Background: The role of computed tomography (CT) in the assessment of pulmonary involvement in systemic sclerosis is witnessing constant updates with the development of scores and tools.

Objectives: The aim of our study was to look for a correlation between CT scan, clinical and respiratory functional data and to evaluate the severity of diffuse infiltrative lung disease using the Goh' score.

Methods: It was a retrospective and descriptive study carried out at the Internal Medicine Department of Mongi Slim Hospital. It included data of patients with SSc with pulmonary involvement. We used the Goh CT score and the modified Goh score (with 6 levels) to assess the severity of lung involvement.

Results: 31 patients were included. The mean age of our patients was 50 years. The predominant elemental lesions on chest CT were ground-glass opacities (78%), septal thickening (77%) and traction bronchiectasis or bronchiolectasis (70%). The most common type of interstitial lung disease was non-specific interstitial pneumonia (65%) followed by usual interstitial pneumonia (23%). The statistical analysis showed associations between clinical, respiratory functional and imaging data. Decreased forced vital capacity was statistically associated with honeycomb (p=0.04) and non-specific interstitial pneumonia (p=0.05). It was also associated with the extent of lesions according to Goh score (p=0.031) and the modified 6-level Goh score (p=0.024). Crackles at the bases of lungs were associated with the degree of the reticulation extent according to the modified Goh score (p=0.022). A statistically significant relationship was also noted between cough and the extent of ground-glass opacities according to the modified Goh score (p=0.022).

Conclusion: Chest CT allows the assessment of the severity of lung involvement in SSc using semi-quantitative CT scores. We have concluded that the modified Goh score correlates better with clinical abnormalities.

Scleroderma, myositis and related syndromes

AB0894 SYMPTOMS OF GASTROINTESTINAL INVOLVEMENT IN PATIENTS WITH LIMITED AND DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS EVALUATED WITH TWO DIFFERENT SELF-ASSESSMENT TOOLS

Keywords: Gastrointestinal tract, Systemic sclerosis, Patient reported outcomes

M. Vujovic[1], I. Pavlovic2, M. Sefik Bukilica[2,3], G. Radunovic[2,3], P. Ostojic[2,3]. *[1]Institute of Rheumatology, Rheumatology, Belgrade, Serbia*; *[1]Institute of Rheumatology, Rheumatology, Belgrade, Serbia*; *[3]School of Medicine, University of Belgrade, Belgrade, Serbia*

Background: Gastrointestinal (GI) tract is the second most affected organ in systemic sclerosis (SSc).
Objectives: This study aims to analyze the frequency and severity of GI symptoms and their impact on health-related quality of life among patients with limited cutaneous (lcSSc) and diffuse cutaneous systemic sclerosis (dcSSc), as well as in patients with anti-centromere autoantibodies (ACA) and anti-topoisomerase I autoantibodies (ATA).
Methods: Eighty-six consecutive patients with SSc (mean age 59.5 yrs, mean disease duration 11.7 ± 7.9 yrs) were included in this study. LcSSc have had 65 (75.6%) of patients, whilst 21(24.4%) had diffuse form of the disease. ACA were detected in 48 patients (55.8%), ATA in 25 patients (29.1%), two of them had both ACA and ATA (2.3%) and 11 (12.8%) of them had positive antinuclear antibodies (ANA) without specific autoantibodies. We used two self-assessment questionnaires to evaluate the presence and severity of GI symptoms: UCLA-SCTC-GIT 2.0 (1) and the SAQ [2].
Results: There was no difference in percentage of patients with lcSSc and dcSSc who used proton pump inhibitors (41.5%/52.3%), as well as in patients with positive ACA or ATA (45.8%/52%). Symptoms of gastroesophageal reflux (lcSSc: dSSc = 70.7%: 71.4%), distension/bloating (lcSSc: dSSc = 72.3%: 61.9%), diarrhea (lcSSc: dSSc = 27.7%: 42.8%), constipation (lcSSc: dSSc = 44.6%: 33.3%) and fecal soilage (lcSSc: dSSc = 9.2%: 14.3%) were found equally frequent (p>0.05) in patients with lcSSc and dcSSc. GI symptoms were equally common (p>0.05) in patients with ACA and ATA as follows: reflux (ACA: ATA = 70.8%: 80%), distension (ACA: ATA = 77.1%: 64%), diarrhea (ACA: ATA = 33.3%: 28%), constipation (ACA: ATA = 47.9%: 40%) and fecal soilage (ACA: ATA = 8.3%: 16%). Reflux and distension were most frequently present categories, with the highest mean index scores, implicating that these symptoms were most common and severe in our patients. We did not notice significant difference in prevalence and severity of GI symptoms in patients with lcSSc and dcSSc, as well as in patients with ACA and ATA (Table 1). Total GIT score correlated positively with all SAQ indices. Interestingly, index of reflux correlated with the Index of respiratory status (IRS), a distinct domain within the SAQ questionnaire, related to respiratory symptoms, implicating that patients with severe reflux have more serious respiratory symptoms.
Conclusion: Gastrointestinal impairment is very frequent and affects the quality of life in patients with SSc, with no difference regarding the disease subtype or autoantibodies, emphasizing the importance of early diagnose and treatment. These questionnaires may be helpful in early detection of GI involvement.

Table 1. Severity of GI symptoms in different disease subtypes and autoantibodies present. Differences among the groups were not statistically significant (p>0.05).

	lcSSc (n=65)	dcSSc (n=21)	ACA (n=48)	ATA (n=25)
UCLA GIT 2.0 (mean±SD)				
Reflux	0.49 ± 0.53	0.52 ± 0.6	0.51 ± 0.57	0.55 ± 0.52
Distension/Bloating	0.88 ± 0.84	0.52 ± 0.6	0.97 ± 0.85	0.61 ± 0.77
Diarrhea	0.2 ± 0.36	0.43 ± 0.52	0.24 ± 0.39	0.25 ± 0.42
Constipation	0.35 ± 0.48	0.14 ± 0.26	0.36 ± 0.49	0.22 ± 0.35
Fecal soilage	0.15 ± 0.56	0.24 ± 0.62	0.12 ± 0.49	0.3 ± 0.74
Social functioning	0.31 ± 0.4	0.3 ± 0.45	0.35 ± 0.39	0.25 ± 0.4
Emotional well-being	0.32 ± 0.43	0.35 ± 0.63	0.33 ± 0.43	0.26 ± 0.38
Total GIT score	0.45 ± 0.73	0.4 ± 0.47	0.5 ± 0.83	0.37 ± 0.39

dcSSc - diffuse cutaneous systemic sclerosis, lcSSc- limited cutaneous systemic sclerosis, ACA – anti-centromere autoantibodies, ATA – anti-topoisomerase I autoantibodies.

AB0895 SUBCUTANEOUS IMMUNOGLOBULINS IN IDIOPATHIC INFLAMMATORY MYOPATHIES: IS IT TIME FOR A THERAPY DISCONTINUATION SCHEDULE?

Keywords: Myositis, Outcome measures, Quality of care

C. Cardelli[1,2], S. Barsotti[1,3], E. Laurino[1], M. Diomedi[1], F. Fattorini[1], A. Tripoli[4], L. Carli[4], M. Mosca[1]. *[1]University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*; *[2]University of Siena, Department of Medical Biotechnologies, Siena, Italy*; *[3]Ospedale di Livorno, Medicina Interna, Livorno, Italy*; *[4]Azienda Ospedaliero-Universitaria Pisana, Rheumatology Unit, Pisa, Italy*

Background: Subcutaneous immunoglobulins (SCIg) therapy is effective in patients with Idiopathic Inflammatory Myopathies (IIMs), especially in severe and refractory forms of the disease; however, its use is burdened by high costs. Although it is now known that the dosage to be used for the immunomodulatory effect is 2g/kg per month, there are no standardised tapering or discontinuation schemes to date.
Objectives: The aim of the study was to assess whether there are differences in terms of clinical outcomes and patient Quality of Life (QoL) between two different SCIg treatment regimens, involving discontinuation of therapy after the first six months or continuation of the drug for a further six months.
Methods: Within the cohort of IIM patients (2017 EULAR/ACR criteria) followed at our Myositis Clinic, we selected those who were treated with SCIg and, dividing them into two groups according to whether they discontinued therapy after the first six months, we performed a retrospective analysis on data prospectively collected. For each patient, demographic and clinical data (age, sex, disease subset and duration, organ involvement, comorbidities, treatment) were collected from medical charts. The International Myositis Assessment & Clinical Studies Group Disease Activity Core Set Measures (IMACS-CSMs) [Physician Global Activity (PhGA), Patient Global Activity (PGA), 8-items Manual Muscle Testing (MMT8), Health Assessment Questionnaire (HAQ), serological muscle enzymes values] were used to assess the disease activity at baseline and to evaluate the clinical outcomes after six and twelve months from the start of SCIg therapy. Patients' perspective was evaluated also by administration of Patient Reported Outcomes (PROs) not included in the IMACS-CSMs: Short-Form 36 Items Health Survey (SF-36), Functional Assessment of Chronic Illness Therapy Fatigue Subscale (FACIT-F), Hospital Anxiety and Depression Scale (HADS). We then compared the delta of IMACS-CSMs and PROs between the 12-month (12m) and 6-month (6m) assessments to detect any significant changes in patients' health status following the discontinuation of SCIg therapy.
Results: We included 18 patients (12 dermatomyositis, 6 polymyositis; 61.1% female) with a mean age at the beginning of SCIg therapy of 63.8±14.8 years. Of these, 10 (55.6%) discontinued SCIg therapy after 6 months of treatment while 8 (44.4%) continued it for at least one year. We found no differences between the two groups in terms of disease activity and patients' QoL at baseline. At 12 months evaluation, there were no statistically significant differences in PhGA (2.9±1.7 vs 2.5±2.0), MMT8 (67.9±8.0 vs 75.1±6.1) and serum values of muscle enzymes (CPK, LDH, aldolase) between those who had discontinued SCIg after the first 6 months and those who continued the treatment. Patients' QoL was also found not to differ between the two groups, as no statistically significant differences emerged between the scores of HAQ, all SF-36 domains, FACIT-F and HADS anxiety and depression subscales. The delta 12m-6m of QoL assessment parameters showed no differences between the two groups, while there was a worsening of mean PhGA (1.5±1.4 vs -0.5±1.8, p=0.026) and MMT8 (-5.9±6.6 vs 3.3±2.8, p=0.010) in those who discontinued therapy compared with those who continued SCIg.
Conclusion: Although preliminary and with the limitations inherent to the retrospective nature of the study, these data seem to suggest that there are no significant differences in outcomes assessed by IMACS-CSMs and in patient's perception of the disease between different treatment regimens concerning the discontinuation of SCIg. If our findings will be confirmed by future studies on larger cohort of IIM patients, although it appears that there may be a slightly deterioration in muscle function, discontinuing SCIg therapy after the first six months of treatment could reduce health costs, without the risk of significantly compromising patients' quality of care.

AB0896 BEYOND CLINICAL TRIALS: EFFICACY AND SAFETY OF NINTEDANIB IN IPF AND PROGRESSIVE FIBROSING INTERSTITIAL LUNG DISEASES IN CLINICAL PRACTICE

Keywords: Organ damage, Lungs, Real-world evidence

A. I. De Gracia[1], C. Bea[1], E. Fuertes[1], A. De Castro[1], L. Navarro[1], C. Prades[1], D. Ruiz[1], P. Albiol[1], M. J. Forner[1], S. Vela-Bernal[1]. [1]*Hospital Clínic Universitari, Medicina Interna, València, Spain*

Background: Since publication of clinical trials regarding the efficacy of nintedanib in fibrosing ILD, including the ILD associated with autoimmune diseases, its clinical use has increased but not enough real-world data has been published.
Objectives: The aim of our study was to evaluate the efficacy and safety of nintedanib in patients with interstitial lung diseases (ILDs) progressively fibrosing of several etiologies in a spanish third-level hospital.
Methods: A retrospective study was designed to collect clinical and radiological data of 31 patients under treatment with nintedanib, followed up by Internal Medicine, Rheumatology, or Pneumology specialists since 2016.
Results: Chacteristics of the study population are collected in Table 1. The indications for nintedanib were a fibrosis progression in the previous 24 months, determined as a decrease of Forced Vital Capacity higher than 10% in 25 patients (41,67%) or a decrease of 5-10% in 5 patients (8,33%). The increase of fibrosis in CT in 17 patients (28,33%) and a clinical worsening in 25 patients (41,67%) were also indications for treatment, as in pivotal trials. The mean time with nintedanib was 12,58 months (± 13,20). The drug was stopped in 9 patients (29%), 1 of them due to progression and 8 due to adverse effects, none of them severe, being the most frequent gastrointestinal. 12 patients died during follow-up. 7 (58,33%) were diagnosed with IFP, 4 with progressive fibrosis ILD, and 1 with ILD associated with systemic sclerosis. No significant differences between groups were found. Spirometric values were collected before treatment as well as at 3, 6, 12, and 24 months after starting treatment to compare the mean values of FVC (ml), FEV1 (ml), Tiffenau index and DLCO (%). The evolution of spirometric parameters is shown in graphic 1. No significant differences were found between them at baseline and after treatment, in accordance with the expected slowing of the progression to fibrosis. Regarding the evolution in radiological studies, fibrosis progression was only observed in a small percentage of patients.
Conclusion: Nintedanib was one of the first anti-fibrotic drugs with indication in fibrosis ILD. Not only for IPF but also for ILD of diverse aetiology, including those associated with autoimmune diseases, after the publication of clinical trials. Therefore, its use is increasing despite limited inclusion criteria in trials and scarce real-life clinical data. Our real-world study, even with its limitations, shows consistent results with those of the clinical trials, stabilising progression of pulmonary fibrosis in our population for the next 24 months after its start.

THE PRESENCE OF ANTI-U1-RNP ANTIBODY HAS A MILD BUT APPARENT IMPACT ON INTERSTITIAL LUNG DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Lungs, Systemic sclerosis, Autoantibodies

Y. Ito[1], H. Fujimoto[2], Y. Yamamoto[1], A. Nakajima[1]. [1]*Mie University Hospital, Center for Rheumatic Diseases, Tsu, Japan*; [2]*Mie University Graduate School of Medicine, Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, Tsu, Japan*

Background: Interstitial lung disease (ILD) is the leading cause of systemic sclerosis (SSc)-related death[1]. With the availability of antifibrotic agents to slow the progression of SSc-ILD[2], it is important for clinicians to be aware of the antibody profile predicting the severity and progression of SSc-ILD.
Objectives: To determine the impact of anti-U1 ribonucleoprotein antibody (αRNPab) in addition to anti-topoisomerase 1 antibody (ATA) on SSc related interstitial lung disease (ILD).
Methods: Patients with SSc who visited Mie University Hospital between December 2020 to December 2021 were consecutively registered. The severity and progression of ILD on chest computed tomography (CT) were assessed based on the ILD and traction bronchiectasis (TBE) scores, evaluated by using established method [3] with minor modification. We hypothesized that ATA had the greatest impact on ILD, followed by αRNPab, and accordingly stratified patients into three groups: group 1, ATA-positive; group 2, αRNPab-positive; and group 3, double-negative. At registration, patient characteristics were compared according to the presence of ILD, and the severity of ILD were compared among three groups. For patients who had earlier CT scans available, ILD progression was assessed.
Results: Among 48 patients (ILD/non-ILD; n=25/23), αRNPab positivity was significantly higher in the ILD than in the non-ILD group (32%, 0%, p<0.01). In 47 patients, the percentage of patients whose ILD score ≥ 20% was 83.3, 28.5 and 5.8% in groups 1, 2 and 3 (n = 6/7/34), respectively (p<0.01). In 25 patients, the percentage of patients with progressive ILD whose ILD score increased by ≥ 5% was 80.0, 50.0 and 14.3% in groups 1, 2 and 3 (n = 5/6/14), respectively (p<0.01).
Conclusion: The presence of αRNPab significantly affects the presence, severity and progression of SSc-ILD, although the effect is milder than that of ATA.

AB0898 LUNG ULTRASONOGRAPHY FOR THE SCREENING AND PROGNOSTIC STRATIFICATION OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

Keywords: Systematic review, Ultrasound, Systemic sclerosis

A. Alunno[1], N. Piccini[2], E. Pintus[2], J. Schoones[3], M. Matucci-Cerinic[2,4], S. Bellando Randone[2]. *[1]Internal Medicine and Nephrology Division, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy*; *[2]Division of Rheumatology, AOUC, Dept. Experimental and Clinical Medicine, University of Florence, Florence, Italy*; *[3]Leiden University Medical Center, Directorate of Research Policy (formerly Walaeus Library), Leiden, Netherlands*; *[4]IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnIRAR), Milan, Italy*

Background: Interstitial lung disease (ILD) affects almost all systemic sclerosis (SSc) patients and is the major cause of morbidity and mortality. Chest high resolution computed tomography (HRCT) is today the gold standard imaging method to diagnose and disclose the characteristic SSc ILD features. More than a decade ago, ultrasonography (US) has been shown to be a less invasive and radiation-free methodology to screen and show the lung involvement in SSc.
Objectives: To evaluate and confirm the reliability of lung US as a screening tool for SSc ILD.
Methods: A systematic literature search in several databases was conducted following the PICO framework on July 2022. Two researchers independently screened abstracts and titles and full texts were subsequently reviewed to determine eligibility (original research articles enrolling adult SSc patients undergoing lung US and HRCT). Data from eligible articles were extracted and risk of bias (RoB) was assessed with validated tools. Owing to extensive interstudy heterogeneity, narrative summaries had to be used to present the data.
Results: Out of 1656 retrieved articles, only 95 were selected for full text evaluation, and only 15 were considered eligible for inclusion. In these15 studies, published between 2014 and 2022, only 3 of these enrolled a control group of normal subjects. 14 studies had a cross-sectional design and 1 study was a prospective longitudinal study. In 10 studies, information about patient characteristics (SSc subset and/or autoantibody positivity) were lacking (67%). The studies were highly heterogeneous in terms of type of US probe used (2,5-3,5 MHz vs 7-10 MHz), number of scanned sites (ranging between 18 to 72) and US score/threshold to classify the US findings as ILD. The sensitivity of lung US ranged between 73.58 and 100% while the specificity ranged between 55 to 92.3%: 7 studies did not report either sensitivity or specificity or both, and it was not possible to calculate it on the basis of data provided. In 7 studies, feasibility was explored, showing that the scanning of up to 72 sites always took less than 10 minutes. In 3 studies, a good to very good reproducibility (intraclass correlation coefficients=0.95-0.96 and Cohen's k=0.72) was detected. The concordance between US and HRCT in identifying ILD pathological findings was around 80%. The only longitudinal study revealed that the number of B-lines at baseline was correlated with the change of the diffusing capacity for carbon monoxide (DLCO) after 12 months.
Conclusion: The results of our Systematic Literature Review confirm that lung US is a useful screening tool for SScILD. However, the data on the prognostic value of lung US are still too few to draw any definite conclusions. The implementation of routine lung US might allow an early identification and prompt treatment of SSc-ILD patients. However, the lung US procedure still need to be unified and harmonised (e.g. type of probe, number of scanned sites) together with the scoring systems/threshold to allow a comparison of research studies and a broad implementation of lung US in clinical practice.

Background: Rituximab (RTX) is currently the most widely used biologic agent in the treatment of IIM. The main indications for treatment with RTX in IIM are refractory muscle, lung, and skin involvement. There is growing evidence that biologic therapy in IIM has the potential to benefit patients with refractory disease. (1)

Myopathies Panel	0/4 (0%)

Objectives: Describe and analyze the clinical indications for RTX in a cohort of patients with IIM. Describe adverse effects associated with RTX and clinical response to RTX.
Methods: Descriptive, retrospective study, in a single center of patients diagnosed with IIM (Bohan and Peter-ACR/EULAR 2017), who received RTX (1993 to 2022). Patients with follow-up of at least 6 months after first infusion of RTX were included. The following variables were considered: myopathy subtype, clinical manifestations, RTX indication, RTX administration regimen, and adverse events. Significant clinical response to RTX was defined as improvement in organ function or symptoms, or halting of disease progression, or prevention of relapses, such that the patient did not require further immunosuppression or was maintained on stable immunosuppressive therapy, and no more than 10 mg prednisolone/day or additional doses of RTX were given to treat disease relapses or to maintain initial clinical benefit.
Results: Of 138 patients registered with MMII, 17 (12.3%) patients received treatment with RTX. Fourteen (14) patients (10.4%) were included in the analysis. Table 1 describes demographics and clinical characteristics. The main reason for indication was refractory disease (50%) (Table 2). One hundred percent (100%) of patients received glucocorticoids during RTX use at an average daily dose of 25 mg. Methotrexate was co-administered with RTX in the majority of patients and was also the most widely used drug before RTX. Regarding safety, 5 infectious adverse effects (35%) were recorded in 4 patients (28%), 3 of which were deemed as serious (21%). The clinical response to RXT at 3 months was 78.5%, and 71 % at 6 months.

Table 2 -Rituximab

	n 14 (%)
Rituximab Dosage Guidelines:	
A: (1 gr every 15 days) average dose: 1357 gr ± 420	8/14 (57%)
B: (375 mg/m2/body sup) average dose 1730 ±710	6/14 (43%)
Infusion of hospitalized patients	4/14 (28,5%)
Infusion center	10/14 (71,4%)
Main reason for indication:	
Severity of diseases	4/14 (28,5%)
Refractory disease	7/14 (50%)
Both situations	3/14 (21,5%)
Indication of organic involvement (frequency)	
Dysphagia	8/14 (57%)
Cutaneous	5/14 (37,5%)
Peripheral muscles	5/14 (37,5%)
Respiratory muscles	2/14 (14%)

Conclusion: In this cohort of patients with IIM, 12.3% received treatment with RTX and the main indications were dysphagia and refractory disease.
Adverse effects were recorded in 28% of the cases, all infectious, of which 21% were serious. Clinical response was obtained in 78.5% 3 months after the first indication of rituximab, which was maintained in 71% of the patients at 6 months.

AB0900 NINTEDANIB DOES NOT IMPROVE NAILFOLD CAPILLARY ABNORMALITIES IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Lungs, Imaging, Systemic sclerosis

T. Sugimoto[1], H. Watanabe[1], Y. Yoshida[1], S. Mokuda[1], S. Hirata[1]. [1]*Hiroshima University Hospital, Clinical Immunology and Rheumatology, Hiroshima, Japan*

Background: The pathogenesis of SSc consists of three aspects: fibrosis, angiopathy, and immune abnormalities. Nintedanib has been shown to be effective against interstitial lung disease (ILD) as an antifibrotic drug, but it may also have effects on vascular disorders due to its inhibitory effects on FGF, PDGF, and VEGF. While nailfold capillary abnormalities in patients with systemic sclerosis (SSc) may improve with immunosuppressive therapy, no reports have evaluated whether nintedanib improves nailfold capillary abnormalities.
Objectives: To clarify whether nintedanib improves nailfold capillary abnormalities in patients with SSc complicated by ILD.
Methods: This study is a prospective observational study. Among patients diagnosed as having SSc according to the 2013 ACR/EULAR classification criteria, those who started to treat with nintedanib for ILD at our hospital from March 2020 to July 2022 were consecutively registered. The nailfold capillaries were evaluated using a nailfold videocapillaroscopy (NVC), capable of observation at 200x magnification. The evaluation was carried out using the current standardized method. [1] NVC was performed before drug induction and 1 year after drug induction. Only patients who had NVC testing up to 1 year later were included in the evaluation. At the same time, blood tests such as KL-6, SP-A, and SP-D, and respiratory function tests were evaluated. This study has been pre-approved by the Hiroshima University Hospital Ethics Committee. (OySTeR study: Optimal strategy in SSc Treatment for Recovery, approval number: E-1940-1)
Results: Eight patients were analyzed. The mean age was 59 ± 17 years. Female were 7 (87.5%). Six patients (75%) were positive for anti-Scl-70 antibodies. Details of other cases are listed in Table 1. Seven patients (87.5%) had a history of treatment with immunosuppressive therapies. The disease duration was less than 6 years in 5 patients, and 6 years or longer in the remaining 3. Five patients were able to continue nintedanib for 52 weeks: 1 patient discontinued nintedanib after 1 month due to abnormal liver function, 1 patient with diarrhea discontinued after 10 months. All of the patients who were able to continue oral administration were also reduced to 200 mg/day due to diarrhea. Baseline mean FVC, KL-6, SP-A, and SP-D are described in Table 1. The results by NVC pattern were Normal in 1 case, Early in 2 cases, Active in 1 case, Late in 3 cases, and Non-specific in 1 case. Quantitative baseline results for the NVC tests were capillary density (number of capillaries) 5.8 ± 2.2/mm, enlarged capillary score 0.91 ± 0.83, giant capillary score 0.31 ± 0.30, and hemorrhage score 0.22 ± 0.27. 1 year later, the NVC pattern deteriorated from early to active in only one case, but the others remained unchanged. Quantitative results for the NVC test were capillary density 5.8 ± 2.3/mm, enlarged capillary score 0.98 ± 0.95, giant capillary score 0.38 ± 0.48, and hemorrhage score 0.20 ± 0.33. Mean FVC, KL-6, SP-A, and SP-D after 1 year are also shown in Table 1.
Conclusion: Nintedanib tended to improve ILD biomarkers and pulmonary function test results in patients with SSc, but did not improve nailfold capillary abnormalities. Based on this result, combination therapy is preferable to nintedanib alone for improving the pathology of SSc.

AB0901 FUNCTIONAL CAPACITY, BODY COMPOSITION AND DISEASE ACTIVITY ARE ASSOCIATED WITH QUALITY OF LIFE IN PATIENTS WITH MYOSITIS

Keywords: Outcome measures, Quality of life, Myositis

K.Y. Jensen[1], P. Aagaard[2], C. Suetta[3,4], J. Nielsen[2], H. D. Schrøder[5], C. Grønset[6], L. P. Diederichsen[1,7]. [1]*Copenhagen University Hospital - Rigshospitalet, Copenhagen Research Center for Autoimmune Connective Tissue Diseases (COPEACT),*

Copenhagen, Denmark; [2]*University of Southern Denmark, Department of Sports Science and Clinical Biomechanics, Odense, Denmark*; [3]*Bispebjerg And Frederiksberg University Hospital, Department of Geriatric and Palliative Medicine, Geriatric Research Unit, Copenhagen, Denmark*; [4]*Copenhagen University Hospital, Herlev and Gentofte, Department of Medicine, Geriatric Research Unit, Herlev, Denmark*; [5]*Odense University Hospital, Department of Pathology, Odense, Denmark*; [6]*Copenhagen University Hospital - Rigshospitalet, Department of Occupational Therapy and Physiotherapy, Copenhagen, Denmark*; [7]*Odense University Hospital, Center for Rheumatology, Odense, Denmark*

Background: Idiopathic inflammatory myopathies – or briefly myositis – has cardinal traits of muscle weakness [1] and decreased muscle endurance [2] in addition to reduced quality of life (QoL) [3]. However, QoL is complex, and it is unclear which factors affect QoL in patients with myositis. Knowledge of these factors and potential associations to QoL is of importance for evoking changes to a better life for patients with myositis.
Objectives: To investigate the influence of functional capacity, muscle strength, body composition and disease activity and damage on QoL in patients with myositis.
Methods: Measures of functional capacity (functional index 3, 2-minute walk test, timed-up-and- go and 30-s sit-to-stand), muscle strength (5 repetitions maximum strength in leg press, bench press, cable row, knee extension, biceps curl and static handgrip strength; all expressed relative to body mass), leg extensor power (Nottingham Power Rig, relative to body mass), body composition (height adjusted appendicular lean mass and fat mass) and IMACS (International Myositis Assessment & Clinical Studies Group) disease activity and disease damage core set measures were analysed to investigate the impact on QoL (physical- and mental component summary in the Short Form 36 questionnaire (SF-36)).
Results: All functional capacity measures were positively correlated with the physical component summary (PCS); functional index 3 (r^2=0.15, p=0.03), 2-minute walk test (r^2=0.26, p=0.003), timed-up-and-go (r^2=0.14, p=0.03) and 30-sit-to-stand performance (r^2=0.15, p=0.03). Only leg press (r^2=0.15, p=0.04) showed a positive correlation with PCS for measures of muscle strength and power. For body composition, height-adjusted fat mass correlated negatively with PCS (r^2=0.20, p=0.01). Of the IMACS disease activity and disease damage core set measures, Health Assessment Questionnaire (r^2=0.40, p=0.0001), Physician Global Assessment of Disease Damage (r^2=0.44, p<0.001) and Patient Global Assessment of Disease Damage (r^2=0.18, p=0.02) were negatively correlated with PCS. In contrast, none of the investigated outcome parameters were correlated with the mental component summary of SF-36.
Conclusion: In the present group of patients with myositis, functional capacity and muscle strength had positive associations with the physical component summary of the QoL, indicating that future interventions should be directed to improve these factors to ultimately improve QoL. The Health Assessment Questionnaire and Patient/Physician Global Assessment of Disease Damage revealed strong correlations with PCS, supporting that both patient-reported outcome measures (PROMS) and clinician-reported outcomes are highly relevant QoL-related monitoring parameters in patients with myositis.

LEFT VENTRICULAR SYSTOLIC DYSFUNCTION IS RARE BUT PROGNOSTICALLY IMPORTANT IN SYSTEMIC SCLEROSIS

Keywords: Cardiovascular disease, Systemic sclerosis, Heart

J. Fairley[1,2], D. Hansen[2], S. Proudman[3,4], J. A. Sahhar[5,6], G. S. Ngian[5,6], J. Walker[4], L. Host[7], A. La Gerche[1,8,9], D. Prior[9], K. Morrisroe[1,2], W. Stevens[2], M. Nikpour[1,2], L. Ross[1,2]. Background: Reduced left ventricular ejection fraction (LVEF) occurs in only around 5% of unselected SSc cohorts [1]. Subclinical LV systolic dysfunction (LVSD) defined by advanced echocardiographic measures including global longitudinal strain (GLS) may be more prevalent [2].
Objectives: To quantify the frequency of LVSD in SSc as measured by LVEF and LV GLS, and its impact on survival and physical function.
Methods: Included participants in the Australian Scleroderma Cohort Study met ACR/EULAR criteria for SSc and had ≥1 echocardiographic LVEF measurement. Those with secondary causes of LVSD (ischaemia, valvular disease and PAH) were excluded. Chi squared tests, two sample t-tests or Kruskal Wallis tests were used for between group comparison as appropriate. Generalised estimating equations were used to model longitudinal data. Survival analyses were performed using Kaplan-Meier and Cox proportional hazard models.
Results: Of 1145 participants, 2.5% recorded a reduced of LVEF<50% during follow up; 14% had borderline LVEF of ≥50% but <55%; and 83% always a LVEF ≥55%. Only 0.6% ever had a LVEF≤40%. LVEF returned to normal in 66% of those who had recorded a LVEF<50%. Compared to those with normal LVEF, those with reduced LVEF were similar in age, more frequently male (p=0.01), with dcSSc (p<0.01), SSc renal crisis (p=0.02), synovitis (p=0.04) and higher inflammatory markers (p<0.02). Those with reduced LVEF more commonly had myositis (p<0.01), muscle atrophy (p=0.01) and proximal weakness (p<0.01). Use of prednisolone (p=0.03), IVIG (p<0.01), and cyclophosphamide (p<0.01) were more common in those with reduced LVEF. Survival was worse in those with reduced LVEF (Figure 1). Reduced LVEF was associated with a 2.8-fold increased risk of death (95% CI 1.3-6.3, p=0.01: Table 1). Physical function and quality of life were worse in those with reduced LVEF. Multivariate analyses identified shorter six minute walk distance (p=0.01), higher Health Assessment Questionnaire Disability Index scores (p<0.01) and lower Short Form 36 Physical Component Summary scores (p=0.02) in those with reduced LVEF. Participants with reduced LVEF were 3.9-times more likely to record WHO Class III/IV dyspnoea (95%CI 1.8-8.1, p<0.01). LV GLS data were available for 90% of participants at one centre (n=219). Abnormal LV GLS (> -17%) was seen in 30% of those with normal LVEF and 53% with borderline LVEF. LV GLS was lowest in those with reduced LVEF (-17.2%; IQR -14.9 – -18.0%) compared to those with normal (-19.5%; IQR -18.0 – -20.8%) or borderline LVEF (-18.3%; IQR -16.6 – -19.5%; p<0.01). Worst recorded GLS was associated with increased mortality (HR 1.3, 95%CI 1.0-1.6, p=0.02), although this association was attenuated in multivariate analyses (HR 1.2, 95%CI 1.0-1.5, p=0.10).
Conclusion: After excluding secondary causes, reduced LVEF in SSc is rare. Despite the relative infrequency, LVEF<50% is associated with a specific SSc phenotype, worse survival and physical function. Abnormal LV GLS is more prevalent in SSc, seen in 30-50% of those with persistent LVEF≥50%. Further data are required to define the threshold of LVSD in SSc, and to explore the utility of measures of subclinical LVSD such as LV GLS.

EFFICACY AND SAFETY OF NINTEDANIB IN COMBINATION WITH IMMUNOSUPPRESSIVE AGENTS FOR PROGRESSIVE FIBROSING CTD-ILD IN CLINICAL PRACTICE

Keywords: Lungs

Y. Ushio[1], R. Wakiya[1], T. Kameda[1], S. Nakashima[1], H. Shimada[1], T. Miyagi[1], K. Sugihara[1], R. Mino[1], M. Mizusaki[1], K. Chujo[1], H. Dobashi[1]. *[1]Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Kagawa, Japan*

Background: Nintedanib (NTB), a multitargeted tyrosine kinase inhibitor, has been approved in Japan for progressive fibrosing interstitial lung disease (PF-ILD) since May 2020 based on the results of the INBUILD trial [1]. This also made it a new treatment option for connective tissue disease (CTD) that are frequently complicated by ILD. On the other hand, the use of immunosuppressive agents in the treatment of ILD and primary diseases varies by disease type and country.

Objectives: The purpose of this study is to evaluate the efficacy and safety of NTB for progressive fibrosing CTD-ILD treated with immunosuppressive agents at a single center in Japan.

Methods: CTD-ILD patients who received NTB at our institution between 2020 and 2022 were extracted. Among CTD-ILD patients who received NTB, those who met the criteria for PF-ILD (1) were included in this analysis. Efficacy was evaluated by changes in forced vital capacity (FVC), and the monthly rate of decline in FVC (ΔFVC %/M) before and after the initiation of NTB. Changes in KL-6 (Krebs von den Lungen 6), a serum biomarker for ILD, were also analyzed. In addition, these efficacy parameters were compared between two groups; one group that received additional immunosuppressive agents at the same time as NTB administration (NTB+IS group), and the other group that received only NTB (NTB group). Safety was evaluated by the occurrence of adverse events within 12 months.

Results: There were 24 CTD-ILD patients (8 males and 16 females) who received NTB, all of whom met the criteria for PF-ILD. Patient characteristics are shown in Table 1. The most common primary disease was systemic sclerosis in 8 patients (33.3%), followed by polymyositis/dermatomyositis in 6 patients (25.0%). The mean FVC were 56.8±15.1 % and 1600.0±600.1 mL. Mean FVC increased at 6 and 12 months (ΔFVC %: +6.4 %/6M; +8.1 %/12M) and ΔFVC %/M improved from -0.65 %/M to +1.06 %/M after the initiation of NTB. Serum KL-6 decreased significantly at 6 and 12 months (ΔKL-6 U/mL: -233.7 U/mL/6M; -401.4 U/mL/12M). Eleven of the 24 patients received additional immunosuppressive agents at the same time as NTB administration (NTB+IS group). The immunosuppressive agents administrated concurrently were rituximab in 5 patients, glucocorticoids (>20 mg/day prednisone or equivalent) in 4, cyclophosphamide in 2, abatacept in 2, and mycophenolate mofetil in 1. In NTB + IS group, ΔFVC %/M was significantly improved compared with the 13 patients who received only NTB (NTB group) (+1.81%/M vs. +0.20%/M, respectively) (Figure 1). Adverse events (AEs) considered to be related to treatment were diarrhea in 13 patients, nausea in 2 patients, elevations in liver enzymes in 2 patients, and headache in 1 patient, and the dose of NTB was reduced in 11 patients. No patient discontinued NTB due to AEs.

Conclusion: NTB for progressive fibrosing CTD-ILD appeared to be effective and safe in clinical practice. The results also suggested that the combination of NTB and immunosuppressive agents may be an effective treatment strategy. Because this was a small, single-center, observational study, further research is needed to clarify the type and timing of immunosuppressive agents to be used in combination.

Background: There is a breadth of evidence supporting a key role for abnormal B-cell function in the pathogenesis of systemic sclerosis and associated interstitial lung disease (SSc-ILD) [1,2]. A previous pilot study investigated the efficacy of belimumab, a recombinant human immunoglobulin G1 lambda (IgG1λ) monoclonal antibody that binds to and neutralises B-lymphocyte stimulator (BLyS) subsequently inhibiting the survival of B cells [3], in reducing modified Rodnan skin score (mRSS) in 20 patients with SSc [4]. Belimumab is well tolerated and is approved for the treatment of patients with active systemic lupus erythematosus and active lupus nephritis receiving standard therapy [5]. We hypothesise that by reducing the number of B cells and dampening B-cell effector functions in the circulation and tissue, belimumab will reduce inflammation and fibrosis across multiple organ systems in patients with SSc. This will result in the stabilisation of, and/or reduction in, lung function decline and skin thickening in SSc, and improvements in patients' quality of life.

Objectives: To present the design of a randomised controlled trial that will evaluate the efficacy and safety of subcutaneous (SC) belimumab versus placebo in adult patients with SSc-ILD.

Methods: In this global, parallel-group, Phase 2/3, randomised, double-blind, placebo-controlled, two-arm, 52-week study (GSK Study 218224), eligible adults with a documented diagnosis of SSc and ILD (as confirmed by high-resolution computed tomography) will be randomised 1:1 to receive either belimumab 200 mg SC weekly (Arm 1), or matching SC placebo weekly (Arm 2), for 52 weeks (**Figure 1**). Participants will be permitted to continue their stable doses of standard therapy throughout the study. The primary endpoint of the study is absolute change from baseline in forced vital capacity (ml) at Week 52. Key secondary endpoints, analysed at Week 52, include: absolute change from baseline in mRSS, absolute change from baseline in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score, and SSc progression or death. Patient-reported outcomes (listed in the **Figure 1**) will also be assessed. A comprehensive biomarker approach will be implemented to evaluate the belimumab modulating effects on key biological processes involved in SSc pathogenesis (fibrosis and inflammation) in circulation and in skin biopsies. Safety will be monitored throughout the study.

Results: Target sample size is planned to be approximately 300 patients, with 150 patients per arm.

Conclusion: We present the design of a global Phase 2/3 study that will test the efficacy and safety of SC belimumab in patients with SSc-ILD. Together, the study endpoints enable the assessment of the efficacy of belimumab on a broad range of disease manifestations, disease progression, and impact on patient burden and survival.

DEVELOPMENT OF A NEW COMPREHENSIVE ASSAY KIT FOR MYOSITIS-ASSOCIATED ANTIBODIES AND MYOSITIS-SPECIFIC ANTIBODIES EXAMINATION OF CLINICAL USEFULNESS IN INFLAMMATORY MUSCLE DISEASES

Keywords: Autoantibodies, Myositis

T. Hashimoto[1], H. Yasuoka[1]. [1]*Fujita Health University, 1-98, Dengakugakubo, Toyoake, Japan*

Background: Inflammatory muscle diseases are systemic inflammatory disorders that affect not only muscles but also skin, joints, lungs, and heart. Dermatomyositis (DM) and polymyositis (PM) are characterized by the production of antibodies. Measurement of these antibodies is useful for diagnosis, classification of disease type, evaluation of disease activity, prognosis prediction, and determination of therapeutic strategy. However, the sensitivity and specificity vary depending on the measurement method, and some autoantibodies can only be measured in limited laboratories.

Objectives: We developed a novel comprehensive assay kit for myositis-associated antibodies with the aim of developing a rapid and simple detection method for myositis-specific or related autoantibodies. we used a proteome-wide antibody screening and quantification with wet protein arrays consisting of proteins synthesized from proteome-wide human cDNA library (HuPEX). We examined whether this assay kit is clinically useful compared to enzyme-linked immunosolbent assay (ELISA).

Methods: Sera from 47 patients diagnosed or suspected of inflammatory muscle disease were used to measure myositis-specific autoantibodies (anti-ARS, anti-MDA5, anti-TIF1-γ, anti-Mi-2, and anti-SRP, antibodies) and myositis-related autoantibodies (anti-U1RNP, anti-Ku, and anti-PM-Scl, anti-mitochondria antibodies) were measured using a proteome-wide antibody screening and quantification with wet protein arrays consisting of proteins synthesized from proteome-wide human cDNA library (HuPEX) and compared with the results of ELISA, which is commercially available and immunoprecipitation with some autoantibodies (anti-OJ, anti-Zo antibodies). Autoantibodies that were undetectable by the ELISA and positive only on the array were subjected to immunoprecipitation. In immunoprecipitation, primary antibody added to a solution containing an antigen to form an antigen-antibody complex in the solution. Next, a secondary antibody immobilized on the beads is added to adsorb the antigen-antibody complex to the beads. Finally, the antigen was eluted from the beads using SDS and analyzed using SDS-PAGE.

Results: In the 47 cases, the clinical diagnosis was DM in 26 cases, PM in 20 cases, and inclusion body myositis in 1 case. In the ELISA commercially available, 20 cases of anti-ARS antibody (17 cases of DM, 3 cases of PM), 5 cases of anti-MDA5 antibody (Amyopathic DM), 1 case of anti-TIF1-γ antibody (DM), 2 cases of Mi-2 antibody (1 case of DM, 1 case of PM), 2 cases of anti-RNP antibody (PM), and 2 cases of anti-mitochondria antibody (PM).

Compared with the results measured by the ELISA commercially available, eighteen of the 20 cases were positive for anti-ARS antibodies using the proteome-wide antibody screening system and all other autoantibodies were 100% concordant.

In addition, 1 case of DM in which autoantibodies could not be detected by the ELISA was positive for anti-OJ antibody by the proteome-wide antibody screening system. Of the 6 PM cases whose autoantibodies could not be detected by the ELISA, 1 was anti-HMGCR antibody-positive and 1 was anti-Zo antibody-positive, consistent with the clinical diagnosis. Furthermore, among the 4 PM cases who were positive only for anti-SS-A antibody by ELISA, 2 were anti-SRP antibody positive, 1 was anti-Ku antibody positive, and 1 was anti-Ki antibody positive by the proteome-wide antibody screening system. Those samples that could be detected by the array were also confirmed to be positive by immunoprecipitation.

Conclusion: Collectively, proteome-wide screening of antibodies using the *in vitro* proteome can reveal the myositis-associated antibodies of patients and may provide novel clinical biomarkers.

AB0906 SEVERITY OF DIGESTIVE AFFECTATION IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Gastrointestinal tract

R. Redondo Rodriguez[1], A. Garcia Studer[1], F. Ortiz-Márquez[1], N. Al Mashhadani[1], N. Mena-Vázquez[1], L. Cano Garcia[1]. [1]*Instituto de Investigación Biomédica de Málaga (IBIMA)-Plataforma Bionand, Unidad de Gestión Clínica de Reumatología, Málaga, Spain*

Background: Almost 90% of patients with systemic sclerosis (SSc), both the diffuse and limited forms, have gastrointestinal (GI) involvement, which leads to increased morbidity and mortality. The UCLA SCTC GIT 2.0 questionnaire has been used to assess the severity of digestive involvement in patients with SSc.

Objectives: To describe the severity of digestive involvement in a series of patients with SSc and identify factors associated with the severity of digestive involvement.

Methods: ***Design***: Cross-sectional study of a series of cases with SSc from the Regional University Hospital of Malaga recruited between January and December 2022. ***Protocol***: Patients with SSc are regularly followed up in rheumatology clinic, are registered in a database, and they were consecutively invited to participate in this study. The study was approved by the Ethics Committee (Code 1719-N-15) following the recommendations of the Declaration of Helsinki and current legal regulations for Good Clinical Practice. ***The main outcome***: severity of digestive involvement measured by the UCLA SCTC GIT 2.0 questionnaire (total GIT). This questionnaire includes 34 items and 7 multi-item scales (reflux, bloating/swelling, diarrhoea, fecal soiling, constipation, emotional well-being and social functioning) and a total GIT score to assess health-related quality of life (HRQoL) and the severity of GI symptoms in SSc. Total GIT was categorized as follows: (1) none to mild severity from 0.00 to 0.49; (2) moderate from 0.5 to 1.0; and (3) severe to very severe from 1.01 to 3.0. ***Other variables*** included were: epidemiological characteristics, clinical and analytical manifestations, including modified Rodnan skin score (mRSS). ***Statistical analysis***: descriptive, bivariate and multivariate to identify factors associated with the severity of digestive involvement in patients with SSc.

Results: 52 patients were included, 98.1% were women with a mean (SD) age of 60.8 (11.1) years. The clinical-epidemiological characteristics of the included patients are shown in Table 1. A total of 49/51 patients (94.2%) had digestive involvement, of which 18/49 (34.6%) had mild involvement (UCLA 0.01-0.49), 14/49 (26.9%) moderate (UCLA 0.50-1.00) and 17/49 (32.7%) severe or very severe (UCLA 1.01-3.00). Correlations of total GIT were observed with skin thickness measured by mRSS (r=-0.394; p=0.004) and with HRQoL measured with VAS-EQ-5D (r=-3.77; p=0.006). The baseline variables that were independently associated with the severity of digestive involvement measured by UCLA were: skin extension measured by mRSS (β [95% CI] 0.026 [0.008-0.043]; p=0.004), quality of life measured by VAS-EQ-5D (β [95% CI] -0.009 [0.13, -0.15]; p=0.013]) and sex (β [95% CI] -0.942 [0.513, 1.370]; p< 0.001]).

Conclusion: Digestive involvement in SSc patients was frequent, and in almost a third of patients the involvement was severe or very severe. The variables associated with a greater severity of digestive involvement were male gender, low VAS-EQ-5D, and high mRSS.

Table 1. Clinical-epidemiological characteristics of patients with SSc.

Variable	SSc n= 52
Baseline clinical-epidemiological characteristics	
Sex, women, n (%)	51 (98.1)
Age, years, mean (SD)	60.83 (11.1)
Race, Caucasian, n (%)	52 (100.0)
Smoking history	
No smoker, n (%)	35 (67.3)
Smoker, n (%)	3 (5.8)
Ex-smoker, n (%)	14 (26.9)
Modified Rodnan skin score, mean (SD)	10.88 (9.1)
ANA, n (%)	50 (96.2)
Anticentromere, n (%)	28 (53.8)
AntiScl70, n (%)	10 (19.2)
Skin pattern	
Limited, n (%)	40 (76.9)
Diffuse, n (%)	12 (23.1)
BMI, Kg/m^2, mean (SD)	25.59 (4.6)
EQ-5D, mean (SD)	0.59 (0.25)
VAS-EQ-5D, mean (SD)	0.54 (21.6)
Weigh, mean (SD)	62.9 (10.6)
No weightloss, n (%)	27 (51.9)
Weightloss 1-3 Kg, n (%)	17 (32.7)
Weightloss > 3 Kg, n (%)	8 (15.4)

AB0907 HIGH EXPRESSION LEVELS OF TYPE I INTERFERON AND IP-10 IN ANTI-MDA5 ANTIBODY-POSITIVE DERMATOMYOSITIS AND ITS IMPLICATION IN THE PATHOGENESIS

Keywords: Myositis, Cytokines and chemokines, Biomarkers

K. Sato[1], A. Kokuzawa[1], J. Nakamura[1], Y. Kamata[1]. *[1]Jichi Medical University, Division of Rheumatology and Clinical Immunology, Department of Medicine, Shimotsuke, Japan*

Background: Dermatomyositis (DM) patients with anti-melanoma differentiation-associated protein 5 (MDA5) antibodies (Ab) are likely to have rapidly progressing interstitial lung disease and a poor prognosis. Thus, it is important to understand the pathogenesis of the disease.
Objectives: The aim of this study was to identify humoral factor(s) that characterize anti-MDA5 Ab^+ DM and to analyze the cells that produce these factors.
Methods: Twenty-eight cytokines in the serum of patients with anti-MDA5 Ab^+ DM patients were screened and compared with the results of patients with other collagen vascular diseases. We also performed an immunohistochemical analysis of skin rashes (Gottron's signs) from two patients.
Results: Serum levels of interferon gamma-induced protein 10 (IP-10, CXCL10), one of CXCR3 chemokines, were significantly higher in anti-$MDA5^+$ DM patients than in SLE and anti-MDA5 Ab^- DM patients. Moreover, serum interferon (IFN) α2 levels were also higher in anti-$MDA5^+$ DM patients. After initiation of immunosuppressive therapy, IP-10 and IFN-α2 levels decreased rapidly, whereas those of IFN-γ and CXCL9, another CXCR3 chemokine, did not substantially decrease. Skin samples revealed that the IP-10 positive cells in the dermis were positive for CD68 antigen, a monocyte/macrophage marker. In contrast, they contained a few $CD8^+$ cells and almost no $CD4^+$ cells. We also stimulated monocytes from healthy controls with type I and II IFNs *in vitro* and demonstrated that IP-10 was produced in the culture supernatant in a dose-dependent manner.
Conclusion: Our results indicate that IP-10 is highly produced in DM patients with ant-MDA5 Abs. The levels of type I IFN were also high and even exceeded those of SLE. Several reports have shown that not only type II IFN but also type I IFN induces IP-10. Thus, type I IFN/IP-10 axis may play an important role in the pathogenesis of anti-MDA5 Ab^+ DM. Our immunohistochemical analysis of the skin also revealed that IP-10 released from macrophages may prompt infiltration of macrophages themselves, constituting a positive feedback loop in the skin inflammation. Further analyses are required to prove the usefulness of IP-10 as a disease activity and/or prognostic marker of DM with anti-MDA5 Abs.

AB0908 SCREENING AND ANALYSIS OF POSSIBLE DRUGS BINDING TO PDGFRA: A MOLECULAR MODELING STUDY

Keywords: Targeted synthetic drugs, Systemic sclerosis, Disease-modifying Drugs (DMARDs)

M. Mozzicafreddo[1], D. Benfaremo[1,2], C. Paolini[1], S. Agarbati[1], S. Svegliati Baroni[1,2], G. Moroncini[1,2]. *[1]Marche Polytechnic University, Department of Clinical and Molecular Sciences, Ancona, Italy*; *[2]Marche University Hospital, Department of Internal Medicine, Ancona, Italy*

Background: The platelet-derived growth factor receptor (PDGFR) is a membrane tyrosine kinase receptor involved in several metabolic pathways, mainly in tumor progression [1, 2], immune-mediated diseases [3-4], and viral diseases [5].
Objectives: Considering this macromolecule as a druggable target for modulation/inhibition of these conditions, the aim of this work was to find new ligands or new information to design novel effective drugs.
Methods: We performed an initial interaction screening with the human intracellular PDGFRα of about 7200 drugs and natural compounds contained in five independent databases/libraries, implemented in the MTiOpenScreen web server. After selection of 27 compounds, a structural analysis (in particular, molecular docking and molecular dynamics analysis, using SwissDock based on EADock DSS algorithm [6, 7] and GROMACS [8], respectively) of the complexes obtained was performed. Three-dimensional quantitative structure–activity relationship and ADMET analyses were also performed to understand physicochemical properties of that compound to increase affinity and selectivity.
Results: Among these 27 compounds, the drugs Bafetinib, Radotinib, Flumatinib and Imatinib showed the higher affinity for this tyrosine kinase receptor, lying in the nanomolar order, while the natural products, such as curcumin, luteolin and EGCG, included in this group showed submicromolar affinities. All these compounds, through the QSAR and ADMET analysis, provided physicochemical information about an ideal best ligand for PDGFRα.
Conclusion: Although experimental studies are recommended, the structural information obtained could provide useful insight into the future development of PDGFRα inhibitors.

AB0909 IMMUNOEXPRESSION OF TGFB1 IN SKIN IN SYSTEMIC SCLEROSIS

Keywords: Prognostic factors, Systemic sclerosis, Diagnostic Tests

K. Romanowska-Prochnicka[1,2], A. Wajda[3], M. Grabowska[4], M. Legatowicz -Koprowska[5], A. Paradowska-Gorycka[3], M. Olesińska[6]. *[1]Medical University of Warsaw, Department of Biophysics, Physiology and Pathophysiology, Faculty of Health Sciences, Warsaw, Poland*; *[2]National Institute of Geriatrics, Rheumatology and Rehabilitation, Department and Polyclinic of Systemic Connective Tissue Diseases, Warsaw, Poland*; *[3]National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Molecular Biology, Warszawa, Poland*; *[4]Pomeranian Medical University, Department of Histology and Developmental Biology, Faculty of Health Sciences, Szczecin, Poland*; *[5]National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Pathomorphology, Warszawa, Poland*; *[6]National Institute of Geriatrics, Rheumatology and Rehabilitation, Department and Polyclinic of Systemic Connective Tissue Diseases, Warszawa, Poland*

Background: TGF-β pleiotropic functions in inflammation, fibrosis, and vascular remodeling suggest that TGF-β signaling could play a central role as a link between fibrosis and vasculopathy characteristic of SSc. Moreover high mRNA level of TGF β1 in whole blood and high immunoexpression in tissues in SSc patients confirms its role in the SSc pathogenesis.
Objectives: The aim of this study was to determine TGFβ1 immunoexpression in the skin of patients with systemic sclerosis.
Methods: Skin biopsies from 14 patients with SSc (7 female and 7 male) at median age 60 years (19-69) were analyzed by immunohistochemistry method using anti-TGFβ1 primary mouse monoclonal antibody IgG (Abcam, Cambridge, UK; ab190503). Morphological analysis has been conducted by Hematoxylin and eosin (H&E) staining and Masson trichrome staining. The sections were examined using a light microscope Olympus BX 41 (Olympus, Hamburg, Germany). **Patients**. Women and men in the study group did

not statistically differ in age. Men were characterized by significantly higher CRP (p=0.03) but not ESR (p>0.99). In the study group, women were more often characterized by irreversible fibrotic lesions in lungs (HRCT=5), but the frequency of occurence was not statistically significant (p=0.56). Men were characterized by higher mRSS than women, but the difference was not statistically significant (p=0.14).

Results: Histological analysis of the human skin biopsies from patients with systemic sclerosis revealed perivascular edemas, flattening of the dermal papilla and excessive accumulation of collagen in the papillary and reticular layers of the dermis (Figure 1A, B). The fibrosis of the dermis was manifested by the presence of numerous bunches of irregularly distributed collagen fibers (Figure 1B). Moreover, perivascular focal infiltrations of inflammatory cells and reduction of blood vessel density were observed. In the human skin biopsies from patients with systemic sclerosis TGFβ1-positive cells were observed (Figure 1C, D, E). The cells showed various cytoplasmic immunoexpression of TGFβ1 (brown-stained cytoplasm) in keratinocytes (mainly in the basal layer of epidermis) and in fibroblasts of the dermis.

Conclusion: High immunoexpression of TGFβ1 is correlated with mRNA level observed in whole blood in patients with SSc. Patients with limited SSc are characterized by weaker staining in skin biopsy than patients with diffuse SSc. Determination of mRNA TGF β1 level in whole blood seems to be a good diagnostic marker of SSc.

REFERENCE:

[1] AB0603 PDGFA AS A POTENTIAL BLOOD MARKER IN DSSC

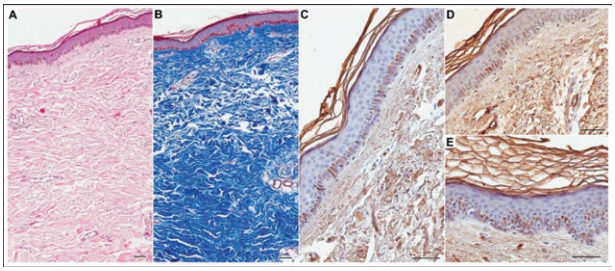

Figure 1. Representative light micrographs of H&E-stained (A), Masson trichrome-stained (B) and TGFβ1 immunostained (C, D, E) human skin biopsies from patients with systemic sclerosis. Skin of patients with systemic sclerosis was characterized by flattening of dermal papilla (A) and fibrosis in papillary and reticular layers of dermis – blue-stained collagen fibers (B). The cytoplasmic immunolocalization of TGFβ1 (brown color) was revealed in the fibroblasts localized in the dermis and keratinocytes in the basal layer of the epidermis. Scale bar - 50 µm.

AB0910 GASTRIC DYSRHYTHMIAS IN PATIENTS WITH EARLY SYSTEMIC SCLEROSIS PROSPECTIVE CROSS-SECTIONAL STUDY

Keywords: Systemic sclerosis, Gastrointestinal tract, Descriptive Studies

D. Seelmann[1], M. P. Poblete[1], S. Saavedra[2], A. M. Madrid[3], C. Von Muhlenbrock[4], C. Estay[3], A. Goecke[1]. [1]*Hospital Clínico de la Universidad de Chile, Reumatología, Santiago, Chile*; [2]*Hospital Clínico Gral. Dr. Raúl Yazigi, Reumatología, Santiago, Chile*; [3]*Hospital Clinico Universidad de Chile, Gastroenterología, Santiago, Chile*; [4]*Universidad de los Andes, Medicina interna, Santiago, Chile*

Background: Systemic sclerosis (SSc) is an autoimmune disorder characterized by vasculopathy and fibrosis of skin and internal organs. Gastrointestinal (GI) system is affected in up to 90% of patients and dysmotility is the primary abnormality [1]. Gastric dismotility contributes to esophageal symptoms and causes nausea, vomiting, abdominal bloating, and early satiety. It also impacts quality of life and when severe is associated with increased mortality [2]. GI dysmotility can be evaluated with Electrogastrography (EGG), a non-invasive and safe test. It measures gastric myoelectrical activity, and when impaired it predicts delayed gastric emptying with an accuracy of 85% [3]. To the date gastric involvement in patients with early SSc has not been directly studied.

Objectives: Describe the prevalence of gastric dysrhythmias in early SSc and the association between GI symptoms and GI dysmotility.

Methods: SSc patients fulfilling the 2013 ACR/EULAR classification criteria with early disease (≤ 3 years from the first non-Raynaud symptom) were included and cross-sectionally assessed. Pregnancy and Diabetes Mellitus were exclusion criteria. All patients signed informed consent. GI symptoms were assessed using the UCLA GIT 2.0 questionnaire [4]. Gastric myoelectrical activity was measured using surface EGG and informed as preprandial, postprandial or continuous brady or tachygastria. Continuous bradygastria was considered a severe abnormality. It was informed by an expert gastroenterologist blinded to patient characteristics. Statistical analyses: Categorical variables were described as frequencies and percentages, and quantitative variables as mean, SD and IQR. The associations between variables were analyzed using the Fisher exact test. Statistical significancy was defined as $p < 0,05$

Results: 30 patients were included, 96,6 % were female, with a mean age of 48.7 years (25–72 years). SSc was limited in 76.6%. 14/28 patients had an anticentromere antinuclear antibody pattern and 6 had anti Scl 70. Organ involvement was interstitial lung disease in 7/29, altered echocardiogram in 10/25 and erosive esophagitis in 11/15. Half of the patients were under immunosuppressive treatment, 43% on methotrexate and 50% mycophenolate. EGG was abnormal in 28/29 patients, 71.4% had bradygastria, 10.7% tachygastria an 17.8% mixed. Bradygastria was mostly preprandial (45%) and continuous (50%). According to the UCLA GIT 2.0 questionnaire, two thirds of the patients had a moderate to severe GI involvement. Other score items are described in Table 1. There was no correlation between symptoms and severity of the gastric motility disorder, but the presence of bradygastria was associated to a worse social functioning score (p 0,018).

Conclusion: Gastric dysrhythmias, especially bradygastria occurs early in systemic sclerosis. Bradygastria was associated with a worse social functioning score.

AB0911 EFFICACY OF LOW-DOSE IL-2 IN PATIENTS WITH MYOSITIS

Keywords: Cytokines and chemokines, Myositis

X. M. Wang[1,2], J. X. Zhang[1,2], P. H. Chai[1,2], Y. Z. Li[1,2], Q. Y. Su[1,2,3], Q. Yu[4], P. F. He[4], X. Li[1,2,3], S. X. Zhang[1,2,3]. Background: Idiopathic inflammatory myopathies (IIMs) are a group of rare and heterogeneous muscle inflammatory diseases characterized by disturbances of regulatory T(Treg) cells. Interleukin (IL)-2 has been rediscovered as a pivotal cell population in the control of autoimmunity, which effectively relieves idiopathic inflammatory myopathies(IIMs) such as polymyositis(PM) and dermatomyositis (DM).

Objectives: This study aimed to systematically evaluate the efficacy of low-dose IL-2 therapy in PM, DM, and IIMs.

Methods: Systematic searches of PubMed, EMBASE, Web of Science, the Cochrane Library and Medline, CNKI, CBM, and Technology Journal Database were performed. Original case reports, case series, observational studies, and clinical trials reporting the changes in the numbers of lymphocyte subsets on

PM, DM, and IIMs patients treated with IL-2 were included. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I^2, and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0)

Results: A total of 5 studies comprising 401 patients were identified(Table 1).The CDASI scores were significantly decreased after IL-2 treatment[SMD=-1.146, 95%CI (-1.591,-0.700), P<0.001].Besides, the number of Tregs cells was significantly increased[SMD=-1.146, 95%CI (-1.591,-0.700), P=0.007], and the subgroup analysis was performed based on the dose of IL-2(Figure 1).

Conclusion: Low-dose IL-2 was promising in the treatment of DM, PM, and IMMs, which could promote the proliferation and functional recovery of Tregs.

Table 1. Available evidence including patients with DM, PM, and IIMs treated with low-dose IL-2.

Study.Year.	Patients (include in analysis)	Gender (female %)	Types of disease	Dosage	CDASI	Tregs

AB0912

RP-ILD IN PATIENTS WITH ANTI-MDA5 POSITIVE ANTIBODIES: CLINICAL EVALUATION AND PROGNOSIS. RETROSPECTIVE DATA FROM A SINGLE CENTER COHORT

Keywords: Lungs, Myositis

L. Ienna[1], L. Iaccarino[1], R. Depascale[1], A. Gamba[1], M. Gasparotto[1], M. Gatto[1], E. Zanatta[1], M. Zen[1], A. Doria[1]. [1]*University of Padua, Rheumatology Unit, Department of Medicine-DIMED, Padua, Italy*

Background: Patients with anti-melanoma differentiation-associated gene 5 antibody-positive (anti-MDA5+) dermatomyositis (DM) often develop a rapidly progressive interstitial lung disease (RP-ILD) associated with high mortality [1].

Objectives: to evaluate clinical features and prognosis of patients with anti-MDA5+ DM who developed RP-ILD.

Methods: Anti-MDA5+ patients were selected from a single center cohort of 198 idiopathic inflammatory myopathies (IIM) patients. Data were collected retrospectively. Onset clinical manifestations considered were muscle, joint, skin and lung involvement. All patients underwent chest high resolution computed tomography (HRCT). RP-ILD was defined by hypoxemia and dyspnea associated with radiological worsening within 3 months from pulmonary symptoms onset [2]. The dosage of ferritin during the follow up was also evaluated. Muscle involvement was assessed by myocytolysis indexes and Manual Muscle Test 8 (MMT-8). Joint and skin involvement was defined by clinical judgment. The therapeutic approach and the clinical outcome were also considered for each patient.

Results: based on inclusion criteria 11 patients were identified, 7 males and 4 females, aged between 30 and 67 years (mean age 55.54±9.58 years). The duration of the follow-up was 19.9±24.25 months. Cutaneous, pulmonary, joint and muscle involvement at onset were 63%, 36%, 36% and 9% respectively. Complete clinical and serological data are shown in Table 1. Ten patients (91%) develop ILD and the most frequently observed radiological pattern was organizing pneumonia (OP) found in 60% of cases, followed by OP/Nonspecific interstitial pneumonia (NSIP) (30%), NSIP (10%). During the disease course, 60% of patients with ILD developed RP-ILD with a mean time of 7.8±7.13 months from onset. RP-ILD patients showed a higher mean ferritin level than in those without (mean 13506±2219.05 vs 473±538.33 ug/L). Immunosuppressive therapy in all RP-ILD patients was based on cyclophosphamide plus tacrolimus and/or plasmapheresis. Two patients underwent extracorporeal membrane oxygenation. Four patients with RP-ILD died (66%), one from SARS-CoV-2 infection and three from respiratory failure. None of the patients with non-RP-ILD died.

Conclusion: in our cohort RP-ILD occurred in 60% of patients with MDA5+ ILD and was characterized by elevated ferritin levels. An intense immunosuppressive combination therapeutic scheme was always required. Nevertheless, mortality rate remained high.

MORTALITY AND ASSOCIATED FACTORS IN 44 PATIENTS WITH SYSTEMIC SCLEROSIS ASSOCIATED PULMONARY ARTERIAL HYPERTENSION FROM TURKEY

Keywords: Systemic sclerosis

S. Amikishiyev[1], Y. Yalçınkaya[1], K. Mammadova[2], N. Aliyeva[1], G. Durak[3], B. Artim-Esen[1], A. Gül[1], A. K. Bilge[4], G. Okumuş[2], M. Inanc[1]. Background: Pulmonary arterial hypertension (PAH) is a severe complication of systemic sclerosis with high mortality. Although new drugs and treatment strategies developed in the last years, the prognosis of prevalent patients has not been sufficiently improved.
Objectives: We aimed to analyze the prevalence, mortality, and prognostic factors in patients with SSc-PAH from our single-center SSc cohort.
Methods: We retrospectively evaluated the association between mortality and demographics, transthoracic echocardiography, right heart catheterization (RHC) and pulmonary function parameters at baseline, and treatment modalities in patients with SSc-PAH that have been assessed and followed up by a multi-disciplinary team.
Results: Forty-four (10.6%) out of 415 patients with SSc were diagnosed as SSc-PAH in 2008-2022. The mean age was 56.6±13.5 years, and 23 (52.3%) patients were deceased during a median follow-up of 45 months. The survival rates were 91% for the first year, 75% for 2 years, 68% for 3 years, and 43.1% for 5 years. The available causes of death were a cardiopulmonary failure in 6 (26%), infection in 6 (26.1%) including one with COVİD-19, and malignancy in 3 (13%) patients. Clinical and hemodynamic findings of the patients were given in Table 1.

Table 1. Demographic, serologic, clinical, and hemodynamic findings of SSc-PAH patients.

Demographics (n)			SSc-PAH

RHC findings			
Systolic PAP (mm Hg), mean (SD)	49.7±15.1	56.2±15.9	0.15
Diastolic PAP (mm Hg), mean (SD)	16.6±3.3	19.6±8.2	0.15
mPAP (mm Hg), mean (SD)	30.7±6.2	34.1±10	0.18
RAP (mm Hg), mean (SD)	7.0±3.5	6.9±2.2	0.95
PVR WU	4.9±3.9	5.3±2.1	0.74
PCWP (mm Hg), mean (SD	11.5±3.0	11.2±3.6	0.70
CO (L/min), mean (SD)	5.0±1.3	3.9±1.2	**0.02**
CI (L/min/m2), mean (SD)	2.7±0.6	2.2±0.8	0.13
Respiratory function tests			
FVC (mL), mean (SD)	2241.7±460.7	1769.2±269.7	**0.001**
DLCO (%), mean (SD)	51.1±22.5	42±11	0.1
6 MWT, mean (SD)	270±160	200±164	0.23

The initial ePASP was significantly high, and cardiac output (CO), and FVC values were significantly lower in deceased patients. The patients who died had more UIP patterns compared to survived patients (Table 1). Initial PAH-specific therapy was monotherapy in 31 (70.5%) and dual therapy in 11 (25%) patients. Fifteen (34%) patients were switched to combined (dual or triple) therapy from monotherapy. Nine/fourteen (22.5%) patients on monotherapy and 13/26 (32.5%) patients on combined therapy died. Four patients could not be given specific therapy for various reasons. Bosentan (11.4%) as monotherapy, ambrisentan and tadalafil (9.1%) as combined therapy were more preferred during follow-up. Median survival time was significantly better on combined therapy compared to monotherapy (44 vs. 61 months, p=0.01) (Figure 1).
Conclusion: Our SSc-PAH cohort consisted of severe patients with a significant number of DcSSc group, ILD especially UIP pattern, anti-Scl-70 positivity, and low baseline FVC and DLCO values. FVC, CO, and 6-MWT were the parameters affecting survival during follow-up. Although combined therapy had better survival rates, poor long-term survival rates warranted the need for early and effective treatment modalities.

CARDIOVASCULAR RISK FACTORS ARE ASSOCIATED WITH INCREASED CRP LEVELS IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Cardiovascular disease, Comorbidities

M. G. Abdelzaher[1,2], D. Feldmann[1,3], U. Heilmeier[1], I. Jandova[1], F. Kollert[1,4], R. Voll[1], S. Finzel[1]. [1]*University Medical Center Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany*; [2]*Mansoura University, 2- Rheumatology and Immunology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura, Egypt*; [3]*Krankenhaus Porz am Rhein, 3- Department of Anesthesiology, Cologne, Germany*; [4]*University of Bern, Department of Rheumatology and Immunology, University Hospital Bern, Bern, Switzerland*

Background: Patients with systemic sclerosis (SSc) are known to have an elevated risk for cardiovascular diseases. Approximately 20-25% of all SSc patients have permanently elevated C-reactive protein (CRP) levels [1,2]. Higher CRP levels are known to be associated with metabolic syndrome and diabetes mellitus (DM) (3), two factors that contribute to cardiovascular risk.
Objectives: To investigate if permanently elevated CRP levels are associated with higher cardiovascular risk in a cohort of 65 patients with SSc.
Methods: Data analysis was carried out in R 4.1 using the packages dplyr, ggplot2, mice and MASS. 65 patients were enrolled in the study; 20 had permanently elevated CRP levels over two years before enrollment (CRP+ group), and 45 had normal CRP levels over 2 year prior enrollment (CRP- group). The following cardiovascular risk factors were selected as candidate predictors of CRP status: The Framingham Score, left and right carotid intima-media thickness (CIMT) on bilateral carotid ultrasound, pathological status of both carotids, presence of plaques in both carotids, number of plaques (0 if none), extent of largest plaque (0 if none), height, weight, body mass index (BMI), presence of arterial hypertension, history of smoking, packyears, DM type 2, chronic kidney disease, and a positive family history (cardiovascular event before the age of 65). We tested each variable as a bivariate predictor of CRP status in a logistic regression model. Subsequently, we used stepwise logistic regression based on the Akaike Information Criterion (AIC) to determine the optimal set of predictors. AIC evaluates model deviance in relation to the number of variables in the model, i.e., it can be used to find the optimal trade-off between model performance (predictive accuracy) and model complexity (number of predictors). Prior to logistic regression analysis, missing values in the dataset were replaced by means of multiple imputation.
Results: In the bivariate logistic regression analyses (Table 1), only the Framingham Score and DM2 were identified as significant predictors, both with a positive weight, i.e., a higher Framingham Score and the presence of DM2 in a given patient were predictive of permanently positive CRP status, respectively. However, due to relatively low sample size, model sensitivity was 65%, and specificity was 86.7%.

Cardiovascular risk factor	*OR*	*t-value*	*p-value*
Age [years]	1.00	0.34	.734
Framingham Score	1.02	2.18	**.033**
CIMT right/ left	1.28/ 1.20	0.84/ 0.86	.402/.395
CIMT pathological right/ left	0.86/ 1.03	-0.78/ 0.18	.440/.860
plaque right/ left	1.16/ 1.19	1.32/ 1.50	.191/.140
number of plaques right/ left	1.12/ 1.11	1.24/ 1.03	.221/.307
largest plaque right/ left [cm]	1.08/ 1.01	1.62/ 0.30	.110/.763
height [m]	1.20	0.29	.772
weight [kg]	1.01	1.75	.085
BMI [kg/m²]	1.02	1.76	.082
arterial hypertension	1.03	0.24	.808
history of smoking	1.14	1.12	.269
Packyears	1.00	0.48	.631
DM 2	1.49	2.03	**.046**
chronic kidney disease	1.12	0.68	.499
positive family history	1.07	0.45	.657

Conclusion: Permanently increased CRP levels are associated with higher Framingham scores and DM type 2 in SSc-patients. These findings are going to be validated in larger and longitudinal cohorts.

AB0915 A STUDY ON THE ASSESSMENT OF CARDIOVASCULAR RISK AND CIMT IN PATIENTS OF SYSTEMIC SCLEROSIS AND CORRELATION OF CIMT WITH QRISK 3 AND DISEASE SEVERITY SCORE

Keywords: Comorbidities, Systemic sclerosis, Autoantibodies

P. Dogga[1], K. Chandwar[2], K. Kishor[1], D. Ekbote[1], J. Dixit[2], U. Dhakad[1], P. Kumar[1]. [1]*King George Medical University, Clinical Immunology and Rheumatology, Lucknow, India*; [2]*SGPGI, Clinical Immunology and Rheumatology, Lucknow, India*

Background: Accelerated atherosclerosis is well-known in connective tissue disease however is less reported in Systemic Sclerosis. There is evidence that atherosclerosis occurs prematurely in Systemic sclerosis. The micro vascular disease is characteristic of SSc, but there is growing evidence of macro vascular disease in SSc patients. Several studies have evaluated the prevalence of atherosclerosis in carotid arteries in patients with SSc by ultrasonography. Increased CIMT and conventional CVD risk factors have well known association with future events of stroke and coronary heart disease.

Objectives:

1. To study the Cardiovascular risk and Carotid Intima medial thickness in patients of Systemic sclerosis and their correlation
2. To assess the Disease Severity by using MEDS score and its correlation with CIMT

Methods: Data of 72 patients including clinical, serological profile and treatment were recorded. Cardiovascular risk by QRISK 3 calculator, CIMT by Ultrasonography are used. Correlation between Cardiovascular profile with CIMT and disease severity were seen. Medsger disease severity score was used to estimate the disease severity. Thirty-four age comparable controls were included.

Results: A total of 72 SSc patients (lcSSc -27, dcSSc -45) were included in the study. F> M (11:1). The median duration of disease enrolled was 2.9 years and time to referral to a specialist was 1.28 years. On patient in our study developed Scleroderma renal crisis and one patient was diagnosed with Adenocarcinoma of lung. Lipid profile showed low HDL, high LDL, TG, Cholesterol as compared to controls. The mean CIMT of the patients showed a significant difference when compared to controls (0.58± 0.09 **vs** 0.56 ±0.10; p=<0.01).The mean mRSS was 23.99±10.44 and mean MEDS score was 8.68±2.76. Forty-three patients (59.7%) out of 72 had ILD documented by HRCT. NSIP in 22 (30.6%) and UIP in 21 (29.2%) patterns on HRCT were observed. The Severity of PAH (Mpap >20 mm Hg) is greater in lcSSc vs dcSSc (30.33±10.50 vs 28.42 ± 7.38). Cyclophosphamide, MMF were used as induction therapies mainly for treatment of ILD. The mean CIMT (0.58± 0.09) showed a significant positive correlation with QRISK3 however it is weak with rho=0.575, p value <0.001. The mean CIMT (0.58± 0.09 mm) showed a negative correlation with mRSS with rho = -0.145 and p value 0.224.

Conclusion: CIMT had positive correlation with PAH (significant, p=0.034) and QRISK3 (significant, p=<0.01). CIMT had negative correlation with mRSS. The mean CIMT showed no correlation with MEDS score.

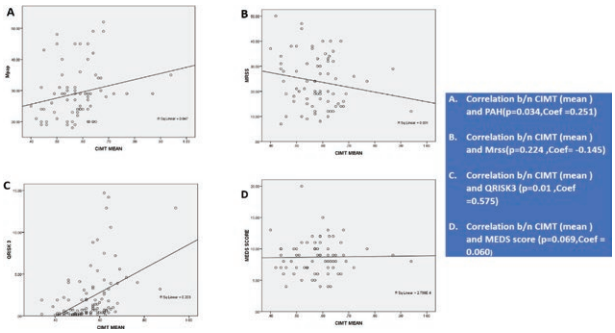

Figure 1. Spearman Correlation of CIMT with Mpap, Mrss, QRISK 3 and MEDS score

Table 1. Clinical parameters and frequency in SSc Subsets:

Parameter	Lcssc n=27 (%)	Dcssc n=45 (%)	P value

AB0916 IDIOPATHIC INFLAMMATORY MYOPATHIES: ABOUT 50 CASES

Keywords: Motor function, Myositis, Autoantibodies

F. Z. El Fekak[1], H. Khibri[1], H. Tassine[1], F. Ibourk el Idrissi[1], S. Belkhattab[1], W. Ammouri[1], M. Maamar[1], H. Harmouche[1], Z. Tazi Mezalek[1], M. Adnaoui[1].

[1]*Ibn Sina University Hospital Center, Internal Medicine/Clinical Hematology, Rabat, Morocco*

Background: Idiopathic inflammatory myopathies are rare autoimmune diseases that affect between two and ten people per million.
Objectives: The aim of our work is to describe the epidemiological, clinical and paraclinical characteristics of autoimmune inflammatory myopathies as well as the therapeutic modalities.
Methods: This is a retrospective study involving 50 inflammatory myopathy patients admitted to Ibn Sina Hospital's internal medicine department between January 2015 and June 2022.
Results: There were 50 patients, 37 women and 13 men (gender ratio M/F: 0. 35). The mean age of onset of symptoms was 45.8 years old, the mean age of diagnosis was 47.6 years old (extremes: 23 and 80 years old) and the mean time between onset of symptoms and positive diagnosis was 14.9 months. The main reason for hospitalization was muscle impairment in 98% of our patients. It was dominated by muscle weakness with a mean score of 3/5 and myalgia. Proximal involvement was predominant. No facial musculature involvement was reported. At the time of diagnosis, dysphagia was present in 42% of cases, and no dysphonia was reported. Cutaneous signs were observed in 78% of cases with erythroderma type 22%, Gottron's papules 20% and manicure sign 16%. General signs were found in 56% of cases predominantly asthenia and weight loss, arthralgia was present in 34.7% of cases. 20% of patients had heart disease, myocarditis type, pericarditis, and arrhythmia in 2 cases each, neurological disease was found in 16% of cases (pyramidal syndrome type in 5 (10%) cases and neurogenic disease in 3 (6%) cases). PID-type pulmonary disease was present in 24% of cases, with complications of pulmonary fibrosis in 4% of cases. Creatine phosphokinase was elevated in 76% of cases with a mean value of 2553 IU/L and extremes between 26 and 25000 IU/L. Fifteen patients at the time of diagnosis had normal CPK contrasting with clinical signs. LDH was increased in 73%, liver cytolysis in 73%, and biologic inflammatory syndrome in 51%. Electromyograms were performed in 80% of cases, showing a myogenic pattern in 82.5% of cases, associated with neurogenic involvement in 25% of cases. Muscle biopsy (performed in 75% of cases) confirmed the diagnosis in 27 patients (77.1%) and in 8 patients the biopsy was normal. Antinuclear antibodies were positive in 70% of the cases, anti-JO1 positive in 26% of the cases, 26.7% of the patients were anti-SSA positive, and 10% of the cases were anti-MI2 positive. The diagnosis was dermatomyositis in 36% of cases, anti-synthetase syndrome in 20% of cases and cancer-associated myositis in 10% (in 5 patients), and overlapping myositis in 28% of cases. No cases of necrotizing myopathies or inclusion myopathies have been reported. The types of neoplasia revealed by idiopathic inflammatory myopathies in our study were: poorly differentiated carcinoma in 3 cases on lymph node biopsies, poorly differentiated adenocarcinoma of metastatic lung in 1 case and one case had Hodgkin's lymphoma. The treatment was based on corticosteroid therapy for all cases. Corticosteroid therapy was associated with an immunosuppressant in 58% of cases (methotrexate in 38% of patients, cyclophosphamide in 20% of patients, azathioprine in 4 patients and 2 patients on MMF). In 32% of patients, IV immunoglobulin therapy was prescribed, and in 8%, Rituximab was prescribed. We found no deaths in our series, with 38% of cases going into complete remission.
Conclusion: The classification criteria for idiopathic inflammatory myopathies have been constantly changing. The diagnosis of inflammatory myopathy can currently be made in common practice when a patient's clinical, muscular histology, and serology support the diagnosis. The elimination of an associated cancer remains a challenge for the practitioner.

A RANDOMIZED CONTROLLED PROSPECTIVE SINGLE-CENTER FEASIBILITY STUDY OF RHEOPHERESIS FOR RAYNAUD'S SYNDROME AND DIGITAL ULCERS IN SYSTEMIC SCLEROSIS (RHEACT) - PRESENTATION OF FIRST INTERIM RESULTS

Keywords: Randomized control trial, Systemic sclerosis

J. G. Rademacher[1], V. Korendovych[1], A. Borisch[1], T. Asendorf[2], P. Korsten[1].
[1]*University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany*; [2]*University Medical Center Göttingen, Department of Medical Statistics, Göttingen, Germany*

Background: Raynaud's phenomenon (RP) and digital ulcers (DU) are frequent manifestations of Systemic Sclerosis (SSc). There are very few available approved drugs with varying efficacy. Rheopheresis (RheoP) is an extracorporeal apheresis technique used to treat microcirculatory disorders by improving blood viscosity. The effect of RheoP in SSc is currently unknown, and here, we report the interim results of the first patients.
Objectives: To determine the efficacy of RheoP compared to Standard of Care (SoC) intravenous iloprost on RCS and DU healing.
Methods: A *randomized controlled prospective single-center feasibility study of Rheopheresis for Raynaud's syndrome and Digital Ulcers in Systemic Sclerosis (RHEACT)* aims to investigate the efficacy of RheoP on the Raynaud Condition Score (RCS) as the primary outcome measure after 16 weeks from baseline. A planned number of 30 patients will be randomized in a 1:1:1 ratio to one of two RheoP treatment groups or assigned to the SoC control group.
Results: We here report the results of the first seven patients. The patient assigned to the RheoP1 group had a baseline Raynaud Condition Score (RCS of 8, which improved to 0 after 16 weeks (the primary endpoint). The two patients randomized to the RheoP2 had a baseline RCS of 8 and 6, respectively, which improved to 4 and stayed unchanged at 6 in the second patient. The four patients assigned to SoC had only minimal improvement. RheoP1 had a significantly lower RCS compared to RheoP2 and SoC at week 16 (*p<0.05). Furthermore, DU completely healed in patients with DU at baseline with either RheoP therapy and avoided amputation in one patient. Exemplary images are shown in figure 2 (A, baseline; B, at week 16).
Conclusion: RheoP improved the RCS and DU better than SoC (Iloprost) treatment alone and avoided amputation in one patient.

AB0918

CLINICAL AND SEROLOGICAL FEATURES OF DERMATOMYOSITIS IN TUNISIA

Keywords: Myositis, Autoantibodies, Motor function

A. Baya Chatti[1], I. Naceur[1], T. Ben Achour[1], F. Said[1], S. Skhiri[1], M. Lamloum[1], M. Khanfir[1], I. Ben Ghorbel[1], M. H. Houman[1]. *[1]RABTA Hospital, Internal Medicine, Tunis, Tunisia*

Background: The spectrum of dermatomyositis (DM), as all idiopathic inflammatory myopathies (IIM), has been evolving steadily from a pathology characterized by muscle weakness and cutaneous rash to a disease with a wide range of systemic manifestations and various muscular phenotypes.
Objectives: The aim of our study was to describe the epidemiological, clinical and paraclinical features of DM in a Tunisian cohort.
Methods: We conducted a retrospective and monocentric study, over a 21-year period. All patients who fulfilled the 2017 ACR/EULAR classification criteria for IIM and were classified among the group "DM" were included.
Results: Among 85 patients with IIM, 46 were classified with DM (54%). The gender ratio (M/F) was 0,4. The mean age at diagnosis was 48,4 ± 14.8 years. Cutaneous manifestations revealed the diagnosis of DM in 82% of cases. Other revealing symptoms were: muscular weakness (20%), joint involvement (18%), pulmonary involvement (11%) and general symptoms (2.6%). Muscular weakness was noted in all patients, myalgia in 87% and amyotrophy in 11% of patients. Motor deficit was predominantly proximal and symmetric in all patients, affecting the hip flexors in 98% of cases, upper limbs in 87% and/or axial muscles in 28%. Distal muscles were affected in 11% of patients. Other involved muscle groups were: oesophageal muscles (59%), laryngeal muscles (15%) and myocardium (4%). High Creatine kinase levels were noted in 87 % of cases with a median level of 1896 IU/L [IQQ=861-4952]. Muscle biopsy, performed in 37 patients, showed perimysial infiltrate (44%), necrosis/regeneration foci (34%), endomysial infiltrate (31%), microangiopathy (16%), muscular atrophy (13%), perifascicular atrophy (9%) and interstitial fibrosis (6%). Cutaneous signs (100%) included eyelid erythema (85%), heliotropic rash (72%), Gottron's papules (61%), manicure sign (30%), Gottron's sign (22%), psoriasiform rash (22%), Raynaud syndrome (20%), vasculitis lesions (15%), telangiectasia (9%), skin ulcerations (9%), calcinosis (9%), skin necrosis (7%), panniculitis (7%) and mechanic's hands (2%). Pulmonary involvement (26%) was represented by diffuse infiltrative lung disease (17%) and inhalation pneumopathy (9%). Arthralgias were noted in 37% of patients and synovitis in 13%. Antinuclear antibodies were found in 65% of patients. Myositis specific antibodies were found in 16 patients (for n=21 available data): anti RNA synthetase (n=6), anti SRP (n=2), anti Mi-2 (n=4), anti-TIF1-γ (n=2), anti MDA5 (n=1) and anti NXP2 (n=1). Twelve patients (26%) were diagnosed with cancer associated myositis. In terms of therapy, all patients were treated with oral corticosteroids. Immunosuppressive therapy, employed in 85% of patients, was indicated for muscular manifestations (90%) and ILD (10%). Intravenous immunoglobulin was administered in seven patients (15%). The median duration of follow up was 44,5 months. On the date of the last consultation, complete clinical and biological remission of muscular manifestations was noted in 70%. Clinical and radiological stability of ILD was noted in seven patients and regression of radiological infiltrates in one patient. Clinical remission of skin manifestations was noted in 87% of patients, at the cost of cutaneous sequelae in 9%. Overall, a relapse was noted in 57% of patients. Seven patients (15%) have died, after a median period of 12 months.
Conclusion: This study highlighted the heterogeneity among DM patients, as evidenced by the variety of systemic manifestations at onset and during the disease course and of immunological data.

AB0919 DYNAMIC OPTICAL COHERENCE TOMOGRAPHY MIGHT BE A VALUABLE TOOL TO ASSESS THERAPEUTIC EFFICACY OF VASOACTIVE THERAPY IN SYSTEMIC SCLEROSIS

Keywords: Diagnostic Tests, Patient reported outcomes

H. Grasshoff[1], K. Adriany[1], L. Ha-Wissel[2], T. Lange[1], J. Hundt[3], G. Riemekasten[1]. *[1]Lübeck, Department of Rheumatology and Clinical Immunology, Lübeck, Germany*; *[2]Lübeck, Department of Dermatology, Allergology and Venereology, Lübeck, Germany*; *[3]Lübeck, Lübeck Institute of Experimental Dermatology (LIED), Lübeck, Germany*

Background: Systemic sclerosis is a rare connective tissue disorder characterized by a triad of inflammation, vasculopathy, and fibrosis. Vasculopathic disease manifestations occur early in disease development and include Raynaud's phenomenon, acral ulcers, necrosis, and pulmonary arterial hypertension. Currently, acral vasculopathy is assessed in clinical practice by nailfold capillary microscopy. However, nailfold capillary microscopy is limited to the nailfold and cannot assess the deeper vascular plexus, changes in dynamic perfusion, or inflammatory and fibrotic disease manifestations. These limitations do not occur with dynamic optical coherence tomography (D-OCT). D-OCT is an imaging technique based on an infrared laser. It allows simultaneous three-dimensional, high-resolution imaging of fibrotic and inflammatory changes as well as vasculopathy in systemic sclerosis [1].
Objectives: The aim of this study was to characterize vascular alterations in the skin of patients with systemic sclerosis and to assess dynamic changes in skin perfusion under vasoactive therapies.
Methods: Twenty-six patients diagnosed with systemic sclerosis according to ACR/EULAR classification criteria 2013 were included in this study. Patients diagnosed with systemic sclerosis received a treatment with iloprost infusion for a duration of five days. Alterations in dynamic perfusion were assessed daily in six locations (nailfold, finger, hand, lower arm, upper arm, ear) using VivoSight OCT. Moreover, alterations in dynamic skin perfusion were assessed under topical treatment with diltiazem (n=13) as well as warmth (n=17). Dynamic perfusion was characterized by the parameters vessel density and vessel diameter. In addition, patients filled questionnaires to assess the severity of vasculopathic disease symptoms and to assess subjective treatment response to iloprost infusion.
Results: Patients were mainly female (73.1%) and of a mean age of 53.6 ± 12.6 years. The majority of the patients were characterized as limited cutaneous systemic sclerosis (76.9%). Seven patients had digital ulcers at the time of study inclusion. Moreover, patients reported that Raynaud's phenomenon occurred with a median frequency of 3.5 attacks per day and the mean duration of Raynaud's phenomenon was 36.9 minutes per day. On a visual analogue scale ranging from 0 to 100, patients rated limitations in daily life due to Raynaud's phenomenon with 48.3 ± 37.3. Whereas the majority of patients (83.3%) reported a subjective benefit, 8.3% reported no change and 8.3% of patients a worsening of acral perfusion under treatment with iloprost infusions. Wilcoxon matched pairs signed rank test did not reveal a significant increase in vessel diameter (p=0.4609) and vessel density (p=0.0681) after topical application of diltiazem. Application of warmth led to a significant increase in vessel diameter ($p < 0.0001$) and vessel density ($p < 0.0001$). Interestingly, therapeutic efficacy assessed by increase in vessel diameter and vessel density differed markedly between individual patients. Prospective assessment of vessel diameter and vessel density under therapy with iloprost infusions yielded heterogeneous regarding the therapeutic efficacy at different sites and timepoints for individual patients.
Conclusion: D-OCT might be a valuable tool to assess vasculopathic alterations and response to vasoactive therapies in the skin of patients with systemic sclerosis. Further studies are required to investigate whether D-OCT might be a technology enabling individual vasoactive treatment in systemic sclerosis in the direction of precision medicine.

AB0920 THE MDA5 ANTIBODY AND ITS RELATIONSHIP WITH AMYOPATHIC DERMATOMYOSITIS

Keywords: Myositis, Autoantibodies

C. Arciniega Larios[1], D. Fernandez Lozano[1], M.Y. Orellana Gómez[1], R. Veroz Gonzalez[1], S. M. Rojas Herrera[1], E. Chamizo Carmona[1]. [1]*Hospital de Mérida, Rheumatology, Mérida, Spain*

Background: The antibody directed against the protein encoded by melanoma differentiation-associated gene 5 (anti-MDA5) is associated with a subgroup of rare inflammatory myopathies characterized by skin lesions typical of classic dermatomyositis with no or minimal involvement of the proximal musculature. The importance of early diagnosis and treatment lies in the rapidly progressive interstitial lung disease that can develop in 50-100% of cases. This can lead to a poor prognosis with a mortality rate between 33 and 66% six months after diagnosis. In less than 5% of cases it is associated with neoplastic disease.
Objectives: To describe the clinical and evolutive characteristics of patients presenting positivity against MDA5 antibody in our hospital.
Methods: An active search for positive MDA5 antibodies in the service of Rheumatology in a 3th level Hospital was performed by collecting epidemiological, clinical and radiological data between the years 2021-2022.
Results: We identified 10 patients with a mean age of 56.8 years (32-86 years), 60% being female (6) and 40% male [4]. Of the total number of patients, only 30% were diagnosed with dermatomyositis. Three patients presented other autoimmune rheumatologic diseases (two of them were diagnosed with systemic lupus erythematosus and one with rheumatoid arthritis), two exclusively with pulmonary involvement, and in two cases no pathology was found. As for the patients diagnosed with dermatomyositis, 100% presented diffuse interstitial lung disease (DIDP) and classic dermatomyositis skin involvement. Arthritis was present in 66.6%, 33.3% were related to incipient breast carcinoma, and 33.3% presented muscular involvement. In all cases treatment was started early with intravenous methylprednisolone boluses associated in 66.6% of cases with intravenous cyclophosphamide and in 66.6% of cases with Tacrolimus. One death was reported due to respiratory failure, probably secondary to progression of the pulmonary disease related to the disease. The rest of the cases presented favorable evolution with remission of skin and joint involvement, as well as stability of pulmonary involvement.
Conclusion: The frequency of hypo- or amyopathic dermatomyositis with positive MDA5 is low. 100% of the cases presented pulmonary involvement at diagnosis, only 30% presented muscular involvement and 30% were associated with neoplasia. One third of the patients with MDA5-positive dermatomyositis died.

AB0921 EFFICACY AND SAFETY OF MACITENTAN IN REFRACTORY DIGITAL ULCERS

Keywords: Systemic sclerosis, Safety, Real-world evidence

M. Retuerto-Guerrero[1], C. Moriano[1], I. Castellví[2], B. Atienza-Mateo[3], E. Diez Álvarez[1]. [1]*Hospital de León, Rheumatology, León, Spain*; [2]*Hospital Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; [3]*Hospital Marqués de Valdecilla, Rheumatology, Santander, Spain*

Background: Raynaud's phenomenon (Rp) is used to describe a symptom complex caused by digital vascular involvement. The presence of digital ulcerations (DU) should prompt further evaluation for secondary causes of Rp. Among the conditions that may be associated with Rp are Systemic Autoimmune Rheumatic Diseases (SARDs), especially Systemic Sclerosis (SSc). DU are a major cause of morbidity and have a high recurrence rate in most patients and may be refractory to multiple treatments. Macitentan is a dual endothelin receptor antagonist authorized to treat pulmonary hypertension. Its efficacy in the treatment of DU associated to SSc has been assessed in two clinical trials (DUAL-1 and DUAL-2)[1], without any visible effects on their prevention or reduction. However, these trials have been criticized on the methodology and profile of the patients included.
Objectives: To assess efficacy and safety of Macitentan in patients suffering from SARDs and refractory DU.
Methods: Spanish observational multicentric study. Data were retrospectively obtained from medical records of 10 patients suffering from SARDs and refractory DU secondary to severe Rp treated with Macitentan 10mg/daily. Total response was defined as the complete healing of DU and partial improvement as the reduction of the number or size of ulcers. Patients with ischemic ulcers caused by other factors were excluded.
Results: We identified 10 patients who has received treatment with Macitentan for DU, median age 59 years (IQR 51-68), 80% female, with a median Rp and DU duration of 56 (IQR 14-214) and 25 (IQR 9-215) months (Table 1). Eight patients were diagnosed with limited SSc; anti-nuclear abs, anti-centromere abs and anti-phospholipidic abs were positive in 90%, 80% and 20% of the patients. Most patients (90%) had received previously treatment with Bosentan, and the reason for withdrawal was inefficacy in 4 cases (44%) and adverse effects (liver toxicity) in 5 (56%). 8 patients had received Intravenous prostanoids with no response. In the beginning of Macitentan the number of DU was 5.5 (IQR 2.3-6) and digital gangrene was reported in one case. Two patients were treated with Macitentan in monotherapy, 6 in combination with calcium antagonists and 2 received triple therapy (Macitentan + Calcium antagonists + PDE5 inhibitor). Just one patient stopped the treatment for adverse effects (lower limb edema). Median follow-up of patients who didn't discontinue the treatment was 3.9 (IQR 2.4-5.7) years. 78% (7/9) of patients had a sustained complete response and 22% (2/9) had a partial response.
Conclusion: Our data show that Macitentan is an effective agent for ischemic digital refractory ulcers in patients suffering from SARDs with a favorable safety profile in clinical practice.

AB0922 CLINICAL CHARACTERISTICS AND CLINICAL OUTCOME OF SYSTEMIC SCLEROSIS OVERLAP SYNDROME (SSC-OS) IN TURKISH PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Lungs, Systemic sclerosis, Epidemiology

I. Vasi[1], R. C. Kardaş[2], R. Duran[3], B. Özkızıltaş[3], D. Yildirim[3], G. T. Alp[4], A. Avanoglu Guler[3], H. Karadeniz[3], H. Küçük[3], A. Erden[3], B. Göker[1], A. Tufan[2], M. A. Ozturk[3]. *[1]Gazi University, Department of Medicine, Division of Rheumatology, ANKARA, Turkey*; *[2]Gazi University, Department of Medicine, Division of Rheumatology, Ankara, Turkey*; *[3]Gazi University, Department of Medicine, Division of Rheumatology, Ankara, Turkey*; *[4]Gazi University, Department of Internal Medicine, Ankara, Turkey*

Background: Systemic sclerosis (SSc, scleroderma) is a systemic autoimmune connective tissue disease (CTD). Disease subsetting specific to the extent of skin sclerosis subdivides SSc into the three following main subtypes: (1) limited cutaneous SSc (lcSSc); (2) diffuse cutaneous SSc (dcSSc) and (3) sine scleroderma SSc (ssSSc). Any SSc subgroup can also have features of one or more other CTDs [1]. When a patient has features of any two CTDs, this satisfies the criteria for SSc-overlap syndrome (SSc-OS)[2].
Objectives: The aim of this study was to determine the clinical, serological features and clinical outcome of systemic sclerosis (SSc) and SSc-overlap syndromes(SSc-OS).
Methods: This study included patients enrolled in the Gazi University Systemic Sclerosis Cohort registry during January 2005 to December 2022. SSc-OS was defined as SSc patients who also met criteria for rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), dermatomyositis (DM), polymyositis (PM) and Sjogren syndrome. Baseline and last follow up characteristics were compared between SSc and SSc-OS.
Results: 41 patients (age 54.0 ± 15.8 years, 90% female, disease duration 8.2 years, 43.9% diffuse cutaneous subset, 26.8% limited cutaneous subset, 41.4 % anti-Scl-70 positivity) were included. SSc-OS were classified 29.2% of patients and 4.8%, 7.3%, 2.4%, and 14.6% of patients were classified as SSc-RA, SSc-SLE, SSc-myositis, SSc-Sjogren. SSc-OS had a higher prevalence of arthralgia/arthritis(p=0.029) and SSc had a higher prevalence of interstitial lung disease(p=0.014).
Conclusion: SSc-OS is associated with prevalance of arthralgia/arthritis. SSc-Sjogren syndrome is the most common overlap syndrome. Primary diffuse SSc patients had a greater decrease DLCO compared with the SSc-overlap patients.

Sangchan[4]. *[1]Khon Kaen University, Department of Medicine, Faculty of Medicine, Khon Kaen, Thailand*; *[2]Ministry of Public Health, Department of Health, The Health Intervention and Technology Assessment Program (HITAP), Nonthaburi, Thailand*; *[3]Khon Kaen University, Department of Statistics, Faculty of Science, Khon Kaen, Thailand*; *[4]Khon Kaen University, Special Medical Center, Srinagarind Hospital, Faculty of Medicine, Khon Kaen, Thailand*

Background: Systemic sclerosis (SSc) patients often become refractory to proton pump inhibitor (PPI)—a standard treatment for gastroesophageal reflux disease (GERD)—and intolerant to PPI in combination with domperidone. PPI with alginic acid is an alternative treatment option, but alginic acid is costly.
Objectives: We compared the costs and effectiveness of alginic acid plus proton pump inhibitor (PPI) versus standard treatments (PPI with/without antacids as needed and lifestyle modifications) for gastroesophageal reflux disease (GERD) in systemic sclerosis (SSc) patients unsuitable for, or intolerant to, domperidone.
Methods: An economic evaluation using the Markov model was conducted among SSc patients between 40 and 65 with GERD, having a partial or non-response to 4 weeks of standard-dose omeprazole (40 mg/d) and being unsuitable for or intolerance to domperidone. Using a societal perspective, we computed the incremental cost-effectiveness ratios (ICERs) in terms of Thai baht (THB) per quality-adjusted life-years (QALY) between a combination of alginic acid plus PPI and standard treatment for GERD. The lifetime time horizon was used.
Results: The ICER for alginic acid plus PPI versus standard treatments was 377,101THB/QALY. According to the one-way sensitivity analysis, the cost of alginic acid was the most impactful parameter. If the market prices of alginic acid plus PPI were reduced by 61%, this treatment option would become cost-effective at the willingness-to-pay threshold of 160,000THB/QALY (34.71 THB/USD data on 3 December 2022). Furthermore, if alginic acid were included in the public health insurance program, the national budget would be increased by 66,313THB per patient resulting in an overall budget increase of 5,106,101 to 8,885,942THB compared to the standard treatment.
Conclusion: Alginic acid plus PPI does not represent good value for money compared to the standard treatment among such SSc patients in Thailand unless its price is reduced significantly.

AB0924 SMART PILL TECHNOLOGY PROVIDES SAFE AND EFFECTIVE ASSESSMENT OF GASTROINTESTINAL FUNCTION IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Gastrointestinal tract, Systemic sclerosis

I. Barua[1], H. Fretheim[1], H. Didriksen[1], M. N. Carstens[1], M. Pesonen[2], V. Sarna[3], Ø. Midtvedt[1], Ø. Molberg[1], A. M. Hoffmann-Vold[1]. *[1]Oslo universitetssykehus HF, Rikshospitalet, Department of Rheumatology, Oslo, Norway*; *[2]Oslo*

universitetssykehus HF, Rikshospitalet, Oslo Centre for Biostatistics and Epidemiology, Oslo, Norway; [3]*Oslo universitetssykehus HF, Rikshospitalet, Department of Gastroenterology, Oslo, Norway*

Background: Gastrointestinal dysmotility is a common complication in systemic sclerosis (Sc) patients including slow colonic transit leading to gastrointestinal tract (GIT) symptoms. Fecal microbiota transplantation (FMT) with ACHIM did not improve lower or total GIT symptoms in SSc patients compared to placebo enrolled in the Norwegian multicenter, double-blind, randomized, placebo-controlled ReSScue trial. It is unclear if transit times were impacted by FMT. The SmartPill wireless motility capsule (SmartPill®), measures transit times and peristalsis in patients and was given to a subgroup of patients in the ReSScue trial.
Objectives: To estimate gut transit time and safety of SmartPill® in patients with SSc and predominant lower GIT symptoms.
Methods: Ten patients from the ReSScue trial were included in this SmartPill substudy. The patients followed the required diets and procedures prior swallowing a pH calibrated SmartPill capsule. Two infusions of ACHIM or placebo at week 0 and 2 were given to all participants. SmartPill was given by all participants at week 0 and 11. The primary outcome of this study was the change of transit times in patients with ACHIM and placebo from week 0 to week 11 and safety.
Results: Ten patients were enrolled to receive a SmartPill®, six patients in the placebo group and four patients in the ACHIM group. Baseline characteristics in the placebo and ACHIM groups were comparable, with 2 (20%) males and 8 (80%) females, 90% with limited systemic sclerosis and a median age of 51 and 53, respectively. At week 0 the placebo group had a whole gut transit time (WGT) 35.8 hours ± 13.2 (mean ± SD) compared to 40 hours± 8.1 in the ACHIM group. At week 12 the WGT for the placebo group was 38.1 hours±7.2 compared to 73.5 hours±49.8 in the ACHIM group. There was no significant difference in the change of estimated gut transit time between placebo and ACHIM group regarding whole gut transit time, p=0.158 for week 0 and p=0.752 for week 12. (Figure 1). One patient experienced a delayed transit time after receiving ACHIM, with 254 hours from ingestion to body exit for the SmartPill®. In four cases, the activation of the capsule failed. These patients were included in the trial with new, functional capsules. The reason for the malfunction remained unclear.
Conclusion: FMT with ACHIM did not improve gastrointestinal transit times in patients with SSc and lower GIT symptoms. Our study demonstrates that the SmartPill® is safe to use for patients with SSc, but we experienced a high number of malfunction.

AB0925 DERMATOMYOSITIS AS A PARANEOPLASTIC SYNDROME OF TONSILLAR CARCINOMA: FIRST REPORTED CASE IN THE UK

Keywords: Myositis, Malignancy, Imaging

A. Younas[1], R. Asif[2], R. Davies[1]. [1]*University Hospital of Wales, Rheumatology, Cardiff, United Kingdom*; [2]*Aneurin Bevan UHB, Rheumatology, Newport, United Kingdom*

Background: Dermatomyositis (DM) has a strong association with Malignancy, with one study showing risk up to five times that of the general population and is the leading cause of death [1]. Occult cancer can result in resistant disease, and early diagnosis can improve patient outcomes. We report a case of occult tonsillar cancer associated with severe DM.
Objectives: Our report sought to report the presentation of occult tonsillar cancer with severe dermatomyositis.
Methods: A 60-year-old usually fit and well gentleman presented with a 4-month history of progressive proximal muscle weakness of upper and lower limbs and a characteristic erythematous rash suggestive of DM. Investigations showed a CK of 6813 U/L typical myositis changes on MRI and positive myositis specific Anti-NXP ab. An initial malignancy screen, including CT TAP, was negative for underlying malignancy. He was commenced on oral Prednisolone at 1mg/kg and was discharged with urgent rheumatology follow-up. However, he was admitted a week later with severe dysphagia and ongoing muscle weakness. An urgent OGD excluded a structural upper GI lesion, and Nasogastric feeding was commenced. He was administered IV methyl Pred 500 mg over three days along with IVIG (2g/kg) but failed to respond with ongoing muscle weakness and dysphagia. A subsequent PET scan showed a right tonsillar mass, later confirmed as tonsillar cancer on biopsy. Following this, the ENT team proceeded with robotic surgery and radical surgical resection of tonsillar cancer. We repeated IVIG every four weeks along with IV Methyl pred 50 mg OD and a PEG tube inserted to meet his nutritional needs. Gradually he started to show signs of improvement with improved mobility, muscle strength, and normal CK levels. He received six cycles of IVIG, and azathioprine was commenced with the weaning of prednisolone to 10 mg after discharge. 6 months after the initial presentation, he mobilized independently with improved swallowing to liquids and a soft diet.
Results: Head and neck cancers are rarely associated with Dermatomyositis, with tonsillar cancer extremely rare. To our knowledge, this is the first reported case of occult tonsillar cancer associated with treatment-resistant DM. Detecting occult cancer can be difficult, especially in cases where the DM symptoms precede cancer diagnosis. The usual first-line cancer screening in inflammatory myopathies includes CT TAP, which can miss a malignancy of the head and neck region. Current evidence does not show a definite benefit of PET scanning over conventional CT for cancer identification [2]. But PET scanning can be very useful in selected patients with a high index of clinical suspicion. Recently published BSR guidelines recommend considering PET scanning for cancer screening [3].
Conclusion: Increased vigilance is required to look for occult cancer, including head and neck cancers, especially in patients with treatment-resistant DM. PET scanning can potentially aid in early cancer diagnosis and guide definitive treatment.

AB0926 LA DISFAGIA EN LA ESCLEROSIS SISTÉMICA SE ASOCIA CON PROBLEMAS NUTRICIONALES Y MALA CALIDAD DE VIDA

Keywords: Systemic sclerosis, Patient reported outcomes, Gastrointestinal tract

L. Cano Garcia[1], A. Garcia Studer[1], F. Ortiz-Márquez[1], I. Ureña[1], N. Mena-Vázquez[1], S. Manrique Arija[1]. [1]*Hospital Regional Universitario de Málaga; Instituto de Investigación Biomédica de Málaga (IBIMA)., Rheumatology, Málaga, Spain*

Background: Digestive involvement is one of the most prevalent manifestations of systemic sclerosis (SSc) with great significance for the health and quality of life of patients.

Objectives: To describe the prevalence of dysphagia and the nutritional status of a series of patients with SSc.

Methods: Design: Cross-sectional descriptive study. Participants: consecutive recruitment of patients with SSc (ACR/EULAR 2013 criteria) followed up in our unit. Follow-up of these patients is carried out every 3 to 6 months in consultation and all patients were registered in a database. 90% of the patients accepted and signed the consent, the rest refused due to travel or work difficulties. Variables: The main variable was dysphagia, defined according to the EAT10 questionnaire (positive ≥3). The dysphagia risk factors evaluated were: malnutrition according to the Mini Nutritional Assessment (MNA) (continuous: 0-14, considering 14 better nutritional status), sarcopenia defined according to the European Working Group on Sarcopenia in Older People (EWGSOP) criteria, prealbumin, polypharmacy (if they take >3 drugs), weight loss of at least 1 kg in the last 3 months, quality of life according to EQ-5D and Steinbrocker functional status. Statistical analysis: descriptive and logistic regression (VD: dysphagia) to identify associated factors.

Results: 52 patients were included, of whom 51 (98.1%) were women, with a mean (SD) age of 60.8 (11.0) years. 32/52 patients (61.5%) had dysphagia (EAT≥3) and 12/52 patients (23.1%) were referred to endocrinology for severe dysphagia (EAT≥20) Table 1. Patients with dysphagia compared with the rest had sarcopenia more frequently (37.5% vs 0.0%; p=0.001), weight loss (65.6% vs 20.0%, p= 0.004) and more polymedicated (87.5% vs 60.0%, p=0.022). Likewise, patients with dysphagia (EAT≥3) had lower values (mean [SD]) of nutrition per MNA screening (11.0 [1.2] vs 13.1 [2.3]; p = 0.001), of EQ5D (0.5 [0.2] vs 0.7 [0.2]; p = 0.004), EVA-EQ5D (48.6 [22.3] vs 62.5 [17.6]; p = 0.023) and in Steinbrocker's functional grade (2.3 [1.0] vs 1.3 [0.6]; p = 0.001). The multivariate analysis identified that MNA screening (0-14) (OR [95% CI], 0.511 [0.317-0.824]; p=0.006) and EQ5D (OR [95% CI], 0.965 [0.932-0.998]; p= 0.036) (R2=0.397) were independently associated with dysphagia (EAT ≥3).

Conclusion: Dysphagia is a common problem in systemic sclerosis and is associated with poorer quality of life and a lower probability of reaching a normal nutritional status. The serious nutritional implications associated with dysphagia must be diagnosed in order to intervene nutritionally in these patients.

Table 1. Clinical-epidemiological characteristics of the 52 patients in SSc

Variable	SS n=52
Woman n (%)	51 (98,1%)
Age mean (SD)	60,8 (11,0)
Limited skin patern n (%)	40 (76,9%)
Disseminated skin patern n (%)	12 (23,1%)
DILD n (%)	17 (32,7%)
HTAP n (%)	5 (9,6%)
Anti-Centromere antibodies n (%)	28 (53,8%)
Anti-Sl70 antibodies n (%)	10 (19,2%)
Other antibodies n (%)	9 (17,3%)
Sarcopenia n (%)	12 (23,1%)
MNA Normal nutritional status n (%)	34 (64,5%)
MNA Risk of malnutrition n (%)	17 (32,7%)
MNA malnutrition n (%)	1 (1,9%)
Weight loss >1kg in the last 3 months n (%)	25 (48,1%)
Polypharmacy n (%)	12(23,1%)
Steinbrocker mean (SD)	1,94 (1,03)
EQ5D mean (SD)	0,593 (0,25)
VAS EQ5D mean (SD)	54 (21,56)

AB0927 SYSTEMIC SCLERODERMA: ABOUT 60 CASES

Keywords: Autoantibodies, Systemic sclerosis, Rare/orphan diseases

A. Taouch[1], W. Ammouri[1], F. Ibourk el Idrissi[1], W. Chawad[1], N. Mouatassim[1], H. Khibri[1], M. Maamar[1], H. Harmouche[1], Z. Tazi Mezalek[1], M. Adnaoui[1]. [1]*Mohamed V university, Souissi Rabat, Department of Internal Medicine-Clinical Hematology, RABAT, Morocco*

Background: Systemic scleroderma is a relatively rare and potentially serious and debilitating connectivitis. It also seems to be different from other diseases in this group, by its pathogenic process that involves several successive or concurrent disorders involving fibroblastic, vascular and dysimmune phenomena. Some impairments condition the functional prognosis and may affect the life-threatening prognosis.

Methods: We conducted a 10-year, single-centric retrospective study (2011 and 2021) of 60 patients followed up for systemic scleroderma at the Internal Medicine Department of the Ibn Sina Hospital in Rabat. We analyzed the statistical data using JAMOVI 2. 2. 5.

Results: We collected 60 files. The sex ratio (F/H) was 5 (50 women/ 10 men), with a mean age of 51±12. 6 (26-76 years). The mean time to diagnosis was 9. 5±38. 9 months (1–180 months). General signs were present in 23 cases (38. 3%) Skin involvement was constant. Raynaud's syndrome was reported in 49 cases (81. 7%) sclerodactyly in 23 cases (38. 3), trophic disorders in 19 cases (31. 7%), telangiectasis in 13 cases (21. 7%) and subcutaneous calcinosis in 5 cases (8. 3%). Rodnan's modified score at admission ranged from 1 to 47/51. Joint manifestations were noted in 36 patients (60%). Lung involvement was objectified in 40 cases (66. 7%), revealing in 22 cases (36%). Interstitial syndrome was observed in 13 cases (21. 7%). Respiratory functional explorations revealed a restrictive syndrome in 23 cases (40%). Chest CT showed diffuse interstitial lung disease in 29 cases (48. 3%), pulmonary fibrosis in 12 cases (20. 3%). Cardiac involvement was detected in 26 cases (43. 3%): pulmonary arterial hypertension in 20 cases (33. 3%); pericarditis in 5 cases (8. 3%); heart failure in 5 cases (8. 3%); and rhythm disturbance in 1 case. Digestive involvement was noted in 17 patients (28. 3%), dominated by oesophageal involvement in all cases, associated with gastric involvement in 6 cases (10%). duodenal garstro esophageal fibroscopy objectified esophagitis and its complications in 17 cases (28. 3%). Neurological involvement was present in 3 cases. Kidney damage was absent from our series. Inflammatory syndrome was present in 37 cases. Anti-nuclear antibodies were positive in 42 cases, anti-Scl70 in 28 cases, anti-centromere in 5 cases, anti-RNP in 6 cases and anti-PM-Scl in 6 cases. An association with another autoimmune disease was noted in 18 patients: Gougerot Sjorgen Syndrome was noted in 5 cases, rheumatoid arthritis in 5 cases, disseminated lupus erythematosus in 5 cases, anti-phospholipid syndrome in 4 cases, primary biliary cirrhosis in 2 cases, hashimoto's thyroiditis in 2 cases, inflammatory myopathy in 1 case and Bullous linear dermatosis to igA in 1 case. Neoplasmic pathology occurred during progression in 3 cases: 1 case of marginal lymphoma and 2 cases of lung cancer. Colchicine was prescribed in 24 cases, D-Penicillamine in 1 case, calcium inhibitors in 31 cases. Corticosteroid therapy was prescribed in 29 cases. Forty-five patients received immunosuppressive therapy and three patients received anti-CD20 (Rituximab) for one patient indicated for rheumatoid arthritis. Complications of immunosuppressive therapy were predominantly infection and impaired liver function. The outcome was favourable in the majority of patients. Late relapses > 6 months were reported in 12 patients, including 8 pulmonary relapses, 1 skin relapses and 1 muscle relapses. The outcome of lung disease was unfavourable in 3 cases. And six patients died. We analyzed several associations such as: lung and heart disease, lung and digestive disease, and heart and digestive disease, the only significant revenue was the association of lung and cardiac disease that was significant (p = 0. 025)

Conclusion: The results of our study are consistent with the literature and confirm the predominance of women and the relatively high incidence of skin, joint, lung and cardiac involvement. Vital prognosis is conditioned by severe visceral damage, especially pulmonary and cardiac.

AB0928 USE OF RITUXIMAB IN SYSTEMIC SCLEROSIS PATIENTS WITH PULMONARY AND DIFFUSE CUTANEOUS INVOLVEMENT. A SERIES OF 15 CASES

Keywords: Real-world evidence, Systemic sclerosis

F. Ortiz Sanjuan[1], E. Grau García[1], C. Riesco Barcena[1], H. Charia[1], A. V. Huaylla Quispe[1], I. Martínez Cordellat[1], L. Mas Sanchez[1], P. Muñoz Martinez[1], C. Nájera Herranz[1], R. Negueroles Albuixech[1], J. E. Oller Rodríguez[1], D. Ramos Castro[1], A. M. Torrat Noves[1], E. Tovar-Sugrañes[1], E. Vicens Bernabeu[1], I. Cánovas Olmos[1], S. Leal Rodriguez[1], L. Gonzalez Puig[1], J. Ivorra Cortés[1], J. A. Román Ivorra[1]. [1]*Hospital Universitario y Politécnico La Fe, Rheumatology, Valencia, Spain*

Background: Systemic sclerosis (SSc) is often difficult to treat and the evidence in support of many of the usual therapies is limited. Abnormalities in B-cell function in SSc are thought to play a role in disease pathology. Furthermore, B-cell infiltrates have been demonstrated in both the skin and lung specimens in SSc. Rituximab (RTX) is a chimeric monoclonal antibody inhibiting CD20-mediated B-cell proliferation and differentiation that has shown promising results for pulmonary and cutaneous involvement of SSc.
Objectives: Our aim was to assess RTX for pulmonary and diffuse cutaneous involvement in real-life patients diagnosed of SSc.
Methods: Retrospective observational study of a wide and unselected series of patients diagnosed as SSc from a single university hospital from 2011 to 2022. Patients were classified as SSc following 2013 ACR/EULAR classification criteria. We reviewed pulmonary function through conventional spirometry and diffusing capacity of lung for carbon monoxide (DLCO). Pulmonary involvement was also assessed by high-resolution chest-CT test. Cutaneous involvement was assessed by modified Rodnan skin score (MRSS).
Results: We included 15 patients with a median [range] age (at the onset of RTX) of 53 [41-78] years (80% women; 20% men). The median [range] of time since diagnosis and treatment onset was 3 [0-12] years. At the diagnosis of SSc, no one of our patients evidenced a restrictive ventilatory pattern. DLCO was below normal limits in 12 patients (80%). Small airway obstruction expressed according decreased maximal (mid-) expiratory flow (MMEF) 25-75 was present in 1 patient (6.7%). Regarding cutaneous involvement, median MRSS at diagnosis was 18.3 [range 4-26]. RTX intravenous treatment regimen employed was 1000 mg (Day 1, followed by 1000 mg on day 15), with a repeat cycle every 6 months if required. After a median [range] follow-up period of 31 [6-100] months, 12 (80%) patients completed a total of 4 RTX cycles. An analysis of the pulmonary function showed that, after RTX, DLCO decreased in 2 of 15 patients (13.3%) and none presented worsening of MMEF 25-75. In all patients there was an improvement of cutaneous involvement. After a median follow-up of 31 [6-100] months during RTX therapy none of the patients presented any new relapse of cutaneous involvement or MRSS progression. The mean difference between MRSS measurement before and after RTX was 6.4±1.2. Only 2 of the patients (13.3%) had to discontinue RTX in the first term due to infusion-related reaction. After RTX treatment, 4 patients (26.7%) died (prostate cancer, SARS-COV-2 pneumonia, sudden cardiac arrest and ictus) has been well tolerated and no severe infections were reported.
Conclusion: In our experience, RTX seems to be a great option in real-life for those patients with pulmonary and diffuse cutaneous involvement due to SSc. However, cardiovascular, infectious and neoplastic complications should be assessed.

AB0929 CLINICALLY AMYOPATHIC DERMATOMYOSITIS (CADM) WITH ANTI–MELANOMA DIFFERENTIATION-ASSOCIATED GENE 5 ANTIBODY POSITIVE: UNDERSTANDING IT'S CLINICAL PRESENTATION AND EXTENT OF LUNG INVOLVEMENT

Keywords: Myositis

T. Mahadevan[1], K. L. Ng[1], M. H. Nordin[1], A. Mohamed Ismail[1]. [1]*Hospital Raja Perempuan Zainab II, Rheumatology, Kelantan, Malaysia*

Background: CADM is a subset of dermatomyositis with cutaneous manifestation in the absence of myositis. Myositis-specific autoantibodies (MSA) permits the delineation of homogenous subgroups of DM. CADM associated with anti-melanoma differentiation-associated gene-5 antibody positive (anti-MDA5+) is typically characterized by the presence of dermatomyositis (DM) skin rash and polyarthralgia and interstitial lung disease (ILD)
Objectives: To elaborate on clinical features and management of two patients presenting with MDA-5 positive CADM and associated interstitial lung disease.
Methods: Patient's clinical notes including laboratory results and images were reviewed.
Results: First Case: 59-year-old lady with underlying hypertension presented with inflammatory symmetrical polyarthritis associated with high rheumatoid factor value for 5 months duration. She was initially diagnosed as seropositive Rheumatoid arthritis and treated with T. Methotrexate 15mg/weekly. She achieved clinical remission within two months of treatment. However, eight months later, she developed progressive shortness of breath and reduce effort tolerance (MMRC III). Examination revealed palmar papules and periungual erythema on bilateral hands, and fine crepitations on lung auscultation. No proximal myopathy and active synovitis. ANA 1:1280 (speckled) and MSA panel revealed MDA-5positive.She was unable to perform the lung function test (weak blow) and high-resolution computed tomography (HRCT) showed fibrotic nonspecific interstitial pneumonia (NSIP). She was started on high dose prednisolone (1mg/kg) and oral cyclosporin 100mg daily. One month post treatment, her reduced effort tolerance improved (MMRC II).
Second Case: 32-year-old lady presented with symmetrical arthritis of proximal interphalangeal joints for one year associated with diffuse erythematous rash over the face and neck for five months. She had one month history of steroid exposure. No associated proximal weakness or reduced effort tolerance. Examination revealed hyperpigmentation over the face and Gottron papule over bilateral hands. Auscultation of lung was clear and no synovitis was noted. ANA 1:80 (speckled) and MSA panel revealed MDA-5 positive. Lung function test was normal, however, high-resolution computed tomography (HRCT) revealed interstitial lung disease with organizing pneumonia. She was started on prednisolone 0.3mg/kg for her cutaneous manifestation. Assessment four months later, showed good effort tolerance and complete resolution of cutaneous manifestation.
Conclusion: Myositis-specific autoantibodies have been found to correlate with clinical features and have also served as a diagnostic and prognostic marker. We suggest all patients with MDA-5 positive to undergo CT imaging irrespective of their respiratory symptoms.

AB0930 THE VALUE OF THE CURRENT DIAGNOSTIC TOOLS IN THE DIAGNOSIS OF INFLAMMATORY MYOPATHIES: A MULTICENTRE STUDY

Keywords: Diagnostic Tests, Myositis, Biomarkers

E. Kaltsonoudis[1], E. Pelechas[1], T. Zoi[1], M. Migkos[1], T. Dimitroulas[2], N. Kougkas[2], A. Drosos[1], P. Voulgari[1]. [1]*University of Ioannina, Medical School, Rheumatology, Ioannina, Greece*; [2]*Aristotle University of Thessaloniki, Rheumatology, Thessaloniki, Greece*

Background: traditionally, the diagnosis of inflammatory myopathies has been based on clinical signs and symptoms (muscle weakness and characteristic skin involvement, especially in dermatomyositis), increased muscle enzymes, electromyographic findings, skin or muscle biopsy, as well as anti-Jo1 antibodies (antisynthetase syndrome). However, this approach has led to significant diagnostic gaps in atypical cases such as in those of pure lung involvement.
Objectives: to evaluate the diagnostic yield of each procedure in a sample of 61 patients who were diagnosed, followed-up and treated in two tertiary university rheumatology clinics in Greece.

Methods: serum samples tested using a myositis panel (Mi-2α, Mi-2β, Ku, PM-Scl100, PM-Scl 75, SRP, Jo-1, PL-7, PL-12, OJ, EJ, Ro-52, TIF1γ, MDA5, NXP2, SAE1) and muscle enzymes (CK, aldolase, LDH, SGOT, SGPT). Electromyography has been carried out in all patients, whereas in 27 with elevated muscle enzymes or muscle weakness an MRI-guided muscle biopsy has been done. In addition, in 8 patients, a skin biopsy has been performed and in all patients a detailed examination (determination of muscle strength) has been performed in all muscle groups.
Results: in 42 cases the diagnosis has been made after a positive myositis panel, while in 20 cases there was also a histological confirmation. In 8 cases, the diagnosis has been made on the grounds of positive clinical features and characteristic findings on the electromyogram. Only 4 patients have been diagnosed on the basis of histological findings in the absence of other laboratory and clinical findings **(table 1)**. The most common autoantibodies in patients with lung involvement were Jo-1, PL-12 and PL-7.
Conclusion: based on the aforementioned results, a myositis panel seems a reasonable and reliable diagnostic strategy as it improves significantly the diagnostic yield of an inflammatory myopathy. In addition, it gives a diagnostic "alibi" for the therapeutic approaches that otherwise can be administered only by histological confirmation. Finally, in patients with atypical signs and symptoms such as lung fibrosis that cannot be attributed elsewhere, a myositis panel should be performed.

AB0931 NUTRITIONAL STATUS EVALUATED BY BIOELCTRICAL IMPEDANCE IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis

G. Cuomo[1], D. Perretta[1], C. Iandoli[1], C. Di Vico[1], P. Adamo[1]. [1]Seconda Università degli Studi di Napoli, Precision of Medicine, Caserta, Italy

Background: Systemic sclerosis (SSc) is a multi-organ disease with significant morbidity and mortality., Gastrointestinal disorders in patients with SSc may play a significant role in deteriorating nutritional status, sometimes the diagnosis of malnutrition is difficult.
Objectives: The aim of the study was to assess the nutritional status of patients with SSc.
Methods: The study included 87 patients (72 female) with diagnosed SSc, mean age 56.7±12.2 years, median 56 years (range 21-76). Anthropometric measurements were performed in all SSc patients and body composition was assessed using electrical bioimpedance (BIA).
Results: Moderate obesity was diagnosed in 7 patients (8%), mild obesity was diagnosed in 7 patients (8%), over-weight in 29 patients (33%), normal-weight in 40 patients (46%) and 5 (5.7%) patients under-weight. By Spearman Rank Correlation we correlated Fat Free Mass (FFM), Visceral Fat Index (VFI), Total Body Water (TBW), Intra-cellular Water (ICW), Extra-cellular Water (ECW) and Body Mass Index (BMI) with age, use of immunosoppressive drugs (DMARD's), use of OH-clorochine, use of corticosteroids, interstitial lung disease (ILD), activity index (AI), diastolic dysfunction (E/A). The results are reported in table 1.
Conclusion: our study shows the importance of the parameters assessed with BIA, particularly the intra and extra-cellular water composition which may represent a prognostic factor for the development of cardiac and pulmonary fibrosis. There is a need to define that of randomized controlled trials on larger case series. Nutritional disorders are common in patients with SSc. The most common disturbance in nutritional status in SSc patients was overweight/obese, which was present in 50% of patients.

AB0932 LONG-TERM CORTICOSTEROID THERAPY WAS ASSOCIATED WITH SIGNIFICANT LIVER FIBROSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis

G. Cuomo[1], C. Iandoli[1], C. Di Vico[1], D. Perretta[1], R. Ferrara[2], L. Rinaldi[2], R. Galiero[2], A. Caturano[2], F. C. Sasso[2]. [1]*Seconda Università degli Studi di Napoli, Precision of Medicine, Caserta, Italy*; [2]*Seconda Università degli Studi di Napoli, Dipartimento di Scienze Mediche e chirurgiche Avanzate, Caserta, Italy*

Background: Fibrotic changes of the internal organs, such as lungs, heart, kidneys, and gastrointestinal tract, characterize the clinical course of both limited (lcSSc) and diffuse cutaneous SSc (dcSSc), potentially leading to organ dysfunction. However, liver involvement is less defined.
Objectives: In a cross-sectional study we investigated the prevalence and predictors of significant liver fibrosis in patients with systemic sclerosis (SSc) who had no evidence of liver diseases due to heavy alcohol consumption, viral infection, drug.
Methods: A total of 65 SSc patients were recruited, satisfied the 2013 ACR)/(EULAR) classification. In addition to the clinical and laboratory data, modified Rodnan skin score (mRSS), and activity index, video-capillaroscopy, echocardiography, and lung function were analysed. Liver stiffness (LS) was measured using transient elastography to assess the degree of liver fibrosis and 7.4 kPa was adopted as the cut-off value for significant liver fibrosis and liver steatosis with CAP values ≥ 248 dB/m were considered consistent with mild steatosis (S1), ≥268 dB/m with moderate steatosis (S2) and ≥280 dB/m with severe steatosis (s3)
Results: The median age of patients (60 women) was 50.5 years (range 20-80) and the median disease duration was 5.5 years (range 1-10). The median LS value was 4.65 kPa (range 3.1-8.3); the median CAP value was 220.5 (164-327). By Spearman Rank Correlation LS value vs age has a p value 0.02 (CI 95% 0.290.64), vs corticosteroid use has a p value 0.0032 (CI95% 0.179-0.731). On the contrary Cap value vs age has a p value 0.026 (CI 95% 0.04-0.64). Forty-six

(70.8%) patients had no fibrosis (F=0); 17 (26%) had a LS value from 5.2 and 7.4; 3 patient (4.6%) LS>7.4 (F3) significant liver fibrosis. Eight patients (12.3%) had mild liver steatosis (CAP value was ≥ 248 dB/m) and 6 patient (9.2%) had moderate steatosis (S2) (CAP value ≥268 dB/m)

Conclusion: In our study **t**he prevalence of significant liver fibrosis was relatively low (4.6%). Long-term corticosteroid therapy was associated with increased liver stiffness on Fibroscan. T**he** low number of patients is a limitation of the study, we await the data relating to a more representative population.

AB0933 RAYNAUD´S PHENOMENON AND RELATED SYNDROMES CLINIC: CHARACTERIZATION OF NEWLY REFERRED PATIENTS AND DIFFERENCES BETWEEN PRIMARY AND SECONDARY RAYNAUD´S PHENOMENON

Keywords: Autoantibodies, Systemic sclerosis, Diagnostic Tests

A. M. Gomes Correia[1], C. Campinho Ferreira[1], E. Costa[1], D. Esperança Almeida[1], J. Silva[1], J. Neves[1], J. Redondo Costa[1], A. R. Ribeiro[1], M. Cerqueira[1].
[1]*Hospital de Braga, Rheumatology, Braga, Portugal*

Background: The Raynaud´s Phenomenon (RP) and Related Syndromes Clinic was created in the Rheumatology Department at Hospital de Braga in order to provide differentiated health care to the population with RP, emerging as a unique outpatient clinic in the country. The aim of this Clinic is to evaluate patients who present with this clinical manifestation in a prompt and multidisciplinary approach, considering the differential diagnosis between the primary and secondary etiology. In this way, adequate monitoring can be carried out, such as performing a Nailfold Videocapillaroscopy (NVC) and early and targeted therapy instituted.

Objectives: Characterize the individuals evaluated in first RP and Related Syndromes Clinic appointments and determine predictive factors allowing to distinguish primary and secondary RP.

Methods: Retrospective, single center study, including patients who were evaluated in first RP and Related Syndromes appointments between February 2021 and December 2022. Sociodemographic variables, clinical data and the results of the complementary study such as anti-nuclear antibodies (ANA) profile and NVC pattern were analyzed. Statistical analysis of the data was performed using SPSS, using the Chi-square and the t-Test independent samples tests, as appropriate. A p value < 0.05 was considered statistically significant.

Results: Fifty four patients were included (female 88,89%, male 11,11%; mean age 52,48±17,06 years), referred to this clinic with the following main reasons: suspected RP (64,82%), suspected connective tissue disease (CTD) (31,48%) and laboratory tests changes (3,7%). Among these patients, 43 patients had RP: primary in 12 (27,91%) and secondary in 31 (72,09%). A total of 42 NVC were performed: normal pattern in 30,95%; nonspecific changes in 28,57%; early scleroderma pattern in 21,43% and active scleroderma pattern in 19,05%. The diagnosis established in the 54 patients evaluated were: acrocyanosis (1,85%), erythema pernio (7,41%), frostbite (1,85%), Achenbach Syndrome (1,85%), Systemic Sclerosis (SSc) (31,48%) - 11,76% Very Early Diagnosis Of SSc; 5,88% SSc diffuse cutaneous form; 82,35% SSc limited cutaneous form -, undifferentiated CTD (3,70%), primary RP (22,22%) and secondary RP non-CTD (22,22%) - includes patients with RP secondary to tobacco, betablockers, SARS-Cov2 infection or autoimunne thyroiditis. 7,42% of the patients didn´t have RP or a rheumatic disease. Ten patients were discharged, with the remaining patients being followed regularly. Table 1 summarizes the characterization of patients with primary and secondary RP. Comparing patients with primary RP with patients with secondary RP, we found that older age, ANA´s positivity, taking betablockers and an altered NVC pattern was statistically significantly associated with the diagnosis of a secondary RP.

Conclusion: With this work, we emphasize the importance of RP investigation in order to establish a definitive diagnosis and an adequate follow up, showing a higher probability of secondary RP in patients with older age, positive ANA´s and who were taking betablockers. It reinforces, as well, the importance of NVC in the evaluation of patients with RP, as significant differences are found between primary and secondary RP, with scleroderma pattern raising the hypothesis of a secondary RP.

Table 1. Characterization of patients with primary and secondary RP and p-value of statistical tests used to compare patients with primary RP and secondary RP for each variable in study.

	Primary RP (n=12)	Secondary RP (n=31)	p-value

AB0934 SYSTEMIC SCLERODERMA IN MEN: A CASE REPORT OF 10 PATIENTS

Keywords: Epidemiology, Rare/orphan diseases, Systemic sclerosis

A. Taouch[1], W. Ammouri[1], F. Ibourk el Idrissi[1], W. Chawad[1], N. Mouatassim[1], H. Khibri[1], M. Maamar[1], H. Harmouche[1], Z. Tazi Mezalek[1], M. Adnaoui[1].
[1]*Mohamed V university, Souissi Rabat, Department of Internal Medicine-Clinical Hematology, RABAT, Morocco*

Background: Systemic scleroderma is a connective tissue disease that is common in women and characterized by vascular alterations associated with skin fibrosis and visceral manifestations. Several particularities of this connectivitis in men are discussed. We propose to show these particularities in men through 10 cases.

OBJECTIVES:

Methods: We identified 10 cases of systemic scleroderma in men among 60 cases of systemic scleroderma collected for our descriptive restrospective study in the internal medicine department of the IBN SINA University Hospital in Rabat. The search for clinical or subclinical visceral involvement was performed in all our patients.

Results: The average age of the patients was 61 ±14.1 years (extremes: 28-74 years) with a delay in diagnosis of 8 months. General signs were found in 3 patients (30%), the skin involvement was made of diffuse sclerosis in 6 cases (60%) and limited in 4 cases (40%); Raynaud's phenomenon was noted in 7 cases (70%). Pulpal ischemia and digital ulcer were noted in 1 and 3 cases respectively. Telangiectasias in 1 case. Joint involvement was present in half of the cases. Pulmonary involvement was present in 6 cases (60%). Pulmonary fibrosis was found in 1 case. Cardiac involvement was found in 6 cases (60%), of which 4 cases had PAH, one case of pericarditis and one case

of heart failure. Esophageal involvement was found in 4 cases (40%). Biologically, an inflammatory syndrome was noted in 4 patients (40%). Antinuclear antibodies were positive in 7 cases (70%). Anti-Scl70 was detected in 4 cases (40%). Capillaroscopy showed lesions suggestive of organic microangiopathy in 2 cases (20%). 4 of our patients were treated with colchicine. Corticosteroids were prescribed in 2 cases. Half of our patients received immunosuppressive treatment, including 3 cases who received monthly courses of cyclophosphamides with relay by Imurel, and 3 patients received treatment by mycophenolate mofetil, stopped in one patient due to hepatic cholestasis. The association with autoimmune diseases was noted in 2 patients, including one with rheumatoid arthritis and one with primary biliary cholangitis 2 cases of neoplasia were observed in our series, the first one was a marginal zone lymphoma and the second one was a pulmonary adenocarcinoma. 3 deaths were reported, one by pulmonary embolism, and the 2 patients who presented a neoplastic pathology.

Conclusion: Despite the small number of our patients, our results agree with those of the literature. The male sex seems to be associated with more severe forms with a shorter diagnostic delay, diffuse skin involvement, severe Raynaud's phenomenon, and early and severe pulmonary involvement.

AB0935 THE MIMIC THAT CAUGHT EVERYONE BY SURPRISE!

Keywords: Skin, Systemic sclerosis, Rare/orphan diseases

K. Kishor[1], P. Dogga[1], S. Mukherjee[1], A. Krishnan[1], A. Wakhlu[2]. *[1]King George's Medical University, Clinical Immunology and Rheumatology, Lucknow, India; [2]Apollomedics Superspeciality Hospitals, Clinical Immunology and Rheumatology, Lucknow, India*

Background: 57-year-old gentleman, a previous smoker, presented with a 12-month history of gradually progressive anasarca that started initially with bilateral lower limbs and involved face, abdomen and entire body over 3-4 months. Four months into his illness, the patient noticed skin changes in the form of hyperpigmentation initially over anterior chest that progressed to involve the face, bilateral upper limbs, abdomen, and lower limbs over next 3 months. It was associated with increased friability, subcutaneous oedema, and spontaneous ecchymosis. Gradually he developed progressive motor weakness, initially in both upper limbs proximally which progressed to involve distal, bilateral lower limbs and trunk with sparing of bowel and bladder functions severely limiting his activities of daily living. Over the next 15 days patient became breathless with rapidly worsening dyspnoea of exertion, dry cough and left sided pleuritic chest pain. There was history of loss of appetite and significant loss of weight 18 kgs over 4 months. General physical examination was suggestive of pallor, diffusely hyperpigmented and fragile skin over the face, neck, upper limbs, hands, back, anterior abdomen, lower limbs with multiple ecchymotic spots and subcutaneous edema with anasarca. Breath sounds were decreased bilaterally over intrascapular, axillary, infra-axillary areas and JVP elevated on Cardio-Respiratory system examination. CNS examination revealed bilateral external ophthalmoplegia with pure motor quadriparesis involving limbs and trunk without sensory, cranial nerve or autonomic involvement, Generalised wasting with asymmetric swelling over right shoulder was seen with reduced active and passive range of movements.

Objectives: Differentials:

1)Scleredema

2)Diffuse cutaneous systemic sclerosis

Methods:

CBC	12/4800/170
Total protein/albumin	6.1/3(g/dl)
ANA/ENA	negative
Urine R/M	normal
FreeT4/TSH/FSH/ Prolactin/HbAIC	normal
CECT chest+ abdomen	B/ pleural effusion with Hepatosplenomegaly
Pleural fluid	Transudative with negative malignant cytology
NCS	Sensorimotor axonal polyneuropathy
SPEP	Light chain myeloma with predominant IgG lamba
Serum free lambda chains	50(5-26)
Serum VEGF	658 (0-200 pg/ml)
Skin biopsy	Amyloidosis (Congo Red stain positive)
Bone marrow exam	Scattered CD 138 positive plasma cells
2D Echo and Cardiac MRI	Restrictive cardiomyopathy
MRI right shoulder	diffuse contrast enhancement in all muscles of right shoulder with subcutaneous edema and scattered fatty changes?infiltrative

Results:

Final diagnosis:

POEMS syndrome with primary amyloidosis.

International Myeloma Working Group criteria fulfilled:

Mandatory criteria-

Polyneuropathy

Monoclonal plasma cell proliferative disorder

Atleast 1 major criteria:

Elevated VEGF levels

Minor criteria:

Organomegaly

Extravascular volume overload

Skin changes

Hematological involvement

Conclusion: The patient was started on treatment after Clinical haematology reference but died due to cardiogenic shock. This interesting case highlights POEMS as a great mimic of changes associated with various autoimmune disorders including scleroderma, SLE and vasculitis syndromes.

Spondyloarthritis - treatment

AB0936 IMPACT OF DIFFERENT BDMARDS ON PATIENT REPORTED OUTCOMES IN AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC REVIEW OF THE LITERATURE AND META-ANALYSIS

Keywords: bDMARD, Pain, Spondyloarthritis

E. Gadon[1], T. Loupret[1], C. Lemaçon[1], P. Bertin[1], P. Vergne-Salle[1]. *[1]CHU Limoges, Rheumatology, Limoges, France*

Background: Pain, fatigue and altered quality of life are frequent complaints in axial spondyloarthritis (axSpA), with an impact on disease activity evaluation, regardless of radiographic or non-radiographic phenotype. No study compares face to face the effects of biologic DMARDs (bDMARDs) on patient reported outcomes (PROs).
Objectives: To evaluate the impact of biologic DMARDs (bDMARDs: anti-TNF and anti-IL17) on three PROs (pain, fatigue, quality of life) in patients with axial spondyloarthritis (axSpA).
Methods: A systematic review was performed in PubMed, Embase until May 2022, and abstracts from EULAR and ACR meetings for the past 3 years. The search included all randomized controlled trials of bDMARDS with outcomes reporting data on pain ("total back pain", "nocturnal back pain"), fatigue (FACIT-F) and quality of life (ASQoL and SF36 PCS and MCS) in patients with axSpA.
Statistical analysis used the inverse variance method to obtain results as mean differences, which were visualized by forest plot. Variation between studies was assessed by calculating the heterogeneity (I^2) with Cochran's Q test.
Results: A total of 25 studies were included in the final analysis, with a total number of 8457 patients. Compared to placebo, treatment with bDMARDs was associated with a significant improvement in pain, fatigue and quality of life. The mean differences were -1.47 (95% CI (-1.72, -1.22)) for total back pain, -1.67 (95% CI (-2.06, -1.28)) for nocturnal back pain, 4.47 (95% CI (3.23, 5. 72)) for FACIT-F, -2.59 (95% CI (-2.68, -2.49)) for ASQoL, 3.68 (95% CI (3.21, 4.15)) for SF36 PCS and 2.79 (95% CI (1.83, 3.75)) for SF36 MCS. For the subgroup analysis comparing the different bDMARDs, the effects on pain were numerically superior with anti-TNF, but the difference was not significant because of the confidence intervals overlapping. There was no difference for the other PROs between anti-TNF and anti-IL17. Heterogeneity was weak except for the "nocturnal back pain" scale. For the subgroup analysis comparing axSpA phenotypes, the improvement of PROs on bDMARDs between radiographic and non-radiographic axSpA was not different, except for the mental component of the SF36 score less improved in the non-radiographic axSpA.
Conclusion: bDMARDs (anti-TNF and anti-IL17) significantly improve pain, fatigue and quality of life compared to placebo in patients with axSpA. No significant difference was observed between anti-TNF and anti-IL-17, nor between radiographic and non-radiographic axSpA, except for the mental component of the SF36.

AB0937 TOFACITINIB EFFICACY AND SAFETY IN PATIENTS WITH ANKYLOSING SPONDYLITIS BY BASELINE C-REACTIVE PROTEIN LEVELS: A POST HOC ANALYSIS

Keywords: Randomized control trial, Targeted synthetic drugs, Spondyloarthritis

A. Deodhar[1], X. Baraliakos[2], M. Magrey[3], L. S. Gensler[4], A. V. Thorat[5], C. Kinch[6], S. Pemmaraju[7], M. J. Cadatal[8], P. Nash[9]. *[1]Oregon Health & Science University, Division of Arthritis and Rheumatic Disease, Portland, OR, United States of America*; *[2]Rheumazentrum Ruhrgebiet Herne, Ruhr-University, Internal Medicine and Rheumatology, Bochum, Westphalia, Germany*; *[3]Case Western Reserve University/University Hospitals, Division of Rheumatology, Cleveland, OH, United States of America*; *[4]University of California at San Francisco, Department of Medicine, Division of Rheumatology, San Francisco, CA, United States of America*; *[5]Pfizer Inc, Inflammation and Immunology, Melbourne, Australia*; *[6]Pfizer Canada ULC, Inflammation and Immunology, Kirkland, QC, Canada*; *[7]Pfizer Inc, Biostatistics, Bengaluru, Karnataka, India*; *[8]Pfizer Inc, Clinical Affairs, City of Makati, Luzon, Philippines*; *[9]Griffith University, School of Medicine, Brisbane, Queensland, Australia*

Background: Elevated baseline (BL) C-reactive protein (CRP) levels can predict treatment response in patients (pts) with ankylosing spondylitis (AS). Tofacitinib is a Janus kinase inhibitor for the treatment of AS.
Objectives: To evaluate the impact of BL CRP levels on tofacitinib efficacy and safety in pts with AS.
Methods: Post hoc analysis of pooled data from placebo (PBO)-controlled, randomised, double-blind trials (NCT01786668, Phase [P]2, 16 weeks; NCT03502616, P3, 48 weeks) in pts with AS on ≥1 dose of tofacitinib or PBO (P3: PBO-treated pts switched to tofacitinib after Week [W]16), by BL CRP: normal (NML) <5 mg/L; elevated (ELV) ≥5 mg/L. Tofacitinib 5 mg twice daily (BID) efficacy was assessed to W12/W16–48 (P3). Endpoints: Assessment of SpondyloArthritis international Society (ASAS) 20/40, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) 50, AS-Disease Activity Score-CRP inactive disease (ASDAS-CRP ID), least squares mean change from BL (Δ) in nocturnal pain and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F). Safety was assessed to W16 and W48.
Results: Of 372 pts, 30.4/69.6% had NML/ELV BL CRP. Both groups had generally similar BL characteristics; more pts with ELV CRP were male, current smokers and had prior biologic disease-modifying antirheumatic drug use. At W12, ASAS20 response was greater for tofacitinib vs PBO in both groups (Figure 1); efficacy maintained to W48. At W12, the difference in response from PBO for tofacitinib was numerically greater for ELV vs NML CRP for ASAS20 (44.7% vs 15.9%), ASAS40 (34.6% vs 17.3%), BASDAI50 (33.8% vs 15.3%), ASDAS-CRP ID (9.5% vs 8.2%), Δnocturnal spinal pain (-2.1 vs -1.4) and ΔFACIT-F (5.2 vs 3.5). For tofacitinib, rates of treatment-emergent adverse events (TEAEs) and infections to W16 trended numerically higher for tofacitinib vs PBO in pts with NML CRP, but were similar to PBO in pts with ELV CRP (Table 1). There were few serious AEs (SAEs), serious infections (SIs) or herpes zoster (HZ) across groups and no deaths. Limitations: small sample size, differences in BL characteristics.

Figure. ASAS20 response rates over time by BL CRP

N, pooled pts in P2 and P3 from BL–W16; N1, pts from P3 from W24–48; SE, standard error

Conclusion: Regardless of BL CRP, at W12, tofacitinib was more efficacious vs PBO; and across endpoints, the differences in response from PBO for tofacitinib were numerically greater in pts with ELV vs NML CRP. Tofacitinib safety rates were consistent with PBO in pts with ELV CRP, but trended higher for tofacitinib vs PBO in pts with NML CRP.

Background: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A.
Objectives: To report Week (Wk) 0–16 safety of BKZ and placebo (PBO) in 2 axial spondyloarthritis (axSpA) and 2 psoriatic arthritis (PsA) phase 3 studies.
Methods: Patients (pts) in 2 safety pools received ≥1 dose of subcutaneous BKZ 160 mg or PBO every 4 wks during Wks 0–16 (double-blind phase) of BE MOBILE 1 + BE MOBILE 2 in axSpA (NCT03928704; 03928743); BE OPTIMAL + BE COMPLETE in PsA (NCT03895203; 03896581) (**Figure 1**) [1-4].
Results: Wk 16 completion rates: 95.8% (PBO), 97.1% (BKZ) in axSpA; 95.9% (PBO), 97.1% (BKZ) in PsA. Most frequently reported treatment-emergent adverse events in ≥3% pts on BKZ were nasopharyngitis, upper respiratory tract infection, oral candidiasis and headache (**Table 1**). See **Table** for adverse events of special interest. Serious infections occurred in 5 pts (axSpA: 1 [0.4%] PBO, 1 [0.3%] BKZ; PsA: 0 PBO, 3 [0.4%] BKZ). Fungal infections were all local and reported as mild/moderate by investigators; more *Candida* infections were seen on BKZ (axSpA: 15 pts [4.3%]; PsA: 18 [2.6%]) than PBO (axSpA: 0; PsA: 2 [0.5%]) and led to discontinuation by 3 pts on BKZ (1 axSpA, 2 PsA). In axSpA pts, uveitis occurred in 11 (4.6%) on PBO and 2 (0.6%) on BKZ; inflammatory bowel disease occurred in 1 (0.4%) pt on PBO, 2 (0.6%) on BKZ. No uveitis/IBD cases in PsA by Wk 16 (PBO or BKZ). No deaths, active tuberculosis, suicidal ideation/behaviour, or major adverse cardiac events were reported in any study to Wk 16.
Conclusion: The overall safety profile of BKZ was in line with previous phase 2 trials in axSpA and PsA, with a low rate of discontinuation. As expected, due to inhibition of IL-17, there was a higher rate of oral candidiasis compared to PBO.

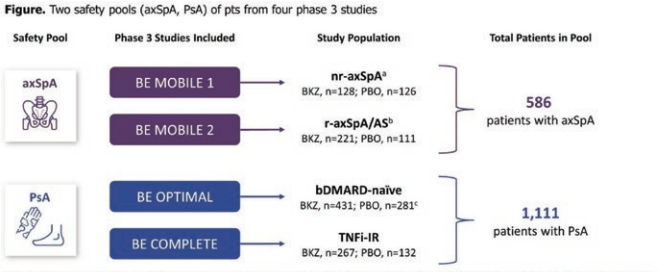

Figure. Two safety pools (axSpA, PsA) of pts from four phase 3 studies

[a]Patients included in BE MOBILE 1 met ASAS classification criteria. Patients with radiographic sacroiliitis were excluded; [b]Patients included in BE MOBILE 2 met modified New York criteria and ASAS classification criteria, therefore the terms r-axSpA and AS may be used interchangeably; [c]BE OPTIMAL also included an adalimumab treatment arm. Patients randomised to this arm are not included in the PsA safety pool.

Abbreviations: AESI: adverse events of special interest; AS: ankylosing spondylitis; ASAS: Assessment of SpondyloArthritis international Society; axSpA: axial spondyloarthritis; bDMARD: biologic disease-modifying antirheumatic drug; BKZ: bimekizumab; IBD: inflammatory bowel disease; nr-axSpA: non-radiographic axSpA; PBO: placebo; PsA: psoriatic arthritis; pt: patient; Q4W: every 4 weeks; r-axSpA: radiographic axSpA; TEAE: treatment-emergent adverse event; TNFi-IR: tumour necrosis factor inhibitor-inadequate response.

BONE-RELATED OUTCOME DURING TWO YEARS OF SECUKINUMAB TREATMENT IN PATIENTS WITH ANKYLOSING SPONDYLITIS: RADIOGRAPHIC SPINAL AND FACET INVOLVEMENT, BONE MINERAL DENSITY, VERTEBRAL FRACTURES AND BONE TURNOVER MARKERS

Keywords: Outcome measures, Bone diseases, Spondyloarthritis

M. Siderius[1], S. Arends[1], F. Wink[2], A. Spoorenberg[1]. [1]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; [2]*Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands*

Background: IL17 inhibitors have proven to reduce disease activity in patients with ankylosing spondylitis (AS). AS is an intriguing disease which is characterized by both excessive bone formation and bone loss. Data on the effect of IL17 inhibitors on the different aspects of bone formation as well as bone resorption is still limited.

Objectives: To evaluate radiographic progression of the spine and cervical facet joints, bone mineral density (BMD), vertebral fractures (VF) and serum markers of bone resorption, formation, and mineralization during 2 year of secukinumab treatment in AS patients in daily clinical practice.

Methods: In this explorative study, consecutive AS outpatients from the GLAS cohort who were treated with secukinumab for 2 years were included. Standardized follow-up visits were performed at baseline (before start of secukinumab) and after 3/6 months, 1 and 2 years of treatment. Bone-related outcome was assessed at baseline and after 2 years. Radiographs were blinded for patient characteristics and scored in chronological time order by 2 independent trained readers. Spinal radiographic damage was assessed using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS; 0-72) and cervical facet joint involvement according the 'de Vlam' method (0-15). Radiographic VF were assessed using the Genant method and bone mineral density (BMD) with DEXA. Serum levels of BTM reflecting collagen resorption, collagen formation and facilitation of bone mineralization (sCTX, PINP and BALP, respectively) were measured at all visits. BTM Z-scores were calculated using a healthy reference population to correct for the normal influence of age and gender. Bone-related outcomes were explored using descriptive statistics. Generalized estimating equations were used to analyze BTM over time within patients.

Results: In total, 17 AS patients were eligible for analyses; 53% were male, mean age was 46.6±14.6 years, 82% were HLA-B27 positive, mean ASDAS at baseline was 3.9±1.2, median CRP was 5 (IQR 3 - 26) mg/L, 53% were biological naïve, and median time between diagnosis and start of secukinumab was 5.0 (IQR 1.5-12.0) years. After 2 years of secukinumab treatment, mean ASDAS was 2.2±1.1. At baseline, median mSASSS was 3.3 (IQR 1.3 - 10.2). 10 patients had mSASSS and facet joint data available at baseline and 2 years. Median progression rate was 1.1 units in 2 years and 4 patients (40%) showed progression of ≥2.0 mSASSS units or ≥1 new syndesmophyte. At baseline, median facet joint score was 1.5 (IQR 0.0 - 2.8), with partial or complete ankylosis in 7 (8%) individual facet joints in 5 patients. Median progression rate was 0.5 and 6 (12%) facet joints in 4 patients showed progression to partial or complete ankylosis. At baseline, there were no signs of VF. One traumatic VF (grade 3) occurred during 2 years of follow-up. At baseline, median BMD Z-score (n=12) was -0.6 (-1.5 - -0.4) for the lumbar spine and -0.1 (-1.8 - 0.1) for the hip and BMD remained stable over time. Before secukinumab treatment, median sCTX, PINP and BALP Z-scores were +0.0, -0.60 and +1.2 SD, respectively. The course of sCTX and PINP did not change significantly during follow-up, BALP Z-scores, however, significantly decreased at 2 years compared to baseline (Figure 1).

Conclusion: This explorative study in daily clinical practice with assessments of both new bone formation and bone resorption in AS patients treated with secukinumab showed that there was low radiographic damage at baseline, with little change during 2 years of treatment. Serum BTM levels reflecting the actual bone turnover process corrected for normal influence of age and gender showed high BALP at baseline, indicative for mineralization, which decreased during 2 years of secukinumab treatment.

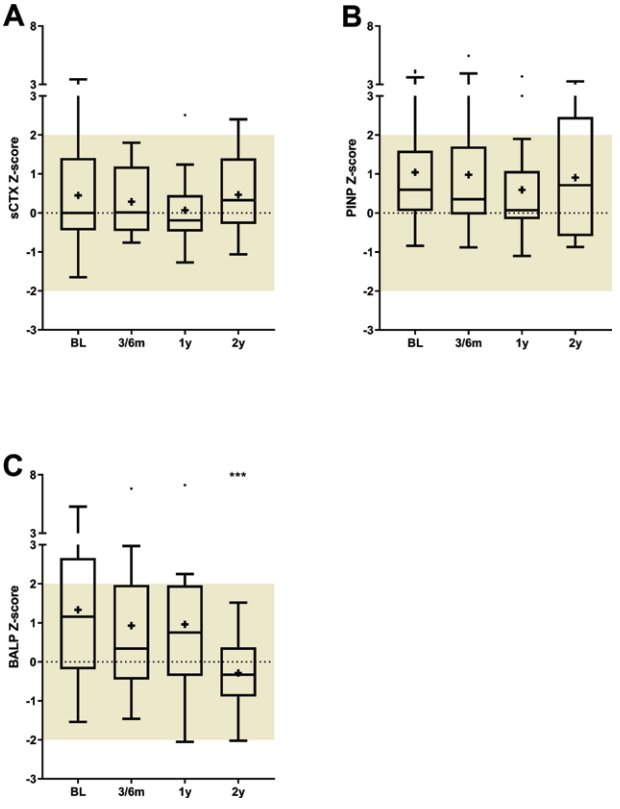

Figure 1. The effect of 2 year of secukinumab treatment on markers of bone turnover sCTX (A), PINP (B) and BALP (C) in patients with AS (n=17). Bar indicates median value.

AB0940

TITLE: CHOICE OF BDMARD AFTER TNFI: DOES IT MATTER IN THE TREATMENT OF SPONDYLOARTHRITIS?

Keywords: bDMARD, Spondyloarthritis

G. D. İşbilir[1], R. C. Kardaş[2], D. Yildirim[2], B. Özkızıltaş[2], I. Vasi[2], R. Duran[2], H. Karadeniz[2], A. Avanoglu Guler[2], A. Erden[2], H. Küçük[2], A. Tufan[2], B. Göker[2], M. A. Ozturk[2]. [1]*Gazi University, Department of Medicine, Ankara, Turkey*; [2]*Gazi University, Department of Medicine, Division of Rheumatology, Ankara, Turkey*

Background: Following the failure of initial biological treatment in spondyloarthritis, switching to an alternative biological drug is possible. However, the data regarding the choice of the drug is limited. ASAS/EULAR guideline on axial spondyloarthritis does not make a distinction between TNFi, IL-17i or JAKi, with certain precautions regarding JAKi [1]. On the other hand, ACR/SAA/SPARTAN guideline recommends IL-17i over a different TNFi in primary failure, based on the assumption that TNF is not the key inflammatory mediator in these patients [2].

Objectives: Our main objective was to compare and contrast the clinical and laboratory features of the patients who received either a TNFi or IL-17i following the failure of the initial biologic treatment in our cohort of spondyloarthritis patients.
Methods: Spondyloarthritis patients followed in our institution between 2014 and 2022 who received a secondary bDMARD following primary or secondary biologic failure were included in our study. ASAS criteria were used to classify patients as having axial or peripheral SpA. Failure was defined as lack of clinical improvement following at least 12 weeks of therapy. Demographic, clinical, laboratory and radiological features of the patients, along with clinical and laboratory response following the second line bDMARD treatment were recorded.
Results: 90 patients were included in our study. 51% were female (N=46), mean age at diagnosis was 35 (SD: 11.9, %95 CI: 32.5–37.6), median duration of disease was 9 years (IQR: 10, minimum: 2 years, maximum: 38 years). 76% (N=68) of patients were classified as axial SpA, remaining 22 were classsifed as peripheral SpA. 68% (N=58) were HLA-B27 positive. Median ASDAS-CRP before the intial bDMARD was 3.7 (IQR: 1.3, min-max: 2.6–5.9). Adalimumab was the most used initial TNFi (48%, N=43). Most common reason of treatment switch was secondary failure (51%, N=41), followed by primary failure (25%, N=20) and side effects (19%, N=15). Following initial treatment failure, 30% of patients (N=27) were switched to a drug with an alternative pathway, with most of them being secukinumab (N=22). Median ASDAS-CRP after initial treatment failure was 3.8 (IQR: 1.0, min-max: 2.5–6.0). There was no difference in type of spondylarthritis, HLA-B27 positivity, ASDAS-CRP score and choice of bDMARD between primary and secondary failure groups. 24% of patients (N=22) achieved clinical remision in the secondary line of bDMARD treatment. The rate of clinical remission was 5% for TNFi and 75% for IL-17i (P<0.001). Duration of disease was shorter for responders (median 4 years vs. 11 years, P=0,03). Gender, HLA-B27 status, presence of enthesitis, dactylitis, uveitis, skin involvement, gastrointestinal involvement and initial ASDAS-CRP score did not differ between responders and non-responders (Table 1).

Table 1. Characteristics of responders and non-responders to secondary line treatment

	Secondary bDMARD		P
	Non-responder	Responder	
Disease duration	11 years (IQR: 12)	4 years (IQR: 5)	**0.033**
SpA classification			
Ax-SpA	52 (77%)	23 (24%)	0.722
Per-SpA	16 (72%)	6 (27%)	
HLA-B27			
Negative	18 (67%)	9 (33%)	0.285
Positive	45 (78%)	13 (22%)	
Second line bDMARD			
TNFi	59 (95%)	3 (5%)	**<0.001**
IL-17i	6 (25%)	18 (75%)	
Other	3 (%75)	1 (%25)	
Second line TNFi			
ADA	12 (86%)	2 (%14)	0.116
ETN	26 (100%)	0	
GOL	4 (80%)	1 (20%)	
IFX	9 (100%)	0	
CZP	8 (100%)	0	

Conclusion: The rate of remission for IL-17i was significantly higher than TNFi following the failure of initial bDMARD failure. There was no difference between clinical and laboratory features of responders and non-responders, except for duration of disease. These findings suggest using an alternative pathway in case of TNFi failure may be preferable.

[1]*Policlinico Umberto 1, Sapienza University of Rome, Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rome, Italy, Rome, Italy*

Background: Studies on drug survival in patients with spondyloarthritis (SpA) in a real-life context are scant.
Objectives: We aimed to examine the real-life data of survival and the reasons for discontinuation or switching of biologic DMARDs (bDMARDs) in patients with axial and peripheral SpA (axSpA and pSpA).
Methods: This is a single-center retrospective longitudinal study in adult consecutive patients with axSpA and pSpA according to ASAS criteria treated with at least one bDMARD. Data are presented as medians (interquartile range [IQR]) for continuous data or as numbers (percentages) for categorical variables. Drug survival distribution curves were computed by the Kaplan-Meier method.
Results: A total of 141 patients (M/F: 72/69), median age 56 years [IQR 15], median disease duration 112 months [IQR 140] were enrolled. Among 57 patients with axSpA, 30 (53%) were HLA-B27-positive, 11 (19%) had had at least one uveitis episode, 4 (7%) were also affected by inflammatory bowel disease; 14 (24%) were taking NSAIDs and 2 (6%) glucocorticoids (GCs). Among 84 patients with pSpA, 50 (66%) were affected by psoriasis, 2 (5%) had had at least one uveitis episode; 16 (18%) were taking NSAIDs, 14 (16%) GCs and 33 (39%) csDMARD. The median duration of follow-up was 28 months (IQR 46). In the axSpA group, the median treatment duration was 32 months (IQR 60), while in the pSpA group was 25 months (IQR 37). Among axSpA patients, adalimumab (ADA) was the most common current bDMARD (58%) followed by etanercept (ETA) (28%), golimumab (GOL) (9%), ustekinumab (UST) (1%), and secukinumab (SEC) (4%). During a follow-up of five years, the comparison between survival curves of these bDMARDs showed significant differences (p= 0.015) (figure 1 A). The reasons for bDMARDs switching were primary failure (PF, 50%), secondary failure (SF, 25%), side effects (SE, 20% - mostly infections). In the pSpA groups, the most common current therapy was ADA (44%) followed by ETA (33%), SEC (12 %),GOL (6%), UST (5 %). As shown in figure 1 B, no significant differences (p= 0.49) in drug survival were found among patients treated with these bDMARDs. The reasons for bDMARDs switching were PF (38%), SF (38%), SE (8% - mostly infections).
Conclusion: In our experience, ADA was the most frequently prescribed bDMARDs as the first choice in patients with axSpA and pSpA. Despite PF and SF being the main causes of treatment discontinuation, a second anti-TNF agent was the preferred option in most cases.

AB0942 ANTI-IL17 TREATMENT AND INCIDENCE OF INFLAMMATORY BOWEL DISEASE: SYSTEMATIC REVIEW AND META-ANALYSIS OF CLINICAL TRIALS

Keywords: Psoriatic arthritis, Spondyloarthritis, bDMARD

R. Dos-Santos[1,2], I. Alcántara[2], D. Fernández Fernández[3], I. González Fernández[1], P. Castro-Santamaria[1], M. Sanchez-Wonenburger[1], A. Mata[1], J. L. Puga Guzmán[1], I. Álvarez[1], V. Busto[1], J. R. Maneiro[1], A. Souto Vilas[4], A. Mera Varela[1,2], E. Perez-Pampín[1,2]. [1]*Clinical University Hospital in Santiago de Compostela, Spain, Rheumatology Department, Santiago de Compostela, Spain*; [2]*Universidade de Santiago de Compostela, Rheumatology Department, Santiago de Compostela, Spain*; [3]*Clinical University Hospital in Ourense, Spain, Rheumatology Department, Ourense, Spain*; [4]*Clinical University Hospital in Pontevedra, Rheumatology Department, Pontevedra, Spain*

Background: A warning about appearance or worsening of inflammatory bowel disease (IBD) during treatment with anti-IL17 agents has been launched by regulatory agencies in the last years. This caution is based on the relationship between bowel (IBD), joint (spondyloarthritis [SpA]) and skin (psoriasis [Ps]);

regarding immune aspects. As well, anti-IL17 drugs have been proved ineffective in IBD treatment. [1,2]

Objectives: To analyze the incidence of IBD in patients with SpA or Ps treated with anti-IL17 drugs.

Methods: A systematic review about clinical trials has been performed using 4 databases (Medline, Embase, Web of Science, Cochrane Library). There were identified papers assessing the appearance of IBD in clinical trial's participants, previously diagnosed of Ps or SpA, treated with anti-IL17 drugs. A global incidence rate (IR), incidence rate ratio (IRR) and relative risks (RR) were estimated in this population, in paralell and crossover studies. Heterogeneity and risk of bias were also evaluated.

Results: 53 papers were finally selected for performing this meta-analysis. A global IR of IBD diagnosis in Ps/SpA patients under treatment with anti-IL17 was 0.3/100 patients-year (95%CI 0.24-0.37). An IRR of IBD diagnosis in Ps/SpA patients under treatment with anti-IL17 was 0.56 (95%CI 0.34-0.9, p<0.01). A RR of IBD diagnosis in Ps/SpA patients under treatment with anti-IL17 in crossover trials was 0.73 (95%CI 0.27-1.99, p=0.54) (Figure 1).

Conclusion: We cannot afirm that anti-IL17 agents increase the global risk of IBD appearance in Ps or SpA patients. Anti-IL17 drugs may not be avoided in clinical practice concerning Ps and SpA patients, due to IBD prevention.

EVALUATION OF THE EFFECT OF TUMOR NECROSIS FACTOR - A THERAPY ON 24-HOUR AMBULATORY BLOOD PRESSURE MEASUREMENT AND SLEEP QUALITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Cardiovascular disease, Spondyloarthritis

K. Moral[1], E. Bilgin[2], O. Karadag[2], U. Kalyoncu[2], A. Akdoğan[2], Ş. A. Bilgen[2], S. Kiraz[2], A. İ. Ertenli[2], T. Yıldırım[3], L. Kılıç[2]. *[1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey*; *[2]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[3]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Nephrology, Ankara, Turkey*

Background: Increased cardiovascular mortality has been reported in AS patients. There are studies showing the positive effects of anti-TNF-α therapy on both cardiovascular mortality and sleep quality. (1,2)

Objectives: To determine the changes in sleep quality and 24-hour blood pressure readings in patients with axial spondiloarthritis (axSpA) after treatment with anti- tumor necrosis factor TNF-α therapy.

Methods: Patients with axSpA who were admitted to Hacettepe University Hospital Rheumatology outpatient clinic between 01.03.2021 and 01.12.2021, anti-TNF-naive and without a history of cardiovascular disease were included. Disease activitiy assesment (ESR, CRP, BASDAI and BASFI), ambulatory blood pressure measurement (AMBP) and sleep quality evaluated by pittsburgh sleep quality index questionare (PSQI) were assessed before ant-TNF therapy (0.month) and after anti-TNF-α therapy (3.month).

Results: Totally, 28 patients with axSpA (mean (SD) age 40.0 (10.4) years, female:16(57.1%) patients) were included in to this study (table-1). The 0th and 3th month ABPM measurements of the patients in our study were within the normotensive limits. Both disease activity scores and median PSQI scores [8.5 (4.0-12.8)] were high and sleep quality was poor in 71% of the patients. Although there was a significant decrease in disease activity scores and a significant improvement in sleep quality at the 3. month after anti-TNF- α therapy, no significant changes were observed in ABPM parameters such as Ambulatory Arterial Stiffness İndex (AASI), Average real Variability (ARV), Pulse Pressure İndex (PPI), Sleeptroughsurge and Prewaking surge compared to pre-treatment. While after anti- anti-TNF-α therapy the percentage of patients with dipper phenomena increased in the 3. month, this increase was not statistically significant (46.4% (0. month) vs. 60.7% (3. month); p=0.388). Furthermore, the change in nighttime systolic blood pressure reduction was statistically significant respectively ([4.8% ((-7) – 9.2) (0. month) vs. 9.2% (4.7-11.1) (3. month); p=0.020], while there was no statistically significant difference in the change in nighttime diastolic blood pressure reduction respectively ([6.4% (1.5-14.7) vs. 9.6% (5.0-15.8); p=0.112] (table-2).

Conclusion: This study shows that anti-TNF-α treatment has positive effects on modifiable cardiovascular risk factors by increasing sleep quality and increasing nighttime blood pressure reduction. Prospective and long-term studies are needed.

COMORBIDITIES IN THE SPONDYLOARTHRITIS GISEA COHORT: AN AVERAGE TREATMENT EFFECT ANALYSIS ON PATIENTS TREATED WITH BDMARDS

Keywords: bDMARD, Comorbidities, Artificial Intelligence

L. Scagnellato[1], A. Collesei[2], G. Cozzi[1], M. Lorenzin[1], A. Doria[1], G. Lapadula[3], R. Ramonda[1]. *[1]Padova University Hospital, Rheumatology Unit, Department of Medicine DIMED, Padova, Italy*; *[2]Institute Oncology Veneto, Cancer Genomics Core Lab, Padova, Italy*; *[3]Polytechnic University of Bari, Rheumatology, DiMePre-Jo, Bari, Italy*

Background: The treatment of Spondyloarthritis (SpA) has enormously improved thanks to bDMARDs, which are usually safe but they still require some caution because of their interference with the immune system homeostasis. ATE is a still evolving method designed to study the causal relationship between treatment and outcome.

Objectives: We endeavoured to investigate the impact of TNF-inhibitors (TNFi), anti-interleukin17 or interleukin12/23 monoclonal antibodies (anti-IL) on comorbidities among SpA patients enrolled in the Italian GISEA Registry, using an average treatment effect (ATE) analysis.

Methods: SpA patients from the GISEA Registry were divided into groups according to pharmacological exposure: no treatment (G0), TNFi (G1) and anti-IL (G2). In each group, the prevalence and incidence of infectious, cardiopulmonary, endocrinological, non-inflammatory gastrointestinal disease (NIGID), oncologic, renal and neurologic comorbidities were evaluated. Thus, each comorbidity was fitted for ATE and baseline features were evaluated for importance.

Results: This multi-centre Italian GISEA study comprised 4458 SpA patients (G0=495 patients, G1=3113 patients, G2=815 patients). Cardiovascular disease was the most prevalent and incident comorbidity in all groups, with no significant difference between groups. ATE showed no increased risk of solid cancer in G1 and G2 (G1 vs. G0 = 0,42 95% CI 0,20-0,85; G2 vs. G0 = 0,26 95% CI 0,08-0,71), but significantly higher prevalence and incidence in G0 (14.07/1000 patient-years, p=0,0001). Conversely, a significantly higher risk of NIGID and fibromyalgia was found in G1 and G2 vs. G0 (NIGID: G1 vs. G0 =1.56 95% CI 1.06-2.33, G2 vs. G0 =1.91 95% CI 1.05-3.24; fibromyalgia: G1 vs. G0 1.69 95% CI 1.05-2.68, G2 vs. G0 2.13 95% CI 1.14-3.41). No treatment risk modification was observed concerning haematological malignancies, cardiovascular events and endocrinological comorbidities.

Conclusion: Overall, this study reveals that bDMARDs have only a slight interference of the occurrence of comorbidities in SpA patients, underlining the appropriateness of the use of bDMARDs in current clinical practice. Some caveats pertain to NIGID and fibromyalgia. Importantly, causality may yield more reliable and relevant clinical information, flattening the unbalance between observational data and clinical trials.

Table 1. Prevalence and incidence of selected comorbidities in the GISEA Cohort and results of the Average Treatment Effect Analysis (ATE).

