AB0462 COMPARING INJECTION OF LOCAL ANESTHESIA IN OVERLYING SKIN TO NOT GIVING IT PRIOR TO INTRAARTICULAR INJECTION OF GLUCOCORTICOID - A RANDOMIZED CONTROLLED TRIAL

Keywords: Rheumatoid arthritis, Pain, Inflammatory arthritides

V. Dhir[1], A. Shaji[1], C. B. Prasad[1], G. Naidu[1], A. Sharma[1], S. K. Sharma[1], S. Jain[1], S. Bhutungru[1], B. Ghai[2]. *[1]Postgraduate Institute of Medical Education and Research, Chandigarh, Rheumatology Division, Internal Medicine, Chandigarh, India; [2]Postgraduate Institute of Medical Education and Research, Anaesthesiology and Intensive Care, Chandigarh, India*

Background: There is no consensus among rheumatologists on giving local anesthesia to the overlying skin prior to an intra-articular injection of glucocorticoid.
Objectives: Compare procedural pain in intra-articular injection between using local anesthesia to overlying skin or not.
Methods: Open label randomized controlled trial included patients with rheumatoid arthritis or spondyloarthritis undergoing intra-articular injections (of glucocorticoid) to paired medium-large joints. First the left joint was injected followed by right joint after a gap of 10-minutes. Randomization was done by online software using serial permuted blocks of varying sizes (4, 6 and 8) whether local anesthesia (5ml of 2% Lignocaine using a 23G needle) would be given to the left or right joint. Primary endpoint was immediate procedural pain felt by the patient using the 'Numerical Rating Scale and Faces Pain Scale-Revised. Secondary endpoints were 1-hour pain assessment, patient preference and complications. Paired t-test and Wilcoxon Signed Ranked test was used (paired data). Trial#CTRI/2021/07/034777
Results: This study included 42 patients undergoing paired joint injections (84 joints); joints were knee (21 patients. 42 joints), wrists (14 patients, 28 joints), ankles (5 patients, 10 joints) and elbows (2 patients, 4 joints). In 21 patients, the left joint was given local anesthesia and in the other 21 patients, the right Joint was given local anesthesia. Most had rheumatoid arthritis (37) and minority had spondyloarthritis [5]. Their mean age (±SD) was 44.6 ± 14 years and 71% were females. There was a significantly lower immediate procedural pain in the joint over which the skin was given local anaesthesia compared to that not (4.7 (1.7), 5.6 (1.6), p<0.01, difference -1.1, 95% CI -1.5 to -0.7) (Table 1, Figure 1A). This was also reduced pain at 1-hour post procedure (3.3 (1.4), 4.0 (1.6), p<0.01). Majority of patients (78.6%) preferred the procedure with local anaesthesia (Figure 1B). There was no difference in complications of hypopigmentation or purpura nor in residual pain prick-site at 1-month.
Conclusion: Local anaesthesia of the overlying skin led to a definite but modest reduction in pain felt by the patient during intraarticular injection.

Table 1. Procedural pain felt by patients in their joint injected with or without local anesthesia at immediate (0 hour) and 1 hour post procedure

Pain using NRS-FPS	Joint with local anesthesia, n=42 Mean (SD)	Joint without LA, n=42 Mean (SD)	p-value
0 Hours	4.7 (1.7)	5.6 (1.6)	<0.01
1 Hour	3.3 (1.4)	4.0 (1.6)	<0.01

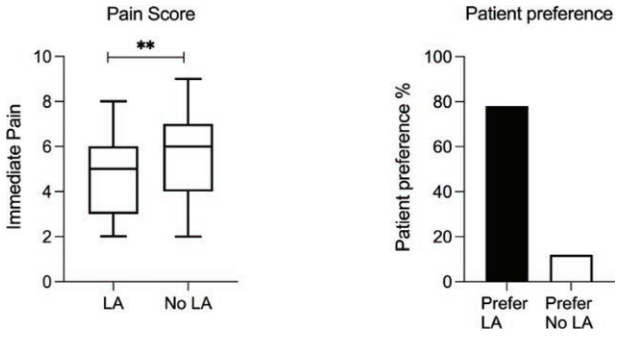

Figure 1. Procedural pain felt by patients in their joint injected with or without local anesthesia at immediate (0 hour) and the patient preference for future injections with or without local anesthesia

AB0463 THE IMPACT OF PHARMACOVIGILANCE RISK ASSESSMENT COMMITTEE (PRAC) RECOMMENDATIONS ON THE REAL-LIFE USE OF JANUS KINASES INHIBITORS FOR RHEUMATOID ARTHRITIS

Keywords: Comorbidities, Targeted synthetic drugs, Rheumatoid arthritis

E. G. Favalli[1,2], M. Ferrito[1,2], R. DI Taranto[1,2], M. Biggioggero[2], F. Orsini[1,2], S. Germinario[1,2], G. Cincinelli[1,2], R. Caporali[1,2]. *[1]University of Milan, Department of Clinical Sciences and Community Health, Milano, Italy; [2]ASST G. Pini-CTO, Department of Rheumatology and Medical Sciences, Milan, Italy*

Background: In November 2022 the EMA's Pharmacovigilance Risk Assessment Committee (PRAC) recommended measures to minimize the risk of serious adverse events associated with the use of Janus kinase inhibitors (JAKis).
Objectives: The aim of the study was to evaluate in a real-life cohort the impact of PRAC recommendations on the use of JAKis for the treatment of patients with rheumatoid arthritis (RA) and to describe their clinical characteristics. The rate of JAKi discontinuation because of major cardiovascular (CV) events (MACE), venous thromboembolism (VTE), or cancer was also analyzed according to PRAC limitations.
Methods: We conducted a retrospective analysis of RA patients treated with a JAKi from a single-centre, tertiary care hospital. The study population was stratified into patients eligible or not to JAKis in accordance with PRAC indications. We considered as ineligible: patients >65 years old; current or former long-term smokers; patients carrying increased risk of MACE (defined according to ORAL SURVEILLANCE trial[1] inclusion criteria [>50 years old and having at least one CV risk factor]), VTE (according to International Society on Thrombosis and Haemostasis categorization[2]), or cancer (defined as previous history of malignancy). In the ineligible group, a descriptive analysis of individual reasons for contraindication to JAKis was conducted. An analysis of reasons for JAKi discontinuation was performed in the whole population over a mean follow-up period of 20.9 months.
Results: Of 194 patients enrolled, 114 (57.9%) were classified as ineligible according to the PRAC definition (n=39 [34.2%] >65 years old; n=80 [70.2%] at increased risk of MACE; n=35 [30.7%] smokers; n=23 [20.2%] at increased risk of VTE, n=8 [7.0%] with history of malignancy). As detailed in Table 1, 52 (45.6%) patients fulfilled only one, 49 (43.0%) two, and 13 (11.4%) three or more PRAC criteria. Among patients ineligible for a single factor, this was high risk of MACE in 42.3% of cases. Compared with eligible ones, ineligible patients were more often obese (18.4% vs 0%; *p*<0,001), had a higher mean disease duration (15 vs 12 years; *p*=0.01), JAKis therapy duration (17.5 vs 10 months; p=0.02), mean HAQ score (1 vs 0.125; *p*<0.001), and prevalence of arterial hypertension (43% vs 12.5%; *p*<0.001), non-ischaemic heart disease (13.2% vs 3.8%; *p*=0.03), hyperlipidemia (53.5% vs 12.5%; *p*<0.001), and diabetes (7.9% vs 1,3%; p=0.04). The discontinuation rate due to adverse events was similar in eligible (5.0%) and non-eligible (7.0%) patients (p=0.57). We observed two withdrawals for VTE, one withdrawal for non-fatal stroke and one for solid malignancy (all in the ineligible group).
Conclusion: Our analysis shows that rigorous application of PRAC recommendations in a real-life setting would result in a large proportion of RA patients being excluded from treatment with JAKis, apparently without a consequent significant reduction in the rate of serious adverse events. A better quantification of the risk for MACE, VTE, and malignancy is advocated to improve our decision-making process in the management of RA.

AB0464 EFFICACY OF ANTI-FIBROTIC AGENTS IN RHEUMATOID ARTHRITIS ASSOCIATED INTERSTITIAL LUNG DISEASE: SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Rheumatoid arthritis, Systematic review, Lungs

R. Dos-Santos[1,2], P. Rodríguez Alonso[2], D. Fernández Fernández[3], I. González Fernández[1], P. Castro-Santamaria[1], M. Sanchez-Wonenburger[1], J. L. Puga Guzmán[1], A. Mata[1], I. Álvarez[1], V. Busto[1], J. R. Maneiro[1], A. Souto Vilas[1], A. Mera Varela[1,2], E. Perez-Pampín[1,2]. *[1]Clinical University Hospital in Santiago de Compostela, Rheumatology Department, Santiago de Compostela, Spain; [2]Universidade de Santiago de Compostela, Rheumatology Department, Santiago de Compostela, Spain; [3]CInical University Hospital in Ourense, Rheumatology Department, Ourense, Spain*

Background: The management of rheumatoid arthritis associated interstitial lung disease (RA-ILD) is mainly carried out with RA treatment. Anti-fibrotic drugs have been approved for idiopathic pulmonary fibrosis (IPF), decreasing peogression of the disease. The similarities between IPF and RA-ILD support the potential benefit of anti-fibrotic drugs, highlighting that nintedanib has been approved for other chronic fibrosing ILD.[1,2,3]
Objectives: To assess the efficacy of Nintedanib and Pirfenidone in RA-ILD patients.
Methods: A systematic review of the literature was performed in Medline, Cochrane Library, Web of Science and Embase databases and abstracts from EULAR and ACR were also screened. Language (English and Spanish) was the only limit for the search strategy. After eliminating duplicates and a first screening by title and abstract, records were included in the final selection for complete reading. Finally, papers included fitted inclusion criteria (RA-ILD diagnosis and anti-fibrotic treatment). A meta-analysis was performed when at least 2 comparable results were found in different studies.
Results: 24 records fitted inclusion criteria, of which 7 correspond to 2 randomized controlled clinical trials, 1 prospective case series, 4 case reports and 12 bibliographic reviews. Regarding quantitative summary, a significant less mean forced vital capacity (FVC) decrement in RA-ILD patients under anti-fibrotic treatment was found in comparison to placebo (SMD -3.42; 95%CI -4.19,-2.64; p=0.000) (Figure 1).
Conclusion: We found statistically differences between anti-fibrotic drugs and placebo concerning FVC improvement in RA-ILD patients. There does not seem to be differences between deaths and perceived quality of life. More studies with major capacity for statistical inference are needed.

AB0465 EFFICACY AND SAFETY OF LOW-DOSE IL-2 IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Cytokines and chemokines, Rheumatoid arthritis

Q. Y. Su[1,2,3], X. M. Wang[1,2], J. X. Zhang[1,2], C. R. Bai[1,2], P. H. Chai[1,2], Q. Yu[4], P. F. He[4], X. LI[1,2,3], S. X. Zhang[1,2,3]. *[1]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [2]Shanxi Medical University, Ministry of Education, Key laboratory of Cellular Physiology, Taiyuan, China; [3]Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [4]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*

Background: Interleukin (IL)-2 is a key cytokine for tipping the balance of Treg and effector T cells, which can effectively relieve rheumatoid arthritis(RA).
Objectives: This study aimed to systematically evaluate the efficacy and safety of low-dose IL-2 therapy in RA.
Methods: Systematic searches of PubMed, EMBASE, Web of Science, the Cochrane Library and Medline, CNKI, CBM, and Technology Journal Database were performed. Original case reports, case series, observational studies, and clinical trials reporting the efficacy or safety data on RA patients treated with IL-2 were included. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I[2], and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0)
Results: Thirteen studies comprising 1161 patients were identified (Table 1). After the low-dose IL-2 treatment, there were significant decreases in diseases activity measures such a DAS28[SMD=- 2.631, 95%CI (-3.526,-1.737), P<0.001], SJC[SMD=- 1.066, 95%CI (-1.467,-0.664), P<0.001], TJC[SMD=- 1.032, 95%CI (-1.193,-0.871), P<0.001], ESR[SMD=- 1.315, 95%CI (-1.883,-0.748), P<0.001], and CRP [SMD=- 0.824, 95%CI (-0.997,-0.652), P<0.001]. The values of BUN were increasedand the values of Cr was no statistical differences. The value of ALT was increased while the value of AST was decreased.Blood cell counts such as WBC, PLT and LY were significantly increased and RBC was no statistical difference. Meanwhile, the value of Hb was also no statistical difference(Figure 1). Besides, the numbers of CD4+T cells, CD8+T cells, Th1 cells, Th2 cells, Th17 cells and Tregs were significantly increased after IL-2 injection [SMD=0.819, 95%CI (0.692,0.946), P<0.001; SMD=0.388, 95%CI(0.222,0.554), P<0.001;SMD=0.634, 95%CI (0.436,0.832), P<0.001; SMD=0.521, 95%CI(0.366,0.676), P<0.001;SMD=0.626, 95%CI (0.475,0.776), P<0.001; SMD=1.177, 95%CI(0.941,1.412), P<0.001], while there were no statistical differences in the number of NK cells after IL-2 treatment. Importantly,the ratio of Th17/Tregs was significantly decreased[SMD=-0.700, 95%CI (-0.852,-0.549), P<0.001] and the radio of Th1/Th2 was no statistical difference(Figure 2).After the low-dose IL-2 treatment,the serious adverse event rate reported among all these studies was 0.083 (95%CI 0.051-0.114)(Figure 3).

Table 1. Available evidence including patients with RA treated with low-dose IL-2.

Study.Year.	Patients (include in analysis)	Gender (female %)	Dosage	DAS28	SJC	TJC

IDENTIFICATION OF POTENTIAL BLOOD BIOMARKERS FOR JAK INHIBITOR TREATMENT-RELATED PATHWAYS THROUGH BULK RNA SEQUENCING ANALYSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Genetics/epigenetics, Targeted synthetic drugs

H. H. Chen[1], T. M. Ko[2]. *[1]Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China; [2]National Yang Ming Chiao Tung University, Department of Biological Science and Technology, Hsinchu, Taiwan, Republic of China*

Background: Targeted small molecule therapy that inhibits receptor-mediated signaling via Janus kinase (JAK)–signal transducer and activator of transcription (STAT) pathways has become an established strategy for the treatment of rheumatoid arthritis (RA). The rationale for using these inhibitors is that JAKs have critical roles in specific pathological mechanisms and thus their targeted inhibition can lead to effective disease control. Despite JAK inhibitors (JAKi) having been approved for the treatment of RA and other systemic or organ-specific autoimmune diseases, the DAS28 response to JAKi is highly variable, emphasizing the need for reliable biomarkers.
Objectives: To reveal the potential impact of JAKi on treating RA patients, we aim to identify the biomarkers related to the responses of JAKi from blood bulk RNA-seq.

Methods: To better understand the molecular mechanisms of JAKi, we analyzed the global transcriptomics profile (using bulk RNA-seq) in peripheral blood mononuclear cells (PBMCs) that were collected from three RA patients before and after the treatment of JAKi.
Results: Comparing the responder and non-responder groups, we identified 1366 upregulated differentially expressed genes (DEGs) and 1366 upregulated differentially expressed genes (DEGs), and 1630 DEGs. To reveal further insight into the biological roles of the DEGs, we performed GO pathway analysis. Compared with responders, we found that the non-responders have a higher inflammation rate. In addition, non-responders have higher expression of genes that are involved in the JAKs signaling pathway. Specifically, gene profiling of non-responder represents higher Type I and II interferon pathway. In contrast, gene profiling of the responder represents a higher IL-12 pathway.

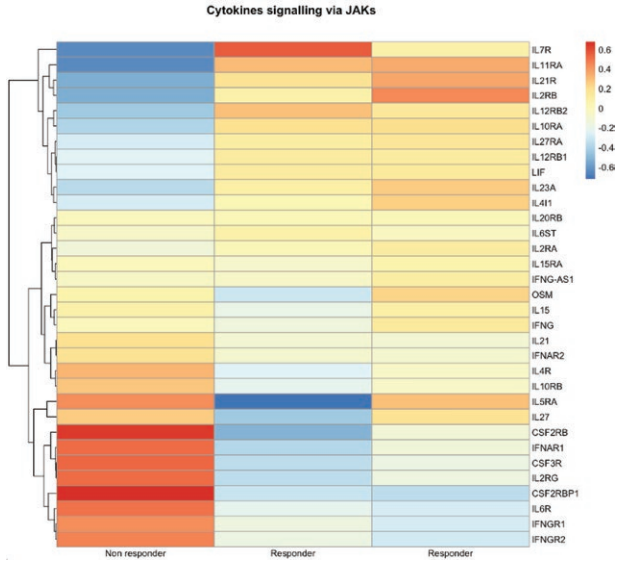

Figure 1.

Conclusion: These changes were accompanied by changes in broader immune cell composition, based on the deconvolution of bulk RNA-sequencing data. In summary, our study revealed several phenotypic and cellular changes that underlie the clinical improvement with JAKi.

AB0467 STEROID-SPARING EFFECT OF TOFACITINIB. TAPERING AND WITHDRAWAL OF GLUCOCORTICOIDS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Targeted synthetic drugs, Clinical trials, Tapering

F. R. Spinelli[1], C. Garufi[1], S. Mancuso[1], F. Ceccarelli[1], S. Truglia[1], F. Conti[1].
[1]*Sapienza University of Rome, Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Rheumatology Unit, Roma, Italy*

Background: The 2022 updated EULAR recommendations for the management of Rheumatoid Arthritis (RA) suggest tapering and discontinuation of oral glucocorticoids (GC), as rapidly as clinically feasible [1]. Considering GC as a "bridging therapy" to promptly reduce symptoms and control inflammation until the maximum effect of the Disease Modifying Anti-Rheumatic Drugs (DMARDs) is reached, the rapid effect of Janus Kinase (JAK) inhibitors could allow a fast and safe tapering of GC.
Objectives: We aimed to evaluate the steroid-sparing effect of adding tofacitinib in RA patients with inadequate response to MTX.
Methods: In this open label study, we enrolled patients with moderate-to-severe RA, on stable prednisone dose (5-12.5 mg/day) starting tofacitinib. After 1 month, in patients achieving at least a moderate EUALR response (>1.2 points reduction in DAS28 score), GC was tapered according to pre-specified schedule until complete withdrawal at week-12. The sample size of 30 patients was estimated assuming a 12-weeks response rate of 30% with a confidence interval of 90% and a margin of error of 15%. Disease activity was assessed after 4, 12, 24 and 48 weeks of treatment. The primary endpoint of the study was the percentage of patients discontinuing GCs after 12 weeks of treatment with tofacitinib. Secondary endpoints were: 1) the percentage of patients requiring a new GC course during the 12-months follow-up, 2) the percentage of patients in clinical remission or low disease activity at week 12, 24 and 48. At each visit laboratory tests, complete physical examination and other safety assessments were performed with particular interest to serious infections, Varicella Zoster virus reactivation, Major Cardiovascular Adverse Events (MACE), thromboembolic events and malignancy. Adverse events leading withdrawal of tofacitinib were also recorded.
Results: We enrolled 30 patients (26F: 4M, mean age 60±13 years, mean disease duration 13.2±7.8 years). The primary endpoint was achieved: 9 patients (30%) discontinued GC at week-12. At week 24 and 48, 12 patients (40%) had discontinued prednisone. The median prednisone dose decreased from a median dose of 5 mg/day (interquartile range 5-10 mg) to 2.5 (0-5), 2.5(0-5) mg/day at week 12 and 48 ($p<0.00001$ vs baseline). Multivariate analysis showed that factors negatively associated with GC withdrawal after 12 weeks were age ($p=0.014$), disease duration ($p=0.045$), and baseline PGA ($p=0.028$). During the follow up 4 patients had to increase the dose of GC from 1.2 (IQR 1-25-2.5) to 5; one more patient had to reintroduce 5 mg of prednisone after stopping at week 12. Discontinuation of glucocorticoids did not affect target achievement at week 12: a similar percentage of patients who discontinued or not discontinued GC achieved remission or low disease activity at week 12 (Figure 1A), and the percentage of patients who achieved the target increased throughout follow-up with no difference according to glucocorticoid therapy (Figure 1B). Three out of the 30 patients discontinued tofacitinib for adverse events (one for the onset of endometrial malignancy after 5 months of treatment, one for serious infection and one for paresthesia). As for the adverse events of special interest, none of the patients reported Varicella Zoster reactivation and no case of MACE nor thromboembolic events were recorded.
Conclusion: The rapid effect of tofacitinib in long standing RA patients allowed a significant reduction of the daily prednisone dose leading to the discontinuation of glucocorticoids in up to 30% of patients, without limiting the drug effectiveness.

AB0468 DRUG RETENTION AND SAFETY OF JANUS KINASE INHIBITORS IN RHEUMATOID ARTHRITIS PATIENTS - REAL WORLD EXPERIENCE FROM A SINGLE CENTRE IN UK

Keywords: Rheumatoid arthritis, Real-world evidence, Disease-modifying drugs (DMARDs)

H. Muhammed[1], F. Waliul[1], A. Ajibade[1], S. Pelia[1], G. Hirsch[1], T. Adizie[1], T. Sheeran[1,2], S. Venkatachalam[1]. [1]*The Royal Wolverhampton Hospital NHS Trust, Cannock and Wolverhampton Rheumatology Centre, Wolverhampton,*

United Kingdom; [2]University of Wolverhampton, Health Sciences, Wolverhampton, United Kingdom

Background: Tofacitinib, baricitinib, upadacitinib and filgotinib are the Janus kinase inhibitors (JAKi) approved for the treatment of rheumatoid arthritis (RA) in the UK. We report our real-world experience in a cohort of RA patients commenced on JAKi in a regional centre in the UK.
Objectives: To study drug retention rates and adverse events of JAKi in RA patients in the real- world scenario.
Methods: Data of patients with RA initiated on JAKi from February 2018 to August 2022 were retrospectively collected from hospital and primary care records. Kaplan-Meier curve was plotted for the cumulative drug retention rate. Crude event rates for various adverse events were calculated per 100 patient-years. Hazard ratios were calculated for adverse events for tofacitinib vs baricitinib after adjusting for baseline variability using inverse probability of treatment weighting (IPTW). Statistical analysis was done using R studio.
Results: During the study period 356 patients were initiated on JAKi (Baricitinib: 266, Tofacitinib: 48, Upadacitinib: 33 and Filgotinib: 9). Baseline characteristics of patients are given in Table 1. Over 734.6 patient-years follow up 92 (25.6%) discontinued JAKi. Drug retention rate at 2 years, 3 years and 4 years was 74.2%, 67.5% and 61.5% respectively (Figure 1). Most common reason for discontinuation was lack/loss of response (42.3%). Infections led to discontinuation in 13 patients and cardiovascular events in 5 patients. Lymphopenia, rash, oral ulcer, anemia, weight gain, high cholesterol, diverticulitis, and lymphedema were the other adverse events which resulted in discontinuation. Ten patients died while on treatment with JAKi. Six patients had a major adverse cardiovascular event (MACE) - 4 acute coronary events and 2 strokes. Nine patients had a venous thromboembolic event (VTE) while one patient had central retinal artery occlusion. Event rates for MACE and VTE were 0.8(0.3-1.7) and 1.2(0.5-2.3) respectively. Herpes zoster (HZ) occurred in 13 patients with an event rate of 1.8(1.0-3.1). Incident malignancies were noted in 14 patients on JAKi. Event rate was 1.1(0.5-2.2) for malignancies excluding 6 non-melanoma skin cancers. There were no statistically significant differences in the incidence of adverse events between tofacitinib and baricitinib. Hazard ratios for discontinuation, MACE, Pulmonary embolism, HZ, and malignancy were 0.7 (0.4-1.4), 2.0 (0.3-10.8), 0.2(0.02-1.4), 0.8(0.2-3.3) and 1.2(0.3-5.0) respectively for tofacitinib compared to baricitinib. Upadacitinib and filgotinib had shorter follow up duration to draw any meaningful conclusion.
Conclusion: JAKi in this real-world population of RA patients had high persistence rates. MACE, VTE, HZ and infections remain adverse events of concern.

BASELINE MODIFIED TOTAL SHARP SCORE MAY BE A PREDICTOR FOR FLARE AND SUCCESSIVE JOINT DAMAGE IN TAPERING OF METHOTREXATE

Keywords: Prognostic factors, Rheumatoid arthritis

K. Tanaka[1], K. Yujiro[2], T. Kawahata[1], M. Yuichi[3], T. Okubo[4], T. Sato[5], S. Abe[6], H. Ito[6], K. Katayama[5]. *[1]Asahikawa Medical University, Division of Metabolism and Biosystemic Science, Gastroenterology, Hematology/Oncology, Department of Medicine, Asahikawa, Japan; [2]Sapporo Rheumatology and Immunology Clinic, Rheumatology, Sapporo, Japan; [3]Asahikawa Medical University, Department of Medicine, Division of Rheumatology, Asahikawa, Japan; [4]Katayama Orthopedic Rheumatology Clinic, Radiology, Asahikawa, Japan; [5]Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan; [6]Asahikawa Medical University, Department of Orthopedic Surgery, Asahikawa, Japan*

Background: Many studies have reported the reduction or discontinuation of biologics in the treatment of rheumatoid arthritis (RA). In contrast, studies on tapering methotrexate (MTX) have been limited [1,2]. We prospectively reported whether bone destruction will progress at 48 weeks after tapering or discontinuing MTX in 79 RA patients in this meeting[3]. 34 patients (total 113 patients) were added for further analysis.
Objectives: According to tapering response, predictors for successful tapering MTX and progression of bone destruction were determined.
Methods: The subjects were RA patients who had maintained low disease activity or lower for 24 weeks or more in DAS28-CRP after MTX administration. Patients having PDUS Grade 2 or 3 per site by bilateral hand ultrasonography (26 areas) were excluded in this study owing to risk for joint destruction. Tapering of MTX dose was done every 2-3 months based on “shared decision between the patient and doctor.” The joint destruction was evaluated by joint X-ray evaluation by modified total Sharp scoring (mTSS) at 1 year after the start

of tapering MTX. Evaluation of clinical disease activity, severe adverse events, and the continuation rate during MTX tapering were also evaluated. According to tapering response, predictors for successful tapering MTX and progression of bone destruction were determined. Statistical analysis was performed by t-test, Mann-Whitney U test or one-way analysis of variance using EZR ver 1.37[4].

Results: Patients' demographic data were as follows, mean age:60.8 yrs, female: male: 88 pts:25pts, disease duration: 66.1 months, mean MTX dose: 8.51mg/week, mean DAS28-CRP: 1.55, ACPA:179.9 U/ml, ACPA positive(%): 72.6, RF: 48.1 IU/ml, RF(%):48.1, mean mTSS:17.6, ΔmTSS>1: 8.8% (10 cases) According to previous report, 113 RA patients were divided into three groups; Flared (F) group (22 patients), Less tapering (L) group, (37 patients) Good tapering (G) group (54 patients). As shown in Table 1A, significant differences were observed among the three groups in MTX dose at 6M(F vs G, P<0.01, L vs G, P<0.01), MTX dose at 12M(F vs L, P=0.01. F vs G, P<0.01, L vs G <0.01), DAS28-CRP at 12M (F vs L,G,P<0.05), ΔmTSS/y(Fvs G, P<0.05), baseline CDAI value (L vs G group, P<0.05), CDAI, SDAI at 12M(F vs G, P<0.05, F vs L, P<0.05), D-VAS at 12M(F vs L,G, P<0.01). Table 1B shows significant differences between F group and unflared (L+G) group in baseline mTSS (P<0.05), ΔmTSS/y(P<0.01), CDAI,SDAI, doctor VAS at 12M(P<0.01), MMP3 at 12M(P<0.05). Severe adverse events; cancer(stomach, lung) 2, MTX associated lymphoma(brain) 1, pneumoniae 1. These results indicated baseline mTSS may be a predictor for flare and flare response may be a predictor for joint destruction. Baseline CDAI may be a predictor for good response.

Conclusion: Baseline mTSS may be a predictor for flare successive joint damage in MTX tapering. Keeping low CDAI not DAS28 is important for good tapering.

AB0470 EFFECT OF TOFACITINIB IN MODULATING PLATELET FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Safety, Targeted synthetic drugs

D. Mauro[1], D. Iacono[1], I. Pantano[1], M. Raimondi[1], M. L. Marchesano[1], F. Riccio[1], A. Pellegrino[1], V. Liakouli[1], F. Ciccia[1]. *[1]University of Campania L. Vanvitelli, Rheumatology Unit, Department of Precision Medicine, Naples, Italy*

Background: Recent data suggested an association between Tofacitinib treatment and increased cardiovascular events in patients with Rheumatoid arthritis. Janus Kinase inhibitors (JAKi), specifically JAK3, have been demonstrated to be one of the regulators of platelet function. Treating platelets with thrombin induces tyrosine phosphorylation of the JAK3 target substrates STAT1 and STAT3, and JAK3 deficiency in mice reduces platelet aggregation and improves event-free survival in thromboplastin-induced thromboembolism.

Objectives: This study aimed to study the ability of the JAK1/JAK3 inhibitor, Tofacitinib, to influence platelet activity in patients with Rheumatoid Arthritis.

