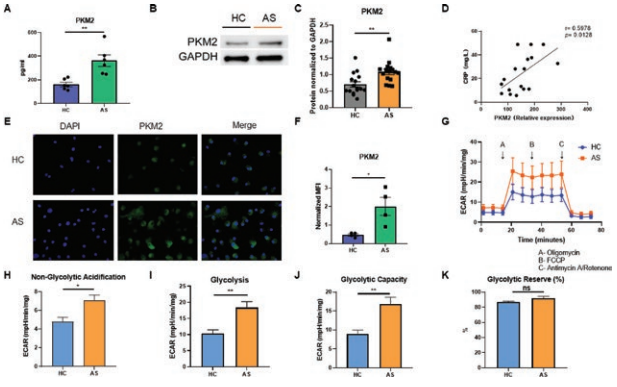

Figure 1. AS-derived M1 macrophage presents with more PKM2 and glycolysis. Circulating monocytes from HC and AS were differentiated into moncyte-derived macrophages. They were then activated into M1 type with LPS/IFN-γ for 24 h. A. Concentrations of PKM2 in HC and AS plasma measured by ELISA. N=6. B-C. Immunoblotting of PKM2 protein among HC and AS patients. N=16. D. Correlation between serum CRP and *PKM2* mRNA expression. N=17. E-F. Confocal images were acquired in ex vivo–generated macrophages stimulated with LPS/IFN-γ for 24 h and stained with anti-PKM2 (green). Nuclei were localized by DAPI (blue). The bar graph represents averaged data from experiments quantifying the fluorescent signal (n = 4 HC and 4 AS patients). G-K. Glycolysis assays in macrophages were evaluated with the Seahorse Bioscience XF96 analyzer by adding test agents in order of 1, oligomycin; 2, FCCP; 3, antimycin A/rotenone. Summarized graphs from 6 HC and 8 AS patients were shown.

POS0427 PROSTAGLANDIN E2 CONTROLS THE METABOLIC ADAPTATION OF T CELLS TO THE INTESTINAL MICROENVIRONMENT

Keywords: -omics, Adaptive immunity, Gastrointestinal tract

M. Villa[1]. [1]*Medical University of Graz, Division of Rheumatology and Immunology, Graz, Austria*

Background: Immune cells must adapt to different environments during the course of an immune response, such as during their transition from lymph nodes to peripheral tissues.
Objectives: We studied the adaptation of $CD8^+$ T cells to the intestinal microenvironment and how this process shapes their residency in the gut. Investigation of this process will lead to the identification of tissue-specific mechanisms to target $CD8^+$ T cell function in a gut-restricted manner.
Methods: We explored the adaptation of $CD8^+$ T cells to the intestinal microenvironment using single cell RNA and antibody sequencing, mass spectrometry-based metabolomic approaches, CRISPR-Cas9 gene editing, and in vivo mouse models of intestinal infection.
Results: $CD8^+$ T cells progressively remodel their transcriptome and surface phenotype as they acquire gut residency, and downregulate expression of mitochondrial genes. Human and mouse gut-resident $CD8^+$ T cells have reduced mitochondrial mass, but maintain a viable energy balance to sustain their function. We found that the intestinal microenvironment is rich in prostaglandin E_2 (PGE_2), which drives mitochondrial depolarization in $CD8^+$ T cells. Consequently, these cells engage autophagy to clear depolarized mitochondria, and enhance glutathione synthesis to scavenge reactive oxygen species (ROS) that result from mitochondrial depolarization. Impairing PGE_2 sensing promotes $CD8^+$ T cell accumulation in the gut, while tampering with autophagy and glutathione negatively impacts the T cell population.
Conclusion: A PGE_2-autophagy-glutathione axis defines the metabolic adaptation of $CD8^+$ T cells to the intestinal microenvironment, to ultimately influence the T cell pool.

POS0428 EFFECTOR ACTIVITY OF CXCR3+ CD8 T CELL IS REGULATED BY GLUT1-MEDIATED METABOLIC REPROGRAMMING TOWARD GLYCOLYSIS AND INVOLVED IN SPONDYLOARTHRITIS PATHOGENESIS

Keywords: Adaptive immunity, Spondyloarthritis

ミ. コロヤス[1], M. Akiyama[1], T. Kaburaki[1], K. Yoshimoto[1], Y. Kaneko[1]. [1]*Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Although T cell metabolism has recently attracted attention as a key regulator of immune responses, the molecular mechanisms underlying the expression of effector functions in human T cells are still poorly understood. T cell metabolism is postulated to be involved in the development of autoimmune diseases by regulating the expression of its effector functions.
Objectives: In this study, we examined the association of metabolic pathways with effector function activity in human T cells. We further investigated the involvement of the identified metabolic pathways in the pathogenesis of autoimmune

diseases using the two representative autoimmune arthritis samples, spondyloarthritis (SpA) and rheumatoid arthritis (RA).
Methods: Metabolism-related cell surface transporters (GLUT1, LAT1, and ASCT2) were examined for their expression levels in CD8 T cells and CD4 T cells from peripheral blood using flow cytometry and Western blotting. Cell survival rate was examined in cultured cells under condition of glucose supply or depletion for 6 days. We comprehensively analyzed the expression of metabolic enzymes in CXCR3+CD8 T cells and CXCR3-CD8 T cells using bulk RNA-seq data. We investigated the effects of metabolic-related transporters on the ability to produce inflammatory cytokines (TNF and IFNγ) using inhibitors. Whole blood samples were freshly obtained from active, treatment-naïve patients with SpA (n=15) and RA (n=25), or healthy controls (HC, n=11) and analyzed by flow cytometry. Phenotype and metabolic enzyme expression of T cells in the synovial fluids of patients were also analyzed employing bulk RNA-seq data.
Results: Among metabolic transporters, GLUT1 was found to be expressed at the protein level specifically on CD8 T cells but not CD4 T cells in human peripheral blood. Functional experiments confirmed that CD8 T cells depended on glucose supply to maintain their cell survival compared to CD4 T cells. Interestingly, exploratory experiments revealed that among CD8 T cells, the viability of CXCR3+CD8 T cells was particularly dependent on glucose supply. In line with that, comprehensive analysis by RNA-seq data revealed that CXCR3+CD8 T cells had enhanced expression of glycolytic enzymes, including *GLUT1*, compared to CXCR3-CD8 T cells. Validation by flow cytometry also confirmed the elevated GLUT1 level at the protein expression in CXCR3+CD8 T cells than in CXCR3-CD8 T cells. Importantly, CXCR3+CD8 T cells had higher effector function activity than CXCR3-CD8 T cells in producing TNF and IFNγ, which was significantly reduced by inhibiting GLUT1 function or depleting glucose. Of note, GLUT1 expression level in CD8 T cells was significantly higher in SpA compared with RA and HC. In addition, proportion of CXCR3+CD8 T cells in peripheral blood was specifically increased in SpA compared with RA and HC (P<0.0001 and P<0.001, respectively). Furthermore, CXCR3+CD8 T cells in peripheral blood from SpA patients had significantly higher expression of GLUT1 compared to CXCR3-CD8 T cells (P<0.0001). Finally, CD8 T cells in the synovial fluids of SpA patients showed dominant *CXCR3* expression and higher expression of *GLUT1* among metabolic enzymes, exhibiting their effector activity.
Conclusion: Our results demonstrate that CXCR3+CD8 T cells exhibit higher effector activity than other CD8 T cell phenotypes, regulated by GLUT1-mediated metabolic reprogramming toward glycolysis. GLUT1-high CXCR3+CD8 T cells may be involved in SpA pathogenesis.

THE COMPLEMENT SYSTEM AND RESPONSE TO TNF INHIBITION IN PATIENTS WITH RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS. POST HOC ANALYSIS FROM CONSUL, A LONGITUDINAL MULTI-CENTER RCT COHORT OF R-AXSPA-PATIENTS WITH A HIGH RISK OF STRUCTURAL PROGRESSION INITIATING TREATMENT WITH TNF-INHIBITOR

Keywords: Spondyloarthritis, Innate immunity, bDMARD

C. E. Mistegaard[1,2,3], A. Troldborg[1,2,3], A. G. Loft[1,3], S. Thiel[2], B. Muche[4], V. Rios Rodriguez[4], M. Torgutalp[4], M. Protopopov[4], J. Listing[4], J. Sieper[4], D. Poddubnyy[4], F. Proft[4]. *[1]Aarhus Universitetshospital, Department of Rheumatology, Aarhus, Denmark; [2]Aarhus University, Department of Biomedicin, Aarhus, Denmark; [3]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [4]Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology (Including Nutrition Medicine), Berlin, Germany*

Background: The pathogenesis of axial spondyloarthritis (axSpA) remains largely unexplained, but recent evidence supports an involvement of the innate immune system. The lectin pathway (LP) of complement activation plays an essential role in innate immunity. Previous studies have shown that elevated levels of specific complement proteins are associated with disease activity in axSpA. However, little is known about alterations in LP proteins and complement activation in relation to treatment with TNF-inhibitors (TNF-I).
Objectives: To determine changes in LP protein levels and complement activation in a longitudinal multi-center cohort of axSpA-patients with high disease activity from the RCT CONSUL before and after 12 weeks of treatment with a TNF-I. Furthermore, to investigate the correlations between LP protein levels, and disease activity, and treatment response.
Methods: Serum samples at baseline and after 12 weeks of treatment with the TNF-I golimumab were obtained from 108 radiographic axSpA-patients with high disease activity (BASDAI ≥4) and high risk for radiographic progression (elevated CRP or ≥1 syndesmophyte present at inclusion) recruited from the CONSUL cohort. Serum levels of the LP proteins MBL, CL-L1, H-ficolin, L-ficolin, M-ficolin, MASP-1, MASP-2, MASP-3, and MAp44, and complement activation product C3dg were measured by immunoassays.
Results: Serum levels of L-ficolin, M-ficolin, MBL, MAp44, and C3dg decreased significantly after 12 weeks of treatment with TNF-I, whereas serum levels of MASP-3 and CL-L1 increased significantly (Figure 1). After adjustment for CRP, significant changes were observed for L-ficolin, M-ficolin, MASP-1, MASP-2, MASP-3, and MAp44. Baseline serum levels of L-ficolin, M-ficolin, and C3dg correlated positively with baseline ASDAS-CRP (Spearman's rho 0.290, 0.190, and 0.328, respectively, all p<0.05), whereas baseline MASP-1 and MAp44 correlated negatively with baseline ASDAS-CRP (Spearman's rho -0.204, and -0.218, respectively, both p<0.05). In a univariate logistic regression analysis, baseline serum levels of MASP-1 predicted achievement of clinical important improvement (ΔASDAS≥1.1) at week 12, and baseline serum levels of C3dg predicted inactive disease (ASDAS<1.3) at week 12. In corresponding multivariate logistic regression analyses, only C3dg remained significantly associated with inactive disease (ASDAS<1.3) (p = 0.025).
Conclusion: Baseline serum levels of L-ficolin, M-ficolin and C3dg correlated positively with baseline ASDAS-CRP, and the protein serum levels decreased significantly after TNF-I therapy. Baseline levels of complement activation measured by C3dg predicted achievement of inactive disease (ASDAS<1.3) at week 12 in both a univariate and a multivariate logistic regression analysis. Our findings suggest an involvement of the complement system in the underlying inflammatory processes of axSpA and prompt further investigations.

Table 1. Baseline demographics of the investigated patient population from the CONSUL RCT (n = 108)

Age, median (IQR)	38 (31-49)
Male, n (%)	77 (71)
HLA-B27 positive, n (%)	89 (82)
Previous treatment with bDMARD, n (%)	26 (24)
Time since diagnosis in years, median (IQR)	3.0 (0.0-9.0)
Years since onset of symptoms, median (IQR)	12 (6.0-21.0)
CRP, mg/L (IQR)	9.1 (4.1-20)
Elevated CRP (> 5mg/L), n (%)	75 (69)
mSASSS, median (IQR)	4.3 (0.3-18)[#]
Syndemophytes present, median (IQR)	1.6 (0.0-6.3)[#]
Presence of ≥1 syndesmophyte(s) [§], n (%)	43 (48) [#]
ASDAS-CRP, median (IQR)	3.6 (3.1-4.1)
BASDAI, median (IQR)	6.2 (5.2-7.0)
BASFI, median (IQR)	5.2 (4.0-6.4)

[§] Determined by 3 calibrated readers blinded for clinical data. [#] data available on n = 89

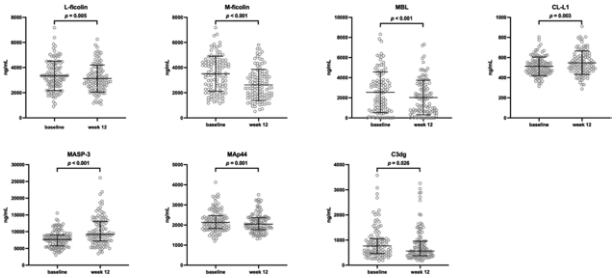

Figure 1. Differences in lectin pathway protein serum levels were compared by paired t-tests. Bars indicate median and IQR (MASP-3, MAp44, and C3dg) or mean and sd (L-ficolin, M-ficolin, MBL, and CL-L1).

THE EXPANDED CD21LOW B CELL SUBPOPULATION IN ANKYLOSING SPONDYLITIS CONSISTS MAINLY OF UNMUTATED ANTIGEN-INEXPERIENCED CELLS THAT ARE CLONALLY RELATED TO MEMORY B CELLS AND PLASMABLASTS

Keywords: Spondyloarthritis, Adaptive immunity, Cell biology

R. Wilbrink[1], L. Van der Weele[2], A. Spoorenberg[1], N. De Vries[2], F. G. M. Kroese[1], G. M. Verstappen[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immnuology, Groningen, Netherlands; [2]Amsterdam University Medical Center, Rheumatology and Clinical Immnuology, Amsterdam, Netherlands*

Background: The role of B cells in the pathogenesis of ankylosing spondylitis (AS) remains relatively understudied. Nevertheless, available evidence shows presence of B cells at sites of inflammation, higher frequencies of circulating plasmablasts, presence of autoantibodies and beneficial results of B cell depleting therapy with rituximab [1]. We observed previously that a subpopulation of $CD27^-$ B cells, characterized by low expression of the complement receptor CD21 ($CD21^{low}$), is increased in patients with AS and patients with primary Sjogren's syndrome (pSS), a typical B cell mediated systemic autoimmune disease [2]. These $CD21^{low}CD38^{low}CD27^-$ B cells display a pro-inflammatory phenotype, suggestive for a pathogenic role.
Objectives: To gain insight into the origin of these $CD21^{low}CD38^{low}CD27^-$ B cells we analysed the mutation status of the immunoglobulin heavy chain variable (IGHV) gene regions in the total B cell compartment, $CD21^{low}$ B cell subpopulations and plasmablasts in AS patients in comparison to pSS patients and healthy donors (HD). In addition, we investigated clonal relations between $CD21^{low}$ B cell subpopulations and plasmablasts in AS.
Methods: RNA was isolated from sorted total B cells ($CD19^+$), two $CD21^{low}$ B cell populations ($CD21^{low}CD38^{low}CD27^-$ and $CD21^{low}CD38^{low}CD27^+$) and plasmablasts ($CD19^+CD38^{++}CD27^+$) from peripheral mononuclear cells of 10 AS patients fulfilling the mNY criteria (mean age 46 ± 9 years, 60% male, mean ASDAS 2.3 ± 0.8, all HLA-B27+), 10 sex- and age-matched HDs (mean age 48 ± 21 years, 60% male) and 10 age-matched pSS patients (mean age 46 ± 9 years, 20% male). Repertoire analysis of the B cell receptor heavy chain was performed using high throughput sequencing on the Illumina MiSeq Platform. Sequences were analyzed for degree of somatic hypermutation, usage of immunoglobulin heavy chain variable (IGHV) and joining (IGHJ) regions and clonal relationships.
Results: IGHV sequences with identical heavy chain CDR3 regions were grouped together and were defined as a clone. Analysis of the IGHV mutation status in $CD21^{low}$ B cells revealed that the majority of clones (71% SD ± 14.1) in the $CD21^{low}CD38^{low}CD27^-$ subset from patients with AS consisted of clones with a low mutation rate (0-2 mutations in the IGHV region) (Figure 1b). On the contrary, most of the clones in the $CD21^{low}CD38^{low}CD27^+$ (49% SD ± 12.5) and plasmablasts (59% SD ± 12.7) subsets were clones with a higher mutation load (>10 mutations in the IGHV region). A similar mutational pattern was seen in pSS patients and HDs. In AS, IGHV3 and IGHJ4 family genes were predominantly used (Figure 1c). However, we observed no differences in family gene usage among B cell subsets nor between groups. To investigate clonal relationships we performed a CDR3 amino acid network analysis on the top 100 most expanded clones per subset in AS patients and found that the $CD21^{low}CD38^{low}CD27^-$ subset shared more clones with the $CD21^{low}CD38^{low}CD27^+$ subset (median 3.0 (0.8-7.0 IQR), p< 0.05) compared to plasmablasts (median 0.0 (0-1.3 IQR).
Conclusion: This study shows that the expanded circulating $CD21^{low}CD38^{low}CD27^-$ B cell population in AS consists mainly of antigen-inexperienced cells. The presence of shared clones with their $CD27^+$ counterpart and plasmablasts suggest that the three subsets are to some extent related. Hence, $CD21^{low}CD38^{low}CD27^-$ B cells may differentiate towards $CD21^{low}CD38^{low}CD27^+$ B cells and plasmablasts. The relative roles of these $CD21^{low}$ B cell subsets and plasmablasts in AS pathogenesis remain to be established.

GOBLET CELL SPECIFIC ANTI-APOPTOTIC ROLE OF INTERLEUKIN-24 IN SPONDYLOARTHRITIS-ASSOCIATED ILEITIS

Keywords: Gastrointestinal tract, Spondyloarthritis, Cell biology

A. Cameron[1], R. Giri[2], J. Begun[2], T. Wells[1], A. S. Bergot[1], R. Thomas[1]. *[1]Frazer Institute, The University of Queensland, Woolloongabba, Australia; [2]Mater Research Institute - UQ, Translational Research Institute, Woolloongabba, Australia*

Background: Spondyloarthritis (SpA) is characterised by chronic debilitating axial and peripheral joint inflammation, often concomitant with inflammatory bowel disease (IBD)-like gut phenotypes. However, the contribution of extra-articular gut pathologies to SpA is not well understood. The $ZAP\text{-}70^{W163C}$ BALB/c (SKG) mouse model of SpA develop chronic arthritis, spondylitis and IBD-like ileitis commencing from 1 week after intraperitoneal curdlan injection with characteristic interleukin-23-dependent gut dysbiosis, endoplasmic reticulum (ER) stress and goblet cell depletion. The cytokine interleukin-24 (IL-24) was first described to promote ER stress-mediated apoptosis in damaged tumour cells without harming normal cells. Conversely, IL-24 attenuated cell death in a liver damage model. IL-24 levels were increased in the synovial fluid in SpA and in the colon in IBD.
Objectives: Since, in both IBD and SpA, gut dysbiosis and mucus depletion promote goblet cell stress and apoptosis, we therefore assessed the role of gut derived IL-24 in ER stress-mediated apoptosis in SpA.
Methods: Ileal histology sections from curdlan-treated SKG mice were stained with Alcian blue staining or immunofluorescence (IF) using an anti-IL-24 Ab. The human $MUC2^{hi}$ colonic epithelial cell line, LS-174T was compared to the $MUC2^{low}$ colonic epithelial line HT-29 after induction of ER stress with SERCA-inhibitor thapsigargin in the presence of IL-24 or control siRNA. Gene expression was analysed by RT-qPCR and protein by Western Blot or flow cytometry.

Results: Naïve SKG ileum displayed dysbiosis with increased expression of ER stress markers *Grp78, sXBP1*, *CHOP* and reduced mucin staining. After curdlan treatment, goblet cell numbers were decreased and *Il24* mRNA was increased compared to BALB/c controls. By IF, IL-24 localized to the goblet cells of the ileum in SKG and BALB/c mice and 2 weeks post curdlan, ileal goblet cell number was correlated with IL-24 staining intensity. In $MUC2^{hi}$ LS-174T but not $MUC2^{low}$ HT-29 cells, thapsigargin induced a rapid and transient increase in *Il24* transcription and subsequent ER stress with *CHOP* induction, suggesting an acute goblet cell-specific response associated with high mucus production. IL-24 knockdown in LS-174T increased ER stress and apoptosis including increased *CHOP*, *DR5* and active caspase 3 expression.
Conclusion: Despite goblet cell IL-24 over-expression in dysbiotic naïve SKG ileum, goblet cell loss due to stress associated with increased mucus production also depletes IL-24. In an in vitro model of goblet cell stress, IL-24 mitigates ER stress-induced apoptosis, suggesting that IL-24 production in SKG ileum is insufficient to prevent the disease cascade that commences with goblet cell apoptosis and epithelial barrier breakdown.

POS0432 CHARACTERIZATION OF THE CARDIOVASCULAR DISEASE PROTEOMIC PROFILE IN SPONDYLOARTHRITIS PATIENTS: POTENTIAL BIOMARKERS FOR PERSISTENT INFLAMMATION

Keywords: Biomarkers, Cardiovascular disease, Spondyloarthritis

I. Arias de la Rosa[1], M. L. Ladehesa Pineda[1], C. López-Medina[2], M. Ruiz-Ponce[1], L. Cuesta López[2], M. Á. Puche Larrubia[1], M. D. C. Abalos-Aguilera[1], P. Ortiz Buitrago[1], C. Perez-Sanchez[3], C. Lopez-Pedrera[1], A. Escudero Contreras[1], E. Collantes Estevez[2], N. Barbarroja Puerto[2]. *[1]IMIBIC/Reina Sofia Hospital/University of Cordoba, Rheumatology Service, Cordoba, Spain; [2]IMIBIC/University of Cordoba/Reina Sofia Hospital, Medical and Surgical Sciences, Cordoba, Spain; [3]IMIBIC/University of Cordoba/Reina Sofia Hospital, Cell biology, Physiology and Immunology, Cordoba, Spain*

Background: patients with Spondyloarthritis (SpA) have an increased risk of cardiovascular disease. Taking into account the strong relationship between inflammation and CVD, there is an urgent need to identify different molecular drivers of CVD signs and their association with inflammation.
Objectives: to investigate the alteration of CVD-related proteins in the plasma of SpA patients, their association with clinical features, and to evaluate their potential role as biomarkers for the identification of persistent inflammation.
Methods: a cross-sectional study including 120 patients with SpA and 30 age-sex-matched healthy donors (HDs) was carried out. Clinical and laboratory parameters and CVD risk factors were recorded. To measure the presence of persistent inflammation, levels of c-reactive protein (CRP) were collected retrospectively for 5 years previous to the study, a patient was considered to have persistent inflammation with increased CRP in at least 50% of the measures during the previous 5 years. Levels of 92 proteins with a recognized role in CVD were analyzed in the plasma using proximity extension assay (PEA) technology (Olink Target 96 CVD III panel, Cobiomic Biosciences).
Results: SpA patients showed higher rates of CVD comorbidities compared to HDs. Plasma levels of TNF-R1, RARRES-2, CHI3L1, PGLYRP-1, CTSD, UPAR, IL2RA, TIMP-4, CTSB, GDF-15, MMP-9, and PDGF-A were significantly increased in SpA compared to HDs. Specifically, these proteins are also related to biological processes such as neutrophil degranulation, immune response, cell activation, atherosclerosis, apoptosis, and inflammatory response. Besides, a significant alteration of these CVD-related proteins in SpA was also associated with the presence of arterial hypertension, insulin resistance, obesity, hyperuricemia, and high levels of acute phase reactants. 36% of SpA patients displayed persistence of inflammation. Interestingly, SpA patients with persistent inflammation showed higher levels of ankylosing spondylitis disease activity (ASDAS) score, CRP, glucose, complement component 3, and lower levels of HDL-cholesterol and apolipoprotein A compared to SpA patients with non-persistent inflammation, suggesting the relationship of inflammation with metabolic alterations. In addition, 8 out of 12 CVD-related proteins altered in SpA patients were specifically changed in patients with persistent inflammation: MMP-9, RARRES-2, PGLYRP-1, UPAR, TNF-R1, PDGF-A, IL-2RA and GDF-15, highlighting levels of MMP-9 protein as a potential biomarker for persistent inflammation in SpA (AUC=0.796 p>0.0001).
Conclusion: 1) SpA patients show an altered CVD proteome profile which is strongly associated with CVD risk factors and clinical inflammatory markers, 2) SpA patients with persistent inflammation display a deeper alteration in their plasma CVD protein pattern suggesting the link between subclinical CVD risk and the chronic inflammation, and 3) this study identifies novel potential biomarkers to distinguish SpA patients with persistent inflammation. POS0433 RELATIONSHIP BETWEEN MIRNA-1-3P, INTERLEUKIN-17 AND TUMOR NECROSIS FACTOR IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Genetics/Epigenetics, Biomarkers

A. Pekacova[1,2], J. Baloun[1], K. Bubova[1,2], M. Gregová[1,2], S. Forejtova[1,2], J. Horinkova[1,2], M. Husakova[1,2], K. Mintalova[1], V. Cervenak[3], M. Tomčík[1,2], J. Vencovský[1,2], K. Pavelka[1,2], L. Šenolt[1,2]. *[1]Institute of Rheumatology, Experimental Rheumatology, Prague, Czech Republic; [2]First Faculty of Medicine Charles University, Prague, Czech Republic; [3]St Anne's University Hospital and Faculty of Medicine, Masaryk University, Department of Imaging, Brno, Czech Republic*

Background: microRNAs (miRNAs) are small non-coding RNAs that can regulate gene expression and mirror the patient's health condition. miRNAs deregulation is considered a crucial factor in the development and progression of various diseases, including axial spondyloarthritis (axSpA) [1].
Objectives: The aim of the study was to profile the miRNome of peripheral blood mononuclear cells (PBMCs), to identify specific miRNAs and their association with several cytokines, axSpA disease activity and spinal impairment.
Methods: Massive parallel sequencing (MPS, Ilumina) was performed for miRNAs profiling in 96 subjects (38 patients with non-radiographic (nr-) axSpA, 38 patients with radiographic (r-) axSpA and 20 healthy controls (HC)). The expression of candidate miRNAs was validated using the qRT-PCR system (SmartChip) on a new cohort of 47 patients with nr-axSpA, 44 patients with r-axSpA and 50 HC. Disease activity was determined using C-reactive protein (CRP) and Ankylosing Spondylitis Disease Activity Score (ASDAS). Radiographs of the cervical and lumbar spine were assessed by two independent blinded readers using modified Stoke Ankylosing Spondylitis *Spine* Score (mSASSS). We employed DESeq2 and generalized linear modelling with a negative binomial assumption (GLM-NB) to evaluate the association of candidate miRNAs to the radiographic form, ASDAS and CRP. Linear modelling was used to determine the association between miRNAs and laboratory/clinical parameters adjusted for CRP, age and sex.
Results: MPS detected 432 miRNAs; however, only 90 miRNAs passed through the selection criteria ($p<0.05$, BaseMean>10, the difference in log2FC>0.5). We selected 45 miRNAs for validation based on the selection criteria and the literature. We validated miR-1-3p ($p=0.006$, FC=1.757) to be upregulated and miR-1248 ($p=0.002$, FC=-1.125) and miR-1246 ($p=0.002$, FC = -1.125) to be downregulated in patients with axSpA compared to HC. In addition, the expression of miR-1-3p correlated with the plasma levels of IL-17 ($p=0.016$, $\tau=0.25$) and TNF ($p=0.028$, $\tau=0.22$), but not with the gene expression of IL-17 or TNF in PBMCs. miR-1-3p ($p=0.039$, $\beta=0.665$) as well as miR-1248 ($p<0.001$, $\beta=-0.207$) correlated with the IL-6 gene expression in PBMCs. None of the miRNAs distinguished between radiographic and non-radiographic disease or correlated with disease activity or radiographic spinal impairment.
Conclusion: This cross-sectional study failed to demonstrate association between cellular miRNAs, disease activity or spinal impairment, but the association between miR-1-3p, IL-17 and TNF may suggest its role in the pathogenesis of axSpA.

Background: Ankylosing spondylitis (AS) is a rheumatic disease characterized by chronic inflammation. Several lines of evidence implicate interleukin (IL)-17A-secreting T helper (Th)17 cells in AS pathogenesis. One of the receptors of Th17 cell, C-C motif chemokine ligand 20 (CCL20) is known to attract C-C chemokine receptor 6 (CCR6) expressing cells to the site of inflammation. However, the role and mechanisms of CCL20 in AS are not well understood.
Objectives: Therefore, this study aimed to evaluate the function of CCL20 in patients with AS.
Methods: Peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) were obtained from AS patients. Inflammatory cytokine-producing cells were analyzed using flow cytometry and enzyme-linked immunosorbent assay (ELISA). To determine the direct effect of cell migration in the presence of CCL20, a transwell migration assay was performed. In in vivo experiments, SKG mice were treated with either CCL20 blocking antibody or isotype control antibody. Clinical signs of mice were monitored twice a week and scored by two independent observers. At the experimental endpoint, specimens of the ankle was obtained from mice. Two blinded readers then performed pathological scoring for arthritis using immunohistochemistry.
Results: IL-17A producing cells were significantly higher expressed in SFMCs of AS patients than in PBMCs of AS or healthy controls. CCL20-positive cells showed significantly increased IL-17A production than CCL20-negative cells. To confirm the relationship between CCL20 and IL-17A production, IL-17A expression was observed with either CCL20 agonist or antagonist. Treatment with CCL20 agonist showed an increase in IL-17A in PBMCs from AS patients. Meanwhile decreasing IL-17A level was observed in SFMCs from AS patients when treated with CCL20 inhibitors. In cell migration assay experiments, cell migration increased when CCL20 was added to the CD4-positive cells. In an vivo model, CCL20 inhibitors significantly suppressed arthritis symptoms (Figure 1). In addition, histologic evaluation showed that mice treated with CCL20 inhibitor had lower arthritis scores than isotype-treated control mice.
Conclusion: This study demonstrates CCL20 blockade improved joint inflammation in AS. Therefore, CCL20-target therapy could be a promising treatment for AS.

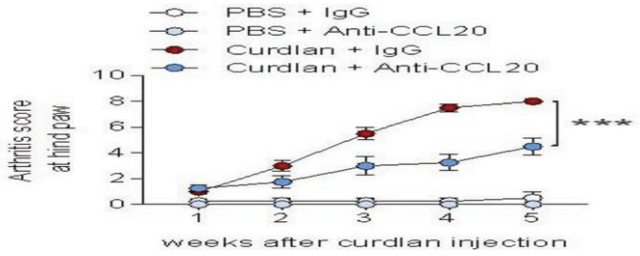

Figure 1. CCL20 Inhibition ameliorates peripheral arthritis in SKG mice

POS0435 PEPTIDE-BASED VACCINE TARGETING IL17A ATTENUATES EXPERIMENTAL SPONDYLOARTHRITIS INHLA-B27 TRANSGENIC RATS

Keywords: Animal models, Spondyloarthritis

H. Hayashi[1], J. Sun[1], H. Nakagami[1], T. Tomita[2]. *[1]Osaka University Graduate School of Medicine, Health Development and Medicine, Suita, Japan; [2]Morinomiya University, Health Sciences, Osaka, Japan*

Background: Ankylosing spondylitis (AS) is one of the major diseases in spondyloarthritis (SpA). HLA-B27 is known as a genetic risk factor for AS. Recent lines of evidence suggests that IL-23/IL-17 axis strongly contributes to AS.
Objectives: This study was to assess the efficacy of IL17A peptide-based vaccine on the SpA manifestations in model rat.
Methods: HLA-B27/human beta 2 -microglobulin transgenic rats were immunized with heat-inactivated Mycobacterium Tuberculosis (MT) to develop spondylitis and arthritis as an experimental spondyloarthritis model after 3 times immunization with KLH-conjugated IL17A peptide-based vaccine with alum adjuvant. IL17A antibody titer was assessed by ELISA, and arthritis score and joint thickness was monitored twice a week. At 9 weeks, joints of ankle and spine were collected to analyzed by histological analysis and realtime PCR for evaluation of inflammation and bone remodeling. Moreover, heart, liver, and lung were also collected for safety assessment by HE staining.
Results: IL17A peptide-based vaccine with alum adjuvant successfully induced antibody production, and suppressed arthritis score and joint thickness. X-ray and histological analysis showed that enthesitis, bone destruction, and new bone formation were inhibited by IL-17A vaccine. Moreover, SpA-induced expression of IL17A-related inflammatory- and bone remodeling molecules were down-regulated in the ankle and spine. Finally, IL-17A vaccine had no tissue damage by histological analysis.
Conclusion: These data showed that peptide-based vaccine targeting IL-17A prevented SpA phenotype in heat-inactivated Mycobacterium Tuberculosis-induced SpA model in HLA-B27/human beta 2 microglobulin transgenic rats. IL17A-peptide based vaccine can be a therapeutic option for SpA treatment.

POS0436 INCREASED EXPRESSION OF PATHWAYS INVOLVED IN B CELL ACTIVATION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis, Cell biology, Adaptive immunity

R. Wilbrink[1], A. Spoorenberg[1], F. G. M. Kroese[1], G. M. Verstappen[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immnuology, Groningen, Netherlands*

Background: In spite of advancements in treatment of ankylosing spondylitis (AS), its pathogenesis remains incompletely understood. The current evidence suggests that AS is both an autoinflammatory and autoimmune disease involving innate immune cells along with autoreactive lymphocytes. B cells have received little attention regarding their role in the pathogenesis of ankylosing spondylitis (AS), although the available evidence shows presence of B cells at inflammatory sites, imbalances in B cell subsets, presence of autoantibodies (anti-CD74/CLIP), and beneficial effects of B cell depletion (anti-CD20) with rituximab [1]. In AS, the overarching picture portrays increased B cell activation, although it is unclear whether B cells directly affect pathogenesis, or are merely bystanders in the disease process.
Objectives: Our main objective was to study gene expression and gene signalling pathways involved in B cell activation in AS. To this end, we analysed the transcriptomic profile of isolated peripheral B cells from AS patients, healthy donors (HD) and patients with primary Sjögren syndrome (pSS), a typical B-cell-associated autoimmune disease.
Methods: RNA was isolated from $CD19^+$ B cells sorted from peripheral blood mononuclear cells of 8 AS patients (mean age 48.0 ± 9.7 years, 63% male, mean ASDAS 2.5 ± 0.7), 8 sex and age-matched HDs (42.3 ± 17.8 years, 63% male) and 8 age-matched pSS patients (48.4 ± 17.8 years, 13% male). Next, characterization of differentially expressed genes was performed using transcriptomic analysis by the NanoString nCounter Autoimmune Profiling Panel, which utilizes a direct hybridization technique without PCR amplification. After normalization and z-score scaling of pathway genes, pathway scores were calculated based on the first principle component using nCounter advanced analysis software. P-values <0.05 were considered significant.
Results: All samples passed quality control, except for one pSS patient sample that was being flagged as an outlier by the nCounter advanced analyses software. Analysis of differential gene expression between AS patients and HDs revealed upregulation of 8 genes, including *MAPK14*, *KMT2A* and *PKM*, in B

cells from AS patients, and downregulation of two genes, *DDIT4* and *ATG5*. In AS patients, the relative expression of B cell receptor (BCR) signalling (n=60 genes) and Fc receptors and phagocytosis (n=55 genes) pathway genes were both significantly enriched compared to HDs (*Figure 1*). Although not significant, these pathways also displayed higher pathway scores in pSS patients compared to HDs (P=0.30 and P=0.37, respectively). Other gene pathways involved in B cell activation, such as toll-like receptor signalling were not significantly enriched.
Conclusion: In this study, we observed several differentially expressed genes involved in signal transduction pathways in B cells from AS patients. Furthermore, we showed increased expression of gene pathways involved in B cell activation in patients with AS compared to HDs. The BCR-mediated activation in AS displays similarities to a bona fide autoimmune disease pSS. These results suggest active involvement of B cells in the disease process of AS.

POS0437 **WITHDRAWN**

POS0438 **IDENTIFICATION OF THREE AUTOPHAGY-RELATED HUB BIOMARKERS OF ANKYLOSING SPONDYLITIS VIA BIOINFORMATICS ANALYSIS OF RNA SEQUENCING DATA OF MACROPHAGES**

Keywords: Innate immunity, Spondyloarthritis, Biomarkers

Y. Liang[1], Y. Jiang[1], W. Weng[1], J. Chen[1], X. Luo[1], J. Gu[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Autophagy is associated with the occurrence and progression of a variety of diseases, such as cancers, cardiovascular diseases, and autoimmune diseases. Ankylosing spondylitis (AS) is a chronic inflammatory disease. Its pathological feature includes local infiltration of inflammatory cells among which macrophages play a dominant role [1]. Currently, previous studies have confirmed that autophagy may be involved in the occurrence and development of autoimmune diseases, such as AS [2]. However, there are few articles discussing which molecule plays a key role in the progress of autophagy of macrophage in patient with AS.
Objectives: This study aimed to detect gene expression in macrophages that originated from peripheral blood mononuclear cells (PBMC) in patients with AS by RNA sequencing (RNA seq) technology, and to identify underlying autophagy-related genes of AS by bioinformatics analysis.
Methods: Peripheral blood mononuclear cells (PBMC) from 4 cases of AS and 4 cases of healthy control (HC) from were isolated and differentiated into M1 macrophages. These cells were then sent to BGI company for RNA seq. Then, Gene

Set Enrichment Analysis (GSEA) enrichment analysis, screening of differentially expressed genes (DEGs), Gene Ontology (GO) function annotation, Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis of DEGs were conducted. Protein-Protein Interaction (PPI) network of DEGs was constructed, and cluster association analysis was performed by MOCDE plug-in in ctyoscape software. Human autophagy-related genes were downloaded from Human Autophagy Database (HADb). Finally, we took the intersected of human autophagy-related genes and those involved in the top 5 clusters by cluster association analysis.

Results: 1467 DEGs were identified by DESeq2 package in R. Among them, 384 genes were significantly up-regulated while 1083 genes were significantly down-regulated. GO and KEGG enrichment analysis of DEGs revealed several terms related to cell cycle. GSEA analysis of all sequencing data revealed a number of terms related to cell cycle and lysosomes. The PPI network of 1467 DEGs was constructed by using STRING database, and 45 clusters were obtained by using MOCDE plug-in of cytoscape software for cluster association analysis. The intersection of genes involved in the top 5 clusters and 219 autophagy-related genes downloaded from HADb were conducted to obtain 3 autophagy-related genes of AS, which were *BIRC5*, *TP53* and *CTSB*.

Conclusion: Through RNA seq and bioinformatics analysis, we identified 3 potential autophagy-related genes of AS. *BIRC5*, *TP53* and *CTSB* may inhibit the occurrence and development of AS by regulating autophagy.

POS0439 SCREENING FOR PLASMA BIOMARKERS PREDICTING RADIOGRAPHIC PROGRESSION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A PRELIMINARY STUDY

Keywords: -omics, Spondyloarthritis, Biomarkers

J. Baloun[1,2], K. Bubová[1,2], A. Pekacova[1,2], L. Ondrejčáková[1,2], V. Červeňák[3], M. Gregová[1,2], S. Forejtova[1,2], J. Horinkova[1,2], J. Gatterova[1,2], M. Tomčík[1,2], J. Vencovský[1,2], K. Pavelka[1,2], L. Šenolt[1,2]. *[1]Institute of Rheumatology, Department of Experimental Rheumatology, Prague, Czech Republic; [2]First Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic; [3]St. Anne's University Hospital, Masaryk University Faculty of Medicine, Department of Clinical Imaging, Prague, Czech Republic*

Background: Axial spondyloarthritis (AxSpA) is an immune-mediated rheumatic disease that has a significant impact on a patient's quality of life. Therefore, early diagnosis and recognition of patients with potentially rapid structural progression of the disease are of great importance.

Objectives: This study aimed to investigate proteomic data in patients' plasma to discover candidate biomarkers differentiating axSpA patients with radiographic progression after two years.

Methods: A cohort of 20 patients with axSpA was selected based on the radiographic progression for the purpose of this preliminary study. Baseline and two-year radiographs of the cervical and lumbar spine were independently assessed by two blinded readers using modified Stoke Ankylosing Spondylitis *Spine* Score (mSASSS). No radiographic progression and significant radiographic progression were characterized as a change in mSASSS ≤0 and >2, respectively, from baseline to year two. Disease activity was determined using C-reactive protein (CRP), Ankylosing Spondylitis Disease Activity Score (ASDAS) and Bath Ankylosing Spondylitis Activity Disease Activity Index (BASDAI). The proteome of the plasma samples was profiled using liquid chromatography with tandem mass spectrometry detection, and the difference in protein concentration was evaluated using linear mixed-effects modelling.

Results: Our cohort included ten patients without radiographic spinal progression (mean±SD age 34.9±9.0 years, 40% female) and ten patients (mean±SD age 40.8±9.0 years, 40% female) who developed the progression after two years (mean±SD change in mSASSS 9.88±5.1). Additionally, of all included patients, 14 were classified as radiographic axSpA (mean±SD age 36.9±8.6 years, 28.6% female) and six as non-radiographic axSpA (mean±SD age 40.2±9.2 years, 66.7% female). The high-throughput profiling of plasma proteome detected 489 quantifiable proteins and our statistical analysis revealed 30 proteins with different concentrations between patients without and with radiographic progression ($p<0.05$ for all). Out of these proteins, haptoglobin (1.76-fold, $p<0.001$) and serum amyloid P-component (SAP) (1.57-fold, $p<0.001$) were upregulated, while gelsolin (1.23-fold, $p = 0.001$) was downregulated in patients with mSASSS progression compared to those without radiographic progression (Figure 1A). In addition, all these proteins significantly correlated with mSASSS, CRP or ASDAS (Figure 1B). However, after adjustment for CRP, only SAP and gelsolin, which were previously associated with axSpA[1,2], were independently associated with structural progression.

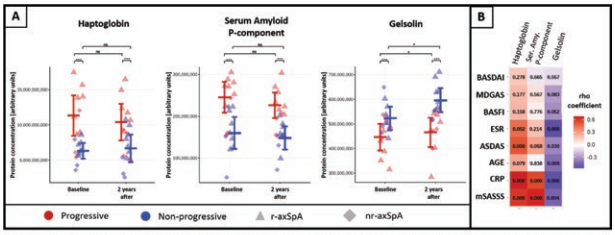

Figure 1 – A) Three candidate proteins with the potential to predict radiographic progression in axSpA. The error bars represent 95% confidence intervals with the mean for patients with or without mSASSS progression. *p-values* show statistical significance between depicted pairwise comparisons computed from linear mixed-effect models. (*** $p < 0.001$; * $p < 0.05$; ns – non-significant). Patients with and without mSASSS progression are coloured in red and blue, respectively, and radiographic (r-) and non-radiographic (nr-) axSpA patients are depicted as triangles and diamonds, respectively. B) Correlation matrix of three candidate proteins and selected clinical parameters. The matrix included *p-values* and the colour indicates the strength and direction of Spearman's coefficient (rho).

Conclusion: We identified two plasma proteins with the potential to independently predict the radiographic progression of axSpA. Further studies in a larger cohort of patients are needed to validate these data.

POS0440 INCREASED FREQUENCY OF ACTIVATED MAIT CELLS EXPRESSING THE GUT HOMING RECEPTOR CCR9 IN PATIENTS WITH RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Gastrointestinal tract, Innate immunity

E. Toussirot[1], C. Laheurte[2], E. Gravelin[3], C. Vauchy[4], M. Puyraveau[5], P. Saas[6]. *[1]University Hospital, CIC-1431, Besancon, France; [2]EFS Bourgogne-Franche-Comté, INSERM UMR1098 plateforme de biomonitoring, Besancon, France; [3]EFS Bourgogne Franche Comté, INSERM UMR 1098 plateforme bio monitoring, Besancon, France; [4]University Hospital, CIC-1431, Besancon, France; [5]University Hospital, Biostatistics CIC-1431, Besancon, France; [6]Etablissement Français du Sang, INSERM UMR1098/Université de Franche Comté Labex Lipstic, Besancon, France*

Background: MAIT (mucosal associated invariant T) cells are involved in mucosa defense against bacteria. This cellular subset is characterized by a semi-invariant αβ TCR and the expression of CD161. In patients with axial spondyloarthritis (ax SpA), previous works reported a decreased frequency of circulating MAIT cells compared to normal subjects. IL-17A is a relevant cytokine involved in SpA pathophysiology. MAIT cells are a cellular source of IL-17 and IL-17$^+$ MAIT cells were found increased in ax SpA. We have previously reported an increased frequency of IFNγ$^+$/IL-17$^+$ MAIT cells as well as IL-22$^+$ MAIT cells in ax SpA[1].
Objectives: In this study, we aimed to complete our previous results by evaluating activation markers and chemokine receptor/integrin expression, especially those for gut homing, in MAIT cells.
Methods: patients exhibited ax SpA (ASAS criteria) with a radiographic (r-ax SpA) or non-radiographic (nr-ax SpA) form. They all were under NSAIDs and biologic naïve. Healthy subjects were recruited as controls (HC). Circulating CD4$^+$ and CD8$^+$ T cells and MAIT cells were determined on blood samples by single platform flow cytometry (Cytoflex, Beckman Coulter). MAIT cells were identified by the co-expression of CD3, CD161 and TCRα7.2. In each subpopulation, we examined the expression of CD26, CD69, CCR9 and CD49d integrin.
Results: 26 patients were included (11 r-ax SpA: 9 males [M]; mean age 54.1 ± 19.6 years; disease duration: 16.2 years; ASDAS score: 4.1; and 15 nr-ax SpA: 7 M; age: 36.4 ± 1.3; ASDAS: 5.6) and 27 HC (16 M; age: 43 ± 12.7). In patients with r-ax SpA, we observed an increased frequency of activated CD3$^+$ CD69$^+$ MAIT cells and CD3$^+$ MAIT cells expressing the gut homing markers CCR9 and CD49d, as compared to HC ($p < 0.05$). These higher frequencies were not observed in patients with nr-ax SpA. In addition, when examining the CD8$^+$ MAIT population, similar higher frequencies of cells positive for CD69, CCR9 and CD49d were observed in patients with r-ax SpA compared to HC and patients with nr-ax SpA ($p<0.01$ and $p<0.05$, respectively).These modifications were specific for MAIT cells and were not observed in conventional CD4$^+$ or CD8$^+$ T lymphocytes.

Table.

	HC	r-ax SpA	nr-ax SpA
% CD69$^+$ MAIT CD3$^+$	18.4 ± 9.9	**28.3** ± 14.7 *	19.7 ± 10.3
% CD69$^+$ MAIT CD8$^+$	19.1 ± 11.4	**29.5** ± 15.6 *	20.8 ± 12.0
% CD49d$^+$CCR9$^+$ MAIT CD3$^+$	1.6 ± 1.7	**2.5** ± 1.6 *	1.9 ± 2.3
% CD49d$^+$CCR9$^+$ MAIT CD8$^+$	1.4 ± 1.7	**2.5** ± 1.8**	1.7 ± 2

Conclusion: Patients with r-ax SpA are characterized by an increased frequency of activated MAIT cells that expressed homing receptors (chemokine and integrin) for the gut. These results confirm that MAIT cells are altered in ax SpA and highlight the relationships between ax SpA and gut inflammation, especially for the radiographic form.

Gemelli IRCCS, Pathology Institute, Rome, Italy; [6]Fondazione Policlinico Universitario A. Gemelli IRCCS, Division of Rheumatology, Rome, Italy*

Background: Spondyloarthritis (SpA) and Inflammatory Bowel Disease (IBD) share some common pathogenetic pathways and a broad spectrum of clinical manifestations, laboratory and imaging features. How intestinal involvement affects SpA clinical and biological aspects remains unexplored and can be help in the SpA and IBD management.
Objectives: To define immunological and synovial and bowel tissues characteristics in SpA associated or not with IBD.
Methods: Forty-one SpA patients (22 SpA+IBD+ and 19 SpA+IBD-) and 50 IBD patients (control group, SpA-IBD+) were enrolled. Both category presented patients at beginning of a new biologic treatment. Upon enrolled, demographic, clinical and ultrasound features were collected for each patient. Peripheral venous blood and faecal samples were collected for each patients to determine IL-17A, TNF-alpha and sTREM1 plasmatic level and intestinal microbiota respectively. Moreover, patients with SpA underwent to the biopsy of the synovial membrane in order to assess the degree of inflammation, according to the Krenn Score (KSS).
Results: Considering intestinal involvement, SpA+IBD- showed a tendency of more severe synovitis grade compared to SpA+IBD+ (KSS: 3.00 (1.25-4.75) vs 1.50 (1.00-3.00) respectively, p: 0.059) and, considering SpA whole cohort, KSS directly correlated with inflammatory status assessed by CRP level (R: 0.540, p: 0.001). Considering the SpA and IBD whole cohort, articular and intestinal involvement affect cytokines levels independently from treatment: sTREM1 level was higher in SpA than in IBD (413 (247-563) vs 290 (220-344) pg/ml respectively, p: 0.003) and IL-17A level in SpA+IBD- vs SpA-IBD+ (0.49 (0.25-0.97) vs 1.00 (0.50-2.05) pg/ml respectively, p: 0.041), with direct correlation between sTREM1 and the clinical and synovial tissue aspects. Finally, regardless of intestinal involvement, SpA presented peculiar species richness and overall faecal microbiome composition compared to SpA-IBD+ with a significant difference between alpha and beta difference between these groups (p: 0.003 and p: 0.001 respectively).
Conclusion: SpA associated with the intestinal involvement present specific cytokines profile, synovial tissue features and faecal microbiome composition compared to SpA without IBD. These peculiar features can help in the management of SpA with or without intestinal involvement.

Rheumatoid arthritis - prognosis, predictors and outcome

POS0442 ENDOCITRULLINATION OF RA AUTOANTIGENS IS MORE ABUNDANT THAN C-TERMINAL CITRULLINATION IN THE GINGIVAL CREVICULAR FLUID OF ANTI-CCP POSITIVE AT-RISK INDIVIDUALS WITH PERIODONTAL DISEASE BUT NO SYNOVITIS

Keywords: Inflammatory arthritides

X. Yu[1], S. Hester[2], K. Harnden[3,4], R. Chowdhury[4], L. Duquenne[3,4], R. Letton[5], Z. Mustufvi[5], J. Meade[1], T. Do[1], R. Fischer[2], K. Midwood[6], P. Emery[3,4], K. Mankia[3,4]. *[1]Oral Biology, University of Leeds, Leeds, United Kingdom; [2]Target Discovery Institute, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; [3]NIHR, Leeds Biomedical Research Centre, Leeds, United Kingdom; [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [5]School of Dentistry, University of Leeds, Leeds, United Kingdom; [6]Kennedy Institute of Rheumatology, Oxford University, Oxford, United Kingdom*

Background: RA autoimmunity may be initiated at mucosal sites, including the periodontium. Anti-CCP positive at-risk individuals without synovitis (CCP+ at-risk) have an increased prevalence of periodontal disease (PD) and *Porphyromonas gingivalis* and an oral dysbiosis [1]. *P gingivalis* preferentially citrullinates C-terminal peptides by virtue of its peptidylarginine deiminase (PPAD) enzyme (2), whereas other periodontal bacteria predominantly induce endocitrullination [3]. These factors may trigger anti-citrullinated protein antibodies (ACPA), although the relative contribution of local C-terminal and endocitrullination is unclear.

Objectives: To determine the relative abundance of endo- and C-terminally citrullinated RA autoantigens in the gingival crevicular fluid (GCF) of CCP+ at-risk individuals with PD compared with controls.

Methods: CCP+ at-risk were identified from a UK cohort of anti-CCP+ individuals with musculoskeletal symptoms but no clinical synovitis. CCP+ at-risk underwent comprehensive periodontal assessment by a dentist, including GCF sampling from periodontally diseased sites. Control subjects (i.e. CCP-) with and without periodontal disease were also sampled. GCF was analysed by liquid chromatography mass spectrometry/mass spectrometry (LC-MS/MS) to identify endo- and C-terminally citrullinated peptides. The t-test was used for the statistical analysis.

Results: 25 CCP+ at-risk, 9 and 10 controls with and without PD respectively underwent GCF sampling. Mass spectrometry identified citrullination in 114 proteins in GCF, including 16 RA autoantigens (vimentin, myeloid cell nuclear differentiation antigen, keratin (type I/II cytoskeletal), heterogeneous nuclear ribonucleoprotein (A2/B1, K and U), fibrinogen (alpha and beta chain), histone (H1.4, H1.5, H1x, and H4), actin (cytoplasmic 2), apolipoprotein (A-I and A-IV)). In CCP+ at-risk with PD and controls without PD there was higher total abundance of endocitrullinated RA autoantigens compared with c-terminal citrullinated autoantigens in GCF ($p<0.05$, Figure 1). In CCP+ at-risk with PD 15 endocitrullinated RA autoantigens compared with only 4 C-terminally citrullinated RA autoantigens were identified (Figure 1). Fewer citrullinated RA autoantigens were identified in control subjects compared with CCP+ at-risk. More endocitrullinated compared with C-terminally citrullinated RA autoantigens were identified in controls with and without PD (Figure 1).

Conclusion: Several citrullinated RA autoantigens are present in the GCF of CCP+ at-risk individuals with periodontal disease but no synovitis. We identified endocitrullination as generally more abundant than C-terminal citrullination in both CCP+ at-risk and seronegative controls, suggesting PPAD may not be the primary source of citrullination. These data support the hypothesis that local citrullination of RA autoantigens at the periodontium may be an early driver of the ACPA response in RA.

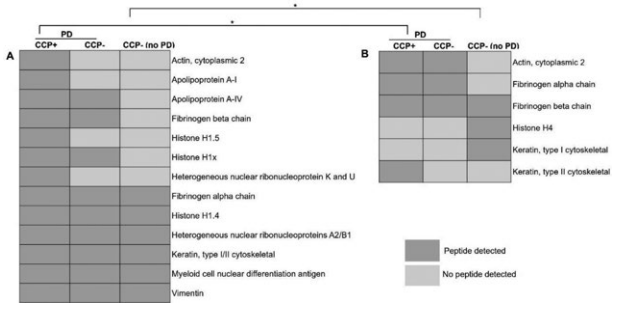

Figure 1. Citrullinated RA autoantigens in gingival crevicular fluid (GCF) samples. **(A)** Endocitrullinated RA autoantigens. **(B)** C-terminal citrullinated RA autoantigens. * indicates *p* value < 0.05, t-test. PD: periodontal disease; CCP+: anti-CCP positive individuals with new musculoskeletal symptoms but no synovitis; CCP-: anti-CCP negative individuals without musculoskeletal symptoms or synovitis.

POS0443 CLINICAL OUTCOMES OF ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS WHO UNDERWENT PERCUTANEOUS CORONARY INTERVENTION: A NATIONWIDE COHORT STUDY

Keywords: Rheumatoid arthritis, Cardiovascular disease

B. Y. Kim[1], L. Kyung-Ann[2], J. H. Jung[3], S. W. Nam[4], J. E. Park[5]. *[1]Gangneung Asan Hospital, University of Ulsan College of Medicine, Department of Internal Medicine, Gangneung, Korea, Rep. of (South Korea); [2]Soonchunhyang University Seoul Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); [3]Korea University College of Medicine, Department of Internal Medicine, Ansan, Korea, Rep. of (South Korea); [4]Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine, Department of Internal Medicine, Wonju, Korea, Rep. of (South Korea); [5]Konkuk University Chungju Hospital, Department of Internal Medicine, Chungju, Korea, Rep. of (South Korea)*

Background: Rheumatoid arthritis (RA), a systemic inflammatory arthritis, is associated with an increased risk of cardiovascular disease. Despite an increased proportion of elderly patients with RA and an increased prevalence of patients with RA undergoing percutaneous coronary intervention (PCI), studies on the PCI outcomes in elderly patients with RA are limited and controversial.

Objectives: This study aimed to evaluate the prognosis of elderly patients with and without RA who underwent PCI and the risk factors associated with the prognosis.

Methods: The Korean National Health Insurance Service claims database was used to extract data on 74623 patients (14,074 patients with RA and 60,549 patients without RA) aged 65 years or older who were diagnosed with acute coronary syndrome and underwent PCI between 2008 and 2019. The primary outcome was all-cause mortality between elderly patients with and without RA. The secondary outcome was all-cause mortality in elderly patients with RA who consist of patients with elderly onset RA that manifests after the age of 65 years and elderly patients who presented with young onset RA earlier in life.

Results: During a 10-year follow-up, the survival rate was lower in patients with RA than in those without RA (with RA: 53.7% vs. without RA: 58.3%, log-rank $P<0.001$). Compared to patients without RA, patients with elderly onset RA have poor survival outcomes and patients with young onset RA have good survival outcomes (with elderly onset RA: 48.1% vs. with young onset RA: 73.7% vs. without RA: 58.3%, log-rank $P<0.001$). Multivariable logistic regression analyses showed that diabetes mellitus (hazard ratio (HR) 1.39, 95% confidence intervals (CI) 1.35-1.43, $P<0.001$), chronic kidney disease (HR=3.97, 95% CI 3.63-4.34, $P<0.001$), and PCI due to myocardial infarction (HR=1.35, 95% CI 1.33-1.37, $P<0.001$) were the independent risk factors for all-cause mortality.

Conclusion: Elderly patients with RA who underwent PCI for acute coronary syndrome have an increased rate of all-cause mortality compared to general elderly patients. Among elderly patients with RA, patients with elderly onset RA particularly have poor survival outcomes. Based on the aspects of RA and cardiovascular disease in elderly patients, the clinical practice should focus on more detailed and active secondary prevention methods for a better prognosis.

POS0445

MORTALITY TRENDS AMONG RHEUMATOID ARTHRITIS PATIENTS IN WESTERN AUSTRALIA

Keywords: Rheumatoid arthritis

K. Almutairi[1], C. Inderjeeth[1], D. Preen[2], H. Keen[1], J. Nossent[1]. *[1]The University of Western Australia, School of Medicine, Crawley, Australia; [2]The University of Western Australia, School of Population and Global Health, Crawley, Australia*

Background: Mortality rates for patients with Rheumatoid Arthritis (RA) have reportedly improved in the past decades due to increasing access to specialised rheumatology care [1], early introduction of DMARDs with combination regimens [2], and subsequent biologics therapies [3]. However, the mortality rate remains higher than the general population, reducing the life expectancy by approximately ten years [4-5]. With scarce comparative data on mortality in Australian RA patients, we investigated temporal changes in standardised mortality rates for RA patients using longitudinal linked population-wide health data in Western Australia (WA) over the period 1980 to 2015.
Objectives: The aim of the study to estimate temporal standardised mortality rates over a 35-year period and identified leading causes of death and measured median Years Lost in a large RA cohort.
Methods: The study included 17,125 patients with a first-time hospital contact for RA (ICD-10-AM M05.00–M06.99 and ICD-9-AM 714) in the study period. Standardised mortality rate ratios (SMRRs) for the RA cohort versus the WA general population was estimated using direct age standardisation. We analysed temporal trends over death dates, causes from the WA death registry, and measured median Years of Life Lost by subtracting an individual's death age from their remaining life expectancy based on the Australian Government Actuary Life Table.
Results: Over the study period, SMRR was 2.5-folds (95%CI: 2.52-2.65) higher for RA patients than for the general population (Table 1), with a sex- and age-specific SMRR of 2.24 (95%CI 2.15–2.34) in males and 3.09 (95%CI 3.00–3.19) in females (Figure 1). The overall leading causes of death were diseases of the circulatory system, except among 30-44-year-olds in the 1991–2000 period, neoplasm was the leading cause of death. The median life years lost for the RA cohort were 5.7 years for females and 5.1 years for males over the study period (Table 1).
Conclusion: The mortality rate in RA patients in WA has decreased but remains higher than in Australian population. Malignant neoplasms were the second leading causes of death, and lung cancer was leading cause of cancer mortality. Together these data demonstrate the importance of screening and management for comorbidities in RA patients, especially cancer.

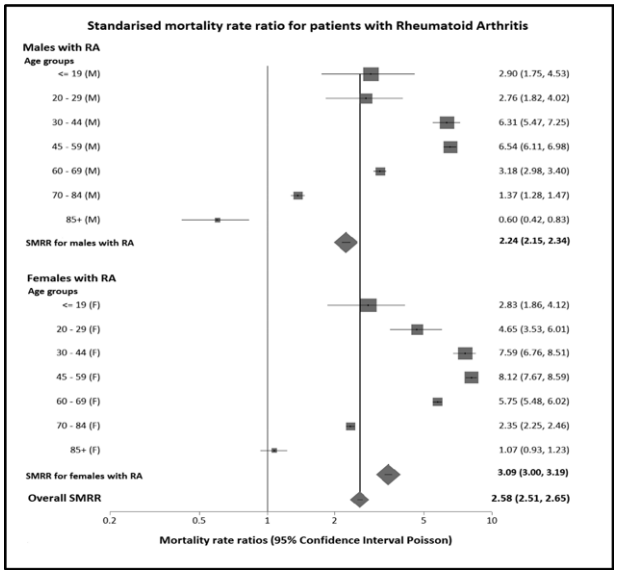

Figure 1. Standardised mortality rate ratios for patients with Rheumatoid Arthritis by sex and age in Western Australia (1980- 2015). RA= Rheumatoid Arthritis, M= Male, F= Female, SMMR= Standardised mortality rate ratio.

Table 1. The median life years lost for the Rheumatoid Arthritis cohort over study time periods.

RA cohort	Females		Male	
Median life years lost	**Median (IQR)**	**Percentage change (%)**	**Median (IQR)**	**Percentage change (%)**
Study periods				
1980- 2015	5.1 (3.4-8)	-	5.7 (3.9- 9.1)	-
1980- 1990	6.1 (4.4- 9.4)	0.0	7.4 (5-10.2)	0.0
1991- 2000	5.4 (3.7-8)	-11.5	5.9 (4.1- 9.3)	-20.3
2001- 2010	4.6 (3.2-7.3)	-14.8	5.0 (3.6- 8.3)	-15.3
2011- 2015	4.3 (3.1- 7.7)	- 6.5	5.2 (3.4- 9.1)	4.0

POS0446 URINARY METHOTREXATE DOSAGE AS AN ADHERENCE MEASUREMENT IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Epidemiology, Disease-modifying drugs (DMARDs), Treat to target

N. Theate[1], M. Geoffroy[1], L. Kanagaratnam[2], C. Gozalo[3], B. Loïs[1], I. Charlot-Lambrecht[1], A. Hittinger[1], Z. Djerada[3], J. H. Salmon[3]. *[1]CHU de Reims, Rhumatologie, 51100, France; [2]CHU de Reims, Aide méthodologique, pôle recherche et santé publique, 51100, France; [3]CHU de Reims, Pharmacologie, 51100, France*

Background: Non-adherence to rheumatoid arthritis treatments is common and must be identified, especially with the treat-to-target strategy. A methotrexate (MTX) urinary dosage (METU) was developed using high performance liquid chromatography by spectrometry method (HPLC-MS/MS).

Objectives: The aim of our study was to assess medication compliance for MTX in RA using METU under real-life conditions and to compare it with the usual indirect adherence measurement techniques.

Methods: We conducted a prospective study at the CHU de Reims. Patient inclusion comprised of RA patients over 18 years old who have been using MTX for more than 6 months. Patients were invited to fill demographic, clinical and psychological datas and other adherence measurement techniques (the CQR and the MPR). A urinary sample was taken to measure MTX and information about tolerance were collected through the MISS questionnaire.

Results: 84 patients with RA were analyzed, 26 using oral MTX and 58 subcutaneous MTX; 73% female, mean age 61.5 years, mean dose 15mg/week, 62% associated with biotherapy. 77 patients (91.7%) were adherent to treatment according to METU, whereas MPR and CQR reported less adherence (69.5% and 61.9% respectively). MPR and METU were not significantly different in subcutaneous MTX users (p = 0,059). Non-adherent patients had a higher number of tender joints and CRP value.

Table 1. Comparison's results of the different adherence measurement techniques.

Adherence	PO + SC (n=84)	P-value	SC (n = 58)	P-value
METU	**91,7%** (83,6 – 96,6) n = 77	x	91,4 (81,0 - 97,1) n = 53	x
MPR	69,5% (58,4 – 79,2)* n = 57	< 0,05	77,6 (64,7 – 87,5) n = 45	0,059
CQR	61,9% (50,7 – 72,3) n = 52	< 0,05	63,8 (50,1 – 76,0) n = 37	< 0,05

*2 missing data

Conclusion: This is the largest study evaluating MTX adherence treatment in RA patients using a urinary dosage. We identified that indirect adherence measurements did not reflect real life adherence. METU can be used in RA patients with unexplained response to treatment before escalating therapeutic strategy.

POS0447 DIFFICULTIES TO SLEEP EXPLAIN HIGH PATIENT REPORTED OUTCOMES VALUES IN PATIENTS WITH INFLAMMATORY ARTHRITIS WITH NO SWOLLEN JOINTS

Keywords: Outcome measures

L. Weman[1], H. Salo[2], L. Kuusalo[3], J. Huhtakangas[4], P. Vähäsalo[5], M. Backström[6], J. Kärki[7], T. Sokka-Isler[8]. *[1]University of Eastern Finland, Faculty of Health Sciences, Kuopio, Finland; [2]Finnish Institute for Health and Welfare, Data and analytics, Helsinki, Finland; [3]Turku University Hospital, Centre for Rheumatology and Clinical Immunology, Turku, Finland; [4]Kuopio University Hospital, Division of Rheumatology, Kuopio, Finland; [5]University of Oulu, PEDEGO Research Unit, Oulu, Finland; [6]Vaasa Central Hospital, Department of Pediatrics, Vaasa, Finland; [7]Kanta-Häme Central Hospital, Department of Children and Adolescents, Hämeenlinna, Finland; [8]Central Finland Central Hospital, Department of rheumatology, Jyväskylä, Finland*

Background: Patient reported outcomes (PROs) are valuable tools to understand how a patient is doing. Patient self-report of pain, fatigue and global health on a 100 mm Visual Analog Scale are routine measures in rheumatology and may be interpreted as measures of disease activity.

Objectives: To study whether good/poor sleep influences other clinical measures in patients with psoriatic arthritis (PsA) and rheumatoid arthritis (RA).

Methods: A total of 13527 (72 % female) patients with rheumatoid arthritis (RA) and 3644 (52 % female) patients with psoriatic arthritis (PsA) were identified in the Finnish national quality register for inflammatory arthritides. Clinical data from the most recent outpatient clinic visit between January 1st 2021 to July 31st 2022 was used in this study. Patients were divided into groups by self-reported difficulty to sleep on a MDHAQ question "over the last week, were you able to get a good night's sleep" with response options "without any difficulty" and "with some difficulty" as good sleep and "with much difficulty" and "unable to do" as poor sleep. Median values with interquartile ranges of other clinical measures were compared between the groups. Descriptive statistics and regression models were used for comparison with p=0.05 as a threshold for statistical significance.

Results: The mean (SD) age was 62 (14) for patients with RA and 55 (14) for patients with PsA. A total of 16 % of RA patients and 22 % of PsA patients had poor sleep. The values for DAS28, SJC 66, TJC 68, CRP and ESR were low and similar in patients with poor sleep and good sleep. The VAS-values for pain, fatigue and PGA for RA patients with good sleep were 18 (6, 40), 17 (4, 42) and 23 (9, 46) and 54 (29, 74), 64 (43, 80) and 56 (39, 72) (p<0.001 for all comparisons) for patients with poor sleep. In patients with PsA, the corresponding numbers were 20 (6, 41), 17 (4, 40) and 19 (6, 38) and 59 (36, 74), 66 (44, 81) and 56 (38, 73) (p<0.001 for all comparisons). The results were similar for PROs in patients with PsA (n=942) and RA (n=2861) with an SJC66 of 0. (Figure 1.)

Conclusion: The assessment of sleep is crucial for patients presenting severe symptoms without markers of disease activity.

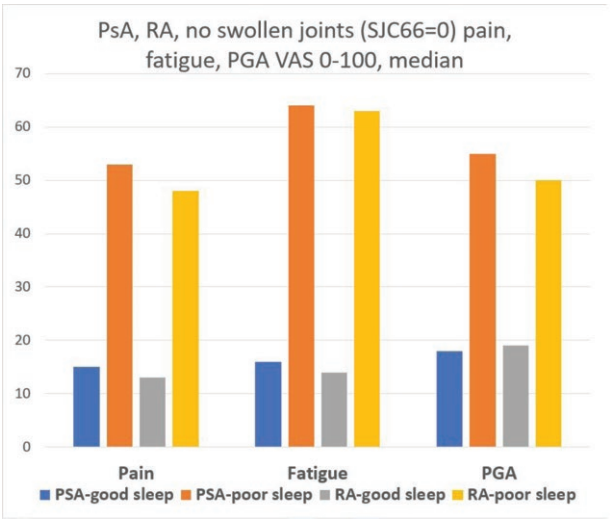

Figure 1. Median VAS-values for pain, fatigue and PGA in patients with PsA and RA with poor sleep and good sleep. All patients had no swollen joints.

POS0448

IDENTIFICATION OF JOINT LOCATIONS IN AN EARLY RHEUMATOID ARTHRITIS COHORT AS A CHARACTERISTIC OF DISEASE SEVERITY AND RESPONSE TO METHOTREXATE, DATA FROM THE ERA-UCLOUVAIN BRUSSELS COHORT

Keywords: Descriptive studies, Rheumatoid arthritis, Prognostic factors

L. Bricman[1], E. Sapart[1], T. Sokolova[1], A. Avramovska[1], P. Durez[1]. [1]*Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCLouvain) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium*

Background: Early RA patients (ERA pts) often present with different areas of joint involvement, but limited data exist to identify which specific joint locations may be indicative of greater disease severity.
Objectives: This analysis investigated the baseline (BL) prevalence of swelling, tenderness and erosions in individual joint locations and their possible association with disease characteristics, prognostic factors and response to Methotrexate (MTX) in a cohort of ERA pts.
Methods: This analysis was based on data from the ERA UCLouvain Brussels cohort in which patients were included according the ACR/EULAR 2010 criteria and naïve to DMARDs. The physician assessed prevalence of BL individual swollen and tender joint status (present, absent) through a physical examination. The joint count includes 44 joints. Similarly, all patient and RA characteristics were collected. The association between BL swelling, tender, erosions and disease characteristics was investigated for each individual joint. Remission rates (DAS28-CRP < 2.6) in patients treated only with MTX were assessed in order to analyze the correlation with BL joint location.
Results: BL location of each swollen, tender, or erosive joint (44 joints) is summarized in Table 1:

Table 1.

N=452*2	Total Erosives (%)	Total Swollen (%)	Total Tender (%)
Shoulders	2 (0%)	27 (3%)	225 (25%)
Elbows	0 (0%)	74 (8%)	139 (15%)
Wrists	**69 (8%)**	**515 (57%)**	**459 (51%)**
Knees	1 (0%)	186 (21%)	270 (30%)
Ankles	1 (0%)	209 (23%)	266 (29%)
MCP1	29 (3%)	**251 (28%)**	266 (29%)
MCP2	47 (5%)	**311 (34%)**	**303 (34%)**
MCP3	36 (4%)	**235 (26%)**	272 (30%)
MCP4	18 (2%)	75 (8%)	161 (18%)
MCP5	21 (2%)	89 (10%)	174 (19%)
PIP1	8 (1%)	89 (10%)	96 (11%)
PIP2	18 (2%)	**351 (39%)**	**338 (37%)**
PIP3	14 (2%)	**358 (40%)**	**332 (37%)**
PIP4	17 (2%)	178 (20%)	242 (27%)
PIP5	11 (1%)	151 (17%)	221 (24%)
MTP1	**53 (6%)**	67 (7%)	187 (21%)
MTP2	**55 (6%)**	166 (18%)	281 (31%)
MTP3	**80 (9%)**	169 (19%)	295 (33%)
MTP4	45 (5%)	114 (13%)	263 (29%)
MTP5	**128 (14%)**	70 (8%)	192 (21%)

The most frequent swollen joint was the wrist (57%), followed by PIP3 (40%) and PIP2 (39%), MCP2 (34%), MCP1 (28%) and MCP3 (26%). Erosions were most frequent in MTP5 (14%), MTP3 (9%), wrists (8%), MTP1 and MTP2 (6%). Swollen and tender joints were well associated except for shoulder (3% vs 25%), wrist (8% vs 15%) and MTP (see table 1).We found a significant correlation between erosion and swelling for wrists, MCP1-3 joints and MTP1-5 joints. As expected, erosive joint was observed first in MTP5 (14%) followed by the MTP3 (9%) and the wrist (8%). MTP4 and 5 joint locations were more present in younger and MCP 2-4 in older patients. BL swelling in the large size joints (knee, elbow, shoulder and ankle), in the medium size joint (wrist) and the small size joints (only MCP3, IPP 1, 2 and MTP5) was highly associated with higher DAS28-CRP*. BL swelling of the MCP1, 3, 4; MTP 1,2, 5 was associated with erosive disease. In contrast, swelling of the knee was correlated with non erosive and seronegative RA. Swelling of joint location such as knee, shoulder, ankle, MCP 1-5, MTP1, 5 and IPP 1, 2 was significantly correlated with a higher HAQ. Only swelling of MTP1, 2, 5 was associated with the presence of ACPA antibodies. No difference was observed for smoking habits and gender. Comparison between BL joint location in patients achieving remission or not has been evaluated. Patients with BL erosion and swelling in the feet responded less to MTX of non-response (respectively 18,2% vs 35.1% and 25% vs 35.1%). For patients with swollen wrist, we observed the same trend without significance. Smoking habits and rheumatoid factor positivity were more present in the non-responder group (29.6% and 66.1% versus 14% and 46.5%).

Conclusion: In our cohort of ERA naïve to DMARD, swelling was most present in wrist and hand joints (PIP 3 and 2). Erosions were most frequent in MTP joints and wrist. Clinical response to MTX was poorer in patients with swelling of the wrist and feet as well as erosion of the feet. Joint location could be an additional prognostic factor in ERA for severity and response to MTX suggesting more intensive therapy.

PRESENCE OF PERIODONTAL DISEASE AND THE INCIDENCE OF INFLAMMATORY ARTHRITIDES IN THE GENERAL POPULATION: DATA FROM THE UK BIOBANK

Keywords: Rheumatoid arthritis, Psoriatic arthritis, Inflammatory arthritides

H. R. Yun[1], S. S. Ahn[1]. [1]*Yonsei University College of Medicine, Internal Medicine, Yongin, Korea, Rep. of (South Korea)*

Background: Patients with inflammatory arthritides (IA) are now recognized to present with inflammation in the periodontium frequently. However, the association between signs of periodontal inflammation and IA onset has been poorly described in the existing literature.
Objectives: To investigate the association between periodontal disease and the development of inflammatory arthritides (IA) in the general population.
Methods: In total, 489,125 participants from the UK Biobank without a previous history of rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA) were enrolled. The primary outcome was the incidence of IA, which was a composite of RA, AS, and PsA according to the presence of periodontal disease based on self-reported oral health indicators. Multivariate Cox proportional hazard regression analyses using four different models were performed to assess the association between periodontal disease and IA development.
Results: In all, 86,905 and 402,220 individuals were categorized as with and without periodontal disease, respectively. Cox hazard analysis indicated that the presence of periodontal disease was an independent predictor of the occurrence of composite outcomes of IA, which was also consistent for RA and AS. Significant associations were found to be consistent in the four Cox models and were replicated even when different criteria were used to define periodontal disease. Subgroup analyses indicated that periodontal disease was associated with an increased RA risk in those aged <60 years, and this risk was persistent for both male and female patients and for patients with seropositive/seronegative RA.
Conclusion: Self-reported periodontal disease is associated with IA incidence in participants included in the UK Biobank, particularly for RA and AS. Higher clinical attention and optimal dental care in patients with signs of periodontal disease may be recommended for early disease detection and for reducing this risk.

MORTALITY AND CAUSES OF DEATH IN A LARGE COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS: A POPULATION-BASED STUDY

Keywords: Comorbidities, Outcome measures, Rheumatoid arthritis

F. Vesentini[1], M. Zen[1], L. Salmaso[2], C. Barbiellini Amidei[3], U. Fedeli[3], S. Bellio[2], F. Arru[1], A. Giollo[4], M. Saia[2], A. Doria[1]. *[1]University of Padua, DIMED - Rheumatology Unit, Padua, Italy; [2]Azienda Zero, Veneto Region, Clinical Governance Unit, Padova, Italy; [3]Azienda Zero, Veneto Region, Epidemiological Department, Padua, Italy; [4]Azienda Ospedaliera Padova, DIMED - Rheumatology Unit, Padua, Italy*

Background: Whether or not in the last years mortality is still increased in RA patients compared to the general population is controversial.

Objectives: To assess mortality rates (MRs), standardized mortality ratios (SMRs), and causes of death in Rheumatoid Arthritis (RA) in a population-based study.

Methods: We analyzed linked administrative health databases of the Veneto Region (Italy, 4,900,000 residents): the population registry, where all residents are recorded, was linked with healthcare co-payments exemptions, hospital discharge records, and mortality records. RA was defined by a healthcare copayment exemption for or any hospital diagnosis of RA. We analyzed all-cause mortality until December 31, 2020. MRs per 1,000 were stratified by year, sex, and age group. SMRs were derived, by comparing MRs of the general regional population. Causes of death were coded using the ICD-10 coding system and were available until 31/12/2020; they were grouped in: RA, infectious diseases, cardiovascular diseases (CVD), cancer, diabetes, or others.

Results: Between 2012 and 2020, 7,435 deaths among 37,996 RA prevalent cases occurred, corresponding to an average annual standardized MR of 32.2 (95% CI 31.5; 33.0) per 1,000 persons. The median (IQR) age at death was 83 years (77-88), lower in males (81, 75-86) compared to females (84, 78-89). Standardized MR was higher in males than in females (41.3, 95% 39.05-43.2 vs. 29.5, 95% CI 28.7-30.3); notably, this was true across all age groups (Table 1). Causes of death were CVD 2,735 (37.1%), cancer 1,519 (20.6%), infections 827 (11.2%), RA 352 (4.8%), diabetes 208 (2.8%), trauma, poisoning, or post-surgical/procedural complications 197 (2.7%), and others 1,532 (20.6%). Out of 12,875 incident RA patients, 1,288 died during the study period, corresponding to a mortality rate of 21.3 (95% CI 20.2-22.5). The distribution of causes of death among incident cases was comparable to that observed among prevalent cases. Overall SMR was 1.28 (95% CI 1.21-1.35) and was higher in younger patients (<45 years old: 2.15, 95% CI 0.93-4.24) (Figure 1). Eight-year survival was significantly affected by age at diagnosis: 98.8% (95% CI 98.1%-99.2%) in patients aged <50 years, 95.8% (94.5%-96.8%) in patients aged 50-59, 94.2% (92.2%-95.7%) in patients aged 60-64, 84.1% (81.7%-86.2%) in those aged 65-75, and 48.4% (45%-51.6%) in those aged >75 years.

Conclusion: Standardized mortality ratio is slightly increased in RA patients compared to the general population, especially in younger patients. Despite that, eight-year survival in subjects <49 is good. CVD and cancer represent the main causes of death in RA, whereas therapy-related complications such as infections account for a low proportion of deceases.

Table 1. Deaths and mortality rates among 37,996 prevalent RA cases (2012 - 2021).

POS0451 POOR SLEEP QUALITY INCREASES PRESENTEEISM BUT NOT ABSENTEEISM IN RA PATIENTS

Keywords: Patient reported outcomes, Work-related issues, Rheumatoid arthritis

Z. Guła[1,2], P. Kuszmiersz[1,2], J. Gąsowski[3], G. Haugeberg[4,5], M. Korkosz[1,2]. *[1]Jagiellonian University Medical College, Krakow, Poland, Department of Rheumatology and Immunology, Kraków, Poland; [2]University Hospital, Division of Rheumatology and Immunology, Kraków, Poland; [3]University Hospital, Division of Internal Medicine and Geriatrics, Kraków, Poland; [4]Sorlandet Hospital, Research Department, Kristiansand, Norway; [5]NTNU, Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Trondheim, Norway*

Background: Patients with inflammatory arthritis frequently suffer from poor sleep affecting their quality of life and work productivity i.e., higher presenteeism reflecting the disability to concentrate on work tasks despite being present at work. Sleep disturbances are reported to be more related to emotional factors than activity of the disease. However, sleep quality is rarely assessed in daily rheumatological practice and only few patients receive treatment for insomnia. Assessing sleep quality in MDHAQ form on a scale from 0 (without any difficulty) to 3 (unable to do) could be a simple tool to identify patients who need more profound evaluation of sleep disorders and intervention aimed at improving their work efficiency.
Objectives: Assessing the relationship between sleep quality and work outcomes in patients with rheumatoid arthritis (RA) by 1) evaluating the frequency of sleep disorders according to 0–3-point scale in MDHAQ form 2) finding a cut-off point for presenteeism and absenteeism discriminating patients with or without sleep disturbances and 3) defining the association between disease activity, sleep quality and work outcomes.
Methods: Cross sectional study of one year data from PolNorRHEUMA registry. Sleep assessment was based on MDHAQ, and patients were categorized into 4 groups according to the severity of sleep disorders. To assess presenteeism and absenteeism we used the Work Productivity and Activity Impairment Questionnaire (WPAI). The results were obtained using STATISTICA Tibco 13.3 software. All continuous variables were non-normally distributed, thus were presented in the manuscript as a median and compared by Mann-Whitney U-test, Kruskal-Wallis or multiple repetition test. To assess the point discriminating between different groups of patients depending on the severity of the sleep disorder, the cut-off point of presenteeism was calculated based on receiver operating characteristic (ROC) curves.
Results: Among 250 adult patients with RA, 63 (25%) didn't have ANY difficulties with sleep, 130 (52%) had SOME, 43 (17%) had MUCH and 14 (6%) were UNABLE to sleep. After analyzing 130 available WPAI questionnaires, we found that the cut-off value for presenteeism of 40% differentiates people with good sleep (MDHAQ sleep= 0 and 1) from those with a poor sleep (MDHAQ sleep = 2 and 3) whereas the cut-off = 10% differentiate group with no sleep disorders from group 1+2+3 combined. Interestingly, no such relation was found for absenteeism. Patients with poor sleep were significantly older, had higher BMI, DAS28, SJC and TJC (but not ESR and CRP), higher pain, joint pain and fatigue. After adjusting for age, sex, BMI, and CRP we found positive association between presenteeism and MDHAQ sleep score, TJC and morning stiffness (beta=11.6, beta=0.9, beta=8.36 respectively) but no association with SJC. Only 16 (6,4%) patients received treatment for insomnia.
Conclusion: Poor sleep quality according to MDHAQ indicates a very high presenteeism and poor work productivity, with no influence on absenteeism. Sleep, TJC and morning stiffness but no other disease activity parameters contribute to presenteeism. Scoring 2 or 3 in a question regarding sleep quality in the MDHAQ form should lead to sleep evaluation and specific intervention, independent of RA activity.

POS0452 DIAGNOSTIC AND PROGNOSTIC ROLE OF SERUM KL-6 IN RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

Keywords: Lungs, Biomarkers, Rheumatoid arthritis

J. C. Sarmiento-Monroy[1], A. Pérez-Isidro[2,3], R. Castellanos Moreira[4], V. Ruiz[1], B. Frade-Sosa[1], A. Azuaga[1], J. Ramírez[1], R. Morlà[1], A. Ponce Fernandez[1], P. Corzo Garcia[1], S. M. Farietta Varela[1], A. Colmenero[5], M. Morales-Ruiz[3,5], E. Ruiz-Ortiz[2,3], O. Viñas[2,3], F. Hernández-González[6], J. Sellarés[3,6], J. D. D. Cañete[1], R. Sanmartí[1], J. A. Gómez-Puerta[1]. *[1]Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain; [2]Hospital Clínic de Barcelona, Immunology, Barcelona, Spain; [3]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Immunology, Barcelona, Spain; [4]Bristol Myers Squibb, Rheumatology, Madrid, Spain; [5]Hospital Clínic de Barcelona, Biochemistry and Molecular Genetics, Barcelona, Spain; [6]Hospital Clínic de Barcelona, Pulmonary Medicine, Barcelona, Spain*

Background: Interstitial lung disease (ILD) is one of the leading causes of morbidity and premature mortality in rheumatoid arthritis (RA) patients. Some studies have shown that Krebs von den Lungen-6 (KL-6) may be a valuable biomarker for diagnosis and stratifying prognosis in Rheumatoid Arthritis-Associated Interstitial Lung Disease (RA-ILD).
Objectives: To evaluate the diagnostic and prognostic value of serum KL-6 in RA-ILD patients.
Methods: We conducted a retrospective study that included patients with RA (ACR/EULAR 2010 criteria) with available KL-6 data measured in blood serum at study enrolment. Patients were evaluated between February 2017 and October 2019 at a single center. ILD was diagnosed by high-resolution computed tomography (HRCT) and confirmed by a multidisciplinary committee. Serum KL-6 levels were measured by Lumipulse G KL-6 Kit (Fujirebio, Japan), using Chemiluminescent enzyme immunoassay (CLEIA). The reference value for KL-6 in healthy subjects was 118-627 U/mL. The inter-assay variation coefficient of the reagent was ≤ 4.4%. We performed a bivariate analysis according to the presence of ILD and high levels of KL-6. Mortality was assessed in December 2022 by medical chart review.
Results: A total of 166 patients were included (36 RA-ILD and 130 RA-non-ILD). Patient baseline characteristics were as follows: female gender 76.5%, mean age 62.9 ± 12.3 years, mean disease duration 9.1 ± 8.7 years, RF positive 66.3%, anti-CCP positive 85.5%, erosive disease 56.0%, and mean DAS28 3.0. The median follow-up period was 5 years (IQR 4.0–5.0). At baseline, patients with RA-ILD were older (69.9 ± 16.1 vs. 60.9 ± 12.3 years; p<0.001), were more frequently males (36.1% vs. 20.0%; p=0.044), had a longer disease duration (12.2 ± 1.3 vs. 8.3 ± 8.7 years; p=0.020), had higher RF titers (412.1 ± 120.5 vs. 165.6 ± 221.1; p<0.001), had a higher disease activity (DAS28 3.7 ± 0.2 vs. 2.8 ± 1.1; p<0.001), and higher mortality (33.3% vs. 9.2%; p<0.001). Among RA-ILD patients at baseline, the median FVC and DLco (% predicted value) were 79 (IQR 72.6–87.0) and 60 (IQR 49.0–70.4), respectively. Usual interstitial pneumonia (UIP) was the predominant pattern at HRCT in half of the patients (18/36). The mean serum KL-6 level at baseline was 513.1 ± 480.1 U/mL. KL-6 levels were abnormally elevated in 35 patients (21.0%). Serum levels of KL-6 in the RA-ILD group were significantly higher than those in the RA-non-ILD group

(884.0 ± 134.6 vs. 410.4 ± 262.4 U/mL; p<0.001). Patients with high KL-6 had a higher prevalence of RA-ILD (54.3% vs. 13.0%; p<0.001) and UIP pattern at HRCT (22.9% vs. 7.6%; p<0.001), as well as higher mortality (34.3% vs. 9.2%; p<0.001) (**Table 1**). During follow-up, 24 (14.5%) patients died, mainly due to respiratory infections (62.5%). The median time to death was 20 months (IQR 7.0–29.0).

Conclusion: Our results suggest that high KL-6 levels might be helpful as a biomarker for diagnosis and prognosis stratification in patients with RA-ILD, especially in patients with UIP pattern at HRCT.

POS0453 BASELINE PREVALENCE AND FACTORS ASSOCIATED WITH INTERSTITIAL LUNG DISEASE IN TWO RHEUMATOID ARTHRITIS INCEPTION COHORTS IN THE UK

Keywords: Lungs, Comorbidities, Rheumatoid arthritis

R. Dacheva[1], A. Busby[2], P. Kiely[3], A. Young[2], D. Walsh[4], D. Mcwilliams[4], J. Galloway[5,6], E. Nikiphorou[5,6]. *[1]Diagnostic and Consultation Center "St. Ivan Rilski", UMHAT "St. Ivan Rilski", Rheumatology, Sofia, Bulgaria; [2]University of Hertfordshire, Centre for Health Services and Clinical Research, Life and Medical Sciences, Hatfield, United Kingdom; [3]St George's University Hospitals NHS Foundation Trust, Department of Rheumatology, London, United Kingdom; [4]University of Nottingham, Pain Centre Versus Arthritis, Academic Rheumatology, Nottingham, United Kingdom; [5]King's College London, Centre for Rheumatic Diseases, London, United Kingdom; [6]King's College Hospital, Rheumatology Department, London, United Kingdom*

Background: Rheumatoid arthritis (RA) is a chronic, inflammatory disease with interstitial lung disease (ILD) being an important extra-articular manifestation, associated with significant morbidity and mortality.

Objectives: To determine the prevalence of ILD at time of RA diagnosis and identify baseline independent factors associated with ILD.

Methods: Two early inception cohorts (1986-2001) were used: the early RA network (ERAN) and the early RA study (ERAS). Socio-demographic, clinical and laboratory measures were recorded at baseline, 6 months and yearly thereafter. Baseline variables collected and included in analyses were: seropositivity, body mass index (BMI), ethnicity, measures of deprivation, smoking status. Comorbidity burden was evaluated using the rheumatic disease comorbidity index (RDCI). Baseline prevalence (proportion of individuals with ILD at baseline) and 95% confidence interval was estimated. Multivariable regression analyses were performed to identify risk factors at baseline associated with RA-ILD development. Multiple imputation was used for missing data.

Results: Data from a total of 2701 patients were included in the study, from whom 101 patients were diagnosed with ILD. Follow up was up to 25 years (mean 6.8 years); 75% of patients followed for ≥10 years. Of these, 12% had ILD at baseline; 46% were diagnosed with ILD during follow up and 43% were diagnosed with ILD post-mortem. The estimated prevalence of ILD at baseline was 0.44% (95% CI 0.19% to 0.69%). Univariable analyses of baseline factors showed age at onset (p<0.001), ever smoking (p=0.010), seropositivity (p=0.002), RDCI (p<0.001) and lung disease (p<0.001) to be associated with developing RA-ILD. Multivariable logistic regression showed age at onset (OR 1.03, 95% CI 1.01 to 1.05), seropositivity (OR 2.39, 95% CI 1.27 to 4.50) and ever smoking (OR 2.01, 95% CI 1.16 to 3.50) to be associated with ILD development. An increase in RDCI predicted higher ILD (OR 1.46, 95% CI 1.16 to 1.82). More recent recruitment year into the cohort was associated with decreased odds of developing ILD.

Table 1. Univariable and Multivariable Analyses.

Baseline Variables	Univariable analysis		Multivariable analysis	
	Odds Ratio (95% CI)	p-value	All comorbidities (n=2,689) Odds Ratio (95% CI)	Lung Disease (n=2,689) Odds Ratio (95% CI)
Age at onset *(years)*	1.03 (1.02, 1.05)	<0.001	1.03 (1.01, 1.05)**	1.03 (1.02, 1.05)**
Female Gender	0.56 (0.37, 0.86)	0.009	0.74 (0.47, 1.16)	0.74 (0.47, 1.16)
Minority Ethnicity	1.94 (0.76, 4.91)	0.201	-	-
IMD quintile	0.91 (0.77, 1.07)	0.243	-	-
Ever Smoked#	1.91 (1.15, 3.15)	0.010	2.01 (1.16, 3.50)*	2.01 (1.20, 3.38)**
Recruitment year	0.98 (0.95, 1.01)	0.146	0.95 (0.93, 0.98)**	0.97 (0.94, 0.99)*
Body Mass Index *(kg/m^2)*	0.99 (0.95, 1.04)	0.706	-	-
HAQ-DI	1.21 (0.92, 1.58)	0.172	-	-
DAS28	1.09 (0.93, 1.27)	0.279	-	-
Seropositive#	2.40 (1.29, 4.44)	0.002	2.39 (1.27, 4.50)**	2.57 (1.37, 4.85)**
Time to DMARD *(months)*	1.01 (1.00, 1.02)	0.183	-	-
RDCI	1.51 (1.24, 1.83)	<0.001	1.46 (1.16, 1.82)**	-
Lung disease	5.29 (3.12, 8.96)	<0.001	-	4.69 (2.72, 8.08)**

*IMD: Index of Multiple Deprivation, HAQ-DI: Health Assessment Questionnaire Disability Index, DAS28: Disease Activity Score 28 joint count, RDCI: Rheumatic Diseases Comorbidity Index**p<0.01, *p<0.05# Imputed values*

Conclusion: Baseline prevalence of ILD was very low. Seropositivity, smoking, higher comorbidity burden and age at onset increased the odds of subsequent ILD development. Identifying RA-ILD predictors early on is important to ensure appropriate screening, timely diagnosis and treatment.

WHAT ROLE DO SOCIOECONOMIC FACTORS PLAY IN PATIENTS WITH PERSISTENT ACTIVE RHEUMATOID ARTHRITIS? DATA FROM A LARGE UK EARLY INFLAMMATORY ARTHRITIS AUDIT

Keywords: Registries, Rheumatoid arthritis, Prognostic factors

M. Adas[1], S. Norton[1,2], A. Cope[3], M. H. Buch[4], J. Galloway[1], E. Nikiphorou[1,5].
[1]King's College London, Centre for Rheumatic Disease, London, United Kingdom; [2]King's College London, Psychology Department, London, United Kingdom; [3]King's College London, Department of Inflammation Biology, London, United Kingdom; [4]The University of Manchester, Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom; [5]King's College Hospital, Rheumatology Department, London, United Kingdom

Background: The basis for progression to a refractory disease state in up to 20% of patients with rheumatoid arthritis (RA) is unclear. Recent evidence suggests that non-biological characteristics, such as psychosocial factors, may interplay with biological (disease-related) factors to drive refractory disease in inflammatory arthritis[1].

Objectives: To explore which biological and non-biological factors associate with persistent active RA (pactiveRA) in the first year, despite use of conventional synthetic DMARDs.

Methods: Observational cohort data from adult early RA patients in the National Early Inflammatory Arthritis Audit (NEIAA) across England and Wales between May 2018 and Oct 2022, were acquired. Patients were defined as having pactiveRA based on three consecutive Disease Activity Scores (DAS28) of >3.2 at baseline, three and 12 months of follow up. Controlled RA (contRA) was defined as patients with a DAS28 ≤ 3.2 at the three and 12 month time-points, (having started off with a baseline DAS28 of >3.2). Univariable, followed by multivariable analyses were applied, the latter using stepwise forward logistic regression to explore associations with pactiveRA. PactiveRA status was used as the outcome variable. Age and gender were included in the models as a priori, with socioeconomic variables handled as the main independent variables (social deprivation, smoking-status and comorbidities) of interest, followed by clinical variables.

Results: A total of 682 patients with pactiveRA and 1,026 contRA patients were included. Compared to contRA, patients with pactiveRA were younger (aged 58, interquartile range (IQR): 49, 67) vs (62, IQR: 52,72), included more females (69% vs 59%), were current or ex-smokers, and more likely to have depression, lung and gastrointestinal disease. Also, patients with pactiveRA had worse scores in patient reported outcomes at baseline and Patient Health Questionnaire Anxiety and Depression Screener. Logistic regression results are summarised in the Table 1. Age, gender, living in a socially deprived area and being an ex or current smoker, were independently associated with pactiveRA in models controlling for markers of disease severity (seropositivity). Baseline corticosteroid use was also associated with pactiveRA (p<0.05 for all) and having a concomitant diagnosis of depression, odds ratio (OR) 2.30 (95%CI: 1.67,3.17), lung disease OR 1.46 (95%CI: 1.14,1.86) and gastric ulcer OR 1.71 (95%CI: 1.17,2.50) were significantly related to pactiveRA.

Conclusion: Sociodemographic factors (age, gender) and living in socially deprived areas were all associated with pactiveRA, independent of clinical and disease characteristics. Identifying 'adverse' socioeconomic factors that could drive persistent active disease early in the disease process, can help tailor interventions according to individual characteristics and need.

POS0456

ASSESSMENT OF CLINICAL FEATURES AS PREDICTORS OF INADEQUATE RESPONSE TO TNFI THERAPIES—FURTHER ANALYSIS OF THE MOLECULAR SIGNATURE RESPONSE CLASSIFIER

Keywords: Biomarkers, Rheumatoid arthritis, Artificial intelligence

V. Strand[1], T. Mellors[2], A. Jones[2], L. Zhang[2], J. Withers[3], S. Asgarian[3], V. Akmaev[2], D. Ghiassian[2]. *[1]Stanford University, Division of Immunology/Rheumatology, Palo Alto, United States of America; [2]Scipher Medicine Corporation, Data Science, Waltham, United States of America; [3]Scipher Medicine Corporation, Medical, Clinical & Regulatory, Waltham, United States of America*

Background: Clinical and molecular features have been used to predict how RA patients will respond to distinct treatments. Clinical datasets are more readily available, more easily analyzed, and less costly to obtain than are molecular datasets [1]. But predictions based on clinical features alone are usually insufficiently reliable for deciding among treatment options [2]. Although molecular features are increasingly valuable for predicting treatment responses [3], physicians are often uncertain whether it is necessary to consider molecular measures [4]. And health care providers must determine whether the benefits of using molecular datasets justify their added costs. The molecular signature response classifier (MSRC) uses clinical features and molecular (genomic and serologic) features to identify RA patients unlikely to adequately respond to TNFi therapies [5]. But the relative contribution of clinical and molecular features to MSRC performance has yet to be fully addressed. This information is invaluable because most RA patients respond inadequately to their initial treatments and response-prediction classifiers offer much promise for improving patient outcomes.

Objectives: Our objective was to evaluate how well clinical features alone predict inadequate TNFi responses in the patient cohort used for developing the MSRC.

Methods: Clinical features (sex, body mass index, and patient global assessment) and molecular features (expression levels of 8 genes, 10 single nucleotide polymorphisms, anti-CCP, and CRP) for RA patients in the CERTAIN study were described [5]. ACR50 at 6 months was the primary outcome defining response. The cohort was divided into a training set (n = 143) and a validation set (n = 175). Predictive models were trained through repeated cross-validation by using a random forest machine learning algorithm on 80% of the training data (n = 114); models were optimized by validation on the remaining 20% (n = 29). The final model was built on the entire training data set. Performance was then evaluated on the validation set (n = 175) and reported as area under the receiver operating characteristic curve (AUC). All statistical analyses were performed by using Python 3.7.6.

Results: Classifier performance when using only molecular features (AUC, 0.65–0.68) was better than its performance when using only clinical ones (AUC, 0.41–0.60) (Table 1). Classifier performance was best when using combined molecular and clinical features (AUC, 0.65–0.68).

Table. Prediction of inadequate ACR50 response to TNFi therapies

Features[a]	AUC (cross validation)	AUC (validation)
Molecular and clinical features	0.65	0.68
Molecular features	0.60	0.63
Clinical features	0.41	0.60
BMI	0.54	0.49
PtGA	0.43	0.51
Sex	0.53	0.59

Abbreviations: anti-CCP, anti-cyclic citrullinated protein; AUC, area under the receiver operating characteristic curve; CRP, C-reactive protein; BMI, body mass index; PtGA, patient global assessment; SNP, single nucleotide polymorphisms

[a] Features are considered in combination as part of a random forest model

Conclusion: These results confirm the importance of including molecular features in TNFi response–prediction models. Identifying new molecular biomarkers of treatment response can help address prediction challenges caused by the heterogeneity of RA. And considering clinical and molecular features together, with other assessments increases the predictive performance of precision medicine tests such as the MSRC.

ASSOCIATION BETWEEN METHOTREXATE USE AND LYMPHOMA IN RHEUMATOID ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

Keywords: Systematic review, Epidemiology, Rheumatoid arthritis

S. A. Alexander[1], D. Louden[2], G. Hughes[2], G. A. Starkebaum[2], N. Singh[2]. *[1]University of Utah Hospital, Rheumatology, Salt Lake City, United States of America; [2]University of Washington, Rheumatology, Seattle, United States of America*

Background: Rheumatoid Arthritis (RA) is associated with an increased risk of lymphoma compared to the general population, which has been attributed to increased disease activity (1, 2). By decreasing RA disease activity, methotrexate could potentially help to reduce the risk of lymphoma development; however, there are conflicting data in the literature.

Objectives: To perform systematic literature review to evaluate the association between use of methotrexate in RA and the risk of developing lymphoma.

Methods: A systematic literature search was performed using the PubMed, Embase, and Cochrane Central Register of Controlled Trials from inception through December 9, 2021. The search was limited to observational studies and randomized controlled trials (RCT) published in English that evaluated the association between use of MTX in RA and the development of lymphoma. Case series and reports were excluded. Two authors independently extracted data from final articles using a predefined data abstraction form and conflicts were resolved by a third reviewer. Quality assessments were performed.

Results: The study identification and selection process are summarized in **Figure 1.** Of the initial 839 articles identified, only eight articles met the eligibility criteria. The characteristics of these studies are depicted in **Table 1**. These were mostly observational studies except one RCT. Study sample sizes varied from 160 to 20,000 patients with RA. Five studies reported the odds/hazards ratio of occurrence of lymphoma in patients exposed to methotrexate versus not exposed to methotrexate. Three studies compared risk of lymphoma development in RA patients treated with methotrexate versus other biological DMARD of which one was an RCT. Most of the studies adjusted for variables such as age, sex, RA disease activity measures and inflammatory markers, concomitant RA medications and risk factors for cancer and RA. Of the eight studies, six did not find a significant association between MTX use and lymphoma, while two studies, conducted in Japan, reported a significant association. Included studies were of moderate to high quality. The heterogeneity of the included studies precluded conducting a meta-analysis.

Conclusion: While there are conflicting data regarding the role of MTX in lymphomagenesis in RA, we observed that a majority of high-quality epidemiologic studies did not support an association between MTX use and development of lymphoma. Only two studies from Japan reported an association between MTX use and development of lymphoma.

Bartlett[11,12], V. Bykerk[1]. *[1]Hospital for Special Surgery Main Hospital, Rheumatology, New York, United States of America; [2]Northwestern University, Rheumatology, Evanston, United States of America; [3]McGill, Statistics, Montreal, Canada; [4]Centre integre universitaire de sante et de services sociaux de l'Estrie-CIUSSSE-CHUS and universite de Sherbrooke, Rheumatology, Sherbrooke, Canada; [5]University of Calgary, Rheumatology, Calgary, Canada; [6]Univeristy of Manitoba, Rheumatology, Winnipeg, Canada; [7]University of Toronto, Rheumatology, Toronto, Canada; [8]Center of Arthritis Excellence, Rheumatology, Newmarket, Canada; [9]Universite de Laval, Rheumatology, Quebec, Canada; [10]Western University, Rheumatology, London, Canada; [11]McGill, Rheumatology, Epidemiology, Montreal, Canada; [12]Johns Hopkins, Medicine, Baltimore, United States of America*

Background: Newly diagnosed RA patients seen in routine care may present with more tender than swollen joints, that can persist throughout their early RA treatment. Little is known, about the impact of these tender-swollen joint count differences (TSJD) on patient-reported outcome measures (PROMs), such as function, pain interference, social participation and other health-related quality of life (HR-QoL) outcomes.

Objectives: Our objective was to estimate the impact of TSJD on PROMs in the first year following RA diagnosis, and whether associations may vary by type of joint involvement (small vs large).

Methods: Data were from patients with active, early RA (symptoms<1 year, CDAI>2.8) enrolled in the Canadian Early Arthritis Cohort (CATCH) who completed detailed clinical assessments and PROMs including the PROMIS-29 (physical function, social participation, pain interference, fatigue, sleep disturbance, anxiety and depression) at baseline, 3-,6- and 12-month between Jan 2016 and Aug 2022. 28-tender and 28-swollen joint counts (including 6 large and 22 small-joints) were performed by rheumatology team members. TSJD were calculated by subtracting SJC from TJC at each visit and categorized as <=0, 1-4, 5-6, 7+. Adjusted associations between repeated measures of TSJD and PROMIS-29 HR-QoL domains were estimated in separate linear-mixed models adjusted for age, sex, education, smoking, comorbidities, osteoarthritis/back pain, and RA treatment. Stratified analyses by large vs small TSJD were also performed to examine potential differential impacts by joint distribution.

Results: 547 eligible early RA patients (70% female, mean (SD) age 56(15) years, mean (SD) disease duration 5.3 (2.9) months) evaluated at baseline. 287 (52%) had TSJD score>0. Of these, scores ranged from 1 to 4 in 200 (37%), 5 to 6 in 41 (8%) and 7+ in 46 (8%). The frequency of TSJD>0 decreased from 52% at BL to 32% at 12-months. Adjusted mean-change scores in all PROMIS-29 measures were worse with higher TSJDs over 1-year follow-up (Figure 1). TSJD 1 to 4 and >7 were associated with worse mean-change T scores for all PROMIS29 outcomes, with TSJD>7 showing more pronounced worsening in physical function -2.6 [-4.0, -1.2] and participation satisfaction -3.5 [-5.3, -1.7] (negative scores indicating more impairment). Worse mean-change T scores in symptoms were also associated with TSJD>7 (positive scores indicating worse symptoms): pain interference 5.2 [3.5,6.9], fatigue 4.0 [2.1, 5.8], sleep problems 3.0 [1.4, 4.5], anxiety 2.1 [0.4, 3.8] and depression 2.0 [0.4, 3.7). There were fewer scores of TSJD 5 to 6, which was associated with worse mean-change scores in function, social participation and pain interference. The most striking mean-change scores were seen for large joint-TSJD scores of 5 to 6 in PROMIS function -6.1 [-10.3, -1.9] and social participation -6.1 [-11.6, -0.6], pain interference 6.6 [1.5, 11.7], compared to those found with small joint-TSJD and 28 joint-TSJD. Large joint -TSJD scores 1 to 4 were also associated with worse mean-change scores for all PROMIS measures.

Conclusion: Over half of patients with eRA have more tender than swollen joints, which persists in a third of patients. An increased TSJD score is associated with worse function, pain interference, social participation, and other HR-QoL outcomes over 1-year of follow-up. TSJD thresholds of 1 to 4 and >7 were associated with worsening of all PROMIS-29 outcomes. Having more tender than swollen large joints, at thresholds of 1 to 4 and 5 to 6, was associated with the most pronounced worsening of PROMs. Elevated TSJD assessment, especially in large-joints may help identify patients likely to experience worse outcomes.

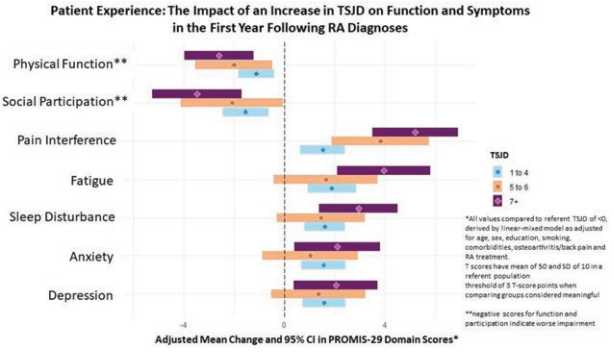

Figure 1.

The impact from and persistence of predominantly tender joints supports a need to identify early interventions.

POS0459 CALPROTECTIN HAS BETTER PREDICTION OF OBJECTIVE ASSESSMENTS OF INFLAMMATION THAN CRP OR ESR; RESULTS FROM TWO NORWEGIAN COHORTS OF EARLY OR ESTABLISHED RA

Keywords: Biomarkers, Rheumatoid arthritis, Ultrasound

H. B. Hammer[1,2], L. Mathsson-Alm[3], I. Gehring[4], J. Sexton[5], E. A. Haavardsholm[1,2], J. Askling[6]. *[1]Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Dept of Rheumatology, Oslo, Norway; [2]Faculty of Medicine, University of Oslo, Oslo, Norway; [3]Thermo Fisher Scientific, Phadia AB, Uppsala, Sweden; [4]Thermo Fisher Scientific, Freiburg, Freiburg, Germany; [5]Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Diakonhjemmet Hospital, Oslo, Norway; [6]Karolinska Institutet, Department of Medicine, Solna, Stockholm, Sweden*

Background: Inflammatory laboratory markers predicting response to medication would be useful in the clinics. Two Norwegian cohorts of early or established RA patients included in the NORA study (a Nordic multi-centre study exploring personalized medicine in RA) were used to explore the predictive value of calprotectin, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR).

Objectives: To explore the associations between calprotectin, CRP, ESR, and clinical disease activity assessments, and to explore the predictive value of these inflammatory markers on clinical and ultrasound (US) examinations.

Methods: Two cohorts were included; 1. Patients with early RA initiating methotrexate (the ARCTIC step-up, treat-to-target randomized study [1] (230 patients, mean (SD) age 51.5 (13.7) years, disease duration 0.6 (0.5) years, 61% women, 81% anti-CCP positive) and 2. Patients with established RA initiating a biologic disease-modifying anti-rheumatic drug (the ULRABIT cohort [2]) (209 patients (mean (SD) age 53.3 (13.2) years, disease duration 10.0 (8.8) years, 81% women, 80% anti-CCP positive). Both cohorts were assessed by clinical (tender/swollen 28 joints (TJC/SJC), physician's global assessment (PhGA), patient's global assessment (PGA) and pain), laboratory and comprehensive US examinations (grey scale and power Doppler of 36 joints) at baseline, 1 and 3 months (half of the early RA cohort US only at baseline). Calprotectin (measured by use of FEIA (Thermo Fisher)), CRP and ESR (inhouse methods) were assessed at treatment start and at one month in both cohorts. Correlations were analysed by Spearman. Baseline and 1-month levels of calprotectin, CRP or ESR were explored by linear regression for prediction of 3 months results of objective (US, SJC, PhGA) and subjective (TJC, PGA, pain) measures of disease activity (adjusted for age, gender, and disease duration) giving R-squared (95% CI obtained by bootstrapping (percentile intervals and 1000 bootstrap replications)).

Results: The correlations between baseline levels of calprotectin and SJC28/PhGA were 0.34-0.56 in the two cohorts, with corresponding correlations for CRP of 0.25-0.46, and ESR 0.23-0.50 (all p<0.001), and lower correlations with TJC28, PGA and pain (median 0.25 (range 0.04-0.35). Calprotectin and CRP were predictive of the objective inflammatory variables in both cohorts (Table 1), with calprotectin having the highest R-squares, and calprotectin had better prediction than CRP and ESR in established RA (p<0.05).

Conclusion: The laboratory markers had highest correlations with the more objective assessments. Calprotectin was superior to CRP and ESR for prediction of the objective disease activity variables. Thus, calprotectin may have added value in clinical evaluation of inflammatory activity in RA patients.

Background: The benefit and harms of low-dose glucocorticoid (GC) therapy for established rheumatoid arthritis (RA) in combination with biological and targeted synthetic disease-modifying anti-rheumatic drugs (b/tsDMARDs) are uncertain.
Objectives: We investigated the effect of b/tsDMARDs on concomitant GC therapy among people with RA and the impact of low-dose GC therapy on disease activity and comorbidities.
Methods: This was an observational, monocentric, prospective study. We enrolled all RA patients who started their first b/tsDMARD between 2015 and 2020, excluding those with overlapped connective tissue diseases. The primary outcome was the odds ratio (OR) of persistent GC discontinuation at month 36 (M36), as assessed through multivariable logistic regression. We defined persistent GC discontinuation if GC therapy was not prescribed for ≥2 consecutive visits after 24 months. Secondary outcomes were the marginal means of prednisone daily dose and disease activity score in 28 joints (DAS28) with C-reactive protein (CRP) over three years estimated through repeated-measures analysis of covariance. Analyses were adjusted for age, sex, disease duration, seropositivity, baseline DAS28 or GC dose. The impact of low-dose GC therapy on comorbidities and disease activity was also evaluated.
Results: This inception cohort comprised 371 RA patients initiating their first b/tsDMARD: tumor necrosis factor inhibitors (n=298; 80.3%), abatacept (n=47; 12.7%), tocilizumab (n=11, 3.0%), rituximab (n=9; 2.4%), Janus kinase inhibitors (n=9; 1.6%). b/tsDMARDs were combined with low-dose GC therapy in 65% of patients at baseline, decreasing to 42% at M36. After starting b/tsDMARDs, the median (10th-90th percentile) dose of prednisone decreased from 5 (2-10) at baseline to 2.5 (0-5) mg daily at M36. The most decrease in prednisone dose occurred within the first six months of b/tsDMARD therapy. Persistent GC discontinuation was achieved in 23% of patients during follow-up, with a significantly higher discontinuation rate (34%) and a trend for lower exposure to GC therapy after M24 in patients diagnosed in the last decade compared to older cohorts (**Figure 1A**). Patients who discontinued GC therapy persistently were significantly younger (52 vs 59 years), had shorter disease duration (9 vs 13 years), more swollen joints (6 vs 4) and greater patient global assessment (65 vs 55 mm), and received higher doses of methotrexate (14 vs 12 mg/w). After accounting for confounders, patients who discontinued GC therapy persistently did not show worse disease control over time (**Figure 1B**) whilst developed less cardiovascular disease, especially hypertension (9% vs 19%, p=0.023) and coronary artery disease (0% vs 4.6%, p=0.044). Changing the molecular targets of b/tsDMARDs did not yield higher odds of persistent GC therapy discontinuation than keeping the initial drug class; in contrast, GC persistent discontinuation was less likely in older patients with longer disease duration (Table 1). Patients refractory to more than three b/tsDMARDs classes had numerically higher disease activity and received more prednisone during follow-up (**Figures 1C and D**).

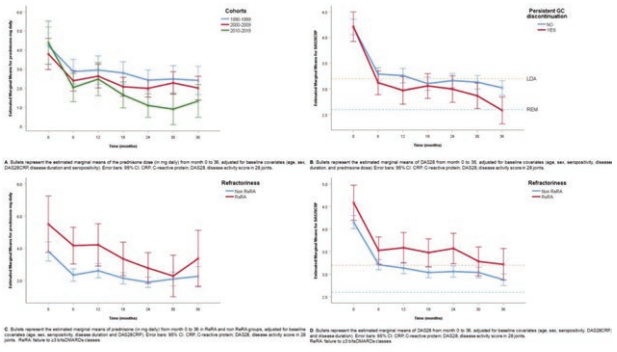

Figure 1.

Table 1. Multivariable logistic regression of persistent GC discontinuation among RA patients on b/tsDMARDs

	P-value	OR	95% CI (inferior)	95% CI (superior)
Disease duration, years	**0.011**	0.96	0.93	0.99
Age, every five years increase	**0.009**	0.88	0.80	0.97
DAS28CRP	0.253	1.14	0.91	1.43
Switch (vs no switch)	0.521			
1 switch	0.309	1.38	0.74	2.59
≥2 switch	0.320	1.40	0.72	2.69

CI, confidence interval; CRP, C-reactive protein; DAS28, disease activity score in 28 joints; OR, odds ratio; PtGA, patient global assessment. Multivariable logistic regression with persistent GC discontinuation as the outcome.

Conclusion: Low-dose GC therapy for RA persists in the majority of patients despite intensive use of b/tsDMARDs, yet is associated with cardiovascular morbidity and negligible effect on disease activity. This study also highlights a trend towards less reliance on GC therapy over the past 30 years.

POS0461

AN INCREASE IN ULTRASOUND JOINT INFLAMMATION OCCURS WHEN ANTI-CCP POSITIVE AT-RISK INDIVIDUALS WITH SUBCLINICAL SYNOVITIS PROGRESS TO INFLAMMATORY ARTHRITIS

Keywords: Ultrasound, Rheumatoid arthritis, Imaging

K. Harnden[1], A. Di Matteo[1,2], D. Esperança Almeida[1,3], E. De Lorenzis[1,2], L. Duquenne[1,2], L. Garcia-Montoya[1,4], J. Nam[1,2], P. Emery[1,2], K. Mankia[1,2].
[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [2]Leeds Teaching Hospitals Trust, Rheumatology, Leeds, United Kingdom; [3]Hospital de Braga, Serviço de Reumatologia, Braga, Portugal; [4]The Rotheram NHS Foundation Trust, Rheumatology, Rotherham, United Kingdom

Background: Anti-CCP+ at-risk individuals with musculoskeletal (MSK) symptoms and subclinical synovitis on ultrasound (US) are at high risk of developing inflammatory arthritis (IA). The accepted standard practice is to initiate treatment at progression rather than in the pre-rheumatoid arthritis (RA) phase when they do not have clinical synovitis [1].
Objectives: We aimed to determine whether imaging characteristics change when individuals with pre-RA progress to IA in order to inform the optimal window of opportunity for therapeutic interventions.
Methods: Anti-CCP+ at-risk individuals with MSK symptoms but no clinical synovitis from the Leeds CCP cohort were selected for having US subclinical synovitis [Grey scale (GS) ≥1 and Power Doppler (PD) ≥1] prior to IA development and a further US scan performed at clinical synovitis onset (i.e. progression). The US protocol included the metacarpophalangeal joints (MCPJs), proximal interphalangeal joints, wrists, elbows, knees, ankles, second-fifth metatarsophalangeal joints, extensor carpi ulnaris and finger flexor tendons. US PD and GS synovitis were scored semi-quantitatively (0-3) according to EULAR/OMERACT. At patient level, total GS and PD scores were compared between scans. Change on US in the joints that became clinically swollen was also assessed. Early morning stiffness (EMS) and 44 tender joint count (TJC) were compared between scans. Wilcoxon signed-rank tests were conducted for comparisons.
Results: Forty-six CCP+ at-risk individuals were identified. The mean age was 57.4 (± 13.3), 91.3% had high titre CCP levels (≥ 3x upper limit of normal) and 60.9% were Rheumatoid Factor positive. The median US scan interval was 3.5 months (IQR 1.25-8.75). EMS increased between scans (median of 20 [IQR 0-60] to 75 [IQR 30-173] minutes [p = 0.048]) as did TJC (median 2 [IQR 1-7] to 6 [IQR 2-13] [p=0.001]. On US (Table 1), at patient level the overall burden of PD in the joints increased at IA progression, trending towards significance. The overall burden of GS did not increase. PD in the MCPJs and MCP and wrist joints combined increased significantly. GS at the elbows also significantly increased. There was no significant increase in tendon GS or PD. At joint level PD increased in joints that were swollen at progression and GS increased with a trend towards significance. Non-swollen joints did not change.
Conclusion: A marked increase in US joint inflammation occurs when CCP+ at-risk individuals with subclinical synovitis on US progress from pre-RA to

Table 1. Changes on Ultrasound from first visit with subclinical synovitis to second visit at progression to RA.

	Visit 1: US subclinical synovitis	Visit 2: Progression to IA	P-value

clinical arthritis. This is particularly evident in MCPJs, wrist joints and joints that become clinically swollen. This marked increased in ultrasound joint inflammation at progression is accompanied by a significant increase in EMS and tender joints. Intervening when at-risk individuals have subclinical synovitis may represent a window of opportunity to prevent the rapid increase in ultrasound joint inflammation that occurs with the onset of joint swelling.

POS0462 CLINICAL PARAMETERS AFFECTING QUALITY OF LIFE IN PATIENT WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Outcome measures, Quality of life

I. Yoshii[1]. [1]*Yoshii Clinic, Musculoskeletal Medicine, Shimanto City, Japan*

Background: Under the treat-to-target strategies, patient with rheumatoid arthritis (RA) has achieved clinical remission in a major population, however, the impact on the quality of life remains controversial. The relationship between quality of life and disease activity control, pain control, and functional capacity control needs to be clarified.

Objectives: This study aims to clarify the influence of clinical parameters on the quality of life in patients with RA.

Methods: In this study, Patient with RA who was monitored with simplified disease activity index (SDAI) as a disease activity indicator, health assessment questionnaire disability index (HAQ-DI) as a functional capacity indicator, pain score using a visual analog scale (PS-VAS) as a pain grade indicator, EuroQol-5th dimension with 5 lines (EQ5D-5L) as a quality of life indicator, and measured Sharp/van der Heijde score (SHS) as a joint deformity indicator from the start of treatment (baseline) since January 2016, were recruited. Association between EQ5D-5L and other parameters such as gender, age, SDAI, PS-VAS, SHS, and HAQ-DI was statistically evaluated at baseline and at last observation, and change between the two periods using linear regression analysis with multivariate model.

Results: A total of 538 patients were included in the study. The female gender rate was 73.4%, and mean values at the baseline and at the last observation were 67.2 and 73.2 (age), 12.7 and 4.4 (SDAI), 49.3 and 46.4 (SHS), 35.4 and 24.5 (PS-VAS), 0.487 and 0.498 (HAQ-DI), and 0.755 and 0.825 (EQ5D-5L), respectively. All of these parameters were significantly different between the two periods. EQ5D-5L at baseline correlated significantly with HAQ-DI and PS-VAS, and their beta values were -0.604 and -0.444, respectively. EQ5D-5L at the last observation correlated significantly with SDAI, HAQ-DI, and PS-VAS at the last observation, and their beta values were -0.04, -0.623, and -0.099, respectively. When the last values of these parameters were divided by value at the baseline and the change from the baseline to the last observation, EQ5D-5L at the last observation correlated significantly with both of baseline and the change of all of SDAI, HAQ-DI, and PS-VAS, and their beta values were -0.439, -0.493, -0.143, 0.547, 0.605, and 0.139 for SDAI, HAQ-DI, PS-VAS at the baseline, and those change from the baseline to the last observation, respectively.

Conclusion: Quality of life in RA patients depends on disease activity control, pain control, and functional capacity. These variables could be controllable by treatment.

Background: In rheumatoid arthritis (RA) the identification of specific autoantibodies is crucial for an earlier diagnosis and stratification of patients according to different disease phenotypes. Autoantibodies directed against carbamylated proteins (anti-CarP) have been recently identified [1] as predictors for RA development [2]. Anti-CarP antibodies are associated with more severe RA, in particular in anti-citrullinated peptide antibodies (ACPA) negative RA patients [3].

Objectives: To determine the frequency of positive anti-CarP antibody in a real-life cohort of RA patients on synthetic and biologic disease-modifying antirheumatic drugs (DMARDs) and their association with radiological damage and disease activity.

Methods: The study is an open-label, observational, cross-sectional study, including 69 patients with RA according to ACR/ EULAR 2010 criteria, treated with synthetic and biological DMARDs. The control group consisted of 16 healthy controls (HC). The study was approved by institutional Ethical Committee and patients signed the Informed Consent. Circulating levels of anti-CarP antibodies were determined at baseline visit by commercial ELISA anti-CarP quantitative sandwich immunoassay (cut-off value 6 ng/ml). Articular X-rays were performed within 6 months of the baseline to define the presence of erosions. RA disease activity (DAS28 CRP) was assessed. Pearson χ^2 test, Wilcoxon test or Kruskall- Wallis test was used, as appropriate. Spearman rank-order correlation coefficient was applied for continuous variables. A multivariable logistic regression model was performed to assess prognostic variables on damage.

Results: Anti-CarP antibodies were positive in 35% of RA patients and no antibodies were found in HC. One quarter (4/17) of seronegative RA patients were anti-CarP positive. All anti-CarP positive and RF/ ACPA negative patients had radiological evidence of erosions and a moderate disease activity (DAS28 CRP 3.60± 0.58) and disability (HAQ-DI 0.70± 0.13). In all RA patients, a positive correlation between levels of anti-CarP antibodies and DAS28 CRP (p =0.0003; Spearman r = 0.4829) was found. Furthermore, 87% of anti-CarP positive patients had erosions. The multivariable logistic regression model suggested that disease activity and higher levels of anti-Carp antibodies were significant predictors for the presence of erosions. There was a greater number of erosions in patients with active disease (OR 1.31, 95% CI [1.14, 1.63]) and those with a higher levels of anti-CarP antibodies (OR1.66,95% CI [1.28, 2.37]).

Conclusion: Anti-CarP antibodies were present in a significant number of RA patients and those with higher circulating levels had higher disease activity and a greater occurrence of radiological damage. Further larger studies are warranted to better understand the clinical significance of anti-CarP antibodies in RA.

POS0464 **DISEASE-AGNOSTIC SELF-MANAGEMENT PROGRAM: IMPACT ON DISEASE ACTIVITY AND HEALTH RELATED QUALITY OF LIFE MEASURES FOR PATIENTS LIVING WITH CHRONIC INFLAMMATORY ARTHRITIS**

Keywords: Inflammatory arthritides, Patient reported outcomes, Self-management

Y. El Miedany[1], D. Palmer[2], M. H. Abu-Zaid[3], W. Hassan[4], S. A. Mahran[5], M. Elgaafary[6], S. Saber[7], S. A. A. Tabra[3], W. Elwakil[8]. *[1]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom; [2]North Middlesex University Hospital, Rheumatology, London, United Kingdom; [3]Faculty Of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; [4]Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Benha, Egypt; [5]Faculty of Medicine - Assiut University, Rheumatology and Rehabilitation, Assiut, Egypt; [6]Faculty of Medicine, Ain Shams University, Community and Public Health, Cairo, Egypt; [7]Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt; [8]Faculty of Medicine Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt*

Background: Agnostic approach refers to strategy that is generalized so that it is interoperable among various disorders or systems. In general, regardless of the underlying specific pathology, patients prioritize which self-management strategy they would like to start with according to their own requirements. They also select the issues they would like to address based on their individual perceptions of ability, need and context. Therefore, implementation of a disease-agnostic self-management program is a key priority to optimize the care of patients with chronic inflammatory arthritis.
Objectives: To determine, based on self-efficacy theory, the effectiveness of a disease-agnostic self-management program which can be undertaken by the individual inflammatory arthritis patient in any sequence to meet his/her specific needs.
Methods: Prospective multi-center assessment of patients with inflammatory arthritis, who were randomly assigned to either a 16-week program in self-management (intervention group, n = 121) or standard care for rheumatology (control group, n = 120). The program is composed of 4-arms: joint learn, joint change, joint-cise and joint act [1]. The patient is free to choose whichever component of the program that meets his/her individual requirement. Outcome variables were assessed at baseline and 6-, and 12-months after commencement of the intervention. This included measures of disease activity, adherence to therapy, motivation, functional disability, and quality of life.
Results: The intervention group included patients living with rheumatoid arthritis (30 patients), psoriatic arthritis (30 patients), lupus (30 patients), and osteoarthritis (31 patients). The mean age of participants (96 females [79.3%], 25 males [20.7%]) was 54.3+3.51 years. There was no significant difference on comparing the baseline characteristics and variables between the two groups. At 6-months following initiation of the self-management program, when compared to the control group, there was significantly better improvement in the intervention group patients' motivation score ($p< 0.05$), functional ability ($p< 0.05$) as well as quality of life ($p< 0.05$). At 12-months follow-up, the self-management intervention demonstrated improvement for disease activity (effect size 1.4). Similarly, there was improvement of the patients' adherence to therapy ($P<0.01$) in the intervention group.
Conclusion: Results suggest that disease-agnostic self-management improves disease activity scores as well as patient-reported outcomes regardless of patient diagnosis. Enhancing patients' capacity to deal with the burden of chronic inflammatory arthritis disease plays a vital role in their long-term management. Longer duration of self-management training and increased follow-up time are required to incorporate lifestyle changes.

Elwakil[10]. *[1]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom; [2]Faculty of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; [3]North Middlesex University Hospital, Rheumatology, London, United Kingdom; [4]Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Benha, Egypt; [5]Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt; [6]Faculty of Medicine - Assiut University, Rheumatology and Rehabilitation, Assiut, Egypt; [7]Faculty of Medicine, Ain Shams University, Community and Public Health, Cairo, Egypt; [8]Faculty of Medicine Alexandria University, Rheumatology Unit Internal Medicine Department, Alexandria, Egypt; [9]University College London, Computer Sciences, London, United Kingdom; [10]Faculty of Medicine Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt*

Background: Self-management is a vital component of successful inflammatory arthritis management. In contrast to the traditional medical model of care, self-management underscores the importance of collaborative, interactive care between the patient and the healthcare professional rather than one-way, passive care from the rheumatologist to the patient. In theory, patient-targeted e-Health tools enable the arthritic patients to implement self-management into their disease management and reach their own health-related goals. Yet the outcomes and early evidence about patient targeted e-Health and its consequence on self-management are mixed.
Objectives: To assess the feasibility of using an e-health intervention to improve the self-management abilities of rheumatoid arthritis patients.
Methods: Prospective multi-center randomized controlled assessment of rheumatoid patients with inflammatory arthritis. Using a 1:1 allocation ratio, patients were randomly assigned to either intervention group (112 patients) or control group (112 patients). The intervention was in the form of online access to educate and facilitate patients' ability to monitor and self-manage their arthritis. The patients had the opportunity to track their symptoms, self-management approaches and goals, medical therapy use, functional ability and quality of life. Specific e-health self-management approaches were made available for the self-management of fatigue, sleep disturbance and pain. Outcome variables were assessed at baseline and 6-, and 12-months after commencement of the intervention. This included measures of disease activity, adherence to therapy, patient motivation, functional disability, and quality of life. The primary outcome measure was self-management ability measured by the Patient Motivation Measure [1]. Secondary outcome measures include disease activity score, levels of fatigue, pain, functional ability, quality of life and adherence to therapy.
Results: The mean age of participants was 53.6+4.62 years. There was no significant difference on comparing the baseline characteristics and variables between the two study groups. At 6-months, when compared to the control group following the initiation of the online self-management program, in the intervention group, there was significantly higher improvement in the patients' motivation score ($p< 0.05$). At 12-months follow-up, the online self-management intervention demonstrated improvement for disease activity (effect size 1.3), functional ability ($p< 0.05$), quality of life ($p< 0.05$) as well as adherence to therapy ($p< 0.01$) in in comparison to the control group.
Conclusion: Results revealed that the online technology-enhanced self-management intervention did improve rheumatoid arthritis patients' self-management ability and health outcomes. Direct access to the health information on the Internet (or diagnostic apps on a smartphone) can help arthritic patients not only to self-manage their health issues, but also leads to lessening uncertainty, stress, and avoidance.

POS0466

INTERIM UPDATE ON BASELINE CHARACTERISTICS AND EFFECTIVENESS FROM A PROSPECTIVE OBSERVATIONAL STUDY OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA) TREATED WITH FILGOTINIB (FILOSOPHY)

Keywords: Rheumatoid arthritis, Real-world evidence, Patient reported outcomes

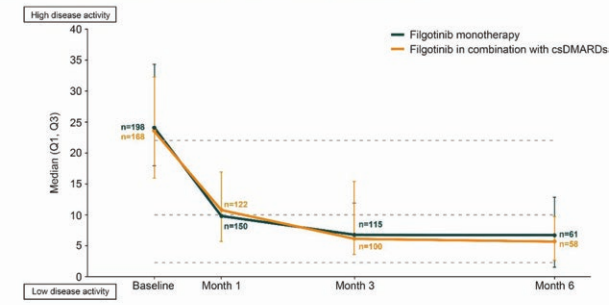
R. Caporali[1,2], J. Avouac[3], K. Bevers[4], G. R. Burmester[5], T. Debray[6], F. De Leonardis[7], K. Harris[8], N. Betteridge[9], S. Romero-Yuste[10], P. Verschueren[11], M. Zignani[7], J. Galloway[12]. *[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]ASST Gaetano Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy; [3]Hôpital Cochin, AP-HP Centre - Université Paris Cité, Rheumatology A Department, Paris, France; [4]Sint Maartenskliniek, Department of Rheumatology, Nijmegen, Netherlands; [5]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [6]Galapagos NV, Biostatistics, Mechelen, Belgium; [7]Galapagos GmbH, Medical Affairs, Basel, Switzerland; [8]Galapagos NV, Medical Affairs, Mechelen, Belgium; [9]Neil Betteridge Associates, -, London, United Kingdom; [10]University Hospital Complex of Pontevedra, Department of Rheumatology, Pontevedra, Spain; [11]University Hospital Leuven and KU Leuven, Department of Rheumatology, Leuven, Belgium; [12]King's College London, Centre for Rheumatic Diseases, London, United Kingdom*

Background: Filgotinib (FIL) is a preferential oral Janus kinase (JAK) 1 inhibitor for the treatment of RA. Efficacy of FIL has been demonstrated in clinical trials. To assess effectiveness in a real-world setting, a phase 4 study of FIL (FILOSOPHY; NCT04871919) in patients with RA is ongoing in Europe.

Objectives: To report baseline characteristics and interim efficacy data (up to 6 months) in the first 480 patients treated in FILOSOPHY.

Methods: FILOSOPHY is a prospective, observational study, in which approximately 1500 adults with moderate to severe active RA, who are prescribed FIL for the first time and in accordance with the product label in daily practice, will be enrolled. We report interim baseline demographics, disease characteristics, prior treatments, and reasons for starting FIL. We assessed disease activity at baseline, and Months 1, 3 and 6, via Clinical Disease Activity Index (CDAI) and Disease Activity Score in 28 joints–C-reactive protein (DAS28-CRP) and two electronically collected patient-reported outcome (PRO) measures at baseline, Week 1–4, and Months 3 and 6: pain (using a 10-cm visual analog scale [VAS]) and fatigue (via the Functional Assessment of Chronic Illness Therapy–Fatigue scale [FACIT-F]). The proportion of patients with minimal clinically important difference (MCID) in FACIT-F (≥4.0 change from baseline) and VAS pain (≤–10-mm change from baseline) at Month 6 was assessed. A repeated measurements model was used to estimate the least squares (LS) mean change from baseline in CDAI and FACIT-F.

Results: Of the 480 treated patients by the end of June 2022, 73.1% were female, mean (standard deviation [SD]) age was 57.6 (11.5) years, RA duration was 10.4 (9.4) years, BMI was 27.6 (5.7) kg/m^2, 28 tender joint count was 8.6 (6.9), and 28 swollen joint count was 5.6 (5.2). A total of 45.2% of patients were positive for rheumatoid factor and/or anti-citrullinated peptide antibody. Over half of patients (57.5%) had received prior biologic disease-modifying antirheumatic drugs (DMARDs; **Table 1**) and18.3% prior targeted synthetic DMARDs. FIL was started due to inadequate response (36.3%), loss of response (50.6%) or intolerance (non-allergic) (7.7%) to previous treatment (other reasons/missing data accounted for 5.4% of patients). Most patients (91.9%) received FIL 200 mg; 8.1% received FIL 100 mg (**Table 1**). FIL monotherapy was taken by 52.9% of patients, while 45.6% received FIL in combination with conventional synthetic DMARDs. Improvements from baseline to Month 6 were observed in CDAI (LS mean change [standard error; SE]: –15.8 [1.0]; **Figure 1** shows median CDAI over time) and DAS28-CRP (LS mean change [SE]: –1.8 [0.1]). Improvements from baseline to Month 6 were also observed for PROs; at Month 6, 54.2% and 65.0% of patients had an MCID from baseline in FACIT-F and VAS pain score, respectively.



Conclusion: Preliminary 6-month data indicate rapid improvements with FIL treatment, which were seen as early as 4 weeks for disease activity and as early as 1 week for pain and fatigue. Similar effects were seen with FIL monotherapy and combination therapy. Long-term follow-up is needed to further evaluate disease outcomes.

Table 1. Demographics, prior and current treatments

DISCORDANCE IN PATIENT AND EVALUATOR GLOBAL ASSESSMENT OF DISEASE ACTIVITY OVER TIME AND ACROSS DISEASE ACTIVITY LEVELS IN RECENT-ONSET RHEUMATOID ARTHRITIS

Keywords: Real-world evidence, Rheumatoid arthritis, Patient reported outcomes

A. A. Couture[1], N. Carrier[2], S. Roux[3], H. Allard-Chamard[3], P. Liang[3], G. Boire[3]. *[1]University of Sherbrooke, Medicine, Sherbrooke, Canada; [2]CIUSSS de l'Estrie - CHUS, Rheumatology, Sherbrooke, Canada; [3]University of Sherbrooke, Medicine - Rheumatology, Sherbrooke, Canada*

Background: Treatment of rheumatoid arthritis (RA) aims to achieve remission or at least low disease activity. Composite measures (e.g. SDAI) to measure RA disease activity usually incorporate patient (PGA) and evaluator (EGA) global assessments. EGA and PGA are often discordant, reflecting divergences in evaluation of disease impact and potentially towards therapeutic goals.
Objectives: Patient vs Physician (PGA – EGA) discordance was evaluated according to disease duration over 5 years and to concomitant SDAI scores.
Methods: Demographics, clinical and serological variables, radiographic damage (Sharp van der Heijde scores), treatments, comorbidities, and Patient-Reported Outcomes (function, depression and coping with disease) were collected at baseline (median symptom duration 3.7 months) and at 12, 18, 30, 42 and 60 months from symptom onset. EGA and PGA were reported using a 0-10 cm visual analog scale (VAS). PGA-EGA discordance was divided in four subgroups[1]: negative discordance group (<-1 cm), concordance group (≥-1cm and ≤+1 cm), positive discordance group I (>1 cm and ≤3 cm) and group II (>3 cm).
Results: We included 822 patients from the prospective longitudinal Early Undifferentiated PolyArthritis (EUPA) cohort of recent-onset inflammatory arthritis. At baseline, concordance was present in 27.3 %, 24.9% in negative discordance and 47.8% in positive discordance (25.9 % group I and 21.9 % group II). Over 60 months, concordance increased to 45.7%, negative discordance decreased to 7.7%, while positive discordant groups remained stable (46.4 % at 5 years). Although prevalence was stable at a group level, only 40% of patients remained in positive discordance Group II over time. In positive discordant groups, patients were younger (median 58,6 years group I and 59,8 years group II, p <0.003), had higher functional impact (M-HAQ ≥1, 46.3 % to 50.2 % p <0.001), fewer tender and swollen joints (p <0.0001), but rated higher for pain, fatigue, sleep (p <0.0001) and depression (CES-D, median score 18 for both groups, p <0.005). Concordance was most frequent in remission, negative discordance in high disease activity, while group I positive discordance remained stable independent of disease activity. Group II positive discordance was highest (35-38%) with low or moderate disease activity.
Conclusion: In this longitudinal prospective study of patients with early arthritis, almost half evaluated their global disease activity worse than the evaluator (positive discordance) and this proportion remained stable up to 60 months. Patients in positive discordant group were younger and reported higher functional impact, pain, fatigue, poor sleep and more symptoms of depression but had lower tender and swollen joint counts. Concordance was best when in remission. Negative discordance increased with disease activity. Mild positive discordance (Group I) was stable at 25%, independent of disease activity and disease duration. Marked positive discordance (Group II) was stable over time and more prevalent with low/moderate disease activity.

POS0468

A PREDICTION MODEL FOR SWITCHING OF BIOLOGICS AND TSDMARDS IN RHEUMATOID ARTHRITIS

Keywords: Prognostic factors, Registries

L. Cappelli[1], G. Reed[2], J. Kremer[3]. *[1]Johns Hopkins School of Medicine, Rheumatology, Baltimore, United States of America; [2]UMass Chan Medical School, Medicine, Worcester, United States of America; [3]Corrona Research Foundation, Rheumatology, Delray Beach, United States of America*

Background: Patients with rheumatoid arthritis (RA) have many options for biologic therapy both within treatment classes and across differing mechanisms of action, but the lack of predictability of treatment response and failure can be frustrating for patients and physicians. Rheumatologists longitudinally collect patient and physician reported measurements as a part of routine clinical care that can be used for prediction of outcomes [1]. Harnessing data regularly collected to monitor RA to inform treatment decision making could improve patient care.
Objectives: To develop a readily usable model with data collected in clinical care at preceding visits to predict the probability of switching biologic at a subsequent clinic visit
Methods: Patients were drawn from the CorEvitas (formerly CORRONA) registry and were adults over the age of 18 with a diagnosis of RA. The study matched patients who switched biologics with control patients who had not switched biologics; the cohort was divided into a training and test set for prediction model development and validation. Switchers: RA patients initiating a biologic/tsdmard and switching to another biologic/tsDMARD with at least two prior visits to the switch while on drug. Visits prior to the switch were between 2 and 12 months before. Control visit: Patient visits while still on initiated drug with at least 2 visits prior while on drug; next visit could not be a discontinuation or switch. A control visit was matched to a switch visit within 2 months of time from initiation by drug class and prior biologic experience. Pairs of control-switch visits were divided into a training (60%) and test set (40%). Using the training set, best subset regression, lasso and elastic net methods were used to determine the best potential models. Area under the ROC curve was used for the final selection of best model and estimated coefficients of this model were applied to the test data set to predict switching. Change in disease activity measures had a non-linear association with switching and were fit using linear splines with a knot at zero.
Results: A total of 5050 patients were included, 3016 in the training and 2034 in the test dataset. The average age was 59.6, the majority were female (3998, 79.2%), and the average duration of RA at the time of switch or control visit was 12.8 years. The final model included prior CDAI by category, prior patient pain measurement, change in CDAI from baseline, age group, and number of prior

biologics which were significantly associated (either positively or negatively) with switching biologics (Table 1). The area under the ROC curve was 0.690 for this model with the training dataset (Figure 1). The model was then applied to the test data with similar performance; the area under the ROC curve was 0.687 (Figure 1).
Conclusion: We developed a simple model to determine the probability of switching biologics for RA at the following clinic visit. This could be incorporated into the electronic medical records or used as an application to give clinicians more information about their patient's trajectory and likelihood of failing a biologic.

Background: In experimental settings, early treatment is associated with better outcomes in rheumatoid arthritis (RA), underpinning the concept of a "window of opportunity". Under real-life conditions, though, the long-term maintenance of such benefits is uncertain.
Objectives: To assess the long-term maintenance of expected clinical benefits associated with early RA treatment under real-life conditions.
Methods: Adults meeting the ACR/EULAR (2010) criteria for RA were included. The participants had long-standing disease, been followed up in 11 healthcare centers in Brazil as part of the REAL study. [1] Individuals whose treatment had been initiated within 6 months of disease onset were compared with those treated for the first time only later on. Disease activity (DAS28-CRP), physical function (HAQ) and the presence of erosive disease were evaluated. Chi-squared and t tests, along with logistic and linear regression were used to verify associations. p-values < 0.05 were deemed significant. The study received ethical approval, and all participants gave informed consent.
Results: 995 participants were included; 89.6% female; 56% white. The mean (SD) age was 56.8 (11.6) years; cumulative schooling years: 8.1 (4.25). The median (IQR) disease duration was 147 (81–236) months. Rheumatoid factor was positive in 77.6%. The mean (SD) DAS28 was 3.28 (1.38); median (IQR) HAQ score: 0.750 (0.250–1.500). Erosive disease occurred in 54.2%. Table 1 compares early- vs. late-treated patients, showing small effect sizes in clinical outcomes. After adjusting for age, schooling years, disease duration and corticosteroid use, early treatment was no longer an independent predictor of DAS28 scores ($\beta = 0.153$; p = 0.160), HAQ scores ($\beta = 0.023$; p = 0.682) or erosive disease [Exp(β) = 0.926; p = 0.626].
Conclusion: In long-standing RA, only small differences in disease activity, physical function and erosive disease were associated with early or late initial treatment. After adjusting for confounders, these differences vanished, indicating that beyond the "window" of opportunity lies a "building" of continued disease management, which might be of even greater relevance for the long-term outcomes in real-life settings.

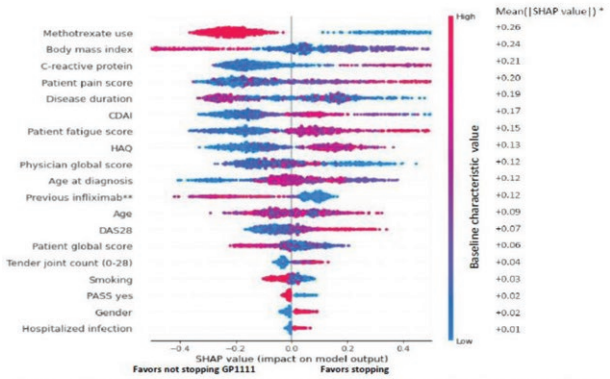
POS0470 A MACHINE LEARNING MODEL FOR IDENTIFYING IMPORTANT CLINICAL VARIABLES AND PREDICTING ONE-YEAR TREATMENT RETENTION IN PATIENTS WITH RHEUMATOID ARTHRITIS PERFORMING AN INFLIXIMAB BIOSIMILAR-TO-BIOSIMILAR SWITCH

Keywords: Prognostic factors, Artificial intelligence, Rheumatoid arthritis

N. Prenga[1,2,3], H. Nabi[1,4], N. Steen Krogh[3], A. Akkoc[3,5], M. L. Hetland[1,6], B. Glintborg[1,6]. *[1]University Hospital of Copenhagen Rigshospitalet, DANBIO and Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Glostrup, Denmark; [2]University of Copenhagen, Department of Computer Science (DIKU), Copenhagen, Denmark; [3]ZiteLab ApS, Frederiksberg, Denmark; [4]Faculty of Health and Medical Sciences, University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [5]IT University of Copenhagen, Copenhagen, Denmark; [6]University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark*



Background: In Denmark, a nationwide mandatory infliximab biosimilar-to-biosimilar switch, from CT-P13 to GP1111, was recently conducted in patients with rheumatoid arthritis (RA) to save costs (ref). It is of interest to identify patients having favorable outcomes based on clinical characteristics at time of switch.
Objectives: We aimed to explore important baseline clinical factors by implementing a robust machine learning (ML) model to predict one-year GP1111 treatment retention.
Methods: Patients with RA who performed a biosimilar-to-biosimilar switch from CT-P13 to GP1111 between April 2019 -Feb 2020 (=switchers) were identified in the nationwide DANBIO registry. Clinical characteristics at GP1111 start (=baseline) were identified in DANBIO and through linkage to national patient registries (comorbidities). Missing baseline data were estimated using Multivariate Imputation by Chained Equations (20 imputations). A tree-based algorithm Extreme Gradient Boosting (XGBoost) was used to predict main outcome, defined as stop of GP1111 during one year of follow-up (stop/no stop). Contributing baseline characteristics were investigated as SHAP values. Due to imbalanced dataset (low stop rate), the ML model excellently predicted the majority outcome (no stop) but poorly the minority (stop). Thus, we incorporated rebalancing strategies (Random Oversampling, ROS, Random Undersampling, RUS, Synthetic Minority Oversampling Technique, SMOTE, Near Miss Algorithm, NearMiss) and the performance was inspected (confusion matrix). Optimal cut-offs (thresholds) were identified by Youden Index, Receiver Operating Characteristic Curve (ROC), Precision-Recall Curve to improve model-performance for the minority outcome. Analyses were performed in R and Python.
Results: We included 685 RA switchers whereof 17% stopped GP1111 during one year of follow-up (**Table 1**). SHAP values for 26 characteristics were investigated (**Figure 1**, see footnote). The ranges for accuracy and Area Under the ROC (AUC) were 79-87% and 0.78-0.85, with specificity and sensitivity ranging 0.79-0.99 and 0.01-0.12 respectively. This indicated a high true negative rate (specificity, predicting no stop of GP1111) and low true positive rate (sensitivity) i.e., poor prediction of GP1111 stop. With oversampling and undersampling methods, ranges for accuracy and AUC were 60-87% and 0.60-0.87 respectively, with specificity ranging 0.61-0.73 and sensitivity 0.50-0.67 corresponding to a higher true positive rate. This could be explained by RUS and NearMiss removing data from majority outcome and by ROS and SMOTE adding data to the minority outcome. Optimal threshold methods resulted in higher true positive rates and with a range for accuracy 70-85% (specificity 0.67-0.74, sensitivity 0.66-0.76).

Table 1. Baseline characteristics in switchers. Stratified by stop/no stop of GP1111 during one year of follow-up

	No stop	Stop
Number of patients, n (%)	571 (83)	114 (17)
Female, %	70	65
Age, years	47 (35, 56)	48 (37, 57)
CDAI	4 (2,8)	8 (4,13)
CRP, mg/L	2 (1, 5)	4 (1, 12)
Concomitant methotrexate, %	78	61
Body mass index, kg/m2	25 (22, 29)	24 (22,27)
HAQ	0.5 (0.1, 1.1)	1.0 (0.5, 1.5)
Disease duration, years	11 (5, 20)	8 (5, 13)
Physician global, VAS, mm	5 (2,10)	8 (2,20)
Patient pain VAS, mm	22 (8, 43)	37 (22, 70)

Numbers are median (IQR) unless otherwise stated

Figure. Machine Learning (ML) model with SHAP values for baseline characteristics

Beeswarm plot. The plot shows how the baseline characteristics of each patient affect the prediction of the ML model towards either stop or no stop of GP1111.
The x-axis stands for SHAP values, and in the y-axis the baseline characteristics. Each point in the plot is one SHAP value for a given patient. Red color means a high baseline value and blue color means a low baseline value. Variables are sorted by their mean absolute SHAP value in descending order with most important variables at the top. The further away from the vertical line at x=0, the larger the impact on the prediction. Negative SHAP values are contributing to increased chance towards not stopping GP1111, while positive SHAP values are pushing the model prediction towards stop of GP1111. As examples, methotrexate use (i.e., red color) has negative SHAP values indicating a change towards not stopping GP1111, high values of fatigue scores (red color) indicate a change towards stop of GP1111, low values of C-reactive protein (blue color) indicate a change towards not stopping GP1111. Variables with little impact are not shown (e.g., comorbidities, swollen joint count)
**Mean absolute SHAP values for prediction model*
***Previous treatment with infliximab oriainator*

Conclusion: We implemented a robust machine learning model for predicting one-year retention in infliximab switchers and identified important baseline clinical characteristics. However, the model was challenged by imbalanced data (low stop rate) which was overcome by oversampling methods and optimal cut-offs. Careful methodological considerations are needed when advanced statistical models are applied to imbalanced datasets.

POS0471 SPECIFIC SYMPTOM CLUSTERS AT DIAGNOSIS SIGNAL A POORER EARLY RA PROGNOSIS: DATA FROM THE CANADIAN EARLY ARTHRITIS COHORT

Keywords: Rheumatoid arthritis, Patient reported outcomes, Epidemiology

S. J. Bartlett[1,2], C. O. Bingham[2], O. Schieir[3], M. F. Valois[3], G. Boire[4], J. Pope[5], L. Bessette[6], C. Thorne[7], D. Tin[7], C. Hitchon[8], G. Hazlewood[9], E. Keystone[10], V. Bykerk[11]. *[1]McGill University & McGill University Health Centre, Medicine, Montreal, Canada; [2]Johns Hopkins Arthritis, Medicine, Baltimore, United States of America; [3]McGill University, Medicine, Montreal, Canada; [4]Sherbrooke, University of Sherbrooke, Sherbrooke, Canada; [5]Western University, Medicine, London, Canada; [6]Québec City, Medicine, Québec City, Canada; [7]CARE, Rheumatology, Newmarket, Canada; [8]University of Manitoba, Rheumatology, Winnipeg, Canada; [9]University of Calgary, Medicine, Calgary, Canada; [10]RheumKey, Rheumatology, Toronto, Canada; [11]Hospital for Special Surgery, Rheumatology, New York, United States of America*

Background: Early RA is characterized by multiple symptoms that impact daily function and HRQL. Little is known about whether there are symptom clusters evident at diagnosis that could identify patients with a poorer prognosis, or the stability of clusters over time.
Objectives: To identify patient-reported symptom clusters at RA diagnosis, associated sociodemographic and RA characteristics, and the stability of clusters over the first 6 months.
Methods: Using data from the Canadian Early Arthritis Cohort (CATCH), we applied **latent class analysis** with baseline PROMIS-29 pain, fatigue, depression, anxiety, and sleep scores to select relevant symptoms and levels using AIC, BIC, G-square and log-likelihood results. Baseline PRO and clinical differences among clusters were compared. Next, we evaluated the stability of these clusters at 3 and 6 months. **Latent transition analysis** was used to estimate the probability of transitioning among classes.

Results: The sample included 310 adults with a new RA diagnosis, with 6-month PROs available, and who were MTX naïve at baseline. Participants had a mean age 56, CDAI 29.3, and symptoms for 5 months; 67% were women and 78% White. The optimal symptom set included pain, fatigue, depression, and anxiety (levels: none, mild, moderate, severe). We identified 4 clusters: **Minimal** (12%); **Moderate Pain Dominant** (40%); **Multiple Moderate-Severe** (35%); and **Multiple Mild** (11%). Clusters had similar sociodemographics except **Minimal** were slightly older and less female; SJC and TJC were similar among classes **Multiple Mild** or **Moderate-Severe** classes had significantly worse mood and sleep (Table 1). More patients in **Multiple Moderate-Severe** and **Moderate Pain** had parenteral steroids whereas numerically more in **Minimal** or **Multiple Mild** groups were on oral steroids. RA Participant Characteristics around diagnosis by symptom clusters.

Table 1.

Baseline Values (mean SD, N %)	Minimal N=38 (12%)	Moderate Pain N=124 (40%)	Multiple Moderate-Severe N=114 (37%)	Multiple Mild N=34 (11%)	SIG
Patient Global (0-10)	2.6 (2.4)	4.8 (2.3)	6.9 (2.0)	3.9 (2.2)	<0.0001
PROMIS-29					
Anxiety > 55	1 (3%)	15 (12%)	108 (95%)	28 (82%)	<0.0001
Depression > 55	0 (0%)	14 (11%)	100 (88%)	22 (65%)	<0.0001
Fatigue > 55	3 (8%)	49 (40%)	106 (93%)	12 (35%)	<0.0001
Pain Interference > 55	0 (0%)	124 (100%)	113 (99%)	25 (74%)	<0.0001
Physical Function < 45	9 (24%)	107 (86%)	111 (97%)	25 (74%)	<0.0001
Participation < 45	5 (13%)	81 (65%)	108 (95%)	17 (50%)	<0.0001
Sleep > 55	2 (5%)	46 (37%)	88 (77%)	17 (50%)	<0.0001
Physical Function (0-10)	2.9 (2.3)	6.1 (2.4)	7.7 (1.9)	4.2 (2.7)	<0.0001
Stiffness (0-10)	3.2 (2.4)	6.3 (2.4)	7.7 (1.8)	4.3 (2.3)	<0.0001
Oral steroids	16 (42%)	40 (32%)	29 (25%)	14 (41%)	0.1470
Parenteral steroids	**8 (21%)**	**44 (35%)**	**62 (54%)**	**7 (21%)**	**<0.0001**
TJC-28, median (IQR)	8 (6,12)	9 (5,13)	9 (5,13)	7 (5,12)	0.4626
SJC-28, median (IQR)	7 (5,12)	8 (4,12)	7 (4,12)	6 (3,11)	0.4396
CDAI, mean (SD)	**25.5 (11.4)**	**29.2 (12.7)**	**32.0 (14.0)**	**24.8 (12.6)**	**0.0103**

Substantial improvement was evident in 67% at 3 months (42% **Minimal,** 25% **Multiple Mild;** Figure 1). At 6 months, 45% were **Minimal** and 25% **Multiple Mild**. The best prognosis was for **Minimal**; almost all stayed **Minimal** at 3 (95%) and 6 (87%) months. Next best was **Moderate Pain** where 71% improved (**Minimal** 64%; **Multiple Mild** 7%). A poorer prognosis was seen for **Multiple Moderate-Severe**: at 3 months, 61% improved (13% **Minimal**, 33% **Multiple Mild**). **Multiple Mild** also were less likely to improve with 11% **Minimal** and 6% worsening by 3 months.

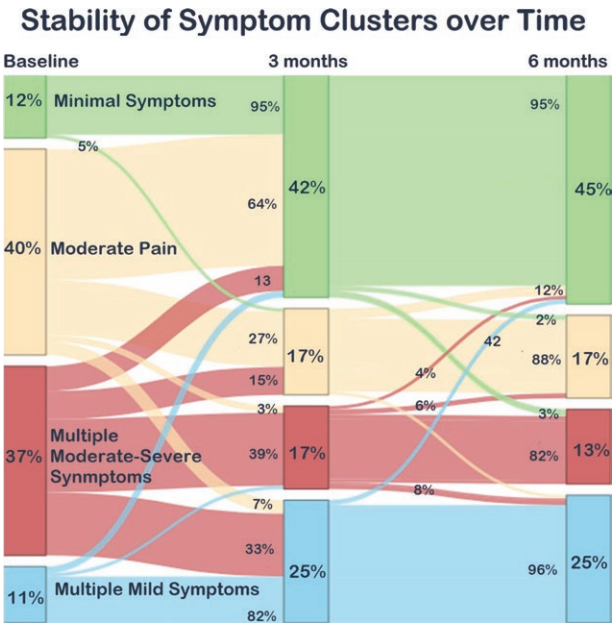

Figure 1.

Conclusion: In this large early RA cohort, we identified 4 distinct symptom clusters around diagnosis that were stable over 6 months and had distinct PRO profiles. At baseline, most (70%) participants were classified as **Moderate Pain Dominant** or **Multiple Moderate Symptoms**; the remainder had **minimal or multiple mild symptoms**. By examining symptom clusters, we found more homogeneous groups of patients. Our results also suggested that having multiple symptoms around diagnosis was associated with less improvement over the first 6 months, and may signal a more guarded prognosis for symptom improvement and HRQL in early RA.

POS0472

TREATMENT RESPONSE TO INTRAMUSCULAR STEROIDS IN PATIENTS LIVING WITH RHEUMATOID ARTHRITIS: AN EXPLORATORY ANALYSIS USING TRACKED DAILY SYMPTOMS

Keywords: Telemedicine, Patient reported outcomes, Epidemiology

M. Al-Attar[1], J. Gandrup[2], S. Van der Veer[3], W. Dixon[1,2]. *[1]Salford Care Organisation, Rheumatology Department, Salford Royal Hospital, Manchester, United Kingdom; [2]University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; [3]University of Manchester, Centre for Health Informatics, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom*

Background: Current understanding of treatment response is largely based on patient recollection at infrequent clinic appointments, which introduces inaccuracies through recall error. Real-time patient-reported symptom data collected frequently following an intervention could improve our understanding of treatment response, facilitating better clinical decision making.

Objectives: Our exploratory analysis reports a case-series of patients who used the Remote Monitoring of Rheumatoid Arthritis (REMORA) smartphone-app for daily symptom tracking, evaluating their longitudinal pain-scores following intramuscular (IM) steroids to determine the duration and extent of treatment response.

Methods: We identified patients participating in the REMORA study Nov 2021-Sep 2022 who received an IM steroid. Concomitant disease-modifying medications were noted. Daily pain scores (out of 10) from 10 days preceding the injection and 8 weeks following were analysed. Analysis was based on the following definitions: [1] Pre-injection pain score: mean pain-score in the 10 days preceding injection; [2] Response (Y/N): ≥1 day of pain score <[1]; [3] Response start time: the day following injection; [4] End of response: first date following injection with pain score ≥[1]; [5] Response duration: number of days between [3] and [4]; [6] Average pain-score response: mean pain score during [5]; [7] Nadir pain score response: lowest pain score during [5]; [8] Average pain score improvement: difference between [1] and [6]; [9] Maximum pain score improvement: difference between [1] and [7].

Results: Thirty-two patients were identified for inclusion, of whom 6 received ≥1 steroid injections. In total 9 injections were given. Pre-injection pain scores ranged 3.33-9.29. Seven injections demonstrated response, 2 did not. Of the responders, duration ranged 1-54 days (median 9 days); average pain score improvement ranged 0.14-5.33 (median 3.33); maximum pain score improvement ranged 0.14-7.00 (median 4.33). Table 1 summarises our results. Figure 1 demonstrates the patterns of treatment response for each steroid injection.

Table 1. individual treatment response and demographic data

Injection number (patient number)	Age (years)	Sex (M/F)	Concomitant drugs during analysis period	IM steroid dose (mg)	Response (Y/N)	Response duration (days)	Pre-injection pain score	Average pain score response	Nadir pain score response	Average pain score improvement	Maximum pain score improvement
1 (1)	30	M	MTX	120	Y	9	7.33	4.00	3.00	3.33	4.33
2 (1)	30	M	MTX, SSZ	120	Y	10	8.00	2.67	1.00	5.33	7.00
3 (1)	30	M		180	Y	9	5.40	1.80	1.00	3.60	4.40
4 (2)	53	F	MTX, HCQ	120	Y	7	3.33	3.00	3.00	0.14	0.14
5 (3)	52	M	MTX	160	Y	1	5.75	4.00	4.00	1.67	1.67

					Range (Median)	1-54 (9)	3.33-9.29 (5.75)	1.80-4.00 (2.67)	1.00-4.00 (1)	0.14-5.33 (3.33)	0.14-7.00 (4.33)

MTX: Methotrexate; SSZ: Sulfasalazine; HCQ: Hydroxychloroquine

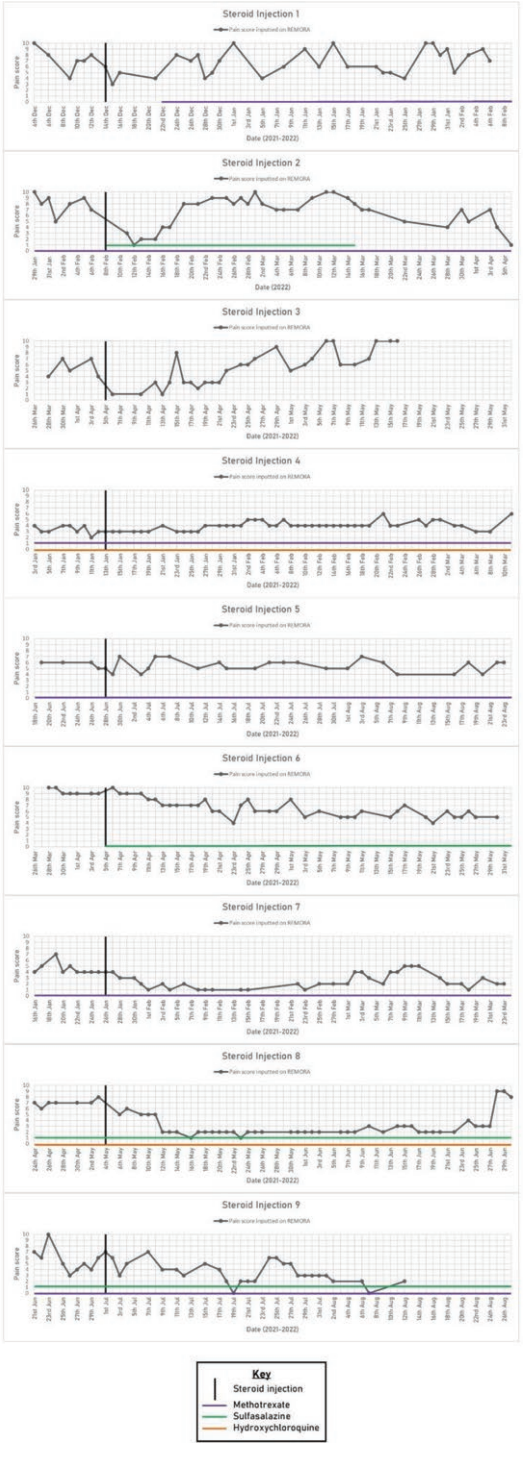

Figure 1. patterns of treatment response to IM steroids and concomitant therapies

Conclusion: Smartphone-based remote monitoring has the potential to improve clinical care for people living with rheumatoid arthritis. In this analysis, we demonstrated a novel means to accurately assess treatment response using tracked symptom data. The duration and extent of response to steroid injections was quantified for all participants, data which is typically imprecise and relies on recall. In these preliminary results, response duration was shorter, and pain score improvement was smaller, than anticipated. Analysis of tracked symptom data across a larger population may help to identify treatment responder characteristics, supporting more targeted therapeutic strategies. This has significant implications for high-cost drugs such as biologics. Further work is required to develop consensus definitions for treatment response and disease activity in time-series data, and a means to account for the effects of concomitant drugs.

Background: Rheumatoid Arthritis (RA) is a common inflammatory arthritis. Current ACR-EULAR classification criteria for RA include joint involvement, immunological markers {Rheumatoid factor (RF) and Anti-citrullinated protein antibody (ACPA)}, inflammatory markers {Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)}, and symptom duration. But these markers are not 100% accurate for RA. A meta-analysis found sensitivity and specificity of RF and ACPA to be 69% & 85% and 67% & 95% respectively [1]. There is a need for new biomarkers that can increase accuracy of RA diagnosis, one such marker is 14-3-3η protein which is a pro-inflammatory mediator and can serve as a diagnostic and prognostic marker and a potential therapeutic target in RA patients [2,3].

OBJECTIVES:

- Assess 14-3-3η protein levels in RA patients.
- Compare positivity rates of 14-3-3η to RF and ACPA.
- See association between 14-3-3η levels and disease activity.

Methods: 78 RA cases and 78 age & sex matched healthy controls were enrolled. Inclusion criteria were RA diagnosis (as per 2010 ACR/EULAR criteria), age above 18 years. Patients with any other disease & pregnant females were excluded. DAS28-ESR scoring was done. Blood was collected and tested for ESR, CRP, RF, ACPA, and 14-3-3η protein using ELISA.

Results: Mean age in years in cases and controls was 41.71 and 41.37 respectively. 88% participants were females. Median disease duration was 32.5 months, median tender joint count was 4.50 and median swollen joint count was 1. Mean ESR in cases & controls was 32.41 ± 18.8 mm and 10.79 ± 3.49 mm respectively ($p=0.001$). CRP was positive in 70.5% cases & 11.5% controls ($p < 0.001$), RF in 88.5% cases & 11.5% controls ($p < 0.001$) and ACPA in 73% cases & none of the controls ($p < 0.001$). Mean 14-3-3η protein levels (ng/ml) were 7.61 ± 2.55 in cases and 0.73 ± 0.43 in controls ($p < 0.001$); 7.64 ± 2.62 in seropositive cases and 7.18 ± 1.62 in seronegative cases ($p =0.673$). There was a significant difference between 14-3-3η protein levels in seronegative patients and controls ($p= 0.001$).14-3-3η protein levels had no correlation with RF/ACPA positivity ($p= 0.965$) (Figure 1). Mean 14-3-3η protein levels (ng/ml) in patients in "remission"

(as per DAS28-ESR) was 5.71± 2.50, while the levels(ng/ml) in patients in low, moderate, and high disease activity were 8.58 ± 4.04, 6.98 ± 1.00 and 8.36 ± 2.62 respectively (p= 0.020). The sensitivity and specificity of RF were 88.5% each, of 14-3-3η was 100% and 90.1% respectively and that of ACPA were 73.1% and 100% respectively. 14-3-3η protein had higher sensitivity than the other 2 biomarkers (p=0.001). ROC curve suggested the ideal cut-off of 14-3-3η protein to be 1.14 ng/ml with a sensitivity of 100% and a specificity of 90.1%. When RF and ACPA were combined, the sensitivity and specificity were 96.9% and 88.5% respectively. When 14-3-3η was combined with RF, sensitivity, and specificity was 100% and 79.7% respectively while it was 100% and 90.1% respectively when 14-3-3η was combined with ACPA. Thus, 14-3-3η protein increased the sensitivity of RF and ACPA.

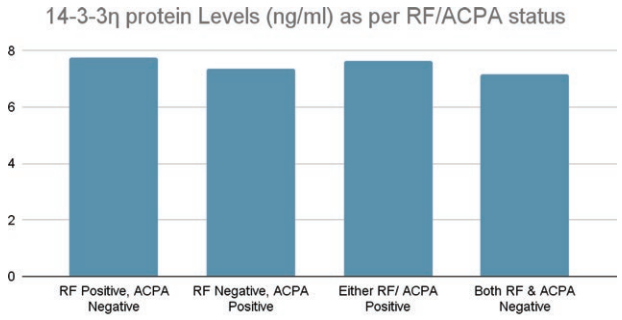

Figure 1

Conclusion: 14-3-3η protein levels are significantly raised in both seropositive and seronegative RA patients and it does not depend on RF or ACPA. 14-3-3η protein increases the sensitivity of RF and ACPA in RA diagnosis and should be included as an additional test in evaluation of RA patients.

FACTORS ASSOCIATED WITH EROSIVE RHEUMATOID ARTHRITIS, A MULTIMARKER PRINCIPAL COMPONENT ANALYSIS (PCA) AND PRINCIPAL COMPONENT REGRESSION (PCR) ANALYSIS

Keywords: Bone diseases, Rheumatoid arthritis, Biomarkers

G. Adami[1], G. Orsolini[1], A. Fassio[1], O. Viapiana[1], E. Sorio[1], C. Benini[1], D. Gatti[1], D. Bertelle[1], M. Rossini[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*

Background: Various clinical (disease activity, seropositive RA etc.) and metabolic risk factors (Dkk1 etc.) have been associated with erosive rheumatoid arthritis (RA). However, such risk factors might be intertwined, and multicollinearity might reduce our ability to discern the individual contribution to erosive score. Principal component analysis (PCA) is statistical technique for reducing dataset's dimension and principal component regression (PCR) is a regression analysis based on PCA. PCR overcomes the multicollinearity problem.

Objectives: To investigate the clinical and bone metabolic risk factors associated with erosive RA using PCA and PCR.

Methods: We conducted a cross-sectional analysis on seropositive RA patients not responding to first-level disease-modifying antirheumatic drug, candidate to bDMARD treatment. Clinical, radiographic (both hands and feet x-ray), laboratoristic and densitometric (BMD parameters were collected. Sharp van der Heijde Score (SvdHS) was calculated by two independent readers. Serum samples were collected and assayed for C-terminal telopeptide of type I collagen (CTX), Procollagen I Intact N-Terminal Peptide (P1NP), Dkk1, Sclerostin (SOST), 25-OH-Vitamin D (VitD), and PTH. PCA was applied to reduce dimensionality of the dataset and find clusters of variables recording largely redundant information. PCs were selected based on eigenvalues explaining >75% of total variance. PCR was used to predict the SvdHS. Results were analyzed using PCA package on GraphPad Prism version 9.5.0 for Windows, GraphPad Software, San Diego, California USA.

Results: 62 RA patients aged 57.2 years (SD 12.1) were consecutively enrolled. Mean DAS28-CRP was 4.17 (SD 1.27) and median SvdHS was 24 (IQR 12-53). The loadings plot (**Figure 1**) shows the clusters of correlated variables in the dataset (vectors). In **Table 1** are presented the results of the PCR with SvdHS as outcome. We found that age, GC treatment, ACPA titer, RF titer, CRP levels, ESR, CTX serum levels and Dkk1 serum levels were significantly positively correlated with SvdHS, whereas P1nP serum levels and PGA were negatively correlated with SvdHS.

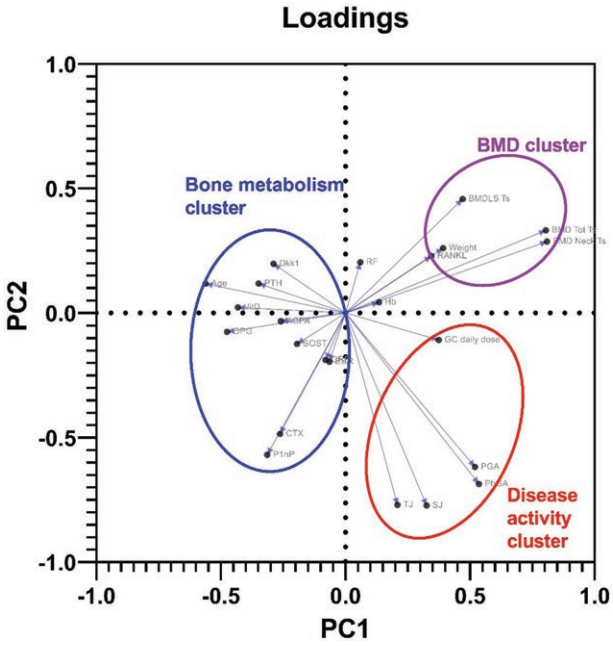

Figure 1. Loadings plot from PCA. When the vectors are close, forming a small angle, the two variables they represent are positively correlated. If they meet each other at 90°, they are not likely to be correlated. When they diverge and form a large angle (close to 180°), they are negative correlated.

Table 1. Results of the principal component regression (PCR) analysis

Variable	Estimate	Standard error	P value
Intercept	-13,85	26,92	0,61
Age	**0,54**	**0,18**	**0,006**

POS0475 FACTORS INFLUENCING ACCEPTANCE AND PERSISTENCE OF ELECTRONIC PATIENT-REPORTED OUTCOMES COLLECTION IN A REAL-WORLD CLINICAL SETTING

Keywords: Patient reported outcomes, Rheumatoid arthritis, Health Services Research

I. Biliavska[1,2], E. Lenguerrand[3], J. Tobias[1,3,4], P. Hamann[3,4]. [1]*University of Bristol, MRC Integrative Epidemiology Unit, Population Health Sciences, Bristol Medical School, Bristol, United Kingdom;* [2]*SI NSC "Institute of Cardiology named after acad. M.D.Strazhesko" NAMS of Ukraine, Department of Non-coronary Heart Disease, Rheumatology and Therapy, Kyiv, Ukraine;* [3]*University of Bristol, Musculoskeletal Research Unit, Translational Health Sciences, Bristol Medical School, Bristol, United Kingdom;* [4]*North Bristol NHS Trust, Bristol, Rheumatology, Bristol, United Kingdom*

Background: Rheumatoid arthritis (RA) has a relapsing-remitting nature, making it difficult to predict when patients should be seen. Collection of patient-reported outcomes (PROs) effectively communicates patients' disease experiences. However, certain factors could impact the utilization and persistence of PROs collection.

Objectives: To explore the impact of demographic, clinical parameters on acceptance and long-term utilization of smartphone application (app) for electronic PROs (ePROs) collection.

Methods: A retrospective analysis of anonymized data collected through app as part of routine care delivered in outpatient clinic at North Bristol NHS Trust. Patients agreed to use a smartphone-based diary (LivingWith) to record disease activity between appointments by reporting weekly RAPID3, HAQ every 28 days. 28 tender/swollen joint count (JC) could also be assessed. Patients with ≥1 record were analyzed, including all reports until last follow-up. Disease activity and disability categories were defined on baseline RAPID3, HAQ scores [1,2]. Mean and SD or median and IQR were reported. T-test, Mann–Whitney U, Kruskal–Wallis tests were used. Kaplan-Meier analysis was produced. Statistical tests were performed using Stata 16.1 (StataCorp, USA) and RStudio V.1.4.1717.