Incidence of comorbidities (number of events; events/1000 patient-years)

Comorbidity	No treatment (G0) N=494	TNFi (G1) N =3113	AntiIL (G2) N=815	P value (ANOVA)
Cardiovascular disease	10 events; 16.90	114 events; 28.81	26 events; 26.44	0,0794
Endocrinological disease	7 events; 11.35	60 events; 9.30	15 events; 13.83	0,6678
Fibromyalgia	5 events; 6.72	102 events; 13.42	33 events; 25.19	**0,0095**
Gastrointestinal (non IBD) disease	8 events; 12.41	110 events; 16.48	33 events; 19.68	**0,0408**
Haematologic malignancy	0 events; 0	2 events; 0.26	0 events; 0	0,6498
Solid cancer	10 events; 14.07	13 events; 1.71	5 events; 3.79	**0,0001**

Average treatment effect (ATE) analysis

Outcome (comorbidity) RR (CI 95%)	TNFi vs. no treatment (G1 vs. G0)	antiIL vs. no treatment (G2 vs. G0)	antiIL vs. TNFi (G2 vs. G1)
Cardiovascular	1.41 (0.99-1.99)	1.66 (1-2.97)	1.16 (0.91-1.55)
Endocrinologic	1.27 (0.76-2.05)	1.41 (0.68-2.72)	1.09 (0.74-1.54)
Fibromyalgia	**1.69 (1.05-2.68)**	**2.13 (1.14-3.41)**	1.25 (0.95-1.51)
GI (non IBD)	**1.56 (1.06-2.33)**	**1.91 (1.05-3.24)**	1.21 (0.92-1.51)
Haematologic malignancy	0.78 (0.14-2.88)	0.81 (0.04-4.67)	0.78 (0.20-1.96)
Solid cancer	**0.42 (0.20-0.85)**	**0.26 (0.08-0.71)**	**0.61 (0.33-0.96)**

Legend: G0= Group 0, no treatment= no biologic DMARD, G1= Group 1, TNFi= Tumour necrosis factor inhibitors, G2= Group 2, antiIL= anti-interleukin17 and anti-interleukin17/23 monoclonal antibodies, N= numerosity of the group, IBD= inflammatory bowel disease, RR= relative risk, CI 95%= confidence interval 95%. Significant results are in bold characters.

ASSESSMENT OF THE RISK OF LIVER FIBROSIS IN SPONDYLOARTHRITIS TREATED WITH SECUKINUMAB: A SINGLE-CENTER RETROSPECTIVE OBSERVATIONAL STUDY

Keywords: Disease-modifying Drugs (DMARDs), Spondyloarthritis, Psoriatic arthritis

F. Verhoeven[1,2], C. Prati[1,2], V. DI Martino[3,4], T. Thevenot[3,4], D. Wendling[1,4], W. V. Delphine[3,4]. *[1]CHU Besancon, Rheumatology, Besançon, France*; *[2]Université de Franche Comté, EA4267 PEPITE, Besançon, France*; *[3]CHU Besancon, Hepatology, Besançon, France*; *[4]Université de Franche Comté, EA 4266 EPILAB, Besançon, France*

Background: The prevalence of non-alcoholic steatopathy (NAFLD) is increasing in chronic inflammatory rheumatisms. NAFLD may favor the development of liver fibrosis, which may lead to cirrhosis and its complications including hepatocellular carcinoma. The process of hepatic fibrogenesis involves inflammatory mechanisms with an overexpression of TNF but also of IL 17. Thus, the use of anti-TNF alpha is associated with a decrease in the incidence of hepatic fibrosis. Anti-IL-17 could also have an effect on fibrogenesis but this has not been studied in spondyloarthritis.

Objectives: The aim of this study was to assess, non-invasively, the risk of liver fibrosis using the FIB-4 score, in patients treated with anti-IL-17.

Methods: A single-center retrospective observational study was performed. We included all consecutive patients followed between 2015 and 2022 for axial spondyloarthritis (axSpA) meeting the ASAS 2009 criteria or psoriatic arthritis (PsA) meeting the CASPAR criteria, treated for at least 12 months with secukinumab, and for whom at least 12 months of biological follow-up was available. For each patient, we collected demographic data, clinical data, associated treatments, and levels of AST, ALT, platelets at initiation of treatment and after 12 months of treatment. We assessed the FIB-4 score (age(years) * ASAT (U/L))/(platelets (109/L)*√ALAT (U/L))at M0, M12, and M24. Fischer's exact test was used for comparison between categorical variables and Student's t test for quantitative variables.

Results: 38 patients, (20 PsA, 18 axSpA; 60% women in both groups; mean age 57 years in PsA group and 46 years in axSpA group (p<0.01)) were included. The mean disease duration was 10 ± 4 years in the PsA group and 11 ± 5 years in the axSpA group. 78% of axSpA were HLA B27 positive versus 20% of PsA (p<0.01). There was a trend towards a higher prevalence of NAFLD (30% vs. 5%, p=0.09) and previous methotrexate use was more frequent (100% VS 39%, p<0.01) in PsA. The FIB4 score was higher in the PsA group at baseline (1.30 ± 0.24 VS 0.74 ± 0.05; p=0.04). This difference remained significant after 12 months of treatment (1.34 ± 0.25 vs. 0.79 ± 0.06; p=0.048). At M0, no axSpA patient had a FIB4 > 1.3 vs. 6 in the PsA group. At M12, one axSpA patient had a FIB4>1.3 (and <2.0) vs. 6 in the PsA group (including 4 patients with a FIB4>2.0). At M24, one axSpA patient out of 6 had a FIB4>1.3 (and <2.0) versus 3 in the PsA group out of 13 (including 1 patient with FiB4>2.0 and 1 with FiB4<1.3 at inclusion). The overall change in FiB-4 score at 1 year was not different in the PsA and axSpA groups (-0.62 ± 0.25 vs. -0.59 ± 0.27; p=NS). Finally, PsA patients suffer from NAFLD did not worsen their FiB4 score (2.08 ±1.6 at M0 VS 2.02 ± 1.07 at M12; p=NS).

Conclusion: In PsA and axSpA, 1-year treatment with secukinumab is not associated with an increase in FIB-4 even in patients known to have NAFLD. This study requires confirmation in a larger cohort.

A META-ANALYSIS TO EVALUATE THE EFFICACY AND SAFETY OF IGURATIMOD ON ACTIVITY AX-SPA

Keywords: Spondyloarthritis, Disease-modifying Drugs (DMARDs)

Y. Li[1], L. Hu[1], Z. Zhao[1], Z. Hu[1], J. Zhang[1], J. Zhu[1], F. Huang[1]. [1]*The First Medical Center, Chinese PLA General Hospital, Department of Rheumatology and Immunology, Beijing, China*

Background: Iguratimod is a newly-developed small molecular anti-rheumatic drug, which can inhibit the effects of prostaglandin E2, TNF-α and IL-17. Iguratimod had been reported to be effective in the treatment of SpA. Iguratimod was implied to be of potential efficacy on ax-SpA.
Objectives: This study was aimed to demonstrated the efficacy and safety of Iguratimod on activity ax-SpA (ASDAS>2.1).
Methods: We performed a meta-analysis to systemically evaluate the efficacy and safety of Iguratimod by gathering the published RCTs about the treatment of Iguratimod in ax-SpA, mean differences (MD) and 95% CI of the change of back pain, morning stiffness, PhGA, ASDAS, BASDAI, BASFI and concertation of TNF-α, ESR and CRP were calculated. Besides, the odds ratio (OR) and 95% CI of the ASAS 20, ASAS 40, partial remission of ASAS, ASAS 5/6 were calculated as well.
Results: 7 RCTs were admitted into the meta-analysis, including 186 cases in the control group and 208 cases in the Iguratimod group. The control group was treated with NSAIDs monotherapy or NSAIDs combined with DMARDs, and the range of follow-ups was 12-24 weeks. The improvement of back pain (MD -1.76, 95% CI: -2.33 ~ -1.20, P<0.001), morning stiffness (MD -11.27, 95% CI: -13.57 ~ -8.96, P<0.001), PhGA (MD -2.86, 95% CI: -5.45 ~ -0.26, P<0.05), ASDAS (MD -0.8, 95% CI: -1.26 ~ -0.33, P<0.001), BASDAI (MD -1.19, 95% CI: -1.59 ~ -0.78, P<0.001), BASFI (MD -0.92, 95% CI: -1.29 ~ -0.55, P<0.001), ASAS 20 (OR 11.94, 95% CI: 5.30 ~ 26.91, P<0.001), ASAS 40 (OR 4.46, 95% CI: 1.95 ~ 10.16, P<0.001), partial remission of ASAS (OR 17.69, 95% CI: 4.06 ~ 77.08, P<0.001) in the Iguratimod treatment group were better than those in the control group, as well as for concertation of ESR (MD -8.77, 95% CI: -15.37 ~ -2.18, P<0.001), CRP (MD -4.44, 95% CI: -6.66 ~ -2.23, P<0.001) and TNF-α (MD -6.98, 95% CI: -7.72 ~ -6.24, P<0.01). There was no significant difference in the reported adverse events between the two groups.
Conclusion: Iguratimod is effective and well-tolerated during the treatment and thus could be a new pharmaceutical option for activity ax-SpA patients.

Background: Pain is a debilitating symptom of ankylosing spondylitis (AS) that negatively affects patients' lives. Upadacitinib (UPA), a Janus kinase inhibitor approved for the treatment of AS and other inflammatory diseases, showed significant efficacy vs placebo (PBO) in the phase 2/3 SELECT-AXIS 1 study in patients with AS who were biologic-naive and in the phase 3 SELECT-AXIS 2 study in patients with active AS who had an inadequate response (IR) to biological therapy [1,2]. Improvement in pain outcomes with UPA was also previously demonstrated in the SELECT-AXIS 1 study [3].
Objectives: The objective of this post-hoc analysis of SELECT-AXIS 2 was to evaluate the efficacy of UPA vs PBO on multiple pain assessments through 14 weeks in patients with IR to a biologic disease-modifying antirheumatic drug (bDMARD-IR).
Methods: SELECT-AXIS 2 (NCT04169373) enrolled adults with active AS with IR to biological therapy, including patients who discontinued biologics due to lack of efficacy or intolerance [1]. Patients were randomized 1:1 to UPA 15 mg once daily (QD) or PBO for 14 weeks. Pain endpoints evaluated here included the proportion of patients achieving ≥30%, ≥50%, and ≥70% reduction from baseline, minimal clinically important difference (MCID, defined as ≥1 point reduction or ≥15% reduction from baseline), and much better improvement (MBI, defined as ≥2 point reduction and ≥33% reduction from baseline) in Patient's Global Assessment (PGA) of pain, total back pain, and nocturnal back pain on a 0–10 numeric rating scale [3,4]. Non-responder imputation incorporating multiple imputation to handle missing data due to COVID-19 was used.
Results: A total of 211 patients received UPA 15 mg QD and 209 patients received PBO. Higher proportions of patients receiving UPA vs PBO achieved ≥30% and ≥50% reductions in PGA of pain, total back pain, and nocturnal back pain as early as week 2 that were sustained at all time points through 14 weeks (nominal *P*<0.05; **Figure 1a-c**). Achievement of ≥70% reductions in PGA of pain and nocturnal back pain were higher at week 4 and sustained thereafter (**Figures 1a** and **1c**), and achievement of ≥70% reduction in total back pain was higher at week 2 and week 8, but not week 4, and sustained thereafter (**Figure 1b**). Results were similar for the proportion of patients achieving MCID and MBI, with improvements in PGA of pain, total back pain, and nocturnal back pain for UPA vs PBO as early as week 1 (MCID) or week 2 (MBI) that were sustained through week 14 (all nominal *P*<0.001; **Table 1**).

Figure 1. Proportion of Patients Achieving ⩾30%, ⩾50%, and ⩾70% Reduction in Pain Outcomes Over Time (NRI-MI)

BL, baseline; NRI-MI, non-responder imputation incorporating multiple imputation to handle missing data due to COVID-19; PBO, placebo; PGA, Patient's Global Assessment; UPA, upadacitinib. *Nominal *P*<0.05 UPA vs PBO.

Table 1. Achievement of MCID and MBI in Pain Outcomes at Week 14 (NRI-MI)

	Responder Rate (95% CI), %		
Pain Outcomes	**UPA 15 mg**	**PBO**	**Nominal *P* Value**
PGA of pain			
MCID	81.0 (75.8–86.3)	62.7 (56.1–69.2)	<0.0001
MBI	60.7 (54.1–67.3)	24.9 (19.0–30.7)	<0.0001
Total back pain			
MCID	80.1 (74.7–85.5)	65.1 (58.6–71.5)	0.0005
MBI	58.3 (51.6–64.9)	25.4 (19.5–31.3)	<0.0001
Nocturnal back pain			
MCID	82.9 (77.9–88.0)	61.3 (54.7–67.9)	<0.0001
MBI	61.6 (55.0–68.2)	32.1 (25.7–38.4)	<0.0001

MBI, much better improvement; MCID, minimal clinically important difference; NRI-MI, non-responder imputation incorporating multiple imputation to handle missing data due to COVID-19; PBO, placebo; PGA, Patient's Global Assessment; UPA, upadacitinib.

Conclusion: In patients with active AS who were bDMARD-IR, greater proportions of patients treated with UPA achieved rapid and clinically meaningful reductions in pain vs PBO as early as week 2 that were sustained through 14 weeks across multiple pain assessments.

AB0948 SPERM PARAMETERS DIFFER AMONG DIFFERENT SPONDYLOARTHROPATHY CATEGORIES- A PROSPECTIVE CONTROLLED PILOT STUDY

Keywords: Pregnancy and reproduction, Inflammatory arthritides, Psoriatic arthritis

M. Micu[1], A. Duțu[2], S. Surd[3], M. Mihai[4], A. Micu[5]. [1]*Rehabilitation Clinical Hospital Cluj Napoca, Rheumatology Division, Cluj Napoca, Romania*; [2]*"Iuliu Haţieganu" University of Medicine and Pharmacy Cluj-Napoca, Department of Medical Biochemistry, Cluj Napoca, Romania*; [3]*"Iuliu Hatieganu" University of Medicine and Pharmacy Cluj-Napoca, Assisted Reproduction Department, Cluj Napoca, Romania*; [4]*ASTRA Outpatient Clinic Sibiu, Rheumatology, Sibiu, Romania*; [5]*"Iuliu Haţieganu" University of Medicine and Pharmacy Cluj-Napoca, "Iuliu Haţieganu" University of Medicine and Pharmacy Cluj-Napoca, Cluj Napoca, Romania*

Background: Fertility impairment may occur in men diagnosed with inflammatory arthritis. High disease activity, sex hormones imbalance and some disease modifying drugs are important factors considered to be involved in this phenomenon [1]. Sperm parameters assessment is of key importance in clinical practice. Studies focusing on fertility assessment in patients diagnosed with spondyloarthritides (SpA) showed discordant results [1]. Indeed, long term treatment with Methotrexate (MTX) raised concerns about its potential negative impact on male fertility although more recent studies do not confirm it [1,2].

Objectives: To identify potential differences in sperm analysis among patients with ankylosing spondylitis (AS) and psoriatic arthritis (PSA) and to assess the impact of long-term low and intermediate doses of MTX on sperm parameters.

Methods: Consecutive active SpA patients were recruited for sperm parameters assessment. Demographics, type of disease, disease duration, validated activity/skin scores, current therapies and sperm parameters were recorded. Patients in the PSA group underwent sperm parameters assessment at baseline and after chronic MTX treatment. A healthy age matched control group underwent parallel sperm parameters assessment.

Results: Out of 33 SpA patients, 20 patients accepted to undergo sperm parameters evaluation. 15 patients were diagnosed with AS (7 solely with axial involvement) and 5 patients were diagnosed with PSA. Table 1. presents the most important monitored parameters. All patients presented high disease activity measured by ASDAS and DAPSA. All patients had mild Psoriasis Area and Severity Index scores. Both AS patient groups (purely axial, and axial + peripheral) showed comparable sperm parameters to the control group. Chronic MTX therapy was given to 5 AS patients (refractory to Salazopyrin therapy). This subgroup presented normozoospermia. Sperm parameters were profoundly altered in all PSA patients, at baseline and during follow up, when compared to both the AS and control groups. Chronic MTX administration in the PSA group did not supplementarily alter the sperm parameters. On the contrary, in 2 patients a mild sperm concentration and motility increase was detected at follow up.

Table 1. Demographics, type of disease, disease duration, MTX exposure and sperm parameters in AS and PSA patients versus controls.

Demographics	Axial SpA (n=7)	Axial and peripheral SpA (n=8)	PSA (n=5)	Controls (n=25)
Age (years, mean±SD)	35.85±8.37	31.71±7.97	36±12.54	34.52±5.1
Disease duration (years, mean±SD)	4.14±2.11	4±2.5	3.22±1.74	-
Sperm characteristics				
Sperm concentration ($nx10^6$/ml, mean and limits, NV>15)	60.71(15-110)	43.25 (7-66)	6.025 (0.1-12)	61.32 (0-160)
Total motility (%, SD, NV>40)	65±15.81	62.57±10.81	33.12±19.19	51.68±21.49
Normal morphology (%, NV>4)	65±23.22	54±9.70	13.87±1.12	56.12±16.14
Normozoospermia (%)	85.71	87.50	0	68
Normoastenozoospermia (%)	0	0	0	20
Oligospermia (%)	14.28	0	40	12
Oligoastenozoospermia (%)	0	12.50	60	0
Treatment				
Methotrexate 15-20 mg/week (number of patients)	0	5	5	0

SD-standard deviation, NV-normal values

Conclusion: Our data suggest that PSA patients represent a distinct group inside the SpA disease spectrum and fertility impairment is already a manifestation of early disease. AS patients with early disease onset undergoing treatment (including MTX) have sperm parameters comparable to those of the controls. Chronic MTX therapy in dosages between 15-20 mg/week do not have a negative impact on sperm parameters.

AB0949 COEXISTING INFLAMMATORY BOWEL DISEASE AND ANKYLOSING SPONDYLITIS: MANAGEMENT AND CLINICAL OUTCOMES

Keywords: Comorbidities, Gastrointestinal tract, Spondyloarthritis

E. Savin[1], O. Gendelman[1,2], A. Levartovsky[3], M. Lidar[2], H. Amital[1,2], S. Ben-Horin[3], U. Kopylov[3]. [1]*Sheba Medical Center, Department of Medicine 'B', Ramat Gan, Israel*; [2]*Sheba Medical Center, Rheumatology Unit, Ramat Gan, Israel*; [3]*Sheba Medical Center, Department of Gastroenterology, Ramat Gan, Israel*

Background: Ankylosing spondylitis (AS), which occurs in about 10% of inflammatory bowel disease (IBD) patients [1], is more common in Crohn's disease and does not correlate with bowel activity [2]. The occurrence of IBD in patients with AS is 4-16% [3-5].

Objectives: To investigate the patterns of treatment modifications following newly diagnosed AS in patients with IBD or a new IBD diagnosis in patients with AS.

Methods: This is a retrospective observational study that included patients with coexisting IBD and AS that were followed simultaneously by the gastroenterology and the rheumatology departments of the Sheba Medical Center. Patients with a follow-up duration of at least 3 months since the second diagnosis were included.

Results: The cohort consisted of 68 patients, 41 with a first diagnosis of IBD (fIBD-group) and 27 with a first diagnosis of AS (fAS-group). Patients in the fAS-group were younger (median age of 36 years, inter quartile range (IQR) 25-48 vs. 43 years IQR 35-56, p=0.043), had more Crohn's disease (92.6% vs. 68.3%, p=0.016), had a shorter interval up to the second diagnosis (median of 3 years, IQR 1-6 vs. 6 years, IQR 2-11.5, p=0.03), and had an increased rate of past/current biologic treatment (81% vs. 51%, p=0.019) compared with the fIBD-group.

Therapy modifications rates were 78% in the fIBD-group and 96% in the fAS-group. The most common modification for the fIBD-group was initiation of biologic therapy in 18/32 patients (Adalimumab 44%, Infliximab 33%, Golimumab 5.75%, Etanercept 5.75%, Certolizumab pegol 5.75%, Ustekinumab 5.75%). In the fAS-group, switching biologic agent to Adalimumab or Infliximab (42%) and ceasing NSAIDs (27%) were the most common (Figure 1). At 1-year follow-up there were no significant differences in clinical outcomes (treatment failure, surgery/hospitalization, clinical remission) between fIBD and fAS groups. However, patients in both groups with treatment modifications, had a trend for higher rate of IBD clinical remission than patients without (72% vs. 40%, p=0.066). No difference was found in AS clinical outcome.

Conclusion: Treatment modifications are common among newly coexisting IBD and AS patients, preferably biologic drug modifications. These modifications may contribute to IBD clinical remission.

AB0950 COST-EFFECTIVE THERAPY IN AXIAL SPONDYLARTHRITIS: A COMPARATIVE ANALYSIS OF TWO TREATMENT STRATEGIES

Keywords: Targeted synthetic drugs, Spondyloarthritis, Tapering

P. Vasanth[1], S. Rajendran2, A. Jacob Mathew[1], R. Goel[1], J. Mathew[1].
[1]Christain Medical College Vellore, Department of Clinical Immunology and Rheumatology, Vellore, India; *[1]Christain Medical College Vellore, Department of Clinical Immunology and Rheumatology, Vellore, India*

Background: Biologic disease-modifying anti-rheumatic drugs (bDMARDs) remain inaccessible to a majority of patients in resource-poor countries due to high cost. Cost-saving strategies including the use of generic bDMARDs with an early de-escalation schedule instead of continued standard dose or using generic small molecules such as tofacitinib or baricitinib are being explored for the treatment of axial spondyloarthritis (AxSPA). The generic molecules are cheaper in India as compared with the rest of the world.

Objectives: To compare the efficacy, safety, and cost of generic tofacitinib and disease activity-directed early de-escalation schedule of intended copies of adalimumab (ADA), the most commonly used bDMARD available in India.

Methods: In this retrospective study, patients diagnosed with AxSpA in a tertiary care center in India, initiated on tofacitinib (TOFA), and had at least one follow-up visit from January 2021 to November 2022, were included. Patients who received ADA due to moderate to high disease activity with an early de-escalation schedule, during the same period were included as historical diseased controls. Early de-escalation was defined as increasing the interval between 2 doses of ADA by 1 week every 3 months within 12 months of initiation of the drug. The baseline demographic, clinical presentation, and response to treatment and adverse drug reactions were compared between patients on TOFA and ADA. An Ankylosing spondylitis disease activity score (ASDAS-CRP) of <2.1 was considered a good response to treatment. The descriptive data are presented as mean± SD or median (Interquartile range) or percentages. Fisher's exact test and Mann Whitney U test were used to compare categorical and continuous parameters, respectively, between TOFA and ADA. The average monthly cost of therapy was calculated for both groups.

Results: Among 240 patients who received TOFA, 155 patients satisfied the inclusion criteria, while 40 patients received early de-escalation of ADA. The age (33.0±951 and 33.6±13.3 years, p= 0.66), gender [males n=131 (86.8%) and 32 (80.0%), p = 0.32], median disease duration [7 (4-11) and 7 (4.3-11.0) years] and CRP [22.1 (10.2-44.5) and 23.85(14.48-71.50) mg/L, p= 0.32] were similar for patients who received TOFA and ADA, respectively. The frequency of uveitis, peripheral arthritis, and HLA B27 positivity was similar between the two therapies. Majority of patients [124(82.1%) in the TOFA group and 32 (80%) in the ADA group] in both the groups received concomitant conventional DMARDs, while 36 (23.8%) patients on TOFA received prior TNF inhibitors. During a follow-up period of 6 (3-9) months, 129 (86.7%) of 151 patients on TOFA achieved low disease activity or inactive disease status as compared with 37 patients (92.5%) who received ADA (p = 0.42). Adverse drug reaction requiring drug discontinuation was observed in 6 patients on TOFA (transaminitis in 3, herpes zoster in 2, 1 infective spondylodiscitis) and in 5 patients receiving ADA (transaminitis in 4 and abdominal tuberculosis in 1).

Conclusion: Tofacitinib therapy is comparable to the early dose de-escalation strategy of adalimumab in terms of treatment response and safety in Indian patients with AxSPA.

AB0951 EFFICACY AND SAFETY OF UPADACITINIB IN ANKYLOSING SPONDYLITIS. REAL WORLD DATA

Keywords: Spondyloarthritis, bDMARD

C. Merino Argumánez[1], C. Secada-Gómez[2], C. Vergara[3], A. Urruticoechea-Arana[4], S. Alonso Castro[5], M. L. García-Vivar[6], M. Moreno[7], R. Almodovar González[8], R. Blanco[2], J. Sanz[1]. *[1]Hospital Universitario Puerta de Hierro Majadahonda, Rheumatology, Majadahonda, Spain*; *[2]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*; *[3]Hospital Universitario Infanta Sofía, Rheumatology, Madrid, Spain*; *[4]Hospital Can Misses, Rheumatology, Ibiza, Spain*; *[5]Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Spain*; *[6]Hospital Universitario de Basurto, Rheumatology, Bilbao, Spain*; *[7]Hospital Universitario Parc Taulí, Rheumatology, Sabadell, Spain*; *[8]Hospital Universitario Fundación de Alcorcón, Rheumatology, Madrid, Spain*

Background: Upadacitinib is a selective and reversible inhibitor of Janus Kinases (JAKs) that preferentially inhibits signaling via JAK1 or JAK1/3. JAK1 inhibition with upadacitinib modulates JAK-dependet cytokine signaling, thereby decreasing the inflammatory burden of different immune-mediated diseases. Upadacitinib is approved for the treatment of rheumatoid arthritis, psoriatic arthritis, non-radiographic axial spondyloarthritis, ankylosing spondylitis (radiographic axial spondyloarthritis), ulcerative colitis, and atopic dermatitis. In the case of ankylosing spondylitis, the drug has been approved for use in Spain since March 2022.

Objectives: The present study aims to evaluate the first data on safety and efficacy of upadacitinib use in ankylosing spondylitis in real clinical practice.

Methods: Retrospective observational multicenter study that included patients of 8 Spanish hospitals. Demographic data, personal history, and clinical course of patients diagnosed with ankylosing spondylitis treated with upadacitinib at participating centers were collected.

Results: Forty-four patients with ankylosing spondylitis who received upadacitinib for a mean time (SD) of 8.7 (7.4) months were included in the study. They had received previous biological treatments in 86 % of cases, 30% of patients at least 5. An improvement was observed in 70 % of patients as measured by subjective patient-reported improvement. The treatment was

suspended in the 27.3% of patients, the main reason for suspension was inefficacy. A higher percentage of suspension was found in patients who had received a greater number of previous biological treatments. Adverse effects were reported in 8 patients, the most serious being one episode of tachyarrhythmia, one episode of deep vein thrombosis, one episode of peptic ulcer and one episode of herpes zoster, and the most frequent adverse effect being headache.

Conclusion: 70% of patients with ankylosing spondylitis who received upadacitinib for a median time of 8.7 months experienced subjective improvement in their symptoms.

AB0952 COMPARISON OF THE EFFECT BETWEEN BISPHOSPHONATE AND DENOSUMAB ON BONE MINERAL DENSITY AND RADIOGRAPHIC PROGRESSION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A PILOT STUDY

Keywords: Spondyloarthritis

M. Y. Kim[1], K. Y. Kang[1], Y. S. Hong[1]. [1]*The Catholic University of Korea, Incheon St. Mary's Hospital, Department of Rheumatology, Incheon, Korea, Rep. of (South Korea)*

Background: Osteoporosis is a frequent complication of ankylosing spondylitis (AS). Althogh there are no clear guidelines for the treatment of this secondary osteoporosis in AS, antiosteoporotic agents including bisphosphonate were used according to the same guidelines for primary osteoporosis. Also, approved by European Medicines Agency (EMA) in 2010, denosumab is being widely used.

Objectives: To compare the effect between bisphosphonate and denosumab on bone mineral density and radiographic progression in patients with AS for one year.

Methods: Among twenty-four patients with AS, sixteen patients were treated with bisphosphonate and nine patients with denosumab. BMD in the lumbar spine and right femur was measured by dual energy x-ray absorptiometry (DEXA) at baseline and one year after treatment. Radiographic progression was scored using the modified Stoke AS Spinal Score (mSASSS). Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS), and bone markers (bone-specific alkaline phosphatase (ALP), Collagen type 1 cross-linked C-telopeptide) were used to assess disease activity.

Results: Mean BMD values in the lumbar spine and total hip at one year increased when compared to those at baseline in both the bisphosphnate and denosumab groups (P=0.006 and 0.007 in bisphosphonate group, 0.015 and 0.036 in denosumab group). The increment was greater in denosumab group. The mean BMD in L-spine and total hip increased by 11.0% and 4.9% in denosumab group, while 9.0% and 2.7% in bisphosphonate group. There were no differences in disease activities such as BASDAI, ASDAS-CRP, ESR, and CRP between two groups. mSASSS and number of syndesmophyte also revealed no significant differences, suggesting that denosumab does not adversely affect disease activity and radiographic scores compared to bisphosphonate.

Table 1. Comparisons of the changes of clinical measure and radiographic scores between bisphophonate and denosumab

Change from baseline to year one	Bisphosphonate (n=15)	Denosumab (n=9)	P-value
BASDAI	1.5 ± 2.4	2.9 ± 2.8	0.215
ASDAS-CRP	0.9± 1.2	1.7 ± 1.3	0.174
ESR, mm/h	17.2 ± 24.8	31.0 ± 35.9	0.519
CRP, mg/l	13.7 ± 31.5	24.5 ± 44.0	0.446
Bone-specific ALP, μg/l	-0.7 ± 14.6	4.2 ± 4.3	0.379
C-telopeptide, ng/ml	-0.7 ± 2.7	0.128 ± 0.1	0.411
mSASSS in C- and L-spine	0.7 ± 0.9	0.4 ± 1.4	0.411
Number of syndesmophytes in C- and L-spine[a]	0.1 ± 0.3	0.2 ± 0.4	0.558

Changes are calculated as base value subtracted from one year value. BASDAI: Bath Ankylosing Spondylitis Disease Activity Index. ASDAS: Ankylosing Spondylitis Disease Activity Score. ALP: ankaline phosphatase. mSASSS: modified SASSS. C-: cervical. L-: lumbar.

Conclusion: Both bisphosphonate and denosumab increase L-spine and total hip BMD, while not affecting disease activity and spinal new bone formation. Further prospective studies with larger subject numbers are needed.

AB0953 THE EFFECTIVENESS OF IL-23 INHIBITORS ON AXIAL SPONDYLARTHRITIS AND AXIAL PSORIATIC ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Psoriatic arthritis, Spondyloarthritis

S. Al Nokhatha[1], S. Maguire[2], K. Alnaqbi[1]. [1]*Tawam Hospital, Rheumatology, Abu Dhabi, United Arab Emirates*; [2]*St James's Hospital, Rheumatology, Dublin, Ireland*

Background: Axial spondylarthritis (axSpA) is an immune-mediated systemic chronic inflammatory arthritis involving the axial skeleton that may involve peripheral joints. Nonsteroidal anti-inflammatory drugs are first line therapy in the management of axSpA, however for many patients NSAID monotherapy is not sufficient to induce disease remission. Given the known efficacy of biologics in spondyloarthritis and the heterogenicity of these conditions, treatment choices should take into account all relevant disease domains. Interleukin-23 has been identified as a promising therapeutic target in SpA and PsA based on a significant body of evidence. Interleukin 23 inhibitors have produced inconsistent results when used to treat axial spondylarthritis and axial psoriatic arthritis.(1,2) Thus, there is a need for a holistic understanding of the use of IL23 inhibitors in axial conditions in particular spondylarthritis and psoriatic arthritis to provide appropriate evidence-based management and mitigate the growing burden of these diseases.

Objectives: To explore the latest reported literature on the effectiveness of IL 23 inhibitors in axial spondylarthritis and psoriatic arthritis.

Methods: A systematic literature review was conducted. The following databases were searched: Pubmed, Mendely EMBASE, MEDLINE (OVID), CINAHL, Cochrane Library (central) and Web of Science. The search strategy included terms related to the axial spondylarthritis and axial psoriatic arthritis and specifying the medications of study interest Ustekinumab, Risankizumab, Guselkumab or Tildrakizumab. The search was restricted to studies published in English from inception until June 2022. Randomized controlled trials, observational studies, or systematic reviews were eligible. Screening of titles, abstracts, and subsequent full text assessment were conducted independently by two independent reviewers. Outcomes assessed were BASDIA, BASDAI 50,modified BASDAI, BASFI and ASDAS.

Results: Total of 4456 studies were identified, 9 studies of which 5 studies examining axial spondylarthritis (Four RCTs and 1 prospective study) and 4 studies examining axial psoriatic arthritis (two prospective observational studies and two post hoc-analysis) were deemed suitable for inclusion. In contrast to one prospective observational study, 4 RCT (3 ustekinumab, 1 risankizumab) did not support the use of IL23 inhibitors in axSpA based on the analyzed outcome measures of interest. Pooling of results for the three ustekinumab trials (BASDAI50, BASFI, and ASDAS) (figure 1) demonstrated that the drug was not efficacious in treating axSpA. However, trials in axial PsA investigations showed an improvement in BASDAI, modified BASDAI, and ASDAS.

Conclusion: The results of this meta-analysis would support the use of IL-23 inhibiting medications in the treatment of axial PsA. However, this is not the case for axSpA, as these drugs failed to demonstrate a significant improvement in patient outcomes in axSpA patient populations. This meta-analysis raises several interesting questions regarding differences in pathogenesis of axSpA and axial PsA. It also supports the need for ongoing drug development in axSpA, as biologic options remain limited compared to other forms of inflammatory arthritis.

IMPACT OF CHRONIC KIDNEY DISEASE IN PATIENTS WITH AS USING BIOLOGIC AGENTS

Keywords: Comorbidities, bDMARD, Spondyloarthritis

G. Sandal Uzun[1], İ. Y. Çakır[2], E. Bilgin[1], B. Farisogullari[1], G. Ayan[1], Z. Özsoy[1], M. Ekici[1], E. Unaldi[1], S. A. Germe[1], B. Fırlatan[1], G. S. Kart Bayram[1], L. Kılıç3, O. Karadag[1], A. Akdoğan[1], Ş. A. Bilgen[1], S. Kiraz[1], A. İ. Ertenli[1], U. Kalyoncu[1]. *[1]Hacettepe Univercity Faculty of Medicine, Department of Internal Medicine Division of Rheumatology, Hacettepe University Medical Faculty, Ankara, Turkey, Ankara, Turkey*; *[2]Hacettepe Univercity Faculty of Medicine, Department of Internal Medicine, Hacettepe University Medical Faculty, Ankara, Turkey, Ankara, Turkey*; *[1]Hacettepe Univercity Faculty of Medicine, Department of Internal Medicine Division of Rheumatology, Hacettepe University Medical Faculty, Ankara, Turkey, Ankara, Turkey*

Background: Although renal involvement is an rare extra-articular involvement in patients with ankylosing spondylitis (AS), medications and accopamyning comorbidities may adversly affect renal functions [1].
Objectives: To determine the frequency and impact of CKD in patients with AS using biologic disease modyfying anti-rheumatic drugs (bDMARDs).
Methods: Between 2005 and November 2021, 3207 patients diagnosed with AS according to the modified New York criteria were enrolled in the Hacettepe University biological database (HUR-BIO). The 2012 Kidney Disease: Improving Global Outcomes (KDIGO) guideline was used for the definition of CKD to evaluate the renal function of patients. Glomerular filtration rate (GFR) was calculated with the MDRD (modified Modification of Diet in Renal Disease) formula, taking into account the creatinine value, age and gender parameters of the patients [2]. CKD was detected in 39 (1,2%) patients. Age-sex matched 41 non-CKD AS patients were selected as the control group. Demographic and clinical characteristics and mortality rates of AS patients with and without CKD were compared.
Results: Of 39 AS-CKD patients, 25 (64.1%) had CKD before the initation of bDMARD and and 14 (35.8%) developed CKD during follow-up after treatment was started. Patients with AS-CKD had longer duration of symptoms and disease (Table 1). Comorbidities such as hypertension, coronary artery disease and amyloidosis were more prevalent in patients with AS-CKD. At a median follow-up of 2.48(0.1-20.1) years, mortality was observed in 11(28.2%) patients in the AS-CKD group, while no mortality was observed in the age-sex matched AS-nonCKD group (p<0.001, Figure 1). The mortality rate in patients with AS-CKD was 12.6 per 1000 patient-years, and 4 (10.2%) of deaths were during the COVID-19 pandemia.

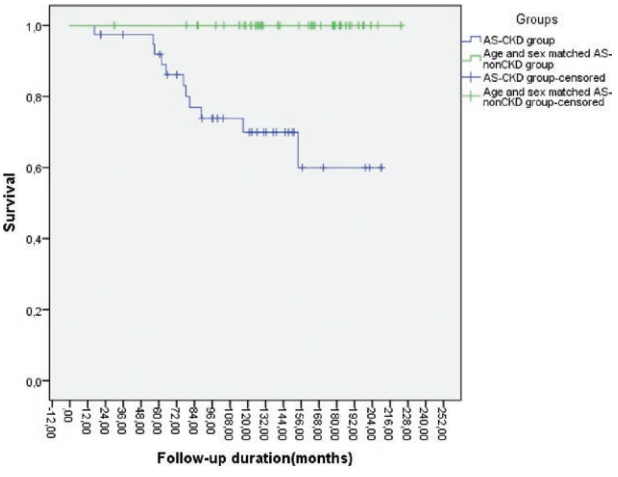

Figure 1.

Conclusion: Both comorbid disease burden and mortality seem to be increased in patients with AS-CKD. Increased mortality was more pronounced during the COVID-19 pandemia.

WITHDRAWAL FROM PROFESSIONAL LIFE DUE TO HIGH DISEASE ACTIVITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH TUMOUR NECROSIS FACTOR INHIBITORS AND/OR NONSTEROIDAL ANTI-INFLAMMATORY DRUGS IN ROUTINE CARE: RESULTS FROM THE MULTINATIONAL "INVISIBLE" STUDY

Keywords: Spondyloarthritis, Descriptive Studies, Outcome measures

J. Brandt-Juergens[1], J. Haschka[2], R. Finsterwalder[3], A. Casier[4], A. Kill[5], S. Dierckx[6]. *[1]Berlin, Specialized Practice for Rheumatology, Berlin, Germany*; *[2]Vienna, Rheuma-Zentrum Wien-Oberlaa, Vienna, Austria*; *[3]Vienna, Immunology, Hepatology & Dermatology, Vienna, Austria*; *[4]Vilvoorde, Immunology, Hepatology & Dermatology, Vilvoorde, Belgium*; *[5]Nuremberg, Immunology, Hepatology & Dermatology, Nuremberg, Germany*; *[6]Yvoir, CHU UCL Namur-Site Godinne, Yvoir, Belgium*

Background: Ankylosing Spondylitis (AS) is an inflammatory rheumatic disease affecting the axial skeleton (1), with a prevalence of up to 0.5% in Europe (2; 3), and occurs equally in men and women [4]. Nonsteroidal Anti-Inflammatory Drugs (NSAIDs) and biological Disease-Modifying Antirheumatic Drugs (bDMARDs) such as Tumour Necrosis Factor inhibitors (TNFi) are the first choice in pharmacological treatments for AS patients (5; 6). Data on employment situation in correlation with disease activity and disease duration in AS patients treated in real life settings in Europe are limited.
Objectives: To evaluate the disease activity status and assess participation in professional life in relation to treatment response following at least 12 weeks of treatment with TNFi and/or NSAIDs.
Methods: INVISIBLE was a multinational, cross-sectional, non-interventional study in Germany, Austria and Belgium. Adult patients with confirmed diagnosis of AS for at least 6 months and ongoing treatment with TNFi and/or NSAIDs for at least 12 weeks prior to enrolment were included. Primary data were collected at a single visit using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS) and collecting current demographic data including employment status using the categories employed, unemployed, parental leave, retired and sick leave (>6 weeks). Medical history data were collected from available patient files.
Results: 747 adult AS patients (67% male) were included in this analysis. The patients were 47.9±13.1 years of age. Symptom duration was 18.2±13.0 years. 22.9% of patients received NSAIDs, 41.6% TNFi, 29.7% both NSAIDs and TNFi, and 5.4% other treatment for at least 12 weeks prior to enrolment. BASDAI was

3.4±2.3 and ASDAS 2.2±1.0. Patient's disease activity assessment (Visual Analogue Scale 0-100) showed on average 35.8±27.5 and patients with BASDAI ≥4 reported significantly higher disease activity compared to patients with BASDAI <4 (59.7±20.7 vs. 20.7±19.7, p<0.001). 72.5% of patients were employed and 9.9% unemployed or in sick leave for >6 weeks. More patients with a BASDAI ≥4 were unemployed or in sick leave regardless of type of treatment and duration of symptoms compared to patients with a BASDAI <4 (see Table 1).

Conclusion: Results from the non-interventional study INVISIBLE showed that a higher proportion of AS patients receiving NSAIDs and/or TNFi with high disease activity according to BASDAI are not participating in professional life. These results suggest that in some patients, disease control and treatment response are suboptimal under current treatment strategy.

AB0956 APPLICATION OF THE DIFFICULT-TO-TREAT CONCEPT FOR AXIAL SPONDYLOARTHRITIS

Keywords: Real-world evidence, Spondyloarthritis, bDMARD

L. Berbel Arcobé[1], M. Roig Kim[1], E. Brugarolas Martinez[1], A. Domingo Carnice[2], P. Vidal Montal[1], M. Aguilar Coll[1], J. Palacios Olid[1], P. Maymo Paituvi[1], X. Juanola-Roura[1]. *[1]Bellvitge University Hospital, Rheumatology, L'Hospitalet de Llobregat, Spain*; *[2]Bellvitge University Hospital, Clinical Pharmacology, L'Hospitalet de Llobregat, Spain*

Background: The term "Difficult-to-Treat" (D2T) includes those patients who have persistent disease activity despite of having undergone several guideline-based treatments. This concept has been defined by EULAR for rheumatoid arthritis (RA) [1], thus could be analogously used for patients with Axial Spondyloarthritis (axSpA). In a recent publication [2] authors suggest that, among other criteria, axSpA patients could be classified as D2T when they require three or more biological drugs (bDMARDs) to control their disease.

Objectives: To describe the characteristics of axSpA patients who have undergone treatment with bDMARDs from a third-level university hospital and compare those who have received a maximum of two bDMARDs (group A) versus those who have received three or more (group B).

Methods: Descriptive, retrospective and unicentric study. Patients with axSpA diagnosis based on ASAS classification criteria, from March 2011 to December 2022, pulled from a specific database were included. They were separated into two groups according to the number of bDMARDs they had been under. Sociodemographic, clinical, radiographic and therapeutic variables were gathered.

Results: A total of 193 patients met the ASAS criteria for the diagnosis of axSpA and had received at least one bDMARD. The studied variables for each group are summarised in Table 1. Out of 193 patients (71% men; mean age 46,4 +/- 14 years old) 158 (81,9%) belonged to group A and 35 (18,1%) belonged to group B. There were no statistically significant differences between both groups. However, a tendency towards history of psoriasis, positive HLA B27 and elevated CRP at diagnosis was observed in those patients from group B.

Conclusion: The need of three or more bDMARDs in SpA is not infrequent in patients with axSpA and has similar proportions to RA. There has not been an agreement on stablished criteria for a D2T axSpA, but they could resemble those already defined for RA. Describing D2T for axSpA would be useful to identify those interrelated factors that may be associated with an increased activity upon diagnosis (high CRP) or the presence of extra musculoskeletal manifestations (psoriasis).

AB0957 IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES AMONG PATIENTS WITH RESOLUTION OF ENTHESITIS AND/OR DACTYLITIS: POST HOC ANALYSES FROM THE KEEPSAKE 1 AND 2 TRIALS OF RISANKIZUMAB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

Keywords: Spondyloarthritis, Enthesitis, Pain

S. Kwatra[1], S. Khattri[2], A. Amin[3], R. Liu[4], B. Padilla[4], A. M. Soliman[4], B. Kaplan[4], D. Mcgonagle[5,6]. *[1]Johns Hopkins University, Department of Dermatology, Baltimore, United States of America*; *[2]Mount Sinai, Department of Dermatology, New York, United States of America*; *[3]Northwestern Medicine Dermatology, Dermatology, Chicago, United States of America*; *[4]AbbVie, Department of Immunology, North Chicago, United States of America*; *[5]University of Washington, Division of*

Rheumatology, Seattle, United States of America; [6]*University of Leeds, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Enthesitis and dactylitis are associated with greater disease activity and reduced quality of life. Results from the phase 3 randomized, placebo-controlled KEEPsAKE 1 and 2 studies (NCT03675308; NCT03671148) of risankizumab in active PsA showed greater resolution of enthesitis and dactylitis with risankizumab 150 mg vs placebo at week 24.
Objectives: This post hoc analysis evaluated improvements in patient-reported outcomes (PROs) among patients who had enthesitis (n=444), dactylitis (n=188), or both (n=128) at baseline and achieved resolution of enthesitis, dactylitis, or both with blinded risankizumab at weeks 0, 4, 16, and open-label risankizumab every 12 weeks thereafter.
Methods: Assessments included achievement of minimal clinically important differences (MCID) in pain (≥10-mm decrease on visual analog scale), Health Assessment Questionnaire-Disability Index (HAQ-DI; ≥0.35-unit decrease), and Functional Assessment of Chronic Illness Therapy (FACIT-Fatigue; ≥4-point increase). Nonresponder imputation (with multiple imputation for COVID-19–related missing data at week 24) was used.
Results: Many patients who achieved resolution of enthesitis at week 24|week 52 also achieved MCID in pain (66.4%|71.4%), HAQ-DI (58.2%|63.4%), and FACIT-Fatigue (59.0%|72.1%). Many patients who achieved resolution of dactylitis at week 24|week 52 also achieved MCID in pain, (72.2%|81.7%), HAQ-DI (56.3%|66.2%), and FACIT-Fatigue (67.7%|69.9%). Many patients who achieved resolution of both enthesitis and dactylitis at week 24|week 52 also achieved MCID in pain (82.1%|86.4%) HAQ-DI (66.7%|69.2%), and FACIT-Fatigue (71.4%|74.6%). PRO results for patients for who did not achieve resolution of enthesitis and/or dactylitis will be presented.
Conclusion: Majority of patients who achieved resolution of enthesitis and/or dactylitis with risankizumab also reported improvements in pain, disability, and fatigue.

AB0958 A STUDY ON EARLY TAPERING OF TOFACITINIB IN ANKYLOSING SPONDYLITIS: A HIT AND RUN STRATEGY

Keywords: Tapering, Spondyloarthritis, Targeted synthetic drugs

V. Viswanath[1], H. Sreekumar[1], L. Sreekumari Ramachandran[1], A. G. Varier[1]. [1]*Dr Vishad Viswanath's IRIS Centre for Arthritis & Rheumatology, Rheumatology, Thiruvananthapuram, India*

Background: Tofacitinib is emerging as a cost-effective drug in managing ankylosing spondylitis (AS) [1]. Tofacitinib (XELJANZ) was FDA-approved for the use of active AS in December 2021. Safety concerns have been raised about the long-term use of Tofacitinib following the ORAL surveillance trial data [2]. However, in developing countries, the cost is a primary concern, and Tofacitinib, an oral drug, can be considered an alternative to biologicals. This study investigates whether early tapering can mitigate the safety risk and attain sustained remission.
Objectives: To assess the efficacy of early tapering of tofacitinib on disease activity in adult patients with active AS.
Methods: This observational study enrolled 22 consecutive patients aged ≥18 years diagnosed with active AS, meeting the ASAS criteria [3]. Patients received tofacitinib 10mg per day. ASDAS CRP was calculated at 0 and 6 months to monitor the response. The primary and secondary endpoints were early tapering of tofacitinib within six months of initiation and assessment of ASDAS CRP at six months, respectively. Assessment of the safety profile was done monthly.
Results: In our study, the mean ASDAS CRP at the initiation of tofacitinib was 2.24 (SD 1.13). After six months of treatment, the mean ASDAS CRP was 0.9 (SD 0.6), with remission in 77.27% (17 of 22). Tapering was initiated at a mean of 4.4 months (SD 3.18) and as early as one month. 41%of patients (9 of 22) had attained remission with early tapering of Tofacitinib and in 9%of patients (2 of 22), we could successfully stop Tofacitinib with sustained remission. Transaminitis occurred in 22% (5 of 22), of which in 2 patients drug had to be stopped.Two2 patients (9%) had to be switched to biologicals due to non-responsiveness. There were no deaths, malignancies, major adverse cardiovascular events, thromboembolic events, or opportunistic infections.
Conclusion: In our study of 22 patients, we find that Tofacitinib can be a cost-effective treatment option in patients with AS who cannot afford biologicals, especially in a developing economy like India. However, recent concerns about the drug's long-term safety preclude its optimal use. Early tapering of Tofacitinib demonstrates no increased incidence of flares and helps maintain remission. A hit-and-run strategy of early tapering of Tofacitinib would benefit patients with AS in the Indian context. We find that early tapering is effective in at least some of the patients, and it can reduce the cost of treatment as well as potential adverse reactions.

AB0959 SECUKINUMAB SURVIVAL AND ASSOCIATED DEMOGRAPHIC CHARACTERISTICS IN PATIENTS WITH SPONDYLOARTHRITIS AND PSORIASIC ARTHRITIS IN A REAL CLINICAL SETTING

Keywords: Safety, Spondyloarthritis

M. López I Gómez[1], U. Astigarraga Urkia[2], L. Ibarrola[2], I. Pineiro[2], J. Mendizabal[2], G. Sada Urmeneta[2], N. Del Val del Amo[2], I. Paniagua Zudaire[2], L. Garrido Courel[2], R. Gutierrez[2], L. Horcada[2], C. Fito-Manteca[2]. [1]*Hospital Universitario Arava, Rheumatology, Vitoria, Spain*; [2]*Hospital Universitario de Navarra, Rheumatology, Pamplona, Spain*

Background: Secukinumab (SCK) is a human monoclonal antibody (IgG1) directed against IL-17A, approved for the treatment of plaque psoriasis, psoriatic arthritis (PsA) and axial spondyloarthritis (AxSpA). Data from randomized controlled clinical trials (RCTs) have shown that SCK has a low frequency of treatment discontinuation. We currently have little consistent data on long-term survival of SCK in patients with AxSpA and PsA in regular clinical practice. Therefore, we aimed to evaluate the drug retention of SCK in actual clinical practice, causes for discontinuation and factors associated with SCK suspension in patients diagnosed with PsA or AxSpA who receive or have received such therapy.
Objectives: We aimed to evaluate the drug retention rate, causes for treatment discontinuation and factors associated with SCK persistence in patients with AxSpA and PsA in a real clinical setting.
Methods: A retrospective cohort study was carried out including patients diagnosed of axSpA fulfilling the ASAS classification criteria and PsA fulfilling the CASPAR classification criteria. A total of 90 patients were included in the study treated with SCK between 2016 and 2022 in the rheumatology service of the Hospital Universitario de Navarra. All patients included started SCK at least 12 months before the data extraction.
Drug survival in months was analyzed by Kaplan-Meier curves while predictive factors of discontinuation were evaluated using a Cox regression analysis. The reason of suspension was also recollected.
Results: We included 90 patients (46 AxSpA and 44 PsA). The mean age at diagnosis was 44.5 years (SD 11.1) and the mean age at SCK initiation was 51.6 (SD 11.4). The median time from diagnosis to onset of SCK was 4.2 months (IQR 9.8) (Table 1). Eighty-three (92.2%) patients were treated with one or more biologics prior to SCK, median number of previous biologics was 2 (IQR 0-5). The average treatment duration was 31.8 months (SD 75.1). The 1 and 2-year retention rates for SCK in the AxSpA group was 83 and 71%, respectively, while for the PsA group it was 69 and 52% respectively (Fig 1). Thirty-five (38.88%)

patients discontinued treatment, 29 (82,85%) due to inefficacy, 1 (2,85%) by their own decision, 4 (11,42%) due to persistent mechanical pain and 1 (2,85%) due to neoplasia. The factors associated with lower risk of discontinuation were higher IMC (p = 0.025) and diabetes (p = 0.04). None of the other clinical variables evaluated had a statistically significant association with a lower or higher risk of discontinuation or discontinuation. No patient presented infections that required discontinuation of the drug.

Conclusion: SCK showed a very high retention rate in a population that has been previously exposed to several biological therapies both in AxSpa and PsA groups. According to previous reports [1], cardiometabolic comorbidities such as obesity and diabetes appear to be associated with better SCK survival and therefore this drug could be an optimal therapy for patients with cardiometabolic risk factors.

EFFECT OF BODY MASS INDEX ON TREATMENT RESPONSE OF BIOLOGIC-/TARGETED SYNTHETIC DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHRITIS

Keywords: Inflammatory arthritides, bDMARD, Comorbidities

C. G. Gialouri[1], M. Pappa[2], G. Evangelatos[2], E. Nikiphorou[3], G. E. Fragoulis[2].
[1]National and Kapodistrian University of Athens, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, Medical School, National and Kapodistrian University of Athens,"Hippokration" General Hospital of Athens, Athens, Greece; *[2]National and Kapodistrian University of Athens, Rheumatology Unit, First Department of Propaedeutic Internal Medicine, Medical School, National and Kapodistrian University of Athens, "Laiko" General Hospital of Athens, Athens, Greece*; *[3]King's College Hospital, London, UK., Centre for Rheumatic Diseases, Rheumatology Department, London, United Kingdom*

Background: Overweight and/or obese patients with inflammatory arthritis (IA) have higher disease activity and lower chances of achieving as well as maintaining the treatment targets. Obesity also appears to negatively affect the response to tumor necrosis factor (TNF) inhibitors in patients with IA. The efficacy of other biologic (b) and of targeted-synthetic (ts) DMARDs in overweight/obese patients with IA, including rheumatoid arthritis –RA, psoriatic arthritis –PsA, axial spondyloarthritis –AxSpA, is unclear.

Objectives: To conduct a systematic literature review (SLR) to explore the effect of weight/body-mass-index (BMI) on the efficacy of all b-/ts-DMARDs approved for the treatment of RA, PsA and AxSpA.

Methods: For this PROSPERO-registered SLR, we searched PubMed, Scopus and Cohrane-Library up to June 21st 2022. PICO-format was as follows: Population: adults with RA, PsA or AxSpA and low/normal weight/BMI; Intervention: treatment with approved b-/ts-DMARDs; Comparator: adults with RA, PsA or AxSpA and high/abnormal weight/BMI; Outcome: any outcome used for the assessment of treatment response (e.g DAS28, ACR20, drug-survival). The search query included the following keywords in the article's title and/or abstract: ("psoriatic arthritis" OR "rheumatoid arthritis" OR "inflammatory arthritis" OR "ankylosing spondylitis" OR "axial spondyloarthritis" OR "non-radiographic axial spondyloarthritis") AND (DMARDs OR bDMARDs OR tsDMARDs OR tofacitinib OR upadacitinib OR baricitinib OR filgotinib OR apremilast OR anti-TNF OR etanercept OR infliximab OR adalimumab OR golimumab OR certolizumab OR abatacept OR rituximab OR tocilizumab OR anti-IL-6 OR anti-IL-17 OR anti-IL-23 OR anti-IL-12/23 OR ustekinumab OR guselkumab OR risankizumab OR secukinumab OR ixekizumab OR "janus kinase inhibitors" OR "JAK inhibitor") AND ("body mass index" OR BMI OR obes* OR weight). Clinical-trials and observational studies were included. The screening and selection process was conducted independently by two reviewers. Risk of bias (ROB) was assessed using the RoB2-Cochrane tool and Newcastle-Ottawa scale for randomized and non-randomized studies, respectively.

Results: Out of 996 references, 192 full-text articles were reviewed and 75 eventually fulfilled the inclusion criteria (of which 10 studies were retrieved through manual-search). Number of studies, most of which were of medium RoB, was: 34 for TNF-inhibitors, 4 for IL-12/23 inhibitors, 1 for IL-23 inhibitor, 7 for IL-17 inhibitors, 18 for tocilizumab, 8 for abatacept, 3 for rituximab and 5 for JAK-inhibitors. The efficacy of TNF-inhibitors was found to be affected by the BMI in all forms of IA with the effect being similar across various TNF-inhibitors. In contrast, the favorable results of IL-23 and IL-17 inhibitors do not appear to be influenced by increased BMI in patients with PsA or AxSpA. Similar evidence exists for tocilizumab and abatacept, while no conclusion can be drawn for rituximab. More data are needed for JAK-inhibitors, although the effect of weight/BMI does not seem to be significant so far (**Figure-1**).

Conclusion: Weight/BMI should be considered in the treatment-plan of patients with IA, with its effect being more pronounced for TNF-inhibitors compared to other b-/ts-DMARDs.

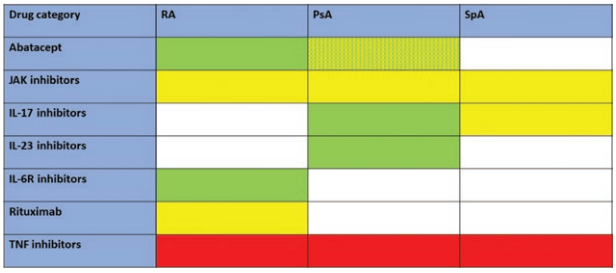

Figure -1 The effect of weight/BMI on the efficacy of the approved b- and ts-DMARDs for RA, PsA and AxSpA. Red color: negative effect, green color: no effect, yellow color: limited data, green/yellow knitting: possibly no effect but limited data, white: not applicable.

Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease most often affecting young adult males and linked to the HLA B27 antigen in more than 90% of cases. The classic age of onset of symptoms is in most cases between 20 and 30 years. However, it is known that the disease can start in early childhood and that there are cases appearing after 50 years.

The aim of this study is to compare the efficacy of biotherapy in juvenile onset spondyloarthritis and adult onset spondyloarthritis using data from the biotherapy registry of the Moroccan Society of Rheumatology BRSMR.

Objectives: To evaluate the real-life effectiveness of biologic therapies in patients with ankylosing spondylitis (AS) according to age of disease onset.

Methods: A cross-sectional multicenter observational study was conducted; the data source was the Moroccan Registry of Biological Therapies in Rheumatic Diseases (RBSMR Registry). Patients, included from May 2017 to January 2019, were all adult patients (age >18 years), with APS, according to the ASAS classification criteria for APS 2009. Therapeutic efficacy was assessed by ASDAS-CRP, a therapeutic response was defined by an ASDAS-CRP less than 1.3. The therapeutic response to biological treatment after 1, 2 and 3 years of evaluation was compared between two groups: group a: juvenile spondyloarthritis with age of onset less than 16 years and group b: spondyloarthritis in patients over 16 years.

Results: 194 patients were included in the study. Concerning group a (26 patients 13%): The mean age was 26.15 ± 7.05 years, the sex ratio was 4.2. 92.3% of the patients had axial involvement, 79.2% had peripheral involvement and 41.7% had enthesic involvement. The mean erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) on admission were 41.6±29.2 mm/h and 39.51 [6.98;58.25] respectively. HLA B27 was positive in 100% of patients. The mean ASDAS CRP was 3.6±1.14; 1.5±1.22; 1.8±1.3; 1.25 [0.85; 3.35] at baseline and then at 1 year,2 years and 3 years respectively. As for group b (120 patients 62%): The mean age was 44.61 ±12.14 years, the sex ratio was 1.4. 97.5% of the patients had axial involvement, 66.1% had peripheral involvement and 63.6% had enthesic involvement. The mean erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) at admission were 38.36 [16.55] and 26.43 [5.9; 40], respectively. HLA B27 was positive in 63.3% of patients. The mean ASDAS CRP was 3.35±1.5; 1.9±1.09; 1.6±1.3; 1.8±0.93 at baseline and then at 1 year,2 years and 3 years respectively. The analysis revealed no statistically significant difference between the two groups regarding the therapeutic response to biological treatment (p=0.16; p=0.73; p=0.26 at one, two and three years respectively).

Conclusion: Spondyloarthritis, whether it starts in childhood or in adulthood, has similar clinical and radiological manifestations. Similarly, the response to treatment is identical to that obtained in patients with an adult onset. Biotherapy opens a new avenue for the treatment of juvenile spondyloarthritis. Our study as well as the literature data confirm the efficacy of biotherapy and its good tolerance in our patients with APS whatever the age of onset of the disease.

Key words: spondyloarthritis, biotherapy, age of disease, RBSMR registry.

COMPARISON BETWEEN SECUKINUMAB AND IXEKIZUMAB IN PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHRITIS: A SINGLE CENTER EXPERIENCE

Keywords: bDMARD, Psoriatic arthritis, Spondyloarthritis

C. Cannistrà[1], E. Fiorentini[1], L. Cometi[1], L. Tofani[2], S. Bellando-Randone[1], S. Guiducci[1]. [1]*University of Florence, Clinical and Experimental Medicine, Rheumatology Unit, Florence, Italy*; [2]*University of Florence, Statistics, Informatics, Applications, Florence, Italy*

Background: The pathogenesis of SpA has not been completely elucidated, but several pieces of evidence suggest that interleukin (IL)17-A plays a pivotal role in this group of diseases. Both anti-IL-17A drugs Secukinumab (SEC) and Ixekizumab (IXE) have shown efficacy in treating multiple facets of SpA. (2)

Objectives: Our study aimed to compare the effect of SEC and IXE in our cohort of patients with PsA or axSpA.

Methods: We retrospective analyzed our clinical database, enrolling patients with PsA or axSpA treated with SEC or IXE. We collected disease activity scales and scores at baseline (0) and after 3, 6 and 12 months of treatment: BASDAI (Bath Ankylosing Spondylitis Disease Activity Index), DAPSA (Disease Activity Index for Psoriatic Arthritis), VAS (Visual Analog Scale) for pain, PGA (Patient Global Assessment), and PHGA (Physician Global Assessment).

Results: We selected 73 patients, 55 with PsA (75.30%) and 18 with axSpA (24.70%). In the SEC cohort, we found 52 patients, mainly females (73.00%), mean age of 57.00 ± 11.47 years; in the IXE cohort, there were 21 patients, 71.43% females, mean age of 53.81 ±11.17 years. Peripheral involvement was present in the majority of patients (88.46% vs. 100%), while axial involvement was predominant in SEC treated patients (61.54% vs. 28.57%). The presence of dactylitis was similar in the two groups (15.38% vs. 14.29%), enthesitis prevailed in SEC cohort (75.00% vs. 57.14%) while cutaneous psoriasis in the IXE cohort (44.23% vs. 80.95%). During follow-up, BASDAI and DAPSA decreased significantly in both SEC and IXE groups, especially in the first trimester, with a similar trend during the

second trimester (significant only for SEC). When compared with each other, SEC and IXE appeared to have a similar effect on both scales, except for a significantly greater reduction of BASDAI in the first trimester for SEC, which however was no longer present when the values were adjusted for the starting BASDAI value (Table 1). Analyzing PGA, PHGA, and VAS pain, we observed a significant trend in reduction in the first trimester for both drugs, then maintained only for SEC, significantly greater for SEC than IXE in both trimesters. The analysis of the adjusted values confirmed the significant decrease in BASDAI DAPSA PGA PHGA and VAS for both SEC and IXE, especially until 6 months after baseline.

Conclusion: Our data confirmed that SEC and IXE are both valid options for the treatment of PsA and axSpA, without significant differences when comparing the two drugs.

AB0963 SAFETY OF DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS IN SPONDYLOARTHRITIS: A RETROSPECTIVE REVIEW FROM A SOUTH AFRICAN RHEUMATOLOGY CENTRE

Keywords: Spondyloarthritis, Disease-modifying Drugs (DMARDs)

G. S. Tarr[1,2], H. Reuter[1,2], T. Mann[1,3]. [1]*Mediclinic Winelands Orthopaedic Hospital & Mediclinic Winelands Day Clinic, Rheumatology, Stellenbosch, South Africa*; [2]*Stellenbosch University, Division of Rheumatology, Department of Medicine, Stellenbosch, South Africa*; [3]*Stellenbosch University, Division of Orthopaedic Surgery, Department of Surgical Sciences, Stellenbosch, South Africa*

Background: The long-term immune-suppressive effects of Disease Modifying anti-Rheumatic Drugs (DMARDs) have long been a concern for serious adverse effects (SAE). Other developing countries, e.g. Brazil, used their registry to report a higher incidence of serious infections in the bDMARD treated patients compared with sDMARDs [1]. There are no published articles about the true incidence and nature of SAEs in Spondyloarthropathy (SpA) patients treated with bDMARDs in the South African context.

Objectives: To describe the incidence of SAEs amongst patients with SpA treated with b- and s-DMARDs at a rheumatology centre in the Western Cape, South Africa.

Methods: A retrospective medical record review was conducted, involving patients with SpA seen at a private rheumatology clinic in Stellenbosch, Western Cape, between the 1 January 2014 and 31 December 2021. Demographic, clinical, and patient reported SAEs were recorded for those treated with b- and s-DMARDs. Incidence of SAEs was calculated and presented with 95% confidence intervals.

Results: Incidence of SAEs recorded between 1 January 2014 and 31 December 2021. A total of 92 patients were included, 59 bDMARD exposed and 33 treated only with sDMARDs (bDMARD naïve). The accumulated exposure was 300 person-years (p-y) for those on bDMARDs and 140 p-y for those on sDMARDS only. Twenty two SAEs were reported during the study period: 14 infective, 4 major adverse cardiac events, 3 malignant (prostate, uterine, and thymoma), and 1 pulmonary complication. Twenty SAE's occurred whilst on a DMARD, one occurred 37 days after stopping etanercept, and a single SAE was excluded as it occurred 2 years after stopping infliximab. All SAEs were associated with hospitalisation and there were two deaths (one related to multi-organ failure, the other COVID-19 related). The SAE incidence for the sDMARD control group was 2.1/100 p-y (95% C.I. 0.5-5.8/100 p-y) and 6.0/100 p-y (95% C.I. 3.7-9.3/100 p-y) in the bDMARD study group. Of the anti-TNF inhibitors assessed, etanercept had the lowest SAE incidence at 3.8 events/100 p-y (95% C.I. 1.2-9.3/100 p-y) (see Table 1).

Table 1: Incidence of SAEs

	n	Person-years	Infective	CVS	Malignant	Other	Total SAEs	Incidence of SAEs per 100 person-years (95% C.I.)
Adalimumab	37	102,1	4	1	1		6	5.9 (2.4-12.2)
Etanercept	31	104,1	2	2			4	3.8 (1.2-9.3)
Golimumab	18	52,1	2		1		3	5.8 (1.5-15.7)
Infliximab	9	33,9	3			1	4	11.8 (3.7-28.5)
Secukinumab	6	7,2	1				1	13.9 (0.7-68.5)
Ustekinumab	1	0,6					0	-
sDMARDs only	33	139,8	1	1	1		3	2.1 (0.5-5.8)
Total			13	4	3	1	21	
bDMARD groups								
Monoclonal antibodies[a]	64	188.1	9	1	2	1	13	6.9 (3.8-11.5)
All anti-TNF[b]	95	292.2	11	3	2	1	17	5.8 (3.5-9.1)
All bDMARDs	101	299.2	12	3	2	1	18	6.0 (3.7-9.3)

2. [a]Adalimumab, Golimumab, Infliximab. [b]Adalimumab, Golimumab, Infliximab, Etanercept, *bDMARD – biologic Disease Modifying Anti-Rheumatic Drug; n – number; SAE – Serious Adverse Event; sDMARD- synthetic Disease Modifying Anti-Rheumatic Drug;*

Conclusion: The preliminary results of this retrospective review of SpA patients attending a private rheumatology clinic in a developing country suggests that infliximab treated patients were 5.5 times more likely to develop an SAE compared to patients on sDMARDs. Overall patients exposed to monoclonal antibodies were 3.2 times as likely to develop an SAE compared to those receiving sDMARDs, with respiratory infections the most commonly reported SAE.

AB0964 THERAPEUTIC DRUG MONITORING OF INFLIXIMAB IN INFLAMMATORY RHEUMATIC DISEASES: REAL-LIFE DATA IN A COHORT OF PATIENTS

Keywords: Spondyloarthritis, bDMARD, Rheumatoid arthritis

M. Martin Lopez[1], N. Molina Esteban[1], O. Cabrera[2], J. L. Pablos[1]. [1]*Hospital Universitario 12 de Octubre, Instituto de investigación i+12, Rheumatology, Madrid, Spain*; [2]*Hospital Universitario 12 de Octubre, Immunology, Madrid, Spain*

Background: Therapeutic drug monitoring (TDM) could be helpful in several clinical situations such as loss of response to therapy, the interpretation of side effects to therapy and to determine dose adjustments [1].

Objectives: To investigate the influence of demographic and clinical characteristics on circulating infliximab (IFX) levels and the clinical relevance of measuring IFX trough levels (ITL) in patients with inflammatory arthritis treated with IFX.

Methods: Unicentric observational retrospective study conducted in a tertiary hospital between January 2018 and December 2022. Patients with spondyloarthritis (SpA) and rheumatoid arthritis (RA) treated with IFX and having been performed a serum ITL determination during follow-up were included. Patients were classified into two groups depending on the disease activity, descriptive statistics and a comparative analysis were performed. The continuous data were compared using the Mann-Whitney U test or the Student t-test, and the frequency data with the Pearson $\chi 2$ or Fisher exact tests. Univariable and multivariable logistic regression models were employed to investigate the influence of demographic and clinical characteristics in ITL and immunogenicity. Serum dependent ROC curves were used to determine the ITL that best predicted good clinical response.

Results: A total of 91 patients, 78 SpA and 13 RA were included. Their demographic and clinical characteristics are shown in Table 1. All patients who had remission or low disease activity (LDA) in the ITL measurement remained without activity at 12 months. 34 of 41 (83%) patients with disease activity achieved remission or LDA at 12 months of ITL measurement with a significant improvement in the disease activity ($p < .001$). In the univariable analysis, the presence of rheumatoid factor (OR 0.1; CI95% 0.03 – 0.7), methotrexate use (4.5; 0.8 –2.5), sulfasalazine use (7.7; 1.3 – 4.4) and disease activity (0.06; 0.02 – 0.2) are associated with ITL ($p < .1$). Regarding immunogenicity, we observed an association with female sex (2.5; 0.8 – 7.6), rheumatoid factor (1.8; 3.7 – 8.6), ACPA positive (4.1; 0.9 – 1.9), disease duration (0.9; 0.9 – 1.0), IFX duration (0.8; 0.7 – 0.9), baseline SpA activity (2.9; 0.9 – 9.2) and disease activity (31.4; 3.9 – 2.5), all $p < .1$. However, in the multivariable analysis only was confirmed the association between ITL and immunogenicity with disease activity, and between immunogenicity with IFX duration ($p < .05$). In our cohort, the optimal cut-off of ITL in RA patients was 1.5 µg/mL and 6.7 µg/mL for SpA (Fig).

Conclusion: TDM appears to be a useful technique for the control of inflammatory arthritis. Demographic and clinical characteristics can influence drug levels that are important to know to decrease immunogenicity when possible. More studies still need to be carried out to analyze the therapeutic range of biologics.

EXTRA-AXIAL MANIFESTATIONS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: THE COURSE AND RESPONSE TO THERAPEUTIC AGENTS

Keywords: Remission, Disease-modifying Drugs (DMARDs), Spondyloarthritis

A. Yılmaz[1], E. Bektaş[1], A. Canik[2], B. Artim-Esen[3], M. Inanc[3], A. Gül[3], Y. Yalçınkaya[3]. *[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey*; *[2]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey*; *[3]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease involving the axial skeleton and commonly include some coexisting extra-axial manifestations (EAMs) [1] which may have an influence on prognosis and treatment decisions [2].
Objectives: We aim to show the characteristics of EAMs in patients with axSpA and to assess the progress under different therapeutic agents.
Methods: In this retrospective cohort study; medical records of all patients with axSpA who fulfilled ASAS classification criteria and were followed up between 1980 to 2022 at our tertiary referral outpatient clinic were screened. The data of 201 (59.7% males) patients who had sacroiliitis (by using X-Ray or MRI) and coexisted EAMs was recorded into a pre-defined protocol. Demographics and progress of EAMs under different therapeutic agents were analysed.
Results: The mean age and duration of follow-up period were 34 years (IQR 25-43) and 144 months (IQR 84-213). Prevalence of family history and HLAB27 were 30.6% (38/124) and 77.4% (65/84). Non-radiographic sacroiliitis was observed in 21.9%. Peripheral arthritis (60%) was the most common EAM and followed by uveitis (46%), IBD (17%), psoriasis (14%), enthesitis (13%) and dactylitis (5%). Demographics and treatment details are shown in *Table 1* and *Figure 1*. Approximately, half of the patients were treatment naive at onset of each EAMs. Anterior uveitis and psoriasis were frequently occured despite using bDMARDs (31% and 39%). Fifty nine percentage of the patients with psoriasis and one third of patients with uveitis and dactylitis required a switch to bDMARDs.
Conclusion: In patients with axSpA, some of EAMs required treatment switches and relapses occured despite treatment optimization. Determining appropriate and efficaceous treatment algorithms according to presence of EAMs should be one of the main goals of axSpA management strategies.

EFFICACY AND SAFETY OF SECUKINUMAB IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: SINGLE CENTER EXPERIENCE

Keywords: Disease-modifying Drugs (DMARDs), bDMARD, Spondyloarthritis

F. Taş[1], S. Gulle[2], F. Onen[2], İ. Sari[2]. [1]*Dokuz Eylul University School of Medicine, Internal Medicine, Izmir, Turkey*; [2]*Dokuz Eylul University School of Medicine, Rheumatology, Izmir, Turkey*

Background: Secukinumab (SCK), the first-in-class human monoclonal antibody against interleukin-17A, has been approved for the treatment of AS in many countries, including the US and EU. The efficacy of subcutaneous secukinumab in the treatment of Ax-SpA was primarily evaluated in five multicenter, phase III studies that included four randomized double-blind studies (MEASURE Studies). However, there are few studies evaluating long-term SCK efficacy in real-life data in patients with AxSpA [1,2].
Objectives: Our aim in this study is to retrospectively evaluate the clinical findings and treatment response status of patients who were followed up with the diagnosis of Ax-SpA and using SCK.
Methods: A total of 60 patients who were followed up with the diagnosis of akSpA in our rheumatology clinic were included in the study. Demographic characteristics of the patients, comorbidities, duration of symptoms, delay in diagnosis, biologics and DMARDS were recorded. In the evaluation of the patients, BASDAI, BASFI, ASDAS, VAS pain, and VAS global scores were recorded as baseline, 3, 6, 12 and 24th months. The number and order of treatment before SEC in patients using bDMARDs were also examined, and SCK efficacy and drug retention characteristics were investigated between the biological treatment naive and resistant groups. Variables were analyzed at 95% confidence level, and p value less than 0.05 was considered significant.
Results: Follow-up data of 60 patients diagnosed with SpA (n=50 AS and n=10 nr-AxSpA) followed in a single center (inception cohort) were evaluated. Of these patients, 15 (25%) were bDMARD naive patients and 45 (75%) had used ≥1 bDMARD before SEC. The age and gender distribution was similar between the bDMARD naive and ≥1 bDMARD group. At 1-year follow-up, 1 and 7 patients discontinued their treatment in the ≥1 bDMARD group and the SCK group, respectively (p<0.001) (Table 1). The retention rate at 24 months was 80% and 49% in the naive and ≥1 bDMARD patients, respectively (p=0.026) (Figure 1). In our study, no significant drug-related serious adverse events or safety problems were encountered in the follow-up of secukinumab treatment for more than 36 months.
Conclusion: We found that SCK treatment in patients with Ax-SpA had better clinical response and higher drug survival rates in biologic naive patients, similar to TNFi treatment in real-life data. However, better drug retention rates were found in naive patients compared to patients using >1 bdmard, which is consistent with the results of previous studies.

REFRACTORY ACHILLES ENTHESITIS SUCESSFULY TRAETED BY IXEKIZUMAB LOCAL INJECTION

Keywords: bDMARD, Spondyloarthritis, Enthesitis

A. Abogamal[1]. [1]*Al-Azhar Faculty of Medicine, Rheumatology, Cairo, Egypt*

Background: Axial spondyloarthropathy (axSpA) is a chronic autoimmune inflammatory disease that involves the axial skeleton with inflammatory back pain as the most common presenting symptom. [1] Apart from the axial joints, enthesis are frequently involved in spondyloarthopathy (SPA) and clinical enthesitis reported to affects 10% – 60% of SPA patients. Enthesitis usually involves the lower limb and heel pain represents a significant clinical challenge due to frequent presence of Achilles enthesitis (AE), retrocalcaneal bursitis (RB) and plantar fasciitis, plus a

treatment challenge in refractory cases that usually not controlled by conventional DMARDs and fails to respond to biological treatment [2-4].
Objectives: To describe a successful management of refractory case of AE after US guided Ixekizumab injection to the RB.
Methods: Male 42 y old known case of axSpA for 22 y with +ve HLAB27 and bilateral AE. initially treated with salazopyrine, and NSAIIDs with no response and treatment escalated to Infleximab with secondary failure after 6 months, switched etanercept injection with primary failure. Patinet achived god clinical responce on adalimumab which was maintained up to 7y, followed by secondry faliure due to antidrug antibodies, resolved by addding Methotrexate. July 2019, developed hepatotoxicity due to methotrexate with discontinuation. December 2019, patient switched to Ixekizumab with successful control of his disease. Apart from the course of axial disease, January 2019 his heel pain becomes refractory to treatment VAS 8 with US assessment shows AE, RB, and tendinitis with positive Doppler signals. pain was partially responding to the added physiotherapy and NSAIDs with VAS fluctuating between 5 and 6 on both sides. February 2020, after initiation of Ixekizumab AE resoluted on the right-side VAS 0, while the left side still symptomatic VAS 6. US of the left Achilles insertion shows hypoechogenety of the tendon, distended RB, positive Doppler signals involving the bursa and extending to the tendon body. Figure 1 March 2020, an US guided injection with Triamcinolone acetate 20mg infiltrated to the RB failed to control pain with partial response for two weeks. July 2020, an US guided injection of the RB with Ixekizumab 80mg arranged two weeks after application of the systemic Ixekizumab.

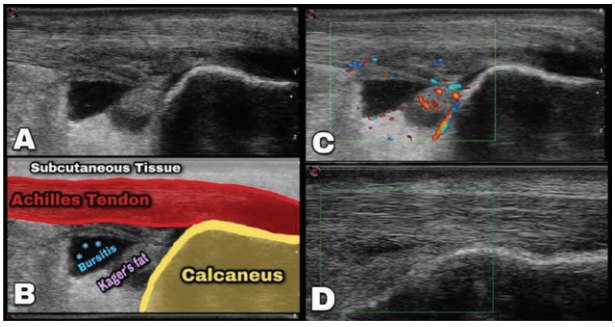

Figure 1. long axis scan of the left Achilles tendon; A: Grey scale shows hypoechogenecity of the tendon, with retrocalcaneal bursitis, B: corresponding Cartoon, C: positive color Doppler at the tendon and bursa, D: post Ixekizumab injection; resolution of the Doppler signals and bursitis.

Results: Three months after Ixekizumab local injection, heel pain drops to VAS 0, with radiological improvement in US; resolution of the Doppler signals and the RB. On follow up from July 2020 - January 2022; Resolution of heel pain, AE and RB persists since the application of Ixekizumab, with normalized Doppler and RB. Figure 1
Conclusion: US Guided local application of Ixekizumab successfully help to resolve pain and inflammation in a refractory case of AE.

AB0968 RAPID ONSET OF EFFICACY IN CHINESE PATIENTS WITH ACTIVE RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS TREATED WITH IXEKIZUMAB: A PHASE 3 STUDY

Keywords: Outcome measures, Clinical Trials

Y. Xue[1], J. Hu[2], D. Liu[3], J. Li[4], H. Wu[5], C. Tan[6], L. Dai[7], Y. Yan[8], H. Li[8], H. Zou[1]. *[1]Huashan Hospital affiliated to Fudan University, Department of Rheumatology and Immunology, Shang Hai, China*; *[2]Pingxiang People's Hospital, Department of Rheumatology and Immunology, Ping Xiang, China*; *[3]Shenzhen People's Hospital, Department of Rheumatology, Shen Zhen, China*; *[4]Zhuzhou Central Hospital, Department of Rheumatology and Immunology, Zhu Zhou, China*; *[5]The Second Affiliated Hospital Zhejiang University School of Medicine, Department of Rheumatology, Zhe Jiang, China*; *[6]West China Hospital of Sichuan University, Department of Rheumatology and Immunology, Si Chuan, China*; *[7]Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Department of Rheumatology, Guang Zhou, China*; *[8]Eli Lilly and Company, Rheumatology and Immunology, Shang Hai, China*

Background: Ixekizumab, a high-affinity monoclonal antibody that selectively targets interleukin-17A, has demonstrated efficacy in global clinical trials in patients with active radiographic axial spondyloarthritis (r-axSpA)/ankylosing spondylitis (AS) [1,2]. Rapid onset of clinical improvement is one of the most important needs of treatment for r-axSpA patients.
Objectives: To evaluate the onset time of ixekizumab in Chinese patients with r-axSpA.
Methods: This report evaluated efficacy onset time of r-axSpA patients treated with ixekizumab compared with placebo based on data from a phase 3 study in China. The major secondary efficacy measures in this report included Assessment of Spondyloarthritis International Society (ASAS) 40 response, ASAS 20 response, change from baseline in Ankylosing Spondylitis Disease Activity Score (ASDAS), change from baseline in Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), change from baseline in Bath Ankylosing Spondylitis Functional Index (BASFI), and ASDAS <2.1 response. Other secondary efficacy measures in this report included change from baseline of ASAS individual components (like patient global, Spinal pain, Inflammation, high sensitivity C-reactive protein [hsCRP]), proportion of patients who experience clinically important improvement (change of ASDAS from baseline ≥1.1), major improvement (change of ASDAS from baseline ≥2.0), and BASDAI 50 response. All efficacy measures were evaluated from week 0 through week 52. A logistic regression model and mixed-effects model of repeated measures (MMRM) were used to analyze categorical and continuous measures from week 0 to 16 (placebo-controlled period), and categorical missing data were imputed using non-responder imputation (NRI).
Results: More patients achieved ASAS40 and ASAS20 response as early as week 1 ($p = 0.042$ and $p < 0.001$) in the ixekizumab-treated group compared with placebo. In addition, statistically significant ($p < 0.05$) improvements were observed as early as week 1 for the ixekizumab group compared to placebo in almost all efficacy measures mentioned above. For other outcomes including proportion of patients who experience major improvement and BASDAI 50 response, differences were evident ($p < 0.05$) by week 2 in the ixekizumab group compared with placebo. Furthermore, ixekizumab sustained high efficacy in all efficacy measures through 52 weeks.
Conclusion: Ixekizumab demonstrated a rapid onset of efficacy improvements on ASAS response, ASAS core set values, disease activity and function in Chinese patients with r-axSpA.

Background: Spondyloarthritis is a group of chronic inflammatory rheumatism most often affecting young adults. Biological background treatments have revolutionized their care, although some patients have failed these treatments.
Objectives: To estimate the prevalence of failure of the first biological treatment during spondyloarthritis and the factors associated with this failure.
Methods: Our study included patients with Spondyloarthritis retained according to the ASAS criteria, having an age > 18 years, treated with biological treatment, having given their written informed consent, in the 10 rheumatology departments in Morocco, collected from the RBSMR registry, a multicenter historical-prospective registry. Primary failure was defined as failure at 6 months of treatment and secondary failure as failure at more than 6 months of treatment. Patients were assessed every six months with a scheduled follow-up of three years. Inclusion began in June 2017 and ended in January 2019, when the database was first frozen.
Results: 194 patients included. The average age was 40.23 years +/- 13.68, the sex ratio was 1.73 M/F, the average duration of evolution was 615.9 weeks +/- 349.12. An HLA B27 antigen was positive in 66% of patients. Peripheral involvement was found in 70% of patients, axial involvement in 96.4% of patients and enthesic involvement in 61.5% of patients. Radiographic sacroiliitis was present in 87.6% of patients, radiographic coxitis in 40.7% and sonographic coxitis in 19.8%. Regarding extra-articular manifestations, 14.5% of patients had anterior uveitis, 6.9% had cutaneous psoriasis, and 10.7% had associated chronic inflammatory bowel disease. The ASDAS CRP was in high activity in 50.9% of the patients and the BASDAI (spondyloarthritis activity index) more than 4 in 79.2% of the patients. At the first visit, 22.5% of patients were taking corticosteroid therapy and 53.8% were taking csDMARDs. The most widely used biological was Etanercept with a percentage of 33%. Over a follow-up period of 03 years, 05 primary failures were objectified and 17 secondary failures to the first biological treatment (08 failures at the 12th month, 06 failures at the 18th month and 03 failures at the 24th month), the prevalence of failure of the first biological was 8.76%. In bivariate analysis, no statistically significant factors were observed associated with the failure of the first biological during the visit of the 6th month, the 12th month or that of the 24th month. At the visit of the 18th month, the average BASDAI as well as that of the C reactive protein (CRP) was statistically higher in patients who failed the first biological.
Conclusion: The failure of the first biological is a rather rare situation in our study. Certain factors were significantly associated with this failure and must be taken into account when managing patients, namely high values of BASDAI and CRP. Higher values of the Bath Spondylitis Functional Index (BASFI) or CRP at baseline are predictors of a greater risk of failure of the first biological found in the literature.

AB0970 GREAT DIVERSITY IN B/TSDMARD TREATMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AROUND THE WORLD AND THE COMPARISONS WITH THE 2022 UPDATED ASAS-EULAR RECOMMENDATIONS

Keywords: Spondyloarthritis, bDMARD, Treat to target

F. Y. Wu[1], I. P. Lee[1], C. F. Su[1], S. H. Lin[1], C. J. Chiang[1], C. C. Chang[2,3], Y. S. Chang[1,3]. [1]*Shuang Ho Hospital, Taipei Medical University, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, New Taipei City, Taiwan, Republic of China*; [2]*Taipei Medical University Hospital, Division of Rheumatology, Immunology and Allergy, Department of Internal Medicine, Taipei, Taiwan, Republic of China*; [3]*School of Medicine, College of Medicine, Taipei Medical University, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China*

Background: The 2022 updated ASAS-EULAR recommendations for the management of axial spondyloarthritis (SpA) uses the Ankylosing Spondylitis Disease Activity Scores(ASDAS) ≥2.1 as the single disease activity index indicated for the using of b/tDMARDs. Unlike the care of rheumatoid arthritis, there is a diversity in the disease activity criteria for b/tsDMARDs in axSpA worldwide, which is worthy of note.
Objectives: This study aimed to **investigate the diversity of b/tsDMARDs using in axSpA care worldwide** in the light of the 2022 ASAS-EULAR recommendations for SpA, by comparing the population fulfilled each disease activity criteria indicated for b/tsDMARDs.
Methods: Biologic-naïve patients fulfilled the ASAS axSpA criteria were recruited in the rheumatology clinic in the Shuang-Ho Hospital from 2018 to 2020. In each visit, disease activity including BASDAI, ASDAS-CRP, ESR and CRP were recorded and the fulfillment of different disease activity criteria indicated for b/tsDMARDs were labelled, including the latest two versions of ASAS-EULAR recommendations and the reimbursement criteria of Australia, Singapore, Korea, Hong Kong, Canada and Taiwan. The data having the highest disease activity of each patient were selected for analysis, and the complete data including every visit recorded were also analyzed as sensitivity test. The population size fulfilled different activity criteria were compared.
Results: This study recruited 396 biologic-naive patients with axSpA with 1390 disease activity data totally. The mean age was 41 years, and among the cohort, 129(32.6%) were female. In the 396 disease activity measures, there were 262(66.2%) patients met the disease activity criteria for b/tsDMARDs according to the 2022 ASAS-EULAR recommendations, which was more than twice the population (121) indicated by the activity criteria of the prior version. In comparison with the 2022 recommendations, the disease activity criteria of many countries are stricter leading to less b/tsDMARDs using. Using the population indicated by the 2022 recommendations as reference, the rate of patients eligible by the disease activity criteria in different countries varied greatly, which ranged from as low as 8.40% in Taiwan to 100% in Singapore. The result was consistent in analyzing the whole 1390 dataset.
Conclusion: There is a great expansion of the population indicated for b/tsDMARDs brought by the 2022 update, in comparison with the 2016 version. There is a great diversity for b/tsDMARDs using in axSpA care around the world. In some countries, a surprisingly huge disparity in b/tsDMARDs using was noted. Only less than 10% patients indicated for b/tsDMARDs using by the 2022 ASAS-EULAR recommendation met the reimbursement criteria in Taiwan, analyzed in the single measure setting.

AB0971 EFFECTIVENESS OF IGURATIMOD IN THE TREATMENT OF AXIAL SPONDYLOARTHRITIS-REAL WORLD DATA FROM CHINA

Keywords: Spondyloarthritis, Real-world evidence, Disease-modifying Drugs (DMARDs)

Y. Li[1,1], Z. Zhao[1], L. Hu[1,1], Z. Hu[1], J. Jin[1], J. Zhang[1], J. Zhu[1], F. Huang[1]. [1]*The First Medical Center, Chinese PLA General Hospital, Department of Rheumatology and Immunology, Beijing, China*

Background: Axial spondyloarthritis (ax-SpA) is a group of chronic auto-inflammatory diseases. Tumor necrosis factor-alpha (TNF-α) and interleukin-17 (IL-17) were demonstrated to play an irreplaceable role in the pathogenesis of ax-SpA. Iguratimod is a newly-developed small molecular anti-rheumatic drug, which can inhibit the effects of prostaglandin E2, TNF-α and IL-17 [1]. The efficacy and safety of Iguratimod in the treatment of rheumatoid arthritis (RA) have been fully studied and approved to the treatment of active RA in China and Japan [2]. Iguratimod had been reported to be effective in the treatment of ax-SpA [3], despite those studies were limited and of small-example size.

Objectives: In consideration of the efficacy of Iguratimod in the treatment of RA and the overlap of disease pathogenesis between RA and SpA, Iguratimod was implied to be of potential efficacy on ax-SpA. This study was aimed to demonstrated the efficacy and safety of Iguratimod on ax-SpA in the real word from China.

Methods: 1993 patients with ax-SpA who visited the outpatient rheumatology clinics in the First Medical Center of Chinese PLA General Hospital between April 2016 to June 2022, were collected and screened. Patients treated with NSAIDs only, combined with sulfasalazine (SSZ) or Iguratimod for over 6 months were admitted into analysis. Those three groups of patients were also matched by propensity score on a ratio of 1:1:1, by age, gender and ASDAS at baseline. Multilevel models for repeated measurement data were conducted to compare the differences of ASDAS, back pain, ESR and CRP level between the three groups of patients during the 18 months follow-ups.

Results: 302 patients with ax-SpA were included in the real-world study and they were followed at a mean 6-month interval for 3 times (median follow-up 17.55 months, interquartile range 16-20 months). 161, 96 and 45 patients fell into the NSAIDs only, NSAIDs combined with SSZ or Iguratimod group. At the baseline, those three groups of patients had significantly different back pain scores, PGA, PhGA, ASDAS, ESR and CRP level (P<0.05). At the end of follow-up, patients treated with Iguratimod had significant improvement on the primary endpoint (ASDAS, 1.51±0.67 vs. 2.07±0.90, P<0.001) and secondary endpoint (BASDAI, 1.48±0.94 vs. 1.98±1.49, *P*=0.027; Back pain scores, 1.91±1.14 vs. 2.64±1.69, *P*=0.007; PGA, 2.07±1.39 vs. 2.78±1.57, *P*=0.015; PhGA, 2.20±1.16 vs. 2.96±1.45, *P*=0.003; CRP, 3.47 mg/L vs. 5.20 mg/L, *P*=0.017) than that at the baseline. Patients treated with NSAIDs and Iguratimod had higher clinically important improvement rate that that treated with NSAIDs combined with SSZ (26.66% vs. 8.33%, *P*=0.008) or NSAIDs only (26.66% vs. 8.70%, *P*=0.004). 135 patients were matched by propensity score matching (45 patients on each group) and after adjusting for potential confounding factors, patients treated with NSAIDs and Iguratimod had greater improvement on ASDAS than that on patients treated with NSAIDs combined with SSZ (β<0.001, 95% CI: 0.000 ~ 0.001, *P*=0.043) or NSAIDs only (β<0.001, 95% CI: 0.000 ~ 0.001, *P*=0.033).

Conclusion: Iguratimod had significant add-on effect on the decrease of disease activity and alleviation of back pain than monotherapy of NSAIDs or NSAIDs combined with SSZ. Iguratimod is effective and well-tolerated during the treatment and thus could be a new pharmaceutical option for ax-SpA patients.

AB0972 EFFICACY OF TILDRAKIZUMAB IN PATIENTS WITH PSORIASIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Systematic review, Skin

Q. Y. Su[1,2,3], H. Zhou[1,2], R. T. Shen[1,2], W. J. Hao[1,2], X. Y. Zhang[1,2], Y. X. Li[1,2], G. M. Xia[1,2], J. Y. Ren[1,2], Q. Yu[4], P. F. He[4], X. Li[1,2,3], S. X. Zhang[1,2,3]. *[1]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*; *[2]Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taiyuan, China*; *[3]Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; *[4]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*

Background: Psoriasis is a common chronic inflammatory disease of the skin[1]. The IL-23/IL-17 immune pathway plays a vital role in promoting Psoriasis pathogenesis[2]. Tildrakizumab, a humanized IgG1 monoclonal antibody against interleukin 23 p19, is currently used in the treatment of patients with psoriasis.

Objectives: This study aimed to evaluate the efficacy of tildrakizumab in the treatment of psoriasis.

Methods: Five databases, including PubMed, Embase, Medline, Web of Science, and Cochrane Library, were retrieved from their establishment to January 2, 2023. We used the EndNote X9 software to filter the retrieved articles according to the inclusion and exclusion criteria. Heterogeneity was tested using I-squared (I2). When I2>50%, we choosed the random effects model for data analysis, conversely, a fixed effects model. Publication bias was assessed using the Egger test. All analyzes were performed in STATA 12.0.

Results: We included 6 studies, 2,395 patients in the Tildrakizumab group and 552 patients in the placebo group (Table 1). Results of the meta-analysis showed that 68% of patients with psoriasis met the PAIS75 remission criteria after taking Tildrakizumab [Rate =0.68 95%CI(0.66, 0.70), P<0.001], and they had significantly higher PASI75 response rates than the placebo group [RR=11.390, 95%CI (8.08, 16.06), P<0.001]. Compared to the placebo group, patients in the Tildrakizumab group had a significantly higher remission rate of PASI90 [RR=26.751, 95%CI (15.282,46.827), P<0.001]. In addition, patients taking Tildrakizumab had an average 15-point reduction in PASI scores [Rate=-14.854 95%CI(-19.146, -10.561), P<0.001], and 45% of patients achieved PASI100 remission criteria [Rate= 0.450, 95%CI (0.131, 0.769), P=0.006] (Figure 1).

Conclusion: This study showed that Tildrakizumab improved disease activity and increased clinical remission rates in patients with psoriasis, demonstrating a better therapeutic effect.

AB0973 REAL-WORLD EFFECTIVENESS AND SAFETY OF SECUKINUMAB IN SPONDYLOARTHRITIS AND PSORIASIC ARTHRITIS

Keywords: Real-world evidence, Psoriatic arthritis, Spondyloarthritis

U. Astigarraga Urkia[1], M. López I Gómez[2], I. Pineiro[1], L. Ibarrola Paino[1], G. Sada Urmeneta[1], J. Mendizabal[1], N. Del Val del Amo[1], L. Garrido Courel[1], I. Paniagua Zudaire[1], L. Horcada[1], R. Gutierrez[1], C. Fito-Manteca[1]. [1]*Hospital Universitario de Navarra, Rheumatology, Pamplona, Spain*; [2]*Hospital Universitario Arava, Rheumatology, Vitoria, Spain*

Background: Secukinumab (SEC) is a human monoclonal antibody (IgG1) aimed against IL-17A, a proinflammatory cytokine involved in the pathogenesis of psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA). It is already well known that C-reactive protein (CRP) is an important inflammatory biomarker and that it could be used as a variable of its efficacy. More recently, it has been published that the neutrophil lymphocyte ratio (NLR) [1] an inflammatory biomarker, could be predictive of CV events occurrence and all cause mortality. In this study, we intend to evaluate effectiveness and safety with SEC with conventional and non-conventional scales in patients with Spondiloartrhitis.
Objectives: To evaluate the long-term effectiveness and safety of SEC in patients with axSpA and PsA in an actual clinical setting.
Methods: We designed a single center retrospective and longitudinal observational study including patients diagnosed of axSpA fulfilling the ASAS classification criteria and PsA fulfilling the CASPAR classification criteria. Between 2016 and 2022, a total of 90 patients were included in the study treated with SEC in the rheumatology service of the Hospital Universitario de Navarra. All patients included started SEC treatment at least 1 year before the data extraction. For the axSpA CRP, the Ankylosing Spondylitis Disease Activity Score (ASDAS) scale, the patient's visual analog scale (VAS) and NLR [1] were analyzed. In the PsA group VAS, CRP and NLR were assessed. In both groups the variables were analyzed at baseline, 12 and 24 months. Safety was evaluated by analyzing intercurrent infections or neoplasms that required discontinuation.
Results: We included a total of 90 patients (46 axSpA and 44 PsA), 45(50%) of which were female. The mean age at diagnosis was 44.5 years (SD 11.1) while the mean age at SEC initiation was 51.6 (SD 11.4). The median time from diagnosis to onset of SEC was 5 years (IQR 2-11) (Table 1). Eighty-three (92.2%) patients were treated with one or more biologic drugs prior to SEC, median 2 (IQR 0-5). The mean CRP before starting SEC was 9mg/L (SD 17.6), VAS 7 (SD 2) and NLR 1.9 (SD 1). A statistically significant improvement was observed in both pathologies when it comes to CRP at 24 months (p 0.049) but not at 12 months (Table 1). VAS presented a statically significant improvement at 12 and 24 months of treatment (p 0.008 and 0.012 respectively). There were no statistically significant differences in NRL in any group. Regarding ASDAS in the axSpA group, 4,34% showed a great improvement while 26% of them showed clinical improvement. None of the baseline characteristics included in the analysis showed significant association with SEC performance on these variables. None of our patients experienced serious adverse reactions, infections or malignancies during the use of SEC.
Conclusion: In our cohort, SEC showed to be effective in axSpa and PsA patients, displaying statistically significant improvements in VAS at 12 and 24 months and CRP at 24 months. SEC safety profile in our cohort was consistent with the well-established safety profile of this drug.

AB0974 **TREATMENT OF AXIAL SPONDYLOARTHRITIS WITH SECUKINUMAB: A REAL-LIFE RETROSPECTIVE COHORT STUDY**

Keywords: bDMARD, Spondyloarthritis

L. Smiljanic Tomicevic[1], I. Padjen[1], M. Martinić[1], M. Mayer[1], B. Anić[1]. [1]*University of Zagreb, School of Medicine, University Hospital Center Zagreb, Division of Clinical Immunology and Rheumatology, Department of Internal Medicine, Zagreb, Croatia*

Background: Data from several large prospective studies have demonstrated that secukinumab is an efficient and safe treatment choice for axial spondyloarthritis (axSpA) [1].
Objectives: The aim of our study was to evaluate data from a real-life cohort of patients with axSpA treated with secukinumab.
Methods: We retrospectively analysed data from our institutional registry of axSpA patients (radiographic and non-radiographic) treated with secukinumab. We analysed the features of patients who continued secukinumab at their last visit and those who discontinued the drug over the follow-up period. We used the Kaplan-Meier curve to estimate the cumulative retention rate of secukinumab.
Results: A total of 57 patients were enrolled in our study. Among them, 26 (45,6%) were women, and 31 (54,4%) were men. The median age was 50 (22-71). There were 26 (45,6%) patients who were bDMARD naïve and 31 (54,4%) patients that had used at least one bDMARD before secukinumab. Among the naïve group, 4 (14,4%) patients discontinued secukinumab, whereas among the group with former bDMARD usage, 12 (38,7%) people discontinued treatment. The ineffectiveness of the drug was the most common reason for discontinuation in both groups. Regarding adverse effects, two people reported respiratory infections. We did not record significant drug safety complications in our cohort. The duration of treatment was 6,5 years. The survival rate of the drug was 91% after six months, 83,4% after 12 months, 75% after 24 months, and 66,6% after 48 months. Table 1 shows detailed clinical aspects of the cohort.
Conclusion: Our data confirmed a good survival rate of secukinumab in patients with axial spondyloarthritis. However, results showed that fewer biologically naïve patients discontinued the secukinumab treatment than those who received the drug after the failure of another biologic.

Spondyloarthritis - clinical aspects (other than treatment)

AB0975 THE ACCURACY ON THE SELF-REPORTED DIAGNOSIS OF IMIDS IS LOWER AMONG RHEUMATIC PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Keywords: Patient information and education

R. De Francisco[1], S. Alonso Castro[2], R. Queiró Silva[2], I. Pérez-Martínez[1], A. Castaño[1], M. Celada-Sendino[1], J. Santos Juanes[3], V. Rolle[4], M. Gueimonde[5], S. Riestra[1]. *[1]Hospital Universitario Central de Asturias, Gastroenterology, Oviedo, Spain*; *[2]Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Spain*; *[3]Hospital Universitario Central de Asturias, Dermatology, Oviedo, Spain*; *[4]Hospital Universitario Central de Asturias, Instituto de Investigación Sanitaria del Principado de Asturias, Oviedo, Spain*; *[5]Instituto de Investigación Sanitaria del Principado de Asturias, Diet, Microbiota and Health Group, Oviedo, Spain*

Background: The association of several immune-mediated inflammatory diseases (IMIDs) in the same patient is well known[1]. Rheumatologic and dermatologic IMIDs are frequently diagnosed in patients with inflammatory bowel disease (IBD)[1]. However, the degree of knowledge that patients with IBD have about the coexistence of other IMIDs is little studied.
Objectives: Our aim was to evaluate the accuracy of self-reporting of IMIDs by patients with IBD.
Methods: Prospective, unicentric study that included patients attended in person at the IBD Unit of the Central University Hospital of Asturias (Oviedo-Spain) between August 2020 and December 2021. Patients were invited to participate in the study, and, after signing the informed consent, they answered a questionnaire about the presence or not of 50 IMIDs (self-reported diagnosis). The diagnosis of an IMID was confirmed in the medical records of each patient (reference diagnosis). Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy (proportion of subjects correctly classified) of self-reporting was calculated. Statistical analyses were performed with R software version 4.0.2.
Results: A total of 1621 patients were included. Forty-four percent of patients had ulcerative colitis, 53% Crohn's disease and 3% an IBD-unclassified, sex distribution was 1:1, and the age at diagnosis of IBD was 38 ± 15.2 years. Seven hundred and twelve patients were receiving mesalazine, 67 corticosteroids, 394 immunomodulators and 532 biologics. Six hundred and twenty-seven (39%) patients were diagnosed with at least one IMID, 177 (10.9%) with two, 49 (3%) with three, and 17 (1%) with more than three. Sixteen percent of patients had a rheumatologic IMID and 15% a cutaneous IMID. Self-reporting of IMIDs by IBD patients showed a sensitivity, specificity, PPV, NPV and accuracy of 0.75 (95%CI 0.73-0,78), 0.89 (95%CI 0.86-0.91), 0.92 (95%CI 0.89-0.93), 0.69 (95%CI 0.66-0.73) and 0.81 (95%CI 0.79-0.83), respectively. Accuracy of self-reported diagnosis of IMIDs was lower among the rheumatic IMID group (Table 1).
Conclusion: Eighty-one percent of patients with IBD are able to correctly identify the coexistence or not of other IMIDs. It was observed that in the case of rheumatologic IMIDs there is a significant percentage of patients who do not know whether or not they suffer from one of these conditions.

AB0976 LOW SPINAL RADIOGRAPHIC PROGRESSION AFTER A MEAN OF 15 YEARS OF FOLLOW-UP IN A COHORT OF PATIENTS AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Descriptive Studies

R. E. M. Granados[1,2], S. Dans-Caballero[1,2], M. L. Ladehesa Pineda[1,2], M. Á. Puche Larrubia[1,2], D. Ruíz-Vilchez[1,2], M. C. Ábalos-Aguilera[1,2], A. Escudero Contreras[1,2,3], E. Collantes Estevez[2,3], C. López-Medina[1,2,3]. *[1]Reina Sofia University Hospital, Rheumatology Department, Cordoba, Spain*; *[2]Maimonides Biomedical Research Institute of Cordoba, (IMIBIC), Cordoba, Spain*; *[3]University of Cordoba, Medicine, Cordoba, Spain*

Background: Axial spondyloarthritis (axSpA) is characterized by progressive structural damage on the sacroiliac joints and/or the spine. The progression is assessed by conventional radiology through available scales such as the mSASSS (modified Stoke Ankylosing Spondylitis Spinal Score) in the spine. However, data on long-term radiographic progression and factors associated with such progression are scarce.
Objectives: To evaluate the radiographic progression of the spine in patients with axSpA after a mean of 15 years of follow-up as well as the factors associated with such progression.
Methods: Patients with axSpA included in 2006-2007 in the multicentre Spanish registry REGISPONSER and pertaining to the Reina Sofia Hospital were re-evaluated in 2021-2022. Spine (cervical and lumbar) radiographs were obtained with the aim to be compared with those obtained in 2007. Two trained blinded readers scored the mSASSS in radiographs from both visits (baseline and current). First, intraclass correlation coefficients (ICC) were calculated to evaluate the agreement between both readers in mSASSS. Mean mSASSS of both readers in both timepoints were calculated and the absolute progression (ΔmSASSS) was evaluated. In addition, we evaluated the mean and median progression per year dividing the ΔmSASSS by the years of follow-up in each patient. Then, the median progression per year was used to divide patients in "low progressors" and "high progressors". Baseline characteristics between these two groups were compared using univariate analysis.
Results: A total of 77 axSpA patients with both baseline and current radiographs were included. A total of 53 (68.8%) were male and the mean disease duration was 10.15 (SD 9.2) years. All of them were naïve to bDMARD at baseline and 38% had radiographic sacroiliitis. The mean years of follow-up (i.e, mean time separating the radiographs) was 15 years (SD 3.3). ICC between the two readers was moderate for mSASSS at baseline (0.73, 95%CI 0.26-0.88) and at the 15 years visit (0.65, 95%CI 0.11-0.84). After a mean of 15y of follow-up, the mean progression was 0.54 (SD 0.55) points in mSASSS per year and the median progression was 0.38 points per year. A total of 37 (48%) patients were considered "low progressors" (i.e., median progression <0.38 points per year) and 40 (52%) were considered as "high progressors" (i.e., median progression ≥0.38 points per year). The only significant variable associated with "high progression" was low back pain before the diagnosis (82.5% vs. 48.6%, p-value 0.003). Neither sex, smoking, disease duration, HLAB27 or c-reactive protein were associated with the "high progression" group.
Conclusion: In this stablished axSpA population, the mean and median progression were 0.54 and 0.38 points in mSASSS per year respectively, which is lower than what has been reported in similar cohorts (i.e., change in 2 points in mSASSS). Only low back pain was found as predictor of spinal radiographic progression.

AB0977 CHANGES IN ASDAS AND SYMPTOMS OF ANXIETY AND DEPRESSION IN AXIAL SPONDYLOARTHRITIS: LATENT TRAJECTORY ANALYSIS

Keywords: Spondyloarthritis, Epidemiology

S. S. Zhao[1], C. Webers[2], E. Nikiphorou[3], D. Van der Heijde[4], J. Braun[5], U. Kiltz[5], S. Ramiro[6], A. Boonen[2]. [1]*University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [2]*Maastricht University, Maastricht University Medical Center, Maastricht, Netherlands*; [3]*King's College London, Centre for Rheumatic Diseases, London, United Kingdom*; [4]*Leiden and Zuyderland Medical Center, Leiden University Medical Center, Heerlen, Netherlands*; [5]*Ruhr-University Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany*; [6]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*

Background: Disease-assessment in axial spondyloarthritis (axSpA) includes subjective measures that do not necessarily reflect inflammatory processes in the spine and joints. Mental health comorbidities such as anxiety and depression can be secondary to inflammatory and non-inflammatory processes. There may be subgroups that respond differently to axSpA treatment, for example, discordance in these indices whereby disease activity improves but not mental health. Understanding such potential subgroups and their characteristics can support individualised care.

Objectives: To apply data-driven approaches to longitudinal disease activity (ASDAS) and Hospital Anxiety and Depression Scale (HADS) subscores for anxiety (HADS-A) and depression (HADS-D) to identify potential groups with discordant trajectories.

Methods: This was an ancillary analysis of the data collected for the Assessment of SpondyloArthritis international Society Health Index (ASAS HI) Validation Study. We included individuals who fulfilled ASAS criteria for axSpA and required a therapeutic change (initiation of NSAID, csDMARDs or TNFi) due to active disease. Those with diagnosis of peripheral SpA were excluded. Participants were assessed at baseline and one follow-up. Group-based trajectory models were used to group individuals based on shared trajectories of ASDAS, HADS-A and HADS-D. These three dependent variables were standardised (scale 0 to 10), then included in linear models with a time indicator (baseline or follow-up) as the independent variable. We selected the optimum number of groups through statistical fit. Individuals were assigned to the group with the highest posterior probability of membership. Patient and disease characteristics were compared across groups.

Results: Of 206 participants (mean age 37 years, 65% male), 73 (35%) started NSAIDs, 23 (11%) csDMARD and 109 (53%) TNFi (Table 1). The optimum number of trajectory groups was 4 (Figure 1). Three indices changed concordantly regardless of the number of latent groups. Group descriptions are relative: Group (G) 1 (54%) started with low scores for all three indices, G2 (34%) moderate, and G3 (5%) high. Mean improvements in ASDAS were numerically similar across these groups. G4 (7%) had the greatest improvement across all three indices. Initiated therapy differed with G3 and 4 more frequently starting TNFi.

Conclusion: Results of this study show that ASDAS and symptoms of anxiety and depression are closely related and change concordantly with treatment, and suggest that reported musculoskeletal and mental health symptoms influence each other. There were no clear differences in patient or disease characteristics across these groups except for age. Whether axSpA patients benefit from knowing that mental health symptoms generally improve jointly with disease activity when starting treatment remains to be shown.

Table 1. Clinical and disease characteristics across the four latent groups.

ASSOCIATION OF SLEEP QUALITY WITH DISEASE ACTIVITY, INFLAMMATION, MOBILITY, AND FUNCTION AMONG PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Quality of life, Patient reported outcomes

I. P. Lee[1], F. Y. Wu[1], C. F. Su[1], S. H. Lin[1], Y. S. Chang[1,2]. [1]*Shuang Ho Hospital, Taipei Medical University, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, New Taipei City, Taiwan, Republic of China*; [2]*School of Medicine, College of Medicine, Taipei Medical University, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China*

Background: Inflammation and ankylosis of the axial skeleton are two major features of axial spondyloarthritis (axSpA), which cause midnight pain and immobility of back, respectively. Both features may lead to sleep problem. Nevertheless, which of the two features influence sleep most is less studied. Moreover, there are many disease activity measurements, including BASDAI, ASDAS, ESR and CRP, among these measurements, which one could best predict sleep disturbance are still unknown.

Objectives: This pilot study aimed to discover the association between different measurements of axSpA and sleep disturbance.

Methods: This cross-sectional study recruited patients with axSpA from the rheumatology clinic in the Shuang-Ho hospital from 2018 to 2020. The Pittsburgh Sleep Quality Index (PSQI) was used to assess sleep quality together with other clinical measurements, including BASDAI, ESR, CRP and ASDAS-CRP for disease activity, BASMI for mobility and BASFI for function. The features associated with poor sleep quality (PSQI > 5) were identified. All the domains of sleep disturbance were compared between patients with different level of disease activity classified by each activity measurement.

Results: This cross-sectional study recruited 322 patients with axSpA, among them 72% were male, and the mean age was 42 years. There were 249 (77.3%) patients had poor sleep quality (PSQI>5). Poor sleepers had significantly higher BASDAI, ASDAS-CRP and BASFI, while there was no significant difference in sex, age, ESR, CRP and BASMI. Patients with higher BASDAI had significantly poorer sleep quality in almost all domains of PSQI (figure 1A), while higher level of ESR or CRP could not discriminate poor sleeper in every domain of PSQI (figure 1C,1D). ASDAS-CRP had a moderate discriminability, which was believed brought by the integrated components of BASDAI in the index.

Conclusion: Lots of patients (77.3%) with axSpA were poor sleeper, which is worthy note in clinical care. Mobility seems to have less influence on sleep than disease activity. Although BASDAI was believed too subjective as a disease activity index, it performed the best to discriminate poorer sleep quality in almost all domains of sleep. Although ESR and CRP were more objective disease activity markers of axSpA and have better relevance to the MRI-demonstrated inflammation, both the inflammatory markers had no value in the care of sleep in axSpA patients surprisingly. In conclusion, BASDAI still had value in axSpA care, and the elements of BASDAI make ASDAS a more comprehensive index than ESR or CRP alone.

Table 1. Differences in characteristics and features between axial spondyloarthritis patients with different sleep quality

	Poor sleep quality (N=249)	Good sleep quality (N=73)	p-value
Male (n, %)	179 (72%)	57(78%)	0.89
Age (yr)	41.84(13.3)	39.3(13.32)	0.14
BASMI	1.83 (1.85)	1.42 (1.66)	0.0958
BASFI	1.95 (2.16)	1.26 (1.85)	<0.05
BASDAI	4.04 (2.24)	2.54 (1.92)	<0.001
ASDAS-CRP	2.46 (1.14)	1.97 (0.85)	<0.001
ESR (mm/hr)	16 (15.76)	15.5 (17.24)	0.8186
CRP (mg/dl)	9.36 (16.43)	8.6 (12.21)	0.67

SELF-REPORTED AND PHYSICIAN´S ASSESSMENT OF INFLAMMATORY BACK PAIN ACCORDING TO ASAS CRITERIA: IS IT THE SAME? RESULTS FROM THE SHERPAS STUDY

Keywords: Spondyloarthritis, Health Services Research, Quality of care

D. Benavent[1], M. Tapia-Viñé[2], D. Bernabeu[2], V. Muley[2], C. Plasencia[1], A. Balsa[1], V. Navarro-Compán[1]. [1]*Hospital La Paz, Department of Rheumatology, Madrid, Spain*; [2]*Hospital La Paz, Department of Radiology, Madrid, Spain*

Background: Inflammatory back pain (IBP) is the core symptom in patients with axial spondyloarthritis (axSpA). For its assessment, experts recommend using the Assessment of SpondyloArthritis International Society (ASAS) criteria. Advances in telemedicine and online screening strategies require to evaluate whether self-reported perform equally to physicians' assessment.
Objectives: To assess the agreement and correlation between self-reported and physician´s assessments of ASAS IBP criteria and evaluate their performance compared with rheumatologist´s judgement for IBP.
Methods: The "Strategy for a Hospital Early Referral in Patients with Axial Spondyloarthritis" (SHERPAS) is a prospective ongoing study recruiting young patients (18 to 40 years) with chronic back pain asked to undergo an MRI of the spine by other specialists different than rheumatologists in a tertiary hospital, starting in September 2021. After inclusion, an additional MRI of the sacroiliac joints (SIJ), followed by a rheumatology visit and eligible blood tests were performed. IBP was assessed in 3 different independent ways: i) ASAS criteria asked verbatim by the rheumatologist (*ASAS-IBP-phy criteria*), ii) ASAS criteria embedded in a self-reported questionnaire (*ASAS-IBP-self reported*), and iii) according to rheumatologist judgement in the interview (*IBP-rheumatologist*). Dataset for this interim analysis was locked in October 2022. Kappa statistic (κ) and tetrachoric correlation coefficient (rt) were calculated to assess the agreement and correlation between ASAS-IBP-phy criteria and ASAS-IBP-self reported. Overall accuracy, sensitivity, specificity, positive and negative predictive values for each IBP assessment method were calculated, using IBP-rheumatologist as gold standard.
Results: Among 152 recruited patients, 85 (55.9%) were female; mean (SD) age was 34.2 (5.3) years. 66/152 (43.4%) patients reported IBP by at least one of the three assessments, and 24 (15.8%) patients presented back pain as assessed by the three methods altogether. Venn diagrams representing the overlap between the different IBP assessments are shown in **Figure 1**. A moderate agreement (κ =0.48) and strong correlation (rt=0.7) were found between ASAS-IBP-self reported and ASAS-IBP-phy criteria. While ASAS-IBP-phy criteria showed a strong level of agreement and very strong correlation with IBP-rheumatologist (κ = 0.74, rt= 0.94), ASAS-IBP-self reported showed a moderate agreement and moderate correlation with this outcome (κ = 0.44, rt=0.67). ASAS-IBP-phy criteria showed better performance than ASAS-IBP-self reported for capturing IBP- rheumatologist [accuracy of 0.89 (95%CI 0.83- 0.94) vs 0.77 (95%CI 0.70- 0.84)] **(Table 1)**.
Conclusion: ASAS criteria to define IBP show higher level of agreement and correlation with IBP rheumatologist overall judgement when assessed by physician as compared to a self-reported assessment. These results call for caution when extrapolating use of experts IBP criteria from clinical to online setting and suggest that clinicians should prioritize physician assessment over self-report to define this.

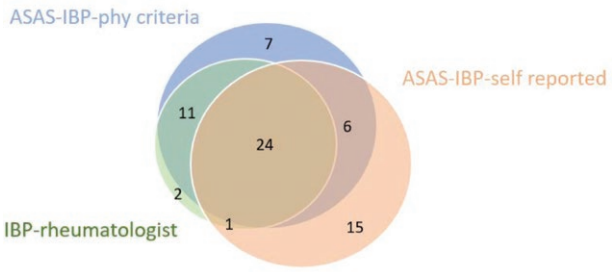

Figure 1. Number of patients showing IBP by each method of assessment

Table 1. Utility measures for each IBP assessment method to capture IBP according to rheumatologist judgement

AB0980

HOW DO SPONDYLOARTHRITIS START? IDENTIFICATION OF THE FIRST SYMPTOMS ACCORDING TO THE DIAGNOSIS AND HLA-B27. DATA FROM REGISPONSER AND RESPONDIA REGISTRIES

Keywords: Spondyloarthritis, Registries

M. Á. Puche Larrubia[1,2,3], M. L. Ladehesa Pineda[1,2,3], F. U. Pilar[2,3], A. Escudero Contreras[1,2,3], J. Vazquez Mellado[4], E. Collantes Estevez[2,3], C. López-Medina[1,2,3]. [1]*Reina Sofía University Hospital, Rheumatology, Cordoba, Spain*;

[2]Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), GC-05 Group., Cordoba, Spain; [3]University of Cordoba, Medical and Surgical Sciences Department, Cordoba, Spain; [4]Hospital general de México, Rheumatology, Ciudad de México, Mexico

Background: The definition for early spondyloarthritis (SpA) implies the correct identification of the initial symptom of SpA. There is currently no consensus on whether only musculoskeletal manifestations (MM) or also extra-MM (EMM) should be considered as the onset of SpA.
Objectives: a) To describe the initial symptom (either MM or EMM) in the different SpA subtypes; b) to describe the initial symptom stratified by the clinical diagnosis and by the presence of HLA-B27; c) to analyze the clinical factors associated with different forms of initiation.
Methods: Observational, cross-sectional and multicenter study, including patients with a diagnosis of SpA (Ankylosing Spondylitis (AS), AS associated with Psoriasis (AS-Pso), AS associated with Inflammatory Bowel Disease (AS-IBD), Psoriatic Arthritis (PsA), Reactive Arthritis (ReA), Juvenile Spa (Juv-SpA), Arthritis associated with IBD (A-IBD) and undifferentiated SpA (u-SpA)) from REGISPONSER and RESPONDIA registries. Investigators responses to the question "Indicate the first sign or symptom attributable to the disease" have been recorded. The date of appearance of each MM and EMM feature was collected, allowing to determine the first symptom(s) in each patient. Differences in the first symptom across diagnosis and between HLA-B27 carriers were compared using the chi-square test. Finally, factors associated with the most prevalent initial symptom were evaluated.
Results: A total of 4411 patients were included. AS (54.9%), PsA (18.7%) and uSpA (11.1%) were the most prevalent diagnosis. In the overall population, low back pain (60.3%) was the most prevalent initial symptom followed by buttock pain (35.3%) and lower limbs arthritis (39.9%). The percentage of patients who started the disease with each symptom according to the diagnosis is represented in Figure 1. In AS patients, the absence of HLA-B27 lead to an increment in the probability of initiating the disease with cervical pain (25.6% vs. 15.5%), enthesitis (18.8% vs. 12.4%) and coxitis (15.7% vs. 8.4%) in comparison with HLA-B27 positives. In PsA, the initiation with upper limb arthritis (61% vs. 38.4%) and psoriasis (62.1% vs. 37%) was more prevalent in HLA-B27 negatives, while the initiation with low back pain (22.1% vs. 38.4%) and buttock pain 13.6% vs. 28.8%) was more prevalent in HLA-B27 positives. In AS-Pso, the absence of HLA-B27 was more frequently associated with peripheral features and psoriasis as first symptom. In the whole population, factors associated with cervical pain vs. low back pain as first symptom were cutaneous psoriasis, negative HLA-B27 and peripheral involvement (arthritis, enthesitis and dactylitis). On the other hand, factors associated with upper limbs arthritis vs. lower limbs arthritis as first symptom were female gender, cutaneous psoriasis, HLA-B27 negative and absence of axial symptoms.
Conclusion: In this SpA population, the most prevalent initial symptoms were musculoskeletal (i.e., low back pain, buttock pain and lower limbs arthritis), with differences across diagnosis and depending on the presence of HLA-B27 antigen. In AS patients the absence of the HLA-B27 seems to be associated with cervicalgia and peripheral involvement as first symptom, while in PsA it was associated with upper limbs involvement as initial symptom.
Funding: this ancillary analysis has been funded with a research grant "Ayudas en Investigación en SpA SER-GRESSER" from the Spanish Society of Rheumatology (SER).

HIGH PREVALENCE OF IRRITABLE BOWEL SYNDROME IN AXIAL SPONDYLOARTHRITIS: A CROSS SECTIONAL MULTICENTRIC OBSERVATIONAL STUDY

Keywords: Gastrointestinal tract, Spondyloarthritis

J. Bernard[1], T. Barnetche[2], A. Charlotte[3], D. Jerome[4], M. Vandermissen[5], J. Landrin[2], C. Lukas[3], A. Ruyssen-Witrand[4], P. Vergne-Salle[6], A. Tournadre[7].
[1]CHU Gabriel-Montpied, Rheumatology, Clermont-Ferrand, France; [2]Hospital Center University De Bordeaux, Rheumatology, Bordeaux, France; [3]Hospital Center University De Montpellier, Rheumatology, Montpellier, France; [4]Hospital Center University De Toulouse, Rheumatology,Toulouse, France; [5]CHU Dupuytren 1, Rheumatology, Limoges, France; [6]CHU Dupuytren 1, Rheumatology, Limoges, France; [7]CHU Gabriel-Montpied, Rheumatology, Clermont-Ferrand, France

Background: Axial spondyloarthritis (ax-SpA) is a heterogeneous disease including extra-articular manifestations that can impact both disease severity and quality of life[1]. Among them, gastrointestinal symptoms can be related to inflammatory bowel disease (IBD), but also to functional disorder of the gastrointestinal tract such as irritable bowel syndrome (IBS)[2][3]. IBS and IBD are associated with multiple comorbidities and lifestyle behaviors including diet and physical activity.
Objectives: The objectives of this study were to evaluate the prevalence of IBS, IBD and associated factors including demographic and ax-SpA characteristics, treatments and adherence, lifestyle behaviors, and comorbidities.
Methods: A cross-sectional, multicenter study was conducted at rheumatology departments in 5 university hospitals (Bordeaux, Clermont-Ferrand, Limoges, Montpellier, and Toulouse). Patients with ax-SpA (ASAS criteria) treated by biologics were recruited from June 2021 to June 2022. Patients completed an anonymous self-questionnaire evaluating demographic data, lifestyle behaviors, treatment adherence (Girerd questionnaire) and IBS (Roma IV criteria). A medical questionnaire on ax-SpA characteristics, activity and treatments, was completed by rheumatologists.
Results: 500 patients were included in the study (mean age 49.5±13.8 years, 47 % women, mean disease duration 14.7±11 years, and mean BASDAI 3.6±2.1). Sacroiliitis was observed in 51 % on radiographs and 56 % on MRI, HLA-B27 positivity in 71 %. 86 % of the patients received TNF inhibitors, 13% IL17 inhibitors, 1% IL12/IL23 inhibitors, and 25 % NSAIDs. Good adherence (Girerd score = 0) was reported in 49 % of patients. A medical diet was followed by 26 patients (5%) and non-medical diet by 47 patients (9 %). Most of non-medical diets were lactose (22 patients) and gluten-free diets (11 patients). IBS was present in 124 patients (25 %). Female gender (60 %, p=0.001), unemployment (27 %, p=0.013), higher disease activity (BASDAI, p<0.001), worse functional score (BASFI, p<0.001), multiple lines of biologics (p=0.002), fibromyalgia (34%, p<0.001), anxiety (41%, p<0.001), depression (16%, p=0.037) and lower physical activity (p=0.001) were associated with IBS. No difference was noted regarding diet between patients with or without IBS. IBD was observed in 53 patients (11%). Among them, 41 had Crohn disease (77%), 12 ulcerative colitis (23%), 7/53 being considered active by rheumatologists (15%). Proportion of females was higher (63%, p=0.017) in patients with IBD, whereas HLA-B27 was less present (54%, p=0.016). Patients with IBD received less NSAIDs (p<0.001). The use of TNF inhibitors was as frequent as for patients with no IBD whereas IL17 and IL12/IL23 inhibitors were less frequently used (p=0.01). In contrast to IBS, there was no observed difference in comorbidities and physical activity. The prevalence of IBS was similar between patients with or without IBD (respectively 11/53 (21%) vs. 113/447 (25%)).
Conclusion: Prevalence of IBS is high in ax-SpA, accounting for a quarter of patients, and should be screened in the presence of gastrointestinal symptoms. The presence of IBS is not associated with IBD, nor diets. It is associated with female gender, anxiety, depression and fibromyalgia. Patients with IBS seem to have a more difficult to treat disease characterized by higher activity, worse functional scores, and multiple lines of treatments.

AB0982 GISCASPA – STUDY OF SUBCLINICAL GUT INVOLVEMENT IN AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Gastrointestinal tract

C. Mazeda[1,2], S. F. Azevedo[1,2], S. P. Silva[1,2], J. P. Vilas[1,2], C. Pinto Oliveira[1,2], I. Cunha[1,2], G. Eugénio[1,2], A. Barcelos[1,2,3]. [1]*Centro Hospitalar Baixo Vouga, Rheumatology, Aveiro, Portugal*; [2]*Egas Moniz Health Alliance Academic Clinical Center, Egas Moniz Health Alliance Academic Clinical Center, Aveiro, Portugal*; [3]*Universidade NOVA de Lisboa, Comprehensive Health Research Center, Lisboa, Portugal*

Background: Axial spondyloarthritis (axSpA) had a predilection for the axial skeleton and belong to the group of Spondyloarthritis, a set of inflammatory rheumatic diseases with common clinical, radiologic, and serologic features in which extraarticular manifestations are frequent, including inflammatory bowel disease (IBD). The link between SpA and IBD has been recognized for decades, with 5-10% of axial SpA patients suffering from concurrent IBD.[2] But, emerging evidence suggests that subclinical gut inflammation in patients with SpA is an important pathophysiological event that plays a role in disease pathogenesis. However, it is difficult to detect subclinical gut inflammation since it is largely asymptomatic. Faecal calprotectin (FC) is a very sensitive marker for inflammation in the gastrointestinal tract. The role of FC in patients with SpA is not clearly defined, but some studies suggest that FC levels may predict the onset of IBD and may be related to disease activity.
Objectives: To test the validity of FC as a marker of intestinal inflammation in patients with axSpA and to investigate factors associated with increased FC levels in patients with axSpA.
Methods: Patients involved fulfilled ASAS classification criteria for axSpA and were divided into two groups - ankylosing spondylitis (AS) or non-radiographic axSpA (nr-axSpA); a control group without rheumatologic diseases or IBD was also included. All patients and controls answered a structured questionnaire about the presence of gastrointestinal symptoms - Red Flags Questionnaire for IBD and underwent FC measurement with enzyme-linked immunosorbent assay (≥50 mg/g was considered positive). Patients treated with oral NSAIDs should undergo adequate washout (at least 3 weeks). In patients, BASDAI, BASFI, ASDAS-PCR and BASMI were recorded. A general analysis was performed; p-value ≤0.05 was statistically significant.
Results: We included 64 patients (34 with AS and 30 with nr-axSpA) and 25 controls. Demographic, clinical data is represented in table 1. In AS group, 2.9% had nocturnal diarrhoea, first-degree relative with confirmed IBD and rectal urgency; in nr-axSpA, 6.7% had abdominal pain 30-45 minutes after meals and 3.3% chronic abdominal pain; all controls were asymptomatic. Elevated FC was observed in 32.4% of AS patients (129.2±404.0), 23.3% of nr-axSpA patients (70.9±114.4) and 4.2% of controls (21.9±18.4). FC was significantly higher in each axSpA subtype vs controls (p=0.03). There were no statistically significant differences in ASDAS, BASDAI, BASFI or BASMI scores between axSpA patients with normal vs high FC levels.

Table 1. Characteristics of the population according to axSpA groups and controls.

	AS (n=34)	axSpA (n=30)	Controls (n=25)	*P**
Age (years), mean±SD	55.5±14.7	44.9±13.3	40.2±14.0	**0.004**
Sex (F/M)	15/19	18/12	13/11	0.205
Age at disease onset (years), mean±SD	11.8±7.7	5.4±3.3	-	**<0.001**
Comorbidities, n (%)				
Arterial Hypertension	13(38.2)	10(33.3)	1(4)	0.166
Dyslipidemia	8(23.5)	7(23.3)	2(8)	0.985
Diabetes Mellitus	3(8.8)	2(6.7)	0	0.748
Obesity	1(2.9)	1(3.3)	0	
Smoking status, n (%)	4(11.8)	1(3.3)	1(4)	0.850
Peripheral involvement, n (%)	9(26.5)	5(16.7)	-	0.344
Dactylitis (ever), n (%)	0	1(3.3)	-	0.283
Enthesitis (ever), n (%)	1(2.9)	2(6.7)	-	0.482
Uveitis (ever), n (%)	9(26.5)	4(13.3)	-	0.192
Positivity HLA-B27, n (%)	25(73.5)	13(43.3)	-	**0.014**
BASDAI, mean±SD	3.4±2.5	3.8±2.4	-	0.589
BASFI, mean±SD	3.3±2.5	3.3±2.1	-	0.981
ASDAS-PCR, mean±SD	2.3±1.0	2.4±1.1	-	0.070
BASMI, mean±SD	4.2±1.8	3.1±1.7	-	0.226
Therapeutic, n (%)			-	
AINEs**	16 (47.1)	14 (46.7)		0.124
cDMARDs	2 (5.9)	2 (6.7)		0.897
bDMARDs	9 (26.5)	11 (36.7)		0.408

*Comparison between nr-axSpA and AS groups.** washout before collecting stool.

Conclusion: In patients with axSpA, gut inflammation measured by FC was higher than among controls and it was also higher in patients with AS than in nr-axSpA. We also found that high FC values were not associated with more pronounced gastrointestinal symptoms. Thus, studies with a larger population and invasive studies are needed to assess the impact that this marker may have on the management of this pathology.

AB0983 THE DIFFERENCE IN DISEASE ACTIVITY SCORES AND TREATMENT RESPONSE ACCORDING TO GENDER IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Outcome measures

J. Lee[1], S. Y. Kang[1], S. Lee[1], H. Kim[1], E. M. Koh[2], H. S. Cha[1]. [1]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*Health Insurance Review and Assessment Service, Healthcare Review and Assessment Committee, Wonjoo, Korea, Rep. of (South Korea)*

Background: Measurement of disease activity of axial spondyloarthritis (axSpA) is mainly dependent on the patient reporting outcomes. It is known that there are differences in patient reporting outcomes between men and women.
Objectives: We investigated the differences in disease activity scores before and after treatment with biologic disease-modifying antirheumatic drugs (bDMARDs) between gender.
Methods: Data were retrieved from the Korean College of Rheumatology Biologics therapy (KOBIO) registry. axSpA patients from December 2012 to August 2021 were included in the study. Bath ankylosing spondylitis disease activity index (BASDAI) and ankylosing spondylitis disease activity score (ASDAS) at the first visit after starting bDMARDs were compared between male and female patients. Generalized linear model analyses were conducted to check the relationship between the change in disease activity scores and gender with the correction of other clinical variables.
Results: In total, 1,753 patients (1,343 male and 410 female patients) were included in the analyses. At baseline, male patients were younger, had longer disease duration, and had a higher ratio of HLA-B27 positive patients, higher ratio of radiographic disease, lower BASDAI, and higher CRP level. At the first follow-up

visit, male patients achieved BASDAI < 4 more significantly than female patients (79.57% vs. 71.54%, p < 0.0010). However, the proportion of patients who achieved ASDAS low disease activity (< 2.1) and ASDAS inactive disease (<1.3) were not significantly different between gender (71.14% vs. 71.5%, p = 0.8892; 38.82% vs. 39.44%, p = 0.8265, respectively). The difference in BASDAI between the first follow-up visit and baseline was statistically significantly related to gender after adjusting for other clinical information at baseline (p = 0.0033). In the same analysis, the difference in ASDAS was not significantly related to gender (p = 0.1303).
Conclusion: Depending on the method of calculating disease activity, the interpretation of treatment response of bDMARDs may differ between gender.

Table 1. The results of the multivariate generalized linear model of the relationship between the change in disease activity scores and clinical variables, including gender

Background: Magnetic resonance imaging (MRI) is the most sensitive imaging modality for the detection of sacroiliitis. Diagnosing sacroiliitis on MRI is not always straightforward and can be challenging in some cases.
Objectives: To evaluate the prevalence of sacroiliitis (according to ASAS criteria) and other diagnoses in sacroiliac MRI. To analyse/compare these diagnoses by sex, age and service requesting the study.
Methods: This is a cross-sectional, multicentre, descriptive, retrospective study in a hospital and/or specialised care setting. Consecutive MRI examinations (in adults) of the sacroiliac joints (SIJ) performed between 1 de Enero de 2019 y el 31 de Diciembre del 2019 were retrospectively evaluated for the presence of structural and active sacroiliitis findings according to the Assessment of SpondyloArthritis International Society guidelines. Alternative diagnoses, including degenerative changes, diffuse idiopathic skeletal hyperostosis (DISH), osteitis condensans ilii (OCI), septic sacroiliitis/discitis, stress reaction and anatomic variants, were registered.
Results: We evaluated 1,283 MRI examinations, 526 (41%) males, average age 46.7 ± 14 years. 71.6% of the requests are from the Rheumatology service, 15.8% from Orthopedic Surgery and Traumatology and 12.5% from other services. 70% of the MRIs were reported by a radiologist expert in the locomotor system. Findings suggestive of axial spondyloarthritis were found in 353 (27.5%). Sacroiliitis was found in 71 examinations (25%) and alternative diagnoses were suggested in 87 (31%) (OCI 8.9%, anatomic variants 5.3%, septic sacroiliitis/discitis 5.3%, degenerative findings 4.3%, DISH 1.5%, stress reaction 0.7%, tumor 0.3%). A normal examination was found in the remaining 123 examinations. Patients with alternative diagnoses were older than those with sacroiliitis (62 vs. 47 years of age, respectively, P > 0.05). Alternative diagnoses in the SIJ were significantly more common in females (66) than in males (21), P < 0.05.

Table 1.

MRI Diagnosis	Principal	2nd	3rd diagn
Without alterations	452 (35.2)	6 (0.5)	3 (0.2)
Degenerative changes of the SIJ	152 (11.8)	37 (2.9)	5 (0.4)
Sacroiliitis with erosions	147 (11.5)		
Sacroiliitis BME + erosions	157 (12.2)	11 (0.9)	
Degenerative disc disease L5-S1	103 (8)	141 (11)	12 (0.9)
BME (without ASAS criteria)	82 (6.4)	32 (2.5)	4 (0.3)
Sacroilitis with BME	73 (5.7)		
Other	40 (3.1)	29 (2.3)	7 (0.5)
Lumbosacral transition abnormality	18 (1.4)	27 (2.1)	10 (0.8)
Osteitis condensans ilii	17 (1.3)	7 (0.5)	2 (0.2)
Fracture	12 (0.9)	2 (0.2)	
Tumor	16 (1.2)	4 (0.3)	
Diffuse idiopathic skeletal hyperostosi (DISH)	6 (0.5)	1 (0.1)	1 (0.1)
Anatomical variants of SIJ	6 (0.5)	11 (0.9)	1 (0.1)
Septic Arthritis	2 (0.2)		
Gout		1 (0.1)	

Conclusion: A substantial proportion of patients with suspected sacroiliitis had normal SIJ while the rest were more commonly diagnosed with pathologies other than inflammatory sacroiliitis. A referral by an experienced rheumatologist may improve the sensitivity and specificity of this important examination.

AB0985 COSTOVERTEBRAL AND COSTOTRANSVERSE JOINT INVOLVEMENT IN SPONDYLARTHRITIS BY ROUTINE CHEST COMPUTED TOMOGRAPHY

Keywords: Spondyloarthritis

E. B. Ata[1], G. Durhan[2], E. Bilgin[3], M. Ariyurek[2], U. Kalyoncu[3]. *[1]Hacettepe University, Internal Medicine, Ankara, Turkey*; *[2]Hacettepe University, Radiology, Ankara, Turkey*; *[3]Hacettepe University, Rheumatology, Ankara, Turkey*

Background: In spondyloarthritis (SpA) patients, costovertebral (CV) and costotransverse (CTr) joint are affected however these involvements are not routinely examined in clinical practice. Clinical characteristics of these involvements need further assessment.
Objectives: In this study, we aimed to determine the characteristics of CV and CTr joint involvements in SpA patients by routine chest computed tomography (CT).
Methods: SpA patients who have been requested a chest CT for any reason between January 2010 and December 2020 were retrieved from medical records and included in this retrospective cross-sectional analysis. Of these subjects, 281 had a diagnosis of SpA confirmed with patients records and sacroiliac imaging. After the patient population was created, the patients were sorted according to the registration number and divided into groups of ten. One patient was selected from each group. Thirty age- and sex-matched rheumatoid arthritis (RA) patients and 30 healthy controls were selected. Thorax CT were re-examined for CV and CTr joints by an experienced radiologist. All joints were classified as: Normal (0); suspicious [1], mild [2], moderate [3], and severe [4]. A total of 44 joints were evaluated for each patient, 24 CV and 20 CTr joints.
Results: Of the SpA patients, 206 (73.3%) were diagnosed with AS, 63 (22.4%) with psoriatic arthritis (PsA), and 12 (4.3%) with non-radiographic axial SpA (nr-AxSpA). 34 (54%) of PsA patients had axial PsA. Total scores of CV joint were different between diseases (AS 35 (0-96), PsA 16 (0-73), axial PsA 16 (0-73), peripheral PsA 20 (1-53), nr-AxSpA 6.5 (0-42), RA 15.5 (0-50), healthy control 13 (0-48) (p<0.001))

(Figure 1). Similarly, total scores of CTr joint were different between diseases (AS 16 (0-80), PsA 13 (0-34), axial PsA 12 (0-34), peripheral PsA 14 (0-32), nr-AxSpA 14 (2-31), RA 6.5 (0-24), healthy control 4 (0-20) (p<0.001)). In AS patients, 123 were male and 83 were female. Male AS patients had higher CV and CTr scores than female AS patients (Male CV score:52 (0-96) CTr score:20 (0-80); Female CV score:22 (0-96), CTr score:12 (0-79), p<0.001). In male AS patients, strong negative correlations between chest expansion and joint involvement of CV (r=-0.612, p<0.001) and CTr (r=-0.618, p<0.001) were found. In addition, strong positive correlations were observed between CV joints and lumbar modified stoke ankylosing spondylitis spinal score (mSASSS) (r=0.742 p<0.001), CV joints and cervical mSASSS score (r=0.754 p<0.001), CTr joints and lumbar mSASSS score (r=0.638 p<0.001), CTr and cervical mSASSS score (r=0.654 p<0.001).

Conclusion: In this study, we have found that CV and CTr joint involvement on thorax CT were more severe in AS patients and were associated with mSASSS and it negatively affects chest expansion. In a study with 25 AS patients, CV and CTr joint involvements were 80% and 60%, respectively and negative correlation with chest expansion were observed [1]. Another study showed moderate correlation mSASSS and arthritis of CV or CTr joints in AxSpA patients with MRI [2]. Our results are in line with the literature. In the light of these results, it may be beneficial to evaluate these joints, which have the potential to be overlooked clinically, and to initiate patients with CTr and CV joint involvement in exercise programs in the early period.

AB0986 QUALITY STANDARDS FOR PATIENTS WITH AXSPA – STATUS QUO OF DIAGNOSTIC AND THERAPEUTIC MANAGEMENT OF AXSPA PATIENTS IN GERMANY

Keywords: Spondyloarthritis, Quality of care

J. F. Schmidt[1], U. Kiltz[2], C. Stammann[3], J. Schubert-Haack[3], J. Strunk[4], H. J. Lakomek[5], J. Braun[2], M. Rudwaleit[1]. [1]*Klinikum Bielefeld, University of Bielefeld, Bielefeld, Germany*; [2]*Rheumazentrum Ruhrgebiet, Ruhr University Bochum, Herne, Germany*; [3]*AQUA-Institut, Evaluation and Implementation Research, Göttingen, Germany*; [4]*Krankenhaus Porz am Rhein gGmbH, Köln, Germany*; [5]*Mühlenkreiskliniken | Johannes Wesling Klinikum Minden, Minden, Germany*

Background: Despite the availability of national and international recommendations for management of patients with axial spondyloarthritis (axSpA), shortcomings in the delivery of high level quality of care in daily practice likely exist in many health care systems. To optimize diagnostic and therapeutic approaches for axSpA patients, 9 quality standards (QS) were developed by ASAS (Assessment of SpondyloArthritis international Society) [1]. These international QS have been recently adapted in Germany [1, 2].

Objectives: To determine the status of quality of care delivered to axSpA patients in 2021 across Germany, with special reference to the new ASAS QS.

Methods: As part of a multicentre study, the Continuous Outcome Benchmarking in Rheumatology (KOBRA) project in Germany, patients with axSpA were surveyed regarding the 9 ASAS QS: QS1 - time until referral; QS2 - time to specialist; QS3 - time span of diagnostic work-up; QS4 - monitoring of disease activity; QS5 - discussion of biological treatment in case of insufficient NSAID therapy; QS6 - benefit of regular exercise; QS7 - offers for disease educational courses; QS8 - time to contact with the rheumatologist in case of flare or drug adverse events; QS9 - annual review.

Results: A total of 417 axSpA patients on an in-patient basis in 27 rheumatology clinics were surveyed; mean age 50.7 yrs; mean symptom duration 14.6 years; 53.4% had r-axSpA, 71.4% BASDAI>4, and 81.2% ASDAS>2.1. Regarding the 9 ASAS QS, 31.7% of the patients received a referral to a rheumatologist within 3 working days after initial suspicion of an axSpA (QS1). 36.0% of referred patients received an appointment with the rheumatologist within 3 weeks (QS2). The diagnostic work-up by the rheumatologist was completed within 2 months in 63.2% of the patients (QS3). Monitoring of the disease activity with validated scores at least once every 6 months was performed in 50.2% (QS4). 62.9% of patients were treated with NSAIDs, of whom 66.2% described therapy as insufficient. In 14.6% of patients, rheumatologist did not discuss a potential treatment escalation to biologics despite the insufficient response to NSAIDs (QS5). About ¾ of patients (72.6%) reported being informed about the positive effects of regular exercise (QS6). Only 35.7% received an offer for an educational course including disease management within 2 months after diagnosis (QS7). In case of flare or adverse events, urgent contact to rheumatology within 2 business days took place in only 35.1% of patients (QS8). 51.4% of patients have undergone an annual assessment of life circumstances and disease influencing cofactors (QS9). Of note, relevant gender differences were identified: the waiting time for an appointment with a rheumatologist was longer for women (>3 months, 32.3% vs. 18.0%), and female patients reported more often an insufficient NSAID therapy than males (71.3% vs. 59.8%) despite similar rates of NSAID use. In patients insufficiently treated with NSAIDs, therapy with a biologic was less often discussed with females (17.2% vs. 10.4%). Despite, more women were treated with a biologic (42.6% vs. 35.1%). Contact with the rheumatologist, if urgently needed, within <7 working days took place more often in women (60.5% vs. 45.9%).

Conclusion: This is the first project to assess the quality of care according to the ASAS QS among axSpA patients in Germany. The quality of care was acceptable in some areas (e.g. escalation to biological therapy) but needs improvement in others (e.g. rapid access to rheumatology for diagnosis and in case of urgent matters, educational offers). Relevant gender differences were identified. Overall, this data provides important guidance for the improvement of rheumatologic care in daily practice.

Background: There is increasing evidence of differences between males and females in axial spondyloarthritis (axSpA), but the source is restricted to specific geographic locations or populations.
Objectives: This analysis aims to assess gender differences in a large sample of patients included in the International Map of Axial Spondyloarthritis (IMAS) study from around the globe.
Methods: IMAS is a cross-sectional online survey (2017-2022) of 5,557 unselected axSpA patients from 27 countries. The current analysis looked at the differences in a variety of patient and disease characteristics/assessments between males and females. The factors evaluated were: sociodemographic (age, educational level, marital status, employment status, and patient organization membership), health behaviours (smoking, alcohol consumption, and physical activity), disease characteristics (age at symptom onset, diagnostic delay, HLA-B27, family history of axSpA, uveitis, inflammatory bowel disease), patient-reported outcomes (disease activity [0-10] on the BASDAI scale, spinal stiffness [3-12], functional limitation [0-54], and mental health [0-12] using GHQ-12 scale), mental comorbidities (anxiety, depression, and sleep disorders), and treatments (NSAIDs, csDMARDs and bDMARDs).
Results: Data from 5,555 patients reporting gender were analyzed: 3,492 from Europe, 769 from North America, 600 from Asia, 548 from Latin America, and 146 from Africa. Globally, 55.4% were females, with higher proportions in South Africa (82.2%) and lower in Asia (20.8%; **Figure 1**). Compared to males, females were of a younger age, more frequently university educated, more often divorced, more commonly on permanent sick leave, and less often members of patient organizations (**Table 1**). With respect to health behaviours, male participants smoked and drank more than females. Compared to males, diagnostic delay was significantly longer (by 2.4 years) while the rate of HLA-B27 positivity and family history with axSpA were lower in females. With respect to patient-reported outcomes, females presented with higher disease activity, greater functional limitation, and poorer mental health. The use of axSpA drug treatment was more common in females with a higher proportion having ever taken NSAIDs, csDMARDs and bDMARDS (**Table 1**).
Conclusion: Globally, females with axSpA practiced better health behaviors and reported lower frequency of HLA-B27 positivity but had longer diagnostic delay. Despite more frequently receiving medication, females presented with higher disease activity, greater functional limitation, and worse mental health. Reducing the disease burden and diagnostic delay in females is crucial to improving axSpA care around the world.

GENETIC EVIDENCE FOR A BIDIRECTIONAL CAUSAL RELATIONSHIP BETWEEN ANKYLOSING SPONDYLITIS AND CARDIOVASCULAR DISEASE

Keywords: Spondyloarthritis, Cardiovascular disease

R. T. Shen[1,2], L. K. Qi[1,2], Y. Q. Bai[1,2], L. Niu[1,2], X. Y. Yin[1,2], Q. Yu[3], P. F. He[3], X. Li[1,2,4], S. X. Zhang[1,2,4]. Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease[1]. Mounting evidence suggests an increased risk of cardiovascular disease (CVD) in patients with AS. And cardiovascular problems in AS patients have been identified as the primary cause of death[2]. Furthermore, few studies have examined whether CVD directly impacts AS, making the link between AS and CVD less complete. In this study, we conducted a bi-directional Mendelian randomization (MR) analysis to investigate the causal relationship between these two traits.
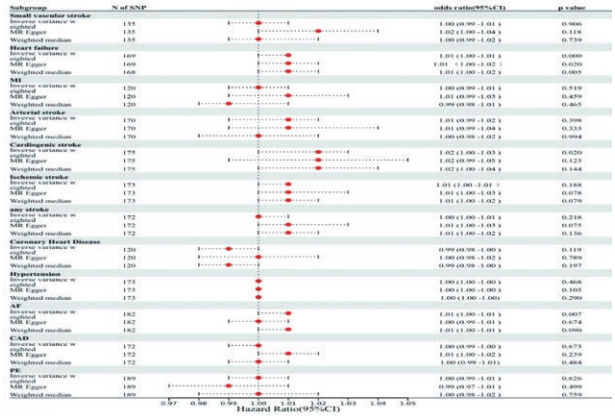
Objectives: This study aimed to investigate the bidirectional causal effects of AS and CVD.
Methods: Genetic instruments for AS were obtained from the Finnish database, including 2,252 cases and 227,388 controls. The summary data for 12 CVD were retrieved from genome-wide association studies (GWAS). We utilized the inverse variance weighted (IVW), MR-Egger regression and weighted-median (WME) analysis to test the casual relationship. Sensitivity analysis

is used for hypothesis testing and estimating the tangible impact between exposure and results.

Results: The study indicated that AS increased the genetic susceptibility to cardiogenic stroke (IVW:OR: 1.05, 95% CI: 1.01-1.10, p = 0.03), heart failure (HF) (IVW: OR=1.01, 95% CI=1.00-1.01, P=0.0004) and atrial fibrillation (AF) (IVW: OR= 1.01, 95% CI= 1.00-1.01, P= 0.007). Small vessel stroke (SVS) was positively associated with an increased risk of AS (IVW: OR=1.20, 95% CI=0.77-1.41, P=0.022).



Conclusion: AS may be a risk factor for CVD such as cardiogenic stroke, HF, and AF. At the same time, for patients of SVS, the risk of developing AS was 1.20 times. Inflammation may be one of the main pathways linking this causality.

AB0989 **ARE OSTEOPOROSIS AND FRACTURES NEGLECTED ISSUES IN AXIAL SPONDYLOARTHRITIS? DATA FROM A CROSS-SECTIONAL MONOCENTRIC STUDY**

Keywords: Spondyloarthritis, Comorbidities, Osteoporosis

C. Crotti[1], F. Orsini[1,2], R. Di Taranto[1,2], M. Ferrito[1,2], A. Amati[1,2], M. Biggioggero[1], M. Varenna[1,3], E. G. Favalli[1,2], R. Caporali[1,2]. *[1]ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy*; *[2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*; *[3]ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Bone Disease Unit, Milan, Italy*

Background: Prevalence of osteoporosis (OP) and fractures (Fx) in spondyloarthritis (SpA) is frequently overlooked[1]. Axial (ax-) involvement, particularly in ankylosing spondylitis (AS), is associated with seeming increased lumbar spine bone mineral density (BMD) while vertebral fractures are present in up to 43% of patients with AS. Bone densitometry is considered the gold standard for osteoporosis diagnosis and fracture risk assessment.

Objectives: To investigate predictors of OP and prevalence of Fx in a population of ax-SpA patients.

Methods: Data were cross-sectionally extracted from a monocentric registry including SpA patients with axial involvement [AS, ax- Psoriatic Arthritis (ax-PsA), non-radiographic ax-SpA (nr-axSPA), IBD associated-SpA] at their last evaluation in a tertiary rheumatology center between August and December 2022. Comparisons were performed by T test and chi-square test; logistic regression was used to analyze the predictors of OP screening assessed by dual-energy x-ray absorptiometry (DXA) and other collected variables.

Results: The overall population included 385 patients (35.6% female; mean age±SD 48.5±12.7 yrs; 42.9% AS, 33% nr-axSpA, 20.5% ax-PsA, 3.6% IBD-SpA; 43.9% HLAB27 positive; 42.3% postmenopausal females; 7.8% patients with previous diagnosis of OP). Almost 10% of the entire population experienced Fx (n=38): 16 vertebral Fx, 2 femoral Fx, and 24 non-vertebral/ non femoral Fx. The presence of previous fragility Fx was significantly associated with menopause (39% vs 12.4%, p<0.001), older age (56.6±10.11 vs 47.6±12.65, p<0.001), elevated ESR (median 13 mm/h (IQR 7-24) vs 9 (5-19), p=0.04) and higher ASDAS-CRP (median 1.28 (1-2.6) vs 1.05 (0.6-1.7), p=0.03), and previous OP diagnosis (50% vs 3.1%, p<0.001). DXA was performed only in 11.7% of the population. DXA was mainly performed in females (64.5% vs 31.8%, p<0.001), post-menopausal women (57.8% vs 9.4%, p< 0.001), older patients (58.6±12.5 vs 47.2±8.9, p<0.001), patients with previous diagnosis of disthyroidism (11.1% vs 4.7%, p=0.08), OP (53.4% vs 1.8%, p<0.001), patients with previous Fx (46.7% vs 5%, p<0.001), both vertebral Fx (26.7% vs 1.2%, p<0.001) and non-vertebral/non femoral Fx (24.5% vs 3.9%, p<0.001). DXA was significantly more frequently performed in patients supplemented with vitamin D (86.7% vs 29.4%, p<0.001), calcium (53.4% vs 4.1%, p<0.001), and receiving bisphosphonate therapy (26.7% vs 1.8%, p<0.001) or on bone loss inducing drugs (44.4% vs 21.3, p=0.001). DXA was significantly less frequently evaluated in current smokers (1.5% vs 24.7%, p=0.04) and ax-PsA subtype (8.9% vs 22%, p=0.04). Factors associated with OP screening by DXA were menopause [OR 17.8, 95% CI 2.3-135, p=0.005], and bone loss inducing drugs (OR 3.2, 95% CI 1.12-9.16, p=0.030). Predictor of Fx was the presence of elevated disease burden expressed as ASDASCRP (OR 1.9, 95% CI 1.2-3.2, p=0.012).

Conclusion: Our data confirm that OP is an underestimated comorbidity in axSpA patients, particularly males or younger patients. Fragility Fx is related with disease burden, confirming that inflammation mostly triggers bone loss. Not all risk factors for OP are correctly addressed, such as active smoke. We should aim to better evaluate OP as a SpA comorbidity to early detect patients at high risk of fragility Fx to treat them properly.

Background: Obstructive sleep apnea (OSA) is a common chronic disorder, characterized by recurrent collapse of the upper airway during sleep. OSA is associated with comorbidities, such as ischemic heart disease, hypertension, arrhythmias, and others. The spectrum of spondyloarthritis (SpA) encompasses several diseases, including ankylosing spondylitis, psoriatic arthritis, inflammatory bowel disease related arthropathy, reactive arthritis, and undifferentiated SpA, sharing common clinical manifestations. It is important to gather more data on the prevalence of OSA, as diagnosing and treating comorbidities is an essential part of the management of inflammatory diseases. There are several reports on the association between OSA and ankylosing spondylitis with conflicting results. To date, studies evaluating the association between OsA and broader spectrum of SpA are lacking.

Objectives: To examine the prevalence and severity of OSA in patients with SpA with or without axial involvement compared to healthy controls. Predictive factors for OSA, such as disease activity, SpA subtypes, axial involvement and medical treatment, were assessed as well.

Methods: This was a controlled cross-sectional study. The study cohort consisted of consecutive patients with SpA defined by the ASAS classification criteria. Clinical and demographic characteristics of the cohort were retrieved from patients' files. Disease activity scores and sleep quality questionnaires were administered at enrolment. All participants underwent a single night home sleeping test using a validated diagnostic device. OSA was defined as apnea-hypopnea index (AHI) ≥5, and moderate-severe OSA as AHI≥15.

Results: Forty-two consecutive patients with SpA and 33 healthy controls were recruited to this study. Patients' characteristics are shown in **table 1**. OSA was diagnosed in 34 patients (81%) with SpA compared to 15 (33%) in the control group (P<0.01) **figure, panel A**. Moderate-severe OSA was found in 14 (33%) patients in the SpA group vs. 1 (3%) in the healthy control group (P<0.01) **figure, panel B**. Other sleep indices, such as sleep efficiency, sleep stages and sleep latency, didn't show any significant difference between the groups. There was also no correlation between SpA activity scores, BASDAI and ASDAS, sleep scores, drug therapy and the presence of OSA. In a logistic regression analysis, older age, elevated body mass index and axial involvement were associated with the presence of OSA.

Conclusion: In this study, OSA, including moderate-severe OSA, was significantly more prevalent in patients with SpA in comparison with healthy controls. Axial involvement predicted the presence of OSA in SpA. Our study emphasizes the importance of sleep assessment and diagnosing OSA in patients with SpA, in order to provide treatment, improve the quality of life and reduce the impact of comorbidities.

Table 1. Patients and Controls Characteristics

	SpA	Controls
General Characteristics		
Age (years)	50.2 ± 13.2	43.8 ± 11.0
Male, n (%)	27 (64.3)	22 (66.7)
BMI, Kg/m²	29.5 ± 9.4	25.2 ± 2.9
Disease characteristics		
Mean disease duration (years ± SD)	12.2 ± 13.1	
ASDAS (mean ± SD)	2.48 ± 1.24	
BASDAI (mean ± SD)	6.25 ± 6.76	
Pain-VAS (mean ± SD)	51.6 ± 31.1	
HAQ (mean ± SD)	3.4 ± 2.81	0.41 ± 1.42
Axial involvement, n (%)	30 (71%)	
Sleep and Fibromyalgia Scores		
ESS, (mean ± SD)	6.8 ± 3.9	6.8 ±5.62
PSQI, (mean ± SD)	7.4 ± 4.42	7.7 ± 4.83
WPI, (mean ± SD)	4.5 ± 5.1	2.07 ± 3.32
SSS, (mean ± SD)	4.6 ± 3.4	3.03 ± 3.22

SpA, Spondyloarthritis; BMI, body mass index; SD, Standard Deviation; ASDAS, Ankylosing Spondylitis Disease Activity Score; BASDAI, Bath Ankylosing Spondylitis Disease Activity Score; Pain-VAS, Pain Visual Analog Scale; HAQ, Health Assessment Questionaire; ESS, Epworth Sleepiness Scale; PSQI, Pittsburgh Sleep Quality Index; WPI, Widespread Pain Symptoms; SSS, Symptoms Severity Scores.

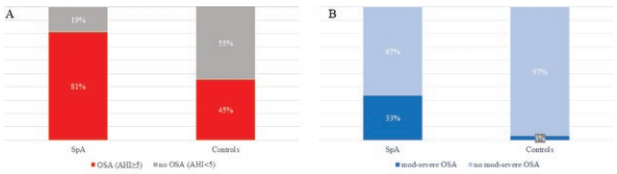

Figure. Panel A. obstructive sleep apnea in spondyloarthritis patients compared to healthy controls. p<0.01. Panel B. moderate to severe obstructive sleep apnea (AHI≥15) in spondyloarthritis patients compared to healthy controls. AB0991 RADIOGRAPHIC EVALUATION OF FOOT SPURS IN SPONDYLOARTHRITIS

Keywords: Spondyloarthritis

H. H. Gezer[1], O. Pehlivan[2], M. T. Duruöz[3]. [1]*Ümraniye Training and Research Hospital, Rheumatology, İstanbul, Turkey*; [2]*Ümraniye Training and Research Hospital, Rheumatology, Istanbul, Turkey*; [3]*Marmara University School of Medicine, PMR Department, Rheumatology Division, Istanbul, Turkey*

Background: Although bone spurs are frequently seen in non-inflammatory diseases, they can also be seen with inflammation of the enthesis areas, especially in spondyloarthritis (SpA).

Objectives: To investigate the radiological evaluation of foot spurs in SpA and compare the characteristics between the SpA and degenerative diseases.

Methods: This ongoing study included 168 (124 women) patients with radiographic plantar or achilles spur. Age, disease duration, and body mass indexes were recorded. Patients were categorized with inflammatory [non-radiographic SpA (nr-AxSpA), radiographic SpA (r-AxSpA), psoriatic arthritis (PsA), and other) and non-inflammatory [osteoarthritis (OA) and diffuse idiopathic skeletal hyperostosis (DISH)]. Foot radiographs of the plantar region, achilles, and other regions (anterior ankle, posterior ankle, and tarsal bones) were examined for the spurs. The spur caharacteristics were evaluated. Three measurements were taken from each radiograph: plantar spur base, mid-segment, and length in millimeters. The differences were compared between SpA patients and controls.

Results: The mean age of the patients was 50.8 (SD:11.3) years, and the mean disease duration was 55.1 (SD:55.8) months. One hundred twenthy eight (76.2%) were in the inflammatory group [PsA (n=56), r-axSpA (n=30), nr-axSpA (n=27), other SpA (n=14)], while 40 (23.8%) were in the non-inflammatory [OA (n=35), DISH (n=5)] group. Plantar spur base, midsegment, and length were higher in the non-inflammatory group than in the inflammatory group (p<0.05). Fluffy structure and erosion in the plantar spur were more common in the inflammatory group (p<0.05). The characteristics of the spurs were not different between diseases in the inflammatory group (p>0.05). Plantar spur lengths in the PsA patients were significantly higher than in the non-PsA SpA group (p=0.028 and 0.003); other spur features between groups were not different (p>0.05).

Conclusion: Spurs are smaller and erosion and fluffy appearance are more common in SpA patients compared to non-inflammatory conditions. Spur characteristics are not different among SpA group diseases; only the plantar spur lengths were higher in patients with PsA. Although calcaneal and achilles spurs are frequently evaluated in clinical practice, approximately half of the patients also have spurs in the tarsal bone.

AB0992 **THE POTENTIAL IMPACT OF HLA-B27 AND HLA-B51 HAPLOTYPE ON PATTERNS OF NON-INFECTIOUS UVEITIS**

Keywords: Spondyloarthritis, Behcet's disease, Uveitis

M. Fatica[1], P. Triggianese[1], E. Greco[1], P. Conigliaro[1], A. D'antonio[1], B. Monosi[1], B. Kroegler[1], A. Bergamini[1], M. S. Chimenti[1]. [1]*University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Department of Systems Medicine, Rome, Italy*

Background: Non-infectious uveitis (NIU) include diseases characterized by the inflammation of the vascular tunica of the eye that can cause significant ocular impairment up to blindness, and systemic inflammatory rheumatic diseases (RDs) represent one of their major causes [1]. NIU can be widely heterogeneous in terms of course, laterality, and anatomical involvement, while their clinical presentation may be influenced by associated RDs and certain HLA haplotypes [2].
Objectives: To explore the potential impact of HLA-B27 and HLA-B51 haplotypes on clinical presentation of NIU from patients who were referred to a 3rd level Rheumatologic Clinic in Italy.
Methods: A cross-sectional study was conducted. Selection criteria consisted of having a diagnosis of NIU in an age of onset ≥ 18 years old regardless of etiology among patients who were admitted to the 3rd level Rheumatologic Clinic at "Tor Vergata" University Hospital (Rome, Italy) between January 2018 and October 2022. Data were collected from medical records: age of NIU onset, recurrence and anatomic patterns of affected eyes according to the Standardization of Uveitis Nomenclature (SUN) working group, HLA-B27 and HLA-B51 positivity, and associated RDs were analyzed.
Results: Among the NIU cohort (n= 144), 76 of them underwent HLA-B haplotype typing: 26 (34.2%) showed HLA-B27 positivity while 16 HLA-B51 positivity (21.1%), without a gender difference. Patients HLA-B27(+) had more frequently anterior NIU (AU, 88.5% vs 60%, p=0.01), acute course (69.2 vs 44%, p=0.03), and unilateral involvement (69.2% vs 42%, p=0.02) than patients HLA-B27(-) (Figure 1). HLA-B27(+)-NIU had a significantly prevalent diagnosis of axial-spondylarthritis (ax-SpA, 53.8% vs 6%, p<0.00001) than HLA-B27(-)-NIU. Differently, patients with HLA-B51(+) had mostly posterior NIU (PU, 68.8% vs 16.7%, p<0.00005), recurrent/chronic course (68.8% vs 40%, p=0.04), and bilateral involvement (81.3% vs 33.3%, p=0.0005) than patients HLA-B51(-) (Figure 1). A diagnosis of Behçet's Disease (BD) was performed more frequently in HLA-B51(+) than in HLA-B51(-) patients (75% vs 6.7%, p<0.00001). The age of NIU onset was significantly younger in HLA-B51(+) than in HLA-B51(-) (34.1±13.8 vs 41.1±13.2 yo, p=0.003), while there was no statistically significant difference in age of NIU onset between HLA-B27(+) and HLA-B27(-) (38.38±13.7 yo vs 40.49±13.5 yo. p>0.05).
Conclusion: Our population-based findings describe how HLA-B27 and HLA-B51 haplotypes can impact NIU patterns and suggest a relevant role of an early HLA typing study of NIU patients for the definition of targeted diagnostic and therapeutic strategies.

AB0993 **CONTROL OF CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH SPONDYLOARTHROPATHIES VERSUS RHEUMATOID ARTHRITIS**

Keywords: Cardiovascular disease, Rheumatoid arthritis, Quality of care

C. Desmet[1], V. Ursachi[1], N. G. Manolache[1], A. Nzeusseu Toukap[2], M. Stoenoiu[3]. [1]*Cliniques Universitaires Saint-Luc, Rheumatology, Brussels, Belgium*; [2]*Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Rheumatology, Brussels, Belgium*; [3]*Cliniques Universitaires Saint-Luc, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Rheumatology, Brussels, Belgium*

Background: It has been reported that management of cardiovascular (CV) risk factors is suboptimal in patients with rheumatoid arthritis (RA). Whether this also applies to psoriatic arthritis (PsA) or ankylosing spondylitis (AS) patients is unknown.
Objectives: The main objective of this study was to compare control of CV risk factors among disease groups.
Methods: Information on CV risk factors was collected in consecutive adult patients from rheumatology clinic, with RA, PsA or AS. Hypertension (HTN) was defined as systolic blood pressure (BP) ≥140 mmHg, diastolic BP ≥ 90 mmHg

and/or antihypertensive treatment, hypercholesterolemia as LDL-cholesterol ≥ 100 mg/L and/or lipid-lowering treatment. Treatment goals were defined according to European Society of Cardiology and EULAR guidelines.

Results: We included 520 patients (54% women; 46% RA, 22% PsA, 32% AS). Mean age and disease duration were 52.1±14.1 and 11.0±10.6 years, respectively. Out of 520 patients, 203 (39%) had HTN, among whom 140 (69%) were treated and 86 (42%) were controlled; 293 (56%) had HC, among whom 88 (30%) were treated and 51 (17%) were controlled; 30 (6%) had type 2 diabetes, among whom 18 (60%) were controlled. Current smoking was present in 100 patients (19%), obesity in 136 patients (26%) and increased waist circumference in 192 patients (37%). Compared to RA patients, patients with spondyloarthropathies were less often in remission (40% vs. 54%, p<0.005). Furthermore, patients with spondyloarthropathies differed from RA patients by a lower proportion of treated (56% vs. 84%, p<0.001) and treated-to-target (24% vs. 64% p<0.001) HTN, a higher proportion of active smokers (28% vs. 12%, p<0.01), and lower physical activity (29% vs. 46%, p<0.001). Control of LDL-cholesterol was poor in both groups (17% vs.18%, p=0.95). No significant difference between groups was found for diabetes, overweight and obesity.

Conclusion: Compared to patients with RA, patients with spondyloarthropathies were less well controlled both for disease activity and CV risk factors. Furthermore, lipid control was poor in both groups. If confirmed in a multicentre cohort, these results may help orienting CV prevention strategies and increasing awareness both in physicians and patients, with emphasis on spondyloarthropathies.

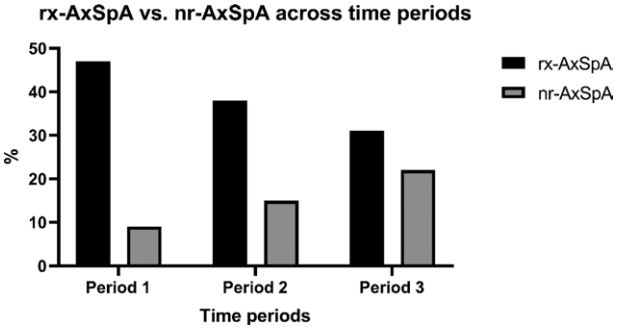
AB0994 HOW SPONDYLOARTHRITIS PROFILE HAS EVOLVED OVERTIME: RESULTS FROM GESPA COLOMBIAN COHORT

Keywords: Geographical differences, Spondyloarthritis, Enthesitis

J. C. Santacruz Devia[1], J. Londono[1], A. M. Santos[1], G. Rodríguez Salas[1], I. Rueda[1], M. J. Mantilla[1], J. Rueda[1], S. Arias[1], J. M. Bello-Gualtero[1], E. Calvo[1], M. Cardiel[2], C. F. Pacheco Tena[3], V. Navarro-Compán[4]. *[1]University of La Sabana, Military Central Hospital, Spondyloarthritis study group (GESPA), Bogotá, Colombia*; *[2]Clinica de Morelia, Centro de investigación, Michoacán, Mexico*; *[3]Universidad Autónoma de Chihuahua, Facultad de Medicina y Ciencias Biomédicas, Chihuahua, Mexico*; *[4]La Paz University Hospital, Department of Rheumatology, Madrid, Spain*

Background: Over the last two decades, our knowledge of spondyloarthritis (SpA) has been improved. The awareness of this disease within the medical community and the implementation of advances in clinical practice are unclear, especially in some geographical regions less well represented in research studies.

Objectives: The aim of our study was to evaluate the changes overtime in disease profile in patients with SpA from a Colombian cohort.



Methods: Data from 471 patients recruited in a prospective Colombian cohort of Spondyloarthritis patients (diagnosed according to rheumatologist), with registries from 90' to the date was analyzed. Three time periods were stablished for the analysis, the first period from the first registry until October 10, 2003; the second period from October 10, 2003 to October 26, 2010; and the third period from October 26, 2010 to December 31, 2021. The patients were reclassified according to ASAS classification using the information available, and judgment from a group of four expert rheumatologists.

Results: 471 patients were included in the study, period 1 (n = 158), period 2 (n = 150) and period 3 (n = 163). There were no differences in sex distribution across three periods. Time to diagnosis was shorter in period 1 than 3 (table 1). The frequency of r-AxSpA diagnosis was proportionally higher in period 1 (47.5%), than period 2 (38.2%), and 3 (31.3%), P = 0.013. For another hand, the frequency of nr-AxSpA diagnosis was lower in the period 1 (9.5%) than period 2 (15.1%), and 3 (22.1%) (view graphic). The frequency of peripheral SpA diagnosis was similar across the three periods (38% vs. 39.5% vs. 37.4%, for periods 1, 2 and 3 respectively, P = 0.8). The presence of dactylitis at physical examination was most common in the first period (10.8%) than the last two periods (3.3% and 3.7%), P = 0.007. There were no differences in frequency of dactylitis, arthritis or uveitis. There were no statistically significant differences in frequency of HLA-B27 (42.4% vs. 44.8% vs. 48.6%, for periods 1, 2 and 3, respectively, P = 0.2) or HLA-B15 (14.4% vs. 8.2% vs. 15%, for periods 1, 2 and 3, respectively, P = 0.2) across the three periods. The metrology analysis showed higher physical limitation in the first period (thoracic expansion < 2.5 cms and modified Schober < 5 cms) than in the last two period (view table 1). The history of psoriasis in SpA patients was higher in period 1 (7.6%) than period 2 (2.6%), and 3 (2.5%), P = 0.036. Infections preceding SpA symptoms onset were most frequent in period 1 (32.9%) than period 2 (29.6%) and 3 (16.6%), P = 0.002.

Conclusion: The profile of patients with SpA has evolved over time in Colombia. While the frequency of peripheral SpA has remained unchanged over time, the incidence of non-radiographic axial forms has increased over time. Furthermore, functional limitation in SpA, infections preceding symptoms, and dactylitis are less common than 20 years ago. These results highlight the impact of advances in rheumatology and the awareness of the medical community about this disease in Colombia, allowing an earlier diagnosis or the diagnosis of less evident forms of SpA.

Table 1.

Variable	< November 11, 2003	November 11, 2003 – October 26, 2010	> October 26, 2010	P value
Total	158	150	163

AB0995 ASSESSMENT OF MATRIX METALLOPROTEINASE-3 IN SPONDYLOARTHRITIS: CORRELATION WITH DISEASE ACTIVITY

Keywords: Biomarkers, Patient reported outcomes, Spondyloarthritis

M. Slouma[1], S. Bouzid[1], L. Kharrat[1], A. Tezeghdenti[2], E. Ghazouani[2], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1], B. Louzir[3]. *[1]The Principal Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia*; *[2]The Principal Military Hospital of Instruction of Tunis, Immunology, Tunis, Tunisia*; *[3]The Principal Military Hospital of Instruction of Tunis, Internal Medicine, Tunis, Tunisia*

Background: Several studies showed that the activity of proteinases, including matrix metalloproteinases (MMPs), is increased in inflamed tissue, via the overproduction of pro-inflammatory cytokines, in spondyloarthritis (SpA) [1].