Methods: We enrolled patients with a diagnosis of RA according to the ACR/EULAR 2010 ACR/EULAR criteria. Peripheral blood was obtained from RA patients at the baseline and after 1, 3 and 6 months of Tofacitinib therapy.
Platelet aggregation assay was performed by optical aggregometry stimulated with the thromboxane A_2 receptor in RA patients and controls. The aggregation test was performed before starting the therapy with Tofacitinib and after one month, three months and six months.

Results: 25 RA patients treated with Tofacitinib were recruited, 86% female and 14 % male, with a mean age of 56.5 years (SD 9.7 yrs.), mean disease duration of 16.3 years, mean ESR 28.2 mm, mean CRP 0.9 mg/dl, mean SDAI 18.2 and mean prednisone equivalent dose 3.75 mg/die. 78% of the patients were positive for Rheumatoid factor and 57.1% for ACPA. Looking at the classical risk factors, 35.7 had hypertension, 21.4% had hypercholesterolemia, 16.2% had diabetes, and 14.2% were smokers.; only one patient had a previous cardiovascular event. The platelet aggregation was not influenced by Tofacitinib treatment at any time points (T1, T3 and T6) at any Thromboxane dose (5uM and 20 uM), furthermore did not differ from patients and controls basally (64%, SD 15.84% vs 62%, SD 10.5%).

Conclusion: In conclusion, Tofacitinib does not increase platelet aggregation in patients treated for Rheumatoid Arthritis.

AB0471 FEASIBILITY STUDY OF METHOTREXATE USE IMPROVEMENT IN RHEUMATOID ARTHRITIS (MIRA) USING BIOMARKER FEEDBACK: QUALITATIVE RESULTS FROM PATIENT INTERVIEWS

Keywords: Biomarkers, Rheumatoid arthritis, Qualitative research methods

J. Bluett[1], P. Doran[2], K. Hyrich[1], B. Keevil[3], A. Barton[1]. *[1]The University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom; [2]The University of Manchester, School of Social Sciences, Manchester, United Kingdom; [3]Manchester University NHS FT, 5Department of Clinical Biochemistry, Manchester, United Kingdom*

Background: MTX non-adherence is associated with reduced response, increased healthcare costs to the NHS and reduced quality of life for the patient. Often the prescriber is unable to determine if a patient is taking their medication as prescribed. There is a need to measure adherence directly to facilitate more precise and objective measurements of adherence to add to the clinicians tools and help to open up honest discussions and supportive interventions with patients. Our group has previously developed a sensitive biochemical assay for the detection of MTX adherence, MIRA is a feasibility trial designed to assess the feasibility of a randomised controlled trial of MTX biochemical adherence biofeedback. This paper reports on the patients' perspectives on adherence monitoring.

Objectives: MIRA is a prospective multi-centre randomised controlled trial to examine the feasibility of a fully powered randomised controlled trial to examine if

a biochemical adherence guided intervention is superior to standard clinical care in RA patients prescribed MTX.

Methods: RA patients prescribed oral MTX for ≥ two years were randomised 1:1 to receive biochemical adherence biofeedback or control. Clinico-demographics, biochemical MTX adherence and DAS-28 and were measured at baseline and three months. Participants in the intervention cohort were telephoned with their biochemical adherence results and adherence was explored. The semi-structured interviews were used to evaluate a sample of patient perspectives about and engagement with the intervention (n=10, visit 4). Ethical approval for MIRA was given by the North West - Haydock Research Ethics Committee (19/NW/0047) and all participants provided written informed consent.

Results: 57 trial participants were recruited, withdrawal rate was 14% and reasons given were intercurrent illness, lost contact, withdrawn consent and one patient died during follow-up leaving full outcome data available for 49 participants. A total of nine semi-structured interviews were recorded and analysed in the qualitative arm of the study. The themes from the interviews were grouped in relation to the core concepts of normalisation process theory, these were: coherence, cognitive participation, collective action, reflexive monitoring. Density mapping of the themes suggested that *comprehension* of the study purpose might have been limited. However, there were high levels of *reflexive monitoring* and most of the reflections were of a positive nature. Additionally, the intensity of data relating to *cognitive participation* and *collective action* suggest that participants were fully engaged in the trial and were supportive of the intervention and trial process.

Conclusion: The results of the MIRA trial have demonstrated that the use of a biochemical adherence blood test with biofeedback is feasible as part of a clinical trial. Qualitative findings suggested that participants reported that they were happy to take part in the trial. In contrast to expectations, participants were happy to have their MTX adherence monitored.

AB0472 FILGOTINIB FOR RHEUMATOID ARTHRITIS - AN OBSERVATIONAL STUDY TO ASSESS CLINICAL EFFECTIVENESS IN NHS LOTHIAN

Keywords: Real-world evidence, Targeted synthetic drugs, Rheumatoid arthritis

C. Box[1], E. Swann[1], H. Harris[1], N. Mckay[1]. [1]*Western General Hospital, Rheumatic Diseases Unit, Edinburgh, United Kingdom*

Background: Filgotinib (Jyseleca) is a Janus-kinase (JAK) inhibitor which in 2021 was approved for use in the UK in moderate or severe rheumatoid arthritis (RA) either as monotherapy or in combination with Methotrexate. A reduced dose of 100 mg is recommended for patients aged 75 years or over, or with moderate or severe renal impairment. Clinical efficacy of filgotinib alongside a conventional disease-modifying anti-rheumatic drug (cDMARD) was demonstrated in the FINCH 1 and FINCH 2 trials [1,2] but evidence of real-world effectiveness is currently limited.

Objectives: To describe a cohort of patients prescribed filgotinib (Jyseleca) for RA in NHS Lothian and assess clinical response and discontinuation rates in regular clinical practice.

Methods: The electronic patient record was reviewed for patients prescribed filgotinib in NHS Lothian between December 2021 and August 2022. Baseline data was recorded including time since diagnosis of RA, previous and concurrent treatment, duration of treatment with filgotnib and discontinuation reason if applicable. Comorbidities of interstitial lung disease (ILD), prior venous thromboembolism (VTE), major adverse cardiovascular events (MACE) or malignancy were recorded. Steroid prescriptions at the time of commencing filgotinib were recorded. DAS-28 scores within 6 months prior to starting filgotinib were recorded where they had been performed, along with most recent DAS-28 scores.

Results: 145 patients were prescribed filgotinib for RA; 106 females and 39 males. Median age was 64 years. Median treatment duration was 213 days. 35 (24.1%) patients were treated with the reduced 100mg dose. 14 (9.7%) discontinued treatment. 120 (82.8%) were previously treated with an alternative biologic DMARD. 59 (40.7%) had failed multiple biologic DMARDs of different classes. 19 (13.1%) switched directly to filgotinib from an alternative JAK inhibitor. Pre-treatment DAS-28 scores were recorded in 53 (36.6%), with a mean score of 5.07. DAS-28 scores following commencement of filgotinib were recorded in 29 (20.0%), with a mean score of 3.50. Pre-treatment tender (TJC) and swollen (SJC) joint counts were recorded in 86 (59.3%), with mean TJC 10.35 and SJC 6.50. Post-treatment counts were recorded in 46 (31.7%), with mean TJC 4.65 and SJC 2.91. Pre-treatment patient visual assessment score (VAS) of global health was recorded in 71 (49.0%), with mean VAS 62. Post-treatment VAS was recorded in 32 (22.1%), with mean VAS 43. 12 (8.3%) patients had DAS-28 scores recorded before and after. 7 were classed as a good response by EULAR criteria, 2 were a moderate response, and 3 were non-responders.

Conclusion: The drug survival rate of 90.3% after efficacy assessment at clinical review suggests a good tolerance, patient acceptability and clinical effectiveness. This Edinburgh-based, real-world, unselected patient cohort includes a high rate of multidrug-resistant RA yet sustains a high drug survival rate at 6 months. The cohort is limited by the lack of accurate DAS-28 recording in the clinical record. This may in part reflect the Lothian model of treating imaging-confirmed synovitis in the absence of a DAS-28 result.

AB0473 THE EFFICACY OF METHOTREXATE MONOTHERAPY STRATEGY CHOSEN AS FIRST-LINE DMARD THERAPY IN PATIENTS WITH NEWLY DIAGNOSED RHEUMATOID ARTHRITIS: RETROSPECTIVE EVALUATION OF SINGLE TERTIARY CENTER EXPERIENCE

Keywords: Remission, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

N. Erdik[1], C. Arslantürk Güneysu[1], S. M. Türk[1], G. Yavuzbilge[1], D. Karatas[1], M. Kalçık Unan[1], E. Gönüllü[1]. [1]*Sakarya University, Rheumatology, Sakarya, Turkey*

Background: Rheumatoid Arthritis (RA) is a chronic systemic disease in which immunologically mediated inflammation of synovia-lined joints can disrupt joint structure and function. Methotrexate is the first recommended conventional disease-modifying antirheumatic drugs (DMARD) when diagnosed in patients with RA. The goal of treatment is low disease activity or remission [1].

Objectives: It was aimed to retrospectively evaluate the response of patients who received methotrexate (MTX) monotherapy as a first-line DMARD strategy in newly diagnosed RA patients.

Methods: Between January 2018-September 2022, 642 patients diagnosed with RA in the Department of Internal Medicine Rheumatology of Sakarya University were retrospectively analyzed. All patients fulfilled the criteria for the 2010 Rheumatoid arthritis classification. Patients with newly diagnosed RA and obtaining MTX monotherapy as the first conventional DMARD strategy were included in the study. Patients diagnosed in another center and initially started conventional DMARD combination therapy were excluded from the study. Patients who discontinued treatment due to side effects were excluded and 73 were included in the study. Age, gender, rheumatoid factor and anticitrulized peptide antibody levels of the patients were recorded. Disease activity was evaluated at 0-3-6 months with the Disease Activity Score Calculator for Rheumatoid Arthritis (DAS-28). Data were analyzed using the computer program SPSS 21. Wilcoxon Signed Rank test and Friedman test were used from non-parametric tests. $p<0.05$ was considered statistically significant.

Results: The mean age of the patients was 54.82±11.65 years. Before MTX treatment, 27 (37.0%) patients had moderate DAS-28 scores and 46 (63.0%) patients had high disease activity. In the third months after MTX treatment, 44 (60.3%) patients were in remission or low disease activity, and 29 (39.7%) patients were moderate or high disease activity. In the sixth months after MTX treatment, 61 (83.6%) patients were in remission or low disease activity, and 12 (16.4%) patients were moderate or high disease activity (Table 1). The median DAS-28 score of the patients before MTX treatment was 5.51 (min-max: 3.49-7.77), the median score of the third months after treatment was 2.86 (min-max: 0.77-5.63) and the sixth months after treatment was 2.33 (min-max: 0.77-5.24). A significant improvement was observed in the DAS-28 score evaluated during the

treatment (p<0.001). When the patients were divided into two groups, seronegative and seropositive, DAS-28 scores were found to be significantly decreased after treatment in both groups.

Table 1. Disease activity rates before and after treatment.

Disease activity	Before MTX treatment (n, %)	MTX treatment 3rd month (n, %)	MTX treatment 6th month (n, %)
Remission	0	30 (%41.0)	48 (%65.8)
Low	0	14 (%19.3)	13 (%17.8)
Moderate	27 (%37.0)	26 (%35.6)	11 (%15.1)
High	46 (%63.0)	3 (%4.1)	1 (%1.3)
	73	73	73
Remission + Low	0	44 (%60.3)	61 (%83.6)
Moderate + High	73 (%100)	29 (%39.7)	12 (%16.4)
	73	73	73

Conclusion: Methotrexate is the first recommended conventional DMARD when diagnosed in patients with rheumatoid arthritis. However, clinical practice for monotherapy or combination use is quite heterogeneous. In this study, it was shown that the efficacy of MTX monotherapy was high in patients who were planned as the first conventional DMARD strategy, and the rate of patients who achieved the goal the sixth months increased.

AB0474 REAL-WORLD SINGLE CENTER USE OF UPADACITINIB IN RHEUMATOID ARTHRITIS PATIENTS, INCLUDING THOSE REFRACTORY TO FIRST-GENERATION JAK INHIBITORS

Keywords: Rheumatoid arthritis, Targeted synthetic drugs, Real-world evidence

M. Kamiya[1], S. Mori[2], K. Yamazaki[2], N. Oka[2], N. Shoukaku[2], D. Togawa[2].
[1]Ikoma City Hospital, Orthopaedic Surgery, Ikoma-city, Japan; [2]Nara Hospital, Kindai University, Orthopaedic Surgery, Ikoma-city, Japan

Background: In practice, bDMARDs and subsequent first-generation JAK inhibitors (JAKi) have significantly improved the management of rheumatoid arthritis (RA), but there are still patients refractory or intolerant to multiple b/tsDMARDs. The fact that first-generation JAKi inhibit more than one JAK molecule has given rise to hopes that second-generation JAKi with enhanced kinase selectivity may maximize efficacy and enable a safer profile. Although a matched-adjusted indirect comparative study, differences in efficacy between some of the two JAKi drugs have been demonstrated, suggesting that second-generation JAKi may be effective for RA patients who are intolerant or have inadequate responses to first-generation JAKi.

Objectives: We evaluated the real-world course of upadacitinib (UPA), a second-generation JAKi, in a single-center cohort of RA patients, including refractory patients with resistance to first-generation JAK inhibitors.

Methods: All RA patients who started UPA between May 2021 and June 2022, including those who had previously received tofacitinib (TOF) and/or baricitinib (BAR), were eligible for the study. Kaplan-Meier survival rates were calculated based on ineffectiveness or intolerance as the reason for discontinuation. DAS28-ESR score, PRO (VAS for pain and stiffness), and patient satisfaction on a 7-point scale were recorded at baseline, 3 months, and 6 months. In addition, RF factor antibody titers before and after UPA administration, concomitant MTX and PSL doses, and UPA dose at 6 months were recorded. The above items were evaluated in subgroups of JAKi-non-use cases and the number of JAKi used in the past. In addition, reasons for discontinuation of administration were also investigated.

Results: UPA was administered to 122 patients, 85.2% of whom were female, age (S.D.) 69.7 (11.9) years, weight 52.5 (8.4) kg, duration of RA (S.D.) 15.8 (10.3) years, and 97.5% of whom were RF or anti-CCP antibody positive. A median of 2.5 bDMARDs had been administered, including 37 patients who received IL-6 inhibitors. 52 patients (1st JAKi group) did not use any JAKi, 51 patients (2nd JAKi group) used one type (15 TOF, 36 BAR), and 19 patients (3rd JAKi group) used two types. Survival rates at 6 months were 92.3%, 90.2%, and 94.7% (P=0.83) in each group, and none of the 82 patients who could be followed for more than 12 months discontinued between 6 and 12 months. The mean DAS28-ESR (S.D.) at baseline was 3.91 (0.78) overall, but significantly improved to 2.79 (0.82) at 6 months (P<0.05). 67.3%, 70.6% and 47.4% of patients in each group had low disease activity. The VAS for pain and stiffness improved significantly in the 1st and 2nd JAKi groups, including treatment satisfaction. 88% of patients had decreased RF factor antibody titer. 62.5% of patients received UPA less than 7.5 mg/day at 6 months, including those who received UPA every other day. The rate of concomitant use of PSL (<5 mg) remained unchanged at 10.7%, and the rate of MTX decreased from 27.7% to 7.1%, mainly in the 1st JAKi group. 4 patients developed herpes zoster within 6 months and UPA was resumed after a temporary suspension. 2 patients discontinued UPA due to inadequate efficacy and 8 due to adverse events. Adverse events requiring hospitalization were bacterial pneumonia, putaminal hemorrhage, and sudden death with suspected acute myocardial infarction.

Conclusion: UPA was effective in RA patients, including first-generation JAKi-resistant patients, with few cases of discontinuation due to inadequate efficacy. Although some Japanese patients taper off UPA due to their light weight, advanced age, or complications, more than 60% of patients maintained efficacy with UPA at 7.5 mg/day or less, suggesting that taper-off is feasible. After disease activity decreased, tapering or discontinuation of concomitant MTX was prioritized, but there were no cases of apparent flares, again confirming the efficacy of UPA alone. In addition to the long-term safety of UPA, head-to-head between JAKi and JAKi to bDMARDs should be considered in the future.

AB0475 TRANSCRANIAL DIRECT CURRENT STIMULATION DECREASES CHRONIC PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS: A RANDOMIZED, CONTROLLED, DOUBLE-BLIND CLINICAL TRIAL

Keywords: Rheumatoid arthritis, Pain

S. Pilotti[1,2], R. Cavalheiro Do Espírito Santo[1,2], B. França[1,3], L. Santos[1,2], M. L. Gasparini Vieira[1,2], T. J. Santos de Souza[2], B. Ermel[2], A. L. Mallmann[1,2], D. Pereira[4], W. Caumo[1,3], R. Xavier[1,2]. *[1]UFRGS, Programa de Pós-graduação em Ciências Médicas UFRGS, Porto Alegre, Brazil; [2]HCPA, Laboratório de Doenças Autoimunes, Serviço de Reumatologia, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [3]HCPA, Laboratório de Dor e Neuromodulação, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [4]HCPA, Serviço de Pesquisa e Desenvolvimento em Engenharia Biomédica, Porto Alegre, Brazil*

Background: Rheumatoid Arthritis (RA) patients often present chronic pain that may persist beyond therapeutic control of objective signs of inflammation [1] and may cause significant physical and psychological impairments. Complex mechanisms encompassing peripheral and central sensitization seem to be involved [2]. In fibromyalgia patients, Transcranial Direct Current Stimulation (tDCS) appears to be effective for decreasing chronic pain symptoms [3].

Objectives: To verify the effect of active tDCS on pain and clinical symptoms in RA patients.

Methods: This double-blind randomized pilot clinical trial recruited women aged between 18 and 70 years diagnosed with RA and stable (3 months) low inflammatory status (CRP < 10 mg/L, ESR < 20 mm/h, swollen joint count ≤ 1) and persistent pain (VAS-pain > 4cm), from the Rheumatology ambulatory clinic of Hospital de Clínicas de Porto Alegre/Brazil. The patients were randomized into two different groups: active tDCS (A-tDCS) and Sham (S-tDCS). The 20 sessions of tDCS (2mA) were applied at home daily, for 20 min, 5 days/week. Main outcome was pain by visual analogue scale (VAS cm) after 4 weeks. Additional evaluations: pressure pain threshold (PPT,Kg), disease activity (DAS28-CRP), physical function (HAQ-DI), fatigue (FACIT-F), central sensitisation (Central Sensitization Inventory - CSI), and safety. The Paired-sample t test, the Wilcoxon test, the T-tests for independent samples, the Mann-Whitney test and the Generalized estimating equations (GEE) were performed using a gamma model were performed (accepted at p ≤0.05).

Results: Twelve patients have completed this pilot study (A-tDCS, n=6 and S-tDCS, n=6). At baseline, there are no differences in clinical features between groups (Table 1). After the 4-week intervention, the time of intervention was associated with changes on VAS-pain (p=0.004). There was between groups a trend towards a statistically significant difference for the A-tDCS group (p=0.063). Both groups had improvements on HAQ-DI, FACIT-F and CSI. On the other hand, the CRP, DAS28-CRP and PPT did not change (p>0.05) in both groups (Table 1). All patients reported low intensity of itch as an adverse effect during the session of tDCS.

Table 1. Results at baseline and after 4 weeks of tDCS intervention within and between groups.

Variable	Baseline		After tDCS	
	A-tDCS(n=6)	S-tDCS(n=6)	A-tDCS(n=6)	S-tDCS(n=6)
Age (years), mean	54.3±11.1	57.3±9.1	-	-
Disease duration, median	8.0 (5.0-10.2)	11 (6.2-30.5)	-	-
CRP, median (mg/L)	3.5(2.0-10.0)	2.0(1.0-3.7)	3.0(1.7-7.0)	2.5(1.7-8.7)
DAS28-CRP, mean	2.9±1.0	2.3±0.5	2.5±0.9	2.2±0.4
HAQ-DI, mean	1.7±0.4	1.6±0.5	1.0±0.5*	1.1±0.6*
FACIT-F, mean	22.0±10.0	28.6±9.2	16.3±9.9*	13.3±11.1*
CSI, mean	50.6±8.2	63.7±10.5	29.6±14.4*	30.6±13.1*
PPT (Kg), median	2.2(2.0-2.9)	2.3(1.8-4.2)	2.6(2.8-2.8)	1.9(1.1-4.2)
VAS (cm), median	6.5(1.7-7.0)	6.0(1.7-8.7)	5.0(2.5-6.0)*	5.0(3.5-7.0)
Leflunomida, n (%)	2.0 (33,3)	2.0 (33,3)	-	-
MTX, n (%)	2.0 (33,3)	5.0 (83,3)	-	-
bDMARDS, n (%)	1.0 (16.7)	0.0 (0.0)	-	-

p, Difference value at baseline and after intervention with tDCS (within groups)(p≤0.05)*.

Conclusion: These preliminary findings revealed that daily treatment with tDCS compared to sham stimulation over 4 weeks may improve the chronic pain in RA patients, despite the placebo effect observed for physical function, fatigue, PPT and central sensitization. The intervention was well tolerated. Thus, tDCS appears to be a promising auxiliary tool in the treatment of patients with low-inflammation RA who have chronic pain, but larger and longer studies are needed to confirm this observation and optimize it.

AB0476 AFTER JAK INHIBITOR FAILURE, 'SWITCHING' OR 'CYCLING'?

Keywords: Rheumatoid arthritis, Targeted synthetic drugs

P. Muñoz Martinez[1], L. Mas Sanchez[1], E. Grau García[1], A. M. Torrat Noves[1], D. Ramos Castro[1], C. Riesco Barcena[1], A. V. Huaylla Quispe[1], S. Leal Rodriguez[1], I. Cánovas Olmos[1], H. Charia[1], L. Gonzalez Puig[1], J. Ivorra Cortés[1], I. Martínez Cordellat[1], C. Nájera Herranz[1], R. Negueroles Albuixech[1], J. E. Oller Rodríguez[1], F. Ortiz-Sanjuán[1], E. Tovar-Sugrañes[1], E. Vicens Bernabeu[1], J. A. Román Ivorra[1]. *[1]HUP La Fe, Rheumatology Department, Valencia, Spain*

Background: The appearance of JAK inhibitors (JAKi) in the last few years has proved a great clinical application in rheumatic pathology and it has become an innovative and widely used therapeutic line. Nevertheless, the evidence of therapeutic alternatives in real life after the failure of a first JAK inhibitor is limited: a second JAKi or the change in therapeutic target.

Objectives: To analyze the treatment alternatives after JAKi failure in real life conditions.

Methods: Retrospective longitudinal observational study of patients that started JAKi treatment later discontinued between 2013 and 2022. Demographic and clinical variables were collected from the electronic medical record. 'Switching' and 'cycling' were analyzed depending on the prescribed therapy after the JAKi, classifying them in the following targets: anti-TNF, anti-IL6, anti-CTLA4, anti-IL12/23, anti-IL17, anti-IL23, another JAKi or other situations.

Results: Out of 265 JAKi prescriptions, 95 failures to JAKi treatment were included in this study. The most recurrent indication was Rheumatoid Arthritis (n=71), and the JAKi with higher failure rate was tofacitinib (n=61), with an average follow-up of 6 months (see Table 1). The most frequent cause of end of treatment was adverse reaction (34.74%), followed by secondary failure (28.42%) and primary failure (21.05%). After all the JAKi failures, cycling another JAKi was the most frequent therapeutical choice (n=25), followed by a switching to other families like anti-TNF (n=16) or anti-IL6 (n=15).

Conclusion: After a first JAKi failure, cycling another JAKi is the most recurrent alternative in our series, used most frequently in patients that present a secondary failure. Switching was the most frequent alternative used with patients who stopped receiving the treatment due to side effects.

AB0477 EFFICACY AND SAFETY OF UPADACITINIB IN RHEUMATHOID ARTHRITIS: REAL-LIFE EXPERIENCE FROM A MULTICENTRIC ITALIAN STUDY

Keywords: Targeted synthetic drugs, Ultrasound, Real-world evidence

C. Baldi[1], S. Parisi[2], P. Falsetti[1], F. Nacci[3], M. C. Ditto[2], M. D'alessandro[4], M. Capassoni[3], J. Sota[1], E. Conticini[1], C. L. Peroni[2], L. Cometi[3], E. Fusaro[2], B. Frediani[1], S. Guiducci[3]. *[1]University of Siena, Rheumatology Unit, Department of Medicine, Surgery and Neurosciences, University of Siena, SIENA, Italy; [2]Rheumatology Unit, Azienda Ospedaliero Universitaria Città della Salute e Della Scienza di Torino, Torino, Italy; [3]Rheumatology Unit, University of Florence, Department of Experimental and Clinical Medicine, Firenze, Italy; [4]University of Siena, Respiratory Disease and Lung Transplantation Unit, SIENA, Italy*

Background: Upadacitinib (UPA), a JAK inhibitor engineered for a greater selectivity towards JAK1, has demonstrated a favourable benefit-to-risk profile in rheumatoid arthritis (RA) patients with an inadequate response to cDMARDs and biologic agents in randomized clinical trials. However, real-life data on its efficacy and safety are limited. We herein provide the first prospective multicentre experience on UPA efficacy and safety profile in RA in a real-life context, focusing on clinimetric and ultrasonographic (US) data.

Objectives: The primary aim of the study was to assess changes in clinimetric and US scores between different time point observations (baseline, 1 month, 3 months and 6 months). Secondary aims were to: (i) estimate the impact of biologic line of treatment and of concomitant therapies on response to therapy;

(ii) explore changes in laboratory parameters; (iii) find potential predictive factors associated with response to therapy.
Methods: Medical records of consecutive RA patients treated with UPA and referred to three Italian tertiary Centers were prospectively reviewed. Adult patients meeting ACR/EULAR classification criteria for RA were enrolled.
Results: Our real-life experience confirms the efficacy in terms of clinical and US improvement as well as displaying a good safety profile. The combination therapy with a conventional immunosuppressants predicts a significantly lower clinical and US improvement, likely reflecting a more severe and aggressive course worthy of ad-hoc and more in-depth investigation. An improvement in the SDAI and DAS28CRP was observed, already from the first month of therapy and has been maintained over time. In conclusion, these results demonstrated the short term efficacy of Upadacitinib 15 mg for up to 6 months and providing a prompt improvement of PROs. Even if further studies are needed to clarify those results, these novel findings may provide new insight for the management of UPA treatment in clinical practice.

FRENCH REAL-LIFE DATA ON THE 18-MONTH EFFECTIVENESS OF TOFACITINIB ACCORDING TO CONCOMITANT USE OF CSDMARD IN PATIENTS WITH RHEUMATOID ARTHRITIS: INTERIM RESULTS OF THE OBSERVATIONAL STUDY, DEFACTO

Keywords: Targeted synthetic drugs, Real-world evidence, Rheumatoid arthritis

C. Gaujoux-Viala[1,2], A. Basch[3], S. Lassoued[4], F. Coury-Lucas[5], M. Kessouri[6], A. Saighi[6], Y. Brault[7], P. A. Squara[6], T. Lequerre[8], C. Salliot[9]. *[1]Desbrest Institute of Epidemiology and Public Health (IDESP), Univ Montpellier, INSERM, Rheumatology, Montpellier, France; [2]Nîmes Hospital CHU, Rheumatology, Nîmes, France; [3]Infirmerie Protestante Clinic, Lyon, Rheumatology, Caluire-et-Cuire, France; [4]Cahors Hospital Centre, Rheumatology, Cahors, France; [5]Lyon Sud Hospital, Rheumatology, Pierre-Bénite, France; [6]Pfizer, Medical, Paris, France; [7]Pfizer, Statistic, Paris, France; [8]Rouen University Hospital (CHU) & Inserm U905, Rheumatology, Rouen, France; [9]Orléans Regional Hospital Centre (CHR), Rheumatology, Orléans, France*

Background: Tofacitinib, an oral JAK inhibitor, is indicated for the treatment of adult patients with moderate to severe active rheumatoid arthritis (RA) for which we have no real-life effectiveness data in a French RA population.
Objectives: To describe tofacitinib effectiveness profile according to concomitant use of csDMARD in a French prospective observational study, DeFacTo.
Methods: DeFacTo, is an ongoing observational study with the primary objective of identifying predictive factors of Tofacitinib maintenance in real-life RA patients. The results described here are based on a descriptive interim analysis of its effectiveness at 18 months.
Results: Among 314 pts enrolled in the study, 301 (POP1) were included in this effectiveness analysis, including 274 (POP2) patients with follow-up ≥ 18 months on 03/15/2022 (date of analysis) with a median exposure duration of 538 [Q1; Q3: 381; 554] days. At baseline, among POP2: 168 (POP3) patients were treated with tofacitinib used concomitantly with at least one csDMARDs vs 106 (POP4) tofacitinib monotherapy. In POP3 vs POP4 respectively, 76.8% vs 84.9% were female, with a mean (± SD) age of 59.5 (10.8) vs 59.9 (12.1), median disease duration of 8.6 years [Q1;Q3: 3.2; 18.6] vs 11.1 [Q1;Q3: 5.3; 19.4)], 40.3% vs 52.4% patients had erosions, 80.5% vs 76.5% had FR+ and 77.7% vs 75.0% had ACPA+. Median CRP was 7.0 [Q1;Q3: 2.9; 18.0] vs 8.0 [Q1;Q3: 3.0; 18.1], and mean DAS28-4 CRP was 4.4 ±1.1 vs 4.7 ±1.0, in POP3 and POP4 respectively. Result showed a decrease in inflammatory markers, pain, and DAS28-CRP activity scores in both groups. At 18 months of follow-up, 24.4% and 24.5% of the pts achieved DAS28-CRP remission in POP 3 and POP 4 respectively (Table 1). Note that missing data and treatment discontinuation were considered as failures which resulted in an underestimation of LDA and remission at 18 months.