Results: 306 (81.4%) patients had completed both questionnaires, 16.2% just RAPID3, and 2.4% only HAQ. 74% of participants were women with mean age 56±14. 27(6.7%) of patients didn't provide either RAPID or HAQ and assessed only 28 JC. The median number of completed records for RAPID3 and HAQ was 10 [4;31] and 4 [2;10] respectively. The median number of days following registration when the first ePRO was completed was 9 [0;17] for RAPID3 and 4 [0; 32.5] for HAQ. The median time between ePRO completion was 13 days [8;29] for RAPID3 and 29 days [3; 483] for HAQ. The median RAPID3 score was 10.5 [5.6;15.9] and HAQ score 1.02 [0.5;1.625]. The median period [CI] for patients' app engagement for RAPID3 was 67 weeks [55;83], for HAQ 48 weeks [36;60] (Figure 1). Demographic parameters at the registration as well as baseline disease activity and disability categories had no clear relationship with patient engagement in app use (Table 1).

Table 1. The impact of demographic and clinical factors on the persistence of ePROs collection.

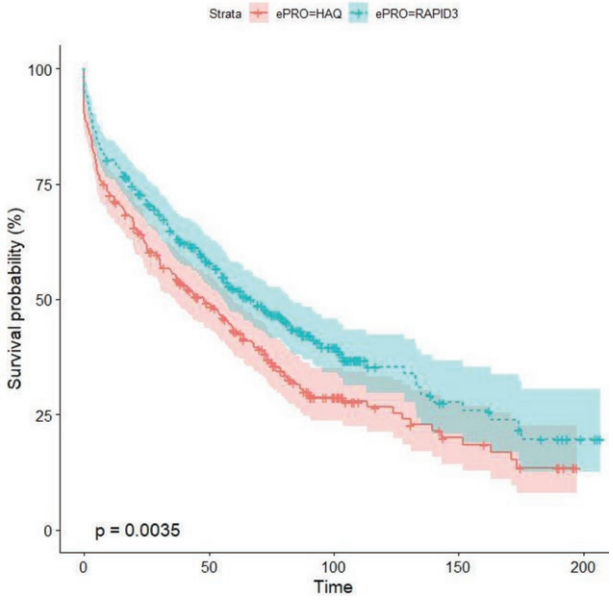

Figure 1. Patient engagement in the app.* Time in weeks

Conclusion: PROs collection provides valuable information on effectiveness and tolerability of health interventions. Patients' engagement in reporting decreases over time, suggesting the importance of reinforcement. Neither age, gender nor baseline clinical status appeared to be related to patient reporting persistence.

POS0476 QUANTIFICATION OF REFERRAL BIAS IN PATIENT- AND CLINICIAN-REPORTED MEASURES OF RHEUMATOID ARTHRITIS SEVERITY BY GEOGRAPHIC DISTANCE FROM AN ACADEMIC RHEUMATOLOGY CENTER

Keywords: Geographical differences, Patient reported outcomes, Rheumatoid arthritis

J. M. Davis III[1], S. Achenbach[2], C. Arment[1], D. Bekele[1], V. Kronzer[1], T. Mason[1], E. Myasoedova[1], L. Peterson[1], K. Wright[1], C. S. Crowson[2]. [1]*Mayo Clinic, Rheumatology, Rochester, United States of America;* [2]*Mayo Clinic, Quantitative Health Sciences, Rochester, United States of America*

Background: Systematic bias to greater severity of rheumatoid arthritis (RA) is often presumed to exist in patients referred for evaluation at academic centers. However, the magnitude of this potential bias has not been quantified to our knowledge.

Objectives: The objective was to test the hypothesis that patients in a referral population have greater RA severity based on both patient- and clinician-reported measures than local patients.

Methods: This study included eligible patients with RA who attended an in-person or virtual appointment in the outpatient rheumatology clinic at an academic center between 1/1/2020 and 10/28/2021. RA was defined by at least 2 ICD-10 diagnosis codes ≥30 days but <2 years apart plus use of a qualifying RA medication. Referral population was ascertained by geographic distance from patient residence to the clinic building and categorized as local, <50 miles; regional, ≥50 to <150 miles; or national/international, ≥150 miles. Data were collected from the electronic health records for patient-reported and clinician-reported measures of disease severity. Patient-reported measures included global pain, global arthritis, and Patient-Reported Outcomes Information System (PROMIS)

computer adaptive tests for Pain Interference, Fatigue, Physical Function, and Ability to Participate in Social Roles and Activities. Chi-square or Kruskal-Wallis tests were used to analyze differences between groups, adjusting for age at the clinic visit and sex. Linear regression models were used to test for differences between groups in PROMIS measures and Clinical Disease Activity Index (CDAI), adjusting for age, sex, race/ethnicity, and appointment type (new vs. established).

Results: The study population included 3220 patients with RA, including 1631 local, 956 regional, and 633 national/international patients. Overall, mean (SD) age was 62.9 (13.7) yrs., 2312 (72%) were female, and 2947 (91.5%) were in-person visits. Proportions of new patients in the local, regional, and national/international populations were 5%, 9%, and 17%, respectively. All PROMIS measures were available within 7 days of appointment for 2677 (83%) patients, with no differences between groups (p = 0.394). Regional and national/international patients had significantly higher global pain, pain interference, and fatigue and significantly lower physical function and ability to participate than local patients. Regression analysis showed that regional and national/international patients had higher pain interference (on average: 1.3 and 1.6 units; p<0.001 and p<0.001, respectively) and worse physical function (on average: -1.0 and -2.2 units; p=0.008 and p<0.001, respectively) than local referent patients, adjusting for age, sex, race/ethnicity, and appointment type. In contrast, there were no significant differences between groups in CDAI (on average for regional and national/international: 0.3 and 1.1 units; p=0.73 and p=0.29, respectively).

Variable	Local (n = 1631)	Regional (n = 956)	National/ International (n = 633)	Total (n = 3220)	p
Global pain score (0-100)	35.9 (29.2)	39.5 (29.0)	41.8 (30.6)	38.2 (29.5)	0.002
PROMIS T-scores					
Pain Interference	57.0 (8.3)	58.4 (8.3)	58.8 (8.4)	57.8 (8.4)	<0.001
Fatigue	53.5 (9.6)	54.9 (9.8)	56.2 (10.1)	54.4 (9.8)	<0.001
Physical Function	42.4 (8.8)	41.2 (8.2)	40.0 (8.6)	41.6 (8.6)	<0.001
Ability to Participate	50.3 (9.1)	48.5 (9.4)	47.4 (9.2)	49.2 (9.3)	<0.001
Clinical Disease Activity Index	12.2 (11.7)	12.2 (10.7)	13.4 (12.1)	12.4 (11.5)	0.44
C-reactive protein, mg/L	7.8 (11.5)	7.2 (10.9)	7.9 (11.7)	7.6 (11.4)	0.99

Values are mean (SD) or number (%).

Conclusion: Referral bias by geographic distance from the outpatient rheumatology clinic is more evident in patient-reported than clinician-reported measures of RA severity. The findings inform the interpretation of RA disease severity measures in clinical practice and research and highlight the importance of patient-reported outcome measures.

RELATIONSHIP BETWEEN SHARED EPITOPE STATUS AND REFRACTORY RHEUMATOID ARTHRITIS

Keywords: Registries, Biomarkers, Rheumatoid arthritis

K. Wipfler[1], S. Pedro[1], U. Sbarigia[2], F. Zazzetti[3], A. Sheahan[4], I. Lin[5], E. Alemao[6], K. Michaud[1]. *[1]FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, United States of America; [2]Janssen, Pharmaceutica NV, Beerse, Belgium; [3]Janssen, Pharmaceutical Companies of Johnson & Johnson, Horsham, PA, United States of America; [4]Janssen, Global Research and Development Epidemiology, Titusville, NJ, United States of America; [5]Janssen, Scientific Affairs, Horsham, PA, United States of America; [6]Janssen, Global Services, Horsham, PA, United States of America*

Background: Despite major advances in rheumatoid arthritis (RA) treatment and the improved outcomes that have been associated with the expanding number of advanced therapies available, a substantial number of patients are refractory to multiple biologics. To understand the mechanisms behind refractory RA (reRA) and ultimately improve therapies tailored to individuals, a better understanding of associated factors is necessary. The shared epitope (SE) is an amino acid sequence motif coded by several HLA-DRB1 alleles that are overrepresented among people with RA and is associated with the production of anti-citrullinated protein antibodies.

Objectives: To characterize the relationship between SE status and risk of developing refractory RA.

Methods: Participants in FORWARD, The National Databank for Rheumatic Diseases, with RA, high-resolution HLA-DRB1 typing, no history of biologic use at study entry, and subsequent exposure to one or more biologics were included. The reRA group included participants with exposure to at least three biologics while under observation. Those who used a single biologic with continued use for at least two years during observation comprised the comparison non-refractory group. Descriptive statistics for each group were calculated at initiation of first biologic. Significance was assessed with Fisher's exact tests and Mann-Whitney U tests (p<0.05), as appropriate. Logistic regression was used to determine the relationship between shared epitope status and baseline odds of becoming refractory.

Results: Characteristics of the 70 participants that met inclusion criteria are presented in Table 1. Several covariates varied significantly by refractory group, but these differences were attenuated in adjusted models. SE positive individuals had significantly lower odds of becoming refractory, a relationship that remained consistent with varying model complexity (Figure 1; OR [95% CI] 0.16 [0.05, 0.49] in univariate model; p=0.001). HLA-DRB1*04:01 was the only SE positive allele independently associated with nonrefractory status (p=0.036; data for other alleles not shown).

Conclusion: In this cohort, individuals with RA who are SE positive were less likely to be refractory to multiple biologics. This relationship appears to be primarily the result of the HLA-DRB1*04:01 allele rather than any other alleles associated with SE positivity. These findings suggest that SE positive individuals with RA are more likely to find success with their first biologic, while SE negative individuals may be more likely to cycle through multiple biologics. Ongoing and future work will investigate this relationship further and assess whether these results remain consistent when using varying definitions of reRA.

FACTORS ASSOCIATED WITH PERSISTENTLY HIGH HAQ-DI SCORE IN RA PATIENTS UNDER B/TSDMARDS: LONGITUDINAL ANALYSIS OF HURBIO SINGLE CENTER REGISTRY

Keywords: Rheumatoid arthritis, bDMARD, Outcome measures

E. Bilgin[1], E. Öztürk[2], B. Fırlatan[1], M. Ekici[1], G. S. Kart Bayram[1], E. Unaldi[1], G. Ayan[1], G. Sandal Uzun[1], Z. Özsoy[1], S. A. Germe[1], B. Farisogullari[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], A. İ. Ertenli[1], P. Özdemir[2], U. Kalyoncu[1], S. Kiraz[1]. *[1]Hacettepe University, Rheumatology, Ankara, Turkey; [2]Hacettepe University, Biostatistics, Ankara, Turkey*

Background: Health Assessment Questionnaire-Disability Index (HAQ-DI) is a widely-used and accepted instrument for the functional assessment of rheumatoid arthritis (RA) patients.
Objectives: Our aim was to determine the related factors with persistently high HAQ-DI scores in RA patients using b/tsDMARDS.
Methods: RA patients prescribed with b/tsDMARds, registered to Hacettepe University Biologic Registry (HURBIO), had HAQ-DI score ≥1 at baseline assessment and had at least five follow-up visits, were grouped into 3, hypothetically, according to HAQ-DI scores at each of the first five follow-up visit. Group 1 was "persistently-low HAQ-DI score <1" and had HAQ-DI score lower than one at each visit; group 2 was ''floating HAQ around 1" who had at least one visit HAQ-DI score above one and HAQ-DI score below 1; group 3 was "persistently-high HAQ-DI score <1" who had HAQ-DI score higher than one at each visit. Baseline demographic, disease, and treatment characteristics were recorded. Multinomial logistic regression for females and multiple logistic regression for males (as group 3 had no males) was done to reveal associated factors.
Results: A total of 194 patients (89.7% female) were included. Groups 1,2, and 3 consisted of 58 (29.9%), 111 (57.2%), and 25 (12.9%) patients. All patients in group 3 were female. RA disease duration, the time between RA diagnosis and b/tsDMARD initiation, RF negativity, and baseline HAQ-DI score were higher in group 3 compared to other groups (**Table 1**). Multinomial logistic regression revealed several associated factors (OR, 95%CI) for females;

- group 2 over group 1: **being obese (3.0 (1.4-6.4), p=0.004),** negative RF (0.5 (0.2-1.2), p=0.13), using non-anti-TNF (2.1 (0.9-4.8), p=0.07), diagnosis-treatment initiation duration (per 1 year) (1.0 (0.9-1.1), p=0.85)
- group 3 over group 1: being obese (0.9 (0.3-3.0), p=0.88), **negative RF (5.2 (1.4-18.6), p=0.012)**, **using non-anti-TNF (9.5 (1.8-52.6), p=0.009), diagnosis-treatment initiation duration (per 1 year) (1.1 (1.05-1.112), p=0.001)**
- This model classified 61% of the patients correctly.

There was no significant associated factor for males.

Table. Baseline demographic and disease-related characteristics of RA patients (HAQ-DI≥1) prescribed b/tsDMARD (n=194)

	Persistently-low HAQ (<1) (n=58, 29.9%)	Floating HAQ around 1 (n=111,57.2%)	Persistently-high HAQ (≥1) (n=25, 12.9%)	p

- Sequential anti-TNF/non-anti-TNF (or vice versa)	12 (20.7)	43 (38.7)	9 (36.0)	0.06

BMI: Body mass index, CCP: Cyclic citrullinated peptide, DAS28: Disease activity score, HAQ-DI: Health assessment questionnaire disability index, RA: Rheumatoid arthritis, RF: Rheumatoid factor, SD: Standard deviation, SCJ: Swollen joint count, TNF: Tissue necrosis factor, TJC: Tender joint count, VAS: Visual analog scale

Conclusion: RA patients are still away from good functional status. According to the results of this study, clinicians should treat RA earlier and increase the sensitivity of management dynamics in RF-negative and obese patients. Whether anti-TNFs or non-anti-TNFs work better on functionality should be interpreted cautiously, even if it remained statistically significant in the multivariable model.

POS0479

THE PROGNOSTIC INFLAMMATORY AND NUTRITIONAL INDEX (PINI) IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Diet and nutrition, Prognostic factors

M. Ardhaoui[1], J. Mahbouba[1,1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. *[1]Fattouma Bourguiba Hospital, Rheumatology, Monastir, Tunisia*

Background: Malnutrition and inflammation are closely related in rheumatoid arthritis (RA). The Prognostic Inflammatory and Nutritional Index (PINI) is a tool assessing the risk of malnutrition-related complications. It combines the determination of two inflammatory and two nutritional proteins.
Objectives: The aim of our study was to calculate the PINI in elderly patients with RA and to determine its relationship with the disease parameters.
Methods: This is a cross-sectional study including patients aged 65 years or older and followed for RA. Disease activity was assessed using the DAS28 score. Functional impact was measured using the HAQ score. Nutritional status was assessed using the Mini-Nutritional Assessment (MNA). The PINI was calculated as follows: Orosomucoid (g/L) × CRP (mg/L)/ albumin (g/L) × prealbumin (mg/L).
Results: Forty patients were enrolled. There were 33 women (82.5%) and 7 men (17.5%). The mean age was 68.37±4.70 years [65-82]. The median duration of disease progression was 11 years with an IQR of [2.45-16.5]. The mean DAS28 was 3.57±1.32 [1.5-6.8]. The mean HAQ score was 1.5±0.53 [0.37-2.6]. The mean MNA score was 20.25±4.5 [8-27.5]. According to the MNA, 22 patients (55%) were at risk of developing undernutrition and 10 patients (25%) were malnourished. The median PINI was 1.77 with an IQR of [0.47-10.21] and extremes ranging from 0.05 to 222.16. Patients were stratified according to PINI score as follows: 13 patients (32.5%) had a normal PINI of less than 1, while 27 patients (67.5%) had a PINI ≥ 1, indicating a risk of undernutrition-related complications. Of these patients with PINI ≥ 1: 18 patients (45%) had a low risk (PINI between 1 and 10), 4 patients (10%) had a moderate risk (PINI between 10 and 20), 2 patients (5%) had a high risk (PINI between 21 and 30) and 3 patients (7.5%) had a life-threatening risk (PINI > 30). Comparison between RA patients with PINI ≥ 1 and PINI < 1 showed a statistically significant difference for acute phase proteins (CRP (p=0.018), haptoglobin (p=0.04)). DAS28 score was significantly higher in the PINI ≥ 1 group (p=0.009), as well as the HAQ score (p=0.004). However, no significant differences were observed concerning the age (p=0.07), gender (p=0.3), duration of the disease (p=0.12), ESR (p=0.7) or MNA (p=0.2).
Conclusion: In our study, 67.5% of the patients were at risk of undernutrition-related complications as assessed by the PINI. This tool seems to be interesting for predicting disease activity, functional impairment and inflammation in RA elderly patients.

ULTRASOUND SYNOVITIS AND NEUTROPHILIC ACTIVITY MARKERS (PLASMA CALPROTECTIN AND NEUTROPHIL EXTRACELLULAR TRAPS) IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING BIOLOGICAL OR JAK INHIBITORS

Keywords: Rheumatoid arthritis, Biomarkers, Ultrasound

A. Ponce Fernandez[1], B. Frade-Sosa2, J. Ramírez2, S. M. Farietta Varela2, E. Ruiz-Ortiz[3], O. Viñas[3], J. Yagüe[4], J. M. Auge[4], A. Azuaga2, J. C. Sarmiento-Monroy2, R. Morlà2, V. Ruiz2, P. Corzo Garcia2, N. Sapena2, Y. Romero[1], J. D. D. Cañete2, J. A. Gómez-Puerta2, R. Sanmartí2. *[1]Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain; [1]Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain; [3]Hospital Clínic de Barcelona, Centre de Diagnòstic Biomèdic. Immunology., Barcelona, Spain; [4]Hospital Clinic, Biochemistry and Molecular Genetics, Barcelona, Spain*

Background: Studies have shown an association between active synovitis measured by ultrasound (US) with plasma calprotectin in rheumatoid arthritis (RA) patients [1]. Neutrophil extracellular traps (NETs) may play a pathogenetic role in RA [2]. Elevated plasma NETs have been observed in RA patients, although their association with disease activity is unclear. No studies have analyzed the association between NETs remnants and US synovitis in RA

Objectives: To analyse whether plasma calprotectin and NETs remnants are associated with synovial inflammation measured by US in patients with established RA treated with biological therapies or JAK inhibitors (JAKi).

Methods: Observational cross-sectional study. RA patients (ACR/EULAR 2010) receiving treatment with biologic DMARDs (IL6 inhibitors (IL6i), TNF inhibitors (antiTNF), rituximab (RTX)) or JAKi) were consecutively included regardless of disease activity and previous therapy. Clinical disease activity indexes and laboratory parameters of inflammation were evaluated. Plasma calprotectin was analysed. Plasma levels of elastase-DNA (EN-DNA) and histone-DNA complex (H_3-DNA) (NETs remnants) were examined using a home-made ELISA test. Joint US of both hands was evaluated and graded according to Szudlarek's score. The synovial hypertrophy (SH), power Doppler (PD) and the total score (SH+PD) was calculated. US active synovitis as previously defined (3) was calculated (SH ≥ 2 + PD ≥1). A correlation study between neutrophilic markers and US scores was made.

Results: 101 RA patients (91% female, 86% seropositive (RF and/or ACPA) were included. Mean age was 55.4 ±12.1 yrs and the mean RA duration was 15.4 ±9.5 yrs. 78 received treatment with biologics (45 IL6i, 30 antiTNF and 3 RTX) and 23 JAKi. Mean DAS28, CDAI and SDAI were 3.19, 12 and 13 respectively. Low disease activity or remission (CDA<10) were found in 56 patients (54.5%). Mean total US score was 12.7 ±13.7 and US active synovitis was found in 69 patients (69.8%). Means levels of plasma calprotectin were 0.98 µg/ml ±1.4 and plasma NETs remnants were 1.1 ±0.4 (EN-DNA) and 0.9 ±0.08(H3-DNA) [Table 1]. Plasma NETs remnants were not correlated with any US scores. Calprotectin correlated moderately with US scores (ρ between 0.54 and 0.60, p<0.001). There was no correlation between both NETs remnants and calprotectin levels. Mean calprotectin levels were significantly higher in patients with US active synovitis (1.28 vs 0.35 µg/ml, p<0.001) but NETs remnants were not (data not shown). The lack of correlation between NETs and US scores was observed in all therapeutic groups.

Table 1. Clinical and laboratory characteristics

	IL6i n 45	JAKi n 23	AntiTNF n 30	RTX n 3	Total n101

POS0481 BONE EDEMA IN MRI IS MORE ASSOCIATED WITH RAPID RADIOGRAPHIC PROGRESSION THAN CLINICALLY RELEVANT RADIOGRAPHIC PROGRESSION.

Keywords: Imaging, Rheumatoid arthritis

K. Katayama[1], T. Okubo[2], T. Sato[1], T. Kawahata[3], K. Tanaka[3], M. Yuichi[4], S. Abe[5], H. Ito[5]. *[1]Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan; [2]Katayama Orthopedic Rheumatology Clinic, Radiology, Asahikawa, Japan; [3]Asahikawa Medical University, Division of Metabolism and Biosystemic Science, Gastroenterology, Hematology/Oncology, Department of Medicine, Asahikawa, Japan; [4]Asahikawa Medical University, 3Department of Medicine, Division of Rheumatology, Asahikawa, Japan; [5]Asahikawa Medical University, Department of Orthopedic Surgery, Asahikawa, Japan*

Background: Rapid radiographic progression (RRP) is selected as one of the risk factors for difficult- to- treat RA, which needs to be resolved as soon as possible. Logistic progression models for RRP have been reported for a long time. Vanier et al. recently reported a newly logistic model which is constituted by high CRP levels (>30mg/L), the number of swollen joints, RF positivity, and the existence of bone erosion by pooling individual data from 2 cohorts and 3 clinical trials. On the other hand, EULAR recommendations for imaging were published, in which MRI bone oedema was an independent and strong predictor for joint destruction. We previously reported that extensive bone marrow edema (BE) determined by hand MRI is a prognostic indicator for rapid radiographic progression in MTX inadequate response to early RA treated with MTX+ Adalimumab combination therapy [1].

Objectives: To clarify, association of BE with RRP using the clinical data in RA patients treated with conventional synthetic(cs) DMARDs.

Methods: At first, baseline data of 108 non-RRP patients and 47 clinically relevant radiographic progression (CRRP) +RRP patients were statistically compared. Secondly, background data of 13 CRRP and 34 RRP patients were compared. MRI of affected joints (mostly hands) were taken and patents were divided into two groups by existence or non-existence of BE.

Results: As shown in Table 1A, short duration, high BE rate, high DAS28-ESR (baseline), high CRP levels, high mTSS, high yearly progression of mTSS were observed in RRP +CRRP group compared with non-RRP. Table 1B showed that only the rate of BE is higher in RRP group compared with CRRP group.

Conclusion: BE may be a possible prognostic factor for RRP and more associated with RRP than CRRP.

PATIENT CENTERED- TREAT TO TARGET- DISEASE SPECIFIC GUIDELINES: EXPANDING THE PERTINENCE OF CLINICAL PRACTICE GUIDELINES TO PATIENTS

Keywords: Treat to target, Rheumatoid arthritis, Outcome measures

Y. El Miedany[1], M. H. Abu-Zaid[2], S. A. Mahran[3], M. Elgaafary[4], M. Elwy[5], W. Hassan[6], S. Saber[5], S. A. A. Tabra[2], W. Elwakil[7]. *[1]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom; [2]Faculty Of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; [3]Faculty of Medicine - Assiut University, Rheumatology and Rehabilitation, Assiut, Egypt; [4]Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt; [5]Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt; [6]Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Benha, Egypt; [7]Faculty of Medicine Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt*

Background: Although all patients present unique biopsychosocial contexts, the care of inflammatory arthritis patients is particularly complicated by the interaction of multiple factors. Advocates of patient- centered care identify that the best way to manage complex patients is through comprehensive treatment strategies that can adapt to the nuances of individual contexts. Recently published disease specific, patient centered national clinical guidelines for inflammatory arthritis [1] represent a model of care that can be fit for standard, disease-oriented patients' management.
Objectives: To assess for the outcomes of indiscriminately implementing individual, disease-specific treatment strategies in standard clinical practice for the treatment of inflammatory arthritis and its impact on the disease activity measures as well as patient reported outcomes.
Methods: A 12-month multicenter, randomized study compared standard care with patient-centered, Treat to Target (T2T) management of inflammatory arthritis. All patients completed patient reported outcome measures [2]. Regular appointments were delivered by specially trained rheumatologists who kept a record of the clinical assessments, medication titration, patient reported outcomes, self-management, psychosocial support and motivation score. The primary outcome was 12-month remission assessed using the Disease Activity Score for 28 joints using ESR (DAS28-ESR). Secondary outcomes included fatigue, functional disability, quality of life and motivation levels.
Results: 297 rheumatoid arthritis patients were screened and randomized (149 Treat to Target management; 148 standard care); 269 (90.6%) patients had their 12-month outcomes completed. Patient centered treat to target management increased DAS28-ESR 12-month remissions compared to standard care (43% vs 22%, p = 0.004). Patient centered T2T management also significantly increased prevalence of those who achieved DAS28-ESR low disease activity scores. (38% vs 23%, p = 0.005). In addition, it substantially improved patients' functional ability (0.4 + 0.2 Vs 1.1 + 0.3, p< 0.01), quality of life (0.6 + 0.2 Vs 1.2 + 0.5, p< 0.01), reduced fatigue (4.2 + 1.3 Vs 6.8 + 1.6, p< 0.01). Motivation score was higher in the T2T cohort (8.4 + 1.3 Vs 5.7 + 2.1, p< 0.05). There was no evidence that serious adverse events (patient centered T2T management =14 vs standard care =12) or other adverse events (112 vs 106) differed in both groups.
Conclusion: More patients achieve the treatment target of remissions or low disease activity status. There were greater improvements in patient reported outcomes, functional ability, fatigue as well as motivation. In the meantime, there were no more harms. Patient centered T2T clinical guidelines are able to provide condition-specific guidance on how one would optimally manage a disease tailored to the individual patient's requirements.

PATIENT-PHYSICIAN DISCORDANCE IN DISEASE ACTIVITY ASSESSMENT IS ASSOCIATED WITH LESS CONSISTENT TREAT-TO-TARGET IMPLEMENTATION, IMPAIRING REMISSION OUTCOMES IN EARLY RA: A POST-HOC MEDIATION ANALYSIS OF THE CARERA TRIAL

Keywords: Rheumatoid arthritis, Patient reported outcomes, Treat to target

M. Doumen[1,2], V. Stouten[1], S. Pazmino[1], E. De Meyst[1,2], D. C. Diederik[3], D. Bertrand[1], J. Joly[2], R. Westhovens[1,2], P. Verschueren[1,2]. *[1]KU Leuven, Department of Development and Regeneration, Skeletal Biology and Engineering Research Center, Leuven, Belgium; [2]University Hospitals Leuven, Rheumatology, Leuven, Belgium; [3]Vrije Universiteit Brussel, Department of Public Health, Biostatistics and Medical Informatics Research Group, Brussels, Belgium*

Background: A treat-to-target (T2T) approach improves outcomes of rheumatoid arthritis (RA). However, T2T is applied in only two-thirds of real-world visits, while patient satisfaction, engagement and treatment success improve when patients and rheumatologists agree over T2T goals [1]. Consequently, discordance between patients' and rheumatologists' views on disease activity might hamper T2T implementation, impairing outcomes.
Objectives: To assess if patient-physician discordance in disease activity assessment affects the likelihood of T2T being applied, and how this influences remission.
Methods: This was a post-hoc analysis of the 2-year pragmatic randomized trial Care in early RA (CareRA), which compared several DMARD regimens with/without bridging glucocorticoids, in treatment-naïve patients with early RA. The trial was guided by T2T: during the first year, the protocol mandated specific DMARD adaptations in case of DAS28-CRP >3.2, with documentation of reasons for non-adherence. From week 52 onwards, treatment was at the rheumatologists' discretion. For each patient, we quantified T2T implementation as the proportion of study visits where DMARD treatment was adapted when DAS28-CRP was >3.2. Patient-physician discordance was defined by the discordance score (DS)[2], a weighted difference between patient-reported and clinical/laboratory outcomes, ranging from -1 to 1 with values >0 implying relatively more patient-perceived disease impact. First, we examined the longitudinal association between the DS and T2T implementation with a generalized linear mixed model (GLMM) adjusted for age, sex, autoantibodies, treatment, Rheumatic Disease Comorbidity Index and number of previous DMARDs. Additionally, we studied the association between time-varying DS, T2T implementation and the odds of remission (SDAI ≤3.3) at year 2, using a multilevel mediation model clustered within individual patients. All study visits until year 2 or drop-out were considered, with no imputation of missing treatment information. Other missingness was handled with multiple imputation.
Results: In all, 379 patients were included in CareRA, 322 of whom completed the trial. Over 2 years, 3129 follow-up visits with available treatment information took place. On 445 (14%) of these visits, DAS28-CRP was >3.2, and DMARD treatment was adapted in 217/445 (49%) of such cases. T2T use declined over time and was consistently lower during the second trial year, where treatment was no longer protocolized, with T2T implementation ranging from 52-66% in year 1 and from 17-38% in year 2. The mean DS was higher on visits where T2T was not applied (0.33 [SD 0.17]) than on T2T visits (0.18 [SD 0.17], p <0.001). In the GLMM, higher DS was associated with a lower probability of T2T being applied (OR 0.62 [95% CI 0.55-0.69] for 0.1 increase on DS, p <0.001). In multilevel mediation analysis, higher DS over time was associated with decreased odds of remission at year 2, and this effect was partly mediated by lower T2T implementation (Figure 1).
Conclusion: Patient-physician discordance in disease activity assessment was associated with a decreased probability of achieving remission. This association was partly explained by rheumatologists appearing less likely to apply a T2T strategy when their assessment of disease activity differed from the patient's. These findings highlight the importance of an open dialogue between physicians and patients about their evaluation of disease activity before applying this as a target for treatment modification.

POS0484

HIGH ANTI-CCP LEVEL AND FEMALE GENDER ARE ASSOCIATED WITH PROGRESSION TO PERSISTENT ARTHRITIS IN PATIENTS WITH PALINDROMIC RHEUMATISM; RESULTS OF A UK PROSPECTIVE COHORT STUDY

Keywords: Rheumatoid arthritis, Autoantibodies

R. Chowdhury[1], F. Shuweihdi[2], N. Sidhu[3], L. Duquenne[3], L. Garcia-Montoya[3], J. Nam[3], A. DI Matteo[3], K. Harnden[3], P. Emery[3], K. Mankia[3]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [2]University of Leeds, Leeds Institute of Health Sciences, Leeds, United Kingdom; [3]Univerisity of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: Palindromic rheumatism (PR) is a recognised precursor of rheumatoid arthritis (RA) and is characterised by episodic flares of pain and swelling in and around joints [1]. Up to 50% of PR patients will progress to persistent arthritis (PA) [1]. However, PR is challenging to identify and study longitudinally and risk factors for progression remain unclear [1]. This is the first large UK prospective PR cohort study describing risk factors in patients with PR, the majority of whom were treatment naïve at baseline.

Objectives: To investigate baseline risk factors associated with progression to PA in PR patients.

Methods: Patients with suspected PR were recruited to the Leeds PR cohort from regional primary care and secondary care referrals. In the absence of an accepted classification criteria, PR was defined as 'a confirmed history or physical examination consistent with episodes of joint pain and swelling that returned to normal between episodes in the absence of an alternative diagnosis' [2]. At baseline, a comprehensive set of clinical, imaging, serological and immunogenetic parameters was assessed. Patients were monitored at 3 monthly intervals for the first year, then 6 monthly or earlier if clinically indicated. Progression to PA was defined by the presence of at least one tender and swollen joint confirmed by a rheumatologist, which persisted for at least 3 weeks. Baseline variables included in the analysis were: age, smoking status, gender, first degree relative with RA, time interval between flares, number of joints typically affected in a flare, wrist joint involvement in flares, hand joint involvement in flares, HLA DR shared epitope (SE), anti-CCP status, rheumatoid factor status and DMARD use during follow up. Cox regression analysis identified factors associated with progression to PA using the R statistical program. Model discrimination, using concordance index, was 0.741.

Results: 161 patients were followed between July 2008 and December 2022. 32% (51/161) of patients developed PA after a median of 12 months. 90% (46/51) of progressors met criteria for RA. 90% (145/161) of patients were DMARD naive at baseline. Cox regression showed female gender (HR 2.7, CI 1.2-6.0, p=0.01) and high anti-CCP level (> 3X upper limit of normal range) (HR 6.1, CI 1.9-19, p=0.004) were associated with progression to PA. Flares in joints of the hands was found to be protective (HR 0.3, CI 0.1-0.9, p= 0.04). Typical involvement of < 3 joints in flares was also protective, with a trend towards significance (HR 0.4, CI 0.1-1.0, p=0.05). The remaining variables including frequency of flares, HLA DR SE and DMARD exposure were not associated with progression status.

Table 1. Variables shown to be significantly protective or predictive of persistent arthritis. Number of joints in a typical flare was borderline significant. ULN: Upper Limit of Normal, Ref: Reference

Baseline Variable		Progressors n= 51		Non Progressors n=110		HR	95% CI		P Value
		n	%	n	%				
Gender	Male	11	22	39	35	Ref			
	Female	40	78	71	65	2.75	1.25	6.05	0.01
Typical No. of joints affected in flares	>4	15	29	25	23	Ref			
	<3	31	61	79	72	0.43	0.18	1.00	0.05
Hand Joint involvement in flares	Absent	7	14	13	12	Ref			
	Present	30	59	80	73	0.38	0.15	0.97	0.04
Anti-CCP Antibody	Negative	7	14	56	51	Ref			
	Positive< 3 x ULN	2	4	9	8	1.71	0.28	10.49	0.55
	Positive >3x ULN	41	80	45	41	6.12	1.90	19.73	0.004

Conclusion: In patients with PR, female gender and high anti-CCP level were associated with progression to PA. Conversely, hand joint involvement and flares typically affecting <3 joints were protective. These data provide novel insights into the natural history of PR and will inform a risk stratification model for monitoring and early therapeutic intervention.

FATIGUE USING PATIENT-REPORTED OUTCOMES MEASUREMENT INFORMATION SYSTEM (PROMIS) AND ITS RELATIONSHIP WITH DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS: A PROSPECTIVE STUDY FROM INDIA

Keywords: Treat to target, Rheumatoid arthritis, Patient reported outcomes

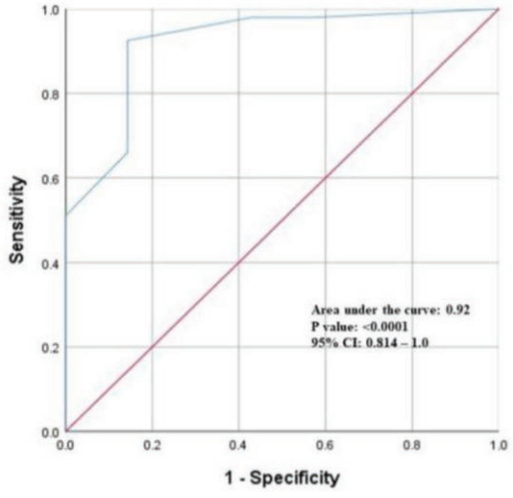
A. Kumar P H[1], P.S. Kumar[1], R. Sivaprasad[1], N. K[1], K. Shukla[2], M. K. Garg[1,3], M. Gopalakrishnan[1]. *[1]All India Institute of Medical Sciences (AIIMS), Jodhpur,*

Department of Internal Medicine, Jodhpur, India; [2]All India Institute of Medical Sciences (AIIMS), Jodhpur, Department of Biochemistry, Jodhpur, India; [3]All India Institute of Medical Sciences (AIIMS), Jodhpur, Department of Endocrinology, Jodhpur, India

Background: Fatigue in rheumatoid arthritis (RA) is common, overwhelming and plays a key role in patients' perception of the disease and strongly influences global assessment [1]. While fatigue in RA has no internationally accepted definition, it is multidimensional and has an inconsistent association with disease activity in different populations with very few studies from India [2, 3].

Objectives: To determine the relationship between fatigue as measured by Patient-Reported Outcomes Measurement Information System (PROMIS) fatigue raw score with disease activity in patients with RA. To determine the predictors of fatigue in patients with RA.

Methods: A longitudinal study was conducted from January 2021 to December 2022 after Ethics Committee approval in patients with RA enrolled at our rheumatology clinic providing care to >450 patients with RA, in a tertiary care hospital. Fatigue (PROMIS Fatigue-short form 7a), patient assessment of global disease activity (PtGA), Disease Activity Score (DAS28), and Clinical Disease Activity Index (CDAI) were measured. Serum samples for interleukin-6 (IL-6), and tumor necrosis factor alpha (TNF-α) were collected and stored at -80^0 C. Relationship of fatigue was examined with age, hemoglobin, serum vitamin D3, TNF-α, and IL-6 using Spearman correlation coefficient. A Receiver Operating Characteristic (ROC) curve was constructed to determine the optimal PROMIS cut-off for defining PtGA >2. Binary logistic regression analysis was used to assess predictors fatigue.



Results: One hundred and fifty-four patients were enrolled, of whom 133 (86.3%) were females, 103 were reassessed at 6 months (85.4% females). All were on conventional disease-modifying antirheumatic drugs. Patients in remission using DAS28 were 9.7% (n = 15) and 52.4% (n = 54) and remission/low disease activity (LDA) based on CDAI <10 were 13.6% (n = 21) and 68.9% (n = 71) at enrolment and 6 months respectively. There was a significant reduction in median PROMIS at 6 months from 19(11) to 16(7) (p<0.0001). PROMIS was significantly lower in those with remission/LDA based on CDAI (p<0.0001) and DAS28 remission at enrolment and 6 months (p = 0.012 and 0.015 respectively). PROMIS >11 had 93.8% sensitivity and 78.6% specificity to predict PtGA >2 (AUC 0.92, 95% CI 0.81 - 1.00, P <0.0001) (Figure 1). PROMIS >11 was present in 89% at enrolment and 82.5% at 6 months. Age, hemoglobin, serum vitamin D3, TNF-α, and IL-6 had no correlation with fatigue. DAS28, CDAI, sleep (Pittsburgh Sleep Quality Index - PSQI), and depression (Patient Health Questionnaire - PHQ-9) were significant predictors of PROMIS >11 (Table 1).

Conclusion: Fatigue is a significant problem in RA. A PROMIS score of 11 may be an acceptable cut-off for our population. Though fatigue improved with the treat-to-target approach, further studies are needed to determine if it is meaningful for patients. Along with disease activity, addressing sleep and depression is important in managing fatigue.

Table 1. Predictors of fatigue (n= 154)

Predictors	Odds ratio (95% CI)	P value
PSQI	2.31(1.45 - 3.69)	<0.0001
PHQ-9	4.38 (2.16 - 8.89)	<0.0001
CDAI	1.26 (1.13 - 1.39)	<0.0001
DAS28	2.87 (1.72 - 4.79)	<0.0001

CHARACTERISTICS OF RHEUMATOID ARTHRITIS PATIENTS WHO ACHIEVE REMISSION AFTER 2022 AMERICAN COLLEGE OF RHEUMATOLOGY/ EUROPEAN ALLIANCE OF ASSOCIATION FOR RHEUMATOLOGY REVISED REMISSION CRITERIA APPLICATION

Keywords: Real-world evidence, Remission, Rheumatoid arthritis

Y. Hirano[1], Y. Saito[1]. *[1]Toyohashi Municipal Hospital, Rheumatology,Toyohashi, Japan*

Background: In 2011, the American College of Rheumatology (ACR) and European League Against Rheumatism (formerly European Alliance of Association for Rheumatology [EULAR]) developed two new definitions for remission for rheumatoid arthritis (RA) clinical trials and in clinical practice [1]: Boolean-based definition and index-based definition (simplified disease activity index: SDAI). The 2011 Boolean based definition (Boolean 1.0 [B1R]) required each of the four core set variables (tender joint count, swollen joint count, patient assessment of global disease activity [PtGA, cm], and C-reactive protein [CRP, mg/dl]) to have a value of ≤1. B1R is the most stringent remission criteria and discrepancies between B1R and SDAI were highlighted. In 2022, the ACR and EULAR validated and approved a Boolean remission (Boolean 2.0 [B2R]) revision in which the PtGA threshold was set at ≤2 [2]. Although the RA patient number who achieved remission by B2R definition increased due to the PtGA threshold change, the characteristics of those who were newly included in the remission criteria are unknown.

Objectives: This cross-sectional retrospective study investigated the characteristics of RA patients who were newly included in the remission criteria after B2R application in daily clinical practice.

Methods: Toyohashi RA Database (TRAD) data from 2021 was used, which is a single-center retrospective data collection. Once a year cross-sectional data was included in TRAD such as basic patients' characteristics, RA disease activity, laboratory data, and medication data. A total of 469 RA patients and 611 RA patients were categorized in B1R and in B2R, respectively, among the 1020 RA patients registered in the TRAD 2021 data. New remission criteria entries after B2R application were 142. Cross-sectional data described below were compared between B1R and B2 1R: age, gender, RA disease duration, rheumatoid factor (RF) positivity and anti-cyclic citrullinate protein antibody (ACPA), Steinbrocker stage and class, medication information at the time of survey, CRP value and erythrocyte sedimentation rate, modified health assessment questionnaire (mHAQ), and concomitant osteoporosis (OP). Univariate analysis by Mann Whitney U-test or Chi square test was initially performed between B1R and B2-1R. Subsequently, multivariate analysis was performed using selected variables, which were statistically significant between the two groups by logistic regression analysis. P < 0.05 was considered as statistically significant.

Results: The number of RA patients in remission state increased by 30.3% by B2R application. Statistically significant differences by univariate analysis were found in the following variables (mean values or percentage in B1R/B2-1R): RA disease duration (11.3/15.5 years), RF positive ratio (70.2/79.9%), RF titer (94.4/132.8 IU/ml), ACPA positive rate (71.5/80.9%), ACPA titer (226.9/322.3 U/ml), %stage III+IV (45.6/63.4%), %btDMARDs (40.1/51.4%), mHAQ (0.11/0.28), and %OP concomitant (32.0/46.5%). Multivariate analysis results were shown in the Table 1. mHAQ in B2-1R was significantly worse compared with that in B1R.

Conclusion: New B2R application increased the RA patient number in remission state. RA patient characteristics in B2-1R were with: longer disease duration, more seropositivity, more joint damage, treated with more intensive medications, especially worse physical function, and increased concomitant OP.

POS0487 DISENTANGLING HETEROGENEITY IN CONTEMPORARY UNDIFFERENTIATED ARTHRITIS – A LARGE COHORT STUDY USING LATENT CLASS ANALYSIS

Keywords: Remission, Outcome measures, Rheumatoid arthritis

N. Den Hollander[1], M. Verstappen[1], B. Van Dijk[1], A. Van der Helm – van Mil[1,2], H. W. Van Steenbergen[1]. *[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands; [2]Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands*

Background: Undifferentiated arthritis (UA) is considered to be heterogenous and consists of subgroups, this notion is affirmed by differences in disease course, varying from spontaneous resolution of arthritis to RA-development.

Objectives: We aimed to identify homogeneous subgroups within UA based on a combination of clinical features and thereafter to relate these to the outcomes spontaneous resolution and RA-development. These outcomes can only be studied in UA-patients in which DMARD-treatment does not influence the natural disease course; these cohorts are scarce.

Methods: We studied ACPA-negative UA-patients, defined as not-fulfilling 1987-/2010-RA-criteria nor having an alternate diagnosis, consecutively included in the Leiden Early Arthritis Clinic between 1993-2006, when early DMARD-treatment in UA was infrequent. Latent Class Analysis was used to identify subgroups based on a combination of clinical features (e.g. symptom characteristics, physical examination, laboratory tests). Within these subgroups, test-characteristics were assessed for spontaneous-resolution of arthritis (defined as spontaneous resolution of arthritis without DMARD-treatment) and RA-development within 1 year.

Results: 310 consecutive UA-patients were studied. Five classes were identified: location and number of swollen joints were most distinguishing. Classes were characterized by: 1) polyarthritis, often symmetric 2) oligoarthritis, frequently with subacute onset, 3) wrist-monoarthritis, often with subacute onset, increased BMI and without morning stiffness, 4) small-joint monoarthritis, often without increased acute phase reactants, and 5) large-joint monoarthritis, often with subacute onset. Studying the classes in relation to the outcomes revealed that the majority of patients without spontaneous resolution were not included in the classes characterised by monoarthritis (specificity >90%). In addition, patients who developed RA were infrequent in the monoarthritis classes (sensitivity <7%).

Conclusion: Using a data-driven unsupervised approach, five subgroups within contemporary UA were identified. These subgroups have differences in the natural course of disease.

Ying[10], M. C. Wan[11], J. M. Lee[12], L. S. Tam[1]. *[1]The Chinese University of Hong Kong, Department of Medicine & Therapeutics, Hong Kong, Hong Kong (SAR); [2]Tuen Mun Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); [3]Queen Mary Hospital, Department of Medicine, Hong Kong, Hong Kong (SAR); [4]Kwong Wah Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); [5]Pok Oi Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); [6]Tseung Kwan O Hospital, Department of Medicine, Hong Kong, Hong Kong (SAR); [7]Caritas Medical Centre, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); [8]Queen Elizabeth Hospital, Department of Medicine, Hong Kong, Hong Kong (SAR); [9]Pamela Youde Nethersole Eastern Hospital, Department of Medicine, Hong Kong, Hong Kong (SAR); [10]Princess Margaret Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); [11]Ruttonjee Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR); [12]Tai Po Hospital, Department of Medicine & Geriatrics, Hong Kong, Hong Kong (SAR)*

Background: Rheumatoid Arthritis (RA) is associated with functional impairment and disability. With the 2022 revision of the Boolean remission criteria, more patients can classified as achieving remission and the revised version also increases the agreement with index-based remission criteria without jeopardising predictive value for radiographic or functional outcomes. Whether achieving sustained Boolean 2.0 remission using a treat-to-target strategy aiming can prevent functional impairment in the long-term measured using the Health Assessment Questionnaires Disability Index (HAQ-DI) would need to be addressed.

Objectives: This retrospective study aims to explore the impact of sustained remission classified under the revised Boolean 2.0 criteria on HAQ-DI score.

Methods: The data was retrieved from the Clinical Rheumatology Systematic Treat-to-target (T2T) in Asia Leadership (CRYSTAL) registry. Early RA patients with symptoms onset less than 2 years were recruited between 2012-2018. All patients received a treat-to-target treatment strategy aiming at remission and had been followed for 5 years. Swollen joint count (SJC), tender joint count (TJC), Patient global assessment (PtGA), CRP levels, and HAQ-DI were recorded. Patients were classified into two groups: patients achieved Boolean 2.0 remission in both the first and second year (Early-Sustained Remission (ESR) Group), and patients who did not (Non-ESR group).

Results: The data of 236 patients were retrieved. 57 (24.2%) of them were classified as ESR group and 166 (70.3%) were in Non-ESR group (Table 1). The average HAQ-DI score was lower in the ESR group in the second, third, fourth and fifth year compared to the Non-ESR group with $p \leq 0.001$ [year 1: 0.097 ± 0.218 vs 0.403 ± 0.465; year 2: 0.143 ± 0.267 vs 0.421 ± 0.452; year 3: 0.212 ± 0.339 vs 0.476 ± 0.59; year 4: 0.232 ± 0.358 vs 0.457 ± 0.566] (Figure 1).

Conclusion: T2T aiming at achieving Boolean 2.0 remission in the first two years could be considered in clinical use for maintaining a lower functional impairment in the long term.

POS0489

PREDICTIVE FACTORS FOR THE FLARE OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA) IN ULTRASOUND REMISSION (US-R)

Keywords: Rheumatoid arthritis, Remission, Ultrasound

T. Abe[1], Y. Oono[1], K. Tsuboi[2], M. Nakano[1], C. Ogita[1], M. Tamura[1], T. Hashimoto[1], N. Azuma[1], K. Matsui[1]. [1]*Hyogo Medical University, Division of Diabetes, Endocrinology and Clinical Immunology, Department of Internal Medicine, Nishinomiya City, Japan;* [2]*Kobe Citizen Medical Center West Hospital, Rheumatology, Kobe City, Japan*

Background: Flares are frequent in patients with rheumatoid arthritis(RA), with 30–50% experiencing a disease flare within the first 2 years of clinical remission(CR). Ultrasound (US) synovitis despite CR have more subsequent flares than those who show both CR and ultrasound remission(USR). Plenty of studies examined clinical course and predictive factors for flare among patients with RA in CR or LDA. But few studies have examined those with USR and using US as daily rheumatologic practice through a follow-up period. Therefore, the clinical course and flare predictor of RA patients in US-R under daily US practice is unclear.
Objectives: The objective of this study among RA patients in CR/LDA with USR under on-demand and yearly US practice was as follows (1) to investigate the clinical course and change of disease activity from baseline, (2) to investigate the predictive factors for the flare over 2 years.
Methods: All patients met the following criteria: (1) RA classified according to the American College of Rheumatology (ACR) 2010 revised criteria; (2) age >18 years; (3) at least 12 months disease duration; (4) maintaining the same RA treatment at least 6 months; (5) being in CR or LDA according to either DAS28 CRP or SADI/CDAI; (6) being in USR. USR was defined as absence of joint synovitis, tenditis, tenosynovitis in the bilateral wrist, 2nd-5th MCP and PIP joints, and any tender or swollen joints. Demographic and treatment characteristics, clinical dates, US assessment were evaluated at the time of baseline, 1-year, and 2-years (yearly-US). US was additionally assessed if the patients showed clinical manifestations of the flare in any period (on-demand US). Questionnaires were also collected at baseline to assess physical function, psychiatric disorders and catastrophizing: HAQ-DI, BS-POP and Pain Catastrophizing Scale (PCS). Rheumatologists could employ DMARD treatment as an individual approach based on the joint decision between the patient and the rheumatologist without any restrictions. The flare was defined when patients received additional DMARD or glucocorticoids or encountered Power Doppler (PD) US flare. Baseline factors for the shorter time to the flare were analyzed by multivariate COX regression analysis, adjusting for age, gender, BMI, and DAS28 CRP. A P value ≤ 0.05 was regarded as being significant. All analyses were performed with EZR statistical software.
Results: In total, 85 patients were enrolled in the study. Baseline characteristics are depicted in Table 1. 62 patients (73%) fulfilled CR criteria. The change of DAS28-CRP from baseline to 1-year and 2-years was -0.1±0.7, -0.08±0.75. The rate of LDA/CR and USR was as follows: 92% and 91% at 1-year, 90% and 89% at 2-years. Over 2 years, 35 patients (42%) had the flare and the mean time to the flare was 11.8±7.0 months. PDUS flares were reported in 4 patients (5%) at 1-year and 2-year US assessment, even though they had no clinical signs of flares. An association of ACPA (HR=2.6, 95%CI:1.0-6.9, p=0.05), Stage III (HR=4.2, 95%CI:1.5-11.6, p=0.005), CRP (HR=21.9, 95% CI:3.5-137, p<0.001), opioids use (HR=5.8, 95% CI:2.0-17, p=0.001) on the shorter time to the flare was revealed. CR, DMARD treatment, HAQ-DI, BS-POP, and Pain Catastrophizing Scale (PCS) were not associated with the flare.
Conclusion: Under on-demand and yearly US assessment over 2 years for RA patients in LDA/CR with USR, the flare occurred frequently but most of the patients showed sustained LDA/CR and USR at 1- year and 2- years. Baseline factors should be considered for predicting the flare.

Osteoporosis

POS0490

SERUM LEVELS OF BONE TURNOVER MARKERS, ESTABLISHING Z-SCORES FOR USE IN RESEARCH AND DAILY CLINICAL PRACTICE: DATA FROM A DUTCH HEALTHY REFERENCE COHORT

Keywords: Bone diseases, Osteoporosis, Diagnostic tests

M. Siderius[1], S. Arends[1], A. Muller Kobold[2], L. Wagenmakers[2], K. Koerts[2], A. Spoorenberg[1], E. Van der Veer[2]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]University Medical Center Groningen, Laboratory Medicine, Groningen, Netherlands*

Background: Bone turnover markers (BTM) reflect specific processes or aspects of bone (re)modeling. Their dynamic character provides additional information regarding the current status and balance of bone metabolism. Measurement of BTM is clinically relevant and common in patients with osteoporosis and other bone-related disease such as inflammatory rheumatic diseases as axial spondyloarthritis (axSpA). BTM can attribute to the diagnostic workup as well as treatment monitoring. Interpretation of absolute values is difficult as these are highly influenced by age and gender, which complicates data interpretation and comparison of studies involving BTM. In previous research, we used BTM Z-scores to study the effect of biological therapy on the course of BTM in patients with axSpA [1, 2].
Objectives: To establish BTM reference values based on widely used BTM assays and/or automated immunoassay platforms. that can be used to calculate Z-scores to correct for the normal influence of age and gender.
Methods: Serum markers of collagen resorption, bone regulation, collagen formation and facilitator of bone mineralization (sCTX, OC, PINP and BALP, respectively) were measured in volunteers without bone-related diseases/abnormalities. Assays were conducted in a ISO certified specialized routine diagnostic laboratory. Raw data was plotted, gender-specific age cohorts were established based on the distribution of the data and subsequently their respective means and standard deviations were calculated. Z-scores can be calculated using these reference values to correct for the normal influence of age and gender on BTM.
Results: In total, 856 individuals were included, of which 486 (57%) were female. Individuals were aged between 7 and 70 years. Highest serum levels of BTM were found in childhood and puberty. Peak levels are higher in boys than girls and prevail at later ages. In adults, BTM levels decrease before reaching stable nadir levels. For the calculation of Z-scores below the age of 20 years, intervals of one year were needed due to the change in BTM activity. In adults, 10-year reference cohorts could be established in order to calculate Z-scores (Figure 1). As example, a male of 40 years with a serum PINP level of 70.0 ng/mL has a Z-score of 1.56. At the age of 60, his PINP levels remained 70.0 ng/mL, which corresponds to a Z-score of 2.73. Despite the absence of change in absolute levels of PINP, Z-scores do indicate a large increase not only compared to the previous measurement but also compared to the reference population matched for age and gender.

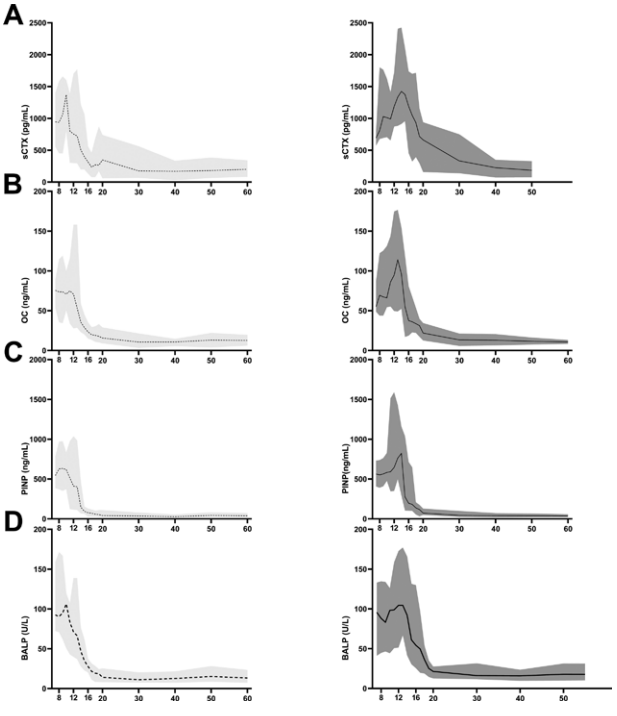

Figure 1. Median and P3-97 serum levels of sCTX(A), OC (B), PINP (C) and BALP (D) in females and males of a healthy reference cohort (---; female, —; male).

Conclusion: With our data, Z-scores of sCTX, OC, PINP and BALP can be calculated using reference categories (for age and gender) of mainly Caucasian volunteers representative for the normal population. BTM Z-scores facilitate harmonization of data interpretation in both daily clinical practice and research. This is especially important in (rheumatic) diseases with known aberrant bone metabolism as axSpA or (secondary) osteoporosis.

EVALUATION OF FRACTURE PREVALENCE AND RISK IN A MONOCENTRIC COHORT OF PATIENTS WITH NON-METASTATIC BREAST CANCER IN ADJUVANT ENDOCRINE THERAPY TREATED WITH ANTIRESORPTIVE DRUGS

Keywords: Bone diseases, Osteoporosis, Malignancy

M. Pontalti[1], M. Felicetti[1], M. A. Jaber[1], R. Bortolotti[1]. *[1]S. Chiara Hospital, Rheumatology Unit, Trento, Italy*

Background: Bone loss is one of the major long-term side effects of adjuvant endocrine therapy for breast cancer. There is limited consensus on how to accurately assess fracture risk in this setting. Many trials showed the effectiveness of antiresorptive drugs in preventing the loss of bone mineral density (BMD) and, consequently, reducing fracture risk [1].
Objectives: Our study aims to investigate osteoporotic fractures prevalence and to assess the age adjusted fractures risk in breast cancer patients receiving AET and treated with antiresorptive drugs. Moreover, we analyzed differences in terms of clinical features and outcomes between patients treated with denosumab (DMAB) or bisphosphonates (BPs), and examined variations in biochemical markers of bone turnover and densitometric values to assess the effects of each antiresorptive medication.
Methods: In this monocentric, retrospective, non-randomized cohort study we enrolled patients with non-metastatic breast cancer who received at least 5 years of AET and were treated with DMABs or BPs. We retrieved demographic and clinical data pertaining to the cancer characteristics and the osteoporotic risk at the start of the antiresorptive therapy (baseline), as well as serum levels of C-terminal telopeptide of type I collagen (CTX), vitamin D, parathyroid hormone (PTH), and densitometric data (DXA) at baseline and at 24 months.
Results: We enrolled 120 patients, 38 on DMABs and 82 on BPs. During a median follow-up of 32 months (24-38), 16 (13.3%) fractured at least once. At baseline, the latter had lower BMI [22 kg/m^2 (21-27) vs 24 kg/m^2 (20-26), p=0.043], higher prevalence of osteoporosis (12/16 vs 35/104, p=0.002), higher prevalence of prior fractures (8/16 vs 15/104, p=0.003), and lower AET exposure time [2.7 years (1.2-3.7) vs 3.8 years (2.4-5.8), p=0.008]. In age-adjusted Cox-proportional model, a history of previous fractures and BMD at the femoral neck <-2 at baseline were associated with higher fracture risk [HR 7.8 (2.7-22.9), p<0.001, and HR 3.4 (1.1-10.4), p=0.033, respectively], whereas higher levels of vitamin D resulted protective [HR 0.7 (0.5-0.9), p=0.010]. AET exposure time and the type of antiresorptive drug, instead, had no impact on the fracture risk. Patients who received DMAB had significantly lower levels of vitamin D, age and AET exposure time [33 ng/ml (26-39) vs 36 ng/ml (30-41), p=0.022, 55 years (10.2) vs 60 years (9.1), p=0.008, and 2.9 years (2.0-4.4) vs 3.9 years (2.6-5.9), p=0.014, correspondingly]. At 24 months, both medications were successful in reducing serum levels of bone resorption markers and increasing densitometric values. The DMAB group experienced substantially larger BMD increases in the lumbar spine and femoral neck [respectively, +9.0% (+4.2/+19.8) vs +3.3% (-1.3/+6.6), p<0.001, and +6.1% (+2.2/+15.5) vs +0.7% (-3.5/+4.4), p<0.001].
Conclusion: The frequency of fractures tends to stay high in women receiving AET even if on antiresorptive drugs despite biochemical and instrumental improvements, indicating the existence of other concurrent processes of bone damage. To enable quick management of bone health-related issues, a thorough

risk assessment must be done at the moment AET is started. When given based on risk stratification, DMABs and BPs seem to have comparable antifracture effectiveness profiles. DMAB, however, was more successful in increasing BMD over time. Whatever the case, we found that appropriate vitamin D supplementation is advised throughout AET.

POS0492 ASSESSMENT OF OSTEOPOROSIS AND VERTEBRAL FRACTURE RISK BY OPPORTUNISTIC BONE MINERAL DENSITY (BMD) MEASUREMENT ON CHOLINE PET/CT IN PATIENTS WITH PROSTATE CANCER (HORM-OS PROJECT)

Keywords: Bone diseases, Osteoporosis, Imaging

A. Dauchez[1], C. Dariane[2], J. Fechtenbaum[1], S. Bodard[3], S. Guinebert[3], F. Allioux[4], M. O. Timsit[2], C. Roux[1], F. Hyafil[4], K. Briot[1], O. Fogel[1]. *[1]Cochin Hospital, Rheumatology, Paris, France; [2]European Hospital Georges Pompidou, Urology, Paris, France; [3]Necker Hospital, Radiology, Paris, France; [4]European Hospital Georges Pompidou, Nuclear medecine, Paris, France*

Background: Androgen deprivation therapy (ADT) is central in the management of advanced prostate cancer (PCa) but is associated with bone loss and occurrence of osteoporosis and fracture. Dual-energy x-ray absorptiometry (DXA) is recommended when starting ADT but is rarely done. Opportunistic measurement of bone mineral density (BMD) on CT has been proposed to improve osteoporosis screening in the general population, but has not been evaluated in PCa. Choline PET/CT (chPET/CT) is frequently used to identify the recurrence of PCa and/or search for metastasis.

Objectives: The objectives were to demonstrate the feasibility of using chPET/CT in comparison to the CT scan for opportunistic screening of osteoporosis and to describe the pet/ct-derived BMD and the prevalence of osteoporotic vertebral fracture in patients with PCa.

Methods: Between 2020 and 2022, we identified 171 PET/CT from 136 patients in the database of the nuclear medicine department of our tertiary center. We focused on chPET/CT. Among these patients, we identified those with a CT within 6 months before or after the chPET/CT to compare the BMD values between these 2 exams. BMD estimation was performed by 4 blinded readers (2 rheumatologists and 2 radiologists) on a 200-mm² trabecular bone area by a standardized method, on L1 vertebrae in axial section. Assessment of vertebral fractures and metastasis was performed on the entire spine in sagittal section. Demographic, clinical and treatments information have been collected blind from the reading of the images. Spearman coefficient and t-test were used for continuous variables and chi square test was used for dichotomous variables.

Results: We identified 93 PCa patients with chPET-CT including 29 with a CT within 6 months. The mean age was 74 years old (± 8.6), and mean BMI was 26.9 kg/m² (± 5.2). Forty-one patients (44%) smoked or had smoked. ChPET/CT was performed for newly-diagnosed PCa in 36.6%, for suspicion of recurrence in 59.1% or as simple follow-up for 4.3%. Twelve patients (12.9%) had fractures and 20 (21.5%) had metastasis. Also, 39 patients (42%) were already on ADT with a mean duration of 21.4 ± 31.6 months. First, we compared BMD measurement on both chPET/CT and CT in the 29 patients. The mean BMD on L1 vertebrae was similar between the 2 exams (125 ± 51.1 and 128 ± 42.4 HU respectively on chPET-CT and CT) and correlated well ($k = 0.7$; $p < 0.001$). Then, we measured the pet/ct-derived BMD on the whole cohort. The mean BMD was 125 HU (± 50.7). Increasing age was significantly correlated with decreased BMD ($k = -0.315$; $p < 0.001$). There was no correlation between BMI and BMD ($k = 0.02$; $p = 0.87$). The mean BMD was 123 HU (± 51.6) in patients who smoked or had smoked, compared with 138 HU (± 45.8) in non-smokers ($p = 0.11$). The mean BMD in patients already on ADT was 114 HU (± 56.2), compared with 127 HU (± 42.1) in others ($p = 0.17$). Among the 39 patients on ADT, there was a nonsignificant trend toward decreased BMD with increased ADT duration ($k = -0.27$; $p = 0.1$). Interestingly we found a significant decreased BMD for patients with fracture compared to those without fracture (mean BMD = 82.6 ± 42.9 vs 131 ± 49; $p < 0.01$). A cut-off of 100 HU has recently been published on CT to define patients at risk for bone complications. Here, we identified 24.7% patients with a BMD < 100 HU. These patients were more likely to have vertebral fracture compared to those with a BMD > 100 HU (30.4% vs 7.1% of fracture; $p < 0.01$).

Conclusion: This study demonstrates the feasibility of using chPET-CT for opportunistic screening for osteoporosis in PCa. Bone disease was frequent in this population, 13% patients had fractures and almost 25% had a BMD < 100 HU. Pet/ct-BMD seemed to be of interest for screening patients at risk of fracture. A prospective study will validate the interest of this approach and its impact on the management of osteoporosis in these patients.

POS0493 PREVALENCE AND INCIDENCE OF OSTEOPOROTIC VERTEBRAL FRACTURE IN NON SMALL CELL LUNG CANCER: ANALYSIS OF A 289 PATIENTS COHORT

Keywords: Bone diseases, Malignancy, Osteoporosis

E. Ebstein[1], P. Brocard[1], G. Soussi[2], R. Khoury[3], A. Khalil[3], M. Forien[1], S. Ottaviani[1], G. Zalcman[2], P. Dieudé[1], V. Gounant[2]. *[1]Hôpital Bichat - APHP, Rheumatology, Paris, France; [2]Hôpital Bichat - APHP, Thoracic Oncology, Paris, France; [3]Hôpital Bichat - APHP, Radiology, Paris, France*

Background: The recent use of targeted therapies and immunotherapy has considerably improved the survival of patients with Non-Small Cell Lung Cancer (NSCLC), in particular metastatic ones. In this new era, it is relevant to look at the comorbidities affecting the quality of life and potentially the prognosis of NSCLC. Due to shared risk factors (tobacco, corticosteroid therapy, radiotherapy); osteoporosis is a comorbidity of interest in the context of NSCLC.

Objectives: The aim of our study was to establish the prevalence and incidence of osteoporotic vertebral fractures (OVF), the risk factors for incident OFV, and impact on survival of incident OFV.

Methods: This retrospective observational single-center study was conducted in the thoracic oncology clinic (Bichat University Hospital, AP-HP Paris, France), between January 2021 and July 2021. Consecutive patients followed for NSCLC were included in this study. The following data were collected (a) demographic characteristics such as gender, age, height and weight, BMI, smoking status, alcool intake (b) NSCLC characteristics such as histology, date of biopsy that resulted in the diagnostic of NSCLC, cancer stage (absence or presence of metastasis, including bone metastasis). Treatments received were collected a) oral corticosteroids (10 mg or more per day of prednisone or equivalent, for at least 2 weeks, in the last 2 years) b) anti-resorptive therapy (bisphosphonate, denosumab) c) local or systemic cancer treatment (surgery, radiotherapy, immunotherapy, chemotherapy and/or target treatment). We defined inclusion by the first thoraco-abominopelvic CT performed for the NSCLC extension assessment at diagnosis. We defined end of follow-up by the last TAP-CT available. We proceed to a double-blind lecture of TAP CT (rheumatologist and radiologist) to evaluate the presence of vertebral fracture: prevalent or incident, its nature (osteoporotic or metastatic), the number and localization. We also measure CT attenuation (Hounsfield unit [HU]) value of L1. Survival was assessed as of August 26, 2022.

Results: We included 289 patients: 162 males (56%), mean age 66.4years old. Eightt-two percent of patients were current or past smokers (42 ± 22 number of year smoking) and 22% consumed alcohol regularly. The mean BMI was 24.7 ± 5.0 kg/m². Seventy-eight percent had an adenocarcinoma and 18% a squamous cell carcinoma. Sixty one percent of patients had a metastatic cancer, including 25% of bone metastatsis. The mean follow-up time was 36.3 ± 29.4 months. At inclusion, 31 of the 289 had an OFV, for 40 OFV (24 thoracic, 16 lumbar, mean 1.3 ± 0.6 OFV per patient). The prevalence at inclusion was therefore 10.7%. At end of follow-up, 23.2% of patients (67/289) had an OVF. During the follow up of 36 ± 29 months: 36 patients had an incident OFV. The incidence of OVF was 12.5%. Ninety-seven OFV occurred (68 thoracic, 29 lumbar). Median time to incident OVF was 13 months [6.7; 21.2]. In univariate analysis (Table 1), the risk factor of OVF were: age ($p=0.036$), BMI <19kg/m² ($p <0.01$), steroid use ($p<0.001$), and radiotherapy ($p = 0.036$), UH in L1 at inclusion (HR 0.986, $p <0.001$) In multivariate analysis, BMI <19kg/m² ($p=0.01$), steroid use ($p<0.001$), HU in L1 at inclusion ((HR adjusted: 0,985, $p = 0.003$) were independent risk factor of incident OVF. Median survival was 80 months in the incident OVF group and was not reached in the patients without incident OVF ($p =0.074$, Image 1).

Conclusion: In our population, prevalence of OVF at inclusion was 10.7%. Incidence was 12.5% during a mean follow up of 36 months. Occurrence of a new OVF may have an impact on survival. Presence of OVF and UH in L1 should be evaluated systematically during NSCLC follow up. We should pay more attention to this population, in order to prescribe preventive anti-resorptive drugs if needed.

Table 1. characteristics of patient with and without osteoporotic vertebral fracture (OVF).

Characteristics	Incident OFV (n=37)	No OVF (n= 222)	P (univariate)
Age (yo)	**71.2 ± 10.4**	65.5 ± 11.1	**0.036**
Gender masculin, n (%)	19 (53%)	127 (57%)	0.738
Current or past smoker, n (%)	32 (89%)	175 (80%)	0.260
Alcool abuse, n (%)	8 (23%)	48 (23%)	1
Mean BMI (kg/cm²)	**23.6 ± 4.8**	**25.0 ± 5.1**	**<0.001**
Pathology -adenocarcinoma -squamous cell carcinoma	24 (67%) 6 (19%)	169 (77%) 32 (15%)	0.417
Metastasis, n (%) (inclusion/end of follow up)	17 (47%) / 25 (69%)	117 (53%) / 149 (68)	0.866
Bone metastasis, n (%) (inclusion/end of follow up)	8 (22%) / 13 (36%)	44 (20%) / 63 (29%)	0.752
CT attenuation in L1, moy (UH)	**123.0 ± 44.4**	**170.5 ± 51.4**	**<0.001**
Steroid use, n (%)	**12 (33%)**	**29 (13%)**	**<0.001**
Radiotherapy, n (%)	**11 (31%)**	**42 (19%)**	**0.036**
Anti-resorptive drugs, n (%)	7 (19%)	31 (11%)	0.417

POS0494 DEVELOPMENT AND VALIDATION OF A QUESTIONNAIRE FOR PRE-ROMOSOZUMAB THERAPY SCREENING

Keywords: Patient reported outcomes, Osteoporosis, Quality of care

Y. El Miedany[1], M. Toth[2], M. Elgaafary[3], S. Bahlas[4], M. Elwy[5], S. A. Mahran[6], M. H. Abu-Zaid[7], S. A. A. Tabra[7], W. Elwakil[8]. *[1]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom; [2]King's College London - Darent Valley Hospital, General Medicine, Dartford, United Kingdom; [3]Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt; [4]King Abdulaziz University, Rheumatology, Jeddah, Saudi Arabia; [5]Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt; [6]Faculty of Medicine - Assiut University, Rheumatology and Rehabilitation, Assiut, Egypt; [7]Faculty Of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; [8]Faculty of Medicine Alexandria University, Rheumatology and Rehabilitation, Alexandria, Egypt*

Background: Romosozumab has expanded the osteoporosis management options in postmenopausal women who are at very high risk of fracture. Romosozumab has dual mechanism of action as it modulates both bone formation and bone resorption and aims to achieve optimal fracture prevention. While Romosozumab appears to have a generally manageable tolerability profile, extra clinical experience is required to, more definitively, establish its efficacy and safety. Romosozumab is contraindicated in patients with past history of myocardial infarction and stroke. Currently there is no tool to screen osteoporosis patients for Romosozumab contraindications.
Objectives: To develop a questionnaire for pre-Romosozumab therapy screening for use in standard clinical practice.
Methods: The Pre-Romosozumab screening questionnaire was conceptualized based on frameworks used by the WHO Quality of Life tool and the PROMIS. Initially, review of the literature and cognitive interviews held with physicians with special interest in bone health, patients, osteoporosis nurses, and outpatient managers were conducted to identify item pool of questions. Item selection and reduction was achieved based on patients as well as an interdisciplinary group of specialists. Rasch and internal consistency reliability analyses were implemented. The questionnaire included 5 main categories which are patient-centred: 1. Patient's anthropometric measures, 2. items specifically linked to Romosozumab indications and contraindications, 3. Self-completed Fracture risk assessment, 4. Current medication(s), 5. Comorbidities. The answers to the questions were compared to the patients' notes. Comprehensibility was assessed using numerical visual analogue scale [0-10].
Results: The developed questionnaire is composed of 2-pages. Page-1 to be self-completed by the patient to screen for any possible contraindication to Romosozumab therapy, current medications, and comorbidities. Page-2 is to be completed by the treating health care professional and it includes information of how this patient meets the prescribing recommendations for Romosozumab. The primary screening questionnaire contained 15 items; all met the minimum acceptable value of 0.81 for item-level content validity index. Using exploratory factor analysis (EFA), four factors (intrapersonal-psychological, intrapersonal-cognitive, provider-related, and socio-economic reasons) were assessed, and Cronbach's alpha coefficient of 0.79, 0.86, 0.79, and 0.81, respectively, were identified. The reliability of the questionnaire (r = 0.88) was confirmed. The questionnaire showed also a high degree of comprehensibility (9.6).
Conclusion: The questionnaire is a valid and reliable instrument that can be used in standard practice to pre-screen patients identified as candidates for Romosozumab therapy. The questionnaire achieved high degree of comprehensibility.

POS0495 PREVALENCE AND RISK FACTORS OF OSTEOPOROSIS IN A BELGIAN COHORT OF LUNG TRANSPLANTATION CANDIDATES: THE PROGRES STUDY

Keywords: Bone diseases, Osteoporosis, Lungs

E. Curraj[1], F. Carlier[2], M. Dumonceaux[2], P. Evrard[2], B. Rondelet[3], J. P. Devogelaer[4], Y. Boutsen[1]. *[1]CHU UCL Namur, Rheumatology, Yvoir, Belgium; [2]CHU UCL Namur, Pneumology, Yvoir, Belgium; [3]CHU UCL Namur, Thoracic Surgery, Yvoir, Belgium; [4]Cliniques Universitaires Saint-Luc, Rheumatology, Brussels, Belgium*

Background: Few data are available on the incidence of osteoporosis (OP) in end-stage pulmonary diseases, particularly in lung transplant candidates. Yet, organ transplantation can be accompanied by low bone mineral density (BMD) owing to immunosuppressive therapy, particularly with oral glucocorticoids (GCs) use.
Objectives: Our primary aim was to evaluate the prevalence and therapeutic management of OP in lung transplant candidates. Our second objective was to determine the risk factors associated with OP, including the type of respiratory disorder.
Methods: We included 198 patients (103 women) out of 388 screened for lung transplantation at our institution between January 1998 and December 2020. BMD, measured by Dual-energy X-ray absorptiometry (DXA, Hologic (t-m)) at the lumbar spine (LS), total hip (TH), and femoral neck (FN), vertebral fracture assessment (VFA), as well as previous major osteoporotic fracture (MOF), were recorded. We systematically collected well-recognized OP risk factors, along with other factors suspected of affecting BMD such as inhaled (i) GCs use, pulmonary function tests, hypoxemia and type of pulmonary disorder.
Results: OP, as defined by BMD values (T-score ≤ -2.5) and/or fragility fracture (FF), MOF and/or vertebral fractures (VF), was observed in 118 patients (59.6%). Among these patients, 54 (45.8%) had only a T-score ≤ -2.5, while 36 (30.5%) had only an FF, with predominant vertebral fractures (77.8%). The median age (IQR) of the study population was 58 years (53.0-62.0), and 59 years in OP patients (54.2-62.0). Mean T-scores (±SD) were -1.62±1.52 at the LS, -1.43±1.05 at the TH and -1.98±1.14 at the FN. Mean T-scores (±SD) in OP patients were -2.15±1.31, -1.87±0.93 and -2.44±1.03, respectively. The mean (±SD) ten-year probability of major osteoporotic fracture assessed by the FRAX algorithms (FRAX score) was 11.6±11.2 %, and the mean FRAX adjusted to GCs dose (±SD) was 12.0±12.1 %. Nighty-eight patients (49.5%) achieved intervention threshold adjusted for age based on FRAX results

and 110 patients (55.6%) when FRAX was adjusted to GCs dose. Seventy-eight OP patients (66.1%) achieved the FRAX intervention threshold, of whom 53 (67.9%) received calcium and/or vitamin D and 33 (42.3%) had received an add-on therapy, mostly a bisphosphonate (n=23, 69.7%) or denosumab (n=4, 12.1%). Eighty-four OP patients (71.2%) achieved the FRAX intervention threshold adjusted to GCs dose, of whom 59 (70.2%) received calcium and/or vitamin D and 37 (44.5%) had received an add-on therapy, mostly a bisphosphonate (n=25, 67.6%) or denosumab (n=5, 13.5%). Thirty-six OP patients (30.5%), 18 patients (33.3%) with only a T-score ≤ -2.5 and 12 patients with only an FF, did not receive any medication. In total, 153 patients had a chronic obstructive pulmonary disease (COPD, 77.3%), 33 an interstitial lung disease (ILD, 16.3%) and 12 (6.1%) suffered from another pulmonary disease. Among OP patients, 102 had a COPD (86.4%), 12 an ILD (10.2%) and 4 (3.4%) suffered from another pulmonary disease. Lower BMI, iGCs use, COPD, reduced FVC and severely impaired FEV1/FVC ratio were associated with OP. GCs treatment was associated with FF, regardless of the daily dosage.

Conclusion: Most of lung transplant candidates were suffering from OP and one third suffered from FF. Thus, performing DXA and VFA should be recommended in lung transplant candidates in order to start adequate osteoporosis treatment before lung transplantation. This is even more important in COPD patients, as this population displays an increased risk of OP compared to other end-stage diseases. OP diagnosis is important in those patients as their risk of fracture is likely to increase after transplantation. The large proportion of untreated (or insufficiently treated) patients stressed the need to develop specific strategies in this field. Finally, controlling some risk factors is crucial for the management and prevention of OP, for instance by, at least, tapering the dosage of both oral and inhaled GCs.

Table 1.

	All Patients (n=198)	OP patients (n=118)	Non-OP (n=80)
Age, y (median and IQR)	58.0 (53.3-62.0)	59.0 (54.2-62.0)	57.0 (52.0-62.0)
BMI, kg/m² (mean ± SD)	23.1 ± 4.7	22.2±4.6	24.3±4.6
GCs use, n (%)	154 (77.8)	94 (79.7)	60 (75.0)
iGCs use, n (%)	155 (78.3)	99 (83.9)	56 (70.0)
COPD, n (%)	153 (77.3)	102 (86.4)	44 (55.0)
FEV1, % PV (median and IQR)	23.0 (19.0-35.0)	22.0 (19.0-28.0)	28.0 (20.0-52.7)
FVC, % of PV (median and IQR)	60.0 (49.0-75.0)	58.0 (48.0-71.0)	64.0 (50.0-77.2)
FEV1/FVC ratio (median and IQR)	41.0 (35.0-57.0)	40.0 (35.0-48.0)	49.5 (35.7-93.2)
T-score ≤ -2.5, n (%)	54 (27.3)	54 (45.8)	NA

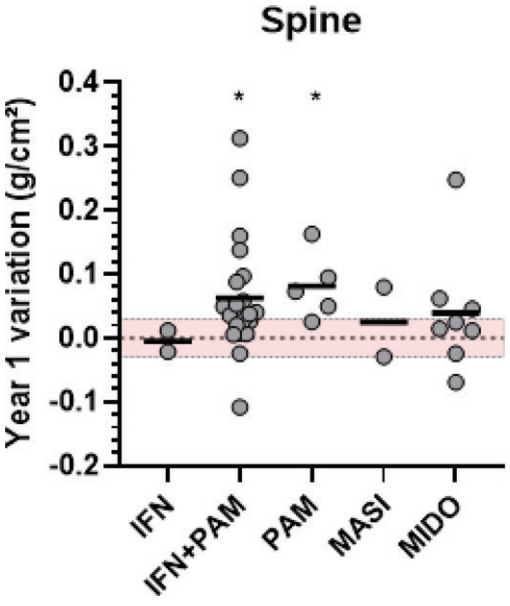
MANAGEMENT OF OSTEOPOROSIS IN PATIENTS WITH SYSTEMIC MASTOCYTOSIS: A MONOCENTRIC EXPERT CENTRE EXPERIENCE

Keywords: Bone diseases, Osteoporosis, Rare/orphan diseases

C. Nezzar[1], P. Alary[1], A. Ruyssen-Witrand[1], G. Couture[1], M. Severino-Freire[2], M. Laroche[1], A. Constantin[1], C. Bulai Livideanu[2], Y. Degboe[1]. [1]*CHU de Toulouse, Rheumatology, Toulouse, France;* [2]*CHU de Toulouse, Dermatology and Mastocytosis Expert Centre (CEREMAST), Toulouse, France*



Background: Systemic mastocytosis (SM) is a rare clonal mast cell disease, associated with vertebral osteoporosis (OP) in ~30% of the patients. This OP frequently leads to multiple vertebral fractures, in particular in young or premenopausal patients. To date, experts in the field recommend the use of bisphosphonates as first line therapy [1], or alternatively interferon alfa [2]. However, data regarding treatments efficacy, and regarding the optimal strategy are scarce. Especially, usefulness of mastocytosis-specific treatments is still to be established.

Objectives: To evaluate the clinical and the densitometric efficacy of various treatment regimen for osteoporosis, over 1 year, in patients with systemic mastocytosis.

Methods: We retrospectively analysed demographic, clinical (including new fragility fractures occurrence), biological and densitometric data of patients from our expert centre (CEREMAST), from 2010 to 2022. All patients fulfilled the WHO criteria for systemic mastocytosis and had osteoporosis defined as either a history of fragility fracture or a T-score <-2.5 SD. We evaluated bone mineral density (BMD) by DXA, and the occurrence of fracture, at initiation and after 1 year of exposure to the following treatment for SM-related osteoporosis: interferon alfa 2a (IFN), combination of interferon & monthly pamidronate (IFN+PAM), pamidronate (PAM, monthly in 4 patients, quarterly in 1), masitinib (MASI), and midostaurin (MIDO). IFN+PAM was proposed preferentially to patients with severe osteoporosis and multiple vertebral fractures. PAM was proposed in case of refusal of IFN, or contra-indication to IFN, or additional cause of osteoporosis for which IFN use would not be relevant. Values are reported as mean (+/-SD). Least significant change for BMD was 0.03 g/cm². Baseline and year-1 BMD were compared by a paired t-test. A p-value <0.05 was considered as significant.

Results: We included 37 osteoporotic patients with SM. Thirty-four patients had an indolent SM, 1 had a SM with associated haematological neoplasm, and 2 had an aggressive form. The mean age at diagnosis was 53.5 (+/-12.7) years, with 54.1% of women. Mean lumbar T-score was -2.4 (+/-1.7). Mean hip T-score was -1.8 (+/-0.8). Importantly, 81.1% had history of fragility fractures, and among them 96.6% had vertebral fractures. The mean number of vertebral fractures was 3.6 (+/-3.1) per patient. Two patients were exposed to IFN, 21 to IFN+PAM, 5 to PAM, 2 to MASI, and 9 to MIDO. Among patients treated by MIDO, 2 had prior exposure to IFN+PAM. One patient from the MIDO group and 1 patient from the MASI group were concomitantly exposed to bisphosphonates (respectively alendronate and zoledronate). Regarding treatments efficacy, IFN+PAM and PAM significantly improved BMD (see Figure 1). Two patients treated by IFN+PAM developed an additional vertebral fracture during the first year of follow-up, at 6- and 8-months post-treatment initiation. Importantly, these patients had 4 and 7 vertebral fractures prior treatment.

Conclusion: Our data show that monthly pamidronate, and combination of interferon & pamidronate improve BMD and may reduce fracture risk over 1 year in SM. Conversely, our data do not support the use of interferon monotherapy or midostaurin as preferred strategy in patients with severe osteoporosis. Usefulness of masitinib, and of recent tyrosine kinase inhibitors needs further studies in this population.

POS0497

ROMOSOZUMAB AS A TREATMENT AFTER BISPHOSPHONATE OR FOR OSTEOPOROSIS WITH T-SCORE≦-2.5 IN CLINICAL PRACTICE

Keywords: Real-world evidence, Rheumatoid arthritis, Osteoporosis

Y. Hirano[1], Y. Saito[1]. [1]*Toyohashi Municipal Hospital, Rheumatology,Toyohashi, Japan*

Background: Romosozumab (ROMO) is an antisclerostin antibody that is used in the treatment of severe osteoporosis (OP). In March 2019, ROMO was approved for use in Japan for treating severe OP in clinical practice, causing an increase in its prescription in our institute. Although efficacy data for ROMO have been presented in clinical trials, there is a lack of real-world data. In our experience, ROMO treatment results in significant bone mineral density (BMD) gain in some patients, but not all. Therefore, understanding the efficacy of ROMO treatments in groups of patients frequency treated with ROMO in real-world clinical practice is essential.
Objectives: This study investigated the efficacy of a 12-month ROMO treatment in patients with OP and explored the efficacy as a treatment after bisphosphonate (BP) or for OP with T-score≦-2.5.
Methods: Our study included 64 patients with OP, who were started on ROMO treatment between June 2019and August 2021. The following information was collected: 1) baseline characteristics, 2) time-course of BMD (lumbar spine [LS] and total hip [TH]) and bone turnover markers (BTM; bone-specific alkaline phosphatase [BAP], type I procollagen-N-propeptide [P1NP], type I procollagen-N-propeptide [NTX], and tartrate-resistant acid phosphatase-5b [TRACP-5b]), 3) BMD outcomes as a treatment after BP or for OP patients with T-score≦-2.5.
Results: 1) The mean age of the participants was 72.4 years (59 female and five male). Of the 64 understudied patients, 84.4% had past insufficiency fractures, whereas 29.7% had been treated with concomitant prednisolone. Furthermore, 22 patients had primary OP, 24 had rheumatoid arthritis, 15 had glucocorticoid-induced OP, and three had other conditions. Pretreatments for OP were BP (44 patients), denosumab (6), selective estrogen receptor modulator (5), activated vitamin D (2), none (5), and daily teriparatide (1). 2) Both mean LS- and TH-BMD significantly increased in the patients for whom ROMO administration was continued for 12 months. The average percentage changes of LS- and TH-BMD were +6.6% and +1.6% at six months and +11.0% and +2.7% at 12 months, respectively. However, BAP and P1NP increased steeply at one month, followed by a gradual decrease. As observed, the average percentage changes of BAP and P1NP were +68.7% and +167.8% at one month, +47.6% and +84.3%at six months, and +20.2% and +41.5% at 12 months, respectively. The results also showed that TRACP-5b decreased from one to 12 months, with the average percentage changes being -15.1% at one month, -3.5% at six months, and -6.2% at 12 months. Moreover, NTX, a bone-resorptive marker, was slightly increased during ROMO treatment. 3) In 44 patients treated with ROMO after BP, the average percentage changes of LS- and TH-BMD were +5.7% and +1.7% at six months and +9.2% and +2.4% at 12 months, respectively. The average percentage changes of BAP and P1NP were +74.0% and +189.9% at one month, +39.5% and +65.3% at six months, and +17.7% and +36.6% at 12 months, respectively. TRACP-5b decreased from one to 12 months, with the average percentage changes being -14.7% at one month, -2.8% at six months, and -6.6% at 12 months. In 23 patients with baseline LS T-score≦-2.5, the average percentage changes of LS-BMD were +6.3% at six months and +11.8% at 12 months. 21.7% of patients reached LS T-score>-2.5 at 12 months. In 24 patients with baseline TH T-score≦-2.5, the average percentage changes of LS-BMD were +2.3% at six months and +3.1% at 12 months. 20.8% of patients reached LS T-score>-2.5 at 12 months.
Conclusion: ROMO treatments rapidly increased BMD, especially LS-BMD, and changed BTM after one month in both treatment after BP and OP with T-score≦-2.5.

POS0498

RISK WEIGHT CALCULATION OF CANDIDATE VARIANTS FOR INCIDENT MAJOR OSTEOPOROTIC FRACTURE IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Prognostic factors, Validation, Osteoporosis

I. Yoshii[1], N. Sawada[2]. [1]*Yoshii Clinic, Musculoskeletal Medicine, Shimanto City, Japan;* [2]*Dohgo Onsen Hospital, Rheumatology, Matsuyama, Japan*

Background: Incidental osteoporotic fractures are one of the serious comorbidities in patients with rheumatic disease (RD). However, no comprehensive treatment criteria exist to prevent these fractures.
Objectives: The purpose of this study is to develop criteria and assess the validity of the criteria using retrospective cohort data.
Methods: Patients with RDs who were treated for more than one year were picked up in the study. The patients were followed up with blood tests including cystatin C (CysC) every 3 months. Bone mineral density (BMD) using dual-energy X-ray absorptive densitometry was measured annually. Comorbidities, presence of prevalent osteoporotic fracture, and habitual tastes such as alcohol drinking and current smoking were picked up at the initiation of treatment (baseline). The primary endpoint was incidental osteoporotic fractures (inc-OF). Patients were followed up until December 2022, unless censored by death, loss of follow-up, or dropping out due to admission to a nursing home. Candidate risk factors, with these significant differences between groups with OF and without OF, were demonstrated using Mann-Whitney U-test, for incident OF and were evaluated using a cox regression analysis with the univariate model. Risk weights of each factor were calculated using risk ratio and beta-value. The total risk weight for each patient (TRW) was determined by summarizing the risk weight of each factor. Receiver operating characteristics (ROC) analysis was tested in order to determine the area under the curve (AUC) and the cut-off index (COI). Finally, a chi-square test was also performed in regard to anti-osteoporotic drug administration after baseline (OPD).
Results: A total of 1228 patients in these 345 males and 883 females were included. The mean age at baseline was 77.7 years old, and the mean follow-up period was 40.2 months. Background RDs were 761 with rheumatoid arthritis, 163 with psoriatic arthritis, 99 with Sjogren syndrome, 65 with pustulosis palmaris et plantaris, 48 with systemic lupus erythematosus, 24 with ankylosing spondylitis, 19 with systemic sclerosis, 16 with ulcerative colitis, 12 with Behçet's disease, 4 with polymyositis/dermatomyositis, 3 with mixed connective tissue disease, 3 with familial Mediterranean fever, and 1 with polyarteritis nodosa. Picked-up factors were the presence of pre-OF, estimated glomerular filtration rate using CysC (eGFR), T-score in the lumbar spine (LS) and in the femoral neck (FN), number of comorbidities (nCom), presence of diabetes mellitus (DM), hypertension (HT), hyperlipidemia (HL), chronic obstructive pulmonary diseases (COPD), insomnia, cognitive impairment (CI), musculoskeletal ambulation disability symptom complex (MADS), disuse, neuromuscular diseases (NMD), and polypharmacy (PPs) at baseline. Risk ratios, beta-values, p-values, and calculated risk weights in these factors were shown in Table 1. The mean TRW in patients was 66.7 in the group with inc-OF and 138.4 in the group with no incident OF (p<0.001). The AUC was 0.787 and the COI was 93.6 with 80.4% and 68.8% of sensitivity and specificity, respectively (p<0.001). OPD was administrated in 341 patients of the 471 TRW positive group in whom 299 did not have inc-OF, whereas, in the 164 patients of the 757 TRW negative group, only 10 had inc-OF.
Conclusion: A novel evaluation system for osteoporosis treatment should be a numerical system that summarizes adding risk weight of each candidate factor.

Table 1. Risk ratios, beta-values, p-values, and calculated risk weights in variants

variant	risk ratio	beta	p	risk weight
eGFR≦72.0	2.06	0.719	<0.001	28

POS0499 DIFFERENCES IN FRACTURE RISK IN PATIENTS WITH DISCORDANT BONE MINERAL DENSITY IN THE HIPS: OBSERVATIONAL STUDY

Keywords: Osteoporosis, Epidemiology, Bone diseases

A. Saeed[1], M. Bukhari[1]. [1]*Lancaster University, Faculty of Health and Medicine, Bailrigg, United Kingdom*

Background: Osteoporosis is a condition characterised by low bone mineral density (BMD) and is associated with increased risk of fractures and subsequent increased morbidity and mortality. The usual sites of BMD measurements are either the non-dominant hip or the spine. The hip is used to predict fracture risk using the FRAX™ tool. Some patients have a different BMD as shown by their T scores in the contralateral hip.
Objectives: This study aimed to ascertain whether patients significantly discordant in their BMD on the contralateral hip have a different risk for fractures.
Methods: Data from a dual-energy x-ray absorptiometry (DEXA) scanner in the North West of England were used. Patients who were referred between 2004-2011 were studied. Patients had both hips scanned as well as risk factors and presence of fracture recorded. Data collected included age, sex, height, weight, BMI, history of fractures, rheumatoid arthritis status, smoking status, alcohol use and malabsorption. Those that had a BMD T-score difference of either greater than or equal +1 SD or -1SD were considered to have discordant hips. These two groups were compared using independent sample t-tests for continuous variables and chi-squared tests for categorical variables. Logistic models were then fitted to look at the odds of fracture in each group.
Results: The hip T-scores of 35759 patients were measured. Mean age was 62.17 (±12.78) with 84.16% being female. There were 15287 (42.75%) who had discordant hips. The odds ratio for the measured risk factors and the association with fracture are shown in **Table 1** below.

Table 1. Odds ratio of risk factors for patients with non-discordant and discordant hips

Risk factor	Whole Group	Non-Discordant	Discordant	Odds Ratio (95% CI)
Age (Years) Mean (SD)	62.17 (±12.78)	63.11 (±12.86)	60.92 (±12.55	0.987 (0.985-0.988)
Height (cm) Mean (SD)	161.87 (±8.30)	162.30 (±8.36)	161.31 (±8.17)	0.986 (0.983-0.988)
Weight (Kg) Mean (SD)	70.35 (±15.33)	71.40 (±15.74)	68.96 (±14.64)	0.989 (0.988-0.991)
BMI (Kg/m^2) Mean (SD)	26.80 (±5.25)	27.06 (±5.38)	26.45 (±5.04)	0.978 (0.974-0.982)
Female (%)	84.16	83.09	85.60	1.209 (1.141-1.282)
Alcohol Use (%)	5.02	6.96	2.41	0.331 (0.294-0.371)
Rheumatoid Arthritis Status (%)	4.27	5.34	2.83	0.516 (0.461-0.578)
Smoking Status (%)	26.24	36.13	12.99	0.264 (0.250-0.279)
Fracture (%)	34.08	32.11	36.72	1.227 (1.174-1.282)
Family History of Osteoporosis (%)	11.88	16.29	5.97	0.327 (0.302-0.352)
Steroid Use (%)	21.05	23.52	17.75	0.702 (0.666-0.740)
Malabsorption (%)	10.66	14.14	6.01	0.388 (0.359-0.419)

Conclusion: Hip discordance might be associated with adverse risk factors such as increased frequency of fractures. Measuring BMD of both hips could give a better estimate of future fracture risk. Further analysis of a subset from this group will be explored and presented.

POS0500 OSTEOPOROSIS IS UNCOMMON IN EARLY CLONAL MAST CELL DISORDERS

Keywords: Osteoporosis, Rare/orphan diseases, Bone diseases

Y. Degboe[1,2], M. Severino-Freire[3], G. Couture[1], P. A. Apoil[4], N. Gaudenzio[2], O. Hermine[5], A. Ruyssen-Witrand[1], A. Constantin[1,2], C. Paul[3], M. Laroche[1], C. Bulai Livideanu[3]. [1]*CHU de Toulouse, Rheumatology, Toulouse, France;* [2]*INSERM UMR1291, Infinity, Toulouse, France;* [3]*CHU de Toulouse, Dermatology and Mastocytosis Expert Centre (CEREMAST), Toulouse, France;* [4]*CHU de Toulouse, Immunology, Toulouse, France;* [5]*AP-HP Necker Hospital, Department of Hematology and Mastocytosis Expert Centre (CEREMAST), Paris, France*

Background: Indolent systemic mastocytosis (ISM) is a hematological disease frequently associated with vertebral osteoporosis (OP) and subsequent vertebral fractures. The natural history of this OP remains unclear. Importantly, we do not know whether OP represents an early event triggered alongside mast cell abnormalities. Experts in the field recently introduced the debated concept of "pre-ISM" to refer to patients with abnormal clonal mast cells and clinical repercussions who do not fulfill the criteria for ISM [1]. These patients can be considered as having an early clonal mast cell disorder (cMCD).
Objectives: To describe OP in patients with cMCD and to compare osteoporosis characteristics of early cMCD patients to those of ISM patients.
Methods: We retrospectively analyzed clinical, biological and densitometric data of 40 cMCD and 135 ISM patients from the mastocytosis expert center (CEREMAST) in Toulouse. Data normality was tested by a Shapiro-Wilk normality test. Comparisons between subgroups were performed using: Student's t-test for the normally distributed data, a non-parametric Wilcoxon rank-sum test for non-normally distributed data, and Fisher's exact test (or chi-square test if appropriate) for dichotomous variables. A p-value <0.05 was considered statistically significant with a 95% confidence interval (CI).
Results: OP (12.5 vs 34.1%) and vertebral fractures (5.0 vs 18.5%) were significantly less frequent in the early cMCD population. Most patients with OP and vertebral fractures in the cMCD group had the usual risk factors for OP.

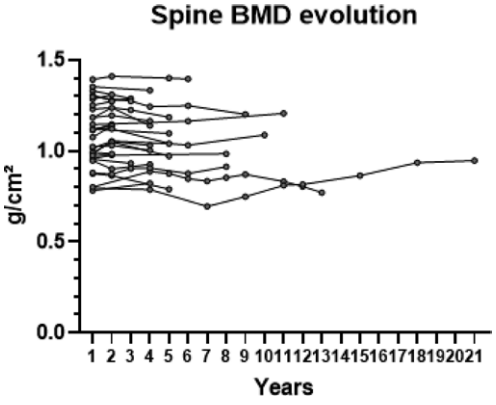

Figure 1.

Crosslaps levels were similar, but bone marrow tryptase was higher in the ISM group (159 ng/mL +/- 310 *vs* 1481 +/- 4910; p<0.0001). Short-term (1 year) and long-term (see Figure 1) analysis of BMD in the cMCD group, showed stable BMD over time. Interestingly, the only cMCD patient with a typical ISM-like OP had high bone marrow tryptase, developed bone marrow KIT mutation during follow-up, and had a family history of ISM. Our data show that OP is not a common clinical finding in early cMCD. When OP and fractures occur in cMCD, they differ from the usual phenotype of ISM bone fragility.
Conclusion: Our findings suggest that in most early cMCD patients, the meaning and management of OP differ from that of OP in ISM. Prospective longitudinal studies and the validation of predictors are needed to identify the minority of cMCD patients developing ISM-related OP.

POS0501 INVESTIGATING THE PREDICTORS OF ONE VERSUS MANY FRACTURES IN MALES REFERRED FOR BMD ASSESSMENT: AN OBSERVATIONAL COHORT STUDY

Keywords: Bone diseases, Epidemiology, Osteoporosis

A. Khan[1], H. Amin[1], N. Rossi[1], M. Bukhari[1]. [1]*Royal Lancaster Infirmary, Rheumatology, Lancaster, United Kingdom*

Background: Currently there exists limited data around predictors of osteoporosis as well as fragility fractures in men.[1] It is therefore important to understand the determinants of poor bone health in males and thus predicators of fractures to help deliver optimal care. Males referred for Bone Mineral Density (BMD) estimation are a good source of exploring such predictors of fractures. We sought to investigate the determinants of one versus many fractures in a population of males routinely referred for BMD estimation using Dual X-Ray Absorptiometry (DEXA) scans.
Objectives: The aim of this study is to assess the predictors of one vs multiple fractures in males routinely referred for DEXA scans, in an observational cohort.

Methods: Data was obtained from patients referred to secondary care in the northwest of England who subsequently were assessed for low BMD via DEXA. Males referred between 2004 and 2019 were selected and data collected at attendance included patients' full medical history and body habitus. Logistic models reporting odds ratio were used to examine the predictive factors for one versus multiple fractures in the cohort.
Results: A total of 5390 male patients were included in this analysis, the median age at scan was 66 years and the mean age was 76.6 +/- 13.7 (SD). A total of 1853 fractures occurred in our population of males. Varying modifiable and non-modifiable factors were identified as predictors of fractures. Modifiable factors included those who drank excess alcohol. Patients who had a history of excess alcohol consumption were more likely to have multiple fractures OR: 1.260 (CI: 1.02-1.26) (p= 0.030). Furthermore, BMD at the left neck of femur was protective for multiple fractures OR: 0.938 (CI: 0.89-0.99) (p= 0.018). Interestingly the BMD at the right neck of femur was not predictive of multiple fractures. In terms of non-modifiable risk factors, height was statistically significant in being protective against fractures in this cohort OR: 0.991 (CI: 0.98-0.99) (p= 0.016). Rheumatoid arthritis, steroid use, family history and coeliac disease all produced insignificant results when predicting one versus many fractures in this male cohort. A summary of the results can be seen in Table 1.

Table 1. A summary of the predictors of fractures in males referred for BMD assessment.

Predictor	Odds Ratio	Confidence Interval	p-value
Excess Alcohol	1.260	1.02-1.26	0.030
BMD L NOF	0.938	0.89-0.99	0.018
BMD R NOF	0.966	0.91-1.03	0.255
Height	0.991	0.98-0.99	0.016

Conclusion: This study identifies factors predictive of multiple fractures among males referred for BMD assessment. Our analysis shows that a history of excess alcohol consumption, altered BMD results at the left neck of femur, and height were statistically significant in the prediction of multiple fractures. Our previous study also found a relationship between excess alcohol consumption and patterns of fractures in males. Further research is required to better understand both this link and alcohol's importance in the pathophysiology of osteoporosis in men. Such research is also imperative in hypothesising specific factors relating to fractures adjusted and unadjusted for age.

POS0502 IMPLEMENTATION OF A CLINICAL CARE PATHWAY FOR SYSTEMATIC BONE FRAGILITY ASSESSMENT AT THE INITIATION OF ANDROGEN DEPRIVATION IN PROSTATE CANCER PATIENTS (HORMOS PROJECT)

Keywords: Osteoporosis, Bone diseases, Best practices

O. Fogel[1], C. Dariane[2], J. E. Bibault[3], S. Kreps[3], C. Thibault[4], C. Gervais[4], A. Rochand[4], C. Meynard[3], E. Rapeaud[3], S. Hmila[2], F. Audenet[2], S. Oudard[4], A. Mejean[2], C. Roux[1], M. O. Timsit[2], K. Briot[1]. *[1]Cochin Hospital, Rheumatology, Paris, France; [2]European Hospital Georges-Pompidou, Urology, Paris, France; [3]European Hospital Georges-Pompidou, Radiation Oncology, Paris, France; [4]European Hospital Georges-Pompidou, Clinical Oncology, Paris, France*

Background: Androgen deprivation therapy (ADT) in prostate cancer (PCa) is associated with an increased risk of bone fragility including bone loss, osteoporosis and fractures. Although international recommendations suggest performing dual-energy x-ray absorptiometry (DXA) at the initiation of treatment, less than 10% of patients do it. The implementation of a standardised clinical care pathway could help prevent bone-related complications in patients starting ADT.
Objectives: To improve screening for bone fragility in patients starting ADT for PCa by setting up a clinical care pathway. To describe the characteristic of patients with PCa starting ADT.
Methods: The radiation oncologists, medical oncologists or urologists from a tertiary center systematically referred all patients starting any ADT for PCa to our rheumatology department for a bone-health assessment including a DXA and clinics with a bone specialist. The effectiveness of the pathway was assessed by the number of patients who performed DXA at the initiation of ADT.
Results: Between March and December 2022, 116 of the 119 patients (97%) referred to our department were able to have a bone assessment within an average of 36 +/- 15 days. The three patients not seen in the care pathway did not wish to come for a new medical appointment. Among the 116 patients, mean age at first visit was 75+/-7 years old, mean BMI 26.9 +/- 4.7 kg/m^2, 56% were previous or current smoker and Charlson Comorbidity Index was 4.75 +/- 2.5 with 20% diabetes, 15% peripheral vascular disease, 11% coronaropathy and 10% chronic kidney disease. Regarding PCa, 65% were on a localized or locally-advanced stage while 35% were metastatic and overall, 44% presented with a high risk histo-pronostic score (ISUP 4 or 5). Sixty-four patients (55%) were scheduled to concomitant prostatic external beam radiation, as initial or salvage therapy. Median PSA at diagnosis was 16 ng/ml (8.8-38.5) At inclusion, 70% of patients were newly-diagnosed PCa while 30% were recurrent PCa. ADT was prescribed alone for 65% of patients or in combination with new hormone-therapy (NHT) for 35% of patients and 26% with concomitant corticosteroids with a mean dose of 10 +/-4 mg. The mean duration of previous ADT for relapsing patients was 16 +/- 20 months. Regarding bone disease, 11% patients had previous bone fracture mainly in the spine, 15% had familial history of hip fracture and 20% reported a fall within the past year. Forty-two percent of patients had vitamin D supplementation but only one was previously treated with an anti-osteoporotic agent. Finally, 114 patients had a DXA. A lumbar BMD T-score ≤-2.5 was found for 9 patients, ≤ -2 for 17 patients. A hip BMD T-score ≤ -2.5 was found for 12 patients and ≤ -2 for 35 patients. A T-score ≤ -2.5 to at least one site was found in 18 patients (16%) and ≤ -2 for 41 patients (35%). After BMD assessment, an anti-osteoporotic treatment was prescribed in 40% of patients with bisphosphonate (71%) or denosumab (29%).
Conclusion: This clinical care pathway allowed 97% of patients to have a bone assessment when starting ADT for PCa. This cohort of 116 patients confirms the high prevalence of low BMD among these patients and the need to screen and treat patients to prevent bone-related complications.

POS0503 RISK OF CARDIOEMBOLIC ISCHAEMIC STROKE AMONG NEW USERS OF ORAL BISPHOSPHONATES: A NESTED CASE-CONTROL STUDY

Keywords: Cardiovascular disease, Osteoporosis, Epidemiology

S. Rodriguez-Martin[1], D. Barreira-Hernández[1], R. Mazzucchelli[2], M. Gil[3], A. García-Lledó[4], L. Izquierdo-Esteban[5], A. Pérez-Gómez[6], A. Rodríguez-Miguel[7], F. De Abajo[8,9]. *[1]Hospital Universitario Príncipe de Asturias, 1.Department of Biomedical Sciences (Pharmacology), Alcalá de Henares, Spain; [2]Hospital Universitario Fundación Alcorcón, Rheumatology, Alcorcon, Spain; [3]Agencia Española de Medicamentos y Productos Sanitarios (AEMPS), Pharmacoepidemiology and Pharmacovigilance, Madrid, Spain; [4]Hospital Universitario Príncipe de Asturias, Cardiology, Alcalá de Henares, Spain; [5]Hospital Universitario Príncipe de Asturias, Neurology, Alcalá de Henares, Spain; [6]Hospital Universitario Príncipe de Asturias, Rheumatology, Alcalá de Henares, Spain; [7]Hospital Universitario Príncipe de Asturias, Clinical Pharmacology Unit, Alcalá de Henares, Spain; [8]Alcalá University, Biomedical Sciences, Alcalá de Henares, Spain; [7]Hospital Universitario Príncipe de Asturias, Clinical Pharmacology Unit, Alcalá de Henares, Spain*

Background: Bisphosphonates have been associated with atrial fibrillation, but studies carried out thus far have not shown that they are also associated with an increased risk of ischaemic stroke (IS). None, however, separated by IS subtype (cardioembolic vs non-cardioembolic).
Objectives: The present study aimed to test the hypothesis that use of oral bisphosphonates (oBs) increases specifically the risk of cardioembolic IS.
Methods: A nested case-control study was performed using the Spanish primary healthcare database BIFAP (period: 2002-2015). Incident cases of IS were identified and classified as cardioembolic or non-cardioembolic. Five controls per case were randomly selected, matched for exact age, sex, and index date (first recording of IS). The association of IS (overall and by subtype) with the use of oBs within the last year before index date was assessed by computing the adjusted odds ratios (AOR) and their corresponding 95%CI using conditional logistic regression. Only oBs initiators were considered. (Figure 1).
Results: A total of 4,568 cardioembolic IS cases (matched with 21,697 controls) and 9,213 non-cardioembolic IS cases (matched with 44,212 controls) were included. For cardioembolic IS, the use of oBs was associated with an AOR of 1.35(1.10-1.66), in a duration dependent manner (AOR≤1year=1.10;0.82-1.49; AOR>1-3years=1.41;1.01-1.97; AOR>3years=1.81;1.25-2.62; p for trend=0.001). Such increased risk only appeared when patients used concomitantly calcium supplements and was completely blunted by anticoagulants. No increased risk was observed for non-cardioembolic IS (AOR=1.03;0.88-1.21).
Conclusion: The long-term use of oBs with calcium supplements increases the risk of cardioembolic IS, while leaves materially unaffected the risk of non-cardioembolic IS.

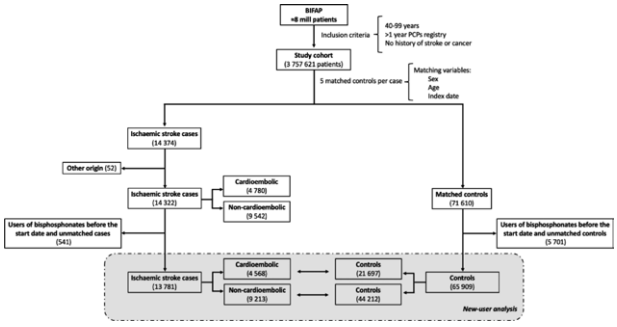

Figure 1.

POS0504 COMPARISON BETWEEN « SYSTEMATIC » VERSUS « RECOMMENDATION-BASED » VERTEBRAL FRACTURE ASSESSMENT REALIZATION DURING DUAL ENERGY X-RAY ABSORPTIOMETRY EXAMINATION

Keywords: Osteoporosis, Bone diseases

M. Mina[1], P. Salpetier[1], L. Seidel[2], M. Leroy[1], L. Leonori[1], M. Malaise[1], C. Ribbens[1], O. Malaise[1]. *[1]University Hospital of Liège, Rheumatology Department, Liège, Belgium; [2]University Hospital of Liège, Biostatistic Department, Liège, Belgium*

Background: Realization of a thoraco-lumbar lateral view X-ray (Vertebral Fracture Assessment, VFA) when performing Dual Energy X-ray Absorptiometry (DEXA) is proposed in international guidelines to detect asymptomatic vertebral fractures. However, there is no clear consensus regarding indications of its realization.
Objectives: First, we compared the efficiency of a systematic VFA realization during DEXA versus its realization according to different criteria available in literature. Second, we looked after risk factors associated with vertebral fractures.
Methods: 401 successive patients underwent DEXA with a thoraco-lumbar lateral view X-ray (VFA). Medical files were retrospectively reviewed to determine if the patient should have benefited from a VFA according to the ISCD (International Society for Clinical Densitometry) 2007 criteria, ISCD 2015, NOF (National Osteoporosis fundation) 2014, SFR (French Society of Rheumatology), NHG (Nederlands Huisartsen Genootschap) 2nd revision or NHG 3rd revision.
Results: Among 401 successive patients who underwent systematic VFA, a vertebral fracture was observed in 71 patients (17.7%). 74, 54, 62, 73, 12 and 53% of patients should have undergone a VFA according to the ISCD 2007, ISCD 2015, NOF 2014, SFR, NHG criteria 2nd revision and NHG 3rd revision respectively. With the exception of the NGH 2nd revision criteria which only identified 28.2% of fractures, there was no significant difference in fracture detection between "systematic VFA" and "VFA realized following the recommendations" groups. Criteria sensitivity varied between 81.7 and 91.6% of detection, with the best detection performance for SFR criteria. The ISCD 2015 criteria presented the best sensitivity/ specificity ratio of detection. The NHG2 criteria were the most specific (40.8% of VFA positive for fracture) but they lack of sensitivity, compared to systematic use, missed the detection of 51 fractures (12.7%). The detection of a vertebral fracture was significantly more frequent in patients with low bone mineral density at lumbar spine, femoral neck, but also wrist. Age, menopause, height loss, hip fracture in a parent, back pain, COPD, active smoking and inhibitor of proton pump (PPI) use were also associated with higher fracture detection.
Conclusion: VFA realization based on literature criteria has a detection sensitivity between 82 and 92% (with the exception of the NHG 2nd revision criteria), with the SFR criteria having the best detection capacity and the ISCD 2015 criteria the best sensitivity/ specificity ratio. Use of the VFA realization criteria may help to better determine the selection of patients requiring a VFA: VFA realization based on these criteria did not detect significantly less fracture that the systematic VFA realization. Low bone density, loss of height and history of hip fracture in parents were associated with vertebral fracture. Among medical history, attention should be paid to COPD, smoking and PPI use, also associated with the demonstration of a vertebral fracture.

POS0505 FREQUENCY OF DYSMOBILITY SYNDROME IN PATIENTS WITH RMD AND ITS RELATIONSHIP WITH FRACTURES AND FRAILTY

Keywords: Sarcopenia, Comorbidities, Osteoporosis

B. Buehring[1,2], R. Parvaee[2], C. Mueller[2], I. Andreica[2], D. Kiefer[2], U. Kiltz[2], S. Tsiami[2], M. Pourhassan[3], T. Westhoff[3], R. Wirth[3], X. Baraliakos[2], N. Babel[3], J. Braun[2]. *[1]Krankenhaus St. Josef, Bergisches Rheuma-Zentrum, Wuppertal, Germany; [2]Ruhr-Universität Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany; [3]Ruhr-Universität Bochum, Marienhospital Herne, Herne, Germany*

Background: Dysmobility Syndrome (DS) is a novel concept to characterize musculoskeletal (MSK) health. DS includes parameters for osteoporosis, sarcopenia and falls [1]. It has been associated with fractures and mortality in community dwelling older adults [2-4] but has never been applied to patients with rheumatic and musculoskeletal diseases (RMD).
Objectives: To study the prevalence of DS and the association of DS with frailty and major osteoporotic fractures (MOF) in patients with inflammatory and non-inflammatory RMD.
Methods: Patients with inflammatory and non-inflammatory RMD aged 65 and older were recruited at a tertiary rheumatology hospital. DS was defined using published cut-offs [1, 2] of the following parameters: Osteoporosis (DXA T-score ≤ -2.5), obesity (DXA % body fat > 30% in men; > 40% in women), low appendicular lean mass (ALM/height^2 <7.26 kg/m^2 in men; < 5.45 kg/m^2 in women), low grip strength (< 30kg in men; < 20kg in women), slow gait speed (< 1.0 m/s) and falls (history of one or more falls within last year). A score of ≥ 3 was defined as having DS. The FRAIL-scale[5] was used to quantify frailty. Historical data on MOF as defined by FRAX (https://frax.shef.ac.uk/frax/) was collected.
Results: 141 patients (103 women/38 men) were included in the analysis. Mean age was 73 years. Of the total population, 80% had an inflammatory RMD (of those 45% had Rheumatoid Arthritis) as their primary diagnosis. Patients with non-inflammatory diseases had either degenerative spine and/or joint disease and/or fibromyalgia. Mean disease duration was 5 years. Mean DS score was 2.8 (for more demographic data see Table 1). 81/141 (57.5%) participants met DS criteria. DS was more common in women compared to men (63.1 vs. 42.1%, p= 0.0252) and in inflammatory RMD compared to non-inflammatory (61,1 vs. 42.9%, p=0.0811). Patients with DS reported fractures twice as often as those without DS (33,3 vs. 16.6%, p=0.0261). The frequency of individuals with a history of MOF increased with DS score (see Figure 1). Additionally, there was a significant association between DS and FRAIL scores in a univariate linear regression analysis (R^2=0,22, p<0.001).
Conclusion: This primary study to explore the prevalence of DS in patients with RMD showed that more than half of participants met DS criteria. Similar to studies of community dwelling older adults, fractures were more common in patients with DS. Importantly, a positive association of frailty and DS was seen. Further studies are needed to examine whether DS can be used clinically to better characterize overall MSK health in patients with RMD and whether a standardized management of DS will improve outcomes in these patients.

POS0506 RISK FACTOR ANALYSIS OF FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Bone diseases, Osteoporosis

S. Takahara[1], A. Uefuji[1,2], N. Nakagawa[1,2]. [1]*Hyogo Prefectural Kakogawa Medical Center, Orthopaedic Surgery, Kakogawa, Japan;* [2]*Hyogo Prefectural Kakogawa Medical Center, Reumatology, Kakogawa, Japan*

Background: Patients with rheumatoid arthritis (RA) commonly develop osteoporosis and fragility fractures due to differentiation and induction of osteoclast, steroid use, and inactivities of daily life [1-3]. The prevalence of osteoporosis during long-term RA has been reported to be as high as 19-32%, and RA patients have 1.5-2.3 times the risk of fracture as non-RA patients. However, the relationship between bone mineral density and fracture risk in RA patients is not clear, and there are few reports on bone mineral density and fracture location in RA patients.

Objectives: To investigate the incidence of fracture and fracture site in RA patients, and to explore the risk factors for fragility fractures in RA patients.

Methods:

1. A total of 4785 RA patients were included. We extracted new incidence of fracture from medical record and investigated the location of fractures.
2. A total of 4270 patients including non-RA patients who had dual-energy X-ray absorptiometry (DEXA) were analyzed. The RA group was divided into two groups: RAfx+ group with fracture and RAfx- group without fracture. Young Adult Mean (YAM) values were compared between groups based on DEXA data from 3634 patients in the non-RA group, 147 patients in the RAfx+ group, and 489 patients in the RAfx- group.
3. The demographics, and clinical characteristics of 636 RA patients who had DEXA were investigated. Bone mineral density (YAM value), osteoporosis treatment intervention, steroid use, biologic drug use, the levels of anti-CCP (cyclic citrullinated peptide) antibody, and BMI (body mass index) were analyzed between two groups.

Results:

1. Of the 4785 RA patients, a total of 550 fractures occurred in 384 patients (8.0%). The mean age was 70.5 and 63 years old in the fracture and non-fracture groups, respectively, and was significantly higher in the fracture group (p<0.01). The most common fracture sites were vertebral (205 fractures), following 57 proximal femur fractures, 55 thoracic fractures, and 41 pelvic fractures.
2. The %YAM of femur was 73.9% in the non-RA group, 67.7% in the RAfx+ group, and 76.0% in the RAfx- group, and %YAM of lumber spine was 85.5% in the non-RA group, 81.0% in the RAfx+ group, and 88.1% in the RAfx- group, with the RAfx+ group having significantly lower values (p < 0.01). After age and sex matching, 147 patients were allocated to each group, respectively. Young adult mean (YAM) values of femur were 67.7/73.7% and those of lumbar spine were 81.0/86.0% in group A/B, both of which were significant (p<0.01, 0.01, respectively).
3. In univariate analysis, a history of osteoporosis intervention, especially denosumab use, and a history of steroid use were associated with fracture incidence (p = 0.02, 0.002, 0.03, respectively) significantly. In multivariate analysis, YAM value of femur (OR: 0.386), a history of steroid use (OR: 2.04), and osteoporosis intervention (OR: 0.413) were significantly associated with the incidence of fractures.

Conclusion: New fractures occurred in 8.0% of RA patients, with vertebral fractures being the most common. RA patients with fractures had significantly lower femoral/lumbar YAM values than RA patients without fractures. steroid use, low femoral bone density, and lack of osteoporosis intervention were factors significantly associated with fracture occurrence in RA patients.

POS0507 OSTEOPOROSIS IN SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY IN A MONOCENTRIC CENTER. ANY ROLE FOR CALCINOSIS?

Keywords: Bone diseases, Systemic sclerosis, Osteoporosis

M. Cadar[1], G. Pellegrino[1], D. M. Reza Beigi[1], I. Bisconti[1], F. R. DI Ciommo[1], S. Truglia[1], F. Conti[1], V. Riccieri[1]. [1]*Sapienza University of Rome, Clinical Internal, Anesthesiological and Cardiovascular Sciences, Roma, Italy*

Background: Systemic sclerosis (SSc) is a rare and progressive autoimmune disease, that has been associated with an increased risk of osteoporosis (OP), but risk factors are still debated [1,2].

Objectives: The aim of our study was to investigate the risk factors for osteoporosis in SSc and to evaluate if any feature of the disease could increase the risk of osteoporosis.

Methods: In this cross-sectional study we included 60 consecutive patients, fulfilling the 2013 ACR/EULAR classification criteria of SSc[3], attending our Rheumatology Unit from July to December 2022. All the 60 patients performed a Dual-energy X-ray absorptiometry (DXA) between 2020 and 2022. Osteoporosis was defined as a T score less than -2.5 SD and osteopenia as a T-score between -1.0 and -2.5 SD, according to WHO definitions. We divided patients in two groups according to the diagnosis of osteoporosis (OP+) and non osteoporosis including osteopenia (OP-). We collected the main clinical-demographic and laboratory features of the patients and we assess the presence of any association with OP.

Results: All 60 patients were women with an average age (mean±SD) of 70.5±10.1 years, 35 had a diagnosis of osteoporosis (OP+ group) and 25 patients were included in OP- group, in which 17 patients had osteopenia. The two groups were comparable for age, disease duration, menopause and smoking habit. We found statistically significant differences between the two groups with BMI (21.97±3.47 in OP+ vs 24.04±3.63 in OP-, p=0.04), modified Rodnan Skin Score (mRSS) (8.91±12.19 vs 3.20±4.71, p=0.03) and presence of calcinosis (12 in OP+ vs 1 in OP-, p=0.005), pitting scars (17 vs 5, p=0.03) and telangiectasia (28 vs 13, p=0.02). Performing simple logistic regression analyses we confirmed the association of calcinosis (OR 12.52, CI 2.2-237.3, p=0.02), pitting scars (OR 2.02, CI 1.08-11.97, p=0.04) and telangiectasia (OR 2.24, CI 1.21-12.09, p=0.02) with the presence of OP. There was no difference between the two groups for NVC scleroderma pattern, autoantibodies and presence of digital ulcers. (Table 1).

Conclusion: This retrospective study confirms the association of OP with lower BMI in SSc. An increased mRSS and the presence of calcinosis, telangiectasias and pitting scars were also associated to OP in our patients. These SSc features deserve to pinpoint an early evaluation of bone health in our patients and an early referral to DXA, independently from the traditional risk factors of OP. Of interest, in our opinion, is the rather high prevalence of calcinosis in the OP+ group, confirming data from other authors[4] and suggesting a possible common pathogenically pathway in calcinosis development.

A RANDOMISED CONTROLLED TRIAL COMPARING ANAKINRA VERSUS STEROIDS FOR THE TREATMENT OF GOUT ATTACKS IN PEOPLE WITH RENAL DISEASE (ASGARD): A FEASIBILITY STUDY

Keywords: Gout, Randomized control trial, Kidneys

G. Balasubramaniam[1,2], M. Almond[3], P. Harnett[4], J. Zhang[5], D. Turner[6], J. Scales[7], C. Moore[2], K. Hayden[2], E. Roddy[8], C. Mallen[8], N. Ng[9], S. Bhagat[10], A. Rutherford[11], B. Dasgupta[2]. *[1]Mid and South Essex NHS Trust, Kidney Centre, Basildon, United Kingdom; [2]Anglia Ruskin University, School of Medicine, Chelmsford, United Kingdom; [3]Anglia Ruskin University, Veterans and Family Institute for Military and Social Research, Chelmsford, United Kingdom; [4]Princess Elizabeth Hospital, Medicine, St. Peter Port, Guernsey; [5]Anglia Ruskin University, Medical Technology Research Centre, Chelmsford, United Kingdom; [6]University of East Anglia, Norwich Medical School, Norwich, United Kingdom; [7]University of Essex, School of Health and Social Care, Colchester, United Kingdom; [8]Keele University, School of Medicine, Staffordshire, United Kingdom; [9]Guy's and St Thomas' NHS Foundation Trust, Department of Rheumatology, London, United Kingdom; [10]West Suffolk NHS Foundation Trust, Department of Rheumatology, Bury St Edmunds, United Kingdom; [11]King's College Hospital NHS Foundation Trust, Department of Rheumatology, London, United Kingdom*

Background: Title: A study to determine the feasibility of undertaking a definitive randomised multi-centre, double-blind, double-dummy controlled study of Anakinra vs. intramuscular methylprednisolone acetate for acute gout attacks in patients with chronic kidney disease. Gout is common in people with chronic kidney disease (CKD) where effective treatments like non-steroidal anti-inflammatory drugs are contra-indicated. Anakinra, an IL-1 receptor antagonist, could be an important treatment option for treating gout flares in people with CKD (eGFR<60mls/min/1.73m2).
Objectives: Aim: to assess the feasibility of the design and procedures for a future definitive randomised trial of anakinra in people with moderate to severe CKD. Specific objectives were to: test recruitment and retention; test eligibility criteria; collect outcome data to inform sample and power calculations for a future trial; collect economic data to inform a future economic evaluation; and assess capacity for to scale up to a larger trial.
Methods: Design: two-parallel group, double-blind, double-dummy, multicentre randomised feasibility trial comparing subcutaneous anakinra 100mg for 5 days with a single injection of intramuscular methylprednisolone acetate 120 mg for treating gout flares in people with CKD (eGFR <60mls/min/1.73m2). Participants were planned to be recruited from five sites in the South East region of the UK over 15 months, the target sample size was 32. Proposed primary outcome was self-assessed pain intensity using Visual Analogue Scale (VAS) (0–100mm) and 5-point Likert scale. Proposed secondary outcome measures consisted of physician assessment of joint; assessment of activity limitation and quality of life using Health Assessment Questionnaire Disability Index, 36-Item Short Form Survey, Five-level EuroQol Five-Dimensional Questionnaire and Lower Extremity Functional Scale.
Results: 21 patients were randomised (anakinra 10, depo-Medrone 11), 3 were lost to follow-up. Mean age was 72 years and mean eGFR was 43.6 mls/min/1.73m2. The first metatarsophalangeal joint was the commonest joint affected (10/21). 2 participants were taking urate-lowering therapy although 16 reported previous flares. Mean overall change in pain from baseline was 35.88 by VAS and 1.69 by Likert scale. Functional assessment and quality of life assessment was highly completed. The baseline assessment was low for the SF-36 and HAQ-DI, the LEFS showed a trend of improvement and the HAD-QI showed a decline from day 7 to week 8. Health resource use was higher when assessed by health records compared to self-reporting. Qualitative feedback from participants alluded to high questionnaire burden and delays in receiving treatment. There were no serious adverse events or reactions. One patient needed rescue medication 10 days later for recrudescence of flare in the anakinra arm. We met three out of its four success criteria: recruiting at least 70% of eligible patients; 85% of participants completing 5 out of 7 pain outcome measure; and ≤10% treatment cross-over or failure.
Conclusion: Our study did not meet its entire feasibility target due to poor recruitment. This was compounded by various factors which may be possible to overcome. Aspects to rationalise the study would be utilising VAS and patient reported Likert, without physician assessment of joints. Functional assessment and quality of life assessment could be reconciled to using EQ-5D-5L and SF-36 at day 1, day 7 and week 8 minimising the questionnaire burden. We did not find good functional assessment with the LEFS and HAQ-DI, the gout flare score may be a possible alternative, bearing in mind the impact of questionnaire burden. A future definitive trial may be feasible if we are able to overcome challenges in recruitment, better ways of case finding, and initiating randomised treatment during gout flare. Our study is the first gout study looking specifically at people with advanced CKD and showed good safety and efficacy with these agents for this group of patients.

POS0509

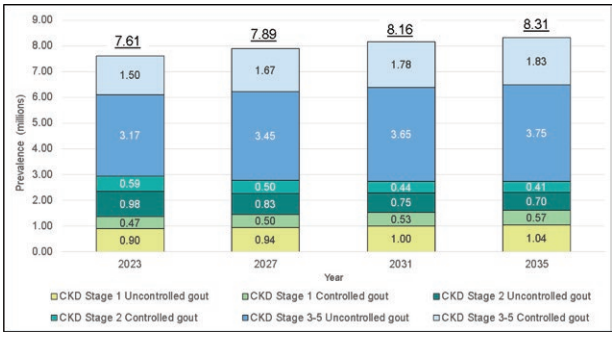
PROJECTING THE FUTURE HEALTH AND ECONOMIC BURDEN OF CONTROLLED AND UNCONTROLLED GOUT IN THE CHRONIC KIDNEY DISEASE POPULATION IN THE US: PRELIMINARY RESULTS USING MICROSIMULATION MODELLING METHODS

Keywords: Kidneys, Gout, Epidemiology

J. Card-Gowers[1], L. Webber[1], L. Retat[1], M. Piotrowski[1], B. Lamoreaux[2], B. Marder[2], A. Kumar[2]. *[1]HealthLumen Ltd, Epidemiological Modelling, London, United Kingdom; [2]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: Chronic kidney disease (CKD) and gout are major public health concerns. The prevalence of gout (4%) and hyperuricemia (20%) is high in the general population and progressively increases as kidney function decreases [1,2]. An increasing number of people in the US are living with both gout and

CKD, posing a significant health and quality of life (QoL) burden to patients while putting economic pressure on the healthcare system. Moreover, current gout management in the US is sub-optimal, with a large number of gout patients remaining untreated, undertreated, or uncontrolled [3].



Objectives: To quantify the2023-2035 health and economic burden of controlled and uncontrolled gout in the US CKD population.

Methods: A validated microsimulation model was used to project gout burden in the US CKD population, which was reproduced virtually using United Nations data [4]. Each individual was assigned estimated glomerular filtration rate (eGFR), albuminuria, and serum urate (SU) values, which were extracted through analysis of the US NHANES (2011 to 2018). The prevalence of self-reported gout by age, sex, and CKD stage was also examined. Controlled and uncontrolled gout costs, eGFR decline rates, tophi and flare probabilities were drawn from the literature. Uncontrolled gout was defined as SU >6 mg/dL and ≥2 flares/yr or the presence of tophi. The microsimulation was run between2023 and 2035.

Results: The simulation predicts a 9.2% growth in the prevalence of gout and CKD in the US between2023 and 2035, from 7.6 million to 8.3 million patients, respectively. By 2035, 10.2% of CKD patients (5.5 million) are projected to have uncontrolled gout (**Graph 1**), an annual average increase of 37,000 patients each year to 2035. This compares with 5.2% of CKD patients (2.8 million) with controlled gout by 2035. The number of people living with gout and advanced CKD (stages 3-5) is projected to grow by 19.4%, from 4.7 million patients in2023 to 5.8 million patients by 2035, of which the majority (67.2%) will have uncontrolled gout. Factors driving this increase are predominantly population growth and ageing. Tophi and flare occurrence are similarly projected to increase. The resulting combined direct and indirect costs of gout in CKD patients are projected to increase from $43.5 billion in2023 to $47.5 billion by 2035. This equates to a cumulative cost of $594.4 billion over the next 12 years, of which 76% is due to uncontrolled gout **(Table 1)**. If all gout in CKD was controlled, the US could save $169.9 billion between2023 and 2035.

Table 1. Annual costs of controlled and uncontrolled gout in CKD (2023 US$, Billions)

Year	Cost of controlled gout	Cost of uncontrolled gout
2023	10.5	33.1
2029	11.1	34.8
2035	11.5	36.0
Cumulative (2023 – 2035)	143.7	450.7

Graph 1. Gout prevalence, by CKD stage (1, 2, and 3-5), in the US, between2023 and 2035

Conclusion: In US CKD patients, gout prevalence and symptoms (tophi, flares) are projected to rise markedly between2023 and 2035, posing a substantial and increasing health, economic, and QoL burden. Uncontrolled gout is projected to contribute most to the health and economic burden of gout in CKD. Urate-lowering interventions may help reduce this burden by lowering the proportion of uncontrolled gout. Such measures would therefore reduce costs and healthcare utilisation while leading to QoL improvements in CKD patients with gout.

POS0510 INTERMITTENT FASTING REDUCES CRYSTAL-INDUCED INFLAMMATION

Keywords: Gout, Crystal arthritis, Diet and nutrition

N. Pham[1,2], T. W. Chirayath[1], F. Castelli[3], F. Fenaille[3], A. L. Nguyen[3], F. Brial[1], A. Latourte[1], F. Lioté[1], P. Richette[1], T. Bardin[1], H. K. Ea[1]. *[1]INSERM URM1132 - BIOSCAR, Lariboisière Hospital, Paris, France; [2]Haiphong University of Medicine and Pharmacy, Internal Medicine Department, Haiphong, Vietnam; [3]Laboratoire d'études du Métabolisme des Médicaments UMS 28, CEA Saclay, Gif-sur-Yvette, France*

Background: Inflammation induced by monosodium urate (MSU) and calcium pyrophosphate (CPP) crystals depends on interleukin (IL)-1β activated by the NLRP3 inflammasome. The inflammatory response can be modulated by diet, fasting, and caloric restriction.

Objectives: To determine whether intermittent fasting reduces MSU and CPP crystal-induced inflammation.

Methods: Crystal-induced inflammation was assessed using both types of crystals *in vivo* in the air pouch model in 8-week-old wild-type male mice fed either with a normal ad libitum diet or intermittent fasting (IF) (every over day fast, 2 days during 1 week). Inflammatory cytokine production (IL1β and CXCL-1) was assessed in the pouch lavages and the cellular infiltrate analyzed by histology (H&E staining). Metabolomic analyses were performed by high-performance liquid chromatography coupled to high-resolution mass spectrometry (LC-HRMS) on air pouch membrane, serum, and liver samples. Changes in metabolites associated with diet interventions were studied by the Metaboanalyst platform and we established the metabolic profiles for each experimental condition. In vitro, human monocytes THP-1 were stimulated by sterile synthetic crystals of MSU and CPP while the production of inflammatory cytokines was quantified by ELISA. To assess the role of glutamine/glutamate metabolism pathway related to IF in microcrystalline disease, the concentrations of glutamine/glutamate in synovial fluids (SF) from patients with gout, CPP-related disease and osteoarthritis (OA) were quantified by ultra-performance liquid chromatography coupled to tandem mass spectrometry (UPLC-MS/MS).

Results: Inflammation induced by MSU and CPP crystals was drastically decreased by IF compared with normal diet: IL-1β (MSU 0.0 vs. 30.0 pg/ml; CPP 0.0 vs. 47.5 pg/ml p<0.0001); CXCL-1 (MSU 67.5 vs. 186.8 pg/ml, CPP 156.1 vs. 549.5 pg/ml, p<0.005); as were cell infiltration assessed by number of cells in the air pouch lavages (MSU 0.2 x 10^6 vs. 1.1 x 10^6; CPP 0.4 x 10^6 vs 2.9 x 10^6; p<0.0001) and membrane histology semi-quantitative score (MSU 0.6 vs 3.0; CPP 0.8 vs 2.7; p<0.0001). Reduction of inflammation by IF was associated with significant changes in membrane, serum and liver metabolites. IF increased ketone bodies (hydroxybutyric acid) as well as cholic acid, acetyl glycine, hydroxy caproic acid. In contrast, IF decreased carbohydrate metabolites, as well as glutamate and succinic semi-aldehyde. Many metabolic pathways were altered by IF such as galactose, starch, sucrose, aspartate, glutamate, alanine and arginine metabolism. Interestingly, the glutamine and glutamate metabolic pathway was enriched in serum, membrane and liver compartments. Glutamine/glutamate involvement in microcrystal-induced inflammation was evidenced in SFs. SF concentration of glutamine was decreased during gout and CPP flares compared to OA effusion (gout 352.3 µM and CPP 357.5 µM vs OA 509.3 µM, p<0.0001 and p<0.0001 respectively) while the concentration of glutamate increased in gout (gout 212.5 µM vs 58.0 µM, p<0.0001; CPP 66.1 vs 58.0 µM, p=0.4). The glutamine/glutamate ratio was decreased in synovial fluids of crystal-related diseases compared to OA (gout 1.4 and CPP 6.1 vs OA 9.4, p<0.0001 and p<0.05 respectively). *In vitro*, crystal-induced inflammatory cytokine production was decreased by overnight serum deprivation (IL-1β: MSU 1446 vs 5464 pg/ml; CPP 3670 vs 7797 pg/ml, p<0.005; TNF-α: MSU 7.0 vs 47.0 pg/ml; CPP 15.6 vs 89.3 pg/ml, p<0.05; IL-8: MSU 2896 vs 9781 pg/ml; CPP 3984 vs 6820 pg/ml, p<0.01). The inhibition of crystal-induced IL-1β production by serum deprivation was abrogated when cells were treated with 3-MA, an autophagy inhibitor (MSU 1446 vs 4912 pg/ml; CPP 3670 vs 9367 pg/ml, p<0.005).

Conclusion: Intermittent fasting alleviates crystal-induced inflammation by altering many metabolic pathways, particularly those associated with glutamine and glutamate. Further studies are needed to determine how IF modulates metabolism to dampen crystal-induced inflammation.

POS0511 LIFESTYLE MODIFICATION FOR THE PREVENTION OF CARDIOVASCULAR DISEASE IN PATIENTS WITH GOUT

Keywords: Lifestyles, Gout, Cardiovascular disease

S. M. Jung[1], K. J. Kim[1], J. S. Yun[2]. *[1]St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Suwon, Korea, Rep. of (South Korea); [2]St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Division of Endocrinology, Department of Internal Medicine, Suwon, Korea, Rep. of (South Korea)*

Background: High morbidity and mortality of cardiovascular (CV) disease in patients with gout draw attention to CV risk management in daily clinical practice.
Objectives: To evaluate the effect of a favorable lifestyle on the incident CV events in patients with gout.
Methods: We identified 9,110 patients with gout from UK Biobank Cohort based on the combination of self-report and/or hospital diagnostic codes. Lifestyle behaviors defined by smoking status, physical activity, obesity and diet were categorized into favorable (≥ 3 healthy factors), intermediate (2 healthy factors), and unfavorable patterns (0-1 healthy factor). CV risk was estimated in participants with and without gout according to serum uric acid (SUA) levels and lifestyle patterns.
Results: Incidence rate of CVD was significantly higher in patients with gout than in participants without gout (11.38 vs 5.49 per 1000 person-year). A positive correlation was observed between SUA level and CV risk in the general population, whereas CV risk was consistently high in gout population, regardless of SUA level. A favorable lifestyle was associated with lower CV risk in both patients with gout and participants without gout. In all categories of SUA levels (< 6mg/dL, normal; 6-8.9 mg/dL, high; ≥ 9mg/dL, very high), CV risk was significantly lower in gout patients with a favorable lifestyle than in those with a unfavorable lifestyle.
Conclusion: Patients with gout are at high risk of CVD even with SUA levels in the normal range. Lifestyle modification can be an effective and inexpensive therapeutic strategy to prevent CV events in patients with gout.

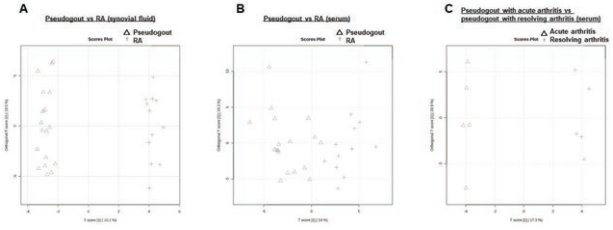
POS0512 DIAGNOSTIC AND DIFFERENTIAL BIOMARKERS IDENTIFIED BY METABOLOMIC ANALYSIS IN PATIENTS WITH PSEUDOGOUT

Keywords: Biomarkers, Crystal arthritis, -Omics



S. Takahashi[1,2], M. Takahashi[2], Y. Tanimoto[1], T. Yamaoka[1], M. Katayama[1], S. Hatachi[1], M. Shinohara[3,4], S. Kumagai[1,2]. *[1]Shinko Hospital, The Center for Reumatic Disease, Kobe, Japan; [2]Shinko Hospital, The Shinko Institute for Medical Research, Kobe, Japan; [3]Kobe University Graduate School of Medicine, The Integrated Center for Mass Spectrometry, Kobe, Japan; [4]Kobe University Graduate School of Medicine, Division of Molecular Epidemiology, Kobe, Japan*

Background: Pseudogout is an acute arthritis induced by calcium pyrophosphate dehydrate crystal deposition (CPPD) [1]. Pseudogout most commonly involves one or several large joints, such as the knee or wrist, typically tender and swollen [2]. The pathogenic mechanism of CPPD is partially understood, and the etiology of attacks is unclear. There is no diagnostic serum biomarker for pseudogout. CPPD disease is best diagnosed by identifying positively birefringent, typically rhomboid-shaped crystals in the synovial fluid of affected joints. However, CPPD disease and rheumatoid arthritis (RA) often coexist, and the similarity of pseudogout with acute flares of RA might lead to misdiagnosis.
Objectives: To identify the metabolites which characterize pseudogout compared with RA and to identify serum biomarkers of pseudogout using metabolomic analysis of serum and synovial fluid.
Methods: We collected serum and synovial fluid from 18 pseudogout patients and 12 RA patients with acute flares. We also collected serum from five pseudogout patients after resolving arthritis. We performed a metabolomic analysis of the samples using gas chromatography-mass spectrometry (GC-MS). Metabolites contributing to the differentiation between pseudogout with acute arthritis, pseudogout with resolving arthritis, and RA were determined by analysis of the orthogonal partial least-squares discriminant analysis (OPLS-DA) weightings (variable importance in the projection (VIP)>1, the absolute value of modeled correlation (|p(corr)|) > 0.5 in the S-plot) and Wilcoxon rank sum test ($p < 0.05$).
Results: A total of 123 metabolites from synovial fluid and 101 metabolites from serum were identified by GC-MS. By using OPLS-DA (Figure 1) and Wilcoxon rank sum test, nine metabolites from synovial fluid and 19 metabolites from serum were selected as the metabolites that contributed to the differentiation between pseudogout and RA, and nine metabolites from serum were selected as the metabolites that contributed to the differentiation between pseudogout with acute arthritis and pseudogout with resolving arthritis. Among the selected metabolites, we identified five metabolites which characterized pseudogout compared with RA and two metabolites which elevated in pseudogout with acute arthritis compared with both RA and pseudogout with resolving arthritis.
Conclusion: By metabolomic analysis, we identified metabolites that differentiate pseudogout from RA and the potential serum diagnostic biomarkers for pseudogout.

POS0513 QUALITY OF LIFE AND CLINICAL GOUT ASSESSMENT CHANGES IN UNCONTROLLED GOUT PATIENTS UNDERGOING PEGLOTICASE THERAPY AS PART OF THE MIRROR RANDOMIZED CONTROLLED TRIAL

Keywords: Quality of life, Gout, Randomized control trial

J. Botson[1], K. Obermeyer[2], B. Lamoreaux[3], L. Padnick-Silver[3], S. Verma[2], M. E. Weinblatt[4], J. Peterson[5]. *[1]Orthopedic Physicians Alaska, Rheumatology, Anchorage, United States of America; [2]Horizon Therapeutics Plc, Research and Development, Deerfield, United States of America; [3]Horizon Therapeutics Plc, Medical Affairs, Deerfield, United States of America; [4]Brigham and Women's Hospital, Division of Rheumatology, Immunology and Allergy, Boston, United States of America; [5]Western Washington Arthritis Clinic, Rheumatology, Bothell, United States of America*

Background: Refractory/uncontrolled gout can severely limit physical function and impact patient quality of life [1,2]. Unfortunately, limited treatment options exist for patients intolerant of or refractory to oral urate-lowering therapies. Pegloticase can lower serum urate (SU) in these patients [3] with demonstrated quality of life and physical function benefits [4]. The MIRROR RCT trial showed increased SU-response rates (71.0% vs. 38.5%) with lower infusion reaction risk (4.2% vs. 30.6%) when pegloticase was co-administered with methotrexate (MTX) vs. placebo (PBO), but patient-reported outcomes (PROs) from this study have not been reported [5].
Objectives: To report the prespecified PROs and gout-related clinical measures through Month 12 of pegloticase + MTX/PBO co-therapy in MIRROR RCT trial participants.
Methods: Patients with uncontrolled gout (sUA≥7 mg/dL, ULT failure/intolerance, and ≥1 of the following: ≥1 tophus, ≥2 flares in past year, chronic gouty arthritis) were administered pegloticase (biweekly 8 mg infusion) plus either oral MTX (15 mg/wk) or PBO. The study included 2-wk MTX tolerance, 4-wk blinded MTX/PBO Run-in, and 52-wk pegloticase+MTX/PBO Treatment periods. Key

exclusion criteria were being immunocompromised, G6PD deficiency, eGFR <40 ml/min/1.73m^2, or MTX contraindication. PROs included change from baseline (CFB) to Wk 52 in Health Assessment Questionnaire (HAQ) indices (secondary endpoints in ranked order: Disability [DI, score 0-3, MCID=0.22[4]], Pain [score 0-100, MCID=10[4]], Health [score 0-100, MCID=10[4]]). Physician Global Assessment of Gout (PhGA; score 0-10, MCID=1[4]), and tender [68 count]/swollen [66 count] joint counts [TJC/SJC], with decreases in measures reflecting improvement. Analyses were performed on the intent-to-treat population (ITT; all randomized patients). Least-square mean (±SE) CFB to Wk 52 was analyzed using a mixed-model for repeated measures, adjusting for baseline score, baseline tophi presence, treatment group, visit, visit by treatment group interaction, and visit by baseline interaction.

Results: 152 patients made up the ITT (100 randomized to MTX, 52 randomized to PBO). At baseline (before MTX exposure, Wk -6) HAQ scores indicated some disability, high pre-therapy pain, and somewhat poor overall health (mean [±SD] DI, Pain, Health: MTX: 0.7±0.7, 43.7±30.3, 44.9±28.6, respectively; PBO: 0.8±0.8, 40.5±28.6, 39.1±27.4, respectively). Baseline PhGA was similar between groups (MTX: 5.5±2.1, PBO: 5.4±2.2) but the MTX group had fewer affected joints (TJC: 6.7±8.4 vs. 11.0±15.9, SJC: 5.4±7.8 vs. 8.3±12.2). All HAQ measures progressively improved during treatment (**Figure 1**), but the treatment group difference in the Wk 52 CFB in HAQ-DI was not statistically significant, making further PRO analyses exploratory in nature. PhGA score improved (mean[±SE] Wk 52 CFB: -4.2±0.2 vs.-3.8±0.3), with a median observed score of 1.0 and 1.0 in the MTX and PBO groups, respectively, at Wk 52. TJC and SJC markedly declined during Treatment (mean[±SE] CFB TJC: -6.1±0.5 vs. -7.0±0.8, SJC: -5.1±0.4 vs. -6.0±0.6; MTX vs. PBO, both p >0.21), declining to a mean (±SD) TJC at Wk 52 of 1.4±4.6 and SJC of 1.4±4.5 in the MTX group and a TJC of 0.6±1.0 and SJC of 1.1±2.9 in the PBO group.

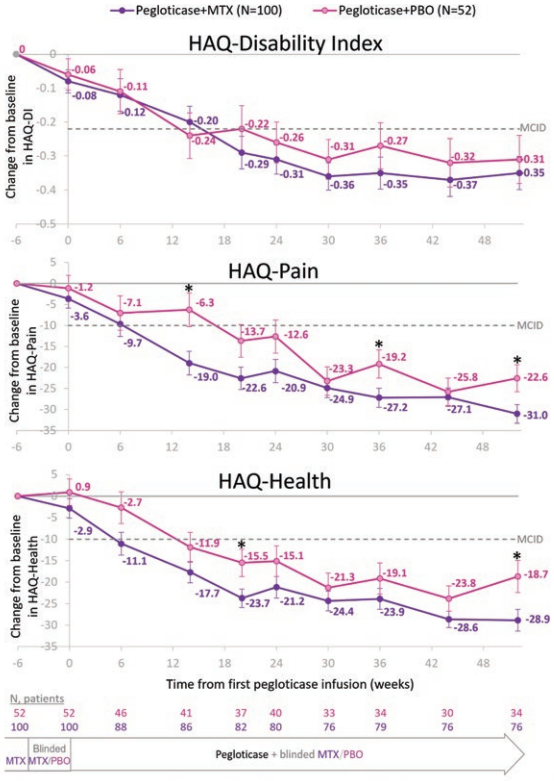

Figure. Change from baseline in HAQ-DI (**Top**), Pain (**Middle**), and Health (**Bottom**) during pegloticase+MTX and pegloticase+PBO co-therapy. Baseline was defined as prior to MTX exposure (Week -6), with Day 1 defined as first pegloticase infusion. Data points represent least-square mean change from baseline estimated analyzed using a mixed-model for repeated measures, adjusting for baseline score, baseline tophi presence, treatment group, visit, visit by treatment group interaction, and visit by baseline interaction. The dotted line represents MCID for each measure. Error bars represent standard error. *treatment group difference p<0.05. HAQ, Heath Assessment Questionnaire; CFB, change from baseline; DI, disability index; MCID, minimum clinically important difference; MTX, methotrexate; PBO, placebo.

Conclusion: Pegloticase treatment resulted in meaningful improvements in both clinical measures and quality of life in patients with uncontrolled gout. Patients co-treated with MTX experienced greater improvements in HAQ-Pain and Health scores after 52 wks of therapy, likely reflective of the higher urate-lowering response rate observed in the presence of MTX immunomodulation [5].

BONE EROSION REMODELING AFTER DEPLETION OF MONOSODIUM URATE DEPOSITION WITH INTENSIVE URATE-LOWERING WITH PEGLOTICASE IN PATIENTS WITH UNCONTROLLED GOUT: MIRROR RCT DUAL-ENERGY CT FINDINGS

Keywords: Imaging, Gout

N. Dalbeth[1], J. Botson[2], K. Saag[3], A. Kumar[4], L. Padnick-Silver[4], B. Lamoreaux[4], F. Becce[5]. *[1]University of Auckland, Department of Medicine, Auckland, New Zealand; [2]Orthopedic Physicians Alaska, Rheumatology, Anchorage, United States of America; [3]University of Alabama at Birmingham, Department of Medicine, Birmingham, United States of America; [4]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America; [5]Lausanne University Hosptial, University of Lausanne, Department of Diagnostic and Interventional Radiology, Lausanne, Switzerland*

Background: Monosodium urate (MSU) crystal deposits can be visualized and quantified with dual-energy CT (DECT) [1], with DECT studies showing an association between MSU deposition and bone erosion [2]. Pegloticase rapidly lowers serum urate (SU) to near zero in uncontrolled gout patients (pts), with methotrexate (MTX) co-therapy recommended to increase SU lowering response rate (71% vs 39% with pegloticase+placebo [PBO]) and decrease infusion reaction risk (4% vs 31%; MIRROR RCT) [3]. MIRROR open-label trial (pegloticase+MTX co-therapy for ≤52 wks) DECT findings showed rapid, progressive MSU deposition volume (V_{MSU}) reduction with subsequent bone erosion remodeling in the 2 imaged pts [4]. The MIRROR RCT trial had a larger number of pts who underwent serial DECT imaging during pegloticase+MTX/PBO co-therapy, the findings of which are reported here.

Objectives: To examine V_{MSU} and bone erosion imaging findings of MIRROR RCT participants who underwent serial DECT imaging.

Methods: Pts were randomized 2:1 to receive oral MTX (15 mg/wk) or PBO as co-therapy to pegloticase (8 mg biweekly infusions). Serial images were obtained at DECT-capable sites using a standard acquisition protocol at prespecified time points during the 52-wk treatment period (Day 1 [first pegloticase infusion]; Wks 14, 24, 52). Bilateral hand/wrist, elbow, foot/ankle, and knee images were obtained. Images were post-processed using default settings and interpreted by an independent central reader blinded to treatment group and SU lowering response. V_{MSU} was measured in each scan. Up to 3 of the largest bone erosions per imaged region were assessed for evidence of remodeling, defined as a decrease in size, recortication, and/or new bone formation. Erosion size was evaluated as the product of the largest longitudinal and axial slice dimensions. Pts with baseline and Wk 52 images were included in analyses, excluding imaged regions with a baseline V_{MSU} <0.5 cm^3 to prevent large contributions of potential DECT artifacts [5]. DECT-imaged regions were also radiographed and photographed.

Results: 6 pts receiving pegloticase+MTX co-therapy and 2 pts receiving pegloticase+PBO co-therapy were included in analyses. In the MTX group, 5 pts had SU <6 mg/dL during Month 6 and received 52 wks of pegloticase+MTX co-therapy; 1 pt discontinued pegloticase+MTX at Wk 6 due to SU rise, continuing on allopurinol (mean SU on allopurinol = 4.6 mg/dL). In the PBO group, 1 pt had sustained SU-lowering through Month 6 and received 42 wks of pegloticase+PBO, continuing on febuxostat (mean SU on febuxostat = 5.2 mg/dL); 1 pt discontinued pegloticase+PBO at Wk 6 due to SU rise, continuing on allopurinol (mean SU on allopurinol = 3.0 mg/dL). V_{MSU} markedly decreased during therapy in both treatment groups (Wk 52, MTX: -94% ±9% [9 imaging regions of 6 pts], PBO: -96% ±3% [4 imaging regions of 2 pts]). Evidence of concomitant bone erosion remodeling (**Figure 1**) was observed in 69% (29/42) of evaluated erosions (9/12

[75%] imaged regions; 6/8 [75%] pts). Of the 29 erosions with remodeling, 100% had a decrease in size (mean: -7% change at Wk 52), with recortication (4 erosions [14%]) and new bone formation (3 erosions [10%]) also observed in some erosions.

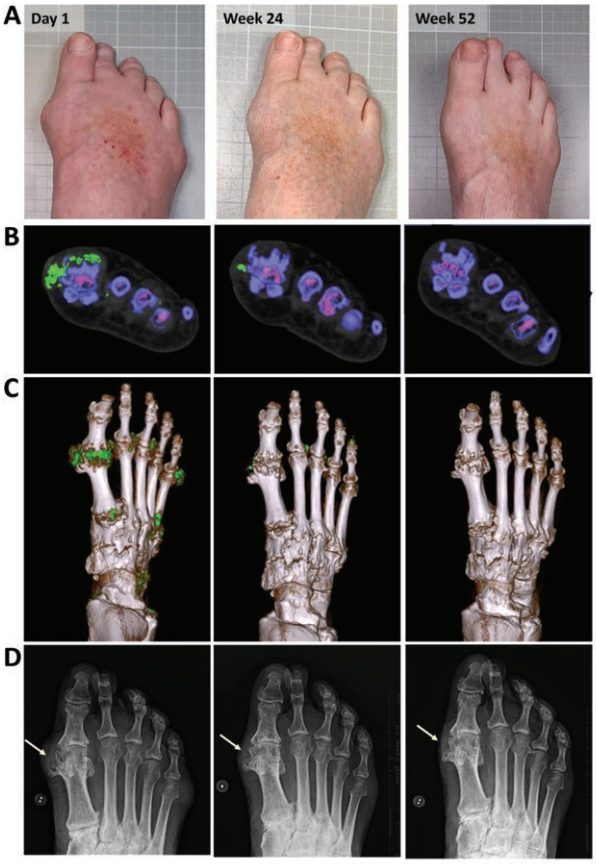

Figure. Serial photographs (**A**), DECT images (**B, C**), and radiographs (**D**) of the right foot of a patient who received 52-weeks of pegloticase (8mg biweekly infusion) and methotrexate (15 mg/week orally) co-therapy. The patient had sustained intensive urate-lowering during Month 6 and Month 12 (SU <1.0 mg/dL at Weeks 24, 52) and, by Week 52, bilateral feet monosodium urate crystal deposition volume had decreased to 0.3 cm^3 from a baseline of 23.5 cm^3 (**C**). Arrows indicate bone erosion remodeling at the first metatarsophalangeal joint.

Conclusion: In agreement with a prior serial DECT study [4], rapid and near complete V_{MSU} depletion was observed within 1 year of initiating pegloticase therapy. Concomitant bone erosion remodeling was also observed after 52 wks of intensive urate-lowering therapy. In these limited cases, DECT findings were similar between treatment groups. It is likely that SU-lowering, not MTX use, resulted in DECT changes, but further study is needed. However, these analyses suggest that bone remodeling is possible following MSU crystal depletion.

POS0515

THE POTENTIAL CAUSAL RELATIONSHIP BETWEEN PHYSICAL ACTIVITY, LEISURE SEDENTARY BEHAVIORS, AND GOUT

Keywords: Genetics/epigenetics, Gout

J. Y. Chen[1,2], Q. Feng[1,2], Z. Liu[1,2], Q. Yu[3], P. F. He[3], X. LI[1,2,4], S. X. Zhang[1,2,4].
[1]Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China; [2]Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, China; [3]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China; [4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China

Background: Gout is a type of inflammatory arthritis caused by the deposition of monosodium urate crystals onto diverse body joints [1]. Physical activity (PA) can reduce patients' pain caused by gout and Leisure sedentary behaviors (LSB) do harm to even normal people [2]. However, the genetic causality between PA/LSB and gout remains to be seen.

Objectives: In this study, we aimed to systematically evaluate the causal relationship between PA/LSB and gout.

Methods: We performed a two-sample Mendelian Randomization (MR) analysis to investigate the potential causality between PA/LSB and gout susceptibility. PA included five phenotypes: accelerometer-based PA, vigorous physical exercise (VPA), moderate to vigorous physical activity (MVPA), moderate physical activity 10+ minutes, and vigorous physical activity 10+ minutes. The summary data of PA were obtained from a genome-wide association study (GWAS) in UK Biobank [3]. LSB included four phenotypes: time spent watching television (TV), time spent using a computer, time spent driving, and time spent using a mobile phone. And the data of LSB was also derived from the GWAS of the UK Biobank. The gout GWAS (2,115 cases and 67,259 controls) was derived from the Global Urate Genetics Consortium. Single nucleotide polymorphisms (SNPs) that were independent ($r2 < 0.001$) and strongly related to PA/LSB ($p < 1 \times 10\text{-}7$, $F>10$) were selected as instrumental variables (IVs). Besides, we removed confounding IVs associated with alcohol, neutrophils, and BMI. The inverse variance-weighted (IVW), MR-Egger, and weighted median methods were employed to evaluate the causal effect between PA/LSB and gout. Among them, IVW is the principal method. Pleiotropic and heterogeneity assessment and sensitivity analyses were implemented with Cochran's Q test, MR-Egger intercept analysis, and the leave-one-out analysis.

Results: After removing confounders, the causality between genetically predicted accelerometer-assessed PA and risk of gout was indicated by IVW [OR=1.15, 95%CI: 1.02—1.31, p=0.0242]. No obvious causal relationship was observed between other PA/LSB and gout. (P>0.05) MR-Egger and weighted median were consistent with IVW results. No pleiotropy or heterogeneity of the IVs was found. Details of the results are shown in Figure 1.

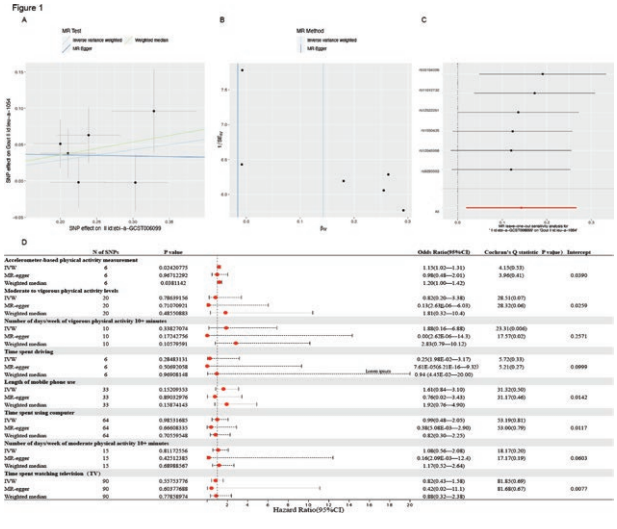

Figure 1. The causal associations between physical activity (PA), leisure sedentary behaviors (LSB), and gout were evaluated by the odds ratio (OR) values of IVW, MR-Egger, and Weighted median. Scatter plots (A), funnel plots (B), and leave-one-out analysis (C) from genetically predicted accelerometer assessed PA on gout.

Conclusion: Our findings supported a causal effect of accelerometer-measured PA on the increased risk of gout. No associations between other PA/LSB and gout were observed. Further research is needed to explore how physical activity affects gout.

POS0516 PERFORMANCE OF NURSE-LED GOUT CARE IN A PRIVATE HEALTHCARE SYSTEM. A RANDOMISED CONTROLLED TRIAL

Keywords: Non-pharmacological interventions, Gout, Randomized control trial

B. Ankli[1], N. Miehe[1], D. Kyburz[2], N. Daikeler[2], B. Bannert[2], T. Daikeler[2]. *[1]University of Basel, Faculty of Medicine, Basel, Switzerland; [2]Universitätsspital Basel, Department of Rheumatology, Basel, Switzerland*

Background: Nurse-led gout care has been studied mainly in managed healthcare systems [1].

Objectives: To investigate the effectiveness of a structured nurse-led gout programme in a private healthcare system.

Methods: A randomised single-blinded controlled trial with two study arms was performed. The inclusion criteria were the fulfilment of the 2015 ACR/EULAR gout classification criteria(2) and the indication for urate-lowering therapy (ULT). The inclusion period lasted 2 years and the intervention period 6 months. Physician FU visits took place at 6 and 12 months from baseline (BL). The achievement rate of the target serum acid level (SUA, ≤ 360 µmol/l) at the 6-month-FU served as the primary endpoint. In the intervention group, during the first six months after inclusion, a structured treat-to-target (T2T)-programme led by trained nurses was performed. In both groups, the patients were followed by their treating physicians without specific recommendations. We performed descriptive statistics. Categorical variables were reported as frequencies and compared using Fisher's exact test. Continuous variables were compared using Student's t-test or the Mann-Whitney U test in case of non-normal distribution.

Results: A total of 46 patients were included, of which 19 were randomised to the intervention group and 27 to the control group. Dropouts occurred in 6 patients in the intervention group and 3 in the control group. The median age was 69 years, and a pronounced male overrepresentation was found. 38% of the patients in the intervention group vs 53% in the control group were obese. Alcohol consumption was frequent in both groups (63% vs 59% of the patients). At BL, most patients were under an anti-inflammatory treatment (colchicine, steroids, NSAIDs). ULT was similar in both groups with a low median dosage of Allopurinol (250 mg/day at the 12 m FU). BL characteristics and outcomes are presented in *Table 1.*

Table 1. Baseline Characteristics and Outcome

Medians, (IQR), frequencies in %	BL		6-month-FU		12-month- FU	
Intervention (I)/ Controls (C)	I	C	I	C	I	C
n pat	19	27	16	23	17	24
Acute flare/arthritis	15(78.9%)	19(70.3%)	5 (31.3%)	7 (41.1%)	2 (12.5%)	4 (16.6%)
Oligo-/Polyarthritis	7	5	1	0	1	0
n pat with tophi	8 (42.1%)	5 (18.5%)	1	1	1	0
SUA [µmol/l]	**534.0(390.5; 606.3)**	487.0(411.0; 532.0)	**339.0 (285.8; 407.8)**	360.0 (304.0; 445.0)	342.5 (295.8; 415)	375.0 (268.5; 451.0)
GFR CKD EPI [ml/min/1.73m2]	**57.0** (44.8; 87.5)	**67.0** (43.0; 88.5)	65.5(51.3; 90.8)	75.0(56.0; 93.0)	65.5(53.0; 85)	70.0(62.0; 90.0)

Conclusion: There was no significant advantage over the standard of care regarding SUA reduction. However, the intervention patients showed twice as often impaired kidney function (grade 3-5) and tophaceous gout. Nevertheless, these patients reduced SUA levels better after 6 months (36% vs 26% reduction) and 64% of them achieved the SUA target after 12 months (vs 47% in the control group).

A. M. Herrero-Beites[1], C. Vazquez-Puente[2], M. D. C. Modesto-Caballero[2], F. Perez-Ruiz[2]. *[1]Gorlizeko Erietxea, Rehabilitation Division, Gorliz, Spain; [2]Cruces University Hospital, Rheumatology Division, Barakaldo, Spain*

Background: Non-rational prescription of tests in clinical practice may induce inefficient performances, misdiagnosis, and inappropriate consultations.

Objectives: We analyzed the prescription and results of antinuclear antibodies (ANA) prescription before first consultation to a rheumatology unit in a disease with commonly high diagnostic accuracy based on clinical findings: gout.

Methods: In the decade 2013-2022 the prescription and results of ANA testing prior to first rheumatology visit was added to the database, along with general data and variables related to comorbid conditions and clinical characteristics of gout. We made an analysis of variables plausibly associated with ANA prescription and biennial changes through n the rate of prescription.

Results: From Jan 2013 to Dec 2022, 504 patients gave written consent for data inclusion, 66 (13.7%) women and 415 men (86.3%), with mean age at entrance in the cohort of 73±14 and 65±14 years, respectively. ANA had been prescribed to 114 (23.7%) subjects, in 28/66 (42.4%) women and 86/415 men (p<0.001). No differences for prescription were observed in other variables, such as age, time from onset, flares per year, tophi, or polyarticular distribution. The rate of ANA prescription was not related to the diagnostic for consultation: arthralgia (24.4%), arthritis (21.7%) or gout (25.3%). 31/114 (27.2%) ANA tests were positive (90% with title <1/400), but only led to a new diagnosis (autoimmune hepatitis), and two had a previous diagnosis (Sjögren´s Syndrome and Systemic Lupus). The rate of positive ANA was much higher in women (12/28, 42.9%) than in men (8/86, 22.1%). The rate of ANA prescriptions showed a biennial and significative increase during the last decade (p= 0.007): 11.3% in 2013-14, 21.4% in 2015-16, 34.9% in 1016-2017, and 31.1% in 2021-22. A valley in ANA prescriptions was observed during SARS-COV2 pandemia 2019-2020 (19.7%).

Conclusion: In a rheumatic disease with quite typical clinical presentation as gout, the rate of ANA prescription prior to rheumatology consultation is unexpectedly high, and the highest in women, despite old age and absence of systemic clinic. The rate of positive ANA in the elder in our setting is quite high, especially in women, and may lead to misdiagnosis and inefficient management: a new VOMIT.

POS0518 TREATMENT OF GOUT AND ITS EFFECTS ON METABOLIC SYNDROME

Keywords: Gout, Cardiovascular disease, Crystal arthritis

R. Kuppuraju[1], P. May[2], T. Millliken[2], S. Kitancho[2], D. Bulbin[1]. *[1]Geisinger Medical Center, Rheumatology, Danville, United States of America; [2]Geisinger Medical Center, Population Health Sciences, Danville, United States of America*

Background: There is a known relationship between elevated serum urate (SUA) levels and renal, cardiovascular (CV), and metabolic disease. However, the precise reasons for this remain poorly defined. The CANTOS trial found a significant decrease in nonfatal MI, stroke, or CV death in patients (PTs) treated with canakinumab vs placebo. The LoDoCo2 trial found a decrease in CV death, nonprocedural MI, ischemic stroke, and ischemia-driven need for coronary revascularization in PTs treated with colchicine vs placebo. This suggests that inflammation is an independent risk factor for CV disease. The GOSPEL 4 trial found that French PTs with early-onset gout (EOG), a diagnosis (DX) < age 40, had slightly more arthritis, significantly less chronic stage 3 or 4 kidney disease (CKD) compared to common gout (CG) PTs, DX ≥ age 40. Metabolic syndrome was significantly more prevalent in the CG group. To our knowledge, no study has investigated the effects of EOG vs CG on incidence of metabolic-related diseases in a rural population in the US.
Objectives: To investigate whether early DX and control of gout results in lower incidence of metabolic-related diseases in a rural setting.
Methods: We conducted a retrospective analysis of PTs with gout at a rural tertiary care center. We identified PTs seen Jan 2016-Dec 2020 with a gout DX. Charts were reviewed for: sex; age at DX; age at the time of gout DX and at the last medical encounter; HbA1c level; SUA level; and BMI. Charts were reviewed for urate-lowering therapy (ULT) prescriptions, atherosclerotic cardiovascular disease (ASCVD)/peripheral arterial disease (PAD), diabetes mellitus (DM), hypertension (HTN), and CKD. We compared demographic and clinical characteristics between EOG and CG PTs using chi-square tests for categorical data and the Kruskal-Wallis test. All analyses were performed using SAS version 9.4.
Results: For baseline demographics, see Table 1. Of 12,362 charts reviewed, 692 had EOG, and 11,670 had CG. More PTs in the CG group had ASCVD/PAD (4.6% vs 0.3%, p <.0001), DM (38.2% vs 15.5%, p <.0001), HTN (83.8% vs 44.9%, p <.0001), CKD (43.4% vs 7.1%, p <.0001), and tophi (5.3% vs 0.0%, p <.0001). CG PTs had higher mean initial HbA1c (6.5 vs 6.1, p <.0001) and last HbA1c (6.1 vs 5.6, p <.0001). PTs in the EOG group had higher mean initial SUA levels (8.2 vs 7.1, p <.0001) and last SUA levels (7.5 vs 6.3, p <.0001). There was no significant difference in ULT use (72.6% vs 71.1%, p = 0.3856).
Conclusion: Our study suggests PTs with EOG had significantly lower rates of ASCVD/PAD, DM, CKD, tophi and lower A1c levels. Given that EOG and CG patient's ULT use was similar, this shows that EOG PTs on ULT are less likely to develop the comorbidities associated with gouty arthritis. We further intend to look at EOG time to comorbidity DX event.

POS0519

THE ANALGESIC EFFICACY OF THERAPIES USED FOR COMPLEX REGIONAL PAIN SYNDROME: A SYSTEMATIC REVIEW

Keywords: Quality of life, Systematic review, Pain

C. Shekarsarai[1], N. Gullick[2]. [1]*University of Warwick, Medical School, Coventry, United Kingdom;* [2]*University Hospital Coventry and Warwickshire, Rheumatology, Coventry, United Kingdom*

Background: Complex regional pain syndrome (CRPS) is a multifactorial chronic pain condition which arises following commonplace injuries such as fractures. Pharmacological and non-pharmacological treatments including physiotherapy have been used to reduce pain but there is an unmet need for novel effective therapies.
Objectives: To review clinical trials for CRPS and evaluate effectiveness for reducing pain.
Methods: A PICO approach was used to search MEDLINE, PubMed, COCHRANE LIBRARY, EMBASE, CINAHL and Web of Science for studies published between 2003 to 2022. Keywords such as "Complex Regional Pain Syndrome", and its previous label "Reflex Sympathetic Dystrophy" were used, alongside "pharmacological" and "non-pharmacological interventions". The studies included were confined to adults clinically diagnosed with CRPS, that were written in English. Additional studies were also found via citation searching of references from eligible reports.
Results: The search strategy generated 41 RCTs in total (Figure 1). Pharmacological interventions such as bisphosphonates showed consistently significant improvement in pain, in addition to ketamine and steroids which yielded some successful outcomes. Interventional therapies such as local anaesthetics, sympathetic blocks, and nervous system stimulations also demonstrated potential. Finally, mirror therapy, motor imagery programs and virtual reality revealed partial improvement. Conversely, Pain Exposure Physical Therapy (PEPT), immunosuppressant drugs, free radical scavengers, anti-convulsants, calcitonin, immunoglobulins, Fluidotherapy and occlusal splints had no significant effects on pain outcomes. The Cochrane risk of bias tool was used to assess the quality of studies involved, for which the lower quality RCTs were those lacking full blinding or selectively reporting outcomes.

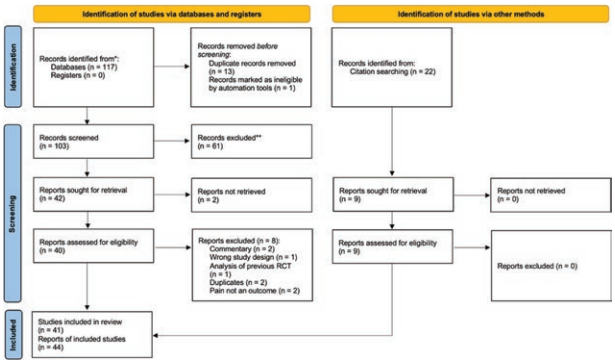

Figure 1. PRISMA flow diagram depicting the screening precesses used from database searching and citation searching.

Conclusion: Bisphosphonates provide the most consistent benefit in pain reduction in CRPS with larger effects than other interventions. Many studies of other interventions were small or of lower quality. Overall, larger, high-quality trials are required to validate any promising findings for other pharmacological and non-pharmacological therapies.

POS0520 CARDIOVASCULAR SAFETY OF FEBUXOSTAT IN PATIENTS WITH GOUT OR HYPERURICEMIA: A SYSTEMATIC REVIEW OF RANDOMIZED CONTROLLED TRIALS

Keywords: Gout, Crystal arthritis

R. Ghossan[1], O. Aitisha[2], F. Fayad[2], P. Richette[3], T. Bardin[4]. *[1]Cochin hospital, Rheumatology, Paris, France; [2]Hotel-Dieu de France University hospital, Rheumatology, Beirut, Lebanon; [3]Hôpital Lariboisiere APHP, Rheumatology, Beirut, France; [4]Hôpital Lariboisiere, Rheumatology, Paris, France*

Background: To this date, a causal relationship between febuxostat and cardiovascular disease remains controversial as comparison between trials can be challenging and may lead to misleading conclusions especially when facing heterogeneous cardiovascular outcomes.

Objectives: We aimed to compare the cardiovascular outcomes in the most pertinent trials of Febuxostat compared to controls.

Methods: We searched electronic databases using a PICOS-style approach search strategy of randomized controlled trials on cardiovascular outcomes of Febuxostat in patients with gout or hyperuricemia. We conducted a quality and risk of bias assessment of the included clinical trials. The definition of MACE as well as all reported cardiovascular outcomes were retrieved from every involved trial.

Results: Of the 1173 records identified from all sources, 20 RCTs were included in the analysis. Mean duration of follow-up was 69.7 ± 81.5 weeks and Febuxostat dose ranged from 10 to 240 mg with 80 mg being the most commonly used dosage. Overall, the quality of evidence deriving from all RCTs showed concerns in most studies (65%). Major cardiovascular event (MACE) was defined in 7 of the 20 RCTs (35%) and cardiovascular outcome reporting was very heterogeneous. Overall, data of cardiovascular safety of Febuxostat were reassuring.

Conclusion: Our systematic review showed no alarming increase of cardiovascular mortality and outcomes in Febuxostat treated patients except for the CARES trial in which the credibility of the results is biased by the high rate of drug discontinuation and of most importantly, withdrawal from follow-up. FAST trial results, backed up with real-world data cohort studies, were robust and reassuring with regard to the cardiovascular safety of Febuxostat in most white males with gout including elderly patients. This should lead the regulatory agencies to reconsider the limitations imposed on the use of Febuxostat in patients with non-severe CV burden.