Objectives: Our study aimed to assess the correlation between serum levels of MMP-3 and disease activity in SpA.
Methods: We conducted a cross-sectional study including patients with SpA, diagnosed according to ASAS 2009 criteria. ELISA technique was used to measure MMP-3 serum levels. CRP and ESR were also measured. Disease activity was assessed with Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP). Pearson correlation coefficient was calculated.
Results: We included 82 patients. The mean age was 45.32 ± 13.41 years [20-80]. Male to female ratio was 3.82. The mean disease duration was 7.57 ± 7.79 years. Radiographic axial SpA (r-AxSpA) and psoriatic arthritis (PsA) were noted in 65.9% (n=54) and 34.1% (n=28) of cases, respectively. The mean MMP-3 serum levels were 64.14 + 187.31 ng/mL [1.75 – 1237.36]. The mean CRP and ESR levels were 20.64 + 24.52 mg/l and 35.46 + 31.69 mm, respectively. The mean BASDAI and ASDAS-CRP were 3.26 ± 1.89 and 2.98 ± 1.45, respectively. MMP-3 serum levels correlated significantly with inflammatory biomarkers: CRP (r=0.314, **p=0.004**) and ESR (r=0.291, **p=0.013**). A correlation was also found with ASDAS-CRP (r=0.245, **p=0.028**). However, no correlation was found between MMP-3 serum levels and BASDAI (r=0.204, p=0.070).
Conclusion: Our results showed that MMP-3 serum levels correlate significantly with inflammatory biomarkers (CRP and ESR) and with ASDAS-CRP. MMP-3 seems to be a promising biomarker for disease activity in SpA.

AB0996 PERCEIVED EFFECTS OF HEALTH STATUS ON SEXUAL ACTIVITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS OVER A 5-YEAR PERIOD

Keywords: Spondyloarthritis, Patient reported outcomes, Outcome measures

K. H. Berg[1], G. Rohde[2,3], H. Vestaby[2,3], G. Haugeberg[2,4]. *[1]Institute of Psychososial Health, Univercity of Agder, Grimstad, Norway*; *[2]Devision of Research, Sørlandet Hospital SSHF, 4604, Norway*; *[3]Department of Health and Nursing Science, Univercity of Agder, 4604, Norway*; *[4]Devision of Rheumatology, Departemnt of Neurocience, Norwegian Univercity of Science and Technology, NTNU, Trondheim, Norway*

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disorder of the axial skeleton and may involve peripheral joints, entheses and other organs, which may cause pain, fatigue, stiffness, loss of physical function. The persons health status may influence on sexual activity and enjoyment. Sexual activity is one of the key functions in human beings and affects both quality of life (QOL) and sexual QOL.
Objectives: To explore perceived effects of health status on sexual activity in patients with axSpA over a 5-year period.
Methods: Patients with axSpA were consecutively recruited from two public outpatient rheumatology clinics in Southern Norway (Martina Hansens Hospital (MHH), and Sørlandet Hospital (SSHF)). A broad specter of data was collected which included: demographic (age, weight, employment, education, married or cohabiting and if they had a partner to have sex with), disease activity and damage (MASES, CRP, BASMI, 68 tender and 66 swollen joints), current medication (NSAID, CsDMARD and bDMARD) and comorbidities (yes/no). A summed score was generated to reflect overall co-morbidity. Quality of life were measured by 15D, which also included a question on perceived influence of health status on sexual activity. Item 15 in the 15D questionnaire was used to study the effect of health status on sexual activity. with the following response options: My state of health: has no adverse effect on my sexual activity, slight effect, considerable effect, makes sexual activity almost impossible, makes sexual activity impossible to analyze the effects of health on sexual activity, we dichotomized the five responses to item 15 in the 15D instrument, which were related to sexual activity. Responses 1 and 2 were grouped into “no/little effects” and the other three categories were grouped into “large effects”. The same data collection performed at baseline was also performed at the five-year follow-up.
Results: A total of 245 patients (168 men and 77 women) with (At baseline the mean age was 46 years (SD ± 11.9) mean disease duration 13.9 years (SD ± 11.4). At 5-years follow-up 44 (18%) patients reported their health status to have large effects on their sexual activity, while 200 (82%) reported no/little effect. The same pattern was seen at baseline. However, 24 patients changed from reporting large effect at baseline to no/little effect at 5-year follow-up, while 26 patients changed from no/little effect to large effect. When comparing patients reporting their health status to have no/little effect on sexual activity versus the one with large effect on sexual activity, the same pattern of differences was seen at both baseline and 5-year follow-up. However, the differences seemed to be more prominent at 5-year follow-up. Focusing on 5-years follow-up differences; patients reporting their health status to have a large effect on sexual activity were older (54 (10) years vs 50 (11) years, p=0.014), fewer were employed (74% vs 47%, p<0.001), exercised less (77% vs 92%, p=0.003), had more co-morbidities (1.5 (1.3) vs 0.8 (1.1), p=0.002), higher CRP (10.2 (19.1) vs 4.6 (7.0), p=0.002), higher BASDAI (4.7 (2.2) vs 2.5 (2.0), p<0.001) higher BASFI (3.9 (2.2) vs 2.0 (2.0), p<0.001), higher BAS-G (5.3 (2.6) vs 2.6 (2.4), p<0.001 and higher HAQ (0.81 (0.45) vs 0.37 (0.4), p<0.001).
Conclusion: Approximately 20% of axSpA patients reported their health status to have a large negative effect on their sexual activity both at baseline and 5-year follow-up. From baseline to 5-year follow-up there has been an increase in comorbidities, and the increase has been larger in patients reporting the disease to have a large negative effect on sexual activity.

AB0997 THE RADIOGRAPHIC ENTHESIS INDEX (REI) FACILITATES THE DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS: RESULTS FROM GESPA COLOMBIAN COHORT

Keywords: Enthesitis, Diagnostic tests, Spondyloarthritis

E. Calvo[1], I. Rueda[2,3], A. M. Santos[3], G. Rodríguez Salas[2,3], M. J. Mantilla[2,2,3], J. Rueda[3], J. C. Santacruz Devia[3], S. Arias[2,3], J. G. Ballesteros[2], M. Cardiel[4], C. F. Pacheco Tena[5], J. Londono[2]. *[1]Universidad Nacional de Colombia, Medicine, Bogotá, Colombia*; *[2]Hospital Militar Central, Rheumatology, Bogotá, Colombia*; *[3]Universidad de La Sabana, Medicine, Chía, Colombia*; *[4]Clinical Morelia Monarch, Rheumatology, Morelia, Mexico*; *[5]Universidad Autónoma de Chihuahua, Biomédicas, Chihuahua, Mexico*

Background: Spondyloarthritis (SpA) refers to a group of related but phenotypically distinct disorders: psoriatic arthritis, arthritis related to inflammatory bowel disease, reactive arthritis, a subgroup of juvenile idiopathic arthritis, and ankylosing spondylitis. [1]. Patients with SpA can be distinguished, according to their clinical presentation, as axial SpA or peripheral SpA patients [2]. Each of these diseases is characterized by distinct clinical and laboratory characteristics, and each features a wide spectrum of clinical presentations, facts that highlight the dynamism and progression of SpA.
Objectives: To evaluate the diagnostic performance of radiography in the evaluation of enthesitis in the pelvis and its usefulness in the diagnosis of SpA.
Methods: This study was a historical cohort study from 2005 to 2020. Eligible patients were adults (≥18 years of age) with SpA according to the Assessment of Spondyloarthritis international Society (ASAS) criteria, and the control group were patients with chronic lumbar pain (more than three months) with non-inflammatory characteristics, without meeting ASAS criteria for SPA, and who assisted neurosurgery and rheumatology consultations in the Hospital Militar Central, Bogotá DC. The pelvic radiography had an anteroposterior view with gut preparation with laxative, the coccyx and pubic symphysis were aligned with the midline, and the distance between the tip of the coccyx and the upper limit of the coccyx was more than 2.5 cm. We used three zones of tendinous insertion in the pelvis. Zone one (ZI) is the iliopubic ramus; zone two (ZII) is the pubic symphysis; zone three (ZIII) is the ischiopubic ramus. In addition, a grading system was created from zero to four (grade 0: normal; grade I: periostial wishkering and/or osteopenia; grade II: periostial wishkering, osteopenia, sclerosis and erosions; and grade III: grade II findings in addition to the presence of ripple or waving patterns > 2 mm outside the cortex). The scores of each zone of the REI, without discriminating by laterality, were added to give the total REI as a result.
Results: The cohort have 450 patients, we selected 150 patients for the initial evaluation. Eleven (17.19%) were females and fifty-three (82.12%) were males. In the non-SpA, grade 0 was the most frequent in the three zones of REI, while grades II and III were more frequent in the SpA group; those outcomes were statistically significant. Zone III had the highest degree of enthesitis according to the REI classification (63.4%) in the SpA group, with a probability greater than 99% that these findings are related to SpA and not by chance.
Conclusion: Conventional pelvis radiography is still useful for SpA diagnosis, not just for sacroiliac joint and lumbar spine involvement assessment but also for the evaluation of the pelvic enthesis, which gives essential information for the diagnosis of SpA.

AB0998 DIFFERENCES IN PSYCHOLOGICAL BURDEN AND IN QUALITY OF LIFE MEASURES BETWEEN GENDERS IN SPONDYLOARTHRITIS PATIENTS-ANALYSIS OF A MONOCENTRIC COHORT

Keywords: Gender/diversity issues, Quality of life, Spondyloarthritis

C. Cigolini[1], F. Fattorini[1], C. Cardelli[1], G. Marchetti[1], A. Delle Sedie[1], L. Carli[1], M. Mosca[1]. [1]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

Background: Spondyloarthropathies (SpA) are chronic inflammatory arthritis, characterized by both peripheral and axial skeletal involvement and some typical extra-articular marks; they tend to associate with several comorbidities and can increase the risk of an impaired quality of life (QoL). Already published data show SpA expression differs based on gender; in particular, women are at higher risk of a more pronounced peripheral disease activity and show a greater burden of the disease, thus having worse values of Patient Reported Outcomes (PROs). It is well known that a compromission in physical functioning and psychological sphere may compromise productivity of patients and subsequently increase health costs.
Objectives: The aim of our study was to assess the differences between male and female sex in the prevalence of mood disorders, fatigue and parameters of QoL in a monocentric cohort of patients with SpA.
Methods: Adult patients diagnosed with Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS) according to the CASPAR (ClASsification criteria for Psoriatic Arthritis) and to Assessment of SpondyloArthritis international Society (ASAS) criteria, regularly followed at the SpA clinic of our unit, were consecutively enrolled from April to December 2022. Epidemiologic, clinic and clinimetric data were collected. Each patient filled in the following Patient Reported Outcomes: Hospital Anxiety and Depression Scale (HADS), FACIT-Fatigue (FACIT-F) and SHORT-FORM 36 (SF-36). Intergroups comparisons were assessed by using Chi-square, t-test and ANOVA. P values <0.05 were considered significant.
Results: A total of 200 patients were enrolled; 85 (42.5%) were women, with a mean age of 56.84±12.22 years and a mean disease duration of 12.91±10.3 years. One hundred and thirty-five patients (67.5%) had a diagnosis of PsA (M/F 79/56), while 59 (29.5%) had a diagnosis of AS (M/F 36/23) and 6 (3%) of Enteropathic Arthritis (M/F 0/6). Women showed worse FACIT-F values than men, (mean 35.20 vs 40.23, p-value 0.002) and a greater impairment of QoL expressed by statistically significant lower values of almost all the domains of SF-36 (exception for Global Health). Moreover, the values of HADS resulted higher in female sex both for the anxiety and depression domains (p-value <0.001 and 0.039 respectively).
Conclusion: The analysis of our cohort confirmed that women affected by SpA suffer from anxiety and depression more often than men, develop a higher level of fatigue and have an overall worse QoL in both psychological and physical domains. These data should sensitize rheumatologists in the assessment of this subgroup of patients. The clinician should not only focus on the disease activity evaluation and therapy or in managing of the comorbidities, but also on the psychological and functional status of the patients, developing strategies able to avoid or delay the onset of their impairment in daily life and to optimize with specific therapies, rehabilitation or psychological support their compromission, when already established. This approach could finally improve the social burden and health cost of women with SpA.

AB0999 RELIABILITY OF INFLAMMATORY BACK PAIN CRITERIA AS A TOOL FOR DIFFERENTIATION BETWEEN INFLAMMATORY AND MECHANICAL BACK PAIN AMONG EGYPTIAN PATIENTS

Keywords: Patient reported outcomes, Pain, Spondyloarthritis

M. A. Mortada[1], N. Ehab[1], E. Elshahawy[1], S. Elnaggar[1]. [1]*Zagazig University, Rheumatology, Zagazig, Egypt*

Background: Inflammatory back pain (IBP) is a key symptom of axial spondyloarthritis (AxSpA). Most items of the IBP criteria are subjective and liable to change depending on the patient's expression. (1)
Objectives: Assessment of the sensitivity, specificity, and reliability of IBP parameters and sets in patients with AxSpA.
Methods: This case-control study was conducted on 2 groups: the first group included 103 patients with AxSpA, and the other group included 103 patients with chronic mechanical back pain. A standardized questionnaire, addressing all items included in Calin, Berlin, and ASAS criteria sets, was applied by 2 rheumatologists (one senior and one junior) to both groups. The sensitivity, specificity, and reliability of the 3 sets and individual parameters were assessed.
Results: Morning stiffness > 30 minutes was the most specific parameter (81%), while the insidious onset was the most sensitive (98%). Calin set was the most sensitive set (88.1%), but it had the least specificity (60%). Adding the item of Morning stiffness > 30 minutes to Calin criteria resulted in improving the specificity of Calin criteria to 81%. Reliability of all parameters and the 3 sets showed moderate agreement (kappa 0.422–0.588) except for Morning stiffness > 30 minutes which showed good agreement (kappa 0.736) and night pain which showed fair agreement (kappa 0.388) (Table 1).

Table 1. Reliability of IBP parameters and criteria sets

IBP parameter	Kappa Agreement
Age of onset less than 40 years	1.000
Insidious onset	0.581
Morning stiffness	0.588
Morning stiffness more than 30 min	0.736
Improvement with exercise	0.566
No improvement with rest	0.422
Improvement with exercise and no improvement with rest	0.508
Night pain	0.388
Awakening in night due to pain	0.553
Buttock pain	0.504
Global Evaluation	0.951
Criteria	
Calin	0.556
Berlin	0.496
ASAS	0.455
modified. Calin	0.694

Conclusion: Most IBP parameters and criteria have moderate reliability and average sensitivity and specificity. There may be a need for an objective tool to differentiate between inflammatory and mechanical back pain.

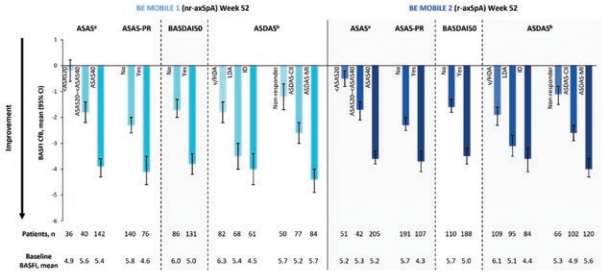
Background: Patients with axial spondyloarthritis (axSpA) can experience a significant burden due to the pain, fatigue and impaired physical function resulting from the disease.[1]

Objectives: To assess how achievement of increasingly stringent clinical response criteria and lower disease activity levels translates into improvements in physical function, sleep and health-related quality of life (HRQoL) in patients with axSpA.

Methods: This post hoc analysis reports results from the phase 3 studies, BE MOBILE 1 (NCT03928704; non-radiographic axSpA [nr-axSpA]) and BE MOBILE 2 (NCT03928743; radiographic axSpA [r-axSpA], i.e., ankylosing spondylitis[2]) at Week (Wk) 52. In BE MOBILE 1, patients met the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA and had elevated C-reactive protein and/or MRI sacroiliitis. In BE MOBILE 2, patients had radiographic sacroiliitis, fulfilling modified New York criteria. All patients who completed Wk 52 and reached specified clinical response criteria (**ASAS**: ASAS20 not reached [<ASAS20], ASAS20 reached but not ASAS40 [ASAS20–<ASAS40], ASAS40 reached [ASAS40]; **ASAS-PR**: Yes, No; **BASDAI50**: Yes, No), **ASDAS** (≥2.1, ≥1.3–<2.1, <1.3) or **ASDAS responses** (major improvement [change from baseline ≥2.0], clinically important improvement [change ≥1.1 but <2.0], non-response [change <1.1]) were pooled regardless of their original treatment arm (placebo then BKZ from Wk 16 or continuous BKZ 160 mg Q4W; all subcutaneous BKZ), by study. Associations between achievement of these clinical responses and improvements in patient-reported measures of physical function (**BASFI**; **SF-36 PCS**), sleep (**MOS Sleep-R Index;** 12 item measure, higher scores reflect more of the attribute implied by the scale) and HRQoL (**ASQoL**) were assessed. Observed case data are reported.



Results: Most patients completed Wk 52 (nr-axSpA: 220/254 [86.6%]; r-axSpA: 298/332 [89.8%]). Baseline demographics and disease characteristics were generally similar between nr-axSpA and r-axSpA patients, aside from gender, HLA-B27 status, symptom duration and time since first diagnosis, indicating similar burden of symptom severity, reduced physical function and HRQoL. Across studies, patients achieving increasingly stringent ASAS responses presented sequentially greater mean (95% confidence interval) improvements from baseline in BASFI (**Figure 1**) and SF-36 PCS score (nr-axSpA: <ASAS20: 5.1 [2.5, 7.7], ASAS20–<ASAS40: 9.5 [7.1, 11.8], ASAS40: 14.6 [13.1, 16.2]; r-axSpA: 5.9 [4.1, 7.7], 8.4 [6.6, 10.2], 14.6 [13.3, 15.9]). Achievement of higher ASAS response was also associated with sequentially greater mean improvements from baseline in MOS Sleep-R index scores (nr-axSpA: <ASAS20: 3.6 [1.3, 6.0], ASAS20–<ASAS40: 3.9 [1.6, 6.2], ASAS40: 9.0 [7.4, 10.6]; r-axSpA: 0.7 [−1.2, 2.6], 4.9 [2.5, 7.3], 8.2 [7.2, 9.3]) and ASQoL (nr-axSpA: <ASAS20: −2.2 [−3.7, −0.7], ASAS20–<ASAS40: −4.3 [−5.5, −3.2], ASAS40: −7.2 [−7.9, −6.5]; r-axSpA: −2.0 [−3.0, −1.1], −4.3 [−5.1, −3.4], −6.9 [−7.5, −6.3]). Similar sequential improvements from baseline in BASFI, SF-36 PCS, MOS-Sleep R index and ASQoL were observed with achievement of ASAS-PR, BASDAI50, and ASDAS-related outcome measures. Improvements in BASFI, SF-36 PCS, MOS Sleep-R index and ASQoL were of similar amplitude between nr-axSpA and r-axSpA patients.

Conclusion: Patients with nr-axSpA and r-axSpA who achieved increasingly stringent clinical response criteria and lower levels of disease activity at Wk 52 reported greater improvements in physical function, sleep function and HRQoL. Similar amplitudes of improvement for each response level were observed across the axSpA disease spectrum.

Figure. Association between ASAS response criteria, ASAS -PR, BASDAI response, ASDAS status and ASDAS response at Wk 52 and mean change from baseline in physical function (BASFI) [OC]

Data reported as observed case. Categories are mutually exclusive. BASFI is a component of ASAS response criteria. [a]Patients were stratified into groups based on ASAS clinical response criteria: those who did not achieve ASAS20 (<20), those who achieved ASAS20 but not ASAS4 0 (20–<40) and those who achieved ASAS40 (≥40); [b]Levels of ASDAS disease activity were defined as very/high disease activity (v/HDA; ≥ 2 .1), low disease activity (LDA; ≥1.3–<2.1), inactive disease (ID; <1.3). Levels of ASDAS response were defined as ASDAS -MI (change from baseline [CfB] ≥2.0), ASDAS-CII (CfB ≥1.1 but <2.0) and non-response (CfB <1.1).

Abbreviations: ASAS: Assessment of SpondyloArthritis International Society; ASAS-PR: ASAS partial remission; ASDAS: Ankylosing Spondylitis Disease Activity Index; ASDAS-CII: ASDAS clinically important improvement; ASDAS-MI: ASDAS major improvement; ASQoL: Ankylosing Spondylitis Quality of Life; axSpA: axial spondyloarthritis; BASDAI50: Bath Ankylosing Spondylitis Disease Activity Index 50% improvement; BASFI: Bath Ankylosing Spondylitis Functional Index; BKZ: bimekizumab; CfB: change from baseline; CI: confidence interval; HDA: high disease activity; HLA-B27: human leukocyte antigen B27; HRQoL: health-related quality of life; ID: inactive disease; LDA: low disease activity; MOS: medical outcomes study; n: number; nr-axSpA: non-radiographic axial spondyloarthritis; PCS: physical component summary; Q4W: every four weeks; r-axSpA: radiographic axial spondyloarthritis; SF-36: short form -36; v: very; Wk: week.

PROPOSAL OF SIMPLIFIED CT SYNDESMOPHYTE SCORE (SCTSS) AND COMPARISON WITH CTSS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Bone diseases, Spondyloarthritis, Imaging

H. R. Kim[1], H. K. Min[2], S. H. Lee[1]. [1]*Konkuk University School of Medicine, Rheumatology, Seoul, Korea, Rep. of (South Korea)*; [2]*Konkuk University Medical Center, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: The CT syndesmophyte score (CTSS) can evaluate spinal progression more precisely than mSASSS in ankylosing spondylitis (AS); however, it is complex and time consuming.

Objectives: Here, we propose a simplified CTSS (sCTSS) for measuring spinal structural changes in AS.

Methods: Patients with AS were recruited from a single tertiary hospital. Baseline and 2-year follow-up whole spine CT images were used to calculate CTSS and sCTSS. The sCTSS used the anterior and posterior vertebral corners, and ranged 0–184. Intraclass correlation coefficients (ICC) were calculated, as well as the smallest detectable changes.

Results: Fifty AS patients were included. For reader 1, the mean sCTSS at baseline and 2-year follow-up were 11.7 ± 14.6 and 15.8 ± 16.1, whereas those for

reader 2 were 12.0 ± 12.5 and 15.8 ± 15.7, respectively. The ICCs for CTSS at baseline and at 2-year follow-up were 0.97 (95% confidence interval [CI] 0.96–0.99) and 0.98 (0.97–0.99), respectively, and that for changes over the 2 years was 0.48 (95% CI 0.23–0.67). For sCTSS, the ICCs were 0.96 (95% CI 0.92–0.97), 0.97 (95% CI 0.94–0.98), and 0.58 (95% CI 0.36–0.74), respectively. Detection rates for syndesmophyte progression were comparable between CTSS and sCTSS. The detection rate for syndesmophytes on only lateral side was 13.2 and 11.4%, and 11.4 and 15.2% at baseline and 2-year follow-up (reader 1 and 2).

Conclusion: sCTSS and CTSS showed similar detection rates for syndesmophyte progression. sCTSS may be a reliable method for evaluating spinal structural damage in AS.

AB1002 LONGER DIAGNOSTIC DELAY, SEVERE FATIGUE AND LESS USE OF TNF-INHIBITORS ARE ASSOCIATED WITH UNACCEPTABLE AXIAL PAIN IN 354 SWEDISH PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Pain

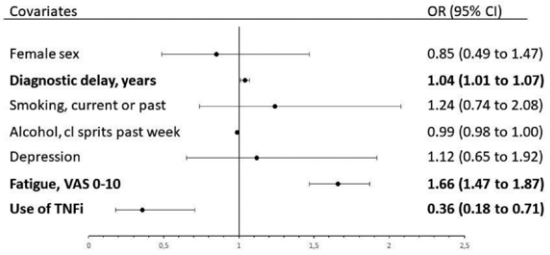
A. Deminger[1,2], Å. Wilde[2], E. Klingberg[1,2], J. Backman Renman[3], H. Forsblad-D'elia[1,2]. [1]*Institute of Medicine, Sahlgrenska Academy at University of Gothenburg, Department of Rheumatology and Inflammation Research, Göteborg, Sweden*; [2]*Region Västra Götaland, Sahlgrenska University Hospital, Department of Rheumatology, Göteborg, Sweden*; [3]*Section of Medicine, Umeå University, Department of Public Health and Clinical Medicine, Umeå, Sweden*

Background: Pain has been shown to be the most important consequence of the disease in affecting health in patients with axial spondyloarthritis[1].

Objectives: To assess factors associated with unacceptable axial pain in patients with long-standing ankylosing spondylitis (AS) overall and by sex.

Methods: Patients with AS (modified NY-criteria) from two geographically separated regions in Sweden were included in this cross-sectional, observational study. Primary outcome was axial pain (question number 2 from Bath Ankylosing Spondylitis Disease Activity Index (BASDAI)) dichotomised in VAS < or ≥ 4 based on patient unacceptable pain[2]. Independent variables were selected based on previous knowledge and hypotheses of factors associated with pain. Information was collected from questionnaires (demographics, lifestyle habits, fatigue (BASDAI question number 1), symptoms of depression (from EQ-5D), medications), calculation of body mass index (BMI), blood sample (C-reactive protein (CRP)), and lateral spinal radiographs (assessment of spinal new bone formation with modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS)). Univariate and multivariable logistic regression analyses (dependent variable VAS axial pain ≥ 4) were used overall and stratified by sex. Variables with univariate *p*-values ≤ 0.1 were included in the multivariable model if not too highly correlated.

Results: In total, 354 patients were included, 62 % men, mean (SD) age 52 (13) years, symptom duration 27 (13) years and delay in diagnosis 9 (8) years. Mean (SD) VAS axial pain was 4.2 (2.6) with no significant difference between men and women (p = 0.30). However, in patients with unacceptable axial pain (VAS ≥ 4), n=177 (50%), significantly higher proportion of women reported unacceptable pain compared to men, 57 % vs 46 %, p = 0.049. In univariate analyses, unacceptable axial pain was associated with longer disease duration, longer delay in diagnosis, more severe fatigue, more symptoms of depression, lower alcohol consumption and less treatment with TNF-inhibitors. There was no association between unacceptable axial pain and age, civil state single, educational level, BMI, smoking status, mSASSS, CRP or use of NSAIDs. In the multivariable analysis, unacceptable axial pain was independently associated with longer delay in diagnosis and more severe fatigue, whereas use of TNF-inhibitor reduced the risk of having unacceptable pain (Figure 1). In the multivariable analyses stratified by sex, the same variables were associated with unacceptable pain in men as in the whole group; OR (95 % CI) for delay in diagnosis 1.08 (1.03 to 1.14), fatigue 2.0 (1.65 to 2.41) and use of TNF-inhibitor 0.23 (0.09 to 0.61). In women, fatigue was the only factor independently associated with unacceptable axial pain, OR (95 % CI) 1.32 (1.12 to 1.56).



Conclusion: In this cross-sectional study of patients with long-standing AS, 50 % of the patients had unacceptable axial pain. Even though a higher proportion of the women were affected, female sex was not independently associated with unacceptable axial pain. There were some sex-differences. Delay in diagnosis was associated with higher risk, and use of TNF-inhibitor was associated with lower risk of unacceptable axial pain only in men. The sex-difference possibly due to few women using TNF-inhibitors. Fatigue was independently associated with axial pain in both sexes. This study underpins the importance of early diagnosis in AS.

AB1003 IMPROVED CLINICAL OUTCOMES AND PATIENT ENGAGEMENT THROUGH AN INTEGRATED ELECTRONIC PATIENT REPORTED OUTCOME WITH THE HOSPITAL ELECTRONIC PATIENT RECORD IN SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Patient reported outcomes, Outcome measures

A. Chan[1], K. Rigler[1], L. Van Rossen[2]. [1]*Royal Berkshire NHS Foundation Trust, Department of Rheumatology, Reading, United Kingdom*; [2]*East Kent Hospitals N H S Trust, Department of Rheumatology, Canterbury, United Kingdom*

Background: Patient-reported outcome measures (PROMs) have been at the forefront of the assessment of spondyloarthritis (SpA). With the increasing adoption of electronic health records (EHRs), collecting PROMs electronically (ePROMs) presents an opportunity for advancing patient care in SpA. ePROMs were incorporated into our SpA clinics at the Royal Berkshire Hospital since the start of 2018. Collecting patient data remotely brings the patients' perspective into routine clinical care without delay. Moreover, connection to EHRs have led to a seamless integrated optimised care process.

Objectives: The objective of this programme was to evaluate the clinical effectiveness and practicality of implementing a fully integrated ePROMs into the hospital EHR in real world clinic settings. The interoperability across different information technology (IT) modules was assessed. We also evaluated the interaction with the patients through the assessment of satisfaction and completion rates of ePROMs.

Methods: AxSpA patients meeting the ASAS criteria completed the outcome measures BASDAI, BASFI, Spinal NPRS, and BASG. PsA patients meeting the CASPAR criteria completed patient assessed tender joint, swollen joint, global assessment and PSAID-12. The period of the data collection for this study was January 2021 to December 2022. Patients were sent reminders to complete ePROMs through email or text messaging before each appointment and every 6 months. Ad-hoc scores went sent out according to clinical need. Appointments were expedited or deferred depending on the values and trends in the ePROMS. Time saved in clinic was measured.

Results: There were 1141 patients with AxSpA and PsA who were sent ePROMs over a 2 year period (2021-22). The mean (SD) age for AxSpA patients were 42.7(11.2) and PsA 52 (7.9) years. 536 (47%) patients were on biologics. At baseline, the completion of was 38% (437/1141). At month 12, it was 63% (722/1141) and at month 24, reached 73% (836/1141), Figure 1. Both AxSpA and PsA patients had similar rates of uptake of ePROMs between months 0 and 24 (40% to 72% in AxSpA and 35% to 73% in PsA). At group level, there was a trend to the reduction in mean (SD) ASDAS at months 0, 6, 12, 18 and 24 (3.8±1.2, 3.3±1.1, 3.0±1.5, 2.2±0.9, 1.9±1.0) and BASDAI (4.6±2.7, 4.5±1.9, 3.9±2.4, 3.8.±2.3, 3.6±1.2). In the PsA group, there was also a trend to the reduction in the mean (SD) PSAID-12 level (4.1±1.8, 3.8±0.8, 3.6±1.2, 3.4±1.1, 3.1±1.3). The reduction in ASDAS, BASDAI and PSAID-12 was most evident in patients on biologic treatments. In patients with an ASDAS of < 1.3 or PSAID-12 <2, appointments were moved from 6 to 12 monthly. In this group of

patients, the appointments were also switched from face to face to teleclinics. This resulted in a saving of 280 hours of clinical time. Over 90% of clinician and patient user rated the ePROMs as good to excellent. In patients not completing ePROMS (308/1141, 27%) paper forms were used. Factors for not completing ePROMs include multiple forms, frequency of forms sent, lack of understanding of process, data safety concerns, lack of IT access and patient choice.

Conclusion: The development of a clinician dashboard captured a range of multidimensional ePROMs that was used proactively to support patient management and patient-centric appointment scheduling. Using ePROMs increased the uptake and acceptability of completing patient outcomes. A trend based on ePROMs collated over a period of time was more informative, particularly when considered alongside interventions that were introduced into the clinics such as self-referral to physiotherapy, digital psychological therapy and biologic treatments. This enabled the clinical team use ePROMs as part of remote monitoring to implement patient-initiated follow up (PIFU) and schedule teleconsultations when clinically appropriate. The integrated ePROMS system allows clinical encounters where needed and more individualised care.

AB1004

ACCURACY OF ICD10-AM M45 CODE FOR ANKYLOSING SPONDYLITIS IN A WESTERN AUSTRALIAN HOSPITAL COHORT

Keywords: Descriptive studies, Spondyloarthritis

M. Isbel[1,2], K. Makin[1], J. Nossent[1,2]. [1]*Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia*; [2]*University of Western Australia, School of Medicine, Perth, Australia*

Background: Administrative linked health data (ALHD) facilitates epidemiological research of Ankylosing Spondylitis (AS) but best practice requires dataset validation[1]. While ICD10-code M45 is used to identify AS populations internationally it is also used to code "Rheumatoid arthritis of the spine"[2]. Neither background AS nor Rheumatoid arthritis (RA) is captured in ICD coding, unless actively flaring whilst the patient is admitted.

Objectives: To define the accuracy of ICD 10 Australian Modification (ICD10AM) code M45 in identifying AS patients in a tertiary hospital.

Methods: Retrospective audit of patients with an electronic hospital discharge code M45 between 2000 and 2015. Patient records were manually reviewed to confirm presence of AS based on following criteria a) radiological evidence of Grade IV sacroiliitis or "bamboo spine" b) fulfilment of classification criteria (1984 Modified NY, 1991 AMOR, 2002 ESSG and 2009 ASAS criteria)[3] c) letter from treating rheumatologist confirming AS d) Biological DMARD (bDMARD) prescription for treating confirmed AS. Cases that were not able to meet AS criteria and had a likely alternative diagnosis documented by their treating team had this detail noted, but not assessed against formal criteria. All patients were then evaluated to for presence of an RA code ever during that patient's lifetime. Codes used to define RA included by codes M08.0* M8.2*, M8.3*, M8.4*, M8.8*, M8.9*, M05.*, M06.* (ICD10) or 714 (ICD9).

Results: Of 155 cases reviewed, eighty-six (55.4%) met audit criteria for AS. Of the 69 cases not meeting audit criteria for AS, 35 (72%) had RA ICD codes applied during their lifetime and a further 15 had background RA recorded in their notes. Five cases met AS audit criteria and had RA code applied. Excluding patients ever tagged with an RA code reduced AS case finding by 6% and raised overall accuracy to 67.5%. If background RA is also excluded, accuracy is 78.9%.

Conclusion: Overall raw accuracy of the ICD10AM M45 code in identifying AS patients was low, with RA acting as a significant confounder. This bears significant implications for international ALHD research reliant on this code for case finding. Excluding those ever coded with RA significantly improved accuracy and is recommended for future research. Our data support the call for scrutiny of international variations of ICD taxonomy[4].

Spondyloarthritis - clinical aspects (other than treatment)

AB1005 ASSOCIATION BETWEEN CHANGES IN SERUM ALKALINE PHOSPHATASE LEVELS AND RADIOGRAPHIC PROGRESSION IN ANKYLOSING SPONDYLITIS

Keywords: Biomarkers, Prognostic factors, Spondyloarthritis

T. H. Kim[1], S. Y. Park[2], J. H. Shin[1], S. Lee[3], K. B. Joo[1], B. S. Koo[4]. [1]*Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea)*; [2]*Korea National Open University, Department of Statistics and Data Science, Seoul, Korea, Rep. of (South Korea)*; [3]*Hanyang University Hospital for Rheumatic Diseases, Department of Radiology, Seoul, Korea, Rep. of (South Korea)*; [4]*Inje University Seoul Paik Hospital, Inje University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: The changes in bone metabolism may occur earlier than those that can be identified on radiography. Although studies have evaluated the changes in inflammatory markers that precede radiographic progression, no studies have evaluated the relationship between the timing of changes in bone metabolism and radiographic progression in patients with AS.
Objectives: To determine the relationship between serum alkaline phosphatase levels and radiographic changes over time in ankylosing spondylitis.
Methods: This retrospective study evaluated the electronic medical records of patients with ankylosing spondylitis between January 2001 and December 2018. Longitudinal data including serum alkaline phosphatase levels were imputed by linear interpolation at 3-month intervals. Among the serum alkaline phosphatase levels for 8 years prior to measurement of the modified Stoke Ankylosing Spondylitis Spinal Score, the serum alkaline phosphatase level having the highest beta coefficient with the modified Stoke Ankylosing Spondylitis Spinal Score was selected. Linear mixed models with the selected serum alkaline phosphatase levels and the modified Stoke Ankylosing Spondylitis Spinal Score, including clinical variables, were investigated.
Results: Overall, 1122 patients were included, with a mean follow-up period of 8.20 (standard deviation: 2.85) years. Of the series of serum alkaline phosphatase levels, the level in the previous 5 years and 3 months showed the highest beta coefficient with the modified Stoke Ankylosing Spondylitis Spinal Score (Figure 1). In the linear mixed model including clinical variables, the serum alkaline phosphatase level 5 years and 3 months before radiographic changes was significantly associated with the modified Stoke Ankylosing Spondylitis Spinal Score (β=0.021, 95% confidence interval: 0.017–0.025, p<.001).
Conclusion: Serum alkaline phosphatase levels measured at approximately 5 years before may be a surrogate marker for predicting spinal radiographic changes. Long-term prospective clinical and experimental studies of > 5 years are required for biomarker discovery or therapeutic research on the radiographic progression of ankylosing spondylitis.

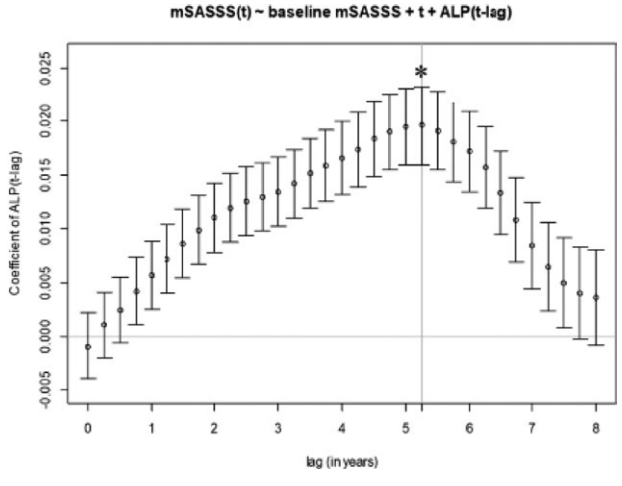

Figure 1. Beta coefficients of ALP levels to calculate the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). ALP levels 5 years and 3 months before measured mSASSS had the highest significant beta coefficient (0.020, 95% CI 0.016–0.023) with mSASSS (asterisk).mSASSS, the modified Stoke Ankylosing Spondylitis Spinal Score; ALP, alkaline phosphatase.

AB1006 PULMONARY MANIFESTATIONS OF AXIAL SPONDYLOARTHRITIS (AXSPA): A SYSTEMATIC LITERATURE REVIEW

Keywords: Systematic review, Spondyloarthritis, Lungs

K. Vakil-Gilani[1], T. Cordova[1], D. Saifer[1], A. Deodhar[1]. [1]Oregon Health & Science University, Rheumatology, Portland, United States of America

Background: Common extra musculoskeletal manifestations (EMM) of axSpA include uveitis, inflammatory bowel disease, and psoriasis; and some of the uncommon manifestations include aortic incompetence, conduction abnormalities and IgA nephropathy. We felt that an updated and comprehensive review of pulmonary manifestations of axial spondyloarthritis was needed.
Objectives: To conduct a systematic literature review (SLR) using 2020 PRISMA guidelines on the spectrum of pulmonary manifestations in axial spondyloarthritis.
Methods: Using the 2020 PRISMA guidelines, we conducted a systematic literature review in the PubMed data base. The following MeSH combinations were used: (1) Ankylosing Spondylitis (AS) and interstitial lung disease, (2) AS and lung disease, (3) AS and obstructive sleep apnea, (4) non-radiographic axial spondyloarthritis (nr-axSpA)and lung disease (5) nr-axSpA and obstructive sleep apnea (6) nr-axSpA and interstitial lung disease (7) AS and/or axSpA and obstructive sleep apnea and/or thoracic wall disease. Our search timeline was limited to the past 40 years. The same combination terms were also hand searched. Reviewing of articles were divided between two authors.
Results: Our search led to a total of 10,948 articles and 10,919 were excluded based on relevance after title review (n=10,905), case report study design (n=6), and lack of access to the full manuscript (n=2). Additional 6 articles were excluded based on relevance after the entire manuscripts were read. Twenty nine full length manuscript were ultimately included for further study. All studies included patients with a diagnosis of AS rather than axSpA. The majority of studies were cross-sectional (n=12) followed by review articles (n=10 including one systematic review), and finally cohort studies (n=5 prospective and 1 retrospective). Mean disease duration range was 7.0-31 years. Average age of participants was 30.6 to 57.2, and majority were males (57.1-100%). The most common pulmonary manifestation (40-90%) was pleuro-parenchymal abnormalities noted on high resolution CT scan (HRCT) followed by abnormal pulmonary function tests (PFTs) (15-57%), chest wall movement restriction (50% with manubriosternal and sternoclavicular enthesitis and chest wall pain in 30-60%) and obstructive sleep apnea (OSA) (8.8%-47.8% of AS patients which was significantly higher than controls in all studies except one). OSA was associated with long disease duration and low age at onset of disease. HRCT abnormalities described were interstitial lung disease in 13.7-22%, spontaneous pneumothorax (0.29%), apical fibrosis (1.2%-19%), ground glass opacities (3.6-15%), nodules (3.8-40%), pleural thickening (3.8-45%), honey-combing (5.8%), parenchymal bands (5.8-41%), interlobular septal thickening (5.8-45%), bronchial wall thickening (7.1-41%), emphysema 9-45%, bronchiectasis (9.5-33%), subpleural bands (10.9-35%), tracheal dilation (11.1%), linear opacities (11.7%), and lymphadenopathy (16.7-28.6%). Frequency of apical fibrosis and bronchiectasis increased with disease duration. Subpleural nodules and parenchymal bands were found early in the disease course. Among those with abnormal PFTs, majority were restrictive in pattern (20-57%). A link between COPD and AS was found (46% in one cross-sectional study with 1.45 higher incidence compared to controls).
Conclusion: In our SLR, we identified various pulmonary manifestation in AS patient – the commonest being parenchymal lung disease as seen on HRCT – but there is a lack of controlled trials. Furthermore, there are no data in nr-axSpA patients which remains a major unmet need. No data were available on whether current advanced therapies are disease modifying from pulmonary perspective. Prospective studies are required to evaluate efficacy of novel treatments on lung disease.

AB1007 NEUROPATHIC PAIN AS A PREDICTOR OF FUNCTIONAL DISORDERS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Pain

I. Kedyk[1], M. Stanislavchuk[1]. [1]*Vinnytsia National Pirogov Medical University, Department of Internal medicine №1, Vinnytsia, Ukraine*

Background: Ankylosing spondylitis (AS) is one of the most actual problems in modern rheumatology. AS is characterized by a violation of functional abilities, which causes a decrease in the quality of life and invalidation of patients. The main symptom of AS is chronic pain, which persists in some cases not only due to inflammation, but also due to the neuropathic component of pain, however, this issue needs additional investigation [1].
Objectives: To assess functional status and its association with neuropathic pain in patients with AS.
Methods: Following the principles of biomedical ethics, on the basis of informed consent, we clinically examined 133 patients (men - 71%) diagnosed with AS according to the modified New York criteria. The presence of neuropathic pain (NP) was assessed by the Leeds Neuropathic Pain Rating Scale (LANSS) and by the Diagnostic Questionnaire for Neuropathic Pain (DN4). Disease activity was assessed by the BASDAI (Bath Ankylosing Spondylitis Disease Assessment Index) and ASDAS (Ankylosing Spondylitis Disease Activity Score). Functional disorders in AS were evaluated according to the BASFI (Bath AS Functional Index) and BASMI (Bath Ankylosing Spondylitis Metrology Index). The HAQ (Health Assessment Questionnaire) questionnaire was used to assess functional capabilities. Statistical analysis was carried out by the methods of variational statistics in the SPSS22 software package (©SPSS Inc.). Significance of differences between groups (p) was measured using the Mann-Whitney test. Results are presented as mean with standard deviation (M±SD).
Results: In patients with AS, the prevalence of NP according to the LANSS was 34.8%. Presence of NP in women was found significantly more often than in men: 52.3% versus 31.1%. According to DN4 data, 37.7% of patients have NP, and the ratio of women to men is 59.1 to 32.2. The NP according to both scales was found in 33.1% of AS patients, significantly more often in women than in men: 51.4% versus 29.7%. Moderate and high disease activity according to the BASDAI and ASDAS prevailed in our patients, and the average values were at the level of 5.5±1.7 and 3.54±0.83, respectively. Functional impairment according to the BASMI in patients with NP was significantly higher in comparing with the group without NP (4.0±2.1 versus 5.1±2.2; p<0.01). At the same time, according to the BASMI, it was established that among all patients with AS, the absence of functional disorders occurred only in 7.0% of patients, moderate disorders - in 68.3%, and severe disorders - in 24.7 % of patients. Pronounced functional disorders prevailed in the group of patients with NP (39.6% vs. 17%). Similar data were obtained by the BASFI (4.3±2.1 versus 6.6±1.6; p<0.01). The presence of functional disorders according to the BASFI was found in 70.7% of all AS patients. At the same time, functional disorders were found in 93.2% of patients with NP. The functional disability according to the HAQ in patients with NP was significantly higher than in the group without NP, which indicates that NP is associated with more pronounced functional disorders - 1.23±0.45 versus 0.91±0.51 (p<0, 01).
Conclusion: The presence of NP in AS patients is a common phenomenon. NP has a close relationship with functional abilities in patients with AS and can be consider as a predictor of severe functional disorders.

AB1008 TIME, DURATION AND ORDER OF APPEARANCE OF EXTRA-ARTICULAR MANIFESTATIONS IN SPONDYLARTHRITIS: CLINICAL RISK FACTORS

Keywords: Spondyloarthritis, Epidemiology, Prognostic factors

C. Marco Pascual[1], A. García-Alija[2], H. S. Park[2,3], A. Laiz[2,3], P. Moya Alvarado[2,3], A. Casals Urquiza[2], C. Diaz-Torne[2,3], H. Codes[2], L. Sainz Comas[2], S. Ros[2], S. P. Fernandez-Sanchez[2], I. Castellví[2,3], B. Magallares[2,3], A. Garcia-Gullien[1], J. L. Tandaipan[1,2], C. Pitarch Grau[1], A. M. Millán Arciniegas[2], H. Corominas[1,2,3]. [1]*Hospital Dos de Maig, Rheumatology, Barcelona, Spain*; [2]*Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; [3]*Universitat Autònoma de Barcelona, Medicine, Barcelona, Spain*

Background: Little is known about the chronologic order of appearance of extra-articular symptoms and spondylarthritis (SpA) symptoms and its effect in disease progression. Most information is based on population-based registries or big data that may lack precision.
Objectives: To describe duration, time until diagnosis and order of appearance of the articular and extra-articular (psoriasis, uveitis, or inflammatory bowel disease) symptoms. To evaluate factors associated with time from extra-articular symptoms onset until appearance of SpA symptoms.
Methods: A retrospective cohort study was conducted. Inclusion criteria were patients that met ASAS criteria visited at the SpA clinic between July – October 2022. Other autoimmune rheumatic diseases were excluded. Data were collected previously reviewing patient records available from the electronic and paper database of the hospital. Additional information was retrieved by the shared medical history database of the Catalan Institute of Health which attends the 99.2% of the population. Missing data were collected prospectively by patient interview. Univariate linear regression was conducted to study association.
Results: From 91 patients 54 (59.3%) were male and mean age was 63.9 (SD 14.3). There were 46 (50.5%) patients with exclusively peripheral SpA and 17 (16.5%) exclusively axial SpA. History of extraarticular symptoms were observed in 69 (76.6%) of the patients and 33 (37.1%) were HLA-B27 positive. In 49 (54.8%) patients extra-articular symptoms appeared before SpA. The median disease duration since SpA diagnosis was 11 year (IQR 14). Median time for SpA diagnosis since articular symptoms onset was 2 years (IQR 8). The median time from the extra-articular symptoms until the appearance of articular symptoms was 2 years (IQR 30). The associations of SpA features and time since first extra-articular symptoms until articular symptoms appearance is detailed in table 1. HLA-B27 positivity and axial disease showed a negative linear association while peripheral disease showed a positive linear association.

Table 1.

Variables	Coef (p)
Age (year)	0.15 (0.42)
Male	0.65 (0.91)
Smoker	-2.31 (0.54)
B27 positivity	**-21.4 (0.00)**
Elevate CRP	-1.16 (0.86)
Erosions	1.97 (0.77)
Radiographic sacroiliitis	-4.43 (0.24)
Peripheral SpA	**16 (0.03)**
Axial SpA	**-23.8 (0.01)**
Peripheral and Axial	**-13 (0.02)**

Conclusion: Most patients presented extra-articular manifestation before articular symptoms onset.
The median delay since first articular symptoms until SpA diagnosis was 2 years. Longer time between extra-articular manifestation and articular symptoms was liniarly associated with peripheral disease.
Axial disease and HLA-B27 were linearly associated with shorter time between the two symptoms.

AB1009 INVERSE CORRELATION BETWEEN NONHDL CHOLESTEROL AND INFLAMMATORY BOWEL DISEASE IN SPONDYLOARTHRITIS: A NEW LIPID PARADOX

Keywords: Comorbidities, Spondyloarthritis, Cardiovascular disease

J. Rubio Ubeda[1], A. Peña-Almagro[1], L. Salvatierra Velasco[1], E. Raya[1], J. Salvatierra[1]. [1]*Hospital Universitario Clínico San Cecilio, Rheumatology, Granada, Spain*

Background: In Spondyloarthritis (SpA) a higher prevalence of cardiovascular comorbidities has been observed, such as diabetes mellitus (DM), arterial hypertension (AHT), dyslipidaemia (DLP), obesity and metabolic syndrome [1].

In recent years, several studies have established a causal relationship between non-HDL cholesterol (non-HDLC) levels and cardiovascular diseases. Non-HDLC offers a wide vision of proatherogenic lipoproteins containing apolipoprotein B (apoB) -VLDL, IDL, LDL, chylomicron remnants and Lp(a)- without being interfered by triglyceride concentrations. Thus, non-HDLC has become an innovative cardiovascular risk (CVR) biomarker. Therefore, the *Multinational Cardiovascular Risk Consortium* [2] recently published a set of recommendations estimating CVR based on non-HDLC levels. We have analyzed in a cohort of patients with SpA possible associations between clinic and laboratory data, and non-HDLC serum levels.

Objectives: To analyse in patients with SpA whether there is a relationship between disease-dependent variables (C-reactive protein [CRP] levels, erythrocyte sedimentation rate [ESR], presence of HLA-B27, axial or peripheral involvement, structural damage, and extra-articular manifestations) with non-HDLC serum levels.

Methods: Observational, cross-sectional, single-centre study, which included a sample of 104 patients with both radiographic and non-radiographic SpA, in whom each disease-dependent variable was analyzed individually for its possible association with non-HDLC serum levels. Classical CVR factors were also analyzed.

Results: Of 104 patients included most of them were women (54,8%), mean age was 43 years, 33,7% smoked, HLA-B27 was positive in 52,9% of patients, with mean CRP levels of 9,83 mg/L and ESR of 17,92 mm/h. Axial involvement prevailed over peripheral (92,3% vs 26%). Extra-articular manifestations were distributed as follows: 13,5% uveitis, 7,7% inflammatory bowel disease (IBD) and 4,8% psoriasis. 43,3% of patients had structural damage. None of these patients suffered from cardiovascular disease prior to diagnosis. Regarding the classic CVR factors: AHT was observed in 16,3%, DM in 1.92%, obesity (BMI >30) in 14.4%. Mean non-HDLC was 144.19 mg/dL (± 36,1), giving this population a 12,87% probability of suffering cardiovascular disease at the age of 75. For CVR estimation, we categorized non-HDLC levels according to low (100 - <145 mg/dL), moderate (145 - <185 mg/dL), high (185 - <220) and very high (≥220 mg/dL) levels. Lower mean concentrations of non-HDLC were found in those patients with IBD (117,6 ± 35,7 mg/dL), compared to those without intestinal involvement (146 ± 35,5 mg/dL) (p<0,05). No statistically significant relationships were observed between non-HDLC and the rest of disease-dependent variables.

Conclusion: In our cohort of patients, mean levels of non-HDLC were elevated (144 mg/dL), giving patients a 13% probability of suffering cardiovascular disease at the age of 75. Of clinical and laboratory features analyzed, we observed lower serum concentration of non-HDLC in patients with IBD. This could be explained by lipid malabsorption, as inflammatory damage of the intestinal epithelium decreases the synthesis of apo-B48, which is necessary for both chylomicron formation and hepatic synthesis of apo-B100 [3]. This may turn into lower serum levels of non-HDLC. Therefore, presence of IBD in patients with SpA should be kept in mind when defining non-HDLC levels as an estimator of CVR.

Background: Active axial spondyloarthritis (axSpA) is associated with poorer physical and mental health outcomes.

Objectives: This study aims to assess the prevalence of clinically active disease in axSpA and its associated factors in a large sample of patients from the International Map of Axial Spondyloarthritis (IMAS) study from around the globe.

Methods: IMAS is a cross-sectional online survey (2017-2022) including 5,557 unselected axSpA patients. Patients were divided between those with active disease (BASDAI < 4) and those without active disease (BASDAI ≥ 4). The factors evaluated were: age, gender, physical activity engagement, work-related issues, work choice and difficulty finding a job due to axSpA, number of self-reported symptomatic body regions, diagnostic delay, HLA-B27, extra-musculoskeletal manifestations, spinal stiffness (3-12), functional limitation (0-54), mental health using GHQ-12 scale (0-12), and treatments (NSAIDs, csDMARDs and bDMARDs). Mann-Whitney, chi-square test and logistic regression analysis were used to evaluate the possible association of the investigated factors with active disease in axSpA patients.

Results: 5,295 patients who had responded to the BASDAI scale in IMAS survey were included in the present study: 3,231 were from Europe, 770 from North America, 600 from Asia, 548 from Latin America, and 146 from Africa. The mean age was 43.8±12.9 years and 55.4% were females. Patient reported a mean BASDAI of 5.4 (**Figure 1**) with 75% having active disease (BASDAI≥4). In South Africa, 87.0% of patients reported having active disease, compared to 68.5% in Asia. Compared to patients with non-active disease, patients with active disease were more likely to be older, female, physically inactive, experience work-related issues, have greater difficulty finding a job and faced limited work choice due to axSpA, had higher number of self-reported symptomatic body regions, longer diagnostic delay, higher proportion of HLA-B27 negative, presence of inflammatory bowel disease, greater spinal stiffness, higher functional limitation, worse mental health, and greater use of csDMARDs. In the multivariable logistic regression, the factors associated with active disease were the presence of work-related issues due to axSpA, difficulty finding a job due to axSpA, higher number of self-reported symptomatic body regions, greater spinal stiffness, higher functional limitation, longer diagnostic delay, HLA-B27 negative, and worse mental health (**Table 1**).

Conclusion: Globally, three in four patients with axSpA reported clinically active disease, with higher proportion of patients with active disease in South Africa and lower in Asia. The causal relationship between the identified factors and clinical disease activity is complex and may vary from patient to patient. Our results underline the complexity of the clinical disease activity concept in axSpA and underline the need of a holistic approach in the patient management.

CO-DIAGNOSIS SPONDYLOARTHRITIS AND INFLAMMATORY BOWEL DISEASE: THE ENTRY MODE MATTERS

Keywords: Gastrointestinal tract, Descriptive studies, Spondyloarthritis

J. Michel[1], C. Prati[1,2], L. Vuitton[3], D. Wendling[1,4], F. Verhoeven[1,4]. *[1]CHU Besancon, Rheumatology, Besançon, France*; *[2]Université de Franche Comté, EA 4267 PEPITE, Besancon, France*; *[3]CHU Besancon, Gastroenterology, Besancon, France*; *[4]Université de Franche Comte, EA 4266 EPILAB, Besançon, France*

Background: There is a clear pathophysiological link between spondyloarthritis (SpA) and Inflammatory Bowel Disease (IBD), so that 10% of IBD is estimated to have SpA and 10% of SpA is estimated to have IBD. Recently, Luchetti et al [1] demonstrated an increased level of bacterial translocation in cases of co-diagnosis of SpA and IBD compared to patients with IBD alone. These data suggest that the presence of this codiagnosis is associated with a more inflammatory and therefore a more active pathology.
Objectives: The aim of this study is to describe this population and to evaluate the impact of timing of diagnoses.
Methods: A single-centre retrospective observational study was conducted. We included all consecutive patients followed between 2015 and 2022 for spondyloarthritis (SpA) meeting the ASAS 2009 criteria and IBD histologically proven. For each patient, we collected demographics, smoking, extrarticular manifestations, imaging data and the number of bDMARDs used and bDMARD combinations. We then compared the populations according to first diagnosis, SpA or IBD. Fischer's exact test was used for comparison between categorical variables and Student's t test for quantitative variables.
Results: A total of 62 patients, 51% male and 67% HLA B27+, were included. In 61% of the cases, IBD was diagnosed first. The majority of IBD patients were diagnosed with Crohn's disease (68%) with a mean age at diagnosis of 35.7 (±12.9) years. Concerning spondyloarthritis, it was mostly axial (95%), 55% of which was radiographic axial, with a mean age at diagnosis of 36.8 (±13.4) years. Psoriasis was present in 24% and uveitis in 24% of cases, active smoking in 66%, and a physical job in 20% of cases. Patients had used an average of 3 bDMARDs and 10% are treated with a combination of bDMARDs. When SpA was diagnosed first, patient characteristics were different from those whose IBD was diagnosed first, with a mean age at diagnosis of SpA of 29.8 (±11.6) years (versus 41.6 (±12.6) years; P< 0.001) and a mean age at diagnosis of IBD of 31.9 (±11.8) years (versus 38.6 (+/-13) years; p= 0.043). When the codiagnosis was initiated by SpA, the prevalence of HLA B27 was 83% (versus 42%; p<0.01), psoriasis 17% (versus 29%; p=0.27) and uveitis 35% (versus 16%; p=0.087). Finally, radiographic damage was more frequent when SpA started first, with 86% of radiographic sacroiliitis (versus 34%; p< 0.001) and 44% of syndesmophytes (versus 13%; p= 0.036).
Conclusion: The population of patients with a co-diagnosis of SpA and IBD is a particular and difficult to treat population with an average of 3 different bDMARDs used and 10% of bDMARDs combination. Within this population, we identified two different clusters of patients according to the first diagnosis.

AN INCREASED FREQUENCY OF ANKYLOSING SPONDYLITIS HAS BEEN FOUND IN THE SPOUSES OF SPONDYLOARTHRITIS/ANKYLOSING SPONDYLITIS PATIENTS: ENVIRONMENTAL FACTORS MAY PLAY A ROLE IN SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Epidemiology

M. Ekici[1], E. Bilgin[1], E. Unaldi[1], F. Gülbahçe İncesu[2], L. Kılıç[1], U. Kalyoncu[1]. *[1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[2]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey*

Background: It is known that genetic and environmental factors play a role in the pathogenesis of spondyloarthritis (SpA). [1] It can be thought that spouses living in the same house are exposed to similar environmental factors.
Objectives: This study aimed to investigate whether common living space increases the frequency of SpA development in unrelated spouses of SpA patients.
Methods: Between November 2021 and June 2022, 680 SpA patients who applied to the Hacettepe University rheumatology outpatient clinic were included. Patients were divided into ankylosing spondylitis (AS), non-radiographic SpA, and peripheral SpA. The patients were asked whether their spouses had SpA, and if they had SpA diagnosis, they were called to the outpatient clinic, and their diagnosis was confirmed. The family history of the patients and their use of bDMARDs were also noted. It was also checked whether the patients whose spouses had SpA findings fulfilled the AS criteria.
Results: 680 SpA patients were evaluated. There were 582(85.6%) AS, 72(10.6%) nr AxSpA, and 26 only peripheral SpA (3.8%). 49.4% of the patients

were male, and the mean age was 45.6 (10.4). The mean follow-up period of the patients was 10.6 (7.9) years. Of all patients, 468 (55.1%) were using a bDMARD at the time of evaluation. 12 SpA patients stated that their spouses had SpA. In the review of these patients, it was found that four patients did not have SpA, and one of them had PsA. Spouses of patients with nr AxSpA and peripheral SpA did not have AS/SpA AS was detected in the spouses of 7 patients. The incidence of AS in the entire SpA patient group was calculated as 7/695 (1.01% (0.4-2.1)). The incidence of AS in spouses of AS patients are 7/582 (1.20% (0.5-2.5)) calculated. 2 of 7 wives were cousins' children. The incidence of AS in unrelated spouses of AS patients are 5/580 (0.86% (0.3-2)). Only one of the spouses with AS knew her spouse's diagnosis at the time of marriage, while the other six were diagnosed after marriage. The median time for these patients to be diagnosed after marriage is 22 (7-32) years.

Conclusion: In the Turkish population, the frequency of AS was 0.49%, and the frequency of SpA was 1.05%. [2] The incidence of AS in the spouses of SpA patients has increased approximately two times compared to the average Turkish population. A 2.4-fold increased risk was found in AS patients. This situation may be related to environmental factors that play a role in the pathogenesis of SpA disease. However, the fact that half of the patients were using bDMARDs suggests that they were analyzed in the group with the potential for more severe disease. The results require confirmation in more extensive studies.

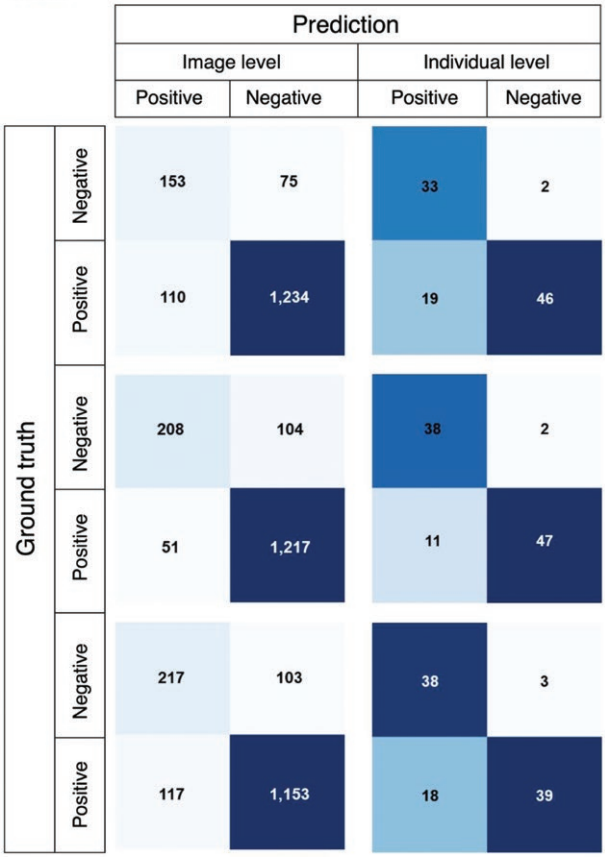
AB1013 ARTIFICIAL INTELLIGENCE FOR DETECTION OF INFLAMMATORY SACROILIITIS IN MAGNETIC RESONANCE IMAGING IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Artificial intelligence, Imaging, Spondyloarthritis

J. Lee[1], S. Y. Kang[1], S. Lee[1], H. Kim[1], E. M. Koh[2], H. S. Cha[1]. [1]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*Health Insurance Review and Assessment Service, Healthcare Review and Assessment Committee, Wonjoo, Korea, Rep. of (South Korea)*

Background: Magnetic resonance imaging (MRI) is frequently used to evaluate active inflammatory sacroiliitis for early axial spondyloarthritis (axSpA) diagnosis. However, evaluation of sacroiliitis in MRI requires expertise because noninflammatory degenerative changes can mimic axSpA, and the semiquantitative diagnosis remains subject to significant variation. Artificial intelligence could function as assistance for inflammatory sacroiliitis detection.



Objectives: This study aimed to develop artificial intelligence for detecting inflammatory sacroiliitis for axSpA in MRI.

Methods: This retrospective study included MRI examinations of patients with clinical suspicion of axSpA collected at Samsung Medical Center between January 2010 and December 2021. Only the patients who performed short tau inversion recovery (STIR) MRI of the sacroiliac joints were included. Active inflammatory lesions consisting of bone marrow edema (BME) were identified independently by a rheumatologist and a radiologist using the Assessment of SpondyloArthritis international Society (ASAS) definition of MRI sacroiliitis. We propose a two-stage deep learning framework that combines a sacroiliac joints (SIJs) localization network with a BME classification network. First, the Faster R-CNN network extracts regions of interest (ROI) to localize the SIJs using whole MR images. Here, Maximum Intensity Projection (MIP) using three consecutive images of SIJs ROI is applied to enhance the low intensity of BME and consider the contextual information between images. Second, the VGG-19 network determines the presence of BME on individual MR images of localized SIJs ROIs with a resolution of 128x256. During the training process, we augmented the positive dataset 6-fold using blurring, contrast, noise, rotation, and sharpening because of the smaller number of data than the negative dataset. The prediction models were evaluated using 3-round, 3-fold cross-validation. The performance of BME classification was measured using accuracy and area under the receiver operating characteristic curve (AUC-ROC) curve.

Results: A total of 296 participants with 4,746 MRI images were included in the study. Inflammatory sacroiliitis was identified in 864 MRI images from 119 participants. The mean average intersection over unions (IoU) of ROIs to localize the SIJs was 0.742 for the right side and 0.744 for the left side. The mean accuracy and AUC-ROC of inflammatory sacroiliitis were 0.898 and 0.830 for image level and 0.801 and 0.827 for patient level, respectively. The confusion matrices of inflammatory sacroiliitis prediction are shown in Figure 1. In the original model, without using MIP and dataset augmentation, the mean accuracy and AUC-ROC were 0.867 and 0.609 for image level and 0.717 and 0.620 for individual level. Compared to the original model, improved performances of inflammatory sacroiliitis could be observed.

Conclusion: Artificial intelligence can detect inflammatory sacroiliitis for axSpA according to the ASAS definition in MRI.

Figure 1. The confusion matrices of classification of inflammatory sacroiliitis prediction by image-based and individual-based in first round.

Background: Axial Spondyloarthritis is an umbrella term including radiographic (r-axSpA) and non-radiographic (nr-axSpA) forms which has been initially suggested by Assessment of SpondyloArthritis International Society (ASAS) as a different stages of the disease. Within time, studies have tried to answer whether these two entities represent distinct features, and the debate is still ongoing.

Objectives: The objective of this study is to define the similarities and differences of r-AxSpA and nr-AxSpA patients using a large national registry data.

Methods: TReasure is a national, multicentre, longitudinal, and observational database, initiated in Turkey in 2017 [1]. This database included patients with inflammatory arthritis, rheumatoid arthritis, axial-and peripheral SpA at the time of the first introduction of biological treatment. At the time of this analysis database consisted of 7015 SpA patients. All patients registered to the database fulfill the 2009 ASAS classification criteria. For this analysis, patients were categorized into r-AxSpA and nr-AxSpA and demographic and clinical characteristics of patients were determined.

Results: There were 4629 (86.7%) patients with r-AxSpA, 707 (13.3%) patients with nr-AxSpA patients. *Demographic differences*; r-AxSpA group were older (45 (16) vs 41 (14), p<0.001) and male predominant (59.6% vs 46.0%, p<0.001), with longer disease duration at bDMARD initiation (3.0 (6.9) vs 1.1 (3.4) years, p<0.001) and more smoker (61.4% vs 50.4%, p<0.001). *SpA clinic/genetic differences*; r-AxSpA group had less arthritis (7.7% vs 27.5%, p<0.001), heel pain (11.1% vs 40.8%, p<0.001), dactylitis (3.4% vs 8.1%, p<0.001), psoriasis (10.2% vs 14.5%, p<0.001), SpA family history (28.2% vs 40.8%, p<0.001), IBD (4.5% vs 7.4%, p=0.001) and more HLA-B27 positivity (58.2% vs 51.4%, p<0.001), similar uveitis rate (13.2% vs 14.8%). *SpA Outcome measures (bDMARD baseline) differences;* r-AxSpA group had worse functionality and quality of life measured by BASFI (5.0 (3.0) vs 4.0 (3.9), p<0.001), HAQ-DI 0.63 (0.40) vs 0.55 (0.65), p=0.029) respectively. Worse metrology by BASMI 3.2 (2.6) vs 1.7 (2.1), p<0.001) and high disease activity by ASDAS-CRP (3.64 (1.28) vs 3.24 (1.33), p<0.001) with higher CRP (12 (21.8) vs 7.3 (15.0) p<0.001) was observed. *SpA imaging differences;* r-AxSpA group had higher rate of `any syndesmophytes `(26.6% vs 5.4%, p<0.001), hip involvement (24.6% vs 4.5%, p<0.001), hip prosthesis (2.3% vs 0.3%, p<0.001), MRI structural lesions (63.6% vs 37.3%, p<0.001), and less active MRI lesions (74.6% vs 87.0%, p<0.001). No significant difference was observed in the physician decision on the b-DMARD choice at baseline (p=0.673).

Conclusion: A significant proportion of SpA patients who were initiated bDMARD have r-SpA. Although the two entities are seen as the continuum of each other, they have significant differences in terms of demographic, clinical, genetic, functional, metrology, activity and imaging characteristics. On the other hand, there is no difference in treatment choices at the stage of bDMARD initiation.

FETUIN-A: A NEW BIOMARKER OF BONE DAMAGE IN EARLY AXIAL SPONDYLARTHRITIS. RESULTS OF AN INTERIM ANALYSIS OF THE SPACE STUDY

Keywords: Diagnostic tests, Imaging, Spondyloarthritis

M. Favero[1], F. Ometto[2,3], E. Belluzzi[4], G. Cozzi[3], L. Scagnellato[3], F. Oliviero[3], P. Ruggieri[4], M. Lorenzin[3], A. Doria[3], R. Ramonda[5]. Background: Fetuin-A serum levels have been variably associated with radiological damage in axial spondyloarthritis (axSpA).

Objectives: The aim of this study was to evaluate the association of fetuin-A with the presence of radiographical sacroiliitis and syndesmophytes in early axSpA and to identify predictors of radiological damage in the sacroiliac joints (SIJ) after 24 months.

Methods: Patients with axSpA in the Italian cohort of the SpondyloArthritis-Caught-Early (SPACE) study were included. Physical examinations, laboratory tests (including fetuin-A), SIJ and spinal plain radiographs and MRIs at T0 (diagnosis) and at T24 were considered. Radiological damage in the SIJ was defined according to modified New York (mNY) criteria.

Results: Fifty-seven patients were included (41.2% males, average chronic back pain duration of 13.2±6 months). Fetuin-A levels were lower in patients with radiological sacroiliitis compared to those without at T0 (205.7±59.7 vs 249.7±50.4 µg/mL, respectively, p <0.001) and at T24 (222.3±51.5vs 272.3±91.6 µg/mL, p=0.03) (Table 1). T0 fetuin-A levels significantly correlated with mNY score at T0 and at T24, and T24 fetuin-A levels with mNY at T24 (Figure 1). At T0, fetuin-A levels were significantly higher in non-smokers, in patients with heel enthesitis and in those with a family history of axSpA; at T24 levels were higher in females, in patients with higher ESR/CRP at T0 and in those with radiological sacroiliitis at T0 (Table 1). Following multivariable analysis, fetuin-A at T0 resulted negatively associated with the likelihood of radiological sacroiliitis (OR=0.9 per 10-unit increase (95%CI 0.8, 0.999), p=0.048); but not with syndesmophytes. Fetuin-A at T0 and T24 were associated with mNY at T0 (β -0.5, p<0.001) and at T24 (β -0.3, p<0.001), respectively; T0 fetuin-A levels did not achieve statistical significance in predicting mNY at T24 (β -0.9, p<0.001).

Conclusion: Fetuin-A levels were negatively associated with radiological damage of the SIJ, but not of the spine, in early axSpA and after 2 years of follow-up. Fetuin-A levels may serve as biomarker to identify patients with a more severe disease and early structural damage.

AB1016 ERECTILE DYSFUNCTION IN ANKYLOSING SPONDYLITIS: ASSOCIATIONS WITH DISEASE-RELATED PARAMETERS

Keywords: Patient reported outcomes, Comorbidities, Spondyloarthritis

S. Lukovic[1], N. Tomonjic[1], J. Đurđević[1], S. Novkovic[1], O. Stanković[1], B. Barac[1,2], G. Radunovic[1,2], P. Ostojic[1,2]. [1]*Institute of Rheumatology, Rheumatology, Belgrade, Serbia*; [2]*University of Belgrade - Faculty of Medicine, Internal Medicine, Belgrade, Serbia*

Background: Ankylosing spondylitis (AS) is a chronic, inflammatory, autoimmune disease that dominantly affects younger men. (1) Patients with AS often experience chronic musculoskeletal pain, fatigue and stiffness, which may contribute to psychological distress and sexual dysfunction (SD). (2)
Objectives: The study aimed to assess prevalence of ED in patients with AS and identify potential associations between clinical parameters related to AS and the presence of ED.
Methods: This observational cross-sectional study was approved by the local Ethics Committee. Forty consecutive male patients with the AS (mean age 42.8 ± 8.9 years) and 60 healthy men (mean age 38.9 ± 10.9 years) were included. All subjects filled-in the International Index of Erectile Function (IIEF) questionnaire, as well as the Beck anxiety inventory (BAI) and the Beck depression inventory (BDI). In patients with AS disease activity was evaluated using the Ankylosing Spondylitis Disease Activity Score (ASDAS) and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), functional ability using the Bath Ankylosing Spondylitis Functional Index (BASFI), and quality of life using the Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire.
Results: ED was significantly more frequent in patients with AS (21/40, 52.5%) compared to controls (52.5%: 25%, p=0.049). Moreover, the mean value of IIEF score was significantly (p=0.035) lower in AS patients (22.3 ± 8,9) than in the control group (25.7 ± 7.5). There was no significant difference in BAI and BDI scores between patients with AS and ED and patients with ED in the control group. Parameters reflecting disease activity (ASDAS, BASDAI, CRP) and functionality (BASFI) were somewhat higher in the patients with AS and ED in comparison to patients without ED. However, these findings were not statistically significant. According to ASQoL scores, patients with AS and ED had a worse quality of life compared to patients with AS but without ED (p=0.022). AS patients with ED had more severe symptoms of depression than AS patients without ED (p=0.034). Univariate logistic regression showed that BDI and ASQoL scores were associated with the presence of ED. However, multivariate logistic regression analysis showed that ASQoL was an independent prognostic factor for the presence of ED in patients with AS. The increase in one unit of ASQoL score increased the risk of having ED for 17.5% (p=0.035).
Conclusion: The prevalence of ED in patients with AS was higher than in healthy controls. Poor quality of life (according to ASQoL) was the only parameter, independently associated with the presence of ED. It is necessary to raise awareness of ED in patients with AS.

AB1017 DETERMINANTS OF SLEEP DISORDERS IN AXIAL SPONDYLOARTHRITIS: A CONTROLLED STUDY

Keywords: Quality of life, Spondyloarthritis, Patient reported outcomes

C. Valera-Ribera[1], E. Valls-Pascual[1], A. Mayo-Juanatey[1], E. Flores-Fernández[1], P. Andújar-Brazal[1], I. Vázquez-Gómez[1], A. Ybañez Garcia[1], À. Martínez-Ferrer[1], J. J. Alegre Sancho[1]. [1]*Doctor Peset University Hospital, Rheumatology, Valencia, Spain*

Background: Axial spondyloarthritis (axSpA) is a chronic joint disease, characterized by inflammation and damage of the axial skeleton. It is frequent for patients to experience pain during periods of rest, such as during night sleep. A limited number of studies address the relationship between axSpA and sleep quality (SQ), although it represents a major concern for patients. Moreover, most of these studies lack a control group and do not explore the different areas of sleep.
Objectives: To describe the prevalence of sleep disorders in patients with axSpA and compare it with a healthy population. To analyse the determinant factors associated with SQ in both populations. To analyse the effect of structural damage, disease activity and its specific treatments on sleep quality.
Methods: We conducted a cross-sectional study. The cohort was composed of adult axSpA patients followed in the Rheumatology outpatient clinic at Doctor Peset University Hospital, and age- and gender-matched healthy individuals. Participants with known sleep diseases were excluded. The following variables were collected for both patients and controls: age, gender, perceived health, weekly physical activity, employment situation, and annual level of income, history of anxiety and/or depression and active treatment for it. The following variables were collected for axSpA patients: year of diagnose, BASFI, BASDAI and ASAS-HI scores, current dosage of glucocorticoids, use of NSAIDs and conventional, biologic or targeted synthetic DMARDs, and presence of syndesmophytes on plain radiography. The Pittsburgh Sleep Quality Index (PSQI) questionnaire, which evaluates sleep quality and disturbances over a month time interval, was applied. This questionnaire studies 7 different sleep domains: subjective quality, latency, duration, efficiency, disturbances, use of sleeping medication, and daytime dysfunction. A regression model was created to estimate the influence of the collected variables on the results of this questionnaire.
Results: 57 axSpA patients and 50 healthy controls were included. There were no statistical differences in mean age and sex percentage between both groups. According PSQI scores, 87.72% of patients and a 62% of controls were classified as “poor” sleepers. SQ was related to axSpA (p = 0.002), anxiety (p = 0.003), perceived health (p = 0.001) and physical activity levels (p = 0.006). The domains of subjective sleep quality, latency, duration, efficiency and sleep disturbances were negatively affected by axSpA (p < 0.05). The estimated odds ratio of having a sleep disorder was 5.63 times higher in patients diagnosed with axSpA. With regards to AS patients; anxiety (p < 0,001), physical activity (p = 0,015), BASDAI scores (p = 0,001), BASFI scores (p = 0,038) and axial syndesmophytes (p=0,028) were found to affect the PSQI score.
Conclusion: Patients with axSpA have a poorer sleep quality when compared to healthy individuals. AxSpA affects subjective sleep quality, latency, duration, efficiency and sleep disturbances. Disease activity and the presence of syndesmophytes have a detrimental effect, whereas physical activity has a positive effect on SQ. Therefore, these factors must be considered when attending this area of our patient’s health. The PSQI questionnaire provides a complete approach to sleep health and should be considered a complementary tool for the management of axSpA patients.

AB1018 BASELINE CHARACTERISTICS OF AN EARLY SPONDYLOARTHRITIS COHORT IN HONG KONG

Keywords: Geographical differences, Spondyloarthritis, Descriptive studies

J. So[1], A. S. De Craemer[2,3], M. De Hooge[2,3], S. L. Lau[4], F. Van den Bosch[2,3], D. Elewaut[2,3], L. S. Tam[4]. [1]*Prince of Wales Hospital, Department of Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*; [2]*Ghent University Hospital, Department of Internal Medicine and Pediatrics, Ghent, Belgium*; [3]*Center for Inflammation Research, VIB-UGent, Zwijnaarde, Belgium*; [4]*The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*

Background: Axial Spondyloarthritis (axSpA) is characterized by inflammation of the sacroiliac joint and the spine. It is a heterogeneous disease with variable musculoskeletal and extra-articular manifestations. The **Be**l**G**ian **I**nflammatory **A**rthritis and spo**N**dylitis cohor**T** (Be-Giant) is a cohort that recruited newly diagnosed SpA patients in Belgium and prospectively followed up the patients.

Objectives: Given the difference in genetic susceptibility and environmental exposure, we aimed to compare the disease nature, clinical presentation, and prognosis between Chinese and Caucasian axSpA patients.

Methods: The SPARK cohort (**SP**ondylo**AR**thritis in Hong **K**ong) resembled the Be-Giant cohort. Newly diagnosed, biologic naïve Chinese axSpA patients who fulfilled ASAS classification criteria were recruited. All patients underwent standardized clinical, laboratory and radiographic assessments as per Be-Giant protocol.

Results: A total of 53 newly diagnosed axSpA patients were recruited in the SPARK cohort (Table 1). The mean age at diagnosis (32 years old) and symptom duration (2 years) were comparable in both cohorts. There was a slight male predominance (59%) in the SPARK cohort as compared to the Be-Giant cohort (50%). More patients were HLAB27 positive in Chinese patients (SPARK 96% vs Be-Giant 71%). In both cohorts, less than one-fifth of the patients had radiographic sacroiliitis according to modified New York criteria (SPARK 17% vs Be-Giant 18%). Patients in the Be-Giant cohort and the SPARK cohort had similar disease activity clinically by ASDAS-CRP (SPARK 2.4 (SD 0.9) vs Be-Giant 2.6 (SD 1.0)) and radiographically by positive MRI SIJ according to the ASAS definition (SPARK 53% vs Be-Giant 87%). More patients in the SPARK cohort (37%) experienced uveitis compared to the Be-Giant cohort (12%). Around 9% and 5% of axSpA patients in Be-Giant cohort suffered from psoriasis and inflammatory bowel diseases (IBD) respectively while none in SPARK cohort did. Enthesitis (28%) and dactylitis (3.8%) were more common in Chinese as compared to Belgians. Whereas peripheral arthritis and dactylitis were more common in Belgians than Chinese axSpA patients.

Conclusion: Caucasian and Chinese axSpA patients display a similar burden regarding axial disease, yet appear to be different in the extent on peripheral and extra-musculoskeletal manifestations.

Table 1. Baseline demographic and clinical characteristics of newly diagnosed axial SpA patients

	Be-Giant cohort (n=257)	SPARK cohort (n=53)
Male, no %	128 (49.8%)	31 (58.5%)
Age at diagnosis, years	32 (8.3)	32(7.9)
Symptoms duration, months	27 (10-83)	24 (13-54)
Current smoker, no %	52 (20.5%)	10 (18.9%)
HLAB27, no %	181 (70.7%)	51 (96.2%)

AB1019 ANALYSIS OF DEMOGRAPHIC AND CLINICAL CHARACTERISTICS OF ENTEROPATHIC SPONDYLOARTHRITIS IN A TERTIARY CARE HOSPITAL

Keywords: Spondyloarthritis, Epidemiology, Gastrointestinal tract

P. Pérez-García[1], I. González Fernández[1], J. Ordas Martínez[1], C. Sieiro Santos[1], C. Álvarez Castro[1], C. Moriano[1], M. E. Vallejo Pascual[2], E. Diez Álvarez[1]. [1]*Complejo Asistencial Universitario de León, Rheumatology, León, Spain*; [2]*University of León, Faculty CCEE and Business, León, Spain*

Background: Enteropathic spondyloarthritis (eSpA), is a type of inflammatory joint disease that is related to inflammatory bowel diseases (IBD). Both spondyloarthritis (SpA) and IBD share clinical, genetic and immunological features. Arthritis can occur before, during or after IBD. The treatment of this disease is based on the use of NSAIDS and corticoids as well as the use of csDMARDs and bDMARDs.

Objectives: To describe the demographic, clinical and serological characteristics, as well as the onset pattern, radiological involvement, smoking habit, activity disease and comorbidities such as cardiovascular risk factors (CVRF) in patients with eSpA. To analize the most commonly used drugs in these patients and the therapeutic response.

Methods: We performed a descriptive observational study of patients with eSpA diagnosed in the Hospital of León between 1980 and 2022. The variables analysed were sex, date onset of IBD and SpA, time between the two diagnoses, pattern of SpA involvement, type of IBD, HLAB27, toxic habits, family history, arthralgias, uveítis, psoriasis, dactylitis, radiological involvement (sacroilitis, syndesmophytes) and treatments received. The activity disease was assessed by BASDAI Index.

Results: The patient´s features are shown in Table 1. We included 56 patients, half men and half women. The 57,1% of the cases debut with IBD. Crohn's Disease (CD) was the most represented IBD. The 41,1% had a peripheral SpA (16,1% oligoarticular arthritis and 25% polyarticular arthritis); the 32,1% patients presented an axial SpA and 26,8% had a mixed pattern. Peripheral SpA was the most represented form. The time elapsed between joint involvement and IBD was < 5 years in the 50% of the sample analyzed. HLAB27 was positive in 28,6% of the sample and the 35,7% showed BASDAI > 4. We found associated uveitis and psoriasis in 14,3% and 16,1% of the cases. The 57,1% of eSpA had CVRF, the most prevalent was dyslipemia (39,3%). The 53,6% had radiological involvement (sacroilitis 48.2%, syndesmophytes 21.4%). Radiological involvement was significantly greater in smoker patients (p=0.003), probably due to higher associated inflammatory activity. 78.6% of SpA were treated with cDMARDs and methotrexate was the most used (51.8%), followed by azathioprine, 5-ASA, and leflunomide. 73.2% of the cases received bDMARDs and anti-TNF was the most used (73.2%), followed by IL12-23 inhibitors, JAK inhibitors and anti-integrin.

The most frequent cause of discontinuation of methotrexate was side effects (16.1%), especially digestive intolerance; while in patients treated with anti-TNF was secondary failure (19.6%)

Table 1. Demographic, clinical, serological features, radiological involvement and treatments of the eSPA patients.

Characteristics	Patients (n=56) Median; IQR or n(%)
Sex F/M	28(50)/28(50)

o Azathioprine	21(37,5)
o 5-ASA	16(28,6)
o Leflunomide	1(1,8)
- bDMARDs	41(73,2)
o antiTNF	41(73,2)
o IL12-23 inhibitors	9(16,1)
o JAK inhibitors	7(12,5)
o antiintegrin	5(8,9)

Conclusion: In our study, most patients with enteropathic spondyloarthritis first presented intestinal symptoms. The most frequent patterns were peripheral spondyloarthritis and Chron's disease, and we found HLA B27+ in around a third of the sample. Smoking was associated with greater radiological involvement in the form of sacroiliitis and syndesmophytes.

Multidisciplinary work between gastroenterology and rheumatology is essential for the diagnosis and treatment of enteropathic spondyloarthritis. These results are consistent with the literature.

AB1020 MUSCULOSKELETAL INVOLVEMENT IN INFLAMMATORY BOWEL DISEASE PATIENTS: A MONOCENTRIC EXPERIENCE

Keywords: Inflammatory arthritides, Spondyloarthritis

A. Delle Sedie[1], L. Ceccarelli[2], F. Costa[2], F. Fattorini[1], C. Cigolini[1], M. Mosca[1], L. Carli[1]. *[1]University of Pisa, Rheumatology Unit, Pisa, Italy*; *[2]University of Pisa, Gastroenterology Unit, Pisa, Italy*

Background: Musculoskeletal (MSK) symptoms, varying from arthralgia to arthritis are frequently reported by patients (pts) with inflammatory bowel diseases (IBD). A peripheral or axial joint involvement has been reported with a similar range from 5 to 30% and a definite spondyloarthritis (SpA) diagnosis is present in up to 46% of patients with IBD [1-8]. To date, a more comprehensive disease control is requested and the optimization of the treatment (choosing a mono or a combination therapy strategy) to improve both gastrointestinal and musculoskeletal is mandatory.

Objectives: To evaluate the rate of MSK involvement in a mono centric cohort of IBD pts and the consequent need to optimize their therapeutical schemes.

Methods: A gastroenterologist working in the IBD out-patient clinic had selected IBD patients who should be referred to the rheumatologic visit, on the basis of the results of a questionnaire aimed at highlighting the presence of clinical features suggestive of SpA. From January 1st 2017 to December 31st 2022 IBD pts have been evaluated by a rheumatologist expert in SpA. In case of doubts about the diagnosis, further examinations were requested. The diagnosis of SpA was made following the ASAS criteria of 2011.

Results: A total of 288 pts were sent to the rheumatologist (140 CD, 127 UC, 21 not defined IBD). One hundred sixty-eight pts received only one rheumatological visit while, one hundred two were evaluated twice or more times. To make a diagnosis, 37 MRI (30 for sacroiliac joints), 30 ultrasound assessment (mostly hands, wrists or feet), 19 X-rays and 23 blood tests were requested. Most of pts (196/288, 68%) were not classified as SpA; 50/288 (17.4%) were peripheral SpA and 24/288 (8.3%) were axial SpA, in 18/288 (6.3%) there was an isolated entheseal involvement. The rheumatologist recommended a therapeutical optimization in 138 IBD pts (47.9%). In particular, a DMARD was added in 59 pts and a bDMARD was prescribed in 6 for rheumatological indications; moreover, in 73 cases, a choice between two different therapeutical approaches was suggested to the gastroenterologist, in order to improve the control of MSK disease activity on the basis of IBD course.

Conclusion: Our results confirm the already published prevalence of MSK involvement in IBD patients. A relevant number of IBD pts, after the rheumatological evaluation, were classified as peripheral (17.4%) or axial (8.3%) SpA. In about half of IBD pts, a therapeutical modification was recommended by the rheumatologist, aiming at improving the control of MSK disease activity in the context of the IBD course. These data confirm the importance of a close collaboration between gastroenterologists and rheumatologists, to optimize the clinical assessment of IBD pts, thus improving their quality of care [9].

Background: The term axial spondyloarthritis covers both patients with non-radiographic (nr-axSpA) and ankylosing spondylitis (AS). Axial spondyloarthritis (axSpA) is a chronic disease that typically affects the axial skeleton, and produces varying degrees of pain, stiffness, and fatigue [1-2].

Objectives: The aim of this study is to describe the burden of disease from the patient´s perspective who participated in the International Map of Axial Spondyloarthritis in Argentina.
Methods: IMAS is a cross-sectional online survey including axSpA patients from around the globe. In this study, Argentinian axSpA patients ≥ 18 years old with AS or nr-axSpA, who provided informed consent and participated in the IMAS survey, were included. To determine disease burden from patient´s perspective BASDAI and GHQ-12 scale were performed. In addition, data on demographic, clinical and treatment characteristics were included to describe the daily life of these patients. Numerical variables are expressed as mean (standard deviation) or median (interquartile range), while categorical variables are expressed as count and percentage.
Results: 115 individuals (67 men) were included. Mean ± SD age of surveyed participants was 46.9 ± 12.3 years. 76.5% reported being diagnosed with ankylosing spondylitis. Most of them (n: 98) live in Buenos Aires and surroundings. The median BASDAI score was 5.1 (IQR: 3.5), 66.1% had a BASDAI score > 4. The mental state (psychological distress) was affected in less than half, 41.7% of the participants showed a GHQ-12 >3. The delay in diagnosis was 4 years (SD 8). Biologics were prescribed in 88 out of 115 (76.5%) patients and 92% were on them at the time of the survey. The most frequently reported associated health conditions were anxiety and sleep disorders. The main hopes revealed by the respondents were to stop the disease (87%), recover quality of life (72%), and improve mobility (56%).
Conclusion: This is the first study of the International Map of Axial Spondyloarthritis in Argentina. In this sample of patients with axSpA, a substantial proportion were active in their disease, although most of them were under biological treatment. The delay in diagnosis was less than that reported in other series, and we should not underestimate the anxiety and sleep disorders suffered by these patients.

AB1022 EARLY DIAGNOSIS OF SPONDYLOARTHRITIS AND OTHER RHEUMATIC DISEASES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A PROSPECTIVE STUDY BASED ON A SCREENING QUESTIONNAIRE AND EARLY REFERRAL TO THE RHEUMATOLOGIST

Keywords: Spondyloarthritis, Gastrointestinal tract, Inflammatory arthritides

M. C. Miceli[1], S. Renna[2], A. Orlando[2], G. Provenzano[1]. [1]*Azienda Ospedaliera "Ospedali Riuniti Villa Sofia-Cervello", Rheumatology Unit, Palermo, Italy*; [2]*Azienda Ospedaliera "Ospedali Riuniti Villa Sofia-Cervello", IBD Unit, Palermo, Italy*

Background: Patients (pts) with inflammatory bowel disease (IBD) frequently disclose muscoloskeletal (MSK) symptoms. About 15-20% of these pts are affected by spondyloartritis (SpA) and almost 50% have mechanical back pain and non-inflammatory arthralgyas [1]. Notably, up to 30% of them may have fibromyalgic syndrome (FMS) [2], although there are limited data on this issue. Early and accurate diagnosis of articular involvement in IBD pts is crucial to allow a personalized therapeutic approach and mostly an unmet need.
Objectives: Early diagnosis of axial-SpA (Ax-SpA) and peripheral SpA (p-SpA) in IBD pts with MSK symptoms and definition of other rheumatologic causes of pain in these complex pts.
Methods: A prospective cohort of IBD outpatients without a previous clear diagnosis of rheumatic disease was evaluated with the self-administered DETAIL questionnaire [3], which has been recently validated as a useful screening tool for early detection of SpA in IBD [4]. Pts with at least 3 out of 6 points of the score (the risk cohort) underwent a full clinical rheumatological evaluation and ultrasonographic (US) assessment of 6 enthesis (according to MASEI score). Pts fulfilling ASAS classification criteria were diagnosed as having p-Spa or ax-Spa. Rheumatoid arthritis (RA) and FMS were also diagnosed according to ACR 2010 criteria.
Results: 660 IBD pts were administered the questionnaire. Ninetytwo pts (14%) were selected for rheumatological evaluation: 69/92 pts (75%) were female, the median age was 48 (±12.7) years and the mean BMI was 23.8 (±3.7). Sixtyseven pts (73%) were affected by Crohn disease, 23 pts (25%) by ulcerative colitis and 2 pts (2%) had indeterminate colitis. The median disease duration was 11.6 (±9.3) years. Fiftytwo pts (56,5%) were in biologic therapy (77% with anti-TNF, 15,3% con Vedolizumab and 7,7% with Ustekinumab). Overall, 38/92 pts (41%) were classified as having arthritis [25 (66%) p-SpA, 11 (23%) ax-SpA, 3 (1%) RA. Notably, in 9 of these pts coexisted FMS. 54/92 pts (58.6%) of the risk cohort did not fullfill arthritis classification criteria: 32 pts (60%) were diagnosed as having osteoarthritis or aspecific arthralgias and 22 pts (41%) fullfilled FMS criteria. Notably, in the whole risk cohort there were 31 pts (41%) with FMS. Concerning US assessment, the statistical analysis only showed marginal correlation between MASEI score and ax-SpA diagnosis (p=0.086) but no correlation with p-SpA.
Conclusion: This study confirm that the DETAIL questionnaire may be a useful screening tool in order to select IBD pts needing rheumatologic evaluation and get an early diagnosis of SpA. However, our data also show that IBD pts with MSK symptoms often have other non-inflammatory rheumatic diseases. Notably, in our series US did not represent a sensitive method in identifying pts with SpA.

AB1023 THE DIFFERENTIAL CHARACTERISTIC OF SPONDYLOARTHRITIS PATIENTS WHO CANNOT BE CLASSIFIED ACCORDING TO ASAS: RESULTS FROM THE GESPA COLOMBIAN COHORT

Keywords: Descriptive studies, Spondyloarthritis

G. Rodríguez Salas[1], A. M. Santos[1], V. Navarro-Compán[2], M. J. Mantilla[1], I. Rueda[1], J. C. Santacruz Devia[1], S. Arias[1], J. Rueda[1], J. G. Ballesteros[1], E. Calvo[1], M. Cardiel[3], C. F. Pacheco Tena[4], J. Londono[1]. Background: The Assessment of SpondyloArthritis International Society (ASAS) classification criteria for SpA has changed the approach to the disease, enhancing the performance of the classification process. However, regardless of the ASAS classification criteria were developed according to a global cohort of patients, Latin American patients were not included in a significant number. SpA patients from our region have unique characteristics that may impact the SpA classification. Other alleles than HLA-B27 have been identified, the frequency of HLA-B15 was reported to be 19.1% in the Latin American SpA population [1], compared to 3.3% in the healthy population [2].
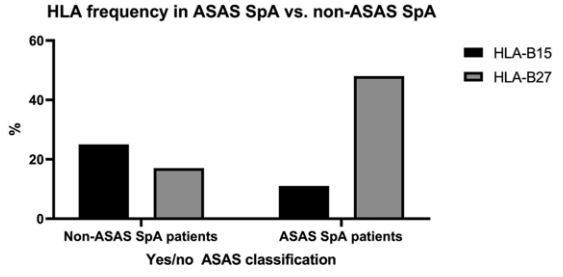
Objectives: The aims of our study were to describe the demographics, clinical, genetic characteristics, and metrology of patients diagnosed with SpA by a rheumatologist but who did not meet ASAS classification criteria and compare them to patients who fulfilled ASAS classification criteria.



Methods: A longitudinal and analytic study was conducted on a cohort of Colombian SpA patients. Patients were evaluated in a SpA clinic at two institutions from 1990 to the present. All patients were classified according to ASAS. Patients included before 2011 were reclassified according to ASAS by a group of two rheumatologists.
Results: We enrolled 473 SpA patients; of these, 437 (92.39%) fulfilled ASAS classification criteria, and 37 (7.6%) had a diagnosis by rheumatologists but did not fulfil ASAS classification criteria for neither axial or peripheral SpA. There were no differences in gender distribution between both groups (table 1). Patients who did not fulfill ASAS classification had a lower frequency of enthesitis (36.1% vs. 79.2%, P = 0.00), dactylitis (5.6% vs. 19%, P = 0.04), arthritis (30.6 vs. 71.6%, P = 0.00), and lower frequency of history of infections preceding SpA onset (2.8% vs. 27.9%, P = 0.01) than patients classified by ASAS, respectively. There were no differences in the frequency of uveitis, psoriasis, inflammatory spinal pain, or familiar history of SpA (P = 0.3). The frequency of SpA with axial symptoms at the onset of the disease was higher in patients unclassified by ASAS (Table 1). Non-ASAS SpA patients had a higher frequency of HLA-B15 (25% vs. 11.8%, P = 0.01), and lower frequency of HLA-B27 (16.7% vs. 48.2%, P = 0.01) than ASAS SpA patients, respectively (Graphic 1). The BASFI and BASDAI were comparable between two groups (Table 1)
Conclusion: Most patients diagnosed as SpA by rheumatologists in a Colombian cohort fulfilled ASAS classification criteria. Only 7% did not fulfil the criteria. Of these patients, the demographic characteristics, disease activity and functional compromise were comparable to patients classified by ASAS. Interestingly, the frequency of HLA-B15 is high in both groups, but it is significantly higher in unclassified individuals. These results highlight the significance of HLA alleles other than HLA-B27 and their potential diagnostic value for SpA in LatinAmerica.

AB1024

IMPACT OF DISEASE ACTIVITY ON FUNCTIONAL IMPAIRMENT IN PATIENTS WITH SPONDYLOARTHRITIS IS DIFFERENT ACCORDING TO THE DEGREE OF RADIOGRAPHIC PROGRESSION: RESULT FROM SNUH-AS COHORT

Keywords: Spondyloarthritis, Motor function

J. I. Jung[1], J. Y. Kim[1], J. K. Park[1], E. Y. Lee[1], E. B. Lee[1], J. W. Park[1]. [1]*Seoul National University Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Although previous studies suggested that physical functioning is largely driven by disease activity in patients with spondyloarthritis (SpA), its relationship to radiographic progression has not been thoroughly investigated.
Objectives: The aim of this study was to investigate whether the effect of disease activity on physical function varies according to the radiographic progression in SpA patients.
Methods: This cross-sectional study used baseline data from the patients in a single-center, prospective cohort of SpA. Disease activity was assessed through Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Ankylosing Spondylitis Disease Activity Score (ASDAS). Physical function was measured using Bath Ankylosing Spondylitis Functional Index (BASFI) and functional impairment of the patients was defined as BASFI ≥4. Radiographic progression of SpA was assessed using modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Clinical factors related to functional impairment of the patient were investigated using logistic regression analysis.
Results: A total of 221 patients were analyzed. Mean (SD) age at baseline was 43.4 (14.1) yeas and 176 (79.6%) were male. Mean (SD) disease duration of the included patients was 7.5 (9.5) years. Remission or low disease activity (LDA, ASDAS-CRP < 2.1) was achieved in 149 (67.4%) patients. Mean (SD) mSASSS was 19.5 (20.6) and 96 (43.4%) patients had at least one syndesmophyte on baseline spinal radiographs. At the baseline, functional impairment was present in 41 (18.6%) patients. Univariable analysis showed that older age at diagnosis, shorter disease duration based on two years, and higher ASDAS-CRP were associated with functional impairment. Although the effect of ASDAS-CRP on the outcome was consistent in the multivariable analysis (adjusted OR 2.46 [95% CI 1.70-3.58]), it was significantly different according to the severity of radiographic progression (*P* value for interaction = 0.001). In the absence of bridging syndesmophyte, increase in ASDAS-CRP was associated with more frequent functional impairment (adjusted OR 5.12 [2.61-10.05]). By contrast, in the subgroup of patients with bridging syndesmophyte, ASDAS-CRP did not increase the likelihood for functional impairment (adjusted OR 1.14 [0.70-1.86]). In fact, in the subgroup without bridging syndesmophyte, no patient with LDA showed a functional impairment. However, in advanced patients with bridging syndesmophyte, the rate of functional impairment was 23.8% despite achieving LDA. (Figure 1)

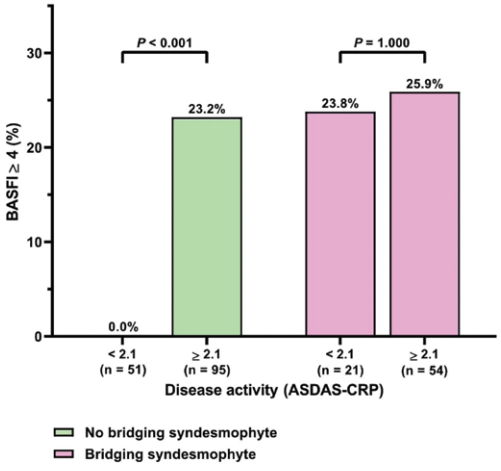

Figure 1.

Conclusion: In the presence of advanced radiographic progression, low disease activity was not significantly associated with less functional impairment in patients with SpA, which suggests that early diagnosis and optimal treatment are critical for better physical function.

ASSESSING THE DIFFERENCE BETWEEN RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN A TWO-CENTER DESCRIPTIVE STUDY WITH MEXICAN PATIENTS

Keywords: Geographical differences, Spondyloarthritis, Descriptive Studies

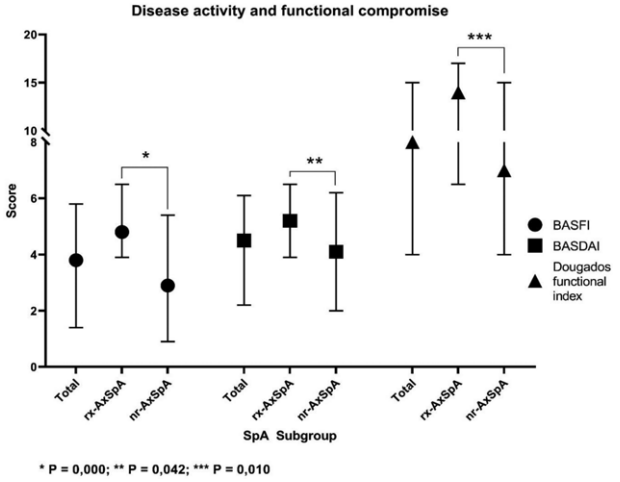
A. M. Santos[1], G. Rodríguez Salas[1], I. Rueda[1], M. J. Mantilla[1], J. C. Santacruz Devia[1], S. Arias[1], J. M. Bello-Gualtero[1], E. Calvo[1], J. Rueda[1], M. Cardiel[2], C. F. Pacheco Tena[3], J. Londono[4], R. Burgos-Vargas[5]. *[1]University of La Sabana, Military Central Hospital, Spondyloarthritis Study Group (GESPA), Bogotá, Colombia*; *[2]Clinica de Morelia, Centro de investigación, Michoacán, Mexico*; *[3]Universidad Autónoma de Chihuahua, Facultad de Medicina y Ciencias Biomédicas, Chihuahua, Mexico*; *[4]University of La Sabana, Military Central Hospital, Spondyloarthritis Study Group (GESPA), Bogotá City, Colombia*; *[5]Hospital General de Mexico, Department of Rheumatology, Mexico City, Mexico*

Background: Spondyloarthritis (SpA) is a group of inflammatory rheumatic diseases that have some key features in common. According to ASAS, this condition is classified into three main disease groups: radiographic axial SpA (r-AxSpA), non-radiographic axial SpA (nr-axSpA), and peripheral SpA (pSpA). All patients with SpA with predominantly axial involvement are considered to have axial SpA, patients with significant radiographic sacroiliitis according to the modified New York criteria have r-axSpA. Patients without radiographic sacroilitis but with axial disease have nr-axSpA. More information is needed about the difference between these groups, especially in other populations like ours.

Objectives: The objectives of this study are to systematically compare the demographic, clinical, and laboratory characteristics, disease onset, and physical examination findings of patients with r-AxSpA and nr-AxSpA; and identify factors that could predict a subtype of the disease.

Methods: Data from 148 patients over 18 years collected between 1998 and 2005 from Hospital General de México and Instituto Nacional de Ciencias Médicas y Nutrición. Patients classified according to ASAS criteria. We selected patients with nr-AxSpA and r-AxSpA and compared, clinical, demographic, and clinimetric variables. Logistic regression analysis was applied to identify the parameters associated with r-AxSpA or nr-AxSpA. Exclusion criteria included patients under biologic treatment.

Results: This study included 148 adult Mexican patients; general characteristics are exposed in table 1. HLA-B*27 was present in 57% of patients. Patients with nr – AxSpA were more women (41.4% vs 21.8%; P <0.05), with less presence of HLA-B27 (54.3% vs 92.7%, P < 0.05) compared to the r – axSpA group. R-AxSpA patients were younger at symptom onset (16 vs. 21 years; P < 0.01) than nr – axSpA (Image 1). Patients with nr – AxSpA had more history of infection preceding disease onset (32.9% vs 9.1%; P < 0.05), and less frequency of uveitis (10% vs 25.5% P < 0.05), more dactylitis (12.9% vs. 0%, P < 0.01), less painful entheses (3 vs. 6 P < 0.01), and less axial enthesopathy (1 vs. 4 P < 0.05) than r-AxSpA patients. The measures of thoracic expandability, modified Schober, right and left flexion test, were significantly lower in r-AxSpA group than in the nr-AxSpA group, p < 0.01). patients with r-AxSpA had higher Bath Ankylosing Spondylitis Functional Index (BASFI) (4.8 vs 2.9%; P < 0.01), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) (5.2 vs 4.1; P < 0.01), Dougados functional index (14% vs 7%; P < 0.05) than nr – AxSpA. Logistic regression shows that the factors that most influence the presentation of r-AxSpA are the history of uveitis (OR 14, 95% CI 2.3-85), HLA-B27 (OR 7, 97, 95% CI, 2.96-122), gender (male) (OR 6.16, 95% CI, 1.47-25.7), axial enthesopathy count (OR 1.17 95% CI, 1.03-1.33). The history of infection is a protective factor against radiographic disease (OR 0.19, 95% CI 0,04 – 0,91).



Conclusion: This study provides insight into the differences that may affect the prediction of radiographic progression in patients with nr-AxSpA. We found that patients with radiographic disease had a younger age of presentation, mostly male, higher prevalence of HLA-B27, more history of uveitis, fewer episodes of dactylitis, more axial enthesopathy, and higher disease activity.

AB1026

THE TIME OF INTESTINAL BOWEL DISEASE ONSET IS ASSOCIATED WITH THE PHENOTYPE AND DIAGNOSIS IN PATIENTS WITH SPONDYLOARTHRITIS. RESULTS FROM REGISPONSER REGISTRY

Keywords: Gastrointestinal tract, Spondyloarthritis

I. Gómez-García[1,2,3,4], M. L. Ladehesa Pineda[1,2,3], A. Escudero Contreras[1,2,3], F. U. Pilar[1,2,3], E. Collantes Estevez[1,2,3], P. Ruiz-Limon[5,6,7], C. López-Medina[1,2,3]. *[1]Hospital Universitario Reina Sofia, Rheumatology, Córdoba, Spain*; *[2]University of Cordoba, Medicine, Córdoba, Spain*; *[3]Instituto Maimónides de Investigación Biomédica de Córdoba, GC05 – Systemic And Chronic Inflammatory Autoimmune Diseases of the Locomotor System and Connective Tissue, Córdoba, Spain*; *[4]Hospital Público Santa Bárbara, Internal Medicine, Puertollano, Spain*; *[5]Hospital Universitario Virgen de la Victoria, Endocrinology and Nutrition, Málaga, Spain*; *[6]Instituto de Investigación Biomédica de Málaga - Plataforma BIONAND, Endocrinology and Nutrition, Málaga, Spain*; *[7]Carlos III Health Institute, CIBEROBN, Madrid, Spain*

Background: Our group has evaluated the impact of the time of appearance of some extramusculoskeletal manifestations in spondyloarthritis. However, we still need to know more about the impact of both the inflammatory bowel disease (IBD) itself and its moment of appearance with respect to rheumatic symptoms.

Objectives: a) to compare SpA characteristics in patients with and without IBD and b) To compare the clinical characteristics and the rheumatologist's diagnosis in SpA patients with IBD according to the onset of IBD (before vs. after the appearance of rheumatic symptoms).

Methods: This was a cross-sectional study with data extracted from the REGISPONSER (Spondyloarthritis Registry of the Spanish Rheumatology Society) registry. Dates of SpA and IBD onset were available. Two groups were classified depending on the time of appearance of IBD (before or after rheumatic symptoms). The clinical characteristics, disease activity, radiographic damage, functional ability and rheumatologists' diagnoses were compared between the

two groups. Univariate and multivariate logistic regressions were conducted to evaluate the factors associated with each group and chi-square test to evaluate differences in phenotype and rheumatologists' diagnoses.
Results: A total of 123 of 2367 (5.2%) patients included in the REGISPONSER registry were diagnosed with IBD but 20 patients did not have available date of IBD onset. There was less prevalence of HLA-B27, psoriasis and dactylitis, and less frequency of uveitis in patients with IBD vs patients with SpA without IBD. Moreover, these patients were younger and had less disease duration, and less disease activity (by ASDAS and BASDAI indexes) and functional ability (by BASRI index). Among patients with IBD, 54 (52.4%) already had IBD at the moment of rheumatic symptoms onset, while 49 patients (47.6%) began with IBD after the SpA onset. Peripheral phenotype [10 (18.5%) vs 1 (2%)] was more frequently observed in patients who had been already diagnosed of IBD when rheumatic symptoms began while axial involvement had a lower prevalence [25 (46.3%) vs 33 (67.3%)]. There also were significant differences in rheumatologist's diagnosis in these patients, with a less frequency of ankylosing spondyloarthritis diagnosis [31 (57.5%) vs 42 (85.7%)] in the first group. After performing a multivariate analysis with demographic and clinical characteristics, we obtained a shorter diagnosis delay [0.90 (CI95% CI 0.82-0.98)] and a less prevalence of HLA-B27 antigen [0.19 (CI95 % 0.07-0.52)] in the former group.
Conclusion: SpA patients with IBD have a less severe disease with less prevalence of extramsuculoskeletal imanifestations. When IBD began before the rheumatic symptoms, it was associated to an earlier diagnosis and a more frequent peripheral phenotype.

Background: Uveitis is the most common extra-articular manifestation of Spondyloarthritis (SpA).
Objectives: The aim of this study was to determine the prevalence of uveitis in patients with SpA in a multicenter series and to identify factors associated with its occurrence.
Methods: A multicenter descriptive analytical study, including patients followed for SpA in 8 rheumatology departments from 6 different regions in Morocco. All data were measured by standard instruments. Demographic, clinical, paraclinical and therapeutic data of the disease were collected. Disease activity was assessed by BASDAI and ASDAS-CRP scores. Data analysis was done by SPSS.20 software, the p significance level was set at 0.05.
Results: The study had included 700 patients followed for SpA, 54% of whom were men. The mean age at diagnosis was 40.42 + 14.19 years. The average diagnosis delay was 59.76 months. The percentage of patients who smoked was 15.6%. A family history of SpA was noted in 11.7%. SpA was non-radiographic in 14% of cases. Bilateral sacroiliitis was described in 49.4%. Coxitis was present in 32.5%. Juvenile SpA represented 15.5% of cases. The prevalence of HLA-B27 was 65.51%. Systemic involvement was dominated by uveitis (11.3%), it was unilateral in 59.5%, bilateral in 28.6% and tilted in 11.9%, anterior in 95.7%. Evolution of the uveitis was acute in 88.9% and chronic in 11.1%. The mean of BASDAI and ASDAS ware 4.42 ±1.67 and 3.19 ±1.24 respectively. The mean CRP and erythrocyte sedimentation rate (ESR) were 35.5 mg/l and 43.3mm respectively. The mean BASDAI was significantly higher in SpA with uveitis (p=0.025). Biological treatments, in particular tumor necrosis factor-α (TNF-α) inhibitors were more prescribed in patients with uveitis; 47.5% versus 30.9% in SpA without uveitis, with a significant difference (p=0.006). Uveitis was less present in SpA associated with inflammatory bowel disease (p=0.004). However, we did not find a significant association with gender (p=0.61), age at diagnosis (p=0.69), age of onset of symptoms (p=0.8), diagnostic delay (p=0, 58), smoking (p=0.06), clinical forms of SpA (p=0.71), coxitis (p=0.6), HLA B27 antigen (p=0.17), ESR (p=0.56), CRP (p=0.99) and ASDAS-CRP (p=0.51).
Conclusion: In our study, the prevalence of uveitis was 11.3%. Its presence was associated with a higher activity according to the BASDAI, and it was associated with a higher use of biological treatments.

AB1028 IS THERE AN ASSOCIATION BETWEEN SERUM LEVELS OF BIOMARKERS OF OSTEOPROLIFERATION AND MARKERS OF INFLAMMATION IN SPONDYLOARTHRITIS?

Keywords: Spondyloarthritis, Biomarkers

Z. Zeineb[1], K. Maatallah[1], I. Ayadi[2], H. Ferjani[1], M. Kallel Sellami[2], D. Ben Nessib[1], D. Elhaj Mahmoud[2], W. Kaabachi[2], D. Kaffel[1], L. Laadhar[2], W. Hamdi[1]. [1]*Faculty of Medicine of Tunis, University Tunis El Manar, Tunisia, Rheumatology Department, Kassab Orthopedics Institute, Ksar Saïd, Tunisia, Tunis, Tunisia*; [2]*Faculty of Medicine of Tunis, University Tunis El Manar, Tunisia, Immunology Departement, La Rabta Hospital, Tunis, Tunis, Tunisia*

Background: The two most studied inhibitors of the Wnt signaling pathway in spondyloarthritis (SpA) are Dickkopf-1 (DKK-1) and Sclerostin. Their dysfunction would be responsible for bone formation phenomena. Osteoprotegerin (OPG), a potent inhibitor of osteoclasts and regulated by the Wnt pathway, has also been implicated in this osteoformation phenomenon.
Objectives: Our work aimed to determine the associations between serum levels of DKK-1, Sclerostin, OPG, and markers of inflammation in SpA.
Methods: It was a cross-sectional study including patients with SpA meeting ASAS criteria. Data collected included sociodemographic and disease characteristics, C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR). Biomarker assays were performed using an ELISA technique.
Results: One hundred and nine patients were included, 68 men and 41 women. The mean age of the patients was 43 ± 12 years [19-79]. The mean age of disease onset was 30.6 ± 11 years [5-56]. The mean duration of SpA at inclusion was 12.6 ± 9.8 years [1 - 62]. Forty-nine percent of patients had a biological inflammatory syndrome (BIS). The mean ESR was 28.6 ± 21.2 mm/h [10 - 110 mm/h], and the mean CRP value was 15.2 ± 23.4 mg/L [1 - 153 mg/L]. Median serum levels, in pg/mL, of DKK-1, Sclerostin, and OPG were 146.7 [0-455.3], 32.8 [0-488], and 471 [0-1613.6], respectively. The biological inflammatory syndrome was not associated with DKK1 level (p=0.800). It tended to be associated with OPG and Sclerostin levels (p=0.085 and p= 0.051, respectively). ESR was negatively correlated with Sclerostin (r=-0.222; p=0.022). The CRP level appeared to be negatively correlated with OPG (r=-0.161; p=0.099) and Sclerostin levels (r=-0.181; p=0.064).
Conclusion: An association between markers of inflammation and inhibitors of the wnt signaling pathway as well as OPG was shown by our study, suggesting that actors of systemic inflammation may influence the secretion of these biomarkers.

Background: Sacroiliac radiographs in axial spondyloarthritis (axSpA) allow the evaluation of sacroiliac and hip joint involvement, as well as the symphysis region and ischial enthesis regions. In this study.
Objectives: It is planned to test and review the relationship between the presence of ischial enthesitis and disease-related factors, the presence of peripheral enthesitis and other radiological features of involvement.
Methods: Of 355 patients with axSpA diagnosis and follow-up sacroiliac joint radiography evaluated for ischial enthesitis were included in the study. Since the presence of ischial enthesitis was detected in 1 patient in non-radiographic axSpA patients, the analysis was performed with radiographic axSpA patients. Demographic, clinical and laboratory characteristics of the patients were recorded. Irregular appearance in the region where tendons and ligaments attach to the bone (lower region) in the pubic arms in the sacroiliac joint X-ray was evaluated as ischial enthesitis. Radiological evaluation was performed by a rheumatologist (EDE) and a radiologist (AS). The relationship between the presence of ischial enthesitis and other factors was tested with both univariate and multivariate analysis methods.
Results: The mean age at diagnosis (±SD) was 42 (11.9) and 74% of the patients included in the study were male. Demographic and radiological characteristics of the study group are summarized in Table 1. Ischial enthesitis was detected in 57 (16.1%) patients. Gender (p=0.006), symptom duration (p<0.001), duration of diagnosis (p=0.002), HLA-B27 positivity (p=0.09), radiographic hip involvement (p=0.09) total sacroiliac joint score (p<0.001), baseline cervical mSASS score (p<0.001), basal lumbar mSASS score (p<0.001), presence of symphysis (p<0.001), serum CRP level (p=0.014) found to be associated with ischial enthesitis in univariate analysis. There was no correlation between the presence of ischial enthesitis and heel pain (p=0.61) or SPARCC enthesitis score (p=0.59). In the two models established in the multivariate analysis, serum CRP level (p=0.022), presence of cervical syndesmophyte (p=0.042), presence of total ankylosis in the sacroiliac joint (p=0.012) and SIE score (p=0.001) were found to be independent variables associated with the presence of ischial enthesis.
Conclusion: Although ischial enthesitis can be seen independently of clinical heel pain in axSpA patients, it can also be an indicator of radiographic damage.

AB1030 FACTORS ASSOCIATED WITH CERVICAL INVOLVEMENT PROGRESSION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis

E. Durak Ediboglu[1], A. Sinci[2], D. Solmaz[3], E. Erpek[3], H. Cinakli[3], G. Alp[3], E. Otman Akat[3], A. Özkan[3], İ. Kurut Aysin[3], H. Kocaayan[3], M. Ozmen[3], S. Akar[3]. *[1]Hatay Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey*; *[2]Izmir Katip Çelebi University, Department of Radiology, Izmir, Turkey*; *[3]Izmir Katip Çelebi University, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey*

Background: The evaluation of cervical, lumbar spinal structures and hip joint has been important and this is reflected in the variables in the scoring systems in patients with axial spondyloarthritis.
Objectives: In this study, it was aimed to investigate the factors affecting cervical spinal progression.
Methods: The patients with the diagnosis of axSpA who were followed-up at least two years, and whose cervical mSAS scores were evaluated by servical X-ray were included in the study. A change of 1 unit or more in the modified Stoke Ankylosing Spondylitis Spine score (mSASS) between two radiographs taken at least two years apart was considered progression. Radiological evaluation was done by a rheumatologist (EDE) and a radiologist (AS). Demographic, clinical and laboratory characteristics of the patients were recorded. The relationship between the presence of cervical progression and other factors was tested with both univariate and multivariate analysis.
Results: Of the 237 patients included in the study, 62% were male and the median age at diagnosis (IQR) was 33 (14) and 68.8% of the patients were radiographic axSpA. The demographic, clinical and laboratory characteristics of the study groups were summarized in Table 1. Cervical progression was detected in 42 of the patients (17.7%) with cervical radiography in the median (IQR) 3 (2) follow-up period. Presence of cervical progression was related with symptom duration (p=0.004), age at symptom onset (p=0.011), age at diagnosis (p<0.001), presence of total ankylosis in sacroiliac joint X-ray (SIE score=8) (p<0.001), cervical mSAS score (p<0.001), total SSI score (0-8) (p<0.001), baseline cervical mSAS score (p<0.001), presence of cervical syndesmophyte (p<0.001), baseline lumbal mSAS score (p<0.001), the presence of lumbal syndesmophyte (p<0.001). Cervical progression was not associated with HLA-B27, smoking, presence of either extramusculoskeletal or peripheral involvement, baseline disease activity scores (BASDAI, ASDAS-CRP). In two different models were established in multivariate analysis, age at diagnosis(p<0.001), presence of cervical syndesmophyte (p=0.014), sacroiliac joint score (p=0.004) were associated with cervical progression.
Conclusion: It should be kept in mind that the age at diagnosis, presence of spinal involvement and sacroiliac joint score may be predictors of cervical spinal progression in the follow-up of patients in axSpA.

AB1031 ENDOTHELIAL DYSFUNCTION AND SUBCLINICAL ATHEROSCLEROSIS IN RADIOGRAPHIC AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHROPATHY

Keywords: Comorbidities, Cardiovascular disease, Spondyloarthritis

M. H. Abu-Zaid[1], N. F. Darwish[1], S. A. A. Tabra[1]. *[1]*Tanta University. Faculty of Medicine, Rheumatology and Rehabilitation, Tanta, Egypt

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease which includes radiographic subtype [ankylosing spondylitis (AS)], and non-radiographic subtype (nr-axSpA)[1]. Chronic inflammatory disorders, such as axSpA, are associated with increasing cardiovascular (CV) risk which is mainly due to the inflammatory burden[2].
Objectives: Evaluation of endothelial dysfunction and subclinical atherosclerosis in axSpA and comparison between in AS and nr-axSpA regarding disease activity, functional status and Subclinical atherosclerotic disease.
Methods: Eighty Patients fulfilling the ASAS classification criteria plus 60 healthy individuals were included in this study. Patients were divided into two groups;

50 patients with AS (GI) and 30 patients with nr-axSpA (G II), while G III was the control group. Patients with nr-axSpA were defined as the absence of definite sacroiliac (SI) joint changes on plain radiograph but with active sacroiliitis on MRI and at least one of the characteristic traits of SpA according to the 2009 ASAS criteria[3]. Demographic data, duration of the disease, delay in diagnosis, extra-articular manifestations, smoking, comorbidities and detailed medication history were taken. Disease activity were assessed by Ankylosing Spondylitis Disease Activity Score (ASDAS) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Physical function was assessed by the Bath Ankylosing Spondylitis Functioning Index (BASFI) & patient-reported outcome measures (PROMs). Serum endothelin-1 and carotid intima-media thickness (cIMT) were measured to assess endothelial dysfunction and subclinical atherosclerosis.

Results: There was no significant difference between the GI & GII regarding age and gender (p>0.05), while AS patients had longer mean disease duration than nr-axSpA (6.6 years vs 3.7 years, P < 0.001). Forty-eight patients out of 50 in G I were receiving biological therapy while 23 patients from 30 in G II were receiving biological therapy with significant difference between the two groups (p=0.02). There were no significant differences between GI and GII regarding comorbidity, and smoking status (p>0.05). Regarding disease activity; we found no significant difference between GI and GII in ASDAS-CRP (2.0±0.9, & 2.2±1.02 respectively), also there was no significant difference between GI and GII in ASDAS (3.9±1.3, & 4.1±1.1 respectively). There was no notable differences between the AS and nr-axSpA neither in BASFI nor in PROMs (p>0.05). The serum endothelin-1 was significantly elevated in both patients' groups when compared with controls (GI: 2.3±1.5, GII: 2.05±1.3, controls: 0.76±0.5) with no significant difference between GI and GII (p>0.05). When we measured cIMT we noticed a significant increase in the thickness of cIM of patients in comparison with controls (P < 0.01), while there was no significant difference between the AS and nr-axSpA (p>0.05). We found 6 AS patients had atheromatus plaque, while 4 patients had atheromatus plaque in nr-axSpA group with no significant difference between the 2 groups (p= 0.86) There was positive correlation between endotheline-1, cIMT and both ASDAS-CRP & BASFI.

Conclusion: Axial spondyloarthritis patients (either AS or nr-axSpA) had higher risks for endothelial dysfunction and subclinical atherosclerosis. patients with AS & nr-axSpA shared a comparable disease activity, functional disability and endothelial dysfunction.

Background: Ankylosing spondylitis (AS) is associated with cardiac manifestations such as aortic regurgitation. However, contemporary follow-up studies are lacking.

Objectives: To investigate the course of aortic regurgitation and proximal aortic root diameter in patients with AS examined with echocardiography at baseline (2009-2011) and at follow-up (2014).

Methods: At baseline, 187 patients with AS (56% men, mean age 50 years) were examined with echocardiography, of whom 34 (18%) had an aortic regurgitation of mild to severe grade[1]. Of these 34 patients, 26 agreed to participate in a follow-up with echocardiography in 2014. In addition, we re-assessed 26 sex- and age-matched patients from the same AS cohort, but without aortic regurgitation at baseline. The presence and severity of aortic regurgitation (none, mild, moderate, severe) as well as the proximal aortic root diameter were assessed. Related-samples Wilcoxon signed rank test was used to analyze the change (Δ) in aortic root diameter from baseline to follow-up, divided by patients with and without aortic regurgitation at baseline and stratified by sex. Mann-Whitney U test was used to compare the Δ aortic root diameter in patients with and without an aortic regurgitation at baseline.

Results: In total 52 patients (54% men, mean age (SD) 62 (11)) were re-examined in 2014. The time between the baseline and follow-up echocardiography examination ranged between 3.0 to 4.7 years with a median of 4.3 years. There were no statistically significant differences in aortic root diameter between baseline and follow-up as shown in Table 1. The distribution of Δ aortic root diameter was not statistically different in patients with an aortic regurgitation at baseline compared to the patients without. The change in aortic regurgitation grade from baseline to follow-up is presented in Figure 1. Of the 26 patients with aortic regurgitation at baseline, two had a more severe grade, eight had a lower grade, and 16 an unchanged grade of aortic regurgitation at follow-up. Of the 26 patients without aortic regurgitation at baseline, two had developed a mild grade of aortic regurgitation at follow-up.

Table 1.

	Patients with aortic regurgitation at baseline (n=26)	Patients without aortic regurgitation at baseline (n=26)
ΔAortic root diameter,mm		
Overall	-1 (-3, 0.25)	-1 (-2, 1.25)
Men	-1 (-3, 2.25)	-1 (-3.5, 1.25)
Women	-0.5 (-3, 0)	0 (-1.75, 1.75)

Δ, change in aortic root diameter from baseline to follow-up. The data is presented in median (25th percentile, 75th percentile).

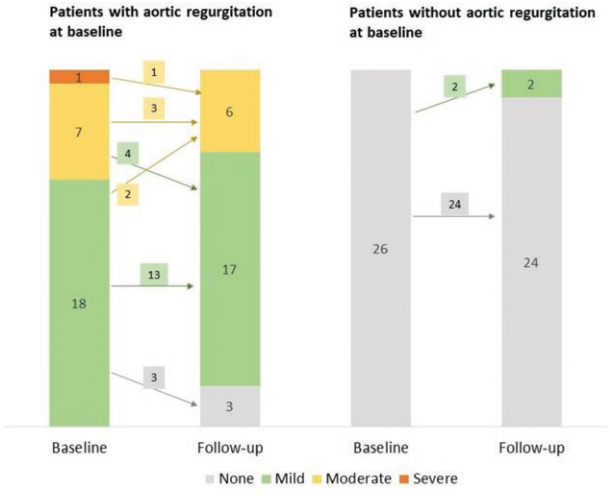

Figure 1.

Conclusion: Although aortic regurgitation like other AS related manifestations might vary over time, the majority of AS patients examined with echocardiography at baseline and after three to five years had an unchanged grade of aortic regurgitation at follow-up.

AB1033 THE RELATIONSHIP BETWEEN LONG-TERM USE OF NONSTEROIDAL ANTI-INFLAMMATORY DRUGS AND KIDNEY FUNCTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Kidneys, Safety

B. S. Koo[1], S. Hwang[2], S. Y. Park[3], J. H. Shin[4], T. H. Kim[4]. *[1]Inje University Seoul Paik, Rheumatology, Seoul, Korea, Rep. of (South Korea)*; *[2]Inje University Seoul Paik, Nephrology, Seoul, Korea, Rep. of (South Korea)*; *[3]Korea National Open University (KNOU), Seoul, Statistics, Seoul, Korea, Rep. of (South Korea)*; *[4]Hanyang University Hospital, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Although nonsteroidal anti-inflammatory drugs (NSAIDs) are the first-line treatment for ankylosing spondylitis (AS), their effect on kidney function remains unclear.
Objectives: This longitudinal study investigated the correlation between long-term NSAID use and kidney function in patients with AS using electronic medical records.
Methods: The electronic medical records of 1,280 patients with AS collected from a single center between January 2001 and December 2018 were reviewed. The Assessment of Spondyloarthritis International Society (ASAS) NSAID Intake Score was used to determine the cumulative dose of all NSAIDs prescribed for a different time intervals. Each ASAS NSAID Intake Score was obtained for intervals of 6 months, 1 year, 2 years, 3 years, 5 years, and 10 years. The correlation between the ASAS NSAID Intake Score and final estimated glomerular filtration rate (eGFR) for each interval was investigated.
Results: The mean ASAS Intake Scores for 6-month, 1-year, 2-year, 3-year, 5-year, and 10-year intervals were 55.30, 49.28, 44.84, 44.14, 44.61, and 41.17, respectively (Figure 1). At each interval, the pearson correlation coefficients were -0.018 (95% CI: -0.031 – -0.006, p=0.004), -0.021 (95% CI: -0.039 – -0.004, p=0.018), -0.045 (95% CI: -0.071 – -0.019, p=0.001), -0.069 (95% CI: -0.102 – -0.037, p<0.001), -0.070 (95% CI: -0.114 – -0.026, p=0.002), -0.019 (95% CI: -0.099 – 0.062, p=0.645), respectively. There was a very weak negative relationship between ASAS Intake Score and eGFR at each interval.
Conclusion: Long-term NSAID use did not correlate with kidney function based on real-world data in patients with AS.

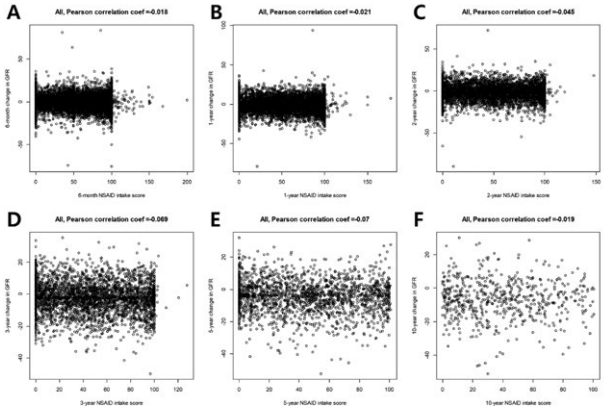

Figure 1. Scatter plots for NSAID intake score and eGFR changes of 6 months (A), 1 year (B), 2 years (C), 3 years (D), 5 years (E), and 10 years (F) interval in overall patients.

AB1034 COSTOVERTEBRAL JOINTS INVOLVEMENT IN RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: A CASE-SERIES COMPUTED TOMOGRAPHY STUDY

Keywords: Spondyloarthritis

A. Shouval[1], S. Croitoru[2], S. Keret[3], I. Eshed[4], G. Slobodin[3]. *[1]Bnai Zion Medical Center/ויצ ינב יאופרה זכרמה, Rheumatology, Haifa, Israel*; *[2]Bnai Zion Medical Center/ויצ ינב יאופרה זכרמה, Radiology, Haifa, Israel*; *[3]Bnai Zion Medical Center/ויצ ינב יאופרה זכרמה, Reumatology, Haifa, Israel*; *[4]Tel-HaShomer The Sheba Medical Center, Radiology, Ramat Gan, Israel*

Background: The involvement of the costovertebral joints (CVJ) and its radiographic patterns in patients with radiographic axial spondyloarthritis (rAxSpA) and thoracic pain were described more than three decades ago, however the extent and details of structural damage in the CVJ have never been assessed.
Objectives: To evaluate structural changes of CVJ in patients with rAxSpA using available computed tomography (CT) studies.
Methods: Available chest or thoracic spine CT studies of 17 patients with rAxSpA and 17 patients with rheumatoid arthritis (RA) were analyzed. Ankylosis, erosions, joint space narrowing and osteophytes of both components of the CVJ, including head-vertebral joints (HVJ) and costotransverse joints (CTJ), were noted and compared between patient groups. The distribution of the structural changes of the CVJ along the thoracic spine was assessed.
Results: The groups were similar by patients' average age, but the rAxSpA group included more males (11/17) compared to the RA group (4/17, p=0.036). In all, 748 CVJ were assessed in each patient group, including 408 head-vertebral joints (HVJ) and 340 costotransverse joints (CTJ). rAxSpA patients had significantly more total CVJ lesions (p<0.001 for all comparisons), more lesions in the HVJ (p<0.001, for all comparisons), and more lesions in the CTJ (p≤0.005, for all comparisons, except for osteophytes), compared to RA group. All types of lesions, including ankylosis, erosions, narrowing, and osteophytes, were seen more frequently in rAxSpA patients. Joint space narrowing and ankylosis of the CVJ were the most frequently seen findings in rAxSpA and were distributed throughout the thoracic spine.
Conclusion: Structural pathology of the CVJ was more commonly observed in patients with rAxSpA than in RA patients in this study.

Spondyloarthritis - clinical aspects (other than treatment)

AB1035 TRANSLATION AND CROSS-CULTURAL ADAPTATION OF THE ASAS HEALTH INDEX ENVIRONMENTAL FACTORS ITEM SET INTO SWEDISH AND ASSESSMENT OF RELIABILITY OF THE SWEDISH VERSIONS OF ASAS HEALTH INDEX AND ENVIRONMENTAL FACTORS ITEM SET

Keywords: Outcome measures, Spondyloarthritis, Quality of life

C. Feldthusen[1,2], M. Hallström[1,3], A. D'elia[4], A. Deminger[1,3], U. Kiltz[5], H. Forsblad-D'elia[1,3]. *[1]Institute of Medicine, Sahlgrenska Academy at University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; *[2]Region Västra Götaland, Sahlgrenska University Hospital, Department of Occupational Therapy and Physiotherapi, Gothenburg, Sweden*; *[3]Region Västra Götaland, Sahlgrenska University Hospital, Department of Rheumatology, Gothenburg, Sweden*; *[4]Institute of Population Health, Policy and Systems, University of Liverpool, Department of Public Health, Liverpool, United Kingdom*; *[5]Ruhr-Universität Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany*

Background: The impact of axial spondyloarthritis (axSpA) on health-related quality of life can be substantial[1], affecting both physical and mental health[2]. There is a need to assess the effect with disease-specific instruments. A global collaboration developed the Assessments of SpondyloArthritis international Society Health Index (ASAS HI) and Environmental Factors Item Set (EFIS). These instruments measure everyday function and health across aspects typical and relevant for patients with axSpA[3]. These instruments have been translated into 35 languages[4] but only the ASAS HI component has been translated into Swedish.

Objectives: To translate and culturally adapt EFIS into Swedish, and to assess reliability of the Swedish ASAS HI and EFIS.

Methods: Patients with axSpA were recruited from the rheumatology clinic at Sahlgrenska University Hospital, Sweden. ASAS HI and EFIS contain 17 and 9 items respectively, with dichotomous response options; "I agree" or "I do not agree". The total sum of ASAS HI ranges from 0 to 17, lower score indicating better health status. EFIS does not provide a sum score due to its multidimensional nature. Translation and cultural adaptation of EFIS was carried out using a forward–backward procedure consisting of: Initial translation; synthesis of the translations; back translation; expert committee review; field testing with cognitive debriefing[5]. The translations were performed separately by translators with clinical perspective and professional translators with no medical or clinical background. Reliability was analysed by internal consistency, evaluated with the Cronbach's alpha coefficient for ASAS-HI, and test-retest reliability using the intraclass correlation coefficient (ICC) for ASAS-HI (sum-score) and EFIS (discrete items).

Results: Ten patients were recruited to the field test and 61 patients to the reliability study of which 53 (87%) returned a second questionnaire after 1 week and were included in the test-retest reliability study (Table 1). *Translation and cross-cultural adaptation of the EFIS*. The translators produced a prefinal Swedish version of EFIS. The field test was performed in 10 patients and resulted in minor rewording. *Internal consistency.* ASAS HI scores showed an acceptable internal consistency; Cronbach's alpha 0.79. *Test-retest reliability.* ASAS HI sum score showed excellent reliability; ICC (95% CI) 0.87 (0.78-0.93), P-value <0.001. ASAS EFIS individual items reliability ranged from poor for item 2, 3 and 8 to excellent for item 1 and 9; ICC (95% CI) from -0.43 (-0.83 to 0.41), P-value 0.56, to 0.89 (0.81 to 0.94), P-value <0.01.

Conclusion: A Swedish version of EFIS has been produced and uploaded on ASAS website[4]. The Swedish version of ASAS-HI showed acceptable internal consistency and excellent test- retest reliability. Test-retest reliability for individual items of EFIS varied from poor to excellent.

AB1036 FACTORS ASSOCIATED WITH HIP INVOLVEMENT IN SPONDYLOARTHRITIS

Keywords: Epidemiology, Enthesitis

S. Oulebsir[1], S. Affaf[1], S. Bennedjema[1], A. Djebbari[1], B. Abdelatif[2], M. Houbi[1], A. Abi Ayad[1], C. Makhloufi-Dahou[3]. *[1]HCA Hospital Kouba, Departement of Rheumatology, Kouba, Algeria*; *[2]hospital Bouchaoui, Departement of Rheumatology, Bouchaoui, Algeria*; *[3]Hospital Bab El Oued, Departement of Rheumatology, Algiers, Algeria*

Background: Hip involvement in spondyloarthritis determines a large part of the functional prognosis and affects negatively the patient's life. Identifying these factors could influence our management strategy by developing specific therapeutic protocols.

Objectives: The objective of this work is to determine the factors associated with hip involvement during spondyloarthritis.

Methods: The study is a single-center prospective observational study, carried out during the period extending between January 2020 and January 2022. Spa patients meeting the criteria for ASAS were included. On a patient-by-patient basis, clinical, biological, and imaging data were collected.

Results: In total, 259 patients with consecutive spondyloarthritis were assessed. Of these, 80 patients (30.88%) had hip involvement associated with spondyloarthritis, including 66 men and 14 women (gender ratio = 4.7), with an average age of 37.66 and 11.3 years. It was bilateral in 70% of cases, and inaugural in over half of patients (55% of cases). The biological inflammatory syndrome was observed in 72.5% of cases and HLA B 27 was found in ¾ of patients. The anatomio-radiological forms observed were: the destructive form (36.76%), the condensant constructive form (22.05%), the initial form (24.26%), and the synostotic form (16.91%). TNF alpha treatment was initiated in 85% of cases, with a third of patients receiving PTH. Factors related to hip involvement were: functional impotence (BASFI), limitation of spinal and joint mobility (BASMI, inter-malleolar distance), structural damage to the SpA (total BASRI), presence of HLA B27, and initiation of anti-TNF alpha treatment. On the other hand, the age of hip involvement and spa, gender, bilateral involvement, high scores of the BASDAI and ASDAS indices, and the presence of a biological inflammatory syndrome did not seem to be involved.

Conclusion: The occurrence of hip involvement during spondyloarthritis seems to be frequent in our country. Hip involvement is one of the elements of poor prognosis and its presence predicts a severe form of the disease.

AB1037 ARE THE CLINICAL SCALES USED TO ASSESS DISEASE ACTIVITY AND FUNCTIONAL ABILITY IN AXIAL SPONDYLOARTHROPATHY REALLY RELIABLE?

Keywords: Spondyloarthritis

M. A. Mortada[1], N. Ehab[1], S. Elnaggar[2], E. Elshahawy[2]. [1]*Zagazig University, Rheumatology, Zagazig, Egypt*; [2]*Zagazig University, Commnity, Zagazig, Egypt*

Background: Evaluation of disease activity and functional impairment in Axial spondyloarthritis (AxSpA) are important in therapeutic plan. Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS) and The Bath Ankylosing Spondylitis Functional Index (BASFI) scores are based largely on subjective measures, which liable to change depending on patient's expression, culture, and awareness.
Objectives: Assessment of reliability of BASFAI, BASDAI, ASDAS-ESR, and ASDAS-CRP as a total score and individual questions in patients with AxSpA.
Methods: This cross-sectional study was conducted on 103 patients with AxSpA according to the ASAS classification criteria for AxSpA. Each patient completed BASFAI, BASDAI, ASDAS-ESR, and ASDAS-CRP during their routine visit for follow up with one rheumatologist. Then the same patients completed the three questionnaires again in the same day or on the second day with another rheumatologist.
Results: Internal consistency and reliability of ASDAS-ESR, ASDAS-CRP, BASDAI, and BASFAI scores was good (ICC was 0.841, 0.820, 0.767, and 0.852 respectively). Reliability of BASFAI score was better than that of ASDAS-ESR, ASDAS-CRP, BASDAI scores, and that of ASDAS-ESR, ASDAS-CRP was better than reliability of BASDAI score.

Table 1. Interclass Correlation Coefficient of BASFAI in AxSpA patients reported by observer 1 and observer 2

Variables	Cronbach's Alpha	ICC	CI
1) Putting on your socks or tights without help or aids (e.g sock aid) (F1).	0.931	0.871	0.815-0.911
2) Bending from the waist to pick up a pen from the floor without aid (F2).	0.903	0.823	0.749-0.877
3) Reaching up to a high shelf without help or aids (e.g helping hand) (F3).	0.837	0.719	0.612-0.801
4) Getting up from an armless chair without your hands or any other help (F4).	0.751	0.601	0.462-0.711
5) Getting up off the floor without help from lying on your back(F5).	0.779	0.638	0.508-0.740
6)Standing unsupported for 10 minutes without discomfort (F6).	0.707	0.547	0.396-0.669
7) Climbing 12-15steps without using a handrail or walking aid (F7).	0.863	0.760	0.664-0.831
8) Looking over your shoulder without turning your body (F8).	0.887	0.798	0.715-0.858
9)Doing physically demanding activities (e.g physiotherapy exercises, gardening or sports) (F9).	0.817	0.690	0.573-0.779
10) Doing a full day's activities whether it be at home or at work (F10).	0.748	0.598	0.458-0.709
Total BASFAI Score	0.920	0.852	0.789-0.898

ICC (.21 to.4) was indicative of fair agreement, ICC (.41 to.6) was indicative of moderate agreement, ICC (.61 to.8) was indicative of substantial agreement, ICC (.81 to.99) was indicative of almost perfect agreement, and ICC (1) was indicative of perfect agreement.

Conclusion: Some questions of ASDAS, BASDAI, and BASFAI scores are more reliable than others, this depends on the question. The answers of the questions that assess sensation of pain, are liable to change. While the answers of other questions that assess stiffness or assess its duration are less liable to change. Questions that assess certain daily activity are more reliable than that assess the ability to do more than one activity.

AB1038 RELATIONSHIP BETWEEN ANKYLOSIS AND PHYSICAL FUNCTION ASSESSMENT IN ANKYLOSING SPONDYLITIS

Keywords: Quality of life, Spondyloarthritis, Patient reported outcomes

M. Suzuki[1], K. Kishimoto[1], D. Kihira[1], R. Sato[1], J. Hasegawa[1], M. Maeda[1], Y. Ohashi[1], K. Terabe[1], S. Asai[1], S. Imagama[1]. [1]*Nagoya University Graduate School of Medicine, Department of Orthopedic Surgery and Rheumatology, Nagoya, Japan*

Background: Ankylosing spondylitis (AS) is a progressive inflammatory disease affecting the spine and large joints of the extremities. Ankylosis of the spine and sacroiliac joints affects patients not only physically but also psychologically and socially, resulting in a significant decline in quality of life (QOL) and disruption of daily activities [1]. However, it is unclear to what extent the progression of the disease affects physical function and patient subjective evaluation.
Objectives: The purpose of this study was to investigate the relationship between the degree of progression of ankylosis, physical function, and frailty in patients with AS.
Methods: Twenty-four patients with AS attending our hospital who underwent full spine computer tomography (CT) and physical function assessment were included in the study. The anterior-posterior, intervertebral joint, and interspinous process ankylosis sites and number of ankylosis (whole spine/cervical spine/thoracic spine/lumbar spine) and sacroiliac joint ankylosis were evaluated in each vertebra. Patient-objective measures of physical function included gait speed, grip strength, Timed Up and Go test (TUG), time of five sit-to-stand, and Bath Ankylosing Spondylitis Metrology Index (BASMI), and patient-subjective measures of physical function included Bath Ankylosing Spondylitis Functional Index (BASFI), Kihon Checklist (KCL), the 25-question Geriatric Locomotive Function Scale (GLFS-25), and Beck Depression Inventory (BDI-II) as subjective assessments. Spearman's rank correlation coefficient was used to analyze the correlation between the degree of progression of ankylosis and each of the assessment items.
Results: The mean age (± standard deviation) at the time of the study was 40±15 years, 79% were male, 50% were HLA-B27 positive, and the disease duration was 13±9 years. Age was significantly correlated with the number of thoracic spine ankylosis (r=0.449), and disease duration with the number of total spine/cervical spine/thoracic spine/sacroiliac joint ankylosis (r=0.600/0.553/0.635/0.510). BASMI, an objective patient assessment, showed a significant correlation with the number of total spine/cervical spine/thoracic spine/lumbar spine ankylosis (r=0.732/0.653/0.707/0.615), but not with walking speed, grip strength, TUG, or time of five sit-to-stand. BASFI, a subjective patient assessment, showed a significant correlation with the number of total spine/ cervical spine/ thoracic spine/ lumbar spine ankylosis(r=0.680/0.729/0.600/0.469), and the GLFS-25 (r=0.418/0.500) with the number of total spine/ cervical spine ankylosis. BDI-II, an assessment of psychiatric symptoms, and KCL, an assessment of frailty, showed no correlation with the number of ankylosis.
Conclusion: BASFI and GLFS-25, physical function assessments, were significantly correlated with spinal ankylosis in AS patients, and the degree of progression of spinal ankylosis was found to interfere with daily life.

AB1039 A COMPARATIVE STUDY TO ASSESS THE DIFFERENCES IN DISEASE CHARACTERISTICS IN PATIENTS WITH NON-RADIOGRAPHIC AND RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Descriptive studies, Inflammatory arthritides

S. Ghosh[1], K. Telang[1], L. Sharma[1], D. Yadavalli[1], W. Kazi[1], V. Singal[1], R. Gupta[1]. [1]*Medanta - The Medicity, Rheumatology & Clinical Immunology, Gurgaon, India*

Background: Spondyloarthritis (SpA) is an umbrella term for a group of clinically heterogeneous chronic inflammatory diseases, with Ankylosing Spondylitis (AS) having the characteristic radiographic features of sacroiliitis and spinal deformities, while the other subtypes of SpA have some common as well as unique

articular and extra-articular manifestations. Recent advances in early diagnosis have differentiated axial SpA into radiographic and non-radiographic subsets but the exact differences between them are debatable.

Objectives: This study was conducted to assess and compare the clinical, laboratory, and radiologic characteristics of Indian patients with radiographic and non-radiographic axial SpA.

Methods: This was a cross-sectional, observational, comparative study conducted at a 1250-bedded tertiary care hospital. Between February 2020 and December 2021, all consecutive adult patients classified as having Axial Spondyloarthritis as per the Assessment of Spondyloarthritis international Society (ASAS) 2009 Classification Criteria and with symptom duration of at least 3 years were included in the study after taking their informed consent. Patients were classified as radiographic (AS) or non-radiographic Axial SpA (nr-Axial SpA) by two independent and blinded rheumatologists with over twenty years of experience in their field each, based on findings on anteroposterior plain radiographs in the supine position. Demographic details, articular and extra-articular manifestations, comorbidities, and relevant family history were assessed along with the levels of inflammatory markers and HLA B27 status. The study was approved by the Institutional Review Board and the Institutional Ethics Committee.

Results: 209 patients consented to this study, with 160 being classified as radiographic and 49 as non-radiographic axial SpA. 79.4% of the patients were male. The mean age at symptom onset was 27.69 ± 9.33 years for our cohort, with a median duration of 50 months. There was a significantly higher proportion of males (85% vs 15%, p <0.001), patients with enthesitis (74% vs 41%, p 0.05), and hypertension among the radiographic subgroup. 44% of our patients had bilateral Grade 2 changes on their sacroiliac joint radiographs according to the modified New York Criteria, and there was a significant positive correlation between increasing symptom duration and worsening radiographic grades of sacroiliitis, but there were no significant differences in the remaining clinical features, HLA B27 positivity, or age at symptom onset among the AS and nr-Axial SpA patients. Mean values of BASDAI, BASMI, and ASDAS-ESR scores were also significantly higher in patients with radiographic Axial SpA.

Conclusion: Data from our Indian cohort of axial Spondyloarthritis revealed a significant association of radiographic disease with male gender and the presence of enthesitis, as well as higher mean values of inflammatory markers and composite scores. However, non-radiographic axial SpA was similar to AS as far as most other features were concerned. With increasing symptom duration, the majority of patients may develop radiographic disease, and they may be considered as two ends of the same spectrum, justifying early therapy even in nr-axial SpA.

AB1040 CHARACTERIZATION OF ANXIETY AND DEPRESSION AND THEIR IMPACT ON DISEASE ACTIVITY, FATIGUE AND QUALITY OF LIFE IN SPONDYLARTHRITIS PATIENTS TREATED WITH ANTI-TUMOR NECROSIS FACTOR ALPHA AGENTS

Keywords: bDMARD, Spondyloarthritis, Quality of life

D. Santos Oliveira[1,2,3], A. Martins[1,2], R. Nicolau[2,4], C. Vaz[1,2], T. Martins-Rocha[1,2], A. Bernardo[1], M. Bernardes[1,2], L. Costa[1]. *[1]Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal*; *[2]Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal*; *[3]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; *[4]Centro Hospitalar Tondela-Viseu, Viseu, Rheumatology Department, Viseu, Portugal*

Background: The psychological health of patients with spondylarthritis (SpA) influences their response to anti-tumor necrosis factor alpha (anti-TNF-α) therapy. However, little is known about the correlation between anxiety and depression symptoms and clinical outcomes over time.

Objectives: Hence, based on clinical practice setting, this study, aimed to explore the impact of anxiety and depression symptoms on clinical outcomes in patients with SpA treated with anti-TNF-α agents over time.

Methods: An observational retrospective longitudinal cohort study was conducted. Adult patients with diagnosis of SpA according to Assessment of Spondylarthritis International Society (ASAS) classification criteria, who started their first anti-TNFα agent between 2002 and 2022 were included. Sociodemographic, clinical and laboratory data were obtained from the national register Reuma.pt at the time of initiation of the first anti-TNF-α agent and after 12 months (M). Anxiety and depression symptoms were assessed by Hospital Anxiety and Depression Scale (HADS). A score ≥8 on the HADS-Anxiety and HADS-Depression indicates the presence of clinically significant anxiety and depression symptoms, respectively. Ankylosing Spondylitis (AS) Disease Activity Score with CRP (ASDAS-CRP) and Bath AS Disease Activity Index (BASDAI) were assessed to measure disease activity. Pain Visual-Analogue-Scale (VAS), Bath AS Functional Index (BASFI) and Bath AS Metrological Index (BASMI) were also collected to assess pain severity and disability. To evaluate enthesitis the Maastricht AS enthesitis score (MASES) was performed. Clinical response was evaluated by ASDAS response. Fatigue was evaluated using Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue: score ≤ 39 indicates the presence of clinically significant fatigue and health-related quality of life with EQ-5D. In order to correlate anxiety and depression with clinical outcomes, Pearson coefficient was used. Linear regression models adjusted for age, gender and disease duration were used to assess the impact of anxiety and depression symptoms on clinical outcomes.

Results: A total of 130 patients with SpA (mean age of 40.6±10.8 years old; 85.4% female; 74% with AS) with a median disease duration of 7 [4-14] years were included. Nearly half (50.6%) of patients had anxiety, 33.8% depression and 30% had both anxiety and depression symptoms. At the baseline, the median of anxiety and depression symptoms was 8 [4.5-12] and 6 [3-8], respectively. At the baseline, there were statistically significant correlations between anxiety and depression symptoms and pain-VAS at night (r_p=0.47, p=0.03 and r_p=0.6, p=0.004, respectively); between depression symptoms and BASMI (r_p=-0.34, p=0.006) and between anxiety and depression symptoms and EQ-5D (r_p=-0.56, p=0.04 and r_p=-0.65, p=0.011, respectively). At 12M, there were statistically significant correlations between anxiety symptoms and BASDAI (r_p=0.23, p=0.03), FACIT-Fatigue (r_p=-0.68, p<0.001) and EQ-5D (r_p=-0.51, p=0.001); and between depression (r_p=-0.65, p<0.001) and EQ-5D (r_p=-0.59, p<0.001). In the multivariable regression models, depression symptoms at baseline moment predicted VAS at night (β=0.6, p=0.06). At 12M anxiety symptoms predicted BASDAI (β=0.2, p=0.027), FACIT-Fatigue (β=-0.7, p<0.001) and EQ-5D (β=-0.5, p<0.002); depression symptoms also predicted EQ-5D (β=-0.6, p<0.001).

Conclusion: Anxiety and depression are common conditions in patients with SpA treated with anti-TNF-α agents. After 12M of treatment, anxiety and depression symptoms predicted worse quality of life and anxiety also predicted higher disease activity and fatigue. Our results encourage the assessment and monitoring of anxiety and depression symptoms over time in these patients in order to design more individualized multidisciplinary approaches. Further longitudinal research is needed to explore the impact of anti-TNF-α agents on anxiety and depression symptoms.

AB1041 AUTOMATED VERTEBRAL FRACTURE ASSESSMENT AS A SCREENING TOOL IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Outcome measures, Imaging, Spondyloarthritis

M. Siderius[1], L. Bares[1], N. Littmann[1], G. Richter[1], Y. Van der Knaap[2], R. Slart[2,3], A. Spoorenberg[1], S. Arends[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]University Medical Center Groningen, Nuclear Medicine and Molecular Imaging, Groningen, Netherlands*; *[3]University of Twente, Biomedical Photonic Imaging, Enschede, Netherlands*

Background: Bone loss reflected by low bone mineral density (BMD) is common in axial spondyloarthritis (axSpA) and often already noticed at early stages of disease. Severe bone loss may lead to vertebral fractures (VF). Prevalent VF, low BMD and older age are well-known risk factors for the development of new VF. Manual assessment of VF according to the method of Genant et al.1 is considered as the gold standard, however, this is time consuming in research and clinical settings. Nowadays, when performing BMD measurements an automated VF assessment (aVFA) can be generated which potentially could be a useful screening method for detecting VF in patients with axSpA.

Objectives: To investigate the performance of aVFA in comparison to manual assessment of radiographic VF according to Genant method in patients with axSpA.
Methods: In this pilot study, we included axSpA patients from the GLAS cohort who underwent DEXA with aVFA and had spinal radiographs available within 1 year. Two independent trained readers assessed the vertebral bodies on the lateral view of the thoracic and lumbar spine for radiographic VFs. Anterior, middle, and posterior heights of the 4th thoracic vertebra (Th4) to the 4th lumbar vertebra (L4) were exactly measured. VFA scans were analyzed from T4 to L4 by using a viewer (QDR, Hologic) with software supplied by the manufacturer in which a computer-aided fracture assessment semi-automatically performs total vertebral assessment for each vertebra (T4–L4) on a lateral VFA image. In both methods, radiographic VF were defined according to the method of Genant et al.[1]. A prevalent VF was defined as ≥20% reduction in any vertebral height. Vertebrae were categorized as grade 0 (normal, <20% height reduction), grade 1 (mild, ≥20-<25% reduction), grade 2 (moderate, ≥25-≤40% reduction) or grade 3 (severe, >40% reduction) fractures. Agreement was compared at vertebral level.
Results: In total, 40 axSpA patients were included; 58% were male, mean age was 46.2±14.2 years, mean symptom duration was 18.0±12.4, 80% were HLA-B27 positive, mean ASDAS was 2.1±1.0 and median mSASSS (n=35) was 5.2 (IQR 1.2-18.3). At group level, median BMD T-score and BMD Z-score of the lumbar spine was -0.5 (-1.3-0.8) and -0.1 (-1.0-1.7), respectively. Osteoporosis was found in 1 (2.6%) patient and 15 (38.5%) patients had osteopenia, of these 56% were male and mean age was 46.7 ± 14.1years. In 477 (91.7%) vertebrae, there was absolute agreement on the aVFA and manual assessment (missing, normal or fracture and accompanying grade and fracture shape). In total, manual assessment detected 2 radiographic VF in 2 patients and aVFA detected 10 VF in 6 patients. The 2 fractures found with the manual method were seen in the lumbar spine, both grade 2 and wedged or biconcave shaped). The 10 aVFA fractures were found in the thoracic (n=5) and lumbar (n=5) spine; grade 1 (n=5), grade 2 (n=4) or grade 3 (n=1) and wedged (n=4) or biconcave (n=6) shaped. The fractures detected with manual assessment were both also detected with aVFA, but the fracture grading was different for one of these fractures (manual grade 2 vs. aVFA grade 3). 8 fractures detected with aVFA were not found with manual assessment. In 6 of these cases, the patient had extensive radiographic damage. X-ray quality was low in the 2 remaining cases. Regarding vertebrae defined as missing; aVFA could not assess 26 (5%) vertebrae compared to 8 (1.5%) for manual assessment.
Conclusion: In this pilot study using data from our observational cohort, aVFA seems a good first screening tool for the detection of radiographic VF in axSpA patients, since no fractures were missed. However, these VF should be confirmed with manual assessment especially in axSpA patients with extensive radiographic damage. A larger study population in which more VF can be identified is needed to more reliably calculate sensitivity and specificity of aVFA.

AB1042 PATIENT CHARACTERISTICS AND SPA FEATURES IN RECENTLY DIAGNOSED AXIAL SPONDYLOARTHRITIS PATIENTS STRATIFIED FOR CLINICAL DIAGNOSIS AND ASAS CLASSIFICATION CRITERIA; RESULTS FROM STANDARD-OF-CARE COHORT

Keywords: Gender/diversity issues, Spondyloarthritis, Epidemiology

J. M. Nijmeijer[1], S. Kieskamp[1], F. Wink[2], S. Arends[1], A. Spoorenberg[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]Medical Center Leeuwarden, Reumatology, Leeuwarden, Netherlands*

Background: In axial spondyloarthritis (axSpA), besides the characteristic symptoms of chronic (inflammatory) back pain and stiffness, patients may suffer from peripheral and extra-skeletal manifestations. Within axSpA, patients can be diagnosed with ankylosing spondylitis (AS) or non-radiographic axSpA (nr-axSpA) based upon the presence or absence of radiographic sacroiliitis. Furthermore, patients can be classified as axSpA according to the ASAS criteria into the imaging arm for which radiographic sacroiilitis and/or sacroiliitis on MRI is mandatory or into the clinical arm for which the presence of HLA-B27 is mandatory. Until now, little is known about patient characteristics in these subgroups of axSpA with a recent axSpA diagnosis.
Objectives: To explore patient characteristics and SpA features in recently diagnosed axSpA patients diagnosed as AS or nr-axSpA and in patients fulfilling the imaging or clinical arm of the ASAS classification criteria.
Methods: This cross-sectional analysis included consecutive axSpA patients between 2009 and 2019 diagnosed no more than 1 year before inclusion in the Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort. Demographic data and all SpA features based on the ASAS classification criteria (sacroiliitis on pelvic radiograph according to the modified New York criteria, sacroiliitis on MRI according to the ASAS criteria, inflammatory back pain (IBP) according to the ASAS criteria; peripheral manifestations (peripheral arthritis, enthesitis and dactylitis); extra-skeletal manifestations (uveitis, psoriasis, inflammatory bowel disease); good response to a NSAID; family history of SpA; HLA-B27 status and CRP level) were collected at the GLAS baseline visits. Characteristics and features of the following axSpA subgroups were analyzed: clinical diagnosis AS vs. nr-axSpA, imaging arm vs. clinical arm of the ASAS classification criteria, only axial disease vs. axSpA with ≥1 peripheral manifestation.
Results: In total, 319 aSpA patients were included, with a mean age of 38.2 ± 12.0 years, 175 (55%) were male, median symptom duration was 25 (19-34) years and 242 (76%) were HLA-B27 positive. 177 (55%) patients were diagnosed with AS and 142 (45%) with nr-axial SpA. AS patients were more often male (65% vs. 42%, p<0.001), had more often IBP (89% vs. 76%, p=0.004), more often a SpA family history (38% vs 22%, p=0.002) and higher CRP (median 5 vs. 2, p=0.001) compared to patients diagnosed with nr-axSpA. The number of SpA features was not significantly different between patients diagnosed with AS or nr-axSpA (median 3.7 vs. 3.7, p=0.73). 265 (83%) axSpA patients fulfilled the imaging arm and 54 (17%) patients fulfilled the clinical arm. Patients fulfilling the clinical arm were per definition all HLA-B27 positive (100% vs. 71%, p<0.001), had more often IBP (92% vs. 80%, p=0.040) and a positive SpA family history (51% vs. 25%, p<0.001) compared to patients fulfilling the imaging arm. Furthermore, patients from the clinical arm showed a higher CRP (median 4 vs. 2, p=0.028) and had more SpA features (median 4.1 vs. 3.6, p=0.019). 200 (64%) axSpA patients had only axial involvement without peripheral manifestations and 111 (36%) axSpA patients had ≥1 peripheral manifestations, of which 69% had a history of peripheral arthritis, 37% enthesitis and 17% dactylitis. Accordingly, axSpA patients with peripheral manifestations presented significantly more SpA features than patients with only axial involvement (median 4.5 vs. 3.2, p<0.001).
Conclusion: In this large cross-sectional study of recently diagnosed (<1 year) axSpA patients, the presence of IBP, positive family history and higher CRP occurred significantly more often in patients diagnosed with AS compared to patients diagnosed with nr-axSpA and in patients fulfilling the clinical arm compared to patients fulfilling the imaging arm of the ASAS classification criteria.

AB1043 PRESENCE OF FAMILY HISTORY MAY CONTRIBUTE TO STRUCTURAL DAMAGE IN NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS UNLIKE RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis

A. Özkan[1], E. Durak Ediboglu[1], H. Kocaayan[1], İ. Kurut Aysin[1], G. Alp[1], E. Erpek[1], E. Otman Akad[1], H. Cinakli[1], D. Solmaz[1], S. Akar[1]. *[1]İzmir Katip Çelebi University Atatürk Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey*

Background:
Objectives: Evaluation of the frequency of family history according to ASAS in patients with axial spondyloarthritis (axSpA) and review of its relationship with clinical features, activity and structural damage.
Methods: In total 578 patients (age: 39.9 ±11.5; male patient: 357, 61.8%) followed in a single center axSpA cohort were included in the study. The study group was consisting 65% radiographic axSpA (r-axSpA). Demographic data and disease related characteristics including disease activity, function, quality of life and spinal mobility were collected. Structural damage was evaluated by using modified Stoke Ankylosing Spondylitis Spine Score (mSASSS).
Results: A family history was found in 153 (26.4%) patients according to ASAS. AS (115; 75%) and psoriasis (54; 35.3%) were the most common diseases in family history. Female sex 45.1% vs 35.8%; p:0.042), longer symptom duration

(16.6 ± 11.7 vs 13.6 ± 9.4; p:0.045), higher body mass index (26.7 ± 4.6 vs 26.0 ± 4.8; p:0.043) and psoriasis (13.1% vs 3.8%; p<0.001) were more frequent in familial cases. HLA B27 positivity was higher tendency without statistical significance in patient with family history (66.4% vs 56.7%; p:0.60). In terms of structural damage, basal syndesmophyte, basal mSSASS, mSSASS progression and new syndesmophyte development could not differ between the groups. Family history was found in 30% of nr-axSpA patients. HLA B27 positivity, higher baseline mSSASS and basal syndesmophyte frequency were found more frequently in patient with family history among nr-AxSpA. And also more mSSASS progression was detected in the same group (Table 1). In the r-axSpA group, there was no difference in structural damage or radiological progression, except for longer symptom duration in those with a family history.

Conclusion: There was a significant frequency of family history in AxSpA and it might be contribute to the disease phenotype at different rates. The presence of family history in both baseline and follow-up data, especially in radiographic, seems to increase severity in disease subgroups.

SELF-REPORTED HIDRADENITIS SUPPURATIVA-LIKE SKIN SYMPTOMS IN PATIENTS WITH SPONDYLOARTHRITIS: RESULTS FROM AN ONLINE SURVEY

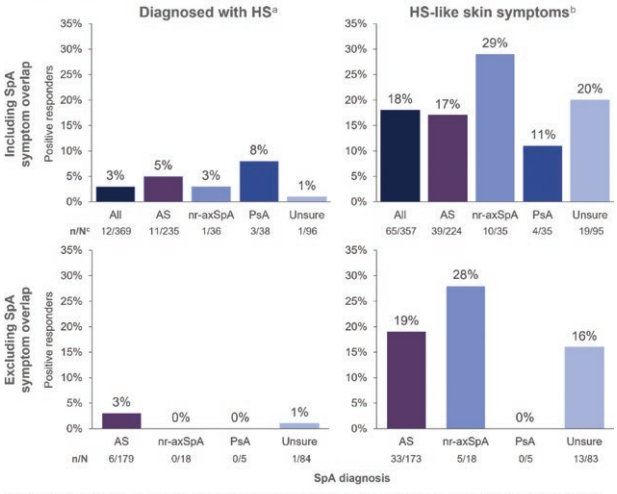
Keywords: Spondyloarthritis, Skin, Psoriatic arthritis

A. Spoorenberg[1], M. Kim[2], I. Pansar[3], H. Lapidus Glassner[4]. [1]*University Medical Center Groningen, Department of Rheumatology and Immunology, Groningen, Netherlands*; [2]*UCB Pharma, N/A, Atlanta, United States of America*; [3]*UCB Pharma, N/A, Brussels, Belgium*; [4]*MyHealthTeam, N/A, San Francisco, United States of America*

Background: Hidradenitis suppurativa (HS) is a chronic immune-mediated disease with known associations with other chronic auto-inflammatory diseases, such as inflammatory bowel disease and spondyloarthritis (SpA).[1–3] However, real-world data on the occurrence of HS in patients with SpA are limited.

Objectives: To explore the proportion of patients with SpA who report having an HS diagnosis from a doctor or report having undiagnosed skin symptoms similar to HS.

Methods: An online survey with validated questions about HS diagnoses/symptoms was conducted from 1–22 September 2021 among users of the social network MySpondylitisTeam, aged ≥21 years and reporting a SpA diagnosis (principally ankylosing spondylitis [AS; also known as radiographic axial spondyloarthritis], non-radiographic axial spondyloarthritis [nr-axSpA], or psoriatic arthritis [PsA]), or a SpA diagnosis but without knowing the specific subtype.[1] Prototypical pictures of HS symptoms were included to help participants identify these symptoms.



Results: 369/448 participants with self-reported SpA diagnoses completed the full survey; 81% were female, 69% aged 50–70 years and most from the US (87%; with a further 8% from the UK and 2% from Canada). While most participants reported that a doctor had diagnosed them with one SpA subtype, others reported diagnoses of >1 SpA subtype, potentially reflecting symptom overlap with different SpA subtypes (SpA symptom overlap) (**Figure 1**). Three percent (12/369) of participants reported an existing HS diagnosis; of the remaining 357 participants without an HS diagnosis, 18% (65/357) self-reported skin symptoms resembling HS. Among the principal SpA subtypes studied, an HS diagnosis was most frequent among participants with PsA (8%; 3/38), while undiagnosed HS-like skin symptoms were reported by 11% (4/35) of the participants with PsA who did not report an HS diagnosis. All participants with PsA and either an HS diagnosis or undiagnosed HS-like skin symptoms also reported having SpA symptom overlap (**Figure 1**). The participants with nr-axSpA exhibited the highest proportion of undiagnosed HS-like skin symptoms (29%; 10/35, including participants reporting SpA symptom overlap) while very low rates of HS diagnoses were reported (**Figure 1**). Among those reporting undiagnosed HS-like skin symptoms (or unsure if they have them), 48% (34/71) had previously discussed their skin symptoms with a healthcare professional. These participants mainly reported being told that their skin symptoms were due to infected hair follicles (44%; 15/34) or cysts (24%; 8/34).

Conclusion: Of the participants surveyed, very few reported an HS diagnosis while a considerably higher proportion reported skin symptoms resembling HS. Despite the limitations and potential biases inherent in online surveys, these results suggest that HS may be underdiagnosed in patients with SpA and highlight a need for further research and potentially, greater awareness of HS in the clinical care of patients with SpA.

Figure. Participants with SpA who self-reported being diagnosed with HS by a doctor (left) or having skin symptoms resembling HS (right)

[a]Results taken from Q8 of the survey, which included the following text: 'Has a doctor ever diagnosed you with HS?'; [b]Results taken from Q9 of the survey, which included the following text and an example picture (not included here): 'We would like to understand whether you have had any signs of HS. HS is a chronic inflammation of the hair follicles. It can occur in the groin or buttocks area, in the armpits, under breasts, on the thighs, or on the back or neck. Signs of HS may not always look like this, but this photo is one example of how it may appear. Have you had painful, recurring abscesses, boils, or lesions on your skin in the past six months?' Participants who answered affirmatively to Q8 were asked not to respond to Q9; [c]Participants (N=369) reporting >1 SpA diagnosis feature in multiple SpA subtype categories.

Abbreviations: AS: ankylosing spondylitis; HS: hidradenitis suppurativa; nr-axSpA: non-radiographic axial spondyloarthritis; PsA: psoriatic arthritis; SpA: spondyloarthritis.

AB1045 IS IT POSSIBLE TO DETECT CHRONIC LESIONS ON MRI IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS?

Keywords: Imaging, Spondyloarthritis

S. Dimitrov[1], S. Hristova[1], R. Moraliyska[1], S. Bogdanova-Petrova[1], T. Shivacheva[1], T. Georgiev[1]. [1]*Medical University Varna, Rheumatology, Varna, Bulgaria*

Background: The absence of categorical radiographic evidence of structural changes in the sacroiliac joints serves to distinguish AS from nr-axSpA. Both groups of patients are characterized by active inflammatory changes, established by magnetic resonance tomography (MRI) of the sacroiliac joints, which, with the progression of the disease, are structurally progressive.
Objectives: To determine whether it is possible to detect erosions, subchondral osteosclerosis and bone marrow metaplasia on a magnetic resonance imaging of the sacroiliac joints in patients with non-radiographic axial spondyloarthritis and symptom duration less than 3 years.
Methods: A cross-sectional survey was conducted with rheumatologists and their consulting patients in Bulgaria from February 2012 through April 2019. Patients who had a rheumatologist confirmed diagnosis of nr-axSpA were eligible to participate. All patients met ASAS criteria for IBP with duration from 3 months to 2 years. All patients had no changes reported after the conventional X-ray of the sacroiliac joints and a performed subsequent MRI. Sacroiliac joint inflammation was assessed using the Canadian Spondyloarthritis Research Consortium (SPARCC). The SPARCC scores of sacroiliac joint inflammation and sacroiliac joint structural damage (SSSD) (erosions, bony brain metaplasia and subchondral osteosclerosis) were evaluated by both - a radiologist and rheumatologist.
Results: A total of 98 patients with non-radiographic were included in this analysis. A higher proportion of patients were male patients (51% vs 37%). The mean age was 33.8±7.71 with mean symptoms duration 0.76±0.26 years. MRI showed bone marrow edema (BME) in all 98 patients and at least 1 structural lesion in 32 patients (92.5%). The most prevalent chronic lesions were erosive changes in 7.14% (n = 7) and narrowed joint space in 7.14% (n = 7). Fat metaplasia was found in 5.10% (n = 5) in the patients with nonradiographic spondyloarthritis. The mean values of SPARCC score in patients with the different arm of nr-ax SpA is 22.42 ± 15.18. The burden of disease activity measured by BASDAI, ASDAS-CRP and VAS as well as ASQoL did not differ in patients with SSSD compared with those with BME only (p>0.05)
Conclusion: Patients with nr-ax SpA are characterized by a short duration of symptoms. Regardless of this recent onset and initially normal X-ray image of the sacroiliac joints, in some patients there are objective data of previous inflammation of the sacroiliac joints that may had not be detected on X-ray. That arise the question of low sensitivity of conventional radiography as well as the presence of risk factors for rapid structural damage and progression in some patients with nr-ax SpA.