Table 1. Characteristics at inclusion and effectiveness at 18 months

	Baseline, n=274		At 18 month, n=274		Difference from baseline to M18	
Variables in LS mean ± SE or % of pts	Patients with at least one concomitant csDMARD treatment (N=168)	Patients without concomitant csDMARD treatment (N=106)	Patients with at least one concomitant csDMARD treatment (N=168)	Patients without concomitant csDMARD treatment (N=106)	Patients with at least one concomitant csDMARD treatment (N=168)	Patients without concomitant csDMARD treatment (N=106)
PtGA*	57.78 ± 1.67	61.43 ± 2.09	29.68 ± 2.97	35.40 ± 3.38	-28.10± 3.15	-26.03± 3.87
CRP* (mg/l)	15.25± 1.88	13.67± 1.45	5.16± 0.97	4.87± 0.82	-10.09 ± 2.00	-8.80 ± 1.52
DAS28-4 CRP*	4.38 ±0.09	4.68 ±0.10	2.49 ± 0.14	2.85 ± 0.13	-1.88 ± 0.15	-1.83 ± 0.16
ACR-EULAR boolean criteria†	3.0	0.9	12.5	14.2	9.5	13.3
LDA†, % pts	11.9	3.8	35.7	37.7	23.8	33.9
- DAS28 CRP ≤3,2	7.1	2.8	23.2	25.5	16.1	22.7
- DAS28 VS ≤3,2						
Remission†, % pts	5.4	2.8	24.4	24.5	19.0	21.7
- DAS28 CRP <2,6	3.6	1.9	16.1	12.3	12.5	10.4
- DAS28 VS <2,6						

* Missing data handled with mixed models for repeated measures ǂ Missing data and treatment discontinuations considered failures (122 patients with missing data, 39 treatment discontinuations).

Conclusion: This intermediate analysis from real-life study showed that tofacitinib in RA patients is effective with or without csDMARD.

Rheumatoid arthritis - non biologic treatment and small molecules

AB0479 **BARICITINIB AND UPADACITINIB AFFECT THE LEVELS OF BONE DESTRUCTION MARKERS AND BONE FORMATION INDICATORS IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Keywords: Rheumatoid arthritis, Bone diseases, Disease-modifying drugs (DMARDs)

A. Felis-Giemza[1], W. Kurowska[2], M. Marecka-Kuzdub[1], E. Kuca-Warnawin[2], M. Massalska[2], W. Maśliński[2]. [1]*National Institute of Geriatrics, Rheumatology and Rehabilitation, Biological Therapy Center, Warsaw, Poland;* [2]*National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Pathophysiology and Immunology, Warsaw, Poland*

Background: Janus kinase inhibitors (JAKis) baricitinib and upadacitinib inhibit the radiographic progression of joint damage in patients with rheumatoid arthritis (RA) [1-3]. Recent findings indicate that treatment with JAKi can lead to the repair of arthritic bone erosions [4]. However, although the immunomodulatory effects of JAKis have been extensively studied in inflammatory diseases, the effects of JAKis on bone metabolism in patients with RA are not fully understood.
Objectives: To investigate the effect of baricitinib and upadacitinib on the levels of bone destruction markers and bone formation indicators in the peripheral blood of patients with RA.
Methods: The study included 14 patients with RA (all women, aged 23–65 years, mean age 47.7 ± 12.4 years) with high disease activity at baseline (median DAS 28-ESR 5.625, range: 5.11–7.17); median ESR 11.50 mm/h (range 5.00–60.00 mm/h); median CRP 12.15 mg/ml (range 1.00–40.00 mg/ml). Peripheral blood plasma samples were collected from patients prior to JAKi treatment, and during therapy with baricitinib 4 mg once daily (n=9) or upadacitinib 15 mg once daily (n=5). Concentrations of C-telopeptide fragments of type I collagen (CTX-I), osteocalcin, Receptor Activator for Nuclear Factor κ B Ligand (RANKL), and osteoprotegerin (OPG) were measured in plasma by the enzyme-linked immunosorbent assays. Changes in the variables were assessed using paired Student t-test or Wilcoxon matched-pair signed rank test (depending on the type of data distribution). P-values <0,05 were considered significant.
Results: The median duration of treatment with JAKi was 12 months (range 7–18 months). Eleven (78.6%) patients were treated for more than 12 months. The effects of JAKis were analyzed in two-time intervals: after 5-8 months of therapy and after 12 months of therapy. The median DAS 28-ESR decreased to 2.83 (range 1.13–7.56, p=0,014), after 5-8 months of therapy, and to 2.53 (range 0.75–7.34, p=0.002) after 12 months of therapy. The concentration of bone turnover marker CTX-I decreased gradually during JAKi treatment from a median pre-treatment level of 247.1 ng/ml (range 50.0–1228.0 ng/ml) to 186.0 ng/ml (range 0.0–394.0 ng/ml) after 5-8 months of therapy, and 78.0 ng/ml (range 0.0–481.0; p=0.031) after 12 months of therapy. Conversely, treatment with JAKi resulted in a gradual increase in the median osteocalcin concentration from a pre-treatment level of 17.0 ng/ml (5.0–37.0 ng/ml) to 24.0 ng/ml (6–92 ng/ml) and 28.6 ng/ml (11.0–43.0 ng/ml) after 5-8 months and 12 months of therapy (p=0.027), respectively. In a subgroup of 6 patients (2 treated with upadacitinib and 4 treated with baricitinib), a decrease in RANKL/OPG concentration ratios were observed after 5-8 months or/and after 12 months of therapy (from pre-treatment median ratio of 0.23, range: 0.09–1.26 to 0.11, range: 0.00–0.87 after therapy; p=0.03). In 5 patients, the RANKL/OPG ratio did not change during treatment with baricitinib or upadacitinib.
Conclusion: The decrease in the concentration of CTX-I, a marker of bone destruction, with a simultaneous increase in the concentration of osteocalcin, a marker of bone formation, and a decrease (at least in a subgroup of patients) in the concentration of RANKL, a stimulator of bone resorption, in relation to its receptor-decoy OPG, suggests that treatment with baricitinib and upadacitinib may promote bone anabolic processes in patients with RA.

AB0480 **IS TRADITIONAL CHINESE MEDICINE A GOOD OPTION IN METHOTREXATE-BASED COMBINATION THERAPIES IN RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND BAYESIAN NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS**

Keywords: Clinical Trials, Randomized control trial, Rheumatoid arthritis

Z. Yang[1], Q. Liang[1], Y. Liang[1], M. Wang[1,2,3,4,5], R. Huang[1,3,4,5]. [1]*Guangzhou University of Chinese Medicine,The Second Affiliated Hospital, Guangzhou, China;* [2]*University Medical Center Utrecht, Center for Molecular Medicine, Utrecht, Netherlands;* [3]*Guangzhou University of Chinese Medicine, Guangdong Provincial Key Laboratory of Clinical Research on Traditional Chinese Medicine Syndrome, Guangzhou, China;* [4]*Guangzhou University of Chinese Medicine, Guangdong-Hong Kong-Macau Joint lab on Chinese Medicine and Immune Disease Research, Guangzhou, China;* [5]*The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, State Key Laboratory of Dampness Syndrome of Chinese Medicine, Guangzhou, China*

Background: Former findings suggested that MTX-based combination therapies show improved efficacy and safety compared to monotherapy [1]. Several studies [2] have been conducted analysis on MTX-based combination therapies, but there is a lack of systematic analysis involving MTX+TCM (Traditional Chinese medicine) therapies.
Objectives: To assess the effectiveness and adverse events of Methotrexate-based (MTX-based) combination therapies(especially MTX + TCM therapies) in rheumatoid arthritis (RA) treatment.
Methods: A comprehensive search of PubMed, Embase, the Cochrane Library, China National Knowledge Infrastructure (CNKI), the Database for Chinese Technical Periodicals and Wanfang data was done without language restriction. A systematic review and network meta-analysis included randomized controlled trials of MTX-based combination therapies and methotrexate monotherapy. The ability of different regimens to reduce rheumatoid factors and inflammatory indicators and the probability of adverse reactions were compared. This study has been registered with PROSPERO under the number CRD42022265799.
Results: A total of 37 studies, including 3119 patients, were eligible for inclusion. Meta-analysis results showed that methotrexate combined with other DMARDs or Traditional Chinese Medicine (TCM) could reduce serum Rheumatoid Factor (RF) and C-reactive protein (CRP) levels to some extent, but the therapies combined with TCM were more effective and had a lower rate of adverse effects. The results of RF reducing ability were ranked in ascending order: MTX-+LEF+TCM > MTX+SSZ+HCQ > MTX+LEF >MTX+TCM >MTX+HCQ >MTX. While the results of CRP reducing ability were ranked in ascending order: MTX+LEF+TCM>MTX+SSZ+HCQ>MTX+LEF>MTX+TCM>MTX+HCQ.
Conclusion: Overall, MTX-based combination therapies are an effective treatment, and the combination of TCM and MTX-based combination therapies is more effective and safer. For treating rheumatoid arthritis or patients with an inadequate response to MTX, MTX-based combination therapies remain an alternative, cost-effective option. To support and validate the potential of TCM and MTX-based combination therapies in treating RA, large-scale, high-quality RCTs should be conducted in the future to provide more accurate and complete data.

Background: Janus kinase (JAK) inhibitors have been approved for the treatment of Rheumatoid Arthitis (RA) and other systemic or organ-specific autoimmune diseases. Sustained remission or low disease activity are target treatments recomended by European League Against Rheumatism (EULAR) in RA patients [1]. Upadacitinib (UPA), a reversible, oral JAK inhibitor, has been engineered to have a greater selectivity for JAK1 vs JAK2, JAK3, and tyrosine kinase. In the Phase 3 SELECT clinical trial program, UPA has been shown to be effective and well tollerate in patients with RA [2]. However, data on the use of UPA in real-world clinical practice are limited.

Objectives: To evaluate UPA effectiveness in RA patients and to report the main reasons of suspension and the most relevant factor related to treatment persistence.

Methods: In 25 Italian rheumatological referral centers, all RA consecutive patients who received UPA were enrolled. Anamnestic data, treatment history and RA disease activity at baseline were recorded. The 6 and 12 months UPA retention rate was assessed with the Kaplan-Meier curve methods. The Cox analysis investigated the effect of age, sex, smoke habit, ACPA/RF presence, disease duration, DAS28-CRP, line of treatment, concomitant csDMARD treatment on UPA retention rate. A p-value < 0.05 was considered statistically significant.

Results: The one-hundred-eleven enrolled patients median age 57 (IQR 50-65 yrs); M:F 28:83; disease duration 78 (IQR 40-170 months). The median observation period was 6.1 (IQR 3.2-10.2) months. The observation lasted 812 patients-months. The majority of patients (54.0%) were in mono-therapy and received steroids (respectively 54.0% and 58.6%) (Table 1). The UPA retention rate at 6, 12 months was, respectively 90.4% and 74.7% (Figure 1). The main discontinuation reason was lack of efficacy (42% of interruptions), cancer onset and infections (both 11%). No thromboembolic events were reported. According to the Cox analysis, no one of the above mentioned parameters were associated to high risk of treatment interruption.

Table 1. Baseline characteristics UPA

Characteristics		Value
M:F		28:83
Age, median [IQR] yrs		58 [50-65]

Konrad[13], Y. Levine[14], D. Chernoff[14], M. Richardson[15]. *[1]Austin Neurosurgeons (Arise Medical Center), Neurosurgery, Austin, United States of America; [2]Carolina Neurosurgery & Spine Associates, Neurosurgery, Charlotte, United States of America; [3]Loma Linda University Health, Neurosurgery, Loma Linda, United States of America; [4]Integris Baptist Medical Center, Head and Neck Surgery, Oklahoma City, United States of America; [5]Henry Ford Medical Group, Neurosurgery, Detroit, United States of America; [6]University of Maryland Medical Center, Neurosurgery, Baltimore, United States of America; [7]The Feinstein Institutes for Medical Research, Institute of Bioelectronic Medicine, Manhasset, United States of America; [8]University of New Mexico Hospital, Neurosurgery, Albuquerque, United States of America; [9]Marcus Neuroscience Institute, Neurosurgery, Boca Raton, United States of America; [10]University of Washington, Neurosurgery, Seattle, United States of America; [11]Phoenix Children's Hospital, Neurosurgery, Phoenix, United States of America; [12]The University of Texas Southwestern Medical Center, Neurological Surgery, Dallas, United States of America; [13]West Virginia University Hospital, Neurosurgery, Morgantown, United States of America; [14]SetPoint Medical, Research and Development, Valencia, United States of America; [15]Massachusetts General Hospital, Neurosurgery, Boston, United States of America*

Background: An urgent need exists for differentiated RA therapies that are safer and cost-effective to expand treatment approaches for non-responders to disease-modifying anti-rheumatic drugs (DMARDs). Electrical stimulation of the vagus nerve activates the inflammatory reflex and has been shown to inhibit the production and release of inflammatory cytokines and decrease clinical signs and symptoms in chronic inflammatory diseases, including rheumatoid arthritis [1].

Objectives: The RESET-RA Study (NCT04539964) was designed to determine the safety and efficacy of a novel neuroimmune modulation device for treating rheumatoid arthritis. Presented here are data on the safety of the surgical implantation and use of this device in the first 60 human subjects enrolled in the study.

Methods: The RESET-RA study is a randomized, double-blind, sham-controlled, multi-center, two-stage pivotal study to evaluate the safety and efficacy of a novel neuroimmune modulation device in patients with moderate-to-severe RA who are incomplete responders or are intolerant to one or more biologic or targeted synthetic DMARDs. The device system (*SetPoint Medical*, Valencia, CA) consists of 2 implanted components: a miniature, rechargeable, leadless pulse generator that is surgically implanted in the neck on the left vagus nerve and a silicon sleeve referred to as a positioning and orientation device (POD) that holds the generator in close approximation to the nerve; and two external components: a wireless charger and an iPad application for programming the pulse generation. All subjects were implanted with the study device. One to three weeks after the implant procedure, subjects were randomly assigned (1:1) to receive either active or sham stimulation (control). The safety of the surgical procedure, device, and device stimulation was blindly assessed after 12 weeks of stimulation therapy.

Results: All device implant procedures were completed with no intraoperative complications, infections, or surgical revisions. No unanticipated adverse events (AEs) were reported during the perioperative period and at the end of 12 weeks of follow-up. No study discontinuations were due to AEs, and no subjects died during the study. There were no serious AEs related to the device, stimulation, or explant procedures. There were two serious AEs related to the implant procedure: vocal cord paresis and prolonged hoarseness were reported in two subjects and are known risks of implanting a device on the vagus nerve. The vocal cord paresis resolved following vocal cord augmentation with injectable filler and speech therapy; the other SAE is ongoing and improving with speech therapy.

Conclusion: Initial results demonstrated that implantation and programming of the novel neuroimmune modulation device was safe, and the surgical procedure and device were well tolerated. Full results from this study, including the clinical efficacy, will be presented after the study is fully enrolled and data is analyzed to determine potential of neuroimmune modulation for treating rheumatoid arthritis.

AB0483 FILGOTINIB IS EFFECTIVE AND SAFE IN RA PATIENTS AFTER FAILURE TO MULTIPLE BDMARDS AND TO OTHER JAK INHIBITORS: DATA FROM A MONOCENTRIC PERSPECTIVE COHORT STUDY

Keywords: Rheumatoid arthritis, Real-world evidence, Targeted synthetic drugs

F. Arru[1], M. Zen[1], M. Salvato[1], F. Vesentini[1], K. Botsios[1], T. Del Ross[1], M. Favaro[1], A. Giollo[1], A. Doria[1]. *[1]University of Padova, Department of Medicine DIMED, Padua, Italy*

Background: The JAK-1 inhibitor filgotinib has been recently licensed for Rheumatoid Arthritis (RA), thus real-world evidence is lacking.

Objectives: Our aim was to assess safety and efficacy of filgotinib in a real-world setting.

Methods: In this prospective monocentric study, we included all patients with RA (ACR/EULAR 2010 criteria) regularly followed-up (every 2-6 months), undergoing therapy with filgotinib between 09/2021-01/2023. Disease activity was measured by DAS28-CRP, CDAI, and SDAI; TJC, SJC, patients (Pt) and physician (Ph) global assessment (0-10), the proportion of patients achieving DAS28-remission, concomitant csDMARDs and glucocorticoids (GC), comorbidities, and adverse events (AE) during filgotinib treatment were collected. Discontinuations for inefficacy or AE were recorded.

Results: We enrolled 58 RA patients: 33 (62%) on filgotinib monotherapy, 5 (9%) b/tsDMARD-naïve, 15 (26%) already treated with ≥ 2 classes of bDMARDs (multi-failure), 9 (17%) previously treated with JAK-inhibitors. Mean±SD follow-up was 9±5 months, with 30 (52%) and 8 (14%) patients having ≥6 and ≥12-month follow-up (fu). Among patients with ≥6 months of follow up there was a significant improvement in swollen and tender joint counts, PtGA, PhGA and composite disease activity measures (Table 1). Seventeen patients (57%) achieved DAS28-CRP remission. Compared to the general cohort's data, multi-failure patients and those failing a prior JAKi showed a similar DAS28-CRP response; in addition, multi-failure and filgotinib monotherapy patients reached comparable DAS28-CRP remission rates (Table 1). Among patients reaching 12 month fu, response rates were maintained (Table 1). During filgotinib therapy there was a trend towards a reduction in both GC users and mean GC dose (Table 1). Overall, 17 patients (29%) experienced ≥1 AE, of whom 2 (3%) were SAE (1 ILD progression, 1 death due to pneumonia). Six patients (10%) discontinued

Table 1. Characteristics of AR patients treated with filgotinib at baseline, t6, t12

Demographics and RA history			Baseline	6 months	p- value (m0 vs m6)	12 months	p-value (m6 vs m12)

Cardiovascular n(%)	1 (2%)	GC users n(%)	18 (60%)	14 (46%)	n.s.	3 (37%)	n.s.
		GC Dose * mean ± SD (mg of prednisone equivalent)	6.2 ± 3.6	4.7 ± 2.5	n.s.	2.5 ± 0.5	n.s.

n.c. not calculated; n.s. not significant

filgotinib: 1 (2%) due to primary inefficacy, 5 for AE/SAE (9%). No cardiovascular events were recorded.

Conclusion: Real-world treatment with filgotinib was associated with clinical improvement and low AE rate. Multi-failure and JAKi experienced patients benefited from filgotinib therapy. In this cohort of RA patients with low prevalence of comorbidities, no MACE or venous thrombotic events were observed.

AB0484 DO JAK INHIBITORS IMPROVE PATIENT FATIGUE IN RHEUMATOID ARTHRITIS? RESULTS FROM A PATIENT SURVEY

Keywords: Inflammatory arthritides, Rheumatoid arthritis, bDMARD

G. Dulay[1], L. Goh[1]. [1]*Portsmouth Hospitals University NHS Trust, Rheumatology, Portsmouth, United Kingdom*

Background: Fatigue is a common symptom reported by up to three-quarters of patients with Rheumatoid Arthritis (RA) [1]. There is often no clear correlation between fatigue and RA disease activity [2]. There is a paucity of data on treatment of fatigue in patients with RA [2]. Fatigue remains one of the key unmet needs in patients with RA. Janus Kinase inhibitors (JAKi) are a group of targeted synthetic treatments used in RA with good clinical efficacy data in randomised controlled trials. There is clinical data to suggest that JAKi treatment can improve several patient-reported outcomes including fatigue [3].

Objectives: The aim was to establish whether fatigue was 'significantly improved' after at least 12 weeks of JAKi treatment. Only patients with a diagnosis of Rheumatoid Arthritis and features or a history of fatigue were included. A second question was incorporated to assess whether any improvement seen was noticed within the first 2 weeks of treatment.

Methods: A simple clinic-based patient survey was undertaken in patients with RA on a JAKi treatment. The first 20 patients with RA and fatigue are included in this sample. The following binary question(s) were asked: 1)Has your fatigue 'significantly improved' on JAKi treatment? 2)If so, was the improvement seen within 2 weeks of starting JAKi treatment? All patients had been on JAKi treatment for at least 12 weeks. The questions were asked prospectively to patients whilst being reviewed for their routine rheumatology outpatient clinic appointments.

Results: 13 out of 20 (65%) patients said that their fatigue had 'significantly improved' on JAKi treatment. 7 out of these 13 (54%) patients said that the improvement occurred within 2 weeks of starting JAKi treatment. Out of the 20 patients included in this sample, 11 were on Baricitinib, 5 on Upadacitinib and 4 on Filgotinib. No patients in in this sample were on Tofacitinib (Tofacitinib was not excluded by design). The majority of the patients included in this survey had been on prior biological treatment(s) or targeted synthetic disease modifying treatment. Most of the patients had one or more co-morbidities and over half of the patients were taking concomitant disease-modifying treatments for their RA. It is important to note that factors around fatigue in RA, such as; comorbidities (including chronic pain and fibromyalgia), sleep pattern, and features of low mood were beyond the scope of the survey and thus not asked about.

Conclusion: Whilst acknowledging the modest sample size and simplicity of our patient survey, our data suggests some benefit of JAKi treatment on fatigue in patients with RA. The benefits seen are broadly in keeping with what is seen in our wider local clinical practice. Our survey suggests that the improvement in fatigue can occur rapidly, with the majority of patients noting improvement within just 2 weeks. More detailed (including qualitative) data would be useful to support these initial findings from this patient survey and explore the role of JAKi treatment on fatigue in patients with RA.

AB0485 SAFETY ANALYSIS OF JAKINIBS IN REAL CLINICAL PRACTICE IN A COHORT OF 116 PATIENTS

Keywords: Safety, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

L. Salvatierra Velasco[1], A. Belmonte Mora[1], J. Rubio Ubeda[1], P. Morales-Garrido[1], J. Salvatierra[1], E. Raya[1]. [1]*Hospital Universitario Clínico San Ceclio, Reumatología, Granada, Spain*

Background: Janus kinase inhibitors (JAKinibs) have demonstrated efficacy in the treatment of rheumatoid arthritis (RA) and spondyloarthritis (SpA), although their safety profile continues to be analysed due to the possible increase in adverse events (AEs) in relation to anti-TNFs (mild and severe infections, haematological alterations, thromboembolism, increase in neoplasms).

Objectives: To evaluate in real clinical practice the AEs of JAKinibs in a cohort of patients with RA and SpA. In addition, adherence and reasons for discontinuation (1st or 2nd failure, AE) are analysed.

Methods: Observational study of 116 patients diagnosed with RA or SpA who received treatment with JAKinibis (tofacitinib, baricitinib, upadacitinib) after failure of treatment with different classical synthetic (FAMEsc) or biological (FAMEb) disease-modifying drugs. The following data were analysed: demographic characteristics of the patients, years of disease progression, 1st or 2nd failures and AE.

Results: Mean age was 52 years, with Baricitinib being older (60 years -SD 13.6), higher prevalence of females in all groups, and a disease progression time of about 10 years. Mean number of FAMEsc was 1.6 and mean number of FAMEb was 2,3 to Tofacitinib(Tofa), 2,76 to Baricitinib(Bari) and 4,4 to Upadacitinib(Upa). 71 (63%) patients had active corticosteroid therapy. The median treatment time with Tofa was 8.8 months, Bari 9.5 and Upa 2.4 months. Most frequent AEs with Tofa were urinary tract infections(UTI) (11.9%, 7 cases) and headaches (8.47%, 5 cases). There were 3 cases of herpes zoster (5.1%), one of which was recurrent, and 2 cases respectively of tachycardia and gastrointestinal intolerance (3.4%). With Baricitnib, 2(5%) cases of UTI and 2(5%) of influenza A were reported. Most

frequent AEs related to Upadacitinb are gastrointestinal intolerance, labialis and facial herpes, anterior uveitis and recurrent UTI, with 1 case for each adverse event. There were 4 success with Baricitinib treatment: 2 due to severe COVID, 1 influenza A and 1 due to stroke. 17 patients had 1st failure to Tofa(28.81%), 8 to Bari20.0%) and 3 to Upa(18.75%); 7(11.86%) and 2(5%) patients had 2nd failure to Tofa and Bari respectively, no with Upa. Mean CRP to Tofa-SD 18.9-was 17.19, 20-SD 22.7- to Bari and 24.2-SD 27.40- to Upa. Mean ESR-SD 15.3- was 25.4, -SD 26.4 and 44.3 -SD 32-, respectively. At 6 months, 36(62%) were continuing on Tofa, 22(56%) on Bari and 4(27%) on Upa. At 12 months, 27(46.6%) were still on Tofa and 12 on Bari(30.8%) and no patients were on upa.

Table 1.

	Tofa	Bari	Upa
Mean age	49	60	47
Male	19%	18%	20%
Female	81%	82%	80%
Time course of disease(years)	8	11	11
Permanence 6 months	62%	56%	27%
Permanence 12 months	46,6%	31%	0%
Patients with corticotherapy	62%	64%	60%
Previous biological drugs	2,3 SD 2	2,8 SD 2,3	4,4 SD 2,9
Patients who discontinued the drug	62%	59%	33%
Mean CRP at the end of treatment	17	20	24
Mean end-of-treatment ESR	25	26	44
Repeated AEs	UTI(7) Headache(5) Shingles(3) Nephritic colic(2) Gastrointestinal intolerance(2) Tachycardia(2)	UTI(4) Headache(2)	
Serious AEs	Shingles (3)	Varicella encephalopathy(1) Stroke(1) Shingles (1)	
1st failure	28,8%	20%	18,7%
2nd failure	11,9%	5%	0%
Success		SARS-Cov2(2) Influenza(1) Stroke(1)	

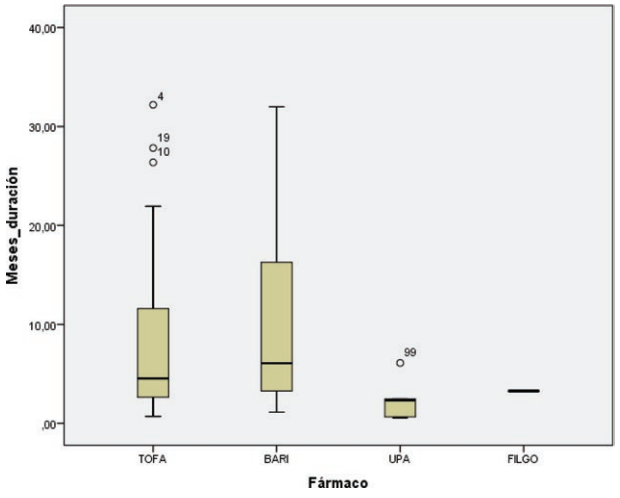

Figure 1. *Months stay pharmaco*

Conclusion: Most frequent adverse events with JAKinibs are mild infections, except gastrointestinal complaints with upadacitinib. Serious adverse events, including 3 deaths from viral infections, were observed, mostly in patients over 65 years. Most frequent cause of discontinuation was treatment failure. We believe that further observational studies are needed to stratify and profile the risk of infection with JAKinibs.

AB0486 LIVER FIBROSIS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH METHOTREXATE: HYPOALBUMINEMIA, THE BIOLOGICAL PITFALL

Keywords: Rheumatoid arthritis

W. Lahmar[1], M. Slouma[1], G. Mohamed[2], O. Dhrif[3], N. Abdelli[2], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1]. *[1]Military Teaching Hospital, Rheumatology, Tunis, Tunisia; [2]Military Teaching Hospital, Gastroenterology, Tunis, Tunisia; [3]University of Tunis El Manar, Internal Medecine, Tunis, Tunisia*

Background: The relationship between hepatic fibrosis and cumulative doses of methotrexate (MTX) in rheumatoid arthritis (RA) patients is an emerging discussion. Hypoalbuminemia is known to be a potential risk factor for toxicity by methotrexate, mainly hematological toxicity and myelosuppression.

Objectives: The aim of our study was to investigate the biological associated factors with liver fibrosis in RA patients treated with MTX.

Methods: It was a cross-sectional study over nine months [April-December 2021], including RA patients under MTX, recruited from the Rheumatology department of Military Hospital. Liver stiffness was assessed by Fibroscan. Fibrosis and significant liver fibrosis were defined as liver stiffness higher than 6 and 8kPa, respectively. Liver enzymes (AST and ALT), alkaline phosphatase (ALP) and albuminemia were measured. Statistical analyses were performed using SPSS.