POS0521 MORTALITY RATE OF GOUT PATIENTS HAS BEEN INCREASED IN KOREA

Keywords: Gout

K. W. Moon[1]. *[1]Kangwon National University Hospital, Department of Internal Medicine, Chuncheon-si, Korea, Rep. of (South Korea)*

Background: Many epidemiologic studies support an association between gout and increased premature mortality. However, there has been no study on mortality and cause of death in Korean patients with gout with large scale data. Therefore, we intended to investigate the risk of death, the change of mortality rate over time, and main cause of death in Korean patient with gout with the national insurance database.

Objectives: The purpose of this study is to assess the mortality rate, trends of mortality rate over time, and cause of death of gout patients in Korea.

Methods: Using Korean National Health Insurance Service data, we conducted a cohort study on gout patients. Gout patients were defined as those aged ≥ 20 years who were diagnosed as gout between 2002 and 2014, and control patients were matched with gout patients (1:1 ratio) after frequency matching for age, sex and index year. Primary outcome was all-cause mortality and observation period was between 2007 and 2015. Covariates were age, sex and comorbidities (hypertension, diabetes, chronic renal failure, ischemic heart disease, cerebrovascular disease and cancer). We calculated standardized mortality rate (SMR), and hazard ratio (HR) in Cox regression, adjusting potential confounders.

Results: This study included 18,406 gout patients and an equal number of matched controls. Baseline characteristics of gout and control patients are displayed in Table 1. Total 1,926 deaths occurred, and SMR of gout patients showed increasing tendency from 2007 to 2015 (Figure 1). The most common cause of death in Korean gout patients was chronic renal failure. Multivariate Cox regression analysis showed that gout patients showed increased risks of all-cause mortality (HR 1.182, 95% CI 1.098-1.274) after adjusting age, sex, and comorbidities.

Conclusion: Gout patients were associated with higher risk of all-cause mortality. The mortality rate of gout patients showed increasing tendency between 2007 and 2015, and most common cause of death was chronic renal failure.

POS0522 UTILIZATION OF A GOUT ANALYZER (U-GAN) FOR CRYSTAL EXAMINATION IN CLINICAL PRACTICE

Keywords: Diagnostic tests, Crystal arthritis

T. Kise[1,2], N. Yokogawa[2], Y. Miyoshi[2], M. Utsunomiya[2], Y. Nagai[2], K. Shimada[2].
[1]Regional Independent Administrative Corporation Naha City Hospital, Department of Nephrology and Rheumatology, Naha, Okinawa, Japan; [2]Tokyo Metropolitan Tama Medical Center, Department of Rheumatic Diseases, Fuchu, Tokyo, Japan

Background: Synovial fluid (SF) crystal analysis performed with a compensated polarized microscopy is the gold standard for identifying calcium pyrophosphate (CPP) and monosodium urate (MSU) crystals. Since a fully equipped compensated polarized microscope is not widely available, a gout analyzer (U-GAN, Olympus) is alternatively used in many countries. By attaching the analyzer in a slider-compatible revolving nosepiece, examination using compensated polarization can be easily performed by operating the lever.
Objectives: To evaluate the utility of crystal examination using U-GAN®.
Methods: We prospectively performed different crystal identification methods in 30 patients with knee joint effusion at Tokyo Metropolitan Tama Medical Center from February 2020 to March 2021. Rheumatologists who routinely use compensated polarized microscope blindly evaluated the non-centrifuged SF using three methods: 1) morphologic identification under ordinary light, 2) use of U-GAN®, and 3) use of fully-equipped compensated microscope (MT9300, Meiji Techno) in this order. In addition, in-hospital commercial laboratory technicians evaluated the sediment using U-GAN® after centrifugation (3000 rpm for 5 min).
Results: Total 30 SF were evaluated. By compensated polarized microscope, 15 were found crystal-positive (11 for CPP and 4 for MSU). The detection of both CPP and MSU by the in-hospital laboratory technician were in perfect agreement. Before centrifugation, the sensitivity of ordinal microscope and U-GAN® were 73.3% (11/15) and 80.0% (12/15), respectively (specificity 100% in both). When using U-GAN®, 3 (2 CPP and 1 MSU) were additionally detected after centrifugation.
Conclusion: U-GAN® can be used for detection of both CPP and MSU in clinical practice.

POS0523 FEASIBILITY STUDY OF AN ELECTRONIC HEALTH RECORD-BASED GOUT REGISTRY

Keywords: Registries, Gout

N. Bürgisser[1,2], D. Mongin[2], P. Darbellay Farhoumand[1], O. Braillard[3], K. Lauper[2], D. Courvoisier[2,4]. *[1]Geneva University Hospitals, Division of General Internal Medicine, Geneva, Switzerland; [2]Geneva University Hospitals, Division of Rheumatology, Geneva, Switzerland; [3]Geneva University Hospitals, Division of Primary Care Medicine, Geneva, Switzerland; [4]Geneva University Hospitals, Quality of Care Unit, Geneva, Switzerland*

Background: Gout is the most common inflammatory rheumatism worldwide. Despite guidelines on acute and chronic management, it remains largely undertreated [1]. To evaluate the current standard of gout care, there is an unmet need for gout registers, especially in the non-rheumatology setting. The vast clinical information available in electronic health record (EHR) allows the implementation of registers to assess clinical indicators and monitor them following quality improvement programs. The Geneva University Hospitals (HUG), a 2000-beds tertiary hospital, provides multi-specialty in- and outpatient services, including care to vulnerable population (inmate, uninsured) with a unified EHR and thus represent an ideal setting for this purpose.
Objectives: To establish an EHR-based gout registry, to assess the correct identification of gout patients by manual chart review, and to evaluate the objective validity of gout diagnosis based on the ACR-EULAR 2015 gout classification criteria [2].
Methods: EHR of patients > 18 years old admitted to or consulting at the HUG between 01.01.2013 and 15.11.2022 were screened based on the presence of at least one of four criteria: ICD-10-GM gout diagnosis (M10), gout-related terms (gout, tophi or podagra) in the list of diagnosis, prescription of urate-lowering therapy (allopurinol, probenecid, febuxostat) among non-leukemia or lymphoma-suffering patient (ICD-10-GM code C81 to C96 were excluded), or uric acid crystal in synovial fluid. For each criterion, a sample of 20 medical charts were fully reviewed. The positive predictive value (PPV) to detect a true gout was established if a gout diagnosis was mentioned by any doctor in any part of the EHR. To further assess the validity of the gout diagnosis, the 2015 ACR-EULAR gout criteria was scored. Gout patients without any acute arthritis during any encounter with the HUG were classified as having an antecedent gout.
Results: The four criteria identified 7'046 patients suffering from gout, among which 33.4% were deceased. Most patients were identified by the drugs criterion (Figure 1). A large proportion of patients (43.2% of outpatients and 72,8% of inpatients) were identified by the presence of urate-lowering therapy only, without the mention of any gout diagnosis. Furthermore, 9.7% and 2.6% in the out- and inpatient setting respectively had a positive punction that wasn't associated with a documented diagnosis. PPV were 100% for ICD-10-GM code, list of diagnosis and punction, and 75% for urate-lowering therapy, while PPV based on a combined query (any criterion) was 93.8% to detect a gout patient in the charts. Among the 80 charts reviewed, 55 patients had at least one documented gout attack and 25 had an antecedent gout. Of the 55 patients with an acute gout, which allowed the use of the ACR-EULAR 2015 classification, 39 patients (70.9%) had a positive articular punction for uric acid or the presence of tophus as observed by a trained examiner. The remaining 16 patients (29.1%) had a mean score (SD) of 5.5 (2.39) for the ACR-EULAR 2015 classification (threshold to classify as gout is ≥8). The lack of clinical information available (documented presence of tophus, precise clinical course of symptoms) and lack of diagnostic imaging to assess gout complication might explain the low score, among these patients with a high probability of gout according to the chart review.
Conclusion: We demonstrate the feasibility of an EHR-based gout registry, with good positive predictive value and the ability to identify patients without a documented gout diagnosis in their EHR. The next step is to expend the queries to look for gout diagnosis in all of the patient's documents and imaging reports and to estimate the negative predictive value in a sample of patients without any criteria, yet with risk factors of gout.

POS0524 CXCL12 AND CXCR4 AS NOVEL BIOMARKERS IN PATIENTS WITH GOUTY ARTHRITIS

Keywords: Gout, Biomarkers, Inflammatory arthritides

S. K. Kim[1], J. Y. Choe[1], H. Lee[1], J. W. Kim[1]. [1]*Catholic University of Daegu School of Medicine, Division of Rheumatology, Department of Internal Medicine, Daegu, Korea, Rep. of (South Korea)*

Background: CXCR4 binds to its ligand CXC chemokine CXCL12 and plays a role in induction of recruitment of inflammatory cells including leukocytes and endothelial cells. The CXCL12/CXCR4 axis has been implicated in the pathogenesis of some types of inflammatory arthritis and autoimmune diseases including rheumatoid arthritis, osteoarthritis, systemic lupus erythematosus, and ankylosing spondylitis. Evidence of the pathogenic role of CXCR4 and CXCL12 in uric acid-induced inflammation has not been presented.
Objectives: The aim of this study is to evaluate the expression of chemokine receptor CXCR4 and its ligand CXCL12 in patients with gout and uric acid-induced inflammation.
Methods: Forty patients with intercritical gout and 27 controls were consecutively enrolled. Serum levels of interleukin-1β (IL-1β, IL-18, CXCL12, and CXCR4 were assessed using enzyme-linked immunosorbent assay. Gene and protein expression for these target molecules was measured in human U937 cells incubated with monosodium urate (MSU) crystals using real-time reverse transcription polymerase chain reaction and Western blot analysis.
Results: Patients with intercritical gout showed higher serum IL-1β, IL-18, and CXCL12 levels than those in controls, but not serum CXCR4 level. Serum CXCR4 level in gout patients was associated with serum IL-18 level, uric acid level, and uric acid/creatinine ratio (r = 0.331, p = 0.037; r = 0.346, p = 0.028; r = 0.361, p = 0.022, respectively). U937 cells treated with MSU crystals significantly induced CXCL12 and CXCR4 mRNA and protein expression, in addition to IL-1β and IL-18. In cells transfected with IL-1β siRNA or IL-18 siRNA, CXCL12 and CXCR4 expression was downregulated compared to non-transfected cells in MSU crystal-induced inflammation. Receiver operator characteristic (ROC) curve analysis showed that serum CXCL12 for the diagnosis of gout was an area under roc curve (AUC) of 0.690 (p = 0.009).
Conclusion: This study reveals that CXCL12 and CXCR4 are involved in the pathogenesis of uric acid-induced inflammation and gouty arthritis.

POS0525 WORSENING BURDEN OF GOUT AMONG ASIAN AMERICAN ADULTS – GENERAL POPULATION-BASED STUDY (2011-2018)

Keywords: Gender/diversity issues, Gout, Epidemiology

C. Yokose[1,2], N. Mccormick[1,2,3], N. Lu[3], S. Tanikella[1], K. Lin[1], A. Joshi[4,5], L. Raffield[6], E. Warner[7], T. Merriman[8], J. Hsu[9], K. Saag[8], Y. Zhang[1,2], H. Choi[1,2]. Background: Asian Americans are the fastest-growing racial/ethnic group in the US. Gout disparities in Black Americans have been explained by socio-clinical factors; however, no data are available among Asians living in Western countries, despite their disproportionately worsening metabolic health.
Objectives: To determine the prevalence of gout and serum urate concentrations according to race/ethnicity and the potential impact of social determinants of health and clinical factors.
Methods: Using data from the latest NHANES cycles (2011-2018) in which Asian race data were collected, we determined the prevalence of gout and serum urate concentrations according to race/ethnicity and the potential impact of social determinants of health and clinical factors. We sought to replicate the Asian-White differences in the UK Biobank.
Results: Gout now affects 12.1 million Americans, with its prevalence increasing from 3.6% (95% CI, 2.8, 4.5) in 2011-2012 to 5.1% (4.2, 5.9) in 2017-2018 (p-trend=0.03); this trend nullified after excluding Asians (p-trend, 0.11) or after age adjustment (p-trend, 0.06). During the same period, age- and sex-adjusted prevalence among Asian Americans doubled from 3.3% to 6.6% (p-trend=0.007) to exceed all other racial/ethnic groups in 2017-2018 (**Figure 1**), with age- and sex-adjusted odds ratio (OR; Asian vs. White) of 1.61 (1.03, 2.51) and socio-clinical-factor-adjusted multivariable OR of 2.62 (1.59, 4.33) (**Table 1**). The latest gout prevalence among Americans ≥65 years was 10.0% among Whites and 14.8% among Asians (including 23.6% of Asian men). Serum urate concentrations also increased between 2011-2018 among Asian Americans (p-trend=0.009). The Asian-White disparity was also present in the UK Biobank (**Table 1**).
Conclusion: Gout now affects >12 million US adults due to an aging population and rising prevalence among Asian Americans, which surpassed all other racial/ethnic groups in 2017-2018. This Asian-White disparity does not appear to be driven by socio-clinical factors.

Figure 1. Trends in Gout Prevalence* by Race/Ethnicity: NHANES 2011-2018**

*Age-standardized prevalence

**Data are presented incorporating sample weights and adjusted for clusters and strata of the complex sample design of NHANES 2011-2018.

PAIN PROCESSING IS ALTERED ABOVE PAGETIC BONE

Keywords: Pain, Bone diseases

K. Berg[1], D. Dockrell[1], T. Aspray[2], L. Colvin[3], E. Dennison[4], H. Divyateja[5], N. Ghouri[6,7], R. Keen[8], T. O'neill[9], F. Rahman[10], M. Siddiqi[11], S. Tuck[12], J. Turton[13], S. Ralston[1]. *[1]University of Edinburgh, Centre for Genomics and Experimental Medicine, Edinburgh, United Kingdom; [2]Newcastle University, Freeman Hospital, Newcastle upon Tyne, United Kingdom; [3]University of Dundee, Division of Population Health and Genomics, Dundee, United Kingdom; [4]University of Southampton,The MRC Lifecourse Epidemiology Unit, Southampton, United Kingdom; [5]Nottingham University Hospital, Chemical Pathology, Nottingham, United Kingdom; [6]University of Glasgow, School of Medicine, Glasgow, United Kingdom; [7]Queen Elizabeth University Hospital, Department of Diabetes and Endocrinology, Glasgow, United Kingdom; [8]Royal National Orthopaedic Hospital, Metabolic Bone Disease Centre, London, United Kingdom; [9]University of Manchester, Manchester Institute for Collaborative Research on Ageing, Manchester, United Kingdom; [10]University Hospitals of Leicester NHS Trust, Metabolic Medicine & Chemical Pathology, Leicester, United Kingdom; [11]Liverpool University Hospitals Foundation Trust,Aintree University Hospital, Liverpool, United Kingdom; [12]James Cook University Hospital, Department of Rheumatology, Middlesbrough, United Kingdom; [13]University Hospital Llandough, Department of Rheumatology, Cardiff, United Kingdom*

Background: Pain is the most common symptom of Paget's Disease of Bone (PDB) and affects between 60% and 70% of patients who present to clinic in the UK, but its mechanisms are incompletely understood [1]. Quantitative sensory testing (QST) has historically been used in the assessment of neuropathic pain [2]. but has precedent in patients with bone metastases and osteoarthritis [3,4]. In this study we used QST to dissect the mechanisms of pain in PDB, taking advantage of the disease's focal nature which allows the participant to act as their own control by testing at a contralateral site.

Objectives: To explore the sensory profiles of PDB patients with and without musculoskeletal pain.

Methods: All study data was collected and stored on the secure web-based software platform Research Electronic Data Capture (REDCap). Quantitative sensory testing (QST) measured the sensory response to various stimuli applied to the skin overlying the Pagetic bone and compared this to an unaffected site in 120 study participants. Differences between QST assessments in sites overlying Pagetic bone and control sites were assessed by the Mann-Whitney test.

Results: Significantly higher pain scores were reported above the site of PDB when compared to the control site, irrespective of whether the patient complained of musculoskeletal pain. The differences were apparent for hot roller testing ($p = 0.047$), pain threshold testing ($p = 0.007$), pin prick testing ($p = <0.001$) (see Figure 1), and wind-up pinprick testing ($p = <0.001$). Pain thresholds were significantly reduced above Pagetic bone ($p = 0.007$). Additionally, temporal summation scores were significantly higher ($p = 0.007$) in the pain subgroup compared with the no pain subgroup which could indicate higher levels of central sensitisation in patients who experience pain.

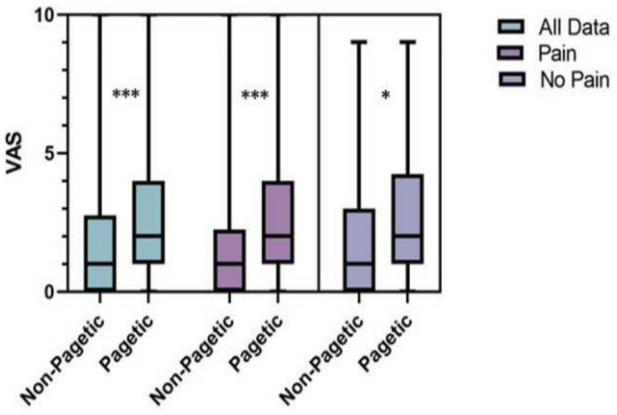

Figure 1. Visual Analogue Scale (VAS) scores reported following Single Pin Prick Testing. Data is split in to the full dataset, the 'Pain' reporting subgroup, and the 'No Pain' reporting subgroup.

Conclusion: This study illustrates that there are significant differences in the way that sensation is processed above Pagetic bone when compared to unaffected contralateral sites, regardless of the presence of current musculoskeletal pain. Our data suggest that patients who experience pain may do so, in part, because of higher levels of central sensitisation.

POS0527 THE PRESENCE OF MONOSODIUM URATE DEPOSITS IN THE JOINTS OF PATIENTS WITH ASYMPTOMATIC HYPERURICEMIA IS ASSOCIATED WITH A HIGHER CARDIOVASCULAR RISK, BUT NOT WITH MORE ADVANCED KIDNEY DAMAGE

Keywords: Kidneys, Crystal arthritis, Ultrasound

R. Gancheva[1], A. Koundurdjiev[2], T. Kundurzhiev[3], Z. Kolarov[4], P. Peteva[5], I. Koundurdjieva[6], L. Marinchev[5]. *[1]University Hospital "Sofiamed", Sofia University St. Kliment Ohridski, Clinic of Rheumatology, Sofia, Bulgaria; [2]University Hospital "St. Iv. Background: Epidemiological studies conducted in patients (pts) from the general population and pts with chronic renal failure have shown that uric acid is an independent risk factor for the development and progression of kidney disease. Uric acid damages the kidneys by causing systemic and glomerular hypertension. Hyperuricemia is connected to arteriolosclerosis, characterized by arterial wall thickening and hyalinosis.
Objectives: To evaluate the association between asymptomatic hyperuricemia and renal damage and to establish whether the presence of monosodium urate (MSU) deposits in the joints of these pts is related to more advanced renal alterations.
Methods: This was a single-center cross-sectional study, including 73 consecutive pts divided into 34 pts with osteoarthritis (controls), 25 subjects with asymptomatic hyperuricemia and no ultrasound (US) evidence of MSU crystals in the joints and 14 individuals with asymptomatic hyperuricemia and MSU deposits in the joints. Pts underwent bilateral US examination of the joints of the hands, elbows, knees, ankles, feet and the kidneys. Measurements of the joints were conducted with a high-frequency linear transducer 4-15 MHz. The existence of double contour sign, intra-tendinous MSU aggregates, "snow storm", tophi, tophi with erosions, or a combination of these US features was assessed. Kidneys were examined with 3.5 MHz transducer, working with pulse Doppler frequency of 2.5 MHz. Renal length, parenchymal thickness and echogenicity were determined. The presence or absence of nephrolithiasis was reported. By means of the value of renal resistive index (RRI) we judged for intrarenal blood flow. Statistical analyzes were done by One-Sample Kolmogorov-Smirnov, t-test, Chi-square or Fisher`s exact test.
Results: The distribution of males and females (p=0.441), smokers and non-smokers (p=0.147), pts with arterial hypertension and normotensive individuals (p=0.298) as well as subjects with diabetes and without diabetes (p=0.775) and pts with dyslipidemia and normal lipid levels (p=1.000) was similar among the groups. The proportion of pts who had suffered with cardiovascular event was the highest in the group of asymptomatic hyperuricemia with MSU deposits in the joints (21.4%) compared to the group of osteoarthritis (14%) and hyperuricemia without MSU crystals in the joints (0%), (p=0.048). In the group of osteoarthritis the share of pts with eGFR < 90 ml/min was the lowest (5.9%) in comparison to the group of hyperuricemia without MSU deposits in the joints (29.2%) and hyperuricemia with crystals in the joints (46.2%), (p=0.005). The percentage of obese pts was the highest in hyperuricemia with MSU crystals in the joints (57.1%), but without reaching a significant difference with hyperuricemia without crystals in the joints (40%) and the group of osteoarthritis (29.4%), (p=0.195). The echogenicity of the kidneys (p=0.630) and the distribution of nephrolithiasis (p=0.596) was equal among the groups. Pts with hyperuricemia and MSU deposits in the joints compared to those with osteoarthritis had higher BMI (mean±SD; 31.79±5.92 kg/m^2 vs 28.06±4.27 kg/m^2, p=0.018) and smaller kidney size (mean±SD; 55.36±5.58 mm vs 59.58±5.12 mm, p=0.015). The comparison of hyperuricemia without MSU deposits in the joints to osteoarthritis group demonstrated a significant difference only in the age (mean±SD; 49.7±16.4 years vs 61.5±9.4 years, p=0.001). Finally, the comparison of the two groups with hyperuricemia showed that subjects with MSU deposits in the joints had higher BMI (mean±SD; 31.79±5.92 kg/m^2 vs 28.26±4.41 kg/m^2, p=0.041) with no difference in the age (p=0.072), kidney size (p=0.141), RRI (p=0.296), eGFR (p=0.528) and thickness of renal parenchyma (p=0.232).
Conclusion: Hyperuricemia independently of the presence of articular crystals is associated with similar kidney damage. Cardiovascular risk is higher when MSU crystals are found by US in the joints.

POS0528 PATIENT EXPERIENCES WITH CHRONIC REFRACTORY GOUT AND ITS IMPACT ON HEALTH-RELATED QUALITY OF LIFE

Keywords: Patient reported outcomes, Quality of life, Gout

A. Oladapo[1], V. Strand[2], N. Kragh[3], N. Johnson[4], C. Yousefian[4], D. Brooks[4], H. Sharp[4], C. Kim[4], M. Pillinger[5]. *[1]Swedish Orphan Biovitrum AB, HEOR and RWE, Boston, United States of America; [2]Stanford University, Division of Immunology/Rheumatology, Palo Alto, United States of America; [3]Swedish Orphan Biovitrum AB, Global Health Outcomes Value & Patient Access, Stockholm, Sweden; [4]Endpoint Outcomes (a Lumanity company), Research, Boston, United States of America; [5]NYU Grossman School of Medicine, Division of Rheumatology, New York, United States of America*

Background: Gout is a common inflammatory rheumatic disease, with elevated uric acid leading to deposition of monosodium urate crystals within joints [1]. Chronic refractory gout (CRG), also known as refractory or uncontrolled gout, is associated with unexpected disease flares characterized by severe and debilitating pain. Long-term symptoms include painful inflammatory arthritis, impaired physical function, and health-related quality of life (HRQoL), and tophi-related joint destruction [1].
Objectives: This study aimed to 1) develop and refine a conceptual model of patient-identified CRG symptoms and their impact on HRQoL; and 2) confirm that the 36-item Short Form Health Survey V2.0 (SF-36) and Health Assessment Questionnaire-Disability Index (HAQ-DI) are relevant to patients with CRG by mapping items to the CRG conceptual model.
Methods: A targeted literature review of the 10 years prior to August 2021 was conducted to assess the symptoms and impacts of CRG, alongside the use of SF-36 and HAQ-DI in previous clinical trials. The review results contributed to an initial conceptual model of signs, symptoms and impacts of CRG. This model was then refined using concept elicitation interviews (CEI) conducted with patients who have clinically confirmed CRG (≥3 gout flares within 18 months of screening; or presence of ≥1 tophus; or current diagnosis of gouty arthritis [defined as joint damage due to gout]). Interviews contained open-ended questions and patients were asked about duration, frequency, and severity for each concept; bothersome impacts were rated on a scale of 0–10. The refined model was then assessed against SF-36 and HAQ-DI to determine their suitability for evaluating disease burden in patients with CRG.
Results: Findings from the literature review identified the following commonly referenced symptoms, signs and impacts of gout that served as the basis of the draft conceptual model: bodily pain, joint swelling/inflammation, tophi, joint pain, joint tenderness, anxiety, depression, sleep effects, and work effects. Impacts were organized into five domains: activities of daily living (e.g., difficulty dressing), emotional (e.g., anxiety), physical (e.g., decreased mobility), social (e.g., stigma), and work/school (e.g., productivity). Twenty patients were interviewed. Most were male (70%) and non-Hispanic white (55%), with a mean (standard deviation) age of 55.9 (±12.1) years. Most patients (60%) reported having multiple (>3) and/or severe gout flares within the past 6 months, and most commonly 1–3 tophi (45%). The most frequently reported signs and symptoms included bodily pain, joint swelling, and tenderness (90% each). Others included joint pain (80%), joint stiffness (70%), and tophi (70%). Joint pain was rated as the most bothersome symptom (mean = 9.1). The most frequently reported impacts were difficulty climbing one or several flights of stairs (100% each), followed by completing chores, running errands and shopping, climbing five steps, putting on shoes, walking outdoors on flat ground, and emotional impacts (95% each). Impacts reported varied depending on the affected joints. The most bothersome impact reported was walking outdoors (mean = 9.6). All concepts discussed in the interviews were reviewed to determine whether they reflected the items included in SF-36 and HAQ-DI. Each assessed item from the two instruments was reported as relevant by at least 25% of participants and thus mapped consistently to concepts elicited by participants. Results of the CEI were used to revise the conceptual model (Figure 1).

Conclusion: Symptoms and associated impacts of CRG on HRQoL are multi-faceted, revealing a burden of disease that affects most aspects of a patient's life (Figure 1). Based on the interview data, all assessed items of SF-36 and HAQ-DI mapped directly to the domains and concepts included in the conceptual model, providing evidence that both questionnaires are suitable for assessing the burden of CRG.

POS0529 USING SOCIAL MEDIA CONVERSATIONS TO UNDERSTAND PATIENT CARE: FACTORS DRIVING PROACTIVE VS REACTIVE MANAGEMENT OF GOUT

Keywords: Gout, Patient reported outcomes, Quality of care

M. Flurie[1], M. Converse[1], K. Davidson[2], D. Hernandez[3], H. Hernandez[1], G. Ho[4], B. LaMoreaux[5], C. Parker[4], C. DeFelice[1], M. Picone[1], E. R. Wassman[1].
[1]TREND Community, Real-World Evidence, Philadelphia, United States of America; [2]Horizon Therapeutics, Patient Advocacy, Deerfield, United States of America; [3]Global Healthy Living Foundation, Medical Affairs and Hispanic Outreach, Nyack, United States of America; [4]Gout Support Group of America, Patient Advocacy, Austin, United States of America; [5]Horizon Therapeutics, Rheumatology, Deerfield, United States of America

Background: To understand the needs of a particular community, it is imperative to actively listen to and interpret the patient experience. We used a proprietary artificial intelligence (AI) analytics engine that uses natural language processing to evaluate social media conversations in online gout communities. Gout is a chronic disease defined by uric acid crystal deposits which induce painful arthritis flares/flare-ups [1]. Managing gout can be characterized by two approaches: proactive and reactive management. Proactive management refers to scheduled, prophylactic care (e.g., regular doctor visits, treating underlying illness), whereas reactive management is spontaneous care driven by symptom onset (e.g., urgent care/walk-in clinic visits). The ideal management strategy is debated. Subspecialty groups recommend a proactive "treat-to-target" strategy focused on uric acid. The American College of Physicians recommends "treat-to-symptom control" without a "treat-to-uric acid-target" strategy. We assessed patient views on each to improve our understanding of these management methods.

Objectives: The current study aimed to identify gout symptoms associated with reactive management. We also wanted to contrast the sentiment of online gout community conversations when describing proactive vs reactive therapeutic experiences.

Methods: We evaluated 2 social media sources: a private Facebook group, The Gout Support Group of America (1000+ members, 99 countries), which had 50,000 posts/comments gathered in 2021-2022; and a public subreddit (r/gout) (9000+ members) with 125,000 posts/comments from 2011-2022. Our AI engine first tagged all posts/comments discussing proactive or reactive care experiences. Entity recognition was then used to identify the most frequently mentioned clinical findings in conversations by care type. We then fit a logistic regression model in which clinical finding mentions predicted care type. To characterize the general sentiment of conversations, the engine scored all posts/comments from –1 (most negative) to 1 (most positive) using a pretrained sentiment tagger.

Results: Flares, pain, uric acid, and swelling were the most frequently mentioned in both proactive and reactive conversations. Reactive care gout conversations (n = 1253 posts/comments from 624 users) were associated with a significantly higher probability of mentioning 'pain' and 'swelling' and a significantly lower probability of mentioning 'uric acid' than were proactive care conversations (n = 1205 posts/comments, 521 users). Mentioning 'flares' did not significantly impact the probability of mentioning either care type. Sentiment analysis showed that reactive care statements had a significantly lower mean sentiment score; indicating discussions about reactive care experiences tended to be more negative than those about proactive care.

Conclusion: In analyzing gout social media posts, we found that flares, pain, swelling, and concerns related to uric acid were primary motivators for individuals seeking gout care. Conversations mentioning 'pain' were twice as likely to mention reactive care compared to proactive gout conversations. Analysis also showed that reactive care gout conversations tended to be more negative, supporting the position that proactive management may be more beneficial for individuals with gout overall. This type of information can be used to identify and address patients' areas of concern or dissatisfaction. Future work should continue exploring these patient-reported perspectives and experiences so clinicians, caregivers, and patients can better understand and guide care-based management decisions.

POS0530 ANALYSIS OF APPROPRIATE DURATION OF COLCHICINE PROPHYLAXIS TO MAXIMIZE THE PERSISTENCE OF XANTHINE OXIDASE INHIBITORS AS THE FIRST-LINE URATE LOWERING THERAPY IN PATIENTS WITH GOUT USING THE KOREAN HEALTH INSURANCE REVIEW AND ASSESSMENT SERVICE DATABASE: DOES 6 MONTHS' DURATION MATTER?

Keywords: Gout, Crystal arthritis, Epidemiology

A. Kim[1], S. G. Lee[1], B. W. Song[1], D. H. Moon[1]. [1]*Pusan National University Hospital, Rheumatology, Busan, Korea, Rep. of (South Korea)*

Background: International guidelines for gout recommend at least 3 to 6 months of prophylaxis against gout attack for gout patients who start urate lowering therapy (ULT) [1-3], but there is lack of strong evidences supporting whether up to 6 months duration of gout flare prophylaxis is associated with the improvement the long-term adherence of ULT in real-world clinical settings.
Objectives: We aimed to investigate the appropriate duration of colchicine prophylaxis to maximize the long-term persistence of xanthine oxidase inhibitors (XOIs) as the first-line ULT in patients with gout using nationwide claim database. In particular, we attempt to compare which one is more effective in adherence to ULT between 6 months and 3 months duration of colchicine prophylaxis.
Methods: This is a nationwide population-based retrospective cohort study using the Korean Health Insurance Review and Assessment (HIRA) database. Gout patients ≥ 20 years who newly initiated allopurinol or febuxostat as the first-line ULT from July 2015 and June 2017 and received XOIs for ≧6 months were analyzed. Patients were followed-up to Jun 2019. Persistence of ULT was defined as continuation of allopurinol or febuxostat without an interruption for a period longer than 60 days (permissible gap), the time duration from the index date to the discontinuation of ULT. XOIs persistence was compared according to the 6 months of duration of colchicine prophylaxis such as (1) ≥6 months and proportion of days covered (PDC) ≥0.8 ("≥ 6 months group") and (2) <6 months or PDC <0.8 ("< 6 months group"). For additional subgroup analysis, we also compared the persistence of XOIs according to the 3 months of duration of colchicine prophylaxis ("≥ 3 months group" vs "< 3 months group").
Results: A total of 43,926 eligible gout patients (colchicine prophylaxis ≥6 months: n=2,784, colchicine prophylaxis <6 months: n=41,142 and colchicine prophylaxis ≥3 months: n=3,333, colchicine prophylaxis <3 months: n=40,593) were identified in HIRA database. The majority was male (82.6%) and the mean age was 58.6 years. Allopurinol (65.2%) was more frequently prescribed than febuxostat (34.8%). During the study period, 23,475 (53.4%) patients stopped XOIs. XOIs discontinuation occurred in 1,498 (53.8%) and 21,977 (53.4%) gout patients in the ≥ 6 months group and < 6 months group, respectively. In addition, 1,777 (53%) and 21,698 (53.5%) patients in the ≥ 3 months group and < 3 months group stopped XOIs, respectively. In multivariable Cox regression models revealed that colchicine prophylaxis ≥6 months did not significantly reduce the risk for discontinuation of XOIs compared with colchicine prophylaxis <6 months (HR=0.961, p=0.139). Otherwise, colchicine prophylaxis ≥3 months was significantly associated with a lower risk of non-persistence to XOIs after adjusting confounding factors (HR=0.95, p=0.041).
Conclusion: Our data suggest that at least 3 months of colchicine prophylaxis may be more appropriate than at least 6 months' duration in terms of maximizing the persistence of XOIs in gout patients.

POS0531 EVALUATION OF THE KNOWLEDGE OF INTERNAL MEDICINE PHYSICIANS, FINAL-YEAR MEDICAL STUDENTS AND RHEUMATOLOGISTS REGARDING THE DIAGNOSIS AND MANAGEMENT OF GOUT IN SWITZERLAND

Keywords: Quality of care, Gout

C. Melong Pianta[1], B. Gilbert[1], M. J. Nissen[1], C. Gabay[1], K. Lauper[1]. [1]*Hôpitaux Universitaires de Genève (HUG), Medecine/Division of Rheumatology, Genève, Switzerland*

Background: Gout is the most common inflammatory rheumatism in adults [1]. Its prevalence and incidence have doubled in the last two decades. However, it is commonly undertreated despite numerous therapeutic options and the availability of international recommendations.
Objectives: To explore the reasons why gout is undertreated, we aimed to assess and compare the knowledge of primary care physicians (internists), rheumatologists, and final-year medical students regarding the diagnosis and management of gout in Switzerland with mandatory continuing education for physicians.
Methods: We conducted a multicenter cross-sectional study between December 2021 and August 2022. All primary care physicians and hospital internists practicing in academic hospitals in Switzerland, rheumatology specialists, and final-year medical students from all 6 Swiss faculties of medicine were invited to complete an online questionnaire based on the EULAR 2016, 2018, and ACR 2020 recommendations. This multiple choice questionnaire consisted of 28 questions including 68 positive answers (since more than one positive answer was possible for each question) on gout diagnosis, management of an acute attack, indication to start hypouricaemic treatment and management of patients with renal failure. Participants were considered as having responded successfully to the questionnaire with at least 2/3 (45) correct answers.
Results: In total, we received approval for participation from 16 academic hospitals, 4 faculties of medicine, and the Swiss Society of Rheumatology. We included a total of 378 participants: 97 medical students, 210 internists and 71 rheumatologists.

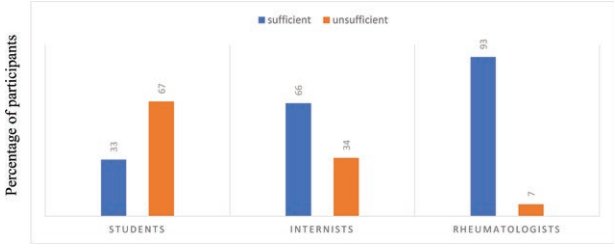

Figure 1. Percentage of participants who responded successfully to the questionnaire

Only 33% of final-year medical students demonstrated sufficient knowledge about how to manage gout, compared to 66% of internists and 93% of rheumatologists. 55%, 48% and 14% in the student, internist and rheumatologist groups respectively did not know what type of crystals were found during a gout attack. The majority of participants in the different groups were familiar with at least one of the treatments that should be used for the management of a first acute attack of gout. Most participants in all 3 groups did not know the indications for initiation of hypouricaemic therapy. 80% of students, 62% of internists and 18% of rheumatologists were unaware of the target urate serum level to aim for when introducing hypouricaemic therapy and more than three-quarters of the students and internists thought that 300 mg was the maximal possible dose of allopurinol.
Conclusion: These results suggest that knowledge about the diagnosis and management of gout is sub-optimal among final-year medical students and primary care physicians across Switzerland. Although most rheumatologists demonstrated good knowledge about the management of gout, a surprising proportion did not, despite being experts in this field. Knowledge about the diagnosis and management of gout needs to be improved.

Infection-related rheumatic diseases

POS0532 GLOBAL ULTRASOUND SYNOVITIS SCORE MAY REFLECT DEVELOPMENT OF CHRONIC POST-CHIKUNGUNYA RHEUMATISM

Keywords: Infection-related RMDs, Outcome measures, Ultrasound

H. Watson[1,2], J. Del Valle Mendoza[3], W. Silva Caso[3], M. Aguilar Luis[3], A. Nizzardo[4], G. Calusi[4], M. Mandron[5], M. A. D'agostino[6]. *[1]Evotec ID (Lyon), Clinical Development and Translational Medicine, Lyon, France; [2]Aarhus University, Hepatology and Gastroenterology, Aarhus, Denmark; [3]Instituto de Investigación Nutricional, Instituto de Investigación Nutricional, Lima, Peru; [4]Aptuit (Verona) Srl, Pharmacometrics, Verona, Italy; [5]Evotec (France) SAS - Campus Curie, Clinical Development, Toulouse, France; [6]Università Cattolica del Sacro Cuore, Rheumatology, Roma, Italy*

Background: Chronic musculoskeletal (MSK) symptoms such as arthralgia and arthritis develop in up to half of patients after acute chikungunya virus (CHIKV) infection. While MSK complaints are common during the acute infection, chronic post-CHIKV rheumatism represents a more severe outcome and is usually assessed by joint counts, laboratory markers and patient-reported outcomes (PROs). Ultrasound (US) may be a practical tool for predicting and confirming the development of chronic CHIKV.
Objectives: To evaluate the clinical relevance of MSKUS findings in post-chikungunya rheumatism.
Methods: 80 patients with acute CHIKV infection were enrolled in a prospective cohort study in Jaén, Peru. Clinical exam, US scans using grey-scale and power Doppler (PDUS), and serum inflammatory markers were performed at inclusion and at 3-month follow-up. Patients completed the RAPID3 outcome assessment and a MSK stiffness questionnaire. Joint counts and PDUS scans included 20 pairs of joints. Global synovitis and tenosynovitis scores were calculated following the EULAR-OMERACT recommendations for rheumatoid arthritis (GLOESS).
Results: 59 patients (mean age 35 years, 68% female) were assessed both in the acute infection stage and at 3-month follow-up. 21 patients (35%) met strict criteria for defining chronic CHIKV rheumatism with a mean 4.4 (±2.2) tender joints and RAPID3 scores >6. In the acute infection phase, global PDUS synovitis and tenosynovitis scores correlated moderately with tender joint count and with pain severity, joint stiffness and RAPID3 scores, but were not strongly predictive of patients who went on to develop chronic arthralgia. After 3 months, global PDUS synovitis scores correlated more strongly with tender joint count (r=0.53, p<0.0001), pain severity (r=0.60, p<0.0001), joint stiffness (r=0.53, p<0.0001) and RAPID3 scores (r=0.60, p<0.0001) (Table 1).
Conclusion: Global PDUS synovitis and tenosynovitis scores may be an objective measure of disease severity in patients developing chronic CHIKV rheumatism. Further validation with longer-term follow-up is needed.

Table 1. Correlation of synovitis and tenosynovitis PDUS scores with clinical examination and patient-reported outcomes (n=59).

POS0533 RISK OF SEVERE INFECTIONS IN IMMUNE MEDIATED INFLAMMATORY DISEASES WITH IMMUNOGLOBULIN DEFICIENCY UNDER RITUXIMAB THERAPY

Keywords: Infection-related RMDs, Adaptive immunity, bDMARD

J. Morel[1], C. Rempenault[1], T. Lea[1], C. Daien[1], B. Combe[1], P. Guilpain[2], C. Lukas[1]. *[1]Hopital Lapeyronie, Rheumatology, Montpellier, France; [2]University Hospital Center Saint Eloi Hospital, Internal Medicine and Multi-Organic Diseases, Montpellier, France*

Background: Rituximab (RTX) is effective in treating immune-mediated inflammatory diseases (IMID). Hypogammaglobulinemia may occur under RTX and may increase infection risk.
Objectives: Since data are controversial, we evaluated the risk of severe infection in patients with IMID and hypogammaglobulinemia under RTX therapy.
Methods: We conducted a retrospective single-center study retrieving all patients treated with RTX for IMID. We calculated the incidence of RTX-induced immunoglobulin (Ig) deficiency, the type of Ig deficiency, the incidence of severe infection, and risk factors for severe infection.
Results: 311 patients were analyzed. Mean follow-up was 62.6 months. Exposure was 1623.7 patient-years. 15% of patients developed at least 1 severe infection. Incidence rate was 2.77/100 PY. 29 patients had prevalent Ig deficiency before being treated with RTX. 68 patients developed hypogammaglobulinemia, mainly for IgM (12%) and IgG (8%). Severe infection rate was higher in patients with prevalent Ig deficiency (RR 1.73; 95% CI 0.85-3.53), with significant difference in survival model (Log-Rank test: p=0.033). On the other hand, no excess risk of infection was observed in patients developing Ig deficiency under RTX in univariate analysis (RR 0.68; 95% CI 0.31-1.47) or in survival analyses after adjustment for confounding factors (type of IMID (RA versus other IMID), cumulative dose of RTX, presence of chronic pulmonary comorbidities, use of an immunosuppressive drug at inclusion, and mean dose of GCs collected at each cycle of RTX during follow-up) (Log-Rank test: p=0.399). Chronic lung disease and glucocorticoids (GCs) use during follow-up were associated with an increased risk of severe infection.
Conclusion: We did not observe an increased risk of severe infection in RTX-induced Ig deficiency. However, we found an increased risk of severe infection in case of prevalent Ig deficiency prior to RTX. In case of Ig deficiency, RTX management should be discussed on a case-by-case basis, according to an individual assessment of the infectious risk, especially when GCs therapy is used and chronic lung diseases are present.

POS0534 PREDICTORS OF SERIOUS INFECTIONS IN RHEUMATOID ARTHRITIS – A PROSPECTIVE BRAZILIAN COHORT

Keywords: Real-world evidence, Rheumatoid arthritis, Infection-related RMDs

A. L. Bagno de Almeida[1], M. F. Guimarães[1], M. Raquel Da Costa Pinto[1], L. Pereira[2], A. P. Gomides[3], K. Bonfiglioli[4], P. Louzada Jr[5], R. Giorgi[6], G. Castro[7], S. Radominski[8], C. Brenol[9], A. Pugliesi[10], L. Mota[3], G. Da Rocha Castelar Pinheiro[2]. *[1]Universidade Federal de Minas Gerais, Reumatologia, Belo Horizonte, Brazil; [2]Universidade do Estado do Rio de Janeiro, Rheumatology, Rio de Janeiro, Brazil; [3]Universidade de Brasília, Rheumatology, Brasilia, Brazil; [4]Faculdade de Medicina, Universidade de São Paulo, Rheumatology, São Paulo, Brazil; [5]Universidade de São Paulo, Rheumatology, Ribeirão Preto, Brazil; [6]Hospital do Servidor Público Estadual de São Paulo, Rheumatology, São Paulo, Brazil; [7]Universidade do Sul de Santa Catarina-Unisul, Rheumatology, Florianópolis, Brazil; [8]Universidade Federal do Paraná´, Rheumatology, Curitiba, Brazil; [9]Universidade Federal do Rio Grande do Sul, Rheumatology, Porto Alegre, Brazil; [10]Universidade Estadual de Campinas, Rheumatology, Campinas, Brazil*

Background: Infectious intercurrences increase mortality and morbidity and often limit immunosuppressive treatment in rheumatoid arthritis (RA) patients [1].The risk of infection in this population may be influenced by factors related to treatment, the characteristics of rheumatic disease and the clinical and social conditions of patients [2].
Objectives: This study aims to evaluate the incidence and factors related to the occurrence of serious infections, defined as the need for hospitalization or the use of intravenous antibiotics for the treatment, among patients with rheumatoid arthritis in Brazil.
Methods: We analyzed data from the REAL [3], a prospective observational study, that evaluated Brazilian RA patients, with clinical and laboratory data

collected over a year in eleven tertiary health care centers. Were included patients with 18 years or older, who fulfilled classification criteria for RA and were previously followed up in rheumatology services for at least 6 months prior to inclusion. Exclusion criteria was the absence of information regarding the occurrence of infections in two or more visits. Univariate and multivariate analyses were performed from the adjustment of the logistic regression model *Generalized Estimating Equations* (GEE), with the primary outcome being the occurrence of serious infection. We assessed the corticosteroid dose that was most associated with the occurrence of serious infections, maximizing sum of sensitivity and specificity.

Results: 841 patients were included with an average follow-up time of 11,2 months (SD 2,4). Eighty-nine serious infections occurred, corresponding to 13 infections per 100 patient-years. The association between corticosteroid use and severe infections was dose-dependent until daily doses equal to or higher than 15 mg of prednisone (or equivalent) in which the highest association was found. Pulmonary fibrosis, chronic kidney disease (CKD) and central nervous system disease increased the chances of serious infection by 3.2 times (95% CI: 1.5 to 6.9), 3.6 times (95% CI: 1.2 to 10.4) and 2.4 times (95% CI: 1.2 to 5.0), respectively. The use of corticosteroids in moderate doses increased the chances by 5.4 times (95% CI: 2.3 to 12.4), and for each increase of 1 unit in the health assessment questionnaire (HAQ), the chance increased 60% (95% CI: 20 to 120%).

Table 1. Multivariable analysis

	Coef.	Value-p	OR	95% CI
Time (Visit)	0,81	<0,001	2,2	(1,8-2,8)
Pulmonary fibrosis	1,17	0,003	3,2	(1,5-6,9)
Chronic kidney disease	1,27	0,02	3,6	(1,2-10,4)
CNS Diseases	0,89	0,015	2,4	(1,2-5,0)
Prednisone (or equivalent) dose (≥ 15 mg)	1,68	<0,001	5,4	(2,3-12,4)
HAQ	0,46	0,005	1,6	(1,2-2,2)

Legend: Coef - coefficients. OR - Odds Ratio. 95%CI - 95% confidence interval. CNS - Central nervoussystem diseases. HAQ - health assessment questionnaire

Conclusion: We observed a high incidence rate of serious infections in this Brazilian cohort compared with cohorts from developed countries. The factors that were independently associated with them were neurological and pulmonary comorbidities, reduced kidney function, use of corticosteroids in moderate doses and reduced functionality. These findings may affect therapeutic decisions in RA patients.

POS0535 IS THERE A DECREASED RISK OF DEVELOPING CF ARTHROPATHY IN CF PATIENTS UNDERGOING TREATMENT THAT TARGETS THE F508DEL MUTATION?

Keywords: Inflammatory arthritides, Lungs, Ultrasound

K. Schmiedeberg[1,2], A. L. Walter[3], L. Joos[1], M. Brutsche[3], J. Von Kempis[1], A. Rubbert-Roth[1]. *[1]Kantonsspital St.Gallen, Division of Rheumatology, St. Gallen, Switzerland; [2]University Hospital Bern, Department of Rheumatology and Immunology, Bern, Switzerland; [3]Kantonsspital St.Gallen, Division of Pneumology, St. Gallen, Switzerland*

Background: Cystic fibrosis (CF) is characterized by mutations within the CFTR (cystic fibrosis transmembrane conductance regulator) gene that result in a defect of the chloride transporter protein in different organs, particularly in the lung. Musculoskeletal symptoms have been reported in up to 29% of CF patients [1], most frequently as recurrent episodes of mono- or polyarthritis in joints of hands and feet. Recently, potent CFTR modulator therapies targeting the F508del mutation in CF have become available (i.e., Trikafta© - consisting of a triple combination of elexacaftor, tezacaftor, and ivacaftor) that increase CFTR protein availability and function at cell surfaces.

Objectives: To characterize musculoskeletal symptoms in a cohort of consecutive CF patients.

Methods: 25 CF patients were enrolled in this monocentric, prospective, and cross-sectional cohort study. Rheumatologic evaluation included clinical and laboratory parameters. Data were analyzed by covariance (ANCOVA) models, using the general linear model approach. Correlation analyses were performed calculating nonparametric Spearman correlation rank coefficients.

Results: Baseline characteristics are outlined in Table 1. 22/25 CF patients were under CFTR modulator treatment with a mean treatment duration of 13 + 4 months. Arthralgias and myalgias were reported in 48% and 20% of patients, respectively. Arthritis, mainly involving small joints, was clinically detected in 6/25 (24%) patients and confirmed by ultrasound (US) in 3/6 patients. Self-reported myalgias, but not self-reported arthralgias, were significantly associated with the presence of swollen joints ($r = 0.7452$, $p < 0.0001$), tender joints, ($r = 0.6674$, $p = 0.0003$), a positive squeeze test ($r = 0.5898$, $p = 0.0019$) and morning stiffness ($r = 0.6556$, $p = 0.0004$) (Table 1). Disease activity as assessed by the Simplified Disease Activity Index (SDAI) was moderate (mean 18 + 3). CCP and rheumatoid factor (RF) were detected in one patient not on CFTR modulator therapy (with US synovitis of PIP). Two patients on CFTR modulator therapy tested positive for RF. Another patient was seronegative but synovitis was confirmed by US.

Of note, longer duration of CFTR modulator therapy was significantly associated with a lower number of tender joints ($r = -0.410$ $p = 0.054$), swollen joints ($r = -0.400$, $p = 0.048$) and a lower CRP ($r = -0.509$, $p = 0.048$) (Figure 1).

Conclusion: The current cohort study confirms that musculoskeletal symptoms are frequent in adult CF patients. Self-reported myalgias were significantly associated with arthritis mainly involving small joints. Interestingly, longer duration of CFTR modulator therapy was associated with a decreased number of tender and swollen joints in line with the assumption that amelioration of mucosal airway inflammation may decrease the risk of developing CF arthropathy.

SAFETY OF BIVALENT SARS-COV-2 VACCINES AS A SECOND BOOSTER DOSE IN ARTHRITIS PATIENTS ON IMMUNOSUPPRESSIVE THERAPIES

Keywords: Vaccination/immunization, Safety, COVID

H. Ørbo[1,2], I. Jyssum[1,2], A. T. Tveter[1], I. E. Christensen[1,2], J. Sexton[1], K. H. Bjørlykke[2,3], G. B. Kro[4], T. K. Kvien[1,2], L. A. Munthe[2,5,6], G. Grodeland[2,5], S. Mjaaland[7], J. T. Vaage[5], E. A. Haavardsholm[1,2], K. K. Jørgensen[3], S. Aarrestad Provan[1], S. W. Syversen[1], G. L. Goll[1]. *[1]Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway; [2]University of Oslo (UiO), Institute of Clinical Medicine, Oslo, Norway; [3]Akershus University Hospital, Department of Gastroenterology, Lørenskog, Norway; [4]Oslo University Hospital, Department of Microbiology, Oslo, Norway; [5]Oslo University Hospital, Department of Immunology, Oslo, Norway; [6]University of Oslo (UiO), KG Jebsen Centre for B cell Malignancies, Oslo, Norway; [7]Norwegian Institute of Public Health, Department of Method Development and Analytics, Oslo, Norway*

Background: Safety and efficacy of updated bivalent vaccines, containing both the original vaccine variant of SARS-CoV-2 Spike and either Omicron variants BA.1 or BA.4/5, are of particular interest in arthritis patients on immunosuppressive therapies. With the continuous emergence of new viral variants, it is important to evaluate whether updated vaccines induce more adverse events in this patient group.
Objectives: To examine if a second booster dose with updated bivalent vaccine increases the risk of adverse events, compared to the first booster dose with monovalent vaccines.
Methods: The prospective Nor-vaC study investigates vaccine responses in patients with immune mediated inflammatory diseases using immunosuppressive therapies (1). The present analyses included arthritis patients who received two booster doses. Patients received available vaccines according to the Norwegian vaccination program. The current recommendation in the Norwegian arthritis population is a three-dose primary vaccination series followed by two booster doses. Adverse events following vaccines doses were self-reported through questionnaires. Adverse events following the first (monovalent) and second (bivalent) booster were compared with McNemar's test.
Results: Between 7th of July 2021 and 6th of December 2022 a total of 243 arthritis patients (127 rheumatoid arthritis, 65 psoriatic arthritis, 51 spondyloarthritis) on immunosuppressive therapies (Table 1) received a first, monovalent (BNT162b2, mRNA-1273) and a second, bivalent booster dose (BNT162b2 (WT/OMI BA.1), mRNA-1273.214, BNT162b2 (WT/OMI BA.4/BA.5)). Adverse events were recorded within 2 weeks in all patients (Figure 1). In total, 45 vs 49 (19% vs 20 %) patients reported any adverse event after a second, bivalent booster dose, compared to the first, monovalent booster, respectively. There was no significant difference in adverse events overall (p= 0.57). The most common adverse events after the second booster were pain at injection site (12 %), flu-like symptoms (9 %) and headache (6 %). No new safety signals emerged. A total of 15 (6 %) patients reported a disease flare after receiving the second, bivalent booster, compared to 21 (8 %) after the first, monovalent booster.
Conclusion: There was no difference in adverse events between the monovalent, first booster, and the bivalent, second booster, indicating that bivalent vaccines are safe in this patient group.

Background: Data on serological immunity after three doses and the long-term immunogenicity (persistence) of COVID-19 vaccine in patients with inflammatory rheumatic diseases (IRD) treated with different immunomodulating drugs are still limited.

Objectives: To elucidate if 1) a third dose COVID-19 vaccine improves antibody responses, compared to two doses, in patients with IRD treated with biologic or targeted synthetic DMARD (b/tsDMARDs) treatment given as monotherapy or in combination with conventional synthetic DMARDs (csDMARDs) compared to controls, and 2) the persistence of antibody response after two doses of COVID-19 vaccine in IRD patients.

Methods: Antibody levels to two antigens representing Spike full length protein and Spike S1 and a Nucleocapsid C-terminal fragment (used to confirm previous COVID-19 infection) were measured in serum samples collected 2-12 and 21-40 weeks after the second vaccine dose and 2-12 weeks after the third dose using a multiplex bead-based serology assay. A sufficient antibody response (seropositivity) was defined as having antibodies over the cut-off level for both spike antigens (1). WT (wild type) anti-Spike IgG and omicron BA.1 and BA.2 variants were measured. Patients with IRD receiving immunomodulating treatment, regularly followed at a rheumatology department and a group of controls were recruited from five Swedish region.

Results: In total, 323 of 414 patients with IRD and 36 controls who received three vaccine doses participated in this part of the study. Following treatment groups were included: rituximab (n=118; 68% female; mean age 67 years), abatacept (n=18; 72% female; mean age 64 years), IL6r inhibitors (n=60; 73% female; mean age 64 years), JAK-inhibitors (n=44; 80% female, mean age 52 years), TNF-inhibitors (n=59; 70% female; mean age 47 years;), IL12/23/17 inhibitors (n=24; 46% female; mean age 54 years) and controls (n=36; 75% female, mean age 51 years). b/ts DMARD treatment was given as monotherapy or in combination with csDMARD, methotrexate (MTX) being the most frequently used csDMARD (32.5%). Compared to results after two vaccine doses, proportion (%) of seropositivity after three vaccine doses increased significantly in groups rituximab +/- DMARD (p=0.003 and p=0.004, respectively), IL6r inhibitors +DMARD (p=0.02), and abatacept+DMARD (p=0.01). However, the proportion of seropositivity after three vaccine doses was still significantly lower in rituximab treated patients (52%) compared to other treatment groups or controls (p<0.001) (Figure 1A/B). Antibody response to WT, omicron sBA.1 and sBA.2 showed similar pattern with the lowest levels among patients treated with rituximab. When antibody response was compared between 2-12 weeks and 21-40 weeks after second dose, the proportion of seropositive rituximab treated patients decreased from 34.9 % to 32.6%. All patients with JAK inhibitors and with JAK-inhibitors and IL6r-inhibitors seropositive 21-40 weeks after the second vaccine dose. Patients treated with other bDMARDs were not included in this analysis due to limited number participants.

Conclusion: In this Swedish study including IRD patients receiving different b/t DMARDs, a sufficient immunogenicity of the third dose of COVID-19 vaccine was observed in all treatments with exception for rituximab. However, the increased proportion of seropositivity after the third COVID-19 vaccine doses in rituximab and other patients with insufficient response to two doses including response to the omicron variants, supports the current recommendations on additional booster doses. The immunogenicity of two vaccine doses was preserved to 40 weeks in majority of patients treated with different immunomodulating treatment with exception for rituximab.

Rodriguez de la Peña[3], S. Sanchez - Ramon[4], G. Mato Chaín[5], G. Candelas2. *[1]Hospital Clínico San Carlos, Rheumatology Department, Madrid, Spain; [1]Hospital Clínico San Carlos, Rheumatology Department, Madrid, Spain; [3]Hospital Clínico San Carlos, Immunology Department, Madrid, Spain; [4]Hospital Clínico San Carlos, Clinical Immunology Department, Madrid, Spain; [5]Hospital Clínico San Carlos, Preventive Medicine Department, Madrid, Spain*

Background: Data on cellular and humoral immunogenicity triggered by SARS-CoV-2 vaccines in patients with autoimmune rheumatic diseases (ARDs) are limited. While current vaccine efforts have focused on the induction of neutralizing antibodies against SARS-CoV-2, T-cell immunity may also provide protection against infection. Experimental data suggest that CD8+ T cell responses may have a protective role in the presence of decreasing or sub protective antibody titers [1].

Objectives: The aim of this project is to describe the serological and T cell responses to the third dose of vaccine (either with BNT162b2 mRNA or ChAdOx1 nCoV-19 replication-deficient adenoviral vector vaccines) in a cohort of patients with ARDs (rheumatoid arthritis and spondyloarthropathies) treated with biologic therapies, to describe the impact of these treatments on vaccine response in this patient population. As a second objective, we will describe the characteristics of patients who did not present an adequate immunogenic response.

Methods: Case-control study. We studied in 79 patients with ARDs and in 31 healthy controls, anti-SARS-CoV-2 specific interferon-gamma (IFN-γ) production measured by IGRA between 8-12 weeks after the third dose of anti-SARS-CoV-2 vaccine. In addition, humoral response was measured by anti-S1 IgG antibody production measured by chemiluminescent microparticle immunoassay. Statistical comparison between categorical variables was performed by Fisher's or $\chi 2$ test. For quantitative variables by Kruskal-Wallis test or Mann-Whitney test.

Results: 79 patients with ARDs (48 women, 31 men; mean age 58±11.4) 43 (54%), with rheumatoid arthritis and 36 (45.6%) with spondyloarthropathies. 32 (49.5%) of them were on glucocorticoid treatment (mean dose 4.92 mg/day), 25

(31.6%) on methotrexate and 56 (70.9%) on anti-TNF. Post-vaccination results showed positive T-cell immune responses in 68 of 79 (86.1%) ARDs patients with mean IFN- γ anti-SARS-CoV-2 titers of 1,606.85 mUI/ml. 7 (8.9%) of ARDs patients showed negative IFN-γ SARS-CoV-2 levels, while 4 (5%) had borderline titers. 100% of patients with previous COVID 19 disease had positive cellular responses. Within the group of negative or borderline cellular responses, 7 of 10 were men (70%), with no significant differences in terms of diagnosis, comorbidities or immunosuppressive treatments used. In the control group, 100% presented positive cellular responses. Anti-Spike IgG antibodies were detectable in all patients with ARDs as in the control group.

Conclusion: Our preliminary data show that most patients with ARD were able to generate an adequate specific cellular response after vaccination against SARS-CoV-2, emphasizing the relevance of vaccination in this group. Specific antibody responses secondary to anti-SARS-CoV-2 vaccination were detected in all patients with ARD. Our data could support the relevance of these immune responses to personalize prevention, vaccination decision-making and treatment in this subgroup of patients.

Background: Commercially available ELISA-based antibody tests are used to evaluate vaccination success against SARS-CoV-2 as recommended for immunocompromised and at-risk patients by medical committees in Germany and Austria [1,2], but it is unclear whether they correlate with neutralization of the Omicron variant.

Objectives: The objective was to compare the test performance of different ELISA-based SARS-CoV-2 wild-type or adapted Omicron BA.1 antibody test systems with wild-type and BA.1 virus neutralization as measured by pseudovirus neutralisation tests (pVNT).

Methods: 269 serum samples of a cohort of 44 non-immunosuppressed participants and 65 MTX-treated rheumatic patients taken before and after COVID-19 booster vaccinations were measured using COVID-19 antibody testing systems with wild-type and Omicron BA.1 antigens developed by three different manufacturers (surrogate virus neutralization test cPass, and binding antibody tests QuantiVac and SeraSpot), as well as with a pVNT. The pVNT was considered the gold standard for determining the presence and level of anti-SARS-CoV-2 antibodies.

Results: All three wild type ELISAs showed excellent test performance compared with wild type neutralization in pVNT. However, out of 56 samples without Omicron BA.1 neutralization in pVNT, 71.4% showed positive results in at least one and 28.6% in all three wild-type ELISAs at the manufacturer-defined cut-offs. Omicron ELISAs showed either decreased specificity (57.1% and 55.4% for binding ELISAs) or sensitivity (51.2% in cPass) compared to Omicron neutralization in pVNT. The proportion of any false positive results among all samples decreased from 26.5% before to 3.2% after booster vaccination, however binding antibody test specificities remained below 70%. Detailed results for all test systems can be found in Table 1 and Figure 1.

Conclusion: Decisions for booster vaccination or passive immunization of at-risk patients should not be based solely on antibody tests, because they do not indicate neutralization of Omicron as reliably as they did against wild-type.

Background: A growing number of articles describe new-onset inflammatory rheumatic diseases (IRD) - including inflammatory joint diseases (IJD), polymyalgia rheumatica (PMR), connective tissue diseases (CTD) and vasculitis - in close temporal association with SARS-CoV-2 infection (1). On the other hand, also the exposure to vaccines may elicit autoimmunity and reports of IRD following vaccination with anti-COVID-19 vaccines appeared in literature since the earliest phases of the vaccination campaign (2,3).

Objectives: The aim of the present study was to contribute to the knowledge on the spectrum of new-onset post-COVID-19 and post-vaccine IRD with a comparative analysis from a large multicentric observational study.

Methods: In the present cohort study, we collected consecutive cases of IRD or acrosyndrome encountered during routine clinical practice from November 2021 to October 2022 (12 months) satisfying one of the following inclusion criteria: a) onset of the rheumatic manifestations within four weeks from SARS-CoV-2 infection, confirmed by nasopharyngeal swab OR, b) onset of the rheumatic manifestations within four weeks from the administration of one of the COVID-19 vaccines approved for administration in Italy during the collection period. Exclusion criteria were a past history of any IRD or acrosyndrome.

Results: A total of 270 cases were entered in the database. Three records were excluded because identified as mechanical pain (n = 1) or fibromyalgia (n = 2). The final analysis cohort comprised a total of 267 patients, of which 122 (45.2%) patients in the post-COVID-19 (age 54 ± 17 years, 69.7% females) and 145 (54.8%) patients (age 58 ± 16 years, 66.2% females) in the post-vaccine cohorts. Mean delay between COVID-19 diagnosis or vaccine administration and rheumatic manifestations development was 14.5 ± 7.8 vs 13.9 ± 8.5 days, respectively (p = 0.59). Distribution of various IRD categories differed between the two cohorts (Figure 1): the post-COVID-19 cohort had a higher percentage of patients classified as having IJD (52.5% vs 37.2%, p = 0.013) while the post-vaccine cohort had a higher prevalence of patients classified as PMR (33.1% vs 21.3%, p = 0.032). No differences were detected in the percentage of patients diagnosed with CTD (19.7% vs 20.7%, p = 0.837) or vasculitis (6.6% vs 9.0%, p = 0.467).

Conclusion: Although temporal association does not imply causation, our study reports the largest cohort of post-COVID-19 and post-vaccine IRD described to date and supports the hypothesis that new-onset IRD may be triggered by SARS-CoV-2 infection or COVID-19 vaccines. The spectrum of possible clinical manifestations is broad and includes different IJD, PMR, CTD and vasculitis in both cohorts. Our data also suggest a differential pattern of expression: while IJD are the most common IRD following SARS-CoV-2 infection, PMR is relatively more frequent after vaccine administration.

POS0542 LYMPHOCYTES POPULATIONS AND AUTOANTIBODIES, IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS: A LONG-TERM STUDY OF COVID-19 CASES AND NON-COVID-19 CONTROLS

Keywords: COVID, Rheumatoid arthritis

J. Arias-Aponte[1], A. Gómez-López[1], P. D. Nieto-Zambrano[2], M. C. Cortés-Osma[2], H. F. Restrepo-Guerrero[1], M. L. Monsalve-Córdoba[1], E. Garavito-Rodríguez[1], R. Parra-Medina[3], L. Villarreal[4], A. Rojas-Villarraga[3], P. Santos-Moreno[2].

Background: COVID-19 infection favors multiple chronic disparities in the base health status, currently known as post-COVID syndrome (PCS), that can be related to immunological variations. It is important to determine if these alterations (both clinical and immunological) exist in a long-term period in patients with rheumatoid arthritis (RA) who have suffered from this infection.
Objectives: The aim of this study was to assess the immunological [Lymphocyte populations (LP) and Autoantibodies (Ab)] and clinical profile of RA patients who suffered from COVID-19 and compare it with non-COVID-19 RA patients.
Methods: A nested Case-control study of RA patients evaluated under a multidisciplinary model and strict follow-up with a treat to target strategy (T2T). Cases: RA patients and confirmed COVID-19 infection in the last 24 months and Controls: RA patients with no history of this infection. Subgroups in cases: a) Long covid (LC): symptoms after infection that persist for ≥4 weeks; b) PCS: symptoms persist for ≥12 weeks and c) symptoms < 4 weeks. Sociodemographic, clinical, and paraclinical variables of RA and COVID-19 infection (in cases) were captured. Antinuclear antibodies (ANAS), anticardiolipin antibodies, LP (BD FACSDuet™ - BD FACSLyric™ multiparameter flow cytometry) T, C, and NK were evaluated. Univariate and bivariate analyzes (STATA 17) were performed. Approval ethics committee was obtained.
Results: A total of 300 patients were included (148 cases and 152 controls; 87.3% women). Median age 59 years (Interquartile range -IQR 11), disease duration 12 years (IQR 12). The 71.86% were in low disease activity. There were no significant differences in sociodemographic and clinical characteristics between cases and controls. Cases had a time since infection of 18.5 months (IQR 7). Of the total cases, 69% presented LC and 63% with PCS. No significant differences were found between cases and controls in the LP T, B and NK, nor in the Abs evaluated. Similarly, there were no differences in the immune profile evaluated when comparing patients with LC and PCS with those with symptoms < 4 weeks after COVID-19 infection.

Table 1. Profile of autoantibodies and lymphocyte populations.

[a] Chi-square Pearson [b] Median-IQR [c] U Mann-Whitney Test

Conclusion: The results propose a general description of a specific population of patients with RA with low disease activity, under treatment in a strict follow-up model, in which no differences were found in the behavior of the immunological profile (independent of symptoms of LC and PCS) evaluated long-term after infection with those who did not have COVID-19. This suggest that they return to their basal homeostatic state, something that has not yet been reported up to now. These results should forwardly be replicated in populations with other characteristics of RA.

POS0543 DETECTION OF SARS COV-2 ANTIBODIES FOLLOWING VACCINATION IN PATIENTS WITH RHEUMATIC MUSCULOSKELETAL DISEASE (DECODIR) – A REPORT FROM A DANISH PROSPECTIVE COHORT STUDY

Keywords: Inflammatory arthritides, Autoantibodies, COVID

C. Graversgaard[1], K. Schreiber[1,2,3], H. Jakobsen[1], R. Petersen[1], A. B. Bojesen[1], N. Steen Krogh[4], B. Glintborg[4,5], M. L. Hetland[4,5], O. Hendricks[1,2,6]. *[1]Danish Hospital for Rheumatic Diseases, Department of Rheumatology, Sønderborg, Denmark; [2]University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; [3]Guy's and St Thomas' NHS Foundation Trust, Thrombosis and Haemostasis, London, United Kingdom; [4]Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Rigshospitalet, DANBIO, The Danish Rheumatologic Biobank and Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Copenhagen, Denmark; [5]Faculty of Health and Medical Sciences, University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [6]Bonn-Rhein-Sieg University of Applied Science, Paul Ehrlich Society, Bonn, Germany*

Background: The COVID-19 pandemic caused concerns whether patients with rheumatic musculoskeletal disease (RMD) treated with conventional (cs) or biologic (b) disease modifying drugs (DMARDs) and/or prednisolone exhibit an adequate immune response to the applied SARS-CoV2 vaccines.
Objectives: We established the DECODIR study to assess and compare the efficacy of the SARS-CoV2 vaccines administered as part of the national vaccine rollout: BNT162b2 vaccine (Pfizer/BioNTech) and mRNA-1273 vaccine (Moderna). The vaccines were offered as two doses four weeks apart; followed by a booster vaccination six months later. This national regimen included inflammatory rheumatic patients regardless of their respective anti-inflammatory treatment. We used patients' SARS-CoV2 IgG serum level as proxy for vaccination response (1).
Methods: The study was conducted as a longitudinal prospective cohort study. Patients with rheumatoid arthritis (RA), spondyloarthropathies (SpA) or psoriatic arthritis (PsA) receiving their outpatient treatment at the Danish Hospital for Rheumatic Diseases, Sonderborg, and monitored in the Danish DANBIO registry, were included. Blood samples, Disease activity and treatment information (cs/bDMARD, prednisolone) were collected at baseline (i.e. prior to vaccination), after six weeks, six and twelve months. SARS-CoV-2 IgG levels in serum were assessed by ELISA (Thermo-Fischer), and manufacturer's cut-off (>=10 EliA U/mL) selected as definition of sufficient IgG response. Antibody response was measured and compared at all four time points. Associations between antibody response, age, gender, disease (RA/PsA/SpA), treatment (none, cs/bDMARD or prednisolone) and disease activity were tested using proportional odds regression and bootstrapped tests of medians. Results were reported using mean, median (IqR) and bootstrapped 95% confidence interval (CI) of the median.
Results: A total of 243 patients were included at baseline and all were followed-up after six weeks; data from 233 patients were available at six months and for 229 patients at twelve months' follow-up. Those 229 patients had completed the national vaccination programme. The measurements performed 6 months after baseline demonstrated a *per se* decrease of IgG levels for the whole study population (median of 2.08 EliA U/mL at 6 months vs. 16 EliA U/mL at 6 weeks). The final measurements performed after twelve months demonstrated a significant increase of IgG levels. Thus, the completed vaccination programme, was followed by a significant increase in IgG levels (median of 100 EliA U/mL at twelve months vs. 16.5 EliA U/mL at six months, $p < 0.001$). Sufficient response rates were now recorded in all treatment scenarios, also in patients treated with prednisolone or combination of csDMARD and bDMARD. These two groups were at 6 months characterized by significant lower response rates, when compared with patients without any DMARD treatment.
Conclusion: Completed vaccination programme defined as two doses plus booster vaccination resulted in a sufficient vaccination response as measured by IgG levels regardless of RA treatment. It is noteworthy that IgG levels increased markedly in patients treated with a combination of cs/bDMARD or oral prednisolone, who had low IgG levels (below manufacturer's cut-off >=10 EliA U/mL) after 6 months. Our results strongly support the efficacy of the complete vaccination

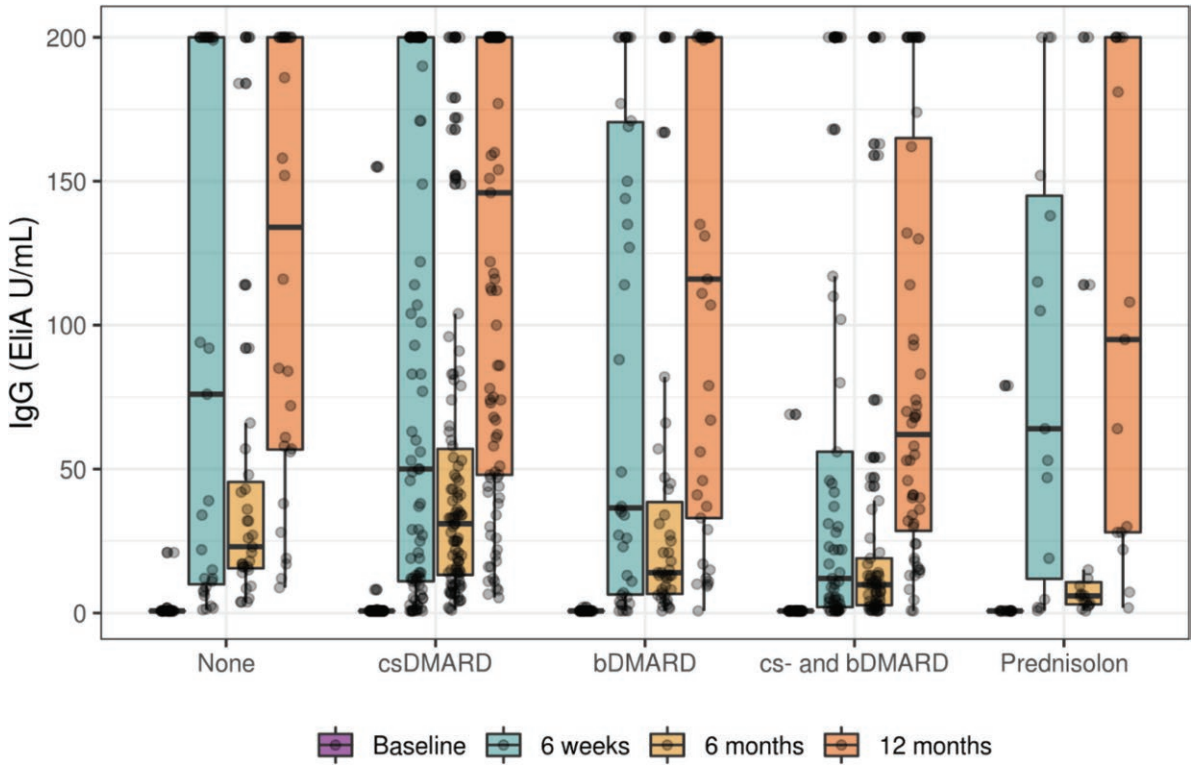

Figure 1. Serum IgG-levels at baseline, 6 weeks, 6 months and 12 months; stratified by antirheumatic treatment. (*Box plot showing median and interquartile range*).

programme including the 3rd booster vaccine in patients with inflammatory rheumatic diseases.

THE CONTRIBUTION OF THE 3RD AND 4TH BOOSTER BNT162B2 MRNA VACCINES TO PREVENT SEVERE COVID-19 AMONG AUTOIMMUNE INFLAMMATORY RHEUMATOID DISEASES (AIRD) PATIENTS DURING THE OMICRON OUTBREAKS

Keywords: Vaccination/immunization, bDMARD, COVID

Y. Braun-Moscovici[1], M. Kaplan[2], M. Braun[3], R. Dr[1], D. Markovits[1], S. Giryes[1], V. Shataylo[1], R. Erlich[1], K. Toledano[1], F. Hasan[1], K. Dolnikov[1], Y. Tavor[1], A. Balbir-Gurman[1]. *[1]Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Rheumatology Institute, Haifa, Israel; [2]Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Biochemistry Laboratory, Haifa, Israel; [3]Hadassah Medical Center, Hebrew University of Jerusalem, Bioinformatics, Jerusalem, Israel*

Background: The 3rd booster of mRNA vaccines against SARS COV2 was highly efficient against delta variant but data regarding the efficacy of the 3rd and 4th boosters against the omicron variants, among AIRD pts are scarce.

Objectives: We aimed to assess the effect of the 3rd and 4th booster mRNA vaccines against SARS CoV2, in preventing severe COVID-19, in AIRD patients (pts) treated with immunomodulating drugs.

Methods: 212 pts (mean age(SD) 57(13), disease duration 11.2(7.4), who received the 3rd booster (Pfizer) were included in the study. We performed serology tests 24 weeks after the second dose of vaccine and 4-8 weeks after the 3rd booster. IgG Antibodies (Ab) against SARS COV2 virus were detected using the SARS-Cov-2 IgG II Quant (Abbott) assay. The test was considered positive above 50 AU/ml. Data regarding COVID-19 infection during the 5th outbreak (omicron) were collected from the medical files. The length of observation period was defined as the time from the 3rd booster to the last hospital visit or COVID 19 diagnosis, whichever occurred first.

Results: The 3rd booster administration (Pfizer) significantly augmented the humoral response (from mean(SD) 1121(4723) AU/ml to 12153(13687)). 58 patients received the 4th booster and 18 the 5th booster. COVID-19 was diagnosed in 103 pts (49%) within mean(SD) 224.8(106.5) days after the 3rd booster vaccination. 109 pts remained free of disease during mean(SD) follow-up 230.6(133.9). Following the 4th booster, 26 (45%) out of 58pts contracted COVID-19 within mean(SD) 97.6(78.7) days after the vaccination. One 70 year old patient (vaccinated 3 times) died and 2 other pts (rituximab treated) had severe COVID-19. The IgG Ab titer after the 3rd booster was lower in pts who contracted COVID 19 compared to those uninfected (mean(SD), median 8777.9(11716.4),3475 AU/ml vs 15348.1(14649.1),10801, p=0.004). There were no statistically significant differences between the pts with COVID-19 and those without, regarding age, type of disease, treatment and humoral response 24 weeks after the 2nd vaccination.

Conclusion: Despite an enhanced humoral response obtained after the 3rd booster, 49% of AIRD pts vaccinated with 3 doses and 45% of pts vaccinated with 4 doses had COVID-19 during the omicron outbreaks. Higher humoral response to the 3rd booster was associated with a lower rate of COVID19. The booster vaccines conferred 99% protection against severe COVID-19.

POS0545

PRE-EXPOSURE PROPHYLAXIS OF COVID-19 WITH TIXAGEVIMAB AND CILGAVIMAB IN RHEUMATOLOGIC PATIENTS TREATED WITH RITUXIMAB: DATA FROM A SINGLE-CENTRE COHORT

Keywords: COVID, bDMARD

M. Manara[1], M. Sette[1,2], L. Giudice[1,2], M. Biggioggero[1], N. Del Papa[1], E. G. Favalli[1,2], M. Gerosa[1,2], F. Ingegnoli[1,2], R. Caporali[1,2]. *[1]ASST G. Pini-CTO,*

Department of Rheumatology and Medical Sciences, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Background: Rheumatologic patients treated with Rituximab (RTX) are at higher risk of severe COVID-19 and death. The B-cell depletive treatment significantly affects B cell functions involved in anti-SARS-CoV-2 response, leading to relevant impacts on the clinical and serological course of infection, long-term immunity, and vaccine responses. In light of these observations, pre-exposure prophylaxis (PrEP) of COVID-19 with Tixagevimab and Cilgavimab (TGM/CGM) was recently approved in Italy for all patients treated with RTX in the previous year, independently of their serological status against SARS-CoV-2.
Objectives: We aimed to evaluate the efficacy and safety of TGM/CGM in a single-centre cohort of rheumatologic patients treated with RTX.
Methods: From October 2022, all patients who had been treated with RTX in the previous 12 months and who underwent clinical assessment at our rheumatologic tertiary centre were screened for eligibility to PrEP of COVID-19 with TGM/CGM. According to the indications of the Italian Medicines Agency (AIFA), we excluded subjects with major cardiovascular risk factors and/or coagulation abnormalities; those who reported a previous allergic reaction to any anti-COVID19 vaccine were referred to an allergologist for an evaluation before TGM/CGM administration. Patients who agreed to be treated with TGM/CGM signed an informed consent. Clinical and demographic features were collected at baseline, and follow-up phone assessment was performed the day after and 1 month after TGM/CGM administration, to assess treatment tolerability and new COVID-19- related events. A descriptive analysis was performed.
Results: From 1 October 2022 to 31 December 2022, 90 subjects were screened for eligibility to TGM/CGM. Among them, 11 were excluded for contraindications due to comorbidities and 55 refused TGM/CGM administration. Among patients who agreed to receive PrEP of COVID-19, 21 received TGM/CGM before 31 December 2022 and 3 were scheduled for January2023. Patients treated with TGM/CGM had a mean age of 54 years (standard deviation: 17) and 19 (90.5%) were female; 9 were affected by rheumatoid arthritis and 12 by other rheumatologic diseases (3 systemic lupus erythematosus, 2 systemic sclerosis, 1 Sjögren syndrome, 1 juvenile idiopathic arthritis, 3 anti-synthetase syndrome, 2 vasculitides). Most of them had completed the vaccination schedule against COVID-19 (19, 90.5%) and 9 (42.8%) reported an infectious event by SARS-CoV-2 in the previous year. One month after TGM/CGM administration, no patient reported adverse events related to TGM/CGM nor COVID-19 related symptoms.
Conclusion: PrEP of COVID-19 with TGM/CGM was well tolerated in our population of rheumatologic patients treated with RTX in the previous year and no COVID-19 related symptoms were observed in the month of follow-up after TGM/CGM administration. Future observations may provide further data on long-term efficacy of TGM/CGM in preventing COVID-19.

Background: Treatment with Rituximab (RTX) in patients with rheumatic diseases (RD) has presented a challenge during the COVID-19 pandemic, as RTX leads to markedly reduced and often undetectable antibody responses after COVID-19 vaccination (1).
Objectives: To investigate the effect of COVID-19 mRNA revaccination (two doses) on the antibody response in patients with RD who were initial vaccine non-responders. Further, to examine if B-cell levels or T-cell responses before revaccination predicted seroconversion.
Methods: From a RD cohort (COPANARD) vaccinated with the standard two-dose COVID-19 vaccinations, we enrolled cases without detectable antibody responses (n=17) and controls with detectable antibody response (n=29). Blood donors (n=32) were included as additional controls. Samples were collected before and six weeks after completed revaccination. Total antibodies (abs) and specific IgG, IgA, and IgM against SARS-CoV-2 spike protein, SARS-CoV-2 neutralizing abs, and SARS-CoV-2 reacting CD4+ and CD8+ T-cells were measured before and after revaccination. B-cells (CD19+CD45+) were quantified before revaccination. This study was funded by the Danish Rheumatism Association.
Results: Patient demographics are given in Table 1. Forty-seven percent of cases had detectable total SARS-CoV-2 abs and neutralizing abs after revaccination. However, antibody levels were significantly lower than in controls and blood donors ($p<0.008$), Figure 1A+B. Revaccination induced an antibody class switch in cases with a decrease in detectable IgM abs (Baseline 11/17, Followup 3/17) and increase in IgG. No significant difference was observed in T-cell responses before and after revaccination between the three groups, Figure 1C. The proportion of cases with detectable CD4+ T cells increased from 69% to 88% ($p=0.25$), and for CD8+ T cells, the proportion decreased from 88% to 82% ($p=1.00$). Only 29% of cases had measurable B-cells compared to 100% of controls and blood donors, Figure 1D. Fifty percent of revaccinated cases who seroconverted had measurable B-cells before revaccination, Figure 1D. Univariate logistic regression analysis was performed to analyze if active RTX treatment, the presence of B-cells, or a positive T-cell response prior to revaccination predicted seroconversion of total SARS-CoV-2-abs in the patient cohort. We did not find a significant explanatory effect of either variable in the univariate logistic models, data not shown.

Table 1. Demographics

	Cases Revaccination, n=17		Controls Boost, n=29	
Female sex, no(%)	14	82%	21	72%
Age, median (IQR)	65	49 - 70	67	62 - 72
Disease duration, years	15	10 - 18	22	9 - 31
Rheumatoid Arthritis/SLE	13/4		10/19	
None DMARD	5	29%	8	28%
Prednisone	4	24%	1	3%

Time from RTX to revaccination, months	9	5-12	49	

A+B. Presence and levels of Total SARS-CoV-2 abs and neutralizing abs. Pie charts indicate the presence of measurable abs and neutralizing abs inhibitory activity. B=baseline. For controls that all received a single booster mRNA dose, abs were additionally measured 2 and 6 weeks after boost (F2 and F3 under controls). For cases receiving full two-dose revaccination, abs were measured 2 weeks after the 3rd and 2 + 6 weeks after the 4th dose (marked F1, F2, and F3, respectively, under cases) C SARS-CoV-2 SPIKE specific CD4+ and CD8+ T-cells in cases, controls, and blood donors D Correlation between CD19+CD45+ B-cells pre-revaccination and antibody levels.

Figure 1.

Conclusion: In conclusion, forty-seven percent of initial non-responders were able to seroconvert after two-dose revaccination. However, plasma concentrations of the antibodies against SARS-COV-2 and the levels of neutralizing capacity remained significantly lower than in immunocompetent blood donors. B-cell levels or T-cell responses before revaccination did not predict seroconversion. Our study suggests that patients with RDs who did not mount a detectable serological response to a COVID-19 mRNA vaccine have a T cell response similar to immunocompetent controls. Future studies should establish the antibody levels that identify RD patients without sufficient protection against SARS-CoV-2 infection.

Background: We recently performed a long-term, model-based comparison of the humoral immunogenicity following two-dose vaccination with BNT162b2 and mRNA-1273 in individuals from SCQM, the Swiss cohort for patients with inflammatory rheumatic diseases (IRD). Vaccination with mRNA-1273 resulted in higher humoral immunogenicity compared to BNT162b2 throughout 24 weeks post second vaccine dose [1]. In booster vaccinations, the dose of mRNA-1273 was reduced and it is currently unknown if there was a difference in SARS-CoV-2 infections in BNT162b2 and mRNA-1273 recipients with IRD after the third vaccine dose.

Objectives: To investigate the risk of test-positive SARS-CoV-2 infection after three doses of BNT162b2 or mRNA-1273 in IRD patients.

Methods: Adult patients from the SCQM registry who previously participated in an observational cohort study comparing vaccine-induced humoral immune responses following two doses of BNT162b2 or mRNA-1273 were invited to participate in the next phase of the study. Participants answered study questionnaires via the mySCQM patient app, including on subsequent vaccine doses and SARS-CoV-2 infections, here taken as patient-reported positive PCR or antigen tests. Pre and post third vaccination anti-SARS-CoV-2 IgG (anti-S1) levels were quantified by testing self-collected capillary blood samples using the EUROIMMUN ELISA as previously described [1]. To analyze the risk of infection, we used a Cox proportional hazards model. The time of the third mRNA COVID-19 vaccine dose administration was taken as the baseline. Patient follow-up ended on the minimum date of the following events: testing positive for SARS-CoV-2 infection after the third mRNA COVID-19 vaccine dose, receiving a fourth vaccine dose, last data entry in the mySCQM patient app, or study end (2022-12-01). Patients whose follow-up ended in the first 14 days after the third vaccine dose were excluded from the analysis.

Results: 445 patients were included in the study (67% female; mean age 54 yrs; 36% RA, 36% axSpA, 21% PsA, 7% undifferentiated arthritis). Patients received their third dose of mRNA COVID-19 vaccine between 2021-08-06 and 2022-04-04 (BNT162b2: mRNA-1273 51%:49%; homologous vaccination applied in 95% of patients). Between 2021-12-08 and 2022-11-24, 175 patients reported a positive SARS-CoV-2 test occurring at least 14 days after the third vaccine dose (Figure 1A), only 3 of whom required hospitalization. We found no statistically significant difference in the risk of SARS-CoV-2 infection post third dose due to the vaccine received (mRNA-1273 vs BNT162b2) (Figure 1B). Higher anti-S1 levels at baseline were statistically significantly associated with a lower risk of infection post third vaccine dose. A prior SARS-CoV-2 infection also statistically significantly reduced the risk of infection post third vaccine dose.

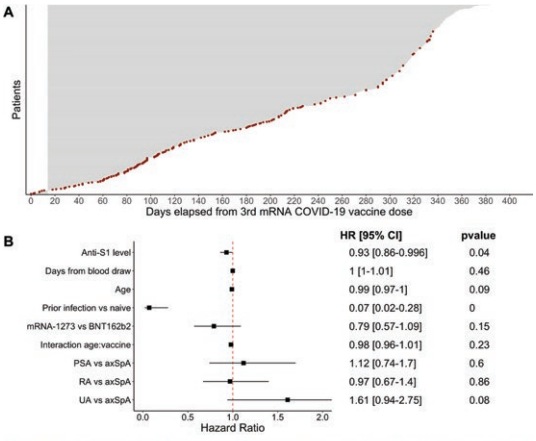

Figure 1. A) **Follow-up time (time at risk) for study** participants sorted by the individual end of follow-up as a function of days elapsed from third mRNA COVID-19 vaccine dose. Ten patients whose follow-up ended within the first 14 days post third vaccine dose were excluded from the analysis. Red dots indicate events, i.e. reporting of SARS-CoV-2 infection. B) **Hazard ratios** with 95% confidence intervals for SARS-CoV-2 infection post third mRNA COVID-19 vaccine dose for model covariates. 'Anti-S1 level': the humoral antibody level at the blood draw taken closest and prior to the date of the third vaccine dose; 'Days from blood draw': the days elapsed from the date of the last blood draw closest to the that of the third vaccine dose and the date of the third vaccine dose; 'Age': the age at baseline (date of third vaccine dose); 'Prior infection vs naïve': prior reported SARS-CoV-2 infection vs none reported; 'Interaction age:vaccine': interaction term showing how the HR of mRNA-1273 vs BNT162b2 changes with increasing age; RA: rheumatoid arthritis; axSpA: axial spondyloarthritis; PsA: psoriatic arthritis; UA: undifferentiated arthritis.

Conclusion: The risk of SARS-CoV-2 infection did not statistically significantly differ between mRNA-1273 and BNT162b2 recipients following a third vaccine dose. Higher anti-S1 levels at the time of the third mRNA COVID-19 vaccine dose, as well as a prior infection, were associated with a statistically significant lower risk of test-positive SARS-CoV-2 infections during follow-up in patients with IRD.

POS0548 HUMORAL AND CELLULAR IMMUNOGENICITY OF THE THIRD DOSE OF MRNA VACCINES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ON BELIMUMAB

Keywords: Systemic lupus erythematosus, COVID, Diagnostic tests

Q. Luca[1], G. De Marchi[1], R. Domenis[2], N. Cabas[1], S. Guella[1], A. Paradiso[2], C. Fabro[1], A. P. Beltrami[2], S. De Vita[1], F. Curcio[2]. *[1]Division of Rheumatology, Academic Hospital "Santa Maria della Misericordia", Udine, Department of Medicine (DAME), 33100, Italy; [2]Institute of Clinical Pathology, Academic Hospital "Santa Maria della Misericordia", ASUFC, Udine, Department of Medicine (DAME), 33100, Italy*

Background: SARS-CoV-2 vaccination with mRNA vaccine (mRNA-1273 e BNT 162b2) represented the cornerstone of the pandemic strategy to prevent severe complications of infection. Immunosuppressive therapies potentially reduce both humoral and cellular-mediated response to vaccination, undermining its protective effect [1].
Objectives: To evaluate humoral and T-cell cellular-mediated immune response after three doses of SARS-CoV-2 mRNA vaccines in patients with systemic lupus erythematosus (SLE) under Belimumab.
Methods: 12 patients on Belimumab and 13 age-matched healthy volunteers were recruited. Patients were in remission or in low disease activity, and they were taking no corticosteroids or only low doses. None of the patients and controls had detectable anti-SARS-CoV-2 antibodies due to previous exposure to the virus. All the patients received three doses of mRNA anti-SARS-CoV-2 vaccines and the humoral and cellular-mediated response were tested 4 weeks after the second dose (T0), 6 months after the second dose (T1) and 4 weeks after the third dose (T2). Comparison with the control group was performed only at time T0 (i.e., 4 weeks after the second dose) since healthy controls didn't attend the third vaccine dose with an overlapping timing Total anti-SARS-CoV-2 RBD antibodies were analyzed using a diagnostic assay, while cellular-mediated response was evaluated using the interferon-gamma release assay (IGRA).
Results: A humoral response was documented in all the patients at T0 (median 459; IQR 225.25-758.5), but the antibody titer significantly declined from T0 to T1 (median 44.7; IQR: 30.3-202; p=0.0066). At T2, the antibody titer significantly increased from T1 (median 2500; IQR: 2500-2500), and it was not different from T0 (respectively p<0.0001, p=0.66). Cellular-mediated response significantly declined from T0 to T1 (p=0.003) but not from T0 to T2 (p=0.3) (Figure 1). No differences were found between patients and controls at T0 as regards both humoral and cellular responses (p=1.0 and p=0.09 for humoral and cellular responses, respectively).
Conclusion: Even if the low number of patients cannot establish definitive conclusions, the third dose of mRNA COVID-19 vaccine can restore both humoral and cellular immune response in SLE patients on Belimumab. In addition, the comparison with a control group of healthy people provided by our study, even if restricted to the T0, showed a similar vaccine response in SLE Belimumab-exposed patients. Overall, our results confirm the concept that in immunocompromised patients the third vaccine dose is not a booster dose, but it is a necessary completion of a regular vaccination cycle. Indeed, the significant decline of the antibody titer after 6 months from the second dose and the incomplete T-cell-mediated cellular response after the third dose in a percentage of patients support the potential role of a fourth dose as a booster dose for those patients exposed to B-cell targeted therapies, like Belimumab or Rituximab.

Background: Although many studies have been conducted on COVID-19 in recent years, there are still unanswered questions regarding breakthrough infections (BTIs), particularly in patients with systemic lupus erythematosus (SLE).
Objectives: This study aimed to determine the occurrence of breakthrough COVID-19 infections in patients with SLE versus other autoimmune rheumatic diseases (AIRDs), non-rheumatic autoimmune diseases (nrAIDs), and healthy controls (HCs).
Methods: The study was based on data from the COVAD questionnaire which amassed a total of 10,783 complete responses from patients with SLE, AIRD, or

nrAIRD, and HCs. After exclusion of individuals who were unvaccinated, those who received one vaccine dose only, and those with uncertain responses regarding the vaccine doses, a total of 9,595 patients formed the study population of the present investigation. If a COVID-19 infection occurred after the initial two vaccine doses and at least one booster dose (at least three doses in total, herein termed full vaccination), it was considered a BTI. Data were analysed using multivariable regression models. Statistically significant results were denoted by *p* values <0.05.

Results: A total of 7,016/9,595 (73.1%) individuals were fully vaccinated. Among those, 1,002 (14.2%) reported at least one BTI, and 166 (2.3%) reported at least two BTIs. Among SLE patients, 867/1,218 (71.2%) were fully vaccinated. Among fully vaccinated SLE patients, 137 (15.8%) reported at least one BTI while 28 (3.2%) reported at least two BTIs. BTI frequencies in fully vaccinated SLE patients were comparable to those of other AIRDs (OR: 1.0; 95% CI: 0.8–1.3; *p*=0.447) and nrAIDS (OR: 0.9; 95% CI: 0.6–1.3; *p*=0.856) but higher compared with HCs (OR: 1.2; 95% CI: 1.0–1.6; *p*=0.022). For SLE patients with three vaccine doses, 113/137 (82.5%) reported at least one BTI while the corresponding number for four vaccine doses was 24/137 (17.5%). Compared with HCs (OR: 10.6; 95% CI: 1.2–93.0; *p*=0.032) and other AIRDs (OR: 3.5; 95% CI: 1.08–11.5; *p*=0.036), SLE patients showed higher frequencies of hospitalisation. AID multimorbidity was associated with a 15-fold increased risk for a need of advanced treatment for COVID-19 (OR: 15.3; 95% CI: 2.6–88.2; *p*=0.002).

Conclusion: COVID-19 BTIs occurred in nearly 1 every 6th fully vaccinated patient with SLE, and 20% more frequently in this patient population compared with fully vaccinated HCs. Moreover, BTIs in SLE patients were more severe compared with BTIs in HCs or patients with AIRDs other than SLE, resulting in a greater need for hospitalisation. AID multimorbidity contributed to a more severe COVID-19 BTI requiring advanced management. These insights call for greater attention to vaccination in the vulnerable group of SLE patients, with appropriate risk stratification towards optimised vaccination strategies.

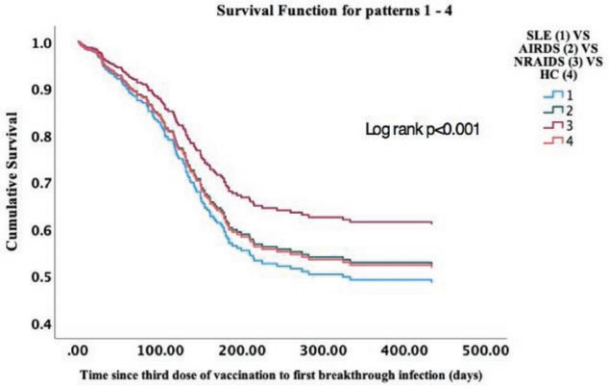

Figure 1. Survival analysis across patients with SLE, AIRDs, or nrAIDs, and HCs. SLE: systemic lupus erythematosus; AIRD: autoimmune rheumatic disease; nrAID: non-rheumatic autoimmune disease; HC: healthy control.

POS0550 IMMUNE RESPONSE AFTER VACCINATION AGAINST SARS-COV2 IN PATIENTS WITH IMMUNOMEDIATED DISEASES (RIM-COV PROJECT)

Keywords: COVID, Vaccination/immunization

Universidad de Alcalá, Clinical Biostatistic Unit, Madrid, Spain

Background: It is known that patients with immunomodulatory treatment may have less immune response to vaccines. Since SARS-CoV2 infection appeared, several vaccines have been developed. In previous studies, it has been observed that some subgroups of patients has a lower antibody response after SARS-Cov2 vaccination, especially patients treated with Rituximab (an anti-CD20 monoclonal antibody); but also in those treated with Mycophenolate Mofetil, Abatacept, JAK inhibitors, anti tumor necrosis factor (TNF) α, Methotrexate or Glucocorticoids. In some studies, an absence of humoral response but the presence of a T-cell response after vaccination has been observed in patients with B-cell depletion, even without finding differences between patients treated with rituximab compared with other immunomodulatory therapies or healthy controls. As well, it has been described a lower T-cell response in patients treated with anti-CTLA4, anti-interleukin 6 or antiTNFα.

Objectives: Our objective is to identify factors that influence humoral and cellular immune responses to SARS-CoV-2 vaccines in patients with immune-mediated rheumatic diseases (IMRDs) in treatment with disease-modifying anti-rheumatic drugs (DMARDs) and in healthy subjects as a control.

Methods: A total of 140 consecutive patients and 24 healthy controls were included in this observational cross-sectional single-centre study. Two months after second or third COVID-19 vaccine dose (BNT162b2 [Pfizer/BioNTech], mRNA-1273 [Moderna] or AZD1222 [AstraZeneca]), we quantified IgG anti-SARS-CoV-2 antibodies by chemiluminescent immunoassay of micro-particles and Interferon (IFN)-gamma production by T cells stimulated with SARS-CoV-2 peptides using an IFN-gamma release assay test. IgG anti-SARS-CoV-2 levels below 1800 AU/ml or IFN-gamma levels below 0.15 IU/ml were considered as a suboptimal humoral or cellular immune response, respectively. Multivariate analyses were used for exploring influence of different factors in these suboptimal immune responses.

Results: Of the140 patients, 101 were women and 39, men, with a median age of 55.9 (46.1-69.7) years and a disease duration of 13 years (6-20.8). 106 patients had a diagnosis of autoimmune arthropathy and 34, of systemic autoimmune disease. The higher risk of having a poor humoral response after the vaccination was shown in those patients receiving only two vaccine doses (OR: 7.83 (2.94-20.83);

p<0.0001), patients with diagnosis of systemic autoimmune disease (OR: 4.73 (1.47-15.21); p=0.009) or patients receiving treatment with Rituximab (OR: 13.17 (3.68-47.11); p<0.0001). There was a moderate association between suboptimal cellular immune response and older age (OR: 1.03 (1.01-1.05); p < 0.01). Receiving only two vaccine doses (OR: 4.02 (1.7- 9.5); p<0.001) and older age (OR: 1.04 (1.01-1.07); p<0.006) were associated with both suboptimal antibody and cellular immune responses to SARS-CoV2 vaccines, without agreement between both immune responses (kappa factor=0.198).

Conclusion: This study allows the early identification of suboptimal responders to SARS-CoV2 vaccines among patients with IMRDs who receive immunomodulatory therapy, and shows the need of a booster dose in elderly patients and, maybe, in patients with systemic autoimmune disease or those who are treated with Rituximab. Future studies demonstrating if these suboptimal immune responses are associated to more severe COVID-19 are required.

POS0551 SARS-COV-2 BREAKTHROUGH INFECTION IN COVID-19-VACCINATED ADOLESCENTS AND YOUNG ADULTS WITH CHILDHOOD-ONSET RHEUMATIC DISEASES

Keywords: COVID, Vaccination/immunization

T. Arkachaisri[1,2], K. L. Teh[1], Y. X. Book[1], S. F. Hoh[3], X. Gao[3], L. Das[1], J. G. Yeo[1,2]. *[1]KK Women's and Children's Hospital, Rheumatology and Immunology, Singapore, Singapore; [2]Duke-NUS Medical School, Rheumatology and Immunology, Singapore, Singapore; [3]KK Women's and Children's Hospital, Department of Nursing, Singapore, Singapore*

Background: Although robust humoral immune response after 2-dosed COVID-19 mRNA vaccination was demonstrated in adolescents and young adults (AYAs) with childhood-onset rheumatic diseases (cRDs) [1], data on prevalence and risk factors of SARS-CoV-2 breakthrough infection are limited.

Objectives: To describe the clinical characteristics and risk factors for SARS-CoV-2 breakthrough infection in vaccinated AYAs with cRD from our prospective and ongoing cRDs COVID-19 vaccination cohort.

Methods: Patients were recruited from March 2021 – December 2022 at KK Women's and Children's Hospital, Singapore. Breakthrough infections were defined as symptomatic infections occurring ≥14 days after the second dose in a two-dose series [2]. Humoral immunogenicity was assessed at 2-3 weeks after first vaccine dose and 1, 3, and 6 months after the second dose by the cPass™ SARS-CoV-2 Neutralisation Antibody (nAb) Assay and calibrated against the World Health Organisation International Standard for SARS-CoV-2 antibodies (WHO-nAb).

Results: 170 fully COVID-19 mRNA vaccinated patients (71% Chinese, 47% male) were included, Table 1. 141 patients received 3rd vaccine, 6 months after the full series. 51% had breakthrough infection at a median of 5.6 (IQR 4.0-6.8, n=22) and 3.7 (IQR 1.3-5.4, n=55) months after 2nd or 3rd vaccines, respectively, with mainly mild symptoms (5% admission). The median WHO-nAb was significantly lower in those with breakthrough infection (987.3 IU/ml, IQR 361.0 - 2083.4 vs 1892.1 IU/ml, IQR 1052.5 - 2657.7, p<0.001). Older patients had decreased risk of breakthrough SARS-CoV-2 infection (OR 0.83, 95% CI 0.739-0.936, p=0.002). A WHO-nAb titre of < 1000 IU/ml increased the risk of breakthrough SARS-CoV-2 infection (OR 4.16, 95% CI 1.964-8.794, p<0.001). Significantly more patients with infection were taking anti-TNF. Withholding methotrexate or mycophenolate mofetil did not impact the breakthrough infection risk.

Conclusion: Despite a robust humoral immune response to COVID-19 mRNA 2-dosed vaccination, one-half of the AYAs with cRDs had breakthrough infections, albeit mild disease. Younger patients and WHO-nAb < 1000 IU/ml increased the risk of infection. Additional vaccine is needed sooner than 6 months after the 2nd dose to prevent infection. Longitudinal data are being collected to determine the vaccine booster interval in our cohort.

Table 1. Clinical characteristics of vaccinated AYA with cRD

Clinical characteristics	Total	No infection, n=83	Infection, n=87	p
Male	80 (47.1)	40 (48.2)	40 (46.0)	0.772
Age (yrs)	16.7 (14.7-19.5)	17.6 (15.1-20.0)	16.3 (14.1-19.2)	0.022
Diagnosis				0.742
Juvenile Idiopathic Arthritis	98 (57.6)	47 (56.6)	51 (58.6)	
Systemic Lupus Erythematosus	30 (17.6)	14 (16.9)	16 (18.4)	
Other Connective tissue diseases	21 (12.4)	13 (15.6)	8 (9.1)	
Others	21 (12.4)	9 (10.8)	12 (13.8)	
Medication				
Prednisolone	32 (18.8)	14 (16.9)	18 (20.7)	0.524
Anti-TNF	57 (33.5)	21 (25.3)	36 (41.1)	0.026
Hydroxychloroquine	43 (25.3)	24 (28.9)	19 (21.8)	0.289
Azathioprine	6 (3.5)	5 (6.0)	1 (1.1)	0.111
Mycophenolate mofetil (MMF)	22 (12.9)	13 (15.7)	9 (10.3)	0.302
Methotrexate (MTX)	42 (24.7)	18 (21.7)	24 (27.6)	0.373
Holding MTX	34 (81.0)	14 (77.8)	20 (83.3)	0.650
Holding MMF	7 (41.2)	4 (36.4)	3 (50.0)	0.644
Patients with WHO-nAb* titer < 1000 IU/ml (before infection or after vaccination)	54 (36.0)	20 (24.1)	34 (50.7)	0.001

POS0552 NEUTROPHIL EXTRACELLULAR TRAPS AND B-CELL ACTIVATING FACTOR AS MARKERS TO PREDICT AND MONITOR ADVERSE EFFECTS AFTER COVID-19 VACCINES

Keywords: Disease-modifying Drugs (DMARDs), Vaccination/Immunization, Biomarkers

Y. M. Kuo[1], Z. Y. Lai[2], C. C. Hsu[3], C. J. Jung[2]. *[1]National Taiwan University College of Medicine and National Taiwan University University Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China; [2]College of Medicine, Taipei Medical University, Microbiology and Immunology, School of Medicine, Taipei, Taiwan, Republic of China; [3]National Taiwan University College of Medicine and National Taiwan University University Hospital, Division of Infection, Department of Internal Medicine, Taipei, Taiwan, Republic of China*

Background: Vaccine-induced immune thrombotic thrombocytopenia (VITT) has also been reported to be related to NETosis. However, whether non-VITT adverse events(AE) and AEs due to non-adenovirus vectors-COVID-19 vaccines are related to NET formation has not been confirmed.

Objectives: We hypothesized that COVID-19 Vaccine could induce circulating products of NETosis in fashion similar to the SARS-CoV-2.

Methods: Citrullinated histone H3 (citH3) and B-cell activating factor(BAFF) serum levels were check in healthy donors(HD) who received two doses of mRNA-1273(Moderna) or ChAdOx1 nCoV-19 vaccines in National Taiwan University Hospital, a tertiary medical center in northern Taiwan. Serial blood tests were done on the day before COVID-19 vaccination(Day 0), before mRNA-1273 boosters (booster Day 0) and 30 days after the boosters (booster Day 30). Therefore, two cohorts, MM-M and AA-M were enrolled from March 2021 to Jan 2022. A REDCap online survey of adverse effects 0-7 days after each vaccination was also performed. Grading of AEs were defined as the previous COVID-19 vaccine trial(KidCOVE trial) described. In addition to HD cohorts, serial antiphospholipid antibodies and citH3 serum titers were also monitored in a case series of three anti-BAFF(belimumab) treated patients, who were hospitalized due to severe AEs after COVID-19 vaccines. We had excluded concomitant COVID-19 infections since all HDs and hospitalized patients were negative for serial SARS-CoV-2 nucleocapsid antibody.

Results: We analyzed two HD cohorts as a whole(n=34), the serum citH3 on booster Day 0 were lowest among the HDs who experienced no AEs from booster Day 0 to Day 7(2.8±1.4 v.s. 12.3±10.8ng/ml(HD with Grade 1 to Grade 3 AEs), p<0.01, U test). Only serum citH3 on booster Day 0 but not on other time points could predict AEs due to COVID-19 vaccines. In addition, the serum BAFF on booster Day 0 were lowest among the HDs who reported no AEs from booster Day 0 to Day 7(1646.1±794.7 v.s. 723.4±218.5pg/ml(HD with ≥Grade 1 AEs), p<0.01). For the three hospitalized AZ-mRNA vaccine experienced patients, two patients suffered fatigue due to hypoperfusion at multiple area brain SPECT, and

one experienced refractory abdominal pain due to mesenteric vein thrombosis soon(eight, 24, and 67 days) after the last doses of COVID-19 vaccinations. Two of them had moderate clinical improvement and both citH3/IgM anticardiolipin decreased after belimumab monthly administration while one needed further IVIG treatment and salvage plasma exchange. In HDs who received two doses of ChAdOx1 vaccines(AZ) and a Moderna booster(AA-M cohort), citH3 increased most significantly after two doses of AZ (p=0.01, U test, cohort AA-M, n=26, Figure 1A) BAFF also increased significantly after two doses of AZ (p<0.001, Figure 1B) Brown-Forsythe heteroscedasticity test indicated their values of three time points were unequal(p=0.04). However, in HDs who received three doses of Moderna, citH3 only numerically increased after two doses of Moderna (p=0.13, U test, cohort MM-M, n=8, Figure 1C.) BAFF did not fluctuate after two doses of Moderna and even after the third dosage of Moderna. Brown-Forsythe test indicated BAFF were equal(p=0.87, Figure 1D.) A trend of higher NET formation and BAFF induction due to adenovirus vectors-COVID-19 vaccine were observed in comparison with mRNA-1273. It has been hypothesized antiplatelet factor 4 may occur after heparin or AZ vaccines due to similarity shared by anionic surfaces in adenoviral vector and heparin molecule. Further profiling of autoantibodies after various COVID-19 vaccines and *in vitro* platelet-neutrophil axis activation test may elucidate the mechanism by which induce NETosis as demonstrated in our cohort.

Conclusion: Dynamic serum citH3 level revealed that neutrophil extracellular traps may play important roles in AEs due to COVID-19 vaccines.

POS0553 TIXAGEVIMAB AND CILGAVIMAB IN RITUXIMAB-TREATED RHEUMATOLOGIC PATIENTS: A REAL-LIFE EXPERIENCE

Keywords: COVID, Real-world evidence

C. Bonini[1], P. Triggianese[1], B. Kroegler[1], A. Bergamini[1], M. S. Chimenti[1].
[1]*University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Rome, Italy*

Background: Rheumatologic patients receiving B cell-depleting therapy (BCDT), such as Rituximab (RTX), have relevant defects in humoral responses to a variety of vaccines. Moreover, RTX-treated patients appear vulnerable to breakthrough infections often showing worst outcomes. Monoclonal antibodies have been developed to provide passive immunity against SARS-CoV-2 in patients with depressed immune systems. Tixagevimab-Cilgavimab (TIX/CIL) is a monoclonal antibody that has been shown to reduce the risk of COVID-19 infections in immunocompromised patients and could be administered as pre-exposure prophylaxis or as targeted anti-SARS-CoV-2 treatment. Few data on real-life evidence on TIX/CIL in RTX-treated rheumatologic patients have been documented.

Objectives: The objectives of this study were to identify breakthrough COVID-19 infections and to evaluate outcomes in RTX-treated rheumatologic patients who underwent pre-exposure prophylaxis or treatment with TIX/CIL.

Methods: In this retrospective cohort study, we included 13 rheumatologic patients referring to the 3rd level Rheumatology Unit at the Tor Vergata University Hospital in Rome (Italy) who were treated with RTX for remission induction and/or maintenance and received TIX/CIL dose of 600 mg (300 mg Tixagevimab-300 mg Cilgavimab), between February and December 2022. A review of medical records was completed. Data on the rheumatologic disease, immunosuppressive treatment, COVID-19 vaccine status, TIX/CIL administration, peripheral blood CD19 cells and IgG levels before and after TIX/CIL administration were registered.

Results: The mean (±SD) age of included patients was 69 (±9) years, with 92.3% women. The cohort was diagnosed with Rheumatoid Arthritis (RA, 76.9%), Sjogren Syndrome (7.7%), Systemic Sclerosis (7.7%), Dermatomyositis (7.7%); one subject received RTX also for concomitant Multiple Sclerosis. Most patients received COVID-19 vaccines, and all but one received a third dose. All patients received a TIX/CIL dose of 600 mg (300 mg Tixagevimab-300 mg Cilgavimab), the majority (84.6%) of them as pre-exposure prophylaxis, while in 2 patients (15.4%) TIX/CIL was administered as a targeted anti-SARS-CoV-2 treatment. At the time TIX/CIL was administered, patients had a disease duration of 16±8 years. In patients undergoing pre-exposure prophylaxis, serum IgG levels before and after TIX/CIL administration were variable. Pre-TIX/CIL IgG levels were normal (54.5%), low (27.3%), and not available (18.2%). Post-TIX/CIL IgG levels were normal (72.7%), not available (18.2%) and low (9.1%). In those with documented pre- and post-TIX/CIL IgG levels, the levels did not change except for one patient with a normal post-TIX/CIL IgG level compared to a low pre-TIX/CIL IgG level. In addition, before getting TIX/CIL, CD19 was depleted (54.5%) and unavailable (45.5%) among patients. Post-TIX/CIL, CD19 was depleted (63.6%) and unavailable (36.4%). In those with documented pre-TIX/CIL and post-TIX/CIL CD19, the number of cells did not change. Among the 84.6% of patients who received TIX/CIL as a pre-exposure prophylaxis, one patient (9.1%) developed breakthrough COVID-19 disease, with mild symptoms (fever<38°C lasting<2 days, cough, fatigue) and no need of hospitalization. Among the 15.4% of patients who received TIX/CIL as a targeted treatment, none of them required hospitalization. The mean time from the onset of COVID-19 disease to TIX/CIL administration was 3±1.4 days. Regarding rheumatologic diseases, all patients continued RTX-therapy with a mean duration of treatment of 4±0.5 months and remained in remission.

Conclusion: Our findings, including mainly RA-patients, highlight the role of an adequate passive immunity in immunosuppressed patients. However, pre-exposure treatment can be crucial as well as the need to use early anti-viral agents/anti- SARS-CoV-2 mAb in most fragile patients. Larger cohorts and further measures are needed to support that challenge and to better investigate the interplay between RTX and monoclonal antibodies in treated patients.

POS0554 ANTIPHOSPHOLIPID ANTIBODIES AND VASCULAR THROMBOSIS IN PATIENTS WITH THE MOST SEVERE FORMS OF COVID-19

Keywords: Autoantibodies, Anti-phospholipid syndrome, COVID

M. Zlatkovic-Svenda[1,2], M. Zdravković[3,4], M. Ovuka[5], M. Ogrič[6], S. Čučnik[6,7], P. Zigon[6,8]. [1]*University of Belgrade - Faculty of Medicine, Institute of Rheumatology, Belgrade, Serbia;* [2]*Faculty of Medicine Foča/ University of East Sarajevo, Internal Medicine, Foča, Bosnia and Herzegovina;* [3]*University Clinical Hospital Center Bezanijska kosa, Belgrade, Serbia, Internal Medicine, Belgrade, Serbia;* [4]*University of Belgrade - Faculty of Medicine, Internal Medicine, Belgrade, Serbia;* [5]*Clinical Hospital Center Pancevo, Serbia, Internal Medicine, Pančevo, Serbia;* [6]*University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia;* [7]*University of Ljubljana, Faculty of Pharmacy, Ljubljana, Slovenia;* [8]*University of Primorska, FAMNIT, Koper, Slovenia*

Background: The presence of antiphospholipid antibodies (aPL) has been observed in patients with COVID-19 (1,2), suggesting that they may be associated with deep vein thrombosis, pulmonary embolism, or stroke in severe cases

(3). Antiphospholipid syndrome (APS) is a systemic autoimmune disorder and the most common form of acquired thrombophilia globally. At least one clinical criterion, vascular thrombosis (arterial, venous or microthrombosis) or pregnancy morbidity and at least one laboratory criterion- positive aPL two times at least 12 weeks apart: lupus anticoagulant (LA), anticardiolipin (aCL), anti-β2-glycoprotein 1 (anti-β2GPI) antibody, have to be met for international APS classification criteria(4). Several reports also associate anti-phosphatidylserine/prothrombin antibodies (aPS/PT) with APS.

Objectives: To combine clinical data on arterial/venous thrombosis and pregnancy complications before and during hospitalisation with aPL laboratory findings at 4 time points (hospital admission, worsening of COVID-19, hospital discharge, and follow-up) in patients with the most severe forms of COVID-19 infection.

Methods: Patients with COVID-19 pneumonia were consequetively enrolled, as they were admitted to the General hospital Pancevo. Exclusion criteria were previous diagnosis of inflammatory rheumatic disease and diagnosis of APS. Clinical data were obtained from the medical records. Laboratory results, including LA, aCL, anti-β2GPI, and aPS/PT antibodies were taken at hospital admission, worsening (defined as cytokine storm, connection of the patient to the respirator, use of the anti-IL-6 drug- Tocilizumab), at hospital discharge and at 3-months follow-up and sent to University Medical Centre Ljubljana, Slovenia for analysis. Statistics was performed by using SPSS 21.

Results: 111 patients with COVID-19 pneumonia were recruited; 7 patients died during hospitalisation (none were aPL-positive on admission and at the time of worsening), 3 due to pulmonary artery embolism. All patients were treated according to a predefined protocol which included antibiotics, corticosteroids, anticoagulation therapy and specific comorbidity drugs; patients with hypoxia were supported with oxygen. During hospitalisation, pulmonary artery thrombosis occurred in 5 patients, one was aPL-positive at all time points (was diagnosed with APS), others were negative. In addition, 9/101 patients had a history of thrombosis (5 arterial thrombosis (coronary and cerebral arteries), none of whom was aPL-positive on admission and at follow-up, and 4 venous thrombosis, one of which was aPL-positive at all time points and received an APS diagnosis). Among 9/101 patients with a history of thrombosis, 55.6% were transiently positive at the time of discharge, compared to patients without prior thrombosis, in whom 26.1% were transiently positive at the hospital release (p=0.074). Two patients had a history of pregnancy complications (both had miscarriage after 10th week of gestation), but did not have aPL positivity at any time point.

Conclusion: Although aPL was expected to be associated with vascular disease in the most severe forms of COVID-19, all patients that have died in our cohort were aPL negative. At hospital discharge, 56% of patients with a history of arterial or venous thrombosis had positive aPL that became negative at the 3-months follow-up (were transienlty positive), which should be considered when prescribing therapy after hospitalisation.

POS0555

HIGH DOSE INTRAVENOUS ANAKINRA TREATMENT IS SAFE AND EFFECTIVE IN SEVERE AND CRITICAL COVID-19 PATIENTS: A PROPENSITY SCORE MATCHED STUDY IN A SINGLE CENTER

Keywords: COVID, bDMARD, Real-world evidence

M. Bektaş[1], S. Yüce[2], M. Ay[3], M. Uyar[3], M. Önder[4], M. İ. Kılıç[5]. *[1]Aksaray Trainig and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Aksaray, Turkey; [2]Istanbul Faculty of Medicine, Department of Public Health and Biostatistics, Istanbul, Turkey; [3]Aksaray Trainig and Research Hospital, Emergency Medicine, Aksaray, Turkey; [4]Aksaray Trainig and Research Hospital, Department of Pyhsical Therapy and Rehabilitation, Division of Rheumatology, Aksaray, Turkey; [5]Aksaray Trainig and Research Hospital, Department of Internal Medicine, Aksaray, Turkey*

Background: In COVID-19 severe disease course such as need of intensive care unit (ICU) as well as development of mortality is mainly due to cytokine storm.

Objectives: In this study, we aimed to evaluate the high dose intravenous anakinra treatment response and outcome in patients with severe and critical COVID-19 compared to standard of care.

Methods: This retrospective observational study was carried out at a tertiary referral center. The study population consisted of two groups as follows; the patients receiving high dose intravenous anakinra (anakinra group) between 01.09.2021 and 01.02.2022 and the patients treated with standard of care (SoC, control group) as historical control group who were hospitalized between 01.07.2021 and 01.09.2021.

Results: After the propensity score 1:1 matching 79 patients in anakinra and 79 patients in SoC matched and included into the analysis. Mean±SD patient age was 67.4±16.7 and 67.1±16.3 years in anakinra and SoC group, respectively (p=0.9). Male gender was 38 (48.7 %) in anakinra and 36 (46.2 %) SoC (p=0.8). Overall, ICU admission was in 14.1 % (n=11) and 30.8 % (n=24) (p=0.013; OR: 6.2), intubation in 12.8 % (n=10) and 16.7 % (n=13) patients (p=0.5), 14.1 % (n=11) and 32.1 % (n=25) patients died in anakinra and control group, respectively (p=0.008; OR: 7.1)

Conclusion: In our study mortality was lower in patients receiving anakinra compared to SoC. Intravenous high dose anakinra is safe and effective treatment in patients with severe and critical COVID-19.

POS0556 LONG COVID IN RHEUMATOID ARTHRITIS AND IN PSORIATIC ARTHRITIS: CLINICAL PATTERN AND GENDER-BASED DIFFERENCES FROM A SINGLE-CENTRE CASE-CONTROL STUDY

Keywords: COVID, Rheumatoid arthritis, Psoriatic arthritis

M. Ferraioli[1], L. De Marco[1], L. Fiannacca[1], M. Iacovantuono[1], B. Monosi[1], P. Triggianese[1], P. Conigliaro[1], A. Bergamini[1], M. S. Chimenti[1]. [1]*Rheumatology, Allergology and Clinical Immunology, Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy*

Background: Long Covid (LC) refers to prolonged symptoms after Sars-CoV2 infection not explained by alternative diagnosis lasting 4-12 weeks as defined by the National Institute for Health and Care Excellence. Few studies explored LC in rheumatic diseases patients (RD) concluding that they present persistent symptoms after infection, although lacking a healthy control (HC) group.
Objectives: To evaluate incidence and clinical features of LC on patients affected by Rheumatoid (RA) or Psoriatic arthritis (PsA) as well as infection's influence on disease activity.
Methods: A monocentric retrospective case-control study was conducted on consecutive outpatients affected by RA or PsA in Low Disease Activity or remission, referring to the Rheumatology Unit of University of Tor Vergata (Rome, Italy) between Sep '21 - Sep '22. Inclusion criteria: age ≥ 18 years, proven Sars-CoV2 infection between Jun '21 – Jun '22, 3 doses anti Sars-CoV2 vaccination, recovered for at least 12 weeks, diagnosis of PsA/RA before Feb '20. Exclusion criteria: symptoms explained by other diagnosis (as fibromyalgia, COPD ecc), hospitalization for Sars-CoV2. Patient were evaluated at 12 weeks after infection: demographic data, baseline comorbidities, ongoing therapy at infection and symptoms during and after infection were recorded; disease related data were recorded referred to the last clinical assessment too. Clinical features were compared among RA and PsA and with HC than among females and males patients.
Results: 120 (60 PsA/60 RA) patients and 60 HC were enrolled (Table 1). Patients compared to HC reported higher incidence of dyspnoea during infection while at resolution: lower VAS general health (GH), higher asthenia, joint pain and higher incidence of dyspnoea, chest pain, sleep disturbances and depression. All patients continued their therapy during infection and no differences were found about baseline comorbidities and ongoing therapy. No statistical differences emerged between PsA and RA patients among them but when compared with HC both presented higher VAS fatigue, joint pain, lower GH and a longer duration of anosmia and anageusia after infection. Moreover, PsA presented higher incidence of chest pain after infection and headache during and after infection; RA reported higher incidence of chest pain and headache after infection and dyspnoea during and after. Regarding gender: females reported higher VAS disease activity, asthenia and higher incidence of joint pain, dyspnoea, depression and sleep disturbances at infection resolution. Lastly, female PsA patients presented higher DAPSA score after infection than man. Disease related items were compared before and after infection (Figure 1): statistical significant differences emerged regarding VAS disease activity, asthenia, joint pain and GH in RA and PsA patients.
Conclusion: Here, we documented that RD patients – particularly females - suffer from a higher burden after Sars-Cov2 infection showing statistical significant higher incidence of symptoms than HC and a worsening of disease activity although no disease flare were registered. Thus, LC carrying a significant burden is becoming an urgent health issue that needs immediate prioritization to prevent another *national health disaster* that could be a further blow to health systems.

POS0557 COVID-19 OUTCOMES IN KOREAN PATIENTS WITH GOUT

Keywords: Crystal arthritis, COVID

M. J. Kim[1], B. Ryu[2], S. Yi[3], J. W. Park[4], Y. Jang[1], K. Shin[1]. [1]*Seoul Metropolitan Government–Seoul National University Hospital Boramae Medical Center, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea);* [2]*Seoul Metropolitan Government–Seoul National University Hospital Boramae Medical Center, Biomedical Research Institute, Seoul, Korea, Rep. of (South Korea);* [3]*Seoul National University Hospital, Biomedical Research Institute, Seoul, Korea, Rep. of (South Korea);* [4]*Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Patients with autoimmune inflammatory rheumatic diseases are at higher risk for coronavirus disease (COVID)-19 hospitalization and worse clinical outcomes compared with the general population. However, data on the association between COVID-19 outcomes and gout, or gout-related medications are still lacking.
Objectives: We aimed to compare COVID-19 related clinical outcomes in gout vs. non-gout patients.
Methods: We conducted a retrospective cohort study using the electronic health record-based databases of Seoul National University hospital (SNUH) from January 2021 to April 2022 mapped to a common data model. Patients with gout and without gout were matched using a large-scale propensity score (PS) algorithm. The clinical outcomes of interest were COVID-19 infection, severe COVID-19 outcomes defined as the use of mechanical ventilation, tracheostomy or extracorporeal membrane oxygenation, and death within 30 days of COVID-19 diagnosis. The hazard ratio (HR) for gout vs. non-gout patients derived by Cox proportional hazard models were estimated utilizing a 1:5 PS-matched cohort.
Results: 2,683 patients with gout and 417,035 patients without gout were identified among the patients who visited SNUH. After 1:5 PS matching, 1,363 gout patients and 4,030 non-gout patients remained for the analysis. The risk of COVID-19 infection was not significantly different between patients with gout and those without gout (HR 1.07 [95% CI 0.59-1.84]). Within the first month after the COVID-19 diagnosis, there was also no significant difference in the risk of hospitalization (HR 0.57 [95% CI 0.03-3.90], severe COVID-19 outcomes (HR 2.90 [95% CI 0.54-13.71]), or death (HR 1.35 [95% CI 0.06-16.24]).
Conclusion: Patients with gout did not have an increased risk of COVID-19 infection or worse clinical outcomes. Updates of temporal trends of COVID-19 outcomes in gout patients are yet warranted as new SARS-CoV-2 variants emerge.

Background: Viral infections can trigger flare of autoimmune rheumatic diseases through upregulation of interferon axis. However, global data on flares of AIRDs following COVID-19 infection is scarce.
Objectives: We aimed to study the prevalence and characteristics of patient-self reported flare of AIRDs following COVID-19 infection as part of the ongoing COVID-19 Vaccination in Autoimmune Diseases (COVAD) study.
Methods: The COVAD study, a cross-sectional patient-self reported electronic survey (157 collaborators, 106 countries) collected data on COVID-19 infection, vaccination and flares among AIRDs. The flares were patient self-reported. AIRDs with flare and without flare were compared. Descriptive stats and binary logistic regression (BLR) (adjusting for age, gender, ethnicity, vaccine type, type of immunosuppression, comorbidities, COVID-19 antibody status, and clinical features during previous COVID-19 infection) were performed.
Results: Of the 15165 respondents, 824 patients with AIRDs who contracted COVID-19 infection were identified. Most of the respondents were Caucasians (53.8%), females (86.5%), and had received the Pfizer-BioNTech vaccine (42.8%). Less than half were on glucocorticoids (41.0%), and methotrexate was the most commonly used immunosuppressant (29.9%). One-third (n=324, 36.9%) of patients with AIRDs reported flare following COVID-19 infection. Women and patients with comorbidities such as asthma, chronic obstructive pulmonary disease, diabetes mellitus, mental health disorders, and those with AID comorbidities had higher odds of flare compared to others (Table 1). Notably, certain features of COVID-19 disease such as joint pain (3.1; 2.0-4.9; <0.001), cough (1.5; 1.04-1.2; 0.030), and abdominal pain (2.5; 1.2-5.0; 0.011) were associated with increased risk of flares in BLR while the vaccine type, number of vaccine doses and autoantibodies against COVID-19 were not predictive. Patients who reported flares had worse PROMIS PF10 physical health scores (p=0.038), pain VAS (p<0.001), and lower mental health scores (p<0.001) compared to those who did not report flares.
Conclusion: One in three patients with AIRDs reported post-COVID-19 disease flares. A past history of asthma, comorbidities and those with certain acute COVID-19 symptoms were at higher risk.

POS0559 **ACCELERATED WANING OF HUMORAL IMMUNE RESPONSE TO A THIRD COVID-19 VACCINATION IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASES**

Keywords: Vaccination/immunization, COVID

D. Mrak[1], F. Kartnig[1], D. Sieghart[1], E. Simader[1], H. Radner[1], P. Mandl[1], L. Göschl[1], P. Hofer[2], T. Deimel[1], I. Gessl[1], R. Kain[2], S. Winkler[3], J. S. Smolen[1], T. Perkmann[4], H. Haslacher[4], D. Aletaha[3], L. Heinz[1], M. Bonelli[1]. *[1]Medical University of Vienna, Division of Rheumatology, Vienna, Austria; [2]Medical University of Vienna, Department of Pathology, Wien, Austria; [3]Medical University of Vienna, Division of Infectious Diseases and Tropical Medicine, Wien, Austria; [4]Medical University of Vienna, Department of Laboratory Medicine, Wien, Austria*

Background: A 3rd COVID-19 vaccination is currently recommended for patients under immunosuppression. However, a fast decline of antibodies against the SARS-CoV-2 receptor-binding domain (RBD) of the spike protein has been observed.
Objectives: It remains unclear whether immunosuppressive therapy affects kinetics of humoral and cellular immune responses.
Methods: 50 patients under immunosuppression and 42 healthy controls (HCs) received a 3rd dose of an mRNA-based vaccine and were monitored over a 12-weeks period. Humoral immune response was assessed 4 and 12 weeks after 3rd dose. Antibodies were quantified using the Elecsys Anti-SARS-CoV-2 Spike immunoassay against the receptor-binding domain (RBD) of the spike protein. SARS-CoV-2-specific T cell responses were quantified by IFN-γ ELISpot assays. Adverse events, including SARS-CoV-2 infections, were monitored over a 12-week period.
Results: At week 12, reduced anti-RBD antibody levels were observed in IMID patients as compared to HCs (median antibody level 5345 BAU/ml [1781 – 10208] versus 9650 BAU/ml [6633 - 16050], p < 0.001). Reduction in relative antibody levels was significantly higher in IMID patients as compared to HCs at week 12 (p < 0.001). Lowest anti-RBD antibody levels were detected in IMID patients who received biological diseases modifying anti-rheumatic drugs (DMARDs) or a combination therapy with conventional synthetic and biological DMARDs. Number of SARS-CoV-2-specific T cells against wildtype and Omicron variants remained stable over 12 weeks in IMID patients. No serious adverse events were reported.
Conclusion: Due to a fast decline in anti-RBD antibodies in IMID patients an early 4th vaccination should be considered in this vulnerable group of patients.

POS0560 **OUTCOME OF NEONATES BORN TO PATIENTS WITH RHEUMATIC DISEASES COMPARED TO HEALTHY CONTROLS**

Keywords: Pregnancy and reproduction

A. C. Pecher[1], J. Niessen[2], P. Jakubowski[3], H. Abele[3], J. Henes[1]. *[1]University Hospital Tuebingen, Centre for Interdisciplinary Clinical Immunology, Rheumatology and Autoinflammatory diseases, Tuebingen, Germany; [2]University Hospital Tuebingen, Medical school, Tuebingen, Germany; [3]University Hospital Tuebingen, Department of Obstetrics and Gynecology, Tuebingen, Germany*

Background: In general, more women are affected by rheumatic diseases and often during their reproductive age. Due to disease activity and/or specific autoantibodies autoimmune diseases might lead to impaired fetal outcome. Data from large registries help to improve information on the risks for patients and infants and thus enable us to better advise our patients.
Objectives: To analyse fetal outcome of babies born to patients with rheumatic diseases by different parameters and compare to healthy controls.
Methods: This study compares registry data from 2012–2022 from a specialized centre. We included 351 pregnancies from patients with rheumatic diseases and 1298 from age-matched HC.
Results: Patients with rheumatic diseases were distributed as follows: 58% CTD, 15% RA, 13% SpA, 5% autoinflammatory diseases and 4% vasculitis. Spontaneous abortion rate with 5% was comparable to the general population [1], APGAR, and umbilical cord pH were comparable to HC. Babies born to patients with rheumatic diseases have a significantly different outcome compared to HC: they present with lower birth weight (3245g vs 3038g; p<0.001) and length (50.7cm vs.49.7cm; p<0.001), higher number of intrauterine growth retardation (IUGR; 3% vs 7%; p<0.05) and are more often preterm (10% vs 16%; p<0.01). There is also a difference in the delivery mode, with a significant higher rate of scheduled caesarean birth rate (12%vs.32%;p<0.001),however not of unplanned caesarean birth. We also observed higher number of congenital anomalies (6%vs.12%;p<0.01) usage of postpartal continuous positive airway pressure (CPAP) therapy (4%vs.12%;p<0.001) and transfer to specialized neonatal care (10%vs.19%;p<0.001).When comparing different groups of rheumatic diseases, our analysis shows mainly abnormalities for CTD (especially SLE, Sjogren's syndrome and undifferentiated CTD),with high rates of small for gestational age (SGA; SLE:19%, SS:28%; UCTD:28%), high proportion of planned caesarean birth (SLE:44%).However, congenital anomalies were also more prominent in the group of patients with SpA. Interestingly, in the age group >35years patients and HC assimilated, eg we did not observe significant differences for birth weight anymore.
Conclusion: Fetal outcome of neonates born to patients with rheumatic diseases in general is favourable, as we observed a live birth rate of 95%. This is also supported by important parameters as APGAR and umbilical cord pH, which did not differ in between groups. However, the number of children born before 37gw and lower birth weight/length is significantly higher compared to HC. This has been suggested by us and other groups [2-4], but we here compare the fetal outcome of patients to an age-matched HC group from the same hospital, and therefore more comparable and valid data. One might speculate, that higher rates of preterm births explain the higher admission rate to neonatal care and CPAP therapy. Our data reveal, however, that these differences mainly affect patients with CTD, especially SLE, SS, UCTD, which is of special interest for the risk assessment in the treatment of pregnant patients with rheumatic diseases. Even though spontaneous abortion rates do not differ to the general population, we observed a significantly higher number of congenital anomalies. Further studies are necessary to determine the underlying cause, as both, disease activity and immunosuppressant medication might be responsible.

POS0561 THE LEAKY PIPELINE IN CLINICAL RHEUMATOLOGY ACROSS EUROPE – RESULTS FROM AN ONLINE SURVEY

Keywords: Work-related issues, Health services research, Gender/diversity issues

J. Sautner[1], I. Grabner[2], A. Posch[3,4], C. Duftner[5]. *[1]State Hospital Stockerau, Department of Internal Medicine II, Karl Landsteiner Institute for Clinical Rheumatology, Stockerau, Austria; [2]Vienna University of Economics and Business Administration, Institute for Strategy and Managerial Accounting, Vienna, Austria; [3]IMC University of Applied Sciences Krems, Institute of Tourism, Wine Business and Marketing, Krems an der Donau, Austria; [4]Institute for Accounting, University of Bern, Bern, Switzerland; [5]Medical University of Innsbruck/Tirol Kliniken GmbH, Department of Internal Medicine, Clinical Division of Internal Medicine II, Innsbruck, Austria*

Background: While more than 50% of medical students and residents are women, their proportion drastically diminishes within higher ranks and leadership roles, a phenomenon also known as the "leaky pipeline".

Objectives: We aimed to evaluate the leaky pipeline among rheumatologists across Europe and to assess determinants inducing rheumatologists to leave hospitals.

Methods: Experts in the field of economics developed a questionnaire (50 thematic blocks, containing 172 single items) with relevance to the leaky pipeline. with scientific focus on the leaky pipeline among rheumatologists, which was distributed electronically by national scientific societies of EULAR countries and by individual contacts. We performed common factor analysis, univariate t-tests and multivariate regression analyses to appraise our dataset using Stata Version 17 (StataCorp, Texas, USA).

Results: 311 hospital-based rheumatologists from 23/45 EULAR countries (52.7% females, 47.3% males) responded to the questionnaire. The phenomenon of the leaky pipeline was present for the entire sample. Of 64% female rheumatologists only 34.2% departments' directors were female, with noteworthy regional differences (Table 1). Female doctors reported higher intentions to leave their hospitals ($\beta = 0.28$, $p < 0.05$) and lower commitment towards their current organization ($\beta = -0.34$, $p < 0.05$) when compared to males. Additionally, women reported lower levels of job satisfaction ($\beta = -0.26$, $p < 0.10$), promotion justice ($\beta = -0.55$, $p < 0.01$), and career perspectives ($\beta = -0.15$, $p < 0.10$, one-tailed) than men, explaining their lower organizational commitment.

Conclusion: Female rheumatologists perceive worse job opportunities and satisfaction than males. Many reasons for the leaky pipeline are beyond the control of organizations. By our results, organizations should be encouraged to reconsider and adjust their performance management practices enabling an equitable work environment.

Table 1. Leaky pipeline among rheumatologists working in hospitals across Europe

Overall Sample (n = 311)	
Percentage of female doctors in department	64.0%
Percentage of female doctors employed as senior physicians in department	49.2%
Percentage of female department heads	31.8%
Germany/Austria/Switzerland (n = 91)	
Percentage of female doctors in department	51.0%
Percentage of female doctors employed as senior physicians in department	42.2%
Percentage of female department heads	7.7%
Northern European Countries (n = 19)	
Percentage of female doctors in department	56.4%
Percentage of female doctors employed as senior physicians in department	50.5%
Percentage of female department heads	47.4%
Southern European Countries (n = 58)	
Percentage of female doctors in department	62.9%
Percentage of female doctors employed as senior physicians in department	36.4%
Percentage of female department heads	24.1%
Eastern European Countries (n = 133)	
Percentage of female doctors in department	73.4%
Percentage of female doctors employed as senior physicians in department	57.0%
Percentage of female department heads	45.9%

POS0562 FREQUENCY OF IN-PERSON AND VIRTUAL VISITS FOR RHEUMATOID ARTHRITIS: ANALYSIS OF THREE YEARS OF VISIT DATA BEFORE AND AFTER THE COVID PANDEMIC

Keywords: COVID, Telemedicine, Rheumatoid arthritis

D. Solomon[1], M. Jiang[2], L. Santacroce[1], R. Rudin[1]. *[1]Brigham and Women's Hospital, Harvard Medical School, Rheumatology, Boston, MA, United States of America; [2]Michael G. DeGroote School of Medicine, McMaster University, Faculty of Medicine, Windsor, Canada*

Background: Few data have been published regarding appropriate visit frequency in rheumatoid arthritis (RA). While guidelines suggest more frequent visits early in disease and when disease is active, there are few descriptions of visit frequency. Also, visit frequency may have changed during the COVID pandemic.

Objectives: We examined visit frequency and types of visits (in-person versus virtual) for patients with RA seen at one US academic medical center during the 18 months before COVID lockdown, 3 months of lockdown, and 18 months after.

Methods: We extracted data from 11 clinically focused rheumatologists' practices at an academic medical center and created a sample of 257 patients with rheumatologist-diagnosed RA. The study period of interest encompassed the 18 months prior to COVID pandemic (Nov 2018 – Feb 2020), the 3 months of COVID lockdown (rheumatology clinic closed except emergencies, March – May 2020), and the 18 months after lockdown (June 2020 – Sept 2021); patients were required to have ≥1 visit prior and ≥1 visit after the lockdown to be included. We estimated: 1) monthly volume of in-person and virtual visits (telephone-only or video) for the RA study cohort, and 2) annual median patient visit frequencies. In addition, we assessed predictors of a patient's visit volume using multivariable linear regression over the pre- and post-lockdown periods. Variables tested included RA disease characteristics (CRP, serologic status, and DMARD use), patient demographics and comorbid conditions, and rheumatologist.

Results: Patient characteristics are shown in the **Table 1**. Patients' median age was 58y, 84% were female; 82% used any DMARD; 20% used only csDMARDs; and 61.5% used a t/bDMARD. Visit volume over 39 months is illustrated by visit type in the **Figure 1**. In the 18 months prior to the COVID pandemic, median annual visit frequency per patient was 2.7 (IQR 2.0, 3.3), with an overall median monthly visit volume of 61 (IQR 51, 58). Overall visit volume remained consistent post-lockdown: median annual visit frequency per patient 2.7 (IQR 2.0, 3.3), with an overall median monthly visit volume of 68 (50, 73). As expected, median monthly visit volume was reduced during the lockdown period: 58 (IQR 51, 65); but it rebounded to pre-pandemic levels within 9 months. During the first 3 months post-lockdown, virtual visits comprised 61% of all visits (51% video,

Table 1. Baseline Characteristics of 257 Patients with Rheumatoid Arthritis Followed in this Cohort

Patient Characteristics	N (%) or median (interquartile range)
Age, years	58.2 (48.7, 65.8)
Female sex	216 (84.0%)
Charlson-Deyo comorbidity index	1.0 (1.0, 1.0)
Race	
Black	11 (4.3%)
Other	21 (8.2%)
White	225 (87.5%)
Seropositive (n = 128)	87 (68.0%)

Disease modifying anti-rheumatic drug (DMARD) use	
csDMARD	147 (57.2%)
t/bDMARD	158 (61.5%)
Both	95 (37.0%)
Neither	47 (18.3%)
Non-steroidal anti-inflammatory drugs (NSAID) use	61 (23.7%)
Glucocorticoid (oral) use	84 (32.7%)
Opioid use	38 (14.8%)

*rheumatoid factor or anti-CCP antibody

10% telephone only). By the 12th month post-lockdown, virtual visits comprised 11% of all visits; all were video. The following variables associated with increased patient visit volume during the pre- and post-lockdown periods (36 months): older age and fewer comorbidities. When specific rheumatologists were added as fixed effects, these variables strengthened in their significance; additionally, several rheumatologists were associated with significant increases in visit volume.
Conclusion: The COVID pandemic caused a disruption in rheumatology practice with a rapid substitution of virtual visits. Office visit volume for RA rebounded relatively quickly in one US-based academic practice. Virtual visits were common during and immediately after lockdown but became less common over time. Several variables, unrelated to RA, were associated with visit volume.

POS0563

USE OF A DIGITAL SOLUTION TO MONITOR CHRONIC INFLAMMATORY RHEUMATIC MUSCULOSKELETAL DISEASES: FINAL RESULTS OF THE DIGIREUMA STUDY

Keywords: Outcome measures, Self-management, Health services research

D. Benavent[1], L. Fernández-Luque[2], M. Sanz[3], V. Navarro-Compán[1], M. Novella-Navarro[1], I. Bilionis[2], E. Calvo-Aranda[3], L. Lojo[3], A. Balsa[1], C. Plasencia[1]. [1]*Hospital La Paz-IdiPaz, Department of Rheumatology, Madrid, Spain;* [2]*Adhera Health Inc, Palo Alto, United States of America;* [3]*Hospital Infanta Leonor, Department of Rheumatology, Madrid, Spain*

Background: Patients with rheumatic and musculoskeletal diseases (RMDs) require a tailored follow-up, which may be limited by the healthcare resources. Innovative tools that save time need to be implemented effectively in the clinical care of patients with RMDs.
Objectives: To test the feasibility of a digital solution for real-time monitoring of electronic patient reported outcomes (ePROs) in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA).
Methods: Digireuma was a bicentric 6-month prospective study including patients with RA and SpA, using a digital solution, namely Adhera Rheumatology Digital Program. During follow-up, patients had a hybrid follow-up: face-to-face -baseline and 6 months visits-and digital. In the digital follow-up, patients were asked to report disease specific ePROs on a pre-established basis in the mobile solution- including at least one assessment per week. In addition, flares and incidences with medication were available to be reported at any time. Four rheumatologists monitored these outcomes, and contacted patients when deemed necessary (**Figure 1**). Assessment measures included patient global assessment (PGA) of disease activity, (self-reported) tender joint count (TJC) and swollen joint count (SJC), Health Assessment Questionnaire (HAQ) and pain visual analogue scale (VAS), for patients with RA; PGA, TJC, SJC, BASDAI, and ASAS-Health Index, for patients with SpA. All measures were delivered every two weeks. Engagement at 3 and 6 months was assessed.
Results: Out of 56 recruited patients, 51 (24/27 (89%) RA, 27/29 (93%) SpA) downloaded and used the mobile solution and 47 (84%) submitted at least one ePROs entry. Median age (IQR) was 47 (13.2) and 40 (16.0) years in the RA and SpA groups, respectively. 20/27 (74%) patients with RA and 14/29 (48%) with SpA were female. In the RA group there were a total of 2156 digital solution accesses (57 per patient) in 6 months, while patients with SpA had a total of 1644 accesses (29 per patient). ePROs measurements outcomes at baseline and 6 months are shown in **Table 1**. Patients with RA completed a median of 6710 ePROs interactions during follow-up, whereas patients with SpA completed a median of 4315. Regarding alerts, among a total of 52 notifications, 47 were deemed necessary to be contacted (5 cases were assessed directly in a programmed consultation, due to time-proximity). Among all alerts, 45 were flares (31 RA, 14 SpA) and 4 problems with the medication (3 causes were not registered). Of the 47 cases that were contacted, 36 (77%) were managed remotely, 9 (19%) required a face-to-face intervention and in 2 (4%) cases it was not possible to reach patients before consultation. Regarding engagement, at three months 26 patients (55%)- 15 with RA and 11 with SpA- continued submitting data periodically, while at six months 22 patients (47%)- 13 with RA and 9 with SpA- continued submitting any data.
Conclusion: This study shows that ePROs can be used to monitor disease activity, flares, and medication issues in patients with RA and SpA, with three out of four alerts being managed remotely. After six months, more than half of the patients showed non-adherence to the monitoring plan/digital solution. The participation of both healthcare professionals and patients is critical for the successful implementation of mobile health in clinical practice, specially to identify long term usage strategies.

POS0564 THE IMPACT OF BIOSIMILAR SWITCHING POLICIES IN INFLAMMATORY ARTHRITIS ON UPTAKE AND SPENDING IN BRITISH COLUMBIA, CANADA

Keywords: bDMARD

A. Mcclean[1], M. Harrison[2,3], L. Cheng[1], M. Tadrous[4], F. Clement[5], N. Bansback[1,3], M. Law[1]. [1]*University of British Columbia, School of Population and Public Health, Vancouver, Canada;* [2]*University of British Columbia, Pharmaceutical Sciences, Vancouver, Canada;* [3]*Providence Health Care, Centre for Health Evaluation and Outcome Sciences, Vancouver, Canada;* [4]*University of Toronto, Leslie Dan Faculty of Pharmacy, Toronto, Canada;* [5]*University of Calgary, O'Brien Institute for Public Health, Calgary, Canada*

Background: The uptake of biosimilars has been suboptimal in North America. In response, in 2019, British Columbia (BC) became the first jurisdiction in North America to require patients with inflammatory arthritis to switch to a biosimilar version of infliximab and etanercept to maintain public coverage through the 'Biosimilars Initiative' policy. In 2021 this policy was extended to include adalimumab. The Biosimilars Initiative extended a previous policy which required people starting a biologic to use a biosimilar. Large commercial insurers which provide supplementary drug coverage also introduced biosimilars policies in line with the BC provincial government. Under both biosimilar switching policies, exceptional coverage to reference products was allowed if medically needed.
Objectives: To quantify the impact of the Biosimilars Initiative and the initial policy requiring new initiators to a biologic to use a biosimilar on uptake and spending on biosimilar infliximab, etanercept, and adalimumab in British Columbia (BC).
Methods: Administrative claims data in BC from January 2013 through March2023 were analyzed using interrupted time series analysis, a quasi-experimental study design commonly used to evaluate policy changes. Two policy interventions were evaluated: (1) *new starts*, whereby individuals initiating infliximab, etanercept, or adalimumab for the first time were required to start the biosimilar (implemented between Feb 2016 and July 2017), and (2) *mandatory switching*, which required those already receiving infliximab or etanercept (implemented between May and Nov 2019), or adalimumab (implemented between April and October 2012) to switch to the biosimilar version in order to maintain coverage. A segmented linear regression was used to model the level and trend change in biosimilar etanercept and infliximab utilization and spending before and after the two policy interventions.
Results: We identified 208,984 BC residents ≥18 years who qualified for public drug coverage, were treated with etanercept or infliximab, and were eligible for analysis between January 2013 and November 2020. After the *new start* policy, we detected a small gradual increase in the proportion of biosimilar etanercept prescriptions dispensed of 0.65% (95%CI 0.44, 0.85) per month. The monthly trend related to the proportion of total spending on biosimilar etanercept also increased (0.51, 95%CI 0.28, 0.73). After the *mandatory switching* policy (the Biosimilars Initiative), there was a sustained increase in the proportion of biosimilar etanercept and infliximab prescriptions dispensed of 76.98% (95%CI 75.56, 78.41) and 58.43% (95%CI 52.11, 64.75), respectively. Similarly, there was a persistent increase in spending on biosimilar etanercept and infliximab of 78.22% (95%CI 76.65, 79.79) and 71.23% (95%CI 66.82, 75.65), respectively. Similar results were seen for adalimumab which was switched later.

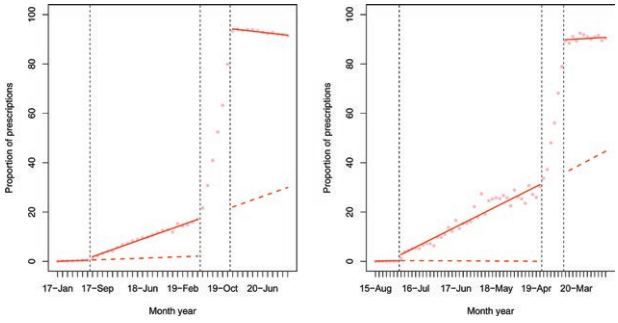

Figure 1. Overall proportion of prescriptions dispensed that were biosimilar etanercept and infliximab

Conclusion: Our study found *new start* policies resulted in small, gradual increases in biosimilar utilization. However, the *mandatory switch* policy, the Biosimilars Initiative, resulted in a marked immediate and sustained impact on uptake. Further analysis will examine changes in other health utilization, and long-term impact on prescribing patterns. These findings may be particularly relevant to areas with a more concentrated insurance system where mandatory switching policies could lead to greater savings.

POS0565 TOLERABILITY AND SAFETY OF RECOMBINANT ZOSTER VACCINE IN PATIENTS WITH INFLAMMATORY RHEUMATIC MUSCULOSKELETAL DISEASES - A PROSPECTIVE LONGITUDINAL STUDY OVER 6 MONTHS

Keywords: Safety, Vaccination/immunization, Infection-related RMDs

I. Andreica[1], S. Reale[1], G. Intini[1], B. Wilde[2], D. Kiefer[1], P. Sewerin[1], H. Kavruk[1], D. Karagkiozidou[1], B. Guminski[1], A. Kribben[2], X. Baraliakos[1], J. Braun[1], U. Kiltz[1]. [1]*Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany;* [2]*Universitätsklinikum Essen, Nephrology, Essen, Germany*

Background: Herpes zoster (HZ) is common in the elderly with a lifetime risk of 25% (1). The primary risk factors for HZ are advanced age and immunosuppression. The recombinant zoster vaccine (RZV) contains recombinant glycoprotein E, the main target of CD4+T-cells.
Objectives: To describe the safety of RZV in patients with inflammatory rheumatic and musculoskeletal diseases (RMD).
Methods: Adult patients with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) and giant cell arteritis (GCA) who had an indication to receive RZV were prospectively included. Data on demographics, vaccination, RMD diagnosis, disease activity, immunosuppressive treatments, flares, adverse events (AEs) and zoster breakthrough infections were collected at month 0, 2, 3 and 6. A flare was defined as change in ASDAS ≥ 0.9 for axSpA, change in DAS-28>1.2 for RA, or clinical signs for GCA and/or CRP ≥ 0.5 mg/dl and/or ≥30 mm. Descriptive analyses were performed.
Results: 50 patients were included of whom 18 (36.0%) had a history of HZ (Table 1). All patients received RZV at month 0, and 49 patients also at month 2. Safety assessments were performed in 49, 48 and 36 patients in months 2, 3 and 6, respectively. A total of 62, 35, 11 AE in 38, 33, and 10 patients, respectively, were reported (Figure 1). Localized AE (n=69 (63.9%)) were far more common than generalized AE (n=28 (25.9%)). Pain at the site of injection in 46 (42.6%) patients was the most frequent AE followed by fatigue (12 (11.0%)), redness at the injection site in (9 (8.3%)), swelling at the injection site (7 (6.4%)) and fever (5 (4.6%)). Serious AEs were reported in 6 patients (2 RA, 4 GCA). None of them with causal relation to RZV. No patient reported an AE of special interest. Out of 6, 4 and 4 flares reported by patients at month 2, 3 and 6, respectively, no one fulfilled predefined flare criteria and were rated as mild to moderate. However, 3 patients (2 GCA, 1 RA) were hospitalized due to flares. No episodes of HZ occurred.
Conclusion: The majority of patients tolerated RZV well with only a few reports of flare and serious AEs. Majority of AEs occurred within few days after vaccination. These findings are reassuring for rheumatologists and potential vaccine recipients and support confidence in RZV safety in patients with RMD.

POS0566

SURVIVAL ON TREATMENT AFTER SWITCHING TO A BIOSIMILAR: POPULATION-BASED EVIDENCE FROM A NATURAL EXPERIMENT DUE TO A POLICY CHANGE

Keywords: Health services research, bDMARD, Inflammatory arthritides

D. Lacaille[1,2], J. A. Aviña-Zubieta[1,2], Y. Zheng[1], N. Lu[1], H. Xie[1,3]. *[1]Arthritis Research Canada, Arthrite-Recherche Canada, Vancouver, Canada; [2]University of British Columbia, Department of Medicine, Vancouver, Canada; [3]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada*

Background: In the province of British Columbia (BC), Canada, a health policy implemented in July 2017 mandated that all new anti-TNF prescriptions for which a biosimilar exists, i.e., etanercept and infliximab at the time, be dispensed a biosimilar rather than the originator, for universal cost coverage by BC PharmaCare. In May-December 2019, a further policy mandated that current users of anti-TNF agents be switched to the corresponding biosimilar.

Objectives: The objective of this study is to compare the survival on treatment (as a surrogate marker of effectiveness and safety), between biosimilar switchers vs. users of originator Anti-TNF for inflammatory arthritis, after and before the health policy change.

Methods: Study Cohort: Using administrative data and validated definitions, we identified etanercept and infliximab users with rheumatoid arthritis (RA), psoriasis or psoriatic arthritis (Pso/PsA), or ankylosing spondylitis and other spondyloarthritis (SpA). Biosimilar switchers were current biologic users who switched to the corresponding biosimilar during the period of May to December 2019. Historical controls were randomly selected from all new users of originator etanercept and infliximab before July 2017, matched to biosimilar switchers on sex, previous number of biologics used, and disease. Controls were assigned an index date such that duration of originator anti-TNF therapy was the same at switching/index date for switchers and controls. Outcomes: Discontinuation was defined as no prescription renewal for at least 6 months. Statistical method: We followed patients from switching/index date to discontinuation, or for two yearsor until last health care utilization (if moving out-of-province), or end date of the follow-up (April 30, 2019 for originators, and December 31, 2021 for switchers), whichever occurred first. Weighted Cox proportional hazards models with propensity score overlap weighting estimated the HR of discontinuing anti-TNF agents for controls and switchers, adjusting for duration of of anti-TNF agent use at switch/index date, age, sex, socio-economic status (low income subsidy), rural vs urban residence, health authority, arthritis type, number of prior biologic agents, comorbidities, and other IA drugs used (MTX, non MTX DMARDs and glucocorticosteroids), all measured at time of switching/index date.

Results: A total of 1631 biosimilar switchers (1402 eternercept; 229 infliximab) were included in this study: 556(67.2%) RA, 178(21.5%) SpA, 93(11.2%) Pso/PsA patients. Table 1 shows numbers, rates (per 100 person-years), and hazard ratio of discontinuation among biosimilar switchers compared with originator users. Figure 1 shows survival on treatment. The discontinuation rates for the biosimilar eternacept users was similar to the originator users (15.42 vs 15.63) per 100 PYs: HR (95% CI) 1.02 (0.87, 1.19 [p=0.718]). The biosimilar infliximab switchers had a slightly lower discontinuation rate than the originator users, however the difference in rate and risk of discontinuation were not statistically significant (8.76 vs 11.29) per 100 PYs: HR (95% CI) 0.85 (0.54, 1.36 [p=0.503]).

Conclusion: Population-based data on real-world experience mandating switching from originator to biosimilar etanercept and infliximab for IA revealed the biosimilar switchers have comparable duration of treatment to the original medications.

Table 1. Discontinuation of anti-TNF in biosimilar switchers and originator controls.

Anti-TNF Drug	Cohort	discontinuation/ sample (N)	Median Follow-up, Years	Rate Per 100 PYs	Weighted CoxPH HR (95% CI)	p
Etanercept	Originator	347/1402	1.58	15.63	1.00	
	Biosimilar	354/1402	1.64	15.42	1.02(0.87,1.19)	0.820
Infliximab	Originator	44/229	1.70	11.29	1.00	
	Biosimilar	36/229	1.80	8.76	0.85(0.54,1.36)	0.503

COMPARISON OF SURVIVAL ON TREATMENT AMONG NEW USERS OF BIOSIMILAR VS. ORIGINATOR BIOLOGICS IN INFLAMMATORY ARTHRITIS: POPULATION-BASED EVIDENCE FROM A NATURAL EXPERIMENT DUE TO A POLICY CHANGE

Keywords: Health services research, bDMARD, Inflammatory arthritides

D. Lacaille[1,2], J. A. Aviña-Zubieta[1,2], Y. Zheng[1], N. Lu[1], H. Xie[1,3]. *[1]Arthritis Research Canada, Arthrite-Recherche Canada, Vancouver, Canada; [2]University of British Columbia, Department of Medicine, Vancouver, Canada; [3]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada*

Background: British Columbia (BC) health policy mandated the use of biosimilars, when available, for all new anti-TNF prescriptions after June 2017.
Objectives: To compare drug survival (surrogate marker of effectiveness and safety) after initiation of etanercept and infliximab for inflammatory arthritis in new users of biosimilars vs. originators, using historical controls pre-policy change.
Methods: Using administrative health data, we identified all incident users of a new anti-TNF with rheumatoid arthritis (RA), psoriasis or psoriatic arthritis (Pso/PsA), or ankylosing spondylitis (AS). The biosimilar cohort started etanercept or infliximab between 07/01/2017 and 12/31/2019, were followed until 12/31/2020 (post-policy period). Historical controls started etanercept/infliximab originators between 01/01/2014 and 06/30/2016, were followed until 06/30/2017 (pre-policy period). To control for potential temporal trends, new users of adalimumab (no biosimilar available then) served as comparators. Discontinuation was defined as no prescription renewal for ≥6 mos. Individuals were followed from anti-TNF initiation until discontinuation or censoring due to death, moving out-of-province, or follow-up end, whichever occurred first. We applied weighted Cox Proportional Hazard Models that handle non-proportional hazards combined with propensity overlap weighting to estimate the adjusted hazard ratio (aHR) of discontinuing anti-TNFs, in people who started a biosimilar vs. the respective originator, after controlling for potential confounders. To control for temporal trend, we employed the difference-in-difference (DID) method, comparing drug survival among new biosimilar vs. originator etanercept/infliximab users with adalimumab users post- vs. pre-policy change, computed as the difference between the logarithms of aHRs for etanercept/infliximab and for adalimumab. We report the exponential of DID estimates (i.e. the ratio of the two aHRs).
Results: Our sample included 827 biosimilar etanercept users (RA:576, AS:171, Pso/PsA:80) and 271 infliximab users (RA:150, AS:54, Pso/PsA:67); 1312 etanercept and 230 infliximab originator users; and 2213 adalimumab originator users post- and 1773 pre-policy change. Discontinuation rates per 100 PY are shown in Table 1A. After adjusting for baseline covariates (Table 1B), and accounting for temporal trends (Table 1C), the risk of discontinuation was similar for biosimilar vs. originator etanercept and infliximab users.
Conclusion: Real-world population-based data in BC shows that incident users of biosimilar etanercept and infliximab for inflammatory arthritis have comparable duration of treatment to users of originators.

Table 1. Discontinuation of biosimilar and originator anti-TNFs before and after policy change

1A. Discontinuation rates

Drug	Period	Discontinuation/Follow-up N	Years	Rate (per 100 person-year)
ADALIMUMAB	Pre-policy	808/1773	2454	32.92
	Post-policy	1076/2213	2959	36.36
ETANERCEPT	Originator	650/1312	1752	37.10
	Biosimilar	381/827	1029	37.02
INFLIXIMAB	Originator	103/230	344	29.97
	Biosimilar	138/271	364	37.96

1B. Hazard Ratio (post- vs. pre- policy change)

Drug	Univariate Cox PH cHR (95%CI)	p value	Multivariable Cox PH* aHR (95%CI)	p value
ADALIMUMAB	1.08(0.98,1.18)	0.11	1.08(0.98,1.19)	0.11
ETANERCEPT	0.97(0.84,1.10)	0.60	0.97(0.85,1.11)	0.65
INFLIXIMAB	1.10(0.84,1.43)	0.50	1.11(0.86,1.45)	0.42

1C. Ratio of Hazard Ratio**

	Univariate Cox PH Ratio of cHR (95%CI)	p value	Multivariable Cox PH* Ratio of aHR (95%CI)	p value
ETANERCEPT	0.90(0.76,1.05)	0.19	0.90(0.76,1.06)	0.20
INFLIXIMAB	1.02(0.77,1.35)	0.91	1.03(0.78,1.37)	0.83

*Adjusted for age, sex, socioeconomic status, rural vs. urban, health authority, arthritis type, arthritis duration, no. prior biologic agents, comorbidities, steroid and DMARDs use, measured at anti-TNF start.**Ratio of Hazard Ratios of etanercept or infliximab to adalimumab.

THE RATIO BETWEEN BIOLOGICAL AND GLUCOCORTICOID USE IN VARIOUS COUNTRIES WORLDWIDE: RESULTS FROM THE METEOR REGISTRY

Keywords: Rheumatoid arthritis, Real-world evidence, Geographical differences

I. Nevins[1], C. Allaart[1], D. Vega-Morales[2], L. L. Winchow[3], A. Chopra[4], A. M. Rodrigues[5], T. Huizinga[1], M. Boers[6], S. A. Bergstra[1]. *[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands; [2]Hospital General de Zona 17, Instituto Mexicano del Seguro Social, Rheumatology, Monterrey,*

Mexico; [3]Chris Hani Baragwanath Academic Hospital, Rheumatology, Johannesburg, South Africa; [4]Center of rheumatic diseases, Rheumatology, Pune, India; [5]Hospital Lusiadas, Rheumatology, Lisbon, Portugal; [6]Amsterdam UMC - VU University Medical Center, Rheumatology, Amsterdam, Netherlands

Background: Previously a study in the QUEST-RA database, based on rheumatoid arthritis (RA) patients included between January 2005 and June 2006, has shown that the ratio between biological disease modifying antirheumatic drug (bDMARD) use and glucocorticoid (GC) use strongly differs between countries. Considering the difference in affordability between bDMARDs and GCs, it may be hypothesized, that when less bMDARDs are used, glucocorticoid use increases.
Objectives: To investigate globally, in more recent data, the ratio between bDMARD and GC use, and to assess whether this relates to a country's socio-economic status (SES).
Methods: Data on bDMARD and GC use between 1-1-2007 and 28-12-2020 were extracted from the METEOR registry: an international database capturing daily clinical practice data from patients with a clinical diagnosis of RA. The ratio between the proportion of patients who had ever used a bDMARD and the proportion of patients who had ever used a GC, with no concomitant bDMARD use, during a total follow up duration of two years (bDMARD/GC ratio) was calculated per country. Univariable linear regression was used to analyze the bDMARD/GC ratios according to publicly available country-level indicators of SES (Worldbank, OECD).
Results: Data from 10,856 patients covering eight countries showed varying proportions of bDMARD use. The number of patients included ranged from 64 (Spain) to 8484 (India). Baseline characteristics varied per country (Table 1) The percentage of patients who used a bDMARD (with or without a GC) during two years follow up ranged from 1% (South Africa, India) to 26% (United States, state of Massachusetts) and for those who used a GC at some time during two years follow up ranged from 19% (Great Britain) to 94% (South Africa). Higher country-level wealth measured in GDP per capita, health expenditure and household net adjusted disposable income were related to a higher bDMARD/GC ratio. For every 10,000 Intl$ increase in GDP per capita, household net adjusted disposable income and health expenditure per capita, the bDMARD/GC ratio (range 0 to 1) was observed to increase by a value of β 0.1 (Figure 1A, 95% CI 0.05;0.1, p<0.05), β 0.2 (Figure 1B, 95% CI 0.08;0.3, p<0.05) and β 0.6 (Figure 1C, 95% CI 0.4;0.8, p<0.05), respectively.
Conclusion: In this analysis based on a worldwide cohort capturing 8 countries, we show that the bDMARD/GC ratio differs across countries. These differences are significantly related to general country-level indicators of level of wealth, where greater wealth went with a higher proportion of patients using bDMARDs and/or a smaller proportion of patients using GCs.

POS0569 IDENTIFYING THE IMPACTS OF ARTHRITIS ON LABOUR MARKET PARTICIPATION: AN OBSERVATIONAL STUDY IN BRITAIN

Keywords: Health services research, Rheumatoid arthritis, Work-related issues

J. Higgerson[1], W. Whittaker[1], M. Eden[1], K. Payne[1], S. Verstappen[2]. *[1]University of Manchester, Manchester Centre for Health Economics, Manchester, United Kingdom; [2]University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom*

Background: Existing evidence of the impacts of rheumatic and musculoskeletal diseases (RMDs), including those with arthritis, compared to those without RMDs on labour market participation is limited. Furthermore, most studies are cross-sectional.
Objectives: To compare labour market outcomes in people with arthritis versus those without.
Methods: We utilise 10 waves of the UK Household Longitudinal Survey (2009-2019) which contains annual observations of a representative sample of individuals in Britain. The data contain labour market participation measures (employment, unemployment, non-participation due long-term sickness, and retirement) and data for those employed including whether the respondent has been off work for health reasons, job sector type and employing sector. These are observed over time, enabling assessments of changes in activity. Arthritis was self-reported (type of arthritis is not identifiable). Multivariable linear and non-linear probability regression models were estimated for: i) sickness absence (employed individuals), ii) transitions to unemployment (employed individuals), iii) transitions to long-term sick (employed, unemployed individuals), and iv) transitions to retirement (employed, unemployed, long-term sick individuals). The sample concerns those aged 30-64. The key covariate of interest is an indicator for whether the respondent has reported arthritis. The panel nature of the data permits accounting for unobserved heterogeneity (fixed-effects). A range of potentially confounding factors were adjusted for including: age (40-49, 50-59, 60-64, ref: 30-39), job sector (intermediate, routine, ref: managerial), employing sector (public sector, ref: private sector), year indicators, and the presence of other long-term conditions. Additional analyses interacted arthritis with age, job sector and employing sector, and other long-term conditions to test whether the impact of arthritis differs between these groups.
Results: The results were robust to linear or non-linear probability model specifications. Sample sizes representing individual-year observations for the sickness absence, and transitions to long-term sick, unemployment, and retirement were 166,878, 167,681, 166,994, and 169,811 respectively. 1.06% reported sickness absence and 8.31% reported arthritis. Those with arthritis had a greater probability of sickness absence than those without arthritis (1.35 percentage points (pp), p-value <0.001). The effects of arthritis did not vary by age, job sector, public sector employment, or for those with other long-term conditions. 0.04% transition to unemployment and 8.31% reported arthritis. Those with arthritis were no more likely to become unemployed (0.01 pp, p-value=0.148). The effects of arthritis was no different by age, employing sector, job sector, or for those with other long-term conditions. 0.36% transition to long-term sick and 8.38% reported arthritis. Those with arthritis were more likely to move into long-term sick (0.64 pp, p-value<0.001). The effects of arthritis did not differ by age or by whether the individual's employing sector was public nor by job sector; but was greater for those with other long-term conditions (8.92 pp, p=0.030). 1.22% transition to retirement over the period and 8.56% reported arthritis. Those with arthritis were more likely to retire in the following year (1.43 pp, p-value <0.001). The effects of arthritis was greater with age (40-49 (0.51 pp, p<0.001), 50-59 (1.90 pp, p=0.004) and 60-64 (4.69 pp, p<0.001)); was less for those in routine job role sectors (-1.16 pp, p=0.052), but not different for those in public sector jobs or for those with other long-term conditions.
Conclusion: The findings provide evidence of the detrimental impacts arthritis has on labour market participation and highlights those groups of the population for which the impacts of arthritis are greater, providing insight into where targeted support may be required by employers and policymakers to support labour market participation for those with arthritis.

POS0570

IMPACT OF CLINICIAN-RELATED FACTORS ON PHONE CONSULTATIONS IN RHEUMATOLOGY – ANALYSIS OF MEDICAL VS NON-MEDICAL CLINICIANS' OUTCOMES FROM A COVID-19 INITIATIVE

Keywords: Telemedicine, COVID, Health services research

M. Hannides[1], S. Wig[1], S. Vasireddy[1]. *[1]Bolton NHS Foundation Trust, Rheumatology, Bolton, United Kingdom*

Background: Since COVID-19 pandemic, there have been changes in clinical practice to limit transmission, such as switching to remote consultations. Our department switched to delivering remote consultations during lockdown without suspending service. Patients were offered choice of either video or phone consultation. It is unclear if the medical vs non-medical status of clinicians has any influence on remote consultations.
Objectives: We aimed to study the influence of medical vs non-medical status of clinicians on phone consultations in our experience during the pandemic.
Methods: Between 15/10/2020 and 09/11/2020, 12 clinicians in our service completed data collection forms after each remote consultation, recording the technology used (video vs phone); technical problems encountered; discharge and subsequent appointment status; and technical aspects of the consultation itself using 11-point numerical rating scales (NRS) (Time Adequate; Relevant History; Physical Exam; Management Plan; and Communication Quality). Data were analysed in SPSS version 25 using chi-square tests and Mann-Whitney U tests for comparisons..
Results: Six medical clinicians (3 consultant rheumatologists, 2 Specialty Trainee Registrars and 1 Foundation Year 2 doctor) and six non-medical clinicians (3 Specialist Nurses, 1 Advanced Rheumatology Practitioner and 2 Senior Rheumatology Pharmacists) completed 285 forms. As non-medical clinicians didn't do new patient consultations, and as some clinicians did not do video consultations, these consultations were excluded. The remaining were follow-up patient phone consultations (n=196). Medical vs non-medical clinician appointments were 34.7% (n= 68), vs 65.3% (n=128). Medical and non-medical clinicians had a similar proportion of female patients (72.1%, n=49 vs 63.3%, n=81; p=0.22); similar mean age of their patients (63 vs 62 years; p=0.53); similar rates of technical problems reported (13.1%, n=8 vs 16.4%, n=19; p=0.57); and similar rates of interpreter use (3%, n=2 vs 3.5%, n=4; p=0.86). Medical clinicians had lower mean scores compared to the non-medical clinicians on NRS for Time Adequate (8.37 vs 8.57; p=0.013); Relevant History (8.55 vs 9.02; p<0.001); Management Plan (6.91 vs 8.17; p<0.001); and Communication Quality (7.85 vs 8.81, p<0.001); and had no significant difference in scores for Physical Exam (0.63 vs 1.75; p=0.19). Medical clinicians had a non-significant trend for higher rate of subsequent face-to-face appointments (21.9%, n=11 vs 11.6%, n=14; p=0.10); and a higher rate of discharge outcome compared with non-medical clinicians (23.5%, n=16 vs 1.6% n=2; p<0.001).
Conclusion: There were no significant differences between medical and non-medical clinicians in distributions of patients' gender or age, and rates of technical problems and interpreter use. While there was a non-significant trend for lower scores on Physical Exam NRS for medical clinicians, both mean scores were low reflecting the difficulty of this assessment in a phone consultation. Medical clinicians rated their consultations significantly lower in four of the NRS, potentially reflecting the complexity of medical problems of patients booked into medical clinicians' clinics compared to potentially patients with more stable disease in non-medical clinicians' clinics. Similarly, the lower discharge rate from non-medical clinicians' clinics could reflect a higher proportion of patients on established disease needing long-term follow-up. Further studies with larger numbers would help clarify these issues.

