Peter Korsten (Germany)
Caroline Ospelt (Switzerland)
Christophe Richez (France)
Paul Studenic (Austria)

Guidelines for Authors and Reviewers

Full instructions are available online at http://ard.bmj.com/pages/authors. Articles must be submitted electronically at http://mc.manuscriptcentral.com/ard. Authors retain copyright but are required to grant ARD an exclusive licence to publish. (http://ard.bmj.com/pages/authors/).

Annals of the Rheumatic Diseases publishes original work on all aspects of rheumatology and disorders of connective tissue. Laboratory and clinical studies are equally welcome

Subscription Information

ARD is published monthly; subscribers receive all supplements
ISSN 0003-4967 (print); 1468-2060 (online)

Institutional Rates 2023

Print
£1,283

Online
Site licences are priced on FTE basis and allow access by the whole institution. Details available online at http://journals.bmj.com/content/subscribers or contact the Subscription Manager in the UK (see above right)

Personal Rates 2023

Print (includes online access at no additional cost)
£483

Online only
£264

EULAR congress delegates
Delegates receive a Continuous Professional Development package that includes a 12 month complimentary subscription to *ARD* in print and/or online

Personal print or online only and institutional print subscriptions may be purchased online at http://journals.bmj.com/content/subscribers (payment by Visa/Mastercard only)

Residents of some EC countries must pay VAT; for details, call us or visit http://journals.bmj.com/content/subscribers

For more information on subscription rates or to subscribe online please visit ard/bmj.com/pages/contact-us/

Scientific Abstracts

Welcome Address
EULAR 2023 Abstracts Reviewers

Oral Presentations

OP0001–OP0008	ABSTRACT OPENING PLENARY	1
OP0011	Epigenetics in chronic inflammation	8
OP0013	Precision medicine in SLE: where are we?	9
OP0014–OP0021	Adaptive immunity (T cells and B cells) in rheumatic diseases	10
OP0022–OP0029	Comorbidities in RMD	14
OP0023	Comorbidities in RMD	15
OP0030–OP0037	Improving our understanding of RMDs in children and young people	20
OP0038–OP0045	From hearts to lungs: comobidities in RA	24
OP0046–OP0053	GC to new therapies	30
OP0054–OP0061	Clinical aspects and Treatment of axSpA: effects and predictors of effects	35
OP0062–OP0069	New clinical aspects in psoriatic arthritis	42
OP0070–OP0077	Emerging a New Era in Osteoarthritis Therapies	48
OP0078–OP0085	COVID 19: A pandemic with a long tail	53
OP0094	Fibroblast activation in rheumatic diseases	64
OP0095	Autoinflammation – the next chapter	64
OP0096–OP0103	Genetics and EpiGenetics of RMDs	65
OP0104–OP0111	Innate Immunity in Pathogenesis of RMDs	70
OP0112–OP0119	Pathogenic clues to systemic sclerosis and myositis	74
OP0120–OP0127	Predictors of outcome in early rheumatoid arthritis	78
OP0128–OP0135	There is still a lot to SAY about biologicals for RA!	84
OP0136–OP0143	The future perspectives in the treatment of SLE & Sjören's	90
OP0144–OP0151	Risk factors and their treatment in the progression of osteoarthritis	95
OP0152–OP0159	Crystal arthritis: what is new?	100
OP0160–OP0167	New Insights in the care and management of JIA	106
OP0168–OP0175	Advances in imaging in rheumatic musculoskeletal disorders	112
OP0185–OP0186	Single-cell omics in Rheumatic diseases	122
OP0187	Spondyloarthritis across the ages	123
OP0188	Why is performing a good systematic literature review (SLR) so difficult?	124
OP0189	Talking about Remission	125
OP0190	Artificial Intelligence in Medicine: Chances & Challenges	126
OP0193	Clinical and molecular differences across sexes in Rheumatic Disease	128
OP0194–OP0201	Pain in RMDs	129
OP0202–OP0209	Understanding Treatment response and novel treatment approaches in RA	133
OP0210–OP0217	Novel insights into disease taxonomy and immunophenotyping	138
OP0218–OP0225	Rheumatoid arthritis: new small molecules and old DMARDs	143
OP0226–OP0233	Updates on management and outcomes in SLE and Sjogren syndrome	149
OP0234–OP0241	Update on the treatment of scleroderma lung disease	154
OP0242–OP0249	Osteoporosis	161
OP0250–OP0257	New evidence on IgG4-related and rare autoinflammatory diseases	165
OP0258–OP0265	New insights form epidemiology and public health	171
OP0266–OP0273	Epidemiology, risk and prediction of risk	176
OP0289–OP0290	The promise of health literacy in clinical care	189
OP0291	Cell activation pathways in RMDs	190
OP0292	Inborn errors of Immunity and autoimmune / inflammatory rheumatic disorders: What can we learn?	191
OP0293	Neutrophil dysregulation in systemic lupus erythematosus	191
OP0295–OP0296	Insights into gout management	192
OP0296	Insights into gout management	192
OP0298	Exploring the spectrum of bone inflammatory disorders across the life course	193
OP0300	Treating to Target: Challenges across the life course	194
OP0301	Predicting remission and flare	195
OP0304–OP0305	ANCA-associated vasculitis	196

Late breaking abstracts

LB0001–LB0006	Late-Breaking Oral Abstracts	200
LB0007	Prehabilitation to increase treatment success in rheumatology	203
LB0008	Neutrophil dysregulation in systemic lupus erythematosus	204
LB0009	EULAR Recommendations	205

Poster Tours

POS0001–POS0009	Adaptive immunity (T cells and B cells) in rheumatic diseases	206
POS0010–POS0018	Rheumatoid arthritis-aetiology, pathogenesis and animal models	210
POS0019–POS0029	Contemporary clinical topics in psoriatic arthritis	215
POS0030–POS0038	RA is more than just joints	222
POS0039–POS0048	Disease mechanisms in spondylarthritis	228
POS0049–POS0059	Tapering, drug retention and predictors of response	233
POS0082–POS0090	All about Crystal arthritis I	253
POS0091–POS0100	Vessels in flames	259
POS0101–POS0110	Remarkable Findings in OA Clinical Research	263
POS0111–POS0120	A novel journey into SLE, Sjogren and APS	270
POS0121–POS0131	Outcome of scleroderma and related syndromes	277
POS0132–POS0142	What's new in Paediatric RMDs?	285
POS0143–POS0152	Pathogenic pathways in Systemic Sclerosis and Myositis	292
POS0153–POS0162	New developments in imaging in rheumatology	298
POS0163–POS0172	Systemic lupus erythematosus, Sjogren's syndrome and anti-phospholipid syndrome: clinical aspects	304
POS0173–POS0182	bDMARDS in RA 2.0: about the good and the bad	310
POS0183–POS0191	All about Crystal arthritis II	317
POS0214–POS0223	People with burning vessels	334
POS0224–POS0233	Treatment in psoriatic arthritis on the move	339
POS0234–POS0243	Innate Immunity and Autoinflammation	349
POS0244–POS0254	Everything you need to know about managing in axSpA	356
POS0255–POS0265	Pain in RMDs	364
POS0266–POS0276	All about COVID-19 in Rheumatology	370
POS0277–POS0287	Advances in our care of children and young people with JIA	379
POS0288–POS0297	Molecular and metabolic biomarkers of activity, severity and response to treatment	385
POS0298–POS0306	Clinical aspects of spondyloarthritis	391
POS0307–POS0316	Original perspectives on old DMARDs and new small molecules in rheumatoid arthritis	397
POS0317–POS0327	Early RA and comorbidities	404
POS0329–POS0337	Osteoarthritis: novel prospects	410
POS0338–POS0347	Beyond the crystal ball	416
POS0348–POS0358	Genetic Determinants of Clinical Phenotypes	423
POS0359–POS0367	Impact of sex on disease pathogenesis and outcome	430
POS0368–POS0377	Health, public health and health services	436
POS0378–POS0387	Touring the landscape of epidemiology	442
POS0388–POS0398	Osteoporosis	448

Poster View

POS0399–POS0415	Osteo arthritis, aetiology, pathology and animal models	455
POS0416–POS0417	Spine, mechanical musculoskeletal problems, local soft tissue disorders	463
POS0418–POS0421	Bone diseases, aetiology, pathology and animal models	465
POS0422–POS0441	Spondyloarthritis - aetiology, pathogenesis and animal models	467
POS0442–POS0489	Rheumatoid arthritis - prognosis, predictors and outcome	477
POS0490–POS0507	Osteoporosis	507
POS0508–POS0531	Crystal diseases, metabolic bone diseases other than osteoporosis	516
POS0532–POS0535	Infection-related rheumatic diseases	530
POS0537–POS0559	COVID-19	532
POS0560–POS0573	Public health, health services research, and health economics	547
POS0574–POS0576	Educational cases	557
POS0603–POS0629	Systemic sclerosis, myositis and related syndromes - aetiology, pathogenesis and animal models	574
POS0630–POS0641	Rheumatoid arthritis - biological DMARDs	590
POS0642–POS0649	Epidemiology, risk factors for disease or disease progression	598
POS0650–POS0692	Spondyloarthritis - clinical aspects (other than treatment)	603

POS0693–POS0737	Vasculitis - large vessel vasculitis	631
POS1603	Vasculitis - large vessel vasculitis	658
POS0738–POS0739	Basic and translational science in paediatric rheumatology	659
POS0740–POS0777	Paediatric rheumatology	660
POS0778–POS0780	Clinical cases	680
POS0807–POS0821	SLE, Sjön's and APS - aetiology, pathogenesis and animal models	698
POS0822–POS0866	Rheumatoid arthritis - non biologic treatment and small molecules	706
POS0867–POS0884	Psoriatic arthritis - clinical aspects (other than treatment)	739
POS0885–POS0933	Diagnostics and imaging procedures	750
POS0934–POS0974	Epidemiology, risk factors for disease or disease progression	779
POS0975–POS0981	Validation of outcome measures and biomarkers	803
POS0982–POS0984	Clinical cases	807
POS1008	Adaptive immunity (T cells and B cells) in rheumatic diseases	820
POS1009–POS1011	Innate immunity in rheumatic diseases	820
POS1012–POS1049	Rheumatoid arthritis - aetiology, pathogenesis and animal models	822

ABSTRACT OPENING PLENARY

OP0001 DECONVOLUTING IMMUNOLOGICAL AND CLINICAL HETEROGENEITY ACROSS AUTOIMMUNE RHEUMATIC DISEASES BY COHORT-WIDE IMMUNO-PHENOTYPING

Keywords: Systemic lupus erythematosus, Genetics/Epigenetics, Rheumatoid arthritis

H. Tanaka[1,2], Y. Okada[2,3,4], S. Nakayamada[1], Y. Miyazaki[1], S. Namba[2], K. Sonehara[2,3], Y. Shirai[2], K. Yamamoto[2], K. Sonomoto[1], Y. Tanaka[1]. Background: Autoimmune rheumatic diseases (AIRDs) are systemic but heterogeneous diseases characterized by orchestration of disrupted self-tolerance of immune systems. We face a challenge in characterizing clinical immune features and selecting best treatment strategy of the AIRD patients.
Objectives: Deconvolution of immunological and clinical heterogeneity within and across AIRDs is an essential step towards implementation of personalized medicine. Immuno-phenotypes, immune-related cell types in peripheral blood mononuclear cells quantified by flow-cytometry analysis, can less invasively describe immune profiles of individuals and is considered as a promising technique.
Methods: We conducted large-scale and cohort-wide immuno-phenotyping of 46 peripheral immune cells using the Human Immunology Protocol of comprehensive 8-color flow cytometric analysis. The dataset consisted of >1,000 Japanese patients of 11 AIRDs and controls with deep clinical information registered at the FLOW study, including rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), systemic sclerosis (SSc), ANCA related vasculitis (AAV), idiopathic inflammatory myopathy (IIM), psoriasis, IgG4 related disease (IgG4RD), mixed connective tissue disease (MCTD), ankylosing spondylitis (AS), Sjogren's syndrome (SjS), and giant cell aortitis (GCA). In depth and longitudinal clinical analysis was conducted for the identified RA patient clusters registered at the FIRST registry. Inborn human genetics represented by genome-wide polygenic risk score (PRS) were estimated for the RA patients.
Results: Multimodal clustering of immuno-phenotypes deciphered underlying disease-cell type network, providing immune cell type specificity shared or distinct across AIRDs, such as close immunological network of MCTD with SLE rather than with SSc. Individual patient-level clustering deconvoluted the AIRD patients into several clusters with different immunological features (**Figure 1A**). Of these, RA- or SLE-like clusters were exclusively dominant, showing immunological polarization between RA and SLE across AIRDs (the patient clusters 4-6 and 1-3 for RA and SLE, respectively; **Figure 1B**). In depth and longitudinal clinical analysis of RA revealed that such patient clusters differentially defined clinical heterogeneity in disease activity and treatment responses, which were supported by immune cell-type specificity (e.g., decreased regulatory T cells associated with treatment resistance in the RA patients with SLE-like immuno-phenotypes). PRS based on RA case-control genome-wide association study (GWAS) and within-case stratified RA GWAS were associated with patient characteristics, disease activity, and immuno-phenotypes of the RA patients, such as dendritic cells for RA-interstitial lung disease.
Conclusion: Our study demonstrated a value of cohort-wide and cross-disease immuno-phenotyping to elucidate clinically heterogenous patient subtypes existing within the single disease in an immune cell type-specific manner.

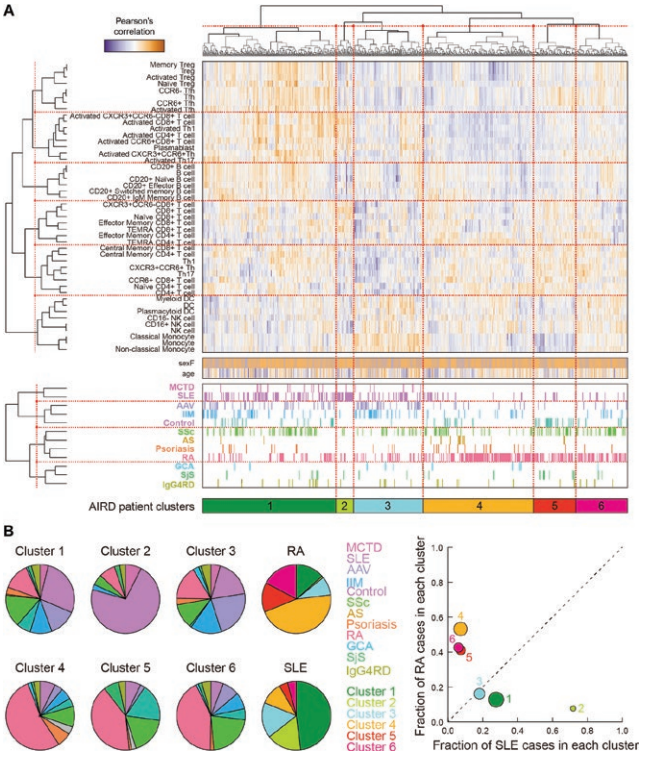

Figure 1. Patient-level clustering of the 11 AIRDs based on the cohort-wide immuno-phenotypes

OP0002 EXPLORING THE USE OF ARTIFICIAL INTELLIGENCE IN PREDICTING RHEUMATOID ARTHRITIS, BASED ON EXTREMITY MR SCANS IN EARLY ARTHRITIS AND CLINICALLY SUSPECT ARTHRALGIA PATIENTS

Keywords: Imaging, Rheumatoid arthritis, Artificial Intelligence

Y. Li[1], D. Shamonin[1], T. Hassanzadeh[1], M. Reijnierse[2], A. Van der Helm – van Mil[3], B. Stoel[1]. [1]*Leiden University Medical Center, Division of Image Processing, Department of Radiology, Leiden, Netherlands*; [2]*Leiden University Medical Center, Department of Radiology, Leiden, Netherlands*; [3]*Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*

Background: Predicting early rheumatoid arthritis (RA) from extremity MRI facilitates timely treatment, possibly preventing chronicity. Image interpretation by Artificial Intelligence (AI) may provide more accurate predictions than visual scoring.
Objectives: We developed a deep learning AI-method that automatically analyzes extremity MR scans by pre- and post-processing images, in order to predict RA at an early stage.
Methods: MR scans of the hands and feet from a total of 1974 patients were collected, consisting of 1247 early onset arthritis (EAC) patients, of whom 538 developed RA in two years, and 727 clinically suspect arthralgia (CSA) patients, of whom 113 developed RA. MRI scans were preprocessed automatically through background removal, slice-by-slice normalization and central slice selection. Subsequently, a self-supervised deep learning model was pre-trained to fill-in parts of the image that have been blinded by square patches (Figure 1(a), top row). Finally, after transferring the resulting weights, the model was fine-tuned to predict RA development (see Figure 1 (a) bottom row). The model was evaluated through 5-fold cross-validation and in a held-out test set (n=312 for EAC and n=146 for CSA). The model's accuracy was evaluated with the area under the receiver operator curve (AUC). An improved class activation map was developed and applied to indicate, which areas were most important to the AI decision.
Results: On the test set, the proposed model obtained a mean AUC of 0.683 in the EAC group, and 0.727 in the CSA group, using MR scans of the hands (wrist and metacarpophalangeal joints). Models trained separately on the wrists, MCPs and feet, received a mean AUC of 0.679, 0.647, 0.664, and 0.688, 0.669, 0.715, for the EAC and CSA group, respectively (see Table 1). These accuracies were close to the expert-level using RAMRIS, with reported AUCs of 0.74 and 0.69 in predicting RA in CSA [1]. According to the proposed visualization method,

the deep learning models predict RA, based on very similar patterns of known (teno-)synovial inflammation and bone marrow edema (see Figure 1 (b)).

Table 1. The overall performance, mean AUC (±SD)

Method:	Input			AUC RA in EAC	AUC RA in CSA
	Wrist	MCP	Foot		
MR scans + AI models	√			0.679 (±0.021)	0.688 (±0.039)
		√		0.647 (±0.015)	0.669 (±0.024)
			√	0.664 (±0.009)	0.715 (±0.026)
	√	√		0.683 (±0.025)	**0.727 (±0.037)**
	√	√	√	**0.707 (±0.016)**	0.708 (±0.068)

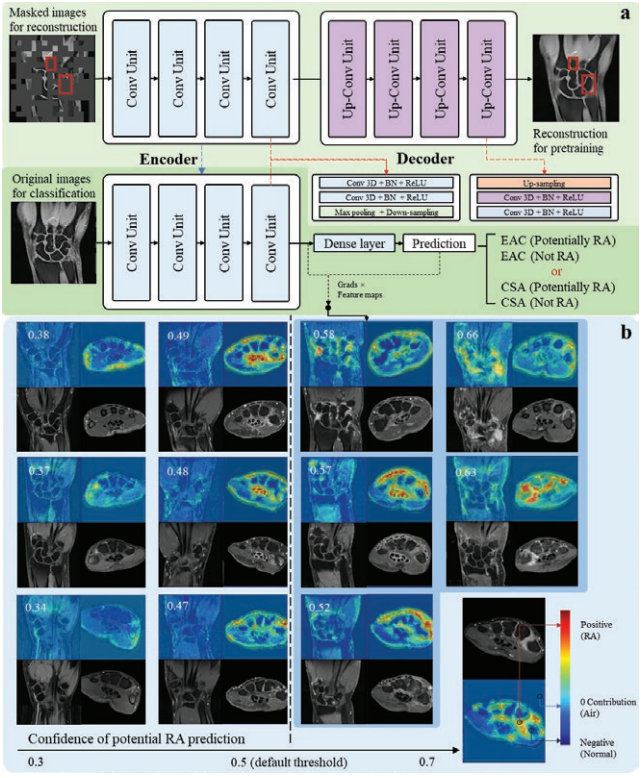

Figure 1. The overall workflow of the AI model and visualization examples from correctly-predicted samples.

Conclusion: Automatic RA prediction is feasible, using AI interpretation of MRI scans. AI performed close to the level of human experts. Including MRI data from healthy controls, as used in RAMRIS-based prediction [1], will probably improve the AI prediction further. The new visualization method not only confirms the significance of known inflammatory features but may also point to new imaging biomarkers, giving a different perspective of understanding RA.

OP0003 TASK-SHIFTING IN HAND-OSTEOARTHRITIS CARE

Keywords: Randomized control trial, Osteoarthritis, Health Services Research

A. Polster[1], L. Asphaug[2], A. T. Tveter[1], K. Bergsmark[1], B. Christensen[3], I. K. Haugen[1], M. Hermann-Eriksen[4], Å. Hove[4], A. Prøven[5], T. Hennig[5], T. A. Sjøvold[5], I. Kjeken[1]. [1]*Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*; [2]*Oslo University Hospital, Health Economics, Oslo, Norway*; [3]*Diakonhjemmet Hospital, Department for Rheumatology and Research, Oslo, Norway*; [4]*Diakonhjemmet Hospital, Division of Clinical Service, Oslo, Norway*; [5]*Martina Hansen Hospital, Sandvika, Norway*

Background: Hand-osteoarthritis (HOA) is a prevalent rheumatic joint disease that significantly reduces quality of life. In Norway, HOA should mainly be managed in primary care, but patients often have insufficient access to recommended treatment options there and are instead frequently referred to rheumatologists. This leads to high healthcare costs and reduces the access to rheumatologists for patients with inflammatory rheumatic diseases, for whom early diagnosis, disease modifying medication and tight controls may induce remission and prevent irreversible joint damage and long-term disability. Delegating the healthcare management and treatment of HOA to allied health professions such as occupational therapists may therefore free scarce healthcare resources and improve overall health economics.

Objectives: In this study we evaluated a new model of care in specialist healthcare, where HOA patients receive their first consultation by occupational therapists instead of rheumatologists. The objective was to test the non-inferiority of occupational therapist-led care (OTC) compared to rheumatologist-led care (RC) with regards to effectiveness defined as proportion of responders (based on OMERACT/OARSI criteria) and safety. In addition, we conducted a health economics evaluation comparing Quality-adjusted life years (QUALYs) and treatment costs between the treatment groups and conducted a cost-economics analysis.

Methods: We conducted a randomized controlled multicentre parallel group trial in which we recruited 400 patients with symptomatic HOA and no signs of possible inflammatory rheumatic disease at two Norwegian hospitals. Participants were randomized (1:1, computer-based) to either OTC (n=200) or RC (n=200). Various demographic and clinical parameters were registered at baseline. Disease activity (numeric rating scale, NRS, 0-10, 0=no disease activity), pain (NRS, 0-10, 0=no pain) and function (using the MAP-hand questionnaire, 18 items averaged to a 1-4 score, 1=no problems) were registered at baseline and 6 months post-intervention, and the delta was used to determine if patients were responders/non-responders based on OMERACT/OARSI criteria. Chi2-test and logistic regression were used to compare the proportion of responders/non-responder per treatment arm, and to analyse the relationship between response status (as dependent variable) and treatment arm (as independent variables). Results of the logistic regression are presented as odds ratio (OR) with 95% confidence interval (CI). Safety analysis was conducted by screening healthcare journals 12 months post-baseline for new diagnoses and adverse events related to musculoskeletal diseases. QUALYs were calculated using data from EQ-5D weighted with preference weights from the general population. To evaluate cost-effectiveness, we calculated and compared the incremental cost-effectiveness ratio (ICER).

Results: Mean age was 63.6 years (SD=10.01), 80.8 % were female. No statistical difference between the treatment arms was found in any baseline variables. In the RC group, 48 patients (25.8%) met the primary outcome criteria for treatment response. In the OTC group, also 48 (25.4%) were classified as responders. The proportion of responders did not differ by treatment group (X2 (1, N = 337) = 0.0012, p =.97). Treatment group did not significantly predict response status (OR=0.99, CI=0.62-1.59, p = 0.97). No notable safety-related events were found in either group. No statistically significant differences were found regarding QUALYs and overall treatment costs, and cost-effectiveness was marginal.

Conclusion: We found no statistically significant difference regarding proportion of treatment responders between the two treatment arms, suggesting non-inferiority of OTC compared to RC with regards to effectiveness and safety. While the cost-effectiveness analysis showed no clear benefit for either of the treatment options, delegating HOA treatment to OTs may free RT time and improve healthcare accessibility for urgent diagnoses, and thus prove a valuable opportunity to optimize future healthcare allocation.

OP0004 LUPUS100.ORG – A STEP CHANGE IN ACCESS TO QUALITY INFORMATION FOR EUROPEAN LUPUS PATIENTS

Keywords: Patient information and education, Systemic lupus erythematosus, Self-management

Z. Karakikla-Mitsakou[1], A. Cornet[2], I. D. Povilaite[3], M. Olsen[4], K. Blomkvist Sporre[5], N. Z. Serrano[6], M. Misuno[7]. [1]*Lupus Europe, PAN, London, United Kingdom*; [2]*Lupus Europe, HQ, Brussels, Belgium*; [3]*Lupus Europe, PAN, Vilnius, Lithuania*; [4]*Lupus Europe, PAN, Reykjavík, Iceland*; [5]*Lupus Europe, PAN, Stockholm, Sweden*; [6]*Lupus Europe, PAN, Dubai, United Arab Emirates*; [7]*Lupus Europe, PAN, Krakow, Poland*

Background: Quality of information on lupus on the internet is a real issue. ''Word of mouth'', rumours, unchecked data, or unconfirmed research increase

confusion, create anxiety and can lead to incorrect actions. Patients need access to quality information about lupus. Therapeutic Patient Education (TPE) is a key part of the self-management of chronic conditions; an essential component of TPE is access to valid information. Most patients in Europe don't speak English.
Objectives: To provide access to quality information on lupus online, in the native language of 95%+ of the European population.
Methods: The first step was to get the project endorsed by specialised lupus doctors, ERN ReCONNET. The French book "lupus en 100 questions" (initiated by FAI2R) was used as a starting point. Patients from the Lupus Europe Patient Advisory Network (PAN) and doctors worked together to create the English version. The least internationally relevant questions were removed to make space for new questions suggested by Lupus Europe's PAN. Answers for the new questions were constructed collaboratively between patients and doctors. The other questions were translated to English, updated where needed and adapted for international use. The resulting English document was distributed to ERN ReCONNET SLE working group doctors and to all PAN members, and feedback was incorporated. This master version was then put online and served as starting point for an ambitious multilingual translation. The translation process included generating an initial draft translation through Deepl Pro, and then upgrading this by a Doctor-Patient native speaker team. In parallel, a process has been established to collect comments and suggestions so that content can be maintained and upgraded on a continuous basis while keeping all language versions synchronised.
Results: lupus100.org in English was launched at the European Lupus Meeting in October 2022 and has to date received 8,900 visits. 18 translations have been completed and 10 of them are under final validation. The international launch of the multilingual website will take place on May 10, World Lupus day.
Conclusion: This effort will provide access to quality information about lupus to 95% of European lupus patients in their own language, eliminating a big barrier to quality information. Thanks to the effective collaboration between patients and doctors, quality of information can be guaranteed and information truly answers the patient concerns. Both national groups and the ERN network of doctors will ensure effective dissemination, so patients in all European countries are aware of the initiative.

Background: Unacceptable diagnostic delay in axial Spondyloarthritis (axSpA) remains an issue. In 2009, the longitudinal SPondyloArthritis Caught Early (SPACE)-cohort started to assess the prevalence of axSpA and the reliability of an early diagnosis in patients with chronic back (CBP) of unknown origin. Here we present one of the main outcomes of SPACE.
Objectives: To assess the two-year (2y) prevalence of an axSpA diagnosis among patients with recent onset CBP referred to the rheumatologist; To investigate the sustainability of a baseline (BL) diagnosis of axSpA when reviewed after 2y; And to explore patient-differences between BL and 2y, in those with and without an axSpA diagnosis.
Methods: We analysed the 2y data from SPACE, a European inception cohort of patients (age <45y) with CBP of recent onset (≥3 months, ≤2y) and unknown origin. The full diagnostic work-up included all clinical SpA-features, acute phase reactants, HLA-B27, radiographs and MRI of the sacroiliac joints (SI-CR and SI-MRI) and spine (data not shown). Patients with increased likelihood of having axSpA (≥1 major or ≥2 minor prespecified SpA-features) were eligible for follow-up with the remaining patients excluded per protocol. The clinical diagnosis at 2y was the main outcome of this study. At each visit, the treating rheumatologist judged on the presence or absence of axSpA (axSpA or no-axSpA) with a level of confidence (LoC) on a numeric rating scale (0: *not confident at all* to 10: *very confident)*. The main outcome was the presence of 'definite axSpA' at 2y, defined as a clinical diagnosis of axSpA with a LoC ≥7 (complete follow-up) or at the two last available visits if 2y visit was missing. 'No axSpA' was defined as not having axSpA at 2y (with LoC ≥7; or if LoC <7, plus an alternative diagnosis for CBP reported). All other patients were considered having an 'uncertain' diagnosis. The ASAS classification criteria were computed using sacroiliitis central reading results in definite axSpA patients. We assessed the prevalence of definite axSpA at 2y as well as changes in diagnosis over time, and descriptively summarised BL characteristics.
Results: A total of 555 CBP patients were included (Leiden n=383, Oslo n=97, Amsterdam n=48, and Gouda n=27). A diagnosis of definite axSpA was given to 175 (32%) patients at BL and 166 (30%) at 2y (***Figure 1***). The mean (SD) LoC's were 8.1 (2.0) and 8.7 (1.0), with 155/175 (89%) and 145/166 (87%) fulfilling ASAS classification criteria, respectively. BL diagnostic judgments were relatively unequivocal and remained rather stable: At 2y, 6% of the BL diagnoses of definite axSpA were refuted; and -*vice versa*: 9% of those who did not obtain a BL diagnosis of axSpA 'gained' one at 2y. Residual diagnostic uncertainty remained in 14% of CBP-patients. Expectedly, BL SpA-related features were more prevalent in the 2y definite axSpA group (***Table 1***). (The presence or absence of) imaging-detected sacroiliitis at BL appeared the best discriminator between axSpA and no axSpA at 2y.
Conclusion: One third of patients with CBP of recent onset referred to the rheumatologist has definite axSpA. Most of these patients can be unequivocally and reliably diagnosed at their first assessment. None of the many SpA-features suffices alone, but imaging discriminates best.

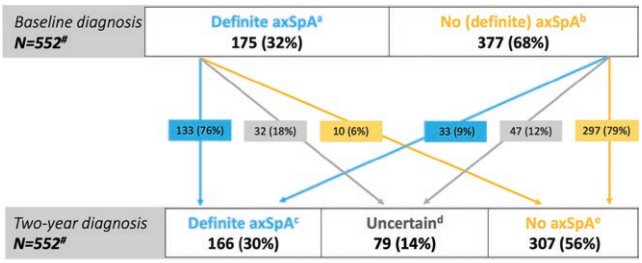

Figure 1. Diagnosis course from baseline (BL) to the two-year (2y) anchor visit.
axSpA: axial Spondyloarthritis; [a] patients diagnosed at BL with axSpA with a Level of Confidence (LoC) ≥7; [b] patients diagnosed at BL with axSpA (LoC <7) or with no axSpA (any LoC); [c] patients diagnosed with axSpA with a LoC ≥7 at 2y (if complete follow-up) or at the last two available visits (if missing the 2y visit); [d] patients diagnosed with axSpA with a LoC <7 at 2y (or LoC ≥7, if only baseline observation available), and patients with axSpA with LoC <7 at the last available observation and no consistent diagnosis at the last two observations nor alternative no axSpA diagnosis given at the last observation; [e] patients with no axSpA at the last observation over 2y with LoC ≥7 (or if <7, plus an alternative no axSpA diagnosis reported, e.g. fibromyalgia or aspecific back pain).

Table 1. Baseline characteristics by 2y diagnosis of patients with chronic back pain duration of ≥3 months but ≤2y, < 45y of age

	Definite axSpA N=166	Uncertain N=79	No axSpA N=307

Background: Interstitial lung disease (ILD) is a common (extra-articular) pulmonary manifestation of rheumatoid arthritis (RA). In RA, use of biologic or targeted synthetic disease-modifying drugs (b/tsDMARDs) have been linked to ILD, whereas the risk attributable to MTX use remains unclear. In psoriatic arthritis (PsA), few studies have investigated the risk of ILD, let alone in relation to use of MTX and b/tsDMARDs.
Objectives: To assess the incidence of ILD in patients with RA or PsA initiating a b/tsDMARD (vs. the general population), compare the risk of ILDs across b/tsDMARDS and investigate the role of MTX co-medication.
Methods: Patients with RA or PsA initiating a b/tsDMARD were identified in rheumatology registers from Denmark, Finland, Iceland, Norway and Sweden. Details of b/tsDMARD treatment, MTX co-medication, and disease activity at treatment initiation were retrieved. Gender and age-matched general population subjects were available from four countries. The incidence of ILD was assessed through linkages to national hospital and death registers with cases defined as patients who had been given an ILD diagnoses on more than one occasions. Subjects with a history of ILD prior to b/tsDMARD initiation were excluded. In multivariable models, we calculated the hazard ratios (HR) for ILD in individual patients starting b/tsDMARDs vs. population subjects, following each patient from treatment start until the first of ILD event, end of, death, or five years of follow-up. In separate on-treatment analyses we compared the risk of ILD between b/tsDMARDS initiators using etanercept treatment as a reference, and between those using vs. not using MTX (reference) as co-medication. Follow-up in on-treatment analyses was defined as time to first of ILD event, end of treatment plus 29 days, death or five years. For these analyses one patient could have several treatment courses in a time-split cox-regression analyses.
Results: 37.010 patients with RA, 12.341 patients with PsA and 569.451 population subjects, were identified, contributing 300, 30 and 400 ILD cases during follow-up, respectively. HR for ILD (vs. the general population) was 10.1 (95% CI 8.6 to 11.9) in RA and 5.0 (3.4 to 7.4) in PsA patients initiating a b/tsDMARD. In on-treatment analyses 69 608/21 340 b/ts DMARD treatment-courses were identified in RA/PsA patients with 558 and 46 ILD events during follow-up, respectively Among patients with RA a significantly increased HR (vs. etanercept) was only noted for rituximab 1.7 (1.2 to 2.4). No b/tsDMARD increased the risk of ILD in patients with PsA. MTX co-medication was used in 51.3%/42.2% of RA/PsA patients but did not give an increased risk of ILD compared to no use of MTX-co-medication (Figure 1 shows details of results for RA populations).
Conclusion: Among RA and PsA patients initiating b/tsDMARDs, the risk of ILD was higher than in the general population, and the risk of ILD in RA was approximately twice that of PsA patients. In these preliminary analyses, the increased risk of ILD in RA patients initiating treatment with rituximab may indicated a channeling bias. When used in clinical practice, MTX co-medication is not a risk factor for ILD in RA/PsA patients initiating b/tsDMARD therapy.

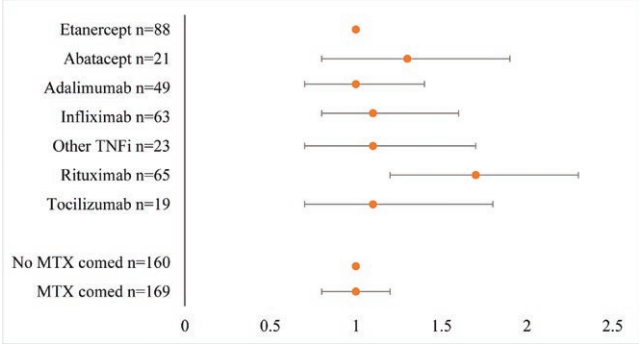

Figure 1. Risk of ILD across b/tsDMARD treatment and methotrexate co-medication in patients with rheumatoid arthritis. (Hazard ratios (95% CI). Etanercept 21 079 patients, adalimumab 12 018, abatacept 4 973, infliximab 12 636, Other TNFis 5 424, other bDMARDs 244 (not shown, no events) Rituximab 6 917, tsDMARDs 1 248 (not shown, no events), Tocilizumab 5 067

Background: A rise in the incidence of selected autoimmune disorders has been described, raising the question as to whether the overall incidence of autoimmune disorders might be on the rise due to environmental factors. However, reliable estimates of disease incidence and trends over time, particularly as pertains to autoimmune diseases as a group, are not available. Commonalities and differences between individual diseases also remain poorly understood.

Objectives: To investigate the incidence and prevalence for 19 of the most common autoimmune diseases, to assess trends over time, by sex, age, socioeconomic status, season and region, and to examine rates of co-occurrence among autoimmune diseases.

Methods: We used linked primary and secondary electronic health records of 22 million individuals from the Clinical Practice Research Datalink (CPRD), a cohort that is representative of the UK population in terms of age and sex. We calculated incidence and prevalence of 19 autoimmune disorders from 2000 to 2019 and used negative binomial regression models to investigate temporal trends and variation by age, sex, socioeconomic status, season of onset and region. To characterise co-occurrence of autoimmune diseases, we calculated incidence rate ratios, comparing incidence rates of comorbid autoimmune disease among patients with a first autoimmune disease with incidence rates in the general population, using negative binomial regression models, adjusted for age and sex.

Results: Among the 22,009,375 individuals included in the study, we identified a total of 978 872patients with a new diagnosis of at least one autoimmune disease between 2000 and 2019 (mean (SD) age: 54.0 (21.4) years, 64% women). Over the study period, age-standardised incidence rates of autoimmune diseases increased by 4%, similarly for men and women. The largest increases were seen in Graves' disease, coeliac disease and Sjogren's syndrome, for which incidences have doubled over the past two decades. Two conditions exhibited a significant decrease in incidence (Hashimoto's thyroiditis and pernicious anaemia). Taken together the 19 autoimmune disorders examined affected 10.2% of the population over the study period (13.1% of women, 7.4% of men). A socioeconomic gradient was evident across several diseases, including Graves' disease, pernicious anaemia, rheumatoid arthritis, and systemic lupus erythematosus. Seasonal variations were observed for type 1 diabetes (more commonly diagnosed in winter) and vitiligo (more commonly diagnosed in summer), and regional variations were observed for a range of conditions. Autoimmune disorders were commonly associated with each other, particularly Sjogren's, systemic lupus erythematosus and systemic sclerosis. Patients with type 1 diabetes also had significantly higher rates of Addison's, coeliac, and thyroid diseases, and multiple sclerosis stood out as having low rates of co-occurrence with other autoimmune diseases.

Conclusion: Autoimmune diseases affect about one in ten individuals. Their burden continues to increase over time, albeit at varying rates across individual diseases. The socioeconomic, seasonal, and regional disparities observed among several autoimmune disorders, implicate environmental factors in disease pathogenesis. The interrelations between autoimmune diseases are commensurate with shared pathogenetic mechanisms or predisposing factors, particularly among connective tissue diseases and among endocrine diseases.

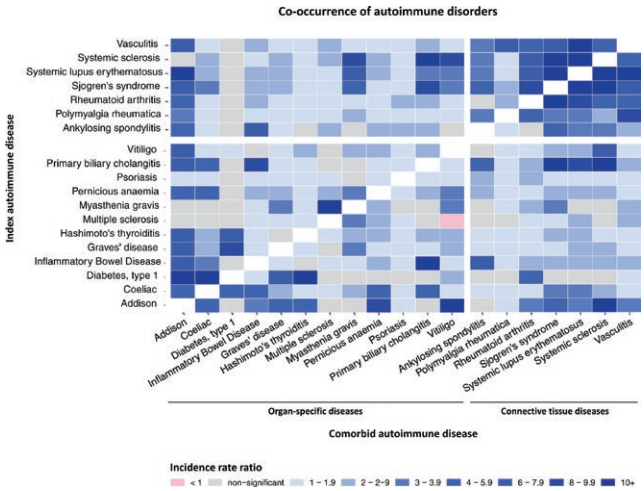

Figure 1. Incidence rate ratios for development of comorbid autoimmune disease among index populations with autoimmune disease compared with the general population

Incidence rate ratios were calculated for development of a second (comorbid) autoimmune disease among index populations with pre-existing autoimmune disease compared with the general population using negative binomial regression models adjusted for age and sex. Diabetes refers to childhood-onset type 1 diabetes (people aged <20 years at diagnosis).

Background: The multifaceted clinical presentation in crystal-induced arthropathies (CiA) poses challenges to imaging.
Objectives: To formulate evidence-based recommendations on the use of imaging in the diagnosis and management of CiA.
Methods: Following EULAR standard operating procedures a task force of 25 stakeholders from 11 countries was created. Four systematic literature searches were performed in MEDLINE, EMBASE and CENTRAL to guide task force decisions, answering 14 research questions on the role of imaging in gout, calcium pyrophosphate and basic calcium phosphate deposition disease. Level of agreement (LoA) with each overarching principle and recommendation was assessed by numerical rating scale (0-10).
Results: Five overarching principles and 10 recommendations were produced on the role of imaging in making a diagnosis, monitoring, predicting, guiding intervention, and patient education in CiA (Table 1). Overall, the LoA for the recommendations was very high (8.5-9.9).
Conclusion: These are the first recommendations that encompass all common forms of CiA and guide the use of established imaging modalities in this disease group.

Table 1. EULAR recommendations for the use of imaging in CiA in clinical practice

Overarching principles	Level of agreement Mean (standard deviation)
A. CiA are typically characterized by intermittent, acute episodes of inflammation, but may also exhibit a persistent disease course with or without superimposed flares.	9.8 (0.5)
B. Imaging in CiA provides useful information on crystal deposition, inflammation, and structural damage.	9.8 (0.5)
C. The presence of imaging abnormalities, in particular those related to crystal deposition, may not always be related to clinical manifestations.	9.8 (0.5)
D. Patient information (medical history, physical/laboratory examination, synovial fluid/tissue analysis) should be taken into account when imaging is considered in CiA.	9.7 (0.7)
E. Imaging in CiA should be performed and interpreted by trained health care professionals.	9.9 (0.4)
Recommendations	
1. When performing imaging in CiA, both symptomatic areas and disease-specific target sites (i.e. MTP1 in gout, wrist and knee in CPPD, shoulder in BCPD) should be considered.	9.7 (0.5)
2. In the diagnostic assessment of gout, US and DECT are both recommended imaging modalities.	9.7 (0.6)
3. When characteristic features of MSU crystal deposition on US (i.e. double contour sign or tophi) or on DECT are identified, synovial fluid analysis is not needed to confirm a diagnosis of gout.	8.8 (1.8)
4. In the diagnostic assessment of CPPD, CR and US (or CT if axial involvement is suspected) are recommended imaging modalities.	9.6 (0.9)
5. In the diagnostic assessment of BCPD, imaging is necessary; CR or US are the recommended modalities.	9.1 (1.7)
6. In gout, US and DECT can be used to monitor crystal deposition and in case of US, also inflammation. Both modalities provide additional information on top of clinical and biochemical assessment. In case US/DECT are not available, CR can be used to assess structural damage due to gout. The decision on when to repeat imaging depends on the clinical circumstances.	9.3 (1.2)
7. In CPPD and BCPD serial imaging is not recommended, unless there is an unexpected change in clinical characteristics.	9.4 (1.2)
8. In gout, assessing the amount of MSU crystal deposition by US or DECT may be used to predict future flares.	8.5 (1.7)
9. If synovial fluid analysis is required in the assessment of CiA, US-guidance should be used in cases where aspiration based on anatomical landmarks is challenging.	9.7 (0.5)
10. Showing and explaining imaging findings of CiA to people with such conditions may help them understand their condition and improve treatment adherence in gout.	9.4 (0.9)

BCPD: basic calcium phosphate deposition disease; CiA: crystal-induced arthropathies; CPPD: calcium pyrophosphate deposition disease; CR: conventional radiography; CT: computed tomography; DECT: dual-energy computed tomography; MSU: monosodium urate; MTP: metatarsophalangeal joint; US: ultrasound

"Buy one - get 4 free" - RMDs and comorbidities

OP0009-PARE **CREATIVITY AND CO-PRODUCTION TO SUPPORT PEOPLE LIVING WITH CHRONIC PAIN WITH THEIR MENTAL HEALTH**

Keywords: Mental health, Pain, Patient information and education

L. Campbell[1], P. Callaghan[2], C. A. Chew-Graham[3], K. Dziedzic[1], N. Evans[1], T. Kingstone[3], L. Group[1], K. Stevenson[4]. [1]*Keele University, Impact Accelerator Unit, Newcastle Under Lyme, United Kingdom*; [2]*Patient and Public Member, Keele University, Newcastle Under Lyme, United Kingdom*; [3]*Medical School, Keele University, Newcaste Under Lyme, United Kingdom*; [4]*Midlands Partnership NHS Foundation Trust, Physiotherapy Department, Stoke on Trent, United Kingdom*

Background: As many as 1-in-5 people are living with chronic pain (pain for three or more months) in the UK. Living with a long-term health condition can increase the likelihood of experiencing poor mental health. Having access to high-quality resources to raise mental health awareness and support good mental health among this population is crucial. Co-production of patient-facing resources with people with lived experience of health conditions (experts by experience) has been acknowledged as an important way of achieving impact and engagement.
Objectives: To describe how branding and design expertise was used to co-produce with experts by experience evidence-based, patient-facing animations to support the mental health needs of people with chronic pain.
Methods: A task and finish group (n=10) met virtually six times over 12 months from March 2020. The group included patients, public, representatives of charities, hospital volunteers, researchers and design experts. The group started with a blank canvas and worked together to decide which evidence-based messages to include in the resources, their format and style, and where and how they would be implemented. The group decided to create one website to host branded resources:

- A positive and informative animation and social media content
- Free online training for healthcare professionals, public and volunteers to improve awareness of the links between pain and mental health
- A library of local support resources

The marketing and design experts facilitated collaborative working to develop clinical (physiotherapist, general practitioner) and patient (retired, volunteer, carer) 'personas' to better understand the intended resource end-users. The group explored in-depth the emotions, thoughts and actions conveyed by the resources through word clouds and brainstorming. This helped the group to create a brand, the central character and provided vision for the style of the resources. Through facilitated discussion with design experts, the group co-produced animation storyboards, the plain language text on the website, training package, animation and local support library, and the final overall brand by choosing logos, colour schemes, fonts and images.
Results: The group chose Support, Progression and Freedom through 'Mind and Movement' as the key words on which to base the resources. Patients and the public suggested that a human character would not represent all people living with chronic pain; so, a bee was chosen to be the central character. It was agreed that the bee personified the key words whilst generating an engaging theme. The group agreed to name the resource package 'BeeFree' with the website slogan 'a support hive for mind and movement'. All resources were based around five evidence-based messages (Get Active, Get Talking, Get Creative, Eat Well and Sleep Well) called 'The Hive Five' and were housed on a new branded website - www.beefree.org.uk BeeFree was successfully launched online via regional NHS Trusts, charity and voluntary groups, First Contact Physiotherapy networks and social media in 2021. Patients and the public championed the resources and facilitated the launch. Challenges for the clinical group members included negotiating time and commitment to the work amidst multiple pandemic-related NHS pressures, and for the public group members there were difficulties adapting to working collaboratively online.

Figure 1.

Conclusion: Co-creating a positive, recognisable brand with patients and the public can facilitate the promotion and impact of evidence-based messages into healthcare. In the pandemic online co-production approaches offered creative adaptations to bring together stakeholders. Utilising design expertise and taking time to build and nurture relationships with patients and the public resulted in valuable and insightful co-production and consequently highly accessible and engaging resources.

OP0010-PARE **PRELIMINARY FINDINGS OF QUALITATIVE EXPLORATION OF THE EFFECTIVENESS OF AN ONLINE "FATIGUE AND ACTIVITY MANAGEMENT EDUCATION IN WORK" (FAME-W) INTERVENTION FOR INDIVIDUALS WITH INFLAMMATORY ARTHRITIS**

Keywords: Self-management, Work-related issues, Telemedicine

S. Karkon[1], F. O'shea[2], R. Conway[2], M. Doran[2], A. O' Gorman[3], H. Mccormack[3], B. Irudayaraj[4], D. Connolly[1]. [1]*Trinity College Dublin, Occupational Therapy, Dublin, Ireland*; [2]*St James's Hospital, Rheumatology, Dublin 8, Ireland*; [3]*St James's Hospital, Occupational Therapy, Dublin 8, Ireland*; [4]*University Hospital Waterford, Occupational Therapy, Waterford, Ireland*

Background: A Fatigue and Activity Management Education in Work (FAME-W) programme was developed for individuals with inflammatory arthritis to manage fatigue in work (McCormick, 2018). FAME-W was designed as an in-person programme; however, due to COVID-19 pandemic it was modified to be an online group-based self-management intervention.
Objectives: This study tested the effectiveness of an online format of FAME-W for future use by occupational therapist to help individuals with inflammatory arthritis to stay in work.
Methods: Participants were randomly allocated to intervention or control groups. Participants in the intervention group received the online four-week FAME-W and the control group participants received a FAME-W handbook. Participants in the intervention group attended a focus group immediately after the completion of the online FAME-W programme. A qualitative descriptive design was used with semi-structured focus groups. Data were analysed by thematic analysis (Braun and Clark, 2021).
Results: Twenty-six individuals took part in five separate focus groups. The average number of participants per group was 5 individuals with the largest group having 8 and smallest having 3 participants. The majority of participants were female, working full time and had Rheumatoid Arthritis. The four themes emerging from the focus groups were: "content and delivery of the programme" where participants discussed the relevance of the content to their symptoms and the online delivery format of FAME-W. In the second theme, participants discussed "understanding the effects of symptoms on their own and combined" and how symptoms effect mood, work, cognitive and physical abilities. In the third theme, "implementing the knowledge gained from the programme" through goal setting and practicality of the self-management strategies provided were discussed. Final theme "impact of the FAME-W on symptoms and work" including reassurance of normalising symptoms, change in mindset and approach to their condition were discussed.

Table 1.

Themes	Quotes
Content and delivery of the programme	"Each of the four sections were all very relevant" "I am quite happy that it is online because face to face would depend on location if I had the choice"
Understanding the effects of symptoms on their own and combined	"Now I know that I can sleep better when I manage my pain, and I can manage my pain by managing fatigue" "When you have a long-term illness, you don't look at the symptoms individually, you need to break it and look at it individually to know how to manage it"
Implementing the knowledge gained from the programme	"I'm in a different place today than I was four weeks ago. I am doing well now. So, for me the goal setting is excellent" "Helps you implement the knowledge into your regular routine and check in with yourself"
Impact of the FAME-W on symptoms and work	"Just a lightbulb moment to say, great, this is not my fault, because you can blame yourself for all the symptoms"

Conclusion: Preliminary results show that participants found the online FAME-W to be effective, relevant, reassuring, and helpful. These results suggest that work-related self-management skills are essential in assisting participants with symptom management in the workplace. Furthermore, these preliminary results suggest that the online format of FAME-W may be helpful for individuals with inflammatory arthritis to stay in work and it may become a standard part of clinical care for occupational therapists.

Epigenetics in chronic inflammation

OP0011 EPITRANSCRIPTOME EDITING REPRESENTS AN ADDITIONAL LAYER OF IMMUNE-RELATED EPIGENETIC MEMORY OF MONOCYTES IN HUMAN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Keywords: Systemic lupus erythematosus, Genetics/Epigenetics, Innate immunity

A. Banos[1], A. Kloetgen[2], K. Katsiki[1], A. Filia[1], D. Nikolopoulos[1,3], A. Tsirigos[2], D. Boumpas[1,3]. *[1]Biomedical Research Foundation Academy of Athens, Laboratory of Autoimmunity and Inflammation, Center of Clinical, Experimental Surgery and Translational Research, Athens, Greece*; *[2]Applied Bioinformatics Laboratories and Department of Pathology, New York University School of Medicine, New York, United States of America*; *[3]Medical School, National and Kapodistrian University of Athens Medical School, 4th Department of Internal Medicine, Attikon University Hospital, Athens, Greece*

Background: Monocytes are key effector cells in human systemic lupus erythematosus (SLE). Cytokine production, antigen presentation and initiation/amplification of tissue inflammation[1] represent some of output functions of transcriptional rewiring within the inflammatory milieu of the disease. Epitranscriptome includes all functionally relevant changes to the RNA level (transcriptome), reforming RNA metabolism and fine-tuning gene expression[2].

Objectives: To construct the transcriptional map of monocytes in lupus patients and impose the A-to-I base editing events as co-factor of the disease pathogenesis.

Methods: A cohort of 8 SLE patients (SLEDAI≥8) and 5 age/sex matched healthy volunteers was used for this study. PBMCs were obtained through Ficoll centrifugation and monocytes were isolated with $CD14^+$ magnetic bead selection. Total RNA was extracted and mRNA libraries were generated. Single-end 75-bp mRNA sequencing was performed on Illumina NextSeq 500. Differential expression analysis was performed using edgeR package. Genes with a false discovery rate of ≤0.05 and a fold change of >1.5 were considered statistically significantly deregulated. Significant differentially expressed genes (DEGs) were used for pathway and gene ontology (GO) analysis using g:Profiler webserver[3]. For base editing events, JACUSA2 was utilized for base calling and list refinement was performed by the following criteria: (a) known editing sites based on REDIportal, (b) the number of reads with "G" at the putative editing site is at least 10 and (b) the editing level per sample, defined as 100 n(G)/[n(A)+n(G)], is at least 20%, (c) JACUSA2 call-2 score for differential editing between SLE and healthy was 1.5.

Results: Differential gene expression analysis produced a list of 764 statistically significant genes, 492 of which are upregulated and 272 downregulated. Gene enrichment analysis concluded that DEGs are participating in transcription regulation, signal transduction, regulation of immune processes and apoptosis/cell death. IL-17 signaling pathway and RNA metabolic process are part of the pathogenetic profile of lupus monocytes. Interestingly, *ADARB1*, key regulator of RNA editing, is upregulated (logFC=0.76, pval=0.018). A-to-I editing events found to be significant, contain among others *GDI2* (UTR3 region/signaling mediator), *ARPC2* (Alu region/actin polymerization) and *CERK* (UTR3 region/ inflammation) regulatory regions. A complex network of transcriptomic and epitranscriptomic alterations embeds immune-related genes and affects multiple cellular processes.

Conclusion: Transcriptional machinery and signal transduction molecules exhibit abnormal expression during transcriptional rewiring in monocytes of lupus patients. Our data support RNA editing as an additional player of immune-related epigenetic memory of monocytes, further integrating inflammatory cues and enhancing autoimmune identity of the disease.

How to treat older people with RMD

OP0012-HPR CENTRAL SENSITIZATION HAS MAJOR IMPACT ON DISEASE ACTIVITY, FUNCTIONAL DISABILITY AND FRAILTY IN PATIENTS WITH RA

Keywords: Patient reported outcomes, Rheumatoid arthritis, Outcome measures

L. Quartuccio[1], F. R. Spinelli[2], S. Farah[3], C. Bazzani[4], F. Nacci[5], M. Fornaro[6], D. Iacono[7], C. Baldi[8], S. Perniola[9], S. Longhino[1], F. Salaffi[3]. *[1]1Division of Rheumatology, Academic Hospital "Santa Maria della Misericordia", ASUFC, University of Udine, Department of Medicine (DAME), Udine, Italy*; *[2]Rheumatology Unit, Sapienza Università di Roma, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari-Reumatologia, Roma, Italy*; *[3]Rheumatology Clinic, Università Politecnica delle Marche, Department of Clinical and Molecular Sciences, Jesi, Italy*; *[4]4 U.O. Reumatologia e Immunologia Clinica, ASST Spedali Civili di Brescia, Brescia, Italy*; *[5]SODc Reumatologia, Dipartimento di Medicina Sperimentale e Clinica Azienda Ospedaliero Universitaria Careggi, Firenze, Italy*; *[6]Rheumatology Unit, Department of Precision and Regenerative Medicine and Ionian Area, Bari, Italy*; *[7]Unità Operativa di Reumatologia, Dipartimento di Medicina di precisione, Università degli Studi della Campania, Napoli, Italy*; *[8]Rheumatology Unit - Siena University Hospital, Department of Medicine, Surgery and Neurosciences, Siena, Italy*; *[9]Division of Clinical Immunology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, Italy*

Background: Central sensitization (CS) assessed with Central sensitization Inventory (CSI) is significantly associated with functional disability and frailty in patients with rheumatoid arthritis (RA). Frailty is common in RA and associated with hospitalization and mortality. Frailty in RA is dynamic and, for some, may be ameliorated through controlling disease activity and functional disability.

Objectives: Our aim was to investigate the prevalence of CS in patients with RA and its association with measures of disease activity, functional disability, and frailty.

Methods: We administered to all the subjects in the study the CS inventory (CSI), a questionnaire that has been used for the diagnosis of CS. Demographic and clinical characteristics were collected as well as measures of disease activity [RAID), functional disability (ROAD) and Kihon Checklist (KCL) screening tool to identify community-dwelling adults vulnerable to frailty potentially at risk of becoming dependent. Patients with fibromyalgia were excluded from the study.

Results: Of the 192 included RA patients, mean CSI score was 36.7 ±15.5 and 36.5% scored >40, which indicates a high probability of CS. Mean CDAI score was 16.8 ± 12.4 and mean RAID 5.0 ± 2.0. A CSI score >40 was significantly associated with higher RAID (mean 5.7 vs. 4.6; F-ratio 12.28; p=0.001), higher

ROAD (mean 4.3 vs. 3.0; F-ratio 17.37; p<0.001) and higher Kihon score (mean 9.1 vs. 5.7; F-ratio 29.88; p<0.001).

Conclusion: CS is strongly related to patient-reported disease activity, functional disability and frailty in patients with RA independently from other patient-and disease-related aspects. CS is an important determinant of functional disability in patients with chronic inflammatory arthritides. Therefore, special attention should be paid to RA patients, in whom the concomitant diagnosis of CS should be routinely ruled out.

Precision medicine in SLE: where are we?

OP0013

APPLYING STANDARD CLASSIFICATION CRITERIA EXCLUDES UP TO A HALF OF ALL PATIENTS FROM CONNECTIVE TISSUE DISEASES (CTD) CLINICAL TRIALS

Keywords: Sjögren syndrome, Systemic sclerosis, Systemic lupus erythematosus

S. Dyball[1], M. Rodziewicz[1], A. V. Madenidou[1], J. Reynolds[2,3], A. Herrick[4,5], S. Haque[6], H. Chinoy[4,5], E. Bruce[7], B. Parker[7], I. N. Bruce[1,7,8]. [1]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [2]*University of Birmingham, Rheumatology Research Group, Institute of Inflammation and Ageing, Birmingham, United Kingdom*; [3]*Sandwell and West Birmingham NHS Trust, Rheumatology Department, Birmingham, United Kingdom*; [4]*Northern Care Alliance NHS Foundation Trust, Department of Rheumatology, Salford Royal Hospital, Salford, United Kingdom*; [5]*The University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom*; [6]*Manchester NHS Foundation Trust, Rheumatology Department, University Hospital of South Manchester, Manchester, United Kingdom*; [7]*Manchester University Hospitals NHS Foundation Trust, The Kellgren Centre of Rheumatology, Manchester, United Kingdom*; [8]*NIHR Manchester Biomedical Research Unit, The University of Manchester, Manchester, United Kingdom*

Background: Classification criteria aim to identify a homogenous population of patients with a high specificity for clinical research.

Objectives: To determine how connective tissue disease (CTD) phase III trials utilise classification criteria within their inclusion and exclusion criteria. We then applied the most commonly used classification criteria to a large cohort of patients with an existing CTD diagnosis to explore which patients would be included and excluded from trials.

Methods: A comprehensive review of all major published phase III trials in CTDs was performed using clinicaltrials.gov (Nov 22). We included trials of biological or DMARD therapy, and excluded open label trials and long-term extensions. Adult patients (May 14 - July 22) were recruited from five rheumatology centres in North West England into the LEAP cohort. Patients were eligible for inclusion if they had ≥1 clinical feature of a CTD and ≥1 antibody within the ANA spectrum. The physician (rheumatologist) diagnosis at time of recruitment was used as the primary classifier of patients. Classification criteria utilised in the majority of clinical trials were systematically applied to this cohort, irrespective of clinical diagnosis.

Results: There were 49 trials in CTDs identified from 1909 records: systemic lupus erythematosus (SLE)=29, systemic sclerosis (SSc)=7, idiopathic inflammatory myopathy (IIM)=7 and primary Sjögren's syndrome (pSS)=6. There were no trials in MCTD or UCTD. The majority of trials (N=47, 95.9%) required patients to meet classification criteria for their respective disease. The ACR-1997 for SLE, 2002 American European Consensus Criteria (AECG) criteria for pSS, ACR criteria for SSc 1980, and Bohan and Peter for IIM were the most commonly employed criteria. The majority of pSS (N=5, 83.3%) and SSc (N=4, 57.1%) trials excluded patients with other overlapping CTDs, whereas only a minority of IIM (N=1, 14.3%) and SLE (N=2, 6.9%) trials mandated this. A further 2 (28.6%) IIM and 2 (6.9%) SLE trials excluded CTD patients with specific overlapping features, e.g. SSc with significant pulmonary hypertension. 15 trials (30.6%) allowed exclusion of significant coexisting diseases at the investigators' discretion and 18 (36.7%) made no reference. 391 patients were recruited to the LEAP cohort (Female: 352 [90.0%], median [IQR] age: 52 [40-59] years, median [IQR] disease duration: 6.1 [2.9-13.2] years). 254 (65.0%) patients met classification criteria for at least one CTD (Table 1). 222 (74.0%) patients with pSS, SLE, SSc or IIM, met the classification criteria for their respective diagnosis. Of these, 26/222 (6.7%) met criteria for >1 CTD. In total, 196/391 (50.1%) would be eligible, and 195/391 (49.9%) ineligible for recruitment to a phase III trial, based upon their physician diagnosis, and trial eligibility criteria. Patients eligible to participate were similar in age (*p= 0.882*), gender (*p=0.601*) and ethnic background (*p= 0.822*) but had longer median disease duration (7.5 vs 5.2 years, *p=0.024*) to those ineligible.

Table 1. The proportion of patients meeting classification criteria utilised in clinical trials, by physician diagnosis

	SLE	pSS	UCTD	SSc	MCTD	IIM	Overall
	N=164	N=77	N=61	N=37	N=30	N=22	N=391
Bohan and Peter for IIM	2 (1.2)	0 (0)	0 (0)	3 (8.1)	2 (6.7)	9 (40.9)	16 (4.1)
ACR/EULAR Systemic sclerosis 2013	1 (0.6)	0 (0)	0 (0)	30 (81.1)	8 (26.7)	4 (18.2)	43 (11.0)
AECG Sjögren's	10 (6.1)	45 (58.4)	0 (0)	0 (0)	1 (3.3)	1 (4.5)	57 (14.6)
ACR SLE 1997	138 (84.1)	14 (18.2)	0 (0)	2 (5.4)	14 (46.7)	5 (22.7)	173 (44.2)

Conclusion: Clinical trial recruitment is challenging, in part due to due to strict eligibility criteria. In an unselected, real-world cohort of CTD patients, up to a half would be excluded due to classification criteria, overlapping features or a lack of trials within their disease. Directly targeting molecular pathology in biomarker driven basket trials could potentially revolutionise drug development by benefitting those with an undifferentiated or overlap condition who would be traditionally excluded from clinical trials.

Adaptive immunity (T cells and B cells) in rheumatic diseases

OP0014 SHARED MOLECULAR TARGETS OF APOPTOSIS IN CHRONIC INFLAMMATION AND AUTOIMMUNITY: HOW TO BLOCK AUTOIMMUNE ARTHRITIS

Keywords: Autoantibodies, Animal Models, Cell biology

J. Paris[1], L. Ghezil[1], L. Tourneur[2], G. Bousquet[1], G. Falgarone[1]. [1]*Université Sorbonne Paris Nord, INSERM UMR_S942 MASCOT, Bobigny, France*; [2]*Université Paris Cité, INSERM UMR_S942 MASCOT, Paris, France*

Background: Aging is associated with an increased incidence of cancers and autoimmune diseases, which share pathophysiological mechanisms. Understanding these common pathways would make it possible to better define a certain risk linked to the disease or their treatment and to decipher new therapeutic targets in autoimmunity. Using an original individual approach to constitutional genetics at low penetrance, our team identified a constitutional mutation pR988C, c2962C> T of MET gene (tyrosine kinase receptor MET) in a patient with autoimmune diseases and malignant tumors. This mutation results in the constitutive activation of MET receptor and to the expression of an autoimmune phenotype associating a diffuse Sjögren disease with histological synovitis in transgenic MET mice [1]. The MET receptor (hepatocyte growth factor, HGF) participates in the regulation of physiological defensive responses following organs failure and its role has been proposed in several inflammatory diseases. In addition, the MET pathway has been implicated in the modification of the dendritic cells phenotype and the response of T cells with cancerous diseases.
Objectives: The objective of our work is to study the histological and cellular phenomenon of transition between self-reactivity and aggressive auto-immunity. Our new genetic model appears to be a good candidate to study the mechanisms involved in autoimmunity transition. To this purpose, we have three objectives i) to describe the effects of the genetic pressure in our model of MET mutated mice, ii) to induce in vivo inflammation with LPS or HGF in heterozygous/homozygous MET mice to assess the autoimmunity induced by external factors, iii) to study the function of immune cells of mutated MET mice.
Methods: Using heterozygous or homozygous mutated MET mice, we *in vivo* stimulated them for 6 months with LPS or HGF, to add an environmental pressure. Mice were systematically assessed for clinical symptoms, autoantibodies production, histological phenotypes, immune cells phenotyping, bone marrow at euthanasia. We focused on the functional phenotype of bone marrow dendritic cells (BMDC) with assessment of co-stimulatory molecular surface expression, cytokine production, endocytosis, allogeneic reactivity.
Results: We confirmed that heterozygous MET mice develop systemic autoimmune diseases and observed that homozygous mice have a more severe clinical phenotype (Figure 1). Homozygous MET mice have severe inflammatory infiltrates and higher circulating autoantibody levels. We observed an increase in monomacrophagic pro-inflammatory subpopulations in the bone marrow parallel to the MET gene expression, higher with homozygotous mice as compared to heterozygotous and to non-transgenic mice. Stimulation with HGF or LPS increased the inflammatory status, with a maximum peaking in LPS treated MET homozygotous mice. We confirmed that, *in vitro* stimulation of BMDC with HGF induces an intermediate phenotype of maturation dendritic cells whatever the status of transgenic mice. Furthermore, dendritic cells obtained from mice exposed to LPS have an exhausted phenotype, in parallel with the high level of inflammation in tissues. Studying apoptosis phenotype, we observed a shift in cell death pathways that could be the relying mechanism of autoimmune prone phenotype linked to the MET mutation.
Conclusion: The model of transgenic mice appears ideal for studying the transition phenomena of autoreactivity versus autoimmune disease and the functional involvement of dendritic cells. We confirmed the direct involvement of the MET gene in autoimmunity. For the first time, we showed that the change in cell death pathways could be the direct origin of the emergence of autoimmunity. These preliminary results, for which additional experiments are underway, open up physiopathological and therapeutic perspectives.

Background: Immune checkpoint inhibitor (ICI) therapies used to treat cancer, such as anti-PD1 antibodies, can induce autoimmune conditions. The T cells responsible for mediating such iatrogenic autoimmunity, their activation profiles and characteristics remain unclear.
Objectives: To investigate the transcriptomic and clonotypic features, activation, and role of infiltrating T cells in patient joints affected by ICI-induced inflammatory arthritis (ICI-arthritis).
Methods: Paired TCR and scRNA-seq was performed on synovial fluid (SF) CD8 T cells from ICI-arthritis (ICI-A) to determine their transcriptomic and clonotypic features. Detailed immunophenotyping was performed on SF mononuclear cells using mass cytometry and flow cytometry to identify significantly altered populations in ICI-A compared to seropositive rheumatoid arthritis (RA) and psoriatic arthritis (PsA). Further, bulk RNA-seq was performed on altered SF CD8 T cell subsets from the three arthritides to investigate differences in activation profiles and immune pathways enriched. *In vitro* cytotoxicity assays were performed by measuring annexin staining in fibroblasts co-cultured with various CD8 subsets from synovial fluid and blood. Mass cytometry was performed on PBMCs from melanoma patients to assess changes before and after checkpoint blockade and bulk TCR-seq of ICI-bound (IgG4+/-) non-naive CD8 T cells was used to analyze TCRs enriched in blood and synovial fluid of ICI-arthritis patients.
Results: Single cell transcriptomic and antigen receptor repertoire analyses highlighted clonal expansion of an activated effector CD8 T cell population in the joints and blood of ICI-arthritis patients (n = 6). These CD8 T cells, identified as $CD38^{hi}CD127^{-}$, were uniquely enriched in ICI-arthritis joints compared to RA and PsA and displayed an elevated interferon signature. *In vitro*, type I interferon induced CD8 T cells to acquire the ICI-associated $CD38^{hi}$ phenotype and boosted cytotoxic function in a novel cytotoxicity assay. In a cohort of patients with advanced melanoma, anti-PD-1 and anti-CTLA-4 therapy dramatically expanded circulating $CD38^{hi}CD127^{-}$ T cells more so than any other T cell

population. CD38^{hi}CD127^{-} T cells were Ki67+ and were frequently bound by the therapeutic anti-PD-1 drug. In ICI-arthritis patients, anti-PD-1 drug-bound CD8 T cells in circulation showed marked clonal overlap with drug-bound CD8 T cells from synovial fluid, but almost no overlap was observed between drug-bound cells in the synovial fluid and non-drug-bound cells in blood (**Figure 1**).
Conclusion: These results suggest that ICI therapy directly targets CD8 T cells in patients with ICI-arthritis to induce a novel autoimmune pathology that is distinct from the prototypical spontaneous autoimmune arthritides.

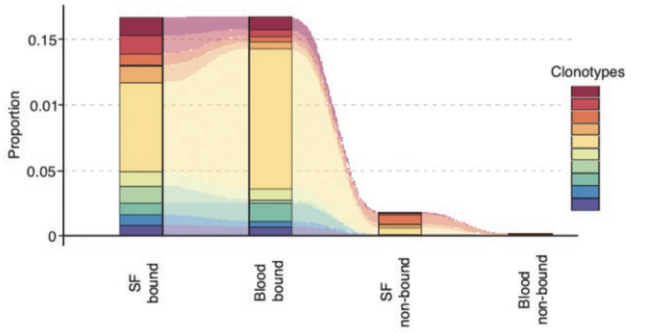

Fig.1: Anti-PD-1 drug-bound CD8 T cells in circulation and synovial fluid are clonally linked in ICI arthritis patients.
CD8 T cells from paired blood and synovial fluid from ICI-arthritis patients on an anti-PD-1 therapy, were sorted into anti-IgG4+ (drug-bound) or anti-IgG4- (non-drug-bound) populations. Alluvial plot representation of one patient showing the 10 most abundant clonotypes in the drug-bound synovial fluid CD8 T cells demonstrating substantial overlap in these large clones between drug-bound cells in synovial fluid and blood, and much less sharing with non-drug-bound cells. Representative plot of 3 patients.

OP0016 ABATACEPT TO SILENCE ANTI-CITRULLINATED PROTEIN ANTIBODY-EXPRESSING B CELLS IN RHEUMATOID ARTHRITIS: THE ASCARA TRIAL

Keywords: Rheumatoid arthritis, Randomized control trial, Biomarkers

N. Blomberg[1], J. Kwekkeboom[1], S. Böhringer[2], T. Huizinga[1], R. Toes[1], H. U. Scherer[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Leiden University Medical Center (LUMC), Biomedical Data Sciences, Leiden, Netherlands*

Background: Rheumatoid arthritis (RA) is one of the most prevalent systemic autoimmune diseases. Despite clinically effective drugs, RA remains a chronic disease with frequent disease flares upon drug tapering. Patients harbouring anti-citrullinated protein antibodies (ACPA) most frequently relapse and rarely achieve drug-free remission. We observed that in established RA, ACPA-expressing memory B cells (mBC) are highly activated, proliferate, secrete pro-inflammatory cytokines and differentiate into plasmablasts [1]. This phenotype points to continuous, T helper cell-driven stimulation of the ACPA B cell response and persists in patients in clinical remission induced by conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs), suggesting ongoing immunological disease activity (IDA) despite clinically quiescent disease. Persistent IDA may be responsible for disease flares, making immunological remission a potential treatment target required for cure.
Objectives: To test the hypothesis that CTLA4-Ig (abatacept), a biological DMARD that blocks co-stimulatory signals such as those provided by helper T cells to B cells, can impact on IDA, as evidenced by the induction of a silent, non-proliferative phenotype of ACPA-expressing mBC.
Methods: We conducted a single-center, randomized, open-label clinical trial in which patients with newly diagnosed, untreated RA (n=42) were treated with either methotrexate (MTX, n=21) or abatacept/MTX (ABA/MTX) combination therapy (n=21) for 6 months. Frequency and phenotypic characteristics of peripheral blood ACPA-expressing B cells were assessed directly ex-vivo by flow-cytometry at baseline (BL), 3 months (V2) and 6 months (V3). The expression of Ki-67 (primary endpoint), CD80, CD86 and HLA-DR were used to determine the activation state of the B cells in either group, next to B cell lineage and differentiation markers. Tetanus-toxoid (TT) specific B cells served as antigen-specific controls. Clinical disease characteristics as well as serum parameters were assessed in parallel. Differences between treatment groups were statistically analyzed using a mixed effect model with random slope and intercept.

Results: Of patients receiving treatment, n=14 in the ABA/MTX and n=16 in the MTX monotherapy arm harboured ACPA-expressing mBC in the circulation at sufficient frequency for phenotypic analysis. Patients with untreated RA exhibited a highly active ACPA mBC response, in line with previous results [1]. Both MTX and ABA/MTX reduced clinical disease activity at 6 months to a similar extent (p=0.33). The frequency of circulating ACPA-expressing mBC remained unaffected in either group. However, while ACPA-expressing mBC maintained their highly active phenotype in the MTX group, ABA/MTX impacted on the ACPA mBC response by significantly reducing the expression of Ki-67, CD86 and CD80. The expression of HLA-DR did not change upon treatment.

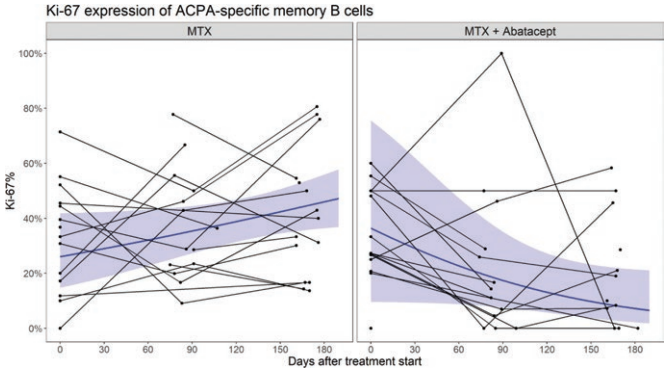

Figure 1.

Conclusion: The ASCARA study provides first evidence that the activation of ACPA-expressing mBC can be therapeutically modulated towards a phenotype compatible with immunological remission. ABA/MTX, but not MTX alone had this modulatory effect, indicating that potentially important immunological drivers of RA disease processes are resistant to MTX-mediated effects. Interestingly, the phenotype induced by ABA/MTX resembles that observed in patients in sustained drug-free remission as well as in individuals with clinically suspect arthralgia that do not convert to RA (long-term non-converters, (1)). Follow-up analysis of the ASCARA study with ABA discontinuation beyond V3 will elucidate the stability of this effect and its relation to clinical disease characteristics.

OP0017 ACTIVE LUPUS NEPHRITIS PATIENTS DISPLAY AN INCREASED PROPORTION OF RECENTLY ACTIVATED NAÏVE DNA-REACTIVE B CELLS

Keywords: Adaptive immunity, Kidneys, Systemic lupus erythematosus

K. Wangriatisak[1,2], F. Faustini[2,3], R. Kumar[2,4], C. De Vries[2,4], P. Pisitkun[5], P. Chootong[1], V. Malmström[2,4], I. Gunnarsson[2,3]. Background: Altered composition of B cell compartments is known in patients with systemic lupus erythematosus (SLE). However, similar characterisation of the disease-associated autoreactive B cells remains scarce. Elucidating the autoreactive B cell subsets and their association to lupus manifestations may provide tools for monitoring, biomarkers and even identifying possible targets for future therapeutic intervention.
Objectives: To investigate phenotypic characteristics of extrafollicular B cell subsets in a cohort of SLE patients.

Methods: Twelve SLE patients, including nine with positive anti-dsDNA antibodies (75%), and ten healthy controls (HCs) were recruited for this study. Data was represented as median and interquartile range (IQR). To identify DNA-reactive B cells, surrogate peptide (DWEYSVWLSN) that serves as dsDNA mimotope was used, as previously shown (1, 2). The phenotype of peripheral B cell subsets and DNA-reactive B cells was analyzed by spectral flow cytometric analysis. The correlations between different B cell populations and Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) scores, clinical manifestations and laboratory data were assessed.

Results: In SLE patients, median SLEDAI-2K score was 14.5 (4.5-19.5), median age and disease duration were 32 (29-48.5) and 10 (1-13) years, respectively. Eight patients presented with lupus nephritis (LN), with proliferative (class III/IV, n = 2), membranous (class V, n = 1) and mixed histological pattern (class III & V, n = 3 and class IV & V, n = 2). Phenotypic analysis showed an expansion of recently activated, so called activated naïve (aNAV: $CD11c^+CXCR5^-CD21^-CD27^-IgD^+$, p = 0.0005), double negative 2 B cells (DN2: $CD11c^+CXCR5^-CD21^-CD27^-IgD^-$, p = 0.0001) and double negative 3 B cells (DN3: $CD11c^-CXCR5^-CD21^-CD27^-IgD^-$, p = 0.005) in the blood of the total SLE patient group compared to HC, with aNAV B cells frequency being higher in LN patients (Figure 1). DNA-reactive B cells were mostly represented by an aNAV phenotype ($CD11c^+CXCR5^-CD21^-$) which overexpressed CD11c and CD80. Moreover, a significantly increased percentage of such autoreactive B cells was observed in LN patients (median (IQR) 0.13% (0.095-0.160) compared with non-LN patients (median (IQR) 0.056% (0.042-0.070), p = 0.0357). The percentage of aNAV B cells were positively correlated with disease activity measured as SLEDAI-2K index (r = 0.619, p = 0.036). These aNAV B cells also had a positive correlation with DN2 (r = 0.578, p = 0.049) and plasmablasts (r = 0.420, p = 0.041).

Conclusion: Our data show that aNAV B cells are expanded in SLE and display autoreactivity to dsDNA. The association between the frequency of aNAV B cells and disease activity, and with lupus nephritis suggests that these cells may be used as a monitoring biomarker in the disease.

Background: Cellular senescence is a state of proliferation arrest of cells occurring and cleared during normal aging. However, the persistence and accumulation of senescent cells has been implicated in the pathogenesis of age-related diseases like rheumatoid arthritis (RA). Aging is an important risk factor of RA, a chronic autoimmune disease in which loss of immune tolerance and systemic autoimmunity precedes clinical onset of disease. Lymph node stromal cells (LNSCs) are important regulators of peripheral tolerance. Accordingly, accumulating senescent LNSCs may potentially lead to defective peripheral tolerance and the development of systemic autoimmune disease.

Objectives: In this study we investigated the senescence phenotype of LNSCs during health, systemic autoimmunity and RA. Additionally, we examined whether dasatinib treatment could restore their cellular phenotype and function.

Methods: LNSCs were isolated and cultured from inguinal lymph node needle biopsies from autoantibody positive individuals with arthralgia and therefore at risk of developing RA (RA-risk individuals), RA patients and seronegative healthy volunteers. The senescent phenotype and the effect of dasatinib treatment were assessed using quantitative PCR, flow cytometry, microscopy and live-cell analysis.

Results: Cell size, granularity and autofluorescence were significantly higher in RA LNSCs compared with control LNSCs. Stainings indicate more senescence associated β-galactosidase activity, more lipofuscin granules and increased DNA damage in RA-risk and RA LNSCs compared with control LNSCs. Moreover, we found altered gene expression levels of senescence associated genes in LNSCs from RA patients. Functional experiments showed no difference in proliferation and migration capacity between donor groups. Strikingly, the capacity to repair irradiation induced DNA damage was significantly lower in RA-risk and RA LNSCs compared with control LNSCs. Treating LNSCs with dasatinib significantly improved cell size and DNA repair capacity of cultured LNSCs.

Conclusion: We observed premature aging of lymphoid stroma in RA patients and to lesser extent already in individuals at risk of developing RA, which could partly be restored by dasatinib treatment. Premature aging of LNSCs may negatively impact the local niche by inducing inflammation and senescence in nearby cells. However, consequences of prematurely aged lymphoid stroma remain inconclusive providing a rationale for investigating the effect on immune cell responses.

OP0020 THE CELLULAR METABOLISM OF SLE NK CELLS IS PRIMARILY ALTERED AT THE LEVEL OF MITOCHONDRIAL HOMEOSTASIS

Keywords: Systemic lupus erythematosus, Innate immunity, Cell biology

N. Fluder[1], M. Humbel[1], C. Ribi[1], D. Comte[1]. [1]Lausanne University Hospital, Immunology and allergy, Lausanne, Switzerland

Background: Systemic lupus erythematosus (SLE) is a multi-systemic inflammatory disease, of unknown etiology, which involves the development of autoreactive cells and a loss of tolerance to self. Natural Killer (NK) cells represent a group of innate immune cells that play a pivotal role in the interaction between the innate and adaptive immune system. In patients with SLE, NK cells are decreased in the peripheral blood, exhibit reduced cytotoxicity, and impaired cytokine production.(1, 2) To date, few studies have explored the molecular mechanisms underlying NK cell dysfunction in SLE.

Objectives: To characterize the immunometabolic alterations of NK cells from patients with SLE.

Methods: SLE and healthy NK cells were isolated from human PBMCs. Glycolysis and mitochondrial respiration (OXPHOS) were measured using Seahorse real-time metabolic assay. Mitochondrial function (membrane potential, mitochondrial mass), superoxide levels and lysosomes acidification were assessed by flow cytometry. Mitochondrial membrane potential and mass were analyzed by confocal microscopy (CM). Mitochondrial DNA was quantified by qPCR. Mitochondrial structure was examined by transmission electron microscopy (EM). Functional (cytokine production, degranulation) assays were performed in parallel with mitochondrial mass measurement by flow cytometry. Quantitative proteomic analysis was conducted focusing on the expression of proteins involved in mitochondrial homeostasis.

Results: We first examined the cellular metabolism of SLE NK cells in comparison to healthy NK cells. We observed that OXPHOS is significantly increased in SLE NK cells, while glycolysis is similar to healthy controls. Due to this alteration in oxidative phosphorylation, we conducted experiments to examine the mitochondrial fitness of SLE NK cells. We showed that mitochondrial mass is increased, while mitochondrial activity is decreased in SLE NK cells, suggesting an accumulation of dysfunctional mitochondria. SLE NK cell mitochondria displayed increased superoxide levels and elevated lysosomal acidification, compared to healthy NK cells. qPCR analysis showed no significant difference. in mitochondrial DNA between SLE NK cells and healthy controls suggesting that the size of mitochondria is increased but not their number in SLE NK cells. Examination of the mitochondrial structure in SLE NK cells by TEM, showed cristae disorganization. Quantitative proteomic analysis showed that SLE NK cells express high levels of proteins associated with mitochondrial synthesis (mitochondrial import receptor TOM6) and OXPHOS (ATP synthase F(0), NADH deshydrogenase1 C1). In parallel, we observed a reduction in proteins key for mitochondrial clearance such as E3 ubiquitin ligases (RNF181, MARCHF5), as well as lysosomal acidification (Proton-transporting V-Type ATPase), in SLE NK cells.

Conclusion: SLE NK cells exhibit impaired mitochondrial respiration, which is linked to an accumulation of large mitochondria with cristae disorganization. These results suggest an alteration in mitochondrial degradation in SLE NK cells related to dysfunctional mitophagy. Taken together, these data suggest that impaired mitochondrial function and homeostasis represent a major feature of SLE pathogenesis.

OP0021 STRATIFICATION OF PATIENTS WITH SJÖGREN'S SYNDROME BY JOINT MULTI-MODAL ANALYSIS OF CIRCULATING B CELLS

Keywords: Sjögren syndrome, Adaptive immunity, Autoantibodies

G. Arvidsson[1], P. Czarnewski[2], A. Johansson[3], A. Raine[1], J. Imgenberg-Kreuz[3], J. Nordlund[1], G. Nordmark[3], A. C. Syvänen[1]. [1]*Uppsala University, Department of Medical Sciences, Molecular Precision Medicine, and Science for Life Laboratory, Uppsala, Sweden*; [2]*Stockholm University, Science for Life Laboratory, Department of Biochemistry and Biophysics and National Bioinformatics Infrastructure Sweden, Solna, Sweden*; [3]*Uppsala University, Department of Medical Sciences, Rheumatology, and Science for Life Laboratory, Uppsala, Sweden*

Background: B cells are important in the pathogenesis of primary Sjögren's syndrome (pSS) with hypergammaglobulinemia, SSA/SSB autoantibodies and an increased risk of B cell lymphoma [1]. Patients with pSS positive for SSA/SSB autoantibodies are more prone to systemic disease manifestations and adverse outcomes. Only few studied have investigated peripheral blood mononuclear cells at single cell resolution and primarily reported differences in the T cell compartment while the B cells were only briefly considered [2,3].

Objectives: We aimed to determine the role of peripheral B cell subtype composition, gene expression and B cell receptor (BCR) usage in patients with pSS stratified for SSA/SSB antibodies.

Methods: Over 230 000 B cells were isolated by negative selection from peripheral blood of 24 pSS patients (n=6 SSA+, n=8 SSA- and n=10 SSA and SSB+ (SSAB)) and four healthy controls. Single cell gene expression and targeted BCR libraries were generated and processed for RNA and VDJ sequencing.

Results: Gene expression-based clustering and cell annotation defined 16 B cell subtypes. We show that pSS patients have a heterogeneous circulating B cell composition, with SSAB patients presenting the highest and lowest proportion of naïve and memory B cells, respectively. Interferon-induced genes were upregulated across all B cell subtypes with the highest levels in the SSAB group. Differential usage of Immunoglobulin Heavy Chain (*IGH*) genes, showed that memory B cells from SSAB patients displayed a higher proportion of *IGHM* expressing cells and cells with unmutated VDJ transcripts, including *IGHV1-69* and *IGHV4-34*, compared to other pSS patient groups and controls, indicating altered somatic hypermutation and class switching processes. Comparison with

previous studies revealed heterogeneous clonotype pools, with little overlap in CDR3 sequences. Joint principal component analysis using scRNA-seq and scVDJ-seq data including B cell subtype composition, IFN-score, *IGH* constant gene usage, *IGHV* usage and VDJ mutation status allowed unsupervised stratification pSS patients that correlated to disease manifestations and antibody status.

Conclusion: Combining single cell gene expression and VDJ sequence data we describe heterogeneity and molecular characteristics in B cells from pSS patients with different autoantibody profiles. Our results may provide clues to intrinsic differences in B cells that affect the phenotype and outcome, and allow stratification of pSS patients at improved resolution.

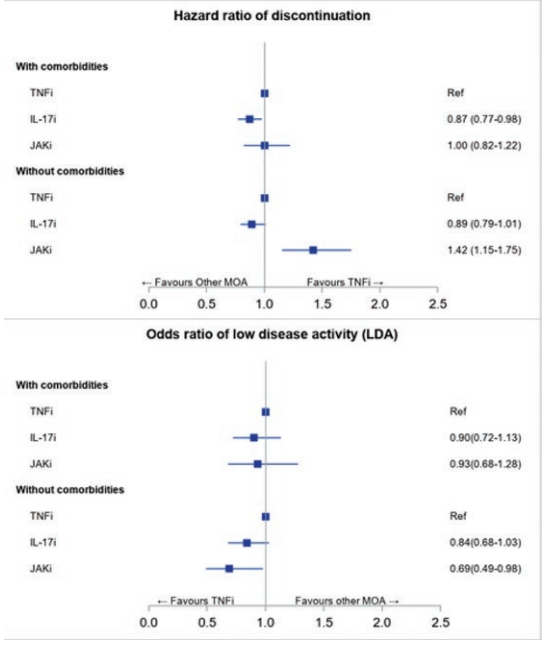
Background: Considering recent safety concerns for JAK-inhibitors (JAKi), clinicians need to make informed treatment decisions balancing expected effectiveness against risk for adverse events (AE). Current guidelines specifically caution that the use of JAKi in patients with pre-existing comorbidities increases risk of AE, but more data are needed regarding expected drug performance in these patients.

Objectives: To compare 1-year treatment retention and 6-month effectiveness in PsA patients with or without comorbidities at treatment start for A) IL17i versus TNFi, and B) JAKi versus TNFi.



Methods: Patients with PsA starting TNFi, IL17i or JAKi in routine care (years 2012-2020), were included from 5 Nordic rheumatology registries. Due to preferred use of IL17i and JAKi in bDMARD-experienced patients, b/tsDMARD naïve patients were excluded. Baseline patient characteristics were identified, as well as 6- and 12-month follow-up data. Linkage to national patient registries was used to identify comorbidities at treatment start (0-5 years for congestive heart disease, ischemic heart disease, thrombosis, depression/anxiety, chronic obstructive or interstitial pulmonary disease, diabetes, hospitalized infection, and chronic kidney disease; ever for malignancies). Hazard ratios (HR) for discontinuation at 1 year were estimated through Cox regression, while odds ratios (OR) at 6 months for low disease activity (LDA, DAPSA28≤14, LUNDEX adjusted) were estimated using logistic regression (adjusted for baseline variables, see Figure 1 text). Multiple imputation was performed to account for missing baseline data. For sensitivity, analyses limiting the TNFi group to adalimumab-treated patients were performed.

Results: A total of 10 276 treatment starts among 6118 patients with PsA were included. Patients initiating a TNFi were more often men and more often used concomitant csDMARDs, and they were less likely to have any (vs. none) of the above-mentioned comorbidities at treatment start (43%) compared to IL17i (46%) and JAKi (55%). IL17i and JAKi were frequently used in patients having failed >3 b/tsDMARDs (Table 1). Patients with a comorbidity were less likely to discontinue IL17i vs. TNFi (HR=0.87, 95%CI 0.77-0.98), no difference was seen for JAKi vs TNFi. Patients without comorbidities were less likely to discontinue IL17i than TNFi but more likely to discontinue JAKi (HR=1.42, 1.15-1.75) (Figure 1). For LDA, among patients with at least one co-morbidity, there was no difference in the chance of reaching LDA between TNFi (33%), IL17i (30%) and JAKi (29%). Among patients without comorbidities, the odds of reaching LDA were lower for JAKi and for IL17i vs. TNFi (Figure 1). Sensitivity analyses replacing TNFi with adalimumab showed similar estimates for both discontinuation and effectiveness (not shown).

Table 1. Baseline characteristics and outcomes stratified by previous comorbidities and treatment. Numbers are mean (SD) unless otherwise stated

Figure 1
Discontinuation at 1 year with hazard ratio (HR), and effectiveness at 6 months with odds ratio (OR) of low disease activity (LDA).Adjusted for age (and the quadratic term), sex, country, line of treatment, disease duration, csDMARD use, C-reactive protein, patient global score, and treatment start year. MOA=Mode of action

Conclusion: Comorbidities impact treatment outcomes in patients with PsA. The retention and effectiveness of JAKi and TNFi are similar in patients with (but not in patients without) at least one pre-existing comorbidity. Further analyses exploring impact of the number of comorbidities and of specific comorbidities are planned.

Objectives: This study aimed to: 1) Analyze the circulating inflammatory profile of Rheumatoid Arthritis (RA) patients, in order to recognize distinctive clinical phenotypes associated with CV risk; 2) Evaluate modulatory effects of TNF inhibitors (TNFi), JAK-STAT inhibitors (JAKInibs) and IL-6R inhibitors (IL6Ri); 3) Characterize underlying molecular mechanisms involved in endothelial dysfunction.
Methods: Two hundred and eight RA patients and 45 healthy donors (HD) were recruited. Serum inflammatory profile was assessed by analyzing 27 cytokines/chemokines -Luminex assays-, and biomolecules related to NETosis and oxidative stress -by base-plate kits-. Parallel extensive clinical analyses were performed. TNFi, JAKinibs and IL-6Ri effects were evaluated, respectively, in 45, 20 and 17 RA patients after 6 months. Lastly, mechanistic *in vitro* studies were developed in cultured endothelial cells (ECs) and changes in protein expression were evaluated in cell lysates by proximity extension assay technology, analyzing a panel of 88 proteins related to CV disease.
Results: Unsupervised-clustering identified 3 clusters representing specific molecular profiles. Clinically, even in the presence of similar disease score (DAS28) and positivity for autoantibodies, cluster 1 (C1) identified RA-patients expressing high inflammatory mediators' levels, the highest CV-risk score, and a preponderance of atheroma plaques. Conversely, RA-patients conforming C3 showed the lowest inflammatory profile and the lowest CV-risk score. Lastly, C2 characterized an intermediate phenotype. Comparative analyses with a cohort of 98 RA patients presenting previous CV events, demonstrated that their inflammatory profile mimicked that found in C1, supporting the association of this altered shape with the CV status. *In vivo*, both biological and targeted-synthetic DMARDs' therapy reduced DAS28-score and re-established normal levels of several altered biomolecules, reflecting a key role in the CV-risk control. *In vitro*, RA patients' serum pool from cluster 1 promoted in cultured ECs increased expression of several CV-related proteins, further prevented-albeit in an specific way- by the pre-incubation with TNFi (Etanercept), JAKinibs (Baricitinib) and anti-IL6Ri (Tocilizumab).
CONCLUSION:
1. The systemic inflammatory profile of RA identified patients' subgroups with enhanced CV-risk, not associated with their disease activity status.
2. Both biological and targeted-synthetic DMARDs re-established normal levels of circulating inflammatory biomolecules, reducing the CV-risk in RA.
3. *In vitro* studies revealed that RA-serum inflammatory mediators directly induced endothelial damage which might be prevented by effect of both, biological and targeted-synthetic DMARDs' therapy.

Thus, the analysis of the RA patients circulating molecular profile might contribute to improve the personalized clinical management of these patients and their CV risk.

OP0024 DOES ANTIRHEUMATIC MEDICAL TREATMENT OF RHEUMATOID ARTHRITIS AFFECT SURVIVAL AFTER FIRST ACUTE MYOCARDIAL INFARCTION

Keywords: Comorbidities, Disease-modifying drugs (DMARDs), Cardiovascular disease

M. Skielta[1], L. Söderström[2], S. Rantapää Dahlqvist[1], A. Södergren[1], T. Mooe[3]. [1]*Umea University, Public Health and Clinical Medicine/Rheumatology, Umea, Sweden*; [2]*Östersund Hospital, Unit of Research, Östersund, Sweden*; [3]*Umea University, Public health and Clinical Medicine, Östersund, Sweden*

Background: Our previous study showed that rheumatoid arthritis (RA) was associated with higher one-year mortality after first acute myocardial infarction (AMI). Studies have shown increased mortality already within 30 days after cardiovascular events (AMI or stroke) in RA patients compared to non-RA patients.
Objectives: We aimed to study if antirheumatic medical treatment affected survival within 30 days after a first AMI in patients with RA versus non-RA patients.
Methods: Data for 198944 patients with a first AMI were drawn from the Swedish Register of Information and Knowledge about Swedish Heart Intensive Care Admissions for 2006-2017. We used the National Patient Register to identify RA patients with AMI. RA was defined as ≥2 visits to a Rheumatology or Internal Medicine department with a diagnosis of RA, 3725 patients were diagnosed. Antirheumatic medical treatment prescribed during six months prior to the first AMI in RA and non-RA patients was obtained from the National Prescribed Drug Register. The drugs and all their combinations were divided into five groups: Corticosteroids, NSAID (Non-steroidal anti-inflammatory drug), csDMARD (conventional syntethic Disease-modifying antirheumatic drug), anti-TNF (anti Tumor Necrosis Factor), bDMARD (biological Disease-modifying antirheumatic drug). Logistic regression analysis was used to identify variables associated with increased mortality within 30 days after first AMI in each treatment group.
Results: Increased risk of death was found in the corticosteroid group in both non-RA and RA groups (OR 1.61 and 1.66). Treatment with csDMARD and anti-TNF in the RA group were associated with increased survival (OR 0.81 and 0.72), Table 1.
Conclusion: We showed that patients treated with corticosteroids had an increased risk of death after first AMI. RA patients treated with csDMARD and anti-TNF had an increased survival which could imply that high inflammatory activity in RA patients may be part of the explanation of the increased mortality after first AMI.

MORTALITY AND MAJOR ADVERSE CARDIOVASCULAR EVENTS AFTER GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONIST INITIATION IN PATIENTS WITH AUTOIMMUNE DISEASES AND TYPE 2 DIABETES: A POPULATION-BASED STUDY

Keywords: Cardiovascular disease, Comorbidities, Epidemiology

D. Karacabeyli[1], N. Lu[2,3], N. Mccormick[2,3], H. Choi[2,3], D. Lacaille[1,2], J. A. Aviña-Zubieta[1,2]. [1]*The University of British Columbia, Medicine (Division of Rheumatology), Vancouver, Canada*; [2]*Arthritis Research Canada, Rheumatology, Vancouver, Canada*; [3]*Massachusetts General Hospital, Medicine (Division of Rheumatology, Allergy, and Immunology), Boston, United States of America*

Background: Patients with autoimmune rheumatic diseases are at higher risk of cardiovascular complications and premature mortality[1,2], possibly related to chronic inflammation. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are used to treat type 2 diabetes and obesity (two pro-inflammatory states associated with systemic autoimmune diseases) and have anti-inflammatory properties[4], but their clinical effects on cardiovascular outcomes and mortality in patients with autoimmune diseases remain unknown.
Objectives: To assess the risk of all-cause mortality and major adverse cardiovascular events (MACE) in patients with autoimmune diseases and type 2 diabetes initiating GLP-1 RAs versus dipeptidyl peptidase-4 inhibitors (DPP-4is).
Methods: We performed a sequential propensity score (PS) overlap weighted population-based cohort study using administrative health data from British Columbia. Data included diagnostic codes from physician visits and hospitalizations in a universal health care system, all pharmacy-dispensed medications, and vital statistics from January 1, 2010, to December 31, 2021. All patients with an autoimmune disease (i.e., rheumatoid arthritis, psoriatic disease, ankylosing spondylitis, inflammatory bowel disease, or a systemic autoimmune rheumatic disease) and type 2 diabetes who newly initiated a GLP-1 RA or DPP-4i were identified using ICD-9/10 codes. The primary outcome of interest was all-cause mortality. The secondary outcome was MACE (composite of cardiovascular death, myocardial infarction, and ischemic stroke). Herpes zoster reactivation was assessed as a negative control outcome. Cox proportional hazard regression models with PS overlap weighting were used.
Results: We identified 10,855 patients with autoimmune diseases and type 2 diabetes who newly initiated a GLP-1 RA or DPP-4i. All-cause mortality rate was lower among initiators of GLP-1 RAs compared to initiators of DPP-4is, with a weighted hazard ratio (HR) of 0.48 (95% CI, 0.31-0.75) and rate difference (RD) of -9.4 (95% CI, -16.0 to -2.7) per 1000 person-years (Table 1). Rates of MACE were also lower with GLP-1 RA versus DPP-4i exposure (HR 0.66 [CI, 0.50-0.88], RD -10.5 [CI, -20.4 to -0.8]). There was no difference in the risk of herpes zoster reactivation (HR 0.96 [CI, 0.65-1.43).
Conclusion: In patients with autoimmune diseases and type 2 diabetes, GLP-1 RA exposure is associated with a lower risk of all-cause mortality and MACE compared to DPP-4i exposure. Further research is needed to explore potential adiposity-dependent and independent mechanisms through which GLP-1 RAs may reduce cardiovascular risk for patients with autoimmune rheumatic diseases.

INCREASED VASCULAR INFLAMMATION ON PET-CT IN PSORIATIC ARTHRITIS PATIENTS IN COMPARISON WITH HEALTHY CONTROLS

Keywords: Psoriatic arthritis, Cardiovascular disease, Imaging

N. J. Kleinrensink[1,2], W. Foppen[2], N. Seddiqi[2], H. Vonkeman[3], K. Suijkerbuijk[4], M. Jansen[1], P. De Jong[2], M. W. Heijstek[1], J. Spierings[1]. [1]*UMC Utrecht, Department of Rheumatology & Clinical Immunology, Utrecht, Netherlands*; [2]*UMC Utrecht, Department of Radiology, Utrecht, Netherlands*; [3]*Medisch Spectrum Twente, Department of Rheumatology, Enschede, Netherlands*; [4]*UMC Utrecht, Department of Medical Oncology, Utrecht, Netherlands*

Background: Patients with psoriatic arthritis (PsA) have an increased risk of cardiovascular disease, possibly due to a chronic inflammatory state.

Objectives: The main objective of this study was to investigate whether vascular inflammation, measured with 18-fluorodeoxyglucose positron emission tomography/computed tomography (PET/CT), is elevated in PsA patients.
Methods: We included 75 PsA patients with active peripheral arthritis (≥2 tender and swollen joints) from an ongoing clinical trial (EudraCT 2017-003900-28), and a retrospective group of 40 controls with melanoma, without distant metastases and not receiving immunotherapy. Both PsA patients and controls were aged 18-75 years. The main outcome measure was aortic vascular inflammation, which was measured using target-to-background-ratios (TBR) on PET/CT. Clinical disease activity in PsA was assessed with joint counts, body surface area and the composite measure Disease Activity index for PsA. Laboratory assessments included the inflammatory parameters C-reactive protein and Erythrocyte Sedimentation Rate. Vascular inflammation was compared between PsA patients and controls in univariate analysis with an unpaired t-test with equal variances. A multiple linear regression analysis was performed to adjust for age, gender, body mass index and mean arterial pressure (MAP). Associations of clinical parameters of disease activity in PsA with vascular inflammation were assessed using Spearman's correlation coefficient.
Results: Vascular inflammation was increased in PsA patients in comparison with controls (mean TBR for entire aorta respectively 1.53±0.15 and 1.42±0.13; P<0.001; Figure 1). This association remained significant after adjusting for gender, age, body mass index and mean arterial pressure (P=0.002). In individuals with PsA, vascular inflammation was not associated with disease-related parameters. There were no significant differences between PsA patients and controls regarding age, mean arterial pressure (MAP) and history of CVD. PsA patients had a higher BMI in comparison with healthy controls (Table 1).
Conclusion: Aortic vascular inflammation was increased in patients with active PsA compared with controls. This evidence suggests that inflammation in PsA is not limited to skin and joints, but also involves the cardiovascular system.

Table 1. Patients' characteristics

Characteristic[a]	PsA (N=75)	Controls (N=40)	p-value

University of Perugia., Department of Medicine and Surgery, Perugia, Italy*

Background: Rheumatoid arthritis (RA) patients are at high risk for atherosclerotic cardiovascular disease (CVD) and mortality, and dyslipidemia represents a modifiable CV risk factor significantly contributing to the increased risk. However, dyslipidemia is frequently underestimated and inadequately managed in rheumatologic clinical practice.
Objectives: The aim of the present study was to investigate how dyslipidemia in RA patients is managed in a real-life setting for primary prevention strategies.
Methods: A cross-sectional study of RA patients of the Cardiovascular Obesity and Rheumatic DISeases (CORDIS) cohort [1], with no previous CVD and with available lipid levels was performed. All patients were stratified by the Systematic COronary Risk Evaluation (SCORE) algorithm for CV risk [2] and the application of primary preventive strategy was assessed in accordance with the 2019 European Society of Cardiology (ESC)/European Atherosclerosis Society (EAS) guidelines for the management of dyslipidaemias [3].
Results: A total of 1296 RA patients (79% females) with a mean age of 59±12 years were included. According to the SCORE algorithm, 457 (35.5%) patients were at moderate CV risk (1-5%), 455 (35.1%) at high CV risk (5-10%), and 384 (29.6%) at very high (>10%) CV risk. None was at low CV risk (<1%). Eighty percent of the whole cohort was eligible for statin therapy, but only 22.3% was on treatment at inclusion, and 38.2% presented lipid levels on target. Among patients at high and/or very-high SCORE risk, 70% were not on statin treatment even if recommended and 26.7% were not at lipid target even if under statin use. Among patients at moderate SCORE risk, 208 (45.5%) were at lipid target and 31(14.9%) of them were on statin therapy. Globally 565 (43.6%) patients were not on treatment for dyslipidemia even if recommended according to ESC/EAS guidelines (Figure 1). Of note, about 80% of RA patients at high or very high CV risk were on anti-hypertensive and/or antiaggregant treatment.
Conclusion: Statin therapy prescription is suboptimal in RA despite a relevant proportion of patients meeting indications according to LDL thresholds and/or

SCORE algorithm. Preventive CV strategies seem mainly focused on anti-hypertensive or antiplatelet therapy. Rheumatologists should pay close attention to lipid levels and preventive therapeutic interventions to reduce the CV risk of RA patients.

IMMUNOMODULATORY MEDICATIONS AND OUTCOMES OF PATIENTS WITH PRE-EXISTING RHEUMATOID ARTHRITIS USING IMMUNE CHECKPOINT INHIBITORS TO TREAT CANCER

Keywords: Malignancy, Rheumatoid arthritis

S. Arabelovic[1], K. Mccarter[2], T. Wolfgang[1], X. Wang[1], K. Yoshida[1], E. Banasiak[1], G. Qian[1], E. Kowalski[1], K. Vanni[1], N. Leboeuf[3], E. Buchbinder[4], L. Gedmintas[1], L. Macfarlane[1], D. Rao[1], N. Shadick[1], E. Gravallese[1], J. Sparks[1].
[1]*Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, United States of America*; [2]*Brigham and Women's Hospital, Department of Medicine, Boston, United States of America*; [3]*Brigham and Women's Hospital, Department of Dermatology, Boston, United States of America*; [4]*Dana-Farber Cancer Institute, Department of Medicine, Boston, United States of America*

Background: Immune checkpoint inhibitors (ICI) stimulate the immune system to treat cancer but may cause flares of pre-existing immune-mediated diseases such as rheumatoid arthritis (RA). Disease-modifying antirheumatic drugs (DMARDs) used to treat RA may attenuate ICI efficacy. Studies suggest that experiencing flare of a pre-existing disease after ICI may portend a mortality benefit, but no studies have examined whether RA flare after ICI initiation is associated with mortality.
Objectives: To describe the management and outcomes of patients with pre-existing RA after ICI initiation for cancer.
Methods: Retrospective cohort study of patients with pre-existing RA initiating ICI for cancer treatment at Dana-Farber Cancer Institute and Mass General Brigham in Boston, MA, USA (April 2011 to April 2022). Included patients: 1) RA diagnosis code prior to ICI initiation, 2) Met 2010 ACR/EULAR RA criteria by record review. We performed medical record review for data on demographics, cancer, RA disease activity/flares after ICI initiation, DMARDs, ICI disruption, and mortality. We described DMARDs at ICI initiation and for treatment of RA flares. We examined whether RA flare after ICI initiation was associated with mortality using Cox regression in a landmark analysis of those who survived at least 3 months after ICI initiation.
Results: Among 11,901 patients who initiated ICI for cancer treatment, 100 pre-existing RA patients were included (mean age 70.3 years, 63% female, 89% on PD-1 monotherapy, 50% lung cancer). At ICI initiation, 82% had remission/low RA disease activity, 24% were on glucocorticoids (median prednisone dose 10 mg/day), 35% on conventional DMARDs and 10% on biologic DMARDs (**Table 1**). None discontinued glucocorticoids and 3/35 (9%) discontinued DMARDs in anticipation of starting ICI. RA flare after ICI occurred in 46/100 (46%, **Figure 1**) (grade 1 in 16/46 [35%], grade 2 in 25/46 [54%], grade 3 in 5/46 [11%]; 2/46 [4%] required hospitalization for RA flare); 15/46 (33%) that flared had a concomitant immune-related adverse event. RA flares occurred a median of 7 days (IQR 4, 21), usually after the first ICI infusion (ICI cycle IQR 1, 3). RA flares were treated with glucocorticoids (36/46, 78%), often prescribed by oncologists (19/36, 53%), and median initial prednisone dose was 20 mg/day. Treatments of RA flares included DMARDs (19/46, 41%), NSAIDs (12/46, 26%), and intra-articular glucocorticoid injections (5/46, 11%). DMARDs used to treat RA flare included: methotrexate (6/19, 32%), TNF inhibitors (4/19, 21%), hydroxychloroquine (3/19, 16%), sulfasalazine (2/19, 11%), and rituximab (1/19, 5%). ICI was paused or discontinued due to RA flare in 6/46 (13%). Among those who survived at least 3 months, RA flare was not associated with mortality (adjusted hazard ratio 1.24, 95%CI 0.71-2.16).
Conclusion: In this largest study to date of patients with pre-existing RA initiating ICI, 46% flared, often after initial ICI infusion, but were mostly mild and managed with typical therapies. A minority had severe RA flares requiring disruption of ICI, but RA flares were not associated with mortality. These results reiterate that pre-existing RA should not be considered a contraindication to ICI treatment for cancer.

Table 1. Characteristics at index date of immune checkpoint inhibitor initiation.

	Pre-existing RA patients (n=100)
Mean age, years (SD)	70.3 (10.6)
Female sex	63%
PD-1/PD-L1 monotherapy	93%
CTLA-4 and combination	7%
Lung cancer	50%
Melanoma	20%
Genitourinary tract cancer	9%
Median RA duration, years (IQR)	9.4 (4.8, 17.4)
Seropositive	59/83 (71%)
Most recent disease activity	
Remission/low	63/77 (82%)
Moderate/high	14/77 (18%)
Glucocorticoid	24%
Hydroxychloroquine	15%
Sulfasalazine/leflunomide	11%
Methotrexate	9%
Rituximab	5%
IL-6 receptor inhibitors	2%
Tumor necrosis factor inhibitors/tofacitinib	3%

Cappelli[11]. *[1]Hospital for Special Surgery/Weill Cornell Medicine, Rheumatology, New York, United States of America*; *[2]MD Anderson, Internal Medicine, Houston, United States of America*; *[3]University of Chicago, Rheumatology, Chicago, United States of America*; *[4]Brigham and Women's Hospital, Rheumatology, Boston, United States of America*; *[5]Cleveland Clinic, Rheumatology, Cleveland, United States of America*; *[6]Hospital for Special Surgery, Rheumatology, NEW YORK, United States of America*; *[7]Hospital for Special Surgery/Weill Cornell Medicine, Rheumatology, NEW YORK, United States of America*; *[8]MD Anderson, Medicine, Houston, United States of America*; *[9]Detroit Medical Center, Medicine, Detroit, United States of America*; *[10]MD Anderson, Melanoma Medical Oncology, Houston, United States of America*; *[11]Johns Hopkins University, Rheumatology, Baltimore, United States of America*

Background: Immune checkpoint inhibitor associated arthritis (ICI-A) commonly persists for months to years, even after ICI cessation.[1]

Objectives: To compare the safety and effectiveness of biologic and conventional disease modifying anti-rheumatic drugs (DMARDs) for ICI-A.

Methods: Retrospective multicenter observational study. Inclusion: 1) diagnosis of ICI-A and 2) treatment with a tumor necrosis factor inhibitor (TNFi), interleukin-6 receptor inhibitor (IL6Ri) and/or methotrexate (MTX). Exclusion: preexisting autoimmune disease. The primary outcome was time to cancer progression from ICI initiation. Patients whose cancer progressed prior to DMARD initiation were excluded from this analysis. The secondary outcome was time to arthritis control from DMARD initiation, defined as grade 1 arthritis and prednisone ≤10mg/day. Cox proportional hazard models were generated, adjusting for confounders. A sensitivity analysis was performed incorporating a time dependent variable "time from ICI initiation to DMARD initiation."

Results: 147 patients were included, mean (SD) age 60.3 (11.9) years, 66 (45%) females. Sixty percent had received PD1/PDL1 monotherapy, 30% received combination CTLA4/PD1. Eighty percent had stage IV cancer. ICI-A treatment was TNFi in 33 (22%), IL6Ri 42 (29%), MTX 72 (49%) (**Table 1**). A Kaplan-Meier curve showing time to cancer progression by DMARD is shown in **Figure 1**. In an unadjusted Cox model with MTX as the reference, time to cancer progression with a TNFi was HR 2.51 (95% CI 0.91-6.93, p=0.075) and for IL6Ri HR 2.36 (95% CI 0.91-6.12, p=0.078). After adjustment for the time dependent variable, time to cancer progression was significantly shorter for TNFi-treated patients compared to MTX, HR 3.27 (95% CI 1.21-8.84, p=0.019). The result for IL6Ri was HR 2.31 (95% CI 0.98-5.41, p=0.055). Time to arthritis control was significantly faster for TNFi compared to MTX, HR 1.91 (95% CI 1.06-3.45, p=0.032) in an adjusted Cox model. Results for IL6Ri were HR 1.66 (95% CI 0.93-2.97, p=0.089). Results for cancer progression and arthritis control were similar in the subset of patients with melanoma.

Conclusion: Treatment of ICI-A with biologic DMARDs is associated with more rapid arthritis control than with MTX but may be associated with a shorter time to cancer progression. A prospective randomized controlled trial is needed to verify these findings and to identify the optimal approach to managing patients with high grade ICI-A.

Improving our understanding of RMDs in children and young people

OP0030 DIFFERENTIAL GENE EXPRESSION IN RESPONSE TO TOFACITNIB TREATMENT IN POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS

Keywords: bDMARD, -omics, Inflammatory arthritides

E. Eloseily[1], A. Pickering[2], S. Dhakal[1], H. Brunner[1,3], A. Grom[1,3], S. Thornton[1,3]. *[1]Cincinnati Children's Hospital Medical Center, Division of Pediatric Rheumatology, Cincinnati, United States of America*; *[2]Harvard Medical School, Department of Biomedical Informatics, Boston, United States of America*; *[3]University of Cincinnati, Department of Pediatrics, Cincinnati, United States of America*

Background: Despite advances in the understanding of juvenile idiopathic arthritis (JIA) pathophysiology, personalized treatments informed by gene transcriptomic profiles remain elusive.
Objectives: To examine the relationship between changes in gene expression and treatment response in patients with JIA treated with tofacitinib.
Methods: Whole blood samples from patients with JIA were collected using Paxgene tubes at baseline (BL) and again at week (wk) 18 of treatment with tofacitinib as part of a clinical trial (NCT02592434) [1]. Patients were classified as treatment responders (TR) if they achieved at least a JIA-American College of Rheumatology score of (JIA-ACR70) or above (N_{BL}=47; N_{WK18}=38); and non-responders (NR) improvement was no more than a JIA-ACR30 response (N_{BL}=20; N_{WK18}=8). Bulk RNA was isolated, subjected to globin/rRNA depletion, and used for generation of cDNA libraries for subsequent sequencing. RNA sequencing via Illumina Nova-seq generated 50 million reads per sample. Gene expression was compared in TR and NR (BL, wk18; change BL to wk18). Kallisto 0.48.0 was used for pseudo-quantification (GRCh38 release 94 index). Differential expression and Gene Ontology (GO) over-representation analyses were performed with dseqr 0.34.0.
Results: Significant differential expression (FDR<0.05) was observed in 10,138 genes between BL and wk18. GO over-representation analysis was performed separately for up- and down-regulated genes with FDR<0.05 and absolute logFC>0.8 (n=231). For genes down-regulated with treatment (BL-wk18), ontologies related to negative regulation of gene expression, type I and type II interferon pathways were significantly over-represented (FDR<0.05), while ontologies for synapse organization and activity were over-represented among up-regulated genes (Figure 1). The latter might reflect the normalization of the immunological synapse leading to improved cytotoxic NK and T cell functions, the impairment of which has been proposed to escalate the production of IFN-γ and other proinflammatory cytokines [2]. There were no significantly differentially expressed genes (FDR < 0.05) between TR vs. NR at BL or wk18. Exploratory GO analysis in NR vs. TR at baseline (FDR<0.13, n=76 genes) suggests up-regulation of genes in ontologies related to the activation of MAP kinase activity.
Conclusion: Tofacitinib treatment in JIA patients leads to widespread changes in whole blood transcriptional profiles. The most significant transcriptional changes observed included the down-regulation of genes associated with type I and type II interferon pathways, and the up-regulation of genes involved in synapse organization and activity. Potential association of MAP-kinase activation in NR at baseline needs to be further explored. MAP-kinase is one of the signalling pathways in inflammatory arthritis that can be targeted by small molecules other than JAK inhibitors. Thus, patients with a predominantly active MAP-kinase pathway could be less likely to respond to tofacitinib. If confirmed, these findings might be useful to personalize JIA treatment in the future.

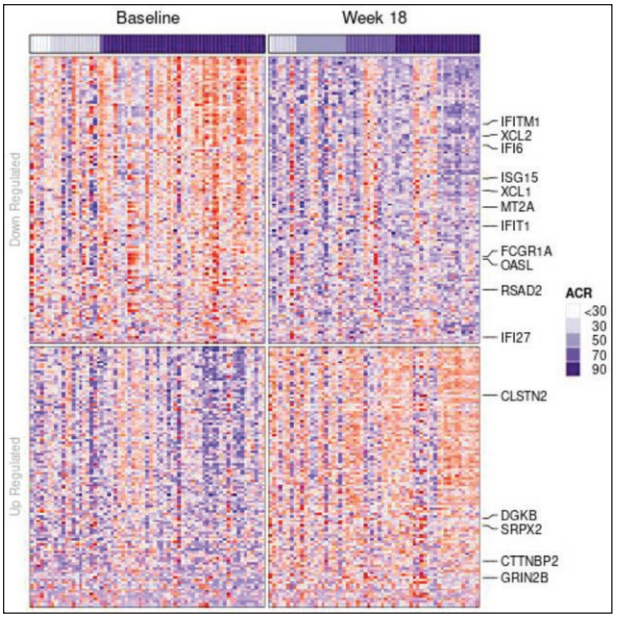

Figure 1. Heatmap showing differentially expressed genes (FDR < 0.05 and |logFC| > 1) at week 18 vs baseline in JIA patients receiving tofacitinib. Annotated genes are from ontologies related to type I and type II interferon activity (down-regulated), as well as from ontologies related to synapse organization (up-regulated).

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children. Our group has recently demonstrated that extended oligoarticular and polyarticular JIA mostly evolve to a rheumatoid arthritis (RA)-like phenotype in adulthood. Disturbances in B cells, T follicular helper (Tfh) and T follicular regulatory (Tfr) cell immune responses are associated with RA pathogenesis, but their exact role in JIA development is poorly understood.
Objectives: The main goal of this study was to characterize the frequency and phenotype of B, Tfh and Tfr cells in peripheral blood and the cytokine environment present in circulation in children with with extended oligoarticular JIA (eoJIA) and polyarticular JIA (pJIA) when compared to healthy controls, children with persistent oligoarticular JIA (poJIA) and adult JIA patients.
Methods: Blood samples were collected from 105 JIA patients (children and adults) and 50 age- and gender-matched healthy individuals. Peripheral blood mononuclear

cells were isolated and the frequency and phenotype of B, Tfh and Tfr cells were evaluated by flow cytometry. Serum levels of APRIL, BAFF, IL-1β, IL-2, IL-4, IL-6, IL-10, IL-17A, IL-21, IL-22, IFN-γ, PD-1, PD-L1, sCD40L, CXCL13 and TNF were measured by multiplex bead-based immunoassay and/ or ELISA in all groups included.
Results: The frequency of B, Tfh and Tfr cells was similar between JIA patients and controls. Children with eoJIA and pJIA, but not poJIA, had significantly lower frequencies of plasmablasts, regulatory T cells and higher levels of Th17-like Tfh cells in circulation when compared to controls. Furthermore, APRIL, BAFF, IL-6 and IL-17A serum levels were significantly higher in pediatric eoJIA and pJIA patients when compared to controls. These immunological alterations were not found in adult JIA patients in comparison to controls.
Conclusion: Changes in B and Tfh cell subpopulations, but not in Tfr cells, were found in peripheral blood of children with eoJIA and pJIA when compared to controls. Our results suggest a potential role and/ or activation profile of B and Th17-like Tfh cells in the pathogenesis of eoJIA and pJIA, but not poJIA.

OP0032 MULTI-PARAMETRIC ANALYSIS EVIDENCES TRAFFICKING OF CIRCULATORY CXCR3+CCR6+ CD4+ T CELLS AS A SOURCE OF TH1- AND TH17-MEDIATED INFLAMMATION IN THE ENTHESITIS-RELATED ARTHRITIS (ERA) SYNOVIUM

Keywords: Synovium, Adaptive immunity, Cytokines and chemokines

S. H. Tay[1,2], J. Y. Leong[2,3], M. Wasser[2,3], A. J. M. Lim[2], J. G. Yeo[2,3,4], T. Arkachaisri[3,4], S. Albani[2,3,4]. *[1]Duke-NUS Medical School, MD-PhD Programme, Singapore, Singapore*; *[2]Translational Immunology Institute, SingHealth Duke-NUS Academic Centre, Singapore, Singapore*; *[3]Duke-NUS Medical School, SingHealth Duke-NUS Paediatrics ACP, Singapore, Singapore*; *[4]KK Women's and Children's Hospital, Division of Medicine, Singapore, Singapore*

Background: Enthesitis-related arthritis (ERA), a common subtype of juvenile idiopathic arthritis (JIA), carries a poor prognosis. Current therapies, including anti-TNF agents, are limited in controlling disease. There is a poor understanding of ERA immunopathogenesis, especially the ontogeny of synovial pro-inflammatory T cells, which limits prognostic and therapeutic targets.
Objectives: We aim to compare, using a high-dimensional approach, the synovial and circulatory immune architectures of active ERA patients. Through this, we aim to identify CD4+ T cell subsets strongly associated with synovial inflammation in active ERA patients. We also aim to assess differentiation, cytokine production and regulation of candidate CD4+ T cell subsets.
Methods: We interrogated, using mass cytometry, CD45+ immune cells from the synovium (n=10) and circulation (n=30) of ERA patients with active joint inflammation, as well from blood of healthy paediatric controls (n=30). FlowSOM clustering were performed with functionally and phenotypically important immune markers. Multiple Mann-Whitney U tests with Holm-Sidak correction identified significantly different cluster frequencies. Significant clusters were validated with supervised gating on FlowJo. To evaluate CXCR3+CCR6+ CD4+ T cells, we sorted CXCR3+CCR6+ Teffs and Tregs from active ERA SFMCs and PBMCs with FACS. We then conducted in-vitro maturation and Treg suppression assays on sorted cells.
Results: The ERA synovium has a deranged immune architecture that is distinct from the circulation, and this involves innate and adaptive immune perturbations. The ERA synovium is enriched with CD4+ T effector memory cells (median: 68.45% vs. 23.85% of total CD4+ T cells; p<0.0001), of which IFNγ+ (44.85% vs. 4.08% of total CD4+ T cells; p<0.0001), IL-17A+ (2.62% vs. 0.66% of total CD4+ T cells; p<0.0001) and TNFa+ (10.64% vs. 2.52% of total CD4+ T cells; p<0.0001) producers dominate. The ERA synovium is also enriched with CXCR3+CCR6+ CD4+ T cells, which are present at lower numbers and activation status in the ERA circulation (6.64% vs. 2.00% of total CD4+ T cells; p<0.0001). Under in-vitro TCR stimulation, synovial CXCR3+CCR6+ CD4+ Teffs mature into IFNγ, IL-17A, and dual IFNγ-IL-17A producers. Synovial CXCR3+CCR6+ CD4+ Tregs are bona fide Tregs that suppress their Teff counterparts. However, CXCR3+CCR6+ CD4+ Tregs are not proportionately expanded relative to CXCR3+CCR6+ CD4+ Teffs in the ERA synovium.
Conclusion: In ERA, the immune architecture of the inflamed synovium is profoundly perturbed, whereby Th1 and Th17 cells are the main CD4+ T cell drivers of disease. CXCR3+CCR6+ CD4+ Teffs are possible precursors of Th1- and Th17-mediated synovial inflammation, and may be inadequately regulated during disease. The results provide mechanistic support for therapeutic targeting of the Th1 and Th17 pathways, as well as CXCR3 and CCR6 signalling to curb T cell-mediated inflammation.

OP0033 ANALYSIS OF B CELL SUBSETS AND B CELL CYTOKINES IN PEDIATRIC SJOGREN'S SYNDROME

Keywords: Sjögren syndrome, Cell biology, Adaptive immunity

R. Nicolai[1], C. Bracaglia[1], A. Boni[1], I. Caiello[1], D. Pires Marafon[1], F. De Benedetti[1], E. Marasco[1]. *[1]Bambino Gesu' Children Hospital, Unit of Rheumatology, Rome, Italy*

Background: Pediatric Sjögren's syndrome (pSS) is a rare disorder that is often diagnosed late due to the lack of validated diagnostic criteria and validated biomarkers. The pathogenesis is largely unknown, but there is evidence of involvement of both the innate and adaptive branch of the immune system. Immunological overactivity is central in the pathogenesis of pSS. Several studies showed the presence of B cells abnormalities in patients with SS with an expansion of naïve B cells and a decrease in the frequency of memory B cells.
Objectives: We set out to investigate the distribution of B cell subsets and B cell cytokines in patients with pSS at disease onset and at follow up visits.
Methods: A monocentric retrospective cohort study was conducted on 23 patients with pSS enrolled at the department of Rheumatology of Bambino Gesù Children's Hospital. Serum levels of CXCL13 and BAFF were analyzed by ELISA. B cell phenotype was assessed on peripheral blood mononuclear cells (PBMCs) by flow cytometry. Systemic disease activity was evaluated by ESSDAI (EULAR Sjogren's syndrome disease activity index) and Clinical-ESSDAI score (Clin-ESSDAI), according to 2020 EULAR recommendations; active disease was defined by ClinESSDAI ≥1 and remission by ClinESSDAI=0. As controls we selected age-matched people with no diagnosis of pSS or any other systemic autoimmune disease.
Results: Serum levels of CXCL13 and BAFF were significantly higher in patients with pSS than the control group (p<0.05) (Figure 1A). We correlated levels of biomarkers with clinical and laboratory parameters: we observed a positive correlation between hypergammaglobulinemia and BAFF (rho=+0,80). Analysis of B-cell subsets at disease onset revealed the expansion of a population of atypical memory B cells (p=0,00049) and a reduction in IgM memory B cells (p=0,0034) compared to the control group (Figure 1B). We then compared the distribution of B cell subpopulations at disease onset (pre) with samples obtained at follow-up (post) for each patient no significant differences were observed (Figure 1B). We also investigated the distribution of Tfh cells in patients with pSS and we observed a significant expansion of CXCR5$^-$PD1^{hi} T_{fh} (Figure 1B).
Conclusion: Patients with pSS showed high levels of CXCL13 and BAFF at disease onset. Alteration in B cell subsets are present in patients with pSS compared to controls, with an expansion of atypical memory B cells and T_{fh}. The B cell abnormalities are not affected by treatment. Our data confirm an hyperactivation of the humoral immune system in patients with pSS and provide evidence for their development as biomarkers and to develop new therapeutic strategies aimed at controlling B cell hyperactivation in pediatric patients with SS.

Background: Differential diagnosis in children with signs of unprovoked inflammation can be challenging. In particular, differentiating systemic-onset juvenile idiopathic arthritis (SJIA) from other diagnoses is difficult in individuals presenting with fever of unknown origin. We have recently validated myeloid-related protein 8/14 (MRP8/14, S100A8/A9, calprotectin) serum analyses as a helpful tool supporting the diagnosis of SJIA. The results could be confirmed with a commercial ELISA. However, further optimization of the analytical technology will be important to enable large-scale use in routine laboratory settings.
Objectives: To evaluate the accuracy in identifying children with SJIA, the performance of an immunoturbidimetric assay for measurements of serum-calprotectin (BÜHLMANN sCAL turbo) on an automated laboratory instrument was tested in serum samples of children with various conditions.
Methods: Samples from 650 children were available with diagnoses SJIA (n=99), non-systemic JIA (n=169), infections (n=51), other inflammatory diseases (n=161), and acute lymphatic leukemia (ALL, n=147). In addition, samples from 23 healthy controls were included. The patients with systemic inflammatory diseases were collected at Muenster University as reported before.[1] Patients with non-systemic JIA were from the Nordic JIA cohort as previously described in detail.[2] The ALL cohort included consecutive cases from Aalborg and Aarhus University Hospitals.[3] The BÜHLMANN sCAL turbo test is a particle enhanced immuno-turbidimetric assay (PETIA) and was compared to the established MRP8/14 ELISA from BÜHLMANN (EK-MRP8/14). The sCAL PETIA has a range of 230-15,000 ng/mL (extended range up to 225,000 ng/ml by dilution of 1:15) in sample volumes of only 2-3 µl and was implemented into the automated laboratory setting at the central clinical laboratory of the University Hospital Muenster as a rapid test available on demand.
Results: The sCAL turbo assay showed an excellent correlation to the MRP8/14 ELISA used in the previous validation studies (r=0.99, p<0.001). It could reliably differentiate SJIA from all other diagnoses with significant accuracy (cut-off at 9,100 ng/ml, sensitivity 93%, specificity 87%, ROC area under curve 0.961, p<0.001). Results are shown in Table 1 and Figure 1.

Table 1. Accuracy (ROC analyses) of sCAL turbo measurements in differentiating groups of patients

	SJIA vs all groups	*SJIA vs infections*	*SJIA vs ALL*	*SJIA vs others*
AUC (95%CI)	0.961 (0.943-0.978)	0.908 (0.862-0.953)	0.992 (0.985-0.999)	0.958 (0.934-0.981)
Cut-Off (ng/ml)	9,100	10,500	9,100	9,100
Sensitivity (%)	93	82	99	93
Specificity (%)	87	84	87	86

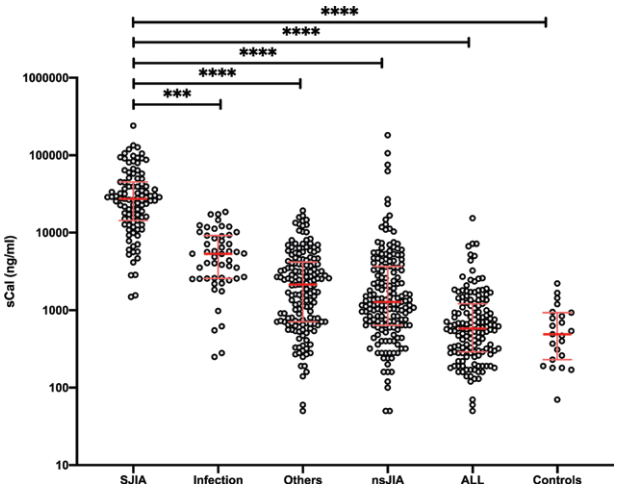

Figure 1. Results of sCAL turbo measurements in different groups of patients (red line showing median, error bars showing interquartile range; *** p<0.001, **** p<0.0001)

Conclusion: MRP8/14 (S100A8/A9, calprotectin) serum analyses have been validated as a helpful tool supporting the diagnosis of SJIA in children with prolonged fever or inflammatory disease. Here we show that an immunoturbidimetric assay for detection of serum-calprotectin on an automated laboratory instrument can be implemented in clinical laboratory settings to facilitate its use as a diagnostic routine test in clinical practice.

OP0035

THE USE OF CHILDHOOD LLDAS: FIRST RESULTS IN A REAL-LIFE LONGITUDINAL CHILDHOOD LUPUS COHORT SHOW GOOD FEASIBILITY BUT DIFFICULT ATTAINMENT

Keywords: Treat to target, Systemic lupus erythematosus

S. Bergkamp[1], T. Kanagasabapathy[1], M. Gruppen[1], T. Kuijpers[1], A. Nassar-Sheikh Rashid[1], J. M. Van den Berg[1], D. Schonenberg-Meinema[1]. [1]Amsterdam UMC, locatie AMC, Pediatric Immunology, Rheumatology and Infectious Diseases, Amsterdam, Netherlands

Background: Almost half of childhood-onset SLE (cSLE) patients show damage within 5 years after disease onset, which is partially disease- and partially

drug-related [1]. Therefore, the challenge in (c)SLE is not only to lower disease activity, but also to minimalize glucocorticoid toxicity. Treat-to-target (T2T) has been a new type of approach to improve long-term patient outcomes by adapting treatment regimens until the target is met. For T2T, the concept of Lupus-Low-Disease-Activity-State (LLDAS) as a target in SLE has been defined which contains a SLE disease activity index (SLEDAI) ≤ 4 and a maximum prednisolone use of 7.5mg/day [2]. This adult LLDAS (aLLDAS) has been shown to be a feasible target in cSLE patients and attainment leads to lowering risk for severe flare and cumulative damage [3]. Another cSLE cohort study demonstrated that all patients were able to reach aLLDAS (median 186 days) and 72.5% remained in aLLDAS >50% of time [4]. Recently, an international cSLE T2T Task Force has adapted the LLDAS definition specifically for cSLE patients (cLLDAS) by Delphi surveys and consensus meetings, with an addition of a calculated prednisolone dose per body weight in maximum dose of 0.15 mg/kg/day and an absolute maximum of 7,5 mg/day (Smith et al., submitted).

Objectives: The first objective was to investigate if the time to reach first aLLDAS and cLLDAS differs in cSLE. The second objective was to observe if cSLE patients maintain in cLLDAS for 50% of follow-up time (cLLDAS-50).

Methods: Data from a prospective longitudinal cSLE cohort were used, with patient/parent consent. Patients were classified as cSLE by SLICC 2012 criteria with a disease onset < 18 years old. Definitions were: aLLDAS according to Franklyn (2), disease activity score by SLEDAI-2K, cLLDAS by cLSE T2T Task Force (Smith et al. submitted) and damage according to SLICC Damage Index. cLLDAS-50 was defined as attainment of cLLDAS in more than 50% of follow-up. Binary regression analysis was used for testing co-variates for attaining cLLDAS-50 with significance for p<0.05.

Results: 43 cSLE patients were studied, with a median age of symptom onset at 13.6 years, median age at diagnosis of 14.6 years and median follow-up of 4.6 years (range 1-13 years). Mean number of visits was 10.9 per patient. Mean SLEDAI at diagnosis was 15.4 (SD 10.4, range 2-43). Use of MMF was in 62.8%, AZA in 37.2%, and use of HCQ in 100% of patients. 41.9% of patients used a biologic (rituximab or belimumab) at any time point. Each patient reached aLLDAS and cLLDAS at least once during follow-up. Mean time to reach first aLLDAS/cLLDAS was 8.8 months and 9.7 months respectively. Only 58.1% (25/43) of patients were able to maintain cLLDAS-50. The use of biologic(s) had a inversely correlation on reaching cLLDAS-50 (p=0.005), but time to start biologic(s) was not taken into account. Shorter time to cLLDAS was correlated with attaining cLLDAS-50 (p=0.025). SLEDAI at diagnosis, renal/neurological disease and compliance problems were not correlated with attaining cLLDAS-50.

Conclusion: In a longitudinal cSLE cohort, reaching cLLDAS occurred later than aLLDAS, emphasizing the need for an adapted LLDAS definition for cSLE. This study shows that reaching cLLDAS in cSLE is feasible, but attaining cLLDAS-50 is difficult. Earlier starting of glucocorticoid-sparing drugs (such as biologics) seems necessary in a severe subgroup not retaining, or not reaching, cLLDAS.

Background: Familial Mediterranean fever (FMF) is the most common autoinflammatory disease worldwide. It affects mainly population from Mediterranean origin and is associated with *MEFV* exon 10 mutations. FMF is characterized by short and recurrent attacks of fever, abdominal or thoracic pain that lasts less than three days [1]. Several studies reported that FMF diagnosis may be missed or delayed even in countries with a high prevalence of the disease such Turkey and Israel but real causes explaining diagnostic delay in FMF are not totally elucidated.

Objectives: Our aim was to study a large cohort of European FMF patients to identify the frequency and associated factors of diagnosis delay.

Methods: Clinical data were extracted from the Juvenile Inflammatory Rheumatism (JIR)- cohort. All FMF patients fulfilled Livneh Criteria and had a sequencing of *MEFV* exon 10 available [2]. We defined FMF-diagnostic delay (d-FMF) as a duration between the onset of the symptoms and FMF diagnosis of more than 10 years.

Results: We enrolled 960 FMF patients; delayed diagnosis (d-FMF) was noted in 20% of patients (n=200) whereas 80% of other patients (FMF) (n=760) had the diagnosis made within the 10 years from the onset of symptoms. d-FMF patients were significantly older than other FMF with a median age of 46.4 years old versus 15.5 (p < 0.0001). Concerning women, the percentage of d-FMF was higher than other FMF patients (56% versus 47%, p=0.03). Regarding the clinical presentation during FMF attacks, the difference was not statistically significant on abdominal pain, musculoskeletal symptoms and chest pain. Only, erysipelas-like erythema was more frequently observed among d-FMF patients (33% versus 22%, p=0.0003). The percentage of patients with one or two pathogenic *MEFV* mutation was not different between d-FMF and other FMF patients. AA amyloidosis was significantly more frequent in d-FMF than FMF (10 % versus 2.6 %, p< 0.0001). As well, d-FMF patients received significantly more biotherapy compared to other FMF (18% versus 3.8%, p<0.0001).

Conclusion: Twenty percent of FMF patients were misdiagnosed before being officially diagnosed as FMF with significantly more women; this could be linked to the differential diagnosis of abdominal attacks with period pains, as frequently reported be women patients. Another clinical feature is erysipelas-like erythema which seems not be known as a pathognomonic symptom of FMF by all practitioners; this finding was previously reported in Israel and Turkey were the disease is however highly prevalent [4,5]. In conclusion, FMF delay is still significantly high nowadays. To our knowledge, our study is the first cohort study to investigate diagnostic wandering and the factors associated with long diagnostic wandering in a large European cohort. Education and better communication on this disease to patients and practitioners could be fruitful to improve FMF earlier diagnosis.

ADHERENCE TO URATE-LOWERING THERAPY AFFECTS THE RISK OF CARDIOVASCULAR EVENTS IN PATIENTS WITH GOUT

Keywords: Cardiovascular disease, Real-world evidence, Gout

M. J. Kim[1], J. Sun[2], K. W. Moon[3], Y. Jang[1], K. Shin[1]. *[1]Seoul Metropolitan Government–Seoul National University Hospital Boramae Medical Center, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[2]Seoul Metropolitan Government–Seoul National University Hospital Boramae Medical Center, Medical Research Collaborating Center, Seoul, Korea, Rep. of (South Korea)*; *[3]Kangwon National University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Chuncheon, Korea, Rep. of (South Korea)*

Background: The benefit of urate-lowering therapy (ULT) on cardiovascular diseases is still controversial. One confounding factor of its association is the adherence to ULT. The impact of adherence to ULT on major adverse cardiovascular events (MACE) has not yet been characterized.
Objectives: We aimed to investigate the patterns of adherence to ULT and their long-term effects on the risk of MACE in patients with gout.
Methods: Using the Korean national health insurance database, we identified 48,600 patients with gout who were 40 years-old or older and started ULT (allopurinol or febuxostat) in 2013-2014. Patient groups were determined based on ULT adherence at 1 and 3 years after its initiation. Non-adherence was defined by the ratio (<80%) of the proportion days covered during the reference period. Patients were divided into 4 groups: persistently adherent (n=11,087), first adherent/later non-adherent (n=4,492), first non-adherent/later adherent (n=5,486), and persistently non-adherent (n=27,535). The primary outcome was the occurrence of MACE (a composite of acute myocardial infarction, revascularization, or acute ischemic stroke) identified in the claims database. The hazard ratio (HR) derived by Cox proportional hazards models was calculated adjusting for age, sex, and comorbidities.
Results: The median follow-up period was 5.2 (interquartile range, 4.6-5.6) years. The persistently non-adherent group had a significantly higher risk of MACE than the persistently adherent group (adjusted HR, 1.14 [95% CI, 1.05-1.24]). The first non-adherent/later adherent group had a significantly lower risk of MACE than the persistently non-adherent group (adjusted HR, 0.85 [95% CI, 0.76-0.96]). The risk of MACE was comparable between the persistently adherent group and the first adherent/later non-adherent group (adjusted HR, 1.03 [95% CI, 0.91-1.17]).
Conclusion: Sustained non-adherent to ULT significantly increases the risk of MACE in patients with gout. Regained adherence to ULT was associated with a lower risk of MACE compared with sustained non-adherence.

OP0038

THE RISK OF ACUTE CORONARY SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO ATTAINED REMISSION WITH METHOTREXATE OR A TUMOR NECROSIS FACTOR INHIBITOR.

Keywords: Real-world evidence, bDMARD, Rheumatoid arthritis

B. Delcoigne[1], L. Ljung[1], S. Aarrestad Provan[2], E. Kristianslund[2], J. Askling[1].
[1]Karolinska Institutet, Department of Medicine Solna - Clinical Epidemiology Division, Stockholm, Sweden; *[2]Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway*

Background: Patients with rheumatoid arthritis (RA) are at higher risk for cardiovascular disease including acute coronary syndromes (ACS) than the general population. Systemic inflammation may mediate some of this increased risk. Treatment with disease modifying anti-rheumatic drugs (DMARDs) may induce remission and thereby lower any increase in ACS risk related to RA inflammation, but the size of this risk reduction vs. rates in the general population, and whether there are, in addition, DMARD-specific beneficial effects on ACS risk, remain unknown.
Objectives: To compare the incidence rates of ACS in patients with RA who attain remission while treated with a tumor necrosis factor inhibitor (TNFi) vs. methotrexate (MTX), and to anchor these incidence rates to those in the general population.
Methods: We defined and pooled treatment cohorts of patients with RA from clinical rheumatology registers in Norway and Sweden who started MTX or a TNFi between January 01, 2012 and December 31, 2021. To be eligible, patients had to start MTX or TNFi while not being in remission (swollen joint count (SJC) >1 or c-reactive protein (CRP) >10 mg/dL or erythrocyte sedimentation rate (ESR) >20), and had to attain remission in a time window of 90 to 548 days after treatment start. They were followed up for one year from the first date at which remission was recorded until any ACS (as assessed through register linkages) or a censoring event (first of: death from other cause than ACS, emigration, treatment discontinuation (+90 days), a new DMARD treatment start, first non-remission date, end of the study). Patients had to be free from a history of ACS in the 5 years before start of follow-up. One patient could contribute several treatment episodes. We compared the incidence rates of ACS between the two DMARD cohorts using Cox regression analyses with robust standard errors and different adjustments: 1. Country; 2. Country, age, sex, calendar year; 3. Country, age, sex, calendar year, RA disease duration, use of oral corticosteroids, comorbidities (hyperlipidemia, hypertension, diabetes), smoking. The main disease activity (DA) metric for defining remission was DAS28 (DAS28-ESR ≤2.6 or DAS28-CRP ≤2.4). Other metrics were used in sensitivity analyses, including SJC=0, CRP≤10 mg/dL, and patient global health assessment (PGA) ≤14. For each of the Swedish RA patients, general population controls were matched on age and sex and similarly followed-up for ACS.
Results: 14,488 treatment courses with MTX and 13,056 with TNFi were included (25,283 from Sweden and 1786 from Norway). DAS28 remission in the allowed time-window was achieved in 5867 (40%) for MTX and 4147 (32%) for TNFi. At start of follow-up, and compared to the TNFi cohort, the MTX cohort included more male patients (35% vs. 27%), was older (mean age 64 years vs. 58), had a lower disease duration (1.3 years vs. 7.5), was more often treated with steroids (62% vs. 43%), and had more often recorded comorbidities. 70% of the patients in the TNFi cohort were treated with concomitant MTX. During the one-year follow-up (7570 person-years) 15 ACS events were recorded in the MTX cohort and 12 in the TNFi cohort, corresponding to crude incidence rates of 3.4 (95% confidence interval (CI) 2.0-5.6) and 3.8 (95% CI 2.2-6.7) per 1000 person-years. Comparing these incidence rates, the fully adjusted Cox regression analysis (model 3) provided a HR (95% CI) of 1.19 (0.48-2.93) for TNFi vs. MTX. Using other DA metrics provided similar and statistically non-significant estimates (Figure 1). In the matched general population subjects (Sweden only), we observed 128 events. The comparison of the treated (MTX or TNFi) patients in remission to the general population provided a HR (95% CI) of 1.08 (0.70-1.64), adjusted for age, sex and calendar year.
Conclusion: Patients with RA who reach remission on MTX have a similar ACS risk as those reaching remission on TNFi. The incidence rates of ACS in patients in remission were comparable to the incidence rate in the general population.

TOWARDS UNDERSTANDING THE FAVORABLE EFFECT OF INCREASED BMI ON RADIOGRAPHIC PROGRESSION: A LARGE MRI-STUDY IN AN EARLY ARTHRITIS INCEPTION COHORT

Keywords: Rheumatoid arthritis, Imaging, Comorbidities

N. Den Hollander[1], A. Van der Helm – van Mil[1,2], H. W. Van Steenbergen[1].
[1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*;
[2]*Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands*

Background: Obesity is considered a risk factor for RA-development. Paradoxically, in RA obesity is associated with less severe radiographic progression. A previous MRI-study suggested that obesity associated with less osteitis and synovitis.
Objectives: To increase our understanding of the favorable association between obesity and radiographic progression, we performed a large MRI-study and aimed to 1) validate the association between BMI and MRI-detected osteitis/synovitis, 2) study whether this is a subgroup-effect in ACPA-positive/-negative RA or a general effect in early arthritides (also in 'non-RA diagnoses') and 3) study whether increased BMI associates with MRI-detected erosive progression, since MRI-detected erosive progression may follow osteitis but precedes radiographic progression.
Methods: We studied 1,029 patients (454 RA, 575 other arthritides), consecutively included in the Leiden Early Arthritis Clinic. At baseline, clinical parameters(including BMI) were measured and patients underwent hand-and-foot MRI that were RAMRIS-scored. 149 RA-patients underwent follow-up MRIs. Associations between baseline BMI and MRI-detected osteitis/synovitis, and baseline BMI and MRI-detected erosive progression were assessed using linear-regression and Poisson mixed-models.
Results: In RA, higher BMI associated with less osteitis(β=0.95; 95%CI=0.93-0.97) but not with synovitis, validating the previously found association with osteitis. The association of BMI with less osteitis was present in ACPA-positive RA(β=0.93; 95%CI=0.91-0.96), ACPA-negative RA(β=0.96; 95%CI=0.94-0.98) and other arthritides(β=0.98; 95%CI=0.96-0.996). During 2-years follow-up overweight and obese RA-patients had less MRI-detected erosive progression than normal-weight RA-patients(IRR=0.989, p-value=0.02 and IRR=0.989, p-value=0.03 respectively). This indicates that the MRI-detected erosive progression was 0.989 times lower per month or 23% lower over 2 years (IRR for one month 0.989, thus 0.989^24=0.77 over 2 years), in both overweight and obese patients, compared to normal weight patients (Figure 1A). Comparable results were found in both ACPA-positive and negative RA (Figure 1B and 1C).
Conclusion: High BMI associated with less osteitis at disease-onset; this was present in all early arthritis patients and not confined to ACPA-positive RA. Moreover, overweight/obesity in RA associated with less severe MRI-detected erosive progression over time. These findings substantiate the previously reported observation of less severe radiographic progression in obese RA-patients and bring us a step forward in unraveling the contradictory association between high BMI and less erosive disease, which is essential in a time where overweight and obesity keep increasing.

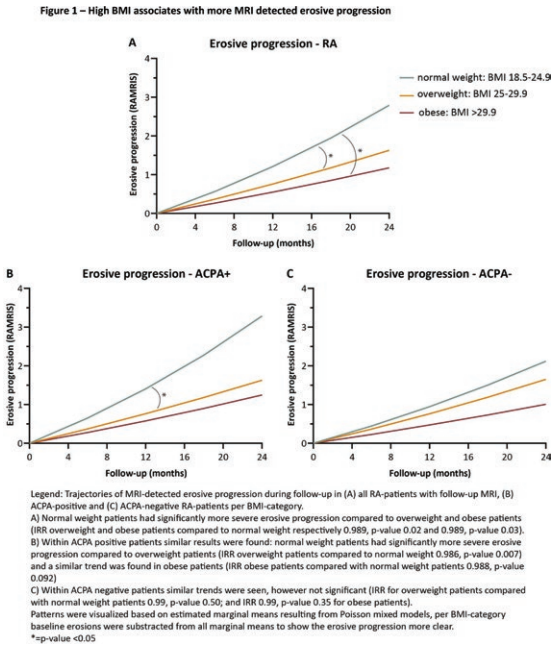

Figure 1. High BMI associates with more MRI detected erosive progression

CHANGES IN BODY WEIGHT AND BODY COMPOSITION IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AGED 65+ TREATED WITH 2-YEAR LOW-DOSE ADD-ON PREDNISOLONE IN THE RANDOMISED DOUBLE-BLIND PLACEBO-CONTROLLED GLORIA TRIAL

Keywords: Sarcopenia, Rheumatoid arthritis, Randomized control trial

M. Güler-Yüksel[1], M. Kuijper[1], R. Bos[2], E. Molenaar[3], J. Emmering[4], S. Eshuis[5], H. Adams[6], F. Reimann[2], M. Boers[7], M. R. Kok[1]. [1]*Maasstad Hospital, Rheumatology and Immunology, Rotterdam, Netherlands*; [2]*Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands*; [3]*Groene Hart Hospital, Rheumatology, Gouda, Netherlands*; [4]*Maasstad Hospital, Radiology and Nuclear Medicine, Rotterdam, Netherlands*; [5]*Medical Center Leeuwarden, Nuclear Medicine, Leeuwarden, Netherlands*; [6]*Groene Hart hospital, Nuclear Medicine, Gouda, Netherlands*; [7]*Amsterdam UMC, Epidemiology & Data Science, Amsterdam, Netherlands*

Background: Weight gain is one of the most feared patient-reported adverse event of glucocorticoids, however the effect of low-dose prednisolone on body weight and composition in RA still has to be unraveled.
Objectives: Current study is a substudy of the GLORIA trial.[1] We report changes in body weight of the whole study population, and relate these to changes in disease activity, and changes in body composition in a subgroup of patients.
Methods: The GLORIA trial, a pragmatic, placebo-controlled, double-blind, randomised controlled trial investigated the balance of benefit and harm of 2 years of prednisolone 5 mg/day added to standard care in 451 patients with active RA aged 65+.[1] In current study 449 patients were included, and body weight and disease activity score of 28 joints (DAS28) were measured at baseline and after 3, 6, 12, 18 and 24 months. In 57 patients body composition was assessed at baseline and after 2 years with dual-energy X-ray absorptiometry. Data were analysed with longitudinal mixed models, and log-ratio analysis to evaluate the mutual changes in body composition, given as the proportions total lean mass, total fat mass, and total bone mass.
Results: Body weight changed by mean (95% CI) 0.9 (0.3;1.6) kg on prednisolone after 2 years, versus –0.4 (–1.1;0.2) kg on placebo, with a difference between treatment groups of 1.3 (0.5;2.2) kg (p<0.01). In multivariable regression analysis, the effect of AUC DAS28 0–2 years was not significantly associated with weight change (p=0.18). The change in body composition after 2 years was different in

prednisolone compared to placebo patients (log-ratio analysis, p=0.02; Table 1). Prednisolone patients showed small but favorable changes in body composition, i.e. lean mass increases exceeding fat mass increases, with trends in differences for total lean mass and lean mass index, and even significant differences for appendicular lean mass (p=0.02), and its corresponding index (p<0.01). No differences in change were seen in total fat mass, nor in fat distribution over the body, i.e. trunk, extremities and head (log-ratio analysis, p=0.93).

Conclusion: Patients with active RA aged 65+ treated with prednisolone 5 mg/day for 2 years gained about 1 kg in weight, compared to non-significant weight loss on placebo. This weight gain is a direct effect of the glucocorticoid treatment, and not significantly dependent of decrease in disease activity. The small increase in weight is mostly (appendicular) lean mass, rather than increase or redistribution of fat mass traditionally associated with glucocorticoid treatment.

LIFETIME MULTIMORBIDITY PROGRESSION IN RHEUMATOID ARTHRITIS: A MULTISTATE MODELLING ANALYSIS OF 20 YEAR DATA FROM THE NORFOLK ARTHRITIS REGISTER

Keywords: Comorbidities, Patient reported outcomes, Rheumatoid arthritis

P. Saha[1,2], J. Dainty[1], M. Yates[1,2], E. Kulinskaya[3], A. Macgregor[1,2]. [1]*University of East Anglia, Norwich Medical School, Norwich, United Kingdom*; [2]*Norfolk and Norwich University Hospital, Department of Rheumatology, Norwich, United Kingdom*; [3]*University of East Anglia, School of Computing Sciences, Norwich, United Kingdom*

Background: The relationship between multiple long term conditions (MLTC) and rheumatoid arthritis (RA) is well known; however the trajectory of accumulation of MLTC and the factors that influence the rate of progression of MLTC following the onset of RA are yet to be fully established. The Norfolk Arthritis Register (NOAR) is a cohort study established in 1989 to record incident cases of early inflammatory arthritis, and is unique in its long follow-up period of up to 20 years. Here we examine the pattern of MLTC progression in the cohort, and apply a multistate model to examine the factors that influence MLTC progression.

Objectives:

- Describe the patten of MLTC progression among newly diagnosed cases with RA over the disease course.
- Develop and apply a multistate model to examine the rate of accumulation of MLTC among people with RA following disease onset.
- Examine predictors that influence the rate of MLTC at different timepoints in the disease course.

Methods: The Norfolk Arthritis Register (NOAR) is an inception cohort of early inflammatory arthritis established in 1989, with over 4500 cases of new onset inflammatory arthritis. Cases were recruited in primary care or from hospital clinics, and inclusion criteria were age >16 years with 2 swollen joints lasting ≥4 weeks. The analysis focused on 13 self-reported chronic diseases involving multiple organ systems ascertained at each follow up point over an interval of 20 years. A multistate model was constructed to examine the accumulation of the number of MLTCs over time ('states') since the onset of disease. Death was included as a separate state. Demographic data at baseline and follow up was included in the model. The multistate model was implemented in the R package *msm,* which provides longitudinal information on the transfer rates from the lower to higher levels of MLTC-M and to death. Multivariate multiple imputation (nburn=1000, 5 datasets) was used to impute missing values using R packages *mice* and *jomo*.

Results: The analysis is based on 4674 patients observed 2 to 15 times; this provided 33,356 records in total. The number of comorbidities increases over time from onset of RA, rho=0.299 (p-value < 2.2e-16). This increase was more pronounced than the increase by age, rho=0.159 (p-value < 2.2e-16), suggesting that inflammation drives number of comorbidities more than age. There were 269 unique combinations of MLTC. The most frequent single morbidities were hypertension, depression and lung disease, with frequencies 0.325, 0.320, and 0.167, respectively (0.812 total probability). The multistate model (Figure 1) considered six defined MLTC states corresponding to total number of MLTC conditions: ranging from State-1 representing RA alone to State-6 representing death. The best fitting model proved to be an additive model including the 5 predictors of gender, age of onset, BMI, smoking status and logDMARDs. Males had significantly higher hazards of accumulation of MLTCs and mortality risk. The total number of MLTCs alone were not associated with the hazard of death. Being overweight significantly increases hazards of progression from State-2 to State-3, and 3 to 4, but also did not affect hazards of death. Ex and non-smokers had significantly lower hazards of accumulation of MLTCs and death, and the number of DMARDs reduced disease progression from State-2 to State-3, and 3 to 4, but did not affect mortality.

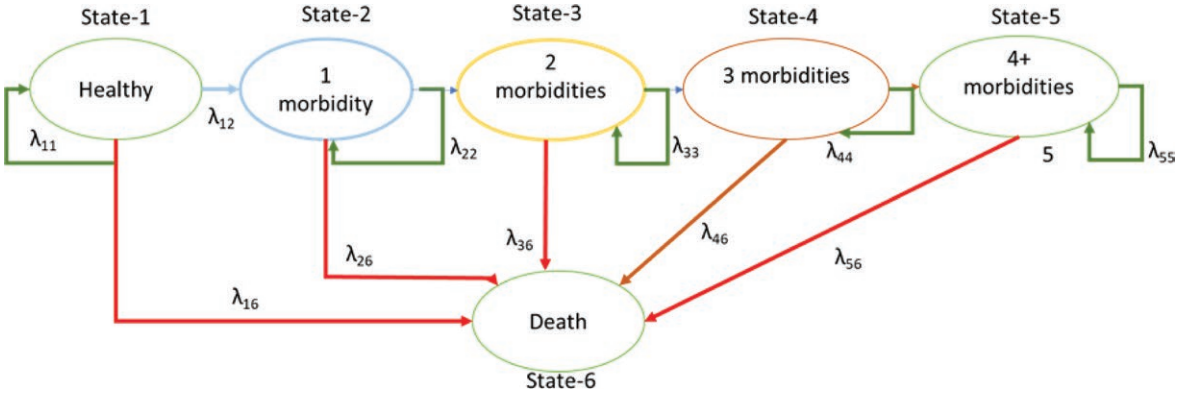

Figure 1. State transitions (arrows) and transition rates (λ) between 6 states in NOAR

Conclusion: This study provides a comprehensive long-term picture of the rate and pattern of accumulation of multimorbidity in RA over the disease course. MLTC involved most patients with RA over time. Smoking, obesity and the use of disease modifying drugs were all found to influence the rate of MLTC accumulation across a range of organ systems. The data suggest that sustained control of inflammation in RA, both through drug interventions and lifestyle management is an important part of limiting the risk of MLTC development throughout the disease course.

OP0042 VACCINATION RATE, ADVERSE REACTIONS, AND REASONS FOR NONVACCINATION OF COVID-19 VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS IN A JAPANESE REAL-WORLD CLINICAL PRACTICE

Keywords: Rheumatoid arthritis, COVID, Vaccination/Immunization

Y. Hirano[1], Y. Saito[1]. *[1]Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan*

Background: The first coronavirus infection was confirmed in Wuhan City, People's Republic of China, in December 2019. On January 30, 2020, the World Health Organization declared the novel coronavirus disease a public health emergency of international concern. On March 11, 2020, World Health Organization announced that the new coronavirus infection can be regarded as a pandemic because of the global spread of the infection. The world's first authorization for a coronavirus disease 2019 vaccine (CV) in the UK was in December 2020. The first authorization for a CV in Japan was in February 2021. A maximum of five times of vaccination had been performed in Japanese people until January 2023. Patients with rheumatoid arthritis (RA) are generally immunocompromised because of the drugs used for RA treatment. Patients with RA are recommended to receive a CV in the 2021 update of the EULAR recommendations for the management of rheumatic and musculoskeletal diseases in the context of SARS-CoV-2 [1]. However, some patients with RA rejected CV for various reasons or reports of adverse reactions (ARs) in clinical practice. Real-world clinical information on CV is necessary for better relationships between patients with RA and their physicians.

Objectives: This retrospective study aimed to determine the vaccination rate, ARs, and reasons for nonvaccination of CV in patients with RA in clinical practice.

Methods: The vaccination rate, ARs, and reasons for nonvaccination of CV in patients with RA on clinical records of our institute were investigated up to the third vaccination. Patients were divided into three age groups: 0–64 years old (YG), 65–74 years old (OG), and >75 years old (VOG). The association between age groups and vaccination rates was also investigated. The Cochran–Armitage test was used for statistical analysis.

Results: Regarding patient background (n = 610), the mean age was 67.8 years (YG, n = 207; OG, n = 196; VOG, n = 207; female, 75.1%; mean RA duration, 14.1 years). The vaccination rate among all patients was 8.4% for nonvaccination; 91.6% for the first dose; 91.3%, second dose; and 86.6%, third dose. A significant decrease over time was observed ($p < 0.01$). Nonvaccination was observed in 13.0%, 9.2%, and 2.9% of those in YG, OG, and VOG, respectively. A higher rate of nonvaccination was observed in the YG ($p < 0.01$). The results of the analysis by age group were 87.0%/90.8%/97.1% (first dose), 87.0%/90.3%/96.6% (second dose), and 77.8%/86.7%/95.2% (third dose) among the YG/OG/VOG, respectively (Figure 1). No statistically significant decrease in the vaccination rate was found over time in OG ($p = 0.19$) and VOG ($p = 0.30$) but not in VOG ($p = 0.01$). ARs occurred in 8.2%, 14.5%, and 16.1% of the patients receiving the first, second, and third doses, respectively. Among the reasons for nonvaccination, 35 (68.6%) patients were concerned about ARs to CV and 6 (11.8%) thought that CV was unnecessary.

Conclusion: CV rate in our cohort was higher than that of whole nation in Japan (81.4% for the first dose, 80.4% for the second dose, 67.8% for the third dose). CV rate has been declining steadily in patients with RA, with a stronger trend in younger age groups. Fear of ARs was the most frequent reason for nonvaccination.

OP0043 IMPACT OF CARDIOVASCULAR COMORBIDITIES ON EFFICACY OF TOFACITINIB VS TNFI IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Cardiovascular disease, Comorbidities

M. H. Buch[1], M. Mortezavi[2], J. Giles[3], C. Charles-Schoeman[4], G. Karpouzas[5], H. Jo[6], K. Kwok[6], E. Nagy[7], J. L. Rivas[8], A. Yndestad[9]. *[1]NHR Manchester Biomedical Research Centre and University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom*; *[2]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; *[3]Columbia University, Vagelos College of Physicians & Surgeons, Department of Medicine, Division of Rheumatology, New York, NY, United States of America*; *[4]University of California Los Angeles, Department of Medicine, Division of Rheumatology, Los Angeles, CA, United States of America*; *[5]Harbor-UCLA Medical Center, Department of Internal Medicine, Division of Rheumatology and the Lundquist Institute, Torrance, CA, United States of America*; *[6]Pfizer Inc, Statistics, New York, NY, United States of America*; *[7]Pfizer Ltd, Safety Surveillance and Risk Management, Tadworth, United Kingdom*; *[8]Pfizer SLU, Inflammation and Immunology, Madrid, Spain*; *[9]Pfizer Inc, Inflammation and Immunology, Oslo, Norway*

Background: Patients (pts) with rheumatoid arthritis (RA) and a history of atherosclerotic cardiovascular (CV) disease (HxASCVD) have a higher risk of major adverse CV events (MACE) with tofacitinib vs tumour necrosis factor inhibitors (TNFi), whereas risk difference is not detected in pts with no HxASCVD.[1]

Objectives: To further explore the benefit/risk profile of tofacitinib by assessing efficacy in pts with RA with and without HxASCVD.

