adverse cardiovascular events, although patients are screened for risk factors prior to commencement, and MHRA alerts led to discontinuation if risk factors developed during treatment.

Conclusion: In this real-world population, tofacitinib followed by baricitinib had the highest discontinuation rates. While discontinuation rates for the 2nd generation JAK inhibitors appear more promising, patient numbers were lower. The most common reasons for discontinuation were primary inefficacy and toxic adverse events. Further real-world observational data is needed, particularly from multi-ethnic patient populations, to increase confidence levels in JAK inhibitor prescribing.

Background: The EULAR 2022 guidelines for the management of rheumatoid arthritis (RA) recommends methotrexate (MTX) combined with short-term corticoids (CS) as a 1st line standard of care [1]. In the event of an inadequate response to MTX and the presence of a poor RA prognosis factor, recommendations include initiation of biological (bDMARD) or synthetic (tsDMARD) targeted therapy in combination with MTX. Corticoids should be tapered as clinically feasible.

Objectives: Based on inclusion results of STRATEGE 2, we explore the evolution of therapeutic strategies after the initiation of a 1st b/tsDMARD, focusing on CS. Then patients' profiles with or without CS were investigated.

Methods: STRATEGE2 is a non-interventional, prospective study including RA patients treated with MTX for at least 3 months and requiring initiation of a first b/tsDMARD due to disease activity. Evolution of main treatments was followed during 12 months. Data regarding therapeutic strategies were collected at inclusion (baseline treatment and end-of-visit prescription) and at 12 months (treatment at the 12 months visit entry and the end-of-visit prescription).

Results: Between Feb. 2019 and Dec. 2020, 186 RA patients were included, among them 173 being reviewed at the 12 months visit. Cohort baseline conditions: 75.1% female, mean age 56.1 ±13.7 years, mean diagnostic oldness of 5.6 ±7.3 years, MTX treatment since 4.3 ±5.4 years. At the end of the inclusion visit, rheumatologists initiated a first targeted therapy. Then, patients were reviewed 12 months after inclusion (377.8 ±41.5 days). Patients' clinical conditions and treatments prescriptions are presented in the Table 1 here after.

Table 1.

	Inclusion consultation N = 173		12 months after inclusion N= 171	
	Baseline condition	After b/tsDMARD Prescription	Entry	After prescription
Mean DAS28	4.3 ±1.2		2.6 ±1.1	
Radiographic features, n (%)	82 (47.7)		NA	
Radiographic progression, n (%)	NA		5 (3.3)	
Extra-articular manifestations, n (%)	27 (16.2)		11 (6.7)	
Mean HAQ	1.0 ±0.7		0.7 ±0.7	
MTX (N + Discontinued)	173	169+4	143+28	141+30
→ Mean dosage (mg/week)	18.8 ±4.2	17.9 ±4.4	16.4 ±4.5	16.0 ±4.5
→ SC (%)	71.7	66.9	59.4	59.4
b/tsDMARD (N*+ Discontinued)	NA	173	149*+18	148*+19
Corticosteroids therapy (N*)	172	172	170*	170*
→ Yes, n (%)	86 (50.0)	80 (46.5)	66 (38.8)	68 (40.0)
→ Mean dosage (mg/day)	9.6 ±6.0	8.6 ±4.9	9.1 ±9.0	9.7 ±10.9
→ Median (Q1-Q3)	7.5 (5.0-10.0)	7.5 (5.0-10.0)	5.0	5.0 (5.0-10.0)
→ Min-Max	2.5-30.0	2.5-20.0	(5.0-10.0) 2.0-60.0	2.5-60.0

N* excludes missing data

Differences between patients' profiles with or without CS were investigated. At baseline, profiles tend to show some differences between patients treated by CS vs others compared to the full population: Age (57.4 ±14.1 vs 54.9 ±13.2; full population mean: 56.1 ±13.7), unemployed (50.0% vs 34.9%; full: 43.9%), normal body mass index (38.4% vs 51.2%; full: 44.6%), at least one comorbidity (48.8% vs 54.7%; full: 51.4%) and DAS28 score (4.5 ±1.1 vs 4.1 ±1.2; full: 4.3 ±1.2). At 12 months, the number of patients treated by CS decrease (from 50 to 40%). Patients' profiles still treated by CS are similar to inclusion except for "at least one comorbidity" (54.4% vs 50.0%; full: 51.4%).

Conclusion: One year after the initiation of a b/tsDMARD the proportion of patients treated by CS is still important with high doses. These patients are older, present comorbidities and active disease. This long-term maintenance of CS is not in line with the Eular guidelines which recommend discontinuing CS as rapidly as clinically feasible. Further analyses on patients' profiles are ongoing and supplementary data on 24 months follow-up may help to better understand the use of long-term CS in those patients.