ASSOCIATION BETWEEN DIAGNOSIS DELAY AND DISEASE ACTIVITY WITH BURDEN OF THE DISEASE IN 4150 EUROPEAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Patient reported outcomes, Systemic lupus erythematosus, Quality of life

A. Cornet[1], J. Andersen[2], F. Marchiori[2], A. Sturiene[2], A. Edwards[2], P. Mertz[3], L. Arnaud[3]. *[1]Lupus Europe, HQ, Brussels, Belgium; [2]Lupus Europe, PAN, Brussels, Belgium; [3]Hôpital de Hautepierre - Hôpitaux Universitaires de Strasbourg, Service de Rhumatologie, Strasbourg, France*

Background: Despite significant improvements in diagnosis delay and treatment strategies, the burden of Systemic Lupus Erythematosus (SLE) remains high.
Objectives: The objective of the study was to assess the association between diagnosis delay, disease activity and burden on daily life (BoDL) in a large sample of European patients with SLE.
Methods: In May 2020, Lupus Europe, the European umbrella patient association for SLE, conducted a multilingual anonymous online cross-sectional study to individuals with a self-reported physician's diagnosis of SLE living in Europe. The BoDL score was computed using 1 to 5 Likert scales on 5 domains (mobility, anxiety/depression, self-care, daily activities and pain/discomfort) and the sum was transposed on a 0 (minimum Burden on daily life) to 100 (maximum BoDL) scale. Comparisons between independent groups were made using the Mann-Whitney test for continuous outcomes and the Chi-2 test (or Fisher's exact test) for quantitative data.
Results: Data of 4,150 SLE patients from 35 European countries were analysed. The mean (±SD) BoDL score in the study population was 37.8 (±18.7) with a modest downward trend of the BoDL based on age (from 33.4% to 42.1% from age less than 25 to age 65 - a loss of up to 9% points over up to 40 years). The diagnosis delay was reported to be <2 years in 1903 participants (47.5%), between 2 and <5 years in 1056 (26.3%) and ≥5 years or more in 1049 (26.2%). 142 did not answer.. Those with a diagnosis of SLE within 2 years of first symptoms had significantly lower mean Burden on daily life scores than those diagnosed after 5 years (33.6 versus 44.0, p<0.001). This trend is deemed robust as it was found across almost all European countries. These results highlight the importance of improving current diagnosis delay for SLE as a way to improve the burden of the disease on daily life. A total of 2980 (71.8%) patients felt that their "lupus has been under control over the last 3 months" while 1166 (28.1%) did not. 4 did not answer. The Burden on daily life score was significantly better in SLE patients feeling that their lupus had been under control during the past 3 months versus the others (34.0% versus 47.6%, p<0.001). Again, this trend was found across almost all European countries.
Conclusion: This large patient survey reveals both the importance of prompt SLE diagnosis as well the relationship between disease activity and disease burden upon the daily life of European lupus patients. Further improvements should focus on reducing the diagnosis delay and identifying new therapeutic strategies for those with uncontrolled disease. Healthcare pathways, which may accelerate diagnosis and optimize therapeutic management, are necessary to improve patients' outcomes in SLE.

IMMUNOGENICITY AND SAFETY OF ADJUVANTED RECOMBINANT ZOSTER VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

Keywords: Vaccination/immunization, Adaptive immunity, Rheumatoid arthritis

S. Kojima[1], T. Iwamoto[1], Y. Kobayashi[2], M. Kato[3], F. Takizawa[3], T. Ida[1], Y. Toda[1], K. Miyachi[1], J. Suzuki[1], A. Iwata[1], S. Furuta[1], K. Ikeda[1], K. Suzuki[1], H. Nakajima[1,4]. *[1]Chiba University, Department of Allergy and Clinical Immunology, Graduate School of Medicine, Chiba, Japan; [2]Chiba Aoba Municipal Hospital, Department of Internal Medicine, Chiba, Japan; [3]Seikeikai Chiba Medical Center, Department of Internal Medicine, Chiba, Japan; [4]Chiba University, Synergy Institute for Futuristic Mucosal Vaccine Research and Development, Chiba, Japan*

Background: Herpes zoster (HZ) is caused by the reactivation of latent varicella-zoster virus (VZV) due to a decline in VZV-specific cell-mediated immunity (CMI) with increasing age and immunocompromised conditions [1]. Patients with rheumatoid arthritis (RA) treated with disease-modifying anti-rheumatic drugs (DMARDs) are at a high risk of developing HZ [2, 3]. An adjuvanted recombinant VZV glycoprotein E (gE) subunit vaccine (RZV) has been shown to be effective in preventing HZ in immunocompetent elderly populations. However, its efficacy and safety profile remain largely unknown in RA patients.
Objectives: This study aimed to determine the immunogenicity and safety of RZV in patients with RA treated with DMARDs.
Methods: This longitudinal prospective study enrolled 53 RA patients treated with DMARDs (csDMARDs, n=20; bDMARDs, n=23; and tsDMARDs, n=10) and 10 individuals with no history of immunosuppressive treatment as controls. All the participants were aged ≥50 years. The participants received two intramuscular RZV injections 2 months apart. VZV-specific CMI and humoral immunity (HI)

were assessed at 0 and 3 months after the first vaccination using flow cytometry and enzyme immunoassay. To assess CMI, the frequencies of VZV gE-specific $CD4^+$ $CD40L^+$ T cells expressing at least one activation cytokine (CD4[2+] T cells): IFN-γ, IL-2, and TNF-α were examined by flow cytometry. CMI responders were defined as a CD4[2+] T cell frequency ≥320 per 10^6 $CD4^+$ T cells counted (for participants with pre-vaccination frequencies below 320 per 10^6 $CD4^+$ T cells counted) or a ≥2-fold increase in CD4[2+] T cells (for those CD4[2+] T cells were already ≥320 per 10^6 $CD4^+$ T cells counted at the time of pre-vaccination). CMI and HI response rates were compared between all patients with RA (n=53) and controls (n=10). The participants were followed up for 6 months after the first RZV administration for HZ onset. Baseline characteristics and information regarding adverse events were collected.

Results: Patients' age and disease duration were 70 years old and 11 years, respectively. DAS28-CRP and CDAI scores at enrollment were 1.4 and 2.1, respectively. Thirty-six percent of RA patients had a history of HZ before the administration of RZV. VZV-specific CMI (controls: p=0.002, csDMARDs: p=0.012, bDMARDs: p=0.001, and tsDMARDs: p=0.002) (Figure 1A) and HI (controls: p=0.002, csDMARDs: p<0.001, bDMARDs: p<0.001, tsDMARDs: p=0.002) were significantly increased in DMARDs-treated RA patients after RZV administration, and the magnitudes of those responses were not significantly different between DMARDs-treated RA patients and controls. However, the vaccine response rate of CMI of DMARDs-treated RA patients was significantly lower than that of the controls (51% vs. 90%, p=0.034) (Figure 1B), whereas the response rate of HI was not (66% vs. 70%, p>0.999). In addition, no significant baseline factors affecting CMI responses, including DMARDs use, were identified between RA patients with and without CMI responses. RZV-related adverse events were generally mild, and all participants received two doses of RZV. RZV-induced RA flares occurred in two patients (3.8%) but were also mild and controllable.

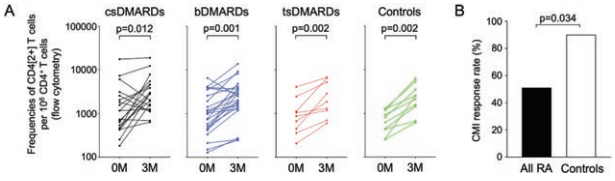

Figure 1. CMI responses to VZV in patients with RA and controls before and after RZV administration.

(A) The frequencies of VZV gE-specific CD4[2+] T cells were examined by flow cytometry.

(B) Vaccine response rate of CMI in all participants.

Conclusion: RZV is robustly immunogenic and has a clinically acceptable safety profile in elderly RA patients receiving DMARDs.

Background: Comorbidities have a profound impact on the QoL of patients living with autoimmune rheumatic diseases (AIRDs). Unfortunately, global data on the burden of comorbidities and its impact on health outcomes in this vulnerable group is scarce.

Objectives: We studied the prevalence, distribution and clustering of comorbidities and multimorbidity among patients with AIRDs and healthy controls (HCs) and its impact on health outcomes, utilizing data from the ongoing 2nd COVAD study.

Methods: The COVAD study is a global e-survey that embodies patient voice while empowering collaborators and young researchers. The study group of 157 physicians across 106 countries from February-June 2022 captured details of AIRDs, autoimmune and non-autoimmune comorbidities, and validated patient reported outcomes. Human Development Index (UNDP 2021-22) of country of residence was taken as a surrogate marker for socioeconomic status (SES). Basic multimorbidity (BM), Complex multimorbidity (CM), Autoimmune multimorbidity (AM) are defined as the co-occurrence of ≥2 non-rheumatic comorbidities, ≥3 non-rheumatic chronic conditions affecting ≥3 different organ systems [1] and ≥3 autoimmune diseases (AIDs) in an individual respectively. PROMIS global physical health (PGP), mental health (PGM), fatigue 4a (F4a) and physical function short form (SF10) scores were calculated for the different groups and compared using descriptive statistics, linear regression and cluster analysis (hierarchical followed by K means).

Results: Of 17,612 total respondents, 6149 (62.7%) had underlying AIRDs and 3652 (37.3%) were HCs, with female (80.8%) and Caucasian (53.9%) predominance in the former. All types of multimorbidity were more frequent in AIRDs than HCs, including any comorbidity (77.1% versus 25.0%; OR: 2.9; 2.7-3.2), BM (21.0% vs 6.2%; 4.0; 3.4-4.6), and CM (3.1% vs 0.5%; 6.4; 3.9-10.4), and with prevalence increasing with age (p<0.001) (Figure 1A, B). Comorbidity prevalence was the highest among Americans and Australians (72% each). Patients with AIRDs had poorer health outcomes than HCs, including lower PGP, PGM, SF10, F4a scores (all p<0.001). Among AIRDs, those with comorbidities had lower physical function and PROMIS scores (PGP, PGM, and SF10), and reported fatigue more often (all p<0.001). Female gender, and underlying BM and AM particularly predisposed patients to worse physical health (lower PGP, lower SF10a) and mental health outcomes (lower PGM). While advanced age (-1.815; <0.001), and lower SES (0.871; 0.027) specifically predicted poorer physical function (lower SF10a). Fatigue (higher F4a) was seen more frequently among women (1.711; <0.001), and those with BM (1.142; 0.002); AM (1.768; 0.011), and higher SEC (0.478; 0.016). Cluster analysis of patients with AIRDs revealed 2 clusters (Figure 1C 1D); cluster 1 with low PGP, PGM, SF10 and high F4a; cluster 2 with high PGP, PGM, SF10 and low F4a. The clusters differed predominantly based on the frequency of comorbidities; any comorbidity (59.7% vs 41.8%; p<0.001), BM (28.5% vs 14.7%; 0.001); CM (4.5% vs 1.9%; <0.001), and AM (10.0% vs 4.0%; <0.001).

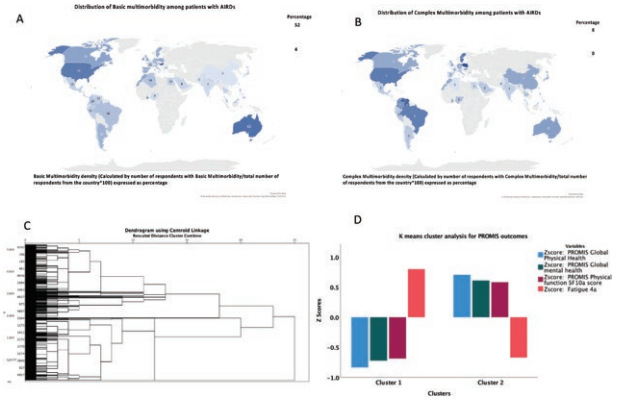

Figure 1. A, B Distribution of basic multimorbidity, complex multimorbidity among patients with AIRDs (expressed as percentage), C, D Hierarchical and K means cluster analysis of PROMIS outcomes among AIRDs.

Conclusion: Comorbidities complicate three-quarters of individuals living with AIRDs, and have an outsized impact on self-reported physical function, perceived fatigue, and QoL. Substantial regional differences call for further exploration of key drivers of this important aspect to allow optimized multidisciplinary and holistic care in anticipation of poorer outcomes.

Educational cases

POS0574 **THE GREAT MASQUERADER OF RHEUMATOLOGICAL SYMPTOMS: A CASE REPORT**

Keywords: Imaging, Vasculitis, Cardiovascular disease

S. M. Chiu[1], V. Dhir[2]. *[1]PGIMER, Internal Medicine (Rheumatology), Chandigarh, India; [2]PGIMER Chandigarh, Internal medicine (Rheumatology), Chandigarh, India*

Background: Primary cardiac tumors are extremely rare,and out of those atrial myxoma is the most common benign tumor (75%).Around 75% of the atrial myxoma cases arise from left side of the heart and present differently from right sided. Due to its varied presentation in regard to constitutional,embolic and obstructive features it mimics vasculitis.
Objectives: To create awareness about the atrial myxoma, the great mimicker of vasculitis and comment upon its clinical course and complications if not treated timely.
Methods: Case report and Discussion.
Results: 34 year old female with no past medical history came to the Rheumatology Department after failure to be diagnosed. She had 8 months history of pain in her finger tips, toes, small joints and Raynauds phenomenon. Intermittent fever associated with chills, palpitations, sweating and significant weight loss was noted during the course of illness. Before visiting our clinic, she was treated for Typhoid fever but she didn't respond. At presentation, her vitals and physical examination including auscultation was unrevealing.Her blood counts showed Hb at 8g/dL, metabolic panel,LFTs,coagulation profile were normal.But had high ESR levels in multiple reports ranging from 60-168mm/hour. CRP was also positive. Hypocomplementmia and increase in alpha-globulins were observed.ANA positive,dsDNA negative APLA, P and C-ANCA and Cryoglobulins were also negative. PET-CT was negative for avid FDG uptake in any organ. Patient was given iron formulations intravenously and was advised to cardiology in view of significant palpitations which was not given much attention before.Echo showed 4.1x 3.3cm, pedunculated mass arising from inter-atrial septum and anterior mitral leaflet (Figure 1).Patient was started on ecosprin and advised surgery which got postponed due to patient having complications of acute limb ischemia and stroke in right fronto-parietal lobe (Figure 1.) subsequently. She had multiple embolectomies of right brachial and bilateral femoral arteries, later followed by craniectomy and decompression from the hemorrhage with subsequent cranioplasty and at lastly removal of mass. The surgical pathological report of mass showed features characteristic of myxoma which concluded the diagnosis.After surgeries,the patient is doing much better.Her Hb levels have improved to 12g/dL and the ESR level came back to normal.Though there is residual weakness due to stroke but she has shown significant recovery in terms of modified Rankin scale of 3.No more systemic complaints like fever, fatigue, Raynauds phenomenon and digital pain are observed.In this case, duration from onset of symptoms to hospitalization for life threatening was complete one year with added 6 months to significant recovery from complications.

from complications.

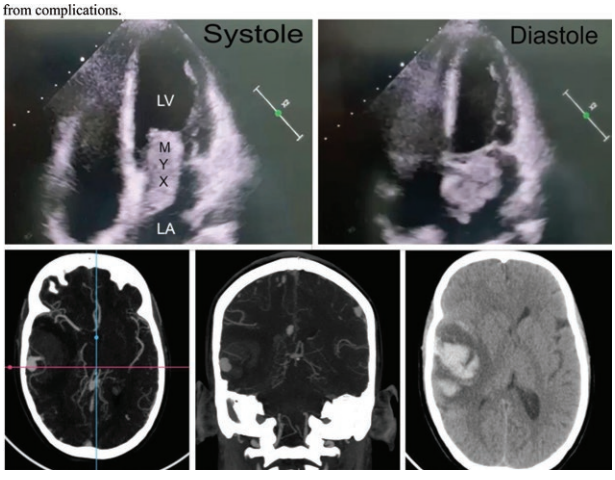

Figure 1. *Top Left and Right, Echocardiography during systole and diastole demonstrating dynamic myxoma propulsion into the left atrium.Bottom Left to Right, CT angiography- multiple saccular aneurysm from distal cortical branches of bilateral cerebral arteries with large aneurysm in close relation to the right temporal hematoma, likely ruptured.NCCT head- Right frontal bleed* LA- left atrium, LV= left ventricle, Myx - Myxoma

Conclusion: Myxoma, a rare intracardiac benign neoplasm due to release of inflammatory cytokines like IL-6 and embolic mechanism can present as inflammatory rheumatic disease. Diagnosing this great masquerader can be challenging even for a specialist but timely ordering of certain non-invasive tests could be life saving for the patient. For example in this case, Echocardiography or Cardiac MRI are critical. Therefore, having high diagnostic suspicion is very important when dealing with vasculitis and its mimics.

POS0575 **OSTEOMALACIA INDUCED BY HYPOPHOSPHATEMIA – ROLE OF FGF 23: TWO CLINICAL CASES REPORT**

Keywords: Osteoporosis, Education, Bone diseases

E. Costa[1], C. Campinho Ferreira2, A. M. Gomes Correia2, D. Esperança Almeida2, P. Pereira2, J. Silva2, M. Cerqueira2, J. Redondo Costa2, A. R. Ribeiro2, J. Neves2. *[1]Hospital de Braga, Rheumatology, Braga, Portugal; [1]Hospital de Braga, Rheumatology, Braga, Portugal*

Background: Osteomalacia is a bone disorder characterized by decreased bone mineralization. Vitamin D deficiency and hypophosphatemia are the most frequent causes. Fibroblast growth factor 23 (FGF23) is a hormone secreted by osteocytes in response to increased calcitriol and serum phosphate levels. FGF23 main function is phosphate serum levels regulation, decreasing sodium-phosphate cotransporter expression on the proximal convoluted tubule. Thus, FGF23 reduces calcium reabsorption and increases urine phosphate excretion. FGF23 may also suppress 1α-hydroxylase, reducing vitamin D activation and calcium reabsorption.
Objectives: To increase the awareness of hypophosphatemia-induced osteomalacia.
Methods: Case reports and discussion.
Results: Case 1 – A 63-year-old man, hospitalized for total hip arthroplasty secondary to non-traumatic bilateral femoral neck fracture was evaluated by rheumatology on suspicion of osteoporosis. Medical history was relevant for a progressive paraparesis of lower limbs 6 years ago and which etiological investigation revealed a mesenchymal tumor in the body of the ninth dorsal vertebrae compressing the spinal cord. A multidisciplinary discussion concluded that the tumor was unresectable, but the patient underwent decompressive surgery to relieve neurological symptoms one year later. The patient also reported a history of multiple non-traumatic fractures in the past five years, including ribs, ankle, pelvis, femoral neck, and scapula, and denied any articular or bone pain. In laboratory evaluation, serum phosphate levels were below the laboratory detection limit, calcium and vitamin D were decreased, parathormone (PTH) was in the normal range and serum alkaline phosphatase (AF) was increased. Serum FGF23 levels were 6 times above the upper limit of normal (ULN). Thus, the diagnosis of oncogenic osteomalacia induced by an FGF23-producing mesenchymal tumor was made. The patient started intravenous phosphate repositioning in the intermediate care unit and then he continued oral phosphate, calcium, and vitamin D supplementation at home. Currently, the patient is in the oncology outpatient clinic, and he was proposed to initiate treatment with burosumab (anti-FGF23 antibody). **Case 2 –** A 57-year-old woman with Rendu-Osler-Weber syndrome and iron deficiency anemia, chronically supplemented with ferric carboxymaltose, was referred to the rheumatology outpatient clinic because of a right second metatarsal bone fracture associated with hypophosphatemia, vitamin D deficiency, AF and PTH elevation (above 3 times the ULN and 2 times the ULN, respectively), and normal calcium levels. Measurement of FGF23 serum levels revealed an elevation of 3 times the ULN. The diagnosis of FGF23-induced hypophosphatemia was made. The patient started oral phosphate and vitamin D supplementation and the formulation of intravenous iron was changed. Six months after the initial evaluation, the previously abnormal analytical values were within the normal range.
Conclusion: Osteomalacia has multiple identified causes like vitamin D deficiency, hypophosphatemia, chronic kidney disease, renal tubular acidosis, and hypophosphatasia. FGF23 is a hormone that regulates phosphate metabolism. There are several types of genetic and acquired FGF23-related hypophosphatemia, like X-linked hypophosphatemia and FGF23-producing mesenchymal tumors, respectively. In case 2, it is thought that the key mechanism responsible for the effect of iron results from the disproportionate inhibition of FGF23 degradation by the carbohydrates present in intravenous formulations with a consequent increase in its concentration and activity. The risk of hypophosphatemia and osteomalacia appears to be greater with iron carboxymaltose than with other intravenous iron formulations.

Background: Anti-TIF1-γ antibody is specifically associated with paraneoplastic dermatomyositis (DM) [1], but this serum marker has seldom been reported after cancer immunotherapy. Immune checkpoint inhibitors frequently cause immune-mediated endocrine, gastrointestinal, and cutaneous syndromes [2] and de novo DM cases have also been described and successfully treated using glucocorticoids and intravenous immunoglobulin (IVIG) [3].
Objectives: We report the case of a man developing anti-TIF1-γ positive DM following immunotherapy with progressively worsening dysphagia refractory to glucocorticoids, immunosuppressants, and IVIG.
Methods: Case report.
Results: In February 2021 a 47-year-old man was diagnosed with skin melanoma that was surgically resected and treated with adjuvant ipilimumab and nivolumab, leading to complete remission. After three months, he developed *de novo* thyroiditis, hepatitis, colitis, and experienced rapid progression of previous vitiligo, along with muscle weakness and 5X CK elevation. His rheumatological workup included positive ANA at indirect immunofluorescence (1:640 titer, speckled pattern), and high-titer anti-TIF1-γ antibodies. Inflammatory myositis was diagnosed and treated with glucocorticoids (prednisone 1 mg/kg) and mofetil mycophenolate (MMF, 3 g/d) with initial benefit on muscle function. In September 2021, the patient had a metastasis-negative lymph node evaluation and suspended MMF for surgery with a subsequent rapidly progressive deterioration of muscle function, with dysphonia, dysphagia, and typical DM skin lesions (**Figure 1**) with pancytopenia (hemoglobin 9 g/dL, white blood cells 1500/mmc, platelets 40.000/mmc). Further oncological evaluation (total body CT scan, brain MRI) was negative for the recurrence of malignancy or the presence of myasthenia gravis and neuropathy. Methylprednisolone pulses (500 mg for 3 days) were started, followed by high dose IVIG (5 g/kg), with marginal improvement on muscle function, normalization of CK levels, but no effect on dysphagia which required PEG tube placement. MMF was restarted but rapidly stopped because of septic shock requiring intensive care unit admission, followed by recurrent severe infections, contraindicating further immunosuppression. Six monthly high-dose IVIG infusions were continued [4] with minimal effect. Worsening tetra-paresis, absolute dysphagia, impaired cough, and inability to manage salivary secretions led to massive aspiration pneumonia. The man developed acute respiratory insufficiency, septic shock, and multiorgan failure, and died 13 months after the onset of DM.
Conclusion: Worsening myopathy, typical skin lesions, and concomitant immune-related adverse events should raise suspicion of DM in patients receiving immune checkpoint inhibitors [3]. Balancing the risks of DM disease flare, malignancy, and severe infections is of paramount importance when choosing the most appropriate therapy. Patients with anti-TIF1-γ DM following immunotherapy may also manifest tetra-paresis, dysphagia, and severe pancytopenia.

Patient information and education

POS0577-PARE **EVALUATION OF PATIENT SATISFACTION WITH REMOTE SELF-INJECTION TRAINING: A SINGLE-CENTRE PATIENT-REPORTED SURVEY**

Keywords: Inflammatory arthritides, Patient reported outcomes, Patient information and education

S. Mccourt[1], M. Andiappan[2]. *[1]Southern Health and Social Care Trust, Rheumatology, Craigavon, United Kingdom; [2]Open Health, Real World Evidence, Marlow, United Kingdom*

Background: Subcutaneous self-injection of methotrexate (SC MTX) is used for the treatment of several inflammatory diseases. All newly initiated patients should be educated and trained in the proper injection technique by their healthcare provider (HCP), with the first injection performed under medical supervision. This training has typically been conducted during face-to-face consultations, however since the start of the COVID-19 pandemic it has been necessary to conduct training remotely due to the cancellation of clinics.
Objectives: To understand patient-reported experiences and satisfaction with remote SC MTX self-injection training.
Methods: A cross-sectional electronic survey was administered between 11 October 2022 and 30 November 2022 to patients at Southern Health and Social Care Trust who had recently been trained via telephone or video conference [VC] on how to self-inject methotrexate using a pre-filled, auto-injector pen. Patients were aged ≥18 with a range of arthritis types, including rheumatoid, psoriatic, polyarticular juvenile idiopathic and chronic reactive inflammatory arthritis. Remote training was delivered by the patient's nurse as per routine practice (independently of this survey). Patients were sent a patient information pack (PIP) prior to the training consultation. During the training, the nurse discussed the process of injecting with the auto-injector pen before virtually supervising the first injection. The survey consisted of 14 questions; topics included experiences and satisfaction with preparation for the HCP appointment, the training consultation itself and post-training experiences and preferences. The responses were analysed descriptively on an item-by-item basis.
Results: In total 73 patients completed the survey; 77% (n=56/73) were female, and 96% (n=70/73) had no prior experience with a SC MTX auto-injector pen. The training was completed by telephone for 92% (n=67/73) of patients and by VC for 8% (n=6/73). 99% (n=72/73) received a PIP in advance of their training consultation and 92% (n=67/73) received this by post. 67% (n=49/73) of patients

strongly agreed and 26% (n=19/73) agreed that they felt prepared for the training after receiving the PIP; 78% (n=57/73) of patients strongly agreed and 22% (n=16/73) agreed that it was easy to read and understand, whilst 52% (n=38/73) strongly agreed and 32% (n=23/73) agreed that the PIP was helpful and did not require additional instructions before the appointment. 84% (n=61/73) took 15 minutes or less to complete the training with their HCP. None of the participants felt confused or did not understand the training instructions from their HCP, 78% (n=57/73) strongly agreed and 19% (n=14/73) agreed that the remote training was helpful and made them feel more confident to use the injector pen on their own and 97% (n=71/73) did not need to contact their HCP for more training or advice following their appointment. When asked about the main advantages of remote training, 32% (n=23/73) agreed it was more convenient, 25% (n=18/73) agreed that it was time saving and 30% (n=22/73) agreed that not having to attend the hospital was beneficial. 85% (n=62/73) strongly agreed and 14% (n=10/73) agreed that they were satisfied with the remote training provided and 82% (n=60/73) strongly agreed and 18% (n=13/73) agreed that they would recommend the remote training to another patient.

Conclusion: These findings provide new insight into patients' experiences with self-injection training when delivered remotely by their HCP. The patient information pack and training consultation were well received as most patients found it helpful, convenient and time saving.

POS0578-PARE IMPROVED EDUCATION IS NEEDED FOR INDIVIDUALS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: INSIGHTS FROM A SOCIAL MEDIA LISTENING QUALITATIVE ANALYSIS

Keywords: Systemic lupus erythematosus, Descriptive Studies, Patient information and education

J. Barbosa[1], C. Henning[2], A. Mian[3], C. Harrison[4], E. Scott[5], S. Burriss[6]. [1]*GSK, Medical Affairs Excellence, Dublin, Ireland;* [2]*GSK, Global Medical Affairs, Durham, NC, United States of America;* [3]*GSK, Global Medical Affairs, Brentford, United Kingdom;* [4]*LupusChat, N/A, New York, NY, United States of America;* [5]*Lupus Research Alliance, N/A, New York, NY, United States of America;* [6]*GSK, Value, Evidence and Outcomes, Collegeville, PA, United States of America*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease affecting multiple organs, including the kidneys in lupus nephritis (LN) [1]. Individuals living with SLE have impaired quality-of-life compared with the general population [1]. and a growing number are using social media for health-related information [2]. Thus, social media is a useful source of data to examine their experiences and concerns [3].

Objectives: To understand the perspective of individuals living with SLE/LN on their disease management and to assess where they seek information, how their personal perspective impacts their care, and what may be needed to improve care/experience.

Methods: This qualitative analysis used the Sprinklr social media listening tool to search historical posts across 11 countries, including the USA, the UK and Japan, between May 2021 and February 2022, using predefined keywords. Main data sources were Twitter, Instagram, Reddit, Facebook, Weibo and SLE-specialised websites. Publicly shared posts relating to SLE/LN were captured and key themes were analysed.

Results: Overall, 23,084 posts were exported; of these, 12,037 were in scope and mentioned SLE/LN disease and/or therapeutics. Of the 12,037 posts, 6424 were related to SLE/LN disease alone (diagnosis and management) and 5387 to therapeutics. The remaining 226 posts did not add any value to the analysis and were not considered. From analysis of the posts, many individuals with SLE/LN appeared to understand their condition and could identify symptoms (e.g., SLE: pain, fatigue, rash; LN: foamy urine, blood creatinine). However, there was a lack of knowledge of diagnostic and disease monitoring tests such as anti-nuclear antibodies. Individuals with SLE/LN also described not receiving enough explanation of their laboratory results. Based on the posts, physician focus on measurable disease activity and clinical trial data did not resonate with individuals with SLE/LN. Quality-of-life and patient-reported outcomes would be the preferred focus of discussion and may improve perception of their care. Individuals with SLE/LN reported being busy and symptoms of their disease (e.g. too tired or forget to take their medication) as reasons for poor adherence.

According to the posts, the most used SLE/LN drugs included methotrexate, hydroxychloroquine (HCQ), prednisolone, mycophenolate mofetil and azathioprine. Individuals with SLE/LN generally had positive sentiment towards their individual standard therapies (except for HCQ). Awareness of long-term side effects was generally high; however, some individuals with SLE/LN were not aware that long-term use of steroids may contribute to organ damage. Individuals with SLE/LN reported many barriers preventing them from focusing on long-term goals of disease management and achieving better outcomes, including diagnosis delays, daily disease impact, concerns with treatment effectiveness, safety, onset of response, and due to misleading information on social media.

Conclusion: Insights from this analysis suggest that improved education for individuals with SLE/LN on disease-specific tests/tools, laboratory results, treatments, and treatment effects could improve shared decision-making, including a needed shift in focus from short-term to long-term improvements. It could also help address discordance between physicians and individuals with SLE/LN on medication decision-making and adherence [4]. It is vital to consider known health disparities when providing education, as barriers such as racial discrimination have been associated with increased SLE disease activity and organ damage [5]. A change in care and clinical trials towards more collaborative and patient-centric care could also improve adherence and outcomes.

POS0579-PARE REUMA REGIE, SELF-MANAGEMENT TRAINING BY AND FOR PATIENTS

Keywords: Patient information and education, Self-management

A. Marchal[1], J. De Reu[1], N. Creten[1]. [1]*ReumaNet, ReumaNet, Zaventem, Belgium*

Background: No self-management training for people with RMDs exists yet in Belgium. In its vision, ReumaNet is convinced that patients' expertise adds great value in several areas. This includes self-management. Instead of consulting external organisations, ReumaNet developed a self-management training by the patient experts themselves. The training is based on the major themes identified in the study by J. Ammerlaan, et al "Self-management in patients with RA: a qualitative study from the patient's perspective" and takes into account the recommendations for the implementation of self-management strategies drawn up by EULAR in June 2021.

Objectives: The aim of the training is for participants to gather the ability to understand their disease and cope with practical, physical and psychological consequences linked to their RMD.

Methods: The training is structured based on the patient journey: each person with an RMD goes through a number of stages as part of coping with his/her condition. This patient journey is the common thread throughout the training; a simple and efficient tool to guide patients towards their final goal. Via reflection and exercises, participants can identify their personal obstacles and challenges and are empowered to face daily challenges, due to their RMD. The training takes the form of a four-day training with an overnight stay, because we are convinced that 'taking a break from the daily routine' can provide sufficient distance, both literally and figuratively, for self-reflection. Moreover, there is then extra space for informal contact, which can enhance the group atmosphere. There is also the possibility of delving deeper into certain topics during a short evening session, should participants feel the need. During this four-day course in March2023, we provide 18 hours of training, using professional insights (f.e. webinars with specialists, certified return to work coordinator

ReumaNet, lifestyle coach,…) and personal experience. The training itself is developed by three patient experts and will be delivered to a group of up to 12 participants. The training is a collaboration with Samana, a Christian health organisation in Belgium. They provide logistical and financial support. Before implementation, the training content was reviewed by a group of trained patient experts from ReumaNet.

Results: During the training, the participants get enough tools to be able to steer their mindset in a more positive way, by actively dealing with challenges linked to their specific condition, f.e. good sleep quality, self-care, dealing with stress, fatigue and pain. Also provided tools in the context of communication, bringing in necessary help and social support, sexuality and professional reintegration empower participants to take matters into their own hands. Over all, participants are empowered to face their own challenges in daily life. They gather the ability to understand their disease and cope with practical, physical and psychological consequences.

Conclusion: No such training exists yet in Belgium and there is a high demand for it. We will repeat this self-management training annually. In addition, we are looking for other ways to organise this training: online, or via (semi-) daily training days for example.

POS0580-PARE PATIENT ADHERENCE TO OSTEOPOROSIS TREATMENT IS HIGHER WITH CAREGIVER EDUCATION

Keywords: Patient information and education, Best practices, Osteoporosis

S. Samieva[1], J. Polyakova[2], L. Seewordova[2], E. Papichev[2], Y. Akhverdyan[2], B. Zavodovsky[2]. *[1]Medical Center of the Executive Office of the President of the Republic of Tajikistan, Endocrinology Department, Dushanbe, Tajikistan; [2]Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Treatment and Prevention of Joint Disease Laboratory, Volgograd, Russian Federation*

Background: Treatment adherence to osteoporosis treatment remains low. Additional factors: the elderly age of patients, congestive disorders, high comorbidity, fears of side effects of drugs, fear of calcium deposits in the vessels, kidneys and gallbladder, the absence of obvious clinical manifestations of the disease lead to refusal or unreasonable interruptions in therapy for osteoporosis.

Objectives: Eo analyze the Treatment adherence to osteoporosis therapy of single patients, patients living in a family and patients coming to an appointment with a caring relative.

Methods: The analysis of outpatient records of 300 patients observed in the center for the diagnosis and treatment of osteoporosis was carried out. The study included all patients who visited the center in the period from the beginning of 2020 until reaching the enrollment of 100 people according to the ranked criterion. A total of 3 groups were recruited: 1st - single patients, N=100, 2nd - living in a family N=100, 3rd - coming to an appointment with a caring relative/social worker, N=100. The following were assessed: the completeness of the examination, the frequency of subsequent visits, adherence to therapy and the result of treatment according to densitometry data and repeated fractures. The observation period is 3 years. Patients who did not come to the follow-up examination (DXA) after 3 years were excluded from the study.

Results: 15.7% (47 people) withdrew from the study due to non-appearance for return visits. When calling patients, it was found that 6% (18 people) were going to start treatment, but did not start for various reasons, 9.7% (29) started taking vitamin D and continued to take it until the package was over, 5% (15 people) started taking vitamin D preparations (patients from 9.7% of the above) and calcium preparations were taken from 1 to 3 months, after which they stopped taking them, considering that the course of treatment was completed. 2.3% (7 people) died within 3 years from various causes (4 out of 1 gr, 1 out of 2, 2 out of 3). The final statistical analysis included 246 people. The results are presented in Table 1.

Table 1.

N=246	Single patients, N=65, 100%	Living in a family, N=87, 100%	With a caring relative/ social worker, N=94, 100%
Have passed a full examination	31; 47,7%	60; 69%	89; 94,7%
Attended all consultations or called/ wrote to the doctor	20; 30,7%	56; 64,4%	92; 97,9%
Treatment adherence to basic therapy	18; 27,7%	61; 70,1%	84; 89,4%
Treatment adherence to pathogenetic therapy	32; 49,2%	76; 87,4%	92; 97,9%
Positive dynamics, including DRA	27; 36,9%	52; 59,8%	76; 80,8%
A new fracture in 3 years	4; 6,2%	1; 1,2%	1; 1,1%

Conclusion: As a result of the analysis, it was confirmed that the highest adherence to examination and therapy was in patients who applied with a caregiver. Caregivers perceive verbal information better, seek repeated clarifications more often when questions arise about therapy and examination results, help patients solve technical problems (get to the center, purchase medicine, calculate dietary calcium, find a physical education video course). As a result of higher adherence to non-pharmacological and pharmacological treatment, the increase in bone mineral density in the 3rd group of patients was maximum. In the 1st group of patients, due to low adherence to therapy and the worst arrangement of life, by the 3rd year of observation, a higher percentage of fractures (6.2%) was revealed, differences in the frequency of fractures in the 2nd and 3rd groups over 3 years observation was not detected (1.2% and 1.1%) due to the short observation period and a relatively small sample of patients.

POS0581-PARE VACCINATIONS IN PATIENTS WITH CHRONIC INFLAMMATORY DISEASES, PATIENT KNOWLEDGE AND AWARENESS: RESULTS FROM A NORDIC SURVEY

Keywords: Vaccination/immunization, Health services research, Patient information and education

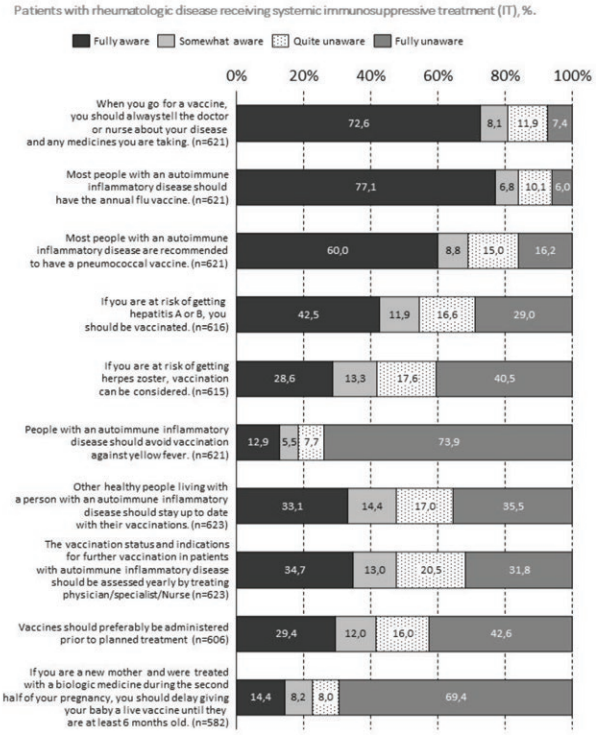
M. C. Kapetanovic[1,2], R. Mandla[3], M. Seddighzadeh[4], S. Thiesen Gren[5], M. Palmroth[6], D. Henrohn[4,7], A. G. Frostrup[5], A. M. Hiltunen[8], J. Ranta[8], A. K. Asikainen[8], V. J. Anttila[9]. *[1]Lund University, Department of Clinical Sciences, Lund, Sweden; [2]Skåne University Hospital, Section of Rheumatology, Skåne, Sweden; [3]Pfizer AS, Medical Affairs, Lysaker, Norway; [4]Pfizer AB, Medical Affairs, Sollentuna, Sweden; [5]Pfizer Denmark, Medical Affairs, Ballerup, Denmark; [6]Pfizer Oy, Medical Affairs, Helsinki, Finland; [7]Uppsala University, Department of Medical Sciences, Uppsala, Sweden; [8]Nordic Healthcare Group, Finland, Helsinki, Finland; [9]Helsinki University Hospital, Department of Infectious Diseases, Helsinki, Finland*

Background: Patients with chronic inflammatory diseases (CID) have an increased risk for contracting infections. For patients with rheumatic diseases EULAR recommends protecting them from vaccine-preventable diseases.

Objectives: To assess the knowledge and awareness of common vaccinations and extent of immunization among patients with CID in Denmark, Finland, Norway, Sweden (Nordics), and to identify gaps between the existing EULAR vaccination recommendations and current practice as experienced by patients.

Methods: A structured anonymous online survey for patients with CID ((rheumatological disease (RD), inflammatory bowel disease (IBD) and dermatological diseases (DD)) was conducted in 2022. The survey was answered by 1748 respondents (1031 patients with RD, 543 with IBD and 563 with DD).

Results: Among respondents, 89% were female and 58% had disease duration of above 10 years. In total, 56% were treated in specialised and 32% in primary care. Majority had ongoing systemic immunosuppressive treatment (IT) (65%). Majority of RD (59%) and IBD (66%) patients were treated in specialised care whereas minority of DD patients (38%) were treated in specialised care. Forty-nine percent (49%) responded that their healthcare professional (HCP) did not inform them about the increased risk of infection – however, 55% of the respondents believed



they are somewhat or much more likely to suffer from infections than those without CID or treatment, 33% thought there is no difference and 13% did not know there is a difference. In total 68% of respondents considered it important to get vaccinated due to CID or IT. The number was particularly high in RD group (74%), although 63% stated they had not received any information regarding vaccinations at the start of their treatment. Commonly recommended vaccinations by the HCP were COVID 19 (66%), influenza (63%) and pneumococcal (45%) vaccination. When comparing respondents ≥65 and <65 years, there was a difference in how often the influenza (71% vs. 57%) and pneumococcal (57% vs. 38%), but not COVID 19 vaccination (68% vs. 65%), were recommended. In addition, 74% and 75% of respondents receiving IT were recommended influenza and COVID 19 vaccination, respectively. In total, 22% had their vaccination status checked before initiating treatment; the lowest percentage was in DD (16%) and the highest in RD (25%). However, 44% of respondents received influenza vaccination before initiation of treatment. Moreover, 62% and 74% of respondents received influenza and COVID 19 vaccination while on treatment, respectively. Eighty-six percent (86%) did not receive a vaccination plan in relation to their CID and treatment. Moreover, 64% of the respondents (RD 57%; DD 71% and IBD 66%) did not have vaccination status assessed on a regular basis. Forty-three percent (43%) were dissatisfied with the follow-up of vaccination status by their HCP. Respondents of age ≥65 years were more satisfied than the younger ones (34% vs. 25% very satisfied) and respondents with RD were more satisfied than those with IBD or DD (33% vs. 25% vs. 20%). Forty-four percent (44%) responded that the information on vaccinations related to their CID and treatment was difficult to find and 71% would like to receive more information. The respondents with RD had different level of awareness regarding EULAR vaccination recommendations. The degree of awareness among patients with RD treated with IT are presented in Figure 1.

Conclusion: This Nordic survey provides insights on patients' information needs, information sources and own experiences related to recommendations on vaccinations in relation to their CID and IT. The results confirm a gap between patients' expectations and needs vs. the information they actually receive. Our findings demonstrate a need for increased awareness among patients, providers and HCP regarding EULAR vaccination recommendations in patients with RD.

Building patient led organisations

POS0582-PARE MEASURES FOR IMPROVING FEEDBACK TO PATIENT RESEARCH PARTNERS IN PARTICIPATORY RESEARCH PROJECTS

Keywords: Patient information and education

J. Clausen[1]. [1]*Deutsche Rheuma-Liga Bundesverband e.V., Scientific Adviser, Bonn, Germany*

Background: The acceptance of participatory research has increased in recent years. However, discussions during the meeting of the EULAR Study Group for Collaborative Research (EULAR conference 2022, Copenhagen) revealed the risk of mere "tokenism" in participatory research projects. In Germany, with more than 60 participatory research projects in the field of rheumatology, "tokenism" is also a matter of discussion in this country.

Objectives: One aspect of tokenism is that patient research partners (PRPs) are involved in the preparation of the application at the beginning of a research project, but they are neglected after the funding application has been submitted, resulting in a lack of feedback from the research projects. The German Rheumatism League (Deutsche Rheuma-Liga, DRL) tried to find ways to improve and uphold continuous communication between scientists and PRPs during all phases of research projects.

Methods: In May 2022, the DRL conducted a survey among the active PRPs on (a) how regularly the PRPs are informed about the status of the research projects, (b) whether contact is usually unsolicited and (c), how the communication was rated overall. Based on the evaluation, measures were discussed to improve communication, and supporting tools were developed. A new survey will be carried out after one year.

Results: In May 2022, the PRPs had not received any information from the research projects for an average of 124 days. However, the timelines varied greatly between ongoing projects (on average 77 days) and for those projects whose applications were only under submission and were waiting for the confirmation of funding ("application phase"; on average 280 days). In about 40% of all projects, the overall flow of information was rated as "bad" or "very bad". Based on these results, the DRL discussed measures with the PRPs as to what adequate communication looks like and how it can be guaranteed that it takes place. Supporting tools were developed and incorporated into the process of coordinating the PRPs. In addition, the DRL discussed what appropriate consequences might be put in place for projects that hesitate to adapt their communication behaviour.

Conclusion: The long absence of any communication, especially during the "application phase", was assessed as unacceptable. In a follow-up survey with PRPs, in May2023, we shall evaluate the impact of the developed tools and discuss and act upon the findings.

Background: Growing evidence points to considerable mental health impacts of the prolonged COVID-19 pandemic, though data from longitudinal studies in rheumatic diseases are sparse.
Objectives: We explored distinct trajectories ofdepressive symptoms in the year prior to and throughout the first 2-years of the COVID-19 pandemic inadults with RA.
Methods: CATCH is a prospective multi-center study of adults with early RA (symptoms <1 year; 81% met 2010 ACR/EULAR criteria at enrolment) who receive care from rheumatologists across Canada. Prior to the pandemic, participants completed PROs and rheumatologists conducted RA assessments during scheduled in-person study visits. After March 2020, ongoing collection of PROs continued at in-person and remote visits. We used group-based trajectory modeling to identify latent groups with at least mild depression (PROMIS 4a depression score ≥55) in participants with ≥1 visits in the year prior to the pandemic (3/19-2/20) and ≥1 visits during pandemic (3/20-1/22) and identified prepandemic individual and clinical characteristics and PROs associated with each trajectory.
Results: The analytic sample included 989 participants with a mean (SD) age of 60 (14) and disease duration of 6 (4) years. 73% were women, 84% white, 60% had completed some post-secondary education, and 77% were in CDAI REM/LDA at visit closest to the start of pandemic. The best model included 4 groups (posterior probabilities ≥0.80 for each group): 1) **Resilient** (none-minimal depression throughout: N=594; 60%); **Worsening** (none/minimal to mild: N=222;22%); **Improving** (mild-resilient: N=80;8%); and **Persistent** (moderate-severe throughout: N=93;9%)(Figure 1). As compared with the Resilient group, those with Worsening Depression were more likely to be female, have a higher prepandemic CDAI, MD and patient global, and report worse pain, disability, anxiety, depression, fatigue, sleep disturbance, and lower participation (Table 1).

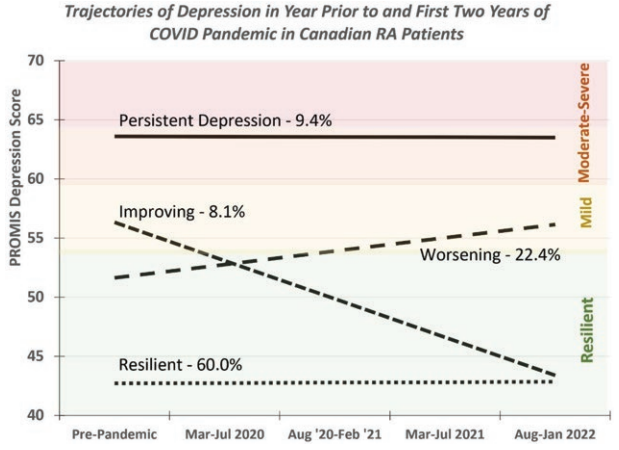

Figure 1.

Table 1.

Mean(SD); N(%)	Worsening N=222 (22%)	Resilient N=594 (60%)	Improving N=80 (8%)	Persistent N=93 (9%)	SIG

Conclusion: Although 60% of Canadian RA patients had consistently good mental health during the first 2 years of the COVID-19 pandemic, more than 1 in 5 reported deteriorating mood suggesting a cumulative impact over time; 9% had persistent depression and 8% improving mood. The proportion of adults with RA with at least mild symptoms of depression may be more than twice that reported for the general Canadian population. Participants with worsening depressive symptoms during the pandemic were more likely to be female, have higher prepandemic disease activity, symptoms, disability, and higher impairments in participation. Given the impact of depression on quality of life, inflammation, and disease management, vulnerable groups may benefit from more frequent evaluation and additional support from rheumatology providers.

HPR Interventions (educational, physical, social and psychological)

POS0585-HPR

EFFECTIVENESS OF INSPIRATORY MUSCLE TRAINING ON AEROBIC CAPACITY, RESPIRATORY FUNCTIONS AND RESPIRATORY MUSCLE STRENGTH IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: A SINGLE-BLINDED RANDOMISED CONTROLLED TRIAL

Keywords: Physical therapy/physiotherapy, Randomized control trial, Lungs

D. C. Saraç[1], D. Bayraktar[1], D. Ozer Kaya[1], O. Altug-Gucenmez[2], D. Oskay[3].
[1]Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; [2]University of Health Sciences, Dr. Behçet Uz Pediatric Diseases and Surgery Training and Research Hospital, Department of Pediatric Rheumatology, Izmir, Turkey; [3]Gazi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey

Background: Children with juvenile idiopathic arthritis (JIA) may present lower aerobic capacity, lung volumes, and respiratory muscle strength compared to their healthy peers [1].
Objectives: This study aimed to investigate the effectiveness of inspiratory muscle training (IMT) on aerobic capacity, lung volumes, respiratory muscle strength, functional capacity, and quality of life in children with JIA.
Methods: Thirty-three children with JIA who were on the same biologic disease modifying anti-rheumatic drugs for at least three months were included and divided into two groups as exercise group (n=17, mean age: 15.1±2.2 years, 12 male) and control group (n=16, mean age: 15.7±1.6 years, 11 male). Exercise group performed IMT daily for eight weeks. Initial IMT load was set as the 60% of maximal inspiratory pressure (PI_{max}) and was increased by %10 every two weeks. Control group received no additional intervention. Forced vital capacity

(FVC), forced expiratory volume in one second (FEV_1), FVC/FEV_1 ratio, PI_{max}, and maximal expiratory pressure (PE_{max}) were evaluated using a portable pulmonary function test device (Cosmed Pony FX, Rome, Italy). Participants performed a maximal Cardiopulmonary Exercise Test to measure maximal oxygen consumption (VO_{2peak}), metabolic equivalent (MET) and maximal heart rate. Six-minute walking distance (6MWD) was used to evaluate lower-extremity related functional capacity. The Pediatric Quality of Life Inventory (PedsQL) 3.0 Arthritis Module was used to evaluate the quality of life. Participants were evaluated at baseline and at the end of eight weeks.

Results: The groups were similar at baseline. FVC, FEV_1, PI_{max}, PE_{max}, VO_{2peak}, and MET significantly improved at the end of eight weeks in the exercise group ($p<0.05$), while no significant differences were observed in the control group ($p>0.05$). The difference over time in FVC, FEV_1, PI_{max}, VO_{2peak}, and MET were significantly higher in the exercise group compared to control group ($p<0.05$, Table 1). No other between group differences were detected ($p>0.05$).

Conclusion: IMT seems beneficial for improving respiratory functions in children with JIA.

POS0586-HPR SARCOPENIA IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS OLDER THAN 65 YEARS: PREVALENCE AND PREDISPOSING FACTORS

Keywords: Sarcopenia, Spondyloarthritis

L. Cano Garcia[1], J. Vacas[2], P. J. Armenteros Ortiz[2], F. G. Jiménez-Núñez[2], G. Diaz-Cordobes[1], S. Manrique Arija[1]. *[1]Hospital Regional Universitario de Málaga; Instituto de Investigación Biomédica de Málaga (IBIMA)., Rheumatology, Málaga, Spain; [2]Hospital Universitario Reina Sofía, Instituto Maimónides de Investigación Biomédica (IMIBIC), Universidad de Córdoba, Rheumatology, Córdoba, Spain*

Background: Sarcopenia is a muscle disease that presents as a loss of skeletal muscle mass and function. It is a condition associated with chronic diseases and aging that predicts disability, hospitalization and death.

Objectives: To describe the prevalence of sarcopenia and identify risk factors associated with sarcopenia in patients with spondyloarthritis (SpA) older than 65 years.

Methods: Design: Case-control study. Participants: Cases: They were recruited by simple random sampling among patients over 65 years of age with SpA (ACR/EULAR 2010 criteria) treated at 2 university hospitals. Controls: They were recruited for convenience by asking the cases to attend a consultation with a person of the same age (+/- 5 years) and sex. Variables: The main variable: sarcopenia, defined according to the European Working Group on Sarcopenia in Older People (EWGSOPII) 2019 criteria. The risk factors for sarcopenia evaluated were: economic level, malnutrition, measured with the Mini Nutritional Assessment (MNA), toxic habits, comorbidities and Charlson index, physical activity measured with the Global Physical Activity Questionnaire (GPAQ) and Short Physical Performance Battery (SPPB), muscle assessment measured by ultrasound. Other variables were: hemoglobin, calcium, vitamins D and B12, albumin, C-reactive protein, BMI (body mass index), polypharmacy (≥5), quality of life (EQ-5D) and factors related to SpA: activity of disease measured with BASDAI and ASDAS, physical function measured with BASFI, and treatments. Statistical analysis: descriptive and multivariate analysis was performed to identify factors associated with sarcopenia in SpA.

Results: 36 patients and 36 controls were recruited, of whom 54 (75%) were men, with a mean (± SD) age of 70 years (±4.37). Of the 36 patients with SpA, 20 (55.6%) had axial SpA and 15 (44.5) had SpA with axial and peripheral involvement with a mean of 32 years (±10.9) of disease. The prevalence of sarcopenia in patients with SpA is 8.3%. No differences were found in sarcopenia between patients [3(8.3%) and controls [1(2.8%)], p=0.614.Patients with SpA who had sarcopenia, compared with those who did not, had a mean years of evolution of their major disease [45.6 (±3.1) Vs 31.06 (± 10.5)], p=0.24; worse performance tests in the Short Physical Performance Battery (p=0.26), in relation to ultrasound parameters, a lower thickness was observed in the right forearm 75% radial and left forearm 66% radial [11.1(0.2) Vs 14, 7(2.4)], p=0.17 and left rectus femoris area [11.5(1.2)Vs15.4(2.8)], p=0.26, greater thigh fat right to 50% [25.6(4.7) Vs 15.2(8.3)], p=0.041 and lower albumin levels [7.17(21.5) Vs 19.02(608, 5)] p=0.053. On the other hand, no significant differences were found in the rest of the parameters studied for disease activity, disability, quality of life (EQ-5D), malnutrition, toxic habits, comorbidities or physical activity. In the multivariate model, the years of disease evolution (p=0.041) Table 1 were identified as an independent predictor of sarcopenia in patients with SpA. This model would explain 33% of sarcopenia in RA (R2=0.37).

Conclusion: In our study we found no differences in sarcopenia in patients older than 65 years with SpA compared to controls. The longer evolution time of their disease in patients with SpA is associated with a greater risk of sarcopenia.

POS0587-HPR IMPACT OF COMBINED INTERVENTION WITH CLINICAL NURSE SPECIALIST IN THE MANAGEMENT OF CARDIOVASCULAR RISK IN PATIENTS WITH GOUT

Keywords: Cardiovascular disease, Gout, Non-pharmacological interventions

E. Calvo-Aranda[1], C. M. Gomez-Gonzalez2, J. A. Angel-Sesmero[1], M. Novella-Navarro[3], P. Cardoso Peñafiel2. *[1]Hospital Universitario Infanta Leonor, Rheumatology, Madrid, Spain; [1]Hospital Universitario Infanta Leonor, Rheumatology, Madrid, Spain; [3]La Paz University Hospital, Rheumatology, Madrid, Spain*

Background: Gout is associated with increased cardiovascular risk (CVR). Traditional CVR factors (CVRF) are frequently present in patients with gout, further worsening the prognosis. Several studies have shown that clinical nurse specialist (CNS) contributes effectively to the management of gout.

Objectives: To analyze the detection of CVRF in patients with gout in a rheumatology consultation with CNS and to evaluate short-term changes after a targeted approach.

Methods: Patients with gout according to ACR/EULAR 2015 criteria referred from Primary/Specialized Care due to poor control of the disease. At the first visit, demographic and clinical variables were collected: age, sex, smoking, alcohol consumption, duration of gout, tophi, comorbidities, urate-lowering treatment

(ULT) and concomitant drugs. A blood test and review of previous tests from the last year were performed, as well as measurement of blood pressure (BP), weight and abdominal circumference. Nurse-managed calls were made to monitor home measurements and check adherence/tolerance to pharmacological (start/adjustment of ULT, antihypertensive, lipid-lowering and anti-diabetes drugs) and non-pharmacological approach (gout education, dietary/lifestyle recommendations) initiated at the first visit, according to the Spanish gout guideline and EULAR recommendations for CVR management in rheumatic diseases. We count on multidisciplinary collaboration with other specialists. After 6 months, an in-person visit was made with the same measurements to determine potential changes. A descriptive analysis of the sample was performed. The Wilcoxon test was used to evaluate the variation in the parameters studied. The outcome variable was determined as improvement versus no improvement of the dependent variable. Chi-square and Mann Whitney U tests were used to evaluate the differences.

Results: Forty patients who met the inclusion criteria were included. 98% were male, with a median age of 66 (58-75) years, severe gout (83% tophaceous, median duration 7 years) and marked presence of CVRF (smoking 23%, hypertension 78%, dyslipidemia 55%, diabetes 23%), some of them previously undetected (10% hypertensive, 3% dyslipidemic, 3% diabetic), and related comorbidities (ischemic heart disease 8%, cerebrovascular disease 5%, chronic kidney disease 20%). Fifty-five percent were not taking ULT and 53% used non-steroidal anti-inflammatory drugs (NSAIDs) on a regular basis. At the first visit, ULT was started/adjusted in 95% of patients, antihypertensive in 15%, lipid-lowering drugs in 13%, and anti-diabetes drugs in 8%. At 6 months, there was a significant improvement in sUA and BP, and a non-statistically significant weight reduction (Table 1). Serum uric acid (sUA) target was achieved in 93% of patients (37/40 <6 mg/dl, 29/40 <5 mg/dl). The use of NSAIDs was reduced to 5%. Four out of 9 smokers quit. Systolic BP improved in 73% of patients and diastolic BP in 70%. Dietary and habit modifications, therapeutic adjustments and multidisciplinary care were significantly associated with improved BP (p=0.02).

Conclusion: In patients with difficult-to-treat gout and high CVR, combined intervention with CNS allows substantial short-term changes in CVRF, a drastic reduction in NSAID consumption and a high percentage of success in achieving the sUA target.

HPR Measuring health (development and measurement properties of PROs, tests, devices)

POS0588-HPR

DISCOVERING THE POTENTIAL OF DIGITAL BIOMARKERS IN THE WORK PROCESS OF THE RHEUMATOLOGY HEALTHCARE PROFESSIONALS, A DESIGN THINKING APPROACH. PRELIMINARY RESULTS OF THE HEALTHCARE PROFESSIONALS PERSPECTIVE

Keywords: Biomarkers, Health services research, Qualitative research methods

P. De Groot[1], J. Luime[1], M. Vis[1], M. R. Kok[2], I. Tchetverikov[3]. *[1]Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands; [2]Maasstad Hospital, Rheumatology, Rotterdam, Netherlands; [3]Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands*

Background: During times of social-distancing, in-person outpatient visits were greatly reduced. Health care professionals (HCPs) were dependent on the patient's reported experience of their disease activity in their assessments of the wellbeing and inflammatory state, due to lack of physical assessments. *Digital biomarkers* can support real-world continuous measurements and offer a method for remote quantification of inflammatory joint disease. They are defined as objective, quantifiable, physiological and behavioural data that are collected and measured with digital devices [1].

Objectives: This study uncovers the HCPs perspective on current manners of disease activity monitoring, easing their workload and the potential of digital biomarkers.

Methods: A Design Thinking approach is followed for digital biomarker development. It is a human-centered problem solving approach that leverages iteration, empathy and collective idea generation to tackle complex challenges [2]. Semi-structured online focus group discussions were conducted. Pilot 1-1 interviews were executed to assess the interview script. The script is underpinned by the graphical framework for clinical decision making [3] and the theoretical domain framework [4]. One moderator and three alternating observers facilitated the sessions. All interviews were audio-recorded, transcribed to verbatim and coded.

Results: In total 6 focus groups were organised, with a total of 28 HCPs. Participants were rheumatologists (N= 19, age 47 ± 9, 50% male) and rheumatology nurses (N = 9, age 51 ± 6, 0% male). The main findings from the interviews about digital biomarkers in relation to current practices were: *Trust;* HCPs felt self-assured about their own abilities of physical evaluation, reading patients and their gut feeling. Trust in flare detection with digital biomarkers and machine learning was low. It was expected that much disease activity is missed and many false-positive flares are detected. Biomarkers should be valid, reliable and sensitive to change. *Innovation should improve quality of care;* No consensus about a golden standard of care exists. HCPs were afraid that with digital biomarkers personal interaction recedes to the background and quality of care is compromised. Personal interaction was marked as essential to raise sensitive topics and stimulate therapy adherence. *Benefits of digital biomarkers;* HCPs enjoyed the delivery of efficient and effective care. They disliked repetition and the high administrative burden. In the HCPs opinion digital biomarkers could establish disease activity prior to the consultation, so time could be spent on what matters to the patient. New technologies should however not add to frustrations and make way for things that really matter.

Conclusion: The following problem statement from the HCPs perspective can be formulated: "In limited time we take many actions. We spend time on both disease and emotional support of our patients. Our workload is high and trivial tasks such as administration take too much of our time. Instead we want to focus on what's relevant to the patient. We are confident about our own abilities and, only if technology is proven to be valuable, valid, reliable and accepted by our patients it can be used in clinical practice."

POS0589-HPR NATURE AND SEVERITY OF FUNCTIONAL LIMITATIONS ACCORDING TO THE HEALTH ASSESSMENT QUESTIONNAIRE DISABILITY INDEX IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SEVERE FUNCTIONAL DISABILITY

Keywords: Rheumatoid arthritis, Patient reported outcomes, Outcome measures

M. Van Wissen[1], M. G. J. Gademan[1,2], C. Van den Ende[3,4], M. Teuwen[1], W. Peter[1], D. Van Schaardenburg[5], A. Den Broeder[4,6], T. P. M. Vliet Vlieland[1], S. Van Weely[1]. *[1]Leiden University Medical Center, Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; [2]Leiden University Medical Center, Clinical epidemiology, Leiden, Netherlands; [3]Sint Maartenskliniek, Research, Nijmegen, Netherlands; [4]Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands; [5]Reade, Center for Rehabilitation and Rheumatology, Amsterdam, Netherlands; [6]Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands*

Background: Despite the availability of effective medical treatment, there is still a subgroup of people with Rheumatoid Arthritis (RA) who have considerable functional limitations due to persistently high disease activity, joint destruction or deformities and/or comorbidities. More insight into the nature and severity of these functional limitations is important to provide adequate treatment matching the needs of this specific subgroup.
Objectives: To describe the nature and severity of functional limitations in patients with RA and severe functional limitations, identified by the Health Assessment Questionnaire Disability Index (HAQ-DI).
Methods: Baseline data from people with RA and severe limitations in physical functioning participating in a randomized controlled trial on the (cost-)effectiveness of longstanding physical therapy as compared to usual care [1] were used. Patients completed the HAQ-DI (Dutch version)[2, 3], a reliable, valid and widely used questionnaire reflecting problems in activities of daily living and consisting of 20 items divided over eight domains (Dressing and grooming, Arising, Eating, Walking, Personal hygiene, Reaching, Gripping and Usual activities). Each item is scored on a 4-point scale ranging from 0 to 3 (no difficulty - unable to perform), with the total HAQ-DI score ranging from 0 to 3 (no disability - severe disability). This preliminary data analysis does not yet take into account the use of assistance/assistive devices. Gender, age, sex and disease duration were recorded, and the EuroQol 5 Dimensions 5 Levels (EQ-5D-5L) administered for health related quality of life (HRQoL) (Single index score (-0.446-1.000), and visual analogue scale (EQ-VAS, 0-100), higher scores indicating better HRQoL).
Results: From 2020-2021, 215 people with RA were included (n=194; 90% women, mean age (standard deviation) of 58.8 (12.9) years and median disease duration (Interquartile Range (IQR)) of 19 (9-27) years (n=166)). The median EQ-5D-5L index and EQ-VAS were 0.6 (0.3-0.7) and 59 (41 -70), respectively. The median total HAQ-DI score was 1.5 (1.1-1.9). The majority (83%, n=179) had a total HAQ-DI score ≥1 indicating moderate to severe activity limitations. The mean HAQ-DI domain scores and the percentage of patients within each domain reporting no/some/much difficulty or inability to perform everyday activities are shown in Figure 1.The median number of domains with a score ≥1 was 8 (range 3-8, IQR 7-8, mean 7.1). More than half of the participants had a domain score ≥1 in all 8 domains (52%, n=111), almost a quarter in 7 domains (24%, n=52), 13% (n=28) in 6 domains and the minority (11%, n=24) in 5 or less domains. The highest proportion of patients with a maximum score of 3 were seen in the domains Personal hygiene (42%) and Reaching (28%), followed by Usual activities and Eating (15% and 14%, respectively). For Gripping, Arising, Walking and Dressing and grooming the proportions of patients with the maximum score was less than 8%.
Conclusion: In a subgroup of patients with RA and severe functional disability, the majority had limitations in almost all the domains of the HAQ-DI. Most severe limitations were seen in Reaching and Personal hygiene and the least severe for Arising and Dressing and grooming. In daily clinical practice, a comprehensive assessment of all areas of daily activities in this subgroup of RA patients is necessary, and because the functional limitations are present and significant in all domains, extensive support from multiple healthcare professionals may be indicated.

POS0590-HPR IDENTIFICATION OF RESPONDER AND DISEASE ACTIVITY THRESHOLDS FOR THE PSORIATIC ARTHRITIS IMPACT OF DISEASE-12 (PSAID-12) QUESTIONNAIRE USING POOLED DATA FROM TWO PHASE 3 TRIALS OF BIMEKIZUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Clinical trials, Patient reported outcomes

L. Gossec[1,2], L. Coates[3], A. M. Orbai[4], M. De Wit[5], C. Pelligra[6], J. Lambert[7], V. Ciaravino[7], B. Ink[8], V. Taieb[7], D. D. Gladman[9]. *[1]Sorbonne Université, N/A, Paris, France; [2]AP-HP, Pitié-Salpêtrière Hospital, N/A, Paris, France; [3]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; [4]Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, United States of America; [5]Stichting Tools, N/A, Amsterdam, Netherlands; [6]Evidera, N/A, Medellín, Colombia; [7]UCB Pharma, N/A, Colombes, France; [8]UCB Pharma, N/A, Slough, United Kingdom; [9]University of Toronto, Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, University Health Network, Ontario, Canada*

Background: Psoriatic arthritis (PsA) can significantly impact patients' (pts) quality of life due to pain, fatigue and reduced physical function [1]. The PsA Impact of Disease-12 (PsAID-12) questionnaire is a 12-item pt-reported outcome measure developed to assess the impact of PsA on 12 physical, social and psychological domains [2,3].
Objectives: To determine responder thresholds (clinically meaningful within-pt improvement) and disease activity thresholds for the PsAID-12 total and single-item domain scores for pts with active PsA to complement preliminary thresholds published for the total score [2,4].
Methods: Pooled data from two phase 3 trials (BE OPTIMAL [NCT03895203] and BE COMPLETE [NCT03896581]) of subcutaneous bimekizumab 160 mg every 4 weeks (wks) were used to estimate responder and disease activity thresholds for the PsAID-12 in pts with moderate-to-severe PsA. Each study included a 16-wk double-blind, placebo-controlled phase; BE OPTIMAL included an adalimumab reference arm. Data used were observed scores at baseline (BL) and Wk 16 for all randomised pts with ≥1 non-missing PsAID-12 single-item domain score at any

scheduled visit. Anchor-based analyses (using the American College of Rheumatology [ACR] response criteria and PsA Disease Activity Score [PASDAS]) and distribution-based analyses (one standard error of measurement, and half of the baseline standard deviation [SD]) were used to determine responder thresholds at Wk 16. The maximum Youden index values from the receiver operating characteristic (ROC) curve analyses (using PASDAS and Disease Activity Index for PsA [DAPSA] scores as anchors; **Figure 1**) were used to determine disease activity thresholds.

Results: In 1,252 pts, mean (SD) PsAID-12 total score decreased from 4.19 (1.94) at BL to 2.65 (2.02) at Wk 16. Single-item domain scores ranged from 1.34 (2.13) for depression to 5.56 (2.26) for pain at BL and from 0.91 (1.80) for depression to 3.76 (2.51) for pain at Wk 16. The Wk 16 responder threshold for the PsAID-12 total score was identified as a 2-point decrease. For 8 PsAID-12 single-item domain scores, Wk 16 responder thresholds were identified as 3-point decreases. For the remaining 4 single-item domains (anxiety, fear and uncertainty; embarrassment and/or shame; social participation; depression), responder thresholds could not be determined due to floor effects at BL (absence of these symptoms in a high proportion of pts). Disease activity thresholds for the PsAID-12 total score were identified: ≤1.15, >1.15–≤1.95, >1.95–≤3.60 and >3.60 for Remission, Low, Moderate and High Disease Activity, respectively (**Figure 1**). Disease activity thresholds for PsAID-12 single-item domain scores are reported in the **Table 1**.

Conclusion: This analysis defined responder and disease activity thresholds for the PsAID-12 total score and most single-item domain scores, which can be used to assess treatment efficacy and disease impact in pts with PsA.

Table 1. Disease activity threshold estimates for PsAID-12 total and single-item domain scores

	Remission	Low Disease Activity	Moderate Disease Activity	High Disease Activity
Total score	**≤1.15**	**>1.15–≤1.95**	**>1.95–≤3.60**	**>3.60**
Single-item domain score				
Pain	≤2	3	4	≥5
Fatigue	≤1	2	3 or 4	≥5
Skin problems	≤1	2	3 or 4	≥5
Work and/or leisure activities	≤1	2	3 or 4	≥5
Functional capacity	≤1	2	3 or 4	≥5
Discomfort	≤1	2	3 or 4	≥5
Sleep disturbance	≤1		2 or 3	≥4
Coping	≤1	2	3 or 4	≥5
Anxiety, fear and uncertainty[a]	-	-	-	-
Embarrassment and/or shame[a]	-	-	-	-
Social participation	≤1		2	≥3
Depression[a]	-	-	-	-

[a]Cutoffs for disease activity thresholds could not be determined as these domains did not demonstrate good discriminant power (area under curve <0.70). PsAID-12 score ranges from 0–10 (higher scores indicate worse status).

Orange markers indicate cutoffs corresponding to the maximum Youden index values.

Abbreviations: DAPSA: Disease Activity Index for Psoriatic Arthritis; PASDAS: Psoriatic Arthritis Disease Activity Score; PsAID-12: Psoriatic Arthritis Impact of Disease-12; ROC: Receiver Operating Characteristic.

POS0591-HPR THE UTILITY OF NOVEL ACCELEROMETER METRICS FOR CHARACTERISING CLINICAL FEATURES IN PATIENTS LIVING WITH RHEUMATOID ARTHRITIS

Keywords: Outcome measures, Rheumatoid arthritis

S. Fenton[1,1,2,3,4], S. Allen[1,2,3], C. O'brien[5], A. Rowlands[6,7], J. Duda[1,3], J. Veldhuijzen van Zanten[1,3,4], G. Metsios[4,8], L. Breen[1,2,3], J. Lord[2,3,9], C. Greig[1,2,3], G. Kitas[4]. *[1]University of Birmingham, School of Sport, Exercise and Rehabilitation Sciences, Birmingham, United Kingdom; [2]National Institute for Health Research, Birmingham Biomedical Research Centre, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [3]MRC-Versus Arthritis Centre for Musculoskeletal Ageing Research, University of Birmingham, Birmingham, United Kingdom; [4]Russells Hall Hospital, The Dudley Group NHS Foundation Trust, Rheumatology, Dudley, United Kingdom; [5]University of Surrey, School of Psychology, Surrey, United Kingdom; [6]University of Leicester, Diabetes Research Centre, Leicester General Hospital, Leicester, United Kingdom; [7]NIHR Leicester Biomedical Research Centre, Leicester General Hospital, Leicester, United Kingdom; [8]University of Thessaly, Department of Nutrition and Dietetics, Thessaly, Greece; [9]University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom*

Background: Research-grade accelerometers are commonly used to measure physical activity (PA) in rheumatology research, demonstrating superior reliability and validity relative to self-report methods. Several accelerometers offer manufacturer software and embedded proprietary algorithms to reduce the complexities of data processing. However, algorithms vary between device brands, and hinder standardisation of data processing and analysis. Best practice in PA research is now therefore considered to be the collection and analysis of raw accelerometer data, to which transparent and replicable data transformation methods can be carried out post-processing. Novel metrics include average acceleration, intensity gradient, and MX metrics, which represent PA volume, intensity and patterns, and have not been examined in rheumatic diseases.

Objectives: To explore the utility of novel accelerometer metrics for characterising clinical features in Rheumatoid Arthritis (RA), i.e. disease activity and severity, cardiovascular disease (CVD) risk.

Methods: People living with RA (n = 104) provided demographic data, medical history, a fasted blood sample, and completed the health assessment questionnaire (HAQ, disease severity). Disease activity was measured using the Disease Activity Score 28-CRP (DAS28-CRP), and CVD risk determined using the QRISK3. Participants wore a GT3X Actigraph accelerometer on their right hip for 7-days during waking hours. Accelerometer data were analysed using GGIR (v.2.1-1) to determine average acceleration (AA, m*g*, proxy for daily volume of PA), intensity gradient (IG = distribution of PA across the day) and MX metrics (acceleration above which a person's most active "X" mins are accumulated e.g., M5 = most active 5 mins). A higher AA and more positive IG indicate a

favourable activity profile. *Statistical analyses:* Participants were grouped according to DAS28-CRP (remission = <2.6, low = 2.6 - 3.1, moderate = 3.2 – 5.1, high = >5.1) disease severity (HAQ; low = <1, moderate = 1 – 1.9, high = ≥2) and QRISK3 (low = <10%, moderate = 10 - 19%, high = ≥20%. Between group differences in AA and IG were analysed using analysis of variance, adjusted for accelerometer wear time. Radar plots were produced in R, to illustrate differences in MX metrics according to clinical features.

Results: Valid accelerometer data (≥10hr on ≥4 days), were available for n = 102 participants (M ±SD, AA = 13.7 ±5.2 m*g*, IG = -2.91±.36). Participants in remission and with low CVD risk, demonstrated a better activity profile (i.e. [M ±SE, all p<.05] significantly higher AA [DAS28-CRP = 17.9 ±1.1; QRISK3 = AA = 15.4 ±0.6] and more positive IG [DAS28-CRP = -2.62 ±0/07, QRISK3 = 2.80 ±0.04], compared to patients with moderate or high disease activity and CVD risk (DAS28-CRP [moderate, AA = 12.8 ±0.6, IG = -2.99±.04] and [high, AA = 11.2 ±1.1, IG = -3.07±.08], QRISK3 [moderate, AA = 12.0 ±1.0; IG = -3.0 ±0.07] and [high AA = 10.3 ±1.1; IG = -3.16 ±0.08]). For disease severity IG was significantly more positive in patients with low (-2.78 ±0.05) vs. high (-3.10 ±0.08) HAQ scores. Radar plots (**Figure 1**) showed the intensity of the most active accumulated 2-45 mins (M2-M45) was greater (with M10 exceeding 75m*g*) among participants with better disease profiles (i.e. remission/low DAS28-CRP, HAQ and QRISK3 scores vs. moderate/high).

Conclusion: This is the first study to demonstrate the clinical utility of novel accelerometer metrics in RA. Results suggest higher AA, more positive IGs, and accumulating ≥10 mins at an intensity indicative of a slow walk (M10 >75m*g*), is characteristic of more favourable disease profiles. Future studies utilising these raw accelerometer metrics could provide valuable, standardised accelerometer data that can be used to deliver more personalised care (i.e. precision medicine).

Background: Biologic disease-modifying antirheumatic drugs (bDMARDs) offer promising results for rheumatoid arthritis (RA) patients in general, but a substantial percentage of patients do not respond to them. It is important to predict the response before the treatment so that unnecessary adversities for the patients and costs for the healthcare system can be avoided. We developed a model to predict remissions in patients treated with bDMARDs and to identify important clinical features associated with remission using several machine learning (ML) models system that works with readily-available demographic and clinical factors for prediction of response to DAS-28.

Objectives: In this study, we established a machine learning model using data from the Kuwait Registry for Rheumatic Diseases (KRRD) and show its application to identifying clinical variables predictive of remission in RA patients treated with biologics.

Methods: We gathered the follow-up data of 1,000 patients treated with bDMARDs (etanercept, adalimumab, golimumab, infliximab, abatacept, and tocilizumab) from KRRD. Patients were recruited from public hospitals in Kuwait between February 2013 to September 2022. Remission (DAS-28 less than 2.6) was predicted at 1-year follow-up using baseline clinical data obtained at the time of enrollment. Machine learning methods system (including: lasso, ridge, support vector machine, random forest, XGBoost, and Shapley additive explanation (SHAP)) were used for the predictions.

Results: The ranges for accuracy and area under the receiver operating characteristic of the newly developed machine learning model for predicting remission were 52.8–72.9% and 0.463–0.719, respectively. The Shapley plot in XAI showed that the impacts of the variables on predicting remission differed for each bDMARD. The most important features were age for adalimumab, rheumatoid factor for etanercept, erythrocyte sedimentation rate for infliximab and golimumab, disease duration for abatacept, and C-reactive protein for tocilizumab, with mean SHAP values of – 0.250, – 0.234, – 0.514, – 0.227, – 0.804, and 0.135, respectively.

Conclusion: Our proposed machine learning model system successfully identified clinical features that were predictive of remission in each of the bDMARDs. This approach may be useful for improving treatment outcomes by identifying clinical information related to remissions in patients with rheumatoid arthritis.

POS0593-HPR

PRELIMINARY EVALUATION OF THE RHEUMATOID ARTHRITIS FOOT DISEASE ACTIVITY INDEX (RADAI-F5) AS A SCREENING TOOL FOR FOOT-RELATED DISABILITY

Keywords: Outcome measures, Patient reported outcomes, Rheumatoid arthritis

A. Hoque[1], M. Steultjens[1], D. Dickson[1], G. Hendry[1]. [1]*Glasgow Caledonian University, Podiatry and Radiography, Glasgow, United Kingdom*

Background: Impaired foot function in patients with rheumatoid arthritis (RA) can contribute to impairment and disability during daily activities [1]. RA foot disability has been studied extensively, although foot disease activity and its association with future foot impairment have not. The Rheumatoid Arthritis Foot Disease Activity Index (RADAI-F5) is a clinically feasible, valid, and reliable patient-reported outcome measure (PROM) that can be employed with the DAS-28 to evaluate RA foot disease activity [2]. Existing evidence supports the construct validity of the RADAI-F5, however predicative validity must be demonstrated for any newly created screening instruments.

Objectives: This study aims to evaluate the predictive validity of the RADAI-F5 for foot-related disability in RA.

Methods: This study drew its data from a randomised controlled trial comparing prefabricated versus customised foot orthoses for RA patients [3]. At baseline, six months, and 12 months, the patients' disability levels were examined using the Foot Function Index disability subscale (FFIdis). The newly created RADAI-F5 was gathered at baseline, one week, and six months. In the absence of recognised threshold cut-off values, the median split method was utilised to dichotomize FFIdis scores for poor and mild foot disability at 12 months. Two consecutive occurrences of moderate-high foot disease (RADAI-F5 > 3.45) at baseline and six months constituted poor foot disease activity. The predictive value of foot disability at 12 months was investigated using IBM SPSS bivariate binary logistic regression analysis controlling for baseline foot disability scores. The odds ratios (OR) and 95% confidence intervals (CI) were obtained, and a significance level of $P < 0.05$ was established.
Results: 51 patients, 36 of whom were female, with a mean [standard deviation, ±SD] age of 53.5 [±12.18] and disease duration of 8.34 [±6.57] years completed the 6-month and 12-month FFI follow-ups. At baseline and 6 months, mean [±SD] RADAI-F5 scores were 5.56 [± 2.07] and 4.12 [± 2.54], respectively. At 0 and 6 months, 75.2% and 52.5% of the sample, respectively, had moderate-high foot disease activity, whereas at 12 months, the prevalence of poor foot disability was 48.6%. Binary logistic regression identified that having two consecutive episodes of moderate-high foot disease was an independent predictor of poor foot disability at 12(OR=3.44, 95% CI= 1.04-11.40, $p < 0.05$).
Conclusion: The RADAI-F5 is an accurate predictor of foot-related disability. In clinical practice, the RADAI-F5 may be used as a screening tool to identify individuals who are at risk for persistent foot disability. Combining the RADAI-F5 with common physical outcome measures can improve the prediction of foot impairment.

POS0594-HPR PSYCHOMETRIC AND CROSS-CULTURAL VALIDITY OF THE MEASURE OF ACTIVITY PERFORMANCE OF THE HAND (MAP-HAND) ACROSS THREE EUROPEAN COUNTRIES (SWITZERLAND, TURKEY AND THE UK)

Keywords: Patient reported outcomes

M. Horton[1], Y. Prior[2], A. Hammond[2], E. Tonga[3,4], K. Niedermann Schneider[5], N. Gilanliogullari[2,6], I. Kjeken[7]. [1]*University of Leeds, Leeds Psychometric Laboratory for Health Sciences, Leeds, United Kingdom*; [2]*University of Salford, Centre for Human Movement and Rehabilitation, Salford, United Kingdom*; [3]*Marmara University, Faculty of Health Sciences, Department of Physiotherapy, Istanbul, Turkey*; [4]*University of Leicester, Diabetes Research Center, College of Life Sciences, Leicester, United Kingdom*; [5]*Zurich University of Applied Sciences, Institute of Physiotherapy, Switzerland, Switzerland*; [6]*European University of Lefke, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Lefke, Turkey*; [7]*Diakonhjemmet Hospital, Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*

Background: The MAP-Hand scale comprises 18 patient-generated items which assess hand activity among people with rheumatoid arthritis (RA). All items are scored on a 0–3 scale and are summed into a total score (0 to 54).
Objectives: The MAP-Hand is already fully validated within a UK population [1], and this study aims to assess the validity, stability and comparability across German-speaking Swiss and Turkish RA samples.
Methods: The MAP-Hand was assessed using Rasch model psychometric assessment methodology. Within the original UK validation, all items were assessed individually, then combined into four testlets (super-items) in order to account for observed local dependency among the items. This analytic strategy was replicated, where the psychometric properties of the scale items were assessed separately within each country-specific samples, and then across a merged sample of all three countries. A differential item function (DIF) analysis was used to assess scale stability across countries.
Results: When the countries are considered separately, although slight differences are apparent, the operation of the instrument appears to be very similar across Switzerland, Turkey, and the UK. Although there is a degree of scale misfit in all countries, the scale-sample targeting and the scale reliability are both excellent (Person Separation Index = 0.93-0.95; Cronbach's Alpha = 0.96-0.97), and the response categories function well across all items. However, there is a large degree of inter-item dependency present, and the MAP-Hand displays apparent multidimensionality within all three countries. Additionally, some individual items display Rasch model misfit to some extent, although these items are variable across the three countries. When the items were re-configured into four testlets, this accounted for the inter-item dependency, also improving the model fit and unidimensionality of the scale within all three countries separately, as well as when the data is merged into a single dataset. Some significant country-DIF was observed on the 'Dressing' testlet (comprised of items 1-3), but this was found to have no significant effect on total person score estimates. Despite the testlet re-structuring creating a narrower scale range, the scale-sample targeting and scale reliability remain high (Person Separation Index = 0.86-0.91; Cronbach's Alpha = 0.93).
Conclusion: It is recommended that the four-testlet structure is implemented across all three countries, as this offers a pragmatic approach to the utility and comparative scoring of the MAPHAND across the UK, Switzerland and Turkey. Although the re-structuring creates a narrower scale range and apparent reduction in the reliability, this is indicative of the initial dependency that is present, and suggests that the original reliability values are over-inflated.

POS0595-HPR WILLINGNESS TO USE REMOTE CARE AMONG PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Patient reported outcomes, Telemedicine

E. E. Kvernberg Thomassen[1], A. T. Tveter[1], I. J. Berg[2], E. Kristianslund[2], N. Osteras[1]. [1]*Diakonhjemmet Hospital, Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Norwegian National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway*; [2]*Diakonhjemmet Hospital, Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*

Background: Remote care is an alternative to standard care for patients with axial spondyloarthritis (axSpA) and may facilitate accurate and timely management of disease. However, there is limited knowledge on factors related to the patients' willingness to use remote care.
Objectives: To assess the willingness to use remote care among patients with axSpA and compare characteristics of patients at different levels of such willingness.
Methods: We used baseline data from a randomised controlled trial on remote care of axSpA (ReMonit). Patients with a clinical axSpA diagnosis fulfilling ASAS-criteria for axSpA, treated with TNFi and with low disease activity (ASDAS<2.1) were recruited at a single outpatient clinic. Years since diagnosis were retrieved from medical records, and self-reported education and work status. Willingness to use remote care was measured by scoring the statement "I want to use remote care" using a 4-point Likert scale (strongly disagree – strongly agree). Patients were then divided into three groups (disagree/agree/strongly agree) based on their willingness to use remote care. eHealth Literacy was measured using three scales of the eHealth Literacy Questionnaire (eHLQ) using a 4-point Likert scale (1=strongly disagree – 4=strongly agree, 4=best score). Bath Ankylosing Spondylitis Functional Index (BASFI, 0-10, 0=best score), and a single item from the Work Productivity and Activity Impairment (WPAI) Questionnaire scored 0-10, 0=best score) were used to measure self-reported physical function. Differences between groups on baseline characteristics were assessed using Kruskal Wallis tests with Dunn's post-hoc test.
Results: 242 patients were included, mean age 43 years (SD 11.7) and 75 % male. Most patients were willing to use remote care (strongly agree: 53.3%, agree: 43.0% and disagree: 3.7%). Descriptive and comparative analyses between groups show a trend toward younger males with higher education and full-time employment being more willing to use remote care. Moreover, patients

with higher willingness to use remote care had good physical function, fewer years since axSpA diagnosis and high eHealth literacy (Table 1).
Conclusion: Nearly all patients included in this trial of remote care of axSpA wanted to use remote care. Significant differences in baseline characteristics were revealed between the three groups according to their willingness to use remote care. However, precaution must be taken due to a small number of participants in the "disagree"-group.

Table 1. Sample characteristics grouped by willingness to use remote care

	Statement: "I want to use remote care"		
	Disagree (n=9)	Agree (n=104)	Strongly agree (n=129)
Age, mean (SD)	50.1 (16.1)	45.2 (11.7)$	41.5 (11.1)
Males, n (%)	7 (77.8)	77 (74.0)	98 (75.9)
Education level[1], n (%)			
Primary school	2 (22.2)	3 (3.0)	3 (2.3)
High school	1 (11.1)	19 (18.4)	18 (14.0)
University level	6 (66.6)	81 (78.6)	108 (83.7)
Work status, n (%)			
Full time	5 (55.6)	80 (77)	109 (84.5)
Age retired	1 (11.1)	5 (4.8)	4 (3.1)
Disability benefit	1 (11.1)	4 (3.8)	4 (3.1)
Other[2]	2 (22.2)	15 (14.4)	12 (9.3)
Years since axSpA diagnosis, mean (SD)	19.7 (19.9)	14.9 (10.4)	13 (9.7)
BASFI, mean (SD)	1 (1.5)	0.9 (0.9)$	0.5 (0.9)
WPAI Item 6, mean (SD)	1.7 (1.5)†	1.2 (1.4)$	0.7 (1.1)
eHLQ Scale 1[3], mean (SD)	2.8 (0.8)†	2.9 (2.9)$	3.5 (3.5)
eHLQ Scale 3[4], mean (SD)	3.0 (0.8)†	3.2 (0.4)$	3.8 (0.2)
eHLQ Scale 5[5], mean (SD)	2.5 (0.6)†	2.9 (0.4)$	3.6 (3.6)

$: Significant difference (p=<0.05) between Agree and Strongly agree, †: Significant difference (p=<0.05) between Strongly Agree and Disagree, [1]n=241 due to 1 missing, [2]Other: receiving social benefits, on sick leave, student/housekeeping, part time work and unemployed, [3]Using technology to process health information, [4]Ability to actively engage with digital services, [5]Motivated to engage with digital services, [6]Ability to perform daily activities, BASFI: Bath ankylosing spondylitis functional index; eHLQ: eHealth literacy Questionnaire, WPAI: Work Productivity and Activity Impairment.

POS0596-HPR GOUT PATIENTS' PERSPECTIVE ON CONTINUATION OR DISCONTINUATION OF URATE-LOWERING THERAPY WHEN REMISSION HAS BEEN ACHIEVED: A MIXED METHODS STUDY

Keywords: Gout, Qualitative research methods, Remission

I. R. Peeters[1,2,3], F. Veenstra[1,2,3], J. E. Vriezekolk[3], C. Van den Ende[3,4], A. Den Broeder[1,3,4], S. A. C. Wanten[1], N. Van Herwaarden[1,3,5], L. M. Verhoef[3], M. Flendrie[1,3]. *[1]Sint Maartenskliniek, Department of Rheumatology, Sint Maartenskliniek, Ubbergen, the Netherlands, Ubbergen, Netherlands*; *[2]Radboud University Nijmegen, Research Institute for Health Sciences, Nijmegen, Netherlands*; *[3]Sint Maartenskliniek, Department of Research & Innovation, Ubbergen, Netherlands*; *[4]Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands*; *[5]Radboud University Medical Center, Department of Pharmacology, Nijmegen, Netherlands*

Background: Long-term gout management is based on reducing serum urate by using urate-lowering therapy (ULT) [1, 2]. A lifelong treat-to-target approach is advocated, though a ULT (taper to) stop attempt can be considered (treat-to-avoid symptoms approach) during remission[1]. It is yet unclear if either is a superior strategy when remission has been achieved. Exploring gout patients' beliefs on these long-term ULT strategies is important for optimising gout management.
Objectives: To identify factors that influence the decision for continuation (treat-to-target) or discontinuation (treat-to-avoid symptoms) of ULT and to determine their perceived relative importance in gout patients in remission.
Methods: A mixed methods design was used. First, semi-structured interviews (substudy 1 EULAR POS1477 2020) were held to identify barriers and facilitators for continuation and discontinuation of ULT using inductive thematic analysis. These items were then summarized by a multidisciplinary team (including a patient partner) in neutrally formulated items. These items were subsequently used in a Maximum Difference Scaling study (MaxDiff, substudy 2) to rank them and to determine their relative importance based on utility scores (preference score). A rescaled probability score (RPS) was generated with a 0-100 range (the higher the score, the more important the item). For example, an item with an RPS of 8 is twice as important as an item with an RPS of 4. Patients of both studies were recruited from general practitioners and from the rheumatology department of the Sint Maartenskliniek (both in the Netherlands). The semi-structurered interviews as well as the MaxDiff experiment have been pilot tested.
Results: Substudy 1 and 2 included 18 and 156 patients, respectively (see Table 1). The semi-structured interviews yielded 46 barriers/ facilitators and were summarized in 22 items, divided into 10 overarching themes (logistics, lifestyle, role of serum urate, physician role, scientific knowledge, general medication use, anti-inflammatory use, gout flares, ULT use and long-term gout effects). Figure 1 shows their ranking (substudy 2). The 'risk of joint damage' (RPS 8.77) was the most important item, and is 26 times more important than the least important item, 'cost of my gout treatment' (RPS 0.34).
Conclusion: In particular, items concerning (control of) disease activity (flares, joint damage) play a role when gout patients in remission consider (dis)continuation of ULT. Costs, logistics and monitoring by physician were deemed less important. These results provide a basis for shared decision making between physicians and patients, and show which items should at least be discussed when considering ULT (dis)continuation in the remission phase.

POS0597-HPR HEALTH LITERACY IN INDIVIDUALS WITH KNEE PAIN - A MIXED METHOD STUDY

Keywords: Pain, Self-management, Osteoarthritis

C. Sylwander[1,2], A. Klopstad Wahl[3], M. Andersson[1,4,5], E. Haglund[1,4,5], I. Larsson[1,2,4]. *[1]Spenshult Research and Development Centre, Halmstad, Sweden*; *[2]Halmstad University, School of Health and Welfare, Halmstad, Sweden*; *[3]University of Oslo, Department of Interdisciplinary Health*

Sciences, Oslo, Norway; [4]*Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden*; [5]*Halmstad University, Department of Environmental and Biosciences School of Business, Innovation and Sustainability, Halmstad, Sweden*

Background: Health literacy (HL) is the ability to access, understand, appraise, and apply health information [1]. A low level of HL is associated with worse pain problems, poorer self-care, and an obstacle for health-promoting interventions among individuals with chronic pain and radiographic knee osteoarthritis (rKOA).
Objectives: To examine 1) the level of HL and associations with chronic pain, rKOA, lifestyle habits and health status, and 2) to explore the individuals' experiences of HL.
Methods: The study has a convergent parallel mixed-method design, including 221 individuals with knee pain (148 women, mean age 56±8 years). A purposeful sample of 19 individuals (11 women, 8 men) was selected for interviews. Quantitative data were general HL (GHL) assessed by HLS-EU-Q16, electronic HL (eHL) by eHEALS, pain distribution by a pain figure, rKOA by x-rays, lifestyle habits, and health status via SF-36. GHL and eHL were merged into one variable, "HL", where sufficient HL was defined as having a sufficient level of GHL or eHL. Statistical analyses were Chi^2 test, Mann-Whitney U-test, univariate and multivariate logistic regressions. Qualitative data consisted of individual semi-structured interviews that were analysed using manifest qualitative content analysis with an abductive approach based on the HLS-EU health literacy matrix [2].
Results: Of the 221 participants, 29% reported limited HL. Those with limited HL reported lower education, less usability and importance of the internet for accessing health information and making informed health-related decisions, and lower general health (GH) compared to the group with sufficient HL (data not shown). Higher education, CRP, a healthier diet, and minor alcohol consumption were associated with sufficient HL (Table 1). Only higher education and GH remained associated when adding GH to the multivariate analysis. Individuals' experiences of HL were described as 1) Searching for information influences the decision-making process by being an active searcher or passive receiver; 2) Processing of information influences the decision-making process by having light, moderate or high processing of the information; and 3) Taking a stand on the information influences the decision-making process based on trust and/or motivation (Figure 1).
Conclusion: Limited HL was found in one-third of the individuals with knee pain. CRP and healthy lifestyle habits were associated with sufficient HL, but higher education and health status had the strongest association. The search, level of process and standpoint on the health information influenced the decision on action. More research on HL is needed to gain knowledge of how to develop health promotion to prevent worsening pain problems in individuals with knee pain.

POS0598-HPR WHAT DO USERS OF RHEUMATOID ARTHRITIS ONLINE FORUMS TALK ABOUT? APPLYING A DEEP LEARNING APPROACH TO UNCOVER COMMON THEMES

Keywords: Rheumatoid arthritis, Artificial intelligence, Descriptive Studies

P. Kerkhof[1]. [1]*Vrije Universiteit Amsterdam, Communication Science, Amsterdam, Netherlands*

Background: Social media platforms have become a vital resource for individuals seeking information and support regarding health issues, including rheumatoid arthritis (RA). As such, the content generated on these platforms represents a valuable source of data for gaining insight into patients' perspectives on RA. However, previous research in this area has primarily relied on qualitative analyses of small sample sizes, limiting the ability to extract meaningful insights from social media content related to RA. With the advancement of machine learning techniques, it is now possible to analyze and extract insights from large volumes of social media posts related to RA.
Objectives: The purpose of this study was to identify the most common topics discussed in a large dataset of submissions about RA on Reddit, one of the world's largest online forums.
Methods: The data for this study was collected from the two largest Reddit forums ("subreddits") dedicated to RA, r/rheumatoid arthritis and r/rheumatoid, which have 18.9k and 7.6k members respectively. We retrieved all submissions but excluded responses in our analyses. All deleted or duplicate submissions and those with fewer than 10 words were removed, retaining 11,094 submissions from over 5,000 users for the analysis. To identify common themes, we applied topic modeling, a technique in natural language processing that identifies underlying themes or topics in a collection of documents. We used the Bertopic Python package (Grootendorst, 2022), which employs deep learning techniques to perform the topic modeling.
Results: The data indicates a significant increase in submissions to the two subreddits, rising from 113 in 2014 to 2892 in 2021 and 1928 in the first 8 months of 2022. Upon analysis, 65 topics were identified, with 4162 submissions (37.5%) remaining unclassified. A topic specifically dedicated to requests to participate in surveys was removed as it did not pertain to the experiences of forum users. Among the remaining topics, the top 10 accounted for 44.90% of all submissions. To better understand each topic, a sample of 10 submissions with the highest probability for that topic were examined (Table 1).

Table 1. Top 10 most frequent topics

Topic	n of submissions	Share of total*
Side effects of methotrexate	526	8.02%
COVID & vaccines	462	7.04%
Mental health	438	6.68%
RF and anti CCP test results	331	5.04%
RA of friends, partners, and close relatives	262	3.99%
Complaints about rheumatologist	212	3.23%
Questions about Humira	188	2.87%
Questions about prednisone	182	2.77%
Diets and RA	175	2.67%
Early symptoms of possible RA	170	2.59%
Exercise and RA	168	2.56%

* After excluding unclassified topics

Three of the ten topics pertained to specific medications - methotrexate, Humira, and prednisone, accounting for 12.71% of the total. The most prevalent topic, at 8.02%, focused on the side effects of methotrexate, with many submissions inquiring about symptoms such as nausea. The second most common topic, at 7.04%, primarily revolved around COVID-19 and related issues, with some

pre-COVID vaccine discussions also included. In 2021, COVID-related discussions were the most prevalent topic. The third most frequent topic (6.68% of total), dealt with mental health and the emotional struggles faced by those living with RA.

Conclusion: The surge in submissions on Reddit demonstrates its growing popularity as an online forum for discussing topics related to RA. Utilizing deep learning-based topic modeling has proven to be an effective method for extracting meaningful topics from the questions and experiences shared by users. The vast amount of data generated by Reddit, in combination with advanced machine learning techniques, enables both an overview of the various topics discussed and a detailed examination of specific topics. This makes the use of social media data a valuable source of insight into the concerns of RA platform users.

POS0599-HPR QUALITY OF REPORTING OF HARMS IN CLINICAL TRIALS ON EXERCISE THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS OR AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC REVIEW

Keywords: Safety, Inflammatory arthritides, Systematic review

M. Teuwen[1], T. P. M. Vliet Vlieland[1], S. Van Weely[1], J. Schoones[2], A. K. Rausch Osthoff[3], C. Juhl[4,5], K. Niedermann Schneider[3], M. G. J. Gademan[1,6], C. Van den Ende[7,8]. *[1]Leiden University Medical Center (LUMC), Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands*; *[2]Leiden University Medical Center (LUMC), Directorate of Research Policy (Walaeus Library), Leiden, Netherlands*; *[3]Zurich University of Applied Sciences, School of Health Sciences, Institute of Physiotherapy, Winterthur, Switzerland*; *[4]University of Southern Denmark, Deparment of Sports Science and Biomechanics, Odense, Denmark*; *[5]University Hospital of Copenhagen, Herlev and Gentofte, Department of Physiotherapy and Occupational Therapy, København, Denmark*; *[6]Leiden University Medical Center (LUMC), Department of Clinical Epidemiology, Leiden, Netherlands*; *[7]Sint Maartenskliniek, Department of Research, Ubbergen, Netherlands*; *[8]Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands*

Background: Exercise therapy has proven effective for people with rheumatic and musculoskeletal diseases (RMDs), including those with inflammatory arthritis such as rheumatoid arthritis (RA) or axial spondyloarthritis (axSpA) [1-2]. Exercise therapy is generally considered safe for people with RMDs, although the evidence is scarce. A few reviews reported on the nature and risk of harms of exercise therapy in RMDs, but none of them specifically addressed the quality of reporting of harms of exercise therapy in studies including people with inflammatory arthritis.

Objectives: This study aimed to describe the quality of reporting of harms in clinical studies on the effectiveness of exercise therapy in people with RA or axSpA.

Methods: RCTs with at least one treatment arm consisting of supervised exercise therapy in people with RA or axSpA were included. Eight electronic databases were searched up to November 2021. Two researchers independently selected studies for inclusion and extracted data and in case of disagreement a third researcher was consulted. Data extraction included study characteristics and fulfillment of a set of quality aspects derived from the Consolidated Standards of Reporting Trials (CONSORT) Extension for Reporting Harms Outcomes [3], predefined on the basis of consensus among authors (Table 1). Harms outcomes were defined as adverse events reported on individual level irrespective of causality or negative effects on group level (only if explicitly designated as measurement of potential harm). We considered the reporting on harms outcomes of sufficient quality if the authors reported at least 1) the methodology for active surveillance of harms outcomes (item 2a); and 2) the observed number and the nature of harms (items 3b and 3c).

Results: The search yielded 5921 records, of which 64 studies (n= 41 RA, n=23 axSpA; described in 83 papers) were included. Of those studies in RA and axSpA, 34 (83%) and 15 (65%) included any information on harms, with 12 (29%) and 3 (13%) reporting active surveillance and 22 (54%) and 5 (22%) reporting on harms outcomes in the results section, respectively (see Table 1). In total, 10 of the 41 (24%) RA studies and 2 of the 23 (9%) axSpA studies fulfilled the predefined criteria for sufficient quality of reporting.

Conclusion: The quality of reporting on harms outcomes is insufficient in the majority of RCTs on exercise therapy in people with RA or axSpA, with overall poorer quality in studies on axSpA which impedes substantiated conclusions about harms of exercise therapy. Our findings stress the need for consensus on the definition, classification, assessment and reporting of harms outcomes in trials on the effects of exercise therapy.

Background: The rheumatoid arthritis (RA) treatment landscape is diverse, with multiple therapies available that differ in several attributes such as mode of administration and benefit-risk profile. Patients and prescribers face challenging trade-offs during treatment selection to accommodate patients' circumstances in order to ensure comprehensive disease management. EULAR recommendations for RA management emphasize the need to recognize patient preferences in shared decision-making (SDM). Therefore, it is essential to understand how preferences differ in the RA patient population.

Objectives: This study elicited trade-offs that RA patients were willing to make during treatment selection while accounting for preference heterogeneity.

Methods: An online discrete choice experiment (DCE) was conducted from September to October 2021 in which RA patients were required to elicit their preferences for attributes of treatments for RA (Figure 1) and make trade-offs between them. Attributes were selected and defined based on literature review and

qualitative patient interviews, and were then tested in a quantitative pilot. Main data collection consisted of an online survey in which participants were asked to repeatedly choose between hypothetical treatments. Eligible patients were ≥18 years old, diagnosed with RA, currently received systemic disease-modifying anti-rheumatic drug therapy for RA, and were residents of France, Germany, Italy, Spain, United Kingdom, or United States. Male patients were oversampled to support subgroup analysis of preferences for effects on sperm parameters. Data were analyzed using a correlated mixed logit model and differences in preferences between sex and age were explored. Relative attribute importance (RAI) scores and maximum acceptable risk (MAR) measures were derived from the estimates.

Results: A total of 2,090 patients participated; 42% were female with predefined oversampling of male patients, with a mean age of 45.2 years (range 18–83). Estimated effects were significant for all attributes (p<0.001), implying that they all influenced treatment choices and suggesting preferences differed between participants. Average RAI scores revealed different priorities (p<0.001) between males and females (Figure 1). While reducing pain and negative effect on semen parameters was most important to male patients, female patients were most concerned by risk of blood clots and serious infections. The remaining attributes were of lower importance but were still relevant. However, no single attribute explained treatment preferences by more than 30%. Preferences were also affected by patients' age: patients aged 18-44 years placed less importance on frequency and mode of treatment administration (p<0.05) than older age groups. Patients were willing to make benefit-risk trade-offs; they accepted extra risks of blood clots (male: 1.8%; female: 0.8%), serious infections (male: 2.5%; female: 1.0%), or negative effects on sperm (male: 7.4%) for an oral pill every day instead of injection once a week. They also accepted extra risks of blood clots (male: 2.3%; female: 1.2%), serious infections (male: 3.2%; female: 1.6%), or negative effects on sperm (male: 10.4%) for reducing amount of pain from 30% to 10%. Similar observations were made for improved performance of daily activities. However, acceptable trade-offs varied between patients (p<0.05).

Conclusion: Preferences of RA patients were driven by benefits and risks of RA treatments, with no single attribute dominating the decision making. Patients were willing to accept higher risk of serious infections and blood clots in exchange for improvements in pain, daily activities, or administration convenience. These findings emphasize the importance of considering the entire treatment profile, including benefits, risks, and administration to support SDM between providers and patients.

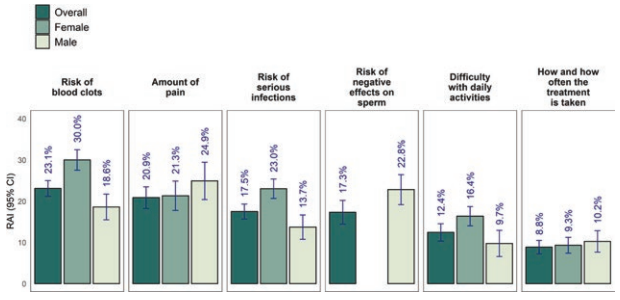

Figure 1. RAI overall and by sex

Preference drivers: males – pain, blood clots; females – blood clots, infections, pain. Sperm risk data are based on male responses only.

POS0601-HPR DOING EVERYTHING POSSIBLE TO PRIORITIZE WORK: LIVED WORK EXPERIENCE OF YOUNG ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Qualitative research methods, Systemic lupus erythematosus, Work-related issues

M. Golding[1,2], F. Nishat[3], K. Merrill[2], R. Kaur[1,2], J. Stinson[3], J. Protudjer[1,2], R. Woodgate[1,2,4], C. Peschken[5], D. Lacaille[6], U. Oguzoglo[7], Z. Touma[8], L. Lim[1,2]. [1]*Children's Hospital Research Institute of Manitoba, Paediatrics, Winnipeg, Canada*; [2]*University of Manitoba, Paediatrics, Winnipeg, Canada*; [3]*University of Toronto, Paediatrics, Toronto, Canada*; [4]*Canada Research Chair, Tier 1, Paediatrics, Winnipeg, Canada*; [5]*University of Manitoba, Medicine, Winnipeg, Canada*; [6]*University of British Columbia, Medicine, Vancouver, Canada*; [7]*University of Manitoba, Economics, Winnipeg, Canada*; [8]*University of Toronto, Internal Medicine, Toronto, Canada*

Background: Young adulthood (18-30 years) is a critical life-stage when individuals launch into independence, establishing employment. Failure to establish employment during young adulthood is associated with reduced lifetime socioeconomic achievement. A few studies focused on studying employment outcomes in young adults with systemic lupus erythematosus (YASLE) showed less full-time work than general population, substantial absenteeism and productivity loss. Studying the lived work experience of YASLE can broaden our understanding in this area from the patients' perspectives.

Objectives: To describe the early work experiences of YASLE and explore their perceptions of SLE influences on their work.

Methods: This was a qualitative descriptive study. Young adults with childhood- or adult onset SLE were recruited from 2 adult rheumatology clinics (Oct 2021-Aug 2022) in Manitoba and Ontario. Inclusion criteria: YASLE who were employed, unemployed (looking for work or not), or work disabled. Potential participants were purposely sampled for diversity in: sex/gender, age of onset, major organ disease, occupation groups. All completed a pre-interview questionnaire to provide demographic, SLE and work-related information. Semi-structured interviews were conducted individually via video conference, focusing on their work experiences, future aspirations and perceived SLE influences. Interviews were audio-recorded, transcribed verbatim and analyzed using a reflexive thematic analysis.

Results: Of 18 participants, 13 identified as females, 1 as non-binary; median age 25 (22- 29, 25-75th percentile) years. Participants' identified ethnicities: 7/18 Asian, 5/18 White, 2/18 Indigenous, 4/18 other. 7/18 were childhood-onset SLE, 9/18 had major organ disease. 12/18 were employed full-time, 3/18 unemployed/ looking for work, 3/18 unemployed/ not looking to work. 6/18 worked in managerial/ professional jobs. Three have current work accommodations, 2/3 for SLE. 13/18 report highest education to be university/ postgraduate. Most participants perceived themselves to be functioning relatively well at work despite modest physical, cognitive limitations. Two main themes emerged:

1) "Getting by, with some help" describes many factors that participants cited as critical in helping them stay in the workforce. Most of the factors mapped to the underlying construct of control over their work. Participants who have the flexibility to manage their time, physical positions and environment perceived fewer issues staying in work Participants also reported increasing recognition (over time) of the importance of medication adherence in disease control, which helped them to stay in work. Other frequently cited facilitators also included sedentary jobs and the availability of social support.
2) "Tough choices: work or health over everything else" describes how participants struggled to find a balance between their health, work and social life. Many described multiple strategies to prioritize work while trying to preserve their health: rest more, avoid commute, avoid stress, help or transfer responsibility for chores, limiting social activities. A few however deemed the costs of work to be too great and chose to prioritize their health by avoiding work altogether.

Conclusion: Most YASLE report being employed and setting a high priority on work. They recognized the importance of their health in helping them to work. They diverted considerable energy/ resources from other aspects of life to maintain work. This begs

the question of whether this approach could be sustainable beyond this life stage. However, this work on YASLE patients also identified multiple potential targets of interventions to help them continue working. By focusing on young adulthood, this will ensure that our strategies will be most appropriate for their life-stage, maximizing impacts.

POS0602-HPR MORE ACTIVITY LIMITATIONS AND LOWER QUALITY OF LIFE IN PERSONS WITH SYSTEMIC SCLEROSIS WITH THREE OR MORE SYMPTOMS THAN IN THOSE WITH TWO SYMPTOMS

Keywords: Patient reported outcomes, Systemic sclerosis

H. Pettersson[1,2], S. Pettersson[3,4], M. Regardt[2,3]. *[1]Karolinska Institutet, Medicine Solna, Unit of Rheumatology, Stockholm, Sweden*; *[2]Karolinska University Hospital, Occupational therapy/Physiotherapy, Stockholm, Sweden*; *[3]Karolinska Institutet, Department of Neurobiology, Care Sciences and Society, Stockholm, Sweden*; *[4]Karolinska University Hospital, Rheumatology, Stockholm, Sweden*

Background: Systemic sclerosis (SSc) is an inflammatory rheumatic disease affecting skin and internal organs (1). Little is known about how many symptoms persons with SSc (pwSSc) report ever and currently and how they impact activities and quality of life (QoL).

Objectives: To investigate what symptoms pwSSc report as most troublesome ever and currently and how the number of current symptoms affect activities and QoL.

Methods: In an SSc study at Karolinska University Hospital data were collected using open ended questions of what symptoms pwSSc considered most troublesome ever and currently. The self-reported answers were analyzed using qualitative analysis and categorized with an inductive approach. Participants answered Scleroderma Health Assessment Questionnaire, SHAQ, with the symptom severity Visual Analogue Scales, VAS, and Quality of Life, QoL, measured with EuroQoL, EQ VAS. Analysis was done to investigate what categories/symptoms pwSSc reported most troublesome ever and currently and if the number of symptoms currently present impact activities and QoL. Differences in reported symptoms ever and currently were analyzed with non-parametric tests when investigating differences between participants with 0-2 and ≥3 reported symptoms currently.

Results: A total of 291 pwSSc, median age 60 yrs, 83% women, participated. 254 (87.3%) pwSSc reported symptoms ever and 260 (89.3%) symptoms currently. 38,5% of the participants had three or more symptoms currently present. These pwSSc also perceived more activity limitation (p=0.006) and less QoL (p=0.023) than those with fewer symptoms. The median score of SHAQ (activity limitation) was 0,0 (0-3) and EQ VAS (QoL) was 62 (0-100) in the whole group. Among pwSSc with 0-2 symptoms currently the score of SHAQ was 0.38 and EQ VAS was 70 and in those with ≥3 symptoms the median score of SHAQ was 0,63 and EQ VAS was 70, p=0.006 and p=0.023.

Conclusion: PwSSc and ≥3 self-reported symptoms have a higher disease severity, more activity limitations and a lower QoL than persons with fewer symptoms. Health professionals need to focus resources on pwSSc with more reported symptoms to lessen activity limitations and improve QoL in pwSSc.

Background: Autoantibodies are found in up to 80% of patients with idiopathic inflammatory myopathies (IIM) and are associated with distinct clinical phenotypes [1]. Autoantibodies targeting cytosolic 5´-nucleotidase 1A (anti-cN1A) are currently the only known serum biomarker for the subgroup inclusion body myositis (IBM) (2), although detected even in other autoimmune diseases.
Objectives: To identify new autoimmune targets in IIM by antigen bead array assay.
Methods: In a first cross-sectional exploratory study, 357 antigens representing 268 proteins were incubated with plasma samples from 219 IIM (108 Polymyositis (PM), 80 Dermatomyositis (DM) and 31 IBM) patients, 349 Systemic Lupus Erythematosus (SLE) patients and 306 population controls for screening of IgG reactivity by antigen bead array. All samples were identified in the local biobank of the Rheumatology clinic, Karolinska University Hospital. Interesting results obtained for the IBM subgroup were then validated in an independent larger cohort of 287 patients with IBM followed at nine European rheumatological or neurological centers. IBM serum samples were explored by antigen bead array and results validated by western blot. As controls, serum samples from 30 patients with PM and 30 with DM, HLA-matched with the IBM Swedish cohort, were included. Demographics, laboratory, clinical, and muscle biopsy data of the IBM cohort was retrieved.
Results: In the exploratory study IgG reactivity towards NADH dehydrogenase 1 α subcomplex 11 (NDUFA11), a subunit of the membrane-bound mitochondrial respiratory chain complex I, was discovered with higher frequency in the IBM (9,7%) than PM (2,8%) and DM samples (2,5%), although the difference was not statistically significant. Anti-NDUFA11 IgG was also found in 2,3% of SLE and 2,6% of population control samples. In the validation study anti-NDUFA11 autoantibodies were detected in 11/287 IBM patients (3,8%), 0/30 PM and 0/30 DM patients. Reactivity against NDUFA11 could be confirmed by western blot (Table 1, Figure 1). The eleven anti-NDUFA11 positive patients showed a trend of lower frequency of wheelchair/walker ever use and higher creatine kinase levels at time of IBM diagnosis compared to the anti-NDUFA11 negative group. Ragged red fibers were significantly more prevalent in anti-NDUFA11 positive than negative patients (p=0.04). Anti-cN1A autoantibodies were detected in 98/287 (34,1%) of IBM, 3/30 (10%) DM and 9/29 (31%) PM patients, p=0.03. Coexistence of anti NDUFA11 and anti-cN1A antibodies was observed in 3 IBM patients.
Conclusion: Our results reveal a new autoimmune target in the mitochondrial respiratory chain complex I that might be specifically associated with IBM. This is of particular interest as mitochondrial abnormalities are known histological findings in muscle biopsies of IBM patients.

POS0604

ACTIVATION OF TYPE I INTERFERON PATHWAY IN SERA OF PATIENTS WITH ANTI-MELANOMA DIFFERENTIATION-ASSOCIATED GENE 5 ANTIBODY-POSITIVE DERMATOMYOSITIS

Keywords: Myositis, Cytokines and chemokines

S. Nakamura[1], Y. Katsumata[1], Y. Okamoto[1], M. Harigai[1]. [1]*Tokyo Women's Medical University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: We have previously reported that anti-melanoma differentiation-associated gene 5 (MDA5) antibodies are more frequently associated with rapidly progressive ILD (RP-ILD) and amyopathic dermatomyositis (DM) than anti-aminoacyl-tRNA synthetase (ARS) antibodies and that serum ferritin levels are higher in anti-MDA5-positive patients and serve as a relevant biomarker for RP-ILD [1]. Thus, it is speculated that anti-MDA5 DM and anti-ARS idiopathic inflammatory myopathies (IIMs) have distinct pathomechanisms. It was reported that type I interferon (IFN) gene signature was upregulated in the peripheral blood mononuclear cells and the skin tissues from the anti-MDA5 DM patients [2]. However, the role of type I IFN in anti-MDA5 DM has yet to be fully elucidated.
Objectives: We aimed to determine the activity of IFN-α/β and IFN regulatory factor (IRF) in sera of patients with anti-MDA5 antibody-positive DM with ILD,

compare them to those of patients with anti-ARS antibody-positive polymyositis (PM) and DM with ILD, and investigate their association with clinical features.
Methods: Serum samples were collected from clinically active adult patients with anti-MDA5 antibody-positive DM (MDA5, *n* = 22), and anti-ARS antibody-positive PM and DM (ARS, *n* = 21) as well as healthy controls (HCs, *n* = 32). PM/DM were classified according to the 2017 EULAR/ACR classification criteria for IIMs. Only patients with ILD diagnosed on high-resolution computed tomography findings and HCs were included. Patients complicated by infection or malignancy were excluded. The reporter cell lines (purchased from InvivoGen) which secrete embryonic alkaline phosphatase (SEAP) in response to IFN-α/β and those secrete luciferase and SEAP in response to activation of IRFs and nuclear factor kappa B (NF-κB), respectively, were incubated with 20% (v/v) serum samples. The levels of SEAP and luciferase in supernatants were measured using a multi-mode microplate reader and their association with clinical features was statistically analyzed. IFNAR2-knockout reporter cells were also used.
Results: The sera of MDA5 patients demonstrated significantly higher IFN-α/β and IRF activities than those of ARS patients and HCs ($p < 0.001$ in all the comparisons), whereas no significant difference was detected in the NF-κB activities (Figure 1). The assays using IFNAR2-knockout reporter cells showed no significant difference in IRF or NF-κB activities. The serum ferritin levels in MDA5 patients were significantly higher than those in ARS patients (mean 679.7 ng/mL vs. 321.3 ng/mL, $p = 0.03$). The IFN-α/β and IRF activities induced by the MDA5 patients sera were correlated with the serum ferritin levels ($r = 0.53$ and 0.54, respectively), whereas they did not significantly correlate with the serum KL-6 levels, percent-predicted forced vital capacity (%FVC), or percent-predicted diffusing capacity of the lung for carbon monoxide (%DLCO).
Conclusion: IFN-α/β and IRF activities and their association with ferritin were demonstrated in sera of anti-MDA5-positive DM patients with ILD but not in those of anti-ARS-positive PM/DM patients with ILD. The present study suggests that activation of type I interferon pathway may be involved in the pathomechanisms of anti-MDA5 DM with ILD.

POS0606 DETECTION OF HISRS SPECIFIC AUTOREACTIVE CD4+ T CELLS IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Cell biology, Adaptive immunity, Myositis

B. Horuluoglu[1], A. S. Galindo-Feria[1,2], R. Kumar[1], G. Kozhukh[1], J. S. Díaz-Boada[1], D. Ramsköld[3], K. Chemin[1], V. Malmström[1], I. E. Lundberg[1,2].
[1]Karolinska Insitutet, Division of Rheumatology, Center for Molecular Medicine, Department of Medicine, Solna, Stockholm, Sweden; *[2]Karolinska University Hospital, Department of Gastro, Dermatology and Rheumatology, Stockholm, Sweden*; *[3]Karolinska Insitutet, Department of Cell and Molecular Biology, Stockholm, Sweden*

Background: Idiopathic inflammatory myopathies (IIM) or myositis are a group of chronic autoimmune disorders represented by lesions in muscle, skin, joints and lung. One of the most common autoantibodies with a prevalence of 25-35 % is anti-Jo1, targeting histidyl-transfer RNA synthetase (HisRS). Importance of T-cells in disease is established by their presence at sites of inflammation such as the muscle. We have shown that upon stimulation of PBMC with HisRS, $CD4^+$T-cells are activated and produce inflammatory cytokines. Genetic association of HLA-DRB1*03:01 further implicates the recognition of autoantigens by $CD4^+$T-cells. However, the presence of antigen specific $CD4^+$T-cells has not yet been shown in patients with IIM.
Objectives: The aim of this project is to identify HisRS $CD4^+$T-cells using HLA Class-II tetramers (Tmr) and single T cell receptor (TCR) sequencing.
Methods: HLA-DRB1*03:01 monomers with selected HisRS- and tetanus peptides as controls were produced in E.coli. The peptides were covalently linked to the HLA b-chain via a flexible peptide linker. HLA-tetramers were assembled using a commercial APC or PE labeled streptavidin. The efficacy of Tmrs was validated upon stimulation of PBMCs from HLA-matched healthy controls with tetanus peptide. In parallel, upregulation of T cell activation markers such as PD-1, CD69, CD137 was also investigated. Next, we stimulated PBMCs from anti-Jo1 positive patients with IIM that were HLA-DRB1*03 (n=10) with both tetanus and HisRS peptides and cultured the cells for 6 days followed by tetramer staining. Fluorospot was performed for the detection of IFNg and IL2 secreting cells and culture supernatants were collected for cytokine analysis using cytokine bead arrays. Summary of the workflow is presented in Figure 1.
Results: We detected HisRS+$CD4^+$T cells from 5 out of 10 patients using tetramers upon stimulation with HisRS peptide. We detected increased IFNg levels in the supernatants where Tmr+ cells were detected further supporting the activation of T cells. HisRS$^+CD4^+$T cells from patients (n=5) were single cell sorted and TCR a/b chains were sequenced (n=538). A bioinformatics pipeline for the alignment and assembly of the TCR sequences, was developed and the clonality analysis revealed presence of expanded T cell clones in 4 out of 5 patients. Expanded T cells had high mean fluorescent intensity values (MFI) for HisRS tetramers, suggesting the responsiveness of autoreactive T-cells to HisRS.
Conclusion: IIM are rare, chronic autoimmune disorders with no available cure. Previous studies indicate the importance of T cells in this disease. However, the phenotype and role of these cells in the disease pathogenesis has not been fully established. Our results indicate the presence of HisRS+$CD4^+$T-cells in IIM which will introduce the possibility of new targeted treatment approaches.

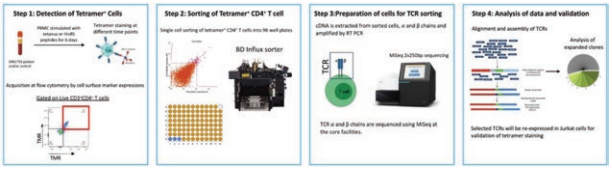

Figure 1. Summary of experimental setup starting from the stimulation of PBMCs and tetramer staining (Step 1), sorting of tetramer+ cells (Step 2), preparation of cells for TCR sequencing (Step 3) and analysis of TCRs (Step 4).

POS0607 BREPOCITINIB PREVENTS TYPE-I INTERFERON INDUCED DAMAGE IN CULTURED MYOCYTES AND ENDOTHELIAL CELLS INDICATING A POTENTIAL ROLE IN THE TREATMENT OF DERMATOMYOSITIS

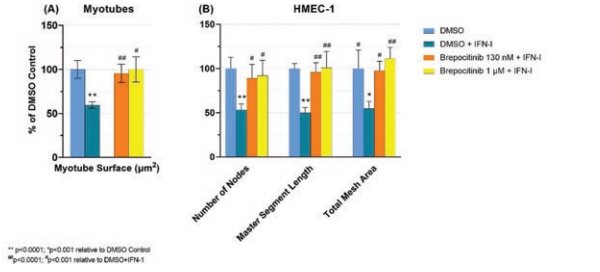
Keywords: Myositis, Targeted synthetic drugs, Cytokines and chemokines

J. Vencovský[1], J. Feldman[2], L. Mcconnachie[2], B. Johnson[2]. *[1]Institute of Rheumatology, Rheumatology, Prague, Czech Republic*; *[2]Priovant Therapeutics, Early Development, Durham, United States of America*

Background: Dermatomyositis (DM), an idiopathic inflammatory myopathy, is a chronic and often debilitating condition characterized by a hallmark skin rash (e.g., Gottron's sign and heliotrope rash) with perifascicular atrophy and subsequent muscle weakness [1]. The pathogenesis of DM involves dysregulation of Type I interferon (IFN-I) signalling and other cytokines (IFN-γ, IL-12, and IL-23). The kinases, TYK2 and JAK1, are essential for the signalling pathway of these cytokines. Brepocitinib, a selective and potent dual TYK2/JAK1 inhibitor is in development for the treatment of DM and is expected to reduce signalling of these cytokines, particularly IFN-I, and ameliorate the symptoms of disease.
Objectives: To evaluate the efficacy of brepocitinib in preventing IFN-I induced pathological changes characteristic of DM in human skeletal muscle and microvascular endothelial cells in vitro.
Methods: Human skeletal muscle myoblasts were cultured and differentiated into myotubes then treated with vehicle control or IFN-I (recombinant Human IFN

alpha A and Human IFN alpha D) to induce cellular damage. Myotubes were also preincubated for 1 hour with brepocitinib (1 μM or 130 nM, the latter is equivalent to the average free plasma concentration after administration of 30 mg once-daily) prior to IFN-I treatment. Immunofluorescence staining followed by image analysis to determine myosin 4 surface area were conducted after 48 hours of IFN-I treatment. Human dermal microvascular endothelial cells (HMEC-1) were cultured and, once vascular networks were established, cells were treated with IFN-I or vehicle control. Cells were also preincubated for 1 hour with brepocitinib as described above. Under light microscopy 9 hours after treatment, the number of nodes, master segment length, and total mesh area were analyzed. To determine statistical significance, one-way ANOVA followed by Tukey's multiple comparison post-hoc analyses were performed.

Results: Myosin surface area was reduced by ~40%, relative to vehicle treated control, in myotubes exposed to IFN-I ($p<0.0001$). This cytokine induced damage was almost completely prevented by brepocitinib preincubation (both 130 nM and 1 μM) with mean myosin surface areas of 96% and 100% of the vehicle control, respectively. The differences between IFN-I treatment alone and brepocitinib were significant ($p<0.0001$ [1 μM] and $P<0.001$ [130 nM]). Similarly, HMEC-1 exposure to IFN-I significantly reduced the mean number of nodes, mean master segment length, and mean total mesh area by 47 to 50% relative to vehicle control ($p<0.0001$ nodes and segments, $p<0.001$ mesh area). With brepocitinib preincubation, this damage was prevented with the mean number of nodes, master segment lengths, and total mesh area ranging from 89 to 111% of vehicle control. These differences were statistically different from the IFN-I treatment at both brepocitinib concentrations and all endpoints ($p<0.001$ for all conditions).



Conclusion: One of the most debilitating aspects of DM is muscle weakness resulting from perifascicular atrophy leading to significant impacts on quality of life for these patients[2]. We report here the ability of brepocitinib to prevent IFN-I induced damage in both myocytes and microvasculature in culture at clinically relevant concentrations, providing further pharmacologic rationale for brepocitinib in the treatment of DM.

POS0608 TARGETING THE JAK/STAT PATHWAY IN MYOSITIS INHIBITS B CELL PROLIFERATION, DIFFERENTIATION AND ANTIBODY PRODUCTION

Keywords: Autoantibodies, Adaptive immunity, Myositis

A. Merino-Vico[1,2], J. P. Van Hamburg[1,2], L. Landman[1,2], J. Raaphorst[1,3], A. J. Van der Kooi[1,3], S. Tas[1,2]. *[1]Amsterdam Rheumatology & Immunology Center, Amsterdam UMC/University of Amsterdam, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[2]Amsterdam UMC/University of Amsterdam, Department of Experimental Immunology, Amsterdam, Netherlands*; *[3]Amsterdam UMC/University of Amsterdam, Department of Neurology, Amsterdam, Netherlands*

Background: Idiopathic inflammatory myopathies (IIM) or myositis are characterized as inflammatory, autoimmune disorders with a wide spectrum of symptoms and affected tissues. The presence of circulating autoantibodies and B-lineage cells in affected tissues, point towards an essential role of B cells in the pathogenesis of IIM. This sparked interest in the B cell depleting anti-CD20 antibody rituximab as a new treatment opportunity in IIM. However, despite its beneficial effects, rituximab results in long-term B cell depletion and does not target CD20-negative, long-lived plasma cells, which may maintain the autoimmune response. Hence, further research aimed at more specific and reversible therapies targeting B and plasma cells is warranted. The Janus kinase (JAK)-signal transducer and activator of transcription (STAT) signalling pathway is essential for several aspects of B cell biology, making it an attractive novel target for patients with IIM.

Objectives: To study whether targeting the JAK-STAT signalling pathway using tofacitinib, a small molecule inhibitor specific for JAK1/JAK3, impairs essential functions of B cells isolated from patients with IIM.

Methods: B lineage cell phenotyping was performed by flow cytometry, using PBMCs obtained from 3 IIM phenotypes (dermatomyositis, overlap-myositis, anti-synthetase syndrome) and healthy donors (HD). Functional assays were performed culturing PBMCs in the presence of tofacitinib, and the stimuli IL-21/anti-CD40 or IL-2/CpG to activate JAK/STAT signalling in a T cell-independent or T cell-dependent manner, respectively. After a 6-day culture, the effects of tofacitinib on B cell proliferation, differentiation, and antibody production were assessed by flow cytometry and ELISA.

Results: Peripheral blood B cell composition from patients with IIM showed reduced fractions of memory B cells, and an increase in transitional and naive B cells in comparison to HD reference values. Targeting JAK/STAT signalling using tofacitinib significantly reduced IL-21/anti-CD40 induced B cell proliferation, plasmablast differentiation and antibody production in B cells of patients with IIM and HD. However, this effect was observed to a lesser extent upon stimulation with IL-2/CpG. Interestingly, tofacitinib exerted its effects irrespective of the IIM phenotype.

Conclusion: Our data demonstrate that the composition of the peripheral B cell compartment in IIM patients is altered. Furthermore, tofacitinib treatment *in vitro* results in the inhibition of functional B cell responses, including proliferation, plasmablast differentiation, and antibody production, which was irrespective of the clinical phenotype. Consequently, targeting of JAK/STAT signalling may represent a novel treatment modality in myositis.

POS0609 EXPANDED CYTOTOXIC CD8+ T CELL CLONES CHARACTERIZE THE BLOOD OF INCLUSION BODY MYOSITIS PATIENTS

Keywords: Myositis, -Omics, Rare/orphan diseases

L. Shakib[1], M. Fein[2], A. Bloostein[3], D. Fernandez[3], L. Donlin[2]. *[1]Weill Cornell Medicine, Physiology, Biophysics and Systems Biolgy, New York, United States of America*; *[2]Hospital for Special Surgery Main Hospital, Research, New York, United States of America*; *[3]Hospital for Special Surgery Main Hospital, Rheumatology, New York, United States of America*

Background: Inclusion body myositis (IBM) is an inflammatory myopathy, characterized by CD8+ T cell infiltration of muscle and patients present with progressive muscle weakness and atrophy, leading to disability due to no FDA-approved therapies. Patients with IBM have been noted to frequently exhibit aberrant expansion of circulating CD8+ T cells, even satisfying classification criteria for T cell large granular lymphocytic leukemia (T-LGL) in >50% of cases, in one study[1]. However, high-resolution profiling of the transcriptome and TCR repertoire in IBM are lacking.

Objectives: To evaluate the TCR repertoire of circulatory CD8+ T cells, allowing us to simultaneously define the transcriptomes of expanded and non-expanded clonotypes in blood of IBM patients and healthy age-matched blood donors.

Methods: 13 IBM patients and 9 age-matched healthy controls were sorted for either non-naïve CD8+ T cells and/or CD8+CD57+ T cells by flow cytometry. Single-cell RNA and TCR sequencing was performed to profile the whole gene expression, coupled with paired TCRa and TCRb chains, at single-cell resolution. Additional markers during flow cytometry allowed for further identification of aberrant populations in IBM compared to age-matched healthy controls.

Results: Our results found IBM CD8+ T cell were highly expanded compared to age-matched healthy controls. These CD8+ T cells were identified in both the broad non-naïve T cell population, as well as the specific CD8+ CD57+ T cell subset. Enrichment of T-LGL leukemia genes, in addition to CD8+ effector function, cytotoxicity and inflammatory chemokines and cytokines were found in expanded clonotypes, with a higher gene expression found in hyperexpanded clones compared to minimally expanded clonotypes. Absence of common TCR clonotypes between patients in IBM was found, a pattern also seen in T-LGL

leukemia. GSEA analysis also confirmed a downregulation of cell apoptosis processes in hyperexpanded clonotypes, a feature of T-LGL leukemia clones.
Conclusion: Significant clonal expansion of CD8+ T cells in the blood was found in our IBM cohort compared to our age-matched healthy controls. Additionally, these hyperexpanded clonotypes have various T-LGL leukemia gene markers, in addition to elevated cytotoxic and T cell activation genes in comparison to their minimally expanded counterparts. These results highlight how the blood compartment of IBM, a progressive muscle disease, is important in IBM and how future studies and therapies should be targeting these aberrant blood CD8+ T cell clones.

Background: Ku-antibodies are one of the myositis-associated antibodies linked with muscle involvement in many connective tissue diseases. The histopathological pattern of Ku$^+$ myositis is described diversely with inflammatory and necrotic aspects, however, a detailed morphological characterization of Ku$^+$ myositis is still missing.
Objectives: The aim of the study was to analyze histopathological and transcriptional aspects of patients with Ku$^+$ myositis to gain new insights in possible pathophysiological mechanisms.
Methods: 23 biopsy samples from patients with clinical and morphological signs of myositis and positive Ku-antibodies were studied by histopathology, immunohistochemistry, and quantitative polymerase chain reaction (qPCR) and compared with biopsies derived from non-disease controls (NDCs) and immune-mediated necrotizing myopathy (IMNM) at the Department of Neuropathology of Charité university hospital Berlin.
Results: Mean patient's age was 55 years, 91% were women and the most common rheumatological diagnosis was overlap with systemic sclerosis (30%), followed by isolated myositis (26%) and overlap with primary sjögren's syndrome or rheumatoid arthritis (13% respectively). Creatine kinase elevation was present in 91% of the patients. Histopathologically, we noticed a broad phenotype spectrum with mild to severe myositis with predominantly MHC class I overexpression and milder MHC class II overexpression. 87% of the biopsies showed necrosis combined with inflammatory aspects of variable degree. Infiltrates were mainly CD68$^+$ cells (average of 213 cells per 10 high power fields (HPF)), followed by CD3$^+$ cells (76 cells/10 HPF), whereas CD20$^+$ or CD138$^+$ cells were rare (8 respectively 14 cells/10 HPF). Furthermore, we detected small vacuoles in 59% and large areas of p62$^+$ aggregates in 62% of the biopsies. Similarly, aggregates of LC3 and myotilin were found in 60% and 76% respectively. Immunofluorescence staining showed co-localization of p62 and myotilin indicating protein aggregates and induction of autophagy pathways. *P62* gene expression was neither elevated in Ku$^+$ patients nor in IMNM patients compared to NDC (*Figure 1A*). *SIGLEC1* gene expression was significantly elevated in Ku$^+$ patients compared to IMNM patients and NDC (*Figure 1B*).
Conclusion: In this study, we defined a histopathological pattern of Ku$^+$ myositis with predominant MHC class I expression, necrosis, small vacuoles and inflammation as well as peculiar p62$^+$ and LC3$^+$ aggregation in severely inflammatory biopsy samples. Whilst there definitely is a broad spectrum of presentation, MHC class I expression, necrosis and p62/LC3$^+$ aggregates seem to be the defining aspects of the histopathological presentation.

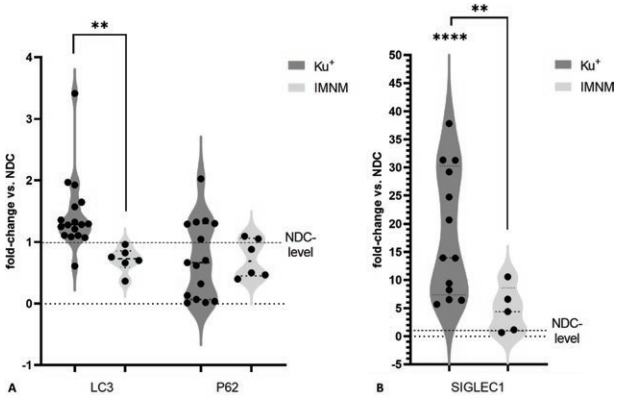

Figure 1. Transcriptional analysis of *LC3*, *P62* and *SIGLEC1* Quantitative polymerase chain reaction was used to analyze the gene expression of *LC3*, *P62* and *SIGLEC1*. Violin plots display fold-change versus non disease controls (NDC), calculated by [2^-(ΔCT Ku$^+$ patients/immune-mediated necrotizing myositis (IMNM) -ΔCT NDC)].
A *LC3* gene levels are elevated in Ku$^+$ patients compared to IMNM (p=0.0015), whilst *P62* levels do not differ from NDC.
B *SIGLEC1* gene expression is significantly elevated in Ku$^+$ patients compared to IMNM patients (p=0.0026) and NDC (p<0.0001).

POS0611 SHARED MONOCYTE CYTOKINE SIGNATURE INDUCED BY SERUM FROM PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTI-MDA5 ANTIBODY-POSITIVE DERMATOMYOSITIS THROUGH TYPE I INTERFERON PATHWAY

Keywords: Systemic lupus erythematosus, Cytokines and chemokines, Myositis

S. Nakamura[1], Y. Okamoto[1], Y. Katsumata[1], M. Harigai[1]. *[1]Tokyo Women's Medical University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Type I interferon (IFN) plays a pivotal role in the pathogenesis of systemic lupus erythematosus (SLE) and dermatomyositis (DM)/polymyositis (PM) as typically evidenced by upregulation of type I IFN-stimulated genes (ISGs) in peripheral immune cells [1]. In addition, a distinct monocyte cytokine signature, which was induced by plasma from pediatric SLE patients and abrogated by Janus kinase (JAK) inhibition, was reported [2]. However, contribution of serum factors to expression of ISGs was not fully elucidated.
Objectives: To investigate the cytokine induction profile in multiple myeloid lineages by serum from patients with SLE or DM/PM using the whole blood stimulation system and identify the signaling pathway relavant to the monocyte cytokine signature.
Methods: Serum was collected from newly diagnosed, untreated, and clinically active adult patients with SLE (SLE group), anti-MDA5 antibody-positive DM (MDA5 group), and anti-aminoacyl-tRNA synthetase (ARS)

antibody-positive DM/PM (ARS group), and healthy controls (HCs) (n = 10 for each group). Heparinized whole blood from healthy donors was incubated with control serum (10 v/v%), patient serum (10 v/v%), or IFN-β in the presence of protein transport inhibitor cocktail for 6 hours. Red blood cells were lysed, and then leucocytes were fixed at a single step. Intracellular staining was performed and expression of 11 cytokines in $CD14^+$ monocytes, $CD1c^+$ dendritic cells (DCs), and $CD123^+$ DCs were analyzed using flow cytometry. A cut-off level was determined by 2% positivity of each cytokine in unstimulated condition. For transcriptomic analyses, sorted $CD14^+$ monocytes from healthy donors were incubated with serum (SLE, MDA5, ARS, or HCs), or IFN-β (n = 3 for each group) for 4 hours, and bulk RNA-sequencing was performed using the Illumina NextSeq 500 platform. RNA-seq raw sequence reads analysis and pathway analysis were performed using the Strand NGS software. To evaluate significance of JAK-signal transducer and activator of transcription (STAT) pathway, whole blood from healthy donors was pre-incubated with upadacitinib, a JAK1 inhibitor, stimulated with patient serum for 6 hours, and analyzed for cytokine expression as described above.

Results: Serum from SLE and MDA5 groups induced significantly higher monocyte chemoattractant protein-1 (MCP1) and interleukin-1 receptor antagonist (IL-1RA) expression in $CD14^+$monocytes than serum from HCs (Figure 1). These monocyte cytokine signatures were closely resembled that induced by IFN-β stimulation. Serum from ARS group did not induce any significant cytokine expression in $CD14^+$ monocytes. No significant cytokine expression was observed in $CD1c^+$ DCs or $CD123^+$ DCs. RNA-seq demonstrated that 612 and 462 genes were upregulated (fold change >2 relative to control) following stimulation with serum from SLE and MDA5 groups, respectively. In these upregulated genes, 383 genes were commonly upregulated across SLE and MDA5 groups and IFN-β. Pathway analysis revealed similar transcriptional profiles in SLE and MDA5 groups: upregulated genes were most frequently involved in IFN-αβ signaling pathway including multiple ISGs and STAT1/2. Upadacitinib significantly abrogated the monocyte cytokine signature, and MCP1 and IL-1RA expression induced by serum from SLE and MDA5 groups in a dose-dependent manner (p < 0.001 in all analyses).

Conclusion: These results suggest that serum factors in patients with active SLE and anti-MDA5 antibody-positive DM can induce shared monocyte cytokine signature through type I IFN pathway. $CD14^+$ monocytes 'primed' by serum might contribute to the pathogenesis of these diseases.

POS0612 GENE ANALYSIS REVEALED THE USEFULNESS OF TRIPLE THERAPY WITH BARICITINIB, RITUXIMAB AND TACROLIMS FOR ANTI-MDA5 ANTIBODY POSITIVE DERMATOMYOSITIS (MDA5-DM)

Keywords: Myositis

M. Sakamoto[1], Y. Nakai[1], Y. Sato[2], Y. Koyama[1]. [1]*Japanese Red Cross Okayama Hospital, Division of Rheumatology, Center for Autoimmune Diseases, okayama, Japan*; [2]*DNA Chip Research Inc, Medical Laboratory, Tokyo, Japan*

Background: Anti-MDA5 antibody positive dermatomyositis (MDA5-DM) is characterized by high mortality due to rapid progressive ILD. MDA5 is a cytosolic protein and a family of RIG-I like receptor, which functions as a virus RNA sensor and induces the production of such as type-1 IFN. Although little is known about the pathogenesis of MDA5-DM, it is notable that the similarities were reported between COVID-19 infection and MDA5-DM. It may suggest that there is a common underlying autoinflammatory mechanism. We reported that in MDA5-DM, (1) RIG-I-like receptor signaling is enhanced and (2) antiviral responses such as type 1 IFN signaling are also enhanced as compare with anti-ARS-antibody positive DM, and (3) the key for survival is suppression of RIG-I-like and IFN signaling (EULAR2022, POS0390). We also found that a significant role for uncontrolled macrophage in the pathogenesis of ILD by our autopsy case. Recently, it has been reported that tacrolimus (TAC) and cyclophosphamide (CY) combination therapy (TC-Tx) has improved the prognosis of cases with early onset of the disease, but there are cases that cannot be saved. Therefore, we devised BRT therapy (BRT-Tx). The Tx combines baricitinib (BAR), which inhibits GM-CSF and IFN-mediated signaling and effectively suppresses uncontrolled macrophages, with rituximab (RTX) and TAC, which rapidly inhibits B and T cell interaction and ultimately prevents anti-MDA5 antibody production.

Objectives: To determine the differences in gene expression between BRT and TC-Tx for MDA5-DM in peripheral blood.

Methods: Total of 6 MDA5-DM (TC: 3, BRT: 3) were included and all of them had multiple poor prognostic factors. Peripheral whole blood was collected at just before and 2-3 months after the treatment. RNA was extracted, and quantified using a next-generation sequencer. Differentially Expressed Genes (DEGs) were identified by pre vs. post treatment. Gene Ontology (GO), clustering and Gene Set Variation Analysis (GSVA) were performed to DEGs. As one BRT case was added since our last year's report, we also reanalyzed the surviving vs. fatal cases. The IFN signature was scored separately for Types 1, 2, and 3, and the changes between pre- and post-treatment were investigated.

Results: Two of three cases with TC died during treatment, while all three cases on BRT recovered. The cluster analysis of the DEGs separated deaths from survivors, not by type of treatment. Comparing surviving and dead cases, GO analysis revealed that the immune system via immunoglobulins and B cells was significantly suppressed in surviving cases. GO analysis of DEGs in each therapeutic group showed that expression of B cell-related genes such as lymphocyte proliferation and B cell receptor signaling pathway were significantly suppressed in BRT-Tx. On the other hand, TC-Tx significantly suppressed such pathways as cell proliferation and cell surface receptor signaling, and was less specific for the target cells than BRT-Tx. The changes in IFN signature score after treatment showed an increase in type 2 and 3 IFN scores in all fatal cases and an increase in type 1 IFN score in one fatal case.

Conclusion: BRT-Tx significantly suppressed gene expression associated with B cells, while TC-Tx was characterized by low specificity of therapeutic targets and suppression of total cell proliferation. Comparison of surviving and dead cases revealed that the combination of RTX contributed to the success of treatment, as suppression of the immune system mediated by immunoglobulins and B cells is the key for survival. Analysis of the IFN signature revealed an increase in IFN score after treatment in fatal cases, indicating that the combination of BAR is beneficial. The superiority of BRT-Tx seems clear from the fact that all patients survived with BRT-Tx while only one/three patients survived with TC-Tx.

Scleroderma Unit Dept. Geriatric Medicine, Florence, Italy; [5]*University of Zurich, Department of Rheumatology, University Hospital Zurich, Zurich, Germany*; [6]*San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: Gastrointestinal tract (GIT) is affected in approximately 90% of systemic sclerosis (SSc) patients from the earliest disease stages. Microbiota has recently emerged as an important environmental factor in SSc pathogenesis.
Objectives: to test differences in the taxa composition of the fecal microbiota of very early SSc (VEDOSS) and established SSc patients.
Methods: Twenty-nine SSc patients classified according to the ACR/EULAR 2013 criteria (27 female, mean ± SD disease duration 13.1±9.2 years) and 21 VEDOSS patients (19 female, mean± SD disease duration 6.4±5.2 years) were consecutively enrolled. For each patient, demographic, clinical and laboratoristic data were recorded and stool samples were collected. GI involvement and quality of life were investigated with UCLA-Gastrointestinal Tract Questionnaire (GIT)2.0 and Short Form Health Survey-36 (SF36). Microbiota was assessed through 16S rRNA Next Generation Gene-Sequencing analysis.
Results: We found a different fecal microbiota profile between SSc and VEDOSS. In particular, classes of *Bacilli* and *Choriobacteria*, orders of *Desulfovibrionales* and *Lactobacillales,* the family of *Eggerthellaceae*, the genera *Enterococcus, Lactobacillus*, *Streptococcus*, *Sutterella* and *Uncultured-Rhodospirillales* were statistically significant increased in SSc, while the class of *Clostridia*, the family of *Oscillospiraceae* and the order *UCG-002* were statistically significant increased in VEDOSS (Figure 1).

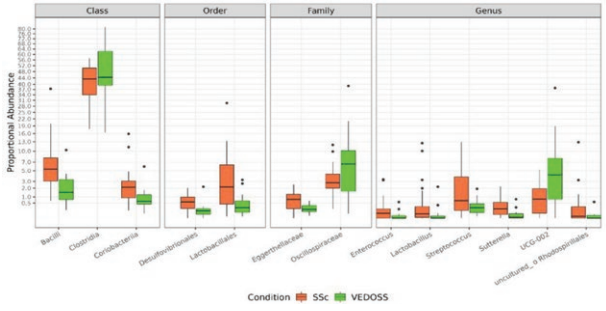

Figure 1. Boxplot showing the results of taxa-level differential abundance analysis between SSC and VEDOSS patients in fecal samples. Plot titles report the shrinked Log2 fold change (according to the DESeq2 function lfcShrink). All results have a p-value < 0.05.

VEDOSS patients had significantly higher SF-36-physical component score than SSc, a trend for higher SF-36-mental component summary (MCS), while no difference in the UCLA-GIT2.0 score (Table 1).

Table 1. SF 36 and UCLA GIT 2.0 score in VEDOSS and SSc patients

	VEDOSS (M ± DS)	SSc (M ± DS)	p-value
SF-36-physical component summary	47,8 ± 8,3	40,7 ± 8,3	<0,01
SF-36-mental component summary	46,3 ± 9,2	40,4 ±11,6	0,06
UCLA-GIT 2.0	0,3 ± 0,3	0,4 ± 0,4	NS

In SSc patients, we observed a significant positive association between the genus *Uncultured-Rhodospirillates* and MCS, and between both genera *Lactobacillus* and *Uncultured-Rhodospirillates* and UCLA-GIT 2.0 score. In VEDOSS we found a significant positive correlation between both *Bacilli* class and *Lactobacillus* genus and MCS.
Conclusion: Our data show, for the first time, a different microbiota composition in SSc and VEDOSS patients. In particular, we observed an increased abundance of genus *Lactobacillus* in SSc patients. However, no significant differences in the UCLA GIT score between the two groups were observed, confirming that GI symptoms also affect VEDOSS patients. Both these findings could suggest that the increased *Lactobacillus* values in SSc patients should raise the suspicion of more severe GIT involvement. This may account for the poor result of a lactobacillus-based probiotic treatment, usually observed in literature. It is necessary to confirm these data on larger groups of patients in the two phases of the disease.

POS0614 INTERLEUKIN-17 MEDIATED INFLAMMATORY AND PRO-FIBROTIC ACTIVITY OF SKIN FIBROBLASTS DERIVED FROM SYSTEMIC SCLEROSIS PATIENTS (SSC) COMPARED WITH HEALTHY CONTROLS (HC)

Keywords: Cytokines and chemokines, Innate immunity, Systemic sclerosis

G. Aßmann[1], J. Weghorn[1], M. Bewarder[2], F. Gellrich[1], C. Rittich[1], C. Pfoehler[3], F. Neumann[4]. [1]*RUB University Hospital JWK Minden, Rheumatology, Minden, Germany*; [2]*University Medical School of Saarland, Internal Medicine I, Oncology, Hematology, Rheumatology, Homburg, Germany*; [3]*University Medical School of Saarland, Dermatology, Homburg, Germany*; [4]*University Medical School of Saarland, Jose-Carreras Institution for Gene Therapy, Homburg, Germany*

Background: Systemic sclerosis (SSc) is an autoimmune connective tissue disease defined by fibrosis of skin an internal organs as well as vascular impairment. Furthermore, in addition to the fibrosis several autoimmune features of SSc often show a phenotype of auto-inflammation. As recently published T-cell proliferation and, in particular, T helper 17 (Th17) cells with their cytokine interleukin-17 seem to play an important role in the pathogenesis of the fibro-inflammatory environment of the tissue in SSc.
Objectives: Here we investigated cultures of skin fibroblasts derived from SSc and healthy controls (HC) to evaluate the different expression of pro-inflammatory and pro-fibrotic proteins and cytokines (defined as biomarkers) after stimulation of interleukin-17 (IL-17) and tumor growth factor-beta (TGF-β), measured by concentrations in the cellular supernatant.
Methods: The current study was approved by the Ethics Committee at the Saarland University, all participants of the study gave their written informed consent for their participation in the study. SSc patients (n = 8, aged 43 to 65 years) and healthy controls (n = 4, aged 40 to 53 years) underwent a skin biopsy of the lateral abdominal wall. Fibroblasts isolated from the surgical samples were cultured for 5-8 passages according to standard procedures. The cells were stimulated by 25 ng/ml of IL-17 or 2.5 ng/ml of TGF-β for 48 h. The supernatant of the different fibroblast cultures was analysed for the following biomarkers: pro-inflammatory cytokines such as interleukin-1-beta, interleukin-6 (IL-6), interleukin-8 (IL-8), preferentially anti-fibrinolytic and/or pro-fibrotic proteins such as matrix metalloproteinase-1 (MMP-1), monocyte chemotactic protein 1 (MCP-1), procollagen, insulin-like growth factor-binding protein 3 (IGFPB-3), and Lysyloxidase-1 (LOX-1). The concentrations of these biomarkers were analysed applying commercial ELISA standard tests (IL-1β, IL-6, IL-8, MCP-1, MMP-1, procollagen, and IGFBP-3). The differences between SSc and HC (without and after stimulation with IL-17 or TGB-β, respectively) were statistically analysed by t-test (with fisher`s correction).
Results: IL-6, MCP-1 and procollagen secreted by native fibroblasts showed a significant higher concentration in SSc compared to HC in unstimulated conditions. In contrast, the anti-fibrotic efficient protein MMP-1 reached a significant lower concentration in SSc-derived fibroblasts, the significant differences between SSc and HC could also be reproduced after IL-17 stimulation (Table 1), whereas after stimulation with TGF-β the differences between SSc and HC were only significant for IL-6 and MCP-1. The remaining proteins and cytokines which were investigated (IL-1-β, IGFPB-3, LOX-1) do not resulted in significant differences.

Table 1. biomarkers cell culture supernatants of fibroblasts derived from SSc patients and HC

Growth	IL-6		MCP-1		MMP-1		Procollagen	
condition	SSc	HC	SSc	HC	SSc	HC	SSc	HC
Native	**0.22***	**0.03**	**0.37***	**0.12**	**13.53***	**35.96**	**885.3***	**333.0**
+/- SE	0.04	0.01	0.04	0.02	1.36	4.89	32.6	50.9
after IL-17	**3.95***	**1.57**	**6.20***	**2.99**	**77.41****	**162.22**	**957.2****	**323.8**

after TGF-β	**0.81**	**0.60**	**0.47**	**0.37**	**9.67***	**17.83**	**875.4****	**525.8**
+/- SE	0.10	1.70	0.06	0.10	2.34	2.13	43.3	50.3

Biomarker concentrations given in ng/ml; significant differences of concentrations between SSc and HC without or after stimulation (with TGF-β or IL-17, respectively) with * p-value p < 0.05 or ** p-value < 0.01

Conclusion: Skin fibroblasts in SSc patients showed significantly stronger pro-inflammatory and pro-fibrotic properties compared with healthy controls as an indication of the fibro-inflammatory character of the disease. Furthermore, the significant increase of the expression of IL-6, MCP-1, procollagen and the decrease of the anti-fibrotic efficient protein MMP-1 after IL-17 stimulation suggests IL-17 as a well promising target in SSc.

Ruiz-Ortiz[1,2]. *[1]Centre de Diagnòstic Biomèdic, Hospital Clínic de Barcelona, Immunology Department, Barcelona, Spain*; *[2]Institut d'Investigacions Biomèdiques August Pi i Sunyer, IDIBAPS, Barcelona, Spain*; *[3]Hospital Clínic de Barcelona, Autoimmune Diseases Department, Barcelona, Spain*; *[4]Hospital Clínic de Barcelona, Internal Medicine Department, Barcelona, Spain*; *[5]Respiratory Institute, Hospital Clínic de Barcelona, Pneumology Department, Barcelona, Spain*; *[6]Headquarters & Technology Center Autoimmunity, Werfen, Research and Development, San Diego, CA, United States of America*

Background: Systemic Sclerosis (SSc) is an autoimmune disease characterized by excessive fibrosis, inflammation and vasculopathy of the skin and internal organs. Interstitial lung disease (ILD) is the most important cause of mortality. Multiple autoantibodies (Abs) against nuclear proteins are present in >95% of patients. Anti-Topoisomerase-I (ATA), anti-CENP-B (ACA) and anti-RNA-polymerase-III (RNAP3) Abs are included in the 2013 SSc ACR/EULAR classification criteria. The detection of additional Abs is of interest to identify seronegative cases or specific clinical phenotypes. The particle-based-multi-analyte technology (PMAT) is a multiplexed system based on antigen covered paramagnetic particles with unique signatures. It allows to simultaneously obtain different autoantibody results.

Objectives: The aim of this study was to evaluate the clinical performance of PMAT-Aptiva in a cohort of SSc patients from Hospital Clínic de Barcelona.

Methods: Study cohort includes serum samples of patients with SSc (n=138), disease controls with other autoimmune diseases (n=205) and healthy blood donors (n=25). Demographic characteristics and clinical manifestations of patients were collected. SSc specific (ATA, ACA or RNAP3) or SSc associated (Ro52, U1-RNP, Ku, Th/To (Rpp25 and Rpp38), Fibrillarin, Pm/Scl, BICD2, MIT3, Mup44, PUF60 (isoforms 1, 2 and 6), RNPC3r, RNPC3 (peptide 1, 2, 3, 4 and 5), RuvBL1/2, SMN1 and TERF1) Abs were tested on Aptiva by PMAT technology (Werfen, San Diego, USA). The prevalence of Abs was measured based on the manufacturer's recommended cut-offs. CTD-Essential has calibrated units (FLU) whereas other novel biomarkers were RUO (MFI). Associations between categorical variables were determined with Fisher's exact test. The relative measure of an effect was expressed as the odds ratio and the 95% CI when considering Ab positivity as the exposure. Results with p values <0.05 were considered statistically significant.

Results: From SSc patients, 109/138 (79.0%) were positive for ACA (n=71; 51.4%), ATA (n=29; 21.0%), RNAP3 (n=7; 5.1%) or double positive ACA-ATA (n=2; 1.4%) Abs, while the remaining 29/138 (21.0%) were negative for these three Abs. Nineteen of the 29 (65.5%) negative patients were also negative for all tested novel biomarkers. In 10/29 (34.6%) either single or multi-positivity was observed for anti-Pm/Scl, U1-RNP, Th/To (Rpp25 and Rpp38), TERF1 and Ro52 Abs. Specificity for all SSc related biomarkers was over 93.0%. MIT3 and Ro52 were the most prevalent non SSc criteria Abs (17.4% and 16.6%, respectively). As expected, ACA, ATA and RNAP3 previously known associations with specific cutaneous phenotype and ATA and RNAP3 with the presence of ILD were confirmed (Table 1). Interestingly, Rpp38 and RuvBL1 were more frequently found in patients with ILD. Additionally, PUF60 isoform 6 was associated with the presence of diffuse cutaneous phenotype whereas TERF1 was more prevalent in patients with diastolic dysfunction. We did not find association between any of the Abs studied and neoplasia, cardiac arrhythmias or conduction disturbances, pericarditis or myocardial damage, myositis, pulmonary hypertension or esophageal motility disorders.

Conclusion: In our SSc cohort, PMAT-Aptiva showed a proper specificity and represents a suitable option for patients' evaluation. Confirmation of promising clinical associations for novel markers PUF60 (isoform 1 and 6), FHL1, RuvBL1 and TERF1 in larger SSc cohorts is warranted.

POS0616 THE CHARACTERISTICS OF PROGRESSIVE FIBROSING INTERSTITIAL LUNG DISEASE IN CONNECTIVE TISSUE DISEASES WITH SINGLE-CELL RNA SEQUENCING OF BRONCHOALVEOLAR LAVAGE FLUID

Keywords: -Omics, Comorbidities, Lungs

W. Fujii[1], A. Sakashita[1], A. Hirano[1], K. Baßler[2], M. Kadoya[3], A. Omoto[3], W. Fukuda[3], T. Seno[1], M. Wada[1], M. Kohno[1], Y. Kawahito[1]. *[1]Kyoto Prefectural*

University of Medicine, Inflammation and Immunology, Kyoto, Japan; [2]*Aimed Analytics, Data Analytics, Bonn, Germany*; [3]*Japanese Red Cross Kyoto Daiichi Hospital, Center for Rheumatic Disease, Kyoto, Japan*

Background: Connective tissue disease-associated interstitial lung disease (CTD-ILD) is a severe complication of rheumatic and musculoskeletal diseases, e.g. rheumatoid arthritis (RA), dermatomyositis (DM), systemic sclerosis (SSc) and so on. CTD-ILD is a heterogeneous syndrome driven by different diseases and cell types. This complexity provides a challenging field for elucidating the mechanism of the disease. Although some patients with CTD-ILD develop progressive fibrosing interstitial lung disease (PF-ILD) like as other ILD despite immunosuppressive treatment, it is difficult to predict which patients develop PF-ILD before treatment.

Objectives: The objective of this study is to find characteristics of immune cells and predictive biomarkers of PF-ILD in CTD-ILD patients.

Methods: We collected BALF and blood from 30 CTD-ILD and 12 idiopathic interstitial pneumonia (IIP) patients before treatment. Twelve out of 42 patients fulfilled PF-ILD criteria[1] in 1 year period. PF-ILD patients included 3 RA, 2 DM, 2 Sjögren syndrome, 1 ANCA-associated vasculitis, and 4 IIP patients. We applied Seq-Well, a portable platform of single-cell RNA sequencing[2], to analyze gene expressions in immune cells in BALF and blood. We compared the distribution of immune cells and differential gene expressions in BALF and blood between PF-ILD patients and patients without PF-ILD in CTD-ILD and IIP patients.

Results: We found that alveolar macrophages are the most abundant cell types in BALF of PF-ILD patients. We further classified alveolar macrophages and neutrophils into more detailed subsets based on their gene expression patterns and compared them between PF-ILD and patients without PF-ILD. In PF-ILD patients, we found increased $CXCL10^+$, $CXCL8^+$ alveolar macrophages and complement activation associated genes were upregulated in BALF. Moreover, we found increased interferon-induced proteins with tetratricopeptide repeats $(IFIT)^+$, $MMP\text{-}9^+$ and immature neutrophils, which were reported to be associated with severe COVID-19 pneumonia[3], in the blood of PF-ILD patients. Differentially expressed gene analysis revealed high levels of high mobility group box (HMGB)-2, IL-1β, and complement activation associated genes in alveolar macrophages in PF-ILD patients.

Conclusion: Alveolar macrophage phenotypes were changed in BALF while neutrophil phenotypes were changed in the blood of PF-ILD in CTD-ILD and IIP patients, which are consistent with the characteristics of severe COVID-19 pneumonia patients, suggesting common pathological pathways of lung fibrosis. We propose the hypothesis that alveolar macrophage phenotypic changes lead to complement and cytokine/chemokine mediated neutrophil activation and progression of PF-ILD (Figure 1). These cell subpopulations and up-regulated genes would be potential biomarkers or therapeutic target of PF-ILD in CTD-ILD patients.

POS0617 THE GASOTRANSMITTER HYDROGEN SULFIDE PROTECTS AGAINST CALCIFIC TENDINOPATHY VIA INHIBITION OF LYSYL OXIDASES

Keywords: Cell biology, Animal models

S. Nasi[1], I. Bernabei[1], E. Faure[1], D. Kronenberg[2], J. Bertrand[3], D. Ehirchiou[1], R. Stange[2], T. Hügle[1], N. Busso[1]. [1]*Lausanne University Hospital, CHUV, Department of Musculoskeletal Medicine, Lausanne, Switzerland*; [2]*Institute of Musculoskeletal Medicine, Department of Regenerative Musculoskeletal Medicine, Muenster, Germany*; [3]*Otto-von-Guericke University, Department of Orthopaedic Surgery, Magdeburg, Germany*

Background: Pathological calcification ((PC), *i.e.* the deposition of calcium-containing crystals) in tendons is a hallmark of calcific tendinopathy (CT), a disease associated with pain, tendon rupture, and disability. Currently, only symptomatic treatments exist for CT and none of them target specifically calcification. Intriguingly, the gasotransmitter H_2S has recently emerged as a potential anti-calcifying molecule [1].

Objectives: To establish in CT the potential anti-calcifying effect of hydrogen sulfide (H_2S) and of the H_2S-producing enzyme cystathionine gamma lyase (CSE), and the underlying mechanisms involved.

Methods: Wild type (WT) and CSE knock-out (KO) tenocytes were isolated from adult mice Achilles' tendons. Tenocyte were cultured in αMEM + 10% FBS + 50µg/ml ascorbic acid (Control medium) in presence of 10% calciprotein particles (calcification medium, CM). Spontaneous Achilles' tendon CT in old mice (35 weeks old) and surgery-induced Achilles' tendon CT in8-12 weeks old mice were quantified by micro computed tomography. Dynamic Young's modulus was measured in 35 weeks old mice as previously described [2]. Immunohistochemistry was performed on human and murine tendon sections with anti-CSE and anti-LOX and anti-LOXL2rabbit polyclonal antibodies. LOX expression was analyzed by qPCR and by Western-blot. LOX(L) activity was quantified in cells supernatants and lysates.

Results: *In vitro*, tenocyte calcification (in CM) was inhibited by exogenous H_2S-donors, while it was exacerbated in CSE KO tenocytes, producing as expected less H_2S than WT. Reduced calcification in tenocytes exposed to H_2S was accompanied by decreased expression of genes coding for BMP2, BMP4 and decreased activation of the BMP signaling pathway (pSMAD1/5/8).

Accordingly, BMPs expression and BMPs-pathway activation were exacerbated in CSE KO tenocytes compared to WT tenocytes. The protective role of CSE-H_2S was confirmed *in vivo.* Indeed, in aged mice, micro computed tomography revealed exacerbated Achilles' tendon calcification in CSE KO mice compared to WT. Interestingly, CSE deficiency led to reduced biomechanical strength, as the dynamic Young's modulus was significantly decreased upon increased tendon displacement. Furthermore, using a tenotomy model of CT, we found an inverse correlation between CSE expression and calcification in tendons. This was confirmed in human tendons from CT patients, which exhibited decreased CSE expression where calcification was present. In parallel experiments, we found that calcification in tenocytes was significantly reduced by addition of BAPN, a pan-inhibitor of lysyl oxidases (LOX(L)) enzymes. LOX(L) family includes 5 enzymes LOX and LOX1-4, catalysing elastin and collagen cross-links. We next investigated if the anti-calcfiying effect of H_2S in CT could be mediated by inhibition of LOX(L). Indeed, in CM-stimulated tenocytes we found that H_2S impacts both LOX/LOX2 expression (as CSE deficiency increased significantly LOX/LOX2 gene expression) and LOX(L) activity (as CSE deficiency increased LOX(L) activity and conversely H_2S dose-dependently inhibited LOX(L) activity in WT tenocytes. Finally, *in vivo* we discovered that, CSE was inversely correlated with calcification and LOX and LOXL2 expression in mouse and human tendons.
Conclusion: Altogether, our results suggest that increasing H_2S levels in tenocytes could represent a future strategy to prevent or decrease calcification in CT, likely via down-modulation of LOX(L) expression and activity.

POS0618 QUANTITATIVE RADIOMIC RISK SCORE STRATIFIES RESPONSE TO ANTI-FIBROTIC TREATMENT IN A PRECLINICAL LUNG FIBROSIS MODEL

Keywords: Imaging, Lungs, Animal models

Maurer[1]. *[1]University Hospital Bern, University of Bern, Department for Biomedical Research, Bern, Switzerland*; *[2]University Hospital zurich, University of Zurich, Center of Experimental Rheumatology, Zurich, Switzerland*; *[3]University Hospital Zurich, University of Zurich, Department of Radiation Oncology, Zurich, Switzerland*; *[4]University Hospital Zurich, University of Zurich, Institute of Diagnostic and Interventional Radiology, Zurich, Switzerland*; *[5]University of Bern, Core Facility Proteomics & Mass Spectrometry, Bern, Switzerland*; *[6]University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Schlieren, Switzerland*; *[7]Helmholtz Zentrum München, Institute of Lung Health and Immunity (LHI), Comprehensive Pneumology Center, Munich, Germany*

Background: Anti-fibrotic drugs aim at slowing disease progression in patients with fibrosing interstitial lung disease (ILD). Currently, only repeated pulmonary function tests and/or serial chest high resolution computed tomography (HRCT) scans spanning long periods can identify treatment responders. Imaging omics data («radiomics») from HRCT scans, which integrate pathophysiological information of the whole lung, may provide a powerful tool not only for prediction of disease progression as shown previously, but also for timely stratification of treatment response on an individual base[1].
Objectives: To explore the potential of HRCT-based radiomics for stratification of treatment response to an established anti-fibrotic drug in a preclinical model of fibrosing ILD.
Methods: Fibrosing ILD was induced in mice by intratracheal instillation of 2 U/kg bleomycin on day 0. Treatment with (a) the (non)receptor tyrosine kinase inhibitor nintedanib at 60 mg/kg q.d. (n=10) or (b) vehicle-only (n=13) q.d. was administered by gavage from day 7 to 21. Lung pre- and post-treatment MicroCT scans were acquired at 35 µm resolution from each mouse. Lung tissue was collected post-mortem on day 21. Radiomic features (n=1'386) were calculated from semi-automatically defined 3D lung volumes using the in-house developed software Z-Rad. Calculation of our composite quantitative radiomic risk score (qRISSc), developed for risk stratification of systemic sclerosis patients with ILD, was performed as previously described[1]. Changes between pre- and post-treatment conditions (=delta qRISSc) were used to stratify treatment response. Ashcroft scoring was used to evaluate severity of fibrosis. Markers of fibrosis and inflammation, as well as drug-associated targets, were assessed by gene expression profiling and immunostainings. Lung proteome profiles were acquired by mass spectrometry in data-independent acquisition mode using a nanoLC-MS/MS workflow. Analysis of differentially expressed proteins and pathway enrichment were performed using R packages «limma» and «clusterProfiler», respectively.
Results: Post-treatment, non-omics readouts showed that response to treatment was heterogeneous with varied inter-individual responses. Yet, time-resolved radiomics analysis, capturing the individual pre- and post-treatment disease status, reliably allowed the detection of treatment response. A delta qRISSc threshold was established to distinguish responders from non-responders. Immunostainings of corresponding tissue revealed reduced infiltrates of αSMA+ myofibroblasts and F4/80+ macrophages in responders. In addition, transcriptional levels of fibrotic (*Col1a1*, *Col3a1*, *Fn1*), inflammatory (*Ccl2*, *Il6*), and nintedanib-associated (*Tgfb1*, *Timp1*, *Cxcl1*) targets were lower in these samples. Differential protein expression analysis demonstrated that proteins downregulated in responders were enriched in pathways related to fibrosing ILD pathophysiology (Figure 1A). To identify a molecular basis of delta qRISSc, we performed correlation analysis to the proteome profiles of all samples, including controls. Thereby, qRISSc increase (=non-response) strongly correlated with activation of pathways related to fibrosis and nintedanib mode of action (Figure 1B). These results indicate that radiomic signature changes reflect drug response on a molecular level.

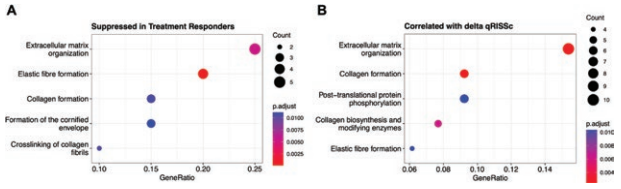

Figure 1. Reactome pathway enrichment analysis. (**A**) Differentially expressed proteins downregulated in treatment responders ($log_2FC<-0.3$, $p<0.05$). (**B**) Proteins correlated with delta qRISSc (Spearman's $\rho>0.5$, $p<0.05$).

Conclusion: Upon clinical validation, HRCT-based radiomics may provide a powerful tool for early distinction of patients benefiting from anti-fibrotic therapy and thus serve as a foundation for a more individualized and improved patient management.

Background: Systemic sclerosis-interstitial lung disease (SSc-ILD) is a severe complication that affects most SSc patients causing one-third of SSc-related

deaths [1]. There is an unmet need for predictive biomarkers of ILD to identify patients at risk, prior to clinical manifestation. Activated IFN-induced chemokines and proteins are implicated in the early inflammatory phase of SSc-ILD [2]. CXCL10 is an IFN-induced chemokine that is important in the chemoattraction of inflammatory cells in SSc-affected tissue [3,4].

Objectives: We investigated CXCL10 serum levels in SSc, SSc-ILD, and healthy controls (HCs) to understand whether CXCL10 levels differ between groups and potentially play a role in ILD pathogenesis. We also sought whether CXCL10 levels in serum mirror those in the lungs to investigate whether systemic levels reflect those of the affected organ locally. The transcriptomic study investigated CXCL10 expression in inflammatory SSc-ILD lung sections compared to fibrotic sections to show whether CXCL10 is more prominent in early disease. We also assessed whether CXCL10 could serve as a predictive biomarker for the new onset of SSc-ILD. Finally, to better comprehend the clinical observations, *in vitro* studies aimed to reveal the inflammatory/fibrotic effects of local and systemic fluids of SSc-ILD patients compared to SSc without ILD and controls.

Methods: One-hundred sixty-five SSc patients (SSc-ILD = 41) and 13 age- and sex- matched HCs were retrospectively followed from 2013 to 2020. Furthermore, 15 SSc patients (SSc-ILD = 7) were prospectively recruited for bronchoalveolar lavage (BAL) procedure. CXCL10 mRNA and protein levels were measured on various levels (serum, BAL, and SSc-ILD lung tissues) by ELISA and nanoString transcriptomic assay. Spearman's correlations were performed between CXCL10 levels in serum and lungs. Kaplan-Meier analyses were performed to evaluate predictability of SSc-ILD using CXCL10 levels at baseline. Human primary lung fibroblasts were treated with BAL fluid or serum from SSc without ILD or SSc-ILD patients. After stimulation, inflammatory (IL-6 and CXCL10)/fibrotic (α-SMA and TGF-β) genes were assessed using qPCR.

Results: At baseline, serum CXCL10 was significantly higher in SSc-ILD patients compared to SSc without ILD [Median (IQR): 126 (66-282) vs 79 (50-122), p = 0.004] and HCs [Median (IQR): vs. 4 (4-9), p < 0.0001]. BAL fluid CXCL10 levels in SSc-ILD patients were not significantly higher than those in SSc without ILD [Median (IQR): 457 (42-725) vs 134 (72-333), p = 0.2). However, BAL CXCL10 levels significantly correlated with serum levels (r = 0.7, p = 0.007). The nanoString showed that CXCL10 gene expression is significantly higher in inflammatory lung tissue compared to fibrotic tissue (fold change = 2.3, p = 0.029). Kaplan-Meier survival analysis (Figure 1) revealed that CXCL10 levels >3rd quartile at baseline in SSc patients significantly predicted new onset of ILD (p = 0.023). The *in vitro* studies showed that CXCL10 and IL-6 were significantly overexpressed in lung fibroblasts treated with SSc-ILD BAL fluid or serum compared to SSc without ILD [(CXCL10: p = 0.0043; p = 0.0087), (IL-6: p = 0.0022; p = 0.0043), respectively) and controls (all: p = 0.0022). On the contrary, TGF-β and α-SMA expression did not change after treatment in all groups.

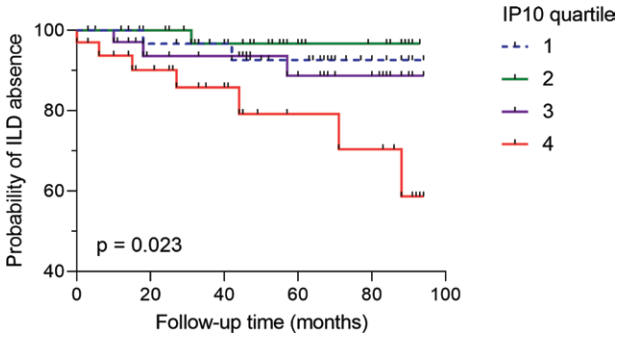

Figure 1. Kaplan-Meier survival curve according to baseline CXCL10 levels quartiles.

Conclusion: CXCL10 is a potential predictive biomarker for new onset of ILD in SSc patients. Further longitudinal studies with larger sample sizes are needed to verify the capability of CXCL10 to predict ILD. Additionally, our nanoString and *in vitro* data suggest that CXCL10 may play a significant role in the early development of SSc-ILD which might be amenable to therapeutic interventions.