Methods: ORAL Surveillance (NCT02092467) was an open-label, post-authorisation safety study that included pts with active RA despite methotrexate treatment, aged ≥50 years and with ≥1 additional CV risk factor.[2] Pts were randomised 1:1:1 to receive tofacitinib 5 or 10 mg twice daily (BID) or TNFi. In this post hoc analysis, pts were categorised by HxASCVD; for pts with no HxASCVD, 10-year risk of ASCVD was determined using the pooled cohort equations calculator[3] with a 1.5x multiplier applied per EULAR guidelines.[4] Odds ratios (ORs) were presented to compare tofacitinib vs TNFi in achieving remission (Clinical Disease Activity Index [CDAI] ≤2.8) or low disease activity (LDA; CDAI ≤10) at Month 6. ORs and adjusted rates of remission and LDA were obtained from a Generalised Estimating Equation repeated measures model, including baseline (BL) value, visit, treatment, treatment × visit and disease duration.

Results: Of 4362 pts, 640 had a HxASCVD, and 3722 had no HxASCVD, of which 3672 had BL CV scores calculated. Full pt demographics and BL disease characteristics have been published.[1,2] Mean BL CDAI scores across

treatment groups ranged from 37.6–41.0 for pts with a HxASCVD or non-missing BL CV scores. ORs and the percentage of pts achieving remission and LDA with tofacitinib vs TNFi at Month 6 are shown in the Table 1 and Figure 1, respectively. ORs were greater for pts receiving tofacitinib vs TNFi in the Overall population, and in pts with no HxASCVD, and were similar in pts with a HxASCVD. Pts with high or intermediate CV risk scores tended to be more likely to reach remission or LDA with tofacitinib vs TNFi, as were pts with low–borderline risk scores who received tofacitinib 10 mg BID.

Table 1. ORs of tofacitinib vs TNFi for achieving remission or LDA at Month 6

	N	Remission (CDAI ≤2.8)		LDA (CDAI ≤10)	
		OR vs TNFi	(95% CI)	OR vs TNFi	(95% CI)
Overall					
Tofacitinib 5 mg BID	1414	1.32	(1.04, 1.67)	1.31	(1.12, 1.53)
Tofacitinib 10 mg BID	1391	1.48	(1.17, 1.88)	1.43	(1.22, 1.67)
HxASCVD					
Tofacitinib 5 mg BID	196	0.89	(0.46, 1.70)	1.43	(0.94, 2.19)
Tofacitinib 10 mg BID	211	1.48	(0.82, 2.65)	1.22	(0.81, 1.84)
No HxASCVD					
Tofacitinib 5 mg BID	1218	1.40	(1.08, 1.82)	1.29	(1.09, 1.52)
Tofacitinib 10 mg BID	1180	1.48	(1.14, 1.92)	1.47	(1.24, 1.74)
High CV risk (≥20%)					
Tofacitinib 5 mg BID	250	1.80	(1.03, 3.13)	1.35	(0.95, 1.94)
Tofacitinib 10 mg BID	269	1.52	(0.86, 2.68)	1.11	(0.78, 1.58)
Intermediate CV risk (≥7.5–<20%)					
Tofacitinib 5 mg BID	456	1.64	(1.07, 2.54)	1.43	(1.10, 1.88)
Tofacitinib 10 mg BID	474	1.52	(0.98, 2.34)	1.77	(1.35, 2.33)
Low–borderline CV risk (<7.5%)					
Tofacitinib 5 mg BID	496	0.99	(0.66, 1.48)	1.13	(0.87, 1.47)
Tofacitinib 10 mg BID	420	1.46	(0.98, 2.16)	1.49	(1.12, 1.97)

For pts randomised to tofacitinib 10 mg BID who had their dose reduced to 5 mg BID due to a protocol amendment in 2019, data collected after pts were switched to 5 mg BID were counted in the tofacitinib 10 mg BID groupCI, confidence interval; N, number of evaluable pts

Figure. Percentage of pts achieving remission or LDA with tofacitinib[a] vs TNFi at Month 6 for pts overall and by HxASCVD

[a]For pts randomised to the tofacitinib 10 mg BID group who had their dose of tofacitinib reduced to 5 mg BID due to a protocol amendment in 2019, data collected after pts were switched to tofacitinib 5 mg BID were counted in the tofacitinib 10 mg BID group
[b]The darker shaded portion of each bar represents the percentage of pts achieving remission (CDAI ≤2.8); the full bar represents the percentage of pts achieving LDA (CDAI ≤10)
[c]Data for the high, intermediate and low–borderline CV risk categories were derived from pts with no HxASCVD, in whom the 10-year risk of ASCVD was calculated using the pooled cohort equations calculator[3]
N, number of evaluable pts

Conclusion: In pts with no HxASCVD, the efficacy of tofacitinib is at least as good as TNFi, and risk of MACE is comparable.[1] In pts with HxASCVD, clinicians should consider that risk of MACE with tofacitinib is higher vs TNFi,[1] while efficacy is similar. Overall, our findings further characterise the benefit/risk of tofacitinib by risk category, and provide a means to risk-stratify pts such that tofacitinib can be considered an effective treatment option where appropriate.

OP0044

DOES RHEUMATOID ARTHRITIS PATIENTS' RISK OF OVERALL AND SITE SPECIFIC CANCER DIFFERS FROM THE GENERAL POPULATION? A NATIONAL CLAIMS DATABASE COHORT STUDY IN THE ERA OF BIOLOGICAL TREATMENTS

Keywords: Rheumatoid arthritis, Epidemiology, Comorbidities

M. Beydon[1], S. Pinto[1], Y. De-Rycke[2], B. Fautrel[3], X. Mariette[4], R. Seror[4], F. Tubach[2]. [1]*Institute Pierre Louis Epidemiology and Public Health, Public Health, Paris, France*; [2]*Institute Pierre Louis Epidemiology and Public Health, Cephepi CIC-1901, Paris, France*; [3]*University Hospitals Pitié Salpêtrière - Charles Foix, Rheumatology, Paris, France*; [4]*Bicetre Hospital, Viral infection and immunology, INSERM U1184, Le Kremlin-Bicêtre, France*

Background: Earlier studies, before the era of biologics, showed that rheumatoid arthritis (RA) patients were at higher risk of overall malignancies, with an excess relative risk of 28% compared to the general population. This risk is mostly carried by specific cancers such as lung cancer, lymphomas along with skin cancers. An update of cancer incidence is warranted in order to explore whether cancer risk has been modified in the era of biological and targeted DMARDs.
Objectives: To estimate the risk of cancer in patients with rheumatoid arthritis compared to the general population.
Methods: We conducted a nationwide population-based study within the French national claim database "Système National des Données de Santé" (SNDS) between January 1st 2010 and December 31st 2020. We estimated the age and sex-standardized incidence ratios (SIR) and [95% CI] of cancer (all sites, site specific and hematologic malignancies) of RA patients, with the French population as reference, by use of the French Network of Population-Based Cancer Registries (FRANCIM). SIR were estimated with Poisson regression models.
Results: During the study period, 257,075 patients met the eligibility criteria, who contributed to a total of 1,906,742 person-years for the main analysis. RA patients had an increased risk of overall malignancy (SIR 1.20 [1.17-1.23]), particularly lung (SIR 1.41 [1.36-1.46], bladder (SIR 2.38 [2.25-2.51]), ears-nose-throat (SIR 1.40 [1.31-1.50]), cervix (SIR 1.80 [1.62-2.01]), prostate (SIR 1.08 [1.04, 1.13]), melanoma (SIR 1.37 [1.29-1.46]) cancers, marginal zone (SIR 1.22 [1.06-1.42]), diffuse large b cell (SIR 1.79 [1.63-1.96]), and Hodgkin (SIR 2.68 [2.23-3.18]) lymphomas, and multiple myeloma (SIR 1.50 [1.36-1.65]). Of note, some cancers were less frequent than in the general population such as pancreatic cancer (SIR 0.90, [0.83-0.97]) as well as breast and uterine body cancers (SIR 0.91 [0.88-0.94] and SIR 0.77 [0.71-0.84] respectively). Subgroup analyses revealed that the risk of overall malignancy was significantly less increased in women (SIR 1.08 [1.06-1.10]) than in men (SIR 1.34 [1.31-1.36]) (between group difference p < 0.001). Whereas, the risk of pancreatic cancer was only decreased in men but not in women (SIR 0.83 [0.75-0.91] vs SIR 1.04 [0.92-1.17] respectively, p < 0.001). Full details are presented in the Figure 1 below. Overall risk of cancer

was increased in patients treated with csDMARD (SIR 1.15 [1.13-1.17]), Tumor Necrosis Factor inhibitors (SIR 1.11, [1.07-1.15]), abatacept (SIR 1.27 [1.16-1.39]) and rituximab (SIR 1.43 [1.31-1.55]) versus the general population, however this association was not found in patients exposed to anti-IL6 (SIR 1.00 [0.90-1.10]) and Janus Kinase inhibitors (SIR 0.97 [0.77-1.21]).
Conclusion: In the era of biologics, RA patients remain at greater risk of overall malignancy and some site-specific cancers, not only lung cancer and lymphoma. This higher incidence of overall malignancy was observed in RA patients treated with almost all type of DMARD or bDMARD. However, no causal relationship between treatments and cancer incidence can be drawn as indication bias was not taken into account. Of note, we observed a lower incidence of breast, pancreatic and uterine body cancers than the general population.

Background: Potential associations between targeted therapies and a new cancer in patients with an inflammatory arthritis (IA) and a history of malignant disease are a frequent concern in daily rheumatology practice. IA and/or immunomodulatory drugs might confer a specific risk of malignancy. No evidence-based framework has been proposed to guide clinicians on the benefit/risk balance when initiating or reinitiating a targeted therapy (bDMARDs/tsDMARDs) in this context.
Objectives: This initiative aimed to develop points to consider (PTC) to assist rheumatologists. when initiating/reinitiating a targeted therapy in the context of a previous malignancy.
Methods: Following EULAR standardised operating procedures, a task force of 2 patient representatives. and 25 experts (comprising 2 methodologists, 2 EMEUNET members, 1 oncologist. and 20 rheumatologists) first met to define the research questions for a systematic literature review concerning patients with IA and a history of cancer and other relevant information for consideration including: incidence of cancer in targeted therapy-treated patients and no history of cancer, translational research in onco-rheumatology, management with targeted therapy of immune-related adverse events of checkpoint inhibitors. In a second meeting, the task force formulated. the overarching principles and the PTC.
Results: The group formulated 5 overarching principles and 8 PTC relevant to the initiation of targeted therapies in patients with IA and a history of cancer. Major themes included a) the need to assess. the individualized risk of cancer recurrence based on the characteristics of the patient, the cancer and the underlying disease; b) the importance of engaging with specialists caring for the cancer and. to define treatment based on a shared decision between the patient and the rheumatologist; c) the possibility to initiate without delay an appropriate targeted therapy for the treatment of. the IA in patients in remission of their cancer; d) the proposal to prefer anti-cytokine bDMARDs. over other treatment options in patients with history of solid cancer and to prefer. B cell depleting therapy in patients with a history of lymphoma; e) the proposal to use JAK inhibitors and abatacept with caution, and only in the absence of therapeutic alternatives, based on. the significant increase in cancer incidence in patients without a history of cancer, with tofacitinib compared to anti-TNF in a randomized clinical trial, and a modest but significant increase. with abatacept compared to other bDMARDs in some observational studies.
Conclusion: The 2023 EULAR Points to Consider provide guidance on the management of targeted therapies. in patients with IA and a history of cancer. The research agenda highlights the need for studies. to evaluate targeted therapies other than TNF inhibitors and anti-CD20 to address the evidence gaps in this setting.

GC to new therapies

OP0046 REAL-WORLD ORAL GLUCOCORTICOID USE IN SYSTEMIC LUPUS ERYTHEMATOSUS: A NATION-WIDE POPULATION-BASED STUDY USING THE FRENCH NATIONAL MEDICO-ADMINISTRATIVE DATABASE (LUPIN-F STUDY)

Keywords: Systemic lupus erythematosus, Real-world evidence

L. Arnaud[1], C. Fabry-Vendrand[2], R. Todea[2], B. Vidal[2], C. Juliette[3], J. Robert[3], S. Bouée[3], G. Thabut[2]

[1]University Hospitals of Strasbourg, Department of Rheumatology, Strasbourg, France; *[2]AstraZeneca, Medical Department, Courbevoie, France*; *[3]CEMKA, RWE, Bourg La Reine, France.*

Background: The daily dose of oral glucocorticoids (OCS) is associated with damage in Systemic Lupus Erythematosus (SLE), and OCS reduction is a major goal of SLE care. However, evidence regarding the real-world use of OCS in nation-wide populations are currently lacking.

Objectives: The aim of this study was to analyze the use of OCS in French patients with SLE, at the national level, using medico-administrative data.

Methods: This study used the French health-insurance claims database (SNDS), which contains pseudonymized individual data for over 66 million people. SLE patients were identified with the ICD-10 diagnosis code for SLE (M32), documented as a chronic condition or associated to hospital stay. Included SLE patients were defined as patients alive on January 1st 2020 whenever the SLE diagnosis occurred. SLE comorbidities and OCS complications were identified through validated algorithms. Real-world use of treatments was identified through drug deliveries in pharmacies and daily OCS doses (expressed in prednisone-equivalent) were calculated for the year 2019. Comparisons were made to age- and gender-matched controls without SLE from the general population.

Results: A total of 32,173 patients with SLE (mean age 49.9 ± 16.0 years; 86.1% women) were alive on January 1st 2020, with a mean disease duration of 7.1 ± 6.2 years. Among these prevalent SLE patients, 48.2% were treated with OCS. The mean daily dose of OCS was below 5 mg/day in 35.7%, between 5 and 7.5 mg/day in 6.4% and above 7.5 mg/day in 6.1%. OCS use was significantly more frequent in women, in patients with CMUc (specific health coverage for low income patients) and decreased with age (p<0.0001, for all). SLE-specific comorbidities, including glomerular disease, skin involvement, polyarthritis, pleurisy, pericarditis, and thrombocytopenia, were significantly increased in patients with higher doses of OCS (p<0.0001, for all). Use of SLE treatments other than OCS was significantly increased in patients with higher doses of OCS (p<0.0001, for all) (Table 1). Strikingly, 14.6% of patients receiving 5 to 7.5 mg of OCS per day and 14.2% of those receiving more than 7.5 mg per day were not treated with antimalarial drugs, immunosuppressives or other biologic treatments for SLE. Complications of OCS, including cardiovascular diseases, infections, osteoporosis, and obesity, were significantly increased in SLE patients receiving ≥ 5 mg per day of OCS (p<0.0001 for all). The overall annual mean cost of healthcare consumptions from a societal perspective in 2019 was 6,048€ for prevalent SLE patients and 2,601€ for matched controls (p<0.0001). Among prevalent SLE patients, the cost increased significantly according to the OCS daily dose: 4,633€ for patients without OCS, 6,383€ (daily dose of 0-5 mg/day), 9,815€ (5-7.5 mg/day) and 13,861€ (above 7.5 mg/day).

Conclusion: To the best of our knowledge, this is the first nation-wide study reporting on real-life use of OCS in patients with SLE. The proportion of patients treated with high-dose OCS ≥ 7.5mg/day remains unacceptably high and associated with increased comorbidities, OCS complications and significantly increased healthcare costs. Also, over 14% of patients receiving OCS doses ≥ 5 mg/day were not treated with antimalarial drugs, immunosuppressives or other biologic treatments for SLE. These results highlight the need for tight disease control and implementation of robust OCS-sparing strategies in SLE.

Table 1. Proportion of patients treated with SLE treatments other than corticosteroids in 2019

	No OCS	OCS 0-5 mg/day	OCS 5-7.5 mg/day	OCS ≥ 7.5 mg/day	p-value
Antimalarials (Hydroxychloroquine/ Chloroquine)	8,826 (53.0%)	7,286 (63.5%)	1,505 (72.9%)	1,416 (71.9%)	<0.0001
Methotrexate	958 (5.7%)	1,405 (12.2%)	361 (17.5%)	358 (18.2%)	<0.0001
Mycophenolate mofetil	337 (2.0%)	878 (7.6%)	350 (17.0%)	496 (25.2%)	<0.0001

OP0047 WITHDRAWAL OF MAINTENANCE GLUCOCORTICOID VERSUS OTHER IMMUNOSUPPRESSANTS AMONG PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN LONG TERM CLINICAL REMISSION: INTERIM ANALYSIS OF A NON-INFERIORITY RANDOMISED CONTROLLED TRIAL

Keywords: Randomized control trial, Tapering, Systemic lupus erythematosus

A. Gopal[1], C. Kavadichanda[1], M. Thabah[1], C. Mariaselvam[1], V. Negi[1,2].
[1]Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Clinical Immunology, Puducherry, India; *[2]AIIMS Bilaspur, Director, Bilaspur, India*

Background: Attempts to stop glucocorticoids (GC) among lupus patients in long term remission have been successful. Continuing other immunosuppressive (IS) agents indefinitely is currently the norm and this approach results in significant infectious, psychological and economic burden on patients. Moreover, there is no pathophysiological basis to withdraw GC over the other IS agents, except for the indirect evidence of higher adverse effects with continued low dose GC use. Hence, there is a need to assess, if the approach to taper steroids first is the right way in lupus.

Objectives: To compare the outcome of glucocorticoid withdrawal versus immunosuppressant withdrawal in patients of SLE in clinical remission.

Methods: This is a single centre, non-inferiority, open-label stratified randomized (1:1) controlled trial. Patients with SLE who were on IS for at least 3 years, in DORIS remission for a minimum of 1-year preceding screening and were on stable prednisolone dose of ≤7.5mg/day plus a maintenance non biological IS were included. Stratification was done based on duration of IS use (<3 years and ≥ 3 years), and presence of proliferative lupus nephritis. All patients continued HCQ during the study. Prednisolone or IS was tapered gradually over 3 months after randomisation. Primary end point was proportion experiencing a flare [SELENA-SLEDAI flare index (SFI)] and BILAG index at 52 weeks. Secondary end points were time to flare and severity of flare. Non-inferiority margin considered was 10%. For this abstract, data of maximum available follow up period for each patient was used.

Results: A total of 117 patients were randomised into steroid withdrawal (n=58) and IS withdrawal (n=59). Overall, 72% of the patients were in prolonged remission (DORIS remission on treatment >5 years). Median duration of available follow up is 46 weeks. There was a total of 23 flares of which 20 were mild-moderate and 3 were severe flares (SFI). Proportion of patients experiencing a flare was numerically higher in the steroid withdrawal group (15 vs 8 patients, RR 1.91 (0.88-4.15), p=0.09). (Table 1). Time to first flare was 27 days and 18 days following intervention in steroid and IS arm respectively. Severity of flare and time of first flare were not significantly different between the two groups (HR=0.49, 95%CI (0.20-1.15), p=0.096) (Figure 1). Severe flares were 2(3.4%) vs 1(1.7%) and mild-moderate flares were 13(22.4%) and 7(11.9%) in the steroid versus IS withdrawal arm respectively. There was one death due to MI secondary to ASCVD in a patient on IS withdrawal.

Conclusion: Immunosuppressant withdrawal is noninferior to steroid withdrawal in patients with SLE in long term clinical remission. Identifying the individuals who are likely to flare is of utmost importance which can pave the way for a more personalised drug withdrawal approach.

Table 1. Results of primary and secondary endpoints at maximum available follow up period (mean:46 weeks)

Background: Some studies demonstrated that withdrawal of low-dose glucocorticoids in clinically quiescent systemic lupus erythematosus (SLE) patients increased the risk of flare [1]. An international survey of 130 clinicians showed that persistent abnormal serology led to a reluctance to reduce or discontinue medications [2].
Objectives: To assess the risk of flare and damage accrual after tapering glucocorticoids in serologically active clinically quiescent (SACQ) patients with SLE. Association of other medications with flare in SACQ patients was also analyzed.
Methods: We used data from the Asia Pacific Lupus Collaboration cohort, prospectively collected from SLE patients (ACR/SLICC criteria) observed for at least 2 visits between 2013 and 2020. Disease activity and medication details were captured at enrolment and at routine visits. SACQ was defined at any visit as the state with serological activity (increased anti-dsDNA or hypocomplementemia) but without clinical activity as measured by SLEDAI-2K. Patients treated with 0 to 7.5 mg/day of prednisolone at a SACQ visit were analyzed after stratification according to the initial dosages of prednisolone. Cox proportional hazard models were used to assess the time-dependent relationship between decreasing prednisolone in SACQ patients and disease flares captured with the SELENA flare index at each subsequent visit, as well as subsequent damage accrual (≥1-point increase in SLICC/ACR damage index [SDI]). Each patient was observed for up to 2 years or until each outcome event occurred.
Results: From a total of 4,106 patients, 1,850 patients with SACQ and 8,905 visits were analyzed: 742, 271, and 180 patients experienced overall flare, severe flare, and increase in SDI, respectively. Tapering prednisolone was not associated with subsequent overall or severe flare: Each unit decrease in prednisolone dosage (1 mg/day) resulted in adjusted HRs 1.02 (95%CI, 0.99–1.05) and 0.98 (95%CI, 0.96–1.00) for overall and severe flare, respectively, in the group with initial prednisolone dosages of 0–7.5 mg/day. However, among SACQ patients, antimalarial use was significantly associated with reduced overall and severe flare in the groups with initial prednisolone of 0–7.5 or 0–5 mg/day. In addition, immunosuppressive use was significantly associated with reduced severe flare but not overall flare in these groups. Decreasing the dosage of prednisolone was significantly negatively associated with damage accrual in the groups with initial prednisolone dosages of 0–7.5 mg/day (adjusted HR [95%CI], 0.97 [0.96–0.99]) and 5–7.5 mg/day (adjusted HR [95%CI], 0.96 [0.94–0.99]) but not 0–5 mg/day (adjusted HR [95%CI], 0.98 [0.95–1.01]).

Table 1. Summary results of association between decreasing the prednisolone dosages and disease flares or damage accrual in SLE patients with SACQ

Initial prednisolone dosage (mg/day)	Overall disease flare	Severe disease flare	Increase in SDI
0 ≤ prednisolone ≤7.5	1.02 (0.99–1.05), $p = 0.27$	0.98 (0.96–1.00), $p = 0.11$	0.97 (0.96–0.99), $p < 0.01$
0 ≤ prednisolone ≤5	1.02 (0.98–1.06), $p = 0.41$	0.98 (0.96–1.01), $p = 0.28$	0.98 (0.95–1.01), $p = 0.14$
5 < prednisolone ≤7.5	1.01 (0.96–1.06), $p = 0.84$	0.98 (0.92–1.03), $p = 0.41$	0.97 (0.96–0.99), $p < 0.01$

* HRs (95% CIs) per unit decrease in prednisolone dosages (1 mg/day) were calculated using Cox proportional hazard models and adjusted by initial prednisolone dosage, antimalarial, immunosuppressive, disease duration, SLEDAI-2K, age at visit, gender, and ethnicity.

Conclusion: Tapering prednisolone was not significantly associated with subsequent flare in SLE patients who were SACQ. Antimalarial and immunosuppressive use were associated with reduced risk of flares in SACQ patients. Tapering prednisolone was associated with reduced risk of damage accrual in SACQ patients treated with more than 5 mg/day of prednisolone. These findings suggest glucocorticoid tapering is safe and protective in SLE patients in SACQ.

OP0049 AN IMMUNE TARGETED, NON-TOXIC CORTICOSTEROID FOR THE TREATMENT OF SEVERE AUTOIMMUNE DISEASE

Keywords: Targeted synthetic drugs, Systemic lupus erythematosus, bDMARD

J. Rothstein[1], K. Bell[1], C. Carriere[1], X. Huang[1], A. Barave[1], M. Day[1], A. Kuta[1], N. Schwertner[1], S. Seregin[1]. [1]ImmuNext, Research and Development, Lebanon, United States of America

Background: Glucocorticoids (GC) (aka corticosteroids) are a class of drugs with broad range anti-inflammatory and immunosuppressive activities making them the most potent anti-inflammatory drugs. However, chronic or high dose systemic exposure consistently leads to grievous dose limiting toxicities as in multiple organs including brain, liver and bone.. Altogether, these toxicities prevent GC from being a true panacea in the management of inflammatory diseases particularly in the case of chronic diseases. Targeting GC to immune cells will solve this problem as toxicity mostly occurs in non-immune tissues and cells that are unnecessary for therapeutic efficacy.

Objectives: The objective of INX200 is to give patients a non-toxic glucocorticoid that provides anti-inflammatory efficacy without any glucocorticoid toxicity in a once-per month injection.

Methods: We have achieved specific targeting of GC to the immune system with INX200, an antibody-drug conjugate (ADC). INX200 is a fully humanized immune-targeting monoclonal antibody with silent Fc domain and conjugated through a cleavable linker to budesonide. Validation experiments were conducted using human target knock-in mice, mouse surrogate antibodies and non-human primates in various inflammation and chronic disease models.

Results: We show that INX200 targets both lymphoid and myeloid cells with minimal off-target activity outside the immune compartment. This translates to reduced toxicity when compared to free GC as measured by the lack of impact on the Hypothalamic-Pituitary-Adrenal axis (no changes in corticosterone levels) and bones (no changes in GC- activated transcription) both in mice and non-human primates. INX200 rapidly internalizes allowing for robust and efficient uptake of the ADC thereby providing superior loading of GC into immune cells which results in therapeutic equivalence to free GC at 1/10th of the dose. One dose of INX200 also leads to substantially longer exposure (>3 weeks) when compared to free GC (<24h) both in mice and non-human primates. Additionally, we show that in both acute and chronic inflammation models (Figure 1), INX200 is therapeutically as broadly efficacious as free GC demonstrating that GC targeting to immune cells is sufficient for full GC anti-inflammatory efficacy. Finally, developability studies show that INX200 is stable at high concentration and as such suitable for subcutaneous administration.

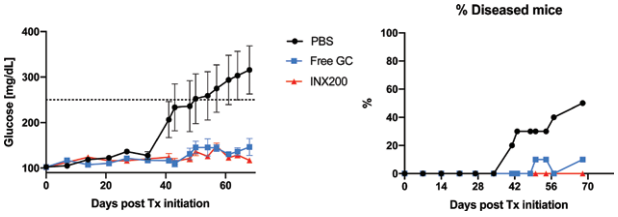

Figure 1. INX200 has equivalent efficacy to free GC at <1/10th of the dose in controlling disease development in the type 1 diabetes NOD mouse model. NOD mice were enrolled at 12-week old; INX200 (red) was dosed once a week at 10 mg/Kg (= 0.2 mg/Kg of GC payload) and free GC (blue) in water at 2 mg/kg per day. Left graph shows blood glucose levels over time of treatment, the dashed line indicating diabetic glucose levels as >250 mg/dL. Right graph shows the % of diseased mice over time (n=10 mice, experiment repeated twice).

Conclusion: INX200 retains all the efficacy/potent therapeutic activities of GC but with little to no side effects. The successful targeting of GC to the immune system with the sparing of non-hematopoietic toxicities, offers a transformative advance in GC-based drugs for the treatment of severe, chronic inflammatory diseases such as IBD, lupus and asthma.

Department of Environmental Medicine, Solna, Sweden*

Background: Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease that leads to significant worsening of quality of life and mortality. The

enormous molecular heterogeneity of SLE is reflected in different clinical manifestations, disease progression and also in a different drug efficacy across patients[1]. Lupus nephritis (LN) is the most severe SLE manifestation with the potential of rapidly evolving into irreversible chronic kidney disease and kidney failure if not adequately followed and treated. Mycophenolate mofetil (MMF) is the most widely used first-line treatment for LN, being ineffective or partially effective in 15-30 percent of the patients[2]. Reasons for non-response are still unknown and low or moderate drug efficacy may lead to aggravation of the disease. Treat-to-target approaches where personalized molecular patterns guide therapeutic decisions, are rapidly growing in medical fields such as oncology, but remain unmet within clinical rheumatology[3]. In addition, pathological molecular dysregulation behind SLE fluctuates within a non-linear clinical course and unpredictable patterns of flares and remissions, hindering the development of effective and robust predictive biomarkers for both diagnosis and drug responsiveness[4].

Objectives: The development of new, more effective therapies to treat LN is an urgent unmet need. The objective of this work is to define the cellular and molecular immune landscape behind non-response to MMF to finally apply this knowledge within routine clinical practice.

Methods: A longitudinal cohort comprising gene-expression and clinical data of 97 MMF responder and 28 non-responder blood samples was retrospectively analyzed. Differential gene expression and functional analysis were performed. Response rate was measured based on blood cell proportions. Single-cell RNA sequencing data was analyzed to identify the cell subtypes influencing non-response and their contributing genes and regulation mechanisms.

Results: A robust signature comprising 41 differentially expressed genes defined non-response to MMF and cellular profiles that favor the response to the drug in the patients were revealed. The response rate to MMF increases the lower the B cell/T cell ratio. Single-cell RNA sequencing showed that overexpression of the IFITM-family of genes in age-associated B cells, plasma cells, myeloid dendritic cells and macrophages was behind the non-response signature.

Conclusion: Blood cell subtypes and genes mediating non-response to MMF were revealed, opening a new scenario for the development of new therapeutic strategies for LN.

OP0051 LUPUS LOW DISEASE ACTIVITY STATE ATTAINMENT IN THE PHASE 3 PLACEBO-CONTROLLED TULIP LONG-TERM EXTENSION TRIAL OF ANIFROLUMAB

Keywords: Treat to target, Systemic lupus erythematosus, Clinical Trials

E. F. Morand[1], R. Van Vollenhoven[2], R. Furie[3], K. Kalunian[4], S. Yavuz[5], G. Abreu[6], C. Lindholm[5], H. Al-Mossawi[7]. *[1]Monash University, Centre for Inflammatory Diseases, Melbourne, Australia*; *[2]University of Amsterdam, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[3]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Division of Rheumatology, Great Neck, NY, United States of America*; *[4]University of California, San Diego, Rheumatology, Allergy and Immunology, La Jolla, CA, United States of America*; *[5]AstraZeneca, Clinical Development, Late Respiratory and Immunology, BioPharmaceuticals R&D, Gaithersburg, MD, United States of America*; *[6]AstraZeneca, Biometrics, Late Respiratory and Immunology, BioPharmaceuticals R&D, Gothenburg, Sweden*; *[7]AstraZeneca, Clinical Development, Late Respiratory and Immunology, BioPharmaceuticals R&D, Cambridge, United Kingdom*

Background: The Lupus Low Disease Activity State (LLDAS) has been prospectively validated as protective from flares, damage accrual, and mortality and is an important treatment goal in patients with SLE.[1] Recent analysis of pooled data from 2 phase 3 trials (TULIP-1 and TULIP-2) found that LLDAS attainment was achieved earlier, more frequently, and for a more sustained period with anifrolumab vs placebo in patients with moderate to severe SLE.[2]

Objectives: We investigated the long-term impact of anifrolumab compared with placebo on LLDAS attainment over the 1 year TULIP-1/TULIP-2 and 3 year long-term extension (LTE) study periods.[3]

Methods: TULIP-1 and TULIP-2 (NCT02446912, NCT02446899) were randomized, placebo-controlled, 52-week trials of IV anifrolumab (Q4W, 48 weeks) in patients with moderate to severe SLE despite standard therapy. Following the double-blind treatment period of the TULIP trials, patients could reconsent to participate in the 3-year, randomized, blinded, placebo-controlled LTE study (NCT02794285).[3] Here, data were analyzed by timepoint from TULIP baseline through the end of the LTE (Week 208) for patients who were assigned and received the same study drug (anifrolumab 300 mg or placebo) during the TULIP+LTE periods. LLDAS attainment was defined as all of the following: SLEDAI-2K ≤4 without major organ activity, no new disease activity, Physician's Global Assessment [0–3] ≤1, prednisone or equivalent ≤7.5 mg/day, standard immunosuppressant dosing, no use of restricted medications (considered only during the pooled TULIP-1/TULIP-2 period but not during the LTE period), and no investigational product (IP) discontinuation. LLDAS percentages and cumulative time in LLDAS were compared using a Cochran–Mantel–Haenszel approach, and response rates were compared using logistic regression. Last observation carried forward was used to impute missing data for TULIP-1/TULIP-2, but not for data captured in the LTE. All *P*-values are nominal.

Results: Data from 369 patients (anifrolumab 300 mg, n=257; placebo, n=112) were evaluable for the 4-year TULIP+LTE study period. At the last TULIP visit (Week 52), 39.3% of the anifrolumab group and 27.9% of the placebo group were in LLDAS (odds ratio [OR] 1.6, 95% CI 1.0–2.7, *P*=0.049). At the first visit of the LTE (Week 64), 33.5% of the anifrolumab group and 22.8% of the placebo group were in LLDAS (OR 1.7, 95% CI 1.0–2.9, *P*=0.038). LLDAS attainment was relatively stable for the first 3 years (up to Week 156) and declined slightly in Year 4; this decrease likely reflects the proportions of patients who discontinued IP over time (Figure 1). However, attainment of LLDAS favored anifrolumab vs placebo at all timepoints up to Week 208 (OR 2.7, 95% CI 1.3–5.6, *P*=0.007). For the combined 4-year TULIP+LTE period, greater cumulative time (*P*=0.001) and percentage of time (*P*=0.006) was spent in LLDAS by patients receiving anifrolumab compared with placebo. Cumulative time in LLDAS at a threshold of ≥20% also favored anifrolumab (OR 2.2, 95% CI 1.4–3.5, *P*=0.001); a similar trend was seen with a threshold of ≥50%, although this did not reach statistical significance (OR 1.4, 95% CI 0.8–2.4, *P*=0.217). Compared with placebo, patients treated with anifrolumab were more likely to be in sustained LLDAS for ≥3 consecutive visits (49.4% vs 35.1%; OR 1.8, 95% CI 1.1–2.8, *P*=0.018), ≥5 consecutive visits (32.6% vs 20.1%; OR 1.8, 95% CI 1.0–3.1, *P*=0.033), or ≥7 consecutive visits (22.2% vs 11.6%; OR 2.1, 95% CI 1.1–4.1, *P*=0.028).

Conclusion: Anifrolumab 300 mg treatment was associated with more frequent, prolonged, and sustained LLDAS compared with placebo during the 4-year TULIP+LTE period.

OP0052 PREDICTORS OF RENAL FLARES IN SYSTEMIC LUPUS ERYTHEMATOSUS: A POST-HOC ANALYSIS OF FOUR PHASE III CLINICAL TRIALS OF BELIMUMAB

Keywords: Systemic lupus erythematosus, Kidneys, Biomarkers

S. Jägerback[1,2], A. Gomez[1], I. Parodis[1,3]. [1]*Karolinska Institutet and Karolinska University Hospital, Stockholm, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden*; [2]*Danderyd University Hospital, Division of Rheumatology, Danderyd, Sweden*; [3]*Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden*

Background: In patients with systemic lupus erythematosus (SLE), renal involvement is associated with high morbidity, and renal flares are major contributors to poor long-term prognosis. Identification of patients at risk of developing renal flares despite immunosuppressant therapy is imperative to optimise management.

Objectives: To identify predictors of renal flares in patients receiving treatment for active extra-renal SLE.

Methods: Data from BLISS-52 (NCT00424476), BLISS-76 (NCT00410384), BLISS Northeast Asia (NEA; NCT01345253), and BLISS-SC (NCT01484496) were used (N=3225). The trials included patients with active, seropositive SLE and excluded active severe renal SLE. Participants were assigned to belimumab or placebo, on top of non-biologic standard therapy. We investigated anti-dsDNA, anti-Sm, anti-ribosomal P, and anti-cardiolipin (aCL) antibodies, low C3 and low C4 levels, B cell activating factor (BAFF), serum albumin, serum creatinine, and proteinuria at baseline as potential predictors of renal flares during a 52-week follow-up. We used Cox regression models to evaluate traditional disease features as predictors of renal flares in the pooled trial population. We also performed subgroup analysis of belimumab and placebo recipients. Covariates in the adjusted models included age, sex, ethnicity, body mass index, organ damage, baseline extra-renal activity (SLEDAI-2K score excluding renal and immunological descriptors), current or former renal SLE history (renal BILAG A–D), baseline use of glucocorticoids, antimalarials, and immunosuppressants, and use of belimumab.

Results: The mean age of the study population was 36.7 years, 94% were women, 54.6% had current or former renal involvement at baseline, and 192 developed a renal flare after a median follow-up time of 197 (IQR: 85–330) days from baseline. Patients with current or former renal involvement at baseline displayed a >9-fold increased hazard to develop a new renal flare (HR: 9.4; 95% CI: 5.0–17.7; P<0.001). In the pooled study population, baseline serum albumin (adjusted HR 0.9; 95% CI: 0.9–0.9; P<0.001), proteinuria (adjusted HR: 1.3; 95% CI: 1.2–1.4; P<0.001), and low C3 levels (adjusted HR: 1.8; 95% CI: 1.3–2.5; P<0.001) were robust determinants of subsequent renal flare occurrence; similar associations were found in the belimumab and placebo subgroups. Furthermore, we observed an association between anti-dsDNA positivity and renal flare development in univariable models (HR: 2.1; 95% CI: 1.4–3.2; P<0.001 in the pooled population), which attenuated in multivariable models (Figure 1). Positive levels of anti-Sm antibodies were associated with renal flare occurrence in the placebo (adjusted HR: 2.9; 95% CI: 1.5–5.6; P=0.002) but not in the belimumab subgroup, whereas anti-ribosomal P antibodies were associated with renal flare development in belimumab-treated (HR: 2.8; 95% CI: 1.5–5.0; P<0.001) but not in placebo-treated patients. Finally, positive levels of aCL antibodies (any isotype) predicted renal flare development in the belimumab group (adjusted HR: 1.8; 95% CI: 1.1–2.8; P=0.020) but yielded a negative association in the placebo group (adjusted HR: 0.4; 95% CI: 0.2–0.9; P=0.028).

Conclusion: Current or former renal involvement, high baseline proteinuria levels, hypoalbuminaemia, and C3 consumption were robust determinants of imminent renal flares. Beyond anti-dsDNA, anti-ribosomal P and aCL antibody positivity may prove valuable early signals of imminent renal flares in patients treated with belimumab. Anti-Sm positivity predicted imminent renal flares in patients treated with non-biological standard therapy, but not in belimumab-treated patients, assumably due to benefit conferred from belimumab in anti-Sm positive individuals, as shown previously [1].

OP0053 EFFICACY AND SAFETY OF BARICITINIB IN PATIENTS WITH ACTIVE LUPUS NEPHRITIS: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED PHASE 3 TRIAL

Keywords: Systemic lupus erythematosus, Remission, Randomized control trial

M. Hassanien[1], A. Moshrif[2], H. Hetta[3]. [1]*Assuit University, Rheumatology, Assuit, Egypt*; [2]*Assuit branch Azhar University, Rheumatology, Assuit, Egypt*; [3]*University of Cincinnati, College of Medicine, Internal Medicine, Cincinnati, United States of America*

Background: Baricitinib a selective Janus kinase (JAK) inhibitors 1&2 have been recognized as a potential therapeutic option in systemic lupus (SLE), also known Baricitinib, a JAK inhibitor, has demonstrated efficacy and safety in the treatment of dermatitis and arthritis 1; however, no JAK inhibitor studies have been conducted in lupus nephritis (LN) to dat.e.

Objectives: To assess the efficacy and safety of Baricitinib in patients (pts) with active LN.

Methods: The study is a randomized, double-blind, active competitor (cyclophosphamide)-controlled, phase 3 trial registered on clinicaltrials.com (NCT05432531), enrolled adults ≥18 years with a clinical diagnosis of LN (who also fulfilled classification criteria for LN grade III & IV), who had objective signs of active nephritis consistent with persistent proteinuria>0.5 g/day and/or cellular casts at screening, and who had SLEDAI-2K > 4 and patient assessment of anti-ds DNA and C3 serum levels at study entry. Pts were randomized 1:1 to receive Group 1: oral Baricitinib 4mg once daily and PBO saline infusion monthly, Group 2: oral PBO tablet and cyclophosphamide (0.7mg/m2) infusion monthly during a 6-months double-blind treatment period. The primary endpoint was proteinuria, response at week 12 and 24. Multiplicity-controlled secondary endpoints assessed at week 12 &24 included C3, anti-ds-DNA and SLEDAI-2K, and their changes from baseline, Treatment adverse events was recorded.

Results: Of 65 pts randomized at baseline, 60 enrolled in the study (Baricitinib 4mg, n=30; cyclophosphamide, n=30) and 100% received study drug through week 24. Baseline demographic and disease characteristics were balanced across treatment groups and consistent with an active LN population, all were females, 58% LN grade III; mean age 32.4 years; mean SLEDAI-2K 6.9; mean C3 12.1mg/L). A significantly reduction in proteinuria response rate at week 12 was achieved in group 1 vs group 2 (70% vs 43%; P<0.0001). Statistical significance was also achieved in the first 12 of the 24 w multiplicity-controlled secondary endpoints (C3 and SLEDAI-2k) at week 12 in group 1 compared with group 2 (P<0.01). The proportion of pts who experienced adverse events was similar between treatment groups (group 1, 48%; group 2, 46%). Serious adverse events leading to discontinuation were reported in 2 (6.6%) pts treated with Baricitinib and 1 (3.3%) pts treated with cyclophosphamide, respectively (serious infection or herpes zoster), major adverse cardiovascular events, venous thromboembolic events, were not reported in the study.

Conclusion: Baricitinib 4mg once daily demonstrated significantly good improvements in disease activity, proteinuria, C3, anti-ds-DNA, than cyclophosphamide after 12 &24 weeks of treatment in pts with active LN. The safety profile of Baricitinib 4mg was consistent with what has been observed with other inflammatory musculoskeletal diseases, and no new risks were identified. These results support the potential use of Baricitinib 4mg in pts with active LN.

Table 1. Patients showed ≥ 50% reduction in their initial Proteinuria level.

Variable	Group 1 (n=30)	Group 2 (n=30)	P value
4th w	17/30, 56.6%	9/30, 30%	
8th w	20/30, 66.6%	10/30, 33.3%

Landewé[3,8], D. Van der Heijde[1], F. A. Van Gaalen[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[2]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; *[3]Zuyderland Medisch Centrum, Rheumatology, Kerkrade, Netherlands*; *[4]Diakonhjemmet Hospital, Rheumatology, Oslo, Norway*; *[5]Groene Hart Ziekenhuis, Rheumatology, Gouda, Netherlands*; *[6]Lund University, Rheumatology, Department of Clinical Sciences, Malmo, Sweden*; *[7]University Hospital of Padova, Rheumatology, Padua, Italy*; *[8]Amsterdam University Medical Center, Rheumatology, Amsterdam, Netherlands*

Background: We have shown in the SPACE cohort that a diagnosis of early axial spondyloarthritis (axSpA) can be made in patients with chronic back pain (CBP) of less than two years (2y). However, diagnostic uncertainty can be an obstacle towards initiating disease-modifying treatment. The value of repeated assessments of SpA features for a definite clinical diagnosis is yet to be determined.
Objectives: To assess the yield of repeated assessments of SpA features over 2y to make a *definite axSpA* diagnosis in patients with recent onset CBP referred to the rheumatologist, and to describe the characteristics of patients that change to *definite axSpA* over time.
Methods: We used the 2y data from the SPACE cohort, a European multicentre inception cohort of patients (age <45y) with CBP of recent onset (≥3 months, ≤2y) included from 2009 to 2016. The diagnostic work-up consisted of patient history, physical examination, acute phase reactants (APR) and HLA-B27 testing, radiographs and MRI of the sacroiliac joints (SI-CR and SI-MRI) and spine (not shown). In patients with ≥1 major or ≥2 minor prespecified SpA features, clinical assessments, APR, and imaging were repeated at 1y and 2y visits. At each visit, the rheumatologist reported a clinical diagnosis of *axSpA* or *no axSpA* with level of confidence (LoC; numeric rating scale from 0 (*not confident at all*) to 10 (*very confident*)). Herein, we categorized patients by diagnosis likelihood. At baseline (BL), two categories were defined: 'Definite *axSpA/no axSpA*' when the diagnosis was given with a LoC ≥7 and 'Uncertain *axSpA/no axSpA*' if LOC <7. At 2y, the following categories were defined: 'definite, most likely and possible axSpA' and 'possible, most likely and definite no axSpA' (***Figure 1***). The ASAS classification criteria were applied using central reading. We explored the diagnostic course over 2y. In patients shifting from *no axSpA* (*definite* or *uncertain*) or *uncertain axSpA* at BL to *definite axSpA* at 2y, SpA features were investigated over time.
Results: We included 552 patients. *Definite axSpA* was attributed to 175 (32%) patients at BL and 166 (30%) at 2y (***Figure 1***); 155/175 (89%) and 145/166 (87%) fulfilled ASAS classification criteria, respectively. Of the 175 patients with *definite axSpA* at BL, 133 retained the diagnosis, and only 13 changed to *no axSpA* at 2y. Although still considered as axSpA by the rheumatologist, 29 *definite axSpA* patients at BL were no longer definite axSpA at 2y, due to decrease in LOC to <7 (n=14) or incomplete follow-up (n=15). Overall, the diagnosis changed to *definite axSpA* over 2y in 33 patients (BL: 16 *uncertain axSpA*, 12 *uncertain no axSpA*, and 5 *definite no axSpA*); on average, 3 SpA features were already present at BL and 1 to 2 new SpA features developed over 2y (***Table 1***), with response to NSAIDs and MRI sacroiliitis being the most frequently captured over time.
Conclusion: The yield of repeated assessments of SpA features in patients with CBP suspected of axSpA was modest for the new *definite axSpA* diagnosis at 2y. Most SpA features were already present at BL, with imaging findings and response to NSAIDs appearing as frequent incident SpA features potentially adding to a *definite axSpA* diagnosis over time.

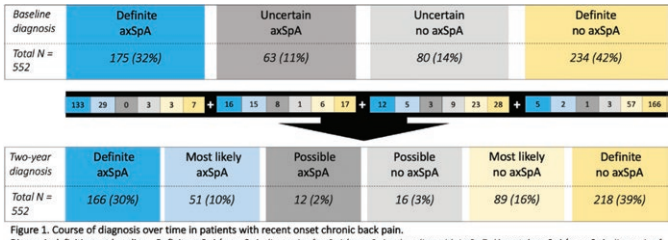

Figure 1. Course of diagnosis over time in patients with recent onset chronic back pain.
Diagnosis definitions at baseline - ***Definite axSpA/no axSpA:*** diagnosis of *axSpA/no axSpA* at baseline with LoC ≥7; ***Uncertain axSpA/no axSpA:*** diagnosis of *axSpA/no axSpA* with LoC <7. **Diagnosis definitions at two years (last observation carried forward approach if two-year visit data was missing)** - ***Definite axSpA:*** diagnosis of *axSpA* with a LoC ≥7 at two years (complete follow-up) or at the two last available visits (missing at the two-year visit); ***Most likely axSpA:*** diagnosis of axSpA with LOC <7 at two years, plus a consistent diagnosis of axSpA in the two last visits (complete follow-up) or diagnosis of *axSpA* with LoC ≥7 at the last visit only (missing at the two-year visit); ***Possible axSpA:*** diagnosis of *axSpA* with LOC <7 at two years, plus no consistent diagnosis of *axSpA* in the last two visits (complete follow-up) or diagnosis of *axSpA* with LoC <7 at the last visit (missing at the two-year visit); ***Possible no axSpA:*** diagnosis of *no axSpA* with LOC <7, plus no consistent diagnosis of *no axSpA* in the last two visits (complete follow-up) or *no axSpA* diagnosis with LoC <7 at the last visit and no alternative diagnosis reported (missing at the two-year visit); ***Most likely no axSpA:*** diagnosis of *no axSpA* with LOC <7, plus a consistent diagnosis of *no axSpA* in the last two available visits (complete follow-up) or diagnosis of *no axSpA* with LoC ≥7 at the last visit only or if LoC <7, plus an alternative diagnosis reported (missing at the two-year visit); ***Definite no axSpA:*** diagnosis of *no axSpA* with a LoC ≥7 at two years (complete follow-up) or at the two last available visits (missing at the two-year visit).

Background: There is a growing interest in understanding the early disease stages of axial and peripheral SpA (axSpA and pSpA). In order to facilitate this, standardized definitions are needed for research purposes.
Objectives: To develop a consensual definition for the terms "early axSpA" and "early pSpA" in the research setting under the auspices of the Assessment of SpondyloArthritis international Society (ASAS).
Methods: The ASAS-SPEAR (SPondyloarthritis EARly definition) steering committee convened an international working group (WG). Five consecutive steps were followed: i) Systematic literature review (SLR) to identify existing definitions of early axSpA/pSpA and to summarize the evidence on the relationship between early treatment and clinical response in SpA[1,2]; ii) Discussion of SLR results within the WG and ASAS community (2022 annual meeting); iii) A three-round Delphi survey (Apr-Nov 2022) inviting all ASAS members to select the items that should be considered for the definition of the terms (using a Likert scale 1-9). In total, 20 items relating to three different aspects (axial symptoms, duration of symptoms and radiographic damage involvement) were voted on. Consensus was defined as acceptance or rejection if ≥70% of responses fell within 7-9 or 1-3 on the Likert scale, respectively; iv) Presentation of Delphi survey results to the WG and later to the ASAS community; v) Final discussion, voting and endorsement by ASAS members (2023 annual meeting).
Results: After discussing the results of the SLR[1,2] (step i) with the ASAS community, consensus was to proceed with an expert-based consensual definition for early axSpA (81% full ASAS members voted in favor) but not for pSpA (54% voted against) (step ii). Importantly, it was decided that the definition should be based on the symptom duration (91% in favor) taking solely axial symptoms into account (77% in favor). A total of 151-164/209 (72-78%) ASAS members participated in the Delphi survey rounds (step iii). Consensus was achieved to define early axSpA as a duration of symptoms of ≤2 years. Relating to axial symptoms, consensus was reached for acceptance of 6 items (axial symptoms should include cervical pain, thoracic pain, back pain, buttock pain and morning stiffness and be defined by a rheumatologist) and rejection of 2 items (should not include shoulder pain and hip pain). In addition, consensus was achieved to define early axSpA regardless of the presence/absence of radiographic damage (Table 1). Following the discussion of the Delphi survey results the WG agreed that in patients with a diagnosis of axSpA **"early axSpA" should be defined as a duration of ≤2 years of axial symptoms. Axial symptoms should include spinal/buttock pain or morning stiffness and should be considered by a rheumatologist as related to axSpA, Figure 1.** The WG proposal was discussed and endorsed by the ASAS community with 88% full ASAS members voting in favor (step v).
Conclusion: Early axSpA has for the first time been defined based on expert consensus. This ASAS definition should be used in research studies addressing early axSpA.

OP0056 SENSITIVITY TO CHANGE OF STRUCTURAL LESIONS IN EARLY AXIAL SPONDYLOARTHRITIS AFTER 10 YEARS OF FOLLOW UP. DATA FROM DESIR COHORT

Keywords: Spondyloarthritis, Imaging

C. López-Medina[1,2], A. Moltó[2], A. Sepriano[3,4], S. Ramiro[4,5], M. Dougados[2].

[4]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [5]*Zuyderland Medical Center, Rheumatology, Heerlen, Netherlands*

Background: The change over time of the structural damage of axial spondyloarthritis (axSpA) is important to consider since it may reflect the severity of the disease. In axSpA this structural damage can be evaluated either at the sacroiliac joints (SIJ) or spine level, and also either on conventional radiographs or Magnetic Resonance Imaging (MRI).
Objectives: To evaluate the sensitivity to change of different structural imaging outcomes over 10 years of follow-up in patients with early axSpA.
Methods: Patients with early onset (≤3 years) axSpA (according to the treating rheumatologist) from the DESIR cohort were included. Radiographs and MRI of the SIJ and spine were obtained at baseline, 1, 2, 5 and 10 years in 4 separate reading waves. Images were scored by 3 trained central readers (wave 1 only 2 readers with one adjudicator) unaware of chronology. The yearly rate of change (ROC) of each outcome was analyzed using generalized estimation equations (GEEs) including all patients with ≥1 score from ≥1 reader from ≥1 wave and using time (years) as explanatory variable. All outcomes (see the list on Table 1) were standardized (difference between the individual's value and the population mean divided by the population SD). In addition, the relative standardized ROC (i.e., the standardized yearly ROC of an outcome divided by the corresponding rate of a reference imaging outcome) was calculated, with a value >1 reflecting larger sensitivity, and <1 lower sensitivity compared to the reference. Finally, the relative standardized ROC per anatomic site was calculated.
Results: Among all locations and modalities, the change in ≥3 fatty lesions was the outcome with the highest sensitivity to change (standardized ROC 0.073 per year). Considering as reference the modified New York criteria (mNY), the two most sensitive to change outcomes in SIJ (taking into account both MRI and radiographs) were ≥3 fatty lesions and the absolute number of fatty lesions on MRI (relative standardized ROC per year 4.867 and 4.130, respectively). Similarly, the most sensitive to change lesion in the spine (both MRI and radiographs) was the mSASSS score (relative standardized ROC per year 1.778) considering ≥1 syndesmophyte as the reference.
Conclusion: MRI structural outcomes in the SIJ, in particular fatty lesions, are more sensitive to change than radiographic outcomes. On the other hand, mSASSS remains the most sensitive method, even if compared to MRI of the spine.

Table 1. Sensitivity of change of the structural lesions.

	Standardized ROC per year	Relative standardized ROC	Relative standardized ROC per anatomic site
Pelvic radiographs			
mNY dichotomous	0.015	1 (reference)	1 (reference)

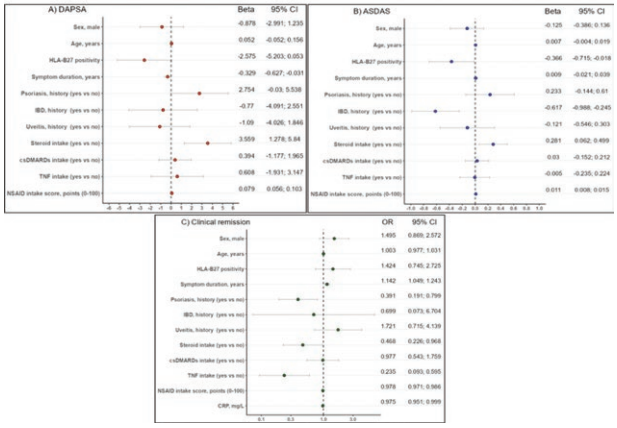
OP0057

FACTORS ASSOCIATED WITH ACHIEVING REMISSION IN PATIENTS WITH EARLY PERIPHERAL SPONDYLOARTHRITIS: 10-YEAR RESULTS FROM THE GERMAN SPONDYLOARTHRITIS INCEPTION COHORT (GESPIC)

Keywords: Epidemiology, Registries, Spondyloarthritis



M. Torgutalp[1], X. Peng[1], F. Proft[1], V. Rios Rodriguez[1], J. Rademacher[1,2], M. Protopopov[1], H. Haibel[1], M. Rudwaleit[3], J. Sieper[1], D. Poddubnyy[1]. Background: Depending on leading manifestation, Spondyloarthritis (SpA) is classified as axial (axSpA) or peripheral SpA (pSpA). Achieving of remission/inactive disease is key goal in treatment of SpA, including pSpA. Results from recent worldwide ASAS PerSpA study showed that nearly 10% of SpA patients were identified as having pSpA (as opposed to other forms of SpA) by rheumatologist, but there are still no long-term observational studies focusing on outcomes including disease activity/remission in pSpA.
Objectives: To investigate factors associated with disease activity and achievement of remission over a period of up to 10 years of clinical observation in early pSpA patients.
Methods: Data from patients diagnosed with pSpA in GESPIC (with predominant peripheral manifestations, symptom duration of up to 5 years and not classified as axSpA) according to rheumatologist were used for this study. Visits were scheduled every 6 months for 2 years, then annually up to year 10. Clinical characteristics, examination (arthritis, enthesitis), and activity (questionnaires and laboratory) were collected at visits. Association between parameters and disease activity/remission [defined by Disease Activity in Psoriatic Arthritis (DAPSA), Axial SpA Disease Activity Score (ASDAS), and clinical remission (complete absence of arthritis or enthesitis)], was analysed by generalized estimating equations (GEE).
Results: The mean age of 115 pSpA patients (51.3% male) was 37.3 ± 12.2 years, and 71 (61.7%) patients were HLA-B27 positive. Baseline DAPSA and ASDAS were 13.3 ± 8.1 and 2.4 ± 0.9. During follow up 48 (41.7%), 46 (41.7%), and 94 (81.9%) patients reached at least once DAPSA remission (DAPSA <4), ASDAS-Inactive disease (ASDAS<1.3), and clinical remission, respectively. In univariable analyses, female sex, older age, HLA-B27 negativity, current and history of psoriasis, steroid, csDMARDs and higher NSAID intake were associated with higher DAPSA and lower odds of remission. Similar results were observed regarding ASDAS and clinical remission (Table 1). Multivariable analyses showed that history of psoriasis, HLA-B27 negativity, steroid intake, and higher NSAID intake were associated with higher DAPSA and ASDAS scores (Figure 1A,B), while longer symptom duration, psoriasis history, steroid, TNFi and higher NSAID intake, and higher CRP were associated with lower odds of remission (Figure 1C).
Conclusion: Several parameters associated with higher disease activity and absence of remission were identified. Psoriasis and higher CRP were associated with lower odds of achieving clinical remission, while an association with drug usage is likely a consequence of high disease activity.

OP0058 PREDICTION OF LOW DISEASE ACTIVITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH SECUKINUMAB IN REAL WORLD – DATA FROM THE GERMAN AQUILA STUDY

Keywords: Real-world evidence, Spondyloarthritis, Artificial Intelligence

A. Vodencarevic[1], J. Brandt-Juergens[2], D. Peterlik[1], B. Gmeiner[1], U. Kiltz[3].
[1]Novartis, Novartis Pharma GmbH, Nürnberg, Germany; *[2]Rheumatologie, Schwerpunktpraxis, Berlin, Germany*; *[3]Rheumazentrum Ruhrgebiet, Herne und Ruhr-Universität Bochum, Herne, Germany*

Background: Secukinumab (SEC) proved to be an effective treatment for patients suffering from ankylosing spondylitis (AS) in randomized clinical trials [1]. There is only limited knowledge on prediction of low disease activity (LDA) and treatment strategy in AS patients under SEC treatment in routine clinical care.
Objectives: Using real-world data from the German non-interventional study AQUILA [2], the main objectives were (1) to predict LDA in individual AS patients treated with SEC through machine learning methods and (2) to identify the most important predictors and their influence on the prediction using explainable artificial intelligence (XAI).
Methods: Data of 580 AS patients from the AQUILA study were used. Thirty-two demographic, clinical and treatment parameters at baseline (BL) served as input data to develop prediction models. LDA was defined as Bath ankylosing spondylitis disease activity index (BASDAI) ≤ 2.0 at week (w) 16 (+/- 6 w). Samples were divided into training (70%) and validation (30%) cohorts. Ten different prediction models were applied and compared. Model performance was measured using area under the receiver operating characteristic curve (AUROC) which represents the probability that a randomly selected patient with LDA will have higher prediction to achieve LDA than a patient with moderate/high disease activity. Additionally, sensitivity and specificity of the prediction model were computed and express the proportion of correctly identified patients who reach or don't reach LDA at w16, respectively. Shapley XAI estimated importance and impact of each predictor based on how it affected the change in individual prediction [3].
Results: The most influencing predictor was BASDAI at BL, followed by the number of pretreatments with biologics, C-reactive protein (CRP), assessment of spondyloarthritis international society health index (ASAS-HI) and patient height (**Figure 1 A**). AUROC of the best performing prediction model was 0.84. Sensitivity and specificity were 0.87 and 0.67, respectively. Applied XAI approach showed that the lower the BL values of BASDAI, ASAS-HI and number of pretreatments with biologics were, the higher the probability of reaching LDA at w16 was. The opposite was the case for BL values of CRP and body height (**Figure 1 A**). The approach also provided visual explanations of patient-individual predictions: Variables with values shown in green color increased probability of reaching LDA at w16, whereas red ones showed the opposite effect (**Figure 1 B**).
Conclusion: A promising prediction model accuracy of LDA in AS patients treated with SEC could be reached and validated. Identified main predictors at BL, such as BASDAI and number of pretreatments with biologics, and their direction of influence on the prediction of LDA mostly match the existing clinical knowledge [4]. The analysis showed that XAI can provide useful clinical insights into patient-individual predictions, potentially guiding AS treatment decisions in future.

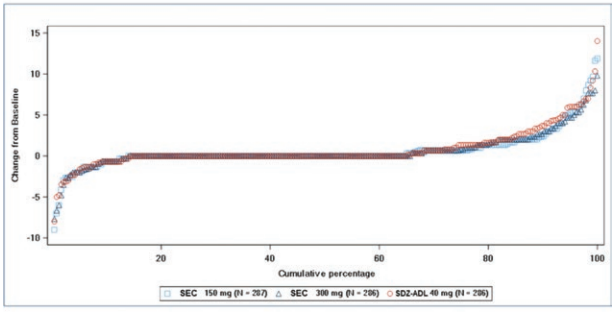
Background: Limited data exist on the effect of biologics in slowing radiographic progression in patients (pts) with radiographic axial spondyloarthritis (r-axSpA). Two-year data from MEASURE 1 showed low radiographic progression with secukinumab (SEC).[1]

Objectives: To compare the effect of SEC vs adalimumab biosimilar (SDZ-ADL) on spinal radiographic progression from SURPASS,[2,3] the first head-to-head study in r-axSpA.

Methods: In this phase IIIb study, bio-naïve pts with active r-axSpA with a BASDAI ≥4, spinal pain score ≥4 (range 0–10), total back pain score ≥40 mm (range 0–100 mm), and with hs-CRP ≥5 mg/L or ≥1 syndesmophyte(s) on spinal radiograph were randomised (1:1:1) to SEC (150/300 mg; dose-blinded) or SDZ-ADL (40 mg; open label). Radiographs and MRIs were reviewed by 3 independent central readers (no adjudication performed) blinded to treatment and chronology of images. Primary endpoint was the proportion of pts with no radiographic progression (change from baseline [CFB] in modified Stoke AS Spinal Score [mSASSS] ≤0.5) on SEC vs SDZ-ADL at week (wk) 104 (superiority testing). Secondary endpoints included CFB-mSASSS at wk 104, proportion of pts with ≥1 syndesmophyte(s) at baseline (BSL) with no new syndesmophytes(s) at wk 104, CFB-MRI Berlin sacroiliac joint (SIJ) inflammation score, CFB-AS Spine MRI-activity (ASspiMRI-a) Berlin modification score, and safety.



Results: Overall, 859 pts received SEC 150 mg (n=287), 300 mg (n=286), or SDZ-ADL (n=286). With 78.5% male, mean age 42.1 years, mSASSS 16.6, BASDAI 7.1, hsCRP 20.4 mg/L, and 73% with ≥1 syndesmophyte(s), this population had high risk of radiographic progression. At wk 104, cumulative distribution of CFB-mSASSS was similar across arms (**Figure 1**). Proportion of pts with no radiographic progression was 66.1%, 66.9%, and 65.6% (*P*=ns, both SEC doses) while mean CFB-mSASSS was 0.54, 0.55, and 0.72 with SEC 150 mg, 300 mg, and SDZ-ADL. Overall, 56.9%, 53.8%, and 53.3% of pts in SEC 150 mg, 300 mg, and SDZ-ADL arms, with a BSL ≥1 syndesmophyte(s) did not develop new syndesmophyte(s) by wk 104 (**Table 1**). In the MRI sub-set (N=418), mean SIJ scores at BSL and wk 16 were 2.54 and 0.98 (SEC 150 mg), 1.96 and 0.92 (SEC 300 mg), and 1.59 and 0.38 (SDZ-ADL); corresponding spine scores were 3.50 and 1.79, 2.56 and 1.25, and 3.00 and 0.71.

Conclusion: Spinal radiographic progression over 2 years was low with no significant difference between SEC and SDZ-ADL arms. No new safety signals were identified.

OP0060 CLINICAL CONSEQUENCES OF INFLIXIMAB IMMUNOGENICITY AND THE IMPACT OF THERAPEUTIC DRUG MONITORING: SECONDARY ANALYSES OF A RANDOMISED CLINICAL TRIAL

Keywords: Rheumatoid arthritis, bDMARD, Spondyloarthritis

M. K. Brun[1,2], K. H. Bjørlykke[2,3], J. E. Gehin[4], D. J. Warren[4], R. A. Klaasen[4], J. Sexton[1], Ø. Sandanger[5], T. K. Kvien[1,2], C. Mørk[6], J. Jahnsen[2,3], N. Bolstad[4], K. K. Jørgensen[3], E. A. Haavardsholm[1,2], G. L. Goll[1], S. W. Syversen[1]. *[1]Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*; *[2]University of Oslo, Institute of Clinical Medicine, Oslo, Norway*; *[3]Akershus University Hospital, Department of Gastroenterology, Lørenskog, Norway*; *[4]Norwegian Radium Hospital, Department of Medical Biochemistry, Oslo, Norway*; *[5]Oslo universitetssykehus HF, Rikshospitalet, Section of Dermatology, Oslo, Norway*; *[6]Akershus Dermatologist Center, Akershus Dermatologist Center, Akershus, Norway*

Background: Neutralising anti-drug antibodies (ADAb) are a problem in treatment with TNF-inhibitors (TNFi). Prospective data are needed to better understand how ADAb formation impacts safety and treatment outcomes of TNFi. Proactive therapeutic drug monitoring (TDM) allows for timely detection of ADAb and this strategy may have a role in reducing the negative clinical consequences of ADAb.
Objectives: To explore the temporal relation between anti-infliximab antibody formation and treatment outcomes and adverse events, and to assess the impact of TDM as a strategy to reduce these consequences.
Methods: Patients with immune mediated inflammatory diseases on infliximab therapy (n=615; 181 spondyloarthritis, 120 rheumatoid arthritis, 72 psoriatic arthritis, 114 ulcerative colitis, 83 Crohns disease and 45 psoriasis) were included in the Norwegian Drug Monitoring (NOR-DRUM) trials (1, 2) and randomised to TDM or standard infliximab therapy. Patients were followed for 30 and 52 weeks in the NOR-DRUM A (induction therapy) and NOR-DRUM B (maintenance therapy) trials, respectively. Neutralising ADAb were assessed with a drug sensitive automated fluorescence assay at each infusion. In this sub-study, we assessed the risk of; failure to achieve remission (analysis A), disease worsening during maintenance therapy (analysis B), treatment discontinuation (analysis C) and adverse events (analysis D) in patients developing ADAb compared to patients without ADAb using logistic- or cox regression and Kaplan-Meier survival analyses, stratified by TDM or standard therapy. Regression analyses were adjusted for potential confounders (Table 1). Remission and disease worsening were defined by disease specific composite scores (1, 2).
Results: ADAb were detected in 147/615 (24 %) patients. Patients with ADAb had higher risk of not achieving remission 30 weeks after initiating infliximab therapy (odds ratio (OR) 2.4, 95 % confidence interval (CI) 1.3-4.2, P<0.01) (Table 1, Figure 1A) and of having a disease worsening during 52 weeks of infliximab maintenance therapy (hazard ratio (HR) 2.1, CI 1.4-3.3, P<0.001) (Figure 1B). ADAb formation was not significantly associated with adverse events in general, but the risk of infusion reactions was highly increased in patients with ADAb (HR 29, CI 11-78, P<0.001). The risk of infliximab treatment discontinuation was increased in ADAb positive patients (HR 6.5, CI 4.7-8.9, P<0.001). Patients developing ADAb in the TDM group had lower risk of disease worsening or an infusion reaction than patients with ADAb in the standard infliximab therapy group (Table 1, Figure 1B and C). Patients with ADAb discontinued infliximab treatment more often in the TDM group than in the control group (Table 1, Figure 1D).
Conclusion: Formation of ADAb led to poorer clinical outcomes both during induction and maintenance therapy with infliximab and increased the risk of infusion reactions. Early detection of ADAb by proactive TDM reduced the negative consequences of ADAb, both on infliximab effectiveness and safety, highlighting the role of proactive TDM in optimising TNFi therapy.

Table 1. Treatment and safety outcomes related to ADAb formation and TDM

Analysis A) Non-remission	**OR (CI)**	**P**
ADAb	2.4 (1.3-4.2)	<0.01
TDM	1.0 (0.7-1.5)	0.9
Analysis B) Disease worsening	**HR (CI)**	**P**
ADAb	2.1 (1.4,3.2)	<0.01
TDM	0.4 (0.3-0.6)	<0.001
Analysis C) Infusion reaction	**HR (CI)**	**P**
ADAb	29 (11-78)	<0.001
TDM	0.3 (0.1-0.7)	<0.01
Analysis D) Treatment discontinuation	**HR (CI)**	**P**
ADAb	6.5 (4.7-8.9)	<0.001
TDM	1.4 (1.0-1.8)	0.03

Results from multivariable logistic (A)- or cox (B-D) regression models including the covariates: ADAb, TDM, age, sex, diagnosis, comedication. Results shown in table are risk of A) non-remission week 30, B) disease worsening during 52 weeks of maintenance therapy, C) infusion reactions and D) infliximab treatment discontinuation for patients developing ADAb and for patents in the TDM group.

Background: Extra-musculoskeletal manifestations (EMMs) are common in patients with spondyloarthritis (SpA), but there are limited data on the impact of upadacitinib (UPA), an oral JAK inhibitor, on EMMs in SpA patients.
Objectives: To assess the development of EMMs among patients with PsA, AS, or non-radiographic axial spondyloarthritis (nr-axSpA) treated with UPA 15 mg (UPA15) or placebo (PBO) in the SELECT clinical trial program.
Methods: This analysis includes safety data from UPA trials in PsA (2 trials),[1,2] AS (2 trials),[3,4] and nr-axSpA (1 trial).[5] All trials were designed with initial randomization to UPA or PBO for a pre-specified number of weeks, followed by a second open-label extension where PBO-treated patients were switched to UPA. Treatment-emergent adverse events (TEAEs) of EMMs, including uveitis, inflammatory bowel disease (IBD), and psoriasis, were assessed; as psoriasis is considered a core manifestation of PsA, it was only evaluated as an EMM in AS and nr-axSpA.[6] TEAEs were defined as an AE with onset on or after first dose of study drug and ≤30 days after last dose and summarized for PsA (pooled PBO to week 24 and pooled UPA15 to data cut-off [15 Aug 2022]), AS (pooled PBO to week 14 and pooled UPA15 to data cut-off), and nr-axSpA (PBO to week 52 and UPA15 to data cut-off). EMMs are reported as exposure-adjusted event rates (EAERs; events/100 patient years [E/100 PY]) and are stratified by patients with a reported history (flare) of the respective EMM vs those without a history (new onset).
Results: The vast majority (92-99%) of patients across PsA, AS, and nr-axSpA did not have a prior history of EMMs at baseline (**Table 1**). In PsA, development of uveitis and IBD were low regardless of treatment or prior history (**Figure 1**). In AS, development of uveitis was numerically higher (E/100 PY [95% CI]) in patients treated with PBO (total: 7.5 [2.7, 16.3]) vs UPA15 (total: 2.8 [1.8, 4.1]) and in patients with a prior history of uveitis (PBO: 6.2 [2.0, 14.5], UPA15: 2.1 [1.3, 3.3]) vs no prior history (PBO: 1.2 [0.0, 6.9]; UPA15: 0.6 [0.2, 1.4]); occurrence of IBD and psoriasis were low regardless of treatment or prior history. In nr-axSpA, development of uveitis was low regardless of prior history, while the total rate was numerically higher in patients treated with PBO (2.1 [0.4, 6.3]) vs UPA15 (0.9 [0.2, 2.7]); occurrence of IBD and psoriasis were low or absent.
Conclusion: Data from this post-hoc analysis describe adverse events of relevant EMMs in the SELECT program and should be interpretated with caution as the efficacy of UPA in patients with specific EMMs was not systematically evaluated, as well as the overall low number of events observed. Development of EMMs in patients treated with UPA15 was generally low across PsA, AS, and nr-axSpA. Uveitis was numerically higher in patients treated with PBO vs UPA, and particularly in patients with AS. A better understanding of the impact of UPA across EMMs in SpA, and subsequent follow-up analyses, may help clinicians make informed treatment decisions and guide future treatment recommendations.

Background: The transition from psoriasis (PsO) to PsA is of considerable interest for potential prevention and interception of PsA[1].
Objectives: To formulate EULAR points to consider (PtC) for the development of data-driven guidance and consensus for clinical trials and clinical practice in the field of prevention/interception of PsA.
Methods: A multidisciplinary EULAR task force of 30 European members was established and the EULAR standardized operating procedures were followed.
Results: Nomenclature was proposed for 3 stages towards PsA development: i) PsO patients at higher risk of PsA (i.e., nail disease, obesity, severe PsO); ii) subclinical PsA (those at more imminent risk of PsA for arthralgia and imaging abnormalities) and iii) clinical PsA that most typically manifests as synovitis *(Figure 1)*. For the purpose of prevention, our SLR showed that the vast majority of new PsA presented with synovitis. Thus, the presence of synovitis in PsO could be used as an outcome for prevention trials. Five overarching principles (OAPs) addressed the nature of PsA at its onset and underline the importance of collaboration between rheumatologists and dermatologists *(Table 1)*.The 10 PtC highlight arthralgia plus imaging abnormalities as key elements of subclinical PsA that can be used as potential short-term predictors of PsA development and useful criteria to design trials for PsA interception *(Table 1)*.
Conclusion: These PtC are helpful to define the features of PsO patients suspicious for progression to PsA. This information may ultimately facilitate identification of those who could benefit from a therapeutic intervention to attenuate, delay, or prevent PsA development.

Table 1.

Overarching Principles	Level of Evidence	Level of Agreement
A.PsO patients may develop PsA at different time-points.		9.7± 0.7
B.Close collaboration between dermatologists and rheumatologists is important to understand and optimize PsA prevention, interception and early diagnosis.		9.7± 0.6
C.The identification of risk factors for PsA development in PsO patients may influence therapy choices for PsO.		8.9± 1.3
D.The rheumatologist has a key role in the diagnosis and management of PsA.		9.7± 0.6
E.Certain systemic treatments of PsO may reduce the risk of transition to PsA.		8.4± 1.8
Points to Consider		
1.Arthralgia in PsO patients should be considered as a risk factor for PsA, taking into account alternative diagnoses such as osteoarthritis and fibromyalgia.	3a	9.2± 1.3
2.In PsO patients, joint and entheseal pain and functional limitation should be enquired about regularly and, if present, referral to a rheumatologist should be considered	3b	9.3± 0.9
3.Imaging in PsO could be used to help identify those at risk for PsA; in particular to detect synovio-entheseal involvement/abnormalities	3b	9.1± 1.2
4.Imaging abnormalities in the absence of musculoskeletal symptoms should be considered carefully in order to avoid the risk of inappropriate treatment	3b	9.5± 0.9
5.The combination of musculoskeletal symptoms and imaging abnormalities in PsO, without a diagnosis of PsA, should be considered as an entry criterion for clinical trials to prevent the transition to PsA	5	8.8± 1.2
6.In the context of clinical trials, patients with PsO and clinically evident synovitis should be considered to have PsA, when alternative diagnoses have been excluded	5	9.3± 0.8
7.In PsO patients that require systemic treatment, the risk of transition to PsA should be taken into account in the choice of treatment	5	9.1± 1.3
8.PsO patients with obesity, nail disease and/or extensive PsO should be considered at increased risk for PsA over the longer term	3a	9.3± 0.9
9.PsO patients should be informed about the risk of developing PsA and prompted to report their symptoms to facilitate early PsA recognition	5	9.5± 0.8
10.In PsO patients, risk factors for PsA development should be regularly assessed over time	5	9.5± 0.8

OP0063

PSA PATIENTS RECEIVING MONOTHERAPY WITH BDMARD/TSDMARD DO NOT DIFFER IN CLINICAL PARAMETERS FROM PATIENTS RECEIVING BDMARD/TSDMARD IN COMBINATION WITH MTX - DATA FROM RABBIT-SPA

Keywords: Registries, Psoriatic arthritis

A. Regierer[1], D. Kiefer[2], G. Schett[3], A. Krause[4], P. Sewerin[2], A. Weiß[1], A. Strangfeld[1]. [1]*Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology, Berlin, Germany*; [2]*Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*; [3]*University Clinic, Rheumatology and Immunology, Erlangen, Germany*; [4]*Immanuel Hospital, Department of Rheumatology, Clinical Immunology and Osteology, Berlin, Germany*

Background: While in RA, methotrexate (MTX) increases the efficacy of most biologic (b) and targeted synthetic (ts) disease modifying anti-rheumatic drugs (DMARDs), the situation in PSA may be substantially different.

Objectives: To compare clinical and patient reported baseline parameters of PsA patients starting bDMARD/tsDMARD monotherapy with those starting these treatments in combination with MTX as well as to assess the drug retention rates in the two groups.

Methods: RABBIT-SpA is a prospective longitudinal cohort study including axSpA and PsA patients enrolled at initiation of a new conventional or bDMARD/tsDMARD treatment. In this analysis, PsA patients newly enrolled at initiation of bDMARD/tsDMARD treatment were stratified into two groups: as monotherapy or in combination with MTX. Treatment retention was compared by drug survival analysis.

Results: 69% of the patients (n=833) started bDMARD/tsDMARD as monotherapy. Combination treatment with MTX was started in 31% of the patients (n=369). In 85% of the patients in the combination group, MTX had previously been given as monotherapy and treatment was then escalated with the addition of a bDMARD/tsDMARD. Baseline clinical parameters were very similar between the two groups (Table 1). No difference between the groups was found in the six different PsA domains skin, joints, dactylitis, enthesitis, nail psoriasis, and axial involvement. Only the patients´ satisfaction with tolerability of the current treatment (4 point Likert scale) was significantly better in the combination group.

Table 1. Patient characteristics by the two treatment groups

	b/tsDMARD mono	b/tsDMARD +MTX	Total
n	833	369	1202
Females, n (%)	486 (58)	213 (58)	699 (58)
Age, mean (SD)	51.9 (12.6)	52.2 (12.1)	52 (12.4)
BMI, mean (SD)	29.1 (6)	28.7 (5.9)	29 (6)
CRP mg/l, mean (SD)	7.2 (11.5)	7.6 (13.7)	7.3 (12.2)
TJC (0-68), mean (SD)	7 (8.2)	6.9 (7.6)	7 (8)
SJC (0-66), mean (SD)	3.5 (5.1)	2.8 (3.8)	3.3 (4.8)
Number of sites with enthesitis, mean (SD)	0.6 (1.6)	0.7 (1.8)	0.6 (1.7)
Dactylitis, n (%)	161 (20)	60 (16)	221 (19)
Axial manifestation, n (%)	180 (22)	76 (21)	256 (22)
Affected body surface area in %, mean (SD)	8.7 (15.8)	7.9 (13.2)	8.5 (15)
Nail psoriasis, n (%)	345 (42)	148 (40)	493 (41)
Uveitis, n (%)	18 (2)	3 (1)	21 (2)
IBD, n (%)	18 (2)	3 (1)	21 (2)
Number of comorbidities, mean (SD)	2.2 (2.3)	2.1 (2.2)	2.2 (2.3)
Physician global disease activity, mean (SD)	5.1 (1.9)	5.3 (1.9)	5.2 (1.9)
Physician skin disease activity, mean (SD)	3.3 (2.5)	3.1 (2.6)	3.2 (2.5)
DAPSA, mean (SD)	22.9 (14)	22.4 (12.9)	22.7 (13.7)
Patient global disease activity, mean (SD)	5.7 (2.4)	5.7 (2.4)	5.7 (2.4)
Patient pain, mean (SD)	5.6 (2.4)	5.6 (2.4)	5.6 (2.4)
DLQI, mean (SD)	6.4 (6.4)	4.8 (5.9)	5.9 (6.3)
HAQ, mean (SD)	1 (0.7)	0.9 (0.7)	1 (0.7)
bDMARDs before, n (%)	380 (46)	122 (33)	502 (42)
csDMARDs before, n (%)	647 (78)	332 (90)	979 (81)
MTX before, n (%)	598 (72)	325 (88)	923 (77)
Glucocorticoids, n (%)	234 (29)	125 (36)	359 (31)
Patient satisfaction with the current treatment, n (%)	260 (43)	149 (52)	409 (46)
Patient satisfaction with the tolerability of the current treatment, n (%)	349 (60)	217 (76)	566 (66)

Drug retention rates did not differ between the two groups (p=0.19; Figure 1). After 6 months, 62% of patients with combination and 58% of those receiving bDMARD/tsDMARD as monotherapy were still on their respective treatment.

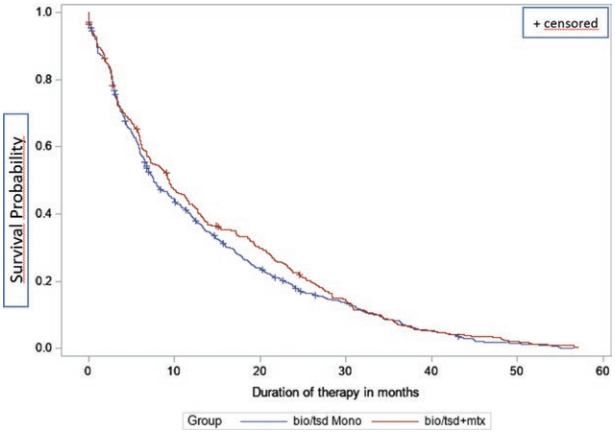

Figure 1. Drug retention rates

Conclusion: Baseline clinical parameters did not differ whether a PsA patient was started on bDMARD/tsDMARDs monotherapy or MTX-bDMARD/tsDMARDs combination. Especially parameters usually taken into account for GRAPPA or EULAR treatment recommendations, such as the number of swollen or tender joints, the number of involved enthesial sites and the severity of affected skin did not differ between the two treatment groups. Also drug retention rates were very similar. It seems that in routine care, the decision to continue or stop MTX at escalation to bDMARD/tsDMARD treatment mostly depends on the subjective tolerability of the ongoing MTX treatment.

OP0064 OBESITY IN PSORIATIC ARTHRITIS IS INCREASINGLY AFFECTING MEN AND APPEARS LESS DEPENDENT OF SOCIOECONOMIC STATUS THAN IN THE GENERAL POPULATION

Keywords: Epidemiology, Psoriatic arthritis, Comorbidities

M. Stirnimann[1], J. T. Maul[2], E. Vallejo-Yagüe[3], A. M. Burden[3], B. Moeller[4], M. J. Nissen[5], S. Kissling[6], O. Distler[1], C. Ospelt[1], A. Ciurea[1], R. Micheroli[1]. *[1]University of Zurich, University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland*; *[2]University of Zurich, University Hospital Zurich, Department of Dermatology and Venereology, Zurich, Switzerland*; *[3]ETH Zurich, Institute of Pharmaceutical Sciences, Department of Chemistry and Applied Biosciences, Zurich, Switzerland*; *[4]Inselspital University Hospital Bern, Department of Rheumatology, Immunology and Allergology, Bern, Switzerland*; *[5]Geneva University Hospitals, Division of Rheumatology, Geneva, Switzerland*; *[6]Swiss Clinical Quality Management Foundation, Statistics Group, Zurich, Switzerland*

Background: Obesity in psoriatic arthritis (PsA) is associated with an elevated cardiovascular risk and higher disease activity. It represents a negative prognostic marker with a lower probability of remission on biologic therapy. Furthermore, obese patients with psoriasis have an increased risk of developing PsA. However, the prevalence of obesity in PsA compared with the general population and associated socioeconomic factors that would allow interventions targeted at these individuals are unknown.
Objectives: This study aimed to compare the prevalence of obesity in PsA patients and individuals from the general population at several time points and within those time points and find socioeconomic characteristics for obesity in PsA patients.
Methods: We compared the distribution of different body mass index (BMI) groups between patients with PsA from the Swiss Clinical Quality Management (SCQM) cohort and individuals from the general Swiss population using publicly available data from the Federal Statistical Office collected in 2007, 2012, and 2017. Patients were grouped into four BMI categories: underweight (BMI <18.5), normal weight (BMI 18.5 to <25), overweight (BMI 25 to <30) and obese (BMI ≥30). A comparison of BMI categories between the general Swiss population and PsA patients was performed by sex and level of education using the Chi-Squared Goodness of Fit test. Patient characteristics were compared using Fisher's exact test for categorical variables.
Results: The PsA population recruited to the SCQM registry increased from 517 patients in 2007 (54.5% male, mean (SD) age 47.9 (22.7) years) to 1245 patients in 2017 (51.7% male, mean (SD) age 53.1 (23.9) years). Within this timeline the mean (SD) BMI of 26.6 (10.0) in 2007 raised to 27.5 (10.6) in 2017, representing a significant change (p<0.001). Compared to the general Swiss population, the proportions of obese and overweight individuals were significantly higher in PsA patients at all collected time points (e.g., in 2017: 27.2% being obese and 36.6% being overweight in PsA patients compared to 11.3% being obese and 30.6% being overweight in the general Swiss population) (Figure 1A). In male PsA patients, the proportion of obesity increased, while female PsA patients had a slightly lower proportion of obese patients in 2017 than in 2012 (proportions of obese PsA patients in 2007, 2012 and 2017: 17.9%, 23.0%, and 27.3% in males compared to 22.4%, 28.8%, and 27.1% in females, respectively) (Figure 1B). Compared to the general Swiss population, the proportion of obese and overweight PsA patients was higher in both sexes at all three time points. Higher socioeconomic status represented by a higher level of education was associated with lower proportions of obesity and overweight in the general Swiss population at all three time points. However, patients with PsA lacked those differences in 2007. A decrease of obesity and overweight proportions in PsA patients exists only between secondary to tertiary education in 2012 and 2017. Between mandatory and secondary education, the proportions stay similar (Figure 1C shows the distribution of the BMI groups within education levels using data from 2017). In addition, PsA patients who worked in physically demanding occupations (e.g., transport, manufacturing or agriculture) had a comparable proportion of overweight and obesity as patients who worked in less physically demanding occupations (e.g., office workers, homemakers, teachers) (p=0.13).
Conclusion: Overweight and obesity are much more prevalent in patients with PsA than in the general population. Men have shown an increasing trend of obesity in recent years, and our data suggest that it is not only the socially disadvantaged who are at risk. There is an urgent need to address the expanding obesity epidemic in PsA with future public health incentives that should consider our findings.

OP0065 THE DETERMINANTS OF RADIOGRAPHIC PROGRESSION IN EARLY PSA PATIENTS

Keywords: Outcome measures, Imaging, Psoriatic arthritis

G. H. Koc[1], M. R. Kok[2], J. Luime[1], I. Tchetverikov[3], F. R. Kasiem[1], K. Wervers[1], Y. Goekoop-Ruiterman[4], L. A. Korswagen[5], F. Fodili[6], M. Van Oosterhout[7], N. H. A. M. Denissen[8], R. Dolhain[1], M. Vis[1]. *[1]Erasmus MC, Rheumatology, Rotterdam, Netherlands*; *[2]Maasstad Hospital, Rheumatology, Rotterdam, Netherlands*; *[3]Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands*; *[4]Haga Hospital, Rheumatology, Zuid-holland, Netherlands*; *[5]Franciscus Gasthuis & Vlietland, Rheumatology, Rotterdam, Netherlands*; *[6]Reumazorg Zuid West Nederland, Rheumatology, Roosendaal, Netherlands*; *[7]Groene Hart Ziekenhuis, Rheumatology, Gouda, Netherlands*; *[8]Amphia Hospital, Rheumatology, North Brabant, Netherlands*

Background: Psoriatic arthritis (PsA) is inflammatory arthritis associated with a progressive erosive disease which had been reported in more than one-half of patients with PsA and is often associated with functional impairment [1]. Despite advances in diagnosis and therapy, radiographic structural damage is still prevalent in PsA. To shed light on this topic, we studied which clinical characteristics determine radiographic progression using conventional radiography.
Objectives: Our aim is to assess baseline clinical parameters as determinants for radiographic progression in early PsA patients at 2-year follow-up.
Methods: The study population consisted of 358 PsA patients from the DEPAR study which consists of PsA patients who were newly diagnosed from 11 centers in the Netherlands. Radiographic progression was measured with the modified Total Sharp Score(mTSS). The proportion of patients with radiographic progression was defined as a change in(ΔmTSS)>1.97(the smallest detectable change) over 2 years of follow-up. Baseline clinical parameters comparisons between groups at diagnosis were made by Student's t-test, chi-squared test, ANCOVA(age, gender baseline CRP and baseline mTSS were used as confounders). All clinical data are observed, without imputation; except for the mTSS values, which were imputed using the linear interpolation approach.
Results: Of the 358 early PsA patients, change in mTSS(mean(S.D.) was found 1.23(5.21), and 42 were in the radiographic progression group at follow-up 2-year(12%). At diagnosis, the mean age of the progression group was older than the non-progression group(57 ± 14 vs 50 ± 14). Patients who had a radiographic progression in 2 years had significantly higher median scores in mTSS(22, IQR =4-48 vs 0, IQR =0-2) and in joint space narrowing score(JSN)(13, IQR =1-23 vs 0, IQR = 0-1) at diagnosis. The erosion score in progressors followed poorer results compared to non-progressors but there was no significance. In addition, the patients with progressive mTSS had a significantly higher prevalence of erosive disease at baseline(57% versus 18%). The progression group had higher swollen joint counts (median(IQR)) but was no difference in statistics. However, the percentage of the presence of swollen joints was significantly greater in the progression group at baseline(93% vs 78%)(Figure 1). Baseline CRP levels were higher in progressions than non-progressions, but there was no difference between groups as a continuous measure(12.3(18.4) vs 8.5(13.6)). Furthermore, the progression group had a significantly higher percentage of patients with CRP levels of more than 1 mg/dl(88% vs. 74%). Meanwhile, DAPSA, ESR, and the baseline presence of dactylitis/enthesitis did not differ between the groups. We also observed a difference in initial treatments between progressors and non-progressors.
Conclusion: According to this real-world longitudinal cohort, early PsA patients have low radiographic progressions with the current treatment protocols. Baseline clinical determinants for radiographic progression at follow-up 2 years are older age, swollen joints, erosive disease, JSN score, and baseline CRP levels (>1 mg/dl).

OP0066

HIGHER COMORBIDITY BURDEN IN EARLY PSORIATIC ARTHRITIS AS COMPARED TO EARLY RHEUMATOID ARTHRITIS: CLUES FOR PATHOGENESIS OF PSORIATIC DISEASE

Keywords: Rheumatoid arthritis, Psoriatic arthritis, Comorbidities

A. Ishchenko[1], R. Lories[2], P. Verschueren[2], K. De Vlam[2]. *[1]UZ Gasthuisberg, Rheumatology, Leuven, Belgium*; *[2]UZ Gasthuisberg, Rheumatology, Leuven, Belgium*

Background: Prevalence of comorbidities and cardiovascular risk factors in rheumatoid arthritis (RA) and psoriatic arthritis (PsA) is higher than in general population. Chronic systemic inflammation is perceived as a major cause of increased comorbid conditions. Obesity and certain metabolic disturbances are present at early stages of the PsA suggesting a link between certain comorbidities and PsA at a pathophysiological level.
Objectives: The aim of the study was to investigate which comorbidities contribute to metabolic burden and cardiovascular morbidity in early PsA and to compare the rate of comorbidities to sex and age matched healthy volunteers and early RA patients.
Methods: Clinical, demographic data and comorbidities were collected from patients with PsA (all CASPAR positive), RA (all 2010 ACR positive) from two prospective multicenter cohorts (METAPSA&CARRERA) and from healthy volunteers (matched by sex and age). Patients were naïve to DMARD treatment and had symptom duration of < 2 years.
Results: Patients with PsA (67) and RA (50) were compared to healthy volunteers (61) (Table 1). The overall number of comorbidities was high in PsA (74.6%), RA (66.7%) and control group (60.7%) (p=0.238). However, more PsA patients had multiple comorbidities than RA patients and controls (p=0.007). PsA and RA patients had above normal BMI, higher than matched controls. RA group had a higher proportion of smokers than PsA group and controls. Number of patients having cardiovascular risk factors was higher in PsA (82.1%) and in RA (88.9%) as compared to controls (62.3%) (p=0.003). The most frequent comorbidity was dyslipidemia in both RA and PsA. The rate of hyperuricemia and depression were significantly higher in PsA than in RA and controls. The rate of obesity, type 2 diabetes mellitus, arterial hypertension, COPD, gout, malignancy was similar in PsA and RA but higher than in controls. Patients with PsA had higher Charlson comorbidity index and higher rate of cardiovascular disease as compared to RA and control group (p=0.005).
Conclusion: In conclusion, patients with PsA have a high cardiovascular and metabolic burden already at early stages of the disease. They have higher rate of multiple comorbidities and higher of cardiovascular morbidity as compared to age-matched early RA patients despite comparable BMI and similar rates of obesity. This suggests that metabolic disturbances, present at early stages of PsA might be linked to PsA at a pathophysiological level.

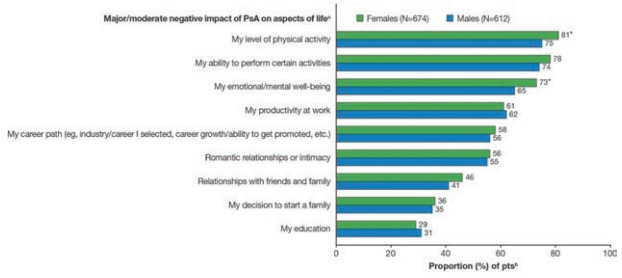
SEX DIFFERENCES IN PERCEPTIONS OF PSORIATIC ARTHRITIS DISEASE IMPACT, MANAGEMENT AND PHYSICIAN INTERACTIONS: RESULTS FROM A GLOBAL PATIENT SURVEY

Keywords: Gender/diversity issues, Quality of life, Psoriatic arthritis



L. Eder[1], P. Richette[2], L. Coates[3], V. F. Azevedo[4], J. C. Cappelleri[5], M. Hoang[6], J. Moser[7], C. Kinch[8], M. Kessouri[9]. *[1]Women's College Research Institute, University of Toronto, Division of Rheumatology, Toronto, ON, Canada*; *[2]Laribosière Hospital, Paris Cité University, Rheumatology Department, Paris, France*; *[3]University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; *[4]Hospital de Clínicas at the Federal University of Paraná, Brazil, Department of Internal Medicine, Curitiba, Paraná, Brazil*; *[5]Pfizer Inc, Statistical Research and Data Science Center, Groton, CT, United States of America*; *[6]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; *[7]The Harris Poll, Media Communications Research, Rochester, NY, United States of America*; *[8]Pfizer Canada ULC, Inflammation and Immunology, Kirkland, QC, Canada*; *[9]Pfizer Inc, Inflammation and Immunology, Paris, France*

Background: Women with psoriatic arthritis (PsA) have more severe disease activity and lower health-related quality of life vs men.[1]
Objectives: To assess sex differences in disease impact perceptions and physician interactions with patients (pts) with PsA using global survey data.
Methods: An online survey by The Harris Poll (2 Nov 2017–12 Mar 2018) included 1286 pts from 8 countries, aged ≥18 years, who had PsA for >1 year, visited a rheumatologist/dermatologist in the past 12 months and had used ≥1 disease-modifying antirheumatic drug (DMARD) for PsA.[2] Results were stratified post hoc by sex; analysed descriptively and by binomial (chi-squared) tests.

Percentages/binomial tests of the final global data were adjusted for size of each country's adult population. Statistically significant differences (p<0.05) were described as more/higher.

Results: 52% of pts were female; 24% from Europe (France/Spain/UK). Mean age of females/males (41.3/41.0 years) and time since diagnosis (9.2/8.8 years) were similar. More females had anxiety (32% vs 24%), osteoarthritis (17% vs 9%), had taken a steroid (57% vs 43%) and were taking any DMARD (biologic and oral DMARDs; 20% vs 15%). More females vs males reported a major/moderate negative PsA impact on physical activity (81% vs 75%) and emotional/mental well-being (73% vs 65%); major/moderate impact on other life aspects, such as work productivity, was similar between sexes (Figure 1). More females vs males reported the following because of PsA: emotional distress (65% vs 50%), stopped social activities (49% vs 41%) and went on permanent work disability (14% vs 9%); more males vs females reported lower work productivity (47% vs 38%) because of PsA. Switching treatment due to joint symptoms (41% vs 28%) and side effects (35% vs 22%) were higher in females vs males; switching due to potential serious side effect concerns (29% vs 16%) and symptoms being under control (18% vs 9%) were higher in males vs females. More females vs males were very satisfied with their rheumatologist's communication (60% vs 51%), and discussed treatment goals (83% vs 78%), impact on ability to conduct daily activities (82% vs 73%) and response to and/or satisfaction with treatment regimen (81% vs 72%; Table 1). Pt ability to describe their PsA diagnosis/recall symptoms may limit the study.

Figure. Major/moderate negative impacts of PsA for female vs male pts

*p<0.05 for females vs males
[a]How much of a negative impact, if any, has PsA had on each of the following aspects of your life?
[b]% based on weighted n (adjusted for size of each country's adult population)
N, number of pts that answered question

Table 1. Communication satisfaction[a] with rheumatologist, and discussion topics[b] between pts and their rheumatologist

n, yes, (%)[c]	Female (N=620)	Male (N=552)
Satisfaction[a]		
Very satisfied	371 (60)*	281 (51)
Somewhat satisfied	174 (28)*	214 (39)
Somewhat dissatisfied	40 (6)	33 (6)
Very dissatisfied	36 (6)	24 (4)
Discussion topics[b]		
Treatment goals	515 (83)*	428 (78)
Overall health	507 (82)	444 (80)
Physical exam of musculoskeletal symptoms	509 (82)	432 (78)
Impact on ability to conduct daily activities	510 (82)*	403 (73)
Response to and/or satisfaction with treatment regimen	500 (81)*	396 (72)
Impact on physical activity	491 (79)	413 (75)
Physical exam of skin/nail symptoms	469 (76)	406 (74)
Back pain (pain/stiffness)	467 (75)	411 (74)
Disease management plan	448 (72)	411 (74)
Unusual fatigue	430 (69)	370 (67)

*p<0.05 for females vs males. [a]How satisfied are you with the communication you currently have with your rheumatologist regarding PsA? (Among pts who visited a rheumatologist in the past 12 months). [b]In the last 12 months, have you discussed/conducted the following with your rheumatologist regarding PsA?. [c]% and binomial tests based on weighted data (adjusted for size of each country's adult population). N, number of pts that answered question; n, number of pts with satisfaction level or who participated in each discussion topic

Conclusion: More women vs men reported a major/moderate PsA impact on physical and emotional/mental well-being. More women were very satisfied with communication and discussed treatment goals with their rheumatologist. It is important to consider how sex impacts a pt's experience with PsA.

BARRIERS TO OVERCOME IN THE ACHIEVEMENT TO THE TREATMENT GOAL IN PSORIATIC ARTHRITIS; CENTRAL SENSITIZATION AND NEUROPATHIC PAIN

Keywords: Fibromyalgia, Pain, Psoriatic arthritis

G. Alp[1], İ. Kurut Aysin[1], E. Durak Ediboglu[1], E. Otman Akad[1], H. Cinakli[1], E. Erpek[1], A. Özkan[1], H. Kocaayan[1], D. Solmaz[1], S. Akar[1]. [7]Izmir Katip Celebi University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, İzmir, Turkey

Background: Chronic inflammation in inflammatory arthritis can trigger both peripheral and central sensitization (CS) through central modifications of pain pathways. CS is an abnormal pain management mechanism involving the central nervous system.

Objectives: To evaluate the frequency of CS and neuropathic pain (NP) in patients with psoriatic arthritis (PsA) and its relationship with disease activity and functional status.

Methods: Patients classified as PsA according to CASPAR classification criteria were included in this cross-sectional study. Disease activity was evaluated with DAPSA, VAS, pain and fatigue level (0-100 mm), quality of life with HAQ, CS with CS inventory (CSI). A score of 40 point was used to predict the presence of CS. CS score of <30 was also categorized as subclinical, 30 -39 as mild, 40-49 as moderate, 50-59 as severe and ≥60 as extreme. NP was evaluated with the DN4 (Douleur Neuropathique en 4 questions) scale. The presence of anxiety and depression were evaluated by using the Hospital Anxiety and Depression questionnaire (HADS) and fibromyalgia syndrome (FMS) by ACR 2016 criteria.

Results: İn total 114 PsA patients (78 [68.4%] female, mean age: 48.8 ±11.6 years, median disease duration was 4 [9] years) were included in the study. The median DAPSA score was 15.2(16), with approximately half of the patients were in remission or low disease activity. The proportion of patients with LEI≥1 was 28.9%, median BSA was 1(2), BASDAI was 3.8(3.6), BASFI was 2[4]. Of our patients 39.8% were receiving biological treatment. 61.4% of the patients had at least one comorbidity. CS was detected in 49 (42.9%) and NP in 24 (23.7%) patients. The median CSI score was 35.5 (IQR 29) Among patients with CS and NP the percentage of female was higher. DAPSA, PGA, PhGA, Pain VAS, TJC were found to be significantly higher and HAQ scores were found to be worse in patients with CS and NP. In addition,the percentage of patients with a LEI ≥1 was found 44.9% in patients with CS, and body mass index was found to be higher in patients with NP **(Table 1).** Duration of disease, CRP, ESR, BSA, usage of biological therapy, treatment with GCs, comorbidities were similar between the groups. Anxiety were higher in patıent with CS and NP, and depression was higher in only CS patients. While all 11 patients with FMS had NP, only 8 had CS. Sixteen (%32.7) patients with CS also had NP and 16 (66.7%) patients with NP had also CS. The positive correlation between PGA, PhGA, DAPSA, HAQ and CS severity in PsA patients **(Figure 1)**.

Conclusion: The results of the present study revealed that both CS and NP are common in PsA, and FMS accompanies 22.4% of those patients. CS and NP affect quality of life and functionality. In PsA patients, especially in cases where treatment goals cannot be achieved, it may be useful to evaluate the presence of concomitant CS and NP.

Table 1. Comparison of characteristics of PsA patients with and without central sensitization and neuropathic pain

CHRONIC TENOSYNOVITIS IS ASSOCIATED WITH LOSS OF GRIP STRENGTH IN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Ultrasound, Diagnostic Tests

S. Bayat[1,2], B. Coppers[1,2], A. Kleyer[1,2], E. T. Godonou[1,2], L. Valor[1,2], D. Simon[1,2], F. Fagni[1,2], G. Corte[1,2], V. Schönau[1,2], K. Tascilar[1,2], A. Hueber[3], M. Sticherling[4], G. Schett[1,2], A. M. Liphardt[1,2]. *[1]Friedrich-Alexander University (FAU) Erlangen-Nürnberg, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany*; *[2]Friedrich-Alexander University (FAU) Erlangen-Nürnberg, Deutsches Zentrum Immuntherapie, Universitätsklinikum Erlangen, Erlangen, Germany*; *[3]Klinikum Nürnberg Nord, Rheumatology, Nürnberg, Germany*; *[4]Friedrich-Alexander University (FAU) Erlangen-Nürnberg, Dermatology, Erlangen, Germany*

Background: Rheumatic diseases result in joint destruction and impaired physical function [1]. We recently showed, that hand function based on objective tests may serve as a biomarker representing subclinical inflammation in psoriasis (Pso) patients and thus could support the early detection of psoriatic arthritis (PsA) onset [2]. Hand function tests are relevant for objective assessment of musculoskeletal function in relation to disease activity in PsA [3], However, the relationship of hand function with the synovitis and tenosynovitis detected by ultrasound (US) in PsA and Pso patients has not been well studied.

Objectives: To investigate the association of synovitis and tenosynovitis detected by US in greyscale (GS) and power doppler (PD) activity with grip strength and fine motor skills in patients with PsA and Pso.

Methods: PsA and Pso patients were recruited from the Rheumatology Department at the University Hospital erlangen, for this cross-sectional study. After giving written informed consent, subject characteristics were recorded and study participants underwent bilateral US of the wrists, metacarpophalangeal (MCP) joints, and flexor tendons of all fingers. Each joint was examined by GS (0-3), PD (0-3) and finally a combined score (PDUS: PD + GS) was calculated (0-3) [4]. The flexor tendon was scanned in GS (0/1) and with PD [0-3]. US activity considered either a synovitis or tenosynovitis score ≥1. Activity in tender joint count (TJC) and swollen joint count (SJC) 68/66 was considered ≥1 tender or ≥1 swollen joint. Hand function was assessed by vigorimetric grip strength (lbf) and the fine motor skill MPUT (Moberg pick-up test). For the analysis, patients' hands were either divided in dominant/non-dominant or patient reported affected/non-affected hand. A correlation matrix was applied to measure the linear relation between the pairs of synovitis and tenosynovitis scores, grip strength and MPUT for both hands, using the Spearman correlation method.

Results: 106 patients (40 PsA, 66 Pso) participated in this study. Subject characteristics and general outcomes are summarized in Table 1. While grip strength was higher in the dominant hand ($p<0.001$), MPUT times are comparable between the dominant vs. non-dominant hands ($p=0.056$) but was faster in the non-affected hand ($p=0.008$). Low to moderate positive correlations were observed between both, overall GS synovitis score (MCP 2-5 + wrist) ($r=0.24$, $p<0.05$), and PDUS ($r=0.23$, $p<0.05$) with MPUT. In US active patients, a high correlation between grip strength and GS tenosynovitis score in digit 2 ($r=-0.566$, $p=0.028$) was detected. When considering patients with US in addition to SJC/TJC activity, imaging modalities did not correlate with hand function.

Conclusion: These findings indicate that the synovitis detected by greyscale is related with fine motor skills and tenosynovitis in greyscale with grip strength. This suggests, that chronic tenosynovitis has a greater impact on hand function than the acute inflammatory phase. When considering patients with TJC68/SJC66 ≥1 this relation is not present, suggesting that clinically assessed joint count, unlike ultrasonography, does not correlate with hand function impairment.

Table 1. Participants characteristics, clinical scores, functional tests and ultrasound scores by group.

	PsA	Pso
Characteristics, Mean (SD)		
Age (years)	47.5(12.3)	43.6(14.1)
Sex (Woman/Man)	15/25	26/40
Clinical Scores, Mean (SD)		
TJC 68/SJC 66	3.4(5.1)/ 0.4(1)	0.5(0.9)/ 0.2(1.3)
Visual Analogue Scale Global	43.7(30.6)	25.0(23.6)
Functional tests, Mean (SD)

Emerging a New Era in Osteoarthritis Therapies

OP0070 METHODS - A RANDOMIZED CONTROLLED TRIAL OF METHOTREXATE TO TREAT HAND OSTEOARTHRITIS WITH SYNOVITIS

Keywords: Disease-modifying drugs (DMARDs), Randomized control trial, Osteoarthritis

Y. Wang[1], G. Jones[2], H. Keen[3], C. Hill[4], A. Wluka[1], J. Kasza[1], A. Teichtahl[5], R. O'sullivan[6], F. Cicuttini[1]. [1]*Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia*; [2]*University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*; [3]*University of Western Australia, School of Medicine, Perth, Australia*; [4]*University of Adelaide, Department of Medicine, Adelaide, Australia*; [5]*Alfred Hospital, Rheumatology, Melbourne, Australia*; [6]*Lumus Imaging, Lumus Imaging, Melbourne, Australia*

Background: Hand osteoarthritis (OA) with synovitis is a common clinically identifiable phenotype which is associated with pain and disease progression. Methotrexate is a low-cost, well-established and effective treatment for inflammatory arthritis with a well-described safety profile. A previous randomized controlled trial showed no superiority of 10 mg methotrexate over placebo in pain relief at 3 or 12 months in patients with erosive hand OA[1]. No study has examined methotrexate in hand OA with inflammatory phenotype.

Objectives: To examine whether methotrexate reduced pain and improved function over 6 months in patients with hand OA and synovitis.

Methods: In a multicentre, randomized, double-blind, placebo-controlled trial, patients with symptomatic hand OA and MRI-detected synovitis were recruited and randomly assigned in a 1:1 ratio to receive methotrexate 20 mg (n=50) or identical placebo (n=47) once weekly for 6 months. The primary outcome was pain reduction (assessed by 100mm visual analogue scale, VAS) at 6 months. Secondary outcomes included changes in physical function and quality of life assessed using Australian Canadian Osteoarthritis Hand Index (AUSCAN), Functional Index for Hand Osteoarthritis (FIHOA), Health Assessment Questionnaire (HAQ), and Michigan Hand Outcomes Questionnaire (MHQ). Adverse events were recorded. The primary analysis was by intention to treat, including all participants in their randomized groups. Mixed linear regression models were fit to continuous outcomes, adjusting for baseline values of outcome, sex and site, and the clustering of measurements within participants.

Results: Of 97 patients [mean age 61.4 (SD 6.7) years, 68 (70.1%) female], 82 (84.5%) provided the 6-month primary outcome. At 6 months, the methotrexate group had greater reduction in VAS pain (-15.2 vs -7.7, difference -9.9, 95% CI -19.3 to -0.6) (Figure 1), AUSCAN pain (-55.3 vs -13.5, diff -47.0, 95% CI -91.5 to -2.5) and stiffness (-14.5 vs -2.9, diff -11.4, 95% CI -20.8 to -2.0) than the placebo group (Table 1). The between-group differences were not clinically meaningful for change in AUSCAN function [-52.7 (-127.3 to 21.9)], FIHOA [-0.9 (-3.4 to 1.7)], HAQ [-0.0 (-0.2 to 0.2)], or MHQ [5.5 (-0.3 to 11.3)]. Incidence of adverse events was 62.0% in methotrexate and 59.6% in placebo group.

Conclusion: This study provides high-quality evidence for the effect of methotrexate (20 mg once weekly) on reducing pain and stiffness over 6 months in patients with hand OA and synovitis. The results have the potential to inform clinical practice guidelines for the management of hand OA with the inflammatory phenotype.

OP0071 EFFECT OF DENOSUMAB ON STRUCTURE MODIFICATION IN EROSIVE HAND OSTEOARTHRITIS: RESULTS OF A 48-WEEKS, MONOCENTRIC, RANDOMIZED, PLACEBO-CONTROLLED, DOUBLE-BLIND PHASE 2 STUDY AND OPEN LABEL EXTENSION PHASE

Keywords: Clinical Trials, Osteoarthritis

R. Wittoek[1], G. Verbruggen[1], T. Vanhaverbeke[1], D. Elewaut[1]. [1]Gent University, Rheumatology, Gent, Belgium

Background: Erosive hand osteoarthritis (OA) is a disabling disease with limited therapeutic options. Denosumab, a Receptor Activator of Nuclear Factor kappa-β Ligand inhibitor affects bone resorption and osteoclast activity.

Objectives: The purpose of this clinical trial was to study the structure modifying effect of denosumab in patients with erosive hand OA, and to explore the clinical benefits and safety of subcutaneous denosumab 60 mg every 3 months versus placebo.

Methods: One hundred patients with erosive hand OA were randomly allocated to placebo or denosumab in a monocentric clinical trial during 48 weeks, followed by an open-label extension phase through week 96. The primary radiographic endpoint was change in total Ghent University Scoring System (GUSS) score at week 24. GUSS (0-300) is a semi-quantitative scoring system specifically developed to combine scoring of both aspects of radiographic changes in erosive hand OA, being erosive progression (decrease of score) and signs of repair (increase of score) (1) and able to detect changes on short term [2]. The secondary endpoint was the percentage of new erosive joints at week 48. Exploratory clinical outcomes (e.g., pain, tender joint count, swollen joint count, grip strength, the Australian-Canadian Hand Osteoarthritis Index and the Functional Index for Hand Osteoarthritis) were assessed. Radiographic and clinical changes after 96 weeks of treatments were measured. Safety outcomes including (serious) adverse events, laboratory changes and changes in bone mineral density by dual-energy X-ray absorptiometry were registered. Primary efficacy analyses were performed in an intention-to-treat approach. Changes in GUSS were analysed at joint level with generalized estimating equations, accounting for within-patient clustering. Robust standard errors were used and the working correlation structure specified exchangeable. Trial registration number: EUDRACT CT 2015-003223-53.

Results: 51 and 49 patients received subcutaneous administration of denosumab and placebo respectively. Total change GUSS was found statistically higher in denosumab compared to placebo at week 24 (mean change GUSS = 8.9 (95% CI: 1.0 - 16.9; p = 0.024))(Figure 1A). This difference further increased at week 48 (ΔGUSS = 14.3 (95% CI: 4.6 – 24.0; p = 0.003)). Development of new erosive joints was significantly lower in denosumab (1.8%) compared to placebo (7.0%) at week 48 (OR = 0.23 (95% CI: 0.10 to 0.50); p < 0.001)(Figure 1B). After open-label treatment through week 96, both groups continued remodelling and both pain and function significantly improved compared to baseline. Equal numbers of adverse events occurred in both groups.

Conclusion: Denosumab has clear structure modifying effects in erosive hand OA compared to placebo: significantly less erosive progression occurs after 24 weeks treatment, and the treatment effect enhances after 48 weeks. Symptom improvement was observed after sustained treatment.

Background: Osteoarthritis is a major contributor to pain and disability worldwide [1]. Considering that inflammation plays an important role in the development of osteoarthritis, anti-inflammatory drugs may slow the progression of the disease [2].
Objectives: To examine whether years-long use of colchicine 0.5 mg daily reduces incident total knee replacements (TKRs) and total hip replacements (THRs).
Methods: We performed a post-hoc analysis of data collected in the LoDoCo2 trial to determine the time to first knee or hip replacement. A Cox proportional hazard model was used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for colchicine 0.5 mg once daily as compared to placebo. Sensitivity analyses were performed by excluding patients known with gout at baseline (to avoid possible carry-over effects as colchicine is used to prevent gout attacks) or by excluding the patients who had joint surgery within the first 3 months after randomization (to avoid any bias related to planned joint surgery prior to randomization). All analyses were performed on an intention-to-treat basis.
Results: Among the 5522 randomized LoDoCo2 trial participants, 2762 received colchicine and 2760 placebo during a median duration of follow-up of 28.6 months (interquartile range, 20.5 to 44.4). The mean (SD) age was 66 (8.6) years and 846 (15.3%) were female. During the trial, TKR/ THR was performed in 68 patients (2.5%) in the colchicine group and in 97 patients (3.5%) in the placebo group (HR, 0.69; 95% CI, 0.51-0.95; p = 0.02) (Table 1 and Figure 1). In a sensitivity analysis that excluded patients with gout similar results were obtained, while omitting joint replacements that took place in the first three months of follow-up yielded in an even larger rate reduction of TKR/ THR (Table 1).

Table 1. Incidence rates and hazard ratios for hip and knee replacements according to treatment.

Trial cohort/ subgroup	Placebo (n=2760)		Colchicine (n=2762)		Hazard ratio (95% CI)
	No. of patients/ total no. (%)	*No. of events/100 person-yrs*	*No. of patients/ total no. (%)*	*No. of events/100 person-yrs*	
Full trial population					
TKR/ THR events	97/2760 (3.5)	1.30	68/2762 (2.5)	0.90	0.69 (0.51-0.95)
Participants with gout at baseline excluded					
TKR/ THR events	89/2534 (3.5)	1.30	61/2542 (2.4)	0.88	0.68 (0.49-0.94)
TKR/ THR in the first three months excluded					
TKR/ THR events	96/2760 (3.5)	1.29	59/2762 (2.1)	0.78	0.61 (0.44-0.84)

TKR/ THR= total knee replacement/ total hip replacement

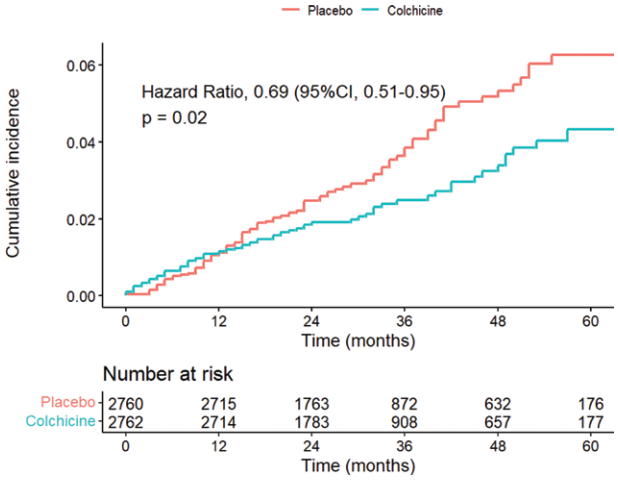

Figure 1. Cumulative incidence rates for time to first total knee/hip replacement in the full trial population.Cumulative incidence of time to first total knee/hip replacement in participants receiving colchicine in comparison with placebo once daily. Data are shown on an enlarged y-axis.

Conclusion: In this post-hoc analysis of the LoDoCo2 trial, use of colchicine 0.5 mg daily was associated with a reduced risk of TKR/ THR. Further investigation of long-term therapy with colchicine to slow disease progression in osteoarthritis is warranted.

Background: Colchicine has been suggested as a treatment for osteoarthritis symptoms, but evidence is contradictory.[1]
Objectives: To investigate the clinical efficacy and safety of colchicine compared with placebo in people with hand osteoarthritis.
Methods: In this double-blind, randomised, placebo-controlled trial we recruited adults from a dedicated outpatient clinic in Denmark. Eligibility criteria included symptomatic hand osteoarthritis and finger pain of at least 40 mm on a 100-mm visual analogue scale (VAS). The hand with the most severe finger pain at inclusion was considered the target hand. Participants were randomly assigned to 0.5 mg colchicine or placebo taken orally twice daily for 12 weeks. The primary endpoint was change from baseline to week 12 in target hand finger pain, assessed on a 100-mm VAS with a pre-specified minimal clinically important difference of 15 mm, in the intention-to-treat population. The study was registered prospectively at ClinicalTrials.gov, NCT04601883.
Results: We screened 186 people for eligibility between January 15, 2021 and March 3, 2022 and randomly assigned 100 participants: 50 (50%) to colchicine and 50 (50%) to placebo. All participants completed the study. The mean changes from baseline to week 12 in finger pain were -13.9 mm (SE 2.8) in the colchicine group, and -13.5 mm (2.8) in the placebo group with a between-group difference (colchicine versus placebo) of -0.4 mm (95% CI -7.6 to 6.7; p = 0.90). The efficacy on primary and secondary outcomes is summarized in the Table 1. In the colchicine group, there were 76 adverse events in 36 (72%) participants and one serious adverse advent. In the placebo group, there were 42 adverse events in 22 (44%) participants and two serious adverse events. Serious adverse events were unrelated to treatment.

Table 1. Changes from baseline in primary and secondary outcomes at week 12 in the ITT population

	Colchicine (n = 50)	Placebo (n=50)	Difference between groups (95% CI)	*P* value
Primary outcome				
VAS pain fingers target hand (0-100), mm	-13·9 (2·8)	-13·5 (2·8)	-0·4 (-7.6 to 6.7)	0.90
Secondary outcomes				
VAS patient global assessment (0-100), mm	-12.4 (2.8)	-11.2 (2.8)	-1.2 (-8.3 to 5.9)	*
AUSCAN function (0-90)	-10.5 (2.1)	-8.3 (2.1)	-2.2 (-7.6 to 3.2)	*
AUSCAN pain (0-50)	-7.8 (1.2)	-5.3 (1.2)	-2.4 (-5.4 to 0.5)	*
Grip strength target hand, N	9.4 (4.0)	14.1 (4.0)	-4.7 (-14.8 to 5.4)	*
EQ-5D quality of life (-0.624 to 1.000)	0.032 (0.011)	0.000 (0.011)	0.032 (0.004 to 0.060)	*
Tender joint count target hand (0-15)	-1.0 (0.2)	-0.8 (0.2)	-0.2 (-0.7 to 0.4)	*
VAS pain thumb base target hand (0-100), mm	-11.9 (2.8)	-10.0 (2.8)	-1.9 (-9.0 to 5.1)	*
OMERACT-OARSI responders†, n (%)	23 (46%)	22 (44%)	OR: 1.1 (0.5 to 2.5)	*

Group values are least squares means (standard error), and contrasts are differences in least square means (95% confidence intervals), unless otherwise stated. AUSCAN: Australian/Canadian hand index score. CI: Confidence interval. EQ-5D: European Quality of Life 5 Dimensions. ITT: Intention-to-treat. OMERACT-OARSI: Outcome Measures in Rheumatology - Osteoarthritis Research Society International. VAS: Visual analogue scale. *As no significant effect was found for the primary outcome, *P* values are not reported for subsequent analysis according to gatekeeping. †OMERACT-OARSI responders are the proportion of responders and the difference is reported as odds ratio (95% CI). The AUSCAN function subscale scores were rescaled from 0-90 to 0-100 for the calculation of OMERACT-OARSI responders.

Conclusion: In people with painful hand osteoarthritis, treatment with 0·5 mg of colchicine twice daily for 12 weeks did not effectively relieve pain and treatment with colchicine was associated with more adverse events.

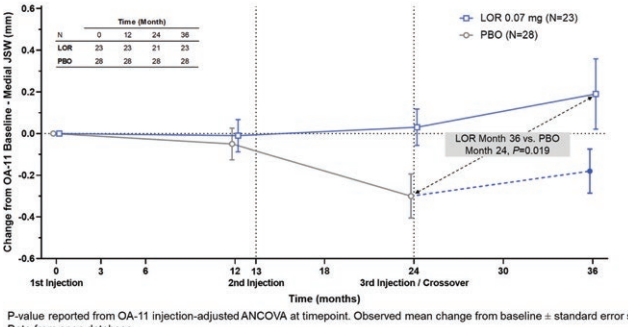
RADIOGRAPHIC AND PAIN OUTCOMES FROM A PHASE 3 EXTENSION STUDY EVALUATING THE SAFETY AND EFFICACY OF LORECIVIVINT IN SUBJECTS WITH SEVERE OSTEOARTHRITIS OF THE KNEE (OA-07): SINGLE BLIND AND CROSSOVER RESULTS

Keywords: Clinical Trials, Osteoarthritis



Y. Yazici[1], C. Swearingen[2], V. Lopez[2], J. Britt[2], S. Kennedy[3], J. Tambiah[3], T. Mcalindon[4]. *[1]NYU Grossman School of Medicine, Rheumatology, New York, United States of America*; *[2]Biosplice Therapeutics, Biostatistics, San Diego, United States of America*; *[3]Biosplice Therapeutics, Clinical Development and External Innovation, San Diego, United States of America*; *[4]Tufts Medical Center, Rheumatology, Boston, United States of America*

Background: Knee osteoarthritis (OA) is a common joint disorder associated with pain, disability, and joint damage. An unmet need remains for safe, efficacious treatments for symptoms and disease modification. Lorecivivint (LOR), a novel intra-articular (IA) CLK/DYRK inhibitor thought to modulate Wnt and inflammatory pathways, has previously appeared safe, demonstrated patient-reported outcome (PRO) improvements compared with placebo (PBO), and maintenance of radiographic medial joint space width (JSW).
Objectives: An ongoing extension study, OA-07 (NCT04520607), continues to evaluate LOR safety and efficacy with primary and secondary efficacy outcomes of medial JSW (mm) and Pain Numerical Rating Scale (NRS [0-10]), WOMAC Pain [0-100], and WOMAC Function [0-100], respectively. Preliminary data up to 36 months are reported.
Methods: Participants with structurally advanced (medial JSW 1.5-4 mm) knee OA who completed the parent Phase 3 LOR trial were enrolled into OA-07. At the beginning of the single-blind (participants and investigators blinded) extension Year 1, participants received a repeat injection according to the initial randomized treatment (LOR or PBO). In Year 2 and annually thereafter, all participants (LOR and PBO) received an open-label 0.07 mg, IA LOR injection. The extension trial commenced in July 2020 with clinic visits every six months. Baseline-adjusted ANCOVA was used to

estimate difference between LOR and PBO on outcomes using the OA-07 baseline. Treatment effect at Month 36 was estimated using marginal comparison from baseline-adjusted ANCOVA to a last PBO observation prior to crossover for LOR only. Concordance between OA-07 baseline-adjusted medial JSW change and pain response was conducted for 36 month completers using logistic regression.

Results: 277 subjects (mean age 61.0 ± 8.2 years, BMI 31.8 ± 4.9 kg/m^2, female 62.8%, KL3 45.5%, 67.1% bilaterally symptomatic, mean baseline medial JSW 2.63 ± 0.69 mm, 68.6% medial JSW < 3 mm) were enrolled. LOR appeared safe and well-tolerated, consistent with its previously observed safety profile. At 24 months, the LOR treatment arm showed reduced medial JSW loss compared to placebo: LOR -0.11 (± 0.05) mm (n=111) vs. PBO -0.20 (± 0.05) mm (n=119) (Δ=0.09 mm, 95% CI [-0.06, 0.23], *P*=0.246). The 36-month LOR completers demonstrated continued improvement with LOR (n=21) medial JSW change of 0.03 (± 0.11) mm vs. PBO (n=28) -0.30 (± 0.09) mm (Δ=0.33 mm, 95% CI [0.05, 0.62], P=0.023) at 24 months. At 36 months, LOR medial JSW change was +0.19 (± 0.14) mm (n=23), a difference of -0.49 mm (*P*=0.019) in medial JSW with LOR in comparison to the last PBO measure before crossover at 24 months (Figure 1). Average change from extension baseline to 24 months in Pain NRS was -0.25 (± 0.19) for LOR (n=121) compared to 0.09 (± 0.19) for placebo (n=130) (Δ=-0.34, 95% CI [-0.87, 0.19], *P*=0.207). Similar trends were seen for LOR treatment effect over PBO at 24 months for WOMAC Function Δ=-4.90 (95% CI [-9.92, 0.13], *P*=0.056) and WOMAC Pain Δ=-5.18 (95% CI [-10.28, -0.08], *P*=0.047). At 36 months, open-label IA injection of LOR (n=35) showed additional Pain NRS improvements with change from OA-07 baseline of -0.91 (±0.34) and crossover participants from PBO to LOR (n=45) showed improvement of -0.43 (±0.30). Good concordance was shown between change in medial JSW and at least a 20% improvement in Pain NRS at 36 months (n=20, AUC=0.719).

Figure 1: Change in Medial Joint Space Width in OA-07 from OA-11 Baseline
FAS 36-month completer analysis

P-value reported from OA-11 injection-adjusted ANCOVA at timepoint. Observed mean change from baseline ± standard error shown. Data from open database.

Conclusion: LOR continues to appear safe and well tolerated. A potential benefit of LOR 0.07 mg compared with PBO in medial JSW is observed 12 months after the extension baseline (second overall) injection, which persisted and improved in those who have completed an additional 12 months (total 36 months, after three injections) and in PBO participants who crossed over to active treatment with LOR. Potential LOR benefit compared to PBO is also seen across PROs along with preliminary good concordance data between medial JSW and pain improvement. This study is ongoing.

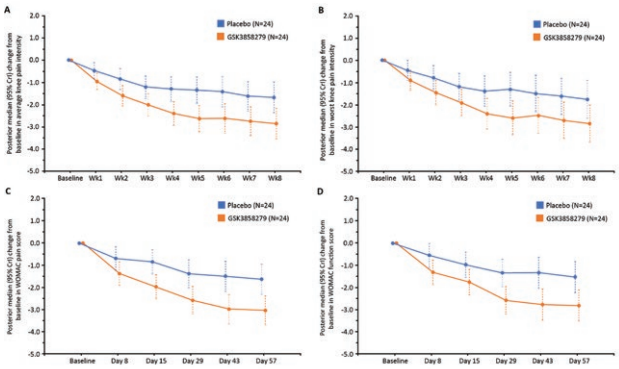
Background: Chronic pain is an unmet need in osteoarthritis (OA) as current therapies have limited analgesia and side effects. The chemokine CCL17 mediates inflammatory pain and blocking CCL17 (via anti-CCL17 monoclonal antibodies [mAb] or CCL17 knock-out) reduces pain and joint disease in murine arthritis. GSK3858279 is a novel, high affinity, human mAb that functionally inhibits CCL17.

Objectives: To present efficacy, safety, pharmacokinetic (PK) and immunogenicity data from Part B of a first-in-human, 2 part, phase I, randomized, double-blind, placebo (PBO)-controlled study evaluating GSK3858279 for OA pain (NCT03485365).

Methods: Participants with knee OA per ACR criteria, Kellgren and Lawrence (KL) score ≥2 and average daily pain score 4–9 by 11-point numerical rating scale (NRS) were randomised (1:1) to weekly subcutaneous (SC) GSK3858279 or PBO for 8 weeks. Co-primary endpoints were change from baseline (CFB) to Week 8 in average and worst knee pain intensity. Participants completed a daily pain NRS. Pain medication was prohibited, except paracetamol (≤3g/day) as rescue medication (not 24 h before a study visit). Exploratory endpoints included CFB in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain and function scores. Samples for analysis of GSK3858279 serum concentration and immunogenicity were collected to Week 20. A Bayesian repeated measures model using non-informative priors was fitted to CFB data; 95% credible intervals (CrI) for treatment differences were calculated.

Results: All 48 participants in Part B completed the study (2 participants in the PBO arm discontinued treatment). Participant characteristics were comparable, however more participants in the GSK3858279 arm were male and KL grade 4 (**Table 1**). GSK3858279 was rapidly absorbed after SC administration (median T_{max} ~2 days), with steady concentrations predicted by Week 8. Anti-GSK3858279 Abs were detected in 5/24 (21%) and 1/24 (4%) participants who received GSK3858279 and PBO, respectively; PK profiles for these participants were consistent with profiles in those without anti-drug Abs. For the co-primary endpoints of average and worst knee pain intensity, GSK3858279 showed greater improvement vs PBO at all timepoints (**Figure 1**). At Week 8, the difference (95% CrI) in CFB for GSK3858279 vs PBO was –1.18 (–2.15, –0.20) and –1.09 (–2.29, 0.12) for average and worst knee pain intensity, respectively (probability of true difference <0: >99% and 96%). GSK3858279 showed greater improvement in WOMAC pain and function scores vs PBO (**Figure 1**). At Day 57, the difference (95% CrI) in CFB for GSK3858279 vs PBO was –1.41 (–2.35, –0.46) for pain and –1.29 (–2.28, –0.29) for function (probability of true difference <0: >99% for both). Adverse events (AE) occurred in 21/24 (88%) and 15/24 (63%) participants, GSK3858279 and PBO, respectively. There were no serious AEs or deaths.



Conclusion: Weekly dosing for 8 weeks with GSK3858279 has clinical activity (improved pain scores) and a favourable safety profile in patients with OA knee pain. These compelling data warrant further study of the effectiveness and safety of GSK3858279 in people with OA pain.

Table 1. Baseline characteristics

	Placebo (N=24)	GSK3858279 (N=24)	All (N=48)
Male	11 (46)	16 (67)	27 (56)
Age, years	59.0 [51–75]	58.5 [46–74]	59.0 [46–75]
Race			
White	24 (100)	23 (96)	47 (98)
Asian	0 (0)	1 (4)	1 (2)
Body mass index, kg/m^2	28.3 [24–35]	29.7 [23–34]	29.2 [23–35]
Kellgren and Lawrence score			
Grade 2	12 (50)	8 (33)	20 (42)
Grade 3	8 (33)	8 (33)	16 (33)
Grade 4	4 (17)	8 (33)	12 (25)
Average knee pain intensity[a]	5.5 [4.0–7.8]	5.3 [4.0–7.4]	5.3 [4.0–7.8]
Worst knee pain intensity[a]	6.0 [4.0–8.0]	6.2 [4.2–8.6]	6.1 [4.0–8.6]
WOMAC Pain score[a]	5.3 [2.6–9.0]	5.5 [2.8–7.0]	5.4 [2.6–9.0]
WOMAC Function score[a]	5.2 [1.6–9.4]	5.5 [1.7–7.5]	5.4 [1.6–9.4]

Data are n (%) or median [range]. [a]11-point numerical rating scale: 0 (no pain/difficulty) to 10 (worst imaginable pain/difficulty). WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index.

Figure. Posterior median change from baseline in average (A) and worst (B) knee pain intensity score, and WOMAC pain (C) and function (D) score

Average and worst knee pain intensity and WOMAC pain and function were assessed by participants using an 11-point numerical rating scale, where scores range from 0 (no pain/difficulty) to 10 (worst imaginable pain/difficulty). All analyses were performed in the intent-to-treat population using a Bayesian repeated measures model adjusting for treatment, week, baseline and the treatment by week and baseline by week interactions using non-informative priors. (A, B) For each assessment visit, the mean average and mean worst pain scores for the 7 days preceding the visit were calculated for each participant. Data available for n=24 for all visits for GSK3858279, and for n=24 (Baseline, Wks 1 and 2), n=23 (Wks 3, 4 and 6), and n=22 (Wk 5, 7, and 8) for placebo. (C, D) Across the assessed timepoints, data were available for n=22–24 for both GSK3858279 and placebo. CrI, credible interval; Wk, Week; WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index.

Background: The existing EULAR Recommendations for the non-pharmacological core management of hip and knee osteoarthritis (OA) were published in 2013. A considerable number of new studies on various non-pharmacological treatment modalities have been published since then. Hence, it is time to update the Recommendations for the non-pharmacological core management of hip and knee OA.

Objectives: The objective of this project was to perform an updated systematic literature review and to update the 2013 EULAR Recommendations for the non-pharmacological core management of hip and knee osteoarthritis, accordingly.

Methods: The standardised operating procedures for EULAR-endorsed Recommendations [1] were used as a framework for this project. A multi-disciplinary Task Force (TF) including 9 physiotherapists, 6 rheumatologists, 2 orthopaedic surgeons, 2 psychologists, 2 patient research partners, 1 occupational therapist, 1 nurse, 1 general practitioner and 1 nutrition expert from 13 European countries was established. Based on the original search strategy underpinning the original 11 recommendations, 11 updated PICOs (Population, Intervention, Control, Outcome) were agreed upon by the TF members in the first digital meeting in January 2022. Systematic literature searches were conducted from 1st January, 2012 until 27th May, 2022 aiming to identify new evidence related to non-pharmacological core treatment interventions for hip and knee OA. Evidence was primarily collected from published systematic reviews (SRs) and secondarily, from randomised controlled trials (RCTs) if no relevant, updated SR was available. The retrieved evidence was discussed in 5 digital subgroup meetings and subsequently presented to all TF members in the second plenary digital meeting in November 2022. Here, the recommendations were revised based on the new evidence and discussions and TF members voted on each newly proposed recommendation to reach consensus (more than 75 % in favour). After the meeting TF members completed a web-based survey to ascertain the Level of Agreement (LoA) (0-10, 10=totally agree) with each recommendation and prioritize the order of the recommendations for implementation activities.

Results: Based on evidence from 67 SRs and 31 RCTs, the TF agreed to rephrase and change two of the 11 existing recommendations into two overarching principles; one concerning the initial assessment with a biopsychosocial approach and one on the use of shared decision-making in treatment. The remaining 9 original recommendations were revised into 8 updated recommendations, as the recommendations on footwear and on walking aids and other assistive devices were combined. The 8 updated recommendations concern the application of: 1) an individualised, multicomponent management plan; 2) delivery of information, education and self-management strategies; 3) delivery of exercise with adequate dosage and progression; 4) the mode of delivery of exercise; 5) education on maintaining a healthy weight and support with weight loss when indicated; 6) advice on walking aids and assistive devices; 7) work-related advice; and 8) application of behaviour-change techniques to improve lifestyle. The lowest mean LOA for the 8 revised recommendations was 9.2 and the highest 9.8. Recommendation 2) was ranked by the TF as having the highest priority for implementation.

Conclusion: The updated overarching principles and recommendations for the non-pharmacological core management of hip and knee OA are based on previous evidence and on new evidence from relevant SRs and RCTs published during the last 10 years and on discussions by a multi-disciplinary TF. A plan for dissemination and implementation will be developed, with emphasis on the recommendation on patient education, with the ultimate aim to improve the quality of care for people with hip and knee OA.

JOINT DISTRACTION USING AN INTENDED DEVICE FOR KNEE OSTEOARTHRITIS: A PROSPECTIVE TWO-YEAR FOLLOW-UP

Keywords: Osteoarthritis, Non-pharmacological interventions

T. Struik[1], S. Mastbergen[1], R. Brouwer[2], R. Custers[3], R. Van Geenen[4], K. Heusdens[5], P. Emans[6], M. Jansen[1]. Background: Knee distraction (KD) treatment for young (<65 years) patients with end-stage knee osteoarthritis (OA) has previously been shown to successfully postpone a knee arthroplasty for years by reducing pain, improving function, and inducing joint tissue repair.[1] During KD treatment, the tibia and femur are separated ~5 mm for ~6 weeks using an external fixation device. The studies performed thus far have used proof-of-concept medical devices intended for other applications than KD. Recently, the first device specifically designed and intended for KD treatment has been developed.
Objectives: The purpose of the current study was to evaluate the clinical efficacy of this intended device.
Methods: In 5 hospitals, 65 patients with end-stage knee OA, in general practice considered for arthroplasty or high tibial osteotomy, were offered KD treatment. Inclusion criteria included age ≤65 years, BMI <35 kg/m^2 with weight ≤110 kg, sufficient knee stability and physical condition, KL grade ≥2, malalignment ≤10 degrees, no history of inflammatory or septic arthritis. KD was performed according to a standardized protocol. Before and 1 and 2 years after treatment, standardized knee radiographs were performed and patients filled out WOMAC (for pain and function, 0-100, primary clinical outcome) and SF-36 (quality of life, 0-100, secondary outcome) questionnaires. From the radiographs, minimum joint space width (JSW, mm, primary structural outcome) was measured by 1 experienced observer and baseline KL grade was determined. Use of self-reported pain medication (paracetamol, opioids, NSAIDs) and intra-articular injections were registered, as were adverse events. Changes over 2 years were evaluated for statistical significance with paired t-tests for continuous variables and McNemar's tests for categorical variables. For the WOMAC, clinical significance was evaluated as well, on group level defined as an increase of ≥15 points and on individual level using OARSI-OMERACT response criteria. The influence of adverse effects on 2-year changes in primary outcomes was analyzed with independent t-tests.
Results: Of the 65 patients (age: 53.3±6.7; BMI: 28.0±3.2; sex: 38 (55%) male; KL grade 0/1/2/3/4: 0 (0%)/ 7 (11%)/ 26 (40%)/ 23 (36%)/ 9 (14%)), 49 patients completed 2 years follow-up. 1 Patient did not complete treatment, 7 patients received arthroplasty (3 in the 1st year) and 8 patients were lost to follow-up in the 2nd year. The total WOMAC score showed a statistically and clinically significant improvement at 1 and 2 years (+26 and +24 points; Figure 1), as did all subscales (all p<0.001). After 1 year 72% of patients were clinical responders, at 2 years this was reduced to 55%. The minimum radiographic joint space width improved over 1 (+0.5 mm; p<0.001) and 2 (+0.4 mm; p=0.015) years (Figure 1), as did the physical SF-36 (+10 points; p<0.001). The most common adverse event was pin tract infection, experienced by 43 (66%) of patients, in the majority successfully treated with oral antibiotics. In 2 cases hospitalization and/or intravenous antibiotics were needed. 8 Patients experienced device-related complications. None of the complications influenced the 2-year outcomes. Before treatment, 42% of patients used pain medication, which had nearly been halved 1 (23%; p=0.02) and 2 years (29%; p=0.27) post-treatment. In total 12 (18%) patients had received an intra-articular injection before KD treatment, of whom 5 (8%) steroids and 3 (5%) hyaluronic acid. Both in the 1st and 2nd year after treatment, 1 patient (2%) received an injection.
Conclusion: Patients treated with the first device intended for KD treatment showed significant clinical and structural improvement after 1 and 2 years. Importantly, the effect was clinically relevant, as a majority of patients were clinical responders and pain medication use decreased. Long-term evaluation will show whether arthroplasty can be postponed successfully as well.

PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES ARE NOT AT INCREASED RISK OF LONG-COVID: DATA FROM A LARGE PROSPECTIVE CONTROLLED COHORT STUDY

Keywords: Epidemiology, COVID, Inflammatory arthritides

L. Boekel[1], S. Atiqi[1], M. Leeuw[1], F. Hooijberg[1], Y. Besten[1], W. Lems[1,2], A. Boonen[3], S. Tas[4], M. Nurmohamed[1,2], T. Rispens[5], G. Wolbink[1]. Background: Studies on long-term consequences of COVID-19, commonly referred to as long-COVID, in patients with inflammatory rheumatic diseases (iRD) are still scarce, and available data are heterogeneous and largely inconclusive. In addition, it is unknown whether correctly classifying patients with iRD as long-COVID cases is complicated by increased background noise due to the occurrence of persistent symptoms that could be attributed to both long-COVID and iRD.

Objectives: The primary objective was to compare the risk of developing long-COVID after a SARS-CoV-2 infection with the Omicron variant between patients with iRD and age and sex matched healthy controls. A secondary objective was to compare the prevalence of the different persistent symptoms observed in long-COVID between patients with iRD and healthy controls with and without a history of COVID-19.
Methods: We collected data from participants enrolled in a Dutch prospective cohort study that was designed to compare the disease severity of COVID-19 between iRD patients and healthy controls from the start of the pandemic. Demographic and clinical data, including data on the occurrence of SARS-CoV-2 infections, were collected via online questionnaires. On March 10, 2022, all study participants were asked about the occurrence, onset, severity and duration of persistent symptoms during the first two years of the COVID-19 pandemic, independent of their history with COVID-19. Subsequently, we prospectively monitored a subset of the cohort, participants with a PCR or antigen confirmed SARS-CoV-2 Omicron infection, for COVID-19 sequelae. In line with WHO guidelines, long-COVID cases were defined as participants who reported persistent symptoms that lasted at least 8 weeks, started after the onset and within 3 months of a confirmed SARS-CoV-2 infection, and could not be explained by an alternative diagnosis. Descriptive statistics, logistic regression analyses and Kaplan Meier survival analyses were used for statistical analyses.
Results: A total of 1974 iRD patients and 733 healthy controls participated, of whom 468 (24%) patients and 218 (30%) controls had a SARS-CoV-2 Omicron infection. Of those, 361 (77%) patients and 172 (79%) controls completed COVID-19 sequelae questionnaires. More patients compared to controls fulfilled long-COVID criteria; 77 (21%) vs. 23 (13%) respectively (OR: 1.73, 95% CI: 1.04 – 2.87, *P* 0.03; Table 1). However, the effect attenuated after adjusting for potential confounders (aOR: 1.49, 95% CI: 0.88 – 2.52, *P* 0.14; Table 1). Post-hoc evaluation of covariables in the regression model showed that higher BMI and worse disease severity of the acute infection phase of SARS-CoV-2 were significantly associated with higher odds of developing long-COVID (Table 1). Fatigue and loss of fitness were the most frequently reported symptoms in both iRD patients and healthy controls with long-COVID, and recovery time from long-COVID was similar for patients and controls (*P* 0.47). Lastly, persistent symptoms were reported more frequently by participants with a history of COVID-19 compared to those without a history of COVID-19; 43% of iRD patients vs. 33% of controls with a history of COVID-19, and 21% of iRD patients vs. 11% of controls without a history of COVID-19.
Conclusion: We found that 21% of iRD patients and 13% of healthy controls met WHO-criteria for long-COVID after a SARS-CoV-2 Omicron infection. However, confounding by BMI and severity of the acute infection phase of SARS-CoV-2 attenuated this difference, and the duration of long-COVID was similar between patients and controls. In addition, since more iRD patients than healthy controls without a history of COVID-19 reported symptoms that are also observed in long-COVID, we believe that the observed difference in long-COVID between patients and controls could in part also be explained by clinical manifestations of underlying rheumatic diseases. We therefore conclude that iRD patients are not more susceptible for long-COVID than people from the general population.

Table 1. Regression analyses in participants with a SARS-CoV-2 Omicron infection.

Risk of developing long-COVID				
Univariable model		OR	95% CI	P-value
	Healthy controls*	1.00	-	
	Patients with rheumatic diseases	1.73	(1.04 – 2.87)	**0.03**
Multivariable model				
	Healthy controls*	1.00	-	
	Patients with rheumatic diseases	1.49	(0.88 – 2.52)	0.14
	Age	1.02	(1.00 – 1.12)	0.14
	Sex			
	male sex*	1.00	-	
	female sex	1.09	(0.66 – 1.81)	0.88
	BMI	1.06	(1.01 – 1.12)	**0.02**
	Cardiovascular disease	0.88	(0.66 – 1.81)	0.73
	Pulmonary disease	1.15	(0.56 – 2.37)	0.71
	Severity of acute infection phase of SARS-CoV-2 #			
	WHO severity score < 3*	1.00	-	
	WHO severity score ≥ 3	3.05	(1.80 – 5.19)	**<0.001**

*Table showing results of logistic regression analyses. Data are odds ratios (OR) with corresponding 95% confidence intervals (CI's) and P values. *Reference group. #A WHO score of 1 indicates asymptomatic infection, a score of 2 indicates mild disease without need for assistance, a score of 3 indicates mild disease with need for assistance (ie, could not care for themselves in daily life due to the severity of their symptoms) but no hospitalisation, a score of 4 or higher indicates admission to hospital, intenstive care unit or death. P value < 0.05 was considered statistically significant.*

Background: Due to geographic isolation and border controls, Aotearoa New Zealand attained high levels of population coronavirus disease-19 (COVID-19) vaccination before widespread community transmission of Omicron variant COVID-19 in early 2022. This provides a unique opportunity to examine outcomes in people with rheumatic diseases immunologically naive to COVID-19.
Objectives: This study aims to describe the outcomes of Omicron variant COVID-19 infection in people with rheumatic diseases in Aotearoa New Zealand.
Methods: We conducted an observational study of people with inflammatory rheumatic disease and COVID-19 infection from centers in Aotearoa New Zealand between 1 February to 30 April 2022. Data were collected via the Global Rheumatology Alliance Registry, including demographic and rheumatic disease characteristics and COVID-19 vaccination and outcomes. Multivariable logistic regression was used to explore associations of demographic and clinical factors with COVID-19 hospitalisation and death.
Results: A total of 1599 cases were included, with 98% from three hospitals that systematically identified all patients from rheumatology clinics who had COVID-19 infection. At the time of COVID-19 infection, 1513 cases (94.6%) had received at least two COVID-19 vaccinations. Hospitalisation occurred for 104 (6.5%) cases, and 10 (0.6%) patients died. A lower frequency of hospitalisation was seen in cases who had received at least two vaccinations (5.9%), compared to cases who were unvaccinated (20.6%) or who received a single vaccine dose (10.7%). In multivariable adjusted models, people with gout (OR 2.2 95% CI 1.02, 4.77) or connective tissue diseases (CTD) (OR 2.78 CI 1.61, 4.80) had increased risk of the combined outcome of hospitalisation and death, compared to people with inflammatory arthritis. Glucocorticoid and rituximab use were associated with 3 to 6 times higher odds of hospitalization and/or death. All cases who died had three or more co-morbidities associated with a known higher risk of poor outcomes or were over 60 years old.
Conclusion: In this cohort of people with inflammatory rheumatic diseases with high vaccination rates, severe outcomes from Omicron variant COVID-19 were infrequent. The hospitalisation rate during COVID-19 infection was higher in people who had not completed the primary vaccination course, had gout or CTD, and used glucocorticoids. These findings suggest that outcomes of Omicron variant COVID-19 infection among people with rheumatic disease who are vaccinated but immunologically naive to prior COVID-19 variant infections were favorable.
Acknowledgements: There was no specific funding for data collection. Data analysis was funded by the COVID-19 Global Rheumatology Alliance. The Global Rheumatology Alliance registries are supported by the American College of Rheumatology and European Alliance of Associations of Rheumatology but the views expressed here are of the authors. We thank our colleagues who entered patients to the cohort who include Ms J Heslett, Dr S Bourke, Dr E Chan, Dr S Jordan, Dr K Lindsay, Dr R Murdoch and Dr S Stebbings,

Background: Patients with immune mediated inflammatory diseases (IMIDs) on immunosuppressive therapies are known to be at greater risk of severe COVID-19 disease, hospitalisation and death. Protective levels of anti-Spike antibodies following vaccination are yet to be determined.
Objectives: To examine whether post-vaccination anti-Spike antibody levels were predictive of breakthrough infection and the clinical outcome of COVID-19.
Methods: The Nor-vaC study is a prospective cohort study that includes IMID patients on immunosuppressive therapies[1]. In the present analyses we included patients who provided post-vaccination samples and responded to follow-up questionnaires after three vaccine doses. Hospital records and the Norwegian Death Cause Registry provided information on hospital admissions and cause of death. Anti-Spike antibody levels were measured 2 – 4 weeks after vaccination. Analyses were performed using a cox-regression with time running from two weeks post 3rd vaccine dose until COVID-19 or a 4th vaccine dose, adjusting for age, sex, diagnosis, medication and comorbidity, with calendar month as a time varying covariate.
Results: A total of 1051 IMID patients (375 rheumatoid arthritis (RA), 148 psoriatic arthritis (PsA), 155 spondyloarthritis (SpA), 215 Crohn's disease (CD), 158 ulcerative colitis (UC)) on immunosuppressive therapies were included in these analyses, median age 56 (IQR 43 – 65), and 586 (56%) female, with an observation period spanning from July 7th 2021 to December 14th 2022. Patients had received either BNT162b2 (61%) or mRNA-1273 (39%) as a 3rd dose. Immunosuppressive medication included TNF inhibitors (TNFi) mono[a]- (41%) or combination therapy[b] (23%), methotrexate (16%), interleukin (IL) inhibitors[c] (5%), janus kinase (JAK) inhibitors[d] (3%), vedolizumab (5%) and other medication[e](2%).
During the observation period 265 patients (25%) were registered with COVID-19 after the 3rd vaccine dose. In total, 24 patients had COVID-19 before the Omicron variant became predominant in Norway (1st January 2022). Symptoms of COVID-19 for more than two weeks were reported by 53 patients (20 %). One patient was hospitalised, and no patients died due to COVID-19 during the observation period. A post-vaccination antibody level above 12.000 BAU/ml gave a reduced risk of clinical COVID-19 infection (hazard ratio (HR) 0.56, p=0.007, 95% CI (0.36, 0.85) (Figure 1). Antibody levels above this cut-off were found in 10 % of patients. The presence of comorbidities (HR 1.85, p = 0.001, 95% CI (1.27,2.70)) or UC (HR 1.6, p= 0.001, 95 %CI (1.11, 2.35) increased the risk of breakthrough infections.
Post-vaccination anti-Spike antibody levels were not associated with duration of COVID-19 over two weeks.
Conclusion: Patients with the highest post-vaccination anti-Spike levels had a lower risk of COVID-19 infection, supporting the role of repeated vaccination in IMID patients on immunosuppressive therapies. These results also underline the good prognosis of Omicron infections in vaccinated IMID patients. Though patients knowing they had low anti-Spike levels may have shielded during periods of high transmission, the absence of severe infections and deaths in this large cohort indicates that low antibody levels did not greatly increase risk of severe COVID-19.
[a]TNF inhibitors: infliximab, etanercept, adalimumab, golimumab, certolizumab pegol.
[b]Combination therapy: methotrexate, sulfasalazine, leflunomide, azathioprine.
[c]IL-inhibitors: tocilizumab, secukinumab.
[d]JAK-inhibitors: filgotinib, baricitinib, upadacitinib, tofacitinib.
[e]Other: abatacept, sulfasalazine, leflunomide, azathioprine.

Background: Global data on COVID-19 breakthrough infections (BI) following COVID-19 vaccination among autoimmune rheumatic diseases (AIRDs) and especially rheumatoid arthritis (RA) is scarce.

Objectives: This study aimed to examine the characteristics of COVID-19 BI among patients with RA and compare them with AIRDs and healthy controls (HCs).

Methods: A global e-survey, January-May 2022, collected data on COVID-19 vaccination, and BI in patients with RA, AIRDs, non-rheumatic autoimmune disease (nrAIDs), and HCs. BI was defined as infection after both primary or booster vaccine doses. Severe BI was defined as the need for hospitalization, including intensive unit care, oxygen therapy, or advanced treatment in the form of monoclonal antibodies.

Results: Of the 9595 vaccinated respondents of the e-survey, 3224 (33.6%) reported COVID-19. One BI was reported in 323/1802 (17.9%) patients with RA, 584/3869 (15.0%) patients with other AIRDs, and 467/3435 (13.5%) HCs. Similarly, second BI was reported by 280 (8.6%); 42 (2.3%) among RA, 90 (2.3%) among other AIRDs, and 124 (3.6%) among HCs.

The prevalence of first BI in patients with RA was higher than that in those with AIRDs (OR=1.2; 95%CI=1.1-1.4; p=0.001) and HCs (OR=1.4; 95%CI=1.2-1.6; p<0.001), but similar to nrAIDs (p=0.783). The prevalence of second BI was lower in patients with RA than in HCs (OR=0.6; 95%CI=0.4-0.9; p=0.012) and nrAIDs (OR=0.4; 95%CI=0.2-0.7; p=0.004), but similar to AIRDs (p=0.991). When compared with HCs, patients with RA reported significantly higher joint pain, hospitalizations, and need for advanced treatment at first BI. Patients with RA from very high HDI countries had lower hazard of first BI than those from high HDI countries (HR=0.026; 95%CI=0.001-0.6; p=0.027). Rituximab use predicted more frequent hospitalization (OR=3.4; 95%CI=1.3-11.4; p=0.045) and severe BI (OR=3.0; 95%CI=1.2-7.3; p=0.014).

Conclusion: Nearly one in five patients with RA reported BI. BI prevalence was higher in patients with RA and of higher severity than in HCs. Country HDI was an important determinant of outcomes, suggesting potential impact of environmental dynamics, local vaccination policy, and syndemic constructs that merit further exploration. Rituximab use predicted more frequent hospitalizations and more severe BI.

Background: COVID-19 vaccine hesitancy among pregnant and breastfeeding women with autoimmune diseases (AID) is often attributed to the fear of adverse events (AE) and disease flares (DF). No data are available regarding COVID-19 vaccine safety in this population.

Objectives: We aimed at describing delayed-onset (>7 days) vaccine-related AE (minor and major), DF, and related AID treatment modifications from the COVID-19 Vaccination in Autoimmune Diseases (COVAD) study.

Methods: Among complete responses from 9201 participants as of June 21, 2022, 6787 (73.8%) were women. Six subgroups were identified upon diagnosis of AID vs healthy controls (HC) and their pregnancy/breastfeeding status at the time of any dose of vaccine (Figure 1).

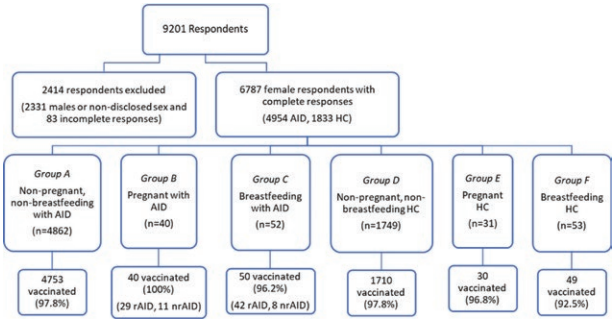

Figure 1. Flowchart of the study. AID: autoimmune diseases; HC: healthy controls; rAID: rheumatic AID; nrAID: non-rheumatic AID.

Results: Forty pregnant and 52 breastfeeding AID patients were identified and their vaccination rates (at least one dose) was 100% and 96.2%, respectively (Table 1). Overall AE, minor AE, and major AE were reported significantly more frequently by pregnant than non-pregnant patients (45% vs. 26%, p=0.01; 40% vs. 25.9%, p=0.03; 17.5% vs. 4.6%, p<0.01), but no difference was found in comparison with pregnant HC. No difference was observed between breastfeeding patients and HC. Post-vaccination DF were reported by 17.5% of pregnant and 20% of breastfeeding patients, and by 18% of age- and disease-matched control patients (n=2315). All DF in pregnant/breastfeeding patients were managed with glucocorticoids and a fifth of them required initiation or change in immunosuppressive treatment.

Conclusion: This study provides the first insights into the safety of COVID-19 vaccination during the antenatal period in women with AID. While AEs were more commonly reported by pregnant patients with AID, these were no higher than among pregnant healthy controls without AID. These observations are reassuring, likely to strengthen physician-patient communication and overcome hesitancy as the benefits for the mother and fetus by passive immunization are likely to overweigh the potential risks of AE and DF.

Background: COVID-19 pneumonia is often associated with hyperinflammation. The efficacy and security of anakinra in patients with severe COVID-19 pneumonia and hyperinflammation are still unclear.
Objectives: The primary endpoint was the proportion of patients not requiring mechanical ventilation up to 15 days after treatment initiation, assessed on an intention-to-treat-basis.
Methods: A multicentre, randomised, open-label, two-arm phase 2/3 trial was conducted at 12 hospitals in Spain. Adult patients with severe pneumonia were randomly assigned (1:1) to receive either usual standard of care plus anakinra (anakinra group) or usual standard of care alone (SoC group). Anakinra was given at a dose of 100 mg four times a day intravenously. The trial is registered with ClinicalTrials.gov; NCT04443881.
Results: Between 8 May 2020 and 1 March 2021, a total of 179 patients were randomly assigned to the anakinra group (n=92) or to the SoC group (n=87). The proportion of patients not requiring mechanical ventilation up to day 15 was not significantly different between groups (77.1% for Anakinra group vs 85.9% for SoC group, risk ratio 0·90 [95% CI 0·77–1·04]; p=0·16). Anakinra did not result in any difference in time to mechanical ventilation (HR 1·72 [95% CI 0·82-3·62], p=0·14). There was no significant difference between groups in the proportion of patients not requiring invasive mechanical ventilation up to day 15 (RR 0·99 [95% CI 0·88–1·11]; p=1·00).
Conclusion: Anakinra did not prevent the need for mechanical ventilation or reduce mortality risk compared with standard of care alone in hospitalised patients with severe COVID-19

OP0084 POSSIBLE ROLE OF PEPTIDE EPITOPES OF COVID-19 BNT-162B2 MRNA VACCINE IN FOMENTING AUTOIMMUNITY: AN IN SILICO ANALYSIS

Keywords: Adaptive immunity, Vaccination/Immunization, COVID

R. Talotta[1]. [1]University Hospital "G. Martino "; Clinical and Experimental Medicine, Messina, Italy

Background: Following the launch of the global COVID-19 vaccination campaign, there have been increased reports of autoimmune diseases developing de novo following vaccination. These cases include rheumatoid arthritis, autoimmune hepatitis, immune thrombotic thrombocytopenia, and connective tissue diseases. Nevertheless, COVID-19 vaccines are considered safe for patients with autoimmune diseases and are strongly recommended.
Objectives: The aim of this in silico analysis is to investigate the presence of protein epitopes encoded by the BNT-162b2 mRNA vaccine, one of the most commonly administered COVID-19 vaccines, that could elicit an aberrant adaptive immune response in predisposed individuals.
Methods: The FASTA sequence of the protein encoded by the BNT-162b2 vaccine was retrieved from http://genome.ucsc.edu and used as a key input to the Immune Epitope Database and Analysis Resource (www.iedb.org). Linear peptides with 90% BLAST homology were selected, and T-cell, B-cell, and MHC ligand assays without MHC restriction were searched and evaluated. HLA-disease associations were screened on the HLA-SPREAD platform (https://hla-spread.igib.res.in) by selecting only positive markers.
Results: A total of 183 epitopes were found, corresponding to 178 SARS-CoV-2 and 5 SARS-CoV spike epitopes, respectively. Results were obtained from 22 T-cell assays, 398 B-cell assays, and 2 MHC ligand assays. Complementary receptors included 1080 T-cell receptors and 0 B-cell receptors.
Specifically, the IEDB_epitope:1329790 (NATNVVIKVCEFQFCNDPFLGVYY) was shown to bind to HLA-DRB1*15:02 and HLA-DRB1*15:03 alleles, whereas the IEDB_epitope:1392457 (TKCTLKSFTVEKGIYQTSNFRVQPT) was reported to bind to HLA-DRB1*07:01, HLA-DRB1*03:01, HLA-DRB3*01:01, and HLA-DRB4*01:01 alleles. The HLA alleles detected were found to be positively associated with various immunological disorders (Table 1).

Table 1. MHC-restricted epitopes of the BNT-162b2 vaccine and potentially associated immunological conditions

Epitope	Assay	MHC molecule	Associated disease (population)
NATNVVIKVCEFQFCNDPFLGVYY + OX(C10)	cellular MHC/ mass spectrometry ligand presentation	HLA-DRB1*15:02	Takayasu arteritis (Japanese) Arthritis (Taiwanese) Scleroderma (Japanese) Colitis (Japanese)
		HLA-DRB1*15:03	Systemic lupus erythematosus (Mexican American)
TKCTLKSFTVEKGIYQTSNFRVQPT + SCM(K2)	as above	HLA-DRB1*07:01	Allergy, hypersensitivity (Caucasian)
		HLA-DRB1*03:01	Type 1 diabetes (African) Sarcoidosis, good prognosis (Finnish)
		HLA-DRB3*01:01	Graves' disease (Caucasian) Thymoma (Caucasian) Sarcoidosis (Scandinavian) Autoimmune hepatitis (Caucasian)
		HLA-DRB4*01:01	Vitiligo (Saudi Arabian)

Conclusion: Similar to the SARS-CoV-2 spike protein, the protein product of the BNT-162b2 mRNA vaccine contains immunogenic epitopes that may trigger autoimmune phenomena in predisposed individuals. Genotyping for HLA alleles may help identify at-risk individuals. However, further research is needed to elucidate the underlying mechanisms and potential clinical implications.