Results: Sixty-eight patients were included. The mean age was 51.60+11.82 years. The male-to-female ratio was 0.45. The mean disease duration was 8.29 + 6.48 years. The mean weekly intake of methotrexate was 13.76+3.91mg. The mean cumulative dose was 3508.87+3390.48 mg. The mean values of albuminemia were: 35.39 + 5.18 g/L [16.20 – 43.40]; AST 20.50 + 8.32 IU [11-52]; ALT 19.52 + 9.42 IU [5 -46] and ALP: 82.95 + 38.82 IU [10-240] and were all in the normal range. Four patients (6%) had elevated AST and ALP in 4 (6%) cases. Hypoalbuminemia was noted in 34% (n=23) of the cases. Mean liver stiffness was 4.50 + 1.53kPa. Nine patients had fibrosis, and 4 had significant fibrosis. On the univariate study, we found that hypoalbuminemia was associated with liver stiffness (OR=4.941,$CI_{95\%}$[1.107–22.057],p=0.034), along with increased ALP (OR=5.002, IC95% [1.086–67.252], p=0.025). We did not find correlation between and liver stiffness and albuminemia (r: -0.132, p=0.665), liver enzymes: AST (r: 0.036, p= 0.335) ALT (0.086, p= 0.476), nor ALP (r:0.111, p= 0.560).

Conclusion: Hypoalbuminemia leads to an increase in unbound MTX. It is this fraction that contribute to the development of liver damage. Along with the biological liver function, a particular attention is then needed to serum albumin when treating RA patients with MTX.

AB0487 EVALUATION OF EFFICACY OF PEFICITINIB FOR RHEUMATOID ARTHRITIS: A MULTICENTER, RETROSPECTIVE STUDY IN JAPAN

Keywords: Safety, Targeted synthetic drugs, Rheumatoid arthritis

M. Mitsuhashi[1], Y. Kunishita[1], K. Harita[1], C. Honda[1], Y. Uzawa[1,2], S. Ohta[1], T. Okubo[2], T. Igarashi[1], S. Nagaoka[1]. *[1]Yokohama Minami Kyosai Hospital, Department of Rheumatology, Yokohama, Japan; [2]Saiseikai Yokohamashi Nanbu Hospital, Department of Rheumatology, Yokohama shi Konan ku Konandai 3-2-10, Japan*

Background: Peficitinib (PEF) is the third Janus-kinase inhibitor (JAKi) approved for rheumatoid arthritis (RA) in Japan. Although PEF has the characteristic action of inhibiting all JAK subtypes, mainly JAK3, in vitro [1,2], there is slightly less variety of clinical studies showing the efficacy of PEF for RA compared with other JAKi; it is necessary to verify the clinical efficacy and safety [3,4].

Objectives: To examine the efficacy and safety of PEF for RA and explore the predictive factors related to the discontinuation due to the inadequately effective.

Methods: Patients who received PEF for RA at Yokohama Minami Kyosai Hospital and Saiseikai Yokohamashi Nanbu Hospital from July 2019 to December 2022 were included in the study. Patient background, clinical parameters, administration period of PEF, reason for discontinuation of PEF were collected retrospectively from the electronic medical records. All analyses were performed using SPSS. The log-rank test was used to compare continuation rates, and binomial

logistic analysis was used to explore predictive factors related to the discontinuation of PEF due to the inadequately effective.

Results: Fifty-seven patients were included in the study. The mean age at PEF initiation and DAS28-ESR were 75.6 ± 15.3 years old and 4.9 ± 1.3, respectively, and DAS28-ESR was significantly improved by 3.1 ± 1.1 at six months after ($p < 0.005$). The 1-year continuation rate of PEF among all patients was 42.8 %, and the rate among patients who had not previously used biologics and JAKi (NAÏVE) was significantly higher than among those who had previously used them (EXPERIENCE) (Figure 1). Univariate analysis of factors associated with discontinuation of PEF due to inadequate response identified the following factors: younger age at PEF initiation, seropositivity for anti-CCP antibodies (ACPA), and EXPERIENCE (Table 1). Of these factors, multivariate analysis showed significant differences in age at PEF initiation and ACPA seropositivity (Table 1), but no significant differences in persistence rates were found between patients with and without ACPA in sera in this analysis population (1-year continuation rate: 42.9% vs. 76.9%, $p = 0.081$). There were several limitations in this study as follows; the race of the patients was Japanese only, the study was retrospective, validation by a multiracial prospective study would have been desirable, and the small number of cases may have resulted in the imprecision of statistically significant differences, and further accumulation of cases is desirable.

Conclusion: PEF demonstrated certain effects on the elderly RA population in real-world clinical practice in Japan. This study suggests that patient characteristics that could be expected to be effective, being particularly elderly and ACPA-negative, were suggested, but in addition, patients who had not previously used biologics and JAKi were shown to have a higher continuation rate.

AB0488 COMPARISON OF TWO METHOTREXATE INITIATION STRATEGIES IN RHEUMATOID ARTHRITIS IN CURRENT PRACTICE

Keywords: Treat to target, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

P. Vidal[1], M. Thomas[2], A. Combier[2], A. Steelandt[2], J. Narváez[1], J. M. Nolla[1], Y. Allanore[2], J. Avouac[2]. *[1]Bellvitge University Hospital, Rheumatology, L'Hospitalet de Llobregat, Spain; [2]Cochin Hospital, Rheumatology, Paris, France*

Objectives: To compare the efficacy and tolerance at 3 and 6 months of two methotrexate (MTX) initiation strategies in rheumatoid arthritis (RA).

Methods: Retrospective, monocentric, cross-sectional study including patients with RA who initiated MTX as first-line therapy during the last 2 years according to one of the following 2 strategies: a "classic" strategy defined by an initiation of oral MTX a dose of 10-15 mg/week or an "aggressive" strategy, defined by an initiation of subcutaneous (SC) MTX at a dose of 15 mg/week SC or >15 mg/week either orally or SC. Each strategy allowed the possibility to increase the doses and/or switch to the SC route at 3 months. Efficacy was assessed at 3 and 6 months using the DAS28-CRP. The tolerance of each strategy was also assessed at month 3 and 6.

Results: We included 101 patients (85 women) with a mean age of 55±12 years and disease duration of 5±6 months. The frequency of rheumatoid factors, anti-CCP antibodies and erosions was 83%, 81% and 38% respectively. 61 patients initiated MTX according to the "classic" strategy, with an increase of dose and/or a switch to the SC route at 3 months for 31 patients, and 40 patients started treatment according to the "aggressive" strategy, with an increase of dose and/or switch to the SC route at 3 months for 14 patients. There was no difference between these 2 groups in terms of age, gender, disease duration, antibody status, frequency of bone erosions, body mass index, comorbidities and disease activity at baseline. Efficacy at 3 months was significantly higher with the "aggressive" strategy (reduction of the DAS28-CRP from 4.34±0.91 to 2.39±0.75, mean difference of 1.95±1.21, p<0.001) compared to the "classic" strategy (reduction of the DAS28-CRP from 4.09±0.62 to 2.88±0.73, mean difference of 1.21±0.90, p=0.12) (**Figure 1**). The improvement of tender/swollen joint counts, patient global assessment and CRP levels was also significantly more important at 3 months with the "aggressive" strategy (**Table 1**). At 6 months, although the DAS28-CRP was similar in the 2 groups (**Figure 1**), less patients from the "aggressive" strategy subgroup required an escalation to a targeted biologic/synthetic therapy compared to the "classic" strategy (12/40, 30% vs. 29/61, 48%, p=0.073). The frequency of digestive side effects at 3 months was significantly lower in the "aggressive" strategy (3/40, 7,5% vs. 16/61, 26%, p=0.021). The frequency of hepatic cytolysis at 3 month was higher in the aggressive strategy (4/40, 10% vs. 1/61, 1,6%, p=0.057). The frequency of asthenia at 3 months was similar in both groups (7/4, 18% vs. 6/61, 10%, p=0.25). Only one infection was observed in the "classic" strategy and no hematological side effect was recorded. At 6 months, the cumulative incidence of side effects was 23% with the "aggressive" strategy compared to 46% with the "classic" strategy (p=0.015). Only one treatment discontinuation was noted in the "aggressive" subgroup vs. 9 in the "classic" subgroup (p=0.042).

Conclusion: This study suggests that it is possible to use a more aggressive initiation strategy of MTX in RA in routine clinical practice. This strategy allows to obtain an earlier clinical response and it is associated with a better tolerance than the classic strategy. These results need to be confirmed in prospective studies.

Table 1. Evaluation of efficacy parameter at 3 months according to the methotrexate initiation strategy

	"Classic" strategy (n=61)	"Aggressive" strategy (n=40)	p-value
Variation of tender joint count	-2.6±3.4	-4.4±4.9	0.032
Variation of swollen joint count	-2.0±5	-4.7±4.0	0.005
Variation of PGA-VAS	-24±25	-40±35	0.009
Variation of CRP (mg/L)	-1.8±13	-15±20	<0.001

PGA-VAS: patient Global Assessment - Visual Analogic Scale

MAJOR ADVERSE CARDIOVASCULAR EVENTS AND MALIGNANCY POST JAK INHIBITORS INITIATION, A 4-YEAR EXPERIENCE FROM QATAR POPULATION

Keywords: Malignancy, Targeted synthetic drugs, Cardiovascular disease

O. Alsaed[1], A. Poil[1], M. Ahmed[1], S. Al Emadi[1]. [1]*Hamad Medical Corporation, Medicine/Rheumatology, Doha, Qatar*

Background: In contrast to ORAL Surveillance data, reports from real world data did not show difference in rates of major adverse cardiovascular events (MACE) and malignancy between tofacitinib and biologic disease modifying anti-rheumatic drugs (b-DMARDs) [1-3].
Objectives: Investigate the rate of MACE and malignancy post janus kinase inhibitors (JAK-i) initiation in Qatar population.
Methods: All JAK-i prescriptions were captured electronically from the database of the pharmacy of Hamad Medical Corporation (HMC) from January 2018 to November 2022. Patients with non-dispensed prescriptions were excluded from the analysis. Electronic medical records of patients who received any class of JAK-i were reviewed retrospectively to identify demographic and clinical characteristics, starting and stopping date of JAK-i, MACE and malignancy events post JAK-i initiation.
Results: 219 JAK-i course therapies (tofacitinib 193, upadacitinib 14 and baricitinib 12) were identified from the database of the pharmacy of HMC. Six patients were excluded from the analysis as they were prescribed with JAK-i but their prescriptions were not dispensed. Five patients received two classes of JAK-i due to treatment failure. Mean (standard deviation [SD]) time of JAK-i exposure was 25 (17) months. A total of 208 patients included in the analysis with mean (SD) age at JAK-i initiation was 45.9 (14) years. Females were 72% of the cohort. JAK-i was prescribed for the following indications: rheumatoid arthritis 129 (60%), psoriatic arthritis 28 (13.1%), alopecia 29 (13.6%), spondyloarthropathy (SPA) 16 (7.5%), inflammatory bowel disease (IBD) 8 (3.8%), other rheumatic diseases 5 (2.3%). Two patients were having IBD with peripheral and axial SPA involvement. In patients with rheumatic diseases, JAK-i was received in 102 (55%) b-DMARDs naïve patients, post one b-DMARDs in 38 (20%) and post ≥ 2 in 46 (25%) patients. The comorbidity profile (hypertension, dyslipidemia, diabetes mellitus, and coronary artery disease) was 27%,25%, 23%, and 5.6%, respectively. New cancer diagnosis (follicular thyroid) was confirmed in one patient post tofacitinib and one patient developed lymphoma relapse after tofacitinib initiation. One ischemic cerebrovascular accident (CVA) identified post tofacitinib initiation. This patient was in atrial fibrillation when CVA occurred. No venous thromboembolism events reported from this cohort.
Conclusion: MACE and malignancy rates are very low in JAK-i users in Qatar population. Comparator group is needed for further evaluation the association of the use of JAK-i and risk of MACE and malignancy.

PREVALENCE OF RISK FACTORS FOR CARDIOVASCULAR EVENTS, MALIGNANCY OR THROMBOEMBOLIC EVENTS IN RHEUMATOID ARTHRITIS UNDER JAK INHIBITORS IN A REAL-LIFE MONOCENTRIC COHORT

Keywords: Comorbidities, Real-world evidence, Safety

I. Giovannini[1], R. Agarinis[1], S. Cacioppo[1], S. Sacco[1], G. De Marchi[1], E. DI Poi[1], A. Zabotti[1], L. Quartuccio[1], S. De Vita[1]. [1]*Rheumatology Clinic, Azienda Sanitaria Universitaria Friuli Centrale c/o University of Udine, Udine, Italy*

Background: Rheumatoid arthritis (RA) is an inflammatory, autoimmune disease, characterized by joint inflammation that can lead to irreversible joint damage and significant disability. The immunomodulatory therapies have dramatically changed the patient management, and the introduction of Janus kinase inhibitors (JAKi) leads the way to an oral, efficacious treatment for RA. Among JAKi, tofacitinib and baricitinib are considered as pan-JAKi (pJAKi) while upadacitinib and filgotinib as selective JAKi (sJAKi) drugs. However, recent safety issue has been highlighted, and the 2022 update of the EULAR recommendations for the management of RA suggests to consider the use of a JAKi only after risk assessment [1].
Objectives: This study aims to describe a monocentric experience of JAKi treatment in RA patients in a real-life setting, focusing on the prevalence of emerging risk factors.
Methods: Patients diagnosed with RA according to 2010 ACR/EULAR criteria and treated in a routine clinical setting with JAKi were retrospectively recruited from our rheumatologic clinic from May 2017 to August 2022. We evaluated the risk assessment according to the 2022 update of the recommendation, as reported below, to describe a real-life experience in the use of JAKi. In details we evaluated: age (over 65 years), smoking status, cardiovascular risk factors (such as diabetes, obesity, hypertension), risk factors for malignancy (current or previous history of malignancy other than successfully treated non-melanoma skin cancer), risk factors for thromboembolic events (history of myocardial infarction or heart failure, cancer, inherited blood clotting disorders or a history of blood clots, as well as patients taking combined hormonal contraceptives or hormone replacement therapy, undergoing major surgery or immobile).
Results: 205 RA patients treated with JAKi were included in our study. 133 underwent pJAK treatment, and 77 underwent sJAK treatment. Overall, 167 JAKi treatments were started in female patients. 128 were positive for rheumatoid factor, and 102 for anti–citrullinated protein antibody. 96/205 JAKi treatments were started in patients over 65 (46,8%), 45 were smokers (22%), 76 presented

cardiovascular risk factors (37%), 20 showed risk for malignancy (9,8%) and 21 for risk factors for thromboembolic events (10,2%). More details are reported in Table 1. At least 2 risk factors were reported in 30,7% of the population, and 11,7% presented at least 3 risk factors.

Conclusion: This study highlights the relative high prevalence of risk factors in a real-life population of RA patients treated with JAKi. The clinical effectiveness of JAKi has already been assessed by clinical trial and real-life experience, whereas the safety issue still remains to be further explored. Further studies are needed to define the RA sub-populations at highest risk for safety, and those patients who could benefit from an early JAKi treatment.

AB0491 COMPARATIVE STUDY ON THE SHORT-TERM EFFICACY AND OUTCOME OF JANUS KINASE INHIBITORS: A SINGLE-CENTER RETROSPECTIVE OBSERVATIONAL STUDY

Keywords: Rheumatoid arthritis, Targeted synthetic drugs, Safety

F. D'alessandro[1], E. Laurino[1], M. Cazzato[1], R. Morganti[2], C. Baldini[1], M. Mosca[1]. [1]*Santa Chiara Hospital, Rheumatology, Pisa, Italy;* [2]*Santa Chiara Hospital, Section of statistics, Pisa, Italy*

Background: In recent years the use of Janus Kinase Inhibitors (JAK-Is) in rheumatoid arthritis (RA) has entered daily practice.In vitro studies they have shown a different selectivity [1], which however has not yet been confirmed in real life studies. Furthermore, considering recent developments, an in-depth study regarding the global safety of these drugs is needed.

Objectives: To address potential differences in the safety of Janus kinase inhibitors and short-term efficacy on disease activity we characterized their safety profile in RA patient population.

Methods: Single center retrospective observational study. The sample consisted of 68 patients receiving any of the following JAK-is: Tofacitinib, Upadacitinib, Filgotinib, Baricitinib, with a mean of 19.3 months of therapy and a diagnosis of RA according to the ACR/EULAR 2010 criteria. We collected and recorded the clinical features; any infections or adverse reactions during therapy; clinimetry at time 0 and at 6 months. For the statistical analysis, the $\chi 2$ (chi-square) test was used to evaluate whether there were statistical differences with respect to categorical variables, Anova one-way to evaluate any statistical difference with respect to continuous variables; mixed effects model and paired t-test for clinimetry comparison.

Results: We found no statistically significant differences between JAK-Is in the following outcomes: symptomatic Covid, p=0.388, new malignancies p=0.348, cardiovascular events p=0.788, thrombocytosis p=0.681, neutropenia p=0.962, lymphopenia p=0.935, anemia p=0.227, need to use glucocorticoids p=0.13, need to use Dmards p= 0.217, permanent discontinuation of therapy = 0.353. In our sample we had only development of 2 cardiovascular events, 1 DVT and a new diagnosis of cancer. Anova one-way showed no difference in the number zoster episodes (p=0.587), or other serious infections (p=0.193). The paired t-test showed that there was a class effect on the reduction of activity indices already after 6 months of therapy (DAS 28 pcr p=0.017, SDAI p=0.054, CDAI p=0.021). However, the mixed effects model showed that there was no molecule more effective in reducing disease activity considering the outcomes at 6 months (DAS 28 pcr p=0.445, SDAI p=0.639, CDAI p=0.467).

Table 1. Correlation with JAK-Is and outcomes.

	Number of events	Correlation with JAK-Is (p value)
Symptomatic covid	19	0.388
New malignancies	1	0.348
Cardiovascular events	2	0.788
DVT	1	0.348
Thrombocytosis	3	0.681
Neutropenia	4	0.962
Lymphopenia	1	0.935
Anemia	20	0.227
Need to use glucocorticoids	29	0.130
Dmard	8	0.217
Permanent discontinuation of therapy	35	0.353
Total number of zoster episodes	45	0.587
Total number of serious infections	60	0.193

Conclusion: The originality of our study was to compare the four different molecules in a real-life study. We prove that JAK inhibition is effective in a real-world population of RA patients. The lack of diversity between JAK-Is in efficacy outcomes, adverse reactions and infections could be explained by considering that their selectivity has only been demonstrated in vitro-studies. Meta-analyses performed on clinical trials confirmed lack of diversity in outcomes [2]. Furthermore, JAK is known to dimerize when activated in biological systems, but the percentage of different dimers is unknown. Therefore, further comparative studies are needed to verify their selectivity in real-life studies.

AB0492 ANEMIA IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH JAK INHIBITORS

Keywords: Rheumatoid arthritis, Targeted synthetic drugs, Safety

Y. Takeuchi[1], M. Konishi[1], H. Hirabayashi[1], M. Tokuda[1]. [1]*Sanuki municipal hospital, Rheumatology, Kagawa, Japan*

Background: Recently, the safety of JAK inhibitors in the treatment of rheumatoid arthritis(RA) about malignancy and major adverse cardiac events has been highlighted [1], but there are still few reports on their effects on anemia. Filgotinib (FIL) is known to be a highly JAK1-selective agent with little effect on EPO-mediated JAK2 signaling [2].

Objectives: We investigated the effect of FIL on anemia in RA patients treated with JAK inhibitors at our hospital, comparing with other JAK inhibitors (non-FIL).

Methods: 73 patients who used 4 JAK inhibitors (filgotinib, tofacitinib, baricitinib, upadacitinib) after 2013 were divided into FIL group (16 patients) and non-FIL group (57 patients) respectively. Hemoglobin (Hb) trends at 3 and 6 months after the start of JAK inhibitors were investigated retrospectively. Subsequently, the investigation was performed with propensity score matching by age, gender, baseline Hb, CRP, s-Cre, presence of anemia treatments, presence of corticosterids/DMARDs, and history of previous bDMARDs/JAK inhibitor use. And, among the FIL group, we also examined whether there was a difference in Hb change depending on the history of JAK inhibitor use.

Results: Hb levels at the baseline were 10.5 g/dl in the FIL group and 11.6 g/dl in the non-FIL group, but there was no significant difference. The patients in the FIL group were significantly more likely to have used bDMARDs, other JAK inhibitors, and anemia treatments on starting FIL. Both at 3 and 6 months, although Hb levels were significantly increased in the FIL group ($P<0.05$), the anemia progressed over time in the non-FIL group despite exclusion of hemorrhagic anemia (Figures 1,2). The results after propensity score matching were also similar ($P<0.05$). There were no differences in CRP or RA disease activity at 0, 3, and 6 months. And then, compared to the FIL group with no history of JAK inhibitor use, the group that switched to FIL as a 2nd JAK inhibitor showed a significant Hb increase ($P<0.05$).

Conclusion: Compared to other JAK inhibitors, FIL did not reduce Hb levels and that could be maintained for a long time. In patients with anemia concerned with JAK inhibitors, switching to FIL is possible to make RA treatment safer and more successful.

AB0493

THE EFFICACY AND SAFETY OF TOFACITINIB IN THE TREATMENT OF DMARDS NAIVE RHEUMATOID ARTHRITIS PATIENTS (EASTERN STUDY)

Keywords: Rheumatoid arthritis, Targeted synthetic drugs

J. Zhao[1], Y. Wang[1], Z. Zhang[1]. *[1]Peking University First Hospital, Rheumatology and Clinical Immunology, Beijing, China*

Background: Janus kinase (JAK) inhibitor is a great addition to the therapeutic options for rheumatoid arthritis (RA). However, the the clinical efficacy and safety of tofacitinib comparing with methotrexate (MTX) was not elucidated.

Objectives: We conducted a controlled randomized clinical trial in treatment naive rheumatoid arthritis (RA) patients to explore the clinical efficacy and safety of tofacitinib (TOFA) comparing with MTX.

Methods: In this open-label, randomized, and controlled clinical trial, treatment naive RA patients at the status of medium or high disease activity [simplified disease activity index (SDAI)>3.3] were randomized at 1:1 ratio into TOFA and MTX groups. Patients in TOFA group received tofacitinib 5 mg twice per day and patients in MTX group received MTX 10-15 mg once per week plus betamethasone 1ml muscle injection at enrollment. The rate of disease activity improvement (defined as SDAI decreased >50% against baseline or at least 10) at week 12 was taken as primary outcome. Patients who did not achieve improvement transferred to the other group. Secondary outcomes included the rates of remission, low disease activity (LDA) and change of disease activity scores.

Results: 100 patients were enrolled in the study with 49 in TOFA group and 51 in MTX group. The improvement rate was much higher in TOFA group than in MTX group [29.3% (12/41) vs 7.5% (3/40), p=0.025]. The rate of remission and low disease activity at week 4 and week 12 were comparable between the two groups. The change of SDAI [17.9 (7.3-30.3) vs 10.8 (5.5-17.4), p=0.062], CDAI [7 (4.8-16) vs 15 (7.5-26), p=0.011], DAS28-CRP [2.1 (1.2-3.4) vs 1.4 (0.7-2.1), p=0.010] and DAS28-ESR [3.8 (2.5-5.2) vs 2.7 (1.8-3.9), p=0.005] at week 12 were all more significant in TOFA group than in MTX group. The total adverse event rate was high in MTX group than in TOFA group [28% (14/50) vs % (4/49), p=0.022]. Considering specific adverse events, the rates of liver damage [16% (8/50) vs 0, p=0.001] and dizzy [6% (3/50) vs 0, p=0.041] were higher in MTX group than in TOFA group.

Conclusion: For treatment naive RA patients, tofacitinib can bring higher rate of improvement of disease activity.

ADIPOSITY SEEMS TO NOT INTERFERE WITH THE JAK INHIBITORS RESPONSE IN RHEUMATOID ARTHRITIS: AN EXPLORATORY STUDY

Keywords: Targeted synthetic drugs, Rheumatoid arthritis, Prognostic factors

E. Tovar-Sugrañes[1,2,3], M. Andrés[1,4], V. Jovani[1,4], S. Gomez-Sabater[1,4], R. Caño-Alameda[1,4], P. Vela Casasempere[1,4]. *[1]Instituto de Investigación Sanitaria y Biomédica de Alicante (ISABIAL), Rheumatology, Alicante (Alacant), Spain; [2]Institut d'Investigació Sanitària La Fe de València, Rheumatology, València, Spain; [3]Hospital la Fe, Rheumatology, Valencia, Spain; [4]General University Hospital of Alicante, Rheumatology, Alacant, Spain*

Background: Cumulative data show how an excess body weight may hamper the activity of some anti-rheumatic drugs in rheumatoid arthritis (RA), but we lack studies in this regard on the new JAK-kinase inhibitors (JAKinibs).
Objectives: To prospectively evaluate the impact of adiposity on the anti-inflammatory response of JAKinibs in RA.
Methods: Observational, prospective, single-center exploratory study. We sequentially included adult patients from tertiary center clinics, with a clinical diagnosis of RA and a new JAKinib prescription by their treating rheumatologists. Only JAKinibs-naïve patients were allowed. For this analysis, during the follow up, csDMARD was required to remain unchanged. Patients participating in weight loss or bariatric surgery programs were also excluded. We used three different definitions for *adiposity*: A) body mass index (BMI), as kg/m2; B) body fat percentage, measured by impedancemetry; and C) blood levels of LDL and HDL cholesterol and triglycerides. We defined dyslipidemia as total cholesterol >200mg/dl and/or triglycerides >150mg/dl at blood tests. The potential modulating effect of adiposity on the effectiveness of JAKinib therapy was assessed on the change of DAS28-CRP and DAS28-ESR between baseline and 3 months later (when the peak action of JAKinibs is theoretically met). ANOVA regression was used to compare changes in DAS28 CRP/ESR regarding adiposity variables. When significant associations were found, a multivariate linear regression model was built. Software R v.4.2.1 was used.
Results: From an initial sample of 20 patients, 4 were excluded from analysis (2 stopping JAKinib due to intolerance, 2 as the cDMARD dose was modified), which finally left 16 participants. Median age was 57years (IQR 50.75 to 65.5) and 75% were females. Four patients were bDMARD-naïve and 9 were on concurrent csDMARD. 75% (n=12) of the subjects received 4mg baricitinib daily, the remaining 4 cases received 15mg upadacitinib daily. Median BMI was 27.7kg/m^2 (IQR 26.25 to 31.38), being 31.5% thus obese. Median body fat percentage was 34.95% (31.38 to 40.55). Ten patients achieved the dyslipidemia cutoff, 75 % of whom received lipid lowering treatment. Patients had mostly moderate-high activity measured by DAS28 at baseline (81.25%), while after 3 months no patient was on high activity and 62.5% and 56.25% (CRP/ESR) showed low activity and remission, respectively. The results for the association analyses between adiposity and changes in DAS28-ESR are given in **Table 1**. No association was found neither for BMI or body fat percentage, while a positive, independent relation with triglycerides was noted (not with LDL o HDL). No adiposity variables were found associated with changes in DAS28-CRP.

Table 1. DAS28-ESR regression analysis. Covariates included on multivariate model were JAKinib choice, time between visits and concurrent cDMARD.

	Univariate		Multivariate	
	β (95%CI)	p	β (95%CI)	p
BMI	-0.019 (-0.397 to 0.048)	0.694		
Body Fat %	-0.050 (-1.353 to 0.037)	0.186		
HDL-ch	-0.026 (-1.812 to 0.014)	0.080		
LDL-ch	0.007 (-0.952 to 0.007)	0.349		
Tryglicerides	0.007 (0.003 to 2.250)	0.032	0.01 (0.004 to 0.015)	0.004

Conclusion: No relevant impact of adiposity was noted on the anti-inflammatory effect of JAKinibs after three months of use in RA patients. Our findings support no dose adjustment for JAKinibs, independently of their weight or adiposity. This study should be replicated in larger studies to confirm our observations.

Background: Rheumatoid arthritis (RA) is a chronic inflammatory/autoimmune arthritis that causes pain, stiffness, swelling, loss of joint function, and a rise in acute-phase reactant levels. Vitamin D(VD) deficiency is linked to RA.
Objectives: The aim of this study was to summarize the association between serum vitamin D levels and RA and systematically evaluate the efficacy of VD supplementation in RA treatment.
Methods: Literature searches were conducted using PubMed, EMBASE, Web of Science, Clinical Trials.gov, Wanfang database, Weipu database, Chinese National Knowledge Infrastructure and Cochrane databases to identify available articles (up to January 1, 2023). Stata v.12.0 was used for the meta-analysis. And the results are presented both tabulated and graphically.
Results: In the study between serum vitamin D levels and RA, 26 studies, including 3,328 patients and 2,223 healthy controls, were identified (Table 2). Compared with the control group, the serum vitamin D level in the RA group was significantly reduced[SMD=-1.523, 95%CI (-1.590,-1.457), P=0.000]. Vitamin D was inversely correlated with disease activity. About the efficacy of VD supplementation in RA treatment, 7 studies comprising 392 patients were identified (Table 1). After the VD treatment, 91.28% of patients had distinct clinical remission, 47.72% were completely cured. After receiving VD therapy, patients with RA had significant decreases in DAS-28[SMD= -2.19, 95%CI (-2.58,-1.80), P=0.000], ESR [SMD=-2.12, 95%CI (-2.50,-1.74), P=0.000], CRP [SMD=- 1.84, 95%CI (-2.22,-1.45), P=0.000], SJC [SMD=-2.53, 95%CI (-2.71,-2.34), P=0.000], TJC [SMD=-3.45, 95%CI (-3.67,-3.23), P=0.000], and the Morning stiffness time [SMD=- 2.32, 95%CI (-2.72,-1.92), P=0.000]. None serious adverse events were reported among all these studies. Meta-analysis of 2 studies, including 420 patients with RA, showed that the incidence of adverse events was 19.46%.
Conclusion: Patients with RA had vitamin D deficiency, which was associated with the activity. Vitamin D supplementation did statistically significantly improve the RA.