AB1046 LEVEL OF VITAMIN D IN MEN WITH ANKYLOSING SPONDYLITIS, CONNECTION WITH DISEASE ACTIVITY AND SEASONALITY

Keywords: Spondyloarthritis, Vitamin D

S. Shevchuk[1], O. Pavliuk[1], O. Shevchuk[2], O. Zviahina[1]. [1]*National Pirogov Memorial Medical University, Department of Internal Medicine #2, Vinnytsia, Ukraine*; [2]*National Pirogov Memorial Medical University, Department of Pharmacology, Vinnytsia, Ukraine*

Background: It is known that in ankylosing spondylitis (AS) there is a decrease in the level of vitamin D in blood serum. Its status in these patients can be determined by both exogenous (deficiencies in the diet of products that are its main sources) and endogenous (ecological problems, urbanization, seasonality) factors. In addition, the availability of vitamin D in this cohort of patients can be determined by the course of the disease. In particular, the role of vitamin D in suppressing the proliferation of T-cells and reducing the production of interleukin-2, interferon-γ, tumor necrosis factor-α, etc. is well-known. The frequency of vitamin D deficiency in the Ukrainian population of patients with AS is unknown, and the study of the relationship between vitamin D and disease activity and seasonality is also worthy of attention.
Objectives: To determine vitamin D availability in men with AS and to assess its relationship with seasonality and activity of the disease.
Methods: 81 men with AS were examined with an average age of 41,0±0,1 years and duration of the disease of 9,0±0,6 years. The diagnosis of AS was made according to the modified New York criteria (1984) and the ASAS criteria (2009). Seasonal measurements of vitamin D content in blood serum were carried out in the autumn-summer and winter-spring periods. Disease activity was determined on the basis of BASDAI and ASDAS-CRB indices.
Results: In men with AS, vitamin D deficiency was detected in 35 (43,2%) people, an insufficient level in 25 (30,9%) cases, and in 21 (25,9%) patients, it was within the normal range. In the control group, optimal levels of vitamin D wer.e. found in 7 (30,4%) examined patients, 9 (39,2%) patients showed insufficiency and 7 (30,4%) patients had vitamin D deficiency. It is shown that the share of people with vitamin D deficiency is the highest in the spring period (61,8%), and the winter and summer periods did not significantly affect vitamin D availability. Vitamin levels were also closely associated with high activity of the inflammatory process. In particular, in the group of patients with a high degree of activity (BASDAI > 4 points), vitamin D deficiency was detected in 52,6% of people, which is 2,5 times higher than in the group of patients with moderate activity of AS (20,8%). Similar regularities were found according to the ASDAS index. In addition, it is the activity of the inflammatory process that is key in the occurrence of vitamin D deficiency, since regardless of the season (winter/summer), reliable correlations are established between the level of the vitamin on the one hand and the activity according to ASDAS and BASDAI on the other hand (r = -0,30; -0,27 p<0,05).
Conclusion: Vitamin D deficiency occurs with a high frequency (43,2%) in men suffering from AS. Despite the fact that there are seasonal fluctuations in vitamin D levels, its status is determined precisely by the activity of the inflammatory process.

AB1047 COMORBIDITY WITH FIBROMYALGIA IS ASSOCIATED WITH INCREASED JOINT SWELLING, HIGH DISEASE ACTIVITY AND REDUCED PRODUCTIVITY IN THAI PATIENTS WITH SPONDYLOARTHRITIS

Keywords: Fibromyalgia, Spondyloarthritis

P. Chiowchanwisawakit[1], S. Srivorrapattarakul[1]. [1]*Faculty of Medicine, Siriraj Hospital, Mahidol University, Department of Medicine, Bangkok, Thailand*

Background: Spondyloarthritis (SpA) is a chronic inflammatory disease and may present with diffuse pain. Fibromyalgia (FM) is a non-inflammatory diffuse pain syndrome and may be a co-morbid disease of SpA. No prior study of prevalence FM and its effect on Thai patients with SpA.
Objectives: To estimate the prevalence and explore the associated factor of fibromyalgia among patients with spondyloarthritis in Thailand.
Methods: This was a cross-sectional study. Thai patients with SpA were consecutively recruited. FM was diagnosed according to the 2016 revision of the 2010/ 2011 American College of Rheumatology diagnostic criteria. The characteristics of the patients, physical examination, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Work Productivity and Impairment Questionnaire and EuroQoL-5 dimensions (EQ5D) were collected. The Fischer exact test or the Mann-Whitney U test was used to compare the associated factors.
Results: Of the total of 218 patients with 113(51.8%) female, mean age of 49.5 years, and median disease duration of 6 years, 12 (5.5%) were diagnosed with FM. Pain areas and symptoms between the patients with and without FM was

shown at Figure 1. FM patients were associated with a higher median tender joint count [1.0 vs 0, *p*=0.020] and swollen joint count [1.5 vs 0, *p*=0.037], BASDAI>4/10 [7(58.3%) vs 34(16.5%), *p*=0.002], mean EQ5D index [0.6 vs 0.88, *p*=0.001], median overall work impairment [65 vs 10%, *p*=0.002], and activity impairment [50 vs 10%, *p*=0.001] than those without FM.

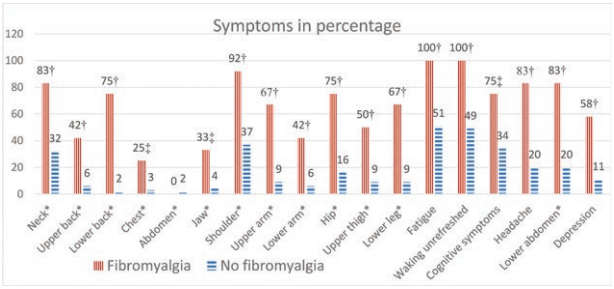

Figure 1. Pain areas and symptoms according to the 2016 Revisions fibromyalgia diagnostic criteria comparing participants with fibromyalgia and without fibromyalgia.*, pain; †, p-value <0.001; ‡, p-value <0.05 and >0.001

Conclusion: The prevalence of FM among Thai patients with SpA is low. However, it is important to identify and treat because it is associated with reduced productivity and poor quality of life. Active inflammation is associated with FM. Controlling SpA disease may also help to control FM.

AB1048 ENTHESAL ULTRASOUND ABNORMALITIES CAN PRECEDE SPA DEVELOPMENT IN ASYMPTOMATIC IBD PATIENTS. A RETROSPECTIVE STUDY

Keywords: Spondyloarthritis, Enthesitis, Ultrasound

A. Batticciotto[1], F. Campanaro[1], G. M. C. La Paglia[2], A. Locatelli[2], M. Vaiano[3], S. Ardizzone[3], A. Cappelli[1], P. Sarzi-Puttini[4]. [1]*ASST dei Sette Laghi, Internal Medicine Department - Rheumatology Unit, Varese, Italy*; [2]*ASST Fatebenefratelli Sacco - L. Sacco University Hospital, Rheumatology Department, Milano, Italy*; [3]*ASST Fatebenefratelli Sacco, Gastroenterology Department, Milano, Italy*; [4]*IRCCS Galeazzi Orthopedic Institute, Rheumatology Department, Milan, Italy*

Background: Nearly four million people worldwide are affected by Inflammatory Bowel Diseases (IBD) and approximately 25-40% of them develop extra-intestinal manifestations, such as arthritis and enthesitis. Enthesis inflammation is a cornerstone in Spondyloarthritis (SpA) but there are few data concerning prevalence, clinical presentation and prognostic value of enthesitis in IBD patients. Ultrasound (US) assessment has emerged as a feasible, reliable and easily accessible technique for the detection of enthesis abnormalities. Recently a systematic review about the predictive value of the US elementary lesions in IBD patients was performed [1]. Multicenter studies performed on IBD patients without clinical signs of SpA demonstrated high prevalence of US entheses abnormalities such as dishomogeneous echostructure and Power Doppler (PD) positivity [2-3]. The predictive role of these abnormalities is up to now unknown.

Objectives: To find US abnormalities that can predict or frequently precede the development of SpA in a population of IBD patients asymptomatic for entheseal involvement.

Methods: We conducted a retrospective analysis of clinical and US enthesis data coming from 29 patients affected by IBD without clinical signs of SpA evaluated in the period between 2010 and 2012 at the combined Gastroenterology/Pediatrics/Rheumatology Clinic and still in follow up in the Gastroenterology and Rheumatologic Unit of L. Sacco University Hospital in 2022. After a long term follow-up from the first combined US (according to MASEI score with ESAOTE MyLab 70 linear probe 6-18 MHz) and clinical evaluation we retrospectively analyze the patient's clinical record in order to find which patients developed clinically a SpA according to the Assessment of SpondyloArthritis international Society (ASAS) criteria [4]. Medium MASEI score and the presence of US elementary entheseal lesions at baseline of patients that develop SpA were compared by chi-squared test with those without signs of joint involvement.

Results: After an average follow-up of ten years we evaluated data from 29 patients (19 F and 10 M) with a mean age of 33,38 (range 17-82) years and mean disease duration of 14,1 (range 11-33) years. Four patients out of 29 (14%) developed a SpA. Reviewing their US baseline evaluation and comparing it with those of patients that didn't develop the disease we have found that the medium MASEI score of those who developed a SpA was statistically higher (18 ± 13,3 Vs 8,2 ± 6,6 p=0,02). Focusing on US elementary lesions (Table 1) we can underline that all patients developing SpA had at baseline at least one entheses with a positive PD signal (Vs 9/25 of the comparing group (p=0,02).

Conclusion: MASEI score and PD US positivity at enthesal level are possible predicting factors for the development of SpA in IBD patients. Further investigations from long term prospective studies need to confirm these preliminary data.

AB1049 THE STATUS OF BREG CELLS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Biomarkers, Systematic review

J. Luo[1,2], Q. Li[1,2], Q. Y. Su[1,2,3], X. T. Bi[1,2], Y. Zhang[1,2], M. Wang[1,2], Z. R. Wen[1,2], Y. C. Zhao[1,2], Q. Yu[4], P. F. He[4], X. Li[1,2,3], S. X. Zhang[1,2,3]. [1]*Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, Shanxi, China*; [2]*Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; [3]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi, China*; [4]*Ministry of Education, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*

Background: Ankylosing spondylitis (AS) is a common chronic inflammatory autoimmune disease that primarily affects the sacroiliac joints, spine and peripheral joints, and attachments of ligaments. Regulatory B cells (Bregs) are unique subpopulations of B cells with immune-regulating properties. Interestingly, different subsets of Breg cells have distinct markers and phenotypes and participate in self-immune regulation in different ways. However, the level of Breg cells in AS remains debated.

Objectives: This study aims to clarify the proportions of Breg cells with unique, controversial cellular markers in AS patients.

Methods: We explored the proportion of Breg cells in AS patients by searching literature through January 10, 2023, from 11 Databases. Random effects model was used to pool data. Heterogeneity and risk of bias were examined with the I-squared index (I^2) statistic. Inconsistency was evaluated using the I^2 and Egger tests to evaluate potential publication bias (STATA v.12.0).

Results: A total of 7 case-control studies involving 278 AS patients and 237 healthy controls (HCs) were included in this study(Table 1). No significant difference in the proportions of Breg cells was evident between AS patients and

HCs[SMD=-0.324, 95%CI(-0.971, 0.323), P=0.327]. Because of a significant statistical heterogeneity observed [p<0.1, I^2=89.2%], we conducted sub-analyses based on individual definitions of Breg cells. We found that the proportions of $CD19^+CD24^{hi}CD38^{hi}$ Breg cells have no significant difference between AS and HCs [SMD=-0.546, 95%CI (-1.126, 0.034), P=0.065](Figure 1). The level of $CD19^+CD24^{hi}CD27^+$ Breg cells was increased in AS compared to that of HCs[SMD=0.965, 95%CI (0.339, 1.590), P=0.003] with no publication bias based on the Egger tests (t=1.35, p=0.236).

Conclusion: The levels of $CD19^+CD24^{hi}CD27^+$ Breg cells were significantly increased in AS patients, suggesting that the abnormalities of Breg cell numbers and function are the critical causes in the development of AS.

Table 1. Characteristics of the individual studies included in the meta-analysis.

THE LEVELS OF FECAL CALPROTECTIN, SERUM INTERLEUKIN 17/23, MALONDIALDEHYDE, GLUTATHIONE PEROXIDASE IN THE PATIENTS WITH AXIAL SPONDYLOARTHRITIS AND THEIR CORRELATIONS WITH CLINICAL, LABORATORY PARAMETERS, DISEASE ACTIVITY SCALES

Keywords: Cytokines and chemokines, Spondyloarthritis, Gastrointestinal tract

M. Soysal[1], Ş. Kutlay[2], E. Devrim[3], Ç. Fidan[3], D. Gökmen[4], P. Yalçın[2]. *[1]Kırklareli Training and Research Hospital, Physical Medicine and Rehabilitation, Kırklareli, Turkey*; *[2]Ankara University Faculty of Medicine, Physical Medicine and Rehabilitation, Ankara, Turkey*; *[3]Ankara University Faculty of Medicine, Medical Biochemistry, Ankara, Turkey*; *[4]Ankara University Faculty of Medicine, Biostatistics, Ankara, Turkey*

Background: Recent studies in the literature show that the fCal, some proinflammatory cytokines, oxidant/antioxidant markers are associated with disease activity in SpA(1,2,3).
Objectives: The aim of this study was to compare the levels of fCal, serum IL-17/23, malondialdehyde (MDA) and glutathione peroxidase (GPx) between the patients with axSpA treated with NSAID or anti-TNF and the control group; to evaluate the correlations of them with laboratory, clinical parameters, and disease activity scales.
Methods: 75 people from the outpatient clinic at Department of PMR Rheumatology Department, Ankara University were included in this cross-sectional study. Patients have met the ASAS classification criteria for axSpA. 25 volunteers participated in per group (NSAID group/anti-TNF group/the control group). The study was approved by the Clinical Research Ethics Committee, and all participants signed an informed consent form. Individuals participating in the study were evaluated with disease activity scales, ESR, and CRP. Via ELISA method, fCal level from stool samples and IL-17/23 level from serum samples; and via spectrophotometric method, the levels of MDA and GPx were measured.
Results: Fecal calprotectin level was found to be higher in the NSAID group than in anti-TNF group and to be at the lowest level in the control group, which is not statistically significant (p=0.05). In the anti-TNF group, the level of IL-23 is higher than that of the NSAID group (p=0.000). A weak positive correlation was detected between CRP and fCal level in the axSpA group (p=0.009/r=0.380). No relationship between fCal and disease activity scales was observed. It was detected that IL-17 has a weak positive correlation with BASDAI, ASDAS-CRP (p=0.035/r=0.311) and has a strong positive correlation with MASES (p=0.000/r=0.794). No relationship between IL-23 and disease activity scales was found. A weak positive correlation of MDA with BASFI and BASDAI was detected (p=0,018/r=0,355) (p=0,002/r=0,452). It was found a weak negative correlation between IL-23 and GPx (p=0,000/r=0,499), however no statistically significant relationship between the other levels was observed.
Conclusion: The fact that fCal level in the NSAID group is higher than the anti-TNF Group supports the literature that NSAIDs cause leaky gut syndrome by adversely affecting the gut microbiota. Higher fCal level in the NSAID group makes us think that in addition to intestinal inflammation caused by the disease, it is originated by the NSAID treatment[1]. In our study, the reason why the level of IL-23 in the NSAID group is lower may be the underlying mechanism through PGE2, and the reason why it is higher in the anti-TNF group may be that anti-TNF treatment has not had enough effect on the IL-17/23 pathway[2,4]. Especially the relationship of IL-17 level with MASES using for the clinical evaluation of the enthesitis areas, clinically shows us the role of the IL-17/23 pathway in the entheseal inflammation as well[5].

PREGNANCY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Pregnancy and reproduction

S. Gore[1], R. Tambe[1], N. Sunil[1], A. Raut[1], P. Patil[2]. [1]*Poona College of Pharmacy, Bharati Vidyapeeth Deemed to be University, Clinical Pharmacy, Pune, India*; [2]*Pune Rheumatology Center, Rheumatology, Pune, India*

Background: There is limited information available on the course of axial spondyloarthritis (AxSpA) during pregnancy, in contrast to other chronic inflammatory disorders. AxSpA poses a special set of challenges because it has anatomical and inflammatory consequences on pregnancy.
Objectives: The aim of this study was to evaluate the course of AxSpA during pregnancy.
Methods: In order to evaluate the course of AxSpA during pregnancy, an observational descriptive retrospective study was carried out at a private rheumatology clinic. Data were gathered using a self-administered questionnaire from 70 women who were diagnosed with AxSpA prior to pregnancy.
Results: The average age at disease onset was 23.6 years. Approximately one-third (35.7%) of patients said their AxSpA symptoms were worse during pregnancy, compared to 64.2% who said their symptoms got better. The postpartum flare was reported by 52.5% women. The mode of delivery was by cesarean section in 76% patients. Back pain and stiffness during pregnancy were the most prevalent symptoms. None of the patients had extra-articular manifestations during pregnancy or postpartum. Adverse pregnancy outcomes were reported by 15.7% patients. In our study, we found that the majority of women avoided using drugs even when they felt the need to do so out of concern for the foetus.
Conclusion: A large number of patients reported ease of symptoms during pregnancy. Due to the significant risk of flare, patients should be followed up during post-partum period. AxSpA females have an increased prevalence of cesarean sections.

AB1052 COMPARISON OF HIP INVOLVEMENT IN ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLARTHRITIS- A RETROSPECTIVE STUDY

Keywords: Spondyloarthritis

S. F. Azevedo[1,2], C. Mazeda[1,2], S. P. Silva[1,2], C. Pinto Oliveira[1,2], A. Barcelos[1,2,3]. [1]*Centro Hospitalar do Baixo Vouga, Rheumatology Department, Aveiro, Portugal*; [2]*Egas Moniz Health Alliance, Academic Clinical Center, Aveiro, Portugal*; [3]*Comprehensive Health Research Center, Universidade NOVA de Lisboa, Lisboa, Portugal*

Background: Hip involvement is common in axial spondylarthritis (axSpA), with several studies reporting a prevalence as high as 36% in Ankylosing spondylitis (AS)[1,2]. Hip involvement represents a negative impact on the quality of life and daily functionality in these patients[2]. Although some studies identify radiographic sacroiliitis as a predictor of hip involvement in Spondylarthritis[2], there are no studies aiming to directly compare patients with AS and Non-radiographic axial spondylarthritis (Nr-axSpA).
Objectives: The purpose of our study is to compare the hip involvement between AS and Nr-axSpA and to evaluate predictors of hip involvement in axSpA.
Methods: A retrospective study was performed during the last trimester of 2022 including patients with axSpA (all patients fulfill ASAS criteria) followed in a Portuguese Rheumatology Center. Patients were divided into two groups: patients with AS (group 1) and patients with Nr-axSpA (group 2). Sociodemographic, clinical, and laboratory data were collected. Hip involvement was evaluated by imaging and defined by a BASRI-h >1. Descriptive analysis was performed using means and standard deviation (SD), medians, and Interquartile range (IQR) for continuous data, and frequencies and percentages for qualitative variables. Clinical, laboratory, and radiological findings were compared between patients with AS and Nr-axSpA using parametric and non-parametric tests. A multivariate analysis, with a stepwise backward binary logistic regression, was performed to identify risk factors independently associated with hip involvement. Significance was set at a p-value ≤ 0.05.
Results: 106 patients were enrolled in the study, 58 (54.7%) with AS and 48 (45.3%) with Nr-axSpA (mean age was 56.03 ±13.05 years, with 50% of females in AS group, and 43.96 ±11.31 years, with 64.58% females in Nr-axSpA group). AS patients were older and had longer disease duration (p<0.001). There were no differences regarding the presence of extra-articular manifestations, HLA-B27 positivity, inflammation markers, disease activity scores, treatment, or comorbidities between groups. Of all patients, 44.3% had hip involvement, and 26.4% were symptomatic (pain and/or limited mobilization). Hip involvement was significantly more prevalent among AS patients (60.34% Vs 25%, p< 0.001). On univariate analysis, age (p=0.001), disease duration (p<0.001), radiographic sacroiliitis (p<0.001), higher C reactive protein levels (p=0.03), high blood pressure (p=0.03) and type 2 *Diabetes Mellitus* (p=0.03) were associated with hip involvement in axSpA patients. Although, on multivariate analysis, only age and the presence of radiographic sacroiliitis were found as independent risk factors [age: OR1.04 CI(1.04-1.07), p=0.03; radiographic sacroiliitis: OR3.10 CI(1.25-7.68), p=0.01].
Conclusion: Our study suggests that hip involvement is frequent in axSpA, mainly in those with AS. Older age and the presence of radiographic sacroiliitis were potential independent risk factors for hip involvement, reinforcing the importance of closely monitoring this subset of patients, thus potentially minimizing its negative impact on patients' quality of life and functionality.

AB1053 MATRIX METALLOPROTEINASE-3: A BIOMARKER OF SPONDYLOARTHRITIS

Keywords: Biomarkers, Spondyloarthritis, Diagnostic tests

M. Slouma[1], S. Bouzid[1], L. Kharrat[1], A. Tezeghdenti[2], E. Ghazouani[2], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1], B. Louzir[3]. [1]*The Principal Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia*; [2]*The Principal Military Hospital of Instruction of Tunis, Immunology, Tunis, Tunisia*; [3]*The Principal Military Hospital of Instruction of Tunis, Internal Medicine, Tunis, Tunisia*

Background: Several studies reported that matrix metalloproteinase 3 (MMP-3), an enzyme of the proteolytic system, is implicated in the pathogenesis and progression of several rheumatic diseases [1].
Objectives: We aimed to compare MMP-3 serum levels between spondyloarthritis (SpA) patients and healthy controls.
Methods: We conducted a case-control study, including 164 subjects divided into two groups, all matched for age and gender: G1 including 82 SpA patients, diagnosed according to ASAS 2009 criteria, and G0 including 82 healthy controls. ELISA technique was used to measure MMP-3 serum levels. Statistical analyses were carried out using SPSS software.
Results: Each group included 65 men. The mean age was 45.32 ± 13.41 years. The mean disease duration was 7.57 ± 7.79 years. Radiographic axial SoA (r-AxSpA) and psoriatic arthritis (PsA) were noted in 65.9% (n=54) and 34.1% (n=28) of cases, respectively. In G1, axial manifestations were noted in 81.7% (n=67). A peripheral syndrome was associated in 45% (n=18): arthritis in 42.7% (n=35) and enthesitis in 14.6% (n=12). The mean MMP-3 serum levels were statistically higher in G1 than in G0 (G1: 64.14 ± 187.31 [1.75 – 1237.36] versus G0: 12.06 ± 10.99 ng/mL [2.98 – 58.94], **p=0.01**). MMP-3 serum levels were significantly higher in PsA than in r-AxSpA patients (141.65 ± 306.33 [2- 1238] ng/mL versus 23.95 ± 31.67 [3 - 149] ng/mL, **p=0.006**). The cutoff of 10.43 ng/mL could discriminate G1 from G0 with a sensitivity and a specificity of 67.1% and 61% respectively (AUC: 0.647, p=0.001).
Conclusion: Our study showed that MMP-3 serum levels were significantly higher in SpA patients compared to controls. This finding suggests that MMP-3 plays a role in the pathogenesis of SpA. However, MMP-3 did not have high sensitivity and specificity in discriminating patients from healthy controls. Thus, MMP-3 was not a good biomarker for the diagnosis of SpA.

AB1054 SPONDYLOARTHRITIS IN FIRST DEGREE RELATIVES OF ANKYLOSING SPONDYLITIS PATIENTS

Keywords: Imaging, Spondyloarthritis, Genetics/epigenetics

K. Bubová[1], L. Hasikova[1], M. Gregová[1], K. Mintalova[1], S. Forejtova[1], L. Šenolt[1]. [1]*Institute of Rheumatology, Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic*

Background: Ankylosing spondylitis (AS) is a relatively common inflammatory rheumatic disease with a strong familial risk and heritability.
Objectives: The aim of this study was to examine first-degree relatives of patients diagnosed with AS to determine the presence of active sacroiliitis, fulfilment of Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axial and/or peripheral spondyloarthritis (SpA), and the clinical diagnosis of SpA.
Methods: One hundred subjects without a previous rheumatological diagnosis with a first-degree relative treated for AS were included in the study. Clinical data were collected and rheumatological examinations were performed by trained rheumatologists. Magnetic resonance imaging (MRI) of the sacroiliac joints (SIJ) was read by a trained rheumatologist who was blinded to all patient data. Subjects were further divided into both SpA (according to ASAS classification criteria and clinician opinion) and non-SpA subgroups.
Results: A total of 26 subjects met ASAS classification criteria for SpA, of which the diagnosis of SpA was confirmed in 14 subjects (13 subjects met ASAS classification criteria for axial and 1 subject for peripheral SpA). In addition, 12 individuals met the clinical arm of the ASAS classification criteria for axSpA, but were not diagnosed with axSpA in the clinicians' opinion. Active sacroiliitis as defined by MRI was present in all 13 individuals diagnosed with axSpA, 7 (54%) of whom already had advanced radiographic changes on conventional radiographs of the SIJ. In addition, active sacroiliitis defined by MRI was also present in 4 individuals who did not have back pain. The data are shown in Figure 1. Analysis of clinical characteristics showed a significant difference in CRP and BASDAI between the SpA vs. non-SpA subgroups (8.8 (±10.5) vs. 2.3 (±4.1) mg/l, p=0.0048, and 3.1 (±1.8) vs. 1.76 (±1.78), respectively). Individuals diagnosed with SpA were more likely to be HLA-B27 positive and had inflammatory back pain compared to the non-SpA subgroup (87% vs. 43%, p=0.0069 and 57% vs. 9%, p=0.0002, respectively). Individuals who were not diagnosed with SpA but met the clinical arm of the ASAS classification criteria for axSpA were excluded from the analysis. Other clinical characteristics and differences between subgroups are shown in Table 1.
Conclusion: In this cross-sectional study, a quarter of the relatives of patients with first-degree AS met the classification criteria for SpA, and 14% were diagnosed with SpA based on physician opinion. These individuals had a significantly higher prevalence of HLA-B27, inflammatory back pain, and disease activity indices. It should be kept in mind that in a small proportion of individuals, active sacroiliitis may be present in relatives with first-degree AS even in the absence of back pain.

Background: In addition to the extra-articular manifestations associated with spondyloarthritis such as IBD, psoriasis and uveitis, spondyloarthritis is linked to an increased risk of comorbidities.

Objectives: To study the prevalence of comorbidities in spondyloarthritis (SPA) at inclusion and 36-month follow-up and their influence on disease activity and functional outcome in a cohort of patients followed for SPA from the Moroccan registry of biological therapies in rheumatic diseases (RBSMR Registry).
Methods: Data were analyzed from cohort of 194 patients with SPA from the RBSMR Registry including comorbidities (hypertension, diabetes, dyslipidemia, obesity, osteoporosis, sedentary lifestyle, gastrointestinal ulcer, smoking, depression, fibromyalgia) and disease activity scores at inclusion (M0) and at 36-month follow-up (M36).
Results: The mean age was 40,23 ± 13,68 ans. The sex-ratio (M/W) was 1,73. 96.4 % of the patients had axial involvement, 70 % had peripheral involvement and 61.5 % had enthesitis. SPA was radiographic in 88.1 % of the cases. The mean duration of disease was 615,90 ± 349,12 weeks. 57,2% of patients had at least one comorbidity, among whom the median comorbidity count was 1 (range 1-5).

Table 1. comparison between prevalence of comorbidities at M0 and M36.

Comorbidity	Prevalence at inclusion (M0)	Prevalence at 36-month follow-up (M36)
Sedentary behaviour	29,4% (n=57)	31,4% (n=61)
Osteoporosis	11,3% (n=22)	13,4% (n=26)
Smoking	10,8% (n=21)	10,8% (n=21)
Hypertension	5,7% (n=11)	9,3% (n=18)
Obesity	8,2% (n=16)	8,2% (n=16)
Tuberculosis	6,7% (n=13)	11,34% (n=22)
Diabetes	5,2% (n=10)	6,2% (n=12)
Gastrointestinal ulcer	2,6% (n=5)	3,1% (n=6)
Dyslipidemia	1,5% (n=3)	2,6% (n=5)
Cancer	0% (n=0)	1,0%(n=2)
Depression	2,6% (n=5)	2,6% (n=5)
Fibromyalgia	2,1% (n=4)	2,1% (n=4)

Table 2. Comparison between patients with or without comorbidities.

Parameter	Patients with at least one comorbidity (57,2%)	Patients without comorbidities (42,8%)	p
ESR (mm/h)	36,24	36,97	0,163
CRP (mg/l)	42,14	27,00	**0,002**
ASDAS-CRP	3,67	2,50	**0,003**
BASDAI	5,10	4,50	0,098
BASFI	6,10	4,16	**0,028**

Conclusion: In our study, the presence of comorbidities was correlated with more severe disease activity. Better management of these comorbidities may result in better outcome of patients with SPA.

AB1056 ASSESSMENT OF PULMONARY CIRCULATION WITH STRESS ECHOCARDIOGRAPHY IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS

Keywords: Imaging, Cardiovascular disease, Spondyloarthritis

S. Burcsar[1], B. Morvai-Illes[2], M. Monoki[3], A. Varga[3], G. Agoston[3], A. Balog[1]. *[1]University of Szeged, Rheumatology and Immunology, Szeged, Hungary*; *[2]University of Szeged, Family Medicine, Szeged, Hungary*; *[3]University of Szeged, Family Medicine, Szeged, Hungary*

Background: Extra-articular features are common in ankylosing spondylitis (AS) and in psoriatic arthritis PsA. Cardiac involvement are less frequent but may be severe. The anterior chest wall pain and sterno-costal arthritis can lead to reduced chest expansion, which may contribute to the progression of cardio-pulmonary manifestations. We aimed to assess the response of the pulmonary circulation unit during stress in AS and PsA patients.
OBJECTIVES:
Methods: A total of 71 patients were enrolled in the study: 28 of them had AS (age 50.8±11.8 years), 17 APs (age 52.1±13.5 years), and 26 were healthy individuals (age 54.23±9.9 years). 74,1 % of AS patient, 11,1 % of PsA patient had ankylosis at the time of assessment. To the maximally tolerated workload, all subjects underwent resting and exercise stress echocardiography on a supine bicycle ergometer. Echocardiographic measurements were taken at rest, at 50 watts workload, and at maximal exercise.
Results: AS patients had significantly higher pulmonary artery systolic pressure (PASP; AS: 32.6±16.8 mmHg, APs: 21.6±12.7 mmHg, p<0.05) and pulmonary vascular resistance (PVR; AS: 1.3±0.4 WU, PsA: 1.1±0.3 WU, p<0.05) at maximal workload, while the right ventricular-pulmonary arterial (RV-PA) coupling at peak stress was higher in APs patients (AS: 1.2±0.6 mm/mmHg, PsA: 1.8±1.1 mm/mmHg, p<0.05). Comparing to the control group, AS and PsA patients had significantly higher resting PASP (control: 12.6±6.4 mmHg; AS: 22.8±7.6 mmHg, p<0.001; PsA: 21.4±7.0 mmHg, p<0.001), lower resting RV-PA coupling (control: 2.7±1.4 mm/mmHg; AS: 1.3±0.4, p<0.001; PsA 1.3±0.4 mm/mmHg, p<0.001), and higher peak PVR (control: 0.6±0.4 WU; AS: 1.3±0.4, p<0.001; PsA: 1.1±0.3 WU, p<0.005). One-way analysis of variance of the three groups also showed significant differences in the resting PASP (p<0.001), peak PASP (p<0.05), resting RV-PA coupling (p<0.001), peak PVR (p<0.001). At maximal workload, the AS patient had higher E/e' in ankylosing group.
Conclusion: Stress echocardiography is a promising, radiation-free method for assessing the subclinical cardiopulmonary changes among AS and PsA patients. The changes of PVR during stress may highlight the pulmonary complications in the subclinical stage. Higher E/e' in ankylosing group can refer to the influence of ankylosis on the left ventricular filling.

AB1057 INTERPRETATION OF DISEASE-SPECIFIC QUESTIONNAIRES ON DISEASE ACTIVITY, FUNCTIONAL CAPACITY AND QUALITY OF LIFE IN DAILY PRACTICE IN AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Outcome measures, Patient reported outcomes

S. Tsiami[1], K. Klavdianou[2], I. Redeker[1], Y. E. Oezdemir[1], P. Sewerin[1], D. Kiefer[1], I. Andreica[1], U. Kiltz[1], X. Baraliakos[1]. *[1]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany*; *[2]Asklepieion' General Hospital, Voula, Department of Rheumatology, Athens, Greece*

Background: In axial spondyloarthritis (axSpA), assessment of disease activity and physical function in clinical studies relies on patient-reported outcomes (PRO) such as patient's global, BASDAI, ASDAS and BASFI. However, it still remains unclear how response criteria adequately reflects the patients' opinion on disease status in daily practice.
Objectives: Investigate whether the results of PROs used in clinical studies with axSpA are indeed related to patient's opinion on disease status as reported in daily clinical routine.
Methods: Data were retrieved from the very first and from the last five visits within a timeframe of 5 years. Patient´s clinical characteristics, physician's global assessment and PROs (ASDAS, BASDAI, BASFI) were assessed at each visit. Status and change of all assessed information during follow-up were compared with patient´s opinion on symptoms related to axSpA, categorized into absent, mild, severe or very severe.
Results: 3.120 visits with median follow-up (IQR) 4.7 (4.3) years from 557 axSpA patients were analyzed. Absent/mild symptoms were stated in 98.7% and 90.9% of visits with inactive or low ASDAS disease status, while in 67.9% and 39.3% of visits showing association to high or very high ASDAS disease activity status, respectively (Figure 1). In comparison, BASDAI<4 was found in 90.8% of visits with absent/mild symptoms, while BASDAI≥4 showed severe symptoms in 48.1% of visits (Figure 1). Achievement of ASAS40 was associated with 92.4% visits reporting absent/mild symptoms, while this was the case in 76.4% visits despite not reaching ASAS40. Similar data were observed for ASAS20. Severe symptoms were reported in 0.6% patients achieving vs. 30.1% patients not achieving ASAS partial remission (PR). BASFI correlated with patients' opinion regarding symptoms at each visit.
Conclusion: Low disease activity as assessed by ASDAS or BASDAI were associated with mild symptoms in the majority of visits over a period of up to 5 years. Interestingly, a large proportion of visits showed low disease activity even when not achieving ASAS20 or ASAS40 responses or ASAS-PR.

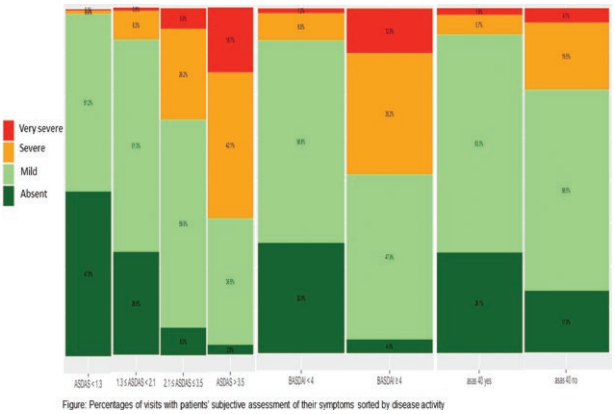

Figure: Percentages of visits with patients' subjective assessment of their symptoms sorted by disease activity

AB1058 GENDER DIFFERENCES IN SPONDYLOARTHRITIS: FOCUS OF THE CLINICAL BURDEN OF DISEASE IN FEMALE PATIENTS

Keywords: Spondyloarthritis, Gender/diversity issues, Comorbidities

F. Fattorini[1], C. Cigolini[1], C. Cardelli[1], G. Marchetti[1], A. Delle Sedie[1], L. Carli[1], M. Mosca[1]. [1]*Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy*

Background: Spondyloarthritis (SpA) are a group of systemic autoimmune diseases, mainly affecting musculoskeletal system, with typical axial or peripheral forms. Recent data from the literature show significant differences in SpA subsets, levels of disease activity, drug efficacy and quality of life between male and female sex. [1, 2] It is well known how disease activity and comorbidities could compromise physical function and quality of life of SpA patients.
Objectives: To describe the clinical characteristics of women with SpA in our single-centre cohort compared to men, in relation to clinical characteristics, disease activity, therapy and comorbidities.
Methods: Adult patients with a diagnosis of Psoriatic Arthritis (PsA) and Axial Spondyloarthritis (AxSpA) according to CASPAR (ClASsification criteria for Psoriatic Arthritis) and to Assessment of SpondyloArthritis international Society (ASAS) criteria, regularly followed at the SpA clinic of our unit, were consecutively enrolled from April to December 2022. Their epidemiologic, clinic and clinimetric data were collected. Intergroups comparisons were assessed by using Chi-square, t-test and ANOVA. P values <0.05 were considered significant.
Results: A total of 200 patients were enrolled, 115 male (57.5%) and 85 female (42.5%) with comparable mean age values (M 56.13±14.48 years, F 56.84±12.22 years; p=0.508) and with a significantly shorter disease duration in women (12.9±10.3 years vs 17.05±12.08 years; p<0.001). No differences in the distribution of PsA or AxSpA based on gender were observed. Six patients had a diagnosis of enteropathic SpA; all of them were women. Taking into account the clinimetric evaluations, female patients show higher values of both Disease Activity Index for Psoriatic Arthritis DAPSA (15.63 vs 9.40; p=0.003), Leeds Enthesitis Index (LEI) (0.46 vs 0.16; p=0.02) and Spondyloarthritis Research Consortium of Canada (SPARCC) Enthesitis Index (0.7 vs 0.4; p=0.05). The total number of drugs [both Biological disease modifying anti-rheumatic drugs (bDMARDs) and conventional synthetic DMARDs)] taken for disease control was 4.47±2.45 for women and 3.79±2.07 for men (p=0.012); no differences were observed between the 2 groups for any specific drug. Among the comorbidities, none of them was more prevalent in men, while osteoporosis (OP) (p=0,006), mood disorders (0,009), fibromyalgia (FM) (p<0,000015), osteoarthritis (OA) (0,007) and thyroid disease (p<0,000015) were significantly more frequent in women.
Conclusion: Women of our cohort show a significantly higher risk of developing an inflammatory bowel disease than men. Female patients have also higher levels of peripheral disease activity, both on joints and enthesis; moreover, they show a significantly lower persistence in drug therapy. Besides, they have a more complex disease, suffering more frequently of OP, OA, FM and thyroid diseases than men. Finally, it is very interesting to note how women tend to develop a much more complex disease, even with a significantly shorter disease duration than male patients. These data confirm how rheumatologists should focus on the assessment of women with SpA, aiming at promoting a closer monitoring of gastrointestinal symptoms, peripheral arthritis and enthesitis and at preventing the development of comorbid conditions, thus optimizing also their quality of life and physical functioning.

AB1059 NETRIN-1 IN SPONDYLOARTHRITIS: A NOVEL MARKER TO PREDICT DISEASE ACTIVITY?

Keywords: Biomarkers, Real-world evidence, Spondyloarthritis

F. Baykal[1], S. Erten[2], S. C. Güven[3], A. Kor[2], F. Eren[4], S. Neşelioğlu[4], B. Polat[3], K. Gok[3], B. Armagan[3], I. Dogan[2], Y. Maraş[3], S. Başer[1], O. Erel[4]. [1]*Yıldırım Beyazıt University Medical School, Internal Medicine, Ankara, Turkey*; [2]*Yıldırım Beyazıt University Medical School, Internal Medicine, Rheumatology, Ankara, Turkey*; [3]*Ankara City Hospital, Rheumatology, Ankara, Turkey*; [4]*Yıldırım Beyazıt University Medical School, Biochemistry, Ankara, Turkey*

Background: Netrin-1 is a chemorepulsant and inhibits the migration of monocytes, neutrophils and lymphocytes by activation of its receptors. It has been revealed that netrin-1 can limit the inflammatory response, reduce tissue damage due to hypoxia and simultaneously suppress apoptosis. Due to this immune regulatory role, it has been hypothesized that netrin-1 can be used as a biomarker in rheumatic diseases.
Objectives: To compare plasma netrin-1 levels in axial spondyloarthritis (SpA) patients with the healthy subjects and to evaluate its relationship with disease activity and other clinical and laboratory parameters.
Methods: Patients with axial SpA between the ages of 18-65 who applied to Ankara City Hospital Rheumatology outpatient clinic between November 2021 and January 2022 were consecutively enrolled upon acceptance to participate. Pregnant patients, patients with systemic disease other than axial SpA and patients who were taking regular medication other than axial SpA treatment were excluded. A control group was formed from healthy volunteers with similar age and gender characteristics. In both groups, in addition to regular laboratory tests netrin-1 level was measured by an Enzyme Linked ImmunoSorbent Assay (ELISA) kit with an analytical unit of pg/mL (Elabscience, Texas, USA, Catalog No: E-EL-H2328; Lot No: GZWTKZ5SWK).
Results: A total of 60 axial SpA patients and 56 healthy controls were included in the study. There was no statistically significant difference between the groups in terms of age, gender andnetrin-1 levels between patients and controls (Table 1). Data regarding clinical characteristics, HLA-B27 positivity, acute phase reactants at the time of evaluation and disease activity scores of the axial SpA group was presented in Table 1. No significant differences were observed in netrin-1 levels in any comparison among all axial SpA patients, in ankylosing spondylitis (AS) and nonradiographic axial spondyloarthritis (nr-ax SpA) patient subgroups, and in healthy controls (all axial SpA vs control p=0,361, AS vs nr-axSpA p=0,790, AS vs control p=0,360, nr-axSpA vs control p=0,700). Netrin-1 levels had a significant positive correlation with BASDAI (r=0,301 p=0,032), ASDAS CRP (r=0,320 p=0,022), VAS pain (r=0,340 p=0,015).
Conclusion: Our results demonstrated a positive correlation between netrin-1 levels and disease activity in axial SpA patients, implying that netrin-1 may come to the forefront as a novel biomarker to predict disease activity in axial SpA.

Spondyloarthritis - clinical aspects (other than treatment)

AB1060 EXPLORING DISEASE ACTIVITY AND PATIENT CHARACTERISTICS IN ANKYLOSING SPONDYLITIS (AS) IN EUROPE

Keywords: Spondyloarthritis

D. Baldock[1], M. Thoo[2], R. Connolly[3], E. Baynton[1]. [1]*United Kingdom, Ipsos Healthcare, London, United Kingdom*; [2]*Kuala Lumpur, Ipsos Healthcare, Kuala Lumpur, Malaysia*; [3]*New York, Ipsos Healthcare, New York, United States of America*

Background: Ankylosing Spondylitis (AS) is a form of arthritis that primarily affects the spine. It causes inflammation of the spinal joints that can lead to severe, chronic pain and discomfort[1]. The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is the most frequently used patient-reported outcome to measure disease activity in axial spondyloarthritis. There is no validated definition for disease remission using BASDAI, although a threshold of ≤3 has been used in clinical trials for low disease activity[2].
Objectives: The objective of this study was to examine AS patient characteristics of those with low disease activity (LDA) (BASDAI score ≤3), highlighting any nuances in treating these patients.
Methods: A multi-centre online medical chart review study of patients with AS was conducted between July 2022 – September 2022 among UK, FR, DE, IT & ES rheumatologists practicing across hospital and private practices. Physicians were screened for practice duration and patient volume. Charts of patients prescribed with biologics were included in the analysis.
Results: 262 sampled physicians collectively reported 524 AS patients. From the reported AS patients, 277 were recorded as having achieved LDA ('LDA') and 165 were recorded as not having achieved LDA ('not LDA'). Among not LDA reported patients, a higher proportion were female vs the LDA cohort (32% vs 19%). Reported not LDA patients were more likely to suffer any additional co-morbidities vs LDA cohort (63% vs 44%). When analysing disease severity (physician-defined) status between these two patient groups, reported not LDA patients were more likely to be recorded as 'mild' at diagnosis vs LDA (14% vs 4%). In contrast, current (i.e. at time of consult) disease severity was more likely to be recorded as moderate/severe for the not LDA cohort vs the LDA cohort (76% vs 20%). In addition, reported not LDA patients recorded with higher mean disease and haematology scores.

Table 1. Reported patient disease and haematology scores (mean)

Reported AS patients	Tender joint count (TJC)	Swollen joint count (SJC)	C-reactive protein (CRP)	Erythrocyte Sedimentation Rate (ESR)
Achieved LDA	0.8	0.4	10.7	3.6
Not achieved LDA	3.4	2.2	28.9	15.5

The most prominent biologic therapy class used to treat both patient groups are still TNFis; notable JAKi usage is more prominent in the not LDA cohort vs the LDA cohort (9% vs 3%).

Conclusion: From the sample surveyed, it appears the not achieved LDA group are milder at diagnosis but show a greater disease severity/activity on their most recent consultation compared to the LDA cohort – it could be inferred that initial mild severity resulted in a lesser need to treat earlier and, as such, disease progression ensued. There may therefore be an argument to treat early with advanced therapies, regardless of initial disease severity. Further investigation using comparator cohort is warranted.

AB1061 CORRELATION OF SERUM SUBFATIN, CTHRC1, CTRP3, CTRP6 LEVELS WITH DISEASE ACTIVITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Prognostic factors, Spondyloarthritis

İ. M. Baytaroğlu Uçar[1], G. Sargin[2], A. Tuzcu[3], S. Cildag[2], T. Senturk[4]. [1]*1Usak Training & Research Hospital, Rheumatology, Usak, Turkey*; [2]*Aydin Adnan Menderes University, Rheumatology, Aydin, Turkey*; [3]*Aydin Adnan Menderes University, Biochemistry, Aydin, Turkey*; [4]*Aydın, Rheumatology, Aydin, Turkey*

Background: It has been determined that biological treatments affect the serum concentration of these biomarkers independently of disease activity. As current adipokines and known modulators of inflammation, it may play a role in evaluating the efficacy of treatment, especially in cases using biologic agents.
Objectives: To analyze novel biomarkers from the C1q TNF superfamily and their function in autoimmune inflammatory rheumatic disorders, as well as to look for a biomarker capable of evaluating both the clinical disease activity and aiding in the evaluation of therapy efficacy.
Methods: Sixty-one AxSpa patients and 30 healthy controls were enrolled in the study. Serum biomarkers subfatin, CTHRC1, CTRP3, CTRP6, IL-6, IL-17, TNF-α and disease activity indexes BASDAI, BASFI, MASES, ASDAS-ESR/CRP were evaluated and compared. Patients were then classified, and their serum biomarkers were also assessed according to their disease activity scores, and further according to their treatment regimens.
Results: None of the examined biomarkers revealed a discernible difference between patients and healthy controls. Although the difference was not statistically significant, healthy controls were found to have lower median concentrations of serum subfatin, CTHRC1, CTRP3, CTRP6, IL-6, IL-17, and TNF-α. Furthermore, no association between the research biomarkers and clinical disease activity was seen once the patients were categorized according to the severity of their disease. Finally, it was discovered that biological therapies had an impact on these biomarkers' serum concentrations (Table 1) regardless of the disease's activity.
Conclusion: Circulating levels of subfatin, CTHRC1, CTRP3, CTRP6, IL-6, IL-17, and TNF-α, which are novel adipokines and well-known inflammatory mediators, may be important for determining treatment effectiveness, particularly in patients receiving biologics. We were unable to prove a connection between serum biomarker levels and clinical disease activity, though.

Table 1. The comparison between different treatment groups

	Biologics(n=43)	cDMARD(n=18)	p-value
Age (years)	43±9	34±9	**0.02**

AB1062 RENAL INVOLVEMENT IN SPONDYLOARTHRITIS

Keywords: Descriptive studies, Spondyloarthritis, Kidneys

S. Bouden[1], M. Ben Messaoud[1], O. Saidane[1], L. Rouached[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], L. Abdelmoula[1]. [1]Hospital Charles Nicolle, Rheumatology, Tunis, Tunisia

Background: Spondyloarthritis (SpA) encompasses a group of inflammatory diseases characterized by enthesitis, axial and eventually peripheral skeletal involvement. Extra-articular manifestations are common and important systemic features of SpA. The most common extra-articular manifestations are represented by uveitis, bowel disease, skin, heart, lung and kidney involvement. Renal complications are frequent among patients with SpA.
Objectives: The aim of the present study was to assess the epidemiologic, clinical, biological and histological features of renal diseases in SpA.
Methods: A retrospective monocentric study was performed including patients diagnosed with SpA according to the ASAS criteria. Baseline data were obtained during the period from 2002 to 2022. We reviewed sex, age, disease duration and results of laboratory examination and urinalysis in order to detect renal abnormalities.

Results: A total of 107 patients were enrolled in the study, including 78 men and 29 women. The median age was 42 years [16-74]. Renal abnormalities were diagnosed in 8 cases (7.4%), all of them were men. The median age of the patients at the time of diagnosing renal complications was 46 years [21-62]. Renal involvement onset was diagnosed after a mean follow-up of 9.6 years [1-21] from the SpA diagnosis. We noted nonsteroidal antiinflammatory agents (NSAID) intake in 4 cases. Three patients were treated with salazopyrin and one with azathioprine. Among the 8 patients who presented renal abnormalities, we noticed: proteinuria in 5 patients, microscopic hematuria in 2 patients, macroscopic hematuria in 1 patient, nephrotic syndrome in 2 patients and decreased renal function in 2 patients. Secondary renal amyloidosis (4 patients) and Immunoglobulin A nephropathy (2 patients) were the most common causes of renal involvement followed by nephrolithiasis (2 patients). Amyloid deposits were histologically proven by salivary gland biopsy in one case and by renal biopsy in 2 cases. Concerning the Immunoglobulin A nephropathy, the diagnosis was made by renal biopsy and the serum IgA level was normal. Six patients were treated with tumor necrosis factor (TNF)-alpha blocker therapy, with a good outcome only in 4 cases. Only one patient evolved to the end stage renal disease.
Conclusion: The finding of a significant renal abnormality in 7.4% of patients suggests that evidence of renal involvement should be actively sought in this disease by monitoring renal function and urinalysis at regular intervals.

AB1063 PREDICTORS OF ACTIVITY OF ANKYLOSING SPONDYLITIS DURING PREGNANCY

Keywords: Spondyloarthritis, Pregnancy and reproduction

M. Ajdynan[1], N. Melkonyan[1], E. Guryanova[2], N. Zhuravleva[2], V. Diomidova[2]. *[1]Yerevan State Medical University, Department Internal Diseases, Yerevan, Armenia; [2]Chuvash State University by I. N. Ulianov, Department Internal Diseases, Cheboksary, Russian Federation*

Background: The ratio of men and women suffering from ankylosing spondylitis (AS) approaches 1:1. Many women aged 30-40 think about motherhood, which makes it important to study the problem of pregnancy in AS.
Objectives: Assess predictors of AS activity during pregnancy.
Methods: The study included 38 pregnant women who met the New York criteria for ankylosing spondylitis, 1984. The average age of patients was 32.6±6.8 years, age at the onset of the disease was 22.8±12.9 years, disease duration was 132, 9±67.3 months The BASDAI index for 1-3 months before conception, in the I, II and III trimesters averaged 2.2±1.85; 2.7±1.72; 3.3±1.87 and 3.4±2.15, respectively. 11 (28.9%) patients received genetically engineered biological preparations (GEBP) 1–3 months before pregnancy, 8 (21.05%) patients in the month of conception, 4 (10, 5%), 4 (10.5%) and 1 (2.6%) women, respectively. Non-steroidal anti-inflammatory drugs in I, II and III (up to 32 weeks) trimesters were taken by 11 (28.9%), 23 (60.5%) and 16 (42.1%) women, respectively. 25 (65.7%) women planned an observed pregnancy. Most of the patients (n = 28) were included in the study in the first trimester of gestation, 7 - in the II, 1 - in the III trimester. The visits were carried out at 10-11, 20-21 and 31-32 weeks of pregnancy.
Results: In the first trimester of pregnancy with the level of activity according to BASDAI, there were the following significant correlation coefficients: the level of BASDAI (rs=0.71) and back pain (rs=0.71) 1-3 months before conception, smoking experience (rs=0, 39), pregnancy planning with a rheumatologist (rs=-0.35), p<0.05 in all cases. In the second trimester, we can talk about the effect on the activity of the level of BASDAI in the first trimester (rs=0.33) and the fact of pregnancy planning (rs=-0.79). In the third trimester, BASDAI activity was influenced by early follow-up with a rheumatologist (rs=-0.37), pregnancy planning (rs=-0.52), exercise therapy in the third trimester (rs=-0.37). Risk factors for high AS activity (BASDAI>4) were high AS activity 1-3 months before conception (odds ratio (OR) in the I and II trimesters - 23 and 7, respectively; 95% CI; p<0.01), lack of pregnancy planning (OR for trimesters 9.2; 32.5 and 15.9, respectively; 95% CI, p<0.01), the abolition of biologics on the eve of pregnancy and in the first trimester (OR in the II and III trimesters - 23.9 and 22.4, respectively; 95% CI, p<0.01). In addition, risk factors for high AS activity in the third trimester were BASDAI>4 in the first (OR - 7.1; CI 95%, p<0.05) and second trimesters of pregnancy (OR - 9.55; CI 95%, p <0.05).
Conclusion: Lack of pregnancy planning, the value of the BASDAI index at the time of conception and in the first trimester of pregnancy, the abolition of biologics 1-3 months before conception and in the first trimester are predictors of AS activity throughout the gestation period.

AB1064 THE RELATIONSHIP BETWEEN DISEASE ACTIVITY AND CENTRAL SENSITIZATION IN SPONDYLOARTHROPATHY PATIENTS RECEIVING BIOLOGICAL TREATMENT

Keywords: Spondyloarthritis

N. Öz[1], A. Ozer[1], M. T. Duruöz[1]. *[1]Marmara University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Division of Rheumatology, İstanbul, Turkey*

Background: Spondyloarthritis (SpA) is a chronic systemic inflammatory disease. Most patients with SpA complain of chronic pain during the course of the disease. Chronic pain can be explained by central sensitization (SS).
Objectives: Our aim was to investigate the relationship between disease activity and SS in patients with SpA receiving biologic therapy.
Methods: 92 patients with SpA who met the ASAS criteria were included in this *retrospective* study. Demographic characteristics of patients, comorbidities, drug treatments used, Bath Ankylosing Spondylitis Metrology Index (BASMI), Bath Ankylosing Spondylitis Functional Index (BASFI), visual analog scale (VAS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Index (ASDAS-CRP), Maastricht Ankylosing Spondylitis Enthesitis Score (MASES), Central Sensitization Scale (SSS) were calculated. Patients were divided into 2 groups according to BASDAI score <4 low disease activity and ≥4 high disease activity. All parameters between groups were compared. The correlation between the patients' SSQ scores and their BASDAI and ASDAS-CRP scores was analyzed. In addition, ROC analysis was performed to estimate the disease activity of the SS value and the optimal threshold value was determined.
Results: The proportion of patients with high disease activity was 41.3% (n=38 patients). There was no statistically significant difference between the low disease activity (group 1) and high disease activity (group 2) groups in terms of age, gender, body mass index, comorbid diseases, and the medical treatment (NSAID, steroid, methotrexate, sulfasalazine). There was no statistically significant difference between the groups in ESH, CRP and vitamin D levels. SS, MASES, BASFI, and ASDAS-CRP were found to be significantly higher in group 2 patients, respectively (40.87 ± 12.26 vs. 26.78 ± 11.81, p < 0.001; 6.32 ± 3.60 vs. 3.69 ± 3.05, p = 0.001; 5.77 ± 2.12 against 2.80 ± 1.33, p < 0.001, 3.35 ± 0.70 versus 2.43 ± 0.45, p < 0.001). A moderate correlation was found between the SS scale and ASDAS-CRP (r:0.421; p<0.001) and BASDAI (r:0.581; p<0.001). ROC curve analysis showed that the optimal threshold value of the SS scale score for high disease activity was 31.5% with 78.3% sensitivity and 76.1% specificity (AUC: 0.802, 95% CI: 0.687-0.917, p<0.001) (Figure 1).
Conclusion: It has been shown that the central sensitization scale, which is a simple and applicable scale, can be used to evaluate disease activity in SpA patients receiving biologic therapy.

AB1065 BERTOLOTTI SYNDROME: AN UNDER RECOGNIZED CAUSE OF INFLAMMATORY BACK PAIN?

Keywords: Spondyloarthritis, Pain, Quality of life

S. Stebbings[1], C. White2, T. Doyle2. *[1]University of Otago, Department of Medicine, Dunedin School of Medicine, Dunedin, New Zealand*; *[1]University of Otago, Department of Medicine, Dunedin School of Medicine, Dunedin, New Zealand*

Background: Bertolotti syndrome describes a lumbosacral transitional vertebra (LSTV) which causes symptoms, usually low back pain. LATV is a congenital anomaly where the L5 vertebra has an unusual morphology. Bertolotti syndrome is an under-recognised condition by clinicians.
Objectives: To clarify the presentation of Bertolotti syndrome, whether there are features of inflammatory back pain (IBP) and the effect on quality of life.
Methods: In this pilot study, 62 patients with LSTV were identified on imaging (plain x-ray). Imaging was performed for a variety of indications, predominently for back pain. In total, 34 patients agreed to take part, with 18 returning questionnaires. Questionnaires were selected for face vailidity and included: Calin IBP Questionnaire, EQ-5D Questionnaire, Visual analogue pain scale (VAS-P). In view of Covid restrictions all contact was by phone and questionnaires were completed online or returned via post. Plain X-rays visualising the lumbar spine were assessed for radiological features of LSTV.
Results: Seventeen (94%) of the participants (n=18) recorded a VAS-P score >3, indicating a clinically significant level of pain. The mean VAS-P score was 6 (range of 2-9). 89% of respondents scored at least 3/5 in the Calin questionnaire. Of the 5 features of inflammatory back pain in the Calin questionnaire, 4 out of the 5 were reported by most respondents. The exception was 'improvement on exercise', which was only reported by 18% of respondents. Quality of life was impaired-EQ-5D (mean: 0.503, range -0.074 to 0.796). The commonest radiological abnormality was enlarged transverse process (100%) followed by pseudoarticulation with the sacrum (83%) and scoliosis (33%). Presence of sclerosis and/or osteoarthritis at the pseudoarticulation was associated with worse pain scores. Female respondents reported worse pain.
Conclusion: These results suggest Bertolotti syndrome is associated with pain in the majority of patients and affects quality of life,. The character and site of the pain suggests that Bertollotti syndrome should be considered in the differential diagnosis of spondyloarthritis.

Background: Valve degeneration is prevalent in Spondylarthritis (SpA) patients according to descriptive studies, but it is also common in general population. Disease burden may be a key factor for valve degeneration in SpA.
Objectives: Compare clinical, radiographic and laboratory parameters between patients with spondylarthritis (SpA) with aortic valve sclerosis (AVS)
Compare disease duration since onset of symptoms, diagnosis, and age in patients with AVS and patients without AVS.
Methods: A retrospective cohort study was conducted. Eligible patients were 219 SpA patients that met ASAS criteria visited the SpA clinic between July – October 2022. A total of 75 patients that had an echocardiography carried out after SpA diagnosis were included. Aortic valve surgery, rheumatic valve disease, endocarditis and bicuspid valves were excluded. Missing information about SpA were collected prospectively. Comparison between groups was conducted using t test or U-Mann Whitney test according to variable distribution. Proportions were compared using risk difference (RD) or odds ratio (OR).
Results: AVS was observed in 30 (39.5%) patients. Description and comparison of the sample is summarized in Table 1. Age had an OR of 1.17 (95% CI 1.1-1.3) with minor increase of risk for AVS. Duration of disease and delay in diagnosis were similar in both groups. Smoking had a protective effect for AVS with OR former smoker 0.36 (95% CI 0.12-1.11) and OR smokers 0.13 (95% CI 0.03-0.61). Other echocardiographic findings of the patients were: mild aortic insufficiency in 15 (19.5%) and moderate in 3 (3.9%). Mean aortic root diameter was 34.4mm (SD 3.67). Aortic root was dilated in 9 (11.7%).

Table 1.

Time related variables	All (n=75)	AVS (n=30)	No AVS (n=45)	p
Years from 1st symptom to diagnosis, p50 (IQR)	2 (9)	2 (12)	2 (9)	0.59
Years of disease duration since 1st symptom, p50 (IQR)	16.5 (16.5)	15 (19)	17 (16)	0.30
Years of disease duration since diagnosis, p50 (IQR)	11 (15)	9.5 (14)	11 (16)	0.65
Age, mean (SD)	60.9 (15.0)	71.0(9.9)	54.3(15.1)	**0.00**
Clinical variable, n (%)				
Male	30 (61.3)	17 (56.7)	29 (64.4)	0.50
Hypertension	47 (62.7)	22 (73.3)	25 (55.6)	0.12
Dyslipidemia	49 (65.3)	20 (66.7)	29 (64.4)	0.84
Diabetes	22 (29.3)	8 (26.7)	14 (31.3)	0.68
Ischemic heart disease	9 (12)	5 (16.7)	4 (8.9)	0.31
Non-smoker	21(28)	13(43.3)	8(17.8)	**0.02**
Former	35(46.7)	13(43.3)	22(48.9)	
Smoker	17(22.7)	3 (10)	14(31.1)	
B27	24 (35.3)	11 (39.3)	13 (32.5)	0.56
High CRP	49 (73.1)	20 (71.4)	29 (74.4)	0.79
Enthesitis	32 (42.7)	12 (40)	20 (44.4)	0.70
Uveitis	7 (9.3)	3 (10)	4 (8.9)	0.85
Psoriasis	44 (45.9)	20 (66.7)	24 (53.3)	0.34
Nail psoriasis	34 (45.3)	14 (46.7)	20 (44.4)	0.75
Inflammatory bowel disease	1 (1.3)	1 (3.3)	0	0.21

Conclusion: Age showed small but statistically significant association with AVS. Disease duration measured since diagnosis or onset of 1st symptom did not show significant association. Surprisingly, smokers showed less AVS.

AB1067 OPTIC NEURITIS IN SPONDYLARTHRITIS NAÏVE TO TNFA INHIBITORS: A SYSTEMATIC LITERATURE REVIEW

Keywords: Spondyloarthritis

A. D. Bilous[1], B. Balan[2], D. Racz[3], L. Cujbă[4], M. M. Tamas[1,3], N. D. Radics[5], S. Rednic[1,3], C. Pamfil[1,3]. *[1]Emergency Clinical County Hospital Cluj-Napoca, Rheumatology, Cluj-Napoca, Romania*; *[2]Hôpitaux Iris Sud, Rheumatology, Brussels, Belgium*; *[3]Iuliu Haţieganu University of Medicine and Pharmacy, Rheumatology, Cluj-Napoca, Romania*; *[4]Iuliu Haţieganu University of Medicine and Pharmacy, Ophthalmology, Cluj-Napoca, Romania*; *[5]Turda Municipal Hospital, Rheumatology, Turda, Romania*

Background: Optic neuritis (ON) is the expression of many diseases: demyelinating (MS or NMOSD), autoimmune (sarcoidosis, systemic erythematous lupus, Sjogren's syndrome, etc.), infectious (syphilis, tuberculosis, toxoplasma etc.), or genetic disorders such as Leber's Hereditary Optic Neuropathy or Kjer's optic atrophy[1]. In spondyloarthropathies (SpA), ON occurs as a demyelinating adverse event to TNFα inhibitors; however, cases of ON in SpA naïve to TNFα also have been reported.
Objectives: We aimed to assess the directionality and/or causality between SpA and ON in patients naïve to TNFα inhibitors.
Methods: The systematic literature review was performed according to the PRISMA guidelines[2] in four databases (PubMed, Scopus, Embase and Ovid) for studies published from database inception until 01.12.2022. Additionally, we searched the electronic database of our Rheumatology Department for patients with a diagnosis of both SpA and ON. We excluded patients with ON secondary to therapy with TNFα inhibitors and pediatric cases.
Results: We identified 529 studies across the databases. After eliminating duplicates and applying exclusion criteria, we found eight publications (describing nine patients) eligible for review. We identified two additional cases in the electronic database of our center which met the requirements. Among the 11 patients with SpA and ON, 7 (63.63%) were female; the great majority had ankylosing spondylitis (90.9%) and one patient had psoriatic arthritis. HLA-B27 was positive in 8 (72.7%) patients. More than half of the cases (54.54%) were of Asian origin, two (18.18%) were Caucasian; in the rest, the origin was not specified. Bilateral eye involvement occurred in 6 patients, most of whom (83.33%) were HLA B27 positive. Six patients (54.54%) experienced at least one episode of relapse. The workup for demyelinating diseases included anti-MOG antibodies (performed in three, positive in one case) and anti-AQP4 antibodies (tested in six, positive in one). Oligoclonal bands were assessed in a limited number of cases (36%) and were reported positive in one of four tested patients; a diagnosis of demyelinating disease (NMO-SD or MS) was established in 3 (27%) patients. No thorough infectious disease screening was reported in any of the published cases. Various treatment protocols were employed in the management of ON; only 3/11 (27%) patients followed the standardized ON treatment regimen (ONTT)[3]. In seven patients, ON resulted in the complete loss of vision or perception of light.
Conclusion: Literature reports of the association of NO and SpA are scarce, pointing to the coexistence, rather than a causative association between the two diseases. Patients with SpA who develop ON should undergo a thorough screening for an underlying etiology. Timely standardized treatment for ON is mandatory to improve the outcome of patients with ON.

AB1068

THE ROLE OF HEPCIDIN IN THE FORMATION OF ANEMICAL SYNDROME IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND ITS SIGNIFICANCE IN THE DIFFERENTIATION OF ANEMIA OF CHRONIC DISEASE, IRON DEFICIENCY ANEMIA AND THEIR COMBINATION

Keywords: Spondyloarthritis, Diagnostic tests

O. Zviahina[1], S. Shevchuk[1], O. Pavliuk[1]. *[1]*National Pirogov Memorial Medical University, Vinnytsya, Internal Medicine Chair # 2, Vinnytsia, Ukraine

Background: Anemia is a frequent comorbid condition in ankylosing spondylitis (AS) patients. Anemia of chronic disease (ACD), iron deficiency anemia (IDA) and their combination are most often found in patients. The differential diagnosis between ACD and IDA is important because they require different treatment and at the same time is complicated due to the presence of an inflammatory component.
Objectives: To establish the role of hepcidin in the formation of anemic syndrome in AS patients and its significance in differentiating anemia of chronic disease, iron deficiency anemia and their combination.
Methods: The study included 76 patients diagnosed with AS according to the modified New York criteria (1984) and 26 controls. Among them, there were 47 patients without anemia and 29 patients with anemia (IDA, n=7; ACD with iron deficiency, n=6; ACD, n=15, folate deficiency anemia, n=1). The diagnostic list included a complete blood count, serum iron, total iron-binding capacity, transferrin saturation, serum ferritin, soluble transferrin receptors (sTfR), and hepcidin. In the literature, there are no clear criteria for gradation of hepcidin levels, therefore, for further analysis, a percentile comparison was performed and indicators corresponding to P25 (up to 25 ng/ml), P25 - P75 (25-35 ng/ml) and P75 (above 35 ng/ml) were selected control group. The statistical processing of the obtained results was carried out using the Microsoft Office Excel 2007 statistical software package.
Results: In the group of AS patients, 41 patients (54%) had hepcidin levels >P75, 16 (21%) - <P25, and 19 (25%) within P25 - P75. Hepcidin levels in patients with anemia were 1.4 times higher (51.77 ± 4.62 ng/ml) than in people without anemia (36.08 ± 2.57 ng/ml). The level of hepcidin (35.84±7.50 ng/ml) in patients with IDA is practically comparable to the group of patients without anemia. The level of hepcidin (62.78±5.94 ng/ml) is 1.7 times higher in people with ACD than in people with IDA ($p<0.05$). Patients with ACD and iron deficiency in terms of hepcidin level occupy an intermediate place (48.53±9.50 ng/ml), which may indicate an important role in the pathogenesis of ACD and can be used as a diagnostic marker for the differential diagnosis of ACD and IDA. In the group of patients without anemia, we found no significant relationship between hepcidin and indicators of red blood and ferrokinetics. While in individuals with anemia we found the relationship of hepcidin with serum iron ($r=0.26$; $p<0.05$), soluble transferrin receptors ($r=-0.15$; $p<0.05$) and transferrin saturation coefficient ($r=0.17$; $p<0.05$).
Conclusion: For AS patients, for the early differential diagnosis of the types of anemia (ACD, IDA, and ACD with iron deficiency), in addition to traditional methods, the complex of laboratory tests should include determination of the hepcidin level in blood serum. A high level of hepcidin indicates the presence of ACD.

GENDER DIFFERENCES IN PRESENTATION, CLASSIFICATION, AND DISEASE ACTIVITY OF SPONDYLOARTHRITIS: RESULTS FROM GESPA COLOMBIAN COHORT

Keywords: Spondyloarthritis, Geographical differences, Gender/diversity issues

M. J. Mantilla[1], G. Rodríguez Salas[1], A. M. Santos[2], V. Navarro-Compán[3], I. Rueda[2], J. C. Santacruz Devia[1], J. G. Ballesteros[1], E. Calvo[2], S. Arias[2], J. Rueda[2], M. Cardiel[4], C. F. Pacheco Tena[5], J. Londono[1]. *[1]Universidad of La Sabana - Millitary Central Hospital, Spondyloarthritis Study Group (GESPA), Bogotá, Colombia*; *[2]Universidad Nacional, Spondyloarthritis Study Group (GESPA), Bogotá, Colombia*; *[3]La Paz University Hospital, Department of Rheumatology, Madrid, Spain*; *[4]Clinica de Morelia, Centro de investigación, Michoacán, Mexico*; *[5]Universidad Autónoma de Chihuahua, Facultad de Medicina y Ciencias Biomédicas, Chihuahua, Mexico*

Background: Spondyloarthritis (SpA) is a chronic inflammatory rheumatic disorder composed of axial (AxSpA) and peripheral (pSpA) disease. AxSpA is further subdivided into radiographic AxSpA (r-AxSpA) and non-radiographic AxSpA (r-AxSpA). Historically, SpA was mostly a male disease. However, actual disease awareness has changed the approach, allowing women to be included to a greater extent.

Objectives: Few studies have explored the male and female disease features in Latin American population. The aim of this study was to examine the clinical presentation, disease onset characteristics, metrology, HLA frequency, and clinical characteristics of male and female SpA patients.
Methods: We used a cohort of Colombian SpA patients from 1990 to the current day. Patients were evaluated by rheumatologists, filled out validated questionaries, and were classified according to the Assessment of SpondyloArthritis International Society (ASAS) classification criteria at the time of diagnosis. Using the available information, patients enrolled before to 2011 were reclassified according to ASAS. We compared the features of both genders and used SPSS 26.0 to conduct statistical analysis.
Results: In this study, 469 SpA patients from a Colombian SpA cohort were included. There were 164 (34.9%) females and 305 (65.1%) males total. There were no statistically significant differences in ASAS classification; 61.2% of females and 50.6% of males had AxSpA, P = 0.3. However, nr-AxSpA was more prevalent among females (20.6%) than males (13.3%), P = 0.01. In all groups the frequency of HLA-B15 was comparable (15.9% vs. 11.2%, P = 0.1). And the prevalence of HLA-B27 was greater in men than in women (52.4% vs. 33.3%, P < 0.01). The symptoms at the onset of the disease had similar distribution in both sexes (table 1). Enthesopathy was more prevalent among women than males (82.4% vs. 72.4%, P = 0.02). but no arthritis, uveitis, psoriasis, and inflammatory bowel disease (table 1). In males, disease onset was more acute (40.7% vs. 27.3%, P = 0.04). Age at beginning of the disease was 32 (24.5 – 41.1) years for females and 24.89 (20.5 – 31.7) years for males (P < 0.01). The time to diagnosis (in months) was 39 (11.5 – 126) for females and 13 (3 – 71) for males (P < 0.01). Women had more functional impairment measured by BASFI, disease activity measured by BASDAI, and self-reported illness activity than men, although men had a higher C-reactive protein (CRP) (P < 0.01) (Table 1).
Conclusion: Nr-AxSpA is more frequent in women than in men, although radiographic disease is more prominent in men. The prevalence of HLA-B27 is higher in men with SpA. Males are older at the onset of the disease and were diagnosed sooner than females. Females had more disease activity as measured by BASDAI and functional impairment as measured by BASFI, whereas males have lower CRP levels.

Table 1.

		Female	Male	P value

CERVICAL SPINE INVOLVEMENT IN AXIAL SPONDYLOARTHRITIS. RADIOGRAPHIC CHARACTERISTICS AND ASSOCIATED FACTORS

Keywords: Imaging, Spondyloarthritis, Descriptive studies

L. Berbel Arcobé[1], X. Michelena[2], J. A. Narvaez[3], J. M. Nolla[1], J. Palacios Olid[1], P. Maymo Paituvi[1], X. Juanola-Roura[1]. *[1]Bellvitge University Hospital, Rheumatology, L'Hospitalet de Llobregat, Spain*; *[2]Vall d'Hebron University Hospital, Rheumatology, Barcelona, Spain*; *[3]Bellvitge University Hospital, Radiology, L'Hospitalet de Llobregat, Spain*

Background: The study of the cervical spine (CS) in axial spondyloarthritis (axSpA) and its radiographic characteristics including the zygapophyseal joints (ZJ) may be helpful for early diagnosis, establishing a prognosis and sharpening treatment choices.
Objectives: To describe the prevalence and characteristics of CS involvement in a cohort of patients with axSpA and its associated factors, who have been followed up in the Rheumatology Department of a third level university hospital.
Methods: Descriptive, retrospective and unicentric study. Patients with an axSpA diagnosis based on the ASAS classification criteria, from March 2011 to December 2022, retrieved from a dedicated axSpA database were included. Sociodemographic, clinical, radiographic and therapeutic variables were gathered. They were separated into two groups according to CS involvement; "CS group" as patients with BASRI≥2 in CS and/or a score ≥3 in ZJ measured by De Vlam method[1]; and "no CS group" as controls.
Results: A total of 340 patients were included (71.8% men; mean age 57,4 ± 14,9 years). CS involvement is common among axSpA (n=182; 53,5%). ZJ involvement was observed in 99 patients (29,1%), and of those, 21 did not show concomitant structural damage in the vertebral bodies. A total of 83 patients (24,4%) had damage in the vertebral bodies exclusively, and 37 (10,9%) had CS involvement without radiographic involvement of the lumbar spine (LS) (29,7% women). Patients from the CS group were predominantly men, older, had a higher BMI and higher prevalence of smoking (Table 1). They also showed higher disease activity (BASDAI and ASDAS CRP), worse function (BASFI), worse mobility in CS and LS, as well as more structural damage in both LS and sacroiliac joints. No differences were found between groups for positive HLA B27, age at diagnosis, familiar history, presence of arthritis, enthesitis, dactylitis or extra musculoskeletal manifestations (uveitis, psoriasis or IBD).
Conclusion: The radiographic evaluation of the CS is relevant in axSpA, and it should be performed routinely, as well as the evaluation of the ZJ, as they are commonly involved in axSpA and related to higher disease activity and worse function.

MICRONUTRIENTS DEFICIENCY IN ENTEROPATHIC SPONDYLOARTHRITIS: EXPLORING THE INTERPLAY BETWEEN JOINT AND GUT DISEASES IN A CASE-CONTROL STUDY

Keywords: Spondyloarthritis

P. Triggianese[1], M. Fatica[1], B. Neri[2], A. D'antonio[1], E. Calabrese[2], S. Schiavone[2], A. Bergamini[1], L. Biancone[2], M. S. Chimenti[1]. [1]*University of Rome Tor Vergata, Rheumatology Allergology and Clinical Immunology, Rome, Italy*; [2]*University of Rome Tor Vergata, Gastroenterology Unit, Rome, Italy*

Background: Micronutrient deficiency (MND) is common among patients with certain chronic inflammatory diseases. MND is associated with a pro-inflammatory status and co-morbidities. Recent evidence documented a relevant prevalence of MND in Spondyloarthritis (SpA) and its interplay with gender and inflammatory-dependent dysmetabolism[1]. MND in patients with Enteropathic Spondyloarthritis (ESpA) has not been analyzed even though the concomitant occurrence of Inflammatory Bowel Disease (IBD) and SpA might strongly impact MNDs.
Objectives: In this study, we aimed at comparing for the first time the occurrence of anemia and deficiencies of ferritin (Fe), vitamin B12 (B12), folic acid (FA), and vitamin D [25(OH)D] in patients with ESpA, IBD without SpA, and isolated SpA.
Methods: In a prospective case-control study, consecutive subjects were enrolled among ESpA (Cases), IBD (Controls-1), and SpA (Controls-2) patients referring to combined gastro-rheumatologic outpatient Clinic at the "Tor Vergata" University Hospital (Rome, Italy). Each Case (ESpA) was retrospectively matched (1:1) for IBD type with one IBD subject from Controls-1 group. Inclusion criteria: 1) age ≥18 years; 2) follow up (≥2 visits/year); 3) recent (<3 mos) micronutrients data. Additional inclusion criteria for Cases: 1) diagnosis of SpA, 2) diagnosis of IBD. Additional inclusion criteria: 1) for Controls-1: diagnosis of IBD; 2) for Controls-2: diagnosis of SpA. Additional exclusion criteria: 1) for Controls-1: diagnosis of SpA; 2) for Controls-2: diagnosis of IBD. Mean and standard deviation (SD) express normally distributed variables; for non-symmetric distributed data, median and range were used. Continuous variables were compared by using either unpaired T test or the Mann-Whitney U test, as appropriate. Categorical variables were were compared using the Chi-squared test or Fisher's exact test, as appropriate. P value<0.05 was significant.
Results: One hundred ESpA (Cases) were enrolled and matched with 100 IBD (Controls-1, n=58 Crohn's Disease - CD, n=42 Ulcerative Colitis - UC), and 100 SpA including 81% psoriatic-SpA (Controls-2). The median age was comparable between groups (Cases, 50 [20-77]; Controls-1; 48.5 [19-86], Controls-2; 53 [26-77]), while male gender was more frequent in Controls-1 than Cases (P=0.0001). The median IBD duration was shorter in Cases than in Controls-1 (P<0.0001) while the frequency of IBD-related surgery was comparable between the two groups. In patients with CD (n=58 in both groups), lesions distribution was comparable between Cases and Controls-1; differently, penetrating CD was less frequent in Cases vs Controls-1 (P=0.02). Cases had a shorter SpA disease duration (P=0.004) and a higher rate of patients in moderate/high SpA disease activity than Controls-2 (P=0.02). Anemia (Hb≤12 g/dl) was slightly prevalent in Cases and Controls-1 (15% and 19%, respectively) than in Controls-2 (7%) while Fe deficiency (Fe≤15 ng/dL) was similar between Cases and Controls-1 and significantly prevalent in both Cases and Controls-1 than Controls-2 (P=0.001 for both). The B12 deficiency (≤200 pmol/l) was similar between Cases and Controls-1 but it resulted more frequent in Controls-1 than Controls-2 (P=0.04). The rate of folate defect (≤4 ng/ml) was similar between Cases and Controls-1 but it resulted less frequent in Controls-2 than in both Cases (P=0.002) and Controls-1 (P=0.00001). The 25(OH)D deficiency (≤20 ng/ml) was more frequent in Controls-2 than Cases (P=0.02).
Conclusion: In ESpA, MND results relevant and appears comparable with MND revealed in IBD patients without SpA. The isolated SpA seems to be related mainly with vitamin D deficiency that in turn might be linked to SpA disease duration and activity.

ANKYLOSING SPONDYLITIS: UNEARTHING THE ASSOCIATION BETWEEN ACTIVE SACROILIITIS ON MRI AND C-REACTIVE PROTEIN AS A MARKER OF INFLAMMATION

Keywords: Imaging, Spondyloarthritis

H. EL-Kasmi[1], N. Akasbi[1], I. El Mezouar[1], M. Omari[2], T. Harzy[1]. [1]المركز الاستشفائي الجامعي الحسن الثاني, *Rheumatology, Fes, Morocco*; [2]المركز الاستشفائي الجامعي الحسن الثاني, *Laboratory of Epidemiology, Clinical Research and Community Health, Faculty of Medicine and Pharmacy, Sidi Mohammed Ben Abdellah University, Fes, Morocco*

Background: Ankylosing spondylitis (AS) is a chronic autoimmune disorder that causes inflammation in the joints, particularly the sacroiliac joints. Magnetic resonance imaging (MRI) is a non-invasive and objective tool that can be used for early diagnosis of AS. C-reactive protein (CRP) is a biomarker that is commonly used to evaluate disease activity in AS patients, and is included in the Ankylosing Spondylitis Disease Activity Score with C-reactive protein (ASDAS-CRP).
Objectives: The primary outcome of the study to investigate the association between active sacroiliitis on MRI and CRP levels in AS patients. The secondary outcome was to identify other parameters that may be associated with sacroiliitis activity in AS patients. The study was a retrospective analysis that included 140 AS patients who had MRI of their sacroiliac joints between January 2011 and March 2022.
Methods: Retrospective study was conducted on all SpA cases that were established between January 2011 and March 2022. The study aimed to explore the relationship between sacroiliitis as detected on MRI and C - reactive protein (CRP) levels in patients with Ankylosing Spondylitis. Magnetic Resonance Imaging (MRI) of the sacroiliac joints was performed on all patients using coronal oblique T1, T2 and STIR weighted sequences. Active sacroiliitis was defined as the presence of inflammatory lesions according to the ASAS (Assessment of SpondyloArthritis international Society) criteria. CRP was considered high if it was greater than or equal to 6 mg/L. The statistical analysis was performed using the Fisher and Chi-Squared test and a p-value of 0.05 was considered as the level of significance.
Results: MRI of the sacroiliac joints was performed in 140 patients; the mean age was 47.54± 14.46 years with a predominantly female sex ratio of 0.34 (M/F). The mean duration of evolution was 5.40± 5.13. Active sacroiliitis was found in 65% of the patients, it was bilateral in 31.4%, unilateral in 28.6% (15% left and 13.6% right). An elevated CRP was found in 60.3% of the patients, the mean CRP was 21.79± 44.68, and the mean sedimentation rate was 26.04± 26.12. Active sacroiliitis did not have a statically significant association with an elevated CRP level. For the other clinico-biological parameters, Young onset was significantly associated with active sacroiliitis (p<0.05).
Conclusion: In conclusion, this study did not demonstrate a significant association between CRP levels and active sacroiliitis on MRI in patients with AS. However, the study suggests that MRI may allow for an early diagnosis of AS in the absence of biological inflammation, and that young onset may be a risk factor for active sacroiliitis in AS patients. Further studies are needed to validate these findings and to better understand the relationship between CRP levels, imaging, and sacroiliitis activity in AS patients.

IS THERE A RELATIONSHIP BETWEEN BONE TURNOVER MARKERS AND DISEASE ACTIVITY IN TUNISIAN SPONDYLOARTHRITIS PATIENTS?

Keywords: Spondyloarthritis, Vitamin D

S. Rekik[1], S. Rahmouni[1], K. Zouaoui[1], S. Boussaid[1], H. Ajlani[2], H. Sahli[1], M. Elleuch[1]. [1]*La Rabta hospital, Rheumatology, Tunis, Tunisia*; [2]*Yasminette Ben Arous Hospital, Rheumatology, Ben Arous, Tunisia*

Background: It has been reported that disease activity was correlated to the alterations in vitamin D metabolism and increased bone resorption in patients with spondyloarthritis (SpA).
Objectives: To investigate the relationship between bone turnover markers, Vitamin D levels and disease activity in SpA patients.
Methods: In this cross-sectional study, we included patients with SpA.
In addition to the routine blood and urine tests, serum 25-(OH)D3, bone turnover markers (osteocalcin and Alkaline phosphatase (ALP) for formation, and serum C-terminal telopeptide (CTX) for resorption) of all participants were also measured. The disease activity was evaluated by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and AS disease activity scores (ASDAS-CRP) and the functional status by Bath Ankylosing Spondylitis Functional Index (BASFI).
Results: We included 79 patients (56 males, 23 females; mean age: 46.3 ± 1.9 years). The mean 25(OH)D, Calcium, Phosphor, ALP, PTH, Osteocalcin, CTX values were 17.7± 9.8 ng/ml, 89.70±12 (mg/l), 36.10 ±9.5 (mg/l), 84.6± 28.5(UI/l), 38.5 ±25.7 (pg/ml), 23.7± 9 (ng/ml), 0.57± 0.32(ng/ml), respectively. The mean

BASDAI, ASDAS-CRP, BASFI, and CRP were 4.13±2.11, 3.21±1.19, 4.5±2.25 and 20.97±12,5 mg/l respectively. There were negative correlation between PTH levels and disease duration (p: 0.029, r: -0.248), ASDAS-CRP (p=0.017, p=-0,433) and CRP levels (p=0.014, r=-0.332). The present study didn't show any correlation between both APL, osteocalcin levels and BASDAI, BASFI, ASDAS-CRP (p>0.05). We couldn't find any correlation between CTX and disease activity scores.

Conclusion: Bone formation markers (APL and osteocalcin) and bone resorption markers (CTX **I**) did not correlate with disease activity. However, PTH levels were negatively correlated with disease activity in patients with SpA.

AB1074 TO ASSESS ADHERENCE TO OMERACT/ASAS RECOMMENDATION FOR MRI PROTOCOL IN AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis

D. Hassan[1], M. Shahzad[2], A. Jilani[2]. *[1]Hammersmith Hospital, Department of Rheumatology, London, United Kingdom*; *[2]Hammersmith Hospital, Rheumatology, London, United Kingdom*

Background: The interpretation of MRI in Axial Spondyloarthritis (AxSpA) has been a topic of much debate and controversy. The OMERACT/ASAS MRI group devised a list of recommendations for the protocol used in diagnostic MRI for AxSpA [1]. MRI of the sacroiliac joints (SIJs) is of crucial importance in confirming a diagnosis of AxSpA in patient presenting with back pain and a positive interpretation has a major impact on early diagnosis. The lack of agreement on a positive MRI and limited expertise in interpreting these MRI images [2] is the main stumbling block in the long diagnostic delay still seen in patient with AxSpA [3].

Objectives: We carried out a retrospective survey to assess the protocol being used in the Radiology department for requests for diagnostic MRI of spine and SIJs in patient presenting with features of inflammatory back pain. The recommended protocol is to perform short T1 inversion recovery (STIR)and T1 weighted sequences of the whole spine in sagittal view and coronal oblique views of the SIJs.

Methods: Data was collected retrospectively on 57 patients confirmed to have a diagnosis of AxSpA made by a rheumatologist, from 2015 to 2022. The protocol used for the MRi imaging was confirmed from the available radiological reports and where required further clarification of the protocol used was confirmed by the help of the performing and reporting radiologist. We also made note of the HLA-B27 status of this cohort and the use of NSAIDS and c DMARD and subsequent use of biological agents.

Results: Of the 57 patients included in this study, 25 were female and 32 were male. Just over one third of the patients (n= 23) were HLA-B27 positive, with under a third were HLA-B27 negative (n= 20), and in about a quarter of the cohort this had either not been checked or was not documented. In this cohort 16 patients were diagnosed within two years of onset of symptoms and about a third (n=23) within 5 years of onset of first symptoms. The duration of first onset of symptoms to diagnosis ranged from 7 months to a maximum of 10 years, giving a mean value of just over 7 years. Out of the 57 patients studied, about a third (n=26) had their first MRI according to the SpA protocol. A subsequent MRI was carried out in 19 patients and 11 of these were according to the SpA protocol.

Conclusion: The correct SpA protocol is still not being applied to all inflammatory back pain imaging requests. In this study we note that although this has improved in subsequent imaging, the fact remains, that not all Radiologists are fully compliant with the use of the correct SpA protocol. This is adding to the diagnostic delay and hence commencement of appropriate treatment to control the disease and prevent further progression and structural changes in the spine and SIJs. We recommend that all rheumatologists proactively and regularly audit their radiology department to improve the awareness and hence implement the correct protocol for MRI imaging in AxSpA.

AB1075 CHARACTERISTICS OF COLOMBIAN PATIENTS WITH SPONDYLOARTHRITIS: DIFFERENCES BETWEEN AXIAL AND PERIPHERAL RESULTS FROM THE GESPA COLOMBIAN COHORT

Keywords: Spondyloarthritis, Epidemiology, Descriptive studies

J. Londono[1,2], I. Rueda[1,2], A. M. Santos[2], G. Rodríguez Salas[1,2], M. J. Mantilla[2], J. C. Santacruz Devia[2], S. Arias[2], J. Rueda[2], J. M. Bello-Gualtero[1], E. Calvo[3], M. Cardiel[4], C. F. Pacheco Tena[5]. *[1]Hospital Militar Central, Rheumatology, Bogotá, Colombia*; *[2]Universidad de La Sabana, Medicine, Chía, Colombia*; *[3]Universidad Nacional de Colombia, Medicine, Bogotá, Colombia*; *[4]Clínica de Morelia, Michoacan, Michoacan, Mexico*; *[5]Universidad Autónoma de Chihuahua, Medicine, Chihuahua, Mexico*

Background: Spondyloarthritis groups several diseases with similar clinical, biochemical, and imaging characteristics. These similarities have allowed this disease to be classified since 2009 as both axial or peripheral. The Latin American population with spondyloarthritis presents differential characteristics that do not allow it to be adequately classified by the current ASAS criteria, and because there are few latin cohorts of patients with spondyloarthritis, it is necessary to continue with the construction of said cohorts to improve the knowledge of the disease in our region, improving our participation in the construction of more inclusive criteria.

Objectives: To describe the clinical, biochemical, and imaging characteristics of Colombian patients diagnosed with spondyloarthritis at a reference institution in Bogotá DC.

Methods: Patients with a diagnosis of spondyloarthritis were chosen according to the assessment carried out by four expert rheumatologists at a reference institution in Bogotá DC, Colombia, between 2002 and 2015. They underwent a survey that included clinical, biochemical, and imaging characteristics and were followed up in a rheumatology clinic.

Results: 473 patients were recruited between 2002 and 2015, with 65.1% men, 83.7% being of mixed race, a mean age of onset of the disease of 29.5 years, and a median delay in the diagnosis of the disease of 24 months. According to the ASAS classification, there were 189 axial patients and 223 peripheral patients; there were no differences between the age of onset of symptoms, sex, race, or duration of the first symptom between both groups. The axial patients had the longest delay in diagnosis (P = 0.03); more low back pain and less arthritis as initial symptoms (P 0.001); a higher frequency of insidious onset of arthritis (P 0.001); greater pain in the spine, stiffness, and inflammatory characteristics of pain (P 0.001). Patients with axSpA presented with more enthesitis (P = 0.03), less arthritis (P = 0.02), limited chest expansion (P = 0.03), and sacroiliitis on physical examination (P = 0.001). Patients with pSpA have a lower frequency of HLA-B27 (P 0.001) but a higher frequency of other HLA alleles (P = 0.01), such as HLA-B15 (P = 0.001), with a higher ESR (P = 0.03).

Conclusion: Colombian patients with SpA are predominantly young men, with pSpA being the most frequent. AxSpA patients present a longer delay in diagnosis, more low back pain and less arthritis as initial symptoms, greater pain and stiffness of the spine compared to patients with pSpA spondyloarthritis, but the latter present more of the HLA-B15 allele, a higher frequency of previous infection and higher ESR than patients with axSpA.

AB1076 SPECTRUM OF AXIAL SPONDYLOARTHRITIS IN COLOMBIAN'S PATIENTS: NON-RADIOGRAPHIC VS RADIOGRAPHIC AXIAL SPA. RESULTS FROM GESPA COLOMBIAN COHORT

Keywords: Epidemiology, Spondyloarthritis

I. Rueda[1,2], G. Rodríguez Salas[1,2], A. M. Santos[1], M. J. Mantilla[1,2], J. C. Santacruz Devia[1], E. Calvo[3], J. G. Ballesteros[2], S. Arias[1], J. Rueda[1], M. Cardiel[4], C. F. Pacheco Tena[5], V. Navarro-Compán[6], J. Londono[1,2]. *[1]Universidad de La Sabana, Cundinamarca, Chía, Colombia*; *[2]Hospital Militar Central, Bogota DC, Bogotá, Colombia*; *[3]Colombia National University Hospital, Bogotá DC, Bogotá, Colombia*; *[4]Clínica de Morelia, Michoacan, Michoacan, Mexico*; *[5]Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, Mexico*; *[6]La Paz University Hospital, Medicine, Madrid, Spain*

Background: Spondyloarthritis encompasses several diseases with similar clinical, biochemical, and imaging features. Since 2009, these characteristics have allowed this disease to be classified into axial and peripheral, with the presence of chronic spinal pain and the age of onset of the disease being important criteria for the classification of axial spondyloarthritis[1]. Interest in non-radiographic axial spondyloarthritis has recently increased [2], but this information is limited in our population.
Objectives: To differentiate the clinical, biochemical, and imaging characteristics of one Colombian cohort of patients with radiographic and non-radiographic axial spondyloarthritis.
Methods: Patients with axial spondyloarthritis were consecutively recruited at a reference institution in Colombia from 2002 to 2015. A structured survey was conducted at the time of the diagnosis of the disease, which included sociodemographic, clinical, biochemical, and imaging variables. The presence of sacroiliitis was evaluated by locar radiologist. Patients and disease characteristics were comparated nr-axSpA and r-axSpA.
Results: A total of 258 patients with axial spondyloarthritis were recruited between 2002 and 2015, of whom 69.6% (185 patients) were radiographic axial and the remaining 30.4% (73 patients) were non-radiographic axial. When comparing the two groups (radiographic vs. non-radiographic axial), not differences were observated in sex, the age of onset, the duration of the disease, initial symptom, number of swollen joints, duration of morning stiffness, number of painful entheses. Compared with r-axSpA, patients with nr-axSpA had greater presence of HLA-B15 (P=0,04), presence of inflammatory spinal pain (P=0,01), history of relatives with spondyloarthritis (P=0,03), longer duration of enthesitis (P=,001), low back pain (P=0,007) and gluteal pain (P=0,003) in the first episode, and greater chest expansion (P=0,001) and distance in the Schober test (P<0,001) in non-radiographic axial versus radiographic axial patients.
Conclusion: Colombian patients with non-radiographic axial spondyloarthritis have higher presence of HLA-B15, higher frequency of inflammatory spinal pain, family history of spondyloarthritis, low back pain, and gluteal pain during the first episode of the disease, greater chest expansion and distance on the Schober test than patients with radiographic axial spondyloarthritis.

AB1077 THE PREVALENCE AND ASSOCIATED FACTORS OF SARCOPENIA IN AXIAL SPONDYLOARTHRITIS

Keywords: Sarcopenia

N. Kanjanavaikoon[1], P. Saisirivechakun[1], S. Chaiamnuay[1]. [1]*Phramongkutklao Hospital, Medicine, Bangkok, Thailand*

Background: Sarcopenia consists of decreasing muscle strength, muscle mass and physical performance. Muscle wasting is common in chronic inflammatory diseases, such as spondyloarthritis (SpA).
Objectives: This research aims to determine the prevalence and associated factors of sarcopenia in Thai ankylosing spondylitis patients.
Methods: A cross-sectional study was conducted at Phramongkutklao Hospital between January 2020 and February 2021. One hundred and four axial spondyloarthritis (ax-SpA) patients who met the 2009 ASAS criteria were enrolled. Sarcopenia related factors and disease characteristics were recorded. Sarcopenia was diagnosed according to the Asian Working Group for Sarcopenia 2019. Appendicular skeletal muscle mass was measured by antero-posterior dual-energy X-ray absorptiometry. Strength, Ambulation, Rising from a chair, Stair climbing and history of Falling (SARC-F) was evaluated. Muscle strength was measured by hand grip strength and chair stand time. Physical performance was assessed by 6-meter walk and time up and go tests. Logistic regression was performed to identify factors associated with sarcopenia.
Results: Most patients were male (77%) with the mean (standard deviation: SD) age and disease duration were 42.64 (12.19) and 8.3 (8.5) years. The mean BMI (SD) was 23.80 (4.44). The prevalence of sarcopenia was 22.1%. There was no difference in disease activities (BASDAI and ASDAS) between ax-SpA patients with and without sarcopenia. Factors independently associated with sarcopenia were age and low BMI with the adjusted odd ratios and 95% confidence interval of 27.319 (3.69-202) and 12.517 (1.67-93.76) respectively.
Conclusion: Sarcopenia is common in ax-SpA patients. It is independently associated with older age and low BMI, but not disease activity.

AB1078 SPONDYLOARTHRITIS AND INFLAMMATORY BOWEL DISEASE (IBD): CLINICAL AND PARACLINICAL CHARACTERISTICS

Keywords: Descriptive studies, Enthesitis, Comorbidities

H. Bara[1], H. Arabi[1], F. E. Bennani[1], A. Mougui[1], I. El Bouchti[1,1]. [1]*University Hospital Mohammed VI Marrakech, Rheumatology, Marrakech, Morocco*

Background: Spondyloarthritis (SpA) is a group of chronic inflammatory rheumatic diseases characterized by enthesis involvement. SpA can be associated with extra-articular manifestations, in particular Inflammatory bowel disease (IBD)
Objectives: The objective of the study is to compare the clinical and paraclinical characteristics of a population of patients with spondyloarthritis (SpA) associated to IBD and patients without IBD.
Methods: Retrospective study conducted in the Rheumatology Department, including patients followed up for SpA for SpA between 2004 and 2021.
Results: Our study involved a population of 333 patients with SpA. he averages age was 40.5 years. Men constituted 54.1%. Smokers represented 13.5% of the cases, diabetics 7.5%, hypertensives 8.4% and 9.9% of patients had IBD. In univariate analysis: patients with SpA with IBD had more uveitis (p=0.001), more stage VI sacroiliitis (p=0.0001), more syndesmophytes p= 0.02) and a more active disease according to the BASDAI (p= 0.011). In multivariate analysis, SpA with IBD was associated with uveitis (OR 3.53) and to a BASDAI higher than 4 (OR 2.7).
Conclusion: In our study, uveitis, stage VI sacroiliitis, and syndesmophytes were more frequent in patients with SpA and IBD, with a more active disease.

AB1079 CLINICAL, RADIOLOGICAL AND BIOLOGICAL CHARACTERISTICS OF SPONDYLOARTHRITIS WITH COXITIS

Keywords: Spondyloarthritis, Prognostic factors

H. Arabi[1], F. Idrissi Zaki[1], H. Tebaa[1], A. Mougui[1], I. El Bouchti[1]. [1]*Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Rheumatology, Marrakech, Morocco, Rheumatology, Marrakesh, Morocco*

Background: Spondyloarthritis (SpA) is the most common chronic inflammatory rheumatic disease with hip involvement, which is a marker of disease severity, given its major functional impact.
Objectives: Determine the clinical, biological and radiological characteristics of SpA with coxitis, and to determine the factors associated with its occurrence.
Methods: Retrospective and analytic study including patients with SpA. Clinical demographics, biological radiological data, and activity scores were collected. The significance threshold was set for a value of p<0.05.
Results: These were 333 patients, of which 54.1% were men. The mean age was 40.52±15.05 years, and the mean age at onset was 32.02±15.42. The percentage of smoking patients was 11.1%. HLA-B27 was positive in 57% and uveitis was present in 7.2% of patients. Coxitis was present in 25.52% of patients, it was inaugural in 10.5% and bilateral in 71.76% of cases. Coxitis was more common in men; the male gender accounted for 76.47% in SpA with coxitis versus 46.37% without coxitis (p<0.001). The mean age of SpA onset was lower in patients who developed coxitis (24.4±13.75 years versus 34.6±15.14 years; p = 0.014). Pure axial form and low back and buttock pain were more noted in patients with coxitis (18.8% versus 13.3% p=0.022, 31.7% versus 18.9% p=0.018 respectively). Enthesopathy was more common in SpA without coxitis (56.86% versus 35.3%, p=0.001). There was no significant difference between the two groups for CRP and erythrocyte sedimentation rate (p=0.91; p=0.35), nor for ASDAS and BASDAI (p=0.95; p=0.38 respectively). Also a frequency not modified by the presence or absence of coxitis was noted, in particular for the family history of SpA, smoking, HLA-B27, uveitis, the existence of radiographic sacroilitis.
In multivariate analysis, coxitis was associated with male gender, early age of onset, and pure axial form.
Conclusion: Our study showed that the presence of coxitis was associated with early disease onset, male sex and pure axial form of SpA.

AB1080 IS HLA-B27 ASSOCIATED WITH BIOMARKERS OF OSTEOFORMATION IN SPONDYLOARTHRITIS? RESULTS OF A STUDY FROM NORTH AFRICA

Keywords: Biomarkers, Spondyloarthritis

K. Maatallah[1], Z. Zeineb[1], I. Ayadi[2], H. Ferjani[1], M. Kallel Sellami[2], D. Ben Nessib[1], D. Elhaj Mahmoud[2], W. Kaabachi[2], D. Kaffel[1], L. Laadhar[2], W. Hamdi[1]. [1]*Faculty of Medicine of Tunis, University Tunis El Manar, Tunisia, Rheumatology Department, Kassab Orthopedics Institute, Ksar Saïd, Tunisia, Tunis, Tunisia*; [2]*Faculty of Medicine of Tunis, University Tunis El Manar, Tunisia, Immunology Departement, La Rabta Hospital, Tunis, Tunis, Tunisia*

Background: The Wnt signaling pathway is a signaling pathway regulating bone metabolism. Dickkopf1 (DKK-1) and Sclerostin are potent inhibitors of this pathway, and their dysfunction would be responsible for osteoformation phenomena in patients with spondyloarthritis (SpA). Osteoprotegerin (OPG), a potent inhibitor of osteoclasts and regulated by the Wnt pathway, has also been implicated in this osteoformation phenomenon.
Objectives: Our work aimed to determine the associations between serum levels of DKK-1, Sclerostin, OPG, and the HLA B-27 allele.
Methods: It was a cross-sectional study including patients with SpA (meeting ASAS criteria). Data collected included sociodemographic and disease characteristics. Biomarker assays were performed using an ELISA technique. Human leukocyte antigen typing was performed by a specific polymerase chain reaction.
Results: One hundred and nine patients were included, with a mean age of 43 ± 12 [19-79] years and a sex ratio M/F of 1.65. The mean age of onset of the disease was 30.6 ± 11 years. Seven patients had a juvenile onset of the disease. HLA B27 allele was present in 30 patients (27.52%). The respective medians [range] of serum levels, in pg/mL, of DKK-1, Sclerostin, and OPG were 146.7 [0-455,3], 32.8[0-488], and 471 [0-1613,6]. HLA B27 was not associated with any of these biomarkers (DKK-1; p=0.744), (Sclerostin; p=0.870), (OPG; p=0.835).
Conclusion: Our study suggests that there is no association between inhibitors of the Wnt signaling pathway as well as OPG and HLA B27.

AB1081 THE PRESENCE OF SYMPHYSIS IN PATIENTS WITH AXIAL SPONDYLITIS MAY BE A SIGN OF RADIOGRAPHIC DAMAGE

Keywords: Spondyloarthritis

E. Durak Ediboglu[1], A. Sinci[2], D. Solmaz[3], H. Kocaayan[3], E. Erpek[3], A. Özkan[3], S. Akar[3]. [1]*Hatay Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Hatay, Turkey*; [2]*Izmir Katip Çelebi University, Department of Radiology, Izmir, Turkey*; [3]*Izmir Katip Çelebi University, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey*

Background: Sacroiliac joint radiographs allow the evaluation of the symphysis region and ischial enthesis regions as well as the evaluation of the sacroiliac and hip joints in patients with axial spondyloarthritis (axSpA).
Objectives: In this study; It is planned to test and review the relationship between the presence of symphysis and disease-related factors and other radiological involvement features.
Methods: Of 384 patients with axSpA and whose sacroiliac joint radiographies were evaluated for symphysitis were included in the study. Since the presence of symphysis was not detected in non-radiographic axSpA patients in our cohort, the analysis was performed with radiographic axSpA patients. Demographic, clinical and laboratory characteristics of the patients were recorded. Irregular appearance in the symphysis pubis on the sacroiliac joint X-ray was evaluated as symphysis. Raiological evaluation were done by a rheumatologist (EDE) and a radiologist (AS). The relationship between the presence of symphysitis and other factors was tested with both univariate and multivariate analysis methods.
Results: The mean age at diagnosis (±SD) was 42.1 (±11.9) and 73.7% of the 384 patients included in the study were male. Demographic, clinical and laboratory characteristics of the study group were summarized in Table 1. Symphysitis was detected in 49 (12.8%) patients on the sacroiliac joint radiograph. The presence of symphysis were associated with duration of symptoms (p<0.001), duration of diagnosis (p<0.001), HLA-B27 positivity (p=0.001), radiographic hip involvement in the evaluated radiographs (p=0.006), total sacroiliac joint score (4-8) (p<0.001), baseline cervical mSAS score (p<0.001), basal lumbal mSAS score (p<0.001), serum CRP level (p=0.001), ASDAS-CRP score (p=0.030)). The presence of symphysitis was not found to be associated with gender, age at diagnosis, extramusculoskeletal and peripheral involvement. In multivariate analysis, the presence of radiological symphysitis was found to be associated with the presence of total ankylosis in the sacroiliac joints (p=0.034) and hip involvement(p=0.019).
Conclusion: Symphysitis in AxSpA patients may be an indicator of radiological damage as well as accompanying other involvements.

Psoriatic arthritis - treatment

AB1082 **EARLY CLINICAL RESPONSE AS A PREDICTOR OF LONG-TERM HEALTH-RELATED QUALITY OF LIFE IMPROVEMENTS IN PATIENTS WITH PSORIATIC ARTHRITIS AND TNFI-IR RECEIVING GUSELKUMAB (COSMOS)**

Keywords: Quality of life, Outcome measures, Psoriatic arthritis

L. Gossec[1], D. Aletaha[2], P. Sewerin[3], A. Zabotti[4], F. Van den Bosch[5], M. Efficace[6], F. Lavie[7], M. Zimmermann[8], M. Sharaf[9], I. Mcinnes[10]. Background: Improvement in health-related quality of life (HRQoL) is a key goal of psoriatic arthritis (PsA) therapy.[1,2] Here, we assess whether early clinical response predicts long-term improvement in HRQoL for patients (pts) with PsA and inadequate response to 1–2 tumour necrosis factor inhibitors (TNFi-IR).
Objectives: Assess the association between early clinical response across various PsA domains and HRQoL at Week (W)48, as well as identify baseline (BL) characteristics that could predict early response in guselkumab (GUS)-treated TNFi-IR PsA pts in the Phase 3b COSMOS trial.
Methods: In the randomized controlled COSMOS trial (NCT03796858),[3] adults with active PsA (swollen/tender joint counts [SJC/TJC] each ≥3) and TNFi-IR were randomized 2:1 to receive subcutaneous injections of either GUS 100 mg (at W0, W4, then every 8 weeks through W44) or placebo (at W0, W4, W12, W20, followed by GUS at W16 [early escape] or at W24 [planned], W28, W36, W44). Only pts randomized to GUS were included in this analysis. Long-term improvements in HRQoL were defined as changes from BL to W48 in 36-item short-form survey (SF-36) physical and mental component summary (PCS and MCS) and Dermatology Life Quality Index (DLQI) scores. Early clinical response was defined as achievement of the following criteria at W4 or W8: American College of Rheumatology (ACR)20, pt pain on a visual analogue scale (VAS) ≤15, SJC ≤1, skin VAS ≤20, and health assessment questionnaire – disability index. (HAQ-DI) ≤0.5. In addition, Psoriasis Area and Severity Index (PASI) ≤1 was considered at W16 – the earliest PASI assessment. Analyses were restricted to pts not meeting the respective early response criteria at BL. Long-term HRQoL improvements were compared between pts achieving vs not achieving early response criteria by means of Student's. t-test and by multivariate linear regression models adjusting for demographic and BL pt disease characteristics. Results from the multivariate linear regression analyses are presented here. Demographic and BL pt disease characteristics predicting early clinical response were investigated using multivariate logistic regression.
Results: Overall, 189 pts were randomized to GUS, with a mean age of 49.1 years, and 45.5% were male. Among pts not meeting the respective early response criteria at BL, GUS led to. 2.7–19.0% and 4.3–38.4% of pts achieving one of the clinical responses of interest as early as W4 and W8, respectively. SF-36 PCS improvement from BL to W48 was significantly associated with ACR20 response, SJC ≤1 and HAQ-DI ≤0.5 achievement at W4 as well as at W8. There were no significant findings for SF-36 MCS. DLQI improvement from BL to W48 was significantly associated with ACR20 and skin VAS ≤20 at W8 (**Figure 1**). Improvements in SF-36 PCS, SF-36 MCS and DLQI at W48 were all significantly associated with achievement of PASI ≤1 at W16. Multivariate logistic regression identified significant (P<0.05) associations between males and early clinical response at W8 (ACR20: odds ratio [OR]=1.98; HAQ-DI ≤0.5: OR=3.71), BL SJC and. SJC ≤1 at W8 (OR=0.84), BL HAQ-DI and HAQ-DI ≤0.5 at W8 (OR=0.23), and BL skin VAS and skin VAS ≤20 at W8 (OR=0.98).
Conclusion: For pts receiving GUS, ACR20 response at W4 and W8 was positively associated with SF-36 PCS improvement from BL to W48, and also at W8 with DLQI improvement from BL to W48. Therefore, early clinical response is relevant for HRQoL improvements over time. These results may help in shared decision-making processes.

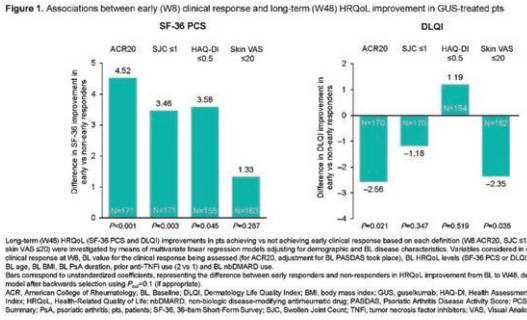

Figure 1. Associations between early (W8) clinical response and long-term (W48) HRQoL improvement in GUS-treated pts

Long-term (W48) HRQoL (SF-36 PCS and DLQI) improvements in pts achieving vs not achieving early clinical response based on each definition (W8 ACR20, SJC ≤1, HAQ-DI ≤0.5 and skin VAS ≤20) were investigated by means of multivariate linear regression models adjusting for demographic and BL disease characteristics. Variables considered in each model were: clinical response at W8, BL value for the clinical response being assessed (for ACR20, adjustment for BL PASDAS took place), BL HRQoL levels (SF-36 PCS or DLQI, accordingly), sex, BL age, BL BMI, BL PsA duration, prior anti-TNFi use (2 vs 1) and BL nbDMARD use.
Bars correspond to unstandardized coefficients, representing the difference between early responders and non-responders in HRQoL, improvement from BL to W48, derived from the best-fitting model after backwards selection using P_{out}=0.1 (if appropriate).

AB1083 **HALF OF THE PSORIATIC ARTHRITIS PATIENTS IN A GERMAN CLAIMS DATA COHORT EXPERIENCE POLYPHARMACY**

Keywords: Psoriatic arthritis, Comorbidities, Health services research

K. Albrecht[1], A. Regierer[1], A. Strangfeld[1,2], U. Marschall[3], J. Callhoff[1,4]. [1]*German Rheumatism Research Centre, Epidemiology and Health Services Research, Berlin, Germany*; [2]*Charité-Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; [3]*BARMER, Institute for Health System Research, Wuppertal, Germany*; [4]*Charité-Universitätsmedizin Berlin, Institute for Social Medicine, Epidemiology and Health Economics, Berlin, Germany*

Background: Psoriatic arthritis (PsA) therapy and comorbidity almost inevitably lead to the issue of polypharmacy (intake of ≥ 5 medications daily), which may further challenge the management of the disease. There is a lack of data on polypharmacy in PsA.
Objectives: To assess polypharmacy in women and men with PsA.

Methods: From the German BARMER health insurance database, 11,984 persons with PsA and DMARD therapy in 2021 were included and compared to sex and age matched controls without inflammatory arthritis. Medications were grouped by Anatomical Therapeutic Chemical groups. Polypharmacy (≥ 5 concomitant drugs) was compared by sex, age and comorbidity using the Rheumatic disease comorbidity index (RDCI, range 0-9) and the Elixhauser comorbidity index (range 0-31). The mean difference in the medication number between persons with PsA and controls was estimated with a linear regression model.

Results: From all adult persons insured in 2021 (n=7.4 Mio.), 190,000 (2.6%) had a diagnosis of psoriasis (ICD-10-GM Code L40). Of those, 20,245 (11%) had a PsA diagnosis (L40.5 + M07.0-3) and 11,984 received any DMARD therapy. A total of 119,840 persons without diagnoses of inflammatory arthritis were included as controls. A total of 63% of all persons with PsA and DMARD therapy were women and the overall mean age was 60 years (Table 1).

Table 1. Characteristics and frequencies of comorbidities (%) of women and men with PsA and controls in 2021.

	Women	Men	Total	Controls
N	7,565	4,419	11,984	119,840
Female (%)			63	63
Age, mean in years	61 (13)	59 (13)	60 (13)	60 (13)
Comorbidities (%)				
RDCI, mean (SD), range 0-9	1.9 (1.6)	1.7 (1.6)	1.9 (1.6)	-
Elixhauser Score, mean (SD), range 0-31	3.8 (2.6)	3.4 (2.7)	3.6 (2.6)	2.2 (2.2)
Hypertension	56	58	57	42
Diabetes mellitus	20	22	21	13
Other cardiovascular disease	12	17	14	9.7
Stroke	0.9	0.2	0.7	0.3
Lung disease	22	16	20	13
Osteoarthritis	39	28	35	15
Depression	32	21	28	16
Hypothyroidism	26	9	19	14
Ulcer or stomach problem	13	10	12	6.3
Cancer	9.6	10	9.8	9.1
Renal failure	8.4	9.0	8.6	4.2
Osteoporosis	18	7	14	4.8
Fracture	5.5	2.1	4.2	1.5

Polypharmacy was significantly higher in PsA (49%) compared to controls (17%), more frequent in women (52%) compared to men (45%) and strongly increased with age (15% in 18 to 30 yrs., 78% in >80 yrs.) and comorbidity. Comorbidity was more frequent in PsA compared to controls (mean Elixhauser comorbidity score 3.6 vs. 2.2 in controls, table 1). This applies to the conditions of the metabolic syndrome: hypertension (57% vs. 42% in controls), dyslipidemia (32% vs. 27%), diabetes (21% vs. 13%) as well as to all other comorbidities, in particular osteoarthritis (35% vs. 15%) and depression (28% vs. 16%). Compared to controls, all ATC drug classes were significantly more frequent in persons with PsA, most commonly drugs for the musculoskeletal system (81% vs. 30%), immunomodulating agents (56% vs. 2.6%), cardiovasculars (62% vs. 48%), alimentary tract/metabolism (57% vs. 31%) and nervous system (50% vs. 31%) (frequencies for PsA see Figure 1). For each unit increase of the RDCI, the age-adjusted number of medications increased by 0.98 (95% CI 0.95; 1.01) units in men and 0.93 (0.90; 0.96) units in women. Compared to controls, the number of prescribed medications (mean 4.9 (2.8)) was 2.4 (2.34; 2.43) units higher in women and 2.3 (2.21; 2.35) units higher in men.

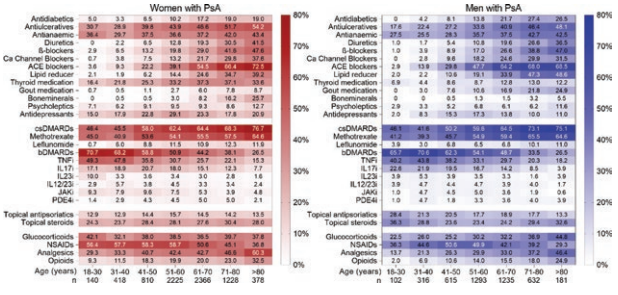

Figure 1. Prescription frequency of medications in 2021 in women and men with PsA by age groups.

Conclusion: Polypharmacy is common in PsA and is composed of PsA-specific medication as well as medication for frequent comorbidities, equally affecting women and men. While DMARD therapy is essential to prevent subsequent damage, systemic GC should be avoided in PsA and analgesics might be dispensable if PsA is well controlled. With regard to the elderly, more frequent therapy with bDMARDs should be discussed which may result in reduced use of analgesics, opioids, and other secondary-induced co-medication.

Background: The Group for Research and Assessment of Psoriasis and PsA advocates addressing all aspects of disease, including optimizing functional status and improving health-related quality of life (HRQoL).[1] Guselkumab (GUS) has demonstrated robust efficacy across key PsA domains at week (W) 24, with effects sustained or further enhanced through 2 years.[2-4] Timing of clinically meaningful improvement in disease activity (DA), functional status, and HRQoL is of interest to PsA patients (pts) and providers.

Objectives: 1) Evaluate effect of GUS on time to minimally clinically important improvements (MCII) in pt reported outcomes and composite measures of DA; 2) Assess association between W4/W8 MCII achievement and later disease control (W24/W52).

Methods: This post hoc analysis evaluated 1120 adults with active PsA despite standard therapies from DISCOVER-1 (D1) (swollen & tender joint counts [SJC/TJC] ≥3 each, CRP ≥0.3 mg/dL, 1-2 prior TNF inhibitors [TNFi] in 31% of pts) and D2 (SJC/TJC ≥5 each, CRP ≥0.6 mg/dL, biologic-naïve). Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO)→GUS 100 mg Q4W at W24. Time to MCII in outcomes of interest, i.e., improvement in cDAPSA ≥5.7, Joint Visual Analogue Scale [VAS] ≥15mm, Pt Pain ≥15mm, HAQ-DI ≥0.35, PASDAS ≥0.8, PtGA ≥15mm, Skin VAS ≥15mm, FACIT-F ≥4, SF-36 PCS ≥5, was compared between GUS vs PBO with Cox regression adjusting for baseline (BL) levels of respective outcome, treatment group, prior TNFi use, and BL DMARD use. MCII achievement was determined using non-responder imputation and compared between GUS and PBO using logistic regression adjusting for the above covariates. The association between MCII achievement at W4/W8 and stringent clinical response at W24/W52 amongst GUS-treated pts was assessed with logistic regression adjusting for prior TNFi use and BL DMARD use.

Results: Time to achieve MCII in all studied outcomes was significantly shorter (hazard ratio range: 1.3-2.5; all p<0.01) for both GUS Q4W and Q8W vs PBO, including cDAPSA as a representative example (**Figure 1**), with curve separation occurring at the first timepoint assessed. MCII rates also were significantly higher with GUS vs PBO at the first timepoint assessed, i.e., W4 for cDAPSA, Joint VAS, Pt Pain, and HAQ-DI and W8 for PASDAS, PtGA, Skin VAS, FACIT-F, and SF-36 PCS (**Table 1**).

W4 achievement of MCII in cDAPSA, Joint VAS, Pt Pain, and HAQ-DI was associated with greater odds of achieving future disease control, defined as ACR50, ACR70, cDAPSA ≤13, PASDAS ≤3.2, and MDA, at W24 (odds ratio [OR] range: 1.5-3.6) and W52 (OR: 1.2-2.4). W8 achievement of MCII in all studied outcomes was also associated with greater odds of achieving disease control at W24 (OR: 1.4-17.2) and W52 (OR: 1.2-5.4).

Conclusion: In pts with active PsA, treatment with GUS was associated with more rapid MCII in both clinical and pt reported outcomes compared with PBO. As early as W4, achievement of MCII vs non-achievement in each studied outcome, particularly PASDAS and cDAPSA, was associated with greater odds of longer-term stringent DA control. Findings highlight the impact of these rapid improvements with GUS - as early as W4 - on the trajectory of long-term pt outcomes.

Background: Guselkumab (GUS) is a fully human, selective interleukin (IL)-23p19 subunit inhibitor. In the phase 3 DISCOVER-2 study of biologic-naïve patients (pts) with active psoriatic arthritis (PsA), GUS significantly reduced the signs and symptoms of disease and radiographic progression vs placebo (PBO),[1] with durable response across multiple disease domains through 2 years.[2] GUS also significantly decreased serum levels of collagen turnover markers,[3] which are elevated in PsA pts vs healthy controls, consistent with diminished progression of structural damage. Further, changes in these and other serum cytokine levels through Week 24 (W24) of GUS treatment are associated with clinical response through 2 years.[4]

Objectives: Further assess effects of GUS on serum cytokine and collagen turnover biomarkers from W24 through W100 (2 years) and explore associations between biomarker levels and longer-term clinical response (W100).

Methods: In DISCOVER-2, biologic-naïve adults with active PsA (swollen joint count ≥5, tender joint count ≥5, C-reactive protein [CRP] ≥0.6 mg/dL) were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4 and then Q8W; or PBO with crossover to GUS Q4W at W24. Blood samples from consenting GUS-treated pts (Q4W and Q8W pooled) were assessed for serum cytokine levels (N=100), including Th17-related effector molecules (IL-17A, IL-17F, IL-22), β-defensin 2 (BD-2), acute phase proteins (CRP, serum amyloid A [SAA], IL-6), and serum collagen turnover biomarkers (N=174; C1M, C3M, C4M, C6M). Using Spearman linear regression and general linear models, pooled changes from baseline (BL) in biomarkers during GUS treatment, correlations between changes in biomarker levels and reductions from BL at three time points (W24, W52, W100) in disease activity (measured by changes in Disease Activity in Psoriatic Arthritis [DAPSA] score, Psoriatic Arthritis Disease Activity Score [PASDAS], Psoriasis Area and Severity Index [PASI] score) were assessed. Associations between biomarker changes and achievement of American College of Rheumatology (ACR)50 response at W100 were also assessed.

Results: Continued treatment with GUS led to significant and sustained reductions in serum cytokines from W24 through W100. Reductions in CRP and IL-6 were associated with changes in DAPSA score, with a similar trend observed for PASDAS. Reductions in BD-2, IL-17A, IL-17F and IL-22 from BL correlated with improvements in the PASI score, and reductions in collagen turnover biomarkers correlated with changes in the PASDAS (Table 1). Continued disease improvement with long-term GUS treatment, assessed clinically using ACR50 response, was supported by the further reductions in CRP, SAA, IL-6 and collagen turnover biomarkers in ACR50 responders at W100 who were ACR50 nonresponders at W24 (Figure 1). Among ACR50 responders at W24, mean reductions in CRP, SAA and IL-6 were sustained through W100.

Conclusion: These results provide molecular evidence that sustained reductions in serum acute phase proteins and collagen turnover biomarkers may contribute to the continuous, durable improvements in joint symptoms and that reductions in Th17-related effector molecules contribute to improvements in skin symptoms seen in PsA pts receiving GUS.

Background: Deucravacitinib is a first-in-class, oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis. Deucravacitinib suppresses signaling of cytokines involved in the pathogenesis of immune-mediated diseases including psoriasis, psoriatic arthritis, and systemic lupus erythematosus. Deucravacitinib was efficacious compared with placebo in phase 2 trials in psoriatic arthritis and systemic lupus erythematosus.[1,2] In two phase 3 trials in patients with moderate to severe plaque psoriasis (POETYK PSO-1 [NCT03624127], PSO-2 [NCT03611751]), deucravacitinib showed superior efficacy versus placebo and apremilast.[3,4] Upon completion of either psoriasis trial, patients could enroll in the POETYK long-term extension (LTE) trial (NCT04036435).
Objectives: To evaluate the incidence rate and severity of adverse events (AEs) due to COVID-19 with deucravacitinib treatment in the POETYK PSO-1 and POETYK PSO-2 trials and open-label POETYK LTE trial.
Methods: In PSO-1 (N=666) and PSO-2 (N=1020), adult patients with moderate to severe plaque psoriasis were randomized 2:1:1 to deucravacitinib 6 mg once daily, placebo, or apremilast 30 mg twice daily. At Week 16, placebo patients in both trials switched to deucravacitinib. Based on their Week 24 PASI response, apremilast patients continued with apremilast or switched to placebo or deucravacitinib. In PSO-1, patients randomized to deucravacitinib continued treatment for 52 weeks; in PSO-2, some patients randomized to deucravacitinib had a randomized treatment withdrawal period. At Week 52, patients could enroll in the open-label LTE and receive deucravacitinib. Incidence rates and severity of COVID-19–related AEs in the POETYK trials (n=1364; 2076.7 person-years [PY] of follow-up) were compared with the Janssen/Johnson & Johnson COVID-19 vaccine trial placebo group (n=19,544; 3096.1 PY of follow-up). This reference population was selected due to the study design and timing of the trial, which occurred when variants were in circulation.
Results: As of October 1, 2021, 1519 patients received ≥1 dose of deucravacitinib over a 2-year follow-up period; 1364 patients met criteria for this analysis, with deucravacitinib exposure since the pandemic onset (estimated to be January 1, 2020). In total, 153 deucravacitinib patients reported a COVID-19–related AE, for an overall exposure-adjusted incidence rate (EAIR) of 7.4/100 PY (95% CI, 6.2–8.6). Serious COVID-19–related AEs occurred in 43 patients (EAIR, 2.1/100 PY; 95% CI, 1.5–2.8), including 30 with COVID-19 and 13 with COVID-19 pneumonia; this rate was within the margins of those for moderate to severe COVID-19 reported in the reference population (EAIR, 16.5/100 PY; 95% CI, 15.0–17.9). Deaths due to COVID-19 occurred in 6 patients (EAIR, 0.3/100 PY; 95% CI, 0.1–0.6), with the COVID-19–related mortality rate being consistent with the reference population (EAIR, 0.23/100 PY; 95% CI, 0.1–0.5). Treatment was discontinued due to COVID-19 or COVID-19 pneumonia in 7 patients, including the 6 patients who died due to COVID-19.
Conclusion: COVID-19 was among the most frequently reported AEs during the 2-year period of the pooled PSO-1, PSO-2, and LTE trials due to the temporal overlap of the pandemic with the trials. However, COVID-19 infection and death rates did not differ from the reference population; most infections were not serious and did not lead to treatment discontinuation. Based on this analysis, deucravacitinib did not appear to increase the risk of COVID-19 nor its progression to severe outcomes.

Background: The IL-23p19-subunit inhibitor guselkumab (GUS) demonstrated clinically meaningful improvements in fatigue through one year of treatment[1] independent of its effects on American College of Rheumatology 20% (ACR20) improvement criteria and Minimal Disease Activity (MDA) achievement[2].
Objectives: In this post-hoc analysis, the Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) scale was used to: (a) evaluate the long-term effect of GUS in maintaining or further improving fatigue between week (W) 52 and W100, and to (b) identify potential early (W8) predictors, in terms of fatigue, for improved long-term fatigue outcomes.
Methods: DISCOVER-2 enrolled adult patients (pts) with active PsA (≥5 swollen and ≥5 tender joints and CRP ≥0.6 mg/dl) who were naïve to biologics/JAK inhibitors. Pts were randomized (1:1:1) and treated with GUS 100 mg every 4W (Q4W); GUS 100mg at W0, W4, then Q8W; or placebo (PBO→GUS Q4W; crossing over to GUS Q4W at W24). Pts with baseline (BL) fatigue levels lower than the normative value (FACIT-F score ≤43)[3] were included in these post hoc analyses (N=681). The proportions of pts with clinically meaningful improvement (≥4 points) from BL in FACIT-F and with normative FACIT-F levels between W52 and W100 were calculated using non-responder imputation (NRI) for missing data and compared over time within each treatment group with the McNemar test. Changes in FACIT-F over time were assessed with mixed models adjusting for time, treatment group, their interaction, and BL FACIT-F score. Receiver operating characteristics (ROC) analyses were conducted using Youden's index to determine optimal cutoffs at W8 for predicting achievement of normative scores and clinically meaningful FACIT-F responses at W100.
Results: At BL, the mean (SD) FACIT-F score was 28.3 (8.7) with similar levels across treatment groups. At W52, 66.1%, 69.6%, 68.0%, and 67.8% of pts in the PBO→GUS Q4W, GUS Q4W, GUS Q8W, and pooled GUS groups, respectively, achieved clinically meaningful improvements from BL in FACIT-F score; response rates were maintained through W100. Normative FACIT-F levels were achieved by 24.9%, 28.1%, 29.4% and 27.5% of pts in each treatment group, respectively, at W52, and by increasingly greater proportions of pts through W100. Significant improvements from BL in FACIT-F scores were observed at W52 (all nominal p<0.05), with further improvements seen from W52 to W100 across all GUS groups (Figure 1). ROC optimal cutoff in FACIT-F improvement from BL to W8 associated with a clinically meaningful improvement in FACIT-F at W100 was ≥2.0 (nominal p<0.0001); while for achieving normative FACIT-F levels at W100, the optimal cutoff in actual FACIT-F score at W8 was ≥39.5 (nominal p<0.0001).

Conclusion: The clinically meaningful improvements in fatigue seen after 1 year of GUS treatment were further enhanced through 2 years, at which time nearly a third of GUS-treated pts reported normative FACIT-F levels. Early targets in FACIT-F levels achieved with GUS were identified to aid in guiding treatment decisions in routine clinical practice.

EARLY CLINICAL IMPROVEMENT AS PREDICTOR OF LONG-TERM HEALTH-RELATED QUALITY OF LIFE IN PSORIATIC ARTHRITIS PATIENTS TREATED WITH GUSELKUMAB: POST-HOC ANALYSIS THROUGH 2 YEARS OF A PHASE-3 STUDY

Keywords: Quality of life, Psoriatic arthritis

I. Mcinnes[1], E. Soriano[2], L. S. Tam[3], N. Shiff[4,5], M. Shawi[6], E. Rampakakis[7,8], J. Curtis[9]. *[1]University of Glasgow, College of Medical Veterinary and Life Sciences, Glasgow, United Kingdom*; *[2]Hospital Italiano de Buenos Aires, Rheumatology, Buenos Aires, University Institute Hospital Italiano de Buenos Aires, Buenos Aires, Argentina*; *[3]The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China*; *[4]Janssen Scientific Affairs, LLC, Immunology, Horsham, PA, United States of America*; *[5]University of Saskatchewan, Adjunct, Department of Community Health & Epidemiology, Saskatoon, Canada*; *[6]Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, PA, United States of America*; *[7]McGill University, Department of Pediatrics, Montreal, Canada*; *[8]JSS Medical Research, Scientific Affairs, Montreal, Canada*; *[9]University of Alabama at Birmingham, Division of Immunology and Rheumatology, Birmingham, AL, United States of America*

Background: Patients (pts) with psoriatic arthritis (PsA) experience lower quality of life than both the general population and pts with psoriasis alone[1,2]. Recent PsA treatment recommendations highlight the importance of maximizing long-term (LT) health-related quality of life (HRQoL) and social participation as primary goals of therapy[3].
Objectives: To determine whether early clinical improvement with guselkumab (GUS) predicts future attainment of enhanced HRQoL.
Methods: DISCOVER-2 enrolled adults naïve to biologics/JAK inhibitors who had active PsA defined as swollen joint count (SJC) ≥5, tender joint count (TJC) ≥5, and C-reactive protein (CRP) ≥0.6 mg/dL. 739 pts were randomized (1:1:1) and treated with GUS 100 mg every 4 weeks (Q4W; n=245); GUS 100 mg at W0, W4, then Q8W (n=248); or placebo (PBO) (n=246). In this post hoc analysis, pts treated with GUS Q4W and GUS Q8W were pooled. Early (W8) clinical improvement was defined as any of: (i) ≥20% improvement in SJC, TJC, pt pain, pt skin visual analog scale (VAS), and Health Assessment Questionnaire-Disability Index (HAQ-DI); (ii) ≥4-point improvement in the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score; (iii) minimally clinically important improvement (MCII) in clinical disease activity in PsA (cDAPSA; ≥5.7 points); (iv) change in Leeds enthesitis index (LEI) and dactylitis severity score (DSS) at W8 among pts with baseline (BL) enthesitis and dactylitis, respectively. Time-averaged changes in HRQoL estimates from BL to W52-100 were determined for Dermatology Life Quality Index (DLQI), EQ-5D Index & VAS, and SF-36 mental (MCS) and physical (PCS) component summary scores. The association between early clinical improvement at W8 and LT HRQoL among GUS-treated pts was assessed with mixed models.
Results: Clinical improvement by W8 was significantly greater among GUS-treated patients compared with PBO. Early clinical improvement with GUS was associated with greater increase in HRQoL (EQ-5D) at W52 through W100, with the exception of SJC on EQ-5D VAS (Figure 1; LEI & DSS results not shown). Similarly, pts achieving early clinical improvement in any domain except DSS and SJC experienced significantly greater benefits in physical function (SF-36 PCS) at W52-W100. Early improvements in skin disease and fatigue were associated with greater improvement in mental health (SF-36 MCS) at W52-W100, while for skin-specific HRQoL (DLQI), early pt skin VAS response was the only predictor of HRQoL at W52-W100. Although significantly lower than in pts with early clinical improvement, benefits in HRQoL were also observed in pts without clinical improvement at W8.
Conclusion: Clinical response at W8 with GUS was associated with significantly greater improvements in HRQoL from W52 through W100. Although pts without early clinical improvement demonstrated benefits in LT HRQoL, early response in distinct PsA domains differentially impacted more specific aspects of HRQoL over 2 years. In contrast, significantly greater improvements in overall and physical HRQoL were observed among responders across several PsA domains.

Figure. Associations Between Early (W8) Clinical Improvement and Long-term (W52-100) HRQoL Improvement in GUS-treated Patients

SJC: 20% improvement in SJC at W8; TJC: 20% improvement in TJC at W8; Pain: 20% improvement in Pain at W8; Skin VAS: 20% improvement in Skin VAS at W8; HAQ: 20% improvement in HAQ at W8; Fatigue: FACIT-fatigue response (≥4 point improvement) at W8; cDAPSA MCII: Minimal clinically important improvement in cDAPSA (≥5.7 point improvement) at W8. *p<0.05; **p< 001. P values represent comparison of early clinical response 'yes' vs. 'no'. 'Yes' bars refer to pts who presented a response as described above in the respective domain at W8. 'No' bars refer to pts who did not present the respective domain at W8. Long-term refers to the change from BL to W52-100 in each HRQoL outcome. Values represent time-averaged least-square mean (95% CI) changes in HRQoL from BL derived from repeated-measures mixed models including the change in HRQoL as the dependent variable and early clinical response, GUS regimen time, BL HRQoL, and BL stratification factors (DMARD use, CRP) as fixed factors.

Background: High levels of complete clearance of plaque psoriasis in high-impact areas such as the scalp, nails, palms and soles have been reported in patients (pts) after 1 year (yr) of bimekizumab (BKZ) treatment.[1]
Objectives: Assess scalp, nail and palmoplantar outcomes over 2 yrs from two BKZ phase 3 trials in moderate to severe plaque psoriasis.
Methods: Data were pooled over 2 yrs from the BE RADIANT phase 3b trial (NCT03536884), including Yr1 of its ongoing open-label extension (OLE), and the 1-yr BE SURE phase 3 trial (NCT03412747) with the ongoing OLE, BE BRIGHT (NCT03598790).[2,3] Pts included were randomised at baseline to BKZ 320 mg every 4 weeks (wks; Q4W) and then continued to receive BKZ Q4W or switched to BKZ every 8 wks (Q8W) at Wk16, and received the same dose on entering the OLE (Q4W/Q4W/Q4W or Q4W/Q8W/Q8W). Regional involvement was analysed using scalp Investigator's Global Assessment (scalp IGA; 5-point scale [0–4]), modified Nail Psoriasis Severity Index (mNAPSI; total fingernail score, 0–130 scale) and palmoplantar (pp)-IGA (5-point scale [0–4]). We report proportions of pts who achieved complete regional clearance (scalp IGA 0, mNAPSI 0, pp-IGA 0) through Yr2 (OLE Wk48) among pts with moderate to severe regional involvement at baseline (scalp IGA ≥3, mNAPSI >10, pp-IGA ≥3). Missing data were imputed as non-response (NRI).
Results: Of pts who entered the OLEs from BE SURE and BE RADIANT, 303 and 323 received BKZ Q4W/Q4W/Q4W and Q4W/Q8W/Q8W, respectively. Of these, 209 (69.0%) and 241 (74.6%) had baseline scalp IGA ≥3; 43 (14.2%) and 44 (13.6%) had pp-IGA ≥3; 100 (33.0%) and 111 (34.4%) had mNAPSI >10. Among pts with baseline scalp IGA ≥3, 78.0% and 81.7% treated with BKZ Q4W/Q4W/Q4W and Q4W/Q8W/Q8W achieved scalp IGA 0 at Wk16, respectively; 80.4% and 79.3% achieved scalp IGA 0 at Yr2 (OLE Wk48) (**Table 1**). Of pts with baseline pp-IGA ≥3, 60.5% and 81.8% treated with BKZ Q4W/Q4W/Q4W and Q4W/Q8W/Q8W achieved pp-IGA 0 at Wk16, respectively; 83.7% and 81.8% achieved pp-IGA 0 at Yr2 (**Table 1**). Of pts with baseline mNAPSI >10, 51.0% and 58.6% treated with BKZ Q4W/Q4W/Q4W and Q4W/Q8W/Q8W achieved mNAPSI 0 at Wk32, respectively; 40.0% and 59.5% achieved mNAPSI 0 at Yr2 (**Table 1**).
Conclusion: A high percentage of BKZ-treated pts achieved complete clearance of scalp and palmoplantar psoriasis at Wk16, which was sustained over 2 yrs. Complete nail clearance continued to increase through Yr1, reflecting the longer timescale required for nail growth, and was generally sustained through Yr2. Proportions of pts achieving complete nail, scalp and palmoplantar clearance were generally comparable between BKZ Q4W/Q4W/Q4W and Q4W/Q8W/Q8W dosing regimens.

EFFICACY OF UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS STRATIFIED BY INVOLVEMENT OF WEIGHT-BEARING JOINT REGIONS: A POST HOC SUBGROUP ANALYSIS OF THE PHASE 3, RANDOMIZED, SELECT-PSA 1 AND SELECT-PSA 2 TRIALS

Keywords: Outcome measures, Randomized control trial, Psoriatic arthritis

K. Mizelle[1], W. Tillett[2,3], M. Ali[4], T. Iyile[4], T. Gao[4], A. Setty[4], J. A. Walsh[5], L. Coates[6]. *[1]Tidewater Physicians Multispecialty Group, Rheumatology, Newport News, United States of America*; *[2]Royal National Hospital for Rheumatic Diseases, Rheumatology, Bath, United States of America*; *[3]University of Bath, Pharmacy and Pharmacology, Bath, United States of America*; *[4]AbbVie, Rheumatology, North Chicago, United States of America*; *[5]University of Utah, Rheumatology, Salt Lake City, United States of America*; *[6]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: Involvement of weight-bearing joints in patients with psoriatic arthritis (PsA) can be associated with reduced activities of daily living and quality of life. Upadacitinib (UPA) is an oral, reversible Janus kinase inhibitor approved for the treatment of active PsA in adults. In the SELECT-PsA 1 and SELECT-PsA 2 trials, treatment with once daily UPA 15 mg (UPA15) or 30 mg (UPA30) resulted in greater improvements in the number of swollen and tender joints as well as other patient- and physician-reported outcomes when compared with placebo.[1-3]

Objectives: To evaluate the long-term efficacy of UPA in patients with PsA and involvement in 1 or more regions of weight-bearing joints.

Methods: The SELECT-PsA 1 (NCT03104400) and SELECT-PsA 2 (NCT03104374) phase 3, randomized, controlled trials enrolled patients ≥ 18 years old with active PsA and intolerance or inadequate response to ≥ 1 nonbiologic disease modifying anti-rheumatic drug (DMARD; SELECT-PsA 1) or biologic DMARD (SELECT-PsA 2). This post hoc analysis of the 2 phase 3 trials stratified patients with involvement in 1 to 6 regions of weight-bearing joints (hips, knees, ankles, midfoot, metatarsophalangeal [MTP], or proximal interphalangeal [PIP]) who were randomized at baseline to receive either UPA15, placebo (PBO), or adalimumab (ADA; only in SELECT-PsA 1); at week 24, PBO-treated patients switched to UPA15 (PBO/UPA15). This analysis did not include patients who received UPA30 or PBO/UPA30. A mixed-effects model with repeated measures was used to analyze the change from baseline to week 104 in 4 patient-reported outcome measures (pain, Health Assessment Questionnaire-Disability Index [HAQ-DI], Work Productivity and Activity Impairment [WPAI] questionnaire, and EuroQol 5 Dimension 5 Level [EQ-5D-5L]) and 1 composite outcome measure (Disease Activity in Psoriatic Arthritis [DAPSA]). UPA safety results in patients with PsA have been previously reported.[1-3]

Results: A total of 1069 patients from the SELECT-PsA 1 trial and 317 patients from the SELECT-PsA 2 trial were included in the pooled analysis. Of all patients with any involvement in regions of weight-bearing joints, > 91% of patients had involvement in ≥ 2 regions. The most common weight-bearing joints with involvement were the PIP (SELECT-PsA 1, 79.8%; SELECT-PsA 2, 84.5%), MTP (71.1%; 73.8%), and knee (62.3%; 64.9%) joints. Improvements from baseline to week 104 were observed with UPA15 treatment in patient-reported outcomes of pain, HAQ-DI, WPAI, EQ-5D-5L, and the DAPSA score across all subgroups of patients with involvement in 1 to 6 regions of weight-bearing joints (**Figure 1**). In general, the magnitude of improvement in outcome scores with UPA15 was greater in patients with involvement in a higher number of regions. Similar improvements from baseline to week 104 in outcome scores were observed in patients who received PBO/UPA15 or ADA to week 104.

Conclusion: UPA15 treatment was associated with long-term improvements in pain, disability, work productivity, disease activity, and quality of life in patients with PsA and involvement in 1 or more regions of weight-bearing joints.

Background: Major depression is some of the numerous comorbidities associated with psoriasis (PsO) and psoriasis arthritis (PsA) [1].
Objectives: Assessing the risk of developing depression in patients with pre-existing PsO treated with different treatment regimens; topical treatment, conventional disease-modifying anti-rheumatic drugs (cDMARDs), and biologic disease-modifying anti-rheumatic drugs (bDMARDs), which had not previously studies sufficiently on real-world data.
Methods: We conducted a retrospective exploratory study with real-world data using the databases of the third largest Israeli health maintenance organization, 'Meuhedet' which covers approximately 1,300,000 subjects. All patients of 'Muehedat' diagnosed with PsO from January 2000 until January 2020 were included in the analysis. Overall, 61,003 patients with PsO were detected. In addition, each PsO patient was paired with four control subjects by gender, age, and ethnicity (general, Arabic, or Orthodox). We defined PsO and PsA according to physicians' diagnoses. Depression included patients with either Selective serotonin reuptake inhibitors (SSRI) treatment or the physicians' diagnoses of depression. The date of the depression incident was defined by the first occurrence of the first to occur. We classified the patients diagnosed with PsA into a separate group; thus, patients were categorized according to their diagnosis (control, PsO or PsA). Furthermore, we analyzed the patients by the most advanced treatment prescribed to the patient; sub-grouped 1- topical therapy, phototherapy, or no therapy, sub-grouped 2 - cDMARDs (methotrexate or sulfasalazine), sub-grouped 3 - bDMARDs (anti-TNF, anti-IL17, or anti-IL12/23 agents) (**Table 1**). The Incident cases of depression were analyzed according to the different lines of therapy mentioned above. In addition, Time-dependent Cox proportional hazard models were used to evaluate the adjusted risk of developing MACE by treatment group.
Results: 231,584 patients were included after exclusion by the defined criteria, contributing a total of 2,917,319 patient-years. Adjusted Cox proportional hazards regression analysis showed that the risk of developing depression in PsO patients treated with topical treatment and those treated with bDMARDs was significantly higher in comparison to controls (Topical, HR: 1.06, CI: 1.04 - 1.09, p-value: <0.001; bDMARDs, HR: 2.08, CI: 1.76 - 2.45, p-value: <0.001). Yet, the risk of developing depression in PsO patients treated with cDMARDs was significantly lower compared to controls (HR: 0.66, CI: 0.5 – 0.87, P-value: 0.003). Similarly, the risk of developing depression in PsA patients treated with topical treatment and those treated with bDMARDs was significantly higher in comparison to controls (Topical, HR: 1.67, CI: 1.56 - 1.78, p-value: <0.001; bDMARDs, HR: 1.86, CI: 1.66 – 2.1, p-value: <0.001). Yet, the risk of depression in PsA patients treated with cDMARDs was not significantly different compared to controls (HR: 0.91, CI: 0.77 – 1.08, p-value: 0.29). (**Figure 1**). This analysis was adjusted to gender, body mass index (BMI), and age of PsO diagnosis; notably, female gender, higher BMI, and older age were all associated with a greater risk of developing depression.
Conclusion: Despite the fact that psoriasis and arthritis severity is higher in patients treated with cDMARDs compared to those treated with topical therapy, cDMARDs have a protective effect on the risk of developing depression. On the contrary, biological treatment increases the risk of depression, possibly due to the high severity of the disease, yet also have a protective effect compared to those treated with topical therapy.

Background: Maintaining daily activities is a critical treatment goal for patients (pts) with psoriatic arthritis (PsA). The Health Assessment Questionnaire-Disability Index (HAQ-DI), a mainstay tool for evaluating physical function in pts with PsA, assesses 20 common activities of daily living that should be evaluated given the heterogeneous clinical presentation of PsA.
Objectives: In this post hoc analysis from DISCOVER (D)-1 and -2, we examined the level of impairment in individual activities of daily living assessed by the HAQ-DI, and the effect of guselkumab (GUS) on pts' ability to accomplish these activities, among pts with active PsA.
Methods: D1/D2 enrolled adults with active PsA despite standard therapies. D1 pts had ≥3 swollen and ≥3 tender joints (SJC/TJC), C-reactive protein (CRP) ≥0.3 mg/dL; 31% had 1-2 prior TNF inhibitors (TNFi). D2 pts had ≥5 SJC/TJC and CRP ≥0.6 mg/dL; all were biologic-naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO). Scores for each of the 20 HAQ-DI items (range: 0-3; 0/1/2=no/some/much difficulty, 3=unable to do) at baseline (BL) and proportion of pts with scores ≥1 or ≥2 were summarized. Ability to achieve ≥1-level or ≥2-level improvement in each HAQ-DI item (in pts with BL score ≥1 or ≥2, respectively) during the 24W PBO-controlled period was compared between GUS- and PBO-treated pts using logistic regression adjusting for BL value, prior TNFi use, and BL DMARD use.
Results: At BL, the mean (SD) HAQ-DI score=1.2-1.3 (0.6) across treatment groups. The majority of pts (84.5%) had a score >0.5, indicating some functional limitation, and reported impairment in one or more activity, with the greatest impact on ability to do chores, dress oneself, and get in/out of bed (Table 1). The proportion of pts achieving ≥1-level improvement across HAQ-DI items was significantly higher with GUS vs. PBO as early as W4 and increased through W24 (Figure 1). Similar patterns were observed for achieving a ≥2-level improvement across HAQ items (data not shown). Responses were numerically similar between GUS Q4W and Q8W.
Conclusion: In the setting of PsA, GUS demonstrated improvements as early as W4 across all HAQ-DI items, including those most impaired at BL, with comparable responses between dosing regimens. These findings may assist the communication between pts and healthcare providers when establishing treatment goals during shared decision making.

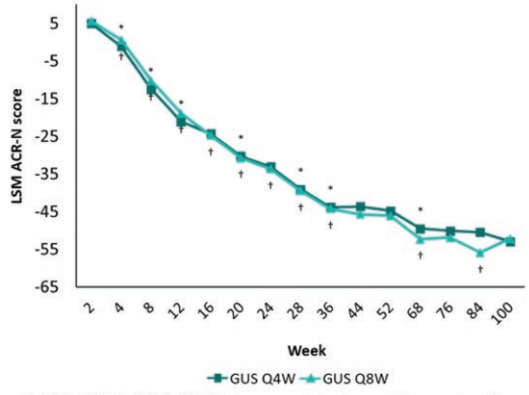
Background: Treatment effects on PsA joint symptoms are assessed by ACR response rates, reflecting percentages of patients (pts) meeting a composite measure of improvement from baseline (BL) at specific timepoints. Alternatively, the ACR-numeric (ACR-N) is a continuous measure of improvement based on 7 ACR components.
Objectives: Contrast performance of ACR response rates with ACR-N in characterizing guselkumab (GUS) treatment effect in PsA and describe duration and extent of continuous improvement with GUS using ACR-N and ACR components through week (W) 100.
Methods: The phase 3 DISCOVER-2 trial enrolled bio-naïve adults with active PsA (swollen and tender joint counts [SJC/TJC] ≥5, C-reactive protein [CRP] ≥0.6 mg/dL). 739 pts were randomized (1:1:1) and treated with GUS 100 mg every 4W (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO) with crossover to GUS Q4W at W24. ACR20/50/70 response rates through W100 were determined using non-responder imputation (NRI) for missing data; GUS Q4W/Q8W and PBO rates were compared through W24. Duration of continuous improvement over 100W of GUS was assessed by contrasting least square mean (LSM) ACR-N and ACR component values between consecutive visits. Percent changes in SJC, TJC, physician global (MDGA), pt global (PtGA), health assessment quality disease index (HAQ-DI), CRP, and pt-pain were also assessed, adjusting for treatment group, BL use of csDMARDs, and respective BL scores.
Results: ACR response rates were significantly greater with GUS Q4W/Q8W vs PBO by W4 (ACR20), W8 (ACR50), and W8-12 (ACR70); significant differences in ACR-N between GUS Q4W/Q8W vs PBO were observed by W2 (GUS Q4W) or W8 (GUS Q8W) (Table 1; nominal p<0.05). Similar responses were observed with GUS Q4W and Q8W. Among GUS-treated pts, nominally significant improvements comparing ACR-N scores across consecutive visits were

observed by W2, with a positive trajectory through W100 (Figure 1). Individual ACR components also significantly improved by W2 and – apart from CRP levels that rapidly plateaued to means <1 mg/dL – continued to improve vs previous visit through W68-84 of GUS (nominal p<0.05).



Conclusion: GUS rapidly improved PsA activity whether assessed by ACR response or ACR-N. Early response was apparent across ACR components, followed by a positive trajectory through 2 years of GUS that yielded low levels of residual disease.

Background: PsA has been associated with an increased risk of cardiovascular disease (CVD), likely due to accelerated atherosclerosis secondary to chronic inflammation.[1] The number of CV risk factors has been shown to correlate with PsA disease activity (DA).[2]

Objectives: Describe effect of guselkumab (GUS) on inflammatory biomarkers that predict CVD, and its efficacy and safety, in patients (pts) with active PsA and concurrent CV risk factors.

Methods: DISCOVER (D)1&2 enrolled adults with active PsA despite standard therapies. D1 pts (31% received 1-2 prior TNF inhibitors [i]), had tender and swollen joint counts (TJC/SJC) each ≥3 and CRP ≥0.3 mg/dL; D2 pts (biologic-naïve) had TJC/SJC each ≥5 and CRP ≥0.6 mg/dL. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO)→GUS 100 mg Q4W at W24. Pts included in this analysis had ≥1 of the following CV risk factors: obesity; smoking (past or current); or history of hypertension, diabetes mellitus (DM), or hyperlipidemia. Changes in high-sensitivity (hs) CRP and neutrophil–lymphocyte ratio (NLR) were compared between GUS vs PBO with mixed models adjusting for baseline (BL) levels. Achievement of endpoints at W24 (missing data imputed as no response) was compared in GUS vs PBO with logistic regression adjusting for BL levels, prior TNFi use, and BL DMARD use: American College of Rheumatology (ACR) response criteria, Investigator's Global Assessment (IGA) of psoriasis score 0/1, DA Index for PsA (DAPSA) low DA (LDA)/remission, PsA DA Score (PASDAS) LDA, minimal DA (MDA), Psoriasis Area and Severity Index (PASI) responses, Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F) response, Health Assessment Questionnaire Disability Index (HAQ-DI) response, and enthesitis and dactylitis resolution. The incidence of major adverse CV events (MACE; cardiovascular death, nonfatal myocardial infarction, or nonfatal stroke) was assessed through W100.

Results: Of 1120 enrolled pts, 758 had ≥1 CV risk factor (259 Q4W, 252 Q8W, 247 PBO); of these, 448 (59%) were obese, 420 (55%) had hypertension, 315 (42%) were smokers, 171 (23%) had hyperlipidemia, and 103 (14%) had DM.

Through W24, GUS significantly reduced hsCRP and NLR vs PBO (Figure 1). Response rates at W24 were significantly higher with GUS vs PBO for all assessed endpoints (Table 1). During the PBO-controlled period, one pt each had a MACE in the PBO (0.9 [95% CI: 0.0-4.9]/100 person-years [PY]) and pooled GUS (0.4; 0.0-2.4)/100PY groups. In the pooled GUS group, the incidence (95% CI) of MACE was 0.2 (0.0-0.8)/100PY over 1 year and 0.3 (0.1-1.0)/100PY over 2 years.

Conclusion: In the subgroup of PsA pts with concurrent CV risk factors, GUS was associated with significant reductions in hsCRP and NLR and significantly higher response rates vs PBO for all PsA domains assessed. MACE incidence was similar to that in the overall D1/D2 population.[3] These findings support the efficacy of GUS on systemic inflammation and its cardiovascular safety.

Background: Pain in PsA has multifaceted origins (e.g., peripheral joint inflammation, axial involvement [axPsA], skin lesions, dactylitis, enthesitis, underlying conditions) and can be difficult to treat. Guselkumab (GUS), a fully human IL-23p19 subunit inhibitor, is effective in treating multiple PsA domains and elicited durable improvement in patient (pt)-reported pain (PtP) in the DISCOVER (D)-1&2 trials[1,2].

Objectives: Assess association between improvement in key PsA manifestations and PtP using 1-year D1&2 data.

Methods: D1&2 enrolled adults with active PsA despite standard therapies[3,4]. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo with crossover to GUS 100 mg Q4W at W24. Treatment groups were pooled (N=1120). Longitudinal associations of improvement in SJC (0-66), TJC (0-68), Leeds enthesitis index (LEI), dactylitis severity score (DSS), Psoriasis Area and Severity Index (PASI), axPsA (N=312), and improvement in overall PtP (0-100 mm) and spinal pain (BASDAI question 2 in pts with axPsA) were assessed. Longitudinal associations of improvement in these PsA manifestations with ≥30%/50%/70% improvements in PtP (PtP-30/50/70) were assessed.

Results: Mean (SD) BL PtP of 61.2 (19.8) indicated substantial burden. Upon adjusting for potential confounders, greater improvement in PASI, SJC, and TJC (mutually adjusted) were each associated with significantly greater improvement in PtP and higher odds of achieving PtP-30 through W52 **(Table 1)**. PASI reduction was also associated with greater odds of PtP-50, as was TJC improvement for PtP-50/70. In pts with BL enthesitis, LEI, PASI, and TJC improvements were each associated with greater PtP improvement and attaining PtP-30/50/70; SJC reduction was only associated with PtP-30. In pts with BL dactylitis, PASI and TJC reductions were significantly associated with PtP improvement. Overall, axPsA presence did not impact the extent of PtP improvement (data not shown). In pts with axPsA, significant associations were observed between spinal pain improvement and TJC and LEI improvement.

Conclusion: Improvements in key PsA manifestations were significantly associated with pain reduction, although to varying extents. TJC reduction had the greatest impact on PtP improvement, likely due to overlap of the construct measured. Psoriasis improvement had a greater impact on pain relief than SJC improvement, highlighting the sensory burden of skin lesions, while enthesitis improvement showed a significant association with both overall and spinal pain relief. These findings underscore the importance of utilizing treatments effective across manifestations to address recalcitrant PsA symptoms.

Background: Despite available PsA treatments, a portion of PsA patients (pts) does not achieve improvements in PsA signs and symptoms according to the American College of Rheumatology (ACR) response criteria.
Objectives: Using data from the phase 3 DISCOVER-1 and DISCOVER-2 (D1/D2) studies in pts with active PsA, the purpose of this analysis was to describe the benefit of the IL-23p19 inhibitor, guselkumab (GUS), vs placebo (PBO) across key PsA domains, including those not comprising the core ACR measures, in pts not meeting ACR response criteria.
Methods: Pts enrolled in D1 and D2 were adults with active PsA despite standard therapies. D1 pts had ≥3 swollen and ≥3 tender joints (SJC; TJC), and C-reactive protein (CRP) ≥0.3 mg/dL; D2 pts had SJC ≥5, TJC ≥5, and CRP ≥0.6 mg/dL. In all, 31% of D1 pts received 1-2 prior tumor necrosis factor inhibitors (TNFi); D2 pts were biologic-naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at Week (W)0, W4, then Q8W; or PBO; PBO pts crossed over to GUS 100 mg Q4W at W24. In this post hoc analysis, patients not meeting ≥20% improvement in ACR response criteria (ACR20) at W24 were included. Changes from baseline (BL) over 24 W in continuous outcomes of interest (SJC; TJC; enthesitis/dactylitis scores; psoriasis area and severity index [PASI] score; Functional Assessment of Chronic Illness Therapy [FACIT]-fatigue score; and 36-item Short Form survey [SF-36] physical [PCS] & mental [MCS] component summary scores) were assessed with repeated measures mixed models adjusting for treatment group, BL non-biologic disease-modifying antirheumatic drug (DMARD) use, and prior TNFi use. Descriptive statistics were produced for categorical outcomes at W24 (Figure 1) using non-responder imputation for missing data.
Results: Of the 1120 pooled D1/D2 pts, 538 did achieve an ACR20 response at W24, including 137 (36.7%) GUS Q4W, 147 (39.2%) GUS Q8W, and 254 (68.3%) PBO pts, and were included in this analysis. A consistently greater proportion of GUS- than PBO-treated pts achieved W24 categorical outcomes, including those relating to skin, tender joints, and dactylitis, with similar findings for GUS Q4W and Q8W (Figure 1). For continuous endpoints, the benefit of GUS was seen as early as W2 for SJC (W4 for Q8W), TJC, dactylitis (W4 for Q8W), and enthesitis (W4 for Q8W); W8 for FACIT-fatigue, SF-36 PCS, and SF-36 MCS (W16 for Q8W); and W16 for PASI; most endpoints continued to improve through W24. Across both GUS treatment groups, 43.5%-48.9% of W24 ACR20 non-responders achieved an ACR20 response by W52.
Conclusion: In this cohort of W24 ACR20 non-responders, GUS-treated pts experienced greater benefits than pts receiving PBO in improving both joint disease and other important PsA domains outside the ACR response criteria, which translated to significant improvements in health-related quality of life. These benefits occurred as early as W2 of GUS treatment, and showed continued improvement over 24 W, such that considerable proportions of W24 ACR non-responders achieved an ACR20 response by W52. Such improvements in key PsA domains over time among the minority of GUS W24 non-responders are consistent with the known immunomodulatory mechanism of GUS.

PASI90 and PASI100 refer to 90% and 100% improvement from BL, respectively, and were assessed in patients with IGA ≥2 and BSA ≥3% at BL. Resolution of dactylitis and enthesitis were assessed in patients with dactylitis and enthesitis at BL, respectively. FACIT-Fatigue Response refers to ≥4-point improvement from BL. SF-36 responses refer to ≥5-point improvement from BL. Number of evaluable ACR20 non-responders differed for Resolution of Dactylitis (Q4W: N=60; Q8W: N=66; PBO: N=107), Resolution of Enthesitis (Q4W: N=94; Q8W: N=91; and PBO: N=173), and PASI 90/100 (Q4W: N=94; Q8W: N=94; PBO: N=182). Mean (SD) SJC levels at BL were 12.7 (8.01), 11.1 (7.18) and 11.6 (7.28) and at W24 were 6.2 (6.76), 5.9 (7.02), 7.2 (7.39) for GUS Q4W, Q8W, and PBO, respectively.
ACR, American College of Rheumatology; BL, baseline; BSA, body surface area; FACIT, Functional Assessment of Chronic Illness Therapy; GUS, guselkumab; IGA, investigator's global assessment; MCS, mental component summary; PASI, psoriasis area and severity index; PBO, placebo; PCS, physical component summary; PsA, psoriatic arthritis; pts, patients; Q4W, every 4 weeks; Q8W, every 8 weeks; SD, standard deviation; SF-36, 36-item short form survey; SJC, swollen joint count; TJC, tender joint count; W, week

Background: This integrated analysis examines long-term incidence rates (IRs) of malignancies in adults with psoriasis (PsO), psoriatic arthritis (PsA), or axial spondyloarthritis (axSpA) who received ≥1 dose of ixekizumab (IXE) up to 5 years (PsO) or 3 years (PsA, axSpA) in clinical trials.

OBJECTIVES:

Methods: IRs of malignancies were assessed across 25 randomized IXE clinical trials (17 PsO, 4 PsA, 4 axSpA). Malignancy rates were analyzed for pooled studies by years of therapy, through March 2022. Exposure-adjusted IRs per 100 patient-years (PY) are reported.

Results: 6892 patients with PsO, 1401 patients with PsA, and 932 patients with axSpA, with a cumulative IXE exposure of 18025.7 PY for PsO, 2247.7 PY for PsA, and 2097.7 PY for axSpA were included in this analysis. The IRs of malignancies at 1-year intervals up to 5 years for patients with PsO, and up to 3 years for patients with PsA and axSpA, remained low (≤1.2/100 PY) and constant. Malignancies occurred in 141/6892 patients with PsO (IR=0.8), 15/1410 patients with PsA (IR=0.7), and 9/932 patients with axSpA (IR=0.4). Of these cases, non-melanoma skin cancer (NMSC) was reported among 55 patients with PsO (IR=0.3) and 9 patients with PsA (IR=0.4). No incidences of NMSC were reported among patients with axSpA.

Conclusion: IRs of treatment-emergent malignancies were low and stable among adult patients with PsO, PsA or axSpA receiving IXE treatment in clinical trials over the time periods examined.

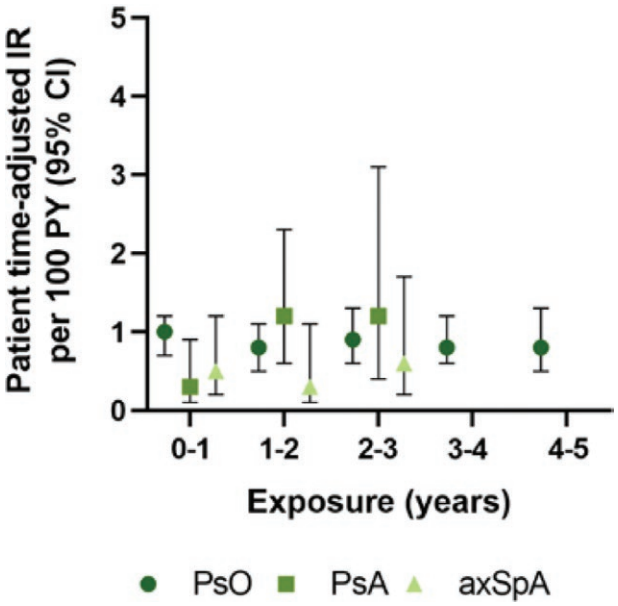

Figure 1. Exposure-adjusted incidence rates (IR) of malignancies across indications by yearly intervals. Data points on the graph are the IR (95% CI)/100 patient-years (PY) at successive year intervals from year 0-5 (PsO), 0-3 (PsA and axSpA). *CI = Confidence interval*.

Background: Tyrosine kinase 2 (TYK2) is an intracellular enzyme involved in IL-23 signaling that is important in the pathogenesis of immune-mediated diseases, including psoriasis, psoriatic arthritis, and systemic lupus erythematosus (SLE). Deucravacitinib is a first-in-class, oral, selective, allosteric TYK2 inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis. Deucravacitinib uniquely binds to the TYK2 regulatory domain rather than the more conserved catalytic domain at which Janus kinase (JAK) 1/2/3 inhibitors bind. Deucravacitinib was efficacious compared with placebo in phase 2 trials in psoriatic arthritis and SLE.[1,2] Furthermore, deucravacitinib was significantly more efficacious than placebo or apremilast and was well tolerated in patients with moderate to severe plaque psoriasis, as observed in the phase 3 POETYK PSO-1 and PSO-2 trials.[3,4] Patients who completed the psoriasis trials could enroll in the ongoing open-label, 240-week long-term extension (LTE) trial.

Objectives: This analysis examined whether changes occurred in blood laboratory parameters upon deucravacitinib treatment in the phase 3 POETYK PSO-1, PSO-2, and LTE trials and, if so, assessed how these compared with signature laboratory changes seen with JAK 1/2/3 inhibitors.

Methods: POETYK PSO-1 (NCT03624127) and PSO-2 (NCT03611751) were 52-week, double-blind trials that randomized patients with moderate to severe plaque psoriasis 2:1:1 to deucravacitinib 6 mg once daily, placebo, or apremilast 30 mg twice daily. Patients receiving placebo switched to deucravacitinib at Week 16, and patients receiving apremilast who failed to achieve ≥50% reduction from baseline in Psoriasis Area and Severity Index (PASI 50; PSO-1) or ≥75% reduction from baseline in PASI (PASI 75; PSO-2) at Week 24 switched to deucravacitinib. At Week 52, all eligible patients enrolled in the LTE trial (NCT04036435) and received open-label deucravacitinib 6 mg once daily. Changes from baseline in hematologic parameters (lymphocytes, neutrophils, platelets, hemoglobin) and lipid and chemistry parameters (cholesterol, creatinine, CPK, ALT) known to be impacted by JAK 1/2/3 inhibitors were assessed through Week 100 (LTE at Week 48). CTCAE grade ≥3 laboratory abnormalities and treatment discontinuations due to laboratory abnormalities were also evaluated.

Results: Patients (n=1519) received ≥1 dose of deucravacitinib in PSO-1, PSO-2, and/or the LTE through the cutoff date of 1 October 2021. In total, 1179 (77.6%) and 584 (38.4%) patients had ≥52 and ≥104 weeks, respectively, of continuous deucravacitinib exposure at the cutoff date, and the median duration of exposure was 682.0 days (97 weeks). No trends for clinically meaningful changes from baseline were observed in any laboratory parameters from Weeks 0–52 in PSO-1 or in the LTE. Grade 3 or 4 abnormalities over 100 weeks of deucravacitinib treatment were rare; incidence rates were comparable with placebo and apremilast through Week 52, and no increases were seen in the LTE. Two patients discontinued deucravacitinib treatment due to laboratory abnormalities (1 lymphopenia, 1 abnormal hepatic function).

Conclusion: No trends for clinically meaningful changes from baseline were observed with deucravacitinib treatment in hematologic, lipid, or chemistry parameters, including signature laboratory changes associated with JAK 1/2/3 inhibitors, for up to 100 weeks. Treatment discontinuations and grade 3 or 4 laboratory abnormalities were rare, consistent with those in the parent studies, and comparable to the incidence rates seen with placebo and apremilast. These results suggest that laboratory monitoring in patients with plaque psoriasis is not warranted with deucravacitinib treatment.

Background: Psoriatic arthritis (PsA) is a disease characterised by heterogeneous joint and skin manifestations, so comprehensive treatment efficacy is best captured by assessment of a broad spectrum of affected domains using composite outcome measures.[1] Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has demonstrated superior efficacy and tolerability to 16 weeks (wks) vs placebo (PBO) in patients (pts) with active PsA in the phase 3 BE OPTIMAL and BE COMPLETE studies.[2,3]

Objectives: To assess the long-term efficacy of BKZ treatment on disease activity using composite outcome measures in pts with active PsA and prior inadequate response or intolerance to tumour necrosis factor alpha inhibitors (TNFi-IR).

Methods: BE COMPLETE (NCT03896581) comprised a 16-wk double-blind, PBO-controlled period. Pts with PsA and TNFi-IR were randomised 2:1 to subcutaneous BKZ 160 mg every 4 wks or PBO. Pts who completed Wk 16 were eligible for entry into BE VITAL (NCT04009499), an open-label extension (OLE) study. Pts receiving PBO switched to BKZ at Wk 16 (PBO/BKZ). The BE VITAL OLE included pts from BE OPTIMAL and BE COMPLETE. Here, we report data up to 1 year for pts randomised at baseline (Wk 0) of BE COMPLETE (52 wks of study drug). Composite measure data up to Wk 52 are reported: minimal and very low disease activity (MDA/VLDA), the composite endpoint of ≥50% improvement in American College of Rheumatology criteria and 100% improvement in Psoriasis Area and Severity Index response (ACR50+PASI100) in pts with baseline psoriasis (≥3% body surface area [BSA]), Disease Activity Index for Psoriatic Arthritis (DAPSA), and Psoriatic Arthritis Disease Activity Score (PASDAS; collected up to Wk 40). Missing data were imputed using non-responder imputation (NRI) or worst-category imputation.

Results: 388/400 (97.0%) pts completed Wk 16 of BE COMPLETE; 377 (94.3%) entered BE VITAL and 347 (86.8%) completed Wk 52. At Wk 16, a higher proportion of BKZ-treated pts achieved composite disease activity thresholds vs PBO-treated pts. Across all composite outcome measures, efficacy was sustained to Wk 52 in pts randomised to BKZ treatment at Wk 0, and pts who switched to BKZ at Wk 16 demonstrated improvements in efficacy responses to Wk 52 (**Figure 1**, **Table 1**). At Wk 16, 6.0% PBO and 44.2% BKZ pts achieved MDA; at Wk 52, this proportion was sustained on BKZ treatment: 33.1% PBO/BKZ and 47.2% BKZ (NRI; **Figure 1**). Improved or sustained responses were also observed for the proportions of PBO/BKZ and BKZ pts achieving VLDA, ACR50+PASI100, DAPSA and PASDAS thresholds at Wk 52 (**Figure 1**; **Table 1**).

Conclusion: BKZ-treated pts with PsA and TNFi-IR demonstrated clinically meaningful improvements in composite measures of disease activity, comprising joint and skin domains, vs PBO at Wk 16. These improvements were sustained up to 1 year on BKZ. Pts who switched to BKZ at Wk 16 showed improvements in efficacy responses up to 1 year.

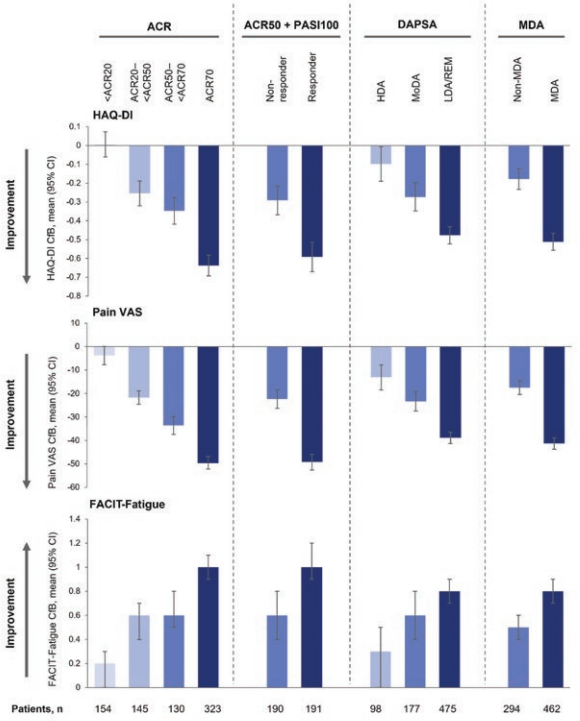
Background: The multiple joint and skin manifestations of psoriatic arthritis (PsA) place a substantial burden on patient quality of life.[1] Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A.

Objectives: To examine the association between achieving increasingly stringent clinical disease control criteria and patient-reported measures of physical function, pain and fatigue in patients (pts) with PsA, using Week (Wk) 52 data from BE OPTIMAL.

Methods: BE OPTIMAL (NCT03895203) comprised a 16-wk double-blind placebo (PBO)-controlled period and a 36-wk treatment blind period. Pts were ≥18 years, biologic disease-modifying antirheumatic drug naïve, with adult-onset, active PsA, ≥3 tender and ≥3 swollen joints. Pts were randomised 3:2:1, subcutaneous BKZ 160 mg every 4 weeks (Q4W):PBO:reference arm (adalimumab 40 mg Q2W). From Wk 16, PBO pts received BKZ 160mg Q4W. In this post hoc analysis, all pts who reached specified disease control criteria (**ACR**: ACR20 not reached [<ACR20], ACR20 reached but not ACR50 [ACR20–<ACR50], ACR50 reached but not ACR70 [ACR50–<ACR70], ACR70 reached [ACR70]; ACR50 and Psoriasis Area and Severity Index 100 [**ACR50+PASI100**]: non-responder, responder; Disease Activity in PsA [**DAPSA**]: high, moderate and low disease activity or remission [HDA, MoDA and LDA/REM, respectively]; Minimal Disease Activity [**MDA**]: non-MDA, MDA) at Wk 52 were pooled regardless of treatment arm. Associations between achieving these criteria and improvements in the following patient-reported physical function and symptom measures were assessed: Health Assessment Questionnaire Disability Index (**HAQ-DI**), Pt's Assessment of Arthritis Pain Visual Analog Scale (**Pain VAS**) and Functional Assessment of Chronic Illness Therapy-Fatigue subscale (**FACIT-Fatigue**). It should be noted that some aspects of the disease control criteria relate to aspects of HAQ-DI and PtAAP. Observed case data were reported.