OP0085 LONGITUDINAL T CELL RESPONSES TO A SERIES OF FOUR SARS-COV-2 VACCINE DOSES OR COVID-19 IN PATIENTS ON TNF INHIBITORS

Keywords: COVID, Vaccination/Immunization, Adaptive immunity

H. Ørbo[1,2], A. S. F. M. Wolf[3], K. H. Bjørlykke[2,4], S. Josefsson[3], G. Solum[3], I. Fadum Kjønstad[3], I. Jyssum[1,2], I. E. Christensen[1,2], A. T. Tveter[1], J. Sexton[1], G. B. Kro[5], G. Grodeland[2,6], T. K. Kvien[1,2], J. Jahnsen[4], J. T. Vaage[6], E. A. Haavardsholm[1,2], S. Aarrestad Provan[1], H. Kared[6,7], L. A. Munthe[6], K. K. Jørgensen[4], S. W. Syversen[1], S. Mjaaland[3], G. L. Goll[1]. [1]Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway; [2]University of Oslo (UiO), Institute of Clinical Medicine, Oslo, Norway; [3]Norwegian Institute of Public Health, Department of Method Development and Analytics, Oslo, Norway; [4]Akershus University Hospital, Department of Gastroenterology, Oslo, Norway; [5]Oslo University Hospital, Department of Microbiology, Oslo, Norway; [6]Oslo University Hospital, Department of Immunology, Oslo, Norway; [7]University of Oslo (UiO), KG Jebsen Centre for B cell Malignancies, Oslo, Norway

Background: T cells are critical for control of viral infection with SARS-CoV-2, but knowledge is lacking on cellular immune responses following repeated vaccination and breakthrough infection in immunosuppressed patients.
Objectives: To examine longitudinal T cell responses across diagnoses, following vaccine series and COVID-19 in patients on tumor necrosis factor inhibitors (TNFi).
Methods: The prospective, observational Nor-vaC study included patients with arthritis (spondyloarthritis, rheumatoid arthritis, psoriatic arthritis) or inflammatory bowel disease (IBD) (ulcerative colitis, Crohns disease) on immunosuppressive therapies [1]. Here, we included patients on TNFi mono- or combination therapy immunised with up to four SARS-CoV-2 vaccine doses with or without

breakthrough infection, collecting peripheral blood mononuclear cells (PBMCs) 2-4 weeks after each immunisation. Samples were incubated with SARS-CoV-2 spike, nucleocapside or membrane peptides. The percentage of responding T cells was measured by flow cytometry (2) (≥0.01% increase in responding CD4 cells, ≥0.001% increase in responding CD8 cells, compared to baseline).

Results: Between February 2021 and December 2022, 144 patients on TNFi (monotherapy n=86 (60%), combination with methotrexate or azathioprine n=58 (40%)) were included (median age 48 years [IQR 33-57]; 51% women) (Table 1). The proportions of arthritis vs IBD patients with CD4 responses after 2 vaccine doses were 75% (12/16 patients) vs 86% (25/29), and after 3 doses 83% (10/12) vs 93% (28/30). In total, 80% (4/5) of arthritis patients showed further increases in CD4 responses after a 4th vaccine dose. Conversely, 81% (13/16) of arthritis patients vs. 55% (16/29) of IBD patients had CD8 T cell responses after two doses, and 67% (8/12) vs. 62% (18/29) after three doses. A 3rd and 4th dose induced higher CD8 responses compared to the previous dose in 55% (6/11) and 100% (5/5) of arthritis patients. Arthritis patients had lower T cell responses than IBD patients after the 3rd dose; median CD4 response 0.024% [IQR 0.009-0.036] vs 0.098% [IQR 0.040-0.182], p=0.0004; median CD8 response 0.003% [IQR 0.001-0.016] vs 0.044% [IQR 0.009-0.140], p=0.0032 (Figure 1). This difference remained robust after adjusting for age and sex, p<0.001, but was no longer detected after the 4th vaccine dose. Breakthrough infection elicited increased T cell responses across all diagnoses to spike (p<0.0001), and to nucleocapsid (p=0.002) and membrane proteins (p=0.001) compared to unstimulated T cells. Also, Spike-specific T cell responses increased compared to the 3rd dose (median CD4 T cell response 0.18% vs. 0.06%, p=0.003; CD8 T cell response 0.08% vs. 0.01%, p<0.0001), but to a lesser extent compared to the 4th dose (median CD4 response 0.18% vs. 0.12%, p=0.05; CD8 response 0.08% vs. 0.05%, p=0.26). There were no differences in cellular response between patients on TNFi mono- or combination therapy (p=0.93).

Conclusion: Patients on TNFi show improved cellular responses following each immunisation, with infection generating a strong and broad T cell response. Arthritis patients had significantly lower CD4+ responses compared to IBD patients after three vaccine doses, but with no difference after the 4th dose. These results support giving a 4th vaccine dose to TNFi-treated patients, with particular benefit for arthritis patients.

Moving into better health

OP0086-HPR THE SWEDISH OSTEOARTHRITIS REGISTRY. TRENDS IN SWEDISH OSTEOARTHRITIS HEALTH CARE BETWEEN 2008- 2021

Keywords: Patient information and education, Descriptive Studies, Osteoarthritis

K. Wetterling[1], T. Jönsson[2], M. Mohaddes[1]. [1]*Institute of Clinical Science, Department of Orthopaedics, Gothenburg, Sweden*; [2]*Division of Sport Science, Department of Health Science, Lund, Sweden*

Background: In 2012 the Swedish national guidelines for osteoarthritis (OA) were published. The guidelines implicit that all patients with OA should obtain information and supervised exercise as first-line intervention and that OA is a clinical, not radiological diagnosis. The Swedish OA registry contains data which measure compliance to the guidelines since 2008 [2].

Objectives: To describe the trends over time from 2008 to 2021 for patients who have received first-line interventions for hip and knee OA in Sweden and adherence of the healthcare staff to the national guidelines.

Methods: Descriptive registry-based study including patients with hip or knee OA who participated in first-line interventions including education and exercise. Data were extracted from the Swedish OA registry between January 1st, 2008, and December 31, 2021. The registry contains patient-reported outcomes and physiotherapist-reported outcomes. In this study the following physiotherapist-reported outcomes were described over time: radiological examination before first-line intervention, if the first-line intervention was given the first time the patient seek health care caused of OA, which explanation patients had been given about their disease, intake of painkillers before the start of first-line intervention and the percent who got supervised exercise >10 times according to the guidelines of OA in Sweden. The following patient-reported outcomes were described over time: mean BMI at the first visit, and mean age at the first visit. To be included in the study, participants had to meet the following criteria: i) clinical diagnosis of OA, with hip or knee OA as the most symptomatic joint, ii) provided 3-month follow-up.

Results: A total of 175 764 participants with hip or knee OA were included in the study. The trends from 2008-2021 showed that the proportion of patients who had a radiological examination before entering the first-line intervention decreased from 97 % to 65 % in men and from 95% to 62 % in women. The proportion of patients who get assess to first-line intervention the first time they seek for their symptoms increased from 4 % to 10 % both in men and women. People that get the correct information about OA increased from 15% to 40 %, and patients that get the explanation that OA was a tear and wear disease decreased from 30 % to 5%. The mean BMI (28) is unchanged over time. The mean age increased from 64 years to 67 years between 2008-2020 but decreased during the covid-19 pandemic to 64 years. The percentage that was given supervised exercise more than 10 times was constant between 2012-2020 at 30 % but decreased during the covid-19 pandemic to 20%.

Conclusion: The results implicit that the implementation of a supported OA self-management program in Sweden has been successful and changed the care given to patients with OA in Sweden. However, the national guidelines for OA, have still not been fully implemented. We need to keep implementing the guidelines so all patients with OA get the first-line intervention at the right time.

OP0087-HPR HIGH INTENSITY EXERCISE IMPROVES GENERAL AND PHYSICAL FATIGUE IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS

Keywords: Physical therapy/Physiotherapy, Randomized control trial, Rheumatoid arthritis

A. Bilberg[1,2], J. Bjersing[3], K. Mannerkorpi[4]. *[1]Gothenburg University, Sahlgrenska Academy, Institute of Neuroscience and Physiology, Section of Health and Rehabilitation, Gothenburg, Sweden*; *[2]Sahlgrenska University Hospital, Department of Rheumatology, Gothenburg, Sweden*; *[3]Gothenburg University, Sahlgrenska Academy, Institut of Medicine, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; *[4]Gothenburg University, Sahlgrenska Academy, Institution of Neuroscience and Physiology, Section of Health and Rehabilitation, Gothenburg, Sweden*

Background: Despite more effective control of inflammation by improved pharmacological therapies, persistent pain and fatigue are still a major problem among patients with rheumatoid arthritis (RA), which often leads to slow deterioration of function and general health.
Objectives: To evaluate the effect of high-intensity exercise on fatigue, pain, and general health in patients with established RA.
Methods: Patients with RA (ACR/EULAR 1987/2010 criteria), disease duration > 12 months, were recruited and randomised to either an exercise group or a control group. The exercise program of 12 weeks comprised supervised cardiorespiratory high-intensity interval exercise and strength exercise twice per week plus an additional non-supervised session of the patient´s own choice. The controls received individual information for physical activity according to the general health recommendations and were encouraged to be active on moderate intensive level ≥150 minutes/week. Outcomes. Self-reported ratings on symptoms were evaluated at baseline (BL) and 3 months (M3): Fatigue, using the Multidimensional Fatigue Inventory (MFI 20) scale, including five subscales; general fatigue, physical fatigue, mental fatigue, reduced activity and reduced motivation (range = 4 to 20 for each subscale, higher score = higher degree of fatigue); visual analogue scale (VAS) was used for the assessment of average pain intensity, fatigue and general health during the last week due to the rheumatic disease (0 = no symptom, 100 = worst possible).
Results: A total of 73 patients median age 49 (86.3% women), median disease activity 2.0 (1,34 to 2.56 IQR) (DAS28-ESR) were included in the study. At 3 months, there was a significant improvement on MFI-20 subscales general fatigue (p=0.002) and physical fatigue (p<0.001) in the intervention group when compared with the control group. No significant differences of change were found for the other subscales, general fatigue, reduced activity and reduced motivation or for VAS fatigue. A significant difference of change was found between the groups for VAS Global (p=0.026) while no significant differences of change was found for VAS pain between the groups. Table 1.
Conclusion: A 12-week exercise program of high intensity had beneficial effects on general fatigue and physical fatigue, in patients with established RA whereas the intervention did not influence pain intensity or general health. A multidimensional scale on fatigue appears to better distinguish changes in fatigue than a one-dimensional scale in patients with established RA.

OP0088-HPR FACTORS ASSOCIATED WITH MEETING RECOMMENDED PHYSICAL ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO HAVE POOR PHYSICAL FUNCTION

Keywords: Patient reported outcomes, Lifestyles, Rheumatoid arthritis

K. Wibring[1,2], S. Bergman[3,4], M. Andersson[3,5,6]. *[1]Spenshult Reserach and Development Centre,., Halmstad, Sweden*; *[2]Capio Movement, Department of Rheumatology, Halmstad, Sweden*; *[3]Spenshult Reserach and Development Center,., Halmstad, Sweden*; *[4]University of Gothenburg,The Sahlgrenska Academy, Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, Gothenburg, Sweden*; *[5]Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden*; *[6]Halmstad University, Department of Environmental and Biosciences School of Business, Innovation and Sustainability, Halmstad, Sweden*

Background: Rheumatoid arthritis (RA) is a chronic disease that often leads to a major impact on physical function and quality of life. It is well known that physical activity is an important part of treatment and improve clinical outcome.
Objectives: The aim was to study factors associated with meeting recommended level of physical activity in people with RA with poorer physical function.
Methods: In 2017, a survey was sent to patients included in the BARFOT (Better Anti-Rheumatic pharmacotherapy) cohort [1]. The questionnaire included questions on age, sex, disease duration, smoking, body mass index (BMI), physical function assessed by health assessment questionnaire (HAQ; 0-3, best to worst), numeric rating scale (NRS) pain (0-10, best to worst), NRS fatigue (0-10, best to worst), disease activity assessed by self-reported 28-tender (TJC, 0-28) and swollen joint count (SJC, 0-28), health-related quality of life assessed by Europol 5-dimension 3-level (EQ5D; 0- 1, worst to best), empowerment assessed by the Swedish Rheumatic Disease Empowerment Scale (SWE-RES-23; 1-5, worst to best), cardiovascular diseases (CVD), and antirheumatic treatment, corticosteroids (CS), conventional disease-modifying antirheumatic drug (cDMARD), biologic DMARD (bDMARD). 1065 patients (69%) answered the questionnaire and were dichotomized based on the median of HAQ, which was 0.5. The group with the worst physical function, HAQ >0.5, was further dichotomized based on whether they met the World Health Organisation (WHO) recommended level of physical activity (pulse-increasing physical activity with moderate intensity at least 150 minutes/week or at least 75 minutes/week with high intensity) or not. Median and interquartile range (IQR) and Mann-Whitney U test or chi-2 were used to analyse differences between groups, when appropriate. A logistic regression model adjusting for age and sex was used to study factors associated with fulfilling the recommendations on physical activity.
Results: The patients with the worst physical function, meeting the criteria for recommended physical activity (RPA), had less pain, and fatigue, fewer swollen and tender joints, less CVD 48% vs. 64% (p<0.001), and fewer were obese than those who did not meet the recommendations (Not RPA), Table 1. They also had a better quality of life and a higher degree of empowerment, Table 1. Factors associated with fulfilling the recommended level of physical activity in the group with the worst physical function were obesity, BMI ≥30 kg/m^{2,} (OR 0.51, 95% CI 0.32-0.83), HAQ (OR 0.32, 95% CI 0.21-0.48), NRS pain (OR 0.84, 95% CI 0.77-0.91), NRS fatigue (OR 0.88, 95% CI 0.82-0.95), TJC (OR 0.97, 95% CI 0.95-1.00) and SJC (OR 0.96, 95% CI 0.93-0.99), EQ5D (OR 8.36, 95% CI 3.74-18.64), SWE-RE-S23 (OR 1.40, 95% CI 1.02-1.93). and cardiovascular diseases

(OR 0.65, 95% CI 0.45-0.95). Medical treatment was not associated with meeting the criteria for physical activity.

Conclusion: The results indicate a complex relationship between various factors that can affect the possibility to be physically active when having RA. Disease-related factors such as pain, fatigue, and tender and swollen joints are important to address, but also the health-related quality of life and empowerment, to be able to improve physical activity in individuals with RA that have poor physical function.

OP0089-HPR PILATES IS BETTER THAN WALKING FOR PATIENTS WITH FIBROMYALGIA: A RANDOMIZED CONTROLLED TRIAL

Keywords: Pain, Fibromyalgia, Non-pharmacological interventions

L. De Araújo Cazotti[1], J. Natour[1], F. Carvalho[1], D. Freitas Pereira[1], A. Jones[1].
[1]Universidade Federal de São Paulo, Rheumatology Division, São Paulo, Brazil

Background: Fibromyalgia (FM) is defined as a chronic syndrome characterized by diffuse musculoskeletal pain and several symptoms that reflect on the functional capacity and quality of life of the affected patients. Different types of exercises are recommended in the treatment of FM. Pilates is a method of physical conditioning that has been frequently used in rehabilitation programs, due to the benefits perceived in musculoskeletal disorders, as well as in other conditions.

Objectives: To evaluate the efficacy of Pilates method compared to aerobic exercise in pain, quality of life related to the disease, depression, quality of life in general, functional capacity, kinesiophobia, catastrophizing, treatment satisfaction and reduction in the use of medication by women presenting FM.

Methods: Sixty-six female patients diagnosed with FM were included, aging 18 to 65, presenting pain between 3 to 8 in numerical pain scale (NPS). Patients with inflammatory rheumatic diseases, neurological diseases, under psychiatric treatment, who have started or changed physical activities or medication in the last three months, patients with uncontrolled cardiorespiratory and cardiovascular diseases or any condition that may limit the practice of exercises, with non-diabetes mellitus controlled and other musculoskeletal diseases that could prevent the use of this method were excluded. The selected patients were randomized into two groups: Pilates and Control. The Pilates group (PG) had Pilates sessions three times a week for 12 weeks. The Control patients (CG) used a treadmill three times a week for 12 weeks. The treatment sessions in both groups lasted 50 minutes and the groups were instructed to use acetaminophen750 mg each 8 hours in case of pain, but the use was controlled. The evaluations were done by blind assessor at baseline (T0), 45 days (T45), 90 days (90) and 180 (T180) days after initiation of the study using the following instruments: for pain: NPS; Fibromyalgia Impact Questionnaire (FIQ), to evaluate the quality of life related to disease; Beck Depression Inventory (BDI) for depression; The short form 36 (SF-36) to evaluate the quality of life in general; the 6-minutes walking test (6MWT) to evaluate the functional capacity; kinesiophobia scale (Tampa) to evaluate the fear of movement; Fear Avoidance Beliefs Questionnaire (FABQ), to evaluate catastrophizing and the Likert scale to evaluate the patient satisfaction towards the treatment.

Results: Thirty four patients were randomized for the GP and 32 for the CG. The groups were homogeneous at baseline. In the comparison between groups over time, we found better results for PG with statistical differences when compared to CG for: pain (p<0,001), disease-related quality of life (p<0,001), psychological status (p=0,026), some domains of SF-36 – pain (p=0,014) and general health status (p<0,044), kinesiophobia scale (p<0,001), reduction in analgesic consumption (p=0,042) and on the Likert scale (p=0,003).

Conclusion: Pilates method is effective in the treatment of women with FM, presenting pain improvement, quality of life related to the disease, psychological status, the SF-36 (pain, general health) domains, the kinesiophobia scale, the analgesic consumption reduction and satisfaction with treatment with better results when compared to walking.

OP0090-HPR ASSOCIATION BETWEEN GRIP AND CORE MUSCLE STRENGTH IN PEOPLE WITH AXIAL SPONDYLOARTHRITIS (AXSPA) AND HEALTHY CONTROLS

Keywords: Spondyloarthritis, Physical therapy/Physiotherapy

A. K. Rausch Osthoff[1], M. Bruderer-Hofstetter[1], L. Ettlin[1], F. Bischofberger[1], S. Papritz[1], A. Schwab[1], F. Weidmann[1], J. Niggli[2], K. Niedermann Schneider[1].
[1]ZHAW Zurich University of Applied Sciences, School of Health Sciences, Institute for Physiotherapy, Winterthur, Switzerland; [2]SVMB, Ankylosing Spondylitis Association Switzerland, Zurich, Switzerland

Background: Regular fitness assessments are part of the group exercise therapy concept for people with axSpA living in Switzerland. Participants ask if their performance is comparable with healthy people, which we cannot answer as no norm data are available. Among others, a test battery measuring the isometric strength endurance of the ventral, lateral, and dorsal core muscle chains (in seconds) is used (Rausch 2020). The core strength endurance test battery (CST) is time-consuming. In contrast, hand grip strength (in kg, Jamar dynamometer) can be tested within a short time and is already used as a substitute for multiple fitness-related tests (Kim 2022).

Objectives: 1) to compare core strength endurance of people with axSpA and healthy controls, and 2) to evaluate if grip strength can be used as a proxy for core strength to reduce the assessment time in people with axSpA.

Methods: Data was collected between April 2021 and December 2022. Data of people with axSpA were taken from the SVMB database of routinely gathered assessment data, and grip strength measurement was added. Further, data of CST and grip strength were collected in healthy controls, recruited from ZHAW staff and local sport clubs. All participants gave written informed consent. To investigate differences between both groups, relevant demographics, core and grip strength measures were compared using Welch Two-sample t-tests and Pearson's Chi[2] test, if appropriate. The associations between grip and core strength were explored through pairwise Spearman rank correlations (R_S) in both groups and sex-specific subgroups. In addition, we fitted linear regression models to the log-transformed data of people with axSpA.

Results: Data from 160 healthy people (50% male, mean age 59.3 (SD 11.47) years) and 122 people with axSpA (58% male, mean age 57.7 (SD 12.1) years) were included. In people with axSpA, mean years since symptoms were 37.3 (SD 24.9), and since diagnosis 29.4 (SD 27.1)). The median BASDAI score was 2.5 (IQR 1.7 – 4.2), and the median ADAS Health index was 3 (IQR 0 – 7). Demographic characteristics (i.e., age, sex, weight, height, BMI, and smoking status) did not differ between groups. However, people with axSpA showed less core strength endurance, measured in seconds: ventral mean difference -28, $p < 0.001$; lateral mean difference -17.1, $p < 0.001$; dorsal mean difference -38.5, $p < 0.001$.

Pairwise correlations in the two groups and sex-specific subgroups are summarized in Table 1.

Table 1. Correlations between grip and core muscle strength endurance in axSpA, healthy controls and sex-specific subgroups

Correlations grip and core strength endurance	People with axSpA (n=112)			Healthy people (n = 160)		
		Females (n=47)	Males (n=65)		Females (n=80)	Males (n=80)
Ventral	R_S = 0.34, 95%CI 0.16 - 0.49	R_S = 0.15, 95%CI -0.15 - 0.43	R_S = 0.29, 95%CI 0.05 - 0.50	R_S = 0.39, 95%CI 0.25 – 0.51	R_S = 0.32, 95%CI 0.12 – 0.51	R_S = 0.15, 95%CI -0.07 – 0.36
Lateral	R_S = 0.33, 95%CI 0.15 - 0.49	R_S = 0.14, 95%CI -0.16 - 0.42	R_S = 0.25, 95%CI -0.001 - 0.47	R_S = 0.51, 95%CI 0.38 – 0.61	RS = 0.46, 95%CI 0.27 – 0.62	R_S = 0.19, 95%CI -0.02 – 0.40
Dorsal	R_S = 0.07, 95%CI -0.13 - 0.27	R_S = 0.16, 95%CI -0.14 - 0.44	R_S = 0.27, 95%CI 0.01 - 0.50	R_S = 0.11, 95% CI -0.04 – 0.26	RS = 0.44, 95%CI 0.24 – 0.60	R_S = 0.05, 95%CI -0.17 – 0.27

The final linear regression model with grip strength as response and core strength, age, and sex as predictors explained 45% of the variability. Significant predictors in the model were ventral core strength endurance, age, and sex, while sex was the predictor with the most considerable effect.

Conclusion: People with axSpA showed lower core muscle strength endurance than healthy individuals. All correlations were small to moderate. The results from the multivariate analysis indicate that core strength endurance measures have only marginal effects on grip strength in people with axSpA. Therefore, grip strength is not appropriate to be used a s a proxy for core strength endurance in people with axSpA and healthy people.

OP0091-HPR VISCERAL ADIPOSE TISSUE IS ASSOCIATED WITH CARDIORESPIRATORY FITNESS, BUT NOT WITH PHYSICAL ACTIVITY AND DISEASE VARIABLES IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Physical therapy/Physiotherapy, Inflammatory arthritides

K. Risum[1,2], K. Godang[3], N. Olarescu[3,4], H. Marstein[5], J. Bollerslev[3,6], H. Sanner[5,7]. *[1]Oslo University Hospital, Section for Orthopaedic Rehabilitation, Oslo, Norway*; *[2]Oslo Metropolitan University, Department of Rehabilitation Science and Health Technology, Oslo, Norway*; *[3]Oslo University Hospital, Section for Specialised Endocrinology, Oslo, Norway*; *[4]University of Oslo, Department of Medical Biochemistry, Oslo, Norway*; *[5]Oslo New University College, Institute for Health, Oslo, Norway*; *[6]University of Oslo, Institute of Clinical Medicine, Oslo, Norway*; *[7]Oslo University Hospital, Section for Rheumatology, Oslo, Norway*

Background: Increased body fat is reported in juvenile idiopathic arthritis (JIA) and may, together with disease activity, represent risk factors for the development of cardiovascular disease (CVD). Visceral adipose tissue (VAT) is particularly associated with risk of CVD, but VAT has been scarcely examined in JIA. Physical activity (PA) and cardiorespiratory fitness (CRF) may counteract unfavorable body composition.
Objectives: To examine associations between VAT and PA, CRF and disease variables in patients with JIA diagnosed in the era of biologics.
Methods: 60 patients, aged between 10-16 years, with persistent oligo- or poly-articular disease (extended oligoarthritis and polyarticular RF +/-), were recruited consecutively at Oslo University Hospital in 2015. VAT (g) was estimated by dual-energy X-ray absorptiometry (DXA). PA was measured with accelerometers during seven consecutive days. CRF was directly measured as peak oxygen uptake (VO_{2peak}) during a continuous graded exercise test on a treadmill until exhaustion. We assessed disease activity with the Juvenile Arthritis Disease Activity Scale 71 (JADAS 71) and functional disability with the Childhood Health Assessment Questionnaire (CHAQ). Cross-sectional associations were analyzed with univariate and multiple linear regression analyses.
Results: Complete data was available in 55 (47 girls) patients. Mean (SD) age was 13.4 (2.2) years. Median (25^{th}-75^{th} percentile) VAT (g), JADAS 71 and CHAQ were 61 (21-131), 3.2 (1.1-4.8) and 0.0 (0.0-0.3), respectively. Biologics was used as treatment by 23 (42 %) of patients. There was a significant inverse association between CRF and VAT (p=0.002) using univariate linear regression analysis (Table 1). Measures of PA and disease variables (JADAS 71 and CHAQ) were not statistically significantly associated with VAT. CRF was the only identified correlate for VAT in the best model fit, also after adjustments for age and sex.
Conclusion: In this well-treated patient cohort, CRF was inversely associated with VAT. Measures of PA and traditional disease variables were not associated with VAT. Our study supports that higher CRF is important for a healthy body composition, including VAT in patients with JIA.

Table 1. Associations between visceral adipose tissue mass and cardiorespiratory fitness, physical activity and disease variables

	Univariate regression analyses		Multiple regression analyses	
	Unstandardized B (95 % CI)	P- value	Unstandardized B (95 % CI)	P- value
Visceral adipose tissue (g)				
CRF (VO_{2peak} mL/kg/min)	-6.5 (-10.4, -2.6)	0.002	-6.5 (-10.4, -2.6)	0.002
Vigorous PA (min)	-2.7 (-5.7-0.3)	0.08		
Moderate PA (min)	0.1 (-0.3, 3.2)	0.94		
Sedentary behavior (min)	-0.1 (-0.6, 0.4)	0.64		
JADAS 71 (0-101)	0.2 (-10.8, 11.2)	0.97		
CHAQ (0-3)	-41.6 (-144.1, 60.8)	0.42		
			R^2 adjusted	0.18

In multiple regression analyses, variables with a p value < 0.20 were included. Nonsignificant variables (p ≥ 0.05) were removed until only significant variables (p < 0.05) remained.CRF *Cardiorespiratory fitness*; VO_{2peak} *Peak oxygen uptake*; PA *Physical activity*; JADAS *Juvenile Arthritis Disease Activity Scale;* CHAQ *Childhood Health Assessment Questionnaire*

OP0092-HPR THE EFFECTIVENESS OF DIGITAL APPLICATIONS PROVIDING PERSONALIZED EXERCISE VIDEOS IN INDIVIDUALS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: A SYSTEMATIC REVIEW WITH META-ANALYSIS

Keywords: Education

T. Davergne[1], P. Meidinger[2], A. Dechartres[3], L. Gossec[4]. *[1]AP-HP Lariboisière-Fernand-Widal, F-75010, Université Paris Cité, Inserm, BIOSCAR, Physical Medicine and Rehabilitation Department, Paris, France*; *[2]TIMC-IMAG UMR CNRS 5525, Université Grenoble Alpes, ThEMAS Team, La Tronche, France*; *[3]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, Centre de Pharmacoépidémiologie (Cephepi), Unité de Recherche Clinique PSL-CFX, CIC-1901, AP-HP, Hôpital Pitié Salpêtrière, Département de Santé Publique, Paris, France*; *[4]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, AP-HP, Pitié-Salpêtrière Hospital, Rheumatology Department, Rheulatology Department, Paris, France*

Background: Among available digital applications (Apps), those providing personalized video exercises (PEV) may be helpful for individuals with rheumatic and musculoskeletal diseases (RMDs) undergoing functional rehabilitation [1,2,3].
Objectives: We aimed to assess the effectiveness of Apps providing PEV to support rehabilitation for people with disability, on functional capacity, confidence in exercise performance, use of care, health-related quality of life, adherence, and adverse events.
Methods: In this systematic review, we searched MEDLINE, CENTRAL and EMBASE databases up to March 2022. All randomized controlled trials evaluating the effect of Apps providing PEV to support rehabilitation for any condition with RMDs requiring physical rehabilitation were included. Selection, extraction and risk of bias assessment (RoB2) were performed by two independent reviewers. Primary outcome was functional capacity at the end of the intervention. Secondary outcomes included confidence in exercise performance, care consumption, health-related quality of life, adherence, and adverse events. A meta-analysis was performed where possible; the magnitude of the effect was assessed with the standardized mean difference (SMD). REGISTRATION: PROSPERO: CRD42022323670
Results: From 1641 identified references, 7 articles (906 participants, 93% adults) were included. The Apps were mostly commercial (7/10); the videos were mostly elaborated by a physiotherapist (8/10). Duration of App use was 3-48 weeks. All included studies had a high overall risk of bias. Low-quality evidence suggested the use of Apps providing PEV led to a significant, small to moderate improvement in physical function (SMD 0.33 [95% CI 0.16 to 0.50], Phet=0.93;

I^2=0%, 6 studies), confidence in exercise performance (SMD 3.69 [3.41 to 4.17], 1 study), quality of life (SMD 0.70 [95% CI 0.46 to 1.09], 1 study) and adherence (SMD 3.38 [95% CI 0.65 to 6.11], Phet=0.93; I^2=0%, 6 studies). Apps did not influence rate of adverse events.

Conclusion: Apps providing PEV to support exercise performance significantly improved physical function, confidence in exercise performance, quality of life and adherence. However, the level of evidence was low: more robust studies are needed to confirm these results.

Let's talk about biomarkers – ask the experts

OP0093-PARE

DISCOVERING THE POTENTIAL VALUES OF DIGITAL BIOMARKERS FOR INFLAMMATORY ARTHRITIS PATIENTS, A DESIGN THINKING APPROACH PRELIMINARY RESULTS OF THE PATIENTS' PERSPECTIVE

Keywords: Biomarkers, Self-management, Telemedicine

P. De Groot[1], I. Tchetverikov[2], Y. Goekoop-Ruiterman[3], M. R. Kok[4], M. Vis[1], W. Olsder[5], J. Foolen[6], R. Bakker[7], J. Luime[5]. *[1]Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands*; *[2]Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands*; *[3]Haga Hospital (Leyweg), Rheumatology, Den Haag, Netherlands*; *[4]Maasstad Hospital, Rheumatology, Rotterdam, Netherlands*; *[5]Erasmus School of Health Policy & Management, Health Services Management & Organisation, Rotterdam, Netherlands*; *[6]Eindhoven University of Technology, Biomedical Engineering, Eindhoven, Netherlands*; *[7]Consortium Beroepsonderwijs, Information Communication Technology, Amersfoort, Netherlands*

Background: The Inflammatory Arthritis (IA) patient population is growing, whilst there already is a shortage of health care professionals (HCPs). It is impossible to meet the future demand for care with the current healthcare system. *Digital biomarkers* are objective, quantifiable, physiological and behavioural data that are collected and measured by means of digital devices [1]. They can support continuous measurements outside the physical confines of the clinical environment and so could help close the gap in healthcare demands.

Objectives: To obtain the patients' insights on disease activity, disease management and care needs; and to empathise with their attitude towards digital biomarkers in order to obtain future directions for digital biomarker development.

Methods: A Design Thinking approach is followed for the development of digital biomarkers in rheumatology. It is a human-centered problem-solving approach that leverages empathy and collective idea generation to tackle complex challenges [2]. Semi-structured focus group discussions, based on the Common Sense Model of Self-Regulation [3], were conducted through 60-minute video conferences. All interviews were audio-recorded, transcribed to verbatim and coded. Results were discussed with our patient partners.

Results: In total 6 focus groups were organised, with a total of 30 IA patients (22 PsA; 8 RA, age 51± 11 years, 48% male, time since diagnosis 7 (3:12,5) years). The main findings were: *Trial and error;* life after diagnosis is marked by trial and error. They need(ed) to learn how and when to listen to their bodies, uncover potential triggers of inflammation and develop appropriate disease management. They felt an urgency to get advice on lifestyle adjustments, career choices and life adaptations, and discuss these with their HCPs and fellow patients. *Role of the HCPs in care needs;* patients visited their HCP for affirmation, reflection and future directions. They often doubted whether their symptoms were rheumatic. Secondly, they wanted to be ensured adverse drug reactions are absent, blood tests brought them peace of mind. Furthermore, consultations were indicated as an obligatory moment of self-reflection. Conversing with their HCP was seen as a reality check and a conversation about (new) options. *Digital Biomarkers;* attitudes towards digital biomarkers varied. Some patients thought it could provide them with deeper insights and reminders before crossing a line. Some patients thought it relevant only for their HCP. They did not want a constant reminder of their disease. Others did not see any additional value as they knew themselves well enough that no device should tell them whether their feelings are true or not.

Conclusion: The following problem statement from the patients' perspective can be formulated; "we suffer from a disease that has turned our lives upside down, we have to cope with it every day. Our learning mechanism is by trial and error. We have to know which activities should be avoided and how to predict the seriousness of a flare. It is difficult to discriminate pain as just pain, from pain as a preceding symptom of flare. The affirmation from our HCPs and our blood results bring us peace of mind. Perhaps, by applying technology, we can speed up our learning process and triggers of flare could be identified. However, one should be mindful of the purpose, the amount of reminders it gives us and the visualisation of our measurements." In general there is no strong resistance to digital biomarkers. However, for future uptake the recorded data should be of clear benefit for the patient.

Fibroblast activation in rheumatic diseases

OP0094

SPATIAL POSITIONING AND MATRIX PROGRAMS OF SYNOVIAL FIBROBLASTS UNDERPIN IMMUNE CELL ORGANISATION AND SYNOVIAL TISSUE PATHOTYPE

Keywords: Synovium, -omics, Rheumatoid arthritis

P. I. Reis Nisa[1], C. Mahony[1], C. Smith[1], C. D. Buckley[2], K. Raza[1], A. Filer[1], D. Windell[2], M. Coles[2], A. Croft[1]. [1]*University of Birmingham, Inflammation and Ageing, Birmingham, United Kingdom*; [2]*University of Oxford, Kennedy Institute for Rheumatology Research, Oxford, United Kingdom*

Background: Rheumatoid arthritis (RA) is highly heterogenous with distinct cellular and molecular tissue pathotypes that associate with disease outcome[1]. The synovial membrane is the primary target tissue and undergoes significant architectural re-modelling in response to inflammation. While fibroblasts are known to shape immune cell compartmentalisation in secondary lymphoid organs, by producing distinct sets of chemokines and remodelling extracellular matrix (ECM)[2], the mechanisms underlying immune cell localisation in the synovium are poorly understood.

Objectives: To define the functional zonation of the inflamed synovium at the single cell and regional tissue level using spatial transcriptomics and multiplex imaging.

Methods: We performed oligonucleotide probe-based spatially resolved transcriptomics on synovial tissue samples obtained by minimally invasive, ultrasound guided synovial tissue biopsies performed in patients with both rheumatoid arthritis (RA) and osteoarthritis (OA) using the 10x Visium platform. A total of 27 tissue biopsies processed sequencing 34170 spot transcriptomes. Each tissue section was composed on 1-8 fragments of synovial tissue from the same donor biopsy sample within each capture area, to maximise tissue representation and account for sampling variability. Cellular deconvolution of spot transcriptomes was performed using single cell reference datasets. Multiplex imaging was obtained to confirm gene profiles and cell types associated with the specific zonation patterns.

Results: We identified six spatially resolved tissue niches (or zones) within synovial membrane defined by gene expression and comprised of distinct populations of stromal and immune cells. Specific patterns of gene expression were observed in each of these sub-synovial tissue zones that link to functions of immune infiltrate recruitment and organisation. This zonation pattern is maintained across pathotypes (Fibroid, Lymphocytic) and spatial gene expression analysis revealed that RA is associated with specific synovial re-modelling and the formation of lymphocytic niches when compared to OA synovial tissue. We next defined zonation areas by manually annotating immune infiltrates (as aggregates) and vasculature, based on histology. From these, we selected fibroblasts specific to immune aggregate zones and peri-vascular zones (Figure 1). We have identified differences in gene expression between these fibroblasts based on their anatomical location. Peri-vascular fibroblasts have gene expression profiles related to myofibroblast differentiation, ECM deposition and modulation (COMP), but also immune cell recruitment (PLA2G2A), cell activation (FOS & FOSB), and lipid metabolism (APOD), also associated with OA synovium. These fibroblasts display either a TGF-β response or NOTCH3 activated[3] gene expression program and are expanded in the fibroid pauci-Immune) tissue pathotype. Immune interacting (peri-aggregate) fibroblasts in contrast, show specific gene expression profiles linked to ECM regulation (POSTN), degradation (MMP3) and co-ordination of ECM remodelling to recruit immune cells (SPARC), and permit aggregate formation. These fibroblasts display a T-cell interacting[4] and IFN-γ gene expression program and along with IL-1β and TNF-α activated lining layer fibroblasts dominate the stromal cell landscape of the lymphoid tissue pathotype.

Conclusion: We demonstrate that cytokine directed fibroblast-immune cell crosstalk, positional identity, and matrix specific, fibroblast gene expression programs are responsible for localising infiltrating immune cells to specific niches within the tissue and defining functional tissue zonation. These data identify novel therapeutically tractable disease pathways that underpin the pathogenicity of synovial tissue fibroblasts in RA.

Autoinflammation – the next chapter

OP0095

MONOSODIUM URATE AND CALCIUM PYROPHOSPHATE CRYSTAL-INDUCED INFLAMMATION RELIES ON CELL VOLUME REGULATION AND LRRRC8/VRAC CHANNEL ACTIVATION

Keywords: Inflammatory arthritides, Gout, Crystal Arthritis

T. W. Chirayath[1], M. Kayatekin[2], I. Rubera[2], N. Pham[1], F. Lioté[1], P. Richette[1], V. Compan[3], F. Rassendren[3], C. Duranton[2], H. K. Ea[1]. [1]*INSERM, Bioscar U1132, Paris, France*; [2]*LP2M - Université Côte d'Azur - CNRS UMR7370, Laboratoire de PhysioMédecine Moléculaire, NICE, France*; [3]*INSERM, Institut de Génomique Fonctionnelle, Montpellier, France*

Background: Monosodium urate (MSU) and calcium pyrophosphate (CPP) crystals are responsible for interleukin (IL)-1β dependent acute arthritis. The release of mature IL-1β is dependent on the NLRP3 inflammasome, which can be activated by other sterile stimuli such as hypo-osmolarity and ATP. During extracellular hypotonic stress, there is cellular swelling secondary to water influx. The cell sets up a defence mechanism, called regulatory volume decrease (RVD), allowing it to return to its initial volume. RVD depends on the anion channel VRAC, a hetero-hexamer composed of members of the LRRC8 family. LRRC8A is the obligatory key protein required to form active VRAC channel. Activation of LRRC8/VRAC channel results in an efflux of anions (mainly chloride) and osmolytes leading to water efflux and cell volume reduction.

Objectives: To evaluate the role of the LRRC8/VRAC channel in cell volume regulation and IL-1β release induced by MSU and CPP crystals.

Methods: In-vitro, primed THP-1 monocytes were stimulated by synthetic sterile MSU and CPP and cytokine production was quantified by ELISA. Cell volume variations were visualized by live video recording and cell surface was measured using ImageJ software. The role of the LRRC8/VRAC channel was evaluated using a pharmacological inhibitor DCPIB or by silencing the LRRC8A subunit (shLRRC8A RNA) in these cells. In vivo, MSU and CPP crystals were injected into air pouches created subcutaneously (mimicking synovial cavity) in wild-type mice and conditional LRRC8A Knock-out mice in the macrophagic lineage (Cxcr-3Cre_Lrrc8aflox/flox). Supernatants and pouch lavages were used to measure cytokine production by ELISA.

Results: MSU-and CPP-induced NF-κB activation was reduced in WT THP-1 cells treated with DCPIB and in THP-1 cells where LRRC8A expression was silenced. Similarly, IL-1β production induced by MSU and CPP crystals was substantially decreased in WT THP-1 treated with DCPIB (MSU 5200 vs 1080 pg/ml; CPP 11500 vs 4980, p<0.0001) and in shLRRC8A THP-1 cells compared to crystal-treated WT cells. MSU and CPP crystals exposure induced a biphasic cell volume change characterised by a significant increase followed by a RVD-like phenomenon. These cell volume changes were abolished in the presence of DCPIB and not observed in shLRRC8A THP-1 cells. In vivo, inflammation induced by MSU and CPP crystals assessed in lavage fluid and conventional histology was lower in Cxcr3Cre_Lrrc8aflox/flox mice as compared with wild-type mice in terms of IL-1β production and cell infiltrate.

Conclusion: These results suggested that MSU and CPP crystal-induced inflammation involved and cell volume variation regulated by VRAC/LRRC8 channel.

Background: Systemic immune-mediated diseases vary in manifestations and pathogenesis. Currently, disease diagnoses and treatments are generally based on clinical symptoms and some specific serological features. Because the diseases share some clinical and pathological features, it is difficult to comprehend the pathogenesis and manage them appropriately. To date, a limited number of studies tried to stratify such patients into some subgroups using the transcriptomic data and molecular patterns [1]; however, the number of included diseases, patients, and transcriptome data were restricted.
Objectives: To identify the significant immune cells forming the diseases and then stratify all patients accordingly, using immunophenotyping and transcriptomic data.
Methods: We performed an integrative analysis of immunophenotyping and bulk RNA-sequence (RNA-seq) on peripheral mononuclear blood cells (PBMC) from patients diagnosed with systemic lupus erythematosus (SLE), mixed connective tissue disease (MCTD), idiopathic inflammatory myopathy (IIM), systemic sclerosis (SSc), rheumatoid arthritis (RA), and large vessel vasculitis (LVV) in the Immune Cell Gene Expression Atlas from the University of Tokyo (ImmuNexUT) [2]. Immunophenotyping data (29 immune cell subsets) were applied to machine learning approaches, a random forest method, and all patients were stratified by k-means clustering. Then, we conducted a transcriptome analysis, including a differentially expressed gene (DEG) analysis and enrichment analysis (5,484 RNA-sequencing data). Finally, we compared clinical features among the clusters (**Figure 1A**).
Results: A total of 254 patients with systemic immune-mediated diseases -78 SLE, 22 MCTD, 63 IIM, 52 SSc, 20 RA, and 19 LVV- were included. To identify important cells to distinguish the diseases, a random forest algorithm was conducted by applying the immunophenotyping data. Using the top 15 important cells, k-means clustering was performed, and all patients were stratified into three clusters (**Figure 1B**). Naïve $CD8^+$ T cells, memory $CD4^+$ T cells, and non-classical monocytes were predominantly in clusters 1, 2, and 3, respectively (**Figure 1C**). Each disease showed skewed distribution in each cluster, such that SLE patients were predominantly in cluster 2 and most of the SSc patients were included in cluster 3 (**Figure 1B**). Next, we conducted DEG and enrichment analysis on 5,484 RNA-sequencing data of each immune cell and found that the number of DEGs in memory $CD4^+$ T cells in cluster 2, and non-classical monocytes in cluster 3 were increased when compared with other clusters, which were consistent with the cell proportions (**Figure 1D**). The gene ontology analysis showed enrichment of genes associated with adaptive immune response in naïve $CD8^+$ T cells in cluster 1, T cell activation response and an innate immune response in memory $CD4^+$ T cells in cluster 2, and vascular process in the circulatory system in non-classical monocytes in cluster 3, suggesting that even the same diseases can be stratified into each cluster based on specific pathogenesis. Uniquely, patients with common clinical features such as arthritis, the positivity of anti-SS-A antibody, and disease spectrums of MCTD were each accumulated in the different, specific cluster.
Conclusion: This large-scale integration of immunophenotyping and transcriptome analysis on the six systemic immune-mediated diseases revealed all patients were classified into three clusters and each one has specific clinical and transcriptomic features. It may enhance the understanding of the pathogenesis of heterogeneous diseases.

Background: Rheumatoid arthritis (RA) is associated with aberrant epigenomic control which obstructs the proper function of CD4 T cells. Bivalent chromatin regions (BvCR), containing histone H3 tail trimethylation at lysine 4 (H3K4me3) and lysine 27 (H3K27me3), act as a major organizer of the 3D nuclear environment required for efficient T cell development. Survivin has gained importance in RA pathogenesis. Survivin is shown to interact with chromatin genome-wide and regulate gene transcription in the IFNg producing CD4 T cells [1].
Objectives: This study investigates survivin cooperation with nucleosome in BvCR and functional effect of this cooperation on CD4 cell phenotype.
Methods: BvCR were identified in CD4 cells by annotation of H3K4me3, H3K27me3 and H3K27ac binding through chromatin immunoprecipitation and sequencing (ChIPseq). Protein binding was quantified through peak score. An overlap of the H3 peaks and Survivin ChIPseq (12 individual CD4 cultures) by at least one bp was identified through R package ChIPPeakAnno. Changes in H3 peaks in CD4 cells treated with a survivin inhibitor YM155 were assessed. Tag normalization was applied to enable comparison between different ChIPseq. Tag prevalence within the BvCR defined the dominant H3 group. Changeable BvCR were defined by alteration in the dominant-H3 group after YM155 treatment. TF ChIPseq colocalization analysis was performed through ReMap2022 database. To analyse effect of BvCR changeability on transcriptome, we performed RNAseq of YM155-treated CD4 cells (n=4). Overlap of BvCR with regulatory elements (RE) was done through GeneHancer database. TF enrichment analysis was performed through GSEA (Broad Institute).

Results: Integration of H3K4me3, H3K27me3 and H3K27ac ChIP-seq identified 6199 BvCR, 66% of those contained survivin peaks. Fluorescence imaging of effector T cells validated nuclear colocalization of survivin with histone proteins. Of those 6199 BvCR, 43.8% were dominated by H3K4me3, which had also the highest survivin peak scores. Complexes of histone modifiers COMPASS, responsible for H3K4 methylation, and SWI/SNF, responsible for counteracting PRC2-guided H3K27me3, colocalized with BvCR. YM155-treatment significantly increased deposition of both H3K4me3 and H3K27me3. Changeable BvCR frequently acquired a K4me3-dominant status after YM155 treatment. This indicates that survivin contributes to regulation of methylation of lysines in H3 tail within BvCR. TF enrichment analysis of genes connected to the BvCR revealed the role of histone demethylases KDM7A (FDR=1.03e-32), PHF2 (FDR=3.47e-19), KDM5D (FDR=1.51e-15) in their transcription. Strongest overall enrichment was identified in H3K4me3-dominant BvCR colocalized with survivin. Integration of BvCR with CD4 RNA-seq revealed 2469 protein-coding genes connected through RE to H3K4me3-dominant BvCR, which sustained transcriptional activity and 346 of those were differentially expressed (DEG, nom p<0.05) in YM155-treated cells. DEG transcriptionally dependent on the TF families of histone modifiers built a strong SWI/SNF-dependent interaction network acting in biological processes of immune system regulation (FDR=1.07e-6. FOXP1, KLF3, FYB1, BCL2), DNA repair (FDR=5.57e-6. MSH6, MGMT, MCM8, UPF1), and RNA polymerase transcription (FDR=1.22e-8. TCF3, ARID5A, RARA). CD4 cell transcriptomics of randomly selected RA patients demonstrated that a) DEG controlled by the H3K4me3-dominant BvCR were upregulated in survivin-high CD4 cells with proinflammatory Th1 phenotype b) DEG had altered expression in CD4 cells of patients treated with JAK-inhibitors.

Conclusion: This study demonstrates that survivin contributes to regulation of lysine methylation in H3 tail within BvCR, which coordinates activity of the SWI/SNF complex in chromatin remodelling and transcription. We demonstrate that survivin inhibition affects this coordinated activity, and thereby impinge on CD4 activation in RA.

OP0098 INFLAMMATORY GENE ENHANCERS ARE SHARED IN SYNOVIAL FIBROBLASTS AND MINOR SALIVARY GLAND FIBROBLASTS

Keywords: Cytokines and chemokines, Sjögren syndrome, Rheumatoid arthritis

L. Moser[1], M. Brunner[2,3], M. Houtman[1], M. Sprecher[1], M. Elhai[1], O. Distler[1], B. Maurer[2,3], C. Ospelt[1], K. Klein[2,3]. *[1]University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland*; *[2]University Hospital Bern, Department of Rheumatology and Immunology, Bern, Switzerland*; *[3]University of Bern, Department of BioMedical Research, Bern, Switzerland*

Background: Cell type- and stimulus-specific enhancers are key regulatory elements in chronic inflammatory rheumatic diseases, such as rheumatoid arthritis (RA) and Sjögren`s syndrome (SjS). Recent transcriptome profiling of synovial fibroblasts (SF) from patients with RA and minor salivary gland-derived fibroblast (SGF) from patients with SjS point to similarities of fibroblast populations derived from these two chronic inflammatory diseases. Enhancer RNAs (eRNAs) are short-lived non-coding RNAs transcribed from cell type-specific enhancers that facilitate the transcription of their linked coding genes. The activation and interference with transcribed enhancers in SF and SGF has not been studied yet.

Objectives: To characterise the activation and regulation of transcribed inflammatory gene enhancers in RA SF and SGF.

Methods: SF were isolated from synovial tissues of patients with RA undergoing joint replacement surgery. SGF were isolated from minor salivary gland biopsies of patients with a suspected SjS, including samples of patients with SjS (n=3) and controls (n=3) that do not fulfil the classification criteria. The expression of eRNAs in SF (n=9) stimulated with TNF (24h; 10 ng/µl) or left untreated, was detected by cap analysis of gene expression followed by sequencing (CAGEseq). RA SF (n=7) and SGF (n=6) were stimulated with TNF (1, 3, 6, 24h; 10 ng/µl), IL1 (1, 24h; 1 ng/ml), or the Toll-like receptor agonists pIC (1, 24h; 10 µg/ml) and LPS (1, 24h; 100 ng/µl). The expression of selected eRNAs and their corresponding coding genes was analysed by real-time PCR. Samples containing the untranscribed RNA were measured in parallel. To study eRNA regulation, SF were treated with the bromodomain inhibitor I-BET (1 µM; 24h), prior to stimulation with TNF.

Results: We have identified and selected a set of TNF-induced eRNAs for the pro-inflammatory genes *CCL2, IL8*, *IL6, CXCL1* and *CCL20* for a more detailed analysis. These eRNAs were located upstream (eCCL2#1, eCCL2#2, eCXCL1#2, eIL6#1, eIL8#1-3), downstream (eCCL2#3, eCCL2#4, eCXCL1#1) and intronic (eCCL20) at distances between 300 bp to 35.6 kb relative to the transcription start sites of the corresponding coding genes. CAGEseq revealed a patient-dependent variability in eRNA expression, with none of the selected eRNAs being present in SF of all nine patients, and the existence of several TNF-induced eRNAs for individual coding genes. By performing TNF time course experiments in SF, we have detected different patterns of eRNAs: (a) eRNAs, that peaked at 1h (eCCL20, eIL8#2, eCCL2#1), (b) at 6h (eCXCL1#1), (c) or at 24h (eIL8#1, eIL8#3, eIL8#4, eCXCL1#2) after stimulation, and (d) eRNAs that were stably expressed over the time points (eCCL2#2, 3, 4). The same set of eRNAs and corresponding coding genes was induced in SGF, indicating that inflammatory gene enhancers are shared in fibroblasts from different localisation and diseases. All inflammatory stimuli induced the expression of eRNAs in SF and SGF. However, we detected some differences regarding the peak of eRNA expression (eCCL2#2, eCCL2#3, eCXCL1#2) and the potency of different stimuli to induce individual eRNAs. Treatment of SF with I-BET suppressed the expression of all eRNAs tested.

Conclusion: SGF, similar to SF, respond to different pro-inflammatory stimuli by inducing the expression of transcribed eRNAs and their corresponding coding genes. The expression of some eRNAs is maintained for up to 24h, contradicting previous reports that eRNAs are short-lived. Bromodomain inhibitors are sufficient to prevent the activation of eRNAs.

OP0099 UNVEILING THE COMPLEX GENE REGULATORY MECHANISMS OF PSORIATIC ARTHRITIS THROUGH CHROMATIN CONFORMATION, GENE EXPRESSION AND CHROMATIN ACCESSIBILITY ANALYSIS IN PRIMARY CELLS

Keywords: Psoriatic arthritis, Genetics/Epigenetics, -omics

C. Shi[1], D. Zhao[1], J. Ding[1], C. Ferrazzano[1], C. Wynn[1], A. Frantzesko[1], R. Hum[2], P. Ho[2], J. Bowes[1,3], A. Barton[1,3,4], M. Rattray[3,5], G. Orozco[1,3,4]. *[1]The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom*; *[2]Manchester Royal Infirmary, Manchester University NHS Foundation Trust, The Kellgren Centre for Rheumatology, Manchester, United Kingdom*; *[3]Manchester University NHS Foundation Trust, Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom*; *[4]The University of Manchester, Lydia Becker Institute of Immunology and Inflammation, Manchester, United Kingdom*; *[5]The University of Manchester, Division of Informatics, Imaging and Data Sciences, Manchester, United Kingdom*

Background: GWAS have identified genetic variants associated with many complex diseases. These primarily affect regulatory elements that can affect expression of distal genes through chromatin interaction mechanisms. Previous studies have used functional genomics and chromatin conformation capture techniques to study the functional impact of these genetic variants [1]. However, such studies have predominantly used data generated from cell lines, which behave differently from primary cells. Additionally, there is a lack of research in Psoriatic Arthritis (PsA), which is a highly heterogenous disease that has been understudied and for which there are few effective treatments.

Objectives: We aimed to study how chromatin conformation and gene expression is altered in primary T cells derived from patients with PsA, and to identify how genetic variants alter gene regulatory mechanisms in a population of individuals.

Methods: Genotype data, together with matching high resolution Hi-C, RNA-seq and ATAC-seq was generated from primary $CD4^+$ and $CD8^+$ T cell samples isolated from the blood (n=55) and synovial fluid (n=9) of patients with PsA and blood of healthy controls (n=19).

Results: We found that chromatin conformation is highly cell-type and context specific. Out of 105,956 total loops, 29,454 were differentially interacting

(FDR<0.1) between CD8$^+$ and CD4$^+$ T cells, and 15,597 (FDR<0.1) between CD8$^+$ T cells isolated from synovial fluid compared to those from blood. These differential loops overlap many disease associated GWAS loci such as the *TNIP1* and *STAT2* PsA loci. We identified 312 genotype associated loops, one of which is associated with a risk locus (*GSDMB*) known to be associated with several autoimmune diseases. Moreover, we found that chromatin conformation correlates strongly with differences in gene expression and chromatin accessibility, particularly with genes related to T cell activation and inflammatory pathways. Next, we compared T cells isolated from blood of PsA patients to controls, but few significant differences were identified (Table 1). Segregating the PsA cohort by disease activity and treatment led to the identification of significantly larger differences. We found numerous differentially expressed genes (DEGs) and differential ATAC-seq peaks in patients with or without active disease, and in those receiving or not receiving biological disease-modifying antirheumatic drugs (bDMARD) (Table 1). Furthermore, there were numerous DEGs and differential ATAC-seq peaks in bDMARD responders (n=8) vs non-responders (n=6) (Figure 1, Table 1). DEGs were enriched for pathways involving immune function such as IL-2 and IL-15 signalling. Differential ATAC-seq peaks were enriched for binding sites for transcription factors such as *RUNX1*, *JUN*, *IRF4* and *STAT2*. Furthermore, one of the differential ATAC-seq peaks we identified overlapped SNPs in the psoriasis *RUNX3* locus.

Table 1. Number of DEGs and differential ATAC-seq peaks in the various comparisons for CD4$^+$ and CD8$^+$ T cells (all FDR<0.1).

Comparison	RNA-seq CD4+	RNA-seq CD8+	ATAC-seq CD4+	ATAC-seq CD8+
Patients vs healthy controls	46	200	0	4
Patients with active disease vs remission	169	36	1675	3
bDMARD treatment effect in non-active disease	90	13	75	14
bDMARD treatment effect active disease	967	295	13176	5069
Remission vs active disease without bDMARD	17	21	0	0
Remission vs active disease treated with bDMARD	1034	374	2559	41

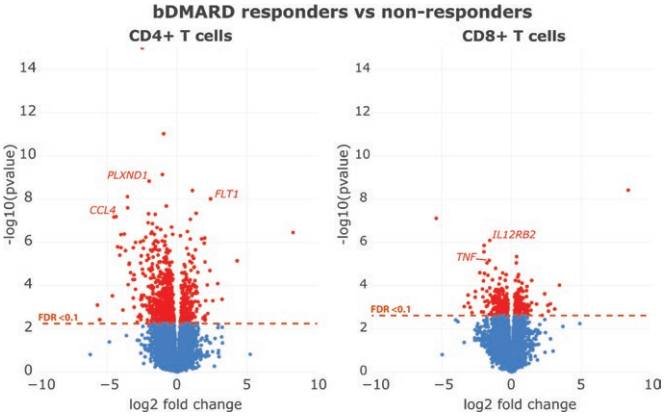

Figure 1. Volcano plot of DEGs between bDMARD responders vs non-responders in CD4$^+$ and CD8$^+$ T cells respectively.

Conclusion: This study provides novel insight into gene regulatory mechanisms, particularly regarding PsA GWAS signals and disease pathogenesis. We identified, for the first time, epigenetic differences correlated with disease severity and treatment response in PsA using primary T cells.

DNA METHYLATION PATTERNS IN CD4+ T CELLS DISCERN SKIN PSORIASIS FROM PSORIATIC ARTHRITIS

Keywords: Adaptive immunity, Psoriatic arthritis, Genetics/Epigenetics

V. Natoli[1,2], A. Charras[1], S. Hofmann[3], S. Northey[1], S. Russ[4], F. Schulze[4], S. Abraham[5], C. Hedrich[1,6]. *[1]Institute of Life Course and Medical Sciences, University of Liverpool, Department of Women's & Children's Health, Liverpool, United Kingdom*; *[2]Università degli Studi di Genova, Dipartimento di Neuroscienze, riabilitazione, oftalmologia, genetica e scienze materno-infantili, DINOGMI, Genova, Italy*; *[3]Klinik und Poliklinik für Kinder- und Jugendmedizin, Universitätsklinikum Carl Gustav Carus, TU Dresden, Dresden, Germany*; *[4]Klinik und Poliklinik für Kinder- und Jugendmedizin, Universitätsklinikum Carl Gustav Carus, TU Dresden, Dresden, Germany*; *[5]Universitätsklinikum Carl Gustav Carus, TU Dresden, Klinik und Poliklinik für Dermatologie, Dresden, Germany*; *[6]Alder Hey Children's NHS Foundation Trust Hospital, Department of Paediatric Rheumatology, Liverpool, United Kingdom*

Background: Psoriasis is a systemic inflammatory disease that primarily affects the skin. Approximately one third of psoriasis patients develop joint involvement and are therefore diagnosed with psoriatic arthritis (PsA). While, in adults, the development of arthritis usually follows skin psoriasis, approximately 15% of patients experience arthritis simultaneously or prior to skin disease. Thus, PsA can be missed, leading to disease progression, damage, and reduced quality of life. Individualized care is complicated by the absence of disease- or outcome-specific biomarkers. While the pathophysiology of psoriasis is incompletely understood, a key role of effector T-cells has been established. Recent studies linked altered DNA methylation with T-cell dysregulation and phenotypical variation between patients.

Objectives: This project aimed to identify disease-associated DNA methylation signatures in CD4$^+$ T-cells from psoriasis and PsA patients as compared to healthy controls that may be used as diagnostic and/or prognostic biomarkers and inform future treatment.

Methods: Peripheral blood samples were collected from 9 healthy controls, 11 skin psoriasis and 8 PsA patients. PBMCs were isolated *ex vivo*, CD4$^+$ T-cells were FACS separated, and genomic DNA was isolated. DNA methylation profiling was performed using the Illumina Human Methylation EPIC 850K platform. Bioinformatic analyses, including gene ontology (GO) and KEGG pathway analysis, were performed using R software (*minfi*, *limma*, *ChAMP*, *DMRcate*, *clusterProfiler*). Flow cytometry datasets were analyzed using *FlowJo*. To identify genes under the control of interferon (IFN), the *Interferome* database was consulted. DNA Methylation Scores were calculated for type I and type II interferons following the method suggested by Björk *et al.* (2020).

Results: Numbers and proportions of CD4$^+$ T-cells did not vary between controls and patients with skin psoriasis or PsA. Furthermore, no differences between controls and patient groups were observed in the proportion of CD4$^+$ T-cell subsets (naïve, central memory, effector memory, CD45RA re-expressing effector memory cells). We detected 820 differentially methylated positions (DMPs) affecting 433 genes in CD4$^+$ T-cells from healthy controls when compared to psoriasis and PsA patients. Based on DMP analyses, groups segregated in principal component (PCA) or partial least-squares discriminant analyses (PLS-DA) (Figure 1). Separation in PLS-DA was centrally influenced by two CGs (cg07021052, cg10687131) localized in *GDF7* (Growth and Differentiation factor 7), which affects T-cell regulatory factors FOXP3 and CTLA4. GO analysis of genes with at least one DMP in their promoter region delivered hypomethylation of genes involved in "negative regulation of focal adhesion assembly", "cell-substrate junction organization" and "regulation of the triglyceride biosynthetic". DNA methylation profiles (855 DMPs affecting 551 genes) distinguished between skin psoriasis and PsA patients; a high proportion of DMPs associated with interferon-regulated genes (68% total: 8.8% type I, 33.5% type II, 23.8% type I and II IFN). GO analysis delivered an enrichment of hypomethylated genes affecting "carboxylic ester hydrolase", "alkyl or aryl group transferase" and "glutathione transferase activity". Notably, we observed a majority DMPs in IFN-related genes when comparing healthy controls with PsA patients (61.9% total: 9.1% type I, 29% type II, 23.8% type I and II IFN) and controls with skin psoriasis patients (62.7% total, 7.7% type I, 31% type II, 24% type I and II IFN). Moreover, DNA methylation calculated for type I and type II IFN-associated genes significantly differed between healthy controls, skin psoriasis and PsA patients.

Conclusion: DNA methylation profiles in CD4+ T-cells discriminate between controls, skin psoriasis and PsA. As DNA methylation signatures may predict disease progression from psoriasis to PsA, they may be applied for molecular patient stratification towards future individualized treatment and care.

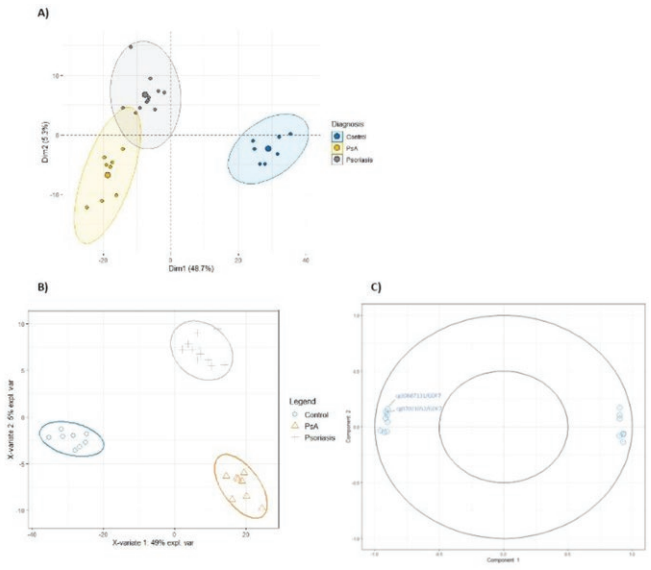

Figure 1: DNA methylation signatures differentiate healthy controls from skin psoriasis and PsA. A) Unsupervised Principal Component Analysis (PCA) of 820 Differentially Methylated Positions (DMP) (FDR p-value: <0.05, $|\Delta\beta|$>0.1) discriminates between healthy controls, skin psoriasis, and PsA patients. B) Supervised Partial Least-Squares Discriminant Analysis (PLS-DA) of the same 820 DMPs (FDR p-value <0.05, $|\Delta\beta|$>0.1) even more clearly separates healthy controls from skin psoriasis and PsA patients. C) Correlation circle plot displaying the 15 DMPs (correlation cutoff 0.9) that primarily contribute to the definition of each component of the PLS-DA. DMPs at cg07021052 and cg10687131 are localized in *GDF7* which affects T-cell regulatory factors FOXP3 and CTLA4.

Molberg[3], C. Sjowall[2], J. Sandling[1], D. Leonard[1]. *[1]Uppsala University, Department of Medical Sciences, Uppsala, Sweden*; *[2]Linköping University, Department of Biomedical and Clinical Sciences, Linköping, Sweden*; *[3]Oslo University Hospital, Department of Rheumatology, Oslo, Norway*; *[4]Lund University, Department of Clinical Sciences, Lund, Sweden*; *[5]Umeå University, Department of Public Health and Clinical Medicine/Rheumatology, Umeå, Sweden*; *[6]Sahlgrenska Academy, University of Gothenburg, Dept of Rheumatology and Inflammation Research, Gothenburg, Sweden*

Background: Lupus nephritis (LN) is one of the main clinical challenges in systemic lupus erythematosus (SLE) and a cause of significant morbidity and mortality. Genetic contribution to SLE pathogenesis is important, and genetic profiling through polygenic risk scores has been shown useful to stratify SLE patients according to dominating molecular disease mechanism.[1] This has not, however, been investigated for specific disease manifestations.
Objectives: In this work, we aimed to investigate associations between B cell polygenic risk scores (PRSs) and disease manifestations in SLE.
Methods: Female patients with SLE (n = 1248) and healthy control individuals (n = 519) were genotyped using Illumina's Global Screening Array. Two PRSs were calculated[2], one including 20 GWS risk loci for SLE in genes assigned to B-cell related pathways according to the KEGG, GO and Reactome databases, and one including a subset of 12 of these genes limited to B-cell activation pathways. PRSs were defined as high in the highest quartile and low in quartile 1-3, and groups were compared by logistic regression (SPSS, version 28.0.1.0). HLA variants HLA-DRB1*03:01 and HLA-DRB1*15:01 were assessed in patients using tag SNPs. A p-value < 0.05 was considered significant.
Results: SLE was more prevalent in individuals with high compared with a low SLE B cell PRS (OR 1.84 (1.42-2.38), p=4.0×10^{-6}) and mean PRS was higher in cases than controls, 2.92 (2.88-2.96) for cases and 2.68 (2.63-2.74) for controls, p = 4.1 × 10^{-11}). Immunologic disorder (ACR -82) and dsDNA antibodies were more prevalent among patients with a high compared with a low SLE B cell PRS (OR 1.44 (1.08-1.93), p=1.4×10^{-2}, and OR 1.47 (1.07-2.01), p=1.8×10^{-2}, for immunologic disorder and dsDNA antibodies, respectively). Also, effect sizes were augmented in patients with HLA risk serotypes HLA-DRB1*03:01 and HLA-DRB1*15:01, with the highest prevalence of dsDNA antibodies (87 %) demonstrated in patients with HLA-DRB1*03/15 +/+ combined with a high SLE B cell PRS (OR 1.64 (1.06-2.54), p = 0.028, for high vs low PRS), Figure 1. Anti-dsDNA antibodies were associated with a higher prevalence of class III or IV nephritis (OR 4.66 (2.78-7.80), p=5.2×10^{-9}) and the prevalence of nephritis according to the ACR-82 criteria was higher in patients with a high compared to patients with a low B cell activation PRS (OR 1.32 (1.00-1.74), p = 0.048). Numerically, a higher prevalence of nephritis (ACR -82) was observed for patients with a high compared with a low SLE B cell PRS, but the difference was not statistically significant (OR 1.20 (0.91-1.59), p = 0.19).
Conclusion: High genetic burden related to B cell function is associated with dsDNA antibody development and LN. Assessing B cell PRSs may be important in order to determine immunologic pathways influencing SLE and to predict clinical phenotype.

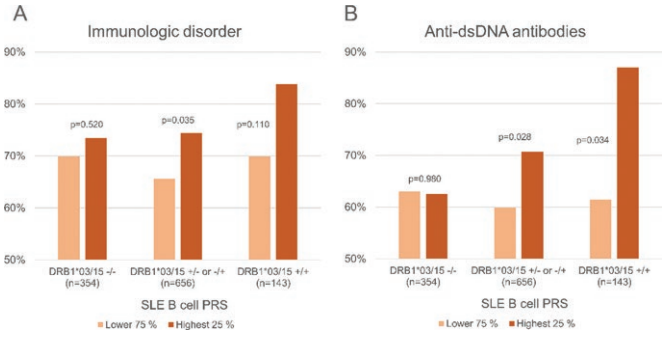

Figure 1. Associations with SLE B cell PRS, immunologic disorder (ACR-82) and anti-dsDNA antibodies in HLA subgroups. Female patients with SLE were stratified into three groups according to HLA-type (positive for HLA-DRB1*03:01 or HLA-DRB1*15:01 (DRB1*03/15 +/- or -/+), positive for both (DRB1*03/15 +/+) or negative for both (DRB1*03/15 -/-) risk variants). Each group was then divided into two groups based on the patients' SLE B cell PRSs (highest quartile or quartile 1-3). Prevalence of immunologic disorder according to the ACR -82 criteria (A) and prevalence of dsDNA antibodies (B) was then calculated for all 6 groups.

Background: Giant cell arteritis (GCA) is a chronic large-vessel vasculitis that affects mainly the aorta and its primary branches, and in Western countries is the most common form of vasculitis in people older than 50 years. The most severe manifestations of GCA include blindness and ischemic stroke caused by occlusion of affected arteries. GCA presents a complex aetiology whose genetic component remains largely unknown. Currently, options for both diagnosis and treatment for this pathology are limited, highlighting the need to better understand the genetic factors involved in susceptibility to GCA.
Objectives: The main goal of this study was to characterise the genetic basis of GCA by performing the largest genome-wide association study (GWAS) in this vasculitis to date.
Methods: A total of 3,498 GCA patients with GCA and 15,550 healthy individuals from ten populations of European ancestry were included in this study. After strict quality controls and imputation, 6,691,294 genetic variants were analysed by logistic regression using the first 10 principal components and sex as covariates. Loci showing a significant (p<5E-8) or suggestive (p<5E-5) association with the disease were selected for functional *in silico* analyses, including causal gene prioritisation with FUMA, enrichment of functional annotations of cell-specific histone marks using GoShifter. Finally, we performed a drug repurposing analysis, by evaluating the proposed mapped genes of the significant loci as targets for approved drug using the DrugBank database, and developed a polygenic risk score (PRS) for GCA susceptibility prediction.
Results: Three risk loci for GCA not previously reported were identified, two of them located in genes related to the vascular endothelial growth factor (VEGF) pathway: *MFGE8* (rs8029053, p=4.96E-8, OR=1.19), encoding lactadherin, and *VTN* (rs704, p=2.75E-9, OR=0.84)], encoding vitronectin; and the third one located in the gene *CCDC25* (rs11782624, p=1.28E-8, OR=1,18), that codifies a receptor of neutrophil extracellular traps (NETs). Additionally, we replicated the associations previously described within the HLA region and the *PLG* gene, which is also involved in angiogenesis. The results of the functional annotation showed that the GCA-associated loci act as regulatory variants influencing gene expression in vascular tissue and immune cell types. Furthermore, we also found a significant enrichment in histone marks in several immune cell types, especially in natural killer cells. The results of the drug repurposing analysis suggest abciximab, an antagonist of the vitronectin protein and approved for the treatment of acute coronary syndrome, as a potential candidate to treat GCA. Finally, the PRS model was best defined by including 28 genetic variants, being capable of identifying a fraction of individuals with more than three times the risk of developing GCA (OR=3.1 [2.1-4.7], p=1.71E-8).
Conclusion: Through the largest genomic study performed in GCA to date, we identified three genetic regions associated with this vasculitis that were not previously reported. These results also identified new physiological pathways and cell types potentially relevant to the development of the disease. These results allowed us to establish a prediction tool for identifying individuals at high-risk for developing GCA and also to propose further investigation of abciximab, a drug that could be potentially repurposed for treatment of GCA.

ANALYSIS OF PROTEIN QUANTITATIVE TRAIL LOCI TO IDENTIFY GENETIC BIOMARKERS OF TREATMENT RESPONSE TO ETANERCEPT IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Genetics/Epigenetics, -omics, Rheumatoid arthritis

S. Ling[1,2], C. F. Yap[1], N. Nair[1,2], J. Bluett[1,2], A. Morgan[3,4,5], J. Isaacs[6,7], A. G. Wilson[8], K. Hyrich[2,9], A. Barton[1,2], D. Plant[1,2]. [1]*The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom*; [2]*NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom*; [3]*University of Leeds, School of Medicine, Leeds, United Kingdom*; [4]*NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*; [5]*NIHR In Vitro Diagnostic Co-Operative, Leeds, United Kingdom*; [6]*Newcastle University, Translational and Clinical Research Institute, Newcastle, United Kingdom*; [7]*Newcastle-upon-Tyne Hospitals NHS Foundation Trust, Musculoskeletal Unit, Newcastle-upon-Tyne, United Kingdom*; [8]*University College Dublin, Conway Institute, Dublin, Ireland*; [9]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*

Background: Treatment response to etanercept in patients with rheumatoid arthritis (RA) is heterogeneous, with up to 40% switching due to failure/ineffectiveness[1]. There are no validated pre-treatment biomarkers of response. Due to

their diverse biological roles, proteins can reflect ongoing RA disease processes and may provide biomarkers of response; however, studying proteins in isolation can lead to challenges in separating the cause from the consequence of inflammation. If protein levels are under genetic control, then potentially, stable pre-treatment genetic biomarkers of etanercept response may be identified.
Objectives: To determine whether there is a genetic basis underlying protein expression in patients with RA treated with etanercept.
Methods: Participants were recruited from a UK-based prospective multi-centre study of patients fulfilling either the 1987 ACR or 2010 ACR/EULAR classification criteria for RA, starting etanercept as a first biologic. Quantitative proteomics were performed using Sequential Window Acquisition of all THeoretical fragment ion spectra mass spectrometry (SWATH-MS). Genotyping was carried out using the Illumina Infinium HumanCoreExome 12 BeadChip kit and genotype calling was carried out using GenomeStudio software (both Illumina, San Diego, CA, USA). Following standard genetic QC and imputation, a protein quantitative trait loci (pQTL) analysis was performed using a linear model adjusted for potential confounding covariates (age, biological sex, disease duration, concurrent DMARD use, seropositive status). A suggestive significance level of p<1E-05 was set for *cis* pQTLs; *trans* pQTLs were not considered due to modest sample size. Significance thresholds were adjusted for false discovery rate and subsequently, any adjusted result with $p < 0.05$ was considered to be significant. pQTLs were sought at baseline and after 3 months of treatment.
Results: 147 participants were recruited, with a median age of 56.39 years [IQR 49.34-64.73], median disease duration of 6 years [IQR 2-13] and of whom 108 (75.52%) were female. 482 unique proteins were available for analysis following proteomics and genetics data QC. At baseline (pre-treatment), 2,184 *cis* pQTLs were identified for 60 proteins (this may reflect many pQTLs in strong linkage disequilibrium with one another). After 3 months of treatment, 1,432 *cis* pQTLs were identified for 68 proteins. 2 proteins measured at pre-treatment had pQTLs (*rs150571376*, p_{adj}=3E-03 and *rs188695391*, p_{adj}=1.07E-02) where the protein expression was also associated with DAS28 at 3 months (TCPH, p_{adj}=1.40E-02 and EHD1, p_{adj}=6.54E-03, respectively).
Conclusion: pQTL analysis carried out in RA patients starting etanercept identified numerous loci that are significantly associated with paired protein expression data. 2 baseline proteins, TCPH and EHD1, were found to be associated with post-treatment DAS28 and also had a genetic basis underlying their expression, and these could prove to be valuable candidates for future study, as both proteins are involved in processes during ATP hydrolysis.

Innate Immunity in Pathogenesis of RMDs

OP0104 NON-CANONICAL NF-κB SIGNALLING IS REQUIRED FOR EXTRATHYMIC AIRE EXPRESSION AND IMMUNOREGULATORY MOLECULES IN CELLS OF THE DENDRITIC LINEAGE

Keywords: Cell biology, Innate immunity

G. Van Laar[1,2], L. Huitema[1,2], B. Helder[1,2], J. Fergusson[2], H. Spits[2], J. P. Van Hamburg[1,2], S. Tas[1,2]. [1]*Amsterdam UMC, Location AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; [2]*Amsterdam UMC, Location AMC, Experimental Immunology, Amsterdam, Netherlands*

Background: The transcription factor Autoimmune Regulator (AIRE) is crucial for the establishment of central tolerance in the thymus. Although thymic expression is mainly restricted to medullary epithelial cells, recent studies have identified peripheral $CD45^+$ extrathymic AIRE-expressing cells (eTACs), which share features with antigen presenting cells, such as dendritic cells (DCs). Although, nuclear factor (NF)-κB signaling has been implicated in thymic AIRE expression, stimuli and pathways that induce extrathymic AIRE expression are hitherto unknown.
Objectives: In this study we aimed to unravel the molecular mechanisms underlying the regulation of extrathymic AIRE expression in eTACs and DCs with a focus on NF-κB signaling.
Methods: Confocal and Vectra Polaris multispectral imaging was performed on secondary lymphoid tissues, including tonsils and lymph nodes to identify and characterize eTACs. Second, we employed a novel sorting strategy to isolate DCs and eTACs from tonsil tissue for RNA-sequencing (seq) to generate transcription profiles. To study the regulation of AIRE, monocyte-derived DCs (moDCs), DCs and eTACs were stimulated by anti-CD40 to induce NF-κB activation. Gene transcription and protein expression levels of AIRE, indoleamine 2,3-dioxygenase (IDO), programmed death ligand-1 (PD-L1) and non-canonical NF-κB signalling components were detected by real time-PCR, flow cytometry, Western blot and/or confocal microscopy. Activation of NF-κB signalling was modulated by siRNA-mediated silencing or using a small molecule inhibitor (SMI) of activating kinases.
Results: In human tonsil and lymph node tissue AIRE+ cells were identified, which displayed DC characteristics, including MHCII and CD40, but were relatively low for the pan DC marker CD11c. Bioinformatic analysis on RNA-seq derived gene expression profiles of sorted eTACs and DCs from tonsil tissue revealed an increased expression of AIRE and immunoregulatory genes, including IDO and PD-L1 in eTACs compared to DCs. In addition, the expression of genes implicated in non-canonical NF-κB signaling, including NIK and CD40, were significantly higher in eTACs compared to DCs. CD40 stimulation has been shown to be critical for IDO production by moDCs. CD40-stimulation of moDCs resulted in the activation of non-canonical NF-κB signaling, which was accompanied by upregulation of AIRE, IDO and PD-L1 expression. Interestingly, the induction of AIRE expression was abrogated by siRNA-mediated silencing of NF-κB-inducing kinase (NIK). Likewise, CD40 stimulation of sorted eTACs and DCs resulted elevated AIRE, IDO and PD-L1 expression levels, albeit 5 fold higher AIRE transcription levels were detected in eTAC. Subsequently, modulation of NIK via an SMI resulted in the abrogation of AIRE, IDO and PD-L1 expression in eTACs and DCs. In contrast, specific modulation of canonical NF-κB signaling had no significant effects on AIRE, IDO and PD-L1 expression in CD40-stimulated eTACs and DCs.
Conclusion: Collectively, our data demonstrate that AIRE expression, as well as the expression of the immunoregulatory molecules IDO and PD-L1 in eTACs and DCs can be induced through CD40 stimulation in a non-canonical NF-κB signaling dependent manner. These findings concerning the regulation of AIRE and immunoregulatory molecule expression may point towards a novel role of eTACs in peripheral tolerance.

OP0105 SINGLE CELL RNASEQ AND FUNCTIONAL STUDIES SUGGEST A ROLE FOR ENTHESIS MESENCHYMAL STEM CELLS RATHER THAN TREGS IN ENTHESIS SOFT TISSUE AND BONE ANCHORAGE SITE IMMUNOMODULATION

Keywords: Enthesitis, Inflammatory arthritides, Innate immunity

A. Altaie[1,2], D. Simone[3], H. Owston[1], M. Attar[3], E. Jones[1], C. D. Buckley[3], S. Sansom[3], D. Mcgonagle[1,2]. [1]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [2]*University of Leeds, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom*; [3]*University of Oxford, Kennedy Institute of Rheumatology, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: The enthesis is a the key target tissue in spondyloarthritis (SpA) with inflammation evident in both the enthesis soft tissue (EST) and the adjacent anchoring peri-entheseal bone (PEB)[1]. The healthy human spinal enthesis harbour, resident mesenchymal stem cells (MSCs), myeloid cells, innate immune cell populations including γδ T cells, innate lymphoid cells (ILCs), conventional T-cells but a lack of FOXP3+ regulatory T cells (Treg) [2, 3]. Given the predominance of stroma in EST and the known immunomodulatory effects of MSCs it is credible that such cells could assume important enthesis location immunomodulatory function.
Objectives: To investigate the single cell RNAseq (scRNAseq) landscape of EST and PEB tissues. Reflecting RNAseq findings we examined immunomodulatory capacity of MSCs derived from EST and PEB in co-cultures with allogeneic CD3/CD28-stimulated $CD4^+$ T cells.
Methods: For scRNAseq, interspinous ligament and spinous process samples from patients undergoing spinal surgery (n=4). Samples were divided into EST and PEB and enzymatically digested. Following viability enrichment, we performed single cell partitioning with 10x Chromium, followed by oligo-barcoded RNA library generation and Illumina sequencing. For the co-culture, EST and PEB were expanded until passage 2 (n=5) using bone marrow MSCs (BM-MSCs) as control standard (n=2). $CD4^+$ $CD25^-$ T-cells from blood were induced to proliferate using CD3/CD28 stimulation with MSCs/$CD4^+$/$CD25^-$ cell co-cultured at

1:1, 2:1, 4:1, and 8:1 ratios for 5 days. T cells proliferation index was calculated and Treg related markers expressed on MSCs including CD73 and CD39 were measured in PEB and EST.

Results: Following quality control, the transcriptome of 25,635 single cells was analysed. The compositional analysis revealed different abundance, such as stromal cells being more abundant in the EST, and haematopoietic precursors almost exclusively in the PEB. Analysis of the main cell populations revealed: the presence of innate and innate-like lymphocyte subpopulations such as MAIT and γδT cells, and a transcriptional gradient in neutrophils, reflecting various stages of maturation. In the T cell compartment, a putative regulatory (Tr1-like) population characterised by *TGFB1* expression, was more abundant than conventional Foxp3+ Tregs. A number of stromal cells expressed the regulatory marker *NT5E* (CD73).). Consistently with scRNAseq, EST-MSCs expressed CD73 significantly more than PEB-MSCs prior to co-culture ($p<0.001$). with significant upregulation with T- cells coculture ($p<0.05$). EST and PEB derived MSCs showed trilineage differentiation to bone, cartilage and fat[3] and significantly supressed $CD4^+$ $CD25^-$ proliferation in dose dependent manner compared to control co-culture ($p<0.001$). Interestingly, PEB-MSCs showed an increase in the CD39 expression after co-culture with T cells compare to PEB-MSCs with no T cells at ratio 1:4 and 1:8 ($P<0.001$). No EST-MSCs CD39 expresion increase after T cells co-culture was noted but PEB-MSCs CD39 expression increased at 1:4 and 1:8 ratio ($P<0.01$, $P<0.01$ respectively.

Conclusion: Our single-cell transcriptomic analysis suggests that EST and PEB have few Tregs and that other T cells and MSCs possess immunomodulatory functions in these tissues. This immunomodulatory activity may be important at these sites of high mechanical stress to maintain homeostasis.

Background: Spreading of inflammation from skin to joint is still an unsolved key aspect of psoriatic arthritis (PsA) pathogenesis. Psoriasis (PsO) usually anticipates the joint manifestations, suggesting the existence of a disease mediated skin-joint crosstalk. However, only 30% of the patients with psoriasis develop PsA overtime.[1] To date, it is still obscure why the inflammatory process in some patients with PsO is restrained to the skin, whereas in other patients it spreads to the joints.

Objectives: Using a pre-clinical model of PsA and PsO, we aimed to investigate the skin-joint axis, i.e. the spreading of psoriatic inflammation from the skin to the joints, and to address its role in PsA pathogenesis.

Methods: The IL-23 overexpression (IL-23OE) mouse model of psoriasis was performed in different genetic backgrounds of KAEDE-transgenic mice expressing a photo-convertible fluorescent reporter to assess cell trafficking from inflamed skin to other organs. Psoriatic skin lesions were irradiated with UV light to trigger the photoswitch from $KAEDE^{GREEN}$ to $KAEDE^{RED}$. Migration of immune cells to joints was determined by light sheet fluorescence microscopy (LSFM) and flow cytometry. Imaging flow cytometry was used to determine the phenotype of cells migrating from the skin to other organs. The interactome of skin-derived migrating cells in joints was characterized by single-cell RNA-sequencing (scRNAseq) and functional analyses. Data were validated in synovial biopsies from PsO and PsA patients by imaging mass cytometry.

Results: IL-23 induced initiation of inflammation at the joints was dependent on the genetic background of the mice as assessed by MRI scan and histological analysis. However, migration of immune cells from psoriatic skin to the joints was observed in both strains, protected and non-protected mice from arthritis, although other organs such as spleen and lymph nodes showed no model dependent skin-derived migration. ScRNAseq and computational fate mapping with RNA velocity analysis revealed CD2+ MCHII+ monocytes as predominant cell type escaping the inflamed skin and entering the synovial tissue. In the pre-differentiated stage, those monocytes showed similar phenotypes in both, arthritis protected and non-protected animals. However, after entering the synovial tissue further differentiation into macrophages resulted into two different phenotypes, with pro-inflammatory characteristics in mice developing arthritis. Interactome analyses between local differentiated skin-derived macrophages and tissue resident synovial cells revealed major implication of synovial fibroblasts shaping the fate of skin-derived monocytes into a protective or pro-inflammatory phenotype with capacity to initiate the cascade of inflammation. Imaging mass cytometry of synovial biopsies from patients with PsO and PsA identified niches of the synovial membrane that were protected from inflammation by a similar fibroblastic fate as observed in the murine setting. Protection from arthritis was associated with significantly increased interactions of those protective fibroblasts with innate lymphoid cells (ILC) type 2, inducing pro-survival signals and resulting into activation of pro-resolving ILC2s.[2]

Conclusion: Spreading of inflammation from the skin to the joint can be initiated by skin-derived monocytes. However, the interaction between migrating monocytes and stromal-resident cells is essential to define the fate towards joint inflammation or joint protection in PsA. The data might provide completely new diagnostic opportunities to estimate the risk of PsO patients to develop PsA in the future.

OP0107 NEUTROPHILS DISPLAY SHARED AND TISSUE-SPECIFIC PHENOTYPES IN INFLAMMATORY ARTHRITIS AND COLITIS

Keywords: Inflammatory arthritides, Innate immunity, Gastrointestinal tract

G. Osmanusta[1,2], T. Exner[1,2], S. E. Leonhardt[1,2], H. M. Lorenz[1], G. Wabnitz[2], W. Merkt[1], A. Gauss[3], R. Grieshaber-Bouyer[1,2]. Background: Neutrophils are essential in physiological and pathological immune processes through cytokine release, formation of neutrophil extracellular traps and crosstalk with the adaptive immune system. While neutrophils display varying phenotypes as a function of maturation stage, organ and inflammatory trigger, it is poorly understood which neutrophil phenotypes are organ-specific and which are shared. Spondyloarthropathies are a family of diseases with highly variable organ involvement, including colitis and arthritis.

Objectives: Our goal was to understand how neutrophils in the inflamed joint and intestine differ from those in blood and which neutrophil states observed in organs are overlapping and distinct.
Methods: We prospectively collected healthy donor blood, paired blood and synovial fluid from patients with active inflammatory arthritis in which a joint aspiration was diagnostically or therapeutically required, and colon biopsies from patients with inflammatory bowel disease (IBD) in which endoscopy was diagnostically required. Neutrophils were enriched from blood using ACK lysis and from colon biopsies by collagenase digestion. Synovial fluid was diluted, filtered and lysis was performed on samples with visible blood contamination. Technical validation of lysis and digestion of blood cells were performed to control for the influence of these procedures on marker expression. Flow cytometry was applied on the day of sample acquisition to fresh, surface-stained neutrophils to measure protein expression. A multiplex sandwich assay utilizing fluorescent antibody-conjugated beads was used to quantify inflammatory cytokine abundance in concomitant patient sera.
Results: In blood, neutrophils from patients with arthritis or inactive IBD did not show prominent surface protein differences compared to healthy donors. In patients with active colitis, expression of HLA-DR and CCR5 was elevated, while CXCR2 expression was reduced. Compared to blood, neutrophils from colon tissue showed downregulation of CD16, CD62L, ICAM-1, IL-17RA and CXCR2 and upregulation of the aging marker CXCR4. These changes were observed irrespective of disease activity. In addition, neutrophils from colon of patients with active inflammation, but not patients in endoscopic remission, showed a marked increase in expression of CD64 and HLA-DR, and the downregulation of CD62L and CXCR2 was more pronounced. We also identified an expanded population of CCR5+ neutrophils in colon tissue, which was more prominent in inflamed samples. While observable in both tissues, neutrophils in synovial fluid showed a stronger upregulation of HLA-DR and CXCR4 compared to colon. Upregulation of CCR5 and CD64, as well as the downregulation of CD16 were less pronounced. In contrast, synovial fluid neutrophils showed an upregulation of ICAM-1, while this marker was downregulated in the colon. Additionally, synovial fluid neutrophils showed an upregulation of TNF-RII, which was absent in blood and colon tissue. In serum, we observed greater abundance of IL-1β, IFN-α2, IL-33, sTNF-RI and sTNF-RII in endoscopically active IBD patients compared to inactive patients. In contrast, measured IL-10 levels were lower in these patients, underscoring the shift to a pro-inflammatory cytokine environment. Independent of disease activity, measured TNF-α levels were higher in patients with Crohn's disease compared to ulcerative colitis.
Conclusion: Tissue infiltrating neutrophils display a range of phenotypes in both inflammatory arthritis and inflammatory bowel disease. These range from mature cells lacking activation markers and resembling circulating neutrophils, to CD64+ HLA-DR+ CXCR4+ CXCR2- CD16low aged and activated cells, as well as CCR5+ pro-NETotic cells, in varying proportion. Elevated serum levels of innate- associated cytokines and an increased activation phenotype during active colitis suggest a strong neutrophil involvement in active IBD. Organ-specific differences in neutrophil effector states may require special approaches for therapeutic intervention.

OP0108 MESENCHYMAL STEM CELLS ACCELERATE INFLAMMATION RESOLUTION THROUGH THE RELEASE OF PGE2 AND SPECIALIZED PRO-RESOLVING MEDIATORS IN EXPERIMENTAL GOUT

Keywords: Innate immunity, -omics, Gout

I. Bermejo[1], I. J. Quevedo-Romero[1], M. Mateos-Fernández[1], C. Herencia[1], A. Mediero[1], G. Herrero-Beaumont[1], R. Largo[1]. [1]IIS-FJD, Bone and Joint Research Unit, Rheumatology, Madrid, Spain

Background: Mesenchymal stem cells (MSC) have been widely recognised as immunoregulatory agents in multiple inflammatory processes, although its specific effect on the modulation of innate immunity remains elusive. In an experimental well-dissected innate immune disease model such as gouty arthritis, MSC administration reduced the intensity and duration of the inflammatory flare. Specialized pro-resolving mediators (SPM) are derived from arachidonic acid (AA) and omega-3 fatty acids and are processed by the cyclooxygenase or lipoxygenase pathways. They dampen inflammation and promote resolution, decreasing neutrophil infiltrate, enhancing apoptosis, inducing efferocytosis by macrophages and promoting their switch from M1 to M2.
Objectives: To study whether MSC administration can directly trigger the resolution pathways modulating the synthesis of SPM and classical prostanoid mediators in the synovial membrane (SM) of rabbits in an experimental model of gout. The mechanisms by which MSC could modulate SPM synthesis were explored in a co-culture system with macrophages stimulated with MSU (monosodium urate crystals).
Methods: Gouty arthritis was induced in male New Zealand rabbits by intra-articular injection of MSU 50mg/kg (MSU group, n=16). Some of these animals systemically received $5x10^6$ human adipose tissue derived MSC (MSU-MSC group, n=8). All animals were euthanized 24 hours after challenge, when SM were collected. We determined the presence of lipoxin A4 (LXA4), maresin (Mar)-1, Mar-2, protectin D (PD)-1, PD-X, prostaglandin E2 (PGE2) and different SPM precursors in the SM employing mass spectrometry and ELISA. The expression of interleukin (IL)-10, indoleamine 2,3-dioxygenase (IDO) and the SPM receptor FPR2 genes were analysed by qPCR. *In vitro*, PMA-differentiated THP-1 macrophages were stimulated with 150 µg/mL MSU and MSCs were added in transwell in the presence or absence of the COX-2 inhibitor NS-398. SPM and IL-10 were analysed in the conditioned media, while cyclooxygenase and lipoxygenase pathways were studied in both cell types by qPCR.
Results: The decrease in the histological damage and in the presence of inflammatory mediators in the SM of gouty rabbits induced by MSC treatment were preceded by a significant increase in the levels of LXA4, Mar-1, Mar-2, PD-1, PDX, and its lipid precursors 14-HDHA and DHA; and by a marked increase in PGE2, in comparison to those observed in the MSU group. MSU-MSC rabbits showed a significant increase in the gene expression of the anti-inflammatory mediators IL-10, IDO-1, and the SPM receptor FPR2 in the SM, in comparison to MSU group. In vitro, we observed that MSC induced a higher release of LXA4, resolvin-D1, PGE2 and PGF2α to the co-culture media of MSU-stimulated THP-1 and increased the presence of IL-10. The pre-treatment of the MSC with the COX-2 inhibitor before the co-culture with MSU-stimulated THP-1, abolished the release of all SPM and IL-10 to the culture media. In addition, MSC induced a pro-resolutive phenotype in MSU-stimulated THP-1, evidenced by the upregulation in the gene expression of IL-10, IDO-1, PGE2 receptors EP2 and EP-3, COX-2, PGE2 synthase, FPR2 and GPR32, and the downregulation of EP-4, and lipoxygenases-12 and -15. Most of these effects were abrogated by COX-2 inhibition.
Conclusion: Our results show that MSC administration modulate the pro-resolving response in the SM of arthritic rabbits through the synthesis of multiple SPM and their precursors, together with an upregulation of FPR2, a receptor involved in pro-resolving signalling. *In vitro*, MSC were able to modulate THP-1 inflammatory phenotype induced by MSU, promoting the anti-inflammatory and pro-resolving response through the release of SPM, prostanoids and the modulation of FPR2, GPR32 and EP receptor presence. PGE2 depletion in MSC evoked a blockade of the pro-resolving program activation, highlighting its relevance in the modulation of the MSC-mediated anti-inflammatory and pro-resolutive response.

OP0109 SINGLE-CELL RNA-SEQ REVEALS DIFFERENCES IN METABOLIC PATHWAYS OF MYELOID CELLS IN THE PROGRESSION OF SLE

Keywords: Systemic lupus erythematosus, Innate immunity, -omics

A. Bylinska[1,2], M. Smith[1], K. Thomas[1,2], C. Guthridge[1], S. Slight-Webb[1], S. Macwana[1], J. A. James[1,2], J. Guthridge[1,2]. [1]*Oklahoma Medical Research Foundation, Arthritis & Clinical Immunology, Oklahoma City, United States of America*; [2]*The University Of Oklahoma Health Sciences Center, Pathology, Oklahoma City, United States of America*

Background: Systemic Lupus Erythematosus (SLE) is an interferon-related autoimmune disease characterized by immune cell dysfunction and is common among women and minorities. A loss of tolerance to self-antigens leads to increased levels of autoantibodies against nuclear components (ANAs) prior to clinical disease onset. However, only about 4-8% develop an autoimmune disease. Patients with incomplete lupus erythematosus (ILE) exhibit some SLE clinical symptoms with most never progressing to SLE. Exact mechanisms involved in myeloid cell dysregulation and the progression of autoimmune disease remains unclear.
Objectives: Determine whether alterations in myeloid cell population frequencies or activation of particular cellular processes is dysregulated in subjects with pre-clinical disease.

Methods: PBMCs from 32 subjects (ANA-, ANA+, ILE and SLE) were sorted with Nanocellect Wolf microfluidic flow cytometer to remove dead and dying cells. Viable isolated single cells were used to do a multiomics single-cell analysis using 10x Genomics 5' scRNA-Seq/137-plex Total-Seq multiomics kit, that also enable BCR and TCR repertoire analysis. Single-cell transcript and proteogenomics library preparation was done on a 10x Chromium X targeting 20,000 cells per channel, each sample encapsulated in a single channel. Normalized, pooled UDI labeled libraries were sequenced on Illumina Nova-Seq S4 flowcell (PE100, depth of 50,000 reads/cell). Data were analyzed for cluster identification, differential gene signatures in Python. Pathway analysis was performed in Ingenuity Pathway Analysis (IPA).
Results: Across all subjects, 9 distinct myeloid clusters (Classical, Non-classical, Intermediate, CCR4+ monocytes) were identified with a community detection algorithm and visualized with Uniform Manifold Approximation Projection (UMAP). The proportion of cells in those clusters varied by disease group. Fractions of non-classical monocytes appear to be higher in ILE, SLE patients than in ANA- and ANA+ subjects. Classical monocytes have increasing cell fractions with disease progression, except ILE subjects that appear to have lower fractions than the other groups. Intermediate monocytes fractions are higher in ANA- controls and lower in the other groups. Pathway analysis revealed further differences within ethnicities (African, European Americans). Upregulation of autophagy related pathways was observed in AA ANA+ compared to ANA- and ILE, however it is downregulated in EA. Oxidative phosphorylation is upregulated in AA SLE compared to ILE and upregulated in AA ANA+ compared to ANA-. On the contrary, that pathway is upregulated in EA ANA+ compared to ANA- and ILE, as well as SLE compared to ILE. Further differences between subpopulations of major monocyte clusters were also observed.
Conclusion: Dysregulation of signaling in monocyte activation appears to be manifesting in either increased oxidative phosphorylation or alteration in cellular apoptotic or autophagy pathway regulation. Alterations in these processes may vary by ancestral background reflected in the heterogeneity one sees in the presentation of lupus or trajectory of disease.

SINGLE CELL RNA-SEQ DISSECTION OF THE SYNOVIAL FLUID IN PSORIATIC ARTHRITIS PATIENTS IDENTIFIES MYELOID CELL SUBSETS RELATED TO TREATMENT RESPONSE WITH BDMARDS

Keywords: bDMARD, -omics, Psoriatic arthritis

R. Tzemach[1,2], O. Elkayam[1,3], A. Polachek[1,3], V. Furer[1,3], S. Y. Wang[2], E. David[2], I. Amit[2]. *[1]Tel Aviv Sourasky Medical Center, Department of Rheumatology, Tel-Aviv, Israel*; *[2]Weizmann Institute of Science, Immunology Department, Rehovot, Israel*; *[3]Tel -Aviv University, Sackler Faculty of Medicine, Tel -Aviv, Israel*

Background: Psoriatic arthritis (PsA) is a complex chronic inflammatory disease involving aberrant activation of the innate and the adaptive immune systems[1]. While the adaptive system in the synovial fluid of PsA patients has been recently described at a single cell level [2], a comprehensive map of the myeloid compartment is still lacking. Anti TNF agents are commonly used as the first biologic DMARDs (bDMARDs) after failure of conventional DMARDs (cDMARDs), though up to 30-40% of PsA patients are anti TNF non-responders[3]. The inflammatory pathways leading to anti TNF or other bDMARDs resistance are unknown and biomarkers to predict treatment response are scarce.
Objectives: 1. To construct a comprehensive immune map of the myeloid compartment in the synovial fluid of naïve and treated PsA patients. 2. To identify gene signatures and immune pathways characteristic of anti TNF or other bDMARDs non-responders.
Methods: This pilot study included PsA patients with active knee arthritis enrolled according to CASPAR criteria, including naïve and treated patients.
We obtained synovial fluid by intra-articular aspiration of the involved knee. For each patient we performed single-cell sorting for CD45+ and MHCII+/CD11c+ to enrich for the myeloid compartment (particularly, dendritic cells and monocytes). We used single cell RNA-seq to dissect the immune landscape of the synovial fluid in PsA patients. Osteoarthritis patients with knee involvement were enrolled as a control. PsA Patients were followed for a minimum of 7 months from sampling day (range 7-30 months) and categorized as responders or non-responders according to the DAPSA score.
Results: We analyzed a total of 91,837 cells from 33 PsA Patients (11 naive, 22 under cDMARDs and bDMARDs: 9 anti-TNF and other 9 bDMARDs) and 7 controls (OA). The synovial fluid myeloid compartment of PsA patients was composed of intermediate monocytes (CD14+ CD16+); TREM2 macrophages; conventional dendritic cells: cDC1 (XCR1, CLEC9A), cDC2 (CD1c, CLEC10A) and migratory DCs (mDC: CCR7, LAMP3, IDO1). Intermediate monocytes were the most abundant cell type in the myeloid compartment. Compared to OA controls, PsA patients' synovial fluid was enriched with T regulatory cells (Treg: CD4+ FOXP3+) and migratory DCs (mDC: CCR7, LAMP3, IDO1). Tregs and TREM2 macrophages were more prevalent among treated than naïve PsA patients. We identified a unique cluster of cDC2 and monocytes with shared molecular signature, characteristic of anti TNF or other bDMARDs non-responders. These clusters demonstrated a high expression of interferon signature genes (ISG15, ISG20, IFI27, IFI6, IFIT3, STAT1) and genes related to the immunoproteasome (PSMB9, PSMB8, PSME2, PSME1, POMP). Two patients with severe deformative PsA highly refractory to treatment demonstrated a distinct cDC1 cluster with a high expression of inhibitory genes, such as IDO1, IL4I1, CMTM6 and NFKB1A.

Immune landscape of synovial fluid in psoriatic arthritis patients.
(a) 2D projection of the immune map.
(b) 2D projection of a selected set of genes over the immune map.
(c) Dot plot showing percentages of lymphocytes in total CD45+ immune cells.
(d) Dot plots showing percentages of selected immune cell subsets in total lymphocytes or myeloid cells.

Figure 1.

Conclusion: Our study provides the first unbiased map of the myeloid compartment of the synovial fluid of PsA patients. We identified clinically significant cell-subsets within the cDC2 and monocytes populations associated with anti -TNF or other bDMARDs non-response, illuminating potential biomarkers and future therapeutic targets.

Background: Prototypically, the synovial tissue in rheumatoid arthritis (RA) is defined by an infiltration of lymphocytes of the adaptive immune system, which contribute to inflammation and joint destruction through the in-situ production of cytokines and autoantibodies. However, synovial histology images across patients have revealed considerable heterogeneity in the types of infiltrating immune cells; some exhibiting dense lymphocyte aggregates, while others are largely devoid of lymphocytes with extensive myeloid cells throughout. These differences may implicate divergent pathologic mechanisms. This diversity of cellular composition across RA synovium was reflected in the recently generated single-cell transcriptomic dataset from the Accelerating Medicines Partnership (AMP) RA/SLE Network, which consisted of >314,000 synovial cells from >70 patients with RA. The macrophage phenotypes differed across tissues with high versus low lymphocyte counts. Specifically, macrophages from tissues with high T cell proportions expressed more *IL1B* and *HBEGF*, while low lymphocyte yet high myeloid proportions in a tissue associated with macrophage expression of *SPP1* and *FN1*. Endothelial-associated TGFβ was upregulated in the lymphocyte-low/myeloid-rich tissues. We thus hypothesized that infiltrating monocytes exposed to the low-lymphocyte/myeloid-rich RA synovium become $SPP1^{hi}$ macrophages after interacting with a combination endothelial-derived TGFβ and stromal derived factors.
Objectives: To identify whether TGFβ and stromal-derived soluble factors are sufficient to polarize immature, blood-derived monocytes into the macrophages found in low-lymphocyte/high myeloid RA synovial tissue.
Methods: $CD14^+$ cells were magnetically isolated from the blood of healthy patients and incubated in media with M-CSF for 24 hours. After incubation with M-CSF, $CD14^+$ cells were co-cultured in a trans-well system with various combinations of RA synovial fibroblasts and recombinant TGFβ for 72 hours. After 72 hours, the cells were prepared for single-cell RNA sequencing. This dataset of cells from this reductionist system was overlayed onto the cell-cluster map algorithm generated by the patient synovial-tissue derived macrophages for direct comparisons.
Results: In the presence of synovial fibroblasts and TGFβ, macrophages had a gene expression program that increased the proportion of macrophages aligning with those found in lymphocyte-low/myeloid-rich synovial tissue. Specifically, the transition of blood monocyte-derived macrophages from a $MERTK^+$ homeostatic, tissue macrophage phenotype into the $SPP1^{hi}$ phenotype. This analysis also showed that macrophages incubated with TGFβ and fibroblasts had higher expression of $SPP1^{hi}$ macrophage cluster marker genes, namely *SPP1, CLEC5A,* and *FN1,* as well as genes that contribute to RA pathogenesis, including *CCL2 and S100A8.*
Conclusion: In conclusion, we have shown that TGFβ and factors derived from synovial stromal cells are sufficient to drive monocytes toward the $SPP1^{hi}$ macrophage phenotype found in myeloid-rich RA synovial tissue. In future experiments, we hope to understand the role these macrophages play in shaping the phenotype of the stromal and endothelial cells they interact with, and whether targeting the generation of these cells represents an effective treatment option for this subset of RA patients.

Pathogenic clues to systemic sclerosis and myositis

OP0112 **EXPANSION OF ACTIVATED CD7+ CYTOTOXIC T CELLS AND NK CELLS IN SSC AND PREVENTION OF FIBROBLAST CONTRACTION THROUGH SELECTIVE IMMUNOTOXIN-MEDIATED DEPLETION OF THESE CELLS**

Keywords: Systemic sclerosis, Adaptive immunity, Treat to target

T. I. Papadimitriou[1], P. Singh[2], A. Van Caam[1], M. Gorris[3], B. Walgreen[1], E. Vitters[1], M. Koenders[1], R. Smeets[4], M. Vonk[1], I. J. M. De Vries[3], P. Van der Kraan[1], M. Huijnen[2], H. Koenen[4], R. M. Thurlings[1]. *[1]Radboudumc, Department of Rheumatology, Nijmegen, Netherlands*; *[2]Radboudumc, Center for Molecular and Biomolecular Informatics, Nijmegen, Netherlands*; *[3]Radboudumc, Department of Tumor Immunology, Nijmegen, Netherlands*; *[4]Radboudumc, Laboratory of Medical Immunology, Department of Laboratory Medicine, NIJMEGEN, Netherlands*

Background: Systemic sclerosis is characterized by vasculopathy, fibrosis and autoimmune inflammation. Adaptive immune and NK cells express co-stimulatory molecules to regulate effector responses in inflammatory conditions. CD7 is a co-stimulatory molecule induced by IFN-γ signaling on T and NK cells that is downregulated upon residency in tissues such as skin [1].
Objectives: Hypothetically, CD7 is upregulated in IFN-γ driven conditions, allowing targeted depletion of pathogenic cells. In this study, we analyzed expression, regulation and targeting of CD7 in SSc tissues and in a patient treated with anti-CD7 immunotoxin (CD7-IT).
Methods: To identify disease-specific activation markers we compared status of T cell activation in SSc skin compared to blood. To do so, single-cell RNA sequencing datasets containing 60,000 skin and blood immune cells from 109 SSc patients versus 65 healthy donors were analyzed. Twentyone-color flow cytometry (n=50) and 8-color multiplex skin immunofluorescence staining (mIF) (n=30) were used for validation and spatial localization. CD7-IT was used to induce subset-specific depletion in vitro, and ex vivo skin explants. Fibroblasts and immune cells were co-cultured in 3D collagen hydrogel to test effect of targeted immune cell depletion on fibroblast contractility. A single patient was treated with immunotoxin on compassionate use basis.
Results: Sc-RNAseq analysis showed that SSc skin is characterized by increased infiltration of CD7+ cells corresponding to $CD8^+GZMB^+$ and $CD56^+GZMB^+$ cytotoxic T and NK cells. Immunohistochemistry also showed that SSc lesional skin exhibits significantly higher infiltration of these $CD7^+$ (T and NK) cells than non-affected skin (Figure 1). Expansion of $CD7^+$ cytotoxic T cells was also observed in SSc blood. A CD7-targeting IT effectively depleted 85% of $CD7^+$ cytotoxic T and NK cells in vitro, and in ex vivo skin. Strikingly, depletion of $CD7^+$ cells prevented fibroblast activation and contraction in a 3D fibroblast-immune cells co-culture assay. Notably, also in vivo administration of CD7-IT significantly eliminated $CD7^+$ cell subsets in patient's blood and skin.
Conclusion: Together, we show strong presence of CD7 on SSc immune cells and that targetting this molecule depletes T and NK cell populations with potential disease modifying results. Our results pave the way for a novel approach in halting SSc related fibrosis.

Background: The beta-amyloid precursor protein cleaving enzyme 1 (BACE1) is well known for its role in the development of Alzheimer's disease via the generation of β-amyloid. Recent publications, including our own, have demonstrated a role for this enzyme in other chronic inflammatory diseases, including type 2 diabetes and cardiovascular disease. However, to date there has been no studies looking into the role of BACE1 in the autoimmune condition Systemic Sclerosis (SSc).
Objectives: The aim of this study was to assess the expression profile of BACE1 in SSc patient samples and investigate the effects of BACE1 inhibitors and siRNA on SSc fibroblast activation.
Methods: Patient fibroblasts were obtained from full thickness forearm skin biopsies from healthy and early diffuse SSc patients. BACE1 was inhibited with 2 specific small molecule inhibitors and siRNA specific to BACE1. Morphogen signalling was activated with recombinant TGF-β, Wnt-3a or the smoothened agonist SAG. A xenotransplant bleomycin mouse model using patient pDC was used to interrogate *in vivo* expression of BACE1 in fibrosis.
Results: Here we show that BACE1 protein levels are elevated in SSc patient skin biopsies. In particular BACE1 was increased in the fibroblasts and endothelial cells of the SSc skin. BACE1 was elevated in isolated dermal fibroblasts grown in culture (2.3 fold increase, N=4). BACE1 protein levels were elevated in the bleomycin skin fibrosis model. Interestingly BACE1 mRNA levels were unaffected in cultured SSc fibroblasts, suggesting a post-translational modification led to the elevated protein levels. Inhibition of BACE1 with small molecule inhibitors (that have been proven safe in phase 1 clinical trials for Alzheimer's) or siRNA blocked pro-fibrotic gene (alpha SMA, Collagen Type 1 and CTGF) expression in SSc fibroblasts. In addition overexpression of BACE1 in healthy fibroblasts resulted in myofibroblast activation (2-fold increase in alpha SMA protein expression). Interestingly overexpression of a BACE1 mutant construct which disrupts the secretase activity of the protein, was unable to induce fibroblast activation. Disruption of BACE1 (with both the inhibitors and siRNA) blocked morphogen mediated fibroblasts activation. The BACE1 inhibitors and siRNA blocked TGF-β, Wnt-3a and Hedgehog mediated alpha-SMA expression in healthy fibroblasts. Furthermore, we show that BACE1 regulation of dermal fibroblast activation was dependent on the β-catenin and Notch signalling pathways. BACE1 ability to regulate non-canonical Wnt receptors led to elevated β-catenin expression which in turn activated the Notch signalling pathway.
Conclusion: This is the first evidence that BACE1 and in particular its secretase activity, plays a role in SSc and fibrosis in general. The ability of BACE1 to regulate SSc fibroblast activation reveals an exciting new therapeutic target in SSc. Several BACE1 inhibitors have been shown to be safe in phase 1 clinical trials for Alzheimer's disease. Future work includes investigating the role of BACE1 in vascular/endothelial cell dysfunction in SSc.

OP0114

ENDOTHELIAL RESPONSE TO TYPE I INTERFERON CONTRIBUTES TO VASCULOPATHY AND FIBROSIS AND PREDICTS DISEASE PROGRESSION OF SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Skin, Cytokines and chemokines

H. Yin[1], Q. Yan[1], L. Lu[1]. *[1]Renji Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Rheumatology, Shanghai, China*

Background: Type I interferon (IFN-1) signature is a hallmark of patients with systemic sclerosis (SSc)[1-2]. However, the meaning of the IFN-1 signature for the pathophysiology and clinical manifestations is less clear, and reported associations are rather weak.
Objectives: This study aims to better understand the significance of IFN-1 in SSc clinical stratification and its contribution to disease deterioration.
Methods: For hypothesis generation, we performed single-cell RNA sequencing (scRNAseq) on skin biopsies (SSc=4, control =2) using the BD Rhapsody platform. A publicly available dataset (GSE138669) of skin scRNAseq (dcSSc=12, control =10) was used for validation. IFN-1 signature was mapped, functionally investigated in a bleomycin plus IFNα2-adeno-associated virus (IFNA2-AAV) induced model, and verified in an SSc cohort (n=61).
Results: In discovery data, endothelial cells (EC) had the most prominent IFN-1 response among dermal non-immune cells. EC from postcapillary venules, arterioles and capillaries were the major responders of IFN-1. Ascending IFN-1 signature presented in total EC from control, lcSSc, to dcSSc and was still true in the EC subclusters above. Endothelial-to-mesenchymal transition (EndoMT) scores increased in parallel. The validation data confirmed IFN-1 signature and EndoMT elevation in total and subgroups of EC. IFNA2-AAV deteriorated bleomycin-induced dermal fibrosis, EndoMT, and perivascular fibrosis and caused blood vessel loss via endothelial apoptosis. In SSc skin biopsies, vascular MX1, an IFN-1 response protein, was increased in total SSc and significantly higher in dcSSc than in lcSSc. To predict disease progression in 6-34 months, the baseline vascular MX1 performed similarly to skin score in total SSc and was superior in the dcSSc subpopulation (Figure 1).
Conclusion: The EC IFN-1 signature distinguished SSc skin subtypes and disease progression efficiently and may contribute to vasculopathy and fibrosis.

Background: Disruption of the skin structure is a central hallmark of Systemic Sclerosis (SSc). Healthy adult human dermis is characterized by a papillary dermis (conic upward papillae with nerve endings, mechanoreceptors, vessels and loose collagen bundles) and a reticular dermis (coarse collagen bundles). In SSc, the dermal structure is disrupted and shifted towards a "reticularized" phenotype with loss of dermal papillae and exaggerated deposition of collagen. Little is known on mechanisms necessary to maintain physiological adult human skin morphology. Evidence from murine experiments suggests that short distance morphogen gradients are necessary for three-dimensional pattern formation in embryonic skin morphogenesis in rodents [1].

OBJECTIVES:

1) to analyze if spatial WNT/β-catenin activation is observed in adult healthy human skin and whether it is altered in fibrosing skin disorders such as SSc
2) to assess whether perturbation of spatial WNT/ β-catenin activation correlates with disruption of physiological skin structure in SSc
3) to analyze whether spatial activation is mimicked in a Wnt-driven murine fibrosis model and can be reverted by overexpression of the endogenous Wnt-antagonist Dkk1

Methods: Dermal skin morphology was quantitatively assessed using HE and trichrome staining of skin sections of 40 SSc patients and 18 healthy controls. Enrichment of papillary and reticular marker genes and WNT target genes in healthy and SSc skin transcriptome were assessed by gene set enrichment analyses using prepublished datasets [2]. Spatial WNT/β-catenin activation was analyzed by RNAscope-in situ hybridization detection of *AXIN2*. Immunofluorescence (IF) staining was performed to detect β-catenin distribution. In addition, skin sections of Wnt10btg- and Dkk/Wnt10btg mice were analyzed.

Results: Here we quantitatively describe a marked decrease of number, area and height of papillary structures in SSc compared to healthy controls. Consistently, papillary/reticular marker gene expression is shifted towards a reticular profile in SSc skin compared to controls. Next, we analyzed whether the expression of WNT3A-regulated target genes is enriched in papillary or reticular gene sets of healthy skin. We observed an enrichment of WNT3A-regulated target genes in papillary gene sets of healthy skin. Consistently, we observed a distinct pattern of spatial distribution of β-catenin-expressing fibroblasts in healthy skin that is disturbed in SSc: In healthy skin, β-catenin-positive fibroblasts were predominantly located in the papillary dermis and the relative amount of β-catenin-expressing fibroblasts was reduced in the reticular part. In contrast, in SSc skin, we observed a 2-fold increase of β-catenin-positive fibroblasts throughout the dermis. A gradient with enrichment of β-catenin-expressing fibroblasts in the papillary layer as observed in healthy skin was no longer detectable in SSc. Confocal imaging suggested increased nuclear accumulation of β-catenin in the reticular dermis compared to the papillary dermis in SSc skin. The loss of spatial WNT activation in SSc was confirmed on a transcriptional level. Interestingly, spatial redistribution of WNT activation is mimicked in Wnt10btg mice compared to wild-type mice and partially reverted by overexpression of the endogenous Wnt antagonist Dkk1. These results suggest that distinct site-specific activation of WNT/β-catenin signaling with a delicate balance of WNT agonists and antagonists might be necessary to maintain and eventually restore physiologic skin integrity in adult human skin.

Conclusion: Our study presents first evidence for a loss of the physiological β-catenin gradient in SSc, associated with a loss of papillary dermal structure. Further analyses of WNT agonists and antagonists spatial distribution and advanced in vitro models mimicking a papillary skin structure will be necessary to better understand mechanisms of skin structure maintenance in healthy adult human skin.

Background: Fibrotic changes in the myocardium and cardiac arrhythmias represent fatal complications in systemic sclerosis (SSc). So far, the underlying mechanisms remain elusive. Mice overexpressing AP-1 family transcription factor Fosl-2 (Fosl-2^{tg}) represent animal model of SSc.
Objectives: We aimed to identify the mechanisms controlling myocardial fibrosis and arrhythmias in SSc.
Methods: Mice overexpressing activator protein-1 transcription factor component Fos-related antigen-2 (Fosl-2^{tg}) and Rag2$^{-/-}$Fosl-2^{tg} mice lacking T and B cells were subjected to study myocardial fibrosis, arrhythmias and response to stress using radiotelemetry, echocardiography and ex-vivo Langendorff-system. Immunohistochemistry/immunofluorescence analyses were used to characterized endomyocardial biopsies (EMBs) of SSc patients with heart failure with or without arrhythmia, and mouse hearts. Cardiac human and mouse fibroblasts were used to evaluate molecular mechanisms using bulk RNA sequencing, qPCR, IF, ELISA, Western blot, Bromodeoxyuridine proliferation assay, senescence associated-β-Galactosidase assay for cell senescence, Caspase Glo 3/7 assay for cell apoptosis and contraction assay.
Results: Fosl-2^{tg} mice showed interstitial cardiac fibrosis with increased numbers of CD45^{-}CD31^{-}Ter119^{-}gp38^{+} cardiac fibroblasts, disorganized connexin 43 and 40 in intercalated discs and deregulated expression of genes controlling conduction system (*Meis1, Nfia*, *Tbx3*, *Sox5*, *Scn10a*, *Kcnq1*, *Scn10a, Nos1ap*). Fosl-2^{tg} mice developed higher heart rate (HR), prolonged QT intervals, arrhythmias with prevalence of premature ventricular contractions, ventricular tachycardias and atrio-ventricular blocks second-degree. QT intervals positively correlated with AV blocks, while QT intervals and AV blocks positively correlated with the disease phenotype and collagen deposition. Fosl-2^{tg} mice showed significantly reduced HR variability in long-term ECG recordings (reduced NN intervals, SDNN, RMSSD, NN6, pNN6), indicating autonomic disbalance with a shift towards increased sympathetic activity. Following stimulation with isoproterenol (ISO) Fosl-2^{tg} mice revealed impaired HR response. Similarly, ex vivo Langendorff-system measurement of HR in the isolated mouse hearts confirmed the abrogated response to ISO stimulation of Fosl-2^{tg} hearts. Immunodeficient Rag2$^{-/-}$Fosl-2^{tg} mice showed no myocardial fibrosis and ECG abnormalities. Transcriptomics analysis of cardiac Rag-2$^{-/-}$Fosl-2^{wt}/Rag2$^{-/-}$Fosl-2^{tg}/Fosl-2^{tg} fibroblasts revealed that systemic inflammation triggered fibrotic and arrhythmogenic alterations while Fosl-2-overexpression mediated profibrotic signature. In human cardiac fibroblasts FOSL-2-overexpression enhanced myofibroblast signature under proinflammatory or profibrotic stimuli. Furthermore, increased numbers of GP38^{+} fibroblasts were detected in FOSL-2-expressing and collagen-rich areas of SSc EMBs.
Conclusion: These results demonstrate that under inflammatory and fibrotic conditions Fosl-2 drives myocardial fibrosis, arrhythmias and causes aberrant response to stress. This mechanism might represent a promising target against increased cardiac disease burden in the immunofibrotic cardiac disorders.

Background: Dermatomyositis (DM) is an autoimmune myopathy responsible for muscle weakness associated with decreased quality of life and increased mortality. Current treatments are empirical, partially effective, expose to a risk of side effects and a high rate of relapse upon discontinuation. DM muscular histology is characterized by lesions of perifascicular fibers consisting of atrophy, overexpression of type I interferon-dependent genes and mitochondrial dysfunctions of unknown origin [1].
Objectives: The objective of the study was to identify innovative therapeutic strategies for DM, based on the identification of the molecular pathways that underlie perifascicular fibers lesions and the repositioning of drugs already approved in humans.
Methods: To reveal the molecular pathways underlying DM perifascicular fibers lesions, perifascicular and endofascicular fibers from 19 patients with recent and untreated myositis (DM, other myositis) or without myopathy were microdissected by laser, their transcriptome was established by RNA sequencing and analyzed by bioinformatic methods. To identify innovative therapeutic strategies based both on DM pathophysiological mechanisms and on existing drugs, the transcriptomic signature specific to DM perifascicular fibers obtained by microdissection experiments was used for a drug repositioning analysis as described by Karatzas et al. [2]. To validate the predications obtained, the effect of drug candidates already used in humans was tested in *in vitro* and *in vivo* preclinical models: in 1) cultured human muscle cells treated with IFN-I and in 2) a mouse model of myositis experimentally induced by immunization against skeletal muscle fast-type C protein.
Results: Transcriptomic analysis of patient's muscle fibers combined with topographic information (perifascicular VS endofascicular localization) revealed that a proteasome deregulation predominant in the perifascicular fibers is a hallmark of DM. The integration of 3 computer databases of drug repositioning allowed the identification of 9 molecules predicted by at least 2 bases to reverse the pathological signature of the perifascicular fibers of patients with DM. The drug with the highest therapeutic potential was a proteasome inhibitor (Ixazomib). A second proteasome inhibitor (MG-132) was also identified. 2 drugs already used for DM (prednisolone and a JAK inhibitor) was identified with a lower therapeutic score. In the cellular model (human myotubes treated with IFN-I) ixazomib and bortezomib reversed the atrophy and the pathological signature of DM perifascicular fibers identified in the microdissection experiments. In the mouse model of myositis, ixazomib and bortezomib restored muscle strength, decreased blood creatine kinase, and reversed the atrophy of muscle fibers.
Conclusion: Proteasome inhibition could be a new effective therapeutic strategy for DM.

OP0118 INTEGRATED ANALYSIS OF SINGLE-CELL AND BULK RNA SEQUENCING DATA REVEALS CELLULAR HETEROGENEITY IN THE SKELETAL MUSCLE OF IDIOPATHIC INFLAMMATORY MYOPATHY

Keywords: Cell biology, Myositis

Z. Honglin[1], L. Hui[1], X. Yizhi[1], S. Xie[1], T. Ding[1], T. Huang[1], S. Liu[1], D. Liu[1], H. Zhang[1]. [1]Xiangya Hospital, Department of Rheumatology and Immunology, Changsha, China

Background: IIMs-affected muscles showed diverse cellular microenvironments, and specific immune activation is involved in the different types of IIMs. Skeletal muscle cells exhibit immunobiological properties and act as nonprofessional antigen-presenting cells in IIMs.
Objectives: We sought to identify the skeletal muscle cells (SMCs) and immune cell populations in IIMs muscles and understand how alterations in these cell subpopulations lead to muscle damage.
Methods: We performed single-cell RNA-sequencing (scRNA-seq) on muscle tissues from 6 IIMs and 3 normal control (NC), and spatial transcriptomics from 2 IIMs and 1 NC. 76 IIMs and 10 NC were analysed by bulk RNA sequencing.
Results: From the scRNA-seq analysis, remarkable heterogeneity of SMCs and immune cells phenotypes were found and spatially organized in IIMs subgroups. They displayed diverse functions and cell-surface proteins. From the

bulk RNA-seq deconvolution analysis, cell clusters with high expression of type 1 interferon-related genes, such as ISG15+ SMCs, CD4+ISG15+ T cells, FCN1+ISG15+ macrophages and KLRC1+XCL1+ NK cells, were specifically cloned in DM; Cell subpopulations involved in mitochondrial changes, such as Mito_high_CD8+ TEFFs, were expanded in anti-Jo1 ASS group, TPM1+ SMCs and Mito_high_NKs has the highest proportion in anti-SRP IMNM. Mito_high_NKs were positively correlated with serum creatine kinase (CK) in IIM patients. scRNA-seq and spatial transcriptomics combined analysis indicated ligand-receptor pairs MIF→(CD74+CD44)/(CD74+CXCR4) play key roles in the interactions of ANKRD2+ SMCs and inflammatory cells. The levels of CD44 and CXCR4 in muscle tissues were positively correlation with CK, lactate dehydrogenase, aspartate aminotransferase and alanine aminotransferase.

Conclusion: Our results demonstrate previously unrecognized SMCs and immune cells phenotypes in IIMs subgroups, and indicate the interactions of SMCs and immune cells are key pathological mechanisms driving muscle damage.

Background: Glucocorticoids (GC) are the first line treatment in myositis.
GC treatment is empirical. Both GC therapeutic and iatrogenic effects are mediated by the glucocorticoid receptor (GR), which is ubiquitously expressed. Our team has recently shown that muscle fibres immuno-metabolic modifications participate to muscle weakness and perpetuation of the disease[1]. Thus, myofibers could be a therapeutic target of GC.

Objectives: To unravel the mechanism of GC therapeutic effect in order to optimize myositis care.

Methods: Experimental myositis (EM) was induced in 8 to 10 week-old C57BL/6J mice through the immunisation against a polypeptide from skeletal muscle fast-type C protein. In order to investigate whether GC target skeletal muscle fibres to elicit their therapeutic response in EM, we generated mice in which GR can be selectively ablated in skeletal muscle fibres in a temporal manner. To this end, EM was induced at day (D) 0 in HSA-Cre-ERT2(tg/0)/GRL2/L2 mice (pre-mutant mice), which express the tamoxifen-dependent CreERT2 recombinase selectively in skelelal muscle fibres and bear two LoxP-flanked GR alleles, as well as in HSA-Cre-ERT2(0/0)/GRL2/L2 littermates, which do not express the recombinase (GRL2/L2 mice). Thus, tamoxifen treatment from D9 to D13 induced GR inactivation in the former mice only, termed hereafter GR(i)skm-/- mice. Mice of both lines were treated by prednisone (PDN) from D14 to D20 at the dose of 1 mg/kg/day by gavage. Grip test was performed at D0, before the 1st PDN administration (D14) and the day before sacrifice (D20). Creatine-kinase (CK) activity assay in serum, muscle histology, immune-cell phenotyping using flow cytometry and gastrocnemius transcriptomic analysis were run. Transcriptomic data were validated in independent mice cohorts, *in vitro* and on human muscle biopsies.

Results: In pre-mutant EM mice at D0 as well as in EM GR(i)skm-/- at D14, muscle strength was similar to that of EM GRL2/L2 mice. At D20, muscle strength was still comparable between V-treated EM GRL2/L2 and GR(i)skm-/- mice. Conversely, PDN treatment did not induce a regain of muscle strength in EM GR(i)skm-/- mice (143.9 vs 175.7 ± 7.5 g in PDN-treated GRL2/L2, p=0.0007). V-treated EM GRL2/L2 and GR(i)skm-/- mice showed a similar increase in serum CK levels at sacrifice. CK decreased only in GRL2/L2 and not in GR(i)skm-/- mice after PDN treatment (146.6 ± 10.9 vs 234.5 ± 10.0 U/l, p=0.002). Although no major differences in the histological inflammatory infiltrate score among the four experimental groups, at muscle flow cytometry, the percentage of proinflammatory macrophages, F4/80-Ly6c-positive, was greater (76% vs 67%, p=0.5) and that of anti-inflammatory macrophages, F4/80-CD206-positive, was lower (12% vs 17%, p=0.7) in PDN-treated GR(i)skm-/- than GRL2/L2 mice suggesting myofiber GR knockout promotes a proinflammatory phenotype in immune cells infiltrate. Strikingly, PDN induced a 3-fold decrease in the percentage of CD8-positive T cells in EM GRL2/L2 mice compared to V-treated EM GRL2/L2 mice (11% vs 29%, p=0.003). This anti-inflammatory effect of PDN was suppressed in PDN-treated EM GR(i)skm-/- mice. Moreover, CD4-CD8 double negative T cells, that inhibit the immune response by killing effector T cells, slightly increased in PDN-treated EM GRL2/L2 compared to V-treated GR L2/L2 mice (35% vs 24%, p=0.2). This effect of PDN was suppressed in PDN-treated EM GR(i)skm-/- mice. Transcriptomic and functional analyses of muscle *in vitro* and *in vivo* demonstrated the importance of epinephrine secreted by the myofibre relaying the effects of GC. The expression of epinephrine by the myofibre in response to GC has been validated in patients with myositis.

Conclusion: Skeletal muscle fibres play a critical role in the GC therapeutic response in myositis through an epinephrine-mediated polarization of inflammatory infiltrate toward an anti-inflammatory phenotype.

Background: Individuals testing positive for anti-cyclic-citrullinated-peptide-antibodies (Anti-CCP) and musculoskeletal (MSK) complaints are at risk for developing rheumatoid arthritis (RA).

Objectives: We aim to identify factors involved in arthritis progression in a population considered at risk for RA.

Methods: Anti-CCP-positive individuals with MSK complaints referred to rheumatologist in the Region Stockholm were recruited. Individuals lacked arthritis at clinical and ultrasound examination and were followed for ≥3 years or until arthritis diagnosis was made. Blood samples from inclusion were analyzed for 9 selected anti-citrullinated-protein-antibody (ACPA) reactivities (citrullinated α-1-enolase, fibrinogen, filaggrin, histone, vimentin and tenascin peptides); as well as a panel of 92 inflammation-associated proteins and HLA-SE alleles. Cox regression was applied to the data and a predictive multivariate model was identified. Results are shown with a confidence interval (CI) of 95 percent.

Results: 267 individuals were recruited. 101 (38%) developed arthritis in median after 14 months (IQR: 6-27). In the multivariate analysis: ACPA reactivity (HR 8.0, CI 2.9-22, p<0.0001), IL15R-α levels (HR 0.6, CI 0.4-0.9, p 0.006), IL6 levels (HR 1.5, CI 1.2-1.8, p<0.0001) and the presence of tenosynovitis as detected by ultrasound (HR 3.4, CI 2.0-6.0, p<0.0001) were significantly associated with arthritis. Diagnostic accuracy for ACPA reactivity test had a sensitivity of 96% (CI 92-99.8), a specificity of 30% (CI 30-46), a positive predictive value of 51% (CI 43-58) and a negative predictive value of 94% (CI 87-99.7). Diagnostic accuracy for ultrasound assessed tenosynovitis had a sensitivity of 17% (CI 9-24), a specificity of 99% (CI 97-100), a positive predictive value of 89% (CI 74-100) and a negative predictive value of 64% (CI 57-70).

Conclusion: We propose a high-risk RA phase characterized by the presence of certain ACPA reactivities, IL15-Rα, IL6, and tenosynovitis, parameters that could be used to identify individuals at particular low risk and high risk for arthritis progression.

OP0121 SYNOVIAL CELLULAR NICHES ARE DETERMINANTS OF ARTHRITIS PERSISTENCE VERSUS RESOLUTION IN EARLY UNTREATED ARTHRITIS

Keywords: -omics, Inflammatory arthritides, Rheumatoid arthritis

A. Filer[1,2], J. D. Turner[1], C. Prada-Medina[3], M. Attar[3], C. D. Buckley[3], S. Sansom[3], K. Raza[1,4]. *[1]University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom*; *[2]University Hospitals Birmingham, Dept of Rheumatology, Birmingham, United Kingdom*; *[3]University of Oxford, The Kennedy Institute Of Rheumatology, Oxford, United Kingdom*; *[4]Sandwell and West Birmingham NHS Trust, Dept of Rheumatology, Birmingham, United Kingdom*

Background: Published synovial research largely focuses on persistent clinical syndromes such as RA and PsA. However spontaneously resolving synovitis is a common manifestation of viral infection (parvovirus, influenza), post-bacterial reactive states and metabolic disease such as gout. The study of synovial tissue taken from such patients using advanced single cell methodologies may provide biomarkers of outcome in early disease but is also a valuable resource to understand mechanisms underlying the subversion of healthy mechanisms of resolution resulting in persistent disease.

Objectives: To use single cell RNA sequencing to understand the cellular interactions governing resolution versus persistence of disease in untreated patients with active arthritis.

Methods: Synovial tissue biopsies were obtained using ultrasound guidance from treatment naïve patients in the Birmingham BEACON early arthritis cohort presenting with at least one clinically swollen joint and a joint amenable to ultrasound guided biopsy. Tissue samples from patients who went on to develop RA (n=15) or PsA (n=7) according to ACR criteria or CASPAR criteria at 24month follow-up, and patients whose arthritis spontaneously resolved (n=5) underwent enzymatic disaggregation and were processed through a multimodal single-cell sequencing approach including the characterisation of the transcriptome and 58 surface-protein-panel profile. Sequenced gene libraries were integrated according to batch and sample using the Harmony integrative algorithm before clustering and annotating cell states using canonical marker genes. Seurat-based automated pipelines were used for variable gene identification and clustering. We used DESeq2 to identify per cell type genes, and weighted gene co-expression network analysis (WGCNA) to identify gene programmes associated with persistence (RA and PSA) versus resolving groups. NAMTI was used to identify unique cellular niches associated with persistence or resolution.

Results: ~90,000 viable cells were sequenced and data normalised, clustered and annotated describing over 80 cellular states across eight main synovial cell types (T, B, Plasma, Plasmacytoid DC, myeloid, fibroblast, mural and vascular). A total of 1945 genes varied significantly with prognosis, distributed unequally across cell types (Table 1).

Table 1.

Cell type	T	B	Plasma	DC	Myeloid	Fibroblast	Mural	Vascular
Upregulated resolving	43	300	0	4	378	270	11	153
Upregulated persisting	37	82	3	1	205	223	7	228

Persistence of arthritis was associated with (i) the presence of plasma cells *per se* and (ii) a phenotypic shift in fibroblast, vascular, myeloid, Th, and B-cell populations with enrichment of SPP1+ Myeloid cell populations. Patients with active arthritis destined to resolve exhibited enrichment of Treg cells. Persistent and resolving states were characterised by significant compositional differences in key lining and sublining fibroblast subpopulations including sublining MMP3 positive cells, and by gene expression programmes related to matrix remodeling and fibroblast:macrophage interactions.

Conclusion: Persistence and spontaneous resolution of synovial inflammation are accompanied by characteristic compositional and mechanistic signatures that can be observed in key cellular niches during active early inflammation. There is potential to exploit such signatures with the aim of disrupting persistent inflammation.

Background: Delineating systemic immune cell signatures in rheumatoid arthritis (RA) has the potential for understanding pathogenesis and stratifying therapeutics accordingly.

Objectives: To evaluate the phosphoprotein signatures in circulating lymphocytes of early RA patients compared with healthy controls across disease trajectory over one year.

Methods: We used phospho-flow cytometry to measure the phosphorylation state of phosphoproteins in basal (unstimulated), and ex vivo stimulated circulating lymphocytes from 55 early RA patients before and after 6- and 12-month treatment with methotrexate (MTX) and compared these to 37 age- and gender-matched healthy controls. Flow cytometry datasets were analysed using FlowSOM, an unbiased clustering algorithm that partitions cell populations based on marker expression patterns.

Results: Multiple differential phosphorylation signatures are expressed across $CD4^+$ and $CD8^+$ T-cells and $CD19^+$ B-cells that differentiate baseline RA from healthy controls; the signatures normalised towards a healthy state following treatment with MTX. Stimulation of cells from RA patients at baseline is refractory to further stimulus-induced phosphorylation, which was recovered following MTX treatment ($p<0.01$).

Conclusion: This comprehensive and unbiased analysis identified discrete clusters of cells exhibiting unique phosphoprotein signatures associated with early RA that differentiates the systemic immune response from healthy controls. Methotrexate treatment recovers this phosphoprotein signature towards a healthy state.

OP0123

AUTOANTIBODIES TO JOINT-RELATED PROTEINS PREDICT REMISSION IN NEW ONSET RA WITH HIGH SPECIFICITY

Keywords: Remission, Rheumatoid arthritis, Autoantibodies

M. Leu Agelii[1], O. Sareila[2], E. Lönnblom[2], K. Forslind[3,4], I. Hafström[5], M. Andersson[4], A. Kastbom[6], C. Sjowall[6], L. T. H. Jacobsson[1], J. Kihlberg[7], R. Holmdahl[2], I. Gjertsson[1]. Background: One of the major challenges in the management of rheumatoid arthritis (RA) is to determine individual treatment and predict the prognosis. On a group level, high disease activity and antibodies specific for citrulline (ACPA) and immunoglobulins (RF) are factors associated with poor prognosis. New alternative biomarkers, which could provide more specific information, are antibodies to disease-related targets in the joints [1]

Objectives: To identify circulating autoantibodies to joint-related proteins (hereafter named JointIDs) that predict disease outcome in patients with new onset RA.

Methods: Sera at diagnosis from BARFOT and TIRA-2 cohorts (n=1986) with new onset RA patients were screened with a bead-based multiplex flow immunoassay to detect IgG autoantibodies against 47 peptides derived from joint proteins (JointIDs) (Lönnblom, under review 2023). Disease outcomes included Boolean remission at 6 and 12 months, swollen joint count (SJC) and radiological progression at 12 months (>8% affected feet joints and >3% affected hand joints) in patients who were without joint damage at inclusion. Multivariate logistic regression and zero-inflated negative binomial models adjusted for clinical factors (age, gender, ACPA, RF, changes in medication at 3 and 6 months) were used to identify JointIDs with the strongest potential to predict prognosis.

Results: Six JointIDs were identified as predictors for these disease outcomes in multivariate analyses. Presence of JointID178 predicted an average decrease in SJC at 6 months with 41% and with 33% at 12 months. Presence of at least 2 of the following factors: JointID178 positive and JointID199 negative at inclusion in combination with male sex identified approx. 40% of the patients in Boolean remission at 6 months with approx. 75% specificity (Table 1). A similar test performance was obtained even for Disease Activity Score 28 remission. The sensitivity and specificity for being in Boolean remission at 12 months if the patients were male, negative for JointID199 and in Boolean remission at 6 months was 13% (CI 9%;16%) and 99% (CI 99%;100%), respectively. RF and ACPA did not predict remission but were the strongest predictors of joint destruction at 12 months although with low specificity (58%). Addition of JointID166 significantly increased the specificity at the expense of sensitivity.

Conclusion: Autoantibodies to joint-related proteins at RA diagnosis can predict remission with a high specificity at 6 and 12 months. This knowledge is of clinical importance as patients positive or negative for these JointIDs in combination with clinical factors may potentially guide future treatment choices.

Table 1. Sensitivity, specificity and AUC for the multivariate models for predicting the different binary outcomes.

Outcome	Predicting factors	AUC (ROC)	Sensitivity (95% CI)	Specificity (95% CI)
Boolean remission at 6 months	If ≥2 of these: JointID178+, JointID199-, sex=male	63%	42% (35%; 49%)	74% (72%; 77%)
	If JointID178+, JointID199-, sex=male	63%	8% (4%; 12%)	98% (97%; 99%)
Boolean remission at 12 months	If ≥2 of these: JointID178+, JointID199-, sex=male	61%	42% (36%; 48%)	76% (73%; 79%)
	If JointID178+, JointID199-, sex=male	61%	8% (5%; 11%)	97% (96%; 98%)
	If JointID199-, sex=male, Booleans remission at 6 months	81%	13% (9%; 16%)	99% (99%; 100%)
Radiological progression	If antiCCP+	70%	82% (74%; 90%)	58% (54%; 62%)
	If antiCCP+, JointID166+	73%	49% (39%; 59%)	82% (79%; 85%)
	If JointID166+, JointID198+	70%	39% (29%; 49%)	86% (83%; 88%)

OP0124

A REDUCED ULTRASOUND SCANNING PROTOCOL OF 3 JOINTS BILATERALLY IMPROVES PREDICTION OF INFLAMMATORY ARTHRITIS PROGRESSION IN ANTI-CCP ANTIBODIES POSITIVE INDIVIDUALS WITH MUSCULOSKELETAL SYMPTOMS

Keywords: Prognostic factors, Ultrasound, Autoantibodies

A. Di Matteo[1], E. De Lorenzis[1], L. Duquenne[1], J. Nam[1], L. Garcia-Montoya[1], K. Harnden[1], R. Chowdhury[1], P. Emery[1], K. Mankia[1]. [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds Teaching Hospital NHS Trust, Leeds, United Kingdom

Background: In anti-CCP positive individuals at-risk of developing rheumatoid arthritis (CCP+ at-risk), ultrasound (US) sub-clinical inflammation and bone erosions (BE) are associated with progression to clinical arthritis[1]. However, the additional value of US in predicting progression to inflammatory arthritis (IA) when compared with routinely available clinical/serological variables has not been well defined. Moreover, which and how many joints need to be scanned for optimum predictive accuracy remains unanswered, with most studies adopting extensive US protocols which are not feasible in clinical practice[1].

OBJECTIVES:

1. In CCP+ at-risk with musculoskeletal (MSK) symptoms but no clinical synovitis, to investigate the additional value of US over and above clinical/serological variables in the prediction of IA.
2. To define an attenuated US scanning protocol, suitable for routine clinical use, for predicting IA development in CCP+ at-risk.

Methods: The proportion of 'progressors' to IA at 24 months was evaluated in 417 CCP+ 'at-risk' with MSK symptoms from the Leeds CCP cohort, who were selected for having an US scan at baseline. The US scanning protocol included 18 joints bilaterally [elbow, wrist, MCP joints 1-5, PIP joints 1-5, knee, ankle, MTP joints 2-5]. US synovitis (grey scale ≥1 and power Doppler signal ≥1) and BE were defined according to the EULAR/OMERACT definitions. Routine demographic/clinical data were collected: age, gender, early morning stiffness (EMS) duration, hands and/or feet tenderness on physical examination, anti-CCP antibodies level and rheumatoid factor (RF) status. Two initial multivariable binary regression models with 10-fold cross-validation for IA development at 24 months included all the clinical/serological variables associated with the outcome ("clinical" model) isolated and in combination with US synovitis and/or BE in any of the 36 joints ("clinical-US full" model). Further models explored the prediction accuracy of the clinical variables and US findings (i.e., synovitis and/or BE) in each single joint to identify the most informative scanning sites according to Akaike Information Criterion (AIC). A final model which included clinical/serological predictors and US assessment of 3 joints bilaterally ("clinical-US short" model) was compared to the "clinical-US full" model. The most predictive joints were included in this "short" model only if determining an improvement in the prediction performance (reduction in AIC≥2).

Results: Of the 417 CCP+ at-risk, 92 (22.1%) progressed to IA within 24 months. The following clinical/serological variables were associated with IA development at univariate analysis: age, smoking exposure, EMS duration ≥60 minutes, hands tenderness, RF positivity and high-level anti-CCP antibodies (all $p<0.05$). Moreover, US synovitis and BE in ≥1 of 36 joints were also associated with IA progression ($p<0.01$). The "clinical-US full" model (AUC 0.785, AIC 380.15) performed better than the "clinical" model (AUC 0.713, AIC 409.51) ($p<0.001$) showing an adjusted odds ratio (OR) for IA onset of 3.16 (95% IC 1.79-5.58) for US synovitis and 2.83 (95% IC 1.35-5.93) for BE. The developed "clinical-US short" model - that included US assessment of wrists, knees and MTP5 joints – performed better than the "clinical" model ($p<0.001$) and similarly (AUC 0.781, AIC 381.41) to the "clinical-US full" model ($\Delta AIC<2$) (Figure 1).

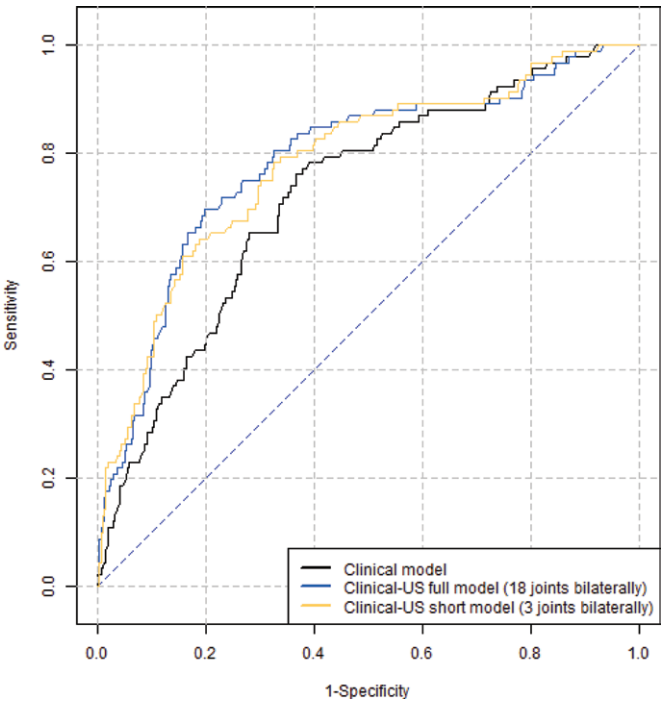

Figure 1.

Conclusion: In CCP+ at-risk with MSK symptoms, US of only 3 joints bilaterally (wrist, knee and MTP5 joint) improved prediction of IA over and above clinical and serological risk factors, performing similarly to an extended research US protocol. This shortened 6 joint US protocol may offer clinically feasible risk prediction, which could be easily incorporated into routine clinical practice.

Background: Lipid mediators are endogenously derived from the metabolism of omega-3 and omega-6 polyunsaturated fatty acids (PUFAs) and have important roles in promoting and resolving inflammation. PUFAs have been implicated in the pathogenesis of systemic inflammatory and autoimmune diseases, including rheumatoid arthritis (RA). Sharing many common pathways and key enzymes, individual lipid mediators may be correlated with one another and can be analyzed in combination as a profile. This study's goal was to determine the association of PUFA-derived lipid mediator profiles with progression from RA-related autoimmunity, a state that can be identified in screened and studied individuals by the presence of peripheral blood anti-citrullinated peptide antibodies (ACPA) autoantibodies in the absence of arthritis, to clinically apparent RA.

Objectives: To identify lipid mediator profiles in the preclinical period that are associated with progression to classifiable RA.

Methods: Using two unique prospective cohorts, the Targeting Immune Responses for Prevention of Rheumatoid Arthritis (TIP-RA) cohort and the Studies of the Etiologies of Rheumatoid Arthritis (SERA) cohort, we followed ACPA positive individuals in the absence of RA at baseline. We followed 81 and 79 participants in TIP-RA and SERA, of which 22 and 18 participants, respectively, developed RA during follow-up based on ACR/EULAR 2010 criteria (**Table 1**). Exposures included concentrations (pg/ml) of lipid mediators quantified from plasma samples via liquid chromatography tandem mass spectrometry, with profiles identified via principal component meta-analysis (metaPCA), which identifies common eigenspace between multiple datasets. Profiles were identified at two time periods: baseline (e.g. study enrollment) and pre-incident RA (just prior to RA in progressors or similar period in non-progressors). For each cohort, a Cox proportional hazard model was developed for each lipid mediator profile, adjusted for shared epitope status, age and smoking status. Meta-analysis was performed for each lipid mediator profile using Fisher's method.

Results: At each cross-section, the top 5 principal components (PC), selected based on scree-plots, were analyzed further. Analysis of the baseline cross-section identified a significant risk profile (baseline PC5, meta HR = 1.28, meta p-value = 0.033) and a suggestive protective profile (baseline PC1, meta HR 0.96, meta p-value = 0.055) associated with RA. The pre-incident RA period identified a significant risk profile (pre-incident RA PC4, meta HR = 1.37, meta p-value = 0.028). **Figure 1** depicts the loading factors for the associated profiles. Both risk profiles (pre-incident RA PC4 and baseline PC5) had a mix of positive and negative loadings corresponding to important lipid mediators that are products of arachidonic acid (ARA) and eicosapentaenoic acid (EPA). These weights suggest higher levels of lipid mediators from EPA (an omega-3 FA) combined with lower levels of lipid mediators from ARA (an omega-6 FA) would be a risk factor for RA. The suggestive protective profile at baseline (baseline PC1) showed important lipid mediators with negative weights only, all high impact lipid mediators being descendants from linoleic acid (an omega-6 fatty acid), with lower levels being protective.

Conclusion: Combinations of lipid mediators show association with progression to RA, identifying multiple targets that could be potentially modulated to prevent the progression of disease.

Table 1. Baseline Demographics of the ACPA+ Populations.

Background: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Usual interstitial pneumonia (UIP) is the most frequent, and severe ILD pattern in RA. Abatacept (ABA) has demonstrated effectiveness in RA-ILD during a 12-month period of treatment [1-2].
Objectives: To assess the effectiveness and safety of ABA in RA-ILD patients with radiological pattern of UIP during a long-term follow-up.
Methods: From a large observational multicenter study of 392 RA-ILD patients treated with ABA, we selected those with UIP. We analyzed from baseline the following outcomes: **a)** forced vital capacity (FVC), **b)** diffusing capacity of the lungs for carbon monoxide (DLCO), **c)** chest high resolution computed tomography (HRCT), **d)** dyspnea (modified Medical Research Council scale) and **e)** arthritis activity (DAS28-ESR).
Results: We included a total of 172 patients with UIP (91 women/81 men; mean age 66.9±10.1 years). Baseline demographic and clinical characteristics are shown in **Table 1**. The median ILD duration up to ABA initiation was relatively short, with a median of 11 [3-39] months. Mean baseline values of FVC and DLCO were >80% and >60%, respectively. During the follow-up, median of 24 [10-44] months, 70.2% and 66.9% of patients showed an improvement/ stabilization of FVC and DLCO, respectively. Evolution of these parameters along 48 months is displayed in **Figure 1**. Available chest HRCT images improved/ stabilized in 64.5% of patients. Stabilization or improvement of dyspnea was found in 78.6% of patients. The majority of patients showed articular remission or low activity (mean DAS28-ESR of 4.3±1.5 at baseline and 2.5±1.5 at 48 months). ABA was withdrawn in 39 (22.6%) patients due to ILD worsening (17), articular inefficacy (9), serious infections (7) and other causes (n=6, development of malignancy in 3, diagnosis of giant cell arteritis and change to tocilizumab in 1, and 2 deceases).
Conclusion: ABA shows a lasting effectiveness and safety in RA-ILD patients with UIP, the most aggressive pattern.

OP0127

HARNESSING THE POWER OF RADIOMICS TO PREDICT SURVIVAL IN PATIENTS WITH RA-ILD

Keywords: Artificial Intelligence, Lungs, Rheumatoid arthritis

V. Venerito[1], A. Manfredi[2], G. Lopalco[1], M. Lavista[1], G. Cassone[2], A. Scardapane[3], M. Sebastiani[2], F. Iannone[1]. [1]*University of Bari, Rheumatology Unit, Department of Precision and Regenerative Medicine and Ionian Area, Bari, Italy*; [2]*Azienda Ospedaliera Policlinico di Modena, University of Modena and Reggio Emilia, Modena, Italy, Rheumatology Unit, Modena, Italy*; [3]*Radiology Unit, University of Bari Aldo Moro, Bari, Italy, Department of Interdisciplinary Medicine, Bari, Italy*

Background: Patients with rheumatoid arthritis (RA) and interstitial lung disease (ILD) have increased mortality compared to the general population and factors capable of predicting RA-ILD long-term clinical outcomes are lacking. In oncology, radiomics allows the quantification of tumour phenotype by analysing the characteristics of medical images [2]. The hypothesis of radiomics is that the distinctive imaging features between disease forms may help make a prognosis and predict the therapeutic response for various conditions, thus providing valuable information for personalised therapy and patient management. Using specific software, it is possible to segment organs on high-resolution computed tomography (HRCT) images and extract many features that may uncover disease characteristics that are not detected by the naked eye.
Objectives: We aimed to investigate whether features from whole lung radiomic analysis of HRCT may. alone predict mortality in RA-ILD patients.
Methods: HRCTs of RA patients from January 2012 to March 2022 were analyzed. The time between the first available HRCT and the last follow-up visit or ILD-related death was recorded. We performed a volumetric analysis in 3D Slicer, automatically segmenting the whole lungs and trachea via the Lung CT Analyzer. The PyRadiomics platform (version 3.01) can extract radiomic data from medical imaging, calculate features and return results as continuous variables. In a Python 3.9 environment, we extracted 120 features for segmented regions. A LASSO-Cox model was carried out by considering ILD-related death as the outcome variable and extracting radiomic features as exposure variables.
Results: We retrieved the HRCTs of 30 RA-ILD patients. The median survival time (interquartile range) was 48 months (36–120 months). Thirteen out of 30 (43.33%) patients died during the observation period. Demographics and clinical features have been reported in Table 1. Whole line segmentation was fast and reliable. The model included either the median grey level intensity within the whole lung segmentation (HR 9.35, 95% CI 1.56–v55.86) as a positive predictor of death and the 10th percentile of the number of included voxels (HR 0.20, 95% CI 0.05–0.84), the voxel-based pre-processing information (HR 0.23, 95% CI 0.06–0.82) and the flatness (HR 0.42, 95% CI 0.18–0.98), negatively correlating to mortality. The correlation of grey level values to their respective voxels (HR 1.52 95% CI 0.82–2.83) was also retained as a confounder. We observed that the hazard function followed the 45-degree line very closely except for huge values of time, demonstrating goodness-of-fit (Figure 2, Panel. B).
Conclusion: Radiomics may predict RA-ILD patients' mortality and may promote HRCT as a digital biomarker regardless of the clinical characteristics of the disease.

Background: Concentrations of methotrexate polyglutamates (MTX-PGs) in erythrocytes have been reported to be associated with efficacy and safety in patients with rheumatoid arthritis (RA) treated with MTX. However, little is known about the pharmacokinetics and pharmacodynamics of MTX-PG concentrations and their relationship with disease control and adverse effects in patients treated with MTX and a tumor necrosis factor inhibitor (TNFi), especially in patients whose MTX dose is reduced at TNFi initiation.

Objectives: To clarify the association between the concentrations of MTX-PGs with efficacy and safety of treatment in patients with RA treated with low dose MTX and high dose MTX in combination with adalimumab, a TNFi.

Methods: The MIRACLE study (NCT03505008) was a multinational, randomized study in patients with RA with inadequate response to MTX. Three hundred MTX-naive patients were enrolled in the study and started and increased MTX to the maximum tolerable dose. Patients who did not achieve remission according to simplified disease activity index (SDAI) at week 24 were randomised to the maximum tolerable dose group or the reduced dose group and started subcutaneous adalimumab 40 mg every other week. We measured the concentrations of MTX-PGs in erythrocytes with liquid chromatograph mass spectrometry at weeks 0, 4, 8, 12, 24, 36, and 48 and analysed the association between the concentration of MTX-PGs with the efficacy and safety of adalimumab.

Results: The previously reported results of the MIRACLE trial showed that the efficacy of adalimumab with reduced dose of concomitant MTX was not inferior to that with maximum tolerable dose of MTX (remission rates at week 48: 44.8 % vs 38.4 %, respectively) with better safety profile (adverse events: 19.7% vs 35.3%, respectively). In the maximum tolerable dose group, MTX dose was 13.5± 3.2 mg/week (0.24± 0.1 mg/kg/week) at week 24 and maintained the dose through 48 weeks. In the reduced dose group, MTX dose was reduced from 12.6± 3.1 mg/week (0.23± 0.1 mg/kg/week) to 7.6± 0.5 mg/week (0.14± 0.0 mg/kg/week) at week 24. The concentration of total MTX-PGs in the maximum tolerable dose group was 109.5± 36.7 nmol/L, 99.9± 40.1 nmol/L, and 96.4± 38.3 nmol/L at weeks 24, 36, and 48, respectively. In the reduced dose group, total MTX-PGs concentration was decreased from 113.5± 55.3 nmol/L at week 24 to 80.7± 53.1 nmol/L at week 36 and 68.9± 54.4 nmol/L at week 48 (Figure 1). The decrease in individual MTX-PG levels were more prominent in long and very long chain MTX-PGs compared with short chains; MTX-PG 1-2, 59.0± 44.7 nmol/L at week 24 to 48.9± 43.8 nmol/L at week 36; MTX PG 3-5, 54.5± 28.8 nmol/L at week 24 to 31.8± 18.7 nmol/L at week 36. In both groups, MTX-PG concentrations at week 48 were not different between patients who achieved SDAI remission and those who did not (95.1 nmol/L vs 98.6 nmol/L in the maximum tolerable dose group, p=0.743; 64.3 nmol/L vs 72.9 nmol/L in the reduced dose group, p=0.556, respectively). On the other hand, patients n the reduced dose group who experienced adverse events after week 24 tended to have higher concentartion of total MTX-PGs than those who did not (140.3 nmol/L vs 106.9 nmol/L at week 24, p=0.050; 97.3 nmol/L vs 63.0 nmol/L at week 48, p=0.069, respectively).

Conclusion: The MIRACLE randomised study demonstrated that total MTX-PG concentrations were not relevant for SDAI remission achievement by combined treatment with methotrexate and adalimumab while patients who experienced adverse events were exposed to higher MTX-PG concentrations.

Background: EULAR recommends methotrexate (MTX), combined with short-term glucocorticoids as first-line treatment for early Rheumatoid Arthritis (RA). In the CareRA trial, the COBRA-Slim regimen (MTX 15 mg/w + step-down prednisone 30, 20, 12.5, 10, 7.5, 5 mg/d), including a treat to target (T2T) approach starting with addition of leflunomide and only at a later stage bDMARDs, provided the best balance between efficacy, safety and cost-effectiveness. The potential advantage of temporary bDMARD use earlier in the T2T setting needs further investigation.

Objectives: To determine the long-term effectiveness of accelerated access to a temporary course of etanercept compared to addition of leflunomide in patients with early RA who insufficiently respond to initial COBRA-Slim induction therapy.

Methods: DMARD-naïve patients with a recent diagnosis of RA (≤1 year ago) were included in the 2-year, open-label, multicentre, pragmatic randomised controlled superiority trial Care in Early RA 2020 (CareRA2020). All patients started the COBRA-Slim induction regimen. Patients were classified as insufficient responders if, even despite MTX dose increase, they did not achieve DAS28-CRP ≤3.2 between week 8 and week 32 or if DAS28-CRP was ≥2.6 at week 32 regardless of MTX dose. Insufficient responders were randomised to either Standard COBRA-Slim (addition of leflunomide 10 mg/d) or COBRA-Slim Bio-induction (addition of etanercept 50 mg/w for 24 weeks). Additional treatment adaptations followed the T2T principle. Primary outcome was the difference in DAS28-CRP over time, determined via a linear mixed model including random intercepts and a random slope for time, adjusting for baseline DAS28-CRP and seropositivity. Missing data were imputed with the Expectation-Maximisation algorithm.

Results: In total, 276 patients were included, of which 155 (56%) were classified as sufficient and 121 (44%) as insufficient responders. Of the insufficient responders, 9 patients were not randomised by investigator decision, 2 were randomisation errors, 55 were randomised to Standard COBRA-Slim, and 55 to COBRA-Slim Bio-Induction. The mean ± SD area under the DAS28-CRP curve over 104 weeks was 232 ± 66 for the initial sufficient responders, 310 ± 82 for the Standard COBRA-Slim group, and 316 ± 73 for the COBRA-Slim Bio-induction group. Both randomisation groups had comparable DAS28-CRP scores over time (ß = -0.095, 95% CI (-0.299 to 0.108), p=0.351). At the end of the trial, 82% (127/155), 9% (5/55), and 36% (20/55) of patients were on csDMARD monotherapy in the initial sufficient responders, Standard COBRA-Slim, and COBRA-slim Bio-induction group, respectively. Moreover, 6% (9/155) sufficient responders, 58% (32/55) in the Standard COBRA-Slim, and 45% (25/55) in the COBRA-Slim Bio-induction group were treated with a b- or tsDMARD.