Background: SSc is an autoimmune disease characterized by vasculopathy and tissue fibrosis. Oxidative stress is prominent in affected organs and is hypothesized to contribute to inflammatory and fibrotic damage. sGC is a heterodimeric enzyme that binds nitric oxide (NO) to a prosthetic heme group and catalyzes the production of cGMP. Released cGMP acts as a second messenger to regulate processes including tissue remodeling and immune/inflammatory response [1]. Pharmacologic modulation of sGC with a class of compounds called sGC stimulators have been shown to exert anti-fibrotic and anti-inflammatory effects in models of SSc [2]. In a phase II study in SSc, patients treated with the sGC stimulator Riociguat showed a trend towards clinical efficacy [3]. The action of sGC stimulators is dependent on NO-sGC complexes bearing a reduced heme molecule. In environments of oxidative stress, as seen in SSc, altered redox balance may limit efficacy of sGC stimulators due to heme oxidation and the formation of a pool of NO-insensitive sGC. A second class of sGC compounds, called sGC activators, are heme-independent and can act as a substitute for the heme-NO complex and in turn activate the sGC enzyme. Thus, sGC activators may show enhanced activity vs. sGC stimulators in conditions of compromised redox balance.

Objectives: To evaluate the efficacy of the potent sGC activator BI 685509 in cellular and in vivo models of SSc pathobiology.

Methods: Human dermal microvascular endothelial cells (HDMVEC) were cultured in normoxic or 1% O_2 conditions in the presence of BI 685509 ranging in doses from 0.04 to 10 µM. After 48 hrs, culture supernatant was collected and the concentration of TGFβ2 was determined. Human platelet rich plasma (PRP) was isolated and activated for 5 minutes with ADP in the presence of BI 685509 or Riociguat at doses of 0.1, 1 or 10 µM. Following activation, supernatants were collected and the level of CXCL4 was measured. For the bleomycin indued skin and lung fibrosis studies, adult female C57Bl/6 mice were used. Mice received intradermal injections of bleomycin every other day for six weeks or a single intratracheal injection. Mice were treated with BI 685509, Riociguat or Nintedanib daily beginning at day 21 (dermal) or 14 (lung) after initiation of bleomycin injection. At 6 (dermal) or 4 (lung) weeks post treatment initiation, skin or lung samples were analyzed via histologic analysis for various cellular and biochemical markers of tissue fibrosis.

Results: In HDMVEC, hypoxia induced production of the tissue remodeling factor TGFβ2 was significantly inhibited upon treatment with BI 685509 (10 µM). In the mouse model of bleomycin induced skin and lung fibrosis, activation of sGC via BI 685509 treatment at 1 mg/kg resulted in significant amelioration of skin thickness and lung fibrosis that was equivalent to mice treated with the standard of care Nintedanib (60 mg/kg) or the sGC stimulator Riociguat (1 mg/kg). Lastly, to mimic a NO deficient environment seen in SSc, human PRP was utilized. Induction of the SSc relevant chemokine

CXCL4 was effectively inhibited in activated PRP treated with the sGC activator BI 685509 whereas minimal inhibition was observed in samples treated with the sGC stimulator Riociguat. Inhibition of CXCL4 production in activated human platelet rich plasma treated with the sGC activator BI 685509

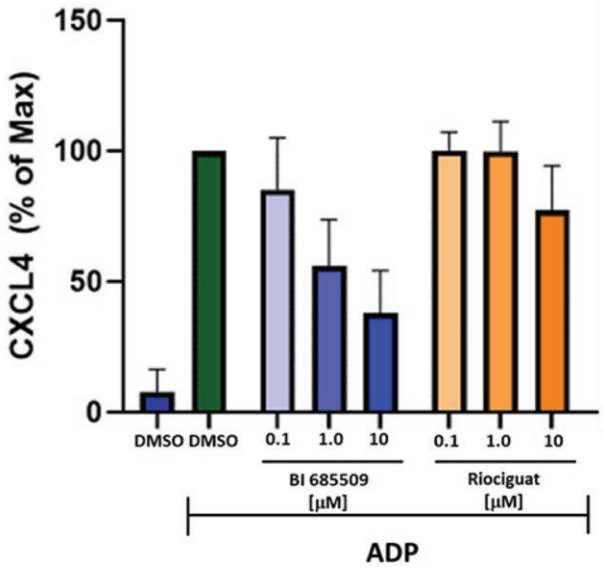

Figure 1.

Conclusion: Collectively, these results point to the use of the sGC activator BI 685509 as a novel treatment for SSc and suggests potential superior effects vs. sGC stimulators like Riociguat in this autoimmune disease.

POS0621 EFFECTS OF B CELL DEPLETION BY CD19-TARGETED CAR-T CELLS IN A MURINE MODEL OF SYSTEMIC SCLEROSIS

Keywords: Animal models, Systemic sclerosis

J. Avouac[1], A. Cauvet[2], C. Orvain[2], M. Boulch[3], P. Bousso[3], Y. Allanore[1].

[1]Cochin Hospital, Rheumatology, Paris, France; *[2]Institut Cochin, INSERM U1016, Paris, France*; *[3]Institut Pasteur, INSERM U1223, Paris, France*

Background: Chimeric antigen receptor (CAR)-T cells represent a potentially curative strategy for B cell malignancies. A first successful clinical experience has been reported in systemic lupus erythematosus, suggesting that CD19-targeted CAR-T cell transfer was feasible and tolerable [1].

Objectives: Since systemic sclerosis (SSc) and SLE are both severe diseases sharing B cell implication in their pathogenesis, we aimed at assessing the efficacy and tolerance of two B cell depletion strategies, including one with CD19-targeted CAR-T cells, in a preclinical model mimicking the severe lung damages observed in SSc.

Methods: B cell depletion strategies were evaluated in the Fra-2 transgenic (Tg) mouse model. We considered a first group of 16 untreated mice, a second group of 15 mice receiving a single intravenous (IV) dose (50 µg) of anti-CD20 monoclonal antibody (mAb) at day 1 and a third group of 8 mice receiving 50 µg anti-CD20 mAb IV at day 1 followed by the IV injection of $20*10^6$ CD19-targeted CAR-T cells at day 3. After 6 weeks, different validated markers of inflammation, lung fibrosis and pulmonary vascular remodeling were assessed.

Results: Following treatment with anti-CD20 mAb, CD19 expression was significantly decreased in peripheral blood and lesional lungs of Fra-2 Tg mice by 59% ($p<0.001$) and 40% ($p=0.019$), respectively, compared to control Fra-2. B cell depletion was even more pronounced in mice treated with CD19-targeted CAR-T cells: CD19 expression was decreased in peripheral blood and lungs of Fra-2 Tg mice by 92% ($p<0.001$) and 85% ($p<0.001$), respectively, compared to control Fra-2. CAR-T cell infusion increased mortality in Fra-2 Tg mice (**Figure 1A**). In line with the above findings, mice receiving CD19-targeted CAR-T cells displayed a significant increase in lung density (mean difference of 55±28 Hounsfield Units, $p=0.038$) (**Figure 1B-C**) and a marked reduction of functional residual capacity (mean difference of 25±9%, $p=0.041$) as compared to control Fra-2 when assessed by chest micro-CT imaging. CAR-T cell infusion significantly increased lung collagen content (mean difference of 11.93±4.44 µg/mL, $p=0.020$) (**Figure 1D**), histological fibrosis score (mean difference 1.74±0.48, $p=0.002$) (**Figure 1E-F**) and right ventricular systolic pressure mean difference 8.52±2.70 mmHg, $p=0.013$) (**Figure 1G**). CAR-T cells accumulated in lesional lungs and promoted T infiltration and activation: a significant increase of CD4+ effector memory T cells was observed in CD19-targeted CAR-T cell-treated Fra-2 Tg mice compared to Fc control Fra-2 Tg mice (mean difference of 32±%, $p=0.001$). Moreover, the fraction of CD69 and PD1-expressing cells was significantly increased within the CD4+ and CD8+ subsets in the lung of CD19-targeted CAR-T cell-treated Fra-2 Tg mice. Treatment with anti-CD20 mAb in monotherapy had no impact on lung inflammation-driven fibrosis and pulmonary hypertension.

Conclusion: B-cell therapies failed to show efficacy in the Fra2 transgenic mice. The exacerbated Fra-2 lung inflammatory burden stimulated accumulation and expansion of activated CD19-targeted CAR-T cells, secondarily inducing T-cell activation and systemic inflammation, finally leading to disease worsening.

Lee[2]. *[1]Gyeongsang National University and Hospital, Rheumatology, Internal Medicine, Changwon-si, Korea, Rep. of (South Korea)*; *[2]Gyeongsang National University and Hospital, Rheumatology, Internal Medicine, Jinju-si, Korea, Rep. of (South Korea)*; *[3]Chonbuk National University Medical School, Biomedical Sciences and Institute for Medical Science, Jeonju, Korea, Rep. of (South Korea)*; *[4]Research Center, BIFIDO Co., Ltd., Research Center, BIFIDO Co., Ltd., Hongcheon, Korea, Rep. of (South Korea)*

Background: Systemic sclerosis (SSc) is a chronic autoimmune disorder characterized by immune abnormalities, vasculopathy, and fibrosis of the internal organs[1]. Because the etiology of SSc is uncertain, drugs that improve the course of the disease and symptom are lacking. Recent data have highlighted the importance of the microbiome and its relevance to SSc. The microbiome can trigger an exacerbation of SSc. On the other hand, it may relieve symptoms. *Lactobacillus* and *Bifidobacterium* strains have been reported to alleviate gastrointestinal symptoms of SSc[2,3]. However, there are no study on the microbiome that improves the major symptoms of SSc, such as dermal and lung fibrosis.
Objectives: This study aims to screen SSc-associated microbiome at the species level using serum and to explore potential microbial targets for SSc treatment. And we evaluated whether the candidate microbial species ameliorate dermal and lung fibrosis.
Methods: We performed an immunoglobulin (Ig) M antibody microarray against 384 microbial species in the serum from SSc patients and healthy control (HC). Then, the antifibrotic effect of candidate microbial species was investigated using a bleomycin (BLM)-induced fibrosis model in mice.
Results: *Bifidobacterium (B.) longum* RAPO, which was less abundant in the serum of patients with SSc than HC, alleviated BLM-induced skin and lung fibrosis in mice. The administration of *B. longum* RAPO normalized fecal microbial diversity with an increase in short-chain fatty acid-producing bacteria. Moreover, infiltrated inflammatory monocytes or macrophages in the spleen, the skin, and bronchoalveolar lavage of BLM-injected mice were significantly reduced by treating *B. longum* RAPO. In vitro, *B. longum* RAPO downregulated LPS-induced inflammatory cytokines gene expression in mouse macrophage cell Raw 264.7.
Conclusion: *B. longum* RAPO could have an antifibrotic effect on skin and lung fibrosis through gut microbial restoration and macrophage regulation in BLM-induced fibrosis mice. Microbial intervention would be a potential option for SSc treatment.

POS0623 INTEGRATED SERUM PROTEOMIC AND METABOLOMIC PROFILES IN SYSTEMIC SCLEROSIS PATIENTS CHARACTERIZE NEW BIOMARKERS ASSOCIATED TO RELEVANT PATHOLOGICAL FEATURES

Keywords: Biomarkers, -Omics, Systemic sclerosis

I. Sanchez-Pareja[1], R. Ortega Castro[1], F. U. Pilar[1], T. Cerdó[1], L. Muñoz-Barrera[1], M. C. Ábalos-Aguilera[1], C. Merlo[1], P. Ortiz Buitrago[1], N. Barbarroja Puerto[2], E. Collantes Estevez[1], M. A. Aguirre[1], C. Perez-Sanchez[3], C. Lopez-Pedrera[1]. *[1]IMIBIC/Reina Sofia Hospital/University of Cordoba, Rheumatology, Córdoba, Spain*; *[2]IMIBIC/Reina Sofia Hospital/University of Cordoba, Medical and Surgical Science, Córdoba, Spain*; *[3]IMIBIC/Reina Sofia Hospital/University of Cordoba, Cell Biology, Physiology and Immunology, Córdoba, Spain*

Background: Systemic sclerosis (SSc) is a heterogeneous multisystemic autoimmune disease, characterized by extensive skin fibrosis, vascular abnormalities, and autoantibodies against various cellular antigens. The integrated analysis of proteomic and metabolomic in SSc might shed light in the pathogenesis of the disease and reveal novel biomarkers.
Objectives: The aim of this study was to characterize the circulating proteomic and metabolomic profiles in SSc and their association with key clinical features.
Methods: Serum NMR metabolomics (Nightingale; 250 metabolites covering glycolysis metabolites, amino acids and lipid measures), and proteomics, involving the analysis of 92 organ damage-related proteins [by proximity extension immunoassay (PEA, Olink)] were performed on serum from 72 SSc patients and 43 age-matched healthy donors (HD).
Main disease complications in the SSC cohort, including lung fibrosis, skin fibrosis, renal, vascular, and esophageal involvement were assessed, and prevalence of circulating autoantibodies, along with standard demographic and inflammatory parameters were analyzed by multiple t-test. Unsupervised hierarchical clustering methodologies were applied using Metaboanalyst software to identify subgroups of patients based on their proteomic profiles. Gene ontology enrichment was used to interrogate the biological meaning of the distinctive molecular signatures identified.
Results: Sixteen circulating proteins related to organ damage (9 increased and 7 reduced) as well as 143 metabolites (37 increased and 101 reduced) were found altered in SSc patients in relation to HD. Unsupervised clustering analyses differentiated 3 patients clusters presenting different proteomic profiles. Clinically, patients belonging to cluster 1 (C1) were characterized by a significant prevalence of multiple organ involvement (84%) in relation to C2 (52%) and C3 (43%), mostly encompassing lung and skin fibrosis and esophageal dysmotility. Immunologically, C1 further displayed the highest percentage of positivity for anti-scl70 antibodies. Nineteen proteins were identified as significantly altered in cluster 1 (C1) in relation to C2 and C3, mostly involved in biological processes such as cell proliferation, apoptosis, cell adhesion, migration, and immune response. Among them, two were functionally linked with cutaneous diseases (CALR and BANK1), two with digestive disorders (FGR and STXBP3) and three with lung disfunction (FOSB, SMAD1 and FOXO1). Levels of some overexpressed proteins in C1 (BID, INPPL1, BANK1 and FOSB) were further related to the positivity for anti-scl70, the specific SSC-autoantibody mostly associated to a bad prognosis and multiple organ involvement in SSC. Interestingly, thirty-five metabolic markers were found deregulated when comparing those proteomic clusters of SSC, comprising lipoprotein subsets, sphingomyelins, cholesterol, lactate, and albumin. Moreover, significant correlations were identified among the levels of proteins and metabolites found deregulated, pointing at a concordance on their involvement in mechanisms underlying the disease process.
CONCLUSION:
1) Serum proteomic and metabolomic signatures are significantly altered in SSC patients and associated to relevant clinical profiles.
2) Clinical classification of SSc patients could be improved based on serum proteomic and metabolomic profile, adding new insights to the underlying pathophysiological mechanisms.

POS0624 BAG3 PROTEIN: A PROMISING NOVEL BIOMARKER OF FIBROSIS IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Biomarkers, Lungs

M. De Marco[1,2], A. Falco[2], F. Reppucci[2], L. Marzullo[1,2], A. Rosati[1,2], G. Armentaro[3], A. Minniti[3], C. Iannone[4], N. Del Papa[3], R. Caporali[4,5], M. C. Turco[1,2]. *[1]University of Salerno, FIBROSYS s.r.l., Baronissi (SA), Italy*; *[2]"Schola Medica Salernitana" University of Salerno, Department of Medicine, Surgery and Dentistry, Baronissi (SA), Italy*; *[3]ASST Gaetano Pini-CTO, Scleroderma Clinic, Rheumatology Dept., Milano, Italy*; *[4]University of Milan, Department of Clinical Sciences and Community Health, Research Center for Adult and Pediatric Rheumatic Diseases, Milano, Italy*; *[5]ASST Gaetano Pini-CTO, Rheumatology Dept., Milano, Italy*

Background: Systemic Sclerosis (SSc) is a rare autoimmune disease characterized by an abnormal remodelling of tissue matrix, leading to fibrosis of skin and internal organs. Despite progresses made in terms of knowledge of pathogenic mechanisms, no study has yet identified specific biomarkers useful for assessing disease evolution and response to therapies. Bcl2-associated athanogene 3 (BAG3) protein is a member of a family of co-chaperones that interact with the ATPase domain of the heat shock protein (Hsp) 70 through their BAG domain. BAG3 is constitutively present in a few normal cell types and some tumours, while its expression is induced by stressful stimuli in a wide variety of cells. BAG3 interacts with several partner proteins regulating different pathways, including apoptosis, autophagy and motility. Recent studies have demonstrated a pivotal role of extracellular BAG3 in pro-tumor cell signaling in the tumor microenvironment, as well as its involvement in the development of fibrosis in tumor tissues

[1]. In addition, a strong correlation between *bag3* gene expression and patients' survival was found in several types of fibrotic tumors [1].

Objectives: Our aim was to evaluate the presence of BAG3 in the serum of patients with SSc and to investigate whether circulating levels of BAG3 could have any relationship with different SSc subsets and disease features.

Methods: We enrolled SSc patients, all classified according to the ACR-EULAR criteria. Videocapillaroscopy (NCV) was performed at the time of serum collection. Lung involvement was assessed by spirometry and high-resolution chest CT. Patients were classified into 3 subgroups (no ILD, limited ILD, and extensive ILD) according to the diagram described by Goh et al.[2]. SSc disease activity was assessed according to the activity indices defined by the EUSTAR score [3]. Evaluation of BAG3 protein in serum samples was performed by a sandwich ELISA assay.

Results: The study cohort included 106 SSc patients (47 were classified with lcSSc and 59 with dcSSc) and 100 sex and age matched healthy controls (HC). Serum levels of BAG3 were significantly higher in SSc patients (mean value 85,3 pg/mL, 95% confidence interval CI 47,2-123,4) when compared with HC (0,68 pg/mL, 95%CI 0,13-1,23) (p=0.001). When analyzed according to disease subset, dcSSc patients showed values (143,3 pg/mL, 95%CI 78-208,5) significantly higher and lcSSc patients (8,7 pg/mL, 95%CI 1,64-15,9,5) (p=0.001). No correlation was found between BAG3 levels and digital ulcers, mRSS and disease activity. Conversely, BAG3 values positively correlated with the extent of lung damage (237,8 pg/mL, 95%CI 131,2-344 in the extensive lung disease vs 16,3 %CI 7,5-25,3 in the limited). Finally, BAG3 values were significantly higher in patients with late NVC pattern in comparison with NVC pattern early/active (p=0.0008).

Conclusion: Recent studies have highlighted a central role of extracellular BAG3 in maintaining the tumour microenvironment, as well as in the development of fibrosis in neoplastic tissues. To our knowledge, the presence of BAG3 in the serum of patients with SSc has never been described in the literature.

Serum levels of BAG3 were found to be significantly higher in the dcSSc, mostly in those with lung involvement. This is not surprising since the diffuse form of disease has more extensive fibrosis, both in the skin and lung, than lcSSc. Accordingly, BAG3 values correlated with the late pattern at NVC, the one most frequently associated with the more advanced and fibrotic stages of the disease. Conversely, serum BAG3 values did not correlate with disease activity, since these scores reflect the evolution and progression of disease rather than the extent of fibrosis. Indeed, the close correlation between BAG3 levels and the more fibrotic features of the disease, suggests that BAG3 might be a new promising marker of fibrosis.

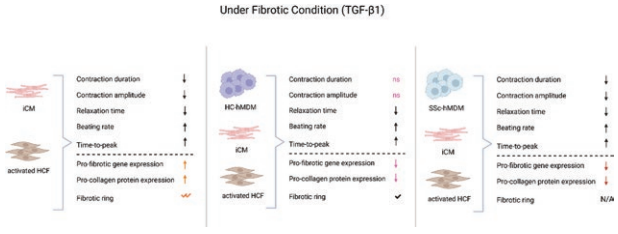
POS0625 EFFECTS OF DIFFERENTIATION STAGES OF HEALTHY AND SSC MACROPHAGES ON THE 3D HUMAN CARDIAC FIBROSIS MODEL

Keywords: Cardiovascular disease, Heart, Systemic sclerosis

L. Provenzale[1], A. Hukara[1], I. Kocherova[1], E. Pachera[1], A. Laimbacher[1], O. Distler[1], P. Blyszczuk[1], G. Kania[1]. [1]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, University of Zurich, Schlieren, Switzerland

Background: Activated cardiac fibroblasts, key regulators of cardiac fibrosis, control contraction of human fibrotic cardiac microtissues (MT)[1]. Macrophages regulate fibrotic process by interfering with the extracellular matrix (ECM) turnover. The heart is one of the primary organs affected in systemic sclerosis (SSc).



Objectives: To study the role of healthy donor- and SSc patient-derived macrophages in the functions of 3 dimensional (D) human cardiac MT fibrosis model.

Methods: CD14$^+$ blood-derived monocytes from healthy controls (HC) and SSc patients were isolated and differentiated into human monocyte-derived macrophages (hMDM) using human monocyte colony-stimulating factor (hM-CSF). A timeline of macrophage differentiation stages was performed by incubation of the CD14$^+$ cells for 1,3,5 and 7 days (d) with hM-CSF. One MT was generated by 4'000 human induced pluripotent stem cell-derived cardiomyocytes (iCM), 1'000 human cardiac fibroblasts (HCF) and 1'000 HC or SSc hMDM, mixed in a ratio 4:1:1 (HC-hMDM:iCM:HCF-MT or SSc-hMDM:iCM:H-CF-MT), and formed by self-assembling in plates with ultra-low-attachment surface. Control MTs were composed with iCM/HCF in a ratio 4:1/4:2 (iCM:H-CF-MT). Two days after MT assembly, the fibrotic condition was induced with transforming growth factor β1 (TGF-β1) for 10d. Contraction of each MT was assessed by recording videos, applying MUSCLEMOTION[2] and subsequent evaluation by relaxation time (ms), contraction amplitude (a.u.), contraction duration (ms), time-to-peak (ms) and beating rate (bpm). The level of fibrosis was analysed on several levels: mRNA by qPCR, ELISA to measure secreted pro-collagen-Iα1, immunohistochemistry (IHC) using Sirius Red to visualize collagen depositions and degree of fibrosis. Apoptosis was assessed using Caspase-3/7 assay.

Results: Control-iCM:HCF-MTs (n=23-49), following TGF-β1 stimulation, revealed a shorter contraction duration (p<0.01) and a lower contraction amplitude (p<0.0001) but not altered contraction duration (p=0.5095) and contraction amplitude (p=0.7298) compared to untreated-iCM:HCF-MTs. Interestingly, untreated-SSc-hMDM:iCM:HCF-MTs showed a shorter time-to-peak (p<0.0001), lower beating rate (p<0.01) and higher contraction amplitude (p<0.01) compared to untreated-HC-hMDM:iCM:HCF-MTs (n=41-81, both conditions 3d). Next, TGF-β1-stimulated SSc-hMDM:iCM:HCF-MTs exhibited a lower contraction duration (p<0.01) and contraction amplitude (p<0.0001), shorter relaxation time (p<0.0001), and higher beating rate (p<0.0001) compared to TGF-β1-stimulated HC-hMDM:iCM:HCF-MTs (n=33-42, both conditions 1d). Upon TGF-β1-stimulation, control-iCM:HCF-MTs showed significantly increased profibrotic genes: *ACTA2* (p<0.001) and *COL1A1* (p<0.01) (n=4-5), secreted human pro-collagen Iα1 (n=9-10, p<0.0001), and formed visible collagen-rich fibrotic ring. Remarkably, under fibrotic conditions, addition of HC or SSc hMDM into iCM:HCF-MTs resulted in lower mRNA expression of *ACTA2* (n=4-5, p<0.05, both conditions 7d) and *COL1A1* (n=4-5, p<0.05, both conditions 7d), lower excretion of human pro-collagen Iα1 protein (n=9-10, p<0.0001, both conditions 7d) and lack of collagen-rich fibrotic ring compared to control-iCM:HCF-MTs. Importantly, independently of culture duration of HC or SSc hMDM, before MT assembly, a similar reduction in profibrotic gene and protein expression was observed. Lastly, the level of apoptosis was similar in all three undifferentiated or TGF-β1-stimulated MTs types.

Conclusion: For the first time, the combination of iCM, HCF and hMDM in a 3D fibrotic cardiac MT model has been established and investigated. Under fibrotic conditions, addition of HC- but not SSc-hMDM into iCM:HCF-MTs influenced MT contractility. Importantly, both HC- and SSc-hMDM reduced TGF-β1-induced fibrotic responses.

POS0626 PERTURBED LIPID METABOLISM IS A CENTRAL METABOLIC REPROGRAMMING HUB IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, -Omics, Skin

B. Burja[1,2], H. Rehrauer[3], D. Paul[4], M. Whitfield[5], M. Tomsic[2], Z. Rotar[2], M. Robinson[4], O. Distler[1], K. Lakota[2], M. Frank Bertoncelj[6]. Background: Perturbed cellular metabolism has been increasingly associated with fibroblast activation in fibrosis. A deeper understanding of metabolic rewiring might help to unravel the interplay between the metabolic and fibrotic pathways in systemic sclerosis (SSc).

Objectives: We aimed to identify transcriptomic alterations in metabolic pathway-related genes in fibrotic SSc skin and unravel whether fibroblasts could contribute to the perturbed skin metabolic networks in SSc.

Methods: We integrated transcriptomic microarray data from skin (clinically affected forearm and non-affected back skin) of 76 SSc patients and 26 healthy controls (HC, forearm skin) from three distinct cohorts (GSE:45485, 59785, 9285/32413). Differentially expressed (DE) genes (FDR<0.05) between healthy and SSc skin were identified using the limma package. The supervised gene set enrichment analysis (GSEA) was based on DE genes using the clusterProfiler package, focusing on metabolic pathways. Transcriptional changes in SSc skin were compared to the TGFβ-induced changes in transcriptomes of primary human skin fibroblasts, measured by RNA-seq and scRNA-seq. For these experiments, cultured healthy skin fibroblasts were treated or not with TGFβ for 24h.

Results: Pathway enrichment analysis of DE gene in skin transcriptomes identified multiple alterations of metabolic pathways in SSc skin (Figure 1A) compared to healthy skin, pointing to enhanced pyrimidine/folate metabolism and suppressed lipid metabolism in SSc skin. Steroid hormone biosynthesis (*AKR1, DHRS11, CYP1A2, SULT2B1, HSD1, EHTM2, HSD11B2*), fatty acid synthesis (*FASN1, FADS1, FADS2, ELOVL, SCD5, PTPLB*), and fatty acid degradation (*ACAT1/2, ACADS, ACAA1/2, ACADM, ACSL3*) were the main downregulated lipid metabolism pathways in SSc skin, particularly in patients with the inflammatory intrinsic gene expression subset. The latter changes were detected in the affected and non-affected SSc skin, suggesting that altered lipid metabolism is a generalized feature of the SSc skin. Furthermore, pathway enrichment analysis of TGFβ-induced transcriptional changes in skin fibroblasts, as detected by RNA-seq and scRNA-seq, suggested that TGFβ-driven reprogramming could significantly contribute to the lipid metabolism perturbations in SSc skin (Figure 1B, C). Specifically, STRING analysis revealed that TGFβ suppressed metabolic networks of glycerophospholipids, arachidonic acid, and fatty acids in cultured skin fibroblasts (Figure 1D).

Conclusion: Our data suggest perturbed lipid metabolic networks in SSc skin and identify skin fibroblasts, exposed to profibrotic milieu, as likely contributors to the altered lipid metabolism in SSc. These results might pave the way to a deeper understanding of the interplay between the metabolic and fibrotic pathways in SSc. Integrating these data with future metabolomic and single-cell studies could accelerate the discovery of potential metabolic targets in SSc.

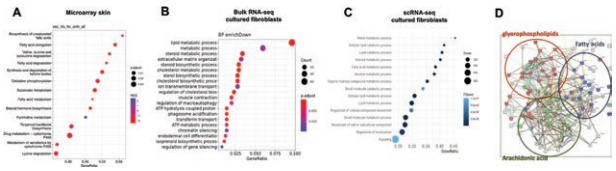

Figure 1. A) Enriched metabolic pathways in SSc skin compared to healthy skin based on DE gene expression. Downregulated GO biological processes in TGFβ-treated cultured healthy skin fibroblasts based on RNAseq (B) and scRNAseq (C) analyses. D) STRING pathway enrichment analysis of downregulated genes (RNA-Seq) linked to lipid metabolism in TGFβ-stimulated skin fibroblasts.

Background: Systemic sclerosis-primary heart involvement (SSc-pHI) accounts for up to one-third of SSc-related deaths and clinically apparent pHI portends poor outcome. Early detection of SSc-pHI is therefore crucial. We have previously shown cardiovascular magnetic resonance (CMR)-detected subclinical myocardial abnormalities. Identifying robust blood biomarkers of SSc-pHI would facilitate diagnostic testing, help to resolve the biological mechanisms underpinning SSC-pHI and potentially identify new targets for drug development.

Objectives: To identify protein biomarkers associated with subclinical cardiovascular abnormalities as defined by CMR measures in SSc patients, and predominant inflammatory and cardiometabolic pathways implicated.

Methods: Seventy-eight patients from CONVAS ('CONnective Tissue Disease and VASculitis Cohort') and ELCASA ('ELectrophysiology and CArdiac imaging in SclerodermA')1 study cohorts underwent CMR imaging. Using Olink Proximity Extension Assay, normalised protein expression (NPX) across cardiometabolic, cardiovascular II/III and inflammation panels was measured in these patients at the time of CMR. Generalised linear regression with Benjamini Hochberg correction for multiple testing was used to identify significant proteins associated with CMR parameters of myocardial oedema/fibrosis [native T1, myocardial extracellular volume (ECV) and late gadolinium enhancement (LGE)] and vascular stiffness [aortic distensibility]. Subsequently, an expanded protein-protein interaction (PPI) network was created using an induced network approach (String-DB) with k-means clustering applied to identify enriched functional clusters that were then subjected to Gene Ontology (GO) and KEGG enrichment analysis.
Results: Of 355 proteins analysed, 70 proteins were associated with myocardial tissue oedema/fibrosis (64 proteins; 26 positively, 38 negatively) and vascular stiffness (6 proteins; 2 positively, 4 negatively). 2 overlapping proteins that associated with focal (LGE) and diffuse fibrosis (ECV) were identified. *Proteins identified include those involved in coagulation cascade (estimate = -1.97, 95%CI = -3.63 to -0.31, adj.p = 0.039), carbohydrate binding and opsonisation activities (estimate = -1.31, 95%CI = -2.19 to -0.43, adj.p = 0.006); and cancer and neovascular inflammatory conditions (estimate = -75.79 95%CI = -119.81 to -31.76, adj.p = 0.002). K-means clustering of the expanded PPI network (enrichment p.value < 1.0e-16) identified 4 clusters (Figure 1) with roles in TNF receptor superfamily binding and NF-kappa B signalling pathway (red); Vascular endothelial growth factor-activated receptor activity and Rap1 signalling pathway (yellow); IL-10 receptor activity and JAK-STAT signalling pathway (blue); and FGF activated class receptor binding and ErbB signalling pathway (green). Proteins associated with CMR detected subclinical myocardial tissue oedema/fibrosis mainly mapped to yellow and blue clusters.
Conclusion: In this first proteomic study of SSc-pHI, we have identified 70 protein biomarkers, with myocardial tissue oedema/fibrosis associated with inflammation and vascular pathways. The next step is to validate these proteins and test the utility of network proteins in an independent patient cohort that could aid detection and diagnosis of SSc-pHI. *Proteins names not disclosed as subject to Intellectual Property discussions via Innovation Factory, University of Manchester.

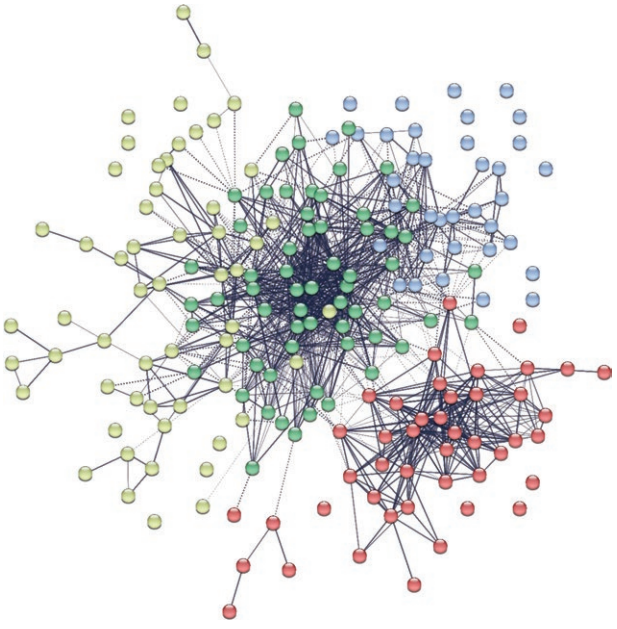

Figure 1. K-means clustering of the expanded PPI network. Four enriched functional clusters were identified using STRINGdb.

POS0628 BARICITINIB AMELIORATES BLEOMYCIN-INDUCED PULMONARY AND SKIN FIBROSIS VIA JAK 1/2 INHIBITON

Keywords: Lungs, Animal models, Systemic sclerosis

S. Gulle[1], A. Çelik[2], B. Lebe[3], Ç. Ulukuş[3], M. Barış[4], D. Harmancı[5], M. Birlik[1], O. Yılmaz[2]. *[1]Dokuz Eylul University School of Medicine, Rheumatology, Izmir, Turkey*; *[2]Dokuz Eylul University, Laboratory Animal Science, Izmir, Turkey*; *[3]Dokuz Eylul University School of Medicine, Pathology, Izmir, Turkey*; *[4]Dokuz Eylul University School of Medicine, Radiology, Izmir, Turkey*; *[5]Ege University, Central Research Test and Analysis Laboratory Application and Research Center, Izmir, Turkey*

Background: Signal transducer and activator of transcription 3 (STAT3) protein is activated in lung fibroblasts and alveolar type II cells (AT-II) and is thought to contribute to fibrosis in lung tissue. Significant JAK/STAT activation was demonstrated in fibroblasts, skin biopsies and scleroderma animal models of patients with Systemic Sclerosis (SSc) [1].
Objectives: The aim of this study was to determine whether inhibition of JAK2/STAT3 in the experimental model of scleroderma is a potential therapeutic strategy for this disease and to investigate the effects of the JAK 1-2 inhibitor Baricitinib (BAR) on the experimental model of dermal and pulmonary fibrosis.
Methods: Thirty-two healthy 6-8 weeks old female C57BL mice with an average weight of 22±3 grams were included in our study. Before the treatment (baseline), day 15 and day 30 (day 30) the same back area was shaved in all mice and skin thickness was measured under the guidance of skin Ultrasound Biomicroscopy (US). US measurements were chosen to be at least >1 cm from the injection area. Whole lung Computed Tomography (CT) scans of each animal were acquired at post-treatment (day 30). H&E and Masson's Trichrome staining were performed to evaluate skin thickness, pulmonary alveolitis, and fibrosis. The Ashcroft score was assessed on Sirius Red stained lung sections post-treatment. For the molecular evaluation of tissue fibrosis, collagen and α-SMA levels were measured in skin and lung tissues by qRTPCR.
Results: We found that BAR resulted in favorable therapeutic outcomes by affecting the inflammation infiltration and collagen deposition both lung and skin tissues. Immunohistochemical results showed that BAR downregulated the levels of COL1A1 and COL1A2.Treatment with JAK 1-2 selective BAR has been shown to ameliorate BLM-induced skin and lung fibrosis at radiological, pathological and molecular measurements.
Conclusion: As a result of our study, the effect of JAK1-2 selective inhibitor baricitinib treatment on reducing skin and lung fibrosis in a mouse model created with BLM was demonstrated with radiological and pathological examinations. We conclude that JAKinh treatments will be an important research area for the treatment of SSc and other fibrotic diseases in the future.

DIFFERENT GUT MICROBIOME PROFILES AMONG PATIENTS WITH SYSTEMIC SCLEROSIS COMPARED TO RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Gastrointestinal tract, Systemic sclerosis

Y. Braun-Moscovici[1], N. Asulin[2], K. Dolnikov[1], V. Shataylo[1], S. Giryes[1], D. Markovits[1], R. Erlich[1], K. Toledano[1], Y. Tavor[1], A. Balbir-Gurman[1], O. Koren[2]. *[1]Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Rheumatology Institute, Haifa, Israel*; *[2]Azriely Faculty of Medicine, Bar-Ilan University, Microbiome research laboratory, Safed, Israel*

Background: A growing body of evidence suggests that the gut microbiota plays a significant role in the development of autoimmune diseases. An altered microbiota composition has been associated with gastrointestinal and extraintestinal features in systemic sclerosis (SSc) patients.
Objectives: To characterize differences in the gut microbiota between SSc patients and rheumatoid arthritis (RA) patients and to look for associations between microbial profiles and SSc subtypes, disease manifestations and treatment.
Methods: SSc and RA patients seen at our center were recruited in a prospective study. The exclusion criteria included antibiotic or probiotic treatment during the month prior to recruitment, recent hospitalizations, BMI>30, diabetes mellitus or concomitant inflammatory bowel disease. Fecal samples were collected and processed and 16S rRNA gene sequences were analyzed using the QIIME2 package. Microbiome composition was determined, beta diversity and alpha diversity were calculated and ANCOM analyses was performed.
Results: During 7/2018-4/2022, 49 SSc patients (mean age [SD] 53.5[13.8] and disease duration 9.4 [8.0] years) and 21 RA patients (mean age [SD] 57.1[10.4] and disease duration 15.1[10.0] years) fulfilled the criteria and were willing to participate in the study. Significant differences in beta diversity (Unweighted q=0.019, and Weighted UniFrac q=0.005) were found between RA and SSc patients' stool microbiota, but not in alpha diversity. Composition analysis revealed higher abundance of Actinomyces and relative paucity of Coprococcus Eutactus among SSc patients compared to RA. Significant variations in beta diversity (unweighted and weighted) were associated with the subtype of SSc (diffuse - 27 vs limited - 22 patients, p [weighted] = 0.01), occurrence of interstitial lung disease (22 patients, p=0.011), renal crisis (3 patients, p=0.016), immunomodulatory treatment (33 patients, p=0.018) and biological treatment (11 patients, p=0.017). Composition analysis revealed higher relative abundance of Firmicutes in patients with GAVE [12]. Patients on biologicals (11) had higher abundance of Synergistaceae and lower of Firmicutes. The changes were consistent in recurrent fecal samples.
Conclusion: Significant differences on beta diversity were found between RA and SSc patients' gut microbiota, but not on alpha diversity. Diffuse SSc, interstitial lung disease, renal crisis and immunomodulatory treatment were associated with shifts in the microbiome of SSc patients. The impact of these changes on SSc disease progression needs further elucidation.

Background: Anti-drug antibodies (ADAb) may be involved in loss of response or primary failure of bDMARDs in rheumatoid arthritis (RA). However, evidence in prospective clinical studies of diminished response to treatment in presence of ADAb is rare and restricted to monoclonal anti-TNF antibodies[1].
Objectives: In this analysis of the prospective European trial ABIRISK we aimed to analyze how ADAb might influence response to several bDMARDs in RA.
Methods: RA patients resistant to methotrexate and starting a bDMARD (anti TNF, anti IL-6 R and anti CD20) were included in 4 countries (ABIRA, NCT02116504). They had a clinical assessment and ADAb quantification at 6, 12, and 15 to 18 months. ADAb were detected using mesoscale discovery (MSD) technology. They were defined as transient if they were negative after a positive time point and persistent positive if they were positive at two sequential visits without negative timepoints afterwards. ADAb positivity was defined as having been ADA positive at least in one visit in the first 12 months. The primary endpoint was the EULAR response at 12 months. Association with ADAb was analyzed using univariate logistic regression. Patients withdrawing for side effects or for inefficacy were considered as non-responders. We also performed a univariate and a multivariate analysis through a generalized estimating equation (GEE) model that analyzes the EULAR response and ADAb status for each visit starting at 6 months. This allows taking advantage of all the data available in the study. The effect of methotrexate on ADAb was also studied. Finally, we performed drug concentration measurements for anti-TNF drugs.
Results: 230 patients were included treated with: adalimumab or infliximab = monoclonal TNFi (mTNFi, N=68); etanercept (ETN, N=82), rituximab (RTX N=30) or tocilizumab (TCZ N=50). ADAb were positive in 38,2% of the mTNFi-treated patients, 50% of the RTX-treated and 20% of the TCZ-treated patients. ADAb positivity was negatively associated with EULAR response at 12 months for all drugs OR=0.20 [0.10-0.42]. Only persistent and not transient ADAb were negatively associated with EULAR response at 12 months (persistent ADAb vs ADAb negative OR 0,17 [0.06-0.43] transient ADAb vs ADAb negative, p=0.57). This was also the case for mTNFi alone (persistent ADAb vs ADAb negative OR 0,1; p=0,0051; transient ADAb vs ADAb negative, p=0,99). 6% of ETN patients presented ADAb, always transient. In the GEE longitudinal analysis there was a negative association between ADAb positivity and response to all treatments (OR 0,36 [0.20-0.64]) and individually for TCZ (OR=0.18 [0.04-0.83]) and mTNFi (OR 0,44; p=0,097 trend). In the multivariate analysis, the ADAb status remained independently associated with non-response to treatment (Figure 1). Methotrexate co treatment at baseline was negatively associated with ADAb (OR=0.5 [0.25-1.00]). There was a significantly lower concentration of adalimumab and infliximab in ADAb positive patients compared to ADAb negative. There was a significantly higher concentration of adalimumab and etanercept in EULAR responder patients compared to EULAR non-responders.
Conclusion: This prospective multicenter study demonstrates that ADAb are frequently detected and associated with non-response to bDMARDs in RA. It is the first study demonstrating the association between ADAb and non-response to TCZ. Monitoring of ADAb should be considered in the personalized management of RA patients particularly in non-responder patients.

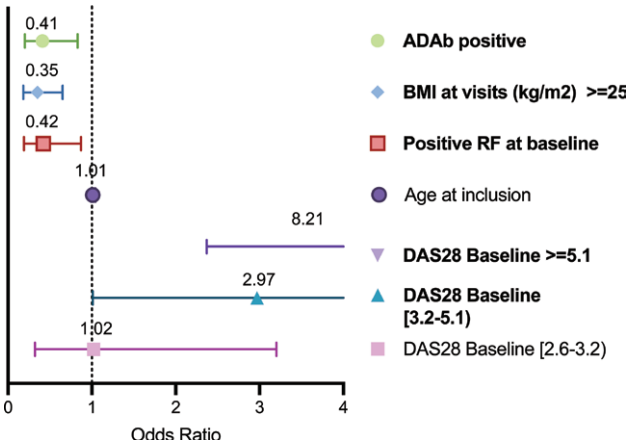

Figure 1. Multivariate analysis of parameters associated with EULAR response in the GEE analysis from M6 onwards.

POS0631

TNF INHIBITOR USE AFFECTS BIRTH WEIGHT INDEPENDENTLY OF THE SFLT-1/PLGF RATIO IN PREGNANT WOMEN WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Pregnancy and reproduction, Biomarkers

C. Witte-Quaak[1], A. Kluivers[2], H. T. Smeele[3], R. I. Neuman[4], L. Saleh[2], A. H. J. Danser[4], R. Dolhain[3]. *[1]Rotterdam, Department of Rheumatology and Department of Internal Medicine; Division of Pharmacology and Vascular Medicine, Rotterdam, Netherlands*; *[2]Erasmus Medical Center, 2.Department of Internal Medicine; Division of Pharmacology and Vascular Medicine and 3.Department of Gynaecology and Obstetrics, Rotterdam, Netherlands*; *[3]Erasmus Medical Center, Department of Rheumatology, Rotterdam, Netherlands*; *[4]Erasmus Medical Center, Department of Internal Medicine; Division of Pharmacology and Vascular Medicine, Rotterdam, Netherlands*

Background: TNF inhibitor (TNFi) use during pregnancy is associated with increased birthweight of the offspring of women with Rheumatoid Arthritis (RA). However, the underlying mechanism of the increased birthweight due to TNFi use is unknown. Prior studies demonstrated an association between biomarkers of placental function such as soluble fms-like Tyrosine Kinase-1 (sFlt-1) and placental growth factor (PlGF) and fetal growth restriction (FGR). We hypothesize that the increased birthweight in the offspring of women with RA treated with TNFi can be explained by better placentation by affecting the levels of biomarkers of placental function or by modulating the impact of these biomarkers on birthweight.

Objectives: To study the modulating impact of sFlt-1 and PlGF on birthweight and the use of TNFi in a cohort of pregnant women with RA.
Methods: Making use of the PreCARA cohort, in which pregnant women with RA are treated according to a treatment protocol aimed at remission. Biomarkers of placental function sFlt-1, PlGF and sFlt-1/PlGF ratio were measured in the first, second and third trimester of pregnancy.
Results: A total of 158 women were included. 52.5% of all patients ever used TNFi during pregnancy. 29.1% used TNFi during all trimesters of pregnancy. The sFlt-1/PlGF ratio is different in each trimester. After correction for confounders, there was no significant difference in sFlt-1 or the sFlt-1/PlGF ratio between patients that did, and did not use TNFα inhibitors (sFlt-1: β-0.000, 95% CI -0.063; 0.063 p = 0.997, PlGF β -0.014, 95% CI -0.06; 0.093 p = 0.721 and sFlt-1/PlGF ratio: β-0.014, 95% CI -0.107; 0.078 p = 0.757). When correlating sFlt-1 and birthweight, we found the previously established correlation in the group that did not use TNFα inhibitors during pregnancy (r = -0.462, p <0.001). However, this correlation disappeared in the group that did use TNFα inhibitors during pregnancy (r = 0.076, p = 0.522).
Conclusion: Our study shows that in pregnant women with RA, the biomarkers of placental function sFlt-1, PlGF and the sFlt-1/PlGF ratio are not related to the use of TNFi. In case of using TNFi, the negative correlation of sFlt-1 on birthweight disappeared, whereas this negative correlation on birthweight persists in the patients not using TNFi. This suggests that TNFi has a downstream effect on sFlt-1 or has an effect separate from sFlt-1. The underlying mechanism of this effect of TNFi on sFlt-1 in relation to birthweight, should be explored in future research.

Table 1. sFlt-1. PlGF and sFlt-1/PlGF ratio values per trimester for all patients that did not use TNFi during pregnancy and patients that used TNFi during pregnancy.

	TNFi -	TNFi +	TNFi all trimesters
Angiogenic marker values	N = 75	N = 83	N = 46
Trimester 1			
sFlt-1	1188 (816 - 1542)	1110 (574 - 1379)	1063,0 (617,8 - 1289,0)
PlGF	31,4 (19,8 - 50,4)	27,8 (16,2 - 46,6)	27,9 (16,7 - 46,1)
sFlt-1/PlGF	33,4 (17,0-51,2)	33,0 (17,8 - 45,9)	31,0 (18,9 - 40,0)
Trimester 2			
sFlt-1	1321 (1051 - 1761)	1557 (1038,5 - 2210,5)	1440,5 (921,8 - 2114,8)
PlGF	346 (240 - 461,5)	360 (247 - 596,5)	351 (195,8 - 541,0)
sFlt-1/PlGF	4,1 (2,3 - 5,9)	4,9 (2,3 - 7,1)	5,7 (2,0 - 8,2)
Trimester 3			
sFflt-1	1933 (1379,5 - 2682)	2011 (1453 - 2820,5)	1771,0 (1278,0 - 2541,0)
PlGF	497 (299,5 - 765)	644 (406,5 - 979,3)	562,0 (365,0 - 869,0)
sFlt-1/PlGF	3,8 (1,8 - 7,3)	3,2 (1,8 - 5,5)	3,1 (1,7 - 5,6)

Background: The formation of neutrophil extracellular traps (NETs) with extrusion of nuclear, granular and cytosolic components from a dying neutrophil, has been described extensively in patients with rheumatoid arthritis (RA), and linked to generation of autoantigens (e.g. citrullinated proteins), inflammation and organ damage. Thus far there have been very few studies describing the effect of treatment in patients with RA on NET formation, and no studies comparing the effects of treatment strategies in (very) early RA.
Objectives: To assess the effects of different initial treatments on NET formation in patients with early RA.
Methods: NORD-STAR is an international, multicenter, open-label, assessor-blinded, phase 4 study where patients with newly diagnosed RA started methotrexate (MTX) and were randomized 1:1:1:1 to a) conventional treatment (either prednisolone tapered to 5mg/day, or sulfasalazine combined with hydroxychloroquine and intra-articular corticosteroids), b) certolizumab pegol, c) abatacept, or d) tocilizumab [1]. This study is a spin-off from the main NORD-STAR study measuring neutrophil biomarkers MPO-DNA (Myeloperoxidase-DNA; NETs) and calprotectin in 24 consecutive Dutch participants and 94 Swedish patients at baseline, 12 weeks and 24 weeks after the start of the treatment. Statistical analysis was done using the Wilcoxon Signed Rank test for paired samples and independent samples median test to compare patients to healthy controls in SPSS version 28.
Results: At baseline patients had elevated levels of NETs and neutrophil activation compared to healthy controls as indicated by calprotectin (median 1080ng/ml vs 133ng/ml, p<0.001) and elevated MPO-DNA (median 7185pM vs 3976pM, p<0.001). Both of the biomarkers decreased significantly at 12 and 24 weeks after treatment in the total group demonstrating reduced neutrophil activity and NET formation. After 24 weeks of treatment, calprotectin was significantly reduced in all groups by up to 93% (Table 1). MPO-DNA showed a more modest reduction of up to 13%, and was relatively similar in all groups, although the reduction in MPO-DNA did not reach statistical significance in the tocilizumab group.

Table 1. Results are reported as median (IQR) due to skewedness of the data. Reductions are reported as a percentage reduction compared to baseline. Measurements are marked with * if p<0.05, ** if p<0.01, * if p<0.001.**

	Baseline	Week 12	Reduction	Week 24	Reduction
Calprotectin (ng/mL)	1080 (1718)	231 (326) ***	-79%	214 (274) ***	-80%
Conventional treatment	1222 (2197)	354 (554) ***	-71%	285 (357) ***	-77%
Certolizumab pegol	1166 (1927)	213 (486) ***	-88%	157 (281) ***	-93%
Abatacept	850 (1323)	269 (313) ***	-68%	220 (354) ***	-74%
Tocilizumab	757 (1346)	169 (195) ***	-54%	184 (168) ***	-53%
MPO-DNA (pM)	7185 (2567)	6503 (2694) ***	-9%	6612 (2542) ***	-8%
Conventional treatment	7057 (4052)	6396 (2878) **	-11%	6629 (3092) **	-8%
Certolizumab pegol	7183 (2733)	6492 (3308) *	-10%	6549 (2608) *	-9%
Abatacept	7727 (2512)	7562 (4708)	-2%	6688 (3882) **	-13%
Tocilizumab	6904 (2168)	6120 (1921)	-11%	6509 (2113)	-6%

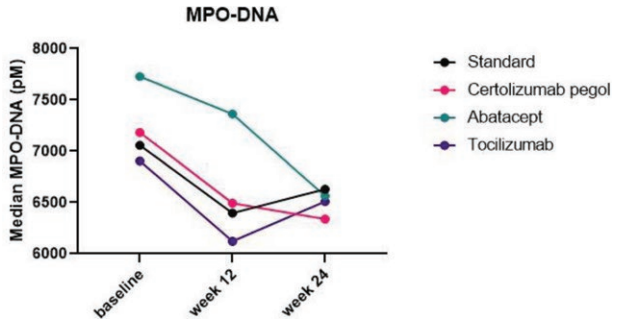

Figure 1. Median MPO-DNA over time (pM)

Conclusion: These results indicate highly elevated neutrophil activation and NET formation in recently diagnosed RA patients. All four treatments studied here reduced these detrimental processes within 3 months. The calprotectin reduction seen in this study is in line with an earlier spin-off study [2]. The rapid decline in these markers may have contributed to the minimal radiological progression that was seen in the NORD-STAR trial.

POS0633 SAFETY OF GENETICALLY PROXIED TNF INHIBITION ON PREGNANCY RELATED OUTCOMES

Keywords: bDMARD, Pregnancy and reproduction, Epidemiology

S. S. Zhao[1], D. Gill[2]. [1]*University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [2]*Imperial College London, Department of Epidemiology and Biostatistics, London, United Kingdom*

Background: TNF inhibitors (TNFi) have greatly improved the management of rheumatoid arthritis and several immune mediated inflammatory diseases. Although these diseases commonly start during childbearing age, the safety of TNFi in pregnancy is unclear, and is unlikely to change as clinical trials continue to exclude pregnant women for concern of harm to the foetus. Lack of scientific evidence to inform treatment decisions can contribute to maternal anxiety and suboptimally controlled disease. Naturally occurring variations in the genes that encode the protein drug target can provide population-level insights into safety, without exposing pregnant women to these drugs.

Objectives: To investigate the association between genetically proxied TNFi and pregnancy related outcomes, namely, spontaneous abortion, preterm birth, pre-eclampsia or eclampsia, gestational hypertension, gestational diabetes mellitus, and birthweight of the firstborn child.

Methods: To proxy TNFi, we selected uncorrelated (r^2>0.1) genome-wide significant ($p<5x10^{-8}$) single nucleotide polymorphisms within the gene encoding TNF receptor 1 (*TNFRSF1A*, build GRCh37/hg19: chromosome 12:6437923-6451280) from a genome wide association study (GWAS) of CRP among 337,199 individuals. CRP was (inverse rank-normal) transformed, with estimates scaled to per standard deviation (SD=4.35 mg/L) change in CRP. We selected CRP as the biomarker because clinical data show its suppression with TNFi. We estimated the F statistics of the instrument (square of the beta divided by square of the standard error) with F >10 being suggestive of adequate instrument strength. Genetic association data for spontaneous abortion (15,073 cases 135,962 female controls), preterm birth (7,678 cases 14,8153 controls), pre-eclampsia or eclampsia (6,436 cases 176,113 controls), gestational hypertension (7,503 cases 176,113 controls) and gestational diabetes (7,676 cases 130,424 controls) were derived from the FinnGen study. Data for firstborn birth weight (grouped into <7, 7 or >7 pounds (~3.2kg)) was obtained from 200,272 women in the UK Biobank. We included a positive control outcome, ankylosing spondylitis, and a negative control, multiple sclerosis. We used ratio method and, where an association was found, applied colocalization to test for genetic confounding.

Results: We identified one variant, rs1800693, to instrument TNFi. The F statistic was 65 suggesting adequate instrument strength. We found no evidence of associations between genetically proxied TNFi and any pregnancy related outcome (Figure 1) except gestational diabetes (OR 0.12 per SD reduction in CRP; 95%CI 0.03 to 0.57; p=0.007). The posterior probability of colocalization between CRP and gestational diabetes in the *TNFRSF1A* gene region was 99% conditional on the presence of a causal variant for the outcome, which provide evidence against genetic confounding.

Conclusion: We found no genetic evidence to suggest that TNFi is harmful for the selected outcomes relating to pregnancy. These results are reassuring and concur with observational data where women were exposed to TNFi during pregnancy. There was evidence that TNFi may be associated with lower risk of gestational diabetes. Further studies are needed to examine whether this is specific to diabetes during pregnancy or more generally. It is important to note that subtle differences in CRP levels through genetic variation may not be comparable to effects of pharmacological inhibition, and life-long exposure studied herein may differ from shorter duration of pharmacological intervention.

POS0634 EVALUATION OF THE SAFETY SKILLS OF PATIENTS WITH BIOLOGICAL DMARDS AFTER A THERAPEUTIC PATIENT EDUCATION PROGRAM

Keywords: bDMARD, Patient information and education

I. Bencharif[1], D. Bendjenna[1], A. Ladjouze-Rezig[2]. [1]*Faculty of Medicine - University of Constantine, Internal Medicine, Constantine, Algeria*; [2]*Faculty of Medicine - University of Algiers, Rheumatology, Algiers, Algeria*

Background: Biological DMARDs (bDMARDs) are well known cause a number of specific complications, including infectious ones. Patients receiving bDMARDs

must know them and acquire self-care and safety skills in order to take charge of themselves in risky situations. This is only possible thanks to therapeutic patient education (TPE) programs in chronic Inflammatory arthritis such as rheumatoid arthritis (RA), spondyloarthritis (SpA) and Psoriatic arthritis (PsA).

Objectives: To evaluate the impact of the therapeutic patient education program "EST-RIC" on the safety skills in patients treated with bDMARDs and on clinical parameters (Disease activity scores, compliance, number of infectious events, number of treatment stops, vaccination rate).

Methods: Non-randomized clinical trial comparing the knowledge and safety skills between two cohorts of patients with RA, SpA or PsA receiving bDMARDs for at least three months in the day hospital center of CHU of Constantine: group TPE (patients joined the "EST-RIC" therapeutic education program) versus group TPE-naive (patients who did not wish to participate).The primary outcome was the acquisition of safety skills at 3 and 6 months measured by the Biosecure questionnaire (0-100 scale), a 55 item validated questionnaire assessing competences to deal with fever, infections, vaccination, and other daily life situations [1]. The secondary outcomes were disease activity scores (DAS 28 for RA and BASDAI for SpA) at 6 months, compliance (Morisky score), number of infectious events, number of treatment stops, vaccination rate at 12 months.

Results: 450 patients were included, with mean age 41,6 ± 12,1 years old; 235 (52,2%) women; 192 (42,7%) had RA; mean disease duration 9,9 ± 6,6 years, 269 (60%) received subcutaneous bDMARDs. 240 patients in group TPE versus 210 patients in group TPE-naive. The median Biosecure score was significantly higher in the group TPE than in the group TPE-naive (75.7/100 versus 57.9/100; p<0.001) at 6 months (Table 1). There was a significant difference in disease activity scores: DAS28 and BASDAI, in rates of vaccination and discontinuation of treatment by forgetfulness. Regarding the observance to treatment or incidence of infectious events, there was no significant difference between the groups TPE and TPE-naive.

Conclusion: Safety is an important issue in the management of inflammatory arthritis treated with bDMARDs. In this trial, therapeutic patient education improves knowledge and safety skills of arthritis patient receiving bDMARDs, and disease activity scores.

POS0635 METHOTREXATE MAINTENANCE ONE YEAR AFTER INITIATION OF A FIRST TARGETED THERAPY: RESULTS OF THE PROSPECTIVE STRATEGE 2 STUDY

Keywords: Rheumatoid arthritis, Treat to target, Disease-modifying drugs (DMARDs)

C. Gaujoux-Viala[1], E. Dernis[2], E. Senbel[3], H. Herman-Demars[4], J. Becker[4], A. Courbeyrette[4], R. M. Flipo[5]. [1]*IDESP, Univ Montpellier, INSERM, Department of Rheumatology, CHU Nîmes, Nîmes, France*; [2]*Le Mans Central Hospital, Rheumatology Department, Le Mans, France*; [3]*Cabinet de Rhumatologie, NA, Marseille, France*; [4]*Nordic Pharma France, Medical Department, Paris, France*; [5]*Centre Hospitalier Universitaire de France, Université de Lille, Lille, France*

Background: Methotrexate (MTX) is the first line standard of care for the management of rheumatoid arthritis (RA). In the event of an inadequate response to MTX and the presence of a poor RA prognosis factor, recommendations include initiation of biological (bDMARD) or synthetic (tsDMARD) targeted therapy in combination with MTX.

Objectives: STRATEGE 2 aims to establish the maintenance of MTX within two years of initiating a first targeted therapy.

Methods: STRATEGE 2 is a non-interventional study including RA patients treated with MTX for at least 3 months and requiring initiation of a first b/tsDMARD due to disease activity. The primary endpoint is maintenance of MTX unchanged within 12 months of initiation of targeted therapy. Non-maintenance is defined as: permanent discontinuation of MTX and/or dose reduction and/or transition from the subcutaneous route (SC) to oral (PO). Then, univariate and multivariate analysis was applied to identify potential predictors of MTX maintenance.

Results: Between Feb. 2019 and Dec. 2020, 53 French sites included 186 RA patients. Among them, data from 180 patients were analysable: 73.4% female, mean age 56.4 ±13.6 years, mean diagnostic oldness of 5.6 ±7.2 years, MTX treatment since 4.3 ±5.3 years, 71.7% via SC and the average dose was 19.9 ±3.9 mg/wk. The mean DAS28 score was 4.3 ±1.2 and the mean HAQ score was 1.0 ±0.7. At the end of the inclusion consultation, rheumatologists initiated a first targeted therapy: 8.6% by bDMARDs (anti-TNF: 58.4%, anti-IL6: 12.7%, Abatacept/Rituximab: 18.5%) and 10.4% by tsDMARDs. MTX was maintained unchanged in 76.1%, changed in 21.7% and stopped in 2.2% of the cases. The changes consisted of a dose reduction to 13.8 ±3.8 mg/wk for 19.4% of patients and a pathway change for 31.4% (from SC to PO). Approximately 12 months (377.8 ± 41.5 days) after initiation of targeted therapy, 95% of patients completed a follow-up visit (N=171). Of these patients, 6.4% had discontinued targeted therapy, 85.9% were on bDMARD (anti-TNF: 50.3%, anti-IL6: 12.8%, Abatacept/Rituximab: 22.8%) and 14.1% on tsDMARD. The average MTX dose was 18.0 ±4.2 mg/wk and MTX was administered SC for 59.4% of patients. According to the composite endpoint definition, MTX was maintained for 40.9% of patients. Non-maintenance was represented by 30% discontinuation, 44% of patients with a dose decrease only, 3% of patients with only a change in route of administration (from SC to PO) and 23% of patients with the two strategies. Using univariate analysis, three factors were selected for the multivariate: age (p=0.009), physicians' mode of practice (p=0.096) and patients who estimate having completely participated in the decision-making for the targeted therapy (p= 0.197). Only age was significative (OR=1.06, 95%CI [1.03,1.10], p<0.001), decision-making shows a strong trend (p=0.052) and both characteristics were adjusted on the mode of practice (p=0.256).

Conclusion: There are many therapeutic adaptations in the year following the initiation of b/tsDMARD. Twelve months after the introduction of b/tsDMARD, more than 8 out of 10 patients retained MTX as a combination therapy. Nearly 46% of patients had an adaptation of this treatment (dose reduction and/or return to the PO route). These practices are in line with the latest EULAR guidelines [1] which recommend the association of b/tsDMARDs with MTX.

POS0636 SHOULD COMPLETE B-CELL DEPLETION BE SUSTAINED IN RITUXIMAB LONG-TERM TREATED PATIENTS FOR RHEUMATOID ARTHRITIS?

Keywords: bDMARD, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

R. Ghossan[1], O. Al Tabaa[2], A. Combier[2], A. Steelandt[2], M. Thomas[2], C. Miceli Richard[2], A. Moltó[2], Y. Allanore[2], J. Avouac[2]. [1]*Cochin Hospital, Rheumatology Department, Paris, France*; [2]*Cochin Hospital, Rheumatology department, Paris, France*

Background: Complete peripheral B cell depletion has been considered as a relevant indicator of short-term response to rituximab (RTX) in rheumatoid arthritis (RA) [1,2]. However, no information is available to validate this observation in RA patients long-term treated with RTX.

Objectives: To determine whether sustained complete B cell (BC) depletion is associated with a better clinical response in RA patients long-term treated with RTX.
Methods: Retrospective routine care study conducted in the Rheumatology department of Cochin hospital. We included consecutive patients fulfilling the ACR/EULAR 2010 classification criteria for RA hospitalized in 2021 for a new RTX infusion. All recruited patients had received at least 3 prior RTX infusions and had disease activity assessment (DAS28 and DAS28-CRP) and CD19 counts (Aquios, Beckman Coulter) available during each of the 4 last infusion visits. The primary endpoint was the course of DAS28 and DAS28-CRP, calculated the day of the last 4 infusion visits according to sustained complete (mean CD19 counts <18/µL) or incomplete (mean CD19 counts ≥18/µL) BC depletion. Secondary endpoints were the frequency of end-of-dose effect and patient self-reported RA flares at each infusion visit, as well as the course of pain/fatigue VAS, CRP and gammaglobulin levels according to complete or incomplete B cell depletion.
Results: We included 126 patients (105 women, 83%) with a mean age of 64±12 years and a mean disease duration of 22± 5 years. Only 43 patients (34%) had maintained complete BC depletion during the last 4 infusions (mean CD19 counts 13±4/µL) (**Figure 1A-B**). Patients with incomplete BC depletion (n=83, mean CD19 counts: 77±73/µL, p<0.001) did not differ from those who maintained complete BC depletion in terms of age, gender, disease duration, structural damages and concomitant treatment. Patients with incomplete BC depletion had a higher frequency of rheumatoid factor (92% vs. 77%, p=0.018) and ACPA (84% vs. 72%, p=0.11); these patients had received RTX for a longer period (99±57 months vs. 69±47 months, p=0.003), with significantly higher number of infusions (14±7 vs. 12±6 infusions, p=0.037) and increased cumulative dose (10±6 g vs. 8±5 g, p=0.10) compared to patients with sustained complete BC depletion. On the other hand, their interval between 2 infusions was significantly longer (8±3 months vs. 6±1 months, p<0.001). The course of DAS28 and DAS28-CRP during the last 4 infusions was not different between the 2 groups (**Figures 1C-D**). The mean DAS28 and DAS28-CRP calculated at the time of last 4 infusion visits did not differ between patients with incomplete or sustained complete BC depletion (DAS28: 2.71±1.06 vs. 3.01±1.10, p=0.33 and DAS28-CRP: 2.53±0.88 vs. 2.88±0.84, p=0.095). The frequency of an end-of-dose effect and self-reported flares was similar between the 2 groups, as well as the evaluation of pain VAS, asthenia VAS, CRP and gammaglobulin levels (**Figures 1E-H**).
Conclusion: Maintaining complete BC depletion is not a therapeutic target to achieve in RA patients in long-term maintenance therapy with RTX. These results show that it is possible to space out RTX infusions to 8 months without loss of clinical benefit, which remains identical to that of patients treated every 6 months with sustained BC depletion. This result may have clinical implications during the COVID-19 pandemic since the antibody response to SARS-CoV-2 vaccination is preferentially obtained in patients with detectable B cells [3].

POS0637

USING THE "POTENTIAL-OUTCOMES FRAMEWORK" TO PREDICT ADDED VALUE OF MORE INTENSIVE INITIAL THERAPY FOR INDIVIDUAL EARLY RA PATIENTS

Keywords: Treat to target, Clinical trials, Rheumatoid arthritis

S. Fadaei[1], P. Welsing[1], J. Spierings[1]. [1]*UMC Utrecht, Rheumatology & Clinical Immunology, Utrecht, Netherlands*

Background: DMARDs are the cornerstone of early RA treatment with Methotrexate (MTX) typically used as a first line treatment. More intensive initial combination therapy has been evaluated in clinical trials showing limited added value with longer follow-up in a treat-to-target (T2T) strategy [1,2]. Such studies report the treatment effect on group level, however, precision medicine requires information on which individuals will respond relevantly better to a more intensive therapy compared to MTX.
Objectives: The aim of this study was to identify whether clinically relevant heterogeneity in treatment effect exist, utilizing a "potential-outcomes framework" approach and to explore whether individual added value of more intensive therapy can be predicted.
Methods: We used data from U-Act-Early. This RCT compared initiating MTX monotherapy, tocilizumab (TCZ), and MTX + TCZ treatment in a T2T strategy in early RA with monthly disease activity assessment [1]. Time averaged CDAI score over 6 months was the primary endpoint. As physician VAS was missing a previously reported modified (m) CDAI was used [2]. Time-averaged mCDAI over 24 months and DAS28 over 6/24 months were secondary outcomes. For each patient we predicted outcomes of the treatments that they were not allocated to using multiple imputation (150 imputations using a random forest method). Predicted Individual Treatment effects (PITE) for each treatment comparison were calculated and the variation in PITEs between patients was evaluated. We used logistic regression to predict added value of more intensive treatment.
Results: Figure 1A shows the average PITE for TCZ + MTX versus MTX monotherapy as initial treatment over 6 months. 134 of 299 patients (45%) would relevantly benefit from MTX + TCZ (green part Figure 1). We defined sufficient added value for an individual patient as Cohen's effect size ≥0.8. Added value of MTX + TCZ could be predicted to a limited extent with the same variables used for imputation (AUC-ROC 0.65 (95% CI 0.56-0.73); Table 1 and Figure 1B). At 24 months 36% could be defined as benefitting from more intensive initial treatment. When using DAS28 as outcome measure 87% and 82% of patients benefitted respectively at 6 and 24 months. Added value could also be predicted to a limited extent (AUC-ROC 0.63 (0.54-0.71); 0.66 (0.56-0.75) and 0.63 (0.54-0.71) respectively) using logistic regression.
Conclusion: Relevant added value of more intense initial treatment for individual early RA patients could be defined and predicted to some extent using clinical predictors. However, thresholds for relevant clinical benefit as well as prediction should be improved and validated.

Background: Recent data from a large cohort showed that biosimilars had no shorter survival than their originator molecules [1]. Although the survival of biological therapies in real practice has been recently analyzed in Spanish patients with rheumatic diseases (2), we do not know if there are differences in treatment survival, depending on whether the patients receive an originator or a biosimilar molecule.
Objectives: The main objective of this study was to compare the retention rate between subcutaneous biosimilar TNFα-blocker molecules and their originators. The secondary objective was to analyze the factors associated to drug survival.
Methods: Retrospective analysis of BIOBADASER cohort, the Spanish multicenter prospective registry of patients with rheumatic diseases with biological disease-modifying anti-rheumatic (bDMARD) or targeted drugs. We included patients who received originator or biosimilar molecules of etanercept or adalimumab for at least 6 months until December 2020. To avoid the *nocebo* effect, patients who had switched from the innovative molecule to the same biosimilar molecule were excluded. The drug retention rate was calculated considering all reasons for discontinuation as completion events, and analyzed using Kaplan-Meier curves for first and subsequent lines of treatment, adjusting for the use of concomitant conventional synthetic DMARD (csDMARD) and corticosteroids (CS). Hazard ratios (HR) were estimated using a Cox regression model, to identify factors associated to differences in the survival rates of biosimilar compared to originator molecules.
Results: A total of 4566 courses of treatment (2543 of adalimumab and 2023 of etanercept) and 4106 patients were included for this analysis. Biosimilars were used as 1st treatment in 51.1% of patients, as 2nd line in 39.2% and 3rd or subsequent lines in 37.7%. The use of csDMARD occurred in 63.8% of the cases and CS in 37.3%. Demographic and basal clinical characteristics of the patients are shown in Table 1. The main reason for discontinuation was inefficacy or loss of efficacy (58.1%), followed by adverse events (18.8%), pregnancies (3.5%), and remission (3.3%). The survival was higher for biosimilars (HR 0.68, 95% CI 0.53-0.98; p=0.002). Neither the disease type, sex, age, disease duration nor the concomitant treatments with CS or csDMARD influenced the retention rate. The survival was lower in smokers (HR 1.23, CI1-1.52; p=0.046), patients with overweight (HR 1.3, 95% CI 1.1-1-6; p=0.006) and 3rd line of treatment (HR 1.34, 95% CI 1.1-1.7; p=0.014). Among patients with adalimumab, survival was associated with JIA (HR 0.37, CI 0.16-0.85; p=0.015) and AS (HR 0.63, CI 0.43-0.91; p=0.015).
Conclusion: In real world practice, the survival of biosimilar TNFα-blocker molecules adalimumab and etanercept is higher compared to their originator molecules. Smoking, overweight and drug use in 3rd or subsequent lines of treatment are associated with a lower retention rate.

POS0639 SWITCHING FROM IL-6R ANTAGONISTS TO OLOKIZUMAB, A DIRECT IL-6 INHIBITOR

Keywords: bDMARD, Rheumatoid arthritis

E. Feist[1], E. Nasonov[2]. *[1]HELIOS Clinic Vogelsang Gommern, Department of Rheumatology, Gommern, Germany*; *[2]V.A. Nasonova Research Institute of Rheumatology, Department of Rheumatology, Moscow, Russian Federation*

Background: Olokizumab (OKZ), an IL-6 ligand inhibitor in doses of 64 mg every two weeks (q2w) or every 4 weeks (q4w) demonstrated significant improvements in signs and symptoms of RA. Due to lack of availability of the IL-6 receptor antagonists tocilizumab and sarilumab in the pandemic COVID-19 situation, RA patients (pts) were switched to OKZ as a registered drug in Russia in 2022.
Objectives: To investigate safety and efficacy of OKZ after switching from an IL-6 receptor inhibitor in clinical practice.
Methods: This retrospective cohort study included available efficacy and safety data of OKZ in pts with RA after switching from tocilizumab (IV or SC) or sarilumab (SC) from 11 of participating centers. Efficacy assessments and routine biochemical data were analyzed using descriptive statistics – mean with standard deviation for continuous parameters and absolute and relative frequency for binary variables. AE were reported by participating centers according to pt's files. The statistical significance of data of the analyzed variable at a particular visit compared with previous visits or with the Switch visit was determined using paired t-test. Fisher's exact test or chi-square test was used to compare the proportion of pts with improvement/no change and worsening. All tests were 2-tailed, and a p-value <0.050 was considered statistically significant. As this is an observational study, the statistical criteria have not been pre-specified and therefore the data presented cannot be considered definitive but should be confirmed in future analyses.
Results: Efficacy and safety results were collected for 110 RA pts with a mean age of 47.8 (15.7) years, including 87 (79.1%) women. 77 (70.0%) pts were RF/ACPA positive. Mean RA duration was 13.1 (8.9) years and mean duration of treatment with an IL-6 receptor antagonist was 47.8 (30.0) months. Mean interval before switching was 54.7 (35.4) days with the main reason of unavailable IL6-R antagonist. Pts were treated with OKZ 64 mg q4w SC. Before initiation of OKZ, an increase of DAS28-CRP was observed due to a prolonged period after the last injection of the IL-6R inhibitor from 2.8 to 3.1 weeks in 32 pts on monotherapy who were transferred to OKZ faster (on average after 41.6 (23.8) days), and

from 2.7 to 3.3 weeks in 73 pts on concomitant sDMARDs (60.0 (38.0) days). DAS28-CRP was improved to 2.8 on the second OKZ visit (S+1) in both groups. Response to OKZ was maintained over a period of 2 months with no difference between pts previously receiving an IL-6 R antagonist. Of note, lower disease activity based on DAS28-CRP of 2.5 and 2.6 was achieved after 8 weeks (S+2) of OKZ therapy compared to the previous IL-6R inhibitors treatment S-1 visit (P less 0.05) (Figure 1).

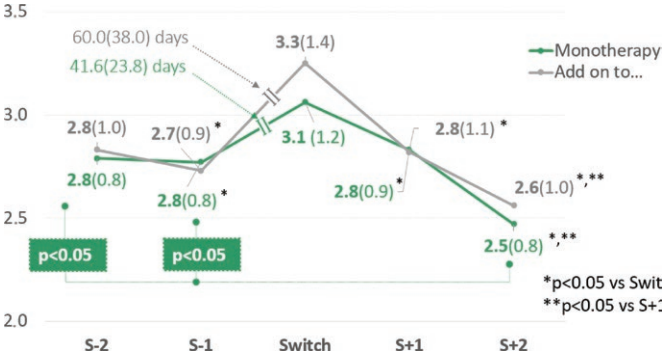

Figure 1. Mean DAS28CRP over time, M(SD)

Abbreviation: S-2 and S-1 last visits before switching– S+1 and S+2 visits after switching, Treatment emergent AE occurred in 7 (6.4%) pts, the most common AE in 3 pts (2.7%) included arthralgia of hands and feet and transient leukopenia in 2 (1.8%) pts. Serious AE were reported by 1 (0.9%) pt (exacerbation of herpes infection that led to treatment discontinuation). No deaths were reported. There were no apparent differences in safety and efficacy outcomes between pts on OKZ monotherapy compared to combined treatment with csDMARDs. Only one pt was switched back to tocilizumab when it became available.

Table 1. Summary of treatment emergent adverse events (safety population)

N	OKZ 64 mg q4w with MTX N=78	OKZ 64 mg q4w monotherapy N=32
Any AE	5	1 carpal canal syndrome
Any serious AE	1	0
Any AE leading to discontinuation of study drug	1	0
Any death	0	0
Any AE of special interest	1	0
Infections	1	0
Laboratory abnormalities	Hyperbilirubin-emia	ALT, AST elevation less than 3 ULN

ALT, alanine transaminase; AST, aspartate transaminase; ULN, upper limit of normal

Conclusion: In pts with RA responding to an IL-6R antagonist, switching to OKZ was safe and well tolerated in clinical practice. The treatment response was maintained and in some pts disease activity moderately decreased in comparison to baseline level both in OKZ mono and combination therapy.

OLOKIZUMAB IMPROVED PATIENT REPORTED OUTCOMES IN MTX AND TNF INCOMPLETE RESPONDER RHEUMATOID ARTHRITIS PATIENTS: RESULTS FROM THE LONG TERM EXTENTION TRIAL

Keywords: Patient reported outcomes, Clinical trials, Rheumatoid arthritis

V. Strand[1], E. Feist[2], E. Nasonov[3], T. Lisitsyna[3], A. Lila[3], S. Kuzkina[4], M. Samsonov[4], R. M. Fleischmann[5,6]. *[1]Stanford University School of Medicine, Division of Immunology/Rheumatology, Palo Alto, United States of America*; *[2]HELIOS Clinic Vogelsang Gommern, Department of Rheumatology, Gommern, Germany*; *[3]V.A. Nasonova Research Institute of Rheumatology, Department of Rheumatology, Moscow, Russian Federation*; *[4]R-Pharm, Medical, Moscow, Russian Federation*; *[5]University of Texas Southwestern Medical Center, Medical, Dalas, United States of America*; *[6]Metroplex Clinical Research Center, Rheumatology, Dallas, United States of America*

Background: Olokizumab (OKZ) is an interleukin-6-inhibitor for treatment of RA. We present patient reported outcomes (PROs) reported in a long-term extension trial (OLE) (ClinicalTrials number NCT03120949).

Objectives: To assess long-term effect of OKZ treatment in patient global assessment of disease activity (PtGA), pain, physical function (HAQ-DI), fatigue (FACIT-F) and health related quality of life (SF-36 physical (PCS) and mental (MCS) component summary and domain scores).

Methods: Patients (pts) who completed phase III core studies (within 24 weeks) were continued on OKZ 64 mg q2w or q4w, or were randomized 1:1 to receive OKZ 64 mg q2w or q4w following placebo (PL) or adalimumab (ADA) in RCTs with an OLE period of up to week 82. PROs through CORE and OLE phases are summarized as observed data by treatment groups using descriptive statistics.

Results: Baseline demographics and disease characteristics of 2104 enrolled pts were comparable between groups. The achieved improvement from CORE baseline to OLE baseline in PtGA, Pain, HAQ-DI, FACIT-F, SF-36 PCS, MCS and all domains under treatment with OKZ q2w and q4w was maintained over the full observation period of 106 weeks (Table 1, Figure 1). SF-36 improvements reported from OLE BL continued (in 5 domains) or increased (in 3 domains: PF, RE and RP) with OKZ until week 82.

Background: The continuous development of biological disease modifying antirheumatic drugs (bDMARDs) in recent years has significantly improved the treatment options for patients suffering from rheumatoid arthritis. Selecting the most effective biologic remains a challenge, since therapy-response is highly individual depending on the patient history, laboratory values and demographics.

Objectives: The aim of this study was to investigate, if non-responders can be detected before therapy start using machine learning models and explainable artificial intelligence to provide a probability of non-response and to identify the most impactful contributing factors to the model output.

Methods: Data from the Austrian Registry for bDMARDs and tsDMARDs in Rheumatic Diseases – BIOREG were obtained. BIOREG provides a real-world data set, which covers rheumatology hospitals and practices throughout Austria. According to EULAR-guidelines the observation time window for treatment response is 6 months and the prediction time horizon was set at 6 months as well. Different machine learning models were trained for Abatacept (ABA), Adalimumab (ADA), Certolizumab (CERT), Etanercept (ETA) and Tocilizumab (TOC) to predict the risk of non-response per treat to target (ttt)-course. Nested cross-validation and hyperparameter tuning (iteration over fixed parameter grid) were applied. To evaluate the prognostic quality per model the area under the receiver operating characteristic (AUROC) was collected and the model with the highest score was selected for further evaluation. By applying the Explainable AI method SHAP (SHapley Additive exPlanations; a game-theoretic approach to evaluate variable importance) to each final model, the most contributing factors and direction of impact were evaluated.

Results: Data from 1397 patients, 2004 (baseline) visits and 22 variables (19 after cleaning) with at least 100 ttt-courses per drug were included in the study. The best models per biologic achieved an AUROC-score of: CERT: 0.76 (95% CI, 0.67–0.86). TOC: 0.72 (95% CI, 0.69–0.79), ABA: 0.71 (95% CI, 0.65–0.77), ADA: 0.67 (95% CI, 0.62–0.76), ETA: 0.68 (95% CI, 0.53–0.85). The explainable AI interpreted visual analytic scores (VAS) as most important variables for ABA, ETA and TOC. High scores were associated with high risk of non-response for these drugs. For ADA, co-therapy with glucocorticoids was the most important and risk-increasing factor. For CERT, the dosage of the prescribed drug was ranked as the most influential variable; high dosages were associated with lower risk of non-response. Interestingly, some variables displayed opposite impacts in different drugs: Male gender was interpreted as risk-increasing for ABA and risk-decreasing for ETA. Moreover, negative rheumatoid-factor was interpreted as risk-decreasing for ABA/ETA, but risk-increasing for ADA/CERT.

Conclusion: The results of our study show that non-responders of biological drugs can be detected with moderate to even good prognostic quality **before** starting a ttt-course, comparable to similar research with different prediction time horizons [1]. The opposite impact of some variables in different bDMARDs as well as the difference in variable importance per bDMARD indicate, that selecting the right drug is highly dependent on the individual patient characteristic. Machine Learning could be of additional support for rheumatologists and patients by providing not only a prediction of ineffectiveness per drug, but also an explanation for the prediction.

TREATMENT PATTERNS OF RHEUMATOID ARTHRITIS DURING TWO DECADES 2000-2020: REAL-WORLD DATA FROM A LARGE ISRAELI HEALTH MAINTENANCE ORGANIZATION

Keywords: bDMARD, Rheumatoid arthritis, Real-world evidence

V. Rosenberg[1,2], O. Elkayam[2,3], G. Chodick[1,2], M. Halperin-Sheinfeld[4], V. Furer[2,3]. [1]*Kahn-Sagol-Maccabi Research and Innovation Institute, Maccabi Healthcare Services, Tel Aviv, Israel*; [2]*Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel*; [3]*Tel Aviv Sourasky Medical Center, Rheumatology, Tel Aviv, Israel*; [4]*Gilead Sciences Israel, Immunology, Hod Hasharon, Israel*

Background: Rheumatoid arthritis (RA) is the most common autoimmune inflammatory arthritis in adults. In recent years, the availability of therapeutic options for RA management has significantly increased. Yet, not all patients receive the recommended therapy (1 and real-world data on RA treatment patterns are limited.

Objectives: We aimed to identify and characterize RA patients, to examine their past and current treatment patterns, and identify factors associated with non-treatment.

Methods: We conducted a retrospective study using the computerized database of Maccabi Healthcare Services (MHS), a large health maintenance organization. Prevalent RA patients on Dec 31 2020 were defined by: ICD-9 code 714.X (≥2 diagnoses by a rheumatologist and/or ≥2 diagnoses by a primary care physician [PCP] and/or ≥1 diagnoses from a hospital with one diagnosis from a PCP); ≥1 rheumatoid factor (RF) test performed; age ≥18 years on the first diagnosis; first diagnosed before Dec 31 2018; MHS members for ≥12 months before and after the first RA diagnosis. RA patients also had to meet at least one of the following criteria: ≥1 purchase of disease modifying anti-rheumatic drugs (DMARDs) and/or ≥2 separate RA diagnoses by a rheumatologist and/or ≥1 positive RF test or anti-cyclic citrullinated peptide antibodies (anti-CCP) test. Patients were characterized according to socio-demographic and clinical factors. Treatment patterns with DMARDs were examined during 2000-2020. Multivariate logistic regression model was used to identify factors associated with current DMARDs treatment in 2020.

Results: We identified 8301 eligible RA patients (Table 1). The proportion of patients initiating treatment with any DMARDs within 12 months of diagnosis gradually increased from 37.8% in 2000 to 69.3% in 2010 and reached 80.0% for those first diagnosed in 2018. During 2000-2009, 60.0%-63.4% of the RA patients were not treated and during 2010-2020 53.8%-57.9% were not treated. Following the introduction of bDMARDs, the proportion of those using bDMARDs and/or tsDMARDs increased (Figure 1). The median time to treatment with the first bDMARDs decreased during follow-up, from 9 years (IQR 6.0-13.0) among those diagnosed in 2000 to 3 years (IQR 1.0-5.0) in those diagnosed in 2009, and to 1 year in those diagnosed in 2018 (IQR 0-1.0). In 2020, only 44.3% of the RA patients were treated with any DMARD. Patients with disease duration of 5-<10 years and disease duration of ≥10 years, were less likely to be treated with any DMARD in 2020 compared to those with disease duration of <5 years (OR 0.7, 95% CI 0.6-0.8; OR 0.6, 95% CI 0.5-0.7, respectively). Seropositive patients and those who initiated treatment with any DMARD within the first 12 months of diagnosis were more likely to be treated (OR 1.8, 95% CI 1.7-2.0; OR 3.5, 95% CI 3.2-3.9, respectively).

Conclusion: We observed an increase in the proportion of RA patients initiating treatment with any DMARD in the first year after diagnosis over the last two decades. Yet, about 55% of all RA patients were untreated in 2020, especially those with longer disease duration. Efforts should be made to optimize the disease management.

Background: Rituximab (RTX) is a murine/human chimeric monoclonal antibody directed against the CD20 receptor expressed on pre-B and mature B cells. Rituximab is used effectively in the treatment of different rheumatic diseases, but it can induce hypogammaglobulinemia as a side effect.

Objectives: To analyze the prevalence of hypogammaglobulinemia and its association with infections in patients with rheumatic diseases treated with RTX.

Methods: Multicenter, retrospective, observational study. Patients with rheumatic diseases treated with RTX in 4 centers in Madrid, in which serum immunoglobulin counts were available, were included. Demographic and clinical variables of the sample were analyzed, and changes in immunoglobulin G concentrations during treatment from baseline were assessed. The chi-square test was used to examine the relationship between variables, considering a P value <0.05 as statistically significant. Logistic regression models were used to analyze the association between hypogammaglobulinemia and sample characteristics.

Results: One hundred and seven patients were included: 18 men (16.8%) and 89 women (83.2%), with a mean age of 55.9 (±13.9) years, a mean disease duration of 13.1 (±0.8) years, and a mean age of 51 (±14.4) years at the start of treatment. The most prevalent diagnoses were rheumatoid arthritis (RA) (50.5%), primary Sjogren's syndrome (pSS) (10.3%), and systemic lupus erythematosus (SLE) (10.3%). Fourteen (13%) patients were treated with RTX monotherapy. The rest

of the patients received concomitant treatment with other immunomodulators such as corticosteroids (64.5%), methotrexate (29%), hydroxychloroquine (27%), leflunomide (9.3%), sulfasalazine (1.9%), or mycophenolate mofetil (2.8%). Twelve (11.21%) patients developed hypogammaglobulinemia (IgG<600 mg/dl): 6 (50%) had RA, 1 (8.3%) SLE, 1 (8.3%) ANCA vasculitis, 1 (8.3%) leukocytoclastic vasculitis, 1 (8.3%) IgG4-related disease, 1 (8.3%) dermatomyositis, and 1 (8.3%) pSS. Patients with hypogammaglobulinemia had significantly lower mean serum IgG concentrations at the start of treatment (876.3 vs 1249.4 mg/dl; p=0.05). In the multivariate analysis, no variable related to hypogammaglobulinemia was found. Fifty-three (49.5%) patients presented infection, of which 17 (15.9%) were serious infections (those that required admission). The distribution of infection cases by groups (patients with and without hypogammaglobulinemia) is shown in Table 1. No significant differences were found in the development of infections or serious infections between patients with and without hypogammaglobulinemia. Only corticosteroid doses equivalent to ≥7.5 mg/day of prednisone were found as a risk factor for the development of infections (OR 3.48, 95% CI: 1.20-0.11; p=0.02).

Table 1. Hypogammaglobulinemia and infections in patients with rheumatic diseases treated with Rituximab.

	No infection (N, %)	Mild infection (N, %)	Serious infection (N, %)
Patients **without** hypogammaglobulinemia	55 (58.51)	24 (25.53)	15 (15.96)
Patients **with** hypogammaglobulinemia	7 (58.33)	3 (25)	2 (16.67)
p value		p=0.991	p=0.950

Conclusion: Patients with hypogammaglobulinemia had significantly lower mean IgG concentrations at the start of treatment with Rituximab than those who did not develop it. No greater frequency or severity of infections was observed between patients with and without hypogammaglobulinemia. Prednisone equivalent daily dose ≥7.5 mg/day was a risk factor for occurrence of infections. Larger sample size studies are needed to confirm these findings.

POS0644 UNDERSTANDING REASONS INFLUENCING PATIENTS' PREFERENCES FOR THE MODE OF ADMINISTRATION OF ANTI-RHEUMATIC DRUGS IN INFLAMMATORY ARTHRITIS. A QUALITATIVE STUDY

Keywords: Patient information and education, Disease-modifying drugs (DMARDs)

C. Beauvais[1], G. Montagu[2], F. Madrisotti[3], S. Gleizes[3], S. Tropé[4], J. Sellam[5], T. Pham[6]. *[1]Hopital Saint Antoine APHP Sorbonne Université, Rheumatology, PARIS, France*; *[2]Unknowns, Strategie et Innovation, Sociology and Research Department, Paris, France*; *[3]Unknowns, Strategie et Innovation, Sociology and Research Department, Paris, France*; *[4]Association nationale de Lutte Contre l'arthrite Rhumatoide, ANDAR, Paris, France*; *[5]Hopital Saint Antoine APHP Sorbonne Université, Rheumatology, Paris, France*; *[6]Hôpital Sainte Marguerite APHM Université Aix Marseille, Rheumatology, Marseille, France*

Background: The mode of administration is the third most important factor influencing patient preferences for the choice of antirheumatic drugs, after treatment benefit and risk of adverse events (ref1), with 30% of patients placing route and frequency of administration as their top choice (ref2).

Objectives: To understand the reasons of preferences of the patients with inflammatory arthritis (IA) towards the mode of administration of DMARDs (disease modifying anti-rheumatic drugs).

Methods: A qualitative study was conducted to explore the patients' perceptions and practices of DMARDs. The interviews were conducted by 3 anthropologists using in-depth semi directive and biographical methods, registered, transcribed and analysed using a thematic content analysis approach. Six domains were explored: (i) daily life with IA, (ii) practices of pharmacological and non-pharmacological treatments, (iii) the patient's social and work relationships, (iv) history of the patient pathway, (v) the patient–doctor relationship, decision-making, and (vi) medication daily management. The themes and subthemes related to the mode of administration (route and frequency of administration) were individualized.

Results: Overall 42 patients were included: 33/42, (33/42), with median age 51 years (17-82): 33 had rheumatoid arthritis (RA), 7 spondyloarthritis (SpA) and 2 psoriatic arthritis (PsA); 22 treated by cDMARDs, 19 by bDMARDs, 12 by JAK inhibitors (JAK-i), in monotherapy or combotherapy, 31 patients having more than 1 line of treatment. Four domains were found to influence patients' preferences: constraints and mental load, rituals and habits, empowerment versus a passive role, representation of disease for the patient and close ones. Subthemes are in Table 1.

Table 1. 8 subthemes associated with preference of patients for mode administration.

Subthemes	Intravenous	Subcutaneous	Oral
Time constraints	Half a day each month or more	Once a week or more	Every day/week
Logistical constraints	To stay available for appointments in hospital	Refrigerator storage, cold chain	No constraints in storage
Mental load	To stay available	Think about medication each week or more	Think about medication each day (for Jak-i)
Rituals	Rituals are managed and imposed by the hospital	Needs specific rituals from the patient	Integrated to existing rituals (i.e. meals)
Risk of forgetting treatment		Know what to do in case of skipped dose	Forgetting is a common phenomenon
Transfer of a medical procedure	Total medicalization, patient has a passive role	A medical procedure needs to be learnt	Tablets are more commonplace
Feeling ill	To go to the hospital makes you feel sick	Seeing the nurse makes you feel sick	Taking the tablets is more routine
The disease is made visible to others	To go to the hospital	« Sharing the fridge » An injection means a more serious disease	Tablets are more unobtrusive

Conclusion: Although many studies have looked for patients preferences, the reasons of the patients' choices for the mode of administration of targeted DMARDs were not well known. The reasons go beyond the simple "fear of needles" and reflect the integration of the treatment in the patients' representations and daily life and the visibility of the disease. This study brings clues that will help shared decision-making.

POS0645 REAL LIFE SAFETY AND SURVIVAL OF TARGETED THERAPIES IN ARTHRITIS PATIENTS OVER AGE OF 65

Keywords: bDMARD, Targeted synthetic drugs

E. Grau García[1], P. Muñoz Martinez[1], L. Mas Sanchez[1], S. Leal Rodriguez[1], I. Martínez Cordellat[1], R. Negueroles Albuixech[1], J. E. Oller Rodríguez[1], F. Ortiz-Sanjuán[1], D. Ramos Castro[1], C. Riesco Barcena[1], A. M. Torrat Noves[1], E. Tovar-Sugrañes[1], E. Vicens Bernabeu[1], H. Charia[1], L. Gonzalez Puig[1], A. V. Huaylla Quispe[1], J. Ivorra Cortés[1], I. Cánovas Olmos[1], C. Nájera Herranz[1], J. A. Román Ivorra[1]. *[1]HUP La Fe, Rheumatology Department, Valencia, Spain*

Background: Prognosis for chronic inflammatory arthritis is drastically improved over previous decades and older patients are treated with targeted therapies (TTs) (biological or synthetic targeted therapies). Clinical trials provide mainly information about TTs in patients below the age of 65, so real-life studies are needed to provide more information about TTs in patients over 65 years of age.

Objectives: To compare clinical and therapeutic profile of arthritis patients undergoing TTs and to analyze safety and therapeutic survival according to different age groups.

Methods: We performed an observational cross-sectional study in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) patients, older than 40 years old, who started biological or anti-JAK therapy between 2000 and 2022 in the Rheumatology Department of HUP La Fe. A comparative analysis and a Kaplan-Meier survival analysis was performed.

Results: 938 patients (62% female) were included in the study, of which 20.3% are PsA, 55.6% RA and 24.1% AS, with a mean age at the beginning of treatment of 57 (10) years and a mean duration of treatment of 68 (64) months. Patients were classified according to the age at the beginning of treatment: 40-65 years and ≥ 65 years of age. 219 patients (23.3%) were over 65 years of age. In the Table 1 we show the comparative analysis between both groups. Higher proportion of arterial hypertension, diabetes mellitus and dislipemia in patients older than 65 years was observed. Using a logistic regression model, an association between conventional DMARD prescription and patients older than 65 years was found (P<0.001), being the methotrexate the most used (44.8%). Anti-TNF therapy was the most extended treatment in both groups of patients,

and an association between anti-IL6 therapy and older patients than 65 years was observed (P<0.001). Previous TTs were more frequent in older patients (P=0.002) and treatment duration was lower in those patients (P<0.001). Adverse events were more commonly found in patients older than 65 years as the reason to TT discontinue (P=0.008), being infections the more frequent.

Table 1. Comparative analysis of clinical profile of different age groups at the beginning of TTs.

Variable	40-65 years N=719	≥65 years N=219	P-value
	Mean (SD)/ n (%)	Mean (SD)/ n (%)	
Age at diagnosis (years)	43 (11)	56 (14)	< 0.001
Age at the beginning of treatment (years)	53 (7)	72 (5)	< 0.001
Time from the diagnosis to the beginning of treatment (years)	10 (10)	17 (12)	< 0.001
Treatment duration (months)	73 (66)	52 (52)	< 0.001
Female sex	425 (59.1%)	156 (71.2%)	0.001
Diagnosis:			
• RA	359 (49.93%)	163 (74.43%)	< 0.001
• PsA	168 (23.37%)	22 (10.05%)	< 0.001
• AS	192 (26.7%)	34 (15.53%)	< 0.001
Arterial hypertension	130 (29%)	84 (57.9%)	< 0.001
Diabetes mellitus	47 (10.5%)	32 (22%)	< 0.001
Dislipemia	124 (27.7%)	61 (42.1%)	< 0.001
Malignancy	54 (13%)	27 (22.5%)	0.016
DMARD concomitant			
• No DMARD	355 (49.4%)	79 (36.1%)	< 0.001
• Methotrexate	246 (34.2%)	98 (44.8%)	0.006
• Leflunomide	72 (10%)	22 (10.1%)	0.999
• Others	37 (5.2%)	20 (9.1%)	0.045
Targeted therapies:			
• ANTI-TNF	399 (55.5%)	86 (39.3%)	< 0.001
• ANTI-JAK	114 (15.9%)	33 (15.1%)	0.862
• ANTI-IL17	84 (11.7%)	12 (5.5%)	0.012
• ANTI-IL6	55 (7.7%)	32 (14.6%)	0.003
• Others	67 (9.3%)	56 (25.6%)	< 0.001
Continuing treatment			
Discontinued treatment by:	559 (77.9%)	158 (72.1%)	0.746
Primary non-response	10 (1.4%)	3 (1.4%)	0.895
Secondary non-response	27 (3.8%)	5 (2.3%)	0.401
Other causes	57 (7.9%)	18 (8.2%)	0.999
Adverse events	65 (9.1%)	35 (15.9%)	0.005
• Infection	11 (1.5%)	8 (3.7%)	0.093
• Malignancy	26 (3.6%)	7 (3.2%)	0.932

Conclusion: The use of conventional DMARDs, adverse events as the reason of treatment suspension and lower therapeutic survival are more frequent in patients older than 65 years of age.

POS0646 RISK FACTORS FOR POSTOPERATIVE COMPLICATIONS IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Outcome measures, Epidemiology, Inflammatory arthritides

D. A. Herrera Van Oostdam[1,2], N. García-Mosqueda[1], C. Abud-Mendoza[1,3]. *[1]Central Hospital Dr. Ignacio Morones Prieto, Reumatología, San Luis Potosí, Mexico*; *[2]General Zone Hospital No. 2 IMSS, Reumatología, San Luis Potosí, Mexico*; *[3]Faculty of Medicine, UASLP, Medicina Interna, San Luis Potosí, Mexico*

Background: Some patients with rheumatic diseases (RD) can require major surgical intervention. There are several risk factors for perioperative complications that must be addressed during de preoperative process [1,2].

Objectives: identify associated factors related to postoperative complications in patients with RD.

Methods: We performed a cohort study of patients with RD that required an elective or an emergency surgery from 2019-2021. We used as controls, patients with No-Rheumatic Diseases (NRD). All patients had preoperative assessment using Lee surgery index and the American College of Surgeons National Quality Improvement Program score (NSQIP), and we estimated disease activity of all RD according to the disease-specific activity scores. We follow-up patients until hospital discharge or death. Univariate and multivariate models were used to determine risk factors for postoperative complications (composite outcome: cardiac or lung complications, blood transfusion, infection, surgery reintervention, respiratory failure, use of vasopressors).

Results: We included 299 patients, 53 patients with RD and 246 NRD. The median age was 49 years in RD. Most patients with RD were women (85%). At baseline NRD patients had higher serum glucose levels, more use of insulin, and had higher rate of acute kidney injury. In the RD-group, 26 had rheumatoid arthritis, 13 systemic lupus erythematosus and 9 others (spondylitis, autoimmune hepatitis, antiphospholipid syndrome, polyarteritis nodosa). Active rheumatic disease was present in 21 patients. Most of the patients with RD (54%) had moderate to high risk of any complication, pneumonia, and risk of wound infection according the NSQIP score. The postoperative complications were higher in RD 37% vs NRD 16% (p=0.0003). Infection developed in 17% of RD patients vs 2.4% of NRD (p < 0.0001), uncontrolled hypertension was present in 3% in RD vs 0.4% in NRD, while hypovolemic shock was more frequent in NRD 4% vs 0%. One patient with RD died. Of the patients with RD, 58% continued with in-hospital glucocorticoid and 22% with another non-glucocorticoid immunosuppressor in-hospital. In the logistic regression analysis, the presence of active RD at the time of surgery (OR 4.9, IC95% 1.4-18) acute preoperative kidney injury (OR 3, IC95% 1.2-7.3) were predictors of post operative complications; type of surgery performed (elective or urgent), and in-hospital use of glucocorticoid, and immunosuppressors were not significant.

Conclusion: We observed higher post operative complications in RD patient's vs controls. The main prognostic factors were active rheumatic disease, preoperative kidney injury, while the type of surgery performed and in-hospital glucocorticoid or immunosuppressors were not associated to post operative complications.

Table 1. Baseline characteristics

	Rheumatic Disease (n=53)	No-Rheumatic Disease (n=246)	*p*-value
Age, median (IQR)	49 (19)	53 (18)	0.04
Female, n (%)	45 (85)	122 (49)	
Diabetes mellitus, n (%)	9 (17)	84 (34)	0.01
Systemic arterial hypertension, n (%)	22 (42)	90 (37)	0.46
Preoperative acute kidney injury, n (%)	1 (1.9)	27 (11)	0.03

POS0647 A COMPARISON OF 20 YEAR DISABILITY OUTCOMES IN VALIDATED CASES OF RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS IN THE NORFOLK ARTHRITIS REGISTER

Keywords: Psoriatic arthritis, Rheumatoid arthritis, Outcome measures

P. Saha[1,2], J. Dainty[1], A. Iftikhar Talib[1], T. Toyoda[1,2], A. Humberstone[2], A. Macgregor[1,2], M. Yates[1,2]. *[1]University of East Anglia, Norwich Medical School, Norwich, United Kingdom*; *[2]Norfolk and Norwich University Hospital, Department of Rheumatology, Norwich, United Kingdom*

Background: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are common inflammatory rheumatic diseases with distinct clinical phenotypes, that can

both result in significant disability. Whilst some data in selected samples report no difference in Health Assessment Questionnaire scores (HAQ) between RA and PsA(1), there is a lack of definitive long term population based data. The Norfolk Arthritis Register (NOAR) is an inception cohort of early inflammatory arthritis established in 1989, with over 4,500 cases of new onset inflammatory arthritis. Cases were recruited in primary care or from hospital clinics, and inclusion criteria were age >16 years with 2 swollen joints lasting ≥4 weeks. Data was collated on demographics and disability through Health Assessment Questionnaires (HAQ) over variable years of follow up (0-20 years); HAQ scores values range from 0 to 3, and the higher the score the greater the disability [2].

Objectives: Our aim was to compare differences between both baseline and follow-up HAQ scores in RA and PsA, in cases selected from the same base population and followed continuously for over 20 years.

Methods: Cases included in this study were recruits into NOAR, who were followed at intervals of 1, 2, 3, 4, 5, 7, 8, 10, 12, 15, 18 and 20 years. Cases of RA were defined using American College of Rheumatology (ACR) criteria; cases of PsA were classified by retrospective clinical record review. Cases with RA were compared to cases with PsA, and data analysis was carried out in R. Independent samples t-tests were used to assess statistical significance of unadjusted HAQ scores.

Results: A total of 1,812 cases of RA (85.4%) and 308 cases of PsA (14.5%) were identified with complete data on sex and age within the NOAR cohort who had recorded HAQ scores. The mean age of onset for RA was 56.3 years (min 18.6 – max 88.6; SD 13.9), and 47.3 years for PsA (min 16 – max 79.9, SD 13.1). Baseline HAQ: Mean baseline HAQ scores were higher for RA at 0.854 (SD 0.704) when compared with PsA at 0.706 (SD 0.688) (p<0.001). Females had higher baseline HAQ scores than males (0.915 vs 0.677) consistent across both disease types which was statistically significant (RA – 0.919 vs. 0.716, p <0.001: PsA – 0.885 vs. 0.533, p <0.001). Follow-up HAQ: Cases were followed up to 20 years. 1,812 cases of RA were identified at baseline, decreasing to 1552 with 1-year follow up (85.6%) and 165 cases with 20-year follow up (9.1%). 308 PsA cases were identified at baseline, 248 followed up at 1-year (80.5%) and 21 cases for 20-years (6.8%). Figure 1 illustrates that cases with RA had higher mean HAQ scores than PsA throughout a follow up period of up to 20 years. Mean HAQ scores accumulated over the follow up period for RA, whilst there was a decrease in HAQ scores after 12 years of follow up for those with PsA before increasing after 18 years.

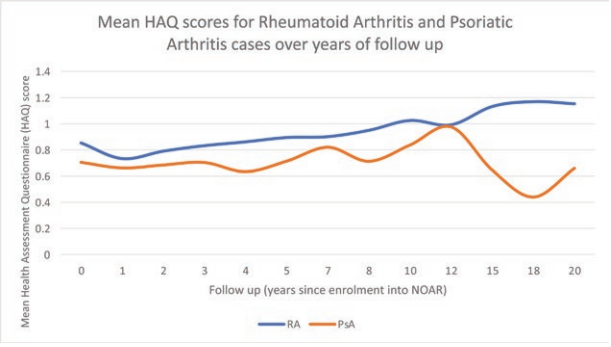

Figure 1. A comparison of the mean Health Assessment Questionnaire scores between Rheumatoid Arthritis and Psoriatic arthritis

Conclusion: The NOAR cohort is unique in its long follow up period of up to 20 years, allowing for the assessment of HAQ longitudinally. The relationship between higher HAQ scores in RA than PsA holds for both baseline HAQ scores and follow-up HAQ scores throughout the follow-up period, supporting the association of RA with greater disability. We hypothesise that this may be due to the nature of joint damage and other comorbidities associated with RA. We also demonstrate from this data that females present with statistically higher baseline HAQ scores than males within both diseases. In conclusion, there are evident trends with higher HAQ scores in RA over PsA consistent over time.

POS0648

EFFECT OF OBESITY ON DISEASE ACTIVITY OF PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: DATA FROM A NATIONWIDE COHORT

Keywords: Prognostic factors, Lifestyles, Rheumatoid arthritis

M. K. Chung[1], B. H. Park[2], H. Park[3], J. Lee[1]. *[1]Ewha Womans University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[2]National Cancer Control Institute, National Cancer Center, Goyang, Korea, Rep. of (South Korea)*; *[3]Ewha Womans University College of Medicine, Department of Preventive Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Rheumatoid arthritis (RA) is a chronic, multifactorial, inflammatory disease, and obesity is one of the risk factors implicated in RA development. Although obesity has been recently reported to be related to disease activity and clinical response of RA, the association between obesity and disease activity of RA is still controversial.

Objectives: This study aimed to investigate the effect of obesity on baseline disease activity and clinical response of patients with early RA.

Methods: Of 5,077 patients with RA enrolled in the Korean observational study network for arthritis (KORONA) registry, a nationwide RA-specific cohort, we identified 1,178 patients with disease duration of <2 years who had both baseline and 2-year follow-up data. Patients were grouped according to their body mass index (BMI): obese (BMI ≥25) and non-obese (BMI <25). Baseline and 2-year follow-up disease activity markers including erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), swollen and tender joints, patient global assessment (PGA), evaluator global assessment (EGA), clinical disease activity index (CDAI), and health assessment questionnaire-disability index (HAQ-DI) were compared between two groups.

Results: Among early RA patients, 282 (23.9%) obese and 896 (76.1%) non-obese patients were identified. The non-obese group showed higher ESR than the obese group at baseline (29.9±0.9 vs 25.6±1.6, p=0.019), and other disease activity variables showed no difference according to the obesity status. When comparing the group who maintained obese (n=176) and non-obese (n=660) for two years, the obese group had higher CRP positivity (37.4% vs 26.9%, p=0.009) while other variables including CDAI showed no significant difference between the two groups.

Conclusion: Obesity was not associated with baseline disease activity and treatment response of patients with early RA. As obesity was related to CRP positivity in 2-year follow-up measurements, the use of disease activity tools containing CRP requires careful attention.

POS0649

WHEN DOES OBESITY EXERT ITS EFFECT IN CONFERRING RISK OF DEVELOPING RA – A LARGE STUDY IN COHORTS OF SYMPTOMATIC PATIENTS AT RISK

Keywords: Rheumatoid arthritis, Outcome measures

Q. Dumoulin[1], D. Krijbolder[1], A. Willemze[2], P. De Jong[3], H. W. Van Steenbergen[1], A. Van der Helm – van Mil[1,3]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Maasstad Hospital, Rheumatology and Clinical Immunology, Rotterdam, Netherlands*; [3]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*

Background: Case-control studies have identified body mass index (BMI) as a risk factor for development of rheumatoid arthritis (RA). However, it is unclear when BMI exerts its effect of increased risk, being either in the asymptomatic stage or in the symptomatic phase of Clinically Suspect Arthralgia (CSA) thereafter.

Objectives: To investigate this, we compared BMI of CSA-patients with the general population and we analyzed associations of BMI with progression to inflammatory arthritis (IA) within CSA-patients.

Methods: Firstly, 602 patients consecutively presenting with CSA were studied and followed during 2 years for development of IA. Their baseline BMI was compared to the mean BMI (corrected for age/gender) of the Dutch population (Statistics Netherlands,CBS,2012-2020). Secondly, cross-sectional associations between BMI and measures of inflammation, tender joint count (TJC-68) and C-reactive protein (CRP), were studied. Finally, the association of BMI and IA development was studied via cox-regression. Findings were validated in 295 additional comparable patients with CSA included in the SONAR (n=178) and TREAT EARLIER trial (placebo arm, n=117)); a pooled analysis was performed.

Results: CSA-patients had a higher mean BMI compared to the general population (26.5 vs 25.3 kg/m^2, p<0.001). Likewise, CSA-patients were more often obese (BMI ≥ 30 kg/m^2) than the general population (22.3 vs 13.8%, Figure 1A); this applied to both ACPA-positive and ACPA-negative patients and was confirmed in the validation cohorts. At baseline, obese CSA-patients had higher TJC-68(β 1.26(1.04;1.52)) and CRP (1.37(1.20;1.57)) than CSA-patients with a normal weight. However, obese CSA-patients did not have an increased risk of IA development (HR 0.66(95%CI 0.39;1.11), Figure 1B). Similarly in the validation cohorts, higher BMI was not associated with RA-development (OR per point BMI 0.98(0.95;1.01) for both cohorts together, Figure 1C)

Conclusion: Obesity is more frequent in CSA compared to the general population. Moreover, obesity is associated with higher inflammation at presentation with CSA but did not entail a higher risk for progression from CSA to IA. Hence, obesity primarily seems to exert its effect in the asymptomatic risk-stage of RA-development.

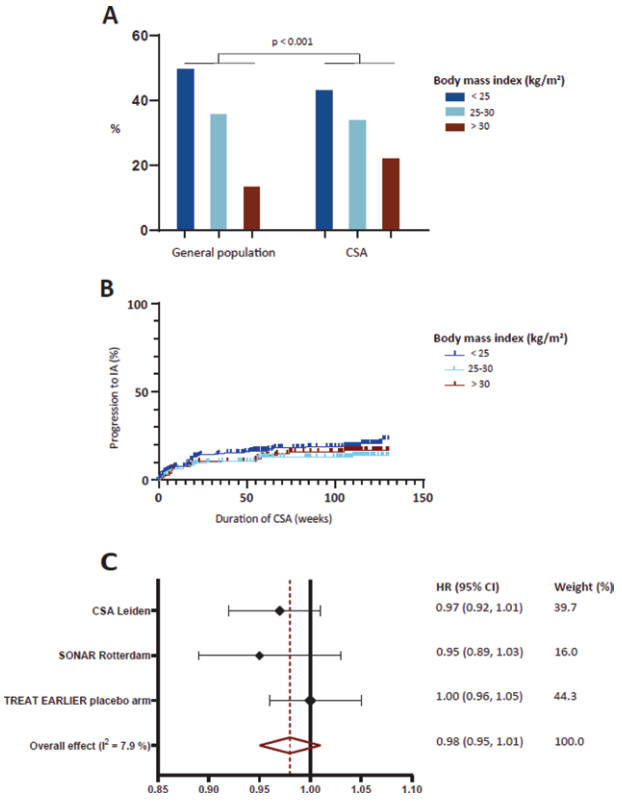

Figure 1. CSA-patients are more often obese than the general population (A); obesity in CSA-patients is not associated with IA development, studied via Kaplan-Meier analysis (B) or via pooled analysis of different cohorts (C).

Spondyloarthritis - clinical aspects (other than treatment)

POS0650

FACING THE ISSUES OF CHANGE IN ENTRY VISIT DIAGNOSIS AND LOST OF FOLLOW-UP OVER TIME IN INCEPTION COHORTS: DATA FROM THE AXIAL SPONDYLARTHRITIS (AXSPA) DESIR COHORT

Keywords: Spondyloarthritis, Epidemiology

C. Serrand[1], M. Dougados[2], T. Lequerre[3], S. Alonso[1], A. Moltó[2]. *[1]CHU Nimes, Department of Biostatistics, Nimes, France*; *[2]Cochin Hospital, Department of rheumatology, PARIS, France*; *[3]CHU Rouen, Department of rheumatology, Rouen, France*

Background: Inception cohorts can be defined as long term follow-up of patients suffering at entry visit from a recent onset disease. Despite their huge advantage to better approach the truth in terms of long term prognosis of the disease, they are usually facing 2 issues: a) the possibility of a change in the entry visit (initial) diagnosis b) the missing data due to patients lost of follow-up.
Objectives: To evaluate both the frequency and the baseline predisposing factors of a) a change in the initial diagnosis b) the risk of loss of follow-up in the DESIR axSpA cohort.
Methods: *Study design*:DESIR is an ongoing (10 year follow-up completed for all the patients) multicenter cohort of recent onset axSpA. *Diagnosis*: At entry visit and during the 10 year follow-up period, this diagnosis was based on the opinion of the treating rheumatologist with the requirement of a highly suspected diagnosis of axSpA at entry visit and after the first 2 years of follow-up the possibility to exclude the patients in case of a change in the initial axSpA diagnosis. *Statistical analysis*: Multiple imputation was used to address missing data and estimates the probabilities of a change in initial axSpA diagnosis for each patient lost of follow up. Predisposing factors of an unchanged initial axSpA diagnosis were then evaluated using a multivariate logistic regression model on imputed data sets. A multivariate cox survival analysis exploring factors associated to the overtime risk of loss of follow-up was also performed.
Results: Of the 708 enrolled patients, 45 were excluded from the cohort because of a documented change in the initial axSpA diagnosis (mechanical low back pain n = 30, fibromyalgia n = 13, chronic inflammatory rheumatic disease (n = 1 and no information n = 1).The classification criteria were fulfilled by 16/45 (36%) versus 413/663 (63%) and 21/45 (47%) versus 522/663 (81%) patients with a documented change versus no change in their entry visit diagnosis according to the ASAS ax-SpA and the AMOR criteria respectively. During the 10 year follow-up period, 300 patients were lost of follow-up. Based on imputation, among these 300 patients, 19 patients were systematically suspected to have a change in their initial axSpA diagnosis in all imputations while 173 patients were never "suspected" for this change; 42 patients were considered as suspected for a change in their initial axSpA diagnosis in at least 70% of imputations. Predisposing factors of an unchanged initial axSpA diagnosis were (odds ratio [95% CI]): radiographic SIJ structural damage: 17.0 [4.1; 71.0]; past or present psoriasis: 5.3 [2.0; 14.3]; CRP ≥ 6 mg/l: 2.7 [1.3; 5.3]; good response to NSAID: 2.5 [1.5; 4.2]; HLA B27 positivity: 2.0 [1.3; 3.3]; anterior chest wall pain: 2.0 [1.2; 3.3] and female gender: 1.9 [1.2; 3.0]. Predisposing factors of the risk of loss of follow-up were: Age at back pain initiation< 45 years old: 1.8 [1.2; 2.9]; CRP < 6 mg/l: 1.5 [1.1; 1.9]; HLA B27 negativity: 1.4 [1.1; 1.8]; educational level < university: 1.4 [1.1; 1.8]; smoker: 1.3 [1.0; 1.6].
Conclusion: These data suggest that a) a change in the entry visit diagnosis and the risk of follow-up have to be considered in inception cohorts b) statistical models including multiple imputations could facilitate the evaluation of long term prognosis of the disease.
Acknowledgements: The authors would like to thank the investigators of the 25 centers and all the 708 enrolled patients. This study has been supported via unrestricted grants from Pfizer france and the French society of Rheumatology.

VACCINATION RATE AND FACTORS ASSOCIATED WITH NON-VACCINATION IN AXIAL SPONDYLOARTHRITIS: A CROSS SECTIONAL PROSPECTIVE MULTICENTRIC OBSERVATIONAL STUDY

Keywords: Vaccination/immunization, Spondyloarthritis, COVID

A. Charlotte[1], T. Barnetche[2], C. Rempenault[1], D. Jerome[3], J. Bernard[4], M. Vandersmissen[5], J. Landrin[2], A. Ruyssen-Witrand[3], P. Vergne-Salle[5], C. Gaujoux-Viala[6], J. Morel[1], A. Tournadre[4], C. Lukas[1]. *[1]Hospital Center University De Montpellier, Rheumatology, Montpellier, France*; *[2]Hospital Center University De Bordeaux, Rheumatology, Bordeaux, France*; *[3]Hospital Center University De Toulouse, Rheumatology, Toulouse, France*; *[4]Site Estaing Clermont-Ferrand University Hospital, Rheumatology, Clermont-Ferrand, France*; *[5]CHU Dupuytren 1, Rheumatology, Limoges, France*; *[6]University Hospital of Nimes, Rheumatology, Nîmes, France*

Background: Patients receiving biological therapy for auto-immune diseases are considered immunodepressed and multiple recent recommendations highlight the need for vaccination against influenza and pneumococcal infections.
Objectives: To evaluate influenza and pneumococcal vaccine coverage in patients receiving biological therapy for spondyloarthritis (SpA), and to identify factors associated with vaccination completion in this population.
Methods: We conducted a prospective cross-sectional study of a cohort of 500 patients taking biological therapy for axial spondyloarthritis between june 2021 and june 2022 in five teaching hospitals in France (university hospital centers Bordeaux, Clermont-Ferrand, Limoges, Montpellier-Nimes and Toulouse). Influenza and pneumococcal vaccine coverage rates were collected using a self-administrated questionnaire. Patients were queried about knowledge and opinions about these vaccines. We also investigated the respective role of physicians and rheumatologists in the care and reasons for not proposing the vaccines. SARS- COV 2 impact and vaccine rates were also assessed. To identify factors associated with influenza vaccination and with pneumococcal vaccination, we performed a univariate and multivariate analysis.
Results: Influenza vaccination was received by 46.8 % (n = 234) of patients. Pneumococcal vaccine had been previously administered to 61.7% (n = 307) of patients. Vaccination coverage against SARS-CoV-2 was high with 91.8% of vaccinated patients. Overall vaccine coverage rates were 34.6% for patients who received both influenza and pneumococcus vaccines and were 33% for those who received influenza, pneumococcus and Sars-COV2 vaccines. Factors associated with vaccinated status were a higher level of education (OR =1.66 (1.03-2.68), p=0.038) and taking part in educational therapy session (OR = 1.85 (1.12-3.06), p= 0.016) for pneumococcus, affiliation to a patients' association (OR=4.10 (1.10-15.2), p=0.035) and intravenous administration of bDMARD (OR = 3.12 (1.76-5.54), p=0,0001) for influenza. Patients reported that they did not seek vaccination (influenza, pneumococcus or both) because (1) they did not receive appropriate information on vaccination and (2) fear possible side effects.
Conclusion: This study showed insufficient vaccine coverage rates in a population at high risk because of exposure to biological therapy. Reasons for not being vaccinated included fear of adverse effects and lack of information and recommendations. Patient information by healthcare professionals about influenza and pneumococcal vaccination has a major impact and physicians should inform patients about vaccination as often as possible.

Background: Standardized and validated outcome measures of disease activity are lacking in the treatment and assessment of uveitis, making it difficult to compare efficacy and response to treatment. In 2014, this working group developed a composite index of ocular inflammatory activity, UVEDAI, which includes 7 variables. The index was validated in a subsequent study conducted in 2019.
Objectives: To determine the interobserver reliability and to demonstrate the sensitivity to change of the UVEDAI index in patients with anterior and non-anterior uveitis who undergo pharmacological treatment.
Methods: The design is an observational, longitudinal, prospective, multicentre study in 7 Spanish hospitals. Patients over 18 years of age diagnosed with active uveitis were included. A complete baseline visit was performed by two ophthalmologists who determined ocular inflammatory activity with the UVEDAI index independently and without contact between them. Ophthalmologist 1 made a new visit at 4 weeks to determine the change in the level of uveal inflammatory activity using the UVEDAI index. The interobserver reliability analysis was performed by calculating the Intraclass Correlation Coefficient (ICC), with the values of the variables and the UVEDAI index obtained by ophthalmologist 1 and ophthalmologist 2 in the most inflamed eye at the baseline visit. Sensitivity to change in the UVEDAI index was assessed at 4 weeks from the start of pharmacological treatment by determining the Clinically Relevant Change (CCR) defined as a change in UVEDAI of 0.8 points between the baseline visit and the 4-week visit.
Results: A total of 111 patients were included, 54.1% were male and the mean age at the time of the visit was 49.9 years. 36.9% of uveitis were idiopathic uveitis, and 58.6% were anterior uveitis. The UVEDAI value was calculated from the score obtained in the 7 variables of the index. The mean value recorded in the most inflamed eye at the baseline visit by ophthalmologist 1 was 1.9, being 1.2 points for anterior uveitis and 2.8 points for intermediate/posterior uveitis. In the interobserver reliability analysis, the ICC for the UVEDAI value was 0.9, and when compared to the mean UVEDAI values obtained by the two ophthalmologists for the most inflamed eye at the baseline visit, no statistically significant differences were found (p-value>0.05), neither for the total sample nor differentiating by anatomical location. As for sensitivity of UVEDAI change, statistically significant differences (p-value=0.00) were found when comparing the mean values of the index measured by ophthalmologist 1 at the baseline visit and at 4 weeks, both in the overall sample and differentiating by anatomic location of uveitis. In all cases, the index value decreased significantly by more than 1 point at the 4-week visit after pharmacological treatment.
Conclusion: The interobserver reliability of the UVEDAI was high in the total sample and in the different variables. Furthermore, the index was sensitive in determining the change in inflammatory activity after treatment in both anterior uveitis and intermediate/posterior uveitis/panuveitis. We believe it is an index of activity that could be used both in routine clinical practice and in clinical studies and trials to compare results objectively.

POS0653 DIAGNOSTIC VALUE OF COMPUTER TOMOGRAPHY FEATURES OF SACROILIITIS FOR ANKYLOSING SPONDYLITIS

Keywords: Imaging, Spondyloarthritis, Diagnostic tests

G. Gerganov[1], T. Georgiev[2], T. Shivacheva[2], S. Bogdanova-Petrova[2], S. Dimitrov[2], R. Moraliyska[3], D. Simeonova[2], S. Hristova[4]. *[1]Medical University "Prof. Dr. Paraskev Stoyanov", Propaedeutics of Internal Medicine, Varna, Bulgaria; [2]Medical University "Prof. Dr. Paraskev Stoyanov", First Department of Internal Medicine, Varna, Bulgaria; [3]Medical University "Prof. Dr. Paraskev Stoyanov", Clinical medical sciences, Varna, Bulgaria; [4]Medical University "Prof. Dr. Paraskev Stoyanov", Department of General Medicine, Varna, Bulgaria*

Background: Radiologic evidence of sacroiliitis is important for the diagnosis, classification, and management of patients with ankylosing spondylitis (AS)[1]. Conventional radiography (CR) has been the most widely utilized imaging modality for the assessment of sacroiliac involvement in axial spondyloarthritis (AxSpA) because of the low radiation dose, ease of operation, and low expenses. CR is used in both the 1984 modified New York criteria and ASAS criteria for classifying AS and AxSpA but lacks sensitivity for early changes. Though MRI detects early changes of the sacroiliac joints, as well as chronic structural changes, its use is limited by the associated cost, procedural time and certain contraindications. Computed tomography (CT) is a modality that enables visualization of erosions, sclerosis, and new bone formation, with the added benefit of multiplanar cross-sectional imaging.
Objectives: We aimed to analyze the diagnostic value of computer tomography (CT) features of sacroiliitis for ankylosing spondylitis in patients with inconclusive CR evidence for sacroiliitis.
Methods: In this retrospective monocentric observational study, 50 patients with chronic low back pain (LPB) with a duration longer than three months in the lumbosacral region were included. Using the patient record data were extracted on age, pain duration, and plain radiography. Eligible patients should have had plain radiography without evident radiographic sacroiliitis. All the patients had undergone a CT scan of the sacroiliac joint that a radiologist and rheumatologist evaluated for subchondral osteosclerosis, erosions, joint space narrowing (JSN), subchondral cysts, and ankylosis. Based on the clinical and instrumental findings, including structural changes characteristic of radiographic sacroiliitis, a final decision by a certified rheumatologist was made and a diagnosis of ankylosing spondylitis was set or ruled out.
Results: The mean age and duration of LBP of the patients were 44.7 (14.7) years and 63.9 months, respectively. Of the 50 included patients, 28 (56%) were females. The mean values of c-reactive protein and erythrocyte sedimentation rate were 13.9 mg/l and 39.4 mm/h. Subchondral osteosclerosis was found in 44 patients (88%), JSN – in 21 patients (42%), erosions – in 17 patients (34%), subchondral cysts – in 10 patients (20%), ankylosis – in 18 patients (36%). Definite CT data for sacroiliitis was seen in 24 patients (48%) and the diagnosis of ankylosing spondylitis was set in 23 patients (46%) of the study group. The likelihood ratios (LR+) for diagnosis of AS were high for erosions (18.4), subchondral cysts (11), ankylosis (6.9) and low for JSN (LR+ 1.9) and ankylosis (LR+ 1.1).
Conclusion: Nearly half of the patients with inconclusive CR evidence for sacroiliitis were diagnosed with AS after CT imaging. Erosions seen on CT increase the likelihood of assuming AS diagnosis. Computed tomography is a useful tool in diagnosing AS, but it is associated with higher ionizing radiation doses.

POS0655 HLA-B27 POSITIVITY IN A LARGE MISCEGENATED POPULATION OF 5,389,143 HEALTHY BLOOD MARROW DONORS IN BRAZIL

Keywords: Genetics/epigenetics, Spondyloarthritis, Epidemiology

G. Resende[1], P. D. Sampaio-Barros[2], C. Saad[2], D. Oliveira[3], J. S. Bueno Filho[4], M. Pinheiro[5]. *[1]Hospital das Clínicas da UFMG, Reumatologia, Belo Horizonte, Brazil; [2]University of São Paulo, Reumatologia, São Paulo, Brazil; [3]Instituto Nacional de Câncer José Alencar Gomes da Silva (INCA), REDOME, Rio de Janeiro, Brazil; [4]Federal University of Lavras, Departamento de Estatística, Lavras, Brazil; [5]Escola Paulista de Medicina, Reumatologia, São Paulo, Brazil*

Background: The prevalence of HLA-B27 gene positivity in healthy Caucasian communities varies between 8-14%. However, there is a lack of information in countries with a high rate of miscegenation, such as Brazil.
Objectives: To estimate the prevalence of HLA-B27 positivity in the Brazilian general population using a large national registry.
Methods: This is a cross-sectional ecological study using the Brazilian Registry of Volunteer Bone Marrow Donors (REDOME) database on HLA-B27 allelic frequency and proportion of positives from healthy donors (18-60 years old). Data were analyzed according to race (by self-reported skin color, according the predetermined five terms used by Brazilian Institute of Geography and Statistics [IBGE]), and geographic region of residence.
Results: From 1994 to 2022, a total of 5,389,143 healthy bone marrow donors were included. The overall positivity for HLA-B27 was 4.35% (CI 95% 4.32-4.37%). There was a difference according to race (Table 1): 4.85% in Whites; 2.92% in Blacks; 3.76% in Pardos (Browns i.e. miscigenated between blacks and whites); 3.95% in Amarelos (Yellows i.e. Asian Brazilians, predominantly of Japanese descent); and 3.18% in Indigenous, p<0.0001. There was also a difference regarding geographic region as shown in Figure 1 (North: 3.62%; Northeast: 3.63%; Southeast: 4.29%; Midwest: 4.5% and 5.25% in South, p<0.0001). The homozygosity rate for the HLA-B27 was 1.32% of all the positives and only 0.06% in the general population.
Conclusion: Our findings provide the first Brazilian national prevalence for HLA-B27 in 4.35%, with differences between races, similar to previously published in another miscegenated population [1]. There is a positivity gradient from North/Northeast (Pardos/Brown predominant population) to South (White predominant population), suggesting that the genetic background related colonization and internal migratory flows, could explain our findings.

POS0656

DOES RADIOGRAPHIC STATUS IMPACT SECUKINUMAB EFFECTIVENESS IN EUROPEAN AXIAL SPONDYLOARTHRITIS PATIENTS TREATED IN ROUTINE CARE?

Keywords: Spondyloarthritis, Real-world evidence, Imaging

S. N. Christiansen[1], S. H. Rasmussen[1], M. Østergaard[1], B. Michelsen[1], K. Pavelka[1], C. Codreanu[1], A. Ciurea[1], B. Glintborg[1], M. J. Santos[1], İ. Sari[1], Z. Rotar[1], B. Gudbjornsson[1], J. Zavada[1], C. Mogosan[1], M. J. Nissen[1], A. G. Loft[1], A. Barcelos[1], Y. Erez[1], K. Pirkmajer[1], G. Gröndal[1], M. L. Hetland[1], L. Midtbøll Ørnbjerg[1]. [1]*European Spondyloartritis Research Collaboration Network (EuroSpA RCN), on behalf of ATTRA (Czech Republic), RRBR (Romania), SCQM (Switzerland), DANBIO (Denmark), Reuma-pt (Portugal), TURKBIO (Turkey), biorx.si (Slovenia) and ICEBIO (Iceland), Copenhagen, Denmark*

Background: The impact of radiographic status on real-world secukinumab treatment effectiveness in axial spondyloarthritis (axSpA) patients is unknown.
Objectives: To compare the treatment effectiveness of secukinumab in radiographic (r-) *vs.* non-radiographic (nr-) axSpA patients treated in routine care across Europe.
Methods: Prospectively collected data on secukinumab-treated axSpA patients with known radiographic status followed in routine care in the EuroSpA collaboration [1] were pooled from 9 countries. Patients were listed as r-axSpA if registered to fulfil the modified New York [2] or the radiographic ASAS classification [3] criteria. If patients were registered to fulfil neither criterion or if they did not fulfil one criterion and the other was unknown, patients were registered as nr-axSpA. Patient-reported outcome (PRO) remission rates including pain (VAS≤20), Bath Ankylosing Spondylitis Disease Activity (BASDAI≤20) and Functional Index (BASFI≤ 20) (all in the form of 0–100 visual analogue scale), and Ankylosing Spondylitis Disease Activity Score-CRP (ASDAS inactive disease <1.3) after 6, 12 and 24 months of secukinumab treatment were calculated. Remission rates in r-axSpA *vs.* nr-axSpA patients were compared by logistic regression analyses in an unadjusted model (MODEL1), a model adjusted for age/gender (MODEL2) and a model adjusted for age/gender/country/previous bDMARD (yes/no)/baseline CRP/years since diagnosis to secukinumab initiation (MODEL3). For MODEL3, parameter estimates (CRP) from 100 imputed data sets were pooled using Multivariate Imputation by Chained Equations.
Results: Patients with r-axSpA had longer disease duration at secukinumab initiation, were more frequently males and HLA-B27 positive compared to nr-axSpA patients. PROs at baseline were largely similar between groups, while CRP and ASDAS-CRP were higher in r-axSpA patients. A higher percentage of nr-axSpA patients had received previous bDMARDs compared to r-axSpA patients. Crude PRO remission rates at 6/12/24-months were significantly lower in nr-axSpA compared to r-axSpA patients (Table 1, Figure 1 (MODEL1)) as were percentages of patients in ASDAS inactive disease (Table 1). However, when adjusting for age/gender (MODEL2) the difference in PROs diminished, and when adjusting for multiple possible confounders (MODEL3), no significant differences were found between the two groups (Figure 1). Differences in percentages of patients in ASDAS inactive disease in r-axSpA *vs.* nr-axSpA patients were almost unaffected by adjustments (Figure 1).
Conclusion: While crude remission rates in European secukinumab-treated patients followed in routine care were higher in r-axSpA compared to nr-axSpA patients, this difference disappeared after adjusting for multiple confounders, and, thus, appeared to be related to other factors than radiographic status.

Background: The efficacy and safety of upadacitinib (UPA), an oral JAK inhibitor, has been demonstrated in phase 3 trials for PsA, [1,2] AS, [3,4] and non-radiographic axial spondyloarthritis (nr-axSpA) [5].

Objectives: To provide a safety update for UPA across PsA, AS, nr-axSpA, and pooled axSpA from the SELECT program.

Methods: Safety data (cut-off: 15 Aug 2022) from 5 UPA trials in PsA (2), AS (2), and nr-axSpA (1) were compiled. Treatment-emergent adverse events (TEAEs; onset on or after first dose and ≤30 days for UPA 15 mg [UPA15], or ≤70 days for adalimumab [ADA], after last dose) were summarized for PsA (pooled UPA15 and ADA [1 study only]), AS (pooled UPA15), nr-axSpA (UPA15), and pooled axSpA (pooled UPA15 from AS and nr-axSpA trials). TEAEs are reported as exposure-adjusted event rates (events/100 patient-years [E/100 PY]). Age-gender adjusted standard incidence ratios (SIRs) using the SEER database and standardized mortality ratios (SMRs) were calculated.

Results: A total of 1789 patients (PsA, n=907; AS, n=596; nr-axSpA, n=286) received ≥1 dose of UPA15, totaling ~3690 PY of exposure (**Table 1**). Overall AEs and serious AEs were highest in PsA, and numerically higher with UPA15 vs ADA; rates were generally similar between AS and nr-axSpA. AEs leading to discontinuation were generally similar across treatment groups and diseases and were numerically lowest in AS. Rates of malignancy excluding non-melanoma skin cancer (NMSC), MACE, and VTE were similar between UPA15 and ADA in PsA and were generally similar across diseases (**Figure 1**). In PsA, higher rates of serious infection, herpes zoster (HZ), lymphopenia, and NMSC were observed with UPA15 vs ADA. The SIR (95% CI) for malignancy excluding NMSC with UPA15 was 0.94 (0.54-1.53) in PsA and 0.58 (0.12-1.69) in pooled axSpA; SIRs for AS (1 case) and nr-axSpA (2 cases) were not calculated separately due to low events. In PsA, the SMR (95% CI) with UPA15 was 0.71 (0.40-1.18), and 0.33 (0.13-0.69) with COVID-19 deaths excluded, suggesting no increased risk of death vs the general population. SMRs were not calculated for AS, nr-axSpA, or pooled axSpA due to low events. Data from this analysis should be interpreted with caution, as it was not enriched for AEs and duration of exposure was more limited for AS and nr-axSpA.

Conclusion: Higher rates of serious infection, HZ, lymphopenia, and NMSC were observed with UPA15 vs ADA in PsA; slightly elevated rates for most of these TEAEs were also observed with UPA15 in PsA vs axSpA. Apart from these differences, UPA15 demonstrated a generally consistent safety profile across disease states, with no new safety signals identified from previous reports.

POS0658 ANKYLOSING SPONDYLITIS IS ASSOCIATED WITH INCREASED PREVALENCE OF VALVULAR HEART DISEASES: A POPULATION BASED STUDY

Keywords: Spondyloarthritis, Heart, Epidemiology

S. Eid[1], K. Sharif[2], L. Fisher[1], Y. S. Patt[1], H. Amital[1], A. Watad[1]. [1]*Sheba Medical Centre, Internal Medicine B, Ramat Gan, Israel*; [2]*Sheba Medical Centre, Internal Medicine B, Jerusalem, Israel*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory arthritis primarily affecting the sacroiliac joint and axial skeleton with associated extraarticular involvement including cardiovascular system disease including aortic value disease with variable reported prevalence.
Objectives: The aim of this study is to determine the prevalence of heart valve disorders in AS patients.
Methods: A retrospective, population-based, cross-sectional study retrieved from the Clalit Health Services (CHS) registry. Cases were defined as having AS, whereas controls were age- and sex- frequency matched in a ratio of 5:1. The prevalence of valvular heart diseases was compared between the two groups, a multivariate logistic regression model was applied to estimate the association after controlling for potential confounders.
Results: We included 4,082 AS patients and 20,397 age- and sex- frequency matched controls. AS patients had a significantly higher prevalence of cardiovascular risk factors (p<0.001) and a higher prevalence of valvular heart disease. In the multivariate logistic regression model, adjusting for multiple confounding factors, AS was independently associated with aortic stenosis (OR 2.25, 95% CI 1.57-3.23, p<0.001), aortic insufficiency (OR 2.44, 95%CI 1.5-3.94, p<0.001), mitral insufficiency (OR 1.75, 95%CI 1.17-2.61, p<0.001) but not mitral stenosis (OR 1.31, 95% CI 0.6-2.7, p=0.47).
Conclusion: Our study reports the increased risk of valvular heart diseases in patients with AS possibly due to the inflammatory milieu associated with the disease process and the result of biomechanical stress affecting the enthesis-like valvular structures.

POS0659 COMPARISON OF METROLOGICAL PROPERTIES OF THE S-SCAISS VERSUS THE SPARCC SCORING SYSTEM FOR THE DETECTION/QUANTIFICATION OF INFLAMMATION AT MRI-SIJ IN SPONDYLARTHRITIS: DATA FROM THE DESIR COHORT

Keywords: Diagnostic tests, Spondyloarthritis

R. Almodovar González[1], P. Zarco-Montejo[1], A. Bueno[2], C. García-Monco[3], E. Pérez-Fernández[4], C. López-Medina[5], M. Dougados[6], R. Mazzucchelli[1]. Background: Different tools to quantify inflammatory changes in sacroiliac (SI) MRI have been developed. The Spondyloarthritis Research Consortium of Canada (SPARCC) appears to be the most sensitive to change, as it has demonstrated a good discriminating capacity. In a previous work of our group, we described the development of a fast, easy and reliable method to quantify the bone marrow edema (BME) in MRI-SIJ, through a semi-automatic process with a computer tool called SCAISS. SCAISS uses both semi-axial and semi-coronal slices from the MRI-SIJ. Since many centres only perform semi-coronal slices, we developed a simplified tool (s-SCAISS) that only requires the assessment of semi-coronal slices.
Objectives: To compare inter-rater reliability, discriminative validity and sensitivity to change using the s-SCAISS system, and compared to the SPARCC system, in patients presenting with inflammatory low back pain suggestive of axial spondyloarthritis from the DEvenir des Spondylarthopathies Indifférenciées Récentes (DESIR) cohort.
Methods: MRI-SIJ image of 206 patients collected at baseline of the DESIR cohort and after a first one year follow-up were analyzed (46.6% male, mean age 33.6 ± 8.8 years). Inter-reader reliability (3 readers for s-SCAISS and 2 central core readers for SPARCC) was assessed using intraclass correlation coefficients (ICC). Discriminative validity testing was performed by calculating the Area Under the Curve (AUC), sensitivity, specificity and likelihood ratios for different cut-off points for the classification of presence/absence of BME in SI, using positive/negative MRI as the gold standard according to DESIR core readers. Sensitivity to change was evaluated in subjects with improvement in illness activity testing

differences between paired measures. Three different criteria were considered to define activity improvement: a change in ASDAS score at 12 months of 1.1 (Clinical Important Improvement -CII-) and 2 points (Major Improvement -MI-) and a reduction ≥ 50% of the initial BASDAI score (BASDAI50).

Results: Inter-rater reliability: Both s-SCAISS and SPARCC showed good inter-reader reliability: In baseline MRI: ICC 0.95 and 0.82, respectively; At 1 year MRI: ICC 0.80 and 0.79, respectively.

Discriminative validity: Of the 206 patients included in our study, 70 (34%) fulfilled the ASAS criteria for presence of Inflammation on MRI, The AUC for EMO detection was excellent for both systems (0.88 and 0.98 for SCAISS and SPARCC, respectively). The optimal cut-off point for s-SCAISS was 60 u (Sens 83%, Esp 80%) and for SPARCC 1.25 u (Sens 93% and Esp 94%). Using the s-SCAISS cut-off point of 60 u, and the one 1.25 for SPARCC, 165 patients (81.3%) and 189 patients (93.1%), respectively were classified in accordance with the ASAS definition of the presence or absence of inflammation at MRI evaluated by the human central readers. Sensitivity to change: Of the 206 patients included, at 1 year after baseline assessment, 48 (23.3%), 17(8.3%) and 54 (26.2%) patients had a CII, MI and BASDAI50, respectively. In these patients with improved disease activity, the mean (SD) s-SCAISS score at baseline was 404.1 (SD 1055.1), 185.7 (262.7) and 375.3 (SD1008.8), respectively. While at 12 months it decreased to 72.6 (SD134.8), 46.1 (SD72.1) and 76 (SD151.7). The means of paired differences were 331.4 (SD 1019.6), 139.7 (SD 240.8) and 298.3 (SD 976.9), respectively, all of them with $p<0.05$. As expected, the AUC for the detection of CII, MI and BASDAI50 for both systems were poor (s-SCAISS 0.61, 0.63 and 0.58 and for SPARCC 0.7, 0.66, 0.60, respectively).

Conclusion: The MRI-SIJ EMO quantification system with s-SCAISS is as reliable and sensitive to change as SPARCC. The apparent advantage of SPARCC over s-SCAISS is artefactualised by the fact that the definition of the presence or absence of ASAS criteria for sacroiliitis is determined by the same readers who assess SPARCC.

Acknowledgements: We thank all DESIR-cohort patients and all individuals involved with creating and maintaining the cohort. The DESIR cohort was sponsored by the Département de la Recherche Clinique et du Développement, Assistance Publique Hôpitaux de Paris. We are also grateful to the heads of the participating regional centres.

POS0660 FACET JOINT INFLAMMATION IS RARE, BUT WHEN PRESENT IT IS ASSOCIATED WITH FACET JOINT ANKYLOSIS IN RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS PATIENTS FROM THE SIAS COHORT

Keywords: Imaging, Spondyloarthritis

M. De Hooge[1], R. Stal[2], A. Sepriano[2,3], X. Baraliakos[4], M. Reijnierse[5], J. Braun[4], D. Van der Heijde[2], F. A. Van Gaalen[2], S. Ramiro[2]. *[1]Ghent University Hospital, Rheumatology, Gent, Belgium*; *[2]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[3]UNL, NOVA Medical School, Lisbon, Portugal*; *[4]Rheumazentrum Ruhrgebiet Herne, Rheumatology, Herne, Germany*; *[5]Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands*

Background: There is still little known on posterior element (PE) inflammation and ankylosis in the facet joints (FJ) of patients with axial spondyloarthritis (axSpA).

Objectives: To assess whether PE inflammation, in particular in the FJ, is associated with new FJ ankylosis on MRI one year later, in patients with radiographic axSpA (r-axSpA).

Methods: Patients with a diagnosis of r-axSpA recruited from Germany (Herne) and the Netherlands (Leiden) were included in the Sensitive Imaging in Ankylosing Spondylitis (SIAS) observational cohort when ≥1 inflammatory lesion on MRI of the spine and 1-18 syndesmophytes were present. Spinal MRIs were performed at baseline, 1 and 2 years. PE inflammatory lesions and FJ ankylosis were both assessed on MRI, per vertebral unit (VU) level by 3 readers independently. FJ inflammation in the cervical spine was not assessed. The probability of developing FJ ankylosis after one year was described conditional on the presence or absence of PE/FJ inflammation at baseline. Multilevel time-lagged auto-regressive GEE was used for the association between PE (or FJ) inflammation and the development of FJ ankylosis one year later, taking the reader and VU levels into account.

Results: In 58 patients MRI scores of at least 2 readers were available. Patients' average age was 49±10) years and 85% was male. Inflammation in PE or FJ at baseline was seen in 34 (59%) and 14 (24%) patients respectively. PE inflammation was distributed throughout the whole spine but most prevalent in the lower part of the thoracic spine (9%-16%). FJ inflammation was infrequently present and was more often reported in the upper thoracic spine (2%-5%) (Figure 1). FJ ankylosis was reported in 15 patients (26%) at baseline and 17 patients (29%) with follow up visits. FJ ankylosis was mainly present in the upper half of the spine (Figure 1). In 19 patients (33%) the development of new FJ ankylosis over 1 or 2 years was seen by at least 1 reader. Of the VU levels with PE or FJ inflammation only very few showed new FJ ankylosis after one year: 2 and 1 VU levels, respectively (Table 1). There was no association between PE inflammation and the development of new FJ ankylosis in the same level after one year (OR=1.15, 95%CI 0.55-2.42). However, FJ inflammation was associated with new facet joint ankylosis one year later (OR=3.79, 95%CI 1.47-9.75).

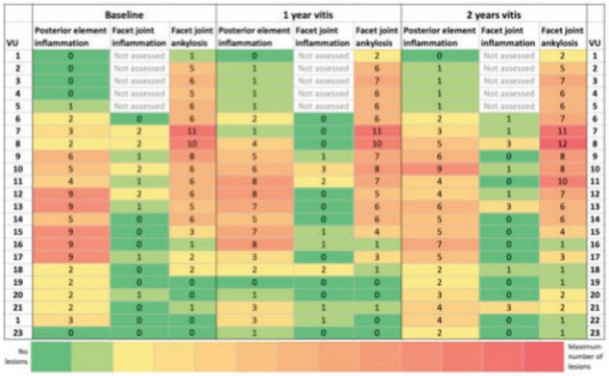

Figure. The extent of posterior element lesions on MRI across the 23 vertebral units (VU) in radiographic axial spondyloarthritis patients with 2 years follow-up.

Table 1. Probability of developing facet joint ankylosis with and without posterior element inflammation present one year before, in r-axSpA patients from the SIAS cohort

Inflammation in any part of the posterior elements			
PE inflammation	New facet joint ankylosis after one year	N*	P (FJ ankylosis | PE inflammation)
0	0	7195	P (FJ ankylosis | 0) = 43/7238 =
0	1	43	0.0059
1	0	511	P (FJ ankylosis | 1) =2/513 =
1	1	2	0.0039
Inflammation only in the facet joint			
Facet joint inflammation	New facet joint ankylosis after one year	N#	P (FJ ankylosis | FJ inflammation)
0	0	5934	P (FJ ankylosis | 0) = 38/5972 =
0	1	38	0.0064
1	0	93	P (FJ ankylosis | 1) =1/94 =
1	1	1	0.0106

PE; posterior elements, *; number of VU levels with inflammation in at least 1 part of the posterior elements (pedicle, facet joint, processes spinosi, soft tissue), #; number of facet joints, FJ; facet joint, P; probability

Conclusion: PE inflammation and FJ ankylosis on MRI were infrequently observed in patients with r-axSpA. No association was found between inflammation in the PE and the development of FJ ankylosis. However, when inflammation in the FJ is present the likelihood of developing FJ ankylosis after 1 year is over 3 times higher compared to FJ without inflammation. This finding adds to the pathophysiological relationship between inflammation and ankylosis at the same anatomical location of the axial skeleton in patients with axSpA.

POS0661

A RADIOMICS MODEL DERIVED FROM T1-WEIGHTED IMAGES FOR EVALUATING STRUCTURAL LESIONS OF THE SACROILIAC JOINT USING LOW-DOSE CT AS THE REFERENCE STANDARD

Keywords: Imaging, Spondyloarthritis

M. Zheng[1], G. Zhu[2], D. Chen[3], Q. Xiao[1], C. Ye[4], T. Lei[4], C. Pan[4], S. Miao[1], L. Ye[3]. *[1]the First Affiliated Hospital of Wenzhou Medical University, Department of Radiology, Wenzhou, China*; *[2]Longgang People's Hospital, Department of Radiology, Wenzhou, China*; *[3]the First Affiliated Hospital of Wenzhou Medical University, Department of Rheumatology, Wenzhou, China*; *[4]Wenzhou Medical University, The First Clinical Medical College, Wenzhou, China*

Background: Detection of structural lesions of the sacroiliac joint (SIJ) in patients with chronic low back pain is crucial for the diagnosis and classification of axial spondyloarthritis (axSpA). With MRI becoming a part of a routine diagnostic approach of axSpA, the question about the value of T1-weighted images (T1WI) evaluating structural lesions raised.
Objectives: To construct and validate a radiomics model based on T1WI to assess SIJ structural lesions in patients with suspected axSpA.
Methods: A total of 266 patients with clinical suspicion of axSpA between December 2016 and January 2022 were enrolled. Structural lesions were assessed by low-dose CT (ldCT) and MRI, respectively. Radiomics features, extracted from SIJ T1WI, were included to generate the radiomics model. Performance of the radiomics model was evaluated by the receiver operating characteristic curve. Point-biserial correlation analysis was used to interpret the associations between the radiomics features and structural lesions.
Results: Structural lesions were found in 122 of 187 patients (65.2%) in the training cohort and 52 of 79 patients (65.8%) in the validation cohort. Using ldCT as the gold standard, the area under the curves (AUCs) of the radiomics model and MRI experienced raters were 0.82 (95% CI: 0.76, 0.88) vs 0.73 (95% CI: 0.67, 0.79) in the training cohort, and 0.82 (95% CI: 0.72, 0.91) vs 0.74 (95% CI: 0.66, 0.83) in the validation cohort. The seven radiomics features included showed significant correlation with various structural lesions (*P* all <0.05). Among them, Wavelet.LHL_firstorder_90Percentile showed the strongest association with fat lesion (r = 0.48, *P*<0.05).
Conclusion: The radiomics analysis with T1WI could effectively detect SIJ structural lesions and each radiomics feature was correlated with different structural lesions significantly, which might inform radiomic-based applications for axSpA intelligent diagnosis.

THE SOCIOECONOMIC PROFILE OF PATIENTS WITH RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IS ASSOCIATED WITH THE SEVERITY OF THE DISEASE AND WITH THE PERMANENT DISABILITY. A CLUSTER ANALYSIS IN A NATIONAL SPANISH REGISTRY

Keywords: Work-related issues, Spondyloarthritis, Outcome measures

C. López-Medina[1], D. Ruiz[2], M. Á. Puche Larrubia[1], M. L. Ladehesa Pineda[1], M. C. Ábalos-Aguilera[2], F. U. Pilar[3], A. Escudero Contreras[3], E. Collantes Estevez[3]. *[1]Reina Sofía University Hospital, Rheumatology, Cordoba, Spain*; *[2]Maimonides Biomedical Research Institute of Cordoba (IMIBIC), GC-05 Group, Cordoba, Spain*; *[3]University of Cordoba, Surgical and Medical Sciences, Cordoba, Spain*

Background: Previous studies have demonstrated that male gender and higher level of education are independently associated with a lower hazard of sick leave in patients with axial Spondyloarthritis (axSpA), while female gender has a disadvantageous effect on employment. However, few studies have identified socio-economic profiles of patients and their association with the severity of the disease and disability.
Objectives: a) to identify clusters of patients with r-axSpA according to their socio-economic characteristics; b) to evaluate the association of these clusters with the severity of the disease and permanent disability.
Methods: REGISPONSER (Spanish Registry of Spondyloarthritis) was a cross-sectional and multicentre study including Spanish patients with spondyloarthritis (SpA) according to the ESSG criteria. Patients considered by their treating rheumatologist as suffering from radiographic axSpA (r-axSpA) or ankylosing spondylitis (AS) were included in this specific analysis. A cluster analysis was conducted using information on sociodemographic (age, sex, race, marital status, education) and socioeconomic characteristics (employment, profession, housing conditions and social level). Multiple correspondence analyses and k-means clustering methods were used. The clinical characteristics, burden of the disease and permanent disability were compared between the different clusters adjusting for disease duration.
Results: A total of 866 patients with r-axSpA were included in the analysis. Two clusters were found according to the socio-economic characteristics (Table 1). Cluster 1 (n=476) showed a profile of patients predominantly married, with secondary/elementary studies, unemployed/housekeepers, nonskilled workers, with good or deficient housing conditions and low-middle social level. On the other hand, cluster 2 (n=479) showed a profile of patients with predominantly university/bachelor studies, employed, with university/technician professions, optimal housing conditions and upper-middle social level. In terms of clinical characteristics and burden of the disease, after adjusting for disease duration, patients from cluster 1 showed older age at the diagnosis (37.9 vs. 32.6), a longer diagnosis delay (7.8 vs. 6.8 years), higher body mass index (27.6 vs. 25.9) and greater structural damage in comparison with cluster 2 (BASRI total (5.7 vs. 4.6) and BASRI cervical (6.9 vs. 5.7)). No differences were found regarding smoking, peripheral and extra-musculoskeletal manifestations. The access to biologic modified antirheumatic drugs (bDMARDs) was similar between the two groups (30.6% vs. 27.5%, p=0.376, for cluster 1 and 2, respectively). However, patients from cluster 1 showed a higher prevalence of permanent disability in comparison with cluster 2 after adjusting for disease duration [30.8% vs. 13.2%, OR 2.58 (95%CI 1.76 - 3.83), p<0.001].
Conclusion: This study suggests that the socio-economic profile of patients with r-axSpA may have implications in the severity of the disease and in permanent disability despite a similar use of bDMARDs.

Table 1. Comparison of the socioeconomic characteristics between the two clusters.

	Cluster 1 N = 476	Cluster 2 N = 390
Sex male vs. Female	75.2%	74.1%
Race white vs. Others	98.5%	99.7%
Married vs. single/ divorced/ widowed	81.5%	71.0%
University/ bachelor studies vs. secondary/ elementary studies/ illiterate	4.4%	73.1%
Employed/ retired vs. unemployed/ housekeeper	51.0%	67.4%
University/ technician profession vs. employee/ skilled/ non-skilled worker	0.4%	49.0%
Luxury/ optimal housing conditions vs. good/ deficient/ inadequate	27.9%	65.9%
Upper/ Upper-middle/ middle social level vs. low-middle/ underclass	8.4%	99.5%

POS0663 GUT INFLAMMATION ASSOCIATED WITH MORE STRUCTURAL DAMAGE IN THE SPINE IN AXIAL SPONDYLOARTHRITIS. RESULTS FROM THE SPARTAKUS COHORT

Keywords: Imaging, Gastrointestinal tract, Spondyloarthritis

J. K. Wallman[1,2], E. Mogard[1,2], J. Sagard[1,2], K. Andréasson[1,2], J. Marsal[3,4], M. Geijer[5,6], T. Olofsson[1,2], E. Lindqvist[1,2]. Background: While 5-10% of axial spondyloarthritis (axSpA) patients have diagnosed inflammatory bowel disease (IBD), 50-60% display microscopic gut inflammation upon examination of mucosal biopsies. Gut inflammation, as measured by faecal calprotectin (F-calprotectin), is more frequent in radiographic (r-axSpA) than non-radiographic axSpA (nr-axSpA) and has been linked to more active disease [1] – a known risk factor for structural damage progression. How gut inflammation relates to the degree of structural damage in the spine, however, remains sparsely studied.

Objectives: To assess if gut inflammation, as measured by elevated F-calprotectin, is associated with more structural damage in the spine in patients with axSpA.

Methods: Patients with clinical axSpA from a defined area of southern Sweden were cross-sectionally examined and classified as nr-axSpA (ASAS criteria; n=85) or r-axSpA (modified NY or ASAS criteria; n=171). Twenty-four (9.4%) subjects had comorbid IBD. Spinal structural damage was quantified by the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS; one experienced reader scored all examinations), and gut inflammation by F-calprotectin (Calpro AS ELISA). mSASSS scores of patients with normal F-calprotectin (<50 mg/kg) were compared to those with elevated (≥50 mg/kg) or substantially elevated (≥150 mg/kg) values, respectively (Mann Whitney U-test). Furthermore, to explore if presence of gut inflammation (F-calprotectin ≥50 mg/kg) was associated with an mSASSS score above the median, logistic regression analysis was used, adjusting for sex, symptom duration, HLA-B27-status, smoking (ever/never), CRP, NSAID (ASAS 3-month NSAID-score) and anti-TNF therapy (yes/no) use. Apart from assessing the overall axSpA group, analyses were also performed limited to subjects with r-axSpA, since both mSASSS and F-calprotectin values were expected to be higher in r-axSpA. Finally, analyses were also repeated after exclusion of patients with IBD as a sensitivity analysis.

Results: Characteristics of the included patients are displayed in the **Table 1**. In the overall axSpA group, mSASSS scores were significantly higher among patients with elevated F-calprotectin, and even more so among those with substantially elevated F-calprotectin, as compared to subjects with normal values (**Figure 1**). Similar results were seen when limiting the assessment to r-axSpA, although here mSASSS was significantly higher only among those with substantially elevated F-calprotectin (**Figure 1**). F-calprotectin ≥50 mg/kg was associated with having an mSASSS score above the median (>2 in the overall axSpA and >5 in the r-axSpA groups, respectively) in both study populations – all axSpA: adjusted odds ratio (OR) 2.2 (95%CI 1.1-4.3), p=0.019; r-axSpA: adjusted OR 2.7 (1.1-6.7), p=0.028. Excluding patients with comorbid IBD rendered similar results.

Conclusion: Presence of gut inflammation, as measured by elevated F-calprotectin, is associated with more structural damage in the spine in patients with established axSpA, as well as specifically in r-axSpA, even after adjustment for known risk factors of spinal damage development. This calls for prospective studies, assessing gut inflammation as a potential predictor of radiographic progression.

Background: Presenteeism is associated with lower work satisfaction and future sick leave in patients with axial spondyloarthritis (axSpA). It is generally assessed as a continuous variable; however, despite a lower precision, categorical variables are more clinically relevant in routine practice.
Objectives: 1) To identify thresholds of presenteeism instruments that reflect unacceptable work status in axSpA and whether those thresholds could predict future adverse work outcomes, 2) to compare the performance of these thresholds with thresholds from traditional outcomes for axSpA and 3) to understand whether thresholds are stable across contextual factors.
Methods: We used data from the 1-year multinational prospective study on Patient-Reported Outcomes in Employment Study in Ankylosing Spondylitis (AS-PROSE). Thresholds to determine when patients consider themselves in 'unacceptable work status' were calculated at baseline for 4 presenteeism instruments (Work Productivity and Activity Impairment questionnaire -WPAI-, Quality and Quantity method -QQ-, Workplace Activity Limitations Scale -WALS- and Work Limitations Questionnaire -WLQ 25-); and for BASDAI and BASFI. We performed receiver operating characteristic (ROC) analysis using as external criteria the Patient Acceptable Work State (PAWS) question 1, addressing ability to perform the current job satisfactorily. We used different approaches (75th percentile, Youden index, Liu method, nearest to 0.1) to determine the optimal cut-off, while balancing over-under diagnosis. Temporal validation was assessed by applying the thresholds in different timepoints. Influence of context (age, gender, nature of work, symptom duration) was explored in subgroup analyses. Finally, accuracy of thresholds to predict "future adverse work outcome" throughout 12 months (defined as sick leave or long-term disability) was assessed.
Results: A total of 366 patients were included: 72% males, mean age 43 (SD 10), with a mean symptom duration of 18.2 (11) years. 15% of the patients considered themselves in an unacceptable work status, and 6% had at least one adverse work outcome during the 12 months. The optimal thresholds of the presenteeism instruments that reflect an unacceptable work status are expressed in the Table 1. BASDAI and BASFI performed similarly to the presenteeism instruments (Figure 1). Across numerous contextual factors the thresholds were stable, except for some underdiagnoses among women and persons with a physical loading job by WPAI-, QQ-, BASDAI- and BASFI-thresholds. The threshold accuracy to predict adverse work outcome over 12 months was similar across all the presenteeism instruments (68-76% of correctly classified patients), except for the QQ (<60%). BASDAI and BASFI also performed slightly worse (66-67%).
Conclusion: Thresholds for presenteeism and health status representing unacceptable work status have been established, showing stability across contextual factors. The capacity of these thresholds to predict future adverse work outcome was somehow lower for all instruments. BASDAI and BASFI had a similar performance.

Table 1. Optimal thresholds for presenteeism measures and patients correctly classified for unacceptable work status and adverse work outcome at 12 months.

	Optimal threshold (SE/SP)	Correctly classified for unacceptable work status n (%)	Correctly classified for AWO at 12 months n (%)
WPAI presenteeism (0-100)	**≥40 (70/86)**	283 (83)	215 (76)
QQ method (0-10)	**≥3 (81/62)**	218 (65)	160 (57)
WALS (0-3)	**≥0.75 (86/75)**	255 (76)	193 (68)
WLQ 25	**≥29 (77/80)**	266 (79)	201 (71)
BASDAI (0-10)	**≥4.7 (81/71)**	245 (73)	290 (67)
BASFI (0-10)	**≥3.5 (81/67)**	232 (69)	185 (66)

[1]*University of California San Francisco, Medicine, Division of Rheumatology, San Francisco, United States of America*; [1]*University of California San Francisco, Medicine, Division of Rheumatology, San Francisco, United States of America*; [3]*Alameda Health System, Medicine, Division of Rheumatology, Oakland, United States of America*; [4]*Charité – Universitätsmedizin Berlin, Medicine, Division of Rheumatology, Berlin, Germany*; [5]*University of Copenhagen, Section for Biostatistics and Evidence-Based Research, the Parker Institute, Copenhagen, Denmark*; [6]*San Francisco VA Healthcare System, Medicine, Division of Rheumatology, San Francisco, United States of America*; [7]*University of California San Francisco, Institute for Health Policy Research, San Francisco, United States of America*

Background: Adults with ankylosing spondylitis (AS), also known as radiographic axial spondyloarthritis, are at a significantly increased risk of fracture relative to the general population. While some studies have evaluated the risk of fracture in AS, we do not have European or U.S. population-level studies assessing different fracture types performed within the last three decades.
Objectives: We evaluated the incidence rate and factors associated with fractures among those with AS using linked data from the national U.S. Rheumatology Informatics System for Effectiveness (RISE) registry and Medicare claims.
Methods: Data were derived from RISE, a large, national electronic health record-based registry, which was linked to Medicare claims from 2016-2018. Patients were required to have at least two visits for AS with a rheumatology provider, ≥ 30 days apart, prior to the baseline period of the study and at least one Medicare claim. One year of baseline characteristics was collected from both RISE and Medicare claims. Subjects were considered to have a historical

fracture (vs. an incident fracture) if a fracture occurred prior to the index date. Patients were followed over time for incident fractures after the index date. Fractures were defined by ICD codes. We examined all fractures, including those of the vertebrae, sternum/ribs, shoulder/clavicle/upper arm/elbow, distal forearm/wrist/hand, pelvis/hip/femur, knee/lower leg, and ankle/foot. First, we calculated the combined incidence of fracture and incidence by fracture type. Second, logistic regression models were constructed to identify factors associated with fracture, including age, sex, race or ethnic group, national area deprivation index, dual-eligibility for Medicare (healthcare for adults aged 65+ and some people with certain conditions/disabilities) and Medicaid (healthcare for those with limited income and resources), Charlson comorbidity index, body mass index, smoking status, osteoporosis diagnosis, historical fracture (fracture prior to index date), and use of glucocorticoids and opioids.

Results: We identified 1,426 adults with AS in RISE who were also observable in Medicare. The mean (SD) age was 69.4 years (9.8), 44.3% were female, and 77.3% were non-Hispanic White. Fractures occurred in 197 AS adults (**Table 1**). The overall incidence rate of fractures among adults with AS was 76.7 (95% CI 66.4-88.6) per 1,000 person-years. The most common fracture was vertebral with an incidence rate of 23.9 per 1,000 person-years (95% CI 18.6-30.7), followed by distal forearm/wrist/hand with an incidence rate of 17.4 per 1,000 person-years (95% CI 13.0-23.4). Age 85+ (OR 3.64, 95% CI 1.79-7.40), historical fracture (OR 5.18, 95% CI 3.40-7.89), and use of opioid drugs (OR 2.20, 95% CI 1.52-3.19) conferred increased odds of fracture; sex did not (**Figure 1**).

Conclusion: In this large U.S. sample of older adults with AS, vertebral fractures were the most common followed by distal forearm/wrist/hand fractures. Those who were older, had a historical fracture and used opioids had higher odds of fracture. Men and women were equally likely to have a fracture. Since chronic opioid use was associated with fracture in AS, this high-risk population should be considered for interventions to mitigate risk.

Table 1. Incidence rate of fractures by type.

First Fracture	N (%)	Incidence Rate per 1,000 person-years	95% CI
Any Fracture	197/1,426	76.7	66.4-88.6
By Fracture Type*			
Vertebral	61 (25.7)	23.9	18.6-30.7
Distal forearm/wrist/hand	45 (19.0)	17.4	13.0-23.4
Ankle/foot	33 (14.0)	12.8	9.1-18.0
Pelvis/hip/femur	29 (12.2)	11.2	7.8-16.1
Sternum/ribs	25 (10.5)	9.6	6.5-14.3
Shoulder/clavicle/upper arm/elbow	24 (10.1)	9.3	6.2-13.8
Knee/lower leg	20 (8.4)	7.7	5.0-11.9

*Subject's first fracture within a category were included in the counts by fracture type. Subjects can appear in more than one fracture type category if another fracture occurred in a different location. Data displays 237 unique fractures in 197 participants.

POS0666 COSTOVERTEBRAL JOINT INVOLVEMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Imaging, Spondyloarthritis

S. M. Jung[1], M. Y. Kim[2], Y. S. Hong[2], S. H. Park[3], K. Y. Kang[2]. *[1]St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Suwon, Korea, Rep. of (South Korea); [2]Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Incheon, Korea, Rep. of (South Korea); [3]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Several previous studies have reported that patients with axial spondyloarthritis (axSpA) presented with thoracic pain due to costovertebral joint arthritis. However, little is known about the prevalence and clinically relevant factors of costovertebral joint involvement in patients with axSpA.

Objectives: To evaluate costovertebral joint involvement in patients with axSpA and to assess its association with disease features.

Methods: We included 150 patients from the Incheon Saint Mary's axSpA observational cohort who underwent whole spine low-dose computed tomography (ldCT). Costovertebral joint abnormalities were scored by two readers on a scale of 0-48 based on the presence or absence of erosion, osteophyte, and ankylosis. The interobserver reliability of costovertebral joint abnormalities was assessed using intraclass correlation coefficients (ICCs). Associations between costovertebral joint abnormality scores and clinical variables were evaluated using a generalized linear model.

Results: Two independent readers found costovertebral joint abnormalities in 74 (49%) patients and 108 (72%) patients. The ICCs of scores for erosion, osteophyte, ankylosis, and total abnormality were 0.85, 0.77, 0.93, and 0.95, respectively. For both readers, total abnormality score was correlated with age, symptom duration, Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath AS functional index (BASFI), CT syndesmophyte score (CTSS), and number of bridging spines. Multivariate analyses showed age, ASDAS, CTSS to be independently associated with total abnormality scores in both readers. The frequency of ankylosed costovertebral joint was 10.2% (reader 1) and 17.0% (reader 2) in patients without radiographic syndesmophytes (n = 62), and 10.3% (reader 1) and 17.2% (reader 2) in patients without radiographic sacroiliitis (n = 29).

Conclusion: Costovertebral joint involvement was common in patients with axSpA, even in the absence of radiographic damage. LdCT is recommended for evaluating structural damage in patients with clinically suspected costovertebral joint involvement.

Background: It is well-established that axial spondyloarthritis (axSpA) is associated with extra-musculoskeletal manifestations such as anterior uveitis, psoriasis, and inflammatory bowel disease (IBD). Although relevant data exists also regarding other specific comorbid diseases, less is reported on the overall comorbidity burden in relation to the background population.
Objectives: To assess the frequency of a wide range of comorbidities, covering most important organ-domains and conditions, in a population-based axSpA cohort, including both non-radiographic (nr-axSpA) and radiographic (r-axSpA) disease, and to compare this to frequencies among matched general population comparator-subjects.
Methods: We included 246 well-characterised axSpA patients (mean age 52 years; 55% male) with established disease from the SPARTAKUS cohort, comprising patients from a defined area of southern Sweden. All patients had undergone a thorough clinical assessment and were classified as nr-axSpA (fulfilling ASAS nr-axSpA criteria; n=82) or r-axSpA (meeting modified New York/ASAS r-axSpA criteria; n=164). Furthermore, for each axSpA patient, 5 comparator-subjects from the general population, matched on sex, age, and residence area, were randomly drawn from the Swedish Population Register (n=1230). The frequency of 55 different comorbidities, covering most important organ-domains, were then investigated through ICD-10 diagnostic codes retrieved from the Skåne Healthcare Register (covering both primary and specialised care) and collected during a 10-year period preceding inclusion in the cohort (for the index cases; and during the same period for their respective comparator-subjects). Univariate logistic regression was used to compare frequencies of the various comorbidities between axSpA patients and comparator-subjects, while employing the Benjamini-Hochberg procedure to account for multiple tests. Comorbidities with <5 events in either group were excluded from the analysis (n=12).
Results: Characteristics of the included patients are displayed in the **Table 1**. Numerically, almost all investigated comorbidities were more frequent among axSpA patients than comparator-subjects (**Figure 1**). The patients showed a significantly higher frequency of known extra-musculoskeletal manifestations: anterior uveitis (28% vs. 1% for comparator-subjects, p<0.001), IBD (10% vs. 1%, p<0.001), and psoriasis (10% vs. 3%, p<0.001). Also, previously less investigated conditions such as degenerative disc disease (17% vs. 6%, p<0.001), fibromyalgia (12% vs. 3%, p<0.001) and nephrolithiasis (8% vs. 3%, p<0.001) were clearly overrepresented. In addition, patients displayed higher proportions of well-known side-effects of NSAIDs: gastritis (21% vs.10%, p<0.001) and hypertension (31% vs. 19%, p<0.001); as well as glucocorticoids (GC): cataract (11% vs. 7%, p=0.010), glaucoma (7% vs. 3%, p=0.008) and vertebral compression (4% vs. 1%, p=0.002); and more patients had been hospitalised for infections (10% vs. 5%, p=0.006).
Conclusion: When assessing a wide range of comorbidities, contemporary axSpA patients have markedly more morbidity than the background population, with an expected overrepresentation of known extra-musculoskeletal manifestations, but also of less explored conditions such as fibromyalgia and nephrolithiasis, that warrant attention and proper management. Although oral GCs are generally not recommended in axSpA, our results underscore that conditions known as side-effects of such medications are common also in this diagnosis, and that treatments need to be closely monitored.

	AxSpA n=246
Male sex	55%
Age, years	52 (13)
Symptom duration, years	26 (14)
Nr-axSpA	33%

Background: Acute anterior uveitis ('uveitis'), or 'iritis', is a common extra musculoskeletal manifestation among patients (pts) with axial spondyloarthritis (axSpA). The prevalence of uveitis varies with HLA-B27 positivity, axSpA subtype and disease duration, reaching >50% in radiographic (r)-axSpA (i.e., ankylosing spondylitis) [1] pts with >40 years symptom duration [2]. Interleukin (IL)-17 has been implicated in the pathogenesis of uveitis; however, inhibition of IL-17A alone may not be optimal for the management of uveitis [3]. Here, we report the incidence of uveitis following inhibition of IL-17A in addition to IL-17F with bimekizumab (BKZ).
Objectives: To compare incidence rates of uveitis in pts with axSpA treated with placebo (PBO) or BKZ 160 mg every four weeks (wks; Q4W) to Wk 16 of the phase (ph)3 trials BE MOBILE 1 and 2. To evaluate incidence rates of uveitis in pts with axSpA treated with BKZ 160 mg Q4W, using pooled ph2b/3 data.

Methods: The ph3 studies BE MOBILE 1 (NCT03928704; non-r-axSpA) and 2 (NCT03928743; r-axSpA) comprised a 16-wk double-blind treatment period (DBTP; subcutaneous BKZ 160 mg Q4W or PBO) followed by a 36-wk maintenance period (all pts received BKZ 160 mg Q4W) [5]. Upon entry to the ongoing BE MOVING open-label extension (OLE; [NCT04436640; cut-off 4 Jul 2022]) at Wk 52, all pts remained on BKZ 160 mg Q4W. The ph2b study BE AGILE (NCT02963506; r-axSpA) comprised a 12-wk double-blind, dose-ranging period followed by a 36-wk randomised period (BKZ 160 or 320 mg Q4W) [4]. Upon entry to the ongoing BE AGILE OLE (NCT03355573; cut-off 4 Jul 2022) at Wk 48, all pts received BKZ 160 mg Q4W. Data were pooled for all pts treated with BKZ 160 mg Q4W in the ph2b/3 trials listed above. Data were pooled separately for pts randomised to BKZ or PBO in the DBTP of BE MOBILE 1 and 2. Uveitis treatment-emergent adverse events (TEAEs) were identified using the preferred terms "autoimmune uveitis", "iridocyclitis", "iritis", and "uveitis", and were reported as both incidence and exposure adjusted incidence rates (EAIRs) per 100 pt years (PY) for all pts who received ≥1 BKZ dose.

Results: Baseline characteristics were reflective of a pt population with moderate-to-severe axSpA **(Table 1)**. In the DBTP of BE MOBILE 1 and 2, uveitis TEAEs occurred in 11/237 (4.6%; EAIR/100 PY [95% CI]: 15.4 [7.7, 27.5]) and 2/349 (0.6%; 1.8 [0.2, 6.7]) of pts randomised to PBO and BKZ (% difference [95% CI]: 4.07 [1.71, 7.60]), respectively **(Figure 1)**. In the 45 PBO-randomised (19.0%) and 52 BKZ-randomised (14.9%) pts with history of uveitis, uveitis TEAEs occurred in 20.0% (EAIR/100 PY [95% CI]: 70.4 [32.2, 133.7]) and 1.9% (6.2 [0.2, 34.8]) of pts, respectively. In the pooled ph2b/3 trial data, total BKZ exposure was 2,034.4 PY (N=848), 130 (15.3%) pts had history of uveitis. Uveitis TEAEs occurred in 25 (2.9%; EAIR/100 PY [95% CI]: 1.2 [0.8, 1.8]) and 14 (10.8%; 4.6 [2.5, 7.7]) pts overall and with history of uveitis, respectively **(Figure 1)**. All uveitis TEAEs were mild/moderate, one event led to discontinuation.