Results: 821/852 (96.4%) pts completed Wk 16; 761 (89.3%) completed Wk 52. Baseline mean (SD) HAQ-DI (0 [best] to 3 [worst]), Pain VAS (0 [best] to 100 [worst]) and FACIT-Fatigue (0 [worst] to 52 [best]) scores were 0.85 (0.59), 55.2 (23.9) and 37.0 (9.7). Pts achieving higher ACR response thresholds demonstrated sequentially greater mean (95% CI) improvements from baseline in HAQ-DI, Pain VAS and FACIT-Fatigue (**Figure 1**). Similar improvements from baseline in HAQ-DI, Pain VAS and FACIT-Fatigue were seen with the achievement of ACR50+PASI100, increasingly stringent DAPSA thresholds and the achievement of MDA (**Figure 1**).

Conclusion: Patients with active PsA who achieved increasingly stringent disease control criteria at Wk 52 reported concomitantly greater improvements in patient-reported measures of physical function, pain and fatigue.

Background: To date only few real-world setting studies evaluated apremilast efficacy in psoriatic arthritis (PsA). Enthesitis and dactylitis are difficult-to-treat features of PsA leading to disability and affecting quality of life.

Objectives: The aims of this study is to evaluate the leed enthesitis index (LEI) and dactlitis index (DAI) at 6 and 12 month in patients on treatment with apremilast.

Methods: All PsA consecutive patients treated with apremilast in fifteen Italian rheumatological referral centers were enrolled. Anamnestic data, treatment history, and PsA disease activity (DAPSA), LEI, DAI at baseline (T0), 6 month (T1) and 12 months (T2) were recorded. The Mann-Whitney test and chi-squared tests assessed the differences between independent group, whereas the Wilcoxon matched pairs signed-rank test assessed the differences between dependent samples. A p-value<0.05 was considered statistically significant.

Results: the total cohort consisted of 209 patients (M/F 94/105) of whom 72 (34.4%) (M/F 29:43) patients had an enthesitis with a median LEI of 3 and 65 patients (31.1%) had dactylitis with a median of DAI of 1; DAPSA at base line was 24.1 in the enthesitis group, and 27.2 in the dactylitis group **(Table 1**). Prior DMARDs use and concomitant DMARDs drugs were more common in LEI groups with respect to DAI group. Compared to base line, Apremilast 30 mg two times per day demonstrated at 6 and 12 months a significantly improvements in LEI **(Figure 1a**; p<0.001 for both T1 vs T0, T2 vs T1), DAI (**Figure 1b;** p<0.001 for both T1 vs T0, T2 vs T1) and DAPSA (**Figure 1c**; p<0.001 for both T1 vs T0, T2 vs T1). In the LEI group, 29 patients (28.7%) reached a remission with LEI=0 at six months and 40 (44%) patients had a sustained improvement with LEI=0 at 12 months. In the DAI group 45 patients (52.9%) had a remission of dactylitis at 6 months and 43 patients (56.6%) had no dactylitis at T1.

Conclusion: Apremilast demonstrated significant and sustained efficacy in real-life Psa patients, including improvements in enthesitis and dactylitis for up to 12 months.

Background: Psoriatic arthritis (PsA) is a chronic systemic inflammatory musculoskeletal disease whose heterogeneous manifestations are classified in multiple domains; moreover, PsA negatively influence many comorbid diseases.[1] As growing evidence suggests, it is important to research drugs active on multiple domains, trying to target therapy for every PsA manifestations. Upadacitinib (UPA) is a selective JAK inhibitor effective in many PsA domains according to randomized controlled trials.[2] However, real-world data on UPA performance in everyday clinical practice are currently lacking.

Objectives: This observational study aims to evaluate real-life efficacy and safety of UPA in the treatment of PsA in a large multicentre cohort. Secondary objectives are: **a.** to obtain the ideal patient profile for UPA therapy; **b.** to stratify clinimetric and laboratoristic responses according to patient manifestation and comorbidities.

Methods: Patients with either peripheral and/or axial PsA, classified according to CASPAR and ASAS criteria, who initiated UPA by clinical indication were enrolled at 10 Italian centers according to the following inclusion criteria: 1a. failure or intolerance towards at least one csDMARD for bio-naïve patients, or 1b. failure of at least one bDMARD for bio-failure patients; 2. active PsA disease, defined according to treat-to-target strategy by the absence of MDA (Minimal Disease Activity); 3. age > 18 years. Patients were assessed at baseline (T0) and at week 12 (T3) and 24 (T6), recording responses in the main clinimetric indices (i.e. TJC, SJC, LEI, DAPSA, ASDAS-CRP, MDA & VLDA) and a complete laboratory panel. Any type of adverse event was recorded at each visit. Data about assessment until week 56 (T12) for all patients will be presented in a future work.

Results: A total of 126 patients, 73 (69.5%) females and 32 (30.5%) males, started therapy with UPA: mean age 55.9±11.2 years, mean BMI 26.8±5.1, mean duration of disease 114.7±100.9 months. Most patients (n.124, 98.4%) show peripheral joint involvement: n.39 (31.4%) with oligoarticular and n.85 (68.6%) with polyarticular pattern. Axial involvement was found in n.56 (44.4%) patients. Most patients (n.89, 70.6%) had failed at least 1 bDMARD. At baseline, all patients show high disease activity (DAPSA 27.7±10.0; ASDAS-CRP 2.4±0.7). The following characteristics were notable: 1. cardio-metabolic diseases more represented in axial and polyarticular involvement; 2. baseline disease activity greater with polyarticular involvement, comorbidities, higher BMI and/or CRP; 3. patients with axial involvement showed a longer disease duration. Follow-up data are available for n.94 (74.6%) patients at T3 and n.66 (52.4%) patients at T6 evaluation, showing response in disease activity scores and patient-reported outcomes (Table 1, Figure 1). A subsequent multivariate logistic regression analysis shows that males (OR 2.53), bio-naïve (OR 4.12) and patients with high baseline CRP (OR 2.49) had the highest probability of MDA response at T6. A few patients (n.10, 7.9%) discontinued UPA during the study due to ineffectiveness (n.7) or adverse events (n.2 moderate thrombocytopenia; n.1 severe hypertension).

Conclusion: Preliminary data are confirming UPA effectiveness and safety in PsA real-life population. These findings will allow more targeted therapy based on patient profiling and disease domains.

Background: Guselkumab (GUS) is associated with robust and sustained improvement in psoriatic arthritis (PsA) signs and symptoms in subgroups of patients (pts) pooled from the phase 3 DISCOVER-1 and DISCOVER-2 trials, across a variety of baseline (BL) pt characteristics through 1[1], and 2 years (DISCOVER-2 only)[2].
Objectives: This post-hoc analysis using DISCOVER-2 data aimed to evaluate the efficacy of GUS in inducing long-term (Week [W]100) stringent disease control in Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA)-recommended domains across BL characteristics.
Methods: DISCOVER-2 enrolled biologic-naïve adults with active PsA defined as ≥5 swollen and ≥5 tender joint counts (SJC; TJC) and C-reactive protein (CRP) ≥0.6 mg/dL. 739 pts were randomized (1:1:1) and treated with GUS 100 mg every 4 weeks (Q4W; n=245); GUS 100 mg at Week 0, Week 4, then every 8 weeks (Q8W; n=248); or placebo (n=246) with crossover to GUS 100 mg Q4W at W24. In this analysis, only GUS-randomized pts were included (n=493). Achievement of the following outcomes at W100 was assessed: minimal disease activity (MDA), American College of Rheumatology 50% improvement (ACR50), ACR70, Investigator's Global Assessment score of 0 (clear skin) (IGA 0), Psoriatic Arthritis Disease Activity Score – low disease activity (PASDAS LDA), resolution of enthesitis and dactylitis, Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) response (≥4-point improvement), and Health Assessment Quality Disease Index (HAQ-DI) response (≥0.35-point improvement). BL characteristics of interest were pt sex, baseline body mass index (BMI), SJC, TJC, PsA duration, CRP, % body surface area (BSA) with psoriasis, and PASI score, and use of conventional synthetic (cs) DMARDs and methotrexate (MTX). Non-responder imputation was used for missing categorical response data.
Results: 442 (90%) GUS-randomized pts completed study treatment through W100. With few exceptions, achievement of MDA response (Figure 1) at Week 100 was demonstrated across a variety of baseline pt characteristics, without consistent differences in proportion of responders across pt subgroups of adequate sample size or between GUS dosing regimens. Similar trends were observed for achievement of ACR50, ACR70, IGA 0, PASDAS LDA, enthesitis resolution, dactylitis resolution, FACIT-F response, and HAQ-DI response.
Conclusion: Irrespective of dosing regimen, treatment with GUS resulted in sustained achievement of several stringent endpoints spanning key GRAPPA-recommended domains through 2 years across a variety of BL demographic and disease characteristics. These results further support the long-term efficacy of GUS across the full spectrum of PsA disease domains and diverse PsA populations.

Background:

Objectives: The objective of this study is to report long-term, end-of-study-program safety outcomes, relating to major adverse cardiovascular events (MACE), in adult patients with psoriasis (PsO), psoriatic arthritis (PsA), and axial spondyloarthritis (AxSpA) who received ≥1 dose of Ixekizumab (IXE) over 5 years (PsO) or 3 years (PsA, axSpA).

Methods: The incidence of MACE was assessed across 25 randomized clinical trials (17 PsO, 4 PsA, 4 axSpA) examining long-term safety of IXE. MACE rates were analyzed for pooled studies by years of therapy, through March 2022. Exposure-adjusted incidence rates (IRs) per 100 patient-years, at successive year intervals are reported.

Results: The incidence of MACE was low among patients with PsO (IR=0.5), PsA (IR=0.5), and axSpA (IR=0.3). In the PsO cohort, of the 103 reported MACE cases, 20 were fatal (19.4%), 57 recovered (55.3%), and 17 recovered with sequelae (16.5%). Of the 12 reported MACE cases in the PsA cohort, 2 were fatal (16.7%), 9 recovered (75.0%), and 1 recovered with sequelae (8.3%). All 6 MACE cases reported in the axSpA cohort recovered (100.0%). IRs were low and stable over the treatment periods. The most common types of MACE reported in the PsO, PsA and axSpA cohorts were non-fatal myocardial infarction (PsO: IR= 0.3; PsA: IR=0.3; axSpA: IR=0.3), nonfatal stroke (PsO: IR=0.1; PsA: IR=0.2) and vascular death (PsO: IR=0.1; PsA: IR=0.1). All MACE cases were confirmed by adjudication.

Conclusion: The incidence of MACE was low and stable over the IXE treatment periods examined.

AB1106 EFFICACY OF RISANKIZUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS:A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Psoriatic arthritis, Systematic review

H. Zhou[1,2], G. M. Xia[1,2], C. Su[1,2], H. Y. Tian[1,2], Y. J. Deng[1,2], X. M. Wang[1,2], J. Y. Ren[1,2], R. T. Shen[1,2], Q. Y. Su[1,2,3], Q. Yu[4], P. F. He[4], X. Li[1,2,3], S. X. Zhang[1,2,3].

Background: Psoriatic arthritis (PsA) is a chronic autoimmune disease that is seen in nearly 30% of patients with psoriasis. As a new targeted treatment drug, risanzumab may provide a new treatment with fewer side effects for patients with psoriasis arthritis. However, there are currently discrepancies in the evaluation of the efficacy of Risankizumab in PsA patients.
Objectives: This study aims to systematically evaluate the efficacy of Risankizumabin patients with PsA.
Methods: We systematically searched PubMed, Embase, Web of Science, Cochrane Library, MEDLINE, Web of Knowledge, Clinical Trials. gov, FDA. gov and print databases (SSRN, bioRxiv, and MedRxiv) from the establishment of the database to January 2, 2023, and conducted data analysis in Stata 12.0. We used the I-squared (I2) to assess the heterogeneity of the included studies in order to select the appropriate model for statistical analysis. A random-effects model will be used when I2>50%, otherwise, a fixed-effect model will be applied. The publication bias was evaluated by using Egger test.
Results: We ultimately included 11 studies that included data on six outcome indexes. The results of the meta-analysis of ACR20 as our main outcome indicator of interest showed patients in the Risankizumab group had a significantly higher ACR20 response rate than those in the placebo group at 24 weeks [RR=1.768, 95%CI (1.572, 1.988), P<0.001]. In addition, compared with the placebo group, the MDA response rate of Risankizumab group significantly higher [RR=1.841, 95%CI 1.084-3.126, P<0.05]. Then, SF-36 score [SMD=0.508, 95%CI (0.337, 0.678), P<0.001] were improved in the Risankizumab group, which was statistically significantly different from the placebo group. For HAQ-DI, the Risankizumab group had significantly lower scores than the placebo group[SMD=-0.273, 95%CI (0.373, 0.172), P<0.001]. However, FACIT-F scores in the Risankizumab group were significantly higher than placebo group [SMD=0.270, 95%CI (0.177, 0.364), P<0.001]. For PASI, patients had an average reduction of 9.8 points after Risankizumab treatment [MD=-9.832, 95%CI (14.367, 5.298), P<0.001]. (Figure 1)
Conclusion: The overall results of the meta-analysis show that Risankizumab treatment can significantly improve the symptoms of PsA such as arthritis and skin symptoms, improve the clinical remission rate and the quality of life of patients. However, taking Risankizumab may also potentially increase fatigue levels in patients.

AB1107 PSORIATIC ARTHRITIS: IMPROVEMENT IN OUTCOMES BUT PERSISTENT SEX DIFFERENCE - 5 YEAR FOLLOW UP STUDY OF A NORWEGIAN OUTPATIENT CLINIC POPULATION

Keywords: Remission, Real-world evidence, Psoriatic arthritis

K. Łosińska[1], B. Michelsen[2], A. Kavanaugh[3], M. Korkosz[1,4], G. Haugeberg[5,6].
[1]University Hospital, Division of Rheumatology and Immunology, Krakow, Poland; *[2]Sørlandet Hospital, Research Department, Kristiansand, Norway*; *[3]University of California, Department of Medicine, School of Medicine, San Diego, La Jolla, CA, United States of America*; *[4]Jagiellonian University Medical College, Department of Rheumatology and Immunology, Krakow, Poland*; *[5]Sørlandet Hospital, Division of Rheumatology, Department of Internal Medicine, Kristiansand, Norway*; *[6]NTNU, Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences,Trondheim, Norway*

Background: Improvement of pharmacological therapies and treatment approaches in psoriatic arthritis (PsA) have led to substantial progress in disease outcomes [1]. Despite this progress there is still a need for improvement in PsA treatment [2].
Objectives: To explore long-term (5 years) changes in disease activity, remission rates and sex-related differences in these outcomes in PsA patients treated in ordinary outpatient clinic.
Methods: Prospective longitudinal cohort study. DAS28, DAPSA, SDAI, CDAI, MDA and Boolean remission criteria for PsA were assessed. Parametric statistics for comparisons of patient characteristics and dependent t test for differences between observation times were used.
Results: 114 PsA patients (49.1% women), baseline mean±SD age was 51.4 ±9.4 years, disease duration 9.2±6.8 years, 24.8% were HLAB27(+), 32.7% currently used NSAIDs, 61.4% csDMARDs, 37.7% b/tsDMARDs. At 5-year follow-up numerical improvement was noted for multiple disease activity measures and PROs (Table 1). Statistically significant increase in remission rates was

[1]women vs men, baseline [2]women vs men, follow-up [3]baseline vs follow-up, all patients

observed for DAS28 and CDAI but not for MDA, SDAI, DAPSA, and Boolean remission for PsA (Figure 1).

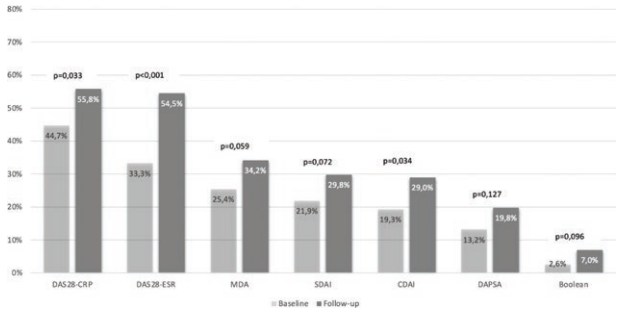

Figure 1. Proportions of PsA patients in remission (total cohort).

During follow-up number of b/tsDMARD users significantly increased (from 37.7% to 48.3% p=0.01), while number of NSAIDs and csDMARDs users significantly decreased (from 32.7% to 21.9% p=0.02, and from 61.4% to 46.5% p<0.01, respectively). Both at baseline and follow-up women reported higher levels of pain, PGA and fatigue, and had higher TJC68, DAPSA, SDAI, CDAI, DAS28 and mHAQ compared to men. Even though mean CRP was higher in men both at baseline and follow-up, men more often achieved remission, regardless which remission definition was applied. A higher proportion of men were treated with b/tsDMARDs (46.6% vs 28.6% at baseline, 60.3% vs 35.7% at follow-up).

Conclusion: Our study adds evidence that improvement in PsA outcome between 2013 and 2020 was achieved, most probably due to more intensified treatment with b/tsDMARDs. Women had higher PROs and disease activity indexes both at baseline and follow-up and were less likely to achieve remission. Despite obtained progress, the number of PsA patients in remission remains unsatisfactory. This may indicate further need to improve both therapeutic approaches and methods of assessing PsA activity and remission.

Background: The efficacy of guselkumab (GUS), a fully human IL-23p19 subunit inhibitor, in patients (pts) with active psoriatic arthritis (PsA) has been previously shown across a variety of PsA domains and baseline (BL) pt characteristics[1-3]. Given the central role of the IL-23/Th17 pathway in PsA, it has been hypothesized that IL-23 inhibition with GUS may provide persistent and durable clinical responses between doses and over time when administered every 8 weeks (Q8W).

Objectives: To assess at the pt level the persistence of effect of GUS Q8W between doses and its durability of effect over time.

Methods: DISCOVER-2 was a phase 3, randomized, double-blind, placebo (PBO)-controlled study that enrolled pts with active PsA despite standard therapies. Pts were biologic-naïve, had tender and swollen joint counts (TJC/SJC) each ≥5, and C-reactive protein (CRP) ≥0.6 mg/dL. Pts were randomized 1:1:1 to GUS 100 mg Q4W; GUS 100 mg at W0, W4, then Q8W; or PBO with crossover to GUS 100 mg Q4W at W24. In the current analysis, only pts treated with GUS Q8W (N=248) were included. Persistence of effect between consecutive dosing visits was described with the proportion of pts maintaining response (as defined below) in outcomes assessed during dosing visits (Disease Activity index for PsA [DAPSA], clinical DAPSA [cDAPSA]). Durability of effect was assessed with the Kaplan Meier estimator of the survival function where each pt contributed follow-up from the first time of achievement of clinical response within the 24-week period and the time of loss of response or last available assessment through W100. Definitions of clinical response included achievement of clear/almost clear skin (investigator's global assessment [IGA] 0/1; among pts with BL IGA>1) or minimal clinically important improvements (MCII) in DAPSA (≥7.25), cDAPSA (≥5.7), skin visual analog scale (VAS; ≥15 mm), and PsA Disease Activity Score (PASDAS; ≥0.8).

Results: Between consecutive (Q8W) dosing visits through W52, the proportion of pts maintaining response ranged from 93.3% (DAPSA MCII between W4 and W12) to 99.1% (DAPSA/cDAPSA MCII between W28 and W36), depending on the time interval. Among pts showing clinical response within the first 24 weeks, the estimated mean (SE) duration of maintenance was 58.6 (2.2) weeks for DAPSA MCII, 52.4 (2.0) weeks for cDAPSA MCII, 75.7 (1.6) weeks for. IGA 0/1, 71.7 (1.9) weeks for skin VAS MCII, and 76.7 (1.4) weeks for PASDAS MCII (Figure 1). As estimated probabilities of maintenance of effect at W100 were between 65% (IGA 0/1) and 90% (PASDAS MCII) for all outcomes assessed, median duration of effect could not be calculated.

Conclusion: Treatment with GUS Q8W was associated with long-lasting effects in both joint- and skin-related outcomes, as well as in multi-domain composite outcomes, in individuals with PsA. These results highlight that, in addition to continuous improvement in clinical response rates over time, GUS Q8W provides consistent and highly durable responses between consecutive doses.

TREATMENT RETENTION AND SAFETY OF IXEKIZUMAB IN A POPULATION WITH PSORIATIC ARTHRITIS REFRACTORY TO BIOLOGIC AND TARGETED SYNTHETIC DMARDS

Keywords: Psoriatic arthritis

I. Braña Abascal[1], S. Burger[1], P. González del Pozo[1], E. Pardo Campo[1], S. Alonso Castro[1], S. Fernández[1], F. Jirout[1], I. Zapico[1], M. Alperi-López[1], R. Queiró Silva[1]. [1]*Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Asturias, Spain*

Background: Information on the performance of ixekizumab (IXE) in patients with psoriatic arthritis (PsA) in clinical practice is scarce.
Objectives: We aimed to analyze the retention rate and safety of IXE in patients with PsA in routine clinical practice. The present study has analyzed drug survival and safety of IXE in patients with PsA under real clinical practice conditions. This information may complement that obtained from the RCTs done to date with this drug.
Methods: Retrospective longitudinal observational single-center study of all patients with PsA who had received at least one dose of IXE. Adverse events (AEs) and drug retention rate were considered the main variables. Survival was analyzed using Kaplan-Meier curves and predictive factors using multivariate Cox regression analysis. The Hazard Ratio (HR) was used as a measure of the association.
Results: Seventy-two patients were included (52 women and 20 men). Median disease duration was 5 years (IQR 3-9). More than 90% have received ≥ 2 biologic and/or targeted synthetic disease modifying anti-rheumatic drugs (DMARDs) prior to IXE. Ixekizumab showed a 1-year retention rate of 65% and a 2-year retention rate of 57% (Figure 1). Regarding discontinuation due to AEs, 0.18 AEs per person-year were identified. The number of previous biologics did not influence drug survival but prior use of methotrexate [HR 2.31 (95%CI 1.05-5.10), p < 0.05] and depression [HR 2.40 (95%CI 1.07-5.41), p < 0.05] increased the risk of IXE discontinuation (Table 1).
Conclusion: Ixekizumab demonstrated high drug persistence in a population of PsA mostly refractory to various lines of systemic therapy. In addition, the aspects that usually penalize the survival of most biologics in PsA (age, duration of disease, female gender, smoking, obesity, prior exposure to other biologics) did not affect drug persistence in this study.

AB1110 EXPLORING LEVELS OF PROTEIN BIOMARKERS IN RESPONSE TO TREATMENT FOR PSORIASIS AND PSORIATIC ARTHRITIS

Keywords: Disease-modifying drugs (DMARDs), Biomarkers, Psoriatic arthritis

R. Offenheim[1], D. Ganatra[1], D. D. Gladman[1,2,3]. [1]*Krembil Research Institute, Rheumatology, Toronto, Canada*; [2]*University of Toronto, Medicine, Toronto, Canada*; [3]*Toronto Western Hospital, Rheumatology, Toronto, Canada*

Background: Psoriatic Arthritis (PsA), an inflammatory arthritis, occurs in 30% of psoriasis patients[1]. Serum chemokine (C-X-C motif) ligand 10 (CXCL10) is elevated in psoriasis patients that will develop PsA[2]. MMP3 is associated with response to Tissue-necrosis factor inhibitor (TNFi) treatment[3]. S100A8, CCL2, and ACP5 are associated with PsA development[4,5,6]. We aimed to compare CXCL10, MMP3, S100A8, ACP5, and CCL2 levels in PsA patients before and after treatment with biologics and in cutaneous psoriasis without arthritis (PsC) patients on and off treatment with biologics.
Objectives: The objective of this study was to evaluate the levels of CXCL10, MMP3, S100A8, CCL2, and ACP5 in serum of psoriasis and PsA patients before and after treatment with biologic agents (TNFi and IL-17i).
Methods: PsA and PsC patients are followed prospectively at the Toronto Western Hospital psoriatic disease clinic. We identified 93 PsA patients on TNFi and 22 on IL-17 inhibitors (IL-17i) and retrieved serum samples before and after therapy. Samples from 30 patients with PsC treated with biologics were matched to 30 patients not treated with biologics were also retrieved from the databank. Using the Luminex Discovery assay we measured CXCL10, MMP3, S-100A8, CCL2, and ACP5 levels. Statistical analysis was performed using Wilcoxon Signed-rank test.
Results: CXCL10 (*P=0.0007*), MMP3 (*P<0.0001*), S100A8 (*P<0.0001*), ACP5 (*P<0.0001*), and CCL2 (*P=0.01*) significantly decreased after TNFi treatment in PsA patients. CXCL10 (*P=0.*04) and ACP5 (*P=0.02*) significantly increased after IL-17i treatment in PsA patients. There were no significant differences between treated and untreated PsC patients.
Conclusion: CXCL10, MMP3, S100A8, ACP5, and CCL2 are potential biomarkers for response to TNFi in PsA patients. CXCL10 and ACP5 are potential biomarkers for response to IL-17i treatment in PsA patients.

Background: Guselkumab (GUS) is a human monoclonal antibody targeting the IL-23 p19 subunit. In the Phase 3b COSMOS trial (NCT03796858), GUS significantly improved disease signs/symptoms vs placebo (PBO) in patients (pts) with psoriatic arthritis (PsA) and an inadequate response (IR) to TNF inhibitor (TNFi) therapy. The primary endpoint of American College of Rheumatology 20% improvement (ACR20) response at Week (W)24 was achieved, with the benefit of GUS vs PBO consistent across subgroups.[1]
Objectives: In this post-hoc analysis, we evaluated if response to GUS across disease domains was maintained through 1 year across various subgroups of these TNFi-IR PsA pts.
Methods: In COSMOS, adults with active PsA (swollen joint count [SJC] ≥ 3 and tender joint count [TJC] ≥ 3) with a lack of efficacy/intolerance to 1–2 TNFi therapies were randomized (2:1) to GUS 100 mg or PBO. Pts in the GUS group were treated at W0, W4, then every 8 weeks (Q8W) to W44; those in the PBO group were treated at W0, W4, W12, and W20, with planned crossover to GUS 100 mg at W24 followed by GUS at W28, W36, and W44. Pts with < 5% improvement from baseline (BL) in SJC and TJC qualified for W16 early escape (EE); EE pts receiving GUS continued treatment, while pts receiving PBO crossed over to GUS. In this analysis, efficacy of GUS in subgroups was evaluated at W24 and W48 via joint (ACR20/50 response), skin (Psoriasis Area and Severity Index [PASI]100 response), and multi-domain (minimal disease activity [MDA] response) outcome measures. Subgroups were defined by selected demographics, disease characteristics, and ongoing medications at BL: sex, body mass index (BMI), SJC, TJC, PsA duration, % psoriatic body surface area (BSA), and conventional synthetic disease-modifying antirheumatic drug (csDMARD) use. Odds ratios (ORs) and 95% confidence intervals (CIs) based on Fisher's exact test for GUS vs PBO are shown overall and for each subgroup at W24. No treatment comparison was performed after W24. Pts who discontinued and/or correctly met EE criteria before W24 were imputed as nonresponders. Missing data were also imputed with no response through W48.
Results: Overall, 285 pts were randomized to GUS (n = 189) or PBO (n = 96). BL characteristics were generally similar between treatment groups, although numeric differences were observed for the proportion of females, joint symptoms, and skin involvement in GUS vs PBO pts. At W16, 39 (21%) pts in the GUS group and 45 (47%) pts in the PBO group were assigned to EE. In this analysis, joint, skin, and multi-domain response rates at W24 were numerically greater in GUS vs PBO pts, with the benefit of GUS consistent across all subgroups of adequate sample size (Figure 1). Response rates with GUS were maintained, or in most cases numerically increased, from W24 to W48, regardless of BL subgroup.
Conclusion: GUS 100 mg Q8W led to consistent improvements vs PBO in joint, skin, and multi-domain outcomes at W24 across subgroups of TNFi-IR PsA pts defined by selected demographics, disease characteristics, and ongoing medications at BL. Response to GUS was maintained or further improved through 1 year of treatment regardless of BL subgroup.

DESCRIPTION OF THE REAL-WORLD TREATMENT PATTERNS OF GUSELKUMAB IN THE MANAGEMENT OF PSORIATIC ARTHRITIS IN AUSTRALIA: AN ANALYSIS FROM THE OPAL DATASET

Keywords: Real-world evidence, Psoriatic arthritis, bDMARD

G. Littlejohn[1,2], N. Anbumurali[1], P. Bird[1,3,4], P. Youssef[1,5,6], C. Osullivan[1], T. Smith[1], D. Sumpton[1,5,7], B. Kane[1,7], A. Mcgeachie[8], S. Spiers[9], C. Deakin[1]. [1]*OPAL Rheumatology Ltd, Rheumatology, Sydney, Australia*; [2]*Monash University, Department of Medicine, Clayton, Australia*; [3]*University of New South Wales, School of Clinical Medicine, Kensington, Australia*; [4]*Emeritus Research, Rheumatology, Botany, Australia*; [5]*University of Sydney, Department of Medicine, Sydney, Australia*; [6]*Royal Prince Alfred Hospital, Department of Rheumatology, Camperdown, Australia*; [7]*Concord Repatriation General Hospital, Department of Rheumatology, Concord, Australia*; [8]*Janssen, Outcomes Research, Macquarie, Australia*; [9]*Janssen, Medical Affairs, Macquarie, Australia*

Background: Guselkumab (GUS) is a novel anti-interleukin 23 (IL-23) p19 antibody that acts as a selective and specific inhibitor of the IL-23 cytokine. GUS has been shown to significantly improve signs and symptoms of active psoriatic arthritis (PsA) and became available for the treatment of PsA in Australia in July 2021. Limited data from large real-world patient populations exist to describe the utilisation of GUS for the management of PsA.

Objectives: To describe the patient demographics and treatment patterns of GUS in a large real-world cohort of Australian adult patients with PsA.

Methods: The OPAL dataset is a collection of deidentified clinical data derived from the electronic medical records of 112 rheumatologists at 43 sites around Australia. Adult patients with a diagnosis of PsA who received at least one prescription of GUS or a biologic or targeted synthetic disease modifying anti-rheumatic drug (b/tsDMARD) between Jul 2021 and Jul 2022, were eligible for inclusion in the analysis. Results were summarised descriptively.

Results: A total of 1,868 patients with PsA, (GUS n=355, TNFi n=795, IL-17Ai n=371 and JAKi n=347) were eligible for inclusion in this study. The median [IQR] age of patients was 55 [44-63] years, and 70.1% were female. At baseline, median disease duration was 5[2-8], 2[1-6], 3[1-7] and 5[3-8] years, for patients treated with GUS, TNFi, IL-17Ai and JAKi, respectively. 17.7% of patients receiving GUS were first line compared with 58.7% of TNFi, 39.4% of IL-17Ai and 19.3% of JAKi treated patients (Table 1). At index, the majority of patients were treated as monotherapy.

Conclusion: These are the first data describing the demographics and treatment patterns of real-world Australian patients with PsA treated with GUS. In this preliminary analysis, a higher proportion of GUS and JAKi were used in later lines of therapy, and patients who initiated GUS or JAKi had a longer median disease duration. This may be due to the different time periods of availability of the different b/tsDMARD, as both GUS and JAKi are newer treatment options for PsA compared with TNFi and IL17Ai. Persistence among patients with PsA treated with GUS is currently being investigated.

Table 1. Demographic features of patients with psoriatic arthritis treated with GUS, TNFi, IL-17Ai or JAKi as any line of therapy.

Feature	Initiators of GUS (n=355)	Initiators of TNFi (n=795)	Initiators of IL-17Ai (n=371)	Initiators of JAKi (n=347)
Gender, Female (n, %)	250 (71.3%)	538 (69.2%)	240 (67%)	251 (73%)
Age at Index, years (median [IQR])	55 [45-63]	51 [41-61]	54 [45.5-64]	55 [48-64]
Duration of disease recorded in Audit4 at Index, years (median [IQR])	5 [2-8]	2 [1-6]	3 [1-7]	5 [3-8]
Line of therapy (n, %)				
Line 1	63 (17.7%)	467 (58.7%)	146 (39.4%)	67 (19.3%)
Line 2	57 (16.1%)	152 (19.1%)	99 (26.7%)	81 (23.3%)
Line 3+	235 (66.2%)	176 (22.1%)	126 (34%)	199 (57.3%)

AB1113

REAL-WORLD USAGE OF BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN PATIENTS WITH PSORIATIC ARTHRITIS IN SWEDEN

Keywords: Disease-modifying drugs (DMARDs), Psoriatic arthritis, Real-world evidence

J. Song[1,2], C. Abé[1,2], J. Banefelt[3], A. Rieem-Dun[3], D. Willems[1], M. Morup[1], V. Taieb[1], I. Lindberg[1], S. Welby[1]. [1]*UCB Pharma, N/A, Braine-l'Alleud, Belgium*; [2]*Karolinska Institute, N/A, Stockholm, Sweden*; [3]*Quantify Research, N/A, Stockholm, Sweden*

Background: Given the growing number of treatment options for psoriatic arthritis (PsA) over the last decades, including a variety of biologic disease-modifying anti-rheumatic drugs (bDMARDs), selecting optimal treatment regimens is critical. Beyond clinical guidelines, understanding how physicians choose between available treatment options based on patient characteristics in real-world settings is of interest to both patients and health care providers.

Objectives: To reveal the patient characteristics (ie. demographics, comorbidities – including concomitant psoriasis [PSO], PsA+PSO and history of bDMARD exposure) in relation to bDMARD type and dosing in patients with PsA, treated in real-world clinical practice.

Methods: This retrospective observational cohort study utilised data from Swedish national administrative health care registers. Adult patients with an existing PsA diagnosis and a new bDMARD pharmacy dispensation between 2017–2021 were identified. Index date was that of the first observed dispensation qualifying as a new bDMARD, ie, without prior exposure to the index biologic. Prior bDMARD exposure and patient characteristics (including comorbidities) were screened for from 2005 and 2001, respectively. For patients initiating secukinumab (SEC), prescribed dosing was reported separately for patients with and without PSO manifestations given the variability in prescribing recommendations.

Results: This study identified 8,658 PsA patients initiating a new bDMARD during the study period, among which 2,706 (31.3%) were already bDMARD-experienced. Patients had a mean age of 52.3 years (SD=13.7), and 45.1% were male. The most frequently prescribed bDMARDs were adalimumab (45.3%), etanercept (31.8%), and SEC (11.3%). As expected, due to their recent market authorisations in PsA, the least frequently prescribed bDMARDs were guselkumab (0.8%) and risankizumab (0.4%). The most frequently observed prescriber speciality was rheumatologist (46.1%). The highest proportion of bDMARD-experienced patients was observed amongst interleukin-17 inhibitors initiators (82.4%), while 19.7% of tumour necrosis factor inhibitor initiators were bDMARD-experienced. Overall, 62.8% of patients had PsA+PSO. Other frequent non-inflammatory comorbidities included hypertension (22.0%), malignancies (12.6%), and depression (11.7%). The proportion of patients with anxiety and depression was higher among those initiating risankizumab compared to those initiating other bDMARDs. Other comorbidities were comparable between groups.

Amongst 981 SEC initiators, 679 (69.2%) had PsA+PSO. Maintenance dose data were available/could be analysed for 901 patients. Most PsA-only patients-initiated SEC at a dose of 150 mg (53.7%), and most PsA+PSO at 300 mg (65.0%). This was similar for maintenance period with 51.8% percent of PsA-only and 62.4% of PsA+PSO patients receiving a maintenance dose of 150 mg and 300 mg, respectively. A similar pattern was observed within bDMARD-naïve and bDMARD-experienced patients regardless of PSO manifestations.

Conclusion: This study provides information on the profiles of PsA patients treated with different bDMARDs and suggest that factors such as PSO manifestations and biologic-experience play important roles in the choice of bDMARD and dosing regimen. Future studies are warranted to identify patient outcomes associated with treatment patterns, including discontinuation and switches over time, which can assist in tailoring therapies to patient needs.

Background: Psoriatic arthritis (PsA) is an inflammatory rheumatic disease characterized by different phenotypes in terms of joint involvement. Apremilast, PDE4 competitive inhibitor, has been introduced in the treatment of adult psoriatic arthritis (PsA) with moderate disease activity. Musculoskeletal ultrasound (MUS) is useful in the assessment of disease, treatment response and follow up in PsA patients. Choosing an effective and safe treatment over time is an increasingly urgent goal given the greater availability of indicated drugs.

Objectives: The aim of this study is to evaluate if MUS assessment before apremilast treatment can improvement its retention rate.

Methods: We enrolled consecutive patients affected by PsA (according to the CASPAR Criteria) from 15 rheumatology centers. The following data were recorded for each patient: age, gender, duration of disease, DAPSA; smoke, comorbilities; concomitant treatment; duration of therapy with apremilast; reason of sospensione, PsA phenotype (poliarticular or oligoarticular) (Table 1). All patients were divided in two subset according to the presence of a MUS assessment before apremilast treatment. The differentes between two groups were calculated by means of the Mann-Whitney and Chi-quadro tests. The Kaplan Meier curve and Cox analysis assessed the retention rate and associated factors. P values < 0.05 were considered statistically significant.

Results: ON Three hundred and fifty patients (m/f: 198/152; median age 60 years, IQR 52-67 years), 40% received MUS examination. In the MUS group there was a moderate disease (medium 22,9 IQR 18,2-29 vs 26,9 IQR 20,3-33,9; p=0,0006) and a prevalence of the oligoarticular pattern (73% vs 44%, p<0,0001). The retention rate was statistically higher in MUS group (Figure 1) (HR 0,57 IC95% 0,35-0,95; p=0,03).

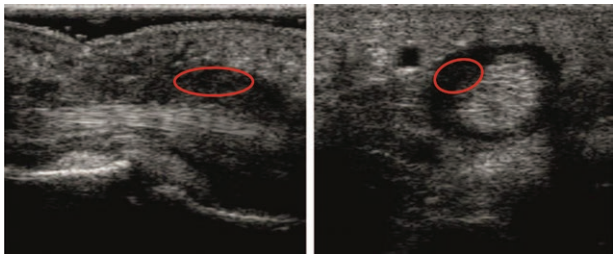

Figure 1. A: Psoriatic arthritis. Longitudinal volar scan of the interphalageal prossimal joint. Tenosinovitis of the flexor tendons ^{0}B: Psoriatic arthritis. Transversal volar scan of the interphalageal prossimal joint. Tenosinovitis of the flexor tendons ()

Conclusion: In PSA patients treated with apremilast, MUS assessment at baseline was associated with an higher retetion rate. MUS could be useful in the PsA treatment algorithm in order to better identify those patients whose characteristics are favourable to apremilast response.

Background: Ixekizumab (IXE), an Interleukin (IL)-17A inhibitor (i), approved for the treatment (tx) of Psoriasis (Pso), psoriatic arthritis (PsA) and axSpA (rad/non rad) have limited real-world data. PRO-SPIRIT is the first large, prospective observational study for IXE in patients (pts) with PsA who start a new biologic/targeted synthetic disease modifying anti-rheumatic drug (b/tsDMARD), with a primary endpoint of persistence at 24 months (M).
Objectives: To describe baseline (BL) characteristics of pts enrolled in PRO-SPIRIT.
Methods: PRO-SPIRIT enrolled pts December 2019-June 2022 in FR, ES, IT, DE, UK, and CA, who started a new b/tsDMARD, approved for PsA. Tx groups are; IXE, secukinumab (SEC), IL-12/-23i, IL-23i, tumor necrosis factor inhibitor (TNFi), Janus kinase inhibitors (JAKi), and Phosphodiesterase-4 inhibitor (PDE4i). Pts' demographic, disease activity, and tx characteristics were recorded at BL, effectiveness outcomes and tx changes at 3, 6,12,18, and 24M. BL descriptive statistics are shown.
Results: The analysis included 1207 pts (2 pts with other tx not shown below). Most were female, had mean age 52.4yrs, poly/oligo-arthritis and enthesitis/dactylitis in similar proportions except for enthesitis in IL12/23i and IL-23i pts.
Pts started on IXE had long disease duration (9.2yrs). Most had prior b/tsDMARDs (69.5%) and 38.7% had active PsO similar to SEC pts. For TNFi pts, mean disease duration was 6.5yrs, 30.8% had received prior b/tsDMARDs, and 30.4% had active PsO. IL-23i pts (n=57) were typified by long disease duration (8.7yrs), high proportions of PsO (50.9%)/nail PsO (50.9%) and prior b/tsDMARD use (78.9%). JAKi pts had long (9.2yrs) disease duration, 72.2% prior b/tsDMARDs experience, and 26.2% had active PsO. IXE and IL23i pts were more often treated on monotherapy.
Conclusion: In PRO-SPIRIT, pts starting IXE showed active PsA, with both joint and often skin involvement, and were mostly treated with monotherapy after failing several b/tsDMARDs. TNFis were often used as 1st line therapy alongside csDMARDs.

Background: We conducted a study using ultrasonography (US) to evidence inflammatory changes (joint-enthesis-ungueal) in active PsA (aPsA) patients who started Apremilast (A) in clinical practice.
Objectives: Obtain a 20, 50, 70 % reduction in the US index (UIC) at 12 months, and study correlation between variables.
Methods: *Phase IV, multicenter, prospective and open-label clinical trial* conducted *in 9 centres* from 2018 to 2021. All patients signed the informed consent. Approval by the ethical committee was obtained, code PSA-PI-006421. PsA patients (≥ 2 swollen joints), ≥ 2 joint US synovitis and ≥ 1 US enthesitis at screening were recruited. 52 weeks follow up (baseline, 1, 6, 9 & 12 months). US & clinic variables, and ESR & CRP were registered at each visit. US scans were scored according to Ficjan et al [1]. Ungueal nail plate (NP) and subungueal thickness (ST) US evaluation of 2nd, 3rd and 5th finger was done.
Results: 48 patients screened and 46 included (2 screening failure) in follow up. 26 completed the study. A 20 % (main objective) reduction in UIC was obtained, until 40%, but not 50/70%. Clinical and US variables were reduced, ESR and CRP did not change during follow-up (Table 1). Strong correlation was observed between UIC and SJC, moderate between UIC and TJC, PGA, PtGA, CRP. A reduction in clinical onychopathy, NP lesion, and slight relation between lesion, and high ST and ST with onychopathy was seen but didn't achieve statistical significance (reduced sample size). 75 adverse events in 33 patients

AB1117 **DRUG SWITCHING IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH TUMOR NECROSIS FACTOR INHIBITOR.**

Keywords: bDMARD, Psoriatic arthritis, Epidemiology

D. Freites Nuñez[1], M. Rodríguez Laguna[1], C. Martinez Prada[1], B. Fernandez[1], C. Lajas[1], L. León[2,3], L. Abasolo[2]. *[1]Hospital Clinico San Carlos, Rheumatology, Madrid, Spain*; *[2]Instituto de Investigación Sanitaria San Carlos (IdISSC)., Rheumatology, Madrid, Spain*; *[3]Universidad Camilo Jose Cela, Health Sciences, Madrid, Spain*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis, characterized by different clinical manifestations and associated comorbidities that requires targeted treatment. Therapy with Tumor necrosis factor inhibitor (TNFi) represents one of first therapeutic choices. However, PsA patients can experience TNFi failure, lack of efficacy, or adverse events. Although rheumatologists are now able to choose between several drugs, there is a lack of standard patient profiles or detailed treatment algorithms that can be followed when patients need to switch their therapy regimens.
Objectives: To evaluate the switching treatments regardless the cause in patients with PsA treated with TNFi as first biologic agent.
Methods: Retrospective longitudinal observational study. Subjects: Cohort of patients attended in the outpatient rheumatology clinic from January 2006 to December 2021, and followed up to June 2022, diagnosed with PsA according to ICD-10 code and on treatment with TNFi. Main outcome: Therapy regimens switching. Covariables: sociodemographic and clinics. Statistical analysis: Descriptive analysis of the switching therapy, global and stratified by treatment courses.
Results: 125 patients with a diagnosis of PsA and on treatment with TNFi were included, 52% were female, the mean age was 47.87 ± 13.29 years. 94 (75.20%) patients had a history psoriasis at baseline and 95 patients (76%) presented peripheral arthritis and 21 (16.80%) referred inflammatory low back pain as a main clinical domain, 50% of the patients presented at least three PsA domains. 232 courses of treatment were recorded throughout follow-up. As a whole, TNFi was the most used drug with 184 (79.31%) courses, adalimumab 78 (42.39), flowed by interleukin-17 inhibitors (IL-17i) with 30 (12.93%) courses of treatment. 82 (65.60%) patients were on concomitant treatment with conventional DMARDs. From the 125 patients, 49 recorded a switching to a second therapy regimen (32 switched to a second TNFi and 17 to another class of drugs, mainly IL-17i). Then, 28 presented a third change (16 to a different TNFi and 12 switched to another class of drugs) and finally 14 patients had a fourth switching (8 patients received a drug other than TNFi). TNFi switching data expressed in course of treatment is shown in Table 1. Switching after TNFi exposure was mainly due to lack of efficacy with 90 (84.11%) courses of treatment, followed by adverse events with 11 (10.28%).
Conclusion: In our study, although most of the TNFi switching was to a different TNFi, we observed a number of PsA patients receiving another class of drugs after TNFi exposure, and this action increased over the consequent treatment cycles.

Table 1. Courses of switching treatment in PsA patients treated with TNFi.

AB1118 **EFFECT OF APREMILAST ON PSORIATIC DISEASE DOMAINS STRATIFIED BY EXTENT OF SKIN INVOLVEMENT IN PATIENTS WITH PSORIATIC ARTHRITIS**

Keywords: Skin, Psoriatic arthritis

A. F. Wells[1], L. Teng[2], S. Colgan[3], C. Deignan[3], S. Jardon[3], Y. Klyachkin[3], A. Majjhoo[4], A. Kavanaugh[5]. *[1]Advocate Aurora Medical Group, Rheumatology & Immunotherapy, Franklin, United States of America*; *[2]Amgen Inc., Statistics, Thousand Oaks, United States of America*; *[3]Amgen Inc., Medical Affairs, Thousand Oaks, United States of America*; *[4]Shores Rheumatology, PC, Rheumatology, Saint Claire Shores, United States of America*; *[5]University of California, San Diego, School of Medicine, Rheumatology, La Jolla, United States of America*

Background: It has been suggested that greater skin involvement in patients with psoriatic arthritis (PsA) may be associated with greater joint disease activity.
Objectives: To assess the impact of APR on PsA disease domains in patients with BSA <3% vs BSA ≥3% at 52 weeks using pooled data from 2 phase 3 trials.
Methods: PALACE 1 & 2 were randomized, placebo (PBO)-controlled, phase 3 studies in patients with active PsA. Eligible patients had ≥3 swollen and ≥3 tender joints despite prior treatment with a conventional systemic Disease Modifying Antirheumatic Drug (csDMARD) and/or biologic DMARD (bDMARD) or concurrent treatment with csDMARD. Patients were randomized to receive APR or PBO for up to 24 weeks, after which all patients received APR until Week 52. This ad-hoc analysis includes pooled data from patients randomized to APR 30 mg BID at Week 0 in these studies. Assessments included change from baseline at Week 52 in Clinical Disease Activity Index for Psoriatic Arthritis (cDAPSA), swollen joint count (SJC), tender joint count (TJC), patient assessment of pain visual analog scale (VAS), and Patient Global Assessment of Disease Activity (PtGA) VAS stratified by baseline psoriasis body surface area (BSA) involvement (<3% vs ≥3%).
Results: Of 330 patients randomized to APR 30 mg BID at Week 0, 171 had BSA <3% and 159 had BSA ≥3%. Of those with available data, 98.2% of patients with BSA <3% and 100% of patients with BSA ≥3% had a history of psoriasis; mean BSA at baseline was 1.2 in the <3% group and 14.3 in the ≥3% group. More patients with BSA ≥3% at baseline were men with higher rates of nail and SJC involvement, and slightly higher rates of oligoarthritis and TJC (**Table 1**). At Week 52, both subgroups showed mean decreases (improvement) from baseline in clinical parameters with APR treatment, including cDAPSA (BSA <3%: -18.0, BSA ≥3%: -23.3), SJC (BSA

<3%: -6.1, BSA ≥3%: -8.7), TJC (BSA <3%: -10.1, BSA ≥3%: -13.0), Patient Assessment of Pain (BSA <3%: -15.5, BSA ≥3%: -18.0), and PtGA (BSA <3%: -11.8, BSA ≥3%: -16.8) (**Table 1**). There were numerically greater decreases in these parameters among patients with baseline BSA ≥3% than those with BSA <3%. Improvements in enthesitis and dactylitis were also observed in both subgroups.

Conclusion: Patients with PsA in PALACE 1 & 2 with higher BSA had higher disease activity in some disease domains at baseline. Both BSA subgroups showed improvement with APR at Week 52 regardless of disease severity, although numerically greater improvements were seen in patients with BSA ≥3%. To our knowledge, this is a novel analysis assessing treatment efficacy in patients with PsA by level of skin involvement.

Table. Baseline Demographics, Disease Characteristics, and Change From Baseline in Efficacy Parameters to Week 52 by BSA Subgroups

GUSELKUMAB EFFICACY AND SAFETY ANALYSIS FOR PSA ACCORDING TO BASELINE CHARACTERISTICS AS GENDER, OBESITY OR PREVIOUS TREATMENT IN REAL LIFE AFTER 52 WEEKS

Keywords: Psoriatic arthritis, Real-world evidence, bDMARD

V. Ruiz DEL Valle[1], I. Martín Martín[1], M. Navidad Fuentes[1], L. Estepa Díaz[1], S. Quirosa Flores[1]. [7]Virgen de las Nieves University Hospital, Rheumatology, Granada, Spain

Background: Guselkumab is a human IgG1λ monoclonal antibody that binds to interleukin 23, a regulatory cytokine that modifies the activity of T lymphocytes, intervening in pathogenic ways that initiate and maintain the activity of Psoriatic Arthritis (PsA). PsA has a wide spread of systemic manifestations where several profiles of disease exist depending on the predominant affection. Guselkumab has been used widely to treat cutaneous psoriatic disease (PsO) and PsA since 2020. Nevertheless, no long-term analysis have been done.

Objectives: To analyze the long term efficacy and safety of Guselkumab at 52 weeks (w). Likewise, relevant demographic data such as sex, weight or previous biological treatment was taken into account.

Methods: A prospective, unicentric, observational study was conducted in patients who met ACR criteria for PsA, who received treatment with Guselkumab for 52 w. Patient demographic and baseline data were recorded and response variables such as DAPSA and BSA index, presence of enthesitis and dactylitis, and drug persistence at 12, 24 and 52 w of treatment were statistically analyzed and compared between different groups of patients stratified by their demographic data and previous biological therapy using Student-T and ANOVA. In addition, adverse events were recorded.

Results: 45 patients with moderate-to-severe PsA were included: 60 % were female, they had a mean BMI of 28.87. Approximately, 60% of patients received Guselkumab in fourth to eighth line of treatment. According to their DAPSA index score, patients were classified into remission, low activity and active disease. 50% of the patients fell under the remission category at w52, with the majority of the remaining in low activity (44%). The percentage of enthesitis and dactylitis presented an important reduction, from 31% and 8.88% at baseline to both 0% at 52 w respectively. BSA also experimented a significant reduction. (Figure 1) At baseline both genders showed a similar mean value for DAPSA which decreased significantly when they reached w 52. There were not differences between genders at the end of the study, however women had an earlier response with significant differences at w 12. Moreover, when we analyzed the population regarding weight, we found that Guselkumab was effective both in normal weight and also in overweight patients being 8/13 of them obese. Finally, studying the previous biologic treatment profiles, we found that better results were expected after anti-TNF or IL-17 inhibitors compared to other drugs. Treatment persistence was 100% after 24 w and 85% after 52 w in those patients who received Guselkumab as 2nd or 3rd line of treatment, but 84% and 63% at 24 and 52 w in those who took it in 4th place or more. No adverse effects were reported and a total of 11 patients abandoned treatment, 10 of them due to primary failure and 1 due to secondary failure.

Conclusion: Guselkumab was effective and safe for the treatment of manifestations of PsA in a real world evidence cohort of patients for 52 w. In addition, Guselkumab was equally effective in men/women as well as overweight patients, showing better results when the patient had followed treatment previously with anti-TNF or IL-17 inhibitors probably because they were less bDMARD-experienced patients. According to this fact, Guselkumab demonstrated an increased survival when administered in the second or third line of treatment compared to advanced lines of treatment.

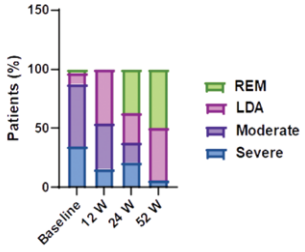

Figure 1. Percentage of patients reaching remission (REM), low disease activity (LDA) or active disease at baseline, 12, 24, and 52 weeks after Guselkumab treatment.

AB1120 REAL-LIFE EFFICACY AND SAFETY OF IXEKIZUMAB IN A COHORT OF PATIENTS WITH PSORIATIC ARTHRITIS: A SINGLE-CENTER RETROSPECTIVE STUDY

Keywords: Psoriatic arthritis, bDMARD, Real-world evidence

E. Bellis[1], D. Donzella[1], G. Crepaldi[1], V. Data[1], M. Gammino[1], V. Guardo[1], C. Lomater[1], E. Marucco[1], M. Saracco[1], A. Iagnocco[1]. [1]*Università di Torino; AO Mauriziano di Torino, Academic Rheumatology Center, Dipartimento Scienze Cliniche e Biologiche, Turin, Italy*

Background: Ixekizumab is a high-affinity monoclonal antibody that selectively targets interleukin-17A and is indicated for psoriasis, psoriatic arthritis (PsA) and axial spondyloarthritis. Literature highlights efficacy and safety in real life in patients affected by psoriasis[1], instead little are data concerning PsA.[2]

Objectives: To retrospectively evaluate the effectiveness and safety of ixekizumab, in a cohort of patients with PsA.

Methods: Patients with a diagnosis of PsA and treated with ixekizumab who visited our outpatient clinic from October 2019 to December 2022 were included in the study. Clinical data were recorded since the first prescription of ixekizumab and at 6-month follow-up visit. Demographic, clinical and laboratory characteristics, treatment, and causes of discontinuation were analyzed. Differences between baseline and 6-months erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), tender joint count (TJC) and swollen joint count (SJC) were analysed.

Results: Main results are reported on Table 1. 76 patients were included in the study, with an average age at the prescription of ixekizumab (T0) of 57.1±13.0 years. Main comorbidities were: hypertension (44.7%), obesity and overweight (44.7%), cardiopathy (19.7%), hepatic steatosis (21.0%), diabetes (13.2%), and hyperlipemia (3.9%). 93.42% of patients presented peripheral arthritis, 30.6% axial involvement, and 42.1 % enthesitis. 28,9% of patients were biologic-naïve, 34,0% received one biologic agent before, and 31.5% two or more biologic agents. 88,2% of patients initiated ixekizumab in combination with a csDMARDs, mainly methotrexate. The indications for the prescription of ixekizumab as a first biologic agent were: multiple comorbidities, severe psoriasis, and intolerance to csDMARDs. 28.9% of patients stopped ixekizumab because of primary failure (31.8%), secondary failure (22.7%), or adverse events (45.5%). 40% of the adverse events were relevant skin reactions at the injection site. No severe adverse events were registered. 60 patients completed 6 months of treatment (T6). In those patients, a statistically significant decrease between the SJC and TJC at baseline and T6 was found (p-value 0.0011 and 0.0006 respectively). No difference in the values of ESR and CRP values between T0 and T6 was present.

Table 1. General characteristics of our cohort and clinical and laboratory findings at baseline and follow-up for patients who completed 6 months of treatment with ixekizumab.

Male/female n. (%)	22 (28.9%)/ 54 (71.1%)		
Mean age at diagnosis (years)	50.0		
Years from diagnosis at the first prescription of ixekizumab (years)	6.7		
Patients: n. 60	**T0**	**T6**	**p-value**
ESR (mm/h)	27.44±23.3	27.56±22.2	0.9741
CRP (mg/dl)	1.58±2.47	0.98±1.7	0.1569
TJC	9.17±6.98	5.02±6.65	0.0011
SJC	1.57±2.75	0.28±0.64	0.0006

Conclusion: There are few data in real life concerning efficacy and safety in patients affected by PsA. In our cohort, ixekizumab significantly improved peripheral arthritis, and it revealed a good safety profile, without severe adverse events during the follow up. Further real-life evaluations on axial involvement, which was not included in this study, are warranted.

AB1121 EFFICACY AND DRUG PERSISTENCE OF NEWLY INITIATED BIOLOGICS IN PSORIATIC ARTHRITIS

Keywords: bDMARD, Real-world evidence, Psoriatic arthritis

L. G. Stanciu[1], M. Agache[1,2], C. E. Ionescu[1,2], L. Enache[1,2], C. Mogosan[1,2], C. Popescu[1,2], C. Codreanu[1,2]. [1]*"Dr. Ion Stoia" Clinical Center for Rheumatic Diseases, Rheumatology, Bucharest, Romania*; [2]*"Carol Davila" University of Medicine and Pharmacy, Rheumatology, Bucharest, Romania*

Background: Psoriatic arthritis (PsA) is a form of spondyloarthritis associated with psoriasis and characterized by joint, entheses and spine inflammation. Numerous therapeutic molecules have appeared in the last decade following breakthroughs in the pathogenesis of the disease [1].

Objectives: The study aimed to evaluate the effectiveness and persistence of first-line biological treatment in PsA in a real-life setting.

Methods: The study included retrospectively all the PsA patients initiated on biologics in a university single center real-life clinical practice between January 2018- December 2021, as reported in the Romanian Register of Rheumatic Diseases [2]. Differences of continuous variables among subgroups were assessed with Mann Whitney tests, while associations of categorical variables were assessed with χ^2 tests, considered significant if $p < 0.05$.

Results: The study included 38 patients with an average age at biologic initiation of 50 ± 16 years, of which 71.1% were women, 34.2% were obese and 10.5% were smoking. The patients had established disease, with an average PsA duration of 9 ± 9 years. Regarding treatment, 44.7% initiated tumor necrosis factor inhibitors (TNFi) and 55.3% interleukin 17 inhibitors (IL-17i). A fraction of 31.6% had biologic monotherapy. After the first 6 months of therapy, 55.3% reached the treatment target (Disease Activity in PSoriatic Arthritis - DAPSA < 14) with a drug persistence of 78.9%, while 65.8% reached target by 12 months with 68.4% drug persistence. There were no differences of DAPSA scores, target frequencies or persistence frequencies at 6 and 12 months between TNFi and IL17i ($p > 0.05$). An equal number of initiations was observed in the pre-pandemic period (2018-2019; 50%) versus the pandemic period (2020-2021; 50%).

Conclusion: Observations in a real-life setting show good efficacy persistence of both TNFi and IL17i in PsA at 6 and 12 months after their initiation. SARS-CoV-2 pandemic did not influence the number of biologic initiations in PsA patients.

GUSELKUMAB VS GOLIMUMAB IN PSA TNFI-INADEQUATE RESPONDERS (EVOLUTION): FORMULATING A PRAGMATIC PHASE 3B RANDOMIZED TRIAL

Keywords: Randomized control trial, Psoriatic arthritis, Real-world evidence

A. Ogdie[1], S. Reddy[2], K. Bush[1], S. Hopkins Gillespie[1], M. E. Husni[3], P. Karmacharya[4], J. Scher[2], M. Perate[5], S. D. Chakravarty[5,6], C. Gong[5], J. A. Walsh[7]. [1]*University of Pennsylvania School of Medicine, Division of Rheumatology, Philadelphia, United States of America*; [2]*NYU Grossman School of Medicine, Department of Medicine, New York, United States of America*; [3]*Cleveland Clinic, Immunology, Cleveland, United States of America*; [4]*Vanderbilt Health, Department of Medicine, Nashville, United States of America*; [5]*Janssen Scientific Affairs, LLC, Immunology, Horsham, United States of America*; [6]*Drexel University College of Medicine, Department of Medicine, Philadelphia, United States of America*; [7]*University of Utah School of Medicine, Department of Medicine, Salt Lake City, United States of America*

Background: Aside from the Tight Control in PsA (TICOPA) study, treatment strategy trials in psoriatic arthritis (PsA), and definitive guidance on managing patients (pts) with inadequate response (IR) to a first tumor necrosis factor inhibitor (TNFi), are lacking. Recent observational studies suggest potentially greater benefit from switching TNFi-IR pts to a new mechanism of action (MOA).[1]
Objectives: Design a pragmatic trial (EVOLUTION) to determine whether switching TNFi-IR PsA pts to a new MOA, specifically to the selective interleukin 23 inhibitor (IL-23i) guselkumab (GUS), is more effective than cycling to a 2nd TNFi (Figure 1).
Methods: To plan the EVOLUTION trial, we assessed pts receiving any biologic in the multicenter longitudinal observational Psoriatic Arthritis Research Consortium (PARC) study.[2] Findings informed expected mean changes in selected outcome measures, enrollment feasibility, and sample size estimates.
Results: 215 pts initiating a biologic in PARC (including later lines of therapy) had data for the outcomes of interest and a 3-6 month follow-up visit. At therapy initiation (baseline [BL]), mean age=50.4 (SD 14.4), 56% were female, 81% were White. Mean BL clinical disease activity in PsA (cDAPSA)=20.0 (15), mean body surface area (BSA)=2.0% (6), 21% were in minimal disease activity (MDA), 43% were in cDAPSA remission/low disease activity (LDA), and 70% had a BSA ≤1%. 113/215 (53%) pts met EVOLUTION's clinical enrollment criteria (Figure 1). Pts who would be eligible for EVOLUTION vs ineligible pts had higher disease activity (mean cDAPSA 29.0 vs 10.0, PtGA 5.6 vs 3.1, Psoriatic Arthritis Impact of Disease Questionnaire [PSAID-12] 5.1 vs 2.6, swollen joint count [SJC] 6.0 vs 0.8, tender joint count [TJC] 11.0 vs 2.4); age and sex distribution were similar. Among EVOLUTION-eligible pts not in MDA at BL, 21% achieved MDA at follow up. Also at follow-up in EVOLUTION-eligible pts not in response at BL, 38% achieved cDAPSA LDA, 38% achieved BSA ≤1%, 30% achieved both, and mean change (Δ) in PtGA= -1.0 (2.5), Δ pt pain= -1.4 (2.7), and Δ PSAID-12= -1.0 (1.9). EVOLUTION'S primary study outcome (cDAPSA LDA + IGA 0/1) will be assessed at 12 months (Table 1), and per clinical practice, pts will be enrolled at the time of switch vs post-washout. Assuming 24%, 45% and 50% of pts in the golimumab (GOL), GUS Q8W and GUS Q4W arms, respectively, would achieve the primary outcome, and a 20% pt dropout rate, a total sample size of 300 pts is anticipated to yield 80 pts per randomized group and provide 80% power to detect a difference in proportions of GUS Q4W vs GOL and GUS Q8W vs GOL pts achieving cDAPSA LDA + IGA 0/1.
Conclusion: The EVOLUTION trial will apply an innovative, pragmatic randomized trial approach to assessing therapy effectiveness by recruiting a treatment-refractory PsA population consistent with that seen in clinical practice. This also includes using a novel primary endpoint (cDAPSA LDA + IGA 0/1) with direct applicability to routine care. This first of its kind head-to-head comparative effectiveness trial in real-world PsA pts will address important knowledge gaps in the management of PsA related to switching from a TNFi to GUS vs cycling to a 2nd TNFi and will build on a longitudinal cohort study used to plan this study.

EFFICACY AND SAFETY OF SECUKINUMAB IN PATIENTS WITH PSORIASIS

Keywords: Psoriatic arthritis, bDMARD

Q. Y. Su[1,2,3], B. R. Zhao[2,3], H. J. Gao[2,3], S. C. Sun[2,3], J. Luo[2,3], Q. Yu[4], P. F. He[4], X. Li[1,2,3], S. X. Zhang[1,2,3]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; [3]*Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*; [4]*Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*

Background: Psoriasis is a chronic, multisystem inflammatory disease with predominantly skin and joint involvement. The interleukin-(IL-)17 axis plays a vital role in the development of psoriasis. Secukinumab (Cosentyx) is a fully human monoclonal antibody that selectively targets IL-17A for the treatment of adult patients with psoriasis[1].
Objectives: This study aimed to systematically evaluate the efficacy and safety of secukinumab therapy in psoriasis.
Methods: Eight databases (PubMed, Web of Science, Embase, Cochrane Library, Web of Knowledge, MEDLINE, Clinical Trials.gov, and FDA.gov) were searched for studies on secukinumab treatment of psoriasis published from the date of establishment of the database to January 3, 2022. A random effect model was used to conduct a meta-analysis of the efficacy and safety of abatacept in patients with RA using (Stata 12.0).
Results: A total of 27 studies with a total of 4470 patients were included. After receiving secukinumab therapy for 12 weeks, The response rate of PASI 75 was 82.2% (95% CI 0.766–0.879,p<0.01), PASI 90 was 66.3%(95% CI 0.609–0.718,p<0.01), and PASI 100 was 42% (95% CI 0.343–0.497,p<0.01). The results showed that more than 80% of patients achieved skin lesion removal in 12 weeks. Considering PGA 0/1 as the secondary endpoint. The percentage of patients who achieved a PGA score of 0 or 1 was 72.3% at 12 weeks (95% CI 0.658–0.788,p=0.005). As for the safety, the incidence of adverse events was 63.7%. Infection is the main adverse effects, with rates of 19.4%. Most of the adverse events were mild and recovered quickly after discontinuation. (Figure 1)
Conclusion: Secukinumab is effective in patients with psoriasis and is generally well tolerated, and thus represents a useful treatment alternative to TNFi and other bDMARDs in adult patients with psoriasis.

AB1124 TOFACITINIB IN PSORIATIC ARTHRITIS -WELL TOLERATED DRUG - REAL LIFE EXPERIENCE

Keywords: Psoriatic arthritis, Targeted synthetic drugs, Safety

V. Petciappan[1], N. Prabu[2], A. Kumar[2], S. Ram[2], G. Anand[2]. *[1]PSG Hospitals, Internal Medicine, Coimbatore, India*; *[2]Sakthi Rheumatology Centre Pvt. Ltd, Rheumatology, Coimbatore, India*

Background: Tofacitinib a small molecule JAK- inhibitors has been approved for use in psoriatic arthritis (PSA) since 2017 while it has shown to be effective in the clinical trials real life data is sparse.With increase in use there has been growing concern about the safety profiles and adverse events which makes it all the more important to have real life data.
Objectives: To review patient records who were treated with tofacitinib for psoriatic arthritis and to assess the tolerance and continuation rate and also assess the occurrence of adverse events like infections, coronary artery disease.
Methods: All PSA patients who were prescribed tofacitinib from JAN-2021 to JUNE 2022 with minimum of 6 months followup were included for analysis. Demographics, weight recordings, lab parameters and occurence of adverse events were noted.
Results: There were a total of 71 patients who were prescribed tofacitinib out of which 46 are continuing and 25 have stopped during this period. The mean age was 47.25 (10.9)yrs the mean disease duration was 4.182 (4.474)yrs The reason for stopping tofacitinib was better(52%) followed inefficacy(24%), and miscellaneous(24%)reasons..When analysing before and after tofacitninb one thing whihc was striking is the significant weight gain among patients with minimum of 3.52(3.06) kg weight gain and this weight gain was consistent even in stopped patients.in comparing the lab parameters before and after tofacitininb there was a significant redcution in CRP,ESR,PLATELET COUNT Table 1 and a minimal but insginificant rise in liver enzymes within the physiological range.When compared to before and after tofacitinib there was increased occurence of fatigue(18.3%), minor infections(11.2%), Gastrointerstinal adverse events (11.2%), alopecia (11.2%), Itching(10.4%), headache(9.8%), UTI(5.6%), cough (4.2%), transaminitis(2.8%), covid(1.7%), zoster(1.4%) and CAD(1.4%).
Conclusion: Tofacitinib in psoriatic arthritis is well tolerated with significant reduction in the inflammatory markers and weight gain but serious adverse events in lesser percentage eventhough it leads to significant weight gain.

Table 1.

PARAMTERS	Before	After	P value
Weight	70.15 (14.19)	72.31 (14.24)	0.000249
ESR	45.29 (28.26)	35.23 (28.33)	0.037
CRP	21.56 (16.38)	10.72 (11.98)	<.0001
PLATELET COUNT	332.92 (88.77)	307.09 (88.18)	0.0046
SGOT	30.33 (9.99)	35.69 (19.92)	0.125

Background: Upadacitinib (UPA) is an inhibitor of JAK kinases recently approved by EMA for the treatment of psoriatic arthritis (PsA) in Europe (January 2021) [1] UPA has shown efficacy in refractory patients to anti-TNF [2]
Objectives: A) to assess efficacy and safety of UPA in the first cases in Spain in clinical practice. **B)** to compare the profile of clinical practice (CP) patients with clinical trial (CT) of UPA in PsA refractory to biologics [2]
Methods: Study of 101 patients of CP with PsA treated with UPA in Spain. The diagnosis of PsA was made using CASPAR criteria. Patients who received one or more dose of UPA with at least one follow-up visit were included. Results are expressed as percentage, mean±SD or median [IRQ]
Results: 101 patients (73♀/28♂), mean age of 43.8 ± 12.1 years **(Table 1).** Pattern joint involvement was: peripheral (n=61) axial (8) and mixed (32) During the PsA evolution patients presented enthesitis (38.6%) nail involvement (22%) and dactylitis (25.7%) Prior to UPA most patients (71.3%) received oral prednisone or equivalent (mean maximum dose 12.04±6.98 mg/d), synthetic immunosuppressants (mean; 1.8±0.9) and biological therapy (TB) (3.4±2.2). TB were: etanercept (n=47), adalimumab (77), infliximab (23), golimumab (21), certolizumab (32), secukinumab (53), ixekizumab (32), ustekinumab (34), Abatacept [2], brodalumab [1] and guselkumab [2]. Apremilast was used in 23, Tofacitinib in 26 and filgotinib in 1 UPA was started (15 mg/24 h) after a mean follow-up of 9.9±7.8 years from PsA diagnosis. Prednisone was used in 47 cases (mean dose, 7.8±5.7 mg/d). UPA was combined with methotrexate (n=30), salazopyrin (7) and leflunomide (15); in the remaining 51 cases (50.50%) was used in monotherapy. At UPA initiation patients presented peripheral arthritis (78%), axial involvement (28,71%), skin involvement (22.8%), enthesitis (22.7%), and dactylitis (11%) Patients of CP compared with CT were younger, more frequently women, refractory to a greater number of TB and received more concomitant corticosteroid **(Table 1)** After a median follow-up of 5.72±4.64 months with UPA, patients showed a prompt improvement in activity indexes (DAS28, DAPSA) **(Figure 1)** and CRP mg/L decreased from a median 2.51 [1.0-8.0] to 1.00 [0.30-5.00] (p <0.006). Extra-articular manifestations also improved: dactylitis in 75% patients, enthesitis (55.56%) and skin involvement (60%) No serious Adverse events (AE) were reported. Minor side effects were observed in 20 patients (19.8%). UPA was discontinued in 31 (20 inefficiency, 4 patient decision, 2 infection, 2 thrombosis, 1 surgery, 1 pregnancy)
Conclusion: In this study, first patients of CP in Spain with UPA in PsA were younger, received concomitant corticosteroid more frequently and were refractory to a greater number of TB than those of CP. As in the UPA CT, it seems effective, rapid and relatively safe in daily CP for refractory Ps.A.

AB1126

LOW-DOSE IL-2 CHANGED LYMPHOCYTE SUBSETS IN PATIENTS WITH PSORIATIC ARTHRITIS.

Keywords: Psoriatic arthritis, Cytokines and chemokines

X. M. Wang[1,2], Q. Y. Su[1,2,3], J. X. Zhang[1,2], Y. Z. Li[1,2], B. R. Zhao[1,2], Q. Yu[4], P. F. He[4], X. Li[1,2,3], S. X. Zhang[1,2,3]. *[1]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*; *[2]Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taiyuan, China*; *[3]Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; *[4]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*

Background: Psoriatic arthritis (PsA) is an autoimmune disease characterized by disturbances of regulatory cells, which were regulated by interleukin (IL)-2.
Objectives: The aim of this study was to systematically evaluate the changes in number of lymphocytes subsets after low-dose IL-2 therapy in psoriatic arthritis(PsA).
Methods: Systematic searches of PubMed, EMBASE, Web of Science, the Cochrane Library and Medline, CNKI, CBM and Technology Journal Database were performed. Original case reports, case series, observational studies and clinical trials reporting the changes in numbers of lymphocytes subsets on PsA patients treated with IL-2 were included. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I^2 and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0)

Results: A total of 3 studies comprising 156 patients were identified(Table 1).The numbers of Tregs were increased after the treatment of IL-2[SMD=0.928, 95%CI (0.004,1.853), P=0.049]. Additionally, there were no statistical differences in the numbers of Th1, Th2 and Th17 cells[SMD=0.213, 95%CI (-0.198,0.623), P=0.310; SMD=0.137, 95%CI(-0.739,1.013), P=0.759;SMD=0.146, 95%CI (-0.430,0.722), P=0.619](Figure 1).
Conclusion: Low-dose IL-2 was promising in the treatment of PsA, which could promote the proliferation and functional recovery of Tregs.

Table 1. Available evidence including patients with PsA treated with low-dose IL-2.

Study.Year.	Patients (include in analysis)	Gender (female %)	Dosage	Tregs
Jia Wang. 2020.	22(22)	NA	0.5 million IU per day for 5 days	before:26.26±10.99 after:70.78±44.82

AB1127

THE RETENTION RATE OF ETANERCEPT AND ADALIMUMAB IN FIRST-LINE AND AFTER NON-MEDICAL SWITCH IN PATIENTS WITH PSORIATIC ARTHRITIS: A COMPARISON BETWEEN ORIGINATORS AND BIOSIMILARS. A SINGLE-CENTER RETROSPECTIVE STUDY.

Keywords: Psoriatic arthritis, bDMARD

V. Rella[1], C. Rotondo[1], N. Maruotti[1], A. Altomare[1], F. Erroi[1], S. Stefania[1], A. Trotta[1], F. P. Cantatore[1], A. Corrado[1]. [1]*Ospedali Riuniti di Foggia, Rheumatology Unit, Department of Medical and Surgical Sciences, Foggia, Italy*

Background: Psoriatic arthritis is a chronic immune-mediated disease that may appear with arthritis and/or enthesitis and systemic manifestations, affecting 0.1-1% of the general population and up to 30% of patients with psoriasis. A greater understanding of the pathogenesis has led to an increase of therapeutic options, namely biotechnological drugs which may prevent the progression of the disease and improve the quality of life by acting on specific pathways. Among these drugs, anti-TNFα agents play an important role. Adalimumab (ADA) and Etanecept (ETA) were the first developed ones, indeed they are defined as "originator" drugs. Subsequently, "biosimilars" have been developed. They are defined by the EMA as highly similar to other biological agents already on the market in terms of qualitative characteristics, biological activity, safety, and efficacy. Spending review and pharmaco-economic policies have almost "imposed" the use of non-medical switching (NMS).
Objectives: The aim of this study is to evaluate the retention rate of ETA and ADA originators, compared to their biosimilar counterparts, in the first line and after NMS, detecting discontinuation for adverse events (AEs) or ineffectiveness, in patients with psoriatic arthritis.
Methods: Fifty-four patients diagnosed with psoriatic arthritis were enrolled (F: 61%; mean age 53.4±13 years, BMI 24.9±3.6), Baseline disease activity was 4, 1 ± 1.1. Inclusion criteria were age >18 years, fulfillment of CASPAR 2006 criteria for PsA, therapy with originators or biosimilar etanercept or adalimumab in the first line, with the possibility of no NMS, stable combined therapy with methotrexate during the observation time. Statistical significance was set at $p \leq 0.05$.
Results: The retention rate of ETA and ADA originators was 541 ± 70 weeks and 486 ± 24 weeks, respectively. The retention rates of biosimilar ETA and biosimilar ADA in the first line were 265 ± 20 weeks and 79 ± 21 weeks, respectively (p=0.231). After NMS, the retention rate of biosimilar ETA and biosimilar ADA was 49.1 ± 13 weeks and 108 ± 12 weeks, respectively. Discontinuation due to AEs were recorded in 8.3% of patients receiving originator ETA, 5% of patients receiving originator ADA, and 31% of patients receiving biosimilar ADA. Discontinuation due to ineffectiveness occurred in 54% of patients treated with originator ETA, in 40% of patients treated with originator ADA, and in 44% of patients treated with biosimilar ADA. In patients treated with biosimilar ETA, no suspensions were recorded either for AEs or for ineffectiveness.
Conclusion: Our data show that the retention rate of originator drugs was higher than that of biosimilars, both when administered in the first line and after a NMS. A greater number of suspensions were recorded for AEs and, to a lesser extent, for ineffectiveness with biosimilar ADA compared to originator ADA, while in patients treated with biosimilar ETA no suspensions were recorded either for AEs or for ineffectiveness.

AB1128

METHOTREXATE MAINTENANCE THERAPY IN PSORIATIC ARTHRITIS

Keywords: Tapering, Disease-modifying drugs (DMARDs), Psoriatic arthritis

E. Hannech[1], S. Miladi[1], A. Fazaa[1], H. Boussaa[1], M. Yasmine[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]Mongi Slim Hospital, Rheumatology Department, Tunis, Tunisia

Background: The management of psoriatic arthritis (PsA) is currently well codified. Methotrexate (MTX) remains the most frequently used DMARD in first-line treatment of peripheral joint disease.
Objectives: We aimed to identify the rate of therapeutic maintenance of MTX during PsA and to determine the date of first biotherapy.
Methods: We conducted a single-center, retrospective study including PsA patients with peripheral joint involvement. Patient and disease characteristics were recorded. We determined the MTX maintenance rate and tolerance profiles. We recorded data related to the first biotherapy.
Results: Twenty-two women and eleven men were included. The mean age was 52.31±12.98 years [21-78]. The mean disease duration was 10.90±5.91 years [1-21]. PsA had an articular peripheral onset in 68.8% of cases and axial and articular peripheral in 31.3% of patients. Psoriasis was present at diagnosis in 27 patients (81.8%). The mean age at diagnosis was 42.70±13.84 years [19-68]. MTX was initiated for all patients after a mean duration of 3.14±2.58 months [1-12]. It was prescribed orally in 86.7% of patients and intramuscularly in 13.3%. The mean duration of treatment was 7.83±5.90 years [1-21]. The maintenance rate at 1 year was 100%, at 2 years was 83.3%, and at 5 years was 70%. MTX was discontinued in 4 patients for adverse events: 3 cases of digestive intolerance and 1 case of liver toxicity. Biotherapy was prescribed for 10 patients (30.3%): Infliximab (2 cases), Adalimumab (2 cases), and Etanercept (6 cases). The time to prescription of the first biotherapy was 4±1.6 years [3-7]. Biotherapy was indicated but not prescribed in 5 patients (15.2%). Causes of non-prescription were mainly lack of social security coverage.
Conclusion: In our study, MTX was the first-line treatment for patients with PsA. The therapeutic maintenance seems to be good reflecting the effectiveness. However, this maintenance is certainly influenced by the socio-economic factors.

Psoriatic arthritis - clinical aspects (other than treatment)

AB1129 **UTILITY OF LOW-DOSE COMPUTED TOMOGRAPHY (LDCT) FOR IDENTIFYING PATIENTS WITH AXIAL PSORIATIC ARTHRITIS (AXPSA) – A CROSS-SECTIONAL STUDY**

Keywords: Diagnostic tests, Psoriatic arthritis

I. T. Cheng[1], H. So[1], J. So[1], J. F. Griffith[2], L. S. Tam[1]. [1]*The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*; [2]*The Chinese University of Hong Kong, Imaging and Interventional Radiology, Hong Kong, Hong Kong (SAR)*

Background: Psoriatic arthritis (PsA) is a multicentric disease with axial involvement being a critical feature. As inflammatory back pain (IBP) may be atypical or even absent, axial PsA is often under diagnosed. Axial PsA (axPsA) is currently diagnosed by identifying sacroiliitis on radiography. However, the detection of radiographic sacroiliitis is not entirely reliable and is challenging in early disease. Recently, magnetic resonance imaging (MRI) has been used to diagnose sacroiliitis to good effect. Even more recently, low dose (<0.5mSv) computed tomography (LDCT) has been used to identify structural changes of sacroiliitis such as erosions and ankylosis. However, the usefulness of LDCT for diagnosing sacroiliitis in axPsA compared to radiography and MRI remains uncertain.
Objectives: To investigate the usefulness of LDCT in diagnosing axPsA-related sacroiliitis compared to radiography and MRI.
Methods: Consecutive biologic disease modifying anti-rheumatic drug (bDMARDs)-naïve patients who fulfilled CASPAR were recruited into this cross-sectional study, regardless of the presence of back pain. Radiographs of the pelvis, LDCT and MRI of the sacroiliac joints were performed.
Results: 33 patients (age: 45 ± 12 years, 23 (70%) male, disease duration: 3.0 ± 6.5 years) were recruited. The cohort had moderate peripheral joint disease (Disease Activity in Psoriatic Arthritis (DAPSA): 18.78 ±1 6.33) and skin disease (Psoriasis Area Severity Index (PASI): 5.40 ± 7.10). Axial disease activity (Ankylosing Spondylitis Disease Activity Score, ASDAS) was 2.52 ± 1.26. Twenty (61%) patients were on conventional synthetic DMARDs. Radiography revealed definite sacroiliitis according to modified New York criteria in 2 (6%) patients while 8 (24%) patients had possible sacroiliitis and 23 (70%) had no sacroiliitis. LDCT revealed sacroiliitis in 9 (27%) patients, including both patients with radiographic sacroiliitis, 7 (88%) of the 8 patients with possible radiographic sacroiliitis and 2 (4%) of 23 patients with normal radiographs (Figure 1). Patient with LDCT-sacroiliitis had longer symptom duration, higher patients' pain score, physician global, enthesitis scores and Bath Ankylosing Spondylitis Metrology Index (BASMI) (Table 1). The presence of human leukocyte antigen (HLA) B27, IBP, and fulfillment of the Assessment of SpondyloArthritis international Society (ASAS) 2009 criteria of axial spondylitis could not differentiate between patients with or without LDCT-sacroiliitis. LDCT had 100% agreement with MRI. MRI detected 9 patients with sacroiliitis, all of whom were identified by LDCT.
Conclusion: LCDT revealed sacroiliitis in 4 times more patients than radiographs. Patients with sacroiliitis had higher disease activity across various disease domains. LDCT had excellent agreement with MRI. LDCT is very helpful for diagnosing axPsA, especially when access to MRI is limited.

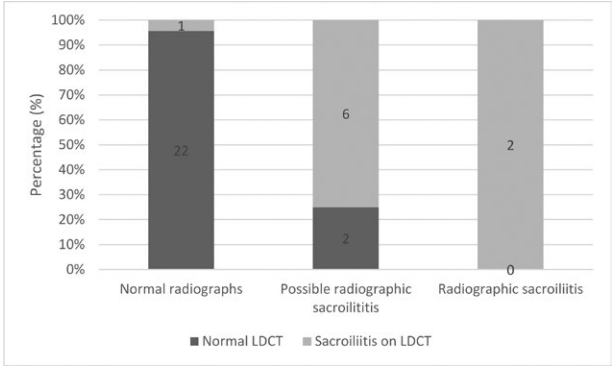

Figure 1. Prevalence of sacroiliitis detected by low dose CT (LDCT) in patients whose radiographs showed normal appearances, possible sacroiliitis and sacroiliitis

Background: Psoriatic arthritis (PsA) is an inflammatory disease that causes inflammation and swelling of the joints and entheses in addition to skin symptoms(PsA)[1]. Chronic psoriatic lesions may increase serum concentrations of low-density lipoprotein cholesterol (LDL-C) by producing large amounts of IL-6 and other pro-inflammatory cytokines, which release free fatty acids, cholesterol, and triglycerides from the adipose tissue[2]. However, whether LDL-C affects articular psoriasis is unclear.
Objectives: We used a two-sample Mendelian randomization (MR) analysis to investigate the causal associations of LDL-C with PsA.
Methods: Firstly, we obtained LDL-C-associated single-nucleotide polymorphisms (SNPs) from a GWAS published by the UK Biobank, including up to disequilibrium (LD) threshold for clumping was set to $r^2 < 0.001$. The clumping window size was set to 10000 kb, and we selected autosomal biallelic SNPs with P-values < 5×10^{-8}. Thirdly, as for MR analyses, F statistics were calculated to evaluate the strength of each instrument, the F-statistic of each SNP> 10, indicating a low risk of weak instrument bias. Inverse variance weighted (IVW) was the primary method to assess the association of genetically predicted LDL-C and PsA risk. Fourthly, MR-Egger and weighted median were applied to validate the results from IVW. The Cochrane Q test and funnel plots were used to test the possible heterogeneity. The directional pleiotropy was separated by intercepting from MR-Egger and MR-presso. Finally, a leave-one-out sensitivity analysis was also performed.
Results: With 158 LDL-C-associated SNPs, LDL-C was a hazard factor for PsA(OR =1.30,95%CI 1.02-1.65, P=0.032), which was consistent in direction with the weighted median(OR=1.38,95%CI,1.00-1.91, P=0.050) and MR-Egger(MR-Egger: OR=1.43, 95%CI 1.01-2.04, P=0.045). Heterogeneity existed in the results(P<0.05). But IVW could provide a robust causal estimate in the presence of heterogeneity[3]. No evidence of pleiotropy was observed (MR-Egger-intercept:

-0.0049, P=0.447), and leave-one-out sensitivity analysis showed that removing any SNP would not change the overall result, suggesting this finding was available. Details of the results were shown in Figure 1.

Figure 1

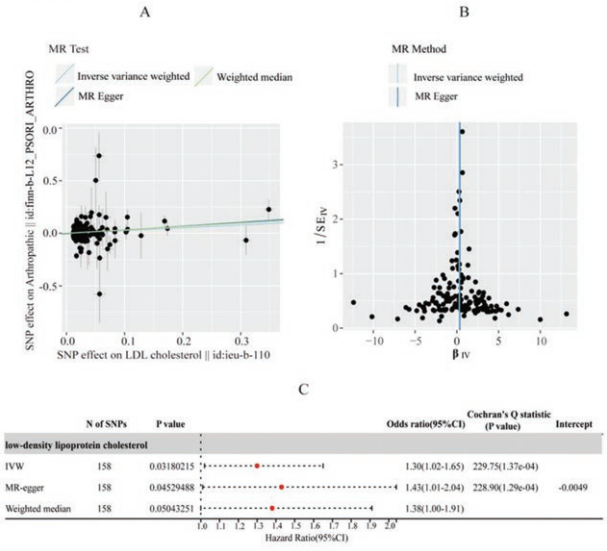

Figure 1. The causal associations between low-density lipoprotein cholesterol (LDL-C) and psoriatic arthritis (PsA) were evaluated by the odds ratio (OR) values of IVW, MR-Egger, and Weighted median. Scatter plot (A), funnel plot (B), and forest plot (C).

Conclusion: LDL-C was a hazard factor for PsA. Monitoring and lowering serum concentrations of LDL-C may make a difference in psoriasis treatment and slow down the process of PsA.

AB1131 PATIENT ACCEPTABLE SYMPTOMS STATE IN PSORIATIC ARTHRITIS: DOES IT DIFFER BETWEEN SEXES?

Keywords: Psoriatic arthritis, Outcome measures, Patient reported outcomes

S. Scriffignano[1], F. M. Perrotta[1], M. Fatica[2], P. Triggianese[2], P. Conigliaro[2], M. Ferraioli[2], M. S. Chimenti[2], E. Lubrano[1]. [1]*Università degli Studi del Molise, Dipartimento di Medicina e Scienze della Salute "Vincenzo Tiberio", Campobasso, Italy*; [2]*Università di Roma Tor Vergata, Reumatologia, Allergologia e Immunologia Clinica, Dipartimento di Medicina dei Sistemi, Roma, Italy*

Background: Patient Acceptable Symptoms State (PASS) is a dichotomous and feasible tool recently validated for Psoriatic Arthritis (PsA). It assesses if the patient accepts her/his disease status by using a simple question: "Think about all the ways your PsA has affected you during the last 48 hours. If you were to remain in the next few months as you were during the last 48 hours, would this be acceptable to you?". A negative answer ("no") denotes a disease status not acceptable for the patient. Due to the recent introduction of PASS in PsA, there are not data about its difference between sexes.

Objectives: To assess PASS differences in PsA based on sexes, characterizing the factors associated with an unacceptable disease state (PASS "no").

Methods: This is a cross sectional study. Patients were consecutively enrolled from January 2022 to December 2022, in two outpatient clinics devoted to PsA. All enrolled patients were adult and had a PsA diagnosis (for at least six months). We assessed PASS and its difference between sexes (χ^2 test). Moreover, we performed two logistic regression models to assess which factors were associated with PASS "no", in both sexes.

Results: Two-hundred and forty-five patients were enrolled. Female less accepted their disease status, compared with male patients, PASS "no" was 49.1% vs 23.5%, (p<0.001) (Table1). The factor associated with a higher probability to have an unacceptable symptoms state was a higher disease activity (Table 2), both for male and female. In particular, for male patients, when DAPSA increases of 1 point, the probability to have a state of PASS "no" increases of 31% (OR 1.31, CI 95% 1.16-1.47), independently by age, disease durations, BMI and BSA. The same result was confirmed for female patients, but with a stronger association: when DAPSA increases of 1 points the probability to have a state of PASS "no" increase of 101% (OR 2.01, CI 95% 1.45-2.77), independently by age, disease durations, BMI, BSA and fibromyalgia. Moreover, fibromyalgia in female patients was not associated with PASS "no".

Table 1 Clinical and demographic characteristics, grouped by sexes.

	All patients n. 245	Female n. 119	Male n. 126	p value
Age, mean (SD)	55 (12)	55 (12)	56 (13)	0.553
Disease duration (months), median (IQR)	94 (49-164)	94 (51-157)	94 (47-165)	0.650
BMI, mean (SD)	27.4 (5.01)	26.7 (5.28)	28.0 (4.68)	0.044
DAPSA, median (IQR)	10.2 (4.3-17.65)	13.45 (6.70-20.70)	7.29 (4-14.42)	<0.001
PASS "no", n. (%)	82/227 (36.1)	55/112 (49.1)	27/115 (23.5)	<0.001
Fibromyalgia, n. (%)	27 (11)	22 (18.5)	5 (4)	<0.001

BMI: Body Mass Index, DAPSA: Disease Activity for Psoriatic Arthritis; IQR: Inter Quartile range; PASS: Patient Acceptable Symptoms State; SD: Standard Deviation.

Table 2 Logistic regression analysis. Factors associated with PASS "no".

	PASS "no"	
Model 1*(male patients)	**OR (CI 95%)**	**p value**
DAPSA	1.31 (1.16-1.47)	<0.001
	PASS "no"	
Model 2*(female patients)	**OR (CI 95%)**	**p value**
DAPSA	2.01 (1.45-2.77)	<0.001
Fibromyalgia (yes)	1.34 (0.21-8.30)	0.715

*Both models were corrected for: age, disease duration, BMI and BSA.
All these predictors did not show any statistically significant association with PASS "no".

Conclusion: Female patients perceive their disease acceptable less than male. A higher disease activity (assessed by DAPSA), in particular for female patients, is the main factor to predict a state of non-acceptance of the disease.

Background: There is a considerable delay in the diagnosis of psoriatic arthritis (PsA) and several screening tools have been proposed for fascilitating the diagnosis of PsA among patients with psoriasis.
Objectives: We aimed to identify all instruments that were developed for screening PsA among psoriasis patients, and to analyze the psychometric properties of these instruments.
Methods: A systematic literature search was conducted to identify all studies for developing and validating instruments that evaluate the presence of psoriatic arthritis among psoriasis patients. Psychometric properties of each instrument including construct validity, reproducibility, internal consistency, sensitivity to change and feasibility were extracted. Additionally, the reasons for false positivity and false negativity with each instrument were tabulated. Literature review and data extraction were performed by two independant reviewers and inconsistencies were resolved by a senior investigator. The systematic review protocol was registered in PROSPERO (CRD42021231734).
Results: The systematic review revealed 15 screening instruments that were evaluated in a total of 42 studies. Psychometric evaluation was available for only 5 of the instruments, assessed in 8 studies. Table shows the psychometric properties of these 5 instruments. Main reasons for false positivity were rheumatoid arthritis, osteoarthritis, mechanical pain and fibromiyalgia for PASE, PEST, CONTEST and EARP, and ankylosing spondylitis and osteoarthritis for PASQ. Main reasons for false negatives were axial involvement for ToPAS and PEST, peripheral involvement for SiPAT, PASE and PAQ, enthesal involvement for PEST, PASE and ToPAS. Among these instruments, EARP had low false negativity and high false positivity rates, while ToPAS II had both low false positivity and low false negativity compared to the other instruments.
Conclusion: Overall, the psychometric properties of PsA screening tools have not been adequately evaluated. There is an unmet need for studies evaluating and comparing psychometric properties of different screening tools in a large patient population, including patients with various PsA features such as enthesitis, axial and peripheral involvement.

Table.

Instrument	Number of studies	Internal consistency	Test-retest reliability	Construct Validity	Criterion validity	Interrater reliability	Sensitivity to change	Feasibility

AB1133 AXIAL PSORIATIC ARTHRITIS: ISOLATED ENTITY OR PHENOTYPE FORM ONLY

Keywords: Psoriatic arthritis, Spondyloarthritis

S. Abdellaoui[1], S. Lefkir[1]. [1]Issad Hssani Beni Messous Hospital, Rheumatology, Algiers, Algeria

Background: The latest literature data increasingly emphasizes the axial involvement of Psoriatic Arthritis (PsA). The clinical and radiographic characteristics suggest that it is a new entity compared to the axial involvement of Ankylosing Spondylitis (AS), while therapeutic advances and cytokine targets suggest that it is a clinical form only.
Objectives: The objective of our study is to compare the characteristics of patients with axial PsA (axPsA) and axial AS (axAS).
Methods: Patients≥18 years old, with axPsA or axAS, during registration in the prospective monocentric register, between August 2012 and August 2022. A rheumatological investigation including: clinical, laboratory and genetic assessments as well as imaging with conventional radiography of pelvic and spine was performed.
Results: Of 250 patients (58 PsA vs 192 AS) with axial involvement, isolated axPsA patients were older at diagnosis (age of diagnosis of axial involvement was 35.8 vs 29.4). Patients with isolated axPsA were more likely to have: Less clinical inflammatory back pain compared with patients with isolated axAS: less limited schöber index (10/14 vs 10/12), finger-to-ground distance often equal to 0 cm in axPsA, less contracture of the paravertebral muscles, less reduction in thoracic expansion (4 vs 2 cm). Less limitation of inguinal pain (hip flexion 100 vs 70), a higher dactylitis count ±SD (0.3±1.2 vs 0.1±0.8), more nail lesions which could suggest looking for an association between nail damage and the presence of dactylitis in PsA, less extensive skin psoriasis [PASI= 2-13] and less presence of uveitis (18.96% (11/58) vs 23,95% (46/192)). Human Leucocyte Antigen (HLAB27) positivity was negatively associated with isolated axPsA disease (20 vs 78%). AxPsA were less frequently had radiographic sacroiliitis with unilateral/asymmetric pattern [On the X-ray, the SI were either normal or slightly modified, deliberately asymmetrical, rarely grade 4, the syndesmophytes were most often asymmetrical, coarse and of lumbar location, the heels were affected in less severe involvement, most often represented by simple shielding] and average patients showed slight spinal/pelvic radiographic progression (OR: 0,14; 95% CI: 0,01, 0,58). Finally, AxPsA had lower BASDAI and HAQ scores (OR 0.10, 95% CI 0,01to 0.47/ OR 0.03, 95% CI 0,00 to 0.17) and lower PRO evaluation (PRO spine pain 39.65 vs 49.47% and PRO fatigue 50 vs 52.6%).
Conclusion: Isolated axial PsA and AS are uncommon, axPsA has different clinical and radiographical characteristics when compared to AS. AxPsA is largely independent of HLAB27, it was associated with distinct radiographic ax AS features, increased spinal progression and low grade radiographic sacroiliitis as well as lower disease activity and impact scores.

AB1134 IMPACT OF INFLAMMATORY BOWEL DISEASE ON DAPSA REMISSION IN PATIENTS WITH PSORIATIC ARTHRITIS: A PROPENSITY SCORE-MATCHED RETROSPECTIVE ANALYSIS OF "CROSS" MULTIDISCIPLINARY PROJECT PATIENTS'.

Keywords: Psoriatic arthritis, Remission

M. Giannotta[1], V. Venerito[1], L. Pacello[2], M. B. Principi[3], C. Foti[2], A. Di Leo[3], F. Iannone[1]. [1]*Policlinico di Bari, Reumatologia, Bari, Italy*; [2]*Policlinico di Bari, Dermatologia, Bari, Italy*; [3]*Policlinico di Bari, Gastroenterologia, Bari, Italy*

Background: Psoriatic Arthritis (PsA) is a chronic inflammatory disease and patients with PsA have an increased risk of developing inflammatory bowel disease (IBD) [1]. It's not clear whether the coexistence of IBDs in PsA patients on bDMARDs is associated with the achievement of clinical outcome.
Objectives: The aim of this study was to identify whether IBDs may impact on 12-month remission of articular disease assessed by Disease Activity Index for Psoriatic Arthritis (DAPSA) in PsA patients on monoclonal anti-TNFα or anti-IL12/23 therapy.
Methods: Patients with classified PsA according to CASPAR criteria with active skin psoriasis who underwent monoclonal anti-TNFα or anti IL12/23 treatment were retrospectively analyzed from January 2019 to May 2021 in our CROSS multidisciplinary outpatient's clinic. Clinical and demographic characteristics as disease severity indices (Disease Activity in Psoriatic Arthritis (DAPSA), Psoriasis Area and severity index (PASI), and Leeds Enthesitis Index LEI) were recorded. We identified those with IBDs (either Chron's disease or Ulcerative Colitis) and assess the intestinal disease activity by specific symptoms (abdominal pain, diarrhoea, intestinal bleeding) or instrumental findings. Propensity score-nearest-neighbour (1:1; caliper= 0,2) algorithm was used to provide two comparable groups. Paired t-Test was used to identify differences between outcome of interest at different follow-up periods and univariate and multivariable logistic regression models were run to identify predictors of DAPSA remission at 12-month follow-up.
Results: Of 123 patients with PsA on monoclonal bDMARDs therapy, the algorithm retrieved a sample of 74 patients (IBD group 37 patients, control group 37 patients)

matched by gender, BMI, age and DAPSA at bDMARDs start. In the PsA+IBD group mean age (± SD) was 55,21 ± 12,73, mean BMI was 27,70 ± 7,75, mean DAPSA was 17,28 ± 13,86, mean HAQ was 0,90 ± 0,74 and mean PASI was 1,13 ± 2,99. In PsA-only group mean age was 47,19 ± 10,23, mean BMI was 27,24 ± 5,10, mean DAPSA was 20,21 ± 12,58, mean HAQ was 0,92 ± 0,77 and mean PASI was 0,94 ± 2,25. The final multivariate model included DAPSA at baseline (OR 0,89 95% CI 0,82-0,97), duration of joint involvement (months, OR 0,99 95% CI, 0,98-0,99), HAQ (OR 0,66 95% CI 0,22-1,93) and presence/absence of IBD. HAQ was retained in the model as a potential confounder. PsA-only patients were more likely to achieve DAPSA remission at 12 month-follow up (OR=7,37; 95% CI 1,58-34,37).
Conclusion: In the management of PsA patients with IBD undergoing monoclonal anti-TNFα or anti-IL12/23 therapy, intestinal involvement has a negative influence on the clinical response of articular disease. For these patients clinicians should consider a low DAPSA at baseline and a shorter PsA disease duration as a predictor of 12-month DAPSA remission.

AB1135 CHARACTERIZING THE MINIMAL DISEASE ACTIVITY DOMAINS ACHIEVED BASED ON DIFFERENT TREATMENTS.

Keywords: Psoriatic arthritis, Outcome measures

S. Scriffignano[1], F. M. Perrotta[1], M. Fatica[2], P. Triggianese[2], P. Conigliaro[2], M. Ferraioli[2], M. S. Chimenti[2], E. Lubrano[1]. [1]*Università degli Studi del Molise, Dipartimento di Medicina e Scienze, della salute "Vincenzo Tiberio", Campobasso, Italy*; [2]*Università di Roma Tor Vergata, Reumatologia, Allergologia e Immunologia Clinica, Dipartimento di Medicina dei Sistemi, Roma, Italy*

Background: Minimal Disease Activity (MDA) is a validated treatment response index for Psoriatic Arthritis (PsA). A status of MDA is reached when 5/7 domains are achieved. Even if MDA is worldwide used, both in clinical trials and in clinical practice, nowadays there are no studies that evaluated any differences in the MDA domains achievement based on various treatments.
Objectives: To characterize the MDA domains achieved based on treatment; to assess which treatment is associated with a higher probability to reach MDA status in clinical practice.
Methods: This is a cross sectional analysis of two longitudinal PsA cohorts. Inclusion criteria were: age ≥18 years, PsA diagnosis for at least 12 months, stable treatment for at least 6 months. Patients were grouped depending on the therapy: group 1: NSAIDs or COX2i or steroids, group 2: csDMARDs, group 3: TNFi, group 4: anti-IL 12-23 or 23, group 5: anti-IL17A, group 6: PD4i. For each group, MDA domains based on therapy were assessed. Logistic regression analysis was performed to assess the association between the treatment groups and the achievement of the MDA, independently by others confounding factors.
Results: Patients enrolled were 220. MDA was achieved in 45.8% of patients. In all treatment groups, the first three MDA domains more achieved were: BSA ≤3, SJC ≤1 and LEI ≤1, instead, in all groups (excepted for the PD4i) the MDA domains less frequently achieved were PtGA ≤2 cm and pain on VAS ≤1.5 cm (Table 1). Moreover, the logistic regression analysis showed a higher probability to achieve MDA for those patients in group 3 and 4 when compared with group 1, independently by age, sex and disease duration (Table 2).

Table 1. For each treatment group, table 1 shows the percentage of patients that achieved each domain.

Total patients n.220

	1st MDA achieved domain (%)	2nd MDA achieved domain (%)	3rd MDA achieved domain (%)	4th MDA achieved domain (%)	5th MDA achieved domain (%)	6th MDA achieved domain (%)	7th MDA achieved domain (%)

BSA: Body Surface Area; HAQ-DI: Health Assessment Questionnaire Disability Index; LEI: Leeds Enthesitis Index; MDA: Minimal Disease Activity; VAS: Visual Analogue Scale, PtGA: Patient Global Assessment; SJC: Swollen Joint Count; TJC: tender Joint Count.

Table 2. Logistic regression analysis; dependent factor: MDA, independent factors: age, sex, disease duration treatment groups.

	MDA	
	OR (CI 95%)	**p value**
Age (years)	0.98 (0.96-1.01)	0.212
Sex (male)	3.54 (1.94-6.45)	<0.001
Disease durations (months)	0.99 (0.99-1.00)	0.337
Treatment group		
Group 2 (vs group 1)	2.10 (0.57-7.67)	0.260
Group 3 (vs group 1)	3.58 (1.26-10.20)	0.016
Group 4 (vs group 1)	5.47 (1.16-25.80)	0.031
Group 5 (vs group 1)	1.64 (0.54-4.89)	0.376
Group 6 (vs group 1)	1.37 (0.24-7.63)	0.719

Group 1: NSAIDs or COX2i or steroids, group 2: csDMARDs, group 3: TNFi, group 4: anti-IL 12-23 or anti-IL23, group 5: anti-IL17, group 6: PD4i; OR: Odds Ratio; CI 95%: Confidence Interval 95%.

Conclusion: In each treatment group, the MDA domains less frequently achieved were PtGA and pain, suggesting that the patient driven domains are still an unmet need. Moreover, the probability to achieve MDA status is higher in patients in group 3 and 4. However, larger and prospective studies needed to confirm these preliminary results, including also the newest therapies recently adopted for PsA.

AB1136 MORTALITY IN PATIENTS WITH PSORIATIC ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Psoriatic arthritis, Prognostic factors

H. Huang[1], W. Xie[1], Y. Geng[1], Y. Fan[1], Z. Zhang[1]. [1]*Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: It remains debated whether patients with psoriatic arthritis (PsA) are at greater risk of mortality.

Objectives: We aimed to determine the magnitude of all-cause mortality risk in patients with PsA compared with the general population through a systematic review and meta-analysis.
Methods: We searched Pubmed, EMBASE and Cochrane Library for studies published from inception to April 2022. STATA meta-analysis software was used to calculate the pooled risk estimates for mortality (standardized mortality ratio, SMR). To address the potential heterogeneity, $\chi 2$ test, I2 statistics, subgroup analysis and sensitivity analysis were used.
Results: Our search identified 3235 articles, of which 18 studies with 134355 patients were eventually included for the analysis. A total of 7518 deaths were observed. Overall, we found a 1.13-fold increased risk of death in PsA patients when compared with the general population (meta-SMR: 1.13, 95% CI 1.03-1.25). Subgroup analyses showed that summary meta-SMR was higher in female patients (1.24 [95% CI 1.10-1.39]; I^2=49.7%) than male patients (0.92 [95% CI 0.62-1.37]; I^2=73.8%).
Conclusion: The existing data indicated approximately 13% increase of mortality among patients with PsA compared with the general population. More attention should be paid to those patients with risky characteristics.

AB1137 BURDEN OF SKIN DISEASE IN PSORIATIC ARTHRITIS PATIENTS

Keywords: Patient reported outcomes, Psoriatic arthritis, Skin

M. Reed[1], H. Boagey[2], B. Milligan[1]. *[1]NHS Greater Glasgow and CLyde, Rheumatology, Glasgow, United Kingdom*; *[2]NHS Greater Glasgow and Clyde, Rheumatology, Glasgow, United Kingdom*

Background: Skin disease is one of the key domains of psoriatic disease (1) and most Psoriatic arthritis patients have skin psoriasis. However skin and joint disease are often managed separately by rheumatologists, dermatologists or primary care health care providers. This can lead to disjointed care, unmet need, and treatment decisions that don't take into account all aspects of this heterogeneous condition.
Objectives: We sought to evaluate how psoriatic skin disease is assessed and managed within our rheumatology services by identifying disease burden, approach to management and patient satisfaction.
Methods: In an existing psoriatic arthritis outpatient rheumatology clinic, patient swere asked to anonymously complete questionnaires on disease extent, management and satisfaction. Patients also completed dermatology quality of life index (DLQI) questionnaires. Case notes and clinic letters were reviewed to collect data relating to patient diagnosis, medications and extent of clinical assessment during consultations over a 4 month period.
Results: Questionnaires were returned by 30 patients. 72% reported problems with psoriasis, with scalp was the most commonly affected body area. 77% participants reported receiving medication to manage joints only, 4% for skin only, 19% for both joints and skin. 13 participants were receiving topical medication for PsA, with the majority being managed by their GP. From the survey, 47% of respondents were asked about their skin in the rheumatology clinic, and 30% were given advice on its management. Of the patients that completed DLQI questionnaires mean score was 3.9 (SD 3.4). Average satisfaction with psoriasis management was 5/10 (SDEV 3.6). Of the 59 consultations from which data was extracted, 54% of consultations discussed joints only, and 37% discussed both joints and skin (remainder no discussion documented). At 45% of appointments joints and skin were examined, and at 35% of appointments joints only were examined (remainder no examination documented).
Conclusion: Psoriatic skin disease appears to be a significant burden in this population of patients, affecting 72% of those surveyed. Over half of these patients required topical therapy to manage their psoriasis, with some requiring systemic treatments. Of these patients, most of the management of their skin condition was done by their GP, with the topic being brought up at rheumatology clinic in only half of cases. Less than half had skin examined at rheumatology clinic and less than a third were advised on management of their skin disease by their rheumatologist. Satisfaction levels with psoriasis management were fairly neutral overall. An integrated approach to care with a focus on opportunistic assessment should be encouraged and has potential to benefit both patient and clinician.

AB1138 DIFFICULT-TO-TREAT PSORIATIC ARTHRITIS: ANALYSIS OF A SINGLE-CENTER COHORT FROM NORTHERN ITALY

Keywords: Psoriatic arthritis, Descriptive studies, bDMARD

G. Cincinelli[1,2], M. Ferrito[1,2], M. Pandolfi[1,1], M. Biggioggero[2], S. Casari[2], M. Cornalba[2], C. Crotti[2], F. Desiati[2], E. G. Favalli[1,2], M. Manara[2], R. Caporali[1,2]. *[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*; *[2]ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy*

Background: The multifaceted nature of psoriatic disease can potentially make its skin, articular, and extra-articular manifestation complex to manage. Biologic disease modifying anti-rheumatic drugs (bDMARDs) have dramatically improved the outcome of patients affected by chronic inflammatory arthritis. However, a satisfactory disease control is not achieved in a proportion of patients. While a "difficult-to-treat" (D2T) definition has been validated in rheumatoid arthritis (RA), it was only recently suggested for psoriatic arthritis (PsA) [1].
Objectives: Based on the proposed definition, we aimed to assess prevalence and characteristics of D2T-PsA in a single-center cohort.
Methods: We conducted a single-center, cross-sectional study. 269 consecutive, adult PsA patients receiving bDMARDs at a tertiary care, dedicated outpatient clinic were enrolled. Demographic, clinical, and clinimetric data, and the Health Assessment Questionnaire (HAQ) were gathered and depicted in Table 1. According to the aforementioned definition, D2T patients were identified as: 1) failure of ≥ 2 b/tsDMARDs (with different mechanisms of action- MoA) after failing csDMARD therapy; 2) signs suggestive of active/progressive disease (defined either as a DAPSA >14 or not achieving MDA; signs or symptoms suggestive of active disease; a rapid radiographic progression; a reduction of quality of life due to PsA symptoms); 3) disease management perceived as problematic by rheumatologists or patients (all three criteria must be met to define D2T patients). Comparison between D2T and non-D2T patients was performed with univariate analyses.
Results: Among 269 PsA patients, only 8 (2.9%) fulfilled D2T definition. In bivariate analysis, D2T patients presented higher rate of osteoarthritis (62.5% vs 24.9%; *p=0.03*), fibromyalgia (62.5% vs 14.94%; *p<0.004*), and therapy with steroids (50% vs 12.1%; *p=0.008*). Furthermore, D2T patients presented significantly higher patient global assessment (PGA 0-10) (7.5 vs 2.00; *p<0.001*) and VAS pain 0-10 (8.00 vs 2.00; *p<0.001*). Among non-D2T patients, 24 were in moderate disease activity (9.19%). Due to the unbalance between the groups numerosity, multivariate analysis was not feasible.
Conclusion: Only few patients satisfied the PsA-D2T definition in our cohort; application of a RA-like D2T definition to a heterogeneous disease as PsA should be discussed more broadly in the future.

Table 1.

AB1139 ASSOCIATION BETWEEN TRIGLYCERIDE-GLUCOSE INDEX AND CAROTID ATHEROSCLEROSIS IN PATIENTS WITH PSORIATIC ARTHRITIS: A CROSS-SECTIONAL STUDY

Keywords: Psoriatic arthritis, Epidemiology, Ultrasound

W. Xie[1], Z. Zhang[1]. [1]Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China

Background: The triglyceride-glucose (TyG) index, proposed as a surrogate marker for insulin resistance, appeared to be a good indicator of clinically overt cardiovascular events and subclinical atherosclerosis in general population.
Objectives: We aimed to investigate the correlation of TyG index with atherosclerotic risk among patients with psoriatic arthritis (PsA).
Methods: This cross-sectional study included 165 consecutive PsA patients receiving carotid ultrasonography with integrated TyG index, calculated as ln [fasting triglycerides (mg/dL)×fasting glucose (mg/dL)/2]. Logistic regression models were applied to analyze the association of TyG index as continuous variables and tertiles with carotid atherosclerosis and carotid artery plaque.
Results: Overall, PsA patients with carotid atherosclerosis had substantially higher TyG index than those without (8.82±0.50 vs. 8.54±0.55, p=0.002). The frequency of carotid atherosclerosis was increased with increases in TyG index tertiles, showing 14.8%, 34.5%, 44.6% for tertile 1, 2 and 3, respectively (p=0.003). Multivariate logistic analyses showed that each 1-unit increase in TyG index was significantly associated with prevalent carotid atherosclerosis (unadjusted OR 2.65 [1.39-5.05]; fully-adjusted OR 2.69 [1.02-7.11]). Compared to patients with tertile 1 of TyG index, the unadjusted and fully-adjusted OR for occurrence of carotid atherosclerosis were 4.64 (1.85-11.60) and 5.10 (1.54-16.93) in patients with tertile 3. Similarly, higher prevalent carotid artery plaque was observed with increasing TyG index (unadjusted OR 3.11 [1.54-6.26]; fully-adjusted OR 3.61 [1.15-11.38]) or with tertile 3 vs. tertile 1 (unadjusted OR 10.20 [2.83-36.82]; fully-adjusted OR 17.89 [2.88-111.11]). Additionally, TyG index provided incremental predictive capacity beyond established risk factors, shown by an increase in discrimination ability (all P < 0.001).
Conclusion: TyG index was positively correlated with the burden of atherosclerosis in PsA patients, independent of traditional cardiovascular risk factors and psoriatic-related factors. These findings suggest that TyG index may be a promising atherosclerotic marker for PsA population.

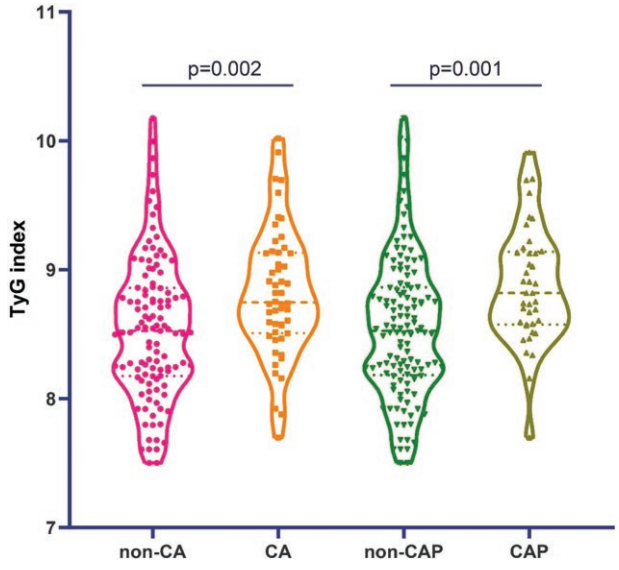

Figure 1. The level of TyG index in patients with psoriatic arthritis, stratified by carotid atherosclerosis (CA), carotid artery plaque (CAP).

AB1140 TREATMENT WITH TNF AND IL17 INHIBITORS DIFFERENTLY AFFECTS SERUM LIPID PROFILE AND TH1/TH2 IMMUNE RESPONSE IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS.

Keywords: bDMARD, Psoriatic arthritis, Cardiovascular disease

K. Bonek[1], S. Szczygielska[1], M. Kajfasz[2], A. Felis-Giemza[3], B. Kwiatkowska[2], M. Wisłowska[1], E. Kuca-Warnawin[4], P. Głuszko[1]. [1]*National Institute of Geriatrics Rheumatology and Rehabilitation, Department of Rheumatology, Warsaw, Poland*; [2]*National Institute of Geriatrics Rheumatology and Rehabilitation, Early Arthritis Clinic, Warsaw, Poland*; [3]*National Institute of Geriatrics Rheumatology and Rehabilitation, Biologic Therapy Centre, Warsaw, Poland*; [4]*National Institute of Geriatrics Rheumatology and Rehabilitation, Department of Pathophysiology and Immunology, Warsaw, Poland*

Background: Psoriatic arthritis (PsA) is a form of spondyloarthritis (SpA) associated with alterations to the serum lipid profile. Current research suggests that biological treatment with TNF and IL-17 inhibitors differently affects the lipid profile and Th cells populations in PsA and ankylosing spondylitis (AS)
Objectives: To investigate the relationship between lipid profile, disease activity and T-cells phenotype changes in patients with SpAs treated with TNF and IL-17 inhibitors.
Methods: A group of 36 SpA patients (AS 14, PsA 22) with high disease activity were assessed at the start and after 6 months of anti TNF (n=19) and anti IL17 (n=17) treatment. Serum lipid profile: triglycerides (TG), total cholesterol (TC), low (LDL), and high-density lipoproteins (HDL), nonHDL, VLDL levels and atherogenic index (AI) were evaluated. Frequency of Th1, Th2, Th1/Th17, Th17 and T regulatory cells (Tregs) was determined by flow cytometry. The Spearman's rank test was used for the statistical analysis of correlations, and the Wilcoxon rank test for dependent sample testing. All data are given as medians and the absolute and relative difference between two variables are expressed as delta.
Results: A significant reduction in disease activity was observed in all treated patients: DAPSA (32,5 vs 4); BASDAI (6,8 vs 1,5; p<0,01), ESR (15 vs 5mm/h; p<0,01) and CRP (6 vs 1mg/l; p=0,03). In all 36 patients, the reduction of disease activity was followed by a mild decrease of TC (205 vs 195mg/dL p<0,01), LDL (120 vs 110mg/dL p<0,02) and non-HDL levels (18 vs 5 vs 12mg/dL, p<0,05). In PsA patients treated with IL-17 inhibitor (n=13) we found a statistically significant, more pronounced decrease in lipid levels compared to AS and PsA patients treated with anti-TNFs i.e: delta of TC (19 vs 12 vs 12mg/dLp=0,03), LDL (23 vs 15 vs 10mg/dL p<0,05) and VLDL (11 vs 4 vs 4,5mg/dl p=0,02). In addition, in PsA group (n=22) after 6 months of treatment, we found reduction of TG (144 vs 94mg/dL p=0,05), VLDL (28,8 vs 20,6mg/dL p=0,04) levels and improvement of AI (4,4 vs 3,5 p=0,03), also deltas of DAPSA correlated positively with deltas of TC (rho=0,6 p=0,03) and nonHDL (rho=0,5 p=0,04). In flow cytometry after 6 months of treatment of all 36 patients we observed a rise of Th1 (11,3 vs 12,6% p=0,05) and a decrease of Th2 (5,7 vs 4,7% p=0,03) cells with almost no change in Treg cells (5,3 vs 5,35%). In PsA patients (n=22) we have found correlations (p<0,05) between decreases of CD4+CD25+ counts and levels of TC (rho=0,6), nonHDL (rho=0,5), AI (rho=0,6) and DAPSA (rho=0,5). Effectiveness of treatment with iTNFs and iIL-17s was comparable in PsA or AS, but some differences were observed in alterations to limphocyte profile. Patients treated with anti-IL-17 (PsA 13/ AS 4) showed a more pronounced increase in the Th1/Th17-like cell percentage (9,3 vs 13,5%; p=0,04) with a decrease of Th2 cells (7,3 vs 3,5%p=0,03) and concomitant increase in Th1 cells (11 vs 13,8%). In patients treated with IL-17 inhibitors increase of Th1 cells correlated negatively (p<0,05) with TG (rho=-0,6), nonHDL (rho=-0,7), LDL(rho=-0,6) levels, VLDL(rho=-0,6) and positively with HDL (rho=0,4). In PsA patients Th1 cells correlated with DAPSA (rho=-0,4). Patients treated with antiTNFs (AS 10/PsA 9) revealed an increase of Th1 cells (10,5 vs 12% p=0,04) and also a decrease of CD4+CD25+ (23 vs 14,5%; p=0,008), but no correlations with lipid profile were found.
Conclusion: Anti TNF and anti IL17 treatment distinctively affects lipid profile and T Cell balance especially in PsA. Patients with SpAs treated with biologics presented a tendency towards reduction of TC and LDL concentrations, but in PsA those changes were stronger with additional reduction of VLDL, non-HDL and TG levels. Alterations in the lipid profile correlate with disease activity in PsA and with a shift in Th cells (increase in the Th1/Th2 ratio with a decrease in the percentage of activated CD4+CD25+ T cells), which was not observed in AS.

AB1141 **PREDICTORS OF X-RAY PROGRESSION IN PATIENTS WITH PSORIATIC ARTHRITIS**

Keywords: Prognostic factors, Psoriatic arthritis, Biomarkers

S. Pötscher[1], H. Radner[1], D. Sieghart[1]. [1]*Medical University of Vienna, Division of Rheumatology, Department of Internal Medicine III, Vienna, Austria*

Background: Psoriasis arthritis (PsA) is a systemic chronic inflammatory disease, which leads to irreversible destruction of the joints. Multiple factors drive the development of this heterogeneous disease including genetic predisposition, environmental triggers, and immunologic dysfunction. Even structural damage differs significantly between patients, with a subset of patients suffering from severe and rapid (rheumatoid arthritis-like) bone destruction (arthritis mutilans), while others experience only modest signs of bone damage, or develop new bone formation.[1]
Objectives: The study aims to identify potential predictors for radiographic such as clinical, radiographic, and laboratory parameters.
Methods: In this retrospective data analysis 231 patients with PsA and at least two available x-rays were included. Radiographs were scored according to Sharp-van-der-Heijde-total Score (mSvdHTH) modified for PsA and a mean annual progression (MAP) rate was calculated by dividing the change in mSvdHTS between two x-rays number of years between them. For each patient, the median of the annual progression rates was calculated. Patients were grouped in no progressors (MAP ≤ 0.5), low progressors (MAP 0.5 < MAP ≤ 2.5) and high progressors (MAP > 2.5). Clinical data such as the clinical disease activity index (CDAI), radiographic data and laboratory data (CRP, ESR, C-terminal Telopeptide) were analysed for their predictive value of radiographic progression using parametric and non-parametric statistical analysis according to the distribution of data. For correlation analysis Spearman´s rank coefficient was used. For group analysis ANOVA was used. Dichotomous variables such as gender or nail involvement were analysed using χ^2-test. Multiple linear regression analysis was used to identify factors influencing radiographic progression.
Results: The mean baseline mSvdHTS in high progressors was 41.59 (43.53), 19.89 (34.93) in low progressors and 16.25 (26.77) in non-progressors. Baseline mSvdHTS was significantly correlated with MAP (ρ=0.27, p=0.002) rate. Group analysis comparing clinical and laboratory parameters in patients again showed significant difference baseline mSvdHTS. The high progression cohort also exhibits greater mean CRP, ESR, CDAI, median first year CDAI, TJC68, SJC66 and a higher percentage of nail involvement than low- or non-progressors but no statistically significant result was found. In a multiple linear regression analysis baseline SvdHS (β = 0.51, 95%CI 0.28-0.73, p=<0.001), median CDAI in the first year after baseline (β = 0.51, 95%CI 0.19-0.83, p=0.018) and CDAI at baseline (β = -0.62, 95%CI -1.05 – -0.19, p=0.043) were significantly associated with mean annual progression. No association was found between MAP and bone turnover markers.
Conclusion: This study shows a clear association of Sharp-van-der-Heijde score at baseline with future radiographic progression. Moreover, the median CDAI in the first year after baseline was associated with radiographic progression.

AB1142 **DOES OBESITY PLAY A ROLE IN FOOT INVOLVEMENT IN PSORIATIC ARTHRITIS?**

Keywords: Spondyloarthritis, Comorbidities, Psoriatic arthritis

S. F. Azevedo[1,2], C. Mazeda[1,2], S. P. Silva[1,2], C. Pinto Oliveira[1,2], A. Barcelos[1,2,3]. [1]*Centro Hospitalar do Baixo Vouga, Rheumatology Department, Aveiro, Portugal*; [2]*Egas Moniz Health Alliance, Academic Clinical Center, Aveiro, Portugal*; [3]*Comprehensive Health Research Center, Universidade NOVA de Lisboa, Lisboa, Portugal*

Background: Several studies have reported a higher prevalence of obesity in Psoriatic Arthritis (PsA)[1]. Obesity may lead to more weight on the joints, namely on the ankle/foot joints, altered mechanics, and repetitive micro-trauma. Foot involvement is common in PsA, including arthritis, dystrophic nails, toe dactylitis and Achilles enthesitis. Obesity has been found to be associated with higher disease activity and worse functionality scores in PsA patients. [1]
Objectives: The purpose of this study was to evaluate the role of obesity in foot involvement in PsA patients.
Methods: A retrospective study including patients with PsA (all patients fulfill CASPAR criteria) followed from January to May 2022, from a Rheumatology Clinic. Patients were divided into two groups: with current or previous foot involvement (assessed clinically or by ultrasound) (group 1) and without current or previous foot involvement (group 2). Sociodemographic, clinical and laboratory data were collected. Obesity was defined as a body mass index greater than or equal to 30 Kg/m^2 and multimorbidity was defined as 2 or more comorbidities. Descriptive analysis was performed using means and standard deviation (SD), medians and Interquartile. range (IQR) for continuous data, and frequencies and percentages for qualitative variables. Clinical, laboratory and radiological findings were compared between patients with and without foot. involvement using parametric and non-parametric tests, with a p-value ≤ 0.05.
Results: A total of 154 patients were enrolled (mean age of 57.08 (±11.54) years and 39.6% were women). Foot involvement was found in 110 patients (71.40%). Obesity was more prevalent among patients with foot involvement – group 1 (40.90% VS 13.64%; p=0.001). Enthesitis was found in 35.10 % of patients with Achilles enthesitis (28%) as the most frequent manifestation. PsA patients in group 1 who were obese had higher prevalence of Achilles enthesitis (p= 0.01). 18.18% of patients had current/previous toe dactylitis and dystrophic nails were found in 37.7% of patients (no differences were encountered between obese and non-obese patients). Multimorbidity were more frequent in PsA patients with foot involvement- group 1 (p=0.04). We found a higher frequency of extra-articular manifestations and higher HAQ disability index values in patients with foot involvement (p=0.03 and p<0.001, respectively). Although we did not find statistically significant differences in the HAQ disability index between obese and non-obese patients with foot involvement, there was a predominance of disability in obese patients. PsA patients in group 1 who are obese have higher C-reactive protein (p=0.01) and higher consumption of non-steroidal anti-inflammatory drugs (p=0.02). We did not find statistically significant differences in swollen and tender joint counts, in conventional and biological DMARDS between obese and non-obese patients in group 1.
Conclusion: Obesity was more prevalent among PsA patients with foot involvement, suggesting its presence may enhance and contribute for foot complaints in these patients. Patients with foot involvement had higher HAQ disability index levels, reflecting the negative impact of foot involvement in daily functionality in these patients. Our study highlights the importance of obesity management in PsA patients with foot involvement. Further studies are needed to develop weight reduction strategies that can applied in clinical practice, in order to improve outcomes related to PsA.

AB1143 **MIR-10B EXPRESSION IN PSORIATIC ARTHRITIS PATIENTS WITH DAPSA SCORE REMISSION OR LOW DISEASE ACTIVITY**

Keywords: Biomarkers, Psoriatic arthritis

Keywords: Psoriatic arthritis, miRNA, Biomarkers

Ş. S. Köksal[1], Z. Öztürk[1], U. Alkurt[1], D. Karatas[1], G. Güney Eskİler[2], E. Çokluk[3], A. Deveci Ozkan[2], Ü. Erkorkmaz[4], E. Gönüllü[1]. [1]*Sakarya University Faculty of Medicine, Department of Rheumatology, Sakarya, Turkey*; [2]*Sakarya University Faculty of Medicine, Department of Medical Biology, Sakarya, Turkey*; [3]*Sakarya University Faculty of Medicine, Department of Medical Biochemistry, Sakarya, Turkey*; [4]*Sakarya University Faculty of Medicine, Department of Medical Biostatistics, Sakarya, Turkey*

Background: Psoriatic arthritis (PsA) is a heterogeneous inflammatory rheumatologic disease associated with psoriasis. The etiopathogenesis of PsA has not been fully elucidated. Although activity scores are used in the follow-up of patients, reliable biomarkers are not yet available. MicroRNAs (miRNA) are non-coding RNA oligonucleotides whose cellular expression levels change in inflammatory and autoimmune diseases and provide gene expression regulation. miRNAs are being investigated for their potential biomarker properties in the diagnosis and follow-up of psoriatic arthritis.
Objectives: In this context, the current study aimed to determine the changes in mir-10b expression level in patients with PsA who have remission/low disease activity according to DAPSA score and in age-sex matched healthy population.

Methods: Ethics committee approval was obtained from Sakarya University Ethics Committee for the study (E-71522473-050.01.04-15102135). RNA isolation, cDNA synthesis and RT-PCR analysis were performed in 30 PsA patients (19 Female and 11 Males) and age/sex matched control group (20 Females and 11 Males) with DAPSA scores in remission or low disease activity, who applied to Sakarya University Internal Medicine Rheumatology Clinic between January 2019 and February 21, miR-10b expression levels. U6 was used as internal control. IBM SPSS Statistics 26 program was used for statistical analysis.

Results: The mean age of the patients with psoriatic arthritis was 47.4±13.4, and the control group was 46.6±12.9 (p=0.78). No gender difference was analyzed between the two groups. (p=0.92).In addition, it was analyzed that the miR-10b expression level was 0.90-fold in PsA patients compared to the control group, and the expression level did not change significantly compared to the control group (p=0.53).

Conclusion: In our study, no statistically significant difference was observed in terms of miR-10b expression in PsA patients with DAPSA remission-low disease activity when compared to healthy controls. Further studies are needed in patients with moderate and high activity psoriatic arthritis.

AB1144 PREVALENCE OF SECONDARY SJOGREN'S SYNDROME IN PSORIASIS AND PSORIATIC ARTHRITIS AND ITS RELATIONSHIP WITH DISEASE CHARACTERISTICS

Keywords: Sjögren syndrome, Psoriatic arthritis

K. Abacar[1], Ş. Çolakoğlu Özkaya[2], T. Ergun[3], S. Kutluğ Ağaçkıran[1], A. Aliyeva[1], G. Sevik[1], P. Atagündüz[1]. *[1]Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; *[2]Marmara University Institute of Health Sciences, Department of Medical Biology and Genetics, Istanbul, Turkey*; *[3]Marmara University School of Medicine, Department of Dermatology, Istanbul, Turkey*

Background: Secondary Sjögren's syndrome (sSS) accompanies many systemic rheumatic diseases at certain rates, including axial spondyloarthritis (axSpA).[1] There are some case reports in which psoriasis or psoriatic arthritis (PsA) with sSS co-existence.[2] However, the prevalence of sSS in psoriasis (PsO) and PsA is not fully addressed. Additionally, clinical and laboratory features that may be associated with sSS, and whether arthritis and sSS are related are not known.

Objectives: This study aims to assess the prevalence of sSS in patients with non-arthritic psoriasis and PsA and illuminate disease features associated with sSS.

Methods: Psoriasis patients diagnosed by a dermatologist and patients classified as PsA who fulfilled the CASPAR criteria were questioned for sicca symptoms consistent with the 2002 American-European Sjogren's Syndrome Consensus Criteria (AECG). The salivary gland scintigraphy of the patients with oral dryness was performed and the unstimulated salivary flow rate (SFR) was measured. Schirmer's test was performed on patients with dry eyes. Anti-Ro antibodies were measured and minor salivary gland biopsies were performed in patients with sicca detected by objective measurements. After the evaluation of the patients, the sSS was classified according to the 2002 AECG. The frequency of sSS in non-arthritic psoriasis and PsA patients were compared. In addition, PsA patients were divided into two groups according to the presence and absence of sSS. PsA-specific characteristics in these two groups were compared.

Results: Of the 184 psoriasis patients who participated in the study, 112 had PsA, and 72 had psoriasis without arthritis. There was no significant age difference between non-arthritic psoriasis and PsA patients (48.3±11.9 and 49.4±13.5, respectively; p=0.59) Similarly, female to male ratio (rates (%): non-arthritic psoriasis: 43/29 (59.7/40.3) PsA: 82/30 (73/27), respectively; p= 0.08) and age of onset of psoriatic skin changes (mean (SD) of non-arthritic psoriasis: 30.3 ±10.9, PsA: 29.4 ±13.2, respectively; p=0.68) did not differ between non-arthritic psoriasis and PsA patients. sSS was more prevalent in PsA patients when compared with the non-arthritic psoriasis group (PsA: 20 (%17.9), non-arthritic psoriasis: 1 (%1.3), p<0.001). None of the patients had a previous diagnosis of sSS. Of the patients with sSS (n=20), 18 had salivary gland involvement detected in salivary gland scintigraphy, four Anti-Ro positivity, and three low unstimulated SFR. All PsA patients with sSS (sSS/PsA) had a positive Schirmer test. sSS/PsA patients were significantly more positive for ANA and had plantar fasciitis more frequently than PsA patients without sSS (Table 1). Although not statistically significant, the age of onset of joint involvement in sSS/PsA patients was higher and was treated less with biological therapy (Table 1).

Conclusion: Secondary Sjögren's syndrome is part of the clinical picture in a substantial proportion of PsA patients and its absence in non-arthritic PsO implies that sSS is arthritis associated. Whether the type of arthritis in sSS/PsA patients has a pattern necessitates larger patient numbers. A higher rate of ANA positivity may suggest the role of B lymphocytes in the progression from PsO to PsA.

AB1145 QUALITY INDICATORS: APPLYING QUALITY MEASURES TO IMPROVE SERVICES AND PATIENT OUTCOMES. A QUALITY IMPROVEMENT INITIATIVE

Keywords: Rheumatoid arthritis, Quality of care, Psoriatic arthritis

Y. El Miedany[1], M. H. Abu-Zaid[2], M. Elwy[3], S. A. Mahran[4], A. Elyasaki[5], M. Elgaafary[6], W. Hassan[7], W. Elwakil[8], S. Saber[3], S. A. A. Tabra[2]. *[1]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom*; *[2]Faculty of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt*; *[3]Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt*; *[4]Faculty of Medicine - Assiut University, Rheumatology and Rehabilitation, Assiut, Egypt*; *[5]Galala University, Rheumatology and Rehabilitation, Attaka, Egypt*; *[6]Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt*; *[7]Faculty of*

Medicine Banha University, Rheumatology and Rehabilitation, Benha, Egypt; [8]*Faculty of Medicine Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt*

Background: The use of quality-of-care indicators is an important strategy to measure and evaluate if the care provided in the standard clinical setting adheres to current evidence informed best practices. Achievement of quality indicators is often reported as a quality score (%). Quality indicators are often developed from guidelines, systematic literature reviews, or expert panel consensus using a systematic approach. The recently developed national guidelines for inflammatory arthritis [1, 2] provided the fundamentals of quality indicators of inflammatory arthritis.
Objectives: To evaluate quality indicators for inflammatory, their use in routine clinical practice reflecting the processes of clinical care and improvement in outcomes.
Methods: Quality measurement was carried out across 5 centers based on six domains of quality: 1. Structure (Describes the innate characteristics of providers and the system and the organisational aspects of care), 2. Process (Assesses actual healthcare service delivered to patients by healthcare providers), 3. Patient experience (Describes the patient's perception of quality of care)[3], 4. Outcome (Assesses the end result or the final goals of the delivered care), 5. Access (Evaluates the provision of timely and appropriate healthcare), 6. Efficiency (Describes the relationship between clinical performance and resource use). Data were logged based on patients' recorded data.
Results: Inflammatory arthritis services are provided in 100% of the centers. 88.3% of the participants voted that they do implement "Treat to Target" approach and quality indicators for the management of inflammatory arthritis in their standard practice. Patient experience was rated positive in 63% whereas Timely treatment target was recorded in 74%. Efficiency evaluation revealed constrains attributed to lack of insurance cover of cost of some recommendations (72.7%).
Conclusion: Irrespective of resource and infrastructure constraints, assessment of all the relevant domains of care, revealed improvement and strengths of all the other measures. Results revealed that the treating rheumatologists not only do adhere to quality indicators required for the management of inflammatory arthritis, but also provide timely and appropriate healthcare that has been well received by the patients. Such results are vital as quality measurement in rheumatology is focused primarily on processes of care, consequently, process measurement facilitates implementing actionable targets for improvement instead of focussing solely on outcomes of care.

Background: Clinical practice guidelines serve many targets, including guiding clinical decision-making process based on best evidence, standardized patient care, improving provider performance, setting standards of practice, and reducing variability in practice. Despite their vital role in standard practice, adherence to guidelines has been reported to be suboptimal. Overall, no information is available of how rheumatologists would interact with recently published national clinical practice guidelines [1, 2].
Objectives: To answer three principal research questions: (i) how far do rheumatologists deviate from the recommended clinical guidelines (ii) What are the major barriers to guidelines adherence? and (iii) What are the factors that would improve guideline adherence?
Methods: This was Cross sectional multi-center, survey-based study. Rheumatologists in 12-centers, covering both the north and south of Egypt, were invited to participate in the study. All outcomes were measured using a validated survey tool. The primary outcome of interest was barriers to guideline adherence. Secondary outcomes included general attitudes toward guidelines and factors that could improve adherence to guidelines. Outcomes were measured by the survey tool. All outcomes were reported on a numerical visual analogue scale (0-100). 55% was defined a priori as a threshold to infer strong association between physician responses and category of interest. P-value <0.05 was used for statistical significance.
Results: 77 rheumatologists participated in the survey. Analysis of the participants experience revealed a broad range of knowledge with 18.2% were still in training (residents), 10.4% have 1-3 years of experience, 14.3% have 3-5 years' experience, 24.7% have 5-10 years of experience whereas 32.5% had more than 10-years of experience. The majority 65% have not been ever involved in clinical guidelines development ($p < 0.001$). 74% agreed/ strongly agreed that they were adequately trained accessing and applying guidelines in their standard practice, whereas 6.5% only disagreed ($p< 0.001$). 58.4% rated their adherence to clinical practice guidelines as high/very high, whereas 38% rated it as average and 2.6% rated it as low ($p< 0.01$). In concordance, 88.3% of the participants voted that they do implement "Treat to Target" approach for the management in their standard practice ($p< 0.001$). Major barriers to guidelines adherence were time constrains due to clinical documents (53.2%), access to relevant guidelines at the point of care (48.1%) as well as lack of insurance cover of cost of some recommendations (72.7%). Factors that would improve guideline adherence included: improved focus on guidelines during training (88.3%), access to relevant guidelines at the point of care (87.4%)
Conclusion: Guidelines have enhanced physician adherence to management recommendations and provide evidence-based, standardized clinical decisions. Results of the work revealed significantly less tendency to deviate from the national guidelines among rheumatologists. Few areas of improvement have been identified including implementing the guidelines in trainee's education courses and consistent access to relevant guidelines at the points of care.

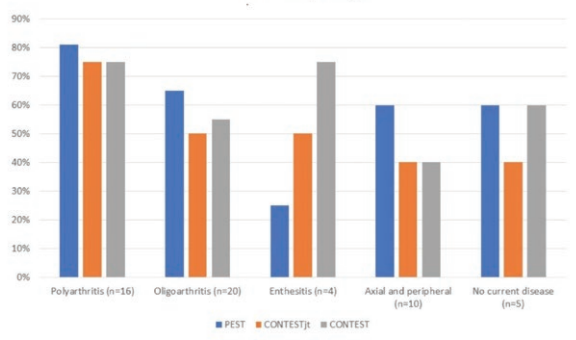
AB1147 THE COMPARATIVE PERFORMANCE OF THREE SCREENING QUESTIONNAIRES FOR PSORIATIC ARTHRITIS IN A PRIMARY CARE SURVEILLANCE PROGRAM



Keywords: Epidemiology, Non-pharmacological interventions, Psoriatic arthritis

P. Helliwell[1], L. Coates[2], M. Ransom[3], S. Brown[3], J. Packham[4], J. Weddell[1], W. Tillett[5], N. Mchugh[5]. [1]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [2]*University of Oxford, Rheumatology, Oxford, United Kingdom*; [3]*University of Leeds, Leeds Institute of Clinical Trials Research, Leeds, United Kingdom*; [4]*University of Nottingham, Academic Unit of Population and Lifespan Science, Nottingham, United Kingdom*; [5]*University of Bath, Department of Life Sciences, Bath, United Kingdom*

Background: There are considerable delays in the diagnosis of psoriatic arthritis (PsA) and earlier diagnosis is likely to lead to better outcomes.
Objectives: The aim of this study was to compare the performance of three PsA screening questionnaires in a primary care psoriasis surveillance program.
Methods: Participants with psoriasis, and not known to have psoriatic arthritis (PsA), were identified from general practice databases and invited to attend a secondary care centre for a clinical assessment. The three patient-completed screening questionnaires (PEST, CONTEST, and CONTEST with a manikin CONTESTjt) were administered along with other patient reported measures and

a clinical examination of skin and joints was performed. Participants who demonstrated signs of inflammatory arthritis suggestive of PsA were referred, via their GP, for a further assessment in a secondary care rheumatology clinic.
Results: A total of 791 participants attended the screening visit and 165 participants were judged to have signs and symptoms of inflammatory arthritis, of which 150 were referred for assessment. Of these 126 were seen and 48 were diagnosed with PsA. The results for each questionnaire were as follows: PEST: Sensitivity 0.625 (95% CI 0.482 to 0.749), specificity 0.757 (0.724 to 0.787). CONTEST: Sensitivity 0.604 (0.461 to 0.731), specificity 0.768 (0.736 to 0.798). CONTESTjt: Sensitivity 0.542 (0.401 to 0.676), specificity 0.834 (0.805 to 0.859). There was no evidence of any significant difference in sensitivity between questionnaires, but CONTESTjt demonstrated marginally superior specificity to PEST. However, the area under the ROC curve was similar for all three instruments. PEST was better at identifying cases of peripheral arthritis, including those with axial involvement, but the CONTEST questionnaires were better at identifying cases of peripheral enthesitis, though numbers were small (Figure 1).
Conclusion: Minimal differences in discriminative ability between the three screening questionnaires were found in this study and no specific recommendation can be made based on these results. The choice of which instrument to choose will depend on other factors, such as simplicity and low patient burden.

Background: In patients with psoriatic arthritis (PsA), discordance between physicians and patients when assessing disease activity has been described as frequent, mainly in European and North American studies. This discordance may negatively impact treatment adherence and shared decision-making processes. Culture and beliefs influence patients' perceptions of health.
Objectives: To evaluate the concordance between patient- (PGA) and physician-global assessment (PhGA) of PsA disease activity and its association with demographic and disease characteristics in a multinational group of patients from Arab countries.
Methods: This multicentric multinational cross-sectional study was conducted in thirteen Arab countries by the Arab League of Associations of Rheumatology (ArLAR) research group (ARCH). During a single routine visit, patients and physicians were requested to rate the PsA disease activity on a numeric scale from 0 (no activity) to 10 (worse activity). In addition, demographic and disease data were collected, as well as PGA and PhGA for psoriasis (PsO) activity, Health Assessment Questionnaire (HAQ), Fibromyalgia Rapid Screening Tool (FiRST), Patient Health Questionnaire (PHQ4) and Disease Activity in Psoriatic Arthritis (DAPSA). First, the correlation between PGA and PhGA for PsA and PsO disease activity was assessed statistically using the Spearman correlation coefficient (PsA and PsA) and graphically using the Bland and Altman method (PsA). Second, concordance between the PGA and PhGA PsA activity (defined as a difference between -2 and 2) was calculated and correlated with demographic and disease factors using multivariable binary logistic regression.
Results: The study included 554 patients from thirteen countries: mean age 45 years (SD 13), 57% females, median disease duration four years (IQR 2-9); 89.2% had skin PsO, and 43.5% had nail PsO. The disease was active overall: mean DAPSA was 19.3 (SD 16.1), HAQ 1.1 (SD 0.8), and PHQ4 3.3 (SD 2.9). The screening test for widespread pain was positive in 18.4% of patients. The mean PGA for PsA activity was 4.7 (SD 2.5), versus a PhGA of 3.9 (SD 2.4). Similarly, PGA for psoriasis activity was 4.0 (SD 2.8), and PhGA was 3.1 (SD 2.6). The correlation between PGA and PhGA was strong for PsA activity (r= 0.738) (with good agreement on Bland and Altman (Figure 1)) and moderate for psoriasis activity (r=0.613). Among 554 patients' measurements, 358 (84.2%) were in concordance with the physician's global assessment. In the multivariable analysis, concordance was independently associated with a high CRP (OR 2.32 [95%CI 1.33; 4.02] and DAPSA category (better concordance in patients in remission (OR 1.02 (95%CI 1.01; 1.03]).
Conclusion: In this unselected sample of patients from Arab countries, there was a strong concordance between PGA and PhGA of PsA activity. This raises questions about patient expectations and pain perceptions in Arab countries. Concordance was stronger for PsA than PsO, indicating that rheumatologists may be more comfortable assessing joints than skin. The patient's evaluation of disease activity needs to be taken into account when considering the disease management plan, especially in patients who are not in remission.

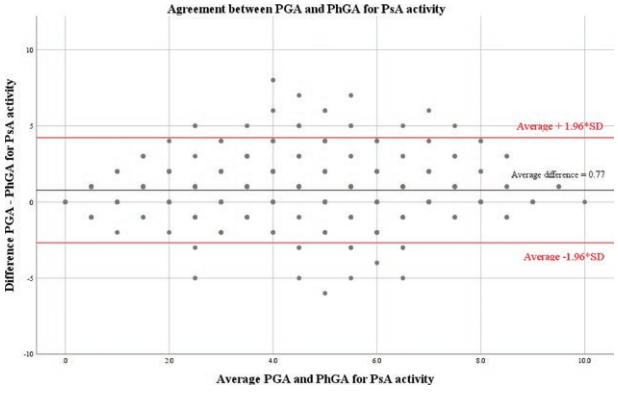

Figure 1. Agreement between PGA (Patient) and PhGA (Physician Global Assessment) of PsA activity using the Bland and Altman plot. Each dot is the difference between PGA and PhGA for a specific patient.

AB1149 **SEX DISTRIBUTION IN PSORIATIC ARTHRITIS: SYSTEMATIC LITERATURE REVIEW**

Keywords: Gender/diversity issues, Epidemiology, Psoriatic arthritis

B. Fırlatan[1], G. S. Kart Bayram[1], G. Ayan[1], U. Kalyoncu[1]. [1]*Hacettepe University Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*

Background: The prevalence of psoriatic arthritis (PsA) is considered equal in male and female patients but recent studies in cohorts of PsA it has been observed that women are more dominant in sex distribution, and the female-male ratio varies between 1.2 and 2 [1]. It is not yet clear whether this is related to a change in the epidemiology of the disease.
Objectives: To assess the female-male ratios in recent PsA studies.
Methods: A systematic review of the literature (from January 2020 to September 2022) was performed using the Pubmed database with keywords and MeSH terms referring to psoriatic arthritis. Randomized controlled, cross-sectional, prospective, and retrospective cohort studies involving ≥20 patients and specifying the number of men and women were considered eligible. Only original articles in English were included. Two independent reviewers performed study selection and data collection. The number of female and male patients, study design, study center, and PsA clinical phenotypes were recorded.
Results: Total of 1469 articles were selected for full-text reading, of which 486 were included for analyses. Overall, the number of studies in which the F/M and M/F ratio ≥1.5 was 86 (17.7%) and 60 (12.4%), respectively. Comparing the study types, it was observed that the female gender was more dominant in cross-sectional studies (p=0.004), Table 1. The sex distribution was more heterogeneous in single-center studies than in multi-center studies. Studies were stratified according to continents; it was found that the number of studies in which the F/M ratio is ≥1.5 was higher in America than the multinational studies (27% vs. 4%). On the other hand, the studies from Asia had higher male predominance.
Conclusion: Although there were some differences observed in sex distribution by study design and continents, overall, the ratio of females to males was similar. The female predominance observed in some studies might be due to selection bias or greater access to the medical system.

Background: Little is known about the chronologic order of appearance of psoriasis (Pso) and psoriatic arthritis (PsA) symptoms and its effect on disease evolution. Most information is based on population-based registries or big data that may lack precision.
Objectives: To evaluate duration and chronologic order of appearance cutaneous and articular manifestations of PsA from 1st symptoms till diagnosis.
To compare differences between patients with symptoms and diagnosis of Pso before PsA with those that manifest Pso after PsA.
Methods: A retrospective cohort study was conducted. Eligible patients were 219 patients that met ASAS criteria visited the SpA clinic between July – October 2022. Finally, 129 patients that met CASPAR criteria and Pso diagnosis were included. Other autoimmune rheumatic diseases were excluded. Data were collected previously reviewing patient records available from the electronic

and paper database of the hospital. Additional information was retrieved by the shared medical history database of the Catalan Institute of Health which attends the 99.2% of the population. Missing data were collected prospectively by patient interview. ANOVA or Kruskall-Wallis test was carried out according to variable distribution.

Results: A total of 129 patients were included from which 98 had all time data related about disease appearance. There were 13.3% of missing data. The median disease evolution in years was 14 years with patients from 1 to 53 years of duration. The description and comparison of the clinical characteristics of each group is summarized in Table 1. Patients that begin with arthritis showed significant association with higher elevated C reactive protein and longer PsA disease duration. Longer time till arthritis appearance as well as more prevalence of Dactylitis was more observed in patients that begin with Pso before arthritis.

SpA related variables, n (%)	Pso before PsA (n=64)	Same time (n=16)	Pso after PsA (n=18)	p
Male	36 (56.3)	9 (56.3)	10 (55.5)	0.99
HLAB27+	12 (18.8)	2 (12.5)	1 (5.6)	0.45
Elevated CRP	29 (45.3)	11(68.8)	14 (77.8)	**0.03**
Nail Pso	40 (62.5)	9 (56.3)	12 (66.7)	0.93
Other Pso	27 (42.2)	8 (50%)	15 (83.3)	0.10
Enthesitis	27 (42.2)	8 (50)	7 (38.9)	0.69
Dactylitis	25 (39.1)	10 (62.5)	3 (16.7)	**0.03**
Uveitis	1 (1.6)	0	1 (5.6)	0.48
Inflammatory bowel disease	0	1 (6.25)	1 (5.6)	0.15
Axial affection	10 (15.6)	2 (12.5)	2 (11.1)	0.80
Family history of Pso	29 (45.3)	3 (18.8)	7 (38.9)	0.23
Family history of SpA	63 (98.4)	14 (87.5)	18 (100)	**0.04**
Time related variables, p50 (IQR)				
Age	59.7 (15.4)	58.5 (16.8)	60.3 (19.6)	0.38
Years from 1st till 2nd manifestation	24.5 (1)	0	8 (9)	**0.00**
Years of delay until PsA diagnosis	3 (0)	1 (7)	5.5 (8)	0.07
Years of disease duration	11 (8)	20 (18.5)	19 (15)	**0.01**

Conclusion: Significantly higher prevalence of CRP elevation in patients that begin with arthritis.

Higher prevalence of dactylitis and longer time until articular manifestation was observed in patients that begin with Pso.

AB1151 COMORBIDITY IN PSORIATIC ARTHRITIS (COMPASS) – INCIDENCE OF DEPRESSIVE SYMPTOMS AND ASSOCIATED FACTORS

Keywords: Epidemiology, Comorbidities, Psoriatic arthritis

A. Avik[1], E. Waldheim[1], S. Geschwind[1], A. Antovic[2,3], V. Oke[1,2]. [1]*Academic Specialist Centre, Centre for Rheumatology, Stockholm, Sweden*; [2]*Karolinska Institutet, Dept of Medicine, Division for Rheumatology, Stockholm, Sweden*; [3]*Karolinska University Hospital, Dept of Rheumatology, Stockholm, Sweden*

Background: Patients with psoriatic arthritis (PsA) demonstrate increased prevalence of several comorbidities, including mental health conditions.

Objectives: Aim of the study was to investigate the prevalence of self-reported depressive symptoms (SRDS) and diagnosis of depression among PsA patients treated at Centre for Rheumatology, Stockholm and investigate associated clinical, laboratory and psychosocial parameters.

Methods: 71 patients were included from prospective cross-sectional COMPASS study. Information regarding disease activity (joint assessment, enthesitis (SPARCC), psoriasis body surface area (BSA)% and psoriasis area severity index (PASI)) were collected. Patient Health Questionnaire-9 (PHQ-9) was used to assess SRDS. Dermatology Life quality Index (DLQI) was used to assess impact of cutaneous symptoms.

Results: 72% of included patients were females, mean age 53.9 years (SD 12.7) and 75% were included at first visit. 52 patients reported a PHQ-9 score of none to mild depression (ND group) and 19 patients a score equal to moderate or severe depression (D group). The D group had significantly more severe somatic disease, including higher swollen (p=0.006) and tender joint counts (p=0.003), higher enthesitis score (p=0.012) and VAS score (p=0.004). Multivariate analyses showed a positive correlation between severity of SRDS and pain (ρ=0.51, p<0.001), DLQI (ρ=0.40, p=0.001), tender/swollen joints (ρ=0.38, p-=0.001/ρ=0.34, p=0.004), enthesitis (ρ=0.27, p=0.032) and PASI (ρ=0.28, p=0.028). Patients reported that the mean time from the first joint symptom to the first visit to rheumatologist was 10.5 years (SD 13.2). Importantly, only those who received the PsA diagnosis and treatment later than 2 years since the onset of symptoms, reported depressive symptoms (PHQ>10 (mild or more severe) or 14 (moderately or severe)).

Conclusion: In our cohort up to 26% of PsA patients display medium to severe depressive symptoms. Importantly, delay of 2 years to the first visit to rheumatologist is associated with SRDS. A severity of SRDS correlates with severity of somatic disease.

AB1152 FATIGUE IN PATIENTS WITH PSORIATIC ARTHRITIS OF EMPLOYABLE AGE

Keywords: Psoriatic arthritis, Patient reported outcomes

N. Tileubek[1], I. Fairushina[2], D. Abdulganieva[2], E. Kirillova[2]. [1]*Institute of Gastroenterology, Hepatology and Metabolism "interna clinic", rheumatology, Almaty, Kazakhstan*; [2]*Kazan State Medical University, Internal Diseases, Kazan, Russian Federation*

Background: Fatigue is an important and underrated multifactorial manifestation of psoriatic arthritis (PsA).

Objectives: The evaluation of frequency and relationship of fatigue with anthropometric, clinical, laboratory, ultrasound (US) data and quality of life (QoL) in patients with PsA of employable age.

Methods: The study included 92 patients with PsA aged 18-59 years. Assessment of fatigue was conducted using a fatigue subscale from the FACIT-F questionnaire. Severity of skin lesions and arthritis was determined with PASI and DAPSA, respectively, as well as anthropometric data, the number of painful and swollen joints and entheses, inflammatory biomarkers, the number of inflamed entheses and entheses with structural changes and the number of active and non-active synovitis detected by US, QoL by SF-36 and DLQI and functionality by HAQ-DI.

Results: In all 92 patients: male - 42 (45.7%), mean age 42.9±9.6 (SD) years (y), PsA duration was 7 (2; 11.8) y, DAPSA 15.2 (10.2; 21.4), PASI 3,8 (1,2; 9,6). Fatigue (FACIT-F values <34 points) was detected in 46 (50%) patients. It was associated with psoriasis (p<0.05) and PsA duration (p<0.01), DAPSA (p<0.01), and clinical enthesitis (p<0.01). At the same time, there was no relation between (b/w) age and anthropometric data (body mass index, waist and hip circumference, waist-to-hip ratio) (p>0.05). FACIT-F score was correlated with physical functioning (SF-36 subscale) and DLQI scores (p<0.01). These data are consistent with findings from other studies, especially with psoriasis burden, despite the fact that the relation b/w fatigue, PASI and psoriatic onychodystrophy (NAPSI) was not found (p>0.05). Association of fatigue with inflammatory markers (ESR, hs-CRP) and US articular and entheseal inflammation was not found (p>0.05). Probably this indicates a greater influence of clinical signs, rather than US that could be explained by the high incidence of asymptomatic course of these changes.

Conclusion: Fatigue was found in 46% of employable aged PsA patients and was associated with clinical signs of PsA, particularly, with its activity and duration. Fatigue has been linked to physical functioning and DLQI scores. Further research is needed to investigate the individual factors that make the greatest influence to the fatigue development. The results of this study may indicate the need for routine fatigue examination among people with active PsA.

AB1153 FATIGUE AND PSORIATIC ARTHRITIS: WHAT CHARACTERISTICS?

Keywords: Descriptive studies, Quality of life, Psoriatic arthritis

A. Ben Amou[1], S. Rahmouni[1], H. Tbini[1], K. Zouaoui[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1], M. Elleuch[1]. [1]RABTA Hospital, Rheumatology, Tunis, Tunisia

Background: Psoriatic arthritis (PsA) can cause an impairment of patients' quality of life. Fatigue is a common and often underestimated symptom in PsA.

Objectives: We aimed to assess the characteristics of fatigue in PsA.

Methods: This was a cross-sectional study including patients with PsA meeting CASPAR criteria. Socio-demographic, clinical and biological data were collected. The FACIT fatigue score (Functional Assessment of Chronic Illness Therapy) was calculated for all patients. It is a 13-item questionnaire evaluated on a five-point scale (4 = no fatigue to 0 = extreme fatigue), with scores from 0 to 52, the highest scores correspond to less fatigue [1].

Results: There were 37 patients, the sex ratio M/F was 2.1. The mean age was 52.46±14.22 years, the mean age at disease onset was 41.32±14.69 years and the mean disease duration was 133.62±112.82 months. The mean BMI was 25.69±5.13 kg/m². The mean CRP was 31.63±37.95 mg/l. The patient global assessment (PGA) of the disease was 50.54±17.47. The mean DAS28-CRP score was 4.06±1.54. The mean BASDAI and ASDAS-CRP scores were 5.06±6.14 and 2.60±1.05, respectively. The mean DAPSA score was 38.31±35.05. The mean BASFI and HAQ were 4.91±2.59 and 1.30±0.93, respectively. The mean FACIT fatigue score was 16.11±11.99 [0-49]. It correlated with mean BMI value (r=0.444; p=0.044), age at disease onset (r=0.421; p=0.016), PGA (r=0.397; p=0.036), and HAQ (r=0.437; p=0.020). Patients with a BMI≥25 kg/m² had a higher FACIT fatigue score (19.94±13.20 vs. 11.00±8.12, p=0.049), In contrast, no correlation was identified with gender, age, smoking, disease duration, axial or peripheral involvement, extra-articular manifestations, high CRP levels, DAS28-CRP, BASDAI, ASDAS-CRP, DAPSA, BASFI, and hip involvement.

Conclusion: Fatigue is an important symptom in PsA and can be responsible for significant psychosocial impact and impairment of quality of life. Its assessment and management should be part of the overall management of PsA.

AB1154 NEW INFLAMMATION PARAMETERS IN PSORIATIC ARTHRITIS: NEUTROPHIL/LYMPHOCYTE AND PLATELET/LYMPHOCYTE RATIOS

Keywords: Psoriatic arthritis

A. Ben Amou[1], S. Rahmouni[1], H. Tbini[1], K. Zouaoui[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1], M. Elleuch[1]. *[1]RABTA Hospital, Rheumatology, Tunis, Tunisia*

Background: Monitoring disease activity in patients with psoriatic arthritis (PsA) is crucial. Commonly used inflammation markers, including C-reactive protein (CRP), lack specificity and sensitivity. Other markers using complete blood count (CBC) parameters have been proposed: neutrophil/lymphocyte ratios (NLR), platelet/lymphocyte ratios (PLR).

Objectives: The aim of this study is to investigate these ratios in PsA.

Methods: A cross-sectional study including patients with PsA meeting CASPAR criteria. Socio-demographic, clinical and biological data were collected. NLR and PLR ratios were calculated from the CBC parameters.

Results: Thirty-seven patients were enrolled; the sex ratio M/F was 2.1. The mean age was 52.46±14.22 years, the mean age at symptoms onset was 41.32±14.69 years. Axial and peripheral involvement were noted in 21 and 31 cases, respectively. Rheumatoid factor, ACPA and ANA were positive in 10, 8 and 9 cases, respectively. At least one extra-articular manifestation was present in 18 cases. Hip involvement was noted in 11 cases. The mean CRP was 31.63±37.95 mg/L. The mean DAS28-CRP, BASDAI, ASDAS-CRP and DAPSA were 4.06±1.54, 5.06±6.14, 2.60±1.05 and 38.31±35.05, respectively. The mean values for leukocytes, neutrophils, and lymphocytes were 10.97±12.95 10^3/mm3, 5.22±2.04 10^3/mm3, and 2.36±0.96 10^3/mm3, respectively. The mean hemoglobin level was 12.73±1.57 g/dl. The mean platelet count was 315.03±119.01 10^3/mm3. The mean NLR and PLR were 2.52±1.31 and 58.05±91.69, respectively. Our statistical study identified a correlation of PLR with CRP (r=0.423; p=0.016), hemoglobin level (r=-0.524; p=0.002) and DAPSA (r=0.487; p=0.047). However, no correlation was found between PLR and age, disease chronology, axial or peripheral involvement, immunological profile, extra-articular manifestations, DAS28-CRP, BASDAI, ASDAS-CRP, and hip involvement. Furthermore, no correlation between NLR and any of the above variables was identified.

Conclusion: This study showed that PLR correlates with CRP, hemoglobin level, and disease activity. These new, inexpensive, and available inflammation markers may be useful in monitoring patients with PsA.

AB1155 SOLUBLE PROGRAMMED CELL DEATH-1 IN PSORIASIS AND PSORIATIC ARTHRITIS PATIENTS

Keywords: Psoriatic arthritis

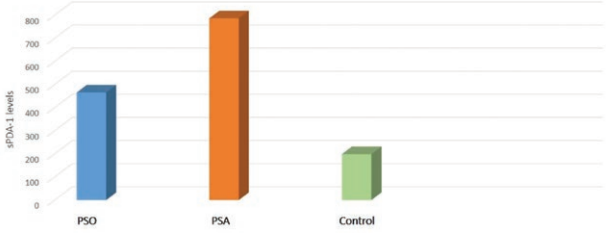
S. A. A. Tabra[1], R. Elsharaby[2], E. S. E. Shaker[3], A. A. Moustafa[4], M. H. Abu-Zaid[1]. *[1]Tanta University. Faculty of Medicine, Rheumatology and Rehabilitation, Tanta, Egypt*; *[2]Tanta University Faculty of Medicine, Clinical Pathology, Tanta, Egypt*; *[3]Tanta University Faculty of Medicine, Dermatology and Venereology, Tanta, Egypt*; *[4]AlAzhar University. New Damietta branch, Rheumatology and Rehabilitation, Damietta, Egypt*

Background: psoriasis (PSO) and Psoriatic arthritis (PsA) are chronic, inflammatory, diseases that affect many sustems[1]. Soluble programmed cell death- 1 (sPD-1) block the PD-1/PD-L1 inhibitory pathway and associated with persistent activation of self-reactive T cells[2].

Objectives: Assess the plasma levels of sPD-1 in PSO and PsA patients and correlate it with the clinical, laboratory, radiological characteristics and disease activity.

Methods: This study included 30 PSO patients (G I), 30 PsA patients (G II), and 40 healthy control (G III). All studied groups were subjected to clinical assessment, PASI and DAPSA scores assessment, musculoskeletal ultrasound (MSUS) assessment of affected areas, laboratory evaluation in form of CBC, ESR, and CRP. Plasma levels of sPD-1 were measured and correlated with different parameters.

Results: There were no significant differences between the three groups regarding demographic data (P>0.05). 19 PSO patients were receiving biological treatment while 21 PsA patients were receiving biological therapy. The remaining patients were receiving conventional DMARDs. PASI score was 20.34± 8.63 & 21.62± 10.53 in GI & GII consequently with no significant difference between PSO & PsA groups (P=0.6). DAPSA score was 10.28±5.39 in G II. Plasma levels of sPD-1 were 465.64±251.16, 786.44±153.96, and 198.73±73.36 in the three groups respectively with significant increase in GI, & GII than controls (P<0.01), sPD-1 was significantly elevated in PsA patients when compared with PSO patients (P<0.01). s-PD-1 levels were elevated in patients who had active synovitis by MSUS. s-PD-1 levels were positively correlated with CRP, PASI score, and DAPSA score. Figure 1 demonstrates sPD-1 levels in the three groups.



Conclusion: Plasma levels of sPD-1 were elevated in PSO and PsA patients and correlated with disease severity and activity. sPD-1 might be good predictor of PSO and PsA disease activity, a new biomarker or target for immunomodulatory therapy.

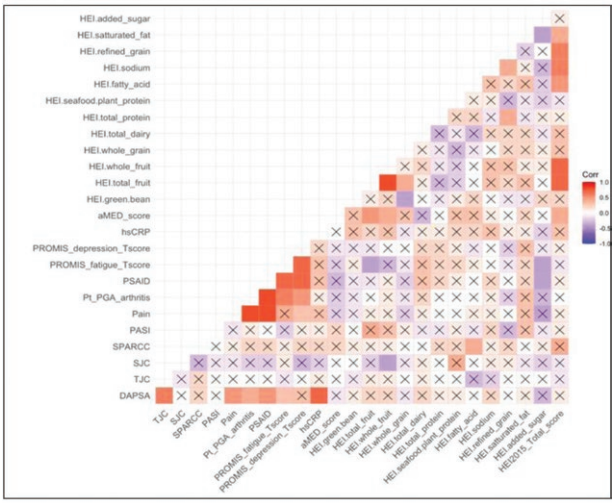
AB1156 METABOLIC DISORDERS AND ABNORMAL DIETARY PATTERNS AND THEIR ASSOCIATION WITH PSORIATIC ARTHRITIS ACTIVITY: THE DIETARY INTERVENTION IN PSA (DIPSA) STUDY

Keywords: Clinical trials, Diet and nutrition, Psoriatic arthritis

L. Eder[1,2], C. Compher[3,4], H. Emandoilidis[1], R. Quinn[5], D. D. Gladman[2,6], V. Chandran[2,6], J. Scher[7,8], A. Ogdie[9]. *[1]Women's College Hospital, Rheumatology, Toronto, Canada*; *[2]University of Toronto, Medicine, Toronto, Canada*; *[3]University of Pennsylvania School of Nursing, Biobehavioral Health Science, Philadelphia, United States of America*; *[4]Hospital of the University of Pennsylvania, Nursing, Philadelphia, United States of America*; *[5]University of Pennsylvania School of Nursing, Office of Nursing Research, Philadelphia, United States of America*; *[6]Toronto Western Hospital, Rheumatology, Toronto, Canada*; *[7]NYU Grossman School of Medicine, Medicine, New York, United States of America*; *[8]NYU Langone Health, NYU Psoriatic Arthritis Center, New York, United States of America*; *[9]Perelman School of Medicine at the University of Pennsylvania, Departments of Medicine and Epidemiology, Philadelphia, United States of America*



Background: Psoriatic Arthritis (PsA) is associated with obesity and its related metabolic abnormalities. The role of diet as an adjunct therapy in PsA remains unclear.
Objectives: We aimed to describe the prevalence of cardiometabolic abnormalities and adherence with healthy eating recommendations among patients participating in the DIPSA study and asses their association with measures of disease activity.
Methods: DIPSA is a randomized controlled trial (NCT04180904) that aims to compare the efficacy of Mediterranean diet and DASH-low caloric diet vs. standard of care as adjunct therapy in patients with PsA who are overweight or obese (BMI>25). Study participants must have Disease Activity in Psoriatic Arthritis (DAPSA) score >10 and be on stable therapy. Baseline information on the first 32 patients enrolled in the study (out of expected 90 patients) was analyzed. The presence of cardiometabolic abnormalities was assessed based on medical history, physical examination and laboratory tests. All participants completed a 24-h dietary recall of foods/beverages consumed during 3 separate weekdays. Healthy Eating Index (HEI) 2015, a diet quality score which evaluates adherence to dietary guidelines for Americans, was calculated. The score includes 13 food components (9 components encouraged, 4 to limit) with a range of 0 (low) to 5 or 10 (high). We describe the baseline cardiometabolic abnormalities and adherence with healthy diet scores and assess their correlation with PsA disease activity measures.
Results: The mean age of study participants was 53.3 years (71.9% females). The mean DAPSA, tender and swollen joint counts were 23.6, 6.6 and 1.1, respectively. A significant proportion of the patients had obesity (71.9%) and related metabolic abnormalities such as dyslipidemia (41.9%), hypertension (37.5%) metabolic syndrome (46.9%). Mean HEI-2015 was 59.3 with higher adherence scores (HEI-2015>50; 25%Q1) found in females than males (91% vs. 57%, respectively, p<0.05). No differences in HEI-2015 scores were found between age and level of education groups. Of the individual HEI-2015 food groups, the lowest adherence scores were found for whole grain and total sodium consumption (Table 1). Significant correlation was found between lower added sugar and both lower fatigue and lower PSAID scores (Figure 1), and correlation between greater whole fruit consumption and lower swollen joint count. Additionally, a correlation was found between the unsaturated than saturated fatty acids and higher enthesitis score.
Conclusion: High prevalence of metabolic abnormalities was found in patients with PsA starting a diet intervention study. Adherence with healthy diet eating recommendations at baseline was higher in female patients and individual foods, particularly sugar and whole fruit consumption, were associated with PsA measures of disease activity. The DIPSA study will determine the role of dietary interventions as adjunct therapy in PsA.

Table 1. Summary of adherence with healthy eating recommendations by Healthy Eating Index (HEI)* 2015 and its individual components (N=29); Mean±SD

HEI-2015 total score (0-100)	59.3±11.4
HEI-2015 total vegetable score (0-5)	4.2 ± 1.2
HEI-2015 total greens and bean score (0-5)	3.4 ± 1.7
HEI-2015 total fruit score (0-5)	2.7 ± 2.1
HEI-2015 whole fruit score (0-5)	2.9 ± 2.1
HEI-2015 total whole grain score (0-10)	2.9 ± 2.9
HEI-2015 total dairy score (0-10)	5.5 ± 2.6
HEI-2015 total protein score (0-5)	4.7 ± 0.7
HEI-2015 total seafood & plant protein score (0-5)	3.5 ± 2
HEI-2015 total fatty acid score (0-10)	5.6 ± 3.1
HEI-2015 total sodium score (0-10)	3.1 ± 2.9
HEI-2015 refined grains score (0-10)	6.8 ± 3.3
HEI-2015 saturated fatty acids score (0-10)	5.5 ± 3.1
HEI-2015 added sugars score (0-10)	8.6 ± 2.2

*Calculation of HEI-2015 was based on an average of self-administered dietary recalls from 3 separate weekdays (ASA24). HEI-2015 total score ranges from 0 (low) to 100 (high). Each individual component ranges from 0 (low) to 5 or 10 (high).

Figure 1: Correlation matrix of HEI (total and sub-scores) and PsA measures of activity. "X" represents p value>0.05.

aMED: adjusted Mediterranean Diet score; HEI: Healthy Eating Index; PASI: psoriasis area and severity index; PSAID: Psoriatic Arthritis Impact of Disease; Pt_PGA_Arthritis: Patient global assessment of PsA; SJC: Swollen joint count; SPARCC: total enthesitis count by SPARCC; TJC: tender joint count

HIGH PREVALENCE OF UNDIAGNOSED PSORIATIC ARTHRITIS AMONG PATIENTS WITH PSORIASIS: ALGERIAN MULTICENTER SCREENING SURVEY USING PURE4 QUESIONNAIRE AND CASPAR CRITERIA.