Conclusion: More than half of the CareRA2020 participants achieved remission with COBRA-Slim induction therapy. DAS28-CRP over 104 weeks was not superior with COBRA-Slim Bio-induction versus the Standard COBRA-Slim T2T regimen in initial insufficient responders. However, compared to the Standard COBRA-Slim group, more patients in the Bio-induction group were treated with csDMARD monotherapy and less with advanced therapies at the end of the study.

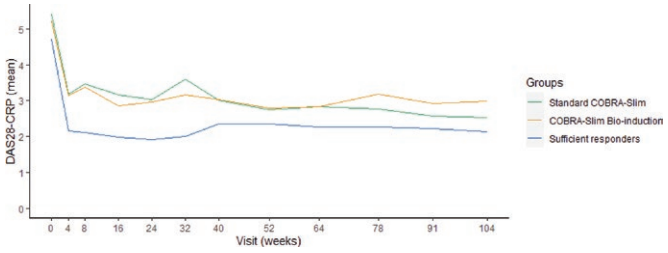

Figure 1. Disease activity evolution during the CareRA2020 trial

Table 1. Baseline characteristics of patients included in the CareRA2020 trial

	Sufficient responders (n=155)	Standard COBRA-Slim (n=55)	COBRA-Slim Bio-induction (n=55)
Sex (female)	66% (103)	75% (41)	69% (38)
Age (years)	54.5 ± 14.0	53.4 ± 13.1	52.5 ± 12.9
Symptom duration (months)	5.0 (3.0 - 9.0)	3.0 (2.0 – 6.0)	4.0 (2.0 – 6.0)
Disease duration (days)	6.0 (1.0 – 20.0)	6.0 (2.0 – 15.0)	7.0 (0.5 – 19.0)
RF and/or ACPA positivity	77% (119)	76% (42)	75% (41)
Erosions present	27% (42)	15% (8)	18% (10)
HAQ (0-3)	1.1 ± 0.7	1.6 ± 0.6	1.5 ± 0.8
PhGA	51.7 ± 19.5	59.5 ± 20.9	55.4 ± 21.0
DAS28-CRP	4.7 ± 1.3	5.4 ± 1.1	5.2 ± 1.3

Background: While genetic and epidemiological factors have been used traditionally to evaluate the risk of developing rheumatoid arthritis (RA), the definition of higher risk states has been refined in more recent years through inclusion of serum autoantibodies and symptom complexes, such as inflammatory joint pain. Data from at risk cohorts have reported rates of progression to RA in excess of 50% over 24 months. These combined features have provided a framework for the design of interception studies, aimed at delaying or preventing RA.

Objectives: We evaluated the feasibility, efficacy and acceptability of T-cell co-stimulation modulation with abatacept in individuals at risk of developing RA in the Arthritis Prevention In the Pre-clinical Phase of RA with Abatacept (APIPPRA) study.

Methods: APIPPRA is a Phase IIB randomised, double blind, placebo-controlled trial recruiting $ACPA^{+}RF^{+}$ or $ACPA^{hi}$ (≥3 x ULN) RF^{-} individuals with arthralgia. Consenting participants were randomised, stratified by gender, smoking status and country, to receive 52 weekly subcutaneous injections of placebo or 125mg abatacept, and followed up for a further 52 weeks after stopping treatment. Exclusion criteria included previous episodes of clinical synovitis, prior corticosteroids or DMARDs. The primary endpoint was the time to development of either clinical synovitis in ≥3 joints, or RA according to ACR/EULAR 2010 criteria, whichever was met first, where joint involvement required swelling. Joint synovitis was confirmed by ultrasonography. The study was powered to detect a 50% reduction in progression in those receiving abatacept. Secondary endpoints included multiple disease activity assessments, the time to commencing DMARDs and/or corticosteroids, X-ray and ultrasound scores, as well as safety data. The main ITT analysis was repeated in a per-protocol population of participants who did not take forbidden medication, and who, in the first year or up to a primary event, had 90% adherence to treatment.

Results: Between December 2014 and January 2019, 280 individuals were evaluated for eligibility across 31 study sites, 28 in the UK and 3 in the Netherlands. Two hundred and thirteen were randomised, 103 to placebo and 110 to abatacept. Mean age was 49 and 77% were female. Ninety-three percent of individuals were $ACPA^{hi}$. Ultrasonography at baseline suggested modest levels of active sub-clinical synovitis (73% of participants with power Doppler score of 0). In total, there were 65 primary outcome events. After stopping treatment at 52 weeks there were 30 events (29%) in the placebo arm and 7 (6%) in the abatacept arm. By the end of the study there were 38 (37%) and 27 (25%) events, respectively, resulting in differences in mean arthritis-free survival time between arms of 99.2 days (95% CI 37.5 – 160.9; *p*-value=0.002), in favour of abatacept. The respective log-rank test for difference in the survival distribution was p=0.044, reflecting a large effect in the first year and convergence over the second year (see Figure 1). The per protocol analysis showed similar results. The cumulative proportion of arthritis-free participants at 52 weeks was 0.692 (SE 0.047) in the placebo arm and 0.928 (SE 0.026) for the abatacept arm, and 0.585 (SE 0.054) for placebo and 0.704 (SE 0.048) for abatacept at 104 weeks. *Post hoc* analysis revealed that individuals with an extended autoantibody profile at baseline were more likely to remain arthritis-free following abatacept therapy. Those treated with abatacept had lower tender joint counts and pain scores during the treatment period, when compared to placebo. There were 4 serious adverse events in the abatacept group and 10 in the placebo group, including two deaths, one in each arm, none deemed attributable to study drug.

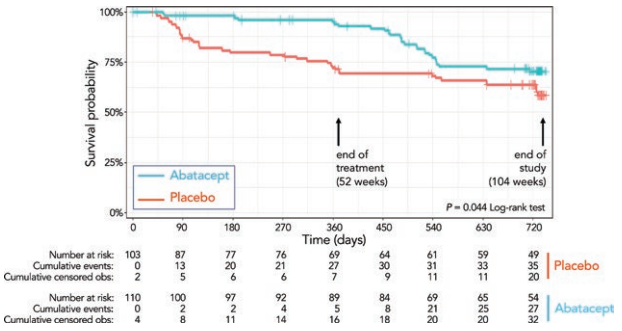

Figure 1.

Conclusion: Therapeutic intervention during the RA at risk phase is feasible, with acceptable safety profiles. T cell co-stimulation modulation with abatacept for 52 weeks showed a reduction in the development of RA over two years. There were no new safety signals.

Acknowledgements: The APIPPRA trial is an Investigator Sponsored Research (ISR) study funded by Bristol Myers Squibb, and jointly sponsored by Guy's and St Thomas' NHS Foundation NHS Trust and King's College London in the UK and Leiden University Medical Center in the Netherlands. Bristol Myers Squibb played no role in data acquisition or analysis.

DISEASE ACTIVITY-GUIDED DOSE OPTIMIZATION INCLUDING DISCONTINUATION OF TNF-INHIBITORS IN RHEUMATOID ARTHRITIS IS EFFECTIVE FOR UP TO 10 YEARS: RESULTS OF THE DRESS STUDY

Keywords: bDMARD, Rheumatoid arthritis, Tapering

C. Van der Togt[1], N. Den Broeder[1], A. Van der Maas[1], A. Den Broeder[1,2], N. Van Herwaarden[1,3]. [1]*Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands*; [2]*Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*; [3]*Radboud University Medical Center, Pharmacology-toxicology, Nijmegen, Netherlands*

Background: Tumor necrosis factor inhibitors (TNFi) are effective in rheumatoid arthritis (RA) but have their drawbacks such as the need for self-injection, infections and costs. To reduce these disadvantages, disease activity-guided dose optimization (DAGDO) has shown to be an effective and safe strategy.[1] During DAGDO, a stepwise dose reduction of the TNFi is performed if allowed by the disease activity. In the Dose Reduction Strategy of Subcutaneous TNFi (DRESS) study, effectiveness and safety of DAGDO has been shown in RA patients for up to three years.[2, 3] However, long term outcomes of DAGDO are scarce, and it is debated whether a discontinuation attempt should be included.

Objectives: To assess 10-year effectiveness of DAGDO of TNFi in the DRESS cohort, specifically 1) disease activity over time, 2) biological and targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARD) dose over time, 3)

proportion of patients with a DAGDO attempt, and 4) proportion of patients with a discontinuation attempt and duration of b/tsDMARD discontinuation.
Methods: Observational follow-up (starting from DRESS baseline) of patients who completed the 3-year DRESS extension. During the DRESS intervention phase (month 0-18), RA patients were randomized to DAGDO or continuation of TNFi (adalimumab or etanercept), but thereafter, DAGDO was allowed for all patients. The DAGDO protocol contained the following steps, displayed as a percentage of the current daily dose to the defined daily dose (DDD): 100%-66%-50%-(33%)-0% (full discontinuation). The disease activity was operationalized as the mean time-weighted (MTW) DAS28-CRP. The specific DRESS TNFi and all b/tsDMARD dose over time were displayed as the MTW dose per year in %DDD. The duration of b/tsDMARD discontinuation was analyzed using the time between discontinuation and restart of the same or another b/tsDMARD, or censoring.
Results: 170 patients (of the original 180) could be included in the study (Table 1). The median follow-up time was 10.0 years (IQR 9.3-10.3) and the MTW DAS28-CRP during the whole period 2.13 (95% CI 2.10-2.16) (Figure 1). The DRESS TNFi dose decreased from 97% at baseline (95% CI 96%-99%) to 49% at year 5 (95% CI 42%-56%) and remained stable thereafter (Figure 1). The dose of any b/tsDMARD was comparable although slightly higher. Of the 161 patients with ≥1 DAGDO attempt of their DRESS TNFi during the study, 119 (74%, 95% CI 66%-80%) tapered until full discontinuation. The median time from discontinuation to restart of the first discontinuation attempt was 8 months (IQR 3 – 45 months), and 25 patients (21%, 95% CI 14%-29%) never had to restart their TNFi or another b/tsDMARD throughout the study.
Conclusion: In this 10-year TNFi dose optimization study, we found a stable low disease activity and halved TNFi dose. The inclusion of discontinuation in DAGDO does not seem to cause disease deterioration and b/tsDMARD free remission for a relevant period of time is possible in a non-negligible number of patients. Overall, this study shows effectiveness of DAGDO of TNFi in RA up to 10 years.

CANCERS AND CARDIOVASCULAR DISEASES IN PATIENTS WITH SEROPOSITIVE RHEUMATOID ARTHRITIS TREATED WITH JAK INHIBITORS AND BIOLOGICS

Keywords: Rheumatoid arthritis, Disease-modifying drugs (DMARDs), Targeted synthetic drugs

S. S. Ahn[1], M. Han[2], I. Jung[2], H. W. Kim[3]. [1]*Yonsei University College of Medicine, Internal Medicine, Yongin, Korea, Rep. of (South Korea)*; [2]*Yonsei University College of Medicine, Department of Biomedical Systems Informatics, Seoul, Korea, Rep. of (South Korea)*; [3]*Yonsei University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Janus kinase inhibitors and biologics (JAKi/biologics) are cornerstone treatments for rheumatoid arthritis (RA).
Objectives: We evaluated the risks of cancers and cardiovascular diseases (CVDs) in patients with seropositive RA (SPRA) treated with JAKi/biologics.
Methods: Patients with new-onset SPRA during 2010–2020 in the national healthcare database were identified. Events of overall and site-specific cancers, as well as CVD outcomes, including deep vein thrombosis, pulmonary embolism, and composite cardiovascular events, were investigated. The relative risk of cancers and CVDs according to treatment was compared by evaluating the incidence rate ratios (IRRs). Time-dependent Cox analyses were performed to evaluate the relationship between JAKi/biologics usage and patient outcomes.
Results: A total of 101,816 and 96,220 patients with SPRA were analyzed for cancers and CVD outcomes, respectively. Compared with patients treated only with conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs), the IRRs of overall cancers and CVDs in patients administered JAKi/biologics were 0.88 (95% confidence interval [CI] 0.86–0.89) and 0.91 (95% CI 0.90–0.92), respectively. Site-specific lung, liver, prostate, and skin cancers were more frequent in JAKi/biologics users; JAKi did not confer a greater risk of overall CVDs and cancers compared with other biologics and csDMARDs. JAKi/biologics usage was not accounted for overall cancers and CVDs in adjusted Cox analyses.
Conclusion: The incidence of overall cancer and CVD were not increased in patients with SPRA treated with JAKi/biologics and was relatively lower than csDMARDs only users, underscoring optimal disease control for risk mitigation. The higher incidence of several sitespecific cancers requires further investigation.

JAKi: Janus kinase inhibitor, csDMARD: conventional synthetic disease-modifying anti-rheumatic drug.

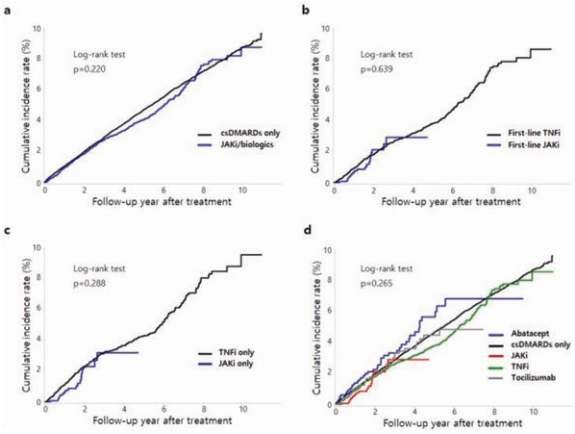

Figure 1. Comparison of cumulative incidence of cancers according to patient treatment

The risk of overall cancers was similar in patients that were (a) prescribed with JAKi/biologics and csDMARDs, as well as in (b) those who used JAKi and TNFi as the first-line treatment. In addition, there was no difference in the incidence of cancers among (c) those who were treated with only JAKi and TNFi during the follow-up and between (d) JAKi, biologics, and csDMARDs users.JAKi: Janus kinase inhibitors, csDMARD: conventional synthetic disease-modifying anti-rheumatic drug, TNFi: tumour necrosis factor-α inhibitor.

OP0133

DO JAKIS WORK THE BEST AMONG THOSE RA PATIENTS WHERE THEIR SAFETY CONCERNS ARE THE HIGHEST?

Keywords: Rheumatoid arthritis, Targeted synthetic drugs, bDMARD

H. Bower[1], T. Frisell[1], D. DI Giuseppe[1], B. Delcoigne[1], J. Askling[1,2]. [1]*Karolinska Institute, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden*; [2]*Karolinska University Hospital, Rheumatology,Theme Inflammation and Ageing, Stockholm, Sweden*

Background: Safety is a driving factor when selecting treatment, but the risks should be balanced against the treatment benefits, relative to alternative treatment options. In JAKis, recent evidence of increased safety risks in older patients with cardiovascular (CV) risk factors, have led to concerns. However, an increased risk among certain patients might still be offset by an increasing benefit in the same patient segment, and vice versa. A full understanding of the JAKi benefit-risk profile thus requires a better understanding of the relative (JAKi vs other treatments) benefits in those patients where their relative safety profile may be worse.
Objectives: To assess the observed and adjusted relative effectiveness (remission and response) of JAKis (and non-TNFi bDMARDs) when compared to TNFi, as used in clinical practice, and to assess whether the predicted effectiveness of either drug class is modified by age and the presence of CV risk factors.
Methods: RA patients initiating treatment with a JAKi, non-TNFi, or TNFi 2016-2021 were followed using the Swedish Rheumatology Quality Register. Good EULAR response and remission (CDAI<=2.8) at 6 months were assessed at return visits (within 90 to 270 days after treatment initiation). Non-responder imputation was implemented where treatment ended prior to 210 days after initiation. Crude probabilities of outcomes were presented by age and having ≥1 CV risk factor (Y/N). Linear regression estimated the risk difference (versus TNFi) in age and CV risk groups, adjusted for sex, baseline DAS28 (response) and CDAI (remission), and line of therapy. Probability of outcome was predicted from logistic regression models, fitted to allow effect modification of treatment cohort by age and CV risk score (ERS-RA score), adjusted for sex, baseline DAS28 (response) and CDAI (remission), and line of therapy.
Results: 10,309 treatment episodes contributed data on response at 6 months, and 12,016 episodes with data on remission. Overall, 21% achieved good EULAR response and 11% reached CDAI remission (Table 1). Crude observed risks overall indicated superior response and remission with TNFi versus JAKi (Table 1). Adjusted risk differences suggested superior outcomes in JAKi versus TNFi, overall, and in those with no CV risk for CDAI remission. Patterns of predicted response and remission varied across age and CV ERS-RA score (Figure 1), with JAKis having superior effectiveness overall once adjusting for line of therapy.
Conclusion: Age and CV risk may modify the absolute and relative effectiveness of JAKis vs. TNFi. Further analyses are planned with the aim of presenting these results at EULAR.

REAL WORLD "POLY-REFRACTORY RA": A RARE BUT UNMET CLINICAL CHALLENGE

Keywords: Rheumatoid arthritis, bDMARD, Ultrasound

P. David[1,2], A. DI Matteo[1,3,4], O. Hen[1,5], S. Dass[6], P. Emery[1,3,6], B. Saleem[6], D. Mcgonagle[1,3,6]. [1]*University Of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [2]*Sheba Medical Center - Tel Hashomer, Internal Medicine B Department, Ramat Gan, Israel*; [3]*Leeds Teaching Hospitals NHS Trust, National Institute for Health Research Leeds Biomedical Research Centre, Leeds, United Kingdom*; [4]*Polytechnic University of Marche, Department of Clinical and Molecular Sciences, Rheumatology Unit, Carlo Urbani Hospital, Jesi, Ancona, Italy*; [5]*Sheba Medical Center - Tel Hashomer, Internal Medicine C Department, Ramat Gan, Israel*; [6]*Leeds Teaching Hospitals NHS Trust, Rheumatology, Chapel Allerton Hospital, Leeds, United Kingdom*

Background: In an age of dose optimization and drug tapering due to excellent conventional (c), biological (b) or targeted synthetic (ts) disease-modifying anti-rheumatic drugs (DMARDs), the fact remains that many patients still have active disease, being therapy refractory, sometimes to multiple DMARDs. In 2021, EULAR defined the term "Difficult-to-treat (D2T) Rheumatoid Arthritis" as failure of two or more different classes of b/tsDMARDs post csDMARDs (1) but the rate of failure to all available DMARD classes in the real-world setting (poly-refractory RA) is not established. Moreover, the DAS-28-CRP score can be elevated in patients with either persistent inflammatory RA (PIRRA) or non-inflammatory RA (NIRRA), where the latter do not benefit from medication change

[2]. PIRRA patients have at least one clinically swollen joint, with objective evidence of active inflammation in power Doppler ultrasound (PDUS), often with elevated CRP levels, whilst NIRRA patients have apparent clinical swelling but absence of PDUS and often normal CRP levels.

Objectives: This study determined the prevalence of EULAR-defined refractory RA (D2T RA) in Leeds. Secondly, we established the prevalence of poly-refractory RA, i.e., patients that failed all available b/tsDMARD classes. Finally, we determined NIRRA/PIRRA phenotypes in refractory disease.

Methods: 1591 RA patients receiving b/ts DMARDs therapy between 2018-2022 were identified as part of a service evaluation, excluding those where DAS-28-CRP was unavailable. Patients fulfilling EULAR-ACR criteria for D2T RA, with DAS-28-CRP≥ 3.2 and US imaging where available were evaluated. Patients were further divided into NIRRA and PIRRA, according to the presence/absence of signs of active synovitis as indicated by PDUS (Figure 1).

Results: 242/1591 (15.2%) met the EULAR D2T criteria of failing at least 2 b/tsDMARDs. 89/1591 (5.6%) failed 2 classes only, with a mean disease duration (mDD) of 11 years. 60/1591 (3.8%) failed 3 classes (mDD= 18) and 52/1591 (3.3%), 4 classes (mDD= 10.5). However, just 41/1591 (2.5%) had poly-refractory RA having failed all 5 classes (mDD= 21). Of them, 37/41 (90%) failed multiple drugs within each class. 4/41 (10%) poly-refractory and 45/242 (18.5%) of all EULAR D2T cases were seronegative. Regarding joint involvement patterns, most had typical small joint RA disease pattern but 26/242 (11%) had a predominant large joint pattern. 18/41 (43%) of the poly-refractory RA group had CRP levels within the normal ranges despite a DAS-28-CRP score above 3.2 (mean DAS-28-CRP of 5.3). 71 D2T RA patients had recent US of clinically involved joints, including 28 poly-refractory RA cases. 18/28 (64%) poly-refractory were considered PIRRA as evidenced by synovial hypertrophy and PDUS positivity in at least one evaluated clinically swollen joint. 32/71 (45%) D2T RA had no signs of active synovitis in PDUS being considered NIRRA. Of them, 17/32 (53%) had no synovial thickening in US in suspected clinically involved joints. Specifically in the poly-refractory group, the CRP levels were within normal ranges in 6/10 (60%) NIRRA patients, while just 7/18 (39%) PIRRA cases had normal CRP levels.

Conclusion: Although 15.2% of Leeds RA patients met the EULAR criteria for D2T RA, real world poly-refractory RA was present in only 2.5%. Almost half of these patients had no PDUS changes on US and/or had normal CRP levels. These findings highlight a twofold clinical challenge in refractory RA with half of this group (both D2T and poly-refractory RA) having true inflammation that may need new mechanisms of action, but the other half would not be likely to benefit from new DMARD treatment strategies.

RISK OF DEMYELINATING EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TUMOUR NECROSIS FACTOR INHIBITORS: A SYSTEMATIC LITERATURE REVIEW

Keywords: bDMARD, Rheumatoid arthritis, Systematic review

I. Castrejon[1,2], L. Silva-Fernández[3], J. A. Gómez-Puerta[4], A. Ortiz[5], N. Mena-Vázquez[6], J. Tornero Molina[7], C. Plasencia[8], J. M. Alvaro-Gracia[1,2]. *[1]Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain*; *[2]Complutense University of Madrid, Department of Medicine, Madrid, Spain*; *[3]Hospital Universitari Son Espases, Rheumatology, Palma, Spain*; *[4]Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain*; *[5]Hospital de La Princesa, Rheumatology, Madrid, Spain*; *[6]Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain*; *[7]Hospital Universitario de Guadalajara, Rheumatology, Guadalajara, Spain*; *[8]La Paz University Hospital, Rheumatology, Madrid, Spain*

Background: Several case reports published in the 2000's indicated that demyelinating diseases could be a serious adverse event following TNF inhibitors (TNFi) treatment. However, initial data from biological therapy registries did not bring enough clarification.

Objectives: To investigate whether treatment with biologics or targeted synthetic DMARDs is associated with an increased risk of demyelinating events among patients with rheumatoid arthritis (RA)

Methods: A systematic search was performed in MEDLINE, EMBASE (up to Oct 2022), and by manual references. Selection criteria: (population) patients with RA; (intervention) treatment with any biologic including TNFi and synthetic DMARDs, (outcome) demyelinating event; (study design) observational studies and randomised clinical trials. Titles and abstracts were screened and data were extracted from the selected studies including quality evaluation, and outcomes of interest.

Results: From 368 identified studies, 4 cohorts and 3 nested case-control studies reported risk of demyelinating events following treatment with biologics, mainly TNFi and anakinra, in one study. Most studies included mixed populations of inflammatory arthritis and patients with RA were analysed as a separate subgroup. Two nested case-control reported an increased risk, but in a mixed population, with no analysis of a subgroup of RA. In general, demyelinating events were very uncommon in patients receiving TNFi, with a marginal increased risk in males with RA in 2 studies (Table 1).

Table 1. Characteristics and incidence rates of demyelinating events in the included studies

Study	Design	Population	Outcome
Lingyi 2022 (1)	Nested case-control Canadian healthcare databases	N= 462/296,918 Rheumatic diseases, mixed population	Case = multiple sclerosis Pooled IRR (95% CI): 2.05 (1.13-3.72)

Kunchok 2020 (3)	Nested case-control Medical records at Mayo Clinic (USA)	N=106 cases/106 controls Autoimmune diseases	Case = Any inflammatory CNS event OR 4.82 (95%CI 1.62-14.36)
Koop 2020 (4)	Combined biologic registers in Sweden and Denmark	N=271 and 51/111,455 RA pts	Incidence Rate: 0.37-0.39/1000 pt-yrs HR (95% CI) TNFi exposed vs non: Sweden: 0.97 (0.72 to 1.33) Denmark: 1.45 (0.74 to 2.81)
Dreyer 2016 (5)	Register-based cohort study DANBIO	N= 27,880 patients with arthritis and TNFi therapy	SIR 1.11 (95% CI 0.63-1.93) RA: 0.65 (95% CI 0.24–1.72) Males: 3.48 (95% CI 1.45–8.37)
Fernandez-Espartero 2011 (6)	BIOBADASER-Spain	N= 9/13,075 RA pts-years	Incident rate in RA: 0.69 (95% CI: 0.36-1.32) MS 0.05 (95% CI: 0.01-0.33), vs Spanish population 0.02-0.04*1000
Bernatsky 2010 (7)	Nested case-control Administrative data in Canada	N= 104,958 RA pts 81 cases and 810 controls	Adjusted rate ratios (95% CI): TNFi 1.31 (0.68 - 2.50) Anakinra 0.80 (0.29 - 2.24) MTX 1.09 (0.63 - 1.89)

Abbreviations: RA, rheumatoid arthritis; SIR, standardized incidence rate; CI, confidence interval; CNS, central nervous system; HR, hazard ratio; OR, odds ratio; MTX, methotrexate; MS, multiple sclerosis; TNFi, tumour necrosis factor inhibitor.

Conclusion: No consistent and significant risk of demyelinating disease following TNFi treatment was found in RA patients. A marginal and slight increase of risk was found in male RA patients. The small number of events is reassuring when considering the use of TNFi. A careful consideration is recommended in individuals at highest risk of demyelinating diseases.

Background: Lupus nephritis (LN) is one of the most common severe clinical manifestations of systemic lupus erythematosus (SLE), occurring in 21%–48% of SLE patients.[1] The kidney is the major organ affected in SLE, with persistent inflammation leading to progressive loss of renal function and chronic kidney disease (CKD). The decline in kidney function leads to an accumulation of metabolic waste products normally cleared by the kidneys, known as uremic toxins. Uremic toxins negatively affect multiple organ systems, causing increased cardiovascular and kidney damage, among other effects.[2] Given the clear link to kidney function, uremic toxins may serve as biomarkers of kidney damage and of treatment response. Anifrolumab, a monoclonal antibody that targets the type I interferon (IFN) receptor subunit 1, is approved for moderate to severe SLE treatment[3] and intensified dosing is being evaluated in a phase 3 study for LN treatment.
Objectives: In this study, we conducted unbiased metabolomic serum profiling to identify novel biomarkers of treatment response and provide insights into the mechanism of action of anifrolumab in LN.
Methods: In the 52-week phase 2 clinical trial TULIP-LN (NCT02547922), 147 patients with active LN were randomized 1:1:1 to receive intravenous anifrolumab every 4 weeks at standard SLE dosing (basic regimen [BR], 300 mg), intensified dosing (intensified regimen [IR], 900 mg for the first 3 doses, 300 mg thereafter), or placebo in addition to standard therapy.[4] Serum samples were obtained from 140 of these patients at baseline (BL) and Weeks 12, 24, and 52. Serum metabolites were analyzed using an unbiased liquid chromatography–mass spectrometry-based approach. Metabolites that were differentially modulated in the anifrolumab IR vs placebo group were identified using a mixed effects model evaluating the interaction of metabolite levels and treatment, adjusted for patients' IFN gene signature (IFNGS) status (high/low) and 24-hour urine protein–creatinine ratio (UPCR >3 or ≤3). Relationships between BL metabolite level and clinical characteristics of kidney damage were assessed by Spearman's correlation. Association of BL metabolite levels with complete renal response were evaluated by logistic regression, adjusted for IFNGS and UPCR status.
Results: Our unbiased metabolomic approach identified 2 metabolites significantly impacted by anifrolumab treatment compared with placebo (Figure 1). Cytosine (Cyt) and indoxyl sulfate (IS) levels were significantly reduced following anifrolumab IR treatment compared with placebo, while an intermediate, non-significant reduction was observed longitudinally with anifrolumab BR. At baseline, Cyt and IS serum levels were positively correlated with serum creatinine and negatively correlated with estimated glomerular filtration rate. Baseline IS levels were also associated with complete renal response at Week 52. Compared to the trend observed in nonresponders, IS levels in responders were reduced from BL to Week 52. A trend in reduction of multiple uremic toxins not limited to IS was detected in the anifrolumab-treated group.
Conclusion: In patients with LN, anifrolumab treatment reduced levels of multiple circulating uremic toxins including IS, a known inducer of cardiovascular damage in CKD.[5] Together, correlations with kidney damage measures at baseline and reductions in IS levels in responders vs nonresponders at Week 52 suggest improvements in kidney function following anifrolumab treatment. Overall, our results contribute to a deeper understanding of how inhibition of type I IFN affects renal disease in LN.

Background: Telitacicept (TACI-Fc fusion protein) is a novel BLyS (B-lymphocyte stimulator)/APRIL (a proliferation-inducing ligand) dual inhibitor, which has been approved in 2021 in China for the treatment of patients with active systemic lupus erythematosus (SLE)[1].
Objectives: Assess the efficacy and safety of telitacicept in SLE patients in a double-blind, randomized, placebo-controlled, phase 3 trial.
Methods: In this study, 335 active SLE patients who were receiving stable standard therapy with positive ANA/anti-dsDNA and a SELENA-SLEDAI score ≥8 were randomized 1:1 to receive telitacicept 160 mg (N=167) or placebo (N=168) subcutaneously weekly for 52 weeks. The primary endpoint was the response rate of SLE responder index 4 (SRI4) at Week 52. Key secondary endpoints included: SELENA-SLEDAI, PGA, immunological biomarkers including C3, C4, IgM, IgG, IgA and $CD19^+$ B cells. Safety was assessed during the study.
Results: Baseline demographics and disease characteristics were comparable between the two groups. The primary endpoint at Week 52 was met, with significantly greater proportion of patients in telitacicept 160 mg group vs placebo group achieving SRI4 response (Table 1). SRI4 response was sustained in telitacicept 160 mg group up to Week 52 (Figure 1A). Significantly greater proportions of subjects in telitacicept 160 mg group had improvement in SELENA-SLEDAI and PGA (Table 1 & Figure 1B, 1C). Rapid and sustained increase of C3 and C4 (Figure 1G, 1H), and reduction of IgM, IgG, IgA and $CD19^+$ B cells (Figure 1D, 1E, 1F, 1I) were observed following telitacicept treatment. Incidences of TEAEs and infections were comparable between the two groups. Most of TEAEs were mild to moderate in severity. A greater proportion of patients receiving placebo had SAEs and serious infections compared with telitacicept 160 mg. (Table 1).

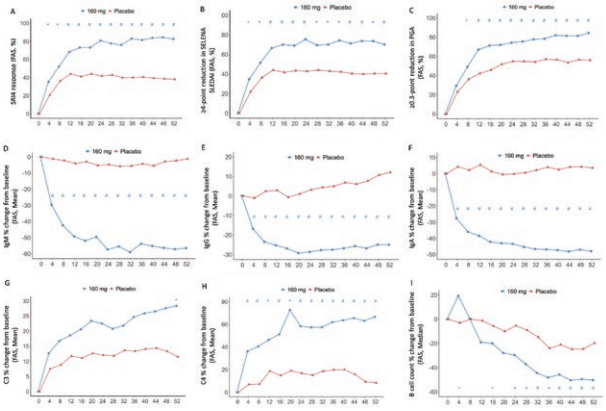

Figure 1. SRI4 Response Rate (A), rate of subjects with improvement in SELENA-SLEDAI (B) and PGA (C) at each visit. Percent (%) change from baseline in IgM (D), IgG (E), IgA (F), C3 (G), C4 (H) and $CD19^+$ B cells (I).$^{\#}$P<0.001 vs. Placebo; †P<0.01 vs. Placebo; $^{+}$P<0.05 vs. Placebo.

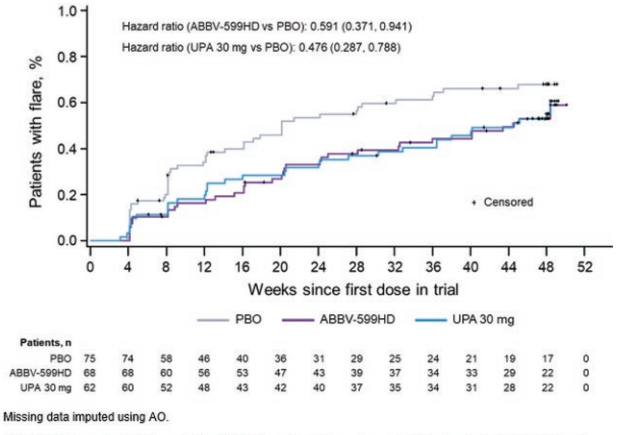
Friedman[8]. *[1]Oklahoma Medical Research Foundation, Arthritis & Clinical Immunology Program, Oklahoma City, United States of America*; *[2]Hospital of University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan*; *[3]King's College London, School of Immunology & Microbial Sciences, London, United Kingdom*; *[4]Guy's Hospital, Department of Rheumatology, London, United Kingdom*; *[5]GCM Medical Group, Rheumatology, San Juan, Puerto Rico*; *[6]CAICI Institute, Rheumatology, Rosario, Argentina*; *[7]Chinese Academy of Medical Sciences & Peking Union Medical College, Department of Rheumatology and Clinical Immunology, Beijing, China*; *[8]AbbVie, Inc, Department of Immunology, North Chicago, United States of America*



Background: ABBV-599 is a novel combination of elsubrutinib (ELS; a selective BTK inhibitor) and upadacitinib (UPA; a JAK inhibitor) that targets non-overlapping signaling pathways associated with systemic lupus erythematosus (SLE).
Objectives: To report results from SLEek, a phase 2, randomized, placebo (PBO)-controlled, parallel-group, multicenter study evaluating efficacy and safety of ABBV-599 and UPA monotherapy in adults with moderately to severely active SLE (NCT03978520).
Methods: Patients (pts) were randomized 1:1:1:1:1 to once daily (QD) ABBV-599 high dose (HD; ELS 60 mg + UPA 30 mg), ABBV-599 low dose (LD; ELS 60 mg + UPA 15 mg), ELS 60 mg, UPA 30 mg, or PBO. The primary endpoint was the proportion of patients at W24 achieving SLE Responder Index-4 (SRI-4) and steroid dose ≤ 10 mg QD; additional efficacy and safety endpoints through W48 are also reported. The pre-specified 2-sided alpha level was 0.1.
Results: 341 patients were enrolled. After a planned interim analysis when 50% of pts reached W24, the ABBV-599LD and ELS 60 mg arms were discontinued for lack of efficacy (no safety concerns). Of 205 continuing pts (ABBV-599HD n = 68, UPA 30 mg n = 62, PBO n = 75), baseline characteristics were well balanced. The primary endpoint (proportion achieving SRI-4 and steroid dose ≤ 10 mg QD at W24 vs PBO) was met by ABBV-599HD and UPA 30 mg. Key secondary endpoints were also achieved at W48 in both groups (**Table 1**). Overall flares and time to first flare were substantially reduced in the ABBV-599HD and UPA 30 mg groups through W48 (**Figure 1**). Anti-double stranded DNA antibodies were significantly decreased with both treatments. TEAEs considered related to study drug were 42.6% ABBV-599HD, 32.3% UPA 30 mg, and 33.3% PBO. There were no malignancies or VTE. There were 3 non-fatal CV events (1 MI on PBO and 2 ruptured cerebral aneurysms [1 each on ABBV-599HD and UPA 30 mg]); all were assessed as unrelated to study drug by investigators. No new safety signals were observed beyond previously known data for UPA or ELS.
Conclusion: ABBV-599HD (ELS 60 mg + UPA 30 mg) and UPA 30 mg demonstrated significant improvements in SLE disease activity and flares with acceptable safety through 48 weeks.

Background: Regulatory T cells (Treg) are critical for maintaining self-tolerance and preventing autoimmunity, and IL-2 is essential for their development, survival and suppressive function. Defects in Treg function and the IL-2 receptor are associated with SLE and have been correlated with disease activity.[1,2] Efavaleukin alfa is an IL-2 mutein Fc fusion protein that preferentially binds the high-affinity IL-2 receptor alpha chain (CD25) to selectively promote Treg expansion.
Objectives: To compare Treg functional phenotypes in healthy controls (phase 1a baseline) with SLE patients (at baseline and post-treatment) enrolled in a phase 1b study of efavaleukin alfa in order to characterize Treg defects in SLE and the effects of IL-2-targeted therapy with efavaleukin alfa on Treg expansion.
Methods: Baseline Treg functional phenotyping data from 64 healthy volunteers (ph1a baseline) were compared with Treg data from phase 1b SLE study subjects. The phase 1b, multiple ascending dose study (NCT03451422) included 5 dose cohorts; a total of 35 patients with SLE (with either elevated anti-dsDNA or ANA) were randomized to receive efavaleukin alfa or placebo SC every 2 weeks (Q2W; cohorts 1, 2, 4, and 5) or every week (QW; cohort 3) for a total of 12 weeks. Pharmacodynamic profiles of lymphocyte subsets were evaluated in peripheral blood. Cell subsets were defined as follows: Treg, CD3+CD4+Foxp3+CD127–; $CD25^{bright}$ Treg, Treg with the highest CD25 expression; CD25– Treg, CD3+CD4+Foxp3+CD127–CD25–; and CD4+ Tcon, CD3+CD4+(-Treg).
Results: At baseline, Treg CD25 expression levels were significantly lower in SLE patients compared with healthy subjects (Figure 1a), and CD25 expression on Foxp3+ Treg negatively correlated with anti-dsDNA autoantibodies (Figure 1b). The percentage of CD25– Tregs was significantly higher in SLE patients than healthy subjects and also correlated with anti-dsDNA at baseline. At day 22 in the phase 1b study, after SLE patients randomized to efavaleukin alfa had received 2 doses, Treg CD25 expression was significantly increased above baseline and comparable to the levels in healthy controls (Figure 1a). The number of $CD25^{bright}$ Tregs in SLE patients was inversely correlated with anti-dsDNA at baseline, with a mean peak increase of 53.8-fold above baseline with efavaleukin alfa treatment. The intensity of CD25 on CD4+ Tcon was not significantly different between healthy subjects and SLE patients and was not increased with efavaleukin alfa treatment.
Conclusion: Treg from SLE patients showed defects in IL-2 signaling evidenced by lower CD25 expression that correlated with anti-dsDNA, suggesting a role for reduced IL-2 signaling in SLE autoimmunity. Efavaleukin alfa treatment selectively restored Treg CD25 expression to levels observed in healthy controls without increasing CD25 expression on Tcon. $CD25^{bright}$ Treg, considered a more suppressive Treg population, were expanded with multiple doses of efavaleukin alfa. Although low baseline SLE disease activity and short treatment duration precluded efficacy analysis, clinical correlations with treatment response will be investigated in the ongoing phase 2b adaptive trial of efavaleukin alfa in SLE.

Background: Despite better treatment modalities some patients with systemic lupus erythematosus (SLE) suffer from severe and treatment-resistant disease. This situation puts patients at high risk for organ failure or even death. Furthermore, many patients with SLE have to take long-term, sometimes even life-long immune suppressive medication to control the disease without being able to enjoy drug-free remission. Recently, we reported that deep B cell depletion using a single infusion with autologous CD19 chimeric antigen receptor (CAR) T cells induced drug-free clinical remission in severe SLE patients with refractory disease [1,2]. This abstract presents the long-term clinical efficacy and safety data of the first seven SLE patients receiving autologous CD19-directed CAR-T cell therapy.
Objectives: To test whether administration of autologous CD19 chimeric antigen receptor (CAR) T cells is tolerable and effective in patients with severe refractory SLE.
Methods: Compassionate use program for patients with severe active SLE showing organ involvement and resistance to multiple immune suppressive treatments. Patients received autologous $1x10^6$ CD19-CAR-T cells/kg body weight by single infusion after standard conditioning therapy (cyclophosphamide/fludarabine). The investigational medicinal product MB-CART19.1 was produced as described before [1,2]. All SLE treatments were stopped before CAR-T cell administration. Patients were followed up as in-patients for the first 10 days after CAR T cell administration, then weekly until the end of the first month, then monthly for three months and every three months thereafter. Tolerability was assessed by monitoring for Cytokine-release syndrome (CRS) and Immune-related effector Cell Neurotoxicity Syndrome (ICANS). Preliminary efficacy was assessed by reaching a Lupus Low Disease Activity State (LLDAS) and DORIS remission.
Results: As per January 2023, seven SLE patients (6 female, 1 male, aged range 19-39) had been treated with CD19 CAR-T cells with a median follow up of 13 months (4 months-22months). Patients had active disease with a median SLEDAI of 10 (range: 8-16), with a median of 4 organs involved (range: 8-16) and a median number of 7 failed treatments (range: 4-15). All patients had active kidney disease. In addition, involvement of the heart, lungs, pleura, joints, skin, muscles and bone marrow were documented. Conditioning was done at the described [1,2] dose with the exception of patients 7, who received only 50% of the dose. All patients received a single infusion of $1x10^6$ autologous CD19-CAR-T cells/kg body weight. No ICANS was observed and CRS if observed were mild (grade I). In vivo, CAR-T cells rapidly expanded peaking at day 9 with a median of 26% of circulating T cells being CAR T cells (range: 11-59%). Expansion of CAR-T cells coincidence with the complete depletion of circulating B cells. B cell aplasia lasted for a median of 120 days (range 58-205). All patients experienced drug-free remission as assessed by DORIS remission criteria and met lupus low activity state (LLDAS) usually within the first three months after CAR T cell therapy. Furthermore, seroconversion with loss of dsDNA antibodies and other autoantibodies was observed. To date, no SLE flare occurred despite complete cessation of treatment.
Conclusion: Taken together, these data suggest that CD19 CAR T-cell therapy can abrogate disease and delete autoimmunity in patients with severe SLE. After CD19 CAR T-cell therapy SLE patients remain in drug free-remission of SLE even if B cells recur. This remission can be long-lasting as the longest disease -free observation period is now 22 months.

Table 1 contains baseline demographic data from seven SLE patients treated with CD19 CAR T-cell therapy. Patient number one to seven, age in years (ys), sex in female (F) and male (M). Disease duration in years (ys). Number (N) of organs involved and number (N) of failed treatments, disease activity at baseline presented with SLE disease activity index (SLEDAI). Conditioning dose referred to 1x cyclophosphamide 1g/m2 and 3x fludarabine 25mg/m2. Maximum of CAR-T cell expansion after administration of 1 million CAR-T cells /kg body weight given as peak of CAR-T cells absolute and percent CAR+ of CD3+ T-cells. Efficacy criteria listed as seroconversion, disappearance of SLE specific antibodies (antidsDNA), Lupus Low Disease Activity State (LLDAS), definitions of remission in systemic lupus erythematosus (DORIS) remission. Adverse events listed at Cytokine-release syndrome (CRS) and Immune-related effector Cell Neurotoxicity Syndrome (ICANS) in grade 0-4.

Background: Primary Sjögren's syndrome (pSS) is a chronic systemic autoimmune disease characterized by B-cell hyperactivity. There are still currently no systemic treatments approved for pSS. Telitacicept (TACI-Fc fusion protein) is a novel BLyS (B-lymphocyte stimulator)/APRIL (a proliferation-inducing ligand) dual inhibitor, which has been approved in 2021 in China for the treatment of patients with active systemic lupus erythematosus (SLE)[1].
Objectives: To evaluate the efficacy and safety of telitacicept in patients with pSS.
Methods: In this phase 2, placebo-controlled study, 42 patients with active pSS (ESSDAI score ≥5) were randomized to 3 treatment arms: placebo (N=14), telitacicept 160 mg (N=14) and telitacicept 240 mg (N=14). Study drugs were administered subcutaneously weekly for 24 weeks. The primary endpoint was the change from baseline in the ESSDAI score at week 24. Key secondary endpoints included: ESSPRI, MFI-20, immunological biomarkers including IgG, IgA, IgM and CD19$^+$ B cells. Safety was assessed during the study.
Results: Baseline demographics and disease characteristics were similar among treatment arms. The ESSDAI score and MFI-20 score decreased from baseline through week 24 in telitacicept 160 mg and 240 mg groups (Figure 1A, 1B). Statistically significant improvements were observed for the ESSDAI score and MFI-20 score both at week 12 and week 24 in the telitacicept 160 mg group; statistically significant improvements were observed for the ESSDAI score at week 12 and MFI-20 score at both week 12 and week 24 in the telitacicept 240 mg group (Table 1). Telitacicept treatment produced rapid and sustained reductions in IgG, IgA, IgM and CD19$^+$ B cells (Figure 1C-F). Incidences of treatment-emergent adverse events (TEAEs) were comparable across treatment arms. Most of TEAEs were mild to moderate in severity. Serious adverse events (SAEs) were infrequent and occurred only in the placebo group. Upper respiratory tract infections were the most common infections. (Table 1)

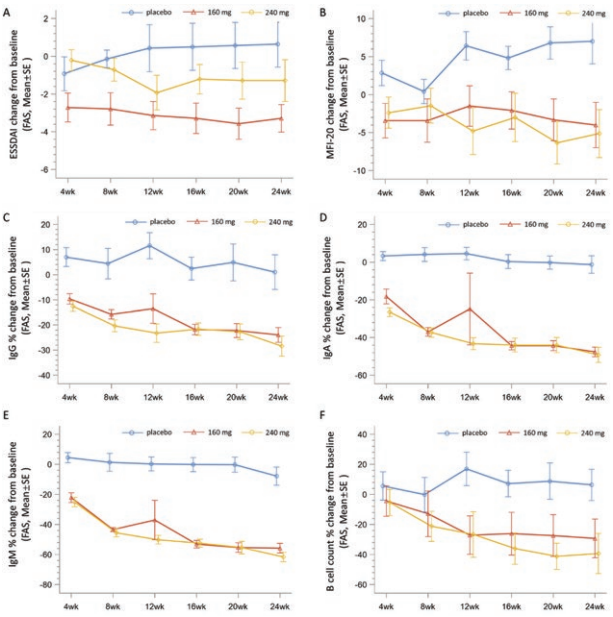

Figure 1. Change from baseline in ESSDAI (A) and MFI-20 (B). Percent (%) change from baseline in IgG (C), IgA (D), IgM (E) and CD19$^+$ B cells (F).

Table 1. Key efficacy and safety data.

Efficacy, FAS	Placebo (N=14)	Telitacicept 160 mg (N=14)	Telitacicept 240 mg (N=14)

EFFICACY AND SAFETY OF DAZODALIBEP (VIB4920/HZN4920) IN SUBJECTS WITH SJÖGREN'S SYNDROME: A PHASE 2, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PROOF OF CONCEPT STUDY

Keywords: Safety, Randomized control trial, Sjögren syndrome

E. W. St. Clair[1], L. Wang[2], I. Alevizos[3], W. Rees[4], A. Baer[5], W. F. Ng[6], G. Noaiseh[7], C. Baldini[8]. *[1]Duke University School of Medicine, Department of Medicine, Durham, United States of America*; *[2]Horizon Therapeutics plc, Biometrics, Rockville, United States of America*; *[3]Horizon Therapeutics plc, R&D Clinical Development, Rockville, United States of America*; *[4]Horizon Therapeutics plc, Research and Development, Rockville, United States of America*; *[5]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States of America*; *[6]Newcastle University, Translational and Clinical Research Institute, Newcastle, United Kingdom*; *[7]University of Kansas, Department of Medicine, Kansas City, United States of America*; *[8]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: Sjögren's syndrome (SS) is a chronic, systemic autoimmune disease affecting exocrine glands, primarily the salivary and tear glands, with potentially severe manifestations in multiple organs. No approved disease-modifying therapies exist. Dazodalibep (DAZ) is a biologic antagonist of CD40L.
Objectives: The objective of this study was to evaluate the efficacy and safety of DAZ therapy in adult SS subjects with moderate-to-high systemic disease activity (NCT04129164).
Methods: We conducted a randomized, double-blind, placebo-controlled, cross-over study to evaluate DAZ therapy in adult SS subjects with moderate-to-high systemic disease activity, as defined by a EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) score ≥ 5. Eligible subjects were randomized 1:1 to receive intravenous DAZ 1500 mg or placebo (PBO) Q2W x 3 doses, then Q4W x 4 additional doses. Starting on Day 169, subjects initially randomized to DAZ received PBO Q4W x 5 doses and subjects randomized to PBO received DAZ Q4W x 5 doses and were then followed for 12 weeks. The primary endpoint was the change from Baseline in ESSDAI at Day 169. Safety assessments included the incidence of adverse (AEs), serious AEs (SAEs), and AEs of special interest (AESIs).
Results: The 74 randomized subjects all received ≥1 dose of study medication (DAZ, N=36; PBO, N=38). The baseline demographics and disease characteristics were balanced between the two groups. The change from Baseline to Day 169 in ESSDAI score (LS mean ± SE), was -6.3 ± 0.6 in DAZ-treated subjects compared to -4.1 ± 0.6 in the PBO group, a difference of -2.2 (p = 0.0167). Compared to the PBO group, the DAZ group showed positive trends in the EULAR Sjögren's Syndrome Patient Reported Index score, and Functional Assessment of Chronic Illness Therapy-Fatigue score at Day 169. A post-hoc responder analysis of subjects achieving high levels (5 and 6 points) of improvement on ESSDAI favored DAZ (61.1% and 60.0%) over PBO (35.1% and 34.3%). The reported AEs were generally mild through Day 169 and similar in frequency between treatment groups. The most frequently reported AEs occurring in ≥5% of DAZ-treated subjects and >PBO were COVID-19, diarrhea, dizziness, ligament sprain, upper respiratory tract infection, contusion, device allergy, fatigue, hypertension, and oropharyngeal pain. Two SAEs were reported in a single DAZ-treated subject: this subject was a 59-year-old female who experienced a grade 3 SAE of COVID-19 infection and later died of unknown cause 46 days after last administration of DAZ (12 days after COVID-19 diagnosis). There was a single AESI of herpes zoster in a DAZ-treated subject.
Conclusion: DAZ is a potential new therapy for the treatment of systemic disease activity in patients with SS. SS subjects with moderate-to-high systemic disease receiving DAZ experienced a statistically significant reduction in disease activity relative to PBO as measured by the improvement in ESSDAI score. Except for a case of severe COVID-19 infection, DAZ therapy in SS subjects appeared to be well tolerated. Larger controlled trials of DAZ therapy for SS are warranted to further explore its safety profile and confirm its clinical efficacy.

Background: Healthy lifestyles are thought to reduce the risk of multiple causes of mortality in general population. However, whether and to what kind of healthy lifestyles could offset the risk of multiple causes of mortality in patients with osteoarthritis (OA) are unknown.

Objectives: This study aimed to investigate the association of both individual and combined healthy lifestyle factors with the risk of all-cause and cause-specific mortality among participants with OA.

Methods: 104,142 OA participants were included from the UK Biobank (mean age 60±7.0). A summed healthy lifestyle score was constructed using body mass index (BMI) and self-reported diet, sleep duration, physical activity, sedentary time, social connection, smoking and alcohol drinking. Restricted cubic spline (RCS) and Cox proportional hazards models were used to examine the associations of individual factors and a combined healthy lifestyle score with the risk of all-cause and cause-specific mortality.

Results: During a median follow-up of 12.7 years, 9915 deaths after the first two years follow-up were recorded. Using RCS models, sleep duration had a U-shaped (with a nadir at 7 h/day), moderate physical activity (MPA) had an L-shaped (with a turning point at 550 min/week), while BMI and vigorous physical activity (VPA) had J-shaped (with turning points at 28 kg/m^2 and 240 min/week respectively) associations with all-cause mortality. In multivariable Cox models, each lifestyle factor was significantly associated with all-cause mortality, and hazard ratios (95%CI) associated with newly constructed healthy lifestyle score (scoring 7-8 vs. 0-2) were 0.29 (0.25-0.35) for all-cause mortality, 0.40 (0.32-0.50) for cancer-cause mortality, 0.22 (0.17-0.30) for cardiovascular disease mortality, 0.27 (0.16-0.48) for digestive-cause mortality and 0.18 (0.12-0.25) for respiratory mortality.

Conclusion: This study introduced a healthy lifestyle pattern that could significantly reduce the risk of all-cause and cause-specific mortalities in OA patients.

ASSOCIATION OF HEALTHY LIFESTYLE, GENETIC SUSCEPTIBILITY AND INCIDENCE OF OSTEOARTHRITIS: A NATIONAL PROSPECTIVE COHORT STUDY

Keywords: Lifestyles, Osteoarthritis, Genetics/Epigenetics

S. Chen[1], Y. Zhang[2], T. Fan[1], M. Zeng[1], J. LI[3], G. Ruan[1,4], P. Cao[1], Y. Zhang[1], X. Shi[1], X. Fang[1], H. Yang[1], Q. Yang[5], C. Ding[1,6], Z. Zhu[1,7]. [1]*Southern Medical University, Clinical Research Centre, Zhujiang Hospital, Guangzhou, China*; [2]*Southern Medical University, Department of Epidemiology, School of Public Health, Guangzhou, China*; [3]*Southern Medical University, Division of Orthopaedic Surgery, Department of Orthopaedics, Nanfang Hospital, Guangzhou, China*; [4]*Guangzhou First People's Hospital, Clinical Research Centre, Guangzhou, China*; [5]*University of Bristol, MRC Integrative Epidemiology Unit, Bristol, United Kingdom*; [6]*University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*; [7]*Southern Medical University, Department of Orthopaedics, Zhujiang Hospital, Guangzhou, China*

Background: Osteoarthritis (OA) is the commonest arthritis worldwide and affects approximately 7% of the global population[1]. Previous studies reported that stick to a healthy lifestyle could reduce the risk of OA[2]. However, whether and to what extent people with different genetic susceptibility of OA could benefit from a healthy lifestyle is still unknown.

Objectives: We aimed to detect the association between healthy lifestyle, genetic susceptibility and incident OA in the UK biobank study.

Methods: After excluding participants with missing data and performing multiple imputation, we included 317884 participants from UK biobank. Lifestyle factors included body mass index (BMI), diet, physical activity, sleep behavior and sedentary behavior. BMI lower than 30 kg/m2 was defined as healthy status. At least

4 of 7 healthy dietary components was defined as healthy diet. Medium level of physical activity (270-660 min/week) was classified as a healthy physical activity for OA. Healthy sleep behaviors were defined as sleep 7–8 h/day. Sedentary time less than 4 hours was regarded as low risk status. The healthy lifestyle score was constructed as the sum of five lifestyle factors, ranging from 0 to 5 and was subsequently categorized into three groups including unfavorable, intermediate and favorable (0–1, 2-3 and 4–5). Genetic susceptibility was calculated by using polygenic risk score (PRS) of OA. Specifically, individual single nucleotide polymorphism (SNP) was coded as 0, 1, and 2 according to the number of risk alleles. The coefficient of significant SNPs of OA reported in previous Genome Wide Association Studies (GWAS) were regarded as weight of genotype of each SNPs. Participants with OA were identified as having a diagnosis using ICD-9 and ICD-10 codes for total/ knee/ hip OA, or were identified as self-reported total/ knee/ hip OA at baseline. Covariates included age, sex, household income, education, deprivation index, glucosamine use and comorbidities. Cox regression analyses were performed to examine the association of healthy lifestyle, genetic susceptibility and incident OA.

Results: Comparing to unfavorable lifestyle, favorable lifestyle was significantly associated with a lower risk of total OA across low, intermediate and high genetic risk groups (HR, 0.64; 95%CI, 0.58-0.70; HR, 0.59; 95%CI, 0.56-0.63 and HR, 0.58; 95%CI, 0.53-0.64, respectively). Favorable lifestyle was also significantly associated with lower risk of knee OA across low, intermediate and high genetic risk groups (HR, 0.40; 95%CI, 0.33-0.48, HR, 0.47, 95%CI, 0.42-0.51 and HR, 0.45; 95%CI, 0.39-0.53, respectively). For hip OA, adherence to favorable lifestyle was also significantly associated with lower risk of OA incidence across low, intermediate and high genetic risk groups (HR, 0.75; 95%CI, 0.62-0.92, HR, 0.65, 95%CI, 0.58-0.72 and HR, 0.75; 95%CI, 0.65-0.88, respectively), compared to unfavorable lifestyle. No significant interaction was detected between lifestyle and PRS for total/ knee/ hip OA.

Conclusion: These data suggest that healthier lifestyle is consistently associated with lower risk of OA, regardless of genetic risks. Our findings highlight the importance of adherence to an overall healthy lifestyle in attenuating the risk of OA.

Background: Osteoarthritis (OA) is a common musculoskeletal disease [1]. Research evidence indicates that exercise can reduce OA patients' joint pain to an extent [2]. However, the genetic causal relationship between physical activity (PA) and OA remains vague.

Objectives: In our study, Mendelian randomization (MR) was conducted to explore the causal assosiation of PA and OA.

Methods: PA was divided into two different phenotypes, including sedentary behavior and physically active behavior. Genome-wide association study (GWAS) data for PA [3] was obtained from the UK Biobank. We selected single nucleotide polymorphisms (SNPs) that were strongly associated ($p < 5 \times 10-8$) with two PA phenotypes and checked them on PhenoScanner removing SNPs associated with confounders. The OA data was derived from a GWAS among 455,221 individuals (77052 samples and 378169 controls) of European descent [4]. To assess the causality of PA on OA, inverse variance weighting (IVW), MR-Egger, and weighted median (WM), were employed. IVW was applied for the principal analysis. To ensure the robustness of our result, Cochran's Q test, MR-Egger intercept test, and leave-one-out analysis were used to assess the sensitivity of the study.

Results: Among the tested sedentary behavior, the length of mobile phone use increases the risk of knee OA (odds ratio (OR):1.560, 95% confidence interval (CI):1.167-2.086, p=2.683×10-3) and hip or knee OA (OR:1.334, 95%CI:1.026-1.734, p=3.141×10-2). After removing SNPs associated with smoking, alcohol consumption, lymphocyte count, and heart disease, we also found evidence of a potential adverse effect of genetically predicted time spent watching television (TV) on knee OA (OR:1.913, CI:1.450-2.523, p=4.388×10-6) and hip or knee OA (OR:1.611, 95%CI:1.288-2.014, p=2.860×10-5). No potential causal link was observed between physically active behavior and OA through the IVW analysis(p>0.05). MR-Egger and WM yielded identical effects to IVW. Any potential heterogeneity or pleiotropy was not found.

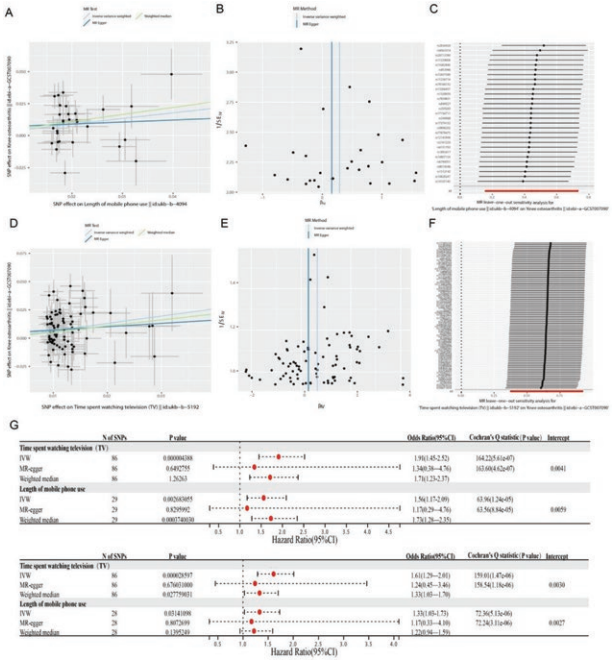

Figure 1. The causal associations between physical activity (PA) and osteoarthritis (OA) were evaluated by the odds ratio (OR) values of IVW, MR-Egger, and WM. Scatter plots (A), funnel plots (B), and leave-one-out plots (C) assessed the length of mobile phone use on the risk of OA. Scatter plots (D), funnel plots (E), and leave-one-out plots (F) assessed the time spent watching television (TV) on the risk of OA. Forest plot (G) of association between PA and OA

Conclusion: Sedentary behavior can increase the risk of OA, but no direct causal relationship is observed between physically active behavior and OA. It indicates that OA patients should avoid a sedentary lifestyle.

COMPARED TO PEOPLE WHO NEVER SMOKED, CURRENT SMOKERS BUT NOT FORMER SMOKERS HAVE WORSE KNEE OSTEOARTHRITIS SYMPTOMS AND STRUCTURAL DEFECTS: INDIVIDUAL PARTICIPANT DATA META-ANALYSES OF MULTI-COHORT DATA

Keywords: Osteoarthritis

Z. Salis[1], A. Sainsbury-Salis[2]. [1]*UNSW Sydney, Centre for Big Data Research in Health, Sydney, Australia*; [2]*The University of Western Australia, School of Human Sciences, Perth, Australia*

Background: As smoking causes inflammation, and inflammation is implicated in the development of osteoarthritis, it is conceivable that smoking would have negative effects on knee osteoarthritis (KOA). However, results from prior studies are controversial and unclear, with some studies even finding that smoking protects against KOA.

Objectives: To describe the association between smoking and KOA (symptoms and structural defects) in people with or at risk of KOA in a multi-cohort study using individual participant data (IPD) meta-analyses, which are considered the 'gold standard' for the synthesis of quantitative evidence.

Methods: We performed IPD meta-analyses using data from three independent cohorts: the Osteoarthritis Initiative (OAI) and the Multicenter Osteoarthritis Study (MOST) from the USA; and the Cohort for Hip and Cohort for Knee (CHECK) from the Netherlands. We assessed the association between smoking status at baseline (never smokers; current smokers; and former smokers) and the outcomes of symptoms and structural defects in KOA, either cross-sectionally at baseline or longitudinally over 4 to 5 years of follow-up. For symptoms, we assessed pain, disability, and stiffness using the Western Ontario and McMaster Universities Arthritis Index (WOMAC). For structural defects, we assessed overall structural defects and three individual structural features (i.e., joint space narrowing; osteophytes on the femoral surface; and osteophytes on the tibial surface), on both the lateral and medial sides of the knee, from radiographs. Overall structural defects were assessed using Kellgren-Lawrence (KL) grades. A knee with a KL grade ≥ 2 is considered to have 'radiographic KOA'. The three individual structural features were assessed using Osteoarthritis Research Society International (OARSI) grades.

Results: We investigated 14,470 knees from 7,304 participants for the outcomes of symptoms, and 12,337 knees from 6,455 participants for the outcomes of structural defects. In our cross-sectional analyses, compared to never smokers, current smokers had baseline scores for pain, disability, and stiffness that were greater by 1.01 (95% confidence interval [CI] 0.60 to 1.41) units, 3.62 (95% CI 2.04 to 5.20) units, and 0.42 (95% CI: 0.29 to 0.54) units, respectively. In contrast, former smokers had baseline scores for pain, disability, and stiffness that were no different from those of never smokers (with differences in scores being 0.11 95% CI: -0.08 to 0.29 units; -0.09 95% CI: -1.14 to 0.97 units; and 0.06 95% CI: -0.08 to 0.20 units, respectively). In terms of structural defects, our cross-sectional analyses showed that neither current smokers nor former smokers were any worse than never smokers with respect to grades for overall structural defects or individual structural features. However, compared to never smokers, current smokers had greater odds of having radiographic KOA (odds ratio [OR] 1.25 95% CI: 1.02 to 1.52), while former smokers were no different from never smokers for this outcome (OR 0.91 95% CI: 0.83 to 1.01). In our longitudinal analyses, compared to never smokers, only one outcome showed a difference between groups. Specifically, current smokers had greater odds of degeneration of the individual structural feature of joint space narrowing on the medial side of the knee over 4 to 5 years of follow-up (OR 1.27 95% CI: 1.01 to 1.60), while former smokers were no different from never smokers for this outcome (OR 1.02 95% CI: 0.84 to 1.24).

Conclusion: Current smoking may have negative effects on, and quitting smoking could be important in preventing or slowing, both the symptoms and structural defects of KOA in people with or at risk of KOA.

OP0148

ASSOCIATIONS OF CHANGES IN BODY COMPOSITION MEASUREMENTS WITH RADIOGRAPHIC PROGRESSION OF HAND OSTEOARTHRITIS: DATA FROM THE DONG-GU STUDY

Keywords: Osteoarthritis

D. J. Park[1], S. E. Choi[1], J. H. Kang[1], S. S. Lee[1]. [1]Chonnam National University Medical School and Hospital, Rheumatology, Gwangju, Korea, Rep. of (South Korea)

Background: Previous studies have found that obesity is a risk factor for hand osteoarthritis (OA), but most have been cross-sectional studies and thus causality is uncertain. Longitudinal studies are instead needed to explore the association between obesity-related characteristics, including fat deposition/distribution and hand OA.

Objectives: The present study examined the association between changes in body composition measurements and the radiographic progression of hand OA in a longitudinal cohort.

Methods: In the Dong-gu Study population, 1,277 patients had hand radiographs at baseline and at the 6-year follow-up. X-rays of the hand joints were scored using a semi-quantitative grading method. Body composition was simultaneously measured in a bioelectrical impedance analysis using an InBody 520 analyzer. The relationship between changes in body composition measurements and the radiographic progression of hand OA was assessed in a multiple linear regression analysis.

Results: Total hand joint scores increased from 16.3 ± 5.74 at baseline to 18.8 ± 8.11 at year 6 ($P < 0.001$). Changes of body mass index, hip circumference (HC), waist-to-hip circumference (WHC), and fat mass were significantly associated with changes in the total hand joint scores ($P = 0.012$, $P < 0.001$, $P = 0.017$, $P = 0.008$, respectively). HC and WHC were significantly associated with radiographic progression of the hand joints, after adjusting for age, sex, physical activity, education status, smoking, alcohol consumption, hypertension, diabetes mellitus, dyslipidemia, chronic pulmonary disease, chronic liver disease, cardiovascular disease, cerebrovascular disease, and malignancy ($P < 0.001$, $P = 0.001$, respectively).

Conclusion: Changes in fat distribution were significantly associated with the radiographic progression of hand OA over 6 years, suggesting a role for the systemic effect of adipose tissue.

BIOMARKERS PROFILING IN OSTEOARTHRITIS PATIENTS WITH AND WITHOUT CHRONIC POSTOPERATIVE PAIN 5 YEARS AFTER TOTAL KNEE REPLACEMENT

Keywords: Pain, Diagnostic Tests, Biomarkers

L. Arendt-Nielsen[1], R. Giordano[2], C. Capriotti[2], M. C. Gerra[3], C. Dallabona[3], K. Kjær Petersen[2]. [1]*Aalborg University/Aalborg University Hospital, Center for Neuroplasticity and Pain, Gistrup, Denmark*; [2]*CNAP/SMI, School of Medicine, Aalborg, Denmark*; [3]*University of Parma, Dipartimento di Genetica, Parma, Italy*

Background: Knee osteoarthritis (KOA) is a pathological condition prevalent in the general population. Exercise and pharmaceutical approaches are first-line treatments and the end-stage treatment is total knee replacement (TKR). Interestingly, around 20% of patients experience chronic postoperative pain and the reason for this is not fully understood. Pain in OA is multifactorial and low-grade chronic inflammation has been indicated as a potential cause. Pre-clinical evidence suggests that pro-inflammatory mediators, such as interleukin 6, can sensitize the peripheral and central nerves and these molecules might be associated to clinical pain. Clinical evidence has demonstrated differences in pro-inflammatory mediators when comparing patients with OA and healthy

individuals. A recent study has linked these profiles to chronic postoperative pain after TKR but an in-depth analysis, as seen for neuropathic and widespread pain is needed to advance the field. Currently, no specific biomarkers have been identified, despite initiatives on focused molecular inflammatory mediators. In an attempt to advance the field, a comprehensive analysis of an extensive network of cytokines, chemokines, and growth factors could identify the role of low-grade inflammation in patients with OA and potentially stratify patients more prone to experiencing pain.

Objectives: This study aimed 1) to evaluate preoperative serum levels of 92 inflammatory biomarkers in KOA patients compared to healthy controls, 2) to investigate preoperative differences of inflammatory biomarkers within different subgroups of patients with KOA and link these subgroups to clinical pain before and after TKR surgery.

Methods: Blood samples from preoperative patients with KOA scheduled for TKR (n=200) and healthy participants (n=39) were collected. After centrifugation of the serum was frozen at -80C until analysis. Serum samples were analyzed for inflammatory markers using the OLINK inflammation panel, which included 92 protein markers. Clinical pain was assessed using a Visual Analog Scale (VAS). Moreover, patients completed the Knee injury and Osteoarthritis Outcome Score (KOOS) questionnaire before and 12 months after TKR. Multivariate data analysis was performed to identify differences between patients and controls. Hierarchical cluster analysis (HCA) and Orthogonal Partial least squares discriminant analysis (OPLS-DA) was used for comparing groups (patients vs controls) and to identify subgroups within patients. T-tests were used to evaluate difference within the KOA cohort in terms of VAS and KOOS scores before and 12 months after TKR.

Results: Multivariate analysis showed that 12 proteins were differentially expressed between patients and controls (P<0.05). Hierarchical cluster and OPLS-DA analysis identified two patient subgroups (pat-1, n = 46; pat-2, n= 72) and 23 proteins were dysregulated comparing these two groups (p<0.01). Postoperative VAS and KOOS assessments were significantly different between the two subgroups (p-<0.05).

Conclusion: The present study suggest a low-grade inflammation in patients with KOA when compared to healthy pain free subjects. Additionally, this study suggests that a high inflammatory subgroup for patients with KOA exist and this group is likely to have more clinical and worst function 12-months after TKR.

OP0150 LONG-TERM EFFECTIVENESS OF A LIFESTYLE PROGRAM FOR OSTEOARTHRITIS: ONE-YEAR FOLLOW-UP OF THE "PLANTS FOR JOINTS" RANDOMIZED CLINICAL TRIAL

Keywords: Osteoarthritis, Non-pharmacological interventions, Diet and Nutrition

C. Wagenaar[1,2], W. Walrabenstein[1,2,3], M. Van der Leeden[1,4,5], M. Gerritsen[1], J. Twisk[6], M. Van der Esch[1,7], H. Van Middendorp[8], P. Weijs[3,9], D. Van Schaardenburg[1,2]. [1]*Reade, Rheumatology, Amsterdam, Netherlands*; [2]*Amsterdam UMC, locatie AMC, Rheumatology & Immunology, Amsterdam, Netherlands*; [3]*Amsterdam University of Applied Sciences, Department of Nutrition and Dietetics, Amsterdam, Netherlands*; [4]*Amsterdam UMC, locatie VUmc, Rehabilitation medicine, Amsterdam, Netherlands*; [5]*Amsterdam Movement Sciences Research Institute, Movement Sciences, Amsterdam, Netherlands*; [6]*Amsterdam UMC, locatie VUmc, Epidemiology and Data Science, Amsterdam, Netherlands*; [7]*Amsterdam University of Applied Sciences, Faculty of Health, Amsterdam, Netherlands*; [8]*Leiden University, Institute of Psychology, Health, Medical, & Neuropsychology unit, Leiden, Netherlands*; [9]*Amsterdam UMC, locatie VUmc, Department of Nutrition and Dietetics, Amsterdam, Netherlands*

Background: The 16-week Plants for Joints (PFJ) multidisciplinary lifestyle program, based on a whole-food plant-based diet, physical activity, and stress management, significantly reduced The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) score compared to usual care in patients with knee and/or hip osteoarthritis (OA) and metabolic syndrome.[1,2]

Objectives: To determine the long-term effectiveness of the PFJ program on pain, stiffness, and function in patients with OA.

Methods: In the PFJ randomized clinical trial, patients with knee and/or hip OA and metabolic syndrome were randomized to receive the PFJ program in addition to usual care, or the control group which received usual care. After this 16-week period the control group also received the PFJ program. After completion of the PFJ program all participants were followed-up for one year with biannual visits and 6 adherence-promoting webinars. Medication changes were assessed at one year as an "increase," "stable," or "decrease" compared to baseline. The primary outcome was pain, stiffness, and function assessed by the WOMAC. Secondary outcomes included anthropometric and metabolic markers. A paired sample T-Test was used to determine the significance of the difference in outcomes at the start of the intervention versus at 1-year follow-up.

Results: Of the 64 participants who completed the initial 16-week clinical trial 84% were female with a mean (SD) age of 63 (6) and body mass index of 33 (5) kg/m² at baseline. The 47 (73%) participants who completed the one-year follow-up had a slightly greater average change in WOMAC score (–11.4 vs. –11.0), weight (–5.3 vs. –3.7 kg), and CRP (–1.2 vs. –0.2 mg/l) compared to non-completers, but showed less improvement in HbA1c (–2.1 vs. –2.9 mmol/mol). After a decrease during the PFJ program, the WOMAC score increased slightly again in the year after the program, whereby a mean 8.8-point difference was still observed after one year for completed cases compared to baseline values (95% CI 13.6 to 4.0; $p < 0.01$) (Figure 1). All components of the WOMAC remained significantly improved compared to before the program except for stiffness (Table 1). Of the 24 (38%) participants using pain medication at baseline, 11 (46%) were able to decrease the dosage or stop one or more medications. Pain medication was stable for 3 participants, and increased for 3, of which 1 newly started using medication. Furthermore, 3 (23%) and 8 (33%) participants decreased diabetes and cholesterol medication respectively while only 1 participant increased cholesterol medication. After the 1-year follow-up period weight and HbA1c remained significantly lower compared to baseline, although there was no longer a significant difference in CRP and LDL cholesterol.

Conclusion: The PFJ lifestyle program significantly decreased pain and improved function in patients with OA and metabolic syndrome and its effects were sustained until one year after program completion, with slightly less pain medication. Metabolic benefits found after the lifestyle intervention were partially sustained possibly indicating attenuated adherence to the lifestyle program in the 1-year follow-up.

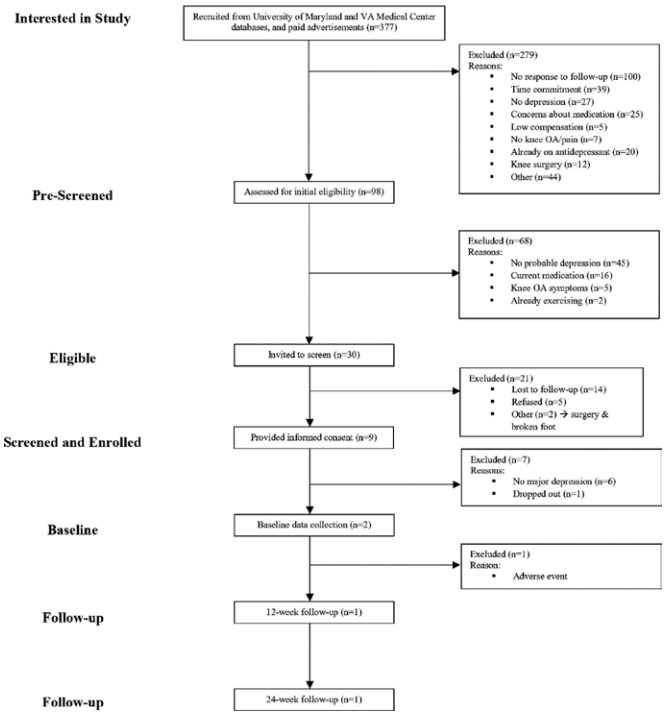
DULOXETINE PLUS EXERCISE FOR KNEE OSTEOARTHRITIS AND DEPRESSION (DEKODE)

Keywords: Non-pharmacological interventions, Mental health, Comorbidities

A. Rathbun[1], R. Mehta[1], A. Ryan[2], Y. Dong[3], B. Beamer[2], J. Golden[1], J. Gallo[4], M. Luborsky[5], M. Shardell[1], J. Peer[3], M. Hochberg[2]. [1]*University of Maryland School of Medicine, Epidemiology and Public Health, Baltimore, United States of America*; [2]*University of Maryland School of Medicine, Medicine, Baltimore, United States of America*; [3]*University of Maryland School of Medicine, Psychiatry, Baltimore, United States of America*; [4]*John Hopkins Bloomberg School of Public Health, Mental Health, Baltimore, United States of America*; [5]*Wayne State University, Anthropology, Detroit, United States of America*

Background: Depression is common in patients with knee OA, and clinical guidelines do not advise treating both conditions simultaneously. However, recent research recommends combining interventions that address symptoms of both conditions to maximize efficacy. Exercise improves pain, disability, and mood, but chronic pain and depression are barriers to physical activity in this population. Duloxetine is indicated to treat neuropathic pain and depression among knee OA patients and could serve as a therapeutic complement to exercise.



Objectives: To assess the feasibility of a 24-week, center-based, aerobic exercise program, plus duloxetine to treat knee OA and depression.

Methods: Participants were recruited between August 2021 and November 2022 from the University of Maryland and VA Maryland Health Care Systems and study advertisements. Inclusion criteria were: English speaking; age 40 years or older; symptomatic knee OA satisfying ACR criteria; major depression according to the SCID-5 (Structured Clinical Interview for DSM-V, ruling out history of bipolar disorder or psychotic symptoms; substance abuse disorder or suicidal ideation in the last year); no plans for knee surgery; and ability to walk on a treadmill. Exclusions included: exercising at least twice per week; taking duloxetine, antipsychotics, benzodiazepines, or opioid analgesics; cognitive impairment; comorbidity precluding exercise; and pregnant or lactating women. Participants began duloxetine (30 mg/day) as they started exercising, titrating up to a daily optimal dose of 60 mg/day. They were expected to complete 3 supervised treadmill walking sessions per week based on an individualized training plan defined by peak heart rate achieved during a graded exercise test. Data were collected at baseline and 12- and 24-weeks. Feasibility was evaluated via recruitment rates, reasons for drop out, and treatment adherence. Depression and pain severity were measured using the Hamilton Depression Rating Scale (HAM-D) and Knee Injury and Osteoarthritis Outcome Score (KOOS) pain subscale, respectively.

Results: Among 377 interested adults, 98 completed telephone pre-screening (Figure 1). Common reasons for not pre-screening included time commitment (n=39), no depression (n=27), concerns about medication (n=25), already on antidepressants (n=20), and knee surgery (n=12). There were 68 ineligible prescreened individuals who did not satisfy criteria for probable depression (n=45), medications (n=16), knee OA symptoms (n=5), or exercise (n=2). The 30 eligible candidates were invited to in-person screening visits, but 21 did not attend, and only 9 were enrolled. These 9 participants were older women (mean age=64.7 years), 8 identified as Black/African American, 7 attended and/or graduated from college, 3 were married, and 4 were retired. During the in-person screening process, 6 participants did not satisfy DSM-V criteria for major depression, 1 voluntarily withdrew from the study, and only 2 satisfied all eligibility criteria. One participant withdrew at baseline due to a non-study related adverse event and another completed the treatment protocol. The participant who completed the study was almost 100% adherent to duloxetine and experienced a reduction in depression severity from baseline to 24 weeks (HAM-D=25 to 1). By contrast, exercise compliance was low, with only 26% of planned sessions completed, and knee pain severity changed little from baseline (KOOS=41.7 to 44.4).

Conclusion: Treating knee OA and depression with a center-based exercise program and duloxetine had low feasibility. Critical design challenges amenable to change included the time commitment of 3 weekly supervised exercise sessions among interested individuals and depressive symptoms not satisfying diagnostic criteria for major depression for persons who wanted treatment. A hybrid or home-based exercise program plus duloxetine may be more feasible, and knee OA patients with depressive symptoms who are at risk for major depression could benefit from preventive intervention.

DIAGNOSTIC PERFORMANCE OF HIP ULTRASOUND IN CALCIUM PYROPHOSPHATE DEPOSITION DISEASE

Keywords: Ultrasound, Validation, Crystal Arthritis

C. Soto[1], S. Y. Solorzano Flores[1], F. Carranza-Enriquez[1], A. Angeles-Acuna[1], P. Flores[1], V. M. Ilizaliturri-Sanchez[2], R. Pichardo[3], L. J. Jara[1], D. Clavijo-Cornejo[1], G. Filippou[4], C. Pineda[1]. [1]*Instituto Nacional de Rehabilitacion, Rheumatology, Mexico City, Mexico*; [2]*Instituto Nacional de Rehabilitacion, Joint Replacement, Mexico City, Mexico*; [3]*Instituto Nacional de Rehabilitacion, Pathology, Mexico City, Mexico*; [4]*Luigi Sacco University Hospital, Rheumatology, Milan, Italy*

Background: Calcium Pyrophosphate Deposition Disease (CPPD) is a chronic and potentially incapacitating disease. The reference standard for its diagnosis is the identification of calcium pyrophosphate (CPP) crystals in synovial fluid. Ultrasound (US) has been proven to be a high-sensibility and specificity tool for diagnosing CPPD. Still, its diagnostic performance for hip joint involvement has yet to be determined.

Objectives: To evaluate the diagnostic performance of US compared with synovial fluid analysis and histopathology (hyaline cartilage, fibrocartilage, synovial membrane) for the identification of hip CPP deposits.

Methods: We included patients older than 50 years with osteoarthritis programmed for hip replacement surgery in a tertiary referral hospital. Patients with an inflammatory or autoimmune rheumatologic disease were excluded. A pre-surgical US of the affected hip was performed with a LOGIQ™e device and a convex transducer (2-5 MHz); the anatomical structures evaluated were the acetabular fibrocartilage (FC) and the hyaline cartilage of the femoral head (HC), video tracking was recorded and a dichotomic score was assigned to determine the presence or absence of CPP deposits (in line with OMERACT definitions). During surgery, a sample of hip synovial fluid was obtained and examined using polarized light microscopy. After surgery, an experimented pathologist examined the FC and HC for CPP crystals.
Results: One hundred patients were included. 54% women with a mean age of 64.8±8.5 years. All patients had advanced osteoarthritis (Kellgren-Lawrence 3 = 33 and Kellgren-Lawrence 4=67; Tönnis 2= 34 and Tönnis 6= 66). A frequency of 62% CPP deposits was found through US examination, of which 19.4% were found on FC, 46.8% on HC, and 33.8% in both. Regarding pathology evaluation, a prevalence of 61% of CPP crystals was found; 13.1% were found on FC, 9.8% were found on HC, and 77.1% were found in both. 33% of patients had synovial effusion and 9% had synovial hypertrophy. Synovial fluid was obtained in 62% of patients, with a median volume of 0.8mL (IQR 0.5-1.5mL), and CPP crystals were found in 19.4% (12/62) of samples. Chondrocalcinosis in XR was found in 10%. A sensitivity of 90% and a specificity of 82% were obtained, the positive predictive value was 89%, and the negative predictive value was 84%. The area under the curve for the US compared with histopathology for the diagnosis of hip CPPD was 0.86 (CI 95% 0.78-0.94) (Figure 1).
Conclusion: US is a valid imaging method with good diagnostic performance for diagnosing CPPD in the hip joint.

DEVELOPMENT OF A PROVISIONAL SELF-REPORTED DEFINITION FOR ACUTE CALCIUM PYROPHOSPHATE CRYSTAL ARTHRITIS: PRELIMINARY RESULTS OF A MULTICENTRE STUDY

Keywords: Crystal arthritis, Outcome measures, Patient reported outcomes

E. Cipolletta[1,2], M. Andrés[3], S. Ottaviani[4], T. Pascart[5], I. Calabuig[3], S. Gomez-Sabater[3], R. Caño-Alameda[3], B. Leger[4], A. Pacaud[5], E. Moscioni[1], P. Muto[6], V. Caira[7], C. Bruno[8], D. Rozza[9], G. Carrara[9], A. Zanetti[9], A. Abhishek[2], E. Filippucci[1]. *[1]Polytechnic University of Marche, Department of Clinical and Molecular Sciences, Ancona, Italy*; *[2]University of Nottingham, Academic Rheumatology, Nottingham, United Kingdom*; *[3]Dr Balmis General University Hospital-ISABIAL, Department of Rheumatology, Alicante, Spain*; *[4]Hôpital Bichat APHP Paris Nord and Université de Paris, Department of Rheumatology, Paris, France*; *[5]Saint-Philibert Hospital, Lille Catholic University, Department of Rheumatology, Lille, France*; *[6]Ospedale San Francesco di Paola, Rheumatology Unit, Cosenza, Italy*; *[7]Ospedale Ferrari Castrovillari, Rheumatology Unit, Cosenza, Italy*; *[8]Ospedale Pugliese-Ciaccio, Rheumatology Unit, Catanzaro, Italy*; *[9]Italian Society of Rheumatology, Epidemiology Research Unit, Milan, Italy*

Background: Acute calcium pyrophosphate (CPP) crystal arthritis is a common clinical presentation of CPP deposition (CPPD) disease, and recurrent episodes occur in 25% of patients with CPPD disease [1]. Although recent studies have evaluated the short-term efficacy of different drugs in acute CPP crystal arthritis [2-4], future studies would focus on reducing the frequency of these episodes in the long-term.
Objectives: To develop a patient-reported definition for acute CPP crystal arthritis in patients with CPPD disease.
Methods: Consecutive patients with a crystal-proven diagnosis of CPPD disease were enrolled in a cross-sectional study during routine inpatient and outpatient clinical care at five centres from France, Italy, and Spain. Patient-reported questions on the features of acute CPP crystal arthritis as per the OMERACT CPPD Working Group were evaluated by a rheumatologist [5]. The opinion of a second expert rheumatologist was the gold standard. Synovial fluid (SF) leukocyte count >2,000 cells/mcl was the reference standard in a sensitivity analysis. Definitions based on the number of criteria independently associated with acute CPP crystal arthritis and classification and regression tree approaches were developed.
Results: Data for 164 patients with CPPD disease were included. Their mean age was 71.8 years (SD 10.7 years), 104 (63.4%) were female. At the time of the assessment, 60/164 (36.6%) participants had acute CPP crystal arthritis, 25 (15.2%) had chronic inflammatory CPP crystal arthritis and 79 (48.2%) OA+CPPD according to the experts. SF was available in 44/164 (26.8%) participants, and 24/44 (54.6%) had a leukocyte count >2,000 cells/mcl in the SF. Patient-reported warm joint, patient-reported swollen joint, time from the pain-onset to-peak-pain (<48 hours), and patient-reported acute CPP crystal inflammatory arthritis were independently associated with the reference standard in multivariate analysis (Table 1). The greatest discriminating power was noted for the presence of 3 or more of the above 4 criteria [sensitivity 86.7% (95%CI: 75.4%-94.1%) and specificity 88.5% (95%CI: 80.7%-93.9%)] in the main analysis. The sensitivity and specificity of this definition using the SF as the gold standard were 83.3% (62.6%-95.3%) and 85.0% (62.1%-96.8%) (Figure 1). A classification tree identified patient-reported warm joint, followed by patient-reported inflammatory arthritis as the most informative variables for identifying acute CPP crystal arthritis [sensitivity 80.0% (95%CI:67.7%-89.2%) and specificity 90.4% (95%CI:83.0%-95.3%)].
Conclusion: Provisional self-reported definitions for acute CPP crystal arthritis in patients with CPPD were developed. The next step in the development of these criteria will be external validation.

OP0154

TOPHI AND CAROTID PLAQUE WERE RISK FACTORS OF MACE IN GOUTY ARTHRITIS PATIENTS: A LONGITUDINAL COHORT STUDY

Keywords: Ultrasound, Real-world evidence, Gout

Y. Wang[1], Z. Zhang[1]. [1]First Hospital of Peking University, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: Patients with gout carry an excess risk for cardiovascular disease (CVD). However, the prevalence of subclinical arthrosclerosis and its relationship with CVD risks and events in gout have not been reported.
Objectives: The objective of this study is to explore whether tophi and subclinical atherosclerosis could predict incident MACE (major adverse cardiac events) in gouty arthritis patients by ultrasonography. Determine whether incorporation of imaging data could improve CV(cardiovascular) risk prediction.
Methods: A single-center, cohort analysis was performed to assess subclinical artheroscelrosis at baseline since 2008. Patients were excluded if they had previous diagnosed CVD or cerabral vascular disease. The outcome of study was first MACE. The presence of subclinical atherosclerosis was assessed by cartoid intima-media thickness (CMIT) and total plaque area (TPA) was determined in a subgroup of patients by ultrasound. Scan of feet and ankles was performed bilaterally by ultrasonography at baseline. The association between tophi, measurements of carotid artherosclerosis and risk of developing and incident MACE was evaluated using Cox proprotional hazards models, with adjustment for the CVD risk scores.
Results: A total of 262 consecutive patients with primary gout were recruited, the mean age was 44.0 years; male 260 (99.2%). After a median follow-up of 10.3 years, 32 (12.2%) had incident MACE ascertained. Cox analysis showed that more than 2 tophi was significantly associated with an increased risk of develping MACE (HR: 9.96, 95%CI 8.89-43.6, *P*=0.001). The association remained significant after adjusting for CV risk scores in the multivariable models. In subgroup analysis, 240 patients had carotid ultrasound assessment, 28 (11.7%) patients experienced a first MACE event. In cox hazards model, which controlled for the CV risk scores, more than 2 tophi (HR 2.12-5.25, *P*<0.05) and and carotid plaque (HR 3.72-4.01, *P*<0.05), were both independent predictor of incident MACE in patients with gout seperately.
Conclusion: The presence of more than 2 tophi and carotid plaque by ultrasound could independently predict MACE in addition to conventional cardiovascular risk factors in gout patients.

CLINICAL IMPACT OF CARDIOVASCULAR MONOSODIUM URATE DEPOSITS MEASURED BY DUAL ENERGY COMPUTED TOMOGRAPHY: A RETROSPECTIVE EVALUATION

Keywords: Gout, Cardiovascular disease, Imaging

J. Held[1], C. Schwabl[2], G. Feuchtner[2], C. Duftner[1], G. Weiss[1], A. Klauser[2]. [1]*Medizinische Universität Innsbruck, Clinical Division of Internal Medicine II, Innsbruck, Austria*; [2]*Medizinische Universität Innsbruck, Department of Radiology, Innsbruck, Austria*

Background: Gout is the most common inflammatory arthritis and doubles the risk of cardiovascular (CV) events.[1] Classical risk calculators like the Framingham risk score fail to sufficiently explain this higher hazard. [2] Recently, MSU deposits were demonstrated in coronary arteries of 86.4% of investigated gout patients and were positively associated with coronary calcium score. [3] So far, however, the significance of these findings on CV events and consequent impact for gout patients is unknown.

Objectives: The aim of this retrospective analysis was to evaluate 1) possible correlations of CV MSU deposits with clinical gout diagnosis 2) the impact of CV MSU deposits on major CV events (MACE) in gout patients.
Methods: All patients, recruited at the radiology department of medical university Innsbruck with clinically suspicion of gout, performed dual energy computed tomography (DECT) of the affected limb and thorax between 01.05.2012 and 01.09.2019. Clinical and laboratory parameters were retrieved from patients´ charts. Classical CV risk factors (diabetes mellitus, smoking status, hypercholesterolemia, arterial hypertension) were evaluated. Medical history review identified the presence of MACE, defined as myocardial infarction and/or stroke. Patients were stratified in gout, hyperuricemia and controls. Gout was defined according to the ACR/EULAR classification criteria [4], uric acid levels over 6 mg/dl or ongoing uric acid lowering treatment without clinical signs of gout specified hyperuricemia patients and control group definition was achieved when uric acid levels were normal without concomitant uric acid lowering therapy and absence of gout symptoms. We performed the $\chi 2$- and Mann-Whitney tests for statistical appraisal of our dataset, using IBM SPSS (version 27). $P < .05$ was used as the cut-off for statistical significance.
Results: Overall, full data sets were available for 189 patients. Out of those, 131 (69.3%) revealed a clinical diagnosis of gout, 50 (38.2%) of these were tophaceous. 35 patients (17.5%) had hyperuricemia and 23 (12,2%) had neither gout nor elevated uric acid levels. Patients with CV MSU deposits (n=85/189, 45%, 62 gout patients, 19 hyperuricemia patients, 4 control patients) revealed higher acute phase reactants [C-reactive protein (p=0,001), erythrocyte sedimentation rate (p=0,007)], uric acid levels (p=0,007) and calcium scores (p<0,001) in comparison to patients without CV MSU deposits. MACE were observed in 35 patients (18.5%) with a higher prevalence in those patients revealing CV MSU deposits (n=22/85, 25,9%) compared to those without CV MSU (n=13/104, 12,5%) (p=0,022). All 22 patients with MACE and CV MSU were gout or hyperuricemia patients (Figure 1).
Conclusion: To our knowledge, this is the first evaluation of clinical features of patients revealing CV MSU deposits detected by DECT. The higher prevalence of MACE in patients with CV MSU deposits may help for risk stratification of gout patients, as classical CV risk scores or laboratory markers fail to identify patients at risk.

INITIATION OF SODIUM-GLUCOSE COTRANSPORTER-2 INHIBITORS AND RECURRENT GOUT FLARES IN GOUT PATIENTS WITH TYPE 2 DIABETES: A GENERAL POPULATION-BASED COHORT STUDY

Keywords: Epidemiology, Cardiovascular disease, Gout

N. Mccormick[1,2,3], C. Yokose[1,3], J. Wei[4], L. Lu[2], D. Wexler[3,5], J. A. Aviña-Zubieta[2,6], M. De Vera[2,7], Y. Zhang[1,3], H. Choi[1,2,3]. [1]*Massachusetts General Hospital, Clinical Epidemiology Program, Boston, United States of America*; [2]*Arthritis Research Canada, n/a, Vancouver, Canada*; [3]*Harvard Medical School, Medicine, Boston, United States of America*; [4]*Xiangya Hospital, Health Management Center, Shan Nan Shi, China*; [5]*Massachusetts General Hospital, Diabetes Center, Boston, United States of America*; [6]*The University of British Columbia, Division of Rheumatology, Vancouver, Canada*; [7]*The University of British Columbia, Faculty of Pharmaceutical Sciences, Vancouver, Canada*

Background: Gout flares may increase risk of cardiovascular events.[1] Sodium-glucose cotransporter-2 inhibitors (SGLT2i) are associated with lower risk of incident gout (primary prevention); however, their role in recurrent flares among gout patients (secondary prevention), and their cardiovascular risk remains unknown.
Objectives: To assess rate of recurrent gout flares in prevalent gout patients with type 2 diabetes initiating SGLT2i versus dipeptidyl peptidase-4 inhibitors (DPP4i), two second-line glucose-lowering agents for type 2 diabetes.
Methods: This new-user, active comparator cohort study used administrative health data covering nearly all residents of British Columbia, Canada from Jan 2014 to June 2022, including all dispensed prescriptions, regardless of funder. Primary outcome was recurrent gout flare counts, ascertained by emergency department (ED), hospitalization, outpatient, and medication dispensing records.[1] We also restricted to flares requiring hospitalization or ED visit, and stratified by sex, age, gout intensity (presence of ≥1 gout-coded encounter or colchicine dispensing over past year) and diuretic and urate-lowering therapy (ULT) use. Myocardial infarction and stroke were secondary outcomes. We also assessed genital infection as positive control and osteoarthritis as negative control. Poisson and Cox proportional hazards models were used with 1:1 propensity matching.
Results: We included 8150 gout patients with type 2 diabetes (mean age 66, 71% male, 59% with cardiovascular disease). Flare rate was lower among SGLT2i initiators (52.4 events per 1000 person-years) than DPP4i initiators (79.7 events per 1000 person-years): rate ratio (RR) 0.66 (95% CI: 0.57, 0.75) and rate difference (RD) -27.4 (-36.0, -18.7). RR and RD for flares requiring hospitalization or ED visit were 0.52 (0.32, 0.84) and -3.4 (-5.8, -0.9), respectively. Results were consistent regardless of sex or age (**Table 1**). RR was also consistent regardless of baseline gout intensity or diuretic or ULT use, though absolute RD was higher in patients with greater gout intensity: -71.6 [-111.1, -32.1] vs. 20.8 [-28.8, -12.7] per 1000 person-years, respectively. Hazard ratio (HR) and RD were 0.69 (0.54, 0.88) and -7.6 (-12.4, -2.8) per 1000 person-years for myocardial infarction; HR, 0.81 (0.62, 1.05) for stroke. For control outcomes, SGLT2i initiators had higher risk of genital infection, while there was no difference in risk of osteoarthritis (**Table 1**).
Conclusion: For gout patients, SGLT2i may offer pleiotropic cardiovascular and recurrent flare frequency benefits.

OP0157 GOUT AND RISK OF PARKINSON'S DISEASE, A POPULATION BASED STUDY FROM WESTERN SWEDEN

Keywords: Epidemiology, Crystal Arthritis, Gout

M. Dehlin[1], F. Bergquist[2,3], T. Zverkova Sandström[1], L. T. H. Jacobsson[1]. [1]*Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; [2]*Institute of Neuroscience and Physiology, University of Gothenburg, Department of Pharmacology, Gothenburg, Sweden*; [3]*Sahlgrenska University Hospital, Dept of Neurology, Gothenburg, Sweden*

Background: Gout affects 1-4% of the population in the industrialized world. Increased levels of serum urate is the strongest risk factor and "path variable" for gout development. Parkinson's disease (PD) is the second most common neurodegenerative disease in the world affecting 1% of the population over the age 60 in North America and Western Europe. A reduced risk of PD has been reported in association with smoking, caffeine consumption and higher serum urate levels.
Objectives: To determine the incidence of PD in all patients with gout compared to matched controls in the region of western Sweden (VGR).
Methods: All incident and prevalent gout cases from 2001 through 2019 were identified in the health care consumption database VEGA covering all health care in VGR. A case of gout was defined as having received a diagnosis of gout (M10) from a physician. Up to 5 controls from the census register were included matched by age, gender and municipality at year of first gout diagnosis (index-year). A case of PD was defined as having been given a diagnosis of PD (G20.9) at a visit to a physician. A PD diagnosis in the index-year and the 1 to 19 years before was considered prevalent in cases and controls and they were censored from the study. Cases and controls were followed until first of; end of study (2019-12-31), incident PD diagnosis, migration or death. Data on comorbidities at baseline/indexyear were retrieved from VEGA and information on education, death and migration were retrieved from registers at the National Board of Health and Welfare. Effect of gout on risk of PD was calculated using time dependent COX regression on whole population and stratified by sex, adjusted for age, sex, educational level, risk factors for gout (diabetes, obesity, chronic kidney disease (CKD)) and PD (cerebrovascular disease (CeVD), chronic obstructive pulmonary disease (COPD) as a proxy for smoking and malignant melanoma (MM)).
Results: We identified 48907 cases of gout (67% male) and 198717 (65% male) matched controls with a mean (SD) age of 68 (15) and 67 (15) respectively. In the case population we found 205 prevalent cases of PD compared to 2205 in the controls (prevalence ratio = 0.91 (95% CI:0.87-0.94)). They were all removed from further analysis. All comorbidities, (hypertension, ischemic heart disease, heart failure, CeVD, diabetes, dyslipidemia, obesity, CKD, COPD, and MM were significantly more common in the gout cases vs controls. During a median follow-up time of 5.8 years we identified 364 (0.7%) incident cases of PD in the gout population compared to 1965 (1.0%) in the controls. Adjusting for only age and sex in time dependent COX regression, (Model 1, Table 1) the relative risk reduction in gout patients for incident PD overall was 25% (HR 0.75; 95% CI:0.70-0.84). In age-adjusted models stratified by sex results were similar, HR 0.77 (95% CI:0.68-0.87) for men and HR = 0.69 (95% CI:0.54-0.87) for women. Adjusting also for known risk factors for gout and PD gave similar point estimates (model 2, Table 1).

Table 1. Time dependent COX regression on risk of incident gout in the total population and stratified by age and sex. Model 1 adjusted for age and sex, model 2 adjusted for age, sex, educational level, diabetes, obesity, CKD, CeVD, COPD, MM. HR = hazard ratio, CI confidence interval

	Model 1		**Model 2**	
	HR 95% CI	p-value	HR 95% CI	p-value
Total population	0.75 (0.70-0.84)	<.0001	0.75 (0.67-0.84)	<.0001
Men	0.77 (0.68-0.87)	<.0001	0.77 (0.68-0.88)	<.0001
Women	0.68 (0.53-0.86)	0.0014	0.68 (0.53-0.86)	0.0016
Age group 18-69				
Total population	0.78 (0.65-0.95)	0.0113	0.78 (0.65-0.95)	0.0137
Men	0.80 (0.65-0.99)	0.0415	0.82 (0.66-1.01)	0.0631
Women	0.67 (0.41-1.08)	0.0967	0.61 (0.37-1.00)	0.0505
Age group 70+				
Total population	0.71 (0.62-0.82)	<.0001	0.72 (0.63-0.84)	<.0001
Men	0.73 (0.62-0.85)	<.0001	0.73 (0.62-0.86)	0.0002
Women	0.68 (0.51-0.89)	0.0049	0.70 (0.53-0.93)	0.0130

Conclusion: Gout is associated with a significant risk reduction for incident PD. This may have implications for management of urate lowering therapy in persons with increased risk for PD and for the understanding of PD pathogenesis.

Background: Gout is the most common inflammatory arthritis worldwide (1) and disease flares are triggered by the deposition of monosodium urate (MSU) crystals in and around the joints as a result of oversaturation of uric acid (urate) in the bloodstream. Macrophages phagocytose the crystals, leading to inflammasome activation and production of proinflammatory cytokines, mainly IL-1β. Neutrophils are recruited to the gouty inflamed site where they phagocytose the crystals, produce reactive oxygen species (ROS) and cast out neutrophil extracellular traps (NETs), the latter proposed to possess both pro- and anti-inflammatory properties in gout (2, 3). Gout patients have an increased risk for cardiovascular disease (4), and it is a paradox that uric acid, the major risk factor for gout and known to possess antioxidative properties, correlates with conditions associated with oxidative stress, such as cardiovascular disease. How urate levels in circulation affects neutrophil ROS production is unclear.

Objectives: To investigate whether peripheral neutrophils from gout patients respond to MSU crystals similarly as neutrophils form healthy controls.

Methods: Patients with polyarticular gout, diagnosed by a rheumatologist and identified at the Rheumatology Unit at Sahlgrenska University hospital and matched controls were included in the study. Peripheral blood from patients and controls were collected. Circulating blood neutrophils were isolated and intracellular ROS production was detected with luminol-amplified chemiluminescence. Quantification of NET Formation was performed by a fluorescence assay. Expression of surface markers was assessed by flow cytometry [5].

Results: MSU crystals stimulated neutrophils from gout patients to produce intracellular ROS and the response in neutrophils from gout patients was significantly higher as compared to the ROS response in control neutrophils. Neutrophils derived from gout patients were not primed with regard to cell surface markers and NET formation.

Conclusion: Blood neutrophils from gout patients display increased ROS responses both at baseline and upon MSU crystal stimulation. It is possible that small circulating MSU crystals in peripheral blood of gout patients increase neutrophil responsiveness and give rise to the enhanced background activity seen in our ROS experiments. Another explanation could be that pro-inflammatory cytokines in the bloodstream of patients with gout rime neutrophils to produce increased amounts of ROS.

New Insights in the care and management of JIA___

OP0160 SUPPORTING CHILDREN AND YOUNG PEOPLE WITH JUVENILE IDIOPATHIC ARTHRITIS IN SCHOOLS, COLLEGES AND OTHER EDUCATIONAL SETTINGS THROUGH SCHOOL TOOLKITS

Keywords: Patient-led research, Education, Patient information and education

R. Beesley[1], R. Beesley[1,2]. [1]*Juvenile Arthritis Research, JAR Project, Tonbridge, United Kingdom*; [2]*European Network for Children with Arthritis, ENCA, Geneva, Switzerland*

Background: Juvenile Idiopathic Arthritis (JIA) is a heterogenous group of autoimmune disorders characterised by chronic joint inflammation, affecting children and young people (CYP) under the age of 16. CYP with JIA experience considerable physical and psychological impacts due to their condition. CYP spend a considerable amount of time at school, college or other educational settings. Whilst most CYP with JIA are able to access education, many require adaptations, awareness of their needs, or specific support to enable them to fully engage in learning. Families of CYP with JIA have reported a lack of awareness and understanding, and requested resources to enable schools to support their children in school.
Objectives: The aim of this work was to develop a School Toolkit to allow teachers and other school staff to confidently support CYP with JIA, and to assess its initial rollout.
Methods: Using a network of parents of CYP with JIA, including those with experience in working in educational settings, UK-based charity Juvenile Arthritis Research developed a resource aimed at schools, colleges, pre-schools and other educational settings: a Toolkit of information and resources. Given awareness of childhood arthritis is low, the Toolkit includes awareness-raising resources, aimed both at staff and all families connected to the school. Increased awareness can help improve diagnosis times and timely access to treatment in those not yet diagnosed. In addition, the Toolkit contains information about what JIA is, resources for schools to provide targeted interventions, and information on how schools can successfully support CYP with JIA. Finally, each Toolkit contains both a presentation for explaining arthritis to children in a classroom or group assembly setting, and a training presentation for delivery to staff, as well as digital copies of key materials and awareness-raising resources for distribution to parents and families. Recipients were invited to complete a short web-based survey to review the Toolkit.
Results: In the first six months after launching the new School Toolkit, around 100 Toolkits have been sent to schools in the UK, potentially providing information that arthritis affects children to over 100,000 families. Schools have advised they are using the resources in their settings, including giving lessons to children to explain what arthritis is, putting up posters highlighting the key signs and symptoms of JIA, and utilising the staff training resources. Feedback from schools was entirely positive, with one teacher reporting "Wow- it's fantastic. The student presentation is particularly impressive with how it translates all the key information in a child-friendly manner."
Conclusion: The development and supply of a Toolkit specifically for use in schools and colleges has helped raise awareness that children get arthritis, and provided resources to train and support school staff enabling them to confidently support CYP with JIA. Utilising the experience and skills of parents and teachers in the development of the Toolkit has ensured all resources are relevant and address the needs of both families and schools. Toolkits can be requested free of charge by schools in the UK from www.jarproject.org/toolkit.
Acknowledgements: Thanks to the children, young people, families and schools involved in the development of this vital resource.
Disclosure of Interests: None Declared.

Objectives: To evaluate 24-month effectiveness and tolerability/safety of tocilizumab (TCZ) versus tumour necrosis factor inhibitor (TNFi), analysing predictors of JADAS remission and minimal disease activity (MDA), comparing 1st and 2nd line TCZ.
Methods: BIKER WA 29358 is a 5-year multi-centre prospective, observational cohort study including polyarticular juvenile idiopathic arthritis (JIA) patients in Germany starting treatment between 2015 and 2020 with TCZ and matched patients starting an approved TNFi such as etanercept, adalimumab or golimumab. Clinical disease activity (JADAS), JADAS MDA/remission at 24 months, safety and drug adherence were assessed and compared between cohorts.
Results: The analysis set consisted of 342 participants with 24-month treatment data (TCZ, n=171; TNFi, n=171) (Table 1). Therefore, patients starting on TCZ were older and had a longer disease duration compared to TNFi patients. Efficacy was demonstrated by a marked and comparable decrease of the JADAS10 in upon both TCZ and TNFi from 14.6+/-6.6 and 14.6+/-6.2 at baseline to 2.5+/-3.4 and 2.7+/-3.6 at month 24. TCZ was used as 2nd line biologic in the majority of patients (84%) while TNFi were mostly 1st line biologics (86%). In the last observation carried forward analysis, at 24 month JADAS remission upon TCZ/TNFi treatment was achieved by 84.6%/76.9% in 1st line biologic users and 62.3/66.7% in 2nd line users. JADAS MDA was achieved in 100%/87.9% in 1st line and 84.4%/91.7% in 2nd line users of TCZ/TNFi. After 24 months of treatment residual disease activity as measured by the JADAS10 (mean +/SD) was lower in the 1st line TCZ cohort compared to the 2nd line (1.0+/-1.2 vs. 2.7+/-3.6), while in the TNFi cohort residual JADAS10 was comparable in 1st or 2nd line (2.7+/-3.8 vs. 2.5+/-2.6). Safety was assessed based on adverse events reporting. 113 (66%) patients in the TCZ cohort and 105 (61%) patients in the TNFi cohort reported adverse events with a higher rate in the TCZ cohort (89 vs. 73/100 patient years (PY), RR 1.2 (95%CI 1.0-1.5), p=0.029, Wald-test) as well as the rate of serious adverse events (10 vs. 3/100 PY; p=0.045). Cytopenias were more common in the TCZ cohort (13 vs. 1; p=0.010) and injection site reactions were more common in the TNFi cohort (13 vs. 6/100 PY, p=0.089). There was no case of death and no opportunistic infection. In the TCZ/TNFi cohorts, 71 (42%)/72 (42%) patients discontinued treatment, 43/30 due to lack of efficacy, 14/22 due to remission and 7/6 due to intolerance, respectively.
Conclusion: In this interim analysis, treatment targets were reached with similar frequency after 24 months of treatment with TCZ or TNFi. TCZ was used predominantly as 2nd line biologic. Higher rates of remission and minimal disease activity were observed in 1st line compared to 2nd line TCZ users. More adverse events were reported in the TCZ cohort but no new safety signals were noted. Observation is ongoing.

Table 1. Baseline patients' characteristics

Baseline patients' characteristics	Tocilizumab, N=171	Matched TNFi controls, N=171	P-value
Age at therapy start, mean (SD)	12.1 (3.5)	10.0 (4.4)	<0.001
Disease Duration, years, mean (SD)	5.4 (4.0)	3.2 (3.1)	<0.001
Rheumatoid-factor negative poly JIA, n (%)	115 (67%)	97 (57%)	n.s.
Rheumatoid-factor positive poly JIA, n (%)	17 (10%)	22 (13%)	n.s.
Extended oligoarthritis, n (%)	39 (23%)	52 (30%)	n.s.
Prior bDMARD, n (%)	143 (84%)	24(14%)	<0.001
Concomitant systemic steroids, n (%)	43 (25%)	42 (25%)	n.s.
Concomitant treatment with MTX, n (%)	93 (54%)	133 (78%)	<0.001
Number of active joints, mean (SD)	6.3 (6.9)	5.6 (4.8)	n.s.
CHAQ-DI, mean (SD)	0.61 (0.62)	0.63 (0.62)	n.s.
JADAS-10, mean (SD)	14.6 (6.6)	14,6 (6.2)	n.s.
Month 12 data			
JADAS-10, mean (SD)	3.5 (4.6)	3.8 (5.4)	n.s.
JADAS-MDA (≤6) -LOCF population	72.7%	77.4%	n.s.
JADAS-remission (≤2.7) -LOCF population	60.9%	57.9%	n.s.
Month 24 data			
JADAS-10, mean (SD)	2.7 (3.6)	2.5 (2.6)	n.s.
JADAS-MDA (≤6) -LOCF population	87.0%	85.2%	n.s.
JADAS-remission (≤2.7) -LOCF population	64.9%	69.1%	n.s.

Background: Juvenile idiopathic arthritis (JIA) often has a relapsing/remitting disease course, but it is not known whether recurrence of inflammation tends to be local.
Objectives: To assess whether JIA joint inflammation recurs locally in the same joints.
Methods: Joints of 91 patients of the BeSt for Kids study, a treat-to-target trial for children with recent-onset oligoarticular (n=11), rheumatoid factor negative polyarticular (n=72) and juvenile psoriatic JIA (n=8), were clinically assessed during two years (10 study visits). The association between joint inflammation at baseline and later inflammation in the same joint was assessed using a multilevel mixed-effects logistic regression model at joint level, adjusted for joint location and time point. With a Poisson model, the association between baseline joint inflammation and the number of study visits at which the same joint was recurrently inflamed (after inactivity of the joint) was tested. To assess whether an association between baseline and later clinical joint inflammation was a specific within-joint association, a permutation test was performed. A statistically significant result ($p<0.05$) indicates that the association between baseline and later joint inflammation is stronger in the observed data than in permutations with comparisons across random joints, suggesting an effect at joint level. To assess whether joint inflammation (ever during follow-up) was associated with radiographic damage (Poznanski Z-score) in the same (wrist) joint, a generalized linear mixed model was used.
Results: Of the 6,097 joints studied, 15% (897) was clinically inflamed at baseline. In 42% (377/897) of those joints, inflammation recurred during follow-up. Joint inflammation at baseline and recurrence of inflammation during follow-up within the three included JIA categories is depicted in Figure 1. Of the joints that became inflamed after the patient had a period of inactive disease, 93% (1,195/1,280) had been previously inflamed. Joint inflammation at baseline was statistically significantly associated with joint inflammation in the same joint during follow-up (OR 3.9, 95% CI 3.5 to 4.4). The association was found in all included JIA categories, although to a different extent (Table 1). Baseline inflammation of a joint was also positively associated with the number of episodes of recurrent joint inflammation in that same joint (IRR 1.6, 95% CI 1.2 to 2.1). The permutation test showed that inflammation during follow-up in a certain joint was better predicted by baseline inflammation of the same joint, than by baseline inflammation of randomly selected other joints ($p<0.001$), confirming a local effect. No statistically significant association was found between joint inflammation in the wrist and local radiographic damage (β 0.17, 95% CI -0.06 to 0.41).

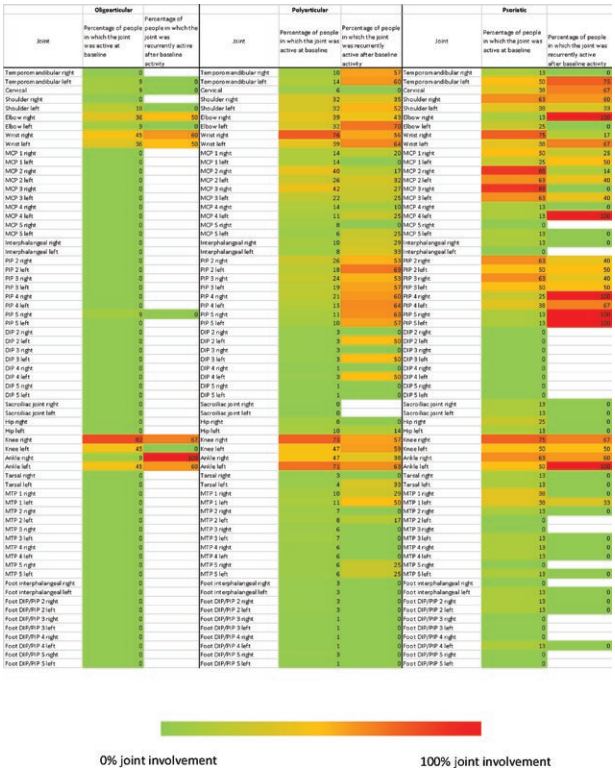

Figure 1. Joint inflammation patterns (joint activity at baseline and local recurrence of joint activity following baseline joint activity) in the three JIA types (oligoarticular, n=11; RF negative polyarticular, n=65, psoriatic, n=25) included in the BeSt for Kids study.

MCP: metacarpophalangeal, PIP: proximal interphalangeal, DIP: distal interphalangeal, MTP: metatarsophalangeal

Conclusion: In JIA, joint inflammation has the tendency to recur multiple times in joints that are clinically inflamed at disease onset. This indicates that local factors might play a role in the processes contributing to JIA flares. These local factors might be a target for new therapies.

Klinikum St. Georg, Pediatric Rheumatology, Leipzig, Germany*

Background: Golimumab (GOL) is approved for treatment of polyarticular juvenile idiopathic arthritis (pJIA) in patients 2 years and older. Data on long-term safety of GOL in this indication are limited.
Objectives: To assess long-term safety and effectiveness of GOL in pJIA patients.
Methods: In this ongoing non-interventional observational study, clinical characteristics, disease activity and safety parameters were analysed using the German Biologics in Paediatric Rheumatology (BiKeR) registry. A total of 141 pJIA-patients treated with GOL were frequency matched by body weight with 282 patients receiving alternative tumor necrosis factor inhibitors (aTNFi) and 135 biologic–naïve patients receiving methotrexate (MTX).
Results: Baseline disease activity (measured by number of active joints and JADAS10) of the GOL and other anti-TNF cohort was similar. The GOL cohort tended to have a longer disease duration and more patients were previously exposed to other biologic agents than the other anti-TNF cohort. Compared to MTX cohort, the GOL cohort had a lower baseline disease activity and less concomitant systemic steroids use (Table 1). The clinical effectiveness of GOL in pJIA is highlighted by a decrease of the mean JADAS 10 from 10.7 (±6.5) (baseline) to 4.4 (±5.0) at 24 months. By 24 months, a JADAS 10 minimal disease activity (JADAS 10 ≤3.8) was reached by 50.0% of patients, whereas 34.2 % of patients were in remission (JADAS 10 ≤1) and the PedACR 30/50/70/90 response rates were 73.7/65.8/60.5/47.4% respectively. In the GOL cohort, 12 SAEs were reported, while in the aTNFi cohort 25 SAEs and in the MTX cohort 5 SAEs were observed (Table 1). One serious infectious event (SI) in the GOL cohort, 6 SIs in the aTNFi and one SI in the MTX cohort were observed. A few incident autoimmune events were reported: 4 in the GOL cohort (1 uveitis, 2 psoriasis, 1 inflammatory bowel disease (IBD)), 10 in the aTNFi cohort (6 uveitis, 2 psoriasis, 2 IBD) and 7 in the MTX cohort (6 uveitis, 1 celiac disease) (Table 1). Among the patients with preexisting uveitis at baseline, 10 out of 39 in the GOL cohort and 5 out of 32 in the aTNFi cohort had uveitis flares, whereas there were no patients with preexisting uveitis in the MTX-cohort. No malignancies were reported in any cohort.
Conclusion: Our interim results show an acceptable safety profile of GOL therapy, comparable to treatment with aTNFi or MTX. AE and serious infection rates between the three cohorts were comparable. No new safety signals were identified. Available data supports the effectiveness of GOL in the treatment of pJIA.

SAFETY AND EFFICACY OF UPADACITINIB FOR PEDIATRIC PATIENTS WITH POLYARTICULAR COURSE JUVENILE IDIOPATHIC ARTHRITIS: AN INTERIM ANALYSIS OF AN OPEN-LABEL, PHASE 1 TRIAL

Keywords: Clinical Trials, Safety, Outcome measures

H. Brunner[1], G. Horneff[2,3], I. Foeldvari[4], J. Anton[5], M. E. Mohamed[6], Y. Qian[6], K. Unnebrink[7], S. Hao[6], H. Camp[6], N. Khan[6], A. Shmagel[6]. *[1]University of Cincinnati, Cincinnati Children's Hospital Medical Center, Rheumatology, Cincinnati, United States of America*; *[2]Asklepios Clinic Sankt Augustin, General Pediatrics, Sankt Augustin, Germany*; *[3]University Hospital of Cologne, Paediatric and Adolescents Medicine, Cologne, Germany*; *[4]Hamburger Zentrum für Kinder- und Jugendrheumatologie, Klinikum Eilbek, Hamburg, Germany*; *[5]Hospital Sant Joan de Déu, Universitat de Barcelona, Pediatric Rheumatology, Barcelona, Spain*; *[6]AbbVie, Rheumatology, North Chicago, United States of America*; *[7]AbbVie Deutschland GmbH & Co. KG, Rheumatology, Ludwigshafen, Germany*

Background: Novel treatment options are needed for pediatric patients with polyarticular-course juvenile idiopathic arthritis (pcJIA). Upadacitinib (UPA) is an oral, selective Janus kinase (JAK) inhibitor with a positive benefit-risk profile in adult patients with moderate-to-severe active rheumatoid arthritis.[1,2]
Objectives: To evaluate the safety and efficacy of UPA in pediatric patients with pcJIA.
Methods: This open-label, 3-part, phase 1 trial (NCT03725007) enrolled pediatric patients aged 2 to < 18 years with pcJIA and ≥ 5 active joints at 31 sites across North America, Europe, and Asia. UPA was dosed as a twice-daily oral solution or once-daily tablet based on body weight. Part 1 evaluated multiple ascending doses of UPA for 7 days. Parts 2 and 3 evaluated long-term safety and efficacy of UPA for up to 156 weeks. This interim analysis (cutoff date of 22 September 2022) evaluated all available safety data in parts 1, 2, and 3; efficacy was evaluated in parts 1 and 2 through week 12. Efficacy endpoints included the JIA American College of Rheumatology (JIA ACR) 30, 50, and 70 response; the Childhood Health Assessment Questionnaire (C-HAQ); and the 27-point Juvenile Arthritis Disease Activity Score based on C-reactive Protein (JADAS-27 [CRP]).
Results: A total of 57 pediatric patients (78.9% female) with mean (SD) age of 9.5 (4.4) years and mean (SD) weight of 38.1 (20.4) kg received UPA; of these, 51 patients were treated in parts 1 and 2. In part 1, 8 (15.7%) of 51

patients reported adverse events (AEs) through 7 days; no patients reported serious AEs or AEs leading to treatment discontinuation. At a mean (median) duration of exposure of 514.9 (412.0) days, 52 (91.2%) of 57 patients reported AEs that were predominately mild to moderate in severity (**Table 1**). The most common treatment-emergent AEs were COVID-19 infection (n = 23/57, 40.4%), upper respiratory tract infection (n = 23/57, 40.4%), nasopharyngitis (n = 13/57, 22.8%), gastroenteritis (n = 10/57, 17.5%), pyrexia (n = 10/57, 17.5%), abdominal pain (n = 9/57, 15.8%), and nausea (n = 8/57, 14.0%). The most common AEs of special interest included elevated creatine phosphokinase levels (n = 6/57, 10.5%), hepatic disorder (n = 3/57, 5.3%), and neutropenia (n = 2/57, 3.5%); all were nonserious events. Six (31.6%) of 19 patients in the group aged 12 to <18 years reported serious AEs and 2 (10.5%) reported AEs leading to treatment discontinuation. A high proportion of patients across all age groups achieved JIA ACR30, 50, and 70 response at week 12 (**Figure 1**). Improvement from baseline to week 12 in C-HAQ and JADAS-27 [CRP] scores was observed across all age groups.

Conclusion: In pediatric patients with pcJIA, UPA was well tolerated and associated with improvements in disease activity and physical function at week 12.

Ruperto[12]. *[1]IRCCS Istituto Giannina Gaslini, Pediatric and Rheumatology Clinic, Genoa, Italy*; *[2]Federal State Autonomous Institution "National Medical Research Center of Children's Health", Ministry of Health of the Russian Federation, Moscow, Russian Federation*; *[3]Rigshospitalet, Pediatric Rheumatology Unit 4272, Copenhagen, Denmark*; *[4]IRCCS Ospedale Pediatrico Bambino Gesù, Division of Rheumatology, Rome, Italy*; *[5]Hippokration General Hospital, Thessaloniki University School of Medicine, First Department of pediatrics, Pediatric Immunology and Rheumatology Referral Center, Thessaloniki, Greece*; *[6]Riga Stradins University, Children University Hospital, Department of Paediatrics, Riga, Latvia*; *[7]Alexandru Ioan Cuza University of Iasi, Pediatric Rheumatology, Iasi, Romania*; *[8]Aghia Sophia Childrens Hospital, First Department of Pediatrics, University of Athens Medical School, Italy*; *[9]Institute for Mother and Child Care, Pediatrics, Bucharest, Italy*; *[10]IRCCS Istituto Giannina Gaslini, Direzione Scientifica, Genoa, Italy*; *[11]Wilhelmina Children's Hospital, Department of Pediatric Immunology and Rheumatology, Utrecht, Netherlands*; *[12]IRCCS Istituto Giannina Gaslini, UOSID Centro Trial, PRINTO, Genoa, Italy*

Background: The better understanding of systemic Juvenile Idiopathic Arthritis (sJIA) pathogenesis and availability of new drugs, such as biologic disease-modifying anti-rheumatic drugs (bDMARDs) specifically dedicated to sJIA, have led to treatment advances that have ameliorated the disease outcome and reduced the use of glucocorticoids. However, published evidence on long term safety data regarding biologic therapies in sJIA is still limited.

Objectives: The objective of the study was to compare the adverse events (AEs) of at least moderate intensity and serious AEs in sJIA patients treated with biologics compared with a cohort treated with csDMARDs (conventional synthetic disease-modifying anti-rheumatic drugs)

Methods: Patients with sJIA, classified according to the International League of Associations for Rheumatology (ILAR), enrolled in the Pharmachild Registry since 2011 and followed up until 31 December 2022 were included. All patients had received at least one bDMARDs or csDMARDs. Those who switched to more than one treatment during the period of observation were assigned only to one group according to the longest time of drug exposure. AEs are reported according to the latest release of the Medical Dictionary for Regulatory Activities (MedDRA, Version 23.1) and were grouped into highest term "System Organ Classes" (SOCs). Frequency of SOCs were analysed. Events repeated for the same SOC in the same patient were counted once in the analysis.

Results: A total of 980 sJIA patients were enrolled, 353 treated with bDMARDs and 627 treated with csDMARDs. The distribution of demographic data was similar in both cohorts, with the exception that the prescription of csDMARDs compared to bDMARDs was more frequent in other continents compared to Europe. As shown in the Table 1, patients in the bDMARDs group developed more frequently infections and infestations (41.4%), skin and subcutaneous tissue disorders (11.3%) and

general disorders and administration site conditions (8.2%) than patients treated with csDMARDs (all p<0.0001). On the other hand, endocrine disorders were more frequent in the csDMARDs group (7.3%, p=0.03). The distribution between other SOCs was similar in children treated with bDMARDs compared with csDMARDsA.
Conclusion: Patients in the bDMARD group had a higher prevalence of infections and skin manifestations when compared with the csDMARDs cohort.

Table 1. Demographics characteristics, number of AEs and frequencies in the complete set. Data presented as n (%). Events with a frequency of > 30 by overall SOC are presented. AEs: adverse events; SOC: system organ class; bDMARDs: biologic disease-modifying anti-rheumatic drugs; csDMARDs conventional synthetic disease-modifying anti-rheumatic drugs.

Background: MAS, a form of secondary hemophagocytic lymphohistiocytosis (sHLH), is a severe, life-threatening complication of rheumatic diseases that occurs most frequently in patients (pts) with sJIA and adult-onset Still's disease (AOSD). MAS is characterized by hyperinflammation and overproduction of interferon γ (IFNγ). Treatment with emapalumab, an anti-IFNγ monoclonal antibody, rapidly neutralized IFNγ and controlled MAS secondary to sJIA in pts with an inadequate response to high-dose glucocorticoids (GCs) in a phase 2 study (parent study).[1]
Objectives: To report outcomes and safety among pts with MAS treated with emapalumab after 12 months of follow-up.
Methods: The parent study enrolled pts with sJIA or AOSD who failed high-dose GCs (≥2 mg/kg/day). Pts who received emapalumab in the parent study (6 mg/kg on day [D] 0, followed by 3 mg/kg every 3 days until D15 and twice weekly until D28) and completed short-term follow-up (≥4 weeks) after last drug administration were invited to participate in this long-term follow-up study. Pts were assessed at follow-up Week (W) 2, W3, D30, D100, Month (M) 6 and M12. Emapalumab was not administered during follow-up. Overall MAS activity was monitored using a visual analog scale, comprehensive clinical evaluation and observation of pts' overall status. Serum samples for pharmacokinetic and pharmacodynamic analysis were collected at each study visit while serum emapalumab remained detectable. Safety was monitored throughout.
Results: All 14 pts (sJIA onset at <16 yrs, n=13; 1 had onset at age 16 yrs, 7 months) in the parent study participated in this long-term follow-up study. 6 pts had a history of 19 MAS episodes prior to the parent study. All prior episodes were treated with high-dose GCs; pts were also treated with anakinra (n=7) and/or cyclosporine A (n=8). 13/14 patients achieved MAS remission by W8, with rapid IFNγ neutralization during the parent study, as shown by decreased CXCL9 levels versus baseline. GCs were rapidly tapered in all pts. 13/14 pts did not present with another MAS episode; 1 MAS episode was reported 11 months after the pt stopped emapalumab (serum emapalumab was undetectable). The terminal elimination phase for emapalumab was slow and linear during follow-up (median $t_{½}$, 24 days). CXCL9 and soluble interleukin-2 receptor levels remained close to, or within, the normal range. GC tapering continued during follow-up: at M12, 5 pts were off GCs and 6 pts were receiving <0.3 mg/kg/day of prednisone. 4 sJIA flares (without MAS) occurred during follow-up. In total, 37 adverse events (AEs) were reported by 12 patients, including 3 serious AEs (SAEs), all unrelated to emapalumab: 1 MAS reactivation, 1 sJIA flare and 1 ankle edema. All SAEs resolved spontaneously or with standard treatment. 10 infectious AEs (9 of viral origin) were reported during follow-up; 4 occurred when serum emapalumab levels were measurable and 6 after emapalumab became undetectable (Table 1). No new safety signals were observed. All pts were alive at M12.

Table 1.

N=14	Emapalumab levels ≥lower limit of quantification (LLOQ)	Emapalumab levels <LLOQ
Infection AEs, n	4	6
Pts with ≥1 infection AE, n (%)	2 (14)	5 (35)
Cytomegalovirus (CMV) infection reactivation	0	0
CMV infection	0	0
Epstein Barr infection	0	1
Rhinovirus infection	1	0
Enterovirus infection	0	1
Viral infection	0	1
Viral upper respiratory tract infection	3	2
Nasopharyngitis	0	0
Viral test positive (CMV, adenovirus, BK polyoma virus, respirovirus)	0	0
Cestode infection	0	1

Conclusion: Most pts with MAS who had failed high-dose GCs and responded to emapalumab remained in remission and continued GC tapering during 12 months of follow-up. Any viral infections during follow-up resolved spontaneously

or with standard treatment, confirming the favorable safety profile of emapalumab. A pivotal clinical trial of emapalumab in patients with sHLH and underlying rheumatic disease is ongoing (EMERALD; NCT05001737).

Background: The EULAR task force "Implementation of a mobile health app for the self-management of juvenile-onset rheumatic and musculoskeletal diseases (jRMDs) during transitional care" aims at designing, developing and implementing a self-management program through a smartphone app (i.e., the EULAR Move-Up app). The first step of this task force was to adapt the current EULAR recommendations/points originally developed for adults, to young people (YP) with jRMDs.

Objectives: Adapting EULAR recommendations/points for patient education, pain management and physical activity for self-management of jRMDs during transitional care.

Methods: A multidisciplinary taskforce of 25 members from 11 European countries was convened. Using a Delphi technique, the level of agreement was established by anonymous online voting in three rounds.

Results: Four overarching principles and 8 points to consider were formulated (Table 1). The agreement was high, ranging from 8.7 to 9.9.

Conclusion: This work will feed into an evidence-based framework to inform the development of the EULAR Move-Up app aiming at improving the quality of transitional care of jRMDs.

Table 1. Overarching principles and points to consider for the self-management of juvenile-onset rheumatic and musculoskeletal diseases during transitional care

	Overarching principles	Agreement (0 to 10)
1	YP with jRMDs should be offered education, physical activity advice and pain management recommendations and provided with access to relevant resources during transitional care, as soon as possible following the diagnosis	9.6
2	Health professionals in rheumatology should consider the use of digital health interventions in transitional care to support self-management	9.5
3	The content and delivery of transitional care should be individually tailored and needs-based according to the patients' priorities, preferences, capabilities and resources	9.6
4	Transitional care interventions should have clear personalised aims, which should be evaluated over time, preferably by a combination of objective and subjective (patient-reported outcome measures) assessments	9.9
	Adapted points to consider in education	
1	Education is a planned interactive learning process designed to support and enable YP with jRMDs to manage their health and chronic condition, and optimise their health and well-being during transitional care	9.5
2	Education should consist of a variety of learning formats and the programme should be designed through a shared decision-making process	9.4
3	Education should include the evaluation of outcomes reflecting both the knowledge acquired and, most importantly, translation to behaviour change	8.7
	Adapted points to consider in pain management	
4	All patients and their carers should be offered education on the importance of maintaining healthy body composition and explained that unhealthy body composition could contribute to pain and disability	9.8
5	Non-pharmacological approaches (e.g., physical activity, lifestyle change, psychological interventions) should be prioritised in newly-diagnosed patients and those in transitional care. If indicated, the patient should receive pharmacological treatment according to the most recent recommendations	9.6
	Adapted points to consider on physical activity	
6	Physical activity is part of a healthy lifestyle and should be optimised during the lifespan of individuals of all ages	9.8
7	Physical activity has health benefits for YP with jRMDs during transitional care and helps establishing healthy behaviours and lifestyles during adulthood	9.8
8	Healthcare providers should consider different formats of delivery of physical activity, in line with YP's preferences and disease requirements	9.6

YP = Young people; jRMDs = juvenile-onset rheumatic and musculoskeletal diseases;

Y. Kayadibi[1], Y. Ozguler[2,3], M. Melikoglu[2,3], S. N. Esatoglu[2,3], U. Kimyon[4], A. Kalyoncu Ucar[1], İ. Adaletli[1], G. Hatemi[2,3]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Radiology, Istanbul, Turkey*; [2]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; [3]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behçet's Disease Research Center, Istanbul, Turkey*; [4]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey*

Background: Superb microvascular imaging (SMI) is a novel technique that provides a more sensitive assessment of small vessels compared to color Doppler US (CDUS), by distinction of low-speed flow signals from motion artifacts. Superficial thrombophlebitis (STM) is a common manifestation in patients with Behçet syndrome (BS) and is thought to be associated with inflammation of the vessel wall rather than a procoagulant state.
Objectives: We aimed to assess STM lesions of patients with BS, together with controls, using SMI.
Methods: We studied 51 BS (16F/35M, mean age:40.6±12.8) patients and 26 non-BS (19F/7M mean age:44.9±11.7) patients with nodular lesions on physical examination. B-mode US, CDUS, PDUS and SMI were performed and recorded by the same radiologist and images were then evaluated by 2 radiologists. Both radiologists were blinded to the diagnoses and to each other's assessments. First, presence/absence of vessel was assessed with CDUS to differentiate STM from erythema nodosum (EN). Then STM lesions were evaluated for the presence/absence of thrombus, vessel wall color-coded signal intensity, and thickness using the imaging modalities defined above. Vessel wall signal intensity was graded into 4 groups according to the percentages of the effected vessel wall area (Grade 0= no signal, Grade 1= < 25%, Grade 2= 25-50%, Grade 3= 50-75%, Grade 4= >75%). CDUS was the gold standard in the final diagnosis of STM. Interobserver reliability was assessed by kappa statistic.
Results: The nodular lesions of 26 BS and 15 non-BS patients were diagnosed as STM (Table 1). The diagnosis was EN in the remaining 25 BS and 11 non-BS patients. SMI showed increased color-coded signal intensity in the vessel wall in patients with STM. We did not observe increased signal intensity in any of the patients with EN. According to the grading system, at least grade 1 or higher vessel-wall signals were detected in 20 BS (77%) patients with STM, in contrast to only 4 (27%) non-BS patients with STM (Table 1). Fifteen of 26 BS patients (58%) had at least grade 2 signal, and 4 of them had halo shaped signals all around the vessel-wall (Figure 1). On the other hand, 3 of 4 non-BS patients (75%) had only grade 1 signal and none of them had grade 4 signal. The interobserver reliability was good (κ=0.87, $p<0.001$).
Conclusion: A high-grade color-coded signal suggesting inflammation of the vessel wall was detected with SMI, in the majority of BS patients with STM. This finding needs to be studied in different vascular lesions of a large number of BS patients together with controls, in order to understand its specificity for BS and its significance.

Table. Comparisons of vessel wall signal intensity in BS vs. non-BS patients with SMI		
	Behçet syndrome (n=51, 35M/16F)	**Non-Behçet syndrome (n=26, 7M/19F)**
Superficial thrombophlebitis n (%)	26 (51)	15 (58)
Vessel wall signal intensity with SMI n (%)		
Grade 0	6 (23)	11 (73)
Grade 1	5 (19)	3 (20)
Grade 2	9 (35)	0
Grade 3	2 (8)	1 (7)
Grade 4	4 (15)	0

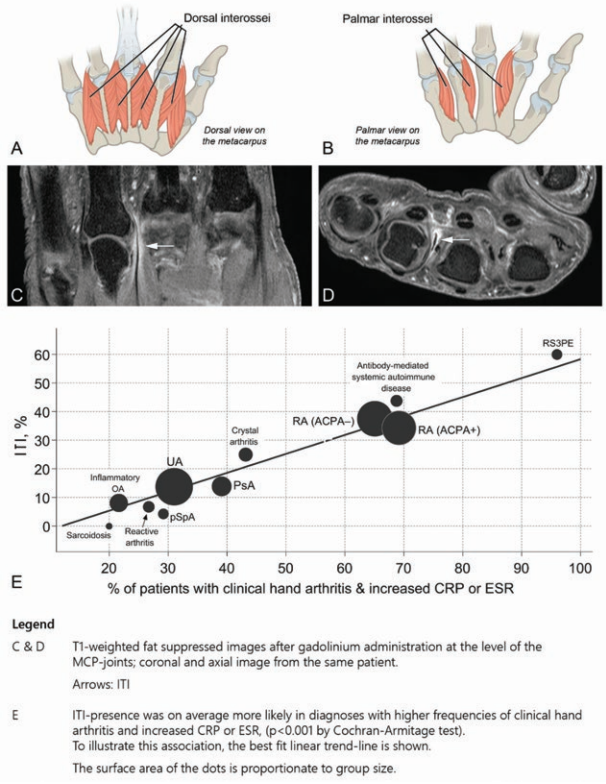
OP0170



INTEROSSEOUS TENDON INFLAMMATION ACROSS THE EARLY ARTHRITIS SPECTRUM: A 10-YEAR MRI-STUDY INVESTIGATING ITS PREVALENCE AT DIAGNOSIS AND RELATION WITH CLINICAL SIGNS

Keywords: Imaging, Rheumatoid arthritis, Inflammatory arthritides

B. Van Dijk[1], N. Den Hollander[1], M. Reijnierse[2], A. Van der Helm – van Mil[2,3]. [1]*Leiden University Medical Centre (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Leiden University Medical Centre (LUMC), Radiology, Leiden, Netherlands*; [3]*Erasmus Medical Centre (EMC), Rheumatology, Rotterdam, Netherlands*

Background: Inflammation around the tendons of the hand interosseous muscles (interosseous tendon inflammation; ITI) was recently identified on MRI in a set of RA and arthralgia patients.
Objectives: However, the prevalence of ITI at diagnosis of RA is unknown, as is its prevalence in other arthritides and its relationship with clinical signs. These questions prompted us to perform this large MRI study.
Methods: 1,205 consecutive patients presenting with early arthritis between 2010-2020 underwent contrast-enhanced hand MRI. MRIs were evaluated, blind to clinical data, for ITI lateral of MCP2-5 and for other local inflammation (synovitis/tenosynovitis/osteitis, in line with the RA-MRI-scoring-system (RAMRIS)). ITI-presence at baseline was studied in relation to the diagnosis and clinical characteristics (i.e. joint swelling, and tenderness) using logistic regression and generalised estimating equations.
Results: 36% of early RA patients (n=532) had ITI; this was similar in ACPA-negative(37%) and ACPA-positive RA patients (34%; p=0.53). ITI occurred regularly in RS3PE (60%) and connective tissue diseases (44%), and less frequently in undifferentiated arthritis (UA;14%), psoriatic arthritis (14%), inflammatory osteoarthritis (8%), reactive arthritis (7%), crystal arthritis (7%) and peripheral spondyloarthritis (4%). ITI occurred more often in diagnoses with frequent arthritis of the hands (p<0.001) and increased acute-phase-reactants (p<0.001). Within RA, ITI occurred together with local MCP synovitis (OR 2.4 (95%CI; 1.7-3.4)), tenosynovitis (2.4 (1.8-3.3)) and osteitis (2.2 (1.6-3.1)) on MRI. Moreover, ITI-presence associated with local MCP tenderness (1.6 (1.2-2.1)) and swelling (1.8 (1.3-2.6)), independent of age and MRI-detected synovitis/tenosynovitis/osteitis.
Conclusion: ITI occurs regularly in RA and other arthritides with preferential involvement of hand-joints and increased acute-phase-reactants. At MCP-level, the presence of ITI associates independently with joint-tenderness and -swelling. Hence, ITI is a newly identified inflamed tissue mainly found in arthritides with particularly extensive and symptomatic inflammation.

Figure. Schematic anatomical illustrations of the (**A**) dorsal and (**B**) palmar interossei; (**C&D**) example MR-images of RA-patients with ITI at MCP4 and (**E**) the frequency of ITI per diagnosis according to the frequency of combined clinical hand arthritis and increased CRP or ESR within diagnoses

Legend

C & D T1-weighted fat suppressed images after gadolinium administration at the level of the MCP-joints; coronal and axial image from the same patient.
Arrows: ITI

E ITI-presence was on average more likely in diagnoses with higher frequencies of clinical hand arthritis and increased CRP or ESR, (p<0.001 by Cochran-Armitage test).
To illustrate this association, the best fit linear trend-line is shown.
The surface area of the dots is proportionate to group size.

OP0171

ADDED VALUE OF FDG-PET/CT TO DETECT AORTIC INVOLVEMENT IN PATIENTS WITH ULTRASOUND PROVEN GIANT CELL ARTERITIS

Keywords: Vasculitis, Imaging, Ultrasound

J. Molina Collada[1], I. Castrejon[1], I. Monjo[2], E. Fernández-Fernández[2], G. Torres Ortiz[2], J. Martínez-Barrio[1], J. M. Alvaro-Gracia[1], E. De Miguel[2]. [1]*Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain*; [2]*La Paz University Hospital, Rheumatology, Madrid, Spain*

Background: Ultrasound (US) can detect signs of large vessel (LV) involvement at axillary, subclavian and carotid arteries of giant cell arteritis (GCA) patients, but has limited access to the thoracic aorta. Although aortic involvement is not routinely evaluated in all patients with GCA, it may cause a life-threatening situation as result of serious complications such as aneurysms or dissection.
Objectives: Our aim is to determine the added value of performing FDG-PET/CT to detect aortitis in patients with US proven GCA and to identify factors associated with aortic involvement.
Methods: Retrospective observational study of patients referred to the US fast track clinics of two academic centres over a 4-years period. Only patients with US proven GCA were included for analysis. Baseline US of cranial and extracranial arteries (carotid, subclavian and axillary) was performed in all patients at diagnosis within 24-48 hours. FDG-PET/CT was performed according to clinician criteria and images were assessed by nuclear medicine physicians. An FDG artery uptake at the thoracic or abdominal aorta higher than liver uptake was defined as aortitis. Between groups comparisons were made in patients with and without aortitis.

Results: Seventy two patients over 186 patients with confirmed GCA by US underwent an FDG-PET/CT (mean age 77 years, 52.8% females). A total of 48 (66.7%) had LV-GCA based on imaging findings, with 29 (40.3%) presenting positive FDG-PET/CT for LV-GCA and 24 (33.3%) presenting artery uptake throughout the aorta suggestive of aortic involvement (Table 1). Only 6 (20.7%) patients had negative US findings of LV-GCA but positive FDG-PET/CT. Among patients with aortitis according to FDG-PET/CT, only 2 (8.3%) had negative US findings of LV-GCA. In contrast, 19 (45.2%) patients with US findings of LV-GCA had negative FDG-PET/CT. Patients with aortitis were younger (68.9 vs 81, p<0.001), more frequently females (79.2% vs 39.6%, p=0.002) and had higher level of platelets (413.4 vs 311.1, p=0014). None of the patients with aortitis referred visual symptoms (0% vs 31.2%, p=0.001) and they presented US signs of LV-GCA more frequently (91.7% vs 41.7%, p<0.001) versus patients without aortic involvement.

Conclusion: FDG-PET/CT can detect aortic involvement in 1 out of every 3 patients with US proven GCA. However, most of these patients show US findings of LV-GCA. In contrast, half of patients with US proven LV-GCA may have negative FDG-PET/CT. Younger and female GCA patients, with thrombocytosis, absence of visual manifestations and US pattern of LV-GCA may present more frequently aortitis by FDG-PET/CT.

LIMITED DIAGNOSTIC AND PROGNOSTIC VALUE OF RADIOGRAPHS OF HANDS AND FEET IN PATIENTS WITH UNDIFFERENTIATED ARTHRITIS SUSPECTED FOR RHEUMATOID ARTHRITIS: A RETROSPECTIVE COHORT STUDY

Keywords: Imaging, Rheumatoid arthritis, Diagnostic Tests

E. Ulijn[1], N. Den Broeder[1], D. Ten Cate[1], K. Van Overdijk[1], H. Demirel[1], R. B. M. Landewé[2], N. Van Herwaarden[1,3], A. Den Broeder[1]. *[1]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands*; *[2]Amsterdam Medical Centre, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[3]RadboudUMC, Pharmacology-Toxicology, Nijmegen, Netherlands*

Background: Current recommendations suggest that the diagnostic workup of Undifferentiated Arthritis (UA) should include radiographs of hands and feet (x-HF) as presence of Rheumatoid Arthritis (RA) associated erosions might be of diagnostic and prognostic value. The diagnostic role of x-HF in RA is reflected in ACR/EULAR 2010 criteria, with erosions typical for RA allowing classification of RA even without fulfillment of the scoring system [1]. Additionally, early erosivity is one of the indicators of a poor RA prognosis [2]. RA seems to evolve into a milder disease at presentation, caused by a secular trend towards milder disease, or lead time effects (presenting earlier in disease course) [3]. Both trends would further decrease the prevalence of RA-associated erosions and thus utility of x-HF might have decreased both for diagnosis and identifying poor prognosis patients.

Objectives: To investigate the prevalence and diagnostic and prognostic value of RA-associated erosions on x-HF in a recent cohort of UA patients.

Methods: A retrospective cohort study in consenting UA patients visiting the rheumatology department at the Sint Maartenskliniek between 2012-2018 was done. UA suspected for RA was defined as 1/ current arthritis, 2/ Rheumatoid Factor (RF)/anti-Cyclic Citrullinated Peptide (anti-CCP) were tested, 3/ x-HF was made, 4/ RA was mentioned in the differential diagnosis. Radiological reports of x-HF were judged by experienced musculoskeletal radiologists, and all x-HF with an erosion mentioned in the report were reassessed by two experienced rheumatologists for typical RA-associated erosions. The prevalence of erosions was estimated, as well as whether RA classification (yes/no) or prognostic group (good/poor) were changed by erosivity. Subgroup-analyses were done for seronegative patients (non-elevated RF/anti-CCP) and patients without elevated Acute Phase Reactants (APR; i.e. ESR and CRP) as they might be expected to gain the most diagnostic and prognostic value from conducting x-HF.

Results: 724 patients were included in the analysis, of which 293 (40.5%) patients were eventually clinically diagnosed with RA during the time they were treated. There was a high agreement between 2010 ACR/EULAR classification criteria for RA and the clinical diagnosis reported by the treating rheumatologist (sensitivity of 79% and specificity of 89.6%). RA-associated erosions were found in 30 out of 724 included patients (4.1%, 2.9-5.9). Of the 437 seronegative patients, five (1.1%, 0.5-2.7) radiographs showed erosive disease. Eight out of 385 patients with non-elevated APR (2.1%, 1-4.1) had erosive disease. The x-HF resulted in a change to a positive RA classification in four out of 724 patients (0.5%, 0.2-1.2). X-HF erosivity changed the classification to prognostically unfavorable in five patients (0.6, 0.2-1.4), *Table 1*. In other words: these patients did not have RF or anti-CCP positivity, high disease activity (DAS28 >5.1), but did have the prognostic factor 'early erosive disease'.

Table 1. prevalence of typical RA erosive disease, and diagnostic/prognostic relevance of x-HF.

	All patients (N=724)	Seronegative (N=437)	Non-elevated APR (N=385)
Erosive disease (n (%, CI))	30 (4.1, 2.9-5.9)	5 (1.1, 0.5-2.7)	8 (2.1, 1-4.1)
Erosions relevant for RA classification with 2010 ACR/EULAR criteria (n (%, CI))	4 (0.5, 0.2-1.2)	2 (0.5, 0.1-1.8)	2 (0.5, 0.1-2.1)
Cases classified as prognostically unfavorable due to the X-HF (n (%, CI))	5 (0.6, 0.2-1.4)	3 (0.7, 0.2-2.1)	2 (0.5, 0.1-2.1)

Conclusion: RA-associated erosions at presentation with UA are rare, and their presence rarely leads to a change in diagnosis or prognosis. Routine x-HF should therefore not be recommended in this context. X-HF made for any specific indication might of course be of value, and our results do not generalize to these cases.

OP0173

CHARACTERIZATION OF AXIAL INVOLVEMENT USING 18F-FLUORIDE PET-CT IN SPONDYLOARTHRITIS PATIENTS

Keywords: Imaging, Spondyloarthritis, Pain

I. Giovannini[1], A. Zabotti[1], S. Diodato[2], C. Cicciò[3], M. Salgarello[2], D. Mcgonagle[4], I. Tinazzi[5]. *[1]Rheumatology Clinic, Azienda Sanitaria Universitaria Friuli Centrale c/o University of Udine, Udine, Italy*; *[2]Department of Nuclear Medicine, IRCCS Sacro Cuore Don Calabria, Negrar di Valpolicella, Italy*; *[3]Departments of Diagnostic Imaging and Interventional Radiology, IRCCS Sacro Cuore Don Calabria, Negrar di Valpolicella, Italy*; *[4]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals Trust*

& The University of Leeds, Leeds, United Kingdom; [5]*Unit of Rheumatology, IRCSS Sacro Cuore Don Calabria, Negrar di Valpolicella, Italy*

Background: Nuclear medicine positron emission tomography (PET) has limited evidence in the clinical management of axial Spondylarthritis (AxSpA). The 18F-fluoride isotope is a bone-specific tracer that is incorporated in the skeleton during bone remodelling. Osteoblastic bone remodeling, that culminates in new bone formation in SpA can be molecularly imaged with 18F PET. Although not widely employed, several studies have shown that 18F is an excellent isotope for evaluating sites of active osteoblastic activity[1], and may be used in the assessment of axial involvement in spondyloarthritis[2].
Objectives: Aim of this study is to identify the pattern of distribution of 18F uptake at baseline using the PET-Computerized Tomography (PET-CT) in the early AxSpA identification in patients with inflammatory back pain (IBP) according to ASAS criteria[3].
Methods: We analyzed data of 18F PET-CT in patients presenting IBP suspicious for SpA. Patients were assessed clinically at baseline and according to clinical practice with assignment of a the final diagnosis of axial SpA after at least two years of follow up, according to the ASAS criteria[4]. We evaluated the baseline 18F PET-CT abnormalities and correlated with the final diagnosis.
Results: 125 patients underwent 18F PET-CT. 83 were female (66,4%), and the mean age at evaluation time was 49.58 years (SD 11.03). Patients were classified into 5 groups according to the rheumatological diagnosis made after at least 2 years of follow-up. Ten patients fulfilled New York criteria for Ankylosing Spondylitis (AS), 28 patients fulfilled CASPAR criteria for Psoriatic Arthritis (PsA), 35 patients fulfilled ASAS criteria for undifferentiated SpA, and 12 patients presented axial-SpA related IBD. 40 patients were not classifiable as AxSpA (not-class AxSpA). The prevalence of 18F PET-CT abnormalities highlight differences in SpA phenotypes, shown in colour coding (Figure 1A). Similar results were reported in the chest, in particular among the sterno-clavicular and acromio-clavicular joints (Figure 1B).
Conclusion: Our study showed a clear pattern of abnormalities detected by 18F PET-CT in the spine and chest of AxSpA patients. 18F PET-CT might help clinicians to characterize the axial involvement in SpA patients.

OP0174 CHEST RADIOGRAPHS PRE-IMMMUNOSUPPRESSION HELP TO IDENTIFY NON TUBERCULOUS INFECTIONS AND INTERSTITIAL LUNG DISEASES, BUT ADD LITTLE TO LATENT TUBERCULOSIS SCREENING

Keywords: Imaging, Real-world evidence, Diagnostic Tests

R. Harrington[1], I. Khan[1], M. Ramakrishnan[2], F. Fitzpatrick[3], L. Durcan[1]. [1]*Beaumont Hospital, Rheumatology, Dublin, Ireland*; [2]*Royal College of Surgeons, School of Medicine, Dublin, Ireland*; [3]*Beaumont Hospital, Microbiology, Dublin, Ireland*

Background: Screening for latent tuberculosis (LTB) using chest x-ray (CXR) and interferon-gamma release assay (IGRA) is standard in patients starting on biologic and immunosuppressive therapies. Our hypothesis is that the CXR does not change management, and we sought to evaluate the additive value of plain radiographs for this purpose in our patients.
Objectives: To retrospectively review all CXRs performed at baseline pre treatment to determine if they provide any additive benefit value to the IGRA LTB screening approach.
Methods: This is a retrospective review of screening practices for LTB in a tertiary referral centre in Ireland, a low prevalence country. We included, 814 patients screened, using CXR and interferon gold release assay (IGRA) over a 5-year period.
Results: The IGRA was positive in 5% (38/814) and indeterminate in 2.5% (20/814), the remainder testing negative. In the IGRA positive group, 15.8% (6/38) had an abnormal CXR. None of these showed changes reflecting prior or active tuberculosis. These showed fibrotic lung disease, consolidations and basal atelectasis. Of those who had an indeterminate IGRA, 45% (9/20) of cases had an abnormal CXR, with one individual report of radiographic evidence of possible prior TB. In those with an abnormal IGRA (positive or indeterminate), the addition of CXR in the screening process changed management in one patient. They were treated for LTBI on the basis of indeterminate IGRA, prior TB contacts, country of origin and other risk factors. The sensitivity of the IGRA alone screening approach was 97.62% when high risk indeterminate results were assumed to have LTB and were treated. The resulting specificity of the IGRA alone approach was 97.80%. The sensitivity of the combined IGRA & subsequent CXR approach was 100% as it was deemed to have captured all actual cases of LTB disease. We acknowledge that this not recognise that IGRA is an imperfect test and assumes that there were no cases of LTB in 756 IGRA negative patients. The specificity of the combined IGRA and subsequent CXR approach remains practically the same at 97.93%.
Conclusion: In conclusion, the clinical utility of the CXR in screening for TB is unclear in this population. The addition of CXR in the screening process only changed management in 1 patient over a 5 year period in this cohort. The incidental identification of interstitial lung diseases and chest infections is of value to patients considering immunosuppression, but is a separate issue to screening for LTB.

OP0175 RELEVANT FEATURES IN FLUORESCENCE OPTICAL IMAGING FOR DIFFERENTIAL DIAGNOSIS OF RHEUMATIC DISEASES AFFECTING THE HANDS

Keywords: Psoriatic arthritis, Imaging, Rheumatoid arthritis

N. Stumper[1], J. Berger[2], V. Failli[2], E. Gedat[2], P. Hoff[1], G. Schmittat[1], A. Briel[2], G. R. Burmester[1], S. Ohrndorf[1]. [1]*Charité - Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; [2]*Xiralite GmbH, Xiralite GmbH, Berlin, Germany*

Background: Accurate and fast diagnosis of rheumatic diseases affecting the hands is essential for further treatment decision. Different rheumatic diseases affecting the hands present characteristic patterns and features in fluorescence optical imaging (FOI) as outlined in previous studies [1, 2].
Objectives: We tested an atlas of image features in FOI for their ability to differentiate various rheumatic joint diseases such as rheumatoid arthritis (RA), osteoarthritis (OA), psoriatic arthritis (PsA) and connective tissue diseases (CTD) like systemic sclerosis (SSc) and systemic lupus erythematodes (SLE) with the aim to identify specific features for differential diagnosis.

Methods: FOI images from patients with RA, OA, PsA and CTD were analysed by two readers blinded for diagnosis and calibrated against each other, using the prima vista mode (PVM) and the 5-phase model. For the latter, the overall time course of FOI in each hand was divided into 5 phases with a computational algorithm. Phases 1 and 2 describe the inflow (start to 15% and 15%-90% on rising edge), phase 3 is the peak phase and phases 4 and 5 comprise the outflow (90%-36.8% and 36.8% to end on falling edge). Twenty-six different features were defined, for example, the signal enhanced forearm (Y), broad signal enhancement along the finger (B), cloudy signal in the hand (W), secondary Raynaud syndrome (R), and underperfused nail bed region (U) (illustrated in the **Figure 1**). The feature frequency in each patient and phase (PVM, 5-phase) was counted and statistically analysed.
Results: In total, 374 patients (115 RA patients; mean age 54.4; SD 12.6; median 54.5), OA (89; 62.1; 7.4; 63.2), PsA (59; 50.0; 11.4; 49.2) and CTD (111; 52.2; 14.9; 54.5) were included in the feature reading. Statistical results (χ^2, diagnostic odds ratio DOR, sensitivity TPR, specificity TNR, positive predictive value PPV, negative predictive value NPV) are given in the **Table 1**. CTD can best be differentiated from RA, OA and PsA on the basis of the feature Y, in which sensitivity is high in all phases. CTD compared to RA in feature Y gives a similar result as in PsA. The other features B, W, R and U show Phase-dependent high specificity for CTD. Other significant image features from the atlas yield high specificity (70%-98%) while having low sensitivity (12%-52%) (data not presented).
Conclusion: This work supports that FOI feature analysis has the potential for differential diagnosis in rheumatic diseases affecting the hands. Feature Y has the ability to differentiate CTD (here mainly SLE/SSc) from RA, OA, and PsA while the features B, W, R and U can exclude CTD from RA, OA and PsA. In the future, FOI could therefore play an important role in the early arthritis clinic.

SELF-MANAGEMENT BEHAVIOUR, ANXIETY AND DEPRESSION IN PATIENTS WITH INFLAMMATORY ARTHRITIS - A CROSS SECTIONAL NATIONWIDE STUDY AMONG >12,000 DANISH PATIENTS

Keywords: Inflammatory arthritides, Health Services Research, Self-management

S. B. Vestergaard[1], B. A. Esbensen[2,3], J. Midtgaard[3,4], B. Glintborg[2,3], M. Aadahl[3,5], P. F. Cromhout[6], A. De Thurah[1,7]. [1]*Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark*; [2]*Center for Rheumatology and Spine Diseases, Center for Head and Orthopaedics, Rigshospitalet, DANBIO and Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Denmark*; [3]*University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*; [4]*Copenhagen University Hospital - Mental Health Services CPH, Centre for Applied Research in Mental Health Care (CARMEN), Mental Health Center Glostrup, Copenhagen, Denmark*; [5]*Bispebjerg and Frederiksberg Hospitals, Center for Clinical Research and Prevention, Copenhagen, Denmark*; [6]*Novo Nordisk A/S, 7061, Søborg, Denmark*; [7]*Aarhus University, Department of Clinical Medicine, Aarhus, Denmark*

Background: Anxiety and depression are the mental health issues most commonly associated with inflammatory arthritis (IA) and the link between mental health issues and poor health outcomes is well-established [1]. European recommendations on self-management in rheumatic and musculoskeletal diseases emphasizes the need to assess mental health regularly [2]. However, little is known about the association between self-management and mental health in IA.
Objectives: To investigate the prevalence of anxiety and depression in patients with IA and evaluate the association of these mental health issues and self-management behavior.
Methods: We conducted a nationwide cross-sectional study among adult Danish patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or spondylarthritis (axSpA). Eligible patients were identified through the Danish Rheumatology database DANBIO and received an electronic questionnaire. The questionnaire covered socio-demographics, self-management behavior and mental health status indicated by the Hospital Anxiety and Depression Scale, a 14-item tool with 2 sub-scales assessing symptoms of anxiety and depression. Self-management behavior was indicated by: *Adherence to treatment* using Compliance Questionnaire Rheumatology-5 item, *Patient activation in healthcare* using two items from the Patient Activation Measure-13 questionnaire and *level of physical activity* covering weekly recommendation from WHO and American College of Sports Medicine. Self-management measures were dichotomized into high or low. Questionnaire data were linked to clinical data from DANBIO. The association between low self-management behaviour and mental health status were estimated using multivariable logistic regression with odds ratios (OR).
Results: A total of 42,407 patients with IA were identified; 30% (N=12,715) completed the questionnaire. Non-responders were younger than responders (60 (±16) vs. 62 (±13) years) with a similar gender distribution (p=0.187). The prevalence of anxiety (HADS-A ≥8) was highest for patients with axSpA (34.5% (95% CI; 32.4; 36.6)) and lowest for patients with RA (22.1% (95% CI: 21.2; 23.0)). Prevalence of depression (HADS-D ≥8) was highest for patients with PsA (27.2% (95%CI: 25.4;29.0)) and lowest for patients with RA 18.6% (95%CI: 17.7;19.4). For both anxiety and depression, the prevalence was higher for women, younger (<55 years), newly diagnosed (<3 years) and patients with basic education. Patients having a clinical level (HADS ≥8) of anxiety and depression were more likely to have low self-management behavior for all included self-management measures (Table 1).

Table 1. Association between mental health issues and self-management behavior

		Adherence to treatment	Patient activation in healthcare		Physical activity
			Can tell when outpatient care is needed	Can handle new situations with health condition	
		OR (95% CI)*	OR (95% CI)*	OR (95% CI)*	OR (95% CI)*
Anxiety	HADS-A ≤7	Ref	Ref	Ref	Ref
	HADS-A 8-10	1.22 (1.09;1.36)	2.33 (2.03;2.68)	2.91 (2.60;3.25)	1.32 (1.18; 1.47)
	HADS-A ≥11	1.41 (1.24;1.60)	4.33 (3.76;4.99)	5.72 (5.03;6.50)	1.62 (1.42;1.85)
Depression	HADS-D ≤7	Ref	Ref	Ref	Ref
	HADS-D 8-10	1.35 (1.20;1.52)	2.97 (2.60;3.39)	3.91 (3.50;4.38)	1.96 (1.74;2.22)
	HADS-D ≥11	1.30 (1.12;1.51)	4.96 (4.24;5.80)	7.09 (6.11;8.22)	2.43 (2.06;2.88)

*Adjusted for age, sex, education. Ref: reference group, low self-management behavior

Conclusion: In this nationwide study, high levels of anxiety and depression were seen among patients with IA. A strong association between anxiety and depression and low self-management behavior was identified. These findings call for a systematic approach in identifying mental health issues in patients with IA.