AB0496 TREATMENT WITH UPADACITINIB IN RA PATIENTS FOR WHICH BIOLOGICAL THERAPY FAILED

Keywords: Rheumatoid arthritis, Patient reported outcomes, Disease-modifying Drugs (DMARDs)

L. Robles Kirkegard[1], E. Rubio Romero[2], P. León[3]. *[1]Servicio Andaluz Salud, Hospital Universitario Virgen del Roció, Madrid, Spain; [2]Servicio Andaluz Salud, Hospital Universitario Virgen del Roció, Sevilla, Spain; [3]Servicio Andaluz Salud, Hospital Universitario Virgen del Roció, Sevilla, Spain*

Background: Upadacitinib is a JAK inhibitor recently approved for rheumatoid arthritis treatment with promising results in its studies for severe moderate RA for which conventional therapies failed.
Objectives: To study and describe the evolution of patients diagnosed with RA and treated with Upadacitinib who had inadequate response to biological therapy in association or not with DMARDs and GC for 1 year.
Methods: A population of 23 patients (19 of them female) with RA on treatment with Upadacitinib was analyzed over 1 year. Using patient-reported outcomes (PROs) to measure disease activity by visual analogue scale (VAS), the HAQ Disability Index (HAQ-DI), Disease Activity Score (DAS28), and morning stiffness duration. The age´s (average ± SD) = 53 ± 10 years and time of disease evolution (average ± SD) = 17.6 ± 23.3 years. Pretreatment DAS28 was (average ± SD) = 7.32 ± 2.41. The initial VAS was (average ± SD) = 7.32 ± 1.88. HAQ (average ± SD) = 2.2 ± 0.5. All patients received previous biologic treatments and 61% (14 patients) combined therapy with DMARDs. Only 2 cases had no glucocorticoid treatment prior to treatment with Upadacitinib.
Results: In 3 months time, most patients (81%, n = 21) treated with Upadacitinib were able to reduce GC dose, and this reduction was maintained 6 months from the beginning of the treatment. After one year of treatment (n = 14), 71% of patients reduce the dose of GC by 53% with respect to the initial dose. Upadacitinib enabled 50% of patients who initiated treatment to discontinue corticosteroid therapy completely. After 3 months of treatment, most patients experienced an enhancement in DAS28 (89%, n = 18), with an average improvement in DAS28 (average ± SD) = 1.87±1.09 units. After one year of treatment most patients (92%, n = 14) achieve a reduction in DAS28 (average ± SD) = 3.813 ± 1.56 units from baseline. Disease remission (DAS28 <3.2) was achieved in up to 25% of patients who initiated treatment with Upadacitinib. Regarding the pain (VAS), 67% of the patients showed improvement after 3 months (n=18), reaching 71% after 6 months (n=17). After 12 months of treatment (n = 14), 85% of patients experienced an improvement in pain, with the final (average ± SD) VAS being 5 ± 2.32 points. Sixty-eight percent of treated patients showed a reduction in morning stiffness after 3 months (n = 19), and this improvement increased up to 84% of treated patients at 6 months (n = 19) and remained so until 12 months (n = 14). Side effects were observed in five patients, consisting of dizziness and nausea. In no case were they a reason for the withdrawal of the drug. Treatment was withdrawn in three patients due to primary failure.
Conclusion: Treatment with Upadacitinib allows GS dose reduction, as well as an improvement in DAS28, VAS and morning stiffness at three months and six of treatment. These data are in line with the evidence published in Upadacitinib pivotal studies, meaning a good alternative in the treatment of patients with moderate or severe RA.

AB0497 THE ROLE OF CORTICOSTEROIDS (PREDNISONE) IN THE TREATMENT OF NEWLY DIAGNOSED RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis

B. Barac[1,2], A. Zekovic[3], T. Divljakovic[4], S. Lukovic[1], G. Radunovic[2,5]. *[1]Institute of Rheumatology, Clinical V Department, Belgrade, Serbia; [2]University of Belgrade, Faculty of Medicine, Beograd, Serbia; [3]Institute of Rheumatology, Clinical III Department, Belgrade, Serbia; [4]Institute of Rheumatology, Clinical VI Department, Belgrade, Serbia; [5]Institute of Rheumatology, Clinical IVa Department, Belgrade, Serbia*

Background: The use of corticosteroids (CSs) in patients with newly diagnosed rheumatoid arthritis (RA) is important in order to reduce the inflammation as well as bridging until achieving the full effect of the basic therapy. In previous years, there were recommendations for the use of different doses of CSs [1-2].
Objectives: To compare the therapeutic effect of initially higher doses of CSs, prednisone (0.3-0.5 mg/kg) with a standard low-dose daily therapy (7.5 mg) in patients with newly diagnosed RA.
Methods: Two groups of 50 patients each with newly diagnosed RA were followed up for a period of 24 months. The groups were homogeneous in terms of sex, age and BMI. The group one (I) consisted of 50 patients who were initially treated with doses of prednisone 0.3-0.5 mg/kg (average initial dose 25mg) by bridging until achieving the full effect of basic therapy with Methotrexate (MTX) (in an average dose of 15 mg/week). The group two (II) consisted of 50 patients who were treated according to standard recommendations with an initial dose of an average of 7.5 mg of prednisone with MTX in an average dose of up to 15 mg/week. In both groups, the doses of prednisone were gradually reduced over a period of 3-6 months. During a period of 24 months (at 6, 12 and 24 months), the following parameters were monitored in all patients: DAS28, HAQ, VAS, CDAI. We also compared the number of corticosteroid-independent patients after 6, 12 and 24 months in both groups, the percentage of patients in remission (DAS28<2.6) and the percentage of patients with a good EULAR DAS28 response (CRP<3.2 or change in DAS28 by >1.2). The number of newly discovered comorbidities during the mentioned therapy, such as newly discovered hypertension, osteoporosis and diabetes mellitus (DM) type II, was also monitored.
Results: Highly statistically significantly lower values of the DAS28 score ($p<0.01$) were found in the group I of patients, treated initially with higher doses of CS after 6 and 12 months, as well as statistically significantly lower values after 24 months ($p<0.5$). Statistically significantly lower HAQ values were also found in group I after 6, highly statistically significantly lower after 12 and statistically significantly lower after 24 months of follow-up ($p<0.5$). For pain VAS, statistically significantly lower values in group I after 6 and 12 months ($p<0.01$) and statistically significantly lower values after 24 months. CDAI values were also statistically significantly lower in group I after 6 and 12 months. A statistically significantly higher percentage of patients were in remission and had a better EULAR response in the group I after 6, 12 and 24 months from the start of therapy ($p<0.05$). Also in the group I which was initially treated with higher doses of CSs, statistically significantly lower number of patients were corticosteroid-dependent after 6, 12 and 24 months. A special difference between the groups is represented by a highly statistically significantly lower number of comorbidities in group I after 24 months from the start of therapy, such as newly discovered hypertension, DM type II and osteoporosis.
Conclusion: The initial use of higher doses of corticosteroids (0.3-0.5 mg/kg) compared to the recommended daily doses of up to 7.5 mg in patients with newly diagnosed rheumatoid arthritis, provide significantly better clinical response in all the parameters DAS28, VAS, CDAI, HAQ, a higher level of corticosteroid-independent patients as well as a lower number of side effects such as newly discovered hypertension, osteoporosis and diabetes mellitus type II, 24 months after starting basic therapy.

Background: Targeted synthetic therapies brought revolutionary progress in rheumatoid arthritis (RA) management and culminated a paradigm shift over a decade. However, only a subset of patients responded clinically and achieved sustained remission. The interindividual factors may vary resulting in failure of therapeutic target and clinical response.
Objectives: We investigated the clinical and sociodemographic predictors of Tofacitinib response in RA patients at three, six and twelve months.
Methods: This retrospective study included 164 RA patients from the nationwide MARBLE registry who received Tofacitinib. Patients' clinical data were extracted from medical records. The response to Tofacitinib in terms of clinical remission, low disease activity (LDA) and DAS28 improvement (EULAR response) were measured at baseline, 3 months, 6 months and 12 months of therapy based on disease activity score (DAS)28 for RA. Factors predicting treatment response were analysed using binary logistic regression analysis.
Results: Our data revealed that at 3-month, 6-month and 12-month of Tofacitinib treatment, 17.7%(n=29), 67.7%(n=111) and 60.4%(n=99) RA patients achieved low disease activity/clinical remission. Further analysis demonstrated that anti-cyclic citrullinated peptide antibody (anti-CCP)-positivity and joint erosion were independently associated with unsatisfactory EULAR response (ie., anti-CCP at 3-month, OR=2.270, p<0.05; 6-month, OR=7.773, p<0.0001; and 12-month, OR=4.645, p<0.0001). Lower frequencies of clinical remission were associated with the presence of erosive joint throughout the three follow-up periods of treatment (OR=2.040 to 3.868; p<0.05), while only anti-CCP positive was found to be significantly associated with lower frequencies of LDA at 6-month and 12-month of treatment (anti-CCP positive, 6-month OR=3.659, p<0.0001 and 12-month OR=2.130; p<0.0001)
Conclusion: Our data suggest that joint erosion and anti-CCP positivity are strong predictive biomarkers for lower achievement of clinical remission, LDA and satisfactory EULAR response in patients with RA receiving tofacitinib treatment.

AB0499

STEP-DOWN APPROACH IN METHOTREXATE USE FOR THE TREATMENT OF RHEUMATOID ARTHRITIS (STEMETRA): A PILOT STUDY DEMONSTRATING EFFICACY AND SAFETY OF SHORT-TERM HIGH DOSE METHOTREXATE

Keywords: Disease-modifying drugs (DMARDs)

M. Pendolino[1], T. Serban[1], D. Camellino[1], P. Diana[1], A. Giusti[1], G. Bianchi[1].
[1]*S.C. Reumatologia, ASL3 Genovese, Scienze Mediche, Genoa, Italy*

Background: Methotrexate (MTX) is the cornerstone of Rheumatoid Arthritis (RA) treatment, showing a suitable efficacy-safety profile, relatively low-cost, and versatile routes and dosage administration. However, there are no clear indications yet on the optimal use of MTX in RA, whereas existing recommendations disagree on relevant aspects (eg. route, starting and maximal dose, titration increase/decrease, and intervals to monitor toxicity) [1].
Objectives: To evaluate the efficacy and the safety of a step-down strategy to use subcutaneous (sc) MTX in patients with RA.
Methods: STEMETRA is a 16-week open-label, monocentric, pilot study. The protocol treatment schedule consisted of the administration of MTX 50 mg sc/week for 4 consecutive weeks, followed by 25 mg/week for 4 weeks, and then 15 mg/week for 4 weeks. All patients received oral supplementation of folinic acid (leucovorin) 12 mg, 12 hours after the injection of MTX.
Results: Fifteen patients (10 females and 5 males; mean age, 60 years (±11)) diagnosed with RA according to 2010 ACR/EULAR classification criteria and naïve to any RA treatment were enrolled. One patient was lost to follow-up after week 12; 4 patients withdrew because of adverse events; therefore, 10 patients concluded the study. A total of 14 adverse events occurred in 7 patients; 7 were of mild entity and tolerated by patients, 3 solved, and 4 were persistent and lead to withdrawal of the drug (Table 1). Mean DAS28(CRP) at baseline was 5.6 (±1.4), whereas, at week 16, mean DAS28(CRP) was 1.6(±1). Most patients who concluded the study achieved ACR70 response and the state of remission (7 out of 10), whereas 3 still showed moderate disease activity.
Conclusion: In this study, step-down MTX approach was effective in inducing remission in most of the patients enrolled. According to data reported in other studies (2,3), one third of them showed adverse events leading to the withdrawal of the drug. On the contrary, different studies in which MTX was used as in current clinical practice (at lower dosages) showed lower efficacy: in the ORAL START study, ACR70 response was reached only in 12% of naïve patients 6 months after MTX monotherapy (4), whereas in the PREMIER study, 26% of patients receiving MTX monotherapy obtained ACR70 response after one year [5]. Thus, short-term higher dose MTX usage could be more effective in order to reach remission earlier. Nonetheless these results should be confirmed in larger populations of patients. In conclusion, this approach could be considered as a valid regimen for a more optimal use of MTX.

AB0500 STUDY OF THE USE AND PRESCRIPTION OF ANALGESICS DURING RHEUMATOID ARTHRITIS (RA)

Keywords: Rheumatoid arthritis, Pain

A. Rafi[1], Z. Baba[1], S. Zniber[1], A. Mougui[1], I. El Bouchti[1]. *[1]Centre Hospitalo-Universitaire Mohammed VI Marrakech, Rheumatology, Marrakech, Morocco*

Background: In rheumatoid arthritis, pain is the major complaint for patients. Analgesic drugs are considered adjuvant treatments and their prescription is generally left to the patient's discretion.
Objectives: The objective was to determine the actual use of analgesics during RA.
Methods: This is a 5-month cross-sectional survey including patients with rheumatoid arthritis, meeting the ACR/EULAR 2010 criteria consulted during the study period were included The use of analgesics was evaluated via a questionnaire with 14 questions. Data was processed by statistical analysis using SPSS 2021 Software.
Results: There are 168 patients, including 24 men and 144 women. The average age was 49.91± 12.96 [20–90]. The average age at onset was 41.69 ±14.65. The average age of diagnosis for RA was 47.17 ±13.71 years. The average DAS28 was 5.32 ±1.35. Only 89 patients were taking analgesics The majority of patients were on disease modifying drug (DMARD) (78%), 145 (86%) were on corticosteroids, 46 (27.38%) were on non-steroidal anti-inflammatory drugs and 89 (53%) were taking analgesics. At the time of the survey 79 patients were not taking analgesics, 69 patients were taking a Tier 1 analgesic, 20 patients were taking a Tier 2 analgesic, none of the patients were taking a Tier 3 analgesic. Analgesics were never used alone. The difference between a pure analgesic and a non-steroidal anti-inflammatory was only known by 45 patients (27%). The difference between central and peripheral analgesic was only known by 15 patients (9%). For only 25 patients, analgesics were effective on diurnal pain in 25 patients and for 64 patients (72%) on nocturnal pain. Only 14 patients, or 15% were taking pain relievers at a fixed time, 60 (67%) only during flare-ups, and 15 (16%) were taking pain relievers at a fixed time with increased dose in case of flare-ups. The prescription of analgesics was the fact of the rheumatologist in 89% of cases, and self-medication in only 11% of cases.
Conclusion: In RA, as in all chronic painful diseases involving functional prognosis, pain is the essential symptom to treat. In our study the use of analgesics was 53%.

Horcada[1], R. Gutierrez[1], C. Fito-Manteca[1]. *[1]Hospital Universitario de Navarra, Rheumatology, Pamplona, Spain; [2]Hospital Universitario de Arava, Rheumatology, Vitoria, Spain*

Background: Janus kinase (JAK)-inhibitors (JAKi) are anti-cytokine monoclonals against cellular targets and small molecule inhibitors of the JAK pathway approved for the treatment of diverse immune-mediated inflammatory diseases, such as rheumatoid arthritis (RA), spondyloarthritis (SpA) or psoriatic arthritis (PsA). Safety data comes mostly from randomized controlled trials, with scarce long-term registry data. Therefore, we aimed to evaluate the major adverse events in patients treated with Janus kinase inhibitors in various immune-mediated inflammatory diseases (RA, PsA and SpA).
Objectives: To evaluate adverse events in patients treated with Janus kinase inhibitors in various immune-mediated inflammatory diseases (RA, PsA and SpA).
Methods: We reviewed 203 patients in Rheumatology department at Navarra University Hospital who underwent treatment with JAKi (Baricitinib, Filgotinib, Tofacitinib and Upadacitinib) and the significant adverse events occurred.
Results: Of our sample of 203 patients, 81,2% were diagnosed RA, 8,8% with PsA, 7,5% with SpA and the remaining 2,5% were indeterminate arthritis. We found that out of the patients diagnosed with RA, 10,83 % had a significant adverse event (22 events in total). A 0,5% had a myocardial infarction, 1,5% stroke, 2,1% arterial thrombosis, 2,1% venous thrombosis, 1,5% developed some type of malignancy and 3,6% reactivation of herpes zoster. One arterial thrombosis happened in the indeterminate arthritis group.
Conclusion: In our series, out of 203 patients treated with JAKi, 11,33% had a significant adverse event. The most common adverse event was the herpes zoster reactivation (3,44%), followed by arterial and venous thrombosis (2,46 and 1,97% respectively). Longer-term follow-up and greater number of patients are necessary to ratify these data.

AB0502 PREVALENCE AND ASSOCIATED FACTORS FOR CONVENTIONAL DISEASE MODIFYING ANTI RHEUMATOID DRUG FAILURE IN PATIENTS WITH RHEUMATOID ARTHRITIS IN A TERTIARY CARE HOSPITAL IN SOUTHERN SRI LANKA

Keywords: Treat to target, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

A. Ediriweera[1], S. Fernando[2], N. Dias[2], R. Hegodaarachchi[2], G. Udumalagala Gamage[1], A. Iranga[2], K. Deshapriya[2]. *[1]Teaching Hospital Karapitiya, Rheumatology and Rehabilitation, Galle, Sri Lanka; [2]Teaching Hospital Karapitiya, Rheumatology and Rehabilitation, Galle, Sri Lanka*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease of unknown etiology marked by a symmetric, peripheral polyarthritis. It is the most common form of chronic inflammatory arthritis and often results in joint damage and physical disability [1]. Among limited studies available in Sri Lanka the community prevalence of early rheumatoid arthritis is 0.7% [2].
Treatment should be aimed at reaching a target of sustained remission or Low Disease Activity (LDA) in every patient [3]. Achieving this target begins with convensional disease modyfying antirheumatic drugs (cDMARDS) and only limited number of biological DMARDS (bDMARD) is available in Sri Lanka.
DMARD failure is a recognized problem in treating patients with rheumatoid arthritis. The poor response to cDMARDs once assessed in individual basis has variety of causes. The next step in managing patients with cDMARD failure is to offer bDMARDs. Biological DMARDs are expensive and give a major cost impact to the health budget especially during the background of economic crisis and the shortage of medicinal drugs. Knowing the prevalence of cDMARD failure is helpful in estimating costs for bDMARDs.
Objectives:
1. To describe the prevalence of cDMARD failure among patients with RA attending the Department of rheumatology and rehabilitation- Teaching Hospital Karapitiya, Galle, sri Lanka
2. To determine the factors associated with cDMARDs failure
3. To describe the distribution of side effects of cDMARD

Methods: This study was carried out in 429 patients with RA attending a Department of Rheumatology & Rehabilitation, Teaching Hospital Karapitiya, Southern Sri Lanka. Disease activity was measured by DAS28 of which moderate or high disease activity taken as a cDMARD failure sample and compared with non-failure sample (low disease activity/remission) to assess possible associated factors for poor response.
Results: Twenty-five point two out of 100 patients (25.2%) were found to have failed respond to cDMARDs, and females showed higher failure rate (17.2%) than males (4.2%). Except for 2.9% of those, all the others had been offered Methotrexate. Discontinuation of methotrexate due to side effects were observed in 5.7% in failure sample. Factors such as age, disease duration, education level, smoking had no significant impact on failure rate.
Conclusion: This study gives an insight to cDMARD failure prevalence which enables to predict the need of biologic DMARDs and impact on health budget. Furthermore, introduction of proper patient education program either individually or as groups would have account for minimum drug discontinuation which in turn

helps with good response rate for cDMARDs. Introduction of injectable version of methotrexate could have helped in some intolerable side effects of methotrexate however, efficacy of this measure will depend on several factors such as cost, willingness of patients to self-inject etc. Finally, conventional DMARDS still play a significant role in the management of this debilitating disease with a comparatively low cost and an acceptable side effect profile.

AB0503 GENICULAR ARTERY EMBOLIZATION IN THE MANAGEMENT OF PERSISTENT JUVENILE IDIOPATHIC ARTHRITIS OF THE KNEE: A CASE REPORT

Keywords: Synovium, Non-pharmacological interventions, Inflammatory arthritides

M. Badii[1], D. Parhar[2,3], S. Badii[4], D. Liu[5,6]. [1]*The University of British Columbia, Medicine/Rheumatology, Vancouver, Canada;* [2]*The University of British Columbia, Radiology, Vancouver, Canada;* [3]*Harvard University, TH Chan School of Public Health, Cambridge, United States of America;* [4]*Canada's Michael Smith Genome Sciences Centre, Computational Science, Vancouver, Canada;* [5]*The University of British Columbia, Radiology, Vancouver, Canada;* [6]*University of Miami, Miller School of Medicine, Miami, United States of America*

Background: Genicular artery embolization (GAE) is rapidly gaining popularity for treatment of patients with recurrent hemarthrosis following knee arthroplasty, and for pain relief in mild-to-moderate osteoarthritis (OA) [1]. Despite the growing evidence of the safety and efficacy of GAE in improving pain and disability in OA, it has yet to be reported in the treatment of patients with inflammatory arthropathy, such as rheumatoid arthritis (RA) or juvenile idiopathic arthritis (JIA).

Objectives: To apply GAE on an adult patient with oligoarticular JIA of the knee and refractory to biologic therapy, and measure improvement of pain symptoms.

Methods: A 40-year-old woman with history of oligoarticular JIA presented with progressively worsening right knee pain and swelling. She had tried several treatments in the past including oral analgesia (NSAIDS, acetaminophen, and opioids), multiple intra-articular steroid injections, therapeutic arthrocentesis, multiple DMARDs (MTX, SSZ, LEF), and had been on biologic therapy (adalimbumab) for the past 8 months, with no noticeable improvement from any of these strategies. Prior to GAE she had pain score of 8/10 on VAS, and Oxford Knee Score (OKS) of 25. The GAE procedure was subsequently performed on an outpatient basis under conscious sedation. A four French angled tip catheter was advanced into the distal SFA and angiography was performed. This demonstrated characteristic synovial hyperemia ("blush") of the synovium along the medial joint space supplied by the musculoarticular branch of the descending genicular artery (DGA), as well as the lateral synovium supplied by the inferior lateral genicular artery (ILGA). Super-selection of the DGA was performed using a 1.9 French microcatheter, with repeat angiogram confirming synovial hyperemia. After administration of intra-arterial nitroglycerin, the DGA was then embolized with 1.0 cc of 100 – 300 µm Embospheres (Merit Medical Systems, South Jordan, UT). Post-embolization super-selective angiogram confirmed a "pruned-tree" appearance of the DGA branches, with no further hyperemia, in keeping with a successful embolization.

Results: The patient tolerated the procedure well and was discharged home same-day. At 6 and 12 months follow-up, the patient continued to report substantial improvement in her symptoms with a pain rating of 1 out of 10 on both rest and mobalization. Her OKS was 35 at 12 months. Her right knee remained in remission on Adalimumab for 12 months post procedure. Figure 1 shows the comparison of the pre and post GAE fat saturated T1 image. Pre GAE, there were synovial thickening and enhancement of the knee capsule. As shown in Figure 1, at 12 months post GAE significant retraction and devascularisation of the synovium has occurred.

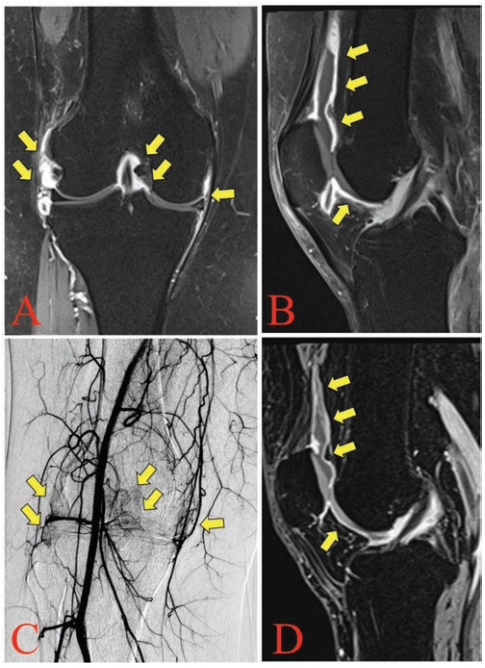

Figure 1. Modulation of Synovitis Pre and Post GAE: Pre GAE sagittal and coronal post contrast (gadolinium) fat saturated T1 image demonstrated synovial thickening and enhancement of the knee capsule (A+B). Coronal digital subtraction angiogram demonstrating corresponding arterial neovascularization/synovitis blush targeted by GAE (C). Post GAE (12 month) sagittal post contrast (gadolinium) T1 fat saturated image demonstrating significant retraction and devascularisation of the synovium (D).

Conclusion: We report the first case of GAE in a patient with inflammatory arthropathy, which showed dramatic and sustained reduction in pain. Though the efficacy, safety, and long-term clinical durability still need further evaluation in the context of inflammatory arthropathy, the positive result in this case posits an exciting avenue for further investigation into the role of transarterial embolization in rheumatologic disease.

AB0504 CARDIOVASCULAR AND ADVERSE EVENTS RISK WITH TOFACITINIB IN RHEUMATOID ARTHRITIS IN THE DOMINICAN REPUBLIC

Keywords: Targeted synthetic drugs, Rheumatoid arthritis, Cardiovascular disease

R. A. Alvarez Santana[1], D. Garcia[1], L. Perez[1], T. Polanco Mora[1], L. Concepción Sanchez[1], I. Paulino[1], I. Mercedes[1], E. Rodriguez Bautista[1], T. Valdez[1], A. Feriz[1], R. Muñoz Louis[1]. [1]*Hospital Padre Billini, Rheumatology, Santo Domingo, Dominican Republic*

Background: Rheumatoid arthritis (RA) is a systemic autoimmune inflammatory disease that affects the synovial membrane of small joints. Tofacitinib (TOF) is the first Janus Kinase Inhibitor (JAKi's) approved by the European Medicines Agency and the Food and Drug Administration for the treatment of RA. This inhibits JAK1 and JAK3 involved in cytokine signaling proinflammatory in RA. Concepcion et al. [1] found that 16% of the patients on TOF presented adverse effects (AEs) and the most frequent of these was dyslipidemia, followed by elevated liver enzymes. Ytterberg et al found an increased risk of MACE with the use of tofacitinib recently [2].

Objectives: To evaluate the risk of cardiovascular and adverse events with tofacitinib in rheumatoid arthritis.

Methods: Retrospective, longitudinal, descriptive. Records from the database of the Rheumatology service of the Hospital Docente Padre Billini were reviewed between January 2016 and December 2021. Inclusion criteria: ≥18 years, diagnosis of RA according to the ACR/EULAR 2010 criteria, TOF 5mg every 12h ≥ 3 months. Exclusion criteria: patients with ≤ 3 months of treatment, history of cardiovascular event, liver disease, moderate anemia, severe neutropenia, history of herpes, absence of > 2 visits. A descriptive analysis of AEs and Major Adverse Cardiovascular Events (MACE) were performed using SPSSv23.
Results: 215 met inclusion criteria. 87% (187) female. Mean age 57 + 11.5 years. Mean disease duration 7.6±2.3 years. HTA 49.8% (107), IMC>30 kg/m2 12.6% (27), DM 11.6% (25). Mean treatment with TOF 5±1.7 years. AEs and MACE 54%(101). AEs 73.3%(74): Hypercholesterolemia 26.7% (27), ALT or AST >3ULN 12.9% (13), herpes virus infection 8.9% (9), PMN: >500 8.9%(9), < 500: 7.9% (8), UTI 4.0% (4), severe anemia 4.0% (4). MACE 26.7%(27): mean age 60.2 + 9.1 years [Acute myocardial infarction (AMI) 63%(17), deep vein thrombosis 29.6%(8), cerebrovascular accident 7.4%(2)].
Conclusion: In our review, AEs were found in half of the patients evaluated. Most of MACE events were associated with older age; the most frequent was AMI. Infections were found in a lower proportion. Little risk of infectious processes is demonstrated with the use of TOF. We must take precaution in those over 55 years of age and with cardiovascular risk comorbidities with the use of TOF consistent with that reported in the world literature.