Keywords: Psoriatic arthritis, Epidemiology

A. Djebbari[1], A. Abi Ayad[1], S. Bennedjema[1], H. Merouan[1], S. Oulebsir[1], B. Abdelatif[1], Z. Rayhan[1], B. Saber[1], A. Noureddine[2], K. Ahmed[3], K. Rafik[4], B. Abderrachid[5]. *[1]HCA Hospital Kouba, Departement of Rheumatology, Kouba Algeria, Algeria*; *[2]Regional Hospital of Constantine, Departtement of Dermatology, Constantine, Algeria*; *[3]Regional Hospital of Bechar, Departtement of Dermatology, Bechar, Algeria*; *[4]HCA Hospital Kouba, Department of Dermatology, Kouba Algier, Algeria*; *[5]Regional Hospital of Blida, Department of Dermatology, Blida, Algeria*

Background: Psoriatic arthritis (PsA) is a polymorphic disease, in term of clinical presentation, severity and evolution. Skin lesion precedes joint damage in 84%, therefore, a multidisciplinary approach associating dermatologist and rheumatologist provide an opportunity for earlier diagnosis, more timely therapy and prevention of disability.
Objectives: To provide Algerian epidemiological data on the Prevalence of undiagnosed PsA among psoriasis patients in dermatology practice. This multicenter screening survey is conduct in order to reduce diagnostic delay and prevent progressive joint involvement and disabilities.
Methods: Between 2019 and 2022, a multicenter cross-sectional trial conducted in four Dermatology Clinics in Algeria (Algiers, Blida, Bechar and Constantine); had recruited patients presenting with plaque psoriasis and no prior rheumatologist-confirmed PsA diagnosis. Patients were screened using the Psoriatic arthritis UnclutteRed screening Evaluation (PURE4) questionnaire and were referred to a rheumatologist for assessment of PsA using classification for psoriatic arthritis criteria CASPAR if they had a PURE 4 score ≥1.Psoriasis characteristics:

Body surface area, psoriasis types, area, severity index, and psoriasis disability index tools were used for assessing psoriasis patients.

Results: The study included 212 patients with psoriasis:64% were male and 36% female. Their median age was 48.12 yr ±11.74. Referring to the type of psoriasis, 72% presented with plaque psoriasis, 16% guttata 6% pustular and 24% with psoriasis of more than one type. Nail disease appeared in 24 % and scalp disease in 26%. PURE 4 was applied to all 212 psoriasis patients; among them n = 53 (25% of all tested patients) had a score ≥1. The sequential application of PURE4 and CASPAR criteria found a prevalence of undiagnosed PsA of 20.28% [95% CI: 9, 23.5]. The PPV of PURE 4 in this setting is 49.23% [95% CI: 39, 67]. Of these patients, 44% of patients with PsA had psoriatic nail disease and scalp involvement seen in 37%. With reference to the PsA type, 30% patients presented with polyarthritis,44% with oligoarthritis,39% with enthésites, dactylitis in 23% and 13%with axial arthritis. The subgroup of patients with PsA had significantly higher rates of obesity (42%) compared to non-PsA. Patients with severe psoriasis(P = 0.001), nail and scalp involvement (P = 0.003) with chronic plaque psoriasis (P = 0.001)associated with obesity (P = 0.0001)were identified as independent positive predictors of PsA.

Conclusion: Screening for PsA in Algerian patients with psoriasis revealed a significant number of undiagnosed cases (20.28%) that should be treated early. Severe psoriasis nail and scalp involvement, and obesity are factors predicting the PsA development.

AB1158 FATIGUE IN ANKYLOSING SPONDYLITIS IS ASSOCIATED WITH DISEASE ACTIVITY BUT NOT IN PSORIATIC ARTHRITIS

Keywords: Comorbidities, Patient reported outcomes

S. Rodriguez-Muguruza[1], S. Castro Oreiro[1], M. J. Poveda[1], N. Del Castillo[1], S. Paredes[2], D. Taverner[2], R. Fontova[1]. *[1]Joan XXIII Hospital, Rheumatology, Tarragona, Spain*; *[2]Sant Joan, Rheumatology, Reus, Spain*

Background: Fatigue is a common symptom in chronic inflammatory diseases. The mechanism by which fatigue occurs is multidimensional. Previous studies suggested that several factors, including physiology, psychology and behavior, may contribute to its pathogenesis. Fatigue is considered one of the most common symptoms in patients with psoriatic arthritis (PsA) and ankylosing spondylitis (AS) with an incidence of 50–70%. Fatigue is a major factor contributing to unsatisfactory treatment outcome and poor quality of life, or even disability. Therefore, from a clinical point of view, how to improve the symptom of fatigue remains a challenge. Identifying factors related to fatigue could be a key to the management of this complex symptom.

Objectives: To compare fatigue and its associated factors in patients with PsA and AS from two university hospitals.

Methods: A cross-sectional analysis was performed in 105 patients (May – December 2022) Fatigue was assessed using 3 instruments: the fatigue subscale of the Short-form 36 survey (fatigue-SF36), the Visual Analogue scale of fatigue (VASf) and the Functional Assessment of chronic illness Therapy Fatigue Scale (FACIT-F). T-test was used to compare mean fatigue between PsA and AS patients. To determine in each patient group the relationship between fatigue (assessed by FACIT-F) and the other variables (DAPSA or ASDAS, CPR, ESR, hemoglobin, HAQ, Hospital Anxiety and depression Scale [HAD] and Brief Pain Inventory [BPI]) a Spearman correlation was performed. A value of $p < 0.05$ was accepted as statistically significant.

Results: A total of 105 patients were included, 55 (52.4%) PsA patients and 50 (47.6%) AS patients. We found that mean fatigue (using 3 instruments) had not significant differences in patients with PsA and AS (Table 1). In patients with PsA and AS, fatigue correlated to HAD, HAQ and pain, but not with CRP, ESR and hemoglobin (Table 2). In AS patients, high disease activity (assess by ASDAS) correlated with high levels of fatigue (lower levels on FACIT-F). However, in patients with PsA, fatigue and disease activity (DAPSA) were not related.

Conclusion: In PsA and AS patients, fatigue seems to be related to subjective but not with objective (analytical) variables. In patients with AS, fatigue was related to disease activity, but in patients with PsA we found no correlation.

Background: The Psoriatic arthritis UnclutteRed screening Evaluation (PURE-4), culturally adapted to Spanish language following the standardized methodology,[1]

was recommended by experts due to the reduced number of items,[2] its high sensitivity/specificity and the feasibility to implement in clinical practice.

Objectives: To confirm the presence/absence of psoriatic arthritis (PsA) according to rheumatologist criteria in patients (pts) with psoriasis (Pso) 1 year after having answered the PURE-4 questionnaire in the dermatology consultation.

Methods: Cross-sectional, observational, multicenter study conducted with primary data collection under conditions of routine clinical practice in Spain. Adult pts (≥18 years old) with Pso diagnosis that voluntarily accepted to participate. Two cross-sectional evaluations. Assessment I allowed to validate the Spanish version of the PURE-4 questionnaire and its results were previously communicated.[3] Data from assessment II (pts without PsA in assessment I were evaluated by the rheumatologist 1 year ±2 months later and performed the PsA diagnostic confirmation according to her/his criteria and collected clinical characteristics) are presented here.

Results: 268 patients pts were included in assessment I, 223 (83.2%) of them without a PsA diagnosis. 219 pts were evaluable in assessment II, as they go to the second visit to rheumatologist: 56.2% male, with a mean (SD) age of 46.8 (12.5) years, a mean (SD) time from Pso diagnosis of 18.7 (12.8) years. Mean (SD) PURE-4 score was 2.4 (1.1) for pts with PsA and 1.2 (1.2) for pts without PsA diagnosis. Among pts who did assessment II, PsA diagnosis was confirmed in 12 (5.5%) pts. Area under the receiver-operating characteristic (ROC) curve was 0.7618 (95% CI: 0.6530, 0.8706) (n=217), confirming the good quality of the questionnaire (Figure 1). Using the Youden index, it was identified a score ≥2 indicative of a possible early presence of PsA, same as in assessment I. PURE-4 questionnaire showed a sensitivity of 75.0% and a specificity of 62.9%. In 63.6% of the cases, the PURE-4 questionnaire classified pts in the same way as the rheumatologist, with a negative predictive value of 97.7%.

Conclusion: Assessment II findings together with the assessment I results, demonstrate the good PsA screening properties of the PURE-4 questionnaire, starting with a ≥2 score, differing from the original questionnaire (≥1).[4] Questions of the PURE-4 questionnaire referring to dactylitis, both buttocks pain and peripheral joint pain with swelling (before age 50) were the most "discriminative" of PsA. The study reinforce the recommendation to assess annually, or ideally every 6 months, the possible PsA presence,[5] as early PsA identification thanks to simple tools such as PURE-4 could help to prevent irreversible joint damage of this disease.

SOFT TISSUE EDEMA VISUALIZED ON MUSCULOSKELETAL ULTRASOUND AS A DIAGNOSTIC TEST FOR PSORIATIC ARTHRITIS: A PILOT COHORT STUDY

Keywords: Psoriatic arthritis, Ultrasound, Rheumatoid arthritis

T. Swami[1], S. Acikgoz[1], U. Gazel[1], C. Ivory[1], R. Chowdhury[1], A. Zahrai[1], S. Aydin[1,2], E. Hepworth[1]. [1]*University of Ottawa, Rheumatology, Ottawa, Canada*; [2]*University of Ottawa, Ottawa Health Research Institute, Ottawa, Canada*

Background: Musculoskeletal ultrasound (MSKUS) is more sensitive than physical examination to detect inflammation in extra-articular structures in psoriatic arthritis (PsA).[1] Peritendinous soft tissue edema on MSKUS has shown to be more frequent in PsA when compared to rheumatoid arthritis (RA).[1,2,3]

Objectives: Here we assess the degree of association between the presence of flexor compartment (FC) soft tissue edema and the diagnosis of PsA with the aim of developing a soft tissue score to differentiate PsA from rheumatoid arthritis (RA).

Methods: This pilot prospective cohort study included 16 PsA and 40 RA patients from the Biologics Clinic at a single centre site in Ottawa. Patients are referred to the biologics clinic if they require initiation of, or changes to their biologic disease modifying antirheumatic drug (bDMARD). In addition to demographic and clinical data, eight MSKUS images were collected from each patient including one Grayscale (GS) and one power Doppler (PD) image of the FC of the 2nd and 3rd bilateral digits using a GE LogicE9 and a linear 15 MHz probe. Images were scored on a 0-2 semiquantitative scale to assess the degree of soft tissue edema, where 0 indicates absent, 1 indicates mild, and 2 indicates severe GS or PD. Following data collection, scoring was completed by two investigators blinded to the patients' diagnosis and in random order. Consensus decision was taken as the final score.

Results: Disease characteristics are provided in table 1. On MSKUS, PsA patients had a statistically significant higher total GS score compared to RA (7.0 vs 5.0, p=0.005). We found that numerically higher number of PsA patients had PD score of 2 in ≥3 fingers (20.0% PsA vs 2.5% RA, p=0.057) and GS score of 2 in ≥3 fingers (43.8% PsA and 22.5% RA, p=0.189). [Table 1]

Table : Patient demographics and disease characteristics

RA = rheumatoid arthritis, PsA = psoriatic arthritis GS = Grayscale, PD = power Doppler, csDMARD = conventional synthetic disease modifying antirheumatic drug, bDMARD = biologic disease modifying antirheumatic drug, TJC-66 = tender joint count using 66 joint count.
*Semiquantitative score of soft tissue edema (0-2) within the flexor compartment images in 2nd and 3rd digits

Conclusion: Our results suggest a possible role for FC soft tissue edema visualized on MSKUS in both GS and PD modes to differentiate PsA from RA. It is also important to understand the impact of soft tissue edema on disease pathogenesis and patient reported outcomes. While our sample size is small, some of the tests reaching reaching statistical significance using non-parametric testing encourages us to repeat this analysis again in the future as our cohort grows. When our sample size allows, we will assess for confounding effect of seropositivity, sex, age, BMI, previous therapy, and disease duration.

RACIAL AND GENDER - BASED DIFFERENCES IN THE PREVALENCE OF METABOLIC COMORBIDITIES AMONG PSORIATIC ARTHRITIS PATIENTS

Keywords: Gender/diversity issues, Comorbidities, Psoriatic arthritis

C. R. Ng[1]. [1]*Hospital Pakar Sultanah Fatimah, Rheumatology Unit, Department of Medicine, Muar, Malaysia*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis that develops in at least 5% of patients with psoriasis. It affects women and men equally. Obesity, diabetes, hypertension and hypercholesterolemia always affect PsA patients.

Objectives: To study the gender and race effect on the prevalence of metabolic comorbidities among PsA patients in Malaysia.

Methods: This is a restrospective study. The medical records of all PsA patients under rheumatology clinic Hospital Sultan Ismail and Hospital Pakar Sultanah Fatimah follow up from 1/1/2009 to 31/12/2022 were reviewed. Data on demography, type of skin disease, joint manifestations and past medical history were obtained and analysed using Chi Square test in SPSS.

Results: We identified 226 patients. 110 were male patients (male to female ratio 0.95). The Malays (128/ 226) were the majority followed by the Chinese (57/226), Indian (38/226) and others (3/226). Most of them were plaque psoriasis (181/226). The commonest joint involvement was peripheral joint (174/226), followed by axial (25/226) and both (27/226). The prevalence of metabolic comorbidities according to gender (male vs female) were: [48/110, 44% vs 57/116, 49%; p =0.407] for hypertension, [35/110, 32% vs 37/116, 32%; p=0.990} for diabetes mellitus, [63/110, 57% vs 65/116, 56%; p= 0.851] for dyslipidemia. There was no association between gender and hypertension, diabetes mellitus and dyslipidemia. The prevalence of metabolic comorbidities according to races (Malay vs non Malay) were:[58/128, 45% vs 47/98, 48%; p=0.693] for hypertension, [40/128, 31% vs 32/98, 33%; p=0.822] for diabetes mellitus, [75/128, 58% vs 53/98, 54%; p= 0.498] for dyslipidemia. There was no association between ethnicity and metabolic comorbidities.

Conclusion: There was no difference in the prevalence of hypertension, diabetes mellitus and dyslipidemia between the gender and races in our patient cohort.

COMPARISON OF SERUM CXCL13 LEVELS BETWEEN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS

Keywords: Prognostic factors, Cytokines and chemokines, Psoriatic arthritis

D. Yildirim[1], I. Vasi[1], M. Baykul[2], M. Gulengul[3], Y. Edek[3], H. Küçük[1], H. Karadeniz[1], E. Adısen[3], A. Erden[1], A. Tufan[1], B. Goker[1], K. Nas[4], M. A. Ozturk[1]. Sakarya,Turkey; [3]*Gazi University Faculty of Medicine, Dermatology,Ankara, Turkey*; [4]*Sakarya University Education and Research Hospital, Rheumatology, Sakarya,Turkey*

Background: Psoriasis is a chronic, autoimmune disease with predominantly skin and joint involvement. Factors leading to the progression of psoriasis to psoriatic arthritis (PsA) is still a mystery in spite of an increasing number of in vivo and in vitro studies. CXCL-13, a B cell chemokine, studied and emphasized in lymphoid pathways, immune responses and pathogenesis of many rheumatologic diseases [1-2]. Moreover, this chemokine is associated with systemic involvement of rheumatic diseases such as lupus nephritis [3].
Objectives: The aim of the study was to evaluate serum CXCL 13 levels in patients with psoriasis and psoriatic athritis and compare with healthy controls.
Methods: 54 patients with psoriasis and 47 patients with psoriatic arthritis and 19 controls were enrolled to the study. Blood samples from study participants were collected and serum CXCL-13 levels were analysed with ELISA method via Human BLC(CXCL 13) kit (BT Lab, Shangai, China).
Results: Age, body mass index and serum PASI scores were similar between two patient groups; but higher when compared to controls (Table 1). Median levels of CXCL-13 levels were significantly higher in patients with psoriatic arthritis and psoriasis when compared to control group (p= 0,001, Figure 1). But serum CXCL-13 levels were similar between psoriasis and psoriatic arthritis groups (p=0,251). Also levels of C reactive protein and sedimentation were higher in patients with psoriatic arthritis, followed by psoriasis and controls (p= 0.024 and 0.02, in order).
Conclusion: Many clinical studies showed that CXCL13 expression is elevated in many autoimmune conditions and related to activity, prognosis and symptomatic status of disease [4]. Also in SLE, this chemokine was associated with extraarticular involvement of disaese [5]. Also previous studies reported increased levels of serum and tissue CXCL-13 in psoriasis and associated with disease severity [6]. We conclude that serum levels of CXCL-13 is associated with psoriasis, but not related with articular involvement.

INVESTIGATION OF SELECTED AUTOANTIBODIES IN PSORIATIC ARTHRITIS AND THEIR ASSOCIATION WITH COMORBIDITIES

Keywords: Psoriatic arthritis, Autoantibodies, Comorbidities

A. K. Inderthal[1], A. Knothe[1], K. Frommer[1], C. Heck[1], M. Arnold[1], I. Tarner[1], W. Hermann[1], C. F. Meneses Villalba[1], U. Müller-Ladner[1], R. Hasseli[1,2], E. Neumann[1]. [1]*Kerckhoff-Klinik, Rheumatology and Clinical Immunolgy, Bad Nauheim, Germany*; [2]*Münster University Hospital, Internal Medicine D, Section of Rheumatology and Clinical Immunolgy, Münster, Germany*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory joint disease. It can result in severe joint destruction and cardiac or pulmonary involvement. So far, no specific autoantibodies have been identified that would simplify the diagnosis of PsA. HLA-B27 positivity is only detectable in 20% of PsA patients. It still takes several years until a diagnosis is established, which is crucial for the treatment. In addition, the disease is associated with a higher body mass index (BMI) and cardiovascular risk.
Objectives: The aim of the study was to identify possible PsA-associated autoantibodies which might enable earlier diagnosis, and to investigate possible associations of these selected autoantibodies with specific comorbidities.
Methods: Both, PsA patients and healthy individuals without known autoimmune disease were included in the study. Sociodemographic data (age, sex, BMI, waist circumference), current disease activity, current rheumatological therapy, cardiovascular diseases and fatigue were investigated. HLA-B27 status was determined and a radiological evaluation of PsA-typical changes in the hands and feet was performed. Serologically, antibodies against ADAMTSL-5, LL37, calpastatin and gliadin were investigated by ELISA.
Results: A total of 107 PsA patients (60% female) and 19 healthy controls (HC) were included. Median age of PsA patients was 59 years (21-80 years), 28% were HLA-B27 positive. Median BMI was 28 kg/m2 (19-48 kg/m2). Cardiovascular disease was present in 65% of patients, which included the following conditions: arterial hypertension, atherosclerosis, heart failure, coronary heart disease (CHD) and myocardial infarction. Antibodies to LL37 were present in 47% of patients compared to 30% of healthy individuals. Antibodies to ADAMTSL-5 were detectable in 47% of patients and 35% of healthy individuals. Calpastatin antibodies were present in 23% of patients and 11% of healthy individuals and against gliadin in 3% of patients and 5% of healthy individuals. In patients with antibodies against LL37, antibodies against ADAMSTL-5 could also be detected in most cases (p< 0.001). In patients with a treatment duration of <5 years more frequently antibodies against calpastatin were detectable compared to those with longer treatment duration (p<0.05).
Conclusion: In summary, none of the antibodies investigated were found to be significantly elevated in PsA-patients compared to HC. However, in the group of patients with a treatment duration <5 years, autoantibodies against calpastatin were detected more frequently. This could suggest that this autoantibody might play a role in the early phase of PsA and immunomodulatory treatment might diminish autoantibody levels.

AB1164 PSAQOL (PSORIATIC ARTHRITIS QUALITY OF LIFE) QUESTIONNAIRE: TRANSLATION, CULTURAL ADAPTATION AND VALIDATION INTO ARABIC LANGUAGE

Keywords: Quality of life, Psoriatic arthritis

R. Tekaya[1], L. Rouached[1], H. Hajji[1], A. Ben Tekaya[1], M. Jones[2], W. Hamdi[3], S. Nabil[4], L. Metoui[5], S. Bouden[1], O. Saidane[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia*; [2]*Charles Nicolle Hospital, Dermatology, Tunis, Tunisia*; [3]*Kassab Institute, Rheumatology, Tunis, Tunisia*; [4]*Faculty of Pharmacy, Immunology Department, Monastir, Tunisia*; [5]*Military Hospital of Tunis, Rheumatology, Tunis, Tunisia*

Background: Psoriatic arthritis (PsA) is a multifaceted inflammatory disease that has a strong negativeimpact on the quality of life of patients. The Psoriatic Arthritis Quality of Life (PsAQoL)questionnaire was the first disease-specific patient derived instrument developed tomeasure the quality of life in patients with PsA.
Objectives: Our objective was to translate the PsAQol into Arabic language and evaluate its reliability and validity in patients with PsA.
Methods: This was a cross-sectional study including patients with PsA. A clinical and biologicalassessment of the patients was performed at inclusion. Translation of the original PsAQoL into Arabic was performed by professional bilingual and lay panel. Eight patients wereinterviewed to assess face and content validity. A separate sample of PsA patients (n=30)were invited to participate in a test-retest postal study in order to investigate reproducibilityand construct validity. One week separated the two administrations. The Arabic versionof Health Assessment Questionnaire (HAQ) was used as comparator instruments forconvergent validity.
Results: Face and content validity were satisfactory. The Arabic version of the PsAQoL was foundto be relevant, understandable and easy to complete in only a few minutes. One item wasexcluded (item 16). It showed having no correlation with neither the other 19 items nor the total score of PsAQol. The Arabic PsAQol had excellent internal consistency (Cronbach'sa=0.926), and test-retest reliability (r=0.982). There was a positive correlation betweenthe total score of the PsAQoL and the Arabic version of HAQ ((Spearman's r=0.838,p<10-3). Exploratory factor analysis had extracted two factors explaining 55% of the totalvariance.
Conclusion: Nineteen items were selected to compose the Arabic version of PsAQoL which was foundto be relevant, understandable and has excellent reliability and construct validity. The newmeasure will be a valuable new tool for use in routine for patients' assessment.

AB1165 ULTRASOUND AS A TOOL FOR EARLY DETECTION OF JUXTAARTICULAR NEW BONE FORMATION IN PSORIATIC ARTHRITIS AND THE ASSOCIATION OF SELECTED BIOMARKERS WITH NEW BONE FORMATION

Keywords: Psoriatic arthritis, Autoantibodies, Ultrasound

A. Knothe[1], K. G. Hermann[2], K. Frommer[1], A. K. Inderthal[1], C. Heck[1], M. Arnold[1], I. Tarner[1], W. Hermann[1], C. F. Meneses Villalba[1], E. Neumann[1], U. Müller-Ladner[1], R. Hasseli[1,3]. [1]*Kerckhoff-Klinik, Rheumatology and Clinical Immunology, Bad Nauheim, Germany*; [2]*Charité – Universitätsmedizin Berlin, Radiology, Berlin, Germany*; [3]*Münster University Hospital, Section of Rheumatology & Clinical Immunology, Münster, Germany*

Background:
Objectives: To investigate whether the new bone formation (NBF) that is typical of psoriatic arthritis (PsA) can also be detected by ultrasound. In addition, we aimed to investigate whether the presence of NBF and specific autoantibodies could facilitate an earlier diagnosis of psoriatic arthritis.
Methods: Patients fulfilling the CASPAR criteria (Classification Criteria for Psoriatic Arthritis) for PsA were included in the study. X-ray examinations of the hands and feet and standardized ultrasound examination of the hands and feet was performed. Antibody levels of calpastatin, LL37, gliadin, and ADAMTSL5 (Thrombospondin type-1 domain-containing protein 6) were determined by serum ELISA.
Results: Seventy-six patients (51% female) compared to 20 healthy controls (70% female) were included. The median age was 57 years (23-86) and the median disease duration was 10 years (1-54). HLA-B27 was positive in every fourth individual. By X-ray, NBFs were detectable in 55% (n=42) of the patients. In the ultrasound examination, these NBFs were also detectable (Figure 1). In addition, in 18 patients, signs of NBF were detectable due to the increased resolution of the ultrasound examination. Regarding the selected autoantibodies, none of the selected antibodies were associated with the presence of PsA or with PsA related NBFs.
Conclusion: In this study, NBFs were detectable radiographically as well as in the ultrasound examination. As ultrasonography is ubiquitously available in rheumatological offices and represents a gentle examination procedure for the patient, repeated X-ray examinations might be avoided, and regular ultrasound investigations might facilitate an earlier detection of PsA.

AB1166 RANDOMIZED CONTROLLED TRIAL TO ANALYSE THE EFFECT OF BLOOD FLOW RESTRICTION TRAINING IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS COMPARED TO CONVENTIONAL RESISTANCE TRAINING – AN INTERIM ANALYSIS

Keywords: Rheumatoid arthritis, Psoriatic arthritis, Non-pharmacological interventions

C. J. Bauer[1], M. Sturhahn[1], C. Behning[2], S. Petzinna[1], P. Brossart[1], P. Preuss[3], V. Schäfer[1]. [1]*University Hospital Bonn, Clinic of Internal Medicine III, Department of Oncology, Haematology, Rheumatology and Clinical Immunology, Bonn, Germany*; [2]*University Hospital Bonn, Department of Medical Biometry, Informatics and Epidemiology, Bonn, Germany*; [3]*University Bonn, University Sports Division, Bonn, Germany*

Background: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are the two most common forms of arthritis with a prevalence of 1% and 0.5% in Europe. Physical activity exerts a major influence on disease activity, symptoms, quality of life, and increased cardiovascular risk [1,2]. In contrast to conventional strength training, Kaatsu blood flow restriction (BFR) training, which was initially developed in Japan as a rehabilitation measure, incorporates pneumatic cuffs

applied to the extremities, which are recurrently inflated with a defined pressure. The inherent blood flow modification promises a less weight-intensive and thus joint-protective strength training, while still preserving sufficient muscular hypertrophy stimulus [3].

Objectives: Ours is the first study in the world to compare the effect of Kaatsu blood flow restriction training to conventional resistance training in RA and PsA patients.

Methods: In this pilot study (ethical approval under Institutional Review Board #217/20), 40 RA and 40 PsA patients are individually randomized to one of three groups: Kaatsu-BFR training (20 patients each), conventional resistance training "CRT" (10 patients each), or the non-exercise group (10 patients each). Training is performed twice weekly over a 12-week period. Standardized recording of disease activity (via FFB-H-P, IPAQ, and DAS 28 or PSAID12, plus clinical examination and CRP), myokine levels, sonographic muscle diameter measurements, bioimpedance analysis and clinical characteristics is performed.

Results: The interim analysis of 9 BFR vs. 4 CRT patients with rheumatoid arthritis showed comparable CRP reduction (mean ± SD: BFR: -1.08 mg/L ± 1.33, CRT: -0.89 mg/L ± 1.94) and reduction in the number of painful joints (mean ± SD: BFR: -0.78 ± 2.44, CRT: -0.76 ± 1.71) during the training period. BFR group results surpassed CRT group results in terms of weight loss (mean ± SD: BFR: -2.9 kg ± 3.6, CRT: -1.9 kg ± 3.1) and body fat mass reduction (mean ± SD: BFR: -2.8 kg ± 5.3, CRT: -0.3 kg ± 2.5). The interim analysis of 4 BFR vs. 4 CRT patients with psoriatic arthritis showed a comparable PSAID reduction (mean ± SD: BFR: -5.1 ± 12.1), CRT: -4.3 ± 9.0) during the training period. BFR group results exceeded CRT group results with regards to CRP reduction (mean ± SD: BFR: -0.15 mg/L ±0.91, CRT: 1.27 mg/L ±2.7), weight loss (mean ± SD: BFR: -2.4 kg ±1.7, CRT: +1.3 kg ±0.7) and body fat mass reduction (mean ± SD: BFR: -2.5 kg ±1.2, CRT: +0.6 kg ±1.0).

Conclusion: These results provide preliminary evidence that 12-week Kaatsu blood flow restriction training exerts a positive effect on disease activity parameters in patients with arthritis. Furthermore, BFR training shows comparable, in parts even more favourable results than CRT, suggesting it as an effective alternative to conventional strength training. Completion of the study data set is expected in March 2023.

AB1167 PREVALENCE OF OBESITY AND EVALUATION OF THE WAIST CIRCUMFERENCE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS IN A HOSPITAL.

Keywords: Psoriatic arthritis, Comorbidities, Rheumatoid arthritis

G. Albaladejo Paredes[1], A. Perez Gonzalez[1], E. Monleon Acosta[1], J. Moreno Morales[1], F. J. Rodriguez Martinez[1], M. R. Oliva Ruiz[1], E. Soriano Navarro[1], A. Uceda Galiano[1], J. M. Andreu Ubero[1], J. León Navarro[1], R. Gimenez Andreu[1], F. Pedrero Martínez[1], V. Cogolludo Campillo[1]. [1]*Hospital General Universitario Santa Lucía, Rheumatology, Cartagena, Spain*

Background: Obesity is a condition characterized by a chronic state of low-grade inflammation due to increased cytokine production in visceral adipose tissue [1].Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PSA) are both autoimmune diseases that share comorbidities such as a high prevalence of obesity, a comorbidity that leads to a lower response to treatment with biologic drugs such as Anti-TNFs [2]. PSA has a higher prevalence of abdominal obesity to RA according to some recent studies [3]. Current research has shown that excess adiposity contributes to the development of cutaneous psoriasis in some patients and suggests that obesity may also be a key factor in the transition from cutaneous psoriasis to arthritis [4], however, it has not been proven the etiological role of obesity in RA [5].

Objectives: To evaluate the waist circumference (WC) and the prevalence of obesity using the Body Mass Index (BMI) in a sample patients from the same hospital with a diagnosis of RA and PSA and to analyze the differences between both diseases.

Methods: It has been carried out an observational, retrospective, single center study. The population included in the study were patients from rheumatology clinic with a diagnosis of RA and PSA who were being treated with biological treatment. The variables analyzed were: age, sex, height (m), body mass (Kg) and WC (cm). The anthropometric variables were measured in the rheumatology nursing clinic. An anthropometric tape was used to measure the WC, taking the height of the navel as a reference in the patients. The BMI was calculated and the World Health Organization classification was used to categorize the patients. A descriptive analysis of the variables analyzed in the study was performed, including the mean and standard deviation (SD) of the continuous quantitative variables (BMI and WC). A one-factor ANOVA was performed to analyze the differences in the variables age, BMI, and WC between RA and PSA patients. Statistical significance was set a priori at $p<0.05$.

Results: In this study a total of 245 RA and 122 PSA patients were included. The WC and BMI data of only 207 patients (121 with RA and 86 with PSA) were completed. The patients with PSA showed higher values of WC, observing significant differences with the patients with RA (103.66±15.05 cm vs 99.38±14.90 cm, p=0.04). However both patients with PSA and with RA showed WC measurements above the recommended values (74.41% vs 74.38%). Regarding BMI, patients with PSA had a higher mean BMI (31.29±6.37 cm vs 28.85±5.84 cm, p<0.043) than patients with RA.

Table 1. Descriptive analysis.

	RA	PSA
N=207	121	86
Age (Mean±SD)	57,31±13,01	56,03±10,74
Sex	26 men (21,5%) 95 women(78,5%)	33 men(38,37%) 53 women (61,63%)
BMI (Mean±SD; min-máx)	28,85±5,84; 18,00-53,78	31,29±6,37; 19,00-49,15
WC (Mean±SD; min-máx)	103.66±15.05; 100,44-106,89	99.38±14.90; 96,70-102,06
WC		
• Men ≥ 102 cm	18 (69,23%)	19 (57,57%)
• Women ≥ 88 cm	72 (75,78%)	45 (84,90%)

Conclusion: In the present study, patients with PSA showed stadistical differences and had higher values of WC and BMI compared to patients with RA, coinciding with recent studies. More studies are necesary to characterize obesity in patiens wih RA and PSA and treat it adequately.

AB1168 AXIAL INVOLVEMENT IN PSORIATIC ARTHRITIS: WHAT PARTICULARITIES?

Keywords: Psoriatic arthritis, Enthesitis, Disease-modifying drugs (DMARDs)

H. Bara[1], A. Rafi[1], F. E. Bennani[1], A. Mougui[1], I. El Bouchti[1]. [1]*University Hospital Mohammed VI Marrakech, Rheumatology, Marrakech, Morocco*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory rheumatism belonging to the spondyloarthritis. It is characterised by a heterogeneous clinical presentation.
Objectives: The aim of our work is to evaluate the characteristics of axial involvement in RPso.
Methods: Retrospective study of 86 patients followed for RPso in the rheumatology department over a period of 7 years from 2014 to 2021. The patients were divided into 2 groups: group 1 (RPso with axial involvement) and group 2 (RPso without axial involvement).
Results: Our study involved a population of 86 patients with RPso, the average age was 44.7 years with a female predominance (58.6%), 16.1% of the patients were diabetics, 9.3% were hypertensive, 9.3% were smokers and 2.4% had a history of psoriasis in the family. Concerning the clinical manifestations, 95.3% of patients had polyarthralgia, 73.3% had polyarthritis, 29.4% had deformities and 86% had axial involvement. The bivariate analysis allowed us to identify the results summarised in the following Table 1:

Table 1.

	Group 1 (74 patients)	Group 2 (12 patients)	P value
Women (%)	63.5	33.3	**0.04**
Duration of evolution (years)	8.07	3.5	**0.012**
Psoriasis (%)	39.1	25	0.3
Polyarthralgias (%)	95.9	91.6	0.2
enthesic syndrome (%)	37.5	68.8	0.08
Dactylitis (%)	6.7	41.6	**0.003**
BASDAI >4	72.97	41.6	**0.03**
Average CRP	28.7	50.6	**0.032**
NSAIDs (%)	40.5	75	**0.026**

Logistic regression analysis identified that patients with axial involvement were more likely to have a longer duration of evolution (OR = 3.5) and elevated CRP (OR = 4.9).

Conclusion: Axial involvement in our study was present in 86 % of the patients and was associated with a long.
duration of evolution and a statistically significant higher average CRP.

AB1169 THE PRESENCE OF PSORİASİS MIGHT INCREASES STRUCTURAL DAMAGE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Psoriatic arthritis

H. Cinakli[1,2], D. Solmaz[2], E. Durak Ediboglu[2], E. Otman Akad[2], G. Alp[2], E. Erpek[2], İ. Kurut Aysin[2], A. Özkan[2], H. Kocaayan[2], S. Gucenmez[2], S. Ketenci[2], M. Ozmen[2], S. Akar[2]. [1]*Kırklareli Educational and Research Hospital, Rheumatology, Kırklareli, Turkey*; [2]*İzmir Katip Çelebi University, Faculty of Medicine, Rheumatology Division, İzmir, Turkey*

Background: Psoriasis is one of the most common extra-articular involvement in axial spondyloarthritis (axSpA) patients.
Objectives: To examine the effect of the presence of psoriasis on the clinical and radiological features of patients with axSpA.
Methods: In this single-center study, 657 axSpA patients (mean age; 39.9±11.7, male gender n:411 [62,7%,]) were included in this analysis, according to the criteria of the Assessment of Spondyloarthritis International Society (ASAS). In addition to the initial demographic, clinical and radiological characteristics of the patients, radiological damage and progression were also evaluated. Demographic and disease-related characteristics were reviewed according to the presence of psoriasis.
Results: In total 43 (6.5%) patients with axSpA had psoriasis. While patients with psoriasis had a higher mean age (44.8±12.4 vs 39.6±11.5; p:0.008), their gender distribution was similar (Table 1). According to the ASAS definition, positive family history (55.6% vs 24.5%; p<0.0001) and basal biological use (41.9% vs 25.9%; p:0.023) rates were also higher in psoriasis patients. While activity scores were found to be similar in patients with and without psoriasis; in the psoriasis group, patient-reported outcome measures (night and general low back pain) and function (BASFI) scores were found to be significantly higher. In addition to the presence of basal cervical (50% vs 31.6%; p:0.032), basal lumbar syndesmophytes (40% vs 18.8%; p<0.006), new syndesmophyte development in the lumbar spine (53.3% vs 10.1%); p<0.0001) rate was higher in axSpA patients with psoriasis. Although the baseline mSASS scores were higher in these patients, the difference did not reach statistical significance. There was no difference between the groups in terms of hip involvement frequency and progression.
Conclusion: Presence of psoriasis might contribute significantly to structural damage and function in axSpA patients, independent of activity.

Table 1. Demographic, some clinical and laboratory characteristics as well as structural characteristics of patients with axial spondyloarthritis with and without psoriasis

	Psöriasis (+) axSpA patients n:43	Psöriasis (-) axSpA patients n:614	*P*

Osteoarthritis

AB1170 TRANSCUTANEOUS VAGUS NERVE STIMULATION AS A PAIN MODULATOR IN KNEE OSTEOARTHRITIS

Keywords: Osteoarthritis

G. G. Elsehrawy[1], M. E. Ibrahim[1], N. A. Moneim[1], M. Hefny[1], N. Elshaarawy[1]. [1]*Suez Canal University, Physical Medicine, Rheumatology and Rehabilitation, Ismailia, Egypt*

Background: We no longer consider Osteoarthritis (OA) as a degenerative disease, but rather as a multifactorial disorder in which low grade, chronic inflammation has a central role. In addition, evidence points to the presence of both peripheral and central nervous system sensitization as sources of pain in OA. Transcutaneous Vagus Nerve Stimulation (tVNS) has shown efficacy on pain, inflammation and central sensitization in other conditions such as fibromyalgia, pelvic pain, and headaches and therefore we hypothesized that tVNS could be an additional line of management for knee OA.
Objectives: To assess the efficacy and safety of tVNS on nociceptive pain, central sensitization, neuropathic pain, depression, anxiety, and physical function in individuals with knee OA.
Methods: Afferents of the auricular branch of vagus nerve were stimulated using an auricular electrode connected to a transcutaneous electrical nerve stimulation (TENS) device. We conducted 30 minutes session once a day for 3 days per week for 12 weeks. Sixty-eight patients with chronic knee OA were allocated randomly into active and sham group (34 patients in each group). The outcome measures included visual analogue scale (VAS), pressure pain threshold (PPT), PainDETECT and Douleur Neuropathique 4 (DN4) questionnaires, hospital anxiety and depression scale (HADS), and knee injury and osteoarthritis outcome score (KOOS). These outcome measures were assessed at baseline, at the end of the stimulation period then after 4 weeks later.
Results: There was a significant improvement in VAS for pain score in the active tVNS group between the baseline and first follow-up visit, and between the baseline and second follow-up visit (P <0.001). The median VAS improvement was 4.0 (3.0 – 5.0) in active group versus 1.0 (1.0 – 2.0) in sham group (p <0.001). PPT in right knee, left knee and right elbow was significantly improved compared to baseline in active tVNS and maintained till 4-weeks post-intervention. On the other hand, in the sham group tVNS, right knee PPT was improved but not maintained. PainDETECT and DN4 questionnaires were statistically improved in active tVNS (p <0.001). In contrast, DN4 questionnaire showed no improvement at all and PainDETECT showed improvement that was not maintained at the end of follow up in sham group. A statistically significant improvement in HADS immediately post intervention in active and sham tVNS (p <0.001), this improvement was maintained only in the active group 4 weeks after intervention. Regarding functional outcomes, the improvement in KOOS was significant in the active group only (31.44 ± 18.49, p > 0.001). No serious adverse events were reported in both study groups.
Conclusion: This study provides preliminary evidence for the beneficial effects of tVNS in OA and raises the possibility of using neuromodulation as an add-on treatment to existing pharmacological and non-pharmacological measures.

AB1171 BARRIERS AND ENABLERS TO UPTAKE OF EVIDENCE-BASED ONLINE EXERCISE TREATMENTS FOR OSTEOARTHRITIS

Keywords: Non-pharmacological interventions, Telemedicine, Osteoarthritis

A. Bhardwaj[1,2], P. Hayes[2,3], J. Browne[4], S. Grealis[4,5], D. Maguire[6], J. O'hora[7], I. Dowling[8], N. Kennedy[1,2], C. Toomey[1,2]. [1]*University of Limerick, School of Allied Health, Limerick, Ireland*; [2]*University of Limerick, Health Research Institute, Limerick, Ireland*; [3]*University of Limerick, School of Medicine, Limerick, Ireland*; [4]*University of Limerick, Patient Representative, MPACT Steering Committee, Limerick, Ireland*; [5]*University College Dublin, EULAR Centre of Excellence, Centre for Arthritis and Rheumatic Diseases, Dublin Academic Medical Centre, Dublin, Ireland*; [6]*National Orthopaedic Hospital Cappagh, Physiotherapy Department, Dublin, Ireland*; [7]*Community Healthcare West, Community Healthcare West, Roscommon, Ireland*; [8]*Ian Dowling Physiotherapy Clinic, Ian Dowling Physiotherapy Clinic, Limerick, Ireland*

Background: Research suggests that delivering evidence-based exercise treatments (ET) for osteoarthritis (OA) online may improve healthcare access and quality of care (de Thurah et al. 2022). Further, such evidence-based online ET were found to be effective and comparable to evidence-based face-to-face ET (Cottrell et al. 2017). Understanding the barriers and enablers of people with OA (PwOA) and physiotherapists (PTs) to uptake of evidence-based online ET may inform efforts to encourage and successfully implement evidence-based practice in routine care for OA.
Objectives: To identify the barriers and enablers of PwOA and PTs to uptake of evidence-based online ET for OA, and to explore the influence of demographics on top-rated barriers and enablers.
Methods: An online survey was circulated to PwOA and PTs in Ireland from March-September 2021. Data items were sought for demographics, and barriers and enablers to evidence-based online ET for OA. Data analysis was performed using frequency distributions to illustrate demographics and the most frequently reported barriers and enablers. Multivariable logistic regression was used to explore the influence of demographics on top-rated barriers and enablers.
Results: 240 stakeholders responded (PwOA=86; PTs=154). PwOA barriers and enablers were related to personal beliefs (e.g., "Preference to wait until I can access face-to-face treatment") and service delivery (e.g., "Improved Wi-Fi and bandwidth"). PT barriers and enablers were related to patient characteristics (e.g., "Patients lack IT resources or knowledge) and organisational readiness (e.g., "Improved IT infrastructure in clinic (e.g., laptops, webcams)"). PTs uptake of evidence-based online ET for OA may be significantly influenced by their work setting (p < 0.05).
Conclusion: Barriers and enablers of PwOA and PTs influencing uptake of evidence-based online ET for OA were related to personal beliefs, service delivery, patient characteristics, and organisational readiness. Future research should examine whether implementation strategies addressing these factors improve uptake and evidence-based practice.

AB1172 SHINS MUSCLE DYSFUNCTION IN FEMALE PATIENTS WITH KNEE OSTEOARTHRITIS

Keywords: Pain, Osteoarthritis

L. Shvets[1], V. Novoseletskyi[2], I. Shapoval[1], L. Perebetiuk[1], V. Khomenko[1], M. Stanislavchuk[1]. [1]*National Pirogov Memorial Medical University, Vinnytsya, Internal Medicine #1, Vinnytsia, Ukraine*; [2]*Communal nonprofit enterprise "Vinnytsya Regional Clinical Hospital named after N. I. Pirogov Vinnytsia Regional Council", Regional Centre of Nephrology and Dialysis, Vinnytsia, Ukraine*

Background: Knee osteoarthritis (OA) is a chronic disease known as a common source of pain and disability globally. OA is among the top 10 causes of physical disability in the elderly population. Loss of muscle mass and lower extremity muscle dysfunction are independently associated with progression of OA and reduction in health status.
Objectives: The investigation was aimed at studying the condition of flexor/extensor shin muscles in patients with knee OA, serum leptin concentrations and analyze correlations between them by statistical methods.
Methods: The study involved 71 patients with knee OA and 32 persons from the control group. There was measured the isometric strength of the flexor/extensor shin muscles and measured leptin serum levels. Muscle strength was measured by using an isokinetic device, approved by a state enterprise "Ukrainian Intellectual Property Institute" (patent #81950). All patients were performed common clinical investigations (complaints, medical history, physical examination data) laboratory, instrumental (knee joint X-ray) examinations, and statistical analysis methods were used.
Results: : It was established that the age of OA patients included in the study ranged from 30 to 76 years and averaged 57,60 ± 11,69 years, and 32 % of the examined patients had had the history disease from 6 to 10 years, and 90,4 % of them suffered from excessive body weight or obesity of a certain degree. The study of maximal isometric force of flexor/extensor muscles of both shins revealed a significant reduction in the muscle strength in OA patients compared

with the individuals from the control group. Thus, apparently healthy individuals had the strength of shin flexor muscles (min-max) within 9,6 – 16,9 kg, while the extensors muscles showed 12,6 – 22,5 kg. The OA patients had the strength of both shin muscle groups within the range of 0,7 – 12,1 kg for the flexor group, and 3,3 – 20,3 kg for extensor muscles. At the same time, like in the control group, the strength of the extensor muscles appeared to be higher than the one of the flexors. The calculated total muscle strength (the sum of the flexor and extensor muscle strength of both limbs) in OA patients was 31,97 ± 9,2 kg, whereas in the apparently healthy persons it was 58,65 ± 6,59 kg (p <0,001). The calculated specific muscle strength (the ratio of the total strength to the patient's BMI) in OA patients was 1,03 ± 0,32 kg against 2,21 ± 0,24 kg in the control group (p <0,001). The above data suggest that OA patients were characterized by a decrease in specific muscle strength, not only in total muscle strength. The total force of muscles of patients in relation to healthy individuals was 1,8 times less, the specific force was less 2,2 times. Using the correlation analysis, we established that there was no correlation between the total muscle strength and OA patients` blood leptin (r = -0,05, p>0,05), however, an inverse correlation between the specific force muscle and leptin concentration (r = -0,2, p = 0,09) was found. Instead, in the control group a statistically unreliable direct correlation between the total muscle strength and leptin level (r = 0,12, p>0,05), and the inverse statistically significant association between the specific strength and the leptin concentration (r = -0,412, p<0,05) were revealed. Such an inverse correlation undeniably suggests that the negative effect of leptin on the condition of muscle tissue and the blood elevation thereof is associated with a decrease in muscle strength. At the same time, a significantly lower coefficient of correlation between leptin concentrations and the specific strength of patients` muscles indicates that, in addition to leptin, the disease itself (OA) makes a significant contribution to the reduction of muscle strength.

Conclusion: Understanding the role of the flexor/extensor shin muscles dysfunction in the pathogenesis of knee OA may help to improve further management approaches.

AB1173 PARAFFIN BATH REDUCES PAIN IN PATIENTS WITH HAND OSTEOARTHRITIS

Keywords: Osteoarthritis, Non-pharmacological interventions, Clinical trials

F. De Azevedo[1], A. Souza Filho[1], R. Nunes[1], C. R. Silveira[2], J. E. Fonseca[3], F. A. Castro Rocha[1]. [1]*Faculdade de Medicina da Universidade Federal do Ceara, Internal Medicine, Fortaleza, Brazil*; [2]*Instituto Sao Carlos de Medicina e Pesquisa, Radiology, Fortaleza, Brazil*; [3]*Centro Hospitalar Universitário Lisboa Norte, Instituto de Medicina Molecular, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Portugal, Rheumatology, Lisboa, Portugal*

Background: In addition to the lack of disease modifying treatments in osteoarthritis (OA), there is also a need for safer and efficacious treatments for pain relief. Patients with hand osteoarthritis (HOA) experience pain that can be incapacitating, which is usually unresponsive to painkillers. Non-pharmacological alternatives are an interesting option for pain relief in HOA.

Objectives: to demonstrate that paraffin baths (PB) provide safe, significant, clinically meaningful pain relief in HOA patients.

Methods: (CAAE:07360819930015045) 67 patients with HOA diagnosis according to ACR criteria were prospectively recruited from March 2020 to August 2022 (interruptions due to COVID pandemic) in private rheumatology services and randomized to receive either 20 min daily sessions of PB, 3 times/week for 4 weeks or a leaflet with information for protection of hand joints (control, C). Baseline demographic, clinical and radiographic (Kellgren-Lawrence, KL score) data were registered. The evaluator was blinded to group allocation. Primary endpoint was 15% reduction of pain on movement (0-10 VAS, visual analogue scale) in the most affected joint of the hand at baseline as compared to pain value at 4w; secondary endpoints were sustained pain reduction at 12w as compared to baseline, increase in grip and pinch strength (KgF) as well as improvement in Cochin hand functional scale (CHFS), FIHOA, and SF-12 scores at 12w as compared to baseline.

Results: baseline characteristics of 34 paraffin and 33 control patients are shown in Table 1; three patients in each group did not return for follow up at 4 weeks; median disease duration was 58(range 3-360) months in both groups; Primary outcome was reached: baseline pain in PB (7.8±1.9) was reduced to 6.4±2.7 (p<0.017) whereas baseline pain in C (7.1±1.8) was not significantly reduced at 4w (6.9±1.9; p=0.7067); reduction of pain in PB was significantly sustained at 12w (6.3±2.9) (p=0.0196). Grip and pinch strength as well as CHFS, FIHOA, and SF-12 scores were similar both at baseline and at 12 weeks in both groups. There were no major adverse events.

Table 1. Baseline characteristics

	Control	PB	P value
Age	60±9	59±10	ns
Women	31(94)	32(94)	ns
BMI	26.6±4	28±5	ns
Month Family income <900 US$	14(42)	21(61)	
K-L>2	24(72)	26(76)	ns
CRP (mg/dL)	0.27±0.19	0.56±0.9	0.123

67 patients were randomized to PB or control treatment; data are mean(%) or SD; ns, non-significant.

Conclusion: PB in a single-blinded prospective randomized trial provided early and sustained pain reduction in HOA. Although larger trials are needed, we believe that spreading of this cheap, easy-to-use method, should be encouraged.

AB1174 BODY COMPOSITION IN POSTMENOPAUSAL WOMEN WITH CHRONIC KNEE PAIN

Keywords: Pain, Osteoarthritis

N. Grygorieva[1], N. Zaverukha[1], A. Musiienko[1], M. Bystrytska[1]. [1]D. F. Chebotarev Institute of Gerontology, NAMS of Ukraine, Clinical Physiology&Pathology of Locomotor Apparatus, Kyiv, Ukraine

Background: Among all the known risk factors, obesity is one of the important risk factors for the incidence and prevalence of osteoarthritis (OA). However, body mass index (BMI), which reflects the severity of obesity, measures only height and weight with no consideration of other obesity-related characteristics, such as fat distribution or deposition. The features of fat deposition and distribution may serve as better indices of the metabolic activity of adipose tissue and can have an important influence on the pain and disability of patients with OA.

Objectives: The study aimed to assess the body composition indices in postmenopausal women with chronic knee pain and its association with pain severity.

Methods: In the single-center study 230 females aged 50-89 years were examined and divided into groups depending on the intensity of chronic (>3 months) knee pain. Knee pain was assessed using the visual analog scale (VAS). Group I consisted of females with mild (VAS < 4 cm) pain (n = 87), group II - subjects with moderate (VAS more than 4, but less than 6 cm) pain (n = 111), and group III - women with severe (VAS ≥ 6 cm) pain (n = 33). The body composition (body weight (BW), height, body mass index (BMI), fat mass (FM), lean mass, appendicular lean mass (ALM) and appendicular lean mass index (ALMI, ALM/height), fat content (fat mass/BW), and ALM/BW) were assessed by dual-energy X-ray absorptiometry (Lunar, Prodigy). Sarcopenia was determined according to ALM (< 15 kg) or ALMI (< 6 kg/m2), obesity - as BMI > 30 kg/m^2, sarcopenic obesity as a combination of high-fat mass/BW (> 40 %) and low ALM/BW (< 23.47 % for females younger than 65 years old and < 19.4 % for females 65 years and older).

Results: All three groups did not significantly differ in age (F = 2.5, p > 0.05), age of menopause (F = 0.6, p > 0.05), and its duration (F = 0.4, p > 0.05). Women of different groups did not differ in height, however, BW was higher in group III than in groups II and I (84.6 ± 13.8 vs. 77.9 ± 13.9 and 73.0 ± 12.1 kg, F = 9.6, p < 0.0001), as BMI (30.6 ± 5.5 vs. 34.2±6.4, and 30.9±4.9 kg/m^2, F = 13.5, p < 0.00001). The females with chronic severe knee pain had higher ALM (P < 0.0001), ALMI (P < 0.000001), and FM/BW (P < 0.05) compared to the women with mild knee pain. The frequency of obesity was 36.8 % in women with mild pain, 52.2 % of subjects in group II and significantly higher among females with severe pain - 63.6 % (χ^2 = 4.5, p < 0.05 in comparison with group I). Sarcopenic obesity was registered in 18.4, 27.9, and 36.4 % of females of the I, II, and III groups, respectively. It was significantly more frequent among women with severe than mild pain (χ^2 = 4.3, p < 0.04). However, sarcopenia was found in 13.8 % of women in group I, 14.4 % of subjects of group II and 6% of group III according to ALM as well as in 11.5, 10.8, and 6 %, respectively according to ALMI without significant differences.

Conclusion: Women with severe chronic knee pain have significantly higher BW, BMI, ALM, and fat mass than females with mild pain. Despite the absence of differences in sarcopenia frequency, the subjects with severe knee pain have not only an increased frequency of obesity but also high sarcopenic obesity.

AB1175 IS DISTAL ENTHESITIS OF EXTENSOR DIGITORUM TENDON A SPECIFIC ULTRASOUND FEATURE OF PSORIATIC ARTHRITIS?

Keywords: Ultrasound, Osteoarthritis, Psoriatic arthritis

S. Bouzid[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], M. Yasmine[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]Mongi Slim Hospital, Rheumatology, Tunis, Tunisia

Background: Distal interphalangeal (DIP) joints are commonly affected in both hand osteoarthritis (OA) and psoriatic arthritis (PsA). However, enthesitis is well known to be a hallmark of spondyloarthritis including PsA.
Objectives: Our study aimed to assess distal enthesitis of extensor digitorum tendon in PsA and hand OA using ultrasonography (US).
Methods: We conducted a cross-sectional study including two groups: Group 1 included patients with hand OA fulfilling American College of Rheumatology criteria and Group 2 included patients with PsA according to CASPAR criteria. All patients underwent a physical examination followed by an US exam. US was performed in all DIP joints. For each joint, the following abnormalities were assessed: synovial thickening, osteophyte, enthesitis, and power Doppler signal (PDS). A quantitative score (0/1) was used for each lesion. Pearson correlation coefficient was calculated.
Results: We examined 160 DIP joints in 20 PsA patients (13 women and 7 men), with a mean age of 55.5 ± 12.1 years [33–77]. We also examined 80 DIP joints in 10 patients with hand OA (9 women and one man), with a mean age was 66±11 years [46–78]. The mean duration of hand OA and PsA symptoms were 4±3 years and 4±7 years, respectively. Synovial thickening of DIP joints was exclusively noted in PsA patients (**p=0.014**). Osteophytes were exclusively seen in hand OA patients (**p=0.08**). The number of enthesitis was significantly higher in the PsA group (2.79±1.75 versus 1.2±1.75, **p=0.028**).
Conclusion: Our study showed that distal enthesitis of extensor digitorum tendon was suggestive of PsA whereas osteophytes were exclusively observed in hand OA.

AB1176 DIAGNOSTIC YIELD OF CT-GUIDED BIOPSY IN SUSPECTED INFECTIOUS SPONDYLODISCITIS

Keywords: Imaging, Osteoarthritis

G. Mouna[1], D. Khalifa[1], H. Saghni[1], R. Fakhfakh[1], N. El Amri[1], K. Baccouche[1], E. Bouajina[1]. [1]Hospital Farhat Hached, Rheumatology, Sousse, Tunisia

Background: Infectious spondylodiscitis is a serious and morbid disease. It is often suspected after magnetic resonance (MR) imaging of the spine. Suspected spondylodiscitis requires further workup, in which computed tomography (CT)-guided needle biopsy plays a crucial role.
Objectives: The aim of this study was to examine the yield of CT-guided biopsy in patients with suspected infectious spondylodiscitis, and to identify factors associated with successful pathogen isolation.
Methods: This is a retrospective study involving infectious spondylodiscitis from January 2010 to december2021. All patients were identified with clinically and radiologically suspected infectious spondylodiscitis who underwent CT-guided biopsy of the vertebral lesion. Patient characteristics and clinical details were evaluated. Parameters were compared in patients with positive and negative microbiological and histologic results.
Results: A total of 42 patients (20 men, 22 women) was included. The mean age was 55.8 years (SD ± 16.7). The mean duration of symptoms was 60.2 days (SD ± 52.7). The final diagnosis was tuberculous spondylodiscitis in 15 patients (23.8%), brucellosis spondylodiscitis in 12 patients (28.6%) and pyogenic spondylodiscitis in 15 patients (47.6%). CT-guided biopsy has a diagnostic yield of 44.8% (13/42). Biopsy was contributory in identifying 8/13 patients (58%) with tuberculous spondylodiscitis, and 5/13 patients (42%) with pyogenic spondylodiscitis. Histological examination was the most sensitive diagnostic modality. The factors associated with successful microbe isolation was duration of symptoms (p=0.01) and not exposed to pre-biopsy antibiotics (p=0.02).
Conclusion: The CT-guided biopsy, as a diagnostic procedure for infectious spondylodiscitis, has a reasonably high diagnostic yield in this disease. A higher yield was identified in patients who has long duration of symptoms and not exposed to pre-biopsy antibiotics.

AB1177 SPINAL EPIDURAL ABSCESS ASSOCIATED WITH INFECTIOUS SPONDYLODISCITIS

Keywords: Osteoarthritis

G. Mouna[1], D. Khalifa[1], H. Saghni[1], R. Fakhfakh[1], N. El Amri[1], K. Baccouche[1], E. Bouajina[1]. [1]Hospital Farhat Hached, Rheumatology, Sousse, Tunisia

Background: Infectious Spondylodiscitis and spinal epidural abscess (SEA) are relatively rare conditions that is rising in incidence. SEA is a challenging entity associated with high morbidity and mortality. That's why early diagnosis is critical in this disease.
Objectives: we aimed to describe the clinical characteristics and outcomes of patients with spinal epidural abscess associated with infectious spondylodiscitis (SEA).
Methods: we conducted a retrospective study from June 2010 to December 2022. We included 42 patients with clinically and radiologically suspected infectious spondylodiscitis. Patient characteristics and outcomes were retrospectively reviewed.
Results: We enrolled 42 patients (23men,19 women) with infectious spondylodiscitis. The mean age was 57.2 years (SD ± 15.7). Twenty-nine patients (72.5%) had SEA. All patients showed varying degrees of focal spinal pain. Fever occurred in 18 patients. Ten patients (34.7%) exhibited neurological deficits. Furthermore, 20 cases (69%) involved lumbar spine, 6 cases (20.7%) involved thoracic spine, and 3 cases (10.3%) involved cervical spine. Abscess locations was Anterior in 14 cases (48.3%), posterior in 5 cases (17,2%), and Circumferential in 10 cases (34.5%). Among 11 SEA patients, 12 cases (41.4%) had infection caused by Mycobacterium tuberculosis, 8 case had infection caused by brucellosis, 5 cases had infection caused by Staphylococcus aureus, one case had infection caused by Staphylococcus coagulase negative, one case had infection caused by Escherichia coli, one case had infection caused by candida albicans, and one case caused by Enterococcus faecalis. All patients underwent conservative treatment, two of which improved symptoms. Five cases undergo surgical treatment, one of which showed improved symptoms, 4 cases had left limb motor and sensitive dysfunction.
Conclusion: SEA is rare and is often difficult to diagnose in the early stage. Early diagnosis, followed by specific therapy is necessary to improve the prognosis of this disease.

AB1178 THE COMPARISON OF PRP ALONE, SUPERVISED EXERCISE ALONE, AND PRP COMBINED WITH SUPERVISED EXERCISE IN MANAGEMENT OF KNEE OSTEOARTHRITIS

Keywords: Clinical trials, Physical therapy/Physiotherapy, Osteoarthritis

S. Karaborklu Argut[1], D. Celik[1], O. Ergin[2], O. Kilicoglu[3]. [1]*Istanbul University-Cerrahpasa, Faculty of Health Science, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey*; [2]*Istanbul University, Istanbul Faculty of Medicine, Department of Orthopedics and Traumatology, Istanbul, Turkey*; [3]*Koc University, Faculty of Medicine, Department of Orthopedics and Traumatology, Istanbul, Turkey*

Background: Platelet-rich plasma (PRP) has sparked widespread interest as a regenerative adjunct therapy, and it is increasingly being used to treat knee osteoarthritis (OA). There is a scarcity of reports on the characterization of injected products, as well as a scarcity of exercise protocols following PRP injections, despite the rising number of studies in the present PRP literature.
Objectives: The purpose of this study was to compare the efficacy of PRP with a supervised exercise program and reveal if the combination of the two treatments is effective in the management of knee OA.
Methods: This is a randomized, single-blinded, prospective, three-arm clinical trial. The PRP group received three weekly injections of fresh, leukocyte-poor PRP. The exercise group followed a structured and supervised exercise regimen for six weeks. These therapies were given in conjunction with the third group. The primary outcome was the change in overall average knee pain scores (on an 11-point numeric pain rating scale, with higher scores indicating worse pain) over a 24-week time period. The secondary outcomes were changes on the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), durations of the functional performance tests, and health-related quality of life. For statistical analysis, the mixed model with repeated measurements (ANOVA) was performed.
Results: A total of eight-hundred four patients with mild to moderate knee osteoarthritis were randomly allocated to three groups. There was a significant group-by-time interaction for overall knee pain ($p<0.001$). Pain reduction from baseline to 24 weeks was greater in PRP&Exercise group (Δ -5.40, 95%CIs -5.28 to -4.39). There were significant group-by-time interactions on the WOMAC total score, durations of the functional performance tests, and physical component of SF-12 ($p<0.012$). Exercise group and PRP&Exercise group had statistically greater impact than PRP alone, with large to very large effect sizes in terms of pain, self-reported function and functional performance tests ($p<0.012$, $\eta p2>0.14$).
Conclusion: PRP demonstrated short-term efficacy comparable to exercise or a combination of PRP and exercise; however, when compared to the other groups, it demonstrated a negative tendency in terms of long-term clinical improvements. PRP alone is not as effective as supervised exercise; however, if a patient has difficulties maintaining exercise programs for any reason, PRP can be offered as an alternative option.

VARIATION OF INTER-RATER RELIABILITY FOR BONE MARROW LESION SCORES IN DIFFERENT REGIONS OF THE KNEE: A STUDY USING KIMRISS

Keywords: Osteoarthritis, Imaging

S. Wichuk[1], P. Bird[2], I. Eshed[3], R. G. Lambert[1], W. P. Maksymowych[4], A. Mcreynolds[1], S. Juhl Pedersen[5], U. Weber[6], J. Paschke[7], J. L. Jaremko[1]. [1]*University of Alberta, Radiology and Diagnostic Imaging, Edmonton, Canada*; [2]*University of New South Wales, Medicine & Health, Sydney, Australia*; [3]*Sheba Medical Center, Diagnostic Imaging, Israel, Israel*; [4]*University of Alberta, Medicine, Edmonton, Canada*; [5]*Rigshospitalet, COPECARE, Copenhagen, Denmark*; [6]*Practice Buchsbaum, Rheumatology, Schaffhausen, Switzerland*; [7]*CARE ARTHRITIS LTD, IT, Edmonton, Canada*

Background: Semi-quantitative magnetic resonance imaging (MRI) scoring is more challenging in some anatomic regions than others. Bone marrow lesion (BML) is an important scoring feature and may be more closely related to clinical outcomes in arthritis in some anatomic regions than others. The Knee Inflammation MRI Scoring System (KIMRISS) scores BML and synovitis-effusion from fluid-sensitive sagittal MRI[1]. Via web-based interface, readers place ready-made overlays onto scorable portions of each bone, divided into grid squares which are scored dichotomously (yes/no) for presence of BML. The total KIMRISS BML score, which sums positive grid squares on all slices, has been previously shown to have high inter-rater reliability for both status and change.
Objectives: We aimed to evaluate patterns of regional variation in inter-rater reliability for BML across the knee via KIMRISS grid elements. This granular analysis serves as a foundation for further study of the relationship of precise BML location to clinical outcomes.
Methods: Baseline MRI from 61 patients in the Osteoarthritis Initiative (OAI) dataset were scored by 8 trained readers using KIMRISS scoring. Total scores for each of the 28 grid overlay regions (14 femur, 10 tibia, 4 patella) were calculated by adding up positive scores from all scorable MRI slices. We calculated descriptive statistics and interclass correlation coefficients (ICC) for all 28 reader pairs, then combined any neighbouring grid locations with ICC <0.5 before recalculating the ICC.
Results: The 8-reader mean (SD) BML scores at each scoring location (Table 1) showed that the mean reader pair ICC was very good (>=0.80) or good (0.70-0.80) for 17/28 (61%) of the grid regions (Figure 1). The lowest ICCs occurred at the inferior patella [P4; mean (SD) ICC=0.52 (0.19)], a small interior region of the femur [mean (SD) ICC=0.49 (0.26)], and the two most posterior regions of the tibia [mean (SD) ICC=0.41 (0.26) and 0.31 (0.33)]. Lower reliability was also found in regions of tibia not immediately adjacent to the tibiofemoral joint (ICC range: 0.60-0.67) as well as posterior non-articular regions of the femur (ICC range: 0.59-0.65). Combining the posterior tibial regions scores (T5+T55) slightly improved ICC compared to separate scores [mean (SD) ICC= 0.40 (0.29)].
Conclusion: Most individual KIMRISS grid squares were scored with high reliability. Decreased reliability in certain regions may be due to lower incidence of BML or anatomical features that lead to difficulty of interpretation at specific locations. Combining neighbouring regions with lower reliability, such as those at the posterior tibia, may increase reliability if discrepancy arises from assigning a positive score for the same lesion to different grid squares between readers. The patterns of reliability demonstrated here support further study of the impact of precise BML location status scores on clinical outcomes.

THE CHANGES OVER TIME OF KNEE STRENGTH AND FUNCTIONAL OUTCOMES BEFORE AND AFTER BILATERAL TOTAL KNEE ARTHROPLASTY

Keywords: Osteoarthritis, Rehabilitation

J. H. Choi[1], W. Jeong[2]. *[1]Jeju National University Hospital, Rehabilitation, Jeju-si, Korea, Rep. of (South Korea)*; *[2]Jeju National University Hospital, Rheumatology, Jeju-si, Korea, Rep. of (South Korea)*

Background: Knee osteoarthritis is the most common joint disorder and is associated with functional disability and pain. Total knee arthroplasty (TKA) is considered as an effective treatment for patients with end-stage knee osteoarthritis. However, most patients experienced deterioration in knee strength and functional outcomes immediately after surgery.
Objectives: The overall aim of this study was to investigate the change over time of knee strength and functional outcomes before and after bilateral total knee arthroplasty.
Methods: Retrospective cohort data of 308 patients who underwent primary bilateral TKA were analyzed. Patients underwent home-based preoperative rehabilitation program (3 times per week for 3 or 4 weeks) including strengthening and resistance training. After TKA, standard rehabilitation program was applied to all patients. Outcome measures were assessed 3 times, preoperatively and at 6 weeks and 3 months after surgery which included performance-based physical function test and self-reported physical function questionnaires. Assessment were included the isometric knee extensor and flexor strength of both knees, timed up-and-go (TUG) test, timed stair climbing test (SCT), 6-minute walk test, isometric knee extensor and flexor strength of both knees, knee flexion and extension range of motion, Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) for pain, stiffness, and functional levels. The knee flexion and extension range of motion (ROM) was assessed 5 times including at the beginning and end of standard rehabilitation.
Results: The knee extensor strength and ROM, and SCT of ascending were worsened at the 6 weeks after surgery, and these measures significantly improved following the 6 weeks. The ROM of knee flexion improved earlier than other physical functions and ROM of knee extension worsened after 6 weeks postoperatively. However, the result of self-reported physical function and other performance-based physical functions continued to improve significantly at 6 weeks and 3 months after surgery.
Conclusion: This study demonstrated that the patients who underwent bilateral TKA surpassed most of their physical functions in the 3 months before surgery. However, the recovery of performance-based physical function and self-reported physical function occurred at different times after surgery. Therefore, a rehabilitation treatment strategy according to these changes of physical functions is needed.

INTRAMUSCULAR METHYLPREDNISOLONE ADMINISTRATION IN HAND OSTEOARTHRITIS PATIENTS: A FEASIBILITY STUDY TO INFORM A RANDOMIZED CONTROLLED TRIAL

Keywords: Osteoarthritis

M. Hartog[1,2], K. Van Keeken[1,2], C. Popa[2,3], C. Van den Ende[2,3]. *[1]Sint Maartenskliniek, Research, Nijmegen, Netherlands*; *[2]Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands*; *[3]Radboudumc, Rheumatology, Nijmegen, Netherlands*

Background: Inflammation is thought to play an important role in hand osteoarthritis (HOA), which is further associated with pain and increased limitation of hand function [1,2]. Therapeutic options in HOA are scarce [3].
Objectives: The aim of this study was twofold: to explore the acceptability of treatment with intramuscular (IM) methylprednisolone (MP) in hand OA by both healthcare providers (HCPs) and hand OA patients, and to observe the response to a single IM MP injection in patients with symptomatic hand OA.
Methods: We adopted a mixed methods design. Firstly, in a qualitative study we examined the acceptability of intramuscular MP using questionnaires with open-ended questions for all health care providers of the Rheumatology Department of the Sint Maartenskliniek and a semi-structured interview for an a-selective group of patients with clinically diagnosed hand OA not previously treated with MP. Secondly, in a prospective observational study the course of symptoms was examined in patients with hand OA who received an intramuscular MP injection as part of routine care. Data on average pain and the intensity of pain in the hands and other joints (both assessed on a Numeric Rating Scale), OA related functional impairment (Functional Index of Hand Osteoarthritis questionnaire), use of analgesics and occurrence of adverse events was collected with a checklist within 3 days after the injection was administered (baseline) and at week 4, 8 and 12 after the injection.
Results: Fourteen health care providers (all rheumatologists) and 15 patients (93.3% female, mean age = 67 years) participated in the first part of the study. HCPs considered intramuscular MP therapy as an effective therapeutic intervention and most patients were very open to get this therapy, yet they all expressed

their concerns about the risk of long-term adverse events. Twenty-two patients with hand OA participated in the second part of the study. Intramuscular MP administration decreased hand pain with 1.96 (week 4), 1.59 (week 8) and 1.23 (week 12), as compared to baseline (Table 1). The average pain in other joints decreased at 4 weeks after MP administration with 0.73 and at 8 weeks HOA related functional impairment decreased with 2.19, as compared to baseline. A total of 13 patients reported 45 adverse events, of which almost half occurred within the first four weeks after MP administration.

Response to therapy	Baseline (n=22)	Week 4 (n=22)	Week 8 (n=21)	Week 12 (n=22)	P value Δ t0 to t4	P value Δ t0 to t8	P value Δ t0 to t12
Average hand pain (0-10), mean (±SD)	5.96 (± 1.43)	4.00 (±2.41)	4.37 (±2.28)	4.73 (±2.00)	0.001	0.002	0.002
Average pain in other joints (0-10), mean (±SD)	5.00 (±2.43)	4.27 (±2.29)	4.41 (±2.22)	4.59 (±2.11)	0.073	0.179	0.226
FIHOA-score (0-30), mean (±SD)	12.96 (± 5.65)	10.64 (±6.26)	10.77 (±5.26)	11.45 (±5.89)	0.052	0.018	0.225
Analgesics use, n (%)	21 (95,5)	19 (86,4)	18 (81,8)	20 (90,9)	0.024	0.021	0.003
Patients with adverse events, n (%)		13 (59)	12 (57)	12 (54,5)			

Conclusion: We found a high acceptability of intramuscular MP treatment for hand OA and our findings suggest that methylprednisolone may reduce pain and improve hand function as quick as 4 weeks after administration, with a persisting effect of almost 3 months. This suggests that it might be a valid long-term therapeutic option in these patients.

AB1182 EFFECTIVENESS OF FATIGUE INTERVENTIONS IN OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Osteoarthritis, Physical therapy/Physiotherapy, Systematic review

H. Fawole[1], O. Osadiaye[1], O. Idowu[2], O. Akinrolie[3], M. Ibekaku[4], M. Ojo[5], A. Oyeyemi[6], J. Riskowski[7]. *[1]University of Benin, Physiotherapy, Benin City, Nigeria*; *[2]Redeemer's University, Physiotherapy, Ede, Nigeria*; *[3]University of Manitoba, Applied Health Sciences, Winnipeg, Canada*; *[4]University of Nigeria, Medical Rehabilitation, Enugu, Nigeria*; *[5]Guy's and St Thomas NHS Foundation Trust, Physiotherapy, London, United Kingdom*; *[6]Arizona State University, Health Solutions, Phoenix, United States of America*; *[7]Johns Hopkins Bloomberg School of Public Health, Department of Correctional Services, Baltimore, United States of America*

Background: Pain and physical function are common factors targeted for osteoarthritis (OA) management. However, fatigue has been reported as an important component of OA experience and a significant concern for people with OA (Power et al., 2008). Despite this, fatigue has received very little attention. However, with increasing interests in fatigue, it is expedient that fatigue be considered a top priority in clinical practice (Overman et al., 2016). Thus, there is dire need for evidence-based fatigue interventions in OA given the paucity of evidence in this area.
Objectives: To identify fatigue interventions and determine the effectiveness of the interventions in reducing fatigue immediately and over time in OA.
Methods: A review protocol was developed and registered with the PROSPERO database, with the ID-CRD42020163730. Studies included comprised peer-reviewed randomized controlled trials (RCTs) that examined the effects of any intervention in the management of fatigue or vitality outcomes in people with upper limb and lower limb OA. Studies that used spiritual, pharmacological or surgical interventions to manage fatigue in patients with upper limb and lower limb OA were excluded. The Cochrane Collaboration's tool for assessing the risk of bias (ROB) was used assess the quality of evidence for the included RCTs. Narrative synthesis was used to summarise the identified fatigue interventions while only studies on exercise interventions were used in the meta-analysis.
Results: Out of 2,586 studies identified from database search, 31 RCTs studies were included after screening for titles, abstracts and full texts. Of the 31 included RCTs, only nine studies were included in the meta-analysis comparing the effects of exercise versus non-exercise interventions on fatigue. From the ROB assessment, 11 RCTs were of low ROB whilst 11 had moderate and 9 high ROB respectively. The narrative synthesis identified 12 interventions for fatigue and these include activity pacing, cognitive behavioural therapy (CBT), yoga, exercise, acupuncture, moxibustion, pain-coping skills, BEMER therapy, modified shoes, massage/aromatherapy, education and thermotherapy. Exercises interventions included strengthening, balance, kinesthesia, and mobilization, hand-based, stretching, aquatic danced-based and web-based exercises. Activity pacing (mean difference [MD]=0.8; (standard deviation [SD]=0.3), CBT (MD=4.32; [SD]=1.85), moxibustion (vitality: MD=-2.61; [standard error]=-1.69) had statistically significant reductive immediate effect on fatigue. The meta-analysis pooled effects showed that exercise interventions on fatigue in OA was not statistically significant both immediately (SMD=-0.10; 95% CI -0.74, 0.54; I^2=94%) and overtime (SMD=-0.79; 95% CI -2.30, 0.73; I^2=98%), although the effects was in favour of exercise interventions relative to other comparison non-exercise interventions.
Conclusion: Activity pacing, CBT and moxibustion interventions showed beneficial effects on fatigue in OA immediately. Cumulatively, the pooled effect of exercise on fatigue was not statistically significant immediately and overtime but the effect was in favour of the exercise interventions relative to other control interventions. However, there is currently insufficient evidence regarding the effectiveness of majority of identified fatigue interventions in this review. Further, the findings of the meta-analysis may have been affected by high level of heterogeneity. Largely populated RCTs with low ROB are needed to ascertain the effectiveness of fatigue interventions in OA population.

AB1183 NEUROPATHIC PAIN IN PRIMARY KNEE OSTEOARTHRITIS

Keywords: Osteoarthritis, Pain

A. Mougui[1], S. Belouaham[1], I. El Bouchti[1]. *[1]Arrazi Hospital, Faculty of Medicine and Pharmacy of Marrakech, Mohammed VI University Hospital, Marrakech, Morocco., Department of Rheumatology, Marrakech, Morocco*

Background: Pain is a major symptom in primary knee osteoarthritis. The mechanisms of this pain are heterogeneous explaining the variable response to different treatments. The presence of a neuropathic pain (NP) may be associated with a different phenotype disease.
Objectives: The present study was conducted to identify the frequency of NP in patients with painful primary knee osteoarthritis, and to investigate its correlation with socio-demographic factors, anthropometric and postural features, physical function, quality of life, and disease severity.
Methods: The study included 200 patients with primary osteoarthritis of the knee who did not have co-morbid disorders and/or were taking drugs that may cause neuropathy. NP was assessed by both Douleur Neuropathique 4 questions (DN4) and painDETECT questionnaires.
Results: The mean age of the patients was 59.15 7.62 years. The majority were women (87.5%). The mean of the body mass index was 24,72±4, 84 kg/m^2. The mean of the quadriceps perimeter was 48,28±4,14cm. The mean of the waist circumference was 93,04±11,43 cm. The mean of the total Womac score was 53,61±4,93. NP was detected in 55.5% of patients according to DN4 questionnaire and in 46% according to painDETECT questionnaire. DN4 score was positively correlated with VAS (VAS Visual analogue Scale)-pain at rest (r_s=0,188; P=0,009), VAS pain on movement (rs=0.173; P=0.0017), Womac pain score (rs=0.157; p=0.030), Womac stiffness score (rs=0.253; p=0.000),

Physical function Womac score (rs=0.271; p=0.000), total Womac score (rs=0.305; p=0.000) and Lequesne index (rs=0.221; p=0.002), and it was negatively correlated with perimeter quadriceps (rs=-.210;p=0.008), while painDETECT score was positively correlated with VAS pain on movement (rs=0.220; p=0.002), Womac stiffness score (rs=0.147; p=0.043), Womac physical function score (rs=0.172; p=0.017), and total Womac score (rs=0.182; p=0.012). The risk factors of NP retained according to DN4 score were longer symptom duration (p=0,030) and a reduced quadriceps perimeter, whereas painDETECT score was associated with high VAS pain on movement (p=0.022).

Conclusion: NP is common in primary knee osteoarthritis. The presence of NP is associated with more painful pathology and extreme disability.

AB1184 ANXIETY, DEPRESSION AND FIBROMYALGIA: SIMILAR PREVALENCE IN OSTEOARTHRITIS AS IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Osteoarthritis, Fibromyalgia

J. Schmukler[1], A. M. Malfait[1], J. Block[1], T. Pincus[1]. *[1]RUSH University Medical Center, Medicine, Division of Rheumatology, Chicago, United States of America*

Background: Non-articular comorbidities, including anxiety (ANX), depression (DEP) and fibromyalgia (FM), are common in patients with rheumatic diseases. Their presence may impact measures of disease activity and responses to treatment. The burden of ANX, DEP and FM has been described in many reports concerning patients with rheumatoid arthritis (RA), but far less information is available concerning these comorbidities in patients with osteoarthritis (OA). It is feasible to screen for these comorbidities in all patients seen in routine care using a multidimensional health assessment questionnaire (MDHAQ)[1,2], completed by patients in 5-10 minutes before seeing the rheumatologist, which includes screening indices for ANX, DEP, and FM.

Objectives: To analyze the prevalence of positive screening for ANX, DEP, and/or FM in patients with OA compared to RA in routine care at an academic rheumatology center.

Methods: All patients seen for routine rheumatology care are asked to complete an MDHAQ, which includes 0-3 physical function and ANX and DEP scales in the patient friendly HAQ format, three 0-10 visual numeric scales (VNS) for pain, fatigue and global status, self-report 0-54 RADAI painful joint count, 60-symptom checklist review of systems (ROS) including ANX and DEP, medical history queries, and 4 indices: RAPID3 (routine assessment of patient index data to assess patient status in all diseases studied), MDHAQ ANX screen (MAS2), MDHAQ DEP screen (MDS2)[1], and fibromyalgia assessment screening tool (FAST4) [2]. MAS2 and MDS2 are positive for ANX or DEP if 0-3 ANX or DEP response is ≥2 OR positive ANX or DEP on the symptom checklist. FAST4 is positive if 3/4: pain VNS ≥6/10, fatigue VNS ≥6/10, self-report painful joint count ≥16/54, and/or symptom checklist ≥16/60. Patients were classified as OA or RA according to primary ICD 10 diagnosis. An MDHAQ database was used to compute retrospectively medians and interquartile ranges (IQR).

Results: The study included 366 OA and 488 RA patients seen between 2013 and 2022. Patients were mostly female and OA patients were slightly older (Table 1). RAPID3 was similar in RA and OA patients. Positive screening for ANX was seen in 28.4% of OA and 21.9% of RA patients (p= 0.04, Table 1), for DEP in 21.6% of OA and 18% of RA patients (p>0.05), and for FM in 20.4% of OA and 20% of RA patients (p>0.05).

Conclusion: Positive ANX, DEP, and FM screening is seen in > 20% of routine care patients with primary diagnoses of OA or RA, at similar levels in OA and RA. Although definitive diagnosis requires a physician, MAS2, MDS2, and FAST4 agree more than 80% with reference standards which are highly associated with positive diagnoses. The results underscore a need for rheumatologists to aware of these comorbidities, easily screened for using an MDHAQ.

AB1185 POLYACRYLAMIDE HYDROGEL FOR THE TREATMENT OF KNEE OSTEOARTHRITIS: 3 YEAR FOLLOW UP RESULTS OF A PROSPECTIVE CLINICAL STUDY

Keywords: Osteoarthritis

H. Bliddal[1], J. Beier[2], A. Hartkopp[3], P. G. Conaghan[4], M. Henriksen[1]. *[1]The Parker Institute, Bispebjerg Frederiksberg Hospital, University of Copenhagen, Copenhagen, Denmark*; *[2]Rheumatology Odense, Odense, Denmark*; *[3]A2 Rheumatology and Sports Medicine, Holte, Denmark*; *[4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds & NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Polyacrylamide hydrogel (iPAAG), manufactured by Contura International, is CE marked for the symptomatic treatment of patients with knee osteoarthritis (OA). iPAAG fulfils an unmet clinical need for an effective, long-acting and safe non-surgical treatment that may postpone knee surgery for those with OA.

Objectives: To evaluate the efficacy and safety of a single injection of 6 ml intra-articular iPAAG on knee symptoms in participants with moderate to severe knee OA for up to 5 years after treatment.

Methods: In this prospective, multicentre study (3 sites in Denmark) participants received a single intra-articular injection of 6 mL Arthrosamid®. The initial 1-year study was extended to follow the participants for up to 5 years. The study was approved by the Danish Health authorities and the local Health Research Ethics committee. All participants provided informed consent prior to study activities and signed a new consent form to participate in the extension phase. Injections were given by an investigator experienced in administering intra-articular injections. Participants could continue analgesics (except 48 hours prior to visits) and non-pharmacological therapy, but topical (on target knee) and systemic corticosteroids or additional injections were not allowed. Outcomes included the WOMAC pain, stiffness and function subscales (0-100 score where 100 was worst) and Patient Global Assessment of disease impact (PGA). Changes from baseline in these outcomes were analysed using a mixed model for repeated measurement (MMRM) with a restricted maximum likelihood-based approach. The estimated changes based on the least square means were presented including 95% confidence limits and corresponding p-values. Additional sensitivity analyses were for the 3-year data. The MMRM analysis was repeated, but only data from the 35 participants that continued into the extension phase were included. In another analysis an ANCOVA model was used where missing values at 3 years were replaced by the participants baseline value (BOCF).

Results: 49 participants (31 females) with mean age of 70 years (range 44 – 86 years) were treated with iPAAG. 46 participants completed the 1-year assessment and 35 participants (22 females) continued into the extension phase. A site closure and the increased length of the study were the most common reasons for not continuing. 29 participants completed the 3-year follow-up.

The originally planned MMRM analysis including all available data from the 49 treated participants showed clinically relevant and statistically significant decreases from baseline to 3 years for each of the 3 WOMAC subscale scores and the PGA (Table 1).

Table 1. Analyses of change from baseline to 3 years in transformed (0-100) WOMAC subscales

	Number of participants		LSMean (95% CI)	p-value
	At baseline	At 3 years		
WOMAC pain subscale				
Planned analysis	49	29	-18.0 (-24.9; -11.1)	<0.0001
Extension participants	35	29	-17.7 (-24.7; -10.8)	<0.0001
Baseline carried forward	49	49	-12.1 (-17.0, -7.3)	<0.0001
WOMAC stiffness subscale	49	29	-16.4 (-22.5; -10.3)	<0.0001
WOMAC Phys. Function subscale	49	29	-14.9 (-21.4; -8.4)	<0.0001
Patient Global Assessment	49	29	-15.0 (-27.6; -2.4)	0.0223

The analysis only using the data from the extension phase participants showed a similar change from baseline in the WOMAC pain subscale compared to the result of the planned analysis (Table 1). The BOCF analysis also showed a clinically relevant and statistically significant decrease in the WOMAC pain subscale from baseline. 74 adverse events have been reported in the study including 19 new events reported between the 2-year and 3-year visits. None of the new events were assessed as related to treatment and Covid-19 infection was the most frequently reported AE in this period. 3 of the new events were SAEs (Covid-19 infection, pre-syncope, uterine prolapse).

Conclusion: Single injections of 6 ml intra-articular iPAAG are well tolerated and continue to provide clinically relevant and statistically significant effectiveness at 3 years after treatment.

AB1186 BODY MASS INDEX EFFECTS QUADRICEPS MUSCLE ARCHITECTURAL CHARACTERISTICS IN PATIENTS WITH KNEE OSTEOARTHRITIS

Keywords: Imaging, Osteoarthritis, Ultrasound

E. Ünüvar[1], N. Cigercioglu[1], H. Apaydın[2], H. Guney Deniz[1]. *[1]Hacettepe University Faculty of Physical Therapy and Rehabilitation, Musculoskeletal Physiotherapy and Rehabilitation, Ankara, Turkey*; *[2]Ankara City Hospital, Department of Rheumatology, Ankara, Turkey*

Background: Sufficient lower extremity muscle mass is necessary for performing functional tasks. It is well known that body mass index (BMI) adversely effect knee cartilage health but in knees with osteoarthritis (OA) it is still unclear how BMI level effect knee muscle architectural characteristics.

Objectives: The aim of this study was to investigate effect of body mass index (BMI) level on quadriceps muscle architecture in patients with knee OA and healthy controls.

Methods: Nineteen patients with OA (mean age= 50.58±4.56 years, mean BMI=28.29±2.51 kg/m2,) and twenty healthy controls (mean age= 48.35±2.83 years, mean BMI=26.76±4.88 kg/m2) were included in the study. Rectus Femoris (RF), Vastus Medialis (VM) and Vastus Lateralis (VL) muscles thickness and pennation angle were evaluated using B-Mode ultrasonography (Esaote MyLab X8 eXP Ultrasound System, Florence, Italy). Ultrasound images were analyzed offline using an image analysis software (Image J, National Institutes of Health, Bethesda, MD, USA) program. When investigating the changes in muscle architecture by group, the effect of BMI was adjusted using covariance analysis (ANCOVA) tests.

Results: There were no differences between age (p=0.073) and BMI (p=0.10) in both groups. Interaction between groupXBMI represented in Table 1. Control group had higher RF muscle thickness, RF pennation angle, VM muscle thickness, VM pennation angle and VL muscle thickness than OA group. There was significant effect of BMI on VM and VL muscle thickness.

Conclusion: Patients with knee osteoarthritis has lower quadriceps muscle thickness and pennation angle than matched healthy controls and BMI was an important factor effecting muscle characteristics. The decrease in VM and VL muscle thickness were associated with increased BMI in knee OA group. These findings highlight the need of body weight control in order to restore muscle thickness in knee OA patients.

AB1187 RELIABILITY AND VALIDITY OF THE CONE EVASION WALK TEST IN HIP OSTEOARTHRITIS

Keywords: Outcome measures, Pain, Osteoarthritis

B. Unver[1], K. S. Kacmaz[2], V. Karatosun[3]. *[1]Dokuz Eylul University, Physical Therapy and Rehabilitation, Izmir, Turkey*; *[2]izmir Katip Celebi University, Physical Therapy and Rehabilitation, Izmir, Turkey*; *[3]Dokuz Eylul University, Orthopedics and Traumatology, Izmir, Turkey*

Background: Hip osteoarthritis (OA) is associated with joint pain and stiffness, reduced balance, impeded mobility, and loss of functional independence [1]. Falls are the leading cause of fatal and nonfatal injuries among older adults and people with hip OA. Fall-related injuries and circumstances such as hip fractures and subsequent arthroplasty procedures put a significant burden on financial resources and healthcare systems [2]. Therefore, the identification and prevention of falls are easier, cheaper, and more effective for all parties in healthcare. The Cone Evasion Walk Test (CEW) is a dual-tasked performance measurement that was designed for evaluating dynamic balance, proactive gait control, and fall risk by assessing the ability to evade obstacles [3].

Objectives: The aim of this study was to investigate the reliability and validity of the CEW in patients with hip OA and estimate the minimal clinically important difference (MCID) of the CEW.

Methods: Twenty-seven patients with hip OA were included in this study. Patients performed trials for the CEW and the Timed up and Go Test (TUG). Between the CEW trials, patients got to rest for an hour.

Results: The analysis showed that the CEW has excellent reliability and validity in hip OA (p<0.001). The relative (ICC coefficient) and absolute (SEM and SRD95) reliability of the CEW were 0.95, 0.53, and 1.46 respectively. The Spearman correlation coefficient with the TUG was 0.65.

Conclusion: The CEW was shown to be effective in terms of evaluating the function, dynamic balance, mobility, and fall risk with an additional attention-demanding task in patients with hip OA. The low MCID value (1.46) provides a sensitive measure of alterations in a patient's condition. Therefore, the CEW may be a better assessor of the proactive gait control, fall risk, mobility, and dynamic balance activities in the everyday community than the existing performance measures.

DYNAMICS OF PAIN SYNDROME DURING 180-DAY TREATMENT WITH UNDENATURED COLLAGEN TYPE II IN COMPARE TO GLUCOSAMINE AND CHONDROITIN COMBINATION

Keywords: Pain, Quality of life, Osteoarthritis

D. Rekalov[1], I. Golovach[2], I. Daniuk[1], R. Kulynych[3], T. Tarasenko[4], I. Bryner[1]. [1]*Zaporizhzhia, Professor Rekalov Rheumatology Clinic, Zaporizhzhia, Ukraine*; [2]*Feofaniya Clinic, Rheumatology, Kyiv, Ukraine*; [3]*Zaporizhzhia State Medical University, Internal Diseases-3, Zaporizhzhia, Ukraine*; [4]*Dnipro, Professor Rekalov Rheumatology Clinic, Dnipro, Ukraine*

Background: OA osteoarthritis is a heterogeneous group of diseases of different etiology with similar biological, morphological, clinical manifestations and consequences, which are based on damage to all articular structures (cartilage, subchondral bone, synovial membrane, ligaments, capsules, periarticular muscles). A key role in the pathogenesis of OA is played by an increase in the catabolic activity of various cytokines, as well as matrix metalloproteinases (MMP) of the cartilage itself.
Objectives: The purpose of the study was to compare the dynamics of pain syndrome (based on Western Ontario McMaster Osteoarthritis Index – WOMAC pain subscale) during 180-day treatment with undenatured collagen type II (UC-II) and glucosamine and chondroitin (G + Ch) combination in patients with Grade II knee OA.
Methods: Patients with Grade II knee OA were investigated. 20 patients were administrated the UC-II during 180-day period, 20 patients took the combination of G + Ch during the same period. WOMAC pain subscale was used to evaluate the effectiveness and was completed before the start of therapy and after 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 90, 120, 150, 180 day of treatment. Visual analog scale (VAS) from 0 to 10 was used for assessment the WOMAC subscale by patient. In this abstract we presented the dynamics of pain during walking and nocturnal pain.
Results: The initial data of pain during walking and nocturnal pain in UC-II group were 6.29±0.37 and 4.35±0.59, after treatment – 2.99±0.37 (-52.46 %, p <0.05) and 1.7±0.41 (-60.92 %, p <0.05). In G + Ch group initial data were 7.05±0.43 and 4.85±0.69, after therapy – 3.85±0.35 (-45.39 %, p <0.05) and 2.85±0.51 (-41.24 %, p <0.05). Comparing groups demonstrated the better results according to decrease of WOMAC pain subscale in the group of UC-II: reduce of pain during walking by 28.76 % and reduce of nocturnal pain by 67.65 % (p <0.05). The analysis of the graph of pain during walking has recorded the beginning of significant pain reducing after 30 day of treatment in both groups (Figure 1). The analysis of the graph of nocturnal pain has showed the beginning of significant pain reducing after 50 day of treatment in both groups. Dynamics of nocturnal pain reducing in the G + Ch group was more unstable with periods of reduced efficiency, while in the UC-II group the dynamics was smooth without fluctuations.

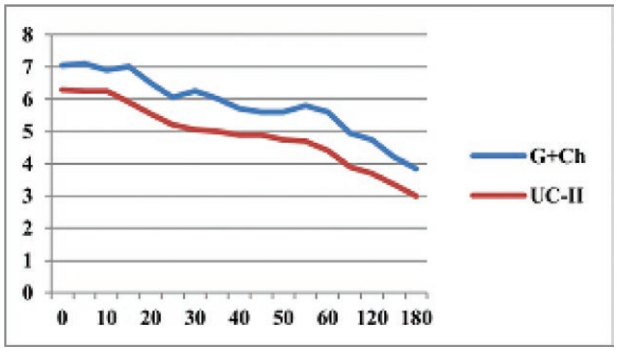

Figure 1.

Conclusion: The therapy of Grade II knee OA with UC-II during 180-day demonstrates the benefit in reducing of pain during walking and nocturnal pain in compare to G + Ch combination. The dynamics of nocturnal pain reducing in the UC-II group characterizes by gradual decline without significant fluctuations.

BOTULINUM TOXIN TYPE A OR SELECTIVE GENICULAR PULSED RADIOFREQUENCY FOR TREATING ADVANCED KNEE OSTEOARTHRITIS

Keywords: Randomized control trial, Pain, Osteoarthritis

M. Hassanien[1], E. Kamel[2], R. Gamal[1], N. Talaat[1], T. Khedr[1], A. Alawamy[2]. [1]*Assuit University, Rheumatology, Assuit, Egypt*; [2]*Assuit University, Anesthesia, Assuit, Egypt*

Background: Knee osteoarthritis was the most common type (6% of all adults). Developing osteoarthritis increases with age. Pain is a key symptom in the decision to seek medical care and is an important antecedent to disability.
Objectives: To discuss the effectiveness, indications, limitations and side effects of botulinum toxin type A and genicular nerves pulsed radiofrequancy for treating osteoarthritis to help clinicians choose the most appropriate treatment.
Methods: Randomized double blind controlled trial study, ***fifty two participants were recruited divided into 2 groups as follows:***Group I (Bx): 25 patients given intra-articular botulinum toxin type A 100 IU sonographically guided in patient with osteoarthritis knee according to American Collage of Rheumatology criteria and in stage 3 or 4 of the Kellgren_Lawrence classification Group II (RF): 27 patient get radiofrequncy ablation of genicular nerves. The primery outcome was Visual analogue pain score (VAS), secondry outcome was stiffness, physical function of each knee using Western Ontario and McMaster University Osteoarthritis Index (WOMAC), and Calculation of Oxford knee score at base line, 4,8,12 and 24 weeks.
Results: 16 female and 9 male in group I versus 10 female and 17 male in group II. The mean age were 54.36±7.8 years, there was significant difference in pain VAS between groups at 4th week (P value = 0.005). A significant difference in WOMAC pain at 4th and 12th weeks (P value > 0.001), WOMAC stiffness at 12th and 24th weeks (P value > 0.001), WOMAC function 4th, 12th and 24th weeks (P value > 0.001) and WOMAC total at 4th, 12th and 24th weeks (P > 0.001).However there were no significant difference in Oxford between the two groups.
Conclusion: Intra-articular Botulinum toxin type A 100 IU can reduce the overall pain and improve the function in Knee osteoarthritis with higher effecacy than Pulsed Radiofrequancy. However. Further research is needed to compare the effect of botulinum toxin type A and Radiofrequancy for the different stages of Osteoarthritis.

Variables	Group I (Botox) (n=25)	Group II (Radiofrequency) (n=27)	*P*-value

ATTITUDES AND BELIEFS REGARDING TREATMENT IN PATIENTS WITH OSTEOARTHRITIS

Keywords: Osteoarthritis, Patient information and education

I. Berrichi[1], F. Z. Taik[1], H. Fouzia[1], N. Soba[2], M. Fourtassi[2,3], F. E. Abourazzak[1]. [1]*Abdelmalek Essaadi University, Faculty of Medicine of Tangier-Tetouan-Al Houceima, University Hospital Mohammed VI, Rheumatology, Tangier, Morocco*; [2]*Abdelmalek Essaadi University, Faculty of Medicine of Tangier-Tetouan-Al Houceima, University Hospital Mohammed VI, Physical Medicine and Rehabilitation, Tangier, Morocco*; [3]*Abdelmalek Essaâdi University, Faculty of Medicine, Physical Medicine and Rehabilitation, CHU Tangier, Tangier, Morocco*

Background: Therapeutic decision is one of the essential procedures for coping with the disease, so adherence to treatment is one of the key elements of care, particularly in patients with degenerative musculoskeletal pathologies, in particular osteoarthritis.

These attitudes can be influenced by beliefs about drugs, which will affect the care and quality of life of patients.
Objectives: The objective of this study is to assess beliefs about medications as well as associated factors in patients with osteoarthritis.
Methods: This is a cross-sectional study that included any patient ≥ 18 years of age followed for knee osteoarthritis or digital osteoarthritis who presents to the rheumatology department. We excludedpatients with psychiatric or memory disorders or who refused to participate in the study. Sociodemographic data, comorbidities, information on functional impact and treatments received were collected. A validated questionnaire: Belief on Medicine Questionnaire (BMQ) specific which allows to evaluate the beliefs of the patients related to the need and the concerns towards the drugs was used. The specific BMQ is made up of two subscales: the first includes questions related to the necessity for treatment, the second includes questions about concerns related to the prescription. Each of the sections is made up of five graduated scales from 1 (strong disagreement) to 5 (strong agreement). The specific BMQ is therefore rendered as two scores ranging from 5 to 25 and can be expressed as a need-concern differential ranging from –20 to +20, which is an equivalent of the benefit-risk ratio perceived by the patient.
Results: We have included 221 patients. The average age was 59.4+-9.8, 88.7% of patients were women. 70.6% of patients were illiterate. 62.1% of patients had comorbidities. 80.5% were followed for knee osteoarthritis and 19.5% for digital osteoarthritis. The median duration of evolution was 8 [2-10] years. For the treatments, 53.8% of the patients in our study were on anti-osteoarthritis treatment, 44.7% had already received an NSAID and 11.7% had already received an injection. The mean of the BMQ- specific necessity was 16.92+-6.33 and 52% of patients strongly believed that drugs are essential to keep them healthy. The average of the BMQ-specific concerns were 14.69+-5.69 The main concerns of patients were the lack of information about the medications they were taking in 45.9% and 38% of patients were concerned about the potentially harmful consequences of their treatment. The median need-concern differential was 2 [-3 - 8] suggesting a positive risk-benefit ratio perceived by the patients. In multivariate linear regression, only functional disability is statistically significantly associated with the need-concern differential (OR=0.24, 95% CI [0.204-0.817], p=0.001).
Conclusion: Moroccan osteoarthritis patients have a positive perception of the benefit-risk ratio towards their treatments. Functional disability is the main factor incriminated in this perception. Therapeutic education must take more place in the management of osteoarthritis patients.

AB1191 FACTORS ASSOCIATED WITH WALKING SPEED IN PATIENTS WITH END-STAGE KNEE ARTHRITIS WHO ARE SCHEDULED FOR TOTAL KNEE ARTHROPLASTY

Keywords: Gastrointestinal tract

S. Yamada[1], T. Ikawa[1], K. Mandai[1], S. Maeda[1], T. Hashimura[1], T. Tachibana[1], H. Ohashi[1], I. Kentaro[1]. [1]Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka City, Japan

Background: Patients with knee joint disorders have impaired mobility, which interferes with their daily lives, resulting in frailty. Various factors are assumed to contribute to the decline in walking speed, which is an indicator of mobility.
Objectives: In this study, we measured the gait speed of patients scheduled to undergo initial total knee arthroplasty (TKA) and examined the factors that correlate best with gait speed.
Methods: Patients with end-stage knee arthritis who underwent initial TKA at our hospital between July 2020 and October 2022, and whose gait speed was measured before surgery with written consent, were included in the study. We investigated the relationship between basic attributes such as age and gender at the time of the survey, pain VAS during walking, clinical evaluation of knee joint function (Knee Society Score: KSS), skeletal muscle mass of both lower limbs (whole-body mode Dual Xray Absorptiometry method), quadriceps muscle strength (flexion and extension strength by dynamometer), and range of motion (degree of flexion and extension), frailty, sarcopenia.
Results: 210 subjects (170 women, mean age 75.5 years) were included in the study. Multivariate analysis was performed using walking speed as the objective variable and age, gender, VAS for pain during walking, KSS, skeletal muscle mass of both lower limbs, quadriceps muscle strength(flexion and extension strength), range of motion(degree of flexion and extension), frailty and sarcopenia as dependent variables. The results showed that age and walking pain VAS and KSS were significantly and independently associated with walking speed (P=0.01, 0.04, 0.05). Gender, skeletal muscle mass of both lower limbs, quadriceps strength (flexion and extension), range of motion (degree of flexion and extension), frailty, and sarcopenia were not found to be significantly associated with walking speed (P = 0.79, 0.13, 0.65, 0.21, 0.68, 0.74, 0.34, 0.20).
Conclusion: Age was found to correlate most with walking speed, with walking speed slowing with increasing age. A correlation between lower quadriceps muscle extension and lower walking speed has been reported previously, but this study did not correlate. Nor did it correlate with lower limb skeletal muscle mass or range of motion. Pain during walking was observed in many cases, so it may not have been significant.

AB1192 RESPONSE TO VISCOSUPPLEMENTATION WITH DIFFERENT TYPES OF INTRA-ARTICULAR HYALURONIC ACIDS IN OSTEOARTHRITIS OF THE KNEE – A RETROGRADE INDIAN COHORT STUDY OF MORE THAN 15 YEARS LONGITUDINAL DATA

Keywords: Outcome measures, Osteoarthritis

A. K. Aggarwal[1], J. Fitzpatrick[2], N. Aggarwal3. [1]*Institute of Rheumatology and Pain, Brij Medical Centre, Rheumatology and Pain, Ghaziabad, India*; [2]*University of Melbourne, Faculty of Medicine, Dentistry and Health Sciences, Parkville, Australia*; [1]*Institute of Rheumatology and Pain, Brij Medical Centre, Rheumatology and Pain, Ghaziabad, India*

Background: Knee osteoarthritis (OA) is a progressive degenerative condition resulting in functional loss, pain and discomfort. [1] The current aim of treatment is alleviation of symptoms, improvement of function and joint preservation. Viscosupplementation (VS) with Intra-articular hyaluronic acid (IAHA) injection has been shown to have protective physiochemical functions and may confer disease-modifying, long term effects in OA. [2][3] However, conflicting guidelines, pooling of results for different molecular weight products, and a paucity of long-term clinical studies has resulted in lack of confidence in the results of IAHA.
Objectives: To determine the primary and sustained response to VS with different types if IAHA in Bilateral Knee OA.
To identify whether the response is different for subgroups which are:

- Type of IAHA,
- Gender - Males (M) or Females (F), and
- Grade of OA treated.

Methods: We did a retrospective analysis of a 15-year cohort from a single Indian centre. The inclusion criteria were adults with bilateral knee OA with functional reduction and radiological KL Grade of III and IV, treated with Non-Animal Stabilized Hyaluronic Acid (NASHA) origin IAHA injections.

Subjects were stratified into two groups based on the molecular weight of the hyaluronic acid used:

- High Molecular Weight - 6-8 mg/ml – 6ml single injections (HMW-HA), or
- Very high Molecular weight – 20 mg/ml – 3 ml injections (VHMW-HA).

The primary outcome measure was responder rates determined by those with improvement in total WOMAC scores of > 30% from baseline versus non-responders. Responders with sustained response of at least 12 months or more were determined.

Results: A total of 2037 (F 1467 (72%) & M 570 (28%)) patients were treated.
The overall responder rate was 1496 (73.4%) (F 1099 (74.9%) & M 397 (69.6%)).
The Primary responder rate was similar for VHMW-HA (73.5% in Gr III OA & 77.0% in Gr IV OA) and HMW-HA (71.0% in Gr III OA & 68.6% in Gr IV OA).
The Sustained response in VHMW-HA was greater (60.5% in Gr III OA & 68.5% in Gr IV OA) versus HMW-HA (47.3% in Gr III OA & 46.7% in Gr IV OA).

Table 1. The results are summarized in Table -1: -

INTERVENTION TYPE		VHMW-HA	VHMW-HA	HMW-HA	HMW-HA	TOTAL	RATE
GRADE OF OA		Grade III OA	Grade IV OA	Grade III OA	Grade IV OA	N	%
TOTAL PATIENTS TREATED	Total (%)	684 (33.6%)	631 (31.0%)	480 (23.6%)	242 (11.9%)	**2037**	
	Females	509	418	352	188	**1467**	**72.0%**
	Males	175	213	128	54	**570**	**28.0%**
PRIMARY RESPONDERS	Total (%)	503 (73.5%)	486 (77.0%)	341 (71.0%)	166 (68.6%)	**1496**	**73.4%**
	Females	394	330	251	124	**1099**	**74.9%**
	Males	109	156	90	42	**397**	**69.6%**
SUSTAINED RESPONDERS	Total (%)	414 (60.5%)	432 (68.5%)	227 (47.3%)	113 (46.7%)	**1186**	**58.2%**
	Females	311	286	166	84	**847**	**77.1%**
	Males	103	146	61	29	**339**	**85.4%**
NON RESPONDERS	Total (%)	181 (26.5%)	145 (23.0%)	139 (29.0%)	76 (31.4%)	**541**	**26.6%**
	Females	115	88	101	64	**368**	**25.1%**
	Males	66	57	38	12	**173**	**30.4%**

Primary responders – Total WOMAC scores improvement of > 30% from baseline, Sustained responders - Sustained WOMAC improvement for >=12 mts., Non-responders - WOMAC change < 30% or Lost to follow up. OA-Osteoarthritis Knees, Grade III and IV OA - radiological KL Grade, VHMW-HA - Very high Molecular weight hyaluronic acid, HMW-HA -High molecular weight hyaluronic acid.

Conclusion: The responders to treatment of 73.4% justify treatment outcome.
The primary response to treatment was similar in all the subgroups – Type of IAHA, Grade of OA and Gender.
However, the sustained response for 12 months or more was far greater in VHMW-HA versus HMW-HA.

IS COMBINING BETTER THAN SINGLE GAIT PARAMETER CHANGES FOR PEOPLE WITH MEDIAL OF KNEE OSTEOARTHRITIS? A STUDY ON THE KINETIC CHANGES INDUCED BY GAIT RETRAINING

Keywords: Osteoarthritis

L. C. Pereira[1,2], B. Ulrich[2], J. Runhaar[1], S. M. A. Bierma-Zeinstra[1], B. M. Jolles[2,3], J. Favre[2]. [1]*Erasmus MC University Medical Center, General Practice, Rotterdam, Netherlands*; [2]*Lausanne University Hospital, Swiss BioMotion Lab, Department of Muscoloskeletal Medicine, Lausanne, Switzerland*; [3]*Institute of Microengineering, Ecole Polytechnique Fédérale Lausanne (EPFL), -, Lausanne, Switzerland*

Background: Gait retraining has been demonstrated to be effective in reducing the peak knee adduction moment (pKAM) in individuals with knee osteoarthritis (KOA). Since medial-compartment loading has been related to both the pKAM and the peak knee flexion moment (pKFM), reducing the pKAM without pondering the changes in pKFM does not ensure a decreased load in the knee. It is unknown whether combining multiple gait parameters is more effective than isolated gait parameter changes in achieving specific kinetic targets for the pKAM and pKFM.
Objectives: To characterize the individual changes in the pKAM and in the pKFM in patients with medial KOA walking with a combination of varied gait parameters. We hypothesised that the number of people achieving the dual kinetic change (2KC) of decreasing the pKAM of at least 10% without increasing the pKFM through a combined parameter gait changes is higher than the number of people achieving it through a single gait parameter change.
Methods: We recruited medial KOA patients (K-L I-III) had a diagnosis confirmed through x-ray. A motion capture system and floor-embedded force-plates were used to measure the kinetics (pKAM and pKFM) and the spatio-temporal parameters (foot progression angle (FPA), step width (SW), stride length (SL) and walking speed) during gait. Gait retraining method used was an augmented-reality system. Each patient performed 81 trials combining three different amplitudes of PFA, SW and SL. Gait speed was controlled. The gait modifications were toeing-in by 15° or 10° or normal, walking width narrower (0.10m) or wider (0.15m) or normal SW, and/or walking with shorter (0.10 or 0.15m 0.15m) or normal SL. Descriptive statistics was used. The data of 17 patients, mean 52.7 years old (SD 15.9), mean height 172.9cm (12.8) and mean BMI 24.9 Kg/m^2 (3.2) was compiled for statistical analysis.
Results: 76.5% of the patients achieved the 2KC with at least one of the combination (Figure 1). Changing one gait parameter led to a 2KC in 7 patients and changing a combination of multiple parameters led to a 2KC in 13 patients. Adding a third to a combination of two gait parameters change "only" added one patient to the total number of patients achieving the targeted 2KC. All patients achieving the 2KC with a single modification were also able to achieve it using two combined modifications. All patients achieving the 2KC with a combination of two gait parameters, achieved it too combining modifications in three parameters. 5.9% of patients achieved the 2KC with a combination of three gait parameters only.
Conclusion: When compared to single-parameter changes, gait-retraining through an augmented-reality setting using a combination of multiple gait parameter changes is more likely to achieve the targeted kinetic changes. Future research should assess the percentage of KOA people retaining the 2KC on both the shorter- and the longer-term.

AB1194 A PROOF OF PRINCIPLE DIETARY INTERVENTION TRIAL TO EXAMINE THE PROTECTIVE EFFECT OF BROCCOLI BIOACTIVES, (SPECIFICALLY SULFORAPHANE), ON OSTEOARTHRITIS

Keywords: Diet and nutrition, Pain, Osteoarthritis

R. Davidson[1], L. Watts2, G. Beasy[3], S. Saha[3], P. Kroon[3], A. Cassidy[4], A. Clark2, W. Fraser2, I. Mcnamara[5], S. Kingsbury[6], P. G. Conaghan[6], I. Clark[7], A. Macgregor2. *[1]University of East Anglia, Norwich Medical School, Norwich, United Kingdom*; *[1]University of East Anglia, Norwich Medical School, Norwich, United Kingdom*; *[3]Quadram Institute Bioscience, Food, Innovation and Health, Norwich, United Kingdom*; *[4]Queen's University Belfast, Institute for Global Food Security, Belfast, United Kingdom*; *[5]Norfolk and Norwich University Hospital, Institute of Orthopaedics, Norwich, United Kingdom*; *[6]University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[7]University of East Anglia, School of Biological Sciences, Norwich, United Kingdom*

Background: Osteoarthritis (OA) accounts for more than a third of chronic moderate to severe pain in the UK. Sulforaphane (SFN) is a naturally occurring phytochemical derived from eating cruciferous vegetables, particularly broccoli. It has several biological activities that promote health, including anti-inflammatory properties. SFN has a potential role in limiting pain and cartilage destruction in OA.
Objectives: In a two centre, placebo-controlled, double-blind, two-arm parallel, RCT, proof of principle study with a primary outcome we evaluated whether dietary SFN (from consumption of broccoli) improves pain in participants with knee OA. Secondary objectives were to determine whether food containing SFN improves knee function, and the feasibility of the study design for an appropriately powered trial.
Methods: Participants with symptomatic and radiographic knee OA were recruited from regions of Norfolk and Leeds in the UK, were over 50 years of age with moderate to severe knee pain (at least 4 on 0-10 numeric rating scale), and radiological evidence of OA (Kellgren-Lawrence score 2-3). The intervention was a sensory-matched soup. Patients received either the intervention soup (300g high glucoraphanin soup (containing broccoli, and base vegetables)) or placebo soup (300g no glucoraphanin soup (base vegetables only)), once daily on 4 days per week. The study duration was 12 weeks with follow-up visits at 6 and 12 weeks. Knee pain and function outcome measures were obtained using WOMAC, an 11-point NRS, the ICOAP questionnaire and use of rescue analgesics/NSAIDS. Creatinine, metabolites of glucoraphanin, matrix metalloproteinase-3 and C-reactive protein were measured in plasma or 24-hour urine samples.
Results: Recruitment was severely curtailed due to the Covid-19 pandemic. In total n= 37 consented and n= 24 met screening criteria with one drop-out at week 12 (control n=17 and intervention n= 7), the recruitment aim was n= 64. Control group was 43% female, and mean age was 70.14 yrs [7.69 SD] (control), and 61.88 yrs [8.58 SD] (intervention). Mean BMI was 26.4[2.91 SD] (control) and 28.2[4.68 SD] (intervention). The intervention resulted in a trend towards a decrease in pain scores for each subscale of WOMAC, ICOAP and NRS measures: total WOMAC median difference from baseline (9.65 [CI:-0.78,20.09]), ICOAP constant (wk 12, 4.83 [CI: -1.99,11.64]) and intermittent pain (wk 12, 2.96 [CI: -0.31,6.24]), NRS overall pain (wk 12, 1.86 [CI: 0.13,3.58]), while a trend for increased satisfaction for knee function (wk12, -1.55 [CI: -3.55,0.44]) was also observed for this group. No change in rescue analgesics/NSAIDS for knee pain was seen in either group. Metabolites of glucoraphanin were detected in plasma and urine samples in the intervention group. Study compliance and intervention adherence was high (>70%-100%) while acceptability for randomisation was 100%.
Conclusion: Patient acceptability, adherence and retention was high and biomarkers and metabolites objectively confirming compliance with the intervention were detected. In this study, although underpowered to observe significant differences for pain, improving trends over time were observed across a range of clinical pain measures including the primary outcome, where the CI encompassed the minimal clinically important difference, requisite for progress to full trial. Given COVID impact on recruitment, the pilot achieved its aims, and we conclude that the intervention was feasible, and a full trial is justified.

AB1195 KNEE OSTEOARTHRITIS AND NEUROPATHIC PAIN: IMPACT OF RADIOGRAPHIC SEVERITY

Keywords: Pain

H. Fouzia[1], F. Z. Taik[1], I. Berrichi[1], N. Soba[2], M. Fourtassi[2], F. E. Abourazzak[1]. *[1]Faculty of Medicine and Pharmacy, Abdelmalek Essaadi University, Department of Rheumatology, CHU Tangier-Tetouan-El Hoceima, Tangier, Morocco*; *[2]Faculty of Medicine and Pharmacy, Abdelmalek Essaadi University, Department of Physical Medicine and Rehabilitation, CHU Tangier-Tetouan-El Hoceima, Tangier, Morocco*

Background: Pain in knee osteoarthritis remains the main symptomatology, classically considered as nociceptive. A neuropathic component of this pain has recently been described. The identification of which is essential for adequate management.
Objectives: The objective of our study is to evaluate the relationship between the prevalence of neuropathic pain and the stages of radiographic severity in gonarthrosis.
Methods: This is a descriptive cross-sectional study of patients with clinically and radiographically retained knee osteoarthritis. The radiographic stage was determined by the Kellgren and Lawrence classification. Neuropathic pain was assessed by the DN4 questionnaire. The neuropathic nature of the pain was retained if the DN4>=4. The patients included were divided into 4 groups according to the radiographic stage.
Results: 173 patients were included. The average age was 58.0±9.19 years. 88.2% were women. 32.7% of patients had neuropathic pain. Average pain VAS was 4.4±2.1. The median duration of evolution was 3.8 years[1-23]. 5.6%, 64.4%, 25.6%, and 4.4%, of the patients studied were classified by radiography as caution, 1, 2, 3, and 4 respectively. The prevalence of neuropathic pain was 16.6%, 34.4%, 35.5% and 33.3% in patients with radiographic severity grade 1, 2, 3, and 4 respectively. When comparing the groups, there was no difference in the DN4 score according to the stage of radiographic severity (p=0.633).
Conclusion: The results of our study suggest that the stage of radiographic severity does not predispose to neuropathic pain in patients with gonarthrosis.

AB1196 NEUROPATHIC PAIN IN GONARTHROSIS: PREVALENCE AND ASSOCIATED FACTORS

Keywords: Pain

H. Fouzia[1], F. Z. Taik[1], I. Berrichi[1], N. Soba[2], M. Fourtassi[2], F. E. Abourazzak[1]. *[1]Faculty of Medicine and Pharmacy, Abdelmalek Essaadi University, Department of Rheumatology, CHU Tangier-Tetouan-El Hoceima, Tangier, Morocco*; *[2]Faculty of Medicine and Pharmacy, Abdelmalek Essaadi University, Department of Physical Medicine and Rehabilitation, CHU Tangier-Tetouan-El Hoceima, Tangier, Morocco*

Background: Pain in knee osteoarthritis remains the main symptomatology, classically considered as nociceptive pain. A neuropathic component of this pain has recently been described. The identification of which is essential for appropriate management.
Objectives: The objective of our study is to evaluate the prevalence of neuropathic pain in patients with knee osteoarthritis, and to identify the associated factors.

Methods: This is a cross-sectional study involving patients with knee osteoarthritis. Sociodemographic and clinical data, including comorbidities, were collected. Neuropathic pain was assessed by the DN4 questionnaire. Neuropathic pain was defined by a DN4 >= 4. Depression, catastrophizing, and central sensitization were assessed by Arabic versions of validated questionnaires, PCS (Pain Catastrophizing Scale) for catastrophizing, and PHQ9 (Patient Health Questionnaire) for depression, CSI (central sensitization inventory) for central sensitization.
Results: 173 patients were included in our study. 88.2% are women. The average age was 58.0±9.19 years. 32.7% had neuropathic pain. VAS mean pain was 4.4±2.1. The median duration of evolution was 3.8 years [1-23]. The average lequesne index was 9.75±3.9. The median of the PCS score was 22 [0 –52], and the median of the PHQ9 score was 7 [0 – 24]. The average CSI score was 38.2±15. 72.6% of patients had comorbidities: 28.8% had obesity and 12.7% were diabetic. In multivariate analysis, only functional disability was associated with the presence of neuropathic pain p=0.04 (OR: 1.19, 95% CI [1.03 – 1.38]. However, pain severity, central sensitization, comorbidities including diabetes and obesity did not come out as associated factors.
Conclusion: Neuropathic pain is quite common in gonarthrosis. Functional disability seems to be an associated factor.

AB1197 CAN OSTEOARTHRITIS, SARCOPENIA AND BODY COMPOSITION PREDICT LOSS OF FUNCTION?

Keywords: Sarcopenia, Osteoarthritis

S. Pais[1,2,3], M. Botelho[3,4], R. Moreira[4], C. Guerreiro[3,4]. [1]*Universidade do Algarve, Faculdade de Medicina e Ciências Biomédicas, Faro, Portugal*; [2]*Comprehensive Health Research Centre (CHRC), Nova Medical School, Lisbon, Portugal*; [3]*ABC-RI, Algarve Biomedical Center Research Institute, Health, Ageing and Kinetic Lab, Faro, Portugal*; [4]*ABC- Algarve Biomedical Center, Sandra Pais Laboratory, Faro, Portugal*

Background: Elderly populations e growing in the majority of Countries in the World. Portugal in currently among the 5 most aged counties with 23,4% of it´s population over 65 and an ageing index of 182[1]. Osteoarthritis is the 3rd cause of responsible for severe disability in adults over 60 years in developed and developing countries[2]. Lack of data at a national or regional level in Portugal compromises the ability to prepare for both health and care need of aged population. Simultaneously the region of Algarve has particular geographic characteristics with 49% of the population living within 2 km from the cost (in 9% of the Algarve's Territory).
Objectives: Are aim was to study our regional population, namely the incidence of Osteoarthritis (OA) and the relation of function ability with OA, Sarcopenia and Body composition.
Methods: This study is a prospective, observational secondary analysis of data from the "*Sarcopenia Screening Study in the Algarve Region*". Subject were recruited through informative flyers that was distributed at Elderly Associations, Senior Universities,… in different areas of the region of Algarve. Subsequently, by appointment, the evaluations were performed. Until June 2022 a total of 270 participants have voluntarily participated. Subjects over 60 were eligible for the study. All gave their informed consent to participate. Clinical diagnose of OA was established according to the NICE Guidelines for knee osteoarthritis diagnose[3]. Functional ability was measures with the Lower Extremity Functional Scale (LEFS)[4], sarcopenia was measures with the SARC-F Questionnaire[5], body composition was evaluated by Medical Body Composition SECA® mBCA515. Data was treated with IBM-SPSS-Statistics version 26.
Results: Of the 270 subjects analyzed for this secondary analyze 75,2% were female (24,8% male), mean age in years 75,39 ± 6,75 (60-93). 70,5% had Knee OA. Statistical differences was found between groups (with and without OA), in LEFS (p<0,001), SARC-F (p<0,001), percentage of fat free mass (p<0,001). A multiple linear regression was carried out to see if having OA, Sarcopenia and percentage of fat free mass can predict LEFS, once all were significantly different within groups, creating a statistically significant model [Z(3,233)=155,957; p<0,001:R^2=0,668] were with having OA (ß=-0,121;t= -271;p=0,003), Sarcopenia (ß=-0,694;t= -16,258;p<0,001), and low muscular mass (ß=0,146;t=3,468 ;p<0,001), can significantly predict diminished lower extremity function.
Conclusion: Looking for the presence of OA, Sarcopenia and low percentage of fat free mass is important when monitoring elderly subjects over time once they can predict the decrease in functional ability.

AB1198 CLINICAL PROFILE OF HAND OSTEOARTHRITIS IN A LOW INCOME POPULATION

Keywords: Descriptive studies, Osteoarthritis, Epidemiology

F. De Azevedo[1], J. P. Borges[1], G. Da Silva[1], J. C. Costa Junior[2], J. E. Fonseca[3], F. A. Castro Rocha[1]. [1]*Faculdade de Medicina da Universidade Federal do Ceara, Internal Medicine, Fortaleza, Brazil*; [2]*Instituto Sao Carlos de Medicina e Pesquisa, Radiology, Fortaleza, Brazil*; [3]*Instituto de Medicina Molecular - Universidade de Lisboa, Rheumatology, Lisboa, Portugal*

Background: hand osteoarthritis (HOA) is a highly prevalent disease that may be impacted by social inequalities. However, there are few studies on HOA from underdeveloped regions.
Objectives: to present clinical characteristics of a HOA cohort from a low-income population.
Methods: clinical data and serum from 70 patients with a diagnosis of HOA fulfilling ACR criteria seen between March 2020 and December 2022 in Fortaleza/Brazil registering hypertension, diabetes, obesity (BMI>30 kg/m²), and concurrent diagnosis of knee or spine OA and "bunions"; pain (VAS, visual analogue scale), X-ray (Kellgren-Lawrence) and ultrasonography (US) [synovitis and power-doppler (PD) sign] of the most affected joint of the hand were recorded, as well as grip and pinch strength (KgF), Cochin hand functional scale (CHFS), FIHOA, and SF-12 scores. Social data included income, occupation [white (WCJ) *vs.* blue (BCJ) colar jobs], education level [>/≤ 8 school-years (SY)].
Results: 70 patients were included, comprising 66(94%) women, mean age 60.3±10.3 with 12(17.1%) below 50 years-old; median disease duration was 72(range 30-120) months. Pain on movement (VAS) was 7.4±1.9, grip strength 14.5±6.4, pinch strength 1.7±1, CHFS 21±14.8, FIHOA 10.3±6.2, and SF-12 32.1±3; 54(77.1%) had KL≥3. All but 2 out of 61 evaluated joints had synovitis at US with only 4(6.7%) displaying positive PD signal; 27(38.5%) had isolated HOA; 9(12.8%), 8(11.4%), and 5(7.1%) had concurrent spine or knee OA or bunions, respectively and 22(31.4%) had ≥2 sites other than HOA; 31(44.2%), 16(22.8%), and 7(10%) had hypertension, obesity and diabetes as comorbidities, respectively; 38(54.2%) declared <900 US$ monthly family earnings, 8(11.4%) had <8SY and 27(38.5%) had occupations classified as BCJ. Mean pain was similar regardless of occupation, literacy (SY) or monthly family income. Although pain in BCJ group (7.9±1.7) was higher than in WCJ group (7.1±2) it did not reach statistical significance (p=0.0576); CHFS, FIHOA and SF-12 scores were similar regardless of occupation, SY or income; total mean CRP was 0.41±0.64 mg/dL; mean CRP in those with concurrent knee OA (0.38±0.25 mg/dL) had a trend to be higher than in isolated HOA patients 0.24±0.1 mg/dL (p=0.0547).
Conclusion: Our results suggest that income and literacy did not influence disease severity in HOA in our low income cohort.

AB1199 PAIN ON WALKING AND PAIN AT REST IN PATIENTS WITH KNEE OSTEOARTHRITIS: IS THERE A DIFFERENCE?

Keywords: Osteoarthritis, Pain

F. Idrissi Zaki[1], A. Rafi[1], A. Mougui[1], I. El Bouchti[1]. [1]CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Rheumatology, Marrakech, Morocco

Background: The knee osteoarthritis (KOA) pain can be divided into two main categories: pain on walking and pain at rest. A thorough understanding of pain is essential for managing KOA. However, few studies have focused on these two types of pain.
Objectives: The objective of this study was to investigate possible factors associated with knee osteoarthritis pain with a focus on the differences between pain on walking and pain at rest.

Methods: Cross-sectional study including 87 patients. All demographic data and visual analog scale (VAS) score at walking, VAS score at rest, Kellgren and Lawrence (KL) stage on radiography, and results of clinical examination were collected. Exclusion criteria were the presence of a total knee prosthesis and patients followed for chronic inflammatory rheumatism. Statistical data analysis was performed using SPSS version 21 software.
Results: This study included 87 patients followed for KOA, with an average age of 63.67+/-5.8 years (46-83 years), and a female predominance (78.3%). In the univariate analyses, significant correlations were found between the VAS score at walking with age (r=0.56, p=0.037), body mass index (BMI) (r=0.61, p=0.023), KL grade (r=0.54, p=0.039) and patellar shock (r=0.46, p=0.044). While the VAS score at rest was only correlated with BMI (r=0.26, p=0.01). And an association between VAS at rest and skin hyperalgesia was noted (p=0.034). The multivariate analysis showed that the significant explanatory factors of the VAS score on walking were BMI > 25kg/m2 (p=0.03) and KL grade >3 (p=0.03). On the other hand, no significant explanatory factor for the VAS score at rest was found.
Conclusion: Predisposing factors were significantly different between the two types of pain, indicating the presence of different pain mechanisms. Pain on walking was more strongly associated with mechanical and structural factors, whereas pain at rest was associated with knee hyperalgesia.

AB1200 WAIST CIRCUMFERENCE AND GONARTHROSIS

Keywords: Osteoarthritis

A. Rafi[1], F. Idrissi Zaki[1], Z. Baba[1], A. Mougui[1], I. El Bouchti[1]. *[1]CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Rheumatology, Marrakech, Morocco*

Background: Overweight, translated into a high body mass index (BMI), is associated with a risk of gonarthrosis, thus, this risk is increased by 15% for each increase of a unit of body mass index (BMI). (1) Various studies indicate that the association of high BMI and abdominal obesity measured by waist circumference leads to increased morbidity especially in obese. But no study has so far shown a sufficiently strong association force between waist circumference and gonarthrosis.(2,3)
Objectives: The objective of our study is to assess the relationship between waist circumference and pain perception and gonarthrosis impact.
Methods: This work included patients followed in consultation for gonarthrosis. For each patient we specified next to the demographic data, the BMI, the waist circumference, and the existence or no pain of the knee or both. The intensity of pain was assessed by the Analog Visual Scale (EVA). Functional impact was assessed by the Lequesne index and Womac score. Knee X-rays were classified according to Kellgren Lawrence (KL) criteria.
Results: A total of 209 patients were included (24 men/185 women). The average age was 57.94± 9.01 years. The average body mass index was 25.15 ±5.47 kg/m2and the average TI was 93.45 ±12.35 cm. The average pain EVA at rest was 1.95 2.53 and at stress 7.89 ±1.30. Womac's average score was 12.3± 8.92 and Lequesne's average index was 6.71 3.20. WOMAC SCORE was significantly higher in gonarthrosis patients with a high waist circumference (p = 0.02). A positive correlation was found between the resting and stress pain EVA and the waist circumference of gonarthrosic patients with respectively (p=0.04, p=0.002). but it is statistically insignificant between the radiographic stages, the lesquene index and waist circumference with (p=0.11, p=0.06, respectively).
Conclusion: The the waist circumference seems to be a predictive factor of the presence of gonalgie and a significant functional impact.

AB1201 DIGITAL SELF-MANAGEMENT, ANALGESIC USE AND PATIENT-REPORTED OUTCOMES IN KNEE OR HIP OSTEOARTHRITIS

Keywords: Telemedicine, Osteoarthritis, Self-management

A. Kiadaliri[1], S. Lohmander[1], L. Dahlberg[1,2]. *[1]Lund University, Clinical Sciences Lund, Lund, Sweden*; *[2]Joint Academy, Science, Malmö, Sweden*

Background: Despite recommendations for exercise therapy, patient education and weight loss as the first-line treatment for osteoarthritis (OA), analgesics are commonly used to manage pain [1].
Objectives: To investigate analgesic use among participants of a digital first-line treatment for knee or hip OA. We also explored the associations between analgesics use and pain/function.
Methods: We included individuals participating in the treatment during December 2021–July 2022 with data on analgesic use at baseline and 12-week follow-up (N=4100, mean [SD] age 64.5 [9.3], 73.3% females). Using self-reported data on analgesic use (paracetamol, NSAIDs, opioids, other) during the past month at baseline and follow up, we created a 4-category variable: non-users ("no" at both), persistent users ("yes" at both), quitters ("yes" at baseline and "no" at follow-up) and new users ("no" at baseline and "yes" at follow-up). Data on NRS Pain (0-10, higher value = more pain) and function, measured by the Knee injury/the Hip disability and Osteoarthritis Outcome Score 12 (KOOS-12/HOOS-12) Function subscale (0-100, higher values = better function), were collected. The McNemar test was used to assess the change in analgesic use. Multivariable logistic regression was used to compare characteristics of analgesics users/non-users at baseline. We applied a linear random intercept model adjusted for baseline characteristics to investigate the associations between analgesics use and pain/ function.
Results: Among included participants, 2517 (61.4%) were analgesic users at baseline. Female sex, hip OA, lower education, higher body mass index, living outside three largest metropolitan cities, rheumatoid arthritis, and walking difficulties were associated with higher odds of analgesic use at baseline. From baseline to 12-week follow up, the proportion of analgesic users dropped by 12.0% (95% CI, 10.5, 13.5), from 61.4% to 49.4%. The results of linear random intercept model suggested that at both baseline and 12-week follow up, persons not using analgesics at the time had better outcomes (Table 1). Moreover, all groups but "new users" experienced improvements in their pain and function following participation in digital program with the greatest improvements observed among "quitters". Interestingly, the magnitude of improvements was comparable for "non-users" and "persistent users".
Conclusion: Participation in a digital self-management program for hip or knee OA was associated with 12% drop in analgesic use. Analgesic use was associated with worse pain and function in these people. Greatest improvements were seen for those who stopped analgesic use. Similar results were reported for a face-to-face first-line treatment in Denmark [1, 2]. These results highlight the importance of providing effective first-line treatment to people with hip or knee OA.

AB1202 PARTICULARITIES OF KNEE OSTEOARTHRITIS FUNCTIONAL IMPACT IN A GERIATRIC POPULATION

Keywords: Osteoarthritis

L. Rouached[1], W. Lahmar[1], S. Bouden[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]. [1]*Charles Nicolle Teaching Hospital, Rheumatology, Tunis, Tunisia*

Background: Knee osteoarthritis (KOA) is the most common of osteoarticular diseases. Its increasing incidence with age means that the geriatric population is particularly exposed.

Objectives: The aim was to study the functional impact of knee OA in elderly subjects.

Methods: A cross-sectional study of 52 patients aged ≥65 years, followed for knee OA. Clinical characteristics of knee OA, pain intensity (VAS) were collected. Functional impact was assessed by the short form of the Knee Injury and Osteoarthritis Outcome Score (KOOS-PS) with a score ranging from 0 (no difficulty) to 100 (extreme difficulty). Radiographic severity was classified according to the Kellgren Lawrence criteria.

Results: The mean age was 73.7±7.8 years and the sex ratio (male/female) was 0.13. KOA was femoro-tibial in 79% and femoro-patellar in 21%, the internal compartment was affected in 98% of cases, and a bilateral involvement was found in 94% of cases. The knees were in varus in 30% of cases, in valgus in 23%. The VAS pain was 6.63±1.89. The mean KOOS-PS score was 48.04±19.1. The radiographic severity stages of KOA according to KL were classified as follows: stage 2 (17%), stage 3 (50%), and stage 4 (33%). A positive and significant correlation between the KOOS and VAS pain was found (r: 0.6; p<0.00). There was no correlation between the KOOS and the radiographic stage (p=0.17), the duration of evolution (p=0.43).

Conclusion: In elderly patients with knee OA, there is no concordance between radiographic severity and functional impact. The latter goes hand in hand with the pain experienced.

AB1203 EVALUATION OF THE URIC ACID AND HEMATOLOGICAL PARAMETERS IN PATIENTS WITH NODAL HAND OSTEOARTHRITIS

Keywords: Diagnostic tests, Osteoarthritis

A. Ünal Engİnar[1]. [1]*Konya City Hospital, Rheumatology, Konya, Turkey*

Background: Osteoarthritis (OA) is the most commonly seen joint disease worldwide. The frequency of OA is increased together with an increase in obesity and ageing. The hand is one of the most frequently involved areas, and hand OA is seen more often in females.

Objectives: To compare patients with symptomatic nodal hand osteoarthritis (OA) with a control group in respect of inflammation parameters, uric acid, and hematological parameters.

Methods: The study included 50 post-menopausal female patients, aged 40-80 years, diagnosed with symptomatic nodal hand OA, and a control group of 50 post-menopausal females in the same age range with no hand OA. Patient data including age, monocyte, neutrophil, lymphocyte, and thrombocyte counts, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) level, uric acid level, and the Kellgren-Lawrence (KL) score obtained from evaluations of hand radiographs, were recorded retrospectively from the hospital information system. The neutrophil-lymphocyte ratio (NLR), thrombocyte-lymphocyte ratio (PLR) were calculated. The data were compared between the two groups.

Results: The data of 100 females were compared, comprising a patient group of 50 patients with symptomatic nodal OA, and a control group of 50 females. Age, monocyte, neutrophil, lymphocyte, and thrombocyte counts, NLR, PLR, ESR, CRP, and uric acid level were compared. With the exception of ESR, no statistically significant difference was determined between the two groups. The ESR was determined to be statistically significantly higher in the patient group than in the control group (p<0.001). When patients with a KL score of 2 and 3 were compared, with the exception of age, no other difference was determined. Patients with a KL score of 3 were seen to be significantly older (p:0.032).

Conclusion: ESR was determined to be significantly higher in patients with symptomatic nodal OA. Clarification of the relationship between inflammation, uric acid, and hand OA, which is a heterogeneous disease, will be useful in the follow-up and treatment of patients.

AB1204 THE COMPARISON OF THREE DIFFERENT MANAGEMENT STRATEGIES FOLLOWING PLATELET RICH PLASMA INJECTION IN PATIENTS WITH KNEE OA

Keywords: Osteoarthritis

S. Bozgeyİk[1], H. Kilinç[2], G. Hurİ[3], H. Guney Deniz[1]. [1]*Hacettepe University, Faculty of Physiotherapy and Rehabilitation, Department of Musculoskeletal Rehabilitation, Ankara, Turkey*; [2]*Hacettepe University, Faculty of Physiotherapy and Rehabilitation, Department of Physical Therapy and Rehabilitation, Ankara, Turkey*; [3]*Hacettepe University, Faculty of Medicine, Department of Orthopedics and Traumatology, Ankara, Turkey*

Background: The main symptoms of patients with knee osteoarthritis (OA) are defined as pain, muscle weakness and functional impairments. Muscle strengthening exercises are recommended in core treatment of conservative management of knee OA [1]. Recently, intraarticular platelet-rich plasma (PRP) injection has gained much attention for the management of knee OA. A combination of different approaches is also recommended for achieving better symptomatic relief.

Objectives: The aim of the study was to compare the effect of PRP plus supervised exercise, PRP plus home exercise and only PRP in patients with knee OA.

Methods: Patients with knee OA aged 45-70 years old were included. The demographic characteristics of the patients were recorded, and they were randomly divided into three groups: PRP plus supervised exercise group (PRP+SEG); PRP plus home exercise group (PRP+HEG); PRP group. The pain was assessed with visual analogue scale (VAS); knee functions were assessed with Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) and the stair test was assessed with a 10-step stair. The PRP+SEG performed the exercises under the supervision of a physiotherapist and PRP+HEG performed the same exercises at home. Both PRP+SEG and PRP+HEG performed a total of 6-week (3 times/week) strengthening exercises for knee and hip muscles. The PRP group received only PRP injection. All assessments were performed at 3rd day after PRP injection and at 6th week.

Results: A total of 41 female patients (mean age: 56.65±±6.64 years; mean BMI: 28.82±5.19 kg/m^2) were randomized (PRP+SEG (n=15); PRP+HEG (n=12); and PRP (n=14)). There was no significant difference between three groups at baseline (p>0.05). There was significant difference in VAS (p=0.001); WOMAC Pain (p=0.003); WOMAC-Function (p=0.001) and WOMAC Total (p=0.001) scores between three groups at 6th week. The PRP+SEG had greater relief in pain both VAS and WOMAC Pain scores and greater improvement in WOMAC Function and WOMAC Total scores compared to PRP+HEG and PRP at 6th week. There was no significant improvement in stair test and WOMAC Stiffness scores for all groups at 6th week (p>0.05) (Table 1).

Conclusion: A combination of supervised exercise with PRP injection resulted in better symptomatic relief in patients with knee OA. Clinicians should consider the

Table 1. Comparison of groups at baseline and at 6th week.

AB1205 IMPACT OF CATASTROPHIZING ON PAIN, FUNCTION, AND PHYSICAL PERFORMANCE IN PATIENTS WITH KNEE OSTEOARTHRITIS

Keywords: Osteoarthritis, Pain

N. Takhrifa[1], F. Z. Taik[1], A. Adnine[1], N. Soba[2], M. Fourtassi[2], F. E. Abourazzak[1]. *[1]Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco; [2]Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco*

Background: Osteoarthritis (OA) is the most common osteoarticular disease, with pain and functional discomfort being the main symptoms leading patients to consult. Catastrophism is defined as an exaggerated negative reaction to an anxiety-provoking stimulus. It is considered to be an important cognitive factor in painful conditions, particularly in osteoarthritis.

Objectives: The aim of this study was to assess the level of catastrophizing and to determine the relationship between catastrophizing and pain intensity, functional impact, and physical performance.

Methods: This is a cross-sectional study conducted in the rheumatology department. Sociodemographic information and comorbidities were collected. Pain was assessed by Visual Analogic Scale (VAS); functional impact by the Lequesne knee index and radiographic stage by the Kellgren and Lawrence scale. The level of catastrophizing was assessed by the validated Moroccan version of the Pain Catastrophizing Scale (PCS). A PCS $\geqslant$ 30 indicate high level of catastrophizing. Physical performance was assessed by the 06min walk test and IPAQ questionnaire.

Results: A total of 178 patients were included. The sociodemographic and clinical characteristics of the patients are presented in (Table 1).

Table 1. Demographic and clinical characteristics of patients

Parameters	PCS <30	PCS >30	P value
Number of patients = 178	105 (59 %)	64 (36 %)	—
Age (Mean ±SD)	59.3±9	57±10.7	*p=0.369*
Femal gender (%)	82.9%	95.3%	***P=0.013***
Comorbidity (%)	68.6%	73.4%	*P=0.654*
Analphabetic (%)	68.6%	71.9%	*P=0.150*
Lequesne score (±SD)	9.3±3.8	10.7±4	*P=0.189*
Radiological stage (±SD)	2.2±0.6	2.4±0.6	*P=0.228*
VAS pain (±SD)	4.1 ± 2.5	5.6 ± 2.8	*P=0.313*
Median time of evolution	3 years[1-7]	4 years[1-10]	*P=0.069*
The mean distance walked in 06 minutes	372 ± 137	355 ± 147	*P=0.586*
Patients with a physical disability	74.3%	80.7%	*P=0.427*

Univariate and multivariate analysis showed the Lequesne index (p=0.008) and anxiety (0.001) were statistically significantly associated with the level of catastrophizing.

Conclusion: The level of catastrophizing seems to have an impact on function and anxiety. However, there was no association between catastrophizing and the walking test. Catastrophism is an important factor to assess at the beginning of the management of a patient with OA.

AB1206 THE SOURCES OF DISEASE-RELATED INFORMATION FOR MOROCCO'S OSTEOARTHRITIS PATIENTS

Keywords: Osteoarthritis, Patient information and education

F. Z. Aharrane[1], F. Z. Taik[1], R. Bensaid[1], N. El Mansouri[1], N. Soba[2], M. Fourtassi[2], F. E. Abourazzak[1]. *[1]Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco; [2]Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco*

Background: In osteoarthritis, the patients have an almost continuous need of information and communication. In addition to the information delivered by health professionals, patients tend to look for other sources to complete it.

Objectives: Our study aims to investigate the non-conventional sources of information used by osteoarthritis patients and to identify the possible associated factors.

Methods: This is a cross-sectional study, conducted in the rheumatology department at the University Hospital Center in Tangier, which included patients diagnosed with osteoarthritis.Data on sociodemographic characteristics, clinical presentations, comorbidities, and the health outcomes of patients were examined. Patients' beliefs and attitudes about disease-related sources of information were assessed by a questionnaire.A list of 12items was proposed to the patients who mentioned the different used sources, their level of trust, and their experience with the effectiveness of these sources. Binary logistic regression was conducted to identify the associated factors with the use of the disease-related sources of information.

Results: We included 221 patients. The mean age was 59.4 ± 9.8, 88.7% of the patients were female, and 69.2% had comorbidities. 80.5% were diagnosed with knee osteoarthritis and 19.5% with hand osteoarthritis. The median of disease duration was 8 [2-10] years. 31.2% of the patients sought information related to their osteoarthritis, the 3 main sources were: peers (21.7%), YouTube (17.2%) and television (13.1%). 12.7% have already applied some of this information. Only 10% of patients discussed the found information with their physicians and 85.4% would like to have health professionals in their online space to answer their questions. In uni and multivariate analysis, age (OR=0.959, IC95% [0.927-0.991], p=0.014) and level of education (OR=1.597, IC95% [1.146-2.224], p=0.006) were statistically significant with the use of non-conventional information sources.

Conclusion: Our study showed that Morocco's osteoarthritis patients, especially those with certain age and level of education, are seeking information about their disease. Rheumatologists need to invest more, especially on virtual spaces, to respond to these requests.

PREVALENCE OF NEUROPATHIC PAIN AND ITS ASSOCIATION WITH CLINICAL OUTCOMES IN PATIENTS WITH PRIMARY KNEE AND HIP OSTEOARTHRITIS

Keywords: Pain, Patient reported outcomes, Outcome measures

D. Santos Oliveira[1,2,3], A. Martins4,5, J. Silveira5, F. Neto[6,7,8], L. Costa4, C. Vaz4,5,9, J. Ferreira-Gomes[6,7,8]. *[1]Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal*; *[2]Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal*; *[3]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; *[1]Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal*; *[2]Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal*; *[6]Faculty of Medicine, University of Porto, Department of Biomedicine, Porto, Portugal*; *[7]University of Porto, i3S - Institute for Research & Innovation in Health, Porto, Portugal*; *[8]University of Porto, IBMC - Institute of Molecular and Cell Biology, Porto, Portugal*; *[3]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*

Background: Osteoarthritis (OA) is a common musculoskeletal disease associated with significant chronic pain and physical disability. The presence of pain with a neuropathic component may be associated with different phenotypes of this condition.
Objectives: Thus, this study aimed to explore the prevalence of neuropathic pain (NP) and its association with sociodemographic characteristics and clinical outcomes (pain severity and disability), in patients with primary knee and hip OA.
Methods: A cross-sectional study involving adult patients with a primary knee and hip OA diagnosis according to American College of Rheumatology (ACR) was conducted. Sociodemographic variables, symptoms and disease duration and pain characteristics were obtained. Pain severity was assessed with Pain Visual Analog Scale (VAS) and functional disability with Health Assessment Questionnaire (HAQ). Western Ontario and McMaster Universities Arthritis Index (WOMAC) was used to assess pain, stiffness and physical function. The pain DETECT scale was used to evaluate NP in these patients. In order to correlate NP with sociodemographic, clinical and pain characteristics, a correlation coefficient was used- Pearson coefficient. Linear and logistic regression models adjusted for age, gender, symptom duration and diagnosis duration were applied to assess the main predictors of NP.
Results: A total of 36 patients (mean age of 65.1±8.9 years old; 72.2% female) with primary knee OA (n=13, 36.1%), hip OA (n=4, 11.1%) and both (n=19, 52.8%) were included. Patients had a mean symptoms duration of 13.3±8.7 years and a median disease duration of 5 [3-13] years. The mean Pain VAS was 5.0±3.4, and the median HAQ of 1 [0.65-1.91]. The mean of WOMAC- pain, -stiffness, -physical function and -total were 11.9±4.2, 4.5±2.2, 37.5±15.4 and 53.8±20, respectively. Characteristics of NP were found in 28 (77.8%) patients and the mean of PAINDETECT scale was 31.1±11.9. None of the patients had treatment aimed at NP. There were positive correlations between NP and Pain-VAS (r_p =0.63, p=0.001), HAQ (r_p =0.33, p=0.005), WOMAC-physical function (r_p =0.41, p=0.027) and WOMAC-total (r_p =0.38, p=0.049). In the multivariable model, Pain-VAS predicted NP (β=0.76, p=0.014).
Conclusion: Our study demonstrated that NP is common in patients with OA. The presence of this type of pain is associated with worse clinical outcomes, namely pain severity and functional disability. Hence, these findings encourage the screening of NP in all patients with knee and hip OA in order to implement more appropriated therapeutic strategies.

AB1208

THE RELATIONSHIP BETWEEN KNEE MUSCLE STRENGTH WITH DISABILITY AND PAIN IN PATIENTS WITH KELLGREN-LAWRENCE GRADE III-IV KNEE OSTEOARTHRITIS: A PILOT STUDY

Keywords: Rehabilitation, Physical therapy/Physiotherapy, Osteoarthritis

I. Ayas[1], Z. Hazar[1], F. Abdulaliyev[2], C. Güngör[2], H. Ozer[2]. *[1]Gazi University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey*; *[2]Gazi University Faculty of Medicine, Department of Orthopedics and Traumatology, Ankara, Turkey*

Background: Knee osteoarthritis (OA) is the most common chronic joint disease and is the main cause of disability and pain. It is important to better understand potentially modifiable risk factors that may reduce disability and pain in advanced knee osteoarthritis.
Objectives: The aim of this study was to investigate the relationship between knee muscle strength with disability and pain in patients with advanced OA.
Methods: Twenty-one patients (66.05 ± 8.02 years, 32.77 ± 5.37 kg/m^2) with Kellgren-Lawrence grade III-IV OA were included in this pilot study. Knee flexion and extension muscle strength were measured with Easy Force® isometric pull dynamometer in accordance with the make test procedure. Disability was measured with Knee Injury and Osteoarthritis Outcome Score (KOOS), and pain intensity was measured with VAS and Pain Catastrophizing Scale (PCS).
Results: The knee flexion strength of the patients was 75.52 ± 29.58 N, and the knee extension strength was 155.42 ± 49.84 N. Knee flexion strength was 17.85 ± 32.06 % and extension strength was 22.60 ± 21.10 % less than the other extremity. The total KOOS scores of the patients were 48.90 ± 24.78 %, PCS scores were 27.58 ± 15.82 and VAS were 8.42 ± 1.69. Flexion muscle strength of patients were moderately correlated with KOOS (r=0.44, p<0.05), but not with PCS and VAS scores. Extension muscle strength of patients was highly correlated with KOOS (r=0.70, p< 0.001), but not with PCS and VAS scores.
Conclusion: In advanced knee osteoarthritis, knee extension strength deteriorated more than knee flexion strength. Exercise interventions for knee extension strength training can provide superior outcomes in knee extensor strength and function but not in pain.

AN INVESTIGATION OF THE VARIABLES INFLUENCING PLATELET-RICH PLASMA FEATURES IN INDIVIDUALS WITH KNEE OSTEOARTHRITIS

Keywords: Synovium, Osteoarthritis, Gender/diversity issues

S. Karaborklu Argut[1], D. Celik[1], O. Ergin[2], O. Kilicoglu[3]. *[1]Istanbul University-Cerrahpasa, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey*; *[2]Istanbul University, Istanbul Faculty of Medicine, Department of Orthopaedics and Traumatology, Istanbul, Turkey*; *[3]Koc University, Faculty of Medicine, Department of Orthopaedics and Traumatology, Istanbul, Turkey*

Background: Platelet Rich Plasma (PRP) has drawn great interest as a regenerative adjunct therapy, and it is increasingly used in management of knee osteoarthritis (OA). The primary goal of PRP injections is to deliver a higher concentration of platelets to the target area than blood circulation does. The features and content of the injected substance are vital when evaluating the effectiveness of PRP.
Objectives: The objective of this study was to investigate the factors affecting the features of PRP in patients with knee OA.
Methods: Potential volunteers with diagnose of symptomatic knee OA were included if they had knee pain greater than 3 points on 11-point numerical pain rating scale. Exclusion criteria were i) lower hemoglobin count than 15g/dL, ii) ongoing anticoagulation therapy, iii) using non-steroidal anti-inflammatory drugs in previous 3 weeks before the participation, iv) previous operation in affected knee v) active infection or malignancy, and vi) impaired cognition. To perform complete cell counts for both whole blood and PRP, 20 ml of the whole blood was drawn from the ante-cubital vein of the patients under sterile conditions. PRP was prepared using a commercially available kit, tubes contains 3.20% concentrated 0,1M of sodium citrate to block the coagulation. After phlebotomy, the tubes were placed swing-out rotor centrifuging device and were centrifuged at 830g for 4 minutes. A correlation analysis was performed between the features of PRP and the patient-related variables, including age, gender, BMIs, smoking status, presence of other diseases, physical activity scores, duration of symptoms, and pain levels. Pearson's correlation coefficient, point bi-serial correlation, and paired sample t test were performed; alpha level was set at 0.05 in all analyses.
Results: A total of 62 patients (mean age: 56.68 ± 7.13 years) were included in the analysis. The dose of injected platelets was 3.25 billion, efficiency of the process was 77%, and the purity rate of the PRP was %98.4. These results indicated "high dose (B)", "medium platelet recovery rate (B)", and "very pure (A)". PRP platelet count was correlated with whole blood platelet count (r=0.81, p<0.001), whole blood WBC count (r=0.39, p=0.002), smoking status (r=0.56, p=0.03), smoking index (-r=0.63, p=0.002), and the presence of hypertension (r=-0.31, p=0.04). PRP WBC and purity of PRP were correlated with smoking status of the patients (r=0.52, p=0.01; r=0.64, p=0.003, respectively). In addition, smoking index for current smokers was shown a good correlation with PRP WBC (r=0.57, p=0.02) and a fair correlation with purity of PRP (r=0.35, p=0.04).

Conclusion: High dose and very pure PRP with medium efficiency was yielded with this PRP preparation procedure. Whole blood platelet count, the presence of hypertension, and the smoking status of the patients can affect the features of the yielded PRP in patients with OA. Considering these factors into account in the clinical decision is important for determining whether PRP is an option in the management of patients with knee osteoarthritis. These results may serve as a guide in terms of patient selection and avoiding unnecessary injections and their associated costs.

AB1210 SEPTIC ARTHRITIS IN HEMODIALYSIS PATIENTS

Keywords: Kidneys, Infection-related RMDs, Descriptive studies

R. Elafram[1], M. Ben Rodhane[1], M. Shaier[1], H. Kamoun[1]. [1]*University of Tunis El Manar, Orthopedics, Tunis, Tunisia*

Background: The frequency of musculoskeletal disorders in hemodialysis patients varies around 60% as the duration of their dialysis increases. Their physiopathology is complex and multifactorial. Septic arthritis represents 30% of these arthropathies.

Objectives: analyze the clinical, biological and radiological characteristics of septic arthritis in hemodialysis patients and to assess the results of the proposed treatment.

proposed treatment.

Methods: This is a retrospective study of 22 observations of septic arthritis in hemodialysis patients identified in our department over a 5-year period (2015-2022).

Results: The mean age was 43 years [22-60]. The sex ratio is equal to 1. The average duration of hemodialysis was 11.5 years [3 months-28 years]. Joint involvement was acute in 17 cases, with a mean duration of 4 days [1 day-1 week]. It was mono-articular, affecting the knee in18 cases and the elbow in 2 case, oligoarticular in 18 cases, and poly-articular in 2 case. Sacroiliitis was noted in 1 case. Biology: sedimentation rate, CRP and procalcitonin were increased in all patients. On standard radiography: obvious signs of arthritis were observed in 17 cases. Ultrasound showed joint effusion in 18 cases. Lumbar and sacral CT scans were performed in 1 case each and revealed multifocal destructive sacral arthropathy in 1 case and were consistent with unilateral sacral ilitis. Scintigraphy was requested twice. Joint biopsy was performed in 15 cases. Surgical treatment was required in 17 case.s. arthrotomy with joint lavage and biopsy of the synovium followed by an adapted antibiotic therapy according to the antibiogranmJe during 3 weeks by IV route relayed by an oral intake during 3 weeks while the antibiotic treatment alone after biopsy was practiced in 3 patients for two cases of polyartlu-itis and one case of deep localization.

Conclusion: Arthropathies of hemodialysis patients can have several clinical aspects. They occur on average after 10 years of hemodialysis.

AB1211 RISK FACTORS OF DEPRESSION IN PATIENTS WITH KNEE OSTEOARTHRITIS

Keywords: Osteoarthritis

S. Elarem[1], I. Haddada[1], A. Haj Salah[1], N. El Feni[2], M. Sghir[1], W. Kessomtini[1]. [1]*Taher Sfar Hospital, PMR, Mahdia, Tunisia*; [2]*Ibn El Jazzar Hospital, PMR, Kairouan, Tunisia*

Background: Knee osteoarthritis (KOA) is among the mean sources of chronic pain and functional disability which may lead to anxiety and depression.

Objectives: The aim of this study was to determine risk factors of depression in patients with KOA.

Methods: We conducted an analytical cross-sectional study over a 3-month period, including patients presenting with KOA. Demographic data, history of KOA and Kellegren and Lawrence radiographic stage were collected. Functional discomfort was assessed by the Lequesne knee index and catastrophizing was assessed by the Pain Catastrophizing Scale (PCS) questionnaire. Psychological assessment was performed by the Hospital Anxiety and Depression (HAD) scale.

Results: Ninety patients with KOA were included. The mean age was 58.76 ± 9.1 years. The mean BMI was 30.19 ± 5.54. The average Lequesne index was 11.33 ± 3.53 and the average PCS was 23.91 ± 11.28. A high depression score was noted in 58.9% of patients. Depression was significantly associated with sex ($p = 0.001$), BMI ($p=0.03$), lequesne index ($p=0.02$) and PCS ($p=0.00009$).

Conclusion: Pain catastrophizing thoughts in KOA and obesity worsen patients' attitudes and psychological profile towards pain and may lead to depression.

AB1212 OSTEOARTICULAR TUBERCULOSIS, A VERY CHALLENGING DIAGNOSIS

Keywords: Rare/orphan diseases, Bone diseases, Osteoarthritis

S. Bachrouch[1], I. Chaabane[1], M. Jlidi[2,3], H. Tounsi[1], Z. Alaya[1], R. Amri[1]. [1]*Mohamed Taher AL Maamouri Hopital, Internal Medicine, Nabeul, Tunisia*; [2]*Mohamed Taher AL Maamouri Hopital, Orthopedic, n, Tunisia*; [3]*Mohamed Taher AL Maamouri Hopital, Orthopedic, Nabeul, Tunisia*

Background: Osteoarticular Tuberculosis (TB) is an uncommon form of extrapulmonary TB, it comprises 2–5% of all TB cases in Tunisia. The most frequent sites of osteoarticular TB infection are the spine, hip, and knee. Diagnosis can be challenging owing to the non-specific and insidious nature of the clinical presentation.

Objectives: Describe clinical features, diagnosis and management of this uncommon clinical entity.

Methods: A retrospective clinical study of TB had been diagnosed in our hospital during the last five years. the diagnosis was made by bacteriological and histological examinations after imaging assessment (MRI, CT scan).

Results: Ten cases were included (6 males and 4 females). The mean age was **53 years (16-72 years**). The average time to diagnosis was 4 months (2-12months). The joints affected were the dorsolambur spine, shoulder, elbow, phalanges, the trochanter-femur and the metatarsal bones. The most common symptoms noted were pain, swelling and restricted motion of the involved joint. Cutaneous fistulas were visualized in one case. Fever and systemic symptoms were present in one case. Radiological findings varied, with lytic lesions, abscesses, and joint destruction observed. All patients presented with pathognomonic histological tubercle appearances, with caseous necrosis, lymphocytes, and Langhans giant cells present and TB-PCR in the pus samples was positive in one case. All patients were treated with anti-TB drugs for 12 months and three patients received corticosteroid therapy. The abscess was drained in six cases. We noted clinical and radiological recovery with medical tuberculosis treatment in all patients.

Conclusion: Osteoarticular TB is a common manifestation of extrapulmonary TB and must not be overlooked. Early detection of osteoarticular TB may prevent limb morbidity. Although anti-TB drugs are the primary treatment for osteoarticular TB, in some cases, surgery is required to establish a diagnosis and gain local infection control.

AB1213 ILLNESS PERCEPTION IN PATIENTS WITH KNEE OSTEOARTHRITIS

Keywords: Cognitive function, Osteoarthritis, Pain

H. Boussaa[1], S. Touil[1], S. Miladi[1], A. Fazaa[1], M. Yasmine[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim University Hospital, Rheumatology,Tunis,Tunisia*

Background: Knee osteoarthritis (OA) can be a source of pain and major functional handicap. If not relieved, it leads to an alteration of the patient's quality of life. The cognitive component of pain varies from one subject to another.
Objectives: The aim of this study was to evaluate the illness perception in patients suffering from knee OA.
Methods: We conducted a cross-sectional study in patients with knee OA. Illness perception was assessed using the French version of the Brief Illness Perception Questionnaire (BIPQ). This questionnaire was developed from the model of Leventhal et al. and aims to assess the different components of the disease. It includes 9 items: 8 quantitative questions on a numerical scale from 0 to 10 and a last item in the form of a qualitative question. The total score varies from 0 to 80, with no predefined thresholds. The higher the score, the more threatening the patient's perception of the disease is. A "p" value inferior to 0.05 was considered significant.
Results: Thirty patients with knee OA responded to the questionnaire. It was about 26 women (87%) and 4 men (13%) with a mean age of 60 years [42-71]. The average duration of the disease was 78 months [12-240]. All patients used tier 1 analgesics and NSAIDs, 33% used tier 2 analgesics and three patients had received corticosteroid knee injection. The mean visual analog scale (VAS) of pain was 6 cm [3-9]. The mean walking distance was 678m [100-1000]. None of the patients used a cane. The mean value of the Lequesne algofunctional index (AFI) was 8.8 [3-15]. Lameness was noted in 13% of patients. The patellar tap test was positive in 47% of cases. The mean values of body mass index (BMI) and waist circumference were 30kg/m² and 96cm, respectively. According to the Kellgren-Lawrence classification, knee OA was at grade 1 in 10% of the cases, grade 2 in 40% of the cases, grade 3 in 40% of the cases, and grade 4 in 10% of the cases. All patients completed the entire questionnaire with a mean score of 45 [36-54], and a mean maximum score of 6/10 for the first question assessing the impact of the disease on the patients' lives. Responses were incomplete for the 9th question which consists on listing 3 reasons that may cause the disease: only 15 patients (50%) cited 3 causes. The main reported factors causing knee OA according to patients were physical activity (83%), age (66%), prolonged standing (62%), and weight (51%). A statistically significant negative correlation was noted between the BIPQ, and age (r=-0.488, p=0.006) and disease duration (r=-0.583, p=0.001). This correlation was not significant with pain VAS, walking distance, BMI, waist circumference and the Lequesne AFI.
Conclusion: Illness perception in patients with knee OA is important to screen in order to deliver a more personalized management.

AB1214 PATIENT OUTCOMES AFTER TIBIAL HIGH OSTEOTOMY

Keywords: Epidemiology, Descriptive studies, Cartilage

R. Elafram[1], M. Ben Rodhane[1], M. Shaier[1], H. Kamoun[1]. [1]*University of Tunis El Manar, Orthopedic,Tunis,Tunisia*

Background: At a time when total or partial arthroplasty is taking on a predominant role in the treatment of medial ferno-tibial gonarthrosis, tibial valgus osteotomy with internal opening and filling with a bone substitute filling with a bone substitute wedge remains for many authors an indication of choice in young patients.
Objectives: The aim of our work is to evaluate the functional and radiological results of this type of osteotomy and to assess the osseointegration and resorption of the bone substitute.
Methods: This was a single-centre retrospective study osteotomies performed in 63 patients, collected between June 2016 and June 2020. We evaluated the functional outcome. Lysholm-Tegner and assessed osseointegration of the classification of the GESTO.
Results: The mean age of our patients was 55.6 ± 8.1 years. The mean body mass index (BMI) was. (BMI) was 31.56 ± 4 Kg.m-': According to the Ahlback classification: stage II was found in 64.7% of cases, stage III and I were found in 23% and 7.7% of cases respectively. 3 patients had stage IV gonarthrosis. The average follow-up was 24 months. There was only one case of plaque sepsis. The Lysholm-Tegner score was improved (p<O,OOl) with a mean gain of 11.82/100. The mean internal laxity was reduced by 6o (p<O, 001). The mean angular correction was 2.65° (p<O,OOl). The postoperative tibial slope did not increase significantly: 5.98° ± 1.65° preoperatively and 6.38° ± 1.63° postoperatively(p=0.208). According to the GESTO classification: the rate of osseointegration rate was 18% at 3 months postoperatively and 98.5% at 6 months postoperatively. 98.5% at 6 months post-operatively. We had only one case of poor integration. At follow-up, no total resorption of the wedge was achieved less than 40% in 89% of cases and less than 60% in 19% of cases. The degree of satisfaction was good or excellent in 97%.
Conclusion: The use of wedges in the internal opening VTO was a determining factor in the determining factor in the accuracy of the correction. It also guarantees the bone capital thanks to its osteo-conductive effect and allows conductor effect and allows us to hope for greater simplicity in the event of a subsequent arthroplasty.

AB1215 ASSOCIATED FACTORS TO POSTURAL BALANCE CONTROL IN KNEE OSTEOARTHRITIS AND COMMON LOW BACK PAIN PATIENTS

Keywords: Rehabilitation, Pain

I. Ksibi[1], L. Rouached[2], W. Lahmar[2], S. Bouden[2], O. Saidane[2], N. Mouhli[1], M. Hfaidh[1], H. Rahali[1], R. Maaoui[1]. [1]*Military Teaching Hospital, Rehabilitation, Tunis,Tunisia*; [2]*Charles Nicolle Teaching Hospital, Rheumatology,Tunis,Tunisia*

Background: Pain induces the alteration of postural balance (PB) mechanisms. Therefore, the PB control is an important element to consider when managing patients with degenerative musculoskeletal diseases(DMD).
Objectives: The aim of our study was to evaluate balance control in patients having knee osteoarthritis (KOA) or low back pain and to identify the associated factors.
Methods: A cross sectional study including patients suffering from common low back pain(LBP) and KOA. We collected the sociodemographic data. We evaluated the PB using a stabilometric platform, realized when the eyes were closed. Analyzed variables were the center of pressure(COP) in the mediolateral(ML) and anteroposterior(AP) axis, the surface area (S), the mean sway velocity(V) and the mean sway energy(E).We divided patients into 2 groups; G1:patients having postural imbalance and G2:patients with a good postural balance profile.
Results: We had 30 patients with a sex ratio at 1.3, a mean age of47±11.14 [23-65] years old. The mean BMI was 28.17±2.1[20.3-39.56]. Twelve patients (40%) suffered from KOA, 18(60%) of them had chronic low back pain, with a mean disease duration of 1.61±1.55[0.10-5] years. Postural profile evaluation revealed a mean S of 265.93±576.3 [1 - 3239]. COP position in the ML axis was 0.68±9.49[-15.7 -24.6] and in the AP: 21.4±21.70[-8.2 – 81.4]. Mean sway V was11.4±3.88 [7.2 – 22.9]. The E was 8.94±89.6[27 – 403]. We detected an abnormal S in 5% of participants, decreased E in 8% of patients. According to the ML axis the COP was: left in one patient and right in 5% of patients. The COP was anterior in 21% of cases. The mean sway V was pathological in 5% of cases. The comparison between both groups did not find any

significant difference concerning gender (p=0.43), the disease (p=0.65). We did not find a significant difference in the means of age (p=0.52), BMI (p=0.3) and underlying disease duration (p=0.31).
Conclusion: Half of the patients with DMD presented a postural imbalance which wasn't explained by sociodemographic or anthropometric parameters. The instrumental evaluation of PB, considering the fall's risk factor is then essential.

AB1216 SYMPTOMATIC SLOW-ACTING DRUGS FOR GONARTHROSIS: BETWEEN EXPECTATIONS AND REALITY

Keywords: Pain, Osteoarthritis

H. Tebaa[1], H. Arabi[1], A. Mougui[1], I. El Bouchti[1]. [1]*CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Rhumatology, Marrakech, Morocco*

Background: Osteoarthritis of the knee is the most common cause of chronic pain and disability in patients. In addition to non-steroidal anti-inflammatory drugs and analgesics, the symptomatic slow-acting anti-arthritic drugs (SAALs) define a specific class of medications used in the symptomatic treatment of osteoarthritis of the knee. With a delayed effect, this family of drugs is used to reduce the intensity of pain and functional discomfort caused by the destruction of cartilage.
Objectives: The objective of this study was to evaluate the fears and expectations of patients before the treatment and the response to the treatment as well as the degree of satisfaction after one year of treatment.
Methods: This study was conducted in the form of an individual questionnaire, 56 patients followed in consultation for a primary gonarthrosis without a period of congestive attack, the diagnosis of knee osteoarthritis was made by and radiography of the knee according to the classification of Kellgren and Lawrence, any patient with secondary osteoarthritis or very disabling gonarthrosis was excluded. Patients were questioned about their fears and expectations before the start of treatment. An evaluation of the therapeutic response after one year was done by different parameters: the visual analogue pain scale (VAS pain), the Lequesne index of the knee, and decrease in analgesic consumption, improvement in walking perimeter and side effects and pain reduction. Global satisfaction was evaluated by a likert scale composed of 7 degrees of satisfaction (from extremely satisfied to extremely dissatisfied).
Results: We included 56 patients, the average age was 44 years, the female sex represented 59%, the average educational level represented 20%. According to the classification of Kellgren and Lawrence, stage 2 represents (40%), stage 3 (52%) and stage 4 (8%). There were 30% of patients on chondroitin-based antiarthritis drugs, 60% on glucosamine and 10% on avocado-soybean unsaponifiable extract. The average VAS pain was 5 ± 1.1, the average Lequesne index (knee) was 7. Fear of pain exacerbation was noted in 15%, 20% were afraid of a functional handicap and 49% were afraid of a probable surgery, 16% had no fear. Before the initiation of treatment, 65% of the patients hoped for an improvement in their function, 49% feared a probable surgery and 16% had no fear. Before the initiation of treatment, 35% thought it was a placebo. The mean VAS pain after treatment was 3±2.2 vs 5 ±1.1 before treatment (p= 0.003), the mean Lequesne index after treatment was 4.9 vs 7 after treatment with a statistically significant difference (p= 0.003), an improvement of the gait perimeter was noted in 51%, 41% reported a reduction in the consumption of analgesics, 3% of patients had side effects such as nausea and and vomiting. After 1 year of treatment, 45% of patients were extremely satisfied with their treatment, 15% were extremely dissatisfied, 10% were satisfied and 30% were not very satisfied.
Conclusion: Patient expectations and satisfaction are important components in the evaluation of quality of care. This new approach is important to guarantee therapeutic adherence.

AB1217 COMORBIDITIES DURING GONARTHROSIS

Keywords: Quality of life, Comorbidities, Osteoarthritis

A. Rafi[1], S. Belouaham[1], Z. Baba[1], A. Mougui[1], I. El Bouchti[1]. [1]*Chu Mohamed Vi Marrakesh - Drh, Rheumatology, Marrakesh, Morocco*

Background: Osteoarthritis of the knee, together with that of the hip, is the most serious disease of osteoarthritis.
Long considered a benign disease, gonarthrosis is nevertheless associated with significant morbidity.
Objectives: To assess the prevalence of co-morbidities in gonarthrosis patients and to assess their impact on pain, functional impact and radiographic progression.
Methods: Our study involved patients with gonarthrosis. Comprehensive comorbidity screening was done. Pain intensity was assessed by the Analogue Visual Scale (EVA). The neuropathic component was assessed by the DN4 score. Functional impact was assessed by the Lequesne index and Womac score. Knee X-rays were classified according to Kellgren Lawrence (KL) criteria.
Results: A total of 215 patients were included (24 men/191 women). The average age was 58.02 ±9.11 years. The mean body mass index was 24.87± 5.39 kg/m2. The main comorbidities were:

COMORBIDITIES	PREVALENCE
Overweight and obesity	40,6%
Heart disease	37,4%
HTA	26%
Diabetes	24,2%
Dyslipidemia	11.2%
Anxiety	9,3%
Ostéoporosis	7,9%
Dysthyroidism	7%
Smoking	3,7%
Neoplasia	1,4%
Chronic kidney disease	0,9%

The visual analogic scale was 7.86± 1.31 and stress at 13.74 ±4.95. The average Womac score was 12.3 ±8.92. The average Lequesne score was 6.71 ±3.20. The average DN4 score was 18.81± 8.9. Comorbidities were associated with age (p = 0.02), DN4 score (p = 0.01), and KL radiographic grades (p = 0.02).
Conclusion: In this study, co-morbidity in gonarthrosis was associated with advanced age, a neuropathic component of pain, and severe structural impairment.

Osteoporosis

AB1218 **ASSOCIATION BETWEEN OSTEOPOROSIS AND DISRUPTION OF GUT MICROBIOTA: A META-ANALYSIS**

Keywords: Osteoporosis

Q. Y. Su[1,2,3], X. Song[2,3], D. Qiao[2,3], G. X. Wang[2,3], X. Y. Yin[2,3], Q. Yu[4], P. F. He[4], X. Li[1,2,3], S. X. Zhang[1,2,3]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; [3]*Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*; [4]*Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*

Background: Osteoporosis(OP) is a systemic disease of the skeleton characterized by decreased bone mineral density and the imbalance of bone, resulting in an increased risk of fragility fractures[1]. Gut microbiota has a mutually beneficial and symbiotic relationship with the host and plays a vital role in the host's metabolism and immune regulation. An expanding body of studies asserts that gut microbiota has a role in bone metabolism and the pathogenesis of osteoporosis[2].
Objectives: This study aimed to confirm the changes of gut microbiota in osteoporosis through meta-analysis.
Methods: We searched PubMed, Embase, MEDLINE, Cochrane Library, CNKI, VIP, CBM, and Wanfang databases from the established to January 10 2023 on gut microbiota diversity in patients with OP. Standardized mean difference(SMD) and 95% confidence interval(CI) were used to evaluate the difference in microbial abundance between the OP and healthy control(HCs).
Results: A total of 16 studies were included in this meta-analysis, including 517 OP and 714 HCs. The summary results showed that there was no significant difference in α diversity index compared with HCs[Simpson index: SMD=0.120, 95%CI(-0.031~0.271), p=0.049; Shannon index: SMD=-0.039, 95%CI(-0.284~0.206), p=0.001; ACE: SMD=0.029; 95%CI(-0.647~0.706), p<0.001; Chao1: SMD=0.000, 95%CI(-0.446~0.446), p<0.001; Observed_species: SMD=0.134, 95%CI(-0.049~0.317), p=0.198]. To eliminate the heterogeneity caused by the difference of the observed species index by the sequencing method, we conducted a subgroup analysis of the observed species, and the results showed that the index obtained by high-throughput sequencing[SMD=0.490, 95%CI(0.084~0.896), p<0.001] was higher than that of HCs.
Conclusion: This study suggested that changes in intestinal microecology were related to OP. More studies should be conducted to explore the specific differences in gut microbiota in OP.