OP0177-HPR HEALTH-RELATED QUALITY OF LIFE PROFILES OF ADULTS WITH ARTHRITIS

Keywords: Mental health, Quality of life

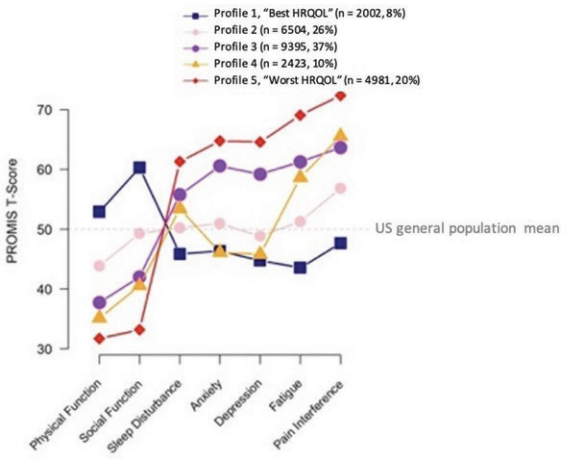
E. Knight[1], K. Carluzzo[1], B. Reeve[2], J. Singh[3], K. Mueller[4], L. Lin[2], K. Schifferdecker[5]. [1]*Dartmouth College, Center for Program Design and Evaluation, Geisel School of Medicine, Hanover, NH, United States of America*; [2]*Duke University School of Medicine, Department of Population Health Sciences, Durham, NC, United States of America*; [3]*University of Alabama at Birmingham, Department of Medicine, Clinical Immunology and Rheumatology, Birmingham, AL, United States of America*; [4]*Arthritis Foundation, Science Strategy, Atlanta, GA, United States of America*; [5]*Dartmouth College, The Dartmouth Institute, Geisel School of Medicine, Hanover, NH, United States of America*

Background: Adults with arthritis display poorer health-related quality of life (HRQOL) than the general population, including greater anxiety, depression, pain, and fatigue, and poorer physical function. Still, arthritis is a variable disease and the impact on HRQOL is heterogeneous in terms of severity and domains of impact. Some factors are associated with HRQOL outcomes in adults with arthritis, though research often focuses on a single outcome (like pain) rather than multiple HRQOL domains simultaneously. Examining protective and risk factors against a constellation of HRQOL outcomes would be beneficial for treatment of arthritis as a disease that impacts multiple areas of patients' lives.

Objectives: We aimed to identify profiles of HRQOL impact using the NIH's Patient-Reported Outcomes Measurement Information System (PROMIS) measures in a sample of adults with arthritis (osteoarthritis, inflammatory arthritis, fibromyalgia; with other arthritis types). We also aimed to identify demographic and clinical factors associated with HRQOL profile membership that serve as protective or risk factors against poor HRQOL outcomes.

Methods: Data including PROMIS measures of physical and social function, sleep disturbance, anxiety, depression, fatigue, and pain interference (PROMIS-29) and emotional support were collected through a national foundation's online survey of adults with arthritis in the U.S. PROMIS T-scores are calibrated with the U.S. general population mean of 50 (SD = 10). Higher function T-scores reflect better functioning and higher symptom T-scores reflect worse symptom burden. We used latent profile analysis (LPA), a patient-centered modeling approach, to characterize the heterogeneity in arthritis patients by clustering them into HRQOL profiles, determined based on statistical model fit and clinical interpretability. Participants were assigned to a HRQOL profile, and we fit a multinomial logistic regression model with HRQOL profile assignment as the outcome (best HRQOL profile as reference group) to determine associations with emotional support and demographic and clinical factors.

Results: We included 25,305 adults with arthritis. The LPA results favored a five-HRQOL profile solution (entropy = 0.83). See Figure 1 for profile details and participant counts. Profile 1 (8% of sample), the best HRQOL group, displayed higher physical and social functioning and lower physical and mental symptoms. Profiles 3 (37% of sample) and 4 (10% of sample) were similar, except those in Profile 4 had reduced anxiety and depression similar to Profile 1. Profile 5 (20% of sample), the worst HRQOL group, displayed mean T-scores close to 2 SDs below the US general population mean. All of the demographic and clinical factors were significant, including arthritis type. Compared to being classified into the best HRQOL group, participants who were unable to work were 39 times (95% CI = 20.35-73.85) more likely to be in the worst HRQOL group as participants who were working. Notably, higher emotional support (95% CI= 0.88-0.89) and starting to exercise (95% CI=0.45-0.70) were associated with a lower likelihood of membership in the worst HRQOL group (Profile 5).



Conclusion: With the exception of the best HRQOL group, all the other HRQOL profiles (92% of sample) had poorer physical function and worse pain interference than the US general population, and elevated depression and anxiety, with some exceptions. Malleable factors such as emotional support and exercise served a protective function. These results highlight the value of considering multiple components of the patient's HRQOL experience alongside treatment options, and the potentially positive impact of interventions beyond medication.

OP0178-HPR YOU FIRST: A COST-EFFECTIVE NURSE-LED PATIENT SUPPORT PROGRAMME – RETROSPECTIVE ANALYSIS FROM A LARGE MULTI-ETHNIC SETTING

Keywords: Real-world evidence, Spondyloarthritis, Psoriatic arthritis

M. Nisar[1], J. Begum2. [1]*Luton & Dunstable University Hospital NHS Foundation Trust, Department of Rheumatology, Luton, United Kingdom*; [1]*Luton & Dunstable University Hospital NHS Foundation Trust, Department of Rheumatology, Luton, United Kingdom*

Background: The global impact of COVID-19 on elective rheumatology services is unprecedented, [1,2] and the number of people on waiting lists for consultant-led elective care in the UK has almost doubled. [3] Implementation of patient support programmes that provide an individualised nurse-led service, such as You First, may help to reduce the strain on healthcare resources. You First is aimed at people who have been prescribed secukinumab, an injectable anti-interleukin 17A monoclonal antibody, for approved indications including psoriatic arthritis (PsA), ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis.
Objectives: This retrospective analysis aimed to evaluate the benefits of the You First patient support programme on the Rheumatology service at a large university teaching hospital with a catchment population of 350,000, of whom 40% are from ethnic minorities.
Methods: The analysis included adult participants who were eligible for treatment with secukinumab according to National Institute for Health and Care Excellence criteria and were enrolled in the You First programme. All You First nurses were registered with the Nursing, and Midwifery Council and underwent specific training, competency assessment and validation to ensure they met all regulatory clinical standards of National Health service (NHS) practice. Each participant was assigned to a dedicated nurse who visited the participant's home to provide routine clinical assessments, routine follow-up visits, phlebotomy service, psychological support visits, injection training and routine secukinumab administration, as required. Participants could also schedule regular nurse telephone calls to discuss any disease or drug related concerns such as secukinumab dosing/adherence check and side effect management. All data gathered during the home visits and telephone calls were reported to the treating physicians. Calculation of cost savings was based on the number of visits carried out as part of You First and the cost that the NHS would have incurred if the visit occurred at the hospital (£2.02 for phlebotomy service, £24 for telephone contact, and £99 for each assessment, routine follow-up visits and psychological support visit). Here we present annualised data from 28 February 2019 to 14 July 2022.
Results: In total, 126 participants with PsA (n=81) and AS (n=45) were observed for 17.2 months on average. At baseline, the mean age was 52.7 years and 39.2% of participants were male. During the timeframe of this analysis, You First nurses had 1160 contact points with the clinical team (793 visits; 367 telephone calls). The median (interquartile range) number of visits and telephone calls carried out as part of the programme per participant per year was 6.4 (4.6–11.3): phlebotomy service 0.4 (0.0–1.6), clinical assessments 1.4 (0.0–2.0), routine follow-up visit 1.6 (0.7–3.1), psychological support visit 0.0 (0.0–0.0) and telephone contact 2.0 (1.0–4.7). This translated to an annual cost saving of £64,156.49 (phlebotomy service £335.90, clinical assessments £15,159.13, routine follow-up visits £36,434.58, psychological support visit £368.90, telephone contact £11,857.99).
Conclusion: Implementation of You First at this large university teaching hospital yielded substantial cost savings for the NHS, with outsourced visits providing the most cost savings. You First allowed people with PsA or AS to be managed at home, freeing NHS capacity for appointments with new and complex patients in the clinic.

Background: Improved work participation is an important goal in rehabilitation, and has important socio-economic benefits. Despite this, there is limited knowledge about how rehabilitation impacts work ability across different diagnostic groups.
Objectives: To examine whether personal and disease-related factors predict changes in self-perceived work ability one year after rehabilitation.
Methods: In a longitudinal multicenter rehabilitation cohort (RehabNytte) 17 rehabilitation centers across Norway recruited more than 3700 patients with rheumatic and musculoskeletal diseases (RMD) as the largest diagnostic group [1]. Participants completed questionnaires at admission and discharge, and after 3, 6 and 12 months. Work ability was self-reported with a single item from the Work Ability Index (WAI) (2), referred to as the Work Ability Scale (WAS), where patients compared their current work ability to their lifetime best on a 0-10 scale (10= best work ability). For the logistic regression analysis WAS was categorized as either low/moderate (≤7) or good/excellent (≥8) [3]. Variables of interest were age, gender, diagnosis (cancer, rheumatic and musculoskeletal diseases, other), comorbidities, health region, education level (low, medium, high), body mass index (BMI), smoking, pain intensity (NRS-scale 0-10) and self-reported health (EuroQol VAS, scale 0-100). Retired patients were removed from analysis. A logistic regression model was fitted with variables individually predicting WAS at 12 months follow up, adjusted for sociodemographic and lifestyle variables and baseline WAS.
Results: Mean age at baseline was 53.3 (13.6) years. Seventy percent were female, 42 % had RMD, 24 % cancers and 33 % other diseases. Mean WAS at baseline (n= 3096) was 3.3 (SD 3.0), which significantly increased to 4.4 (3.2) at 12-months follow-up (n= 2397) ($p<0.001$, Figure 1). Good WAS-score ≥ 8 at 12 months (adjusted for baseline work ability score and BMI) was predicted by high education level, higher age and high self-reported health at baseline, whereas low WAS-score ≤7 was predicted by RMD or cancer diseases, number of comorbidities and higher pain intensity (Table 1, OR in bold indicates $p<0.05$).
Conclusion: In addition to disease- and demographic factors like high age, high education, comorbidities and presence of RMD, changes in work ability scores were related to pain and self-reported health, factors that are modifiable trough rehabilitation.

Table 1. Logistic regression model of work ability 12 months after rehabilitation.

	Work ability

Background: Lack of continuity in rehabilitation across levels of care is a known weakness of existing services. The BRIDGE-intervention was developed to improve the quality and continuity of rehabilitation for patients with rheumatic and musculoskeletal diseases (RMDs) by means of goal directed, coordinated, individually tailored follow-up after rehabilitation discharge. The intervention was evaluated in a multi-center randomised controlled trial (the BRIDGE trial) in Norway.
Objectives: The objective of this study was to explore what patients with RDMs need and receive of follow-up support in their municipality of residence after rehabilitation in secondary healthcare, and whether such follow-up impacts on clinical outcomes 1 year after rehabilitation. Further, to compare these findings with patients' experiences with follow-up support to develop a better understanding of how such follow-up works across levels of care.
Methods: The study had a concurrent mixed methods design in which quantitative and qualitative data were collected in parallel, analyzed separately, before integrated into an overall result. All participants in the intervention group (n=168) of the BRIDGE-trial were included. Quantitative data were patient-reported in an electronic portal. Demographic and disease-specific data were collected on admission to rehabilitation. Data on goal attainment (Patient Specific Functional Scale), physical function (30 seconds Sit-To-Stand test), health related quality of life (EQ5D-5L-index), and health status (EQ-VAS) were reported at discharge, 2, 7 and 12 months after rehabilitation. Needs for follow-up were reported at rehabilitation discharge by ticking off a list of 12 predefined options. The patients were categorized into 4 groups based on their needs for follow-up on discharge (yes/no) and the degree of follow-up received according to stated needs the first year after rehabilitation (none/partial/complete). Quantitative data were analyzed using descriptive statistics, ANCOVAs, and linear regression. Qualitative data about patients' experiences with follow-up were collected in semi-structured interviews with 21 patients and analyzed using reflexive thematic analysis. The results were integrated in the overall interpretation and discussion.
Results: The patients most often reported needs for follow-up from General Practitioner, physiotherapist, and social security services, and did mostly receive (> 85%) these services within 1 year after rehabilitation. There were no significant differences between the 4 groups with regard to characteristics at discharge, or clinical outcomes 1 year after rehabilitation. Received individually tailored follow-up was not shown to significantly influence clinical outcomes, and was, surprisingly, associated with reduced patient reported health 1 year after rehabilitation: EQ-VAS β 0.28 [95% CI -0.48, -0.09], p=0.004. The qualitative analysis resulted in three themes: "Contact between service levels" (established through various actors, processes, documents), "Follow-up keeps the rehabilitation process going" (by increasing motivation and focus on goals and self-effort after discharge), and " Loss of momentum' (linked to personal and structural factors).
Conclusion: Patients with RMDs report needs for follow-up from one or more healthcare services after rehabilitation in secondary care. Clinical outcomes 1 year after rehabilitation appeared to be influenced by several other factors than the actual received follow-up support. Health personnel's competence and structural factors across health service levels, such as waiting lists and limited access to care, seemed to be decisive for the progress of the rehabilitation process over time, together with factors related to the individual patient and his/her life situation. The findings can contribute to increased insight into what promotes continuity in rehabilitation processes, effective follow-up, and better health for this patient group.

OP0181-HPR SOCIO-ECONOMIC, DISEASE-RELATED, AND PERSONAL FACTORS ASSOCIATED WITH PARTICIPATION IN REMOTE FOLLOW-UP IN RHEUMATOID ARTHRITIS – A CROSS-SECTIONAL STUDY

Keywords: Patient reported outcomes, Telemedicine, Rheumatoid arthritis

L. Schougaard[1], L. Knudsen[2,3], B. Grove[1], N. H. Hjøllund[1,4], E. M. Hauge[2,3], A. De Thurah[2,3]. *[1]Gødstrup Hospital, AmbuFlex - Center for Patient-reported Outcomes, Herning, Denmark*; *[2]Aarhus University Hospital, Department of Rheumatology, Aarhus N, Denmark*; *[3]Aarhus University, Department of Clinical Medicine, Aarhus N, Denmark*; *[4]Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus N, Denmark*

Background: Remote follow-up by collecting patient-reported outcome (PRO) measures allows for new opportunities such as real-time monitoring of symptoms and flexible scheduling of hospital visits based on patient needs[1]. In Denmark, a remote PRO-based follow-up intervention has been implemented among outpatients with rheuamtoid arthritis (RA), and today, 35% of the outpatient population attends remote care. However, no study has explored factors associated with participation in remote care.
Objectives: To identify socio-economic, disease-related, and personal factors associated with participation in remote follow-up in RA patients.
Methods: We conducted a cross-sectional study among 775 prevalent RA patients from Aarhus University Hospital. In January 2019, eligible RA patients received an electronic questionnaire, covering health literacy and patient experience regarding involvement and confidence with remote care. In addition, we collected data from nationwide registers regarding socio-economic status, labor market affiliation, and co-morbidity. Associations between register and questionnaire-based factors and remote follow-up were analyzed using multiple logistic regression.
Results: A total of 775 patients were included in the register-based analyses. Since 129 patients did not have a digital mailbox, 646 patients received the electronic questionnaire which was completed by 394 (61%) patients. No labor market attachment and low household income was associated with lower odds for remote follow-up participation (OR 0.53 (95% CI 0.34 – 0.83)) and (OR 0.69

(95% CI 0.48 – 1.00)). Further, a high level of co-morbidity was associated with lower odds for remote follow-up participation compared to a low/medium level of co-morbidity (OR 0.53 (95% CI 0.34 – 0.81)). No association was found between health literacy and remote follow-up. Remote follow-up attendees reported more confidence in remote care (OR 1.33 (95% CI 1.20 – 1.47)).

Conclusion: Patients participating in remote follow-up were more likely attached to the labor market, had higher income levels, had a lower level of comorbidity, and expressed higher confidence in remote care. Future research should focus on how to support RA patients in conventional follow-up to achieve confidence in remote follow-up, as well as increased focus on vulnerable patient groups and the need for differential use of healthcare services.

OP0182-HPR EFFICACY OF NON-PHARMACOLOGICAL INTERVENTIONS: A SYSTEMATIC REVIEW INFORMING THE 2023 EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF FATIGUE IN PEOPLE WITH INFLAMMATORY RHEUMATIC AND MUSCULOSKELETAL DISEASES

Keywords: Non-pharmacological interventions, Patient reported outcomes, Systematic review

E. Santos[1], B. Farisogullari[2], E. Dures[3,4], P. Machado[5,6,7]. [1]*Nursing School of Coimbra (ESEnfC), Health Sciences Research Unit: Nursing (UICISA: E), Coimbra, Portugal*; [2]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; [3]*University of the West of England, School of Health and Social Wellbeing, Bristol, United Kingdom*; [4]*Bristol Royal Infirmary, Academic Rheumatology, Bristol, United Kingdom*; [5]*University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom*; [6]*University College London Hospitals NHS Foundation Trust, National Institute for Health Research (NIHR) University College London Hospitals Biomedical Research Centre, London, United Kingdom*; [7]*Northwick Park Hospital, London North West University Healthcare NHS Trust, Department of Rheumatology, London, United Kingdom*

Background: Several EULAR recommendations for the management of people with specific inflammatory rheumatic and musculoskeletal diseases (I-RMDs) have highlighted the importance of some non-pharmacological interventions in the management of fatigue [1-3]. However, these recommendations are either disease-specific or focusing on a single intervention, and lack an integrated view of the overall evidence for fatigue management with non-pharmacological therapies in the wider context of all I-RMD.

Objectives: To identify the best evidence on the efficacy of non-pharmacological interventions in reducing fatigue in people with I-RMDs and to summarise their safety in the identified studies to inform EULAR recommendations for the management of fatigue in people with I-RMD.

Methods: Systematic review of adults with I-RMD conducted according to the Cochrane Handbook. Search strategy ran in Medline, Embase, Cochrane Library, CINAHL Complete, PEDro, OTseeker and PsycINFO. Assessment of risk of bias, data extraction, and synthesis performed by two reviewers independently. Data pooled in statistical meta-analyses.

Results: From a total of 4,150 records, 454 were selected for full-text review, 82 fulfilled the inclusion criteria, and 55 RCTs were included in meta-analyses. Physical activity or exercise were efficacious in reducing fatigue in rheumatoid arthritis (RA) (SMD=-0.23, p<0.001), systemic lupus erythematosus (SLE) (SMD=-0.54, p=0.04) and spondyloarthritis (SpA) (SMD=-0.94, p<0.001). A reduction in fatigue was also observed in Sjögren's syndrome and systemic sclerosis, although not statistically significant (SMD=-0.83, p=0.21; SMD=-0.66, p=0.06, respectively). Psychoeducational interventions were efficacious in reducing fatigue in RA (SMD=-0.32, p<0.001), but not in SLE (SMD=-0.19, p=0.18). Follow-up models in consultations and multicomponent interventions reduced fatigue in RA, although the effect was not statistically significant (SMD=-0.05, p=0.71; SMD=-0.20, p=0.24, respectively) (**Figure 1**). The narrative results of the RCTs not included in the meta-analysis indicated that several other non-pharmacological interventions were efficacious in reducing fatigue, with reassuring safety results.

Conclusion: Non-pharmacological interventions are efficacious and safe for the management of fatigue in people with I-RMD.

OP0183-PARE CO-DESIGNING JIA TOOLBOX: A PROOF-OF-CONCEPT STUDY ASSESSING PROTOTYPE INNOVATIONS TO HELP SELF-MANAGEMENT IN CHILDREN AND YOUNG PEOPLE WITH RHEUMATIC DISEASE

Keywords: Self-management, Inflammatory arthritides, Non-pharmacological interventions

U. Ankeny[1,2], C. Dunbar[2], N. Dulake[1], J. Langley[1], D. Hawley[2]. [1]*Sheffield Hallam University, Lab4Living, Sheffield, United Kingdom*; [2]*Sheffield Children's Hospital, Paediatric Rheumatology, Sheffield, United Kingdom*

Background: Juvenile idiopathic arthritis (JIA) is the most frequently occurring rheumatic disease of childhood. It causes ongoing joint inflammation, pain and stiffness making everyday activities difficult. Studies have emphasised the negative impacts JIA has across physical, social, psychological, and educational development. Devices exist to assist with daily activities such as washing, eating, or writing. However, a survey we conducted in 2018 highlighted that the majority of these are designed for adults. Those designed for Children and Young People (CYP) are often either difficult to use, stigmatising, patronising, or fail to address their unique needs and contexts. This has resulted in numerous unmet needs and a lack of effective innovations for this population. The innovation, JIA Toolbox, was co-designed, meaning CYP with JIA, their parents, healthcare professionals, teachers and design researchers collectively collaborated throughout its development. Here, we present the intervention stage of the project, where JIA Toolbox was tested and evaluated by CYP with JIA.

Objectives: To evaluate the potential impacts of JIA Toolbox in improving independence and functional ability of CYP with JIA. To obtain real-world feedback on

JIA Toolbox to inform future device refinement. To provide contemporary data on CYP's experiences of living with JIA to inform future innovation.
Methods: JIA Toolbox was tested over a 9-week period. This suite of innovations consisted of:

- Prototype 1: A wearable pain management device
- Prototype 2: A motivational physiotherapy tool
- Prototype 3: A communication aid for use in school

Fig 1. JIA Toolbox

A sample size of 10 CYP (7-16yrs), their parents and teachers were involved. Whilst small, this number was felt adequate due to the individual and qualitative nature of JIA condition experience.
Their involvement included:

- Training sessions for data collection and prototype use. CYP and their parents recorded their daily experience using a digital booklet with specific questions about their condition and prototype use.
- 3-week baseline data collection without JIA Toolbox.
- 5-week intervention data collection with JIA Toolbox.
- 1-week post intervention data collection without JIA Toolbox.
- End of intervention interview.

Results: Analysis of the findings is currently being undertaken. Preliminary results indicate that 70-90% of the sample group found one or more of the innovations highly beneficial, helping with their overall condition management. Prototype 1 was highlighted as an effective therapeutic aid "it helped soothe my knee, I liked how you can position it exactly where it hurts". One patient found it reduced pain when used with joint injections. Prototype 2 was helpful for physiotherapy exercises "to keep count" and "know how long to hold it for" with preliminary data indicating at least 50% of users increased the regularity of their physio stretches over the intervention period. The innovation acted as an ongoing reminder, "it encouraged him to do his physio stretches as he hadn't been doing any before". Prototype 3 "helped communicate when I was in pain and needed help". The use of this intervention depended on the child's individual confidence, with those feeling less confident, relying more on the technology. These users found it beneficial, "the teacher knew I needed a rest break without me having to say anything in front of the rest of the class". Participants also highlighted areas that could be improved to increase ease of use and engagement.
Conclusion: Based on initial results, the proof-of-concept was successful with these innovations proving to be beneficial to CYP with JIA. The patient data will allow refinement of these devices and provide insights into the lived experiences of CYP with JIA. These devices may have applicability to both adult populations with rheumatic disease and CYP with other conditions. Further research will explore these avenues in the future. Next steps include applying for further funding to undertake a feasibility study with a larger sample population.
Acknowledgements: I would like to thank The Children's Hospital Charity, based at Sheffield Children's Hospital, for their funding to undertake this project and ongoing support. I would also like to thank NIHR Children and Young People MedTech Cooperative for their early support and ongoing assistance throughout this project. Special thanks to all of the children, young people, families and teachers who contributed their time and expertise.

E-health - possibilities and pitfalls

OP0184-PARE HOW REPRESENTATIVE ARE PATIENT REPRESENTATIVES? HEALTH LITERACY SCORES AND PROFILES OF REPRESENTATIVES OF PATIENT ORGANISATIONS AS COMPARED TO AN EXISTING SAMPLE OF PEOPLE WITH RMDS

Keywords: Patient information and education, Self-management, Outcome measures

M. M. Bakker[1,2], M. De Wit[3], E. Mateus[3,4], D. Wiek[3], A. Boonen[1,2], R. Osborne[5].
[1]Maastricht University Medical Centre, Internal Medicine, Rheumatology Division, Maastricht, Netherlands; *[2]Maastricht University, CAPHRI - Care and Public Health Research Institute, Maastricht, Netherlands*; *[3]EULAR, PARE, Zürich, Switzerland*; *[4]Universidade NOVA de Lisboa, CHRC - Comprehensive Health Research Centre, NOVA Medical School, Lisbon, Portugal*; *[5]Swinburne University of Technology, Centre for Global Health and Equity, Melbourne, Australia*

Background: Patient organisations are a key resource of information and support for people with rheumatic and musculoskeletal diseases (RMDs). Patient representatives advocate for the development of appropriate resources and provide organisations with a rich range of perspectives, including health literacy strengths, needs and preferences. Health literacy is defined as *"the personal knowledge and competencies that accumulate through daily activities, social interactions and across generations. Personal knowledge and competencies are mediated by the organisational structures and availability of resources that enable people to access, understand, appraise and use information and services in ways that promote and maintain good health and well-being for themselves and those around them"* [1].
Objectives: To identify health literacy strengths and weaknesses among patient representatives of RMD patient organisations, and compare with an existing dataset of people with RMDs attending outpatient rheumatology clinics [2].
Methods: All patient representatives attending the EULAR PARE Conference 2022 were invited to participate in an online survey before the conference. Health literacy was assessed using the Health Literacy Questionnaire (HLQ), which provides scores for nine distinct domains (higher scores being better; scores range 1-4 for domains 1-5, and 1-5 for domains 6-9). The survey also included socio-demographics and health-related characteristics. Hierarchical cluster analysis of patient representatives' HLQ domain scores identified distinct health literacy profiles, based on minimal variance within and maximum variance between profiles. Results were compared with an existing cross-sectional sample of 895 patients with RMDs from different regions in the Netherlands. HLQ domain scores and patient characteristics were compared using chi-square and independent t-tests. Identified health literacy profiles were compared visually using heat maps.
Results: 56 patient representatives completed the survey (76% response rate). Compared to previously surveyed patients, patient representatives were younger (mean ±SD age 49.3±13.0 vs. 61.1±13.9), more often female (79% vs. 49%, p<0.001), more highly educated (79% vs. 24.5% high education, 0% vs. 51% low education, p<0.001), more often employed (64% vs. 33%, p<0.001), and less often of migrant background (7% vs. 18%, p=0.044). Both groups were similar in terms of comorbidities (RDCI = 1.3 vs. 1.2), self-reported health (6.5 vs. 6.4), household (16% vs. 25% living alone) and mastery (20.3 vs. 20.0). Patient representatives scored higher on "3. Actively managing health" (3.1 vs. 2.9, p=0.001 & "5. Critical appraisal of information (3.2 vs. 2.7, p<0.001), but lower on "6. Actively engaging with providers" (3.6 vs. 4.0, p=0.001) & "7. Navigating the health system" (3.5 vs. 3.8, p=0.002). While similar patterns were seen in health literacy profiles, the profiles that represent most complex challenges in the patient survey (representing 16% of patients) were not found among patient representatives (see Figure 1).

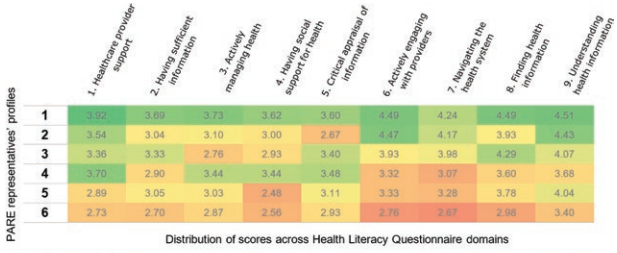

Figure. Heat map of six identified health literacy profiles of patient representatives, showing mean Health Literacy Questionnaire scores per domain for each profile. Colours follow a traffic light sequence: scores marked in red indicate lowest scores (orange = low, yellow = moderate, green = high).

Conclusion: Patient representatives of RMD patient organisations represent diverse profiles of health literacy strengths and weaknesses, but the most complex challenges in the original patient survey were not found. Differences may relate to how patients are selected and supported to become a representative, and how being a representative improves some aspects of health literacy. Patient organisations should take into account that their target population generally has more difficulty actively managing health and critically appraising information, and includes more people with diverse health literacy needs than their patient representatives may report.

Demoruelle[5], K. A. Kuhn[5], F. Zhang[5], T. Bumol[1], V. M. Holers[5], P. Skene[1], X. J. LI[1], G. Firestein[4], T. Torgerson[1], K. Deane[5], A. Savage[1]. *[1]Allen Institute for Immunology, Immunology, Seattle, United States of America*; *[2]Benaroya Research Institute, Center for Interventional Immunology, Seattle, United States of America*; *[3]Benaroya Research Institute, Translational Research Program, Seattle, United States of America*; *[4]University of California San Diego, Department of Medicine, La Jolla, United States of America*; *[5]University of Colorado Anschutz Medical Campus, Department of Medicine, Aurora, United States of America*

Background: RA-associated autoantibodies (RF, ACPA) are detectable before the onset of clinically-apparent inflammatory arthritis (IA) and classifiable RA (i.e. "Clinical RA"), defining a state known as 'At-Risk' for future RA. However, RA prevention trials in individuals in this At-Risk state have shown limited success in prevention. A challenge to developing more effective preventive interventions is that the immune phenotype of the At-Risk state remains incompletely understood.
Objectives: The purpose of this study was to (1) evaluate the hypothesis that ACPA(+) At-Risk individuals have immunopathologic features of Clinical RA, and (2) determine additional molecular features that define the At-Risk state. We propose that such features may help to identify biomarkers and causal pathophysiologic mechanisms that could be treatment or prevention targets. Furthermore, At-Risk immune features could improve prediction of future Clinical RA, as well as be used to monitor responses to therapeutic interventions.
Methods: Using a cross-sectional methodology, we analyzed ACPA(+) individuals without baseline IA (i.e. At-Risk) and age, sex and BMI matched ACPA(-) controls without IA (Table 1). We tested plasma proteomics, peripheral blood mononuclear cell (PBMC) composition by flow cytometry, and PBMC transcriptomes by single-cell RNA-sequencing (scRNA-seq). We further compared these findings to immunophenotypes reported in patients with Clinical RA. All studies were performed as part of a collaborative effort between the Allen Institute for Immunology, University of California San Diego, University of Colorado and Benaroya Research Institute.
Results: We observed significant differences in plasma levels of 138 proteins between ACPA(+) individuals vs. controls, including IL-6 (log2 fold change (FC) = 0.59-0.62, adjusted p value (padj) < 0.05), IL1B (log2 FC = 0.44, padj = 0.006), and CCL3 (log2 FC = 0.60, padj = 0.002). These changes also included additional elevated inflammatory chemokines and cytokines that have been reported in Clinical RA. B cell receptor signaling was one of the most significantly enriched protein pathways in ACPA(+) individuals. These proteomic alterations in ACPA(+) individuals were accompanied by numerous PBMC phenotypic changes, notably an increase in IgD- CD27- B cells (log2 FC = 0.814, padj = 0.002). Furthermore, compared to controls, scRNA-seq of IgD- CD27- B cells from ACPA(+) individuals expressed lower levels of genes previously shown to be increased in IgD- CD27- B cells or autoimmune processes, including SAMHD1 (log2 FC = -0.34, padj < 0.05), ARID3A (log2 FC = -0.32, padj < 0.05), and ZC3H12D (log2 FC = -0.30, padj < 0.05), suggesting dysregulation of this compartment at the preclinical stage.
Conclusion: ACPA(+) At-Risk individuals demonstrate numerous immune-related changes that are similar to changes in established Clinical RA, suggesting the ACPA(+) At-Risk state is on a continuum with Clinical RA. Highlighted are plasma proteomics demonstrating cytokine/chemokine elevations and B cell signaling pathways, and PBMC studies demonstrating specific B cell phenotypes and gene expression. These findings provide insights to potential immunopathologic mechanisms that may impact how we define the 'At-Risk' state, may improve prediction of future RA, and suggest targets for interventions or intermediate endpoints in trials for RA prevention.

Background: Lupus nephritis (LN) is a common and severe complication of systemic lupus erythematosus (SLE) requiring renal biopsy to guide treatment decisions. Despite standard-of-care therapy, a third of patients with LN class III, IV, or V show a progressive decline in kidney function, including those with improved proteinuria. Defining LN heterogeneity using a non-invasive approach is a pressing need to improve treatment.

Objectives: To determine circulating immune cell phenotypes characteristic of LN histology.

Methods: Mass cytometry using four 48-marker panels were applied to characterize peripheral blood mononuclear cells (PBMC) from 140 patients with biopsy-proven class III, IV, or V LN and 40 healthy controls included in the Accelerated Medicine Partnership RA/SLE Network Phase II study. After filtering for quality control and correcting for batch effects, we projected cells in a reduced dimensional space and identified cell neighborhoods and clusters using an unsupervised approach. We implemented covarying neighborhood analysis (CNA) to identify cell populations associated with clinical features.

Results: Compared to controls, LN patients displayed marked enrichment of cell neighborhoods that expressed interferon (IFN)-induced proteins including MX1 (p.adj < 0.001) and Siglec1 (p.adj < 0.001), reflecting a simple, cytometric detection of an IFN signature. Detailed immune cell subsetting using the B cell- (Figure 1A), T cell-, myeloid cell-, and NK cell-focused panels identified several alterations in LN patients compared to controls, including increased $CD27^{-}IgD^{-}$(DN) $CD11c^{+}Tbet^{+}$ B cells (OR 1.6, 95%CI 1.3-2.2, p.adj < 0.001) and T peripheral helper cells (OR 1.8, 95%CI 1.3-2.8, p.adj = 0.002), and decreased plasmacytoid dendritic cells (OR 0.6, 95%CI 0.4-0.8, p.adj < 0.001), adjusting for age, sex, ethnicity and race. LN patients with minimal immunosuppression (IS, n=14) displayed similar results. Comparing patients with proliferative LN (class III or IV +/- V, n=94) versus membranous LN (class V, n=46), we observed the most significant alterations within B cells, with enrichment of a naive B cell population characterized as $CD23^{-}$ and $CD21^{dim}$ (Figure 1B,C). The phenotype of this enriched naive B cell population was distinct from transitional and $CD11c^{+}$ 'activated naive' cells (Figure 1D). This B cell population was also associated with increased histologic NIH activity score (Figure 1B,C) even after adjusting for IS, and with positive anti-dsDNA antibody (p = 0.02). To further understand the LN heterogeneity, we clustered LN patients and controls based on proportions of all PBMC subsets using k-means clustering and projected subjects in a UMAP space. We identified two prominent clusters: cluster 1 included only LN patients, and cluster 2 included all controls and 26 LN patients. LN patients in cluster 2 (Control-like) had significantly lower clinical extrarenal activity (coef -1.1, 95%CI -2.1--0.1, p.adj = 0.03) and IFN-induced protein expression (coef -28.0, 95%CI -36.6—19.4, p.adj < 0.001), adjusting for IS. In addition, these patients had significantly higher histologic chronicity (coef 2.39, 95%CI 1.24-3.53, p.adj < 0.001). In line with these findings, we confirmed by CNA the association of increased histologic chronicity with fewer $MX1^{+}$ or $Siglec1^{+}$ IFN-responsive cells, adjusting for IS (p.adj = 0.002, FDR < 10%).

Conclusion: In addition to profoundly impaired circulating immunophenotype observed in LN patients, we identified a difference in naive B cell states in patients with proliferative LN compared to membranous LN. Based on circulating immunophenotype, we identified a subset of SLE patients with low extrarenal activity and increased histologic evidence of chronic kidney damage. These results nominate potential non-invasive biomarkers associated with LN heterogeneity and highlight altered naive B cell activation in proliferative LN.

Background: Previous studies have suggested there could be regional differences in clinical phenotype of axial spondyloarthritis (axSpA).

Objectives: This analysis aims to explore differences in axSpA clinical phenotype around the world in a large sample of patients included in the International Map of Axial Spondyloarthritis (IMAS).
Methods: IMAS was a cross-sectional online survey (2017-2022) of 5,557 unselected axSpA patients from 27 countries. We analysed across 5 geographic regions the age at onset of symptoms, classification as radiographic or non-radiographic, gender, HLA-B27, axSpA family history, extra-musculoskeletal manifestations (uveitis, inflammatory bowel disease and psoriasis), presence of comorbidities, disease activity (BASDAI), level of spinal stiffness, and treatment (NSAIDs, csDMARDs and bDMARDs). Kruskal-Wallis and chi-square test were used to compare axSpA characteristics across the regions.
Results: 5,557 patients participated in IMAS survey of which 3,493 were from Europe, 770 from North America, 600 from Asia, 548 from Latin America, and 146 from Africa. Results showed statistically significant differences between regions, except for the classification status (radiographic or non-radiographic). Age at onset of symptoms ranged between 25-30 years, and was higher in Latin America as compared to other regions. Diagnostic delay was longest in South Africa and lowest in Asia. The lowest frequency of HLA-B27 positivity was observed in Latin America and the highest in Asia. Family history of SpA was most often recorded in Europe and less often in Asia. All extra-musculoskeletal manifestations included were lowest in Europe compared with other regions. Physical and mental comorbidities were frequent in African patients and less common in Europe and Asia. Mean disease activity (BASDAI) was 5.4, with highest values in South Africa and lowest in Asia. Spinal stiffness was highest in South Africa and lowest in Latin America. Functional limitation was higher in North America and Europe and lower in Asia. Most of the patients had used NSAIDs for their condition and less than half had ever taken csDMARDS; both were more frequent in Latin America and South Africa. Almost half of the patients had ever taken bDMARDs, more frequent being in the Americas (**Map 1**).
Conclusion: There is great heterogeneity of axSpA clinical phenotype presentation around the world. Further understanding of these differences is needed to achieve early diagnosis and initiation of disease treatment in axSpA.

Why is performing a good systematic literature review (SLR) so difficult?

OP0188

IMAGING IN DIAGNOSIS, MONITORING AND OUTCOME PREDICTION OF LARGE VESSEL VASCULITIS: A SYSTEMATIC LITERATURE REVIEW INFORMING THE 2023 UPDATE OF THE EULAR RECOMMENDATIONS

Keywords: Systematic review, Vasculitis, Imaging

P. Bosch[1], M. Bond[2], C. Dejaco[1,2], C. Ponte[3,4], S. Mackie[5,6], L. Falzon[7], W. A. Schmidt[8], S. Ramiro[9,10]. Background: Since the development of the EULAR recommendations for the use of imaging in large vessel vasculitis (LVV) in 2017, new data has emerged in the field of imaging techniques and their application in the diagnosis and follow-up of patients with giant cell arteritis (GCA) and Takayasu arteritis (TAK).
Objectives: To summarize the evidence on different imaging techniques for diagnosis, monitoring, and outcome prediction in LVV in order to inform a EULAR task force updating the recommendations for imaging in LVV.
Methods: Systematic literature review (SLR) on studies published between 2017-2022 on ultrasound (US), magnetic resonance imaging (MRI), computed tomography (CT), positron emission tomography (PET)-CT/MRI and fluorescein angiography in patients with LVV (PROSPERO registration CRD42022360545). Eligible study designs included randomized controlled trials and observational studies but excluded case-controlled studies. Two reviewers independently performed data extraction, synthesis, and risk of bias assessment. For studies on diagnosis, meta-analyses were performed using data from both the original and updated SLR whenever possible. Pooled sensitivities and specificities were obtained by fitting random effects models for all studies and for studies with low risk of bias separately. Meta-analyses were performed in R version 4.2.1. using the "lme4" package. The description of observations without inferences and the heterogeneity of reported data precluded any meta-analysis for outcome prediction or monitoring.
Results: A total of 4696 references were identified. Thirty-eight studies on GCA (n=32), TAK (n=2), and GCA and TAK (n=4) were included through the update, adding up to eighty-one studies from both SLRs. Pooled sensitivities and specificities for US, MRI and PET-CT using a clinical diagnosis of GCA as the reference standard are depicted in Table 1. No studies on the diagnostic value of imaging techniques were found for TAK. The US evaluation of patients with suspected GCA, including the assessment of both cranial and extracranial vessels, showed a higher pooled sensitivity (95%CI) (89% [73%-96%] vs 70% [59%-79%]) and similar specificity (95%CI) (91% [83%-95%] vs 91% [84%-94%]) compared to only including cranial vessels. Studies on outcome prediction (n=5) and monitoring (n=10) reported change of signs of vasculitis along with disease activity and proposed composite scores comprising several vessel territories for US, MRI and PET-CT.
Conclusion: US, MRI and PET-CT revealed a good performance for the diagnosis of GCA. Assessing both cranial and extracranial vessels with US leads to a higher pooled sensitivity with a similar pooled specificity compared to an assessment limited to cranial vessels.

Table 1. Pooled sensitivities and specificities of diagnostic studies on GCA with clinical diagnosis as reference standard

	Index test	Number of studies	Pooled sensitivity (95%CI)	Pooled specificity (95%CI)
All studies	US	23	0.76 (0.66,0.83)	0.91 (0.86,0.94)
	MRI	8	0.82 (0.76,0.86)	0.92 (0.84,0.97)
	PET-CT	5	0.80 (0.70,0.87)	0.91 (0.67,0.98)
Low risk of bias studies	US	8	0.88 (0.83,0.92)	0.96 (0.86,0.99)
	MRI	3	0.81 (0.71,0.89)	0.98 (0.89,1.00)
	PET-CT	4	0.76 (0.67,0.83)	0.95 (0.71,0.99)

Talking about Remission

OP0189

REMISSION CRITERIA GUIDING IMMUNOSUPPRESSIVE THERAPY IN RA: WHICH IS BEST FITTED FOR THIS PURPOSE?

Keywords: Remission, Treat to target, Rheumatoid arthritis

C. Duarte[1], R. J. O. Ferreira[2], P. Welsing[3], J. W. G. Jacobs[3], L. Gossec[4], P. Machado[5], D. Van der Heijde[6], J. A. P. Da Silva[1]. [1]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; [2]*Nursing School of Lisbon (ESEL), Nursing Research, Innovation and Development Centre of Lisbon (CIDNUR), Lisboa, Portugal*; [3]*UMC Utrecht, Rheumatology & Clinical Immunology, Utrecht, Netherlands*; [4]*Sorbonne Université, and Pitié Salpêtrière Hôpital, Rheumatology, Paris, France*; [5]*University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom*; [6]*LUMC, Rheumatology, Leiden, Netherlands*

Background: Remission is the target for the management of rheumatoid arthritis (RA). However, the best definition of remission is still under debate, particularly regarding the inclusion of patient global assessment (PGA).[1] An increased cut-off for PGA (from ≤1 to ≤2cm) was recently proposed by ACR/EULAR for its Boolean-based criteria,[2] but others have suggested to replace PGA by the Physician's Global Assessment (PhGA)[3], or to simply drop PGA (ie, 3-Variable Boolean remission) when the objective is to guide immunosuppressive therapy.[2] Radiographic progression is a relevant reference standard to investigate as outcome of persistent/residual disease activity.

Objectives: To assess which definition of remission best predicts good radiographic outcome (GRO) in RA.

Methods: Meta-analyses using individual patient data (IPD) from 8 randomized controlled trials assessing the efficacy of bDMARDs on radiographic outcomes in RA. Six different definitions of remission were considered: i) The ACR/EULAR Boolean with 4 variables (Boolean 4v) with PGA≤1 (4vPGA); ii) SDAI≤3.3; iii) CDAI≤2.8; iv) Boolean 4v with PGA≤2 (4vPGA2); v) Boolean 4v replacing PGA by PhGA (4vPhGA), and vi) Boolean excluding PGA (3v). Good radiographic outcome (GRO) was defined as an increase of ≤0.5 modified Total Sharp score (mTSS) units. The relationship between achieving each remission definition at 6 and/or 12 months and GRO during the second year was analysed. The pooled probabilities of GRO for the different definitions of remission were estimated and compared, as well as their predictive accuracy (True Positive + True Negative). Meta-analyses were performed using the DerSimonian-Laird random-effects method.

Results: IPD from 4423 patients of 8 RCTs were analysed. 4vPGA remission was achieved by 24.3% of patients and 3V remission by 43.4%. The adoption of the recently proposed PGA≤2 cut-off results in an "in-between" rate of 32.4% (Table 1). GRO was observed in 77.6% of all patients, ranging from 65 to 91% in different trials. GRO among patients achieving remission ranged from 82.4% (3v) to 83.9% (SDAI), without any statistically significant difference between the 6 definitions considered. Boolean 3v remission showed a higher predictive accuracy (51.1%, 95%CI: 46.9-55.6%) than 4vPGA (38.8%, 95%CI: 34.1-43.5%). The 4vPhGA and the 4vPGA2 remission definitions performed in between, providing a correct prediction in 43.8 and 44.8% of the cases, respectively. The performance of SDAI- and CDAI-based definitions were, overall, very similar to that of 4vPGA. (Figure 1)

Table 1. Rates of remission and good radiographic outcomes in the included studies

		Remission at 6 and/or 12-months n (%)			Good Radiographic Outcome n (%)
Trial (year)	N	4vPGA	4vPGA2	3v	ΔmTSS≤0.5
DE019 (2004)	425	68 (16)	94 (22)	113 (27)	297 (70)
TEMPO (2004)	442	113 (26)	156 (35)	204 (46)	330 (75)
COMET (2008)	344	102 (30)	143 (42)	209 (61)	289 (84)
RAPID 1 (2008)	650	177 (27)	243 (37)	320 (49)	508 (78)
RAPID 2 (2009)	417	51 (12)	77 (19)	132 (32)	324 (78)
LITHE (2011)	761	141 (18)	209 (28)	307 (40)	610 (80)
DE013 (2013)	540	156 (29)	175 (32)	206 (38)	351 (65)
FUNCTION (2016)	844	308 (37)	381 (45)	459 (54)	766 (91)
Polled %		24	32*	43*	78
(95% CI)		(18 - 30)	(26 - 39)	(36 - 51)	(71 - 84)

ΔmTSS change in the modified total Sharp score during the second year of follow-up. *p<0.001 when compared with the 4vPGA definition.

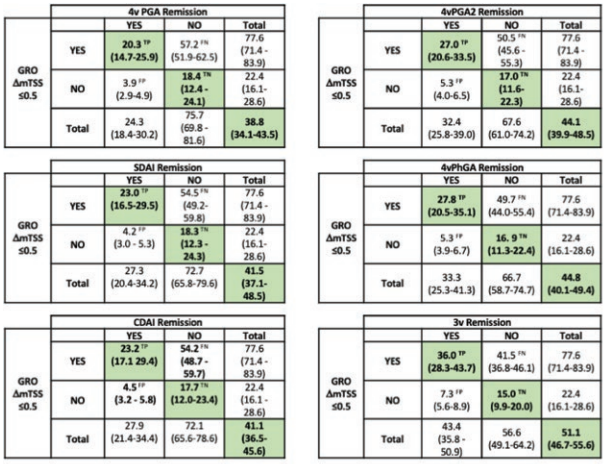

Figure 1: Accuracy of prediction of good radiographic outcome by remission criterion

All meta-analyses used the double arcsine transformation as the preferred method.; 4423 patients were included in GRO analysis; Legend: GRO: Good Radiographic Outcome; TP: True positive, TN: True negative, FP: False positive (risk of undertreatment); FN: False negative (risk of overtreatment). Accurately predicted= TP + TN. Between brackets is the pooled 95% CI.

Conclusion: The Boolean 3v remission provided the most accurate prediction of GRO, even better than 4vPGA2 and 4vPhGA remission. The use of the 3v definition in treatment recommendations would avoid the risk of overtreatment in a significant proportion of patients, with a minor increment in radiographic damage progression, validating 3v-remission as a preferable guide for immunosuppressive treatment. The patient's perspective, which must remain central, is best served by a dedicated autonomous target, rather than PGA: a dual-target approach.

Background: Early diagnosis and treatment of rheumatoid arthritis (RA) improve clinical outcomes. Undifferentiated arthritis (UA) is arthritis that does not fit a specific diagnosis. Half of the UA undergo spontaneous remission, while 30% of cases develop RA. Therefore, in UA, identifying patients at high risk for developing RA and providing close monitoring for those patients is required for early diagnosis and treatment [1]. However, predicting the evolution of UA to RA is still difficult.
Objectives: Machine learning, including deep learning, which is comparable to and in some cases surpasses the performance of human experts, is broadening its application in medicine. This study aims to build a machine-learning model that predicts the development of UA to RA.
Methods: For model training, a total of 322 UA patients in KURAMA cohort were analyzed (Table 1). For variables to train models, we chose 24 clinical features, which are easy to obtain in daily clinical practice. The target variable was the final diagnosis. We built models using Random forest (RF), XGBoost (XGB), Logistic regression (LR), and Deep neural network (DNN) and compared their performances. For model validation, we used data of 88 UA cases in ANSWER cohort (Table 1).
Results: We trained models using 24 clinical parameters at the first clinical visit, performed 10-fold cross-validation, and evaluated model performance by averaging accuracy and AUC. The performance of the models was 73.5%, 74.2%, 74.5%, and 85.1% in precision and 0.760, 0.734, 0.748, and 0.895 in AUC for RF, XGB, LR, and DNN, respectively. DNN showed the highest performance. We then applied the DNN model to external validation data from ANSWER cohort and found that the prediction accuracy was 80.0%.
Conclusion: Using parameters available in clinical practice, we developed a DNN model that effectively predicted RA development in internal and external UA datasets. Applying a machine learning approach might enable identifying patients at high risk of RA progression and improve the clinical management of UA patients.

Exploring and managing inequalities in RMD healthcare

OP0191-HPR

SOMEONE LIKE ME: THE EFFICACY OF A PEER MENTORING INTERVENTION ON DISEASE SELF-MANAGEMENT AND HEALTH-RELATED QUALITY OF LIFE AMONG AFRICAN AMERICAN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Keywords: Quality of life, Systemic lupus erythematosus, Self-management

E. Williams[1], V. Ramakrishnan[2], L. Egede[3], A. Boan[4], T. Caldwell[2], C. Dismuke-Greer[5], J. Rose[6], H. Johnson[7], J. Oates[8]. *[1]University of Rochester Medical Center, Public Health Sciences, Rochester, United States of America*; *[2]Medical University of South Carolina, Public Health Sciences, Charleston, United States of America*; *[3]Medical College of Wisconsin, Medicine, Milwaukee, United States of America*; *[4]Medical University of South Carolina, Pediatrics, Charleston, United States of America*; *[5]VA Palo Alto, Health Economics Resource Center, Palo Alto, United States of America*; *[6]Hospital for Special Surgery, Social Work Programs, New York, United States of America*; *[7]Lupus CSC, NA, Columbia, United States of America*; *[8]Medical University of South Carolina, Rheumatology and Immunology, Charleston, United States of America*

Background: Disease self-management indicates practical ways to deal with pain, fatigue, and stress and can include better nutrition, exercise, understanding treatment options, and better communication. Evidence-based self-management interventions designed to enhance social support and provide health education, among lupus patients, have demonstrated significant improvements in health distress, self-reported global health, and activity limitation, but African Americans and women are still disproportionately impacted by systemic lupus erythematosus (SLE).
Objectives: The purpose of this study was to determine whether participation in a new, culturally tailored peer mentoring intervention was associated with improvements in disease self-management and health related quality of life (HRQOL) among African American women with systemic lupus erythematosus (SLE).
Methods: The Peer Approaches to Lupus Self-Management (PALS) study was a randomized controlled trial wherein modeling and reinforcement of disease self-management skills by peers (mentors) to other African American women with SLE (mentees) was achieved through a combination of educational and informal phone or video interactions with each other. The control condition included small support groups that met on the same schedule as peer mentoring sessions. The Lupus Quality of Life questionnaire (LUP-QOL), which incorporates the Medical Outcomes Study (MOS) Short Form 36 Health Survey (SF-36) and the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), was used to determine HRQOL, and the Patient Activation Measure (PAM) assessed disease self-management or an individual's knowledge, skill, and confidence for managing their health and healthcare. Generalized Linear Mixed Models were used to determine whether the intervention produced a greater change in these main outcomes from baseline, controlling for education, income, and age, reported.
Results: Of the 314 enrolled PALS participants, 138 were mentored (experimental), 132 participated in small support groups (controls), and 44 served as mentors. Although not statistically significant, there were incrementally improving trends in patient activation as the intervention progressed, among mentors and experimental participants and decreasing trends in depression and anxiety among experimental participants. Measures of social functioning (from the LUP-QOL) and coping (or lupus self-efficacy) significantly improved from baseline, among experimental participants (both $p < 0.05$).
Conclusion: Our findings suggest that participation in a peer mentoring intervention led to improvements in disease self-management and HRQOL, in areas of social functioning, coping, depression, and anxiety, among African American women with SLE. Since these factors are related to disease activity and morbidity/damage, future investigations should consider ways in which this approach can augment clinical care on a larger scale.

Mind the gap: improving communication and outcomes

OP0192-PARE

GENERE DONNA – THE COMMUNICATION PROJECT ON GENDER MEDICINE AND AUTOIMMUNE DISEASES, SUPPORTING WOMEN WITH RHEUMATIC AND DERMATOLOGIC AUTOIMMUNE DISEASES

Keywords: Patient information and education, Gender/diversity issues, Pregnancy and reproduction

L. Faravelli[1], A. Celano[2], V. Corazza[3], S. Tonolo[4]. *[1]Vivactis Media For Health, Communication, Milano, Italy*; *[2]APMARR - Associazione Nazionale Persone con Malattie Reumatologiche e Rare - APS, President, Lecce, Italy*; *[3]APIAFCO - Associazione Psoriasici Italiani Amici della Fondazione Corazza, President, Bologna, Italy*; *[4]ANMAR Italia Onlus - Associazione Nazionale Malati Reumatici Onlus, President, Roma, Italy*

Background: The World Health Organization (WHO) defines Gender-specific Medicine as the study of how biological and socioeconomic and cultural differences influence people's health. (1) In autoimmune diseases (AD), particularly rheumatic and dermatologic ones, Gender makes the difference. Among millions of people affected worldwide, 80% are Women. (2) AD can arise more frequently in childbearing age, can impact female fertility and pregnancy outcomes, with consequences on the overall quality of life, both for the people affected and their families and caregivers.
Objectives: Genere Donna is a project aimed at setting up an awareness campaign on Gender Medicine focused on rheumatic and dermatologic autoimmune diseases. It spreads and updates a clear information, validated by experts, about Gender Medicine and rheumatic and dermatologic ADs, to improve knowledge, promoting patients' empowerment and the importance of a gender approach in Public Health.
Methods: Genere Donna has been launched in July 2021. The website www.generedonna.it and the social media profiles are the heart of the project, raising awareness also through adv campaigns (SEM and social media) and ad-hoc content marketing. The close teamwork of the main Italian patients' associations ANMAR (Associazione Nazionale Malati Reumatici Onlus), APMARR (Associazione Nazionale Persone con Malattie Reumatologiche e Rare aps) and APIAFCO (Associazione Psoriasici Italiani Amici della Fondazione Corazza) and some authoritative experts KOLs in AD (5 physicians and a welfare expert) is the key for success. Genere Donna is supported by a digital communication agency.
Results: Over 16 months of activity, there were about 160K website users (70% female, 56% of them are 18-44 years old), over 6.6Mln reach and over 220K interactions on social media, and a strong social community of around 27K people was developed. Over 210 questions received through the "Ask the Expert" service. Genere Donna recently received the patronage from SIR-Società Italiana di Reumatologia (Italian Society of Rheumatology) and SIDeMaST, Società Italiana di Dermatologia e Malattie Sessualmente Trasmesse (Italian Society of Dermatology).
Conclusion: The strong need of clear and verified information around Gender Medicine is testified by the wide number of social media interactions and website visits. The good results reached by Genere Donna up to now and many positive comments coming from the community push the project ahead in the future, to be more and more near to the patients affected by rheumatic and dermatologic ADs.

Clinical and molecular differences across sexes in Rheumatic Disease

OP0193

SEX DIMORPHISM ANALYSIS IN A COHORT OF JIA PATIENTS REVEALS DIFFERING GENETIC RISK FACTORS FOR FEMALES AND MALES

Keywords: Inflammatory arthritides, Genetics/Epigenetics, Gender/diversity issues

M. Tordoff[1], S. Smith[1], A. Morris[1], S. Eyre[1,2], W. Thomson[1,2], J. Bowes[1,2].
[1]The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom; *[2]National Institute of Health Research Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom*

Background: Juvenile idiopathic arthritis (JIA) encompasses a group of childhood onset rheumatic diseases that primarily affect females. JIA has been reported to occur in females and males with a 2:1 ratio, however, systemic JIA is reported to occur equally in sexes and enthesitis-related arthritis (ERA) is reported more frequently in male patients. Genetic risk factors may contribute to the sex dimorphism in JIA incidence, however this contribution has yet to be defined.
Objectives: To investigate, using sex dimorphism analysis, whether genetic risk factors for JIA differ in males and females.
Methods: High quality genotype data was available on 3356 JIA cases (females = 2209, males =1147) and 9196 controls (female =4059, males =5137). Our primary analysis combined sex-specific GWAS summary statistics using the GWAMA software package. Summary statistics were calculated using logistic regression with three principal components as covariates using PLINK. The sex-differentiated p-value (p_{diff}) provided overall evidence for association to JIA allowing for differences between males and females,and the heterogeneity p-value (p_{het}) provided evidence to support a difference in effect estimates between sexes. As a secondary analysis we performed a logistic regression, as above, on all samples and included sex as an interaction term (p_{int}). Amino acid residues in HLA genes and alleles were imputed using SNP2HLA and an association test with sex as an interaction term was implemented on markers of interest.
Results: A total of 6571296 SNPs were analysed after quality control. The strongest signal detected using a logistic regression in females was rs9469137 ($p = 1.7x10^{-80}$) and in males it was rs116666910 ($p = 9.7x10^{-59}$). GWAMA supported evidence of sex heterogeneity for these SNPs, rs9469137 $p_{het} = 2.2x10^{-6}$, $OR_{males} = 2.6$, $OR_{females} = 5.3$, rs116666910 $p_{het} = 1.8x10^{-14}$ $OR_{male} = 4.0$, $OR_{female} = 1.6$. The strongest signal from the sex-specific GWAS was rs9266716, $p_{het} = 1.9x10^{-17}$, $p_{int} = 7.7x10^{-18}$, $OR_{male} = 1.2$, $OR_{female} = 0.6$. These SNPs all map to the HLA region, providing strong evidence for sex dimorphism in this region, therefore sex-specific HLA fine mapping was conducted. This analysis revealed that residues at position 13 of *HLA-DRB1* were strongly associated with JIA in females ($p_{female} = 1.8x10^{-124}$). Glycine at position 13 of *HLA-DRB1* was most strongly associated with JIA in females ($OR_{female} = 3.6$, $p_{female} = 4.1x10^{-65}$, $OR_{male} = 1.9$, $p_{male} = 9.6x10^{-13}$). An association test with sex as an interaction term revealed glycine at position 13 as sex dimorphic, $p = 4.3x10^{-7}$. Associations of residues at position 13 of *HLA-DRB1* have previously been reported in JIA, where the cohort consisted of oligoarthritis and rheumatoid factor negative polyarthritis individuals. These ILAR subtypes have a greater frequency in females. *HLA-B27* was detected as strongly associated with JIA in male patients ($p_{male} = 5.4 x10^{-64}$, $OR_{male} = 3.8$, $p_{female} = 2.5x10^{-9}$, $OR_{female} = 1.6$). An association test with sex as an interaction term revealed *HLA-B27* to be strongly sex dimorphic, $p = 7.5x10^{-15}$. *HLA-B27* is a well-established risk factor for ERA, where males are predominately affected. Outside of the HLA region, the strongest associated SNP was rs58020114, $p_{het} = 6.3x10^{-7}$, $p_{int} = 5.7x10^{-7}$ $OR_{male} = 1.3$, $OR_{female} = 0.7$. This SNP is located near the *BPNT2* gene and had a greater effect size in males.
Conclusion: This analysis reveals that there are several sexually dimorphic genetic risk factors that may affect JIA development in males and females. For the first time markers within the *HLA* region have been detected as sex dimorphic. Understanding the genetic risk factors to JIA development will help to further define the disease, which may aid in disease classification and diagnosis in the future. In particular, the substantial differences in effect estimates observed between males and females suggests that sex-specific polygenic risk scores should be considered when HLA signals are incorporated into these efforts.

Pain in RMDs

OP0194 INFLAMMATION-INDUCED PAIN AND FATIGUE IN FIBROMYALGIA AND ME/CFS AND ROLE OF VARIANT CONNECTIVE TISSUE

Keywords: Fibromyalgia, Cytokines and chemokines, Patient reported outcomes

J. Eccles[1], M. Amato[1], K. Themelis[2], L. Quadt[2], H. Critchley[1], N. Harrison[3], K. Davies[4]. [1]*Brighton and Sussex Medical School, Neuroscience, Falmer, United Kingdom*; [2]*University of Warwick, Psychology, Coventry, United Kingdom*; [3]*University of Cardiff, CUBRIC, Cardiff, United Kingdom*; [4]*Brighton and Sussex Medical School, Clinical and Experiemental Medicine, Falmer, United Kingdom*

Background: Fibromyalgia and ME/CFS are multifaceted conditions with overlapping symptoms(1); the pathophysiological mechanisms are under debate. It remains unclear whether dysregulated inflammation, induced either by an exogenous stimulus (*eg* a virus or other stressor), or autoimmunity, is of prime importance [2].
Objectives: 1. To determine in a novel human model the effects of an *in* vivo inflammatory challenge in the induction of pain and fatigue in fibromyalgia and ME/CFS compared to controls.
2. Explore potential mediators and moderators involved.
Methods: Data were available for 48 patients with confirmed diagnoses of Fibromyalgia and/ or ME/CFS and 22 matched controls, who had undergone a placebo controlled inflammatory challenge (typhoid vaccination) as part of ISRCTN78820481. Participants underwent full research diagnostic evaluation including a hypermobility assessment. Subjective pain and fatigue were assessed after saline injection and typhoid vaccination (VAS). Linear regression models were used to explore predictors, with adjustment for potential confounders (age/gender) and baseline levels as appropriate. Mediation analyses (looking for mechanistic effects) were conducted according to the method of Hayes (3) and mediation considered significant if bootstrapped confidence intervals of the estimated indirect effect did not cross zero. In these mediation analyses predictor variable was group membership (patient or control), outcome variable was change in 1) pain and 2) fatigue induced by challenge and mediators/moderators included change in IL-6 induced by inflammatory challenge and hypermobility features.
Results: Being a patient rather than control significantly predicted inflammation-induced fatigue (B=14.89 (95%CI 3.29-26.50), t=2.56, p=0.013) and pain (B=12.88 (95%CI 0.65-25.10), t=2.11, p=0.039) after adjusting for levels induced by placebo. Induced pain was independently predicted by level of IL-6 induced by inflammatory challenge (B=23.44 (95%CI 5.15-41.72),t=2.57, p=0.013) as was induced fatigue (B=10.63 (95%CI 2.84-18.41), t=2.73, p=0.008) Mediated moderation analyses suggested the link to induced pain and fatigue through induced inflammation was associated with hypermobility features (Index of mediated moderation 11.02 (95%CI 1.45-22.73) and 6.20 (95%CI 0.07-13.64) respectively))
Conclusion: To our knowledge this is the first human study to evaluate directly the effect of an exogenous inflammatory challenge (typhoid vaccination) in a combined group of Fibromyalgia and ME/CFS patients. Il-6 was shown to be a critical mediator. This work strongly supports the hypothesis that inflammation is key to the pathophysiology of ME/CFS. We are evaluating associated CNS inflammation in the model, as well as other associations, such as autonomic dysfunction and hypermobility. Further understanding the mediators involved in the condition should in future open the way to testing targeted anti-inflammatory therapy.

OP0195 TARGETED ABLATION OF KNEE-INNERVATING NOCICEPTORS HAS PROFOUND EFFECTS ON JOINT DAMAGE IN EXPERIMENTAL OSTEOARTHRITIS

Keywords: Osteoarthritis, Animal models

L. Wang[1], S. Ishihara[1], J. LI[1], A. Obeidat[1], R. Miller[1], A. M. Malfait[1]. [1]*Rush University, Rheumatology, Chicago, United States of America*

Background: Sensory afferents abundantly innervate the knee joint. The vast majority of these are pain-sensing nociceptors, which express the voltage-gated sodium channel, $Na_V1.8$. Using $Na_V1.8$Cre-tdTomato reporter mice, we have documented innervation changes that occur with experimental murine osteoarthritis (OA), including sprouting of nociceptors in the medial synovium and in subchondral bone [1]. Upon intra-articular (IA) injection into the mouse knee, adeno-associated virus serotype AAV.PHP.S is retrogradely transported to the lumbar dorsal root ganglia (DRG), where the cell bodies of sensory neurons reside [2].
Objectives: We leveraged this technique to selectively ablate knee-innervating nociceptors by IA injection of AAV.PHP.S carrying diphtheria toxin A (dtA), and determine the effect on joint damage after destabilization of the medial meniscus (DMM).
Methods: Expt. 1: AAV.PHP.S containing pAAV-EF1a-mCherry-flex-dtA (AAV-dtA) was injected into the right knee of 7-week old male C57BL/6 $Na_V1.8$Cre mice (3 µL, 10^{12} vp/mL). Three weeks later, the TLR2 ligand, Pam3CSK4 (3 µg), was injected into these same knees, followed by knee hyperalgesia measurement (using PAM) over 24-hours [3]. $Na_V1.8$Cre mice injected with AAV.PHP.S-EF1a-flex-GFP (AAV-Control) as well as wild type mice injected with AAV-dtA were included as controls (n=6 mice/group). Expt. 2: AAV-dtA or AAV-Control was injected IA into the right knees of 7-week old male $Na_V1.8$Cre mice and 3 weeks later, DMM surgery was performed (n=19 mice/group). Mice were sacrificed 10 or 17 weeks after DMM, and knees collected for histologu using a modified OARSI scoring system (toluidine blue, frontal plane). Expt. 3: Ten-week old male $Na_V1.8$Cre mice underwent DMM surgery, and 4 weeks later, AAV-dtA or AAV-Control was injected IA into the operated knees (n=12 mice/group). Knees were collected 17 weeks after surgery for histology.
Results: Expt. 1: $Na_V1.8$Cre mice injected with AAV-Control and WT mice injected with AAV-dtA responded to TLR2 stimulation, showing markedly decreased knee pain thresholds between 1 and 6 hours after IA injection of Pam3CSK4, as described [3]. In contrast, $Na_V1.8$Cre mice injected with AAV-dtA did not respond to Pam3CSK4, indicating functional effects of ablating knee-innervating nociceptors with AAV-dtA. Expt. 2: Ten weeks after DMM, all mice showed mild OA joint damage, with no difference between groups (Figure 1A). However, while AAV-Control injected joints showed markedly increased cartilage damage by week 17, AAV-dtA injected joints showed no progression of cartilage degeneration compared to week 10. Osteophytes were comparable between the groups. Expt. 3: Seventeen weeks after DMM, mice that had been injected with AAV-dtA 4 weeks *post* DMM showed markedly increased cartilage degeneration, total joint scores, and osteophyte sizes compared to AAV-controls (Figure 1B).

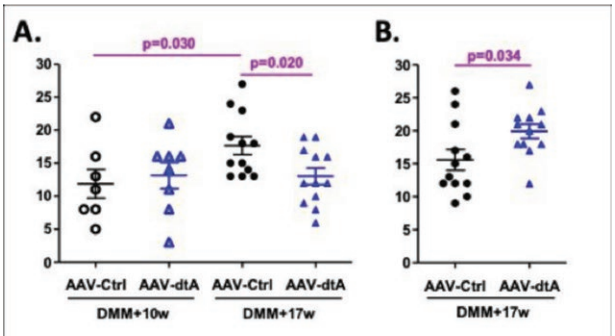

Fig. 1. Cartilage degeneration scores of knee joints 10 or 17 weeks after DMM. (A) AAV-dtA was injected 3 weeks before DMM. (B) AAV-dtA was injected 4 weeks after DMM.

Conclusion: IA delivery of AAV-dtA into enables selective ablation of $Na_V1.8$+ neurons in the knee, as is evident from ablated pain responses to TLR2 stimulation. Experiments in the DMM model revealed a striking effect of ablation of joint nociceptors on joint damage: Nociceptor ablation *before* DMM significantly *attenuated* cartilage degeneration in late stage OA, while ablation of knee nociceptors

after DMM markedly *worsened* joint damage and osteophyte formation. These findings suggest an important role for nociceptors in joint homeostasis, with differential effects if nociceptors are ablated before or after joint damage occurs. Our findings suggest a neurogenic contribution to joint homeostasis. Current work focuses on documenting the joint nociceptive innervation in the different experimental groups, and the relationship with pain.

OP0196 ANTI-TNF TREATMENT MODIFIES PAIN MODULATION DESCENDING PATHWAYS. A PROSPECTIVE, 6 MONTHS STUDY IN ACTIVE CHRONIC INFLAMMATORY RHEUMATISM PATIENTS' NAÏVE OF BDMARD

Keywords: bDMARD, Rheumatoid arthritis, Pain

A. P. Trouvin[1,2,3], A. Simunek[1], J. Coste[1,3,4], T. Medkour[1,2], A. Combier[5], L. Poiroux[5], F. Vidal[6], S. Carvès[1], D. Bouhassira[2,7], S. Perrot[1,2,3]. [1]*Cochin University Hospital, Pain Medicine Department, PARIS, France*; [2]*INSERM, U987, BOULOGNE BILLANCOURT, France*; [3]*Paris Cité University, Medicine, PARIS, France*; [4]*Cochin University Hospital, Biostatistics and Epidemiology, PARIS, France*; [5]*Cochin University Hospital, Rheumatology Department, PARIS, France*; [6]*Ambroise Paré University Hospital, Rheumatology Department, BOULOGNE BILLANCOURT, France*; [7]*Ambroise Paré University Hospital, Pain Medicine Department, BOULOGNE BILLANCOURT, France*

Background: In rheumatoid arthritis (RA) and spondyloarthritis (Spa), persistent pain remains challenging. In active disease, diffuse noxious inhibitory controls (assessed through conditioned pain modulation (CPM)) are impaired [1]. Little is known regarding impairment of pain pathways in patients under bMDARD.
Objectives: The main objective of the RAPID (Rheumatism Pain Inhibitory Descending pathways) study, was to assess descending pain modulation (through CPM paradigm) in patients with active RA or Spa, after introduction of first bDMARD with anti-TNF.
Methods: We included 50 RA and 50 Spa patients with active disease, naïve of bDMARD. We assessed clinical disease variables for patients, together with responses to various psychological questionnaires. All participants underwent QST with the determination of heat and cold pain thresholds (HPT-CPT) on dominant forearm and CPM. CPM paradigm require a conditioning stimulus, here applied to the non-dominant foot (cold circulating bath at 8°C during 1min). Descending pain control was assessed as the change in HPT (in °C) following the conditioning stimulus: the higher the CPM effect, the more efficient the inhibitory control. Patients were followed at 3 and 6 months after TNF inhibitor initiation. At both follow-up visits, clinical monitoring of the rheumatism and repeated thermal QST and CPM.
Results: One hundred patients were included, 59 women, mean age 45.8 (± 14.6) and mean disease duration 7.93 (± 7.96) years. Due to COVID surge 87 patients initiated an anti-TNF, 74 patients completed the follow-up. At 6 months, 40 patients achieved a good therapeutic response (good EULAR response or ASDAS major improvement), 19 patients had a moderate therapeutic response (moderate EULAR response or clinically important improvement) and 15 patients had no therapeutic response. At the end of follow-up, 51 patients were in remission or low disease activity and 47 patients had a pain intensity <4/10. Thermal pain thresholds did not significantly change during follow-up. Mean HPT was at beaseline 42.35°C (+/- 3.68) and at 6 months 42.17°C (+/- 3.67). Mean CPT was at baseline 13.11°C (+/- 10.04) and at 6 months 12.86°C (+/- 9.45). Conditioned pain modulation was significantly changed during follow-up. Mean CPM effect was at baseline 0.25°C (±2.57), 2.64°C (±2.12) at 3 months and 2.96°C (±2.50) at 6 months. At the end of the 6 months follow-up, mean CPM effect was significantly higher in patients with residual mean pain intensity <4/10 compared to patients with persisting pain ≥ 4/10: 3,25°C (± 2,68) vs 2,47 (± 2,11) (p=0.04).
Conclusion: After TNF inhibitor initiation in active RA or SpA, impaired diffuse noxious inhibitory controls are significantly improved. Apart from their articular efficacy, TNF inhibitor have an action on the central nervous system and pain modulation pathways. In patients with persisting pain under bDMARD, diffuse noxious inhibitory controls are not as efficient as patient without residual pain.

OP0197 FACTORS ASSOCIATED WITH LONG-TERM OPIOID USE IN FIBROMYALGIA PATIENTS NEWLY STARTED ON AN OPIOID: RESULTS USING UK PRIMARY CARE ELECTRONIC PATIENT RECORDS

Keywords: Artificial intelligence, Fibromyalgia, Prognostic factors

C. Ramirez Medina[1], M. Feng[1], J. Y. T. Huang[1], D. Jenkins[2], M. Jani[1,3]. [1]*The University of Manchester, Musculoskeletal and Dermatological Science Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [2]*The University of Manchester, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom*; [3]*NIHR Manchester BRC, The University of Manchester, Manchester, United Kingdom*

Background: The impact of the opioid epidemic in North America has caused concern in the United Kingdom and across Europe. Long-term opioid use is associated with several opioid-related harms and adverse outcomes. Fibromyalgia is frequently treated with opioids due to limited therapeutic options. Understanding what factors are associated with long-term opioid use in such patients is the first step in helping to develop targeted interventions for deprescribing.
Objectives: The objective of this study was to (i) quantify the proportion of new opioid users with fibromyalgia who become long-term opioid users (ii) identify risk factors associated with long-term opioid use in fibromyalgia.
Methods: A retrospective cohort study was conducted using data from the Clinical Practice Research Datalink (CPRD). CPRD is a national database of electronic health records within primary care, representation of the UK general population. Fibromyalgia patients without prior cancer who were new opioid users between 01/Jan/2006 and 31/Aug/2021 were included. Long-term opioid use was defined as at least 3 opioid prescriptions issued within a 90-day period, or ≥1 opioid prescription lasting at least 90 days, in the first year of follow-up. Logistic regression analysis and a random forest model were used to identify risk factors related to long-term opioid use. Compared to logistic regression, random forest variable importance measures covered both the effects of individual predictor variables as well as multivariate interactions with other predictor variables. In the random forest model, the mean decrease accuracy (MDA) index to measure the variables' importance was used; the larger the value of the mean decrease accuracy, the more important the variable is.
Results: Of the 28,552 fibromyalgia patients who were new opioids users, 7,375 (26%) became long-term opioid users in the first year. In the fully adjusted logistic regression model, suicide and self-harm (adjusted odds ratio [aOR]: 1.98, 95% confidence interval (CI): 1.72-2.27, p<0.001), substance use disorder (aOR: 2.07, 95%CI: 1.62-2.66, p<0.001), most deprived (Index of Multiple Deprivation (IMD) quintile 5/most deprived, aOR: 1.98, 95%CI: 1.69-2.33, p<0.001, compared with quintile 1/least deprived), obesity (aOR: very severely obese, OR: 2.35, 95%CI: 1.76-3.18, p<0.001) and mean daily morphine milligram equivalents (MME) at

the initiation (High (120-199 MME/day): aOR: 34.81, 95%CI: 18- 78.05, p<0.001 compared to mean daily MME: Low (<50 MME/day)) were associated with higher risk of long-term opioid use. The three most important variables using the random forest model were mean MME/day at initiation (MDA 140), history of suicide and self-harm (MDA 40) and IMD (MDA 30).

Conclusion: Almost 1 in 4 patients with fibromyalgia starting opioids became a long-term opioid user in this nationally representative dataset across the UK within the first year. The dose of initial opioid prescription, high deprivation score, history of suicide and self-harm, substance use disorder and obesity were associated with long-term opioid use.

OP0198 UNSUPERVISED MACHINE LEARNING FOR PATIENT CLUSTERING IN CHRONIC REFRACTORY PAIN SYNDROMES AND FIBROMYALGIA: RESULTS FROM A MULTIMODAL TREATMENT PROGRAM

Keywords: Artificial intelligence, Fibromyalgia

T. Hügle[1], T. Pretat[1], C. Lovejoy[2], P. Ming Azevedo[1]. [1]*University Hospital Lausanne (CHUV), Rheumatology, Lausanne, Switzerland*; [2]*NHS, Medical Doctor, London, United Kingdom*

Background: Chronic Pain Syndromes (CPS), including fibromyalgia (FM), place a significant health and socioeconomic burden. Despite sharing a similar clinical presentation, they are a heterogeneous entity, often with different causes and in association with other conditions. Multimodal treatment programs allow a comprehensive clinical and physical assessment of those patients.

Objectives: The objective of this study is to identify subtypes in CPS patients including primary and secondary FM who were assessed during a two-week multimodal pain management program via an unsupervised machine learning model.

Methods: We collected data from 202 patients as part of a 2-week multimodal pain management program. Clinical features, comorbidities, medications and demographics were collected and patients were assessed by physical and mental questionnaires (e.g. BPI, FABQ, FABQ-W, POAM, HAS, HDS, PCS, TAMPA, OD) before and after the program. There was a weekly interdisciplinary case discussion between rheumatologists, pain specialists, psychiatrists, physiotherapists and occupational therapists. For data analysis, hierarchical agglomerative clusters were generated using the Ward variance minimization algorithm with Euclidean pairwise distances (Python 3.10). The number of clusters was selected by inspecting visualizations (including dendograms and radar plots), in combination with clinical interpretability and utility.

Results: Five patient subtypes with the following characteristics were identified: Cluster 1: Obese men with persisting peripheral and axial musculoskeletal pain, sometimes with an underlying immune-mediated disorder (IMD), poorly responding to disease modifying therapy. Bland psychological evaluation. *Clinical interpretation:* predominantly men in the late 50s. Possibly secondary FM, and/or underlying microcrystalline disorder or inflammatory osteoarthritis. Very closed to psychiatric evaluation or therapy. Cluster 2: Female patients with peripheral and axial pain since childhood or adolescence, sometimes with a post-traumatic stress disorder. Severe sleep problems. *Clinical interpretation*: primary FM, sometimes with an additional traumatic psychological background. Cluster 3: Women with chronic back pain, often with previous (failed) spine surgery. Normal weight. Often polymedication with opioids, antidepressantsants. *Clinical interpretation*: women with lumbar disc degeneration. Sometimes questionable spondylarthritis with refractory lumbar pain despite treatment with biologics. Cluster 4: Patients (men>woman) of younger age with low BMI and hyperlaxity. Peripheral pain of nociplastic character predominates, often since childhood or adolescence. High incidence of depression, anxiety or other psychological conditions. Virtual reality treatment is efficient. *Interpretation:* somatoform pain in younger patients spilled over from adolescence, often with substantial psychiatric comorbidity. Cluster 5: Overweight women in peri-menopause with metabolic syndrome. Axial and peripheral pain. Often use of antidepressants, notably Trazodone. Blood sedimentation rate can be elevated. *Interpretation:* peri-menopausal syndrome in obese patients with pain and low grade inflammation such as bursitis or tenosynovitis.

Conclusion: All five chronic pain phenotypes identified by unsupervised machine learning are consistent with clinical observations. Psychiatric comorbidities are prevalent in all clusters except one, where they may be suppressed. Work disability plays an important role in all patients. In at least two clusters, the pain seems to have its origin in childhood or adolescence. One cluster seems to be particularly influenced by hormonal and metabolic factors.

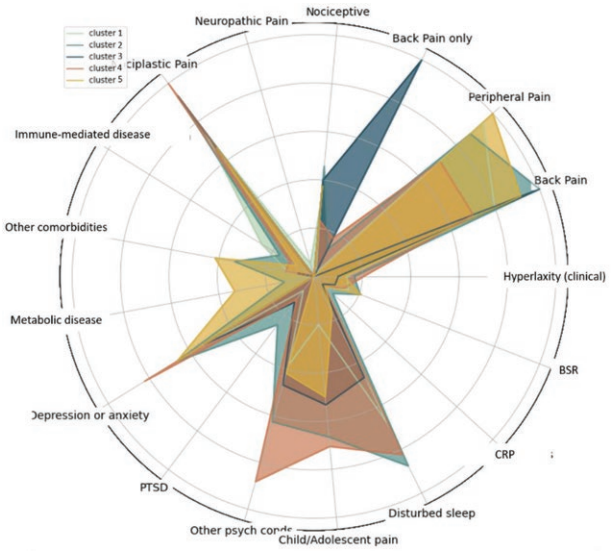

Figure 1. Radar plot of patient clusters. PTSD: Post-traumatic stress disorder. CRP: C-reactive protein, BSR: Blood sedimentation rate.

OP0199 HAND OSTEOARTHRITIS PHENOTYPES AND THEIR ASSOCIATIONS WITH PAIN AND CHANGE IN PAIN

Keywords: Pain, Osteoarthritis

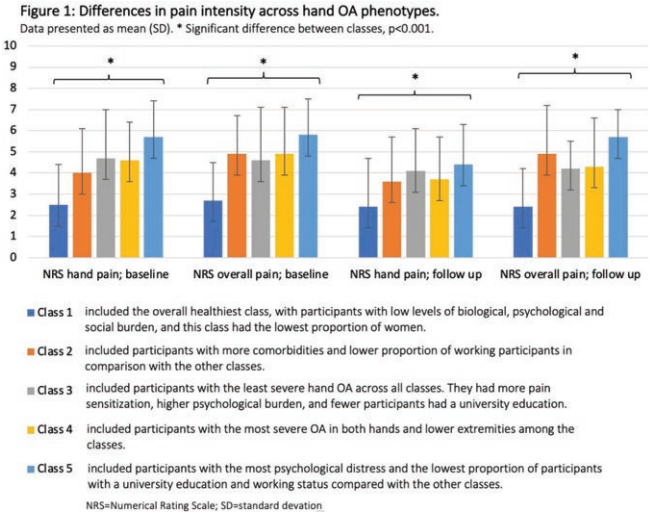
E. Mulrooney[1,2], T. Neogi[3], H. Solveig Dagfinrud[1,2], H. B. Hammer[1,2], P. Steen Pettersen[1,2], T. K. Kvien[1,2], K. Magnusson[4], I. K. Haugen[1,2]. [1]*Diakonhjemmet Hospital, Centre for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*; [2]*University of Oslo, Faculty of Medicine, Oslo, Norway*; [3]*Boston University School of Medicine, Section of Rheumatology, Boston, United States of America*; [4]*Lund University, Department of Clinical Sciences, Lund, Sweden*

Background: Hand osteoarthritis (OA) pain is characterized as heterogeneous and multifactorial. Different pain patterns may be explained by underlying phenotypes, which previously have not been explored.

Objectives: Using the biopsychosocial framework, we aimed to identify possible hand OA phenotypes and explore the associations with pain intensity and change in pain during a four-year follow-up.

Methods: Latent class analysis was used to determine classes of people with hand OA, based on baseline examination (2016-17), followed by posterior fit statistics. Biological, psychological, and social domains were examined by self-reported questionnaires, clinical assessment and imaging. Central pain sensitization was tested by pressure pain thresholds (PPT; kg/cm^2) and temporal summation (TS). Pain intensity at baseline and follow-up (2019-21) was self-reported on a Numeric Rating Scale (0-10) for hand and overall bodily pain the last 24 hours. Change in pain was calculated for both pain measures. Differences of the biopsychosocial variables and pain measures were assessed by one-way ANOVAs and chi-squared tests. The relations of the classes to the pain outcomes were analysed by linear regression.

Results: We identified five classes (Table 1). The highest pain intensity was reported by the class with low OA severity but higher burden of the other factors (Class 5), whilst the class with the most OA severity of the hands and lower extremities (Class 4) reported approximately one point less for pain intensity (Figure 1). Classes showed little change in pain and there was no significant difference (data not shown). Significant differences were found across all classes in association to baseline and follow-up pain. However, not for change in pain (data not shown), except Class 5 and change in hand pain (beta (95% CI); 1.13 (0.02, 2.25)). Class 5 indicated the most hand and overall bodily pain in comparison to the reference group (Class 1) with a beta (95% CI) of 3.27 (2.32, 4.22) and 3.08 (2.10, 4.07) at baseline and 2.04 (1.02, 3.06) and 2.74 (1.73, 3.76) at follow-up, respectively. The difference was smaller when comparing for Class 4 to



the reference group with a beta (95% CI) of 2.15 (1.27, 3.02) and 2.20 (1.27, 3.13) for hand pain and overall bodily pain at baseline, and a beta (95% CI) of 1.38 (0.46, 2.31) and 1.66 (0.74, 2.58) at follow-up. Class 3 indicated similar baseline values as Class 4 (Hand and overall bodily pain: beta (95%) of 2.24 (1.51, 2.97) and 1.89 (1.12, 2.65)).

Conclusion: We identified five potential hand OA phenotypes which associated with pain intensity at baseline and four years later. The phenotype with low OA severity, but more pain sensitization, comorbidities, higher psychological and social burden reported more pain than the phenotype with the most severe OA in the hands and lower extremities, reflecting the discordance between OA severity and pain experience.

Table 1. Characteristics of the biopsychosocial variables across the hand OA phenotypes. Data presented as mean (SD) unless otherwise indicated.

	Class 1	Class 2	Class 3	Class 4	Class 5	P-value

ORAL DELIVERY OF DELTA-9-TETRAHYDROCANNABINOL PROVIDES SYMPTOM AND DISEASE MODIFICATION USING TWO MODELS OF KNEE OSTEOARTHRITIS

Keywords: Osteoarthritis

J. Rockel[1], A. Maglaviceanu[1], H. Fetter Filippini[2], E. Poduch[3], M. Lewis-Bakker[3], J. Garcia[1], T. Leroux[1], H. Clarke[4], R. Bonin[2], L. Kotra[3], M. Kapoor[1]. [1]*Schroeder Arthritis Institute, Orthopedics, Toronto, Canada*; [2]*University of Toronto, Pharmacy, Toronto, Canada*; [3]*University Health Network, Krembil Research Institute, Toronto, Canada*; [4]*University Health Network, Toronto General Hospital, Toronto, Canada*

Background: Osteoarthritis (OA) is a whole joint disease that results in joint pain, cartilage degeneration, and synovitis, ultimately reducing the quality of life of those affected. Current therapies only modify pain and there are no approved OA disease-modifying drugs. Recent studies suggest that individuals with OA are self-medicating with cannabis, with some anecdotally reporting reduced joint pain. One of the most prominent cannabinoids in cannabis is delta-9-tetrahydrocannabinolic acid, which produces the psychoactive compound delta-9-tetrahydrocannabinol (THC) upon decarboxylation. THC can signal via CB1 and CB2 cannabinoid receptors to alter intracellular cAMP levels. CB1 and CB2 are found on joint cells, including chondrocytes and fibroblast-like synoviocytes (FLS). Currently, there are no studies linking THC to disease modification in OA.

Objectives: In this study, we investigated the effects and mechanisms of action of THC on pain and disease modification in pre-clinical models of knee OA.

Methods: 14-16 week (wk)-old male C57BL/6 mice underwent sham or destabilization of the medial meniscus (DMM) surgery to induce knee OA. At 1 wk post-surgery, THC (1, 5 or 10 mg/kg) or vehicle was administered 1 day/wk by intra-articular (IA) injection, or 5 days/wk by oral gavage for 9 wks. Von Frey and Open Field testing were performed to evaluate mechanical allodynia and locomotion/anxiety. 10 wks post-surgery joints were subjected to histopathology. For the monosodium iodoacetate (MIA) model of OA pain, knees of 14-wk-old C57BL/6 mice were injected with saline (control) or MIA (0.5 mg) and mice were administered THC (5 or 10mg/kg) 5 days/wk by oral gavage for 3 wks and Von Frey analyses was performed to evaluate mechanical allodynia. For in vitro studies, human FLS and chondrocytes obtained from OA patients undergoing total knee arthroplasty were subjected to flow cytometry and RNA sequencing with/without THC treatment.

Results: IA administration of THC to DMM mice accelerated cartilage degeneration, increased synovitis, and failed to attenuate mechanical allodynia at all doses (n=5/group). Oral administration of THC at all doses reduced cartilage degeneration, with only 10 mg/kg THC also reducing synovitis (n=10-15/group; Figure 1A&B). IHC of DMM joints (n=6/group) suggested significantly decreased αSMA but not nuclear Ki67 expression in the synovial subintima with THC oral gavage administration. Von Frey tests showed that administration of THC by oral gavage reduced mechanical allodynia in DMM mice at 9 wks post-surgery (n=15/group; Figure 1C). Open field tests indicated that THC had no overt effect on the locomotion or anxiety of sham or DMM mice (n=10/group). Studies using

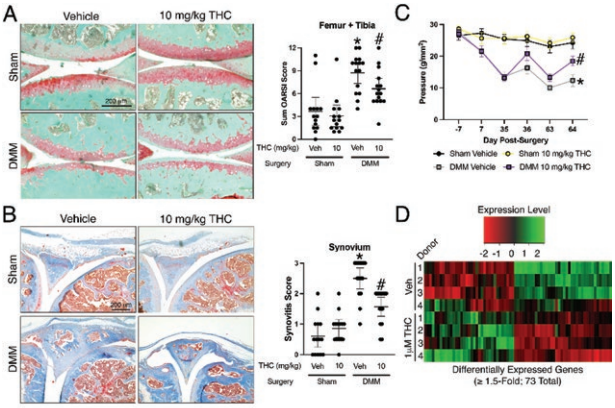

Figure 1. THC administration by oral gavage reduces cartilage degeneration, synovitis and mechanical allodynia in DMM-induced OA mice while in vitro THC treatment of human fibroblast-like synoviocytes modifies select gene expression profiles. Mice received sham or DMM surgery. At one week post-surgery, mice were treated 5 days/week with vehicle (veh; medium chain triglycericde) or 10 mg/kg THC for 9 weeks. Mice were sacrificed at 10 weeks post-surgery. Knee joint sections were stained with Safranin O (A) or Masson's Trichrome (B) for evaluation of cartilage degeneration or synovitis, respectively, by OARSI scoring. Mice were also evaluated for mechanical allodynia (pain) by von Frey analyses (C). (A&B) Data was analyzed by Kruskal-Wallis tests followed by Mann-Whitney post-hoc tests corrected for multiple comparisons using the method of Benjamini, Kreiger and Yekutieli using R v 3.5.03 with coin package v 1.3-24 to account for ties. * or #, $q < 0.05$ compared to all other groups. n = 14 or 15/group. (C) Data was log-transformed prior to analysis by two-way ANOVA followed by multiple comparison's tests using the method of Benjamini, Kreiger and Yekutieli to correct for false-discovery rate. At day 64 post-surgery: *, $q < 0.05$ compared to all other groups; # $q < 0.01$ compared to DMM vehicle and Sham + 10 mg/kg THC groups. n = 15/group. (D) Heat map of genes modified ≥ 1.5-fold in human fibroblast-like synoviocytes treated with vehicle (veh; 0.5% DMSO) or 1uM THC, as determined by RNA sequencing. A total of 35 genes were upregulated and 38 genes were downregulated.

MIA-induced OA mice showed that administration of 10 mg/kg THC by oral gavage also reduced mechanical allodynia (n=10/group) without modifying animal locomotion or anxiety. In vitro, THC treatment of human OA FLS and chondrocytes (n=5 each) increased Annexin V positivity starting at 2.5μM, but not with 1μM THC, as determined by flow cytometry. In cultured OA FLS (n=4), 73 genes were differentially expressed (35 upregulated, 38 downregulated) after treatment with THC compared to vehicle treatment (≥1.5-fold), as determined by RNA sequencing (Figure 1D). Similarly, in OA chondrocytes RNA sequencing (n=4/group), 21 genes (9 upregulated, 12 downregulated) were differentially expressed (≥1.5-fold) after THC treatment. Computational analyses indicated that ECM-related pathways were enriched in the upregulated genes in both fibroblasts and chondrocytes, while lipid/steroid/cholesterol-related pathways were enriched by the downregulated genes in both cell types. 22 common putative transcription factors were also identified as potential regulators of the fibroblast and chondrocyte genes reduced through THC treatment.

Conclusion: Oral administration of 10 mg/kg THC reduced cartilage degeneration and synovitis in DMM mouse knee joints and modified pain responses in DMM and MIA models. JR, AM, HFF share equal first author contribution.

OP0201 INTRA-ARTICULAR INJECTIONS OF TWO LIPOSOMAL ADENOSINE FORMULATIONS PROVIDE SIGNIFICANT PAIN RELIEF AND GAIN IN FUNCTION, IMPROVE COMFORTABLE RANGE OF MOTION AND SLOWED RADIOLOGIC PROGRESSION IN A PRECLINICAL CANINE MODEL OF OSTEOARTHRITIS

Keywords: Osteoarthritis, Cartilage, Pain

D. LI[1], B. N. Cronstein[2], J. Cook[3], C. Bozynski[3], S. Angle[1]. [1]*Regenosince, Inc., Princeton Innovation Center, Princeton, United States of America*; [2]*New York University, School of Medicine, New York, United States of America*; [3]*University of Missouri, School of Medicine, Columbia, United States of America*

Background: Osteoarthritis (OA) affects 10% of global population and its effective non-surgical treatments represent significant unmet need. There has been a rapid escalation in the annual number of arthroplasties, placing a significant burden on patients and healthcare systems. We previously demonstrated that adenosine and its A2A receptor play critical roles in maintaining joint homeostasis. Adenosine treatment prevents structural progression and preserves articular cartilage in rodent models of OA.

Objectives: To test the new, more stable and long-lasting formulations of liposomal adenosine in the treatment of post-traumatic OA in a preclinical canine model.

Methods: OA was induced by arthroscopic medial meniscus release (MR) in 21 purpose-bred hounds ([10M, 11F]). Evidence of OA was documented at two months after MR (pre-Tx). Knees were injected with 3mL of RgnA09M, RgnA09N (3 mg/ml Adenosine; N=7 each) or saline (9 mg/ml NaCl; N=7) for a total of 3 intra-articular (IA) injections each carried out one month apart. RgnA09M and RgnA09N comprised identical lipid composition but varied in particle size and liposome lamellarity. Blinded assessments for knee pain, function and effusion were performed using validated visual analogue scale (VAS) scoring by a board-certified veterinary surgeon. Comfortable range of motion (CROM) was measured using a standard goniometer and radiographic assessments of knee joints were also performed. Results presented are before surgical induction of OA (pre-MR), at pre-Tx, at 4 months (post-Tx) and the time of humane euthanasia (6 months post-Tx) for histology and histopathology. Blood for biomarkers and synovial fluid were collected at same time points. MRIs were used to evaluate cartilage structure and integrity at pre-Tx and 6 months post-Tx. Wilcoxon matched pair signed rank test was used for statistical analyses.

Results: There was demonstrable symptomatic knee OA at pre-Tx with a 26.3% loss in function, increased joint pain score (2.0±0.9 vs 0 at pre-MR), 10% loss of CROM, development of radiographic OA (1.2±0.5 vs. 0 at pre-MR), observable OA on MRI (3.9±0.9 vs. 0 at pre-MR) and joint effusion (2.3±0.9 vs. 0 at pre-MR). Saline treatment provided no benefits. The IA administration of RgnA09M, led to a steady decrease in pain by 65.0% and 74.3%, at 4mo and 6mo post-Tx respectively, with a corresponding 30.9% and 61.8% gain in function. In comparison, the injection of RgnA09N led to decrease in pain by 80.9% at 4mo but a loss of effect to 74.7 % at 6mo post-Tx. A corresponding trend was observed in the gain of function, with an overall gain of 39.7% at 6mo post-Tx (**Figures 1A** and **1B**). Moreover, injections with RgnA09M, improved CROM to near-normal values at 6mo, while RgnA09N significantly improved it at 4mo **(Figure 1C)**. Compared to saline, both RgnA09M and RgnA09N improved radiographic markers by up to 42.6% at 6mo post-Tx **(Figure 1D)**. In saline-treated dogs there was an improvement in the size of effusions initially, but a loss in benefit as time progressed. In contrary, the magnitude of the change was much greater in those treated with both formulations, and it continued to improve over time **(Figure 1E)**. Finally, at 6mo post-Tx, MRIs showed significant slowing in the progression of OA with RgnA09M by 55.3% and with RgnA09N by 42.8% (**Figure 1F**). Histology and biomarker results are pending.

Conclusion: Three IA injections of RgnA09M and RgnA09N were associated with improved symptomatic knee OA including gain in function and decrease in pain and OA progression compared with saline. The persistent improvement lasted 6 months, indicating symptomatic and mechanistic benefits of the treatment. Moreover, liposomal adenosine injections slowed the progression of OA as observed on radiographs and MRIs. These findings provide the first evidence that IA injection of liposomal adenosine improves pain relief, gain in function, CROM, and prevents radiologic progression in a large animal model of post-traumatic OA.

Understanding Treatment response and novel treatment approaches in RA

OP0202 IMMUNOMICS ANALYSIS OF RHEUMATOID ARTHRITIS IDENTIFIED PRECURSOR DENDRITIC CELLS AS A KEY CELL SUBSET OF TREATMENT RESISTANCE

Keywords: Rheumatoid arthritis, -Omics

Background: To date, there have been no comprehensive studies of the immune cells that play a pivotal role in treatment-resistant rheumatoid arthritis (RA).
Objectives: We performed large scale transcriptome analyses of immune cells in peripheral blood prior to treatment in a total of 55 patients with RA to identify the gene expressions and subsets that predict treatment resistance.
Methods: We isolated 18 peripheral blood immune cell subsets of 55 pre-treatment RA patients and 39 healthy controls, and performed RNA sequencing (Figure 1A). Transcriptome changes in RA and treatment effects were systematically characterized. Association between immune cell gene modules and treatment resistance was evaluated. We validated predictive value of identified parameters for treatment resistance using quantitative polymerase chain reaction (qPCR) and mass cytometric analysis cohorts. We also characterized the identified population by synovial single cell RNA-seq analysis.
Results: Immune cells of RA patients were characterized by enhanced interferon and IL6-JAK-STAT3 signaling that demonstrate partial normalization after treatment. A gene expression module of plasmacytoid dendritic cell (pDC) reflecting the expansion of pre-dendritic cell (pre-DC), which is recently identified subpopulation of DCs (1), exhibited strongest association with treatment resistance (Figure 1B-D). Type I interferon signaling was negatively correlated to pre-DC gene expression. qPCR and mass cytometric analysis validated that the pre-DC associated gene expression and the proportion of pre-DC were significantly higher before treatment in treatment-resistant patients (Figure 1E, F). A cluster of synovial DCs showed both features of pre-DC and proinflammatory conventional DC2s (Figure 1G).
Conclusion: Treatment resistance can be predicted by an increase in pre-DC in the peripheral blood of RA patients prior to starting therapy. This result shows the potential for realizing a stratified therapy of RA based on analysis of pre-DC in peripheral blood.

Background: Different molecular targeted therapies affect immune cell phenotypes and signals differently due to their modes of action[1]. Theoretically, it is possible to use these drugs based on a stratification of rheumatoid arthritis (RA) patients. However, despite innovations in the treatment of RA, precision medicine with the development and application of personalized treatments by molecular targeted therapy is still far from its achievement. At least, precision medicine by a single biomarker is not known to be possible[2].
Objectives: To investigate the possibility of precision medicine based on the immune phenotype of peripheral blood, we stratified RA patients by comprehensive flow cytometric immunophenotyping and evaluated the response to targeted therapy.
Methods: This study enrolled 96 healthy controls (HC) and 533 bio-naive RA patients with moderate to severe disease activity acording to CDAI. The Human Immunology Project, a NIH/FOCIS-developed flow cytometric immune cell profiling method on T cells, B cells, NK cells, dendritic cells, and monocytes, was used to stratify the patients using cluster analysis (Ward and UMAP methods). Inverse probability weighting with propensity scores was used to control for patient characteristics and CDAI was used to measure remission achievement after 6 months of targeted molecular therapy for each stratified subgroup.
Results: The mean age was 63.5 years old, and the disease activity was CDAI 27.1. In comparison to HC, CD4 T cell differentiation was noticeably affected in RA patients, with elevated effector T cells and effector memory T cells re-expressing CD45RA (TEMRA). Meanwhile, there was no meaningful change in the

proportion of Th1, Th17, Treg, and Tfh cells as well as B cells, NK cells, monocytes, and dendritic cells subpopulations. Cluster analysis of the immunophenotypes revealed five main groups of RA patients, with roughly equal numbers of patients in each group. When dimension reduction of their immunophenotypes was performed by UMAP, these groups were clearly separated (Figure 1). One of the five groups had an immunophenotype almost identical to that of healthy controls (cluster 1), two groups were moderately different (clusters 2 and 3), and the last two groups had phenotypes characteristic of RA with little overlap with healthy controls (clusters 4 and 5). These 2 groups were accompanied by a marked increase in TEMRA with increased effector memory T cells (cluster 4) and with increased Th1 (cluster 5). There were few differences in baseline clinical findings such as disease activity and ACPA/RF among the groups. Of note, the clinical efficacy of each targeted therapy was statistically different in each group. In the group with immunophenotypes similar to those of healthy subjects (cluster 1) and the moderately different group (cluster 2), JAK inhibitors and IL-6R antibody treatment were effective, while TNF inhibitors were effective in another moderately different group (cluster 3). CTLA4-Ig and TNF inhibitors were effective in the two groups with phenotypes characteristic of RA (clusters 4 and 5). Immunophenotyping after treatment revealed that the first three groups became comparable to the HC phenotype. However, TEMRA dominancy groups (clusters 4 and 5) remained elevated in TEMRA. Interestingly, CTLA4-Ig decreased the proportion of TEMRA.

Conclusion: RA patients can be stratified into five groups, each of which benefited from different molecular targeted therapies. The increase in CD4 TEMRA in peripheral blood was significant in RA patients, and the proportion was virtually unchanged with treatment. Thus, CD4 TEMRA could be the pathogenic memory cells in RA. Our results may be a milestone in achieving precision medicine.

Background: CD4+CXCR5+PD-1^{hi} follicular helper (Tfh) T cells typically dwell in the germinal centers (GCs) of lymphoid organs, provide help to autoantibody secreting B cells and play an important role in the pathogenesis of Rheumatoid Arthritis (RA). Circulating counterparts of Tfh (cTfh) cells have been described in human peripheral blood, their frequencies seem to correlate with the pool of prototypical GC Tfh cells, and are expanded in patients with autoimmune conditions including RA. Abatacept (ABT), by interfering with costimulation, can restrain the generation of Tfh cells. The pathogenic implication of Tfh cells may be more prominent in RA patients with higher cTfh cell frequencies and these subjects could be more likely to respond to therapeutic costimulation blockade with ABT.
Objectives: To examine a). The effect of treatment escalation using TNF blockers (TNFb) or ABT, on the frequency of cTfh cells in RA, and b). The relation of the baseline cTfh cell frequency with the clinical response.
Methods: Peripheral blood was drawn from seropositive RA patients with an incomplete response to csDMARDS (n=41) who initiated biological therapy, according to routine clinical practice, with TNFb (n= 19) (10 Etanercept, 3 Adalimumab, 3 Certolizumab, 2 Golimumab, 1 Infliximab) or ABT (n= 22). cTfh cell frequencies were determined by flow cytometry of freshly isolated PBMCs at the basal visit and 12 months (12M) after starting treatment escalation. For each patient, an age and gender-matched healthy control (HC) was also studied at both time points (n=41).
Results: a). Effect of treatment escalation on the cTfh cell frequency. As compared with HC, RA patients receiving csDMARDs demonstrated an increased frequency of cTfh and also of activated ICOS+ cTfh cells (a-cTfh), and this was observed in both treatment escalation groups. A significant improvement of disease activity (ΔDAS28 >2.0) was apparent in all of the patients at 12M. Nevertheless, the cTfh cell frequency did not vary in patients receiving TNFb; conversely, in subjects receiving ABT it significanly decreased to HC levels. At the same time, the frequency of a-cTfh cells was significantly reduced in both groups; however, in the TNFb group it remained above HC whereas in the ABT group it reached magnitudes comparable to HC. b). Relation of the baseline cTfh cell frequency with the clinical response. In the ABT group, the baseline frequencies of cTfh and a-cTfh had been higher for patients who went on to achieve remission at 12M (12Mr), as compared with those who remained active (12Ma) [Tfh logistic regression OR for remission 25.3, 95% CI (12.2-39.8); ROC AUC 0.94(0.83-1), p<0.0005]; as stated above, the 12M frequencies were no longer elevated; in addition there were no differences between the 12Ma and 12Mr subjects. Conversely, in the TNFb group, the baseline frequencies of cTfh and a-cTfh had been lower for 12Mr as compared with 12Ma patients [Tfh OR for not achieving remission 8.5 (4.3-15.5); ROC AUC 0.77(0.54-0.99), p<0.05]; furthermore, the 12M frequencies showed the same pattern: they had not significantly changed, persisted elevated above HC and remained lower in 12Mr as compared with 12Ma patients. The baseline cTfh cutoff frequency for achieving remission in the ABT group was >0.35% (sensitivity 92.7%, specificity 90%). The baseline cTfh cutoff frequency for not achieving remission in the TNFb group was >0.44% (sensitivity 67.7%, specificity 90%).
Conclusion: ABT but not TNFb, is able to curtail cTfh cell numbers in RA, suggesting that costimulation blockade can restrain germinal center overactivity. Higher baseline cTfh cell frequencies predict a good response to ABT and at the same time, a poor response to TNFb. Therefore, immunophenotyping of patients with an incomplete response to csDMARDs can facilitate a personalized therapeutic strategy for treatment escalation.

OP0205 NANOCATALYTIC TREATMENT USING RU@TIO2 FOR RHEUMATOID ARTHRITIS VIA MACROPHAGE RE-POLARIZATION

Keywords: Animal models, Rheumatoid arthritis

S. Huang[1], L. Qiu[1]. [1]West China Hospital of Sichuan University, Department of Ultrasound, Chengdu, China

Background: Rheumatoid arthritis (RA) is an autoimmune disorder that results in synovitis and joint destruction[1]. Macrophages, one of the various inflammatory cells, particularly infiltrate the RA synovial tissue and cause sustained inflammation that promote RA. And the balance of pro-inflammatory M1 macrophages and anti-inflammatory M2 macrophages in RA joints is affected by overexpressed reactive oxygen species (ROS) and hypoxia synovium, which provides potential targets for the RA treatment.
Objectives: With the aim of alleviating the synovial inflammation in RA and restoring the balance of macrophage subtypes, we develop a catalytic nanoparticle named Ru@TiO_2, which can produce O2 and scavenge ROS to reduce M1 macrophages, switch M1 phenotype to M2 phenotype.
Methods: Ru@TiO_2 was synthesized using the hydrothermal method. The morphology and nanoparticle size were observed using the transmission electron microscopy (TEM). The catalytic ROS-scavenging activities and O_2 generation ability were examined through $\bullet O_2^-$ scavenging, H_2O_2 catalytic elimination and O_2 generation assays. For in vitro experiment, the cytotoxicity of Ru@TiO_2 conducted on RAW 264.7 cells was assessed by flow cytometry. To verify M1 to M2 macrophage phenotype transition and hypoxia alleviation, M1 and M2 markers and HIF-1α expression levels were evaluated by using qRT-PCR and Western Blot, respectively. In vivo, anti-inflammatory efficiency was observed after intra-joint injection of Ru@TiO_2 into collagen-induced arthritis mouse. The clinical scores and paw thickness for the inflamed joints with different treatments at various time points were recorded. Ultrasound (US) was used to assess the inflamed joints after treatment and RNA expression levels of M1 and M2 macrophage markers in synovial tissue were evaluated through qRT-PCR. The statistical significance among multiple groups was examined by using one-way ANOVA.
Results: The Ru@TiO_2 were fusiform in shape with an average size of 67 nm. The evaluation of catalytic ROS scavenging activities and O_2 generation performance of Ru@TiO_2 showed that Ru@TiO_2 can achieve about 60% scavenging ratio to $\bullet O_2^-$ and about 80% producing ratio to O_2 at 30 min. Ru@TiO_2 also showed significantly increased H_2O_2 eliminating activity compared to the TiO_2. In vitro, low cytotoxicity of Ru@TiO_2 was displayed and the decrease of intracellular ROS level was most significant with Ru@TiO_2. In addition, M1 macrophage markers (TNF-α and IL-1β) and HIF-1α expression levels were most prominently declined with Ru@TiO_2. And the increase of M2 macrophage markers (Arg-1 and CD206) was most obvious when using Ru@TiO_2. In vivo, the arthritis scores, paw thickness and thickness of articular cavity assessed by US in Ru@TiO_2 group were the lowest when compared with other treated groups. Moreover, RNA expression levels of M1 and M2 macrophage markers in synovial tissue showed the similar tendency as in vitro.
Conclusion: In this study, the Ru@TiO_2 was successfully synthesized with efficient catalytic ROS scavenging activities and O_2 generation ability for the treatment of RA. In vitro, Ru@TiO_2 shows good cell biocompatibility and effective intracellular ROS scavenging ability. Moreover, Ru@TiO_2 alleviate the hypoxia condition in cells by producing O_2. Furthermore, the significant and efficient polarization of M1 to M2 macrophages and suppression of inflammation were achieved both in vitro and in vivo through the treatment of Ru@TiO_2, which indicated the therapeutic potential of Ru@TiO_2 for RA therapy.

Background: Although the link between gut microbiota and rheumatoid arthritis (RA) pathogenesis is well established, there is still a lack of information regarding the species-level analysis of microbiota. Recently, studies analyzed blood samples, rather than stool samples, to identify disease-related microbiota at the species level.
Objectives: This study aimed to identify RA-related microbiomes at the species level using serum samples from patients with RA and explore the efficacy as well as mechanisms of candidate microbial species for RA treatment using collegen induced arthritis (CIA) mouse model.
Methods: Serum antibody microarray for 384 microbial species was performed from RA patients (n=81) and healthy control (n=50). We verified the therapeutic effect and mechanism of the candidate microbial species by evaluating arthritis severity, immune response, intestinal barrier integrity, and fecal microbiota using CIA mice.
Results: We discovered 36 altered microbial species in patients with RA compared to healthy controls. In particular, *Peptoniphilus gorbachii* (PG) was increased in RA patients, inversely correlated with RA disease activity, and competed with *Porphyromonas gingivalis* which developed and exacerbated RA. Administration of PG suppressed joint inflammation and bone destruction in CIA mice. PG decreases inflammatory T cells and monocytes in the mesenteric and inguinal lymph nodes. Moreover, PG supplementation restored intestinal barrier integrity, with a decreased level of serum zonulin and increased expression of intestinal tight junction proteins. The abundance of fecal microbiota in PG-treated mice correlated with improved intestinal barrier integrity and decreased inflammatory reactions.
Conclusion: Serum microbial antibody microarray could help with the effective discovery of therapeutic microbial RA targets at the species level. Our results suggest that PG exerts a therapeutic effect by restoring intestinal barrier integrity and suppressing the RA-characteristic immunologic response.

Background: RA is the most frequent systemic autoimmune disease that primarily affects multiple joints and causes irreversible bone and cartilage destruction in the absence of treatment [1]. Monocytes-macrophages are key players in the pathogenesis of RA and accumulate in the synovial tissue. Besides resident macrophages, blood monocytes can differentiate into monocyte-derived-macrophages that may join the synovium and have different phenotypes and

functions. The "classically activated macrophage phenotype" is considered to be pro-inflammatory and contribute to RA pathogenesis by secreting pro-inflammatory cytokines. The "alternatively activated macrophage phenotype" is considered to be regulatory and anti-inflammatory in tissues. Actually, there is a continuum from pro-inflammatory to anti-inflammatory macrophages, with high plasticity between the different states. We have previously shown that RA patients, and not patients with other inflammatory rheumatic diseases, have an impaired maturation of monocytes in anti-inflammatory-macrophages with increased differentiation in a pro-inflammatory-phenotype. We have found that an increased expression of miR-155 in monocytes/macrophages could be responsible for this defect and thus, could represent a new therapeutic target in RA ([2]).

Objectives: Our aim is to assess if the defect of monocytes polarization in anti-inflammatory-macrophages and the impact of miR-155 in this defect are present in 2 pre-clinical models of RA: the CIA (collagen-induce-arthritis) and STA mice (Serum transfert arhritis), both in which macrophages infiltration of synovium play a key role in pathophysiology. Then, we have test a new therapeutic strategies to correct this defect using PEG-liposomes containing antagomiR-155-5p.

Methods: AntagomiR-155-5p or antagomiR-control were encapsulated in PEG-liposomes of 100 nm in size and -10mV in zeta potential with high antagomiR loading efficiency (above 80%). Mice were injected intravenously with 1,5nmol/100µL PEG-liposomes containing antagomiR-155-5p or control after induction of arthritis.

Results: As in humans, we found that monocytes defect in anti-inflammatory-macrophages was associated with an increase of miR-155-5p in both mouse models. Moreover, we demonstrated the biodistribution of tagged-PEG-liposomes to inflamed joints 1 hour after injection and as well as their subsequent liver's accumulation after 48 hours, indicative of hepatic clearance, in arthritic mice. Subsequently, we demonstrated that treatment with an antagomiR-155-5p encapsulated in PEG-liposomes was able to decrease joint inflammation, to restore bone-marrow monocytes polarization in anti-inflammatory-macrophages, to reduce immune cells infiltration in synovial tissues, to increase the $CD206^+$ and $CD163^+$ tissue infiltrating macrophages and to decrease expression of mRNAs target of miR-155-5p, without any significant functional change in other immune cells including splenic B and T cells.

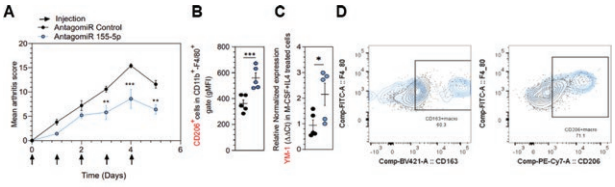

Figure 1: Treatment of STA mice with PEG-liposomes containing antagomiR-control or antagomiR-155-5p. For STA mice, antagomiR-control or 155 entrapped in PEG-liposomes are intravenously injected on days 0, 1, 2, 3, and 4. Mice were evaluated every 2-day, based on a visual scoring scale of the paws with evaluation of the erythema, swelling and ankylosis of each paw (score 1 to 4) **(A)**. The differentiation of sorted bone-marrow monocytes to BMDM-M2 was assessed by flow cytometry with pan-macrophages markers and specific markers of M2 macrophage (CD206) **(B)** and YM-1 relative expression **(C)**. Synovial tissue cells were assessed by flow cytometry analysis using anti-CD45, DUMP channel: CD19-CD3-NK1.1-LY6G, anti-CD11b, anti-F4/80, anti-MHCII, anti-CD64, anti-LY6C, anti-MerTK, anti-CD163, anti-CD206 and anti-CX3CR1. Determination of tissue infiltrating $CD206^+$ or $CD163^+$ macrophages in synovial tissue **(D)**.

Conclusion: The injection of antagomiR-155-5p encapsulated in PEG-liposomes allows delivering small RNA to monocytes/macrophages, lead to reduce joint inflammation in murine models of RA, providing a promising strategy in human disease.

OP0208 MECHANICAL UNLOADING PREVENTED ARTHRITIS IN THE RAT ADJUVANT-INDUCED ARTHRITIS MODEL

Keywords: Rheumatoid arthritis, Animal Models

E. Dalix[1], M. Maalouf[1], A. Vanden-Bossche[1], M. Paul[1], H. Marotte[1,2]. [1]*University of Jean Monnet, INSERM, U1059-SAINBIOSE, Saint-Etienne, France*; [2]*University Hospital of Saint-Etienne, Department of Rheumatology, Saint-Etienne, France*

Background: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatic disease, characterized by synovitis associated with progressive bone loss and joint swelling. The adjuvant-induced arthritis (AIA) model mimics the pathophysiological features of RA, with a very high prevalence and reproducibility. YAP plays a key role in synovial hyperplasia. It is a transcription factor which can be activated in response to inflammation but also by a mechanical stimulus as tissue stiffening. We already showed a decrease arthritis severity by inhibiting YAP in the AIA model [1]. Then, different mechanical challenges could potentially impact arthritis development by regulating YAP.

Objectives: The objective of this study was to investigate the impact of mechanical loading and unloading on the development of arthritis in the AIA model.

Methods: Arthritis was induced in female Lewis rats by injection of the adjuvant *Mycobacterium butyricum*, defining day (D)0. The AIA model normally develops arthritis at D10, with a peak of inflammation at D17 [2]. Rats were randomized into three groups: an AIA+mechanical loading group (n=11) with free access to an activity wheel from D0 to D17, an AIA+mechanical unloading group (n=11) by tail suspension from D0 to D17, and an AIA-only group (n=11) as positive control. Daily clinical monitoring (arthritic index and ankle circumference) was used to follow the progression and severity of arthritis. At D17, the ankles of the rats were collected to perform RT-qPCR.

Results: Arthritis onset was observed at the same time (D10) in the AIA control and AIA+mechanical loading groups with the same kinetic of arthritis index and ankle circumferences. However, the majority of rats in the AIA+mechanical unloading group did not develop any signs of arthritis. At D17, gene expression of YAP and CYR61 (YAP target gene), IL1B, IL6, RANKL, ACP5 (encoding TRAPc), CTSK (encoding cathepsin K), MMP9, and MMP13 was decreased in the ankle of AIA+mechanical unloading rats compared to other groups. In the AIA+ mechanical loading group, rat stopped their physical activity at D10 which may explain the lack of clinical and molecular differences between the AIA and AIA+mechanical loading groups at D17.

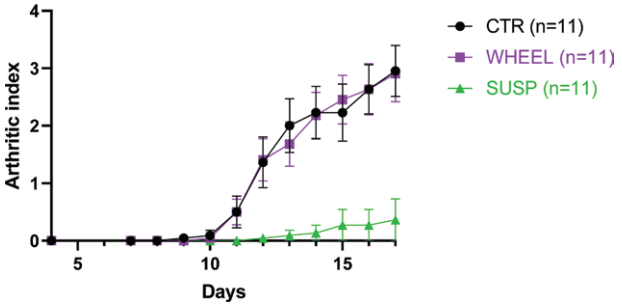

Figure 1. Arthritic index from day(D) 0 to D17 in the AIA control (CTR) group (n=11), the AIA+mechanical loading (WHEEL) group (n=11) and the AIA+mechanical unloading (SUSP) group (n=11).

Conclusion: Mechanical unloading of the hindpaws by the suspension system strongly prevented arthritis by a reduced expression of pro-inflammatory genes, bone resorption, and bone degradation genes. The decrease in inflammation may be partly explained by the decrease in YAP transcriptional activity. Mechanical stress is therefore a key factor in inflammation during AIA. The precise mechanisms linking these two mechanisms are still under investigation.

Background: Increased neovascularization in the inflamed synovium of patients with rheumatoid arthritis (RA) is a pathological feature in the pathogenesis of RA. Key players in RA progression are chronically activated RA synovial fibroblasts (RASF), which secrete proinflammatory factors (e.g. IL-6), proangiogenic

VEGF, IL-11 and matrix metalloproteases (MMP) promoting inflammation, synovial angiogenesis, and invasion of cartilage and bone by degrading the consecutive matrix, resulting in the release of the anti-angiogenic collagen IV fragment canstatin. Canstatin may further activate RASF leading to altered expression of vascular markers such as angiopoietin-2 (ANGPT2) and neovascularization.
Objectives: Analysis of repetitively stimulated RASF- and canstatin-mediated effects on vessel formation in the tube formation assay, in the SCID-mouse model for RA and in synovial tissue of RA patients with respect to ANGPT2 expression and RASF-endothelial cell (EC) interactions.
Methods: 2D tube formation assay was performed using HUVEC seeded on Matrigel. 15% Calcein AM-stained RASF were added. RASF/HUVEC were treated with 0.5µg/ml canstatin. HUVEC were pre-treated with 0.2µg/ml canstatin. RASF were repetitively stimulated three times with 0.05ng/µl IL-1ß every 24h starting at day 2. Tube thickness and the area covered by the formed cellular network were measured. RNA was extracted from tubes and ANGPT2 expression was analysed by qPCR. IL-6 and IL-11 in supernatants were measured by ELISA. Healthy cartilage was subcutaneously co-implanted with RASF into SCID mice. Contralaterally, healthy cartilage without RASF was implanted. Vessel formation was evaluated after 3-45 days. RA and osteoarthritis (OA) synovial tissue was stained for ANGPT2 and CD31.
Results: RASF or HUVEC stimulated once showed a significant IL-6 increase compared to unstimulated controls. After subsequent repetitive stimulation of RASF or HUVEC, a significant decrease in IL-6 (1st stimulation: 5076±1730pg/ml vs. 3rd: 1890±758pg/ml, p<0.0001/ 1st: 488±186pg/ml vs. 3rd: 382±109pg/ml, p=0.041) and IL-11 in RASF (1st: 451±205pg/ml vs. 3rd: 69±51pg/ml, p<0.0001) compared to the first stimulation was observed. Repetitive stimulation of HUVEC+RASF resulted in a significant IL-6 increase for each subsequent stimulation (1st vs. 3rd: p=0.02). RASF significantly reduced tube thickness (22.9µm (SD=6.3) vs. 16.6µm (SD=2.2), p=0.014) and the network area (p<0.0001) and significantly increased ANGPT2 2-fold compared to HUVEC alone. RASF stimulated only once further reduced the network area (p=0.038), while repetitive stimulation significantly attenuated the proinflammatory effect (IL-6, p=0.029). Stimulation of pre-treated HUVEC and unstimulated RASF with canstatin led to disturbed tube formation with reduced tube thickness from 22.9 to 16.9µm (SD=4.4, p=0.011). Co-culture of RASF with pre-treated HUVEC with canstatin further increased the RASF-mediated effect by reducing tube thickness (22.9 to 14.6µm (SD=1.4), p<0.001), with a significant 1.6-fold decrease of ANGPT2. In human RA synovium, ANGPT2 was also found to be significantly upregulated in vessels compared to OA tissue. In SCID mice, RASF-mediated altered vessel formation started at day 3. Helix-like vessels were detectable at early time points of vessel formation in implants with RASF (d3-9), e.g. at day 3, 60% of vessels were helix-like.
Conclusion: RASF induced helix-like vessels in the SCID mouse model suggest an influence on vessel formation. This could be confirmed in vitro as well as on molecular level inducing the vascular marker ANGPT2 in newly formed tubes. ANGPT2-upregulation in vessels was also observed in human RA synovium. Repetitive stimulation of RASF resulted in an inflammatory adjustment to IL-1ß, leading to a significant reduction of IL-6 and improved neovascularization in vitro. The anti-angiogenic canstatin could in part enhance the RASF-mediated effect and was not able to restore RASF-altered tube formation in vitro.

Background: Primary Sjögren's syndrome (pSS) is a B-cell driven systemic auto-immune disease associated with the highest risk of lymphoma among systemic auto-immune diseases. In the prospective ASSESS cohort (395 patients enrolled, with a 10-year follow-up), transcriptomic analysis recently showed the association between baseline peripheral blood overexpression of Bruton's tyrosine kinase (BTK) and lymphoma.
Objectives: This study aimed to confirm the transcriptomic findings at the mRNA and protein level and to evaluate the relevance of BTK as a lymphoma predictor with regards to other predictors.
Methods: BTK mRNA expression was assessed using qRTPCR in whole blood samples from 63 patients (12 patients with a history of lymphoma, 9 patients with incident lymphoma occurring during the 10-year follow-up, 21 patients without lymphoma and no risk factors for lymphoma and 21 patients without lymphoma and ESSDAI ≥ 5). BTK protein expression in peripheral blood was analyzed by flow cytometry in 7 healthy controls, 5 pSS patients without risk factors for lymphoma, 8 pSS patients with ESSDAI ≥5, and 6 pSS patients with lymphoma. In 346 patients of the ASSESS cohort for whom all data were available, the association between pSS-related lymphoma and BTK expression at enrolment, with 9 validated lymphoma predictors (parotid enlargement, purpura, ESSDAI ≥ 5, lymphocytopenia, CD4/CD8 ratio ≤ 0.8, RF positivity, cryoglobulinemia, monoclonal component, and low C4) and other potential biomarkers (serum FLT3L, BAFF, digital interferon alpha, gammaglobulins, IgG, beta2microglobulin, kappa and lambda free light chains, quantitative levels of anti-SSA/SSB) was analyzed. Multivariate analyses took into account in a first model, BTK and the 9 validated predictors of pSS-related lymphoma, and in a second model variables associated with lymphoma in univariate analysis selected by a stepwise procedure.
Results: In qRTPCR, BTK was significantly upregulated between pSS patients with and without lymphoma. In flow cytometry, BTK protein expression in $CD19^+$ B cells (p=0.03), and in most B-cell subpopulations, was significantly increased in patients with lymphoma compared to healthy controls. A gradual increase was observed in BTK expression of $CD19^+$ B cells, between patients without risk factors for lymphoma, those with ESSDAI ≥5, and those with lymphoma. In multivariate analysis, taking into account 9 validated predictors of lymphoma in pSS, BTK expression at enrolment was significantly associated with lymphoma (adjusted OR [aOR] 1.45; 95% CI [1.19-1.82]; p<0.001), along with CD4/CD8 ratio ≤ 0.8 (aOR 6.03; 95% CI [1.23-26.13]; p=0.02). In a second model including 4 biomarkers selected by a stepwise procedure, BTK expression remained significantly associated with lymphoma (aOR 1.36; 95% CI [1.14-1.64]; p<0. 001), as well as serum BAFF levels (mean [SD]:1028.5 pg/ml [710.3]; per 1000 BAFF units, aOR 2.04; 95% CI [1.3-3.19]; p=0.001), low C4 (aOR 4.16; 95% CI [1.43-13.88]; p=0.01) and CD4/CD8 ratio ≤0.8 (aOR 10.62; 95% CI [2.49-44.15]; p=0.001).
Conclusion: These results confirm that increased expression of BTK in peripheral blood is associated with pSS-related lymphoma. These results also show the potential interest of combining B-cell (BTK and BAFF) and T-cell (CD4/CD8 ratio)-related biomarkers to evaluate the risk of lymphoma in pSS.

Background: A decline of urine protein-to-creatinine ratio (UPCR) to < 0.5 is associated with better long-term preservation of kidney function in lupus nephritis (LN). UPCR < 0.5 defines complete response in guidelines and clinical trials when achieved after 1 or 2 years. Biomarkers of early response are needed to guide early treatment changes. We studied longitudinal urine proteomic profiles in LN to identify early predictors of proteinuric response.
Objectives: Identify early predictors of proteinuric response in LN using longitudinal urine proteomic profiles.
Methods: We quantified 1200 biomarkers (Kiloplex, RayBiotech) in urine samples collected on the day of (73%) or within 3 weeks (27%) of kidney biopsy and week 12, 24, or 52 in LN patients (ISN class III, IV, V, or mixed) with proteinuria > 1 g/d. Response was defined at one year from renal biopsy: Complete = UPCR < 0.5, serum creatinine (sCr) < 125% of baseline, prednisone ≤ 10mg/d; Partial = UPCR < 50% from baseline but >0.5, sCr < 125% of baseline, but prednisone allowed to 15 mg/d; Non responder = not meeting previous definitions.
Results: A total of 127 patients were included: 48 (38%) with pure proliferative LN (class III or IV), 41 (32%) with mixed LN (III or IV +/- V), and 38% (30%) with pure membranous LN. Response was complete in 34 (27%), partial in 29 (23%), and none in 64 (50%). There were no urinary biomarkers at baseline that predicted response. We then analyzed the changes in urinary proteins at 3 months compared to baseline. Patients who responded at 1 year showed an early decline in 51 urinary proteins led by CD163, IL-16, and CD206 (macrophage mannose receptor) (**Figure 1A**) which matched the proteomic signature associated with histological activity (**Figure 1B**). No changes were observed in nonresponders. The decline of several urinary biomarkers at 3 months outperformed a decline in UPCR (clinical standard) in predicting the 1 year response. In particular, a decline of CD163 predicted 1 year response in ROC analysis with an area under the curve (AUC) of 83% compared to an AUC of 75% for UPCR decline. In proliferative LN, urinary biomarkers displayed superior performance with an AUC of 91%, 86%, and 78% for the decline of CD206, CD163, and UPCR, respectively (**Figure 1C-D)**. Pathway enrichment analysis identified leukocyte activation, neutrophil degranulation, and matrix degradation as the main pathways reduced at 3 months in responders.

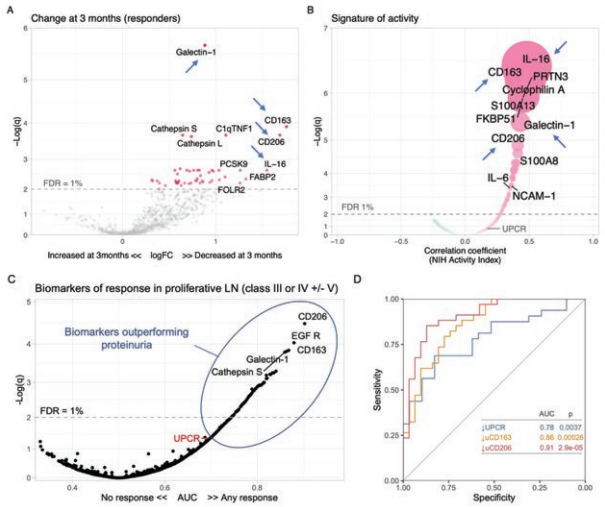

Figure 1.

Conclusion: An early decline in urinary biomarkers of histological activity is associated with proteinuric response at 1 year. These findings indicate that effective immunosuppression induces by three months an immunological response in the kidney that can be noninvasively monitored in the urine. Biomarkers of immunological response outperformed early decline of UPCR, the standard of care, in predicting 1-year proteinuric response, especially in proliferative LN. Because biomarkers of immunological response parallel intrarenal activity, they could detect early treatment response/failure and allow early treatment changes. They could serve as surrogate endpoints in clinical trials. Longitudinal studies are needed to confirm that this immunological response is a better predictor of long-term kidney function preservation than proteinuric responses.

OP0212 **EXAMINING CLINICAL HETEROGENEITY IN PRIMARY SJOGREN'S SYNDROME: PROTEOMIC AND NETWORK ANALYSIS**

Keywords: -omics, Cytokines and chemokines, Sjögren syndrome

J. Berry[1], J. Casement[1], E. Traianos[1], J. Tarn[1], W. F. Ng[1,2]. [1]*Translational and Clinical Research Institute, Newcastle University, Translational and Clinical Research, Newcastle Upon Tyne, United Kingdom*; [2]*NIHR Newcastle Biomedical Research Centre and NIHR Newcastle Clinical Research Facility, Clinical Research Facility, Newcastle Upon Tyne, United Kingdom*

Background: A symptom-based stratification tool using data from three European cohorts identified four clinical subtypes of pSS: Low symptom burden (LSB), high symptom burden (HSB), dryness dominant with fatigue (DDF), and pain dominant with fatigue (PDF).[1] These subtypes have distinct molecular profiles, clinical manifestations, and responses to immunomodulatory therapies. Detailed knowledge of the biological pathways underlying the clinical subtypes is vital to understanding the clinical heterogeneity of pSS and has relevance for trial design and therapeutic development.
Objectives: Clinical manifestations of an immune-mediated inflammatory disease are likely underpinned by networks of dysregulated biological pathways. Proteomic and network analysis was performed to identify biological pathways that are differentially expressed between the pSS subtypes.
Methods: We profiled serum proteins using O-link technology of 180 pSS subjects (45 subjects of each subtype). We used 5 O-link proteomics panels which included 454 proteins. As we anticipate that these serum proteins may act directly or indirectly through interactions with other proteins, we used a network analysis approach. Using the LSB group as a reference we identified differentially expressed proteins. Network reconstruction was performed using the ARACNE algorithm which calculates mutual information between the variables of a multidimensional dataset to construct a protein network.[2] Differential expression estimates were overlaid on these networks to reveal key regions that are differentially expressed between the phenotypes. Statistical analysis was performed in R v4.1.3 and JMP Pro v15 and network visualisation in cytoscape v3.8.2.
Results: The DDF group is characterised clinically by glandular dysfunction. The DDF proteome demonstrated higher expression of chemokines that orchestrate lymphocyte migration and ectopic lymphoid structure formation in the salivary glands and of cytokines promoting B-cell hyperactivity and autoantibody production. In contrast to DDF, the HSB and PDF groups report extra-glandular manifestations such as pain, fatigue, and mood disturbances. HSB and PDF proteomes show increased expression of proteins linked to the inflammatory response, oxidative stress response and cellular metabolism (IL-1α, IL-6, APE/Ref-1, FOXO1, TIGAR and BACH1). Network analysis revealed distinct clusters of proteins that were upregulated or downregulated between different pSS subtypes, providing added support to the concept that distinct molecular pathways contribute to the clinical manifestations of these subtypes.

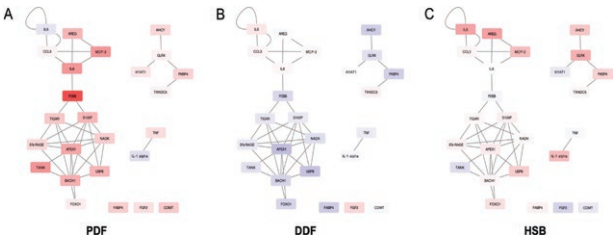

Figure 1. Selected proteins showing differences associated with PDF A), DDF B) and HSB C) subgroups. Derived from ARACNE analysis of protein expression data, nodes represent individual proteins and edges represent the mutual information between nodes. Colour scaling shows estimated difference using LSB as a comparator group, with red indicating higher expression and blue indicating lower expression. Estimates are derived from a generalised linear model post adjustment for baseline age, sex and batch

Conclusion: Protein expression between the clinically distinct pSS subgroups revealed differences in cytokines, chemokines and master transcription factors associated with redox imbalance and altered energy metabolism. Furthermore, the differentially expressed proteins seem to be interrelated in our network

analysis. Our data provide clues to the molecular pathways contributing to the glandular and systemic manifestations of pSS and to potential therapeutic targets for different pSS subgroups.

Background: Antiphospholipid syndrome (APS) is an autoimmune disease defined by arterial or venous events or pregnancy complications in association with autoantibodies against phospholipids. Despite these autoreactive antibodies, B lineage cells remain poorly studied in APS.[1] Besides triple-positivity of autoantibodies and the occurrence of lupus anticoagulant, there are no biomarkers for risk assessment in APS.[2] Characterization of autoantigen-specific B cells hold promise for better understanding APS pathogenesis which may guide targeted immune therapies including identification of biomarkers.

Objectives: The study characterized B cell subsets among patients with primary (pAPS) and secondary APS (sAPS) compared to healthy controls. In particular, we analyzed phosphatidylcholine (PtC)-specific B cells for their frequency of occurrence and immunophenotype related to disease characteristics.

Methods: We analyzed PBMCs from 20 HCs, 25 pAPS and 16 sAPS patients. Using multi-dimensional flow cytometry, we analyzed the expression of 15 surface markers on B cells including the frequency of PtC-specific B lineage cells. We established a novel assay to detect antigen-specific B cells against PtC as a potential correlate of antiphospholipid antibodies as previously reported for autoreactive B1 cells in mice.[3] The obtained cellular subsets and autoreactive cells were subjected to the FlowSOM algorithm in R to identify B cell clusters through an unbiased strategy.

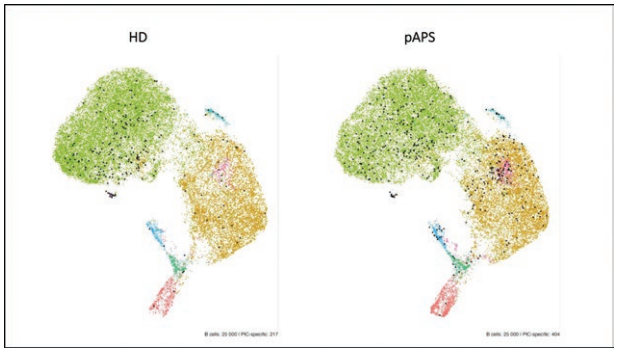

Figure 1. Two-dimensional UMAP for a random subset of 50000 B cells divided by group. Different colors label FlowSOM metaclusters. Clustering was performed on $1.5x10^6$ B cells and 7 surface markers. Black dots represent PtC-specific cells. A significant increase for both total and PtC-specific B cells was observed in the pink cluster for pAPS patients compared to HCs ($p<0.01$). Main clusters: green – naïve, brown – switch memory, red: plasmablasts, pink – pre-switch memory (IgD+/CD24+/CD27+/CD11c+).

Results: pAPS and sAPS patients showed increased frequencies of atypical CD21low as well as CD21low/CD11c+ B cells, most prominent within the IgD+/CD27+ memory compartment (CD21low: $p<0.01$, CD21low/CD11c+: $p<0.001$). We found higher frequencies of total PtC-specific B cells compared to HCs among pAPS in contrast to sAPS patients. In HCs, PtC-specific B cells were found mainly among naïve B cells, while they were significantly enriched within IgD+/CD27+ pre-switch memory B cells in pAPS patients ($p<0.01$). Most notably, high frequencies of PtC-specific IgD+/CD27+ pre-switch memory B cells were associated with a high-risk APS profile according to the EULAR classification criteria ($p<0.05$). Unsupervised FlowSOM clustering identified eight distinct B cell clusters. Remarkably, PtC-reactive memory B cells mainly resided in a unique cluster of IgD+/CD27+/CD21low/CD11c+ memory B cells (**Figure 1**).

Conclusion: Although APS patients carry an overall comparable B cell subset distribution as HCs, increased frequencies of atypical B cells are characteristic of pAPS and sAPS patients. PtC-specific B cells are substantially enriched among memory- and atypical CD21low/ CD11c+ memory B cells in pAPS. The data indicate that there is ongoing induction of autoantigen-specific atypical memory B cells apparently induced outside the germinal centers escaping negative selection.

OP0214 A MULTI-DIMENSIONAL APPROACH REVEALS A DYSREGULATED SYSTEMIC LUPUS ERYTHEMATOSUS IMMUNE RHEOSTAT WITH AN ABNORMAL IMMUNOREGULATORY RESPONSE AND REDUCED CTLA4 EXPRESSION IN EFFECTOR T CELLS

Keywords: Adaptive immunity, Systemic lupus erythematosus, Biomarkers

J. G. Yeo[1,2,3], K. Nay Yaung[1,3], A. Law[3,4], M. Wasser[1,3], T. Arkachaisri[2,3], J. Thumboo[2,3], A. Low[3,4], S. Albani[1,2,3]. *[1]SingHealth Duke-NUS Academic Medical Centre,Translational Immunology Institute, Singapore, Singapore*; *[2]KK Women's and Children's Hospital, Rheumatology and Immunology Service, Singapore, Singapore*; *[3]Duke-NUS Medical School, Duke-NUS Medical School, Singapore, Singapore*; *[4]Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore*

Background: Systemic Lupus Erythematosus (SLE) immunopathogenesis involves a complex network of regulatory and effector cells with its balance constituting an immune rheostat that maintains immune homeostasis. Thus, the disease must be interrogated holistically to identify mechanistically and clinically relevant immune cell subsets for its pathogenesis. There is a crucial unmet need to examine the mechanism of tolerance loss in lupus and identify novel targets for potential therapeutic intervention to improve outcomes.

Objectives: To characterise the SLE immunome holistically and address our hypothesis that SLE is driven dually by an impaired immunoregulatory axis and perturbed immune effector system.

Methods: Forty-one peripheral blood mononuclear cell (PBMC) samples from 26 adult SLE patients and 27 age-matched healthy controls were studied with a 43 markers mass cytometry panel. The SLE patients (23 females) had a median age of 40 (interquartile range [IQR]: 28 to 54) years with a median SLEDAI 2K score of 4 (IQR: 0 to 6). Quality check, batch-effect correction, cell clustering, annotation and visualisation after t-distributed stochastic neighbour embedding (tSNE) dimensional reduction was done using our extended polydimensional immunome characterisation (EPIC) pipeline [1]. Frequencies are expressed as a percentage of total $CD45^+$ PBMC or ratio and described with median and IQR. Statistical significance is defined as $p<0.05$ (Mann-Whitney U test with Bonferroni correction).

Results: Our multi-parametric approach reveals multiple derangements in all the major immune lineages but predominantly in the $CD4^+$ T cell population (Figure 1). Interestingly, there were no significant differences in the memory ($CD45RO^+$) and naïve ($CD45RA^+$) Treg ($CD3^+CD4^+CD25^+Foxp3^+CTLA^+$) subsets between SLE and controls. Instead, an enrichment of an activated memory Treg-like T subset ($CD3^+CD4^+CD45RO^+CD25^-Foxp3^+CTLA^+ICOS^+$) was found in SLE (SLE

versus healthy: 0.86 [0.43 to 1.38]% versus 0.31 [0.24 to 0.42]%, p<0.01). These Treg-like cells do not express CD25, a phenotypic marker for natural Treg cells. Concurrently, there was a significant reduction in CTLA4 expressing naïve non-Treg $CD4^+$ T (effector) cells in lupus (SLE versus healthy: 0.59 [0.40 to 1.11]% versus 2.0 [0.9 to 2.9]%, p<0.01). This was accompanied by a significant reduction in the ratio of $CTLA4^+$ to $CTLA4^-$ naïve non-Treg $TNF\alpha^+$ effector T cells (SLE versus healthy, ratio of $CTLA4^+$ to total naïve non-Treg $TNF\alpha^+$ T cells: 0.14 [0.11 to 0.23] versus 0.33 [0.17 to 0.55], p<0.0001). Additionally, other significant changes such as activated $IL4^+$ T cell subset ($CD3^+CD4^+CD45RA^+HLA\text{-}DR^+IL4^+$) was increased in lupus (SLE versus healthy: 0.30 [0.19 to 0.52]% versus 0.07 [0.05 to 0.12]%, p<0.0001).

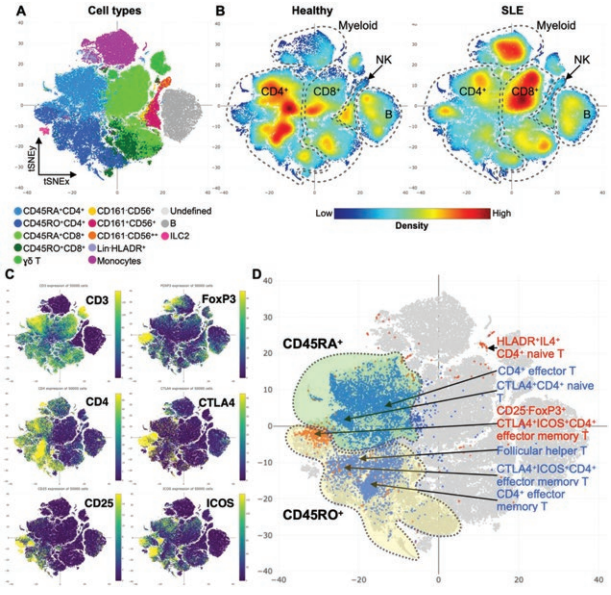

Figure 1. (A) Cell types embedded tSNE plot. **(B)** Healthy and SLE immunomes (Density plots). **(C)** Expression embedded tSNE plots. **(D)** Differentially enriched $CD4^+$ T cell clusters in either healthy or SLE. Blue: significantly increased cell subsets in healthy. Red: significantly increased cell sub-sets in SLE. All plots are derived from a random sampling of 50,000 single-cell events, dimensionally reduced with 43 markers (n=23 healthy and 41 SLE).

Conclusion: There are multiple derangements in the immunoregulatory and effector axes in lupus consistent with its complex immunopathogenesis. The activated CD25 negative Treg-like subset indicates an impaired regulatory response in SLE. The reduced CTLA4 expression in the naïve non-Treg T cells in lupus suggests a perturbed negative feedback mechanism in the effector system. The validation of these results and delineation of the underlying disease mechanisms have translational therapeutic potential.

OP0215 IMMUNOME ANALYSIS INDICATES ROBUST INHIBITION OF PROINFLAMMATORY MEDIATORS UPON LEFLUNOMIDE-HYDROXYCHLOROQUINE COMBINATION THERAPY IN SJÖGREN'S SYNDROME: CXCR3 LIGANDS AS POTENTIAL INFLAMMATORY ENDOTYPE BIOMARKERS.

Keywords: Biomarkers, Sjögren syndrome, Randomized control trial

V. Baloche[1], C. Bogers[1], H. Leavis[1], J. Van Roon[1,2]. [1]*University Medical Center Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands*; [2]*University Medical Center Utrecht, Center of Translational Immunology, Utrecht, Netherlands*

Background: Primary Sjögren's syndrome (pSS) is a chronic autoimmune disorder characterized by lymphocytic infiltration and functional impairment of exocrine glands, resulting in dryness of the eyes, mouth and extra-glandular manifestations in numerous organs. Immunopathology in pSS is associated with prominent B cell hyperactivity reflected by elevated serum IgG levels, autoantibody production, immune complex formation, and complement activation [1]. In a recent double blinded placebo controlled randomized trial, we demonstrated unprecedented robust inhibition of B cell hyperactivity and different disease activity parameters (including primary endpoint ESSDAI) by leflunomide-hydroxychloroquine (LEF-HCQ) combination therapy in the treatment of patients with pSS [2].

Objectives: To assess the potential of LEF-HCQ combination therapy to normalize dysregulated inflammatory cytokine levels in pSS patients, and to identify biomarkers that reflect inflammation, monitor changes in disease activity and predict the treatment response.

Methods: We employed a high-throughput protein Olink proteomic assay (Immuno-Oncology panel) in order to determine the blood serum concentrations of 92 immune biomarkers, assessed at baseline and at the clinical endpoint in placebo (n=8) and verum treated patients (n=21). Welch 2-sample t-test and paired t-test were used to calculate differences for unpaired and paired data, respectively and FDR corrected p values were assessed using the Olink Analyze package available on CRAN.

Results: Of the 92 immune biomarkers, 34 were significantly upregulated in pSS patients compared to healthy controls at the onset of the trial (all at least p<0.05). Moreover, the majority of these inflammatory mediators (24/34) were downregulated after 24 weeks of LEF-HCQ treatment (LGALS9, CCL19, IL10, CXCL10, CXCL11, CXCL13, GZMH, CXCL9, and soluble CD28, CD83, CD27, PDCD1, ADGRG1, PD-L1, CRTAM) with 9 returning to healthy control levels (TNF, IL12, GZMA, and soluble LAG3, IL12RB1, TNFRS9/4-1BB, CD4, KLRD1, CD70). Conversely, no significant alterations were observed in the placebo group. Interestingly, changes in ESSDAI scores were significantly (all at least p<0.05) associated with changes in IL13, TNF, PTN, CXCL9, CXCL11 and soluble LAG3 concentrations. In addition, changes in serum IgG and Rheumatoid Factor levels were both significantly associated with changes in soluble CXCL13, GZMA, CXCL9, soluble CD4 and CD28 concentrations. Based on a machine learning approach (sPLS-DA) we identified baseline levels of CXCL9/10/11 as key markers of the treatment response.

Conclusion: LEF-HCQ treatment robustly inhibits inflammatory activity in pSS patients. The correlation of several mediators with clinical activity parameters indicates that these may have value in monitoring the disease activity. Furthermore, the clinical outcome upon LEF/HCQ treatment seems predetermined by an inflammatory endotype, with circulating biomarkers such as CXCR3 ligands as key determinants. These findings represent an important advance in our understanding of the underlying immunopathology of pSS and could help in the development of more personalized and effective treatment approaches for pSS and potentially other rheumatic diseases.

OP0216 THE CLINICAL AND PATHOLOGICAL ROLES OF AUTOANTIBODIES TARGETING BMP SIGNALING IN SYSTEMIC LUPUS ERYTHEMATOSUS-ASSOCIATED PULMONARY ARTERIAL HYPERTENSION

Keywords: Systemic lupus erythematosus, Autoantibodies, Lungs

J. Qian[1], Y. Xing[2], D. Yufang[1], X. Deng[1], J. Zhao[1], Q. Wang[1], Z. Tian[3], M. LI[1], X. Zeng[1]. [1]*Peking Union Medical College Hospital, Rheumatology, Beijing, China*; [2]*Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, State Key Laboratory of Medical Molecular Biology, Beijing, China*; [3]*Peking Union Medical College Hospital, Cardiology, Beijing, China*

Background: Pulmonary arterial hypertension (PAH) is one of the most severe complications and the leading cause of death in patients with systemic lupus erythematosus (SLE). Pathogenic mechanisms leading to SLE-PAH are still not fully understood. In idiopathic PAH, the dysfunction of the bone morphogenetic protein (BMP) pathway was found to be involved in pulmonary artery remodeling [1]. In SLE-PAH, our previous study identified serum autoantibodies targeting BMP receptors (BMPR) as the potential biomarker, including anti-BMPR2, BMPR1A, and Activin Receptor-Like Kinase type 1 (ALK1) antibodies [2]. However, the clinical and pathological roles of the above autoantibodies targeting BMP signaling in SLE-PAH remain uncertain.

Objectives: To investigate the clinical and pathological roles of autoantibodies targeting BMPR2, BMPR1A, and ALK1 in SLE-PAH.

Methods: Patients of SLE-PAH confirmed by right heart catheterization were enrolled and serum levels of autoantibodies targeting BMPR2, BMPR1A, and ALK1 were measured by ELISA. Patients with SLE-PAH were subtyped by

cluster analysis. Survival and treatment goal achievement were further compared between different clusters. The Id1 and phospho-SMAD1/5 (p-SMAD1/5) levels were examined in human pulmonary artery endothelial cells (hPAEC) under the induction of BMP9 combined with anti-BMPR2, anti-ALK1, and anti-BMPR1A neutralizing antibodies (5 μg/mL). The effect of anti-ALK1 antibodies on the extent of monolayer permeability and apoptosis of hPAEC was further examined.
Results: 60 SLE-PAH patients were enrolled and cluster analysis revealed two distinct clusters according to the positivity of autoantibodies targeting BMP signaling and clinical manifestations. Cluster 1 was a "low-antibody and high-disease activity" cluster while cluster 2 was a "high-antibody and low-disease activity" cluster. Patients in cluster 1 showed a higher proportion of nephropathy (76.9%) and SLE activity, however a low positivity rate of autoantibodies targeting BMP signaling. Patients in cluster 2 were characterized by a higher rate of anti-BMPR2 antibodies (82.4%), anti-ALK antibodies (70.6%), and lower SLE activity. Prognostic analysis showed that the proportion of patients who reached the treatment target was relatively higher in cluster 2. Mechanism study showed that the p-SMAD1/5 level and the Id1expression were decreased, indicating the suppression of BMP signaling in the presence of anti-ALK1 antibodies. Functional studies showed that anti-ALK1 antibodies increased the monolayer permeability of hPAEC. The late-stage apoptosis of hPAECs was also induced by anti-ALK1 antibodies.

Table 1. The clinical features of the patients in cluster 1 and cluster 2.

	Cluster 1 (N=26)	Cluster 2 (N=34)	P
Anti-BMPR2 antibodies	5(19.2)	28(82.4)	**<0.001**
Anti-BMPR1A antibodies	8(30.2)	4(1.8)	0.068
Anti-ALK antibodies	5(19.2)	24(70.6)	**<0.001**
Arthritis	12(46.2)	25(73.5)	**0.031**
Nephropathy	20(76.9)	1(2.9)	**<0.001**
SLEDAI	5.46±4.28	2.62±2.10	**0.001**
WHO III/IV	17(65.4)	14(41.2)	0.063

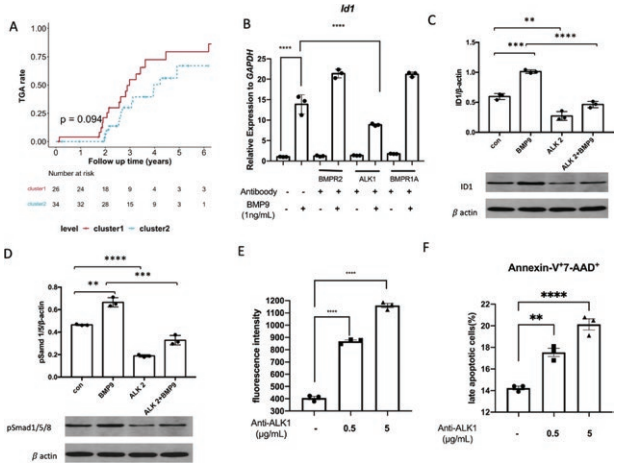

Figure 1. (A). Kaplan-Meier analysis of the prognosis of cluster1 and cluster2. (B) The level of Id1 expression under the induction of anti-BMPR2, anti-ALK1, and anti-BMPR1A antibodies in the presence or absence of BMP9. The ID1 (C) and p-Smad 1/5/8 (D) measured by western blotting under the induction of anti-ALK antibodies, BMP9, or anti-ALK antibodies+ BMP9. The fluorescence of the receiver plate well solution (E) and the percentage of late-stage apoptotic cells (E) under the induction of anti-ALK neutralizing antibodies.

Conclusion: The serum positivity of autoantibodies targeting BMP signaling has clinical potential in dividing SLE-PAH patients into two distinct clusters. The anti-ALK1 antibodies can downregulate BMP signaling and mediate great permeability and apoptosis in hPAECs, which may be involved in the pathogenesis of SLE-PAH.

OP0217

ANTI-RO52 ANTIBODIES ARE ASSOCIATED WITH HIGHER DISEASE SEVERITY IN PATIENTS WITH SJÖGREN DISEASE THROUGH ACTIVATION OF THE INTERFERON PATHWAY

Keywords: Autoantibodies, Sjögren syndrome, Prognostic factors

E. Bettacchioli[1,2], A. Saraux[2,3], A. Tison[2,3], D. Cornec[2,3], M. Dueymes[1,2], N. Foulquier[2], S. Hillion[1,2], A. M. Roguedas-Contios[4], A. A. Benyoussef[5], M. Alarcon-Riquelme[6], J. O. Pers[2], V. Devauchelle-Pensec[2,3]. *[1]CHU Brest, Laboratory of Immunology and Immunotherapy, Brest, France*; *[2]LBAI, UMR1227, Inserm, Brest, France*; *[3]CHRU Brest, Rheumatology Department, Brest, France*; *[4]CHRU Brest, Dermatology Department, Brest, France*; *[5]CHRU Brest, Ophthalmology Department, Brest, France*; *[6]Pfizer/University of Granada/ Andalusian Regional Government, GENYO, Centre for Genomics and Oncological Research, Granada, Spain*

Background: The diagnosis of primary Sjögren Disease (SjD) is currently based on a combination of clinical, histological and biological findings [1]. Current thinking supports anti-Ro60 antibodies as the most specific serum marker, while the impact of anti-Ro52 remains unclear [2].
Objectives: The aim of this study was to characterize the clinical, serological, biological, transcriptomic and interferon profiles of SjD patients according to their anti-Ro52 status and discuss the role of anti-Ro52 in the prognosis of SjD.
Methods: SjD patients were recruited from the European PRECISESADS (378 patients) [3] and the independant Brittany DIApSS cohorts (160 patients) [4]. Four groups were defined: double negative ($Ro52^-/Ro60^-$), isolated anti-Ro52 positive ($Ro52^+$), isolated anti-Ro60 positive ($Ro60^+$), and double positive ($Ro52^+/Ro60^+$) patients. Clinical information, disease activity, and biological markers linked to disease severity were evaluated. Transcriptome data on whole blood by RNAseq and Type I and type II interferon signatures [5,6] were analyzed for PRECISESADS SjD patients.
Results: In both cohorts, arthritis, parotidomegaly, and biological markers (hypergammaglobulinemia, rheumatoid factor and inflammation) [7] were significantly more frequent in the double positive group as compared to other groups. ESSDAI, a score representing systemic activity [8], was also significantly higher in double positive patients compared to the others. Transcriptome analysis demonstrated that anti-Ro52 positivity was associated with a strong interferon pathway activation as the lead cause to explain the clinical associations.
Conclusion: Taken together, these results suggest that SjD patients with anti-Ro52 positivity adopt a more severe phenotype as compared to their negative counterparts, independently of anti-Ro60 positivity.

Rheumatoid arthritis: new small molecules and old DMARDs

OP0218

INCIDENT MALIGNANCIES IN PATIENTS WITH RHEUMATOID ARTHRITIS IN DAILY RHEUMATOLOGICAL CARE

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Malignancy

M. Schaefer[1], Y. Meissner[1], B. Manger[2], S. Berger[3], K. Rockwitz[4], A. Regierer[1], A. Strangfeld[1,5]. [1]*German Rheumatism Research Centre Berlin, Epidemiology and Health Services Research, Berlin, Germany*; [2]*Universitätsklinikum Erlangen, Department of Medicine 3 – Rheumatology and Immunology, Erlangen, Germany*; [3]*Rheumatologist, Private Practice, Naunhof, Germany*; [4]*Rheumatologist, Private Practice, Goslar, Germany*; [5]*Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: Based on results of the post-authorisation safety trial Oral Surveillance (OS, see [1]), the European and US-American regulatory agencies in 2021 issued warnings about malignancy risk associated with the Janus kinase inhibitor (JAKi) tofacitinib and required changes in labelling.
Objectives: To analyse incident malignancies under treatment with JAKi, tumor necrosis factor inhibitors (TNFi), abatacept (ABA), rituximab (RTX), interleukin 6 inhibitors (IL6i) or conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs - bionaive) in patients with rheumatoid arthritis (RA) observed in daily rheumatological care.
Methods: Data from patients without cancer history from the biologics register RABBIT were included with treatment episodes started 01/2017 - 04/2022. Incidence rates (IR) of malignancies (without non melanoma skin cancer, NMSC) per 1000 patient-years (PY) with 95% confidence intervals (CI) and adjusted hazard ratios (HR) were calculated for all and selected patients according to OS inclusion criteria (age ≥ 50 years and ≥ 1 cardiovascular (CV) risk factor) to compare treatment groups to TNFi. Andersen-Gill regression analysis was used with a 6-month risk window, adjusted via stabilized and winsorized inverse probability of treatment weights taking into account age, sex, smoking, disease activity, prior therapies, comorbidities, and type of enrolling institution (clinic vs. private practice) as covariates. Multiple imputation of missing data was applied.
Results: 2763 JAKi, 3403 TNFi, 744 ABA, 834 RTX, 1125 IL6i and 1130 csDMARD initiations were documented. Patients with a JAKi start were less often men and (except RTX patients) slightly older and had a longer RA disease duration (Table 1). The seropositive proportion and the number of prior treatments with biological (b) or targeted (ts) synthetic DMARDs was higher than in TNFi and csDMARD groups, but lower than in ABA and RTX groups.

Table 1. Patient characteristics at the start of a DMARD episode.

*Values are given as mean or percentage. *Age ≥50 years and ≥ 1 CV risk factor (hypertension, coronary heart disease, diabetes, hyperlipoproteinaemia, current smoking)*

151 incident malignancies were reported. Across treatments, patients showed comparable IRs between 7 and 11 events per 1000 PY. Among selected patients IRs were higher (13.2 events per 1000 PY in JAKi patients, 95% CI: 9.5 – 17.9). In adjusted analyses, neither JAKi (HR 1.06, 95% CI: 0.70 - 1.61), ABA (HR 0.73, 0.38 - 1.40), RTX (HR 0.86, 0.42 - 1.75), IL6i (HR 0.79, 0.45 - 1.40) nor csDMARDs (HR 2.07, 0.87 - 4.94) showed a significantly altered risk for malignancies compared with TNFi in unselected patients, with similar results in selected patients.

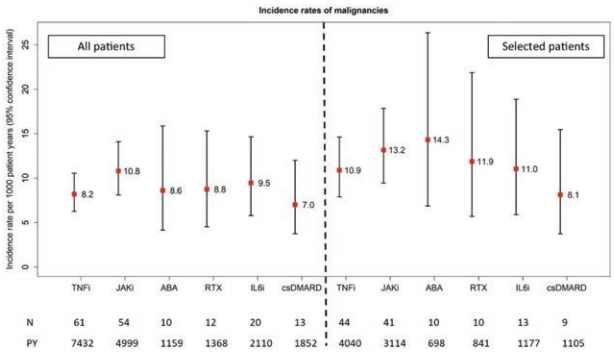

Figure 1. IRs of malignancies (without NMSC) per 1000 PY by treatment group

Conclusion: IR of malignancies in selected patients receiving JAKi in a real-world setting was numerically higher than reported for tofacitinib in OS. However, we found no statistical evidence of an increased malignancy risk with JAKi compared to TNFi, although patients on JAKi were older and had longer disease duration and more previous b/tsDMARDs treatments. Further analyses assessing exposure in terms of treatment duration are needed.

Background: Results of the "ORAL Surveillance" trial showed higher risk of major adverse cardiovascular (CV) events (MACE) for Janus kinase inhibitors (JAKi) than for TNF-inhibitors (TNFi). Currently, there is limited evidence of the real-world cardiovascular safety of JAKi.