AB0505 INTEGRATIVE MEDICINE APPROACH TO SUSTAIN LONG-TERM CONTROL IN CHRONIC RA: AN OBSERVATIONAL PROSPECTIVE STUDY OF A COMBINATION REGIMEN OF CONVENTIONAL DMARD AND AYURVEDIC HERBAL DRUG

Keywords: Tapering, Rheumatoid arthritis, Safety

M. Saluja[1], K. Adam[1], R. Patil[1], A. Chopra[1]. [1]*Center for Rheumatic Diseases, Rheumatology, Pune, India*

Background: Prolonged drug treatment in RA is complicated by related toxicity, inadequate efficacy, other health issues, cost, and compliance. Ayurveda (India) drugs (Ayur) have popularly treated arthritis since ancient times. Few controlled/extended drug studies, both as mono or combination (Ayur plus modern medicine/M-Med) showed impressive outcomes (especially safety). In 2018, we introduced limited integrative treatment in rheumatology practice (community) to improve the outcome of long-drawn chronic RA. We present preliminary experience.
Objectives: To evaluate the one-year outcome of a combination treatment of conventional DMARD with standardized Ayur (herbal drug)
Methods: Consenting patients of chronic RA and clinically well-controlled disease (last 6 months) were selected in no particular order; supervised ongoing standard care with DMARD with/without steroids (previous period, median 5.5 years). SC-1 (Ayur) was added in a fixed stable dose (1 gm tablet, bid); standardized medicinal plant extracts (1 tab contained 50 mg Withania somnifera, 500 mg Boswellia serrata, 50 mg Curcuma longa, 400 mg Phyllanthus emblica), as per Ayurveda pharmacopeia. M-Med (RA) were adjusted at 12-16 weeks intervals based on clinical judgment. Standard follow-up (FU) procedures included a predetermined routine drug toxicity checklist. An Excel (Microsoft) based analysis was performed; standard deviation in parentheses, single sample paired T-test (P, two-tailed). Disease activity was classified according to the standard DAS 28 score. 453 patients qualified (one-year uninterrupted combination treatment and sufficient data) for analysis: 32% remission, 38% low activity (LDA), and 30% borderline moderate activity (MDA). Six months prior, 51% of the latter cohort (mean DAS=3.33 (0.95) were in remission/LDA.
Results: At baseline, the median of age and RA symptom duration respectively was 56 years (12.5) and 11 years (7.4); 80% seropositive RF; 91 % erosive/RA deformity; mean pain VAS(10 cm line)=2.78(1.23), mean HAQ (validated Indian version, maximum score 24)=3.17 (2.95), mean DAS 28= 2.9(0.76), 47% steroids (mean daily dose ≤5 mg pred), median ESR=30(19.4), 22% Hydroxychloroquine, 22% Sulfasalazine,74% Methotrexate (mean 16.3 mg weekly (4.48), and Combo DMARD 23%. At 1 year FU, 57% were in remission, 31% in LDA, and 12 % MDA; median ESR=30 mm (18.8), mean DAS= 2.35 (0.87) (p=0.000), 14% Sulfasalazine, 18% Hydroxychloroquine, 49% steroid, 70 % Methotrexate (mean 15.5 mg (4.6). Though statistically significant, several changes (core variables) were small and clinically considered unimportant. 32% cohort reported brief arthritis flares (1-3) versus 40% in the previous year. 409 clinical adverse events/AE (none serious/hospitalization) were reported during the study period; 121 non-related (drugs), 68 unspecified drugs, 34 Hydroxychloroquine, 25 Sulfasalazine, 136 Methotrexate, and 21 SC-1 (mostly gut and dyspepsia, infrequent mild transaminitis); correspondingly 472 AE were reported in the previous year (non-SC-1). FU data will be presented. The absence of control, placebo response, and floor and ceiling effect (outcome) may complicate the clinical interpretation of the results. Patients continued to be followed till date.
Conclusion: SC-1 (Ayurveda) further improved disease control, albeit modest, and safety in long-drawn chronic RA when combined with ongoing standard modern drugs under prolonged rheumatology care. This augurs well for the future. But first, controlled evaluation (integrative medicine) studies are warranted.

AB0506 DOES JANUS KINASE INHIBITOR INCREASE THE RISK OF HERPES ZOSTER IN PATIENTS WITH RHEUMATOID ARTHRITIS IN SAUDI ARABIA? A MULTICENTER RETROSPECTIVE COHORT STUDY

Keywords: Rheumatoid arthritis, Safety, Infection-related RMDs

O. Abudaowd[1], S. Attar[2], F. Ahmed[3], G. Salama[4], H. Almoallim[5], R. Kaki[3]. [1]*King Faisal Specialist Hospital and Research Center, Internal Medicine, Jeddah, Saudi Arabia;* [2]*King Abdulaziz University Hospital, Internal Medicine, Division of Rheumatology, Jeddah, Saudi Arabia;* [3]*King Abdulaziz University, Department of Infectious Disease and Department of Infection Control and Environmental Health, Jeddah, Saudi Arabia;* [4]*Al Azhar University, Rheumatology, Asir, Saudi Arabia;* [5]*Umm Alqura University, Medicine, Division of Rheumatology, Makkah, Saudi Arabia*

Background: Currently, there is an advancing interest in the Janus kinase (JAK) intracellular pathway since targeted inhibitors are proving to be excellent in the treatment of Rheumatoid arthritis (RA). Nevertheless, this new therapeutic era of small molecules comes at a cost, JAKi is associated with a heightened risk of reactivation of dormant infections herpes zoster (HZ) virus infection. Furthermore, the incidence of HZ in rheumatoid arthritis using JAKi is higher in eastern Asian countries making this study essential for the assessment of its safety among the middle eastern population in a real-world setting.
Objectives: To evaluate the risk of serious infection (SI) and herpes zoster (HZ) in rheumatoid arthritis patients receiving JAK inhibitors.
Methods: Multicenter retrospective cohort study in Saudi Arabia. Rheumatoid arthritis patients aged 18 and above from the period of 2007-2022 were included. Medical records were reviewed, and patients were phone interviewed during 2022 to register an outcome of HZ infection. Chi-square was used to assess for the correlation between various risk factors and HZ infection.
Results: From a total of 308 patients, 108 were on JAKi. JAKi didn't significantly increase the risk of HZ development (OR1.97, 95% CI 0.71- 4.67). Rather, patients on Etanercept had higher risk of HZ (OR 2.88, 95% CI 1.65-2.83). 3 out of the 7 cases who developed HZ were on chronic corticosteroid. However, it wasn't significantly associated with HZ devolvement. Patients with Asian ethnicity were significantly more predisposed to HZ infection (OR 1.2, 95% CI 0.8-4.37). None of the patients received the vaccine prior to HZ infection.
Conclusion: In this multicenter study in Saudi Arabia, JAKi were not associated with the development of HZ among Rheumatoid Arthritis patients in real world setting. Asian ethnicity and etanercept usage were significantly associated with HZ infection.

AB0507 FILGOTINIB MAY BE USEFUL THERAPY FOR RAPID RADIOGRAPHIC PROGRESSION BY REDUCING BONE EDEMA

Keywords: Targeted synthetic drugs, Rheumatoid arthritis

K. Katayama[1], K. Tanaka[2], T. Kawahata[2], M. Yuichi[3], T. Okubo[4], T. Sato[1], S. Abe[5], H. Ito[5]. [1]*Katayama Orthopedic Rheumatology Clinic, Rheumatology, Asahikawa, Japan;* [2]*Asahikawa Medical University, Division of Metabolism and Biosystemic Science, Gastroenterology, Hematology/Oncology, Department of Medicine, Asahikawa, Japan;* [3]*Asahikawa Medical University Hospital, Department of Medicine, Division of Rheumatology, Asahikawa, Japan;* [4]*Katayama Orthopedic Rheumatology Clinic, Radiology, Asahikawa, Japan;* [5]*Asahikawa Medical University, Department of Orthopedic Surgery, Asahikawa, Japan*

Background: Filgotinib is well-known to inhibit bone destruction in patients with RA, particularly those with poor prognostic factors. Recently, Filgotinib, especially at dose 200mg/d has been reported to have good results to inhibiting joint damage in patients with rapid radiographic progression (RRP) condition compared to non-RRP condition in post-hoc study of Finch1(Methotrexate (MTX) iR) or Finch 3(MTX naive) trial [1]. However, little has been reported about the joint protective activity by Filgotinib in the real world. On the other hand, we previously demonstrated that extensive MRI bone edema (BE) in the hand is a prognostic factor for RRP [2].
Objectives: To clarify, filgotinib action for inhibiting RRP, 10 patients who have extensive BE in hands or feet are analyzed for radiographic study for joint destruction from 32 patients treated with Filgotinib+MTX.
Methods: All 32 patients with inadequate response to MTX/Biologics/JAKi who were treated with filgotinib were examined to check for extensive BE in their most painful joints before treatment by MRI(Canon,1.5T).
Blood examination, DAS28-ESR, patient pain and doctor's VAS, mHAQ were routinely examined.
Results: As shown in Table 1, most of the patients were treated with filgotinib 200mg/d +MTX. Patients 1-4 (12 months) and patients 5,6 (2-3 months) had extensive BE in hand and RRP condition at baseline. Finally, the RRPs in all patients improved and BE almost disappeared (patients 1,2). Especially, patient 5 suffered severe BE and RRP during 4 months who was treated with IL-6inhibitor +MTX6mg/w, are tremendously recovering by filgotinib and denosumab (for osteoporosis) from severe joint damage (Figure 1). Patients 7-10 had extensive BE in mid-tarsal (2), toe (1), shoulder (1) and patients 7-9 had disappeared BE and symptoms and patient 10 had disappeared pain (not MRI checked). Finally, most of the patients showed clinical improvement (DAS28-ESR, VAS,HAQ).
Conclusion: Filgotinib (200mg/d)+MTX may be useful therapy for RRP by reducing BE.

AB0508 EFFICACY OF SULFASALAZINE MONOTHERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO HAD FACTORS ASSOCIATED WITH PREFERENCE FOR SULFASALAZINE OVER METHOTREXATE AS THE FIRST-LINE DRUG

Keywords: Rheumatoid arthritis

K. Hattori[1], Y. Kanayama[1]. [1]*Toyota Kosei Hospital, Orthopaedics, Miyoshi, Japan*

Background: Methotrexate (MTX) is the first-line drug in treating patients with rheumatoid arthritis (RA) [1], while some patients have baseline factors and comorbidities which discourage use of MTX. While treatment with sulfasalazine (SSZ) is often performed in these cases, the efficacy of SSZ monotherapy was not well evaluated using recent disease activity assessment measures such as DAS28-CRP, CDAI and HAQ-DI.
Objectives: The aim of this research is to evaluate the efficacy of SSZ monotherapy in RA patients who had baseline factors and comorbidities associated with preference for SSZ over methotrexate as the first-line drug.
Methods: 78 treatment-naïve RA patients who started treatment with SSZ were included. We compared outcomes of SSZ monotherapy in patients with and without each of the following baseline factors and comorbidities: age 75 years or more, seronegative RA, moderate disease activity or less (DAS28-CRP, CDAI and HAQ-DI), and presence of comorbidities in lung, renal and liver.
Results: Baseline disease activity was higher among patients with 75 years old or more compared with those with under 75 years old (DAS28-CRP as 4.9 and 3.9, CDAI as 24 and 17 and HAQ-DI as 1.4 and 0.8), while those were similar at week 24 (DAS28-CRP as 3.3 and 3.2, CDAI as 14 and 12 and HAQ-DI as 0.8 and 0.5). There was no significant difference in disease activity at baseline and week 24 regardless seronegative or seropositive RA. There were also no significant differences in disease activity at baseline and week 24 regardless presence or absence of comorbidities in lung, renal and liver. Disease activity at week 24 tended to be high among patients with high disease activity at baseline comparing to those with moderate or less disease activity at baseline, whereas no statistically significant difference was observed (baseline DAS28-CRP as 5.0 and 3.3 and DAS28-CRP at week 24 as 3.5 and 2.9).
Conclusion: SSZ was similarly effective in treating elderly RA patients, patients with seronegative RA and RA patients with comorbidities in lung, renal and liver, comparing in treating those without any baseline factors and comorbidities.

AB0509

CLINICAL EQUIVALENCE OF GENERIC AND BRANDED TOFACITINIB IN REAL-WORLD: A PROSPECTIVE LONGITUDINAL COHORT STUDY IN RHEUMATOID ARTHRITIS PATIENTS

Keywords: Real-world evidence, Rheumatoid arthritis

J. Zhao[1], H. Huang[1], Z. Zhang[1]. *[1]Peking University First Hospital, Rheumatology and Clinical Immunology, Beijing, China*

Background: The efficacy and safety of Xeljanz® have also been confirmed in RA patients. Varieties of generic tofacitinib have been developed in different countries. However, there is no study comparing the efficacy and safety between generic and brand-name tofacitinib yet.
Objectives: In the current study, we compared the efficacy, safety, and cost-effectiveness between a Chinese generic tofacitinib Kelejia® and the brand-name tofacitinib Xeljanz® in RA patients from a prospective real-world cohort.
Methods: RA patients receiving tofacitinib, either generic (Kelejia®, generic group) or branded (Xeljanz®, branded group) were enrolled. All the patients were followed up until the discontinuation of tofacitinib or last visit. Primary outcome was simplified disease activity index (SDAI) defined remission rate at month 6. Secondary outcomes included the rates of remission and low disease activity (LDA) defined by other composite scores; EULAR response rate and ultrasonic synovitis scores at month 1, 3, 6 and 12. Cost-effectiveness was investigated. Propensity score-based inverse probability of treatment weighting (IPTW) was adopted to reduce selection bias.
Results: 204 patients were enrolled, with 59 in generic group and 145 in branded group. The SDAI defined remission was achieved in 41.1% and 39.2% patients in generic group and branded group at month 6, respectively (p=0.854). The rates of remission and LDA achievement, the changes of clinical disease activity scores, power doppler (PD) and gray scale (GS) synovitis scores at months 1, 3, 6 and 12 from baseline were all comparable between two groups. Similar proportions of patients in two groups achieved moderate/good response. Rates of drug retention (78.0% vs 77.2%, p=0.911) and adverse effect (5.1% vs. 4.8%, p=1.000) were also similar in two groups. Both Kelejia® and Xeljanz® were cost-effective, but Kelejia® had lower average cost-effectiveness ratio.
Conclusion: Generic tofacitinib (Keljia®) showed equivalent clinical efficacy and safety, and better cost-effectiveness comparing with its originator (Xeljanz®). Keljia® can be an alternative to brand-name Tofacitinib.

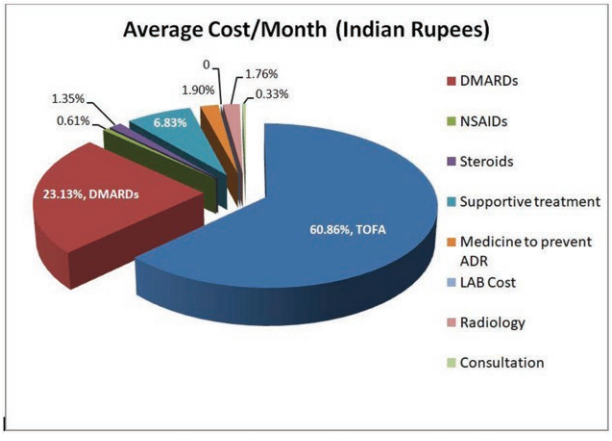
AB0510

COST-EFFECTIVE ANALYSIS OF GENERIC TARGETED SYNTHETIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUG - TOFACITINIB IN RHEUMATOID ARTHRITIS (TIRA CEA STUDY)

Keywords: Rheumatoid arthritis, Targeted synthetic drugs



D. Syngle[1], I. Verma[2], K. Chauhan[3], S. Patyal[3], A. Syngle[3,4]. *[1]Healing Touch Foundation, Research & Innovations, Chandigarh, India; [2]MM College of Pharmacy, MMU, Pharmacy Practice, Mullana, India; [3]Healing Touch City Clinic, Internal Medicine & Rheumatology, Chandigarh, India; [4]Fortis Hospital Mohali, Internal Medicine & Rheumatology, Sahibzada Ajit Singh Nagar, India*

Background: With the introduction of generic version of tsDMARD tofacitinib in different parts of the world, its important to perform a cost-effective analysis of introducing generic tofacitinib to the current treatment sequence for patients with moderate-to-severe rheumatoid arthritis who have inadequate response or intolerance to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs-IR).
Objectives: Perform pharmacoeconomic analysis of introducing generic tofacitinib into the current treatment sequence for patients with moderate-to-severe rheumatoid arthritis who are csDMARDs-IR.
Methods: A prospective, observational study was conducted in 55 consecutive RA Indian patients (Table 1) meeting 2010 Rheumatoid Arthritis Classification Criteria with active disease and an inadequate response or intolerance to conventional disease-modifying antirheumatic drugs randomized to receive tofacitinib 5 mg bd as an add on therapy. All study patients attended the rheumatology OPD with 3 months follow-up. Average cost effectiveness analysis was done by taking HAQ-DI score as a measure of effectiveness. Total cost estimation included cost of the treatment, monitoring cost and adverse effect management.

Table 1. Demographic, clinical and biochemical characteristics of 55 Rheumatoid Arthritis patients

Age (years)	54.93 ± 8.92
Gender: M/F (n)	10/45
BMI (kg/m^2)	24.52 ± 4.58
Disease Duration (yrs)	14.11 ± 6.96
RF Positive	27 (49%)
Anti CCP	12 (21%)
Systolic Blood Pressure (mm Hg)	125.0 ± 10.34
Diastolic Blood Pressure (mm Hg)	84.56 ± 10.44
Disease Duration (years)	5.78 ± 4.84
ESR (mm 1st hr)	36.86 ± 16.47
CRP (mg/dl)	18.47± 19.19
DAS-28	5.31 ± 2.16
HAQ-DI	1.39 ± 0.60

Results: RA patients included in study had established disease with 18.18% males and 81.81% females and 49% were seropositive. Majority of the study RA patients (89%) were on a background regimen of two synthetic DMARDs (MTX and HCQ-80%, MTX and LEF-5.45%, SSZ and HCQ-3.63%,) and 1.81% of the RA patients were on a combination of three sDMARDs. After 3 months treatment with generic tofacitinib and other csDMARDS, the DAS-28 score improved from 5.31 ± 2.16 to 3.81±1.21, p≤0.001 and the mean disability index estimated by HAQ-DI reduced from 1.39± 0.60 to 0.62 ± 0.37, p<0.001. The direct medical cost of treatment of RA per month is 3032.81 rupees (34.39 Euro or 37.31 USD). The average cost effectiveness ratio for the treatment with generic tofacitinib and continuing the use of csDMARDs was Rs 3,938.71 (equivalent to 44.67 Euro or 48.48 USD) to gain or improve one unit of HAQ-DI score. Cost percentage for each head is depicted in Graph 1.
Conclusion: Treatment with generic tofacitinib is effective to control the disease activity and improves disability in RA. Incorporating generic tofacitinib into the csDMARD treatment sequence in active RA patients who have inadequate response or intolerance to csDMARDs is effective to improve the disability index. These results, reflecting the additional costs associated with deteriorating health condition, support the importance of using generic tofacitinib.

Vincent[2], D. Martin[2], M. Chu[5]. *[1]Metroplex Clinical Research Center, NA, Dallas, United States of America; [2]Pfizer Inc, NA, Cambridge, United States of America; [3]Pinnacle Research Group, LLC, NA, Anniston, United States of America; [4]Clinical Research of West Florida, NA, Clearwater, United States of America; [5]Pfizer Inc, NA, Collegeville, United States of America; [6]Pfizer Inc, NA, Groton, United States of America*

Background: PF-06835375 is a humanised, afucosyl IgG1 antibody selective against C-X-C chemokine receptor type 5 (CXCR5), a receptor expressed on B cells, bona fide T follicular helper (Tfh) cells and circulating T follicular helper-like (cTfh) cells. PF-06835375 is in development for autoimmune diseases through depletion of CXCR5-positive B and Tfh cells and antagonism of C-X-C motif chemokine ligand 13-dependent signalling.
Objectives: This first-in-human study evaluated the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of PF-06835375 in patients with seropositive systemic lupus erythematosus (SLE) or rheumatoid arthritis (RA).
Methods: This multi-centre, double-blind, placebo-controlled Phase 1 study enrolled patients aged 18–70 years with seropositive SLE (diagnosed by Systemic Lupus International Collaborating Clinics classification criteria, and positive anti-nuclear antibody titres ≥1:80 and/or anti-dsDNA and/or anti-Smith antibodies) or RA (diagnosed by 2010 ACR/EULAR criteria and positive rheumatoid factor and/or anti-citrullinated peptide antibody), with no minimum disease activity requirement. Patients were randomised to intravenous (IV) PF-06835375 (0.03, 0.1, 0.3, 1, 3 or 6 mg) or placebo in 6 sequential single ascending dose (SAD) cohorts, or to subcutaneous (SC) PF-06835375 (0.3, 1, 3, 6 or 10 mg) or placebo administered on Days 1 and 29 in 5 multiple ascending dose (MAD) cohorts. Pre-and post-dose corticosteroids were permitted to manage infusion or injection reactions at the investigator's discretion. Primary endpoints were incidence of treatment-emergent adverse events (TEAEs) of all casualties, infections and laboratory, vital sign and electrocardiogram (ECG) abnormalities. Secondary endpoints were PK parameters, change in circulating CXCR5-positive B- and cTfh-cell counts and incidence of anti-drug antibodies (ADAs).
Results: In total, 74 patients were randomised and 73 were treated (SAD cohorts: SLE, n=17; RA, n=14; MAD cohorts: SLE, n=22; RA, n=20). Corticosteroids were given in PF-06835375 3 and 6 mg IV cohorts and 3, 6 and 10 mg SC cohorts. Mean (standard deviation) age was 53.3 (10.7) years. Most patients were female (n=65, 89.0%) and White (n=54, 74.0%). In total, 62 patients (84.9%) experienced TEAEs; most were mild or moderate. Serious adverse events were reported in 3 patients (9.7%). One patient (1.4%) discontinued due to a TEAE of disease progression (placebo SC cohort). The most common TEAEs were headache (n=18, 24.7%), pyrexia (n=11, 15.1%) and urinary tract infection (n=9, 12.3%). All infections were mild or moderate. Laboratory abnormalities (placebo IV SAD, PF-06835375 1 mg IV SAD and PF-06835375 3 mg SC MAD) and ECG abnormalities (PF-06835375 0.1, 1 and 6 mg IV SAD) were reported as TEAEs in individual patients. No deaths occurred. In IV SAD cohorts, median T_{max} ranged from 2–4 h and mean CL ranged from 0.021–0.313 L/h. Exposure (AUC_{inf} and C_{max}) generally increased dose-proportionally for doses ≤1 mg and more than dose-proportionally for doses >1 mg. In SC MAD cohorts, median T_{max} ranged from 121–171 h and mean CL/F ranged from 0.07847–0.1171 L/h. Exposure (AUC_{tau} and C_{max}) generally increased dose-proportionally. B- and cTfh-cell counts generally showed dose-dependent reductions across cohorts (range of mean maximum depletion: 67.3–99.3% and 62.4–98.7%, respectively, in SAD, and 91.1–99.6% and 89.5–98.1%, respectively, in MAD cohorts; Figure 1). Mean duration of B- and cTfh-cell depletion extended up to 71.6 and 62.0 days, respectively, in SAD, and 78.5 and 109.5 days, respectively, in MAD cohorts. ADA data did not suggest any clinically relevant impact on PK, PD or safety.

Conclusion: PF-06835375 was generally well tolerated in patients with seropositive SLE and RA with potent and prolonged B- and cTfh-cell depletion, supporting further development as a treatment for autoimmune diseases.

AB0512 INCIDENCE, PREVALENCE AND CURRENT TREATMENT PRACTICE OF SYSTEMIC LUPUS ERYTHEMATOSUS: A GERMAN CLAIMS DATA ANALYSIS

Keywords: Epidemiology, Real-world evidence, Systemic lupus erythematosus

T. Alexander[1], M. Schulte[2], J. Borchert[3], T. Garcia[3], E. Schrom[4]. *[1]Charité – Universitätsmedizin Berlin, Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [2]Amgen GmbH, Medical Affairs, Munich, Germany; [3]WIG2 GmbH, Analytic, Leipzig, Germany; [4]Amgen GmbH, Health Economics and Outcomes Research, Munich, Germany*

Background: Despite recent advances in the management of systemic lupus erythematosus (SLE), patients still suffer from reduced quality of life and increased mortality compared to the general population [1]. The latest data for Germany report a prevalence of 38.6 - 55.8 cases per 100,000 between 2009 and 2014, however more recent data as well as investigations on treatment algorithms in a real world setting are limited [2].
Objectives: To investigate incidence and prevalence of SLE for Germany and to evaluate treatment sequences in adult patients with SLE in Germany.
Methods: In this retrospective claims data analysis, 3017 patients with SLE diagnosis between January 2012 and December 2019 were identified for incidence and prevalence analysis. Out of these, 941 incident patients between January 2012 and December 2017 were selected for analysis of current treatment practice. For this analysis, only patients initiating SLE treatment according to guidelines were considered [1]. The date of the earliest prescription for SLE treatment on or following the SLE diagnosis (index date) was defined as start of sequence of therapy (SOT) 1. A new treatment added or switched to resulted in a new SOT. Up to 3 SOTs were measured during follow-up. SLE severity was recorded as previously described [2].

Results: Incidence rates were stable in both genders in Germany between 2012 and 2019, with women showing 3-4 fold higher incidence rates than men. In contrast, prevalence was rising from 40.5 in 2012 to 59.9 per 100,000 people in 2019, with a stronger trend in female patients (Figure 1). The mean (SD) age of the 941 incident patients identified for the treatment practice analysis was 50.6 (15.5) years, 74.4% were female and the mean (SD) follow-up duration was 1836 (634) days. 681 (70.3%) patients initiated SLE treatment (SOT1), with 246 (26.1%) progressing on to SOT2 and 113 (16.6%) on to SOT3. Monotherapies were most commonly prescribed in SOT1 (52.4%), while the use of combination therapies increases with SOT (SOT1 47.6%, SOT2 76.8%, SOT3 77.9%). Antimalarials in combination with corticosteroids were the most prescribed therapy during SOT1 (30.1%), immunosuppressants combined with corticosteroids during SOT2 (32.5%) and antimalarials combined with immunosuppressants and corticosteroids in SOT3 (36.3%). Combination therapies with biologics were used in 2.5% of patients in SOT2 and 8.8% of patients in SOT3 (Table 1). Disease severity increases with SOT.

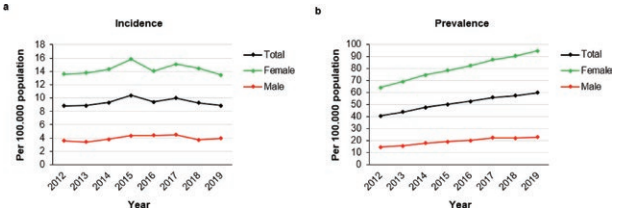

Figure 1

Table 1

Type of therapy	SOT1 (n=681)	SOT2 (n=246)	SOT3 (n=113)
Monotherapy - n(%)	**357(52.42%)**	**57(23.17%)**	**25(22.12%)**
Antimalarials	129(18.94%)	28(11.38%)	10(8.85%)
Immunosuppressants	15(2.20%)	25(10.16%)	14(12.39%)
Biologics	1(0.15%)	4(1.63%)	1(0.88%)
Intravenous Immunoglobulins	1(0.15%)	0(0.00%)	0(0.00%)
Corticosteroids	211(30.98%)	0(0.00%)	0(0.00%)
Combination therapies - n(%)	**324(47.58%)**	**189(76.83%)**	**88(77.88%)**
Antimalarials + IS	7(1.03%)	4(1.63%)	2(1.77%)
Antimalarials + IS + CS	42(6.17%)	49(19.92%)	41(36.28%)
Antimalarials + biologics + CS	1(0.15%)	1(0.41%)	3(2.65%)
Antimalarials + biologics	0(0.00%)	0(0.00%)	1(0.88%)
Antimalarials + CS	205(30.10%)	50(20.33%)	15(13.27%)
Antimalarials + IS + biologics + CS	0(0.00%)	3(1.22%)	0(0.00%)
IS + CS	68(9.99%)	80(32.52%)	20(17.70%)
IS + biologics	0(0.00%)	0(0.00%)	1(0.88%)
IS + biologics + CS	1(0.15%)	1(0.41%)	0(0.00%)
Biologics + CS	0(0.00%)	1(0.41%)	5(4.42%)

IS … Immunosuppressants, CS … Corticosteroids

Conclusion: While incidence of SLE is stable, prevalence is rising among German patients with statutory health insurance. Our data show that for newly diagnosed patients a combination of medication frequently including corticosteroids is required over time to control their disease. These data suggest a persistent unmet need for more effective treatment strategies for better SLE disease management and complement a recent US claims data analysis [3].

AB0513 SCREENING FOR HYDROXYCHLOROQUINE-INDUCED CARDIOMYOPATHY: A PROSPECTIVE OBSERVATION IN PATIENTS WITH CONNECTIVE TISSUE DISEASE WHO HAVE BEEN ON TREATMENT FOR MORE THAN 5 YEARS

Keywords: Disease-modifying drugs (DMARDs), Safety

M. Ford[1], S. Tosounidou[1]. *[1]Birmingham City Hospital, Rheumatology, Birmingham, United Kingdom*

Background: Antimalarial-induced cardiomyopathy is a rare complication of prolonged use of antimalarial treatment. It can present with a conduction disorder, heart failure, or ventricular hypertrophy [1]. A systematic review has highlighted that early recognition and drug withdrawal are crucial and can potentially lead to recovery of cardiac function in up to 45% of patients. Despite this, there remains a significant risk of irreversible damage and death despite discontinuation (12.9% and 30.8% respectively) [2].

Objectives: After identifying our first case of Hydroxychloroquine-induced cardiomyopathy in our department [3], we decided to review the prevalence of this complication in a cohort of patients to determine the need for a screening tool to assess the cardiovascular risk in patients prescribed Hydroxychloroquine for longer than 5 years duration.