Conclusion: The incidence rate of uveitis TEAEs was lower to Wk 16 in axSpA pts randomised to BKZ 160 mg Q4W vs PBO. In the largest pool of ph2b/3 data available at the time of this report, the incidence rate of uveitis with BKZ 160 mg Q4W remained low at 1.2/100 PY.

Background: Association between spondyloarthritis and cardiovascular (CV) diseases is a complex issue with variable outcomes.

Objectives: This study aimed to assess the prevalence rates of CV diseases and to analyze the impact of CV risk factors on CV disease in patients with spondyloarthritis.

Methods: A multi-center cross-sectional study using BioSTAR (Biological and Targeted Synthetic Disease-Modifying Antirheumatic Drugs Registry) database was performed on patients with spondyloarthritis. Socio-demographic, laboratory and clinical, data were collected. Patients with and without major adverse

cardiovascular events (MACE) were grouped as Group 1 and Group 2.The primary outcome was the prevalence rates of CV disease and CV risk factors in the overall group. The secondary outcome was the difference in socio-demographic and clinical characteristics between the groups and predictive risk factors for CV disease.

Results: There were 1457 patients with a mean age of 45.7±10.9 years. The prevalence rate for CV disease was 3% (n=44). The distribution of these diseases was coronary artery disease (n=42), congestive heart failure (n=4), peripheral vascular disorders (n=6), and cerebrovascular events (n=4). Patients in Group 1 were significantly older than those in Group 2 (p<0.001). There were significantly more patients with hypertension, diabetes mellitus, chronic renal failure, dyslipidemia, and malignancy in Group 1 than in Group 2 (p<0.05). Smoking (36.7%), obesity (24.4%), and hypertension (13.8%) were the most prevalent traditional CV risk factors. Hypertension (HR=4.994, 95% CI:1.966-12.683, p=0.001) and dyslipidemia (HR=1.960, 95% CI:1.155-6.676, p=0.024) were the independent predictors for CV disease.

Conclusion: The prevalence rate of CV disease was 3.0% in patients with spondyloarthritis. Hypertension and dyslipidemia were independent CV risk factors for CV disease in patients with spondyloarthritis.

DIAGNOSTIC DELAY IS ASSOCIATED WITH WORSE OUTCOMES IN TERMS OF STRUCTURAL DAMAGE IN PATIENTS WITH RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS. RESULTS FROM REGISPONSER-AS

Keywords: Descriptive Studies, Outcome measures, Spondyloarthritis

M. L. Ladehesa Pineda[1], M. Á. Puche Larrubia[2], F. U. Pilar[1], A. Escudero Contreras[1], E. Collantes Estevez[1], C. López-Medina[1]. [1]*Universitary Hospital Reina Sofía, Córdoba, Spain/IMIBIC/University of Córdoba, Rheumatology, Córdoba, Spain*; [2]*Universitary Hospital Reina Sofía, Córdoba, Spain/IMIBIC/University of Córdoba, Rheumatology, Córdoba, Spain*

Background: Diagnostic delay in axial Spondyloarthritis (axSpA) is longer than in many other rheumatic diseases. It has been demonstrated to be associated with socioeconomic factors, disease presentation [1], HLA-B27 negativity, female sex, psoriasis and younger age at onset [2]. Prolonged delay is associated with poorer long-term outcomes, including functional impairment and quality of life.

Objectives: To evaluate whether diagnostic delay in patients with radiographic axSpA (r-axSpA) is associated with poorer short-term outcomes after two years of follow-up.

Methods: Observational, longitudinal and prospective study including patients from the REGISPONSER-AS study (Spondyloarthritis Registry of the Spanish Rheumatology) with a diagnosis of r-axSpA according to the modified NY criteria. At baseline, the patients were divided into two groups according to the median of diagnosis delay (<5 years, ≥5 years). Binary logistic regression models adjusted for disease duration were constructed to evaluate the association between the diagnosis delay and disease outcomes at two years. The retention rate of the first anti-TNF treatment across the groups was evaluated using a log-rank test.

Results: A total of 729 patients were included. Outcomes at two years according to diagnosis delay are presented in the Table 1. Characteristics related with structural chronic damage (BASRI, occiput wall distance), inflammatory bowel disease (IBD), dactylitis, SF-12 mental component and inability to work were associated with longer diagnosis delay. No differences were found in the retention rate of the first anti-TNF antibody between the groups.

Conclusion: Diagnostic delay is associated with poorer short-term outcomes in terms of structural damage, prevalence of IBD, dactylitis, SF-12 mental component and inability to work in patients with r-axSpA.

Background: Improvement in functioning and health as assessed by the ASAS Health Index (HI) is an important outcome of interventions in patients with axial spondyloarthritis (axSpA). The ability of various ASAS HI thresholds to discriminate between treatment arms of an active comparator trial have been demonstrated recently by our group with absolute improvement in the ASAS HI in general being superior to relative changes [1, 2].

Objectives: To assess whether ASAS HI response measures (absolute improvement of ≥3.0 and relative improvement of ≥30%) and reaching a status of good global functioning (ASAS HI ≤5.0) adequately discriminate between the changes and states in relevant external outcomes.

Methods: In this post-hoc analysis from the tight-controlled, treat-to-target (T2T) trial TICOSPA (2), data of active axSpA patients randomized to either the T2T arm (visits every 4 weeks, prespecified strategy of treatment intensification until achieving low disease activity) or usual care (UC; visits every 12 weeks, treatment at the rheumatologist's discretion) were used. The performance of ASAS HI response- and status scores against change (ASAS-40/ BASDAI-50 response, change in patient global/ BASDAI, and ASDAS improvement) and external status scores (ASAS partial remission, ASDAS status) was assessed, respectively. Analysis were performed by comparing the mean values and proportion of responses of continuous and dichotomous response outcomes, by t-tests. Missing data on outcomes was handled by non-responder imputation (NRI).

Results: ASAS HI was available in 160 patients, both at baseline and at week 48. At w48, an ASAS HI improvement of ≥30%, improvement of ≥3 points and ASAS HI ≤5.0 was achieved by 56 (35%), 51 (31.9%) and 54 (33.7%) patients, respectively. Patients with a meaningful improvement in global functioning had a larger reduction in patient global and disease activity as well a greater chance to reach remission compared to patients with no significant improvement in global functioning (Table 1). Health outcomes were not different between the two response measures of ASAS HI. Patients who achieved ASAS partial remission, ASDAS inactive disease or ASDAS low activity at week 48 were more likely to have an ASAS HI ≤ 5.0 compared with patients who did not achieve such states (Figure 1).

Conclusion: We demonstrated discriminant capacity of both, the relative and the absolute response measures of the ASAS HI. Both thresholds proved to have external validity and were able to discriminate between active treatment arms.

Background: Imaging of the sacroiliac joints, especially with magnetic resonance imaging (MRI), is an important tool for early diagnosis of axial spondyloarthritis (axSpA). Interpretation of sacroiliac joint imaging can vary according to readers' experience, but it is currently unknown if and how imaging assessment differs between academic hospitals and community based rheumatological care.

Objectives: To investigate (1) agreement between local and central reading of sacroiliac joint images (X-ray and MRI) from axSpA patients, and (2) to explore potential differences between patients diagnosed in an academic hospital compared to community centres.

Methods: The BelGian Inflammatory Arthritis and spoNdylitis cohort (Be-GIANT) includes newly diagnosed biological-naïve axSpA patients, that fulfil the ASAS classification criteria, at the outpatient clinic of an academic hospital and eight community centres in Flanders. X-ray and MRI of the sacroiliac joints (SIJ) of patients enrolled between November 2010 and August 2020 were assessed by the local rheumatologist ('local reading') and two calibrated central readers ('central reading') for definite radiographic sacroiliitis according to the modified New York criteria (X-SIJ) and active sacroiliitis according to the ASAS/OMERACT definition of a positive MRI (MRI-SIJ). Central readers resolved discrepant cases by consensus. Inter-reader reliability was assessed with Cohen's Kappa, and % overall, positive and negative agreement.

Results: Among the 271 included patients (n=205 academic hospital, n=66 community hospital), 231 X-SIJ and 208 MRI-SIJ were available for central reading (Table 1). Central readers disagreed with local readers on 30/231 (13%) X-SIJ images (κ=0.44, moderate); 4/231 (1.7%) were reclassified as radiographic sacroiliitis and 26/231 (11.3%) as not showing radiographic sacroiliitis. Overall agreement was higher between central readers and academic rheumatologists

compared to community rheumatologists (90.5% vs. 70.7%, p<0.001). 53/208 (25.4%) MRI-SIJ images were reclassified by central readers (κ=0.36, fair); the majority as negative for active sacroiliitis (51/208, 24.5%). Central readers agreed on the assessment of MRI-SIJ in a higher proportion with academic rheumatologists versus community rheumatologists (77.2% vs. 63.4%, p=0.07).
Conclusion: In newly diagnosed axSpA patients, the prevalence of radiographic sacroiliitis is low. Sacroiliitis on MRI is overcalled by rheumatologists both in academic and non-academic settings, underscoring the need for continuous educational trainings.

POS0673 ARE PATIENTS WITH AXIAL SPONDYLOARTHRITIS WHO WERE BREASTFED LESS PRONE TO MORE ACTIVE AND SEVERE DISEASE?

Keywords: Spondyloarthritis

S. Alonso Castro[1], S. Burger[1], P. González del Pozo[1], I. Braña Abascal[1], E. Pardo Campo[1], M. Alperi-López[1], R. Queiró Silva[1]. [1]Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Spain

Background: Breast milk is the first source of microorganisms that colonize the gastrointestinal tract and a key factor in shaping the intestinal microbiome. It is currently believed that alterations in the intestinal microbiota are key in the pathogenesis of spondyloarthritis (SpA). It has been postulated that breastfeeding could reduce the risk of ankylosing spondylitis, although this claim needs further support [1].
Objectives: To analyze the potential effect of having received breastfeeding on activity and other disease outcomes in patients with axial SpA (axSpA).
Methods: Retrospective longitudinal study of 105 consecutive patients with axSpA. Only patients with reliable information about a history of breastfeeding were included. The following disease outcomes were collected: BASDAI, ASDAS-CRP, BASFI, structural damage (syndesmophytes), and ASAS-HI. The group was divided according to the history or not of breastfeeding, as well as its duration. Both groups were compared by univariate and multivariate regression methods.
Results: Forty-six women and 59 men were included, mean age 43.3 ± 12.5 years, mean age at diagnosis 34.3 ± 10.9 years. Fifty-eight percent had been breastfed for a mean of 5.5 ± 4.6 months, while 42% had not received breast milk. The main characteristics of both groups are shown in Table 1. In the raw estimate, all disease outcomes analyzed were significantly better in patients who had been breastfed. Regardless of sex, disease duration, family history, HLA-B27, use of biologics, obesity, and smoking, patients who were breastfed had a mean 1.13 points less (95% CI: -2.04, -0.23) in the estimate of BASDAI, p < 0.05, and an average of 0.38 points less (95% CI: -0.72, -0.04) in the ASDAS estimate, p < 0.05. After these same adjustments, no association was found between BASFI or structural damage and lactation. Regarding ASAS HI, breastfeeding was associated with a lower impact of the disease with 1.43 points less on average (95% CI: -2.98, 0.11), although the significance was borderline, p = 0.06. Breastfed patients were associated with less severe disease, severity being understood as a sustained combined outcome of BASDAI >4 and/or ASDAS > 2.1 + ASAS-HI > 5 + BASFI > 4 [OR 0,22 (95% CI 0.08-0.57), p < 0.01].
Conclusion: This study points to a potential benefit of breastfeeding on certain disease outcomes (activity and disease impact) in patients with axSpA. This potential beneficial effect of breastfeeding should be confirmed with larger and prospective studies.

POS0674 RENAL SAFETY OF LONG TERM NSAID USE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Keywords: Spondyloarthritis

Y. E. Kim[1], S. Y. Park[2], S. M. Ahn[1], S. Hong[1], C. K. Lee[1], B. Yoo[1], J. S. Oh[3], Y. G. Kim[1]. [1]*University of Ulsan College of Medicine, Department of Rheumatology, Asan Medical Center, Seoul, Korea, Rep. of (South Korea)*; [2]*Korea National Open University, Department of Statistics and Data Science, Seoul,*; [3]*University of Ulsan College of Medicine, Department of Information Medicine, Big Data Research Center, Asan Medical Center, Seoul, Korea, Rep. of (South Korea)*

Background: Nonsteroidal anti-inflammatory drugs (NSAIDs) are the basis of treatment for patients with ankylosing spondylitis (AS) to reduce pain and inflammation. However, long-term NSAID use may cause deterioration of renal function.
Objectives: We aimed to investigate the renal safety from long-term NSAID exposure in patients with AS.
Methods: We extracted clinical information from the electronic medical records of patients with newly diagnosed AS with an observation period of more than one year who were treated at Asan Medical Center from January 1, 2000, to December 31, 2020, excluding patients with chronic kidney disease Stage 4–5, known kidney disease, and malignancy. Renal function was determined by calcuation of the estimated glomerular filtration rate (GFR) using the Modification of Diet in Renal Disease (MDRD) and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations. Patients were stratified into three groups according to initial GFR: Stage 1 (GFR≥90), Stage 2 (60≤GFR<90), and Stage 3 (30≤GFR<60). The GFR values for every 3-year interval were imputed by the linear interpolation method using the measured values before and after each point, and NSAID use in each interval was estimated as the medication possession rate (MPR). To evaluate the association between NSAID use and annual changes in GFR, linear mixed effects models were used and adjusted for key covariates including age, sex, body mass index, baseline GFR, relative dosage of NSAIDs, comorbidities, and comedications.
Results: Among 1,838 patients with AS, the mean age was 38.0 (SD, 13.8) years with a median 6.1 years of follow-up. The majority of 1,386 (75.4%) patients belonged to the Stage 1 group, and the number of patients in the Stage 2 and Stage 3 groups was 442 (24.0%) and 10 (0.5%), respectively. In the multivariable models, the mean annual decrease in GFR was significant (model 1: β=-0.684, 95% CI -0.980 to -0.389, p<0.001; model 2: β=-0.387, 95% CI -0.770 to -0.004, p=0.048), and the MPR of NSAID use was significantly associated with an additional decrease in GFR (model 1: for 100% vs. 0% of MPR, β =-0.5, 95% CI, -0.8 to -0.1, p=0.008; model 2: for highest vs. lowest tertile of MPR, β=-0.519, 95% CI -0.906 to -0.132, p=0.009) in the Stage 1 group but not in patients in the Stage 2 group (Table 1).

Conclusion: This study suggested that long-term use of NSAIDs was associated with a small but significant decrease in GFR in patients with AS with normal initial renal function.

POS0675 LOW RATE OF SWITCHING FROM NR-AXSPA TO R-AXSPA AFTER 10 YEARS OF FOLLOW UP IN EARLY AXIAL SPONDYLOARTHRITIS. DATA FROM DESIR COHORT

Keywords: Imaging, Spondyloarthritis, Prognostic factors

A. Moltó[1], C. López-Medina[1,2], M. De Hooge[3], M. Van Lunteren[4], V. Navarro-Compán[5], A. Sepriano[4,6], S. Ramiro[4,7], M. Dougados[1]. [1]*Université de Paris, Centre de recherche épidémiologie et bio statistique de Sorbonne Paris Cité, APHP, Hôpital Cochin, Rheumatology, Paris, France*; [2]*Reina Sofia University Hospital, IMIBIC, University of Cordoba, Rheumaology, Cordoba, Spain*; [3]*Ghent University Hospital, Rheumatology, Ghent, Belgium*; [4]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [5]*La Paz University Hospital, IdiPaz, Rheumatology, Madrid, Spain*; [6]*NOVA Medical School, UNL, Rheumatology, Lisbon, Portugal*; [7]*Zuyderland Medical Center, Rheumatology, Heerlen, Netherlands*

Background: Previous evidence suggests that radiographic progression occurs slowly in the sacroiliac joints (SIJ) of patients with axial spondyloarthritis and that bone marrow edema (BME) on MRI-SIJ can, at least in part, explain such progression. However, information about the long-term course of radiographic structural damage at the SIJ level in patients with early axSpA is still scarce.

Objectives: To evaluate the proportion of patients switching from non-radiographic axSpA (nr-axSpA) to radiographic axSpA (r-axSpA) after 10 years of follow-up and whether BME on MRI-SIJ at baseline is associated with the r-axSpA status over time.

Methods: Patients with ≤3 years axSpA onset (according to the treating rheumatologist) from the DESIR cohort were included. The radiographic status of the patients (r-axSpA versus nr-axSpA) was based on the fulfillment of the mNY criteria (i.e. at least a bilateral grade 2 or a unilateral grade 3 on pelvic radiographs according to 2 out of 3 central readers). BME on MRI-SIJ was defined as positive ASAS definition according to 2 out 3 central readers at baseline. Information on mNY criteria was obtained in four reading waves: wave 1 (baseline (BL), wave 2 (BL and 2Y), wave 3 (BL, 2 and 5Y) and wave 4 (BL, 5 and 10Y). Images were scored by 3 trained central readers (wave 1: 2 readers + adjudicator), all of them unaware of the chronology of the images and the results of the other modality. A "progressor" was defined as a patient switching from nr-axSpA to r-axSpA. A "regressor" was defined as a patient switching from r-axSpA to nr-axSpA. The % of mNY net progressors (i.e. number of "progressors" minus number of "regressors" divided by the total number of patients) was assessed in "completers" (i.e., with pelvic radiographs available at BL and 10y in wave 4). A sensitivity analysis was conducted using a multilevel GEE model ('integrated analysis') that included all waves from all patients with at least one available mNY score from at least one reader available ("intention-to-follow" population). From this model, we estimated the absolute change per year in the percentage of mNY-positive cases with and without adjusting for the use of anti-TNF drugs. Finally, the effect of BME on MRI-SIJ at baseline on mNY positivity over 10 years, adjusting for potential confounders (Figure 1) were evaluated in a multivariable GEE model in the "intention-to-follow" population.

Results: Completers included 299 patients (mean age 34.5Y and 48.2% males), while the intention-to-follow population included 704 participants (mean age 33.7Y and 46.2% males). In the completers, the net % of progressors (switch from nr-axSpA to r-axSpA) was 5.7%. In the intention-to-follow population, there was a 0.91% (95%CI 0.60-1.20) increase per year in the probability of being mNY-positive (i.e. a progression of 9.1% after 10Y). After adjusting for anti-TNF use, this percentage decreased to 0.48% (95%CI 0.15-0.82) per year. The HLA-B27 status modified the association between BME on MRI-SIJ at baseline and mNY-positivity over 10 years (interaction p-value: <0.001). BME on MRI-SIJ was associated with being mNY positive over time in both HLA-B27 positive (OR 6.25 (95%CI 5.36-7.30)) and HLA-B27 negative patients (OR 3.03 (95%CI 2.42-3.80)), but the association was stronger in the former (Figure 1). In addition, male sex, symptom duration >1.5Y, ASDAS >2.1 (in HLA-B27 negatives) and smoking (in HLA-B27 positives) were also associated with being mNY-positive over 10 years.

Conclusion: Patients with early axSpA have a low likelihood of changing from nr-axSpA to r-axSpA over 10 years, especially when considering the use of anti-TNF. Local inflammation on MRI-SIJ is strongly associated damage accrual in the SIJ over time, in particular in patients who are HLA-B27 positive.

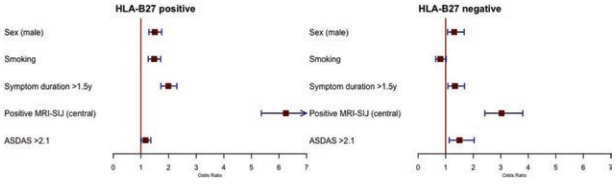

Figure 1. Baseline characteristics associated with radiographic sacroiliitis after 10 years of follow-up in axSpA patients with early onset (multivariable integrated analysis using four DESIR reading waves and stratified on HLA-B27).

POS0676 THE CHALLENGE OF IDENTIFYING DIFFICULT-TO-TREAT AXIAL SPONDYLOARTHRITIS IN CLINICAL PRACTICE: RESULTS FROM LA PAZ-SPA COHORT

Keywords: Treat to target, Spondyloarthritis

M. Juárez[1], D. Benavent[1], V. Navarro-Compán[1], M. Novella-Navarro[1], D. Peiteado[1], A. Villalba[1], I. Monjo[1], L. Nuño[1], A. Balsa[1], C. Plasencia[1]. [1]*Hospital Universitario La Paz, Rheumatology Unit, Madrid, Spain*

Background: Despite pharmacological options for axial spondyloarthritis (axSpA) have increased recently, still one out of three patients do not achieve the recommended target [1].

Objectives: To determine patient and disease characteristics in patients with "difficult to treat" (D2T) axSpA in comparison with "good responders" (GR) and to identify predictive factors of D2T-axSpA.

Methods: Data from an observational prospective cohort recruiting consecutively patients diagnosed of axSpA initiating the first bDMARD from La Paz Hospital between 2004-2019 were analysed. Patients who fulfilled one of the following definitions were included: i) D2T: failure to at least two b/tsDMARDs, ii) GR: patients

remaining treated with the first bDMARD for at least 3 years or stopping it due to disease control. Clinical characteristics, laboratory tests, concomitant treatment and disease activity measures prior to starting the first bDMARD and after 6 months were collected. Also, b/tsDMARD courses were registered. Chi-square or Fisher test were used for qualitative variables and unpaired t-student was used for quantitative variables. Univariable and multivariable logistic binary regression analyses were used.

Results: Out of 101 patients included, 41.6% were classified as D2T and 58.4% as GR. When initiating the first bDMARD, compared with GR, D2T patients had statistically significant shorter symptom duration and more frequently enthesitis, inflammatory bowel disease (IBD), concomitant NSAIDs, smoking habit and comorbidities (hypertension, dyslipidemia, depression or anxiety and fibromyalgia), all p<0.05 (Table 1). However, no significant differences were found in age, sex, BMI, subtype of axSpA, dactylitis, peripheral arthritis, uveitis, psoriasis, concomitant csDMARDs, diabetes mellitus or cardiopathy. While no differences were found for disease activity composite measures (ASDAS, BASDAI) and CRP or ESR, D2T patients had greater scores in BASDAI questions for pain and morning stiffness, TJC, PtGA and PhyGA. After 6 months of starting the first bDMARD, the scores for all disease activity measures, including ASDAS, BASDAI, CRP and ESR were significantly higher in D2T patients. Reasons for b/tsDMARDs discontinuation in D2T patients are shown in Figure 1. In multivariable analysis, smoking habit (OR=6.5, p<0.05), HLAB27 negative (OR=5.8, p<0.05), enthesitis (OR=48.1, p<0.01), baseline TJC (OR=1.2, OR<0.05) and baseline PhyGA (OR=1.05, p<0.05) were independently associated with D2T.

Conclusion: Compared with GR, patients with D2T-axSpA have more frequently poor prognostic factors for therapy response (smoking and HLAB27 negative) and worse response to first bDMARD after 6 months. Further strategies to implement recommendations for not smoking and control of comorbidities should be implemented.

POS0677 THE DEVELOPMENT OF AN OPTIMAL MODEL FOR AUTOCALCULATION OF MSASSS USING DEEP LEARNING IN PATIENTS WITH ANKYLOSING SPONDYLITISDS

Keywords: Spondyloarthritis, Artificial Intelligence, Imaging

H. H. Chen[1], D. Y. Chen[2]. [1]*Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China*; [2]*China Medical University Hospital, Rheumatology and Immunology Center, Taichung, Taiwan, Republic of China*

Background: At present, to detect the structural changes of the spine in ankylosing spondylitis (AS), the most commonly used tool is spine X-ray photography and interpretation by a physician, and a score (modified Stoke Ankylosing Spondylitis Spinal Score, mSASSS) is given. However, because there is more than one spine (12 in total) and each spine joint disease includes at least 5 items, it takes at least 60 minutes to interpret the results of mSASSS and produce scores for each patient's spine. Therefore, because the manual calculation of mSASSS is time-consuming and may introduce interpretation errors, the study aimed to use deep learning to develop an optimal model for auto-calculation of mSASSS in patients with AS.

Methods: We collected 1056 pairs of cervical spine and lumbar spine radiographs in 646 patients with AS at Taichung Veterans General Hospital (TCVGH) from Aug 1, 2001, to Dec 30, 2020. We designed software for annotation (yes, no) of the mSASSS-related characteristics (erosion, sclerosis, squaring, syndesmophyte, bony bridging, spur, blurring) over the anterior corners of the cervical (C) and lumbar (L) spines from lateral views of radiographs. One radiologist (Lan-HHC) and two rheumatologists (Chen-HH, Chen-DY) annotate the characteristics and the final judgement was determined by a majority vote. We use PoseNet model develop a localization system identify spines (from second C-spine to first thoracic spines [C1-T1], from twelveth thoracic spine to first sacrum [T12-S1]). We developed a classification system using DenseNet model to identify the mSASSS-related specific characteristics and then calculate mSASSS.

Results: We randomly selected 211 pairs of radiographs as testing set. The remaining 845 (80%) pairs of images were used for model trainning and testing. Because the number of positive findings of erosion, sclerosis and squaring was quite low in both C-spine and L-spine, we combined radiographs of C-spine and L-spine for AI taining to score erosion, sclerosis and squaring. For detection of C-spine characterisitics, the area under curve (AUC)/specificity/sensitivity/accuracy for bridge, syndesmophyte and osteophyte were 99.8%/98.82%/97.44%/98.48%, 95.7%/94.2%/77.78%./91.67% and 97.5%/95.86%/84.16%/93.75%, respectively. For detection of L-spine chracteristics, the AUC/specificity/sensitivity/accuracy for bridge, syndesmophyte and osteophyte were 99.4%/98.46%/94.02%/97.36%, 94.00%/91.48%/77.97%./89.36% and 96.60%/91.08%/89.69%/90.82%, respectively. For detection of C/L-spine characteristics, the AUC/specificity/sensitivity/accuracy for sclerosis and squaring were 95.60%/93.91%/79.79%/91.58% and 94.40%/92.24%/77.56%./88.55%, respectively. We failed to develop an AI model to detect erosion due to its rarity (2 in C-spine and 8 in L-spine). Using the testing set of 211 paired C-spine and L-spine radiographs, the overall accuracy to detect mSASSS-related characteritics was 86.47%.

Conclusion: At this stage, the accuracy of the AI-assisted mSASSS scoring based on the perspective of the end user was 86.47%, which is expected to have good clinical practicability in TCVGH. Further testing of this mSASSS autocalculation AI model using radiographs from other hospitals is warranted for future clinical implementation in other hospitals.

PERFORMANCE OF CLINICAL, LABORATORY AND IMAGING FEATURES FOR THE DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS - A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

Keywords: Spondyloarthritis, Systematic review

A. D. Vieira Bento Silva[1,2], M. H. Fernandes Lourenco[1,2,3], S. Ramiro[4,5], L. Falzon[6], J. Branco[1,2], D. Van der Heijde[4], R. B. M. Landewé[5,7], A. Sepriano[1,2,4]. *[1]Centro Hospitalar de Lisboa Ocidental - Hospital Egas Moniz, Rheumatology, Lisboa, Portugal*; *[2]Nova Medical School, Comprehensive Health Research Center, Lisboa, Portugal*; *[3]Nova Medical School, Faculdade de Ciências Médicas, Lisboa, Portugal*; *[4]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[5]Zuyderland MC, Rheumatology, Heerlen, Netherlands*; *[6]School of Health and Related Research, University of Sheffield, Health Economics and Decision Science, Sheffield, United Kingdom*; *[7]Amsterdam Rheumatology Center, Rheumatology & clinical immunology, Amsterdam, Netherlands*

Background: The Berlin algorithm for axial spondyloarthritis (axSpA) diagnosis was developed more than 15 years ago. New evidence suggests that the diagnostic performance of some SpA features might not be as good as initially thought.

Objectives: To review the evidence on the performance of SpA features for axSpA diagnosis.

Methods: Systematic literature review and meta-analysis of studies (2004-2021) reporting data on ≥1 SpA feature. The population was defined as adults (≥16 years) with a suspicion or definite clinical diagnosis of axSpA. The diagnostic performance of each SpA feature was tested against the physician diagnosis of axSpA. For each feature, if ≥2 studies analysed the same cohort, the one with the highest number of patients was included. Pooled sensitivity, specificity, positive and negative likelihood ratios (LR+ and LR-) were calculated. Sensitivity analyses were performed to assess the effect of covariates, like feature prevalence in the studies, on the diagnostic performance of SpA features.

Results: In total, 21 studies (19 cohorts) were included, comprising 8574 patients (4089 [48%] with axSpA). Table 1 shows the results of the meta-analysis. Inflammatory back pain (IBP) and good response to nonsteroidal anti-inflammatory drugs (NSAIDs) have low LR- (0.3), meaning that the diagnosis of axSpA is less likely when absent; however, if present they are not helpful in making a diagnosis (LR+ ~1). Peripheral features, extra-musculoskeletal manifestations (EMM) and preceding infection may help in the diagnosis of axSpA when present (LR+ 1.7-4.2), but have little value in its exclusion when absent (LR- 0.8-1.0). Imaging features, elevated C-reactive protein (CRP) and HLA-B27 have good diagnostic performances, reflected by their high LR+ (2.7-17.7) and (relatively) low LR- (0.5-0.7). In a sensitivity analysis the specificity of IBP was lower in studies with high prevalence of this feature (24% versus 78% in studies with low prevalence). The same was observed for buttock pain, peripheral features, uveitis, good response to NSAIDs, elevated CRP and HLA-B27.

Conclusion: Imaging features, HLA-B27 and elevated CRP have high diagnostic value, even though circularity cannot be ruled out. However, HLA-B27, with a LR+ of 2.7, has a worse diagnostic performance than earlier considered. When present, peripheral features and EMM importantly increase the probability of axSpA, while IBP and good response to NSAIDs do not, but are helpful in ruling out the disease when absent. The diagnostic value of most SpA features is somewhat lower compared to previous data.

Table 1. Performance of SpA features for axSpA diagnosis

SpA Feature	Sensitivity % (95% CI)	Specificity % (95% CI)	LR+ (95% CI)	LR- (95% CI)
IBP	84 (73; 91)	51 (31; 71)	1.7 (1.2; 2.5)	0.3 (0.2; 0.5)
Buttock pain	49 (32; 66)	71 (56; 82)	1.7 (1.2; 2.4)	0.7 (0.57; 0.9)

COMPARISON OF ESTABLISHED AND NEW, PRELIMINARY PROPOSED ASAS CUT-OFFS FOR INFLAMMATORY MRI LESIONS IN THE SACROILIAC JOINTS OF AXIAL SPONDYLOARTHRITIS PATIENTS AND IMPLICATIONS FOR RECRUITMENT IN CLINICAL STUDIES

Keywords: Imaging, Clinical Trials, Spondyloarthritis

X. Baraliakos[1], P. Machado[2,3,4], L. Bauer[5], B. Hoepken[5], M. Kim[6], T. Kumke[5], R. Tham[7], M. Rudwaleit[8]. *[1]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Bochum, Germany*; *[2]University College London Hospitals NHS Foundation Trust, Department of Rheumatology, London, United Kingdom*; *[3]University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom*; *[4]Northwick Park Hospital, London North West University Healthcare NHS Trust, Department of Rheumatology, London, United Kingdom*; *[5]UCB Pharma, N/A, Monheim am Rhein, Germany*; *[6]UCB Pharma, N/A, Smyrna, United States of America*; *[7]UCB Pharma, N/A, Slough, United Kingdom*; *[8]University of Bielefeld, Klinikum Bielefeld, Bielefeld, Germany*

Background: The Assessment of SpondyloArthritis international Society (ASAS) recently proposed preliminary, more stringent, data-driven definitions for active and structural MRI lesions of the sacroiliac joint (SIJ) typical of axial spondyloarthritis (axSpA) [1].

Objectives: To assess clinical outcomes of patients (pts) receiving certolizumab pegol (CZP) in the C-OPTIMISE trial who were MRI-positive (MRI+) or negative (MRI–) according to the existing and newly proposed definitions, as well as those who were MRI+ by the existing definition but MRI– by the newly proposed definition (discordant group).

Methods: C-OPTIMISE (NCT02505542) enrolled 736 pts with active axSpA who received 400 mg CZP at Weeks 0, 2, and 4, then 200 mg CZP every two weeks to Week 48 [2]. We report: percentage of pts achieving ASAS ≥40% improvement (ASAS40) response; mean BASDAI change from baseline (CfB) and percentage of pts achieving Ankylosing Spondylitis Disease Activity Score (ASDAS) inactive disease (ID, ASDAS <1.3) to Week 48. In this post hoc analysis, outcomes were stratified by axSpA subgroup (radiographic [r-]/ non-radiographic [nr]-axSpA) and MRI definition. Missing values were imputed using non-responder imputation for ASAS40 and last observation carried forward for continuous variables.

Results: Baseline MRI data were available for 657/736 (89.3%) pts, 358/657 (54.5%) of whom had r-axSpA and 299/657 (45.5%) nr-axSpA. 386/657 pts (58.8%) were classified as MRI+ according to the existing definition compared with 333/657 pts (50.7%) using the newly proposed definition; the discordant group comprised 53/657 pts (8.1%; nr-axSpA: 35/299 [11.7%]; r-axSpA: 18/358 [5.0%]; **Table 1**). A numerically higher proportion of newly proposed definition MRI+ pts achieved ASAS40 at Week 48 vs those fulfilling the existing MRI+ definition; pts in the discordant group responded similarly to those originally classified as MRI– (**Figure 1**). Similar results were observed for mean BASDAI, with significant differences in responses between nr-axSpA pts in the newly proposed MRI+ definition and discordant groups (**Figure 1**). At Week 48, a lower proportion of pts in the discordant group achieved ASDAS inactive disease (ID, ASDAS <1.3) vs those classified as MRI+ according to either the existing or newly proposed definitions; differences between subgroups were more notable among pts with nr-axSpA (discordant group: 15/35 [42.9%]; existing definition MRI+: 112/191 [58.6%]; newly proposed definition MRI+: 97/156 [62.2%]) than with r-axSpA (discordant group: 10/18 [55.6%]; existing definition MRI+: 118/195 [60.5]); newly proposed definition MRI+: 108/177 [61.0%]).

Conclusion: In C-OPTIMISE, 11.7% fewer nr-axSpA pts would have been classified as MRI+ at baseline using the newly proposed definition vs the existing definition. Application of the preliminary MRI definition needs to be evaluated in future clinical trials to confirm its translation into fewer false-positive recruited pts.

DISEASE COURSE OF NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN KOREAN PATIENTS: DATA FROM A LONG-TERM RETROSPECTIVE OBSERVATIONAL COHORT

Keywords: Epidemiology, Descriptive Studies, Spondyloarthritis

O. C. Kwon[1], Y. G. Kim[2], M. C. Park[1]. [1]*Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*University of Ulsan College of Medicine, Asan Medical Center, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Disease course of non-radiographic axial spondyloarthritis (axSpA) has been extensively studied in non-Asian population. However, there are limited data on the disease course of non-radiographic axSpA in Asian population. It is well known that clinical features of non-radiographic axSpA differ according to ethnicities. Therefore, the disease course of non-radiographic axSpA studied in non-Asian population cannot be generalized to Asian population.

Objectives: This study aimed to evaluate the long-term disease course of non-radiographic axSpA in Asian patients and identify factors associated with progression to radiographic axSpA.

Methods: A total of 56 Korean patients with non-radiographic axSpA were included. Disease course was assessed by the rate of progression to radiographic axSpA. Factors associated with the risk of progression to radiographic axSpA were assessed using multivariable Cox proportional hazard regression analysis.

Results: Over a mean observation period of 8.4 ± 3.7 years, 28 of 56 (50.0%) patients progressed to radiographic axSpA. In multivariable Cox proportional hazard regression analysis, the presence of syndesmophytes at diagnosis (adjusted hazard ratio [HR]: 4.50, 95% confidence interval [CI]: 1.54–13.15, p = 0.006) and active sacroiliitis on magnetic resonance imaging (MRI) at diagnosis (adjusted HR: 5.88, 95% CI: 2.05–16.82, p = 0.001) were significantly associated with a higher risk of progression to radiographic axSpA, whereas longer exposure to tumor necrosis factor inhibitors (TNFis) was significantly associated with a lower risk of progression to radiographic axSpA (adjusted HR: 0.89, 95% CI: 0.80–0.98, p = 0.022).

Conclusion: During long-term follow-up, a substantial proportion of Asian patients with non-radiographic axSpA progressed to radiographic axSpA. The presence of syndesmophytes and active sacroiliitis on MRI at the time of non-radiographic axSpA diagnosis were associated with a higher risk of progression to radiographic axSpA, while longer exposure to TNFis was associated with a lower risk of progression to radiographic axSpA.

Objectives: To determine the frequency of inconsistency between the BASDAI and ASDAS-CRP cut-off values in disease activity categorization in patients with axial spondyloarthritis (axSpA) and to characterize the reasons for the discordance.
Methods: In total 575 axSpA patients (mean age: 40.2 ± 11.5; male gender: 358, 62.3%) followed up in a single center and who had both BASDAI and ASDAS-CRP scores at the same visit were included in this analysis. Of them 369 (64.2%) were classified as radiographic axSpA (r -axSpA). A BASDAI score of ≥4 and an ASDAS score of ≥2.1 were used as the cut-off value for the differentiation of inactive/active disease state. The demographic, disease related characteristics of the patients including structural damage were obtained.
Results: Inconsistency in the definition of the disease state according to two composite disease activity measures was found in 146 (25.4%) patients. As a consequence, the concordance rate of the two scales was calculated as 74.6% and corresponding κvalue was 0.458. Of the 274 patients who has inactive disease according to BASDAI, 46.4% were classified as active according to ASDAS-CRP (Figure 1). In our whole group; discordant patients for the disease state distinction according to two measures **had higher CRP values, lower percentage of heel pain, and they were using less biologics**. These patients also **had lower BASFI, HAQ-S, and overall pain scores** (Table 1). When we evaluated inactive patients according to BASDAI, discordant patients were significantly **older, had lower education, higher serum CRP levels, and more frequently peripheral arthritis**. Baseline mSASSS scores were higher in those discordant patients and more patients had syndesmophyte, additionally the progression rate according to mSASSS was higher.
Conclusion: In daily clinical practice discordance in the disease activity definition might be observed in around 25% of axSpA patients according to two widely used composite measures. The results of the present study suggested that patients with high serum CRP levels could be easily classified as inactive according to BASDAI and those patients might have developed more structural damage in disease course. Our results suggest that those patients misclassified according to BASDAI scale had worse functional status and quality of life. In conclusion ASDAS-CRP might be more appropriate disease activity measure in treatment decision.

IDENTIFICATION OF A DIAGNOSTIC MODEL FOR AXIAL SPONDYLOARTHRITIS IN DAILY CLINICAL PRACTICE USING A RANDOM FOREST MACHINE LEARNING APPROACH

Keywords: Spondyloarthritis

I. Redeker[1], S. Tsiami[1], J. Eicker[1], U. Kiltz[1], D. Kiefer[1], I. Andreica[1], P. Sewerin[1], X. Baraliakos[1]. [1]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany

Background: In axial spondyloarthritis (axSpA), early diagnosis plays a key role in preventing disease progression. However, a validated diagnostic algorithm does not exist, while classification criteria are frequently misused diagnostically.
Objectives: To identify which decision model is being used for diagnosing patients with axSpA based on evaluations made in daily practice.
Methods: Complete clinical data of 399 patients who presented with chronic back pain in a specialized university clinic were retrospectively evaluated. All patients received complete rheumatologic examination. The total dataset was randomly split into training and test datasets at a 7/3 ratio. A model was built to classify patients into axSpA and non-axSpA based on the random forest algorithm, an ensemble machine learning technique which allows computing the importance of each variable in the statistical modelling process. The Mean Decrease Gini measure was used for the variable importance. The overall accuracy, sensitivity, specificity, and the area under the receiver operating characteristic (ROC) curve (AUC) in the test dataset were calculated.
Results: In total, 183 patients were diagnosed with axSpA and 216 with non-SpA (Table 1). In the test dataset, the model reached an accuracy of 0.9315, a sensitivity of 0.9634, a specificity of 0.8906, and an AUC of 0.9868 (Figure 1A). HLA-B27 positivity, erosion on SIJ MRI, and elevated CRP played the most important role in the statistical modelling process followed by awakening at second half of

night due to back pain and bone marrow edema and fat metaplasia on SIJ MRI (Figure 1B).

Conclusion: Machine learning-based random forest classifier revealed a high performance in diagnosing patients with chronic back pain with axSpA and excluding patients with non-SpA using clinical, laboratory and imaging characteristics as evaluated in a daily practice scenario of a SpA-specialized clinic. External validation of the model is needed to investigate its clinical utility as a diagnostic decision support tool.

AN EXPLORATORY ANALYSIS OF THE POTENTIAL DISCONNECT BETWEEN OBJECTIVE INFLAMMATORY RESPONSE AND CLINICAL RESPONSE FOLLOWING CERTOLIZUMAB PEGOL TREATMENT IN PATIENTS WITH ACTIVE AXIAL SPONDYLOARTHRITIS

Keywords: Outcome measures, Spondyloarthritis, Clinical trials

M. Rudwaleit[1], F. Van den Bosch[2], H. Marzo-Ortega[3], V. Navarro-Compán[4], R. Tham[5], T. Kumke[6], L. Bauer[6], M. Kim[7], L. S. Gensler[8]. [1]*University of Bielefeld, Klinikum Bielefeld, Bielefeld, Germany*; [2]*Ghent University and VIB Center for Inflammation Research, Department of Internal Medicine and Paediatrics, Ghent, Belgium*; [3]*University of Leeds, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust and Leeds Institute of Molecular Medicine, Leeds, United Kingdom*; [4]*La Paz University Hospital, Department of Rheumatology, IdiPaz, Madrid, Spain*; [5]*UCB Pharma, N/A, Slough, United Kingdom*; [6]*UCB Pharma, N/A, Monheim, Germany*; [7]*UCB Pharma, N/A, Smyrna, United States of America*; [8]*University of California, Department of Medicine, Division of Rheumatology, San Francisco, United States of America*

Background: In clinical trials of axial spondyloarthritis (axSpA), composite measures such as Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) response criteria, Assessment of Spondyloarthritis international Society (ASAS) response criteria, Ankylosing Spondylitis Disease Activity Score (ASDAS) disease activity states and ASDAS response criteria are used. However, these validated measures are largely based on patient (pt)-reported symptoms, which are likely to be confounded by other factors. In pts with active axSpA, certolizumab pegol (CZP) has demonstrated sustained clinical efficacy in clinical outcomes over 204 weeks [1]. However, we hypothesise that reduction of sacroiliac joint (SIJ) and spinal inflammation following treatment with CZP, as measured by MRI and C-reactive protein (CRP) levels, may not necessarily translate into clinical response [2].

Objectives: A post-hoc analysis to evaluate the relationship between objective signs of inflammation (OSI), as measured by MRI/CRP, and clinical outcomes following 12 weeks of CZP treatment in pts with active axSpA.

Methods: Data were analysed from the phase 3 RAPID-axSpA study (NCT01087762) [1]. To improve precision of pt-level estimates, data from two independent readers were pooled in a Mixed Model for Repeated Measures for each response variable; Manhattan plots are presented for ASDAS, BASDAI, CRP, Ankylosing Spondylitis spine MRI (ASspiMRI) Berlin Score and Spondyloarthritis Research Consortium of Canada (SPARCC) MRI SIJ score. Outcomes are reported for pts (initially randomised to either CZP, or to placebo before switching to CZP) prior to CZP treatment (pre-CZP treatment) and following 12 weeks (wks) of treatment (post-CZP treatment).

Results: 136 pts (radiographic axial spondyloarthritis [r-axSpA]: 76; non-radiographic axial spondyloarthritis [nr-axSpA]: 60) had a pre-CZP and ≥1 post-CZP MRI. Pre-CZP demographics for the r-axSpA and nr-axSpA populations are presented in **Table 1**. Following CZP treatment, CRP, ASspiMRI Berlin score, and SPARCC MRI SIJ score were reduced by >50%, in the majority of pts (CRP: 136/136 [100.0%]; BERLIN: 73/136 [53.7%]; SPARCC: 71/136 [52.2%]), and often by >75% (CRP: 18/136 [13.2%]; BERLIN: 53/136 [39.0%]; SPARCC: 50/136 [36.8%]) irrespective of pre-CZP value. However, only a minority of both r-axSpA and nr-axSpA pts (**Figure 1**), showed a >50% reduction in clinical responses (ASDAS: 66/136 [48.5%]; BASDAI: 64/136 [47.1%]). These results were also observed at the individual pt level; >50% improvements in MRI/CRP inflammatory measures did not translate into similar improvements in clinical responses for the majority of pts.

Conclusion: This analysis revealed a potential disconnect between OSI, as measured by MRI and CRP, and clinical outcome responses. In most pts, CZP treatment resulted in a reduction of objective measures of inflammation, irrespective of improvements in clinical symptoms and measures of disease activity. The use of clinical response measures as clinical trial endpoints may therefore underestimate anti-inflammatory treatment effects.

Figure. Change following 12 weeks of CZP treatment in clinical response and measures of objective signs of inflammation in patients with **A)** r-axSpA and **B)** nr-axSpA

Patient treatment sequence: CZP 400 mg at Week 0. Each bar represents a single patient in the cohort of 76 patients (for r-axSpA) or 60 patients (for nr-axSpA). Across all five endpoints, the same patient is indicated by an arrow. The pre- and post-CZP states are indicated by the step-line (the "skyline") and the dark purple line within each bar (Week 12 value), respectively; the space between these points reflects the change in response. Change in response has been grouped into four categories based on the percentage reduction, as shown by the figure legend. Data presented were obtained from a Mixed Model Repeated Measures that was applied to each response variable: for SPARCC MRI SIJ score, ASspiMRI Berlin score, and ASDAS response variables a linear mixed effect model was used to estimate EBLUP with random effects of: reader j overall, reader j in reading campaign k overall, reader j for subject i and reader j for subject i in reading campaign k; for CRP and BASDAI response variables, a linear mixed effects model was used to estimate EBLUP with spatial autocorrelation (using nearby visits to estimate response variable values). ASDAS: Ankylosing Spondylitis Disease Activity Score; ASspiMRI: Ankylosing Spondylitis spine MRI score; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BMI: body mass index; CRP: C-reactive protein; CZP: certolizumab pegol; EBLUP: empirical best linear unbiased predictor; HLA-B27: human leukocyte antigen B27; MRI: magnetic resonance imaging; nr-axSpA: non-radiographic axial spondyloarthritis; OSI: objective signs of inflammation; r-axSpA: radiographic axial spondyloarthritis; SD: standard deviation; SE: standard error; SIJ: sacroiliac joints; SPARCC: Spondyloarthritis Research Consortium of Canada.

INFLAMMATION IS ASSOCIATED WITH INCIDENT HYPERTENSION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A LONGITUDINAL COHORT STUDY

Keywords: Real-world evidence, Spondyloarthritis, Prognostic factors

J. L. H. Shi[1], S. H. M. Lam[1], H. So[1], C. Y. Chan[1], T. K. LI[1], C. C. Szeto[1], L. S. Tam[1]. [1]*The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China*

Background: HT is the most prevalent comorbidity in axSpA (1), and is one of the strongest predictors for accelerated atherosclerosis and atherosclerotic vascular events in the general populations [2]. However, the association between time-varying inflammatory markers, disease activity and drug use and the development of incident hypertension (IHT) remain unknown.

Objectives: To elucidate the tiem-varying risk factors for the development of IHT in patients with axial spondyloarthritis (axSpA).

Methods: We conducted a long-term retrospective cohort study in axSpA patients who were recruited from 2001-2019 from a university clinic in Hong Kong. Patients with HT and/or anti-hypertensive drug use at baseline were excluded. They were followed until the end of 2020. The outcome was IHT, defined by a diagnosis and/or a prescription for an antihypertensive drug. Baseline and time-varying Cox regression analyses adjusting for age, sex, and body mass index (BMI), were used to assess the relationship between inflammatory burden, drug use and IHT.

Results: 413 patients [age: 34(25-43) years, male: 319 (77.2%)] were recruited. After a median follow up of 12 (6-17) years, 58 patients (14%) developed IHT (IHT+group). Among all the baseline variables, disease duration (BLDD) was the only independent predictor for IHT based on the Cox regression model. In the time-varying multivariate Cox regression analysis, ESR level as an inflammatory marker and BLDD longer than 5 or 10 years, remained as the significant independent predictors to increase risk of future IHT (Table 1a and 1b), while ESR≥20, the use of csDMARDs, sulfasalazine or paracetamol were no longer statistically significant. The Kaplan-Meier curve showed the survival probability were significant lower in groups with BLDD longer than 5 or 10 years (Figure 1).

Conclusion: Higher inflammatory burden as reflected by BLDD longer than 5 or 10 years were predictors associated with IHT after adjusting for inflammation marker and traditional CV risk factors. Higher ESR level may also play a role in the development of IHT in these patients.

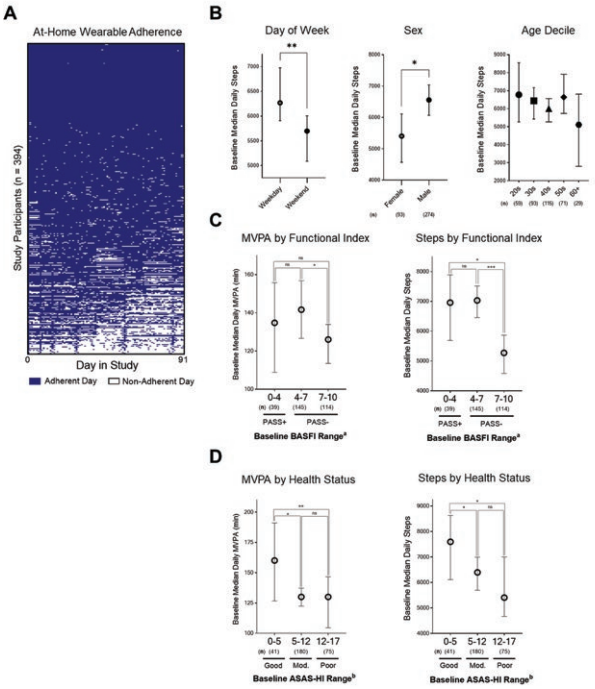
MONITORING PHYSICAL ACTIVITY OF PATIENTS WITH ANKYLOSING SPONDYLITIS IN THE SELECT-AXIS 2 PHASE 3 TRIAL: BASELINE USAGE AND ADHERENCE RESULTS FROM A WEARABLE DEVICE STUDY

Keywords: Spondyloarthritis, Clinical trials, Outcome measures



P. J. Mease[1], R. Grainger[2], D. Webster[3], M. Crouthamel[3], J. Shen[3], Y. Xing[3], A. Shmagel[3], H. Jones[3], J. Curtis[4]. [1]*Swedish Medical Center, Providence St Joseph Health, and University of Washington, Rheumatology Research Division, Seattle, WA, United States of America*; [2]*University of Otago, Wellington, Department of Medicine, Wellington, New Zealand*; [3]*AbbVie Inc, Immunology, North Chicago, IL, United States of America*; [4]*The University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, United States of America*

Background: Exercise can improve the symptoms of axial spondyloarthritis (axSpA) and is recommended as a cornerstone of management for axSpA [1]. Wearable devices can objectively measure physical activity and device-generated data may support development of digitally measured novel endpoints that correlate with treatment response.
Objectives: To report device usage and adherence with wearable technology used to assess the physical activity of people with active ankylosing spondylitis (AS) and inadequate response to biologic DMARD therapy (bDMARD-IR) in the SELECT-AXIS 2 trial, as well as evaluate the association between baseline physical activity and patient-reported measures of functional ability and health.
Methods: Patients in the SELECT-AXIS 2 bDMARD-IR study (NCT04169373), a 1:1 randomized, double-blind, phase 3 trial of upadacitinib vs placebo [2], were required to wear a medical-grade wrist-worn actigraphy device that monitored physical activity during the 14-week, placebo-controlled portion of the study. Eligibility criteria included a diagnosis of active AS and inadequate response to bDMARDs. Wearable device adherence, defined as at least 16 hours per day usage, was evaluated through 14 weeks. Baseline physical activity measurements, including median daily steps and time spent in moderate to vigorous physical activity (MVPA), were defined as those in the first week of device usage after trial entry. Median daily steps at baseline were compared by sex and day of the week (weekend vs weekday) across the entire patient cohort using the Mann–Whitney test; differences in physical activity by age were assessed with the Kruskal–Wallis test. For inclusion in all other baseline analyses, patients were required to have at least 3 out of 7 days with sufficient device use, and average physical activity was calculated over these adherent days. Finally, the comparison between baseline physical activity and functional index (BASFI) or health status (ASAS Health Index [ASAS-HI]) was calculated using the Mann-Whitney test; previously established cutoffs were used to distinguish patients into groups with low, moderate, or high functional ability or health [3,4].
Results: Of 420 total patients, physical activity data was collected from 394 participants, and 312 patients met minimal adherence criteria at baseline (first week). Through 14 weeks, adherence was demonstrated for 83.5% of study days (**Figure 1A**). At baseline, physical activity was higher in men than women and on weekdays than weekends; median daily steps were not significantly different based on age (**Figure 1B**). Baseline mean BASFI and ASAS-HI in the SELECT-AXIS 2 bDMARD-IR AS trial were 6.3 and 9.3 respectively, suggesting relatively high functional limitation. Patients with higher baseline functional impairment (BASFI score >7) did not statistically differ in median daily time spent in MVPA (p=0.366) but took an average of 1690 fewer steps per day (p=0.021) than patients with BASFI scores ≤4 who met the Patient Acceptable Symptom State (PASS) [3] (**Figure 1C**). Patients reporting "poor" health status [4] (ASAS-HI score ≥12 to 17) spent 30.0 fewer minutes in MVPA (p=0.005) and took 2186 fewer steps per day (p=0.010) than those with "good" health status [4] (ASAS-HI scores ≤5; **Figure 1D**).
Conclusion: bDMARD-IR patients with AS in SELECT-AXIS 2 had high adherence with use of a wearable activity monitoring device over 14 weeks. Lower physical activity was generally associated with higher disability scores and poor health status at baseline. These data support the utility of wearable devices for assessing physical activity in people with AS, suggesting the possibility to use such devices to evaluate the impact of targeted therapeutics on passively collected physical activity and functional ability outcomes.

GENDER DIFFERENCES IN THE MANAGEMENT OF SPONDYLOARTHRITIS (SPA) PATIENTS

Keywords: Spondyloarthritis

D. Baldock[1], M. Thoo[2], R. Connolly[3], E. Baynton[1]. [1]*United Kingdom, Ipsos Healthcare, London, United Kingdom*; [2]*Kuala Lumpur, Ipsos Healthcare, Kuala Lumpur, Malaysia*; [3]*New York, Ipsos Healthcare, New York, United States of America*

Background: Spondyloarthritis (SpA) is a family of arthritic rheumatic diseases, including axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA), that primarily affects the spine and joints. It causes inflammation of the spinal and peripheral joints that can lead to severe, chronic pain and discomfort. Diagnosing SpA has proven challenging, particularly for women who are found to be underdiagnosed in AS despite the disease affecting men and women both equally, as there are no current diagnostic criteria for axSpA [1]. Disease activity can be measured through tests such haematology and joint count measurements.

Objectives: The objective of this study was to examine any gender differences in the management of SpA patients and highlight any nuances in treating these patients.
Methods: A multi-centre online medical chart review study of patients with PsA and Axial SpA was conducted between July 2022 – September 2022 among UK, FR, DE, IT & ES rheumatologists practicing across hospital and private practices. Physicians were screened for practice duration and patient volume. Charts of patients prescribed with biologics/tsDMARDS were included in the analysis.
Results: 262 sampled physicians collectively reported 1387 SpA patients. From the reported SpA patients, 812 were recorded as male and 575 as female. The female cohort were recorded with higher instances of co-existing conditions of depression (11.5% vs 5.3%) and anxiety (13.2% vs 8.1%) than men. When evaluating extra articular manifestations, female cohort were recorded with higher nail dystrophy (12.7% vs 8.6%) and psoriasis (36.7% vs 26.4%) than men. In assessing areas the AS patient suffers from, female cohort were recorded with higher peripheral involvement (49.6% vs 34.0%) and males more axial involvement (50.9% vs 28.0%). In assessing disease scores, female cohort were recorded with higher joint counts, haem scores, and PASI score. Physician-defined status of disease severity reported female cohort with higher current severity (48.4% vs 41.5% moderate and severe) and lower remission rates (45.4% vs 36.7% not in remission) in comparison to men.

Table 1. Reported patient disease and haematology scores (mean)

Reported SpA patients	Tender joint count (TJC)	Swollen joint count (SJC)	C-reactive protein (CRP)	Erythrocyte Sedimentation Rate (ESR)	Psoriasis area and severity index (PASI)
Female	3.5	2.0	12.1	21.5	14.2
Male	2.3	1.3	6.8	16.9	11.9

Length of time on current biologic and/or tsDMARD recorded male cohort on treatment for longer timeframe vs females (mean months: 50.2 vs 46.5). The most prominent biologics to treat the two patient groups are TNFis (72.2% male, 68.6% female); alternate modes of action, such as IL-17is and JAKis, are more prominently recorded in females vs males (31.2% vs 27.7%). Drivers of treatment choice – specified by sampled physicians - prioritised efficacy in skin (23.3% vs 19.3%), efficacy in manifestations of PsA beyond skin and joint (13.6% vs 9.6%), and reduction of peripheral joint inflammation (17.0% vs 10.3%) in female cohort versus male cohort.
Conclusion: From the sample surveyed, current disease activity is higher in reported female patients than males in SpA. Additionally, males are more likely to stay on the same bio/tsDMARD versus females, suggesting a disparity in efficacy or unmet needs when evaluating the two cohorts. It is possible that key differentiating identifiers, such as co-existing comorbidities outside axSpA or PsA or extra articular manifestations, can be used when deciding how to treat a patient. Discussion is necessary about gender-specific treatment plans in SpA, as well as factoring in possible mental health burden (anxiety and depression) disparities across gender cohorts. Further investigation using comparator cohort is warranted.

POS0687 LONG TERM (10 YEAR) CLINICAL OUTCOME OF RECENT ONSET AXIAL SPONDYLOARTHRITIS (AXSPA): DATA FROM THE DESIR COHORT

Keywords: Prognostic factors, Spondyloarthritis, Epidemiology

M. Dougados[1], C. Serrand[2], S. Alonso[2], T. Lequerre[3], A. Moltó[1]. *[1]Paris Cité University, Department oi rheumatology Hopital Cochin, paris, France*; *[2]CHU Nimes, Department of biostatistics, Nimes, France*; *[3]CHU Rouen, Department of rheumatology, Rouen, France*

Background: The information related to the long term outcome of a disease is of huge interest for the clinicians in daily practice to facilitate the information of the patients recently diagnosed as axSpA. The data from inception cohorts are better approaching the truth of this long term prognosis in comparison to the conventional retrospective cohorts mainly conducted in patients with advanced and severe disease managed in tertiary referral centers.
Objectives: To evaluate the 10 year clinical outcome (and its predisposing factors) of patients suffering from recent onset axSpA in the DESIR cohort.
Methods: *Study design*: DESIR is an ongoing (10 year follow-up completed for all the patients) multicenter cohort of recent onset axSpA. *Diagnosis*: At entry visit and during the 10 year follow-up period, the diagnosis was based on the opinion of the treating physician with a requirement of a diagnosis of axSpA at entry and the possibility to exclude the patients after the first 2 years follow-up period in case of a change in this diagnosis. *Management during the 10 year period*: the investigators were in charge of the data collection required by the protocol but the management (treatment regimens) was only based on the decision of the treating rheumatologist. *Statistical analysis*: Data presented here are the ones issued a)from the analyses on the completers (observed data) and b) after multiple imputations considering the missing data due to the patients lost of follow-up (imputed data).
Results: Of the 708 enrolled patients, 45 were excluded from the cohort because of a change in the entry visit diagnosis, 3 patients died (suicide n = 1, colorectal cancer n = 1, sudden death n=1), 300 were lost of follow-up and 360 patients completed the 10 year period. *A -Based on the analyses of the 10 year completers (n=360)* No patient necessitated a spinal vertebrotomy, one single patient had a bilateral total hip replacement. A pension from the national health care system was provided to 16% patients because an invalidity related to the axSpA disease. A csDMARD (methotrexate and/or sulfasalazine) has been prescribed in 32% and a biotherapy in 55%. The prevalence of the main extra-musculoskeletal features increased from 18 to 30%, 10 to 18% and 5 to 10% from baseline to year 10 for psoriasis, acute anterior uveitis and inflammatory bowel disease respectively. The prevalence of the main comorbidities increased from 3 to 8%, 0 to 3%, 5 to 15%, 0 to 4%, 1 to 3% and 0 to 2%, from baseline to year 10 respectively for severe GI events, MACE, hypertension, diabetes, tuberculosis and other severe infections respectively. B- *Based on the analyses of the 10 year completers (n=360) (observed data) and the 663 patients with unchanged initial axSpA diagnosis (imputed data)* An acceptable status at year 10 was observed in 77%,70 [63; 77]%,;49% 43 [37; 49]%; 55% 48 [41; 56]% considering an acceptable PASS, BASDAI < 30, ASDAS < 2.1 for the observed (%) and imputed (% and [95%CI]) data respectively. The impact of the disease on the daily life of the patients was evaluated by different parameters: ASAS HI ≤ 5 (41 [35; 47]%, SF36 physical score (42 [40; 44]) and SF36 mental score (43 [40; 46]). The multivariate analysis of the baseline predisposing factors of an acceptable status at year 10 defined as an ASDAS score<2.1 picked-up the following variables: short (<1.5year)delay between the first symptoms and the baseline visit: OR= 1.46[0.93;2.29],socio-professional level (white collar): OR=1.87[1.20;2.90] and baseline BASDAI score<40, OR=1.91[1.23;2.94]
Conclusion: These data are suggesting a favorable 10 year outcome in terms of stringent measures such as the requirement to surgery contrasting with a relatively less favorable outcome with regard to patient reported outcomes. These data should improve and facilitate the information provided to the patients at the time of their diagnosis.
Acknowledgements: The authors would like to thank all the investigators of the 25 participating centers as well as all the 708 enrolled patients.This study has been financially supported via unrestricted grants from PFIZER and the French Society of Rheumatology.

POS0688 COMPARING THE CONSTRUCT VALIDITY AMONG MEASURES OF PAIN AND STIFFNESS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Patient reported outcomes, Spondyloarthritis, Outcome measures

D. Capelusnik[1,2], E. Nikiphorou[3,4], A. Boonen[1,5], D. Van der Heijde[6], R. B. M. Landewé[7], A. Van Tubergen[5], S. Ramiro[6]. *[1]Maastricht University, Care and Public Health Research Institute (CAPHRI, Maastricht, Netherlands*; *[2]Tel Aviv Sourasky Medical Center, Rheumatology, Tel Aviv-Yafo, Israel*; *[3]King's College School, Centre for Rheumatic Diseases, London, United Kingdom*; *[4]King's College Hospital, Rheumatology, London, United Kingdom*; *[5]Maastricht University, Rhaumatology, Maastricht, Netherlands*; *[6]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[7]Amsterdam UMC, locatie VUmc, Department of Rheumatology & Clinical Immunology, Amsterdam, Netherlands*

Background: In the context of the recent update of the ASAS core outcomes set (COS), the preferred comparative validity of the measurement instruments to assess the domains 'Pain' and 'Stiffness' has been questioned as for each domain responsiveness of instruments was comparable. Group discrimination across various external constructs can help provide useful insights and represents unmet need.
Objectives: To compare the group discriminatory capacity, as part of the construct validity, of three instruments to assess pain and three questions of morning stiffness.

Methods: Data from the 8-year visit of patients with r-axSpA from the multinational OASIS cohort was assessed. The available instruments for pain assessment were: i) total spinal pain, ii) spinal pain at night, iii) spinal pain from BASDAI Q2 (addressing neck, back or hip pain); and for morning stiffness: i) severity of morning stiffness (BASDAI Q5), ii) duration of morning stiffness (BASDAI Q6), iii) the combined score between severity and duration of morning stiffness (average BASDAI Q5/6). Data from 8 year-visit were used as the first time-point where all the instruments were obtained on a 0–10 numeric rating scale (as currently used). The discriminatory capacity was assessed through the standardised mean difference (SMD) that is calculated as the difference of the group means divided by the pooled SD of the group means, with a higher value reflecting a higher discriminatory capacity. The external constructs used to compare the ability to discriminate between subgroups of patients were: ASDAS, BASDAI (dichotomized into inactive/active disease), PGA, PhGA, fatigue, BASFI, BASMI and mSASSS (dichotomized by the median).
Results: 98 patients were included: 71% males, mean age 54 (SD 11), with a mean symptom duration of 31 (11) years. The mean (SD) scores for pain were 3.7 (2.3), 2.9 (2.3) and 4.6 (2.6) for spinal pain, spinal pain at night and BASDAI Q2, respectively. The mean (SD) scores of morning stiffness were 3.7 (2.6), 3.3 (3.1) and 3.5 (2.7) for BASDAI Q5, Q6 and Q5/6, respectively. Spinal pain by BASDAI Q2 and total spinal pain had higher SMDs compared to spinal night pain across all group comparisons, with spinal pain BASDAI Q2 performing mostly slightly better (Table 1). Regarding morning stiffness, the severity question (BASDAI Q5) had consistently higher SMDs across all the clinical external constructs, while duration of morning stiffness (BASDAI Q6) performed worse.
Conclusion: Spinal pain from BASDAI Q2 and severity of morning stiffness (BASDAI Q5) are, respectively, the pain and morning stiffness instruments that best discriminate subgroups of patients classified according to disease activity, functional ability, fatigue or spinal mobility. The recommended ASAS COS pain instrument spinal pain BASDAI Q2, was confirmed to discriminate best. In the case of stiffness, the ASAS COS stiffness measure (BASDAI Q5/6) performed well although slightly less than the severity of morning stiffness (BASDAI Q5).

Table 1. Discrimination between subgroups of patients

Assessment measure	ASDAS <2.1 vs ≥2.1 SMD	BASDAI <4 vs ≥4 SMD	Fatigue <5 vs ≥5 SMD	BASFI <4 vs ≥4 SMD	BASMI <4 vs ≥4 SMD	mSASSS <15 vs ≥15 SMD
Total spinal pain	1.57	1.92	1.62	0.92	0.27	-0.32
Spinal night pain	1.07	1.39	1.27	0.78	0.07	-0.20
Spinal pain BASDAI Q2	1.88	2.37	1.65	0.89	0.31	-0.29
Morning stiffness severity BASDAI Q5	1.52	2.14	1.58	0.99	0.26	-0.11
Morning stiffness duration BASDAI Q6	1.18	1.80	1.09	0.83	0.09	-0.14
Morning stiffness average BASDAI Q5/6	1.40	2.14	1.38	0.95	0.17	-0.13

Background: Despite efforts for early detection, delayed diagnosis in axial spondyloarthritis (axSpA) remains an unresolved challenge.
Objectives: This analysis aimed to assess diagnostic delay and its associated factors around the world in a large sample of patients included in the International Map of Axial Spondyloarthritis (IMAS).
Methods: IMAS is a cross-sectional online survey (2017-2022) including 5,557 unselected axSpA patients from 27 countries. Diagnostic delay was calculated as the difference between age at diagnosis and age at symptom onset reported by patients. The independent factors evaluated were: age at symptom onset, disease duration, gender, education level, diagnosed by rheumatologist, number of healthcare professionals (HCPs) seen before diagnosis, HLA-B27, uveitis, and inflammatory bowel disease. The factor world region was introduced as a dummy variable taking Europe as the reference region due to its larger sample size and diagnostic delay close to the overall mean. The Mann-Whitney, Kruskal-Wallis test and Pearson correlation were used to evaluate the differences in diagnostic delay and independent variables. Associations between diagnostic delay and regions, sociodemographic characteristics, as well as disease-related factors were explored through univariable and multivariable linear regression analysis.
Results: Data from 5,327 patients who reported data to calculate diagnostic delay in IMAS survey were analyzed: 3,231 were from Europe, 770 from North America, 600 from Asia, 548 from Latin America, and 146 from Africa. Overall, patients reported a diagnostic delay of 7.4 years (median: 4.0) since symptom onset, with substantial variation across regions, being the highest in South Africa and the lowest in Asia **(Figure 1)**. Furthermore, mean disease duration was 17.1 ± 13.3. Patients with longer diagnostic delay were more frequently female, younger at symptom onset, with more years with the condition, more commonly diagnosed by the rheumatologist, with a higher number of HCPs seen before diagnosis, had experienced uveitis, and inflammatory bowel disease. The variables independently associated with longer diagnostic delay in the final multivariable regression model were: younger age at symptom onset (b=-0.100), more disease duration (b=0.363), female gender (b=2.274), being diagnosed by rheumatologist (b=1.163), higher number of healthcare professionals (HCPs) seen before diagnosis (b=1.033), and presence of uveitis (b=1.286; **Table 1**).
Conclusion: In this global sample of axSpA patients, the mean diagnostic delay was 7.4 years, and had significant differences across regions. Younger age at symptom onset, longer disease duration, female gender, diagnosed by rheumatologist, higher number of HCPs seen before diagnosis, and the presence of uveitis were the parameters associated with a longer diagnostic delay in axSpA patients.

POS0690 IN AXIAL SPONDYLOARTHRITIS, NON-STEROIDAL ANTI-INFLAMMATORY DRUGS REDUCE MRI-APPEARANCE OF SACROILIITIS

Keywords: Imaging, Spondyloarthritis

G. Jones[1], A. Bennett[2], R. Sengupta[3], P. Machado[4], H. Marzo-Ortega[5], L. Aucott[6], G. Macfarlane[1]. [1]*University of Aberdeen, Aberdeen Centre for Arthritis and Musculoskeletal Health (Epidemiology Group), Aberdeen, United Kingdom*; [2]*Defence Medical Rehabilitation Centre (Stanford Hall), Academic Department of Military Rehabilitation, Loughborough, United Kingdom*; [3]*Royal National Hospital For Rheumatic Diseases, Axial Spondyloarthritis Service, Bath, United Kingdom*; [4]*University College London, Centre for Rheumatology and Department of Neuromuscular Diseases, London, United Kingdom*; [5]*University of Leeds, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*; [6]*University of Aberdeen, Health Services Research Unit, Aberdeen, United Kingdom*

Background: MRI evidence of active sacroiliitis (sacroiliac joint bone marrow oedema (BMO)) is commonly used to assist diagnosis and classification of axial spondyloarthritis (axSpA). Non-steroidal anti-inflammatory drugs (NSAIDs) are used as first-line therapy, and for persistent clinical symptoms continuous treatment is recommended. Prescribed in primary care, and widely available over-the-counter, many patients are already taking NSAIDs when they first present to rheumatology.

Objectives: To determine whether NSAID use leads to an underestimation of sacroiliac joint BMO.

Methods: Adults with axSpA were recruited from NHS rheumatology clinics and asked to discontinue their NSAIDs for 1-2wks before undergoing a sacroiliac joint MRI (Scan 1) using a standardised protocol. All participants then re-started their NSAIDs. Those who scanned positive for BMO lesions, as determined using internationally recognised (ASAS) definitions, underwent a second scan 6wks after restarting NSAIDs. Scans were read independently by 2 readers (adjudicated by a 3rd, if required), blinded to participants' clinical characteristics and timepoint. We determined the proportion of participants who scanned negative at Scan 2 (on NSAIDs) who had previously scanned positive at Scan 1 (off NSAIDs).

Results: 311 participants were recruited from 34 centres. Table 1 shows participants' baseline characteristics. Almost all participants (296; 95%) completed the NSAID washout and underwent Scan 1. However, 135 (50%) reported an increase in spinal pain (median increase: 2 points on a 0-10 numerical rating scale; inter-quartile range: 1-3), and 166 (61%) reported worsening of disease activity (median increase in BASDAI: 0.9; 0.5-1.6). At Scan 1, 149 (50%) were positive for BMO lesions. 131 (88%) participants underwent the six-week follow-up scan, of whom 31 scanned negative (24%; 95%CI: 17-32%).

Conclusion: These findings suggest that NSAIDs influence sacroiliac BMO and, where sacroiliiitis is present, around one-in-four show resolution of lesions in the presence of NSAIDs. This has important implications for axSpA diagnosis and classification. If patients with axSpA (or suspected axSpA) are willing to attempt NSAID washout prior to MRI, this should be considered. There may be concerns about increases in disease activity or spinal pain, but we also provide evidence that almost all patients who attempt washout can successfully achieve it.

POS0691 ANALYSIS OF GAIT IN LONGSTANDING AXIAL-SPONDYLOARTHRITIS: A MONOCENTRIC PILOT STUDY

Keywords: Descriptive Studies, Spondyloarthritis, Motor function

M. Congia[1], F. Arippa[2], G. Solinas[1], M. M. Angioni[1], E. Chessa[1], A. Floris[1], M. Naitza[1], M. Piga[1], M. Monticone[3], M. Pau[1], A. Cauli[1]. [1]*Rheumatology Unit, AOU and University of Cagliari, Monserrato, CAGLIARI, Italy, Department of Medical Sciences and Public Health, Cagliari, Italy*; [2]*University of Cagliari, Department of Mechanical, Chemical and Materials Engineering, Cagliari, Italy*; [3]*University of Cagliari, Department of Medical Sciences and Public Health, Cagliari, Italy*

Background: Progression of radiographic damage in axial-spondyloarthropaties is related to higher functionality impairment in longstanding patients, resulting in poorer quality of life and autonomy. Its impact on gait has not been extensively studied yet. Time-up and go (TUG) test and GAIT analysis (GA) are currently used in neurological and musculoskeletal diseases to evaluate changes in patients gait and stance.

Objectives: The aim of this study is to evaluate with standardized procedures modifications of gait in patients with inactive longstanding axSpa with radiographic damage, comparing them with a cohort of sex, age and BMI matched healthy controls.

Methods: Patients followed at Rheumatology Unit of the University Hospital of Cagliari were enrolled. Inclusion criteria were: 1) having a diagnosis of axSpa, 2) having an inactive disease (BASDAI<4, PtGA<20, PhGA<20), 3) evidence of radiographic damage in the most recent spine x-ray available (mSASSS >20), 4) ability to walk autonomously. Exclusion criteria were: 1) deafness, 2) any medical condition that, according to investigators, could expose patients at any excess risk or interfere with the procedures of the study. Patients underwent a TUG test and a gait analysis at the Department of Mechanical, Chemical and Materials Engineering, University of Cagliari. For TUG Test the following parameters were recorded: TUG time, sit-to-stand time, first and second rotation time, stand-to-sit time, walking time. Walking speed and mean step length were recorded using GAIT analysis. Statistical analysis was performed with MANOVA (Pillai's Trace, Wilk's Lambda, Hotelling's Trace, Roy's Largest Roots). Level of statistical significance was set at<0,05.

Results: Fifteen patients and fifteen HC were enrolled in this study. Mean age was 60,1±7,8 years for patients and 61,3±7,8 for HC. Weight and height were similar in both groups (axSpa 76,7 ± 16,8kg vs HC 72 ±7,2kg; axSpa 169,33 ± 8,8cm vs HC 170,4 ± 5,2cm). Disease duration was 27.61±9,67 years, mean mSASSS was 46,33±16,84. All patients were inactive, but showed clinical signs of disease progression (BASMI 5,9±1,19). Thirteen patients were on treatment with bDMARDs (TNF inhibitors), while 2 were off treatment. MANOVA revealed differences between axSPa patients and HC for TUG test (p<0,05). TUG time and walking time were significant longer in axSpa (TUG time 12,88±1,92s vs 10,44±2,18s, p=0,003; walking time 5,69±1,17s vs 3,68±0,8, p<0,001), while other parameters were not different between groups. Finally, axSpa patients were slower (0,95±0,16 m/s vs 1,18±0,17 m/s; p<0,05), and had a shorter step (0,52±0,65 m vs 0,65±0,69 m; p<0,05).

Conclusion: Patients with longstanding axSpa showed a different gait when compared with matched HC: we found that axSpa patients walk slower than HC, and with shorter steps. This could be interpreted as a compensatory behaviour as walking speed slower than 1 m/s has been reported as a risk factor for falling in elderly. In conclusion, we found that disease progression in axSpa patients could interfere with walking speed. Clinical relevance of these findings should be confirmed in future studies, as well as if some medical intervention (e.g. physical therapy) could minimize the impact of disease progression on posture control and walking.

POS0692

CAN THE ASSESSMENT OF DIAGNOSTIC CONFIDENCE BE USED AS A PARAMETER FOR IMAGE READER'S PERFORMANCE IN AXIAL SPONDYLOARTHRITIS? FIRST RESULTS OF THE DAMACT STUDY

Keywords: Imaging, Spondyloarthritis

S. T. Ulas[1,2], F. Radny[1], K. Ziegeler[1], I. Eshed[3], J. Greese[1], D. Deppe[1], C. Stelbrink[1], D. Poddubnyy[4], T. Diekhoff[1,2]. [1]*Charité - Universitätsmedizin Berlin, Department of Radiology, Charité Campus Mitte, Berlin, Germany*; [2]*Charité - Universitätsmedizin Berlin, Berlin Institute of Health, Berlin, Germany*; [3]*Sheba Medical Center, affiliated with the Sackler School of Medicine, Tel Aviv University, Department of Diagnostic Imaging, Tel Aviv, Israel*; [4]*Charité - Universitätsmedizin Berlin, Department of Gastroenterology, Infectious Diseases and Rheumatology, Charité Campus Benjamin Franklin, Berlin, Germany*

Background: Early and accurate diagnosis is essential for the further outcome of patients with axial spondyloarthritis (axSpA). The confident interpretation of image data sets plays a special role in the clinical practice is crucial for diagnosing axSpA. Therefore, the own assessment of the diagnostic confidence (DC) in the evaluation of images plays an increasingly important role. For this reason, the current guidelines from the ASAS working group recommend reporting the diagnostic confidence in the radiological report.

Objectives: The aim of this study was to investigate the validity of self-reported DC on the performance of readers in the diagnosis of axSpA using sacroiliac joint (SIJ) images in X-ray, computed tomography (CT) and magnetic resonance imaging (MRI).

Methods: In total, 163 subjects were included in this retrospective study. In all subjects, X-ray, CT and MRI of the SIJ were available. In total, 9 readers scored the images for the presence or absence of axSpA. The readers were divided into three equal groups according to their experience in musculoskeletal imaging: inexperienced (0 to 1 year of experience), semi-experienced (3 to 8 years of experience) and experienced group (over 8 years of experience). All readers were blinded to clinical data. The DC was collected during the evaluation of the images on a scale from 0 (not sure) to 10 (very sure). Contingency table analysis was performed to assess the reader's performance using the clinical diagnosis (axSpA or non-axSpA) as standard of reference. The mean DC's and standard deviation (SD) were calculated for the correct and incorrect axSpA diagnosis for each readers group separately for X-ray, CT and MRI and their differences were assessed using the unpaired t-tests.

Results: Overall, 89 patients were diagnosed with axSpA and 56 patients with degenerative SIJ disease previously to the scoring. We included 18 healthy subjects in the scoring. The cumulative correct (right-positive) and incorrect (false-positive) axSpA diagnoses were evaluated separately for the different reader groups with the mean DC values, see also Table 1. We showed that the DC differs significantly for the correct and incorrect diagnosis of axSpA in the semi-experienced and in the experienced group in all modalities. However, in the inexperienced group, no significant difference was obtained between the DC's in X-ray and CT.

Conclusion: In this study, we were able to show for the first time that diagnostic confidence is a predictive measurement of the diagnostic performance respective reader in the evaluation of patients with axSpA. This is especially true for the interpretation of MRIs, which showed significant differences in all reader groups. Based on these findings, we hypothesize that the addition of diagnostic confidence in radiological findings is a reliable tool to predict diagnostic performance.

Table 1. Results. DC = diagnostic confidence. SD = standard deviation. n = cumulative number of correct or incorrect axSpA diagnosis.

	Correct axSpA diagnosis	**Incorrect** axSpA diagnosis	**P value**
X-ray	n	n	
Unexperienced (mean DC ± SD)	109 (6.29 ± 1.89)	60 (6.20 ± 1.71)	0.75
Semi experienced (mean DC ± SD)	164 (6.65 ± 2.65)	64 (5.81 ± 2.10)	0.007
Experienced (mean DC ± SD)	173 (7.94 ± 1.82)	61 (6.79 ± 2.24)	<0.0001
CT	n	n	
Unexperienced (mean DC ± SD)	166 (7.15 ± 1.74)	21 (6.78 ± 1.72)	0.10
Semi experienced (mean DC ± SD)	206 (8.38 ± 1.53)	22 (6.77 ± 2.22)	<0.0001
Experienced (mean DC ± SD)	202 (9.16 ± 1.43)	11 (7.18 ± 2.10)	<0.0001
MRI	n	n	
Unexperienced (mean DC ± SD)	184 (6.97 ± 1.85)	55 (5.80 ± 1.95)	<0.0001
Semi experienced (mean DC ± SD)	210 (8.18 ± 1.48)	54 (6.30 ± 1.68)	<0.0001
Experienced (mean DC ± SD)	208 (9.14 ± 1.67)	25 (6.72 ± 2.32)	<0.0001

Vasculitis - large vessel vasculitis

POS0693 ULTRASOUND SHOWS ONGOING VESSEL WALL REMODELING IN GIANT CELL ARTERITIS FOR TWO YEARS AFTER DISCONTINUATION OF TOCILIZUMAB - FOLLOW-UP OF THE GUSTO TRIAL

Keywords: Imaging, Ultrasound, Vasculitis

L. Seitz[1], F. Lötscher[1], S. Reichenbach[1,2], P. Villiger[3], L. Christ[1]. *[1]Inselspital, Bern University Hospital, Rheumatology and Immunology, Bern, Switzerland*; *[2]University of Bern, Institute for Social and Preventive Medicine, Bern, Switzerland*; *[3]Medical Center Monbijou, Rheumatology and Immunology, Bern, Switzerland*

Background: The GUSTO (Giant cell arteritis (GCA) treatment with Ultra-Short glucocorticoids and TOcilizumab) trial evaluated the efficacy and safety of Tocilizumab (TCZ) monotherapy after a 3-day glucocorticoid-pulse in new-onset GCA [1]. Ultrasound measurements of the intima-media thickness (IMT) demonstrated a slow and steady decrease in the temporal arteries and a smaller and delayed effect on the axillary and subclavian arteries with TCZ monotherapy over 52 weeks [2]. Recently, a new Outcome Measures in Rheumatology (OMERACT) GCA ultrasonography score (OGUS) for monitoring disease activity in GCA has been proposed [3].
Objectives: To investigate the evolution of the IMT after discontinuation of TCZ at week 52 in the GUSTO trial. Data up to week 156 are presented (two-year drug-free follow-up).
Methods: Eighteen patients with new-onset GCA were enrolled in the GUSTO trial. [1] Patients received 500mg methylprednisolone intravenously for 3 consecutive days. Thereafter, glucocorticoid treatment was discontinued and TCZ (8mg/kg bodyweight) was administered intravenously, followed by weekly subcutaneous TCZ injections (162mg) from day 10 until week 52. Patients in clinical remission stopped TCZ at week 52 and entered the follow-up study. The maximum IMT of the temporal arteries (common superficial temporal artery, parietal and frontal branch) and IMT at landmarks of the axillary and subclavian arteries were measured bilaterally at weeks 52, 78, 104 and 156. The OGUS is calculated as follows: IMT divided by the rounded cut-off values of IMTs for each segment; the sum of these values is then divided by the number of segments available (maximum of 8 segments; axillary and temporal arteries considered). [3]
Results: At week 52, 13/18 patients were in relapse-free remission and entered the follow-up study. 1/13 patients presented with a minor relapse during the 104 weeks follow-up period. At week 156, 12/13 patients were in relapse-free and drug-free remission. The OGUS showed a steady decline with mean values of 0.90 (standard deviation (SD) 0.19) at week 52, 0.87 (SD 0.16) at week 78, 0.84 (SD 0.15) at week 104, and 0.79 (SD 0.12) at week 156. IMT measurements of one patient after restarting TCZ therapy were excluded (weeks 104 and 156).
Conclusion: After 52 weeks of treatment with TCZ, the IMT in GCA continues to decline during a drug-free period of up to or possibly more than two years. It can take more than one year after treatment discontinuation for the OGUS to become smaller than 1, indicating an average IMT below the rounded diagnostic cut-off values. Our results suggest a long-lasting remodeling phase of the vessel wall after treatment discontinuation.

POS0694 MOLECULAR PHENOTYPING OF GIANT CELL ARTERITIS PATIENTS: ANALYSIS OF THE SERUM PROTEIN PROFILE USING A HIGH THROUGHPUT METHOD

Keywords: Biomarkers, -Omics, Vasculitis

F. Zingg[1], A. Gloor[2], C. Polysopoulos[3], P. Villiger[4], B. Maurer[1], L. Christ[1]. *[1]Inselspital, Bern University Hospital, Department of Rheumatology and Immunology, Bern, Switzerland*; *[2]Inselspital, Bern University Hospital, Department of Internal Medicine, Bern, Switzerland*; *[3]Statistics and Data Management Group, Swiss Clinical Quality Management Foundation, Zurich, Switzerland*; *[4]Medical Center Monbijou, Rheumatology and Immunology, Bern, Switzerland*

Background: There is a lack of biomarkers to profile phenotypes in giant cell arteritis (GCA) and predict potential complications. Serum protein profiling may identify molecular-based phenotypes and facilitate personalized medicine approaches.
Objectives: To investigate the serum protein signature of clinically defined GCA phenotypes and to evaluate whether serum protein-based profiling identified distinct patient clusters.
Methods: We analyzed baseline serum samples from 16 patients with new-onset GCA enrolled in the GUSTO trial (NCT03745586) [1]. Serum samples were collected prior to treatment or with the lowest prior GC-exposure. In total, 1436 differentially expressed proteins (DEPs) were assessed based on proximity extension assay technology. T-test (threshold, adjusted p-value <0.05) was performed with adjustment for multiple testing (Benjamini-Hochberg) to identify DEPs. Supervised and unsupervised cluster analyses were performed. Supervised analysis was stratified based on the three following clinical phenotypes: presence or absence of (i) cranial and (ii) polymyalgia rheumatica (PMR) symptoms, and (iii) response to treatment within the GUSTO trial.
Results: Differences in the serum protein profile were observed based on the presence of cranial GCA and treatment response within the GUSTO trial. We identified 18 DEPs for cranial vs. non-cranial GCA, covering proteins involved in endothelial function (ECE1) or Th17 signaling (IL17RA), and 24 DEPs for response vs. non-response. GCA patients with non-response displayed among others a pronounced Th1 (IL2, IL12) and altered BAFF/APRIL signature. We found no difference based on the presence or absence of PMR-symptoms. Unsupervised hierarchical cluster analysis of the serum protein profile revealed three distinct patient clusters (Figure 1). There was no separation between patients based on clinical parameters except for a tendency to separate GCA patients with (cluster 2) from patients without PMR-symptoms (cluster 1).
Conclusion: Upon further validation, in GCA, molecular profiling of patients based on serum protein signatures has great potential for future individualization of patient management. This is the first study to phenotype new-onset GCA based on the serum protein signature. GCA patients with cranial symptoms and treatment response display a distinct serum protein signature. We found a tendency to cluster GCA patients with concomitant PMR-symptoms. Our findings of different protein signatures might facilitate personalized treatment approaches in GCA.

POS0695

A PROSPECTIVE STUDY EVALUATING A PRE-TEST PROBABILITY SCORE IN THE DIAGNOSIS OF GIANT CELL ARTERITIS

Keywords: Diagnostic tests, Vasculitis, Ultrasound

C. Kirby[1], R. Flood[1], S. Norton[2], J. Galloway[3], R. Mullan[1], G. Murphy[4], D. Kane[1]. *[1]Tallaght University Hospital, Rheumatology, Dublin, Ireland*; *[2]King's College London, Centre for Rheumatic Diseases, London, United Kingdom*; *[3]King's College Hospital, Rheumatology, London, United Kingdom*; *[4]Cork University Hospital, Rheumatology, Cork, Ireland*

Background: Temporal Artery Ultrasound (TAUS) has been increasingly used in recent years to diagnose Giant Cell Arteritis (GCA) but has shown widely disparate results in studies to date [1-3]. A Pre-Test Probability Score (PTPS) has been developed to standardise the estimation of clinical probability of having GCA which, to date, has been validated in only one prospective study [4].

Objectives: To evaluate the diagnostic utility of the PTPS and to investigate whether its use can improve the sensitivity of US.

Methods: We performed a prospective multicentre study of all new referrals to our Rapid Access GCA clinic over 18 months. US of all branches of the Superficial Temporal (STA) and Axillary Arteries (AA) was performed using a GE P9 device. Sonographic abnormalities considered indicative of vasculitis included the halo sign and non-compressible arteries with a thickened intima-media complex [5]. The PTPS (scale 0-30) incorporates a number of variables to quantify the likelihood of having a diagnosis of GCA (Table 1) [4]. We compared results to a clinical diagnosis of GCA at 6 months, verified by 2 rheumatologists. We performed Chi-Square tests with ROC analyses and logistic regression to determine the diagnostic performance of the PTPS, US and of both tools combined.

Table 1. The Pre-Test Probability Score of having a diagnosis of GCA incorporates patient demographics, symptoms, examination findings, laboratory results and relevant false negatives, with a maximum score 30. Y = Yes (present), N = No (absent).

Score	-3	0	+1	+2	+3
Age (years)		≤49	50-60	61-65	≥66
Sex			Male	Female	
Duration of symptoms		>24 weeks	12-24 weeks	6-12 weeks	<6 weeks
CRP		0-5mg/L	6-10 mg/L	11-25mg/L	≥25mg/L
Headaches		N	Y		
Polymyalgia		N		Y	
Constitutional		N	Single		Combination
Ischaemic		N			Y
Visual (AION, CRAO, Field loss, RAPD)		N			Y
TA abnormality		N	Tender	Thick	Pulseless
Extra-cranial artery abnormality		N	Thick	Bruit	Pulseless
Cranial nerve palsy		N			Y
Infection	Y				
Cancer	Y				
Systemic rheumatic disease	Y				
Head and neck pathology	Y				

Results: 72/149 patients had a diagnosis of GCA with a mean age of 73.3 years of whom 58% were males. The PTPS AUC for a diagnosis of GCA was 0.807 (95% CI 0.736-0.875). At scores <10, the PTPS correctly refuted the diagnosis in 91.67%, with lower scores having even higher sensitivities. At scores >13, it correctly identifies the diagnosis in 93.51%, with higher scores having even higher specificities. The TAUS AUC for a diagnosis of GCA was 0.865 (95% CI 0.810- 0.920). A model which combines both PTPS and TAUS out-performs both individual tools with an AUC 0.912 and is illustrated in Figure 1. In the case of positive US, a PTPS ≥6 infers a >60% likelihood of having GCA. In cases of negative US, a PTPS ≤12 infers a <20% likelihood of having GCA.

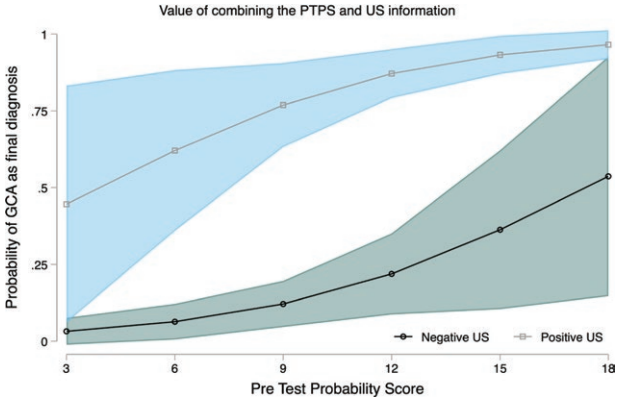

Figure 1. Probability of having a diagnosis of GCA at various PTPS in US-positive (above, blue) and US-negative (below, green) patients, with confidence intervals.

Conclusion: Our study demonstrates a strong correlation between baseline PTPS and a clinical diagnosis of GCA at 6 months, in a large prospective cohort. Although US is superior to PTPS for diagnosis of GCA, a model which combines both tools achieves a sensitivity of 91%, higher than that for US alone. This model can form the basis of an algorithm to guide early corticosteroid use in cases of suspected GCA.

Background: The full glucorticoid (GC)-sparing potential of Tocilizumab (TCZ) and its effect on vascular inflammation in giant cell arteritis (GCA) is currently unknown.
Objectives: To explore the efficacy of TCZ monotherapy after ultra-short pulse GC administration in new onset and relapsing large vessel GCA (LV-GCA).
Methods: This is a single-arm, single-center, open-label proof-of-concept trial (NCT05394909). Patients aged older than 50 years with newly diagnosed or relapsing LV-GCA were enrolled according to the following: PET/CT showing vascular FDG uptake ≥2 in at least one vascular district and considered consistent with active vasculitis and at least one among. 1.ESR >40 mm/h or CRP >10 mg/l 2.Cranial or systemic manifestations of GCA or polymyalgia rheumatica (PMR) Patients taking more than 10 mg/day of prednisone for more than 10 consecutive days in the previous 3 months were excluded. All patients received 500 mg per day methylprednisolone intravenously for 3 consecutive days and weekly subcutaneous TCZ injections from day 4 until week 52. PET/CT was performed in all patients at baseline and at weeks 24 and 52. PETVAS was calculated by a nuclear medicine specialist, and the diameters of the aorta were measured by a radiologist at 4 different levels. Any change of ≥5mm on serial CT was considered a significant progression of aortic damage. Remission was defined by all the following: absence of any clinical signs and symptoms directly attributable to GCA; normalization of acute phase reactants; absence of new/worsened aortic damage at CT; vascular FDG uptake <2 in all vascular districts at PET/CT or overall PET image interpretation of non-active vasculitis by nuclear medicine physician. Relapse was defined as one or more of the following: recurrence of signs or symptoms of GCA or PMR; CRP values greater than 10 mg/L, or ESR values greater than 40 mm/h if these were considered by the investigator to be due to GCA; evidence of worsening vascular FDG uptake at PET/CT. The definition of relapse included the necessity for the introduction of prednisone. The primary endpoints were the reduction of PETVAS at weeks 24 and 52 compared with baseline and the proportion of patients with relapse-free remission at weeks 24 and 52. The secondary endpoint was the proportion of patients with new aortic dilation at weeks 24 and 52.
Results: From March 2019 to November 2020 18 patients were included. The baseline characteristics are reported in the Table 1. A significant reduction of PETVAS was observed at weeks 24 and 52, mean (95% CI) reductions -8.6 (-11.5 to -5.7) and -10.4 (-13.6 to -7.2), p =0.001 and 0.002, respectively. The proportion of patients with relapse-free remission at weeks 24 and 52 was 10 out of 18 (56%, 95% CI 31-78) and 8 out of 17 (47%, 95% CI 23-72), respectively. At weeks 24 and 52 no patient showed new aortic dilation. However, 3 dilated patients at baseline showed a significant increase in aortic diameter (≥5 mm) at week 24, and 1 dilated patient showed a significant increase in aortic diameter at week 52. One patient underwent an aortic aneurysm surgical repair at week 44. 2 (11%) of 18 patients did not respond to treatment, and rescue GC treatment was necessary.
Conclusion: TCZ monotherapy after ultra-short GCs controlled the clinical symptoms of GCA, lowered acute phase responses, and significantly reduced vascular inflammation. 4 of 18 patients (22%) showed significant increase in aortic diameters on serial CT. The effect of TCZ on progression of aortic damage needs larger prospective studies.

Table 1. Baseline characteristics of the patients

Study population (n=18)	
Age, years	68.5 (10.6)
Female	13 (72%)
Newly-diagnosed LV-GCA	9 (50%)
Relapsing LV-GCA	9 (50%)
Glucocorticoid pretreatment	13 (72%)
CRP, mg/L	35 (36)
ESR, mm/h	56 (41)
Symptoms of active vasculitis	15 (83%)
Systemic symptoms	11 (61%)
Polymyalgia rheumatica symptoms	7 (39%)
Signs or symptoms of vascular insufficiency	4 (22%)
Cranial symptoms	1 (6%)
Visual symptoms	0 (0%)
Active vasculitis on PET/CT	18 (100%)
PETVAS	17.3 (5.1)
Aortic dilation	8 (44%)

POS0697 OUTCOME FOR PATIENTS WITH GIANT CELL ARTERITIS (GCA) TREATED WITH TOCILIZUMAB ACCORDING TO NICE GUIDANCE IN A SINGLE TERTIARY UK CENTRE

Keywords: Real-world evidence, Vasculitis, bDMARD

S. Ahmed[1], J. Heaney[1], A. Smith[1], J. Norris[1], B. Thompson[1], A. Lorenzi[1], B. Griffiths[1], G. Reynolds[1]. [1]Newcastle Freeman Hospital, Rheumatology, High Heaton, United Kingdom

Background: In 2018 NICE and NHS England approved one year of weekly subcutaneous tocilizumab for use in relapsing or refractory GCA [1, 2]. During the COVID pandemic NHS England allowed extended use of tocilizumab in selected high risk patients [3]. This extension ended in March 2022. This has created a cohort of patients who are now no longer treated with tocilizumab and may be at risk of GCA flare. Currently, NHS England does not allow retreatment with tocilizumab.
Objectives: This service evaluation used an intention-to-treat approach to retrospectively evaluate patients, who were ratified to receive tocilizumab for GCA according to the NICE guidance. We aimed to describe this cohort of patients for whom the use of tocilizumab had been approved, and their outcomes in terms of complications and disease control.
Methods: 49 patients were ratified to receive tocilizumab between May 2019 and April 2022 by a specialist multidisciplinary team at a single tertiary rheumatology center. Their response was assessed in terms of relapse rates, steroid usage and complications as described below.
Results: 80% of the 49 cohort of patients consisted of females (Table 1). 55% of patients were diagnosed with GCA on combination of clinical history, laboratory and temporal artery duplex findings. 94% (46/49) had at least a week's course of tocilizumab. Around half (51%) had relapsing disease. 6% had first dose as intravenous due to critical ischaemia. 27% (13/49) of patients developed complications whilst on treatment. Six developed cytopenia, 3 acquired infections and 4 stopped due to other reasons. As per guidelines, tocilizumab was stopped after 12 months in 25 patients (51%). 16% stopped treatment early due to complications. 18% had incomplete information. 10% had ongoing treatment. One patient died several months after finishing tocilizumab. 47% had methotrexate as DMARD therapy added prior to tocilizumab commencement (Figure 1). Out of 25 patients who completeted treatment, 24% (6/25) relapsed. 83% of these relapses were diagnosed on recurrence of symptoms and high inflammatory markers. In addition, 3 patients, who had tocilizumab suspended relapsed. 2/3 of these patients had treatment suspended due to infection. 5/9 relapse patients did not have preceding DMARD therapy. 22% (2/9) of relapse patients had PET-CT due to involvement of extra-cranial disease. 56% (5/9) relapsed following a median follow-up of 11 months. Of relapsed patients, seven were treated with increased dose of prednisolone and two patients received 6 months extension of tocilizumab with adequate tolerance and efficacy.
Conclusion: Our data shows good tolerability of tocilizumab and a 24% flare rate amongst patients who completed treatment. This is less than the 50% rate seen in GiACTA and other cohorts, where the majority of which occurred within 6 months of stopping treatment [4]. DMARD treatment may reduce relapse rate, but this will require further study. The data describing the efficacy of treatment beyond one year is limited [3]. However, with no established guidance for treating patients following tocilizumab, extension of treatment is a plausible option.

POS0698 REAPPRAISAL OF LARGE ARTERY INVOLVEMENT IN GIANT CELL ARTERITIS, A POPULATION-BASED COHORT OVER 70 YEARS

Keywords: Epidemiology, Vasculitis, Imaging

M. Elfishawi[1], M. Kaymakci[1], S. Achenbach[2], C. S. Crowson[1,2], T. Kermani[3], W. Cornelia[1], M. Koster[1], K. J. Warrington[1]. [1]*Mayo Clinic, Division of Rheumatology, Department of Internal Medicine, Rochester, United States of America*; [2]*Mayo Clinic, Division of Clinical Trials and Biostatics, Department of Qualitative health Sciences, Rochester, United States of America*; [3]*University of California, Los Angeles, Division of Rheumatology, Department of Internal Medicine, Los Angeles, United States of America*

Background: Screening for large artery manifestations in patients with Giant Cell Arteritis (GCA) has been adopted in clinical practice. However, the effect of recent use of imaging studies on incidence and mortality of large artery manifestations remains unclear.

Objectives: In this study, we aimed to investigate incidence trends and outcomes of large artery manifestations in a population-based cohort of patients with GCA over a span of seven decades.

Methods: The study cohort included patients with incident GCA between 1950-2016 in a defined geographical area. Incident large artery manifestations were defined as aortic aneurysm, aortic dissection, stenosis in the aorta or any of its main branches diagnosed within 1 year prior to the diagnosis of GCA or anytime afterwards. Patients were followed till December 31st, 2020, death, or migration. Cumulative incidence of large artery manifestations adjusted for the competing risk of death was estimated. Cox proportional hazards models adjusted for age and sex were used to assess the association of clinical characteristics with large artery manifestations.

Results: The study included 289 patients with GCA: 222 (77%) females; temporal artery biopsy was positive in 235 patients (81%); mean follow up period was 10.4 ± 7 years; mean age at diagnosis was 76.4 ± 8.2 years. Incident large artery manifestations developed in 104 patients throughout the follow up period, the majority (76%) were found incidentally. Cumulative incidence rates of large artery manifestations at 5 years were 7.3% (95% CI 2.4-22.1%), 15.9% (95% CI 10.6-23.8%) and 27.2% (95% CI 20.2-36.6) for patients diagnosed in 1950-1974, 1975-1999 and 2000-2016, respectively. Moreover, cumulative incidence of large vessel manifestations at 15 years was 14.8% (95% CI 7.0-31.6%), 30.2% (95% CI 23.1-39.4%) and 48.8% (95% CI 38.8-61.3%) for patients diagnosed in 1950-1974, 1975-1999 and 2000-2016, respectively (Figure 1). Patients with GCA diagnosed in 2000-2016 and 1975-1999 had more than 3.5-fold and 2-fold increase in incidence of large artery manifestations (HR:3.49 95%CI 1.67-7.3 and HR: 1.98 95% CI 0.97–4.07, respectively) compared to 1950-1974. However, there was no significant increase in aortic aneurysm or dissection (Table 1). Mortality risk has decreased significantly in patients with large artery manifestations diagnosed in the latest cohort 2000-2016 (HR 0.38 95% CI 0.17–0.81) following non-significant improvements in 1975-1999 (HR 0.61 95% CI 0.29-1.30) compared to 1950-1974 (reference). Clinical predictors for large artery manifestations included weight loss, fatigue, arm claudication, ever smoker and bruit on physical examination. Cranial symptoms were negatively associated with large artery manifestations.

Conclusion: Incidence of large artery manifestations (mainly large artery stenosis) has increased over time likely from increased use of imaging studies. However, the incidence of aortic aneurysm/dissection has been stable over the last 7 decades. Mortality improvement in the recent years may be due to earlier detection of large artery involvement.

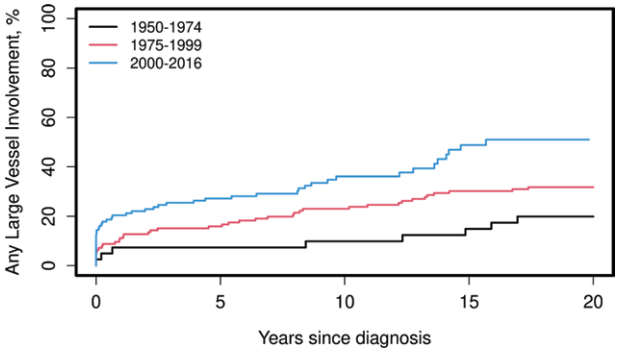

Figure 1. Cumulative incidence for time to any large artery manifestation (large artery stenosis, aortic aneurysm, aortic dissection) in patients with incident GCA 1950-2016 adjusted for the competing risk of death.

Table 1. Cox proportional hazards model showing Age- and Sex-adjusted risk of large artery manifestation among patients with incident GCA 1950-2016

Background: Although the systematic measurement of disease activity facilitates clinical decision making in Giant Cell Arteritis (GCA), no recommendations currently exist on which measures should be applied in clinical practice.
Objectives: To comprehensively evaluate the validity, feasibility, and acceptability of available GCA disease activity measures and derive recommendations for their use in clinical practice.
Methods: This was a 6-phases process which included a combination of a systematic literature review, psychometric analyses, validated group methods, and physician surveys. In phase 1, The GCA clinical Disease Activity Measures Working Group conducted a systematic review of the literature to identify GCA disease activity measures. Applying exclusion criteria: measurement tools were excluded from further consideration if they: (1) measured imaging only; (2) did not report a continuous value; (3) had insufficient information (e.g. not yet published in manuscript form.). Phase 2: Expert panel were asked to rank the remaining measures via an electronic survey. For each measurement tool, expert panel members were asked to indicate whether they were familiar with the measure (yes, no), whether they had ever used the measure (yes, no), and whether they would recommend the measure for clinical use (yes, no). The survey instructed the expert panel to apply the Outcome Measures for Arthritis Clinical Trials (OMERACT) filter of truth, discrimination, and feasibility as a guide when ranking their top five choices for use in clinical practice. The panel members were encouraged to identify additional measures not listed. Phase 3: following teleconferences the list of measures was reduced based on their rankings and panel comments. Phase 4: included comprehensive examination of the psychometric properties (reliability, validity, and responsiveness) of the remaining GCA disease activity measures. Phase 5 included an electronic survey to score the usefulness and feasibility in clinical practice and acceptance to use the tool on a regular basis when caring for patients. Phase 6: the final list of GCA disease activity measures was prepared.
Results: Using the list of specific disease activity measures as keyword searches, the systematic review of the literature resulted in identification of 21 GCA disease activity measures. Application of exclusion criteria and ratings by the expert panel narrowed the list to 10 measures for further evaluation. Practicing rheumatologists rated 7 of these 10 measures as most useful and feasible. From these 7 measures, the working group selected 6 with the best psychometric properties for inclusion in the final set of recommended GCA disease activity measures.
Conclusion: The GCA Clinical Disease Activity Index, has been developed including severity of headache (using 0-100 VAS), acute visual deficit (0-100 VAS), functional disability (0-3), Lab disease activity measures: ESR and CRP, patient global assessment (0-100 VAS), physician global assessment (0-100 VAS). These were identified as they are accurate reflections of disease activity; are sensitive to change; discriminate well between low, moderate, and high disease activity states; have remission criteria; and are feasible to perform in clinical settings.

METABOLIC AND MORPHOLOGIC PET/MR FEATURES IN CRANIAL GIANT CELL ARTERITIS

Keywords: Descriptive Studies, Vasculitis, Imaging

P. Nienhuis[1], C. M. Sørensen[2], K. Keller[3], I. Hansen[3], E. Naeser[3], M. Nyhuus Bendix Rasch[3], E. Brouwer[4], R. Slart[1], A. Dias[5], A. Appelman[1], E. M. Hauge[3], L. C. Gormsen[5], B. Dalsgaard Nielsen[3]. [1]*University Medical Center Groningen, Medical Imaging Center, Groningen, Netherlands*; [2]*The Regional Hospital in Horsens, Department of Medicine, Horsens, Denmark*; [3]*Aarhus University Hospital, Rheumatology, Aarhus, Denmark*; [4]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; [5]*Aarhus University Hospital, Nuclear Medicine, Aarhus, Denmark*

Background: Accurate and timely diagnosis is crucial for patients suspected of having cranial giant cell arteritis (C-GCA) as prompt treatment with high-dose glucocorticoids may prevent severe ischemic complications, such as vision loss. However, the use of high-dose glucocorticoids in patients without proven C-GCA should also be done with caution due to potential side effects. Currently, multiple diagnostic (imaging) tests are required to establish an accurate diagnosis as single tests lack sufficient diagnostic sensitivity. Next to ultrasonography, 18F-Fluorodeoxyglucose Positron Emission Tomography/Computed Tomography (FDG-PET/CT) and Magnetic Resonance Imaging (MRI) are used in clinical practice but carry a significant risk of false negative results. Since FDG-PET imaging measures metabolic activity, while MRI demonstrates morphological changes, combining these modalities may result in a composite hybrid diagnostic test with higher diagnostic accuracy.
Objectives: To describe the metabolic and morphologic imaging features of FDG-PET/MR in patients with diagnosed C-GCA.
Methods: Patients diagnosed with new-onset C-GCA underwent FDG-PET/CT and FDG-PET/ MR at 1 and 2 hours after FDG administration, respectively. Patients who had received treatment with glucocorticoids for more than 3 days prior to imaging were excluded from participating. Diagnosis of C-GCA was determined based on clinical information and the results from ultrasonography and FDG-PET/CT. On FDG-PET/MR imaging, thirteen arteries were evaluated bilaterally. Time-of-Flight (TOF) MR angiography was used to detect arterial stenoses or occlusions which were visually graded as either absent or present. To assess vessel wall thickness, T1-weighted contrast-enhanced (T1WCE) MRI images were visually graded on a scale of 0-3, with 0 indicating no mural enhancement or thickening, 1 indicating slight mural enhancement but no thickening, 2 indicating significant mural enhancement and thickening, and 3 indicating mural and perivascular enhancement and thickening. FDG uptake was visually graded on a scale of 0-2, with 0 indicating no vascular uptake, 1 indicating uptake slightly above background, and 2 indicating uptake significantly above background.
Results: The study included 12 patients with new-onset C-GCA with a median age of 74 years (range 61-84 years), of which 9 were female. The mean C-reactive protein (CRP) concentration was 63.2 (SD 41.0) mg/L, and one patient was receiving daily 60 mg prednisolone at the time of imaging (Figure 1, patient 12). Cranial artery ultrasonography was positive in 9 patients, and FDG-PET/CT was positive in the cranial arteries in 10 patients. All patients had at least one positive artery on T1WCE MRI (score ≥ 2) and all but one patient showed at least one arterial stenosis or occlusion on TOF MR angiography. One patient without FDG uptake FDG-PET/MR did also not show any FDG uptake on FDG-PET/CT. Figure 1 shows a heatmap of (a) presence of stenoses/occlusions, (b) the vessel wall thickening score (0-3), (c) the FDG uptake score (0-2), and (d) the overlap of FDG-PET positivity (score ≥ 1), T1WCE MRI positivity (score ≥ 2), and TOF MR angiography positivity. Data for each patient (1 to 12) is shown for each map in rows and data for each artery (Right and Left) are shown in columns. Vessel wall thickening and FDG-uptake were most seen in the vertebral, maxillary, and occipital arteries. Stenosis was most observed in the maxillary arteries. TOF MRA, T1-weighed contrast-enhanced MRI, and FDG-PET/CT scores agreed in 60% of all arteries, however just 10% of all positive arteries were positive on all three modalities. Agreement was highest (74%) between FDG-PET/CT and T1WCE MRI.
Conclusion: The study found an overlap in morphologic and metabolic features in affected arteries in patients with C-GCA using hybrid FDG-PET/MR. However, it also revealed that these features can occur independently of each other. This suggests that the use of hybrid morphologic and metabolic imaging may provide complementary information, potentially increasing diagnostic accuracy for C-GCA.

POS0701 LONG-TERM EFFICACY OF TOCILIZUMAB MONOTHERAPY AFTER ULTRA-SHORT GLUCOCORTICOID ADMINISTRATION TO TREAT GIANT CELL ARTERITIS – TWO YEAR FOLLOW-UP OF THE GUSTO TRIAL

Keywords: Vasculitis, Clinical trials

L. Christ[1], L. Seitz[1], G. Scholz[1], L. Bütikofer[2], F. Kollert[1], B. Maurer[1], S. Reichenbach[1,3], P. Villiger[4]. [1]*Inselspital, Bern University Hospital, Department of Rheumatology and Immunology, Bern, Switzerland*; [2]*CTU Bern, University of Bern, Bern, Switzerland*; [3]*University of Bern, Institute for Social and Preventive Medicine, Bern, Switzerland*; [4]*Medical Center Monbijou, Rheumatology and Immunology, Bern, Switzerland*

Background: Two randomised controlled trials (RCT) [1, 2] demonstrated a glucocorticoid (GC)-sparing effect of tocilizumab (TCZ) of at least 50% in the treatment of giant cell arteritis (GCA). The GUSTO (GCA treatment with Ultra-Short glucocorticoids and TOcilizumab) trial was set up to evaluate the efficacy and safety of TCZ-monotherapy after a 3-day GC-pulse in new-onset GCA.
Objectives: The objectives of this analysis were to explore the maintenance of remission 2 years after discontinuation of TCZ treatment (drug-free remission) and the effectiveness or retreatment with TCZ after relapse. Data up to week 156 are presented.
Methods: Eighteen patients with newly diagnosed GCA were enrolled in this investigator-initiated, single-arm, single-center, open-label clinical trial [3]. Patients received 500 mg methylprednisolone intravenously for 3 consecutive days. Thereafter, GC treatment was discontinued and TCZ (8 mg/kg body-weight) was administered intravenously, followed by weekly subcutaneous TCZ injections (162 mg) from day 10 until week 52. Patients in clinical remission stopped TCZ at week 52 and entered the follow-up study. Maintenance of efficacy at week 156 included the proportion of patients with complete relapse-free remission of disease at week 156, and time to first relapse after week 52.
Results: At baseline there were 12/18 female patients, and the median age was 72 (range 67-75) years. Overall, 15/18 complained of cranial symptoms (10/18 jaw claudication, 6/18 visual symptoms), 10/18 suffered from polymyalgia rheumatica symptoms, 16/18 had positive ultrasound findings of the cranial arteries, and in 13/18 temporal arterial biopsies showed a characteristic histopathology. At week 52, 13/18 patients were in relapse-free remission and entered the follow-up study. One out of 13 patients presented with a minor relapse at week 72. Remission was achieved after restart of TCZ-monotherapy. At week 156, 12/18 patients were in relapse-free remission.
Conclusion: After a 3-days pulse of methylprednisolone followed by 52 weeks of TCZ monotherapy, drug-free remission was maintained until week 156 in all but one patient entering long-term extension (12/13, 92%). This relapse rate is substantially lower than reported in the RCTs [1,2]. It may – at least in part – be explained by the patient characteristics (exclusively new diagnoses), and presumably by the intensive initial treatment consisting of a 3-day GC pulse, immediately followed by TCZ. As a proof-of-concept study, the protocol is not intended to be used in everyday clinical practice.

POS0702 TREATMENT EFFICACY AND SAFETY OF ADALIMUMAB VERSUS TOCILIZUMAB COMBINED WITH METHOTREXATE AND GLUCOCORTICOIDS IN PATIENTS WITH ACTIVE AND SEVERE TAKAYASU ARTERITIS: A RANDOMIZED, OPEN-LABEL, HEAD-TO-HEAD STUDY

Keywords: Clinical trials, Vasculitis, Treat to target

X. Kong[1], J. Wang[1], L. MA[1], H. Chen[1], Z. Ding[1], X. Jin[2], L. Jiang[1]. [1]*Fudan University, Zhongshan Hospital, Department of Rheumatology, Shanghai, China*; [2]*Fudan University, Zhongshan hospital, Department of Cardiology, Shanghai, China*

Background: Takayasu's arteritis (TAK) is a rare large-vessel vasculitis characterized by granulomatous inflammation in the aorta and its major branches.[1] The affected arteries may become narrowed or even occluded, resulting in ischemia of the corresponding tissue or organs and threatening patient survival.[2] However, effective treatment strategies for TAK are lacking. Although TCZ and TNF-α inhibitors are commonly applied in the treatment of refractory TAK, a formal head-to-head study evaluating their efficacy is lacking. According to retrospective studies,[3, 4] the complete response rate associated with TCZ was slightly better than those associated with TNF-α inhibitors at 6 months (70% vs. 66%; 70% vs. 61%). However, another study indicated a better 3-month complete remission rate associated with TNF-α inhibitors than with TCZ (30% vs. 18%) [5]. Thus, the data are inconclusive regarding which medication is more effective. Furthermore, the 6-month nonresponse and 12-month relapse rates associated with these treatments were approximately 25% and 19%, respectively.[3] Thus, given the inconsistent results obtained thus far in this context, we conducted this randomized, open-label, head-to-head study to compare the efficacy and safety of the TNF-α antibody adalimumab (ADA) and TCZ combined with GCs and MTX in patients with active and severe TAK.
Objectives: This study was aimed at investigating the efficacy and safety of adalimumab (ADA) and tocilizumab (TCZ) in patients with active and severe Takayasu arteritis (TAK) concomitantly treated with glucocorticoids (GCs) and methotrexate (MTX).

Methods: Forty patients were randomized into ADA and TCZ groups (n = 21 and 19, respectively). They were treated with ADA or TCZ combined with GCs and MTX, respectively. The planned follow-up duration was 12 months. The primary end point was the efficacy rate (ER) at 6 months.
Results: The intention to treat (ITT) population included 21 and 19 patients from the ADA and TCZ groups, respectively. In this population, the ERs at 6 months were higher in the ADA group (85.71% *vs.* 52.63%, P = 0.02). Similar tendencies were also noted in per-protocol set (89.47% vs. 62.50%, P = 0.06). At the 6-month time point, the percentages of patients receiving a GC dose of ≤10 mg/day and the cumulative GC dose were similar between the ADA and TCZ groups (47.37% *vs.* 43.75%, P = 0.83; 4200 mg *vs*. 4100 mg, P = 0.15, respectively). Imaging improvement or stabilization was observed in most patients in both groups (ADA *vs.* TCZ: 19/19 *vs.* 15/16, P = 0.27). Adverse event incidence was comparable between the two groups (ADA *vs.* TCZ: 38.10% *vs.* 47.37%, P = 0.55).
Conclusion: ADA probably was more effective than TCZ in combined treatment with GCs and MTX among patients with active and severe TAK.

POS0703 RENAL ARTERY STENOSIS IS NOT ASSOCIATED WITH WORSE SURVIVAL IN TAKAYASU ARTERITIS – DATA FROM A SINGLE-CENTER RETROSPECTIVE COHORT OF 195 PATIENTS

Keywords: Epidemiology, Registries, Vasculitis

D. P. Misra[1], P. Mishra[2], K. Singh[1], U. Rathore[1], D. Thakare[1], N. Jain[3], M. Ora[4], M. Behera[5], S. Gamhbir[4], D. Bhadauria[5], S. Kumar[6], V. Agarwal[1]. [1]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India*; [2]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Biostatistics and Health Informatics, Lucknow, India*; [3]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Radiodiagnosis, Lucknow, India*; [4]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Nuclear Medicine, Lucknow, India*; [5]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Nephrology, Lucknow, India*; [6]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Cardiology, Lucknow, India*

Background: Renal artery stenosis (RAS) is more frequent in Asian patients with Takayasu arteritis (TAK). Few studies have assessed the impact of RAS on the presentation and prognosis of TAK using adjusted analysis.
Objectives: To compare the presentation and prognosis between TAK with or without RAS.
Methods: We compared the clinical presentation and vascular involvement (including angiographic subtypes by Hata's classification) between patients with TAK with or without RAS, with bilateral versus unilateral RAS, and with bilateral RAS versus those without RAS using multivariable-adjusted odds ratios (aOR) with 95% confidence intervals (95%CI) derived after logistic regression. We compared survival between these groups using hazard ratios (HR) with 95%CI adjusted for gender, age at disease onset, delay to diagnosis, baseline disease activity, and inter-group differences. The institute ethics committee provided a waiver of consent for retrospective data retrieval. The institute ethics committee provided a waiver of consent for retrospective data retrieval.
Results: Out of 195 TAK with imaging data available, 106 had RAS [58 bilateral, 48 unilateral; mean(±SD) follow-up 41.50(±43.35) months]. TAK with RAS (mean age 22.99 years) or bilateral RAS (mean age 22.83 years) were younger than without RAS (mean age 28.00 years). TAK with RAS had more hypertension (aOR 4.46, 95%CI 1.81 – 10.99), lower limb claudication (aOR 2.72, 95%CI 1.08 – 6.88), and less frequent upper limb claudication (aOR 0.43, 95%CI 0.19-0.99) and syncope or dizziness (aOR 0.35, 95%CI 0.14 – 0.85) than TAK without RAS. TAK with bilateral RAS had more frequent hypertension (aOR 11.83, 95%CI 1.38-101.16), blurring of vision (aOR 5.97, 95%CI 1.02 – 34.83), and less frequent constitutional symptoms (aOR 0.18, 95%CI 0.06 – 0.51) than those with unilateral RAS. TAK with bilateral RAS had more frequent hypertension (aOR 8.73, 95%CI 1.90-40.06), vascular bruits (aOR 2.94, 95%CI 1.03 – 8.34), and heart failure (aOR 4.16, 95%CI 1.00 – 17.32), and less frequent constitutional symptoms (aOR 0.23, 95%CI 0.09 – 0.62), pulse loss (aOR 0.29, 95%CI 0.11 – 0.77), and syncope or dizziness (aOR 0.21, 95%CI 0.06-0.73) than those without RAS. Hata's type IV and type V were more frequent in TAK with versus without RAS (OR 4.01 and 13.40, respectively), and in those with bilateral RAS versus no RAS (OR 5.97 and 10.94, respectively). Adjusted survival was similar between TAK with or without RAS, with unilateral or bilateral RAS, or with bilateral RAS vs those without RAS (Table 1).
Conclusion: RAS is associated with specific clinical and angiographic features but not with a greater risk of mortality in TAK.

Table 1. Risk estimates for the association of RAS with mortality in TAK

Exposure	Cox regression models*	Hazard ratio (95%CI)
With (n=101) vs without RAS (n=86)	Unadjusted	3.55(0.75–16.83)

POS0704 RISK FACTORS OF DEPRESSION AND ANXIETY IN PATIENTS WITH TAKAYASU ARTERITIS

Keywords: Vasculitis, Mental health, Cytokines and chemokines

Z. Yaxin[1,1,1,1], L. Pan[1,1,1]. [1]Capital Medical University, Rheumatology and Immunology, Beijing Anzhen Hospital, Beijing, China

Background: Takayasu arteritis (TA) is associated with an increased risk of developing complicated comorbidities, which can bring both psychological and physical burdens to the patients. Most cases are young female patients with an onset age of 10 to 40 years [1]. Psychological disorders have long been recognized as important comorbidities of immune diseases. In the case of rheumatoid progress, comorbid depression and anxiety would increase the mortality and heighten the medication, prognostic and economic burden. In patients with TA, there haven't been identified whether comorbid depression and anxiety may lead to an inaccurate evaluation of disease status and lower quality of life [2-5]. The emotional state generated by the TA should not be ignored. The primary aim of this study was to investigate the risk factors of comorbid depression and anxiety in patients with TA.
Objectives: The research is to investigate risk factors of comorbid depression and anxiety in patients with Takayasu arteritis.
Methods: In this observational, longitudianl cohort study, 86 TAK cases were respectively divided into two groups with or without depression and anxiety to identify the risk factors. The Zung Self-Rating Depression and Anxiety Scale (SDS/SAS) are widely applied in many medical researches related to mental health, which displays convincing results and a remarkable degree of consensus on the diagnosis of mood disorders.
Results: Individual patient data were available from 86 subjects, of whom 23 had depression, and 15 had anxiety. Depression was independently associated with Carotidynia, elevated IL-6, and decreased Hb (OR [95%CI] 7.116 [11.508–33.586], p=0.0010; OR [95%CI] 6.669 [1.746–25.470], p=0.005; OR [95%CI] 3.882[1.214–12.420], p=0.020) respectively. We used correlation analysis to find out the association between the level of IL-6 with SDS, SAS scores (r=0.337, p=0.002; r=0.280, p=0.010). The levels of Completement 3, NIH, ITAS.A and ITAS2010 were similarly correlated with SDS score (r=0.232, p=0.032; r=0.280, p=0.009; r=0.332, p=0.002; r=0.323, p=0.002), which wasn't seemed in SAS score.

Conclusion: Clinicians should be alert to risk factors for predisposing patients to mood disorders. TA patients comorbid depression and anxiety should be given more positive treatment to essentially control the disease to improve their emotional state and quality of life.

PEDIATRIC-ONSET TAKAYASU ARTERITIS ASSOCIATES WITH WORSE SURVIVAL THAN ADULT-ONSET TAKAYASU ARTERITIS – DATA FROM A SINGLE-CENTER MATCHED RETROSPECTIVE COHORT STUDY OF 191 PATIENTS

Keywords: Vasculitis, Epidemiology, Registries

D. P. Misra[1], D. Thakare[1], P. Mishra[2], U. Rathore[1], K. Singh[1], M. Behera[3], N. Jain[4], M. Ora[5], D. Bhadauria[3], S. Gamhbir[5], S. Kumar[6], V. Agarwal[1]. [1]*SGPGIMS, Clinical Immunology and Rheumatology, Lucknow, India*; [2]*SGPGIMS, Biostatistics and Health Informatics, Lucknow, India*; [3]*SGPGIMS, Nephrology, Lucknow, India*; [4]*SGPGIMS, Radiodiagnosis, Lucknow, India*; [5]*SGPGIMS, Nuclear Medicine, Lucknow, India*; [6]*SGPGIMS, Cardiology, Lucknow, India*

Background: A subset of Takayasu arteritis (TAK) begins in the pediatric age group (≤18 years). Differences in prognosis between pediatric-onset and adult-onset TAK are unclear.

Objectives: To compare the presentation and prognosis between pediatric-onset and adult-onset TAK.

Methods: The clinical presentation, angiographic features, treatment patterns, disease activity on follow-up, and survival were compared between pediatric-onset and adult-onset TAK. Categorical variables were compared using odds ratios (OR between pediatric-onset and adult-onset TAK, with 95% confidence intervals). Survival for pediatric-onset and adult-onset TAK were presented using Kaplan-Meier plots and compared using log-rank test. Hazards ratios (HR, with 95% confidence intervals) were calculated, both crude and adjusted for prognostic factors. Propensity-score matched analyses adjusted for prognostic factors were conducted to assess adjusted differences in survival between pediatric-onset and adult-onset TAK. A previous meta-analysis of the risk of mortality with pediatric-onset vs adult-onset TAK [1] was updated with the findings from this study. The study was approved by the institutional ethics committee., which waived the requirement for informed consent in view of the retrospective review of chart records.

Results: Heart failure [odds ratio (OR) for pediatric-onset vs adult-onset TAK 2.76, 95%CI 1.12–6.80] and chest pain (OR 3.03, 95%CI 1.11-8.34) were more common in pediatric-onset TAK, and stroke or transient ischemic attack was more frequent in adult-onset TAK (OR 0.31, 95%CI 0.10-0.93). Hata's angiographic type V (OR 1.95, 95%CI 1.00-3.78) was commoner in pediatric-onset TAK, as opposed to Hata's type I in adult-onset TAK (OR 0.18, 95%CI 0.04-0.79). Disease activity at baseline, 6, 12, and 24 months, the use of glucocorticoids and disease-modifying antirheumatic drugs (DMARDs) were similar between pediatric-onset and adult-onset TAK. The unadjusted hazard ratio for mortality with pediatric-onset versus adult-onset TAK was 6.13 (95%CI 1.51-24.91), and after adjustment for prognostic covariates (gender, delay to diagnosis, baseline disease activity, number of conventional and biologic/targeted synthetic DMARDs used), was 4.97 (95%CI 1.20-20.58) (Table 1). Survival was worse for pediatric-onset than adult-onset TAK on unadjusted analyses (Figure 1) and after propensity score matching for these covariates (54 pairs, log rank p value 0.026). Risk ratio for mortality with pediatric-onset vs adult-onset TAK across studies was 2.27 (95%CI 1.05-4.85) after updating a meta-analysis of four observational studies [1] by including the present study.

Conclusion: Pediatric-onset TAK associates with greater mortality than adult-onset TAK. Greater vigilance is required while managing pediatric-onset TAK.

INCREASED ARTERIAL STIFFNESS AND ACCELERATED ATHEROSCLEROSIS IN TAKAYASU ARTERITIS

Keywords: Vasculitis, Cardiovascular disease

A. Kalyoncu Ucar[1], A. Ozdede[2], Y. Kayadibi[1], I. Adaletli[1], M. Melikoglu[2], I. Fresko[2], E. Seyahi[2]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Radiology, Istanbul, Turkey*; [2]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: Cardiovascular diseases are the leading causes of morbidity and mortality in patients with Takayasu arteritis (TAK). Arterial stiffness and accelerated atherosclerosis contribute to the increased risk for cardiovascular morbidities in several inflammatory diseases. Although morphological changes have been well recognized, studies related with functional characteristics in TAK have been few. Shear wave elastography (SWE) is a non-invasive method of ultrasonography (US) to evaluate elasticity of biological tissues, by real time tracking and capturing the pace of the shear waves induced in response to the primary US waves.

Objectives: To evaluate arterial stiffness, as well as intima media thickness (IMT) and atherosclerotic plaques in the carotid arteries using US and SWE among patients with TAK and suitable controls.

ß: unstandardized beta coefficient, CI: confidence intervals for unstandardized beta coefficient, SD: standard deviation, kPa: kilopascal, IMT: intima-media thickness, CCA: common carotid artery, SWE: shear wave elastography, TAK: Takayasu arteritis, SLE: systemic lupus erythematosus, HC: healthy controls. *adjusted for cardiovascular risk factors

Methods: Consecutive patients with TAK (50, 40F/5M; mean age: 39.8±8.2 years) and systemic lupus erythematosus (SLE) (43, 38F/5M; 38.0±7.9 years) attending a single tertiary university hospital were studied in addition to apparently healthy hospital workers (57, 50F/7M: 39.5±7.1 years). Carotid artery IMT and SWE values were assessed using carotid artery B-mode US and SWE. Atherosclerotic plaques were noted. Disease duration, clinical characteristics and information related to immunosuppressive drug use were obtained from the patient's charts. Cardiovascular risk factors were determined.

Results: Study groups were balanced according to the most of the variables including mean age, gender ratio, BMI, past and current smoking history, post-menopausal status, the frequency of diabetes mellitus, the mean total, LDL, and HDL cholesterol levels and the median hsCRP levels (evaluated only in TAK and SLE). The mean systolic and diastolic blood pressure levels were significantly higher in both TAK and SLE patients compared to healthy controls (HC's). As shown in Table 1, the mean IMT in the right and left carotid arteries was significantly higher among patients with TAK, when compared to SLE and HCs. On the other hand, the mean SWE in the carotid artery was significantly increased among both TAK and SLE patients when compared to HCs, whereas patients with TAK had the highest values. After adjusting for cardiovascular risk factors, the significances remained robust. Only patients with TAK were found to have significantly increased frequency of carotid artery plaques (TAK: 22.0%, SLE: 4.7%, HC's: 5.3%, p=0.006). IMT and diastolic blood pressure levels were found to be associated independently with SWE.

Conclusion: Our study indicates that among patients with TAK, both atherosclerosis and arterial stiffness are increased and appear to be closely related. Arterial stiffness along with severe hypertension and accelerated atherosclerosis could contribute to the increased risk for cardiovascular morbidities in TAK. Furthermore, SWE could be an indicator of cardiovascular risk that can be surveyed in TAK.

POS0707 EFFECTIVENESS AND SAFETY OF INTRAVENOUS VERSUS SUBCUTANEOUS TOCILIZUMAB IN TAKAYASU ARTERITIS: MULTICENTER RETROSPECTIVE STUDY

Keywords: Rare/orphan diseases, Vasculitis, Remission

A. Mekinian[1], D. Saadoun[2]. [1]*Sorbonne Université, Internal Medicine, Paris, France*; [2]*Sorbonne university, Internal Medicine, Paris, France*

Background: Recently, the effectiveness of biological therapies such as inhibitors of tumor necrosis factor-α (TNF-α) and IL-6 receptor (tocilizumab) in TAK patients who were refractory to other immunosuppressive therapies has been reported in several studies. We have recently reported a French nationwide registry that showed quite similar effectiveness of TNF-α antagonists and tocilizumab, with acceptable safety profile and significant steroid sparing effect. A recent phase 3, randomized, double blind, placebo-controlled trial of tocilizumab *versus* placebo in TAK failed to reach its primary intention-to-treat analysis, but tocilizumab was favored in a secondary per-protocol analysis regarding TAK time to relapse. Besides its role on refractory patients, intravenous tocilizumab was also evaluated in treatment-naïve TAK patients in the French TOCITAKA prospective multicenter open-labeled trial, showing 6-month remission rates of 80%, of whom 54% were in glucocorticoid-free remission at 6 months.

Objectives: In this large multicenter study, we compared the effectiveness and safety of tocilizumab IV *versus* SC in 109 TAK patients.

Methods: We conducted a retrospective multicenter study in referral centers from France, Italy, Spain, Armenia, Israel, Japan, Tunisia, and Russia regarding biological-targeted therapies in TAK, since January 2017 to September 2019.

Results: A total of 109 TAK patients received at least 3 months tocilizumab therapy and were included in this study. Among them, 91 and 18 patients received IV and SC tocilizumab, respectively. A complete response (NIH<2 with less than 7.5 mg/day of prednisone) at 6 months was evidenced in 69% of TAK patients, of whom 57 (70%) and 11 (69%) patients were on IV and SC tocilizumab, respectively (p=0.95). The factors associated with complete response to tocilizumab at 6 months in multivariate analysis, only age < 30 years (OR = 2.85, 95% CI 1.14; 7.12; p=0.027) and time between TAK diagnosis and tocilizumab initiation (OR = 1.18, 95% CI 1.02; 1.36; p=0.034). During the median follow-up of 30.1 months [0.4; 105.8] and 10.8 [0.1; 46.4] (p<0.0001) in patients who received tocilizumab in IV and SC forms, respectively, the risk of relapse was significantly higher in TAK patients on SC tocilizumab (HR = 2.55, 95%CI 1.08;6.02; p=0.033). The overall cumulative incidence of relapse at 12 months in TAK patients was at 13.7% (95%CI 7.6; 21.5), with 10.3% (95%CI 4.8;18.4) for those on IV tocilizumab *versus* 30.9% (95%CI 10.5;54.2) for patients receiving SC tocilizumab. Adverse events occurred in 14 (15%) patients on IV route and in 2 (11%) on SC tocilizumab.

Conclusion: In this study, we confirm that tocilizumab is effective in TAK, with complete remission being achieving by 70% of DMARDs-refractory TAK patients at 6 months.

POS0708 VALIDATION OF THE REVISED 2022 AMERICAN COLLEGE OF RHEUMATOLOGY/ EULAR CLASSIFICATION CRITERIA FOR TAKAYASU ARTERITIS

Keywords: Diagnostic tests, Vasculitis, Validation

A. Tomelleri[1], R. Padoan[2], C. Kavadichanda[3], A. Jose[3], K. Singh[4], L. Iorio[2], U. Rathore[4], E. Rinaldi[1], E. Baldissera[1], V. Agarwal[4], L. Dagna[1], C. Campochiaro[1], D. P. Misra[4]. [1]*San Raffaele Scientific Institute, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnIRAR), Milan, Italy*; [2]*University of Padova, Division of Rheumatology, Department of Medicine DIMED, Padova, Italy*; [3]*Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Clinical Immunology, Puducherry, India*; [4]*Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Clinical Immunology and Rheumatology, Lucknow, India*

Background: The 2022 American College of Rheumatology (ACR)/European Alliance of Associations for Rheumatology (EULAR) classification criteria for Takayasu arteritis (TAK) were recently published [1].

Objectives: To validate and evaluate the 2022 ACR/EULAR TAK classification criteria in the light of the 1990 ACR TAK classification criteria [2].

Methods: Clinical data of TAK patients from four referral centers (two from Italy and two from India) were reviewed to assess the fulfillment of 2022 ACR/EULAR and 1990 ACR TAK criteria. Control subjects included large-vessel giant cell arteritis (LV-GCA), large vessel vasculitis (LVV) other than TAK or GCA, or non-inflammatory arterial disorders. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), likelihood ratio of a positive test (LR+), likelihood ratio of a negative test (LR-), area under the receiver operating characteristics curve (AUC) at the cut-offs of ≥3 points for 1990 ACR criteria and ≥5 points for 2022 ACR/EULAR criteria were calculated. AUC was also calculated using the actual scores for the 2022 ACR/EULAR criteria. Secondary analyses

were conducted on the basis of sex (male/female), using only LV-GCA as controls, using subjects ≤60 years, and stratified on age (<40, 40-60, >60 years).
Results: 504 TAK [404 females, mean (SD) age at diagnosis 31.7 (12.6) years] and 222 controls [144 LV-GCA, 151 females, mean (SD) age at diagnosis 61.9 (15.4) years] were identified. The 2022 ACR/EULAR criteria had better sensitivity and NPV but had poorer specificity, PPV, LR+, LR-, and AUC at predetermined cut-offs than the 1990 ACR criteria (Table 1). Similar performance of 2022 ACR/EULAR criteria was observed with only LV-GCA as controls (sensitivity 95.83%, specificity 60.42%, AUC 0.781) or in subjects ≤60 years old (sensitivity 95.81%, specificity 61.90%, AUC 0.789). The 2022 ACR/EULAR criteria had a greater specificity (76.06% vs 57.62%) and AUC (0.845 vs 0.771) with similar sensitivity (93% vs 96.53%) in males than in females. Stratified for age [<40 years, n=399, 374 TAK, 25 controls; 40-60 years, n=186, 127 TAK, 59 controls; >60 years, n=141, 3 TAK, 138 controls], sensitivity remained similar (96.26%, 94.49%, 100%, respectively), whereas, specificity was higher for older age groups (52%, 66.10%, 64.49%, respectively). Cut-offs of ≥6 (sensitivity 91.87%, specificity 82.88%) and ≥7 (sensitivity 86.71%, specificity 86.49%) greatly improved balance between sensitivity and specificity (Figure 1).
Conclusion: In this first validation study, the 2022 ACR/EULAR TAK criteria had poorer specificity in real-life than in the development cohort. Higher cut-offs (6 or 7) might improve the performance of these criteria. Higher PPV but lower NPV in the Indian than in the Italian cohort might reflect the different performance of the criteria in different ethnic groups.

COMPARATIVE EFFICACY OF SECUKINUMAB VERSUS TUMOR NECROSIS FACTOR INHIBITORS FOR THE TREATMENT OF TAKAYASU'S ARTERITIS

Keywords: Vasculitis

X. Tian[1,2], M. LI[3], N. Jiang[3], Y. Zhou[3], J. LI[3], P. A. Merkel[4], X. Zeng[3]. [1]*Peking Union Medical College Hospital, Rheumatology, Beijing, China*; [2]*Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College; National Clinical Research Center for Dermatologic and Immunologic Diseases (NCRC-DID), Rheumatology and Clinical Immunnology, Beijing, China*; [3]*Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College; National Clinical Research Center for Dermatologic and Immunologic Diseases (NCRC-DID), Department of Rheumatology and Clinical Immunology, Beijing, China*; [4]*University of Pennsylvania, Division of Rheumatology, Department of Medicine, Division of Epidemiology, Department of Biostatistics, Epidemiology, and Informatics, Philadelphia, United States of America*

Background: Takayasu's arteritis (TAK) is a large-vessel vasculitis that mainly involves the aorta and its primary branches. Glucocorticoids (GCs) are the mainstay of treatment of TAK, especially for the induction of remission. However, the majority of patients experience relapses when the dose of GCs is reduced. Many patients fail to respond to synthetic conventional immunosuppressive drugs. IL-6 and TNF-α have been shown to be involved in the pathogenesis of TAK. Biologic drugs that target IL-6 or TNF-α (TNFis) have been reported to be effective and are recommended for the treatment of TAK refractory to low-dose GC combined with conventional treatment. Recently, Th-17 cells and its related cytokines IL-17A, IL-21, and IL-23 have also been identified as involved in the pathogenesis of TAK, suggesting that targeting IL-17A might be an effective treatment for this disease.
Objectives: This study aimed to investigate the efficacy of secukinumab, an anti-IL-17A monoclonal antibody, compared to treatment with TNFis for the induction of remission of patients with a relapse of TAK.
Methods: This was a prospective, single center, open-label cohort study. Patients with active TAK who failed to respond to treatment with glucocorticoids combined with 2 immunosuppressive agents were treated with either secukinumab or TNFi as an add-on therapy without increase of the dosage of GCs. Complete response was defined as full resolution of signs and symptoms of active disease, normal values of inflammatory markers, no progression on imaging of involved arteries, and dose of glucocorticoid <15mg/d. Partial response was defined as the same as complete response except ESR <40mm/hour and CRP <20mg/L.
Results: Nineteen patients in the secukinumab group and 34 patients in the TNFi group were enrolled. The demographic data and inflammatory markers of the two groups were comparable at baseline. The baseline dose of GC (prednisone) was ≤ 15mg/day in all patients in both treatment groups. The combined complete and partial responses at 3 months for patients treated with secukinumab and TNFi were 31.6% and 58.8% (P =0.506) respectively, and at 6 months were 52.6% and 64.7% (P= 0.389), respectively. Similar responses to both secukinumab and TNFi we also seen for time to initiation of GCs and time to achieving a dose of prednisone ≤ 5mg/day (Figure 1). The ESR, serum CRP, and IL-6 levels were significantly reduced compared with the baseline after 1, 3, and 6 months of treatment in both secukinumab and TNFis treatment groups. In the secukinumab treatment group 6 of 19 (31.6%) patients had their GC dosage tapered and 2 patients reduced the dose of conventional immunosuppressive agents at 6 months. In the TNFi treatment group 18 of 34 (52.9%) patients had their GC dosage tapered and 4 patients reduced the dose of conventional immunosuppressive agents at 6 months. There was no significant difference of the median dose of GC in either treatment group. No arterial structural changes were observed in patients in either the secukinumab or TNFi treatment group at 6 months. Two patients had infectious events in the secukinumab treatment group, one lead to discontinuation of the medication. Two patients in the TNFi treatment group had events leading to withdrawal from the study: one with a severe infection and one with a severe rash.
Conclusion: These results suggest that secukinumab and TNFi are effective treatments for patients with TAK who fail to respond to oral GCs and conventional immunosuppressive agents, with similar response rates at 3 and 6 months.

METABOLIC INFLAMMATORY VOLUME AND TOTAL INFLAMMATORY GLYCOLYSIS: NOVEL PARAMETERS TO EVALUATE DISEASE ACTIVITY ON PET-CT IN TAKAYASU ARTERITIS

Keywords: Vasculitis, Imaging

M. Ora[1], D. P. Misra[2], C. Kavadichanda[3], K. Singh[4], U. Rathore[4], N. Jain[5], V. Agarwal[4], S. Gamhbir[6]. *[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Nuclear Medicine, Lucknow, India*; *[2]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Clinical Immunology and Rheumatology, Lucknow, India*; *[3]Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Clinical Immunology, Puducherry, India*; *[4]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Clinical Immunology and Rheumatology, Lucknow, India*; *[5]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Radiology, Lucknow, India*; *[6]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Nuclear Medicine, Lucknow, India*

Background: 18-fluorodeoxyglucose (FDG) Positron emission tomography-computed tomography (PET-CT) has only moderate concordance with C-reactive protein (CRP) in Takayasu arteritis (TAK).
Objectives: We propose and evaluate the diagnostic accuracy of two new PET-CT parameters, metabolic inflammatory volume (MIV) and total inflammatory glycolysis (TIG) to quantify arterial FDG uptake for active TAK.
Methods: Images of PET-CT of TAK were reviewed to calculate mean standardized uptake value (SUV_{mean}) and maximum standardized uptake value (SUV_{max}), target-to-blood pool ratio (TBR), target-to-liver ratio (TLR), and PET Vasculitis Activity Score (PETVAS) [1]. ESR, CRP, disease activity [using physician global assessment (PGA, active/inactive), Indian TAK Clinical Activity Score 2010 (ITAS2010), ITAS2010 with ESR (ITAS-A-ESR) or CRP (ITAS-A-CRP), Disease Extent Index in TAK (DEI.TAK)] were extracted from clinic files. Regions of interest (ROI) were drawn to calculate MIV in areas of FDG uptake ≥1.5-times SUV_{max} on syngo.via. MIV was semiautomatically calculated after excluding areas of physiological tracer uptake. TIG was calculated by multiplying MIV with SUV_{mean}. MIV and TIG for all areas of arterial FDG uptake were added. Area under the receiver operating characteristics (ROC) curves (AUC, with 95%CI) to predict active disease using PGA with absolute values of SUV_{max}, SUV_{mean}, TBR, TLR, MIV, TIG, PETVAS, CRP, ESR, ITAS2010, ITAS-A-ESR, ITAS-A-CRP, and DEITAK were calculated. Dichotomized cut-offs for active disease [PETVAS ≥5.5 [2],≥10,≥15,or≥20 [1]; CRP≥6 mg/L; ESR≥40 mm/hr; for the remaining parameters, cut-offs correctly classifying disease activity in most patients) were used to calculate sensitivity, specificity, likelihood ratio of a positive test (LR+), likelihood ratio of a negative test (LR-), positive predictive value (PPV), negative predictive value (NPV), and AUC (with 95%CI).Concordance between CRP and PET-CT parameters were assessing kappa statistic. Analyses were performed using STATA 16.1 I/C.
Results: PET-CT of 30 TAK [mean (SD) age 29.9 (11.5) years, 22 females, 29 immunosuppressive-naive) were reviewed. AUC using absolute values ranged between 0.852 to 0.926 (Figure 1). Using dichotomized optimal cut-offs for SUV_{max}, SUV_{mean}, TBR, TLR, MIV, and TIG, MIV and TIG performed better than SUV_{max}, SUV_{mean}, TBR, TLR, PETVAS (at cut-offs 5.5, 10, and 15 – none had PETVAS≥20) to detect active TAK (Table 1). Agreement with CRP for active TAK was similar for MIV (70%) and TIG (70%) with SUV_{max}, SUV_{mean}, TBR, and TLR (each 66.67%), and better than PETVAS [≥5.5 (56.67%), ≥10 (50%), ≥15 (40%), ≥40 (40%)].
Conclusion: Novel PET-CT parameters, MIV and TIG, had comparable performance to established PET-CT parameters and better performance than PETVAS for active TAK, and require further exploration in LVV.

Background: Disease activity indices that accurately assess inflammation in Takayasu's arteritis (TAK) are needed [1]. While clinical assessment is often considered the gold standard, determining if a symptom represents active vasculitis or damage can be challenging in TAK. FDG-PET can directly assess vascular inflammation but specificity of imaging findings, especially in absence of corresponding clinical symptoms, is questionable.
Objectives: The aim was to develop an index to assess disease activity in TAK called TAK Integrated Disease Activity Index (TAIDAI).
Methods: Clinical symptoms associated to TAK were derived from a comprehensive literature review [2]. TAIDAI was assessed in an observational cohort with a stepwise approach. All the symptoms present within 7 days of clinical evaluation were recorded by two clinicians, without determining whether the symptom reflected active disease or damage. Physician global assessment (PhGA) (scale 0-10) and certainty of the assessment (certain vs uncertain) were collected for every visit. Each patient underwent FDG-PET 24 hours after the clinical assessment. Active vasculitis, defined as arterial FDG uptake > liver, was recorded in specific arterial

territories and quantified using the PET Vascular Activity Score (PETVAS) [3]. To score TAIDAI, clinical symptoms are paired with specific arterial territories and only scored if there is active vasculitis by FDG-PET in a corresponding arterial territory. Constitutional symptoms are scored only if CRP ≥10mg/L or ESR≥40mm/hour. To determine content validity, correlations were performed between PhGA, patient-reported global assessment (PtGA, 0-10 scale), ESR, CRP, PETVAS, and TAIDAI. To determine criterion validity, performance characteristics of TAIDAI were calculated relative to clinical assessment, restricted to cases of assessment certainty. To determine responsiveness, TAIDAI scores were assessed longitudinally in patients initiated on tumor necrosis factor inhibitors (TNFi) or tocilizumab (TCZ). Complete response was defined as resolution of all symptoms of active vasculitis plus a daily prednisone dose not exceeding >50% of the pre-treatment visit.

Results: 17 clinical symptoms were identified for inclusion in the index. TAIDAI was calculated for 96 patients over 204 visits. Clinically active disease was present in 62 (30%) visits, with uncertainty of assessment in 82 (40%) visits. Inter-rater agreement for PhGA was poor (45%). At baseline, median TAIDAI was 1 (range 0-9), and 48 (50%) patients had a TAIDAI of 0. TAIDAI > 0 defined active disease with 96% sensitivity and 77% specificity compared to clinical assessment. TAIDAI score correlated most strongly with all other assessments (Table 1). Complete response was observed in 15/20 patients treated with TNFi and 8/11 patients treated with TCZ. A TAIDAI score of 0 was achieved by 21/23 (91%) responders, and TAIDAI remained > 0 for 5/8 (63%) treatment failures.

Conclusion: TAIDAI is a novel disease activity index focused on scoring clinical symptoms only when supported by relevant imaging or laboratory data. TAIDAI should be tested in other cohorts and future clinical trials in TAK.

Background: Subclinical giant cell arteritis (GCA) in polymyalgia rheumatica (PMR) is found in the 22.8% of patients on ultrasound examinations. The outcome and the optimal management of subclinical giant cell arteritis (GCA) in patients with polymyalgia rheumatica (PMR) have not been defined yet.

Objectives: The aim of this study was to investigate the short-term outcome of PMR patients with concurrent subclinical GCA that were included in our multicenter project on the prevalence, characteristics and outcome of subclinical GCA (diagnosed by vascular ultrasound) in PMR [1].

Methods: We analyzed follow up data at 3, 6, 12 and 18 months of consecutive PMR patients from 7 European rheumatology centers. All patients fulfilled 2012 EULAR/ACR Provisional Classification Criteria for Polymyalgia Rheumatica and they had not symptom of clinical GCA. Patients were stratified into two groups: pure PMR and PMR with subclinical GCA, and the outcome between these two groups were compared. A relapse was defined as clinical and/or laboratory worsening of the disease after the initial remission and minor and major relapse EULAR definition was used [2].

Results: We included 116 PMR patients (47 with concurrent subclinical GCA and 69 with pure PMR) followed for a median (IQR) of 21 (17; 23) months. We observed relapses in 35/116 patients (30.2%), 27/47 (57.4%) in PMR with subclinical GCA and 8/69 (11.6%) in pure PMR group (p<0.001). All relapses in the pure PMR group were minor relapses, whereas we observed 2 major relapses in the subclinical GCA group. The dose of corticosteroids used at the baseline visit was significantly higher in the GCA subclinical group, but tapering of steroids occurred faster than recommended by clinical guidelines [2]. Prednisone dose was significantly higher in patients with PMR and subclinical GCA than in patients with pure PMR both at baseline and at month 6 (Table 1). In patients with PMR with subclinical GCA mean starting dose of prednisone was 32.2±16.1 mg in those who relapsed and 36.2±12.8 in those who maintained remission (p=0.166); at 3 months, it was 13.2±7.1 and 18.2±7.9, respectively (p<0.05). Three patients in the PMR with subclinical GCA group received biological therapy at diagnosis; one of them had a minor relapse.

Table 1. Patients characteristics

	Pure PMR (n=69)	Subclinical GCA/PMR (n=47)	p
Age years (mean ± SD)	71.2±8.0	74.8±7.6	0.079
Sex (females %)	59%	52%	0.526
Relapses n (%)	8/69 (11.6%)	27/47 (57.4%)	0.001
Minor Relapses n (%)	8/69 (11.6%)	25/47 (53.2%)	0.001
Major Relapses n (%)	0	2/47 (4.2%)	
Steroids basal (mean ± SD))	18.3±9.1	34±14.8	0.001
Steroids month 3 (mean ± SD)	9.9±5.1	14.6±8.3	0.001
Steroids month 6 (mean ± SD)	5.6±2.1	8.8±6.8	0.037
Steroids month 12 (mean ± SD)	1.7±2.1	8.0±14.2	0.062
Steroids month 18 (mean ± SD)	1.1±1.8	3.6±5.6	0.09

Steroids = mg prednisone; SD = standard deviation; n= number of patients

Conclusion: PMR patients with subclinical GCA had a significantly higher number of relapses during the follow-up than pure PMR group. These results suggest that subclinical GCA in PMR should be treated in the same manner as clinically overt GCA.

POS0713 A HISTORY OF POLYMYALGIA RHEUMATICA IS ASSOCIATED WITH ADVANCED SUPRA-AORTIC VASCULAR DAMAGE AT DIAGNOSIS OF GIANT CELL ARTERITIS

Keywords: Vasculitis, Ultrasound

A. Hemmig[1], M. Aschwanden[2], C. Berger[3,4], D. Kyburz[1,4], N. Mensch[1], D. Staub[2], M. Stegert[1], S. Imfeld[2], T. Daikeler[1,3]. *[1]University Hospital Basel, Department of Rheumatology, Basel, Switzerland*; *[2]University Hospital Basel, Department of Angiology, Basel, Switzerland*; *[3]University Hospital Basel, University Center for Immunology, Basel, Switzerland*; *[4]University Hospital Basel, Department of Biomedicine, Basel, Switzerland*

Background: Subclinical giant cell arteritis (GCA) can be found in imaging studies at diagnosis of polymyalgia rheumatica (PMR) in up to 30% of patients [1]. Newly diagnosed GCA patients with a preceding PMR diagnosis may therefore present with more advanced vasculitic vessel alterations than GCA patients without prior PMR.
Objectives: To compare vascular ultrasound (US) findings in newly diagnosed GCA patients with and without a history of PMR.
Methods: Retrospective analysis of patients with GCA diagnosed at the University Hospital Basel between 12/2006 and 05/2021.
Results: 49 of 311 newly diagnosed GCA patients (15.8%) had a preceding diagnosis of PMR a median of 2.5 (IQR 0.6-5.6) years earlier. US revealed vessel wall alterations typical for vasculitis in the supraaortic vessels (carotid, vertebral, subclavian and/or axillary arteries) more often in patients with prior PMR than without PMR (51% vs 25%, p<0.001). Additionally, patients with prior PMR had more often significant vascular stenoses in the supraaortic vessels that were affected by vasculitis (37.5% vs 13.6%, p=0.03). Patients with and without prior PMR did not differ in terms of ischemic complications of stroke or vision loss at GCA diagnosis nor in the number of vascular segments with atherosclerosis (Table 1). In multivariable analysis, prior PMR was significantly associated with vasculitic vessel wall alterations (OR 4.28, 95% CI 1.92–9.85, p<0.001) adjusted for sex, headache, scalp and temporal artery tenderness. Furthermore, prior PMR was associated with vascular stenoses (4.97, 95% CI 1.4–19.12, p=0.015) adjusted for age, sex, arteriosclerosis, cerebrovascular and coronary heart disease.

Table 1. Patient characteristics

Characteristics	All (n=311)	GCA without history of PMR (n=262)	GCA with history of PMR (n=49)	p-value

Stroke	14 (4.5)	10 (3.8)	4 (8.2)	0.249
Permanent vision loss	45 (14.5)	38 (14.5)	7 (14.3)	0.968
Vasculitis in supraaortic vessels**	90 (28.9)	65 (24.8)	25 (51.0)	<0.001
Vascular stenoses (≥50%)†	17/83 (20.5)	8/59 (13.6)	9/24 (37.5)	0.032

n (%); median (interquartile range) for numeric values.CRP: C-reactive protein, ESR: erythrocyte sedimentation rate, GCA: giant cell arteritis, PMR: polymyalgia rheumatica.*Number of vascular segments with atherosclerosis on ultrasound examination in both carotid, vertebral, subclavian and axillary arteries.**Number of patients with vasculitis in the carotid, vertebral, subclavian and/or axillary arteries.†Number of patients with vascular stenoses in the internal carotid, axillary and/or vertebral arteries affected by vasculitis (n=83).

Conclusion: GCA patients with prior PMR had a more extensive vascular involvement on ultrasound than those without prior PMR at diagnosis. Presence of stenoses could not be explained by arteriosclerosis. Undiagnosed subclinical GCA in patients with previous PMR may be a cause of more advanced vascular changes. These data support the need for screening strategies for GCA in patients with PMR.

Background: The treat-to-target (T2T) concept is not yet a recognized treatment approach in giant cell arteritis (GCA) and polymyalgia rheumatica (PMR). Developing such recommendations is an unmet medical need.
Objectives: To determine therapeutic targets and develop treat-to-target (T2T) recommendations in GCA and PMR.
Methods: We conducted a systematic literature review to retrieve data on treatment targets and outcomes in GCA/PMR as well as to identify the evidence for the effectiveness of T2T-based management approaches in these diseases. Based on evidence and expert opinion, the task force [29 participants from 10 countries (physicians, healthcare professional and patient)] developed recommendations, with consensus obtained through voting. The final level of agreement was provided anonymously.
Results: Five overarching principles and six specific recommendations were formulated (Table 1). Key messages are that the management of GCA and PMR should be based on shared decisions between patient and physician, underpinning the need for urgent treatment of GCA to avoid ischemic complications, and that it should aim at maximizing health-related quality of life in both diseases. The treatment targets are the achievement and maintenance of remission (still in need of ultimate validation), as well as prevention of tissue ischemia and vascular damage. Comorbidities should be considered when assessing disease activity and selecting treatment.
Conclusion: These are the first T2T recommendations for GCA and PMR. Treatment targets and strategies to assess, achieve and maintain these targets have been defined. The research agenda highlights the evidence-gaps and needs for future research.

Table 1. Treat-to-Target (T2T) recommendations in GCA and PMR

Overarching principles	LoE	LoA
A. Clinical management of GCA and PMR should be driven by the awareness that they are closely interrelated conditions in a common spectrum of inflammatory disease and can occur separately, simultaneously or in temporal sequence to each other.	n.a.	9.8 96.3% >8
B. GCA is a medical emergency because of the imminent risk of sight loss and other ischemic events and therefore requires immediate treatment; management usually requires multidisciplinary collaboration.	n.a.	9.9 100% >8
C. Patients should be offered access to information about GCA and PMR, including clinical disease features, patient reported outcomes, potential complications, treatment related benefits and risks, as well as relevant comorbidities.	n.a.	9.7 96.3% >8
D. Management of GCA and PMR should be based on shared decision making between the informed patient and the physician.	n.a.	9.8 100% >8
E. Treatment of GCA and PMR should aim at maximizing health-related quality of life through control of symptoms, preventing disease-related damage and minimizing treatment-related adverse consequences, taking relevant comorbidities into account.	n.a.	9.9 100% >8
Recommendations		
1. The treatment target of GCA and PMR should be remission; remission is the absence of clinical symptoms and systemic inflammation.	5	9.6 96.3% >8
2. Treatment of GCA should also aim to prevent tissue ischemia and vascular damage.	5	9.9 100% >8
3. Treatment selection in GCA and PMR should be based on disease severity and activity, presence of relevant comorbidities and potential predictors of outcome; treatment should be modified as needed during follow-up.	5	9.9 100% >8
4. Comorbidities may influence the assessment of the treatment target and should be considered before modifying treatment.	5	9.8 100% >8
5. Once remission is reached, it should be maintained with the minimal effective dose of medication[#]; drug-free remission may be achieved in a proportion of patients[##].	5[#] - 2[##]	9.9 100% >8
6. Disease activity in GCA and PMR should be monitored regularly, as frequently as every 1-4 weeks until remission has been achieved, and at longer monitoring intervals (for example between 3 and 6 months) in patients in stable remission on therapy; monitoring of patients off therapy should be discussed on an individual basis.	5	9.8 100% >8

SUSTAINED REMISSION FROM WEEKS 16 TO 52 AND WEEKS 24 TO 52 IN PATIENTS TREATED WITH SARILUMAB: POST-HOC ANALYSIS OF SAPHYR TRIAL IN PATIENTS WITH POLYMYALGIA RHEUMATICA

Keywords: Clinical trials, Remission

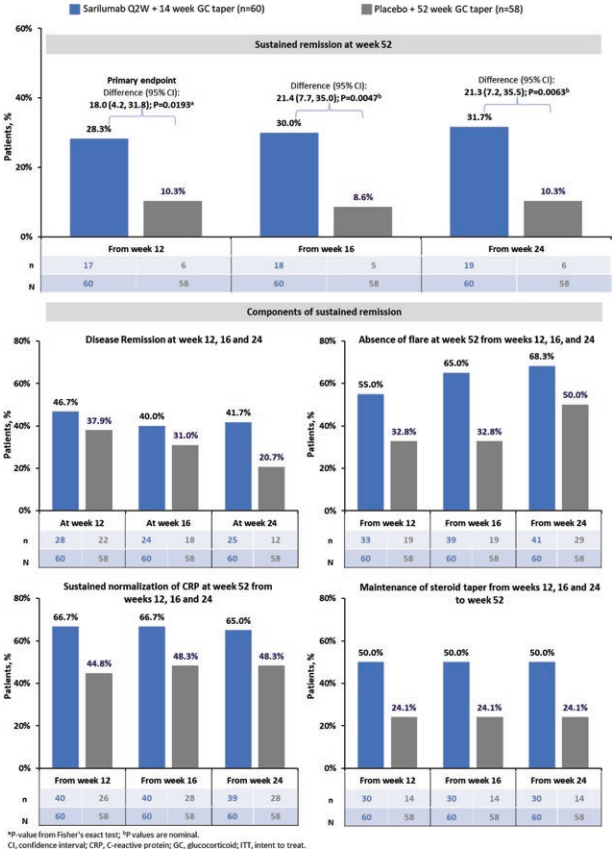
B. Dasgupta[1], A. Praestgaard[2], S. Fiore[2], K. Ford[2], J. Sloane Lazar[2], A. Dua[3], R. Spiera[4]. *[1]Anglia Ruskin University, Rheumatology, East Anglia, United Kingdom*; *[2]Sanofi, Speciality Care, Bridgewater Township, United States of America*; *[3]Northwestern University Feinberg School of Medicine, Vasculitis Center, Division of Rheumatology, Chicago, United States of America*; *[4]Hospital for Special Surgery, Scleroderma, Vasculitis & Myositis Center of Excellence, New York, United States of America*

Background: The SAPHYR study (NCT03600818) in patients with polymyalgia rheumatica (PMR) who were resistant to glucocorticoid (GC) taper met the primary endpoint with a significantly higher proportion of patients in the sarilumab arm versus the comparator arm achieving sustained remission from weeks 12 to 52 (28.3% vs 10.3%; P=0.0193) [1]. Sarilumab, when administered to patients with rheumatoid arthritis at a dose of 200 mg subcutaneously, achieved a steady state within 14 to 16 weeks [2]. Patients treated with sarilumab in SAPHYR may not have reached steady state concentrations by week 12 when disease remission was assessed for the primary endpoint of sustained remission.

Objectives: This post-hoc analysis of the SAPHYR study assessed the proportion of patients achieving sustained remission up to week 52 from week 16 and from week 24.

Methods: Patients were randomized (1:1 ratio) to 52 weeks of treatment with sarilumab 200 mg every 2 weeks (Q2W) + 14 week GC tapered regimen (sarilumab arm) or placebo Q2W + 52 week GC tapered regimen (comparator arm). Here, we assessed the proportion of patients achieving sustained remission and each of the sustained remission components from week 16 and from week 24 to the end of study. Sustained remission was defined as having met all of the following: disease remission at 16 weeks and 24 weeks (no PMR signs and symptoms + CRP normalization [<10 mg/L]); absence of disease flare from weeks 16 to 52 and weeks 24 to 52; sustained reduction of CRP (to <10 mg/L, with no successive elevations to ≥10 mg/L) from weeks 16 to 52 and weeks 24 to 52; and successful adherence to protocol specified GC taper dose from weeks 16 to 52 and weeks 24 to 52. Patients who did not achieve remission, received rescue treatment with open label prednisone (or equivalent), withdrew from the study before week 52, or had missing data that prevented assessment of the primary endpoint were considered as non-responders.

Results: Between Oct 2018 and Jul 2020, 60 patients were randomized to the sarilumab arm and 58 patients to the comparator arm (intent to treat population). A higher proportion of patients in the sarilumab arm, versus the comparator, achieved sustained remission from weeks 16 to 52 (30.0% vs 8.6%; difference [95% CI]: 21.4 [7.7, 35.0]; P=0.0047) and from weeks 24 to 52 (31.7% vs 10.3%; difference [95% CI]: 21.3 [7.2, 35.5]; P=0.0063). This improvement in sustained



remission rate in the sarilumab arm was due to additional responses seen between weeks 12 to 24 **(Figure 1)**. Similarly, all the independent components of the sustained remission were achieved by a higher proportion of patients in the sarilumab arm, versus the comparator arm, during each assessment period. In both the sarilumab arm and the comparator arm, the disease remission rates decreased slightly at weeks 16 and 24 compared with week 12; sarilumab arm 40.0% and 41.7%, respectively vs 46.7% and comparator arm 31.0% and 20.7%, respectively vs 37.9%. Disease remission rates declined due to missing or abnormal CRP, as the proportion of patients with no PMR signs and symptoms increased over time. In the sarilumab arm, the proportion of patients with no disease flare increased from weeks 12 to 52 assessment to weeks 16 to 52 and weeks 24 to 52 assessments, whereas the proportion of patients with sustained CRP normalization or those who adhered to protocol-defined GC taper remained the same during the three assessment periods **(Figure 1).** Safety data were consistent with the know profile of sarilumab and were presented previously [1].

Conclusion: This post-hoc analysis showed that a higher proportion of patients in the sarilumab arm, versus the comparator arm, achieved sustained remission when assessed from week 16 and week 24 up to week 52. Most patients who achieved sustained remission did so rapidly by week 12 with some additional responses seen between week 12 and 24.

DIFFERENCES IN CLINICAL AND ULTRASOUND CHARACTERISTICS OF POLYMYALGIA RHEUMATICA PATIENTS WITH SUBCLINICAL GIANT CELL ARTERITIS COMPARED TO THOSE WITH CLINICAL GIANT CELL ARTERITIS

Keywords: Vasculitis, Ultrasound

S. Cowley[1], C. Kirby[2], P. Harkins[3], R. Mullan4, R. Conway[5], G. Murphy[6], D. Kane4. *[1]Tallaght University Hospital, Department of Rheumatology, Dublin, Ireland*; *[2]Tallaght University Hospital, Department of Rheumatology, Dublin, Ireland*; *[3]St James Hospital, Department of Rheumatology, Dublin, Ireland*; *[2]Tallaght University Hospital, Department of Rheumatology, Dublin, Ireland*; *[5]St James Hospital, Department of Rheumatology, Dublin, Ireland*; *[6]Cork University Hospital, Department of Rheumatology, Cork, Ireland*

Background: It has been reported that more than a quarter of patients with polymyalgia rheumatica (PMR) have subclinical giant cell arteritis (GCA) [1]. Risk markers for subclinical GCA in PMR have not been clearly established and it is unclear if the pattern of vascular involvement on ultrasound differs from that seen in GCA.

Objectives: To identify the characteristics of PMR patients that have subclinical GCA and to compare the ultrasound features of subclinical GCA in PMR to a GCA cohort.

Methods: 58 newly diagnosed PMR patients who met a clinical diagnosis for PMR were examined with ultrasound of their temporal and axillary arteries at time of diagnosis. US of all 6 branches of the superficial temporal arteries and both axillary arteries was performed using a GE P9 device. Sonographic abnormalities considered indicative of vasculitis in the temporal arteries included the halo sign and non-compressible arteries with a thickened intima-media complex. In the axillary arteries, a halo sign, and an intima-media thickness of >1.0mm was considered positive. Clinical and laboratory characteristics were recorded. Halo scores were calculated for positive cases. Ultrasound findings were compared to a cohort of 57 GCA patients.

Results: Our cohort consisted of 58 patients with newly diagnosed PMR. The mean age was 68 years and 48% were male and 53% were female. ACR/EULAR classification criteria were met in 46/58 patients (primarily due to prior corticosteroid use in primary care resulting in normal ESR/CRP). 15 patients (25.8%) were identified as having subclinical GCA on ultrasound. Of these, 12 were male and 3 were female (p=0.0201). The mean ESR at baseline for those with isolated PMR was 35, compared to 53 for those with subclinical GCA (p=0.0419). The mean baseline ESR for our GCA cohort was 58. There was no significant difference in the baseline CRP levels, between those with subclinical GCA and isolated PMR (p=0.1150). The extent of involvement of the temporal and axillary arteries of the 58 patients in the subclinical GCA group was compared to a cohort of 57 GCA patients. The total halo count was the similar for both subclinical GCA and clinical GCA at 4.33 and 4.36. However, GCA patients had higher halo scores in both temporal and axillary vessels of 13.17 and 13.28 respectively, compared to those with subclinical GCA with scores of 5 and 9.6.

Table 1.

	Isolated PMR (43)	Subclinical GCA (15)	GCA (57)
Age (mean + range)	67 (50-84)	70 (53-84)	74 (56-92)
Female	27	3	24
Male	16	12	33
BMI	28.3	27.9	27.8
Mean ESR at baseline (mm/h)	35	53	58
Mean CRP at baseline (mg/l)	24	40	66
Mean Halo count	0	4.33	4.36
Mean temporal artery halo score	0	5	13.17
Mean axillary artery halo score	0	9.60	13.28

Conclusion: PMR patients with subclinical GCA have a similar halo count to patients with clinical GCA suggesting a similar pattern of vascular involvement. However, those with clinical GCA have higher halo scores indicating more advanced vessel oedema which may be a key factor in causing headache symptoms. Male gender and a higher ESR at the time of PMR diagnosis appear to be risk markers for subclinical GCA though this requires analysis in larger cohorts of patients.

POS0717

COMPARISON BETWEEN ORAL AND INTRAMUSCULAR GLUCOCORTICOID THERAPEUTIC SCHEME IN POLYMYALGIA RHEUMATICA: INTERIM ANALYSIS OF PROSPECTIVE SINGLE-CENTRE STUDY

Keywords: Vasculitis

J. Kramarič[1,2], S. Markez[1,2], A. Hočevar[1,2], Z. Rotar[1,2], A. Ambrožič[1,2]. [1]*University Medical Center Ljubljana, Department of Rheumatology, Ljubljana, Slovenia*; [2]*University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia*

Background: Many patients with polymyalgia rheumatica (PMR) require prolonged glucocorticoid (GC) treatment, resulting in high cumulative GC doses. Treatment with intramuscular (IM) methylprednisolone (MP) injections results in considerably lower cumulative dose than conventional oral GC.
Objectives: We aimed to evaluate clinical and laboratory response and relapse frequency between PMR patients treated with oral or IM GC regimens.
Methods: This prospective study included patients with newly diagnosed PMR between October 2021 and September 2022. At diagnosis, patients were randomly allocated to IM or oral MP dosing groups in 1:2 ratio. Both groups followed a predefined MP tapering regimen. IM injections of 120 mg of MP were given every 3 weeks for the first 16 weeks, then every 4 weeks with dose reduction by 20 mg every 12 weeks until 60 mg, then by 20 mg every 16 weeks. Oral MP was started at 16 mg/day then, every 4 weeks, the dose was reduced to: 12 mg, 8 mg, 6 mg and 4 mg. Follow-up visits were performed adhering to protocol. The remission rate and other measures of disease activity were recorded and compared between IM MP and oral MP groups. Descriptive statistics were used to analyse the studied population.
Results: Of the 39 PMR patients (72% female, median (IQR) age 71 (66, 76) years) 26 patients received oral MP and 13 IM MP. Results are presented in Table 1. During follow-up we observed higher ESR values in the IM MP group. We observed slower clinical response in IM MP group at 4 weeks of follow-up. There was no difference between the two groups in clinical response measures at 12 and 24 weeks. During 24 weeks of follow-up, we identified 2 relapses in the oral MP group: 1 patient relapsed when lowering the MP dose to 6 mg/day at 16 weeks and 1 relapsed after discontinuing MP at week 24 due to patient's choice and presented with symptoms of giant cell arteritis. In the IM MP group, we observed no relapses in the first 24 weeks of follow-up, but there were 4 patients with inadequate response to treatment: 2 at week 4 and 2 at week 12. In these cases, we switched to oral MP. Due to the low number of patients in our study, results should be interpreted with caution.
Conclusion: In our cohort, treatment with IM MP compared to oral MP was effective in the majority of patients with PMR, but was associated with higher inadequate response rate and overall slower clinical and laboratory response.

Table 1. Comparison of follow-up data of IM and orally treated PMR patients

Characteristic	Follow-up week	IM MP	oral MP
ESR	0 (N = 39)	58 (50,72)	54 (39, 72)
	4 (N = 39)	31 (20, 43)	10 (7, 14)

Background: The main treatment of polymyalgia rheumatica (PMR) is based on corticosteroid, but sparing agents are a major unmet need and many new treatments are evaluated to avoid corticosteroid side effects in PMR. To monitor the disease, one disease activity score has been developed specifically for polymyalgia rheumatica (PMR), the PMR-AS (activity score) also called CRP-PMR-AS. It is a composite index built as an algebraic sum of morning stiffness, elevation of the upper limbs, physician's global assessment, patient's pain assessment and the C reactive protein (CRP). However, treatments of PM such as IL-6 antagonists or corticosteroid can normalize CRP level. Derived PMR-AS have been described to avoid such bias: erythrocyte sedimentation rate (ESR) PMR-AS, Clinical PMR-AS and CRP-imputed PMR-AS but the concordance and the correlation between these scores are unknown.
Objectives: Our primary objective was to measure the correlation and concordance of the PMR-AS and the other activity scores and our secondary objective was to evaluate the weight of CRP in the PMR-AS.
Methods: The SEMAPHORE trial (Safety and Efficacy of tocilizumab versus Placebo in Polymyalgia rHeumatica with glucocORticoid dEpendence), a superiority randomized double-blind parallel placebo-controlled trial in patients with active PMR despite corticosteroid treatment, investigated whether tocilizumab resulted in higher rates of low disease activity compared to a placebo, after 24 weeks. Four different PMR-AS have been measured. Using kappa coefficient, intra class correlation coefficient, scatter plots and Bland Altman graphics, we evaluated the concordance and correlation between CRP-PMR-AS, ESR PMR-AS, Clinical PMR-AS and imp-CRP PMR-AS across the entire population and by treatment group (placebo versus Tocilizumab) for different cut offs (1.5; 7; 10; 17) at each visit (inclusion, week 4, 8, 12, 16, 20 and 24).
Results: 100 patients received at least one dose of tocilizumab (49 patients) or placebo (51 patients) and were included in the analyses from inclusion to week 24. The correlation between the different PMR activity scores were excellent in the global analysis (Figure 1) but also in the two groups of treatment. Intraclass coefficients were all higher than 0.9 (Table 1). Bland Altman graphics using PMR-AS as a reference showed that differences between scores are low regardless of PMR-AS. Kappa coefficients between CRP-PMR-AS and the other three scores showed a good agreement (>0.8) (Table 1) at week 24.