AB1219 **HOW TO TAILOR THE ANTI-OSTEOPOROSIS TREATMENT IN PATIENTS WITH ADVANCED LIVER DISEASE? VARIATIONS OF RENAL FUNCTION BY CREATININE AND CYSTATIN C**

Keywords: Bone diseases, Biomarkers, Osteoporosis

C. Rodríguez Alvear[1], N. Buendía Sánchez[2], E. Garín Cascales[2], M. D. C. López González[1], E. Perea Martínez[1], A. Avilés[1], I. Calabuig[1], M. L. Peral[3], P. Bernabéu[1], A. Martínez-Sanchis[1], J. J. Esteve Vives[1], P. Vela-Casasempere[1], V. Jovani[1], M. Andrés[1]. [1]*Dr. Balmis General University Hospital, Rheumatology, Alicante, Spain*; [2]*Dr. Balmis General University Hospital, Nefrology, Alicante, Spain*; [3]*Vinalopó General University Hospital, Rheumatology, Elche, Spain*

Background: A rapid bone loss and an increase in fractures have been described after liver transplantation, warranting focused management. Bisphosphonates are effective antiresorptive agents, but with a limited in patients with significant kidney disease, as the drugs are excreted by urine, accumulating and increasing the risk of adverse events (including at the kidney level). The evaluation of renal function in the patient with cirrhosis can be challenging and may be underestimated by standard methods[1]. This issue may impact the choice of the anti-osteoporosis (OP) agent.
Objectives: To compare the variations on bisphosphonate treatment indication across different glomerular filtration rate (GFR) equations in patients with advanced liver disease included in a pre-transplantation study.
Methods: Descriptive cross-sectional study of patients from a tertiary center selected for a multidisciplinary assessment before liver transplantation from February 2019 to December 2022. Sex, age, ethnicity, and serum creatinine and cystatin C (a more sensitive marker than creatinine for the estimation of GFR in patients with cirrhosis[2]) levels are collected. The indication for anti-OP treatment is established in the presence of T< -1.0 by densitometry (DXA), vertebral radiographic wedging or history of a fragility fracture. GFR adjusted by creatinine, cystatin C and creatinine-cystatin C was calculated using the online calculation tool MediCalc®. Results are later categorized as below or above 30ml/min^2 (usual cut-off to contraindicate the use of bisphosphonates[3]), finally comparing the rate of patients with GFR <30 ml/min across three methods. A descriptive study is presented. Comparison of variables are performed by Fisher's exact test. P-values of <0.05 are considered statistically significant.
Results: A total of 162 patients (75.9% men) were included, all Caucasian, with a mean age of 60 years (SD 7.6) and a mean BMI of 27.9 (SD 4.9). Seventy-six percent (n=120) were candidates to anti-OP therapy, and 68.5% (n=111) ultimately received it (88% bisphosphonates, 11% denosumab, and 1% teriparatide). Three percent (n=5) presented a fragility fracture, and 9.5% (n=17) showed a radiographic vertebral fracture. Fifty-one percent (n=80) had osteopenia and 22.9% (n=36) osteoporosis at DXA scans. Regarding renal function, mean serum levels of creatinine and cystatin C were 0.99 mg/dl (SD 1) and 1.7 mg/L (SD 1), respectively. The mean estimated GFR levels using creatinine, cystatin C and creatinine-cystatin were 87 ml/min (SD 24.8), 49.3 (SD 23.4) and 63.9 (SD 23.3), respectively. The percentage of patients with GFR <30ml/min was 1.9% measured by creatinine, 20.5% calculated by cystatin, and 5.6% calculated by creatinine-cystatin (Figure 1). Differences between rates were statistically significant. In this sense, anti-OP therapy was tailored accordingly in 12 patients (10.9%) with treatment indication, using denosumab instead of bisphosphonates. p 0,008 p <0,001

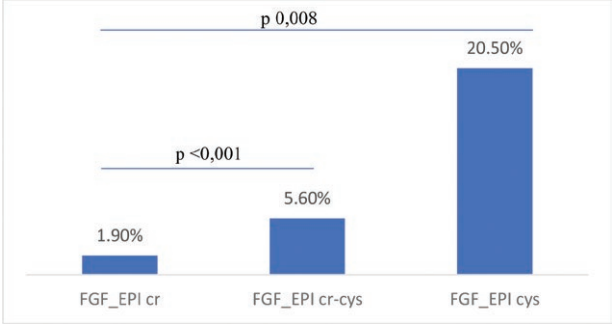

Figure 1. Patients with GFR <30 ml/min by different equations.

Conclusion: In a setting of advanced liver disease candidate to transplantation, renal function estimates significantly varied depending on the GFR equation used, thus largely modifying the rates of patients with contraindication for using bisphosphonates, despite the high fracture risk.
Further studies are necessary to establish the best method to assess the renal function in advanced liver disease patients, in order to tailor anti-OP strategies.

VERTEBRAL FRACTURE CHARACTERISTICS IN AN FLS UNIT ACCORDING TO THE IDENTIFICATION METHOD; EMERGENCY LIST, OUTPATIENT CLINIC OR VFA.

Keywords: Osteoporosis

A. Naranjo[1], A. Molina[2], C. Rodriguez-Lozano[2], N. Martín[3], F. Santana[2], S. Fuentes[2], R. Navarro[4], T. Fernández-Varela[4], J. A. Lorenzo[4], A. Montesdeoca[4], S. Ojeda[2]. *[1]Hospital UNiversitario de Gran Canaria Dr. Negrin, Rheumatology, LAS PALMAS DE G C, Spain*; *[2]Hospital Universitario de Gran Canaria Dr. Negrin, Rheumatology, LAS PALMAS DE G C, Spain*; *[3]Hospital Universitario de Gran Canaria Dr. Negrin, Rehabilitation, LAS PALMAS DE G C, Spain*; *[4]Hospital Universitario de Gran Canaria Dr. Negrin, Orthopedics, LAS PALMAS DE G C, Spain*

Background: The risk o subsequent fracture is very high after a vertebral fracture (VF)
Objectives: To analyze the characteristics of patients with VF seen in a Fracture Liaison Service (FLS).
Methods: Our FLS cares for patients from the emergency list (URG), referred by hospital or primary care doctors (HPC) with VF <12 months, and captured by DXA-VFA (Densitometry - VF Assessment) in patients with non-VF. The database included the FRAX items plus previous treatment and DXA results. Traumatic VFs or VFs with a known age > 1 year, infiltrative or neoplastic diseases, and patients with contraindications for treatment were excluded. The number and grade of VF (Genant's scale) were analyzed.
Results: 570 patients have been included (Table 1). The most frequent route of identification was HPCfollowed by the emergency registry and detection by DXA-VFA. The patients identified by VFA did not report a previous VF, as did 25 of the HPC cases, referred by a report of fracture by the radiologistst or by detection in the consultation by the rheumatologist. Figure 1 shows the identification of patients over the years.

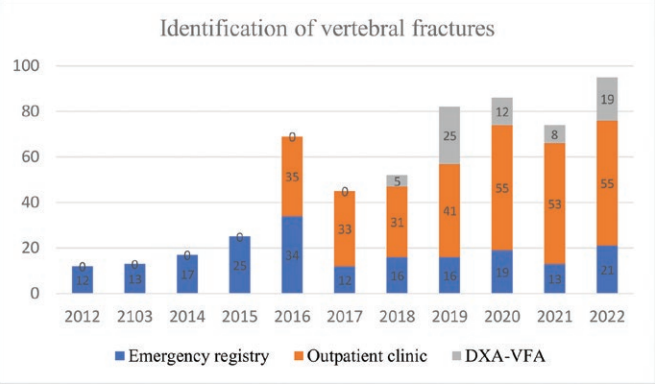

Figure 1.

We observed a higher percentage of grade 3 fractures in those identified in the emergency registry. Those identified by HPC had a higher average number of fractures and a higher percentage of osteoporosis by DXA. In this group there was a greater frequency of previous fracture, as well as rheumatoid arthritis and glucocorticoid use. Patients referred through HPC had a higher adherence to treatment compared with the other groups. The 69 patients detected by DXA-VFA consisted of 30 humerus fractures, 1 pelvic, and 38 forearm, mostly women with a single fracture and lower percentage of osteoporosis by DXA. The adherence to treatment has changed over the years. In 2021 and 2022 it was 93%, compared to 79% in 2012-2020.
Conclusion: All the ways to identify VF are important. The training campaign carried out in the healthcare area, including radiologists, has allowed us to improve the standard. The results will be helpful in the implementation and consolidation of the model based on FLS.

AB1221

CLINICLAL EFFICACY OF SEQUENTIAL TREATMENT AFTER ROMOSOZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARISON WITH PRIMARY OSTEOPOROSIS FOR 24 MONTHS

Keywords: Osteoporosis, Rheumatoid arthritis

Y. Kanayama[1], K. Hattori[1]. *[1]Toyota Kosei Hospital, Orthopedic Surgery and Rheumatology, Toyota, Japan*

Background: Romosozumab (ROMO), a monoclonal antibody that binds sclerostin, increases bone formation and decreases bone resorption. And although it is a novel therapeutic agent for osteoporosis, which has shown high effects of increasing bone density and inhibiting fragile fracture in overseas clinical trials. However the clinical efficacy for rheumatoid arthritis complicated with osteoporosis (RA-OP) is unknown.
Objectives: To evaluate the clinical efficacy of ROMO for 12 months and denosumab (DMB) for 12 months in patients with RA-OP comparison with primary osteoporosis (P-OP) for 24 months.
Methods: RA patients diagnosed according to the 2010 ACR/EULAR criteria. All patients (RA-OP; 12 cases, P-OP; 19 cases) met at least one of the following criteria were eligible; a bone mineral density T score of -2.5 or less at the lumber spine or total hip and either one or more moderate or severe vertebral fractures or two or more mild vertebral fractures. All patients were initiated ROMO from between April, 2019 and July, 2020. The ROMO dose was 210mg at once every 1 months. After 12 months of ROMO, all cases were changed to DMB. In all cases native or activated vitamin D has been used. We reviewed the results for 24 months about the increase and decrease of bone mineral density (BMD) of lumbar spine(LS) and total hip(TH) by DEXA and bone turnover markers, intact n-terminal propeptide type I procollagen(PINP) and tartrate-resistant acid phopshatate form 5b(TRACP-5b).
Results: The gender was all female. Patient background at baseline in RA-OP (n=12) and P-OP (n=19) had a mean age of 72.8 ± 7.0 and 73.9 ± 9.7 (p=0.417); the body mass index were 19.5 ± 3.1 and 20.1 ± 3.6 (p=0.516); the FRAX were 36.0 ± 14.9 and 33.7 ± 16.6 (p=0.529); the number of previous fracture were 5cases (42%) and 13cases (68%) (p=0.142) and the number of previous drug for treatment osteoporosis use were 9cases (75%) and 7cases(38%) (p=0.038). The bone turnover markers and bone mineral density at baseline were as follows; P1NP 62.4 ± 36.2 and 94.6 ± 101.3 (p=0.656); TRACP-5b 485 ± 252 and

546 ± 278 (p=0.516); LS-BMD and T-score 0.79 ± 0.14 and 0.79 ± 0.12 g/cm^2 (p=0.903), -2.82 ± 0.99 and -2.87 ± 0.87 (p=0.919) and TH-BMD 0.55 ± 0.07 and 0.56 ± 0.07 g/cm^2 (p=0.621), -3.14 ± 0.53 and -3.06 ± 0.55 (p=0.682). Clinical findings related to RA-OP at baseline were as follows; disease duration 17.7 ± 16.5 years; CRP 1.25 ± 1.75; DAS28-CRP 3.45 ± 0.99; HAQ 1.56 ± 0.99. The rate of increased LS-BMD from baseline to 6, 12, 18 and 24 months between RA-OP and P-OP were 10.8 ± 8.0% and 11.6 ± 5.7%, (p=0.670) at 6 monts, 15.2 ± 9.5% and 16.4 ± 8.2% (p=0.584) at 12 months, 18.9 ± 10.4% and 21.8 ± 9.4% (p=0.598) at 18 months, 20.6 ± 11.7% and 22.7 ± 9.6% (p=0.730) at 24 months and TH-BMD were 4.1 ± 4.5% and 2.7 ± 3.9%, (p=0.389) at 6 monts, 5.7 ± 6.3% and 6.1 ± 6.0% (p=0.747) at 12 months, 8.4 ± 8.1% and 8.2 ± 5.3% (p=0.747) at 18 months, 8.4 ± 9.8% and 8.8 ± 5.0% (p=0.236) at 24 months (Figures 1, 2).

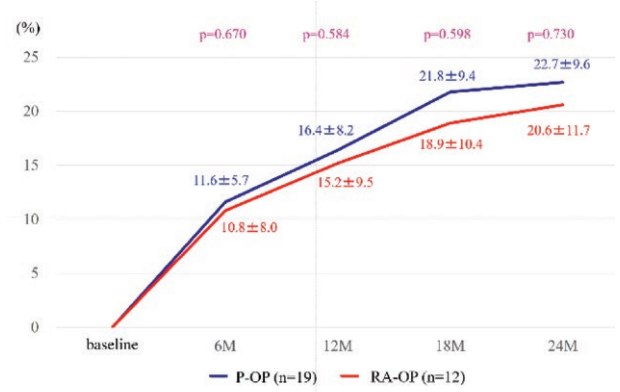

Figure 1 : The rate of increased LS-BMD from baseline to 24 month

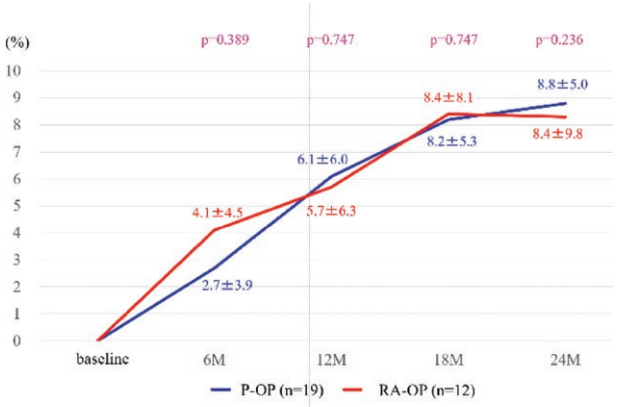

Figure 2 : The rate of increased TH-BMD from baseline to 24 month

Conclusion: Clinical efficacy of treatment with ROMO for 12months and DMB for 12months was extremely effective for RA-OP as well as for P-OP and has the high potential to be an important option in the treatment of RA-OP.

NEUTROPHIL TO LYMPHOCYTE RATIO (NLR) PREDICTS FRACTURE IN PATIENTS ON LONG-TERM GLUCOCORTICOID.

Keywords: Registries, Osteoporosis, Bone diseases

J. Chen[1], T. T. Cheng[1], S. F. Yu[1], H. Y. Kang[2]. [1]*Kaohsiung Chang Gung Memorial Hospital and Chang Gung University, College of Medicine, Division of Rheumatology, Allergy, and Immunology, Department of Internal Medicine, Kaohsiung, Taiwan, Republic of China*; [2]*Center for Menopause and Reproductive Medicine Research, Department of Obstetrics and Gynecology, Kaohsiung Chang-Gung Memorial Hospital and Chang Gung University, College of Medicine, Kaohsiung, Taiwan., Kaohsiung, Taiwan, Republic of China*

Background: Long-term glucocorticoid (GC) exposure leads to systemic bone loss and fracture. In addition, GC is known to increase white blood cell (WBC) amount and change the distribution of differential count (DC). Neutrophil-to-Lymphocyte ratio (NLR) has been studied as an optimal marker of subclinical inflammation, predicting the prognosis of cardiovascular diseases, cancers and even covid-19 infection. For patients under long-term GC exposure, the hemogram change might be a potential parameter to predict prognosis.

Objectives: This pilot study aims to investigate if GC related WBC-DC change, including NLR, is associated with future fractures during 3 years follow-up.

Methods: This retrospective study is based on a registry, conducted in Kaohsiung Chang Gung Memorial Hospital, Taiwan, from September 2014 till April 2021, aimed to monitor bone mineral density (BMD) changes and fractures in patients with autoimmune diseases. All recruited patients were followed at least 3 years and took X-ray images annually to capture new fragility fracture, including morphometric vertebral fractures. We screened participants who used GC continuously at least 3 months before the index day. We recorded the complete blood count (CBC) and WBC-DC values at least twice during the period of 3 months before and after the index day, and excluded patients who were febrile, under infection status, diagnosed as cancers or cardiovascular diseases at the index day. The NLR was calculated by the absolute neutrophil count divided by absolute lymphocyte count individually.

Results: A total of 346 participants were enrolled in current study, and 101 (29.2%) suffered from new fragility fracture in 3 years. Among patients with fracture and non-fracture, conventional fracture risk factors, such as age, BMD, and previous fracture remained significantly different, while the WBC revealed no difference (Table 1). Nevertheless, the absolute neutrophil and lymphocyte count were significantly higher and lower in the fracture group, respectively, and no difference in the monocyte, eosinophil, and basophil count. We compared different WBC ratio, and NLR is significantly higher in the fracture group, providing the odds ratio of 1.24 (95% confidence interval 1.07-1.44, p=0.005). Figure 1 showed that the observed fracture risk raised as the NLR values increased.

Conclusion: In patients under long-term GC, NLR might be a helpful marker to predict fracture, and higher NLR indicates higher fracture risks.

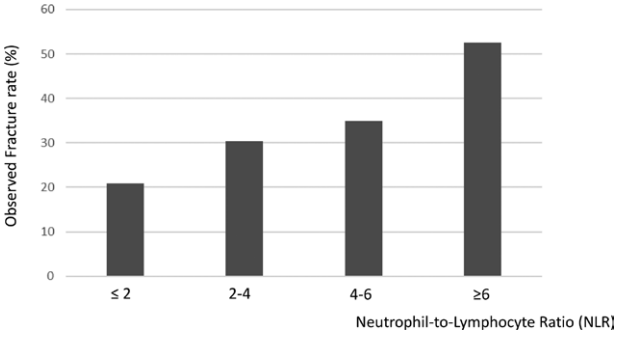

Figure 1. Observed fracture rate is associated with baseline NLR

WHAT ABOUT BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS PATIENTS USING GLUCOCORTICOIDS?

Keywords: Osteoporosis, Comorbidities, Rheumatoid arthritis

A. Dghaies[1], K. Maatallah[1], H. Ferjani[1], D. Ben Nessib[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rheumatology, Manouba, Tunisia*

Background: Osteoporosis is a major co-morbidity to screen for in patients with RA. Inflammation, low activity level, and treatments, particularly glucocorticoids, increase the risk of osteoporosis in RA patients and expose them to a high fracture risk. Few studies examined glucocorticoid-induced osteoporosis in patients with RA, especially in Africa.
Objectives: Our study aimed to compare the densitometric profile of RA patients receiving glucocorticoids with that of patients not receiving glucocorticoids, and to assess the fracture risk by the FRAX.
Methods: We conducted a retrospective observational study including patients with RA according to the ACR EULAR criteria in the rheumatology department of Kassab Institute of orthopaedics. General data, demographics, inflammation markers (sedimentation rate (SR) and C reactive protein (CRP)), and disease activity (DAS28 (CRP)) were collected. We compared the parameters of bone mineral density (BMD) and FRAX score for two groups: G1 patients who received glucocorticoids and G2 patients who did not.
Results: A total of 207 patients with RA (169 women and 38 men) were included. The mean age was 57±12.2 years [29-85]. The mean duration of disease progression was 7.1±7 years [0-41]. Sixty percent of RA patients had positive RF and/or ACPA. Obesity was noted in 34% of cases. The mean SR and CRP were 47.6±27mm, and 21.5±28mg/l, respectively. The mean DAS28 (CRP) was 6.23±4.49. Seventy percent of the patients (n=144) were using systemic corticosteroid therapy with a mean dose of 6.26mg±4.5 [0-15] prednisone equivalent with a mean duration of corticosteroid use of 14 months ±4.5. Forty-two percent of the patients had osteoporosis (T score≤ -2,5 DS), 37% had osteopenia (-2,5 DS <T score≤-1 DS), and 18% had normal BMD (T score>-1 DS). The Table 1 summarizes BMD parameters and Frax score in the two groups.
Conclusion: Patients receiving glucocorticoids had a lower bone density, T-score, and a higher fracture risk. Osteoporosis and the high incidence of osteoporotic fractures are dramatic consequences of glucocorticoid therapy in RA patients, leading to marked impairment of their quality of life.

Table 1: Comparison of the BMD parameters and Frax score in the two groups

		G1	G2	p
BMD	Vertebral site	0,91±0,19	1±0,22	0,008

FREQUENCY OF OSTEOPOROTIC THORACIC VERTEBRAL FRACTURES DETECTED AS INCIDENTAL FINDINGS ON INPATIENT CT SCANS

Keywords: Osteoporosis, Imaging

D. Guevara[1], L. Ávila Garzón[2], M. Villamizar Téllez[3], L. Cardona[4], C. Ibañez[5], J. Cajamarca-Baron[1], A. Escobar[1], E. Calvo[6], A. Rojas-Villarraga[7]. [1]*Fundación Universitaria de Ciencias de la Salud FUCS. Sede Centro Hospital San José, Rheumatology, Bogotá, Colombia*; [2]*Universidad Nacional de Colombia, Physician, Bogotá, Colombia*; [3]*Universidad Nacional de Colombia, Medical Student, Bogotá, Colombia*; [4]*Universidad Nacional de Colombia, Radiology Resident, Bogotá, Colombia*; [5]*Fundación universitaria ciencias de la salud (FUCS), Associate Instructor for Research Vice-Rector, Bogotá, Colombia*; [6]*Colombia National University Hospital, Radiology Associate Instructor, Bogotá, Colombia*; [7]*Fundación universitaria ciencias de la salud (FUCS), Research Titular Professor – Research Institute, Bogotá, Colombia*

Background: Osteoporosis is one of the main public health problems, leading to the appearance of fragility fractures. Within these, there are vertebral fractures, which in their vast majority have an asymptomatic course, which is why they are presented as incidental findings in imaging studies.
Objectives: To estimate the prevalence of insufficiency fractures in the thoracic vertebrae in patients hospitalized for any cause in a Hospital in Bogotá (Colombia).
Methods: Cross-sectional study in a sub population of Latin American patients, older than 50 years with chest tomography indicated during hospitalization in 2020 for reasons other than suspicion of vertebral bone disease. Patients with secondary causes of vertebral fracture, trauma and spinal instrumentation were excluded. Reading by two independent expert researchers with Genant's semi-quantitative visual method and the ABQ method. Clinical and sociodemographic variables were captured (RedCap).Descriptive statistical analysis (STATA 17). The project was approved by the ethics committee.
Results: A total of 317 patients with a mean age of 69.4 years and a predominance of males (57.1%) were included. The most frequent personal history was active smoking (15.8%), use of glucocorticoids in the last 5 years (12.9%), and alcohol consumption (7.5%). A prevalence of vertebral fractures of 8.5% was found, being more frequent in women in 51.8% of the cases, with T11 as the most frequent location (See Table 1 and Figure 1). Only two vertebrae did not define a fracture according to the ABQ method compared to Genant. A disagreement was found in 77.7% of the cases with respect to the final report.
Conclusion: The prevalence of vertebral fractures reported here is lower than that reported in the literature when x-ray imaging is used; it is possible that the use of the tomography influences this result and possibly allows a more objective assessment. Careful evaluation of chest tomographic studies performed during the hospital stay may contribute to an opportune diagnosis of insufficiency fracture associated with osteoporosis.

Table 1. Fractured vertebrae characteristics, n= 42*

Fracture type		
Biconcave	27	64.3
Wedge	12	28.6
Crush	3	7.1
Fractured vertebra		
T3	1	3.7
T4	4	14.8
T5	2	7.4
T6	1	3.7
T7	5	18.5
T8	0	0
T9	2	7.4
T10	5	18.5
T11	14	51.8
T12	8	29.6

* In total, 44 fractured vertebrae were identified; only 42 are described in the table, since only 3 vertebrae were classified in the patient in whom 5 fractured vertebrae were detected.

ASSOCIATION BETWEEN BONE METABOLISM MARKERS AND INCREASES IN BONE MINERAL DENSITY IN PATIENTS WITH POSTMENOPAUSAL OSTEOPOROSIS TREATED WITH ROMOSOZUMAB

Keywords: Osteoporosis

K. Hattori[1], Y. Kanayama[1]. [1]*Toyota Kosei Hospital, Orthopaedics, Miyoshi, Japan*

Background: Osteoporosis is a metabolic bone disorder characterized by a systemic impairment of bone mass and microarchitecture that results in fragility fractures [1]. Romosozumab (Rmab), a humanized monoclonal anti-sclerostin antibody, increases bone mineral density (BMD) and decreases fragility fractures in patients with postmenopausal osteoporosis (PMO) [2]. While an increase in type 1 amino-terminal propeptide (P1NP) and a decrease in tartrate-resistant acid phosphatase 5b (TRACP-5b) are observed early after administration of Rmab, the association between these changes in bone metabolic markers (BTMs) and increases in BMDs was still unknown.

Objectives: The aim of this research is to evaluate association between effect of Rmab on BMD and BTMs in patients with PMO.
Methods: Between March 2019 and August 2021, 34 patients with PMO, who were naïve to treatment of osteoporosis were included. The correlation between baseline characteristics, changes (%-) in BMDs in lumber (L-) and total hip (TH-) at 12 months (-M), and absolute values of P1NP and TRACP-5b and %P1NP and %TRACP-5b at 1, 3, 6M was calculated, respectively. Multiple regression analysis was performed on the factors that showed significant correlations to L- and TH-BMD, respectively.
Results: The mean age was 72.5 years old, mean BMI was 20.6 kg/m^2, mean vertebral fractures were 2.1, mean L- and Th-BMD were 0.762 g/cm^2 and 0.589 g/cm^2, and mean P1NP and TRACP-5b were 107.0 μg/L, and 640.3 mU/dL. %L- and %TH-BMD at 12M were 18.1% and 9.1%. %P1NP at 3M was positively correlated with %L-BMD at 12M, while %P1NP at 1 and 6M and TRACP-5b at each time point showed no significant correlation with %L-BMD at 12M. Multiple regression analysis confirmed that a great increase in P1NP at 3M was associated with a great increase in L-BMD at 12M. No correlation between either P1NP or TRACP-5b at each time point and %TH-BMD at 12M was observed.
Conclusion: We showed that a great increase in P1NP at 3M was a predictive factor of a great increase in L-BMD at 12M in patients with PMO treated with Rmab. On the other hand, there was no association between an increase in TH-BMD and BTMs including P1NP and TRACP-5b.

AB1226 CLINICAL SIGNIFICANCE OF A PATIENT COMPLIANCE IN PREVENTION OF SECONDARY FRACTURES

Keywords: Osteoporosis

E. Simakova[1], I. Zborovskaya[2], B. Zavodovsky[2], L. Seewordova[2], J. Polyakova[3], E. Papichev[2], Y. Akhverdyan[2]. *[1]ACR, Rheumatology, Jupiter, United States of America*; *[2]Research Institute of Rheumatology, Volgograd, Rheumatology, Volgograd, Russian Federation*; *[3]Research Institute of Rheumatology, Volgograd, Rheumatology, Volgograd, Russian Federation*

Objectives: to evaluate the effect of compliance in patients with osteoporosis on the incidence of new fragility fractures.
Methods: The study was performed in two stages. At the 1st stage, a retrospective analysis of outpatient records for the period from December 2019 to December 2021 was completed in the Volgograd Center of Osteoporosis. During Phase II of the study, in December 2022, researchers conducted a telephone survey to identify new fractures.
Results: The analysis included outpatient records of 2236 patients aged 40 to 92 years with DEXA scan. (1897 women and 339 men). 715 patients out of 2236 (control group or 31.98% of all included in the study) were found to have an abnormal DEXA, but lost follow up, among 715 patients from the control group, 509 (71%) patients were diagnosed with osteoporosis, 115 patients had a history of fragility fractures [1,2]. But these patients refused to attend the school for patients with osteoporosis and offered treatment. 158 patients in this group (26.51%) reported new low-traumatic fractures on a telephone survey. The remaining 1521 patients out of 2236 (68.02% of all included in the study) were followed up and treated in our Osteoporosis Center. Of these, 1262 patients (82.97%) were diagnosed with osteoporosis and treated with anti-resorptive therapy [2]. 784 out of 1262 patients (62.12%) were compliant with physician's recommendation, these patients constituted the II group of the study (highly compliant patients). Among these patients, only 11 new low-traumatic fractures (1.4%) were registered. Group III of the study (low compliance patients) consisted of 478 patients (37.88%) with a low physician's compliance.[3]. In this group, 42 new fragility fractures (8.79%) were identified.
Conclusion: 26.51% fragility fractures were registered in patients who refused monitoring and treatment. In the group of low compliance patients, 8.79% of new fractures were detected. While in the group of highly compliant patients, only 1.4% of new fractures were registered.

AB1227 MINDFULNESS OF THE RISK OF FRACTURE IN OSTEOPOROSIS AND THERAPEUTIC ADHERENCE

Keywords: Patient reported outcomes, Osteoporosis, Outcome measures

A. M. Lurati[1], A. Laria[1], P. Faggioli[2], K. Re[1], D. Mazzochhi[1], M. G. Marrazza[1], A. Mazzone[2]. *[1]Fornaroli Hospital, Rheumatology Unit, Magenta, Italy*; *[2]Legnano Hospital, Internal Medicine Unit, Legnano, Italy*

Background: Therapeutic adherence especially in chronic pathologies such as osteoporosis is of enormous importance, the foundation of which is based on close doctor-nurse-patient interaction, functional in informing the patient about the reasons for the proposed treatment and the possible side effects of a therapy that lasts for long periods of time.
Objectives: aim of this longitudinal study was to evaluate whether awareness of one's own fracture risk calculated using the DeFRA algorithm could improve adherence and persistence in anti-fracture treatment in an Italian population affected by osteoporosis and possibly reduce the fracture risk itself.
Methods: during 2018-2019, 309 menopausal women with osteoporosis (mean age 75 years ± 4.8) were enrolled in the present longitudinal study. The fracture risk was calculated with Defra algorithm and all were prescribed oral anti-readsorptive therapy for the first time (alendronate 70mg 1 tablet/week or risedronate 35mg 1 tablet/week). Two groups were therefore created: group A (134 subjects) represented by patients managed according to the Standard Clinical Practice and who were NOT given further information about their fracture risk and who were NOT given the risk card; group B (175 subjects) represented by patients who were provided with all the information regarding the risk of fracture according to the variables collected in the Defra algorithm and who were physically given the fracture risk card (Figure 1). After 18 months the patients had a new DXA densitometric data examined, the DeFRA fracture risk was recalculated and a therapy adherence questionnaire, the OS-MMAS (Osteoporosis-Specific Morisky Medication Adherence Scale). Patients with an OS-MMAS score <6 were categorized as "low adherence", otherwise as "high adherence"
Results: Mean age was not significantly different in the two groups: Group A 75yy±4.7, Group B 74.7yy±4.7 ($p>0.05$). The mean DeFRA value at baseline was 26.7 and 26.8 in Group A and Group B, respectively ($p>0.05$), while at the control it was 27.4 and 25.6 ($p<0.01$). The mean OS-MMAS score was significantly lower in group A than in group B (4.95±2.75 vs 8.25±2.85, $p<0.001$) (Figure 2 and Figure 3). 38.5% of the subjects fell into the "low adherence" category with an OS-MMAS score < 6, 61.5% fell into the "high adherence" category with a score ≥ 6. We found a significant correlation between the belonging group and the punctual values of Defra at 18 months and those of variation of Defra between baseline and 18 months (correlation between belonging to group B and Defra at 18 months -2.74, with the delta values of Defra at 18 months -2.72 respectively, $p<0.01$). The OS-MMAS score was shown to be correlated to belonging to group B (coeff Beta 0.5 $p<0.001$) in a linear regression model including the other variables collected age and Defra value at baseline. The same result was obtained by analyzing the data in terms of "low adherence" and "high adherence", where having an OS-MMAS score greater than or equal to 6 correlated to belonging to group B and not to age or DeFRA score baseline (ExpB 0.170 95% CI 0.103-0.281, $p<0.01$)) in a binary logistic regression model. In turn, the better OS-MMAS score correlated with the improvement over time of the DeFRA fracture risk recalculated at the follow-up visit on the basis of the control DXA data (Spearman's Rho -3.95 $p<0.001$)
Conclusion: The data collected in our study, although preliminary and with obvious limitations related to the smallness of the sample analysed, suggest that a greater awareness on the part of the patient of his or her risk of fracture (in the specific case providing detailed information about the result of the DeFRA algorithm provided during the baseline evaluation), may be associated with a greater long-term adherence to the suggested therapy and above all with a reduction in the risk of fracture over time, as evidenced by a reduction in the risk of DeFRA fracture at the 18-month follow-up.

AB1228

RADIOFREQUENCY ECHOGRAPHIC MULTISPECTROMETRY COMPARED WITH DUAL X-RAY ABSORPTIOMETRY FOR OSTEOPOROSIS DIAGNOSIS ON LUMBAR SPINE AND FEMORAL NECK IN A COLOMBIAN POPULATION

Keywords: Osteoporosis, Diagnostic tests

E. Jauregui[1], K. Gonzalez[1], M. Nuñez[2], J. Londoño[1], B. Corredor[1], J. Huertas[1], C. Cabrera[1]. *[1]Riesgo de fractura S.A, Bogotá, Bogotá, Colombia; [2]Instituto Nacional de Cancerologia, Bogotá, Bogotá, Colombia*

Background: An innovative non-ionizing ultrasound technique for osteoporosis diagnosis, which directly measures the BMD (Bone Mineral Density) of both the lumbar spine and the femoral neck, REMS, has shown significant correlations with BMD values and good levels of concordance with DXA-based diagnoses.
Objectives: Cross-sectional study to establish the concordance of BMD measurement between REMS and the gold standard (DXA) in Colombian adult patients receiving oral steroids.
Methods: Observational, analytical and descriptive, cross-sectional study in adults of both sexes who receive steroids and who attend a rheumatology center in Bogotá-Colombia. Inclusion criteria: Men and women over 18 years. Receiving steroids more than 2.5 mg of prednisone or its equivalent for 3 or more continuous months. Interpretable bone densitometry. Subjects who accepted their participation in the study and signed the informed consent. Exclusion criteria: History of prosthesis implantation in the abdomen and/or buttocks. Known physical deformities and/or previous lumbar spine surgery and/or bilateral hip replacement. Pregnant women. Subjects prevented from performing bone densitometry. The densitometric measurements were made with a compact high-performance equipment from General Electric, model iDXA, by the same technologist at the skeletal sites of interest. In a second moment, the same trained technologist performed the BMD measurement with REMS, using an EchoS machine (Echolight®), equipped with a 3.5 MHz convex transducer. This study was submitted and approved by the institutional ethics committee. The calculation of the sample size was carried out with the prevalence of osteoporosis induced by steroids, for n of 185 individuals. The concordance between the two technologies was evaluated with the weighted Cohen's Kappa index.
Results: 200 patients were included in the study, 162 were women. The median age of the entire cohort was 50.5 years (IQR: 22.2), with a minimum age of 20 and a maximum of 86 years. In women, the median age at menarche was 13 years (IQR: 2) and the median age for menopause was 47 years (IQR: 8), only 2.50% (n = 5) reported having fractures for fragility. 51% of the patients had rheumatoid arthritis, SLE 29% and other diagnoses 20%. Regarding the type of corticosteroid used, 92.5% received prednisolone. The last dose of corticosteroid used in median was 5 mg/day (IQR: 5). In the case of the accumulated dose in the last year, the median was 1825 mg/year (IQR: 1850). For the concordance analysis, 11 patients were excluded because the image of all the lumbar vertebral bodies could not be interpreted with both DXA and REMS techniques. Taking into account the diagnostic classification of each technology, a diagnostic concordance was obtained with the weighted Cohen's Kappa index of $\kappa\ \omega$= 0.72 95%CI: [0.63; 0.81] in the lumbar spine and $\kappa\ \omega$= 0.65 95% CI: [0.54; 0.74] in femoral neck.
Conclusion: In Colombian patients receiving steroids, the diagnostic concordance for BMD measurement between DXA and REMS is good; however, there are factors that affect the measurement, for which further training in REMS is required for the technologist to mitigate errors and improve the concordance between the techniques.

AB1229

COMPARISON OF FRACTURE RISK BY FRAX WITH AND WITHOUT BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Prognostic factors, Osteoporosis, Non-pharmacological interventions

A. Carrazco Chapa[1], K. M. López Serna[1], O. E. Alvarez-González[1], K. A. Mendieta Pedraza[1], M. C. Martínez Rodríguez[1], J. Medina Castillo[1], C. M. Skinner Taylor[1], J. C. Riega-Torres, R. Negrete Lopez[1], D. Á. Galarza-Delgado[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*

Background: FRAX is a well-validated instrument that calculates the probability of a major osteoporotic fracture over the following 10 years based on a set of risk factors such as age, body mass index (BMI), history of fragility fracture, steroid treatments used in patients with autoimmune rheumatic diseases (ARD) such as rheumatoid arthritis (RA), and secondary osteoporosis [1]. The FRAX score obtained without bone mineral density (BMD) is comparable to the fracture risk calculated using BMD values; it aims to identify patients who are likely to benefit from health interventions [2].
Objectives: To compare the fracture risk using FRAX with and without BMD in patients with ARD.
Methods: An observational, cross-sectional, prospective study was carried out at the Rheumatology Clinic in the University Hospital "Dr. José Eleuterio González" in Monterrey, Mexico from September to December 2022. We included > 40 years old ARD patients with a previous BMD test who were evaluated as part of a "Bone Health Program". The risk fracture scores were compared using FRAX with and without BMD. There were classified as low (<10% probability of a major fracture), intermediate (10% - 19% probability) and high risk (≥20% probability). Non-traditional risk factors such as visual problems, periodontal disease, 2 or more falls in the last year, lack of physical activity, the ARD diagnosis or the consumption of disease-modifying drugs (DMARDs), were collected using a semi-structured form. The Kolmogorov-Smirnov test was used to determine normality. Data were presented as percent frequency, mean ± standard deviation (SD), or median and interquartile range (IQR) as appropriate. We used the Mann–Whitney U or Chi-square to analyze the differences between groups. A $p<0.05$ was considered statistically significant. The statistical analysis was performed with SPSS v.25.
Results: A total of 146 patients were included: 142 (97.3%) were women and 4 (2.7%) were men with a mean age of 61.49 ± 9.22. The most frequent BMI was overweight (43.2%), followed by normal (31.5%), obesity grade 1 (13.7%), obesity grade 2 (10.3%) and obesity grade 3 (1.4%). The occupations were housewife (78.8%), employed (17.1%) and owned business (4.1%). The most prevalent main diagnosis was RA (45.9%) followed by osteoporosis (24.7%), osteoarthritis (14.4%), systemic lupus erythematosus (3.4%), Sjogren's syndrome (2.7%) and others (8.9%). The risk factors used by FRAX can be found in **Figure 1.** According to the non-traditional risk factors, 24.7% suffered 2 or more falls in the last year, 26% had periodontal disease, 71.9% were sedentary and 53.8% had visual problems. The median T-score spine was -1.7 [IQR (-2.5) - (-0.8)] and the mean T-score hip was -1.06 ± 1.21. The risk fracture scores using FRAX with and without BMD are in **Table 1**.
Conclusion: Higher hip fracture and major fracture risks were identified in the FRAX without BMD group. We found significant differences between the hip fracture risk of FRAX with and without BMD. Nevertheless, no differences were found in the major fracture risk of FRAX with and without BMD; this is of critical importance if all patients cannot have their BMD measured. The FRAX use makes it possible to offer a larger population a timely diagnosis.

AB1230 CHARACTERISTICS OF FRACTURES TREATED IN THE FIRST YEAR OF OPERATION OF THE FLS OF TUDELA. NAVARRA.

Keywords: Osteoporosis, Descriptive studies, Outcome measures

M. S. Moreno Garcia[1]. [1]*Hospital Reina Sofía, Reumatologia,Tudela, Spain*

Background: Osteoporosis is a common disease with a huge impact on public health due to the great morbidity and mortality and the impact on the quality of life of fractures.The main objective of its approach is to avoid the appearance of osteoporotic fractures, so it is important to devote efforts to diagnose and treat individuals who are most at risk of suffering this type of fractures. In our environment the approach to osteoporotic fracture was deficient, so a specific secondary prevention consultation was launched.
Objectives: To analyze the general characteristics of patients referred to the FLS consultation during their first year of operation at the Reina Sofia Hospital in Tudela. Navarra.
Methods: Retrospective descriptive study including patients referred to the secondary fracture prevention rheumatology (FLS) consultation, from November 2021 to November 2022. Epidemiological characteristics, risk factors, type of fracture, therapeutic acts and adherence to treatment at month, 6 months and 12 months are analyzed.
Results: During the indicated period, 200 patients were referred to FLS consultation from Traumatology, Internal Medicine and Rehabilitation, of which 67% (134) were evaluated during admission for hip fracture, of whom 11 died during admission. 33% of patients were treated on an outpatient basis -with a maximum delay of 6 weeks-, for low-impact fractures of radius (23), proximal humerus (15) and vertebral (28). The mean age of patients with hip fracture was 84.95 years, and that of the rest of osteoporotic fractures treated was 72.95 years, with a ratio of men/ women of 43/157, close to 1/5. The Barthel was also calculated with an average of 90.36. Regarding risk factors: the mean BMI of the patients was 25.56 kg/m2, 23 patients (11.5%) were active smokers, 8 of the women attended (4%) had early menopause, 2 women (1%) were on treatment with aromatase inhibitors, 48 patients (24%) had had a previous fracture and 57.5% of patients had hypovitaminosis D. Only 20 patients (10%) had taken or were being treated for osteoporosis prior to fracture. BMD was requested from 47% of patients. Regarding the treatment prescribed after evaluation in the FLS, 16% was not considered subsidiary to specific pharmacological treatment, but was always given non-pharmacological advice, as well as calcium and vitamin D supplements. Those who were prescribed specific therapy 64% were prescribed antiresorptive and 36% an osteoformer. Regarding adherence to treatment, only 4 patients did not take it within one month of their prescription. The rest followed a correct completion each review call per month, 6 months and one year, although at the time of writing the study there are pending review appointments of 6 and 12 months in patients recruited from the second semester of 2022.
Conclusion: The establishment of standardized units for secondary prevention of fracture is a necessity for the health of the population. In our sample, only 10% of patients treated for osteoporotic fracture had specific therapy before their fracture, but, after assessment in the FLS, the initiation of therapy after osteoporotic fracture was ensured in all subsidiary patients, as well as adequate adherence to treatment.

AB1231 PROFILE OF OSTEOPOROSIS IN YOUNG WOMEN: EXPERIENCE FROM A POPULATION IN SOUTHERN MOROCCO

Keywords: Osteoporosis, Descriptive studies, Bone diseases

H. Tebaa[1], H. Arabi[1], A. Mougui[1], I. El Bouchti[1]. [1]*CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, Rhumatology, Marrakech, Morocco*

Background: Osteoporosis is a generalized skeletal disease characterized by low bone density and alterations in bone microarchitecture. Current definitions and recommendations focus more on postmenopausal osteoporosis with a low number of studies in young pré-menopausal women, which makes it difficult to estimate the prevalence of osteoporosis in this population.
Objectives: To establish the prevalence and determine the etiologies of osteoporosis in young women and their management according to the experience of our department.
Methods: Retrospective descriptive and analytical study including 97 female patients aged less than 45 years, who performed a bone densitometry measurement between the years 2014 and 2022. Data were collected from the bone densitometry database. Osteoporosis was retained if a T score less than or equal to -2.5. Women older than 45 years and or followed for genetic osteopathy were excluded from this study.
Results: There were 97 patients with osteoporosis in this study. The average age was 25 years. Early menopause was found in 15% of cases (10% of cases after chemotherapy). Osteoporosis secondary to endocrinopathy was found in 17% of cases (5% diabetes, 10% primary hyperparathyroidism, 2% Cushing's syndrome). It was secondary to a systemic disease or chronic inflammatory rheumatism in 45% of cases (29% rheumatoid arthritis, 12% spondyloarthropathy, 3% systemic lupus erythematosus and 1 % Horton's disease). The other pathologies found were chronic renal failure in 3% of cases, a notion of prolonged use of corticosteroids in 21% and hormone therapy for breast neoplasia in 14%. 3% of the patients had at least one osteoporotic vertebral fracture. The mean bone mineral density (BMD) in both femurs was 0.727g/cm2. The mean BMD in the spine was 0.965g/cm2. 11% of these patients were treated with oral anti-osteoporotic drugs, 35% were supplemented with vitamin D and calcium.
Conclusion: The discovery of osteoporosis is rare in young women, hence the scarcity of studies in this category of women. It may be of metabolic or drug-induced origin or related to other chronic inflammatory diseases. It should be investigated in the presence of risk factors in order to limit the risk of bone fractures.

AB1232 HIGHER PAIN SCORE MEASURED WITH VISUAL ANALOG SCALE HAS SIGNIFICANT HIGHER RISK OF INCIDENT BONE FRAGILITY FRACTURE

Keywords: Pain, Rheumatoid arthritis, Osteoporosis

I. Yoshii[1], N. Sawada[2], T. Chijiwa[3]. [1]*Yoshii Clinic, Musculoskeletal Medicine, Shimanto City, Japan*; [2]*Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan*; [3]*Kochi Memorial Hospital, Rheumatology, Kochi, Japan*

Background: Bone fragility fracture (BFF) is one of serious troublesome incident in treating patient with rheumatoid arthritis (RA). Previously, sustaining clinical remission with simplified disease activity index (SDAI) was clarified that prevents occurrence of incident BFF [1].
Objectives: We hypothesized that pain degree would correlates with occurrence of incident BFF, because that caused gait disability and bone fragility. The aim of this study is to clarify this issue.
Methods: A retrospective cohort study data was used in the study. Postmenopausal female patients who matched the EULAR/ACR classification criteria under the T2T since August 2010, have been treating RA and were measured bone mineral density (BMD) with dual-energy X-ray absorptiometry, were recruited. The initial target of therapy is the attainment of remission with SDAI within 6 months of initiation. The primary outcome was incident BFF. Follow-up started at BMD measurement (baseline) and continued until the development of the first fracture or censoring at death, loss to follow-up or end of the study. Binary logistic regression analyses (BLR) were determined for incident BFF incidence up to the last observation. Risks for the incidence of BFF was classified as RA specific and general candidate. In general candidate, comorbidities that might affect the incidence of BFF, such as lifestyle-related diseases, increased ability to fall, and pain score using visual analog scale (PS-VAS) were included. anti-citrullinated polypeptide antibodies and rheumatoid factor titers, SDAI score, Health Assessment Questionnaire Disability Index, and Sharp/van der Heijde score were included in RA specific candidate risks. Each evidence was evaluated using Cox regression analysis to identify significantly higher risk factors within 5% in univariate models and to evaluate using multivariate model. In the variants with significant higher risk ratio in the Cox regression analysis, Receiver

operation characteristics (ROC) was examined to determine cut-off index (COI). Finally, statistically evident variants in the ROC study was examined to clarify a validity of the variant as a risk factor using Kaplan-Meier survival curve analysis again.

Results: A total of 239 patients were recruited. Mean age was 73.6 years and mean follow up period was 52.4 months. Mean T-score in the lumbar spine and femoral neck were -2.10 and -1.85. Using BLR, PS-VAS, estimated glomerular filtration ratio based on cystatin C (eGFR_CysC), prevalent BFF (pr-BFF), and SDAI remission rate were significant correlation with incident BFF. In these, PS-VAS and pr-BFF demonstrated significant higher risk ratios using a multivariate cox regression analysis. In the ROC, COI of PS-VAS was 24.6 and the area-under-the-curve was 0.669 ($p<0.001$). Finally, PS-VAS ≥ 24.6 mm had 3.506 fold higher hazard ratio than PS-VAS < 24.6 mm using Kaplan-Meier survival curve analysis.

Conclusion: These results suggested pain control in treating RA is the important task in order to avoid incident BFF in postmenopausal female patients with RA.

AB1233 IMPACT OF RHEUMATOID ARTHRITIS ON THE DENSITOMETRIC STATUS OF WOMEN

Keywords: Rheumatoid arthritis, Osteoporosis

L. Rouached[1], J. Soua[1], S. Bouden[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]. [1]*Charles Nicoles Hospital, Rheumatology Departement, Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatic disease. It can be associated with several comorbidities including osteoporosis (OP). The origin of this bone loss is multifactorial. A fracture episode is the complication of osteoporotic disease and constitutes all the gravity of this disease.

Objectives: The objective of this work was to evaluate bone densitometry (BMD) in women with RA and to identify its relationship with disease parameters.

Methods: This was a cross-sectional study, including patients followed for RA meeting the ACR/EULAR 2010 criteria. For each patient, disease parameters (duration of progression, activity score (DAS28 VS), functional impact (HAQ), corticosteroid intake) were assessed and BMD of the lumbar spine and femoral neck was performed in all patients.

Results: A total of 76 women were included, 66% of whom were postmenopausal. The mean age of the patients was 52.5±9.7 years and the mean duration of RA progression was 11.3±7.9 years. The mean DAS28 VS score was 4.3±1.4 and the mean HAQ was 0.98±0.8. Corticosteroid use was noted in 62 patients (81.5%) at a mean dose of 8.6±3.2mg/day. Regarding the densitometric profile of the patients, the mean BMD values at the vertebral and femoral sites were -1.4±1.3DS and 0.8±1.1DS respectively, and the prevalence of osteoporosis and osteopenia were 21.6% and 46.6% respectively. Patients with osteoporosis (OP) were older (p=0.00), and there was a significant relationship between OP and menopausal status (p=0.007). In contrast, disease parameters (function, activity, duration and treatment) were not associated with the occurrence of osteoporosis in our series: HAQ (p=0.6), disease duration (p=0.3), disease activity (p=0.3) or corticosteroid use (p=0.9).

Conclusion: OP is a frequent comorbidity associated with RA. It should be systematically detected because of its functional and vital complications. In our study, the occurrence of OP was more frequent at an older age during RA and menopausal status. There was no relation with the disease parameters.

AB1234 THE BODY COMPOSITION IMPACT ON OSTEODENSITOMETRY VALUES IN PERSONS OLDER THAN 65 YEARS

Keywords: Diet and nutrition, Osteoporosis, Diagnostic tests

R. Matijevic[1], M. Obradovic[1], O. Dulic[1], M. Vranjes[1], A. Savic[2], T. Icin[3]. [1]*Medical Faculty in Novi Sad, Orthopedic and Trauma Clinic, Novi Sad, Serbia*; [2]*Medical Faculty in Novi Sad, Rheumatology, Novi Sad, Serbia*; [3]*Medical Faculty in Novi Sad, Endocrinology, Novi Sad, Serbia*

Background: The aging process is a normal physiological phenomenon and has an impact on the body composition and physical fitness of the elderly. It is characterized by a progressive increase in total body fat mass, a decrease in muscle mass and changes in distribution in terms of an increase in abdominal fat tissue. These changes in the elderly have a great impact on health, functional capacity, and quality of life. The variability of body composition components contributes to the origin and progression of pathology and disability. Today osteodensitometric examination is considered one of the most versatile imaging techniques for assessing osteoporosis, sarcopenia, and obesity, and is currently the only technique capable of identifying all of these conditions at the same time. Osteoporosis is characterized by low bone mass and microarchitectural bone loss, leading to an increased risk of fracture caused by a minor trauma.

Objectives: To determine the presence of normal values of T score, osteopenia and osteoporosis, to determine the distribution of BMI and values of lean muscle mass, adipose tissue and visceral adipose tissue of the examined population.

Methods: In this retrospective study conducted from March to April 2019 at the University Clinical Center of Vojvodina, 699 respondents of both sexes over 65 participated. Exclusion criteria were established osteoporosis and treatment. The research consisted of collecting general information of the respondents (gender, age, smoking status, level of education, marital status). Body composition (BMD, FM, VAT, LM) was measured by osteodensitometric examination. Also, all subjects body weight, and height were measured and their body mass index (BMI) was determined.

Results: The average age of respondents was 71.92 ± 5.14, most respondents 50.6% have secondary education, 52.2% are married, 9.5% are smokers. The classification of the total T score shows a normal finding in 26.8%, with osteopenia 58.4% and with osteoporosis 14.8% of subjects. According to (BMI) with a normal finding is 16.5%, overweight is 38.5% and obese 45% of respondents. The average BMI of men is 28.79 ± 4.01, and for women the average BMI is 29.92 ± 4.91. The average value of VAT is 1,537 ± 0,820, FM 31,105 ± 9,152 and LM 43,735 ± 8,279. Men have higher average VAT values (2.06 ± 0.90) compared to women (1.32 ± 0.67). The average FM is higher in women (32.49 ± 8.88) than in men (27.60 ± 8.89). The average LM is higher in men (53.38 ± 7.05) than in women (39.92 ± 4.97). Subjects with normal findings were 61.5% obese, with osteopenia 40.2%, and with osteoporosis 28% obese. The measured value of LM in persons with normal findings is 47,921 ± 8,738, with osteopenia 42,342 ± 7,378, with osteoporosis 40,443 ± 6,949. The measured value of FM in persons with normal findings is 34.37 ± 9.51, with osteopenia 30.20 ± 8.75, and with osteoporosis 27.60 ± 7.14. The measured value of VAT in persons with normal findings is 34.37 ± 9.51, with osteopenia 34.37 ± 9.51, with osteoporosis 27.60 ± 7.14.

Conclusion: Higher values of BMI, LM, FM, and VAT have a positive effect on the hip and spine T score, and a protective role against osteoporosis.

AB1235 PREVALENCE OF OSTEOPOROSIS IN AN ALGERIAN POPULATION WITH OSTEOARTHRITIS: CROSS-SECTIONAL STUDY

Keywords: Osteoporosis, Osteoarthritis, Descriptive studies

B. Abdelatif[1], A. Djebbari[2], S. Oulebsir[2], S. Bennedjema[2], C. Makhloufi-Dahou[2,3], A. Abi Ayad[3]. [1]*HMUS, Rhumatology, Algiers, Algeria*; [2]*HCA, Rhumatology, Algeirs, Algeria*; [3]*Hôpital Bab el oued, Rhumatology, Bab el oued, Algeria*

Background: Osteoarthritis is a chronic degenerative rheumatism responsible for a structural modification of bone tissue which can alter its biomechanical qualities. Data are contradictory regarding the relationship between osteoarthritis (OA) and osteoporosis (OP) with some studies showing the increased risk of OP in OA especially in patients awaiting arthroplasty. Failure to consider bone loss in this osteoarthritis population can lead to serious complications such as fracture, which can considerably reduce the quality of life and expose this elderly population to excess mortality.
Objectives: This study aims to identify patients at risk of fracture in osteoarthritis Algerian population and evaluate postoperative bone loss complication in patients undergoing arthroplasty.
Methods: Descriptive, cross-sectional study in patients with knee osteoarthritis candidates for arthroplasty. All patients underwent a rheumatology exploration including clinical, radiological and biological evaluation with a measurement of bone mineral density (BMD) at spine and hip. The results are interpreted according to the WHO classification.
Results: Three hundred patients were recruited with a sex ratio=0.45, the mean age was 67.97 ± 6.78 years and the mean BMI was 30.81 ± 5.37 kg/m2. With regard to bone loss, osteoporosis was present in 26.7% (95% CI: 21.7%-32.1%), while ostepenia was found in 43.7% (CI 38.0%-49.5%).Factors associated with bone loss were: female sex ($P<10^{-6}$), urban habitat (P= 0,001) and age ≥ 60 years (P=0,003).
Conclusion: In this Algerian sample of severe osteoarthritis awaiting arthroplasty, osteoporosis and consequently the risk of fracture are prevalent. Identifying the population with bone loss in these patients could improve overall management and avoid postoperative fractures.

OSTEOPOROSIS AND FRACTURES IN PATIENTS UNDERGOING CHRONIC CORTICOSTEROID THERAPY

Keywords: Prognostic factors, Osteoporosis, Real-world evidence

J. E. Oller Rodríguez[1], E. Grau García[1], C. Riesco Barcena[1], A. V. Huaylla Quispe[1], A. M. Torrat Noves[1], D. Ramos Castro[1], P. Muñoz Martinez[1], L. Mas Sanchez[1], S. Leal Rodriguez[1], I. Cánovas Olmos[1], F. Ortiz-Sanjuán[1], L. Gonzalez Puig[1], J. Ivorra Cortés[1], I. Martínez Cordellat[1], E. Vicens Bernabeu[1], R. Negueroles Albuixech[1], C. Nájera Herranz[1], E. Tovar-Sugrañes[1], H. Charia[1], J. A. Román Ivorra[1]. [1]*La Fe University and Polytechnic Hospital, Rheumatology, València, Spain*

Background: Glucocorticoids are widely used for the treatment of various rheumatic diseases and are one of the major risk factors for bone fragility associated fractures. However, beyond randomized clinical trials, there is little evidence in actual clinical practice.
Objectives: Our aim is to evaluate the appearance of osteoporosis and fractures in patients undergoing corticosteroid therapy.
Methods: We performed an observational retrospective descriptive study with Vasculitis (several subtypes) or Polymyalgia Rheumatica (PMR) patients diagnosed, who had received corticosteroid regimens with doses of at least 5 mg/day of prednisone (or equivalent) for a period of not less than 3 months, and in which the appearance of fractures was monitored for the next 2 years.
Results: We included 234 patients (62.4% females) with a mean age at the onset of corticosteroids of 75.8 years and mean duration corticosteroid regimens of 58 months. The most represented disease was PMR, with 183 patients (78.2%), followed by Large Vessel Vasculitis (12.4%), ANCA positive Small Vessel Vasculitis (4.3%), ANCA negative Small Vessel Vasculitis (3.4%), with a lower proportion of Medium Vessel vasculitis and other diseases such as Relapsing Polychondritis. Furthermore, 29 patients (12.39%) had previous fragility fractures, while 32 patients (13.68%) suffered one or more fractures after the start of corticosteroid therapy, being hip its most frequent location (4.7%), followed by vertebrae (3.8%). Likewise, the mean duration of corticosteroid treatment until the onset of new fractures was 4.5 months. Even without reaching statistical significance, we observed a greater age (80.5 years), a higher presence of the female gender (81.25%) and a previous fracture (18.75%) in patients with new fractures. In addition, 32.91% of patients had densitometric osteoporosis at the beginning of corticosteroid therapy.

Table 1. Comparison between different therapeutic options

Treatment	Patients n (%)	New Fractures n (%)	Fracture-free time: average in years
Alendronate	31 (13.25)	5 (16.13)	5.39
Ibandronate	6 (2.57)	3 (50)	6.51
Risedronate	54 (23.07)	6 (11.11)	5
Zoledronate	8 (3.42)	5 (62.5)	5.03
Bazedoxifene	1 (0.43)	0 (0)	1.19
Denosumab	38 (16.24)	6 (15.79)	4.41
Teriparatide	10 (4.27)	4 (40)	5.2
No treatment	86 (36.75)	3 (3.49)	3.88

We observed an association between fractures and zoledronate treatment (P=0.012), and a tendency for ibandronate (P=0.07). The discreet entity of these differences could be explained by the statistical effect produced by the small number of new fractures, taking into account, moreover, the fact that in our Rheumatology Department we systematically carry out a fracture risk assessment to decide whether and when to start the treatment, and also prescribing more powerful therapeutic options to patients at higher risk of fracture. Finally, we did not observe significant differences in fracture-free time among the most frequent therapeutic options.
Conclusion: We observed a tendency to have a higher frequency of fractures in patients with previous fractures, older age and female gender. Less quantitative prevention of fractures was observed in patients with zoledronate and ibandronate, with no clear differences in fracture-free time.

Crystal diseases, metabolic bone diseases other than osteoporosis

AB1237 ASSOCIATION OF GUT MICROBIOTA WITH RISK OF GOUT

Keywords: Gout

Y. Zhang[1,2], Y. Niu[1,2], Z. Han[1,2], Q. Yu[3], P. F. He[3], X. Li[4], S. X. Zhang[4]. *[1]Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, Shanxi Province, China*; *[2]Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, Shanxi Province, China*; *[3]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, Shanxi Province, China*; *[4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China*

Background: Gout is a prevalent and painful inflammatory arthritis. Increasingly studies have shown that the gut microbiota is associated with gout [1-3]. However, whether these associations reflect a causal relationship is still being determined.
Objectives: To investigate whether there is a causal relationship between intestinal bacteria and gout, we used Mendelian randomization (MR) two-sample analysis.
Methods: Gout-related data were derived from the Integrated Epidemiology Unit (IEU) GWAS database, which included 2115 gout cases and 67259 controls [4]. The data on intestinal bacteria came from the website MRbase. We searched 173 species of bacteria and finally identified 5 genus species, which were the *Eubacterium brachy, Eubacterium hallii, Howardella, Sellimonas,* and *order Mollicutes RF9*. MR-Egger, weighted median, inverse variance weighting (IVW), and MR-PRESSO were used to conduct the double-sample MR analysis. Finally, we excluded the data related to poly-effect and heterogeneity to ensure the robustness of the results.
Results: Five kinds of gut microbiota (*Eubacterium brachy, Eubacterium hallii, Howardella, Sellimonas, and order Mollicutes RF9*) had a causal relationship with gout. According to inverse variance weighted estimation, *Eubacterium hallii*(odds ratio(OR) = 1.660, 95% confidence interval(CI): 1.073-2.569, P = 0.023), *Howardella*(OR = 1.391, 95% CI: 1.058-1.828, P = 0.018) and *Sellimonas*(OR = 1.384, 95% CI: 1.009-1.897, P = 0.044) were risk factors for gout. *Eubacterium brachy*(OR = 0.656, 95% CI: 0.469-0.917, P = 0.014) and *order Mollicutes RF9*(OR = 0.641, 95% CI: 0.471-0.874, P = 0.005) showed protective effect against gout (Figure 1).
Conclusion: This study suggested a causal relationship between these five gut microbiota and gout, providing new implications for future clinical trials on the association between microbiota and gout.

AB1238 LONG-TERM EFFECTIVENESS AND PREDICTORS OF NERIDRONATE TREATMENT OF TYPE I COMPLEX REGIONAL PAIN SYNDROME (CRPS)

Keywords: Rare/orphan diseases, Bone diseases, Pain

G. Adami[1], D. Gatti[1], A. Fassio[1], V. T. Braga[1], C. Benini[1], O. Viapiana[1], D. Bertelle[1], M. Rossini[1]. *[1]University of Verona, Rheumatology Unit, Verona, Italy*

Background: Complex Regional Pain Syndrome (CRPS) is a painful disease that can lead to chronic pain and disability. Bisphosphonates are largely used in the real-life for the treatment of CRPS, but data on long-term effectiveness and its predictors are lacking.
Objectives: The aim of the present study is to describe the real-life effectiveness of IV neridronate on both pain and long-term disability in patients with type I CRPS. Secondary objective is to determine the factors associated with long-term disability and response to treatment.
Methods: We conducted a longitudinal observational study on patients with type I CRPS treated with IV neridronate (400 mg over 4 days). Clinical and demographic characteristics were collected at baseline, after 3 months (M3) and after 12 months (M12) from treatment. Mixed-effect analysis was used to determine the effect of treatment on VAS pain. Multivariable logistic regression was employed to determine the factors associated with long-term response to treatment. We determined "responders" and "early responders" to be those who achieved a ≥50% VAS score reduction between (baseline/pretreatment) and M12 (responders) and M3 (early responders). We defined "excellent responders" based on full recovery from loss of motion at M12 AND VAS pain at M12 less than 20 mm (excellent responders were those patients with mild/moderate/severe loss of motion at baseline who had none loss of motion at M12 AND VAS pain less than 20 mm).
Results: 103 patients with type I CRPS treated with IV neridronate were included in the study. Mean VAS pain decreased significantly at M3 (79.1 mm to 33.1 mm, -45.9 mm, 95% CI 40.1 to 51.8) and M12 (79.1 mm to 17.5 mm, -61.6 mm, 95% CI 55.3 to 67.9) **Figure 1A**. Hyperalgesia and allodynia resolved in 84.3% and 88.1% of patients at M12. Loss of motion resolved in 53.5% of patients. The predictors of "excellent response" at M12 were: gender (male better than female), predisposing event to CRPS (no event being better than any predisposing event), site of CRPS (lower limb being better than upper limb), and early response at M3 on VAS pain (2.5 times the chance of being excellent responder every 10 mm decrease). Predictors of excellent response are presented in **Table 1** (binary logistic regression analysis). **Figure 1B** shows the long-term VAS pain reduction with IV neridronate in patients with or without complete recovery from functional disability ("excellent responders").

Variable	aOR	95% CI	p value
Site of CRPS			
Lower limb vs upper limb	**12.76**	**1.65 to 199.1**	**0.0320**
Predisposing event	**71.31**	**6.511 to 176.1**	**0.0025**
None vs fracture	1.77	0.01 to 276.5	0.8329
Orthopedic surgery vs fracture	19.03	0.72 to 180.9	0.1664
Trauma w/o fracture vs fracture			
Age	0.99	0.94 to 1.05	0.9509
Sex	**14.00**	**2.75 to 104.6**	**0.0037**
Male vs Female			
BMI	0.92	0.75 to 1.11	0.4329
VAS pain at baseline	**0.91**	**0.85 to 0.96**	**0.0040**
VAS pain absolute reduction at M3	**2.51**	**1.68 to 4.18**	**<0.0001**

Conclusion: In this real-life study neridronate was associated with rapid and progressive improvement of symptoms of CRPS which was maintained up to 3 years of follow-up. The predictors of excellent response were early response, lower limb localization, absence of predisposing events and male gender.

AB1239 THE INVERTED J-SHAPED RELATIONSHIP BETWEEN SERUM URIC ACID LEVEL AND ABDOMINAL MUSCLE MASS AMONG KOREAN MALE POPULATION: A SINGLE-CENTER STUDY OF 5114 CASES

Keywords: Gout, Sarcopenia

D. H. Lim[1], S. J. Choi[1]. *[1]Ulsan University Hospital, University of Ulsan College of medicine, Division of Rheumatology, Department of Internal Medicine, Ulsan, Korea, Rep. of (South Korea)*

Background: Sarcopenia is the decline of muscle mass and strength with age. Evidence suggests that oxidative stress and molecular inflammation play important roles in muscle atrophy by interfering with the balance between protein synthesis and breakdown. Uric acid (UA) may be related to sarcopenia through its role as either an antioxidant or pro-oxidant properties. Although the association of serum UA level with sarcopenia has been investigated in previous studies, the results are conflicting.
Objectives: The purpose of this study was to investigate the association of serum UA with abdominal muscle mass using abdominopelvic computed tomography (apCT) among Korean adult men.
Methods: We evaluated 5114 men aged above 20 years, who voluntarily underwent laboratory tests and apCT as a part of general health examination from May 2014 to June 2019. The participants were stratified into quartiles according to their serum UA levels. The low-attenuation abdominal muscle area (LAMA), normal-attenuation abdominal muscle area (NAMA) and total abdominal muscle area (TAMA) were measured using cross-sectional apCT data of the L3 lumbar vertebrae. Between-group comparisons were performed using Pearson's chi-square test for categorical variables, and the ANOVA for numerical variables, as appropriate. The trends between serum UA quartiles and each AMA were analyzed by univariate (ANOVA) and multivariate analysis (ANCOVA).
Results: The mean age of individuals was 52.5 ± 9.37 years and the mean body mass index (BMI) was 24.6 ± 2.92 kg/m^2. In univariate analysis LAMA, NAMA and TAMA were increased continuously across quartiles of serum UA. However, serum UA levels (quartiles) showed an inverted J-shaped curve with NAMA and TAMA, after adjustment for confounding factors including age, BMI, smoking status, hypertension, diabetes, dyslipidemia, glomerular filtration rate, and c-reactive protein (Table 1).
Conclusion: The results suggest that a specific range of serum UA levels may be associated with better abdominal muscle mass in Korean adult men.

Table 1. Adjusted mean value of abdominal muscle mass by serum uric acid quartiles

variables	Uric acid				
	quartile 1 < 5.00 mg/dl (n = 1228)	quartile 2 5.01 ~ 5.80 mg/dl (n = 1328)	quartile 3 5.81 ~ 6.70 mg/dl (n = 1251)	quartile 4 > 6.70 mg/dl (n = 1247)	p-value
LAMA, cm^2	26.7 [a] (26.29-27.20)	26.7 [b] (26.29-27.20)	27.1 (26.65-27.56)	27.9 [a,b] (27.44-28.37)	0.003

AB1240 PERCEPTIONS OF GOUT AND ITS MANAGEMENT PATTERNS: FINDINGS FROM SURVEY AND STRUCTURED INTERVIEWS WITH PRIMARY CARE PHYSICIANS AND RHEUMATOLOGISTS

Keywords: Quality of care, Gout

H. Zimmerman[1], M. Bhagwat[1], R. Laranger[2], L. Padnick-Silver[3], B. Lamoreaux[3]. *[1]Rush University College of Medicine, Department of Internal Medicine, Chicago, United States of America*; *[2]PreScouter Inc., Technical Department, Chicago, United States of America*; *[3]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: Despite the high prevalence of gout worldwide,[1] there is widespread undertreatment of this painful, debilitating inflammatory arthritis.[2,3] Gout patients who maintain serum urate (SU) <6 mg/dL have fewer flares, less joint involvement, and overall better quality of life.[3] However, gout management guidelines differ substantially between the American College of Physicians (ACP)[4] and the American College of Rheumatology (ACR),[5] most notably with ACP recommending oral urate-lowering therapy (ULT; allopurinol, febuxostat, probenicid) use only in patients with frequent gout attacks with no clear SU-target and ACR recommending oral urate-lowering therapy use in all gout patients with tophi, flares, or gout-related bone damage with a treat-to-target approach to an SU <6 mg/dL. Because primary care physicians (PCPs) are often a first point-of-contact for patients suffering from gout, understanding their perceptions and management strategies of gout is of importance.
Objectives: To better understand how PCPs perceive and manage gout.
Methods: An online survey was administered to PCPs regarding perceptions of gout patients, gout severity grading, gout treatment strategies, and gout patient referral patterns. A 5-point Likert scale was used to gauge perceptions and patterns. Additionally, structured 30-60 minute interviews of similar focus were conducted with PCPs and rheumatologists (all interviews conducted by a single interviewer [RL]). These interviews provided further insight into PCP perceptions of gout and allowed similarities and differences between physician types to be examined. A 10-point Likert scale was used to quantify select interview responses.
Results: A total of 56 PCPs completed the online survey, with most practicing in a metropolitan area (84%) and seeing >50 patients/week (66%). 98% of participating PCPs reported seeing <10 known gout cases/week, with 82% having high or very high confidence in their ability to manage gout. Anti-inflammatory treatments (89%), oral ULTs (88%), diet (70%), and biologic therapies (59%) were viewed by most as being highly effective or very highly effective. Further, 63% of PCPs viewed gout patients as always or almost always compliant with medication and 66% of PCPs reported that gout patients never or almost never ask for referral to a gout specialist. However, when PCPs did make a referral, it was most often for severe gout. The low referral rate coincided with the observation that the majority of PCPs (79%) reported most-commonly seeing gout of "medium" severity. Further insight was gained from 5 PCP and 5 rheumatologist interviews conducted. PCPs and rheumatologists viewed gout patient compliance differently, with PCPs perceiving a higher rate of compliance (7.3 vs. 5.7). Both PCPs and specialists expressed that gout flare data collection and gout severity determinant tools would be useful for patient management, including therapy efficacy evaluation.
Conclusion: These findings suggest that, despite widespread undertreatment of gout outside of specialty care,[2] PCPs reported high comfort in managing gout, high compliance of gout patients, and little need for specialty referral except when gout is severe and refractory. Both PCPs and rheumatologists expressed that tools for determining gout severity and tracking gout flares would be helpful. We suggest that such tools could serve as guides for PCPs when monitoring for success of therapy and when to make a rheumatology referral.

AB1241 FACTORS ASSOCIATED TO LOSS FOR FOLLOW-UP IN A PROSPECTIVE GOUT COHORT

Keywords: Gout, Crystal arthritis

F. Perez-Ruiz[1], C. Vazquez-Puente[1], M. D. C. Modesto-Caballero[1], A. M. Herrero-Beites[2]. *[1]Osakidetza, OSI EE-Cruces, Cruces University Hospital, Rheumatology Division, Baracaldo, Spain*; *[2]Gorlizeko Erietxea, Rehabilitation Division, Gorliz, Spain*

Background: Adherence to treatment has been widely studied, but not adherence to follow-up visits.
Objectives: To analyze factors associated to loss for follow-up in patients with gout and with a programmed follow-up visit to the rheumatology office.
Methods: Analysis of data from an inception cohort of patients with gout prospectively followed-up in a university hospital setting. Variables include general data, along with clinical characteristics of gout, comorbidities, treatment and adherence to prescribed urate-lowering therapy (ULT). Those variables associated (p<0.20) in bivariate analysis were included in a multivariate analysis. Patients who did not attend to a visit because they passed were not considered as lost for follow-up.
Results: From a series of 1,442 consecutive patients, 354 (24.5%) were lost for follow-up; 219 (15.2%) did not attended because they died between programmed visits. Mean follow-up until lost for follow-up was 32 months vs. 49 months for patients who still remained in active follow-up. Age (older), gender (women), pooled comorbidity (higher), severity of gout (monoarticular), alcohol intake (<15 g/day), adherence (MPR> 80%), previous treatment (none), and consultation (primary care), were associated to higher rates of loss for follow-up in bivariate analysis. No association was found between persistence on follow-up and time from onset of gout, presence of tophi, number of flares per year, previous and prescribed ULT.

	B	Sig.	Exp(B)	95% C.I.L. for EXP(B)	
				Lower	Upper
Age (year)	**-,029**	**,001**	**,972**	**,955**	**,989**
Primary care consultation	**-1,651**	**,008**	**,192**	**,057**	**,647**
Adherence (MPR > 0.8)	**-1,120**	**,000**	**,326**	**,186**	**,572**
Severity (polyarticular)	***-,358***	***,107***	***,699***	***,416***	***1,17***
Highest comorbidity (Kaiser 3-4)	,199	,519	1,220	,666	2,234
Previous ULT (none)	-,196	,477	1,217	,709	2,089
Gender (male)	,256	,566	1,292	,539	,988
Ethanol >15g/day	,005	,987	,995	,543	1,823

In multivariate analysis (Table 1), only higher age, higher adherence to prescribed, and consultation from primary care were independently associated to persistence on follow-up. Severity of gout (polyarticular disease) seemed to be also associated to persistence, but lacked statistical significance.
Conclusion: In our clinical setting, the profile of patients at higher risk of abandoning prescribed follow-up is that of a younger, poorly adherent, with lower burden of disease and consulting through a assistance "short-cut".

AB1242 GOUT AND VENOUS THROMBOEMBOLISM IN THE US: A NATIONAL PERSPECTIVE

Keywords: Gout, Epidemiology, Cardiovascular disease

G. Singh[1,2], M. Sehgal[2,3], B. Lamoreaux[4], A. Mithal[2]. [1]*Stanford University School of Medicine, Department of Medicine, Stanford, United States of America*; [2]*ICORE, Department of Epidemiology, Woodside, United States of America*; [3]*UCLA, Department of Computer Science, Los Angeles, United States of America*; [4]*Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: Venous thromboembolism (VTE) is a leading cause of preventable death in the USA [1]. Gout has been associated with higher risk of venous thromboembolism [2]. However, there is little nationwide data in the United States (US) on the clinical and economic consequences of of VTE in persons with gout.
Objectives: To study venous thromboembolism (VTE) hospitalizations in patients with gout in the United States (US) and estimate their clinical and economic impact.
Methods: The National Inpatient Sample (NIS) is a stratified random sample of all US community hospitals designed to produce national estimates of inpatient utilization, cost and outcomes. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. Unweighted it contains data from around 7 million hospitalizations a year, weighted it estimates around 35 million hospitalizations nationally. We examined all inpatient hospitalizations in the NIS in 2020, the most recent year of available data, with a primary or secondary diagnosis of gout and venous thromboembolism.
Results: In 2020, there were 32.4 million all-cause hospitalizations in the US, with 19.7 million occurring in persons 45 years or older. Of these, 785,905 hospitalizations occurred in people aged 45 years and over with a diagnosis of gout. These people had a mean age of 71.8 years (95% confidence limits 71.7 - 71.9 years) and were more likely to be men (68.4%). Of these, 79,260 hospitalizations (10.1%) also had concomitant diagnosis of venous thromboembolism. As a comparison, only 8.2% of hospitalizations in the general population 45 years or older had a concomitant diagnosis of VTE (p<0.001 compared to persons with gout). Persons with gout and VTE had a mean age of 71.6 years (95% confidence limit 71.4 - 71.8 years) and were mostly men (62.4%). However, hospitalizations in women with gout were more likely to have VTE (11.0%) compared to men (9.7%). The average cost of each hospitalization was $76,373 (95% confidence limit $73,343 -$ 79,403), with a total annual national cost of $6.1 billion.

Table 1. Percentage of VTE hospitalizations in Gout versus General population

	General population			Gout		
	Total Hospitalizations	Hospitalizations with primary or secondary diagnosis of VTE	Percentage VTE Hospitalizations	Total Hospitalizations	Hospitalizations with primary or secondary diagnosis of VTE	Percentage VTE Hospitalizations
People 45 years and over	19741256	1626055	8.20%	785905	79260	10%
Men 45 years and over	9,919,915	797530	8.04%	541010	52310	9.7%
Women 45 years and over	9,820,250	828450	8.44%	244855	26950	11.0%
Age 45-64 years	7683856	604550	7.9%	210530	21860	10.4%
Age 65 years and older	12057400	1021505	8.5%	575375	57400	10.0%

Conclusion: One out of 10 hospitalizations in persons with gout have a concomitant diagnosis of VTE, significantly higher than the VTE rate in the general population. This calls for increased awareness and steps to prevent the development of VTE in patients with gout.

Background: Cumulative data indicates that 20-30% of subjects with asymptomatic hyperuricemia (AH) have silent monosodium urate (MSU) crystal deposition[1]. For its evaluation, several sonographic examination schemes have been used[2], and the scanning of the 1st metatarsophalangeal (MTP) joint and femoral condyle for double contour (DC) sign, plus 1st MTP for tophi, shows the highest prevalence and discrimination compared to subjects with normouricemia. However, how we should sonographically classify AH with crystal deposits remains to be defined.

Objectives: To compare the variations in prevalence of sonographic deposits in AH across different classification schemes.

Methods: Observational, cross-sectional study. Patients with AH were consecutively recruited from clinics and wards of internal medicine, cardiology, nephrology, endocrinology, rheumatology and primary care units in an academic center. Subjects with a recent serum urate level ≥7mg/dL were included, excluding those under urate-lowering therapy and/or colchicine or with gout or other inflammatory rheumatic disease. Ultrasound was performed by an expert rheumatologist sonographer, blinded to clinical and laboratory data, following 2021 OMERACT definitions for elementary gout lesions (DC sign, tophi, aggregates) and 0-3 grading[3]. The locations scanned bilaterally were knees with patellar tendons, ankles with Achilles' tendons, and 1st and 2nd MTP joints. We applied different definitions for AH with deposits, varying in relation to deposits (any deposits; only DC sign and/or tophi; only grade 2-3 deposits; only grade 2-3 DC sign and/or tophi) or locations (10 locations; reduced 4-joint scheme including knees and 1MTPs; more than 1 location with deposits). Comparisons were performed by Chi2 test.

Results: Seventy-seven participants with AH were studied, 55 males (71.4%) and a mean age of 59.8 years (SD 17.3). Mean body mass index was 31.2 kg/m2 (SD 5.2), and 37.66% and 29.9% suffered from cardiovascular and chronic kidney disease, respectively. Mean uricemia was 7.6 mg/dL (SD 1.6) with a fractional excretion of uric acid of 5.6% (DS 2.2). Regarding the elementary lesions, the median (p25-75) number of locations with DC sign, tophi or aggregates was 0 (0-1), 1 (0-2) and 1 (1-2), respectively. For grade 2-3 lesions, numbers were 0 (0-0), 1 (0-1) and 1 (0-2), respectively. As shown in **Figure 1**, the proportions of sonographic deposits largely varied according to the different classifications considered to define AH with deposits, ranging from 23.38% up to 87.01%, in a significant manner (p<0.050).

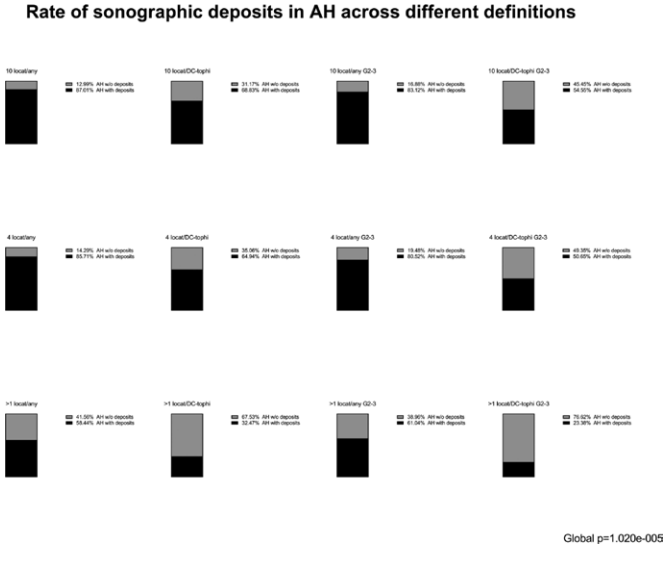

Figure 1. Rate of sonographic deposits in AH across different definitions.

Conclusion: In a multidisciplinary sample of AH, the rates of sonographic deposits dramatically varied across the different classifications used, highlighting the need for an agreed and validated definition that facilitates further research in this setting.

AB1244 CHANGES IN THE GUT MICROBIOTA OF GOUT PATIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Gout

X. Y. Yin[1,2], G. X. Wang[1,2], X. Song[1,2], D. Qiao[1,2], Q. Y. Su[1,2,3], Q. Yu[4], P. F. He[4], X. Li[1,2,3], S. X. Zhang[1,2,3]. [1]*Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; [2]*Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*; [3]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [4]*Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*

Background: Gout is a crystal-related joint disease caused by the deposition of monosodium urate crystals in or around the joints[1][2]. Structural changes or imbalances in the gut microbiota could cause metabolic disorders and participate in the synthesis of purine-metabolizing enzymes and the release of inflammatory cytokines, which is closely related to the occurrence and development of metabolic, immune disease and gout.

Objectives: This study aimed to explore the disorders of intestinal microflora alpha diversity and microbial community composition in patients with gout through meta-analysis.

Methods: According to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA), we comprehensively searched the databases of PubMed, Web of Science, Embase, Cochrane Library, CNKI, VIP, CBM, and Wanfang database without language restrictions. We obtained data related to the alpha diversity index(Shannon index, Simpson index, ACE, Chao1, Observed species) and analyzed phylum and genus composition.

Results: Nine studies, including 423 gout patients and 458 healthy controls(HCs), were included in our analysis. The Simpson index of gout was significantly lower than that of HCs (SMD=-1.037, 95%CI:-1.959~-0.115). There was no significant difference in other alpha diversity indexes between the two groups(Shannon index: SMD=-0.429, 95%CI:-0.900~0.041; ACE: SMD=0.102, 95%CI:-0.918~1.122; Chao1: SMD=0.863, 95%CI:-0.267~1.993; Observed species: SMD= -1.962, 95%CI:-5.011~1.088). We collected the relative abundance of 30 genera of gout and classified them according to the species affiliation. The results showed that the relative abundance of microflora in *proteobacteria* was significantly lower than that of HCs(SMD= -0.498, 95%CI:-0.911~-0.086). However, the relative abundance of microflora in *Fusobacteria*(SMD=0.589, 95%CI:0.249~0.929), *Actinobacteria*(SMD=0.546, 95%CI:0.207~0.885), and *Bacteroides*(SMD=0.395, 95%CI:0.035~0.755) increased in gout patients. We did not observe significant changes in the gut microbes of *Firmicutes*(SMD=-0.210, 95%CI:-0.456~0.036).

Conclusion: This systematic evaluation and meta-analysis showed that the impact of gout microbiota was mainly observed at the level of phylum and genus, but limited to microbial diversity. It is necessary to further study the role and function of specific bacteria and their influence on the physiology and pathology of gout.

AB1245

OSTEOMALACIA RELATED TO BARIATRIC SURGERY: HOW FREQUENT IS IT?

Keywords: Vitamin D, Bone diseases, Descriptive studies

C. A. Chacur[1], A. Mocritcaia[1], H. Florez[1], N. Guañabens[1], A. Monegal[1], P. Peris[1]. [1]*Hospital Clinic, Rheumatology, Barcelona, Spain*

Background: The development of osteoporosis and fractures is a well-documented complication of bariatric surgery (BS), especially with procedures associated with malabsorption. Due to the gradual increase of BS performed worldwide, several national and international societies have developed clinical guidelines for managing these patients, with special attention to osteoporosis prevention and treatment. Nevertheless, these subjects can also develop osteomalacia, which can easily be misdiagnosed as osteoporosis. It is crucial to differentiate osteoporosis and osteomalacia in BS patients since different therapeutic approaches are necessary.
Objectives: To analyse the prevalence of osteomalacia and the main clinical characteristics of subjects with previous BS referred to the Rheumatology Department for osteoporosis treatment.
Methods: This was a retrospective study of a cohort of 46 subjects (aged 42-77 years) referred to the Metabolic Bone Diseases Unit of the Rheumatology Department for evaluating osteoporosis treatment. Clinical data were obtained from an in-depth review of medical records, including the type of BS (restrictive: gastric banding, and sleeve gastrectomy, or malabsorptive surgery: Roux-en-Y gastric bypass [RYGB], biliopancreatic diversion with duodenal switch), time since surgery, previous treatment with calcium and/or vitamin D, anthropometric data, clinical, laboratory, radiologic and densitometric findings. Osteomalacia was diagnosed by compatible bone biopsy and/or by Bingham and Fitzpatrick criteria[1] (two of the following: low calcium, low phosphate, elevated total alkaline phosphatase [TAP] or suggestive radiology).
Results: Five of the 46 patients (10.8%) presented criteria compatible with osteomalacia, two being confirmed by bone biopsy. All subjects with osteomalacia were Caucasian and most were women (4/5) treated with malabsorptive surgery (mainly RYGB) from 4 to 23 years prior to the visit. All presented increased serum TAP values (some presenting a progressive increase 1-3 years prior to the visit). Most subjects showed low serum calcium (4/5) and vitamin D serum levels; the latter were markedly decreased in 4 individuals (with only one presenting values >20 ng/ml). Parathyroid hormone (PTH) levels were increased in all subjects. Bone scan showed a pattern compatible with osteomalacia in all evaluated subjects (4/4) and bone densitometry showed values compatible with densitometric osteoporosis in most (4/5), with four individuals developing fractures/pseudofractures after BS. Three of these subjects were poorly adherent to calcium and vitamin D supplements and in 2 cases higher doses of calcium (3 g/day) and/or parenteral vitamin D administration were necessary to achieve serum vitamin D levels >30 ng/ml and decrease serum PTH levels in the posterior follow-up. Of note, no subject was referred to the Rheumatology Department with clinical suspicion of osteomalacia. Among the remaining 41 subjects, 28 (68%) presented densitometric osteoporosis and 18 (45%) developed fractures (mainly vertebral) after BS; one subject developed primary hyperparathyroidism (treated with surgery). Again, malabsorptive surgery was the most frequent surgical procedure in these subjects.
Conclusion: Nearly 10% of subjects with previous BS referred for osteoporosis treatment may have osteomalacia. Increased serum TAP values should alert clinicians to this diagnosis since it requires a differential treatment approach with some of these patients needing high doses of calcium or even parenteral vitamin D supplementation.

Background: Previous reports suspected that gout patients from Latin-América (LAT) are different to those from developed countries and similar to Asian.
Objectives: We aimed to characterize patients with gout attending to Rheumatologists at Health public institutions and private practices in LAT and its association with socioeconomic status and clinical severity.
Methods: This cross-over, multi-centric, multinational and descriptive study was performed between 2019 and 2022. We invited to participate ≈150 certified rheumatologists from 14 countries in LAT. The project was authorized by IRB. Gout (ACR-EULAR 2015) patients signed informed consent. During face to face and on-line interviews, we discussed clinical variables (≈200), questionnaires and CRFs in Spanish and Portuguese. Demographics, socioeconomic status: (AMAI <111= low socioeconomic status), clinical gout, associated diseases and treatment related variables were included. We defined severe gout (SG) if ≥5 tophi

and/or intradermal tophi. Metabolic syndrome (MS: ≥ 3, ATP3 definitions and criteria). HAQ score, VAS for pain and general health and EuroQoL: EQ5D were obtained during regular visit to Rheumatologist. Data was sent and analyzed at GRESGO (Gout study group) coordination centre). Statistical analysis included mean SD, median, IQR, t test, x2, ANOVA.

Results: Fifty two rheumatologists from 11 countries in LAT sent the data of 500 gout patients. Males (95%), mean (SD): age 57(14), age at onset 41(13), educational level 10(4) and duration of the disease 14 (12) years. The clinical spectrum of gout was evaluated first in 3 groups: 1) **SG** (SG+MS-, n=78, 16%); 2) **MS** (MS+SG1-, n=218, 44%) and 3) **others** (gout: SG- and metabolic data ≤ 2 ATP criteria, n=204, 41%). Second analysis included comparison of extreme groups (SG VS MS) (Table 1).

Conclusion: LAT SG patients were different compared to MS gout ant others. SG are younger males from low educational and socioeconomic status, >familial history of gout. As a consequence, SG patients also had aggressive and active poor controlled disease: >flares, tophi number and size, more hospitalizations and lower quality of life: >HAQ scores and more frequent alterations in the 5 EQ5D domains: (mobility, self-care, daily activities, pain, anxiety and depression) and disability consequences as work impairment. In the other hand, MS group had clearly more data associated to metabolic syndrome and higher cardiovascular risks.

Gout in LAT: SG vs MS comparison of demographics and clinical characteristics.

Background: The formation of the NOD-, LRR-, and pyrin-containing 3 (NLRP3) inflammasome plays a critical role in the initiation of the inflammatory reaction induced by the monosodium urate (MSU) crystals in an acute gout flare. Once assembled, the NLRP3 inflammasome converts pro-interleukin-1β into its active form and initiates IL-1β-dependent inflammation. NLRP3 activation, therefore, occurs upstream of IL-1β, the pivotal cytokine in gouty inflammation and the causative agent mediating symptoms of acute gout flares, including joint pain. Monoclonal antibodies against IL-1β can decrease inflammation and gout flares by neutralizing cicrulating IL-1β and shutting down the IL-1β-mediated inflammatory cascade. However, they must be injected and are associated with immune suppression and increased risk of infection. There remains an unmet need for an orally administered treatment for acute gout flare to safely reduce IL-1β-mediated inflammatory pain without the risk of immunosuppression. In an initial dose-range finding study, PODAGRA I, we reported preliminary evidence of efficacy and safety in this setting with dapansutrile, an orally administered specific inhibitor of the NLRP3 inflammasome.

Objectives: PODAGRA II study is designed to further evaluate the effects of dapansutrile on reducing joint pain and IL-1β-dependent inflammation during acute gout flare.

Methods: The study (NCT05658575/EudraCT 2019-002717-19) is a multicenter, placebo-controlled, prospective, randomized, double-blind trial conducted in the Netherlands, Spain, France, and the USA. A total of 300 patients with acute symptomatic gout flare are being randomized centrally to receive either dapansutrile (2000mg loading dose followed by 1000mg BID) or matching placebo tablets for 7 days (2:1 ratio dapansutrile: placebo). The study is designed to determine the superiority of dapansutrile compared to placebo on the symptoms and signs of an acute gout flare. The primary endpoint is the subject-reported pain intensity score in the target joint (evaluated on a 100-mm visual analogue scale) at 72 hours. Secondary endpoints include patient- and investigator-assessment of response to treatment and the investigator-assessed scores for joint tenderness, swelling, erythema, warmth, and range of motion. A subject-assessed quality-of-life questionnaire will be collected, and biomarkers associated with acute gout inflammation (IL-1 β, IL-6 and CRP) will be evaluated. In order to demonstrate both statistical and clinical significance, approximately 170 and 85 evaluable subjects are needed in the dapansutrile and placebo arms, respectively. This assumes a one-sided significance level of $\alpha = 0.025$, 85% power (1-β), a standard deviation of 25 points, an expected mean difference (Δ=10 points) plus an additional clinical significance of (δ=10 points). To account for dropouts and non-evaluable subjects, up to 200 subjects in the dapansutrile arm, and up to 100 in the placebo arm will be randomized.

	Group Size		
Power (%)	**Dapansutrile**	**Placebo**	**Study Size**
80	150	75	225
85	**170**	**85**	**255**
90	200	100	300
	Group Size		
Std deviation at 85% power	**Dapansutrile**	**Placebo**	**Study Size**
20	110	55	165
25	**170**	**85**	**255**
30	244	122	366

Results: The trial has launched and is currently enrolling subjects.

Conclusion: There is a need for an orally administered, safe, and well-tolerated treatment for acute gout flares. PODAGRA II will be the first placebo-controlled, adequately powered, large, multi-center study with an oral NLRP3-specific inhibitor. As gout is a prototypical disease of NLRP3 activation, this trial will provide important new data on NLRP3 inhibition leading to a reduction in joint pain and associated inflammatory biomarkers in acute gout flare.

AB1248 LESSONS TO BE LEARNED FROM REAL LIFE DATA FROM 98 GOUT PATIENTS USING A URICOSURIC: BENZBROMARONE

Keywords: Crystal arthritis, Treat to target

I. Hotea[1], M. Janssen[2], T. Jansen[2]. [1]*University of Medicine and Pharmacy Iuliu Hatieganu, Rheumatology, Cluj-Napoca, Romania*; [2]*VieCuri Medical Centre, Rheumatology, Venlo, Netherlands*

Background: Decreased renal urate excretion is the predominant driver of attracting gout, an auto-inflammatory disease secondary to hyperuricemia. Therefore there is an interest in effective urate lowering therapies with a uricosuric mode of action.
Objectives: The objective of this study was to analyses the efficacy and safety of uricosuric treatment i.e., benzbromarone in a real-life clinical setting.
Methods: data from gout patients was collected retrospectively from the digital hospital dossiers. Inclusion criterium was a diagnosis of gout (ICD10 code M10). Demographics, clinical variables and laboratory parameters at baseline and 6 months were collected. Efficacy was measured from reaching a serum urate target at 6 months, and/or increase in Fractional Urate Exctretion (FeUA).
Results: We analyzed data from 98 gout patients with an indication of benzbromarone treatment. Patients were 70 (±12) years of age, and 90% was male. After 6 months of treatment 90 out of 98 patients (91%) reached a sUA level <0.36 mmol/l (6mg/dL); We found that efficacy appeared to be best in low excretor type gout defined as FeUA<4.5%, as their FeUA increased from the initial mean value FeUA 3.2% (SD±1.0%) to reach in 6 months with benzbromarone mean FeUA of 12.1% (SD±6.9%). A considerable percentage (38%) is using benzbromarone on average for 3.8 (SD 3.4) years. 4 patients stopped benzbromarone treatment due to decrease renal function, condition that was already present prior to uricosuric initiation.
Conclusion: Using available benzbromarone in a real-life context proved to be efficient in lowering sUA levels in 6 months. Renal function must be considered before indicating benzbromarone. Determining FeUA in gout patients can further help better characterize the patient profile from whom is this the best treatment option.

[1]*University Hospital of Benimessous, Rheumatology, Benimessous, Algeria*

Background: Asymptomatic hyperuricemia is often considered as a biological anomaly, when the appearance of the gouty disease rather represents the evolution towards an inflammatory disease. In this case, the inflammation is usually due to a response to crystal deposits in the tissues, associated with cartilage damage, as seen in osteoarthritis. Although we know that neglected gout can lead to osteoarthritis, we still don't know if there is a link between hyperuricemia and osteoarthritis.
Objectives: The aim of this study is to assess the link between asymptomatic hyperuricemia (AH) and hand osteoarthritis (HO).
Methods: It's a cross-sectional study included 46 patients (28 in the HO group and 18 in a group without HO) with mean age of 67.23 ± 4.67 years, 32 women for 14 men. We collected demographic, clinical, biological (uricemia) and radiographic data. The association between AH and digital osteoarthritis was assessed by logistic regression.
Results: The mean serum uric acid level in patients with osteoarthritis was higher than that of patients without osteoarthritis (6.71 ± 1.13 mg/dl versus 6.26 ± 1.26 mg/dl, p=0.021). Hyperuricemia was more common in older patients with osteoarthritis than in those without osteoarthritis (45% vs. 23%, p=0.001). After adjusting for age, gender, body mass index and other variables, the association between asymptomatic hyperuricemia and osteoarthritis remained significant with an odds ratio [OR] of 2.28, for a 95% confidence interval [CI] (1.18-4.80), p=0.023. Subgroup analyzes were performed by sex where significant associations between asymptomatic hyperuricemia and osteoarthritis were obtained in women (p=0.027).
Conclusion: AH is a common comorbidity in elderly patients with hand osteoarthritis. A significant link has been found between AH and hand osteoarthritis in elderly subjects, especially females.

AB1250 OUTPATIENT FOLLOW-UP AFTER AN EMERGENCY DEPARTMENT VISIT FOR ACUTE GOUT FLARE

Keywords: Health services research, Gout, Crystal arthritis

L. Jackson[1], F. Mugeta[1], E. Mcneeley[1], N. C. Techarukpong[1], K. Aaron[1], J. Booth[2], J. Foster[1], G. Cutter[3], J. Osborne[4], K. Saag[1], M. Danila[1,5].
[1]*University of Alabama at Birmingham, Medicine, Birmingham, United States of America*; [2]*University of Alabama at Birmingham, Emergency Medicine, Birmingham, United States of America*; [3]*University of Alabama at Birmingham, Biostatistics, School of Public Health, Birmingham, United States of America*; [4]*University of Alabama at Birmingham, Computer Science, Birmingham, United States of America*; [5]*Birmingham VA Health Care System, Geriatric Research, Education, and Clinical Center, Birmingham, United States of America*

Background: Patients with acute gout are frequently treated in the emergency department (ED). Appropriate outpatient follow-up for an acute flare after an ED visit is variable and has not been systematically examined.
Objectives: We aimed to determine the characteristics of patients with gout treated in EDs, the nature of their ED visits, and to determine the types and rates of outpatient follow-up after an ED visit for an acute gout flare.
Methods: This study was conducted at one academic medical center that serves patients at 3 EDs (2 urban, 1 suburban) and 1 urban urgent care center. Patients were identified as having a possible acute gout flare upon initial triage in the ED using a previously developed electronic medical record (EMR) gout flare alert. We validated the presence/ absence of an acute gout flare through manual EMR review using adjudicated expert consensus assessed with kappa coefficient as the gold standard. Among those patients identified with an acute gout flare, we abstracted their medical records to determine the presence/ absence of an outpatient visit for gout care within 6 months of the index ED visit. This was defined as having had a documented outpatient visit with any provider (e.g., primary care, rheumatology) with a mention of 'gout' in the free text portion of history of present illness or assessment and plan. We used descriptive statistics to characterize patients with gout and reported the proportion of patients with an acute gout flare that followed up in the outpatient setting after an ED visit.
Results: From September 1, 2021 to February 28, 2022, there were 458 patients identified by the gout flare alert as possibly having an acute gout flare. Of these, 33 patients were excluded from this analysis due to participation in an ongoing randomized clinical trial testing a behavioral intervention to improve gout care. The remaining 425 patients included 72 patients (16.9%) who were determined to have a true gout flare at 85 unique ED visits by manual EMR review by 2 assessors. The kappa coefficient for agreement between the consensus expert determinations of acute gout flare was 0.8. Of those with an acute gout flare, 53 (74%) were men and 49 (68%) were Black or African American. At ED discharge, a majority of patients (64%) were prescribed corticosteroids, while 63% were prescribed opioids. A majority (54%) of ED visits for acute gout occurred between 8am and 5pm, with another 27% occurring between 5pm and midnight. The proportion of patients with an acute gout flare who followed up with an outpatient clinician in our healthcare system was 46% (**Table 1**), with 29% of patients having an outpatient visit within 30 days of the index ED encounter. Only 26 patients (36%) had an outpatient visit addressing gout, and of these, 17 (24%) occurred within 3 months of the index ED visit.
Conclusion: More than half of patients received opioids at discharge among patients with gout treated in the ED, who were mostly Black. Follow-up was ~46% among patients that received gout care in an acute setting, yet only a third saw a clinician who addressed gout. This data will inform sample size calculation for interventional studies testing behavioral interventions focused on promoting improved outpatient follow-up for gout flares.

Table 1. Healthcare utilization among participants following an emergency department visit for acute gout.

Healthcare Outcome	Total, N=72

AB1251 SERUM URIC ACID LEVEL IN INTRACEREBRAL HEMORRHAGE PATIENTS

Keywords: Crystal arthritis, Gout, Cardiovascular disease

D. H. Lim[1]. [1]*Ulsan University Hospital, University of Ulsan College of Medicine, Division of Rheumatology, Department of Internal Medicine, Ulsan, Korea, Rep. of (South Korea)*

Background: Intracerebral hemorrhage (ICH) is a life-threatening type of stroke caused by a rupture of a blood vessel into the brain's parenchyma, accounting for 10~15% of all stroke. Uric acid (UA) is the end product of purine metabolism; it is catalyzed by xanthine oxidase. UA may be related to cerebrovascular diseases through its role as either an antioxidant or pro-oxidant properties. Although the association of serum UA level with ICH has been investigated in previous studies, the results are controversial.
Objectives: In this study, we determined serum UA levels in patients with ICH and assessed its relationship with cerebrovascular risk factors.
Methods: We evaluated 721 patients with ICH who were admitted ton emergent department in tertiary hospital from July 2008 to December 2017 in South Korea. Demographics, laboratory data, neurological course, and brain magnetic resonance imaging (MRI) findings were collected using electrical medical records and picture archiving and communication systems. The participants were stratified into quartiles according to their serum UA levels. Between-group comparisons were performed using Pearson's chi-square test for categorical variables, and the ANOVA for numerical variables, as appropriate.
Results: Among 721 patients with ICH acute stroke. 413 (57.3%) were male. The mean age of patients was 58.9±14.03 and mean value of body mass index was 23.9±6.84 kg/m^2. Mean serum UA levels in the patients studied 5.94±1.70 mg/dl and there was a significant negative correlation between age of patients and their serum UA level ($p < 0.001$, $R = -0.212$). Serum UA level was significantly higher in men (5.82 ± 1.87 mg/dl) than women (4.43 ± 1.33 mg/dl) ($p = 0.03$). Concomitant intraventricular hemorrhage consistently decreased continuously across quartiles of serum UA. However, ICH recurrence and mortality rate did not differ according to serum UA level.
Conclusion: The results suggest that serum UA may be the predictor of intraventricular hemorrhage in ICH patients.

AB1252 BONE CHANGES EVALUATION DURING PREGNANCY BY MEANS OF RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) TECHNOLOGY

Keywords: Ultrasound, Pregnancy and reproduction, Bone diseases

V. A. Degennaro[1], G. Cagninelli[1], S. Casciaro[2], F. Conversano[2], E. Di Pasquo[1], F. A. Lombardi[2], P. Pisani[2], T. Ghi[1]. [1]*University of Parma, Parma, Italy, Department of Medicine and Surgery, Obstetrics and Gynecology Unit, Parma, Italy*; [2]*National Research Council, Lecce, Italy, Institute of Clinical Physiology, Lecce, Italy*

Background: Degennaro, Cagninelli*, Casciaro*, Conversano*, Di Pasquo*, Lombardi*, Pisani*, Ghi.
***Equal contributors in alphabetical order.**
Typically, pregnancy and lactation greatly expose women to develop osteoporosis due to the high demand of calcium from the foetus or neonate. In some cases, especially in the first pregnancies or in the early breastfeeding period, women with persistent lower back pain, are suspected to be at risk for fragility fractures, mostly involving vertebral fractures[1]. Therefore, there is an urgent need to perform an accurate monitoring of the maternal bone health status in order to prevent complications of pregnancy and lactation-associated osteoporosis.
Objectives: Through a longitudinal study, the present work aims to determine the changes of bone status in pregnant women from the first to the third trimester of gestation by means of the non-ionizing Radiofrequency Echographic Multi Spectrometry (REMS) technology.
Methods: A cohort of 43 pregnant women were enrolled in the study. Longitudinal measurement of bone mineral density (BMD) was carried out at the femur during the first (baseline) and third (follow-up) trimesters of pregnancy using the REMS technology. A paired t-test was performed to assess the difference in femoral neck BMD between baseline and follow-up.
Results: Compared to the baseline (first trimester), a significant femoral neck BMD reduction was observed at the follow-up of the third trimester, (0.762 ± 0.075 g/ cm^2 *versus* 0.711 ± 0.074 g/ cm^2, respectively with $p<0.0001$). As a result, an overall BMD decrease of 2.07% has be measured.
Conclusion: As previously demonstrated with this technology, pregnant women have a significant decline of BMD compared with the non-pregnant counterpart[2]. With this study, for the first time, bone changes throughout pregnancy could be determined by means of this technology: a marked bone reduction was demonstrated in the pregnant group during the last trimester of pregnancy. In conclusion, REMS represents an appropriate method for BMD assessment which can be safely employed to monitor the bone status across gestation and lactation.

AB1253 FEBUXOSTAT DOSE ADJUSTMENT ACCORDING TO RENAL FUNCTION TO ATTAIN TARGET SERUM URATE LEVEL: A RETROSPECTIVE COHORT STUDY

Keywords: Gout

Y. E. Kim[1], S. M. Ahn[1], J. S. Oh[1], Y. G. Kim[1], C. K. Lee[1], B. Yoo[1], S. Hong[1]. [1]*University of Ulsan College of Medicine, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Current guideline for gout recommends the use of allopurinol or febuxostat in moderate-to-severe chronic kidney disease (CKD). However, the appropriate febuxostat dosage required to attain the target serum urate (SU) level remains unclear, especially in patients with renal impairment.
Objectives: We aim to investigate the different febuxostat dosages stratified by renal function to achieve the target SU level.
Methods: We collected the clinical and laboratory information of patients using the Clinical Research Data Warehouse system of Asan Medical Center, Seoul, South Korea. Of the 3153 patients with gout and a prescription for febuxostat at a tertiary-care referral center, 731 with initial SU levels >6 mg/dL were collected and categorized, according to their eGFR levels at febuxostat therapy initiation, into three groups based on CKD stage: 1, 2–3, and 4–5. We defined the cumulative febuxostat as the total dose of febuxostat used from the initiation of febuxostat to the moment patient reached the SU target (SU<6 mg/dL).
Results: This cohort of 731 gout patients, with a median age of 52 (IQR, 41-63) years, included 64 (8.8%) women. Compared with the other groups, in the CKD 4–5 group, the mean SU value at febuxostat initiation was significantly higher (9.6 [SD, 3.1] mg/dL; CKD 2–3, 8.6 [SD, 1.6] mg/dL; CKD 1, 8.8 [SD, 1.8] mg/dL; $p<0.001$) and significantly fewer patients achieved the SU target during the follow-up period, median 31 (IQR, 13-55) months. In the subgroup analysis of patients who achieved target SU levels, the cumulative dose of febuxostat was significantly lower in CKD 4-5 patients compared to those with other groups (CKD 4–5, 5.9 (IQR, 2.5–12.0) g; CKD 2–3, 7.1 (IQR, 3.5–15.7) g; CKD 1, 7.0 (IQR, 2.7–20.1) g; p=0.010 for CKD 4–5 and CKD 1, p=0.006 for CKD 4–5 and CKD 2–3). The average febuxostat dose used during 4 months to reach the SU target was 50.0 (IQR, 21.0–101.0) mg in the CKD 4-5 group, which was significantly lower than in other groups (CKD 2–3, 59.3 (IQR, 29.4–130.7) mg; CKD 1, 58.5 (IQR, 22.7–167.8) mg; p=0.006 for CKD 4–5 and CKD 1, p=0.003 for CKD 4–5 and CKD 2–3). In addition, when we examined the clinical factors associated with the required dose of febuxostat to achieve SU target, CKD 4-5 group showed a significant negative correlation with cumulative febuxostat dosage to reach target SU compared with CKD 1 (rho -2.334, p=0.02).

Conclusion: The febuxostat dose required to reach the target SU level was significantly lower in patients with markedly decreased renal function (CKD stage 4–5).

AB1254 ECTOPIC ARTICULAR CALCIFICATIONS AND ARTERIAL OCCLUSIVE DISEASE DUE TO 5-NUCLEOTIDASE DEFICIENCY

Keywords: Inflammatory arthritides, Rare/orphan diseases, Crystal arthritis

M. Maffi[1], G. De Mattia2, M. Mosca2, M. Mazzantini2. *[1]University of Pisa, Rheumatology, Pisa, Italy*; *[1]University of Pisa, Rheumatology, Pisa, Italy*

Background: Calcification of Joints and Arteries (CALJA) is a rare disease presenting with recurrent/chronic arthritis and *claudicatio intermittens* of the lower limbs. Since the discovery of specific mutations of the *5'-nucleotidase* (*NT5E*) gene responsible for the disease, only few cases have been reported.
Objectives: To collect available information about CALJA to better characterize the disease and to raise awareness of this often unrecognized rheumatologic condition.
Methods: All available publications regarding CALJA since its first description in 2011 were included and a case report is described.
Results: A 65-year-old woman, affected by seronegative oligoarthritis since 2007, reported lower limb claudication. In 2021 past medical history consisted of migratory, non-erosive arthritis with asymmetrical involvement of peripheral joints since the age of 30, poorly responsive to glucocorticoids and immunosuppressive therapy. She had never presented any clinical sign of connective tissue disease or microcrystalline arthritis, as shown in X-rays performed in 2007/2010. In November 2021, because of the worsening of the claudication, an arterial color Doppler ultrasound of the lower limbs was performed, which revealed bilateral obliteration of superficial femoral artery, of posterior and anterior tibial arteries, and of lateral plantar arteries. X-rays showed extensive calcifications of the femoral and popliteal arteries as well as widespread articular and periarticular calcific deposits, with the appearance of hydroxyapatite deposits. Laboratory findings included inflammatory markers elevation, whereas calcium-phosphorus metabolism, lipid and glucose profile, blood count, and renal/hepatic function were normal. She had never smoked and had no significant cardiovascular risk factors. Based on the knowledge of a very rare genetic condition called **CAL**cification of **J**oints and **A**rteries (*CALJA,* MIM 211800), *ecto-5'-nucleotidase (NT5E)* gene analysis was performed, which resulted positive for the homozygous inactivating variant NM_002526.3:c.751(1G>A). NT5E activity leads to adenosine production, which in turn inhibits Tissue Non-specific Alkaline Phosphatase (TNAP) synthesis. TNAP degrades PPi into inorganic phosphate, an activator of calcification; therefore, inactivation of NT5E leads to vascular (lower limbs) and periarticular calcification in CALJA patients, with the clinical features of progressive arterial disease and microcrystalline arthritis. To date, 23 patients with CALJA had been reported (*Table 1*). Seventeen patients are female (74%), mean age at diagnosis is 59-year-old and the most common symptoms are intermittent claudication (87%) and joint pain due to periarticular calcification (70%); upper extremities arterial calcifications (9%) and calcific aortic valve stenosis (17%) are less commonly described.
Conclusion: To our knowledge, this patient is the first case of CALJA with variant NM_002526.3:c.751(1G>A) of *NT5E*. Patients presenting with CALJA are often treated with immunosuppressive agents in the suspicion of inflammatory rheumatologic diseases. Thus, it is important for the Rheumatologist to recognize the features of this disease and to keep it in mind in the differential diagnosis of patients suffering from arthritis and/or early osteoarthritis along with lower limb arterial insufficiency.

Table 1. Demographics and clinical characteristics of described patients with CALJA. AVS: aortic valve stenosis, AC: articular calcifications, IC: claudicatio intermittens, UEAC: upper extremities arteries calcifications, RP: Raynaud Phenomenon.

AB1255 PEGLOTICASE + METHOTREXATE COTHERAPY IN UNCONTROLLED GOUT PATIENTS WITH PRIOR PEGLOTICASE MONOTHERAPY FAILURE: FINDINGS OF THE ADVANCE OPEN-LABEL TRIAL

Keywords: Gout, Clinical trials

O. Troum[1,2], J. Botson[3], K. Obermeyer[4], S. Verma[4], B. Lamoreaux[5]. *[1]University of Southern California Keck School of Medicine, Division of Rheumatology, Santa Monica, United States of America*; *[2]Providence Saint John's Health Center, Rheumatology, Santa Monica, United States of America*; *[3]Orthopedic Physicians Alaska, Rheumatology, Anchorage, United States of America*; *[4]Horizon Therapeutics plc, Research and Development, Deerfield, United States of America*; *[5]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: Pegloticase is often the last treatment option for patients (pts) with uncontrolled/refractory gout but anti-drug antibodies (ADAs) cause loss of serum urate [SU] lowering response and infusion reactions (IRs).[1] MIRROR RCT showed higher response rate (71% vs 39% during month 6) and lower IR risk (4% vs 31%) with methotrexate (MTX) cotherapy, which attenuated ADAs in pegloticase-naïve pts.[2] Therefore, retreating pts who previously developed ADAs with pegloticase monotherapy is clinically relevant. The ADVANCE trial examined pegloticase+MTX cotherapy safety and efficacy in pts with prior monotherapy failure.
Objectives: To report interim efficacy and safety findings of the ADVANCE open-label trial.
Methods: Pts with uncontrolled gout (SU ≥6 mg/dL, ULT failure/intolerance, and ≥1 symptom [≥1 tophus, ≥2 flares in past yr, or chronic gouty arthritis) who did not maintain SU-lowering during prior pegloticase monotherapy were included. Key exclusion criteria were prior moderate/severe IR or anaphylaxis to pegloticase, MTX contraindication, current immunosuppressant use, G6PD deficiency, and eGFR<30 mL/min/1.73 m^2. After a 6 wk MTX Run-in (subQ MTX titrated to 25 mg/wk [15 mg/wk if eGFR <45]), pts began pegloticase (8 mg biweekly) + MTX Treatment for 24 wks (option to extend to 48 wks). Pts took 1 mg/d folic acid, gout flare prophylaxis, and pre-infusion IR prophylaxis (included 125 mg IV methylprednisolone). The primary endpoint was proportion with SU-lowering response during Month 6 (SU <6 mg/dL for ≥80% of Wks 20-24). Other key endpoints were response rate during Month 3 (SU <6 mg/dL for ≥80% of Wks 10-14) and IR rate. Safety was evaluated via AEs and laboratory monitoring.
Results: 13 pts began the MTX Run-in; 11 met study criteria and entered pegloticase+MTX Treatment (intent-to-treat population; 91% male, mean [±SD] age: 58.6±11.3 yrs, BMI: 31.8±5.4 kg/m^2, eGFR: 70.2±15.8 [all ≥45]). SU before pegloticase exposure (Day 1) was 8.5±3.2 mg/dL and gout burden was high (gout history: 25.2±8.4 yrs, 91% had tophi, 4.5±3.8 flares in prior 6 months). Prior pegloticase

course range was 2-27 infusions, with last infusion 3.7±2.4 yrs prior (range: 0.7—9.2 yrs). One pt (9%) was a responder during Month 3 and during Month 6 (ongoing treatment through Wk 30 at analysis). 8 pts (73%) met SU-discontinuation criteria (first SU >6mg/dL: 20.8±18.3 days after infusion 1), and 2 (18%) had moderate IRs. 7/13 pts (54%) had ≥1 AE during Run-in (1 SAE); 8/11 (73%) had ≥1 AE during Treatment (0 SAE, all Rheum CTC[3] grade 1 or 2), most commonly gout flare (**Table 1**).

Table 1. Key findings of pegloticase+MTX treatment in pts with prior loss of urate-lowering efficacy during pegloticase monotherapy. AEs reported in >1 pt are listed, along with all SAEs and AEs of special interest.

	MTX Run-in (N=13)	Pegloticase+MTX Treatment (N=11)
Efficacy endpoints		
SU response during Month 6, n (%)	---	1 (9%)
SU response during Month 3, n (%)	---	1 (9%)
Treatment-emergent AEs		
≥1 AE, n (%)	7 (54%)	8 (73%)
Gout flare	6 (46%)	7 (64%)
Arthralgia	1 (8%)	2 (18%)
Infusion reaction*†	0	2 (18%)
Pain in extremity	0	2 (18%)
Fatigue	2 (15%)	0
Anaphylaxis*	0	0
Cardiovascular event*‡	0	0
Serious AEs		
≥1 serious AE, n (%)	1 (8%)	0
Perineal abscess§	1 (8%)	0

*AE of special interest. †throat tightness, erythema, itching, urticaria in 1 pt; back pain in 1 pt. ‡included non-fatal stroke, non-fatal MI, cardiovascular death, CHF. §2 days before first pegloticase infusion, deemed unrelated to MTX.

Conclusion: Treatment response rate with pegloticase+MTX following failed monotherapy was 9%, markedly lower than in pegloticase-naïve pts (71%).[2] IR rate was 18%, higher than in pegloticase-naïve pts (4%),[2] but all were moderate (no anaphylaxis). These findings demonstrate the challenge of overcoming established ADAs against pegloticase and emphasize the importance of initiating immunomodulation before pegloticase therapy.

AB1256 WORTH'S DISEASE (LRP5 HIGH-BONE-MASS): CASE REPORT AND REVIEW OF THE LITERATURE

Keywords: Rare/orphan diseases, Genetics/Epigenetics, Bone diseases

G. De Mattia[1], M. Maffi[1], M. Mosca[1], M. Mazzantini[1]. [1]*University of Pisa, Rheumatology Department, Pisa, Italy*

Background: Worth's disease is a rare autosomal dominant sclerosing bone dysplasia determining high bone mass. It is caused by mutations of the *low-density lipoprotein receptor-related protein 5 (LRP5)* gene. Clinical findings include torus palatinus and craniofacial changes, such as increased gonial angle [1]. The absence of neurological involvement has long been considered a key aspect to discriminate between Worth's disease and Van Buchem's disease, in which cranial nerve deficits and intracranial hypertension are frequent [2]. Alternative names have been employed to describe Worth's disease, such as "autosomal dominant osteosclerosis", "Van Buchem's disease, type 2", and "LRP5 high-bone-mass (HBM)". The rarity of the disorder, the use of several denominations and the lack of reviews have rendered research of information on Worth's disease complicated and confusing.

Objectives: To gather all case reports of Worth's disease and provide comprehensive data on the condition, and to describe a patient with neurological involvement.

Methods: After collecting all case reports, we assessed the prevalence of neurological involvement and other relevant clinical and laboratory findings. A thorough clinical, radiological, and genetic assessment was performed on an affected patient.

Results: A 44-year-old Caucasian woman was referred to us in 2009 for chronic and debilitating dorsolumbar pain (Visual Analogue Scale 8/10). Since her twenties, she has been affected by chronic and disabling low back pain, frontoparietal headache, hypo-/anosmia, and numbness and tingling of arms, face, and oral cavity. She noticed the early appearance of facial changes that became more evident with time. In 1999, external hearing aids were placed due to complete mixed hearing loss caused by the narrowing of internal and external acoustic meati. At presentation, clinical examination revealed prominent jaw, frontal bossing, and torus palatinus. She denied previous bone fractures. Family history was unremarkable. A complete skeletal survey revealed endosteal hyperostosis of the limbs and severe osteosclerosis of clavicles, ribs, vertebrae, hip, and cranium, in the absence of deformities except for a deepened and widened jaw. Bone scintigraphy with technetium-99m was normal. Dual-energy X-ray absorptiometry (*DEXA*) scan revealed T-score +10.8 (Z-score +11.1) and bone mineral density (BMD) of 2.5 g/cm^2 for L1-L4 spine, T-score +6.5 (Z-score +6.2) and BMD of 1.8 g/cm^2 for femoral neck, and T-score +8.5 (Z-score +8.1) and BMD of 2 g/cm^2 for total hip. Markers of bone turnover and calcium metabolism were normal. The ophthalmologic evaluation revealed bilateral papilledema. Head MRI showed mild cerebellar tonsillar herniation through the foramen magnum. Neither pyramidal tract signs nor cerebellar disturbances were present. Genetic analysis detected the A242T mutation in exon 4 of the *LRP5* gene. To date, 169 patients with Worth's disease have been reported since its first description in 1966, including the present case (Table 1). Neurological involvement and increased serum alkaline phosphatase were present in 33 (19.5%) and 14 (8.2%) cases, respectively. Facial changes and torus palatinus were observed in 96 (56.8%) and 63 (37.4%) cases, respectively.

Table 1. Cases of Worth's disease grouped by decade.

Decade	Number of case reports	Cumulative number of cases	High serum alkaline phosphatase	Facial changes	Torus palatinus	Neurological involvement
1960s	2	15	0	9	3	0
1970s	8	42	2	29	20	7
1980s	4	19	1	2	1	4
1990s	4	19	1	7	5	4
2000s	9	48	8	33	20	8
2010s	6	25	2	15	13	9
2020s	Present case	1	0	1	1	1
Total	34	169	14	96	63	33

Conclusion: For the first time, we collected all known case reports of Worth's disease. Neurological involvement is present in one-fifth of the patients, and facial changes are not a consistent finding. Thus, Worth's disease may be asymptomatic and is often incidentally detected in routine radiographs showing generalized osteosclerosis. Our case is the first report of hypo-/anosmia in Worth's disease.

AB1257 EVALUATION OF ADHERENCE TO AND AGREEMENT WITH THE 2020 AMERICAN COLLEGE OF RHEUMATOLOGY GUIDELINE FOR THE MANAGEMENT OF GOUT BY US RHEUMATOLOGISTS

Keywords: Inflammatory arthritides, Gout, Crystal arthritis

N. Schlesinger[1], M. Pillinger[2], P. Lipsky[3]. [1]*Spencer Fox Eccles School of Medicine, University of Utah, Division of Rheumatology, Salt Lake City, United States of America*; [2]*NYU Grossman School of Medicine, Division of Rheumatology, New York, United States of America*; [3]*RILITE Research Institute and AMPEL BioSolutions, LLC, Rheumatology, Charlottesville, United States of America*

Background: In 2020, the American College of Rheumatology (ACR) presented an updated gout treatment guideline.[1]

Objectives: In this report, we evaluated US rheumatologists' stated adherence to and agreement with the 2020 ACR Guideline for the Management of Gout.

Methods: A 57-item questionnaire was administered to US rheumatologists, surveying their adherence to and agreement with the 2020 ACR Guideline for the Management of Gout. Stated adherence scores were based on the number of Guideline recommendations reported to be followed by rheumatologists in practice, whereas stated agreement scores were based on degree of agreement with the recommendations.

Results: All 201 rheumatologists approached completed the questionnaire. Mean age of participants was 50 years, 54% had >15 years of practice experience, and ~70% were in private practice (**Table 1**). Mean overall stated adherence score was 11.5, with a possible maximum of 15, whereas the mean overall stated agreement score was 7.7, with a possible maximum of 14. Rheumatologists with less experience (≤8years; n=49) were likely to claim adherence with more individual ACR recommendations than those with more experience (>8years; n=152) (mean stated adherence score: 12.3 vs 11.3; p<0.05), whereas those who claimed to see

≤75 patients with gout in 6 months (n=66) had a mean stated adherence score of 12.1 vs 11.2 for rheumatologists who claimed to have seen >75 patients ($p<0.05$). Approximately 78% of rheumatologists claimed to follow the guideline for initiating urate lowering therapy (ULT) and 89% were likely to prescribe allopurinol as a first line ULT for all patient types (**Figure 1**). Claimed adherence to recommendations for dosing was lower (43% and 39%, for febuxostat and allopurinol, respectively). Approximately, 92% of the rheumatologists claimed adherence on first-line therapy for gout flares (**Figure 1**). Rheumatologists from academic settings were more likely to prescribe an interleukin-1 inhibitor for gout flares than those in other settings.

Conclusion: The self-reported practice of the surveyed US rheumatologists was generally concordant with the 2020 ACR Guideline for the Management of Gout. However, there were gaps in guideline knowledge and stated adherence among rheumatologists, mainly concerning the dosing of treatment regimens.

AB1258 CAMURATI-ENGELMANN DISEASE: EFFICACY OF ANTI-TNFALFA TREATMENT

Keywords: Rare/orphan diseases, Bone diseases, bDMARD

M. Maffi[1], G. De Mattia[1], M. Mosca[1], M. Mazzantini[1]. [1]*University of Pisa, Rheumatology, Pisa, Italy*

Background: Camurati-Engelmann disease (CED) is a rare osteosclerotic autosomal dominant condition responsible for chronic diaphyseal pain. It is caused by mutations of *Tumor Growth Factor β1 (TGFβ1)* gene. Currently there are no validated therapies for this condition.

Objectives: To test the efficacy of anti-TNFα antibody in a patient affected by CED.

Methods: Etanercept 50 mg per week was administered in a patient with CED. Data regarding pain and assumption of glucocorticoids and non-steroidal anti-inflammatory drugs were collected. Technetium-99m bone scintigraphy was performed at baseline, and after six months of treatment.

Results: A 34-year-old woman came to our attention in 2011 due to chronic pain of lower and upper limbs, especially localized at the diaphyses of long bones. The symptoms began in adolescence, but independently resolved during pregnancy. Two sisters and her 16-year-old son presented with a similar clinical picture. She had no clinical features or laboratory findings compatible with a systemic autoimmune disease. In the same year, along with relevant imaging exams, a genetic evaluation of all family members was performed, with the aim to find a hereditary disease. Compatibly with CED, the mutation *c.505G>A* of exon 2 of TGF*β1* gene was confirmed. Treatment with daily glucocorticoids, losartan and zoledronic acid 5 mg per year was administered, with little benefit for the patient. During an evaluation in 2022 she complained severe pain (visual analogue scale 8/10) unresponsive to 6-methylprednisolone 8 mg and indomethacin 100 mg daily. Technetium-99m bone scintigraphy showed abnormal accumulation in the skull, humeral and femoral diaphysis (Figure 1). Based on a single case report in on a patient with CED and Chron's disease successfully treated with success with an anti-TNFα drug, we decided to administer etanercept 50 mg per week. After 3 months we observed a clear subjective and objective improvement in pain (VAS 4/10) and a reduction in the assumption of indomethacin (150 mg weekly) and 6-methyl prednisolone (4 mg daily). However, technetium-99m bone scintigraphy carried out six months later did not reveal document a reduction in uptake of the tracer.

Conclusion: A patient with CED experienced a significative improvement in symptoms after treatment with anti-TNFα antibody. Our experience opens a window on a possibly new therapeutic option which could be implemented in the treatment of CED unresponsive to traditional drugs.

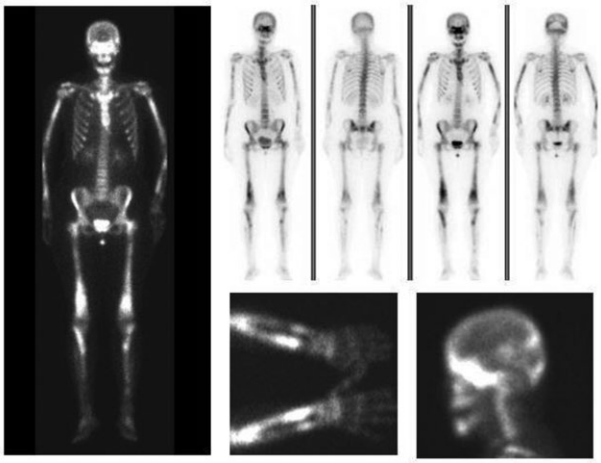

Figure 1. Technetium-99m bone scintigraphy with abnormal tracer accumulation in skull and long bones diaphyses.

AB1259 SERUM IRON LEVELS WERE POSITIVELY ASSOCIATED WITH THE RISK OF HYPERURICEMIA: NHANES 1999-2014

Keywords: Gout, Gender/diversity issues

S. X. Hu[1], H. Lin[1], N. Chen[1], Q. H. Li[2]. [1]*Sun Yat-Sen University, Zhongshan School of Medicine, Guangzhou, China*; [2]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Gunagzhou, China*

Background: Increasing evidence proofs that serum ferritin plays an important role in the development of hyperuricemia (HUA), however, few studies focus on the relationship between serum iron and serum urate (sUA).
Objectives: To examine the relationship between serum iron and serum urate as well as the risk of HUA classified by gender in the US adult population.
Methods: The present cross-sectional study pooled data from 1999 to 2014 National Health and Nutrition Examination Survey (NHANES). The association between serum iron quartiles and hyperuricemia was evaluated by logistic regression. The restricted cubic spline regression was performed to analyze the association between continuous serum iron and sUA.
Results: The study enrolled 25757 participants in total from 1999-2014 annual NHANES cycles. The crude prevalence of hyperuricemia was 11.9%. Serum iron was significantly higher in those with HUA than in those without HUA (16.6μg/dl vs 15.6μg/dl, p<0.0001). Logistic regression showed that serum iron levels were positively associated with the risk of HUA in the whole participants and male participants after adjusting for age, BMI and eGFR (Table 1). A dose-response association was observed in the whole participants (P for trend < 0.05). The restricted cubic spline regression analysis showed that the association between continuous serum iron and sUA was different in male participants and female participants (Figure 1). The curve of male participants showed an increasing trend (folding point 13.3μg/dl, P=0.033), while for women, sUA first increased linearly, but after the folding point (6.6μg/dl, P<0.001) the curve flattened out and the increasing trend was not significant.
Conclusion: Serum iron levels were positively associated with the risk of HUA in men. The correlation between serum iron and serum uric acid was influenced by gender. More studies are needed to confirm this relationship and to find out the mechanisms behind as well as the reasons for the gender differences.

AB1260 EPIDEMIOLOGICAL, CLINICAL AND CHRONOLOGICAL PROFILE OF HOSPITALIZATIONS FOR CRYSTALLINE ARTHROPATHIES IN SOUTHERN TUNISIA: A DECLINE OF 14 YEARS

Keywords: Gout, Nursing, Crystal arthritis

M. Baklouti[1], Y. Mejdoub[1], A. Feki[1,1], H. Maamri[1], N. Ketata[1,2], M. Ben Jmeaa[1], I. Sbouii[1], R. Karray[1], J. Jdidi[1], S. Yaich[1], S. Baklouti[2], J. Dammak[1]. [1]*Hedi Chaker University Hospital, Community Health and Epidemiology Department, Sfax, Tunisia*; [2]*Hedi Chaker University Hospital, Rhumatology Department, Sfax, Tunisia*

Background: Crystalline arthropathies (CA) are a group of joint disorders caused by deposits of crystals in joints and the soft tissues around them. The most common type is gout. Over time, CA could lead to joint damage and even for other serious complications that could require hospitalization.
Objectives: This study aimed to determine the epidemiological, clinical and chronological profile of hospitalizations for CA in southern Tunisia for 14 years.
Methods: This was an observational retrospective study that included patients hospitalized for CA in the Hedi Chaker University Hospital Southern Tunisia, during the period 2003-2016. Data collection was done as part of the continuous survey of hospital morbidity and mortality.
Results: Among 148596 admissions, 187 cases were hospitalized for CA (0.12%), of which 122 subjects (64.9%) were males. The median age of hospitalized patients was 66 years (IQR=[54-75]) years. There were 96 patients (51.3%) aged>65 years. The most frequent type of CA noted was gout with a global frequency of hospitalizations about 72.2% (n=135). Complications were noted among 11 patients (5.9%). They were essentially cardiovascular diseases in 5 cases (2.6%). The mean total cost of hospitalizations for CA was about 507 Tunisian Dinars (IQR=[355-718])Tunisian Dinars. The median length of hospital stay was 10 days (IQR=[6.25-15]) days. A duration>10 days was statistically more frequent among patients with CA other than gout (Odds Ratio (OR)=2.12; p=0.026). Moreover, gout was statistically more frequent among patients aged less than 65 years old (OR=2.8; p=0.002). The study of the evolution profile of hospitalizations for CA showed a global trend statistically constant across the years (Rho=0.17; p=0.54). As well, there were no statistical variability of hospitalizations trends according to CA type specifically gout (Rho=0.28; p=0.32) and other CA types (Rho=0.08; p=0.77) during the survey period.
Conclusion: CA notably gout continue to be a relatively frequent source of hospitalizations in southern Tunisia with a stable chronological trend over the years. Thus, an adequate and a continuous management must be maintained for patients in order to control the complicated forms of these pathologies.

AB1261 DEVELOPMENT AND VALIDATION OF GOUT "TREAT-TO-TARGET" BOOKLET

Keywords: Education, Gout

N. Mustafa[1], M. R. Isa[2], H. Baharuddin[1,3]. [1]*Universiti Teknologi MARA, Department of Internal Medicine, Sungai Buloh, Malaysia*; [2]*Universiti Teknologi MARA, Department of Public Health Medicine, Sungai Buloh, Malaysia*; [3]*Hospital Al-Sultan Abdullah, Department of Internal Medicine, Bandar Puncak Alam, Malaysia*

Background: Gout is a treatable disease but often sub-optimally managed. The main gaps identified in gout management are sub-optimal urate lowering therapy (ULT) adherence and lack of adequate ULT dosage.[1] Nurse-led care by providing individualized information led to a reduction in gout flares and tophi,[2] while a structured gout management programme led by pharmacists[3] resulted in a higher rate of reaching serum uric acid (SUA) compared to usual care. Most patients with gout are being managed in primary care setting where nurse-led or pharmacists-led care may not be realistic, especially in developing countries where human resources are limited. Furthermore, clinic visits for every ULT increment can be burdensome to the healthcare system and even patients. Would a booklet on gout be helpful to improve patients' education and ultimately care of patients with gout?
Objectives: This study was conducted to validate our newly developed Gout 'Treat-to-Target' Booklet, which was intended to document individual patient's data relevant to gout and to provide basic written information on gout, for patients' reference.
Methods: This methodological research was conducted following three stages; stage 1 involved the review of the Malaysian Clinical Practice (CPG) for the

Table 1. Associations of Serum Iron levels with the Prevalence of HU in the US adult population. Weighted

CI, confidence interval; Ref., reference; OR, odd ratio. The model was constructed by using logistic regression.

management of gout[4] and the EULAR evidence-based recommendations for gout management,[1] stage 2 involved adoption of the content which was written into a booklet called Gout 'Treat-to-Target' Booklet, and stage 3 was the evaluation of the booklet for content and face validity. The content validity index (I-CVI) was assessed by 11 healthcare providers who were involved in managing gout patients (four consultant rheumatologists, two general physicians and five medical officers) using a four-point Likert scale regarding relevancy, clarity, simplicity and ambiguity of each item in the booklet. A scale with excellent content validity composed of I-CVI of 0.79. The face validity index (FVI) was performed by 10 patients with gout who were asked to rate each content item independently (rating 1 and 2 represent invalid comprehensiveness and rating 3 and 4 represent valid comprehensiveness). An FVI for each item of >0.79 was considered relevant.

Results: The size of the booklet was 148 x 120 mm, which fits into pockets of trousers. (Figure 1) It consisted of 15 printed pages (excluding the front page) and divided into two segments. The first segment would contain items related to individual patient's data related to gout such as onset of the first symptoms, onset of tophi, cardiovascular co-morbidities, the SUA target, ULT used (including the dates for dose increment), colchicine dose and SUA level at each visit. The second segment consisted of four appendices which contained basic information on gout (appendix 1: treatment options in gout, appendix 2: medication information, appendix 3: gout diet and appendix 4: recommended gout lifestyle). The I-CVI assessed by the 11 experts for all items were >0.79 (minimum 0.9, maximum 1.0), while the FVI evaluated by 10 gout patients for all items were 1.0.

Conclusion: The development and validation process of our Gout 'Treat-to-Target' Booklet was described. This booklet achieved excellent I-CVI and FVI, and thus would be applicable in clinical practice.

AB1262

AMORPHOUS MINERALIZATION, CHONDROID AND/OR OSTEOID FORMATION IN CRYSTAL INDUCED METABOLIC DISORDERS – A COMPARATIVE STUDY OF APATITE RHEUMATISM, CHONDROCALCINOSIS AND PRIMARY SYNOVIAL CHONDROMATOSIS APATITE RHEUMATISM, CHONDROCALCINOSIS, PRIMARY SYNOVIAL CHONDROMATOSIS

Keywords: Synovium, Crystal arthritis

Á. Apáthy[1], M. Bély[2]. [1]*St. Margaret Clinic, Department of Rheumatology, Budapest, Hungary*; [2]*Hospital of the Order of the Brothers of Saint John of God in Budapest, Department of Pathology, Budapest, Hungary*

Background: Apatite rheumatism (**AR**), chondrocalcinosis (**Ch-C**) and primary synovialis chondromatosis (**prSynCh**) are calcium hydroxyapatite (**HA**) and calcium pyrophosphate dihydrate (**CPPD**) crystal induced progressive metabolic diseases, accompanied by more or less amorphous calcium phosphate [$CaPO_4$], calcium carbonate [$CaCO_3$]) deposits, chondroid and/or bone formation [1 – 5].

Objectives: The **aim** of this study was.

(1)to assess the mineralization, chondroid and/or bone formation of **AR**, **Ch-C** and **prSynCh** with conventional histologic stains and histochemical reactions,

(2)to identify **HA** [$Ca_5(PO_4)_3(OH)$] and **CPPD** [$Ca_2P_2O_7.2H_2O$] crystal deposits in conventionally fixed and stained tissue sections in comparison with unstained sections (Bély and Apáthy 2013) [6].

Methods: Ten joints (6 knees, 1 hip, 3 shoulders) of **5** patients with **AR**, **16** joints (8 knees, 4 hips, 1 shoulder, 1 elbow, 2 wrists) of **16** patients with **Ch-C**, and **21** joints (14 knees, 5 hips, 2 elbows) of **20** patients with **prSynCh** were studied histologically. The amount of amorphous calcium phosphate and/or calcium carbonate deposits, furthermore chondroid and/or bone formation were evaluated by a semiobjective score system in conventionally stained tissue sections (**0** - no mineral deposits, chondroid and/or bone formation, **1** – minimal, **2** – moderate, and **3** – abundant). Standard stained and unstained tissue sections were examined with the light microscope and under polarized light, respectively.

Results: Summary of Patients' Demographics.

Table 1.

Clinical diagnosis	Total n of patients (n=41)	Mean age in years at surgery ± SD	Range of age (In years)
Apatite rheumatism (n=5)	**5 of 41**	**74.80±6.91**	**66 – 82**
Female	4	77.00±5.60	69 – 82
Male	1	66.00	66.00
Chondrocalcinosis (n=16)	**16 of 41**	**63.67±21.17**	**39 – 81**
Female	14	62.00±21.93	39 – 81
Male	2	74.00±1.41	73 – 74
Primary synovial chondromatosis – (n=20)	**20 of 41**	**50.20±12.51**	**30 – 76**
Female	13	53.15±10.49	40 – 74
Male	7	44.71±14.90	30 – 76

The amount of amorphous calcium phosphate and/or calcium carbonate deposits was different in all patient groups; the average value of scores in tissue samples of patients with clinical diagnosis of **AR** was (1.80), with **Ch-C** (2.60), and with **prSynCh** (0.556). Chondroid formation in synovial membranes was minimal in tissue samples of patients with the clinical diagnosis of **AR** (0.058) or **Ch-C** (0.050); osteoid or bone formation was not detected (0.0). Massive chondroid formation (with or without osteoid or bone formation) was characteristic for **prSynCh** (2.1351). In tissue sections stained with **HE**, **HA** crystals were found only in **3** (**4.054** %), and **CPPD** in **15** (**20.27** %) of 74 tissue sections of **28** patients with the clinical diagnosis of **AR**, **Ch-C**, or with **prSynCh**. Using Bély and Apáthy's non-staining technique (2013), different amounts of **HA** and **CPPD** crystals were demonstrated in all **28** patients (**100** %) with the clinical diagnosis of **AR**, **Ch-C** and **prSynCh**. In unstained sections **HA** crystals were found in **49**, (**66.216** %), and **CPPD** in **44** (**59.459** %) of 74 tissue samples. The unstained sections were more efficient to demonstrate **HA** or **CPPD** crystals than conventionally stained ones.

Conclusion: Our study indicates that **AR**, **Ch-C** and **prSynCh** are crystal induced maladies and belong to the same group of metabolic diseases. All of these diseases start with **HA** and **CPPD** crystal deposition which provokes an inflammatory reaction. The inflammatory reaction is inhibited or moderated by calcium carbonate [CaCO3] and/or calcium phosphate [CaPO4] deposition in case of **AR** or **Ch**, and is inhibited or moderated by chondroid and/or osteoid formation in case of **prSynCh**. In our view **prSynCh** is a defect variant of metabolic

disorders, characterized by diminished calcium phosphate and/or carbonate production.

AB1263 REGIONAL VARIATIONS OF CARDIOVASCULAR RISK IN GOUT PATIENTS: A NATIONWIDE COHORT STUDY IN KOREA

Keywords: Cardiovascular disease, Gout

B. Ghang[1], B. Yoo[2], J. Kim[1], H. J. Kim[3], H. S. Ahn[3]. *[1]Jeju National University School of Medicine, Jeju National University Hospital, Rheumatology, Jeju, Korea, Rep. of (South Korea)*; *[2]Asan Medical Center, University of Ulsan College of Medicine, Rheumatology, Seoul, Korea, Rep. of (South Korea)*; *[3]College of Medicine, Korea University, Preventive Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Gout is also closely associated with systemic disorders and cardiovascular (CV) risk profiles, such as hypertension, diabetes mellitus, dyslipidemia, chronic kidney disease, alcohol consumption, and obesity.[1] In addition, gout has been suggested as a cause of CV diseases via pathogenic mechanisms such as endothelial dysfunction, oxidative metabolism, platelet adhesiveness, and aggregation. [2-4] Accordingly, several epidemiological studies reported that patients with gout had an increased risk for CV events. [3, 4] In particular, differences in population characteristics between urban regions and other regions are getting more significant owing to recent rapid industrialization. Accordingly, a study on regional differences should be conducted; however, there are still few studies on it.

Objectives: We aimed to investigate the risk of major cardiovascular events in gout patients in different regions.

Methods: This was a nationwide cohort study based on the claims database of the Korean National Health Insurance and the National Health Screening Program. Patients aged 20 to 90 years newly diagnosed with gout after January 2012 were included. After cardiovascular risk profiles before gout diagnosis were adjusted, the relative risks of incident cardiovascular events (myocardial infarction, cerebral infarction, and cerebral hemorrhage) in gout patients in different regions were assessed.

Results: In total, 231,668 patients with gout were studied. Regional differences in cardiovascular risk profiles before the diagnosis were observed. Multivariable analysis showed that patients with gout in Jeolla/Gwangju had a significantly high risk of myocardial infarction (adjusted hazard ratio [aHR] 1.27 [95% confidence interval [CI], 1.02–1.56], P = 0.03). In addition, patients with gout in Gangwon (aHR 1.38 [95% CI, 1.09–1.74], P = 0.01), Jeolla/Gwangju (aHR 1.41 [95% CI, 1.19–1.67], P < 0.01), and Gyeongsang/Busan/Daegu/Ulsan (aHR 1.37 [95% CI, 1.19–1.59], P < 0.01) had a significantly high risk of cerebral infarction.

Conclusion: We found there were regional differences in cardiovascular risk and associated risk factors in gout patients. Physicians should screen gout patients for cardiovascular risk profiles in order to facilitate prompt diagnosis and treatment.

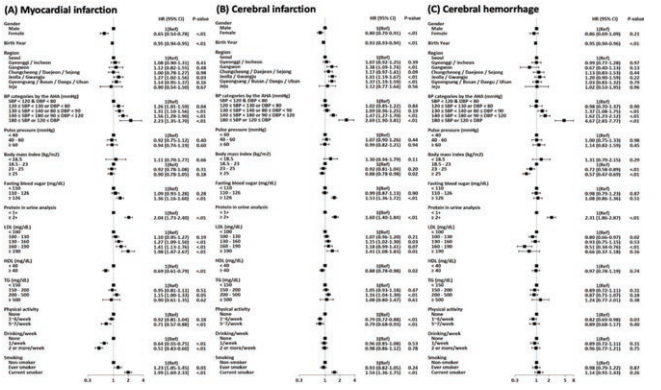

Figure 1. Forest plot of the risk of myocardial infarction (A), cerebral infarction (B), and cerebral hemorrhage (C). AB1264 RHEUMATOLOGISTS BEWARE OF LOW ALP: A CASE OF HYPOPHOSPHATASIA MISDIAGNOSED AS FIBROMYALGIA, CAUSING LONG DIAGNOSTIC DELAY

Keywords: Quality of life, Patient information and education, Rare/orphan diseases

A. Latheef[1], K. Moss2. *[1]St George's University Hospitals NHS Foundation Trust, Rheumatology, London, United Kingdom*; *[1]St George's University Hospitals NHS Foundation Trust, Rheumatology, London, United Kingdom*

Background: Hypophosphatasia(HPP), a rare, inherited metabolic disease featuring low serum alkaline phosphatase (ALP) activity due to ALPL (encoding tissue non-specific alkaline phosphatase) gene mutation[1,2]. A wide-ranging clinical spectrum is often seen due to defective mineralisation affecting teeth, bones, joints and muscles[1]. This disease has a prevalence of 1/6370 in Europe and is often misdiagnosed and underdiagnosed with a diagnostic delay of more than ten years[1] The treatment is often supportive for milder cases and enzyme replacement therapy in severe cases.

Objectives: To share this case to raise awareness among Rheumatologists.

Methods: This 58-year-old Caucasian female had her first HPP symptom as early eruption of deciduous teeth, along with recurrent dental infections and gum problems. She was diagnosed with flat feet at age five, had a big toe fracture at sixteen, followed by a metatarsal fracture. She experienced leg muscle cramps and aches, affecting her performance in sport during school life. At the age of thirty she began noticing weakness in arms and legs, which progressed over the years. She faced significant early morning stiffness along with painful ribs, hips, knees, shoulders, and small joints of feet when walking. She was diagnosed with Fibromyalgia at the age of forty-four. The following ten years she met numerous specialists including rheumatologist, pain specialist and physiotherapists. She was also diagnosed with early osteoarthritis, pernicious anaemia, hyperlipidemia, functional neurological syndrome, and central sensitization syndrome. She had multiple trials of steroids and opioids, all of which were stopped either due to side effects or inefficiency. A major flare of symptoms five years ago rendered her bedbound for three months, following which a chemical pathologist noticed a persistent low ALP levels and decided to investigate for HPP. It took another four years to complete these investigations due to the coronavirus pandemic. Currently, she is unable to weight bear or climb stairs and must stay indoors or in bed during flareup. She moved into a ground floor flat at the age of 54 and use a walking stick occasionally. By 58, she is unable to work and had given up her own business due to pain, weakness, and disability.

Results: On clinical assessment, her height is 160 cm, faced difficulty getting up from chair, has an antalgic waddling gait, with a 6-minute walking distance of 60 metre, stopped after three minutes, and had a Brief Pain Inventory pain severity score of 7/10. Her ALP level is 24 U/L and PLP/PA ratio is 18.8 (ref < 5), and genetic testing showed heterozygous missense variant of ALPL gene mutation.

Conclusion: It took more than forty years to reach a conclusive diagnosis of childhood onset HPP. Low ALP level is a signature of HPP and warrants investigations. Diagnosis can be challenging due to the rareness and variable presentation, however recognition of HPP features is crucial for timely referral, optimal disease management and potential improvement in quality of life.

AB1265 THE INCIDENCE OF ACUTE CORONARY SYNDROME IN GOUT AND ASSOCIATED FACTORS

Keywords: Gout, Heart

I. Roki Chaoui[1], N. Akasbi[1], S. Benmaamar[2], I. El Mezouar[1], T. Harzy[1]. [1]*Hassan II University Hospital, University Sidi Mohamed Ben Abdellah, Faculty of Medicine and Pharmacy, Rheumatology, Fes, Morocco*; [2]*Hassan II University Hospital, University Sidi Mohamed Ben Abdellah, Faculty of Medicine and Pharmacy, Laboratory of Biostatistical, Clinical and Epidemiological Research, Fes, Morocco*

Background: The Gout is a metabolic arthropathy including monosodium urate crystal deposition associated with an increased risk of cardiovascular morbidity and mortality, particularly related to coronary heart disease.
Objectives: The purpose of our work was to determine the frequency of heart attack in our gouty patients and the factors associated with its incidence.
Methods: A retrospective observational study was conducted. The inclusion period was from January 2011 to March 2022.
Results: Our sample included 138 patients. The mean age was 58±13 years and the sex ratio was 1.46 M/W. The mean duration of evolution was 20±28 months. The prevalence of patients with metabolic syndrome including diabetes, hypertension and dyslipidemia was 25.4%, 43.5% and 16.7% of cases respectively. Smoking was present in 9.5% of cases. Medication was found in 31.2% of cases. The disease was mono-articular in 64.5% of cases and poly-articular in 35.5% of cases, with tophus present in 11 patients. Monosodium urate crystals were found in the synovial fluid in 9.4% of cases. The mean uric acid level, C - reactive protein and creatinine were 78.35±22 mg/l; 55.9±86 mg/l and 15±19 mg/l respectively. The number of patients with heart attack in our sample was 22 or 15.9% of cases. In bi-variate analysis, the presence of heart attack in our patients was associated with five factors, age (p=0.007), smoking (p=0.021), drugs including antiplatelet agents (p=0.0001) and loop diuretics (p=0.002), dyslipidemia (p=0.038) and uric acid level (p=0.028). In multivariate analysis, the risk of developing an acute coronary syndrome in our patients followed for gout was increased sevenfold in the presence of smoking (OR=7.591; CI95% [1.474; 39.098]; p=0.015), and fivefold in the presence of dyslipidemia (OR=5.744; CI95% [1.323; 24.947]; p=0.020).
Conclusion: In addition to our work, several previous studies confirm the increased cardiovascular risk of gout but few investigate the predictive factors [1]. Biological studies have indicated that the systemic inflammation induced by the crystals characteristic of gout leads to atherogenesis through endothelial dysfunction [2]. In our sample, the incidence of acute coronary syndrome is associated with smoking and dyslipidemia. The vital prognosis is at stake, hence the need for adequate and early management of this rheumatism as well as the prevention of associated factors.

AB1266 REVIEW OF THE MANAGEMENT OF GOUT BY THE GENERAL PRACTITIONER

Keywords: Gout, Crystal arthritis

F. E. Bennani[1], F. Idrissi Zaki[1], H. Bara[1], A. Mougui[1], I. El Bouchti[1]. [1]*Centre Hospitalo-Universitaire Mohammed VI Marrakech, Rheumatology, Marrakech, Morocco*

Background: Gout is the most common microcrystalline arthritis. It is a life-threatening disease due to joint damage, but also due to renal complications, which depends on adequate management of the disease. Unlike other inflammatory arthritides, gout is largely managed in primary care.
Objectives: The objective of this study is to compare the general practitioners management with international recommendations.
Methods: For this we conducted a survey among 117 general practitioners during 1 month. The questionnaire was established in the form of 7 clinical cases.
Results: Oral colchicine is prescribed as first-line therapy in acute access by 85.3% of physicians. In 69% of the physicians, colchicine is combined with analgesics, prednisone or allopurinol. Allopurinol was prescribed alone by 31.9% of physicians. In case of side effects of colchicine, 49.6% of general practitioners recommend reducing the dose of colchicine, 35% of doctors proposed to stop it, 13.7% and 11.1% proposed to replace it by allopurinol and an analgesic respectively. For the initial assessment to be requested before starting allopurinol, 69.8% of the doctors indicated that the renal assessment is systematic before starting the treatment, while no assessment is necessary is noted by 23.3% of the doctors. Thirty-one physicians have a therapeutic goal of lowering uricemia below 50mg/l in case of tophaceous gout versus 45.7% recommending a level below 60mg/l and 4.3% suggesting a level below 70mg/l. The maximum dose of allopurinol not to be exceeded was 900mg noted by 47% of general practitioners, 300mg, 600mg and 1200mg by 21.4%, 17.1% and 15.4% respectively. Hypo-uricemic treatment is indicated in patients with recurrent attacks, arthropathies, tophus or radiological signs of gout. Thus, 8.5% of the physicians recommend disease-modifying therapy for the recommended indications. Among other things, 36.8% of patients recommend starting hypouricemic treatment in the event of asymptomatic hyperuricemia. Regarding patient education, the majority of doctors advise for weight loss (77.6%) and a low purine diet by (75%).
Conclusion: This work has objectified that gout is often poorly managed by general practitioners suggesting the need for continuing medical education of general practitioners which will certainly help improve practices.

AB1267 THE CORRELATION BETWEEN URIC ACID AND BONE MINERAL DENSITY OF TOTAL HIP WITH BONE MICROARCHITECTURE ANALYSIS IN TOPHACEOUS GOUT PATIENTS

Keywords: Imaging, Bone diseases, Gout

J. Barco Dos Santos[1], G. Rocha[1], L. Peixoto Sales[1], A. Silva Franco[1], V. Caparbo[1], D. Domiciano[1], R. Fuller[1], C. Figueiredo[1], R. M. Pereira[1]. [1]*Hospital das Clínicas HCFMUSP, Faculdade de Medicina, Universidade de São Paulo, Division of Rheumatology, Sao Paulo, Brazil*

Background: Gout is the most common inflammatory arthropathy[1]. It is related to elevated uric acid levels and often associated with bone loss[2]. Furthermore, chronic inflammation has been associated with fragility fractures despite normal bone mass by dual-energy X-ray absorptiometry (DXA). However, the evaluation of bone microstructure in patients with tophaceous gout and its association with bone mineral density (BMD) has not been studied yet.
Objectives: The present study aimed to investigate the correlation between densitometric parameters and bone microstructure using high-resolution peripheral quantitative computed tomography (HR-pQCT) in patients with tophaceous gout.
Methods: Eleven male tophaceous gout (Figure 1) patients were enrolled in this cross-sectional study. Patients using drugs that can affect bone metabolism (e.g bisphosphonates, teriparatide and denosumab), corticosteroid use for more than 3 months and those with end-stage chronic kidney disease were excluded. Demographics and clinicals data were obtained through interviews and medical records. Laboratory tests were performed using standard automated methods. DXA was performed to evaluate the BMD. HR-pQCT at the distal radius and tibia was performed to assess trabecular and cortical volumetric BMD (Tb.vBMD= trabecular volumetric BMD; Ct.vBMD= cortical volumetric BMD), microstructure (Tb.N= trabecular number, Tb.Th= trabecular thickness, Tb.Sp= trabecular separation, Ct.Th= cortical thickness, Co.Po= cortical porosity) and strength (S= stiffness, F.Load= failure load) bone parameters. Pearson's correlation (r) tests were performed.
Results: Demographic data are described in Table 1. Uric acid levels were negatively correlated with HR-pQCT microstructure data, such as Ct.Th tibia (r= -0.720, p= 0.029) and S tibia (r= -0.810, p= 0.008) as well as DXA data, such as lumbar spine BMD (r= -0.685, p=0.02).On the other hand, it

was found a positive correlation between BMD of total hip and Tb.N tibia (r= 0.743, p= 0.035), Ct.Th tibia (r= 0.902, p= 0.005) and S tibia (r= 0.938, p= 0,001).

Conclusion: The results of this study showed that uric acid levels were negatively correlated with tibia bone microarchitecture parameters. However, total hip BMD was positively correlated with these tibia bone microstructure data.

AB1268

FIRST DIAGNOSIS OF MONOSODIUM URATE CRYSTAL FROM CEREBROSPINAL FLUID IN PATIENT WITH NECK PAIN

Keywords: Spondyloarthritis, Crystal arthritis, Gout

W. Jeong[1], J. R. Yoo[1]. [1]*Jeju National University College of Medicine, Internal Medicine, Jeju, Korea, Rep. of (South Korea)*

Background: Gout is a common arthritis caused by the deposition of monosodium urate (MSU) crystals within joints after chronic hyperuricemia. Deposition of MSU in the spine as a rare manifestation of gout, but the actual prevalence of spinal involvement is unknown.

Objectives: We present a vertebral osteomyelitis and spinal meningitis misdiagnosed cervical spinal gout.

Results: An 85-year-old man was admitted due to a 5-day history of fever and neck pain. On admission, physical examination revealed neck pain and stiffness. He had a blood pressure of 140/102 mmHg, pulse rate of 95/min, respiration rate of 18 breaths/min, and body temperature of 38.0°C. Laboratory results revealed a white blood cell count (WBC) of 11,200/mm^3 (reference: 4,000–10,000) and C-reactive protein level of 12.26 mg/dL (reference: 0.0–0.3). Magnetic resonance imaging findings suggested cervical osteomyelitis and meningitis (Figure 1A). Cervical spine computed tomography (CT) revealed curvilinear calcifications of the transverse ligament of the atlas (Figure 1B). After assessing blood cultures, an empirical antibiotics were administered intravenously. On the second day of admission, cerebrospinal fluid (CSF) analysis did not reveal meningitis (WBC 8/μL; glucose and protein levels 79 and 168 mg/dL, respectively), and CSF culture and molecular tests were negative for bacteria and mycobacteria. The patient was diagnosed with crowned dens syndrome and administered with 20 mg prednisolone, and his symptoms dramatically improved. However, CSF examination under polarising microscopy revealed monosodium urate (MSU) crystals (Figure 1C), and dual-energy CT confirmed the calcifications to be MSU crystals (Figure 1D).

Conclusion: Crowned dens syndrome is a rare finding in calcium pyrophosphate deposition disease and may be clinically similar to meningitis, so it should be suspected when the evidence for infection is unclear. Our patient had gout history, and MSU crystals were confirmed by CSF analysis and dual-energy CT, suggesting that the symptoms were caused by gout flare in the cervical spine. Thus, physicians should consider that intrathecal MSU crystal formation can cause meningitis-like symptoms in patients with gout history.

AB1269 HEARING LOSS – A RARE MANIFESTATION OF THE CALCIUM PYROPHOSPHATE DIHYDRATE DEPOSITION DISEASE

Keywords: Descriptive studies, Crystal arthritis

P. Bradna[1]. [1]*University Hospital and Medical Faculty, IInd Dept of Medicine, Hradec Králové, Czech Republic*

Background: Calcium pyrophosphate dihydrate (CaPPD) deposition disease is a illness with a wide range of manifestations from acute gout-like episodic arthritis to an accentuated osteoarthritis picture. A common feature is the deposition of CaPPD crystals in tissues. Middle ear involvement is a rare manifestation of the disease, described in a few case reports.
Objectives: Middle ear involvement is a rare manifestation of the disease, described in a few case reports.
Methods: Histological examination of operating specimen.
HRCT.
Results: 71-year-old man, athlete (tennis, cycling) underwent a partial menisectomy in 2008 for acute knee blockade, in October 2022 he suffered polytrauma after a traffic injury. Het is treated for arterial hypertension. He has never had inflammatory arthritis, joint problems he had only in connection with sports injuries. Last 12 months he has observed a gradually progressing hearing loss, mild dizziness and tinnitus. HRCT of a scull base demonstrated a left-sided osteoma with fixation to the malleus. Tumor mass was removed by surgery. Histology proved calcium pyrophosphate dihydrate crystals in the operating material. We have not demonstrated hyperparathyroidism, hypomagnesemia, or any other primary disease associated with CaPPD deposition. During subsequent X-ray examination, we found the chondrocalcinosis of the menisci of both knees.
Conclusion: Deposits of calcium pyrophosphate in the middle ear region are a rare manifestation of the calcium pyrophosphate dihydrate deposition disease. Clinically, progressive hearing loss may occur, morphologically resemble osteoma and may not be associated with other clinical signs of the underlying disease.

AB1270 ANALYSIS OF PREVALENCE AND RELATED RISK FACTORS OF HYPERURICEMIA IN BOZDUN AKSU PREFECTURE OF XINJIANG

Keywords: Gout

Y. Zhong[1], L. Wu[1]. [1]*People's Hospital of Xinjiang Uygur Autonomous Region, Rheumatology, Urumqi, China*

Objectives: To investigate the prevalence of Hyperuricemia (HUA) in Bozidun Kirghiz Township, Aksu region, Xinjiang, and to explore the risk factors for the occurrence of HUA in the local area.
Methods: A cross-sectional survey study was conducted by randomly selecting 9 villages in Bozidun Kirgiz Township by the whole-group sampling method and using a questionnaire distributed to households. The questionnaire included: general information, history of previous diseases, personal history, and all subjects were measured for he-ight, weight, blood pressure, abdominal circumference, etc. The diagnostic of HUA: serum uric acid (SUA) >420μmol/L in men or >360μmol/L in women.
Results: ①A total of 2138 subjects were surveyed, among which 68 patients with HUA, the prevalence of HUA in Bozidun Kirghiz Township, Aksu regionrate general population was 3.2% (68/2138); the prevalence rate of men was 4.6%, with 45 patients; and the prevalence rate of women was 2.0%, with 23 patients. The peak age of male and female patients was 51~60 years old. ②The prevalence of HUA was lower in those who consumed dairy products, nuts and eggs, and lower in those who consumed more. Different intake of cereals, meat, vegetables and fruits had no effect on the prevalence of HUA.③In terms of different life behaviors, the prevalence of HUA in men who had been smoking was higher than those who had never smoked (57.78%, 28.89%, 13.33%, P=0.017). In the relationship between drinking and HUA, the prevalence rates of male always drinking, ever drinking and never drinking were 80.00%, 11.11% and 3.89%, respectively, showing significant differences(P=0.038);④Multi-factor logistic regression analysis showed that BMI, age, TG, Cr and WBC were risk factors for the occurrence of HUA.
Conclusion: The prevalence of HUA in Bozidun Kirgiz township in Aksu prefecture of Xinjiang is lower than that in other areas with continental climate. High body mass index, old age, high triglyceride, increased creatinine and increased white blood cell count are the risk factors for the development of HUA.

AB1271 FACTORS ASSOCIATED TO FRAGILITY FRACTURES IN RA PATIENTS: IS URIC ACID INCRIMINATED?

Keywords: Osteoporosis, Rheumatoid arthritis

B. Touil[1], N. Akasbi[1], I. El Mezouar[1], T. Harzy[1]. [1]*Sidi Mohammed Ben Abdellah University, Rheumatology Department, FEZ, Morocco*

Background: Rheumatoid arthritis (RA) has been reported to be associated with low bone mineral density (BMD) and increased risk of fractures. Recently, several observational studies have revealed that a higher serum uric acid level was associated with higher bone mineral density (BMD), and therefore, a reduced risk of osteoporosis and fragility fractures in men, post- and perimenopausal women. Although the relationship between serum UA levels and BMD has been evaluated in the general population, data regarding the effect of UA levels on bone loss in patients with RA was lack [1].
Objectives: To evaluate the relationship between UA levels, BMD and fragility fractures (FF) and the different factors associated with the occurrence of FF in RA patients.
Methods: We conducted a cross-sectional study in a single rheumatology hospital in Morocco. All patients satisfied the ACR-EULAR 2010 RA classification criteria. All the patients underwent BMD examination by dual energy x-ray absorptiometry and serum UA levels measurement. Osteoporosis was diagnosed when the T-score was - 2.5 or less. Socio-demographic data, comorbidities, disease-related variables (duration, characteristics, and drugs) were also collected. Statistical analysis were performed with SPSS 22.
Results: We included 88 (85.44%) women and 15 (14.56%) men with a mean age of 52.59 ± 14.77 years old. They had a mean disease duration of 14.27±10.84 years, a mean DAS 28 CRP of 2.59 ±1.35. Their mean lumbar spine, femoral neck and total proximal femur were 0.843 ± 0.134, 0.694 ± 0.111, and 0.826 ± 0.119 respectively. The UA levels were elevated in 10.8 % of patients, dyslipidemia was found in 19.3 % of patients and 38.9 % of the patients had osteoporosis. There was no correlation between UA concentrations and BMD, whether at the lumbar spine femoral neck and total proximal femur, and UA and fragility fractures. However, the occurrence of fragility fractures was significantly associated to BMD at the femoral neck (0.606 ± 0.126 vs 0.705 ± 0.104; p=0.027), to high concentrations of LDLc (3.69 ± 0.38 vs 2.71 ± 0.77 mmol/L; p=0.004), Total cholesterol (5.84 ± 0.74 vs 4.55 ± 0.85 mmol/L; p=0.001), ACPA antibodies titres (364.25 ± 101.35. vs 167.96 ± 120.30; p=0.047), cumulative corticosteroid dose (11057.64 ± 4653.35 vs 1330.20 ± 211.80 mg; p=0.008), to BMI (22.41 ± 4.41 vs 27.24 ± 4.94; p=0.018) and to the glomerular filtration rate (87.43 ± 12.11 vs 103.50 ± 15.38; p=0.018).
Conclusion: Although there was no relation between UA levels, BMD and FF in our population. FF were related to ACPA antibodies, BMD, kidney fonction and corticosteroid use.

Infection-related rheumatic diseases

AB1272 **SHOULD RHEUMATOLOGISTS ROUTINELY REQUEST PARASITE SEROLOGY IN CANDIDATES FOR IMMUNOSUPPRESSIVE TREATMENT? PREVALENCE OF STRONGYLOIDES STERCORALIS IN A NON-ENDEMICAL AREA (CATALONIA, SPAIN)**

Keywords: Inflammatory arthritides, Epidemiology, Infection-related RMDs

J. Font-Urgelles[1,2], S. Mínguez-Blasco[1], M. Lopez de Recalde-Martorell[1], B. Rodríguez-Díez[1], A. Arnau Bartes[3], S. Jonàs-Llauradó[4], A. Flor-Pérez[4], G. Trujillo-Isern[5], D. Estivill Navarrete[5], J. Trapé[5], M. Sallés Lizarzaburu[1]. *[1]Althaia, Xarxa Assistencial Universitària de Manresa, Rheumatology, Manresa, Spain*; *[2]Hospital Universitari Germans Trias i Pujol, Rheumatology, Badalona, Spain*; *[3]Althaia, Xarxa Assistencial Universitària de Manresa, Research Unit, Manresa, Spain*; *[4]Althaia, Xarxa Assistencial Universitària de Manresa, Infectology, Manresa, Spain*; *[5]Althaia, Xarxa Assistencial Universitària de Manresa, Microbiology, Manresa, Spain*

Background: Infection is one of the main causes of morbidity and mortality in patients with autoimmune and immune-mediated diseases (AI/IMID). Multiples recommendations exist for prevention of bacterial and viral infections, however, there are no specific recommendations for parasitosis. Strongyloidiasis is an infection caused by *Strongyloides stercoralis.* This parasite is distributed globally throughout tropical and subtropical areas. The majority of cases in Spain are imported. Often this infection is asymptomatic, however, in immunosuppression situation, severe presentations, hyperinfestation syndrome or disseminated strongyloidosis can occur.
Objectives: To determine the prevalence of positive *S. stercolaris* serology and describe the epidemiological, clinical and analytical characteristics of this subjects.
Methods: Cross-sectional study. Subjects: patients with AI/IMID candidates for immunosuppressive treatment. Study period: patients attended in the Rheumatology Service between June 2018 and December 2022. Main outcome: Prevalence of *positive S. stercoralis* serology. Independent variables: demographic, clinical manifestations and travels to endemic countries. Statistical analysis: descriptive and bivariate analysis.
Results: Three hundred and ten patients were included. The majority were women (63.2%) with a mean age of 55.9 years (SD 14.7) and 9.3% were not born in Spain. Our patients had and inflammatory arthritis (81.2%) or an autoimmune disease (8.1%). At the moment of serology determination, 41.9% received disease-modifying antirheumatic drug and 54.9% prednisone. Positive serology was found in 10 patients (3.2%; 95%CI: 1.6-5.9) and 4 (1.3%; 95%CI: 0.4-3.3) were indeterminate. No patient developed symptomatic infection nor hypereosinophilia. Every positive patient received prophylactic therapy with ivermectin. The 60% of patients didn't referred any epidemiological risk, 10% were born in endemic country but have never returned, 10% were born in endemic country and have visited this country subsequently, and 20% were born in non-endemic country and had travelled to an endemic zone. No differences were observed in the prevalence of *S. stercolaris* according to sex, disease, treatments nor epidemiologic contacts. Patients with positive serology were younger (48.4 years vs 56.2; p=0,048). The highest prevalence of infection was observed in workers of the quinary sector (12%; p=0.072).
Conclusion: Prevalence of *S. stercolaris* infection in rheumatic patients in our area is 3.2%. Increasing migration and international travelling was suspected the most probable cause of this prevalence. Surprisingly no epidemiological risk was referred in 60%. Although none of our patients presented active infection, serological determination and prophylactic treatment should be routinely assessed in candidates for immunosuppressive therapy due to the potential lethality of *S. stercolaris.*

AB1273 **RARE INFECTION RELATED ARTHROPATHIES IN RHEUMATOLOGY: A MULTI-CENTRIC STUDY**

Keywords: Rheumatoid arthritis, Infection-related RMDs, Inflammatory arthritides

A. Pandey[1], A. Dua[2], S. Jain[3], B. D. Pandey[4]. *[1]Apollo Hospitals, Rheumatology, Indore, India*; *[2]Dua' Clinic: Rheumatology and Arthritis Care, Rheumatology, Bilaspur, India*; *[3]Arthritis Clinic, Rheumatology, Saharanpur, India*; *[4]Noida, Rheumatology, Noida, India*

Background: Various infections can mimick inflammatory arthropathies and misdiagnosed as rheumatoid arthritis, Spondyloarthritis or lupus. Occasionally, rare infections prevalent in a specific geographical region may present with arthritis as their first and only symptom which may confuse the clinician leading to incorrect diagnosis and management. Many a times, such patients land up in a rheumatology clinic prior to the diagnosis. Hence, Rheumatologists practicing worldwide should be aware of such manifestations of infectious diseases.
Objectives: Main objective of this multi-centric study was to appraise the clinical features and demographics of various rare infectious diseases (newly or previously diagnosed) that presented with arthritis.
Methods: This retrospective study (January 2022- December 2022) was carried out at 3 tertiary care centres, two in central India (city Indore and Bilaspur) and 1 in northern India (city Saharangpur). Patients who were previously diagnosed with an infectious disease and presented with arthritis were included. Patients with arthritis who were diagnosed as infectious disease were also included. Their details regarding demographics and clinical presentations were collected. Pearson chi-square test was applied and cases were studied according to their Age, Sex, distribution of joints, rheumatoid arthritis (RA) factor and anti cyclic citrullinated peptide (anti-ccp) antibodies positivity,presence of myalgias, rashes, extra-articular manifestations and cutaneous manifestations.
Results: Seventy- nine patients (39 male) were identified. Out of these,34 (43%) patients had chikungunya arthritis, 12 (15.2%) leprosy, 11 (13.9%) Covid-19, 10 (12.9%) Dengue, 4 (5.1%),Hepatitis C, 4 (5.1%) HIV, 3 (3.8%) HCV and 1 (1.3%) Poncet's disease. No significant association was seen among rheumatoid factor (p=0.494) or anti-ccp antibodies positivity (p=0.987) with these diseases. Patients with chikungunya had oligoarthritis (14.7%) or polyarthritis (85.3%). Patients with Covid-19 had oligoarthritis (18.2%), polyarthralgia (27.3%) and polyarthritis (54.5%). Patients with dengue, HCV and Poncet's disease had only polyarthritis. Majority of the patients with hepatitis C and leprosy had polyarthritis. Patients with HIV showed enthesitis (25%), oligoarthritis (25%) and polyarthritis (50%). There was a statistically significant association between presence/ absence of myalgia and infectious diseases (P=0.001). It was absent in patients with hepatitis C. Only about one-third of the patients with leprosy had myalgia; while most of the patients with other infectious diseases had myalgia. 20% of the dengue patients and 41.7% of the leprosy patients had rashes, while rashes were absent in patients with other infectious diseases. Erythema nodosum was seen in only 25% patients with leprosy; while it was absent in the patients with other infectious diseases. Extra-articular manifestations were seen in 35.3% patients with chikungunya, 9.1% with Covid-19, 20% with dengue, 25% with hepatitis C, 33.3% with leprosy and 100% patients with Poncet's disease; while extra-articular manifestations were not seen in patients with HCV and HIV infection. 9.1% patients with Covid-19, 25% with hepatitis C, 25% with HIV, 83.3% with leprosy had cutaneous manifestations, while cutaneous manifestations were not seen in patients with chikungunya arthritis, dengue, HCV and Poncet's disease.
Conclusion: Rheumatological manifestations of various infections can mimic various inflammatory arthritis and can be a diagnostic challenge. Apart from the joint involvement, these infections can also have various extraarticular manifestations as well. One should be aware of such manifestations as increased awareness can prevent diagnostic delay and complications.