Objectives: To assess the incidence of MACE in rheumatoid arthritis (RA) patients treated with JAKi, compared to other biologic agents in a large multi-country real-world population.

Methods: Patients from 14 RA registers from across Europe, Turkey and Québec (Canada), starting JAKi, TNF-inhibitors or bDMARDs with other modes of action (OMA), were included. MACE comprised strokes, myocardial infarctions and transient ischemic attacks and were attributed to a treatment up to 3 months after treatment cessation (except for rituximab for which it was 1 year), loss of follow-up, death or end of study. Incidence rates (IR) of MACE per 1000 patient-years (PY) with 95% confidence intervals (CI) were computed. Poisson regression, with propensity score weighting (including country, disease-, and patient-characteristics, and comorbidities, see Figure 1), was used to obtain adjusted incidence rate ratios (IRR), with 95% CI. A sub-analysis was performed on patients aged ≥ 50 years and ≥ 1 CV risk factor, mimicking the "ORAL Surveillance" trial inclusion criteria (RCT-duplicate cohort).

Results: Over the 50'325 treatment initiations considered (Table 1) in 34'932 patients with a mean follow-up of 2.8 years, 182 incident MACE were reported. Crude incidence was higher for OMA (2.63/1000 PY) than for JAKi (1.76/1000 PY) and TNFi (1.86/1000 PY). The adjusted Poisson regression demonstrated no significant difference in the incidence of MACE between JAKi vs TNFi (IRR = 0.87 (95% CI 0.56; 1.35)), and OMA vs TNFi (IRR = 1.05 (95% CI 0.74; 1.49)) (Figure 1). The RCT-duplicate cohort accounted for 38.4% of treatment courses and had a higher incidence of MACE in each treatment group (OMA: 3.75/1000 PY, JAKi: 2.65/1000 PY, TNFi: 3.48/1000 PY). Similarly to the overall population, no significant difference in the incidence of MACE was observed between JAKi vs TNFi (IRR = 0.78 (95% CI 0.44; 1.38)), and OMA vs TNFi (IRR = 0.84 (95% CI 0.53; 1.32)).

Figure 1: Adjusted Incidence Rate Ratios (IRR) of MACE, compared to TNFi

Propensity score includes: age, gender, disease duration, seropositivity, previous b/tsDMARD, concomitant GC, concomitant csDMARD, DAS28, HAQ, Rheumatic Disease Comorbidity Index

Table 1. Baseline characteristics

	JAKi (TOFA, BARI, UPA, FILGO) n = 12'715	OMA (RITU, TOCI, ABA, SARI) n = 16'048	TNFi (ETN, ADA, GOL, CTZ, IFX) n = 22'102
Treatment duration (median [IQR])	1.4 [0.5, 2.7]	1.3 [0.4, 2.7]	1.5 [0.6, 2.9]
Age (mean (SD))	58.0 (12.4)	59.5 (12.7)	56.5 (13.7)
Female (%)	81.4	79.2	78.4
Disease duration (median [IQR])	11.4 [5.7, 19.0]	12.4 [6.3, 20.7]	9.2 [4.1, 17.0]
Seropositivity (%)	80.5	81.0	75.1
Previous b/ts DMARD (%)			
0	23.3	19.5	44.1
1	22.3	24.8	26.5
2	17.9	21.7	15.5
≥ 3	36.6	33.9	13.9
Concomitant csDMARD (%)			
MTX	22.4	22.4	23.9

other	15.3	18.0	17.7
none	53.0	52.0	44.5
Concomitant GC (%)	44.7	39.8	32.4
CRP (mg/L) (mean (SD))	12.4 (23.2)	13.9 (29.0)	12.5 (23.3)
CDAI (mean (SD))	25.4 (13.9)	22.8 (13.9)	24.7 (13.9)
DAS 28 (mean (SD))	4.7 (1.6)	4.2 (1.7)	4.5 (1.7)
HAQ (mean (SD))	1.2 (0.7)	1.2 (0.8)	1.1 (0.7)
BMI (mean (SD))	27.2 (5.9)	27.3 (5.9)	27.4 (6.3)
Patients with at least one CV risk factor* (%)	54.9	56.6	54.1

csDMARDs = conventional synthetic DMARDs, MTX = methotrexate, GC = glucocorticoids, CRP = C-reactive protein, CDAI = Clinical Disease Activity Index, DAS 28 = Disease Activity Score 28, HAQ = Health Assessment Questionnaire, BMI = Body Mass Index. *Hypertension, hyperlipidaemia, diabetes, smoking, past history of strokes or myocardial infarctions

Conclusion: In this real-world study, including 14 RA registers and all currently available JAKi in the respective countries, we did not find a significantly higher risk of MACE in RA patients treated with JAKi compared to TNFi. Inclusion of other registers to increase the statistical power and the evaluation of other adverse events such as thromboembolic events, cancers and serious infections are planned.

OP0220 INITIAL GLUCOCORTICOID BRIDGING IN RHEUMATOID ARTHRITIS: DOES IT AFFECT GLUCOCORTICOID USE OVER TIME?

Keywords: Clinical Trials, Rheumatoid arthritis, Tapering

L. Van Ouwerkerk[1], P. Verschueren[2], M. Boers[3], P. Emery[4], P. De Jong[5], R. B. M. Landewé[6], W. Lems[3], J. Smolen[7], T. Huizinga[1], C. Allaart[1], S. A. Bergstra[1].

Background: Glucocorticoid (GC) 'bridging' therapy as temporary part of the initial treatment in rheumatoid arthritis (RA) helps to rapidly suppress disease activity. It has been proposed that patients treated with GC bridging (bridgers) may continue to use more GC later in the disease course than patients who did not receive GC bridging (non-bridgers).
Objectives: To compare GC use over time between RA patients in clinical trials randomized to treatment with or without initial GC bridging.
Methods: Data were available from the BeSt, CareRA and COBRA trials, which included study arms with and without initial GC bridging in addition to csDMARD treatment. GC bridging schedules were planned for a minimal duration of 34 (CareRA), 35 (COBRA) and 36 (BeSt) weeks (Table 1). In an individual patient data (IPD) meta-analysis we compared GC use between bridgers and non-bridgers at 12, 18 and 24 months from baseline as primary outcome. Secondary outcomes were the mean cumulative GC dose until 24 months after baseline with and without the bridging period, number of (study defined) flares (DAS28 increase >1.2 or ΔDAS28 >0.6 and ≥3.2 at previous visit), number of DMARD changes (adding a DMARD or switching between DMARDs) and DAS28 over time. We used mixed effects regression analyses including study arm as random effect. To investigate DAS28 over time, an interaction term between treatment group (whether or not started with GC bridging) and time (as categorical variable) was included.
Results: 252/625 patients (40%) were randomized to GC bridging. Baseline characteristics were comparable between bridgers and non-bridgers. Mean DAS28 improved more rapidly in bridgers in the first 6 months (p<0.01, Figure 1A), but the decrease was similar in both groups thereafter. After the planned end of bridging, GC use was low in both groups (Figure 1B). Only at t=12 months, significantly more bridgers than non-bridgers still or again used GC (OR 3.27 (95% CI 1.06; 10.08)). Disregarding the initial bridging schedules there was no difference between the two groups in cumulative dose, 365 mg (95%CI -62; 793), but the cumulative GC dose including the planned bridging schedules was significantly higher for the bridgers (2889 mg (95% CI 1812; 3967), this can be translated to a difference of 4mg a day for 2 years). The incidence rate ratio (IRR) for (study defined) flares was similar between the groups (IRR 1.14 (95%CI 0.86; 1.50), but the IRR for number of DMARD changes was significantly lower in the bridgers (IRR 0.59 (95%CI 0.38; 0.94)).
Conclusion: After GC bridging therapy (on average 35 weeks), bridgers had an increased risk of using GC at 12 months from baseline compared to non-bridgers, but not thereafter. The bridging schedule determined the cumulative GC dose over time, which after the bridging period was similar in bridgers and non-bridgers. After the end of bridging schedules there were no differences in mean DAS28, number of flares (by study definition) or post-bridging cumulative GC dose, but bridgers had a more rapid decrease of DAS28 in the first 6 months (during bridging schedule) and fewer DMARD changes over time.

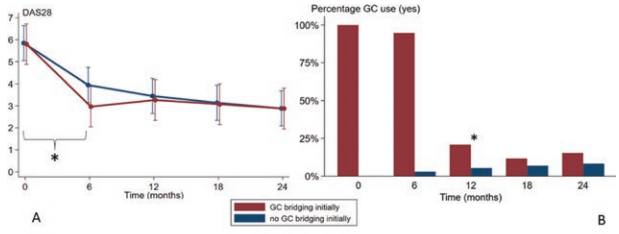

Figure 1. A) Mean DAS28 over time, estimated over 24 months with linear mixed models. Predictive margins are depicted with 95% confidence intervals (CI) as error bars. B) GC use over time for the group that started with GC bridging initially (red) and the group that did not (blue). An asterisk (*) indicates a significant result from the mixed effects regression analyses performed for 12, 18 and 24 months.

Table 1. Overview of the included study arms

	BeSt	COBRA	CareRA
Study arms with GC bridging	*Arm 3 Initial combination therapy*	*Combined treatment arm*	*Low risk group COBRA slim arm*
Initial GC dose	*60mg/day (prednisone) In 7 weeks to 7.5mg/day*	*60mg/day (prednisone)*	*30mg/day (prednisone)*
Tapering to maintenance	*From week 28-36 tapered to zero if DAS≤2.4 for at least 6 months*	*In 6 weeks to 7.5mg/day. From week 29-35 tapered to zero; resume on flare*	*In 5 weeks to 5mg/day From week 28-34 tapered to zero if DAS28(CRP)≤3.2*
Planned end			
DMARD	*MTX 7.5mg/week, increased to 25mg/week if DAS>2.4 after 3 months SSZ 2000mg/day*	*MTX 7.5 mg/week and MTX 15mg/week SSZ 2000mg/day; From week 40-43 MTX tapered to zero; resume on flare*	
Study arms without GC bridging	*Arm 1: Sequential monotherapy; Arm 2: Step up combination therapy: MTX 15mg/week (increased to 25 mg/week if DAS>2.4 after 3 months)*	*Monotherapy arm SSZ 2000 mg/day*	*Low risk group, MTX tight step up arm MTX 15 mg/week*

OP0221 THERAPY WITH JAK INHIBITORS AND THE RISK OF CARDIOVASCULAR EVENTS IN A DUTCH RHEUMATOID ARTHRITIS POPULATION

Keywords: Rheumatoid arthritis, Cardiovascular disease, Targeted synthetic drugs

C. Popa[1,2], M. Opdam[1], N. Den Broeder[1], M. Wientjes[1], A. Den Broeder[1,2].
[1]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands; *[2]Radboudumc, Rheumatology, Nijmegen, Netherlands*

Background: Most of the disease modifying anti-rheumatic drugs (DMARDs) have cardioprotective potential and using them to achieve remission and/or low disease activity in rheumatoid arthritis (RA) importantly diminishes the cardiovascular risk in these patients. Yet for some of these drugs, including JAK-inhibitors, the modulatory effect on cardiovascular risk seems less straightforward [1]. Caution has been advocated recently when using Janus kinase inhibitors (JAKi) in patients with an unfavorable cardiovascular risk profile [2]. For patients who are about to switch medication the decision of giving JAKi can easily be postponed, however for patients in remission while using JAKi the decision to continue or not is much complex and difficult. Therefore, more research into this issue is warranted in order to better guide clinicians in their daily practice.

Objectives: The aim of this study was to investigate the occurrence of cardiovascular events in a large population of RA patients treated with either JAK-inhibitors or other (b)DMARDs, using real-world data.
Methods: Adult RA patients (extrapolated from drug based algorithms), starting a new bDMARD or JAK-inhibitor between August 1st 2017 and January 31st 2022, have been selected from IQVIA's Dutch Real-World Data Longitudinal Prescription database, covering about 63% of outpatient prescriptions in the Netherlands. Study outcome is cardiovascular (CV) event defined as the start of platelet aggregation inhibitors (clopidogrel, prasugrel, ticagrelor, dipyridamol) during study period. The risk of cardiovascular events was estimated using multilevel Poisson regression, adjusted for exposition time and confounders.
Results: In total, 15.191 unique patients were included, with 20.912 treatment episodes with either JAKi (2.090, almost exclusively tofacitinib and baricitinib) or bDMARDs (18.822). Most patients were female (72%) and median age was 62 years. We found a total of 681 CV events occurring during the study period: 48 (2.0 events/100 patient years) during therapy with JAKi and 633 (2.42 events/100 patient years) during therapy with bDMARDs, respectively, resulting in an adjusted incidence risk ratio (IRR) of 0.78 for JAKi compared to bDMARDs (95% confidence interval (CI), 0.56 – 1.10) (Table 1). Subanalysis in patients using either tofacitinib or baricitinib yielded similar results (Table 1). Likewise, RA patients older than 65 years did not have a higher risk for CVD during the therapy with JAKi as compared to those treated with bDMARDs: adjusted IRR 0.78 (95% CI, 0.51 – 1.19).
Conclusion: In the Dutch RA population, the incidence of cardiovascular events in JAKi starters was not higher than in bDMARDs starters, and similar for tofacitinib and baricitinib. These data will further contribute to estimation of the cardiovascular safety of JAKi.

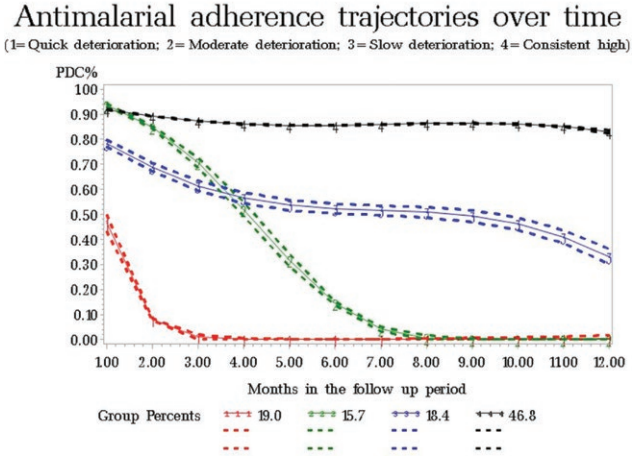
OP0222

TRAJECTORIES OF ANTIMALARIAL ADHERENCE AMONG NEWLY DIAGNOSED RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: A POPULATION-BASED COHORT STUDY

Keywords: Systemic lupus erythematosus, Rheumatoid arthritis, Disease-modifying drugs (DMARDs)



M. R. Hoque[1,2], J. A. Aviña-Zubieta[2,3], D. Lacaille[2,3], M. De Vera[2,4], Y. Qian[5], L. Mccandless[5], J. Esdaile[2,3], H. Xie[1,2]. *[1]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada*; *[2]Arthritis Research Canada, Arthritis Research Canada, Vancouver, Canada*; *[3]The University of British Columbia, Division of Rheumatology, Department of Medicine, Vancouver, Canada*; *[4]The University of British Columbia, Faculty of Pharmaceutical Sciences, Vancouver, Canada*; *[5]The University of British Columbia, Sauder School of Business, Vancouver, Canada*

Background: Adherence to antimalarial regimens are suboptimal in rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) patients. Also, adherence is dynamic in nature, and varies over the time. Computing a single adherence level over a period may not explain the adherence trajectories of antimalarial in RA and SLE patients over time.
Objectives: To identify the groups of patients with similar patterns or trajectories of antimalarial adherence over time and evaluate the baseline determinants of the group membership of adherence trajectories.
Methods: All patients with incident RA/SLE and incident antimalarial use in British Columbia, Canada, between January 1997 and March 2021, were identified using previously published definitions and administrative health data. Patients were followed up for 12 months from the index date, the time when subjects met RA/SLE criteria and were on antimalarials. We calculated a measure of adherence, the proportion of days covered (PDC) for all patients each month. Then, we used group-based trajectory model (GBTM) analysis on monthly PDC values to identify the latent groups of antimalarial adherence trajectories. The number of groups was selected using the AIC and minimum percentage criterion. Finally, we used an ordered logistic regression to evaluate the baseline determinants of the group membership of adherence trajectories. Baseline determinants of adherence for assessment included sociodemographic factors (neighborhood income quartile, region, age, sex), disease-related factors (disease type (RA vs. SLE), disease duration at index date, hypertension, angina, COPD, modified Charlson comorbidity index), healthcare system factors (hospital visits, physician and specialist visits), and medication use factors (glucocorticoids, immunosuppressives, biologics, Cox-2 selective NSAIDs).
Results: We identified 27,510 patients with incident antimalarial use (23,997 RA and 3,513 SLE patients, mean ± SD age 56.8 ± 15.5 years, 74.8% female). Using GBTM analysis, we identified four groups for antimalarial medication adherence trajectories, representing an ordered pattern of antimalarial adherence from worse to better. Those trajectory groups were - Group 1: quick deterioration (19%), Group 2: moderate deterioration (15.7%), Group 3: slow deterioration (18.4%), and Group 4: consistent high adherence (46.8%) (Figure 1). Significant determinants of the group membership of adherence trajectories from the ordinal logistic regression model are shown in Table 1. The odds of better adherence were higher for those who, at baseline, were older, had higher income, had SLE compared with RA, had hypertension, had rheumatologist visits, and used glucocorticoids, immunosuppressives or Cox-2 selective NSAIDs.

Table 1. Determinants of belonging into better adherence trajectory groups: results from an ordinal logistic regression model including only significant factors.

Factors	Adjusted odds ratio (95% CI)
Age	1.009 (1.008-1.011)
Neighborhood income quartile (Ref: 3)	
1	0.914 (0.854-0.978)
2	0.963 (0.899-1.032)
4	1.075 (1.002-1.153)
5	1.041 (0.969-1.117)
SLE vs RA	1.551 (1.444-1.665)
Have hypertension	1.068 (1.002-1.138)
Have angina	0.878 (0.776-0.995)
Have COPD	0.861 (0.761-0.975)
Rheumatologist visits	1.035 (1.022-1.048)
Glucocorticoids use	1.082 (1.033-1.134)
Immunosuppressives use	1.177 (1.117-1.239)
Cox-2 selective NSAIDs use	1.080 (1.017-1.147)
Biologics use	0.559 (0.426-0.734)

Figure 1: Antimalarial adherence trajectory groups from group-based trajectory model analysis

Conclusion: Among incident RA/SLE incident antimalarial users from a population-based cohort, 53.2% did not continuously adhere to the antimalarial regimen in the first year of treatment. We identified four distinct antimalarial adherence trajectory groups in this study. Sociodemographic, disease-related, healthcare system, and medication use factors associated with better adherence trajectories could help inform strategies to improve antimalarial adherence among RA and SLE patients.

Background: Antimalarials (AM) have been related to a lower risk and severity of infections in systemic lupus erythematosus [1], but in rheumatoid arthritis (RA) the results are not unanimously favorable to a possible protective effect exerted by AM [2,3]. In our recent study of RA patients treated with biologic disease modifying anti-rheumatic drugs (bDMARDs) or JAK inhibitors (JAKi), a secondary analysis suggested lower risk of total (25% reduction) and serious infections (47% reduction) with concomitant use of AM [4].
Objectives: To evaluate the association of the use of AM with the risk of total and serious bacterial, viral, fungal and system-specific infections in RA patients treated with conventional synthetic DMARDs (csDMARDs) and/or bDMARDs/JAKi.
Methods: BiobadaBrasil is a multicentric registry-based cohort study of Brazilian patients with rheumatic diseases starting a new csDMARD or their first bDMARD or JAKi [5]. The present analysis includes RA patients recruited from Jan 2009 to Oct 2019, followed-up over one or multiple (up to six) courses of treatment (latest date, Nov 19, 2019) with csDMARDs and/or bDMARDs/JAKi. A treatment course is defined as a period during which the medication scheme of does not change, except for dose adjustments. The primary outcome was the incidence of total infections (SIs) caused by bacteria, viruses and fungi (analyzed separately). The microbiologic etiologic agent was defined by cultural exam or, alternatively, high clinical suspicion, but not all infection had a clearly defined etiology (these ones were excluded from the analysis by etiologic agent). Serious infections according to type of microorganism and system-specific infections served as secondary outcomes. Negative binomial regression with generalized estimating equations (to calculate the incidence rate ratios [ÌRRs]) and extended (frailty) multivariate Cox proportional hazards models were used for statistical analyses (both types of analyses including time- fixed and time-varying covariates over multiple courses of treatment to adjust for confounding).
Results: In total, 1671 patients (2891 treatment courses, 8944.1 patient-years [PY]; most treatment courses [in total, 2335] including bDMARDs or JAKi) were enrolled. AM were used over 512 courses (2036.8 PY) of therapy. The overall incidence of infections caused by bacteria, fungi and viruses were 10.2, 1.9, 1.0/100 PY, respectively. The mIRRs for the primary and secondary outcomes are presented in the Figure 1. There were statistically significant reductions in the risk of serious and non-serious bacterial infections, as wells as serious lower respiratory tract infections, digestive tract infections and those affecting skin or mucosae. These effects were observed regardless of concomitant use or not of bDMARDs/JAKi or methotrexate by the patients.

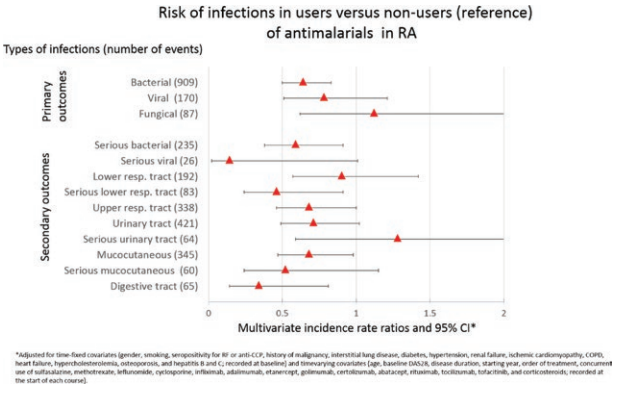

Figure 1.

Conclusion: Among RA patients followed-up in our cohort study, the use of antimalarials was associated with reduction in the risk of bacterial infections, especially serious ones, and there was protection against infections affecting the respiratory and digestive systems and skin/mucosae.

Background: We have previously showed that exposure to methotrexate (MTX) was not associated with sperm quality abnormalities or with sperm DNA damage [1]. Nonetheless, a question that remains unanswered is whether MTX and its bioactive forms, the MTX-polyglutamates (MTX-PGs) can be found in spermatozoa. The intracellular conversion of MTX to MTX-PGs is dependent on a process that is catalyzed by the enzyme folylpolyglutamate synthetase (FPGS). Lower FPGS activity and subsequent inefficient polyglutamylation is well-known phenomenon associated with a rapid efflux of MTX from cells [2]. In this regard, recent studies have showed that a significant reduction of FPGS activity is associated with aberrant pre-mRNA splicing of this enzyme, including partial retention of intron 8 (8PR) and a higher ratio of FPGS 8PR over FPGS wild type (WT) [3]. Whether intracellular MTX and the bioactive MTX-PGs can be detected in the spermatozoa and whether spermatozoa have the enzymatic capabilities (FGPS-activity) for the formation of the MTX-PGs has never been studied before.
Objectives: To evaluate if MTX-PGs can be detected in spermatozoa of men exposed to MTX and to evaluate the FPGS enzymatic activity in spermatozoa. Furthermore, MTX-PGs concentration and FPGS activity in spermatozoa will be compared with those present in red blood cells (RBCs) and peripheral blood mononuclear cells (PBMCs).
Methods: This proof of concept translational study was part of the iFAME-MTX study [1]. Blood and semen samples were obtained from 10 adult men diagnosed with an immune-mediated disease (RA, SpA, psoriasis) after 13 weeks of exposure to MTX (cases) and from 4 adult healthy men (controls). Measurement of MTX-PGs in spermatozoa and RBCs was determined by LC-MS/MS methods [4] using stable isotope labelled MTX-PGs_{1-6} as internal standards. FPGS catalytic activity in spermatozoa, RBCs and PBMCs was analyzed in 10 µg protein extracts [3]. Lastly, RNA was isolated from spermatozoa and PBMCs quantitative real-time PCR were performed to quantify the mRNA expression profiles of folate genes in spermatozoa, in particular FPGS 8PR/WT [3]. Continuous variables were compared using a Mann-Whitney test.
Results: MTX-PG_1 was the predominant form of MTX-PGs detected in spermatozoa. Other MTX-PGs forms (MTX-PG_{2-5}) were not or hardly detectable in spermatozoa after MTX exposure (Figure 1A). Furthermore, comparisons with other cell types revealed that MTX-PGs accumulation in spermatozoa is markedly lower than in RBCs and PBMCs (Figure 1B). Consistent with the lack of MTX-PGs formation, FPGS catalytic activity (reported as pmol 15N-MTX-PG2 formed/h/mg protein) in spermatozoa was statistically significant lower (5.1) compared to PBMCs (183, p=<0.005)). Regarding, mRNA expression profiles of folate genes in spermatozoa, a high FPGS 8PR/WT ratio was observed compared to PBMCs.
Conclusion: This is the first study ever conducted to measure the concentration of MTX-PGs and concomitant FPGS activity in spermatozoa. Hardly any bioactive forms of MTX (MTX-PG) could be detected in spermatozoa. This is related to the fact that spermatozoa have very low FPGS activity and hence

lack the capacity to form MTX-PGs. Mechanistically, the low FPGS activity in spermatozoa is likely associated with a higher ratio of mRNA expression of an alternatively spliced form of the FPGS gene (8PR) over the WT transcript. These results support and clarify our previous findings that treatment with MTX does not affect sperm quality parameters and provides further evidence that MTX can be safely used in men with a wish to become a father.

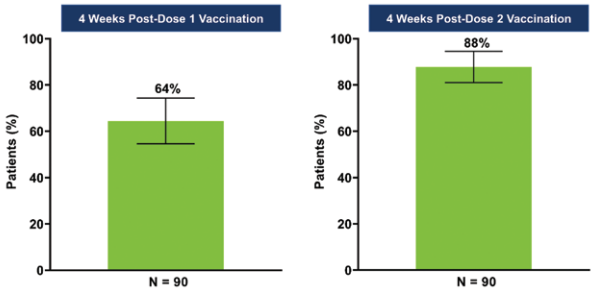
Background: Upadacitinib (UPA) is an oral JAK inhibitor (JAKi) approved for the treatment of RA. JAKi have been associated with an elevated risk of herpes zoster (HZ) in patients (pts) with RA. The adjuvanted recombinant zoster vaccine (RZV, Shingrix) was shown to be well-tolerated and effective in preventing HZ in adults aged ≥ 50 years.[1] The efficacy and safety of RZV have not been studied in pts with RA while on UPA in combination with MTX.

Objectives: To assess the immunogenicity of RZV in pts with RA receiving UPA 15 mg once daily (QD) with background MTX.

Methods: Eligible adults aged ≥ 50 years with RA enrolled in the ongoing SELECT-COMPARE phase 3 trial (NCT02629159) received two RZV doses, administered at the baseline and week (wk) 12 visits. Pts should have been on stable doses of UPA 15 mg QD and background MTX for ≥ 8 wks before the first vaccination and ≥ 4 wks after the second vaccination. Antibody titers were collected pre-vaccination (baseline), 4 wks post-dose 1 vaccination (wk 4), and 4 wks post-dose 2 vaccination (wk 16). The primary endpoint was the proportion of pts with a humoral response to RZV defined as ≥ 4-fold increase in pre-vaccination concentration of anti-glycoprotein E [gE] titer levels at wk 16. Secondary endpoints included humoral response to RZV at wk 4 and the geometric mean fold rise (GMFR) in anti-gE antibody levels at wks 4 and 16. Cell-mediated immunogenicity to RZV was an exploratory endpoint evaluated by the frequencies of gE-specific CD4+ [2+] T cells (CD4+ T cells expressing ≥ 2 of 4 activation markers: IFN-γ, IL-2, TNF-α, and CD40 ligand) measured by flow cytometry at wks 4 and 16 in a sub-cohort of pts.



Results: Of the 95 pts who received ≥ 1 RZV dose, 93 (98%) received both RZV doses. Pts had a mean (standard deviation) age of 62.4 (7.5) years. The median (range) disease duration was 11.7 (4.9–41.6) years and duration of UPA exposure was 3.9 (2.9–5.8) years. At baseline, all but 2 pts were receiving concomitant MTX and half (50%) were taking an oral corticosteroid (CS) at a median daily dose of 5.0 mg. One pt discontinued UPA by wk 16. Blood samples were available from 90/93 pts. Satisfactory humoral responses to RZV occurred in 64% (95% confidence interval [CI]: 55–74) of pts at wk 4 and 88% (81–95) at wk 16 (**Figure 1**). Age (50–< 65 years: 85% [95% CI: 75–94]; ≥ 65 years: 94% [85–100]) and concomitant CS (yes: 87% [77–97]; no: 89% [80–98]) use at baseline did not affect humoral responses at wk 16. GMFR in anti-gE antibody levels compared with baseline values were observed at wks 4 (10.2 [95% CI: 7.3–14.3]) and 16 (22.6 [15.9–32.2]). Among the sub-cohort of pts, nearly two-thirds achieved a cell-mediated immune response to RZV (wk 4: n = 21/34, 62% [95% CI: 45–78]; wk 16: n = 25/38; 66% [51–81]). Within 30 days post-vaccination of either RZV dose, no serious adverse events (AEs) (**Table 1**) or HZ were reported. AEs that were possibly related to RZV were reported in 17% of pts. One death occurred more than 30 days after wk 16 due to COVID-19 pneumonia.

Conclusion: More than three-quarters (88%) of pts with RA receiving UPA 15 mg QD on background MTX achieved a satisfactory humoral response to RZV at wk 16. In a subgroup of pts, two-thirds (66%) achieved a cell-mediated immune response to RZV at wk 16. Age and concomitant CS use did not negatively affect RZV response.

Figure. Proportion of Patients Treated With UPA 15 mg QD and Background MTX Achieving a Humoral Response to RZV 4 Weeks Post-Dose 1 and Post-Dose 2 Vaccination

CI, confidence interval; QD, once daily; RZV, adjuvanted recombinant zoster vaccine; UPA, upadacitinib.
Error bars indicate 95% CI. Number of patients (N = 90) was based on the availability of blood samples collected at the baseline and study visits.
Humoral response to RZV was defined as a ≥ 4-fold increase in pre-vaccination concentration of anti-glycoprotein E titer levels at week 16.

Table 1 . Safety Results Through 30-Days Post-RZV Vaccination in UPA-Treated Patients

Event, n (%)	UPA 15 mg QD (N = 95)
Any AE	38 (40%)
AE with reasonable possibility of being related to UPA[a]	13 (14%)
AE with reasonable possibility of being related to RZV[a]	16 (17%)
Severe AE[b]	1 (1%)
Serious AE	0
AE leading to discontinuation of UPA	0
Death	0

AE, adverse event; QD, once daily; RZV, adjuvanted recombinant zoster vaccine; UPA, upadacitinib. [a]As assessed by the investigator. [b]Hypersensitivity.

Background: The lupus low disease activity state (LLDAS) treat-to-target definition sets a ceiling for acceptable disease and treatment burden in SLE. Definition of Remission in SLE (DORIS) is a more stringent state, but as it is concentric with LLDAS many patients in LLDAS also meet the DORIS remission definition. Studies in cohorts with a majority of patients in remission poorly separate LLDAS and remission, leading to debate about the independent effects of LLDAS on SLE outcomes.

Objectives: We examined whether being in LLDAS but not remission provided protection against adverse outcomes of flare, irreversible organ damage accrual and mortality in patients with SLE.

Methods: Data from a 13-country longitudinal SLE cohort (ACR/SLICC criteria), collected prospectively between 2013 and 2020, were analysed. Organ damage and flare were captured using SLICC Damage Index and SELENA-SLEDAI Flare Index, respectively. LLDAS was defined as Golder *et al.*, 2019 [1] (SLEDAI<4, no new activity, PGA <1, prednisolone (PNL) <7.5 mg/d, antimalarials (AM) and immunosuppressants (IS) allowed). Remission was defined as Vollenhoven *et al*, 2021 [2] (clinical SLEDAI=0, PGA <0.5, PNL<5 mg/d, AM/IS allowed).

Results: 3,811 patients with ≥ 2 visits followed over a median of 2.8 years [IQR: 1.0 to 5.3] were studied. 80 (2.1%) patients died; 717 (21%) accrued organ damage, and 2,142 (56%) experienced mild-moderate or severe flare during the study period. 55% (n=2,099) attained LLDAS but not remission (LLDAS+REM-) at least once, with a median (IQR) cumulative percent-time spent in LLDAS+REM- of 21.5% [9.8, 42.9]. Overall, 63% attained both LLDAS and remission (LLDAS+REM+) with median (IQR) cumulative time 45% [22, 71]; 18% attained LLDAS+REM-., and 19% of patients never attained LLDAS or REM. Compared to patients who never attained LLDAS or remission (LLDAS-REM-), LLDAS+REM- attainment at any time during the study observation period provided significant protection against subsequent flare and damage accrual, and protection against mortality with borderline statistical significance, after adjusting for potential confounding factors (Table 1). Similarly, ≥50% of cumulative observed time in LLDAS+REM- provided significant protection against flare and damage accrual but not mortality, possibly due to lack of power (Table 1). Protective effects of LLDAS+REM+ were also confirmed.

Table 1. Longitudinal associations of LLDAS+REM- attainment with flare, organ damage accrual and mortality

	Flare$_t$	Damage accrual$_t$	Mortality$_t$
	HR1 (95%CI) p-value	*HR2 (95%CI) p-value*	*HR3 (95%CI) p-value*
Not in LLDAS or REM$_{t-1}$	1.00	1.00	1.00
LLDAS+REM-$_{t-1}$	0.66 (0.60, 073) p<0.0001	0.63 (0.52, 0.77) p<0.0001	0.14 (0.02, 1.07) p=0.059
LLDAS+REM+$_{t-1}$	0.57 (0.52, 0.61) p<0.0001	0.46 (0.39, 0.54) p<0.0001	0.22 (0.08, 0.65) P=0.006
<50%T in LLDAS+REM-$_{t-1}$	1.00	1.00	1.00
≥50%T in LLDAS+REM-$_{t-1}$	0.71 (0.62, 0.81) p<0.0001	0.72 (0.56, 0.92) p=0.010	0.39 (0.14, 1.10) p=0.08
<50%T in LLDAS+REM+$_{t-1}$	1.00	1.00	1.00
≥50%T in LLDAS+REM+$_{t-1}$	0.62 (0.56, 0.67) P<0.0001	0.64 (0.53, 0.76) P<0.0001	0.53 (0.19, 1.43) p=0.21

Hazard ratios adjusted for [1]age and national gross domestic product (GDP); [2]age, GDP and baseline organ damage, and [3]GDP and SDI score. T=time.

Conclusion: Attainment of LLDAS provides significant protection against flare and organ damage accrual even when excluding patients who are also meet the definition of remission. LLDAS is an independent predictor of improved outcomes in SLE.

OP0227 IMPROVEMENTS AND CHALLENGES OF SYSTEMIC LUPUS ERYTHEMATOSUS ASSOCIATED PULMONARY ARTERIAL HYPERTENSION: A 10-YEAR MULTICENTER COHORT STUDY

Keywords: Systemic lupus erythematosus, Cardiovascular disease, Treat to target

X. Dong[1], J. Qian[1], J. L. Zhao[1], Q. Wang[1], M. LI[1], X. Zeng[1]. [1]*Peking Union Medical College Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Previous studies have described improved survival in systemic sclerosis (SSc) associated pulmonary arterial hypertension (PAH)[1-2], yet it is unclear whether survival of systemic lupus erythematosus (SLE) associated PAH has also improved.
Objectives: To describe the CSTAR prospective cohort of SLE-PAH patients, explore changes in characteristics, treatment and 5-year survival in the last decade, and possible reasons for survival change.
Methods: A multicenter prospective cohort of SLE-PAH was established, and divided into cohort A (2011.6-2016.5) and cohort B (2016.6-2021.5) according to the date of their baseline right heart catheterization (RHC). Another singlecenter cohort of idiopathic pulmonary arterial hypertension (IPAH) was consecutively recruited as control to describe the baseline characteristic and survival of SLE-PAH patients simultaneously. Disease characteristics, treatment regimen, and all-cause mortality were compared between cohort A and cohort B. Multi-variable cox regression was used to analyze association between treatment goal achievement and survival.
Results: A total of 610 SLE-PAH and 104 IPAH patients were enrolled. Overall, SLE-PAH patients were younger, predominantly female, had lower NT-proBNP level, better function status, better hemodynamic, and higher 5-year survival than IPAH (81.2% vs 56.0%, p<0.001). Compared with cohort A, patients in cohort B showed lower mPAP and PVR, higher CI, and were more likely to receive intensive immunosuppressants and PAH-targeted medication. 5-year survival rate was also higher in cohort B (88.1% vs 72.9%, p=0.01). In multivariable Cox regression, treatment goal achievement of PAH (HR 0.31, 95%CI 0.12-0.81, p=0.017) and reaching lupus low disease activity state (LLDAS) (HR 0.23, 95%CI 0.08-0.67, p=0.007) were both independently associated with a lower mortality.
Conclusion: This is the largest muticenter prospective SLE-PAH cohort to describe disease characteristics and prognosis. This study showed that survival has improved significantly for SLE-PAH. Early detection of PAH in SLE patients, achieving PAH treatment goal as well as LLDAS for SLE contributed to survival improvement.

OP0228 COEXISTING TUBULOINTERSTITIAL INFLAMMATION AND DAMAGE IS A RISK FACTOR FOR CHRONIC KIDNEY DISEASE IN PATIENTS WITH LUPUS NEPHRITIS: RESULTS FROM THE KORNET REGISTRY

Keywords: Systemic lupus erythematosus

D. J. Park[1], S. E. Choi[1], J. H. Kang[1], S. S. Lee[1]. [1]*Chonnam National University Medical School and Hospital, Rheumatology, Gwangju, Korea, Rep. of (South Korea)*

Background: An increasing body of evidence suggests a prognostic role of tubulointerstitial lesions in patients with lupus nephritis (LN). Although persistent tubulointerstitial inflammation (TII) usually precedes tubulointerstitial damage (TID) in LN, the two conditions can be simultaneously present to varying degrees.
Objectives: We examined whether coexisting TII/TID predicts progression to chronic kidney disease (CKD) in LN patients.
Methods: The 175 LN patients enrolled in the study had clinical data obtained at the time of renal biopsy and stored in the KORNET registry. These patients were divided into two groups: those with and without coexisting TII/TID. The two groups were compared with respect to their demographic, clinical, histological, laboratory findings, and long-term prognosis. Uni- and multivariable Cox proportional hazard regression models were used to identify independent risk factors for CKD in LN patients.
Results: Of the 175 LN patients, 110 (62.9%) had coexisting TII/TID and 65 (37.1%) did not. Patients with coexisting TII/TID were older, had higher ESR and 24 h proteinuria, and lower eGFR and hemoglobin levels than those without coexisting TII/TID. Anti-Ro and ribosomal-P antibodies were detected less frequently in patients with coexisting TII/TID. In a histological analysis, patients with coexisting TII/TID more often had LN of the proliferative type and a larger proportion had a chronicity score > 4. During a mean follow-up of 89.9 months, CKD and ESRD developed more frequently in patients with than without coexisting TII/TID. Finally, the coexisting TII/TID was associated with a higher risk for CKD progression: adjusted hazard ratio (HR) = 2.677, 95% confidence interval (CI) (1.333, 5.335), p = 0.006 for all LN patients; HR = 3.265, 95% CI (1.451,7.345) for those with class III, IV and V LN; HR = 3.045, 95% CI (1.289, 7.195) for those with class III, IV, V LN, and eGFR ≥ 30 mL/min/1.73 m^2.
Conclusion: LN patients with coexisting TII/TID are at greater risk for deterioration of kidney function at LN onset and for developing CKD over the long-term.

Background: The mortality in Systemic Lupus Erythematosus (SLE) varies largely across different countries most probably due to social, healthcare and ethnic differences. The contemporary cohorts continue to show higher mortality rates in SLE patients as compared with the general population [1,2]. We need to identify demographic, clinical and serological predictors of mortality in SLE in our country, to improve the prognosis of SLE patients.
Objectives: To analyze the causes and identify predictive factors of mortality of SLE, and to assess the time evolution and chronological changes in Spain.
Methods: We performed a cross-sectional and retrospective study analyzing data from the RELESSER cohort (Spanish Registry of SLE of the Spanish Society of Rheumatology). Sociodemographic, clinical and serological variables, comorbidities and treatments, as well as indicators of disease activity, damage and severity were recorded. We excluded patients with lost information about the death variable and analyzed the differential features of deceased patients in comparisons with survivors through different time stages according to the date of diagnosis: until the 1980's; the 1990's and the first decade of the 21st century. Variables associated with mortality in univariate analysis were entered into different multivariate models to determine which ones were independently associated with the outcome of the disease in each decade.
Results: A total of 3665 patients were included, mostly caucasian female with similar general features regardless of the different time stages analyzed. The 18.4% until the 1980´s, the 5.97% in the 1990´s and up to 2.84% of the individuals in the first decade of the 21st century, had died. The main age of death was similar in the different groups, around 55-58 years old (Table 1). The vascular events were the leading cause of death until the 1980´s, while in the last two decades, were infections.
The older age at diagnosis was predictor of mortality in our cohort. Neither gender nor delay in diagnosis was independently associated with mortality, with the exception of the female sex, which behaved as a protective factor until the 1980's. The mortality predictors in our cohort were the presence of hypocomplementemia and organ damage until the 1980´s; thrombocytopenia, antiphospholipid syndrome and valve disease in the 1990´s; serositis, organ damage and depression in the first decade of the 21st century. Conversely, skin involvement was related to greater survival over the last two decades and comorbidities were associated with mortality in all periods of the study.
The use of high doses of corticosteroids (>30mg/day) was predictor of mortality in each time stage, as well as the use of cyclophosphamide and rituximab from the year 2000. Antimalarial treatment was linked to improved survival in all the decades analyzed.
Conclusion: In the RELESSER cohort, the main cause of death in the last decades were infections. However, until the 1980´s, vascular events were predominant. Older age at diagnosis, the use of corticosteroids and comorbidities were associated with a significant increase in mortality in SLE, while antimalarial treatment was linked to improved survival. Data indicate that organ damage is a risk factor and skin involvement is a protective factor against mortality. Differentially, female sex until the 1980´s was independently associated with improved survival, and depression at the beginning of the 21st century was linked to mortality. Our results must be confirmed in prospective studies that minimize methodological limitations.

OP0230

USING AN INNOVATIVE DIGITAL TOOL FOR THE ASSESSMENT AND PERSONALIZED RECOMMENDATIONS TO COPE WITH FATIGUE IN SYSTEMIC LUPUS ERYTHEMATOSUS: THE LEAF STUDY

Keywords: Systemic lupus erythematosus, Patient reported outcomes, Patient information and education

L. Kawka[1], J. C. Sarmiento-Monroy[2], M. Ugarte-Gil[3], S. Geneton[1], M. Piga[4], L. Arnaud[1]. *[1]Centre Hospitalo-Universitaire de Strasbourg, Rheumatology, Strasbourg, France*; *[2]Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain*; *[3]Hospital Guillermo Almenara Irigoyen, Rheumatology, Lima, Peru*; *[4]University Clinic AOU Cagliari, Rheumatology, Cagliari, Italy*

Background: Fatigue is reported as the most prevalent and bothersome symptom by Systemic Lupus Erythematosus (SLE) patients as it may impair key aspects of the quality of life. Assessing and treating fatigue is therefore an important aspect of SLE care. However, fatigue management is complex due to its multifactorial nature, as well as the need for personalized care which may take time that clinicians might lack during routine consultations.
Digital tools are increasingly used for clinical practice, and may offer promising opportunities to assess and manage fatigue in chronic diseases.
Objectives: The aim of the LEAF study was to study the usefulness of an innovative digital tool to manage fatigue in SLE, first by collecting the main characteristics and factors associated with fatigue in SLE at the individual patient-level using self-report questionnaires and then by providing automatically personalized feedback to these SLE patients as how to cope with fatigue.
Methods: We developed an online digital tool, the «Lupus Expert System for Assessment of Fatigue» (LEAF), which was validated with the patient association Lupus Europe. LEAF contains a multilingual questionnaire that measures the intensity and characteristics of fatigue, using the «Fonctional Assessment of Chronic Illness Therapy – Fatigue Scale» (FACIT-Fatigue), the «Multidimensional Fatigue Inventory» (MFI) and a Numerical Rating Scale (NRS), and assesses potential predictors of fatigue, including disease activity, pain, insomnia, anxiety, depression, stress, fibromyalgia (optional) and physical activity using validated self-reported instruments. Once the assessment is completed, LEAF provides automatically personalized feedback and recommendations to cope with fatigue. Participants to the LEAF study had a diagnosis of SLE confirmed by a medical doctor. Patients evaluated how helpful LEAF was and how much they would recommend it to another patient on a 0-5 scale. Fatigue characteristics were described. Associations between significant fatigue (FACIT-Fatigue<34) and its determinants were evaluated in univariate and multivariate analyses.
Results: Between May and November 2022, 1250 participants were included in the LEAF study. Participants were mostly female (95.2%), with a median age of 43 years old (IQR: 34-51). Significant fatigue (FACIT-Fatigue<34) was reported by 78.9% of patients. NRS median score for fatigue intensity was 7 (IQR: 6-8), on a 0-10 scale. MFI median scores were 15 (IQR: 12-17) for physical fatigue, 13 (IQR: 10-16) for mental fatigue, 14 (IQR: 11-16) for reduced activity and 14 (IQR: 11-17) for reduced motivation, on a 4-20 scale.

In univariate analysis, SLE participants with fatigue (FACIT-Fatigue<34) were more likely to be women (p=0.01), perceived their disease as more active (p<0.0001), had higher levels of pain (p<0.0001), anxiety (p<0.0001), depression (p<0.0001), insomnia (p<0.0001), stress (p<0.0001), and were more likely to have fibromyalgia (p<0.0001), compared to patients without significant fatigue. In multivariable analysis, the parameters independently associated with fatigue were insomnia (p=0.0003), significant pain (p=0.002), fibromyalgia (p=0.008), self-reported active SLE (p=0.02), and high level of stress (p=0.045).
Following LEAF feedback, 93.2% of the participants found LEAF helpful (NRS ≥ 3/5) and 92.3% would recommend it to another SLE patient (NRS ≥ 3/5).
Conclusion: In SLE patients, fatigue was frequent, commonly severe, and associated with a significant reduction of activities and motivation. This further confirms the urgent need to develop new tools to assess and treat fatigue in SLE. Our study demonstrates the usefulness of an innovative digital tool to manage fatigue in SLE.
Acknowledgements: We would like to thank all patients who have participated to the LEAF study, and in particular the patient association Lupus Europe.

Background: 30% of patients with SLE have APS, so clinical thromboembolic, obstetric and laboratory manifestations have been extensively studied in this population. The association between antiphospholipid antibodies (aPL) and non-thrombotic manifestations that are not part of the Sydney classification criteria for APS are particularly important in patients with SLE.
Objectives: To compare the presence of non-criteria non-thrombotic manifestations of APS in patients with SLE and APS, SLE with positive aPL, SLE with negative antibodies and different outcomes such as mortality, hospitalizations and damage score.
Methods: Observational, analytical and cross-sectional multicenter study. Data were obtained from the review of the RELESSAR database. We included patients ≥ 18 years with diagnosis of SLE according to modified ACR 1984 criteria. The diagnosis of APS was made according to the Sidney Criteria 2006. The sample was classified into three groups based on the presence of established APS (Group 1), aPL carrier (Group 2) and aPL negative (Group 3). Non-criteria manifestations were described and compared in the three groups. Continuous variables were compared by Student's or Mann Whitney's T test, and categorical variables by Chi[2] test or Fisher's exact test. In cases where a significant difference was found between the groups, multiple post hoc comparisons were made.
Results: One thousand two hundred and two patients were included, 1,110 (92.3%) were women. One hundred and sixty patients (13.3%) had APS (group 1), 241 (20.04%) were aPL carrier (group 2) and 801 (66.6%) were negative for aPL (group 3). Patients with APS were older than patients in group 2 [42.6 (SD 13.5) vs 38 (SD 14.2), p 0.001] and 3 [42.6 (SD 13.5) vs 39.5 (SD 14.1) p 0.004]. The disease duration was longer in patients with APS compared to patients with SLE and negative aPL (138 months (SD 113) vs 101 (SD 113) (p <0.001). Table 1 shows non-thrombotic manifestations in the three groups. A higher percentage of patients with hemolytic anemia was observed in the APS group (p=0.001) and in the aPL carrier group (p=0.018) compared to negative aPL group. Patients with APS showed a higher proportion of thrombocytopenia when compared to patients with negative aPL (p=0.039). Acute cranial/peripheral neuropathy was more frequently observed in APS group compared to aPL-negative group (p=0.006). APS group was significantly associated with hospitalizations due SLE flares, morbidity and damage index (Table 2). A higher proportion of patients in the APS group had thrombotic events compared to aPL carrier and aPL negative groups (p<0.05).

Table 1. Non-criteria non-thrombotic manifestations

	APS (group 1)	aPL + (group 2)	aPL – (group 3)	*p*
Hemolytic anemia	31 (19.9%)	37 (15.4%)	75 (9.47%)	<0.001
Thrombocytopenia	41 (26.6%)	56 (23.4%)	138 (17.6%)	0.011
Depression	23 (14.8%)	17 (7.05%)	92 (11.6%)	0.041
Acute Neuropathy	10 (6.62%)	9 (3.73%)	14 (1.77%)	0.002

Table 2. Patient prognostic measures

	APS (group 1)	aPL + (group 2)	aPL – (group 3)	*p*
Hospitalizations	96 (62.3%)	119 (49.8%)	401 (50.4%)	0.02
Charlson Score	2.43 (1.92)	2.01 (1.51)	1.95 (1.46)	0.009
SLICC	1.53 (1.66)	1.04 (1.32)	0.960 (1.34)	<0.001

Conclusion: In this nation-wide SLE cohort, neurological and hematological manifestations were frequently observed in patients with secondary APS. Moreover, these patients had higher rate of hospitalization, damage score and comorbidities.

OP0232 DEEP LEARNING ACCURATELY PREDICTS FOCUS SCORE AND DIAGNOSIS OF PRIMARY SJÖGREN SYNDROME USING LABIAL SALIVARY GLAND BIOPSIES

Keywords: Artificial intelligence, Sjögren syndrome

L. Basseto[1], J. Duquesne[1], V. Bouget[1], M. Barnes[2], E. Pontarini[3], A. Gallagher-Syed[2], M. Bombardieri[3], B. Fisher[4], S. Nayar[4], C. Adam[5], T. Lazure[6], X. Mariette[7], S. Bitoun[7]. [1]*Scienta Lab, Research Department,*

Background: The Focus Score (FS) ≥ 1 in minor labial salivary gland (LSG) biopsies is one of the 2 main items (with anti-SSA positivity) to establish the diagnosis of Primary Sjögren Syndrome's (pSS). As such, correctly assessing the FS is crucial for the diagnosis of pSS. However, the histological interpretation of LSG tissue requires specific expertise and poses a challenge to non-specialized centers. Vivino et al. [1] show up to 53% of reclassification after expert center rescoring. Deep learning algorithms using artificial neural networks are increasingly used to assist pathologists and can be designed to provide explainable predictions using heatmaps. Heatmaps show which part of the sample section is used to perform the prediction, thus reducing the black box effect. This is important to allow adoption of accurate FS scoring using machine learning in clinical practice.
Objectives: Based on minor LSG specimen, we developed two deep learning models, the first one to predict the FS (≥ 1 or < 1) and the other to predict pSS diagnosis.
Methods: LSG slides used for the diagnosis of patients suspected of pSS were included in the study from 3 European centers which are part of the NECESSITY consortium, a European H2020 IMI2 project. Three groups were included: patients with sicca symptoms but without pSS (Sicca group), pSS patients with ≥ 1 FS, and pSS patients with <1 FS. All pSS diagnoses were confirmed by rheumatologists from expert centers. Clinical data regarding demographics, disease duration, FS, autoantibodies, and dryness were also collected. All LSG sections used for the pathologic diagnosis were scanned. Two deep learning models were used: one for FS prediction and the other for diagnosis prediction from the biopsies. The models provided a prediction and scored each sub-region of the tissue slides with a risk score. The risk score was used to interpret the algorithm's result and find which areas of the tissue were most significant for the classification (whether FS or diagnosis). For each model, 70% of patients were used for training and 30% for validation. For the FS task, both the validation and test sets include 54% of ≥ 1 FS patients. Similarly, for the pSS task, both the validation and test sets include 67% of pSS+ patients. The algorithm's performance was measured using the area under the ROC curve (AUROC).
Results: The dataset included 327 patients: 145 from Paris-Saclay university (Bicêtre Hospital), 73 from Queen Mary University London and 109 from the University of Birmingham. For binary FS prediction the AUROC was 0.87, and for the pSS diagnosis prediction, the AUROC was 0.84. When areas used to make the prediction were analyzed, the model unsurprisingly identified lymphocyte foci for the FS prediction task (Figure 1). This provides explainability and allows the pathologist to visually confirm the results of the prediction. Results on the validation sets for the two tasks are available in Table 1.

Table 1. Results on the Validation Sets.

Task	AUROC	Positive Predicted Value (PPV)	Negative Predictive Value (NPV)	Specificity	Sensitivity
FS ≥ 1/ FS < 1 Prediction	0.87	0.76	0.83	0.78	0.81
pSS+/- Prediction	0.84	0.83	0.67	0.64	0.84

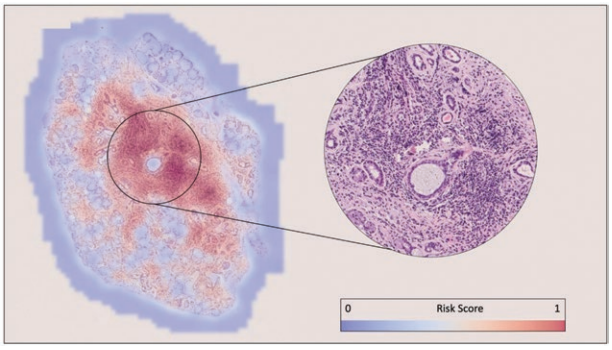

Figure 1. Heatmap Computed from FS Prediction Highlights Lymphocytes.

Conclusion: Deep learning can predict the diagnosis of FS>1 and the diagnosis of pSS with good accuracy. The FS model could represent a valuable help for assisting pathologists who are not experts in oral medicine pathology and reduce their reliance on reference centers. Comprehensive analysis of the tissue areas highlighted by the pSS model paves the way for a better understanding of the disease's physiopathology.

Background: Primary Sjögren Syndrome (pSS) patients have an increased risk of Non-Hodgkin lymphoma (NHL). There is no consensus on the therapeutic management of low-grade NHL. Two strategies can be proposed; either a "wait and see" strategy or an active therapeutic strategy.
Objectives: To describe characteristics of NHL in pSS, therapeutic strategies and impact of these strategies on prognosis of lymphoma and of pSS.
Methods: This multicentric retrospective study included all lymphoma patients of the ASSESS cohort, enriched with patients recruited in Rheumatology and Internal Medicine departments. For each patient, we collected biological and clinical manifestations of pSS, lymphoma's characteristics, and treatment strategy. Progression free survival (PFS) (lymphoma-PFS and pSS relapse free survival) and overall survival (OS) were analyzed.
Results: A total of 106 pSS patients who presented a B cell lymphoma between 1985 and 2019 were included. Among them 14 (13%) had diffuse large B cell lymphoma (DLBCL) and 82 pSS patients presented a low-grade B cell-NHL, mucosa-associated lymphoid tissue (MALT) lymphomas being the most frequent histologic subtype occurring in 68/82 (83%) patients.
Among these 82 patients, a "wait and watch strategy" was chosen in 19 (23%) patients; 63 patients received a specific treatment for lymphoma at lymphoma diagnosis including systemic treatment (chemotherapy and/or immunotherapy) in 49 (60%) patients and local therapy (surgery or radiotherapy) in 14 (17%) patients; 10 patients further received rituximab (RTX) maintenance therapy.
Comparison of treated versus not treated patients is presented in the Table 1. Untreated patients were older and had less pulmonary lymphoma location.
We then analyzed the prognosis after a mean follow up of 6.5 years. Nine patients (11%) died during the follow-up. In multivariate analysis, age (HR= 1.16 [1.06-1.27], p = 0.001) and pulmonary location (HR= 8.15 [1.57-42.3], p = 0.013) were associated with death.
Last, we compared OS, lymphoma PFS and pSS relapse PFS in treated versus not treated patients after propensity score weighting We observed that starting an active treatment for NHL at lymphoma diagnosis did not impact OS and lymphoma PFS (HR= 4.81 [0.48-47.9], p=0.2 and HR=1.12 l0.50- 2.48], p=0.8, respectively). Conversely, treating lymphoma had a protective effect on the risk of pSS relapse (HR 0.4 [0.17-0.95], p = 0.038). Last, among patients treated for lymphoma, we observed that no lymphoma relapse occurred in patients who received maintenance therapy with RTX (0/10 events vs 18/53, p = 0.04).
Conclusion: This study based on a large number of pSS patients with lymphoma shows that age and pulmonary location are independently associated with the risk of death. The choice of treating lymphoma at its diagnosis or not does not affect OS and PFS for lymphoma. However treatment of lymphoma reduced the risk of pSS relapse. This should be taken into account when deciding therapeutic strategy in our pSS patients with lymphoma.

Background: EULAR recommendations for treatment for Systemic Sclerosis (SSc) were last updated in 2017, based on literature up to the end of 2014. The treatment recommendations are among the most cited publication in the field, reflecting their utility both in clinical practice and academic research. In the past 8 years, several important advances have been achieved by the scientific community, with new treatments becoming available and accepted by regulatory authorities.
Objectives: To update the 2017 EULAR recommendations for treatment of SSc, including answers to the 2017 research agenda, new therapeutic questions, and the wealth of newly available evidence.
Methods: Update of previous recommendations was endorsed by EULAR and performed according to the validated methodology. The task force was composed according to recent EULAR guidelines for inclusivity of underrepresented areas of Europe and it consisted of 27 members, including a EULAR endorsed methodologist, 4 fellows, a librarian, one Allied Health Professional and two patient representatives, identified by the Federation of European Scleroderma Associations (FESCA). All centres from the EULAR Scleroderma Trials and Research group (EUSTAR) were invited to review previous questions for Systematic Literature Review (SLR) and propose new ones according to a standardised Delphi approach. A Nominal Group Technique (NGT) exercise was implemented in two rounds for the definition of questions with an 80% agreement threshold. The SLR was conducted with an end date of June 2022, and manually updated to December 2022. Particular attention was dedicated to the 2017 research agenda and new available evidence with matters for detailed discussion and new research agenda also agreed during the NGT.
Results: Sixty-seven clinical questions addressing 24 different interventions were prioritised by the task force for the SLR. The results of the SLR were categorised by level of evidence and grade of recommendations and discussed during the NGT meeting. The procedure resulted in 21 recommendations (instead of 16 in 2017) in 8 clinical domains related to SSc symptoms and organ involvements, including Raynaud's phenomenon, digital ulcers, pulmonary arterial hypertension, scleroderma renal crisis, skin fibrosis, interstitial lung disease, gastrointestinal manifestations and arthritis. Most of the new recommendations were in the field of skin fibrosis and interstitial lung disease, consistent with the research agenda set in 2017. These included recommendations for the use of mycophenolate mofetil, nintedanib, rituximab and tocilizumab for the treatment of these crucial disease manifestations. None of these therapies were present in the 2017 recommendations. Important additions to the future research agenda included targeted therapies for the management of musculoskeletal and gastrointestinal manifestations, calcinosis and the local management of digital ulcers.
Conclusion: The 2023 updates of EULAR recommendations include the first set of synthetic and biological targeted therapies recommended as disease modifying agents for key fibrotic manifestations of systemic sclerosis. While a disease modifying agent or strategy for a comprehensive approach appropriate for all SSc patients is still missing, numerous advances have been achieved since 2017. New, strong evidence is now available to clinicians to better manage patients with this life-threatening condition.

Background: Accurate measurement of disease activity in systemic sclerosis (SSc) remains a significant challenge. Previous activity indices have been criticised for limitations of face and content validity.

Objectives: The Scleroderma Clinical Trials Consortium (SCTC) convened an Activity Index Working Group to develop a disease activity index (SCTC AI) that has face, content and construct validity.

Methods: Consensus was reached regarding the conceptual definition of disease activity in SSc. All SCTC AI items were required to be measures of the agreed upon construct. See Figure 1 for process of item generation. In all Delphi exercises an *a priori* threshold of 70% agreement was applied for items to be included or excluded from subsequent rounds. Items that did not meet the threshold for inclusion across 2 survey rounds were omitted.

Figure 1 Item generation & reduction

Data from the Australian Scleroderma Cohort Study were used to reduce and weight items. Items were weighted using time dependent Cox proportional hazards regression analysis relative to a combined endpoint of mortality and morbidity (SF 36 physical component score (PCS) below cohort median value). Seven provisional items were not collected in the ASCS. A discrete choice experiment was performed to generate relative weightings for these items. Group based trajectory modelling (GBTM) was used to identify trajectory groups to compare the survival of low vs high disease activity groups using Kaplan Meier survival analyses. Cox proportional hazard modelling was used to evaluate the association between activity scores and mortality, morbidity and SCTC Damage Index (SCTC DI) scores.

Results: The definition of disease activity as agreed by the SCTC AI WG is: *Activity in SSc refers to aspects of disease, attributable to SSc, that are potentially reversible, or can be arrested, with time and/or effective therapy. Disease activity may be associated with morbidity and uncontrolled activity may lead to organ dysfunction and mortality.* A 24 item index, spanning nine domains of disease was generated with a maximum score of 140 (Table 1). GBTM identified 3 trajectory groups: low activity (n=856 (49%) median baseline SCTC AI score 4 (IQR 0-6)); medium activity (n=745 (42%) median baseline SCTC AI score 10 (IQR 6-14)); high activity (n=164 (9%) median baseline SCTC AI score 16 (IQR 10-22)). There was a graded risk of death associated with increasing activity levels. 4 year survival was poorer in the high disease activity group compared to the low disease activity group (75% vs 95%, p<0.01). Patients with a SCTC AI ≥15.5 had a HR 3.5 (2.26-5.42 p<0.01) for death and greater morbidity was observed in individuals with a SCTC AI ≥9.5 (HR 1.90 (1.61-2.24 p<0.01). There was a significant relationship between SCTC AI scores and worsening damage; HR 4.43 (3.51-5.60, p<0.01) for 1 unit increase of SCTC DI for each unit increase in SCTC AI.

Conclusion: We present a novel outcome measure to quantify the burden of disease activity in SSc. We have employed a rigorous consensus based methodology in combination with data driven methods, to develop an outcome measure that has face, content and criterion validity. Further work is required to externally validate and confirm the construct and discriminative validity of the SCTC AI.

Table 1. SCTC Activity Index

Item	Score	Item	Score
Change mRSS ≥ +5 points*	7	New ILD on HRCT	4

Elhai[2], S. Jordan[2], E. Langballe[3], Ø. Midtvedt[3], C. Mihai[2], Ø. Molberg[3], O. Distler[2]. [1]*Oslo University Hospital, Rheumatology, Oslo, Norway*; [2]*University Hospital Zurich, University of Zurich, Rheumatology, Zurich, Switzerland*; [3]*Hospital of Southern Norway, Rheumatology, Oslo, Norway*; [4]*Oslo University Hospital, Oslo Centre for Biostatistics and Epidemiology, Oslo, Norway*; [5]*Oslo University Hospital, Respiratory Medicine, Oslo, Norway*

Background: Interstitial lung disease (ILD) progression can be assessed using different definitions. Declining forced vital capacity (FVC) is the simplest and most accepted. Both progressive pulmonary fibrosis (PPF) as defined by the 2022 ATS/ERS/JRS/ALAT guideline, and progressive fibrosing ILD (PF-ILD) as used in INBUILD, define progressive disease by a composite worsening of lung function, respiratory symptoms and changes on high resolution chest tomography (HRCT), but with differences in the specific criteria. These new definitions have not been applied and compared in SSc-ILD yet.
Objectives: To identify variables predicting SSc-ILD progression using three different definitions of progressive disease.
Methods: We included all SSc patients from the Oslo and Zurich cohorts who had ILD on HRCT. ILD progression was defined as (A) PPF guideline criteria with worsening in 2/3 domains over 12 months including (1) respiratory symptoms; (2) absolute decline in FVC >5% or in DLCO >10% and (3) radiological disease progression. (B) PF-ILD INBUILD criteria with (1) FVC decline ≥10%, (2) FVC decline 5-9% and worsening of respiratory symptoms or increased lung fibrosis on HRCT, or (3) worsening of respiratory symptoms and increased lung fibrosis within 24 months. We compared these to ILD progression defined as FVC decline >5%. Variables for ILD progression chosen by expert opinion were tested in multivariable logistic models adjusted for age, sex and treatment and each model was tested using area under curve (AUC) with an AUC of 0.7 defined as acceptable.
Results: Of 231 included SSc-ILD patients from Oslo and Zurich 43 (19%) fulfilled the PPF, 89 (39%) the PF-ILD INBUILD definitions and 71 (31%) showed FVC decline >5%. The final multivariable logistic model predictive for ILD progression defined as FVC>5% decline included baseline FVC, respiratory symptoms (defined as functional class 3 and 4) and the presence of anti-topoisomerase I antibody (ATA). The model was considered as acceptable (AUC=0.70). The model for PF-ILD included diffuse cutaneous SSc (dcSSc), baseline FVC, respiratory symptoms and six-minute walking distance and had an acceptable AUC of 0.73. PPF was only predicted by reduced six minute walking distance, and the model was not acceptable (AUC=0.64).
Conclusion: Progression is common in SSc-ILD, regardless of definition, but the PPF guideline criteria identified fewer progressors than FVC decline >5% and PF-ILD. We identified different variables predicting progression of FVC decline >5% and PF-ILD but could not identify a model with acceptable performance for PPF. This raises concerns about which definition to use in clinical practice and future studies.

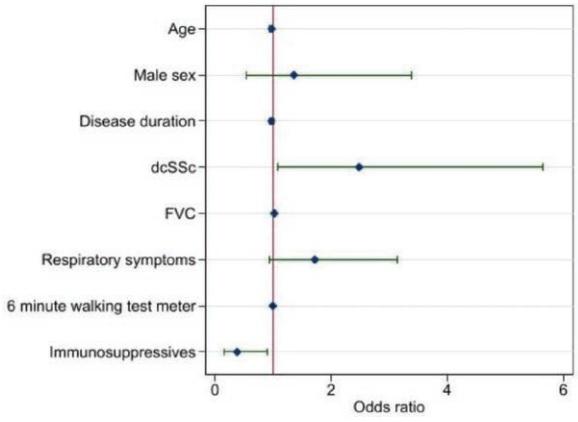

Figure 1. A. Prediction of ILD progression defined by FVC decline >5% (AUC=0.70)
B. Prediction of ILD progression defined as PPF (AUC=0.63)
C. Prediction of ILD progression defined as PF-ILD (AUC=0.73)

OP0237 USE OF NEUTROPHIL/LYMPHOCYTE AND PLATELET/LYMPHOCYTE RATIOS TO DETECT SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

Keywords: Systemic sclerosis, Diagnostic tests, Biomarkers

L. D. Fajardo Hermosillo[1], L. R. María Karina[1]. [1]*Hospital de Especialidades, Centro Médico Nacional de Occidente IMSS, Rheumatology, GUADALAJARA, Mexico*

Background: Interstitial lung disease (ILD) remains as a mainly cause of morbidity and mortality in patients with systemic sclerosis (SSc). New markers to early detection of SSc-ILD are an unmet need [1]. Neutrophil/lymphocyte (NLR) and platelet/lymphocyte (PLR) ratios have emerged as potential biomarkers of systemic inflammation in cancer, cardiovascular disorders, infections and rheumatic diseases [2]. Recently, some studies in South Korea and Turkey have showed correlation of NLR and PLR with erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), disease activity, pulmonary and cutaneous involvement in SSc [3,4]. However, manifestations of SSc present variability in different populations. Could NLR and PLR be used as new biomarkers to detect SSc-ILD in Mexican-Mestizo population?
Objectives: To investigate the usefulness of NLR and PLR to detect SSc-ILD.
Methods: A cross-sectional study, where patients > 18 years of age with a diagnosis of SSc according to EULAR/ACR 2013 criteria and diagnosis of ILD by forced vital capacity (FVC) < 70% and > 5% of affected lung area by diffuse ground-glass opacity or pulmonary fibrosis on high-resolution computed tomography (HRCT) were included. Patients with corticosteroid use, malignancy, iron deficiency anemia and active infections were excluded. *European Scleroderma Trials and Research Group* (EUSTAR) disease activity index was used to determine activity. NLR, PLR, ESR, CRP, EUSTAR disease activity score, modified Rodnan skin score (mRSS) were compared between patients with and without SSc-ILD using U Mann-Whitney test. Spearman´s correlations between NLR or PLR and EUSTAR activity index, mRSS, ESR, CRP, FVC and affected lung area HRCT were analyzed. Receiver operating characteristic (ROC) analysis was performed to assess the best cutoff value for detecting SSc-ILD. Test characteristics, including sensitivity, specificity and diagnostic accuracy (DA) were calculated. Multivariate logistic regression analysis (MLRA) for ILD with their odds ratio (OR) and 95% confidence intervals (95% CI) was conducted establishing NLR, PLR as predicting factors adjusted by age, duration and activity of SSc.
Results: Of 74 patients with SSc 94.6% were women. The mean age [standard deviation (SD)] was 49.8 (14.1) years. The median of disease duration [interquartile range 25-75 (IQR)] was 7 (4.7-12) years and subtype of limited cutaneous SSc was presented in 85.1% of patients. A total of 36 (48.6%) patients had ILD; of them 59% had non-specific interstitial pneumonia and 51.3% showed extensive disease on HRCT. Medians of NLR, PLR, ESR, CRP, mRSS and EUSTAR activity index were higher in SSc-ILD patients (p=< 0.001). For NLR, the cut-off value (COV) was 2.05 and the area under the curve (AUC) was 0.887, with sensitivity, specificity and DA of 91.7%, 71.1% and 81.1% respectively. For PLR, the COV was 184.54 and the AUC was 0.743, with sensitivity, specificity and DA of 58.3%, 89.5% and 74.3%, respectively (**Figure 1**). NLR had a strong correlation with PLR (r=0.696) and affected lung area on HRCT (r=0.654) and moderate correlation with FVC (r=0.527) and EUSTAR activity index (r=0.513) (p=< 0.001). In contrast. PLR only had a weak correlation with EUSTAR activity index (r=0.371; p=<0.001). MLRA showed that NLR > 2.05 (OR 5.42, 95% CI 1.47-20.07, p=0.011) and EUSTAR activity index > 2.5 (OR 2.62, 95% CI 1.38-4.96, p=0.003) remained associated with an increased risk of SSc-ILD.
Conclusion: This study suggests that NLR show better DA than PLR, as well it can be a useful screening tool and a low-cost biomarker to detect SSc-ILD in Mexican-Mestizo patients. Also, NLR is associated with an increased risk of SSc-ILD and present a good correlation with affected lung area on HRCT, FVC and disease activity. However, these observations must be confirmed in larger and prospective studies.

Background: Pre-capillary pulmonary hypertension (precapPH) affects 9-15% of patients with systemic sclerosis (SSc) and may be associated with interstitial lung disease (ILD) of variable extent. Immunosuppressants (IMS) are standard of care for treating ILD, skin or musculoskeletal manifestations in SSc. However, their beneficial effect on precapPH remains unclear.

Objectives: To determine whether exposure to IMS in SSc-precapPH affects morbidity and mortality in the EUSTAR cohort.

Methods: In the approved EUSTAR project CP111, we included SSc patients with precapPH (mPAP ≥21 mmHg, PWP ≤15 mmHg, PVR ≥2 WU) with data on IMS (csDMARDs - prednisone ≥10 mg/day, cyclophosphamide, mycophenolate mofetil, azathioprine, methotrexate; targeted therapies: abatacept, rituximab, tocilizumab, TNFi, JAKi), pulmonary arterial hypertension (PAH) medications (bosentan, macitentan, ambrisentan, sildenafil, tadalafil, riociguat, selexipag, prostanoids) and at least 3 months follow-up after precapPH diagnosis by right heart catheterization. We considered exposure to a drug if it was ongoing at or prescribed after precapPH diagnosis and administered for at least 30 days. Patients were clustered into group 1 or group 3 precapPH based on ILD presence on HRCT and FVC <70%, as proposed in the INCREASE trial. The morbidity-mortality outcome was defined by the first event between death or precapPH worsening (following the SERAPHIN trial: one of ≥15% 6MWD decrease, worsening of NYHA class, onset of right heart failure, additional PAH medication, starting iv/sc prostanoids, lung transplantation, atrial septostomy). We evaluated the association between IMS and time to first event with a multiple Cox regression model for time dependent covariates, with robust Sandwich variance estimate and backward selection. The baseline confounders were chosen on experts' opinion and included SSc-related risk factors for mortality or IMS prescription (sex, age, diffuse skin subset, renal crisis, digital ulcers, muscle weakness, joint synovitis, ILD on HRCT, LVEF%, FVC%, DLCO%) and PAH risk stratification parameters (mPAP, increased BNP/NTproBNP, NYHA class >II, reduced cardiac index, reduced 6MWD). PAH medications (none, mono, double or triple therapy) were also included as time-dependent confounder.

Results: 755 SSc-precapPH patients from 54 EUSTAR centers were included (18% males, age 63±11 years, disease duration 11±9 years, 29% diffuse skin subset, 60% ILD on HRCT): 377 (50%) received IMS [365 (47%) csDMARDs, 68 (9%) targeted therapies] and 642 (85%) PAH medications. Patients treated with IMS had more frequently ILD (78 vs 43%), diffuse skin (41 vs 18%), joint (16 vs 7%) and muscle (22 vs 10%) involvement. In 2.9 (1.2-5.4) years median follow-up, 546 (70%) patients developed a morbidity-mortality event. While overall IMS exposure did not associate with the outcome, targeted therapies were associated with reduced risk of morbidity-mortality [HR 0.59 (95% CI 0.36-0.96), p=0.04; Figure 1a].

Figure 1. Risk over time of morbidity-mortality events in SSc-precapillary PH: panel A) whole cohort; panel B) group 1; panel C) group 3 patients.

When clustering into group 1 [n=561, 40% IMS, n=32 (6%) targeted therapies] or group 3 [n=194, 80% IMS, n=36 (19%) targeted therapies], less morbidity-mortality events were recorded for group 1 (69% vs 81%). Despite the rarer use, the protective effect of targeted therapies for morbidity-mortality was confirmed in group 1 (HR 0.24, 95% CI 0.02-0.64, p=0.01, Figure 1b) but not in group 3 (Figure 1c). When looking at specific target therapies, a risk reduction for the morbidity-mortality outcome was noted for tocilizumab [in the whole cohort (n treated=21; HR 0.37, 95%CI 0.18-0.77, p=0.03) and in group 1 (n treated=10; HR 0.09, 95% CI 0.01-0.69, p=0.02)] and rituximab (in group 1, n treated= 24, HR 0.29, 95% CI 0.10-0.84, p=0.01).

Conclusion: In this large EUSTAR SSc-precapPH cohort, targeted therapies are associated with a significantly reduced risk of mortality and precapPH worsening over time. This is the first large study adjusted for confounders supporting a potential effect of targeted therapies on SSc-precapPH.

OP0239

DOES EARLY IMMUNOSUPPRESSIVE THERAPY PREVENT SYSTEMIC SCLEROSIS ASSOCIATED INTERSTITIAL LUNG DISEASE?

Keywords: Systemic sclerosis, Lungs, Epidemiology

A. Velauthapillai[1], M. Bootsma[1], C. Bruni[2], O. Distler[2], C. Van den Ende[1], M. Vonk[1]. [1]*Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*; [2]*University Hospital Zürich, Rheumatology, Zürich, Switzerland*

Background: Systemic sclerosis (SSc) is an auto-immune disease characterized by a triad of inflammation, vascular damage and fibrosis. Interstitial lung disease(ILD) is a major contributor to impaired quality of life and a leading cause of death in these patients. While recent studies reported a favorable effect on disease course when starting immunosuppressive(IMS) therapy in mild and moderate ILD, no definite evidence of a preventive mechanism of IMS therapy for ILD onset is established(1, 2).

Objectives: The objective of our study was to explore the association between timing of start IMS therapy and the development of ILD.

Methods: A combined cohort was created from the EUSTAR database and Nijmegen Systemic Sclerosis cohort, including patients: 1) aged 18 years or older 2) treated with IMS (i.e. mycophenolate mofetil, methotrexate, cyclophosphamide and rituximab) after SSc diagnosis 3) negative for signs of ILD on high-resolution CT(HRCT) at or within 2 months after start treatment and 4) no prior treatment with biological or antifibrotic in the preceding years. Data between start of first IMS treatment and five years follow-up were analysed. Disease duration (time between first non-Raynaud phenomenon and start IMS) was dichotomized into early and late treatment using a cut-off point of 3 years. ILD-free survival (absence of HRCT confirmed ILD diagnosis) was assessed with unadjusted Kaplan Meier analysis on complete cases and a cox proportional hazard analysis on imputed data adjusting for confounders.

Results: We identified 1037 patients meeting the eligibility criteria. The early treatment group (n= 539, 52 %) showed a higher prevalence of male sex, diffuse cutaneous SSc (dcSSc, 52.9% vs 36.4%, p= 0.001), anti-topoisomerase I antibody positivity (ATA, 51.0% vs. 42.5%, p= 0.01), anti-RNA polymerase III antibody positivity (ARA, 11.7% vs. 5.4%, p=0.009) and elevated C-reactive protein levels (30.6% vs. 22.6%, p=0.03). Further, patients in the early group had a higher modified Rodnan skin score (mRSS, mean(SD) 13.3(9.7) vs. 9.7(8.9), p= 0.001). The incidence of ILD was 46.1% after mean(SD) 3.6(1.4) years of treatment and not significantly different between the groups (mean(95% CI); early: 47% (43-51) vs. late: 45%(40-50), p= 0.64). The unadjusted Kaplan-Meier survival curve on complete cases (Figure 1) shows no differences in ILD-free survival rates between the early and late treatment group. The hazard ratio for ILD in the early treatment group was 1.11 (95% CI: 0.91-1.36) adjusting for gender, dcSSc, Caucasian ethnicity, ATA, ARA, age, forced vital capacity and diffusing capacity for carbon monoxide at baseline.

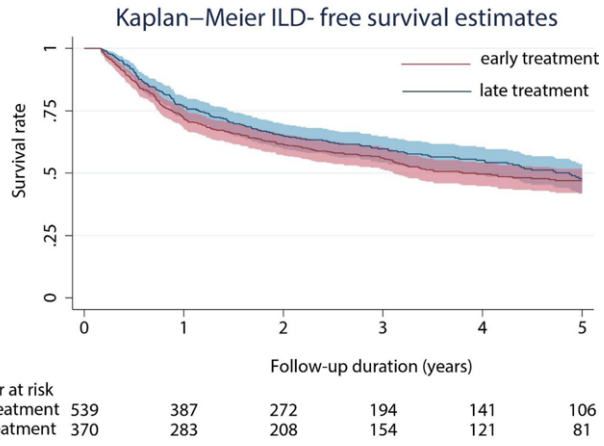

Figure 1. Kaplan Meier curve of ILD- free survival estimates. Survival rate with 95% confidence interval is shown for the early and late treatment group.

Conclusion: Our finding did not confirm a preventive role of early vs. late timing of IMS therapy on ILD development. However, our findings should be interpreted with caution, considering the high inflammatory, ATA-positive enriched nature of the cohort selected, as well as confounding by indication, which cannot be ruled out also after adjusting for other confounding factors.

OP0240

A RANDOMIZED CONTROLLED TRIAL TO COMPARE THE EFFICACY OF TACROLIMUS WITH MYCOPHENOLATE MOFETIL IN PATIENTS WITH SYSTEMIC SCLEROSIS - INTERSTITIAL LUNG DISEASE (INSIST TRIAL)

Keywords: Clinical Trials, Systemic sclerosis, Lungs

J. Mathew[1], C. Kopp[1], S. K. Sharma[1], V. Dhir[1], S. Dhooria[2], A. Sinha[3], S. Jain[1].
[1]Post Graduate Institute of Medical Education & Research, Chandigarh, Internal Medicine, Chandigarh, India; *[2]Post Graduate Institute of Medical Education & Research, Chandigarh, Pulmonary Medicine, Chandigarh, India*; *[3]Post Graduate Institute of Medical Education & Research, Chandigarh, Radiodiagnosis, Chandigarh, India*

Background: Interstitial lung disease in systemic sclerosis(SSc-ILD) is heterogeneous with limited therapeutic options. Mycophenolate mofetil (MMF) is the most commonly used first line agent for SSc-ILD. Tacrolimus has shown promising efficacy in few small case series, and large cohorts of patients with non-SSC-ILD[1], but has never been evaluated in the setting of a clinical trial.
Objectives: To compare the safety and efficacy of Tacrolimus with MMF in patients with progressive SSc-ILD.
Methods: In this single center open labelled, prospective, two-arm parallel group, randomized controlled pilot study (INSIST) conducted between November 2021 to December 2022, patients with progressive ILD (FVC decline >10%) due to SSc, aged between 18-65 years, disease duration <10 years, without concomitant inflammatory myositis, with an FVC of 40-85%, and not having received active immunosuppression other than prednisolone <10mg/day in the last 6 months were randomized to receive either MMF (target dose 2gm/day) or tacrolimus (Max dose-0.075 mg/kg/day; target trough levels- 4-10ng/ml) for 24 weeks. The primary endpoint was the difference in change in FVC% at 24 weeks; secondary outcomes included absolute change in FVC, skin scores, 6-minute walk distance, Mahler's transitional dyspnea index, ACR-CRISS and revised CRISS responses and adverse outcomes. (Trial Reg: CTRI/2021/11/037864)
Results: 25 out of 26 patients (13 in each group) completed 24 weeks follow up. Majority had Anti-Scl 70 positivity (73%) and limited skin disease. At 24 weeks, the mean change in FVC was 4.4% (10.6) and 6.92%(8.4) in the MMF and tacrolimus groups respectively (difference 2.52%, 95% CI (-10.3 to 5.18); p-0.500). All patients on tacrolimus and 85% of patients on MMF had stabilization (ΔFVC% -5% TO 5%) or improvement (ΔFVC%>10%) in lung function. Secondary outcomes were similar between two groups. Subgroup analyses stratified by ILD type, skin involvement at baseline, and early vs late SSc yielded similar results. The mean tacrolimus levels were 4.9 ng/ml(1.47) and the median dose needed to achieve these levels was 4mg/d. No serious adverse events were noted in either group; use of tacrolimus did not result in renal dysfunction or renal crises.
Conclusion: Tacrolimus resulted in comparable improvement to MMF across primary and secondary outcome measures at 24 weeks with a favorable safety profile in patients with SSc ILD. Larger studies with longer follow up are needed to investigate the role of calcineurin inhibitors in SSc.

OP0241

PROGNOSIS OF PATIENTS WITH SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE AFTER THE LUNG TRANSPLANTATION: A RETROSPECTIVE STUDY

Keywords: Non-pharmacological interventions, Systemic sclerosis, Lungs

Y. Nakayama[1], R. Nakashima[1], T. Handa[2], A. Ohsumi[3], Y. Yamada[3], D. Nakajima[3], Y. Yutaka[3], S. Tanaka[3], S. Hamada[2], K. Ikezoe[2], K. Tanizawa[2], M. Shirakashi[1], R. Hiwa[1], H. Tsuji[1], K. Kitagori[1], S. Akizuki[1], H. Yoshifuji[1], H. Date[3], A. Morinobu[1].
[1]Kyoto University, Department of Rheumatology and Clinical Immunology, Kyoto, Japan; *[2]Kyoto University, Department of Respiratory Medicine, Kyoto, Japan*; *[3]Kyoto University, Department of Thoracic Surgery, Kyoto, Japan*

Background: Interstitial lung disease (ILD) is a major complication of systemic sclerosis (SSc) and is associated with mortality [1]. Lung transplantation (LT) is a therapeutic option for advanced SSc-associated ILD (SSc-ILD). However, there is a lack of LT data for SSc-ILD in non-Western populations.
Objectives: We aimed to assess the survival data of patients with SSc-ILD on the LT waiting list and evaluate post-transplant outcomes for SSc-ILD and idiopathic pulmonary fibrosis (IPF) in an Asian LT centre.
Methods: A single-centre retrospective study. Using the LT candidate database at Kyoto University Hospital, patients with SSc-ILD who were registered for deceased LT were identified. To investigate post-transplant outcomes, recipients who underwent LT for SSc-ILD and IPF between February 2002 and April 2022 were also identified from the LT recipient database. Clinical data and outcomes were analyzed.

Results: This study included 29 patients registered for deceased LT between 2010 and 2022 (Table 1). Ten patients received deceased-donor LT (34%), two received living-donor LT (7%), seven died while waiting for LT (24%), and ten survived on the waiting list (34%). The median waiting time from registration to deceased-donor LT was 28.9 months (range 22.3-30.3). The median duration from registration to living-donor LT or death (events) was 6.5 months (range 4.1-14.7). Pulmonary hypertension was associated with mortality or switching to living-donor LT while waiting for deceased LT. In post-transplant analysis, 15 and 20 patients received LT for SSc-ILD and IPF between February 2002 and April 2022, respectively. Lung transplantation recipients showed an improved forced vital capacity with a median of 55.1% at baseline, 65.8% at 6 months and 80.3% at 12 months post-transplant. The estimated 5-year survival rates for post-transplant patients with SSc-ILD or IPF were 86.2% and 55.3%, respectively (log-rank, P = 0.33) (Figure 1).
Conclusion: Lung transplantation is an acceptable treatment for Asian patients with severe SSc-ILD. Further research is needed to determine the optimal time for referral to LT centres for patients with SSc-ILD.

Osteoporosis

OP0242

PROPORTION OF PATIENTS REACHING THE BONE MINERAL DENSITY (BMD) SURROGATE THRESHOLD EFFECT (STE) WITH BISPHOSPHONATES, DENOSUMAB AND TERIPARATIDE

Keywords: Bone diseases, Osteoporosis, Real-world evidence

G. Adami[1], D. Bertelle[1], A. Fassio[1], C. Benini[1], D. Gatti[1], O. Viapiana[1], M. Rossini[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*

Background: The bone mineral density (BMD) surrogate threshold effect (STE) is the change in BMD that can predict a fracture risk reduction with 95% certainty. The STE estimates for changes in total hip BMD have been recently validated by the FNIH-ASBMR SABRE Project.
Objectives: We evaluated the proportion of patients reaching the STEs with anti-osteoporotic medications in real-life.
Methods: We retrieved longitudinal data on women at high risk of fracture initiating an anti-osteoporotic treatment. Kaplan-Meier curves with log-rank tests were employed to analyze the proportion of patients reaching STEs over the time with various anti-osteoporotic treatments. Herein we present the proportion of patients achieving STEs for the lowest (1.8% increase in total hip BMD for all fractures, 1.4% for vertebral fractures and 3.2% for hip fractures) and highest risk reduction (5.1% increase in total hip BMD for >30% risk reduction for all fractures, 4.6% for >50% risk reduction for vertebral fractures and 5.8% for >30% risk reduction for hip fractures).
Results: Baseline and follow-up data from 1,272 women initiating an anti-osteoporotic treatment were available. 807 started bisphosphonates, 386 started denosumab and 79 started teriparatide. Median follow-up time was 2.18 years (IQR 1.47-3.87 years). In Table 1 are presented the proportion of patients reaching various STEs stratified for treatment. The Kaplan-Meier estimate curve for bisphosphonates vs denosumab vs teriparatide showing the proportion of patients reaching various STEs over the time are presented in **figure 1** (log-rank p <0.001 for teriparatide vs bisphosphonates at 2 years and denosumab vs bisphosphonates at 2, 4 and 6 years; log-rank p NS for teriparatide vs denosumab at 2 years).

Table 1. Proportion of patients increasing BMD at 24 months above STEs

Fracture risk reduction	STE (%)	Bisphosphonates	Denosumab	Teriparatide
All fractures				
Any	1.8	24.2	48.5	62.9
>30%	5.1	18.6	39.9	64.5
Vertebral Fractures				
Any	1.4	24.4	49.1	62.9
>50%	4.6	19.1	41.3	60.5
Hip Fractures				
Any	3.2	21.4	46.9	61.4
>30%	5.8	17.7	38.0	59.8

Conclusion: In the present real-life study, a smaller proportion of patients treated with bisphosphonates reached the BMD STEs at 2 years of treatment as compared to denosumab and teriparatide. Nearly all subjects reached STEs at 6 years of follow-up.

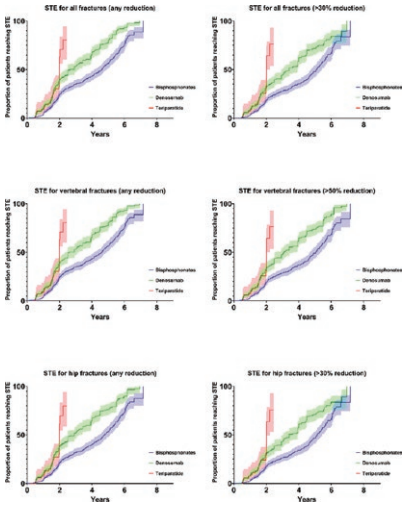

Figure 1. Kaplan-Meier estimate curve for bisphosphonates vs denosumab vs teriparatide showing the proportion of patients reaching various STEs over the time

Alexander[1], B. Muche[1], S. Hermann[1], E. Wiebe[1], F. Buttgereit[1]. *[1]Charité – Universitätsmedizin Berlin, Berlin, Germany, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[2]the Parker Institute, University of Copenhagen, Copenhagen, Denmark, Section for Biostatistics and Evidence-Based Research, Copenhagen, Denmark*; *[3]University of California San Francisco, Division of Rheumatology, San Francisco, United States of America*; *[4]University of Southern Denmark, Odense University Hospital, Research Unit of Rheumatology, Department of Clinical Research, Odense, Denmark*

Background: Patients with inflammatory rheumatic and musculoskeletal diseases (iRMDs) are at increased risk of osteoporosis and fragility fractures. For this population, the question of whether proton pump inhibitor (PPI) intake contributes to that risk has not yet been definitively answered. Prior studies have yielded conflicting results, did not account for over-the-counter use of PPI, and major confounders were unmeasured. In addition, bone microarchitecture as a potential mediator of fracture risk has not been studied.
Objectives: To assess the effect of regular PPI intake on bone mineral density (BMD) and microarchitecture in patients with iRMDs.
Methods: Cross-sectional baseline data from the single center Rh-GIOP cohort ("Glucocorticoid-induced Osteoporosis in Patients with Chronic Inflammatory Rheumatic Diseases or Psoriasis") were used. Briefly, patients with iRMDs were prospectively enrolled and assessed with DXA scans, laboratory testing, and bone-health-related questionnaires since 2015. Regular PPI and glucocorticoid (GC) use were ascertained by both chart review and patient self-report. Three co-primary outcomes (all reported as T-scores) were defined: BMD of the left femoral neck and the lumbar spine, and the trabecular bone score (TBS). The latter is a measure correlating with lumbar vertebrae's microarchitecture and is measured in a subset. Inverse probability of treatment weighting adjusted for the following confounders: age, sex, body mass index, iRMD type, C-reactive protein, current and cumulative GC dose, NSAID use, smoking, alcohol consumption, functional status (Health Assessment Questionnaire), disease duration, bisphosphonate use, chronic kidney disease stage, presence of diabetes mellitus, and frequency of exercise. We investigated whether dose-response relationships were present ("high dose" of >20mg/d vs. "low dose" of ≤20mg/d pantoprazole equivalent) and conducted an additional analysis with an interaction term for GC use. All analyses were based on linear regression models. Multiple imputation with 100 imputations was used to account for missing data (~4%). A detailed prespecified statistical analysis plan with a gatekeeping procedure for statistical testing was followed.
Results: 1,495 patients (75.3% women; mean age 62.6 ± 13.1 years; 49.2% with regular PPI use [of those: 63.1% high dose]) were included. Most patients had a diagnosis of rheumatoid arthritis (37.5%), followed by 25.3% connective tissue diseases, 16% vasculitides, 14.2% spondyloarthropathies, and 7% others. 63.8% used GCs (median dose 5mg/d). In both adjusted and unadjusted analyses, PPI users had lower BMD at both the left femoral neck and the lumbar spine (**Table 1**). Interestingly, differences between PPI users and non-users were only present in the subset of patients concurrently using GCs (data not shown). There was no statistically significant difference in BMD when comparing high and low dose PPI users (all P ≥ 0.52). TBS (n = 389) was similar in PPI users and non-users (**Table 1**).
Conclusion: Loss of BMD (seen at both lumbar spine and left femoral neck) rather than impairment of bone microarchitecture seems to be driving the increased fracture risk seen with PPI use in patients with iRMDs. The negative association between PPI use and BMD appears to be dependent on concurrent GC use.

Table 1.

	PPI use	No PPI use	Contrast	P-value
Crude (unadjusted)				
Left femoral neck	-1.24 (-1.36 to -1.13)	-1.01 (-1.12 to -0.89)	-0.24 (-0.11 to -0.37)	<0.001
Lumbar spine	-0.87 (-1.06 to -0.69)	-0.64 (-0.79 to -0.48)	-0.23 (-0.05 to 0.42)	0.01
Trabecular bone score	1.28 (1.24 to 1.31)	1.30 (1.26 to 1.33)	-0.02 (-0.06 to 0.02)	0.35
Adjusted				
Left femoral neck	-1.24 (-1.36 to -1.13)	-1.08 (-1.27 to -0.88)	-0.17 (-0.35 to 0.01)	0.07
Lumbar spine	-0.87 (-1.06 to -0.69)	-0.62 (-0.83 to -0.41)	-0.25 (-0.47 to -0.04)	0.02
Trabecular bone score	1.28 (1.24 to 1.31)	1.27 (1.24 to 1.31)	0.00 (-0.04 to 0.04)	0.97

Numbers are estimated marginal means and 95% confidence intervals.

OP0244 DISEASE SEVERITY IS ASSOCIATED WITH OSTEOPOROSIS AND FRAGILITY FRACTURES IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Bone diseases, Osteoporosis, Systemic sclerosis

C. Midol[1], E. Wiebe[2], E. Siegert[2,3], D. Huscher[4], H. Béhal[5], D. Launay[1], E. Hachulla[1], V. Sobanski[1], F. Buttgereit[2]. *[1]Univ. Lille, Inserm, CHU Lille, Service de Médecine Interne, U1286 - INFINITE - Institute for Translational Research in Inflammation, Lille, France*; *[2]Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[3]Berlin Institute of Health at Charité, Universitätsmedizin Berlin, Berlin, Germany*; *[4]Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Institute of Biometry and Clinical Epidemiology, and Berlin Institute of Health, Berlin, Germany*; *[5]Univ. Lille, CHU Lille, ULR 2694 - METRICS: Évaluation des Technologies de Santé et des Pratiques Médicales, Biostatistics Department, Lille, France*

Background: Patients with systemic sclerosis (SSc) are at an increased risk for osteoporosis (OP) and associated fragility fractures [1]. The prevalence of osteodensitometric OP has been estimated to range from 16% to 60% [2]. However, the risks factors and the mechanisms driving bone loss in patients with SSc remain elusive. The role of "general" determinants such as higher age and low body mass index (BMI) is well established (3) but their interaction with disease-specific factors is unclear. An association between OP and the cutaneous subset (diffuse or limited skin extent) (3, 4) or disease-specific antibodies (anti-centromere or anti-topoisomerase I antibodies) (5, 6) is controversial.
Objectives: Our objectives in the present study were. (i)to evaluate the prevalence of clinical OP and fragility fractures in a large population of SSc patients; (ii) and to identify potential disease-specific factors for OP in this population.
Methods: This cross-sectional study was based on two large European prospective cohorts of SSc patients with retrospective collection of bone health data. OP was defined as the presence of a T-score below -2.5 at femoral neck or lumbar spine and/or a previous major osteoporotic fracture and/or the prescription of anti-osteoporotic therapy. Long-term therapy with glucocorticoids (GCs) was

defined by a daily prednisone equivalent dose above 2.5 mg for more than 3 months. Age, female sex, BMI and treatment with proton pump inhibitors (PPIs) as predefined risk factors according to published evidence, as well as clinically relevant factors associated with a p-value <0.05 in univariable analyses, after correction for multiple comparison, were implemented into a multivariable logistic regression model.

Results: A total of 932 patients fulfilling the ACR/EULAR 2013 classification criteria were included in the study, followed prospectively in two university hospitals: Lille (n=485) and Berlin (n=447; of which 72 were patients of the Rh-GIOP prospective cohort). The two cohorts were studied separately. The prevalence of OP was 32% in Berlin and 23% in Lille (p=0.003), fragility fractures occurred in 22% and 18% respectively. Multivariable analysis in the Berlin cohort (Figure 1A) indicated that higher age (OR 1.05 [95%CI 1.03 to 1.07], p<0.001), female sex (OR 2.70 [95%CI 1.29 to 5.65], p=0.009), diffuse skin extent (OR 5.03 [95%CI 2.50 to 10.10], p<0.001), low BMI (OR 0.94 [95%CI 0.88 to 0.99], p=0.009), WHO-FC III-IV dyspnea (OR 2.06 [95%CI 1.16-3.67], p=0.014), receiving GCs (OR 1.78 [95%CI 1.10 to 3.17], p=0.026) or PPIs (OR 1.87 [95%CI 1.10 to 3.17], p=0.020) were associated with OP. In the Lille cohort, multivariable analysis (Figure 1B) confirmed the association of OP with higher age (OR 1.06 [95%CI 1.04 to 1.08], p<0.001), GCs use (OR 4.48 [95%CI 2.42 to 8.26], p<0.001), and with anti-topoisomerase I antibody positivity (OR 2.22 [95%CI 1.18 to 4.16], p=0.013).

Conclusion: Our data support a multifactorial etiopathogenesis of OP in SSc: besides common risk-factors for OP such as higher age, female sex, and BMI, several disease specific characteristics were associated with OP, such as SSc severity as reflected by diffuse skin extent and presence of antitopoisomerase I antibodies as well as severe dyspnea and SSc treatment (PPIs and GCs). These findings help to identify patients with SSc at particular risk for OP in clinical practice.

OP0245 THE EFFECTIVENESS OF AN OSTEOPOROSIS REFRACTURE PREVENTION PROGRAMME – A COMPARISON OF TWO AUSTRALIAN RURAL CENTRES USING POPULATION DATABASE LINKAGE

Keywords: Osteoporosis

P. Wong[1], A. Roberts[2], T. Ho[3], J. Thompson[4], J. Williamson5, L. Hay[6]. *[1]Westmead Hospital, Rheumatology, Westmead, Australia*; *[2]New South Wales Ministry of Health, Economics and Analysis Unit, Strategic Reform and Planning Branch, St Leonards, Australia*; *[3]New South Wales Ministry of Health, Biostatistics Training Program, St Leonards, Australia*; *[4]Agency for Clinical Innovation, Musculoskeletal Network, St Leonards, Australia*; *[2]New South Wales Ministry of Health, Economics and Analysis Unit, Strategic Reform and Planning Branch, St Leonards, Australia*; *[6]New South Wales Ministry of Health, Economics and Analysis Unit, Strategic Reform and Planning Branch, St Leonards, Australia*

Background: Despite widespread availability of effective bone protective medications and knowledge that minimal trauma fractures (MTFs) identify those at high risk of re-fracture, treatment of osteoporosis following MTF is poor. An effective way to address this gap is establishment of a fracture liaison service (FLS) where a fracture liaison coordinator coordinates case-finding and bone health management, usually in collaboration with a local medical "champion".

Objectives: To determine the effect of a Fracture Liaison Service (FLS)/Osteoporosis Refracture Prevention (ORP) programme on refracture rates.

Methods: Coffs Harbour (population 80 000) on the mid-north coast of New South Wales (NSW, Australia's most populous state), had a FLS established in July 2012. The comparator was the similar-sized city of Port Macquarie, located 160 km south which did not have an FLS established until 2019. The study population was residents aged ≥ 50 years with a fracture diagnosis recorded on admission to hospital, or on discharge without an admission record by the Emergency Department (ED) between the financial years of 2007/08 and 2017/18. Refracture rates were calculated for those with a recorded index fracture using NSW Health hospital admission and ED presentation data. Cumulative refracture rates were calculated using Kaplan–Meier methods accounting for follow-up time and deaths and adjusted for age, sex and fracture type. Trends in one- to five-year cumulative refracture rates from year of index fracture were also calculated. Annual health service utilisation associated with refracture was calculated using the total number of public hospital admissions, ED presentations and outpatient service events. Any admission or ED presentation with a fracture diagnosis occurring within 28 days of index fracture or refracture was considered part of the same episode of care.

Results: In those aged ≥50 yo, compared to "business and usual" (BAU), there was a 7% reduction in total fractures (n=6190 observed, versus n=6628 projected BAU, 95% confidence interval [95CI] 6270 - 6985; p=0.02) and a 9% reduction in total refractures (n=1709 observed, versus 1869 projected BAU, 95%CI 1768 - 1970; p=0.002) over the 7-year study period for Coffs Harbour. This reduction was

not observed in Port Macquarie or in the rest of the state of NSW. Cumulative adjusted refractures rates for Coffs Harbour were as follows: 1-year 7%, 2-years 13%, 3-years 19%, 4-years 24%, 5 years 29%. Females had higher refractures rates compared to males and having a diagnosis of osteoporosis at time of index fracture was associated with higher refractures rates.
Conclusion: An FLS/ORP programme is associated with a reduction in total fractures and refractures rates. However, refracture rates were higher in Coffs Harbour, a rural centre, compared to pooled statewide data.

OP0246 **ROMOSOZUMAB VERSUS DENOSUMAB IN HIGH-RISK PATIENTS WITH GLUCOCORTICOID-INDUCED OSTEOPOROSIS: A PILOT RANDOMIZED CONTROLLED TRIAL**

Keywords: Clinical trials, Osteoporosis, Randomized control trial

C. C. Mok[1], W. H. MA[2], K. L. Chan[1], L. Y. Ho[1], S. M. Tse[1], S. Chen[3]. *[1]Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[2]Tuen Mun Hospital, Nuclear Medicine, Hong Kong, Hong Kong (SAR)*; *[3]Queen Elizabeth Hospital, Pathology, Hong Kong, Hong Kong (SAR)*

Objectives: To compare the efficacy and safety of romozosumab (ROMO) and denosumab (DEN) in high-risk patients with glucocorticoid (GC)-induced osteoporosis (GIOP).
Methods: Design: A pilot open randomized controlled trial.
Method: Adult patients (≥18 years) who were receiving daily prednisolone dose of ≥5mg/day for ≥12 months and had moderate/high risk of osteoporotic fracture (a history of fragility fracture, DEXA T score ≤-2.5 [age ≥40 years] or Z scores ≤-3.0 [age <40 years] or high risk of 10-year major fracture estimated by FRAX) were included. Participants were given daily calcium and vitamin D and existing bisphosphonates were discontinued. Subjects were randomized by blocks to receive either ROMO (210mg SC monthly) or DEN (60mg SC every 6 months) for 12 months, followed by DEN (60mg every 6 months) for 12 more months in both arms. The primary efficacy end point was the change in bone mineral density (BMD) at the lumbar spine from baseline to month 12. Secondary end points included BMD change at the non-dominant hip and femoral neck at month 12, change in bone turnover markers, new vertebral fractures, change in BMD at the hip and spine at month 24 and adverse events.
Results: Of 70 patients recruited, 63(90%) completed the study (age 62.6±9.1 years; 96% women; 35 each assigned to ROMO or DEN). Underlying medical diseases were systemic lupus erythematosus (51%), rheumatoid arthritis (29%), inflammatory myopathies (9%) and others. The mean prednisolone dose at entry was 6.6±3.5mg/day. Osteoporosis at spine/hip/femoral neck and a history of fragility fracture was present in 34(48.6%) and 35(50%) patients, respectively. Oral bisphosphonates were being used in 33(47%) patients prior to first dose of the study drugs. While the baseline demographics and osteoporosis risk factors were not significantly different between the two groups, ROMO-treated patients had lower hip/femoral neck BMD and serum vitamin D3 levels than those treated with DEN. At month 12, a significant increase in spine BMD was observed in both the ROMO (+7.3±4.5%; p<0.001) and DEN (+2.3±3.1%; p<0.001) groups of patients. The inter-group difference in spine BMD at month 12 was statistically significant after adjustment for baseline BMD values, age, sex, osteoporosis risk factors and the cumulative prednisolone doses in 12 months (p<0.001). The corresponding increase in hip BMD were +1.6%±3.3% (p=0.01) in the ROMO group and +1.6%±2.6% (p=0.003) in the DEN group. No significant inter-group difference in hip BMD was observed after adjustment for the same confounding factors. The increase in femoral neck BMD from baseline to month 12 was not significant in both groups. In DEN-treated patients, both serum CTX (-34.7±54.8%; p=0.002) and P1NP (-35.1±43.3%; p<0.001) dropped significantly from baseline to month 12. However, in the ROMO group, a non-significant drop in CTX (-18.1±76.9%; p=0.18) but increase in P1NP (+1.7±70.3%; p=0.89) was observed. Only one new vertebral fracture developed in the ROMO group at 12m. The commonest adverse event (AE) was self-limiting injection site pain/redness, which was significantly more common in ROMO-treated patients. Post-injection musculoskeletal pain was reported in 2 and 3 patients in the ROMO and DEN group of patients, respectively. Mild hypocalcemia and hypercalcemia were observed in 2 DEN-treated patients. No serious AEs were reported. The 24m data of this study are pending.
Conclusion: Romosozumab was superior to denosumab in raising the spine BMD at month 12 in chronic GC users with high fracture risk. Both drugs were well-tolerated. Romosozumab may offer a new treatment option for GIOP in high-risk patients.

OP0249

IS PREVENTION BETTER THAN CURE? DATA FROM A MONOCENTRIC RANDOMIZED CLINICAL TRIAL TO PREVENT ACUTE PHASE REACTION RELATED TO INTRAVENOUS BISPHOSPHONATES

Keywords: Osteoporosis, Randomized control trial, Bone diseases

R. DI Taranto[1], C. Crotti[1], A. Amati[1,2], F. Zucchi[1], R. Caporali[1,2], M. Varenna[1,3]. [1]*ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy*; [2]*University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*; [3]*ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Bone Disease Unit, Milan, Italy*

Background: Acute phase reaction (APR) is a transient flu-like syndrome with fever, chills, fatigue, malaise, and musculoskeletal symptoms, often occurring 24-36 hours after intravenous bisphosphonates (IV-BPs) administration and usually resolving within 2-3 days[1]. Avoiding APR could increase patients' compliance to treatment and reduce patients' discomfort.
Objectives: In this monocentric, randomized, open-label, parallel-group study, we examined the efficacy of low dose of 6metilprednisone (6MP), paracetamol (PAR) or placebo (PBO) in reducing the incidence of APR.
Methods: We prospectively enrolled patients from March 2022 to December 2022. Patients were randomly allocated to PAR 1000 mg BID for 3 days, 6MP 4 mg BID for 3 days or PBO after IV-BPs (zoledronate (ZOL) 5 mg or neridronate (NER) 100 mg). A scale ranging from 0=absence, 1=mild, 2=moderate, and 3=severe was used to rate symptoms. Arthromyalgia (AM) included arthralgia, myalgia, arthritis, and chest pain; systemic symptoms (SS) included headache, nausea, fatigue, fever, and Health Assessment Questionnaire (HAQ). AM, CS, fever and HAQ were assessed at baseline and at day 4. APR was defined as the worsening of >2 points in AM, CS score, fever (>37.5°), and/or the worsening of 22% or increase of 0.25 in HAQ score[2]. Comparisons were performed by T test and chi-square test. Logistic regression was used to analyze protective and predictive factors for APR occurrence. All patients have signed informed consent.
Results: Ninety-five patients were enrolled: mean age±standard deviation (SD) was 57.0±14.6 yrs, mean BMI±SD was 24.51±4.1, 69.5% females, 70.5% menopausal women, 10.5% had previous exposure to oral BPs. Fourteen patients were under chronic treatment with statins. Patients were treated with BPs for osteoporosis (n=16; 17%), Paget's disease of bone (n=5; 5%) and complex regional pain syndrome type 1 (n=74; 78%). 29 patients were allocated in 6MP arm, 29 in the PAR arm and 37 in the PBO arm. The incidence rates of AM and SS in ZOL were 46.7% and 60%, respectively. The incidence rate of AM and SS in NER were 38.8% and 21.4%, respectively. 6MP prophylaxis significantly reduced the incidence of AM (p=0.03) and HAQ worsening of 22% or increase of 0.25 (p=0.01 and p=0.05, respectively), but did not prevent the incidence of SS (p=0.23). PAR and PBO did not modify the incidence of AM, SS, and worsening of HAQ. Chronic use of statins prevented incidence of AM and worsening of HAQ (p=0.029 and p=0.015, respectively) but did not impact SS score. Previous therapy with oral BPs did not prevent APR. Among protective variables for the incidence of AM were recognized older age (OR 0,95, CI 1.01-1.11, p=0.02) and 6MP prophylaxis (OR 5.0, CI 1.79-22.97, p=0.03). Concomitant statins, previous exposure to oral BPs, 25OH vitamin D3 (25OHD3) serum levels or 25OHD3 ongoing supplementation did not prevent APR. Higher BMI (OR 1.32, CI 1.07-1.65, p=0.01) and treatment with ZOL (OR 31.6, CI 2.3-431.96, p=0.01) were predictive factors for the occurrence of fever.
Conclusion: Our data demonstrated that low dose 6MP prophylaxis is effective in preventing the most common features of APR, compared to PAR or PBO. In contrast to literature, previous exposition to oral BPs, normal 25OHD3 serum levels or 25OHD3 supplementation did not have impact on the occurrence of APR.

A PHASE II PROSPECTIVE TRIAL OF AZACITIDINE IN STEROID-DEPENDENT OR REFRACTORY SYSTEMIC AUTOIMMUNE/INFLAMMATORY DISORDERS AND VEXAS SYNDROME ASSOCIATED WITH MDS AND CMML

Keywords: Vasculitis, Treat to target, Randomized control trial

A. Mekinian[1,1], P. Fenaux[2,2]. [1]*Sorbonne University, Internal Medicine, Paris, France*; [2]*Saint Antoine, Internal Medicine, Paris, France*

Background: Systemic autoimmune and inflammatory disorders (SAID) are underestimated, and potentially life-threatening complications observed in 15-25% of myelodysplastic neoplasms (MDS) and chronic myelomonocytic leukemia (CMML), although pathophysiological links between both types of disorders remain uncertain. In 2020, Beck *et al.* described VEXAS (Vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome (OMIM #301054, defined by the presence of *UBA1* mutations, in patients with severe systemic inflammation, chronic fever, 30% of whom had concurrent MDS. VEXAS is typically associated with refractoriness to conventional immunosuppressive therapies (IST) and dismal prognosis, and prospectively evaluated effective treatment strategies remain to be established. In MDS/CMML patients with concomitant SAID, but no *UBA1* mutation, we and others observed a high incidence of mutations of the epigenetic regulators *TET2* and *IDH1/2*, whose presence correlated with defects in adaptive T lymphocyte homeostasis.
Objectives: This led us to launch a prospective phase II trial of AZA in patients with MDS/CMML and steroid dependent/refractory SAID.
Methods: This prospective open-label, single-arm multicenter, phase II study trial (ClinicalTrials.gov identifier: NCT02985190) was sponsored by the Groupe Francophone des Myélodysplasies (GFM, French MDS group). Celgene Corporation supplied the study drug but did not contribute to data collection or analysis. Eligible criteria were: (1) age ≥18 years (2) revised IPSS (IPSS-R) intermediate

2 or high, or IPSS-R low or intermediate-1 with significant cytopenia (i.e., transfusion dependent anemia resistant to erythropoietin-stimulating agents and/or platelets below 30 G/L or below 50 G/L with bleeding, and/or ANC < 0.5 G/l with infectious complications), (3) SAID defined according to usual international criteria for each SAID (all cases were centrally reviewed by expert internists AM and VJ) (4) steroid resistance or dependence of SAID, defined as the inability to decrease the dose of steroids below 15 mg/day during at least 2 months.

Results: Thirty patients were included between July 2017 and June 2020 in 18 centers, 29 of whom received at least one cycle of AZA and were considered evaluable. Twelve of the 29 patients (41%) were retrospectively found positive for *UBA1* mutation (VEXAS syndrome), while in the remaining cases SAID included inflammatory arthritis (n=6) (rheumatoid arthritis (n=3), undifferentiated (n=2) and psoriasis arthritis (n=1)), unclassified vasculitis (n=3), neutrophilic dermatosis (n=3), unclassified SAID (n=2), systemic lupus erythematosus (SLE), relapsing scleritis and immune thrombocytopenia in one case each. After 6 cycles, 19 patients (66%) had obtained SAID response (including 8 CR and 11 PR), while 10 SAID remained stable and none had progressed. The daily dose of steroids decreased from a median of 50 mg/day (95% CI [40-71]) at AZA onset to 15 mg/day (95% CI [13-31]) (p<0.0001) and 10 mg/day (95% CI [5-10]) (p<0.0001) of prednisone equivalent after 3 and 6 cycles respectively. Median steroid daily dose was lower in SAID responders compared to non-responders after 3 (15 mg/day [12-25] versus 50 mg/day [46-60], p=0.04) and 6 (8 [4-10] versus 33 [21-35], p=0.05) cycles of AZA. Median steroid daily dose did not decrease after 6 cycles of AZA.

Conclusion: Thus, in this prospective trial, 66% of MDS/CMML patients with SAID obtained SAID complete or partial response after 6 cycles of AZA. We observed an important and sustained steroid-sparing effect of AZA, with reduction to a median dose below 10 mg/day of prednisone equivalent after 6 cycles. AZA also yielded hematological response in 59% of the patients, and 88% of hematological responders had concomitant SAID response.

OP0251 CLINICAL FEATURES AND TREATMENT-RELATED OUTCOMES OF IGG4-RELATED DISEASE FROM A LARGE EUROPEAN STUDY COHORT

Keywords: Gastrointestinal tract, Rare/orphan diseases, Geographical differences

Background: IgG4-related disease is an increasingly recognized systemic fibro-inflammatory disorder involving almost any organ system. Most available data on treatment strategies and natural history of IgG4-RD are currently derived from large cohorts from the United States and Asian Countries. Real-life studies addressing the epidemiology, clinical manifestations, and treatment strategies of IgG4-RD in Europe are limited to smaller cohorts from single center experiences.

Objectives: To characterize the epidemiology, clinical manifestations, and response to treatment of IgG4-RD patients in Europe.

Methods: A pan-European registry (PrescrAIP) was set in place to retrospectively analyse adults diagnosed with IgG4-RD from 2005 and 2020 in 42 European university hospitals. Comprehensive diagnostic criteria and organ-specific criteria were used to diagnose IgG4-RD and central validation was applied. Data on disease epidemiology, clinical characteristics, treatment, and outcomes were retrospectively collected from the hospitals' medical records using a REDCap-based electronic case record form. The IgG4-RD responder index was used to assess response to therapy. Predictors of relapse were identified using multivariable logistic regression analysis after correcting for confounders.

Results: 1079 individuals with suspected IgG4-RD were screened but only 735 were diagnosed with IgG4-RD and considered for analysis (69% male; median age 57years; 85% Caucasian). 45% of patients had multiorgan (>=2) involvement (Table 1). Pancreas, salivary glands, and biliary tree were the most frequently involved organs. Steroid-treatment was started in 634 patients; 9 (1%) were lost to follow-up; 79% (496/625) had a complete response, 18% (111/625) had a partial response, and 3% (18/625) did not respond. 95 patients were not treated; 61% (58/95) had spontaneous complete response, 19% (18/95) had partial response, and 10% (9/95) did not respond. Higher daily steroid dose (>0.4mg/kg prednisone equivalent) was as effective as lower dose (<0.4mg/kg) (OR 0.428; 95%CI 0.054-3.387) for inducing disease response. Similarly, longer induction of remission treatment (> 2 weeks) was as effective as shorter therapy (<2 weeks) (OR 0.908; 95%CI 0.818-1.009). Elevated IgG4 levels were independently associated with a decreased chance of complete response (OR 0.639; 95%CI 0.427-0.955). Relapse occurred in 30% of patients. Relapse within 6 months of remission induction were independent of the steroid tapering duration, induction treatment duration, and total cumulative dose. Parenchymal enlargement (OR 0.390, 95%CI 0.167-0.910) and addition of maintenance therapy with immunosuppressive agents were independently associated with fewer relapses at 6 months (OR 0.299, 95%CI 0.120-0.740). No difference between maintenance therapy with glucocorticoids and rituximab was observed in maintaining disease response.

Conclusion: This is the first pan-European study addressing the epidemiological and clinical features of IgG4-RD in Europe. Our study indicates that patients with elevated IgG4 level may need closer monitoring during remission induction and that 0.4mg/kg/day of prednisone equivalent for at least 2 weeks represents the most effective strategy to induce IgG4-RD remission.

Background: CAPS (Cryopyrin-associated periodic fever syndromes) are monogenic autoinflammatory diseases causing great burden to patients due to severe systemic and organ inflammation caused by increased production of interleukin-1β (IL-1β). In clinical trials as well as in real-life, the monoclonal antibody canakinumab (CAN) effectively inhibits IL-1β and results in rapid suppression of CAPS symptoms.

Objectives: The RELIANCE registry explores long-term safety and effectiveness of CAN under routine clinical practice conditions in pediatric (≥2 years) and adult patients with CAPS, including Muckle-Wells syndrome (MWS), familial cold autoinflammatory syndrome (FCAS) and neonatal onset multisystem inflammatory disease (NOMID)/chronic infantile neurological cutaneous and articular syndrome (CINCA).

Methods: This prospective, non-interventional, observational study enrolls patients with clinically confirmed diagnoses of CAPS routinely receiving CAN. Clinical data, physician assessments and patient-reported outcomes are evaluated in 6-monthly intervals.

Results: 107 CAPS patients (53% female; 16% NOMID/CINCA subtypes) were enrolled by December 2022. At baseline, median age was 23 years and median duration of prior CAN treatment was 6 years. 92% of patients received greater than standard dose CAN. 75% of the patients were in disease remission at month 48 by physician assessment. Patients report stable low level disease activity (median 2.0 at baseline and 1.5 at month 48) and fatigue (median 3.0 at baseline and 1.0 at month 48). No relevant differences regarding subtype severity were observed (**Table 1**). At baseline vs. month 48, 46% vs. 50% of patients experienced impairment of social life and 32% vs. 25% reported days off from school or work due to the disease. Severe adverse events (SAE) suspected to be drug-related were reported for N=9 (8.4%) CAPS patients. The incidence rate (IR) per 100 patient-years kept stable over time.

Conclusion: The 48-month interim analysis of the RELIANCE registry demonstrates that long-term CAN treatment is safe and effective in patients with CAPS, independent of subtype severity.

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare, life-threatening, hyperinflammatory syndrome caused by overproduction of proinflammatory cytokines, e.g., interferon gamma (IFNγ).[1,2] Secondary HLH (sHLH) occurs in the context of an underlying disease (e.g., rheumatologic, malignancy, or iatrogenic) and/or an infectious trigger.[1,2] Emapalumab is a fully human anti-IFNγ monoclonal antibody that binds to and neutralizes the biological activity of IFNγ. It was approved by the FDA in 2018 for adults and children with primary HLH with refractory, recurrent, or progressive disease, or intolerance to conventional HLH therapy. Since its approval, real-world evidence on the use of emapalumab in routine clinical setting is limited.[3-5] The REAL-HLH study assessed real-world treatment patterns among patients treated with emapalumab.
Objectives: To describe the demographics, clinical characteristics, and treatment patterns among the subset of patients with physician-reported diagnosis of sHLH treated with emapalumab.
Methods: A retrospective medical chart review conducted across 33 US hospitals identified patients treated with ≥1 dose of emapalumab between November 20, 2018, and October 31, 2021. Data on the subset of patients with sHLH extracted from time of emapalumab initiation to end of data availability, death, or study end (December 31, 2021) are presented.
Results: Overall, 57/105 (54.3%) enrolled patients had a physician-reported diagnosis of sHLH (mean age [± SD] 10.4 [7.6] years). Majority of patients were non-White (63.2%) and male (52.6%). At diagnosis, mean age (±SD) was 9.3 (7.5) years and 15/17 (88.2%) patients with available data met ≥5 of 8 HLH-2004 diagnostic criteria. Underlying disease and/or triggers were identified in 53/57 (92.9%) patients; 22/53 (41.5%) had a single trigger and 31/53 (58.5%) had multiple triggers. Infections (32/53; 60.4%), malignancy (18/53; 34%), rheumatologic disease (11/53; 20.8%), and iatrogenic (6/53; 11.3%) were the most common triggers. Epstein-Barr virus (11/25; 44%) was the most common viral (25/32; 78.1%) infection. At time of emapalumab initiation, 73.7% of patients had received prior treatments with other HLH-related therapies, including corticosteroids, and 62.5% of patients were in the intensive care unit. Emapalumab was mainly initiated for treatment of refractory (42.1%), progressive (29.8%), and recurrent (14%) disease. The median (range) time to emapalumab initiation from diagnosis was 16.5 (1-2278) days. Median (range) treatment duration with emapalumab was 38.0 (1-397) days. Median (range) emapalumab starting dose was 1.1 (0.7-5.9) mg/kg and cumulative treatment dose was 21.3 (1-336.5) mg/kg. Median (range) maximum administered emapalumab dose was 2.3 (0.7-12.5) mg/kg.
Conclusion: This is the first study to report real-world treatment patterns with emapalumab across a diverse patient population with sHLH. A pivotal clinical trial of emapalumab in patients with sHLH and underlying rheumatologic disease is ongoing (NCT05001737).

Background: COPA syndrome is a recently described monogenic autoimmune disease due to heterozygous mutations in *COPA*. COPA syndrome demonstrates considerable phenotypic overlap with SAVI (STING-associated vasculopathy with onset in infancy) due to gain-of-function mutations in STING. Interestingly, while both disorders are characterised by enhanced type I interferon signalling, neither disease is associated with systemic lupus erythematosus (SLE) – challenging classical dogma linking interferon upregulation and lupus.
Objectives: Our aim was to gather a European cohort of COPA patients to better delineate the clinical phenotype of this rare monogenic disorder.
Methods: Assessment of clinical, radiological, immunological and therapeutic data from 27 patients (13 families) with molecularly confirmed COPA syndrome.
Results: Twenty-seven individuals with pathogenic COPA mutations were included. Among them, 20 patients presented with at least one clinical manifestation evocative of COPA syndrome (clinical penetrance of 74.1%). Symptomatic patients were female in 13 (65%) cases with a median age at disease onset of 4 years (0-50). All COPA mutations were inherited in an autosomal dominant pattern except for one that occurred *de novo*. Pulmonary involvement was observed in 16 (80%) patients, with interstitial lung disease (ILD) in most cases (n=13, 65%), diffuse alveolar haemorrhage (DAH) in 5 (25%) individuals and the association of ILD and DAH in 3 (15%) patients. Twelve (60%) patients demonstrated joint involvement of variable severity: 4 (20%) individuals experiencing deforming arthritis including one requiring bilateral knee arthroplasty, 6 (30%) patients had polyarticular arthritis and two (10%) patients presented with isolated arthralgias. Renal disease was observed in three (15%) individuals, manifest as either proliferative glomerulonephritis (n=2) or membranous glomerulonephritis (n=1). Previously undescribed features were noted i.e. cutaneous involvement - acral ulcers, vitiligo and nasal perforation (n=3, 15%), cardiac disease (n=2, 10%), gastrointestinal dysfunction (n=2, 10%), and cytolytic hepatitis (n=1). When tested, 14 (93.9%) patients had positive autoantibodies. When assessed, immunophenotyping showed a mild T-cell lymphopenia, with an excess of naive T CD8+ cells and a defect of memory T CD8+ cells recorded in one patient. All patients explored exhibited elevated IFN alpha protein levels and high IFN signature scores. The IFN signature was mildly positive in half of the clinically asymptomatic individuals assessed. The majority (60%) of patients were treated with corticosteroids and immunosuppressants, ten (50%) received biotherapies and eight (40%) patients are currently under JAK1/2 inhibition.
Conclusion: We report the first European cohort of COPA patients. While confirming the core organ features (lung, joint and kidney) of COPA syndrome, our data expand the phenotype to include cardiac, skin and digestive features, further

demonstrating the clinical overlap with SAVI and other type I interferonopathies, while also highlighting the possibility of isolated organ involvement. We confirm a high level of clinical non-penetrance, which can present a diagnostic challenge and indicates the need to better understand the underlying pathophysiology. In view of current (JAK inhibitors) and potential future targeted therapies, we suggest a requirement to assess IFN pathway status and/or perform sequencing in the case of suggestive features, even in the absence of a familial history.

Bakland[9], A. M. Hoffmann-Vold[6]. *[1]University of Bergen, Clinical Science, Bergen, Norway*; *[2]Stavanger University Hospital, Rheumatology, Stavanger, Norway*; *[3]Oslo University Hospital, Rheumatology, Oslo, Norway*; *[4]University of Oslo, Clinical Medicine, Oslo, Norway*; *[5]Haukeland University Hospital, Rheumatology, Bergen, Norway*; *[6]Oslo University Hospital, Radiology and nuclear medicine, Oslo, Norway*; *[7]St. Olav University Hospital, Rheumatology, Trondheim, Norway*; *[8]Norwegian University of Science and Technology, Neuromedicine and Movement Science, Trondheim, Norway*; *[9]University Hospital of North Norway, Rheumatology, Tromsø, Norway*

Background: The IgG4-related disease (IgG4-RD) responder index (RI) is a validated tool to assess disease activity in IgG4-RD [1]. The RI reflects symptoms attributable to active IgG4-RD as well as relevant findings from the physical examination, imaging and laboratory evaluations, with higher scores reflecting more active disease. Multiorgan involvement and higher RI scores were identified as risk factors for relapse [2], indicating a need for more aggressive treatment. Whole-body ^{18}F-FDG PET/CT is a sensitive technique for detecting foci of active inflammation, but its use is limited by cost and availability. Furthermore, whether ^{18}F-FDG PET/CT detects additional organ manifestations which influence RI and treatment decisions, is largely unknown.

Objectives: To compare performance of a pure clinical RI model (c-RI) and a c-RI with addition of ^{18}F-FDG PET/CT (c-PET-RI) in a well-characterized Norwegian IgG4-RD cohort.

Methods: Adult patients with IgG4-RD seen at the Oslo University Hospital were included if they had performed both ^{18}F-FDG PET/CT and a comprehensive assessment by a rheumatologist within a four-week interval. In each patient, we calculated c-RI from symptoms, clinical examination, and laboratory studies, and c-PET-RI from the c-RI plus the score from pathological ^{18}F-FDG organ uptake on the whole-body PET. Both indices were calculated using data from NOSVAR research registry and electronic medical records. We defined IgG4-RD disease activity as low if RI was ≤ 3 and high if RI was > 3 points. We assessed associations of elevated CRP and serum IgG4 (s-IgG4) with reclassification (discrepancy change in disease activity scores (c-PET-RI – c-RI)) by applying logistic regression with odds ratio (OR) and 95% CI to identify patients in which performing ^{18}F-FDG PET/CT is likely to change treatment decisions.

Results: The study cohort included 53 IgG4-RD patients, of whom 30 had c-RI ≤ 3 points, consistent with low disease activity. In 15/30 patients (50%) with c-RI ≤ 3, the corresponding c-PET-RI was > 3 points, consistent with high disease activity. In these 15 patients, the mean increase in RI points from the ^{18}F-FDG PET/CT was 6.4 (range 2-12). We found that 14 of these 15 patients (93%) had elevated s-IgG4 and 6 (40%) had elevated CRP. In logistic regression analysis, elevated s-IgG4, but not CRP, was strongly associated with reclassification to high disease activity after^{18}F-FDG PET/CT (OR 16.0, 95% CI 1.7-154.6, p = 0.017). Of the 9 patients with c-RI ≤ 3 and normal s-IgG4, only one (11%) was reclassified to high disease activity after ^{18}F-FDG PET/CT.

Conclusion: In IgG4-RD patients with low disease activity by clinical and laboratory assessment (c-RI), elevated s-IgG4 is associated with detection of asymptomatic organ involvement by ^{18}F-FDG PET/CT (c-PET-RI). Hence, evaluation with ^{18}F-FDG PET/CT should be considered in patients with c-RI ≤ 3 points and elevated s-IgG4 to tailor management. In contrast, in patients with c-RI ≤ 3 points and normal s-IgG4, the added yield of ^{18}F-FDG PET/CT appears to be low.

Background: Diagnosing IgG4-related periaortitis/retroperitoneal fibrosis (IgG4-PA/RPF) is often challenging, especially in PA/RPF-limited cases, due to the difficulty in obtaining periaortic/retroperitoneal specimens. In addition to the Japanese diagnostic criteria for IgG4-PA/RPF [1], the 2019 American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) classification criteria for IgG4-related disease (IgG4-RD) [2] have not been validated for IgG4-PA/RPF diagnosis in daily clinical practice.

Objectives: This study aimed to validate the ACR/EULAR classification criteria and the Japanese organ-specific diagnostic criteria in a Japanese cohort of patients with IgG4-related PA/RPF.

Methods: In this nationwide multicenter study, we retrospectively reviewed the medical records of 110 patients with IgG4-PA/RPF and 79 non-IgG4-RD patients (mimickers) diagnosed by experts. Using the collected data, we calculated sensitivity and specificity in both the ACR/EULAR classification criteria and the Japanese diagnostic criteria. To clarify the characteristics of false-negative cases of IgG4-PA/RPF, we compared the clinical features between the false-negative and true-positive cases.

Results: Patients with IgG4-PA/RPF and mimickers had a median age of 70 and 71 years, and were 90% and 68% male, respectively. The final diagnoses of mimickers mainly consisted of non-IgG4-related idiopathic PA/RPF, lymphoma, Takayasu arteritis, giant cell arteritis, and atherosclerotic or infectious aortic aneurysm. The ACR/EULAR classification criteria had a sensitivity of 52% and a specificity of 95%. Of the 53 false-negative cases, 13 did not fulfill the entry criteria, 13 fulfilled one exclusion criterion, and 36 did not achieve sufficient inclusion criteria scores. Compared with the true-positive cases, the false-negative cases had significantly lower serum IgG4, IgG, and IgE levels, higher serum C3 and C4 levels, and lower prevalence of extra-vascular/retroperitoneal lesions; frequency of periaortic/retroperitoneal biopsies (36% vs 37%), frequency of storiform fibrosis and obliterative phlebitis in the obtained specimens, and numbers of infiltrating IgG4-positive cells were similar between the false-negative and true-positive cases. The Japanese diagnostic criteria for IgG4-PA/RPF had a sensitivity of 63% and a specificity of 99% when definite and probable diagnoses in the diagnostic criteria were regarded as a diagnosis of IgG4-PA/RPF (a strict version). When definite, probable, and possible diagnoses were regarded as a diagnosis of IgG4-PA/RPF (a lenient version), the diagnostic criteria had a sensitivity of 95% and a specificity of 90%.

Conclusion: The present study suggests that the 2019 ACR/EULAR classification criteria for IgG4-RD and a strict version of the Japanese diagnostic criteria for IgG4-PA/RPF have an excellent diagnostic specificity in daily clinical practice. A lenient version of the Japanese diagnostic criteria serves as more sensitive criteria, although care should be taken to avoid misdiagnoses for mimickers due to the relatively low specificity.

OP0257 CANAKINUMAB IN THE TREATMENT OF ADULT-ONSET STILL'S DISEASE: LONG TERM DATA FROM A MONOCENTRIC COHORT

Keywords: Innate immunity, bDMARD

N. Farina[1], C. Campochiaro[1], A. Tomelleri[1], G. De Luca[1], E. Baldissera[1], L. Dagna[1]. [1]*IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: Adult-onset Still's disease (AOSD) is a rare autoinflammatory disease whose clinical spectrum encompasses protean and potentially life-threatening manifestations. While glucocorticoids represent the mainstay of the treatment of patients with AOSD, no guidelines are available to guide the approach to refractory patients. Canakinumab – a monoclonal antibody targeting interleukin 1β – has been increasingly used in this scenario with promising results, though long-term efficacy data are scant.

Objectives: To evaluate the efficacy and long-term persistency of canakinumab in patients with AOSD.

Methods: We retrospectively identified patients with AOSD followed-up at our Center who were treated with canakinumab for at least 12 months. Data about demographics, disease features, and treatment history were then collected. The therapeutic efficacy of canakinumab was evaluated on the basis of the modifications of glucocorticoid doses, *Pouchot scores,* C-reactive protein, and ferritin levels during the treatment course. Finally, the drug retention rate of canakinumab at 24 months was obtained.

Results: In our cohort, we identified 25 patients with AOSD treated with canakinumab for at least 12 months. Median age at disease onset was 35 (IQR 25-56) years and median follow-up duration was 24 (IQR 12-41) months. Clinical features of the study population are shown in **Table 1**. The most frequent reason (21 [84%] patients) for the start of IL-1β inhibition was a persistent disease activity. Canakinumab led to remission in all but two patients and, overall, was associated with a significant reduction in glucocorticoid doses, *Pouchot scores*, C-reactive protein and ferritin levels (**Figure 1**). The overall retention rate at 24 months was 93% and no adverse reactions to canakinumab were reported.

Conclusion: Our study confirms – in one of the largest monocentric cohorts described to date – that canakinumab is highly effective in patients with AOSD. Canakinumab was associated with a significant clinical and biochemical improvement in most patients from our cohort and was characterized by a very high long-term retention rate.

New insights form epidemiology and public health

OP0258 RISK OF INCIDENT GOUT ASSOCIATED WITH INITIATION OF SODIUM-GLUCOSE COTRANSPORTER-2 INHIBITORS VERSUS OTHER SECOND-LINE AGENTS AMONG METFORMIN USERS WITH TYPE 2 DIABETES

Keywords: Gout, Epidemiology

C. Yokose[1,2], N. Mccormick[1,2,3], L. Lu[3], J. Wei[4], Y. Zhang[1,2], H. Choi[1,2,3]. *[1]Massachusetts General Hospital, Clinical Epidemiology Program, Boston, United States of America*; *[2]Harvard Medical School, Medicine, Boston, United States of America*; *[3]Arthritis Research Canada, n/a, Vancouver, Canada*; *[4]Xiangya Hospital, Health Management Center, Shan Nan Shi, China*

Background: Sodium-Glucose Cotransporter Type 2 Inhibitors (SGLT2i) are a revolutionary second-line treatment for type 2 diabetes associated with lower risk of cardiovascular and all-cause mortality, heart failure, and chronic kidney disease progression. Many trials have also found SGLT2i lower serum urate levels. However, data on gout risk are limited and the few available prior studies were not specific to those using metformin, the primary target populations of recent landmark trials like GRADE.

Objectives: To emulate recent clinical trials and compare incident gout risk among metformin-treated patients with type 2 diabetes initiating SGLT2i versus second-line type 2 diabetes treatments (glucagon-like peptide-1 receptor agonist [GLP1RA], dipeptidyl peptidase 4 inhibitors [DPP4i] or sulfonylureas).

Methods: We performed a new user, active comparator, population-based cohort study using administrative health data for nearly all residents of British Columbia, Canada from Jan 2014 to June 2022, including all dispensed prescriptions, regardless of funder. A cohort of adults with type 2 diabetes using metformin (first-line therapy) was identified from ICD codes and dispensing data. Primary outcome was incident gout, defined as inpatient or outpatient diagnosis of gout plus dispensing of a gout medication within 14 days, and no prior recorded gout diagnosis. We also stratified by sex, age, and baseline diuretic use. Cox proportional hazards models were used with propensity score overlap weighting. To evaluate reproducibility and for spurious associations, we also assessed for risk of genital infection (for which we expected SGLT2i would have a positive association), and for the risk of any osteoarthritis encounter, a negative control outcome for which we expected a null association.

Results: Hazard ratio (HR) for incident gout associated with SGLT2i initiation was 0.54 (95% CI: 0.39, 0.74) vs. DPP-4i (among n=27,791 type 2 diabetes patients), 0.39 (0.24, 0.62) for SGLT2i vs. GLP1RA initiation (n=19,875 patients), and 0.61 (0.46, 0.80) for SGLT2i vs. sulfonylurea initiation (n=71,625 patients) (**Table 1**). Results were consistent regardless of sex or age or baseline diuretic use. For control outcomes, SGLT2i initiators had higher risk of genital infection, as expected, while there was no difference in risk of osteoarthritis (**Table 1**).

Conclusion: SGLT2i initiation among metformin-treated patients with type 2 diabetes was associated with substantially lower risk of incident gout (i.e., primary prevention), compared with initiation of any other second-line options. Along with its known urate-lowering, as well as cardiovascular and survival benefits, SGLT2i could reduce risk of incident gout substantially for diabetes patients who need second-line agent after metformin.

OP0259 WHITE MATTER HYPERINTENSITY VOLUME IN UK BIOBANK PATIENTS WITH RHEUMATOID ARTHRITIS AND ULCERATIVE COLITIS

Keywords: Imaging, Rheumatoid arthritis, Epidemiology

J. Cox[1], M. De Groot[2], J. Cole[3], S. Williams[1]. *[1]King's College London, Centre for Neuroimaging Sciences, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom*; *[2]GSK - Stevenage, GlaxoSmithKline Research and Development, Stevenage, United Kingdom*; *[3]University College London, Centre for Medical Image Computing, Department of Computer Science, London, United Kingdom*

Background: Rheumatoid arthritis (RA) and ulcerative colitis (UC) both result in higher levels of systemic inflammation and represent a significantly higher risk of cerebrovascular disease. The presence of this systemic inflammation has been linked to central nervous system effects and both diseases have increased rates of fatigue, brain fog and depression. Additionally, systemic inflammation has been implicated in decreasing the integrity of the blood brain barrier and potentially resulting in further involvement of the central nervous system in autoimmune diseases.

Objectives: The increased presence of white matter hyperintensities (WMH) has been proposed as a potential link to the central symptoms reported and the increased prevalence of cerebrovascular accidents in these diseases [1]. The present study aimed to analyse total volume of WMH in patients with RA and UC as compared to matched controls.

Methods: Data from 1,968 individuals in the UK Biobank Imaging sub-study were included in the present study [2]. This was divided into two separate patient populations with separate control groups matched to each in a 1:3 patient:control ratio. Data from 252 individuals (mean age ± SD =65.52 ± 7.03, 71.4% females) were included in the RA patient group with 756 age and sex matched controls (mean age ± SD = 65.52 ± 7.02, 71.4% females). Data from 240 individuals (mean age ± SD = 63.98 ± 7.06, 50.8% females) were included in the UC patient group with 720 age and sex matched controls (mean age ± SD = 63.98 ± 7.05, 50.8% females). This study utilised the total volume of WMH acquired using an automated segmentation approach called BIANCA and provided directly by the UKBiobank. Volumes were taken as a ratio of total brain volume and log transformed prior to a linear model regression being performed. Two separate models were run. One with age, sex, and ICV as covariates and a second model additionally including hypertension.

Results: We observed significantly larger total WMH volume in RA patients when compared to controls in model 1 (difference in WMH volume: 2286.0 mm^3, SD ±84.5, p = 2.0e-08). The Cohen's effect size was *d* = 0.36 [95% CI 0.21, 0.5]. This effect was still substantial even with hypertension added as a covariate in model 2 (p = 3.7e-06). There was also a smaller, but still significant difference seen in UC patients compared to controls (difference in WMH volume: 237.1 mm^3, SD ±82.1, p = 0.003). The Cohen's effect size was *d* = 0.19 [95% CI 0.04, 0.33]. As with the RA population hypertension is a strong contributing factor, however, the p value was still significant in model 2 (p = 0.03).

Conclusion: This is evidence that there is a cerebrovascular component to these diseases and that people with higher WMH burden may be at a higher risk of developing neurocognitive sequalae as part the disease. Further analysis of spatial mapping of WMH could provide further context for whether there are different patterns or distributions between RA and UC which could contribute to different central nervous system symptoms or cerebrovascular health risk factors.

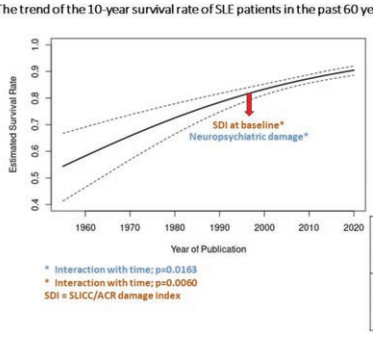
OP0260 GLOBAL TREND OF THE SURVIVAL OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS BETWEEN THE 1950S TO 2020

Keywords: Organ damage, Epidemiology, Systemic lupus erythematosus

T. Lim[1], S. Angkodjojo[2], M. Cheung[3], A. Mak[1]. [1]*National University of Singapore, Medicine, Singapore, Singapore*; [2]*Sengkang General Hospital, General Medicine, Rheumatology & Immunology, Singapore, Singapore*; [3]*National University of Singapore, Psychology, Singapore, Singapore*



Background: The trend of, and the impact of major organ damage on the short- and longer-term survival of patients with systemic lupus erythematosus (SLE) globally over the past 60 years have not been systematically studied by meta-analyses, particularly regarding the impact of the interaction between time and major organ damage on the trend of the survival of patients with SLE.

Objectives: To study the trend of, and the impact of major organ damage and demographically relevant factors on the short (5-year) and longer-term (10-, 15- and 20-year) survival rates of patients with SLE in the past 60 years by random-effects meta-analyses and meta-regression. The meta-analytical method that examines the impact of the interaction between time in terms of year of publication and major organ damage on the trend of the overall survival rates of SLE patients was employed.

Methods: Observational studies that were written in English and reported the survival rates of patients with SLE published between the 1950 and 2021 were searched, identified and extracted from PubMed and EmBase. Studies which only reported survival rates shorter than 5 years were excluded. The effect sizes of the overall 5-, 10-, 15- and 20-year survival rates and their respective trends over time of patients with SLE were determined by random-effects meta-analyses. Meta-regression analyses were conducted to investigate the impact of covariates, including the interaction between the year of publication (time) and factors including major organ damage that comprised cardiovascular, renal, neuropsychiatric and musculoskeletal damage, proportion of female SLE patients in respective studies and regions (including Asia, Europe, Middle East, North America, South America, Oceania and others) where the studies were conducted.

Results: In total, 281 observational studies that were published between 1955 and 2020 were identified and eligible for analyses. The overall 5- and 10-year survival rates of SLE patients increased from 71.82% to 94.27%, and from 58.23% to 90.44%, respectively, from 1960 to 2020. The overall 15-year survival rate of SLE patients increased from 64.36% in the 1980s to 85.00% in 2020, while that of 20-year survival rate increased from 58.82% to 84.02% from 1990 to 2020. The impact of the following interactions with the year of publication (time) on survival increased yearly with statistical significance in the meta-regression analyses. These covariates included the effect of cardiovascular damage on the 5-year survival rate (β=0.0092, SE=0.0045, p=0.0406), SLICC/ACR damage index score at baseline on the 10-year survival rate (β=0.6116, SE=0.2227, p=0.0060), neuropsychiatric damage on both the 5-year (β=0.0048, SE=0.0020, p=0.0163) and 10-year (β=0.0041, SE=0.0019, p=0.0279) survival rates (Figure 1). In addition, the interaction between the proportion of female SLE patients and the year of publication had significant impact on both the 5-year (β=0.0014, SE=0.0006, p=0.0216) and 10-year survival rates (β=0.0014, SE=0.06 p=0.0255). Analyses of the interactions between the time of publication and regions where studies were conducted did not reveal significant impact of their interactions on the short- and longer-term survival in patients with SLE.

Conclusion: Both the short- and longer-term survival of patients with SLE have been increasing steadily from the 1950s to 2020. While cardiovascular damage impacted significantly the 5-year survival rate, neuropsychiatric and overall SLE disease damage at baseline with their interactions with time, exerted a significant impact on the 10-year survival rate of patients with SLE since the 1950s. Although the 15- and 20-year survival rates of SLE patients have been promisingly increasing, more studies are required to further address the determinants of these longer-term survival rates. The impact of sex difference with its interaction with time on the survival of SLE patients require more focused and mechanistic studies.

Year	Predicted 10-year survival	95% CI	
1960	0.58	0.47	0.69
1970	0.66	0.57	0.74
1980	0.73	0.66	0.78
1990	0.78	0.75	0.81
2000	0.83	0.81	0.85
2010	0.87	0.86	0.89
2020	0.90	0.87	0.92
Predicted 15-year survival (an overall aggregate from 1980-2020)	0.80	0.76	0.83
Predicted 20-year survival (an overall aggregate from 1990-2020)	0.79	0.74	0.83

OP0261 THE NATURAL SEQUENCE IN WHICH SUBCLINICALLY INFLAMED JOINT TISSUES PROGRESS TO CLINICAL ARTHRITIS OR SUBSIDE; A STUDY ON SERIAL MRIS IN THE PLACEBO-ARM OF THE TREAT EARLIER TRIAL

Keywords: Synovium, Imaging, Rheumatoid arthritis

D. Krijbolder[1], X. Matthijssen[1], Q. Dumoulin[1], B. Van Dijk[1], H. W. Van Steenbergen[1], D. Boeters[1], A. Willemze[2], A. Schouffoer[3], A. Van der Helm – van Mil[1,4]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Maasstad Hospital, Rheumatology, Rotterdam, Netherlands*; [3]*Haga Hospital, Rheumatology, Den Haag, Netherlands*; [4]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*

Background: Clinical arthritis is the hallmark of rheumatoid arthritis (RA), yet the trajectory in which arthritis develops at tissue-level remains elusive.

Objectives: We hypothesized that subclinical inflammation in different joint tissues (synovitis, tenosynovitis and osteitis) increases in a distinct temporal order in clinically suspect arthralgia (CSA) patients who develop RA, and subsides in a different sequence when CSA spontaneously resolves.

Methods: 185 serial MRIs from CSA-patients with subclinical joint inflammation from the placebo-arm of the TREAT EARLIER trial were studied: 52 MRIs from 21 RA-progressors (performed 1-year and 4-months before and upon RA-development) and 133 MRIs from 35 patients with spontaneous resolution of pain (MRIs at baseline, 4, 12 and 24 months). MRIs were scored for osteitis, synovitis and tenosynovitis. Cross-lagged models evaluated two types of time-patterns between pairs of inflamed tissues: a simultaneous pattern (coinciding change) and a subsequent pattern (inflammatory change in one tissue preceding change in another tissue).

Results: During RA-development, synovitis, tenosynovitis and osteitis increased simultaneously. Furthermore, increasing osteitis in the final 4-months before RA-diagnosis followed incrementing tenosynovitis and synovitis during 1-year to 4-months before RA-diagnosis ($p<0.01$). Expanding osteitis occurred just before RA-development in both ACPA-positive and ACPA-negative RA. During resolution, besides simultaneous decreases, declining tenosynovitis in the first 4-months after CSA-onset preceded decreases in synovitis and osteitis during 4-12 months ($p=0.02$; $p<0.01$).

Conclusion: Natural sequences in subclinical inflammation of different joint tissues were identified, deepening our understanding of arthritis and RA-development. During progression to RA, increasing osteitis followed previous increases in tenosynovitis/synovitis. During resolution, tenosynovitis decreased first, followed by decreasing synovitis and osteitis.

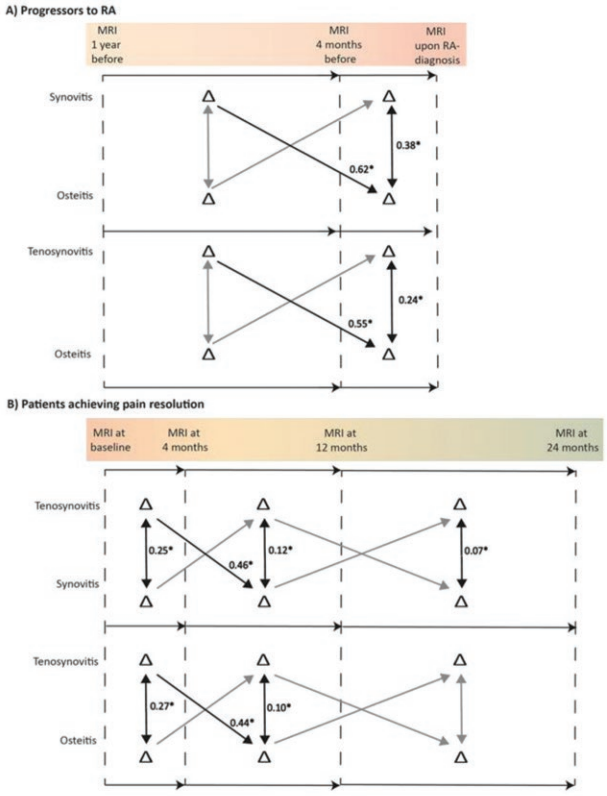

Figure 1. Graphic depiction of simultaneous and subsequent increase (Δ) of inflammation in pairs of different joint tissues during the two intervals in the year before arthritis development (A) and simultaneous and subsequent decrease (Δ) of inflammation in pairs of different joint tissues in patients achieving pain resolution (B)

Legend figure 1. Vertical arrows depict simultaneous inflammatory change in two joint tissues. Diagonal, crossing arrows depict time orders. Estimates represent the proportion of change in inflammation in two tissues that is not explained by other patterns, and are independent of scale. Higher values indicate higher explanation, and a value of 0 indicates no explanation. Statistical significant estimates are given in black with *, non-significant effects are given in grey.

Background: In the field of rheumatology, fertility has been reported impaired in Norwegian women with inflammatory joint diseases (IJDs) [1]. There is, however, limited data regarding fertility in male patients. The iFAME-fertility study found an association between inflammatory arthritis and reduced male fertility [2], underlining the need for a large-scale study. In the current project, we address this knowledge gap.

Objectives: To examine whether inflammatory joint diseases (IJDs) have an impact on men's fertility, measured as number of children per man and proportion of childless men.

Methods: We performed a nation-wide, population-based cohort study. Male patients with IJDs (n = 10,865) collected from the Norwegian Arthritis Registry in 2021 were individually matched 1:5 on birth year, sex, and county of residence, with individuals without IJDs obtained from the National Population Register (n = 54,325). Data regarding births was obtained from the Medical Birth Registry of Norway. We compared the mean number of children per man in the patient group and in the comparison group using paired t-tests, and the proportion of childless men using Cochran–Mantel–Haenszel chi-squared tests.

Results: The mean number of children per man in the patient group was 1.80 versus 1.69 in the comparison group ($p < 0.001$). Altogether, 21% of our patients were childless vs 27% in the comparison group ($p < 0.001$, Figure 1). The difference in number of children between patients and comparison group was highest for those diagnosed after year 2000 and these patients had the comparatively lowest risk of being childless. The differences were less evident for those diagnosed before 2000 (Table 1). Age at diagnosis did not influence fertility (Table 1).

Conclusion: In this large nationwide study, fertility in male patients with IJDs was not reduced compared to controls, neither when examining the number of children per man, nor when looking at the proportion of childless men. Interestingly, we observed a higher fertility rate in male IJD patients than in the comparison group for patients diagnosed after year 2000. The reason for this observation is unknown. Factors associated with getting or having an IJD may influence fertility. An interesting hypothesis is a possible positive impact of new immune modulating drugs introduced after year 2000.

* The Medical Birth Registry contains information about all births in Norway since 1967, and children born before this are not registered. This gives a lower mean no. of children per man, mainly affecting men 41 – 50 years of age in the 1967 - 1985 era.

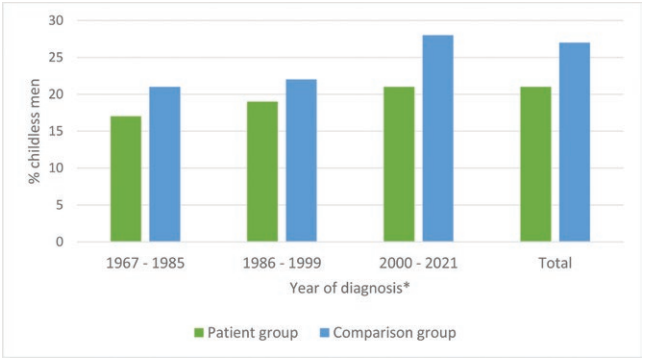

Figure 1. Proportion of childless men.*Treatment eras reflect major changes in treatment strategy for the IJDs – methotrexate from the late 1980s and biological treatment from the early 2000s.

INFLAMMATORY RHEUMATIC DISEASES HAVE BROAD IMPACT ON REPRODUCTIVE HEALTH – A NATIONWIDE EVALUATION AND SYSTEMATIC COMPARISON ACROSS RHEUMATIC DISEASES

Keywords: Pregnancy and reproduction

N. Mars[1,2], A. Kerola[3], K. Eklund[4,5], H. Laivuori[1,6], S. Ripatti[1,2,7], A. Palomäki[1,8], F. Registry[1,9]. *[1]University of Helsinki, Institute for Molecular Medicine Finland, FIMM, HiLIFE, Helsinki, Finland*; *[2]Broad Institute of MIT and Harvard, -, Cambridge, United States of America*; *[3]Helsinki University Hospital, Inflammation Center, Rheumatology, Helsinki, Finland*; *[4]University of Helsinki and Helsinki University Hospital, Department of Rheumatology, Helsinki, Finland*; *[5]Orton Orthopaedic Hospital, -, Helsinki, Finland*; *[6]Tampere University Hospital and Tampere University, Faculty of Medicine and Health Technology, Department of Obstetrics and Gynecology, Tapere, Finland*; *[7]University of Helsinki, Department of Public Health, Helsinki, Finland*; *[8]Turku University Hospital and University of Turku, Centre for Rheumatology and Clinical Immunology, and Department of Medicine, Turku, Finland*; *[9]Finnish Institute for Health and Welfare, -, Helsinki, Finland*

Background: Inflammatory rheumatic diseases (IRDs) affect men and women of reproductive age. The lack of reproductive health studies on IRDs hinders making evidence-based recommendations on fertility preservation, prevention of pregnancy complications, and management of the IRDs during reproductive years.
Objectives: To systematically estimate the impact of IRDs on diverse reproductive outcomes and compare the effects to those observed for other immune-mediated inflammatory diseases.
Methods: The total Finnish population (FinRegistry; N=5,339,804) was linked to nationwide registries (inpatient and outpatient care, and Medical Birth Register covering all live births since 1987, N=1,920,411 births). We focused on seropositive and seronegative rheumatoid arthritis (RA), ankylosing spondylitis (AS), juvenile idiopathic arthritis (JIA), psoriatic arthritis (PsA), systemic lupus erythematosus (SLE), and Sjögren syndrome (SS), selecting individuals born 1964–1984 diagnosed with the IRD before age 30, and 20 sex, birth-year, and education level-matched controls. The patterns were compared to a range of other immune-mediated inflammatory diseases, such as type 1 diabetes, inflammatory bowel disease, and hypothyroidism.
Results: The case count of women with an IRD ranged from 412 for PsA to 1,487 for seropositive RA (mean age range at diagnosis 11.0 in JIA to 25.7 in AS). Women with IRD experienced a higher prevalence of childlessness than controls (mean difference 4.2%, largest in JIA at 9.3%), had fewer children (mean 0.2 fewer, highest in JIA at 0.3 fewer), and the start and end of reproduction were slightly shifted towards an earlier age. Also men with an IRD experienced a higher prevalence of childlessness than controls (mean difference 4.1%, largest in SLE at 11.0%). Overall, the impact was similar in other immune-mediated inflammatory diseases in both women and men, with high variability between diseases. For maternal health conditions, five IRDs showed an elevated risk for pre-eclampsia, with the largest effect size observed for SLE (OR 2.65, 95%CI 1.94–3.62). No elevated risk was observed for gestational diabetes in any of the IRDs. Many of the IRDs were associated with at least one of the ten evaluated adverse perinatal outcomes, such risk of nonelective Caesarean section, and admission to neonatal ICU (**Figure 1**), with the largest effect sizes observed for SLE and SS.

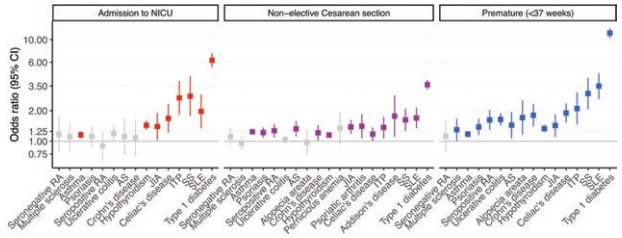

Figure 1. Systematical analysis of perinatal outcomes, with results shown for three of the ten evaluated perinatal outcomes. Results are shown for diseases with over 20 cases for the outcome and associations with p-value >0.05 are shown in gray. NICU = neonatal ICU, ITP = immune thrombocytopenic purpura.

Conclusion: In this comprehensive, nationwide evaluation of reproductive health metrics, we observed widespread impact of IRDs on reproductive health. The effects were comparable to many other immune-mediated inflammatory diseases, but we also observed high variability between diseases. Overall, these findings emphasize the need for further research, and the importance of counseling on reproductive health in both men and women with IRDs.

OP0264

COST-UTILITY OF A PROGRESSIVE SPACING OF TOCILIZUMAB OR ABATACEPT IN PATIENTS WITH RHEUMATOID ARTHRITIS IN SUSTAINED REMISSION: A MEDICO-ECONOMIC ANALYSIS OF THE TOLEDO TRIAL

Keywords: Clinical trials, bDMARD, Rheumatoid arthritis

J. Kedra[1,2], B. Granger[1,3], L. EL Houari[1,3], F. Tubach[1,3], B. Fautrel[1,2]. *[1]Sorbonne Université, INSERM UMRS 1136, Institut Pierre Louis d' Epidemiologie et de Santé Publique, Paris, France*; *[2]AP-HP, Hôpital Pitié Salpêtrière, Rheumatology, Paris, France*; *[3]AP-HP, Hôpital Pitié Salpêtrière, Département de Santé Publique, Centre de Pharmacoépidémiologie (Cephepi), CIC-190, Paris, France*

Background: Biologic Disease Modifying Anti-Rheumatic Drugs (bDMARDs) progressive tapering is a real opportunity in people living with rheumatoid arthritis (RA) having achieved remission both from the patient and the Society perspectives. The ToLEDo (Towards the Lowest Efficacious Dose) trial aimed to assess a disease activity-driven progressive tapering strategy of tocilizumab (TCZ) or abatacept (ABA) compared to their maintenance at full dose in RA patients in sustained remission. Non-inferiority (NI) was not demonstrated in terms of disease activity (primary endpoint) nor relapses, major relapses, radiographic progression (secondary endpoints) [1].
Objectives: The aim of this secondary analysis was to assess the cost-utility of the spacing strategy (S-arm) in the ToLEDo trial compared to full dose maintenance (M-arm).
Methods: The ToLEDo trial is a multicenter 2-year NI randomized open-label controlled trial, which enrolled 228 patients (113 in the S-arm and 115 in the M-arm). A cost-utility analysis was conducted on the per protocol population. In each arm, health benefits were estimated every 6 months by Short Form Health Survey (SF-6D) and EuroQoL (EQ-5D)-derived utility measurements. Cost elicitation integrated health resource use including bDMARD costs (direct cost) as well as productivity loss (indirect cost) using the friction cost method. The incremental cost-utility ratios (ICUR) were calculated by dividing the difference of costs between S-arm and M-arm by the difference of utilities between the 2 arms. 95% confidence interval (95%CI) were calculated by bootstrap (20,000 iterations). The incremental net benefit (INB) was calculated for willingness to pay (WTP) values ranging from 0 to 150,000€. The analyses were replicated using SF-6D (primary analysis) or EQ-5D, and in ABA and TCZ subgroups. Acceptability analyses as well as stochastic sensitivity analyses (simulating costs and utilities using MCMC algorithms) were also performed.
Results: Overall, 178 patients were included (82 in S-arm, 96 in M-arm) in the per protocol analysis. At the end of the follow-up in the S-arm, 15.0% of patients discontinued their biologic, 48.7% spaced the injections, and 36.3% remained at the standard dose. The difference in terms of two-years utility gains between S-arm and M-arm was 0.004 (95%CI -0.012, 0.021) with SF-6D. The difference of total costs between S-arm and M-arm was -4,275 € (95%CI -5,955 to -2,542). The estimated ICUR of the spacing strategy over the maintenance at full dose was €932,003 saved per QALY (95% CI -7,534,788 to 6,720,372) with SF-6D. The INB was 4,734.6€ for a WTP of 100,000€. With a willingness to accept of 0 €/QALY lost, the probability to be cost-effective for the spacing strategy was 70.6% (***Figure 1***). The results were consistent when using EQ-5D-derived utilities, in ABA and TCZ subgroups, as well as in the stochastic sensitivity analyses (***Table 1***).
Conclusion: Although the ToLEDo trial did not demonstrate non-inferiority, the tested disease activity-driven tapering strategy was not associated with health loss in terms of utilities and incurred for substantial cost savings, making this strategy potentially dominant.