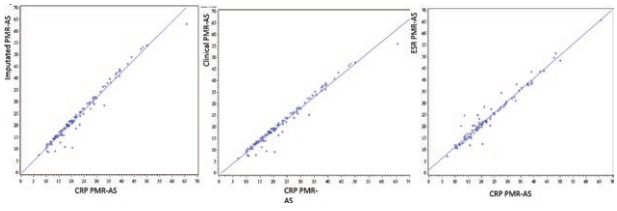

Figure 1. Scatter plots for the whole population at inclusion

Table 1. ICC and kappa between different PMR activity scores for the whole population

ICC (all patients all visits)	ICC (95% CI)
CRP PMR-AS and ESR PMR-AS	0.991 (0.990-0.992)
CRP PMR-AS and Clin PMR-AS	0.991 (0.990-0.992)
CRP PMR-AS and Imp PMR-AS	0.988 (0.987-0.989)
Kappa at week 24 (cut off 10)	**Kappa**
CRP PMR-AS and ESR PMR-AS	0.9562 (0.8961-1)
CRP PMR-AS and Clin PMR-AS	0.9133 (0.8304-0.9962)
CRP PMR-AS and Imp PMR-AS	0.8529 (0.7581-0.9577)

Table 1. Maternal and perinatal outcomes in women with vasculitis followed at a rheumatology-obstetric clinic

Main diagnosis	N (%)	Gestational age at delivery (mean ± SD weeks)	BW (mean ± SD grams)	SGA N (%)	Miscarriages N (%)	FGR N (%)	Preterm births N (%)	Pregnancy flares N (%)	Post-partum flares N (%)
Behçet's disease	18 (58)	38.3 ± 1.5	3013± 494	4/14 (29)	1/18 (6)	0	3/17 (18)	4/17 (24)	4/14 (29)
Polyarteritis nodosa	4 (13)	37.4 ± 0.6	2783± 175	1/4 (25)	0	0	0	2/4 (50)	0
Takayasu arteritis	4 (13)	38.0 ± 2.1	2725± 364	1/4 (25)	0	1/4 (25)	1/4 (25)	1/4 (25)	1/4 (25)
IgA vasculitis	1 (3)	40.3	3435	0	0	0	0	0	0
ANCA-PR3 cutaneous vasculitis	1 (3)	40.9	2845	1	0	0	0	1	0
Relapsing polychondritis	1 (3)	36.0	2040	1	0	1	1	1	1
Cryoglobulinemic vasculitis	1 (3)	35.9	3020	0	0	0	0	0	0
Cryoglobulinemic vasculitis associated with Sjögren's syndrome	1 (3)	39.0	3000	0	0	0	0	0	0
	31 (100)	**38.2 ± 2.1**	**2925± 566**	**8/27 (30)**	**1/31 (3)**	**2/31 (6)**	**5/30 (17)**	**9/25 (36)**	**6/27 (22)**

BW: birthweight; SD: standard deviation; SGA: small for gestational age; FGR: fetal growth restriction

Conclusion: The correlation between different PMR activity scores using or not CRP are excellent reflecting the low weight of CRP in the baseline composite index. In clinical trial using drugs that have an impact on CRP, CRP-PMR-AS or others, including clinical PMR-AS, can be used.

POS0719 MATERNAL AND PERINATAL OUTCOMES IN WOMEN WITH VASCULITIS - A 13-YEAR EXPERIENCE FROM A PORTUGUESE TERTIARY CENTRE

Keywords: Vasculitis, Pregnancy and reproduction

A. R. Lopes[1,2], A. R. Cruz-Machado[1,2], S. C. Barreira[1,2], P. Martins[1,2], C. Araújo[3], M. Centeno[3], C. Ponte[1,2], L. Pinto[3], S. Capela[1,2]. [1]*Centro Hospitalar Universitário Lisboa Norte, Centro Académico de Medicina de Lisboa (CAML), ERN ReCONNET and RITA Full Member, Rheumatology Department, Lisboa, Portugal*; [2]*Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, CAML, Rheumatology Research Unit, Lisboa, Portugal*; [3]*Centro Hospitalar Universitário Lisboa Norte, Obstetrics and Gynaecology Department, Lisboa, Portugal*

Background: The vasculitides are rare conditions that may affect women of childbearing age. These women seem to be at increased risk for developing adverse pregnancy outcomes (APO). Maternal and perinatal outcomes as well as their optimal management during pregnancy remain poorly understood in this population.

Objectives: To describe maternal and perinatal outcomes in women with vasculitis.

Methods: Observational retrospective study including pregnant women with vasculitis followed at a rheumatology-obstetric clinic from 01/2009 to 06/2022.

Results: We identified 31 pregnancies in 24 women with vasculitis. Table 1 summarizes demographic and clinical data. The most frequent diagnosis were Behçet's disease (BD) (18; 58%), polyarteritis nodosa (PAN) (4; 13%) and Takayasu arteritis (TAK) (4; 13%). The mean ± SD age at conception was 33 ± 6 years with a median disease duration of 6 (IQ range 3-12) years, 29 (94%) were in remission by the time of conception. We documented 30 live births, 1 early miscarriage (BD) and there was no perinatal mortality or birth defect. The mean ± SD gestational age at delivery was 38.2 ± 2.1 weeks. Five (17%) viable pregnancies resulted in preterm births - 3 BD, 1 TAK and 1 relapsing polychondritis (RP). Fetal growth restriction was detected in 2 (6%) pregnancies (TAK and RP). Eight (30%) newborns were small for gestational age (SGA), most of them from mothers with BD (4; 29%). Cesarean section (CS) was performed in 8 (26%) patients – 2 (TAK) due to vasculitis activity. Nine (36%) patients relapsed during pregnancy (4 BD; 2 PAN; 1 TAK; 1 RP; 1 ANCA-PR3 cutaneous vasculitis) while 6 (22%) relapsed during the post-partum period (4 BD; 1 TAK and 1 RP). A total of 24 (77%) patients were treated with glucocorticoids (GC), most of them (63%) at low doses (≤5mg/day of prednisolone or equivalent). Seven (23%) patients were treated with conventional DMARDs: 2 TAK and 3 BD with azathioprine and 2 PAN with azathioprine and hydroxychloroquine. Biological DMARDs were prescribed in 2 (6%) patients, both with the diagnosis of TAK: one with a multisegmental aortic disease who received tocilizumab during the first 30 weeks of gestation (WG) and had an uneventful pregnancy, and another patient with an ascending aortic aneurism (AAA) who also received tocilizumab, but from the 24th week onwards showed a gradual worsening of the AAA dimensions (maximum 56 mm). An elective CS at 32 WG was performed in the latter case due to the high risk of aneurysm rupture and a healthy baby with 1900g was born. The occurrence of flares during pregnancy increased the risk for APO (OR 13, 95 CI 2-80; p=0.007). No association was found concerning maternal age or use of DMARDs/GC and the risk of APO (p>0.05).

Conclusion: Most pregnant women with vasculitis managed at out multidisciplinary unit had successful gestations. However, they may still be at risk for developing APO, namely if they experience disease flares during gestation. SGA was the main APO recorded.

POS0720 MEASURING FUNCTIONAL DISABILITY IN GIANT CELL ARTERITIS: THE VALIDITY, RELIABILITY AND RESPONSIVENESS OF THE GCA-DISABILITY INDEX (GCA-DI)

Keywords: Quality of life, Patient reported outcomes, Vasculitis

Y. El Miedany[1], M. Elgaafary[2], M. Toth[3], S. Bahlas[4], M. H. Abu-Zaid[5], W. Hassan[6], D. Palmer[7], S. A. Mahran[8], S. Saber[9], S. A. A. Tabra[5], W. Elwakil[10]. [1]*Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom*; [2]*Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt*; [3]*King's College London, General Medicine, London, United Kingdom*; [4]*King Abdul Aziz University, Rheumatology, Jeddah, Saudi Arabia*; [5]*Faculty Of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt*; [6]*Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Banha, Egypt*; [7]*North Middlesex University Hospital, Rheumatology, London, United Kingdom*; [8]*Faculty of Medicine - Assiut University, Rheumatology and Rehabilitation, Assiut, Egypt*; [9]*Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt*; [10]*Faculty of Medicine Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt*

Background: Giant cell arteritis (GCA) is the most frequent systemic vasculitis, typically affecting patients over 50. The disease burden includes a chronic course and a subsequent prolonged treatment, especially because of a high risk of relapse that affects approximately half of patients. Taken together, the disease and its symptoms, the chronic course and the treatment probably have an impact on the patients' functional ability as well as quality of life. Though functional disability has been identified as a core outcome measure in GCA, few studies have been dedicated to assess for the patients for this core measure.

Objectives: To test the GCA-disability index (GCA-DI) questionnaire for validity, reliability and responsiveness in patients with Giant Cell Arteritis.

Methods: The psychometric properties of GCA-DI were tested in 57 patients with GCA, mean age 63.6 (+/- 5.4), 77.2% women, mean disease duration 2.1 weeks

(+/- 3.1 days). At baseline, all the patients completed the GCA-DI, and the Health Assessment Questionnaire (HAQ). The patients were then asked to return to the clinic after having their blood tests and X-rays done to complete another copy of the questionnaire. Also, all the patients were asked to complete another copy of the questionnaire in their follow up visit in 4-weeks' time. This facilitated the assessment for validity, reliability and responsiveness. In addition, all the patients were asked to complete a copy of multidimensional Patient Reported Outcomes for GCA. Patient global assessment for functional disability was also recorded (0-100 VAS). Of the 57 patients who completed the health status instruments on two occasions, 53 were included in the responsiveness analyses. The test-retest reliability of the GCA-DI questionnaire was calculated using intraclass correlation coefficients (ICCs). Criterion validity was assessed using Spearman's correlations, while responsiveness was evaluated by 3 different methods: (1) effect size (the mean difference between the baseline scores and the follow-up scores divided by the standard deviation of the baseline scores); (2) standardized response mean (the mean change in scores divided by the standard deviation of the change in scores).

Results: GCA-DI fulfilled the established criteria for validity, reliability and responsiveness. Significant correlations were seen between GCA-DI scores and HAQ scores (rho = 0.672), Patient Global Assessment functional disability (rho = 0.629), pain (rho = 0.633), Test-retest reliability was satisfactory, with ICCs of 0.935. The results of responsiveness analysis indicated that the GCA-DI was sensitive to change. Standardized effect size was 2.84 after 4-weeks.

Conclusion: Our data suggest that the GCA-disability index can be considered as a reliable, valid and responsive tool for measuring physical functioning in GCA patients. It is suitable for use in clinical trials and daily clinical practice. Its generalizability and utility for assessing treatment and functional outcomes should be evaluated in larger settings.

POS0721 DIFFERENT PATTERNS OF VASCULAR ULTRASOUND ARE ASSOCIATED WITH DIFFERENT ISCHEMIC COMPLICATIONS IN PATIENTS WITH GIANT CELL ARTERITIS

Keywords: Imaging, Vasculitis, Ultrasound

J. Molina Collada[1], G. Torres Ortiz[2], I. Castrejon[1], I. Monjo[2], E. Fernández-Fernández[2], J. M. Alvaro-Gracia[1], E. De Miguel[2]. *[1]Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain*; *[2]La Paz University Hospital, Rheumatology, Madrid, Spain*

Background: Patients with giant cell arteritis (GCA) can present ischemic complications (IC). Recognizing patients at risk of IC may help to improve GCA long-term outcomes. However, previous studies have failed to identify consistent risk factors for IC in this population, being mainly low systemic inflammation or atherosclerotic risk factors the main findings in some cohorts.

Objectives: Our objective is to determine if a specific pattern of vascular inflammation by ultrasound (US) is associated with different types of IC in patients with GCA.

Methods: A retrospective observational study of patients referred to the US fast track clinics of two academic centres with GCA clinical confirmation over a 4-years period. All patients underwent baseline US of cranial and extracranial arteries (carotid, subclavian and axillary) at the time of referral, and were classified in two categories; cranial or large vessel (LV)-GCA, according to US findings. IC was defined as the occurrence of acute anterior ischemic optic neuropathy (AION) or non-AION (including stroke, acute coronary syndrome, pulmonary embolism or peripheral artery disease) within 3 months after diagnosis, and after excluding other potentially implicated causes. Chi-squared and analysis of variance were performed to explore the association between clinical or US variables with the occurrence of different types of IC.

Results: A total of 42 (22.9%) patients over 188 patients with GCA clinical confirmation evaluated at our clinics had an IC within 3 months after diagnosis, 24 (12.8%) an AION and 19 (10.1%) a non-AION IC (10 stroke, 5 acute coronary syndrome, 4 peripheral artery disease, 2 pulmonary embolism and one case of ischemic colitis). Patient characteristics according to IC type are shown in Table 1. Patients with AION showed more frequently findings of US cranial involvement (100%) versus patients with non-AION IC (63.2%) and without IC (79.3%), p=0.009. In contrast, patients with non-AION IC presented more frequently signs of US LV-GCA (63.2%) versus patients with AION (25%) and without IC (55.2%), p=0.014).

Conclusion: Different patterns of vascular US involvement are associated with different IC in GCA patients. Predominantly cranial-GCA patients have more frequently AION, while predominantly LV-GCA patients have more frequently non-AION IC, as stroke, acute coronary syndrome, pulmonary embolism or peripheral artery disease.

POS0722 EFFECTS ON SOLUBLE IMMUNE CHECKPOINTS INDUCED BY TOCILIZUMAB MONOTHERAPY AFTER ULTRA-SHORT-TERM GLUCOCORTICOIDS IN LARGE VESSEL – GIANT CELL ARTERITIS PATIENTS

Keywords: Cytokines and chemokines, Biomarkers, Vasculitis

M. Bonacini[1], A. Rossi[1], I. Ferrigno[1], C. Catellani[1], V. Buia[1], F. Muratore[2], E. Galli[2], C. Marvisi[2], G. Cassone[3], A. Zerbini[1], C. Salvarani[2,4], S. Croci[1]. *[1]Azienda Unità Sanitaria Locale - IRCCS di Reggio Emilia, Unit of Clinical Immunology, Allergy and Advanced Biotechnologies, Reggio Emilia, Italy*; *[2]Azienda Unità Sanitaria Locale - IRCCS di Reggio Emilia, Unit of Rheumatology, Reggio Emilia, Italy*; *[3]Azienda Ospedaliero Universitaria di Modena, Unit of Rheumatology, Modena, Italy*; *[4]Università degli Studi di Modena e Reggio Emilia, Surgical, Medical and Dental Department of Morphological Sciences related to Transplant, Oncology and Regenerative Medicine, Modena, Italy*

Background: The most affected vessels in Giant cell arteritis (GCA) are the temporary arteries, but in some patients extracranial large vessels are also involved (LV-GCA). Tocilizumab (TCZ), a monoclonal anti-interleukin-6 receptor1 antibody, has been approved as glucocorticoid (GC) sparing agent in patients with GCA. Recently, new therapeutic protocols that combine rapid GC tapering and TCZ are emerging, but their effects on circulating immune cells and mediators are scarcely known [1]. Another clinical need in LV-GCA management is the lack of a gold standard to define disease state. The role of immune checkpoint molecules is tuning the activation of the immune system. They are expressed on the surface of immune cells, but also soluble forms exist. Active GCA patients showed a reduction of CD4+ T cells expressing PD1 and VISTA in comparison to controls [2,3]. We hypothesize that soluble immune checkpoints are modulated by the TCZ and GC combined treatment and that they are biomarkers able to differentiate active from inactive LV-GCA patients.

Objectives:

1) To evaluate the effects of TCZ monotherapy after ultra-short-term GC treatments on soluble immune checkpoints.
2) To identify plasma biomarkers able to discriminate between LV-GCA patients in the active phase from those in remission.

Methods: We included 16 patients with active LV-GCA enrolled in the single-arm open-label clinical trial (NCT05394909) performed at AUSL-IRCCS at Reggio Emilia. Inclusion criteria: PET/CT with FDG uptake ≥2 in at least one vascular district and at least one among ESR >40 mm/h (or CRP >10 mg/L); cranial or systemic manifestations of GCA or polymyalgia rheumatica. Exclusion criteria: more than 10 mg/day of prednisone for more than 10 consecutive days in the previous 3 months. Remission was defined by all the following: absence of any clinical signs and symptoms directly attributable to GCA; normalization of CRP and ESR values; absence of new/worsened vascular damage at CT; vascular FDG uptake <2 in all vascular districts at PET/CT or overall PET image interpretation of non-active vasculitis. All patients received 500 mg per day of methylprednisolone intravenously for three consecutive days and weekly subcutaneous TCZ injections from day 3 until week 52. Plasma samples were collected at baseline before treatment and after GC injections. For 10 patients plasma samples were also collected at week 52. Laboratory data were collected at the same time points. Concentrations of CD137L, CD137, CD27, CTLA4, CD80, CD40, CD40L, GITR, GITRL, ICOSL, IDO, LAG3, MICA, MICB, PD1, PDL1, PDL2, PTX3, TIM3 and VISTA were evaluated in plasma samples by a multiplex bead-based assay with the MAGPIX instrument. Wilcoxon test was used for comparison between groups, Spearman test was used for correlation analysis. $P < 0.05$ was considered statistically significant.

Results: Soluble CD137L, CTLA4, CD40, CD40L, GITR, IDO, PD1 and PDL1 were not detected in almost all of the samples irrespective of treatment and disease phase. Intravenous injections of GC determined a significant reduction of soluble CD137, CD80, GITRL, ICOSL, LAG3, MICA, and MICB and an increase of PTX3 and VISTA levels. After 52 weeks of TCZ as monotherapy, an increase in plasmatic ICOSL and a reduction in LAG3, PTX3, and VISTA were observed compared to baseline. At 52 weeks, 7 patients were classified in remission phase of the disease and 3 patients were active. Changes in immune checkpoint levels occurred irrespective to disease phase. Levels of soluble immune checkpoints did not correlate with ESR and CRP concentrations, markers currently used in clinical practice to evaluate systemic inflammation.

Conclusion: Ultra-short-term GC treatments and TCZ monotherapy modulate the levels of soluble immune checkpoints. The evaluation of the investigated panel of immune checkpoints did not allow to discriminate between LV-GCA patients in different disease phases.

POS0723 ANALYSES OF PLASMA METABOLIC PROTEINS REVEAL BIOMARKERS PREDICTIVE OF SUBSEQUENT DEVELOPMENT OF GIANT CELL ARTERITIS; A PROSPECTIVE STUDY

Keywords: Biomarkers, Vasculitis

K. Wadström[1,2], L. T. H. Jacobsson[3], A. J. Mohammad[4,5], K. J. Warrington[6], E. Matteson[6], M. Jakobsson[7], C. Turesson[8,9]. *[1]Lund University, Department of Clinical Sciences, Malmö, Malmö, Sweden*; *[2]Academic specialist center, Center for Rheumatology, Region Stockholm, Stockholm, Sweden*; *[3]Sahlgrenska Academy, University of Gothenburg, Institute of Medicine, Department of Rheumatology & Inflammation Research, Gothenburg, Sweden*; *[4]Skåne University Hospital, Lund, Department of Rheumatology, Lund, Sweden*; *[5]University of Cambridge, Department of Medicine, Cambridge, United Kingdom*; *[6]Mayo Clinic College of Medicine and Science, Division of Rheumatology, Rochester, United States of America*; *[7]Malmö University, Department of Biomedical Sciences, Faculty of Health and Society, Malmö, Sweden*; *[8]Lund University, Department of Clinical Sciences, Malmö, Malmö, Sweden*; *[9]Skåne University Hospital, Department of Rheumatology, Malmö, Sweden*

Background: Incident cases of of giant cell arteritis (GCA) have a significantly reduced prevalence of diabetes at time of diagnosis (1) and lower fasting blood glucose, lipid levels and body mass index compared to controls have been found years before clinical diagnosis [2,3]. This implicates metabolic pathways in the development of GCA.

Objectives: To investigate the relation between plasma proteins associated with metabolism and subsequent development of GCA.

Methods: Participants in a population-based survey (N=30447), who were subsequently diagnosed with GCA, were identified in a structured process. GCA-free controls, matched for sex, year of birth, and year of screening were selected from the study cohort. Baseline plasma samples were analyzed using the antibody-based OLINK proteomics metabolism panel (92 proteins). Analyses were pre-designated as hypothesis-driven or hypothesis-generating. In the latter, principal component analysis was used to identify groups of proteins that explain the variance in the proteome.

Results: There were 95 cases with a confirmed incident diagnosis of GCA (median 11.4 years after inclusion). Among biomarkers with a priori hypotheses, Adhesion G protein-coupled receptor E2 (ADGRE2) was positively associated and Fructose-1,6-bisphosphatase 1 (FBP1) negatively associated with subsequent GCA (Table 1). In particular, ADGRE2 levels were elevated compared to controls in the subset sampled <8.5 years before diagnosis (Table 1). For meteorin-like protein (Metrnl), the highest impact on the risk of GCA was observed in those sampled closest to diagnosis, with a decreasing trend with longer time to GCA (p=0.03). In the hypothesis generating analyses, elevated levels of receptor tyrosine-like orphan receptor 1 (ROR1) were associated with subsequent GCA.

Conclusion: Our results indicate that changes in levels of plasma proteins that have regulatory effects on the immune system might precede clinical onset of GCA by many years. Among the biomarkers found to be predictive of subsequent GCA, both Metrnl and ADGRE2 are associated with macrophage activation. ROR1 mediated activation of NFkB may be relevant in this context. The negative association with FBP1, which is a rate-controlling enzyme in the gluconeogenic pathway, is compatible with a protective role for glucose metabolites.

POS0724 TRANSORBITAL ULTRASOUND IN NEWLY DIAGNOSED GIANT CELL ARTERITIS – A PROSPECTIVE STUDY

Keywords: Diagnostic tests, Vasculitis, Ultrasound

S. Petzinna[1], L. C. Burg2, J. Terheyden[3], C. J. Bauer[1], C. Behning[4], P. Brossart[1], R. P. Finger[3], V. Schäfer[1]. *[1]University Hospital Bonn, Department of Internal Medicine III, Oncology, Hematology, Rheumatology and Clinical Immunology, Bonn, Germany*; *[1]University Hospital Bonn, Department of Internal Medicine III, Oncology, Hematology, Rheumatology and Clinical Immunology, Bonn, Germany*; *[3]University Hospital Bonn, Department of Opthalmology, Bonn, Germany*; *[4]University Hospital Bonn, Institute of Medical Biometry, Informatics and Epidemiology, Bonn, Germany*

Background: Giant cell arteritis (GCA) is an immune-mediated, granulomatous vasculitis that primarily affects the elderly and results in local vascular changes of

middle-sized and large arteries. A protracted diagnosis delaying high-dose corticosteroid therapy may result in permanent visual loss. Therefore, invasive and time-consuming biopsy of the superficial temporal artery has been replaced by high-resolution vascular ultrasound of the temporal and axillary artery to evaluate extracranial inflammation. Intracranial involvement of the ophthalmic vessels can be visualized by magnetic resonance imaging. Transorbital Ultrasound (TOS), as a simple and inexpensive diagnostic method, could be an option for assessing the optic nerve and the central retinal artery (CRA) and might improve diagnostic sensitivity in GCA, especially in anterior optic neuropathy (AION).

Objectives: The purpose of this study was to assess the utility of TOS in patients with untreated and newly diagnosed GCA.

Methods: Patients with new GCA diagnosed by a board-certified rheumatologist who also met the expanded ACR-EULAR classification criteria were enrolled in the study between October 1, 2018, and May 31, 2022. Each participant underwent TOS to assess the CRA and optic nerve diameter (OND). The eyes of the patients with GCA were categorized as eyes with or without visual impairment (VI), which was defined as transient or persistent visual field loss, diplopia, amaurosis, and blurred vision. Peak systolic velocity (PS), end diastolic velocity (ED), resistance index (RI) of the CRA and OND were recorded.

Results: A total of 54 GCA patients were prospectively enrolled in the study, 27 of whom had VI in at least one eye. To account for repeated measures within a patient, associations between TOS and VI were evaluated using linear mixed-effect models (LME). PS and ED values of the CRA were statistically significant lower in the eyes with GCA manifestation (ß=-1.93; p<0.001 for PS; ß=-0.61; p=0.003 for ED). The RI of the CRA was statistically significant reduced in the eyes with GCA associated VI (ß=-0.04; p=0.007). OND was lower in the eyes with VI, too (ß=-0.36; p=0.06) (Table 1, Figure 1).

Conclusion: In TOS, eyes affected by VI exhibited significantly reduced PS, ED, and RI indicating an inflammatory process of the intracranial vessels leading to impaired blood flow to the optic nerve and contributing to ischemia-associated optic neuropathy. The shown decrease in OND is probably due to reduced blood flow and the resulting lessened vessel diameter and, in the case of a persistent depletion of blood flow, due to atrophic alterations of the optic nerve suggestive of irreversible damage. Therefore, VI in combination with decreased PS, ED, RI and OND may constitute a specific finding in the diagnosis of optic affection in GCA. Our study was the first to prospectively demonstrate the diagnostic value of TOS in untreated and new diagnosed GCA patients as a complementary diagnostic tool to assess GCA associated intracranial inflammation.

Table 1. Mean values of central retinal artery flow velocity, resistance index, optic nerve diameter in patients with/ without visual impairment

	GCA without VI	GCA with VI	LME (ß)	p-value
Peak systolic velocity (SD); cm/s	12.95 (± 3.84)	10.16 (± 4.10)	- 1.93	<0.001
End diastolic velocity (SD); cm/s	3.91 (± 0.12)	3.18 (± 1.27)	-0.61	0.003
Resistance Index (SD)	0.69 (± 0.10)	0.64 (± 0.17)	-0.04	0.007
Optic nerve diameter (SD); mm	5.3 (± 0.99)	4.93 (± 1.1)	-0.36	0.06

Eyes affected by VI exhibited reduced flow velocity and resistance index of the central retinal artery and decreased optic nerve diameter. Abbrev.: GCA: Giant Cell Arteritis, VI: Visual impairment, LME: Linear mixed-effects model, SD: standard deviation

CRANIAL, EXTRACRANIAL AND MIXED INVOLVEMENT IN GIANT CELL ARTERITIS: ANALYSIS OF THE CLINICAL DIFFERENCES

Keywords: Ultrasound, Descriptive studies, vasculitis

m. d. c. uyaguari morocho[1], e. fernández-fernández[1], i. monjo[1], e. de miguel[1].
[1]*la paz university hospital, rheumatology, madrid, spain*

Background: giant cell arteritis (gca) is a systemic vasculitis that affects large vessels, with a higher incidence in patients aged 70 years. It is known that GCA involves temporal arteries and the aorta and its branches either concomitantly or in isolation. Differentiating the characteristics in the expression of these disease subtypes will be relevant for the initial treatment, prognosis and the follow up.

Objectives: To analyze the different clinical and laboratory between the patterns of GCA involvement.

Methods: Retrospective study of new consecutive patients diagnosed with GCA for four years. 90.9% were diagnosed by Color Doppler ultrasound, measuring the superficial temporal arteries, common trunk, their frontal and parietal branches, and the extracranial arteries (axillary, subclavian, and carotid arteries). 9.1% were diagnosed by PET-CT or temporal artery biopsy. Ultrasound diagnosis was according to the OMERACT definitions of the halo sign and an intima-media cut off a thickness of ≥0.34 mm for the temporal arteries, ≥0.42 in the common superficial temporal artery and ≥ 1 mm for the axillary, subclavian, and carotid arteries. Clinical records were reviewed and their demographic, clinical and laboratory data were compared between patterns of ultrasound involvement. The EULAR recommendations of 2018 [1] were used to the remission and relapse.

Results: A total of 163 patients were included, 50.3% women, with a mean age of 79 years. Regarding the GCA subtypes, 78 patients had exclusive involvement of cranial arteries (CGCA), 36 patients had isolated involvement of extracranial giant cell arteritis (LVGCA) and 49 patients had mixed forms with both cranial and extracranial involvement (MGCA) Table 1. The analysis showed that patients with LVGCA present constitutional syndrome more frequently, less anterior Ischemic optic neuropathy (AION) (p<0.001) and less ESR values (p<0.01) than patients with CGCA. Extracranial artery involvement in any of the subtypes showed a significant association with polymyalgia rheumatica (PMR), although this was not exclusive to LVGCA. CGCA was associated with more AION-type ischemic manifestations than LVGCA. Remission maintained for at least 6 months together with corticosteroid-free remission is higher in LVGCA. No statistically significant differences in relapses, both major and minor.

Table 1. Clinical and laboratory characteristics between GCA subtypes

	GCA 163	CGCA 78	LVGCA 36	MGCA 49	CGCA -MGCA p	CGCA -LVGCA p	LVGCA - MGCA p
Female sex, n (%)	82 (50.3)	41 (52.6)	21 (58.3)	20 (40.8)	0.378	0.565	0.134
Age years, mean ± SD	79 ± 7.8	79 ± 7.5	77.6 ± 10	79.2 ± 6.7	0.883	0.435	0.403
ESR, mm/h mean ± SD	57 ± 34	63 ± 37.3	42.2 ± 27.6	47.4 ± 35	**0.019**	**0.003**	0.467
CRP mg/dL mean ± S.D.	52.6 ± 54	54 ± 55.4	43.2 ± 56	49.4 ± 49.4	0.631	0.335	0.588
PMR, n (%)	88 (53.6)	32 (41)	23 (63.9)	33 (66)	**0.005**	**0.023**	0.839
Constitutional symptoms, n (%)	87 (53)	38 (48.7)	25 (69.4)	24 (48)	0.936	**0.038**	**0.047**
AION, n (%)	38 (23)	25 (32)	3 (8.3)	10 (20)	0.135	0.006	0.136
Remission 6 months, n (%)	45 (27.4)	14 (17.9)	15 (41.7)	16 (32)	0.057	0.006	0.393
Glucocorticoid free-remission, n (%)	28 (17)	8 (10.3)	9 (25)	11 (22)	0.068	**0.039**	0.745
Major relapse, n (%)	7 (4.2)	3 (3.8)	3 (8.3)	1 (2)	0.947	0.679	0.751
Minor relapse, n (%)	52 (31.7)	25 (32)	11 (30.6)	16 (32)	0.943	0.947	0.378

CGCA Cranial giant cell arteritis; LVGCA Large vessel giant cell arteritis; MGCA Mixed giant cell arteritis; SD standard deviation; AION anterior Ischemic optic neuropathy; PMR polymyalgia rheumatica; CRP C reactive protein; ESR erythrocyte sedimentation rate.

Conclusion: Clinical features are different between the different GCA patterns. Patients with LVGCA have a greater constitutional syndrome and lower ESR than patients with CGCA. CGCA was associated with more NOIA-type ischemic manifestations than LVGCA. PMR is more frequent in cases with large vessel involvement. There is more maintained and corticosteroid-free remission in patients with LVGCA.

POS0726 RITUXIMAB VERSUS CYCLOPHOSPHAMIDE FOR ANCA- ASSOCIATED VASCULITIS: A COST ANALYSIS

Keywords: Vasculitis

E. Amor[1], B. Mulhearn[1,2], W. Tillett[1,2], C. Cavill[2], S. Tansley[1,2]. [1]*University of Bath, Department of Life Sciences, Bath, United Kingdom*; [2]*Royal United Hospitals, Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom*

Background: Cyclophosphamide (CYC) and Rituximab (RTX) have been found to be of equivalent effectiveness in remission induction of severe ANCA-associated vasculitis (AAV) (1); [2]. American College of Rheumatology in 2019, and more recently EULAR guidance on treatment of AAV, has recommended the use of RTX first-line due to a more favorable side-effect profile [3]. In the UK, in the absence of contraindications, our current guidance still advocates the use of CYC first-line. While RTX biosimilars are available at reduced cost compared to the originator molecule, the drug cost of RTX is far greater than CYC. A change in UK guidance could have significant cost-implications to healthcare services.
Objectives: The objective of this study was to compare the cost RTX and CYC induction regimens for patients with AAV and calculate the cost difference to our department of the two regimens.
Methods: Drug costs for CYC and the current preferred (cheapest) RTX biosimilar was provided by our pharmacy team. Exact drug costs are considered commercially sensitive and are hence not reported here. The Hospital Business Intelligence Unit provided total visit cost data and an average total visit cost for both RTX and CYC was calculated using worked examples. This accounts for cost differences due to in drug administration and the need for medical review. Data was available on the number of patients with AAV who started induction treatment with CYC from January 2022 and December 2022. We were able to calculate a total cost for this and an equivalent cost if these patients had all received RTX induction.
Results: As expected, drug costs for RTX were significantly greater than for CYC. Total visit costs were however similar. The increased total costs for CYC likely largely due to our policy of consultant and multidisciplinary team review prior to each infusion. The total visit cost approximations for cyclophosphamide for patients with AAV treated with CYC between January 2022 to December 2022 was £44,000. When RTX total visit costs were considered, the annual costs for RTX induction for these patients would have been approximately £14,000. Furthermore, as a standard CYC induction is administered as 6 cycles, while RTX is administered as two 1g infusions, if patients treated with CYC had received RTX this would have created an additional 143 hours of availability on our biologics day unit. Other potential time and cost savings we did not measure would include nadir monitoring bloods for CYC done prior to each infusion and pharmacy time in preparing the drugs and associated other medications such as anti-emetics.
Conclusion: The annual net saving if our hospital trust had treated the patients with AAV who received CYC induction with RTX instead, would have equated to £30,000. While this does not take into account subsequent maintenance treatment choices, we can be reassured that a shift towards RTX induction first-line in AAV, is likely to lead to significant cost-savings and would not place an additional financial burden on healthcare resources.

POS0727 DEVELOPMENT OF POSTERIOR UVEITIS IN BEHÇET'S SYNDROME PATIENTS WITH VITREOUS CELLS WITHOUT ANY OTHER POSTERIOR INVOLVEMENT

Keywords: Vasculitis, Uveitis, Behcet's disease

D. Ucar[1,2], B. E. Bircan[3], N. Rustamli[3], B. Batu Oto[1], V. Hamuryudan[4], S. N. Esatoglu[2,4], G. Hatemi[2,4]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophthalmology, Istanbul, Turkey*; [2]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behçet's Disease Research Center, Istanbul, Turkey*; [3]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey*; [4]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: A considerable number of patients with Behçet's syndrome (BS) have vitreous cells on slit lamp examination at the time of diagnosis. However, the prognostic importance of vitreous cells (VC) and their association with the development of posterior uveitis (PU) requiring immunosuppressive treatment is unknown.
Objectives: We aimed to determine the prognostic importance of VC in BS patients.
Methods: The charts of 572 consecutive BS patients fulfilling ISG criteria who were registered between 2010 and 2012 were reviewed. At baseline visit 164 patients had VC in one eye or both eyes. Among the remaining patients, 229 had no eye involvement, 116 patients had bilateral pan or posterior uveitis, 14 had unilateral pan or posterior uveitis and no eye involvement in the other eye, 20 had isolated anterior uveitis, and 29 had insufficient data in their medical records. Among the 164 patients with VC, 110 patients with a follow-up of ≥2 years were included in this study (Figure 1).
Results: At baseline, among the 111 included patients (68 men, mean ± SD age: 31±9 years), 61 had VC in both eyes, 34 had VC in only one eye, and 15 had VC in one eye and PU in the other eye. There was anterior uveitis (AU) in addition to VC in the same eye in 13 patients at baseline (Figure 1).
New PU developed in 26 (24%) patients during a mean follow-up of 1.9±1.1 years.7 patients that developed PU in the eye with VC had had PU in the contralateral eye at baseline. This means 7 of 15 patients with VC in one eye and PU in the contralateral eye developed bilateral PU despite treatment. 2 of these 7 patients had developed AU before they developed PU. Additionally, 6 patients that developed PU in the eye with VC had anterior uveitis in the same eye at baseline.
Conclusion: Careful follow-up is required for patients with VC since one quarter developed PU within 2 years. The presence of PU in the contralateral eye and AU in the same eye may be risk factors for the development of PU in patients with VC.

POS0728 EFFECTIVENESS AND SAFETY OF A 26 WEEK TAPER REGIMEN OF GLUCOCORTICOID IN NEWLY-DIAGNOSED GCA PATIENTS: A REAL LIFE EXPERIENCE

Keywords: Vasculitis

C. Marvisi[1], P. Castrignanò[1], F. Muratore[1], E. Galli[1], S. Croci[2], M. Bonacini[2], L. Boiardi[1], G. Besutti[3], L. Spaggiari[3], A. Versari[4], M. Casali[5], N. Pipitone[1], C. Salvarani[1]. [1]*Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Rheumatology Department, Reggio Emilia, Italy*; [2]*Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Unit of Clinical Immunology, Allergy and Advanced Biotechnologies, Reggio Emilia, Italy*; [3]*Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Radiology Department, Reggio Emilia, Italy*; [4]*Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Nuclear Medicine Department, Reggio Emilia, Italy*; [5]*Azienda Unità Sanitaria Locale di Piacenza, Nuclear Medicine Department, Piacenza, Italy*

Background: The GiACTA [1] was the first trial comparing two standardized prednisone (PDN)-taper protocols (52 week and 26 week) in GCA. Sustained remission rate at week 52 was similar. Patients enrolled in the placebo group with a 26 week taper protocol experienced lower PDN cumulative dose but more flares than those enrolled in the 52 week one.
Objectives: To assess the effectiveness and safety of the 26 week taper regimen of glucocorticoids (GC) used in the GiACTA trial in a prospective cohort of treatment-naive, biopsy-proven GCA.
Methods: Patients with a new diagnosis of biopsy-proven GCA enrolled in the GC arm of the START project (molecular stratification of patients with GCA to tailor GC and tocilizumab therapy) were included [2]. All patients were treated with the 26 week taper regimen of GC used in the GiACTA trial. Disease assessment was performed at baseline and every 12 weeks. In case of disease relapse, GC was increased or restarted with or without adjunctive immunosuppressive treatment. PET/CT was performed in 18 patients at baseline. Large vessel involvement was defined by evidence of vascular FDG uptake ≥liver in at least one vascular district. CT angiography was performed after at least 52 weeks of follow-up in all patients and was compared with baseline CT of the PET scan. The diameter of the aorta was measured at 4 different levels. Aortic dilation was defined by a diameter >40 mm in the ascending aorta, ≥40 mm in the descending aorta and ≥30 mm in the abdominal aorta. Any change of ≥5mm on serial CT was considered significant progression of aortic damage. Remission was defined as the absence of any clinical symptoms attributable to GCA, including a normalization of the acute phase reactants. Relapse was defined as one or more of the following: recurrence of signs or symptoms of GCA or PMR; CRP values greater than 10 mg/L, or ESR values greater than 40 mm/h if these were considered by the investigator to be due to GCA. The definition of relapse included the necessity for intensification of treatment. The primary endpoint was the rate of relapse-free remission at week 52. Secondary endpoints were the rate of remission at the end of follow-up and the proportion of patients with new aortic dilation or worsened aortic damage.
Results: 22 patients were included between December 2018 and February 2022. The baseline characteristics are reported in the Table 1. At week 52, 10 patients (46%, 95% CI 24-68) were in relapse free-remission. After a median (IQR) follow-up of 27.5 (18.5-34) months, 7 patients (32%, 95% CI 14-55) remained in relapse-free remission. 18 patients with baseline PET/CT underwent CT angiography at the end of the follow-up. No patients had evidence of new aortic dilation, significant progression of aortic damage or large vessel stenosis. 15/22 patients (68.2%) had at least one relapse during follow-up. No patients developed visual or cerebrovascular manifestations during relapses. Mean (SD) prednisone cumulative dose was significantly lower in non-relapsing than in relapsing patients at week 52 and at the end of follow-up [3.7 (1.3) vs 4.8 (8.7) g, p=0.017, and 4.3 (2.6) vs 6.8 (1.7) g, p=0.014, respectively]. However, 19/22 (83.4%) patients had at least one GC-related adverse event.
Conclusion: A 26 week taper regimen of GC was effective and safe in inducing and maintaining remission in a sizeable proportion of newly diagnosed cranial GCA patients. If confirmed in larger trials, this faster taper regimen could allow sparing GC, and should be considered as initial treatment in all newly-diagnosed GCA patients, reserving immunosuppressive treatment only in relapsing patients.

POS0729 DIFFERENCES BETWEEN GLUCOCORTICOIDS, CONVENTIONAL DMARDS AND TOCILIZUMAB IN ACHIEVING DISEASE REMISSION AND IN PREVENTING THE PROGRESSION OF DAMAGE IN GIANT CELL ARTERITIS PATIENTS

Keywords: Vasculitis, Outcome measures, Treat to target

F. Davanzo[1], L. Iorio[1], M. Codirenzi[1], R. Padoan[1], A. Doria[1]. [1]University of Padova, Division of Rheumatology, Department of Medicine DIMED, Padova, Italy

Background: Patients with Large Vessel Vasculitis (LVV) may experience severe consequences of the disease, caused by underlying vasculitis and prolonged treatment. A validate damage tool specific to LVV is lacking. Moreover, despite new evidence, the overall assessment of the activity is still an unmet need.
Objectives: The aim of the present study is to evaluate the efficacy of different regimens in achieving clinical, laboratory and imaging disease remission and in preventing the progression of disease-related damage and treatment-related damage, especially glucocorticoids induced, in Giant Cell Arteritis (GCA).
Methods: Consecutive inpatients and outpatients, classified as GCA with LVV involvement, were prospectively enrolled. We included all patients with new diagnosis or relapsing disease who underwent to at least 2 consecutive 18F-FDG PET-CT or MR scan between March 2011 and September 2022. Before every PET scan demographic, clinical data and disease activity were assessed. Remission was defined as absence of signs and symptoms attributable to GCA and normalization of acute phase reactants (ESR <30 mm/H and CRP <1 mg/dL) [1]. For each PET scan the vessel's metabolic activity was evaluated using the Meller's grading and the PETVAS score [2]. The damage was evaluated using the Large-Vessel Vasculitis Index of Damage (LLVDI) and the Composite Glucocorticoid Toxicity Index (GTI), distinct in Cumulative Worsening Score (GTI-CWS) and Aggregate Improvement Score (GTI-AIS) [3,4]. GCA patients were compared according to current treatment regimen: glucocorticoid (GC) monotherapy versus conventional disease modifying anti-rheumatic drug (cDMARDs), and tocilizumab (TCZ).
Results: The study included 49 LV-GCA patients (age 28 [21-48], 71.4% female) exposed to a total of 76 treatment regimens (n = 39 GC monotherapy, n = 21 cDMARDs, n = 16 TCZ). All the treatment led to significant reduction of acute phase reactants (GC-treated: ESR p < 0.001, CRP p < 0.001; cDMARDs - treated: ESR p = 0.033, CRP p = 0.01, and TCZ-treated: ESR p = 0.006, CRP p = 0.003). Significant improvement in PETVAS was observed in all patients: GC treated 12 4-21 vs 7 2-14 (p=0.033), cDMARDs treated 16 5-20 vs 4 3-10.5 (p = 0.039), and TCZ - treated 12 9-20.2 vs 3 1-9 (p < 0.001). Daily prednisone dose at last examination was 5 [0-7.25] mg/d in the cDMARDs group vs 0 [0-5] mg/d in the TCZ group (p = 0.148). GC withdrawal was observed in 82% of TCZ-treated patients, while 58% in the GC group (p=0.112). At last evaluation LLVDI was similar in the three groups (2 [1-6] vs 2 [1-3] vs 3 [2.25-5], p = 0.073). Baseline GTI resulted higher in the TCZ group, when compared to DMARDs and GC (75 [48- 101] vs 49 [35-64] vs 32 [10-74], respectively, p = 0.008). At the last follow-up TCZ-treated patients showed higher GTI-CWS (97 [77-127] vs 72 [48-81] vs 65 [48-103], p = 0.025) than those treated with DMARDs and GC, while no differences were observed in GTI-AIS (0 [- 19 to 33] vs 0 [77.5 to 127] vs 0 [-16 to 18.7], p = 0.154). When considering only those patients who received TCZ as a first line treatment (n=4), GTI-AIS at last follow-up resulted significantly lower compared to DMARDs and GC treated individuals (-30 [-71 to-5.5] vs 0 [77.5 to 127] vs 0 [-16 to 18.7], p = 0.0249).
Conclusion: Tocilizumab treatment significantly reduce vessel's metabolic activity over time, when compared to conventional treatment. None of the three

different treatment regimen reduce the progression of the damage caused by both the vasculitis and the glucocorticoid treatment. TCZ as a first line treatment reduced significantly the GTI-AIS at the last follow up, when compared to the other treatment.

Background: GCA is a critically ischemic large vessel vasculitis, varying in extent, severity and outcomes, hence requires disease stratification using clinical, laboratory and imaging parameters, for targeted management. Although DMARDs are used, the effectiveness in real life, such adjuvants remain un-elucidated. We performed a prospective, multi centre cohort study of new GCA stratified into remitting, relapsing, refractory, ischemic disease.

Objectives: We assessed prognostic factors and compared critical outcomes such as remission with glucocorticoid (GC) monotherapy versus GC plus DMARDs in the first 12 months.

Methods: HAS GCA study (1) recruited consecutive patients with new onset GCA from 7 centres (UK, Italy, Spain, Netherlands). diagnosis was confirmed used a modified GiACTA criteria at 6 months follow up. All underwent ultrasound (bilateral common, parietal, frontal temporal arteries, and axillary arteries) using accepted standard cut-off values [2]. GCA patients had US at baseline,1,3,6,12 months and halo count (HC) and Halo score (Temporal TAHS, axillary AAHS, total THS) assessed [3]. The primary outcome- remission at 12 months (absence of signs/symptoms, CRP<5 mg/dl, prednisolone < 5 mg daily). Results are reported as descriptive statistics.

Results: 229 participants included in the study (GCA- 84 (36.68 %) (Figure 1). Study recruited during Covid pandemic,73 completed,11 lost to follow-up (died -7, withdrawn-4). The deceased/withdrawn patients (compared to completers) were older (80 v74 yrs, p=0.018), preponderantly male (73% v 36%, p=0.043) with visual symptoms (91% v 49%, p=0.010) partial/total sight loss (55% v 21%, p=0.024), lower CRP (21 v 68, p=0.061) and ESR (42 v 62, p= 0.317). Of 73 completers 36 required early DMARDs (<12 weeks) for refractory/relapsing/ischemic/GC related AEs. This group had more LV involvement (50% v 11%, p=0.0003), Remission attained at 12 months 32/36 (89%) in DMARD group was comparable to the remitting GC monotherapy group 33/37 (89%) with comparable cumulative GC doses (Figure 1, Table 1). At 12-months follow up, median TAHS, AAHS and THS reduced from 13 to 3, 12 to 9 and 21.5 to 12, respectively.

Conclusion: Our study suggests, elderly males with visual symptoms, sight loss, lower CRP are a high-risk group with increased mortality within GCA. Difficult to treat disease is seen in half of all patients especially with LV involvement. This group responds well to early DMARD use achieving remission comparable to the remitting group at 12 months. Current therapies fail to achieve remission in 9.5 % of cases. HS and HC show significant improvement mirroring clinical outcomes during first 12 months of therapy.

Background: Ultrasound (US) is recommended as the first-line imaging test in patients with suspected Giant Cell Arteritis (GCA). Traditionally, the US halo sign has been used for diagnosis. We have described a composite Halo Score that allows quantifying vascular inflammation on US. Prospective studies on response and disease monitoring are lacking.
Objectives: To prospectively assess the role of the US and Southend GCA pretest probability score (GCAPS) in diagnosing and monitoring GCA patients. We report 12-month follow-up data on our current recruitment.
Methods: HAS GCA (IRAS#264294) is a prospective, multicentre study recruited from 7 European centres, referrals of suspected GCA to fast-track clinics. Based on the GCAPS [1], patients were stratified in to low, intermediate and high risk categories [2]. Temporal and axillary US Halo Scores were calculated from the halo thickness and extent in bilateral temporal arteries, parietal and frontal branches (TAHS) and axillary arteries (AAHS). These scores were summed (TAHS x1 plus; AAHS x3) to generate a Total Halo Score (THS) [3]. Remission defines as the patient on prednisolone ≤ 5mg at 12 months follow up. Mann Whitney U test was used to compare baseline features between GCA and controls. Wilcoxon signed rank test was used to evaluate disease features at baseline and at 12 months in GCA patients. Sensitivity (Sn), Specificity (Sp) and ROC curve were calculated, where applicable. P value <0.05 is statistically significant.
Results: 229 patients (84 GCA, 145 controls) have been recruited from 7 European centres: 73 completed 12-month follow-up assessments; 11 were lost to follow-up (7 died, 4 withdrew consent due to pandemic). 65 achieved remissions at 12months. Demographics, clinical features, and US results are shown (**Table 1**). Among GCA patients, 60 had cranial, 5 large-vessel and 19 mixed phenotypes. Diseases were diagnosed by US and additional tests such as PET CT. Jaw claudication (54%) and constitutional symptoms (52%) were the dominant features in GCA patients compared to controls. Median age was 75 years in GCA (60% females) and 68 years in controls (69% females). GCA and controls were stratified by GCAPS to Low risk (0% vs 46%; Sn-undefined, Sp-99), Intermediate risk (21% vs 38%; Sn-83, Sp-98) and High risk (79% vs 16%; Sn-99, Sp-91). Optimal GCAPS cut-off point was ≥12 (Sn-89, Sp-78). Median THS was 21.5 in GCA and 8 in controls. Optimal cut-off Halo Score in diagnosis was TAHS ≥6 (Sn-86, Sp-92), AAHS ≥11 (Sn-52, Sp-75), THS ≥17 (Sn-76%, Sp-91%). Baseline Halo Score and CRP levels showed positive correlation (spearman rank correlation). at 12-months follow up, median TAHS, AAHS and THS reduced from 13 to 3, 12 to 9 and 21.5 to 12, respectively (**Figure 1**).
Conclusion: Along with GCAPS, Halo Score successfully discriminates GCA from non GCA mimics and. HS is effective in showing 12-month response. This score may be a useful marker to monitor GCA disease activity.

POS0732

PERFORMANCE OF THE 2022 ACR/EULAR CLASSIFICATION CRITERIA FOR GIANT CELL ARTERITIS IN ROUTINE CLINICAL CARE

Keywords: Ultrasound, Vasculitis, Imaging

J. Molina Collada[1], I. Castrejon[1], I. Monjo[2], E. Fernández-Fernández[2], G. Torres Ortiz[2], J. M. Alvaro-Gracia[1], E. De Miguel[2]. [1]*Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain*; [2]*La Paz University Hospital, Rheumatology, Madrid, Spain*

Background: The 2022 ACR/EULAR giant cell arteritis (GCA) classification criteria have been designed to improve diagnostic accuracy incorporating vascular

imaging modalities and potential large vessel (LV) involvement. These new criteria have been validated in an independent set of patients and controls, with a sensitivity of 87.0% and a specificity of 94.8%, but not tested in routine care.

Objectives: Our objective is to examine the performance of the new 2022 ACR/EULAR GCA classification criteria in this clinical scenario.

Methods: Multicentric retrospective observational study of patients referred to our ultrasound (US) fast track clinic over a 4-year period. The gold standard for GCA diagnosis was clinical confirmation after 6 months of follow-up. Patients with GCA were compared with unselected controls referred to our clinic with suspected GCA. All patients underwent US exam of temporal and extracranial arteries (carotid, subclavian and axillary) within 24-48 hours at baseline. FDG-PET/CT was performed according to standard clinician criteria. Following the new 2022 GCA ACR/EULAR classification criteria, the total score for the 10 items included in the criteria was calculated, with a total cut-off ≥ 6 for the classification of GCA. The performance of these criteria was evaluated in all GCA patients across different subsets of the disease.

Results: A total of 319 patients (188 cases and 131 controls) were included for analysis (mean age 76 years, 58.9% females). Patients with GCA and controls differed in age (78.2 vs 72.9, p<0.001) and sex (females 53.2% vs 67.2%, p=0.013). The diagnostic accuracy of the 2022 ACR/EULAR GCA classification criteria and the previous 1990 ACR GCA classification criteria in different subsets of patients is shown in Table 1. Overall, the new criteria had a sensitivity of 92.6% and a specificity of 74%, using GCA clinical diagnosis as an external criterion and the area under the curve (AUC) was 0.932 (95% CI 0.903 to 0.960). Isolated LV-GCA showed a sensitivity of 62.2% and a specificity of 74% (AUC 0.696 [0.596 – 0.796]) and biopsy-proven GCA showed a sensitivity of 100% and a specificity of 74% (AUC 0.992 [0.981 – 1]).

Conclusion: The new 2022 ACR/EULAR GCA classification criteria showed good diagnostic accuracy of patients with suspected GCA under routine care, and a substantial improvement upon the sensitivity and specificity of the 1990 ACR GCA classification criteria in all patients subsets.

Table 1. Diagnostic accuracy of the new 2022 ACR/EULAR GCA and the 1990 ACR/EULAR classification criteria, with clinical diagnosis serving as the external criteria in all GCA, patients with isolated cranial GCA, isolated LV-GCA, all LV-GCA and biopsy proven GCA. GCA, giant cell arteritis; LV, large vessel; Sens, sensitivity; Spec, specificity; LR+, positive likelihood ratio; LR–, negative likelihood ratio; AUC: area under the ROC curve analysis

		Sens	Spec	LR+	LR-	AUC (95% CI)
All GCA (n = 188) vs controls (n = 131)	2022 ACR/EULAR criteria	92.6%	74%	3.56	0.1	0.932 (0.903 – 0.960)
	1990 ACR criteria	53.2%	80.2%	2.68	0.58	0.719 (0.663 – 0.775)
Isolated cranial GCA (n = 83) vs controls (n = 131)	2022 ACR/EULAR criteria	96.4%	74%	3.71	0.05	0.965 (0.933 – 0.996)
	1990 ACR criteria	61.4%	80.2%	3.1	0.48	0.764 (0.699 – 0.829)
Isolated LV-GCA (n = 37) vs controls (n = 131)	2022 ACR/EULAR criteria	62.2%	74%	2.39	0.51	0.696 (0.596 – 0.796)
	1990 ACR criteria	18.9%	80.2%	0.95	1.01	0.554 (0.455 – 0.653)
Biopsy proven GCA (n = 21) vs controls (n = 131)	2022 ACR/EULAR criteria	100%	74%	3.85	0	0.992 (0.981 – 1)
	1990 ACR criteria	95.2%	80.2%	4.81	0.06	0.931 (0.877 – 0.985)
LV-GCA (with or without cranial GCA) (n = 105) vs control (n=131)	2022 ACR/EULAR criteria	89.5%	74%	3.44	0.14	0.905 (0.865 – 0.946)
	1990 ACR criteria	46.7%	80.2%	2.36	0.66	0.683 (0.616 – 0.751)

POS0733 REPEATING TEMPORAL AND AXILLARY ARTERY ULTRASOUND SCANS IN PATIENTS WITH SUSPECTED GIANT CELL ARTERITIS WITH NEGATIVE SCAN AT PRESENTATION

Keywords: Real-world evidence, Ultrasound, Vasculitis

A. Verdiyeva[1], L. James[1], D. Kurzeja[2], J. Martinho[3,4], R. Luqmani[1]. [1]*Nuffield Orthopaedic Centre, Rheumatology, Oxford, United Kingdom*; [2]*John Radcliffe Hospital, Medicine, Oxford, United Kingdom*; [3]*Hospital de Santa Maria, Rheumatology, Lisboa, Portugal*; [4]*Faculty of Medicine, University of Lisbon, Medicine, Lisboa, Portugal*

Background: Giant cell arteritis (GCA) is a medical emergency due to its risk of severe ischaemic complications such as irreversible blindness [1]. Treatment with systemic glucocorticoids (GC) should be initiated to prevent these complications promptly. However, this can compromise the confirmation of the diagnosis by decreasing the sensitivity of the temporal and axillary artery ultrasound scan (TA and AX US) recommended for GCA diagnosis [1-3]. One possible strategy for managing patients with symptoms suggestive but not typical of GCA, who have an initial negative TA and AX US on GC treatment, is weaning the GC rapidly and performing a second ultrasound off GC, within six weeks of their initial ultrasound. This practice aims to increase the diagnostic yield of the second ultrasound and safely rule out GCA without submitting the patient to unnecessary GC treatment.

Objectives: To assess the safety of repeating a TA and AX US after a rapid GC taper in patients with suggestive but not typical symptoms of GCA and a negative first ultrasound on a high dose GCs.

Methods: This is a retrospective study that included patients with suspected GCA referred to the Rheumatology department at Nuffield Orthopaedic Centre - Oxford, from Oct 2020 to June 2022. The inclusion criteria were: i) negative first TA and AX US while on treatment with GCs ≥30mg/d; ii) first ultrasound performed at least 6 months prior to the data collection; iii) second ultrasound performed within 6 weeks of the first one. The TA and AX US was considered positive when a non-compressible halo sign was present. Data regarding patient demographics, clinical manifestations, treatment, and outcomes was collected using Electronic Patient Records (EPR). The patients' records were also reviewed to check for any subsequent diagnosis of large vessel vasculitis (LVV) within 6 months of the first TA and AX US.

Results: Twenty-nine patients were included, 19/29 (65.5%) were females and the median age at the time of the referral was 65 (range 51-87). The most frequent clinical manifestation at presentation was temporal headache in 23/29 (79.3%) patients, followed by scalp tenderness in 18/29 (62.3%) and visual disturbance in 15/29 (51.7%). Patients were on GC treatment for a median duration of 10 days (range 3-35) with a median cumulative dose of 480mg (range 120 – 1400mg). All patients were on high doses of GCs, of whom 8/29 (27.6%) were on 60mg of prednisolone, 2/29 (6.9%) on 50mg, 17/29 (58.6%) on 40mg and 2/29 (6.9%) on 30mg. GCs were weaned over an average of 12 days (range 0-28). The second ultrasound was performed after stopping GC treatment for a median of 11 days (range 3-30) and the median interval between the two scans was 23 days (range 6-42). Regarding the second ultrasound, 28/29 (96.5%) patients had a negative and 1/29 (3.4%) had a positive TA and AX US. Moreover, 2/29 (6.9%) patients were found to have LVV on subsequent Positron Emission Tomography (PET) scans that were requested due to clinical suspicion of extra-cranial GCA.

Conclusion: This study shows that for patients presenting with symptoms suggestive but not typical of GCA, who were already on GC treatment, rapid taper of GCs and a negative second TA and AX US safely ruled out GCA in 26/29 (89.6%) patients. Although more studies are needed to confirm these preliminary results, this practice should maintain a good diagnostic ability but prevent unnecessary GC toxicity.

Background: The creation of instruments for the structured assessment of disease activity has facilitated the effective use of DMARDs to control disease activity in patients with inflammatory arthritis. Composite measures for Giant Cell Arteritis (GCA) incorporating several key clinical and laboratory variables which allow for a standardized quantitative assessment of GCA disease activity has been recently introduced. These assessment tools for measuring disease activity are of particular benefit in helping to achieve therapeutic goals in patients with GCA, including amelioration of the symptoms and signs of active disease, and the consequent avoidance of functional impairment and restoration of physical function.

Objectives: To identify the preliminary definition of improvement in GCA and the higher thresholds for improvement reflecting significant and major improvement as well as remission.

Methods: In developing criterion for improvement of individual GCA patients, consideration was restricted to the 6 variables identified as outcome measures: severity of headache (0-100), acute visual deficit (0-100), functional disability (0-3), Patient Global Assessment (0-100), Physician global assessment (0-100), ESR and CRP levels. For each variable, the value at baseline were compared with the value at 4-weeks and 12-weeks of treatment to determine the degree of improvement or deterioration that occurred. The percentage of improvement was calculated directly for each of the 6 variables in 51 patients. Using the 6 variables, preliminary analysis was performed to determine the percentage of improvement. Preliminary definition of improvement required >x% improvement in >y of the 6 variables, where "x" was set at 20%, 30%, 40%, 50%, 70%, 90% and 100%, and "y" was set at 2,3,4,5, or 6 variables. To assess the discriminating power of high response percentages (70%, 90% and 100%) the percentage of improvement in the headache severity (as the main outcome measure reflecting the disease activity status) was compared to the change of the rest of the core set measures. The individual improvement criterion identified was then applied prospectively to a cohort of 25 patients diagnosed to have GCA and starting their therapy.

Results: A definition of >50% improvement in 4 or more variables produced the largest difference between patient's assessment at 4-weeks and 12-weeks in comparison to the baseline. Sharpening the cut-offs to 70% or 90% means that the patient should nearly or completely reach a status of remission in order to fulfil such an impressive improvement criterion. Reaching 100% means that the patient has achieved remission. Outcome of the prospective study revealed that 100% of the patients achieved 50% GCA response. Assessing the higher response rates, revealed that 10% of the patients achieved 70%, 30% achieved 90% whereas 60% achieved 100%.

Conclusion: Core sets of valid outcome measures have been defined. GCA response criteria have been developed and showed comparable validity. The 70% (significant improvement), 90% (major improvement) and 100% (remission) GCA improvement criteria showed good discriminating capacity though less than the 50% criteria. GCA response can be used in standard clinical practice to identify disease activity status and response to therapy. Calculation of GCA-N index would be the next step to attain a continuous variable rather than at arbitrary 20%, 50%, and 70% levels. A second advantage is that a continuous index can include recognition of possible deterioration in addition to improvement.

Background: Despite significant advances in the diagnosis and therapy of giant cell arteritis (GCA), relapses during the disease course are common. The exact predictors for their occurrence at diagnosis or during the disease course have not been defined.

Objectives: To evaluate the frequency and predictors of relapses in a real-life GCA cohort.

Methods: Data were derived from an ongoing, multicenter, prospective cohort study of patients with GCA. Patients were evaluated at baseline and approximately 2 years later. Data regarding their demographics, clinical characteristics, treatment patterns, co-morbidities and relapses were retrospectively and prospectively collected and analyzed. Predictors of relapse were examined by logistic regression analyses.

Results: At the 1st cross-sectional evaluation, 254 patients with GCA were included; 68% were women with a mean age of 72.3 years at diagnosis and a mean disease duration of 2 years. Diagnosis had been established by temporal artery biopsy in 67% (n=171) and by ultrasound of temporal arteries in 21% (n=53) of patients. At the 2nd evaluation (median follow-up: 2.02 years), data were available for 199 patients (78%). All patients had been treated initially with glucocorticoids (GCs, mean prednisolone dose = 40 mg/day) and during the disease course additionally with non-biologic (39%, n=59) and/or biologic (16%, n=25) agents. At the 2nd evaluation time point, 73% of patients were still on therapy with GCs (60%) and/or GC-sparing agents (29%: non-biologics: 16%, biologics: 13%). During the prospective follow-up phase of 2 years, 27% (n=43) of patients had at least one disease relapse. Relapsing patients had shorter disease duration at 1st evaluation (1.4 *vs.* 4 years, p=0.015), more frequent large vessel involvement at diagnosis (21% *vs.* 8%, p=0.019) and cardiovascular events (CDV) during follow-up (14% *vs.* 4.2%, p=0.032), and had received a higher GC daily dose at diagnosis (mean 46.2 *vs.* 39.9 mg, p=0.01) compared to the non-relapsing ones. By multivariable logistic regression analysis, large vessel involvement at diagnosis [odds ratio (OR) (95% confidence intervals) = 4.22 (1.14, 15.58)], a cardiovascular event (CVD) during follow-up [OR = 4.60 (1.11, 19.13)] and a higher GC daily dose at diagnosis [OR = 1.04 (1.00, 1.08)] were associated with disease relapses.

Conclusion: In this large, real-life, long -term GCA cohort, despite continued treatment with GCs and/or GC-sparing agents, relapses occurred in 27% of patients. Factors associated with relapses included large vessel involvement and high GC dose at diagnosis as well as cardiovascular events during follow up. These are novel findings that could be useful in the design of the appropriate monitoring and therapeutic strategies in these patients.

POS0736 SYSTOLE AND DIASTOLE ULTRASOUND WALL THICKNESS SHOWS SIGNIFICANT DIFFERENCES THAT AFFECT THE DIAGNOSIS AND ASSESSMENT OF GIANT CELL ARTERITIS

Keywords: Ultrasound, Vasculitis, Comorbidities

E. Brugarolas Martinez[1,2], E. Fernández-Fernández[2], I. Monjo[2], M. D. C. Uyaguari Morocho[2], E. De Miguel[2]. [1]*Bellvitge University Hospital, Rheumatology, L'Hospitalet de Llobregat, Spain*; [2]*La Paz University Hospital, Rheumatology, Madrid, Spain*

Background: In the last few years, several cut-off points for the intima-media thickness (IMT) of temporal arteries (TA) and large vessels (LV) have been proposed for the ultrasound (US) diagnosis of giant cell arteritis (GCA). It has usually been recommended to use the average measure of the higher IMT, but there is currently a lack of consensus on this. We have observed some changes in the IMT measurements depending of if they are performed in systole or diastole.

Objectives: The main objective of this study is to confirm if there are differences in the IMT measurement taken in systole or diastole and if they are clinically relevant.

Methods: Observational retrospective study on consecutive patients of our GCA fast track clinic. The gold standard diagnosis was the opinion of the clinical doctor after at least 6 months of follow-up. US recorded videos, of every explored vessel temporal (common trunk, frontal and parietal branches), subclavian and axillary arteries were reviewed and the IMT of each of them was measured in systole and diastole peaks for comparison. We define an ultrasound result as positive with cut-off values of IMT ≥ 0.34 mm for frontal and parietal branches, ≥ 0.42 mm for the common trunks of TA, and ≥ 1 mm for the axillary and subclavian arteries. Demographic data of the included patients were also collected.
Results: We have included 72 cases, 36 with GCA diagnosis and 36 without GCA (controls). The mean values of age and sex, as well as the IMT in systole and diastole of each vessel are shown in Table 1. There were not significant differences in sex but patients without GCA were younger (p<0.01). The US IMT measurements at the systolic and diastolic times showed statistically significant differences in all the explored vessels, as in patients with GCA as in the control non GCA group. All the IMT measured in diastole showed higher and statistically significant values than those measured in systole, with a mean increment of measurement of 5.3% and 6.5% in TA and 6.4% and 5.6% in LV, respectively in the GCA and control group. This result can be of clinical relevance because if we used diastolic measures, instead of systolic measures, 5/36 (13.8%) cases in controls had halo sign in one isolated vessel (2 cases in parietal right, 1 in common trunk right, 1 in subclavian right, 1 in subclavian left). However, in GCA patients, the number of patients with halo sign did not change, but the number of pathological vessels was increased when the measured was performed in diastole (1 frontal right branch, 1 common trunk right, 4 frontal left branches, 5 common trunks left and 2 axillary right), so this could have influence in the assessment of the disease.
Conclusion: There are significant differences between the IMT measured in systolic and diastolic peaks, with higher values in diastole. The differences are relatively small but may increase the number of false positives (13.8%) in controls, and the number of affected vessels in the GCA group. This should be considered in the diagnosis and assessment of GCA.

Tariq[2], A. Tomelleri[10], B. Dasgupta[2,3]. *[1]University of Groningen, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]Mid and South Essex University Hospital Groups, Southend University Hospital, Rheumatology, Westcliff-on-sea, United Kingdom*; *[3]University of Essex, School of Sport, Rehabilitation and Exercise science, Colchester, United Kingdom*; *[4]University Hospital Limerick, Rheumatology, Limerick, Ireland*; *[5]University of Siena, Rheumatology Unit, Department of Medicine, Surgery and Neurosciences, Siena, Italy*; *[6]University Hospitals Dorset NHS Foundation Trust, Rheumatology, Dorset, United Kingdom*; *[7]Azienda USL - IRCCS - di Reggio Emilia, Rheumatology, Reggio Emilia, Italy*; *[8]University of Modena and Reggio Emilia, Rheumatology, Modena, Italy*; *[9]Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; *[10]San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: Giant cell arteritis (GCA) is an age-linked, critically ischaemic vasculitis where ultrasound (US) serves as an important tool enabling urgent diagnosis and therapy. US scores have been developed to quantify the arterial inflammation in GCA [1,2], but optimal diagnostic cut-off points and potential bias of age and sex on these values remain un-elucidated.
Objectives: To compare the diagnostic accuracy of previously reported US scores for GCA, and to determine whether these scores require correction for age and sex.
Methods: The HAS-GCA study, with a prospective, multicentre, cohort design, recruited 229 consecutive patients with suspected, new-onset GCA from 7 sites located in the UK, Italy, Spain and the Netherlands. All cases underwent bilateral US evaluation of the three temporal artery segments (common superficial, parietal, frontal) and axillary arteries. Intimal-medial thickness (IMT) was measured in each segment. Three ultrasound scores were calculated based on the IMT: halo count (HCount) [1], Halo Score (HScore) [2] and the OMERACT GCA US Score (OGUS) [2]. The definition of halo was based on previously reported IMT cut-off values [3]. The reference standard was the final clinical diagnosis after 6 months follow-up. ROC with AUC analysis was performed. Optimal cut-off points were determined by Youden Index. Group comparisons were made by Mann Whitney U test and correlations by Spearman's rank correlation coefficient. P values < 0.05 were considered statistically significant.
Results: A final diagnosis of GCA was made in 84 patients, whereas 145 cases received an alternative diagnosis (i.e. non-GCA patients). HCount, HScore and OGUS were significantly higher in GCA patients than non-GCA patients. In non-GCA patients, all three scores were significantly higher in men than women, and showed a statistically significant, positive correlation with age. In GCA patients, the US scores showed a positive correlation (HCount and OGUS) or strong trend for a positive correlation (HScore) with age; and the HCount was significantly higher in men. All scores effectively discriminated GCA from non-GCA patients as indicated by ROC analysis: AUC for halo count 0.936 (0.899-0.974), Halo Score 0.894 (0.848-0.939) and OGUS 0.937 (0.902-0.973). The optimal diagnostic cut-off points were: 2 for HCount (sens 86%, spec 92%), 17 for HScore (sens 76%, spec 91%) and 0.80 for OGUS (sens 87%, spec 93%). These diagnostic cut-off points differed in sensitivity and specificity within different age- and sex-defined groups with the highest sensitivity and lowest specificity observed among old (>81yr) male patients. Alternatively, age- and sex-stratified cut-off points could be established for the US scores (Table 1).
Conclusion: All previously reported US scores show excellent diagnostic accuracy for GCA, but are prone to over-diagnose GCA in older males. Our data highlight the need for age- and sex-specific diagnostic cut-off points. The excellent comparative performance of the simple HCount in GCA diagnosis suggests an exciting role in future clinical practice.

TREAT-TO-TARGET STRATEGIES IN GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA: A SYSTEMATIC LITERATURE REVIEW INFORMING AN INTERNATIONAL TASKFORCE

Keywords: Remission, Vasculitis, Treat to target

E. Hysa[1], M. Bond[2], L. Ehlers[3], D. Camellino[4], L. Falzon[5], C. Dejaco[2,6], F. Buttgereit[3], D. Aletaha[7], A. Kerschbaumer[7]. *[1]San Martino Polyclinic, University of Genoa, Italy, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology - Department of Internal Medicine, Genoa, Italy*; *[2]Hospital of Bruneck (ASAA-SABES), Department of Rheumatology, Bruneck, Italy*; *[3]Charitè - Universitätsmedizin Berlin, Corporate Member of Freie, Universität Berlin and Humboldt-Universität zu Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[4]Local Health Trust 3, Division of Rheumatology, Genoa, Italy*; *[5]University of Sheffield, University of Sheffield, South Yorkshire, United Kingdom*; *[6]Medical University Graz, Department of Rheumatology, Graz, Austria*; *[7]Medical University of Vienna, Division of Rheumatology, Department of Medicine III, Vienna, Austria*

Background: Polymyalgia rheumatica (PMR) and Giant cell arteritis (GCA) are chronic inflammatory diseases. Despite the progress made in the management of these conditions, new unmet needs have emerged particularly in terms of prevention of disease- and treatment-related complications. A treat-to-target (T2T) strategy, which has been well established in other rheumatic diseases, has not yet been developed for PMR and GCA.
Objectives: To retrieve current evidence on T2T strategies in PMR and GCA to inform an international task force (TF) developing T2T recommendations.
Methods: A systematic literature review (SLR) was conducted. Medline, EMBASE, Cochrane Library and clinicaltrials.gov (from inception until May 2022), as well as EULAR/ACR abstract databases were searched (2019-2021). Randomized controlled trials (RCTs) and non-randomized interventional studies published in English and answering at least one of the eleven PICO questions on treatment targets and outcomes, were identified (Table 1). The study selection process, data extraction, data synthesis and risk of bias assessment were conducted independently by two investigators.
Results: Of 7809 screened abstracts, 397 were selected for detailed assessment and 76 papers were finally included (31 RCTs, 8 subgroup/exploratory analyses of RCTs and 37 non-randomized interventional studies). No study comparing a T2T strategy against standard of care was identified. In PMR RCTs, treatment-related outcomes were most commonly used (90.9% of RCTs), specifically in terms of the glucocorticoids (GC) cumulative dose and GC tapering, followed by clinical, laboratory and safety targets (63.3% each). Conversely, the most frequently reported outcomes in RCTs in GCA were prevention of relapses (72.2%), remission, treatment, and safety (66.7 % each). Remission and relapses were variably defined in PMR and GCA RCTs but, in most cases, they comprised a combination of clinical and laboratory parameters (Figure 1). The following predictors of poor treatment response were identified: for GCA, data from RCTs yielded female sex, initial prednisone dose <30mg/day, bad baseline patient-reported outcomes, increased inflammatory markers after the achievement of clinical remission and absence of PMR symptoms at baseline as risk factors for treatment failure and an increased relapse rate. In PMR, no high-quality data predicting clinical outcomes were identified. Finally, in RCTs comparing the outcomes of GCA patients with new onset versus established disease, no differences were found, given that treatment was equal in both groups.
Conclusion: This SLR informed an international TF developing T2T recommendations in PMR and GCA. It provides up-to-date evidence while simultaneously highlighting the gaps in current knowledge about T2T strategies in these diseases.

Table 1. Clinical key questions

1. What are the treatment targets and outcomes in GCA/PMR, and how can they be measured (imaging, lab parameters, clinical, PRO)?
2. Is coming-off GC a treatment target in GCA/PMR, and how quickly should it be achieved?
3. What should be the frequency of monitoring disease state/ adapting therapy? How fast and to what extent should disease activity change before requiring treatment modification?
4. How do comorbidities influence T2T outcomes in GCA/PMR?
5. What are comorbidities related to uncontrolled disease activity?
6. Do targets need to be adapted based on the presence of comorbidities?
7. Is residual disease activity acceptable, and to what extent?
8. How can reaching disease targets, reducing/ preventing treatment side effects, and long-term consequences of disease be balanced in GCA/PMR? What is more important: control of disease activity or prevention of treatment related adverse effects?
9. Can treatment success be predicted?
10. What are the predictors of successful treatment reduction (e.g., duration on target)?
11. Do treatment targets differ over time (early vs. established disease)?

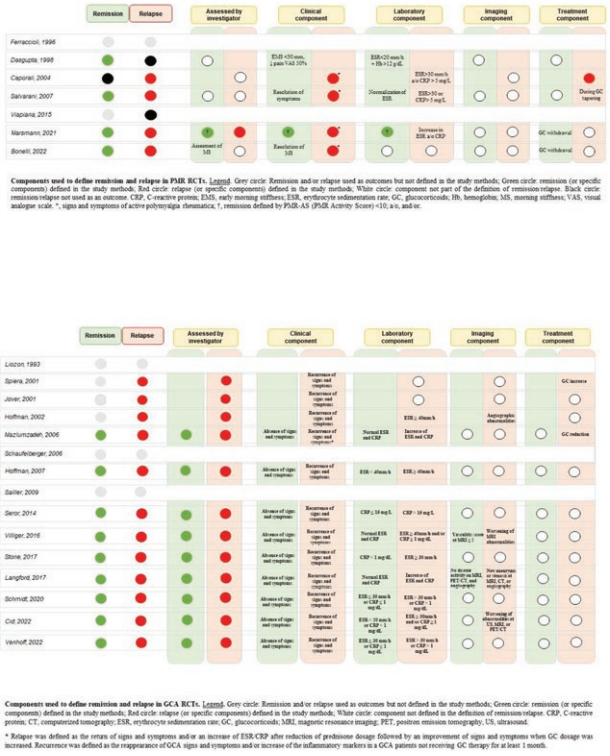

Figure 1. Components used to define remission and relapse in PMR and GCA RCTs

POS0738 CHILDHOOD ABDOMINAL/PELVIC PAIN AS A PREDICTOR OF RECURRENT MUSCULOSKELETAL PAIN IN ADOLESCENT BOYS AND GIRLS: A PROSPECTIVE POPULATION-BASED STUDY

Keywords: Epidemiology, Pain

F. Fernandes[1], N. Navasardyan[1], M. J. Santos[2], M. Talih[3], R. Lucas[1]. [1]*Instituto de Saúde Pública da Universidade do Porto (ISPUP), EPIUnit, Porto, Portugal*; [2]*Hospital Garcia de Orta, Serviço de Reumatologia, Almada, Portugal*; [3]*Faculdade de Medicina da Universidade do Porto - FMUP, CISPFEM, Porto, Portugal*

Background: Primary musculoskeletal pain conditions interfere greatly with the quality of life and are challenging to manage, from the patient's and clinician's perspectives. Susceptibility to chronic musculoskeletal pain syndromes in adulthood can be traced back to childhood when prevention might be most effective. Population-based longitudinal studies in pediatric ages allow for testing different predictors of pain trajectories to assist risk stratification. Recurrent pain experiences in non-musculoskeletal sites are common in young children and may be red flags for future musculoskeletal pain susceptibility [1].
Objectives: We aimed to quantify the prospective association of non-musculoskeletal pain experiences at ages 7 and 10 with recurrent musculoskeletal pain at age 13 in a large population-based cohort of boys and girls.
Methods: We used data from Generation XXI, a population-based birth cohort setup in 2005-06 in the public maternities of Porto, Portugal. Participants were invited to regular follow-up visits at ages 7, 10, and 13 years. In each wave, pain history in the previous 3 months was assessed using the Luebeck Pain Screening Questionnaire, applied to caregivers (ages 7 and 10) and adolescents (age 13). We included only the main pain identified in the questionnaire, and only if it occurred more than once in the previous 3 months. Musculoskeletal pain sites comprised upper/lower limbs, back, neck, shoulders, hips, and generalized musculoskeletal. Non-musculoskeletal sites were head, abdomen/pelvis, or other. We calculated relative risks and 95% confidence intervals for the association between pain sites at ages 7 and 10 and recurrent musculoskeletal pain at age 13. The analysis was stratified by sex at birth.
Results: We included 3833 participants (47.9% girls). Recurrent pain was reported in 28.4% of children at age 7 (25.7% of boys, and 31.3% of girls), 26.6% at age 10 (23.3% of boys, and 30.2% of girls), and 35.1% at age 13 (28.8% of boys, and 41.9% of girls). For girls, the most reported recurrent pain sites before adolescence were abdomen/pelvis (10.3% at 7, and 9.7% at 10), musculoskeletal (8.1% at 7, and 9.0% at 10), and head (7.7% at 7, and 7.3% at 10). In boys, recurrent pain was more frequent in musculoskeletal sites (9.0% at 7, and 9.6% at 10), followed by abdomen/pelvis (7.7% at 7, and 5.0% at 10), and head (5.1% at 7, and 6.0% at 10). As shown in the Figure 1, in 7-year-old girls, only abdominal/pelvic pain was predictive of future musculoskeletal pain at age 13 RR 1.43; (95%CI 1.07, 1.87). At age 10, musculoskeletal pain became predictive of musculoskeletal pain at age 13 [1.44 (1.07 - 1.84)]. In boys aged 7 years, both musculoskeletal and abdominal/pelvic pain were predictive of future musculoskeletal pain at age 13 [1.49 (1.13, 1.91) and 1.40 (1.02, 1.86), respectively]. At age 10 only musculoskeletal pain remained predictive of musculoskeletal pain at age 13 [1.45 (1.11, 1.84)].
Conclusion: In this population-based cohort, musculoskeletal pain in adolescents was preceded by non-musculoskeletal pain experiences - especially abdominal/pelvic pain - during childhood in both boys and girls. Widening the scope to non-musculoskeletal sites may contribute to the early detection and risk stratification of individuals who are more susceptible to developing chronic musculoskeletal pain trajectories.

POS0739 LEUCOCYTE ABNORMALITIES AND CYTOKINE LEVELS IN SYNOVIAL FLUID OF JUVENILE IDIOPATHIC ARTHRITIS PATIENTS: A PRELIMINARY STUDY

Keywords: Cell biology, Cytokines and chemokines, Uveitis

A. Scanu[1], F. Tirelli[1], A. Meneghel[1], R. Luisetto[2], C. Baggio[3], M. L. Cagnato[1], R. Ramonda[3], F. Oliviero[3], G. Martini[1], F. Zulian[1]. [1]*University of Padova, Department of Women's and Children's Health-SDB, Padova, Italy*; [2]*University of Padova, Department of Surgery, Oncology and Gastroenterology-DISCOG, Padova, Italy*; [3]*University of Padova, Department of Medicine-DIMED, Padova, Italy*

Background: Juvenile idiopathic arthritis (JIA) is a heterogeneous group of diseases characterized by joint inflammation and uveitis is the most frequent extra-articular manifestation [1,2]. Although several studies evaluated the differences between the different types of JIA, no specific markers have been identified which would allow early stratification of patients and predict the future disease course. Recently, it has been suggested that rheumatic diseases might be associated with genomic instability and increased sensitivity to DNA damage (3), but it has not yet determined in JIA.
Objectives: To investigate cell populations, cytokine levels, and signs of genotoxicity in synovial fluid (SF) of patients with different JIA subtypes.
Methods: SF was collected from the knees of 24 patients, untreated for at least 6 months prior to enrollment, and fulfilling ILAR criteria (4): 9 with polyarticular (poly)-JIA (age:6.56±4.67 years) and 15 with oligoarticular (oligo)-JIA (age:8.33±5.15 years). Six poly-JIA and 8 oligo-JIA patients were at disease onset. Among the oligo-JIA patients, 12 had positive antinuclear antibodies (ANA+) and 5 had uveitis. SF was examined under optical light microscopy. White cell count (WBC) and the polymorphonuclear cell (PMN) percentage were determined in SF according to standard procedures. May-Grünwald-Giemsa staining was used to determine the percentage of hypo- or hypersegmented PMN, binucleated monocytes, and cells with micronuclei (MN), pyknosis, necrosis, apoptosis and nuclear buds, which are considered biomarkers of genotoxic events. SF IL-1β and IL-8 levels were assayed by ELISA.
Results: WBC count and PMN percentage were higher in SF of patients with poly-JIA than in those with oligo-JIA, albeit not significantly. Comparison between the two groups at disease onset showed that WBC levels and PMN percentage were significantly greater in SF from poly-JIA (poly-JIA WBC:10500±4580.32 cells/mm^3, PMN:59.83±13.75%; oligo-JIA WBC:4850±1050 cells/mm^3, PMN:41.5±16%; $p<0.05$). IL-1β and IL-8 levels were higher in children with poly-JIA, but the difference reached statistical significance only for IL-8 in patients at disease onset (poli-JIA:1253.19±264.4 pg/ml; oligo-JIA:519.67±468.34 pg/ml; $p<0.01$). This group also showed a percentage of cells with MN significantly greater as compared to that in oligo-JIA (poli-JIA:7.1±2.42%; oligo-JIA:1.75±2.05%; $p<0.001$). Although SFs from oligo-JIA-ANA+ patients had higher WBC and PMN percentage than those from oligo-JIA-ANA-, no significant differences were observe between the 2 groups. SFs from oligo-JIA patients with uveitis showed higher but not significant IL-8 levels (554.06±520.26 pg/ml), significantly greater IL-1β concentrations (100.94±76.05 pg/ml; $p<0.05$) and percentage of cells with MN (5.73±3.06%; $p<0.05$), and significantly lower hypersegmented PMN percentage (11.06±8.45%; $p<0.05$) than those from oligo-JIA patients without uveitis (IL-8:280.88±310.11 pg/ml; IL-1β:6.04±15.4 pg/ml; cells with MN:1.96±2.36%; hypersegmented PMN:22.79±8.07%). There was no significant difference in the other studied parameters between the different patient groups.
Conclusion: This study shows that poly-JIA SFs have higher inflammation marker levels than oligo-JIA SFs, and this is observed mostly at the disease onset. The presence of MN may be associated with SF genotoxic effects, and trigger the induction of inflammatory pathways that contribute to disease complications. As hypersegmented PMN suppress T cell proliferation, a low cell number with this phenotype may reflect a persisting antigenic stimulus.

Background: Behçet's syndrome (BS) is an autoinflammatory disease characterized by a variable vessel vasculitis. In children, BS may start early in life, mimicking other autoinflammatory diseases and making the diagnosis challenging. In the past, several criteria have been created for adult BS classification. In 2015, the first set of BS paediatric classification criteria, the PEDBD, was proposed by an international Expert consensus [1].
Objectives: to perform an external validation of the PEDBD criteria in a cohort of internationally validated paediatric BS patients.
Methods: 210 patients (70BS, 40 PFAPA, 35 FMF, 26 MKD, 22 TRAPS, 17 UND/ SURF) were randomly selected from the Eurofever Registry (patients excluded if > 16 years and if included in first PEDBD study). A set of 11 Experts blinded to original diagnosis, were chosen to evaluate the patients: in the 1st round, clinical and serological data were evaluated; in the 2nd round genetic data were added; in the 3rd round the other Experts' votes and comments were shown. Using the expert consensus as gold standard (agreement>80%), the PEDBD, the ISG and the ICBD criteria were applied to BS patients and to the confounding diseases in order to define the sensitivity, specificity and accuracy.
Results: At the end of the 3rd round, a consensus on the initial diagnosis was reached in 112/210 patients (53.3%), with an additional consensus on a different final diagnosis in 27 patients. The BS patients with an agreement (24) were classified as confirmed-BS, and those with an agreement of 60-70% (10) as probable-BS. In confirmed-BS patients, oral ulcers were present in all the patients, genital ulcers in 77%, skin manifestations in 50%, a positive pathergy reaction in 39%, anterior and posterior uveitis in 29 and 27%, retinal vasculitis and papillary oedema in 8% of patients, with a resulting impaired vision in 17%. Venous thrombosis was present in 2 patients (8%). The patients with ocular and vascular involvement were all males. Cranic nerve palsy (17%) was the most frequent neurologic symptom. Abdominal pain was present in 33%, diarrhoea and gastrointestinal bleeding in 13% and anal/perianal ulcers in 8%. 29% presented arthralgia, and 13% arthritis. Fever was present in 50% of patients. HLA-B51 was positive in 69% of patients. When comparing these patients with the confounding diseases, an older age at disease onset, the presence of oral and genital ulcers, skin papulo-pustular lesions, a positive pathergy test and posterior uveitis were BS distinctive elements. The ISG, ICBD and PEDBD criteria were applied to confirmed and probable-BS and to the confounding disease controls, resulting in the following test characteristics (Table 1).

Table 1.

Criteria	Sensitivity	Specificity	Accuracy
ISG	0.50	1.0	0.90
ICBD	0.79	0.98	0.95
PEDBD	0.58	0.99	0.91

Conclusion: the PEDBD criteria were extremely specific but had a lesser sensitivity than ICBD which had a better accuracy. One limitation is that specific monogenetic BS mimics were not included as disease controls, thus the true accuracy of all these criteria may be lower in practice. The complexity of childhood BS suggests that genotyping (incorporating autoinflammatory diseases, BS mimics, and HLA-type) combined with clinical features are likely to yield the most accurate classification criteria, which would require further validation in a larger cohort.

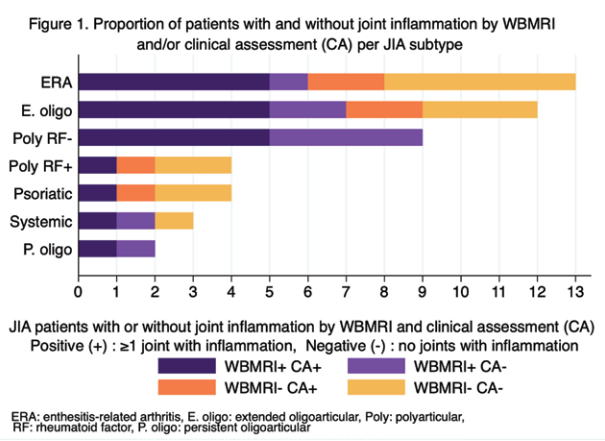
POS0741 CLINICALLY UNSUSPECTED JOINT INFLAMMATION DETECTED BY WBMRI IS MORE FREQUENT IN JIA PATIENTS THAN CONTROLS

Keywords: Inflammatory arthritides, Outcome measures, Imaging

V. Choida[1,2,3], T. Bray[3,4], N. Van Vucht[4], M. A. Abbasi[4], A. Bainbridge[3,5], T. Parry[3], D. Sen[1,2], S. Mallett[3], C. Ciurtin[1,2], M. Hall-Craggs[3,4]. *[1]University College London, Centre for Adolescent Rheumatology Research, London, United Kingdom*; *[2]University College London Hospitals NHS Foundation Trust, Rheumatology, London, United Kingdom*; *[3]University College London, Centre for Medical Imaging, London, United Kingdom*; *[4]University College London Hospitals NHS Foundation Trust, Radiology, London, United Kingdom*; *[5]University College London Hospitals NHS Foundation Trust, Medical Physics, London, United Kingdom*



Background: Whole-body MRI (WBMRI) enables a comprehensive assessment of joint inflammation in children and young people (CYP) with juvenile idiopathic arthritis (JIA). The clinical relevance of WBMRI-detected inflammation in joints requires further assessment.
Objectives: To evaluate the frequency of WBMRI-detected subclinical joint inflammation in CYP with JIA and without inflammatory arthritis. To explore the relationship between WBMRI-detected and clinically detected joint inflammation in patients with JIA.
Methods: CYP aged 14-24 with JIA (any subtype) or non-inflammatory joint pain (controls) were prospectively recruited in a cross-sectional study. All participants underwent a Dixon-based WBMRI scan after being clinically assessed. Based on clinical findings, the CYP with JIA were divided into the active (≥1 active joint or sacroiliitis) and inactive group (no active joints or sacroiliitis). Three musculoskeletal radiologists blindly and independently reviewed the post-contrast images for joint inflammation, and this was considered present if detected by ≥2 radiologists. Peripheral joint inflammation was defined as above-normal intensity synovial enhancement with ≥1 additional feature (synovial hypertrophy, subarticular osteitis, joint effusion or periarticular soft tissue oedema). The frequency of subclinical joint inflammation (WBMRI-detected inflammation in ≥1 clinically inactive joint per participant) was compared between the control and JIA groups, and between the JIA subgroups using unpaired proportions.
Results: 47 CYP with JIA and 13 controls were included. The median age of participants was 17 years (IQR 16 to 20) with 62% and 85% female in JIA and controls respectively. Twenty-seven (57%) participants with JIA were treated with biologic disease-modifying anti-rheumatic drugs (DMARDs) and 29 (62%) with conventional synthetic DMARDs. The frequency of WBMRI-detected joint inflammation was higher in active than inactive JIA patients (Table 1). A higher percentage of patients with JIA were detected to have subclinical inflammation by WBMRI (49%, 23/47) compared to controls (15%, 2/13), difference of 34% (95% CI: 9, 58)). One joint with inflammation was detected by WBMRI in both controls, respectively. Fifty-six per cent (14/25) of JIA patients labelled active clinically had WBMRI-detected subclinical inflammation, compared to 41% (9/22) of clinically inactive JIA patients [difference: 15% (95% CI:-13, 43)]. The proportions of patients classified as active or inactive by both clinical and WBMRI assessment varied between JIA subtypes (Figure 1).
Conclusion: This study demonstrated that WBMRI-detected subclinical joint inflammation is a common finding in JIA, but rare in controls. Inflammation is more common in patients with clinically active compared with inactive disease.

This suggests that inflammation seen on WBMRI is a reflection of disease and not artefactual.

Table 1. Frequency of WBMRI-detected joint inflammation [n (%)] compared to clinical assessment

		Active JIA	Inactive JIA	Difference (95% CI)
WBMRI	**+**	19 (76%)	9 (41%)	35% (9%,62%)
	-	6 (24%)	13 (59%)	
	Total	25	22	

WBMRI +: participants with inflammation in ≥1 joint by WBMRI, WBMRI -: participants without joint inflammation on WBMRI. CI: confidence interval.

POS0742 CLUSTERS OF JUVENILE PSORIATIC ARTHRITIS IDENTIFIED AT INITIAL PRESENTATION TO PAEDIATRIC RHEUMATOLOGY IN A NATIONWIDE UK COHORT

Keywords: Epidemiology, Artificial Intelligence, Psoriatic arthritis

S. Shoop-Worrall[1], C. Ciurtin[2], G. Cleary[3], F. Mcerlane[4], L. Coates[5], N. Geifman[6], K. Hyrich[1,7]. *[1]The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; [2]University College London, Centre for Adolescent Rheumatology, Division of Medicine, London, United Kingdom; [3]Alder Hey Children's Hospital, Paediatric Rheumatology, Liverpool, United Kingdom; [4]Great North Children's Hospital., Paediatric Rheumatology, Newcastle-upon-Tyne, United Kingdom; [5]University of Oxford, Oxford Psoriatic Arthritis Centre, Oxford, United Kingdom; [6]University Of Surrey, School of Health Sciences, Faculty of Health and Medical Sciences, Surrey, United Kingdom; [7]Manchester University NHS Foundation Trust, NIHR Manchester BRC, Manchester Academic Health Science Centre, Manchester, United Kingdom*

Background: The heterogenous presentation and variable clinical response of juvenile psoriatic arthritis (JPsA) to disease-modifying therapies suggests undiscovered subgroups within this disease. Nevertheless, JPsA is often studied under the umbrella of juvenile idiopathic arthritis (JIA), with few studies interrogating JPsA separately. To improve stratified treatment of this rare disease, such subgroups must be uncovered.
Objectives: To identify novel, phenotypically consistent subgroups of children and young people (CYP) with JPsA at the point of first contact with paediatric rheumatology.
Methods: CYP were initially selected if enrolled between January 2001 and December 2019 to the Childhood Arthritis Prospective Study, a UK, multicentre, prospective inception cohort of JIA. Those who had a physician's diagnosis of JPsA at any time point through the 10-year follow-up were included, to allow for onset of psoriatic signs after initial diagnosis. At initial presentation to paediatric rheumatology, clinical features within the ILAR classification criteria for JPsA were collected: an active joint count and the presence or absence of psoriasis, dactylitis and nail abnormalities. Latent class analysis used these features to identify clusters of disease. Between one and ten clusters were tested and an optimal model selected based on statistical fit.
Results: Of 1,753 CYP with JIA recruited to CAPS within the study period, a total of 161 CYP had ever had a diagnosis of JPsA (n=97 diagnosed as JPsA at initial presentation to paediatric rheumatology). The majority were female (61%), of white ethnicity (94%) and the median age at initial presentation was 10 years (IQR 6, 13). The optimal latent class model identified two clusters of JPsA. An oligoarticular cluster (90%, median active joint count (IQR): 2 (1,5)) had a higher proportion of CYP affected by psoriasis (Cluster 1: 29%, Cluster 2: 14%). A polyarticular cluster (10%, median active joint count (IQR): 20 (16, 27)) had a higher proportion with nail abnormalities (Cluster 1: 8%, Cluster 2: 27%). There were similar proportions of dactylitis among the clusters (Cluster 1: 18%, Cluster 2: 15%) (Figure 1).
Conclusion: This study identifies two clusters of JPsA at initial presentation to paediatric rheumatology with differences in key features used to classify this disease. Such subgroups may have different experiences of disease, and future analysis will explore characteristics, alongside disease impact and response to therapy for these groups.

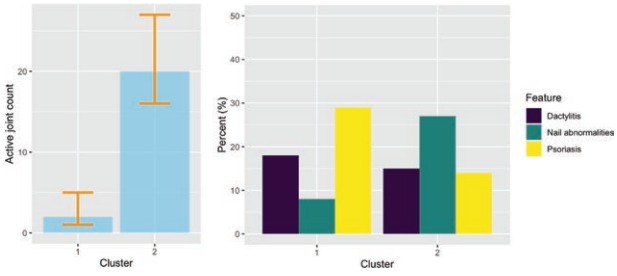

Figure 1. Characteristics of two JPsA clusters identified at initial presentation to paediatric rheumatology

POS0743 THE DIAGNOSTIC AND PROGNOSTIC ROLE OF SYNOVIAL TISSUE ANALYSIS IN JUVENILE IDIOPATHIC ARTHRITIS: A MONOCENTRIC STUDY

Keywords: Synovium, Prognostic factors, Inflammatory arthritides

S. Costi[1], E. Armiraglio[2], F. Pregnolato[3], C. Chighizola[1,3], A. Marino[1], C. Iannone[3,4], A. Amati[3,4], P. Randelli[3,5], A. Parafioriti[2], R. Caporali[1,3,4]. *[1]ASST G.Pini-CTO, Unit of Pediatric Rheumatology, Milan, Italy; [2]ASST G.Pini-CTO, Department of Pathological Anatomy, Milan, Italy; [3]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [4]ASST G.Pini-CTO, Department of Rheumatology and Medical Science, Milan, Italy; [5]ASST G.Pini-CTO, 1° Orthopedic Clinic, Milan, Italy*

Background: Juvenile idiopathic arthritis (JIA) refers to arthritis persisting for more than 6 weeks and presenting before 16 years. Once the diagnosis of JIA has been formulated, clinicians face challenges in tailoring the therapeutic approach upon each patient's clinical features. To date, no study has addressed the role of synovial pathobiology to support the diagnostic approach and guide clinical management in children.
Objectives: This study aimed at investigating the diagnostic role of synovial biopsy in children presenting with arthritis and assess the prognostic significance of synovial histology in predicting clinical outcomes among patients with JIA.
Methods: Medical records of pediatric patients undergoing synovial biopsy between 1995 and 2020 were retrospectively reviewed. Synovial samples were analyzed histologically and immunohistochemically.
Results: Of 99 patients included, synovial biopsy was performed for diagnostic purposes in 65 cases allowing to correctly classify 79% of patients. At histological

analysis on 42 JIA samples, any difference emerged between JIA subsets (Table 1) or treatment-naïve and treatment-experienced subjects. Tissue analysis predicted subsequent disease course: higher number of layers of synovial lining predicted a worse disease course (>4 flares during follow-up) (median 4.5 [IQR 3.0] vs. 3.0 [IQR 2.5], p=0.035), even after adjusting for age at diagnosis and observation time (OR 2.2, 95% CI 1.3-3.9, p=0.007); subjects who had switched >2 bDMARDs had higher prevalence of subsynovial elementary lesions (55.6% vs 10.3%, p=0.005) and fibrin deposits in synovial lining (60.0% vs 22.6%, p=0.049), even after adjustment for observation time and age at diagnosis (OR 8.1, 95% CI 1.03-64.2, p=0.047). At immunohistochemistry on 31 JIA samples, higher CD3 expression was described in polyarticular compared to oligoarticular subset (p=0.040), while no differences were found between persistent and extended oligoarticular subsets (p=0.670). Patients with severe disease course had higher CD20+ cells percentage (OR 7, 95% CI 1.4–35.5, p=0.023), regardless of JIA subset and treatment exposure (Figure 1).

Conclusion: The present study offers several novel insights into the potential role of synovial pathobiology in JIA. Synovial tissue analysis might support the clinicians in the diagnostic approach of pediatric patients presenting with arthritis and guide the clinical management of JIA.

Table 1. Synovial morphological and immunohistochemical features in the overall population and within JIA subtypes.

	Oligo	Poli RF-	ERA	PsA	Systemic	Overall population
Morphologic						
Layers of synovial lining (score), median (IQR)	3.0 (2.0) (n=26)	2.8 (2.4) (n=6)	6.0 (3.0) (n=4)	5.5 (0.0) (n=1)	4.0 (1.0) (n=3)	3.5 (2.6) (n=40)

Background: Multisystem Inflammatory Syndrome in Children (MIS-C) is one of the most feared complications following SARS-CoV2 infection in children and adolescents. Few multinational multicenter studies from Latin America have been published.
Objectives: To describe the clinical presentation, management, and outcomes of MIS-C in Latin America.
Methods: Observational, prospective and retrospective, multicenter study to gather information from 84 participating centers across 16 Latin American countries, between August January 1, 2020 and June 30, 2022.
Results: Of the 1,239 reported cases of MIS-C, 84.2% were previously healthy. The most frequent clinical manifestation in our studied population was abdominal pain (N=804, 64.9%), followed by conjunctival injection (N=784, 63.3%). The median days of fever at the time of hospital admission was 5 and a significant number of subjects required admission to an intensive care unit (N=589, 47.8%). A total of 538 (47.2%) patients had an abnormal initial echocardiogram. Most of the subjects (N= 1,096, 88.7%) were treated with intravenous immunoglobulin

(IVIG), while 76.7% (N= 947) were treated with steroids, of which 10.6% (N= 100) did not receive IVIG. The death rate attributed to MIS-C was 4.88%, with a rate of 3.39% for those initially diagnosed with MIS-C and 8.85% for those whose admission diagnosis was not MIS-C (*P= 0.00001)*.

Conclusion: One of the most significant findings from our study was the death rate, especially in those not initially diagnosed with MIS-C, in whom it was higher. This highlights the importance of increasing awareness and making an earlier diagnosis of MIS-C in Latin America.

POS0745 THE INCIDENCE AND PREVALENCE OF JUVENILE IDIOPATHIC ARTHRITIS DIFFERS BETWEEN ETHNIC GROUPS IN ENGLAND

Keywords: Epidemiology, Gender/diversity issues

R. Beesley[1], K. Hyrich[1,2,3], J. Humphreys[1,2]. [1]*The University of Manchester, Centre for Epidemiology, Manchester, United Kingdom*; [2]*The Kellgren Centre of Rheumatology, Manchester Royal Infirmary, Manchester, United Kingdom*; [3]*National Institute for Health Research, Manchester Biomedical Research Centre, Manchester, United Kingdom*

Background: Juvenile Idiopathic Arthritis (JIA) is a heterogenous group of autoimmune disorders characterised by chronic joint inflammation, affecting children and young people (CYP) under the age of 16. Recent analysis in the UK has updated estimates of the incidence and prevalence of JIA, but the association between ethnicity and JIA has not been investigated in the UK context. Differential rates between ethnic groups could be indicative of underlying biological differences and/or health inequities. Health inequities (avoidable systemic differences in health outcomes for different population groups) may lead to specific ethnic groups being less likely to be referred resulting in delays in diagnosis and apparent differences in incidence rates.

Objectives: To calculate and compare the incidence and prevalence rates of JIA in different ethnic groups in England.

Methods: CYP with JIA were identified in anonymised electronic primary care records (the Clinical Practice Research Datalink (CPRD) Aurum database) using pre-defined read code lists between 1995 and 2011. Cases were further validated through linked Hospital Episode Statistics (HES) data with either >=3 outpatient specialist care (rheumatology/paediatric rheumatology) appointments or a HES inpatient admission coded with JIA, prior to age 16. Ethnic group was extracted from CPRD/HES records and aggregated to broad ethnic groups, as defined by the Office for National Statistics (ONS). Incidence and prevalence rates by broad ethnic group were calculated using CYP under the age of 16 in CPRD, as of December 2011. Indirect standardisation was performed by age and region using ONS Census 2011 data, to account for varying ethnic make-up across different age groups and regions of England. The distribution of observed JIA cases across ethnic groups was subsequently compared with the expected distribution based on population statistics using Chi2.

Results: A total of 314 incident cases were identified in CYP <16y between January 1995 and December 2011 using code lists. The overall age and region indirectly standardised incidence rate was 4.3 per 100,000 population age <16y, varying from 4.7 for White CYP to 1.1 for CYP with Mixed ethnic group. A total of 268 HES-validated cases were identified, giving an indirectly standardised incident rate of 4.3 per 100,000 population age <16y, varying from 4.8 for White CYP to 0.9 for CYP with Mixed ethnic group. In December 2011 there were 471 prevalent cases from code lists (381 validated using HES). The indirectly standardised prevalence rate was 35 per 100,000 CYP under the age of 16 (31 for validated cases), varying from 38 (34) for White CYP to 11 (11) for CYP with Mixed ethnic group.

Table 1. Standardised incidence and prevalence of JIA in CYP by ethnic group in England

Ethnic group	All	White	Mixed	Asian	Black
Proportion of CYP <16y:					
England general 2011, %	-	78.1	5.4	10.2	5.0
JIA, % (95% CI) †	-	86.9 (83.2, 90.7)	1.3 (0.0, 2.5)	7.0 (4.2, 9.8)	1.9 (0.4, 3.4)
Observed:Expected ratio		1.1	0.3	0.7	0.4
Incidence per 100,000 person years CYP <16y, 2011 (95% CI)	4.3 (3.8, 4.8)	4.7 (4.1, 5.3)	1.1 (0.3, 2.8)*	3.0 (1.9, 4.6)	1.7 (0.6, 3.7)*
Prevalence per 100,000 CYP <16y, 2011 (95% CI)	35.1 (32.0, 38.5)	38.3 (34.7, 42.3)	10.8 (4.6, 21.4)*	24.3 (16.8, 33.9)*	24.1 (14.0, 38.6)

* Statistically significant when compared to 'White' ethnic group (p<.05). † Statistically significant when compared to ethnic group distribution in general population, p<.001 Chi-Square.

Conclusion: The incidence and prevalence of JIA amongst CYP in England differs by ethnic group, being highest amongst 'White' CYP and lower amongst other ethnic groups, and is not in keeping with the known distribution of ethnic groups in the <16y England population. Understanding whether this reflects a health inequity or differences in the underlying biology of JIA needs further evaluation.

POS0746 CONTRIBUTION OF GENETIC VARIANTS ASSOCIATED WITH PRIMARY IMMUNODEFICIENCIES IN CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS

Keywords: Systemic lupus erythematosus, Genetics/epigenetics

C. Y. Wu[1], W. L. Fan[2], P. S. Chu[1], P. C. Liao[1], W. I. Lee[1], J. L. Huang[3]. [1]*Chang-Gung Memorial Hospital, Division of Allergy, Asthma, and Rheumatology, Department of Pediatrics, Taoyuan City, Taiwan, Republic of China*; [2]*Chang-Gung Memorial Hospital, Department of Medical Research, Kaohsiung, Taiwan, Republic of China*; [3]*New Taipei Municipal TuCheng Hospital, Department of Pediatrics, New Taipei city, Taiwan, Republic of China*

Background: Dysregulated immune response is the hallmark of autoimmune disorders[1]. Evidences suggested that systemic autoimmune diseases and primary immunodeficiency disorders (PID) may be similar diseases with alternative clinical phenotypes[2].

Objectives: This study aimed to investigate the burden of PID associated genetic variants in the childhood-onset systemic lupus erythematous (cSLE) patients.

Methods: One hundred and eighteen cSLE cases regularly followed at Chang-Gung memorial hospital were enrolled. Targeted next-generation sequencing was applied searching for PID genetic variants. Genetic variants were compared to those of 1,475 unrelated healthy individuals and further filtered by allelic frequency and various functional score systems. Customized immune assays were applied to test the function of the identified variants.

Results: Upon filtration, 36 (30.5%) patients harbored rare variants in PID-associated genes predicted to be damaging. One homozygous *TREX1* (c.294dupA) mutation and four heterozygous variants with possible dominant PID traits, including *BCL11B* (c.G1040T), *NFKB1* (c.T695G), and *NFKB2* (c.G1210A, c.G1651A), were discovered. With recessive traits, variants were found across all PID types; one-fifth involved phagocyte number or function defects. Predicted pathogenic PID variants were more predominant in those with a family history of lupus regardless of infection susceptibility. Moreover, mutational loads were greater among cSLE patients than controls despite sex or age at disease onset. While greater mutational loads were observed among cSLE patients with peri-pubertal disease onset, no significant difference in sex or phenotype were noted among cSLE patients.

Conclusion: Our findings suggest that cSLE is mostly not a monogenic condition. Gene-specific analysis and mutational load investigations suggested that while rare and predicted damaging variants in immunodeficiency related genes may contribute to cSLE susceptibility, genetic investigations of PID disorders may not be warranted for cSLE patients with recurrent infections.

Genova, IRCCS Polyclinic San Martino Hospital, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Medical Specialties, Genova, Italy

Background: Nailfold Video Capillaroscopy (NVC) is a simple, non-invasive diagnostic tool but studies with normal values for capillary density in healthy children are rare. Ethnic background seems to play a role in capillary density; however, this is not well substantiated yet [1,2].
Objectives: In this work, we set out to evaluate influence of ethnic background/skin pigmentation and age on capillary density reading in healthy children. Secondary aim was to investigate whether there is a significant difference in density between different fingers within the same patient.
Methods: Capillaroscopic images from healthy children were obtained in a one-time visit videocapillaroscopy (x200 magnification) addressing the capillary density (i.e. number of capillaries per linear millimeter in the distal row). This parameter was compared to age, sex, ethnicity, skin pigment grade (I-III) and between eight different fingers, excluding the thumbs.
Results: We investigated 145 healthy children with mean age of 11.03 years (SD 3.51). The range of capillary density was 4-11 capillaries per millimetre. We observed a lower capillary density in the 'grade II' (6.4 ± 0.5cap/mm, p<0.001) and 'grade III' (5.9 ± 0.8 cap/mm, p<0.0001) pigmented-classified groups compared to the 'grade I' group (7.0 ± 0.7 cap/mm). We did not find a significant correlation between age and density in the overall group. The fifth fingers on both sides had a significantly lower density compared to the other fingers.
Conclusion: Healthy children <18 years with higher degree of skin pigmentation show a significantly lower nailfold capillary density. In subjects with an African/Afro-Caribbean and North-African/Middle-Eastern ethnicity, a significantly lower mean capillary density was observed compared to subjects with the Caucasian ethnicity (p<0.0001, and p<0.05, respectively. There were no significant differences between other ethnicities. No correlation was found between age and capillary density. The fifth fingers on both hands displayed lower capillary density compared to the other fingers. This needs to be taken into account when describing lower density in paediatric patients with connective tissue diseases.

Background: Systemic juvenile idiopathic arthritis (sJIA) accounts up to 15 % of all patients with JIA and is distinct from the other disease categories due to the association of articular and extraarticular manifestations. The systemic Juvenile Arthritis Disease Activity Score (sJADAS) is a composite disease activity score validated specifically for use in sJIA that includes, beside the four components of the original JADAS, a fifth item aimed to quantify the burden of systemic features. The interpretation of scores on sJADAS requires criteria that identify the states of disease activity. These criteria can be used to monitor the disease course over time and to define therapeutic targets.
Objectives: To compare the clinical and laboratory data of each disease activity state in patients enrolled in the multinational study aimed to define the sJADAS cutoffs.
Methods: Data were extracted from a multinational cross-sectional dataset that included patients diagnosed as sJIA by ILAR criteria, recruited between February 2022 and November 2022. At study visit, each patient was categorized subjectively by the caring physician into one of the following disease activity states: inactive disease (ID), low (or minimal) disease activity (LDA), moderate disease activity (MDA), or high disease activity (HDA). Study data was collected through a standard case report form and entered into an electronic database.
Results: A total of 231 patients were enrolled in 29 centers in 12 countries. The mean age at diagnosis was 5.63 years. 87 patients (37.7%) were judged as having ID, 39 (16.9%) LDA, 46 (19.9%) MDA and 59 (25.5%) HDA. The comparison of the main clinical and laboratory features across patients with the four disease activity states is shown in the Table 1. Overall, the presence of extraarticular manifestations was more common in patients with MDA and HDA (P<0.00001), whereas fever, rash, hepatosplenomegaly, and lymphadenopathy were more frequent in HDA patients (<0.00001). The count of active joints increased progressively from ID to HDA (p<0.00001). The mean values of physician global assessment of disease activity and systemic manifestations, as well as the mean values of acute phase reactants, were highest in patients with HDA, with gradual decrease from MDA to LDA to ID.
Conclusion: This preliminary analysis of the study data indicates that the subjective assessment of disease state by the caring physicians led to discriminate reliably patients with different level of disease activity. This evaluation will, then, serve well as reference for the subsequent analyses aimed to identify the cutoffs for the main disease activity states in sJIA.

POS0749 TRANSITION READINESS AMONG FINNISH ADOLESCENTS WITH JIA

Keywords: Patient information and education, Self-management, Outcome measures

K. Mikola[1], K. Rebane[1], H. Kautiainen[2,3], K. Aalto[1]. [1]*New Children's Hospital, Pediatric Research Center, Helsinki, Finland*; [2]*Kuopio University Hospital, Primary Health Care Unit, Kuopio, Finland*; [3]*Folkhälsan Research Centre, Biomedicum, Helsinki, Finland*

Background: Juvenile idiopathic arthritis (JIA) is the most common persistent rheumatic condition in children [1]. It's nature is chronic (2) and in our own study 40% of patients were transferred to adult clinic when they reached the transition age [3]. A successful transition requires sufficient self-management skills to manage one´s chronic condition and all the tasks involved in it [4]. There are multiple practices to establish the transition readiness and self-management among the adolescents [5].

Objectives: The purpose of our study was to evaluate transition readiness in Finnish patients with JIA and estimate the usefulness of a specific questionnaire. We aimed to find forecasting values for a successful transition and study the possible consequences of an unsuccessful transition to the disease outcome.

Methods: Our questionnaire was inspired by the Canadian Good2Go questionnaire (www.sickkids.ca/en/patients-visitors/transition-adult-care), and it was part of the routine rheumatological visits in our clinic. Eighty-three patients filled it in between June 2011 and December 2013. The questionnaire was given to patients who were likely to be transferred into an adult clinic, that is patients with a long history of ongoing disease activity and ongoing medication. The questions evaluate the self-management in several aspects, e.g., independence in the disease management (medication, appointments, pain control), everyday life (school, future educational plans, mental support, exercise, sexual health), and substance abuse. We used 13 questions with three answer options (yes =2, partly= 1, or no= 0), higher score indicating better readiness. Patients filled in the questionnaire in the pediatric site. We also gathered information from the first adult visit to assess the success of the transition and its relation to disease activity. The transition was defined successful when the patient attended the first visit at an adult care independently, as scheduled, and the medication was carried out as agreed at last pediatric visit.

Results: The cut-off score for a successful transition by ROC-analysis was 24 (OR 6.11 (95% CI: 1.71 to 1.43)). That is, the best estimate for successful transition is when the score is 24 or more. We were able to receive all necessary information to define the success of the transition from 77 patients. In 55 (71%) patients the transition was estimated as a successful. The mean score 22,5 (SD 2,2) in the transition readiness questionnaire is shown in the Figure 1. Seven patients (9 %) received the maximum score.

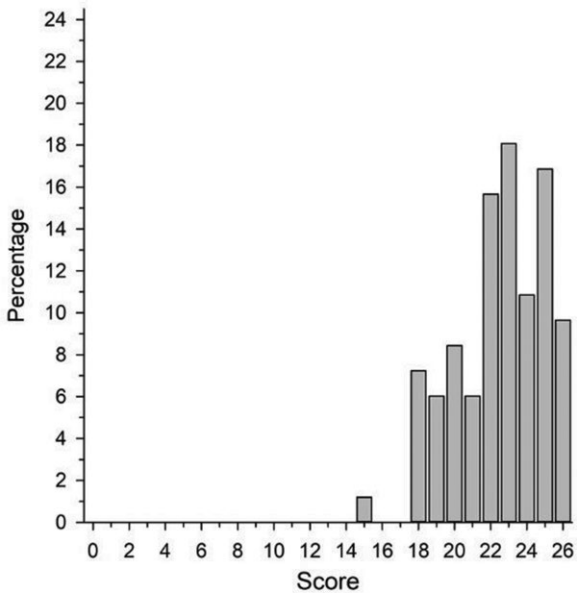

Figure 1. The distribution of scores in the transition readiness questionnaire

At the first adult visit, the DAS28 was assessed in 58 patients. If the transition was defined as unsuccessful (score<24), the DAS28 was higher, mean 2.21 (SD 1.14) and if the transition was defined as successful (score≥24) the DAS28 was better, mean 1.35 (SD 0.48), p<0.001.

Conclusion: We found this questionnaire a useful tool to evaluate transition readiness. Determination of a successful transition helps us to discover those adolescents who need more profound support to improve their self-management skills and thus enhance their transition process. An unsuccessful transition has also impact on disease outcome.

POS0750 RELATIONSHIP OF CLINICAL AND PATIENT-REPORTED OUTCOMES WITH IMAGING MEASURES OF SYNOVITIS IN JUVENILE ARTHRITIS

Keywords: Patient reported outcomes, Inflammatory arthritides, Ultrasound

P. Vega Fernandez[1,2], K. Rogers[1], A. Cassedy[2,3], A. B. Meyers[2,4], T. Ting[1,2]. [1]*Cincinnati Children's Hospital Medical Center, Rheumatology, Cincinnati, United States of America*; [2]*University of Cincinnati, Pediatrics, Cincinnati, United States of America*; [3]*Cincinnati Children's Hospital Medical Center,*

Biostatistics, Cincinnati, United States of America; [4]*Cincinnati Children's Hospital Medical Center, Radiology, Cincinnati, United States of America*

Background: In children with JIA, the use of outcomes measures for the assessment of disease course and health-related quality of life (HRQL) contribute to improvement of the quality of care provided. However, these subjective outcome measures do not always accurately reflect the inflammatory disease burden and may be influenced by comorbid conditions. Musculoskeletal ultrasound (MSUS) and contrast-enhanced MRI imaging measures of synovitis provide an objective assessment of JIA disease activity. A novel MSUS score for knee arthritis (MSUS-knee score) showed strong correlation with the combined Juvenile Arthritis MRI Scoring (JAMRIS) system in children with JIA[1].
Objectives: To determine the relationship of clinical and patient-reported outcomes (PROs) measures with the MSUS-knee score and the JAMRIS system in children with JIA.
Methods: Children with a diagnosis of JIA who received a MSUS of the knee(s) were enrolled. Data collected included knee physical examination findings, disease activity assessment, the Child Health Assessment Questionnaire (CHAQ) and the pediatric PROMIS Mobility measure (t-score mean 50, standard deviation 10). The following measures were asked to the patients specifically for the examined knee: pain, swelling and morning stiffness. A comprehensive knee MSUS examination was performed on all participants by MSUS certified pediatric rheumatologist. MSUS images were scored by pediatric MSUS experts, who were blinded to clinical information using a semiquantitative scoring system (0-normal to 3-severe)[1]. The MSUS-knee score was calculated by adding the abnormal B-mode MSUS scores (score 2 or 3) and the power doppler MSUS scores (score 1 to 3) from the 3 views of MSUS-knee (MSUS-knee score range: 0-15)[1]. A subset of participants received an MRI with and without contrast of the knee. MRI of the knee was scored for presence and severity of synovial thickening and joint effusion as per JAMRIS system[2]. Associations between clinical and PROs outcome measures and imaging measures were assessed using Spearman's Correlation Coefficient.
Results: Forty-eight children (mean age of 12.1 years) contributed 60 visits. Twenty-four knee MRIs were obtained following MSUS of the knee. Patient reported presence of knee swelling was strongly correlated with the MSUS-knee score and moderately correlated with the JAMRIS system. No other significant statistically associations were found between PROs assessing lower extremity pain and physical function, and overall disease status with imaging measures (Table 1).
Conclusion: Imaging measures of JIA disease activity could provide a more accurate assessment of JIA disease state, given low correlation with commonly used outcome measures. Integration of imaging measures into the shared decision-making in daily clinical practice may improve the quality of medical care. Future studies with a larger population are required.

Background: Upadacitinib is a Janus kinase inhibitor with preferential inhibition of JAK1 over other JAK isoforms that has been approved for the treatment of adults with moderate to severe rheumatoid arthritis (RA). Children with polyarticular course juvenile idiopathic arthritis (pcJIA) have similar clinical presentations compared to adult RA. In Phase 3 RA studies in adult patients, the median (5^{th}, 95^{th} percentiles) model-estimated area under the plasma upadacitinib concentration curve AUC over 0-24 hours (AUC_{0-24}) at steady state were 362 (216, 785) and 720 (434, 1531) ng·h/mL after multiple 15 mg and 30 mg once daily (QD) doses, respectively.
Objectives: The objective of this analysis was to characterize upadacitinib pharmacokinetics from a Phase 1 study in children with pcJIA.
Methods: Patients (N = 51) diagnosed with pcJIA were enrolled into one of four groups in an open-label, multiple-dose study (Group 1, 12 to < 18 years, low dose; Group 2, 12 to < 18 years, high dose; Group 3, 6 to < 12 years, low dose; Group 4, 2 to < 6 years, low dose). The low and high doses were selected to provide comparable plasma exposures in pediatrics to 15 mg and 30 mg QD doses of ER tablet formulation in adults, respectively. Patients received bodyweight-based upadacitinib doses either as twice-daily (BID) immediate-release (IR) oral solution or QD extended-release (ER) tablet formulation. Pharmacokinetic assessment was performed at steady state on Study Day 7, after which all patients might continue the study with low dose.
Results: Summary of the demographics of the enrolled patients are shown in Table 1. Pharmacokinetic results from 49 patients with evaluable drug concentrations on Study Day 7 were reported. In Group 1, the geometric mean upadacitinib maximum plasma concentration (C_{max}) and AUC_{0-24} at steady state were 35.1 ng/mL and 269 ng·h/mL, respectively. In Group 2, the geometric mean upadacitinib C_{max} and AUC_{0-24} were 69.8 ng/mL and 553 ng·h/mL, respectively. In Group 3, the geometric mean upadacitinib C_{max} and AUC_{0-24} were 51.0 ng/mL and 346 ng·h/mL, respectively. In Group 4, the geometric mean upadacitinib C_{max} and AUC_{0-24} were 46.6 ng/mL and 369 ng·h/mL, respectively. The median time to maximum upadacitinib concentration was approximately 3 hours and 1 hour; and the harmonic mean functional half-life was approximately 5 hours and 2 hours for the QD ER tablet and the BID IR solution regimens, respectively. Upadacitinib apparent oral clearance increased in pcJIA patients with increasing bodyweight. The mean upadacitinib plasma concentration-time profiles of each group are presented by dosing regimen in Figure 1.
Conclusion: Upadacitinib plasma exposures in pediatric patients with pcJIA were comparable to adult RA patients at the evaluated dosing regimens with the ER tablet or IR solution and at both low and high dose levels. These results support the use of the current bodyweight-based dosing regimen in upadacitinib pediatric studies.

Table 1. Demographics Summary of Enrolled Pediatric pcJIA Patients

		Group 1 (N = 9)	Group 2 (N = 9)	Group 3 (N = 19)	Group 4 (N = 14[a])
Age[b] (years)	Mean ± SD	14.9 ± 1.5	13.9 ± 1.2	9.5 ± 1.6	3.6 ± 1.5
	(Range)	(13 – 17)	(12 – 16)	(6 – 12)	(2 – 6)
Weight (kg)	Mean ± SD	61.3 ± 14.6	51.7 ± 13.0	37.8 ± 14.4	15.1 ± 3.2
	(Range)	(42.0 – 92.9)	(32.5 – 71.5)	(19.7 ± 72.1)	(11.0 ± 22.5)
Sex	Male, N (%)	2 (22.2)	1 (11.1)	4 (21.1)	3 (21.4)
	Female, N (%)	7 (77.8)	8 (88.9)	15 (78.9)	11 (78.6)
Dose Form	Oral Solution, N (%)	0 (0.0)	0 (0.0)	7 (36.8)	14 (100.0)
	Tablet, N (%)	9 (100.0)	9 (100.0)	12 (63.2)	0 (0.0)

a.Two patients were excluded from pharmacokinetic analysis. One patient mistakenly received half dose and the other patient had incomplete PK sample collection.b.Age was determined at the time of screening.

POS0752 MUSCULOSKELETAL INVOLVEMENT IMPAIRS QUALITY OF LIFE IN JUVENILE PSORIATIC ARTHRITIS

Keywords: Quality of life, Psoriatic arthritis, Ultrasound

P. Collado[1], N. Palmou-Fontana[2], P. Mesa del Castillo[3], B. P. Magallares López[4], I. Calvo[5], G. Diaz-Cordobes[6], E. Moreno Ruzafa[7], M. Steiner[8], J. C. Lopez Robledillo[9]. *[1]Hospital Universitario Severo Ochoa, Rheumatology, Madrid, Spain*; *[2]Hospital Universitario Marques De Valdecilla, Rheumatology, Santander, Spain*; *[3]Hospital Universitario La Arrixaca, Paediatric Rheumatology, Murcia, Spain*; *[4]Hospital Universitario San Pau, Rheumatology, Barcelona, Spain*; *[5]Hospital Politecnico Universitario La Fe, Paediatric Rheumatology, Valencia, Spain*; *[6]Hospital Regional De Malaga, Rheumatology, Malaga, Spain*; *[7]Hospital Universitario Vald Hebron, Rheumatology, Barcelona, Spain*; *[8]Hospital Universitario Infanta Sofia, Rheumatology, Madrid, Spain*; *[9]Hospital Universitario Niño Jesus, Paediatric Rheumatology, Madrid, Spain*

Background: Juvenile psoriatic arthritis (JPsA) is one of the least common subtypes of JIA. Information on JPsA is mainly clinical, but scarce regarding the impact of musculoskeletal involvement on children's quality of life.
Objectives: To describe the clinical and ultrasound (US) characteristics of children with JPsA, and to assess their impact using a composite quality of life index, the PsAID (Psoriasis Arthritis Impact of Disease).
Methods: A multicentre cross-sectional observational study recruited consecutive JPsA patients, from January-2020 to May-2022. Inclusion criteria: 1/ age at onset ≤ 16 years, 2/ diagnosis by the prescribing physician based on one of the 2 JPsA diagnostic classification systems (ILAR or Vancouver). All were assessed clinically and US (independently) and completed two questionnaires: PsAID (1) and Child Health Assessment Questionnaire (CHAQ, to measure physical disability). Statistics included correlation Spearman (rho) and PsAID was identified as the dependent variable.
Results: The 48 children included (mean age at inclusion 11±4 years), 71% girls, 67% had oligoarthritis and 80% psoriasis in a first or second-degree relative. Mostly arthritis started before the psoriasis. The median time lag between the diagnosis and the onset of specific musculoskeletal manifestations was 1 year; interquartile range 0.5-2. ANA and HLAB27 were present in 19 (40%) and 5 (10%) of the children, respectively. A history of axial inflammatory symptoms was present in 3 (5%) patients, and unilateral sacroiliitis was confirmed by MRI in only one patient. Psoriasis and dactylitis were the most frequent manifestations identified (≥50%), while uveitis was less common (12%). Twenty-eight (58%) patients used methotrexate, 21 used anti-TNF agents and 14 needed corticosteroid infiltration. The population showed low clinical activity in the DAPSA composite activity index (md 3.5; range 0-25). Similarly, US showed a low number of affected joints but US was slightly superior to clinical examination, while US was clearly superior to detect enthesitis and tenosynovitis, particularly tendons of the fingers. The PsAID index (median 0.4; range 0-9.2) showed low correlation with CHAQ (r 0.3) and high with DAPSA (r 0.7); however, the correlation between PsAID and total joint count was low for both clinical and US assessment (r 0.4). The correlation between PsAID and total joint count was moderate for clinical (r 0.5) and low for US (r 0.4). Children with the presence of enthesitis and clinical dactylitis had a higher mean PsAID score than those without (dactylitis; p=0.002, and enthesitis; p<0.001).
Conclusion: The study supports the existence of an atypical pattern of late-onset JPA characterised by a predominance of girls with peripheral involvement and little uveal involvement. Based on our results, dactylitis and enthesitis have a greater impact on the child's quality of life than joint involvement per se. Studies with a larger sample size and/or disease activity are needed to confirm these findings.

Background: Dermatomyosis is an autoimmune disease that can present in children, adolescents (juvenile dermatomyosis JDM), and adults (adult dermatomyositis DM). The pathological hallmarks of DM are similar between JDM and adult DM, including skin rashes and proximal muscle weakness, however, the manifestations and prevalence of associated autoantibodies vary, depending on age of onset. Myositis specific antibodies (MSA) have been used as a prognostic tool to aid management of disease in both adult DM and JDM. In JDM, anti-TIF1γ is highly prevalent, and is the most common MSA in Caucasian patients. This MSA is associated with malignancy in adult DM [1]. We have previously shown that adult DM patients with cancer have significantly higher frequency and serological level of anti-TIF1γ IgG2 isotype [2]. However, there are limited data on anti-TIF1γ isotypes in JDM.
Objectives: To investigate anti-TIF1γ isotypes as a potential biomarker for clinical manifestations in JDM.
Methods: We conducted a retrospective study to evaluate clinical features of anti-TIF1γ positive patients. This cohort includes 20 patients from French healthcare centres and 11 patients from the UK healthcare centres. Serum samples were first tested for anti-TIF1γ using either lineblot or immunoprecipitation. Within those with anti-TIF1γ antibodies, anti-TIF1γ isotypes including IgG1, IgG2, IgG3 and IgG4 were measured using a multiplex ALBIA assay developed by Aussy et al. (2019) [2].

Results: Out of 31 children, 54.8% (17) were Caucasian, followed by North African (25.8%, n=7), and other minority groups. Male to female ratio was 14/17. All 31 patients had IgG1 isotype, and 14 had more than one isotype of anti-TIF1γ antibody. Although IgG2 isotype of anti-TIF1γ has been shown to be a biomarker for malignancy and mortality in adult DM, there were no reports of malignancy in this paediatric cohort. In our JDM cohort, the rate of IgG2-positive was 25.8% (8/31) which is lower than observed in adult DM of 55% [2]. Two cases in this JDM cohort died: both were positive for IgG4, but both were negative for IgG2.
Interestingly, there were significant differences regarding IgG2 isotype of anti-TIF1γ antibody presence between ethnic groups (p = 0.008). Specifically, although Caucasian patients were the majority, only 1 out of 8 IgG2 positive cases was Caucasian. Between Caucasian and non-Caucasian groups, significant differences were observed when comparing the groups' means (p = 0.02) and variances (p = 0.01). Notably, 4/8 IgG2 positive were found in North African population, making up 44.4% (4/9) of this ethnic group. We also showed that anti-TIF1γ isotypes can change over time. Specifically, of 6 patients tested for anti-TIF1γ isotypes at a second time point, 4 cases had changes in serological levels of anti-TIF1γ isotypes: 2 had lower titer levels, 1 lost positive status for IgG2 and IgG3, and 1 gained positive status for IgG4.
Conclusion: Our study indicates that there may be a relationship between anti-TIF1γ IgG2 isotype and ethnicity. Importantly, although IgG2 is a biomarker for cancer in adult DM, it is not associated with severe onset or manifestations such as mortality or malignancy in JDM patients.

POS0754 PROTEASOME ACTIVITY TEST AS A POTENTIAL CLINICAL TOOL FOR THE DIAGNOSIS OF CHRONIC ATYPICAL NEUTROPHILIC DERMATOSIS WITH LIPODYSTROPHY AND ELEVATED TEMPERATURE (CANDLE) SYNDROME AND RELATED PROTEASOME DISORDERS

Keywords: Diagnostic tests, Rare/orphan diseases, Genetics/epigenetics

Y. Levinsky[1], O. Scheuerman[2], R. Tal[1], G. Amarilyo[1], L. Harel[1]. [1]*Schneider Children's Meidcal Center of Israel, Pediatric Rheumatology Unit, Petah Tikva, Israel*; [2]*Schneider Children's Meical Center of Israel, Pediatrics B, Petah Tikva, Israel*

Background: Chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (CANDLE) syndrome, is an interferonopathy caused by proteasomal dysfunction. Clinical characteristics include early onset inflammation, nodular rashes, hepatosplenomegaly, myositis, panniculitis, lipodystrophy and basal ganglion calcifications. CANDLE and associated syndromes are gouped into the proteasome-associated autoinflammatory syndromes (PRAAS). Our patient presented at age of 3 months with features strongly suggestive of PRAAS. Genetic testing revealed a novel proteasome variant classified as a variant of unknown significance (VUS).
Objectives: Functional testing of the proteasome was undertaken in order to support the suspicion of PRAAS. Our aims are to describe the potential role of this test for aiding in the diagnosis of PRAAS.
Methods: First, interferon signature was obtained and whole exome sequencing was analyzed for the patient and her parents. Nest, samples of whole blood were taken from the patient, parents and 3 healthy controls. PBMC were lysed using activity preserving methods (active extraction). Samples were normalized using BCA enzymatic assay. Activity of the proteasomal subunits was measured using peptides specific to different subunits (caspase, chymotrypsin and trypsin activity).
Results: Interferon signature was abnormally high, suggestive of an interferonopathy. Whole exome sequencing revealed a novel heterozygous variant in a PSMB4, the gene that encodes for β7, a structural non –catalytic subunit of the proteasome classified as a variant of unknown significance (VUS). A pilot analysis of proteasome activity showed a 50% reduction in the catalytic activity of proteasome subunit β1, indicating severe impairment of proteasomal activity, with compensatory hyper-activation of the immunoproteasome subunit β1i (Figure 1). The apparent dysfunction of β1 and hyper activation of β1i suggested a proteasomal assembly dysfunction. Using the above findings, the patient commenced JAK inhibitor (baricitinib) with remarkable clinical improvement (Figure 2).
Conclusion: Proteasomal activity testing may serve as a useful tool for the diagnosis of CNDLE/PRASS in suspicious cases. Since JAK inhibitors may provide an adequate therapeutic response, it is of great importance to timely diagnose this disease in cases where the genetic results are equivocal.

POS0755 TOWARDS THE DEVELOPMENT OF COMPOSITE PARENT-CENTERED DISEASE ACTIVITY SCORES FOR JUVENILE DERMATOMYOSITIS

Keywords: Outcome measures, Myositis, Patient reported outcomes

S. Rosina[1], A. I. Rebollo Giménez[1], L. Tarantola[2], R. Naddei[3], A. Consolaro[1,2], A. Pistorio[4], A. Ravelli[4]. [1]*IRCCS Istituto Giannina Gaslini, UOC Reumatologia e Malattie Infiammatorie, Genova, Italy*; [2]*Università degli Studi di Genova, Dipartimento di Neuroscienze, Riabilitazione, Oftalmologia, Genetica e Scienze Materno-Infantili (DiNOGMI), Genova, Italy*; [3]*Università degli Studi di Napoli Federico II, Dipartimento di Scienze Mediche Traslazionali, Napoli, Italy*; [4]*IRCCS Istituto Giannina Gaslini, Direzione Scientifica, Genova, Italy*

Background: In recent years, increasing attention has been paid to the development of parent- and child-centered composite disease activity scores for the assessment of health status of children with rheumatic diseases.

Objectives: This study is aimed to develop and test an entirely parent-centered composite disease activity score for JDM, named parent Juvenile DermatoMyositis Activity Index (parJDMAI). Two versions of the score, which differed in the fourth item included, were evaluated.
Methods: Both parJDMAI1 and parJDMAI2 include the following items: 1) parent assessment of skin disease activity (Parent Skin Scale) on a 0-5 scale, by giving 1 point to the presence of each of the following: i) rash on eyelids, ii) nose/cheeks, iii) knuckles, iv) trunk/arms, v) skin ulceration; 2) parent assessment of muscle disease activity (Parent Muscle Scale) on a 0-5 scale, by giving 1 point to the presence of each of the following: i) fatigue/discomfort, ii) muscle weakness, iii) muscle pain, iv) voice change, v) difficulty swallowing; 3) parent assessment of child's fatigue on a 0-10 visual analog scale (VAS) (0 = no fatigue; 10 = maximum fatigue). As fourth item, the parJDMAI1 includes the parent global assessment of child's wellbeing, measured on a 0-10 VAS (0 = best; 10 = worst), whereas the parJDMAI2 includes the parent global assessment of disease activity, measured on a 0-10 VAS (0 = no activity; 10 = maximum activity). To give the four components of the tools the same weight, the scores of the Parent Skin and Muscle Scales were doubled. Thus, the total score of both instruments ranges from 0 to 40. Initial validation was conducted on a multicentric sample of 213 patients followed in standard clinical care and evaluated prospectively (number of visits = 577), and on a monocentric sample including 50 patients, all assessed at baseline and 32 also assessed after a median of 3.9 months (number of visits = 82). Validation analyses included calculation of the correlations between individual parJDMAI items and physician-centered JDM outcome measures, and between the total score of parJDMAI1 and parJDMAI2 with that of the global composite disease activity scores for JDM named JDMAI1 and JDMAI2. Because both JDMAI1 and JDMAI2 include the parent global assessment of child's wellbeing, which is also part of parJDMAI1, we also tested the correlations of parJDMAI1 with reduced versions of JDMAI1 and JDMAI2, that included only the 3 physician-centered items. Spearman correlations were defined as low, moderate or high when r_S was < 0.4, ≥ 0.4 and ≤ 0.7, or > 0.7, respectively.
Results: Correlations between individual components of parJDMAI1 and parJDMAI2 and physician-centered JDM outcome measures were low-to-moderate in the multicentric sample, but moderate in the monocentric sample. Likewise, correlations between the scores of parJDMAI1 and parJDMAI2 and that of original and reduced versions of JDMAI1 and JDMAI2 were strong in the monocentric sample, but moderate in the multicentric sample.
Conclusion: The new parent-centered composite disease activity scores revealed satisfactory measurement properties. That correlations with physician-centered outcome measures and original and reduced JDMAI versions were higher in the monocentric sample than in the multicentric cohort indicates that the proposed tools should be further tested in different clinical and cultural environments before their widespread use can be recommended.

Background: Evidence about the effectiveness of the tumor necrosis factor inhibitor adalimumab (ADA) in pediatric patients with non-infectious intermediate uveitis/pars planitis, posterior uveitis and panuveitis is still limited.
Objectives: Aim of this study is to investigate the therapeutic role of ADA in a cohort of pediatric patients with non-anterior uveitis.
Methods: This is an international multicenter study based on real-life data from pediatric patients treated with ADA due to non-anterior uveitis. Data were drawn from the retrospective branch of the AutoInflammatory Disease Alliance (AIDA) registry dedicated to uveitis. Figure 1 provides the flow diagram describing the selection of the patients enrolled on October 1st, 2022.
Results: 21 patients (36 affected eyes) were enrolled. Eleven patients (19 affected eyes) did not experience further ocular inflammation after ADA introduction; 10 cases (17 affected eyes) showed a partial response with reduced frequency of relapses (3 cases), reduced severity of relapses (3 cases) or reduced frequency and severity of relapses (4 cases). The number of ocular flares dropped from 3.91 to 1.1 events/patient/year after ADA introduction (p=0.0009). Macular edema and retinal vasculitis were respectively observed in 18 eyes and 20 eyes at the start of ADA and in 4 eyes and 2 eyes at the last assessment. The mean daily glucocorticoids dosage significantly decreased at the last assessment (p=0.005). As observed in Table 1, intermediate uveitis/pars planitis (p=0.01) and posterior uveitis (p=0.03) were more frequent among patients with full response to ADA; panuveitis was significantly more frequent among patients continuing to experience uveitic flares (p=0.001). Regarding the safety profile, a case of generalized adenopathy was observed.
Conclusion: ADA had a role in all pediatric patients with non-anterior uveitis with a significant glucocorticoid sparing effect. Panuveitis seems to be more frequent among patients continuing to experience uveitic flares.

POS0757 UVEITIS AS PREDICTORS OF RELAPSE AFTER ANTI-TNF TREATMENT WITHDRAWAL IN JUVENILE IDIOPATHIC ARTHRITIS: AN ITALIAN MULTICENTRIC EXPERIENCE

Keywords: bDMARD, Inflammatory arthritides, Prognostic factors

I. Maccora[1,2], M. Trevisan[3], V. Accardo[4], I. Pagnini[1], F. La Torre[5], E. Marrani[1], M. Cattalini[6], M. V. Mastrolia[1], A. Taddio[3], G. Simonini[1,2]. *[1]Meyer Children's Hospital IRCCS, Rheumatology Unit, Florence, Italy*; *[2]University of Florence, NeuroFARBA Department, Florence, Italy*; *[3]Institute of Maternal and Child Health, IRCCS Burlo Garofolo, Pediatric Department, Trieste, Italy*; *[4]University of Florence, School of Human Health Science, Florence, Italy*; *[5]Ospedale "Giovanni XXIII", Azienda Ospedaliero Universitaria Consorziale Policlinico, Pediatric Rheumatology Center, Bari, Italy*; *[6]ASST Spedali Civili di Brescia, University of Brescia, Pediatrics Clinic, Brescia, Italy*

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood. TNF inhibitors (TNFi) have dramatically changed the prognosis of this disease, but once achieved disease remission, it is not clear how and when stop therapy.
Objectives: Our purpose is to describe a multicentric cohort of JIA patients treated with the first course of Adalimumab and Etanercept in whom therapy was discontinued to persistent remission and identify predictors of relapse.
Methods: In a multicentric Italian retrospective study (Florence, Brescia, Trieste and Bari), patients with oligoarticular and polyarticular JIA were enrolled if they stopped therapy for persistent remission after the first course of Adalimumab and Etanercept. We collected demographic, clinical and laboratory data at onset and during biologic treatment.
Results: 136 patients were enrolled (102 female, median age at onset 3 years (R1-15)), of whom 76 (55.9%) had oligoarticular JIA and 55 (40.4%) had uveitis. ANA positivity was found in 99(72.8%) (Table 1). TNFis were started at median age of 6 years (R1-16), with a median time intercourse between TNFi initiation and diagnosis of 12 months (0-127m). Seventy-nine (59.3%) were treated with ADA, and 57 (40.7%) with ETA. Remission was achieved after a median time of 4 months (R 1-32) and TNFi was discontinued after a median time of 30 months (R 6-90). TNFi were stopped in the 76.5% increasing the interval of administration, 18.4% reducing the dose, and 16.9% abrupt discontinuation. 106 patients (79.4%) relapsed after a median time of 6 months (R 0.5-96) for arthritis in 71 (66.9%), uveitis in 19 (17.9%), both in 18 (16.9%). Patients who relapsed were more frequently female (χ^2 5.9 p<0.014), had history of uveitis (χ^2 7.4 p<0.006), younger at onset (median 3 vs 7, p<0.001) and when TNFi was started (6 vs 9.5, p 0.002). Moreover, the time intercourse between diagnosis and TNFi initiation was longer (13 vs 8.5 months, p 0.02) and the weaned of therapy happened in shorter time (6 vs 9 m, p 0.005) (Table 1). Patients who not-relapse suspended TNFi more frequently lengthening intervals of administration (χ^2 5.2 p0.015). Relapse free survival curve after withdrawal evaluated with Kaplan-Meier showed that patients with uveitis had a significantly earlier relapse (Log Rank χ^2 = 12.8 p <0.0001)
Conclusion: Although this is a retrospective study, we highlighted that early age at onset and at TNFi initiation, presence of uveitis and a long time to start biologics seem to be significantly more frequent in subjects who relapse, while stop therapy lengthening the interval of drug administration might be protective.

POS0758 ON DEMAND CANAKINUMAB THERAPY FOR COLCHICINE RESISTANT FAMILIAL MEDITERRANEAN FEVER (FMF) PAEDIATRIC PATIENTS – A MULTICENTER STUDY

Keywords: Quality of care

K. Shehadeh[1], Y. Levinsky[1,2], R. Tal[1,2], S. Kagan[3], T. Zoabi[3], L. Harel[1,2], G. Amarilyo[1,2]. *[1]Tel Aviv University, Scakler School of Medicine, Tel Aviv-Yafo, Israel*; *[2]Schneider- Children's Medical Center, Pediatric Rheumatology Unit, Petah Tikva, Israel*; *[3]Schneider- Children's Medical Center, Pediatric Department B, Petah Tikva, Israel*

Background: Familial Mediterranean fever (FMF) is the most common autoinflammatory disease.

Without therapy, it may lead to the development of secondary amyloidosis. Treatment with colchicine leads to long-term remission in ~70% of patients. 5% are resistant to colchicine therapy (crFMF) and may be treated with monthly dose of canakinumab (anti IL-1beta). However, colchicine, the only drug proved to prevent secondary amyloidosis. Canakinumab is immunosuppressive as well as expensive.
Objectives: To compare on demand canakinumab (COD) dosage policy vs. canakinumab fixed frequency (CFF) policy.
Methods: Data from 3 pediatric rheumatology centers (Schneider, Sheba, Rambam) were collected regarding crFMF patients treated with canakinumab. crFMF patients treated according to the COD policy were given 1 dose of sc-canakinumab injection 4mg/kg (max 150mg), with subsequent doses administered only after an additional attack. CFF patients were given fixed 4 weekly doses according to the manufacturer instructions.
Results: Overall, 51 crFMF (25 COD vs. 26 FCC) with mean follow-up of 22.6 months were included. There were no significant demographic, clinical or genetic differences between the groups. The COD group received significantly lower cumulative canakinumab dosage during the follow-up period (15.68±8.95mg/kg vs.32.5±8.05mg/kg;P<0.001). There were no differences between groups in mean FMF attacks nor in mean CRP levels at the end of follow-up period. None the less, the COD group necessitated higher colchicine doses (0.05±0.01mg/kg vs. 0.03±0.01mg/kg;P<0.001).
Conclusion: COD treatment in crFMF patients is as effective as CFF treatment. Using COD can reduce drug expenses and decrease immunosuppression exposure without negatively influencing the disease control.

Background: Tocilizumab (TCZ) was approved for systemic juvenile idiopathic arthritis (sJIA) as an intravenous formulation in 2008 after its effectiveness and safety were shown in a world-leading clinical trial performed in Japan in 2002–2008.
Objectives: This study aimed to understand the long-term prognosis of patients participating in phases II (Study MRA011JP), III (Study MRA316JP), and III/IV (Study MRA324JP). There were 149 participants in the clinical trial.
Methods: Information on eligible patients was obtained from 12 cooperating institutions approved by the Ethics Committee of Tokyo Women's Medical University and each institution. Patients who could be followed-up were referred and transferred to other hospitals or departments. The following long-term prognoses were assessed: treatment status, including the continuation of TCZ administration during the long-term course of sJIA, disease status (remission rate and clinical phenotype), complications, social adjustment, employment status, and *health-related* quality of life (HRQOL) scale.
Results: Results were collected for 132 cases from ten centers by December 2022. We examined 125 patients (58 males and 67 females) whose medical records were still available and whose final diagnosis was sJIA. The age of the study participants was 18.6 years at the time of the study, 4.3 years at onset, 8.8 years at first TCZ administration, 3.8 years from onset to the first TCZ administration, and 9.1 years from TCZ initiation (all median values). Of the 125 patients, 28 (22.4%) were in medication-free remission and were either under or completely followed-up. Of the 93 patients (74.4%) who continued therapy, 10 (10.8%) were moved to a subcutaneous version of TCZ, which is not yet licensed for the treatment of sJIA in Japan. Ten patients (10.8%) were switched to canakinumab (CAN) due to TCZ primary failure (5 patients), secondary failure (2 patients), side effects (1 patient developed anaphylaxis), or other reasons. Of the 124 patients, 44 (35.5%) changed from acute febrile sJIA to chronic arthritic sJIA, in which chronic arthritis was the primary pathology without systemic inflammation, and 17 of these patients still had active arthritis at the last observation. Corticosteroids were prescribed in 54 of 93 patients (58.1%). Except in one case of sudden death, the causes of death in the four cases that resulted in fatalities were macrophage activation syndrome, sJIA-related interstitial pneumonia, and disseminated aspergillosis. The most commonly observed complications were osteoporosis in 68 (54.4%), infection requiring hospitalization in 32 (25.6%), and hypertension in 25 (20%). The EQ-5D-5L score was 0.91 (mean). The final mean height of the patients whose information was available after the age of 18 years (n = 62) was 157.7 cm for males (mean 170.4 cm in Japanese) and 144.3 cm for females (mean 156.7 cm in Japanese), showing a significant short stature. The college/university enrollment rate was as high as 68.4% (Japanese statistical data: 58.9%), and all but five students were employed.
Conclusion: Seventy-four percent of the patients continued treatment with TCZ or CAN, and conversion to chronic arthritic sJIA was observed in 35.5%. Despite issues such as growth retardation, social adjustment and employment status were promising, suggesting a contribution of treatment.

POS0761 UVEITIS IN OLIGOARTICULAR JUVENILE IDIOPATHIC ARTHRITIS PATIENTS AND IN JUVENILE SPONDYLOARTHRITIS/ENTHESITISRELATED ARTHRITIS – IS THERE ANY DIFFERENCE?

Keywords: Uveitis

A. Martins[1,2], S. Ganhão[3], F. Oliveira Pinheiro[1,2], C. Morais[4], M. Leuzinger-Dias[5], M. Rodrigues[3], L. Figueira[5], I. Brito[2,3]. *[1]São João Universitary Hospital Center, Rheumatology, Porto, Portugal*; *[2]Faculdade de Medicina da Universidade do Porto - FMUP, Medicine, Porto, Portugal*; *[3]São João Universitary Hospital Center, Pediatric and Young Adult Rheumatology Unit, Porto, Portugal*; *[4]São João Universitary Hospital Center, Pediatrics, Porto, Portugal*; *[5]São João Universitary Hospital Center, Ophthalmology, Porto, Portugal*

Background: Juvenile idiopathic arthritis (JIA) is the most common systemic disease causing uveitis in childhood and adolescence. JIA-associated uveitis has an estimated prevalence ranging from 11% to 30%, being higher in patients with oligoarticular JIA (oJIA), and to a lesser degree, in patients with juvenile spondyloarthritis/enthesitis related arthritis (jSpA-ERA), especially in HLA-B27 positive patients.
Objectives: To compare the demographic and laboratory characteristics and clinical outcomes of uveitis in oJIA and jSpA-ERA patients.
Methods: A retrospective single-center study of patients with oJIA and jSpA-ERA followed in a tertiary Hospital was conducted. ILAR classification criteria were fulfilled and sociodemographic, clinical and treatment data were collected from the Portuguese Rheumatic Diseases Register (Reuma.pt) and medical records. Age at onset of uveitis, disease duration, acute-phase reactant proteins at diagnosis, and characteristics of uveitis including complications, medical and surgical treatments were collected. Statistic was performed with independent samples t-test, Mann-Whitney U test, chi-square test and Fisher's exact test. Statistical significance was set at a p-value <0.05.
Results: A total of 75 patients with oJIA (57 females, 76.0%) and 23 patients with jSpA-ERA (6 females, 26.1%) were included. Thirty-five of 98 patients (35.7%) developed uveitis, 28 patients had oJIA (80.0%) and 7 patients had jSpA-ERA (20.0). There were more females in the oJIA with uveitis group (p=0.006) and the age at diagnosis of JIA was lower in oJIA patients (p=0.005). ANA positivity was significantly higher in the oJIA with uveitis group (0.012) and HLA-B27 positivity was significantly higher in the jSpA-ERA with uveitis group (0.002). No significant differences were found in the ESR and CRP values at diagnosis and csDMARD/bDMARD use. Uveitis appeared in younger age in patients with oJIA than in patients with jSpA-ERA (8.4 ± 5.9 years vs 17.8 ± 7.2 years, p=0.001). In addition, the uveitis in the majority of oJIA patients was asymptomatic and the diagnosis was made during eye screening (n=21, 75.0%), as opposed to jSpA-ERA patients, in which the uveitis was symptomatic in the majority of patients (n=6, 85.7%, p=0.003). Concerning uveitis characteristics, anterior uveitis was the most frequent type in the 2 groups (and the only one in jSpA-ERA patients). In oJIA patients, panuveitis occurred in 8 patients (28.6%). However, no significant differences were found regarding the type of uveitis in the 2 groups. Patients with jSpA-ERA had more frequently unilateral alternating uveitis (n=4), followed by unilateral uveitis (same eye, n=3). No one developed bilateral uveitis. In oJIA patients, uveitis was more frequently unilateral (same eye, n=7), followed by bilateral involvement (n=9, 32.1%) and unilateral alternating (n=6, 21.4%). Complications were more frequent in oJIA group (n=15, 53.6%) than in jSpA-ERA (n=1, 14.3%, p=0.62). The most common complications in the oJIA group were cataracts (n=12, 42.9%), band keratopathy (n=8, 28.6%), ocular hypertension (n=8, 28.6%) and synechiae (n=6, 21.4%). Twelve patients (42.9%) with oJIA were submitted to eye surgery. On the contrary, no patient with jSpA-ERA was submitted to eye surgery.
Conclusion: In our study, uveitis manifested in 35.7% of the included patients with oJIA and jSpA-ERA. Uveitis in oJIA patients had poorer outcomes, such as complications and eye surgery requirement. Uveitis seems to have different characteristics depending on the JIA subtype, which leads us to think that possibly different immunologic mechanisms may be involved.

POS0762 ASSOCIATIONS BETWEEN POWER DOPPLER ULTRASOUND FINDINGS AND B-MODE SYNOVITIS AND CLINICAL ARTHRITIS IN JUVENILE IDIOPATHIC ARTHRITIS USING A STANDARDIZED SCANNING APPROACH AND SCORING SYSTEM

Keywords: Ultrasound, Imaging, Inflammatory arthritides

N. K. Sande[1,2], V. Lilleby[1], A. B. Aga[1], E. Kirkhus[3], B. Flato[1,2], P. Bøyesen[1]. *[1]Oslo University Hospital, Department of Rheumatology, Oslo, Norway*; *[2]University of Oslo, Institute of Clinical Medicine, Oslo, Norway*; *[3]Oslo University Hospital, Department of Radiology, Oslo, Norway*

Background: Ultrasound is a valuable tool in the evaluation of synovitis in patients with juvenile idiopathic arthritis (JIA). However, interpretation of Doppler signals in children is challenging due to physiologic vascularization that can be misinterpreted as pathologic findings. Definitions for synovitis in children, including B-mode (BM) and Doppler findings, have been developed and emphasize that only Doppler signals within synovial hypertrophy should be considered as synovitis [1]. So far, few studies have implemented this definition in the evaluation of Doppler findings in children.
Objectives: To describe power Doppler (PD) ultrasound findings in joint regions with BM synovitis in patients with JIA using a standardized scanning protocol and scoring system. Further, to examine associations between PD findings and BM synovitis, clinical arthritis, patient characteristics and disease activity.
Methods: In this cross-sectional study one rheumatologist with broad ultrasound experience, blinded to clinical findings, performed ultrasound examinations in 27 patients with JIA aged 2 to 17 years old with suspected clinical arthritis using the same ultrasound machine with standardized settings. The elbow, wrist, metacarpophalangeal 2-3, proximal interphalangeal 2-3, knee, ankle and metatarsophalangeal 2-3 joints were assessed bilaterally and scored for BM and PD findings using a joint-specific scoring system (grades 0-3) with reference atlas [2]. Pathologic BM and PD findings were defined as grades ≥1. Multilevel mixed-effects ordered logistic regression models were used to explore associations between PD findings and BM synovitis, clinical arthritis, age, sex, JIA subgroup, disease duration and measures of disease activity (Juvenile Arthritis Disease Activity Score (JADAS10), (range 0-40).
Results: Overall, 971 joint regions were evaluated by ultrasound, 129 had BM synovitis and were assessed for PD. PD findings were detected in 45 joint regions (34.9%), most frequently in the lateral parapatellar recess of the knee joint (24.4%) (**Figure 1**). Increasing PD grades were associated with higher BM grades (OR=5.0, 95% CI: 2.7-9.1, p<0.001) and with the presence of clinical arthritis (OR=7.4, 95% CI: 2.7-21.7, p<0.001). PD findings were not associated with age, sex, JIA subgroups, disease duration or JADAS10.
Conclusion: Increasing severity of PD findings were significantly associated with BM synovitis and with the presence of clinical arthritis. These findings suggest that PD signals detected using a standardized ultrasound examination and scoring system can reflect active disease in patients with JIA.

POS0763

AN EVALUATION OF THE EFFICIENCY OF METHOTREXATE IN THE TREATMENT OF JUVENILE ENTHESITIS RELATED ARTHRITIS

Keywords: Disease-modifying drugs (DMARDs), Spondyloarthritis, Enthesitis

L. Krämer[1], I. Foeldvari[2]. [1]*Asklepios Campus Hamburg der Semmelweis Universität Budapest, Humanmedizin, Hamburg, Germany*; [2]*Hamburger Centre for Juvenile and Adolescent Rheumatology, Paediatric and Adolescent Rheumatology, Hamburg, Germany*

Background: Methotrexate (MTX) is quiet commonly used to treat all subtypes of juvenile idiopathic arthritis (JIA). Despite that, there are no studies on the efficiency of MTX treatment in juvenile enthesitis related arthritis (ERA).
Objectives: This study aims to evaluate the efficacy of MTX treatment in children with juvenile arthritis of the ERA subtype.
Methods: We conducted a retrospective chart review from January 2017 to December 2021 of all patients who received MTX for at least 3 months. The clinical manifestation of the ERA was determined by using JADAS and the JSpADA. Good therapeutic response was defined by a reduction of the JSpADA by 0,8 points or more. A JADAS under < 2 was considered minimal disease activity, whereas a JADAS < 1 was interpreted as inactive disease.
Results: We found 188 patients in whom MTX was initiated, 117 (62,23 %) of these patients were treated with MTX for at least three months and therefore fulfilled the criteria for this analysis. At all follow-ups, the patients showed a significant reduction in both scores compared to the start (see Table 1). After three months 49,57 % of the participating patients were considered good responders, after twelve months it was 70 %. Half of the followed patients achieved the state of remission after twelve months, another 12,82 % showed only minimal disease activity at this point.
Conclusion: This study shows the efficacy of MTX as a first-line therapy for the treatment of children with ERA. A comparative study with Sulfasalazine would be interesting.

POS0764

IMPACT OF TOFACITINIB TREATMENT ON HEIGHT IN JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Inflammatory arthritides, Targeted synthetic drugs, Randomized control trial

H. Brunner[1], H. Wasserman[2], M. Saul[3], D. Robinson[4], E. Nagy[5], A. Diehl[6], M. Mortezavi[7]. [1]*Cincinnati Children's Hospital Medical Center, Division of Rheumatology, Department of Pediatrics, Cincinnati, OH, United States of America*; [2]*Cincinnati Children's Hospital Medical Center and University of Cincinnati College of Medicine, Division of Pediatrics, Department of Endocrinology, Cincinnati, OH, United States of America*; [3]*Pfizer Inc, Biomarker Statistics, Gilbert, AZ, United States of America*; [4]*Pfizer Inc, Global Biometrics and Data Management, Cambridge, MA, United States of America*; [5]*Pfizer Ltd, Safety Surveillance and Risk Management, Tadworth, Surrey, United Kingdom*; [6]*Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America*; [7]*Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*

Background: Diminished growth can be a consequence of juvenile idiopathic arthritis (JIA).[1] Growth hormone signals through a Janus kinase (JAK)2 tyrosine kinase-coupled receptor.[2] Tofacitinib, an oral JAK inhibitor approved for JIA, preferentially inhibits signalling by heterodimeric receptors associated with JAK1 and/or JAK3 and has less functional selectivity for JAK2.
Objectives: To evaluate the growth of patients (pts) with JIA treated with tofacitinib.
Methods: This post hoc analysis of the Phase 3 trial of tofacitinib in pts with JIA (NCT02592434; a 44-week, 2-part, double-blind [DB], withdrawal study in 225 pts aged 2–<18 years) enrolled 212 pts (pts with systemic JIA were excluded). In part 1, pts received open-label tofacitinib 5 mg twice daily (BID; or weight-based oral solution) for 18 weeks/flare. In the DB phase, pts achieving JIA/American College of Rheumatology improvement ≥30% by Week 18 were randomised to receive tofacitinib or placebo until Week 44/flare. Pts could then receive tofacitinib in a long-term extension study. Height Z-scores were calculated for pts at baseline (BL), Weeks 18, 44, 68 and 92 using age- and sex-matched reference data from the World Health Organization. A repeated measures mixed-effects analysis of pts who received continuous tofacitinib assessed change in height Z-scores over time. The impact of JIA category, age, sex, race, ethnicity, biologic disease-modifying antirheumatic drug (bDMARD)/conventional synthetic DMARD (csDMARD) use, and C-reactive protein (CRP; normal/elevated) on BL height Z-score was also assessed. A separate analysis assessed the impact of treatment on change in height Z-scores during the DB phase. Growth velocity (cm/year) from BL to Week 44 was calculated.
Results: Ethnicity was the only characteristic associated with BL height Z-score (Table 1). For 83 pts who received continuous tofacitinib, mean (95% confidence intervals [CI]) BL height Z-score was -0.4 (-0.7, -0.1), and was stable up to Week 92 (Figure 1). Mean (95% CI) change in height Z-score from BL of the DB phase (Week 18) to Week 44 was not different for pts receiving tofacitinib (N=56; -0.03 [-0.1, 0.04]) vs placebo (N=36; -0.04 [-0.1, 0.04]). Growth velocities in the 56 pts who received tofacitinib for 44 weeks was within normal range for age and sex with peak values at ages 9–10 years and 11–12 years for females and males, respectively (data not shown).

Table 1. BL Z-score by pt characteristics

Characteristic		n	Median height Z-score (IQR)	Mean height Z-score (SD)	p value[a]
JIA category	Enthesitis-related arthritis	21	0.3 (-0.4–0.9)	0.2 (0.9)	0.17
	Extended oligoarthritis	28	0.1 (-0.6–0.6)	0.1 (1.1)	
	Juvenile psoriatic arthritis	20	-0.1 (-0.8–0.7)	-0.1 (1.0)	
	RF- polyarthritis	104	-0.3 (-1.1–0.4)	-0.4 (1.4)	
	RF+ polyarthritis	39	-0.1 (-1.1–0.6)	-0.3 (1.1)	
Age	2–<6 years	20	-0.4 (-1.3–0.2)	-0.6 (1.0)	0.09
	6–<12 years	58	0.1 (-0.6–0.7)	0.0 (1.2)	
	12–<18 years	134	-0.3 (-1.0–0.6)	-0.3 (1.2)	
Sex	Female	164	-0.3 (-1.0–0.5)	-0.3 (1.2)	0.25
Race	Black/African American	5	0.3 (0.2–0.3)	0.0 (0.8)	0.1
	Other	22	-0.6 (-1.7–0.1)	-0.8 (1.4)	
	White	185	-0.2 (-0.8–0.6)	-0.2 (1.2)	
Ethnicity	Hispanic/Latino	60	-0.6 (-1.5–0.1)	-0.8 (1.5)	<0.001
	Not Hispanic/Latino	152	0.0 (-0.7–0.7)	0.0 (1.0)	
Previous bDMARDs	bDMARD naïve	169	-0.1 (-0.9–0.6)	-0.2 (1.2)	0.49
csDMARDs[b]	Yes	191	-0.3 (-0.9–0.6)	-0.2 (1.2)	0.74
CRP category	Normal	112	0.0 (-0.7–0.6)	-0.1 (1.1)	0.15

[a]Calculated using Kruskal-Wallis rank sum test[b]Methotrexate or otherIQR, interquartile range; n, number of pts with characteristic; RF, rheumatoid factor; SD, standard deviation

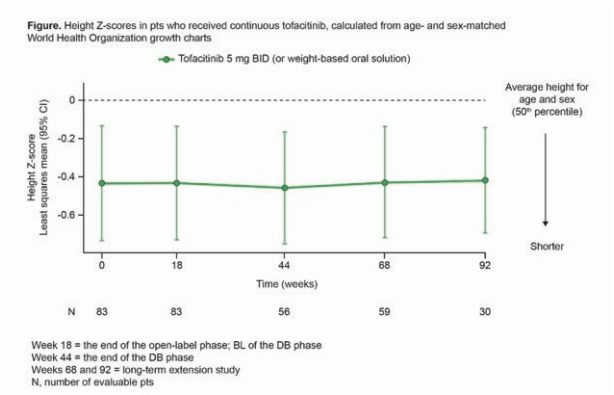

Figure. Height Z-scores in pts who received continuous tofacitinib, calculated from age- and sex-matched World Health Organization growth charts

Week 18 = the end of the open-label phase; BL of the DB phase
Week 44 = the end of the DB phase
Weeks 68 and 92 = long-term extension study
N, number of evaluable pts

Conclusion: In this post hoc analysis, pts with JIA began with near normal height Z-scores and tofacitinib had no negative impact on height Z-scores after 92 weeks. Growth velocity was within the normal range for age up to Week 44. Catch-up growth was not observed, possibly due to the study duration being too short and the BL height Z-scores being near normal.

POS0765 SERUM BASIC FIBROBLAST GROWTH FACTOR IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Biomarkers, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

N. Shevchenko[1,2], O. Pavlova[1]. [1]*V. N. Karazin Kharkiv National University, Department of Pediatrics, Kharkiv, Ukraine*; [2]*SI "Institute of Children and Adolescents Health Care of NAMS of Ukraine", Department of Rheumatology and Comorbid Conditions, Kharkiv, Ukraine*

Background: Patients with rheumatic diseases are at high risk for poor outcomes and gaps in care when severe fibrosis occur, as a result of tissue damage caused by chronic phase of persistent inflammation. Only limited data also controversial results are available on the fibrosis predictors in patients with juvenile idiopathic arthritis (JIA) on long-term methotrexate (MTX) treatment [1,2]

Objectives: To evaluate serum levels of basic fibroblast growth factor (bFGF) in children with juvenile idiopathic arthritis treated with methotrexate.

Methods: 104 patients with polyarthritis (50,96%) and oligoarthritis (40,38%) variants JIA (mean age 13.3 yrs, 59,62 % female, mean age of JIA onset 7.2 yrs, mean disease duration 5.06 yrs) were included in this 4-years prospective study. In 104 children with JIA were treated with MTX 75.96 % (vs. 24.04 % not treated with MTX, 16,35 % were prescribed MTX, but they didn't receive any dose yet on investigation day). Among patients treated with MTX 4.81 % had dose less than 10 mg/m^2/week, 32.69 % 10-12.5 mg/m^2/week, 31.73 % 12.6 - 15 mg/m^2/week, 6.73 % over 15 mg/m^2/week. bFGF levels were determined by bFGF ELISA kits (Elabscience, USA). Serum levels of bFGF were analyzed depending on patients' gender, age, and age of JIA onset, its variant, duration, activity, and presence of MTX in treatment and its dose. Levels of erythrocyte sedimentation rate (ESR), C-reactive protein (C-RP), circulating immune complex (CIC) and antistreptolysin-O (ASL-O) were analyzed in this study.

Results: We evaluated bFGF level for children with JIA (min: 4171.56 pg/ml; Me:7089.28 pg/ml; max: 18011.25 pg/ml). The average level of bFGF significantly increased in children with age of JIA onset from 15 to 18 years versus age of JIA onset up to 3 years ($p = 0.009$) and 11–14 years ($p = 0.014$). It was also found higher bFGF in patients with an average activity according JADAS-27 pattern versus a low one ($p = 0.0005$). Activity according JADAS-27 pattern, levels of ESR, CIC and ASL-O was associated with bFGF level. Mostly bFGF was correlated with with ASL-O (among: boys r=0.45, patients with oligoarthritis r=0.49, moderate disease activity according to JADAS-27 r=0.58, MTX treatment r= 0.38, dose of MTX, 12,5-15mg/m2/week r=0.50 $p < 0.05$), with CIC (among: patients with polyarthritis r=0.37, low disease activity according to JADAS-27 r=0.34, dose of MTX, less 10mg/m2/week r=0.96 $p < 0.05$), with ESR (among: girls r=0.37, patients with polyarthritis r=0.38, $p < 0.05$).

Conclusion: Children with JIA had a higher bFGF level in patients with JIA onset after 15 years old and moderate disease activity. CIC and ESR were corresponded with high bFGF level. Presence of additional streptococcal infection impact on fibrosis formation in children with JIA.

POS0766 CIRCULATING SOLUBLE UROKINASE PLASMINOGEN ACTIVATOR RECEPTOR (SUPAR) ASSOCIATES WITH JOINT DESTRUCTION IN JUVENILE IDIOPATHIC ARTHRITIS: A CASE-CONTROL STUDY WITH LONGITUDINAL FOLLOW-UP

Keywords: Inflammatory arthritides, Prognostic factors, Biomarkers

P. Lewander[1], C. Dahle[2], L. Wirestam3, J. Wetterö3, C. Sjöwall3. [1]*Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection/Rheumatology, Linköping, Sweden*; [2]*Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection/Clinical Immunology, Linköping, Sweden*; [1]*Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection/Rheumatology, Linköping, Sweden*

Background: Reliable biomarkers in the early stages of juvenile idiopathic arthritis (JIA) are scarce. The disease heterogeneity makes it clinically challenging to predict the risk of future permanent joint damage. Some indicators of poor outcome have been identified, e.g. rheumatoid factor (RF) and antibodies against cyclic citrullinated peptides (anti-CCP), but additional biomarkers with predictive potential are warranted in order to start optimal treatment before tissue damage occurs. The soluble urokinase plasminogen activator receptor (suPAR) has been reported as an easily measurable biomarker for prognosis and severity in several diseases, including adult rheumatoid arthritis, systemic lupus erythematosus and other inflammatory conditions [1]. However, to our knowledge, suPAR has never been studied in JIA.

Objectives: We asked whether suPAR could predict a more severe course with erosions in JIA.

Methods: 51 well-characterized patients with recent-onset or established JIA and 50 age- and sex-matched healthy control subjects were included. Blood sampling was performed at inclusion and sera were stored for later analysis of suPAR by suPARnostic ELISA (Virogates, Birkeröd, Denmark). The patients were carefully followed over 3 years and erythrocyte sedimentation rate, C-reactive protein, RF, anti-CCP and antinuclear antibodies were analyzed as part of clinical routine. Signs of joint destructions were evaluated by radiographic investigation of affected joints. Data was evaluated using non-parametrical statistical methods.

Results: Overall, the levels of suPAR did not differ significantly between JIA and controls (Figure 1). Still, the subgroup of subjects with polyarticular disease showed higher suPAR than the controls (p=0.013). In addition, elevated suPAR levels were associated with joint erosions (p=0.022). In two individuals with erosions, high levels of suPAR were found despite absence of RF and anti-CCP.

Conclusion: We present new data on the biomarker suPAR in JIA. The results indicate that, in addition to RF and anti-CCP, analysis of suPAR could be of additional value in predicting the risk of joint erosions. Early analysis of suPAR could potentially guide treatment decision-making in JIA, but our findings call for confirmation in larger cohorts.

POS0767 THE EVALUATION AND IMPORTANCE OF TRANSITION FROM PEDIATRIC TO ADULT RHEUMATOLOGY CARE IN RHEUMATOLOGICAL DISEASES

Keywords: Patient information and education, Descriptive Studies

T. Demirci Yildirim[1], R. Isguder[2], E. Karacura[3], Y. Erez[1], B. Makay[2], F. Onen[1], E. Unsal[2], İ. Sari[1]. [1]*Dokuz Eylul University, Faculty of Medicine, Rheumatology, Izmir, Turkey*; [2]*Dokuz Eylul University, Faculty of Medicine, Pediatric Rheumatology, Izmir, Turkey*; [3]*Dokuz Eylul University, Faculty of Medicine, Internal Medicine, Izmir, Turkey*

Background: The transition from pediatric to adult health care often challenging for young adults with rheumatic diseases. During the transition period, disruptions, diagnostic changes, and treatment differences may occur. The successful transition of the young adult patient to adult care is an important milestone in pediatric rheumatology.
Objectives: In this study, we aimed to examine the diagnosis and treatment changes of transition patients and the characteristics of the transition period in our clinic.
Methods: This was retrospective observational study was carried out in Dokuz Eylul University Pediatric and Adult Rheumatology Department. Patients who followed-up in Pediatric Rheumatology Department transferred to the Adult Rheumatology Department within the last ten years and continued to visit at least once a year were included in this study. If the transition period of the patients was less than three months, it was defined as early transition. Demographic features and educational status, parental divorce, diagnosis changes, and diagnosis-specific treatment changes were recorded.
Results: In total, 962 transitional patients scanned and 210 of them met follow-up criteria. Of the patients, 117 (55.7%) were female, with a median age of 24 (IQR, 21 – 28). Most of patients followed-up juvenile rheumatoid arthritis (JIA) (n=79, 37.6%) and familial Mediterranean fever (FMF) (n=79, 37.6%). Median duration of pediatric rheumatology follow-up was 52 months (IQR, 23 – 87) and 47 (22.%) patients have been treated with biological agent (Table 1). Median transition time was 4 months (1-13 IQR) and the rate of early transition was 46.7%. We found that receiving biological therapy associated with early transition (59.6% vs 40.4%, p=0.040). We also found that Bachelor's degree or higher educational status associated with late transition (40% vs 60%, p=0.025). Rheumatologic diseases were not associated with late transition except FMF, patients with FMF were prone to late transition (32.9% vs 67.1%, p=0.015). Gender and parents' divorce did not associate with transition time (Table 1). The diagnoses of 13% of the participants were changed after they were followed-up in adult rheumatology. The median follow-up period for adult rheumatology was 40 months (15-75 IQR). Biological therapy was started for the first time in 21 patients, the biological therapy of 5 patients was changed, and the biological therapy of 7 patients was discontinued during adult rheumatology follow-up.
Conclusion: We found that most of the patients who were followed-up in pediatric rheumatology in our center did not transition to the adult rheumatology in the same center. Less than half (46.7%) of the patients started to be followed up in adult rheumatology within the first 3 months. Treatment with biological agents was found associated with early transition. Since patients who were treated with biological agent need for a doctor's visit to reach the treatment was considered the main reason for these patients' early transition. We found that Bachelor's degree or higher educational status was associated with late transition. Patients often move to other cities for university may be the reason of the late transition. Transition time did not associate with the rheumatologic diseases except FMF. The reason for the late transition in FMF can be explained by the admission to the hospital frequently with attacks. Transition may be challenging in pediatric rheumatology. The ideal transition to adult rheumatological care should start in the early adolescence period of the patients, planned transition visits may increase the rate of follow-up.