Methods: We identified a selection of patients with a diagnosis of a Connective Tissue Disease who had been prescribed Hydroxychloroquine for longer than 5 years. We performed cardiac screening including N-terminal-pro-BNP (NT-pro-BNP), Troponin I (TnI), Creatine Kinase (CK) and an Electrocardiogram (ECG). A basic tool was used to determine the need for further investigations (Echocardiogram +/- Cardiac magnetic resonance imaging) to evaluate the presence or absence of Hydroxychloroquine-induced cardiomyopathy.

Results: A total of 124 patients met the specified criteria of which 115 were female (92.7%) and 9 were male (7.3%) with a mean age of 48 years. The underlying diagnoses included Systemic Lupus Erythematosus (n=103, 83.1%), Mixed CTD (n=9, 7.3%), Sjögren's Syndrome (n=6, 4.8%), Undifferentiated CTD (n=5, 4.0%), and Systemic Sclerosis (n=1, 0.8%). A total of 40 patients (32.3%) had been prescribed Hydroxychloroquine for 5-10 years duration compared to 84 patients (67.7%) who had been prescribed for over 10 years duration. Daily Hydroxychloroquine dose varied from 0-200mg (n=15, 12.1%), 200mg (n=55, 44.3%), 200-400mg (n=13, 10.5%), and 400mg (n=41, 33.1%). Abnormal results which warranted further investigation included raised levels of NT-pro-BNP (7.6%), TnI (4.2%), and CK (11.7%), and specific features seen on ECG (19.3%). A total of 31 patients were investigated using Echocardiography and none of these patients exhibited features suggestive of cardiomyopathy.

Conclusion: We did not identify any patients within this cohort with features suggestive of Hydroxychloroquine-induced cardiomyopathy. Despite the condition being rare, the true prevalence is unknown. Clinicians should remain vigilant and consider including a cardiovascular risk assessment in the long-term management of patients taking Hydroxychloroquine especially in high-risk patients such as those with a high cumulative dose of the medication [3].

Background: Anifrolumab is a type I interferon (IFN) receptor antagonist approved for treating adults with moderate to severe SLE [1]. The efficacy and safety of anifrolumab was evaluated in two 1-year phase 3 TULIP studies (NCT02446912, NCT02446899), and patients completing treatment in TULIP-1/-2 could enter the 3-year, placebo-controlled long-term extension (LTE) study (NCT02794285) [2-4]. Multiple serological markers are available to monitor SLE; notably, lymphopenia is associated with higher SLE disease activity and damage [5]. Assessing the long-term impact of anifrolumab on lymphocytes and other laboratory markers is of clinical interest.
Objectives: To compare the change over time of laboratory markers in blood samples from adults with SLE treated with anifrolumab vs placebo over the 4-year TULIP-LTE period.
Methods: Eligible patients fulfilled 1997 ACR criteria for SLE at TULIP entry, completed the TULIP treatment periods, and reconsented to participate in the LTE study. Here, we analyze data from patients who were randomized to anifrolumab 300 mg or placebo at TULIP entry and who did not change treatment over the TULIP+LTE period. Blood samples were collected from baseline (BL) until Week 208. Laboratory measures (lymphocytes, hemoglobin, platelets, complement C3 and C4, anti–double-stranded DNA antibodies) were analyzed using standard cell count and enzyme-linked immunosorbent assays. Mean changes from BL to Week 208 were analyzed descriptively.
Results: We present data on 536 patients (anifrolumab 300 mg, n=358; placebo, n=178). Assessing lymphocytes over time revealed a numerically greater increase in the anifrolumab vs placebo group during the TULIP studies which was maintained through the 3-year LTE period (Figure 1). BL laboratory characteristics and changes from BL to Week 208 are shown in the Table 1. Numerically greater increases in hemoglobin levels and platelet counts from BL to Week 208 were observed in patients treated with anifrolumab compared with placebo; mean platelet and hemoglobin levels remained in the normal range at BL and Week 208. Among patients with low C3 levels at BL, there was a numerically greater mean improvement in C3 levels to Week 208 with anifrolumab vs placebo.
Conclusion: Long-term improvement of lymphocytes and other laboratory markers, compared with placebo, indicates that type I IFN inhibition with anifrolumab normalizes SLE-related hematological parameters in patients with SLE. This normalization may relate to disease activity reduction and be relevant to long-term health outcomes and complications.

PHARMACOKINETICS, SELECTIVITY PROFILE, AND EXPOSURE-RESPONSE RELATIONSHIP FOR EFFICACY AND SAFETY IN A PHASE 2 STUDY OF DEUCRAVACITINIB, AN ORAL, SELECTIVE, ALLOSTERIC TYK2 INHIBITOR, IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Targeted synthetic drugs

T. Ide[1], M. Chiney[1], H. Y. T. Bach[1], V. Goti[1], B. Murthy[1], C. Hobar[2], Q. Zhao[3], U. Aras[1]. *[1]Bristol Myers Squibb, Clinical Pharmacology, Princeton, United States of America; [2]Bristol Myers Squibb, Clinical Development, Princeton, United States of America; [3]Bristol Myers Squibb, Research & Early Development, Princeton, United States of America*

Background: Deucravacitinib is a first-in-class, oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis [1,2]. Deucravacitinib binds to the unique TYK2 regulatory domain, conferring greater functional selectivity vs JAK inhibitors, which bind to the catalytic domain. Deucravacitinib showed superior efficacy vs placebo in a phase 2 trial in SLE (NCT03252587) [3].
Objectives: This analysis assessed the pharmacokinetics (PK), selectivity profile compared to JAK inhibitors, and exposure-response (E-R) relationship for efficacy and safety of deucravacitinib in SLE.
Methods: In the phase 2 trial, patients with active SLE were randomized 1:1:1:1 to placebo or deucravacitinib (3 mg BID, 6 mg BID, 12 mg QD). PK analysis included pooled concentration data from 266 SLE patients and 328 phase 1 participants. IC_{50} was determined by *in vitro* whole blood assays and plotted against PK profiles. E-R analyses included data from 356 patients. Logistic regression analyses assessed the relationship between deucravacitinib exposure and probability of achieving efficacy endpoints and safety events at weeks 32 and 48.
Results: Deucravacitinib PK in SLE patients was not meaningfully different from that in phase 1 participants. At 12 mg QD, deucravacitinib C_{max} was 8-fold lower than JAK 1/3 IC_{50} and 47-fold lower than JAK 2/2 IC_{50} (**Figure 1**). In the E-R analyses, the probability of achieving SRI(4) and BICLA at week 32 increased with increasing deucravacitinib C_{minSS}, with 3 mg BID providing near-maximal response. The E-R relationship for infection and infestation was relatively flat, while skin and subcutaneous tissue disorders increased with increasing deucravacitinib C_{minSS}. These E-R relationships were similar at week 48.
Conclusion: Deucravacitinib PK in SLE patients is not meaningfully different from that in phase 1 participants. At clinically relevant exposures, deucravacitinib demonstrates highly selective inhibition of TYK2 vs JAK 1/2/3. The deucravacitinib E-R relationships are well characterized for various efficacy endpoints and safety events.

Background: Litifilimab (BIIB059) is a humanised IgG1 monoclonal antibody targeting BDCA2, a receptor predominantly expressed on plasmacytoid dendritic cells, that negatively regulates production of Type I IFN and proinflammatory chemokines and cytokines [1,2]. Both Part A (SLE) and Part B (CLE) of the randomised, placebo-controlled Phase 2 LILAC study of litifilimab (NCT02847598) met their primary efficacy endpoints at Weeks 24 and 16, respectively [1,2].
Objectives: To evaluate the effect of litifilimab treatment on IFN gene signature (IFNGS) scores and IFNα levels in LILAC participants.
Methods: Expression of a 22-IFNGS and IFNα concentrations were examined over time in whole blood and serum samples, respectively, from the LILAC modified intent-to-treat population (mITT; Part A N=120, Part B N=132) with a baseline biomarker value and at least one post-baseline value. Treatment effects were estimated using a mixed-effects model repeated measures approach (MMRM) and the dose-response relationship was estimated in Part B using a previously described MCP-Mod method [2].
Results: Few participants had low baseline IFNGS scores, so only data for participants with high baseline IFNGS scores are described here.
At the earliest post-baseline timepoint in Part A (Week 1) a sharp reduction in the mean IFNGS score was observed in the litifilimab 450-mg group vs placebo, which was sustained through Week 24 **(Figure 1; Table 1)**. At the earliest timepoint in Part B (Week 2), reductions in mean IFNGS scores were greater than placebo in all three litifilimab dose groups, and the dose effects were sustained through Week 16 **(Figure 1; Table 1)**. A similar pattern of reductions and dose effects was observed with the corresponding IFNα concentrations **(Table 1)**. Statistically significant (P<0.05) changes from baseline in IFNGS scores and IFNα levels were demonstrated for litifilimab 450 mg in Part A and for the 150-mg and 450-mg groups in Part B **(Table 1)**.
In Part B, the IFNGS-high subgroup's IFNGS scores and IFNα concentrations showed a similar dose-response relationship as was observed for the mITT's CLE clinical responses [2].
Conclusion: Litifilimab treatment induced sustained reductions in 22-IFNGS and IFNα concentrations in participants with SLE and CLE.

LONG-TERM SAFETY OF BELIMUMAB AMONG ADULT PATIENTS WITH SLE: POOLED DATA FROM THREE OPEN-LABEL EXTENSION STUDIES OVER 11+ YEARS

Keywords: Clinical trials, Safety, Systemic lupus erythematosus

A. Mian[1], P. Curtis[2], C. Henning[3], M. Khamashta[4], R. Cervera[5], D. J. Wallace[6], M. Tektonidou[7], T. Atsumi[8]. *[1]GSK, Global Medical Affairs, Brentford, United Kingdom; [2]GSK, R&D Biostatistics, Brentford, United Kingdom; [3]GSK, Global Medical Affairs, Durham, NC, United States of America; [4]GSK, Medical Affairs, Dubai, United Arab Emirates; [5]University of Barcelona, Department of Autoimmune Diseases, Hospital Clínic, Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Catalonia, Spain; [6]Cedars-Sinai Medical*

Center, Division of Rheumatology, Los Angeles, CA, United States of America; [7]National and Kapodistrian University of Athens, Rheumatology Unit, First Department of Propaedeutic Internal Medicine, Laiko Hospital, Medical School, Athens, Greece; [8]Hokkaido University Hospital, Department of Rheumatology, Sapporo, Japan

Background: Belimumab is approved for the treatment of systemic lupus erythematosus (SLE) in >75 countries [1]. Clinical trials and long-term extension (LTE) studies have demonstrated the consistent safety profile of belimumab in patients with SLE receiving standard therapy (ST) [2-4]. A pooled analysis of LTE studies could provide a more robust dataset to explore the long-term safety of belimumab.

Objectives: To evaluate the long-term safety of belimumab in adult patients with SLE using pooled data from three multicentre, LTE studies.

Methods: This post hoc analysis pooled data from three belimumab LTE studies: LBSL02 LTE (Phase 2; GSK Study 112626) [2], BLISS-76 LTE (including US patients only; Phase 3; GSK Study 112233) [3], and BLISS-52 + BLISS-76 LTE (excluding US patients from BLISS-76; Phase 3; GSK Study 112234) [4]. Patients were eligible for LTE studies if they completed treatment through Week 72 (LBSL02 and BLISS-76 trials), or Week 48 (BLISS-52 trial). LBSL02 LTE also required an improvement in physician global assessment at Week 72 or 68 versus at first belimumab dose. From the start of each LTE, all enrolled patients received open-label belimumab 10 mg/kg intravenously every 28 days plus ST, regardless of study drug allocation in prior trials. Adverse events (AEs) were assessed at each infusion visit and summarised (based on observed data) any time post baseline (first belimumab dose in prior trial or LTE), and in each year.

Results: In total, 1304 patients were enrolled into the three LTE studies and 1299 (99.6%) received ≥1 dose of study drug (pooled safety population). Cumulative belimumab treated patient-years was 7040.1. Overall, 604 (46.5%) patients completed their respective studies. The main reasons for withdrawal included 'withdrawal by patient' (18.3%) and 'AE' (10.6%). In the pooled safety population, 1054 (81.1%) and 618 (47.6%) patients received steroids and immunosuppressants at baseline, respectively. Over 11+ years, 1267 (97.5%) patients had ≥1 AE (incidence generally decreased yearly; **Table 1**), while 525 (40.4%) had ≥1 serious AE (SAE) and 139 (10.7%) experienced ≥1 AE resulting in study drug discontinuation (incidence of each was stable over time). By system organ class, infections and infestations were the most frequent AE, SAE, and AE resulting in study drug discontinuation. The most common AE of special interest was post-infusion systemic reactions (9.7 events per 100 patient-years). There were 21 (1.6%) deaths in total, 3 (0.2%) were considered possibly related to study drug (cardiogenic shock, lung infection pseudomonal, and pneumonia cytomegaloviral [all n=1]).

Conclusion: Among a large, pooled population of patients with SLE treated with belimumab plus ST for over 11+ years, the incidence of AEs generally decreased or remained stable over time. No new safety concerns were observed. This analysis was limited by use of a self-selected population that had not withdrawn from prior trials, and the open-label nature of the study.

TREATMENT OF PRIMARY SJÖGREN'S SYNDROME BY INHIBITING FCRN: A PHASE 2 RANDOMIZED, PLACEBO CONTROLLED, DOUBLE-BLIND, PROOF OF CONCEPT STUDY WITH EFGARTIGIMOD

Keywords: Sjögren syndrome, Biomarkers, Randomized control trial

I. Peene[1,2], F. G. M. Kroese[3], G. M. Verstappen[3], S. Arends[3], D. Papadopoulou[4], P. Rohane[5], J. Jacobs[4], B. Smith[5], S. Robertson[4], P. Duncombe[4], D. Elewaut[1], H. Bootsma[3]. *[1]Ghent University Hospital, Rheumatology, Gent, Belgium; [2]AZ Sint-Jan, Rheumatology, Brugge, Belgium; [3]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [4]Argenx BV, Clinical Science, Zwijnaarde, Belgium; [5]IQVIA, Clinical, Massachusetts, United States of America*

Background: Primary Sjögren's syndrome (pSS) is a chronic, progressive autoimmune disease, characterized by lymphocytic infiltration and progressive destruction of exocrine glands. B cells play a pivotal role in the development of the disease and this results amongst others in production of IgG autoantibodies (especially those which target SSA/Ro, SSB/La ribonuclear complexes) and rheumatoid factor, as well as elevated levels of serum IgG. In addition to symptoms of dry eyes, dry mouth, chronic pain and fatigue, a substantial subset of patients suffer from extraglandular systemic disease. There are no systemic disease-modifying treatments currently registered for the treatment of pSS. Circulating IgGs are rescued from lysosomal degradation via the neonatal Fc receptor (FcRn), extending their half-life. Efgartigimod is a human IgG Fc fragment engineered to block FcRn, thereby reducing serum IgG levels without impacting other immunoglobulins that are not recycled by FcRn. In phase II and III studies across a range of indications, efgartigimod decreased serum concentrations of total IgG, including pathogenic autoantibodies, without reducing albumin levels. Efgartigimod is well tolerated, and most adverse events were mild.

Objectives: We hypothesize that a reduction in autoantibodies by efgartigimod will target the underlying pathogenesis of pSS and will result in reduced systemic disease activity and symptoms. We present a phase II multicenter, randomized, placebo-controlled, double-blind, proof-of-mechanism study initiated to evaluate the safety and efficacy of efgartigimod in adult participants with pSS.

Methods: Adult patients with pSS fulfilling the ACR-EULAR classification criteria, time since diagnosis of ≤7 years, anti-SSA/Ro positivity, presence of residual salivary flow (UWSF rate >0 and/or SWSF rate >0.10) and moderate to high systemic disease activity (ESSDAI score ≥5) are eligible for participation in the study. Approximately 30 patients will be randomly allocated (2:1) to receive weekly intravenous efgartigimod or placebo for 24 weeks. At the end of the treatment period, participants who complete the study may roll over into an open-label extension (OLE).

Results: The primary endpoint is the proportion of responders to the Composite of Relevant Endpoints for Sjögren's Syndrome (CRESS; response on ≥3 out of 5 items) at week 24. Key secondary endpoints include proportion of responders to the Sjögren's Tool for Assessing Response (STAR) and change from baseline in the clinESSDAI, ESSDAI, and ESSPRI scores. Additional endpoints include changes in parotid gland pathology to understand the effects of efgartigimod on pSS disease pathology and blood-based biomarkers to explore the effect on innate and adaptive immune response. Safety will be assessed by incidence and severity of adverse events and laboratory evaluations.

Conclusion: This phase II study of efgartigimod will evaluate the effect of FcRn inhibition on disease pathology and the potential for therapeutic benefit in patients with pSS.

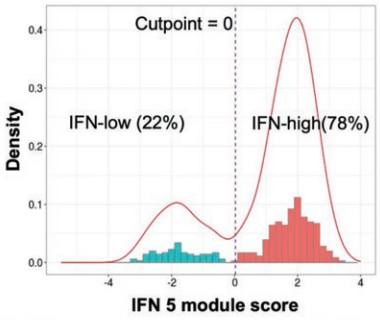
IDENTIFICATION OF AN INTERFERON 5-GENE SIGNATURE SCORE AS A PHARMACODYNAMIC AND POTENTIAL PREDICTIVE BIOMARKER FOR DEUCRAVACITINIB TREATMENT IN A PHASE 2 TRIAL IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Biomarkers, Systemic lupus erythematosus, Targeted synthetic drugs



C. Wu[1], Y. Hu[1], M. K. Crow[2], A. Saxena[3], C. Arriens[4,5], C. Hobar[6], A. Coles[7], I. M. Catlett[8]. *[1]Bristol Myers Squibb, Informatics and Predictive Sciences, Princeton, United States of America; [2]Hospital for Special Surgery, Weill Cornell Medical College, New York-Presbyterian Hospital, Rheumatology, New York, United States of America; [3]NYU Grossman School of Medicine, Department of Medicine, Division of Rheumatology, New York, United States of America; [4]Oklahoma Medical Research Foundation, Arthritis and Clinical Immunology, Rheumatology, Oklahoma City, United States of America; [5]University of Oklahoma Health Sciences Center, Medicine, Oklahoma City, United States of America; [6]Bristol Myers Squibb, Clinical Development, Princeton, United States of America; [7]Bristol Myers Squibb, Global Biometrics and Data Sciences, Princeton, United States of America; [8]Bristol Myers Squibb, Translational Medicine, Princeton, United States of America*

Background: Tyrosine kinase 2 (TYK2) mediates cytokine pathways (eg, Type I IFN) linked with systemic lupus erythematosus (SLE) pathogenesis. Deucravacitinib is a first-in-class, oral, selective, allosteric TYK2 inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis [1,2]. Deucravacitinib was efficacious compared with placebo in a phase 2 SLE trial [3].
Objectives: To develop a customized IFN 5-gene signature score, assess the pharmacodynamic effects of deucravacitinib on the IFN score, and evaluate the score's association with SLE disease activity and clinical response in the phase 2 trial.
Methods: Patients with active SLE were randomized equally to oral placebo or deucravacitinib (3 mg BID, 6 mg BID, or 12 mg QD). DxTerity chemical ligation-dependent probe amplification was used to measure 51 immune system-related genes from whole blood. IFN genes were selected based on distribution, correlations, hierarchical clustering, and consistency of k-means clusters. Serum proteins, blood cell subsets, and antibody profiles were measured by immunoassays and flow cytometry. SRI(4) and BICLA were measured at weeks 32 and 48.
Results: An IFN 5-gene (*MX1*, *HERC5*, *IFIT1*, *RSAD2*, and *EIF2AK2*) signature score was identified and used to classify patients into IFN-high or IFN-low subgroups (**Figure 1**). Higher baseline IFN score was associated with higher baseline SLEDAI and CLASI disease activity scores, higher levels of IFN activity biomarker (eg, IFNα, IFNλ, BAFF, CXCL10) and anti-dsDNA, and lower complement and lymphocyte counts. Baseline IFN score was not predictive of SRI(4) response. A higher baseline IFN score was associated with a significantly higher probability of BICLA response with deucravacitinib 3 mg BID relative to placebo (P=0.014). Deucravacitinib reduced the IFN score from weeks 4 through 44 by >50%.
Conclusion: These data support the IFN 5-gene signature score as a biomarker to classify patients with SLE into IFN-high or IFN-low subgroups; however, clinical response by IFN score was inconsistently improved (**Table 1**). IFN-regulated gene expression performs well as a pharmacodynamic biomarker to confirm deucravacitinib mechanism of action and to aid in phase 3 dose selection.

Background: Regional disparities in the management of systemic lupus erythematosus (SLE) are frequently described. Governance, funding, logistic barriers, and physician choice may be important determinants though scarce data from underrepresented regions limits our understanding.

Objectives: To evaluate global patterns in treatment of SLE and identify the prevalence of comorbidities.

Methods: We identified SLE patients from the COVAD 2 database, consisting of over 20,000 respondents worldwide. Healthy controls (HC) were included to assess population comorbidity levels. Demographics, treatment i.e., corticosteroids (CS), antimalarials, immunosuppressants (IS), cyclophosphamide and biologics plus comorbidity data was recorded. Country Human Development Index (HDI) classification, a composite index formulated by the United Nations to rank countries into tiers of development, was utilised.

Results: 3323 HCs and 1167 SLE patients were included in analysis. Patients from low/medium HDI (lmHDI) countries were younger than those from high/very high HDI (hvhHDI) countries (median age 32, IQR 27-41 vs 41, IQR 32-52 years, p<0.0001). Disease duration was shorter in lmHDI countries (median 5, IQR 3-10 vs 10, IQR 5-19 years, p<0.0001). A higher proportion of SLE patients from lmHDI countries were on CS (73% vs 59%, p=0.0002), antimalarials (81% vs 68%, p=0.0002) and IS (66% vs 53%, p=0.0009) compared with patients from hvhHDI countries. Choice of IS varied with azathioprine prescribed more frequently in lmHDI countries (p=0.049). Biologics use was more common in hvhHDI countries (7% vs 2%, p=0.0055). Comorbidity prevalence was similar between groups, however when adjusted for age, patients with chronic kidney disease were significantly younger in lmHDI countries (36.67 vs 44.64 years, p=0.015), as were patients with coronary artery disease (35.7 vs. 44.6 years, p=0.015) and hypertension (41.5 vs 49.8 years, p=0.003). Results are detailed in Table 1.

Conclusion: To our knowledge, this is the largest study evaluating treatment and comorbidity incidence in SLE populations based on country HDI. We identified striking differences in pharmacological management globally. Cardiovascular comorbidities were seen in younger patients and earlier in the disease course in lmHDI countries, suggestive of premature organ damage. This could be due to limited global access to high-cost medication and increasing access may improve outcomes. Our results call for review of cardiovascular risk guidelines and regional approaches to preventive action as well as pharmacological and non-pharmacological management of patients with established cardiovascular comorbidity.

AB0523 TOXIC EPIDERMAL NECROLYSIS(TEN) IN SYSTEMIC LUPUS ERYTHEMATOSUS(SLE): RESULTS FROM A MULTI-INSTITUTIONAL COHORT FROM INDIA

Keywords: Skin, Systemic lupus erythematosus, Descriptive Studies

K. Chandwar[1], A. Jain[2], P. Ghosh[3], A. Balakrishnan[1], S. Manuel[4], S. Mukherjee[5], A. Paruthi[6], P. Srivastava[7], A. Singh[2,6], A. Wakhlu[8]. *[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India; [2]SMS Medical College & Attached Hospital, Clinical Immunology and Rheumatology, Jaipur, India; [3]IPGME&R and SSKM Hospital, Clinical Immunology and Rheumatology, Kolkata, India; [4]St John's Medical College Hospital, Clinical Immunology and Rheumatology, Bengaluru, India; [5]King George's Medical University, Clinical Immunology and Rheumatology, Lucknow, India; [6]SMS Medical College & Attached Hospital, Internal Medicine, Jaipur, India; [7]Star clinics, Clinical Immunology and Rheumatology, Ahmedabad, India; [8]Apollomedics Super Speciality Hospitals, Clinical Immunology and Rheumatology, Lucknow, India*

Background: Toxic Epidermal Necrolysis(TEN) is a rare but life-threatening manifestation of Systemic Lupus Erythematosus (SLE). Epidermal necrolysis (EN), including Stevens–Johnson syndrome and TEN, is commonly drug induced. Furthermore, flares of SLE may present as EN (TEN-like LE). To the best of our knowledge, this is the largest series of SLE-TEN.

Objectives: The current study aimed to study the clinical characteristics and outcome of SLE-related TEN in the Indian population.

Methods: All patients satisfying ACR/EULAR 2019 criteria for SLE and clinically diagnosed with TEN were retrospectively reviewed and compiled from 7 rheumatology centres across India. Drug-induced TEN were excluded from the analysis.

Results: 16 patients (1 child) were included in the study. The majority of patients were females (13/81.25%). The median age of presentation was 25 (8-50) years, and one-third of patients (5/31.5%) presented with TEN as one of their first manifestations. All patients of TEN had active lupus in more than one domain (Median SLEDAI, 20.5). Involvement of constitutional domain followed by hematological was most common (Figure 1). Involvement of other domains is described in Figure 1. Most patients had low complements (14/87.5%), positive anti-dsDNA (13/81.25%) and anti-SSA positivity (12/75%). Management was dictated by activity in various domains and all patients had received steroids (1mg/kg in 13 and 0.5mg/kg in 3). Half of them received intravenous (IV) pulse steroid therapy and one-fourth were administered IV Immunoglobulins (IVIG). All but one patient were put on a steroid-sparing agent (Table 1). Outcomes were good, with all patients recovering from the TEN episode. Two patients who were lost to follow up, had died at their home and exact cause of death could not be ascertained.

Conclusion: TEN was a presenting manifestation in one-third of the patients with active disease in more than one domain. More than half of the patients had renal involvement and a quarter had Neuropsychiatric lupus (NPSLE). Anti-dsDNA, Anti-SSA positivity and low complements were common in patients with SLE-TEN. All patients required high-dose steroids for acute management of TEN, with maintenance therapy being guided by other domains involved. Though IVIG is often mentioned in literature as the treatment of choice for TEN, Most patients with SLE-TEN did well with pulse and oral Steroids suggesting IVIG could be reserved for patients with severe, resistant disease or in patients with concomitant sepsis.

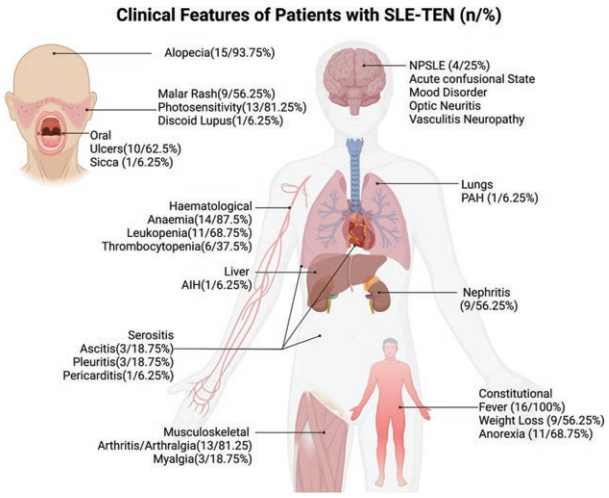

Figure 1. Clinical features of Patients with SLE-TEN (Created with Biorender.com)

Table 1. Serological and Treatment details of Patients with SLE-TEN

Lab Features			Treatment Details		
N=16	No.	%	Acute Management		
DCT	4	25	N=16	No.	%
ANA	16	100	IVIG	4	25%
Anti-DsDNA	13	81.25	Pulse	7	43.75
Low C3	14	87.5	1mg/kg	13	81.25
Low C4	11	68.75	0.5mg/kg	3	18.75
Anti-Sm	5	31.25	Maintenance therapy		
Anti-RNP	5	31.25	AZR	7	43.75
Anti-La	4	25	MMF	2	12.5
Anti-Ro 52	10	62.5	RTX	2	12.5

Boumpas[1,2]. *[1]Attikon University Hospital, Rheumatology and Clinical Immunology Unit, 4th Department of Internal Medicine, Athens, Greece; [2]National and Kapodistrian University of Athens, Athens, Greece; Inflammation & Autoimmunity Lab, Biomedical Research Foundation of the Academy of Athens (BRFAA), Faculty of Medicine, Athens, Greece; [3]Foundation of Research and Technology-Hellas, Institute of Molecular Biology and Biotechnology, Heraklion, Greece; [4]University Hospital of Heraklion and Medical School, Department of Rheumatology and Clinical Immunology, Heraklion, Greece*

Background: Belimumab, a monoclonal antibody against B-cell activating factor (BAFF), is the first biological agent approved in patients with systemic lupus erythematosus (SLE) with persistently active or flaring disease [1].