AB1274 **RISK FACTORS FOR ACTIVE TUBERCULOSIS DURING FOLLOW-UP IN PATIENTS WITH RHEUMATIC IMMUNE DISEASE**

Keywords: Infection-related RMDs, bDMARD

Z. Li[1], L. Wu2, C. Luo2, Y. M. Shi2, X. Chen2, X. Wu2, J. Li2. *[1]People's Hospital of Xinjiang Uygur Autonomous Region, Uygur 830001, China;, Department of Rheumatology and Immunology, Urumqi, China*; *[1]People's Hospital of Xinjiang Uygur Autonomous Region, Uygur 830001, China;, Department of Rheumatology and Immunology, Urumqi, China*

Background: Rheumatic immune disease is a group of diseases caused by the strong immune response to self-antigens, leading to tissue and cell damage, affecting bone, joints, bursa, muscle and its surrounding soft tissues (tendons, ligaments and fascia). The risk of tuberculosis infection in rheumatic immune patients is 2 to 5 times [1-3] than that of the general population. Patients with rheumatic immune diseases require long-term treatment with glucocorticoids and immunosuppressants, and the risk of complicated tuberculosis infection significantly increases in [4]. When active tuberculosis infection occurs in rheumatic immune patients, quite a number of patients have atypical clinical manifestations, severe disease, difficult to cure, long infection time, high fatality rate, which seriously endanger people's health. Therefore, this study intends to explore the risk of active tuberculosis infection using immunosuppression agents and biological agents in patients with rheumatic immune diseases.
Objectives: The risk factors of active TB in rheumatic immune disease patients were explored.
Methods: The confirmed patients who went to the Rheumatology and Immunology Department of Xinjiang Uygur Autonomous Region from December 2014 to June 2015 were included. The clinical data and treatment plan were collected, followed up to December 2021 and the prognosis were collected. The risk factors of active tuberculosis were analyzed by K-M survival curve method.
Results: Data of 499 patients collected in this study, Including: In 213 cases of rheumatoid arthritis, In 79 cases of ankylosing spondylitis, In 84 cases of systemic lupus erythematosus, In 58 cases of Sjogren's syndrome, And 65 patients with other rheumatic diseases; Of them, 62 patients were lost to follow-up, Ten patients have died, Four patients were diagnosed with active TB infection when enrolled; Thus, 423 patients were included in the study, Among these, 109 males (25.8%), In 314 women (74.2%), Mean age was 48.2 ± 13.7 years, The mean follow-up was 80.2 ±7.7 months, Six cases of active tuberculosis (one case was bone tuberculosis, One case had a pleural tuberculosis, The remaining four cases were pulmonary tuberculosis). Survival analysis showed that patients with rheumatic immune diseases had an increased risk of using immunosuppressive agents compared with active TB infection (p=0.039) and an increased risk of using biologics compared with active TB infection (p=0.004). Multivariate COX regression analysis showed that the use of biologics was an independent risk factor in rheumatic immune disease patients with active TB (P=0.011).
Conclusion: Patients with rheumatic diseases have an increased risk of active TB using immunosuppressants or biologic agents , Use of biologic agents is an independent risk factor for the emergence of active TB.

AB1275 **NEISSERIA GONORRHOEAE ARTHRITIS: A GROWING PROBLEM**

Keywords: COVID, Infection-related RMDs, Epidemiology

P. Andújar-Brazal[1], E. Flores-Fernández[1], C. Valera-Ribera[1], I. Vázquez-Gómez[1], E. Valls-Pascual[1], J. J. Alegre Sancho[1]. [1]*Valencia, Hospital Doctor Peset, Valencia, Spain*

Background: *Neisseria Gonorrhoeae* infection (commonly gonococcus) have increased in recent years. Additionally, an increase in the antibiotic-resistance of the bacteria has been detected, including broad-spectrum cephalosporins, which could lead to untreatable complications like arthritis.
Objectives: The goal of this study is to describe the gonococcal arthritis events identified in a Rheumatology service between 2008 and 2022.
Methods: Retrospective longitudinal observational study based on the review of the medical records of patients diagnosed with gonococcal arthritis in the Rheumatology Department of the Doctor Peset University Hospital in Valencia (Spain) since 2008 to 2022. Sociodemographic and clinical variables, antibiotic sensitivity profile and antibiotic therapy used were studied. Evolution of infections were also analyzed.
Results: Eight cases of gonococcal arthritis were recorded in the period analyzed, all of them diagnosed between the years 2021-2022. All patients except one were male. Half of the patients had sexual transmitted infection history, 75% of which were syphilis infected and 25% had previous hepatitis B infection. The most common form of presentation was oligoarthritis. In three cases a component of tenosynovitis was also observed. Diagnostic arthrocentesis was performed in seven of eight cases and a high profitability of synovial fluid culture was observed (only in one patient bacteria was not isolated). All infections showed cephalosporin and azithromycin sensitivity, all of them displayed a favorable evolution (Table 1).

Table 1. Antibiotic sensitivity profile, treatment regimens administered and duration of treatment, need for surgery and evolution of the infection.

CASE	ANTIBIOTIC SENSITIVITY PROFILE	HOSPITAL TREATMENT	OUTPATIENT TREATMENT	NEED FOR SURGERY	EVOLUTION
CASE 1	Ceftriaxone, cefotaxime, cefixime, gentamicin, azithromycin, doxycycline.	Ceftriaxone (6 days).	Cefixime (14 days).	No.	Resolution.
CASE 2	Ceftriaxone, ceftazidime, cefixime, ciprofloxacin, levofloxacin, azithromycin.	Gentamicin + azithromycin (Three days).	Ciprofloxacin (10 days).	No.	Resolution.
CASE 3	Ceftriaxone, cefotaxime, cefixime, azithromycin.	Ceftriaxone (7 days).	Cefixime + Azithromycin (14 days).	No.	Resolution.
CASE 4	Penicillin, ceftriaxone, cefotaxime, aztreonam, rifampicin, azithromycin, chloramphenicol.	Cloxacillin + ceftriaxone (2 days). After ceftriaxone (4 days).	Amoxicillin-clavulanic acid (1 month).	Yes (elbow arthrotomy and debridement).	Resolution.
CASE 5	Ceftriaxone, cefotaxime, rifampicin, ciprofloxacin, clindamycin, azithromycin.	Ceftriaxone (7 days).	Ciprofloxacin (7 days).	No.	Resolution.
CASE 6	Unrealized.	Not hospitalized.	Azithromycin + cefixime (single dose).	No.	Resolution.
CASE 7	Penicillin, ceftriaxone, cefotaxime, cefixime, azithromycin.	Ceftriaxone + cloxacillin + doxycycline (2 days). After ceftriaxone (7 days).	Intravenous ceftriaxone by Home Hospitalization Unit (21 days).	No.	Resolution.
CASE 8	Ceftriaxone, cefotaxime, cefixime, azithromycin.	Patient refuses hospitalization.	Levofloxacin (14 days).	No.	Lost to follow up.

Conclusion: An increase in gonococcal arthritis cases has been detected in the Rheumatology Department of the Doctor Peset University Hospital in the last two years, overlapping with the end of the social restrictions caused by the COVID-19 pandemic. Despite having described in recent years a growing increase antibiotic resistance, in our study the antibiotic sensitivity profiles were favorable without isolating strains resistant to cephalosporins or azithromycin.

AB1276 SCREENING FOR LATENT TUBERCULOSIS INFECTION BEFORE BIOLOGICS IN ALGERIAN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Infection-related RMDs, bDMARD

F. Z. Y. Heddi[1], A. Laouti[1], A. Laradji[1], M. Nour Elhouda[1], N. Djekoun[2], S. Debbah[3], C. Ouadah[4], K. Kheireddine[1], A. Benzaoui[1]. [1]*Oran University Hospital, Rheumatology, Oran, Algeria*; [2]*Zeralda Public Hospital, Internal Medecine, Algiers, Algeria*; [3]*Jijel Public Hospital, Internal Medecine, Jijel, Algeria*; [4]*Bouinan Public Health Establishment, Pulmonology, Blida, Algeria*

Background: The use of biological agents has significantly improved the management of chronic rheumatic diseases (CRD). However, these treatments increase the risk of tuberculosis due to the reactivation of a previous latent tuberculosis infection (LTBI), making its diagnosis and treatment very important prior to initiating therapy.
Objectives: To identify the prevalence of LTBI in Algerian patients with CRD before the initiation of biotherapy.
Methods: We conducted a multicenter, retrospective study over a period of 10 years including patients with CRD receiving biological therapy for at least 6 months. LTBI diagnosis was based on a positive tuberculin skin test (TST) or QuantiFERON-TB Gold In-Tube test (QFT-GIT) without clinical symptoms, and bacteriological and radiographic signs of disease.
Results: 271 (154 men/117 women) were included, and the mean age of patients was 40.6± 12.9 years. The most common CRD was ankylosing spondylitis (57.9%) followed by rheumatoid arthritis (22.1%), psoriatic arthritis (12.2%), and spondyloarthritis associated with inflammatory bowel disease (4.8%). Patients received adalimumab in 117 (43.2%) cases, etanercept in 89 (32.8%) cases, infliximab in 40 (14.8%) cases, tocilizumab in 24 (8.9%) cases and anakinra in 1 case. Medical history of tuberculosis was noted in 3 cases and 4 patients have a history of household contact with tuberculosis. TST was performed in 186 cases and was positive in 13.2%. 261 patients underwent a QFT-GIT, which was positive in 16.9%. The diagnosis of active pulmonary tuberculosis was made in one patient who had positive TST and images of active tuberculosis in the chest X-ray. Quadruple therapy including rifampicin (10mg/kg/day), isoniazid (5mg/kg/day), pyrazinamide (25mg/kg/d) and ethambutol (15mg/kg/d) was prescribed for this patient. However, LTBI was diagnosed in 54 cases (19.9%), 29 had negative TST with positive QFT-GIT. 34 patients received a combination of rifampicin and isoniazid for three months and 20 received the isoniazid monotherapy for six months without developing active disease. Hepatotoxicity was observed in 5.6% of cases. The biological therapy was initiated 10.34±9.96 weeks after chemoprophylaxis, and 55.5% were treated with etanercept. After a follow-up of 23.5±15.7 months 4 cases of active tuberculosis infection were reported (2 lymph nodes, 1 pleural, and 1 intestinal tuberculosis) in patients with initially negative TST and QFT-GIT. One patient had TST conversion and received antibiotic prophylaxis.
Conclusion: Our study showed that the screening and chemoprophylaxis recommendations for LTBI improve the safety of biological treatments. However, because tuberculosis infection remains a potential complication, especially in endemic countries like Algeria, we suggest that annual screening of patients on biotherapy could reduce the risk of active tuberculosis.

AB1277 FACTORS ASSOCIATED WITH THE PRESENCE OF SPINAL EPIDURAL ABSCESS IN SPONDYLODISCITIS

Keywords: Infection-related RMDs

M. Ghali[1], M. Ardhaoui[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, University of Monastir, Rheumatology, Monastir, Tunisia*

Background: Spondylodiscitis (SD) is a severe infectious disease that affects the intervertebral disc and adjacent vertebral bodies, but may also extend to adjacent neural structures and cause a spinal epidural abscess (SEA). The clinical picture of SD is not very specific, but there are clinical and radiological differences that may point to an epidural extension.
Objectives: This study aimed to compare the clinical, biological, and radiological features of spondylodiscitis (SD) with and without spinal epidural abscess (SEA).
Methods: We conducted a retrospective monocentric study involving 90 cases of SD admitted between January 2009 and August 2022 at our rheumatology department. Clinical, laboratory, and radiological data of the patients were collected.
Results: Among the 90 patients with SD, 54 (60%) had a spinal epidural abscess. The mean age of the SEA group was 54 ± 13.52 years [23-82]. A female predominance was observed with a sex ratio (M/F) of 0.92. Thirty-seven patients or 68.5% had at least one comorbidity. Diabetes was the most frequent comorbidity (33.3%). All our patients had back pain on admission. Motor deficits were reported in 48% of the patients with the heaviness of the limbs. Fever was reported in 46.3% of cases. Physical examination revealed spinal stiffness in 23.3% of the patients, motor deficit in 37%, sharp osteotendinous reflexes in 18.5% of the patients, and abolished in 9.25%. The blood tests showed hyperleukocytosis in 18 patients (36%). An erythrocyte sedimentation rate greater (ESR) than 100mm at the first hour was found in 17 patients. C-reactive protein (CRP) greater than 100mg/ml was found in 14 patients. 64.8% had pyogenic spondylodiscitis (mainly Staphylococcus aureus), 11.1% had brucella spondylodiscitis and 24.1% had tubercular spondylodiscitis. MRI confirmed the diagnosis of SEA in all cases. The lesions were located at the cervical level in 9.2% of cases, at the dorsal level in 24 %, and at the lumbar level in 48.1% of cases. The lesions were anterior in 64.8% of cases and anterolateral in 35.2% of cases. The involvement was uni-focal in 63% of cases and extensive in 37% of cases. SEA was significantly more frequent in elderly patients (51.4% vs 48.6% p=0.038). The presence of a neurological deficit (80% vs 20% p=0.016), spinal cord compression (71.4% vs 28.6% p=0.04), and Multifocal involvement (82.6% vs 17.4% p=0.01) were significantly associated with SEA. There was no significant association between the types of germs and the presence of SEA.
Conclusion: In our study, a little more than half of patients with spondylodiscitis had a spinal epidural abscess. This entity was associated with advanced age, multifocal involvement, and neurological deficit. Therefore, a high index of suspicion is warranted when a patient presents these signs.

AB1278 ANALYSIS OF THE DIFFERENCES BETWEEN TUBERCULOSIS PROPHYLAXIS REGIMENS IN BIOLOGIC CANDIDATE PATIENTS

Keywords: Descriptive studies, bDMARD, Safety

L. Mendez Diaz[1], R. J. Gil Velez[1]. [1]*Seville, Rheumatology, Seville, Spain*

Background: Patients with systemic rheumatic disease present alterations in the regulation of the immune system, which may contribute to the reactivation of latent tuberculosis. That risk increases significantly in patients receiving biological treatment (approximately 10%, especially with infliximab). The detection and treatment of latent tuberculosis infection constitutes a fundamental pillar to prevent the evolution of the pathology in patients receiving biological therapy protocolized in the US in the year 2000 by the FDA. Multiple studies have shown that diagnosis and treatment of latent tuberculosis infection is the best method of preventing progression to active tuberculosis.
To prevent that condition que have two types of treatment schemes:
-The short chemoprophylaxis regimen,consisting of the administration of isoniazid together with rifampicin for 3 months
-The long chemoprophylaxis regimen consisting of the administration of isoniazid for a period of 6 months without interruption.
Objectives: To analyze the efficacy,safety and to difference the treatment adherence between the two regimens of chemoprophylaxis in patients who are candidates to start biologic therapy with latent tuberculosis.
Methods: Retrospective descriptive study of a cohort of patients who start biological therapy between (January-December 2021), in the Rheumatology Service of Virgen del Rocio Hospital. Latent tuberculosis screening protocol was performed by Mantoux/Booster and IGRA tests.
Results: We included a total of 223 patients in the study who started treatment with biological therapy, during a period of 12 months, 125 (58,13%) of those where men, 90 patients (41,8%) were women with a mean age of 51.4 years. We started chemoprophylaxis in 32 patients, of whom 15 (46.8%) received short therapy with

isoniazid/rifampicin daily for 3 months, only 1 patient he had to discontinue treatment due to hepatotoxicity. The rest of the patients 17 (53.2%) underwent long therapy for 6 months with isoniazid 300 mg every 24 hours, completing it in 94.2% of the cases. Only one patient had to discontinue due to persistent nausea.

Conclusion: After analyzing the data of our cohort of patients candidates to start biological therapy and after having performed the screening for latent tuberculosis infection(as can be seen in the Table 1 below) a homogeneous group (46.8% in the case of short regime) and (53.2% in the case of long regime) were treated with chemoprophylaxis, without significant differences in terms of adverse effects or adherence in the two therapies performed. The most common cause of discontinuation in both groups was hypertrasaminasaemia and nausea. No tuberculosis reactivation has occurred in any of the groups. Therefore, we conclude that short term therapy is as safe as long therapy and with similar patient adherence. However, long-term studies with a larger number of patients are required to evaluate the two treatment regimens.

AB1279 CLINICAL FEATURES AND FUNCTIONAL OUTCOME OF SURGICALLY TREATED TUBERCULOUS AND BRUCELLAR SPONDYLODISCITIS IN TUNISIA

Keywords: Infection-related RMDs, Motor function

M. Ghanmi[1], N. El Fani[1], S. Mtawaa[1], M. Rouiss[2], H. Sakly[2], M. Gaddour[3], W. Wanes[3], S. Jemni[3]. *[1]University Hospital Ibn Jazar Kairouan, Physical Medicine and Rehabilitation, Kairouan, Tunisia*; *[2]University Hospital Ibn Jazar Kairouan, Infectious Diseases, Kairouan, Tunisia*; *[3]University Hospital Sahloul, Physical Medicine and Rehabilitation, Sousse, Tunisia*

Background: Tuberculous and brucellar spondylodiscitis are still a frequent condition in the Mediterranean countries [1]. Management of spondylodiscitis may require surgical procedures in case of spinal cord or root compression, bone destructions and deformities, unsuccessful medical treatment or large abscesses.

Objectives: To study characteristics and outcome of surgically treated tuberculous and brucellar spondylodiscitis.

Methods: Medical records of patients who presented to the physical therapy and rehabilitation ward or outpatient clinics after spine surgery for spondylodiscitis were retrospectively studied. The study included records from January 2010 to December 2022.

Results: Thirty-two patients were diagnosed with spondylodiscitis for which they underwent surgery. Mean age of diagnosis was 44,6 ± 10.4 years. The sex ratio was 1:1. Atypical presentations caused diagnosis to be delayed in 37,5% of the patients. Back pain was the most frequent symptom seen in 78,12% of the cases, radicular pain was seen in 46,7% of the cases, fever in 37,5% of the patients and abnormal gait in 68,7% of the cases. Tuberculosis caused 71,8% of cases and brucellar infection 28,1% of the cases. On biology, elevated inflammatory markers were noted in 68,7% of the cases. Intradermal reaction for tuberculosis was positive in 11 patients while cultures allowed the diagnosis of tuberculosis in 1 patient. Wright serology test confirmed the diagnosis of brucellar infection in all 9 cases. Vertebral biopsy or intraoperative samples allowed the diagnosis of the tuberculous spondylodiscitis in the remaining cases. Cervical spine location was involved in 9,3% of cases, lumbar spine in 43,75% and dorsal spine in 34,3% of the cases. All patients have been prescribed antibiotics and spinal immobilization. Surgery was indicated in 71.8% of cases for spinal cord decompression and in 28.1% of the cases for voluminous abcesses. Anterior approach was used in 9,3% of the cases and posterior approach in 90.6% of cases. 37.5% of the patients benifited concomitantly with spinal fusion surgery. Post-operative complications were reported in 43,75% of the cases. They consisted in spinal instability in 71,4% of the cases, abcesses in 14,28% of the cases and the emergence of secondary articular localizations in 28,57% of the cases. 25% of the patients underwent a second surgery mainly to stabalize the spine. Before surgery, walking was impossible for 68,7 % of the patients and 12 months after surgery only 37,5% of the patients couldn't walk.

Conclusion: Spinal surgery in tuberculous or brucellar spondylitis are indicated if medical treatment is insufficient and especially in the occurrence of neurological complications. Surgery may be invasive with various complications but sometimes it could be the only option to treat a neurological deficit.

AB1280 PREVALENCE OF LEISHMANIASIS IN A SAMPLE OF PATIENTS TREATED WITH BIOLOGIC THERAPIES

Keywords: Infection-related RMDs, Spondyloarthritis, bDMARD

E. Monleon Acosta[1], G. Albaladejo Paredes[1], A. Perez Gonzalez[1], A. Uceda Galiano[1], J. M. Andreu Ubero[1], J. Moreno Morales[1], F. J. Rodriguez Martinez[1], V. Cogolludo Campillo[1], E. Soriano Navarro[1], M. R. Oliva Ruiz[1], J. León Navarro[1], F. Pedrero Martínez[1], R. Gimenez Andreu[1]. *[1]Hospital General Universitario Santa Lucía, Rheumatology, Cartagena, Spain*

Background: Leishmaniasis is an infectious disease caused by an intracellular parasite of the genus Leishmania. According to the clinical expression, it can be identified: subclinical, cutaneous (CL) and visceral leishmaniasis (VL). The immune response triggered in this type of infections is based in the activation of the TH1 pathway, in which molecules such as TNF α and interleukins such as IL 12 and IL1 are involved [1,2]. In recent years, an increase in the incidence of opportunistic infectious diseases, such as leishmaniasis, has been observed in patients with rheumatological diseases under treatment with anti-TNFα drugs, such as Psoriatic Arthritis (PsA), Ankylosing Spondylitis (AS) or Rheumatoid Arthritis (RA) [1,3,4].

Objectives: Evaluate the prevalence of Leishmaniasis in a sample of patients in a hospital center in treatment with biologic therapies. As secondary objective, study the characteristics of the patients with Leishmania.

Methods: It can been carried out an observational, descriptive, retrospective, and single-center study. The sample consisted of patients followed in a rheumatology department between January 1, 2022 and January 1, 2023, whose only inclusion criteria was to be in treatment with biologic therapies, including a total of 720 subjects, and, only five patients were found with de diagnosis of leishmaniasis.

Results: Five patients were found diagnosed with leishmaniasis in the 720 subjects on biological treatment included in the sample, which represents a prevalence of 0.69%. Three patients were male (60%) and two were female (30%). The mean age was 52.164 ± 10.38 years with a mean duration of rheumatic disease of 13.2 ± 7.8 years. All the subjets were diagnosed with spondyloarthritis: 3 with AS (60%), 1 with PsA (20%) and another with spondyloarthritis associated with inflammatory instetinal

disease (20%). About the forms of leishmaniasis, four subjects were diagnosed with CL (80%) and only one patient was diagnosed with LV (20%). The 100% of the patients diagnosed with LC were on treatment or had been on treatment before with an antiTNFα (75% with adalimumab and 25% with infliximab). The only case diagnosed with LV, was in treatment with an anti-IL 17, although the patient had been on adalimumab up to 3 months prior to diagnosis. It can be stated that 100% of the patients diagnosed with leishmaniasis had received treatment with an anti-TNFα, with a mean duration of the treatment of 6.94 ± 4.7 years.

Table 1. Subjects diagnosed with leishmaniasis included in the study.

Gender/Age	Disease	Current biological	CL/VL	Localization
M43	AS	ADALIMUMAB	LC	thigh
M48	Spondyloarthritis	ADALIMUMAB	LC	elbows
M62	AS	INFLIXIMAB	LC	elbow
W40	PsA	SECUKINUMAB	LV	
W66	AS	ADALIMUMAB	LC	elbow

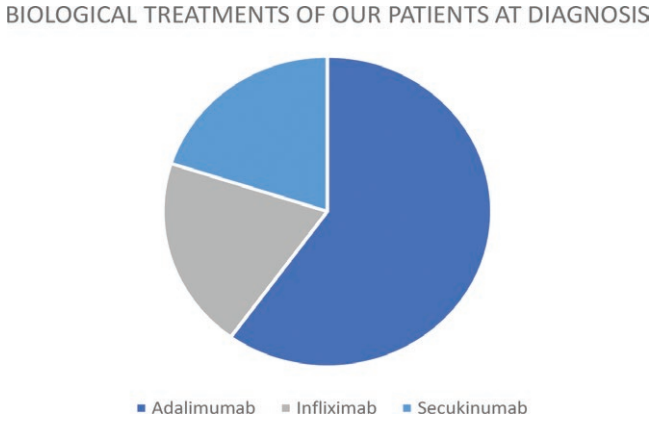

Figure 1. Biological treatment administered at the time of diagnosis of leishmaniasis.

Conclusion: In the present study, 100% of the subjects suffering from Leishmaniasis were on treatment with an anti-TNF α molecule, being adalimumab the most frequent, which coincides with other case series published in the literature.

AB1281

PREDICTIVE FACTORS FOR FAILURE OF NON-OPERATIVE TREATMENT OF SPONDYLODISCITIS ASSOCIATED WITH SPINAL EPIDURAL ABSCESS

Keywords: Infection-related RMDs

M. Ghali[1], M. Ardhaoui[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, University of Monastir, Rheumatology, Monastir, Tunisia*

Background: Spinal epidural abscess (SEA) associated with infectious spondylodiscitis is a rare but serious pathology. It is a serious complication and difficult to diagnose at an early stage. With enough knowledge of risk factors and clinical features, it may be possible to reduce diagnostic delay and treatment failure.

Objectives: The objective of our work was to describe the clinical, radiological, therapeutic, and evolutionary particularities of SEA during infectious spondylodiscitis and to determine factors associated with the failure of conservative treatment.

Methods: We conducted a retrospective study of 54 cases of SEA associated with infectious spondylodiscitis over a period of 13 years [January 2009-April 2022] in the rheumatology department of the Fattouma Bourguiba University Hospital of Monastir. The diagnosis of SEA was retained in clinical, biological, and radiological data.

Results: The mean age was 54 ± 13.52 years [23-82]. A female predominance was observed with a sex ratio (M/F) of 0.92. Thirty-seven patients or 68.5% had at least one comorbidity. Diabetes was the most frequent comorbidity (33.3%). All our patients had back pain on admission. Motor deficits were reported in 48% of the patients with the heaviness of the limbs. Fever was reported in 46.3% of cases. Physical examination revealed spinal stiffness in 23.3% of the patients, motor deficit in 37%, sharp osteotendinous reflexes in 18.5% of the patients, and abolished in 9.25%. The blood tests showed hyperleukocytosis in 18 patients (36%). An erythrocyte sedimentation rate greater (ESR) than 100 mm at the first hour was found in 17 patients. C-reactive protein (CRP) greater than 100 mg/ml was found in 14 patients. 64.8% had pyogenic spondylodiscitis (mainly Staphylococcus aureus), 11.1% had brucella spondylodiscitis and 24.1% had tubercular spondylodiscitis. MRI confirmed the diagnosis of SEA in all cases. The lesions were located at the cervical level in 9.25% of cases, at the dorsal level in 24.07%, and at the lumbar level in 48.14% of cases. The lesions were anterior in 64.8% of cases and anterolateral in 35.2% of cases. The involvement was uni-focal in 63% of cases and extensive in 37% of cases. All our patients had received antibiotic therapy, initially probabilistic and then adapted to the bacteriological results. Immobilization of the spine was indicated in all our patients. Six patients had undergone decompressive surgery after failure of conservative treatment and worsening of the neurological deficit. This treatment consisted of a decompressive laminectomy with debridement of infected tissues. SEA was more frequent in elderly patients (p=0.038), those with a neurological deficit (p=0.016), the presence of spinal cord compression (p=0.04), and in multifocal involvement (p=0.01). When comparing the spinal epidural abscess groups according to the isolated germ, only the diagnostic delay was significantly more important in the course of the brucella SEA (p <0.004). Factors associated with poor evolution under conservative treatment were: diagnostic delay with OR = 0.324 [IC à 95%:0.135-0.777] (p=0.01), neurological deficit with OR = 2.418 [1.187-4.926] (p<0.001), spinal cord compression with OR = 2.77 [1.5-5.07] (p<0.001), and alteration of the general state with OR = 1.41 [1.05-1.87] (p=0.041).

Conclusion: The classical clinical triad of the infectious SEA (back pain + fever + neurological deficit) is not specific enough, hence the delay in diagnosis which has a negative influence on the prognosis. MRI and bacteriological investigation confirms the diagnosis. Early surgical intervention with intravenous antibiotic therapy may be the best choice, especially in patients with progressive neurological deficits. Conservative treatment may be indicated for some patients.

Infection-related rheumatic diseases

AB1282 CLINICAL AND RADIOLOGICAL FEATURES IN BRUCELLA SPONDYLODISCITIS: A DESCRIPTIVE STUDY

Keywords: Epidemiology, Pain

M. Ghanmi[1], N. El Fani[1], S. Mtawaa[1], R. Moncer[2], M. Gaddour[1], W. Wanes[2], S. Jemni[2]. *[1]University Hospital Ibn Jazar Kairouan, Physical Medicine and Rehabilitation, Kairouan, Tunisia*; *[2]University Hospital Sahloul, Physical Medicine and Rehabilitation, Sousse, Tunisia*

Background: Spondylodiscitis is an infectious inflammation that affects the vertebrae, vertebral discs and adjacent structures. Vertebral involvement during brucellosis is considered not only as the most frequent localization but also as the most severe one.
Objectives: The aim of the present study was to describe the clinical and the magnetic resonance imaging features of brucella spondylodiscitis.
Methods: We conducted a retrospective study including 11 patients who have presented in the outpatient clinics of physical medicine and rehabilitation for spinal brucellosis with or without neurological disorders from 2016 to 2021. The diagnosis of brucellosis was based on clinical symptoms, MRI findings and isolation of brucella species in blood or tissue specimens and/or a positive Wright agglutination test.
Results: Eleven patients were included. The mean age was 52.5 years [33-74] (6 males and 5 female). The consumption of unpasteurized dairy was found in 4 patients. The main symptom was an inflammatory back pain and it was found in all patients. It was associated with radiculopathy in 8 cases. The other clinical symptoms were fever in 10 patients, sweats in 4 cases, weight loss in 4 cases and hepatomegaly in 1 patient. The median delay before diagnosis was 5,2 months [1-7]. On examination, we revealed tenderness on palpation in 10 cases and muscular weakness of lower limbs in 5 cases. Brucella agglutination test was ≥1/160 in all cases. Blood cultures were negative in all cases. Median erythrocyte sedimentation rate (ESR) and serum C-reactive protein level were 42 mm and 15 mg/dl respectively. Spondylodiscitis was located in the lumbar dorsal and cervical spine in respectively 8, 2 and 1 cases. The involvement of more than 2 vertebrae was found in 2 cases. The most affected level were the L4-L5 level in 3 cases followed by the T10-T11 level in 2 cases. Associated sacroiliitis was found in one patient. All MRI images of the affected vertebrae showed hypo intense signal on T1 weighted image and hyper intense signal on T2 weighted image. Disc space narrowing was documented in 8 cases. Vertebral body osteolysis was found in 5 cases. Epidural collection was found in 3 cases with a size up to 5cm. Paravertebral and peri-vertebral abscesses were detected in 3 cases. Intradiscal abscesses were observed in 2 cases. Cord compression and involvement of root nerve were noted in respectively 5 and 1 cases. Biopsy was performed in 5 cases, but bacteriological examination was contributory to the diagnosis in 1 case. All patients received antibiotic treatment with a combination of two or three drugs, corticosteroids were prescribed in 5 patients and four patient underwent a surgical intervention.
Conclusion: Although not always specific, MRI findings associated with clinical symptoms may help establish the diagnosis of brucella spondylodiscitis even if bacteriological examinations are negatives [1].

Background: The COVID-19 pandemic has brought uncertainties to rheumatology practice, mainly related to the possibility of triggering disease activity after infection in immune mediated rheumatic diseases (IMRD). To date, there are few data in the literature specifically evaluating this issue.
Objectives: Evaluate the disease activity in IMRD patients after 6 months of the infection, compared to pre infection status.
Methods: ReumaCoV Brasil is a longitudinal study performed at 35 study centers designed to follow-up IMRD patients for 6 months after clinical or laboratorial COVID-19 diagnosis (cases), comparing with patients with IMRD who had not had the infection at the time of inclusion (controls). Demographic data such as age, sex, comorbidities, clinical characteristics, treatment, evolution of COVID-19 and disease activity status were collected using a Research Eletronic Data Capture (REDCap) database on three consecutive visits (inclusion and 6 months). The analysis was carried out on the four diseases with the highest inclusion number in the study: systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA). In addition to specific disease activity assessment metrics, we used patient's global assessment of disease activity (PGA), ranging from 0 to 10, at all visits, with 0 being no activity and 10 being intense activity. All conclusions were drawn considering the significance level of 5%. This study was registered at the Brazilian Registry of Clinical Trials—REBEC, RBR-33YTQC. All patients read and signed the informed consent form before inclusion.
Results: Between May 2020 and January 2021, 2032 patients were included in the registry, and of these, 1322 patients (721 cases and 601 controls), completed 6 months of follow-up, being 550 SLE (42.0%), 497 RA (37.6%) and 176 SpA (13.3%) and 99 (7.4%) PsA. Most patients were female (82.0%); the median age was 46.7 (13.8). Disease activity at the time of enrollment, according to the PGA, was similar between cases and controls, except for patients with RA and AS, where it was higher in controls. After the follow up time, no worsening of activity was observed in any of the diseases evaluated in the case group (Table 1). Despite this, worsening of disease symptoms after COVID-19 was reported by 23.3%, 24.6%, 25.0% and 25.8% of patients with SLE, RA, AS and PsA respectively, not related with disease activity.
Conclusion: In patients with IMRD, no worsening of disease activity was observed after COVID-19 in this cohort of Brazilian patients. Despite this, many patients noticed worsening of symptoms, possibly associated not with the triggering of the activity, but with the so-called long COVID syndrome.

Table 1. Comparison of disease activity, according to PGA, comparing disease activity status at inclusion and after 6 months of follow up, in cases and controls

	INCLUSION			AFTER 6 MONTHS		
	Cases	*Controls*	p-value	*Cases*	*Controls*	p-value
SLE	2 (0-4,5)	2 (0-4)	0,810	2 (0-5)	2 (0-4)	0,172
RA	3 (1-5)	4 (2-6)	0.001	3 (1-5)	3 (1-5,5)	0,731
AS	2 (0-5)	4 (1-6)	0,002	2 (0-5)	3,5 (1-6)	0,044
PsA	2 (0-4)	2 (0-5)	0,816	2 (0-5)	2 (0-5)	0,939

AB1284 COMPARISON OF THE EFFECTS OF COVID-19 AND INFLUENZA VACCINATION ON RHEUMATIC DISEASES: ANALYSES OF PATIENT SURVEY DATA AFTER VACCINATION

Keywords: Patient reported outcomes, Real-world evidence, Vaccination/immunization

J. W. Kim[1], H. A. Kim[1], J. Y. Jung[1], C. H. Suh[1]. *[1]Ajou University School of Medicine, Rheumatology, Suwon, Korea, Rep. of (South Korea)*

Background: As the coronavirus disease 2019 (COVID-19) pandemic continues worldwide, vaccination has been considered an essential medical care to protect people from the COVID-19 and end the pandemic. While vaccine development programs and reported epidemiological data are reassuring us, concerns about the risks and adverse events associated with vaccination in patients with rheumatic diseases.
Objectives: The purpose of this study was to analyse the incidence of adverse events and disease flares after vaccination against COVID-19 and influenza in patients with rheumatic diseases.
Methods: From November 2021 to March 2022, a survey was conducted on those who received COVID-19 and influenza vaccinations among patients with rheumatic diseases at Ajou University Hospital. The questionnaire contained questions about medical history, immunization history, type of injected vaccines, patient-reported adverse events and flare-up of the underlying disease after vaccination, and confirmed diagnosis of COVID-19 or influenza. Based on the results of the survey, we compared the incidence of vaccine-related adverse reactions between the COVID-19 and influenza vaccine and identified the factors affecting adverse events or disease flare.
Results: A total 601 valid questionnaires were obtained. The mean age of patients who participated in the survey was 49.6 years and 80.5% of female. Two hundred fifty-five participants (42.4%) received the complete course of primary vaccination, 342 (56.9%) participants completed the booster dose, and 132 (38.6%) of them received mixing vaccine. The frequency of adverse events (188 [52.2%] vs. 21 [5.8%]; p <0.001) and disease flare (58 [16.2%] vs. 5 [1.4%]; p<0.001) after the COVID -19 vaccination was significantly higher than that of the influenza vaccination. In the risk factor analysis, previous allergic reaction to other vaccination (OR 1.95, CI 1.07-3.70; p=0.034) was the only factors associated with the occurrence of adverse events. Female sex (OR 2.64, CI 1.29-6.17; p=0.014) was associated with higher odds of rheumatic disease flare relative to the male. There was no difference in the post-vaccine response between the mixing and matching vaccine.
Conclusion: In a real-world survey conducted on patients with rheumatic diseases, patient-reported adverse events and underlying disease flares after the COVID-19 vaccine was significantly higher than that of the influenza vaccine.

AB1285 MODELING OF ANTIBODY RESPONSE TO COVID-19 VACCINATIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, COVID, Vaccination/immunization

Y. K. Kim[1], Y. Choi[2], J. I. Jung[1], J. Y. Kim3, M. H. Kim3, J. Curtis[4], E. B. Lee[1]. *[1]Seoul National University Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[2]Seoul National University Hospital, Medical Research Collaborating Center, Seoul, Korea, Rep. of (South Korea)*; *[1]Seoul National University Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[4]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, United States of America*

Background: Understanding the dynamics of humoral immunity after COVID-19 vaccination is crucial in developing vaccination strategies. Antibody response patterns are more complex in patients with rheumatoid arthritis (RA) because of their underlying autoimmunity and immunosuppressive medications. The kinetics of vaccine response in RA patients are not well understood.
Objectives: To construct a model of antibody response to COVID-19 vaccination in patients with RA.
Methods: Two patient groups were included for the study. The first group was composed of RA patients who were enrolled for influenza vaccination study between Oct 6, 2021 and November 3, 2021, in whom serial serum samples were obtained 0, 4, 16 weeks after vaccination. The second group was consecutively enrolled from outpatient clinic between October 6, 2021 and June 3, 2022, in whom serum sample was obtained once. After collecting data on demographics, vaccination and infection history of COVID-19 were obtained by self-report via questionnaire and data from Korean center for disease control. We then measured antibody titers against receptor binding domain of spike protein (anti-RBD) and nucleocapsid (anti-N), using Chemiluminescence microparticle immunosaasy (Abbott, USA) and Electrochemiluminescence immunoassay (Roche, Germany) respectively. The anti-RBD titer was log-transformed to improve normality. Time from vaccination and log of anti-RBD titer was modeled using fractional polynomial. Covariates including age, sex, BMI, underlying disease and immunosuppressive drugs were analyzed using Generalized Estimating Equations to account for repeated measured from a subject.
Results: A total of 736 patients (1042 samples) were enrolled. After excluding patients who experienced COVID-19 infection before sampling (n=84), those unvaccinated (n=44) and uncertain COVID-19 infection history (n=59), the data on 778 samples from 549 patients were analyzed (Group 1: 125, Group 2: 424). Antibody titer reached peak at 12 days after vaccination and decreased exponentially (Figure 1) which fell to 36.5% from peak after 2 months. Compared to the first vaccination, the 3rd and 4th vaccination significantly shifted anti-RBD antibody response curve (28 times, 95% CI 4~195; 32 times 95% CI 4~234, respectively). However, there was no significant shift after the 4th vaccination from the 3rd vaccination (p=0.6405). Multivariable analysis showed that number of vaccinations and sulfasalazine (coefficient: 0.40, 95% CI 0.12~0.68) increased vaccine response but age (coefficient: -0.03, 95% CI -0.04~-0.02), abatacept (coefficient: -2.07, 95% CI -3.30~-0.84) and, JAK inhibitor (coefficient: -0.82, 95% CI -1.34~-0.31) decreased vaccine response.
Conclusion: Anti-RBD response to COVID-19 vaccination showed a peak at 12 days after vaccination and then exponentially decreased in patient with RA. The antibody response is affected by age and medications used for the treatment of RA.

AB1286 HUMORAL AND CELLULAR IMMUNOGENICITY INDUCED BY THIRD BOOSTER OF SARS-COV-2 VACCINES IN PATIENTS WITH RHEUMATIC MUSCULOSKELETAL DISEASES

Keywords: Vaccination/immunization, COVID

Y. Kondo[1], M. Takeshita[1], S. Saito[1], J. Kikuchi[1], H. Hanaoka[1], K. Suzuki[1], Y. Kaneko[1]. *[1]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Amid the coronavirus disease 2019 (COVID-19) crisis, two messenger RNA (mRNA) vaccines against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) have benefited most people worldwide. While healthy people can acquire sufficient humoral immunity against COVID-19 even in the elderly by vaccination with three doses of vaccine., recent studies have shown that complex factors other than age, including the type of vaccines and immunosuppressive drugs, are associated with immunogenicity in patients with rheumatic musculoskeletal disease (RMD). Identifying factors that contribute to the vulnerability of those patients to acquire not only humoral but also cellular immunity to SARS-CoV-2 despite multiple vaccinations is crucial for establishing an appropriate booster vaccine strategy.
Objectives: To assess humoral,and T cell immune responses after third doses of mRNA vaccines against SARS-CoV-2.
Methods: This prospective observational study included consecutive RMD patients treated with immunosuppressant who received three doses of mRNA vaccines including BNT162b2 and mRNA-1273. Blood samples were obtained 2-6 weeks after second and third dose of mRNA vaccines. We measured neutralizing antibody titres, which against the receptor-binding domain (RBD) of the spike protein of SARS-CoV-2 and seroconversion rates to evaluate the humoral responses. We also assessed T-cell immunity responses using interferon releasing assay against SARS-CoV-2.
Results: A total of 586 patients with RMD treated with mmunosuppressive treatments were enrolled. The mean age was 54 years, and 70% of the patients were female. Seroconversion rates and neutralizing antibody titres after third vaccination of SARS-CoV-2 were significantly higher compared to those after second vaccination (seroconversion rate, 94.5% vs 83.6%, p<0.001; titres of neutralizing antibody, 48.2 IU/mL vs 11.0 IU/mL, p<0.001, respectively). Interferon releasing assay after third vaccinations demonstrated that T cell reaction against SARS-CoV-2 was also increased from that of second vaccination (interferon for antigen 1, 1.11.9 vs 0.61.9, p=0.004,interferon for antigen 2, 1.72.6 vs 0.82.3, p=0.004). Humoral and cellular immunogenicity did not differ between the types of third vaccination including full dose of BNT162 and half dose of mRNA1273.(neutralizing antibody titers, 47.8±76.1 IU/mL vs 49.0±60.1 IU/mL, p<0.001; interferon for antigen 1, 1.12.0 vs 1.01.5, p=0.004, respectively). Attenuated humoral response to third vaccination was associated with BNT162b2 as second vaccination age (>60 years old), glucocorticoid (equivalent to prednisolone > 7.5 mg/day), and immunosuppressant use including mycophenolate, and rituximab. On another front, use of mycophenolate and abatacept or tacrolimus but not rituximab were identified as negative factors for T-cell reactions against SARS-CoV-2. Although 53 patients (9.0%) who had been immunised with third-vaccination contracted COVID-19 during Omicron pandemic phase, no one developed severe pulmonary disease that required corticosteroid therapy.
Conclusion: Our results demonstrated third mRNA vaccination booster of SARS-CoV-2 contributed to restore both humeral and cellular immunity in RMD patients with immunosuppressants. We also identified that certain immunosuppressive therapy with older RMD patients having BNT162b2 as a second vaccination may need additional booster vaccination.

AB1287 FACTORS ASSOCIATED WITH ADHERENCE TO ANTI TNF-A THERAPY DURING THE COVID-19 PANDEMIC IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, bDMARD, COVID

W. G. Rojas Zuleta[1], M. Barbosa[1], O. J. Felipe Díaz[1], A. E. Pantoja Marquez[1], J. Canizales[1], C. Becerra-Arias[1], J. H. Donado Gómez[1], N. Duque Zapata[1]. *[1]Medicarte SAS, Center for Immune-Mediated Diseases, Medellín, Colombia*

Background: Rheumatoid Arthritis (RA) patients are effectively treated with anti-TNF-α therapy. However, pharmacological non-adherence limits the achievement of the therapeutic objective. This is a multifactorial behavior where factors such as the route of administration, frequency, tolerance, perception of improvement, polypharmacy and social factors are involved [1,2].
Objectives: To explore the factors associated with non-adherence to anti TNF-α in RA patients during the COVID-19 pandemic.
Methods: This is a cohort of RA patients treated with anti TNF-α in Medicarte SAS, a Colombian center for Immune-Mediated Diseases, between January to December 2021. The program implements strategies such as pharmacotherapeutic support, informed dispensing, phone calls, text messages and home care services to increase adherence. Adherence was defined as dispensing at least 10/12 (>0.80) prescribed monthly doses for 1 year. Sociodemographic characteristics, time in the program, DAS28-CRP, HAQ and treatment were included as exposure variables. For continuous variables, median and interquartile range (IQR) were calculated. Adjusted Odds Ratio (AOR) with logistic regression were calculated, and a p-value <0.05 was considered as statistically significant.
Results: 565 patients were included, 85.8% (n=485) were women, median age 56 years (IQR: 49-65), disease evolution time 13.7 years (IQR: 7.7-20.8), 51% (n=288) had been in the program for more than 3 years, the median time in treatment with anti TNF-α was 3 years (IQR: 1-3) and DAS-28-CRP 2.4 (IQR: 1.6-3.4). The most frequently anti TNF-α prescribed was etanercept 46.0% (n=260), followed by adalimumab 23% (n=130), subcutaneous golimumab 13.3% (n=75), certolizumab 11.0% (n=62) and intravenous golimumab 6.7% (n=38). At the admission, 18.2% (n=103) of the patients had high activity, 38.6% (n=218) mild activity, 9.2% (n=52) low activity and 34% (n=192) were in remission. At the end of follow-up, 6.4% (n=36) of patients had high activity, 18.2% (n=103) mild activity, 14.3% (n= 81) low activity and 61.1% (n= 345) were in remission. The 51.5% (n=291) did not have pharmacological adherence. The use of etanercept (AOR 0.36 CI95% 0.23- 0.58, p < 0.001) and adequate functionality measured through

HAQ (AOR 0.64 CI95% 0.42- 0.97, p < 0.04) were associated with a lower risk of non-adherence. Higher DAS28-CRP at the end of follow up was associated with non-adherence (AOR 1.29 CI95% 1.12 - 1.48, p < 0.001).

Conclusion: During COVID-19 pandemic, the implementation of strategies in the home care patient program guaranteed adherence close to 50% in our cohort. Higher values of DAS28-CRP were associated with non-adherence, whilst etanercept use and a normal HAQ value were associated with a higher probability of adherence.

AB1288 LONG-TERM AND BOOSTER VACCINATION RESPONSES IN PATIENTS WITH GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA

Keywords: Vaccination/immunization, Vasculitis, Disease-modifying drugs (DMARDs)

Y. Van Sleen[1], K. Van der Geest[1], A. Buisman[2], M. Sandovici[1], D. Van Baarle[3], E. Brouwer[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]National Institute for Public Health and the Environment, Centre for Infectious Disease Control, Bilthoven, Netherlands*; *[3]University Medical Center Groningen, Medical Microbiology and Infection Prevention, Groningen, Netherlands*

Background: Vaccination remains essential in preventing morbidity of SARS-CoV-2 infections. We previously showed that >10mg/day prednisolone and methotrexate use were associated with reduced antibody concentrations four weeks after primary vaccination in patients with giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) [1].

Objectives: Here, we performed a follow-up study to measure the decay of antibody concentrations over time and the immunogenicity of SARS-CoV-2 booster vaccination.

Methods: GCA/PMR patients included in the primary vaccination (BNT162b2 or ChAdOx1) study were asked again to donate blood samples six months after primary vaccination (n=24) and one month after booster vaccination (n=46, BNT162b2 or mRNA1273). Data were compared to that of age-, sex-, and vaccine-matched controls (n=58 and n=42, respectively).

Results: Antibody concentrations decreased faster over time in GCA/PMR patients than in controls, but this decrease was not associated with treatment during primary vaccination. Post-booster antibody concentrations were comparable between patients and controls. Antibody concentrations post booster vaccination associated strongly with antibody concentrations post primary vaccination, but not with treatment during booster vaccination. However, the fold-change of post-booster vaccination showed a slight negative correlation with the post-primary vaccine antibodies.

Conclusion: These results indicate that patients with impaired vaccine responses after primary vaccination, have slightly stronger increases in humoral immunity after booster vaccination, but this is not enough to reach a similar protection. The decrease in humoral immunity, and subsequent increase after booster vaccination, is likely not impacted by prednisolone or methotrexate treatment. Rather, these treatments put the patients at an immunogenic disadvantage during primary SARS-CoV-2 vaccination, which is not fully repaired by a single booster vaccination. This longitudinal study in GCA/PMR patients stresses the importance of repeat booster vaccination for patients that used >10mg/day prednisolone or methotrexate during primary vaccination.

Background: Some individuals may have persistent symptoms after COVID-19, a new condition known as long COVID-19. However, these complaints can be misunderstood with disease activity in patients with immune-mediated rheumatic diseases (IMRD), especially fatigue and mental distress.

Objectives: To evaluate fatigue, depression, anxiety, and stress in IMRD patients after 6 months of COVID-19, compared with IMRD patients without COVID-19.

Methods: The ReumaCoV Brasil is a longitudinal study designed to follow-up IMRD patients for 6 months after COVID-19 diagnosis (cases) compared with IMRD patients no COVID-19 (controls). Clinical data, such as age, sex, comorbidities, as well as disease activity measurements and current treatment regarding IMRD, and COVID-19 outcomes were evaluated in all patients. The FACIT questionnaire (Functional Assessment of Chronic Illness Therapy) and the DASS 21 (Depression, Anxiety and Stress Scale - 21 Items) were applied at 6 months after COVID in both groups.

Results: A total of 606 IMRD patients were included, of whom 322 (53.1%) cases and 284 (46.9%) controls. Most patients were female (85.3%) with mean age 46.1 (13.0) years old. Specific disease activity were similar between cases and controls. There was a significant difference between FACIT scores and 3 domains of DASS-21 comparing cases and controls (Figure 1). The factors associated with FACIT were female gender, diabetes, obesity, no comorbidities, COVID manifestations (skin, joint pain, asthenia, diarrhea, and dyspnea), and chronic oral corticosteroid use. DASS-21 Depression was associated with these same factors. Female gender, COVID manifestations as skin, joint pain, asthenia, cough, dyspnea, and chronic oral corticosteroid use were associated with DASS-21-Anxiety. DASS-21 Stress was associated with female gender, asthenia,

Table 1. Final model using binary Logistic Regression analysis to evaluate the preditive factors associated with FACIT and DASS-21 scores

FACIT *Score ≤ 37 x score > 37*[§]			**DASS-21-DEPRESSION** *Score ≤ 6 (normal/mild) x score > 6 (moderate/ severe*			**DASS-21-ANXIETY** *Score ≤ 5 (normal/mild) x score > 5 (moderate/ severe)*			**DASS-21-STRESS** Score ≤ 9 (normal/mild) x score > 9 (moderate/ severe		
Variable	P-value	OR (CI 95%)	Variable	P-value	OR (CI 95%)	Variable	P-value	OR (CI 95%)	Variable	P-value	OR (CI 95%)
Female	0.15	1.83 (1.12-2.98)	No comorbidities	0.029	0.66 (0.46-0.95)	Joint pain	0.002	2.44 (1.39-4.26)	Female	0.012	2.31 (1.20-4.46)
Diabetes	0.006	2.35 (1.28-4.32)	Joint pain**	0.001	2.58 (1.57-4.22)	Dyspnea	0.001	3.61 (2.11-6.19)	Dyspnea	0.001	3.69 (2.09-6.51)

Joint pain	0.005	2.20 (1.41-3.43)	Oral CE	0.048	1.41 (1.00-1.99)						

[§]Lower scores mean worse fatigue; CE: corticosteroid; OR: odds ratio; CI: confiance interval

diarrhea, dyspnea, cough, chronic oral corticosteroid use, and hospitalization. Table 1 shows the variables that remained in the models after the univariate logistic analysis. A weak correlation between disease activity and FACIT was observed in rheumatoid arthritis (p=0.010; r^2 = 0.035) and ankylosing spondylitis patients (p=0.010; r^2 = 0.129). No other correlations were observed between the scores results and disease activity (patient's global assessment - PGA), medications or specific IMRD.

Conclusion: Fatigue and mental changes such as depression, anxiety, and stress, occurred more frequently in IMRD patients who had COVID-19 than in those who did not have COVID-19, especially in women, regardless of disease activity score. Fatigue was more related to female gender, diabetes, obesity, and current joint pain. Mental impairment was more associated with severity of COVID-19, including respiratory and non-respiratory symptoms.

AB1290 **IMPACT OF THE COVID-19 PANDEMIC ON SEPTIC ARTHRITIS MANAGEMENT**

Keywords: Descriptive studies, COVID

S. Zemrani[1], B. Amine[1], I. EL Binoune[1], S. Rostom[1], R. Bahiri[1]. [1]*El Ayachi Hospital, Ibn Sina University Hospital, Department of Rheumatology A, Salé, Morocco*

Background: Since 2020, the SARS-Cov-2 pandemic has disrupted the organization of healthcare systems worldwide.
Objectives: This study aimed to assess the impact of this pandemic on septic arthritis management in a tertiary rheumatology department.
Methods: It was a single-center descriptive case-control study, which included patients hospitalized for septic arthritis between January 2018 and December 2021, whose diagnosis was retained after positive bacterial growthor on culture on according to presumptive criteria. Our patients were divided into two groups: G1: patients hospitalized during the COVID-19 pandemic (2020-2021), and G2: patients hospitalized during a similar period before the COVID-19 pandemic (2018-2019). In both groups, septic arthritis prevalence was calculated, socio-demographic characteristics, risk factors, clinical, paraclinical, and therapeutic data were collected. COVID-19 status was reported in the G1.
Results: Twenty-two patients were enrolled: G1 (n = 15), G2 (n = 7). The prevalence of septic arthritis was 0.77% and 0.36% respectively. The median age was 54.6±12.25 and 54.29±21.81 years old respectively. Diabetes was found in 26, 7% in G1 and 28.6% in G2. During the pandemic, arthropathy and oral corticosteroids use were noted in 53.3% and 28.6% of patients versus 26.7% and 14.3% in G2. The diagnosis delay and the prior use of antibiotic therapy were more significant in G1: 14.08[7-30] d versus 6.5[3.25-19.25] d, and 46.7% versus 14.3%. The knee was the most common localization in both groups. Other joints were affected in G1: shoulder (n = 2), hip (n = 1), and sacroiliac (n = 1). The most common germ was staphylococcus aureus. The duration of hospitalization and duration of antibiotic therapy in G1 and G2 were 26.07±9.12d versus 27.43±10.87d and 50±10d versus 48±25.79d, respectively. Concerning COVID-19 status, 33.3% of patients in G1 have received their vaccination and no recent SARS-Cov2 infection was noted before hospitalization. During the pandemic, synovectomy was required in three patients, one of whom was also transferred to intensive care for septic shock (two of these three patients are being followed for rheumatoid arthritis, and only one has never been vaccinated against COVID-19).
Conclusion: During the COVID-19 pandemic, the prevalence of septic arthritis in our department was higher and the diagnosis was delayed. Duration of hospitalization was not impacted, however, atypical localisations, prior use of antibiotics, recourse to synovectomy, and transfer to intensive care were reported. These results suggest an inadequate and difficult access to healthcare services during the lockdown, as well as an impact of social distancing on the immune system [1, 2]. More studies are needed to confirm these findings.

Background: Cryoglobulinemic Vasculitis (CV) is a rare autoimmune systemic disorder with multiple organ involvement. During the current COVID-19 pandemic, the patients with CV can accounted among frail populations because of the presence of multiple organ involvement, chronic steroid treatment, and more frequent old age.
Objectives: The present study aimed to investigate the prevalence and outcome of COVID-19, as well the safety and immunogenicity of COVID-19 vaccines in a wide CV cohort by a multicenter survey.
Methods: Patients with CV were consecutively recruited at 11 Italian referral centers. CV diagnosis, clinico-serological parameters, COVID-19 tests, and vaccination immunogenicity were carried out according to current methods.
Results: Four-hundred-thirty unselected CV patients (130 M; mean age 70±10.96 years) were recruited from February 2020 to October 2021. COVID-19 prevalence was significantly higher in CV patients compared to the Italian general population (11.9% vs 8.0%, p<0.005); furthermore, we observed a higher mortality in CV subjects with COVID-19 compared to those without (5.9% vs 0.5%, p<0.01). An older age (≥60 years) correlated with a worse COVID-19 outcome. Vaccine was administered in 87% of patients, and 50% received a boostering dose. Disease flares/worsening following the vaccination were significantly less frequent than those associated to COVID-19 (5% vs 14%, p=0.0012). CV patients showed an impaired vaccination immunogenicity compared to controls (p<0.05), as well an increased no-response rate after the booster.
Conclusion: CV patients have a higher risk to develop COVID-19, as well of more severe disease manifestations. Vaccines had a good safety profile in CV patients and of note, the vaccine-related side effects/disease flares were significantly lower compared to those COVID-19-related. However, a quarter of vaccinated individuals do not show detectable seroconversion; this is a major challenge for clinicians. Overall, a close monitoring of these frail patients during the ongoing pandemic is particularly advisable.

EFFECTS OF DMARD TREATMENT ON SARS-COV-2 MRNA VACCINATION IN PATIENTS WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASE: A MATCHED, PROSPECTIVE COHORT STUDY

Keywords: Undifferentiated connective tissue disease, Vasculitis, COVID

E. Simader[1], T. Deimel[2], F. Kartnig[2], S. Tobudic[3], H. Haslacher[4], T. M. Karonitsch[2], D. Mrak[2], T. Nothnagl[5], T. Perkmann[4], H. Lechner-Radner[2], J. Sautner[5], F. Winkler[3], H. Burgmann[3], D. Aletaha[2], S. Winkler[3], S. Blüml[2], P. Mandl[2]. [1]*Medical University of Vienna, Department of Internal Medicine III, Division of Rheumatology, Vienna, Austria*; [2]*Medical University of Vienna, Department of Internal Medicine III, Division of Rheumatology, Vienna, Austria*; [3]*Medical University of Vienna, Department of Internal Medicine I, Division of Infectious Diseases and Tropical Medicine, Vienna, Austria*; [4]*Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria*; [5]*Second Medical Department, Korneuburg-Stockerau Hospital, Lower Austrian Centre for Rheumatology, Stockerau, Austria*

Background: Patients suffering from systemic autoimmune rheumatic disease (SARD) display poor antibody development after two doses of mRNA vaccinations leaving these patients with only limited humoral protection against severe SARS-CoV-2 disease courses. Of key interest is the effect of conventional synthetic (csDMARD) and biological/ targeted drugs (b/tsDMARDs) disease modifying antirheumatic drugs on the time of protection.
Objectives: To compare antibody titer development in patients with vasculitis and connective tissue disease (CTD) with healthy controls 6 months after two mRNA vaccinations and after third immunization. To analyze factors, that affect the velocity of titer decline, well as qualitative humoral response.
Methods: Patients with SARD were enrolled and matched for gender and age with healthy control subjects (HC) and the humoral response after 6 months to two doses of mRNA vaccine BNT162b2 in terms of SARS-COV-2 antibody titer was assessed. In addition to binding antibody units (BAU) we also analyzed neutralizing antibodies. Patients receiving B-cell depleting therapy and those with prior SARS-CoV-2 infection (via detection of nucleocapsid antibodies) were excluded. Differences between two groups were calculated with Wilcoxon signed-rank test.
Results: A total of 53 patients with SARD (42 patients suffering from connective tissue disease and 11 with vasculitis respectively) and 73 HC were analysed. Interestingly only patients receiving a combination therapy of different csDMARDs/ b/tsDMARDs demonstrated diminished antibody titers 6 months after two doses of mRNA vaccine (p-value p-value<0,001), whereas patients receiving only csDMARD as monotherapy displayed comparable antibody levels to healthy controls. This effect was equalized after a third booster vaccination (p-value=0,13). Concerning disease entities, patients with vasculitis seemed to have lower BAU than HC (p-value<0,05) and patients suffering from CTD. After third vaccination both patient groups had lower antibody levels than HC (vasculitis: p-value <0,0001; CTD: p-value p-value<0,01). Lower antibody levels before third vaccination correlated with lower antibodies after third immunization.
Conclusion: Patients with autoimmune rheumatic diseases undergoing combination therapy may be more vulnerable to SARS-CoV-2 infection, due to reduced antibody levels 6 months following two doses of mRNA vaccine. Our data strongly recommends antibody measurements in patients receiving combination therapy and individualized earlier booster vaccination.

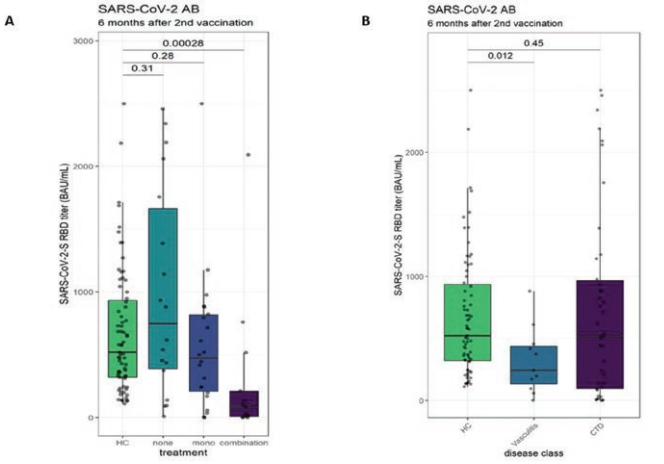

Figure 1. Anti-SARS-Cov-2 S antibody titers. **A**: Antibody titers measured 6 months after two doses of mRNA vaccination in patients with connective tissue disease, vasculitis and healthy controls. **B**, Antibody levels according to disease entity. AB: antibody; BAU: binding antibody unit; CTD: connective tissue disease; HC: healthy control; mono: disease modifying anti-rheumatic drug monotherapy; combination: combination therapy of disease modifying anti-rheumatic drugs; RBD: receptor binding domain;

Background: Little is known about the efficacy of booster COVID-19 vaccination in rituximab (RTX)-treated patients with autoimmune inflammatory rheumatic diseases (AIIRD).
Objectives: To estimate COVID-19 breakthrough infection rate in AIIRD patients treated with RTX compared to patients treated with other therapies and immunocompetent controls.
Methods: This observational multi-center study investigated COVID-19 infection rate and humoral response (anti-S1/S2 IgG) to the BNT162b2 mRNA vaccination in RTX-treated vs non-RTX treated AIIRD patients and immunocompetent controls for 18 months. To investigate the impact of the 3rd and 4th mRNA COVID-19 vaccine doses, a survival analysis was applied. Predictors of time-to-infection were analyzed using a multivariate Cox proportional hazard model.
Results: A total of 115 RTX-treated patients, 590 non-RTX-treated patients, and 121 immunocompetent controls were included in the analysis. AIIRD patients received more vaccine doses than controls, median 3 (range 2-4) vs 2 (2-4), respectively, p<0.0001; the rate of vaccination with the 3rd and 4th vaccine doses were 53.82% (n=402) vs 32.8% (n=41), and 3.88% (n=29) vs 2.4% (n=3), respectively, p <0.0001 for both comparisons. Patients treated with RTX within one year from the last vaccination (n=84) had the lowest anti-S1/S2 IgG level following each vaccination compared to others patients and controls. RTX-treated patients had the highest rate of COVID-19 infection since the start of the vaccination campaign compared to the AIIRD patients in general and controls, 32.26% (40/124), 27.29% (170/623), and 28.8% (36/125), respectively, p=0.2206. During the Omicron surge, time-to infection from the last booster vaccination was shorter among AIIRD patients compared to controls, irrespective of the type of anti-rheumatic therapies (Figure 1A). In a Cox-regression model, a time interval between the RTX treatment and the last vaccination was associated with a lower risk to contract COVID-19, HR 0.998 (95% CI 0.997-1), p=0.0298 (Figure 1B) For each 30-day interval between the RTX treatment and the vaccination date, the risk to contract COVID-19 declined 0.941-fold. The risk to contract COVID-19 among RTX-treated patients within the last year after adjustment to age and S1/S2 serology was HR 2.077, 95% CI 1.056-4.086, p=0.0342. Reassuringly, no cases of severe COVID-19 or COVID-19-related mortality were reported during the Omicron surge.
Conclusion: This study found comparable rates of the Omicron infection rate among vaccinated AIIRD patients treated with RTX and other immunomodulators. Recent exposure to RTX predisposed to a breakthrough COVID-19 infection.

Figure 1A. Covid-19-free survival from the last booster vaccination among rituximab-treated patients, patients treated with other medication, and immunocompetent controls.

AB1294 SAFETY OF COVID-19 VACCINES AND HEALTH CARE UTILIZATION FOLLOWING VACCINATION AMONG ADULTS WITH RHEUMATOID ARTHRITIS – A POPULATION-BASED SELF-CONTROLLED CASE SERIES ANALYSIS

Keywords: Vaccination/immunization, COVID, Rheumatoid arthritis

J. Lee[1], S. Bernatsky[2], J. Kwong[3], Q. Li[4], T. Kwok[5], J. Widdifield[6]. [1]*University of Toronto, Pediatrics, Toronto, Canada*; [2]*Research Institute of the McGill University Health Centre, Centre for Health Outcomes Research, Montreal, Canada*; [3]*University of Toronto, Family Medicine, Toronto, Canada*; [4]*ICES, Chronic Disease & Pharmacotherapy, Toronto, Canada*; [5]*University of Toronto, Medicine, Toronto, Canada*; [6]*Sunnybrook Research Institute, Holland Bone & Joint Research Program, Toronto, Canada*

Background: Although adverse events of special interest (AESIs) following COVID-19 vaccination are considered to be rare, emerging reports have suggested that risk of AESIs may be higher in certain subgroups of individuals. The self-controlled case series method represents a useful approach to study adverse events whereby an individual's risk is compared between a control pre-exposure period and a risk period following vaccine exposure.
Objectives: This study assessed whether COVID-19 vaccines were associated with an increase in AESIs and health care utilization [emergency department (ED) visits, hospitalizations, and rheumatologist visits] among adults with rheumatoid arthritis (RA).
Methods: We used the Ontario RA Database, a validated Canadian population-based cohort. Among adults with an RA diagnosis, we identified those who received at least 1 COVID-19 vaccine. AESI included Bell's Palsy, Idiopathic Thrombocytopenia, Acute Disseminated Encephalomyelitis, Myocarditis, Pericarditis, Guillain-Barre syndrome, Transverse Myelitis, Acute Myocardial Infarction, Anaphylaxis, Stroke, Deep Vein Thrombosis, Pulmonary Embolism, Narcolepsy, Appendicitis, and Disseminated Intravascular Coagulation. Secondary outcomes included all-cause ED visits, hospitalizations, and rheumatology visits (a potential proxy for disease flare). The study end date was March 2022. Self-controlled case series analyses were used to determine event rates in any 21-day risk period following vaccination compared to control periods. For rheumatologist visits, the risk window was confined to a 30-day risk period. Control periods were defined as 6 months prior to the first vaccination [with a 14-day washout period before first dose, as patients may wait until they are in relatively good health before receiving a vaccine]; Control periods in between doses start on Day 22 from the last dose and ends 14 days prior to the next dose; and a final control period commencing after the final dose risk period (up to a maximum of 6 months). Relative incidence (RI) rates were estimated (using Poisson Regression) across risk windows relative to control periods. Relative incidence rate ratios (RIR) in each risk period vs control period were estimated using non-RA comparators (matched on sex, age, and region of residence).
Results: In total 123,466 RA patients and 493,864 comparators were included. 71% of individuals were female and the median age of RA patients was 65 years (IQR: 55-74), with a median RA duration of 9.3 years (IQR: 4.2-17.1). The majority received mRNA vaccines. Within RA, 8,727 (7.1%) received >3 doses, 89,583 (72.6%) received 3 doses, 23,652 (19.2%) received 2 doses, and 1,504 (1.2%) a single dose. Within the general population, 373,735 (75.7%) received 3 doses and only 7,963 (1.6%) received >3 doses. Among RA individuals, relative to control periods, event rates were not significantly increased after the first dose in terms of AESIs (RI 1.05 95% CI 0.90-1.22) or ED visits (RI 0.97 95% CI 0.94-1.01). Hospitalizations were slightly lower for RA patient in post-vaccination versus control periods (RI 0.83 95% CI 0.78-0.88). Compared to control periods, rheumatology visits slightly increased after the first dose (RI 1.08 95% CI 1.07-1.10), then decreased after doses 2-3, normalizing after dose 4. Relative to non-RA comparators, RA individuals had a higher relative incidence rate of AESIs after dose 3 (RIR 1.28 95%CI 1.05-1.56) but no differences in hospitalizations or ED visits. Potential limitations of our study include the possibility that individuals avoided additional doses if they had an adverse event after the first dose, and that access to rheumatologists likely changed over time.
Conclusion: In this self-controlled case series, we did not detect a significant increase in AESI or health care use when comparing pre-vaccine to post-vaccine periods in RA.

Background: Despite the large number of studies on safety of anti-SARS-CoV-2 vaccines in people with rheumatic and musculoskeletal diseases (RMDs), data on Sjögren's syndrome (SS) are scarce.
Objectives: To determine anti-SARS-CoV-2 vaccine-related adverse events (AEs) in the seven-day post-vaccination period in patients with SS vs other connective tissue diseases (CTDs), non-rheumatic autoimmune diseases (nrADs), and healthy controls (HC).
Methods: Data were captured through the COVID-19 Vaccination in Autoimmune Diseases (COVAD) questionnaire (March–December 2021) and analysed to compare frequencies and identify associations with demographic, disease-specific and vaccine-specific variables.
Results: Among 9462 complete respondents having received at least one vaccine dose, 356 were patients with SS, of which 129 with primary (p) SS and 227 with SS associated (a) with other RMDs (rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), systemic sclerosis (SSc) and inflammatory myopathies (IM). SS patients were compared to 1586 patients with other CTDs (RA, SLE, SSc or IM) and without SS, 825 patients with nrADs and 4712 HC. SS patients mean age was 52 years, mean disease duration was 12 years; 94% of patients were females and 68% were Caucasian. Respondents were mainly based in the United Kingdom (19%), United States (15%) and Italy (14%) but in total 33 countries were represented. The BNT162b2 vaccine was the most frequently administrated (47%) and 78% of SS respondents had received 2 doses at the time of survey completion. Mild AEs were reported by 291 (82%) SS patients (p<0.0001 vs 3581 (76%) HC; vs 1296 (82) other CTD and 686 (83%) nrADs; all p=not significant (NS)) and severe AEs by 11 (3%) patients (vs 98 (2%) HC, 52 (3%) other CTDs and 36 (4) nrADs; all p=NS) (Table 1). Younger SS patients were more likely to develop mild AEs (odds ratio (OR): 0.97; 95% confidence interval (CI): 0.95-0.99) while no association with age was observed for severe AEs. Disease activity in the 4 weeks prior vaccination did not affect the development of mild/severe AEs not even when stratifying patients according to ongoing immunosuppressive (IS) and/or glucocorticoid (GC) treatment. Diffuse myalgia and fever were more frequently observed in ChAdOx1nCoV-19 recipients while rash in mRNA-1273 recipients. No differences in overall AE frequency emerged between pSS and aSS (mild AE= OR: 0.8; 95% CI: 0.5-1.4; severe AE: OR). However, while at univariate analysis fever was associated with pSS (OR: 1.95; 95% CI: 1.09-3.5), this was no longer significant when adjusting for vaccine type. The use of IS or GC in the 4 weeks prior vaccination did not affect AE frequency and no differences were observed in those withholding or not their therapy before/after vaccination.
Conclusion: Our data confirm that anti-SARS-CoV-2 vaccination is safe and well tolerated in both pSS and aSS. Data collection is ongoing to gather data about safety of subsequent vaccine doses.

AB1296 EQUATED HOSPITALIZATION RATE OF PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES AS COMPARED TO GENERAL POPULATION – DATA FROM THE SECOND WAVE OF THE COVID-19 PANDEMIC

Keywords: COVID

G. Dallagiacoma[1], C. Weichenberger[2], B. Raffeiner[3], S. Zandonella Callegher[1], P. Matzneller[4], A. Maier[3], L. Karadar[5], A. Masl[5], I. Kuppelwieser[5], E. Hantikainen[2], C. Dejaco[1]. Background: The outbreak of COVID-19 pandemic, caused by the severe acute respiratory syndrome coronavirus 2 (called SARS-CoV-2), has quickly became a global health emergency with over 660 million confirmed cases and over 6 million deaths worldwide. Over the last two years, several registries and cohort studies have collected data about the course and possible predictors of outcomes of COVID-19 infection in of inflammatory rheumatic and musculoskeletal disease (iRMD) patients. However, whether iRMD patients perform differently from the general is not clear, as most studies miss an adequate control group [1].

Objectives: To investigate the clinical manifestations and outcome of coronavirus disease (COVID-19 second wave) in patients with iRMD compared to the general population.

Methods: This is a case-control study of patients with and without an iRMD affected by COVID-19. Patients were selected in South Tyrol health trust, Italy, retrieving data from a single central database. We included patients ≥18 years of age and with a positive SARS-CoV-2 PCR test result between October 1sts 2020 and March 1st, 2021. During the study period, a whole population screening was conducted in South Tyrol with central registration of all results. Cases were identified by linking the diagnosis of a rheumatic disease with the result of the PCR test. Cases were subsequently matched in a 1:2 ratio for age, sex, and date of COVID-19 diagnosis with non iRMD patients (controls). Differences in demographics, clinical features, and outcomes of COVID-19 infection were compared between the two groups. The outcomes analyzed were hospitalization, severe course (ICU, mechanical ventilation/ECMO) and mortality.

Results: The study population consisted of 201 iRMD patients (mean age 60.4 years±14.9; 65.2**%** female) and 360 controls (mean age 59.8 years ± 5.6; 64.7**%** female). Asthenia and malaise were the most common symptoms, reported more frequently in the iRMD as compared to the control group (61.7% vs 43.1%, respectively, p<0.001). The majority of iRMD patients (88.6%) received an immunosuppressive drug at time of COVID-19 diagnosis, 36.3% were under glucocorticoids therapy. iRMD patients more frequently had three or more comorbidities than controls (34.8% vs. 6.1%, p<0.001). iRMD patients received more commonly glucocorticoids to treat COVID-19 disease [n=42 (20.9%) vs n=23 (6.4%), p=<0.001] than controls. The rate of COVID-19 related hospitalization (12.4% vs. 10.6%, p=0.49), severe course (40.0% vs. 44.7%, p=0.80) and mortality (3.5% vs. 4.2%, p=0.82) in iRMD and control group respectively, did not show significant differences. Among hospitalized patients, mechanic ventilation was significantly more common among iRMD than control group [n=5 (20.0%) vs. n=1 (2.6%), p=0.035].

Conclusion: Our study indicates similar rates of admission, severe course and mortality among iRMD and non-iRMD patients affected by COVID-19. However, iRMD patients displayed a higher number of comorbidities and were more frequently treated with glucocorticoids. Among hospitalized patients, mechanical ventilation was more frequently required among iRMD group.

Background: Blood group A has been associated with a higher risk of SARS-CoV-2 infection, although the effect on its severity is being discussed.

Objectives: To evaluate the association between the ABO and Rh antigens and the clinical characteristics and evolution of the SARS-CoV-2 infection in patients with rheumatic diseases.

Methods: SAR-COVID is a national, longitudinal, and observational registry. Patients ≥18 years with a diagnosis of inflammatory or degenerative rheumatic disease, and confirmed SARS-CoV-2 infection (RT-PCR or serology) were included. Data were collected from August 2020 to June 2022. Sociodemographic, clinical data, comorbidities, underlying rheumatic disease, disease activity, and its treatment at the time of SARS-Cov-2 infection diagnosis were recorded. Symptoms of the infection, complications, medical interventions and treatments received for COVID-19 were also documented. The WHO ordinal scale (WHO-OS)[1] was used and severe COVID-19 was defined as WHO-OS ≥5. Patients were categorized as follows: blood group A or non-A, and Rh factor positive or negative. *Statistical analysis:* Descriptive statistics. Chi[2] test or Fischer's exact test and Student's test or Mann-Whitney and Kruskal Wallis test or ANOVA, as appropriate. Multiple logistic regression.

Results: A total of 1356 patients were included, 547 (40,3%) had blood group A and 809 non-A (59,7%). Regarding the Rh factor, 1230 (90,7%) were positive and 126 (9,3%) negative. Age, sex and ethnicity, as well as the presence of comorbidities were comparable between both groups. In both cases, the most frequent rheumatic diseases were rheumatoid arthritis (38,9%; p=0,052), systemic lupus erythematosus (17,4%; p=0,530) and osteoarthritis (10,1%; p=0,888). Patients with non-A blood type presented a higher frequency of psoriatic arthritis (group A 5,1% vs non-A 8,7%; p= 0,015). At the time of SARS-CoV-2 infection diagnosis, the use of glucocorticoids, immunosuppressive and immunomodulatory drugs were similar in both groups. During SARS-CoV-2 infection, more than 90% of patients in both groups were symptomatic (group A 96% vs non-A 94,8%; p= 0,384). Non-A blood group patients had a significantly higher frequency of arthralgia and dysgeusia. In A blood group 18,5% of the patients required hospitalization, 41,0% of them were admitted in the intensive

care unit and 5,9% presented complications, while in the non-A blood group, were 16,7%, 31,1% and 5,5%, respectively (p>0,05 in all the cases). The most frequent complications in both groups were respiratory distress syndrome and sepsis (p>0,05). The outcome of the COVID-19 infection is detailed in Figure 1. In the multivariate analysis, adjusted for poor prognostic factors, patients with A blood type and those with negative Rh factor presented more likely severe COVID-19. (OR 1,75, 95%CI 1,20 - 2,56, p=0,003 and OR 2,63, 95%CI 1,45 - 4,55, p=0,001, respectively).

Conclusion: Blood type A and negative Rh factor were associated with worse COVID-19 outcomes in this national cohort of patients with rheumatic diseases.

PATIENTS WITH AXIAL SPONDYLOARTHRITIS HAVE BETTER SARS-COV-2 OUTCOMES COMPARED WITH PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM THE NATIONAL SAR-COVID REGISTRY

Keywords: COVID, Spondyloarthritis

Background: Patients with rheumatic diseases may present more severe SARS-CoV-2 infection compared to the general population. However, in some studies, hospitalization and mortality due COVID-19 were lower in patients with axial spondyloarthritis (axSpA) compared to other rheumatic diseases.

Objectives: To assess the severity of SARS-CoV-2 infection in patients with axSpA from the SAR-COVID registry, comparing them with patients with rheumatoid arthritis (RA), and to determine the factors associated with poor outcomes and death.

Methods: Patients ≥18 years old from the SAR-COVID national registry with diagnosis of AxSpA (ASAS criteria 2009) and RA (ACR/EULAR criteria 2010) who had confirmed SARS-CoV-2 infection (RT-PCR or positive serology), recruited from August 2020 to June 2022 were included. Sociodemographic and clinical data, comorbidities, treatments and outcomes of the infection were collected. Infection severity was assessed using the WHO-ordinal scale (WHO-OS)[1]: ambulatory [1], mild hospitalizations (2.3 y 4), severe hospitalizations (5.6 y 7) and death [8].

Statistical analysis: Descriptive statistics. Chi[2] or Fischer test and Student T or Mann-Whitney as appropriate. Poisson generalized linear model.

Results: A total of 1226 patients were included, 59 (4.8%) with axSpA and 1167 (95.2%) with RA. RA patients were significantly older, more frequently female, and had a longer disease duration. More than a third of the patients were in remission. 43.9 % presented comorbidities, arterial hypertension being the most frequent. At the time of SARS-Cov-2 diagnosis, patients with RA used glucocorticoids and conventional DMARDs more frequently than those with axSpA, while 74.6% of the latter were under treatment with biological DMARDs being anti-TNF the most used (61%). 94.9 % of the patients in both groups reported symptoms related to SARS-CoV-2 infection. Although the differences were not significant, patients with RA presented more frequently cough, dyspnea, and gastrointestinal symptoms, while those with axSpA reported more frequently odynophagia, anosmia, and dysgeusia. During the SARS-CoV-2 infection, 6.8% and 23.5% of the patients with axSpA and RA were hospitalized, respectively. All of the patients with axSpA were admitted to the general ward, while 26.6% of those with RA to intensive care units. No patient with axSpA had complications or severe COVID-19 (WHO-OS>=5) or died as a result of the infection while mortality in the RA group was 3.3% (Figure 1). In the multivariate analysis adjusted to poor prognosis factors, no association was found between the diagnosis of axSpA and severity of SARS-CoV-2 infection assessed with the WHO-OS (OR -0.18, IC 95%(-0.38, 0.01, p=0.074).

Conclusion: Patients with EspAax did not present complications from SARS-CoV-2 infections and none of them died due COVID-19.

AB1299 THE INCIDENCE OF POST-COVID SYNDROME IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Mental health, Comorbidities, COVID

N. Tileubek[1], N. Shamsutdinova[2], V. Mukhamadieva3, D. Abdulganieva3, R. Abdrakipov[4], S. Lapshina3. [1]*Institute of Gastroenterology, Hepatology and Metabolism "Interna Clinic", Rheumatology, Rheumatology, Almaty, Kazakhstan*; [2]*Kazan State Medical University, Internal Diseases, Kazan, Russian Federation*; [2]*Kazan State Medical University, Internal Diseases, Kazan, Russian Federation*; [4]*Republic Clinical Hospital, rheumatology, Kazan, Russian Federation*

Background: Post-COVID Syndrome occurs in people after coronavirus infection with confirmed SARS-CoV-2 infection or in people with suspected coronavirus infection, usually 3 months after the onset of COVID-19, with symptoms that last at least 2 months and cannot be explained by an alternative diagnosis. Although post-COVID manifestations have been previously studied in the general population, they have not been studied in a specific population of patients with inflammatory rheumatic diseases. The list of post-covid syndromes includes arthralgia, arthritis, myalgia, vasculitis with damage to vessels of various sizes, antiphospholipid syndrome, as well as a number of immunological markers that are characteristic of a wide range of rheumatic diseases [1]
Objectives: to study the incidence of post-COVID syndrome in patients with rheumatic diseases (RD).
Methods: From March 2020 to September 2022, 271 patients with RD who had a novel coronavirus infection (NCI) with a confirmed SARS-CoV-2 PCR result and/or X-ray computed tomography (CT) of the lungs were under observation. Among the patients, 68 (25%) were males, 203 (75%) were females. The median age was 56 [46.65] years. The average duration of RD at the time of NCI was 10.9 [5.15] years. The distribution of patients was as follows: rheumatoid arthritis (RA) - 186 people (68.6%), ankylosing spondylitis (AS) - 46 people (16.9%), psoriatic arthritis (PsA) - 38 people (14%). The results of clinical and laboratory examinations for RD were assessed before the NCI and 3 and 6 months after the NCI. A survey of patients was conducted as part of an in-depth medical examination 3 and 6 months after undergoing NCI for the presence of post-COVID manifestations.
Results: 90.4% of patients noted the persistence or appearance of symptoms after undergoing NCI, and all of them had a combination of at least 3 different groups of symptoms. The most common increase/appearance of pain in the joints was 91.1%. Among the respondents, the second symptom in terms of frequency of occurrence, in 52.9% of cases, were asthenic manifestations in the form of the appearance and intensification of fatigue, muscle pain, headaches. A decrease in working capacity and quality of life was noted by 52.9%. Complaints about a significant increase in dyspnea and a decrease in exercise tolerance were noted by 35.3% of the respondents, while there was no connection with the severity of NCI, and half of the patients had a mild course of NCI. Increased chest pain and/ or palpitations - in 23.5% of people. Half of the patients noticed hair loss and skin rash at 3-6 months after NCI: significant 35.2%, insignificant 20.5%. A slight persistence of elevated temperature since recovery from NCI was recorded in 17.6% of patients. RD stage of remission before NCI was in 9 (3.3%), low degree of activity 58 (21.4%), moderate degree of activity 140 (51.6%), high degree of activity 21 (7.7%), 43 (15.8%) people - no data. Moderate and high degrees of RD activity before NCI influenced the increase in joint pain ($p<0.023$), unstable course of diabetes mellitus ($p<0.032$) by 3 after recovery.
Conclusion: In patients with RD, post-covid manifestations persist, primarily due to articular (91.1%) and general constitutional symptoms (85.3%) from 3 to 6 months after undergoing NCI. Moderate and high degrees of RD activity before NCI significantly affect the severity of the articular syndrome and the unstable course of diabetes mellitus. Therapy for post-COVID syndrome in patients with rheumatological diseases should be personalized and determined by the characteristics of this patient's condition.

AB1300 RHEUMATOLOGICAL MANIFESTATIONS IN A COHORT OF LONG-COVID PATIENTS: SEARCHING FOR POSSIBLE BIOMARKERS

Keywords: COVID

A. Paglionico[1], P. Rizzuti[2], V. Varriano[1], C. Di Mario[3], S. Perniola[1], R. Calvani[4], A. Picca[4], F. Landi[4], M. Tosato[4], B. Tolusso[3], E. Gremese[1,3]. [1]*Fondazione Policlinico Universitario A.Gemelli, IRCCS, Division of Clinical Immunology, Rome, Italy*; [2]*Università Cattolica del Sacro Cuore, -, Rome, Italy*; [3]*Fondazione Policlinico Universitario A. Gemelli IRCCS, Immunology Core Facility, Gemelli Science Technological Park, GSTeP, Rome, Italy*; [4]*Fondazione Policlinico Universitario A. Gemelli IRCCS, -, Rome, Italy*

Background: Approximately 10-20% of patients recovered from SARS-COV-2 infection develop persistent heterogeneous symptoms and autoantibody positivity suggesting persistence of low-grade inflammation.
Objectives: To assess the prevalence of rheumatological manifestations in a cohort of convalescent SARS-CoV-2 patients and to find possible biomarkers.
Methods: Two-hundred and seventy-nine convalescent SARS-CoV-2 patients underwent multidisciplinary assessment in our Post-Covid19 outpatient service (119 females and 160 males; mean age±SD, 55.87±0.88). For each patient, demographic, clinical and immunological data were collected. Long-COVID symptoms were assessed by a questionnaire submitted to patients; IL-1β, IL-6, TNFα and e IL-8 plasma levels were assessed by ELISA (ELLA).
Results: 221 (80.7%) convalescent SARS-CoV-2 patients presented at least one Long-Covid symptom, most frequently fatigue (52.6%), dyspnea (40.7%), arthralgia (28%) and myalgia (28%). The prevalence of symptoms was significantly higher in females ($p = 0.009$) and in patients 60-75 years old ($p = 0.02$) and the presence of symptoms was independent from disease severity and care setting during acute infection. Assessing cytokines plasma levels, we observed that patients presenting Long-COVID arthralgia showed higher IL-6 plasma levels ($p = 0.006$). Moreover, the most common rheumatological symptoms, asthenia and arthralgia, in Long-COVID patients were significantly correlated with female sex ($p = 0.002$), at least one autoantibody positivity ($p = 0.003$) and IL-6 plasma level higher than 2.1 pg/ml ($p = 0.009$).
Conclusion: Rheumatological symptoms are frequent in Long-Covid patients and this study suggests that they are underpinned by persistent dysregulated inflammatory pathways after the acute infection.

AB1301 CYCLOPHOSPHAMIDE THERAPY DURING THE COVID19 PANDEMIC

Keywords: Vasculitis, COVID, Best practices

B. Bitik[1], C. S. Oygur[2], A. Yalçıntaş Kanbur[2], A. E. Yucel[2]. [1]*Başkent University Ankara Hospital, Rheumatology, Ankara, Turkey*; [2]*Başkent University Ankara Hospital, Rheumatology, Ankara, Turkey*

Background: During the Coronavirus disease (COVID-19) pandemic, one of the biggest concerns of rheumatologists and rheumatology patients has been whether the risk or severity of the disease will increase with immunosuppressive therapy. Some drugs have been reported to be associated with adverse Covid19 outcomes [1,2]. Cyclophosphamide (CYC) is a drug that has been used in rheumatology practice for many years. There is not enough data in the literature on the frequency or consequences of COVID-19 while receiving CYC therapy.
Objectives: The aim of this study is to examine the frequency and outcomes of Covid19 in patients who received CYC therapy during the Covid19 pandemic.
Methods: The files of patients who received CYC therapy protocol between March 2020 and March 2022 at Başkent University Faculty of Medicine Ankara Hospital, Rheumatology outpatient clinic were retrospectively reviewed. In our clinic, CYC therapy is administered as an intravenous treatment protocol of 500 mg three times every 10 days, then 500 mg every two weeks. Although the cumulative dose varies depending on the disease and the patient, it is usually planned to be at least three gram. The diagnosis of Covid 19 was made in the patients with clinically compatible radiology and SARS-CoV-2 PCR test results.
Results: A total of 36 patients received CYC during the specified period. CYC indications were ANCA-associated vasculitis in 12 patients, interstitial lung disease

associated with undifferentiated connective tissue disease in 5 patients, SLE in 5 patients, scleroderma in 4 patients, Sjögren's syndrome in 4 patients, Behçet's disease in 1 patient, vasculitis associated with sarcoidosis in 1 patient, rheumatoid vasculitis in 1 patient, leukocytoclastic vasculitis in 1 patient, polymyositis in 1 patient and Takayasu disease in 1 patient.The median age (q1-q3) was 62 (52-68) years. Covid19 infection was detected in only 3 patients (8%) during the CYC therapy protocol. The median cumulative CYC dose for these patients was 3.5g. One out of 3 patient was hospitalized for Covid 19 pneumonia. There was no death due to Covid19.

Conclusion: In this study, it has been shown that CYC therapy was safe during the Covid19 pandemic period.

AB1302 IMPACT OF THE COVID-19 PANDEMIC ON TREATMENT ADHERENCE AND THE ACTIVITY OF RHEUMATOID ARTHRITIS

Keywords: Outcome measures, Rheumatoid arthritis, COVID

M. Ghali[1], M. Ardhaoui[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, University of Monastir, Rheumatology, Monastir,Tunisia*

Background: During the COVID-19 pandemic, repetitive lockdowns and fear of SARS-CoV-2 infection compromised the treatment adherence of immunocompromised patients, particularly those with rheumatoid arthritis (RA). These therapeutic changes have certainly affected RA activity.

Objectives: To assess the treatment adherence among RA patients during COVID-19 and the impact on disease activity.

Methods: We conducted a cross-sectional study involving patients with RA who met the ACR/EULAR 2010 criteria. To evaluate therapeutic adherence we used 2 validated scores: the Compliance Questionnaire of Rheumatology-5 (CQR-5) and the Morisky Medication Adherence Scale-4 (MMAS-4). For each patient, we compared the DAS28 score, visual analog pain scale (VAS), sedimentation rate (ESR), and C-reactive protein (CRP) before and during the pandemic.

Results: We included 190 patients, of whom 155 were women and 35 were men. The average age was 55 ± 13.16 years. During the COVID-19 pandemic, the mean DAS28 score was 4.17 ± 1.03. Poor adherence was observed in 33% of cases according to MMAS-4 and in 34.5% of cases according to CQR-5. Patients who missed at least one consultation appointment accounted for 65% of cases. Teleconsultation was used in 17% of cases. Non-renewal of the prescription was the most frequent reason for therapeutic modification (47%). Sixty patients (31.7%) had contracted COVID-19 and the minor form was the most frequent (86% of cases). Poor therapeutic adherence assessed by the CQR-5 was significantly associated with: rural origin (p<0.001), low intellectual level (p=0.006), missed consultations (p<0.001), non-use of teleconsultation (p<0.001), and high disease activity (p<0.001). Factors associated with poor adherence according to MMAS-4 were: advanced age (p=0.01), rural origin (p=0.007), low intellectual level (p=0.004), comorbidities (p=0.003), failed consultations (p=0.001), non-use of teleconsultation (p<0.001) and SARS-CoV-2 infection (p=0.043). The correlational study showed that compared to pre-pandemic values: pain (p=0.001), ESR (p=0.008), CRP (p=0.04), and DAS-28 (p=0.001) were significantly higher during the pandemic. increased disease activity was significantly associated with the presence of comorbidities (p=0.018), low therapeutic adherence (p<0.001), and missed consultations (p=0.014). There was no significant association between SARS-CoV-2 infection and disease activity.

Conclusion: Treatment adherence of RA patients during the COVID-19 era was challenged. Elderly, illiterate, and rural patients were the most likely to miss their appointments and stop their treatments. These therapeutic changes were responsible for an increase in RA activity. Hence the importance of insisting on good adherence and close medical follow-up.

AB1303 AVASCULAR NECROSIS OF THE FEMORAL HEAD – NOT TO BE OVERLOOKED SEQUELA AFTER COVID 19 INFECTION

Keywords: Bone diseases, COVID

P. Todorov[1], L. Mekenyan2, A. Batalov2. [1]*Medical University of Plovdiv, "Kaspela" University Hospital, Propaedeutic of Internal Disease and Clinic of Rheumatology, Plovdiv, Bulgaria*; [1]*Medical University of Plovdiv, "Kaspela" University Hospital, Propaedeutic of Internal Disease and Clinic of Rheumatology, Plovdiv, Bulgaria*

Background: COVID 19 infection could lead to different sequelae in survivors, known as post-COVID or long COVID 19 syndromes. Some of them are thought to be due to the thrombophylic changes observed in COVID 19 infection, but some are thought to be caused by the administrated (especially high dose) corticosteroid treatment. Avascular necrosis of the femoral head (AVNFH) is a multifactorial disease which leads to compromised vascular supply, ischemia and finally necrosis of the femoral head. As corticosteroids usage and thrombophylic states are among the main known risk factors for the development AVNFH [1], it could be presumed that the frequency of this disease will increase with the COVID 19 pandemic. The exact corticosteroid dose needed for the development of AVNFH is not clear, but it has been stated that a higher daily dose and a larger total cumulative dose increase substantially the risk for the development of osteonecrosis [2].

Objectives: To describe in detail the characteristics of AVNFH diagnosed in patients after COVID 19 infection.

Methods: The study was done in a tertiary university rheumatological clinic. Data was extracted from the records of patients who have been referred to the clinic because of hip pain between June and December 2022. Inclusion criteria were: - a new onset of uni-or bilateral hip pain that started after a documented COVID 19 infection; and an MRI scan of the hip joints showing osteonecrosis of one or both femoral heads. Exclusion criteria were the presence of hip pain prior to the COVID 19 infection, anamnesis of traumatic injuries of the hips or pelvis, personal history of hypercoagulable states.

Results: Nine patients (4 women and 5 men) with an average age 59.1 years (range 38-72) were included in the study. Four patients had been diagnosed with bilateral and five – with unilateral AVNFH, thus 13 hip joints were analysed in total (8 left and 5 right sided). The mean time lap between the COVID 19 infection and the start of the hip pain was 26.2 weeks (range 10-48 weeks). All patients had limited and painful movement in their symptomatic hip(s), especially internal rotation and four of the patients had also elevated CRP levels (mean 11.7 mg/L). The stage of the AVNFH was evaluated according to the Ficat-Arlet classification (0-IV stage). In four hips the AVNFH was stage I, five hips were classified as stage II and the remaining four joints - as stage III. All symptomatic hip joints exhibited effusion/synovitis on both ultrasound examination and the corresponding MRI scan. It should be noted that the presence of hip effusion was found to be related with a worse prognosis in AVNFH [1]. In three patients the amount of the effusion required arthrocentesis and fluid aspiration. The analysis of the joint fluid was consistent with a degenerative disease (i.e., low WBC count with predominant lymphocytes and no crystals). All patients included in our study had received corticosteroids during their COVID19 infection, while 6 of the patients had also been hospitalized due to more severe disease. According to the patients' documentation, the mean cumulative dose of the received corticosteroids was 936.2 mg prednisolone equivalent per patient (range 187-2272 mg).

Conclusion: AVNFH must not be overlooked in a new onset hip pain after COVID 19 infection. Our results show that corticosteroids administrated during the infection and the presence of hip joint effusion on ultrasound are especially suggestive for the development of osteonecrosis, as they were registered in all of our patients. The presence of these two factors necessitates patient referral for an MRI scan of the hips, in order that AVNFH be detected timely.

AB1304 CHRONIC CHILBLAIN-LIKE LESIONS ASSOCIATED WITH THE COVID-19 PANDEMIC

Keywords: Imaging, COVID, Skin

J. Nathan[1], A. Rastogi[2], P. Kiely[1]. *[1]St George's Hospital, Rheumatology, London, United Kingdom*; *[2]St George's Hospital, Radiology, London, United Kingdom*

Background: The term long-covid encompasses a heterogeneous spectrum of chronic symptoms following infection with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) [1].
Objectives: We report the features of chronic chilblain-like digital lesions newly presenting since the start of the covid-19 pandemic. Comparison with primary perniosis and acrocyanosis, reveals a unique phenotype which appears to be a long-covid phenomenon.
Methods: The case records of 26 patients with new onset persistent chilblain-like lesions presenting to the Rheumatology service of St George's University Hospital, London between Autumn 2020 and Spring 2022 were reviewed. Demographic and clinical features, serology, imaging, treatment response and outcome up to Summer 2022 were collated retrospectively.
Results: Chilblain-like lesions first occurred between September and March; 2019/2020 6 cases, 2020/2021 18 cases and 2021/2022 2 cases. Mean age 35.4 (17-60) years, female 88%, white 85%, all non-smokers. Median body mass index (BMI) 20.2, range 17.0 – 33.2. BMI underweight (<18.5) in 27%. All cases reported new red-purple-blue colour changes of the fingers, some with pain, swelling and pruritis, affecting both hands in 12, one hand in 6, and both hands and feet in 8 cases. There was a past history of cold sensitivity or primary Raynaud's in 54%. Covid was confirmed in 3 cases, 2 – 8 months prior to onset of chilblain-like symptoms. Possible covid, unconfirmed, was suspected in 5 cases, 1 – 11 months earlier. Affected digits appeared diffusely erythro-cyanotic in 81%, with blotchy discrete maculo-papular erythematous lesions in 42%, some with both features. Involvement was asymmetric in 54%, thumbs spared in 69%. Complement was low in 50% (8/16), ANA positive in 26% (6/23). MRI of hands showed phalangeal bone marrow oedema in keeping with osteitis in 4/7 cases, and no synovial hypertrophy or entheseal abnormalities. More severe signs and symptoms were associated with low BMI, low C3/4 and a past history of cold sensitivity or Raynauds. Cold avoidance strategies were sufficient for 58%. Pain prompted a trial of NSAIDs, aspirin, nitrates, calcium channel blockers, hydroxychloroquine, oral or topical corticosteroid or topical tacrolimus in 42%. In general, these were at best minimally effective or not tolerated. Four severe cases received sildenafil or tadalafil, effective in 2 cases. In 27% complete remission occurred during the first summer season after symptoms commenced, median duration 6 (range 2 – 10) months. In the remaining 19 cases, chilblain-like symptoms returned or worsened in the subsequent second winter period, with 6/19 entering remission the following summer. For the remaining 13 persistent cases the total duration of symptoms spans more than a year, and in four cases more than 2 years.
Conclusion: This series illustrates a distinct chronic chilblain-like condition. Features similar to primary perniosis include female predominance, middle age, pruritic painful blotchy lesions, asymmetry and low BMI. Features in keeping with acrocyanosis include chronicity, extensive diffuse erythro-cyanotic discoloration, relative improvement in warm weather and lack of association with smoking.

AB1305 RHEUMATOID ARTHRITIS FLARE FOLLOWING COVID-19 VACCINATION IN MALAYSIAN POPULATION AND ITS ASSOCIATED RISK FACTORS

Keywords: Vaccination/immunization, Rheumatoid arthritis, COVID

N. A. Zakaria[1,2], L. Mohd Isa[2], L. Mohamednor[3], B. H. Ng[2], T. Chou Luan[2], F. N. Sulaiman[2], S. Ramasamy[2], W. R. Wan Musa[2], N. S. Shahril[2]. *[1]International Islamic University Malaysia, Kuliyyah of Medicine, Pahang, Malaysia*; *[2]Hospital Putrajaya, Rheumatology Unit, Putrajaya, Malaysia*; *[3]Hospital Putrajaya, Clinical Research Centre, Putrajaya, Malaysia*

Background: Flare of Rheumatoid Arthritis (RA) following COVID-19 vaccination has been reported with a low occurrence observed in those patients with disease remission. However, no local data is available in our multi-ethnic Malaysian population.
Objectives: To evaluate the prevalence of RA flare in Malaysian patients following COVID-19 vaccination and its associated risk factors.
Methods: This was a cross-sectional study assessing RA flare based on patient-reported disease flare through self-administered questionnaires and physician-reported flare. Patient self-reported disease flare was defined as 'a sudden worsening of rheumatology condition or arthritis within 1 month post-vaccination' while physician-reported flare was defined as 'an increment of disease activity score 28-joint documented within 3 months post-vaccination' from either a scheduled or unscheduled clinic visit. A total of 186 RA patients attended the rheumatology clinic in Hospital Putrajaya from May to July 2022 who completed the primary COVID-19 vaccination under the Malaysian National Vaccination Programme were recruited. Demographic data, disease parameters including serology for rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA), cessation of disease modifying anti-rheumatic drugs (DMARDs) around vaccination, type of vaccines and adverse events were examined using descriptive and univariate analyses.
Results: Majority (93%) of RA patients enrolled were female with a mean age of 58 years old (standard deviation, SD 12.2) and mean disease duration was 12 years (SD 7.7). More than half were seropositive (66% RF, 63% ACPA) with 47.4% had double seropositivity (RF and ACPA positive). All patients received DMARDs with the majority (71%) were on methotrexate (MTX), 21.5% were on leflunomide, 17.7% on other DMARDs, with a small proportion (14%) of patients were receiving prednisolone. Only 4.8% of patients were on biologics or targeted synthetic disease modifying anti-rheumatic drugs. Half of the patients were in remission prior to vaccination. 62% of patients received Pfizer-BioNTech vaccine as the primary vaccine, followed by Sinovac-CoronaVac (24.6%) and Oxford-AstraZeneca (13.4%) vaccines. A booster dose had been administered to 80% of patients, of which 88.7% was Pfizer-BioNTech vaccine. MTX therapy were discontinued in 39.4% of patients (n=52) post-vaccination for a week duration. The prevalence of RA flare was only 12.9% (n=24) in which 14 were self-reported and 10 were physician-reported flares (4 severe flare, 6 mild-moderate flare). Flare rates were higher during the first and second dose of vaccination with 29.2% respectively, and only 12.5% were reported after booster vaccination. Common vaccine adverse effects were fever (16.8%), myalgia (8.6%) and arthralgia (6.4%). There were no significant differences in the occurrence of flare post-vaccination between age, gender, disease activity prior to vaccination, types of vaccine, usage of MTX and prednisolone, and discontinuation of MTX post-vaccination. Although seropositivity did not exhibit statistically significant flare rate post vaccination, sub-analysis revealed four times higher rate of flare in those who has double positivity compared to seronegative RA patients (12% vs 4%).
Conclusion: Prevelance of RA flare post-COVID-19 vaccination in Malaysian RA population is low. No significant associated risk factors were identified although double seropositivity appeared to have higher number of flares.

AB1306 HOW DOES COVID-19 VACCINATION AFFECT DISEASE ACTIVITY AND SAFETY IN SECUKINUMAB TREATED PATIENTS WITH AXIAL SPONDYLOARTHRITIS? REAL WORLD DATA FROM THE GERMAN AQUILA STUDY

Keywords: Spondyloarthritis, Vaccination/immunization, COVID

J. Brandt-Juergens[1], K. Gente[2], P. Kästner[3], D. Peterlik[4], U. Kiltz[5]. *[1]Rheumatologie, Schwerpunktpraxis, Berlin, Germany*; *[2]Universitätsklinikum Heidelberg, Medizinische Abteilung V - Rheumatologie, Heidelberg, Germany*; *[3]Ambulantes Rheumazentrum, Medizinisches Versorgungszentrum, Erfurt, Germany*; *[4]Novartis, Novartis Pharma GmbH, Nürnberg, Germany*; *[5]Rheumazentrum Ruhrgebiet, Herne und Ruhr-Universität Bochum, Herne, Germany*

Background: Patients (pts) suffering from a chronic rheumatic condition, such as axial spondyloarthritis (axSpA), and receiving immunosuppressive treatment during the COVID-19 pandemic have been shown to be at higher risk of severe disease outcomes. The German non-interventional study AQUILA provides real-world data in pts with axSpA under secukinumab (SEC) treatment and the influence of COVID-19 vaccination on disease activity (DA) and safety [1].
Objectives: The aim of this interim analysis was to describe selected baseline (BL) characteristics and the effect of vaccination on DA and safety in axSpA pts.
Methods: AQUILA is an ongoing, multi-center study including up to 3000 pts with axSpA or psoriatic arthritis. This analysis focuses on axSpA pts included from May 2019 to Oct 2022 and their vaccination status (no vs ≥1 vaccination) for study time points from BL up to week (w) 52 according to clinical routine. DA was assessed by validated Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) questionnaire and safety by documented number of (serious) adverse events (S)AEs). Only pts with available BL BASDAI were considered and characterized by selected BL parameters, such as demographics and global functioning

(measured by assessment of spondyloarthritis international society health Index, ASAS-HI). Real-world data were analyzed as observed. Vaccination was performed according to prescription and took place at any timepoint throughout observational period of 52 weeks.

Results: Totally, 273 axSpA pts were included. For 56 pts ≥1 vaccination during study was documented: number of vaccinations (75% mRNA-based): n1 = 26 pts, n2 = 20 pts, n3 = 9 pts, n4 = 1 pt.

Both pts groups were comparable regarding the BL characteristics, such as age, smoking status, BMI, physician global assessment (PhGA), and ASAS-HI. Pts with no vaccination received less pretreatments with biologics (59.9% vs 76.8%) and were less affected by comorbidities and extra-articular manifestations (EAMs) than pts with ≥1 vaccination (e.g. depression 6.5% vs 12.5%) (Table 1). There was no difference in mean BASDAI between pts with no and with ≥1 vaccination throughout observational period of 52 weeks (except for a higher mean value in pts with ≥1 vaccination at w16). In both groups, slight improvement was observed in mean BASDAI over time (no vaccination: 5.1 to 3.8, ≥1 vaccination: 5.4 to 3.7) (Figure 1). However, due to different numbers of pts with no and ≥1 vaccination, data must be interpreted carefully. The number of pts with AEs and AEs leading to interruption of SEC was lower in pts with no vs pts with ≥1 vaccination (62.7% vs 75.0% and 13.4% vs 17.9%, respectively) (Table 1), with no new and unexpected safety signals in each group.

Conclusion: In a real-world setting, no differences in DA between axSpA pts with and without vaccination were observed. DA improved similarly up to w52 in both patient groups with similar BL characteristics, though more comorbidities/EAMs were documented in pts with ≥1 vaccination. There were no new safety signals in both groups. Further progress of the AQUILA study will reveal whether this trend will be confirmed with more patients included.

ANALYSIS OF ANTI-SARS-COV-2 S-RBD IGG ANTIBODY LEVELS IN A COHORT OF PATIENTS RECEIVING IL-1 INHIBITORS

Keywords: Vaccination/immunization, COVID

S. Bindoli[1], C. Baggio[1], P. Galozzi[2], F. Vesentini[1], A. Doria[1], A. Padoan[2], P. Sfriso[1]. [1]*University of Padova, Rheumatology Unit-Department of Medicine, Padova, Italy*; [2]*University of Padova, Laboratory Medicine Unit-Department of Medicine, Padova, Italy*

Background: Rheumatological patients are notoriously at increased risk of infections, since they receive immunosuppressive or immunomodulatory drugs, which may reduce the response to vaccination. However, current evidence has shown that several biologics may have little or no influence on the efficacy of COVID-19 vaccination. In this context, anti-IL-1 drugs, commonly employed for the treatment of several autoinflammatory disorders such as Familial Mediterranean Fever (FMF) and adult-onset Still's disease (AOSD), have been successfully used to treat the "hyperinflammatory syndrome", provoked by SARS-CoV-2, by contrasting the cytokine storm and avoiding the more severe consequences of the infection, although not inhibiting the recovery.

Objectives: In this study, our aim is to evaluate the antibody response after COVID-19 vaccination in a group of patients affected by systemic autoinflammatory diseases (SAID) undertaking IL-1 inhibitors, compared to a group of healthy vaccinated controls (HC). Then, we evaluated the course of COVID-19 infection in a group of vaccinated patients treated with anti-IL-1.

Methods: In 43 patients, referred to the Outpatient Autoinflammatory Clinic of the Rheumatology Unit of Padova University Hospital, the serological response after anti-SARS-CoV-2 vaccination was assessed using the CLIA MAGLUMI™ 2000 Plus test, 40 days, and six months after the first vaccination cycle and after the booster dose. Fifty-four full-vaccinated healthcare workers of equal age and sex were enrolled as HCs. Due to significant differences in antibody levels, HC and SAID patients who had COVID-19 were excluded from the analysis. *GraphPad Prism 8* software was used for statistical analysis.

Results: All SAID patients vaccinated with two or three doses developed an adequate antibody response (>33 kBAU/L). No significant differences were observed between antibody levels developed by patients receiving IL-1 inhibitors compared to those not on anti-IL-1 after the first vaccination cycle (T3, p = 0.99, T6, p = 0.99) or the booster dose (p=0.99). The mean antibody titer after booster dose was not different in SAID compared to HC (2276 ± 2653 kBAU/L of HC vs 3738 ± 3974 kBAU/L of SAID, p = 0.99). No gender differences were observed between the antibody titres. With increasing age, a physiological decrease in antibody production was assessed six months after the second vaccine shot in SAID (r = 0.67, p = 0.0003). Overall, 13/43 (30.2%) patients in our cohort had COVID-19 and 5/43 (11.6%) had it after receiving vaccination. None of them developed a severe disease, long-COVID, or experienced flares of the underlying autoinflammatory disease.

Conclusion: In patients receiving anti-IL-1 drugs, the antibody response after vaccination is comparable to the serological response observed in HC. Furthermore, no side effects were observed after vaccination and anti-IL-1 therapies were continued before and after the injections to avoid flare-up of the disease.

COVID-19

AB1308 POLYMYALGIA RHEUMATICA FOLLOWING SARSCOV-2 VACCINATION: A SINGLE CENTER COHORT STUDY

Keywords: Descriptive studies, Vasculitis, Vaccination/immunization

L. Lally[1], A. Bloostein[1], D. Jannat-Khan[1], R. Spiera[1]. [1]*Hospital for Special Surgery, Rheumatology, New York, United States of America*

Background: Polymyalgia rheumatica (PMR) incidence peaks in individuals between 70 and 80 years of age; this same group is also at increased risk of complications and mortality related to COVID-19 infection. Vaccination against SARS-CoV2 is an essential tool in combatting COVID-19. There have been several case reports of PMR following vaccination with mRNA SARS-CoV2 vaccines.
Objectives: The aim of this study was to identify patients with temporal association between mRNA SARS-CoV2 vaccination and PMR onset and to compare characteristics and disease course to those with new onset PMR without temporal association with SARS CoV2 vaccine exposure.
Methods: We conducted a retrospective chart review of all newly diagnosed PMR patients in a single center. Using ICD-10 codes, our EMR was queried to identify patients with newly diagnosed PMR beginning in December 2020, when the first SARS-CoV-2 vaccines were available in the US. Charts were reviewed for demographic information, disease characteristics and vaccination details. Patients who developed onset of PMR symptoms within 6 weeks after vaccination were compared to those whose PMR symptoms occurred without temporal association to vaccination. When available data at 6 and 12 months following diagnosis was collected.
Results: Eighty patients with newly diagnosed PMR between 12/1/2020 and 12/31/2021 were identified. There were 60 patients with new PMR without a temporal association to vaccination who were compared to 20 patients who developed PMR symptoms within 6 weeks of vaccination. Baseline demographics did not differ between the two groups. In the 20 cases with PMR onset after vaccination, symptoms developed a mean 38 days (IQR 19.5-48) after first dose of vaccine and 11.5 days (IQR 1-22) after second dose. There were no differences in baseline demographics, glucocorticoid dosages or relapse rates at 6 and 12 months following diagnosis. There was no association between vaccine manufacturer and PMR onset after vaccination (Table 1)
Conclusion: In this cohort, patients with onset of PMR within 6 weeks following mRNA vaccination against SARS-CoV2 were similar to patients with de novo PMR at diagnosis, with no significant differences in disease course over the first 12 months. This does not support the notion that PMR following vaccination is a unique disease entity. The recognition of new PMR onset following SARS CoV2 vaccine may be coincidental in this common inflammatory disorder in a population with high rates of vaccine exposure.

Table 1.

	Entire Cohort	PMR without temporal association to vaccine	PMR within 6 weeks of vaccine	p-value
N	80	60	20	
Age, median (IQR)	74.5 (71, 80)	75.5 (71, 80)	73.5 (69, 79.5)	0.43
Sex				0.80
Male	40 (50%)	29 (48%)	11 (55%)	
Female	40 (50%)	31 (52%)	9 (45%)	
Vaccine Type				1.00
Moderna	38 (48%)	29 (48%)	9 (45%)	
Pfizer	42 (53%)	31 (52%)	11 (55%)	
Baseline ESR (mm/hr), median (IQR)	44 (24, 65)	42 (24, 63)	44.5 (23, 65)	0.89
CRP at baseline (mg/L), median (IQR)	20 (7.55, 48.5)	20 (9, 42)	14.2 (7, 60.2)	0.77
Initial steroid dose, median (IQR)	20 (15, 30)	20 (15, 24)	20 (15, 37.5)	0.96
Additional vaccine received?				0.55

AB1309 CLINICAL CHARACTERISTICS OF NEW-ONSET IDIOPATHIC INFLAMMATORY MYOPATHIES FOLLOWING SARS-COV-2 INFECTION OR VACCINATION – ANALYSIS OF A CASE SERIES

Keywords: Vaccination/immunization, Myositis, COVID

A. Marian[1], M. M. Tamas[1,2], L. Muntean[1,2], O. M. Resteu[1], D. A. Vaida-Voevod[1,2], I. Felea[1], L. Damian[1], I. Filipescu[1,2], C. Pamfil[1,2], I. Szabo[1,2], S. P. Simon[1,2], S. Rednic[1,2]. [1]*Clinical Emergency County Hospital, Rheumatology, Cluj-Napoca, Romania*; [2]*Iuliu Hatieganu University of Medicine and Pharmacy, Rheumatology, Cluj-Napoca, Romania*

Background: Recent data showed that SARS-CoV-2 infection and vaccination could act as a trigger for different autoimmune diseases, including idiopathic inflammatory myopathies (IIM).
Objectives: The aim of this study was to describe the clinical characteristics of patients diagnosed with IIM following SARS-CoV-2 infection and vaccination in a tertiary rheumatology center.
Methods: We conducted a retrospective analysis on patients newly diagnosed with IIM, from 1 January 2020 to 31 December 2022, using information from the hospital database. The patients were selected according to the ICD-10 codes indicating IIM (M33.0, M33.1, M33.2, and M33.9). The cases with onset of specific IIM symptoms within 6 months after SARS-CoV-2 infection or vaccination were selected for further analysis. Clinical, biological and immunological parameters were assessed using descriptive statistics.
Results: A total of 58 patients newly diagnosed with IIM were identified, and in 10 (17.2 %) patients the onset was after SARS-CoV-2 infection (n = 6) or vaccination (n = 4). All patients diagnosed with IIM following vaccination (F:M=1:1, median age 46 years) received a mRNA vaccine and had the clinical onset within several days to a month after vaccination. Among IIM cases following SARS-CoV-2 infection (F:M=1:1, median age 60.5 years), the clinical onset of myopathy was variable, with a minimum of 14 days and a maximum of 6 months after infection. Myalgia, muscle weakness and elevated levels of creatinine kinase were reported in 9 patients. The average CK level was 2534.6 (3760.8) U/L, ranging from 43 to 11827 U/L. Skin lesions were present in all patients with IIM following vaccination and in 4 cases with IIM after SARS-CoV-2 infection. Mechanic's hands and arthralgia were noted in 5 patients each. Dyspnea and interstitial lung disease (ILD) were reported in 8 cases, with severe pulmonary involvement present in 2 cases. Myocarditis was reported in 2 patients, 1 case from each group. Myositis-specific antibodies (MSAs) and myositis-associated antibodies (MAAs) were reported in 9 patients. Anti-threonyl-tRNA synthetase antibodies (anti-PL7) were present in 5 cases (3 after vaccination and 2 after infection), anti- histidyl-tRNA synthetase antibodies (anti-Jo-1) in 2 patients (in 1 associated with anti-PL7 antibodies), and anti-isoleucyl-tRNA synthetase (anti-OJ antibodies) in 1 patient. ILD was diagnosed in all anti-PL7 antibody positive patients.
Conclusion: Anti-PL7 antibodies are frequent in newly diagnosed IIM following SARS-CoV-2 infection or vaccination. Further studies are needed to investigate the relationship between SARS-CoV-2 infection and vaccination in the occurrence of IIM.

Background: Human SARS-CoV-2 infection is responsible for a large variety of clinical manifestations related to Coronavirus disease-19 (COVID-19) [1]. SARS-CoV-2 can induce microvascular damage, that can be safely detected by nailfold videocapillaroscopy (NVC), as recently demonstrated [2-4]. Virus-induced endothelial dysfunction has been implicated in the pathogenesis of both active infection and long-COVID clinical manifestations (the last as persistence of disease symptoms after at least three months from onset) [5]. The study group on capillaroscopy and microcirculation in rheumatic diseases of the Italian Society of Rheumatology (CAPSIR) carried out an internal survey on the interest of the Italian Centers that perform NVC in participating in a detailed capillaroscopic and clinical data collection in long-COVID patients.
Objectives: To carry out an Italian multicenter cognitive survey on the interest in collecting NVC and clinical data of patients affected by long-COVID with or without previous rheumatological diseases.
Methods: The steering committee of the CAPSIR study group formulated a cognitive questionnaire, entitled "Study on the role of capillaroscopy in patients with long-COVID" (CAPSIR_2 Study), consisting of 27 open or multiple-choice questions. A Google Form of the questionnaire was emailed to all the member of the study group between September and October 2022. Data are reported with a descriptive analysis.
Results: The online questionnaire was completed by 41 CAPSIR members, belonging to 33 different Italian centers. Of note, 63% of participants had already experienced NVC in patients with long-COVID. The primary indication to perform the NVC was the onset of a new Raynaud's phenomenon (46% of cases) and the requests come mainly from General Practitioners (33% of cases). In 2/3 of the cases, patients with long-COVID and previous rheumatic diseases, who underwent NVC examination, represented less than 20% of the total. It should be noted that always in 2/3 of the cases there was no preferential channel for the study of the microcirculation in patients affected by long-COVID nor a NVC investigation prior to the SARS-CoV-2 infection. According to the previous experience of the participants in the interview, the most important NVC parameters considered to be evaluated in long-COVID patients were number of capillaries per linear millimeter (24% of cases), presence of hemorrhages (34% of cases) and giant capillaries (22% of capillaries). All participants (100%) therefore agreed to participate in a further collection of NVC and clinical data in this cohort of patients.
Conclusion: This survey highlighted the interest of Italian Rheumatologists in assessing by NVC the COVID-related microvascular involvement. A consensus has emerged that future research is needed. After this pilot survey, the second part of the CAPSIR_2 Study will concern the collection/analysis before and after the SARS-CoV-2 infection of NVC and clinical data in patients with primary and secondary (to rheumatic diseases) Raynaud's phenomenon and affected by long-COVID versus adequate controls. The aim is to investigate if the presence/severity of the microvascular damage might be involved in the pathogenesis of the clinical manifestations observed in COVID-19 patients after the active infection. CAPSIR_2 Study will be open to all Italian rheumatological centers that participated in the previous national CAPSIR_1 Project [6].

Background: Vaccines anti-SARS-CoV2 showed a good efficacy in prevention of severe COVID-19 [1]. Their potential in induction of autoantibodies (abs) has not been well established [1]. One recent study demonstrated an increase of abs' titer after anti-SARS-CoV2 vaccination only in patients (pts) with already pre-existing positivity [2].
Objectives: To evaluate the potential induction of abs after SARS-CoV2 vaccination in a cohort of pts affected by Rheumatoid Arthritis (RA), Systemic Sclerosis (SSc) or with triple positivity for antiphospholipid antibodies (aPL).
Methods: Consecutive pts affected by RA, SSc or with triple positivity for aPL were enrolled from February 2021 to November 2021. Serum samples were collected before the first (T0) and at least one month after the second administration (T1) of the anti SARS-CoV-2 vaccine. A wide panel of abs were evaluated through routinely methods. Qualitative variables were compared using Chi-square test or Fisher's exact test; quantitative variables were compared using Wilcoxon signed-rank test.
Results: 52 pts were considered [F/M= 48/4; median age=58(51-61.3) years; 15 RA, 19 SSc and 18 with triple positivity for aPL]. Regarding vaccination, 27 pts were administered BNT162b2, 24 mRNA-1273 and 1 Gam-COVID-Vac. No difference regarding frequency of abs' positivity was found between T0 and T1, except for aB2GPI IgG, that showed a reduction in positivity frequency (**Table 1**) No difference was found in the titer of the following abs: anti-dsDNA (p:0.318), anti-MPO (p:0.678) ed anti-PR3 (p:0.139). ACL IgG showed a significant reduction in chemiluminescence (CL) (T0 vs T1: 9.3 CU [6.1-41.6] vs 5.1 CU [2.5-35.7]; p:0.001), but not in ELISA (p:0.480). A significant reduction was found for aCL IgM both in CL (T0 vs T1: 5.7 CU [2.4-17.1] vs 3.4 CU [2.1-13.1]; p:0.006) and ELISA (T0 vs T1: 13.1 IU/ml [11.2-30.5] vs 11.2 IU/ml [11.2-19.5]; p:0.010). A significant reduction was found for aB2GPI IgG in CL (T0 vs T1: 25 CU [9.1-210.7] vs 6.4 CU [6.3-102.2]; p:0.001), but not in ELISA (p:0.953) Titre of aB2GPI IgM remained stable in CL (p:0.078) and ELISA (p:0.211). No variation was observed in ANA positivity. No significant difference was found in anti-ENA titre (p:0.141). None of the pts developed any new symptom or sign of autoimmune disease upon vaccination.
Conclusion: Anti-SARS-CoV2 vaccination didn't induce any clinical sign of autoimmunity in this cohort of pts affected by RA, SSc or with triple positivity for aPL. Serology for abs remained stable in pts' majority; only a fluctuation of aPL titre was found, generally in terms of reduction and without clinical significance.

Background: Limited data on the delayed onset effects of COVID-19 vaccination in patients with idiopathic inflammatory myopathies (IIMs) continues to be a significant cause of hesitancy in this vulnerable group.
Objectives: To analyze the delayed onset adverse events (ADEs) of COVID-19 vaccination in patients with IIMs, other systemic autoimmune and inflammatory disorders (SAIDs), and healthy controls (HCs), using data from the ongoing 2nd COVID-19 Vaccination in Autoimmune Diseases (COVAD) study.
Methods: A validated patient self-reporting e-survey was circulated by the international COVAD study group (157 collaborators, 106 countries) from Feb to June 2022, collecting respondent demographics, comorbidities, IIM/SAID details, COVID-19 infection history and outcomes, and vaccination details including ADEs. Delayed onset (> 7 day) ADEs (including minor and major ADEs and hospitalizations) were analyzed in patients with IIMs, SAIDs, and HCs, using various regression models.
Results: 15,165 total respondents completed the survey, of whom 8759 complete responses from vaccinated individuals [median age 46 (35-58) years, 74.4% females, 45.4% Caucasians] were included in the analysis. Of these, 1390 (15.9%) had IIMs, 50.6% other SAIDs, and 33.5% were HCs. 16.3% of IIMs patients reported minor ADEs, and 10.2% experienced major ADEs, and 2.9% required hospitalization. Patients with IIMs had a lower risk of minor ADEs than other SAIDs, though a higher risk of rashes compared to HCs [OR 4.0 (2.2-7.0), p<0.001]. In the IIMs subgroup, patients with active disease, overlap myositis, and ChadOx1 nCOV-19 (Oxford/AstraZeneca) recipients were at a higher risk of ADEs, while those with inclusion body myositis, and BNT162b2 (Pfizer) vaccine recipients were comparatively protected. Patients with IIMs with co-existing SAIDs were at a higher risk of minor [OR 5.2 (3.3-8.2), p<0.001] and major ADEs [OR 2.1 (1.2-3.8), p<0.05] compared to those with IIMs alone.
Conclusion: Patients with IIMs were at a lower risk of delayed onset COVID-19 vaccine ADEs compared to other SAIDs, though within this patient group, those with active disease, overlap myositis and autoimmune multimorbidity were vulnerable, and warrant close monitoring and long term follow up post COVID-19 vaccination.

Background: COVID-19 is associated with higher morbidity and mortality burdens in immunocompromised individuals, including patients with systemic lupus erythematosus (SLE; 1). These patients might benefit from treatment with anti-SARS-CoV-2-specific antiviral agents and monoclonal antibodies, but clinical evidence is to date limited.
Objectives: to comparatively assess the course of COVID-19 in patients with SLE treated or untreated with COVID-19-specific agents.
Methods: Patients with SLE and COVID-19 treated with antivirals and/or monoclonal antibodies from February 2020 to December 2022 were identified within a three-centre cohort of tertiary referral centres and age-, sex- SLE extension- and SLE duration-matched 1:2 with patients with a history of untreated COVID-19. Data on COVID-19 presentation, course (including time to viral clearance) and sequelae, along with SLE treatment at COVID-19 onset and SLE course after

COVID-19 were collected. COVID-19 severity at presentation was quantitated through a 0-4 analogue scale [2]. Data are expressed as median (interquartile range, IQR) unless otherwise specified.

Results: Over three years, 39% of patients with SLE had at least one COVID-19 event. Eighteen subjects (16 women) were treated with antivirals (n=12) or monoclonal antibodies (n=6) and were matched with 36 controls. There was no difference in the frequency of organ involvement between the two groups. Treated patients were receiving significantly higher prednisone daily doses at COVID-19 onset (6.25 (0-10) vs 0 (0-2.5) mg; p=0.005) and had a higher prevalence of previous high-dose steroid treatments (83% vs 47%; p=0.019) compared to controls. SLE disease activity index (3 (0-5) vs 1 (0-4)) and SLE International Collaborating Clinics Damage Index scores (1 (0-3) vs 0 (0-1)) were also numerically higher in treated patients at COVID-19 onset. Patients in the treated group had more severe COVID-19 at presentation but showed no significant differences with control subjects in terms of COVID-19 resolution, prevalence of sequelae and viral clearance (**Table 1**). There was also no difference in flare occurrence between the two groups (Log-rank=0.02, p=0.889). Two patients reported mild adverse events with monoclonal antibodies (muscle cramps and chest pain, both self-resolving).

Conclusion: These data support the safe use of COVID-19 specific treatments in patients with SLE. Patients treated with antivirals and monoclonal antibodies had a favourable COVID-19 course, despite a more severe presentation and a higher risk of deterioration due to SLE and corticosteroid treatment burden, suggesting the potential efficacy of COVID-specific treatments in preventing severe COVID-19 in patients with SLE.

AB1314 EFFICACY AND SAFETY OF ANTI-SARS-COV-2 VACCINATION IN PEOPLE WITH RMDS: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

Keywords: Vaccination/immunization, COVID, Systematic review

A. Alunno[1], A. Najm[2], F. Kroon[3,4], J. Schoones[5], R. B. M. Landewé[4,6], V. Navarro-Compán[7], P. Machado[8,9,10]. Background: As the third year of the pandemic begins, over 13 billion doses of anti-SARS-CoV-2 vaccines have been administrated worldwide and growing evidence on their efficacy and safety in people with RMDs has accrued.

Objectives: To update our previous systematic literature review (SLR)[1] on efficacy and safety of anti-SARS-CoV-2 vaccination in people with rheumatic and musculoskeletal diseases (RMDs)

Methods: A literature search according to the PICO framework was conducted on July 22, 2022 to identify references in seven databases published after June 1, 2021 (end date of previous SLR). Title and abstracts were independently screened by 3 investigators (AA, AN and FK). Eligibility criteria were stricter in terms of requirement of the inclusion of control group or undertaking a multivariable analysis. However, for some outcomes (e.g., RMD flares), descriptive studies were also included due to the paucity of data. Data extraction and risk of bias (RoB) assessment were performed as in the previous SLR.

Results: Of 1583 references, 219 were included for full text assessment and 30 fulfilled the eligibility criteria. Recent studies confirmed that a full vaccination cycle was generally immunogenic, though the seroconversion rate and the anti-spike antibody (Ab) titre were lower in patients with RMDs compared to healthy controls. Vaccination was also able to induce neutralising antibodies (NAb) but the seroconversion rate and the neutralising activity were lower than in controls. Glucocorticoids, mycophenolate mofetil, rituximab and abatacept were negatively associated with Ab and NAb seroconversion. Two studies specifically investigating RTX-treated RMD patients identified an association between lower dose and longer period of time after the last RTX infusion before vaccination and higher likelihood of Ab seroconversion. The majority of breakthrough infections (B-INFs) were asymptomatic and, if symptomatic, mild to moderate. A higher number of vaccine doses was associated with a lower incidence and severity of B-INFs, although B-INF incidence rate was generally higher in the post-delta variant period. Higher disease activity was associated with higher likelihood of severe/critical B-INFs. Regarding safety, in general, patients with RMDs showed higher rates of mild AEs compared to the general population, however severe AEs were rare, if any. Disease flares have been observed in/reported by less than 10% of patients in the various cohorts and although often requiring treatment with glucocorticoids or change of the ongoing immunosuppressive therapy, hospitalization was generally not needed. Pre-vaccination colchicine prophylaxis seemed useful to prevent gout flares in the post-vaccination trimester.

Conclusion: Overall anti-SARS-CoV-2 vaccination is immunogenic and safe in patients with RMDs. However, careful and individualised assessment of the ongoing therapy and disease activity when planning the vaccination schedule is necessary to minimise the risk of reduced immunogenicity, post-vaccination disease flares and breakthrough infections.

AB1315 EFFECTS OF COVID-19 IN RHEUMATOLOGICAL PAIN CONDITIONS SIX MONTHS AFTER INFECTION

Keywords: Pain, Epidemiology, COVID

B. D. Ebbesen[1], C. Fernández-de-Las-Peñas[2], J. A. Valera-Calero[3], R. Giordano[1], L. Arendt-Nielsen[1]. [1]*Aalborg University & Aalborg University Hospital, School of Medicine, Center for Neuroplasticity and Pain/SMI, Gistrup, Denmark*; [2]*Universidad Rey Juan Carlos, Department of Physical Therapy, Occupational Therapy, Physical Medicine and Rehabilitation, Madrid, Spain*; [3]*Universidad Camilo José Cela, Department of Health, Madrid, Spain*

Background: Up to 60% of COVID-19 survivors develop long-COVID symptoms[1,2]. Musculoskeletal pain is also a common (~11%) symptom of

long-COVID[3,4], but current evidence does not usually differentiate between muscular and joint (arthralgias) symptoms. Data on joint pain as long-COVID symptom is limited to specific populations. Additionally, studies investigating how COVID-19 affects previous rheumatological conditions experienced by the patient before the infection are also scarce.

Objectives: 1, To identify post-COVID changes in those previous joint pain conditions experienced by the patients before SARS-CoV-2 infection.

2, To compare the development of "de novo" joint pain as a long-COVID symptom between previously hospitalized and non-hospitalised COVID-19 survivors.

Methods: This nation-wide, cross-sectional exploratory study was based on a questionnaire collecting demographics, previous rheumatological pain conditions and changes in their symptoms, and the development of joint pain after SARS-CoV-2 infection from a population-based sample in Denmark.

Results: Data from 1.000 randomly previously hospitalised (51.2% males; 60.4±15.2 years; 85.6±18.5kg) and 1.000 randomly previously non-hospitalised COVID-19 survivors (43.5% males; 50.4±15.9 years; 79.2±16.6 kg) were analyzed. Distribution of gender (p<0.001), age (p<0.001), and weight (p<0.001) was different between groups. The presence of joint pain before COVID-19 infection was significantly higher (P=0.01) in hospitalised (3.5%) than in non-hospitalised (1.6%) COVID-19 survivors. No differences in the presence of previous arthritis (P=0.212) or osteoarthritis (P=0.549) were found between the two groups. Both groups experienced similar worsening of symptoms in their previous rheumatological conditions, A significant higher proportion (P<0.001) of hospitalised patients (18.9%) developed "de novo" joint pain when compared with non-hospitalised patients (5.5%).

Conclusion: This exploratory study shows that joint pain seems more likelyto occur in hospitalised patients compared to non-hospitalised patients. Experiencing COVID-19 worsened the symptoms of rheumatological pain conditions in both hospitalised and non-hospitalised COVID-19 survivors. Rheumatological pain will need attention in COVID-19 survivors independently of hospitalisation or not.

Background: Patients with immune-mediated rheumatic diseases (IMRDs) have been prioritized for COVID-19 vaccination to mitigate the infection severity risks. Patients with rheumatoid arthritis (RA) are at a high risk of severe COVID-19 outcomes, especially those under immunosuppression or with comorbidities associated. However, few studies in the literature assessed the safety and immunogenicity of the COVID-19 heterologous vaccine schedules in patients with RA.

Objectives: Evaluate the safety and immunogenicity of two heterologous vaccine schedules against SARS-CoV-2 in patients with RA.

Methods: These data are from the study "SAFER - Safety and Efficacy on COVID-19 Vaccine in Rheumatic Diseases," a Brazilian multicentric prospective phase IV study to evaluate COVID-19 vaccine in IMRDs in Brazil. Immunogenicity and adverse events (AEs) in patients with RA of all centers were assessed after two doses of ChAdOx1 plus additional dose of BNT162b2 or after two doses of inactivated SARS-CoV-2 vaccine CoronaVac plus additional dose of BNT162b2. The titers of neutralizing antibodies against the receptor-biding domain of protein spike (S) of SARS-CoV-2 (anti-RBD) were measured by chemiluminescence test after each dose of immunizers. Proportions between groups were compared using the chi-square and Fisher's exact tests for categorical variables. Clinical Disease Activity Index (CDAI) before and after vaccination was assessed using the McNemar test.

Results: A total of 107 patients with RA were include in the study, most of them female, with a mean age of 46 years. Biological disease modifying anti-rheumatic drugs (DMARDs) were used by 50 % of the patients and conventional synthetics DMARDs in 48 %. Two doses of CoronaVac plus additional dose of BNT162b2 was used in 66 patients and two doses of ChAdOx1 plus additional dose of BNT162b2 in 41. Only mild AEs were observed, mainly after the first dose. The most common AEs after all doses, regardless of the immunizer type, were pain at the injection, headache, arthralgia and myalgia. ChAdOx1 had a higher frequency of pain at the injection (66% vs 32 %, p < 0,001) and arthralgia (68% vs 15%, p < 0,001) compared to CoronaVac. No patients had flare after the vaccination. The titers of anti-RBD after two doses of ChAdOx1 were higher compared to two doses of CoronaVac (6,03 BAU/mL vs 4,67 BAU/mL, p < 0,001). However, after the additional dose of BNT162b2, the anti-RBD titers were similar in both groups (7.28 BAU/mL vs 7.06 BAU/mL, p = 0.56). Only two cases of COVID 19, with mild symptoms, were reported, one in each group.

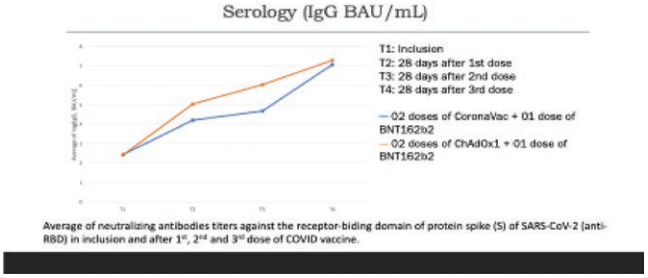

Figure 1.

Conclusion: ChAdOx1, CoronaVac, and BNT162b2 vaccines are safe in RA patients. The frequency of local adverse effects, particularly pain at the injection

site, is high. AEs are more frequent with ChAdOx1, especially after the first dose. The use of the immunizers does not change the degree of inflammatory activity of the disease. The immunogenicity of the two heterologous regimens analyzed was similar.

AB1317 EFFICACY AND SAFETY OF COVID-19 VACCINES IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH DIFFERENT ANTI-RHEUMATIC THERAPIES

Keywords: Rheumatoid arthritis, COVID, Vaccination/immunization

Q. Y. Su[1,2,3], J. Luo[2,3], Y. Zhang[2,3], B. R. Zhao[2,3], Y. Cao[2,3], Q. Yu[4], P. F. He[4], X. Li[1,2,3], S. X. Zhang[1,2,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; *[2]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*; *[3]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; *[4]Ministry of Education, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*

Background: The coronavirus disease (COVID-19) pandemic caused by severe acute respiratory syndrome coronavirus 2 has led to rapid progress in vaccine development to prevent the spread of the disease. Rheumatoid arthritis (RA) is a common systemic inflammatory autoimmune disease that are vulnerable to infection due to their underlying conditions and immunomodulatory therapy.

Objectives: This study aimed to evaluate the seroconversion after SARS-CoV-2 vaccination in patients with RA and the impact of various drugs on seroconversion rates to provide information for clinicians and patients to guide decisions.

Methods: Systematic searches of the CBM, CNKI, China Science and Technology Journal Database, WanFang Data, PubMed, Embase, Web of Science, Cochrane Library, and Medline were performed. We included observational studies evaluating RA patients undergoing SARS-CoV-2 vaccination. Random effects model was used to calculate the pooled efficacy. Heterogeneity and risk of bias were examined with the I-squared index (I^2) statistic. Inconsistency was evaluated using the I^2 and Egger tests to assess potential publication bias (STATA v.12.0).

Results: A total of 5 observational studies comprising 502 RA patients were identified (Table 1).The seropositivity rate in patients with RA was 0.701 (95%CI: 0.531-0.871) after vaccination with SARS-CoV-2 vaccines. Drugs used by patients with RAs had an impact on the seropositivity rate. The seropositivity rate of RA using GC, bDMARDsS, and csDMARDs was 0.713 (95%CI: 0.544-0.982), 0.764 (95%CI: 0.593-0.935) and 0.625 (95%CI: 0.546-0.704), respectively. Patients with csDMARDs treatment had the lowest seropositivity rate while bDMARDs had a high seropositivity rate(Figure 1). The most commonly reported adverse events in RA patients vaccinated with SARS-CoV-2 vaccines were fever (0.101, 95%CI:0.036-0.165), and the lowest rates of adverse events in RA patients was diarrhea(0.053, 95%CI: 0.004-0.101).

Conclusion: After vaccination with SARS-CoV-2 vaccines, the seropositivity rates of RA patients using csDMARDs have the lowest seropositivity rate.

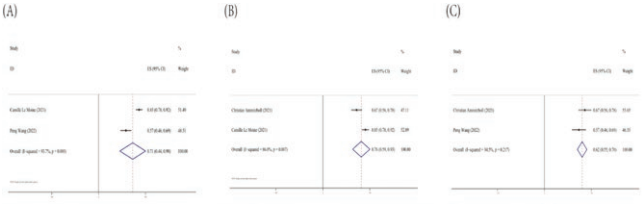

Figure 1: Forest plot of the subgroup meta-analysis of positive serum rate of RA patients who received GC(A),bDMARDs(B), and csDMARDs(C) treatment after COVID-19 vaccination.

Table 1. Characteristics of the individual studies included in the meta-analysis.

AB1318 CLINICAL CHARACTERISTICS & OUTCOMES AMONG PATIENTS WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES AND SARS-COV-2 INFECTION: 2-YEAR DATA FROM A TERTIARY RHEUMATOLOGY CENTRE IN GREECE

Keywords: COVID, Descriptive studies

N. Gerolymatou[1], N. Koletsos[2], T. Zoi[2], T. E. Memi[2], A. Drosos[2], P. Voulgari[2]. *[1]University Hospital of Ioannina, Rheumatology, Ioannina, Greece*; *[2]University Hospital of Ioannina, Rheumatology, Ioannina, Greece*

Background: Patients with autoimmune rheumatic diseases (ARDs) under moderate/severe immunosuppression are considered a high-risk population to develop severe Covid-19 infection.

Objectives: The aim of our study was to describe the clinical characteristics and the outcome of patients with ARD who contracted a Sars-Cov-2 infection.

Methods: Among patients with ARD being followed in our tertiary outpatient rheumatology clinic, we retrospectively identified those infected with SARS-CoV-2 between the beginning of the pandemic and August 2022. Patients' medical files were reviewed for demographics (age, gender and comorbidities) and disease-related characteristics, as well as coronavirus disease (COVID-19) characteristics, including vaccination status, treatment, and outcomes (covid-19 severity, hospitalization, death).

Results: A total of 209 cases of ARD patients with confirmed Covid-19 infection were recorded. Most of them were women (62.7%), with a mean age of 52.4± 13.8 years. The most prevalent ARDs were seronegative spondyloarthropathies (28.7%), systematic lupus erythematosus (21.5%), rheumatoid arthritis (16.5%), and systemic sclerosis (11.5%). More than half of the patients received corticosteroids (57.8%), while the most frequently used immunosuppressants were hydroxychloroquine (30.9%), TNF inhibitors (26.5%), mycophenolate mofetil (24.0%), methotrexate (19.1%) and rituximab (15.2%). One hundred and fifty-eight (76%) patients were either on remission or had mild disease activity. Most of the patients (131/209) had at least one comorbidity, more commonly arterial hypertension (48.5%) and pulmonary disease (45.2%). Most of the patients were vaccinated against Sars-Cov-2 (73.7%), either with two doses (38.0%), three doses (57.0%) or four doses (5.0%) of mRNA-based vaccines. The big majority of the patients (83.3%) were asymptomatic or had mild Covid-19 disease. About half of the patients (53.1%) reported to have received Covid-19 treatment. Thirty-two of them (15.3%) needed hospitalization, and five death cases were reported overall. Among the demographic characteristics, age ($p<0.0001$ for hospitalization) and comorbidities were associated with worse covid-19 outcomes. In particular, cardiovascular disease (OR 5.37, $p=0.001$ for covid-19 severity, OR 6.89, $p=0.001$ for hospitalization), pulmonary disease (OR 3.02, $p=0.006$ for hospitalization), and obesity (OR 3.46, $p=0.044$ for hospitalization) had the stronger associations. Non-vaccination status was also associated with a higher risk for hospitalization (OR 2.68, $p=0.015$). In relation to ARD-related factors, treatment with rituximab (OR 4.11, $p=0.002$ for hospitalization), systemic sclerosis diagnosis (OR 3.45, $p=0.03$ for Covid-19 severity) and myositis diagnosis (OR 4.91, $p=0.033$ for hospitalization) were associated with worse Covid-19 outcomes. On the other hand, spondyloarthropathies appear to be negatively associated with Covid-19 severity (OR=0.27, $p=0.035$).

Conclusion: According to our study, most ARD patients recovered uneventfully from Covid-19. However, there are several indications that we should be vigilant for patients who remain unvaccinated, are older, have a systemic sclerosis or myositis diagnosis, and/or receive intense immunosuppressive regiments such as rituximab.

AB1319 DYNAMIC IMMUNE FEATURES REVEALED BY SINGLE-CELL RNA AND SINGLE-CELL TCR/BCR SEQUENCING IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING SARS-COV-2 BOOSTER VACCINATION

Keywords: COVID, Vaccination/immunization, Rheumatoid arthritis

Y. Fan[1], Y. Geng[1], J. Zhao[1], H. Huang[1], J. Zhang[1], Y. Wang[2], Z. Zhang[1]. *[1]Peking University First Hospital, Rheumatology and Clinical Immunology, Beijing, China*; *[2]Peking University Health Science Center, Department of Immunology, Beijing, China*

Background: Rheumatoid arthritis (RA) is one of the most common autoimmune diseases and have been shown to be more vulnerable to SARS-CoV-2 infection. Numerous COVID-19 vaccines have demonstrated significant efficacy in reducing SARS-CoV-2 infection and severe cases[1]. Booster vaccinations played an imoprtant role in maintaining this protection.

Objectives: The use of COVID-19 vaccines is considered to potentially provoke autoimmunity by molecular mimicry, and subsequently trigger flare of underlying autoimmune diseases[2, 3]. Little is known about the delicate immune responses after inactived SARS-CoV-2 booster vaccination in RA.

Methods: Three RA patients who were in remission were prospectively enrolled. Peripheral blood mononuclear cell (PBMC) were collected 1 week before and after their inactivated SARS-CoV-2 booster vaccination, respectively. Single-cell RNA sequencing (scRNA-seq) combined with scTCR/BCR-seq analyses were performed using the 10x Genomics Single Cell technique.

Results: Vaccination with booster vaccination only had limited impact on the composition of peripheral immune cells in RA patients, but significantly altered the proportion in myeloid cells, B cells and plasma cells. Transcriptomic changes, which were mostly involved in antibody production as well as B cell activation and differentiation, were observed after booster vaccination. No pro-inflammatory response genes were found to be significantly upregulated in SARS-CoV-2 booster vaccinated RA individuals. Moreover, single-cell TCR/BCR analysis showed a different clone expansion and repertoire diversity after booster vaccination.

Conclusion: Our study provide a comprehensive single cell atlas of the peripheral immune response and TCR/BCR immune repertoire profiles to SARS-CoV-2 booster vaccination in RA patients, which helps us to better understand COVID-19 vaccination and immunization.

AB1320 COVID-19 OUTCOME IN AN ITALIAN RHEUMATOID ARTHRITIS COHORT

Keywords: Rheumatoid arthritis, COVID

E. Molteni[1], C. Castellani[1], G. Sciarra[1], L. Di Sanzo[1], G. Bevignani[1], M. Di Franco[1], V. Riccieri[1], C. Alessandri[1], R. Priori[1], F. Conti[1], R. Scrivo[1]. *[1]Sapienza University of Rome, Department of Clinical Internal, Anesthetic and Cardiovascular Sciences, Roma, Italy*

Background: It is known that rheumatologic patients often present a course of COVID-19 similar to that of the general population. Some factors are linked to a worse COVID-19 outcome, such as moderate glucocorticoid (GC) dose, high body mass index (BMI), and comorbidities.

Objectives: To describe the outcome of COVID-19 in patients with rheumatoid arthritis (RA) in terms of symptoms, therapy and need for hospitalization compared to a control group. Also, to evaluate the variation in disease activity before and after COVID-19.

Methods: In this monocentric prospective study, we recruited consecutive adult patients with RA classified according to ACR-EULAR 2010 criteria who received a diagnosis of COVID-19 through molecular or rapid antigen swab tests between September 2020 and December 2022. Demographic and clinical data, including age, BMI, smoking habit, comorbidities, treatment at the diagnosis of COVID-19, duration of COVID-19, symptoms related to the infection and therapy required, together with the vaccination status were collected through a self-administered questionnaire. We compared DAS28-CRP before the infection and at the first visit after the resolution. As controls (Cs), individuals with COVID-19 but with no referred diagnosis of rheumatic/autoimmune disease were recruited.

Results: We enrolled 111 patients affected by RA (males 15%, median age 56 years, IQR 25) and 89 Cs (males 44%, median age 47 years, IQR 43), whose demographic and clinical characteristics are reported in **Table 1**. The median RA disease duration was 108 months (IQR 201). At the COVID-19 diagnosis, 62 patients (56%) were assuming csDMARDs, 67 (60%) bDMARDs, and 18 (16%) GC with a median prednisone equivalent dose of 4 mg/day (IQR 1). DAS28-CRP was available for 62 patients, with a median value of 1.67 (IQR 2.71); 42 patients (60%) were in remission (Figure 1). Before developing COVID-19, only 35 (32%) RA patients and 42 (47%) Cs had completed the vaccinal cycle, which was performed by mRNA vaccine in all the patients and 87% of Cs. The median COVID-19 duration was 18 days (IQR 18) for RA patients and 14 days (IQR 13.5) for Cs ($p>0.7$). Cs reported a significantly higher frequency of constitutional symptoms (headache and asthenia) compared to RA patients ($p<0.00001$). When hospitalization was required, RA patients received heparin more frequently than Cs ($p<0.039$). Once COVID-19 was resolved, RA patients were evaluated after a median of 2 months (IQR 2). DAS28-CRP was available for 68 patients, with a median value of 1.61 (IQR 1.77); 42 patients (68%) were in remission (Figure 1). No differences in terms of COVID-19 duration, clinical manifestations, and therapy emerged comparing RA patients in remission (40; 58%) with patients with the active disease before COVID-19 (29; 42%). Also, in vaccinated subjects, the outcome of COVID-19 was similar in RA patients and Cs, irrespective of RA activity.

Conclusion: COVID-19's impact on patients with RA was not significantly different from the general population, even for patients with active RA. Patients did not suffer from reactivation of RA because of COVID-19. In our opinion, these positive results could be ascribed to the massive vaccination campaign.

Tufan[1,10]. *[1]Gazi University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[2]Hacettepe University Hospital, Department of Internal Medicine, Ankara, Turkey*; *[3]Fırat University, Department of Internal Medicine, Division of Rheumatology, Elazıg, Turkey*; *[4]Etlik City Hospital, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[5]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; *[6]Gazi University, Department of Internal Medicine, Ankara, Turkey*; *[7]University of Health Sciences, Department of Rheumatology, Gülhane Training and Research Hospital, Ankara, Turkey*; *[8]Ankara Yıldırım Beyazıt University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[9]Hacettepe University Hospital, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[10]National Human Genome Research Institute, Inflammatory Disease Section, Bethesda, United States of America*

Background: Coronavirus disease 2019 (COVID-19) caused by severe acute respiratory syndrome-coronavirus-2 (SARS-CoV-2) has diverse and wide array of clinical presentations ranging from asymptomatic to severe disease. The exact pathophysiological mechanism of severe COVID-19 is still obscure; however, unrestrained immune response, exaggerated systemic inflammation, endothelial activation, and vascular damage are implicated in its pathogenesis similar to systemic sclerosis (SSc) and autoimmune diseases [1-2].
Objectives: to assess the clinical presentation and worse outcomes of COVID-19 in SSc patients and evaluate the effects of SSc features on the clinical course of COVID-19
Methods: This multicentre, retrospective, observational study included SSc patients with COVID-19 diagnosis which was confirmed by SARS-CoV-2 RT-PCR or suggestive symptoms with typical radiologic pulmonary findings. Clinical features of SSc and detailed COVID-19 data were provided from medical records ab and patient interviews.
Results: One hundred twelve patients (age mean 51.4±12.8 years, 90.2% female) were included in the study. SSc associated interstitial lung disease (ILD) was evident in 57.1% of the patients. SSc-specific treatments were low-dose glucocorticoids and mycophenolate. We found 25.5% hospitalization, 16.3% respiratory support, 3.6% intensive care unit admission, 2.7% long-COVID, and 2.7% mortality rate in SSc patients. ILD and ≥1 comorbidity were more frequent in inpatients compared to outpatients (82.1% vs 49.4% p= 0.005; 67.9% vs 42.7% p=0.037, respectively). Risk factors for respiratory failure were ILD (OR:7.49, 95%CI:1.63-34.46, p=0.01), ≥1 comorbidity (OR:4.55, 95%CI 1.39-14.88, p=0.01), having a higher physician global assessment score at the last outpatient visit (OR 2.73, 95% CI: 1.22-6.10, p:0.01), and use of MMF at the time of getting the infection (OR: 5.16, 95 %CI: 1.79-14.99, p:0.003) by univariate analysis. Having ≥1 comorbidity was the only significant predictor of the need for respiratory support in COVID-19 (OR:5.78, 95%CI:1.14-29.23, p:0.03). In the early post-COVID-19 period, 17% of patients reported the progression of the Raynaud phenomenon, and 10.6% of patients developed new digital ulcers. Progression or new onset of dyspnea and cough were detected in 28.3% and 11.4% of patients, respectively.
Conclusion: SSc-related ILD, severe disease activity, and use of mycophenolate might be related to adverse outcomes of COVID-19, and having comorbidity is an independent risk factor for respiratory support.

COVID-19 PANDEMIC AND SYSTEMIC INFLAMMATORY RHEUMATIC DISEASES: OUR EXPERIENCE IN DAKAR, SENEGAL (SUB-SAHARAN AFRICA)

Keywords: Disease-modifying drugs (DMARDs), Inflammatory arthritides, COVID

B. S. Kane[1], M. Dieng[1], B. Fall[1], M. Sow[1], A. T. Lemrabott[2], M. A. Ndour[1], A. C. Ndao[1], S. Ndongo[1], A. Pouye[1]. *[1]Cheikh Anta DIOP University, Internal Medicine, Dakar, Senegal*; *[2]Cheikh Anta DIOP University of Dakar, Nephrology, Dakar, Senegal*

Background: There are paucity data regarding the Covid-19 pandemic on the management of systemic autoimmune rheumatic diseases in sub-Saharan Africa.
Objectives: The aim of our study was to assess the impact of the Covid-19 pandemic on the follow-up of patients with systemic inflammatory diseases and their adherence to vaccination against SARS-CoV-2.
Methods: We performed a multicentric cross-sectional study between August 1st and October 31, 2021. The study targeted the patients diagnosed for systemic diseases according to the international criteria. The patients were followed in the departments of Internal Medicine, Rheumatology and Nephrology of 04 hospitals in Dakar (Senegal). The survey was based on records of 13 questions (with responses collected from the patients' medical records) and was completed by a telephone interview with 38 potential questions. All responses were collected using a web-based application and then exported and analyzed using SPSS 26 software.
Results: 131 patients were included with a mean age of 41.5 years (+/-12.4) and a sex ratio of 0.08. Inflammatory rheumatic diseases included: Rheumatoid arthritis (47.3%), Systemic lupus erythematosus (22.9%), Autoimmune myositis (10.7%), Sjögren's syndrome (6.9%), Systemic sclerosis (4.6%), Spondylarthritis (2.3%), Antiphospholipid syndrome (1.5%), ANCA-associated vasculitis (1.5%),

Adult-onset Still's disease (0.8%), Systemic sarcoidosis (0.8%) and Relapsing polychondritis (0.8%). Patients reported missing one or more follow-up appointments in 45%, a drug break (33.6%) regarding particularly the methotrexate (21/44 of patients: 47.7%) and hydroxychloroquine (18/44 patients: 40.9%) with a flare-up of their disease in 31% of cases. Covid-19 infection was confirmed in 11 patients (8.4%). Our survey showed that 47 patients (35.8%) were vaccinated with: Ad.26.COV2.S (40.4%), chAdOx1 nCoV-19 (27.7%) and BBIBP-CorV (31.9%). Side effects were reported by 21 of 47 patients (45%) only after the first dose. 2 of 47 (4.25%) patients had a medically confirmed flare. 84 (64.2%) patients were not vaccinated. Fear of vaccine side effects and the effects of the vaccine on systemic disease were the main reasons for non-adherence to vaccination.

Conclusion: The covid-19 pandemic has had a significant impact on the follow-up of patients with systemic inflammatory diseases in Dakar. Vaccine hesitancy is a reality in these patients.

AB1323 ANALYSIS OF ADVERSE EFFECTS AFTER VACCINATION AGAINST COVID-19 IN PATIENTS WITH IMMUNO-MEDIATED RHEUMATIC DISEASES IN MANAUS – AMAZONAS

Keywords: Epidemiology, Vaccination/immunization, COVID

M. M. Sousa Dias[1], N. Seixas de Melo[1], S. E. B. Dias[1], C. Pinheiro Martins[1], V. Miki Pang Takatani[1], R. Beatriz Nazareth Alagia[1], B. Guimarães Dutra[1], G. Bacellar Marques[1], D. Queiroz Rego[1], D. Buzaglo Gonçalves[1], C. Telles[1], S. Ribeiro[1]. *[1]Universidade Federal do Amazonas, Faculdade de Medicina, Manaus/AM, Brazil*

Background: Immune-Mediated Rheumatic Diseases (IMRD) are characterized by a chronic inflammatory response, have several clinical manifestations and are more susceptible to infections and worse prognosis. Thus, in the context of the COVID-19 pandemic, to reduce morbidity-mortality, vaccination is an effective method of prevention. However, there are not enough studies that encompass this group of patients, leaving many doubts about the adverse effects and its safety and effectiveness.

Objectives: Analyze the adverse effects observed in patients with IMRD after vaccination against COVID-19.

Methods: Observational, longitudinal, ambidirectional research, with follow-up of groups of patients with IMRD immunized with vaccines made available by the Programa Nacional de Vacinação with Coronavac (Instituto Butantan), AstraZeneca (BioManguinhos/Fiocruz), Pfizer/BioNTech and Janssen (Johnson & Johnson). Sociodemographic data and data on the adverse effects presented were collected, recorded through a diary delivered to each patient, filed on an online platform. This study was approved by the local Ethics and Research Committee.

Results: 223 patients over 18 years of age were included, the mean age is 42.79±15, 83% women. The main DRIM: Systemic Lupus Erythematosus (39%) and Rheumatoid Arthritis (33.6%). In the 1st dose, 78.3% of the vaccines applied were Coronavac, 18.9% AstraZeneca and 2.8% Pfizer/BioNTech, the adverse effects found were: Pain at the injection site (49.3%), Headache (43.3%), Tiredness (34.3%) and Nausea (21.6%). In the 2nd dose, with the same vaccines applied as the previous dose, the adverse effects: Pain at the injection site (44.6%), Headache (33.9%), Tiredness and Vertigo (21.5%). In the 3rd dose, 55.3% of AstraZeneca, 44.2% of Pfizer and 0.4% of Janssen, in relation to adverse effects: Pain at the injection site (65.2%), Headache (41.8%), Tiredness (36.2%) and Edema and hardening of the skin at the injection site (31.9%). For the 4th dose, the AstraZeneca (14.9%) and Pfizer (85.1%) vaccines were applied, the adverse effects found: Pain at the injection site (58.5%), Hardening of the skin at the injection site injection (24.4%), Headache (19.5%), Tiredness (17.1%).

Conclusion: It is observed that the adverse effects presented after each administered dose are mild to moderate, more frequent: pain at the injection site and headache without significant differences compared to the general adult population.

Background: Facing the outburst of the COVID-19 pandemic, we gradually comprehend its pathophysiology as a coagulopathy characterized by increased risks of arterial, venous, and microvascular thrombosis. Antiphospholipid syndrome (APS) is an autoimmune, thrombo-inflammatory disease characterized by thrombosis and/or pregnancy loss in the presence of one or more antiphospholipid antibodies (aPL).

Objectives: To evaluate the clinical scenario of COVID-19 in the APS population of patients.

Methods: This is a single-center, observational, cross-sectional study. Data regarding the severity of COVID-19 (severe COVID-19 considered if interstitial pneumonia was diagnosed), COVID-19 vaccinal status, and post-vaccinal reactions (divided into mild, consisting of fever, myalgia, nausea, and severe if thrombosis at any point occurred) were collected from 44 APS patients (21 with primary and 23 with APS associated with systemic lupus erythematosus (SLE), 90.1% female). aPL analysis included the detection of aCL (IgG/IgM), ß2GPI (IgG/IgM), and LA Results were compared to the control group consisting of 31 healthy individuals, with no APS, matched to the APS group regarding age and gender.

Results: At the moment of COVID-19 infection, 75% of the APS group was taking Aspirin, 15.9% warfarin, 2.3% non-vitamin K oral anticoagulant, 59.1% chloroquine, 31.8% corticosteroid, 2.3% methotrexate. None of the above-mentioned medications were taken from a control group. There was no difference regarding the severity of COVID-19 between APS patients and healthy controls: 84.1% of APS had mild and 15.9% severe COVID-19 (p=0.509, p=0.292 respectively). But the difference regarding the need for hospitalization was significant (none of the healthy controls compared to 11.4% APS patients, p=0.0073). Interestingly, COVID-19 occurred in 72.7% of APS patients before the COVID-19 vaccination compared to 35.5% of healthy controls, p=0.001, conversely, a significantly lower percentage of vaccinated APS patients had COVID-19 compared to healthy controls (34.1% to 71.0%, p=0.002). 27% of APS patients had mild post-vaccinal reactions, none with severe.

Conclusion: During the COVID-19 pandemic, APS patients in Serbia were at higher risk for hospitalization. However, there was no difference in the severity of clinical presentation compared to non -the APS population. We can only speculate that APS therapy consisting of Aspirin, Chloroquine, and oral anticoagulant therapy contributed to this finding. Moreover, COVID-19 vaccination in the APS population, followed by a low incidence of mild post-vaccinal reactions, had more benefits in protection than in non-APS individuals.

Avčin[2,3]. *[1]University Children's Hospital, Clinical Institute of Special Laboratory Diagnostics, Ljubljana, Slovenia*; *[2]University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia*; *[3]University Children's Hospital, Department of Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia*

Background: Children infected with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) usually present minimal symptoms or are asymptomatic. Nevertheless, a subset of children 2-6 weeks after the initial SARS-CoV-2 infection develops a postinfectious SARS-CoV-2-related multisystem inflammatory syndrome in (MIS-C). Recently, transient expansion of TRBV11-2 T cell clonotypes in MIS-C was associated with signatures of inflammation and T cell activation, however, the underlying pathophysiology of MIS-C is not fully understood [1].
Objectives: The purpose of our project is to characterize the complexity of cell populations and capture cellular heterogeneity to uncover the regulatory networks and interactions that are disrupted during MIS-C flare with simultaneous profiling of gene expression and open chromatin regions from the same nuclei.
Methods: Samples of peripheral blood mononuclear cells from patients with MIS-C diagnosed at the University Children's Hospital, University Medical Center Ljubljana, were collected during the initial presentation before any treatment and at 6-12 months in remission. The primary aim is to identify which regulatory networks are driving inflammation in MIS-C flare, for which we are performing single cell Multiome ATAC + Gene Expression Sequencing. To enable simultaneous profiling of epigenomic landscape and gene expression from the same nuclei, we are using Chromium Next GEM Single Cell Multiome ATAC + Gene Expression kit from 10X Genomics.
Results: We included 32 patients with MIS-C from whom we collected paired blood samples during the initial presentation before treatment and at 6-12 months in remission. In single cell multiomic experiment we included 10 patients with paired samples, with the most viable cell count prior cryopreservation. All samples that are included into multiomic single cell analysis have 75% - 99% viability prior cryopreservation. In the protocol the key is to remove remaining granulocytes causing high mitochondrial RNA burden and extensively optimize the dilution factor of lysis buffer and the length of cell lysis step in order to get intact nuclei with no significant blebbing. Afterward, the single cell ATAC libraries as well as single-cell gene expression libraries are constructed and sequenced. Data are undergoing pairwise analysis to compare the cell population heterogeneity, expression profile and open chromatin landscape in the time of the initial presentation of MIS-C and in the remission, with Cell ranger software as well as with R package scREG [2], and custom scripting. In the second step we will inspect if the resulting altered transcriptomic signature from single-cell experiment is present on larger cohort. In that regard, we will perform bulk transcriptomic profiling on all paired collected samples during the initial presentation of MIS-C before treatment and at 6-12 months in remission.
Conclusion: The results of this project are expected to enlighten the underlying pathophysiology of MIS-C flare and thus support clinical decision on more targeted treatment. The identified disrupted networks during MIS-C flare could lead the way to establish an early diagnosis and improve long-term outcome, including prevention of myocardial and neuropsychological impairment. Moreover, a better understanding of the disrupted regulatory networks that are driving inflammation in MIS-C, could lead to new insights into diseases with similar clinical presentations as is Kawasaki Disease.

DIFFERENCES IN ADVERSE EVENTS EXPERIENCED BY INDIVIDUALS WITH INFLAMMATORY RHEUMATIC DISEASES AND HEALTHY INDIVIDUALS AFTER SARS-COV-2 VACCINATION

Keywords: Vaccination/immunization, COVID, Safety

L. Huppke[1], C. Gebhardt[1], L. Grümme[1], J. Lichtnekert[1], D. Singh[1], F. Ullrich[1], S. Wolfrum[1], A. Skapenko[1], H. Schulze-Koops[1]. *[1]University of Munich, Division of Rheumatology and Clinical Immunology, Department of Internal Medicine IV, Munich, Germany*

Background: Since individuals with inflammatory rheumatic diseases (IRDs) were excluded from the SARS-CoV-2 vaccination trials (1), uncertainty on the tolerability of the vaccines in this population was high. This caused a lower willingness to be vaccinated compared to the general population. Gaining more information on vaccine reaction in this population is critical.
Objectives: The aim of the study was to improve knowledge of the tolerability of SARS-CoV-2 vaccination in patients with IRD and to identify potential specific risks of this population by comparison with a healthy cohort.
Methods: IRD patients were recruited from the outpatient clinic of the Division of Rheumatology and Clinical Immunology at the hospital of the LMU Munich. Health care workers served as healthy controls. Questionnaires were used to identify adverse effects in all study participants after each SARS-CoV-2 vaccination and to obtain information about patients' disease and therapy. Descriptive statistics and non-parametric tests were used to discern differences between IRD patients and controls.
Results: 235 IRD patients (60% female), mean (±SD) age 54 (±15) years, and 102 healthy individuals (67% female), mean age 48 (±16) years, were recruited between Jan 2021 and Sep 2022. Pain at the injection site and fatigue were the most common adverse events in both groups. (Table 1) Patients presented adverse events significantly less often after the first vaccination (59.6%) compared to healthy individuals (84.3%) (OR=0.274 [95% CI: 0.151-0.497]; P<0.0001). With 58.7% of patients and 78.4% of controls experiencing adverse events after the second vaccination the difference stayed significant (OR=0.391 [0.228-0.670]; P<0.001). Same goes for the third vaccination with 56.4% of patients and 69.3% of controls presenting adverse events (OR=0.573 [0.348-0.946]; P=0.029). No difference was seen when the occurrence of local effects were compared. However, systemic effects were experienced significantly less by patients compared to controls after the first (41.3% vs 59.8%) (P=0.002), second (38.7% vs 58.8%) (P<0.001) and third vaccination (39.0% vs 51.5%) (P=0.036). Younger age and female sex showed higher frequencies of adverse events in both groups. 2% of patients experienced an activation of their IRD. Serious adverse events did not occur.

Table 1. Adverse events experienced after SARS-CoV-2 vaccination in patients and controls

	Patients			Healthy controls		
Adverse effects	**1. vaccination**	**2. vaccination**	**3. vaccination**	**1. vaccination**	**2. vaccination**	**3. vaccination**
	n=235	**n=233**	**n=218**	**n=102**	**n=102**	**n=101**
Local reactions, % (n)						
Any	49.8 (117)	48.9 (115)	47.7 (104)	66·7 (68)	57·8 (59)	49·5 (50)
Pain at the injection site	46.4 (109)	47.2 (110)	45.0 (98)	65·7 (67)	55·9 (57)	47·5 (48)
Swelling at the injection site	12.3 (29)	9.9 (23)	13.3 (29)	10·8 (11)	10·8 (11)	9·9 (10)
Redness at the injection site	8.9 (21)	7.3 (17)	8.7 (19)	7·8 (8)	7·8 (8)	6·9 (7)
Systemic reactions, % (n)						
Any	41.2 (97)	38.7 (91)	39.0 (85)	59·8 (61)	58·8 (60)	51·5 (52)
Fatigue	29.4 (69)	27 (63)	28.0 (61)	42·2 (43)	45·1 (46)	37·6 (38)
Chills	6.8 (16)	8.2 (19)	6.4 (14)	12·7 (13)	15·7 (16)	5·9 (6)
Fever	5.5 (13)	6.4 (15)	6.0 (13)	12·7 (13)	16·7 (17)	8·9 (9)
Headache	15.3 (36)	12.9 (30)	13.3 (29)	22·5 (23)	19·6 (20)	21·8 (22)
Nausea	2.6 (6)	2.1 (5)	3.7 (8)	2·9 (3)	3·9 (4)	0 (0)
Muscle pain	13.2 (31)	12.0 (28)	13.8 (30)	26·5 (27)	25·5 (26)	22·8 (23)
Joint pain	6.8 (16)	5.2 (12)	6.4 (14)	10·8 (11)	11·8 (12)	8·9 (9)
Others	5.1 (12)	5.2 (12)	6.0 (13)	1.0 (1)	3.9 (4)	3.0 (3)

Conclusion: IRD patients are at no higher risk of experiencing adverse events than controls after SARS-CoV-2 vaccination. In fact, systemic effects seem to occur less frequently in patients compared to healthy individuals, which potentially shows an influence of IRDs or their therapies on vaccination reactions.

COVID-19 CUTANEOUS AND SYSTEMIC MANIFESTATIONS AMONG DIFFERENT RACIAL GROUPS: A META-ANALYSIS

Keywords: COVID, Skin

A. El-Said[1], A. Ahmad[2], M. Valenti[3], N. Shah[1], S. Soto[1], S. Beg[4]. *[1]University of Central Florida College of Medicine, College of Medicine, Orlando, United States of America*; *[2]University of Central Florida, Health Sciences, Orlando, United States of America*; *[3]Sapienza University of Rome, College of Medicine, Rome, Italy*; *[4]University of Central Florida College of Medicine, Rheumatology, Orlando, United States of America*

Background: COVID-19 cutaneous manifestations were first reported in February 2020, after a rash was listed as a sign of the virus.[1] In 2020, an article emphasized the absence of images among skin of color with respect to COVID-19 skin manifestations.[2] Without detection and treatment, individuals with skin of color may experience a disproportionate incidence of morbidity and mortality.[3] Discussion of cutaneous findings in skin of color remains limited to reviews and individual studies, and although there are meta-analyses that assess systemic manifestations among different races, investigation of various symptoms among people with skin of color, and overall comparison of systemic manifestations to cutaneous manifestations remains unreported to our knowledge.[4]

Objectives: The objective of this meta-analysis was to quantify the frequency of reported cutaneous and systemic manifestations among different races.

Methods: A search for studies on dermatologic and systemic manifestations associated with COVID-19 published before February 2022 was run on PubMed and Embase. Two independent reviewers screened abstracts and full manuscripts for eligibility based on the following criteria: studies included children or adult patients diagnosed with COVID-19 or temporal association to COVID-19, studies included assessment of cutaneous and systemic manifestations of individuals, studies identified cutaneous and systemic manifestations among different races, and studies were peer-reviewed case reports, original studies, systematic reviews, meta-analyses, and letters to the editor. Race and the most common systemic and dermatologic manifestations were extracted from included studies. Event rates for each outcome by race were pooled using a single-arm meta-analysis and the random-effects model to account for heterogeneity.

Results: Seventeen studies, involving 2,525 patients, were selected. Pooled estimates for multisystem inflammatory syndrome (MIS) for Black, White, and Asian cases were 28% (95% CI, 18.8-40.7, p=0.001), 40.1% (95% CI, 23.0-60.1, p=0.332), and 20% (95% CI, 13.2-29.2, p=0.000), respectively. The most common manifestations were pyrexia, elevated inflammatory markers, cardiac dysfunction, and gastrointestinal symptoms. The frequency of elevated inflammatory markers within Black cases surpassed White and Asian cases (30.9%, 28.7%, and 19.6%). The percentage of Black cases for cardiac dysfunction exceeded White and Asian cases (38.8%, 25%, and 21.2%,). The frequency of pyrexia reported among Asian and Black cases exceeded White cases (26.7%, 24.3%, and 15.3%). The prevalence of dermatologic manifestations in Black cases was 4.2% (95% CI, 0.8-19.8, p=0.000) compared to White and Asian cases, 70.7% (95% CI, 42.9-88.6, p=0.139) and 11.7% (95% CI, 9.0-15.1, p=0.000).

Conclusion: This meta-analysis highlights the discordance in reporting systemic manifestations compared to dermatologic manifestations by race in COVID-19 patients. Further investigation is needed to determine the underlying cause.

Background: The longitudinal efficacy and safety data of vaccines against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) in patients with rheumatic disease (RD) remains unclear.

Objectives: The objective of the study was to examine changes over time in anti-SARS-CoV-2 spike protein IgG (anti-S IgG) values in RD patients compared with controls and investigate the effects of immunosuppressants on the values. Safety of vaccine was also evaluated.

Methods: RD patients receiving glucocorticoids or immunosuppressants who were scheduled to receive two doses of SARS-CoV-2 mRNA vaccines were included. Patients not receiving these drugs and were attending the hospital for diseases other than RD or malignancies served as the control group (CG). Following the guidance of the American College of Rheumatology, some immunosuppressive drugs were withheld before and after vaccinations. Blood samples were collected before and 1, 3, and 6 months (M1, M3, M6) after the vaccinations, and anti-S IgG values were measured using SARS-CoV-2 IgG II Quant Reagent Kit (Abbott Laboratories, USA).