POS0768 CHARACTERISTICS OF PATIENTS WITH DIFFICULT-TO-TREAT JUVENILE IDIOPATHIC ARTHRITIS AT ADULTHOOD IN FRANCE

Keywords: bDMARD, Descriptive studies, Prognostic factors

S. Hecquet[1], M. Thomas[1], A. Combier[1], J. Wipff[1], G. Touanga[1], P. Quartier[2], J. Avouac[1], Y. Allanore[1]. [1]*Cochin Hospital, Rheumatology, Paris, France*; [2]*Necker Hospital, Immuno-Hématologie et Rhumatologie pédiatriques, Paris, France*

Background: An effort to unify the variability of juvenile idiopathic arthritis (JIA) phenotypes was initiated in 1994 resulting in the current categories of systemic JIA, oligoarthritis (persistent or extended), rheumatoid factor (RF)-negative polyarthritis, RF-positive polyarthritis, psoriatic JIA, and enthesitis related arthritis. Recently, EULAR has proposed a definition of difficult-to-treat rheumatoid arthritis (D2TRA) and the concept was later extended to spondyloarthritis and psoriatic arthritis.
Objectives: The aim of this study was to describe difficult-to-treat JIA (D2TJIA) at adulthood based on the EULAR definition of D2TRA.
Methods: We stratified consecutive JIA patients treated at Cochin Hospital in Paris into two groups, a D2TJIA group and a non-D2TJIA group. Based on EULAR definition of D2TRA, we defined D2TJIA as JIAs failing at least two targeted therapies, with a different mechanism of action.
Results: In total, we identified 18 D2TJIA patients (mean age 27.4 years, 67% female) and 88 non-D2TJIA patients (mean age 29.1 years, 70% female). Regarding JIA subtypes, we observed significantly more systemic JIA in the D2T group (39% vs 14%, p=0.02). D2TJIA patients were more likely to have erosions on X-rays (82% vs. 55%, p=0.038). Regarding auto-antibodies, positive anti-CCP

(6.7% vs. 35%, p=0.048) were less common in D2TJIA than in non-D2TJIA patients, and no difference was observed for RF and anti-nuclear antibody positivity (**Table 1**). Compared with non-D2TJIA, patients with D2TJIA had a significantly reduced duration of exposure to the first line of bDMARD (6.5 vs 32 months, p<0.01) (**Table 1**).

Table 1. Characteristics of JIA patients

	Non-D2TJIA (n = 88)	D2TJIA (n = 18)	p
Age, mean (SD)	29.1 (3.53)	27.4 (4.50)	0.14
Female, n (%)	62 (70%)	12 (67%)	0.75
JIA type, n (%)	12 (14)	7 (39)	0.02
Systemic JIA	18 (20)	3 (17)	1
RF-positive polyarthritis	13 (15)	3 (17)	0.7
RF-negative polyarthritis	19 (22)	3 (17)	0.8
Persistent oligoarthritis	4 (5)	1 (5)	1
Extended oligoarthritis	1 (1)	1 (5)	0.3
Psoriatic JIA	21 (24)	1 (5)	0.1
Enthesitis related arthritis			
Age at diagnosis, median [Q25-75]	9.00 [4.00; 13.0]	7.00 [3.00; 8.00]	0.11
Duration of bDMARD 1 (in months), median [Q25-75]	32.0 [16.0; 79.0]	6.50 [4.25; 31.5]	<0.01
Duration of bDMARD 2 (in months), median [Q25-75]	21.0 [7.00; 50.2]	10.0 [4.00; 23.2]	0.17
Duration of bDMARD 3 (in months), median [Q25-75]	6.00 [2.50; 19.0]	13.0 [4.00; 30.0]	0.32
Duration of bDMARD 4 (in months), median [Q25-75]	5.00 [1.00; 28.5]	6.00 [4.00; 15.0]	0.67
Number of used bDMARD, median [Q25-75]	2.00 [1.00; 2.00]	4.00 [3.00; 4.00]	<0.001
Prosthesis, n (%)	11 (12%)	5 (28%)	0.14
Coxitis, n (%)	27 (35%)	9 (53%)	0.16
Inflammatory bowel disease, n (%)	1 (1.2%)	0 (0%)	1
Psoriasis, n (%)	4 (4.7%)	2 (11%)	0.28
Uveitis, n (%)	22 (26%)	3 (17%)	0.55
Erosions, n (%)	47 (55%)	14 (82%)	0.038
Anti-nuclear antibody positive, n (%)	27 (44%)	5 (33%)	0.47
Anti-CCP positive, n (%)	17 (35%)	1 (6.7%)	0.048
RF positive, n (%)	21 (35%)	4 (25%)	0.45

Conclusion: Our work is the first to describe D2TJIA in France. It seemed interesting to raise the question of whether D2T JIA exists, and if so, what could be its potential definition and management. This may serve as a hypothesis and a basis for future reflections. As observed in rheumatoid arthritis, we report significantly more patients with erosions on X-ray in the D2TJIA group compared to the non-D2TJIA patients which supports such stratification. However, D2TJIA patients did not differ from non-D2TJIA patients in terms of demographic data. Interestingly, patients with D2TJIA had a significantly reduced duration of exposure to the first line of bDMARD suggesting early treatment escape and supporting the importance of temporality in defining difficult-to-treat patients. Our work suggests the relevance of identifying patients with D2TJIA. As showed in other inflammatory rheumatic diseases, this can open the door to a better stratification and personalized management. The definition of D2TJIA needs to be validated and temporality seems to be an essential element to consider.

POS0769 VISCERAL ADIPOSE TISSUE AND ADIPOKINES/ CYTOKINES IN JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Inflammatory arthritides, Biomarkers

K. Risum[1,2], N. Olarescu[3,4], K. Godang[3], H. Marstein[5], J. Bollerslev[3,6], H. Sanner[5,7]. [1]*Oslo University Hospital, Section for Orthopaedic Rehabilitation, Oslo, Norway*; [2]*Oslo Metropolitan University, Department of Rehabilitation Science and Health Technology, Oslo, Norway*; [3]*Oslo University Hospital, Section for Specialised Endocrinology, Oslo, Norway*; [4]*University of Oslo, Department of Medical Biochemistry, Oslo, Norway*; [5]*Oslo New University College, Institute for Health, Oslo, Norway*; [6]*University of Oslo, Institute of Clinical Medicine, Oslo, Norway*; [7]*Oslo University Hospital, Section for Rheumatology, Oslo, Norway*

Background: Increased visceral adipose tissue (VAT) associates with markers for rheumatic inflammatory and cardiovascular diseases, but knowledge is sparse in juvenile idiopathic arthritis (JIA).
Objectives: To compare VAT mass, lipid profile and selected adipokines/cytokines in patients with JIA with matched controls, and to explore the role of VAT in disease associated inflammation and cardiovascular risk. Moreover, to explore the differences in circulating biomarkers between poly- and oligoarticular disease.
Methods: 60 patients with JIA (50 girls) age between 10–16 years were consecutively recruited at Oslo University Hospital and 60 age-and sex-matched controls were randomly drawn from the National Registry. The JIA group included 30 patients with persistent oligoarticular JIA (oligo disease) and 30 patients with extended oligoarticular or polyarticular disease RF +/- (poly disease). VAT (g) was estimated by dual-energy x-ray absorptiometry. Lipid profile, CRP and adipokines/cytokines (by ELISA) were analyzed. Differences between groups were tested with parametric or non-parametric analyses as appropriate and associations with univariate and multiple linear regression analyses.
Results: VAT (g) was comparable between patients and controls [median (25^{th} – 75^{th} percentile) 64 (23-149) vs 66 (30-99), p=0.98] and between patients with oligo disease and poly disease [46 (22-123) vs 80 (23-167), p=0.32]. Patients presented lower serum levels of APOA1 and RBP4, and elevated serum levels of IL-6, progranulin and MCP-1 (Table 1) as compared to the controls. Patients with poly disease had lower plasma levels of LDL-C, LILA, IL-1RA, progranulin and VEGF, and elevated serum levels of IL-1b and IL-1b/IL-1RA ratio (Table 1) as compared to patients with oligo disease. No statistically significant differences were seen between neither patients and controls nor patients with oligo disease and poly disease for TC, HDL-C, APOB, CRP, leptin, adiponectin, NGAL, angpl4, angiopoietin, chemerin and resistin. In patients, higher IL-6 [unstandardized B (95% CI) 48.7 (25.1, 72.2), p<0.001], resistin [8.5 (5.1, 11.8), p<0.001] and leptin [2.5 (0.9, 4.0), p=0.002] were identified as correlates for higher VAT. In controls, only higher leptin [unstandardized B (95% CI) 5.3 (3.7, 6.9), p<0.001] was identified as correlate for higher VAT.
Conclusion: Despite similar mass, VAT seems to be closely related to IL-6 and resistin suggesting an active metabolic role in JIA. In addition to IL-6, several pro-inflammatory adipokines/cytokines were increased in JIA potentially playing a role in disease activity. Novel biomarkes, among them IL-1b/IL-1RA system, were identified for differentiating between oligo vs poly disease.

Table 1. Adipokines/cytokines in patients and controls

	Patients (n=60)	Controls (n=60)	p-value patients vs controls	Oligo disease (n=29-30)	Poly disease (n=30)	p-value oligo vs poly disease

POS0770 CAREGIVER BURDEN IN INDIAN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS: A SINGLE HOSPITAL-BASED STUDY

Keywords: Descriptive studies, Patient reported outcomes, Mental health

N. Gowda[1], A. Balakrishnan[1], A. Lawrence[1], A. Aggarwal[1]. [1]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India*

Background: Caring for a child with juvenile idiopathic arthritis (JIA) negatively impacts caregivers. There are no studies on caregiver burden in JIA from South Asia.
Objectives: To assess the caregiver burden in children with JIA from India.
Methods: We conducted this observational study in a Tertiary care center in North India. We translated and culturally adapted the CAREGIVER QUESTIONNAIRE[1] into Hindi and administered it to 145 caregivers of JIA patients age ≤ 18 years from November 2021 to December 2022. We collected their

socio-economic data, clinically examined the child and reviewed their clinic records for disease characteristics including activity and damage. The Juvenile Arthritis Multidimensional Assessment Report was used to assess the physical function and health related quality of life. The CAREGIVER QUESTIONNAIRE was scored[2] to determine impact in various domains.

Results: One hundred and forty-five caregivers participated with median age of 39 (32-45) years. This included 68 (47.9%) fathers, 34 (23.4%) mothers, 22 (15.2%) brothers, 18 (12.4 %) uncles and 1 (0.7%) sister, grandfather and grandmother. The JIA patients had median age of 15 (12-17) years and the male: female ratio 2.4:1. Enthesitis related arthritis was the predominant subtype (65.5%) followed by systemic onset JIA (11.7%), RF+ polyarthritis (9.0%), RF- polyarthritis (6.9%), oligoarticular JIA (6.2%) and extended oligoarticular (0.7%). Majority (69.7%) expressed sadness at diagnosis, and one fourth (28.3%) continued to express sadness. Half (53.4%) of the caregivers neglected their health and one tenth (9.7%) became sick. Two thirds (64.8%) had to borrow money to meet the expenses. Emotional impact scored 12.9 ± 2.3 (range 4-18). Social impact scored 6.1 ± 1.9 (range 2-9), economic impact 2.6 ± 1.0 (range 0-5), labour impact 7.0 ± 4.2 (range 0-15), family impact 6.8 ± 1.6 (range 4-16) relationship impact 0.6 ± 0.5 (range 0-0.8). Impact on spirituality was 0.9 ± 0.6 (range 0-5) and impact of social networks was 0.8 ± 0.8 (min= 0, max=8). Total score was 37.8 ± 9.2 (range 10-84).

Conclusion: JIA has significant emotional, social, economic and labor impact on caregivers. Social support needs to be given to caregivers for caring for children with JIA.

POS0771

JAK INHIBITORS AS TREATMENT OF ADULT PATIENTS WITH PEDIATRIC-ONSET JUVENILE IDIOPATHIC ARTHRITIS: A MONOCENTRIC EXPERIENCE

Keywords: Inflammatory arthritides, bDMARD

M. R. Pellico[1,2], M. Pandolfi[1,2], A. Marino[2], S. Costi[2], M. Cornalba[1,2], I. Pontikaki[2], M. Gattinara[2], R. Caporali[1,2], C. Chighizola[1,2]. [1]*University of Milan, Clinical Sciences and Community Health, Milan, Italy*; [2]*ASST Pini-CTO, Pediatric Rheumatology, Milan, Italy*

Background: JAK inhibitors (JAKi), small molecules that inhibit the Janus kinase enzymes, are increasingly used to treat children with rheumatologic diseases. Clinical experience of JAKi in the management of adult patients with pediatric-onset rheumatic conditions is still scarce.

Objectives: The aim of this study consists in evaluating efficacy and safety of JAKi in a monocentric cohort of adult patients with juvenile idiopathic arthritis (JIA).

Methods: Clinical records of patients attending the rheumatology transition clinic at our centre were retrospectively reviewed; patients were included in case of: i) JIA diagnosis according to current classification criteria (1); ii) age ≥18 years and iii) treatment with JAKi for at least 3 months.

Results: 17 patients that met the inclusion criteria were included in this study. Their demographics and clinical features are detailed in **Table 1**. 9 patients were treated with tofacitinib (52.9%) and 8 subjects (47.1%) received baricitinib. At 3 months, 4 patients (23.5%) achieved disease remission on JAKi: 3 patients achieving remission were treated with baricitinib and 1 with tofacitinib (37.5 vs. 16.7%, p=0.29). None of the patients with systemic JIA and enthesitis-related arthritis obtained remission; the remission rate at 3 months was higher, although not significantly, in the oligoarticular subset compared to the polyarticular subset (37.5 vs. 20%; p=1.0). Disease duration, age at onset and at JAKi start were similar between patients achieving remission and those with active disease (p=0.94, p=0.58 and p=0.72, respectively). Patients with ≤1 active joint involvement at JAKi start had higher remission rate (50 vs. 22.2%; p=0.58). Subjects who achieved remission on JAKi had a significantly lower pre-treatment DAS28 compared to those with still active disease (median DAS28 (IQR) 2.17 (1.9-2.4) and 4.54 (3.8-4.9), respectively; p=0.01, Mann-Whitney U=4). A pre-treatment DAS28 <3.76 predicted response to JAKi with 100% sensitivity and 84.6% specificity (AUC 0.88, p=0.02, 95%CI 0.71-1.05). Concomitant treatment with methotrexate did not significantly affect the remission rate (16.7 vs. 37.5%; p=1.0). This was lower among patients who had been treated with ≥2 biological drugs before JAKi start (9 vs. 66.7%; p=0.05). None of the patients developed side effects during JAKi treatment.

Conclusion: JAKi could represent an effective and safe treatment option for adult JIA patients with low/moderate disease activity, particularly in case of oligoarticular involvement.

A, Rheumatology, Buenos Aires, Argentina*; [19]*Hospital Nacional R. Gutierrez, Rheumatology, Buenos Aires, Argentina*

Background: The term juvenile idiopathic arthritis (JIA) represents a heterogeneous group of disorders, all manifesting joint inflammation, but with different clinical phenotypes, disease course, and outcomes [1,2]. In Argentina, information about patients with JIA is scarce. In our country, different factors such as the diversity of sociodemographic conditions and the disparities in the access to health care, could influence the JIA subtypes prevalence and prognosis of these patients.
Objectives: Describe the sociodemographic and clinical characteristics of patients with different subtypes of JIA.
Methods: Descriptive, retrospective, chart review and multicenter study. Patients were included with a diagnosis of JIA, according to ILAR criteria (2001) and onset of symptoms ≤ 16 years, diagnosis within the last 3 years and with at least 12 months of follow-up since diagnosis by the same physician or treating team. Sociodemographic variables, clinical variables prior to diagnosis by the pediatric rheumatologist, time to specialist consultation, treatments prior to diagnosis and variables at the time of diagnosis by the specialist were recorded: JIA subtype; serological, articular, ocular, and systemic manifestations; associated complications and treatments given.
Results: 320 patients from 17 specialized care centers in Argentina (11 public and 6 private) were included. The mean age at symptom onset was 6.9 years (SD 4.09) and 65.6% of the patients were girls. 94.4% of the patients were in school according to their chronological age. 37.2% and 36.9% of the patients belonged to lower-middle socio-economic strata respectively as measured by the Graffar scale. 96.9% had urban residence and the place of residence in decreasing order were: Province of Buenos Aires, Gran Buenos Aires, CABA, Córdoba, Santa Fe, Jujuy; Salta, Tucumán, Entre Ríos, Catamarca, Chubut, Río Negro, Santiago del Estero, San Juan, Formosa, Chaco, La Pampa, La Rioja, Mendoza, Neuquén and Santa Cruz. 49.1% had private medical insurance and 41.6% public. The mean education (in years) of the parents was 13.6 years (SD 4.16). 54.5% of the cases the first professional visited was the orthopedist. 57.% of patients had received previous treatment: 90.9% non-steroidal anti-inflammatory drugs (NSAIDs) and 5.11% corticosteroids. At diagnosis, JIA subtypes were represented by persistent oligoarthritis (37.8%); polyarthritis FR -(20%); systemic (15%); polyarthritis FR +(12.1%); enthesis-related (6.8%); extended oligoarthritis (2.5%); psoriatic (1.8%) and undifferentiated (0.3%). The median delay by subtype was persistent oligoarthritis (3.00[2.00,4.50]); polyarthritis FR -(3.00[2.00,6.00]); systemic (1.00[100,2.00]); polyarthritis FR +(3. 00 [2.00,6.00]); enthesis-related (7.00 [3.25,12.0]); extended oligoarthritis (3.5 [1.00,4.25]); psoriatic (11.5 [4.75,13.8]) and undifferentiated (1.00 [1.00,1.00]). Articular and serological manifestations were the most frequent. Ocular involvement (12.5%) was more frequent in the oligoarticular subtype. Macrophage activation syndrome was observed in the systemic subtype (2%) and FR - polyarthritis (1.5%). The most used treatments were NSAIDs, cDMARDs, with methotrexate being the first choice. Patients belonging to the systemic (18.7%) and FR+ polyarthritis (5.0%) subtypes were treated with cDMARDs (Anti TNF and IL6 inhibitors).
Conclusion: This is the first national multicenter study of patients with JIA, and the results provide data that should be prioritized, such as shortening the time to specialist consultation. The comprehensive approach to children with JIA should be coordinated by pediatric rheumatologists and supported by a multi- and interdisciplinary team.

POS0773 PRESCRIPTION PATTERNS AND EFFICACY OF THE SECOND BIOLOGIC AGENT IN JUVENILE IDIOPATHIC ARTHRITIS

Keywords: bDMARD, Real-world evidence, Disease-modifying drugs (DMARDs)

A. Marino[1], S. Costi[1], M. R. Pellico[1,2], S. Germinario[1,2], E. Conti[2,3], M. Gattinara[1], C. Chighizola[1], G. Filocamo[3], F. Minoia[3], R. Caporali[1]. [1]*ASST G.Pini-CTO, Pediatric Rheumatology, Milan, Italy*; [2]*University of Milan, Clinical Sciences and Community Health, Milan, Italy*; [3]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Pediatric Rheumatology, Milan, Italy*

Background: Biologic agents (bDMARDs) have dramatically changed the disease course of juvenile idiopathic arthritis (JIA). TNF-α inhibitors (TNFi) are frequently used as first-line treatment, while there are no clear recommendations on the choice of the second bDMARD.
Objectives: We aim to describe the prescription pattern of the second bDMARD in a cohort of non-systemic JIA patients.
Methods: This retrospective cohort study included non-systemic JIA patients treated with at least two bDMARDs followed in two Rheumatology Pediatric tertiary centers in Milan, Italy. Analyses were performed with R commander.
Results: The study cohort included 39 patients; general features of the cohort are reported in Table 1. The median age at the first bDMARD was 5.9 [(interquartile range (IQR) 5.3] years. The prescription pattern of bDMARD is shown in Figure 1. Etanercept and adalimumab were the most frequently prescribed bDMARD (16 and 15 times, respectively). The causes of the first bDMARD discontinuation were the following: articular flare (43%), uveitis flare (33%), both articular and uveitis flare (6%), and adverse events (18%). Discontinuation of the first bDMARD due to articular flare was significantly more frequent in patients treated with adalimumab than with etanercept (73% vs. 25%; p=0.01). Conversely, the rate of bDMARD withdrawn due to active uveitis was higher in etanercept-treated patients than in adalimumab ones (38% vs. 20%; p=0.4). The discontinuation rate due to uveitis was significantly higher in the infliximab group than in the adalimumab group (80% vs. 20%; p=0.03). The median age at the second bDMARD was 9.4 (IQR 7.3) years. The majority of the cohort (80%) received a TNFi as the second bDMARD. Adalimumab was the most prescribed second bDMARD (55%) followed by infliximab (29%); the most frequent switch was from etanercept to adalimumab (13 times) (Figure 1). To note, the concomitant use of MTX decreased significantly between the two bDMARDs courses (85% vs. 64%; p = 0.04). The rate of clinical inactive disease (CID) at 3, 6, and 12 months did not differ significantly between the first and the second bDMARD. The general CID (defined as the ever achievement of CID) rate was lower during the first bDMARD course compared to the second (79% vs. 95%; p=0.04). A non-TNFi was prescribed as the second bDMARD in 8 patients (20%): 4 subjects received abatacept (2 for articular disease and 2 for adverse effects), and 4 subjects were treated with tocilizumab (all for articular disease). Uveitis activity represented the main reason for discontinuation in almost half of the patients who switched to a TNFi as the second bDMARD. No significant differences in efficacy were observed during the second course of bDMARDs between patients treated with TNFi or non-TNFi. Eighteen patients discontinued the second bDMARD: 16/31 (52%) from the TNFi group and 2/8 (25%) from the non-TNFi group. The reasons for discontinuation were articular flare (60%), uveitis flare (22%), both articular and uveitis flare (6%), and adverse events (12%).
Conclusion: Most of the patients in our cohort received a TNFi as the second bDMARD, with a significant proportion of patients being treated without MTX. No

apparent differences were seen between the non-TNFi and TNFi for the achievement of clinical inactive disease. Larger studies are needed to explore the choice of the second bDMARD in JIA.

Table 1. Demographic and clinical features of patients

Clinical features	Switch to TNFi (n=31)	Switch to non-TNFi (n=8)	Overall population (n=39)	p-value
Gender, %F (n)	87 (27)	88 (7)	87 (34)	1
Age at onset of symptoms, median (IQR)	2 (3.7)	3 (5.2)	3 (4)	0.651
Uveitis, % (n)	52 (16)	50 (4)	51 (20)	1
JIA subtype, % (n)				
Oligoarticular	58 (18)	38 (3)	54 (21)	0.432
Polyarticular RF-	19 (6)	50 (4)	25 (10)	0.167
Polyarticular RF +	3 (1)	13 (1)	5 (2)	0.372
Enthesitis-related arthritis	8 (3)	0 (0)	8 (3)	1
Psoriatic arthritis	12 (4)	0 (0)	8 (3)	1
Duration of I bDMARDs, median (IQR)	14 (35)	29.5 (16.8)	18 (31)	0.347
Follow-up time (months), median (IQR)	112 (112)	110.5 (82)	112 (103.5)	0.944

POS0774 CESAREAN SECTION IN WOMEN WITH JUVENILE IDIOPATHIC ARTHRITIS – A POPULATION-BASED STUDY

Keywords: Quality of care, Pregnancy and reproduction, Registries

C. Skorpen[1,2], S. Lydersen[3], K. Å. Salvesen[4], M. Wallenius[1]. [1]*Norwegian University of Science and Technology, Department of neuromedicine and movement science (INB), Trondheim, Norway*; [2]*Ålesund Hospital, Rheumatology, ÅLESUND, Norway*; [3]*Norwegian University of Science and Technology, Regional Centre for child and youth mental health and child welfare, Trondheim, Norway*; [4]*Norwegian University of Science and Technology, Department of Clinical and Molecular Medicine (IKOM), Trondheim, Norway*

Background: The literature on delivery methods in women with juvenile idiopathic arthritis (JIA) is insufficient. Active inflammation is a risk factor for cesarean section (CS) in other arthritic diseases. A CS entails a higher risk for complications than vaginal delivery and a restricted physical activity the first weeks after birth.
Objectives: To explore a possible association of inflammatory active disease and the proportion of CS in women with JIA.
Methods: Data from the Norwegian nationwide observational register RevNatus were linked with data from the Medical Birth Registry of Norway (MBRN). Cases comprised singleton births in women with JIA (n= 196) included in RevNatus 2010 to 2019. Singleton births registered in MBRN during the same period of time and excluding mothers with rheumatic inflammatory diseases (n = 575 798), served as population controls. Disease activity was assessed using Disease Activity Score with CRP (DAS28-CRP-3). We defined inactive JIA as DAS28-CRP-3 < 2.6 and active JIA as DAS28-CRP-3 ≥ 2.6.
Results: CS was more frequent in women with JIA (20.4%) than in population controls (15.6%) and occurred most frequently in inflammatory active JIA (30.0%). Women with JIA had similar risk for elective CS (risk difference 1.1%, 95% CI-1.7 to 5.4) and higher risk for emergency CS (risk difference 3.8%, 95% CI -0.4 to 9.3) compared with population controls. Active disease increased the risk for emergency CS (risk difference 14.0%, 95% CI 4.3 to 27.4).
Conclusion: Women with active JIA had higher risk for emergency CS compared with population controls.

POS0775 ASSESSMENT OF SCHOOLING OUTCOMES OF CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Education, Patient reported outcomes, Inflammatory arthritides

M. Ghali[1], D. Khalifa[1], M. Cheour[1], R. Fakhfakh[1], N. El Amri[1], K. Baccouch[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is the most common inflammatory arthropathy in childhood. It can often be disabling, have an impact on the child's integration, and affect school attendance to varying degrees.
Objectives: The objective of this study was to assess the impact of juvenile idiopathic arthritis (JIA) on children's educational outcomes.
Methods: This is a cross-sectional monocentric study including school-age children with JIA diagnosed according to the International League of Associations of Rheumatology (ILAR) classification criteria. Data were collected for all children on their school level, school difficulties, attendance, and absenteeism. Academic failure was defined by either dropping out of school or grade retention. To evaluate disease activity we used the Disease activity score (DAS-28) for oligoarticular and polyarticular forms, and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score for axial forms. The Childhood Health Assessment Questionnaire (C-HAQ) was used to assess functional disability.
Results: Thirty-six patients were enrolled. The average age was 13.5 ± 5.9 with a female percentage of 55.6 %. The polyarticular form was the most frequent (52.8%) meanly seronegative, followed by the Oligoarticular form (13.9%), then the enthesitis-related form (12.4%). None of our patients was illiterate. Eight children (22.2%) dropped out of school because of their functional disability. Students with JIA who attended school had an absenteeism rate of 67.8%. Slightly more than half of the JIA patients (57.1%) failed at least one grade. Academic failure was associated with a high disease activity (p=0.003), the presence of joint deformities (p=0.002), a high C-HAQ score (p=0.01), and an erythrocyte sedimentation rate: ESR ≥100 mm/h (p=0.02). The absenteeism rate was associated with rural origin (p=0.004), pain level (p=0.02), high disease activity (p=0.01), hip involvement (p=0.001), and a high C-HAQ score (p=0.03).
Conclusion: Our study shows that the schooling of children with JIA was negatively influenced by this disease. Proper control of the disease activity and inflammation will guarantee better school attendance and increase academic performance.

POS0776

STUDY OF GROWTH AND DEVELOPMENT IN INDIAN PATIENTS WITH ENTHESITIS RELATED ARTHRITIS CATEGORY OF JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Inflammatory arthritides

S. Mukherjee[1], N. Kamble[1], P. Kumar[1], U. Dhakad[1]. [1]*King George Medical University, Clinical Immunology and Rheumatology, Lucknow, India*

Background: Juvenile Idiopathic Arthritis (JIA) is an umbrella term for chronic arthritis with onset before 16 years of age. According to ILAR classification criteria it is subdivided in 6 category. Growth failure is a well observed phenomenon in JIA and more so in Systemic onset and polyarticular variants. Except from western literature, in Asian countries Enthesitis Related arthritis (ERA) is more prevalent. In our study, we have studied the growth and development of patients with Enthesitis Related arthritis variant.
Objectives: To assess the prevalence of growth failure and sexual maturity in patients with JIA-ERA and possible association with disease activity, damage and drug therapy.
Methods: We have enrolled all patients of JIA-ERA, visiting rheumatology outdoor patient service in KGMU, Lucknow, from July 2021 to Dec 2021. All the patients must qualify Revised ILAR classification criteria for ERA. Those who have concomitant developmental disorders, secondary amyloidosis and macrophage activation syndrome were excluded from the study. All patients were clinically examined and previous medical records were thoroughly checked. Anthropometric measurement and tanner staging was done at baseline. Growth velocity was observed at follow up visit. This is a Prospective observational study with follow up at 3 and 6 months.
Results: 50 patients of JIA-ERA were enrolled. Majority of them were boys with a male to female ratio of 4.5:1 and mean age of 15.5 years. Mean age of onset was 11.5 years with a mean disease duration of 41.25 months. 32% had family history of SpA in first degree relatives and 12 % had history of uveitis in parents. Only 3 patients (6%) had history of other autoimmune diseases in family. There was no developmental delays in children with JIA-ERA and 47 patients (94%) were vaccinated for their age. 76% patients had inflammatory back pain with significant early morning stiffness at baseline and 18% had purely axial involvement. 20% had active or past history of uveitis, 12% had dactylitis and 30% had enthesitis (predominantly Achilles enthesitis). 76% had achieved age appropriate linear growth with 20% were 2SD above their mid parental height. 12 patients (24%) had significant limb length discrepancies. 64% were underweight for their age with low BMI. 30% patients had delayed sexual maturity in terms of sparse axillary and pubic hair with low tanner stage for that age. In majority of cases growth velocity of 4cm/6month was observed which was quite similar to the pubertal growth spurt of normal reference value. No significant association of growth failure was observed with prior corticosteroid use, disease duration, disease activity (JSPADA and JADAS27) and damage (JADI) score.
Conclusion: Growth failure wasn't well observed in JIA-ERA variants. One third had delayed sexual maturity for their age. Growth velocity was similar to age matched healthy population. No significant association was found with prior corticosteroid use, disease duration, disease activity or damage score.

POS0777

ADALIMUMAB AND ANTI-DRUG ANTIBODIES IN A COHORT OF CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: A SINGLE-CENTER EXPERIENCE

Keywords: Inflammatory arthritides, Targeted synthetic drugs, Outcome measures

G. Tarantino[1], D. Pires Marafon[1], F. Comitini[2], R. Simeoli[3], A. Aquilani[1], R. Nicolai[1], E. Marasco[1], F. De Benedetti[1], S. Magni-Manzoni[1]. [1]*Bambino Gesù Children's Hospital, Rheumatology, Rome, Italy*; [2]*Medicine University - Hospital of Cagliari, Paediatrics, Cagliari, Italy*; [3]*Bambino Gesù Children's Hospital, Metabolic Disease Centre, Rome, Italy*

Background: Adalimumab (ADA), a fully humanized antibody against tumor necrosis factor (TNF)-α, has revolutionized treatment of patients with juvenile idiopathic arthritis (JIA). Although most of these respond within the first weeks, a minority may show loss of response (LOR) after continued exposure. Many studies demonstrate the influence of anti-adalimumab antibodies (AAA) on serum drug concentrations and clinical outcome in adults. However, little information about AAA and LOR is available for children with JIA.
Objectives: To describe demographic and clinical features in a single-center cohort of JIA patients treated with ADA, grouped according to frequency of drug administration (1W vs 2W); to assess ADA levels versus AAA titer and, finally, to investigate possible correlation between LOR to ADA and AAA.
Methods: Records of JIA patients on ADA treatment were retrospectively reviewed with focus on medical history and ELISA (enzyme-linked immunosorbent assay) ADA/AAA levels in a 12-month-period (Feb 2021-Feb 2022). Children with idiopathic uveitis were excluded. Samples furthest from last drug administration was defined as "trough level". Data were analyzed via descriptive statistics (STATA 15.1).
Results: Of 61 JIA patients treated with ADA (49% females), 38 had ANA positive oligoarthritis with almost one large joint involvement at disease onset (T0). None of them presented RF-positive polyarthritis, nor systemic JIA (s-JIA). The median age at T0 was about 3 years. Half of study cohort was b-DMARDS naive at ADA start (T1), while all children were on c-DMARDs. Chronic recurrent uveitis was the main reason for ADA starting, followed-by tenosynovitis and spine or hip active arthritis. At the first ADA/AAA sampling (T2), approximately 15% of patients had active disease, with elbows or wrists as the most frequently involved. Extreme variability was observed between AAA titers (median 7.4 AU/ml) and ADA levels (median 15.4 micrograms/ml), regardless from 1 or 2-weekly administration. ADA levels, compared to the days from last drug administration, reached plateau values corresponding to a pharmacokinetic steady state. Among both study groups, a possible inverse correlation between ADA and AAA was found. We identified 30 JIA patients with clinical (presence of arthritis or uveitis) or laboratory (ESR ≥15 mm/h; CRP> 0.5 mg/dL) disease activity. Among these in only 6 we found very high AAA titers (350.0 - 113.4 AU/mL). In the subgroup of 37 patients with "trough-level" sampling heterogeneous data about AAA titers and drug level distribution were observed.
Conclusion: Our preliminary data showed a possible association between occurrence of AAA and lower ADA levels. However, a targeted risk analysis about high AAA titers and LOR incidence was not available. Monitoring of drug immunogenicity should be implemented in daily practice and become subject of future studies JIA.

METASTATIC ANGIOSARCOMA MASQUERADING AS SYSTEMIC INFLAMMATORY DISEASE WITH REFRACTORY PERICARDITIS

Keywords: Malignancy, Heart

K. Williamson[1]. [1]*Mayo Clinic, Rheumatology, Rochester, United States of America*

Background: Rheumatologists are frequently asked to evaluate patients with acute pericarditis. The majority of cases are idiopathic with systemic autoimmune disease underlying maybe 7% or less of cases in developed countries.[1-2] It is critical to recognize the presence of systemic symptoms or poor prognostic pericarditis features, such as tamponade physiology or poor response to non-steroidal anti-inflammatories, that raise concern for a malignant etiology of pericarditis.[1-2]
Objectives: A case report of a patient presenting with refractory pericarditis caused by metastatic angiosarcoma.
Methods: A 46 year old male presented for evaluation of unresolving pericarditis. Five months prior, he had developed abrupt-onset pericarditic chest pain with associated dyspnea. Initial ED evaluation was notable for normal troponins and non-specific T wave abnormality on ECG. CT chest angiogram revealed a trace pericardial effusion and isolated right axillary lympadenopathy. The patient declined further evaluation. He presented a week later with persistent pericarditic pain. Echocardiogram showed enlargement of the pericardial effusion with possible early tamponade. Respiratory viral testing was negative. C-reactive protein (CRP) was elevated to 20.83mg/dL (Ref ≤0.5mg/dL) and ferritin to 2344.4ng/

mL (Ref 21.8-274.7ng/mL). Soluble IL-2 receptor and blood counts were normal. Rheumatoid factor was weakly positive with ANA, anti-DNA, anti-CCP, and ANCA returning negative. Core needle biopsy of an axillary lymph node was negative for malignancy. Pericardiocentesis was deferred due to patient preference and stability. He was started on colchicine for autoimmune versus idiopathic pericarditis without significant improvement. He was transitioned to prednisone with improvement in his chest pain, effusion, and CRP; dyspnea and hyperferritinemia persisted. Attempts to taper prednisone failed due to flaring of pericarditis. The patient was referred to our center for evaluation of refractory pericarditis and possible systemic inflammatory disease. No signs or symptoms of RA or CTD were present. The patient endorsed recent night sweats, 11 kg of weight loss, and new bone pain. Full body PET/CT was pursued and demonstrated two FDG avid masses adjacent to the right side of the heart along with multiple lytic bone lesions of the spine and pelvis.

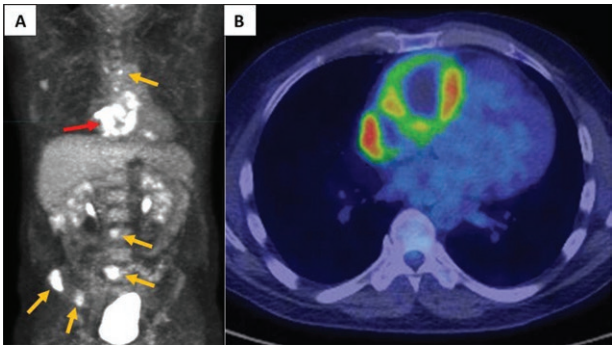

Figure 1. (A) PET Maximum intensity projection showing large cardiac mass (red arrow) and multiple FDG avid bone lesions (yellow arrows). (B) PET Axial fused image showing large FDG avid cardiac mass.

Results: Cardiac CT confirmed malignant-appearing, centrally necrotic mass along the right side of the heart extending to involve the pericardium. Iliac bone biopsy confirmed a diagnosis of metastatic angiosarcoma. He was not a candidate for cardiac tumor resection and was referred to oncology for palliative chemotherapy.

Conclusion: Primary malignant cardiac tumors are a rare cause of pericarditis. Cardiac angiosarcomas are the most common type of primary malignant cardiac tumor. They most commonly arise from the right atrium or pericardium and may present with pericarditis-like symptoms.[3]

BRAIN TUMOR-LIKE LESIONS AS FORM OF PRESENTATION OF NEUROPSYCHIATRIC LUPUS

Keywords: Systemic lupus erythematosus, Imaging

I. L. Mamani Velarde[1], I. Altabás González[1], C. Mouriño Rodríguez[1], S. García Pérez[1], I. Hernández[2], J. M. Pego-Reigosa[1]. [1]*IRIDIS Group (Investigation in Rheumatology and Immune-Diseases), Galicia Sur Health Research Institute (IISGS), Department of Rheumatology, University Hospital of Vigo, Vigo, Spain*; [2]*University Hospital of Vigo, Department of Rheumatology, Vigo, Spain*

Background: Neuropsychiatric (NP) systemic lupus erythematosus (SLE) encompasses a broad spectrum of syndromes.[1] The attribution of the NP manifestations to the disease itself is a challenge and is critical to select the correct treatment. [2]

Objectives: To present a case of a woman with SLE who developed brain tumor-like lesions.

Methods: The clinical manifestations, complementary tests, treatment are described.

Results: 28-year-old woman with a history of SLE with moderate disease (constitutional, cutaneous, musculoskeletal, hematologic and serological) and frequent flares despite treatment with hydroxychloroquine and doses of prednisone up to 20mg/day. She was admitted to the rheumatology service due to a severe flare-up of SLE, with headache, fever, worsening of lesions in photo-exposed areas, lymphadenopathy, arthralgia, nausea, and vomiting. Blood tests showed platelets 60,000/μL, elevated ESR, abnormal liver biochemical, decreased C3, normal urine, with no data of infectious etiology. After treatment with iv methylprednisolone (250mg x 3) and iv belimumab (600mg), she presented clinical and analytical improvement and was discharged from the hospital. Three days later, the patient presented persistent headache and fever, and decreased level of consciousness; laboratory tests showed leukocytosis, anemia, abnormal liver function tests, elevated ESR and CRP. She was referred to the emergency room. On the neurological exam: patient disoriented in time and space, opened her eyes only after painful stimulus, signs of dysarthria, and facial paralysis. CT scan revealed a space-occupying lesion (3 x 2cm), at the level of the right basal nuclei with perilesional edema and collapse of the anterior horn of the right lateral ventricle, discreet mass effect with displacement midline, and similar contralateral involvement. The patient was admitted to the hospital due to a probable primary neoplasm of the central nervous system, without being able to initially exclude infectious, vascular, and inflammatory pathologies. Treatment was started with iv dexamethasone and empiric therapy for bacteria, viruses, fungi, and parasites. The following day, brain MRI (Figure 1, A - B) showed lesions in the right and left basal ganglia, with a mass effect in the right basal ganglia and images of their interior with artifact related to hemosiderin or deoxyhemoglobin, related to history of bleeding from the lesions. Alteration of thickness and irregular subependymal signal in the occipital horns. The stereotaxic brain biopsy showed parenchyma with intense acute inflammatory changes, with necrosis and vascular inflammation, without histopathological features of etiological specificity, and no evidence of neoplasia. The lumbar puncture did not show alterations, cytology without malignant cells, antibodies against onconeuronal proteins negative. Ruled out infectious etiology. Slow progressive improvement in clinical and laboratory manifestations and in imaging tests improvement was seen in response to the therapy with high doses of glucocorticoids and cyclophosphamide pulses. After prolonged hospitalization, she was discharged from the hospital, her neurological status being normal. Brain MRI (Figure 1, C-D), two months after discharge, showed a clear decrease in the size of the brain lesions.

Conclusion: To the best of our knowledge, no brain space-occupying lesions (simulating neoplasms) attributed to SLE have been described. The context of concomitant activity, the negative results for infectious/malignant diseases, and the favorable response to immunosuppressive treatment, support the neuroinflammatory etiology.

POS0780 PSEUDOGOUT OF THE TEMPOROMANDIBULAR JOINT: A CASE REPORT

Keywords: Pain, Ultrasound, Crystal arthritis

B. Maranini[1], S. Mandrioli[2], M. Galiè[2], M. Govoni[1]. [1]*University of Ferrara, Department of Medical Sciences, Ferrara, Italy*; [2]*University of Ferrara, Department of Cranio-Maxillofacial Surgery, Ferrara, Italy*

Background: Deposition of calcium pyrophosphate dihydrate crystals occurs in crystalline arthropathies, such as gout and chondrocalcinosis. Occasionally, crystal deposits may affect the temporomandibular joint (TMJ), especially involving the articular cartilage and fibrocartilage, causing pain and jaw claudication, mimicking giant cell arteritis (GCA). Ultrasound (US) images reveal spotted hyperechoic signals in the articular disk and sometimes a marked destruction of the condyle with erosive changes.
Objectives: To highlight and discuss the potential role of TMJ US in guiding differential diagnosis of orofacial pain syndrome (frontal headache and jaw claudication), arousing the suspicion of GCA.
Methods: Case-report describing an old patient presenting with severe headache and jaw claudication with particular reference to the role of TMJ US in differential diagnosis of an initially suspected GCA.
Results: An 85-year-old woman presented to the Emergency Department with a 2-days history of progressively worsening frontal headache and jaw claudication. She reported no visual loss or polymyalgia rheumatica symptoms. Right temporal artery tenderness was appreciated on clinical examination, without reduced temporal artery pulse. No axillary, brachial, or carotid bruits were appreciated. Neurologic examination was normal; brain computed tomography (CT) revealed no intracerebral hemorrhage or intraparenchymal lesions. Her erythrocyte sedimentation rate was 67 mm per hour, and C-reactive protein level 3.30 mg per deciliter. Temporal artery US revealed no abnormalities (absence of halo sign or arterial stenosis). Since patient complained of chewing pain and given that temporomandibular disorders may be misdiagnosed as GCA, TMJ US was performed revealing the presence of extensive calcifications around the right temporomandibular head and in the meniscus (Figure 1, Panel A). Brain CT images were then carefully reviewed: in the right TMJ massive calcifications surrounding the right temporomandibular head were appreciable (Figure 1, Panel B). Moreover, coronal CT scan of the atlantoaxial region showed calcifications of the alar ligaments, particularly evident on the superior-left side (Figure 1, Panel C). High dose glucocorticoid regimen was then started (Methylprednisolone 40 mg once daily). The patient's pain rapidly improved, steroid was rapidly tapered until withdrawal, with a complete resolution of symptoms within few weeks.
Conclusion: Crowned dens syndrome is characterized by recurrent neck pain related to radiodense deposits of hydroxyapatite or calcium pyrophosphate dihydrate in ligaments around the odontoid process, which create the appearance of a crown or halo surrounding the odontoid process on radiographic imaging. Evidence of inflammation (e.g., fever or elevated levels of C-reactive protein) is usually observed. A short course of steroids, followed by administration of non-steroidal anti-inflammatory medication, usually completely alleviates symptoms. Rarely, temporal arteritis headache may mimic TMJ irradiation pain, or present as jaw claudication. In this case, temporal arteries and TMJ US can enable to discern a halo sign, as a hallmark of giant cell arteritis, from suspicious signs of TMJ disorder. Rapid diagnosis can prevent misdiagnosis, invasive and unnecessary investigations (temporal artery biopsy) and inappropriate treatment (long term steroid regimen, leading to cardiovascular risk and increased bone loss).

Arthritis research

POS0781-PARE RETROSPECTIVE STUDY OF VITAMIN D DEFICIENCY IN RHEUMATOLOGIC PATIENTS DURING THE COVID-19 PANDEMIC IN POLAND

Keywords: COVID, Best practices, Vitamin D

B. Nieradko-Iwanicka[1]. [1]*Medical University of Lublin, Department of Hygiene and Epidemiology, Lublin, Poland*

Background: Before the COVID-19 pandemic it was estimated that nearly 70% of the population is deficient in vitamin D - 25(OH)D <20ng/ml in Poland [1]. The percentage was expected to increase due to indoor isolation during the COVID-19 pandemic. Vitamin D has a positive effect on the condition of the bones, affects the course of autoimmune diseases, the course of neurological diseases, in type 2 diabetes, vitamin D supplementation improves glucose tolerance and reduces insulin resistance [2,3,4].
Objectives: The aim of the retrospective study was to determine what percentage of rheumatology clinic patients suffer from vitamin D deficiency and whether this condition is effectively treated.
Methods: In January 2023, a retrospective analysis of the documentation of 172 patients treated at the Rheumatology Outpatient Clinic in Bełżyce (Poland) in 2022 was conducted.
Results: Results: The mean age of the 172 patients whose documentation was analyzed was 60.43 years (min 19, max 88). There were 132 women (76.8%) and 40 men (23.2%) in this group. The mean concentration of vitamin D was 25.57ng/ml±SD11.9 (min 5.7, max 75, Me 22.8). Vitamin D deficiency was found in 44% (serum concentration <20mg/ml), suboptimal concentration (20-30ng/ml) in 31%, optimal concentration (30-50ng/ml) in 21%, and high concentration (>50ng/ml) ml) in 4%. All those with a deficit or deficiency (75 people) were prescribed cholecalciferol in a dose of 20,000 units orally, 1 capsule twice a week after breakfast for 2 months [5]. Patients with optimal vitamin D levels were advised to take a dose of 2,000 units per day. Among the patients with deficit or deficiency, 48 people came for a follow-up visit to check the level of vitamin D (64% of the group with too low vitamin D concentration; 28% of the entire group whose documentation was analyzed). In the follow-up examination, the mean concentration of vitamin D was 37.14±9.8ng/ml (min 28, max 84, Me 35.3). Therefore, a statistically significant increase in the concentration of vitamin D in the blood was noted ($p<0.05$). In the group of people who came for the follow-up examination, there were 35 women, whose mean age was 60.7 years and 13 men (mean age 68.2 years).

Conclusion:
1. During the COVID-19 pandemic in the group of outpatient rheumatology patients, 75% had a deficiency or suboptimal level of vitamin D.
2. Treatment with cholecalciferol in a dose of 20,000 IU twice a week orally for 2 months is effective treatment of vitamin D deficiency.
3. Too low percentage of patients diagnosed with vitamin D deficiency come for visits and check-ups.

POS0782-PARE MANAGING PSORIATIC ARTHRITIS: PATIENTS' VIEWS AND ATTITUDES TO USING AN ONLINE WELLNESS PROGRAM

Keywords: Psoriatic arthritis

W. B. Nowell[1], A. Degrassi[1], S. Venkatachalam[1], K. Gavigan[1], A. Krivohlavek[1], E. Rivera[1], M. E. Husni[2]. [1]*Global Healthy Living Foundation, Patient-Centered Research, Upper Nyack, United States of America*; [2]*Cleveland Clinic, Rheumatology, Cleveland, United States of America*

Background: Patients diagnosed with psoriatic arthritis (PsA) confront decisions about how to optimize treatment of their chronic disease including patient physician interaction and modifying their own lifestyle choices that may impact their disease outcomes.
Objectives: To examine PsA patients' views and attitudes of managing their disease using a guided online wellness program to address lifestyle behaviors such as nutrition, exercise, sleep, and stress management.
Methods: A cross-sectional online survey was developed with patient and clinician input and administered to US adults with a self-reported diagnosis of PsA in the ArthritisPower registry. Survey questions assessed participant (pt) experience with, and motivations to participate in, an online wellness program through various mechanisms to address nutrition, exercise, sleep and stress management. E-coaching is a validated tool using email coaching as an individualized tailored communication on wellness strategies to improve lifestyle behaviors.
Results: 312 pts completed the survey, of whom 83.0% were female, 91.0% white, mean age 57.1 (SD 11.4) years, and 10.0 (SD 10.2) years since PsA diagnosis. Most pts (93.6%) were diagnosed by a rheumatologist for their PsA. Over 90% of pts reported being 'somewhat likely' or 'very likely' to interact with an online coach at least twice a week or spend one to two hours a week learning about nutrition, exercise, sleep and stress management (90.4% and 92.6%, respectively) if they had the opportunity to take part in a wellness program. However, only 8.7% of pts are currently participating in a structured wellness program. Feeling better was the top motivator for participating in a wellness program (179, 57.4%) followed by the want to improve PsA symptoms (145, 46.5%). About a third of pts would prefer to participate in a wellness program by interacting with an online trained professional (34.0%), followed by attending an online course (16.4%) and reading written material (16.0%) (Table 1). In reporting barriers to wellness changes, cost and not having the energy to make changes were selected by about half of pts (both 47.1%) (Figure 1). Over one-tenth (13.1%) of pts reported having no barriers to participation in wellness programs.
Conclusion: The overwhelming majority of patients report willingness to be involved in a wellness program. Feeling better is a top motivator, while cost and lack of energy to make changes were top barriers to adopting wellness behaviors. Our study results support the use of guided online participation in wellness programs over alternatives such as online courses and written materials. Further studies are needed to elucidate how e-coaching wellness platforms may improve and sustain lifestyle changes in PsA patients.

Table 1. Participation Preferences for a Wellness Program, N=312

	n (%)
Interacting with an online coach (trained professional)	106 (34.0)
Attending an online course	51 (16.4)
Reading written material	50 (16.0)
Watching videos	46 (14.7)
In-person consultation and coaching from a trained professional	45 (14.4)
Attending an in-person class	14 (4.5)

POS0783-PARE WITHDRAWN

POS0784-PARE **RHEUMATOID ARTHRITIS (RA) PATIENT CONCERNS REGARDING ADVERSE EFFECTS OF TREATMENT AND ISSUES OF ADHERENCE**

Keywords: Self-management, Safety, Patient reported outcomes

T. Woodworth[1], M. C. Hay[1], A. Leong[1], D. Furst[1]. [1]*University of California, Los Angeles, David Geffen School of Medicine, Division of Rheumatology, Los Angeles, United States of America*

Objectives: To explore whether rheumatoid arthritis (RA) patients' concerns regarding adverse events (AEs) during their treatment are adequately collected and considered in making treatment decisions.
Methods: Using pilot focus groups,and after obtaining voluntarily 12 RA patients (8 women, 4 men, duration RA 1 to > 20 years) met in groups of 4 and described their concerns regarding how they experience being treated for RA. All patients were from Southern California and spoke and understood english fluently.We recorded/ transcribed three 90-120 minute focus groups. Participants completed an 18 item Beliefs about Medications Questionnaire (BMQ), which included 10 specific arthritis medication questions and 8 questions about doctors. They examined a table describing 75 AEs of concern to oncology patients - the PRO-CTCAE (Patient Reported Outcome-Common Terminology for Adverse Events), and checked AEs they had experienced or were of concern. Data were recorded and transcribed from all 90-120 minutes sessions.. Using Dedoose software, transcriptions were inductively coded and analyzed to identify specific áreas of associated with RA medications. A total of 225 excerpts were extracted to which a total of 607 codes were applied.
Results: AEs associated with medications were the expilicit objective of this study and so we could not estimate the percent of patients with medication-related AE concerns Of the 36 excerpts in which participants discussed AEs while discussing particular types of medications, conventional synthetic DMARD(csDMARD) were more likely to be discussed than biologics/ targeted synthetic DMARD(b/tsDMARD) (58% csDMARDS, 28% b/tsDMARDs, 14% corticosteroids). 42 unprompted comments emphasized self-management strategies 10/42 specificied the context of medications, such as modifying dosages (40%) or stopping medication altogether (60%); of these, 8/10 comments specified csDMARDs or corticosteroids. Four of 12 voiced uncertainty about whether AEs were related to RA, medications, or something else. On the BMQ, participants generally agreed that their health depended on their medications, which protected them from becoming worse and that the medicines did more good than harm. Nevertheless, their medications disrupted their lives, and they worried about long-term effects. Generally, participants did not think doctors used too many medications or placed too much trust in the medications.. In each focus group, participants found the PRO-CTCAE bewildering and raised the specter of cancer due to their medications. The 10 most commonly marked AEs were dry mouth, mouth sores, nausea, bloating, diarrhea, abdominal pain, hair loss, bruising, general pain and fatigue.
Conclusion: Medications were generally viewed positively but AE concerns were more common among those using csDMARD than b/tsDMARDS or corticosteroids. Concerns about AEs triggered self-management strategies, potentially affecting adherence. We suggest that a robust mechanism for patients to explicitly *report the impact* of AEs that they are experiencing could facilitate clinical communication and positively impact adherence.

Psychosocial support

POS0785-PARE **NEWLY DIAGNOSED WITH INFLAMMATORY ARTHRITIS – PATIENTS' EXPERIENCES, THOUGHTS, AND CONCERNS: A QUALITATIVE STUDY**

Keywords: Patient information and education, Inflammatory arthritides, Qualitative research methods

L. Lindgren[1], T. Thomsen[1], M. Aadahl[2], M. L. Hetland[1], A. De Thurah[3], S. Kristensen[1], N. Blum[1], B. A. Esbensen[1]. [1]*Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark*; [2]*Frederiksberg Hospital, Center for Clinical Research and Prevention, Frederiksberg, Denmark*; [3]*Aarhus University Hospital, Department of Rheumatology, Aarhus N., Denmark*

Background: To be diagnosed with inflammatory arthritis (IA) is challenging for the individual, who may experience uncertainty and anxiety [1,2]. We need more knowledge on how health professionals can support patients that have been diagnosed recently. Previous studies have focused on patients' experience of living with IA, but few have aimed to focus on the newly diagnosed.
Objectives: This study aimed to explore patients' experiences, thoughts, and concerns after being diagnosed with IA.
Methods: Participants were patients newly diagnosed with IA (rheumatoid arthritis or psoriatic arthritis) recruited from a feasibility study to a self-management intervention [3]. Data was collected through semi-structured interviews. The analysis was based on reflexive thematic analysis method, which provides a rich and complex understanding of patterns within data [4].
Results: Twelve adults (six men and six women, aged 25-77) diagnosed with rheumatoid arthritis (n=8) or with psoriatic arthritis (n=4) within the last three months, were interviewed at an outpatient rheumatology clinic in Denmark. We identified four main themes: 1) *The intrusiveness of arthritis.* Symptoms affected patients physical and emotional state. The initial symptoms were experienced very differently. For some, symptoms were acute and explosive. In others, disease progression was slow, and participants became more and more invalidated with time. However, all experienced that arthritis affected their mood, and in general, patients were overwhelmed to being diagnosed with arthritis. 2) *Getting familiar with arthritis and its treatment*. Patients requested information about how to manage IA, and several were already seeking information about non-pharmacological treatments such as different diets, meditation, and exercises. The participants paid great attention to how they responded to the pharmacological treatment and how their bodies reacted in different situations. Furthermore, the newly diagnosed also strove to become acquainted with their new body with arthritis. 3) *Adapting to life with arthritis*. Some felt it natural to tell family members about their arthritis. In contrast, others thought it was none of their concern and did not like to bother them. The participants did not want arthritis to be an issue for other people to worry about. 4) *Worries about the future*. Overall, the pharmacological treatment had a profound focus immediately after diagnosis. Worries about the potential lack of effect contributed to great concern and frustration. The worries were related to all aspects of life, including work and family life. However, the newly diagnosed also hoped that symptoms would be acceptable so that everyday life could be restored. Nevertheless, they also realized that they had to rethink how they wanted to prioritize in the future.
Conclusion: The results of this study highlight the complexity of being newly diagnosed with IA. Time after diagnosis is dominated by worries about the benefit and harms of pharmacological treatment and the future. However, the participants did not want to perceive themselves as being sick. Instead, they strove to comfort themselves with hope for successful pharmacological treatment together with taking their own non-pharmacological initiatives.

POS0786-PARE CONNECTING THROUGH SHARING - PUBLISHING A BOOK FOR YOUNG PEOPLE WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES (RMDS) BY YOUNG PEOPLE WITH RMDS

Keywords: Quality of life, Mental health, Self-management

C. Kievit[1], R. Meuldijk[1], S. Van Dijk[1]. [1]*Youth-R-Well.com, Patient Foundation, Asten, Netherlands*

Background: Research has shown that adolescents with chronic conditions such as rheumatic and musculoskeletal diseases (RMD) are more prone to developing psychiatric conditions. Reasons for this could be the common stigmatization that they encounter in their daily life and the feeling of being the only odd one out. Youth-R-Well.com, the Dutch organization for youth (18-30 years) with RMDs, responded to this by providing monthly columns from their peers with RMDs. These columns show the daily life and struggles of young arthritis patients with a touch of humor, thus providing some of the much needed recognition.
Objectives: The main objective of this project is to provide information, recognition and awareness about the daily life and struggles of young RMD patients. By reading the columns that were written lightly humorous, it will be easier for young people to find the much needed recognition that they often lack in their own environment. These columns do not only recognize the often experienced pain and (chronic) fatigue, but also recognize the insecurities that come with living with a RMD, and show ways to face them. By describing their daily life, these young people provide tips on how to approach certain situations. Therefore, besides providing information and recognition, these columns can also function as a tool that increases the self-management of their disease.
Methods: To provide these columns, different young people with a RMD (18-30 years) were asked over the years to regularly write columns that were published on the website of Youth-R-Well.com. To draw more attention to the columns and reach more people, e.g., by distributing the books in hospitals, the columns of one of the writers will be published in a book.
Results: Since 2012, approximately 150 columns have been published on the website of Youth-R-Well.com, from nine different writers. Youth-R-Well.com has received, and still receives, many thankful messages from young people with RMDs, saying that they benefited a lot from the tips and recognition that the columns provided. The book has not been published yet, but Youth-R-Well.com is right now talking to self-publishing companies, and has also received commitments from parties that will take partial responsibility for the costs of publishing.
Conclusion: Publishing columns on a regular basis has helped a lot of young RMD patients in the Netherlands to feel recognized in their struggles with living with a RMD. They have said to have learned a lot about how to cope with certain issues that come with having a RMD. This is something Youth-R-Well.com will definitely continue with. The book is unfortunately not published yet, but will be in the near future.

HPR Patients' perspectives, functioning and health (descriptive: qualitative or quantitative)

POS0787-HPR PHYSICAL ACTIVITY GUIDANCE IN THE RHEUMATOLOGY CLINIC – PATIENT EXPERIENCES AND PREFERENCES. A QUALITATIVE STUDY

Keywords: Qualitative research methods, Lifestyles, Rheumatoid arthritis

T. Thomsen[1,2], M. Aadahl[2,3], M. L. Hetland[1,3], B. A. Esbensen[1,3]. [1]*Rigshospitalet, Copenhagen, Denmark, Copenhagen Centre for Arthritis Research, Centre for Rheumatology and Spine Diseases, Glostrup, Denmark*; [2]*Bispebjerg and Frederiksberg Hospitals, Copenhagen, Denmark, Center for Clinical Research and Prevention, Frederiksberg, Denmark*; [3]*University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*

Background: Evidence of the positive health effects of physical activity (PA) and exercise in patients with rheumatoid arthritis (RA) is well established. Nonetheless, higher proportions of patients with RA are physically inactive compared to the general population [1]. Besides disease-related barriers to engaging in health-enhancing PA, a significant barrier may be the lack of specific PA guidance from healthcare professionals [2].
Objectives: The present national qualitative study aimed to explore daily PA levels and the patients' perspectives on the current and future support from health professionals (HPRs) in promoting PA in patients with RA.
Methods: We recruited participants from five rheumatology departments in Denmark. Recruitment was based on results from an earlier register-based cross-sectional study [3], which aimed to identify socio-demographic and clinical differences between participants and those declining participation in a RCT focusing on promoting light-intensity PA in patients with RA [4]. Accordingly, we used a purposive sampling method to ensure that interview participants variated in age, educational level, smoking status, PA levels, and disease history. Due to COVID-19, the interviews were conducted by telephone, physically, or through online platforms. Data analysis was based on reflexive thematic analysis [5].
Results: Of the 20 participants, 13 were female, and the mean age was 55 years (range 22-77). We generated four themes; 1) *Accept of arthritis is a process*, which was attributed to acknowledging RA as part of life as an essential mental step before the participants could fully adapt PA levels and exercise. 2) *Daily physical activity – motivation and barriers,* where participants described how they generally perceived PA. Also, they described their preferred intensities and types of activities as well as motivations and barriers for engaging in PA. 3*) Experiences with physical activity guidance – your own responsibility?* This theme reflected how participants missed to have more comprehensive and detailed discussions with HPRs in the rheumatology outpatient clinics about PA, - in other words not making it a matter of their own insistence and curiosity. 4*) How, when and where physical activity guidance is provided is essential*, which referred to the participants' preferences and needs for future PA guidance in the rheumatology clinic, including timing, content and location.
Conclusion: The study results emphasize that treating patients with RA should hold an integrated and strengthened focus on PA and exercise in routine care. However, to optimize this focus, HPRs may need adequate training in how to prioritize, guide, and motivate patients towards initiating and maintaining PA in their everyday lives.

Background: Psoriatic arthritis (PsA) is an inflammatory rheumatic disease, associated with the skin disease psoriasis. Health-related quality of life is severely affected and is suggested to be so since these people have two chronic diseases at the same time, a skin disease that causes cosmetic changes and a joint disease that causes functional limitations [1]. Both international collaborations [2] and single studies of outcome measures, disease consequences and experiences of pain in PsA emphasize that pain is one of the most important areas to focus on in the assessment and treatment of this patient group [3]. To the best of our knowledge, no studies with a qualitative design exploring the management of pain from the perspectives of patients with PsA exist.
Objectives: To explore and describe approaches towards pain and its management among patients with PsA.
Methods: A descriptive design with a qualitative inductive approach was used. Semi structured interviews were conducted with 11 participants with PsA (3 men and 8 women) recruited from one outpatient rheumatology clinic in the middle region as well as from a university hospital rheumatology clinic in the northern region of Sweden. Variation in gender, age, disease duration, activity limitation, perceived pain, fatigue, and general health was aimed at by using strategic sampling. Qualitative content analysis was used, and a pattern of theme of meaning, descriptive subthemes, and categories was constructed based on the participants' experiences and perceptions [4, 5].
Results: A main overarching theme of meaning and three subthemes describing participants' management of pain were identified. They were 'Taking charge of life despite the constant murmur of pain' through 'Sorting out vulnerability', 'Reaching acceptance and engagement' and 'Directing focus to change'. Nine categories further described the components of the management; 'face uncertainty for the future', 'consider restrictions', 'illuminate the invisible', 'increase awareness', 'find permissive environment and social support', 'enhance inner endurance', 'reformulate emotions and thoughts ', 'use distracting activities' and 'adjust activities' (Figure 1).

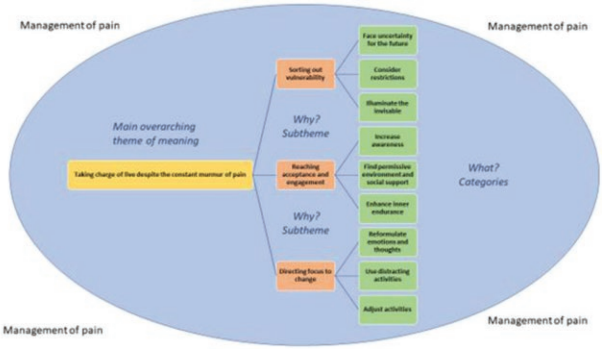

Figure 1.

Conclusion: Dealing with and regulating feelings and thoughts within oneself as well as altering behavior and finding new solutions outside oneself seem to be significant for management of pain among patients with PsA. Grasping an understanding of this complex reality of living with a constant murmur of pain has the potential to improve and enhance the overall care. To support patients in taking charge of life health professionals should be able to provide team-based interventions that are underpinned by self-regulation skills and include cognitive, behavior and affective components.

HPR Service developments, innovation and economics in healthcare

POS0789-HPR STRUCTURES THAT FACILITATE PATIENT ENGAGEMENT IN THE DEVELOPMENT AND DELIVERY OF HEALTH CARE SERVICES: A SYSTEMATIC SCOPING REVIEW

Keywords: Quality of care, Systematic review, Health services research

J. Sagen[1], G. Smedslund[1], A. E. Simonsen[2], A. Habberstad[3], I. Kjeken[1], H. Solveig Dagfinrud[1], R. H. Moe[1]. [1]*Diakonhjemmet Hospital, Norwegian National Advisory Unit on Rehabilitation in Rheumatology (NKRR) REMEDY - Center for Treatment of Rheumatic and Musculoskeletal Diseases, Oslo, Norway*; [2]*Røysumtunet Rehabilitation, Patient Advisory Board, Jaren, Norway*; [3]*The Norwegian Federation of Organisations of Disabled People,The Norwegian Federation of Organisations of Disabled People, Oslo, Norway*

Background: System-level patient engagement (PE) is required to improve future healthcare services. Structures that facilitate PE are likely to be diverse and complex, but are scarcely explored and described.
Objectives: To identify, summarize and map research about system-level PE structures in healthcare services.
Methods: A systematic scoping review was conducted, searching the MEDLINE, EMBASE, Cochrane, and PsycINFO databases. Key search elements were identified using the Population, Context, and Concept framework [1]. The population was patient representatives, healthcare professionals, managers, and leaders. The context includes practices, motives, and outcomes, and the concept was PE in the development and delivery of healthcare services. Studies published between 2005 and 2022 were included. The coding of extracted characteristics was inspired by a PE-adapted model to evaluate the quality of healthcare services [2]. Data was collapsed into structural attributes such as organisation, consistency, and timing of PE initiatives (Table 1), in addition to representativeness, PE knowledge, and finances.
Results: Of 8588 identified records, 37 studies were found to be eligible. Studies aimed to explore the impact of PE initiatives (n=8), increase knowledge and understanding about PE (n=15), and experience, attitudes, or opinions (n=9). Standing committees or panels were the most consistent PE initiatives, often acting as an established part of the structure (Table 1). Lack of PE knowledge was mentioned as a barrier in eighteen studies. Of these, eight reported that multiple stakeholders such as patients, healthcare professionals, and/or managers could benefit from increasing their PE knowledge. In twelve studies, lack of time and/or finances were listed as a barrier. High age, small numbers of patient representatives with time to spare, and professionals repeatedly recruiting the same patient representatives were described as a restriction for sufficient representativeness.
Conclusion: The findings indicate that the PE process may flourish through education, training, experience, and diversity among all PE stakeholders. Sufficient representativeness and PE knowledge were reported as essential structural attributes to facilitate equality and a meaningful co-creation process. Earmarked funds, sufficient to facilitate the PE structure are described as a cornerstone of integrating system-level PE in any environmental and healthcare setting.

POS0790-HPR THE EFFECT OF A GOAL SETTING STRATEGY WITH INTEGRATED FEEDBACK ON GOAL ATTAINMENT IN INFLAMMATORY ARTHRITIS PATIENTS: A MIXED METHOD STUDY

Keywords: Self-management, Patient reported outcomes, Quality of life

K. Van Slingerland[1], P. De Jong[1], R. Dolhain[1], A. Pasma[2]. [1]*Erasmus University Medical Center, Department of Rheumatology, Rotterdam, Netherlands*; [2]*Erasmus University Medical Center, Department of Quality and Patient Care, Rotterdam, Netherlands*

Background: Healthcare is increasingly shifting towards a person-centered care(PCC) approach. Unfortunately, in daily practice, outpatient consultations focus mainly on medical topics, ignoring the impact of the disease on daily life. To understand the impact on patients' daily lives, Patient Reported Outcomes(PROs) can be used. However, it is not enough to only use PROs when offering PCC, because the patient's true values and goals can only be ascertained during a good conversation, in which both medical and patient goals should be addressed.
Objectives: The aim of this study is to evaluate the effect of a goal management strategy with integrated feedback on goal attainment and Health-Related Quality of Life(HRQoL) in inflammatory arthritis(IA) patients. We also explored what type of goals were set.
Methods: Data were used from the Immune Mediate Inflammatory Disease(IMID) registry, a prospective cohort study in which IMID patients were followed with online PRO questionnaires. IA patients with active disease were asked to formulate up to 3 achievable goals within 3 months of follow-up. They could work independently on their goals. Every 2 weeks, patients received an automatically generated e-mail reminder asking them how well they had worked on their goals for the previous 2 weeks. After 3 and 6 months, it was evaluated whether the goals were achieved. If the goals were achieved after 3 months, new goals could be formulated for the next 3 months. Patients' goals were classified into the 14 domains of the Self-management

Table 1. Organisation, consistency, clarity, and timing of PE tasks described in the included studies, related to development and delivery of healthcare services.

Organisational structure			**PE[a] phase**						
	PE task		**PE timing**				**Consistency of PE initiatives**		**Total[c] n= 48 (N =150)**

[a]PE: Patient engagement, [b]Ten studies reported diverse PE initiatives and are reported in more than one PE initiative, [c]N = occurrences, n = primary studies. Light colour indicates few studies, darker indicates more studies.

Web, extended with the domains pain and energy. At each visit (baseline, 3 and 6 months) patients also filled out online questionnaires on goal setting, shared decision making(SDM) and PROs. PRO questionnaires included HRQoL, patient satisfaction(VAS-PS), pain(VAS-pain), general health(VAS-GH) and daily functioning(HAQ). At baseline also a questionnaire on coping styles was filled out.

Results: Ninety-two patients participated in the study. The mean age was 51 years and the most common diagnosis was rheumatoid arthritis. A total of 302 patient goals were set, of which 32% were achieved. Most goals were formulated in the domains lifestyle(14%), pain(13%) and symptoms & side-effects(13%). Fewer goals were formulated in the domains intimate relationships & sexuality(0.6%) and finances(0.3%). In the entire population, HRQoL, VAS-PS, VAS-pain, VAS-GH and HAQ scores did not change over time. However IA patients who did not achieve their goals tended to score worse on HRQoL, VAS-PS and HAQ after 6 months. In contrast, VAS-pain and VAS-GH showed no relation with goal attainment. The patients' most common coping styles were active approach and comforting thoughts.

Conclusion: This study has raised awareness off the importance of patients goal setting. However, the goal-setting process is time consuming and, therefore, health professionals should be trained in goal setting. An online support tool which can be used in preparation for an outpatient clinic visit, can circumvent aforementioned problems. An example of such a tool is the Self-management Web, which help patients organize and prioritize perceived problems in different domains and subsequently helps them to formulate their goals. As a result patients' goals can be concretized immediately during the consultation, which can save time and, therefore, lower the threshold for implementation. Moreover, the incorporation of a feedback mechanism into a goal-setting intervention also seems to have a positive effect on goal attainment. Unfortunately, our intervention showed no effect on HRQoL. However, a general HRQoL measurement may not be sensitive or specific enough to detect change at this point. Possibly self-management and self-efficacy are better outcome measures. These may improve if patients actively address their problems in daily life, set goals to overcome them, and thereby better manage the disease. Therefore, we recommend using more specific outcomes, or qualitative assessment of outcomes, in goal setting studies.

NURSE EDUCATION ON METHOTREXATE FOR PEOPLE WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: A SCOPING REVIEW TO INFORM EDUCATIONAL STANDARDS

Keywords: Patient information and education, Disease-modifying drugs (DMARDs), Nursing

A. Marques[1,2], C. Matos[3,4], P. Livermore[5], E. Nikiphorou[6,7], R. J. O. Ferreira[1,8,9,10]. [1]*Nursing School of Coimbra, Health Sciences Research Unit: Nursing, Coimbra, Portugal*; [2]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Poland*; [3]*Instituto Politécnico de Coimbra, Escola Superior de Tecnologia da Saúde de Coimbra, Coimbra, Portugal*; [4]*QLV Research Consulting, Chief Data Officer, Coimbra, Portugal*; [5]*Great Ormond Street Children's Hospital NHS Foundation Trust, Rheumatology, London, United Kingdom*; [6]*King's College London, Center for Rheumatic Diseases, London, United Kingdom*; [7]*King's College Hospital, Rheumatology, London, United Kingdom*; [8]*Nursing School of Lisbon (ESEL), Nursing Research, Innovation and Development Centre of Lisbon (CIDNUR), Lisbon, Portugal*; [9]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; [10]*QLV Research Consulting, Scieitific Coordinator, Coimbra, Portugal*

Background: Patient education (PE) is a key role of nurses,[1] which includes providing information, training, and support about methotrexate (MTX), an anchor drug in rheumatology. However, there is wide variation in the access to rheumatology nurse consultations in Europe and no standard strategy about when, what, and how nurses should provide PE to these patients.

Objectives: The objective of this scoping review was to provide a comprehensive overview of the existing research on nurse education on MTX for children/youth and adults with Rheumatic and musculoskeletal diseases (RMDs).

Methods: We searched PubMed (MEDLINE), Scopus and Cochrane Database, and CINAHL complete, from inception until march of 2022. Articles on patient education with a focus on MTX exclusively were included. Two independent reviewers performed standardized data extraction and synthesis.

Results: From 292 references identified, 14 fulfilled the inclusion criteria (Figure 1). A Summary of study methods and results are presented in Table 1.

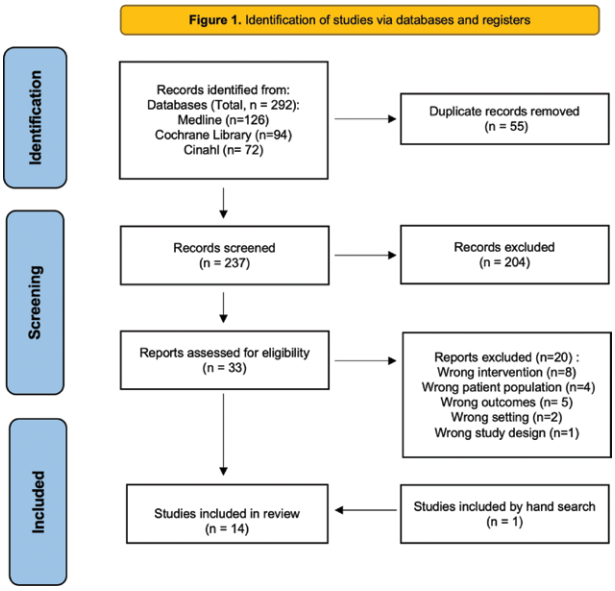

Table 1. Characteristics of included studies

1st Author (year), Country	Study design	Study sample[a]	Results
Burma (1996), EUA	Non-randomised experimental	183	Addition of a supplemental "MTX pocketcard" improve knowledge on MTX
Homer (2009), UK	RCT	62	Better adherence and satisfaction to MTX after nursing counselling
Livermore (2003), UK	Non-randomised experimental	18 families	Teaching families to manage MTX administration at home is feasible
Sowden (2012), UK	Cross-sectional	51	Despite consistent baseline patient education, end-user knowledge and awareness pertinent to MTX safety are limited
Barton (2013), EUA	Cohort	135	Age > 55, less than high school education, better function, and biologic use were independently associated with poor knowledge on MTX
Ciciriello (2014), Australia	Cohort	31	Multimedia patient education program about MTX treatment for RA found to be user-friendly and easily implementable. A validated scale to evaluate MTX-related knowledge was developed.
Katz (2015), Canada	RCT	29	An education video may be a good supplement to standard in-person nurse education for MTX self-injection
Rittberg (2016), Canada	Cross-sectional	60 youtube videos (adults, nurses)	Videos may be a useful additional educational tool
Robinson (2017), UK	Cross-sectional	104 nurses	Nurses' confidence correlated with knowledge about MTX and time in the role of the nurses. The amount of training received correlated with confidence but not with knowledge.
Robinson (2018), UK	Qualitative	6 rheumatology nurses	Nurses described a lack of confidence when they first started counselling patients commencing MTX, with a wide variation in training.
Sørensen (2020), Norway	Qualitative	8 children 11 parents 7 nurses	When clinicians used an acknowledge communication and offered sufficient coping strategies, children seemed to become involved in the procedure and acted with confidence. The initial educational training session may have a great impact on long-term outcomes.
Otón (2021), Spain	Qualitative	12 adult representatives	Barriers and facilitators of adherence to MTX involve: drug-related aspects, patient-physician relationship, social environment, and medication and medical care practicalities.
Robinson (2021), UK	Mixed-methods	10 consultations (adults, nurses)	Consultations generally consisted of communication from nurse to patient rather than a dialogue, with an 'overloading' of the patient with information.
Fayet (2021), France	Retrospective	66	A therapeutic education session improves patients' knowledge about MTX.

a. Adult patients unless stated otherwise

Conclusion: Through this scoping review, we identify that knowledge of MTX improves when education by nurses is provided. Patient education about MTX can be de delivered in different forms and can result in better satisfaction and adherence. More RCTs with powered samples are required.

HPR Interdisciplinary research

POS0792-HPR LIVING WITH RA GIVES NEW INSIGHTS TO LIFE - PATIENTS' EXPERIENCES AFTER 1-2 YEARS OF DMARD TREATMENT

Keywords: Rheumatoid arthritis, Qualitative research methods, Lifestyles

I. Larsson[1,2,3], E. Landgren[2,4,5], E. Lindqvist[4,5], E. Mogard[4,5], M. Nylander[2,6], A. Bremander[2,4,7,8]. *[1]Halmstad University, School of Health and Welfare, Halmstad, Sweden*; *[2]Spenshult Research and Development Centre, FoU, Halmstad, Sweden*; *[3]Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden*; *[4]Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden*; *[5]Skåne University Hospital, Department of Rheumatology, Lund, Sweden*; *[6]Swedish Rheumatism Association,., Stockholm, Sweden*; *[7]University of Southern Denmark, Department of Regional Health Research, Odense, Denmark*; *[8]University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sonderborg, Denmark*

Background: Rheumatoid arthritis (RA) is a disease that greatly impacts all aspects of life. Living with RA affects patients' physical, emotional, psychological, and social health. Patients with RA are treated with disease-modifying anti-rheumatic drugs (DMARDs) and monitored with tight control to achieve low disease activity or remission. Nevertheless, RA can be life-changing when the patients need long-term treatment to control the disease activity. The goal of treatment for patients with chronic diseases such as RA is to achieve optimal health and normal life. It is therefore important to gain knowledge about how patients experience everyday life a short period after the initiation of DMARD treatment.

Objectives: The purpose of the study was to describe patients' experiences of living with RA after 1-2 years of DMARD treatment.

Methods: The study has a qualitative design with an inductive approach. Focus groups (n=17) and individual (n=5) interviews were conducted with 22 patients with RA. The participants consisted of 15 women and 7 men with a mean age of 57 years and a disease duration of 12-21 months. The participants were treated with conventional or biological DMARDS for 12-20 months. The main questions were: "Can you tell me how RA impacts your daily life?" "Which outcomes of your RA are important to you?" The interviews were analyzed with latent qualitative content analysis[1,2], and five categories with an overarching theme emerged (Table 1).

Results: Patients' experiences of living with RA after 1-2 years of DMARD treatment gives new insights to life and were expressed as 1) Surrendering to disease limitations due to being restricted by pain, fatigue, and in function; 2) Adapting to disease limitations by adjusting one´s work balance and one's social life; 3) Transitioning in self-identity due to disease limitations by not recognizing oneself and experiencing a change of bodily appearance and mood; 4) Fighting disease limitations by experiencing joy through exercise, promoting health by exercise and dietary habits, and; 5) Feeling humility despite disease limitations by being grateful for the treatment and seizing the day.

Conclusion: Although patients have been living with RA and treated with DMARD for 1-2 years, they are still struggling to make everyday life work. Although patients adapt their lives to the new conditions, they are affected by symptoms such as fatigue, pain, stiffness, and side effects such as nausea, hair loss, and weight gain. However, patients highlight the positive impact of how exercise influences their health and how living with RA gives new insights to life.

POS0793-HPR OBSERVATIONAL STUDY IN REAL CLINICAL PRACTICE OF THE TREATMENT OF NON-INFECTIOUS UVEITIS

Keywords: Uveitis, Spondyloarthritis, Treat to target

M. D. M. Esteban-Ortega[1], M. Steiner[2], C. Andreu-Vázquezc[3], I. Thuissard Vasallo[3], A. Dóiaz-Rato[4], S. Muñoz-Fernández[5]. *[1]Department of Ophthalmology Infanta Sofía University Hospital, Ophthalmology, San Sebastián De Los Reyes, Madrid, Spain*; *[2]Infanta Sofía University Hospital, Department of Rheumatology, San Sebastián De Los Reyes, Madrid, Spain*; *[3]Faculty of Biomedical and Health Sciences, Universidad Europea de Madrid, Department of Medicine., Madrid, Spain*; *[4]Infanta Sofía University Hospital, Ophthalmology, Madrid, Spain*; *[5]Infanta Sofía University Hospital, Department of Rheumatology, Madrid, Spain*

Background: Uveitis is an ocular disease that is a major cause of morbidity and blindness in the developed world. Although Immunosuppressive drugs and biologic therapy have been shown to be effective in their treatment there are no clear protocols for their use.

Objectives: To describe the characteristics of patients with uveitis associated with immunologic or idiopathic disease who require immunosuppressive treatment and their response in real clinical practice.

Methods: Observational, descriptive, longitudinal, and retrospective study of a cohort of patients diagnosed with uveitis associated with immunologic or idiopathic diseases attended in a multidisciplinary consultation between January 2011 and February 2022. To assess the response to treatment, we evaluated the change in visual acuity and vitritis and the presence of macular edema.

Results: We included 356 patients (mean age at diagnosis 42.8 ± 15.8 years, 50% female). Of the total, 157 (44%) had a single flare and 164 (46%) more than three. The involvement was bilateral in 85 patients (24%) and anterior (73%) and idiopathic (43%) were the most frequent. Twelve percent required treatment with systemic corticosteroids and 66 patients (18.5%) immunosuppressive/biological treatment, methotrexate being the most used (55%). Ten patients of the 66 (15%) started treatment with biologics and 34 (48%) required them at some point during the disease, adalimumab being the most used. Thirty-five patients (53%) needed to change drug due to lack of response. There were no differences between different drugs in the resolution of vitritis and improvement of vision. Disappearance of macular edema was achieved in all patients treated with tocilizumab.

Conclusion: The use of systemic corticosteroids and immunosuppressive/biologics was necessary in a high number of patients with non-infectious uveitis. In our series tocilizumab proved to be significantly more effective in the resolution of macular edema.

Background: According to the world health organization, sexual health (SH) is "a state of physical, emotional, mental and social well-being in relation to sexuality". Studies on the impact of juvenile idiopathic arthritis (JIA) on SH are scarce especially during the critical phase of adolescence. We can ask ourselves: are health professionals (HP) "good" interlocutors for JIA patients?
Objectives: We aimed to determine the expectations of JIA adolescents (10-19 years) and the perceptions of their parents regarding exchanges with HP in the field of SH.
Methods: A multicenter survey was performed in nine French rheumatology centers and three patient associations from September 2021 to April 2022, among JIA patients, aged 18-45 years and their parents. On the advice of two child psychologists and a psychiatrist, we interviewed an adult population to obtain convincing data about their adolescence with the necessary hindsight on the subject. Self-administered questionnaires were designed (for JIA patients and parents) after an extensive literature review and experts' consensus and distributed to participants.
Results: 76 patients and 43 parents completed the anonymous questionnaires. Most patients were women (75%), with a mean age of 26 (7.2) years and an education level higher than high school (89%). Parents were mainly mothers (88%), with a mean age of 54 (5.6) years and an education level higher than high school (56%). Half the patients considered that JIA impacted their love life. The main causes were body complexes (46%) and low self-esteem (40%). The impact on their sex life was not clear-cut. Love life was discussed with parents for 52% and sexual life for 20% of patients. 59% of patients reported they were comfortable to discuss SH with an HP (yet, only 26% had done). Their main sources of information were referees (at school (46%), family (43%)) or social networks (34%). If patients reported that SH has been discussed, it was mainly when the HP was proactive (56%), with the hospital rheumatologist (50%), from a biomedical perspective. Focusing the needs for optimal care, patients and parents agreed to address SH during an individual patient education session in hospital (51% vs 35%), a regular consultation (47% vs 53%) or a dedicated consultation by request of the adolescent without parents being informed (38% vs 21%). Most patients and parents agreed that the HP should be proactive (78% vs 70%). At hospital, for patients, the most competent or the most affordable HP were the gynecologist (68%; 47%, respectively), the rheumatologist (55%; 41%), and the psychologist (53%; 39%). Patients and parents both considered that a peer expert would make patients feel more comfortable (38% vs 37%); however, contrary to patients, fewer parents point out their skills (46% vs 25%, p>0.0276). The opportunity of a suitable moment (64% of patients vs 53% of parents), an HP comfortable with the subject (59% vs 53%), and availability of brochures (45% vs 49%) seemed to be helpful for both. The only statistically significant difference concerned HP gender, less cited by parents (7% vs 43%, p <0.0001). The use of digital resources was significantly more cited by patients than parents (video information (29% vs 9%, p=0.0127); smartphone application (25% vs 9%, p=0.0372)). 79% of patients were looking for general information (impact of JIA and treatments on sexuality), discussion (68%), reassurance (65%), and listening (51%). General information (58%, p=0.0158) and discussion (39%, p=0.0022) were significantly less cited by parents.
Conclusion: To our knowledge, this is the first study to address the SH needs of adolescents with JIA. HPs should take up this real need about SH, especially in hospital for adolescents and their parents. Indeed, there are expectations directly linked to the specifics of the disease. The main difference between patients and parents would be the use of digital tools. There could be an interesting vector of communication with adolescents if the sources are reliable and parents reassured about their content.

POS0795-HPR **STAGE 1 HYPERTENSION CARRIES EXCESSIVE CARDIOVASCULAR RISK IN AXIAL SPONDYLOARTHRITIS PATIENTS: A 12-YEAR LONGITUDINAL COHORT STUDY**

Keywords: Self-management, Cardiovascular disease, Spondyloarthritis

J. L. H. Shi[1], H. So[1], S. H. M. Lam[1], T. K. Li[1], E. Li[1], C. C. Szeto[1], L. S. Tam[1]. *[1]*The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China

Background: Hypertension (HT) is one of the modifiable risk factors for the development of CV event (CVE) [1,2]. The American College of Cardiology/American Heart Association (ACC/AHA) recommended a new definition for arterial HT in adults since 2017 [3]. Whether this new definition of HT is associated with increased CV risk in patients with axSpA remains unknown.
Objectives: To ascertain whether stage 1 hypertension at baseline is a predictor of future cardiovascular event (CVE) in patients with axial spondyloarthritis (axSpA).
Methods: We conducted a retrospective cohort study in axSpA patients who were recruited from 2001-2017. Patients with at least 2 years of follow-up and without prior CVE were divided into three groups according to the calculated mean BP over the first 2-year period (adjusted mean BP) (≥140/90mm Hg, 130-139/80-89mm Hg and <130/80mm Hg). They were followed from baseline until the end of 2020 or occurrence of a first CVE. Multivariate Cox regression analyses adjusting for baseline and time-varying variables were used to assess the relationship between mean BP and with CVE.
Results: Out of the 458 patients fulfilling the inclusion criteria, 56 (12.2%) and 141 (30.8%) had an adjusted mean BP ≥140/90mm Hg and 130–139/80–89mm Hg respectively, and 261 (57.0%) were normotensives. After a median follow-up of 12 [7-18] years, 56 (12.2%) CVE were documented. The incidence rates were 21.4, 14.2 and 5.9 per 1000 patient-years for the three groups respectively. A adjusted mean BP of 130–139/80–89 mm Hg was independently associated with the occurrence of CVE after adjusting for the baseline covariates (Figure 1) as well as time-varying inflammatory burden (Table 1). This association was not significant after adjustment for time-varying traditional CV risk factors.
Conclusion: Stage I hypertension at baseline is associated with increased risk of developing CVE in axSpA patients. This association may be mediated by other traditional CV risk factor.s.

ASSOCIATIONS BETWEEN PAIN REDUCTION AFTER PARTICIPATION IN FIRST-LINE OSTEOARTHRITIS MANAGEMENT PROGRAMS AND PROGRESSION TO JOINT REPLACEMENT: A REGISTER-BASED STUDY OF 44588 PATIENTS WITH HIP OR KNEE OSTEOARTHRITIS

Keywords: Registries, Physical therapy/physiotherapy

K. Gustafsson[1], A. Cronström[2], O. Rolfson[3], E. Ageberg[2], T. Jönsson[4].
[1]*Linköping University, Department of Health, Medicine and Caring Sciences, Linköping, Sweden*; [2]*Lund University, Department of Health Sciences, Lund, Sweden*; [3]*University of Gothenburg, Department of Orthopaedics, Gothenburg, Sweden*; [4]*Lund University, Department of Health Sciences, Sweden, Sweden*

Background: First-line treatment for people with hip and knee OA is education, exercise, and if needed weight control. It has been shown that people participating in first-line treatment experience positive effects on outcomes such as pain (1-3), health-related quality of life, self-efficacy, and function (3), and may postpone the need for total joint replacement [4]. However, it is still unclear if the results from first-line treatment are associated with progression to joint replacement.
Objectives: To investigate the association between changes in pain after participation in first-line OA management programs and progression to joint replacement in persons with hip and knee OA.
Methods: An observational register-based study. Data from the BOA register was merged with data from the Swedish Arthroplasty Register. The primary prognostic factor was the change in pain between baseline and 3-month follow-up. The pain was measured on a numeric rating scale (NRS). The NRS pain comprises an 11-point scale where 0 indicates no pain and 10 indicates the worst possible pain during the last week. In the current study, pain change was categorized into a) much better (≥2 steps of improvement), b) slightly better (1 step of improvement), c) no change in pain, d) slightly worse (1 step of deterioration) and e) much worse (≥2 steps of deterioration). The main outcome was progression to joint replacement. A Cox regression model was applied to investigate the association between changes in pain and progression to joint replacement and presented with Hazard ratios (HR).
Results: Among patients with hip and knee OA, respectively, 26% (n=3555/13876) and 9% (n=2686/30712) progressed to joint replacement. An improvement in pain was associated with a lower probability of progression to surgery while patients who got worse in pain had an increased probability (Table 1).
Conclusion: Progression to joint replacement after participation in first-line treatments for hip and knee OA is influenced by the change in pain intensity. This implies that patients should participate in first-line treatment before being referred to joint replacement.

POS0797-HPR PREVALENCE AND ASSOCIATIONS WITH DEVELOPMENT OF RADIOGRAPHIC KNEE OSTEOARTHRITIS IN INDIVIDUALS WITH KNEE PAIN – A 2-YEAR FOLLOW-UP

Keywords: Osteoarthritis

M. Törnblom[1,2,3], A. Bremander[1,2,4,5], M. Andersson[1,2,6], A. Nilsdotter[7,8], K. Aili[2,9], E. Haglund[1,2,6]. [1]*Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden*; [2]*Spenshult, Research and Development Centre, Halmstad, Sweden*; [3]*Helsingborg Hospital, Department of Rehabilitation, Helsingborg, Sweden*; [4]*University of Southern Denmark, Department of Regional Health Research, Odense, Denmark*; [5]*Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sonderborg, Denmark*; [6]*Halmstad University, Department of Environmental and Biosciences School of Business, Innovation and Sustainability, Halmstad, Sweden*; [7]*Gothenburg University, Department of Orthopaedics, Clinical Sciences, Sahlgrenska Academy, Göteborg, Sweden*; [8]*Sahlgrenska University Hospital, Department of Orthopaedics, Göteborg, Sweden*; [9]*Halmstad University, Department of Health and Sport, School of Health and Welfare, Halmstad, Sweden*

Background: Pain and functional impairment form the basis for a clinical knee osteoarthritis (KOA) diagnosis according to the National Institute for Health and Care Excellence (NICE) guidelines [1]. Enhanced knowledge of the progression from knee pain to radiographic KOA (RKOA), may enable early identification of individuals at risk.
Objectives: To study the development of radiographic knee osteoarthritis in individuals with knee pain over time, and its associations to baseline variables.
Methods: In all 172 individuals (30-67 years) with knee pain, from the Swedish HALLOA cohort (2) were studied from baseline to 2-year follow-up. The individuals were at baseline coded as clinical KOA according to NICE guidelines or not. None had RKOA at baseline. At follow-up they were dichotomised as RKOA or not (Ahlbäck grade 1 or more). Self-reported knee symptoms (the Knee injury and Osteoarthritis Outcome Score (KOOS)), and knee pain intensity (numerical rating scale (NRS)) were assessed. Body composition, functional performance and clinical examination were also assessed. The Chi-Square-test or Mann-Whitney U-test was used for comparisons between groups, and logistic regression for analysis of associations between baseline variables and RKOA at follow-up adjusted for age.
Results: The mean age of the group was 51 (SD 8) years, 67% were women, Body Mass Index (BMI) was 26 (SD 5). The prevalence of RKOA at follow-up were 13% (n=23), and all of them had clinical KOA at baseline according to NICE guidelines. Furthermore, those with RKOA at follow-up had significantly higher BMI median 28.8 (IQR 8.6) vs. 25.1 (5.7), p=0.011, visceral fat area (VFA) 130.7 (88.7) vs. 84.7 (62.4), p=0.009, and knee pain; KOOS sub score Pain 69 (28) vs. 78 (19), p=0.016, and pain intensity 5.0 (5.0) vs. 4.0, (3.0) p=0.039, at baseline. Higher BMI and VFA, worse knee pain intensity, and worse KOOS sub scores for Pain, Symptoms, ADL, and QOL at baseline, were associated with RKOA at follow-up (Table 1). Sex, self-reported morning knee stiffness and restricted knee motion, functional performance tests and clinical examined crepitus, were not associated to RKOA and thus not included in the final analysis (p-value 0.477 - 0.930).
Conclusion: More than one out of ten individuals with clinical KOA developed RKOA already in 2 years. In individuals with knee pain, variables associated with RKOA at follow-up can be detected early through NICE guidelines, assessment of BMI, VFA and self-reported symptoms with KOOS questionnaire as a support to start with early management.

POS0798-HPR PREVALENCE OF RISK FOR ANXIETY AND DEPRESSION IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Mental health, Comorbidities, Epidemiology

L. F. Vega Sevilla[1], M. A. Villarreal-Alarcón[1], D. P. Flores-Gutierrez[1], N. De Avila Gonzalez[1], I. D. J. Hernandez-Galarza[1], J. A. Cardenas-de la Garza[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*

Background: Patients with chronic diseases have a higher prevalence of anxiety and depression. The complex relationship between chronic diseases and mental health disorders can influence each other negatively. (1)
Objectives: To determine anxiety and depression symptoms prevalence in an out-patient rheumatology clinic, and its associated factors.
Methods: This was a cross-sectional study. Patients > 16 years old with a rheumatologic disease were included. Data from medical history were collected. The Hospital Anxiety and Depression Scale (HADS) was applied from March to November 2022. A score from 0-7 points is classified as low risk, 8-10 as intermediate risk, and >11 as high risk. Patients with high risk were referred to an evaluation by Psychiatry in the same clinic. We compared groups according to HADS scores using Kruskal-Wallis or Chi-square test.
Results: A total of 705 patients were included, 658 women, demographic characteristics in Table 1. Most common diagnosis was RA, followed by systemic lupus erythematosus (SLE). High anxiety risk was found in 125 patients, median disease duration of 6 years. Sixteen patients had high risk for depression, median disease duration of 10 years. Intermediate risk of depression was assessed in 15 patients, median disease duration of 10 years. We received 38 patients that accepted to be referred to a psychiatric evaluation. An association was found between high risk of anxiety and gender (p=0.019), no association was found with age or menopause. High risk of anxiety was more prevalent (n=125) than depression (n=16), and patients with intermediate risk for depression showed a higher prevalence of intermediate and high risk for anxiety (p=.000).

Conclusion: We found that high risk of anxiety was more prevalent than depression. Higher risk of anxiety was found in female patients. Almost 1 of every 5 patients with rheumatic diseases has an intermediate risk for anxiety. The implementation of a mental health screening tool can help patients receive earlier attention by a specialist.

EFFECTIVENESS OF AN INTERDISCIPLINARY HEALTH PROMOTION EDUCATIONAL PROGRAM IN IMPROVING THE QUALITY OF LIFE OF INDIVIDUALS WITH FIBROMYALGIA IN BRAZIL: A RANDOMIZED CLINICAL TRIAL OF AMIGOS DE FIBRO

Keywords: Patient information and education, Fibromyalgia, Self-management

M. Antunes[1], F. C. N. Loures[2], A. Schmitt[1], E. Frutos-Bernal[3], A. M. Martín-Nogueras[4], A. Pasqual Marques[1]. [1]*University of São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy (FOFITO), São Paulo,*; [2]*Clínica de Reumatismo Dr. Felipe Rocha Loures, Maringá, Brazil*; [3]*University of Salamanca, Department of Statistics, Faculty of Medicine, Salamanca, Spain*; [4]*University of Salamanca, Faculty of Nursing and Physiotherapy, Salamanca, Spain*

Background: "Amigos de Fibro" (Fibro Friends), is a recent and innovative program created from the joint action of patients and health professionals, which can be an effective educational tool to be implemented in primary health care centers, promoting self-care, quality of life and health promotion in individuals with fibromyalgia in Brazil.

Objectives: Evaluate the effectiveness of an interdisciplinary health promotion educational program called "Amigos de Fibro" in improving pain intensity, symptom severity, quality of life, sleep quality and self-care agency in individuals with fibromyalgia in Brazil.

Methods: A randomized clinical trial was carried out with 24 participants divided into two groups: the experimental group (EG) and the control group (CG). The EG group held online meetings through the Google Meet platform with an interdisciplinary team (10 professionals) that worked in primary health care in Brazil, where they gave lectures and held debates and dynamics on the importance of health promotion and self-care in fibromyalgia. In addition, participants performed a physical exercise protocol. The "Amigos de Fibro" protocol has been previously published and showed good agreement. The control group (CG) received an education and self-care e-book for fibromyalgia that addressed information similar to the EG (*http://www.amigosdefibro.com.br*). Participants were assessed pre and post-intervention. A descriptive analysis of the data was performed, as well as the differences of the independent variables between the intervention and control groups were studied using Student's t test for independent samples. A significance level of 5% was adopted.

Results: The mean age of the participants was 38.7±9.4 years for the EG and 44.9±10.6 for the CG, all (100%) of whom were female in both groups. Compared to the baseline, all EG variables and only the FIQ symptoms domain of the CG showed significant improvements (p<0.005), however, the other CG variables showed improvements, but they were not significant (Table 1).

Table 1. Results of the variables studied in both groups.

	EG			CG		
	Pre-intervention	Post-intervention	p-value	Pre-intervention	Post-intervention	p-value
	Mean±SD	Mean±SD		Mean±SD	Mean±SD	
GDI	14±3,2	8,3±3,0	**<0,001***	13,8±2,5	11,5±3,7	0,066
SS	10,3±1,8	6,9±2,7	**0,001***	10,8±1,0	10,1±1,4	0,244

Caption: EG: Experimental Group; CG: Control Group; SD: Standard deviation; GDI: Generalized Pain Index; SS: Severity of Symptoms; FIQ-R: The Revised Fibromyalgia Impact Questionnaire; VAS: Visual Analog Pain Scale.

Conclusion: "Amigos de Fibro", a light technology in health, was considered with good results and improvement of all studied variables that address the main aspects that promote the health of individuals with fibromyalgia and, therefore, being considered valid for use by health professionals with the target public in primary health care in Brazil, enabling them to act as health promoting agents. Our next steps are to expand knowledge of this program to other countries.

POS0800-HPR

START WITH THE END IN MIND- EMBEDDING AN INTEGRATED SELF MANAGEMENT APPROACH WITHIN ROUTINE CLINICAL CARE FOR NEWLY DIAGNOSED PATIENTS WITH INFLAMMATORY ARTHRITIS

Keywords: Inflammatory arthritides, Prognostic factors, Self-management

J. Harkess[1], E. Webber[2], R. Mclaren[1], A. Mackenzie[3], H. Bett[4], S. Hailwood[5], Y. Robertson[6], T. Dickson[5]. [1]*Whytemans Brae Hospital, Rheumatology, Kirkcaldy, United Kingdom*; [2]*Ninewells Hospital, Psychology, Dundee, United Kingdom*; [3]*Lynebank Hospital, Clinical Psychology, Dunfermline, United Kingdom*; [4]*Fife Health and Social Care Partnership, Rheumatology, Sexual Health and Children's Services, Dunfermline, United Kingdom*; [5]*Whytemans Brae Hospital, Rheumatology, Kirkclady, United Kingdom*; [6]*NHS Fife, Clinical Governance, Windygates, United Kingdom*

Background: Long term outcomes of inflammatory arthritis patients are not only dependent on early identification of symptoms and tight control of disease, but also on the person's abilities to manage the impact of their condition. (1-2) In 2019 Fife Rheumatology Service focussed on early identification of patient's assets for self managment (SM) and those at risk of poorer outcomes with the aim of targeting supported SM resources. EULAR 2021 recommendations endorse the implementation a self management approach within routine care[3].

Objectives:

1. Implement a SM approach as part of routine clinical care.
2. Establish baseline patient characteristics data set to evaluate the effectiveness SM interventions on long term outcomes.

Methods: Identified priorities of the re-design were:

1. Additional investment in psychology to lead the re-design.
2. SM database.
3. SM screening and triage tool, and, a SM check list.
4. Stepped model of care including referral to patient organisations.
5. Feedback from patients, staff and patient organisations.
6. Virtual weekly patient disease and SM virtual multidisciplinary team (VMDT) clinic.
7. SM Digital App.
8. Patient Initiated Review (PIR) system for disease stable and self managing patients.

Results: All 8 priorities were implemented and 315 patients have been referred to the pathway since 25/08/2022. Positive feedback about the pathway and the App has been received from patients, staff and patient organisations. Six patients at 5 months post diagnosis are discussed weekly at our VMDT clinic. Of the total patients referred, 42% were male and 58% were female. The mean age was 56 years, range 16-85 years. Twenty one percent of patients at baseline had low to moderate confidence in managing their inflammatory arthrtis across the 4 subsets of *Emotions, Activities of daily Living (ADLS), Social Interactions* and *Symptoms* of the Patient-Reported Outcomes Measurement Information System-managing chronic conditions.(4) Lowest scores were found in the *Emotions* and *ADLs subsets*. Nineteen percent of patients of working age were not working. Twenty eight percent of patients had moderate to severe disability on the Modified Health Assessment Questionnaire and 54% had moderate to severe depression on the Patient Health Questionnaire-9. Forty two percent of patients fell into the deprived or most depvied categories of the Scottish Index of Multiple Deprivation.

Conclusion: The implementation of a self management approach as per EULAR Recommendations has been well received by key stakeholders and has helped with the early identification of patients' SM needs and highlighted those at risk of poorer outcomes. This data will act as a basis for the application of improvment methodology to assess the effectivness of future interventions and measure long term outcomes. Early indications would suggest targeting resources on improving patients' confidence in managing their mental mealth and ADLs.

POS0801-HPR GREAT EXPECTATIONS: A FATIGUE MANAGEMENT PROGRAMME CAN ALSO IMPROVE SLEEP QUALITY AND MENTAL WELL-BEING IN RHEUMATIC DISEASE PATIENTS

Keywords: Self-management, Non-pharmacological interventions, Mental health

J. Dobson[1], D. Dockrell[1], K. Berg[1], S. Ralston[1], H. Harris[2]. [1]*University of Edinburgh, Bone Research Group, Rheumatic Diseases, Edinburgh, United Kingdom*; [2]*NHS Lothian, Rheumatology, Edinburgh, United Kingdom*

Background: Fatigue is a significant problem for patients with Rheumatic diseases and yet remains overlooked and undertreated[1-3]. It is known to be associated with increased sleep disturbance in this patient group[4] and with poorer mental health[5]. A fatigue management programme (FMP) was developed with the aim of reducing the impact of fatigue on patients. Outcome measures were used to determine whether an improvement in fatigue scores also resulted in an improvement in sleep and mental health.

Objectives: The primary objective was to evaluate whether a reduction in fatigue corresponded with an improvement in sleep quality following attendance at a virtual FMP. The secondary objective was to evaluate the impact of the FMP on patient mental well-being.

Methods: The FMP was based on the RAFT study[6] and patient-reported outcome measures (PROMs) were assessed before and after enrolment to the FMP. The Visual Analogue Scale (Fatigue) (VAS-F) was used to evaluate fatigue scores. The Pittsburgh Sleep Quality Index (PSQI) was used to assess changes in sleep quality. The Patient Health Questionnaire 9-Item (PHQ-9) and the Generalised Anxiety Disorder Assessment (GAD-7) were used to measure depression and anxiety scores respectively.

Results: Gender ratio 5:1 females to males, age range 25-81 with a mean of 51.6 ± 12.3. Patient's diagnoses were equally divided between Rheumatoid Arthritis, Systemic Lupus Erythematosus and other Rheumatic Diseases. Both primary and secondary objectives have been met.

Table 1. PROM scores reported before and after the FMP. Data is shown as mean and standard deviation.

n = 43	Pre-FMP	Post-FMP	p value
VAS-F	74.3 ± 18.4	52.3 ± 22.1	<0.0001
PSQI	11.8 ± 4.8	9.1 ± 4.1	<0.0001
PHQ-9	13.8 ± 6.2	8.9 ± 5.4	<0.0001
GAD-7	8.5 ± 6.4	5.7 ± 5.3	0.0005

Patient's scores significantly improved in all of the PROMs collected for the purposes of this service evaluation (see Table 1). There was a correlation between improvements in VAS-F scores and improvements in PSQI scores (r = 0.365) which was statistically significant (p = 0.016).

Conclusion: An FMP is effective at significantly reducing fatigue, improving sleep quality and mental wellbeing. We have shown that there is a correlation between a reduction in fatigue and an improvement in sleep and this work highlights the importance of such a programme as part of routine care and management of these chronic conditions.

SELF-MANAGEMENT SUPPORT NEEDS OF PATIENTS WITH INFLAMMATORY ARTHRITIS AND THE CONTENT OF SELF-MANAGEMENT INTERVENTIONS: A SCOPING REVIEW

Keywords: Inflammatory arthritides, Self-management, Rehabilitation

A. Damgaard[1,2], J. Primdahl[2,3,4], B. A. Esbensen[5,6], K. M. Latocha[5], A. Bremander[2,3,7,8]. [1]*Aarhus Universitet, Health, Aarhus, Denmark*; [2]*University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark*; [3]*University of Southern Denmark, Department of Regional Health Research, Odense, Denmark*; [4]*University Hospital of Southern Denmark, Sygehus Sønderjylland, Sønderborg, Sønderborg, Denmark*; [5]*Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark*; [6]*The University of Copenhagen, Faculty of Health and Medical Sciences, Department of Clinical Medicine, København, Denmark*; [7]*Lund University, Section of Rheumatology, Department of Clinical Sciences Lund, Lund, Sweden*; [8]*Spenshult Research and Development Centre, Spenshult Research and Development Centre, Halmstad, Sweden*

Background: Studies show varying but beneficial effects of self-management interventions on self-efficacy, symptoms or burdens, such as pain, fatigue, illness perception, and quality of life, supporting the need of multi-disciplinary interventions in rheumatology (1, 2). However, the content of the self-management interventions differs widely [2]. There is a need for an overview of the existing evidence of self-management support needs in patients with inflammatory arthritis (IA) to inform the development of relevant and effective interventions.

Objectives: 1) to identify the evidence for self-management support needs among patients with IA, and 2) to identify the content (theory/theoretical approach, mode of delivery, duration and frequency) of self-management interventions that target patients with IA.

Methods: In May 2021, we performed a scoping review (protocol published at the Open registries network, no. DOI 10.17605/OSF.IO/TVX82)) and conducted a systematic literature search (from 2000 onward) in five databases.

Results: Out of 11,748 records identified, we included 31 articles describing patients' support needs and 33 articles describing the content of self-management interventions (Figure 1). Patients' self-management support needs were categorized into six topics: 1) Disease impact and the pharmacological treatment, 2) Care continuity and relations with health professionals, 3) The importance of non-pharmacological treatment, 4) The need for support from family and friends, 5) Support needs related to work issues, and 6) Contextual preferences for self-management support. Content of the self-management interventions varied widely and the descriptions of the content were deficient and needed clarification (Table 1). The identified topics for support needs were compared with the described content in the included articles (Table 1). Only few self-management interventions focused on patients' need for support concerning work, family, and friends.

Conclusion: Health professionals provided self-management support to patients with IA in various ways. There were gaps between the patients' support needs and the identified interventions. The self-management concept needs to be clearly defined when developing self-management interventions. Further studies are required to investigate various modes of delivery, frequency, and duration to develop effective interventions that meet patients' self-management support needs.

POS0803-HPR

DEVELOPMENT OF A PATIENT-CENTERED MULTIMODAL DISEASE MANAGEMENT PLATFORM FOR THE FIBROMYALGIA-LIKE POST-COVID19 SYNDROME

Keywords: Fibromyalgia, COVID, Patient reported outcomes

M. Blanchard[1], T. Hügle[1], P. Ming Azevedo[1]. [1]*Lausanne University Hospital, Rheumatology, Lausanne, Switzerland*

Background: About 30% of patients with post-COVID19 syndrome satisfy the ACR survey criteria for fibromyalgia. The most common symptoms are chronic fatigue, generalized pain, sleep impairment, anxiety and depression. A substantial part of the patients already suffered from similar symptoms before infection. Digital health solutions have shown efficiency for fibromyalgia, offering specific disease monitoring and multimodal interventions and thus may work in patients with post-Covid19 syndrome.
Objectives: To develop a multimodal, multi-interventional self-management platform for post-COVID19 and potentially other post-viral syndromes patients. To ensure a patient-centric development and evaluate the usability of this solution by performing qualitative user experience research.
Methods: We developed a web-based user interface with a horizontal basic navigation menu consisting of patient reported outcomes, symptoms evolution and interventions. The therapeutic content was created by rheumatologists, psychiatrists, physiotherapists and occupational therapists and included educational content, physical-, respiratory- and olfactory exercises, cognitive behavioral therapy, mindfulness, relaxation training, therapeutic stories and art therapy. Usability and satisfaction surveys have been conducted among 53 post-COVID19 patients and qualitative interviews have been performed.
Results: The frontend design of the platform is shown in Figure 1. 90% of the patients preferred a regular symptoms list questionnaire over a chatbot to collect patient reported outcomes. Longitudinal symptom evaluation is shown in the 'my results' section. 81% of patients expressed their wish that their symptoms are displayed with a benchmark of all other patients and to learn what has helped other patients with similar symptoms. A majority of them were also interested in links to patient communities (63%), so an anonymized discussion forum has been added. Patients preferred active training programs (63%) and information (59%) over interactive and gamified content like quizzes (15%). Interactivity on the web-app was created by accordion function and horizontal navigation within each treatment module. An administrator content management dashboard has been implemented to ensure a flexible and reactive supervision of the platform.
Conclusion: We present a functioning, patient-centered app tailored for patients with post-COVID19 syndrome. Further clinical studies on user experience, adherence, adoption driving factors and efficacy are ongoing.

HPR Measuring health (development and measurement properties of PROs, tests, devices)

POS0804-HPR

INVESTIGATION OF THE VALIDITY AND RELIABILITY OF THE STEP UP AND DOWN TEST IN PATIENTS WITH TOTAL KNEE ARTHROPLASTY SURGERY

Keywords: Physical therapy/physiotherapy, Outcome measures, Osteoarthritis

S. Tarkan[1], B. Unver2, V. Karatosun[3]. [1]*Dokuz Eylul University, Faculty of Physical Therapy and Rehabilitation, İzmir, Turkey*; [1]*Dokuz Eylul University, Faculty of Physical Therapy and Rehabilitation, İzmir, Turkey*; [3]*Dokuz Eylul University, School of Medicine Department of Orthopedics and Traumatology, İzmir, Turkey*

Background: Stair climbing has been showed as the first changing activity in patients with knee osteoarthritis (KOA) [1]. Stair climbing and step tests of patients with KOA are used as measurement tools to determine the functional level of patients and to determine the effectiveness of treatment. Patients with KOA undergoing total knee arthroplasty (TKA) show asymmetrical patterns and slower climbing stairs when the affected limb is compared to the healthy limb [2]. Therefore, unilateral evaluation of the extremity undergoing TKA is important. There are many tests that evaluate stair climbing function in patients with TKA. However, the Step Up and Down (StUD) test, which was previously found to be valid and reliable in knee osteoarthritis, is a 15-second test that can evaluate the affected limb unilaterally, requires only one stair, and is similar to the daily living activities of the patients [3]. For this reason, it would be useful to use it as a criterion in the evaluation of the physical functions of individuals with TKA. However, there is no study on the validity and reliability of the StUD test in patients with TKA.
Objectives: The aim of the study is to measure the validity and reliability of the StUD test in patients with TKA.
Methods: Forty patients (Mean age; 6,87 ± 8,01) with primary TKA included in this study. The test-retest reliability of the StUD test was measured with a 1-hour interval to prevent fatigue. Validity was assessed by testing predefined hypotheses. Therefore, the 30s Chair Stand Test (30sCS), the Hospital for Special Surgery score (HSS) and Short Form-12 Quality Life Questionnaire (SF-12) were used as comparator instruments.
Results: The StUD test showed good correlation with 30sCS test (r=0,706, p<0,001), moderate to low correlation with HSS score (r=0,4, p<0,001), moderate correlation with SF12 score (r=0,508, p<0,001). Test-retest reliability was excellent (ICC= 0,93, %95 CI= 0,87-0,96). Standard error of measurement and smallest real difference at the 95% confidence level for StUD test were respectively 0,34 and 0,94. There was no significant difference in the mean VAS scores measured after the tests or between the first and the second trials (p >.05)
Conclusion: According to the results of our study the StUD test excellent reliability, good validity and high sensitivity in patients with TKA. Additionally, there was no significant increase in pain levels at the end of the test. This result suggests that StUD test can be used the safely without increasing pain levels, and this test can also be tolerated by patients with TKA. The SRD_{95} of StUD test was 0,94. According this, it can be interpreted that the STUD test can be used reliably to monitor small changes in patients' function.

POS0805-HPR **FACE VALIDITY AND RELIABILITY TEST OF THE DANISH VERSION OF THE COMPLIANCE QUESTIONNAIRE RHEUMATOLOGY**

Keywords: Validation, Outcome measures, Patient reported outcomes

L. Raunsbæk Knudsen[1,2], A. De Thurah[1,2]. [1]*Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark*; [2]*Aarhus University, Department of Clinical Medicine, Aarhus, Denmark*

Background: Medication adherence in inflammatory arthritis has been reported to vary from 30% to 80%, despite the fact that non-adherence may cause worsening of symptoms and disease severity [1]. Hence, supporting adherence to medication is an essential part of the treatment and care of patients with rheumatic and musculoskeletal diseases [1]. The Compliance Questionnaire Rheumatology (CQR) measures adherence in rheumatic diseases through 19 items covering drug-taking behaviour to identify the factors that contribute to suboptimal adherence [2].
Objectives: To present the translation of the CQR into Danish and the face validity and reliability test.
Methods: The CQR was translated into Danish according to the International Quality of Life Assessment method (3), which involved forward and backward translations by four independent translators, followed by a face validity test among 10 patients with rheumatoid arthritis. The test–retest reliability of the Danish CQR was evaluated in 49 patients with rheumatoid arthritis using the standard error of the measurement (SEM) converted into the minimally detectable change (MDC) and the intraclass correlation coefficient (ICC). Questionnaires were administered with a minimum of 10 days between assessments.
Results: The face validity test did not lead to substantial corrections. The participants in the reliability test had a mean age of 57.4 years (SD 16.1) and a mean disease duration of 1.13 years (range 2 months–2 years). The mean CQR score in the test and retest was 62.69 (confidence interval (CI) 58.76; 66.63) and 62.51 (CI 58.91; 66.12), respectively, with a SEM of 8.59 (7.16; 10.73) and a MDC of 16.83. A satisfactory test–retest reliability was confirmed by an ICC value of 0.79 (CI 0.68; 0.89) (Table 1).
Conclusion: The Danish CQR has satisfactory test–retest reliability in patients newly diagnosed with rheumatoid arthritis and is thus considered a reliable tool to measure adherence in this group.

Background: Fatigue is a prevalent and debilitating symptom in autoimmune connective tissue diseases (CTDs). Its immunological mechanisms are poorly understood. Although targeted therapies can improve fatigue, the effect is modest and variable. This is likely because, in established disease, immunological drivers of fatigue may be obscured by multifactorial effects from glucocorticoids, accrued damage and comorbidity. However, fatigue frequently pre-dates formal diagnosis or end-organ manifestations, suggesting immunological mechanisms may be better interrogated in the preclinical phase. SLE and primary Sjogren's syndrome (pSS) are preceded by a preclinical phase of anti-nuclear antibody (ANA) positivity with no or non-specific symptoms years before clinically manifest inflammation. Although only a minority ultimately develop overt CTDs, ANA-positive individuals demonstrate complex immune dysregulation including increased interferon (IFN) pathway activation [1]. We hypothesise that immune disturbances underlying fatigue in SLE and pSS are i) established during the earlier ANA-positive preclinical phase; ii) contribute to the symptom burden among ANA-positive individuals, and (iii) are differentially modulated in established disease states.
Objectives: To investigate unique and conserved peripheral blood immune cell transcriptional signatures associated with symptomatic fatigue in ANA-positive preclinical patients and established SLE and pSS.
Methods: Bulk RNASeq was performed on peripheral blood mononuclear cells isolated from 35 ANA-positive preclinical individuals demonstrating ≤1 clinical criterion for classifiable CTD, symptom duration <12 months and naive of therapy, of whom 15 later progressed to SLE/pSS and 20 did not progress. Disease controls with SLE (n=18), pSS (n=10) were also analysed. Weighted gene co-expression network analysis was used to identify gene expression modules associated with fatigue in preclinical subjects. Consensus networks were constructed for Preclinical:SLE and Preclinical:pSS to identify fatigue-associated modular signatures which are retained in established CTDs. Gene ontology enrichment was evaluated using g:profiler.
Results: Within the preclinical transcriptomic network 5 module eigengenes showed significant and specific association with patient fatigue VAS. A type-I IFN signature, centred upon canonical ISGs, *MX1*, *IRF7* and *IFIT5*, was positively correlated with fatigue score (R=0.48, p=0.003) and conserved across preclinical, SLE and pSS networks, with subtly different modular organisation. One further module, enriched for tRNA modification was significantly correlated with fatigue in preclinical subjects (R=0.41, p=0.01) but with no counterpart preserved in either SLE or pSS networks. The modular signature with strongest negative association with fatigue (R= -0.35, p=0.004) in preclinical subjects was enriched for mitogen-activated protein kinase (MAPK) cascades, heat shock and protein folding chaperone activity, and included transcription factors *JUN* and *ATF3*. This signature was retained in pSS patients, but did not persist in the SLE consensus network.
Conclusion: We describe novel modular transcriptomic signatures associated with fatigue in the preclinical phase of autoimmunity which demonstrate differential persistence and activity in SLE and pSS. These pathways may help identify individuals with immune-mediated fatigue most amenable to therapy, and could provide insights into new therapeutic targets for fatigue across a range of autoimmune diseases.

Scatterplot of Gene Significance for fatigue vs. Module Membership (MM) for genes located in two preclinical transcriptomic modules. One module with significant positive association with fatigue (A) is conserved across preclinical, SLE and pSS networks. Another module (B) negatively associated with fatigue was conserved in preclinical and pSS networks but not in SLE.

Background: Primary Sjögren´s syndrome (pSS) is an example of an inflammatory autoimmune disorder largely mediated by IFN responses, leading to damage of exocrine glands that has been linked to autoreactive adaptive immune cells, such as Th17, CD8+ T cell and B cell [1, 2, 3]. However, the potential contribution of different innate immune cells such as Natural Killer (NK) cells and dendritic cells (DC) to pSS pathology remains understudied.
Objectives: We identify the molecular mechanisms regulating pathogenic crosstalk between NK and DC in pSS using samples from pSS patients and an experimental *in vivo* SS model.
Methods: Phenotypical analysis of myeloid and NK cell subsets in PBMCs from 47 pSS patients and 56 healthy donors (HD) was performed by flow cytometry. Histological analysis of SG from n=7 pSS was performed by confocal microscopy. Cytotoxic function of NK cells was assessed by culture with a K562-GFP target cell line. Transcriptional analysis of sorted Mo, CD1c+ and CD141+ cDC from four pSS patients and four HD was performed by RNA-seq. Co-culture between sorted NK cells, Mo and CD1c+ or CD141+ cDCs was used for test functional interactions. Regulation of ligands for NK cell receptors on cDC was analyzed by FACS after stimulation with poly I:C in the absence or the presence of specific siRNAs. Finally, altered DC and NK cell phenotypes and interactions with Th17 and B cells were analyzed in a murine Sjögren-mouse model induced by poly I:C intraperitoneal injections [4] in which we used a depleting anti-NK1.1 antibody or an isotype control each 4 days.
Results: Here, we identified an enriched transitional CD16^{+} CD56^{hi} NK cell subset in pSS individuals associated with higher NK cell cytotoxic function *in vitro*. In addition, elevated proportions of inflammatory CD64^{+} cDC2 exhibiting increased levels of MICa/b (p= <0,01), the ligand for the activating receptor NKG2D, were observed in the blood of these patients. Circulating cDC2 from pSS were capable of efficiently inducing activation of cytotoxic NK cells *ex vivo* and were found near CD56^{+} NK cells in salivary glands (SG) from pSS patients. Interestingly, cDC2 from pSS were characterized by preferential transcriptional activation of IFN signatures associated to the RIG-I/DDX60 pathway and its target genes. These sensors regulate the expression of MICa/b ligands on cDC2. Finally, increased proportions of CD64^{hi} cDC2 (p=<0,0001) expressing RAE-1 (p= <0,01), a murine activating NKG2D ligand, and transitional NKG2D^{+} CD11b^{+} CD27^{+} NK cells (p=<0,001) were present *in vivo* in the SG of an *in vivo* model of

pSS. Remarkably, depletion of NK cells during the inflammation onset prevented subsequent induction of IL-17^{+} CD4 (p= <0,01) and memory IgD^{-} IgM^{-} CD38^{hi} B cells (p=<0,0001) in the SG.

Conclusion: Thus, our study provides novel innate immune cellular and molecular mechanisms contributing to pSS pathology and identifies new potential therapy targets.

POS0809 HARNESSING CELL ENERGY METABOLISM TO SUPPRESS SALIVARY GLAND INFLAMMATION IN SJÖGREN SYNDROME

Keywords: Sjögren syndrome

S. Colafrancesco[1], C. Barbati[1], D. Stefanoni[2], G. Buoncuore[1], R. Izzo[1], F. Giardina[1], A. Gattamelata[1], C. Alessandri[1], F. Conti[1], R. Priori[1]. [1]*Sapienza University of Rome, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Rome, Italy*; [2]*Università Vita Salute San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnIRAR), Milan, Italy*

Background: SG epithelial cells (SGEC) play a key role in sustaining inflammation in Sjögren Syndrome (SS), which is indeed termed an 'autoimmune epithelitis'. However, the mechanisms responsible for the inflammatory activation of SGEC remain largely undetermined. Our line of research indicates that SGECs in SS exhibit profound changes in cell energy metabolism as indicated by aberrant expression of autophagy [1]. Inhibitions of autophagic process results in a down regulation of SGECs activation [1], thus indicating a crucial role of SGEC energy metabolism in the induction of autoimmune epithelitis.

Objectives: Aim of this study is to characterize metabolic changes occurring in SS SGECs and dissect the link between these changes and their acquired pro-inflammatory function.

Methods: SGECs were isolated from minor SG biopsies deriving from patients with SS and sicca. Intracellular metabolomic analysis was performed on direct ex vivo isolated primary SGECs. As read out of functional activation of SS SGECs, supernatants from SGECs coltures were collected to perform ELISA test in order to evaluate the expression of the pro-inflammatory mediator IL-6.

Results: Principal component analysis (PCA) of high-throughput metabolomics analysis of sicca (n=7) and SS (n=7) SGECs revealed a separation along the component 1 axis (46.6% of variance) indicating profound differences in the intracellular metabolome (**Figure 1a**). Unsupervised clustering analysis of metabolites revealed profound metabolic differences between SS and (n=7) sicca (n=7) SGECs (**Figure 1b**). Analysis of selected metabolites confirmed a shift towards increased glycolysis and TCA cycle activation in SS SGECs (**Figure 1c**). Supernatant concentrations of IL-6 were higher in SS (n=21) compared to sicca (n=14) SGECs (**Figure 1d**).

Conclusion: SGECs from SS patients display altered cell energy metabolism with evidence of increased glycolysis and activated TCA cycle. A metabolic driven pro-inflammatory status of SS SGECs seems confirmed by increased basal expression of IL-6. Validation of our metabolomic results, along with transcriptomic and epigenetic studies, is currently ongoing in SGECs from SS and sicca to dissect the link between changes in cell energy metabolism and their acquired pro-inflammatory phenotype.

POS0810 T FOLLICULAR HELPER CELLS IN BLOOD MIRROR SALIVARY GLAND-INFILTRATING T CELLS IN PRIMARY SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome, Adaptive immunity

S. Abe[1], H. Tsuboi[1], H. Toko[1], F. Honda[1], A. Koido[1], H. Miki[1], H. Asashima[1], Y. Kondo[1], I. Matsumoto[1]. [1]*University of Tsukuba, Rheumatology, Tsukuba, Japan*

Background: Although clonal expansion of autoreactive T cells have been identified in the peripheral blood and salivary gland of primary Sjögren's syndrome (pSS) (1), the relationship between peripheral immune environments and inflammatory organs remains still unclear.

Objectives: Here, we examined which T cell subsets in blood share the same T cell receptor (TCR) αβ with T cells infiltrated at labial salivary gland (LSG) in patients with pSS, and evaluated mechanisms of their differentiation.

Methods:

1) TCR repertoires of each effector memory T cell subset (Th1, Th17, Tfh1, Tfh2, Tfh17) in blood, and LSG-infiltrating T cells obtained from the same pSS patient were analyzed by TCR sequence (*n*=1).
2) The proportion of each T cell subset in blood was compared between patients with pSS (*n*=30) and healthy controls (HC) by flow cytometry (*n*=20).

3) The proportion of each T cell subset between blood and LSG was evaluated in patients with pSS by flow cytometry (*n*=7).
4) Based on the above results, by focusing on Tfh cells, Tfh-related gene mRNA expressions (CXCR5, Bcl6, TGF-β, IL-6, IL-12, IL-21) were evaluated in LSG of pSS (*n*=11) and HC (*n*=3).
5) The conditions of Tfh cell differentiation in pSS were examined.
6) Cytokine production from $CD4^+$ T cells cultured under determined Tfh cell differentiation condition in pSS were examined.
7) pSS derived peripheral $CD4^+$ T cells were co-cultured with HC derived naïve B cells under Tfh cell differentiation condition, and effect on B cells differentiation was analyzed.

Results:

1) LSG-infiltrating T cells, and blood Th1, Tfh1, and Tfh2 cells showed higher clonality than Th17, and Tfh17 cells (Figure 1). Blood Tfh1, and Tfh2 cells were the two most frequent subsets comprised by the same T cell clones infiltrating in LSG.
2) Blood Tfh subsets were all significantly increased in patients with pSS than in HC. Among Tfh subsets, both PD-1 and ICOS expression was highest in Tfh1 subsets. Furthermore, the proportion of $PD\text{-}1^+ICOS^+$Tfh1 cells correlated with titers of anti-nuclear antibody, anti-SS-A antibody, and anti-SS-B antibody in pSS.
3) The proportions of memory Tfh subsets, especially Tfh1, was significantly increased in LSG compared with matched peripheral blood in pSS.
4) Expression levels of CXCR5, IL-6, IL-21, and TGF-β in LSG were significantly higher in pSS than HC. TGF-β positively correlated with CXCR5 expression in pSS.
5) $CD4^+$ T cells cultured under CD3/28 and TGF-β stimulation significantly increased CXCR5 expression, and Tfh1 population.
6) Production of IL-21, IL-2, and TNF-α were significantly increased after CD3/28 and TGF-β stimulation.
7) HC derived naïve B cells after co-culturing with pSS derived $CD4^+$ T cells, under Tfh differentiation condition (CD3/28 and TGF-β stimulation) expressed higher CD19, and $CD19^+CD38^+$ B cell population was increased.

Conclusion: Tfh1 cells in blood not only frequently showed high clonal expansion, but also highly shared the same TCRαβ with LSG-infiltrating T cells in pSS. Tfh1 cell proportion was expanded among pSS at both peripheral blood and LSGs, and furthermore, they positively correlated with autoantibody production. They proliferated under TGF-β-enriched environment, such as seen in LSG of pSS. Thus, we conclude that blood Tfh1 subsets has the potential to reflect inflammatory organ immune environment, possibly taking a role on autoantibody production at LSG.

[2]*Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Rheumatology, Berlin, Germany*; [3]*Roche Innovation Center Basel, Roche Innovation Center Basel, Basel, Switzerland*

Background: Autoimmune conditions such as primary Sjögren's syndrome (pSS) and systemic lupus erythematosus (SLE) share clinical and serological features characterized by IFN signature (1), autoantibody formation (2), post-activated phenotype (3) and chronic inflammation. Although the 2019 SLE EULAR/ACR classification criteria facilitate a more precise clinical discrimination between SLE and pSS (4), a better understanding of the distinct immunological patterns of both diseases is required for developing fine-tuned immune modulations as therapeutic interventions.

Objectives: In this study we aimed at characterizing and deep phenotyping of lymphocytes and innate immune cells of patients with SLE and pSS for a better differentiation and understanding of immunological abnormalities.

Methods: Peripheral PBMCs of patients with SLE (n=21) or pSS (n=13) as well as from healthy controls (HD, n=15) were isolated. PBMCs were stained with both a B and a T/innate panel and analyzed using mass cytometry. After manual pre-gating of CD19+, CD3+ and innate immune cells, unbiased clustering analysis was performed and visualized as UMAPs. Clusters were identified and subsequently annotated according to median expression of lineage markers.

Results: Altogether, we identified 13 clusters in the B cell, 12 cluster in the T cell and 13 clusters in the innate compartment with disease dependent variations in frequencies and marker expression. B cell abnormalities were characteristic of SLE while striking T cell abnormalities were more prominent in pSS. IgD-CD27- double negative (DN) B cell sub-clusters were increased in SLE. Among the DN subsets the frequency of the cluster that presented with a lower CD19 expression correlated with PB frequencies. A Comparison of activation markers revealed increased CD86 expression on various B cell clusters of patients with SLE. Further, a memory B cell cluster expressing IgA stood out by higher KI-67 and CD45RO expression. In pSS patients, PD1+ ICOS+ CD4+ T follicular helper cell, CD8 effector memory and terminal differentiated effector memory CD8 T cell clusters were expanded. Notably, checkpoint molecules ICOS, TIGIT and PD1 were upregulated on various T cell clusters. Finally, intermediated monocytes that express CD226 were reduced in SLE when compared to pSS.

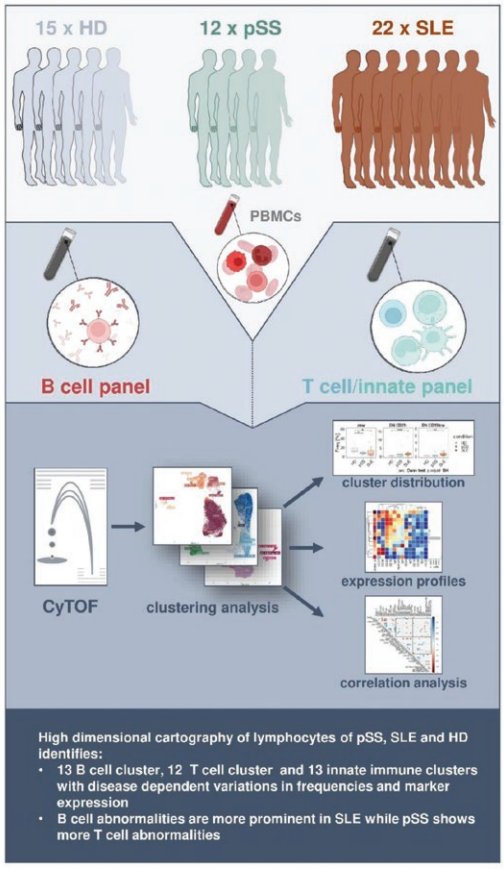

Figure 1. *Workflow of the study to characterize lymphocytes using single-cell mass cytometry in SLE and pSS. (Created with BioRender.com)*

Conclusion: High dimensional characterization of B, T and innate immune cells of patients with SLE or pSS illustrated immunological differences between diseases. SLE showed more B cell abnormalities while T cell alterations were more prominent in pSS consistent with distinct activation pathways driving these diseases. The immunologic abnormalities, distinct for pSS and SLE, might contribute to a better disease monitoring and selective treatment approaches.

POS0812 BINDING OF CXCL13 WITH HEPARAN SULFATE OF SYNDECAN-1 PLAYS AN IMPORTANT ROLE IN PATHOGENESIS OF SJÖGREN'S SYNDROME

Keywords: Cytokines and chemokines, Sjögren syndrome

G. W. Kim[1], N. Y. Lee[2], N. R. Kim[3], S. J. Lee[3], E. J. Lee[1], J. A. Jang[1], E. J. Nam[3]. *[1]Fatima Research Institute, Arthritis and Bone Biology, Daegu, Korea, Rep. of (South Korea)*; *[2]Kyungpook National University School of Medicine, Laboratory Medicine, Daegu, Korea, Rep. of (South Korea)*; *[3]Kyungpook National University School of Medicine, Internal Medicine, Daegu, Korea, Rep. of (South Korea)*

Background: Sjögren's syndrome (SS) is a chronic autoimmune disorder with lymphocytic infiltration in exocrine and non-exocrine epithelia, in which epithelial cells play a critical role in the initiation and amplification of inflammatory processes. Syndecan-1 (SDC-1) is a transmembrane heparan sulfate proteoglycan predominantly expressed on epithelial cells and binds to and regulates heparan sulfate-binding molecules, such as chemokines.

Objectives: In this study, we investigated the expression of SDC-1 and homeostatic chemokines and the colocalization and association of SDC-1 and B cell chemokines in mouse model of primary SS to define the role of SDC-1 in the pathogenesis of SS.

Methods: Female NOD/ShiLtJ between 6 and 12 weeks of age and sex-, and age-matched C57BL10 mice were used. Stimulated salivary flow rates (SFRs), histopathologic findings and expression of growth factor and chemokines were evaluated. Inflammation of the submandibular glands (SMGs) was assessed by the ratio index (the ratio of the area of inflammation to the total area of glandular tissue). SDC-1 level in SMGs and blood were analyzed using dot blot method. Immunofluorescence staining was performed for detection of colocalization of CXCL13 and SDC-1. For SDC-1 and CXCL13 coassociation experiments, immunoprecipitation assay was performed.

Results: The mean SFR was significantly reduced in 12-week-old NOD mice (p=0.013). Periductal inflammatory cell infiltration was detected in the SMGs in 1 of 8 (12.5%) of the 6-week-old and in all of 12-week-old NOD mice. The mean ratio index was 0.1, 4.0, 7.1, and 10.2 in the 6-, 8-, 10-, and 12-week-old NOD mice, respectively. The expression of SDC-1 in inflamed SMGs of NOD mice was elevated, especially on the ductal epithelial cells, and tended to increase as the glandular inflammation progressed. Compared to controls, the concentration of SDC-1 in the SMGs and blood of NOD mice began to increase significantly from the age of 6 weeks (SMGs, 15.6±3.6 vs. 3.5±1.2, p=0.049; Blood, 17.4±1.3, 9.7±1.6, p=0.005). In the NOD mice, the concentration of SDC-1 of SMGs and blood began to be significantly different from the age of 10 weeks (6-week-old vs. 10-week-old mice, SMGs, 15.6±3.6 vs. 25.8±2.7, p=0.033; Blood, 17.4±1.3 vs. 27.7±1.2, p<0.001). Compared to controls, the expression of growth factors in NOD mice was reduced, while the expression of chemokines (CXCL12, CXCL13 and IL-7) and chemokine receptors (CXCR4, CXCR5) was increased. CXCL13 and SDC-1 were detected together on the surface of glandular epithelial cells in the SMGs by immunofluorescent staining. Furthermore, colocalization of SDC-1 and CXCL13 was confirmed by immunofluorescent staining using NMuMG cells which express SDC-1 abundantly. Immunoprecipitation studies demonstrated that SDC-1 formed complexes with CXCL13, which suggested that SDC-1 binds with CXCL13 directly through heparan sulfate on the surface of glandular epithelial cells and participates in an inflammatory pathway through B cell chemotaxis.

Conclusion: These results suggested that increased SDC-1 expression in submandibular glands plays a role in the inflammatory processes through binding of SDC-1 with CXCL13 in pathogenesis of SS.

POS0813 ALTERATION OF ILC HOMEOSTASIS MAINLY CONCERNS SALIVARY GLANDS IN PRIMARY SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome, Innate immunity

L. Kawka[1], R. Felten[1,2], C. Schleiss[2], J. D. Fauny[2], P. Le Van Quyen[3], H. Dumortier[2], F. Monneaux[2], J. E. Gottenberg[1,2]. *[1]Centre Hospitalo-Universitaire de Strasbourg, Rheumatology, Strasbourg, France*; *[2]Institut de Biologie Moléculaire et Cellulaire, Immunologie, Immunopathologie et Chimie Thérapeutique, Strasbourg, France*; *[3]Centre Hospitalo-Universitaire de Strasbourg, Anatomical Pathology, Strasbourg, France*

Background: Little is known about the early stages leading to the autoimmune process in primary Sjögren's syndrome (pSS). Some data suggest the involvement of the innate immunity both in disease initiation and maintenance of autoimmunity in pSS, but more studies are needed to dissect the role of innate immune cell actors. Innate lymphoid cells (ILC) are a recently discovered cell population divided into three groups including type 1, 2 and 3 ILC subsets. While ILC are normally involved in the maintenance of tissue homeostasis, they can also contribute to generate tertiary ectopic lymphoid structures [1], as observed in some patients with pSS, and potentiate inflammatory processes in different chronic inflammatory diseases [2].

Objectives: The aim of this study was to analyze the frequencies of ILC subsets in the peripheral blood (PB) and quantities and location in minor salivary glands (MSG) of pSS patients.

Methods: The frequencies of ILC subsets were analyzed in the PB of 21 pSS patients and 28 healthy controls (HC) by flow cytometry. ILC were identified as CD45+, lineage (CD1a, CD3, CD4, CD14, CD16, CD19, CD34, CD303, FcεRI)- and CD127+. Within the ILC gate, ILC1 were identified as c-kit+ and CRTH2-, ILC2 as CRTH2+, and ILC3 as c-kit+ and CRTH2–. The amounts and location of ILC subsets were studied in the MSG of 13 pSS patients and 5 controls (SC) using immunofluorescence. ILC were defined as lineage (CD3, CD14, CD19)- and CD127+ cells. The expressions of T-bet (nuclear) and CRTH2 (cytoplasmic) were used to distinguish between ILC1 (T-bet+), ILC2 (CRTH2+) and ILC3 (T-bet– and CRTH2-) subsets.

Results: In PB, the frequencies of total circulating ILC and ILC subsets did not differ in pSS patients compared to HC. There was a significantly higher number of circulating ILC1 in pSS patients with positive anti-SSA antibodies (p=0.03) and a lower number of circulating ILC3 in pSS patients with glandular swelling (p=0.01). The proportions of ILC subsets in PB did not correlate with systemic disease activity measured by ClinESSDAI. Most of the ILC identified in MSG of pSS patients were ILC3 (91.1%). The amount of ILC3 was higher in tissues with lymphocytic infiltrates compared to non-infiltrated tissues in pSS patients (p=0.0002) and to normal glandular tissues in SC (p=0.0005). No difference was observed when comparing the quantity of ILC1 and ILC2 in the MSG between pSS patients and SC. ILC3 were preferentially located at the periphery of the infiltrates and were inversely correlated with the surface of T/B lymphocyte infiltrates (r=-0.42, p=0.002). ILC3 were inversely correlated with time since diagnosis (r=-0.69, p= 0.01).

Conclusion: Alteration of ILC homeostasis mainly concerns salivary glands in pSS. The majority of ILC in MSG is composed by ILC3, located at the periphery of lymphocytic infiltrates. ILC3 are more abundant in smaller infiltrates and in

recently diagnosed pSS patients. ILC3 might play a pathogenic role in the development of T and B lymphocyte infiltrates in the early stages of pSS.

POS0814 UNTARGETED METABOLOMICS ANALYSIS OF SEBUM: A NON-INVASIVE STRATEGY THAT SHOWS POTENTIAL TO IDENTIFY NEW BIOMARKERS IN PRIMARY SJÖGREN'S SYNDROME AND SYSTEMIC SCLEROSIS

Keywords: Biomarkers, Sjögren syndrome, -omics

A. Hinrichs[1], S. Blokland[2], J. Vappiani[3], A. Van Maurik[3], A. Ottria[1], A. Kruize[2], H. Leavis[2], T. Radstake[1,4], D. Sevin[5], J. Van Roon[1]. Background: Saliva and tears are easy accessible fluids for biomarker analyses but a major drawback is that a substantial proportion of patients with primary Sjogren's syndrome (pSS) suffers from severe dryness, with limited or no saliva or tear to donate. Thus, novel non-invasive strategies applying state-of-the-art technologies should be welcomed.

Objectives: To evaluate if metabolome analysis of sebum can be used as a non-invasive method to identify skin metabolic signatures in patients with primary Sjogren's syndrome (pSS) as compared to healthy controls and other systemic autoimmune diseases.

Methods: Untargeted metabolomics of sebum samples collected from sebutapes placed on the forehead for 5 minutes was performed using mass spectrometry. Sebum metabolomes of healthy controls (HCs, n=17) and 32 pSS patients were compared (for this abstract only ions from the negative ionization mode are discussed, for the positive ionization mode similar results were found). Additionally, the metabolomes of two other systemic autoimmune diseases, i.e. systemic sclerosis (SSc, n=21) and systemic lupus erythematosus (SLE, n=8), were compared to pSS and HCs. The human biological samples were sourced ethically and their research use was in accord with the terms of the informed consents under an IRB/EC approved protocol.

Results: Modest significant differences were observed between the sebum metabolome of pSS patients as compared to HCs. Unsupervised dimensionality reduction using UMAP showed no strong differences between metabolic signatures of pSS patients and HCs. However, correlation analyses of metabolic changes and disease activity markers did identify several metabolite ions with a good correlation with disease activity. A total of 335 metabolite ions significantly correlated to the European Sjogren's Syndrome Disease activity index (ESSDAI) score, 13 metabolite ions correlated with sIgG and 41 metabolite ions with lymphocytic focus scores (LFS, all spearman r <- 0.50 or >0.50, p<0.05). To understand if pathways in disease activity-associated metabolites may underlie the observed changes we performed pathway enrichment analyses to investigate potential group function of the metabolite ions identified in these comparisons. Two significantly enriched pathways were identified correlating to the ESSDAI score: alpha-linolenic acid metabolism and phenylalanine metabolism. More robust significant differences were identified in patients with systemic sclerosis as compared to healthy controls, indicating metabolites significantly enriched for pathways associated with neurotransmission, including metabolite ions with annotations as L-glutamic acid, noradrenaline, dopamine and 3'-AMP. Interestingly, when analyzing differentially expressed metabolite ions of pSS and SSc patients relative to HCs highly significant and strong correlations were observed (R=0.78 for negative ionization mode), indicating that these diseases might have common metabolic dissimilarities.

Conclusion: This pilot study demonstrates that sebum metabolomics might be a novel strategy to identify biomarkers in pSS and other (systemic) autoimmune diseases. Larger follow-up studies using more targeted metabolomics strategies that take into account potential confounding factors and optimize sebum collection should demonstrate the feasibility of this novel non-invasive monitoring method in molecular profiling of disease.

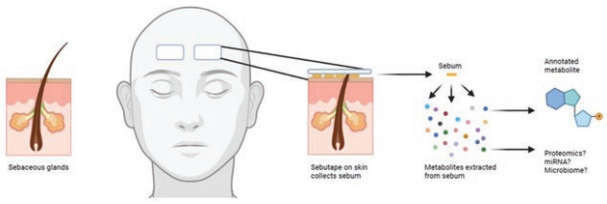

Figure 1. Application of sebutapes to collect sebum from the skin of the forehead for metabolomics analysis. All participants avoided using facial products for 24 hours and did not wash their forehead up to 3 hours prior to sample collection. Before sebum collection the participant's forehead was systematically cleaned with soap and water and 2 Sebutape Adhesive Patches for collecting sebum were applied to the forehead for 5 minutes and stored at -80 °C until analyses.

POS0815 CD40L BLOCKADE WITH DAZODALIBEP (VIB4920/HZN4920) REDUCES BLOOD BIOMARKERS OF T AND B CELL COSTIMULATION IN SUBJECTS WITH SYSTEMIC SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome, Randomized control trial, Biomarkers

M. Smith[1], N. Mittereder[1], M. Gunsior[1], J. Karnell[1], F. Legrand[1], K. Der[1], C. Emson[1], W. Rees[1], I. Alevizos[2], E. W. St. Clair[3]. Background: Dazodalibep (DAZ) is a non-antibody biologic antagonist of CD40L. In several autoimmune diseases, the CD40/CD40L pathway is activated on a variety of cell types, including T cells, B Cells, antigen-presenting cells, and activated epithelial cells. DAZ blocks costimulatory signals between T cells and CD40-expressing B cells, disrupting the development of germinal centers, pathogenic B cells, plasma cells, and autoantibodies that are hallmarks of Sjögren's Syndrome (SS).

Objectives: To evaluate the impact of DAZ on blood biomarkers of B and T cell costimulation in adult SS subjects with moderate-to-high systemic disease activity.

Methods: This was a randomized, double-blind, placebo-controlled, crossover study to evaluate DAZ therapy in adult SS subjects with moderate-to-high systemic disease activity, as defined by a EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) score ≥ 5. Subjects were randomized 1:1 to receive intravenous DAZ 1500 mg or placebo (PBO) Q2W x 3 doses, then Q4W x 4 additional doses (Stage 1). Starting on Day 169, subjects initially randomized to DAZ received PBO Q4W x 5 doses and subjects initially randomized to PBO received DAZ Q4W x 5 doses and were then followed for 12 weeks (Stage 2). B cell subsets downstream of T cell stimulation (Ki67+CD27+ memory, CD27 high CD38 high plasmablasts, and CD11c high atypical memory cells) were assayed via FACS throughout the study period. Serum CXCL13 concentrations, a chemokine essential for GC formation produced by activated follicular T cells, and rheumatoid factor (RF) autoantibodies were also measured.

Results: Concomitant with DAZ-related reductions in ESSDAI observed at Stage 1, significant and rapid reductions were observed in Ki67+CD27+ memory B cells, plasmablasts, CD11c^{high} memory B cells, CXCL13 and RF antibodies from day 15 onwards in subjects who received DAZ as compared to PBO. In Stage 2, similar reductions were found in these biomarkers when PBO-treated subjects were transitioned to DAZ treatment. In DAZ-treated subjects who were transitioned to PBO in stage 2, these biomarkers returned to baseline values while sustained reductions were observed in ESSDAI from baseline through the duration of stage 2.

Conclusion: CD40-CD40L blockade with DAZ in patients with SS reduces systemic disease activity by inhibiting T and B cell costimulation, as evidenced by treatment related reductions in blood biomarkers downstream of these pathways.

Background: Primary Sjögren's syndrome (pSS) is a heterogeneous, chronic, complex systemic autoimmune disease. Patients with pSS exhibit focal lymphocytic sialadenitis in the salivary gland (SG), supporting the SG as the pathogenic center and primary damaged organ in pSS. As of today, but the knowledge of existing pSS disease heterogeneity is still limited and the immune mechanisms of SG injury have been challenging to clarify.
Objectives: To give a comprehensive understanding of cellular heterogeneity in the SG and to define commonalities and discrepancies between the SG and peripheral blood immune cell populations, we performed droplet-based single cell mRNA sequencing (scRNA-seq) (10X Genomics) in pSS patients and non-SS controls.
Methods: 11 patients and 5 non-pSS controls were recruited from the The First Affiliated Hospital of USTC. The non-pSS were subjects who had experienced subjective symptoms of dryness, but no not meet any of the classification criteria of pSS. After resection, SG tissue samples were obtained after labial gland biopsy, rapidly digested to a single-cell suspension and subjected to scRNA-seq using the 10X platform. After rigorous quality control (QC) definition, low-quality cells were filtered. we applied principle component analysis on genes variably expressed across all 72,853 SG cell. In addition, we collected another cohort for blood single-cell RNA sequencing, including an additional 5 pSS patients who fulfilled the same selection criteria and 3 healthy individuals.
Results: A total of 72,853 cells were obtained from all SG samples. Seurat was applied to normalize and cluster the gene expression data, subsequently generating a matrix that identified 11 unique, major cell subpopulations, including epithelial cells, ionocytes, fibroblasts, smooth muscle cells (SMC), endothelial cells, pericytes, melanocytes, T cells, B cells, plasma cells, and myeloid cells. As expected, lymphocytes (T and B cell populations) were significantly increase in the SG of patients with pSS. In addition, epithelial cells of pSS samples had obviously higher numbers of differentially expressed genes (DEGs) than other cell types. Gene ontology (GO) analysis of down-regulated DEGs in SG epithelial cells of pSS patients related to 'salivary secretion' and 'epithelial cell differentiation'. We identified a disease-associated epithelial subpopulation, myoepithelial cell, with characteristically low expression of SOX9, which leads to impaired regeneration of epithelial cells. Our results identified three distinct endothelial subtypes according to the differentially expressed cell markers. We also found that pSS patients have a strikingly increased number of ACKR1^{+} endothelial cells that could potentially promote transendothelial migration from peripheral blood monocyte populations. Using a reciprocal principal component analysis method for the integration of PBMCs and SG scRNA-seq data, we obtained a total of 79,596 immune cell transcriptomes. Among these, we identified five major populations and 36 immune cell clusters, including 4 B cell clusters, 4 plasma cell clusters, 19 T cell clusters, 8 myeloid cell clusters, and natural killer (NK) cells. Additionally, pseudotime trajectory analysis defined a bifurcated differentiation pathway for peripheral B cells and a trajectory leading to three distinct subtypes for peripheral CD4^{+} T cells enriched in the SG of pSS patients. Finally, we provide a series of detailed maps of the global interactions between immune cells and stromal cells, and among stromal cells. Fibroblasts were identified as the center of a stromal-immune interaction network likely responsible for disrupting extracellular matrix formation, impairing epithelial regeneration, and inflammatory progression.
Conclusion: In conclusion, our study provides a preliminary cellular atlas for the SG in Sjögren's Syndrome, opening new avenues of research for therapeutic development to treat this disease.

Background: Primary Sjögren's Syndrome (pSS) is characterized by the presence of antibodies (Ab). Their effector function mainly depends upon the glycan structures attached to their Fc-fragment. Our study is the first to address the value of IgG glycosylation profiles in relation to disease state, salivary gland ultrasound (SGUS) and auto-Ab in patients with probable (prob pSS) and definite pSS (def pSS).
Objectives: To investigate N-glycosylation of IgG in patients from the Belgian Sjögren's Syndrome Transitial Trial (BeSSTT) in relation to pSS state, disease activity, SGUS and the presence of Ab to SSA/Ro52, SSA/Ro60 and SSB.
Methods: The relative amount of sialylated (sial) and galactosylated (gal) IgG was determined by capillary electrophoresis after the endo-S glycosidase assay. 314 sera of the BeSSTT, an observational cohort of patients with def pSS, fulfilling the 2016 ACR/EULAR classification criteria, and of patients with suspected pSS due to presence of either objective sicca or one immunological criterion, were used. Groups were made based on the presence or absence of sicca complaints, objective sicca, anti-SSA Ab and histopathology focus score. SGUS by Hocevar was categorized in negative (0-14), low positive (15-26) and high positive (27-48)[1]. Disease activity using the Eular Sjögren's Syndrome disease activity index (ESSDAI) was categorized in low (0-4), moderate (5-13) and high (14-123). Differences in sial and gal IgG levels were determined using One-way ANOVA and Kruskal-Wallis testing. P-values ≤0.05 were considered statistically significant. Bonferroni correction was applied.
Results: Disease state was addressed in well-defined groups: patients with only sicca complaints, patients with only objective sicca, patients with only anti-SSA/SSB reactivity (prob pSS) and patients with def pSS. Def pSS patients had a significantly lower median percentage of sial and gal IgG compared to patients with only sicca complaints, only objective sicca or only anti-SSA Ab. No significant difference in sial and gal IgG was seen between the latter three groups (Figure 1). Patients with high ESSDAI had a significantly lower percentage of sial and gal IgG versus those with low ESSDAI. In high positive SGUS-score, a significantly lower median percentage of sial IgG and a lower percentage of gal IgG was noted compared to negative or low positive Hocevar score (Figure 1). Mono-anti-Ro52 reactivity, double-anti-Ro52Ro60 reactivity or triple-anti-Ro52Ro60 SSB reactivity had a significantly lower percentage of sial and gal IgG compared to anti-SSA/SSB negative. Strikingly, anti-Ro5260+ and anti-Ro52Ro60 SSB+ had a significantly lower percentage of sial and gal IgG compared to mono anti-Ro60 (Figure 1).
Conclusion: These results indicate that disease state, disease activity, salivary gland involvement and serology profile is strongly associated with different levels of sial and gal IgG in pSS. This highlights the potential role for glycosylation as diagnostic marker and biomarker and its potential role in the pSS pathophysiology.

POS0818 IN PRIMARY SJÖGREN'S SYNDROME CCR9/CXCR5 CO-EXPRESSING EFFECTOR CD4 T CELLS ARE INCREASED AND ARE ENRICHED IN PD-1/ICOS-EXPRESSING T CELLS

Keywords: Sjögren syndrome

A. Hinrichs[1], A. Kruize[2], F. Lafeber[2], H. Leavis[2], J. Van Roon[1]. [1]UMC Utrecht, Rheumatology & Clinical Immunology/CTI, Utrecht, Netherlands; [2]UMC Utrecht, Rheumatology & Clinical Immunology, Utrecht, Netherlands

Background: Primary Sjögren's syndrome (pSS) is an autoimmune disease characterized by B cell hyperactivity. CXCR5+ follicular helper T cells (Tfh), CXCR5-PD-1hi peripheral helper T cells (Tph) and CCR9+ Tfh-like cells have been implicated in driving B cell hyperactivity in pSS (1-3), however, their potential overlap has not been evaluated.
Objectives: To study the overlap between the two CXCR5- cell subsets and to study their PD-1/ICOS expression, hall mark markers, as compared to "true" CXCR5/PD-1/ICOS-expressing Tfh cells.
Methods: We defined Tph cells as CXCR5-PD-1hi memory (CD45RO+), CCR9+ Tfh-like as CXCR5-CCR9+, and CCR9+ Tfh as CXCR5+CCR9+ memory CD4 T cells, as previously described. CXCR5+CCR9+ co-expressing cells were not specified on memory phenotype. Tfh cells were defined as CXCR5+ memory, and "true" Tfh cells as CXCR5+PD-1+ICOS+ memory cells. CXCR5- Tph and CCR9+ Tfh-like cell populations from peripheral blood mononuclear cells of pSS patients (n=12) and age- and gender-matched healthy controls (HC, n=11) were compared by flow cytometry. PD-1/ICOS expression from these cell subsets was compared to each other and to CXCR5+ Tfh cells, taking into account their differentiation status.
Results: In pSS patients the number of Tph cells was significantly increased compared to HC (median 0.53% versus 0.23% of CD4 T cells, p=0.049). Also the number of CCR9+ Tfh-like cells was significantly elevated in pSS patients as compared to HC, i.e. approximately 2.7% in pSS patients versus 1.7% in HC (medians, p=0.019). CCR9 expression was equally distributed between pSS patients and HC in Tph cells. Only a modest number of 2.1% (1.2-3.2%) of Tph cells expressed CCR9 (median with interquartile range), indicating limited overlap. CXCR5+ (Tfh) cells were characterized by the highest frequency of PD-1hi cells, either with or without CCR9 co-expression (PD-1hi expression differed between CXCR5+ T cell subsets compared to CXCR5-CCR9- and CXCR5-CCR9+ T cells, both p<0.0001.) No difference in PD-1hi expression was seen between CXCR5+CCR9- and CXCR5+CCR9+ cells (p=0.57). Within the PD-1hi populations, cells expressing either CXCR5 and/or CCR9 of pSS patients showed a trend of higher ICOS expression compared to HCs, but this was only significant in CCR9+ Tfh-like cells (28.6% and 55%, medians for HC and pSS respectively, p=0.02) PD-1/ICOS expression was higher in memory cells expressing CXCR5 or CCR9. However, the highest expression was found in CXCR5/CCR9 co-expressing T cells, which are enriched in the circulation of pSS patients. PD-1, ICOS, and PD-1/ICOS co-expression was significantly higher on CCR9+ Tfh cells than on CCR9- Tfh cells (in all three comparisons p<0.05).
Conclusion: CXCR5- Tph and CCR9+ Tfh-like cells are two distinct cell populations that both are enriched in pSS patients and can drive B cell hyperactivity in pSS. The known upregulated expression of CCL25 and CXCL13, ligands of CCR9 and CXCR5, at pSS inflammatory sites suggests concerted action to facilitate migration of CXCR5+CCR9+ T cells, which are characterized by the highest frequencies of PD-1/ICOS positive cells. Hence, these co-expressing effector T cells may significantly contribute to the ongoing immune responses in pSS.

ALTERED EXPRESSION OF RNA METHYLATION AND DEAMINATION ENZYMES IN SALIVARY GLANDS FROM SJÖGREN'S SYNDROME PATIENTS

Keywords: Sjögren syndrome, Cytokines and chemokines, Genetics/ epigenetics

D. Jara[1], S. Aguilera[2], P. Carvajal[1], I. Castro[3], M. J. Barrera[4], S. González[5], C. Molina[4], R. Soto-Rifo[6], M. J. González[1]. [1]*Universidad de Chile, Programa de Biología Celular y Molecular, Instituto de Ciencias Biomédicas, Facultad de Medicina, Santiago, Chile*; [2]*Clinica INDISA, Departamento de Reumatología, Santiago, Chile*; [3]*Universidad de Chile, Departamento de Tecnología Médica, Facultad de Medicina, Santiago, Chile*; [4]*Universidad San Sebastián, Facultad de Odontología y ciencias de la rehabilitación, Santiago, Chile*; [5]*Universidad Mayor, Escuela de Odontología, Facultad de Medicina y Ciencias de la Salud, Santiago, Chile*; [6]*Universidad de Chile, Programa de Virología, Instituto de Ciencias Biomédicas, Facultad de Medicina, Santiago, Chile*

Background: Primary Sjögren's syndrome (pSS) is an autoimmune disease characterized by an overactivation of the type I interferon pathway (IFNs I) and differential microRNAs expression in the salivary glands (SG) [1]. In these patients, hsa-miR-145-5p downregulation was found to be associated with increased levels of IFNs I and the overactivation of its pathway [2]. IFNs I can alter miRNA biogenesis by reducing the processing of some primary microRNAs (pri-miRNAs) through diminished interaction with the microprocessor complex, leading to decreased mature microRNA levels [3]. Although the mechanisms involved are not fully understood, changes in adenosine deamination that lead to adenosine to inosine (A-to-I) editing or methylation of the N6-position of adenosines (m6A) in the pri-miRNAs could be participating.
Objectives: To evaluate the expression of pri-miR-145 and the enzymes that methylate (METTL3 and METTL14), demethylate (FTO and ALKBH5), and deaminate (ADAR1p110 and ADAR1p150) adenosines in RNAs of labial SG (LSG) from pSS-patients.
Methods: LSG from 9 pSS-patients and 6 controls as well as HSG cells stimulated with IFNs I (IFN-α or IFN-β) were analyzed. pri-miR-145 levels were determined by TaqMan assays. Enzymes transcript and protein levels were measured by qPCR and Western blot, respectively. The enzymes localization was determined by immunofluorescence.
Results: LSG from pSS-patients showed increased pri-miR-145 levels, which directly correlated with the IFNs I score, a measure of the activation of the IFNs I pathway. LSG from pSS-patients also showed increased METTL3, ALKBH5 and ADAR1p150 levels, with no changes in METTL14 and FTO. ADAR1p150 levels also correlated directly with the IFNs I score. All the enzymes were mainly observed in the nuclei of LSG acinar cells. Finally, stimulation of HSG cells with IFNs I upregulated ADAR1p150
Conclusion: Increased pri-miR-145 levels suggest accumulation of this precursor in LSG of pSS-patients due to lack of processing, which could contribute to the hsa-miR-145-5p downregulation found previously (2) and could be associated to the overactivation of the IFNs I pathway. The overexpression of METTL3, ALKBH5 and ADAR1p150 could lead to changes in RNA methylation or deamination, particularly in pri-miRNAs that alter their processing, which needs further study. Finally, the functional assays suggest an association between the IFNs I overactivation and the ADAR1p50 overexpression observed in SS-patients.

POS0820

SEX-EQTL ANALYSIS REVEALS A SIGNIFICANT SEX-BIAS IN THE EFFECTS OF SJÖGREN'S SYNDROME ASSOCIATED ALLELES ON GENE TRANSCRIPTION

Keywords: Genetics/epigenetics, Sjögren syndrome

G. E. Thorlacius[1], A. Björk[1], M. Wahren-Herlenius[1,2]. [1]*Karolinska Institute, Department of Medicine, Division of Rheumatology, Stockholm, Sweden*; [2]*University of Bergen, Department of Clinical Science, Broegelmann Research Laboratory, Bergen, Norway*

Background: Primary Sjögren's syndrome is a systemic autoimmune disease that affects exocrine glands, particularly the salivary- and lacrimal glands, leading to the hallmark symptoms of mucosal dryness. Patients commonly also experience fatigue, joint and muscle pain. Sjögren's syndrome predominantly affects women, with a female-to-male ratio of 14:1. Genetic risk factors associated with Sjögren's syndrome have been identified, however, the mechanisms behind the profound sex-bias remain incompletely understood.
Objectives: The aim of this study was to analyze whether the sex of a carrier of genetic variants associated with Sjögren's syndrome affects the expression of genes in associated loci.
Methods: Genetically regulated gene expression differences between sexes were identified by identifying expression quantitative trait loci (eQTLs). Databases including the Genotype-Tissue Expression project (GTEx, version 8), and the NHGRI-EBI Catalog of human genome-wide association studies (GWAS catalog) as well as a literature review were utilized to extract information about variants significantly associated with Sjögren's syndrome, and their sex-specific eQTL effects.
Results: Out of 22 non-*HLA* loci identified as associated with Sjögren's syndrome at the genome-wide level, 4 independent loci had one or more significant sex-eQTL effects in the GTEx database in any tissue. These included variants near *IRF5*, *TNIP1*, *SYNGR1* and the *BLK-FAM167A* loci. Additionally, variants in 4 Sjögren's syndrome associated loci within the *HLA* region on chromosome 6 were found to have one or more sex-eQTL effects in the GTEx database. Of the 14 identified sex-eQTLs for Sjögren's associated loci, 10 were female biased.
Conclusion: Sjögren's syndrome is a female biased disease and genetic variants associated with Sjögren's syndrome have discordant effects on gene expression in females compared to males. A majority of the identified effects point towards a more severe effect of these variants in female carriers than male carriers, indicating that females could be more profoundly affected by these genetic risk factors than males. This suggests a mechanism where genetic risk factors could disproportionately increase disease risk in one sex compared to the other.

DIFFERENTIALLY EXPRESSED GENES (DEGS) OVERLAPPED FROM DATASETS FROM PATIENTS WITH SJÖGREN'S SYNDROME (SS) THROUGH INTEGRATIVE BIOINFORMATICS ANALYSIS DISPLAY INTERFERON SIGNATURE

Keywords: Biomarkers, -omics, Sjögren syndrome

R. Martinez[1], M. Gelinas Martin del Campo[1], C. Elizondo Solis[1], A. Montoya Rosales[2], M. Salinas Carmona[1], N. Macias-Segura[1]. [1]*Servicio y Departamento de Inmunología, Service and Department of Immunology, Monterrey, Mexico*; [2]*UANL - CIDICS, Immunomodulators Laboratory, Monterrey, Mexico*

Background: Sjögren's Syndrome is an autoimmune disease comprised by oral and ocular dryness due to destruction of lacrimal and salivary glands. It may be associated with other rheumatological pathologies such as Rheumatoid Arthritis or Systemic Lupus Erythematosus [1]. Bioinformatics has been used to elucidate the pathophysiology underlying rheumatological diseases [2]. Key findings include an Interferon (IFN) signature common to rheumatic diseases and aberrant activation of B and T cells [3]. Nonetheless, they are inconclusive since several studies propose different DEGs.
Objectives: We aimed to identify overlapped genes across datasets of gene expression from patients with primary SS doing an integrative bioinformatics metanalysis.
Methods: A search strategy was designed in the Gene Expression Omnibus platform to identify datasets of gene expression profiling by array experiments in patients with SS. The inclusion criteria were: 1) Assays performed in humans, 2) Inclusion of healthy controls in each dataset, and 3) Data analysis with GEO2R. The exclusion criteria were: 1) Incomplete information of the genes, and 2) Gene expression by RNAseq. DEGs were selected when $p < 0.05$ and log fold change > 2 or < -2. Functional enrichment analysis was realized with free-access platforms GeneMania and DAVID from the significant overlapped genes. A protein-protein interaction (PPI) analysis was constructed with STRING. A topologic interaction network using CytoHubba to find the genes with the highest interaction within the cluster was realized.
Results: 8 datasets qualified to be analyzed. 260 DEGs were identified. 10 DEGs overlapped among the datasets. Prediction analysis yielded 21 co-expressed pairs. Functional enrichment analysis showed 3 biological processes in which those genes participate (Table 1): 20 genes in defense response to virus, 14 in response to virus, and 10 in the negative regulation of the viral genome replication. Most of them belong to the type I IFN signature. PPI analysis showed a cluster of 27 genes and the topological analysis yielded 10 genes (Figure 1).

Table 1. Top 3 biological processes in which the genes participate.

Functional Enrichment Analysis		
Process	**Gene count**	*p Value*
Defense response to virus (Type I IFN Response)	20	1,0E-31
Response to virus	14	3,5E-23
Negative regulation of the viral genome	10	3,2E-18

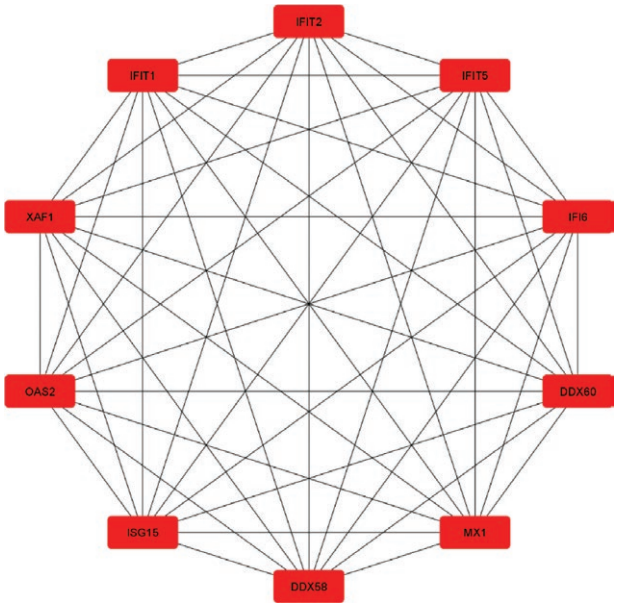

Figure 1. Topologic analysis displaying the Interferon Signature.

Conclusion: We identified DEGs through bioinformatic and functional enrichment analysis. 10 genes appeared in different datasets, while 21 were listed as their co-expressed pairs. These genes play a fundamental role in the processes of Defense response to virus, Response to virus and Negative regulation of the viral genome replication. Most of them belong to the type I IFN signature. An in vivo analysis in patients with primary SS is needed to validate these genes as possible diagnostic biomarkers and even possible therapeutic targets.

DOES CONCOMITANT/NON-CONCOMITANT USE OF MTX WITH BIOLOGICS AND JAK INHIBITORS AFFECT ULTRASOUND FINDING OF INTRA-ARTICULAR SYNOVITIS?

Keywords: Ultrasound, Disease-modifying drugs (DMARDs), bDMARD

T. Okano[1], K. Mamoto[1], Y. Yamada[1], S. Anno[2], Y. Domae[3], A. Yagami[3], S. Washida[3], Y. Yoshida[3], T. Koike[4,5], H. Nakamura[1]. [1]*Osaka Metropolitan University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka, Japan*; [2]*Yodogawa Christian Hospital, Department of Orthopedic Surgery, Osaka, Japan*; [3]*Osaka Metropolitan University Hospital, Central Clinical Laboratory, Osaka, Japan*; [4]*Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan*; [5]*Shirahama Hamayu Hospital, Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan*

Background: Biological disease-modifying antirheumatic drugs (bDMARDs) and janus kinase inhibitors (JAKi) are generally more effective combined with methotrexate (MTX) in patients with rheumatoid arthritis (RA). However, in clinical practice, bDMARDs/JAKi is sometimes used without MTX for such as elderly patients with poor renal function. To date, there are few reports evaluating ultrasound finding of intra-articular synovitis in patients with RA treated bDMARDs/JAKi with or without MTX.

Objectives: Ultrasound finding of intra-articular synovitis in patients with RA treated bDMARDs/JAKi with or without MTX was compared by using propensity score matching.

Methods: A total of 750 RA patients who underwent ultrasound examination were included. Ultrasond examination was performed at the of bilateral first to fifth metacarpophalangeal (MCP) joints, first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) joints, wrist joints (three part of radial, medial and ulnar) and first to fifth metatarsophalangeal (MTP) joints. Of all 750 RA patients, 517 RA patients (68.9%) who treated bDMARDs/JAKi were divided into with or without MTX. Then, patients were matched using the propensity score adjusted for age, sex, duration of RA, disease activity (CDAI), CRP level, and MMP-3 level. The total gray scale (GS) and power Doppler (PD) score (GSUS/ PDUS) were compared between bDMARDs/JAKi treated patients without and with MTX.

Results: There were 159 (30.8%) patients without MTX and 358 (69.2%) patients with MTX. The 151 patients in each group were matched. The mean MTX dose of bDMARDs/JAKi with MTX group was 8.8±3.5 mg/week. Patients' characteristic of bDMARDs/JAKi without MTX and bDMARDs/JAKi with MTX were shown in Table 1. Ultrasound synovial findings were significantly suppressed in the MTX combined group, GSUS 11.6 ± 11.8 vs 8.5 ± 8.0 (p = 0.009) and PDUS 8.3 ± 9.9 vs 5.5 ± 6.2 (p = 0.004). Moreover, US findings were compared in TNF user, non-TNF user and JAKi user. Notably, ultrasound findings were worse in non-TNF inhibitor users without MTX.

Table 1. Patients' characteristic of bDMARDs/JAKi without MTX and bDMARDs/JAKi with MTX.

	bDMARDs/JAKi without MTX (n=151)	bDMARDs/JAKi with MTX (n=151)	p value
Age, y	70.2±10.8	68.4±12.8	0.186
Female, %	82.1	77.5	0.390
BMI, kg/m2	21.9±3.4	22.7±3.4	0.029
Disease duration, y	16.7±11.6	16.2±13.3	0.756
RF+, %	91.4	90.1	0.843
CCP+, %	87.3	85.4	0.728
DAS28 ESR	3.2±1.3	3.3±1.5	0.393
DAS28 CRP	2.8±1.2	2.8±1.2	0.949
SDAI	11.9±10.5	11.2±10.7	0.552
CDAI	11.7±10.4	10.9±10.5	0.499
HAQ	0.76±0.72	0.80±0.87	0.645
ESR mm/h	16.1±19.3	21.3±21.5	0.028
CRP, mg/dL	0.18±0.45	0.26±0.71	0.204
MMP-3, ng/mL	128.0±160.1	114.1±184.9	0.488

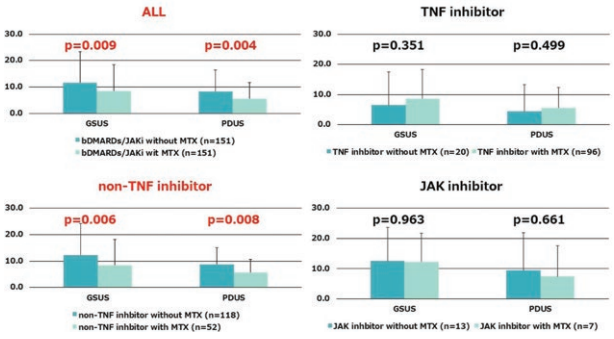

Figure 1. Ultrasound findings of bDMARDs/JAKi without MTX and bDMARDs/JAKi with MTX.

Conclusion: Ultrasound synovial findings in patients with bDMARDs/JAKi was more suppressed with MTX. It was considered necessary to keep in mind that synovitis may persist in patients who are not concomitant with MTX and are using non-TNF inhibitors.

POS0823 UPTAKE OF INFLIXIMAB BIOSIMILARS AMONG U.S. RHEUMATOLOGY PRACTICES THROUGH 2022

Keywords: Registries, bDMARD, Epidemiology

J. Yazdany[1], J. LI[1], E. Roberts[1], R. Stovall[1], G. Schmajuk[1]. [1]*University of California, San Francisco, Medicine/Rheumatology, San Francisco, United States of America*

Background: The first infliximab biosimilar (infliximab-dybb) entered the U.S. market in 2016 and two additional products are now available (infliximab-axxq and infliximab-abda). Biosimilars have significant potential to slow drug spending; however, biosimilar uptake in the U.S. has lagged. Little is known about the impact of additional infliximab biosimilar approvals on market penetration or about patterns of use among rheumatologists.

Objectives: We used the national RISE registry 1) to examine uptake of infliximab biosimilars between 2016 and 2022 and 2) to study physician prescribing of these drugs. For the latter, we analyzed patterns of biosimilar drug use across a national sample of practices and analyzed characteristics of patients who were prescribed biosimilars vs. bio-originator infliximab.