OP0265

WORK PARTICIPATION AND THE COVID19 PANDEMIC: A DUTCH PROSPECTIVE COHORT STUDY IN PEOPLE WITH INFLAMMATORY RHEUMATIC DISEASES AND HEALTHY CONTROLS

Keywords: COVID, Work-related issues

M. Butink[1,2], L. Boekel[3], A. Boonen[1,4], A. De Rijk[2], G. Wolbink[3,5], C. Webers[1,4].
[1]Maastricht University Medical Centre +, Department of Internal Medicine, Division of Rheumatology, Maastricht, Netherlands; *[2]Maastricht University, Department of Social Medicine Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands*; *[3]Amsterdam Rheumatology and Immunology Center, Location Reade, Department of Rheumatology, Amsterdam, Netherlands*; *[4]Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands*; *[5]Sanquin Research and Landsteiner Laboratory Academic Medical Center, Department of Immunopathology, Amsterdam, Netherlands*

Background: People with inflammatory rheumatic diseases (iRD), such as rheumatoid arthritis (RA) and spondyloarthritis (SpA), experience restrictions in work participation. In times of crisis, such as the coronavirus disease 2019 (COVID19) pandemic, people with iRD might be more vulnerable for adverse work outcomes (i.e. (partial) job loss and sick leave) and restrictions in work ability while at work.

Objectives: To (a) compare occurrence of adverse work outcome (AWO) and change in work ability during the first two years of the pandemic (2020-2022), as well as current (2022) work ability, between people with iRD and healthy controls in the Netherlands; (b) understand which subgroups of patients are most vulnerable to incur work participation outcomes; and (c) explore the role of remote work characteristics on work performance.

Methods: Data from a Dutch longitudinal study on COVID19 at Reade and Amsterdam UMC were used. Information about work was collected at one fixed timepoint. Patients (18-67 years) with iRD and controls were asked in March 2022 to answer questions on work participation and their work situation in March 2020 (pre-pandemic; retrospectively) and March 2022 (current). AWO was defined as any of: (1) shift between 2020-2022 from employment to unemployment; or from full to part-time employment; (2) reduction in working hours; (3) ongoing long-term sick leave. Work ability (change and current) was assessed with the Work Ability Index (range 0 [worst] to 10 [best]). Outcomes were compared between groups (iRD vs control) with statistical tests. Multivariable logistic or linear regression analyses were used to explore the associations between iRD and AWO or (change in) work ability. Interactions (effect modification) were tested and, if present, analyses were stratified. The role of remote work factors on remote work performance was described.

Results: In total, 1,438 iRD patients and 526 controls of working age (18-67) participated. The majority was female (67%) and was employed pre-pandemic (69% patients, 84% controls). Patients mainly had RA or SpA (85%). In pre-pandemic employed subjects, 227 patients (23%) and 79 controls (18%) experienced AWO (p=0.04). Only 35 patients (4%) and 12 controls (2%) of these, attributed this to COVID (impact by personal health or national pandemic measures; p=0.36). Logistic regressions of AWO were stratified because of interactions between group and sex, comorbidities or a physically demanding job. In all models, patients were more likely than controls to experience AWO (range OR 1.63 to 3.34 across models, Figure 1), and especially patients with comorbidities or a physically demanding job. Of note, COVID-related AWO was not significantly more likely in patients (OR=1.62, 95%CI 0.80-3.27). Change in work ability during the pandemic did not differ between groups (-0.3 (SD 1.8) patients vs -0.2 (SD 1.6) controls, p=0.38), and regression analyses also did not reveal significant differences. Linear regression of current work ability (stratified by sex due to interaction) showed female patients compared to female controls experienced lower work ability (B=-0.66; 95%CI -0.92 to -0.40), while this was not observed in males. Past SARS-CoV-2 infection was not associated with AWO/work ability. When working remotely, care for children and absence of colleagues had both positive (19% and 24%, resp.) and negative (34% and 57%, resp.) influence on work performance, while employer support and reduced commuting time had positive influence (83% and 86%, resp.).

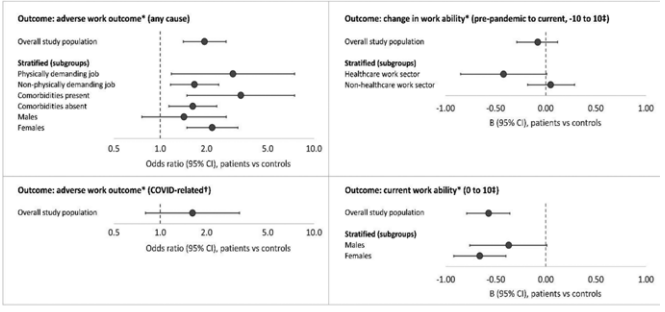

Figure. Association between group (patients vs controls) and adverse work outcome or (change in) work ability. An odds ratio >1 or a B <0 indicate a worse outcome in patients compared to controls (occurrence of adverse work outcome, a greater decrease in work ability or lower current work ability). *Covariables explored in models (forward method, retained if confounder for group and outcome, or if significantly associated with outcome): age, gender, education, comorbidities, past COVID infection, COVID vaccination, work sector, job demands, employment contract, working hours per week, work location. †COVID-related adverse work outcome defined as adverse work outcome attributed by the patient to either impact of COVID on personal health or impact of national pandemic measures.

Conclusion: During the COVID pandemic, patients experienced more AWO than healthy controls, and especially patients with physically demanding jobs and comorbidities were at higher risk. However, the frequency of COVID-related AWO was low and did not differ substantially between patients and controls. A likely explanation is that the governmental support for employers protected those in vulnerable positions, such as patients with iRD.

OP0266 HIGHER RISK OF LUPUS MORTALITY IN URBANIZED THAN IN LESS-URBANIZED NEIGHBORHOODS

Keywords: Geographical differences, Systemic lupus erythematosus, Prognostic factors

R. Sharma[1], E. Yen[2], M. Sim[3], L. Chen[3], R. Singh[2]. [1]*California University of Science and Medicine, Medical Student, Colton, United States of America*; [2]*University of California Los Angeles, Rheumatology, Los Angeles, United States of America*; [3]*University of California Los Angeles, Statistics, Los Angeles, United States of America*

Background: Lupus mortality differs by sex, race/ethnicity, and geographical region in the United States, with females, blacks, and residents of the South census region experiencing higher age-standardized mortality rates relative to their respective reference groups, as revealed by the analysis of aggregated mortality data using the CDC-WONDER database (Yen E, et al, Ann Intern Med 2017; Singh RR and Yen E, Lupus 2018). These aggregate data are limited by observation at the population level. We seek to examine mortality data at the individual level to characterize how where you live can impact your risk of death from lupus. Specifically, how living in a specific neighborhood as defined by the rural-urban continuum codes (RUCC) can influence your overall lupus mortality.
Objectives: Analyze the risk of lupus death relative to all-cause deaths (other than lupus) by RUCC adjusted for sex, race/ethnicity, and age groups.
Methods: We used the individual mortality dataset provided by the Centers for Disease Control and Prevention. The study population comprises all (>99%) deaths in the United States from 2006 to 2011. The primary outcome is lupus listed as the cause of death identified from ICD 10 codes (M321, M328, M329). The primary exposure is the RUCC listed on the death certificate at the time of death. We constructed a multivariate logistic regression model adjusting for known covariates that could influence the outcome including sex, ethnicity/race, and age. We also analyzed for any potential effect modifiers between RUCC and other demographic variables.
Results: From 2006 to 2011, there were 5,430 lupus deaths and 6,286,020 all-cause deaths in the United States. The adjusted odds of lupus vs. all-cause deaths was higher in metro-urbanized area than in less urbanized (odds ratio 0.729 [95% CI 0.651 to 0.816], p<0.0001), thinly populated (0.831 [0.660-1.046], p = NS), and non-metro urbanized (0.951 [0.845-1.070], p=NS). The odds of lupus/all-cause deaths was higher in non-Hispanic black (2.758 [2.573-2.957], p<0.0001), Hispanic (2.350 [2.150-2.568], p<0.0001), and non-Hispanic other (2.242 [1.975-2.546], p<0.0001) than in non-Hispanic white persons; lower in males (0.121 [0.112-0.131], p<0.0001) than females, and in age group 45-64 years (0.586 [0.548-0.627], p<0.0001) and ≥65 years (0.124 [0.115-0.133], p<0.0001) than in <45 year group. There was an interaction between age and RUCC in influencing lupus death risk, with higher lupus/all-cause death risk in non-metro urbanized (p<0.001) and less urbanized areas (p=0.034) than in metro-urbanized areas in decedents ≥65 years.
Conclusion: This study reveals an association between rural-urban residence and odds of dying from lupus after adjusting for sex, ethnicity/race, and age. Comprehensive studies to identify determinants of higher lupus deaths in metro-urbanized areas are needed to address the poor lupus outcome in the high-risk populations.

OP0267 THE PREDICTIVE ACCURACY OF CARDIOVASCULAR RISK PREDICTION TOOLS IN INFLAMMATORY ARTHRITIS

Keywords: Diagnostic tests, Cardiovascular disease, Prognostic factors

D. Hughes[1], S. S. Zhao[2]. [1]*University of Liverpool, Health Data Science, Liverpool, United Kingdom*; [2]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Division of Musculoskeletal and Dermatological Science, School of Biological Sciences, Faculty of Biological Medicine and Health, Manchester, United Kingdom*

Background: Cardiovascular risk prediction tools designed for the general population often underestimate and occasionally overestimate cardiovascular risk in individuals with rheumatoid arthritis. Incidence of cardiovascular disease is also recognised to be increased in individuals with other inflammatory arthritides.
Objectives: To investigate performance of three common cardiovascular risk prediction tools (QRISK-3, Framingham Risk Score and Reynolds Risk Score) in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS). We also compare performance in patients with psoriasis, since it is closely related to PsA, and a non-inflammatory disease, osteoarthritis (OA).
Methods: We utilise primary care records from the Clinical Practice Research Datalink (CPRD) Aurum database and identify individuals with diagnostic codes for each condition. We calculated their 10-year cardiovascular risk using each risk tool, and compared this to their observed outcomes. Discrimination (how well the tool separates CVD cases and non-cases) was assessed using time-dependent (to account for censoring in follow up) Area-under-ROC-curve (AUC), sensitivity, specificity, positive and negative predictive values (using 10% and 20% predicted risk to determine high risk of CVD). Calibration (how well predicted risks match observed risks) of each risk prediction tool was assessed by comparing the observed and predicted risks in deciles of predicted risk for each disease group.
Results: Time-dependent AUC for QRISK3 ranged between 0.697 for patients with osteoarthritis to 0.815 for patients with psoriasis, indicating reasonably good predictive performance (Figure 1). AUC for the Framingham Risk score were similar, whilst the Reynold's Risk Score achieved slightly lower AUCs in this cohort, ranging between 0.640 for patients with osteoarthritis and 0.752 for patients with psoriasis. In general, the Framingham Risk Score was reasonably well calibrated for each condition but underpredicted risk for patients with RA or OA. The Reynold's Risk Score tended to underpredict CVD risk, whilst the QRISK3 score overpredicted CVD risk, especially for the most high-risk individuals.
Conclusion: In general, CVD risk for individuals with RA, AS, PsA, psoriasis, or OA were less accurately predicted using each of the 3 CVD risk prediction tools than the reported accuracies in the original publications. There is a need for specific risk prediction tools for rheumatic conditions.

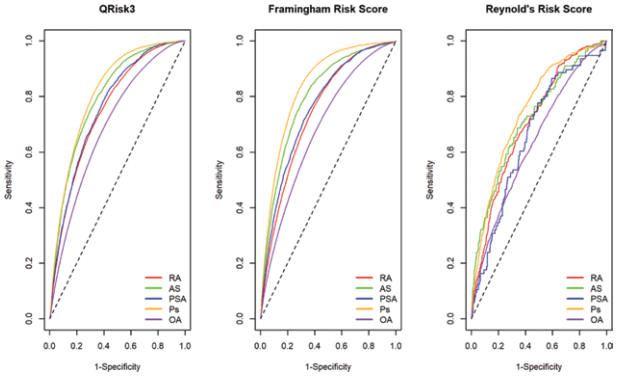

Figure 1. ROC curves for cardiovascular risk prediction in each rheumatic disease using the QRISK-3, Framingham and Reynolds Risk Scores.

OP0268 IMPACT OF MENOPAUSAL TREATMENTS IN FUNCTIONAL DECLINE ON WOMEN WITH RHEUMATOID ARTHRITIS

Keywords: Pregnancy and reproduction, Rheumatoid arthritis, Real-world evidence

S. Pedro[1], E. Mollard[2], K. Michaud[1,3]. [1]*FORWARD, The National Databank for Rheumatic Diseases, Research, Wichita, United States of America*; [2]*University of Nebraska Medical Center, College of Nursing, Omaha, United States of America*; [3]*University of Nebraska Medical Center, Medicine, Omaha, United States of America*

Background: Women with Rheumatoid Arthritis (RA) experience changes in disease development and progression surrounding reproductive and hormonal events, including menopause. In our prior work, women with RA had better functional status prior to menopause and experienced worsening functional decline after menopause [1].
Objectives: The purpose of this study is to investigate how menopausal treatments affect functional decline in women with RA.
Methods: Women with RA participating in the Forward Databank from 2000 through 2022 with a reported menopausal status or not having a menstrual period for 1 year were eligible. Women who were on hormonal contraceptive were excluded. Hormonal replacement therapy (HRT) users were matched 1:1

to non-users by year of HRT initiation (index date). The primary outcome was function measured by Heath Assessment Questionnaire (HAQ) and HRT as primary exposure. Descriptive statistics were used to characterize patients at baseline by HRT exposure. Gaussian GEE models were used (robust SE) to assess the association between HAQ and HRT adjusting for the following confounders: demographics, reproductive history, clinical measures, and treatments. Best model was searched using QIC in a backward selection manner.

Results: 4123 women who have initiated HRT were matched by year of initiation to 4123 non-HRT users after menopause (mean year was 2004). At baseline, HRT users tended to be younger, have higher income, shorter reproductive length, and more comorbidities. No differences were found in pain and patient global as well as DMARD treatment, although HRT-users had higher use of non-hormonal treatments (Table 1). Overall, patients had a median follow-up of 6 years (IQR 3- 10) years with 2 years (IQR 1- 4) years of HRT exposure. HRT users had consistently better HAQ (although with a small effect) when compared to non-users (coef. -0.02 (95% CI, -0.03; -0.01) P<0.001). HAQ was also inversely associated with the age when women started menopause (-0.008 (95%CI (-0.009; -0.006), P<0.001); each year after menopause the HAQ increased by 0.008, which was slight better for HRT users (Figure 1).

Conclusion: HRT use was associated with better functional status, although of modest magnitude. Longer reproductive duration seemed protective for function, but worsening slightly after menopause. Future work is needed to assess the safety profile of HRT regarding incidence of malignancies, cardiovascular events, and osteoporosis.

OP0269

DEVELOPMENT AND EVALUATION OF MACHINE LEARNING ALGORITHMS FOR THE PREDICTION OF OPIOID-RELATED DEATHS AMONG UK PATIENTS WITH NON-CANCER PAIN

Keywords: Outcome measures, Artificial intelligence, Pain

J. Benitez-Aurioles[1], D. Jenkins[1,2], C. Ramirez Medina[3], N. Peek[1,2,4], M. Jani[3,4].
[1]The University of Manchester, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom; *[2]The University of Manchester, NIHR Greater Manchester Patient Safety Translational Research Centre, Manchester, United Kingdom*; *[3]The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; *[4]Manchester University NHS Foundation Trust, Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Wythenshawe, United Kingdom*

Background: There has been a sharp rise in opioid use for non-cancer pain globally, including for rheumatic and musculoskeletal conditions. Despite increased awareness of adverse effects, they remain commonly prescribed in most countries. Clinical prediction models (CPMs) offer the possibility of assessing individual risk allowing better allocation of resources towards those at risk. Machine learning (ML) approaches can address nonlinear relationships and complex interactions between variables and are increasingly used to develop CPMs.

Objectives: To develop, validate, and compare the performance of three CPMs based on regression and ML, which leverage primary care data to estimate the risk of opioid-related death in patients prescribed opioids for non-cancer pain.

Methods: Patients ≥18 years old without prior cancer who were prescribed any opioid between 01/01/2006 and 31/12/2017 were identified in the Clinical Practice Research Datalink (CPRD), representative of national patient data from UK primary care. Only new opioid users were included. Index date was date of first prescription, with censoring at withdrawal from the CPRD or after not having an opioid prescription for two years. Baseline data were extracted from each patient's records, including demographic information, comorbidities, concomitant medications, and the opioid type being prescribed. 49 candidate predictors were used to train three competing risk models: a Fine&Gray regression model with LASSO regularisation, a survival random forest (RF), and a neural network (DeepHit). The outcome was opioid-related mortality and other cause mortality the competing event, defined using a curated ICD-10 codelist. Predictive performance of the models, like area under the receiver characteristic operator curve (AUCROC) were calculated using 5-fold cross validation.

Results: We included a total of 1,029,681 patients, of which 1,240 experienced an opioid-related death, and 52,833 experienced a competing death. The Fine&Gray, RF and DeepHit models achieved average AUCROC values of 0.83(95% CI: 0.81-0.85), 0.78(0.77-0.79) and 0.81(0.80-0.82) respectively (Figure 1). At optimum risk cut point, as per Youden's index, the models achieved sensitivities of 0.82(0.78-0.85), 0.75(0.67-0.82) and 0.80(0.78-0.83), and specificities of 0.78(0.73-0.82), 0.75(0.68-0.83) and 0.78(0.75-0.8) when predicting 12-month risk, respectively. In the Fine&Gray model, factors associated with increased risk were history of substance use disorder (hazards ratio [HR]: 3.40, 95% CI:3.12-3.69) and alcohol abuse (HR:3.07, 95% CI:2.93-3.22). COPD (HR:1.53, 95% CI:1.48-1.58) and moderate liver disease (HR:1.31, 95% CI:0.99-1.63) were the comorbidities associated with highest risk. Morphine (HR:2.39, 95% CI:2.08-2.69) and oxycodone (HR:1.10, 95% CI:1.00-1.20) at initiation and concomitant gabapentinoids (HR:1.99, 95% CI:1.80-2.18) and benzodiazepines (HR:1.30, 95% CI:1.24-1.36) were associated with an increased risk. HR for rheumatologic diseases was 1.08 (95% CI:1.01-1.14).

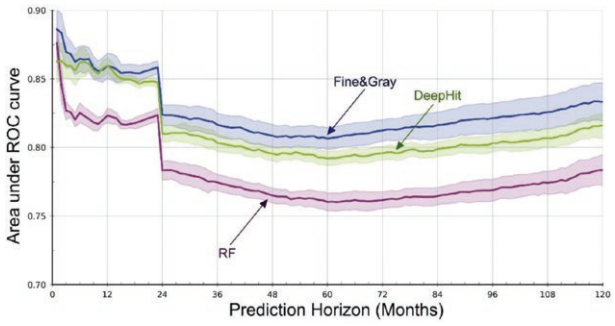

Figure 1. AUCROC of the three models vs. prediction horizon of the model. 95% CI of mean performance shaded.

Conclusion: The Fine&Gray and DeepHit models showed comparable discriminative performance. Substance abuse, lung and liver comorbidities, morphine or oxycodone at initiation and co-prescription of gabapentinoids and benzodiazepine, were some of the factors associated with a higher risk of opioid-related mortality.

OP0270 TARGETED THERAPIES FOR SEVERE IMMUNE-RELATED ADVERSE EVENTS OF IMMUNE CHECKPOINT INHIBITORS ARE NOT ASSOCIATED WITH A WORSE PROGNOSIS

Keywords: Targeted synthetic drugs, bDMARD, Malignancy

N. Sedmak[1], E. Sebbag[2], P. Tran BA Loc3, T. Fabacher[1], T. Bahougne[4], C. Arnold[5], G. Desjeux[6], H. Servy7, N. Meyer[8], E. Sauleau3, R. Seror[9], J. E. Gottenberg[2]. *[1]NHC - New Civil Hospital, Département de l'Information Médicale, Strasbourg, France*; *[2]Hôpital de Hautepierre, Rheumatogy, Strasbourg, France*; *[1]NHC - New Civil Hospital, Département de l'Information Médicale, Strasbourg, France*; *[4]Hautepierre, SERVICE D'ENDOCRINOLODIE DIABÉTOLOGIE ET NUTRITION, Strasbourg, France*; *[5]NHC - New Civil Hospital, Département de la Recherche Clinique et Innovation, Strasbourg, France*; *[6]Sanoia, E-health Services, Gemenos, France*; *[6]Sanoia, E-health Services, Gemenos, France*; *[8]Strasbourg University Hospital, Biostatistics, Strasbourg, France*; *[9]APHP, Rheumatogy, PARIS, France*

Background: In about 10% of patients, the immune response to immune checkpoint inhibitors (ICI) exceeds the anti-tumor response and leads to autoimmune complications (immune-related Adverse Events, irAEs), which can sometimes be severe and require the use of targeted therapies. Two studies recently reported a deleterious impact of targeted therapies on the survival of patients with irAEs.
Objectives: To compare overall survival in patients treated or not with a biological or targeted synthetic DMARD (b/tsDMARD) for an hospitalized irAE.
Methods: All adults included in the French national health database who initiated an ICI between 2014 and 2019, for any type of cancer, were retrospectively analyzed. Follow-up was analyzed between 2013 to 2020, to have a one-year look-back and one year look-ahead period. The occurrence of an irAE during ICI treatment or in the 12 months after its last administration was defined by the combination of (1) hospitalization for a cause evoking an irAE of any nature, except endocrinopathy, and (2) either the discontinuation of the ICI, or the initiation of corticosteroids, or of a conventional DMARD or a b/tsDMARD, or a new recognition as a long-term disabling condition (LTD) for an autoimmune or inflammatory disease. Patients with irAE treated with b/tsDMARD were matched (1:3) at the time they initiated b/tsDMARD to those who did not initiate b/tsDMARD, using a dynamic propensity score calculated every 30 days. The propensity score included gender, age, type of cancer, type of ICI, time from cancer to initiation of ICI and from initiation of ICI to irAE, use of corticosteroids, hospitalization in intensive care unit, type of irAE, number of LTDs, Charlson's index and FDep social deprivation index. Overall survival was compared between the two groups using a Cox model. A sensibility analysis restricted to gastrointestinal and rheumatic irAEs was performed.
Results: 71,723 patients (men: 66.0%, median age: 66 years) initiating an ICI were analyzed. An hospitalized irAE occurred in 7883 patients (11.0%). irAE occurred at a median time of 72 days after ICI initiation, and the 4 more frequent were gastrointestinal (inflammatory colitis, 4.7%), cardiologic (2.0%), rheumatic (1.8%), and pulmonary (1.7%). Median patient follow-up after irAE was 356 days. Mortality after irAE was 4.8% at 1 month and 11.3% at 3 months. After matching, 325 patients were treated for an irAE with a b/tsMDARD (Infliximab (57.7%), Rituximab (25.5%), Tocilizumab (4.2%), Vedolizumab (3.3%), others (9.3%)), including 257 and 40 for a gastrointestinal or rheumatic irAE, respectively. They were compared to 975 patients who were not treated with a b/tsDMARD. The median time from ICI initiation to irAE was well balanced by matching (93 versus 92 days, respectively). ICI was discontinued in 25.4% of b/tsDMARD treated patients patients within 3 months after the irAE, compared to 20.9% in the group not treated with a b/tsDMARD. Mortality after irAEs was 6.8% and 7.6% at 3 months, respectively, and 16.0% and 17.9% at 6 months, respectively. Overall survival whatever the type of irAE did not significantly differ in patients treated with or without a b/tsDMARD (HR=0.87, CI=[0.74, 1.03]), or in patients treated for a rheumatic irAE (HR=0.80, CI=[0.51, 1.25]). Overall survival was significantly improved in gastrointestinal irAE in patients treated with a b/tsDMARD compared to patients not treated with a b/tsDMARD (HR=0.80, CI=[0.66, 0.97]).
Conclusion: In one of the largest study to date in terms of number of hospitalized irAEs and number of b/tsDMARD-treated patients, targeted therapies were not associated with a worse prognosis and significantly improved overall survival in patients with induced colitis, the most frequent and one of the most severe irAEs.

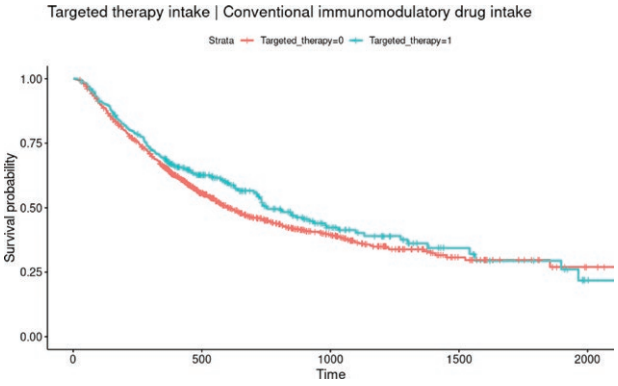

Figure 1. Overall survival in days in patients treated with a b/tsDMARD (blue) or not (red)

OP0271 INCIDENCE OF PSORIATIC ARTHRITIS AND PREVALENCE OF UNDIAGNOSED CASES IN A UK PRIMARY CARE POPULATION FOLLOWED PROSPECTIVELY FOR 2 YEARS - RESULTS FROM THE TUDOR RANDOMIZED CLINICAL TRIAL

Keywords: Psoriatic arthritis, Skin, Epidemiology

N. Mchugh[1], L. Bojke[2], L. Coates[3], C. Davies[4], P. Helliwell[5], J. Packham[6], M. Ransom[4], E. Spackman[7], W. Tillett[1], S. Brown[4]. *[1]University of Bath, Department of Life Sciences, Bath, United Kingdom*; *[2]University of York, Centre for Health Economics, York, United Kingdom*; *[3]University of Oxford, Rheumatology, Oxford, United Kingdom*; *[4]University of Leeds, Leeds Institute of Clinical Trials Research, Leeds, United Kingdom*; *[5]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[6]University of Nottingham, Academic Unit of Population and Lifespan Sciences, Nottingham, United Kingdom*; *[7]University of Calgary, Community Health Sciences, Calgary, Canada*

Background: The incidence of psoriatic arthritis (PsA) in a psoriasis population has been reported to be somewhere between 20 to 300 per 10,000 person years (p-yrs) (1,2), the wide range reflecting differences in the population setting and the methods of ascertaining a diagnosis. A higher incidence is generally found in studies combining active screening and physical examination. However, accurate estimates of incidence and prevalence of undiagnosed disease are needed to inform the timing and cost-effectiveness of community screening in a general population with psoriasis.
Objectives: To determine the annual incidence of PsA in a UK primary care population with pre-existing psoriasis over two years after excluding baseline prevalence of existing and undiagnosed disease.
Methods: TUDOR (Total bUrDen of psORiasis) was a multi-centre, prospective, two-arm parallel-group cluster randomised controlled trial of the early identification of PsA by annual rheumatological assessment (termed Early Surveillance (ES) arm) versus standard care (SC) arm in people with psoriasis identified in primary care. Participants in the ES arm were recruited from primary care records held in 72 participating practices, invited to attend for a health check that included a screening examination for psoriatic arthritis and if the screen was positive their general practitioner was requested to refer them to the local rheumatology service to confirm a final diagnosis of PsA. The incidence reported here is from the ES arm, excludes prevalent cases of PsA identified at baseline and reports incidence at follow-up visits at 12 and 24 months.
Results: In the ES arm, 64 of 826 participants (7.7% (95% CI: 5.9, 9.6)) had a diagnosis of PsA, of whom 43 of 793 were diagnosed from the initial screening

visit, corresponding to a prevalence of undiagnosed PsA at baseline of 5.4% (95% CI: 3.8, 7.0). Fourteen of 511 participants attending a 12-month screen developed PsA over that interval giving an incidence of 274 per 10,000 p-yrs (95% CI: 132 to 416 per 10,000 p-yrs) and another 7 of 444 participants attending the 24-month visit developed PsA giving an incidence of 158 per 10,000 p-yrs (95% CI: 42 to 274 per 10,000 p-yrs). The combined incidence over 2 years was 220 per 10,000 p-yrs (95% CI: 127 to 313 per 10,000 p-yrs).

Conclusion: In the ES arm of TUDOR where participants with psoriasis were screened and examined for the presence of PsA at baseline, 12 months and 24 months, the estimated cumulative incidence of PsA over a 2 year period was 220 per 10,000 p-yrs, that is in keeping with a higher incidence of PsA than that found when relying on health records alone. The long term clinical and cost-effectiveness of screening from the TUDOR trial remains under investigation.

OP0272 EARLY RESPONSE IN RHEUMATOID FACTOR LEVELS PREDICTS SUBSEQUENT CLINICAL RESPONSE TO DISEASE MODIFYING TREATMENT OF RHEUMATOID ARTHRITIS

Keywords: Prognostic factors, Rheumatoid arthritis, Treat to target

V. Konzett[1], D. Aletaha[1]. [1]*Medical University of Vienna, Department of Internal Medicine III, Division of Rheumatology, Wien, Austria*

Background: Rheumatoid factors (RF) are well established prognostic biomarkers in rheumatoid arthritis (RA), but the clinical relevance of their dynamics is not yet well understood. Here, we evaluate the implications of changes in RF levels in RA patients with newly initiated disease modifying (DMARD) treatment.
Objectives: To analyze how early responses of RF levels relate to subsequent disease activity outcomes in RF positive RA patients initiating DMARD treatment.
Methods: We analyzed data from 1999 RA outpatients, starting either a conventional (csDMARD) or biologic/targeted synthetic DMARD (btsDMARD). RF response to treatment was defined as a ≥50% reduction in RF levels or complete seroconversion to RF negativity. We investigated the prognostic implication of early RF response on the timing of achieving disease control as defined by Simplified Disease Activity Index (SDAI) low disease activity (LDA) or remission (REM) in patients with SDAI moderate or high disease activity (MDA/HDA) at baseline. We analyzed the first two years of each treatment segment; patients, who did not reach LDA/REM within two years, or patients who switched therapy within this time frame were censored in this Kaplan Meier analysis. In a Cox proportional hazard model we adjusted the observed effects for gender, age and disease duration, as well as for SDAI at month 3.
Results: RF response (as defined above) to treatment was observed in 11%, 25.5% and 41% of RF positive RA patients at 3, 6 and 12 months after treatment initiation, respectively; RF response was seen in comparable frequency in csDMARD and btsDMARD treated patients (Table 1). LDA or REM by SDAI in patients with MDA or HDA was achieved significantly earlier in RF responders as compared to non-responders (Wilcoxon p=0.042 for csDMARDs, p=0.005 for btsDMARDs). Crude effects of RF response on achieving LDA/REM were highly significant in the Kaplan Meier analysis (p<0.0001; Figure 1) and remained so after adjusting for multiple variables including disease activity levels at 3 months (p<0.0001); in a pooled analysis of all DMARD starts (N = 736), the adjusted Hazard Ratio (HR) for LDA or REM in the RF response group was 1.73 (95% confidence interval: 1.23 to 2.42), compared to the RF non-responders.

Table 1. Baseline data and RF response rates at month 3 after start of csDMARD or btsDMARD therapy; RF response is defined as ≥50% reduction in baseline RF levels or complete seroconversion to RF negativity.

	csDMARD	btsDMARD
N total	1394	566
% female	76.2	81.8
Disease duration years (median [IQR])	0.32 [0.00, 4.8]	5.92 [2.17, 13.32]
SDAI baseline (mean (SD))	18.78 (12.91)	19.11 (13.00)
% RF elevated at baseline	58.82	62.19
RF in U/ml (mean (SD))	187.29 (411.79)	201.58 (430.04)
N RF positive with follow-up data available	801	332
% seroconversion 3 months	3.6	2.7
% 50% reduction 3 months	10.5	8.4
% 50% reduction or seroconversion 3 months	**11.9**	**10.2**

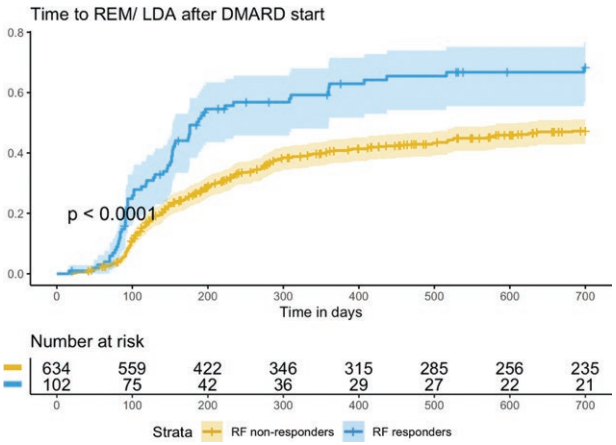

Figure 1. Time to event analysis (inverted Kaplan Meier curve) showing time to first SDAI LDA or REM (SDAI≤11) in RF positive RA patients who started DMARD treatment in MDA/HDA; analysis is stratified by RF response (50% reduction in RF levels or seroconversion at 3 months) or non-response (neither 50% response nor seroconversion); observations were censored at 2 years or switch of treatment (whichever was first). Panel displays pooled analysis of csDMARD starts (n=502) and btsDMARD starts (n=234).

Conclusion: Change in RF levels or complete seroconversion at the 3-month timepoint predict the achievement and timing of treatment goals within a 6 to 24-month period after treatment initiation. This finding was independent of disease activity improvement at 3 months, and may therefore serve as an additional early biomarker in assessing a patient's future chance of achieving treatment targets in RA.

OP0273 LONGITUDINAL TRAJECTORIES OF RENAL FUNCTION IN ANCA-ASSOCIATED VASCULITIS: FINDINGS FROM THE EXPANDED MASS GENERAL BRIGHAM COHORT

Keywords: Kidneys, Organ damage, Vasculitis

J. Hanberg[1], C. Cook[2,3], X. Fu[2,3], H. Choi[2,3,4], Y. Zhang[2,3,4], Z. Wallace[2,3,4]. [1]*Massachusetts General Hospital, Department of Medicine, Boston, United States of America*; [2]*Massachusetts General Hospital, Clinical Epidemiology Program, Mongan Institute, Boston, United States of America*; [3]*Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Boston, United States of America*; [4]*Harvard Medical School, Boston, United States of America*

Background: Renal vasculitis, leading to a spectrum of chronic kidney disease (CKD) and end-stage renal disease (ESRD), is common in ANCA-associated vasculitis (AAV). The longitudinal course of renal dysfunction in AAV has only recently been described quantitatively.(1, 2)
Objectives: To confirm and further describe the longitudinal trajectory of renal function in an expanded AAV cohort.
Methods: We included patients from the Mass General Brigham AAV cohort, a consecutive inception cohort (2002-2022). We required at least 2 measurements of renal function including one "baseline" measurement (+/- 30 d from treatment initiation date, the index date). Renal function was assessed up to monthly between -12 m and +24 m relative to the index date. We used group-based trajectory modeling to identify renal function trajectories. Between-group differences (between all 4 groups) were assessed using the chi-square test and Kruskall-Wallis tests; time to ESRD was compared using the log-rank test.
Results: Among 375 patients, we identified 4 renal trajectory groups: rapid decline (N=23 [6%]), impaired (N=109 [29%]), preserved (N=216 [58%]), and recovery (N=27 [7%]) (**Figure 1**). Median posterior probability of group membership was >0.99, indicating excellent model fit. Age, sex, race and ANCA type were not statistically different between groups. Baseline comorbidity (by Charlson Comorbidity Index) was highest in the rapid decline group, and higher in the impaired compared to the preserved and recovery groups (p<0.001; **Table 1**). There was a strong trend toward hypertension being more common in the rapid decline and recovery groups vs the impaired and preserved groups (p=0.06). The baseline Birmingham Vasculitis Activity Score was higher in the rapid decline (6 [4, 7]) and recovery (6 [4, 9]) groups, compared to the impaired (5 [4, 6.5]) and preserved (4 [3, 6]) groups (p<0.001). ESRD occurred in 49 patients, including

22 (96%) in the rapid decline group, compared to 11 (10%) in impaired, 15 (7%) in preserved and 1 (4%) in the recovery group. Median time to ESRD was <1 m in the rapid decline group vs 3.5 y (IQR 0, 6.8) in impaired and 2.5 y (IQR 0, 5.6) in the preserved group (log-rank p<0.001). ESRD was attributed to active AAV in 91% of cases in the rapid decline group, compared to 45% of impaired and 33% of the preserved group (p=0.01). Clinically significant CKD (eGFR<30 ml/min/1.73m2) was present in a majority of the impaired group at 1, 2 and 5 y, but was less common in the preserved group (p<0.001 at all 3 timepoints).

Conclusion: We confirmed 4 distinct renal trajectory groups in an expanded AAV cohort. Trajectory groups were distinguished by differences in baseline comorbidity, rates of ESRD and CKD, and etiology and timing of ESRD. These findings emphasize the need for additional studies investigating temporal factors mediating these associations.

Background: Methotrexate (MTX) is the first-line drug in the treatment of rheumatoid arthritis (RA) and many other rheumatic and musculoskeletal diseases (RMDs). It is widely recognized that patients prescribed with this, or other similar drugs, should be properly educated, namely by rheumatology nurses,[1] to better understand why and how to take it, the possible side effects and how to prevent and manage them. However, high disparities may exist across European countries regarding patient education (PE) and support about MTX.

Objectives: To assess patients' and clinicians' perspectives and experiences on education and support received about MTX treatment in Europe.

Methods: A survey was developed by a team of international researchers and clinicians, including rheumatology nurses (from adult and paediatric care), a pharmacist, a rheumatologist, and patient representatives. Common and sample-specific questions were conceived for adult patients or carers (≥18 years) of children/young with RMDs, nurses, and physicians working in rheumatology in Europe. The survey was available in English and, for patients, in 12 additional languages, disseminated between May and December 2022. Ethics committee approval was obtained (116_CEIPC/2022_IPC).

Results: Complete responses were obtained from 1536 patients (52% with RA), 154 careers, 335 nurses, and 299 physicians (96% rheumatologists), from 24 European Countries, mainly from Northern (nurses) and Southern Europe (patients and physicians) (Table 1). Only 28% of patients had a specific nurse consultation when they started oral MTX, slightly increasing when the subcutaneous form was prescribed (42%), with variations across Europe, being higher in the Western (43%) and Northern (39%) and lower in Eastern (29%) and Southern (11%). These patients' perspectives are somewhat in line with physicians' perspectives, although according to nurses the access to them is higher, independent of the form of prescription (Table 1). Clinicians perceive higher opportunities to discuss patients' MTX concerns than the patients themselves (Table 1). Patients had more opportunities to voice their concerns (≥7 on a scale from 0 to 10) about MTX before starting it, in Western (57%) and Northern (42%) than in Southern (36%) and Eastern (31%) Europe. According to 47% of nurses, PE occurs on the same day of prescription, with the consultation lasting between 10-30 minutes in 50% of cases or even less than 10' (15%). 37% of nurses do not perform MTX-related follow-up appointments. Only half of the nurses (49%) received specific training to advise patients about MTX (data not shown).

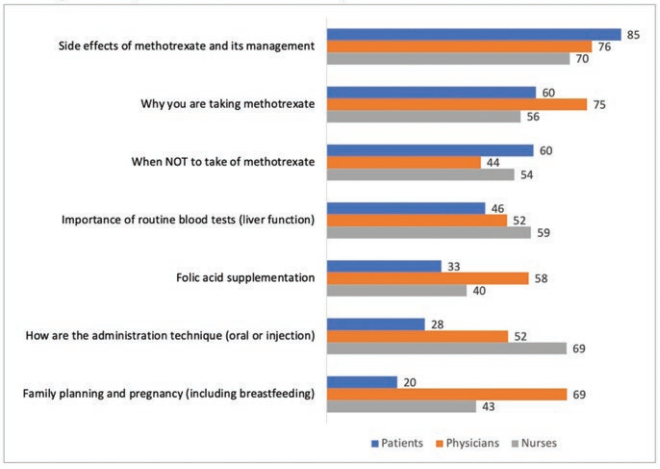

Table 1. Distribution of survey responses across Europe and education opportunities about MTX

		Patients and carers (n=1690)	Nurses (n=335)	Physicians (n=297)
European Region[a]	% North	22	52	21
	% South	37	10	46
	% East	21	17	22
	% West	20	21	11
Based on your experience, does every patient that initiates MTX have at least one educational session with a nurse?	% Yes, both oral and SC	--	61	30
	% yes, only if SC	--	25	31
Have you had an educational session with a nurse at start of…				
oral MTX?	% yes	28	--	--
SC MTX?	% yes	42	--	--
Opportunity to discuss concerns about MTX before starting it (from 0 to 10)	mean (SD)	4.9 (3.9)	7.6 (3.3)	8.6 (1.8)

a. According to United Nations geoscheme.

The priority ranking of topics to be addressed was also assessed, with agreement on the top one (side effects and their management) (Figure 1).

Figure 1 – Top-ranked* areas to address in patient education about Methotrexate

* Ordered by patients' ranking. All participants were given a list of 16 side-effects and asked to select top 5.

Around 77% of patients had/have concerns about potential unpleasant side effects, which were discussed with health professionals (mainly with rheumatologists) in 68% of the cases, despite not being clarified 46% of the times.

Conclusion: PE and support about MTX are unequal across Europe and can be improved by providing opportunities to clarify concerns, namely by providing patients with more access to nursing consultations. There is an overall agreement between patients and clinicians regarding key information areas of education, although a tailored approach is required.

OP0275-HPR 'IT'S A LOT TO TAKE IN': A SYSTEMATIC REVIEW OF THE INFORMATION NEEDS OF PEOPLE WITH INFLAMMATORY ARTHRITIS STARTING METHOTREXATE

Keywords: Patient information and education, Disease-modifying drugs (DMARDs), Systematic review

S. Logan[1], S. Hider[1,2], J. Green[3], S. Ryan[2]. [1]*Keele University, School of Medicine, Keele, United Kingdom*; [2]*Midlands Partnership NHS Foundation Trust, Rheumatology, Haywood Hospital, Staffordshire, United Kingdom*; [3]*Keele University, School of Nursing and Midwifery, Keele, United Kingdom*

Background: Guidelines recommend that people with Inflammatory Arthritis have access to tailored information when starting treatment with Methotrexate (MTX) [1]. It is not known what information people with Inflammatory Arthritis (IA) need to take MTX. Many people have concerns about the risk-benefit profile of MTX and so do not start or continue MTX.

Objectives: To identify and synthesize knowledge of the characteristics, content and preferred format of information that people with IA need to take MTX.

Methods: A PROSPERO registered systematic literature search (CRD42022325249) was conducted using Medline, Embase, Cinahl, PsychInfo, GreyEU, Web of Science and Open Dissertation databases. All full-length articles and conference abstracts identifying information and support needs of people with Inflammatory Arthritis, and oral or sub-cutaneous MTX as the main conventional DMARD considered in the study were assessed for inclusion. The systematic review was conducted and reported in accordance with the Joanna Briggs Institute methodological guidance for Mixed Methods Systematic Reviews [2] using a convergent integrated approach and the standards of the Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA) Statement.

Results: 8468 studies were identified. 169 studies were reviewed by full text of which 13 studies met the inclusion criteria. Seven quantitative studies used cross-sectional internet (n=2), postal (n=2), and rheumatology clinic (n=3) surveys, two mixed methods studies, one cross-sectional survey with clinic observations and one cross-sectional survey and focus group, and four qualitative (one interview and three focus group) studies. The combined studies included 3425 adults over the age of 18 years (20-84 yrs), most were female (71%, n=2434). More people were enrolled into studies (n6) involving people with a diagnosis of Rheumatoid Arthritis (n=2278) than studies (n=7) involving people with IA (n=840). Studies were conducted in the UK (n=4), Netherlands (n=3), Spain (n=2), Australia (n=2), Canada (n=1) and Japan (n=1) and reported in English. Quantitative results were qualitized. Three main themes were identified, with an overarching theme of a need for person-centred information about Methotrexate. 1: Information to support understanding and acceptance of the need for treatment with MTX: Learning about IA diagnosis, rationale for MTX in context of IA, benefits of MTX) 2: Concerns about MTX: including risk, likelihood and management of side effects, drug interactions, impacts upon lifestyle, developing medication self-management skills 3: Content and methods of information delivery: information sources, importance of support from healthcare professionals (hcp), family and friends, value of a therapeutic relationship with hcp.

Conclusion: People with IA have individual, multi-faceted information and support needs about both their condition and MTX, to enable them to take MTX. Further research is recommended to explore a) the expectations of information and support before receiving information about MTX, b) experiences of people receiving information at the time of starting MTX and c) strategies to improve information and support during the course of taking MTX.

OP0276-HPR DAY-TO-DAY FLUCTUATIONS OF FATIGUE IN SYSTEMIC SCLEROSIS

Keywords: Patient reported outcomes, Quality of life, Systemic sclerosis

A. Velauthapillai[1], M. Vonk[1], C. Van den Ende[1], J. E. Vriezekolk[2]. [1]*Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*; [2]*Sint Maartenskliniek, Research and Innovation, Nijmegen, Netherlands*

Background: Systemic sclerosis (SSc) is a rare auto-immune disease with a huge impact on physical health as well as social well-being, with fatigue being the major problem experienced by patients with respect to their well-being [1].

While fatigue is being reported to be fluctuating and unpredictable, the dynamic nature of fatigue is not well understood [1, 2].

Objectives: To examine the within-person fluctuations and clinically meaningful changes in fatigue, as well as the within-person association of fatigue and time-varying determinants in SSc.

Methods: We performed a daily-diary study in adult patients with a clinical diagnosis of SSc. Patients with pulmonary hypertension or severe pulmonary function disturbances (i.e. vital capacity and diffusing capacity for carbon monoxide < 50%) were excluded. During 14 days patients completed daily assessments at four fixed time points (i.e. 9 a.m., 1 p.m., 5 p.m., 9 p.m.) of fatigue severity and time-varying determinants (i.e. negative affect, positive affect, pain, quality of sleep and perceived exertion of physical activity. As proxy for clinical meaningful change in fatigue the probability of acute change(PAC) was assessed, i.e. the chance that change in day-to-day fatigue levels exceeded the minimally clinical important difference for fatigue[3]. Using multilevel models the within-person fluctuations in fatigue and its association with time-varying determinants were examined. Based on the extent of clustering, the time-varying determinants were disentangled into their corresponding levels (within persons (within day as well as across days) and between persons) and added to the multilevel model. Models were adjusted for confounding (i.e. BMI, sex, age, and history of covid-infection) where appropriate.

Results: Fifty-seven patients with SSc, 35% male with mean(SD) age 54.3(14.6) years, participated. The disease duration was mean(SD) 6.9(4.8) years and 29.8 % was diagnosed with diffuse cutaneous SSc. Eighty percent of all observations were completed. During the study period, change in day-to-day level fatigue exceeded the MCID mean(SD) 5.7(1.9) times. The PAC was mean(SD) 0.44(0.14), ranging from 0.08-0.77. For fatigue a between-person variation of 49% and a within-person variation of 51% was observed. With respect to confounders, only BMI was significant in the models for time-varying negative and positive affect. The final models showed significant within-person association with fatigue fluctuations and changes in time-varying determinants within a day, between days and between patients (Table 1).

Conclusion: This is the first quantitative study showing that fatigue in SSc is characterized by a dynamic course and that approximately half of the day-to-day fluctuations are clinically meaningful, confirming the results of qualitative studies[2]. Moreover, when patients reported more fatigue than usual, they also reported more pain, more negative affect, less positive affect, more perceived exertion of physical activity, and worse quality of sleep than usual.

Table 1. Association of within-person fluctuations of fatigue and time-varying determinants at each level. All β are significant (p-value< 0.05). * corrected for BMI, β: regression coefficient, N/A: not applicable.

Within-person fatigue fluctuation	β (95% ci) level 1 within- day	β level(95% ci) 2 between days	β level (95% ci) 3 between patients
Negative affect *	0.44(0.37, 0.51)	0.41(0.31, 0.50)	0.72(0.46, 0.98)
Positive affect *	-0.60(-0.66, -0.53)	-0.61(-0.69, -0.53)	-0.74(-1.05, -0.42)
Pain	0.46(0.39, 0.52)	0.49(0.37, 0.62)	0.48(0.33, 0.62)
Perceived exertion of physical activity	0.19(0.15, 0.24)	0.25(0.16, 0.35)	0.76(0.48, 1.04)

Background: Although the relationship between health literacy and treatment outcome has been reported in certain illnesses[1,2], it remains unclear how health literacy affects treatment selection.
Objectives: This study aims to determine the relationship between health literacy and treatment status in patients with systemic lupus erythematosus (SLE) who have achieved a low disease activity state (LLDAS).
Methods: A cross-sectional study was conducted on 266 SLE patients who had achieved LLDAS, registered in the TRUMP[2]-SLE study[3], an ongoing multicenter cohort study conducted at five academic centers in Japan. The main exposure was the health literacy (scores 0-56) of the enrolled patients, as measured by the 14-item Communicative Critical Health Literacy Scale (FCCHL). The primary outcomes were daily glucocorticoid dose, hydroxychloroquine (HCQ) use, and immunosuppressant use. A secondary outcome was chronic damage measured by Systemic Lupus International Collaborating Clinics-Damage Index (SLICC-DI). Odds ratios (ORs) to assess the relationship between health literacy and treatment status were estimated with adjustment for confounders (age, sex, income, education, disease duration, and SLICC-DI).
Results: The median age of the patients was 47 years (interquartile range [IQR], 36-58), 88% were female, and the median disease duration was 13 years (IQR, 7-20). The median FCCHL score were 3.1 (IQR, 3.0-3.5). The median daily glucocorticoid dose (prednisolone equivalent) was 4 mg (IQR 2-5). HCQ was used in 122 (45.9%) and immunosuppressant was used in 174 (65.4%) of enrolled patients, respectively. FCCHL score were not associated with glucocorticoid dose (r^2 = 0.015). FCCHL score was not statistically different between patients with and without immunosuppressants (median 3.07 [IQR, 2.79-3.36] and 3.04 [IQR, 2.71-3.29], p = 0.81) but statistically different between patients with and without HCQ (median 3.14 [IQR, 2.36-3.93] and 3.00 [IQR, 2.71-3.25], p = 0.0028). After adjustment for confounders, HCQ use was significantly associated with FCCHL score (OR: 2.27, 95% confidence interval: 1.19-4.36). FCCHL score was not statistically associated with SLICC-DI (r^2 = 0.0091).
Conclusion: Even among the SLE patients who have achieved LLDAS, the preference of HCQ usage may vary depending on health literacy.

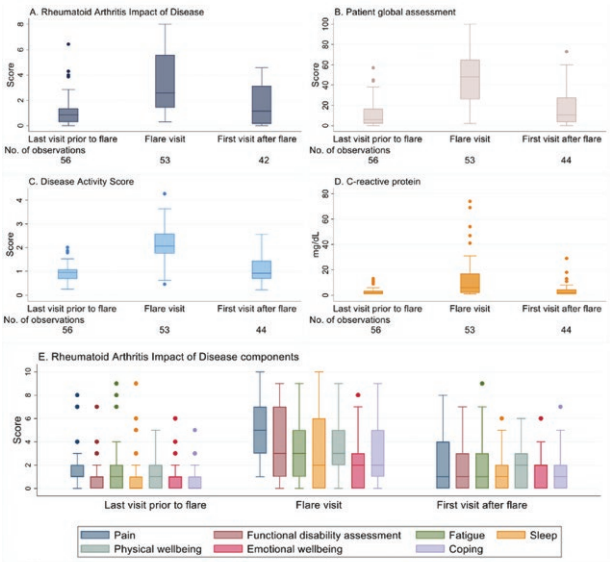
OP0279-HPR



RESPONSIVENESS AND DISCRIMINATIVE ABILITY OF THE RHEUMATOID ARTHRITIS IMPACT OF DISEASE (RAID) SCORE TO CLINICAL DISEASE FLARE: DATA FROM THE DMARD TAPERING ARCTIC REWIND TRIALS

Keywords: Rheumatoid arthritis, Patient reported outcomes, Self-management

K. Holten[1,2], N. P. Sundlisæter[1], J. Sexton[1], L. Nordberg[1], T. Uhlig[1,2], T. K. Kvien[1,2], E. A. Haavardsholm[1,2], S. Lillegraven[1,2], A. B. Aga[1]. [1]*Diakonhjemmet Hospital, Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*; [2]*University of Oslo, Faculty of Medicine, Oslo, Norway*

Background: The Rheumatoid Arthritis Impact of Disease (RAID) is a patient-reported outcome measure (PROM) originating from a EULAR initiative. It supports patient-centered care and shared decision-making between patient and rheumatologist regarding treatment and adjustment of medication. RAID could be a useful tool in remote monitoring, and its association with disease activity is thus of interest.[1] It is not known if RAID is responsive and discriminative to disease activity flares.
Objectives: To explore the responsiveness of the RAID (sum score and single domain scores) to clinical disease flare and to assess its discriminative ability with regard to flare.
Methods: We used data from the two Norwegian multicenter ARCTIC REWIND trials assessing tapering of TNFi and csDMARDs (ClinicalTrials.gov: NCT01881308).[2] Eligible participants had RA (ACR/EULAR 2010 criteria), were in sustained remission for ≥12 months on stable DMARDs with Disease Activity Score (DAS) remission combined with no swollen joints at inclusion. In the TNFi trial, patients were randomized to stable TNFi or tapering to discontinuation of TNFi (stable csDMARD comedication). Patients in the csDMARD trial were randomized to stable or half dose treatment for the first year. Study visits with assessment of disease activity were conducted every four months, if a flare was suspected between visits the patient was seen within a week. Flare was defined as a combination of DAS>1.6, an increase in DAS ≥0.6 units from the previous visit and minimum two swollen joints. If a patient did not fulfill these criteria, a disease flare could be recorded if both the patient and investigator agreed that a clinically significant flare had occurred. If a flare was confirmed, the full dose of the study medication was reinstated or (in the stable-dose group) treatment adjusted according to current recommendations. We evaluated the median RAID score and single domains at the last visit before flare, flare visit and first visit after flare in relation to the suggested ≤2 RAID threshold for patient acceptable symptom state (PASS), and assessed the changes between those visits using Wilcoxon rank-sum test.[3] The ability of RAID to detect disease flare was assessed using the area under the ROC curve (AUC) based on logistic regression models. For comparison, similar analyses were performed for patient global assessment (PGA), DAS and C-reactive protein (CRP).
Results: Of the 248 patients included, 159 (64%) were female. Mean (SD) age and disease duration were 56 (11.8) and 6.3 (5.7) years. For patients who experienced a flare the median (IQR) RAID score was 0.9 (0.3, 1.4) at last visit prior to flare with 86% of scores within the PASS range. At the flare visit median RAID was 2.6 (1.4, 5.6) with only 30% of scores within the PASS range (**Figure 1**). Similar changes were observed in DAS, PGA and CRP. All seven RAID domains increased significantly at the flare visit (p-values < 0.01), with the largest increase in pain (**Figure 1**). According to the AUC analyses the estimated accuracy in detecting flare was high for RAID, but higher for DAS and PGA. CRP was less accurate in detecting flare (**Table 1**).
Conclusion: There was a clinically and statistically significant increase in median RAID score and all single domains of RAID at flare visit, supporting its responsiveness to clinical disease flares. Both RAID and PGA discriminated well between flare and non-flare, hence both PROMs might contribute in early identification of flare and patients who might need an adjustment of medication, in a regular clinical setting as well as in remote monitoring of disease activity.

OP0280-HPR VALIDATION OF A NEW GLUCOCORTICOID-SPECIFIC PATIENT REPORTED OUTCOME QUESTIONNAIRE (THE STEROID PRO)

Keywords: Outcome measures, Quality of life, Patient reported outcomes

S. Bridgewater[1,2], M. Ndosi[1,2], J. Dawson[3], P. Richards[2], C. Silverthorne[1,2], E. Dures[1,2], S. Goodman[4], C. Hill[5,6], S. Mackie[7,8], J. Robson[1,2]. *[1]University of the West of England, Faculty of Health and Applied Sciences, Bristol, United Kingdom*; *[2]University Hospitals Bristol and Weston NHS Foundation Trust, Academic Rheumatology, Bristol, United Kingdom*; *[3]University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom*; *[4]Hospital for Special Surgery, Weill Cornell Medicine, Division of Rheumatology, New York, United States of America*; *[5]The University of Adelaide, Discipline of Medicine, Adelaide, Australia*; *[6]Royal Adelaide Hospital, Rheumatology Unit, Adelaide, Australia*; *[7]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[8]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Glucocorticoids are used in the treatment of a broad range of rheumatic conditions but can have a significant impact on health-related quality of life[1]. In-depth qualitative interviews with patients who have experience of glucocorticoid treatment for their rheumatic disease, from the UK, USA and Australia, were used to develop candidate items for a treatment-specific Patient Reported Outcome Measure (PROM): the Steroid PRO.

Objectives: We aimed to complete the development and validation of the Steroid PRO through use of a cross-cultural validation study.
Methods: This was a cross-sectional online study of adults taking glucocorticoids for a rheumatic disease, from the UK, USA, Australia and New Zealand. A steering committee comprising methodologists, clinicians and patient research partners (PRPs) oversaw the study. The survey was distributed via social media with support from patient groups. Baseline data included: (i) demographics - age, gender, country, ethnicity, educational level; (ii) clinical information - diagnosis, glucocorticoid dose; (iii) 40 candidate items for the Steroid-PRO, developed in a previous qualitative study; (iv) EQ5D-5L. Optional follow-up data collected 3-5 days later: (i) the Steroid PRO candidate items; (ii) a condition change question. After descriptive analysis, iterative testing with Rasch measurement model and exploratory factor analysis (EFA) informed item reduction and established structural validity, reliability and unidimensionality of the final Steroid PRO. Item reduction was based on clinical importance, lack of fit to the Rasch model, and redundancy. Evidence of discriminative validity of the Steroid PRO was established by comparing its scores for participants receiving lower dose glucocorticoid (up to 10 mg) versus higher dose (>10 mg). Intraclass correlation (ICC) between baseline and follow-up was calculated for patients who reported 'no change' compared with 3-5 days ago.
Results: A total of 946 patients returned complete responses at baseline (follow-up: 447 responses). They were from UK, n=743 (78.5%); USA, n=139 (14.7%); Australia, n=59 (6.2%). Their mean age was 57.6 (SD=13.6); 833 (88%) were women. They were treated for inflammatory arthritis (n=194), connective tissue disease and/or vasculitis (n=398), and giant cell arteritis and/or polymyalgia rheumatica (n=341). A total of 25 items were removed due to floor effects and lack of fit to the Rasch model. Iterative discussions between statisticians, clinicians and PRPs ensured that items of high clinical importance were retained. The remaining 15 items showed a satisfactory fit to the model. EFA suggested a scale structure with four domains: Participation (4 items), Appearance (3 items), Psychological (5 items), and Treatment concerns (3 items). PRPs were involved in naming the domains. The 4-domain structure was supported by the Rasch model, confirming construct validity; $\chi 2$=47.82 (DF=36), p=0.899; and reliability (Person Separation Index, PSI=0.757). Total scores also fitted the Rasch model, therefore both domain and total scores will be psychometrically appropriate for use as a repeated measure. A good fit to the Rasch model was also seen across the disease groups with items distributed equally across the three groups. Patients on a lower glucocorticoid dose had lower Steroid PRO domain scores than those receiving higher dose (discriminant validity). ICC between baseline and follow-up ranged from 0.892 to 0.942 (95%CI 0.868 to 0.953) suggesting excellent (test-retest) reliability.
Conclusion: The final Steroid PRO is a 15-item, valid and reliable 4-domain scale measuring the impact of glucocorticoid therapy on HRQoL of people with rheumatic diseases.

PARE Abstract Session

OP0281-PARE LUPUS EUROPE'S PATIENT ADVISORY NETWORK – A HUGE DOUBLE SUCCESS

Keywords: Patient-led research, Best practices

A. Cornet[1], Z. Karakikla-Mitsakou[2], A. Sluijmers[2], A. Somers[2], J. Andersen[2]. *[1]Lupus Europe, HQ, Brussels, Belgium*; *[2]Lupus Europe, PAN, Brussels, Belgium*

Background: Financial and Human Resources are 2 key issues faced by European federations of Patient organisations and limiting their impact. This reality is

also a vicious circle as volunteers are needed to deliver the projects, themselves forming the basis to fund the organisation. When preparing its 2018-2023 strategic plan, Lupus Europe was confronted with this frustrating reality with incomes stagnating around 40,000€/year, just enough to cover its basic operations, convention and few limited size projects.
Objectives: To step change Lupus Europe's development and unlock both the funding and volunteering recruitment bottlenecks by creating an energising Patient Advisory Network.
Methods: As part of its 2018-22 strategic plan discussions, the Lupus Europe designed the structure of a Patient Advisory Network (PAN) as a key way to reach its objectives, in a way that combined both volunteers and sponsors motivation factors. For volunteers, the PAN offered an opportunity to move from a victim of the disease position to that of an actor of the change, working together with other fellows, equally motivated. Initial patients were selected based on their positive energy and desire to change things and grow skills. We identified (web based) opportunities to grow the needed skills, and encouraged participation. Finalising the team charter, drafted by the board, became the first exercise of the team, which then dedicated itself to support projects from academics, clinicians or industry, and work on own lupus Europe projects. The visibility of the PAN quickly became an additional motivator, and many applications to join were received. PAN members agreed that potential remuneration for their work would accrue to Lupus Europe and be used to motivate and reward the group. For sponsors, we redesigned our partnership proposal, using the PAN to step change engagement levels. We asked our sponsors for a leap of faith that we could drive this to success, and that they would benefit from it as much as we would by making our community more vibrant. We also offered to all a sample of what the team could do to support key projects. We engaged with academics to identify valuable projects and asked them to give training to the team. In parallel, we invested some of our savings to fund initial costs, and provided soft skills training for the group. Two years later, we applied and obtained EMA recognition as EMA eligible entity. Early successes boosted the team's morale and helped reach out to more partners. This in turn allowed us to "put the program on steroids", multiplying our support to the group and the number of projects generated by Lupus Europe. Things we had never imagined being able to do by ourselves, like the Living with Lupus survey (5000+ answers) or lupus100.org (info on lupus in 18 languages) were "suddenly" all feasible. In 2022 we recognised most experienced members as Fellows offering an aspirational "path for growth" to all, from trainee to ambassador to expert and Fellow.
Results: 5 years after its start, the PAN is now rich of 23 highly motivated members working on 25 projects (50/50 industry/non-industry) including some of our own design. It is recognised as a best in class organisation, and keeps growing, enabling us to achieve results we could not have dreamed of 5 years ago. Lupus Europe's funding jumped from 40k in 2017 to more than 300k in 2021, allowing to do more projects, invite PAN members to SL Euro or EULAR and professionalise some of our support. It also increased our independence from pharma, as we feel free to say no to any funder we don't fully feel happy with (and we did it already twice!)
Conclusion: The PAN project as transformed lupus Europe from a minimalist federation to the key voice and support of people living with lupus in Europe.
Acknowledgements: Many thanks to LUPUS EUROPE's Patient Advisory Network members whose enthusiasm and commitment has been critical for the success of this project.
Disclosure of Interests: None Declared.
DOI: 10.1136/annrheumdis-2023-eular.2950

OP0282-PARE WORLD ARTHRITIS DAY, A UNIQUE CAMPAIGN

Keywords: Best practices

C. Kyriakou Yiasoumi[1]. [1]*Cyprus League of People with Rheumatism, Raising Awarness, Nicosia, Cyprus*

Background: Since its establishment in 1996, World Arthritis Day is celebrated every year on the 12th of October, across the world and in my country as well. Several events-campaigns, take place aiming to raise awareness among the general public, stakeholders, politicians and people with Rheumatic and Musculoskeletal diseases, health care professionals, elected officials and the relevant governmental authorities. Giving the message to the public about the early symptoms, the importance of early diagnosis, the importance of proper therapy and the importance of managing the disease is the aim of the existence of the day. Our organisation traditionally for this day, organizes big Campaigns among all the above in addition to achieve recognition of the Organization in the General Public. In 2021 for the first year, we established very successfully a new campaign called, <Wear me>. In this campaign, the idea was to engage People and Companies to wear a T-shirt for us. In 2022 the target was bigger than the previous year. The idea was to create text through a photo. As we all know, picture talk more to people than words. These days, with the internet overuse and Social Media's role in our lives, words and pictures pass in front of us, in hundreds every day. We wanted a strong IMAGE to make people curious about RMDs and about our organisation.
Objectives: The major objectives were:

- To raise awareness of WAD.
- To increase the Prevention of RMDs.
- To make our league more popular.
- To become more familiar and recognizable with our new name and logo.
-T o get involved in the campaign more people than in 2021.

Methods: Six months before the WAD, a Task Force for the campaign was established, to build the Action Plan. Without h a very good plan, we can't have a successful campaign. After several meetings and discussions, the action plan was ready four months before the WAD.Main target: to involve 2000 People (we had 1.400 people in 2021), to wear a t-shirt with our logo on the 12th of October 2022. In addition, our prompt was to take a photo, post it on their social media, use the hashtag (#) and the name of our organisation. The Action plan had four Phases: First, contact the people and the companies, by writing two letters, one for those that they participated in the previous year to ask them to stand with us, again and the second one for new companies or people that we wanted to approach for participating in this year campaign.Second, to find funds for the campaign and for purchase the T-Shirts.Third, to deliver all the T-shirts on time and fourth, to be able to Post or Re- Post all the photos on organization's FB page.
Results: Our results were over and above our expectations! Achieving goals: We contact many small and medium local companies, coffee chains, hairdressing salons, gyms, physiotherapists,health insurance companies, pharmacies etc... Schools and municipality employees. We involved doctors, nurses, famous people, athletes, actors, singers, journalists, football players, athletes' teams, politicians and the president of Cyprus Parliament.A lot of TVs and Radio Channels cover the campaign, even some of them wore our T-shirts during the shows all day. We reached over and above our target of the use of T-Shirt.2700 people wore the t-shirt with the logo of our organisation, on the 12th of October 2022. The FB results were extremely positive! The organization's FB page reached 30000 views, the whole week. The FB page had an average of 213% increase in visiting compared to the previous week.
Conclusion: Compare to the previous year, almost twice the number of participants wore our t-shirt. Engagement on Facebook was satisfactory. The hashtag was applied as a caption to the pictures taken. There was a big discussion on social media and TV shows about the campaign. A lot of people were asking to buy the t-shirt to support our league. A lot of people were calling our offices to get information about our services and our programs. The general conclusion is that the need of raising awareness for RMDs is still high.

OP0283-PARE HELLENIC LEAGUE'S AGAINST RHEUMATISM'S SCHOOL OF HEALTH EDUCATION

Keywords: Quality of care, Patient information and education, Best practices

K. Antonopoulou[1], A. Pappa[1], D. Kouvelas[2], N. Malliou[3], K. Tsekoura[1], M. Salamaliki[4], E. Oikonomoula[5], K. Rousta[6]. [1]*Hellenic League Against Rheumatism, Heartquarters, Athens, Greece*; [2]*Aristotle University of Thessalonik, Pharmacology and Clinical Pharmacology, Thessaloniki, Greece*; [3]*Hellenic League Against Rheumatism, Thessaloniki Branch, Thessaloniki, Greece*; [4]*Hellenic League Against Rheumatism, Patra Branch, Patra, Greece*; [5]*Hellenic League Against Rheumatism, Karditsa/Larissa Branch, Karditsa, Greece*; [6]*Hellenic League Against Rheumatism, Trikala Branch, Trikala, Greece*

Background: The more time healthcare professionals spend with patients the better the health outcomes become. Therefore, education seems to play a crucial role for the quality of life not only for the patients but also for the health care costs and the future cost projections that depend on the health outcomes of everyone.
Objectives: Aim of the School of Health Education is to give the opportunity to participants to familiarize themselves with frequently used terminology in everyday clinical practice, to become accustomed in using the common medical language when describing their symptoms to their doctors so that they will have a common ground. Basic goal of this education is for every patient to understand a bit more about concepts such as medications, adverse events, pharmacovigilance etc.

Methods: Interactive live events, of approximately 2hour duration, have already take place in 15 cities of Greece. In the year 2020 COVID restrictions did not allow for such events to be organized. The project will start again during 2023. Speakers in the events were: rheumatologists, general physicians, anesthesiologists, psychiatrists, psychologists, gynecologists, clinical pharmacologists and others.
Results: Over 1800 patients, caregivers, members of the public, stakeholders, members of the local authorities, healthcare professional and others participated in the live events. Handouts and printed material from HELAR/ELEANA were given to participants as well an evaluation form to complete. The events generated a lot of press locally and nationally, with 4 press conferences, 25 press releases, 18 TV interviews and 10 radio interviews.
Conclusion: Publicity and participation in the events showed that patient education is quite important for the patients and the local communities. Since 2020 and the COVID pandemic there has been a shift towards public health issues and health education creating a unique opportunity for HELAR/ELEANA's School of Health Education to be adapted and become once more available for the patients living with an RMD. This time the new version could be either a virtual version or a live version for many more patients, caregivers and the public to be able to attend.
Acknowledgements: Hellenic League Against Rheumatism is grateful to Dimitrios Kouvelas, MD, BPharm, PhD, Professor of Pharmacology and Clinical Pharmacology, Head of the Dept of Clinical Pharmacology, School of Medicine, Aristotle University of Thessaloniki for his precious scientific contribution, implementation and for being the main speaker voluntarily. The School of Health Education was awarded the bronze prize by the Health Care Business Awards in 2019.

OP0284-PARE IPARE – GLOBAL COLLABORATION OF PATIENT ORGANISATIONS FOR THE BENEFIT OF RMD PATIENTS

Keywords: Patient information and education, Best practices, Geographical differences

D. Wiek[1]. [1]*EULAR, Pare, Zuerich, Switzerland*

Background: Rheumatic and musculoskeletal diseases (RMDs) are a burden for individuals and a challenge to healthcare systems. Comparing the current and the future number of rheumatologists and the frequency of RMDs, studies state a huge gap. Another key issue is the uneven distribution of rheumatologists in most countries. These deficits are glaring in low and middle income countries in particular. In sub-Saharan Africa e.g. just in the past 20 years more attention has been drawn to non-communicable diseases. Great challenges exist in Latin America. Patient organisations (POs) offer information and assistance, are competence networks, represent and advocate for patients' interests and needs and play a pivotal role in healthcare systems.
Objectives: Overarching: With its activities IPARE aims at contributing to a world, where RMDs are recognized, prevented and cured, and patient-centredness is an integral part of health care delivery.
The **specific** aims are.

- To connect and exchange with national patient organisations and continental networks/organisations of patient organisations from other continents than Europe.
- To develop, step by step, a network of globally active national POs, national umbrella POs and continental POs.
- To initiate collaborative projects in the field of education, research, quality of care, congress and advocacy.
- To share best practices aiming at developing and supporting POs and pan-continental POs.
- To promote the access to and the exchange at conferences and congresses for RMDs.

Methods: IPARE is a PARE project group embedded in the PARE Sub-Committee „Community Relations", meaning all EULAR regulations will apply. A small project group consisting of representatives from South and Central America, North America, Africa and Europe has been established. We are aiming at enlarging the group (e.g. by having a representative from Asia), but the total number should not exceed 10 in order to work efficiently. After an introductory in-person meeting at the PARE Conference in October the members decided to meet virtually every 6-8 weeks. Webinars are offered every 2-3 months. Aspects of membership, objectives, mode of working were defined.
Results: The project group members identified - in spite of different health care systems, economic statuses and the extent of the deficits - certain commonalities like lack of rheumatologists (in particular lack of paediatric rheumatologists), shortage of health professionals (e.g. nurses, physiotherapists trained for the treatment of RMDs), delayed diagnosis, access to medical treatment according to internationally accepted treatment recommendations, insufficient non-pharmacological treatment, needs to educate the public and create awareness for RMDs and the situation of people with an RMD, research and patient involvement in research. The group developed a first list of items how these deficits could be tackled, how we can collaborate being aware of the fact that national peculiarities and features and language items have to be taken into account if any material will be produced. To avoid duplication and to check what already exists, an inventory list of informative and educational material is being established. A first webinar open to all representatives of international patient organisations is determined for February.
Conclusion: The project group members work with great enthusiasm, are eager to share knowledge and want to learn what can be implemented in their organisations and countries. In addition the group members focus on supranational issues. The project group members share, learn and convey to support implementation.

OP0285-PARE THE USE OF OBJECTS TO EXPERIENCE INFLAMMATORY RHEUMATIC DISEASES IN ORDER TO INCREASE KNOWLEDGE AND UNDERSTANDING THROUGH PERSPECTIVE- TAKING, WITH A FOCUS ON ENHANCING EMPATHY

Keywords: Patient information and education, Mental health, Education

T. C. Wilhelmer[1]. [1]*FH-Vorarlberg, Intermedia, Dornbirn, Austria*

Background: People with chronic diseases often experience little sympathy towards their situation and are in many cases stigmatized. The deficiency of knowledge is one main problem that leads to said lack of understanding. For people with RMDs this leads to the exclusion from social life and has a negative impact on their mental health. To reverse this trend, more innovative methods are needed to promote understanding in society as well as in the personal environment of people with debilitating diseases. This abstract presents a Master-Thesis in the field of Intermedia, created by a Student with an RMD. The paper examines existing methods for communicating understanding of chronic illnesses through media using scenography. It assesses which methods of communication can be used to increase empathy towards physically disabled people and thereby improve their inclusion in society. Using the findings of this research, the student created a concept for a public exhibition.
Objectives: Promote empathy towards disabled and chronically ill people. Educate adults in their function as role models for children, to improve early inclusion. Achieve a long-term change in society, to foster inclusion of persons affected by an RMD in society.
Methods: Examples of different performances of illness and their impact on those affected are gathered and discussed. The analysis contains aspects of the communicative methods that have not yet been researched or sufficiently explored. In the field of rheumatic diseases there are not many innovative methods to educate society about the psychosocial impact that an RMD has on the person affected. Existing materials are mainly targeting patients or their close ones. Public campaigning primarily focuses on medical facts. Research shows that immersive experience is more effective in educating than reading, hearing, or viewing information. The combination of facts and an immersive experience strengthens the learning effect and can have a sustainable impact on people's behaviour. Through immersive experience, there is a possibility to build and strengthen empathy. These factors are significant for the structure of the exhibition.
Results: The concept of the exhibition is based on existing best practice examples and researched methods. The Visitors are confronted with the topic of chronic diseases in an immersive way. The exhibition is sequenced to first get the visitor's attention by vision, followed by the possibility to physically get in touch with the exhibition's artefacts that imitate various symptoms. For instance, they can try on splints or sit on a manipulated chair. The elaborated concept is enclosed within the original thesis, to present the path of experience with the contents. The developed artefacts were tested and are based on several interviews for their suitability and their effectiveness. Their relevance was confirmed.

Graphic 1. Mockup of the exhibition

Conclusion: Research underpins the need for innovative methods to promote understanding of people with RMDs. Considering research, the developed concept with a combination of facts and immersive experience is likely to be successful in strengthening empathy towards chronically ill people. The design of the mobile exhibition is scalable. The concept is gladly shared with other patient organisations and is ready to be put into reality.

OP0286-PARE UNMET NEEDS IN RESEARCH, HOW PATIENTS CAN COLLABORATE:THE EXAMPLE OF NECESSITY

Keywords: Patient information and education, Sjögren syndrome, Patient reported outcomes

C. Bouillot[1], K. M. Hammitt[2], A. Hjertviksten Lindland[3], M. Oosterbaan[4], M. Pincemin[1], L. Stone[5]. *[1]AFGS, Patient association, Paris, France*; *[2]Sjögren's Foundation, Patient association, Reston, United States of America*; *[3]Diagnosegruppe Sjögrens Syndrom, Patient association, Oslo, Norway*; *[4]Nationale Vereniging Sjögrenpatiënten, Patient association, Maarssen, Netherlands*; *[5]BSSA, Patient association, Birmingham, United Kingdom*

Background: NeceSSity stands for "New Clinical Endpoints in primary Sjögren's Syndrome: an Interventional Trial based on stratifYing patients". International consortium involving 25 partners (20 academics, 4 pharma and 1 patient association) funded by the Innovative Medicines Initiative (IMI2), this public-private partnership between EU and EFPIA specifically requested the involvement of Sjögren's patients.

Objectives: Determine realistically the role patients should play and elucidate their added value in such a project.

Methods: A patient association has been included from the beginning of the project (even before submission) as partner and is involved in 6 out of 10 Working Packages (WPs).

Results: Patients were involved in the conception and design of the study. In particular, they established a Patient Advisory Group (PAG). The PAG participated in the creation of the website and the design of lay versions in several languages, reviewed and adapted protocol and consent forms, largely contributed to the creation of STAR, the new primary endpoint assessment score, and participated in dissemination and communication. Patients have an active advocacy role in this project. As the voice of a large Sjögren's community with sometimes major disparities in care, the PAG has been active in participating in the different meetings and supporting and promoting the project to the general public and Health Authorities. As a culmination of the first phase, 20 patients provided valuable input, particularly during the development of STAR, to ensure that the validated clinical endpoints are relevant for patients, raising issues that had not been considered fully, if at all. The opinions expressed by patients during the Delphi Survey contributed substantially to this evaluation tool, taking into account the patient's feelings, which are often poorly evaluated or ignored. This future "gold standard", which will be presented to the EMA and FDA, could not have been developed without the participation of patients. In addition, patients were invited to test a webapp that will serve as an evaluation tool throughout the clinical trial. The feedback from the PAG will contribute to the success of this patient-reported outcome tool and has helped to correct issues to ensure its success during the clinical trial.

Conclusion: Patient involvement in research is now widely accepted and the benefits are clear. The authorities now frequently require validation by patients. It is quite possible to work in harmony, bearing in mind the constraints and specificities of each stakeholder, in particular that patient participation is voluntary and that their health might not allow them to react immediately. Clinicians, researchers and patients have complementary skills and perspectives which, when shared, will strengthen the project.

OP0287-PARE PATIENT AND PUBLIC INVOLVEMENT IN THE IMPLEMENTATION OF RESEARCH

Keywords: Real-world evidence, Best practices, Patient information and education

L. Campbell[1], N. Evans[1], M. Skrybant[2,3], L. Group[1], K. Dziedzic[1]. *[1]Keele University, Impact Accelerator Unit, Newcastle under Lyme, United Kingdom*; *[2]NIHR Applied Research Collaboration, West Midlands, Birmingham, United Kingdom*; *[3]University of Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom*

Background: Patient and Public Involvement and Engagement (PPIE) is now common practice in the design and delivery of arthritis research studies in the UK. Yet PPIE in the implementation of this research into practice is a novel and developing area. Coordinated, planned collaboration and relationship building with patients and the public in communities and health settings into which research will be implemented can facilitate greater impact of research findings. It can provide patients with accessible evidence based knowledge to enable more control in decision making about their own condition.

Objectives: To describe the work of an established group of patients and the public working collaboratively alongside healthcare professionals, researchers and knowledge brokers to actively implement arthritis research evidence into practice.

Methods: The Link Group (n=10 members) meets six times a year to provide meaningful patient and public input and oversight to all implementation projects delivered by the Impact Accelerator Unit, Keele University (UK). Members have links to community, charity, public and patient networks, helping to facilitate the movement of knowledge and evidence based innovations into wider use, nationally and internationally. Link Group task and finish meetings take place according to project demand to co-create strategies to implement research evidence. Roles and responsibilities are identified early on, members attend project operational core groups and ongoing feedback on implementation progress is provided. Link Group members work with researchers (to ensure evidence based messages are included in innovations), healthcare professionals (to discuss how innovations can be best used in clinical practice) and knowledge brokers (to design the finished output and collate all information). Patients, carers and the public contribute valuable knowledge to the process of implementation, including their own experiences of living with arthritis, attitudes and beliefs regarding the healthcare system and knowledge of networks to open up new ways to share innovations.

Results: Link Group members have:

- Co-developed funding applications and research designs to ensure early preparation for implementation, providing advice and support for methods of impact and implementation to be considered by researchers.
- Co-created patient facing resources in a range of formats and for different demographics. For example, evidence based guidebooks, posters, leaflets, animations and infographics for people with arthritis and people with long term pain and mental health (www.jigsaw-e.com / www.beefree.org.uk). The Link Group make sure the language in patient facing resources is easily understood, visuals are engaging and diversity is represented.
- Co-developed a simple, trusted guide summarising current physiotherapy arthritis research, making complex information more accessible and

consequently supporting high-quality care by facilitating discussions between patients and physiotherapists (https://evidence.nihr.ac.uk/wp-content/uploads/2020/09/Moving-Forward-FINAL-August-2020_Pages.pdf).
- Taken patient facing innovations and resources into local community and volunteer groups, given talks at peer-to-peer information events and shared resources digitally via social media to networks.

Conclusion: PPIE in implementation can facilitate the successful implementation of research evidence into practice, for the benefit of people with arthritis. An established patient and public group can provide community insight and 'real world' perspective which can strengthen diversity and reach, and make evidence based research innovations more accessible, relatable and useful in clinical practice. Link Group members have developed a sense of ownership of the innovations that are being implemented and as such are passionate about their work: *"Straightforward information and practical advice, choosing words and pictures to reflect a healthy life, working closely as a team, a cog within a wheel, creating something special, a resource with appeal"* - Link Group member.

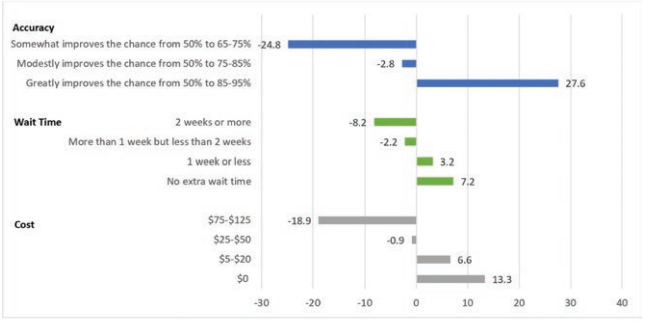
OP0288-PARE PATIENT PERCEPTIONS OF RHEUMATOID ARTHRITIS BLOOD WORK AND UTILITY OF A TEST PREDICTING RESPONSE TO NEW MEDICATION: A CROSS-SECTIONAL SURVEY IN THE ARTHRITISPOWER

Keywords: Biomarkers, Rheumatoid arthritis, Disease-modifying drugs (DMARDs)

W. B. Nowell[1], S. Venkatachalam[1], K. Gavigan[1], M. George[2], J. Withers[3], L. Stradford[1], E. Rivera[1], J. Curtis[4]. [1]*Global Healthy Living Foundation, Research, Nyack, United States of America*; [2]*University of Pennsylvania, Rheumatology, Philadelphia, United States of America*; [3]*Scipher Medicine, Research, Waltham, United States of America*; [4]*University of Alabama at Birmingham, Rheumatology, Birmingham, United States of America*



Background: No published studies have assessed the perspectives of people with RA (pts) on disease-related lab testing and its role in treatment decision-making.
Objectives: Our objective was to examine how pts perceive RA-related lab testing and pts' perceived utility of a blood test to predict treatment response to a new RA medication.
Methods: A cross-sectional survey was developed with input from pts, rheumatologists, researchers, and pt advocates. Members of ArthritisPower with a self-reported physician diagnosis of RA were invited to participate in the online survey which included questions related to reasons for lab testing, plus a choice-based conjoint analysis (CA) exercise to determine how pts value different attributes of a blood test to predict treatment response. For the CA, 48 different hypothetical test characteristics (bundles) were created based on different combinations of 3 test attributes (Accuracy, Wait Time, Cost), each with 3-4 levels. Each pt responded to 5 questions asking them to choose between two of these hypothetical tests, randomized by the Qualtrics survey platform.
Results: During May-June 2022, 405 RA pts completed the survey, of whom 86.7% were female, 89.9% white, mean age of 57.9 (SD 11.6) years. Pts were on the following medications: 75.1% csDMARD, 53.6% bDMARD, 17.8% tsDMARD (not mutually exclusive). Most pts perceived their doctor orders laboratory work to check for active inflammation (85.9%) or assess side effects of medications (81.2%). Pts reported that their rheumatologists most often ordered complete blood counts, liver function tests, CRP and ESR to monitor RA, and felt CRP was most helpful to themselves in understanding their disease activity (Table 1). Most pts worried their current RA medication would stop working (91.4%) and they would waste time trying an RA medication that may not work for them (81.7%). If pts were required to change RA treatments in the future, a majority (89.2%) would be very/extremely interested in a blood test that could help predict whether such new medication would be effective. Highly accurate test results (improving chance RA medication will work from 50% to 85-95%) were more important to pts than low cost (<$20) or minimal wait time (<7 days) (Figure 1).
Conclusion: Most pts consider RA-related blood work to be important for monitoring active inflammation and medication side effects, and felt CRP was most helpful in understanding disease activity. For a test predicting treatment response, patients valued accuracy over cost or wait time.

Table 1. Patient Perceptions of Utility of RA-Related Blood Work, n=405

	Used by Physicians To Monitor RA[a] n (%)	Used by Physicians When Considering Changing Medications[b] n (%)	Useful for Patients to Understand Disease Activity[c] n (%)
Complete blood count (CBC)	322 **(79.5)**	170 (42.0)	128 (31.6)
Liver function tests, kidney tests and/or complete metabolic panel	312 (77.0)	174 (43.0)	140 (34.6)
C-reactive protein (CRP)	269 (66.4)	162 (40.0)	197 **(48.6)**
Erythrocyte sedimentation rate (ESR)	238 (58.8)	181 (37.3)	174 (43.0)

The promise of health literacy in clinical care

OP0289 INEQUITIES IN ARTHRITIS CARE IN CANADA: AN INTERSECTIONAL ANALYSIS OF BIPOC WOMEN

Keywords: Gender/diversity issues, Patient-led research, Health services research

E. Wang[1,2,3], A. Chan[1], K. Lendvoy[1], E. C. Sayre[2], M. Canseco[4], C. L. Koehn[1], T. L. Fox[5]. [1]*Arthritis Consumer Experts, N/A, Vancouver, Canada*; [2]*Arthritis Research Canada, N/A, Vancouver, Canada*; [3]*The University of British Columbia, Rehabilitation Sciences, Vancouver, Canada*; [4]*Research Co., N/A, Vancouver, Canada*; [5]*Fox Wellness Consulting, N/A, Calgary, Canada*

Background: Individuals that belong to ethnic minority groups are at greater risk of developing different forms of arthritis and often experience poorer health outcomes when compared to white patients[1]. BIPOC women are especially susceptible to inequities due to the social determinants of health such as education, income and housing[2]; yet interventions are rarely targeted to meet their specific needs, preferences and values.
Objectives: The aim of this community-led Survey was to identify observable disparities in access to and benefits from health care (HC) services between white and Black, Indigenous and Person of Colour (BIPOC) respondents who identified as Women.
Methods: ACE conducted a 33-question online Survey (Aug 2-19, 2022) in English and French. The Survey was conducted in partnership with Research Co., a public opinion firm. Respondents answered questions regarding sociodemographic information, HC access, HC providers, unfavourable experiences, and information seeking habits. Data were analysed in subgroups and aggregate (including incomplete survey responses). Chi-square tests (exact tests where possible) were used to test for associations.
Results: A total of 1,249 responses were received. 732 (59%) respondents identified as women, 484 (39%) men, 16 (1%) non-binary. Of the women who responded, 163 (22%) identified as BIPOC (including 39 Black, 58 Indigenous, 86 POC), and 569 (78%) as white. Women reported greater barriers to accessing HC compared to men, namely travel (29% vs. 19%) and previous unpleasant experiences (18% vs. 10%). More BIPOC women (68%) experienced barriers compared to white women (56%), the most prominent being time (40% vs. 30%) and language (21% vs. 5%). Overall, interactions with HC providers and rheumatologists were rated similarly between BIPOC women and white women. However, significantly less BIPOC women reported being comfortable asking about medications (27% vs 39%), discomfort (30% vs 43%), and pain (39% vs 50%). When asked what characteristics they looked for in HC providers, significant differences were revealed between BIPOC and white women **[Figure 1].** Overall BIPOC women (14%) reported experiencing discrimination based on gender twice as often as white women (7%), and seven times as often as white men (2%). Further, BIPOC women were seven times as likely to report experiencing ethnicity-based discrimination "often" (8.7%), when compared to white women (1.2%). Results were even more profound for Indigenous women who were 16 times as likely to report experiencing ethnicity-based discrimination "often" (19.6%), when compared to white women (1.2%). Both BIPOC men and women more often turn to family, friends, coworkers, traditional healers, and elders for health information when compared to white respondents. BIPOC women reported being less trusting of certain information sources when compared to white women, specifically patient organizations (11% vs 21%) and official public health websites (55% vs 70%).
Conclusion: Our findings suggest that BIPOC women face unique and disproportionate barriers as well as complex experiences of discrimination when accessing arthritis care. Importantly, BIPOC respondents, in particular BIPOC women, seem to benefit less from their HC interactions. The data further reinforce current literature that calls for the creation of culturally safe spaces and culturally sensitive resources. It is critical for all levels of the health care system to adopt an intersectional lens to better understand and address systemic inequities.

OP0290 WORSE OUTCOMES LINKED TO ETHNICITY FOR THE EARLY TREATMENT OF REFRACTORY SLE: RESULTS FROM THE BILAG-BR

Keywords: Registries, Real-world evidence, Systemic lupus erythematosus

S. Dyball[1], M. Rodziewicz[1], E. Sutton[1], B. Parker[2,3], I. N. Bruce[1,2,3]. [1]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [2]*Manchester NHS Foundation Trust, The Kellgren Centre of Rheumatology, Manchester, United Kingdom*; [3]*The University of Manchester, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom*

Background: SLE more commonly affects non-White populations who suffer higher disease activity and greater damage accrual.
Objectives: To describe differential response of patients with moderate-severe SLE in the UK by ethnic background.
Methods: Patients commencing rituximab (RTX), belimumab or a standard of care medication (SoC) for SLE in the BILAG-BR were analysed over 12 months. Major clinical response (MCR) was defined as a SLEDAI-2K ≤4 at 12 months. Deprivation was measured using English indices of deprivation 2019 decile (EID, 1= most deprived, 10=least). MCR was compared using multivariate logistic regression (reference group: White background; adjusted for age, gender and EID). Missing data were imputed using random forest in R V4.2.1 (package: missForest V.1.5).
Results: 1601 SLE patients (Female=1447 [90.4%], median age [IQR]: 39.9 [31.0-50.6] years) commenced therapy from September 2010-September 2022 (RTX: N=1177, belimumab: N=193, SOC: N=231). 905 (56.5%) were White, 233 (14.6%) were Black, 197 were Indo-Asian, 81 (5.1%) were Chinese/ East Asian, and 60 were of Multiple-Mixed background and 125 (7.8%) preferred not to say. 1,364 (85.2%) patients were taking glucocorticoids (GC) at baseline (median dose [IQR]: 7 [4.5-11.1] mg daily). MCR was achieved in 901 (56.3%) patients at 12 months. Black patients had a higher SLEDAI-2K score at baseline compared with white individuals (Figure 1). Black, East-Asian/ Chinese patients, and Multiple-Mixed ethnic background patients received a higher GC dose at baseline (Table 1). Black, Indo-Asian and Multiple-Mixed background patients were more likely to be in a lower EID. In patients receiving RTX, Black (adjusted OR 0.36 [95%CI 0.25-0.52]) and Indo-Asian (0.42 0.18-0.96)) patients were less likely to achieve MCR. In patients receiving belimumab, Black (0.65 [0.44-0.96]) and Indo-Asian patients (0.29 [0.09-0.93]) were also less likely to have an MCR. Absolute reduction in SLEDAI-2K was similar for each ethnic group.

Table 1. Demographic and clinical data by ethnic background. Data presented as median (IQR) or N (%), with respective *p values* computed with chi² or Kruskall–Wallis test

	White	Black	Indo-Asian	Chinese/ East Asian	Multiple/ Mixed	*p-value*
	(N=905)	(N=233)	(N=197)	(N=81)	(N=60)	
Age (years)	43.9 (33.5-54.4)	39.2 (30.1-47.6)	36.2 (27.2-43.2)	32.3 (25.0-39.2)	35.0 (27.5-45.6)	<0.001
Female	816 (90.2)	220 (94.4)	168 (85.3)	74 (91.4)	57 (95.0)	0.035
Disease duration (years)	5.92 (2.90-11.8)	6.68 (3.31-11.3)	5.54 (2.73-9.93)	4.95 (2.74-8.20)	7.23 (4.11-10.2)	0.0854
Deprivation Decile (EID)	5.00 (4.00-7.00)	4.00 (2.00-5.00)	4.00 (2.00-6.00)	5.00 (3.00-7.00)	4.00 (2.75-6.25)	<0.001
Renal involvement (ever)	301 (33.3)	119 (51.1)	123 (62.4)	60 (74.1)	39 (65.0)	<0.001
Therapy						0.0808
SoC	125 (13.8)	28 (12.0)	41 (20.8)	9 (11.1)	5 (8.3)	
Rituximab	677 (74.8)	165 (70.8)	134 (68.0)	63 (77.8)	50 (83.3)	
Belimumab	103 (11.4)	40 (17.2)	22 (11.2)	9 (11.1)	5 (8.3)	
Current pulse steroids	291 (32.2)	68 (29.2)	77 (39.1)	20 (24.7)	10 (16.7)	<0.001
Current steroid dose (mg)	5.00 (2.00-8.50)	7.50 (4.00-12.0)	6.00 (3.50-10.0)	10.0 (5.50-18.0)	8.50 (5.00-15.3)	<0.001

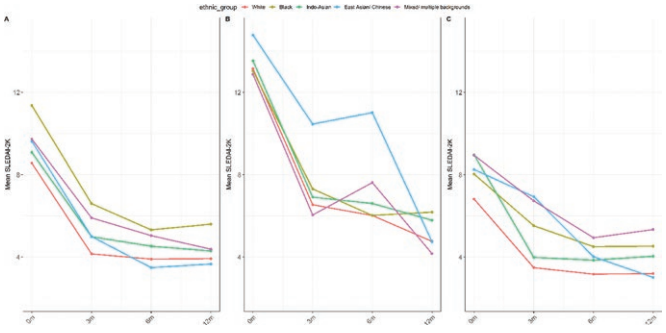

Figure 1. Mean SLEDAI-2K at baseline, 3, 6 and 12 months, in A) Rituximab (n=1089), B) Belimumab (n=179) and C) SoC (n=208) treated patients

Conclusion: Although absolute reduction in disease activity was similar across ethnic backgrounds, obtaining a MCR following treatment was lower in Black and Indo-Asian patients, in part reflecting higher baseline disease activity, but not explained by level of social deprivation; an observation not confined to a single treatment. There is a need for investigation into the drivers of these inequitable outcomes and reappraisal of treat-to-target strategies in these populations.

Cell activation pathways in RMDs

OP0291 **ACUTE PHASE REACTANT OROSOMUCOID-2 DIRECTLY PROMOTES RHEUMATOID INFLAMMATION**

Keywords: Rheumatoid arthritis, Cytokines and chemokines, Synovium

K. M. Kim[1], S. Lee[1], K. G. Lee[1], B. K. Hong[1], Y. J. Park[1,2], S. A. Yoo[1], W. U. Kim[1,3]. *[1]Center for Integrative Rheumatoid Transcriptomics and Dynamics, The Catholic University of Korea, Seoul, Korea, Rep. of (South Korea); [2]Division of Rheumatology, Department of Internal Medicine, St. Vincent's Hospital, The Catholic University of Korea, Suwon, Korea, Suwon, Korea, Rep. of (South Korea); [3]Department of Internal Medicine, The Catholic University of Korea, Seoul, Korea, Seoul, Korea, Rep. of (South Korea)*

Background: Acute phase response is a systematic reaction of organisms. It occurs when the homeostasis of our body is broken by infection, tissue injury, and inflammation. Since most of these acute phase reactants can be rapidly secreted to the blood in response to infection or inflammation, they have been utilized as serum diagnostic markers to predict the activity and outcomes of chronic inflammatory diseases. In recent years, evidence has emerged that some of these acute phase reactants can go beyond simply being useful as diagnostic markers. Studies have shown that they can directly function as immune modulators.

Objectives: To determine whether orsomucoid-2 (ORM2), an acute phase reactant mainly synthesized in the liver, directly contributes to chronic inflammation.

Methods: ORM2 expression was determined by ELISA and immunostaining. Fibroblast-like synoviocytes (FLSs) and macrophages were cultured in the presence of recombinant ORM2. NF-κB and p38 MAP kinase expression levels were assessed by Western blot analysis. Knockdown experiments were carried out using siRNAs for NF-κB p65, p38, and glycophorin C (GYPC). Proximity ligation assay was performed to test the molecular interaction between ORM2 and GYPC. Recombinant ORM2 was injected into the affected joints of mice with IL-1β-induced arthritis.

Results: ORM2 expression was elevated in the sera, synovial fluids, and synovia of patients with rheumatoid arthritis (RA). Major cell types producing ORM2 were synovial macrophages and FLSs. Recombinant ORM2 robustly upregulated IL-6, TNF-α, IL-8, and CCL2 produced by macrophages and/or FLSs of RA patients via NF-κB and p38 MAPK pathways. GYPC was the receptor of ORM2 on synovial macrophages and FLSs. Such an increase by ORM2 was reproduced in mouse macrophages and FLSs. Intra-articular injection of ORM2 promoted the severity of arthritis in mice and accelerated the infiltration of macrophages in affected joints. Moreover, in RA patients, circulating ORM2 levels correlated with disease activity assessed by DAS28 and well represented radiographic progression in 2 years.

Conclusion: Acute phase protein ORM2 can directly increase the production of pro-inflammatory cytokines/chemokines by macrophages and FLSs and promote chronic arthritis in mice, suggesting that it could be a new therapeutic target for RA.

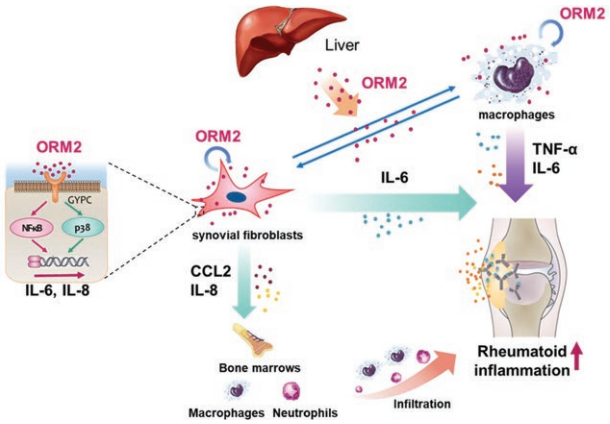

Figure 1. Hypothetical model for ORM2-dictated reciprocal activation of macrophages and FLSs in RA. Under high inflammatory conditions, ORM2 is actively produced from arthritic joints, particularly by stimulation of synovial macrophages and fibroblasts with TNF-α, IL-1, and Toll-like receptor-4 agonists, as well as from the liver. The secreted ORM2 in turn binds to a functional receptor GYPC on RA-FLSs, activates NF-κB and p38 MAP kinase pathways, and then directly induces production of pro-inflammatory cytokines (e.g., IL-6, TNF- α) and chemokines (e.g., IL-8, CCL2) via the two signaling pathways. Resultant cytokines and chemokine can amplify chronic inflammation by further activating macrophages and FLSs and by facilitating recruitment of monocytes and neutrophils to inflamed joints. As a result, more activated macrophages and FLSs can secrete greater amounts of ORM2 and thereby lead to ORM2-centered mutual activation of macrophages and FLSs, constructing a feed-forward cycle of rheumatoid inflammation.

Inborn errors of Immunity and autoimmune / inflammatory rheumatic disorders: What can we learn?

OP0292

MUTATIONS IN DNASE1L3 CAUSING FAMILIAL HYPOCOMPLEMENTEMIC URTICARIAL VASCULITIS AND EARLY ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Genetics/Epigenetics

N. Aljaberi[1], A. Aldhaheri[2], H. Alblooshi[3]. [1]*United Arab Emirates University, Pediatrics, Al Ain, United Arab Emirates*; [2]*Tawam Hospital, Rheumatology, Al Ain, United Arab Emirates*; [3]*United Arab Emirates University, Genetics, Al Ain, United Arab Emirates*

Background: Systemic lupus erythematosus (SLE) is a multisystemic autoimmune disease with several aberrancies in the immune system[1]. Genetics factors are central to understanding the pathophysiology especially in patients with monogenic lupus (single-gene mutation)[2]. Anecdotally, we observe a relatively high prevalence of familial SLE in our region (UAE/Arab regions). Studying the genetics of such cases have yielded gene mutations known to cause SLE. Here we report 3 siblings with mutations in *DNAES1L3* causing SLE and hypocomplementenemic urticarial vasculitis (HUVS)[3].
Objectives: To report the clinical and genetic presentation of 3 siblings with monogenic SLE and HUVS and discuss clinicopathologic correlations.
Methods: The patients were identified through our SLE clinical cohort. Informed consent was obtained from the patients/guardians to participate in our institution's "Mendelian Project" research study. The study is approved by the local IRB committee. Whole exome sequencing (WES) was performed. The results of the initial sequencing were analyzed in the context of the clinical presentation of SLE and HUVS.
Results: Genetic analysis via WES revealed a homozygous *DNASE1L3* variant at c.572A>G; p. Asn191Ser for the 3 affected siblings classified as variant of unknow significance (VUS). The mother and healthy sibling were heterozygous (carrier) for the variant. This indicate that the variant is segregating with the family for SLE. *DNASE1L3* variant c.572A>G, p.Asn191Ser is a novel variant that was not reported previously in the literature or human genetic mutation database (HGMD). Computational (in-silico) pathogenicity prediction tools predicted damaging effect of the variant (PolyPhen: damaging, SIFT: Deleterious, Conservation: high). Clinical and laboratory features are presented in Table 1. All three siblings developed HUVS as the initial manifestation which was confirmed by skin biopsy. In the older siblings who eventually met the criteria for SLE, the HUVS resolved as other SLE symptoms emerged. The youngest sibling has not met criteria for SLE and only has skin involvement with debilitating HUVS (tender lesions and swollen hands/feet). This patient was found to have very low levels of C1q without anti-C1q antibodies. Screening for mutations in C1q was negative. Of note, the HUVS has been the most severe in this patient.

Table 1. Clinical and lab features of the 3 patients.

	Patient 1	Patient 2	Patient 3
Age at onset	13 months	2 years	3 years
Age at SLE diagnosis	N/A	6 years	3 years
Current age	2 years	7 years	17 years
Clinical findings			
HUVS	+[#]	+	+[#]
Fever	+	+	+
Lymphadenopathy	+	+	-
Arthritis	-	-	-
Mucocutaneous ulcers	-	-	-
Glomerulonephritis	-	Class II/V	Class IV
Lab findings			
Positive ANA	-	+	+
Positive anti-dsDNA	-	+	+
Low C3/low C4	+/-	+/-	+/+
Low C1q/anti-C1q antibodies	+/-[$]	NA/NA	NA/NA
↓Hgb/↓WBC/↓plt	+/-/-	-/+/-	+/-/-
↓ IgG	-	-	+
Positive aPLs	-	-	-

[#] HUVS confirmed by skin biopsy. [$] Mutation in C1q gene not detected.

Conclusion: *DNASE1L3* genetic variants contribute to monogenic SLE. This report supports prior literature linking *DNAES1L3* deficiency to HUVS in addition to SLE. Further analysis of the effect of this variant on the immune system and link to C1q deficiency or consumption may shed light on relevant immune mechanisms related to SLE.

Neutrophil dysregulation in systemic lupus erythematosus

OP0293

ANTI-CITRULLINATED HISTONE MONOCLONAL ANTIBODY CIT-013, A DUAL ACTION THERAPEUTIC FOR NEUTROPHIL EXTRACELLULAR TRAP ASSOCIATED AUTOIMMUNE DISEASES

Keywords: Cell biology, Innate immunity, Rheumatoid arthritis

M. Van der Linden[1], S. Kumari[1], D. Montizaan[1], S. Van Dalen[1], A. Kip[1], M. Foster[2], I. Reinieren[1], E. Neubert[3], L. Erpenbeck[4], T. Bruurmijn[1], P. Van Zandvoort[1], P. Vink[1], E. Meldrum[1], H. Van Es[1], R. Chirivi[1]. [1]*Citryll BV, R&D, Oss, Netherlands*; [2]*Experimental Pathology, Consultancy, Benfleet, Essex, United Kingdom*; [3]*Leiden Academic Centre for Drug Research, Division of drug discovery and safety, Leiden, Netherlands*; [4]*University Medical Center Münster, General Dermatology and Venereology, Münster, Germany*

Background: Neutrophil extracellular traps (NETs) contribute to the pathophysiology of multiple inflammatory and autoimmune diseases. Targeting the NETosis pathway has demonstrated significant therapeutic potency in various disease models (Chirivi *et al*., 2021). Here we describe a first in class monoclonal antibody (CIT-013) with high affinity for citrullinated histones H2A and H4 which inhibits NETosis and reduces tissue NET burden *in vivo* with significant anti-inflammatory consequences. CIT-013 is currently in phase 1 clinical trials with phase 2a studies in RA due to commence in 2024.
Objectives: The objective of the current study was to further unravel CIT-013's mode of action. Questions which we wanted to answer are: 1) How and when does CIT-013 interfere with the NETosis pathway?, and 2) what is the faith of CIT-013 opsonized NETs and netting neutrophils? Furthermore, we investigated whether CIT-013's epitope is expressed in rheumatoid arthritis (RA) synovial tissue.
Methods: *In vitro* life imaging studies using neutrophils and macrophages in combination with monovalent as well as bivalent CIT-013 have been performed to investigate CIT-013's mode of action. An *in vivo* lung inflammation mouse model was used to investigate CIT-013's effect on NET burden as well as phagocytic macrophages. Finally, the presence of CIT-013's epitope in human RA synovial tissues was investigated using immunohistochemistry techniques.
Results: Detection of CIT-013 epitopes in RA synovium provides evidence that RA is an autoimmune disease with excessive citrullinated-NETs that can be targeted by CIT-013. We show that CIT-013 acts upon the final stage of NETosis, binding to its chromatin epitopes when plasma membrane integrity is compromised to prevent NET release. Bivalency of CIT-013 is necessary for NETosis inhibition. In addition, we show that CIT-013 binding to NETs and netting neutrophils enhances their phagocytosis by macrophages. Furthermore, we demonstrate that a mouse variant of CIT-013 reduces tissue NET burden *in vivo* at least in part through enhanced macrophage phagocytosis.

Conclusion: Since NETs contribute to the pathophysiology of many immune mediated inflammatory diseases, including autoimmune diseases such as RA, CIT-013's unique ability to both inhibit NET release and enhance NET clearance indicates the importance of this first in class therapeutic antibody as a new emerging therapy.

Insights into gout management

OP0295

A 12-WEEK, RANDOMIZED, DOUBLE-BLINDED, PLACEBO-CONTROLLED, PHASE 2B STUDY OF SAFETY, TOLERABILITY AND EFFICACY OF AR882 IN GOUT PATIENTS

Keywords: Gout, Randomized control trial

J. C. C. Wei[1], R. M. Fleischmann[2], S. Morris[3], E. Polvent[3], Z. Shen[3], A. Clouser Roche[3], V. Hingorani[3], S. Yan[3], L. T. Yeh[3], R. Keenan[3]. *[1]Chung Shan Medical University Hospital, Department of Allergy, Immunology and Rheumatology, Taichung City, Taiwan, Republic of China*; *[2]Metroplex Clinical Research Center, Rheumatology, Dallas, Texas, United States of America*; *[3]Arthrosi Therapeutics Inc, Drug development, San Diego, California, United States of America*

Background: Despite gout being the most common inflammatory arthritis, there remains an unmet need for more effective treatment. AR882 is a novel, potent, and selective uric acid transporter 1 (URAT1) inhibitor in development for the treatment of gout and tophaceous gout. AR882 was well tolerated, including patients with various degrees of renal insufficiency, and has consistently demonstrated robust sUA lowering in multiple clinical trials.

Objectives: This global phase 2b trial is a randomized, double-blinded, placebo-controlled, 12-week study to evaluate the safety, tolerability, and efficacy of AR882 versus placebo in patients with gout.

Methods: The trial recruited patients 18 to 75 years of age with eGFR >30 mL/min across 20 sites in the US, Australia, and Taiwan, who met the ACR/EULAR Gout Classification Criteria. Following gout flare prophylaxis for 10 days, patients received either once-daily AR882 50 mg, AR882 75 mg, or matching placebo for 12 weeks. Blood samples were collected every two weeks through Week 12 for laboratory tests, sUA and pharmacokinetic measurements. Efficacy endpoint was the percent of patients who reached sUA below 6, 5, 4, and 3 mg/dL. Safety including vital signs and electrocardiograms were collected throughout the study.

Results: A total of 140 patients were enrolled in this study. The majority of patients were male (93.6%) and white (58%), followed by Asian (28%) and Black or African (15%). The baseline sUA level was 8.6 (±1.3) mg/dL; mean age 54.3 (24-73) years; mean body weight 96.4 (±17.8) kg. Major comorbidities seen in patients included hypertension (47%), hyperlipidemia (35%), renal insufficiency (34%), arthritis (23%), diabetes (19%), cardiovascular disease (15%), lung disease (11%), and liver disease (5%). Following 12 weeks of treatment, median sUA levels were reduced from baseline 8.6 mg/dL to 3.5 mg/dL with 75 mg and 5.0 mg/dL with 50 mg. No change was observed in the placebo group. At Week 12, 89%, 82%, 63% and 29% of patients achieved < 6, <5, <4 and <3 mg/dL, respectively, in the 75 mg group. In the 50 mg group, 78%, 50%, 8% of patients achieved < 6, <5 and <4 mg/dL, respectively. The sUA lowering effect was similar for three consecutive measurements between Week 8 and 12. There were no serious adverse events in AR882 treated patients. Mild or moderate adverse events including diarrhea, headache, and upper respiratory infection were observed in this study. A total of 65 gout flare incidents were observed and evenly distributed across groups during the 12-week treatment.

Conclusion: The majority of patients receiving AR882 had achieved sUA levels below 5 or 4 mg/dL, which are two key thresholds for more efficient flare and tophi reductions[1][2]. AR882 was well tolerated over the 12-week treatment period and patients with comorbidities did not require any adjustments in management of the diseases while treated with AR882. This study suggests AR882 may offer improved efficacy with acceptable safety compared to existing therapies for gout and may have utility in the treatment of patients across the spectrum of gout including those with severe or refractory disease.

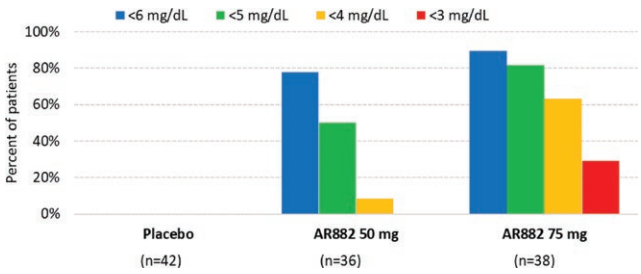

Figure 1. Percent of Patients with sUA at Targets following 12-week Treatment of AR882 or Placebo.

OP0296

CRYSTAL DEPOSITIONS ASSESSED BY ULTRASOUND AND DECT DECREASE DURING TREATMENT AND PREDICTS REDUCED NUMBERS OF FLARES; TWO-YEARS RESULTS FROM THE NOR-GOUT TREAT-TO-TARGET STUDY

Keywords: Imaging, Gout, Ultrasound

H. B. Hammer[1,2], L. F. Karoliussen[1], T. Eskild[3], J. Sexton[1], L. Terslev[4], E. A. Haavardsholm[1,2], T. Uhlig[1,2]. *[1]Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Dept of Rheumatology, Oslo, Norway*; *[2]Faculty of Medicine, University of Oslo, Oslo, Norway*; *[3]Diakonhjemmet Hospital, Dept of Radiology, Oslo, Norway*; *[4]Centre for Rheumatology and Spinal Diseases, Rigshospitalet, Copenhagen University Hospital at Glostrup, Rigshospitalet, Copenhagen University Hospital at Glostrup, Copenhagen, Denmark, Copenhagen, Denmark*

Background: Gout is caused by depositions of monosodium uric acid crystals in joints and tissues which triggers highly painful flares. Serum urate lowering treatment (ULT) reduces the number of flares.

Objectives: To explore the change of crystal depositions assessed by ultrasound and dual energy computer tomography (DECT) for two years, and the associations between depositions and occurrence of flare during the first year of ULT.

Methods: Patients with crystal-proven gout who presented themselves after a recent gout flare and with serum uric acid (sUA) level (>360 µmol/L) were consecutively included (the NOR-Gout study (1,2)). They were followed monthly if needed with increase of ULT to achieve sUA <360 µmol/L (or <300 µmol/L if clinical tophus) as well as flare prophylaxis for 3-6 months. The patients were assessed clinically and by laboratory tests. Information about flares before the visit was collected (numbers year 1, only occurrence year 2). A comprehensive ultrasound assessment (General Electric E9) at baseline, 12 and 24 months was performed using semi-quantitative scoring of MSU depositions (using definitions and scoring system defined by OMERACT of double contour (DC), tophi and aggregates), and examination of bilateral radiocarpal, MCP 2 and MTP 1 joints, triceps, and quadriceps insertions, patellar (proximal and distal) and Achilles tendons as well as distal femur

(maximal flexed knee) and talar cartilage). In addition, DECT (General Electric Discovery CT750 HD) of both feet were performed. Total sum scores of US depositions (DC, tophi and aggregates) or DECT depositions were calculated, as well as US sum scores only of the feet for comparison with DECT. Comparisons were performed by Wilcoxon or Mann-Whitney. Logistic regression explored if flare occurring during 0-3 or 0-12 months was predicted by US or DECT (controlling for age, sex, disease duration and presence of clinical tophus).

Results: 209 patients were included (mean (SD) age 56.4 (13.8) years, time since first flare (disease duration) 7.9 (7.7) years, 95.5% men). During year 1 and 2 patients with flares compared with no flares had higher baseline US and DECT scores ($p<0.05$). The total sum scores of US (DC, tophi and aggregates) and DECT decreased during the study ($p<0.001$ for all, table 1). Figure 1 shows the parallel decrease of depositions in feet by US and DECT (all changes $p<0.001$). During the first year there were median (range) 2 (0-14) flares. At least one flare was seen in 81% the first year, but only in 26% the second year. Baseline total US sum scores predicted flare the first 3 months (DC; $p=0.031$, $\beta=0.113$, total sum score; $p=0.047$, $\beta=1.026$) and baseline DECT predicted flare both at 3 and 12 months ($p=0.014$, $\beta=1.086$ and $p=0.010$, $\beta=1.193$, respectively).

Conclusion: Baseline levels of US and DECT depositions were higher in patients having flare during the study. The amount of crystal depositions in both imaging modalities decreased substantially during ULT as did occurrence of flare. Baseline US and DECT depositions predicted flare during follow-up. Thus, patients should be encouraged to follow a treat-to-target procedure of sUA reduction to reduce both depositions and flares.

Exploring the spectrum of bone inflammatory disorders across the life course

OP0298 **CHRONIC NON-BACTERIAL OSTEOMYELITIS (CNO) AND BONE MINERAL DENSITY**

Keywords: Vitamin D, Bone diseases, Osteoporosis

M. Kasap-Cuceoglu[1], M. Canturk[2], Y. Bayindir[1], A. E. Yıldız[3], Y. Bilginer[1], U. Aydıngoz[3], A. Ozon[2], S. Özen[1]. *[1]Hacettepe University, Department of Pediatrics, Division of Rheumatology, Ankara, Turkey*; *[2]Hacettepe University, Department of Pediatrics, Division of Endocrinology, Ankara, Turkey*; *[3]Hacettepe University, Department of Radiology, Ankara, Turkey*

Background: Chronic nonbacterial osteomyelitis (CNO) is an inflammatory bone disorder that generally affects children.[1] In the absence of accepted diagnostic criteria or clinical/radiological biomarkers, CNO remains a diagnosis of exclusion.[2] Chronic pain and/or bone fractures (vertebral compression fractures) are observed in patients with CNO, just as in severe vitamin D deficiency and osteoporosis.

Objectives: We aim to show the relationship between CNO and bone mineral density and investigate whether osteoporosis with/without vitamin D deficiency can cause challenges in the treatment of CNO.

Methods: We reviewed the charts of all CNO patients followed up between January 2015 and April 2022 in the Department of Pediatric Rheumatology in Hacettepe University, Ankara, Turkey. The diagnosis was confirmed by expert consultant pediatric rheumatologists and radiologists. Demographic and clinical characteristics of patients, 25 OH vitamin D (25[OH]D) level status (N:>20 ng/ml [50 nmol/L]), radiological findings as well as medical treatments were evaluated. A score between -1.1 and -2.4 is classified as osteopenia. A score of -2.5 and below is defined as osteoporosis. In the pediatric population, osteoporosis is a clinical diagnosis and is reserved for those patients with a BMD Z- score less than or equal to -2.0 in combination with a significant fracture. In addition, patients were divided into two groups: receiving nonsteroidal anti-inflammatory drugs (NSAIDs) and/or cDMARDs (Group 1) and receiving TNF inhibitors (TNFi) and/or bisphosphonate (Group 2).

Results: A total of 80 patients (females 53%) were included in this study. The median age at diagnosis of CNO was 7 (1-17) years. Overall, vitamin D level was available before diagnosis in 52/80 (65%) patients, 17 of which were normal, while 35 patients had deficiency (25[OH]D <20 ng/ml [50 nmol/L]). Bone mineral density was studied in 39 patients, normal in 18, osteoporotic in 13, and osteopenic in 8 patients. 23 patients were treated with IV bisphosphonate (pamidronate [PAM]). Among the patients receiving PAM, 10 had a severe deficiency of 25[OH]D (<10 ng/ml), and 1 had osteopenia, 10 had osteoporosis in DEXA. Forty-one patients were treated with TNFi (34 used ETA, 5 ADA, 2 INF). There was no patient with osteoporosis in Group 1 (n=26), it was statistically significant. ($p=0.031$). In Group 2 (n=54), 12 patients (38.7%) were normal, 13 patients (41.9%) had osteoporosis, and six patients (19.3%) had osteopenia. The overall history of bone fractures (long bone, vertebral body) was present on admission in eleven patients (7 osteoporosis, 2 normal BMD, 2 NA). All patients with fractures were treated with PAM as the first-line treatment, and they benefited from this drug ($p=0.013$). In Group 2, 25[OH]D vitamin level was lower than Group 1, although it was not statistically significant. ($p=0.183$) (Table 1)

Conclusion: Patients with normal bone mineral density responded well to DMARD/NSAID, better than the remaining patients, and they did not need alternative treatment. Vitamin D deficiency and/or osteopenia may lead to a more refractory course; thus, it should be monitored effectively in patients with CNO.

Background: Rheumatoid arthritis(RA) is a systemic chronic autoimmune disease that involves inflammatory arthritis with varying severity showing various symptoms like pain, fatigue, and sleep disturbances impacting and reducing the quality of life(QoL).[1] Patients with RA experience reduced QoL, physical and emotional health as well as level of independence etc and they are more likely to suffer from anxiety, depression and low self-esteem, with high levels of associated mortality and suicide.[3] Addressing the need to improve the quality of life and symptom burden for these patients are vital where Digital solutions play an incredibly significant role. These solutions are also helpful in self-management of disease and symptoms.
Objectives: To assess the impact of a digital health program on the quality of life and symptom burden of patients suffering from Rheumatoid Arthritis.
Methods: An interventional trial including an RA patient support program was delivered by Wellthy Care digital platform over a period of 16 weeks. Recruitment of 30 patients was done using a convenient sampling method. Patients who were diagnosed with RA were included in the trial. Patients who were under 18, pregnant/lactating, and with hearing disability were excluded. The program included interventions such as physiotherapy sessions, CBT (cognitive behavioural therapy) counselling, tracking of symptoms, lifestyle counselling, disease awareness and self-management training of symptoms at home. The rheumatoid arthritis impact of disease (RAID) [2] questionnaire, a validated questionnaire was administered to assess seven important patient domains of disease impact (pain, function, fatigue, sleep disturbance, emotional well-being, physical well-being, coping) at baseline and at the end of the program.
Results: The Mean RAID score of the patients at baseline was 4.99 and at endline was 0.737. The impact percentage of program in improvement of symptoms like Pain, Difficulty in doing daily physical activities, Fatigue, Sleep difficulty, level of physical well-being, level of emotional well being were 85.66%, 86.40%, 88.81%, 96.47%, 85.66%, 93.89% respectively. The Paired T-test witnessed significant improvement in symptoms like pain, sleep disturbances, fatigue, difficulty in performing physical activities ($p<0.001$).
Conclusion: Digital therapeutics play a highly significant role in improving the quality of life and reducing the symptom burden of RA patients. The digital patient support program led to meaningful changes in a patient's quality of life as well as symptoms within a few weeks, even when the patient previously failed to experience a good prognosis during the treatment. Patients reported a highly significant improvement in Pain, Fatigue and Sleep disturbances, which improved the quality of life and patient's outlook of the overall treatment and adherence. These digital solutions can be considered as holistic care and integrated with routine supportive care in practice to provide improved patient-centred care. RAID score functions well as a good patient reported outcome measure in routine health care for patients with RA.

Background: Etanercept is a frequently used second-line therapy for juvenile idiopathic arthritis (JIA). It is unknown whether higher doses of etanercept result in better clinical outcomes, but most studies only evaluated doses up to the most commonly used 0.8 mg/kg/week (max 50mg/week).[1] Although higher doses are used off-label in clinical practice, the literature lacks an in-depth description of patients receiving such treatment.
Objectives: To describe the clinical course of JIA-patients that received high-dose etanercept (1.6 mg/kg/week; max 50mg/week) as part of the Best4Kids trial.
Methods: In a single-blinded treatment-strategy trial, patients with oligoarticular JIA, RF-negative polyarticular JIA or juvenile psoriatic arthritis were randomised across three treatment-strategy arms: (1) sequential DMARD-monotherapy (sulfasalazine or methotrexate (MTX)), (2) combination-therapy MTX+6 weeks prednisolone and (3) combination therapy MTX+etanercept.[2] A protocolised treat-to-target approach aiming for inactive disease was used during 24 months follow-up. Treatment was escalated in case of persistent disease-activity or tapered in case of inactive disease. In any treatment-arm patients could eventually escalate from regular to high-dose etanercept alongside MTX 10mg/m2/week. For comparison we studied patients who did not receive high-dose etanercept due to decisions overriding the trial-protocol by the treating paediatrician and/or the patient/parents.
Results: Of the 94 randomised patients, 32 received high-dose etanercept (69% female, median age 6 years (IQR 4-10), median time from baseline 10 months (7-16), median dose 1.3 mg/kg/week (1.1-1.5)). Follow-up was up to 2 years from baseline (median follow-up 24.6 months). Clinical measures of disease-activity decreased largely within 3 months (Figure 1): median VAS-physician from 12 to 4 ($p=0.022$), VAS-patient/parent from 38.5 to 13 ($p=0.003$), VAS pain from 35.5 to 15 ($p=0.030$), number of active joints from 2 to 0.5 ($p=0.12$) and JADAS10 from 7.2 to 2.8 ($p=0.008$). Functional status (CHAQ-score) improved more gradually and ESR remained stable. A comparable pattern of clinical parameters over time was observed in 11 patients (73% girls, median age 8 (IQR 6-9)) who were not escalated to high-dose etanercept despite eligibility according to trial-protocol. In both the high-dose and the comparison group the percentage of patients with inactive disease 6 months after eligibility for dose-increase was 56%. In the high-dose group, 18 out of 32 patients (56%) experienced 26 infectious adverse events (AEs, on average 0.20 events per visit following dose-increase). No serious AEs (SAEs) were recorded after dose-increase. Among the 11 patients who did not receive high-dose etanercept, 4 patients (36%) subsequently experienced 5 infectious AEs (on average 0.11 events per visit); this included one SAE requiring hospitalisation. Findings were similar when one patient who switched to infliximab, instead of maintaining the regular etanercept dose, was excluded from the comparison group.
Conclusion: Escalation to high-dose etanercept was generally followed by meaningful clinical improvement within 3 months. However, non-escalators experienced comparable improvement. These data do not suggest superior clinical outcomes after etanercept dose increase, while there was a potential trend for more (non-severe) infectious AEs. Larger studies are needed to more closely examine outcomes, adverse events and cost-effectiveness of high dose etanercept.

Figure. Clinical parameters over time after etanercept dose increase (orange) and after not escalating to high-dose etanercept despite eligiblity (purple)

Time-point zero = visit of eligibility for etanercept dose increase

Predicting remission and flare

OP0301

THE OPTIMAL THRESHOLDS FOR PATIENT GLOBAL ASSESSMENT IN DEFINING REMISSION DIFFER ACCORDING TO THE AUTOANTIBODY STATUS IN EARLY RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Autoantibodies, Patient reported outcomes

L. De Stefano[1,2], B. D'onofrio[1,2], E. Marazzi[1,2], M. DI Lernia[1,2], E. Cassione Bozzalla[1,2], A. Manzo[1,2], C. Montecucco[1,2], S. Bugatti[1,2].

[1]Università di Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy; *[2]Fondazione IRCCS Policlinico San Matteo, Pavia, Division of Rheumatology, Pavia, Italy*

Background: In rheumatoid arthritis (RA), the patient global assessment (PGA) is influenced by a multitude of factors that may vary over time and in relation to certain disease characteristics [1]. The inclusion of the PGA in the definition of remission and the cut-offs that better guarantee good functional and structural outcomes remain therefore uncertain [2,3].

Objectives: Aim of our study was to investigate the thresholds of the PGA capable of identifying sustained suppression of inflammation and functional integrity in patients with early RA in relation to the autoantibody status.

Methods: Data were retrieved from a prospective monocentric cohort of 810 patients with early RA (<12 months of symptoms at inclusion) with an observation period of 24 months after treatment institution with methotrexate aimed at the achievement of low disease activity. Patients were evaluated for the achievement of Boolean 3-variable (3-v) remission (swollen joint count, tender joint count, and C-reactive protein all ≤1) at any time-point in the first 12 months. The thresholds of the PGA at the time of 3-v remission that best predicted persistence of 3-v remission after 6 months, and normal function (health Assessment Questionnaire, HAQ, ≤0.5) after 12 months were investigated through receiver operating curve (ROC) analyses in autoantibody-positive and –negative patients separately.

Results: A total of 749/810 (92.5%) patients had follow-up data available until month 24. Of them, 390 (52.1%) achieved 3-v remission in the first year of observation after a median (IQR) of 6 (2-9) months. Autoantibody-positive patients showed a trend for earlier 3-v remission (adjusted HR [95% CI] 1.21 [0.99-1.48]). Among patients achieving 3-v remission, 193 (49.5%) maintained 3-v remission after 6 months, without significant differences in relation to the autoantibody status. Normal function after 12 months characterized slightly more autoantibody-positive than –negative patients (91.2% vs 83.3%, p=0.15). The best cut-off values of the PGA capable of predicting persistence of 3-v remission and normal function in autoantibody-positive patients were ≤9 (AUC 0.76) and ≤13 (AUC 0.73), respectively (**Table 1**). The corresponding thresholds in autoantibody-negative patients were ≤20 (AUC 0.75) and ≤21 (AUC 0.69).

Table 1. Performance of PGA thresholds for predicting persistence of remission and normal function

Ab-pos							Ab-neg						
Persistence of 3-v remission													
Criterion	**Sens**	**95% CI**		**Spec**	**95% CI**	**+LR**	**-LR**	**Criterion**	**Sens**	**95% CI**	**Spec**	**95% CI**	**+LR**	**-LR**
≤9	76.1	66.1-84.4		75.8	65.9-84	3.14	0.32	≤20	84.2	75.6-90.7	62.8	52.6-72.1	2.26	0.25
Normal function														
≤13	81.7	74-87	9	68.8	41.3-89	2.61	0.27	≤21	66.7	57.4-75.1	74.2	55.4-88.1	2.58	0.45

Conclusion: Increasing the threshold of the PGA to ≤20 in patients with early RA is associated with sustained suppression of inflammation and good functional outcomes in autoantibody-negative patients. In contrast, in autoantibody-positive patients, a stringent threshold of ≤10 remains optimal.

DATA MATTERS: keeping track of your health information

OP0302-PARE THE INTERNATIONAL MAP OF AXIAL SPONDYLOARTHRITIS GLOBAL REPORT: SUPPORTING THE INCLUSION OF THE PATIENT PERSPECTIVE IN POLICY AND CLINICAL PRACTICE

Keywords: Lifestyles, Real-world evidence, Quality of life

J. Lowe[1], M. Garrido-Cumbrera[2,3], J. Davies[4], A. Phoka[5,6], L. Wermskog[6,7], L. Christen[8]. *[1]Axial Spondyloarthritis International Federation, Projects, London, United Kingdom*; *[2]University of Seville, Health and Territory Research, Seville, Spain*; *[3]Spanish Federation of Spondyloarthritis Associations (CEADE), Executive Dept, Madrid, Spain*; *[4]Axial Spondyloarthritis International Federation, Executive Dept, London, United Kingdom*; *[5]Cyrpus League Against Rheumatism (CYPLAR), Executive Dept, Nicosia, Cyprus*; *[6]Axial Spondyloarthritis International Federation, Board of Trustees, London, United Kingdom*; *[7]Spondyloarthritis Association Norway (Spafo), Executive Dept, Oslo, Norway*; *[8]Novartis Pharma AG, Immunology, Basel, Switzerland*

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic musculoskeletal disease that can lead to chronic pain, structural damage, and disability. It often has a significant physical impact, causes psychological distress and can disrupt every aspect of a patient's life. While scientific research in axSpA has grown significantly, the patient perspective remains insufficiently explored and the disease burden continues to be underestimated. The International Map of Axial Spondyloarthritis (IMAS) is a research initiative of the impact and burden of axSpA from the patient perspective, identifying the unmet needs of axSpA patients and exploring impact beyond solely the physical symptoms.
Objectives: By producing an accessible global report on the results of IMAS, ASIF aim to provide its member organisations with much needed, robust evidence of the impact of the disease. The report will be used to raise awareness of the reality of axSpA, particularly amongst healthcare providers and policy makers; with the intention of incorporating the patient perspective much more into clinical practice and policy. The report also provides patients and their carers with a better insight into axSpA experiences around the world.
Methods: This research is a collaboration between the Axial Spondyloarthritis International Federation (ASIF), the University of Seville and Novartis Pharma AG. ASIF and its members have supported recruitment of survey participants from 27 countries across Europe, Asia, North, Central and South America, and Africa. In total 5,557 people completed the survey, providing a unique insight into how axSpA effects daily life. IMAS collected information through a comprehensive questionnaire of over 120 items on socio-demographics; behaviour; disease diagnosis and characteristics; comorbidities; psychological distress; healthcare utilization; treatments; disease activity; physical activity and limitations; working life; relationships; and the hopes and fears of patients. The ASIF IMAS sub-committee reviewed the global dataset results and agreed the scope of the global report. The IMAS scientific committee also reviewed the result, identifying key findings. ASIF held webinars with its members to seek their feedback on the results; asking them how they would use such a report how it can support their work.
Results: 5,557 axSpA patients participated in IMAS. The mean age was 43.9 years, 55.4% were women, 46.2% had university education, and 48.5% were employed. 20.6% were on sick leave (temporary or permanent), 71.4% had difficulty finding a job due to axSpA, and 71.0% reported work-related issues. Patients' mean diagnostic delay was 7.4 years, disease activity measured by the BASDAI was 5.4 (out of 10), and risk of poor mental health measured by the GHQ-12 was identified in 59.4% of respondents. In addition, patients had a mean of 2 physical comorbidities. The report, which will be translated into a number of languages, includes data on all topics that were collected by IMAS. But at the request of our members, it focusses on the journey to diagnosis; physical and mental health; daily life impact; accessing treatment and care; and hopes and fears. Gender and regional differences are reported on in each of the chapters.
Conclusion: IMAS has shown the global profile of axSpA patients, quantifying and highlighting unmet needs, including unacceptable delay in diagnosis, high disease activity, work-related problems, and poor mental health in axSpA patients worldwide. The global report on IMAS will provide ASIF's members with empirical evidence of the impact of axSpA on a person's life in order to support their awareness and advocacy work. IMAS was recognised when it won the EFPIA Connecting Healthcare 2021 Awards for its ability to bring patients and medical professionals together in an initiative aimed at improving the quality of life of people living with axSpA from around the world.

OP0303-PARE MULTI-STAKEHOLDER CO-CREATION TO FACILITATE CLINICAL TRIAL RECRUITMENT - A FEASIBILITY STUDY

Keywords: Clinical trials, Patient information and education

M. Silva[1], N. Caeyers[2]. *[1]Esperity, Patient Centrics, Brussels, Belgium*; *[2]ReumaNet vzw, ReumaNet, Zaventem, Belgium*

Background: Recruitment for clinical trials remains a hurdle, causing potential delays in bringing innovative treatments to patients. Furthermore, there is not much communication about clinical trials towards the patient population and the general population has a lot of misconceptions around clinical trials. Communication about clinical trials is also subjected to a strict regulatory framework, especially in Europe. The information that can be found online is often in English and difficult to understand for the lay public.
Objectives: For this reason, a feasibility study has been performed to develop a clinical trial portal for Belgium that allows users to search for trials in a local and lay language, while offering the portal to patient organisations and hospitals to receive updates on newly initiated trials.
Methods: During the feasibility study the following aspects have been analysed by organising multi-stakeholder workshops, involving patient representatives and patient organisations (20), hospitals (8), HCPs (14), industry and representatives (10) of the Belgian medicines agency:user expectations, technical considerations, legal restrictions, regulatory and compliance aspects. Based on the multi-stakeholder workshops, a prototype has been developed that has been tested via user validation workshops. For the field of rheumatology, ReumaNet has represented the RMD community.
Results: The result of the feasibility study revealed that only 15% of patient organisations (out of 190) mention clinical trials on their website, out of 140 websites of hospitals, only 16% mention clinical trials, while 2% have a search engine to search for ongoing studies. All academic hospitals (7) had a section dedicated to trials on their website. There was a great interest from the patient community (over 20 PAG participants) and the HCP representatives. A legal analysis has also set a framework for compliant communication about clinical trials to the lay public as well as a GDPR framework to define privacy related aspects of the portal.The portal has been launched in September 2022 as a first version, an improved version with a PAG dashboard is launched in February 2023.
Conclusion: Based on the feasibility study, a clear need was identified to further develop the clinical trial portal in co-creation with the various stakeholders.

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is an ANCA-associated vasculitis characterized by asthma, ear-nose-throat (ENT) manifestations, peripheral hypereosinophilia and systemic vasculitic involvement [1]. Increased serum levels of interleukin 5 (IL-5) have been observed in eosinophilic disorders, including EGPA, and a genome-wide association study identified the IL-5 region as a major EGPA-associated loci [2]. On these bases, an increasing interest is focusing on benralizumab (an IL-5 receptor antagonist approved for severe eosinophilic asthma at the dosage of 30mg every 4 weeks for 3 administrations, then every 8 weeks) as a new potential therapy for EGPA. Following the promising results of a pilot study on 10 patients [3], a randomized double-blind trial is ongoing to assess the efficacy and safety of benralizumab at a higher dosage (30mg/4 weeks), as compared to mepolizumab (another IL-5 inhibitor approved for EGPA) in patients with EGPA (NCT04157348). In the meanwhile, isolated cases of patients with refractory EGPA, successfully treated with benralizumab, have been described in the literature [4,5].
Objectives: This study aimed to assess the efficacy and safety of benralizumab in a multicenter European cohort of patients with EGPA.
Methods: The study included patients with EGPA treated with benralizumab at 28 centers belonging to the European EGPA Study Group. Efficacy and safety outcomes were assessed after 3, 6 and 12 months of treatment. Complete response (CR) was defined as no disease activity (Birmingham Vasculitis Activity Score [BVAS] = 0) and a daily prednisone equivalent dose ≤4 mg. Respiratory outcomes included asthma, ENT manifestations and lung function.
Results: A cohort of 121 patients with EGPA was included. All were treated with benralizumab at the dosage approved for eosinophilic asthma (30mg every 4 weeks for 3 administrations, then every 8 weeks). The proportion of patients meeting the criteria for CR was 16% at 3 months, 26% at 6 months and 46% at 12 months of follow-up (**Table 1**). During follow-up, a drop in BVAS was recorded, from a median score of 3 (IQR 2-8) at baseline to 0 (0-2) at month 3 and 6 and to 0 (0-1) at month 12 (p<0.001 at all timepoints). Regarding respiratory outcomes, the proportion of patients reporting active asthmatic decreased from 94% at baseline to 39% at 3 months (p<0.001), and that of patients with active ENT manifestations decreased from 70% at baseline to 49% at 3 months (p<0.001), with concomitant improvements in lung function. 19 patients experienced adverse events, three requiring hospitalization.
Conclusion: The results from this large European real-world study suggest that benralizumab, at the dosage approved for severe eosinophilic asthma, could be effective and safe to control respiratory EGPA manifestations and overall disease activity.

Background: With improvements in the risks of relapse and mortality in ANCA-associated vasculitis (AAV), a better understanding of disease- and treatment-related complications in people with AAV is necessary to optimize outcomes and personalize care. Multimorbidity (MM) is a patient-centered approach to measuring complications and is defined as the presence of multiple chronic conditions[1]. MM is associated with risk of death and quality of life in other conditions. MM remains poorly understood in AAV[2].
Objectives: To determine the burden of multimorbidity in AAV.
Methods: We used the 2002-2019 Mass General Brigham (MGB) AAV cohort: an inception cohort of consecutive MPO- or PR3-ANCA+ incident AAV cases at a multi-center healthcare system in New England, USA. Comparators without systemic rheumatic disease were identified from MGB and matched to cases (10:1 ratio) by encounter date, age, sex, and race. We adapted a definition of MM as the presence of ≥ 2 of 37 chronic conditions, identified by use of ICD-9/10 codes ≥ twice over ≥ 30 days[1]. Manifestations of AAV (e.g., kidney disease) were excluded from the MM definition. Conditions present ≥ 6 months prior to the index date (date of treatment initiation) were excluded. First, we determined the proportion of cases and comparators with MM using the Aalen-Johansen method, accounting for the competing risks of death and loss to follow up. Second, we used Cox proportional hazard models to estimate the hazard ratio (HR) of MM in cases vs comparators and restricted mean survival time to estimate days free of MM in cases vs comparators. Third, we used latent class analysis to characterize clusters of morbidity among people with MM.
Results: There were 547 cases matched to 5,259 comparators (Table 1); mean age was 59 years and the majority were female (61%) and white (88%). Median follow-up in cases and comparators was 102 months and 66 months, respectively. MM was substantially more common in cases vs comparators and AAV cases had nearly an 8-fold higher risk of MM vs comparators (Figure 1, HR 7.6, 95% CI 6.6-8.7). Over 5 years, each case had an average of 707 fewer days with MM than comparators (963.4 vs 1670.5 days, p<0.001). At 1 year, two clusters of MM in AAV were identified with 76% and 24% captured in Clusters 1A and 1B, respectively. Hypertension and hyperlipidemia were common in Cluster 1A whereas Cluster 1B was characterized by painful conditions (e.g., headache, back pain, GERD). At 2 years, two clusters were identified with 82% and 18% captured in Clusters 2A and 2B. Cluster 2B was distinguished from 2A by a high burden of cardiovascular (CV) and pulmonary disease along with typical CV risk factors. At 5 years, three clusters were identified with 81%, 11%, and 8% captured in Cluster 5A, 5B, and 5C. Morbidities most common in Cluster 5A were hypertension and hyperlipidemia. Cluster 5B was distinguished by a higher burden of CV and pulmonary disease whereas Cluster 5C had the highest burden of certain glucocorticoid toxicities (e.g., osteoporosis, obesity, hypertension).
Conclusion: AAV is associated with a high burden of MM and carries a greater risk of MM than the general population. MM in AAV is characterized by clusters defined by morbidity burdens that vary over disease course and reflect a high impact of disease and its treatment. The development of interventions to prevent MM and minimize its impacts are needed. These findings identify an important

direction for future investigations to improve the care and outcomes of patients with AAV.

Background: Methotrexate (MTX) is the anchor and most prescribed disease-modifying anti-rheumatic drug (DMARD) for inflammatory rheumatic diseases (IRDs). This treatment can be very efficacious but can also have serious, life-threatening side effects. Adequate education and follow-up of patients/carers are therefore essential and dedicated rheumatology nurse consultations are an important part of this. However, many patients across European countries do not have access to these nurse consultations and there are no agreed and clearly defined standards of care on this topic[1].

Objectives: To develop points-to-consider (PtC), based on the best available evidence and experts' opinion, on the nursing education of patients (or carers) with IRDs taking MTX.

Methods: A nominal group of adult and pediatric nurses (n=19) from 16 European countries, one rheumatologist, one pharmacist, and two patients, was established by the Portuguese Association of Health Professionals in Rheumatology (APPSReuma). The group convened virtually to agree on the protocol for developing the PtC, including the research questions for a scoping review and for a European survey to collect patients', nurses' and rheumatologists' experiences and perceptions about MTX education. The results from the scoping review and the surveys (presented elsewhere) were then used to devise and refine overarching principles and specific PtC statements through two virtual meetings and one online Delphi questionnaire. European Standard Operating Procedures for the development of recommendations/PtC were used.[2]

Results: The group reached consensus on three overarching statements and five PtC (Table 1). Almost all PtC were based on available scientific evidence, and all obtained high levels of agreement (>8/10).

Table 1. Points-to-consider for the nursing education of patients/carers taking methotrexate.

#	Overarching Principles	Level of Evidence	Strength of recomendation	Agreement Mean (SD)	Agreement % ≥8
1	All patients prescribed MTX and their carers should receive treatment-specific education.	--	--	9.4 (1.5)	94
2	Education for patients prescribed MTX needs to be ongoing and requires continuous review by the rheumatology team.	--	--	9.5 (1.1.)	94
3	Nurses should have access to training regarding methotrexate treatment and stay up to date through continuous education	--	--	9.5 (0.9)	94
	PtC				
1	Patients prescribed MTX and their carers should be offered education by a nurse when starting treatment, changing the route and when required by the patient.	3	C-D	9.7 (0.6)	100
2	Patients prescribed MTX should have access to a nurse for needs-based education to improve treatment knowledge#, enhance satisfaction with care and quality of life*	#3 *4	#C *D	9.8 (0.5)	100
3	Nurses should support patients and carers with relevant self-management skills related to MTX treatment, to ensure safety and improve self-efficacy.	3	C	9.8 (0.4)	100
4	Education about MTX should be tailored to the individual patient/carer needs.	3	C	9.7 (0.7)	100
5	Education on MTX for patients and carers can be delivered through face-to-face or online interactions, supplemented where necessary by telephone consultations, written or online resources.	3	C	9.4 (1.7)	94
6	Nurses should promote and support adherence to MTX by identifying and discussing potential barriers and facilitators.	3	C	9.7 (0.6)	100

Conclusion: A set of PtC to improve the quality of care provided to patients with IRDs and their carers regarding the education and support that should be provided by nurses specifically on MTX use, has been developed. The ultimate goal is to optimize MTX intake, improve efficacy, reduce side effects and ensure adherence to treatment. A plan is currently underway for the uptake and implementation of these PtC, recognizing the crucial role that the multi-professional rheumatology team plays in this.

"So what now?" - living and planning life while co-existing with an RMD

OP0307-PARE WHAT ARE THE UNMET NEEDS OF PREGNANT PATIENTS DIAGNOSED WITH INFLAMMATORY RHEUMATIC DISEASES RECEIVING CARE IN A HIGHLY SPECIALIZED REPRODUCTIVE RHEUMATOLOGY CENTER? THE RESULTS OF THE CAPRI STUDY

Keywords: Pregnancy and reproduction, Patient information and education

A. Van Steensel - Boon[1], H. Wintjes[1], L. F. Perez-Garcia[1], E. Röder[1], H. T. Smeele[1], L. J. Kranenburg - van Koppen[1], R. Dolhain[1]. [1]*Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands*

Background: Inflammatory rheumatic diseases (RD) often affects women in their childbearing years. Despite extensive counselling, we noticed that in RD patients there is an increasing need of more information concerning pregnancy and parenting. This suggests that there are still unexplored information needs regarding pregnancy and parenting in women with RD. To our knowledge, there are no studies exploring these unidentified information needs.

Objectives: The aim of this study was to evaluate the unmet needs of women diagnosed with RD that received highly specialized care in a tertiary Reproductive Rheumatology center.

Methods: Women (≥18 years) diagnosed with RD (such as rheumatoid arthritis, spondyloarthritis, psoriatic arthritis or juvenile idiopathic arthritis), who were followed-up by the Reproductive Rheumatology team from the Department of Rheumatology of the Erasmus University Medical Center were invited to complete an online questionnaire. The questionnaire was divided into different sections: pre-conception, pregnancy, post-partum, parenthood and support received/needed by informal caregivers such as family, friends, neighbors etc. The questions were related to the support and information provided by the team, problems experienced, unmet needs and the patient's general characteristics. The patients were offered the possibility to give additional remarks (free text). Descriptive statistics were used to represent the outcomes.

Results: From a total of 181 women who were invited to fill out the online questionnaire, 95 women (52%) completed the questionnaire. It concerns women in the age between 22 and 45 (mean of 33yrs), with a RD, who received their first (n=56), second, or third baby between 2019 and 2021. Overall, the care of the rheumatology team was highly rated by the women (satisfaction score of 88 (scale 0-100) for the rheumatologist and 92 (scale 0-100) for the rheumatology nurses) (Table 1). 18 Women (19%) experienced any problem during the period around their delivery and/or post-partum. Six women indicated that their problems persisted. A lack of mental health support regarding disease coping (4 out 6) was the most frequently mentioned persisting problem. In addition 2 out of 6 women indicated a need for additional communication with the rheumatology team regarding information, indication and adjustment of their medication between the regular outpatient clinic visits.

Conclusion: The care provided by the Reproductive Rheumatology team was highly rated by the majority of the women. Nevertheless, the following unmet needs were identified: a) mental health support regarding disease coping and, b) the opportunity to communicate about medication beyond the regular outpatient visits. Despite a very high satisfaction rate of patients treated by the Reproductive Rheumatology team some of them experience health problems that remain unsolved. This will help us to improve our patient-centered care as we aim at matching our care as appropriately as possible to patient needs. In the future, we want to identify the characteristics of the women who need more information, more mental support and, more contact between the regular consults, so we can help them solve their problems and fill their needs.

Background: None of the currently approved treatments for rheumatoid arthritis (RA) can achieve ACR50 in >50% of the patients, and ~20% of the RA patients are considered "difficult to treat", failing ≥2 targeted therapies. TLL-018 is a highly selective dual JAK1/TYK2 inhibitor. Its TYK2 activity might contribute to efficacy in RA patients.
Objectives: Compare efficacy of TLL-018 with tofacitinib in RA patients.
Methods: 101 patients with moderate-to-severe active RA who had inadequate response or were intolerant to methotrexate were randomized (1:1:1:1 ratio) to receive twice-daily oral TLL-018 10mg, 20mg, 30mg or tofacitinib 5mg. After 12-weeks of treatment, patients who achieved ACR50 continue the same treatment, and those who didn't change treatment as follows: patients on tofacitinib and TLL-018 10mg change to TLL-018 20mg; patients on 20mg and 30mg change to or continue 30mg TLL-018. The Primary endpoint is the proportion of patients achieving ACR50 at Week 12. Secondary endpoints include the proportion of patients achieving DAS28-CRP <2.6, ACR20, ACR70 at all scheduled time points, ACR50 at scheduled time points exclude week 12, CDAI and other parameters at 12 week. Safety was assessed via adverse event (AE) and laboratory examinations.
Results: 101 patients were randomized, ~50% of them also had prior bDMARDs and ~30% had prior JAK inhibitors. Demographics and baseline disease characteristics were balanced across treatment arms. At week 12, ACR50 response rates in TLL-018 treated groups [10mg, 20mg and 30mg, 48.0% (95% CI, 28.42 - 67.58), 65.4% (95% CI, 47.10 - 83.67), 72.0% (95% CI, 54.40 - 89.60), respectively] were higher than that for tofacitinib [41.7% (21.94 - 61.39)]. TLL-018 20 and 30mg were statistically superior to tofacitinib (p<0.05). Proportions of patients achieving clinical remission (DAS28-CRP<2.6) at week 12 were 39.1%, 34.8%, 54.5% and 17.4% at week 12 for the 10, 20, 30mg TLL-018 and tofacitinib, respectively. TLL-018 20 and 30mg demonstrated high efficacy in patients who had prior bDMARDs, achieving ACR50 rates of >66%. TLL-018 20mg dramatically improved responses in patients who didn't achieve ACR50 on tofacitinib at week 12. The most frequently reported treatment-emergent AEs were hyperlipidemia and respiratory infection in TLL-018 or tofacitinib-treated patients. There was one case of malignancy in tofacitinib treatment group. No death, venous thromboembolism or major adverse cardiovascular event was observed in the study. (The data cut-off time was December 19th).
Conclusion: TLL-018 20 and 30mg demonstrated superior efficacy over tofacitinib in RA patients, suggesting that inhibition of TYK2, in addition to JAK1, enhances efficacy. TLL-018 was well tolerated with most AEs being Grade 1 or 2 as expected from this class of compounds. No unexpected safety concerns were observed in the study. TLL-018 20 and/or 30mg BID warrants further studies in "difficult to treat" RA patients.

Background: Despite availability of effective therapies for gout, a small proportion of patients suffer from refractory gout and/or are intolerant to standard therapies [1]. In these patients, the inability to maintain serum uric acid (sUA) levels < 6 mg/dL may lead to severe clinical manifestations for which uricase-based therapies can be highly effective, though also immunogenic. SEL-212 is a once-monthly, novel 2-component, sequential uricase-based infusion therapy being investigated in patients with refractory gout. SEL-212 consists of an infusion of tolerogenic nanoparticles containing rapamycin (SEL-110) followed by pegadricase (SEL-037). The intent of this drug combination is to inhibit the formation of anti-uricase antibodies without the need for separate immunosuppressant therapies [2].
Objectives: DISSOLVE I and II (D1 and D2, respectively) evaluated the safety and efficacy of SEL-212 in adults with refractory gout.
Methods: D1 (US Study, 12 months) and D2 (Global Study, 6 months), were placebo-controlled, double-blind, randomized clinical trials that evaluated two dose levels of SEL-110 (0.15 mg/kg [high-dose] or 0.1 mg/kg [low-dose]) prior to SEL-037 (0.2 mg/kg) infusion in adults (19-80 years). Participants with a history of symptomatic gout were enrolled if they had ≥ 3 gout flares within 18 months prior to screening or ≥ 1 tophus or a current diagnosis of gouty arthritis, failed to normalize sUA and control symptoms with any xanthine oxidase inhibitor, and were not previously exposed to a uricase-based therapy. Participants were randomized 1:1:1 between the two doses of SEL-212 and placebo administered intravenously every 28 days for 6 treatments. D1 participants were continued in a 6-month blinded extension phase under the initial treatment conditions (Fig. 1). The primary endpoint was defined as the percentage of participants who achieved and maintained sUA < 6 mg/dL for ≥ 80% of the sixth 28-day treatment period (TP6) in the active treatment groups versus placebo (response rate). Safety and tolerability were assessed through monitoring of adverse events (AEs) and laboratory testing.
Results: A total of 265 participants (D1, n=112 (96% male, 66% ≥ 50 years); D2, n=153 (97% male, 72% ≥ 50 years) were randomized into the three treatment arms. Response rates in all treatment groups were significantly different from placebo (p ≤ 0.0015), with 56% and 47% of participants responding in the high-dose group and 48% and 41% in the low-dose group for D1 and D2, respectively (Table 1). The response rates in participants aged ≥ 50 years were 65% and 48% in the high-dose groups and 47% and 45% in the low-dose groups for D1 and D2, respectively (p ≤ 0.0044 vs placebo). Across all participants in the treatment groups, median sUA levels were reduced by ~96% and ~75% from baseline at TP6 for D1 and D2, respectively (p<0.001 vs placebo). The safety profile of SEL-212 was favorable, with 3.4% and 4.5% of participants experiencing infusion reactions in the high and low-dose groups, respectively. Reports of gout flares were comparable between treatment groups and placebo. Six participants (3.4%) in the pooled active treatment groups experienced treatment-related serious AEs (n=4 anaphylaxis, n=2 gout flares).
Conclusion: In the DISSOLVE trials, once-monthly treatment with SEL-212 demonstrated statistically significant response rates and reductions in sUA versus placebo. The safety profile of SEL-212 was consistent with that of uricase therapies. Targeted immunomodulation with SEL-212 has the potential to provide a new uricase-based treatment option for patients with gout refractory to conventional therapies without the need for traditional immunosuppressants.

LB0003 DAZODALIBEP (VIB4920/HZN4920) IN SJÖGREN'S SUBJECTS WITH AN UNACCEPTABLE SYMPTOM BURDEN: SAFETY AND EFFICACY FROM A PHASE 2, RANDOMIZED, DOUBLE-BLIND STUDY

Topic: 17. SLE, Sjögren's and APS – treatment

Keywords: Safety, Randomized control trial, Sjögren syndrome

E. W. St. Clair[1], I. Alevizos[2], W. Rees[3], L. Wang[4], A. Baer[5], W. F. Ng[6], G. Noaiseh[7], C. Baldini[8]. *[1]Duke University Medical Center, Department of Medicine,, Durham, United States of America*; *[2]Horizon Therapeutics plc, R&D Clinical Development, Rockville,*; *[3]Horizon Therapeutics plc, Research and Development, Rockville,*; *[4]Horizon Therapeutics plc, Biometrics, Rockville,*; *[5]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States of America*; *[6]Newcastle University,Translational and Clinical Research Institute, Newcastle, United Kingdom*; *[7]University of Kansas, Department of Medicine,, Kansas City, United States of America*; *[8]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: Sjögren's is a systemic autoimmune disease associated with marked morbidity and poor health-related quality of life, generally driven by the cardinal symptoms of the disease: dryness, pain, and fatigue (assessed via EULAR Sjögren's Syndrome Patient Reported Index [ESSPRI]). The population of Sjögren's patients with unacceptable symptomatic burden independent of systemic involvement represents a substantial proportion of Sjögren's patients who have largely been excluded from recent trials despite significant disease burden and overall unacceptable health status.
Objectives: The objective of this study (NCT04129164) was to evaluate the efficacy and safety of dazodalibep (DAZ), a non-antibody biologic antagonist of CD40L, in adult Sjögren's subjects with an unacceptable symptom burden but limited systemic organ involvement.
Methods: This was a randomized, double-blind, placebo-controlled, crossover study of DAZ in adult Sjögren's subjects with an unacceptable symptom burden but limited systemic organ involvement, as defined by having an ESSPRI score ≥ 5 and EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) score <5. Eligible subjects were randomized 1:1 to receive intravenous DAZ 1500mg or placebo (PBO) Q2W x 3 doses, then Q4W x 4 additional doses. Starting on Day 169, subjects initially randomized to DAZ received PBO Q4W x 5 doses and subjects randomized to PBO received DAZ Q4W x 5 doses and were then followed for 12 weeks. The primary endpoint was the change from baseline in ESSPRI at Day 169. Safety was also evaluated.
Results: A total of 109 subjects were randomized and received ≥1 dose of study medication (DAZ, N=54; PBO, N=55). The mean (standard deviation) age of subjects was 49.9 (12.1) years and most were female (94.5%). The change from baseline to Day 169 in ESSPRI (LS mean ± SE) was –1.80 ± 0.23 in the DAZ group compared to –0.53 ± 0.23 in the PBO group, a difference of –1.27 ± 0.33 (p = 0.0002). The change from baseline to Day 169 in each of the three domains of ESSPRI was significantly greater in the DAZ group compared to PBO (dryness: p = 0.0066; fatigue: p = 0.0022; pain: p = 0.0010). At Day 169, a significantly larger proportion of DAZ-treated subjects achieved a ≥1 point or ≥15% reduction in ESSPRI relative to PBO (66.7% vs 32.7%; p =0.008). The improvement from baseline to day 169 in the Functional Assessment of Chronic Illness Therapy-Fatigue score (LS mean ± SE) was significantly greater in the DAZ group (8.1 ± 1.4) relative to PBO (2.8 ± 1.4; p = 0.0095). Greater numerical improvement in DAZ-treated subjects was observed for the Ocular Surface Disease Index (–14.0 ± 3.0 vs –8.5 ± 2.9; p = 0.1936) and Patient's Global Impression of Severity (–0.6 ± 0.1 vs –0.4 ± 0.1; p = 0.1781) at Day 169 relative to PBO. Through Day 169, a total of 75 subjects reported an adverse event (AE; DAZ: 37 [68.5%]; PBO: 38 [69.1%]) and the majority were mild/moderate in severity. The most frequently reported AEs occurring in ≥5% of DAZ-treated subjects were COVID-19, nasopharyngitis, anemia, and diarrhea. There were three serious AEs in the DAZ group (pneumonia influenza, post-acute COVID-19 syndrome, and gammopathy) and one in the PBO group (neutropenia). All serious AEs were deemed by investigators to be unrelated to study medication. One subject in the DAZ group discontinued the study due to an AE compared to two subjects in the PBO group.
Conclusion: In this study of Sjögren's subjects with an unacceptable symptom burden but limited systemic organ involvement, the primary endpoint was achieved. DAZ-treated subjects experienced a statistically significant and clinically meaningful improvement in the key subjective symptoms of Sjögren's relative to PBO as measured by the improvement in ESSPRI and associated responder analysis. DAZ therapy was generally safe and well tolerated. Larger trials of DAZ therapy for Sjögren's are warranted to further explore its safety profile and confirm its clinical efficacy.

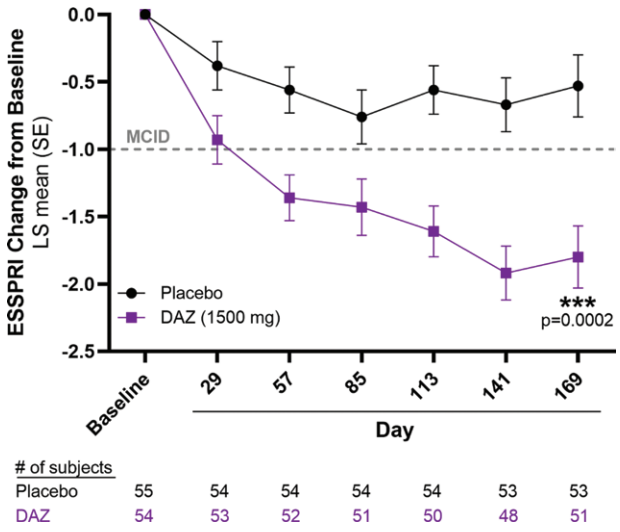

Figure 1. Adjusted Mean Change from Baseline in ESSPRI Score. Dashed line represents the MCID. Data analyzed using MMRM. ESSPRI, EULAR Sjögren's Syndrome Patient Reported Index; LS, least squares; MCID, minimal clinically important difference; SE, standard error.

LB0004 PAEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS (PSLE) PATIENT STRATIFICATION AND HIGH-PERFORMANCE SERUM BIOMARKERS IDENTIFIED RESPONDERS TO STATIN AND PATIENTS WITH HIGH CARDIOVASCULAR RISK IN THE APPLE TRIAL (ATORVASTATIN FOR ATHEROSCLEROSIS PROGRESSION IN PAEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS)

Topic: 11. Basic and translational science in paediatric rheumatology

Keywords: Biomarkers, Randomized control trial, Rare/orphan diseases

C. Ciurtin[1], J. Peng[1], P. Donnes[2], L. Lewandowski[3], S. Ardoin[4], L. Schanberg[5], G. Robinson[1], E. Jury[2]. *[1]University College London, Centre for Adolescent Rheumatology, London, United Kingdom*; *[2]University College London, Centre for Rheumatology, London, United Kingdom*; *[3]NIH, Rheumatology, Bethesda, United States of America*; *[4]Nationwide Children Hospital, Department of Rheumatology, Ohio, United States of America*; *[5]Duke University, Department of Paediatrics, Durham, United States of America*

Background: Paediatric Systemic Lupus Erythematosus (pSLE) is associated with increased risk of atherosclerosis compared to adult-onset SLE. The APPLE trial is the largest investigator-led randomised control trial in pSLE, which tested the effect of atorvastatin vs. placebo for prevention of atherosclerosis progression over 36 months, using carotid intima-media thickness (CIMT) as primary outcome.
Objectives: We aimed to investigate:
1. patient stratification strategies to identify responders to statin in a trial which did not meet the primary outcome as well as.
2. novel high-performance biomarkers of atherosclerosis progression in the APPLE trial to establish which pSLE patients were at risk for atherosclerosis progression even if they did not respond to statin.
Methods: Unsupervised clustering analysis was used to stratify pSLE patients by their baseline CIMT and identify patterns of CIMT progression over 36 months. In-depth metabolomic analysis was performed to identify lipidomic signatures predictive of CIMT progression in both placebo and statin arm. Correlation and univariate regression analyses explored associations between patient, disease characteristics and serum biomarkers (Nightingale platform). Machine learning techniques and ROC analyses were used to identify and validate a serum metabolomic signature of high CIMT progression.
Results: Baseline CIMT stratified pSLE patients (N=151) into three groups with distinct CIMT progression trajectories irrespective of the treatment allocation. Two distinct CIMT progression rates (high vs. low), over 36 months were identified in the placebo group (N=60), while patients treated with atorvastatin (N=61) had three distinct CIMT trajectories (high, intermediate and low progression), not predicted by any of the numerous patient and disease determinants, including serum biomarkers, lipid profile and homocysteine levels, collected as part of the APPLE trial protocol. A robust and novel metabolomic signature predictive of high CIMT progression was identified (AUC = 80.7%) in the placebo arm, which could be used to identify patients at risk of atherosclerosis progression in pSLE. pSLE patients with low rate CIMT progression identified by the CIMT stratification benefitted from treatment with atorvastatin (P= 0.035), providing evidence that the lack of patient stratification led to the negative results of the APPLE trial.
Conclusion: This analysis of the APPLE trial provides novel evidence for the significant heterogeneity of subclinical atherosclerosis in pSLE and its distinct progression trajectories irrespective of treatment allocation, and identified pSLE patients who responded to statin, with implications for future patient stratification for clinical trials. We also showed that in- depth metabolomic signature can identify with better performance that any other biomarkers available, patients at risk for atherosclerosis progression with potential role for long-term cardiovascular risk management in pSLE.

LB0005 RITUXIMAB OBJECTIVE OUTCOME MEASURES TRIAL IN SLE (ROOTS): A DOUBLE-BLIND RANDOMISED PLACEBO-CONTROLLED FEASIBILITY TRIAL

Topic: 17. SLE, Sjögren's and APS – treatment

Keywords: Randomized control trial, Systemic lupus erythematosus, bDMARD

K. Mahmoud[1,2], M. Wilson[1,2], M.Y. MD Yusof[1,2], S. Brown[3], E. Hensor[1,2], E. Vital[1,2]. *[1]Leeds Institute for Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*; *[2]NIHR Biomedical Research Centre, LEEDS TEACHING HOSPITALS NHS trust, Leeds, United Kingdom*; *[3]Leeds Institute for Clinical Trials Research, University of Leeds, Leeds, United Kingdom*

Background: Many new medicines in SLE have not met endpoints in placebo-controlled RCTs even when other evidence indicates that they are effective. Reasons suggested are inclusion of patients with inactive disease, inaccurate or subjective outcome measures that seek to address diverse manifestations, and comparator arms that include excessive glucocorticoid dose.
Objectives: (i) To evaluate the feasibility of a novel trial design focusing on musculoskeletal SLE with objective eligibility criteria and endpoints and a low-dose glucocorticoid standard of care. (ii) To provide preliminary evidence for efficacy of rituximab. (iii) To provide additional validation of outcome measures.
Methods: Adults with SLE were enrolled if they had clinical synovitis and/or ultrasound (US) tenosynovitis and/or positive power Doppler (PD) in ≥1 joint despite stable background therapies including a maximum 10mg prednisolone. Patients were randomized to 1000mg rituximab (Rixathon, RTX) or placebo, on days 1 and 15. Blinded infusions were preceded by 100mg methylprednisolone. Outcome measures, including BILAG-2004, SLEDAI-2K, The Lupus Arthritis and Musculoskeletal Disease Activity Score (LAMDA), tender and swollen joint counts, physician global, patient MSK pain and global VAS, patient reported outcome measures, BICLA, SRI-4 were evaluated monthly. US of both hands and wrists was performed at 0 and 16 weeks. The primary endpoint was overall feasibility. The key efficacy timepoint was 16 weeks. After 16 weeks placebo patients with active disease were eligible for rescue rituximab with repeat follow up timepoints. US and LAMDA were validated against BILAG-MSK improvement at 16 weeks using regression models adjusted for baseline.
Results: Of 35 patients invited, 35 attended screened and consented, 6 were ineligible and 2 withdrew prior to baseline. Of 27 patients randomised, 12 were randomised to placebo, of whom 9 received rescue therapy. All completed ≥16 weeks follow up and 25/27 completed all follow up visits. 24/27 (89%) patients were female, 17/27 (63%) were white, 7/27 (26%) were South Asian. Mean (SD) age was 49.7 (12.7) and disease duration 6.7 (9.0). BILAG MSK domain at baseline was scored A in 7/27 (26%), B in 16/27 (59%) and C in 2/27 (7.4%). B scores were also present in mucocutaneous in 2/27 patients and constitutional in 1/27. At 16 weeks, BILAG-MSK response was significantly associated with improvement in LAMDA (OR 0.48, 95% CI 0.18, 0.84); US joints grey-scale (OR 0.56, 95% CI 0.28, 0.85) and US tendons PD (OR 0.33, 95% CI 0.04, 1.01). No substantive difference between arms in efficacy variables was found at week 16. Unexpectedly, results suggested greater improvement in some outcomes in patients who received methylprednisolone and placebo compared to methylprednisolone and rituximab. These measures then converged by 16 weeks (Figure 1). Pooling all rituximab cycles administered (as initial therapy or as rescue) showed improvement in PGA, Physician MSK VAS, joints GS and joints PD scores and LAMDA, but not Global BILAG, SLEDAI-2K, tender or swollen joint counts or and LupusQoL domain or patient VAS at week 16.
Conclusion: design dedicated to MSK SLE was feasible. The new outcome measures of LAMDA and MSK US were validated against BILAG-MSK; these outcomes should be included in a definitive trial. While not powered to measure efficacy, exploratory analysis suggests unexpectedly greater improvement in patients who received methylprednisolone with placebo compared to methylprednisolone with rituximab at early time points after infusion, later converging by week 16. Meanwhile there was an overall improvement in LAMDA and US at 16 weeks across all RTX cycles administered. In a definitive trial, early assessment of efficacy should be retrained, but longer observation without retreatment may be required to assess the efficacy of RTX in this population.

Background: Notwithstanding the wealth of literature on COVID-19, studies focusing on young people with autoimmune diseases (ADs) are lacking. Despite their younger age, they may have been exposed to immunosuppressants (IS) for longer than older adults, particularly if diagnosed at pediatric age.
Objectives: To determine early (within 7 days) and late (after 7 days) anti-SARS-CoV-2 vaccine-related adverse events (AEs), post-vaccine disease flares, COVID-19 severity and breakthrough infections (B-INFs) in young people with rheumatic diseases (RMDs) and non-rheumatic (nr)-ADs compared to healthy controls (HC).
Methods: The EULAR Young PARE definition was used to classify young patients (18-35 years old). Data were captured through the international COVID-19 Vaccination in AD (COVAD) 1 and 2 questionnaires (covering the years 2021 and 2022) and variables differing across groups in univariable analysis were included in multivariable analysis adjusting for baseline factors defined a priori.
Results: Of 20,685 complete responses, 6010 were from young people (1692 RMD, 400 nrADs, 3918 HC). RMDs and nr-ADs comprised mainly females of Caucasian, Asian and Hispanic ethnicities. Before vaccination, <5% and 7% of nrAD were taking glucocorticoids (GC) or immunosuppressants (IS) other than GC vs 30% GC and >80% IS in RMDs. Over 80% of total responders had received ≥2 vaccine doses.

1) AEs after 1 or 2 doses. Early mild AEs were more frequent in RMDs and nr-ADs compared to HC [RMD vs HC odds ratio (OR) (95% confidence interval (CI)) 2.4 (2.0-3.1); nr-AD vs HC 2.0 (1.4-2.9)]. Injection site pain, headache and fatigue were the most frequent mild AE in all 3 groups, but they were more frequent in nr-AD than in HC and RMD. Fever and chills were also more frequent in nr-AD compared to HC and to RMD. The frequency of late mild AEs after either of the 2 doses was < 10% in all 3 groups with no differences between groups. Severe AEs were < 2% in all groups, with no differences between the first and second dose.
2) AEs after 3 or 4 doses. The frequency of late mild AEs after any dose (1, 2 3 or 4) was < 20% in all 3 groups with no differences between groups. Severe AEs after the third dose were <3%. In the 1417 responders that received a fourth dose, only two (1 RMD and 1 HC) reported AEs (0.1%).
3) Pre-vaccine vs breakthrough infections (B-INFs). The frequency of reported SARS-CoV-2 infections was similar in all groups (RMD=28%, nr-ADs=25%, HC=28%). However, RMD patients reported only one infection more frequently than nrADs and HC, while nrADs reported ≥ 2 infections more frequently than RMD. Pre-vaccine infections were less frequent in RMD vs HC (OR=0.6, 95% CI= 0.4-0.9), but similar in nr-AD vs HC. In contrast, the frequency of B-INFs was higher in RMD vs HC (OR=2.7 95% CI 2.1-3.5), while it was similar in nr-AD vs HC. Regarding the clinical profiles of pre-vaccine infections versus B-INFs, no differences were observed among nrADs whereas in RMD a significantly lower frequency of loss of smell and loss of taste was reported for B-INFs. Less than 5% of total respondents received advanced therapies for SARS-CoV-2 infection.
4) Post-vaccination disease flares: Self-reported disease flares after the second vaccine dose were reported by 10% or RMD and 7% of nrAD patients. Of these, approximately half reported requiring a change in their medications (increased dose/addition of a new IS and/or GC).

Conclusion: This study provides the first detailed exploration of the SARS-CoV2 spectrum in young people with RMDs and nrADs compared to HC and highlights important similarities and differences between disease groups. In fact, despite being less exposed to GC and IS, nr-AD reported a higher number of SARS-CoV-2 infections, no difference in the clinical picture of pre-vaccine infections vs B-INFs and a more pronounced burden of post-vaccine mild AEs after earlier doses compared to RMD. These findings may highlight that in young people the type of disease rather than IS therapy may be more important to influence the vaccine safety and the features of B-INFs.

§ Primary analysis with multiple imputation of estimate, *n*=60. [a]ANCOVA; gender, group, age and baseline value as covariates. [b]Bootstrap CI with 10000 replications. HIIT: High-intensity Interval Training, NRS: Numeric rating scale, VO_{2peak}: Peak oxygen uptake

Background: Cardiorespiratory fitness (CRF) is recognized as an independent risk factor for cardiovascular disease (CVD) and improved CRF associates with lower risk of CVD [1]. High-intensity interval training (HIIT) is an effective mode of exercise to increase CRF. However, HIIT is seldom utilized in physiotherapy primary care in the context of inflammatory joint disease (IJD), and the sustainable effects of HIIT have been questioned [2].
Objectives: To investigate short- and long-term effects of twelve weeks of supervised HIIT in physiotherapy primary care on CRF, pain and fatigue in patients with IJD.
Methods: In this assessor-blinded randomized controlled trial (NCT04922840), 60 patients were allocated to a control group (n=30) or a HIIT group (n=30) that received a 12-week intervention in physiotherapy primary care including two weekly supervised 4x4 minute HIIT sessions at 90-95% peak heart rate and one non-supervised exercise session at moderate intensity. Patients were assessed at baseline, 3 and 6 months. Primary outcome was change in CRF from baseline to 3 months, measured as peak oxygen uptake (VO_{2peak}) by a cardiopulmonary exercise test. Secondary outcomes were pain and fatigue (Numeric Rating Scale 0-10, 0= no pain/fatigue). Group differences were assessed by pre-specified intention-to-treat analysis of covariance with multiple imputation of missing data for the primary outcome. Per-protocol analysis was applied for the primary outcome.
Results: Median age was 59 years (IQR 52-63) and 34 participants (57%) were female. A total of 55 patients completed assessment at 3 and 6 months for the primary outcome; 27 in the HIIT group and 28 in the control group. Following HIIT, there was a significant between-group difference in VO_{2peak} (2.5 mL/kg/min, p<0.01) in favor of the exercise group at 3 months with no corresponding differences in pain and fatigue (Table 1). At 6 months, the between-group difference in VO_{2peak} was maintained (2.6 ml/kg/min, p<0.01) and there were no significant differences in pain and fatigue (Table 1). Per-protocol analysis at 3 months showed a between-group difference in VO_{2peak} (3.2 mL/kg/min, p<0.001, 95% CI 1.7-4.8) in the 19 (70%) patients that adhered to ≥17/24 HIIT sessions compared to the 20 (71%) control group patients that refrained from aerobic exercise.
Conclusion: CRF increased in patients with IJD following 12 weeks of supervised HIIT and the effect was maintained at 6 months. The beneficial response on CRF was not accompanied by changes in pain or fatigue and the intervention can be regarded as feasible in physiotherapy primary care. HIIT is a viable physiotherapy intervention with sustainable effects in patients with IJD.

Neutrophil dysregulation in systemic lupus erythematosus

LB0008

NOVEL PATHOGENETIC MECHANISMS MEDIATED BY DYSREGULATION OF TRIM21-STING-TYPE I INTERFERON AXIS IN LUPUS

Topic: 08. SLE, Sjögren's and APS - aetiology, pathogenesis and animal models

Keywords: Autoantibodies, Systemic lupus erythematosus, Biomarkers

H. W. Park[1], D. S. Kim[2], Y. Park[1], M. L. Cho[3], S. K. Kwok[1,3]. [1]*Seoul St. Mary's hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*The Catholic University of Korea, Department of Biomedicine & Health Sciences, Seoul, Korea, Rep. of (South Korea)*; [3]*Catholic Research Institute of Medical Science, The Rheumatism Research Center, Seoul, Korea, Rep. of (South Korea)*

Background: Tripartite motif-containing protein (TRIM) 21 is an E3 uniquitin-protein ligase, involved in the ubiquitin-dependent proteolysis pathway of various proteins including factors related to type I interferon pathways. Although the presence of autoantibodies against TRIM21 in various autoimmune diseases suggests potential pathogenetic roles, no studies have clarified its exact implications especially in lupus.
Objectives: We aimed to elucidate the functions of TRIM21 in dysregulation of type I interferon signals in lupus.
Methods: To investigate effects of TRIM21 dysfunction in lupus pathogenesis, two independent lupus animal models, the R848-induced model and the B6/*lpr* mice model were performed using TRIM21 knockout mice and their phenotypes and immunological profiles were determined. In addition, we investigated the degree of TRIM21 dysfunction and therapeutic effects of *in vivo* delivery of TRIM21 in MRL/*lpr* mice. To evaluate the E3 ubiquitin ligase activity of TRIM21 for targeted proteins in type I interferon pathways, we performed specialized immunoblot assay.
Results: The R848-induced model and the B6/*lpr* model both presented with more severe lupus-like phenotypes such as nephritis, lymphadenopathies, and inflammatory immune cell profiles in TRIM21 knockout mice than in control mice. TRIM21 deficiency resulted in activation of intracellular factors related to type I interferon pathways such as STING, TBK1, and IRF3 in both models. MRL/*lpr* mice presented with activation of type I interferon pathways including STING, TBK1, and IRF3, and decreased expressions of TRIM21. Overexpression of TRIM21 attenuated the disease phenotypes in MRL/*lpr* mice. Using immunoblot assay, we observed E3 ubiquitin ligase activity of TRIM21 directly targeting STING via the proteasome pathway.

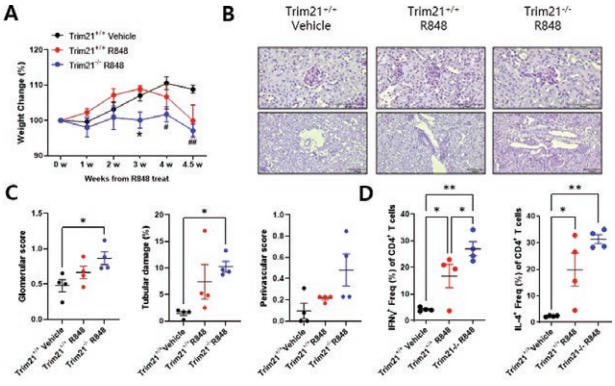

Figure 1.
(A) Bodyweight changes of R848- or vehicle-treated mice. (B) Representative images of H&E-stained kidney tissues from R848- or vehicle-treated mice. (C) Glomerular score, tubular damage score, and perivascular pathology score of kidney tissues from R848- or vehicle-treated mice. (D) Percentages of interferon-gamma-positive or IL-4-positive CD4+ T cells from R848- or vehicle-treated mice.

Conclusion: TRIM21 dysfunction induced dysregulation of STING-type I interferon pathways and exacerbates the disease in lupus animal models. Targeting TRIM21-STING-type I interferon axis can be a novel therapeutic strategy in lupus treatment.

Background: Imaging recommendations for primary large vessel vasculitis (LVV) were developed in 2018. Several new studies have emerged since then, and an update of the original statements was required.

Objectives: To update the recommendations for the use of imaging in LVV.

Methods: A systematic literature review update was performed to retrieve new evidence on ultrasound (US), magnetic resonance imaging (MRI), computed tomography (CT) and [18F]-fluorodeoxyglucose positron emission tomography (FDG-PET) for diagnosis, monitoring and outcome prediction in LVV. The task force consisted of 24 physicians, health professionals and patients from 14 countries.

Results: Three overarching principles and eight recommendations were agreed (Table 1). Compared to the 2018 version, US is now recommended as first line imaging test in all patients with suspected GCA, and axillary arteries should be included in the standard examination. As an alternative to US, cranial and extracranial arteries can be examined by FDG-PET or MRI. For Takayasu arteritis, MRI is the preferred imaging modality; CT or FDG-PET are alternatives. Although imaging is not routinely recommended for follow-up, US, FDG-PET or MRI may be used for assessing vessel abnormalities in LVV patients with suspected relapse, particularly when laboratory markers of inflammation are unreliable. MRA, CTA or US may be used for long-term monitoring of structural damage, particularly at sites of preceding vascular inflammation.

Conclusion: The 2023 recommendations provide up-to-date guidance for the role of imaging in the diagnosis and assessment of patients with (suspected) LVV.

Table 1. Recommendations for the use of imaging in large vessel vasculitis in clinical practice

Overarching principles
A. In patients with suspected GCA, an early imaging test is recommended to support the clinical diagnosis of GCA, assuming high expertise and prompt availability of the imaging technique. Imaging should not delay initiation of treatment.
B. Imaging examination should be done by a trained specialist using appropriate equipment, standardized operational procedures and settings.
C. In patients in whom there is a high clinical suspicion of GCA and a positive imaging result, the diagnosis of GCA may be made without an additional test (biopsy or further imaging). In patients with a low clinical probability and a negative imaging result, the diagnosis of GCA can be considered unlikely. In all other situations (including the case of an inconclusive imaging result), additional efforts towards a diagnosis are necessary.
Recommendations
1. Ultrasound of temporal and axillary arteries should be considered as the first imaging modality to investigate mural inflammatory changes in patients with suspected GCA.
2. High resolution MRI or FDG-PET can be used as alternatives to ultrasound for the assessment of cranial arteries in patients with suspected GCA.
3. FDG-PET, alternatively MRI or CT, can be used for the detection of mural inflammation or luminal changes of extracranial arteries in patients with suspected GCA.
4. In patients with suspected TAK, MRI to investigate mural inflammation or luminal changes should be used as the first imaging test to make a diagnosis of TAK.
5. FDG-PET, CT or ultrasound may be used as alternative imaging modalities in patients with suspected TAK. Ultrasound is of limited value for assessment of the thoracic aorta.
6. Conventional angiography is not recommended for the diagnosis of GCA or TAK as it has been superseded by the previously mentioned imaging modalities.
7. In case of a suspected relapse of GCA or TAK, particularly when laboratory markers of disease activity are unreliable, ultrasound, FDG-PET or alternatively MRI may be considered for the assessment of vessel abnormalities. Imaging is not routinely recommended for patients in clinical and biochemical remission.
8. In patients with GCA or TAK, MRA, CTA or ultrasound of extracranial vessels may be used for long-term monitoring of structural damage, particularly at sites of preceding vascular inflammation. The frequency of screening as well as the imaging method applied should be decided on an individual basis.

Adaptive immunity (T cells and B cells) in rheumatic diseases

POS0001 A NOVEL METHOTREXATE TARGET TP63 SUPPRESSES FOXP3 EXPRESSION AND EXACERBATES AUTOIMMUNE ARTHRITIS

Keywords: Rheumatoid arthritis, Animal Models, Disease-modifying Drugs (DMARDs)

K. Suga[1], A. Suto[1], S. Tanaka[1], T. Kageyama[1], J. Ishikawa[1], A. Iwata[1], S. Furuta[1], K. Ikeda[1], K. Suzuki[1], H. Nakajima[1]. [1]*Chiba University, Department of Allergy and Clinical Immunology, Chiba, Japan*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease characterized by autoreactive T cell activity and the presence of autoantibodies [1]. Although methotrexate (MTX) is well-recognized as the "anchor drug" for the treatment of RA [2], its precise mechanism, except antifolate activity, is largely unknown.
Objectives: The aim of this study was to elucidate a molecular target of MTX and to determine the role of the target molecule in $CD4^+$ T cells.
Methods: We examined comprehensive gene expression profiles of $CD4^+$ T cells by DNA microarray before and after MTX treatment in RA patients. We also examined the role of Tp63, a possible target of MTX, in human/mouse $CD4^+$ T cells.
Results: TP63 was the most significantly downregulated gene in $CD4^+$ T cells of RA patients after MTX treatment. TAp63, an isoform of Tp63, was highly expressed in human/mouse Th17 cells but rarely expressed in Treg cells, and MTX suppressed its expression in vitro. By comparing the comprehensive gene expression profiles between human Th17 cells overexpressing TAp63α and those with TAp63 knockdown, Foxp3 was identified as one of the downregulated genes by TAp63. Reporter assays revealed that TAp63α suppressed the activation of the Foxp3 CNS2 enhancer. TAp63 knockdown in induced-Tregs promoted Foxp3 CNS2 hypomethylation and enhanced suppressive activity of induced-Tregs. Moreover, the severity of arthritis was ameliorated in SCID mice transferred with SKG $CD4^+$ T cells with TAp63 knockdown compared to those with non-silencing.
Conclusion: TAp63 suppresses Foxp3 expression and exacerbates autoimmune arthritis.

Background: Intestinal dysbiosis has been associated with the development and progression of rheumatoid arthritis (RA) [*1].* Microbiota-derived metabolites such as short-chain fatty acids (SCFA) gained attention in research of inflammatory diseases as promising targets for new therapeutics. Previous work in our lab showed the potent preventive effect of SCFA on the onset of inflammatory arthritis (*2, 3*). Although effective potential therapeutic approaches are arising, their underlying mechanisms remain elusive [*4-6].* Cellular derived histamine is considered as pro-inflammatory mediator to induce acute allergic symptoms and to maintain chronicity. Interestingly, we identified an unexpected pro-resolving pathway of SCFA-induced histamine secretion by the gut microbiota. In contrast to the effective, direct Treg inducing 2-week delayed resolving effects of the SCFA propionate, we report on an indirect but ten times faster histamine-mediated pro-resolving mechanism via cells of the nervous system.
Objectives: To understand the rapid pro-resolving effects of microbiota-derived histamine on synovial inflammation.
Methods: We used 16s rRNA sequencing, HPLC size chromatography exclusion, FMT and meta-transcriptomics to assess propionate-induced changes in microbiota composition and the secreted metabolite profile. Mice with collagen- or serum-induced arthritis (CIA/SIA) were treated orally, i.p. or intrathecally with histamine or specific receptor agonists. Cellular changes in spleen, lymph nodes and joints were assessed by Cytek spectral flow cytometry, inflammatory infiltration and bone erosion were analyzed by histology and µCT. We analyzed differences in CNS and PNS via RNAseq of the spinal cord and peripheral nerves. Effects on vessel leakiness and cell infiltration in the inflamed joints were assessed via lightsheet microscopy and in vivo PET-CT.
Results: Here, we show that therapeutic treatment of CIA mice with the SCFA propionate starting from peak of disease (30 dpi) strongly induced resolution of synovial inflammation after 14 days of treatment. We demonstrate that oral propionate-treatment causes beneficial changes in the microbiota composition and thereby alters the secreted metabolite profile. These metabolites are able to induce rapid resolution of inflammation already after 2 days. By untargeted metabolomics we were able to identify histamine as highly potent metabolite that is increased upon propionate treatment. Oral treatment of CIA mice with histamine or a histamine 3 receptor (H3R) agonist significantly improved clinical symptoms. H3R is mainly expressed on cells of the nervous system. Upon oral H3R treatment we found alterations in activation marker expression in the spinal cord. We further were able to identify changes in the composition and activation of spinal cord (CNS) and the N. plantaris (PNS) of arthritic mice induced by H3R agonist treatment through RNAseq. Moreover, lightsheet microscopy and in vivo PET-CT scans revealed alterations in vessel leakiness and cell infiltration in the inflamed joints.
Conclusion: In summary, these data show that the SCFA propionate effectively regulates ongoing inflammation by promoting histamine secretion of the gut microbiota and subsequent H3R-mediated neuronal effector functions that drive the fast resolution of synovial inflammation.

POS0003 HUMAN LYMPH NODE STROMAL CELLS MAINTAIN FOXP3+ REGULATORY T CELLS IN A HLA-DR DEPENDENT MANNER

Keywords: Adaptive immunity, Cell biology, Rheumatoid arthritis

C. Grasso[1], A. M. O'byrne[1], J. F. Semmelink[1], E. Remmerswaal[2], J. W. Bolt[1], R. Mebius[3], L. Van Baarsen[1]. [1]*Amsterdam UMC, location AMC, University of Amsterdam, Department of Rheumatology and Clinical Immunology,*

Laboratory of Experimental Immunology, Amsterdam, Netherlands; [2]Amsterdam UMC, location AMC, University of Amsterdam, Laboratory of Experimental Immunology, Amsterdam, Netherlands; [3]Amsterdam UMC, location VUMC, VU University of Amsterdam, Department of Molecular Cell Biology and Immunology, Amsterdam, Netherlands

Background: Animal studies have shown that lymph node stromal cells (LNSCs) are key players in peripheral tolerance through their capacity to present self-antigens in MHC class II to CD4+ T cells thereby controlling auto-reactivity and humoral response. Thus, it has been suggested that dysfunctional LNSCs may play a role in the breaking of tolerance observed in autoimmune diseases like rheumatoid arthritis (RA), where there is a genetic association with the HLA-DR locus.
Objectives: We hypothesise that human LNSCs from healthy individuals without autoimmunity can express HLA-DR and maintain FOXP3+ regulatory T cells, a process which may be disturbed in LNSCs from RA patients.
Methods: Lymph node needle biopsies were collected from healthy volunteers, autoantibody positive RA-risk individuals and RA patients. In addition, lymph node stromal cells (fibroblasts) and paired peripheral blood mononuclear cells were obtained from non-RA controls. A combination of imaging techniques including spectral analyser, ImageStream, confocal and electron microscopy was used to determine the expression of HLA-DR directly *ex vivo* and on *in vitro* cultured LNSCs. To investigate the ability of these LNSCs to maintain regulatory T cells we employed an *in vitro* system where LNSCs were co-cultured with autologous CD4+ T cells for 72 hours. Subsequently flow cytometry analysis was used to determine the presence of FOXP3+ regulatory T cells.
Results: The presence of lymphocytes induced HLA-DR expression on cultured LNSCs from non-RA controls. The presence of LNSCs within this autologous co-culture model is crucial for maintaining CD25+ CD127- FOXP3+ regulatory T cells. To investigate possible mechanisms for this maintenance we used blocking antibodies for both HLA-DR and interleukin 2 (IL-2) in our system and showed that the maintenance of FOXP3+ regulatory T cells required both HLA-DR and IL-2. In the context of autoimmunity we were able to show that lymph node biopsies from RA patients directly analysed *ex vivo* have a significant reduction in the frequency of HLA-DR+ LNSCs compared to control individuals and those at risk of developing the disease.
Conclusion: Overall, these results indicate an important role for HLA-DR expressing LNSCs in maintaining tolerance within the lymph node, a process that may be dysfunctional in the context of autoimmunity where tolerance is broken.

Background: Autoantibodies to malondialdehyde (MDA) proteins constitute a subset of anti-modified protein autoantibodies (AMPA) in rheumatoid arthritis (RA), which is not directly overlapping with citrulline reactivity. We have previously shown that IgM anti-MDA is prominent in the natural antibody repertoire at birth and may have homeostatic roles. Yet, IgG anti-MDA is elevated in RA and correlates with DAS28, CRP, IL6 and TNF-α [1]. Moreover, RA-derived anti-MDA monoclonal antibodies induce bone erosion and osteoclastogenesis by modulating cell metabolism [2]. MDA is an oxidation-associated reactive aldehyde that together with acetaldehyde (AA) mediates formation of a range of amino acid adducts including linear MDA-lysine, fluorescent MAA-lysine, and intramolecular cross-linking. MDA/MAA proteins carry multiple adduct-variants, and we here propose that distinct subsets of anti-MDA/MAA antibodies, defined based on the MDA-induced molecular structures recognized, have different pathogenic properties. Moreover, we have investigated the presence of class-switched MDA+ B cells in RA synovium, bone marrow, and bronchoalveolar lavage (BAL).
Objectives: Identification of RA MDA+ B cells from different compartments and distinct MDA/MAA reactivity patterns.
Methods: Human recombinant mAbs were generated from single-cell sorted B cells from BAL and bone marrow (n=148) and screened for reactivity to MDA and MAA modified antigens. MDA-cyanoborohydride and MDA/MAA-hapten proteins without cross-linking were used for characterization. Serology screening of IgG reactivity to MAA-BSA was performed as previously described [3].
Results: IgG MAA-reactivity is elevated in 49% of ACPA+ RA patients (n=278) compared to 14% of population controls (n=437). We did not detect any significant increase in IgG anti-MAA in ACPA+ RA-risk individuals at baseline,14% had high anti-MAA (n=263), compared to controls. But for risk-individuals that developed arthritis, anti-MAA levels increased at onset of arthritis with 26% displaying elevated levels (n=53). We identified IgG+ MDA+ cells among RA bone marrow plasma cells and BAL B cells from both early RA and ACPA+ RA-risk, which could be compared to three previously identified RA synovial clones. Seven out of eight investigated clones carried somatic hypermutations (SHM). Interestingly, all clones with SHM were found to specifically target MAA cross-linked structures rather than MDA- or MAA-hapten, while the germline-encoded synovial clone F04 bound strongly to linear MDA-lysine in proteins and peptides. Germline converting resulted in reduced MDA/MAA binding, suggesting different origin of the clones compared to F04. All binding was independent of protein backbone. Yet, only a subset of MAA-selective clones with SHM induced robust TNF-α expression in monocyte-derived macrophages and enhanced osteoclastogenesis.
Conclusion: MDA/MAA positive B cells can be identified in bone marrow and synovium in established RA and in the lungs of early and RA-risk individuals, but serum levels are only increased in conjunction with onset of arthritis and with inflammation. SHM and class-switching suggest affinity maturation and T-cell dependence of these responses. Distinct targeting of different MDA/MAA molecular structures was observed. Future studies will elucidate how MDA recognition patters are related to the anti-MDA inflammatory and bone-modulating properties and disease stages.

Background: T cells of different lineages including cytotoxic T cells have been implicated in the pathogenesis of idiopathic inflammatory myopathies [1]. However, the question of whether the T cell response in muscle is reflective of the peripheral blood response remains to be fully answered.
Objectives: To characterize the T cell receptor (TCRβ) repertoire in peripheral blood and muscle tissues of treatment naïve patients with newly diagnosed idiopathic inflammatory myopathies (IIMs).
Methods: High throughput RNA sequencing of the TCRβ chain was performed in peripheral blood and muscle tissue in twenty newly-diagnosed treatment-naïve IIM patients and healthy controls. Results thereof were correlated with markers of disease activity.
Results: Muscle tissue of IIM patients show more expansion of TCRβ clones and decreased diversity when compared to peripheral of IIM as well as healthy controls (both p=0.0001). Several expanded TCRβ clones in muscle tissue are tissue restricted and cannot be retrieved in peripheral blood. These clones have significantly longer CDR3 regions when compared to clones (also) found in circulation (p=0.0002), while their CDR3 region is more hydrophobic (p<0.01). Network analysis shows that clonal TCR signatures are shared between patients. Increased

clonal expansion in muscle tissue is significantly correlated with increased CK levels (p=0.03), and tends to correlate with decreased muscle strength (p=0.08).
Conclusion: Network analysis of clones in muscle of IIM patients shows shared clusters of sequences across patients. Muscle-restricted TCRβ clones show specific structural features in their T cell receptor, and clonal TCR expansion in muscle tissue is associated with disease activity. These findings indicate that specific clonal T cell responses in muscle tissue act as key players in the pathogenesis of IIM.

POS0006 AUTOREACTIVE B CELLS IN RHEUMATOID ARTHRITIS ARE RECENTLY ACTIVATED AND SHOW LARGE EXPANSIONS OF CXCR3+ ANTIBODY-SECRETING CELLS

Keywords: Adaptive immunity, Cell biology, Rheumatoid arthritis

S. Reijm[1], J. Kwekkeboom[1], N. Blomberg[1], J. Suurmond[1], D. Van der Woude[1], R. Toes[1], H. U. Scherer[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: Many autoimmune diseases (AIDs) are characterized by aberrant, autoreactive B cell responses and autoantibody production. Rheumatoid arthritis (RA) is a common AID in which autoantibodies recognizing post-translational modifications (PTMs), collectively called anti-modified protein antibodies (AMPA), are intimately associated with disease pathogenesis. Previously, we observed that memory B cells (mBC) against one of these PTM-antigens, citrulline, are highly activated. This phenotype persists for years in patients with established disease [1]. The evolution, dynamics and more detailed phenotypic characteristics of the PTM-directed B cell compartment are still ill defined, however, partly owing to challenges linked to the visualization of such cells in human samples and the limitations of conventional flow cytometry. Here, we visualized the autoreactive B cell response against three different PTM antigens (citrulline, homocitrulline, acetyllysine) by spectral flow cytometry, allowing us to address cross-reactivity on the B cell level and to perform deep phenotypic profiling of individual B cell compartments.
Objectives: To develop a detailed understanding of the autoreactive B cell response against PTM-antigens in RA with the aim to elucidate features associated with its cross-reactivity, state of activation in the disease context, and its remarkable persistence for years without signs of exhaustion or decay.
Methods: We developed a spectral flow cytometry staining approach using differentially labelled streptavidin molecules coupled to individual PTM-antigens. B cells reactive to each antigen were identified together in individual samples by double staining for each antigen, while at the same time excluding cells reactive to either arginine or lysine control peptides. This combinatorial staining was further extended by the concomitant visualization of tetanus-toxoid specific B cells and expression levels of various activation and homing markers, and applied to peripheral blood samples of patients with established RA. Importantly, we performed intracellular stainings, allowing us to additionally enumerate and characterize circulating plasmablasts and plasmacells.
Results: We successfully visualized autoreactive B cells directed against different PTM-antigens and their subset distribution in individual patient samples. We observed extensive cross-reactivity against all three PTM antigens with citrulline as dominant antigen. Unsupervised clustering revealed several memory B cell populations, with most autoreactive B cells populating the most recently activated, mostly class-switched, $CD80^{high}CD24^{low}CD21^{low}$ mBC compartment. We also noted large expansions of $CXCR3^+$ IgG or IgA-expressing antibody secreting cells (ASC), comprising up to 50% of the autoreactive B cell compartment. Anti-tetanus toxoid B cells clustered with a different, more resting mBC subset.
Conclusion: Our results identify citrulline as the most prominent antigen recognized by AMPA-expressing B cells. The study highlights the recent and persistent activation state of PTM-reactive mBC and their continuous differentiation towards ASC. Such ASC may home towards CXCR3 ligands known to be abundant in the synovial compartment. This degree of mBC activation was also found in patients with low clinical disease activity scores, indicating that conventional therapeutic interventions may suppress inflammation but fail to silence the most disease-specific autoreactive B cell response in RA. Targeting this compartment may therefore be relevant for future therapeutic interventions aiming at the induction of tolerance and/or permanent cure. Finally, the combinatorial staining approach presented will be a valuable tool to delineate the development of PTM-directed autoimmunity in the pre-disease phase as well as its state of activation in phases of sustained drug-free remission and/or during tolerogenic interventions.

POS0007 KYV-101, A FULLY HUMAN CD19 CAR T CELL GENERATED FROM AUTOIMMUNE PATIENT LYMPHOCYTES, DEMONSTRATES CAR-MEDIATED AND CD19-DEPENDENT ACTIVITY AGAINST AUTOLOGOUS B CELLS

Keywords: Adaptive immunity, Systemic lupus erythematosus, Autoantibodies

S. Park[1], A. Register[2], H. Y. Lee[2], G. Lutzny-Geier[3], M. Aigner[3], M. Andreas[3], G. Schett[4], D. Borie[5], J. Chung[6], C. Kaplan[1]. *[1]Kyverna Therapeutics, Research, Emeryville, United States of America; [2]Kyverna Therapeutics, Technical Operations, Emeryville, United States of America; [3]Friedrich Alexander University Erlangen, University Hospital Erlangen, Internal Medicine 5 – Hematology/Oncology, Erlangen, Germany; [4]Friedrich Alexander University Erlangen, University Hospital Erlangen, Internal Medicine 3 – Rheumatology/Immunology, Erlangen, Germany; [5]Kyverna Therapeutics, Research and Development, Emeryville, United States of America; [6]Kyverna Therapeutics, Clinical Development, Emeryville, United States of America*

Background: A significant unmet medical need remains in the treatment of relapsed and/or refractory B cell-driven autoimmune diseases, including lupus nephritis (LN). The presence of autoantibodies is a hallmark of such diseases and implicates dysregulated B cell function in their pathogenesis. The central role of B cells in these diseases is also supported by the presence of B cells in diseased tissues and the efficacious responses reported with biologic therapies that target B cells. KYV-101 is an autologous CD19 CAR-T cell therapy that depletes pathogenic B cells. Importantly, the CD19 CAR utilized in KYV-101 was previously tested in B-cell lymphoma patients and demonstrated efficacy with an improved safety profile [1]. Since CD19 CAR-T cells target and lyse B cells in both circulation and tissues, a more complete depletion of autoreactive B cells is expected with KYV-101, resulting in better disease control and clinical remission than the current immunotherapies.
Objectives: To demonstrate the CAR-mediated and CD19-dependent activity of KYV-101 against autologous, patient-derived primary B cells.
Methods: Autologous $CD4^+$ and $CD8^+$ T cells were enriched from healthy donors (HD), systemic lupus erythematosus (SLE), LN or other autoimmune patients. KYV-101 CAR T cells were transduced with a lentiviral vector encoding a fully human single-chain variable fragment (scFV) CD19-targeting domain, a CD8α hinge and transmembrane domain, a CD28 cytoplasmic costimulatory domain, and a CD3ζ cytoplasmic domain. The CAR-mediated and CD19-dependent activity of KYV-101 was monitored *in vitro* in a set of cytotoxicity, cytokine release and proliferation studies, in response to either $CD19^+$ target cell lines or autologous, patient-derived primary $CD19^+$ B cells.
Results: Following a 24-hour incubation, KYV-101 generated from HDs or autoimmune patients induced greater and dose-dependent cytotoxicity of both the human $CD19^+$ NALM6 cell line and autologous, patient-derived primary B cells than their respective untransduced control T cells. Moreover, an effector cell dose-dependent increase in the production of cytokines such as IFNγ was also observed following co-culture. In contrast, no differences in cytotoxicity nor cytokine production were observed when $CD19^-$ target cells (K562 or U937 cells) were co-cultured with KYV-101 or untransduced control T cells. In addition, following a 96-hour incubation, KYV-101 generated from HDs or autoimmune patients proliferated when co-cultured with the NALM6 cells and autologous, patient derived primary B cells, whereas substantially lower levels of proliferation were observed in the untransduced control T cells co-cultured with NALM6 or autologous, patient-derived primary B cells or in KYV-101 and untransduced control T cells co-cultured with the $CD19^-$ cell lines K562 and U937.
Conclusion: KYV-101 generated from autoimmune disease patient lymphocytes demonstrates CAR-mediated and CD19-dependent activity against autologous, patient-derived primary B cells and thus represents a novel therapeutic option for the depletion of pathogenic B cells in autoimmune patients.

POS0008 STRATIFICATION OF NEGATIVE, SEROCONVERTED AND PERSISTENTLY POSITIVE THROMBOTIC PRIMARY ANTIPHOSPHOLIPID SYNDROME PATIENTS WITH DISTINCT FOLLICULAR HELPER T CELLS SUBSETS

Keywords: Anti-phospholipid syndrome, Autoantibodies, Adaptive immunity

P. Gaspar[1,2], A. R. Cruz-Machado[2,3], F. Ribeiro[2], V. C. Romão[2,3], L. Graca[2].
[1]Serviço de Medicina 2, Hospital Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal; [2]Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Centro Académico de Medicina de Lisboa, Universidade de Lisboa, Lisbon, Portugal; [3]Serviço de Reumatologia, Hospital Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal

Background: Primary antiphospholipid syndrome (PAPS) is caused by autoantibodies targeting protein-binding phospholipids (aPL)[1]. Follicular helper T (Tfh) and follicular regulatory T cells (Tfr) are critical for antibody production in germinal centres[2], but their role in PAPS is scarcely studied. Some patients remain persistently positive for aPL, while others become seronegative during disease progression[3]. Whether aPL status mirror immunological changes over time is not known.
Objectives: To phenotypically characterize Tfh/Tfr subsets in PAPS and explore the association with previous/current aPL status.
Methods: We prospectively recruited 73 adult thrombotic PAPS patients (Sidney criteria; ≥1 year disease duration) and 24 age- and sex-matched healthy donors (HD). Regardless of lupus anticoagulant (LA) status, patients were categorized in three groups according to aPL (anticardiolipin [ACL] IgM and/or IgG; ß2-glycoprotein [ß2GPI] IgM and/or IgG) profile: NN – previous and current aPL negative, ie, only positive for LA (n=40); PP – previous and current aPL positive (n=20); and PN – previous aPL positive, currently aPL negative (n=13). We considered aPL <30 UQ as negative (ELISA immunoassays). Tfh ($CD4^+FoxP_3^-CD25^-CD45RO^+CXCR5^+$), activated Tfh ($PD1^+ICOS^+$ Tfh), Tfh1-like ($CXCR3^+CCR6^-$ Tfh), Tfh2-like ($CXCR3^-CCR6^-$ Tfh), Tfh17-like ($CXCR3^+CCR6^+$ Tfh), Treg ($CD4^+CD25^+FoxP_3^+$), and Tfr ($CD4^+CD25^+FoxP_3^+CXCR5^+$) cells were analysed by flow cytometry using cryopreserved peripheral blood mononuclear cells. GraphPad Prism version 8 software was used for statistical analysis and p values <0,05 were considered significant.
Results: Most patients were women (n=43, 59%), with a mean age at disease onset of 42±13 years, and a mean disease duration of 8±7 years. Venous thrombosis was the most common first manifestation (53%), and pregnancy comorbidity were present 10% of women. At presentation, aPL positivity were as follows: LA, 70%; ACL IgG and/or IgM, 44%; ß2GPI IgG and/or IgM, 33%; triple positive, 16%. Circulating Tfh and Treg cells were comparable between HD and all APS patients (**Figure 1A and 1B**). Among APS, PP patients had higher frequency of Tfh compared to NN (p=0.047) but not with PN patients. Within the Tfh subset, activated Tfh cells were significantly increased in PP compared to NN (p=0.005) and PN patients (p=0.049), whereas no difference was seen between the latter group and NN patients, and between HD and all APS patients (**Figure 1C**). The frequencies of Tfh1-like and Tfh17-like cells were comparable between all groups, but Tfh2-like cells were decreased in PP compared to NN patients (p=0.008), and similarly distributed among all other groups (**Figure 1D to F**). In the regulatory compartment, circulating Tfr and Tfr/Tfh ratio were significantly increased in PP patients compared to NN (p<0.001; p=0.001) and PN patients (p=0.004; p=0.042) (**Figure 1G and 1H**). No difference was observed between NN and PN patients nor between HD and all APS patients.
Conclusion: Our preliminary results show that in thrombotic PAPS, imbalance of circulating Tfh and Tfr subsets change according to aPL profile. Increased $PD1^+ICOS^+$ Tfh and Tfr cells, and Tfr/Tfh ratio indicates ongoing humoral response in persistently positive patients. These changes are lost after seroconversion with T follicular cells subsets being similar to persistently negative PAPS patients.

Background: Immunological and genetic studies implicate T cells in the initiation and progression of rheumatoid arthritis (RA) [1]. Additionally, the diversity of the T cell repertoire is known to be reduced in RA, suggesting an enrichment of disease related clonal signatures [2].
Objectives: To study whether changes in the T-cell receptor repertoire (TCR) in lymph node (LN) and peripheral blood (PB) precede the onset of arthritis in seropositive at-risk individuals.
Methods: Unique molecular identifier (UMI)-based RNA sequencing of the TCRβ repertoire in LN biopsies and PB was performed in 9 healthy controls and 26 IgM-RF and/or ACPA positive at-risk individuals. Six of these individuals developed arthritis (RA) during at least 3 years of follow-up. PB and LN biopsies were analyzed during the at-risk phase and at RA onset.
Results: The TCRβ repertoire in LNs of autoantibody positive at-risk individuals harbors expanded TCRβ clones which can hardly be found in LNs of healthy controls. Regardless of whether the at-risk individuals developed arthritis or not, expanded TCRβ clones in LNs could be retrieved in peripheral blood. On RA onset, the LNs showed a marked decrease in the diversity of their TCRβ repertoire and, expanded TCRβ clones present during the at-risk phase could still be found in lymph nodes on arthritis onset.
Conclusion: Expanded TCRβ clones are present in lymph nodes and peripheral blood of individuals at risk of developing RA which can be retrieved in peripheral blood. Expanded TCRβ clones present in LNs during the at-risk phase persist on arthritis onset. Our analyses show a clear decrease in the diversity of the TCRβ repertoire towards onset of RA, implicating a key role for T-cell adaptive responses in steering onset of seropositive RA.

Background: Pathological mechanisms in the affected synovial joints in rheumatoid arthritis (RA) and factors contributing to synovial histological heterogeneity, which may impact treatment outcomes, remain largely unexplored at the protein level. Mapping the proteomic landscape of RA-affected synovial tissue (ST) and identifying determinants of synovial pathotypes could provide insights into RA's pathological mechanisms, identify new therapeutic targets, and pave the way for personalized medicine options.
Objectives: To map the proteomic landscape and dysregulated biological pathways in ST and plasma at multiple stages of RA. Through this investigation, the study also aims to identify the molecular and cellular determinants of synovial histological pathotypes in early untreated RA patients.
Methods: ST and matched plasma samples from patients with early untreated RA (ERA) (n = 20) and longstanding RA (LRA) (n = 20), as well as healthy controls (HC) (n = 16) were collected at baseline and at six months follow-up (RA patients only). ST biopsies were collected from the wrist via an ultrasound-guided synovial biopsy procedure (RA patients), or via arthroscopic guidance (HC). Samples were then characterized using discovery proteomics profiling. Comparisons were made between HC versus ERA or LRA at both timepoints, and proteins were regarded as differentially abundant at 5% FDR and a log2-fold change ±2.0 (ST proteins) or ±1.5 (plasma proteins). Next, the molecular and cellular determinants of synovial histological pathotypes were identified in untreated ERA patients by integrating the ST proteome, plasma proteome, Krenn synovitis score, number of circulating immune cells and scores of CD3 (T cells), CD20 (B cells), CD68 (Macrophages) and CD138 (Plasma cells) synovial immune infiltration.
Results: 335 plasma proteins and 3416 ST proteins were identified and quantified. *Plasma proteins*: CRP and SAA1 were overabundant in ERA compared to HC at baseline, but no proteins were differentially abundant in ERA compared to HC at follow-up (Figure 1 A-B). CRP was overabundant in LRA compared to HC at both timepoints (Figure 1 C-D). *Synovial tissue proteins*: In ERA patients 243 proteins were differentially abundant at baseline, but only 114 were differentially abundant at follow-up (Figure 1 E-F). In LRA patients, 216 and 284 proteins were differentially abundant at baseline and follow-up, respectively (Figure 1 G-H). Largely the same biological processes were dysregulated in ERA at baseline and in LRA at both timepoints. However, biological processes related to complement cascade, acute inflammatory response, scavenging of heme from plasma among others, tended to be less dysregulated in ERA patients at follow-up. Finally, data integration identified proteomic and cellular signatures underlying synovial pathotypes, that suggests the difference between lymphoid, myeloid, and fibroid pathotypes is a continuous spectrum that is linearly modellable. Proteins involved in negative regulation of: peptidase/protease activity, hemostasis and wound healing were underabundant in the lymphoid pathotype compared to the fibroid pathotype and to a lesser degree, the myeloid pathotype. Proteins that were involved in various aspects of antibody production were overabundant in the lymphoid pathotype compared to the fibroid pathotype and to a lesser degree, the myeloid pathotype.

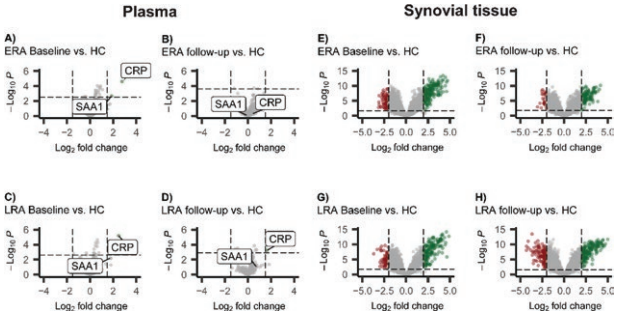

Figure 1. Comparison between plasma and synovial tissue proteomes of early untreated rheumatoid arthritis patients (ERA) or longstanding rheumatoid arthritis (LRA) at baseline or follow-up versus healthy controls.

Conclusion: The study revealed new insights into the proteomic landscape of the synovium in RA, elucidating the pathological mechanisms occurring in the synovium at different stages of disease. Additionally, the study identified a linear proteomic and cellular difference between the lymphoid, myeloid, and fibroid synovial pathotypes in untreated ERA patients, rather than distinct signatures for each pathotype.

POS0011 **LKB1 ALLEVIATES MIGRATION OF FIBROBLAST-LIKE SYNOVIOCYTES FROM RHEUMATOID ARTHRITIS PATIENTS VIA REGULATION OF SLC7A11-MEDIATED ROS SIGNALING**

Keywords: Rheumatoid arthritis

H. R. Lee[1,2], S. J. Yoo[1,2], J. Kim[2], J. A. Park[2], S. W. Kang[1,2]. [1]*Chungnam National University School of Medicine, Research Institute for Medical Sciences, Daejeon, Korea, Rep. of (South Korea);* [2]*Chungnam National University Hospital, Department of Internal Medicine, Division of Rheumatology, Daejeon, Korea, Rep. of (South Korea)*

Background: Liver kinase B1 (LKB1) is known as a tumor suppressor gene and an antioxidant regulator in cancer. We previously reported that LKB1 knock-down increased the expression of reactive oxygen species (ROS) and migration of fibroblast-like synoviocytes (FLS) from rheumatoid arthritis (RA) patients. However, the relative signaling remains unclear in RA.
Objectives: This study aimed to examine the signaling pathway of LKB1 in correlation with migration of FLS from RA.
Methods: Synovial tissues were obtained from RA patients (n=10) who were undergoing synovectomy or joint replacement. Isolated FLS were transfected with siRNA duplex targeting constructs for LKB1 or SLC7A11(solute carrier family 7 member 11, also known as xCT) using lipofectamine reagent. After incubation, expressions of target molecules were evaluated by real-time PCR and

western blot analysis. ROS levels were analyzed with MitoSOX red mitochondrial superoxide indicator using flow cytometry analysis. Cell migratory ability was examined using transwell migration assay and invaded cells were stained with crystal violet. For quantification, the crystal violet dye was eluted with 0.1% sodium dodecyl sulfate (SDS). A769662 was treated as a specific activator of AMPK (AMP-activated protein kinase)-mediated signaling.

Results: When RA FLS were stimulated with recombinant interleukin 17 (IL-17; 10ng/ml) and tumor necrosis factor alpha (TNF-α; 10ng/ml), SLC7A11 expression was markedly decreased. Following LKB1 knock-down for 24h, the protein level of SLC7A11 was also decreased in RA FLS. To determine whether SLC7A11 directly regulates FLS migration, SLC7A11 siRNA was transfected and then analyzed intracellular ROS level and performed transwell assay. SLC7A11 inhibition induced ROS expression (1.74-fold) and migration ability (1.74-fold) compared to control in RA FLS. Next, cells were treated with A769662 for AMPK activation, which is directly phosphorylated by LKB1 stimulation. LKB1 knockdown reduced SLA7A11 level and that decrease was certainly recovered by A769662 treatment. On the other hand, NOX4 expression was increased by LKB1 siRNA, and that increase was suppressed by AMPK activation. LKB1 siRNA induced ROS levels also down regulated by A769662 treatment. When LKB1 inhibition enhanced cell migration about 1.81-fold, and those increases were also reduced in 0.92-fold by AMPK activation compared to control.

Conclusion: These findings suggests that LKB1 regulate ROS production and SLC7A11 expression and, eventually lead to decrease migration, thereby further contributing to alleviate inflammation of RA FLS.

POS0012 THE EXPANSION OF CD4CD8 DOUBLE-POSITIVE T CELLS OF CD4 ORIGIN IS SPECIFIC FOR RHEUMATOID ARTHRITIS AND LINKED TO DISEASE ACTIVITY

Keywords: Adaptive immunity, Inflammatory arthritides, Rheumatoid arthritis

P. Nguyen[1], F. Beck[1], M. Melzer[1], A. M. Glimm[1], M. Krasselt[1], O. Seifert[1], M. Pierer[1], K. Rothe[1], U. Wagner[1]. [1]*Rheumatology Unit, Leipzig University Medical Center, Leipzig, Germany*

Background: CD4CD8 double-positive (DP) T cells are expanded in rheumatoid arthritis (RA) and associated with erosive disease [1]. The majority of DP T cells in the periphery have an effector phenotype and were reported to originate from either CD4 or CD8 single-positive (SP) T cells [2]. DP T cells of CD4 origin express a CD8αα homodimer, corresponding to a CD4+CD8^{low} fluorescence pattern in flow cytometry, while DP T cells of CD8 origin express a CD8αβ heterodimer, which results in a CD4+CD8^{high} pattern. Reports on the presence of polyfunctional CD4+CD8^{low} T cells in RA patients and individuals at risk of RA (3) suggest DP T cells of CD4 origin to be relevant for RA pathogenesis.

Objectives: This study aims to confirm and characterize the role of DP T cells of CD4 origin, or CD4+CD8^{low} T cells, in the context of RA.

Methods: DP T cells and their subpopulations were measured by flow cytometry in the peripheral blood of 53 newly diagnosed RA patients and compared to a cohort of patients with psoriatic arthritis (PsA) (n=52), as well as age-matched healthy donors (n=50). The CMV infection status of all subjects was assessed by a CMV IgG and IgM ELISA. In an independent cohort of 70 RA patients, the surface markers LIR1 and PD1 were measured on all T cells using flow cytometry. Lastly, a prospective study followed the changes in CD4+CD8^{low} T cell frequency in patients with early RA treated with MTX or Abatacept.

Results: Only DP T cells of CD4 origin (CD4+CD8^{low}) are significantly expanded in RA (figure 1A), while the frequency of DP T cells of CD8 origin (CD4+CD8^{high}) is similar to patients with PsA and healthy controls. The expansion of CD4+CD8^{low} T cells is associated with latent CMV infection in all three cohorts. However, CMV+ RA patients have significantly more DP T cells of CD4 origin than CMV+ healthy controls (figure 1B), indicating that CMV positivity is not the only driver of DP T cell expansion. DP T cells of CD4 origin express the senescence marker LIR1 and the exhaustion marker PD1 more often than their CD4 SP counterparts (figure 1C). In RA, CD4+CD8^{low} T cells correlate with DAS28-CRP (r=0.35, p=0.01), indicating a link with disease activity. The frequency of CD4+CD8^{low} T cells were measured in early RA patients before treatment (visit 1, V1), after one month (visit 2, V2) and three months (visit 3, V3) of treatment. Clinically efficacious treatment with abatacept was found to significantly reduce the frequency of CD4+CD8^{low} T cells after three months (mean change -0.09%, p=0.02), while methotrexate treatment did not (mean change -0.03%, p=0.83, figure 1D).

Conclusion: DP T cells of CD4 origin (CD4+CD8^{low} T cells) are frequently expanded in the peripheral blood of RA patients, but not in PsA patients or age-matched healthy individuals. DP T cells of CD8 origin are not expanded in RA or PsA compared to healthy controls. The association of CD4+CD8^{low} DP T cells with CMV seropositivity, as well as the increased LIR1 and PD1 expression, suggest they belong to a chronically stimulated, antigen-experienced cell population. Importantly, these cells are associated with disease activity in RA and show a significant reduction in the peripheral blood after treatment with a T cell-targeting agent. This confirms their role in RA pathogenesis and suggests their potential as a therapeutic target or biomarker for response.

POS0013 25-HYDROXYCHOLESTEROL IN THE PATHOGENESIS OF RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Adaptive immunity

H. Huang[1], Y. Geng[1], Y. Fan[1], Z. Zhang[1]. [1]*Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Rheumatoid arthritis (RA) is an autoimmune disease characterized by synovial inflammation, in which the imbalance of CD4$^+$ T cells plays an important role. 25-hydroxycholesterol (25-HC) is an important regulator of the mevalonate pathway in cholesterol metabolism. Previous studies have suggested that 25-HC may inhibit the transformation of CD4$^+$ T cells from interferon-γ (IFN-γ) $^+$CD4$^+$ T cells to IL-10$^+$CD4$^+$ T cells through the interaction with liver X receptor (LXR), therefore decreasing the expression of IL-10.

Objectives: This study aims to explore the mechanism by which 25-HC promotes the inflammatory process of RA by regulating the phenotypic transformation of

$CD4^+$ T cells through histological and cellular and molecular biology techniques, and propose possible molecular regulatory pathways.
Methods: Patients with RA from December 2019 to January 2022, and gender and age-matched osteoarthritis (OA) and healthy controls (HC) were enrolled. Peripheral blood mononuclear cells (PBMC) and synovial fluid mononuclear cells (SFMC) were collected and $CD4^+$ T cells were sorted by magnetic beads. The expression levels of different phenotypes of $CD4^+$ T cells and important cytokines were analyzed by flow cytometry; the secretion levels of IL-10 and IFN-γ were detected by ELISA technology. In the intervention experiment, the $CD4^+$ T cells were treated with different concentrations of atorvastatin to inhibit the cholesterol metabolism mevalonate pathway and supplement mevalonate acid, and then $CD4^+$ T cell phenotype and cytokine expression were detected. The synovial tissues were obtained from RA and OA patients receiving joint replacement surgery, and the expressions of 25-hydroxycholesterol hydroxylase (CH25H) and LXR were detected by immunohistochemistry and multiplex immunofluorescence. Real-time PCR and Western Blot were used to detect the expression of inflammasome signaling pathway of $CD4^+$ T cells. CH25H was knocked down suing small interfering RNA (siRNA), and the effects of knockdown of CH25H on inflammasome and the effect on the transformation of $CD4^+$ T cells were detected by the above methods.
Results: (1) $IL\text{-}10^+CD4^+$ T cells in PBMC/SFMC of RA patients were significantly lower than HC/OA, as well as the expression of IL-10. After interfering the mevalonate pathway by atorvastatin, the ratio of $IL\text{-}10^+IFN\text{-}\gamma^+CD4^+$ T cells and $IL\text{-}10^+IFN\text{-}\gamma^-CD4^+$ T cells as well as the expression of IL-10 decreased in a concentration-dependent manner. The down-regulation effect induced by atorvastatin was compensated after the supplementation of mevalonate acid. (2) The expressions of CH25H and LXR in $CD4^+$ T cells of RA synovial tissue increased detected by immunohistochemistry and multiplex immunofluorescence, and the expressions of CH25H, LXR and caspase-1 in $CD4^+$ T cells in synovial fluid were found increased by Western Blot, as compared with that of OA. (3) After the successful knockdown of CH25H confirmed by Real-time PCR and Western Blot, a significant decrease in the proportion of $IL\text{-}10^-IFN\text{-}\gamma^+CD4^+$ T cells, and increase in proportion of $IL\text{-}10^+IFN\text{-}\gamma^-CD4^+$ T cells were found in RA patients, accompanied with increase in $IL\text{-}10^+CD4^+$ T cells, while the proportion of $IFN\text{-}\gamma^+CD4^+$ T cells and expression of IL-10 decreased significantly. After supplementation with 25-HC, the siRNA-CH25H-mediated decrease in $IL\text{-}10^+CD4^+$ T cells was reversed and $IFN\text{-}\gamma^+CD4^+$ T cell formation was reduced. Meanwhile, the expression of NLRP3 and activated caspase-1 (capsase-1 p20) in peripheral blood $CD4^+$ T cells was reduced, and could eliminate after supplementation with 25-HC.
Conclusion: In peripheral $CD4^+$ T cells in RA patients, 25-HC may activate the NLRP3 inflammasome through CH25H-LXR pathway, thereby inhibiting the phenotypic transformation of $IFN\text{-}\gamma^+CD4^+$ T cells to $IL\text{-}10^+CD4^+$ T cells, and eventually promoting the inflammatory process in RA. These findings provide new clue for the mechanism of $CD4^+$ T cells in the pathogenesis of RA and suggest that the cholesterol metabolism pathway may become a new target of RA treatment.

POS0014 **SINGLE-CELL PERIPHERAL BLOOD ANALYSIS IDENTIFIES KEY IMMUNE SIGNATURES ASSOCIATED WITH REFRACTORY RHEUMATOID ARTHRITIS**

Keywords: Rheumatoid arthritis, Biomarkers, -omics

Y. Tan[1,2], T. Bhatt[3], M. Sutcliffe[1], J. Fitton[3], P. Emery[3,4], A. Aslam[5], D. Plant[1,2], M. H. Buch[1,2,3]. *[1]Centre for Musculoskeletal Research, Division of Musculoskeletal & Dermatological Sciences, University of Manchester, Manchester, United Kingdom; [2]NIHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom; [3]Leeds Institute of Rheumatic & Musculoskeletal Medicine, Faculty of Medicine & Health, University of Leeds, Leeds, United Kingdom; [4]NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [5]Department of Rheumatology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Refractory rheumatoid arthritis (refRA) persists in the targeted therapy era with up to 20% of patients failing multiple classes of biologic (b) and/or targeted synthetic (ts) DMARDs.[1,2] Currently, there is limited understanding of the immune composition of refRA.
Objectives: To characterise the peripheral immune landscape of patients with refRA as compared to early RA.
Methods: In the Leeds observational cohort study, peripheral blood mononuclear cells were collected from 30 treatment naïve early rheumatoid arthritis (ERA) and 23 refractory rheumatoid arthritis (refRA) patients. ERA patients have <12 months symptoms duration and refRA patients had active (at least moderate disease) RA despite ≥2 classes of b and/or ts DMARDs. Using a panel of 36 antibodies, we conducted mass cytometry by time of flight (CyTOF) analysis to identify alterations in peripheral immune cell subsets and functional markers between ERA and refRA, using unsupervised clustering and linear mixed-effects models, which adjusted for age, sex, seropositivity and batch. A false discovery rate of 0.05 was applied. All analyses were performed using R v4.0.2.
Results: The cohort had a higher proportion of females (73.3% ERA and 87% refRA) and a median age of 61 years. The majority were seropositive (86.7% ERA, 91.3% reRA). Among the refRA patients, median number of failed b/tsDMARDs was 3 (range 2-7). Overall, we identified 17 phenotypically distinct subsets from the immune cell population. ERA and refRA had similar abundance of immune cell sub-populations. However, functional marker differences in these cell subpopulations were observed between refRA and ERA: higher TNFR expression (monocytes, dendritic and FCÎµRI+ cells), CD80 (FCÎµRI+ cells), CD28 (neutrophils), granzyme B (CD4+ naïve T cells), and lower CTLA4 (monocytes), CD127 (NK cells), CD38 (basophils), NKP46 (CD8+ naïve T cells) and PD1 (CD4+ naïve T cells).
Conclusion: We report alteration in the functional profile across multiple immune cell types between refRA and ERA. These findings provide new insights into immunological traits of refRA and potential targets for therapy.

Kim[1,2,10]. *[1]The Catholic University of Korea, Center for Integrative Rheumatoid Transcriptomics and Dynamics, Seoul, Korea, Rep. of (South Korea); [2]The Catholic University of Korea, Department of Biomedicine & Health Sciences, Seoul, Korea, Rep. of (South Korea); [3]Ulsan National Institute of Science and Technology, School of Nano-Bioscience and Chemical Engineering, Ulsan, Korea, Rep. of (South Korea); [4]College of Veterinary Medicine, Chonnam National University, Department of Laboratory Animal Medicine, Gwangju, Korea, Rep. of (South Korea); [5]Yanbian University Hospital, Department of Immunology, Yanji, China; [6]Cancer Research Center, Key Laboratory of Science and Technology Department, Yanji, China; [7]Seoul National University College of Medicine, Department of Microbiology and Immunology, Seoul, Korea, Rep. of (South Korea); [8]Seoul National University College of Medicine, Department of Biomedical Sciences, Seoul, Korea, Rep. of (South Korea); [9]Seoul National University Medical Research Center, Institute of Endemic Diseases, Seoul, Korea, Rep. of (South Korea); [10]The Catholic University of Korea, Department of Internal Medicine, College of Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: The nuclear factor of activated T-cells 5 (NFAT5) is a member of the Rel family of transcription factors that can be activated by hypertonic stimuli [1]. It remains unclear, however, whether NFAT5 is required for damage-associated molecular patterns (DAMPs)-triggered inflammation and immunity. Serum amyloid a(SAA) is an endogenous toll-like receptor (TLR) ligand functioning as a DAMP responds to bacterial endotoxins [2]. In response to infection and inflammation, innate immune cells secrete pro-inflammatory cytokines, in particular IL-1β and TNF-α, to which the liver responds by producing acute-phase reactants [3]. Further identification of such pathologic process by acute-phase reactants will allow for better selection of therapeutic targets as well as a greater understanding of the mechanisms underlying chronic inflammation.

Objectives: To investigate SAA, an acute phase reactant as well as a TLR ligand, activates NFAT5 in macrophages of arthritic joints after being secreted from the liver and thereby promotes chronic inflammation.

Methods: SAA-induced upregulation of NFAT5 expression and activity in RAW264.7 cells, mice bone marrow derived macrophages and human peripheral CD14+ monocytes were assessed by western blot and/or luciferase reporter assays. SAA-accelerated arthritis in mice was generated by injecting SAA (5 μg ×1) in the affected joint of mice with a suboptimal form of IL-1β-induced arthritis, which was induced by injection of methylated bovine serum albumin (mBSA, 200 μg ×1) and/or IL-1β (250 ng ×2). Decrease in arthritis severity and inflammatory cell infiltration by *Nfat5*- and *Tlr2*/4-deficient mice, specific knockout of myeloid *Nfat5*. We used adenoviral vector system and overexpressed SAA gene in the liver exacerbates chronic arthritis in mice.

Results: Like hypertonic stimuli, several damage-associated molecular patterns (DAMPs), including SAA, MRP8, and HMGB1, can induce expression of NFAT5, an osmo-sensitive transcription factor. In particular, acute phase reactant SAA substantially increased NFAT5 expression and activity in RAW 264.7 and primary macrophages. SAA-mediated NFAT5 upregulation was operative via TLR2/4-JNK signaling pathway in macrophages. In addition, triggering of the 'SAA-TLR2/4-NFAT5' axis provoked migration and chemotaxis of macrophages and aggravated chronic arthritis in a CCL2-dependent manner. Intra-articular injection of SAA markedly accelerated macrophage infiltration and arthritis progression in mice. By contrast, genetic ablation of NFAT5 or TLR2/4 rescued the pathology induced by SAA, confirming the SAA-TLR2/4-NFAT5 axis in *vivo*. Myeloid-specific depletion of NFAT5 also attenuated SAA-accelerated arthritis. Notably, chronic arthritis in mice strikingly induced SAA overexpression in the liver. Conversely, forced overexpression of the SAA gene in the liver accelerated joint damage, indicating that the liver contributes to bolstering chronic inflammation at remote sites by secreting SAA.

Conclusion: In summary, this study underscores the importance of the SAA-TLR2/4-NFAT5 axis in innate immunity, suggesting that acute phase reactant SAA mediates mutual interactions between the liver and joints and ultimately aggravates chronic arthritis by enhancing macrophage activation.

HUMAN MONOCLONAL ANTIBODIES DERIVED FROM GINGIVAL TISSUE B CELLS BIND MALONDIALDEHYDE (MDA)-MODIFIED SELF-PROTEINS AND EXACERBATES ARTHRITIS – A NOVEL AUTOIMMUNE LINK BETWEEN INFLAMED GUMS AND JOINTS

Keywords: Autoantibodies, Rheumatoid arthritis

B. Raposo[1], C. De Vries[1], M. Gomes Afonso[1], P. Sahlström[1], L. Israelsson[1], R. Stålesen[1], L. Klareskog[1], V. Malmström[1], B. Réthi[1], C. Grönwall[1], K. Lundberg[1]. [1]*Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden*

Background: Based on an epidemiological association between periodontitis (PD) and rheumatoid (RA) arthritis[1], with oral dysbiosis[2] and jawbone destruction[3] preceding the onset of RA, a causative link between periodontal infection and RA has been proposed. However, the mechanisms remain to be explained. Both gingival and synovial inflammation associate with malondialdehyde (MDA) protein modifications[4], a posttranslational modification linked to oxidative stress. While MDA IgM are part of the natural antibody response, MDA IgG levels are elevated in RA and correlate with disease activity[5]. Moreover, RA joint B-cell derived MDA-reactive monoclonal antibodies (mAb) promote bone erosion and osteoclastogenesis[6], suggesting pathogenic properties. Here we explore MDA-autoimmunity as an etiological link between inflamed gums and joints.
Objectives: To investigate if mAbs derived from gingival tissue (GT) B cells of PD patients bind MDA-modified self-proteins and whether they are pro-arthritogenic.
Methods: Recombinant mAbs (n=38) were generated as human IgG1 from single-cell sorted gingival tissue (GT) B cells of one PD patient with RA (PD/RA) and one PD patient without RA (PD only), and screened by ELISA for binding to MDA-modified and native albumin, fibrinogen and low-density lipoprotein. Three GT mAbs *versus* one isotype control mAb were assayed *in vitro* for TNF production by monocyte-derived macrophages stimulated by LPS (n=7 healthy donors), and two GT mAbs *versus* one isotype control mAb were examined *in vivo* in the collagen type II (CII) antibody-induced arthritis (CAIA) model (n=5 mice/group). Briefly, arthritis was induced in BALB/c mice by *i.v.* injection of 1.5mg anti-CII antibody cocktail together with 1mg GT or control mAb, followed by 25ug LPS on day 3. Arthritis scores and prevalence were recorded daily for two weeks; statistical analysis was performed using repetitive-measure one-way ANOVA with Geisser-Greenhouse correction and Holm-Šidák's multiple comparisons test.
Results: Three GT mAbs from the RA/PD patient and one from the PD-only patient bound MDA-modified self-proteins but not the native counterparts; all other GT mAbs were negative. The MDA-reactive GT B cell clones were class-switched (n=3 IgG+; n=1 IgA+) with 21-50 somatic hypermutations. The GT mAb with the strongest MDA-reactivity – derived from an IgA+ GT B cell isolated from the PD/RA patient – enhanced TNF production in LPS-stimulated macrophages, and exacerbated arthritis with prolonged arthritis, higher arthritis scores ($p<0.05$) and higher disease prevalence ($p<0.001$), see figure 1 below.

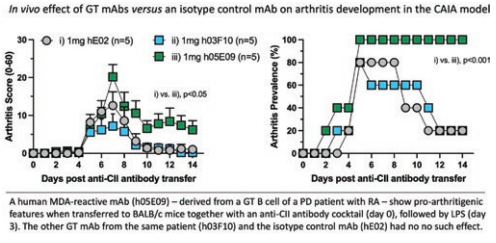

Figure 1.

Conclusion: Here we show that MDA-autoreactive B cells with features of T-cell driven affinity maturation are present in the gum mucosa of PD patients with or without RA. Moreover, that antibodies from one such clone can exacerbate arthritis. Further studies are needed in order to elucidate the mechanisms involved, and to determine if possibly enhanced TNF production via antibody-mediated modulation of macrophage responses could play a role. Taken together, this pilot study supports further research into MDA-autoimmunity as an etiological link between periodontal infection and RA.

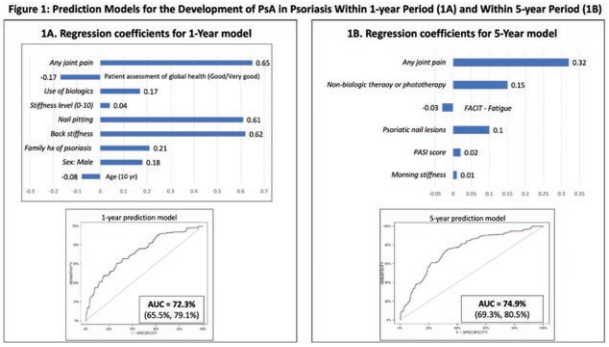
PREDICTION OF PSORIATIC ARTHRITIS TOOL (PRESTO): DEVELOPMENT AND PERFORMANCE OF A NEW SCORING SYSTEM FOR PSORIATIC ARTHRITIS RISK

Keywords: Epidemiology, Spondyloarthritis, Psoriatic arthritis



L. Eder[1,2], K. A. Lee[3], V. Chandran[2,4], J. Widdifield[5,6], A. Drucker[2,7], C. T. Ritchlin[8], C. Rosen[2,9], R. Cook[3], D. D. Gladman[2,4]. *[1]Women's College Hospital, Rheumatology, Toronto, Canada; [2]University of Toronto, Medicine, Toronto, Canada; [3]University of Waterloo, Statistics & Actuarial Science, Waterloo, Canada; [4]Toronto Western Hospital, Rheumatology, Toronto, Canada; [5]Sunnybrook Research Institute, Rheumatology, Toronto, Canada; [6]University of Toronto, Institute of Health Policy, Management & Evaluation, Toronto, Canada; [7]Women's College Hospital, Dermatology, Toronto, Canada; [8]University of Rochester, Medicine, Rochester, United States of America; [9]Toronto Western Hospital, Dermatology, Toronto, Canada*

Background: A simple, scalable tool that identifies psoriasis patients at high risk for developing psoriatic arthritis (PsA) could improve early detection and facilitate early intervention for this conditon. However, no such prediction tool currently exists.
Objectives: Our overall objective is to develop an accurate risk prediction model for the development of PsA and to assess its performance among patients with psoriasis.
Methods: In this longitudinal cohort study we analyzed data from the International Psoriasis and Arthritis Team (IPART) study, a prospective cohort of psoriasis patients without PsA at the time of enrollment. The participants were followed prospectively from 2006 to 2019, and their PsA status was assessed annually by a rheumatologist. Information about their demographics, psoriasis characteristics, co-morbidities, medications and musculoskeletal symptoms was used to develop prediction models for PsA. Penalized binary regression models were used for variable selection while adjusting for psoriasis duration; the stacked LASSO with equal weights was adopted to deal with multiple imputed datasets for incomplete data. Risks of developing PsA over 1- and 5-year time horizons were estimated. Internal validity was assessed using 5-fold cross-validation. Model performance was assessed by the area under the curve (AUC), and calibration plots.
Results: A total of 635 psoriasis patients were analyzed (mean duration of follow up 7.7 years). 51 and 71 patients developed PsA during the 1-year and 5-year periods, respectively. The risk of developing PsA within 1 year was associated with younger age, male sex, family history of psoriasis, back stiffness, nail pitting, level of stiffness, use of biologic medications, patient global assessment of health and pain severity (AUC 72.3, 95% confidence interval (CI) 65.5, 79.1, Figure 1A). The risk of developing PsA within 5 years was associated with morning stiffness, psoriatic nail lesion, psoriasis severity (by PASI), fatigue severity (by FACIT-fatigue), pain severity and use of systemic non-biologic medication or phototherapy (AUC 74.9, 95% CI 69.3, 80.5, Figure 1B). Calibration plots showed reasonable agreement between predicted and observed probabilities. The sensitivity and specificity for a 2.5% probability of PsA onset within 1 year were 54.5% and 75%, respectively. The sensitivity and specificity for a 5% probability of PsA onset within 5 years period were 61.1% and 77%, respectively.
Conclusion: The development of PsA within clinically meaningful time frames can be predicted with reasonable accuracy for psoriasis patients. Additional work is underway to validate these models in external cohorts of psoriasis patients.

Schett[1,2], A. Kleyer[1,2], A. M. Liphardt[1,2]. *[1]Friedrich-Alexander Universität (FAU) Erlangen-Nürnberg & Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [2]Friedrich-Alexander Universität (FAU) Erlangen-Nürnberg & Universitätsklinikum Erlangen, Deutsches Zentrum Immuntherapie, Erlangen, Germany; [3]Klinikum Nürnberg Nord, Rheumatology, Nürnberg, Germany; [4]Friedrich-Alexander University (FAU) Erlangen-Nürnberg & Universitätsklinikum Erlangen, Dermatology, Erlangen, Germany*

Background: In the clinical routine patient reported outcome measures (PROMs) such as the 'Disability of the Arm, Shoulder and Hand Questionnaire' (Quick-DASH) [1], 'Score for the Assessment and quantification of Chronic Rheumatic Affections of the Hands' (SF-SACRAH) [2] and the ´Health Assessment Questionnaire´ (HAQ) [3] are common for assessing functional status and hand involvement in rheumatic diseases [4] while ultrasonography (US) is a cost-effective, reliable imaging technology for grading and monitoring synovitis and tenosynovitis [5]. However, it is unclear, if subjective perceived impairment can be associated with US-detected synovitis or tenosynovitis in patients with psoriatic arthritis (PsA) and psoriasis (Pso).
Objectives: To correlate subjective hand function with the grade of synovitis and tenosynovitis by US (greyscale (GS), power Doppler (PD) activity) in patients with PsA and Pso.
Methods: PsA and Pso patients recruited from the Rheumatology Department at the University Hospital Erlangen were enrolled in this cross-sectional study after giving written informed consent. Patients completed the HAQ-DI, SF-SACRAH and Quick-DASH questionnaires and subject characteristics (age, sex, disease) were recorded. The examining physician performed a bilateral US (Samsung HS40, South Korea; Esaote Mylab Twice, Italy) of the flexor tendons of all fingers and metacarpophalangeal (MCP) joints 2-5 and both wrists. Each joint was examined by GS (score 0-3) and PD (score 0-3) and flexor tendons were scanned in GS (0/1) and with PD (0-3) following the EULAR-OMERACT scoring system [5]. For statistical analysis patients with either a positive synovitis or tenosynovitis score ≥1 were included. A repeated measure correlation analysis was performed, at the intra-individual level, to measures the overall

strength and direction of the linear relationship between the PROMs with US scores.

Results: A total of 106 patients (40 PsA/66 Pso: age 47.5(12.3)/43.6(14.1) years, 63%/61% male) participated in this study. US-activity is listed in Table 1. Moderate positive correlations were detected for GS tenosynovitis score in digit 1 with both, Quick-DASH (r=0.352, p=0.038) and HAQ-DI (r=0.399, p=0.036) and also for GS tenosynovitis score in digit 4 with Quick-DASH (r=0.354, p=0.037). Overall GS synovitis score (MCP 2-5 + wrist) shows a moderate negative correlation with Quick-DASH (r=-0.323, p=0.031) and HAQ-DI (r=-0.477, p=0.002), as does PD tenosynovitis score in digit 1 (r=-0.386, p=0.022) and 3 (r=-0.386, p=0.022) with SF-SACRAH. HAQ-DI, SF-SACRAH and Quick-DASH correlated strongly with each other (r>0.7, p<0.001).

Table 1. Ultrasound activity versus non-activity by group.

Ultrasound Scores, active (score≥1)/non-active	Psoriatic Arthritis	Psoriasis
Greyscale Synovitis	20/20	13/53
Doppler Synovits	7/33	1/65
Greyscale Tenosynovitis	14/26	7/59
Doppler Tenosynovitis	11/29	1/65

Conclusion: Only the grade of chronic tenosynovitis is partially represented in Quick-DASH and HAQ-DI, while synovitis scores are negatively related to them. Surprisingly, worse hand function detected by the most hand-specific questionnaire, SF-SACRAH, was associated with less acute tenosynovitis. While Quick-DASH and HAQ-DI focus on tasks which require sufficient hand strength, the SF-SACRAH focuses on activities demanding fine motor skills, which seems to be less affected by tenosynovitis. Varying correlations of the different PROMs with the US scores have already been described for patients with rheumatoid arthritis [6]. Subjectively perceived hand function does not sufficiently reflect grade of synovitis and tenosynovitis and therefore more sensible functional outcome parameters are required.

COMPARATIVE PROFILING OF SERUM PROTEIN BIOMARKERS AND DISEASE ACTIVITY ACROSS VARIOUS DISEASE DOMAINS IN PATIENTS WITH PSORIATIC ARTHRITIS (PSA)

Keywords: Biomarkers, Psoriatic arthritis

I. T. Cheng[1], M. LI[1], H. So[1], J. J. W. Lee[2], C. K. Wong[3], L. S. Tam[1]. [1]*The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR);* [2]*The Chinese University of Hong Kong, School of Public Health, Hong Kong, Hong Kong (SAR);* [3]*The Chinese University of Hong Kong, Chemical Pathology, Hong Kong, Hong Kong (SAR)*

Background: Psoriatic Arthritis (PsA) is a complex, heterogeneous disease with chronic inflammation. Disease manifestations include the peripheral joint inflammation, dactylitis, enthesitis and skin psoriasis. Chronic inflammation is associated with structural damage, which jeopardize long-term functional ability. Sensitive biomarkers reflecting disease activity in various disease domains are lacking.

Objectives: To define the molecular basis of inflammation in different disease domains through comparative profiling of serum proteins.

Methods: This is a cross-sectional study in patients with PsA. Clinical assessment of inflammation in the peripheral joint (clinical Disease Activity in Psoriatic Arthritis [cDAPSA] and swollen joint count), dactylitis digit count, skin (Psoriasis Activity and Severity Index [PASI]) and enthesis (Leeds enthesitis index) were performed. Blood samples were collected for biomarker assay including 48 cytokines, chemokines, growth and angiogenic factors using the Bio-Rad Bioplex assay1 (Table 1). Levels of selected serum proteins were compared between different disease activity scores across various domains using adjusted linear regression with least absolute shrinkage and selection operator (LASSO) modeling.

Results: 100 PsA patients were recruited (age: 51±11 years, male: 52 (52%), disease duration: 9.0±3 years). The cohort had moderate disease activity (DAPSA: 24.4±14.6; PASI: 6.0±7.2). 53 (53%) and 11 (11%) patients were using conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) and biologic DMARDs (bDMARDs) respectively. Using LASSO regression analysis, biomarkers correlating with peripheral joint inflammation were IFN-γ, IL6, SCF and MCP1, while MIP-1α and β-NGF were related to dactylitis. Biomarkers correlating with skin severity were IP10, M-CSF and eotaxin, while IL8, M-CSF and CTACK were related to enthesitis. Details of biomarkers independent predicting various disease severity are listed in table 2-3.

Conclusion: Comparative serum protein biomarker profiling represents a viable method for distinguishing active inflammation in the various disease domains which may be a step forward towards personalized medicine.

Table 1 – 48 biomarker panel

Cellular cytokine

IFN-α	Interferon-α
IFN-γ	Interferon-γ
IL 9	Interleukin 9
IL12 p40	Interleukin 12 p40 subunit
IL12 p70	Interleukin 12 p70 subunit
IL15	Interleukin 15
IL16	Interleukin 16
IL17	Interleukin 17
IL18	Interleukin 18
IL1ra	Interleukin 1 receptor antagonist
IL1β	Interleukin 1β
IL2	Interleukin 2
IL2ra	Interleukin 2 receptor antagonist
IL3	Interleukin 3
IL7	Interleukin 7
MIF	Migration inhibitory factor
TNFα	tumour necrosis factor α
TNFβ	tumour necrosis factor β
TRAIL	tumour necrosis factor - related apoptosis-inducing ligand

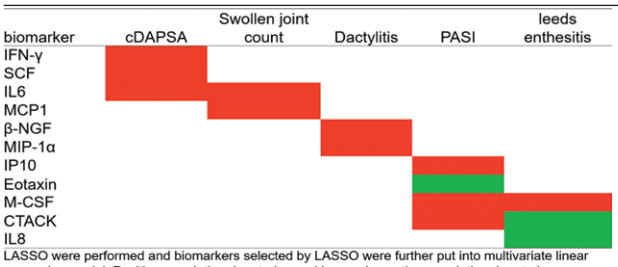
Humoral cytokine

IL10	Interleukin 10
IL13	Interleukin 13
IL1α	Interleukin 1α
IL4	Interleukin 4
IL5	Interleukin 5
IL6	Interleukin 6

Chemokine

CTACK	Cutaneous T cell- attracting chemokine
Eotaxin	Eotaxin
IL8	Interleukin 8
IP10	Interferon gamma-induced protein 10
MCP1	Monocyte chemoattractant protein 1
MCP3	Monocyte Chemotactic Protein 3
MIG	Monokine induced by interferon (IFN)-γ
MIP-1α	Macrophage inflammatory protein 1α
MIP-1β	Macrophage inflammatory protein 1β
RANTES	RANTES
SDF-1α	Stromal cell-derived factor 1α

Growth and angiogenic factors



Basic_FGF	Basic Fibroblast growth factor
G_CSF	Granulocyte colony-stimulating factor
GM_CSF	Granulocyte-macrophage colony-stimulating factor
GRO	Growth-regulated oncogene
HGF	Hepatocyte growth factor
LIF	Leukemia inhibitory factor
M-CSF	Macrophage colony-stimulating factor
PDGF	Platelet-derived growth factor
SCF	Stem Cell Factor
SCGF-β	Stem cell growth factor
VEGF	Vascular endothelial growth factor
β-NGF	Nerve growth factor

Table 2. LASSO regression on various disease activity scores across various disease domains

Predictor	β	95% CI	*p*
cDAPSA			
IFN-γ	0.436	0.014 to 0.858	0.043
IL6	0.104	0.009 to 0.199	0.032
SCF	0.09	0.048 to 0.132	<0.001
Swollen joint count			
IL6	0.037	0.015 to 0.060	0.001
MCP1	0.028	0.010 to 0.046	0.003
Dactylitis			
MIP-1α	0.109	0.026 to 0.191	0.010
β-NGF	0.36	0.110 to 0.610	0.005

POS0022 NAFLD IN PSORIATIC DISEASE: IDENTIFYING PATIENTS AT HIGH RISK OF SERIOUS LIVER DISEASE

Keywords: Comorbidities, Real-world evidence, Psoriatic arthritis

S. Harrison[1,2,3], U. Nandasoma[4], P. Sambi[5], R. Parker[4], C. Chimakurthi[4], P. Laws[5], A. Barr[1,3], C. Vandevelde[1,3], H. Marzo-Ortega[1,1], J. Freeston[1,3].
[1]Chapel Allerton Hospital, Rheumatology, Leeds, United Kingdom; [2]Leeds Institute of Cardiovascular and Metabolic Medicine (LICAMM), the LIGHT building, Leeds, United Kingdom; [3]Leeds Musculoskeletal Biomedical Research Unit, Department of Rheumatology, Leeds, United Kingdom; [4]St James Hospital, Department of Hepatology, Leeds, United Kingdom; [5]Chapel Allerton Hospital, Dermatology, Leeds, United Kingdom

Background: Patients with psoriatic disease(PsD) [psoriasis(PsO) and psoriatic arthritis(PsA)] are at greater risk of non-alcoholic fatty liver disease(NAFLD) and NAFLD-associated fibrosis/cirrhosis compared with the general population and other inflammatory arthritis(1) independent of disease-modifying medications [biological(b)DMARDs or methotrexate(MTX)][2]. Conversely, using these medications in patients with significant NAFLD might accelerate progression to fibrosis/cirrhosis[1]. The Leeds Teaching Hospitals NHS Trust(LTHT) NAFLD screening pathway is not validated in PsD and may underestimate prevalence of NAFLD in PsD[3].

OBJECTIVES:

1. To assess the prevalence of NAFLD in our PsD population
2. To determine the effectiveness of the LTHT NAFLD pathway for identifying PsD patients at risk of fibrosis/cirrhosis

Methods: This audit included consecutive patients from the Leeds Specialist Spondyloarthritis and Dermatology departments who underwent screening for NAFLD fibrosis/cirrhosis using the LTHT pathway. Briefly, patients are first screened using ELF and FIB4 scores. ELF>9.5 and FIB4 >1.45 triggers referral for fibroscan and hepatology opinion. A fibroscan >10 was considered indicative of clinically significant NAFLD. We compared baseline demographics (age, sex, BMI, diabetic status), biochemistry (ALT, AST, platelet count, albumin, hepatitis B and C), and NAFLD screening tests (ELF, FIB4 and fibroscan +/- liver ultrasound and biopsy) with the final hepatology diagnosis (NAFLD/ fibrosis/ cirrhosis/ other). We compared results from our PsD patients and patients with other inflammatory arthritis (Other IA).

Results: Overall 110 patients were included; 86.4% (95/110) PsD, and 14.6% (15/110) Other IA. Regarding demographic and clinical variables, age, sex, BMI, AST, ALT, platelets and albumin were similar between all groups. Other IA patients were more likely to be male and taking bDMARD monotherapy. No PsO patients were taking bDMARDs and over half were on no DMARD(Table 1). ELF scores were higher in the PsO group, possibly because the P3NP peptide (part of the ELF score) may be elevated in active skin PsO. Contrastingly, FIB-4 scores were higher in PsA compared with all other groups. Higher FIB4 scores, but not ELF scores, were associated with a fibroscan score >10 and a diagnosis of NAFLD fibrosis/cirrhosis in PsA (p=0.05 and p=0.09 respectively).

Conclusion: PsA patients had higher rates of significant fibrosis/cirrhosis compared with patients with Other IA. FIB-4 was better than ELF at identifying PsA patients requiring a fibroscan to exclude significant fibrosis/ cirrhosis. Findings will now be validated in a larger prospective cohort study.

Background: Although the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is used to assess the activity of axial disease in patients (pts) with psoriatic arthritis (PsA), only one of its questions is specific to axial symptoms. Alternatively, the Ankylosing Spondylitis Disease Activity Score (ASDAS) excludes assessment of enthesitis, gives less weight to peripheral activity and is considered more objective than the BASDAI.

Objectives: The current post hoc analysis aimed to compare the performance of BASDAI and ASDAS in evaluating symptoms of axial involvement in pts with axial PsA (axPsA).

Methods: Pts enrolled in the DISCOVER-1 (D1) and DISCOVER-2 (D2) studies were adults with active PsA despite standard therapies. D1 pts had ≥3 swollen and ≥3 tender joints (SJC; TJC) and C-reactive protein (CRP) ≥0.3 mg/dL; D2 pts had SJC ≥5, TJC ≥5 and CRP ≥0.6 mg/dL. 31% of D1 pts received 1-2 prior tumor necrosis factor inhibitors; D2 pts were biologic-naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo with crossover to GUS Q4W at W24. axPsA was defined by presence of sacroiliitis based on previous radiograph or magnetic resonance (MR) imaging confirmation. Data were pooled across all treatment groups. In addition to BASDAI and ASDAS, modified versions excluding the peripheral arthritis and enthesitis questions (mBASDAI) and the peripheral arthritis question (mASDAS) were calculated. Normalized (scale of 0-10) versions of ASDAS and mASDAS were calculated based on maximum scores of ≈7 and ≈6.3, respectively. The correlation of BASDAI/mBASDAI and ASDAS/mASDAS with SJC, TJC, enthesitis, Functional Assessment of Chronic Illness Therapy (FACIT)-fatigue, pt pain, pt global, and physician global was assessed with Pearson's correlation coefficient. The cross-sectional and longitudinal (W52) effects of Leeds enthesitis index (LEI), SJC, and axPsA on BASDAI/mBASDAI and ASDAS/mASDAS were assessed with mixed models.

Results: 436 pts with available baseline (BL) BASDAI information were included in the analysis. In pts with axPsA, BASDAI showed weak correlation with SJC, TJC, LEI, and physician global; moderate correlation with fatigue; and strong correlation with pt global and pt pain. Similar results were observed for ASDAS and modified versions. Among pts without axPsA, correlations of BASDAI and ASDAS with SJC, TJC, and LEI remained weak; correlations with pt global and pt pain remained strong. Longitudinally, among pts with and without BL enthesitis, respectively, LEI and SJC showed significant but not clinically important associations with either outcome. Presence of axial disease was associated with significantly greater BASDAI and ASDAS scores, at BL and longitudinally, without differences in the incremental effect on BASDAI, normalized ASDAS, or their modified versions.

Conclusion: In pts with axPsA, the BASDAI and ASDAS performed similarly, with both demonstrating weak correlations with peripheral arthritis and moderate/strong correlations with pt fatigue and pain. The BASDAI and ASDAS also showed similar ability to discern changes in axial disease activity. These results suggest that both BASDAI and ASDAS are valid, and perform comparably, in assessing activity of axial disease in PsA pts.

POS0024 RETENTION RATE OF TNF INHIBITORS (TNFI), ANTI-IL17, AND ANTI-IL12/23 DRUGS IN A SINGLE-CENTER COHORT OF PSORIATIC ARTHRITIS PATIENTS

Keywords: Inflammatory arthritides, bDMARD, Psoriatic arthritis

M. Ferrito[1,2], G. Cincinelli[2,3], M. Manara[2], E. G. Favalli[2,3], R. Caporali[2,3].
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy; [1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Background: During the last decades, it has been proposed to widen the horizons of psoriatic patients under a broader clinical concept of psoriatic disease (PD) encompassing both articular and extra-articular features. The most recent international recommendations on psoriatic arthritis (PsA) management highlight the need to personalize therapeutic strategies based on articular and extra-articular manifestations, such as axial or peripheral involvement and severity of skin psoriasis. Lacking specific recommendations for PsA comorbidities treatment, management decisions are often driven by drugs safety profiles and experience gathered from other rheumatologic diseases, such as rheumatoid arthritis. In the last years, new drugs have been approved for PsA management, expanding the possibility to personalize treatment choice in patients with PsA.

Objectives: Our study aims at evaluating the retention rate of bDMARDs with different mechanism of action (MoA) (TNFi vs non-TNFi) and factors associated with drug suspension in a single-center cohort of PsA patients. Furthermore, we aim to investigate whether demographic and clinical factors (among which comorbidities) could drive the choice of bDMARDs between TNFi and non-TNFi.

Methods: A retrospective cohort from a single-center real-word clinical setting has been collected. A total of 241 bDMARDs therapy courses (155 TNFi drugs, 65 anti-IL-17 drugs, and 21 anti-IL12/IL-23) were analyzed. Bivariate analyses were performed to assess the presence of demographic and clinical features, as well as comorbidities, associated with bDMARDs discontinuation in the TNFi and non-TNFi groups. Further, we conducted survival analysis and Cox regression, in order to individuate the possible predictors of failure among patients receiving TNFi and non-TNFi.

Results: In the bivariate analyses of TNFi and non-TNFi groups we found a lower age at TNFi start (46 years, IQR 45-54 vs 50.5 years, IQR 42-61; p=0.004) as well as a lower proportion of patients with skin psoriasis (65.8% vs 88.4%, p<0.001). Survival analysis showed no significant differences between TNFi and non-TNFi groups. Cox regression individuated fibromyalgia as a predictor of drug failure (HR 3.40, 1.92-6.03; p<0.001) and first line bDMARDs as protective factor (HR 0.46, 0.25-0.88; p=0.019). Lastly, among TNFi courses, fibromyalgia was associated with drug suspension (HR 6.52, 3.16-13.46; p<0.001), while only a trend of significance for skin psoriasis as risk factor for drug failure was shown (HR 2.38, CI 1.00 - 5.66, p=0.05).

Conclusion: This study provides information about clinical and demographic factors associated with retention rates of bDMARDs from a real-life, single-center cohort of PsA patients. In our study, TNFi and non-TNFi drugs had similar retention. Fibromyalgia and skin psoriasis seem to be the major predicted of drug discontinuation; in contrast, a lower failure risk has been observed in first-line treatment course.

Table 1. Cox-regression analysis of predictors of drug discontinuation for the overall PsA population

	Haz. Ratio	Std. Err.	p-value	95% conf. interval
Age	0.992	0.011	0.456	0.970 - 1.014

POS0025 COMBINED NAILFOLD CAPILLAROSCOPY AND ULTRASONOGRAPHY OF THE NAIL-ENTHESIS COMPLEX TO DISCRIMINATE PSORIATIC DISEASE FROM RHEUMATOID ARTHRITIS PATIENTS AND HEALTHY SUBJECTS

Keywords: Ultrasound, Artificial Intelligence, Psoriatic arthritis

G. Cafaro[1], V. Venerito[2], V. Valentini[1], R. Bursi[1], C. Perricone[1], R. Gerli[1], E. Bartoloni[1]. *[1]University of Perugia, Rheumatology Unit - Department of Medicine and Surgery, Perugia, Italy; [2]University of Bari "Aldo Moro", Rheumatology Unit, Department of Emergency and Organ Transplantations, Bari, Italy*

Background: The distal interphalangeal joint (DIP), the extensor tendon enthesis and fingernail, in psoriatic arthritis (PsA) represent a very interesting site where the dermatologic, synovial, and entheseal features of the disease merge. The nail-enthesis complex (NEC) can be well analysed with ultrasound (US),

and the nailfold is the ideal site to assess angiogenesis, another typical feature of psoriatic synovitis, with both power Doppler (PD) and nailfold videocapillaroscopy (NVC). Studies have shown that PsA patients may have differences in the structure of the nail complex and capillaries compared with healthy individuals. No study has combined the two techniques.

Objectives: To evaluate the ability of combined US examination of the NEC and NVC to differentiate PsA from psoriasis (PSO), rheumatoid arthritis (RA), and healthy subjects (HC).

Methods: Twenty age- and sex-matched subjects per group were consecutively enrolled. Each subject was blindly assessed and underwent US of the NEC, NVC, and clinical examination. For the US examination, the nail plate, matrix, and bed were assessed in grayscale (GS) and with PD according to the Brown University Nail Enthesis Scale (BUNES)[1]. For the nail plate, the Wortsman[2] classification was also evaluated. The thickness of the nail plate, matrix, and nail bed were measured. Mean values of 10 digits were used for the analysis. Capillary density, number of microhaemorrhages, tortuous capillaries, ectasia, and ramified capillaries were assessed at NVC. Mean values were calculated for II-V digits in both hands. After excluding subjects with missing values, differences among groups were analysed with Kruskal-Wallis test. US and NVC variables were then included in a K-Means clustering model. The number of clusters was determined using the elbow method. Factor analysis was performed to explain the clustering results. The number of factors was selected using the Scree plot method.

Results: The BUNES GS total score, the BUNES GS score for the plate, and the Wortsman score were significantly lower in HC compared to all other groups. BUNES GS for the plate was higher in PSO than in HC. The number of tortuous capillaries was higher in PsA than in PSO and HC, but not in RA. The clustering model identified five clusters (Figure 1A), showing good separation of PsA and HC. PSO were distributed from cluster 2 to cluster 5 and RA among all clusters. At factor analysis (Figure 1B), all US GS variables loaded on factor 1, US PD variables loaded on factor 2, matrix and bed thickness loaded on factor 3, and number of tortuous capillaries and ectasias loaded on factor 4. Loadings of Factor 5 and 6 were below 0.5.

Conclusion: The results of this pilot study confirm that PsA patients have significant changes in the structure of the NEC compared with healthy subjects. However, most of these changes do not appear to be specific to PsA, as they are also found in PSO and, most surprisingly, in RA where DIP joint involvement is not present. Interestingly, PsA patients appear to have higher numbers of tortuous capillaries compared with PSO and HC, consistent with increased angiogenesis in the synovium. The combined evaluation seems to provide a good distinction between PsA and HC. Not surprisingly, PSO patients clustered closer to PsA (although with significant overlap with HC), which may be due to subclinical involvement. RA patients are distributed among all clusters and have alterations similar to those of PsA. This study does not provide a clear explanation for this phenomenon, and further studies are needed. This pilot study allowed us to identify US and NVC features that can be selected and applied in a prospective study that includes early undifferentiated arthritides and new-onset PSO, to understand whether the observed differences occur early in the disease and whether changes occur during the course of the disease. A larger sample size could also improve the accuracy of the clustering model.

POS0026

THE INDEPENDENT INFLUENCE OF SEX ON THE DISEASE IMPACT DOMAINS IN PSORIATIC ARTHRITIS IS MODEST, ONCE CONFOUNDERS ARE TAKEN INTO ACCOUNT

Keywords: Psoriatic arthritis, Gender/diversity issues

A. Ortolan[1], A. Capacci[1], A. Zoli[1], S. DI Murro[1], F. Cristiano[1], P. Cerasuolo[1], R. La Ferrara[2], L. Lanzo[1], C. Tur[1], P. Rubortone[1], L. Verardi[1], G. Calabrese[1], P. Aquilino[1], G. Peluso[1], M. A. D'agostino[1,2]. *[1]Agostino Gemelli General Hospital Foundation-IRCSS, Division of Rheumatology, Rome, Italy; [2]Catholic University of Sacred Hearth, Division of Rheumatology, Rome, Italy*

Background: Female sex has been associated to higher disease impact in psoriatic arthritis (PsA), as measured by the PsA Impact of Disease (PSAID) questionnaire. However, it is unclear whether sex can influence all different PSAID domains (physical and psychological), or some of them, and whether confounders might be responsible for this association.

Objectives: 1) to assess the impact of sex on each of the 12 PSAID domains, and 2) to correct this association for known confounders, including fibromyalgia, to evaluate the independent effect of sex on each of them.

Methods: Consecutive PsA patients, classified according to CASPAR criteria, attending our tertiary center between January and December 2022 were included. Demographic data, patient history, disease activity indices [Visual Analogue Scale (VAS) of pain and disease activity, Disease Activity in PsA (DAPSA) score) and functional indices (Health Assessment Questionnaire, HAQ) were collected. Impact of the disease was assessed by PSAID 12. Patients' characteristics were compared between men and women with descriptive statistics. Multiple linear regression models were built, having the 12 PSAID domains and total PSAID as outcomes (=13 outcomes), and sex as main independent variable. The crude and adjusted association between sex and each of the outcomes were studied. Namely, models were adjusted for: 1) age and DAPSA; 2) age, DAPSA and fibromyalgia. R[2] was used to measure the proportion of PSAID variance explained by sex. F-change test was used to evaluate if the addition of fibromyalgia as a confounder significantly contributed to improve the model fit.

Results: A total of 190 PsA patients were enrolled, 42% males, disease duration was 7.5±7.6 years. VAS pain, VAS disease activity, HAQ, all the 12 PSAID domains, and DAPSA were significantly higher in females ($p<0.05$). The univariate models having the PSAID domains as outcomes, and sex as independent variable, showed significant negative associations between the two (**Table 1**). R^2 values highlighted that a small proportion of the PSAID variance was explained by sex only ($R^2$0.04-0.15). In the models corrected for age and DAPSA (model group 1, **Table 1**), male sex was a negative independent predictor of some of the PSAID domains (fatigue, work and leisure, functional capacity, discomfort, sleep disturbance, coping and depression). The addition of fibromyalgia as a confounder (model group 2, **Table 1**) significantly improved the model fit for many of the PSAID outcomes, and male sex remained independently associated only to functional capacity and coping.

Conclusion: Sex alone is not able to explain PSAID variability, although it could have a higher impact on functional capacity and coping. More research is needed in order to understand the contextual factors that could explain the differences in PsA impact between men and women.

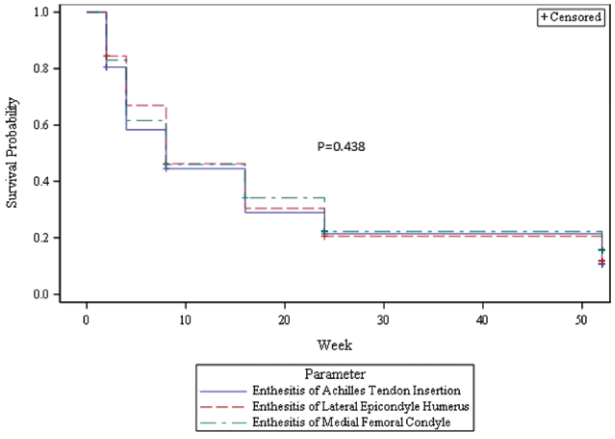
INDIVIDUAL ENTHESEAL POINTS HAVE DIFFERENTIAL FREQUENCY OF INVOLVEMENT AND IMPACT ON PATIENT REPORTED OUTCOMES IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: POOLED ANALYSIS OF TWO PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDIES

Keywords: Enthesitis, Psoriatic arthritis, Patient reported outcomes

L. Coates[1], I. Mcinnes[2], S. Aydin[3], M. Kishimoto[4], P. J. Mease[5], M. Shawi[6], M. Zimmermann[7], E. Rampakakis[8,9], F. Lavie[10], D. Mcgonagle[11]. *[1]University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [2]University of Glasgow, Institute of Infection, Immunity and Inflammation, College of Medical, Veterinary and Life Sciences, Glasgow, United Kingdom; [3]Ottawa Hospital Riverside Campus, Department of Medicine, Ottawa, Canada; [4]Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Tokyo, Japan; [5]Swedish Medical Center, Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America; [6]Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, United States of America; [7]Janssen Scientific Affairs, LLC, Immunology, Zug, Switzerland; [8]McGill University, Department of Pediatrics, Montreal, Canada; [9]JSS Medical Research, Inc., Scientific Affairs, Montreal, Canada; [10]Janssen Cilag Global Medical Affairs, Immunology Global Medical Affairs, Issy les Moulineaux, France; [11]University of Leeds, Leeds Biomedical Research Centre, Leeds, United Kingdom*



Background: In patients (pts) with mono/oligoarticular psoriatic arthritis (PsA), swelling or tenderness of specific joints can be associated with poorer pt-reported outcomes (PROs) and physician global assessment[1]. We hypothesize that location of affected entheseal points may also have differential impact on PROs or time to enthesitis resolution with guselkumab (GUS).
Objectives: (1) Describe the distribution of affected entheseal points in pts with active polyarticular PsA; (2) evaluate the impact of anatomical location of enthesitis and Leeds enthesitis index (LEI) score on pt-reported pain (PtP), pt global assessment (PtGA), and functional status; and (3) compare the time to resolution of each entheseal point following treatment with GUS.
Methods: This post-hoc analysis used pooled data from adults with active PsA, despite standard therapies, from the DISCOVER-1 and -2 studies who were randomized to GUS 100 mg every 4 weeks (Q4W) or at W0, W4, then Q8W. Only pts with baseline (BL) enthesitis were included (N=473). Proportions of pts with enthesitis were determined for each entheseal point assessed by LEI score. Longitudinal impact of LEI score and location of individual entheseal points on PtP, PtGA, and health assessment questionnaire disability index (HAQ-DI), upon adjusting for potential confounders (age, sex, body mass index, prior TNFi use, BL PsA duration, SJC, TJC), was assessed with mixed models for repeated measures through W52. Time to resolution of enthesitis at each anatomical location was assessed with Kaplan-Meier survival analysis.
Results: Approximately half (49.5%) of GUS-randomized pts with BL enthesitis had an LEI score of 1 or 2. The most commonly affected entheseal point was Achilles tendon insertion among both pts with BL enthesitis and pts with an LEI score of 1 or 2. Through W52, higher BL LEI score was associated with increased PtP, PtGA, and HAQ-DI scores (**Table 1**). Of the individual entheseal points assessed, enthesitis of Achilles tendon insertion had the greatest impact on all PROs and enthesitis of medial femoral condyle the least. Following GUS treatment, median time to enthesitis resolution was W8 for each of the three anatomical locations assessed by the LEI (**Figure 1**).
Conclusion: In this population of pts with active polyarticular PsA, Achilles tendon insertion was the most commonly affected entheseal point and more highly associated with worse PtP, PtGA, and functional status. GUS treatment was associated with rapid enthesitis resolution, including resolution of Achilles enthesitis.

POS0028 COMPARATIVE STUDY BETWEEN THE VITACORA AND PSAID QUESTIONNAIRES IN ESTIMATING QUALITY OF LIFE IN PATIENTS WITH PSORIATIC ARTHRITIS

Keywords: Quality of life

I. Braña Abascal[1], S. Burger[1], P. González del Pozo[1], E. Pardo Campo[1], S. Alonso Castro[1], M. Alperi-López[1], R. Queiró Silva[1]. *[1]Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Spain*

Background: Health-related quality of life (HRQoL) is a frequently underestimated aspect in psoriatic arthritis (PsA). There are different instruments to estimate HRQoL in PsA, but they are rarely used.
Objectives: Our objective was to compare the clinimetric capabilities of the VITACORA[1] and PsAID[2] (Psoriatic Arthritis Impact of Disease) questionnaires to assess HRQoL in PsA routine management.
Methods: Forty-five consecutive patients with PsA were recruited, mean age 55 ± 13 years, mean disease duration 8.2 ± 6.1 years, 24 men and 21 women. Disease activity was estimated using DAPSA (Disease Activity index for PsA), and HRQoL using VITACORA and PsAID. The construct and discriminant validity of the VITACORA (Pearson correlation and ROC curves) was analyzed. It must be taken into account that in the VITACORA questionnaire, the higher the value, the better the HRQoL, while in the PsAID the exact opposite occurs. Statistical significance was established at a p value < 0.05. The statistical software R was used.
Results: Fifty-eight percent and 42% of the subjects were under biological and conventional systemic therapy, respectively. Most patients showed good control of their disease, median DAPSA 11.3 (IQR: 8.02-19.3), median PsAID 2.71 (IQR: 1.06-5). The correlation between VITACORA and PsAID was high, r: -0.7 (95% CI: -0.84 to -0.46), p<0.0001, Figure 1. The VITACORA values ranged from 6 to 94. The discriminant validity determined that a VITACORA in the range 6-29 corresponded to a DAPSA high disease activity, a range 30-44 corresponded to a DAPSA moderate activity, and a range 45-95 corresponded with low DAPSA activity. The cut-off to determine an acceptable symptomatic state (PsAID ≤4) corresponded to a VITACORA value ≥ 66 with an area under ROC curve of 0.85 (95%CI: 0.71-0.98).
Conclusion: The VITACORA questionnaire has good discriminant and construct validity, and its clinimetric performance is similar to the PsAID in estimating HRQoL in clinical routine. Either of the two questionnaires could be used to assess this aspect of health in PsA. A VITACORA value ≥ 66 could be a good treatment target.

POS0029 WHOLE SPINE MRI IN AXIAL PSORIATIC ARTHRITIS

Keywords: Spondyloarthritis, Imaging, Psoriatic arthritis

S. Kawaai[1], S. Fukui[1], H. Tamaki[1], T. Nozaki[2], M. Kishimoto[3], M. Okada[1]. *[1]St. Luke's International Hospital, Immuno-Rheumatology Center, Tokyo, Japan; [2]St. Luke's International Hospital, Department of Radiology, Tokyo, Japan; [3]Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Tokyo, Japan*

Background: Psoriatic arthritis (PsA) is known to have symptoms clinically in multiple domains, one of which is the axial lesion. The ASAS classification criteria for axial spondyloarthritis include confirmation of sacroiliitis on x-ray or MRI, but there is no definition or specific imaging studies that have been determined for axial psoriatic arthritis (axPsA).
Objectives: This study aimed to investigate the usefulness of whole spine MRI including all spines and sacroiliac joints in patients with axPsA.
Methods: We retrospectively analyzed the medical records of PsA patients who were underwent whole spine MRI and diagnosed that had axial lesions. PsA was classified according to Classification Criteria for Psoriatic Arthritis (CASPAR) criteria and axPsA was diagnosed by a radiologist specializing in musculoskeletal lesions, especially spondyloarthritis. We analyzed patients' characteristics and MRI findings.
Results: The mean age of the 43 patients was 47.47 (±12.7) years, and 26 (60.5%) were male. The time from onset of PsA to MRI imaging was 7.98 [3.34, 18.65] years. 24 (55.8%) patients had sacroiliac joint involvement and 39 (90.7%) patients had spinal involvement. 15 (34.9%), 25 (58.1%), and 28 (65.1%) had cervical, thoracic, and lumbar spine, respectively.
Conclusion: In this study, about half of the patients had no MRI findings of the sacroiliac joint. On the other hand, spinal lesions were more common. Although sacroiliac joint MRI is usually performed for diagnosis in axial spondyloarthritis, imaging of the sacroiliac joints alone may be insufficient in cases of axPsA, because it is known that there are patients who do not have lesions in the sacroiliac joints but in the spine alone.(1) This study showed that whole spine MRI imaging was considered useful to avoid overlooking spinal lesions which is important for axPsA.

Background: Patients with rheumatoid arthritis (RA) experience higher cardiovascular risk compared to individuals without inflammatory rheumatic disease. Observational studies indicate that methotrexate (MTX) may decrease cardiovascular risk in patients with RA. It is, however, unclear whether sex differentially impacts cardiovascular risk in MTX users and non-users and whether men and women derive equal benefit from methotrexate use.
Objectives: We here explored the influence of sex on cardiovascular risk in MTX nonusers and users. We further evaluated the effect of MTX treatment on cardiovascular risk in males and females with RA.
Methods: We evaluated 4362 patients with RA and no atherosclerotic cardiovascular disease, prospectively included in an international observational cohort [*An Int*ernationa*l C*ardiovascular *C*onsortium for people with *RA* (ATACC-RA)]. Outcomes of interest were (a) major adverse cardiovascular events (MACE) defined as cardiovascular death, non-fatal myocardial infarction or stroke and (b) any ischemic cardiovascular events (CVE) including MACE, stable angina, coronary revascularization, transient ischemic attack and peripheral arterial disease with or without revascularization. Missing covariate data were imputed using multiple imputation with 10 repetitions. Multivariable Cox models stratified by center evaluated the impact of sex, baseline MTX use and their interaction on CVE risk after adjusting for age, hypertension, diabetes, family history of coronary artery disease, smoking, total cholesterol to high-density lipoprotein cholesterol ratio, disease duration, and disease activity score (DAS28 ESR). Two corroborating sensitivity analyses were conducted; The first used inverse probability of treatment weights to balance differences in MTX treated and untreated patients. The second included patients enrolled in the cohort on or after January 1, 2000, when MTX use became more prevalent among enrollees.
Results: There were 237 first MACE and 358 total ischemic CVE recorded during the entire follow-up period. Male sex associated with an 81% and 58% greater risk of MACE and any ischemic CVE, respectively (Figure 1). Among MTX nonusers, incidence of MACE and any ischemic CVE was higher in males [17.6 (95% CI 14.4-21.3) and 24.5 (20.7-28.9) events/1000PY, respectively] compared to females [6.9 (5.7-8.4) and 11.4 (9.8-13.3) events/1000PY respectively, all p for difference<0.001]. In adjusted Cox models, male nonusers had a 2.09-fold higher risk of MACE and 74% higher risk of any ischemic CVE compared to female nonusers (both p<0.001, Figure 1). In contrast, among MTX users, incidence of MACE and any ischemic CVE was not significantly different in males [4.2 (1.7-10.0) and 7.6 (4.0-14.6) events/1000PY, respectively] than females [6.4 (4.4-9.2) and 9.4 (6.9-12.8) events/1000PY, respectively] and sex was not associated with event risk in MTX users in adjusted models. Moreover, among males, MTX use associated with a 66% reduced risk of MACE and 55% reduction in any ischemic CVE (p=0.026 and 0.024, respectively). In contrast, MTX use was not associated with MACE or any ischemic CVE in females [adjusted hazard ratio 1.33 (0.83-2.14) and 1.21 (0.81-1.79) respectively]. Both sensitivity analyses yielded similar results.
Conclusion: RA males not using MTX exhibit higher risk of MACE and any ischemic CVE compared to female nonusers, while no differences are observed between male and female MTX users. Baseline MTX use associated with reduction in the risk of MACE and all ischemic cardiovascular events in males but not females with RA.

DO COMORBIDITIES INCREASE THE RISK OF FAILURE TO REACH REMISSION IN EARLY RHEUMATOID ARTHRITIS PATIENTS RECEIVING METHOTREXATE AS FIRST-LINE THERAPY?

Keywords: Comorbidities, Rheumatoid arthritis, Remission

L. Tidblad[1], H. Westerlind[1], B. Delcoigne[1], J. Askling[1], S. Saevarsdottir[1,2].
[1]Karolinska Institutet, Division of Clinical Epidemiology, Department of Medicine, Solna, Stockholm, Sweden; [2]University of Iceland, Faculty of Medicine, School of Health Sciences, Reykjavik, Iceland

Background: Previous studies have reported that some comorbidities associate with a lower probability of remission in patients with established rheumatoid arthritis (RA).[1, 2] Evidence on whether comorbidities affect remission in DMARD-naïve patients with early RA is, however, lacking. We have recently shown that most patients with early RA, irrespective of comorbidities, receive methotrexate (MTX) in DMARD monotherapy as first-line therapy.[3]
Objectives: The aim of this study is to examine whether specific comorbidities or overall comorbidity burden affect the likelihood of remission on MTX in DMARD monotherapy as first treatment in patients with early RA.
Methods: We included patients with a new RA diagnosis in the Swedish Rheumatology Quality register (SRQ) during 2007 to 2020, in total 11,001 incident RA cases, of whom 67% were female and 69% seropositive. Of these, 8,273 had a follow-up visit at 3 months. Information on comorbidities five years before RA diagnosis was retrieved from the Swedish National Patient Register and information on prescribed drugs 1.5 year before RA diagnosis from the Prescribed Drug Register. Comorbidity diagnoses were grouped into 10 categories (table 1). Disease activity measures were captured through SRQ. The primary outcome measure was failure to reach DAS28 remission, with Boolean, SDAI, CDAI remission, EULAR response and no swollen joints as secondary outcomes. Modified Poisson regression was used to calculate the relative risks of failure to reach remission, in relation to the comorbidities, adjusted for sex and age.
Results: In total, 53% of the RA patients had failed to reach DAS28 remission after 3 months of MTX monotherapy, ranging from 68% among the patients with

psychiatric diagnoses to 48% of the patients with a history of cancer (figure 1). The relative risk of not reaching DAS28 remission after 3 months (table 1) was increased for patients with endocrine (RR:1.08, 95% CI 1.01 to 1.15) or gastrointestinal (RR 1.16, 95% CI 1.03 to 1.30) diseases, previous hospitalisation due to infectious diseases (RR= 1.21, 95% CI 1.06 to 1.38), psychiatric comorbidity (RR: 1.24, 95% CI 1.15 to 1.35) and respiratory diseases (RR=1.16, 95% CI 1.01 to 1.32). The comorbidity burden also associated with lower remission rates, with a 27% higher risk of not reaching DAS28 remission for the patients with ≥3 comorbidity categories compared to patients without comorbidities. A similar pattern was observed for the secondary outcome measures.

Conclusion: Specific comorbidities and the overall comorbidity burden associate with failure to reach remission to MTX as DMARD monotherapy in early RA patients. Comorbidities may be an important factor when assessing treatment outcomes in early RA.

Table 1. Relative risk of failure to reach DAS28 remission at 3 months after initiating methotrexate monotherapy in early RA, by comorbidity categories.

	Relative risk (95% CI)*
Cardiovascular	1.02 (0.93 to 1.12)
Non-cardiac vascular	1.01 (0.95 to 1.07)
Malignant	0.90 (0.81 to 1.00)
Endocrine	**1.08 (1.01 to 1.15)**
Gastrointestinal	**1.16 (1.03 to 1.30)**
Infectious	**1.21 (1.06 to 1.38)**
Chronic kidney	1.38 (0.89 to 2.16)

TARGETS THAT WORK: IDENTIFYING MODIFIABLE PREDICTORS OF PRESENTEEISM OVER ONE YEAR IN WORKERS WITH INFLAMMATORY ARTHRITIS

Keywords: Patient reported outcomes, Work-related issues, Inflammatory arthritides

A. Luquini[1,2], H. Xie[3,4], W. Zhang[5,6], M. Gignac[7,8], D. Lacaille[1,9]. *[1]The University of British Columbia, Department of Medicine, Vancouver, Canada; [2]Arthritis Research Canada, Lacaille Research Team, Vancouver, Canada; [3]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada; [4]Arthritis Research Canada, Statistics, Vancouver, Canada; [5]The University of British Columbia, School of Population and Public Health, Vancouver, Canada; [6]Centre for Health Evaluation and Outcome Sciences (CHÉOS), Health Statistics, Vancouver, Canada; [7]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada; [8]Institute for Work & Health, Scientific Director, Toronto, Canada; [9]Arthritis Research Canada, Scientific Director, Vancouver, Canada*

Background: Inflammatory arthritis (IA) impacts work outcomes and workers' lives. Advancements in treatment have improved work disability (WD) but presenteeism remains a major problem, lacking clear targets for intervention.

Objectives: Identify predictors of presenteeism over 1-year follow-up in workers with IA.

Methods: We designed a prospective observational study analyzing data from the RCT evaluating the Making it Work™ program, an online employment intervention. Participants were recruited in 3 Canadian provinces from rheumatologist practices, consumer organizations and arthritis programs. Eligibility: diagnosis of IA, employed, age 18-59, and concerned about ability to work. Presenteeism was assessed at 0-6-12 mos., using the RA Work Instability Scale (RAWIS, range 0-23). Candidate predictors measured at baseline (bsl.) included sociodemographic characteristics (age, sex, ethnicity, education, marital status, dependents < age 19); disease variables, (arthritis type, physical function [Health Assessment Quest., HAQ II], disease activity [RA Disease Activity Index, RADAI], fatigue [Multidimensional Assessment of Fatigue, MAF], depression [Patient Health Quest. 9, PHQ 9], sleep [Insomnia Severity Index, ISI], number of limiting comorbidities); work-related variables (occupation, self-employment, job strain, arthritis-work spillover, self-efficacy at work, job satisfaction, importance of working, family support for work, no. hours worked per week, job autonomy, physical demand, psychological demands, and decision latitude from the Job Content Quest. [JCQ]). Important bsl. predictors of presenteeism were identified using multivariable linear regression, and linear mixed effect models, with stepwise model selection procedure optimizing Akaike Information criterion (AIC), a commonly used statistical measure and asymptotically equivalent to using cross-validation to compare models. Finally, interaction terms were tested in the model.

Results: A total of 564 participants (mean (SD) age: 45.7(9.9) yrs, 77.8% female, 81.5 % Caucasian, 49.7% RA, 19.7% SpA, 17.0% PsA and 13.7% SLE or another CTD) were recruited. Bsl. median RAWIS (q25,q75) was 11 (7, 15). More job strain, arthritis-work spillover, job physical demand, fatigue, disease activity, and insomnia were associated with worse presenteeism, and better self-efficacy and functional status were associated with better presenteeism (Table 1). Self-efficacy modified the effect of disease activity, physical function and fatigue on presenteeism, and disclosure was associated with greater worsening of presenteeism in women than men (Figure 1).

Conclusion: This study identified key modifiable predictors of presenteeism over one year in workers with IA. These results provide useful information to healthcare professionals, researchers and patients.

Background: Patients with rheumatoid arthritis (RA) are at increased risk of *S. aureus* bacteremia (SAB) compared with the general population.[1] SAB has high mortality and osteoarticular infection (OAI) is a feared complication associated with persistent pain and disability. It remains unclear if RA is associated with increased risk of OAI or death following SAB. [2, 3]

Objectives: To compare risk of OAI and death in SAB patients with and without RA and to assess risk factors for OAI in RA patients including risk associated with antirheumatic treatment.

Methods: Nationwide cohort study of Danish patients with microbiologically verified first-time SAB from 1 January 2006 to 31 December 2018. We identified RA, OAI, vital status, comorbidities, and RA-related clinical characteristics in the rheumatology registry, DANBIO and other national registries. We estimated 90-day cumulative incidence of OAI (in patients without OAI before SAB) and all-cause mortality (all patients). We computed hazard ratios (HR) by multivariate Cox regression adjusted for a priori known risk factors for each outcome.

Results: We identified 18,274 patients with SAB (n=367 with RA). In RA versus (vs.) non-RA, women comprised 62% vs. 37% and median age was 73 years (interquartile range 65; 80) vs. 70 years (59; 82). Prior OAI (0-3 months before SAB) was diagnosed in 4% vs. 2%. The 90-day cumulative incidence of OAI was 23.1% (95% CI 18.8; 27.6) in RA patients vs. 12.5% (12.1; 13.0) in non-RA (**Figure 1**) (HR 1.93 (1.54; 2.41) adjusted for age, sex, calendar year, and diabetes mellitus). In RA, use of tumor necrosis factor inhibitors (TNFi) and orthopedic implants were associated with OAI risk (**Table 1**). Mortality was similar in SAB patients with (35.4% (30.6; 40.3)) and without RA (33.9% (33.2; 34.5) (Figure), (HR 1.04 (0.87; 1.24) adjusted for age, sex, calendar year, chronic liver disease, chronic obstructive pulmonary disease, cancer, congestive heart failure, renal failure).

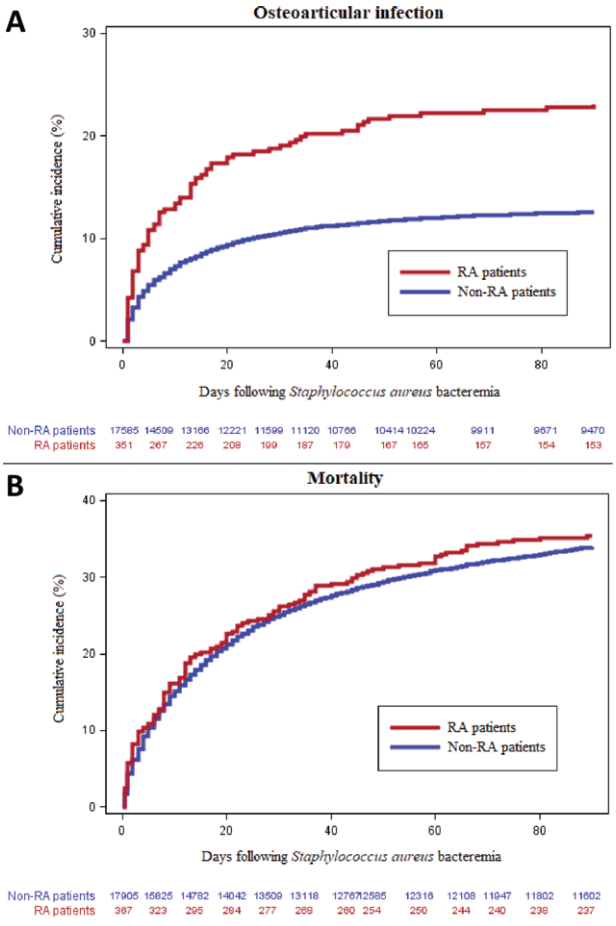

Figure Cumulative incidence of osteoarticular infection (panel A) and death (panel B) 90 days following *S. aureus* bacteremia among patients with and without rheumatoid arthritis (RA) in Denmark from 2006 to 2018.

*age, sex, calendar year, diabetes mellitus, csDMARD use, serostatus, RA disease duration and remaining variables in table.[a] n (%) of all patients with RA (n=367). Analyses were restricted to patients without recent OAI (n=351).bDMARD, biological disease-modifying antirheumatic drugs; csDMARD, conventional synthetic DMARD; HR, hazard ratio; CI, confidence interval; Ref., reference; NA, not applicable (few events)

Conclusion: Nearly one in four patients with RA experienced an osteoarticular infection following *S. aureus* bacteremia compared with one in eight patients without RA. In patients with RA, current TNFi use and orthopedic implants were associated with increased osteoarticular infection risk. One in three patients died, with no difference between patients with and without RA. These findings highlight the need for vigilance when RA patients present with SAB to ensure timely identification of OAI.

Background: Chronic inflammation contributes to enhanced cardiovascular risk in patients with rheumatoid arthritis (RA). Biologic disease modifying antirheumatic drugs (bDMARDs) have been shown to effectively control inflammation in many conventional synthetic DMARD non-responders and improve cardiovascular outcomes.

Objectives: We here explored whether baseline bDMARD use may influence the impact of disease activity and systemic inflammation on long-term cardiovascular risk in patients with RA.

Methods: We studied 4370 patients with RA who were free of cardiovascular disease upon registration to *A*n *In*ternational *C*ardiovascular *C*onsortium for people with *RA* (ATACC-RA) and followed prospectively. Prespecified outcomes included (a) major adverse cardiovascular events (MACE) defined as non-fatal myocardial infarction, non-fatal stroke, or cardiovascular death and (b) any ischemic cardiovascular events (CVE) comprising MACE, coronary revascularization, stable angina pectoris, transient ischemic attack and peripheral arterial disease with or without revascularization. Missing covariate data were imputed using multiple imputation with 10 repetitions. Multivariable Cox models stratified by center evaluated the impact of disease activity [based on 28 joint counts and C-reactive protein (DAS28-CRP)], systemic inflammation (CRP), bDMARD use and their respective interactions on CVE risk after adjusting for age, gender, hypertension, diabetes, family history of CAD, smoking and total cholesterol to high-density lipoprotein ratio. Two corroborating sensitivity analyses were performed; the first included patients enrolled in the cohort on or after January 1, 2000, when bDMARD use became more prevalent among enrollees. The second used inverse probability of treatment weights (IPTW) to balance differences in bDMARD treated and untreated patients.

Results: Throughout 26534 patient years of follow-up, 239 first MACE and 362 total ischemic CVE were recorded. Among bDMARD nonusers, incidence of MACE and any ischemic CVE was [9.3 (95% CI 8.2-10.6) and 14.2 (12.8-15.8) events/1000PY respectively. Corresponding rates for bDMARD users were [5.4 (95% CI 2.9-10.1) and 8.2 (5.0-13.6) events/1000PY respectively. In the entire cohort, DAS-28 CRP and CRP(ln) associated with greater risk of MACE [(adjusted hazards ratio [HR] 1.19 (95%CI 1.06-1.34), p=0.004 and HR 1.15 (1.02-1.28), p=0.017 respectively], while for all ischemic CVE the association was significant for DAS-28 CRP [adjusted HR 1.1 (95%CI 1.07 to 1.30)], but not CRP(ln) [HR 1.06 (0.97 to 1.16)]. In bDMARD nonusers at baseline, higher DAS28-CRP and CRP(ln) associated with greater risk of MACE [adjusted HR 1.21 (95%CI 1.07-1.37), p=0.002 and HR 1.16 (1.04-1.30), p=0.009 respectively]. However, this was not the case in bDMARD users [p-for-interaction= 0.017 and 0.011 correspondingly, Figure 1]. In contrast, no significant interaction between DAS28-CRP or CRP and bDMARD use on any ischemic CVE risk was observed (p-for-interaction= 0.167 and 0.237 respectively). Both sensitivity analyses yielded similar results.

Conclusion: Higher disease activity and systemic inflammation at baseline associated with greater risk of MACE in bDMARD nonusers but not in patients receiving bDMARDs. This may suggest the presence of additional bDMARD-specific benefits directly on atherosclerotic plaque —such as plaque stabilization[1]— above and beyond their effects on systemic inflammation.

Background: Interstitial lung disease (ILD) is a severe complication of rheumatoid arthritis (RA). Abatacept (ABA) has demonstrated efficacy in the treatment of RA-ILD, especially if it is initiated early during the ILD **[1-2].**

Objectives: To compare the efficacy of ABA in RA-ILD patients according to ILD duration.

Methods: National multicenter study of 392 RA-ILD patients treated with ABA. Patients with ABA initiation early in the disease (during the first 6 months since ILD diagnosis) were compared to those in whom ABA was started after 2 years of ILD diagnosis ("early" vs "late" group, respectively). We analyzed in the 2 groups the following outcomes: a) forced vital capacity (FVC), b) diffusing capacity of the lungs for carbon monoxide (DLCO), c) chest high resolution computed tomography (HRCT), d) dyspnea and e) arthritis activity.

Results: A total of 157 patients were included in the "early" group and 135 patients in the "late" group. Baseline demographic and clinical characteristics are shown in Table 1. Mean baseline values of FVC were significantly higher in the "early" group. The evolution of FVC and DLCO for 48 months is shown in Figure 1. Both parameters remained stable during 12 months of ABA therapy, with no statistically significant differences found (although lower stable values of FVC in the "late" group). Available chest HRCT images improved/stabilized in 75% and 51% of patients in the "early" and "late" group, respectively. Stabilization or improvement of dyspnea was found in most patients of both groups.

Conclusion: Our results suggest that an early administration of ABA in RA-ILD may be preferable to preserve lung function. However, treatment with ABA at any time of the course in the ILD seems to prevent interstitial lung progression.

POS0036 SUBSEQUENT HOSPITALIZATIONS FOR OR WITH PSYCHIATRIC DISORDERS IN INDIVIDUALS WITH PRE-EXISTING RHEUMATOID ARTHRITIS AND SPONDYLARTHRITIS: A NATIONAL REGISTRY-BASED RETROSPECTIVE COHORT STUDY

Keywords: Mental health, Real-world evidence, Comorbidities

T. Formanek[1], K. Mladá[2], P. Mohr[3], M. Olejárova[4], K. Pavelka[4], M. Husakova[4]. *[1]University of Cambridge, Department of Psychiatry, Cambridge, United Kingdom; [2]National Institute of Mental Health, Department of Public Mental Health, Klecany, Czech Republic; [3]National Institute of Mental Health, Clinical Center, Klecany, Czech Republic; [4]First Faculty of Medicine, Charles University and Rheumatology Institute, Department of Rheumatology, Prague, Czech Republic*

Background: The crosslink between rheumatic diseases (RD) and psychiatric disorders (PD) has been suggested, particularly due to systemic inflammation and the psycho-social impact of chronic painful experience in patients with RD.
Objectives: In the present study, we investigated the risk of subsequent hospitalization (1) for PD and (2) either for or with PD in cohorts of patients with specific pre-existing RD.
Methods: In this retrospective cohort study, we utilized data from the Czech nation-wide registers of all-cause hospitalizations and deaths. The study consisted of individuals first hospitalized with (1) rheumatoid arthritis (RA; International Classification of Diseases 10th Revision (ICD-10) codes M05 and M06) and (2) spondylarthritis (SpA; ICD-10 codes M07, M45 and M46[1, 8, 9]) in the time-period from 1999 to 2011 (index hospitalization) and counterparts without the respective diseases, exactly matched on age, sex, month and year at the index hospitalization (1:5). The risk of subsequent hospitalization (1) for and (2) either for or with each diagnostic group of PD (ICD-10 codes F0x + G20 and G30, F1x, F2x, F3x, F4x and F5x) arising in the period of five or more years (up to 2017) from the index hospitalization was assessed using stratified Cox proportional hazards models, controlling for deaths occurring in this time-period and adjusting for age, sex and month and year at the index hospitalization. We assessed the risk (1) of being hospitalized for PD (ie, primary diagnosis) and (2) of being hospitalized for or with PD (ie, either primary or secondary diagnosis) separately. For the respective analyses, we excluded individuals who were (1) hospitalized for PD and (2) hospitalized either for or with PD five or more years (up to 1994) prior to the index hospitalization, separately for each diagnostic group of PD. Thus, we effectively created 24 matched cohorts overall. The results are expressed as hazard ratios (HR) with 95% confidence intervals (95% CI).
Results: When considering hospitalizations specifically for PD, the total number of individuals in the RA cohorts ranged from 92,694 to 93,768 and from 31,488 to 32,088 individuals in the SpA cohorts, whereas when considering hospitalizations either for or with PD, the number of individuals in the RA cohorts ranged from 91,290 to 93,726 and from 30,852 to 32,070 individuals in the SpA cohorts. We found that individuals with SpA had an elevated risk of hospitalization for anxiety disorders (1.36; 1.08 to 1.70), when compared with matched counterparts. Conversely, we found that individuals with RA had a decreased risk of hospitalization for substance use disorders (0.58; 0.46 to 0.72). Next, we found that individuals with RA and SpA had an elevated risk of being hospitalized either for or with mood disorders (1.18; 1.06 to 1.31 and 1.26; 1.02 to 1.54) and anxiety disorders (1.24; 1.12 to 1.36 and 1.32; 1.11 to 1.56). In addition to this, people with RA had a higher risk of being hospitalized either for or with organic PD (1.25; 1.16 to 1.35) and people with SpA demonstrated an increased risk for hospitalization listing behavioral syndromes associated with physiological disturbances and physical factors as one of the diagnosis (2.73; 1.59 to 4.71). Conversely, people with RA had a lower risk of being hospitalized either for or with substance use disorders (0.77; 0.68 to 0.87). For the other PD outcomes in people with RA and SpA, the 95% CIs covered a range from decreased to increased risk.
Conclusion: Individuals with RA and SpA seem to have a higher risk of developing a range of PD, when compared with matched counterparts. The detected differences suggest that clinical vigilance and provision of mental health services to affected individuals require further attention.

POS0037 VALIDATION OF DIAGNOSTIC CODES FOR DEMENTIA IN A RHEUMATOID ARTHRITIS POPULATION-BASED COHORT

Keywords: Cognitive Function, Rheumatoid arthritis, Validation

E. Myasoedova[1,2], M. Vassilaki[2], C. Kodishala[1], E. Lovering[1], R. Kumar[1], C. S. Crowson[1,3]. *[1]Mayo Clinic, Rheumatology, Rochester, United States of America; [2]Mayo Clinic, Epidemiology, Rochester, United States of America; [3]Mayo Clinic, Clinical trials and Biostatistics, Rochester, United States of America*

Background: Dementia is a major global mental health problem. The prevalence of dementia is increasing dramatically with increasing life longevity and population aging. Several studies found increased risk of dementia in patients with rheumatoid arthritis (RA) and reported a possibility of mitigating this risk with antirheumatic treatments. The underlying mechanisms for these associations are not fully understood and require further study. As clinical verification of the diagnosis may not be readily available, especially in retrospective observational studies, diagnostic codes can be used. However, performance of diagnostic codes for dementia case identification has not been validated in RA cohorts.
Objectives: To validate the use of ICD-9/10-CM diagnostic codes for dementia identification against diagnostic criteria for dementia in individuals with and without RA using retrospective manual verification of cases.
Methods: This retrospective population-based study included residents of a geographically well-defined area with incident RA based on the 1987 American College of Rheumatology (ACR) classification criteria in 1980-2018. All adult (≥18 years) cases of RA were included and matched (1:1) by age, sex, calendar year, and county to non-RA controls. Dementia case identification using ICD-9/10-CM diagnostic codes from the Charlson comorbidity index was validated against dementia diagnosis based on Diagnostic criteria in Diagnostic and Statistical Manual of Mental Disorders, 4th edition (DSM-IV). DSM-IV criteria were verified by manual records review.
Results: A total of 3,116 individuals (1558 RA cases and 1558 non-RA controls) were included. Mean age 56.2 years; 68% females in both groups; mean (SD) age at the last follow-up was 68.7 (14.7) years for RA cases and 69.6 (15.4) years for non-RA controls. At the time of the last follow-up, there were 202 (13%) patients with one diagnostic code for dementia, 136 (9%) with two diagnostic codes for dementia, and 137 (9%) with a confirmed diagnosis of dementia per DSM-IV. The respective numbers in non-RA controls are 216 (14%); 147 (9%) and 149 (10%). Mean (SD) duration between accumulating two ICD codes and diagnosis verification by DSM-IV was an absolute difference of 1.0 (1.8) years in RA and 1.2 (1.7) years in non-RA. Table 1 summarizes the results of validation analyses. Positive predictive value (PPV) and specificity were higher with the use of 2 ICD codes in the combined cohort (PPV 81.3), in RA cases (PPV 81.6) and in non-RA controls (PPV 80.9). PPV for two diagnostic codes was highest also in patients born in 1892-1934 (PPV 85.7) than in the more recent birth cohorts: 1935-1949 (PPV 77.6).
Conclusion: The ICD-9/10-CM codes for dementia performed equally well against DSM-IV criteria in the retrospective population-based cohort of individuals with RA and in matched non-RA controls, identifying true dementia cases with approximately 80% probability. The PPV was higher in older birth cohorts than in younger birth cohorts, reflecting the higher prevalence of dementia in older adults. The use of ICD-9/10-CM codes from Charlson comorbidity index is acceptable for dementia case identification in patients with RA, especially in older adults, although additional parameters (e.g., number of diagnostic codes) need to be considered.

Table 1. Performance of ICD-9/10-CM code-based definitions of dementia against DSM-IV criteria

UTILIZATION OF CARDIOVASCULAR PREVENTIVE SERVICES IN A RHEUMATOID ARTHRITIS POPULATION BASED COHORT

Keywords: Rheumatoid arthritis, Comorbidities, Cardiovascular disease

D. Montes[1], C. A. Hulshizer[2], E. Myasoedova[2,3], J. M. Davis III, A. Hanson[2], A. Duarte-Garcia[3], G. Figueroa-Parra[3], B. Chevet[4], C. S. Crowson[2,3]. *[1]Mayo Clinic, Department of Internal Medicine, Rochester, United States of America; [2]Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America; [3]Mayo Clinic, Division of Rheumatology, Rochester, United States of America; [4]CHU Brest, Division of Rheumatology, Brest, France*

Background: Rheumatoid arthritis (RA) increases the burden of cardiovascular disease (CVD). Fasting blood glucose, fasting lipoprotein profiles, and blood pressure measurements are recommended at regular intervals to screen for classical CVD risk factors of diabetes mellitus (DM), hyperlipidemia (HLD), and hypertension (HTN), respectively.
Objectives: Our objectives were 1) to perform a contemporary assessment of the trends of CVD preventive service utilization in patients with RA compared to matched non-RA comparators, 2) identify RA patient characteristics that may influence trends in preventive services utilization, and 3) assess how a diagnosis of RA alone influences approaches to CVD prevention compared to the other classical CVD risk factors.
Methods: Inpatient and outpatient medical records for each potential case were manually reviewed. All incident patients fulfilled the 1987 American College of Rheumatology (ACR) classification criteria for RA or the 2010 European League Against Rheumatism (EULAR)/ American College of Rheumatology (ACR) criteria. All ≥19-year-old patients with an RA diagnosis living in an 8-county region on January 1, 2015 (index date), were included and matched (1:1) by sex, age, and county to non-RA comparators. Rates of screening for the classical CVD risk factors were compared between groups using Cox models with adjustment for age, sex, and race.
Results: DM screening was more common among patients with RA ([HR] 1.10, 95% CI 1.01–1.19), as was HTN screening ([HR] 1.37, 95% CI 1.24–1.52). However, HLD screening in RA was similar to comparators ([HR] 0.99, 95%CI 0.89–1.10). RA patient characteristics that influenced classical CVD risk factor screening included: smoking history, obesity, RA duration of < 5 years, older age at the time of RA diagnosis, a higher Charlson comorbidity index, the use of >90 days of glucocorticoid therapy before the index date, the use of disease modifying anti-rheumatic drugs before the index date, and living in the lowest quartile of the Area Deprivation Index within our cohort. Lastly, patients with RA and no classical CVD risk factors had a lower probability of undergoing DM ([HR] 0.67, 95% CI 0.57–0.78) and HLD screening ([HR] 0.65, 95% CI 0.54–0.79) than non-RA patients with one classical CVD risk factor diagnosis. HTN screening was similar between both groups ([HR] 1.01, 95% CI 0.83–1.23).
Conclusion: RA patients undergo CVD preventive screening at rates at least comparable to the general population. However, despite the equivalent-to-higher CVD risk, RA does not appear to be approached as aggressively as traditional CVD risk factors. (1,2) These findings demonstrate an opportunity to improve RA patient care. While EULAR provides guidance for stratifying CVD risk in patients with inflammatory joint disease, there is no equivalent guidance from American medical bodies. (3) Given our findings, clinical practice in the United States could benefit from establishing such recommendations. These recommendations should be forceful in framing RA as conferring an equivalent-to-higher CVD risk as the classical CVD risk factors.

Table 1. Cumulative Incidence of Screenings

	5-year Cumulative Incidence, (95% CI)		
	All RA Patients	**All Non-RA Patients**	**HR**
DM Screening	94.0% (92.6 – 95.3)	93.8% (92.4 – 95.2)	1.10 (1.01 – 1.19)
HTN Screening	99.1% (98.5 – 99.8)	96.3% (95.0 – 97.6)	1.37 (1.24 – 1.52)
HLD Screening	74.3% (71.5 – 77.1)	75.2% (72.5 – 78.1)	0.99 (0.89 – 1.10)

	RA w/o CVD Risk Factors	**Non-RA w/ only 1 CVD Risk Factor**	**HR**
DM Screening RA w/o CVD Risk Factors = 477 Non-RA, Only 1 CVD Risk Factor (HTN or HLD) = 382	91.9% (88.8 – 95.1)	98.9% (98.0 – 99.9)	0.67 (0.57–0.78)
HTN Screening RA w/o CVD Risk Factors = 579 Non-RA, Only 1 CVD Risk Factor (HLD or DM) = 160	99.6% (99.2 – 100)	99.0% (97.0 – 100)	1.01 (0.83–1.23)
HLD Screening RA w/o CVD Risk Factors = 579 Non-RA, Only 1 CVD Risk Factor (HTN or DM) = 248	71.3% (67.1 – 75.8)	84.9% (78.7 – 91.6)	0.65 (0.54–0.79)

CI: confidence interval; HR: hazard ratio

Disease mechanisms in spondylarthritis

POS0039

A MULTIOMICS PLASMA ANALYSIS REVEALS NEW PATHWAYS CENTRAL IN DRIVING INFLAMMATION IN SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Biomarkers

S. R. Greisen[1,2], R. Østgård[1,3], S. E. Rask[1], M. Hvid[1,4], A. G. Jurik[5], U. Syrbe[6], D. Poddubnyy[6], B. Deleuran[1,2]. *[1]Aarhus Univeristy, Biomedicine, Aarhus, Denmark; [2]Aarhus University Hospital, Rheumatology, Aarhus, Denmark; [3]Silkeborg Regional Hospital, Rheumatology, Silkeborg, Denmark; [4]Aarhus University, Clinical Medicine, Aarhus, Denmark; [5]Aarhus University Hospital, Radiology, Aarhus, Denmark; [6]Charité Universitätsmedizin Berlin, Gastroenterology, Infectiology and Rheumatology, Berlin, Germany*

Background: Biochemical and clinical disease activity markers in spondyloarthritis (SpA) remain scarce. In addition, understanding the pathways driving disease progression with a combination of bone formation and bone erosions still remain to be fully elucidated. Anti-TNF-α and anti-IL-17A treatment decrease clinical symptoms and partly limit structural changes, but still disease progression and treatment failure occur.
Objectives: We used an unbiased multiomics plasma analysis to identify inflammatory proteins associated with disease activity and structural changes. Subsequently, some of the identified proteins were investigated in biopsies from the spine and in cells, and synovial fluid from the peripheral joint.
Methods: Blood was obtained from patients with early (eSpA) before and 1 year after start of anti-TNF treatment (n=30). Markers of disease activity included; BASDAI, ASDAS, CRP. Osteitis, bone marrow edema and new bone formation were evaluated by MRI scan of the total spine and the SI-joint at baseline and after 1 year of treatment. Healthy controls (HCs) were age and gender matched (n=15). From patients with long-standing SpA (lsSpA, symptom duration >8 years) with a joint effusion, both blood (n= 8) and synovial fluid (SF) (n=6) was obtained. An O-link based multipanel analysis covering 92 proteins was performed on plasma and synovial fluid. Cells were stained for flow. Facet joint biopsies originated from lsSpA patients undergoing surgery for polysegmental correction of rigid hyperkyphosis. These were stained by immune fluorescence. $P < 0.05$ was accepted as significant.
Results: The multiomics analysis revealed 18 proteins significantly increased at baseline compared to after one year of anti-TNF treatment, among these were CCL3, CCL4, CXCL10, CXCL13, IL-6 and PD-L1 (all adjusted $p<0.05$). All targets correlated with baseline CRP, and except for PD-L1, also with ASDAS, BASDAI and BASMI (all rho >0.4). Baseline CXCL13, IL-6 and PD-L1 also correlated to baseline spinal MRI inflammation (rho>0.4). Furthermore, baseline CXCL13 and IL-6 were associated with spinal MRI inflammation after one year of treatment (rho>0.4). CXCL13 was also increased in synovial fluid from lsSpA patients. CXCL13 was not increased in eSpA compared to HCs, but the receptor for CXCL13, CXCR5 was increased on CD4+ PBMCs from eSpA patients compared to HCs (17.3% vs 12.3%, $p<0.01$). eSpA CD4+ PBMCs did not differ from HC CD4+ PBMCs when investigating general activity markers, including CD69,

CD25 and PD-1. Evaluating the central site of pathology, CXCL13 was highly expressed in the inflamed facet joints (Figure 1).
Conclusion: The multiomics analysis revealed multiple cytokines to be activated in eSpA patients. The early disease is characterized by T cell activity in combination with macrophage and monocyte attractive chemokines. CXCL13 stands out as a chemokine of particular interest, being increased both in eSpA, at the central- and peripheral site of pathology, and associated with structural changes in time. The CXCR5-CXCL13 axis could be an important new axis in understanding SpA disease pathology, serving both as a biomarker for disease severity and progression, but also lead to new targets of treatment.

POS0040 SILENCING OF JOINT FIBROBLAST TO PROTECT FROM JOINT DAMAGE

Keywords: Spondyloarthritis, Disease-modifying Drugs (DMARDs), Inflammatory arthritides

S. Rauber[1], H. Mohammadian[1], M. G. Raimondo[1], M. Vogg[1], L. Lu[1], A. Soare[1], C. Xu[1], J. D. D. Cañete[2], G. Schett[1], A. Ramming[1]. *[1]Friedrich-Alexander-University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Rheumatology & Immunology, Erlangen, Germany; [2]Hospital Clínic de Barcelona e IDIBAPS, Departamento de Reumatología, Barcelona, Spain*

Background: Despite significant progress in the development of targeted biologic therapies for the treatment of chronic inflammatory joint diseases such as rheumatoid arthritis or psoriatic arthritis, more than 40% of patients still record gradual loss of joint function, mostly because of failure to archive complete remission. Herein, persistent joint fibroblast activity leads to continuous destruction of the joint, whereas its inhibition/silencing prevents joint damage despite presence of a residual inflammation[1]. Persistent activation of the joint fibroblasts leads to destruction of the joint[1], and silencing both, inflammation and mesenchymal activation is required to protect joints from damage.
Objectives: Protection from joint damage-especially when complete remission cannot be achieved-is a need that might be met by pharmacological targeting of fibroblasts. We aimed to reprogram fibroblasts, from pro-inflammatory and tissue damaging phenotype to a tissue preserving and anti-inflammatory phenotype as a new promising treatment strategy.
Methods: Single-cell RNA sequencing of sorted synovial fibroblasts and imaging mass cytometry from different mouse models of arthritis (TNFtg, *Il23* overexpression, KBxN serum transfer) were used to map fibroblast heterogeneity. Co-culture experiments were performed with sorted fibroblasts and innate lymphoid cells (ILCs) *in vitro*. For functional proof of concept, animals were treated with blocking and activating antibodies in the aforementioned arthritis models. Validation in human synovial biopsies by imaging mass cytometry and spatial transcriptomics was performed.
Results: Through data analysis of joint fibroblast scRNAseq, spatial transcriptomics, and imaging mass cytometry during joint inflammation and its resolution, we observed high plasticity of joint fibroblast populations. By analyzing single-cell dynamics, we identified transdifferentiation of fibroblasts from a MMP3+/IL-6+ destructive state to a DKK3+ protective phenotype upon DMARD-induced resolution and revealed the underlying molecular processes. We identified a novel DKK3+ fibroblast subtype in joints of patients with rheumatoid arthritis and spondyloarthritis (axial spondyloarthritis, peripheral spondyloarthritis, psoriatic arthritis) that protects against joint damage and actively induces resolution of inflammation, by stimulating type 2 ILCs, which are known cellular components for activation of regulatory T cells and pro-resolving eosinophil granulocytes in the joint[2]. We identified the functionally relevant pathway of type 2 IIC activation by fibroblasts. Drug-induced activation of this pathway resulted in activation of pro-resolving ILC2s/Tregs/eosinophil granulocytes in association with a sharp decrease in inflammation and cartilage and bone destruction.
Conclusion: This new treatment approach might have several advantages over anti-inflammatory drugs. (i) no interference with important defence mechanisms against pathogens and no increased risk of opportunistic infections, (ii) activation of a mechanism that retains tissue integrity, (iii) option to combine with anti-inflammatory drugs, making silencing of fibroblasts to a new tool of disease control.

POS0041 UPREGULATION OF SSP1 (OSTEOPONTIN) BY ADIPOSE TISSUE-DERIVED MESENCHYMAL STEM CELLS OCCURS WITH THE CONTINUOUS MECHANICAL LOAD BUT IS STRONGLY RESTRICTED IN INF-G/TNF-A/IL-22 MICROENVIRONMENT

Keywords: Spondyloarthritis

A. Shouval[1], M. Brant-Roznavi[2], T. Tamari[2], H. Hazan-Molina[2], D. Aizenbud[2], S. Keret[1], L. Saiegh[3], G. Slobodin[1]. *[1]Bnai Zion Medical Center, Rheumatology, Haifa, Israel; [2]Rambam Health Campus, Orthodontics, Haifa, Israel; [3]Bnai Zion Medical Center, Endocrinology, Haifa, Israel*

Background: The interplay between the inflammatory part of the disease and osteogenesis in axial spondyloarthritis (AxSpA) is incompletely understood. It is believed that inflammation triggers the process of new bone formation on the one hand, but the regulation of these phenomena is distinct on the other. An assumption that disease-related osteoproliferation in AxSpA is governed by the complex interplay of inflammation, hormonal or growth factors, and mechanical load has been made. A recent study demonstrated that a pro-inflammatory environment, consisting of interferon-γ (INF-γ) and tumor necrosis factor-α (TNF-α), allowed IL-22-induced proliferation and migration of mesenchymal stem cells (MSc) [1].
Objectives: To examine the influence of continuous mechanical load (CML) on the osteogenic behavior of MSc with or without INF-γ/TNF-α/IL-22 or testosterone exposure.
Methods: Adipose tissue-derived MCs, characterized by $CD90^+$, $CD73^+$, $CD13^+$, $CD45^-$, $CD31^-$, isolated from the adipose tissue of a healthy donor and kindly donated by Bonus BioGroup, Haifa, Israel, were cultured for two weeks without or under CML of 2 gr/cm^2, applied by transparent glass cubes placed on the plates covering the well, in the following conditions: a. osteogenic differentiation medium (ODM) with no additions of cytokines or testosterone; b. ODM with the addition of testosterone, 0.01 μM; c. ODM with the addition of INF-γ (2.5ng/ml), TNF-α (1ng/ml), and IL-22 (0.5ng/ml); d.ODM with the addition of both three cytokines above and testosterone. Real-time PCR for *ALPL, RUNX2, SPP1, BMP2,* and *Col1A1* was performed and analyzed by the ThermoFisher cloud data analysis program (https://thermofisher.com/il/en/home/digital-science/thermo-fisher-connect/all-analysis-modules.html). ΔΔCt and RQ ($2^{-\Delta\Delta CT}$) were calculated, with the results presented in a histogram graph as fold-change (Figure 1).
Results: CML induced significant upregulation of *SSP1*, or osteopontin (OPN), by MSc. However, this effect was almost completely abolished in the presence of INF-γ/TNF-α/IL-22.

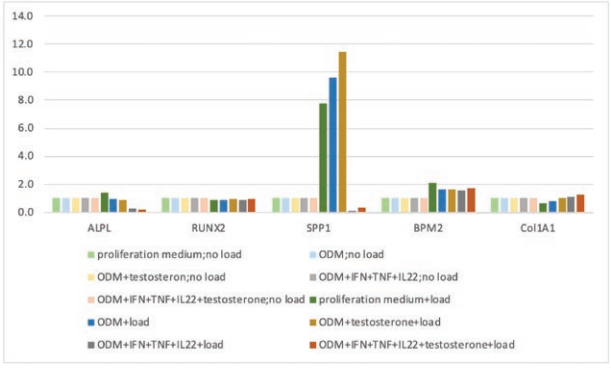

Figure 1. RQ ($2^{-\Delta\Delta CT}$) for mechanical load effect. Samples without mechanical load were used as a reference. ODM – osteogenic differentiation medium; IFN – interferon-γ; TNF – tumor necrosis factor-α; IL-22 – interleukin-22

Conclusion: Increased OPN production by MSc can link mechanical load and new bone formation after the resolution of the inflammatory phase in AxSpA.

Barbarroja Puerto[1]. *[1]IMIBIC/University of Cordoba/Reina Sofia Hospital, Medical and Surgical Sciences, Cordoba, Spain; [2]IMIBIC/University of Cordoba/Reina Sofia Hospital, Cell Biology, Physiology and Immunology, Cordoba, Spain; [3]IMIBIC/University of Cordoba/Reina Sofia Hospital, Rheumatology Service, Cordoba, Spain*

Background: The use of high throughput techniques such as transcriptomic sequencing has recently made considerable progress in the identification of molecular profiles involved in the pathogenesis of chronic autoinflammatory diseases. To date, only a few studies have been carried out in axial spondyloarthritis (axSpA), which would allow the identification of new therapeutic targets and disease biomarkers.

Objectives: 1) To identify clusters of highly correlated genes enriched in biological functions and specific molecular pathways involved in the pathogenesis of axSpA. 2) To study the association between the molecular signatures identified and the clinical-analytical profile of the disease.

Methods: Cross-sectional study including 75 axSpA patients from the CASTRO cohort who underwent an exhaustive clinical evaluation including disease activity and functional limitation, structural damage, and spinal mobility. Additionally, analytical parameters were measured and the carotid intima-media thickness was evaluated by carotid eco-doppler. Mononuclear cells were purified from peripheral blood, and RNA was isolated. RNA from 25 axSpA patients was sequenced using the Illumina platform. For the identification of patient subgroups and the generation of co-expressed gene modules, the "hierarchical clustering" and WGCNA ("Weight gene correlation network analysis") methodologies were used, respectively. Functional analysis of the genes conforming each module was carried out to identify enriched pathways and functions using the EnrichR platform. Hub genes were measured through high throughput PCR (Fluidigm Biomark HD) in a validation cohort of 50 axSpA patients. Association and correlation studies between the molecular and clinical profiles were performed. *In vitro* studies in peripheral blood mononuclear cells (PBMCs) from patients belonging to different molecular clusters were performed.

Results: Unsupervised analysis of the transcriptome revealed the presence of two "clusters" of axSpA patients, clearly differentiated by their molecular and clinical profiles. Specifically, the molecular analysis distinguished patients with longer disease duration, greater disease activity, radiographic damage, and cardiovascular risk. WGCNA identified 11 highly co-expressed modules. Among them, six were differentially expressed between the two clusters, being responsible for the molecular and clinical distinction of those groups. The functional analysis of these 6 gene modules revealed the enrichment of these genes in pathways related to inflammation, oxidative metabolism, proliferation of B and T lymphocytes, immune response, and the increase of cell survival. Finally, key genes were identified within each module ("hub genes"), whose expression was associated with a more active phenotype of the disease such as ALOX5, GAB2, PSMD13, CASP8, NOTCH e ITGA4. Hub genes were validated in an additional cohort of 50 axSpA patients and correlated with mSASSS. Treatment of PBMCs from patients belonging to the two different clusters with autologous serum induced a different expression of genes involved in cell activation and inflammation.

Conclusion: 1) The whole transcriptomic analysis by RNAseq in peripheral mononuclear cells from axSpA patients distinguished, in an unsupervised manner, subgroups of patients with distinctive clinical profiles. 2)The analysis of gene modules identified new pathways and molecular functions potentially involved in the pathophysiology of the disease. Funded by ISCIII (PMP21/00119) co-financed by ERDF, Andalusian Foundation of Rheumatology (FAR).

POS0043 COMPLEMENT IN RADIOGRAPHIC AXSPA – BIOMARKERS OF RADIOGRAPHIC PROGRESSION? POST HOC ANALYSIS FROM CONSUL, A LONGITUDINAL MULTI-CENTER RANDOMIZED CONTROLLED TRIAL COHORT OF AXSPA-PATIENTS WITH A HIGH RISK OF STRUCTURAL PROGRESSION INITIATING TREATMENT WITH TNF-I

Keywords: Innate immunity, bDMARD, Spondyloarthritis

C. E. Mistegaard[1,2,3], A. Troldborg[1,2,3], A. G. Loft[1,3], S. Thiel[2], B. Muche[4], V. Rios Rodriguez[4], M. Torgutalp[4], M. Protopopov[4], J. Listing[4], J. Sieper[4], D. Poddubnyy[4], F. Proft[4]. *[1]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; [2]Aarhus University, Department of Biomedicin, Aarhus, Denmark; [3]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [4]Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany*

Background: The biological processes involved in the development of structural changes associated with radiographic axial spondyloarthritis (r-axSpA) remain largely unraveled. Still, high disease activity, elevated C-reactive protein (CRP), and existing syndesmophytes are associated with radiographic progression. The complement system is an inflammation-generating part of the innate immune system. Animal models have shown inhibition of complement activation to diminish structural changes associated with axSpA [1].

Objectives: This project aimed to investigate complement activation and serum levels of complement proteins and their correlations with radiographic spinal progression over a two years follow-up period in a longitudinal cohort of axSpA patients with active r-axSpA, and high risk of radiographic progression, recruited from the randomized controlled trial CONSUL.

Methods: All patients had active r-axSpA and risk factors for radiographic spinal progression (BASDAI ≥4, and elevated CRP and/ or ≥1 syndesmophyte(s)). Serum samples were collected at baseline (n = 96) and after 108 weeks (n = 89) of TNF-I therapy and analyzed by immunoassays for complement lectin pathway proteins (L-ficolin, M-ficolin, H-ficolin, CL-L1, MBL, MASP-1, MASP-2, MASP-3, and MAp44) and the complement activation product C3dg. X-rays were performed at baseline and after 108 weeks and read blinded for clinical data and chronology by three independent expert readers. New bone formation was defined as the growth of syndesmophyte(s) and/or new syndesmophyte(s) determined by 3-reader-agreement.