Objectives: To determine molecular signatures that may predict response to therapy based on RNA sequencing analysis and the impact of belimumab on previously defined molecular signatures of SLE activity and severity [2,3].
Methods: Whole blood transcriptome samples were obtained from 38 patients with active moderate to severe SLE at baseline and 6 months after initiation of treatment with belimumab. Disease activity was determined using the SLE-DAI-2K while response to treatment was defined as the achievement of lupus low disease activity state (LLDAS) at 6 months (M6). DESeq2 was used to call differentially expressed genes (DEGs) and weighted correlation network analysis (WGCNA) was applied to uncover gene module-traits associations. The impact of the belimumab treatment on the SLE severity signature was evaluated [2].
Results: From 38 patients treated with belimumab, 35 (97,2%) were women, mean age (SD) was 48,2 (±13,5) years and mean SLEDAI-2K (SD) at baseline was 7,2 (±2,1). A total of 44,4% achieved LLDAS at M6. Both, the presence of a molecular signature of type I interferon signaling and the upregulation of BAFF expression correlated with response to treatment at M6 ($p = 0.05$ and $p = 0.02$ respectively). Treatment with belimumab reversed the innate and adaptive immune system signatures in responders at 6-months. Within the non-responders, baseline transcriptome, disturbances related to metabolic processes and rRNA biogenesis were predominantly enriched. A tendency towards downregulation of the severity disease transcriptional signature upon treatment with belimumab was also observed in 6-month responders ($p = 0.3203$).
Conclusion: Both the presence of type I interferon and BAFF gene expression signatures at baseline correlates with response to treatment with belimumab while metabolic processes and rRNA biogenesis correlate with no response. Treatment with belimumab might ameliorate the molecular signatures indicative of disease severity in the 6 month-responders. These data provide a mechanistic basis for the response to treatment.

AB0525 **SUSTAINED RESPONSES TO ANTI-CD38 TREATMENT WITH DARATUMUMAB IN A PATIENT WITH REFRACTORY SYSTEMIC LUPUS ERYTHEMATOSUS**

Keywords: Systemic lupus erythematosus, Adaptive immunity

T. Alexander[1,2], L. Ostendorf[3], R. Biesen[1], A. Radbruch[4], G. R. Burmester[1], F. Hiepe[1,2]. *[1]Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Rheumatology and Clinical Immunology, Berlin, Germany; [2]Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Autoimmunology, Berlin, Germany; [3]Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Nephrology and Intensive Care Unit, Berlin, Germany; [4]Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Cell Biology, Berlin, Germany*

Background: Given their contribution to the chronicity of autoimmune response, long-lived plasma cells (PCs) resemble an attractive treatment target in systemic lupus erythematosus (SLE) and other autoantibody-mediated diseases. We have recently reported the successful treatment of daratumumab, a CD38-targeting human monoclonal antibody, in two refractory patients with SLE [1], demonstrating a clinically relevant depletion of long-lived plasma cells with marked reduction of anti-double-stranded DNA (dsDNA) antibodies and marked clinical improvement in both cases over a follow-up period of 12 months.
Objectives: Here, we describe the long-term clinical and serologic responses of daratumumab treatment in one patient with SLE with a follow-up of 36 months.
Methods: A 51-year-old woman, who suffered from active lupus nephritis WHO class-III/V with nephrotic syndrome, pericarditis, arthritis and skin rash despite treatment with mycophenolate mofetil (MMF), cyclosporine A (CsA), hydroxychloroquine (HCQ) and glucocorticoids (GC), had received 4 weekly intravenous doses of 16mg/kg daratumumab as add on to background medication, which was complemented by subcutaneous 200mg belimumab weekly, starting 4 months after the initiation of daratumumab. Autoantibodies were investigated with ELISA and type-I interferon (IFN-I) activity investigated by measuring SIGLEC-I expression on monocytes with flow cytometry.
Results: During follow-up, the patients´ Urinary Protein/Creatinine Ratio (UPCR) declined from 1197 mg/g at 12 months to 467mg/g Creatinine at the last follow-up, while serum creatinine remained within normal levels (Figure 1A). No flares or novel disease manifestations occurred during the 3-year observation period, although the dosage of MMF was tapered to 1g daily at 21 months and prednisolone discontinued at 33 months, respectively, after the first daratumumab administration. Serologically, serum anti-dsDNA antibodies further decreased from 254 IE/ml at the 12 months follow-up to 38 IE/ml at 36 months (Figure 1B), and complement levels for C3 were consistently within the normal range (Figure 1C). Serum IgG levels remained stable after previous substitution with two doses of 30g intravenous immunoglobulins (Figure 1D). In addition, her initially increased type-I interferon activity, determined by the flow cytometric assessment of SIGLEC-1 on freshly isolated monocytes, completely normalized during follow-up, an effect most strongly observed during the first weeks following daratumumab that further substantiated under belimumab therapy (Figure 1E). At the last follow-up, she was in complete clinical remission, with a SLEDAI-2K of 2 due to slightly elevated dsDNA antibodies (Figure 1F). No severe adverse events occurred during follow-up, and no hospitalization was required for the management of SLE, infections or comorbidities.
Conclusion: Our data demonstrate that the administration of daratumumab as induction therapy for refractory and serologically active SLE may provide sustained clinical responses, when combined with immunosuppression and/or belimumab as maintenance therapy to prevent recurrence of autoreactive PCs. Apparently, depletion of long-lived PCs resulted in a therapeutically relevant reduction of autoantibodies and IFN-I activity, indicating a profound disease modification with resetting the chronic autoreactive immune system into an earlier stage of development, regaining responsiveness to standard therapies. These data suggest further studies to investigate the safety and efficacy of daratumumab in SLE and other autoantibody-mediated autoimmune diseases.

Background: In 2017, Belimumab (BEL) was approved in subcutaneous (SC) version [1]. The effectiveness after switching from intravenous (IV) to SC and patient satisfaction in daily clinical practice has not been studied. During the pandemic, patient follow-up and treatment were significantly affected, including the administration of IV biologic therapies. In some patients, a change from IV to SC, including BEL therapy, was required [2].
Objectives: Our aim was to evaluate in daily clinical practice satisfaction to BEL SC therapy in patients previously treated IV BEL. We hypothesized that SC BEL in SLE patients previously treated with IV BEL was similar in effectiveness and conferred higher satisfaction.
Methods: Observational, multicenter study, conducted in 7 reference centres in Catalonia (Spain). Inclusion criteria: Stable SLE patients (EULAR/ACR 2019) on treatment with BEL SC and previous use of BEL IV (at least 3 months of treatment with BEL IV before switching). Since there are no well-validated tools for SC BEL treatment satisfaction, we used RASQ-SC, validated in patients with lymphoma who switched from Rituximab IV to SC treatment [3], modified for BEL treatment.
Results: Twenty-seven patients were included. Demographic and general characteristics are summarized in Table 1. The mean time from treatment with BEL IV before switch to SC was 26 (SD 21) months. 84% of patients reported confidence in BEL SC. 80% felt that treatment with BEL SC was convenient or very convenient. 85% felt they had gained time with the change. 89% would recommend the SC injection to other patients (Figure 1a,b,c,d). Disease activity (mean SLEDAI) and remission rates remain stable after switching. Patients did not require higher doses of glucocorticoids after the switch (Table 1). No major new side effects were reported.

AB0527 FACTORS ASSOCIATED WITH GLUCOCORTICOID-FREE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS TREATED WITH BELIMUMAB IN THE REAL-WORLD SETTINGS: A SINGLE-CENTER RETROSPECTIVE COHORT STUDY IN JAPAN

Keywords: Real-world evidence, Tapering, Systemic lupus erythematosus

T. Yamane[1], A. Hashiramoto[2]. *[1]Kakogawa Central City Hospital, Department of Rheumatology, Kakogawa, Japan; [2]Kobe University Graduate School of Health Sciences, Department of Biophysics, Kobe, Japan*

Background: The treatment of patients with systemic lupus erythematosus (SLE) involves the progression of organ damage due to both the disease itself and glucocorticoid-induced adverse events [1]. Therefore, achieving glucocorticoid-free status is one of the most important goals in the treatment of SLE [2]. Belimumab has been reported to be effective in SLE patients, particularly with high disease activity, by inhibiting the B-lymphocyte stimulator (BLyS) to reduce disease activity, relapse rate, organ damage, and steroid dosage [3,4]

Objectives: Review the profile of patients who can achieve glucocorticoid-free status with belimumab administration, retrospectively.

Methods: We retrospectively reviewed 47 Japanese SLE patients who received belimumab for at least 1 year in addition to standard of care, including glucocorticoids. Patients were classified into two groups: glucocorticoid-free (GC free) and others (GC continuation) as of August 2022. Trends in C3, C4, and dsDNA antibody titers, SLEDAI-2K scores, and daily glucocorticoid dosage were examined at the start of belimumab and thereafter; at months 12 and 24. At the time of belimumab initiation, differences between the two groups were also examined for age, duration of disease, time from onset or last relapse to belimumab initiation, C3, C4, dsDNA antibody titer, daily glucocorticoid dose, SLEDAI-2K, with or without concomitant hydroxychloroquine and concomitant immunosuppressive drugs, and duration of belimumab treatment. Incidence of adverse event or relapse during the course were also followed. P values were determined using Wilcoxon's signed rank test, Mann-Whitney U test, and Fisher's exact test.

Results: 9 patients (19%) were classified as GC free. In overall patients, C3, C4, dsDNA antibody titer, and SLEDAI score showed significant improvement at 12 and 24 months compared to the baseline. The daily GC dosage was significantly reduced while it was increased in 2 patients (5%). Though there was no significant difference in SLEDAI, C3 was significantly higher in the GC free group at the baseline (P=0.032). There were no cases of discontinuation of belimumab due to adverse events or relapse during the course.

Conclusion: Although low C3 patients are more likely to benefit from belimumab because of higher serum BLyS levels [5], it is worthwhile to introduce belimumab for GC-free even in patients with high C3 levels.

Background: Belimumab (BLM) is a recombinant human IgG-1λ monoclonal antibody that inhibits B-cell activating factor. It is commonly used for treatment of systemic lupus erythematosus (SLE) patients with inadequate control to first-line treatments and inability to taper GC daily dose to acceptable levels. More recently it has been approved for patients with active lupus nephritis.
Objectives: To report baseline profile of SLE patients treated with BLM enrolled in a SLE Spanish registry.
Methods: Multicenter retrospective and longitudinal cohort study including SLE patients treated with BLM in 18 Spanish rheumatology units. Demographic, clinical data and treatments were collected at baseline, 6, 12 months and in the last visit available. Patients starting BLM in different periods (2010-2015 and 2016-2021) were compared regarding the reason of prescription of the drug.
Results: 324 patients (91% female, 84,8% caucasian) were enrolled. Mean (±SD) age at diagnosis: 31.8 years (±11.9); mean disease duration of 8.7 years (±9.07) and mean follow-up 3.8 (±2.7). A total of 319 (98.45%) subjects met SLE 1997 ACR or SLICC 2012 criteria; 217 (68.2%) were anti-dsDNA positive and 224 (69.8%) had low complement levels. At baseline, the mean SLEDAI-2K score was 10.4 (±5.25); 152 (47.5%) of patients had damage with a mean SDI score of 0.83 (±1.2). A total of 289 patients (89.2%) had received disease modifying anti-rheumatic drugs (DMARDs) before BLM: conventional (cDMARDS) in 282 patients (87%) and biologic DMARDs (bDMARDs) in 74 patients (22.8%); 164 (51.9%) had received more than one cDMARDs, methotrexate being the most frequently used (44.4%). Other cDMARDs used were: mycophenolate mofetil in 104 (37.01%), azathioprine in 91 (32.38%), leflunomide in 29 (10.32%), cyclophosphamide in 28 (9.92%) and calcineurin inhibitors in 13 (4.6%) of patients. The most frequent bDMARDs used was Rituximab in 80%. Most patients were receiving antimalarials (83,2%) and glucocorticoids (GC) (91.2%), with a mean dose of 12.3 mg/day. A total of 209 (67.9%) patients were receiving more than 5 mg/day and 180 (58.4%) more than 7.5 mg/day of prednisone. BLM was used in monotherapy in 99 (30.5%) subjects. It was initiated due to disease activity in 307 patients (95%) and/or as a GC sparing agent in 191 patients (59%). Most patients initiated BLM for several concurrent reason; only a few patients received BLM just for maintenance (4/322) or save GC (8/322). At baseline, only 6 patients (1.9%) were in DORIS-21-remission and LLDAS. The main reasons of prescription for ongoing activity were arthritis (65.4%), cutaneous (40.7 %) or both (81%). There were no statistically significant differences in any of the prescription reasons when comparing the periods 2010-2015 and 2016-2021.

Table 1. Type and reasons of prescription of Belimumab

	N (%) or mean (± SD) (n = 324 patients)
Age at prescription of Belimumab (years)	42.3 (± 12.9)
Intravenous Belimumab	215 (66.35%)
Subcutaneous Belimumab	110 (33%)
Reasons of prescription* (multiple response allowed)	
Disease activity	307 (95%)
Maintenance	197 (61%)
Glucocorticoid sparing	191 (59 %)
Activity	
Cutaneous	132 (40.7 %)
Articular	212 (65.4%)
Renal	58 (17,9%)
Hematological	60 (18.5%)
Serosal	47 (14.5%)
Other	29 (8.82%)

Conclusion: In the majority of patients, belimumab was prescribed after the use of other DMARDs and more than 50% of patients had received at least 2 DMARDs and were receiving GC at medium doses. One third of patients received BLM as monotherapy. It was prescribed due to active disease in the vast majority of patients and/or as GC sparing agent. Activity in articular and cutaneous domains were the main reasons of indication. No changes in prescription habits were identified over time.

GLUCOCORTICOIDS WITHDRAWN IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH SEROLOGICALLY ACTIVE CLINICALLY QUIESCENT STATE: A DESIRABLE GOAL

Keywords: Systemic lupus erythematosus, Organ damage, Remission

D. Yufang[1], J. Zhao[1], Q. Wang[1], X. Tian[1], M. LI[1], X. Zeng[1]. *[1]Peking Union Medical College Hospital (PUMCH), Rheumatology, Beijing, China*

Background: Serologically active clinically quiescent (SACQ) is a clinical state of systemic lupus erythematosus (SLE) characterized by high levels of serologic markers without clinical activity. The outcome and treatment strategy after SACQ achievement remains unclear. After achieving the treatment goal, maintaining low-dose glucocorticoids has always been both a blessing and a curse [1,2]. Whether glucocorticoids discontinuation is a desirable goal in patients achieved SACQ was controversial.
Objectives: In this multi-center prospective study, we aimed to identify the risk of flares, organ damage accumulation, and the low-dose glucocorticoids discontinuation feasibility of SLE patients who achieved the clinical state as SACQ.
Methods: This observational study was conducted based on data from the Chinese SLE treatment and research (CSTAR) registry. Demographic characteristics, autoantibody profiles, clinical manifestations, disease activity status, organ damage, and treatment profile were collected at recruitment and during follow-up. SACQ was defined as at least a 6-months period with persistent serologic activity (positive anti-dsDNA antibody, and/or hypocomplementemia), and without clinical activity. Serologically quiescent clinically quiescent (SQCQ) was defined as at least a 6-months period without serologic or clinical activity. The flare was measured according to the SELENA-SLEDAI flare index (SFI). Organ damage is principally assessed using the SLICC damage index (SDI).
Results: Of 4107 SLE patients, 1889 reached the clinical quiescent stage (990 achieved the clinical state as SACQ, and 899 patients achieved SQCQ). Among 990 SACQ patients, 364 (36.7%) underwent flares, 163(16.5%) showed organ damage, 47 (4.7%) developed renal damage, and 21 (2.1%) died during a mean follow-up of 7.30 years. Compared with patients who achieved SQCQ, SACQ patients were at a higher risk of flares (HR=1.47, 95% CI 1.25-1.73 , p<0.001) and renal damage accumulation (HR=2.02, 95% CI 1.23-3.33, p=0.004). Furthermore, 224 (22.6%) SACQ patients withdraw low-dose glucocorticoids and 125 (55.8%) of them did not flare during follow-up. Low-dose glucocorticoids discontinuation was a favorable factor of long-term survival (HR=0.22, 85% CI, 0.05-0.96, P=0.044). As shown in the Figure 1, withdrawing glucocorticoids can reduce organ damage (p=0.0075), especially renal damage accumulation (p=0.045), even experience flares after discontinuation.
(A) (B)

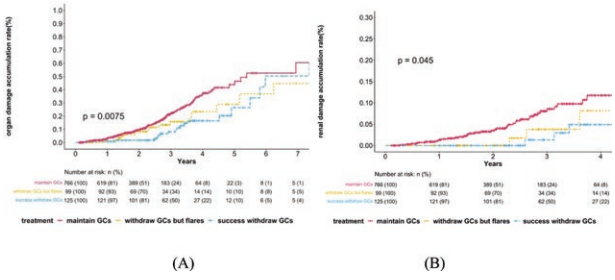

Figure 1. Cumulative probability of new-onset organ damage (A) and renal damage (B) in SACQ patients maintain glucocorticoids, withdraw glucocorticoids but flares, and successful withdraw glucocorticoids.

Conclusion: Our results suggest that low-dose glucocorticoids withdrawal under tight survallance could be considered after achieving the clinical state as SACQ to prevent the accrual of renal damage.

Hobar[7]. *[1]Oklahoma Medical Research Foundation, Arthritis & Clinical Immunology, Rheumatology, Oklahoma City, United States of America; [2]University of Oklahoma Health Sciences Center, Medicine, Oklahoma City, United States of America; [3]Columbia University, Rheumatology, New York, United States of America; [4]Northwell Health, Rheumatology, Great Neck, United States of America; [5]Monash University, School of Clinical Sciences, Victoria, Australia; [6]Amsterdam University Medical Centers, Clinical Immunology and Rheumatology, Amsterdam, Netherlands; [7]Bristol Myers Squibb, Clinical Development, Princeton, United States of America*

Background: Deucravacitinib is a first-in-class, oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis [1,2]. Deucravacitinib demonstrated efficacy across the primary endpoint and all key secondary endpoints in a phase 2 trial in patients with systemic lupus erythematosus (SLE) [3].
Objectives: Here, we describe 2 phase 3 trials currently underway to assess the efficacy and safety of deucravacitinib in patients with active SLE. These phase 3 trials have been designed to replicate the successful elements of the phase 2 trial, including its glucocorticoid-tapering strategy and rigorous management structure [3].
Methods: In these phase 3, randomized, double-blind, placebo-controlled, global trials (POETYK SLE-1 [NCT05617677], POETYK SLE-2 [NCT05620407]), adults (aged 18-75) with active SLE on background standard-of-care treatment will be randomized (1:1) to placebo or deucravacitinib for 52 weeks of double-blind treatment (**Figure 1**). Patients on glucocorticoids will be instructed to taper, unless significant disease activity is present, to a threshold dose level during the double-blind treatment period. At week 52, patients may choose to continue in a 104-week open-label extension phase, in which all patients receive deucravacitinib. Key eligibility criteria and study design are depicted below (**Figure 1**). The primary endpoint of SLE Responder Index (SRI[4]) and all secondary endpoints will be assessed at week 52 (**Table 1**). Safety and tolerability will be assessed throughout the trial.
Results: Planned randomization in each trial includes 490 patients (245 per treatment group) in 27 countries across North and South America, Europe, and Asia-Pacific.
Conclusion: The phase 3 POETYK SLE trials will further evaluate the efficacy and safety of deucravacitinib, an oral, selective, TYK2 inhibitor, in patients with active SLE.

Figure: POETYK SLE-1 and POETYK SLE-2 Trial Design

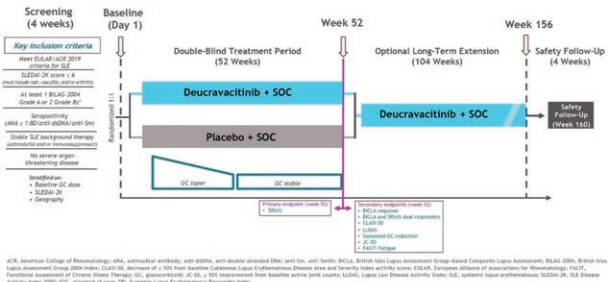

Table 1. Primary and Secondary Endpoints Assessed at Week 52

Primary Endpoint
• Proportion of patients who achieve an SLE Responder Index (SRI[4]) response
Secondary Endpoints
• Proportion of patients who achieve a British Isles Lupus Assessment Group-based Composite Lupus Assessment (BICLA) response
• Proportion of patients with simultaneous achievement of SRI(4) and BICLA response (dual responders)
• Proportion of patients who achieve a ≥ 50% reduction in Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI-50) among patients with CLASI activity score ≥ 10 at baseline
• Proportion of patients who achieve Lupus Low Disease Activity State (LLDAS)
• Proportion of patients maintaining ≤ 7.5 mg/day glucocorticoid dose from weeks 24 to 52
• Proportion of patients who achieve a ≥ 50% reduction in active joints (Joint-Count 50) among patients with ≥ 6 active joints at baseline
• Change from baseline in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score

Van Vollenhoven[12], M. B. Urowitz[13]. *[1]Columbia University Irving Medical Center, Department of Medicine, New York, NY, United States of America; [2]Northwell Health, Division of Rheumatology, Great Neck, NY, United States of America; [3]University of California San Francisco School of Medicine, Division of Rheumatology, San Francisco, CA, United States of America; [4]Rhineland Palatinate, Rheumatology Center, Bad Kreuznach, Germany; [5]Johannes Gutenberg University Mainz, University Medical Centre, Mainz, Germany; [6]Peking University First Hospital, Renal Division, Beijing, China; [7]The University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom; [8]GSK, Medical Affairs, Dubai, United Arab Emirates; [9]GSK, US Medical Affairs, Research Triangle Park, NC, United States of America; [10]GSK, Global Medical Affairs, Stevenage, United Kingdom; [11]GSK, Specialty Care, Global Medical Affairs, Collegeville, PA, United States of America; [12]Amsterdam Rheumatology and Immunology Center and Amsterdam University Medical Centers, Department of Rheumatology, Amsterdam, Netherlands; [13]University of Toronto, Professor Emeritus, Department of Medicine, Toronto, ON, Canada*

Background: We have recently published a working definition of disease modification in lupus nephritis (LN) as 'minimising disease activity with the fewest treatment-associated toxicities and slowing progression to end-stage kidney disease' [1]. As an increasing number of LN medications become available, classification of treatments as disease-modifying is critical in informing treatment decisions.
Objectives: To apply the proposed disease modification criteria to LN treatments.
Methods: Based on a review of a selection of LN clinical trial (n=21) and practice/observational publications (n=18) and authors' clinical experience, we determined whether the LN treatments satisfied the renal disease activity and organ damage disease modification criteria. The proposed disease modification criteria were examined at three time points as shown in the **Table 1**.
Results: All LN treatments met at least one of the renal disease modification criteria at any time point (**Table 1**), with hydroxychloroquine meeting the criteria for confirmed disease modification at >5 years (no change in Systemic Lupus International Collaborating Clinics/American College of Rheumatology Disease Index [SDI] or delayed progression beyond 5 years). Belimumab met more criteria across the three time points than any other biologic treatment. Based on the reviewed literature, many criteria were inconclusive or not available for evaluation. Glucocorticoids did not meet the disease modification criteria beyond 5 years given their negative impact on organ damage progression.
Conclusion: We examined the evidence in the literature for the disease modification potential of LN therapies at 1, 2–5, and >5 years. Categorisation of treatments as disease-modifying is challenging, as studies use multiple agents, and study designs, patient populations, and endpoints/definition of renal response are not consistent between studies. The criteria allowed for the differentiation between LN therapies; future studies will evaluate the minimum number of criteria required to designate disease modification at each of the three time points, so that disease modification can be considered in the care of patients with LN and LN trial design.

THE USE OF BDMARDS IS ASSOCIATED WITH A LOWER PREVALENCE OF BILATERAL CAROTID PLAQUE IN PSA

Keywords: Cardiovascular disease, bDMARD

D. Á. Galarza-Delgado[1], I. J. Colunga-Pedraza[1], J. R. Azpiri-López[2], N. De Avila Gonzalez[1], V. M. Beltran-Aguilar[1], V. Gonzalez-Gonzalez[1], A. G. Arias Peralta[1], J. A. Cardenas-de la Garza[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico;* [2]*Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico*

Background: Psoriatic arthritis (PsA) is an autoimmune rheumatic disease (ARD) [1]. PsA have excessive cardiovascular risk (CVR) because of systematic inflammation that triggers endothelial dysfunction, which in turn induces atherosclerosis and CV disease [2]. Possible beneficial effects of biologic disease modifying antirheumatic drugs (bDMARDs) in patients with ARDs have been seen, particularly those with rheumatoid arthritis. Treatment with TNF inhibitors seems to improve endothelial dysfunction and atherosclerosis [3].
Objectives: To evaluate the presence of carotid disease in patients with PsA using biologics or non-biologics.
Methods: This was a cross-sectional, descriptive study. PsA patients aged 40-75 years, who fulfilled the 2006 CASPAR criteria were recruited. Carotid ultrasound was performed on all study participants, and the presence of carotid plaque (CP), defined as carotid intima-media thickness (cIMT) ≥1.2mm or focal thickness ≥0.5mm, was assessed. Patients were divided into 2 groups according to whether they use bDMARDs or not. Comparisons were done with Chi-square test, Student´s T test and Mann-Whitney's U-test. A p-value ≤0.05 was considered significant.
Results: A total of 67 patients were recruited. Demographic characteristics are shown in Table 1. Twenty-seven were under bDMARD treatment, twenty-five of these were using an anti-TNF. We found a difference in C-reactive protein (CRP) levels (p=0.004), lower in patients with bDMARDs and in the presence of bilateral CP (p=0.041), less prevalent in patients with bDMARDs. The rest of the variables studied did not show significant differences.
Conclusion: We found that PsA patients under bDMARDs therapy had lower levels of CRP and less prevalence of bilateral CP in PsA, therefore strengthens the theory that the less inflammation the less bilateral carotid plaque is present.

AB0533 EFFECT OF RENIN-ANGIOTENSIN SYSTEM INHIBITORS ON RENAL REMISSION IN LUPUS NEPHRITIS: A REAL-WORLD SINGLE-CENTER STUDY

Keywords: Clinical trials, Systemic lupus erythematosus, Kidneys

X. Zhang[1,1,1], H. Huang[1,1], Y. Fan[1], Z. Zhang[1,1]. [1]*Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China*

Background: Renin-angiotensin-system inhibitors (RASi) reduce urinary protein excretion and protect renal function in both diabetic and nondiabetic nephropathy. Few studies have focused on RASi in LN patients.
Objectives: The study aimed to provide real-world evidence to assess the effect of RASi in LN patients.
Methods: A total of 233 LN patients were included; 155 were RASi users, and 78 were not. The rate of proteinuria partial recovery (PPR), complete remission (CR), total remission (TR), the decline and decline rate of proteinuria at 6 and 12 months were compared by Chi-square test and Kaplan–Meier analysis. Propensity score matching (PSM) and Cox regression analysis was performed.
Results: The cumulative rates of PRR, TR and CR were 133 (85.8%), 103 (66.9%), and 53 (34.2%) in the RASi group compared to 66 (87.7%), 55 (71.1%), and 44 (57.2%) in the no RASi group at 6 months, respectively. At 12 months, the cumulative rates of PRR, TR and CR were 144 (99.4%), 115 (76.1%), and 83 (56.0%) in the RASi group and 73 (97.3%), 64 (83.5%) and 54 (71.3%) in the no RASi group, respectively. There was no statistically significant difference in cumulative PRR and TR rates between the two groups (p=0.601 and 0.203). The cumulative CR rate was significantly higher in the no RASi group (p=0.001). The UTP level of the RASi group was consistently higher than that of the no RASi group at 6 [0.5(0.2,1.6) vs. 0.3(0.1,0.7), p=0.003) and 12 months [0.2(0.1,0.6) vs. 0.1(0.1,0.3), p=0.008]. However, the ΔUTP was significantly higher in the RASi group [6 months: 2.6 (1.3, 5.1) vs. 1.2 (0.8, 2.4), p=0.001; 12 months: 3.3 (1.6, 5.4) vs 1.4 (0.9, 2.9), p=0.001], and the decline rate did not reach significance. Meanwhile, the serum SCr showed no difference between the two groups. The results were similar after PSM. Only HCQ usage was a prognostic predictor of PRR (HR 2.110, 95% CI: 1.223, 3.642, p=0.007).
Conclusion: RASi may not benefit the renal remission of LN, and the results need to be interpreted with caution. However, RASi may help to decrease urinary protein. Further high-quality randomized controlled trials are required to evaluate the RASi effects on proteinuria and renal prognosis.

AB0534 TREATING SYSTEMIC LUPUS ERYTHEMATOSUS IN THE 21ST CENTURY: COMBINING RITUXIMAB WITH BELIMUMAB

Keywords: Systemic lupus erythematosus, Treat to target

B. Issayeva[1], A. Mesnyankina[2], E. Aseeva[2], S. Solovyev[2], N. Nikishina[2], S. Issayeva[1], M. Saparbayeva[1], A. Amanzholova[1], A. Razikhova[1], A. Abdulgaziz[1]. [1]*Asfendiyarov Kazakh National Medical University, Rheumatology, Almaty, Kazakhstan;* [2]*Federal State Research Institution (FSRI) named after V.A. Nasonova, Rheumatology, Moscow, Russian Federation*

Objectives: efficacy of combination therapy with rituximab and belimumab in patients with systemic lupus erythematosus.
Methods: The study included 15 SLE pts (1M/14F) criteria with high (SLEDAI2K≥10 – 12pts.) and moderate (SLEDAI2K<10- 3pts.) disease activity; out of them 4 patients had lupus nephritis, 2- vasculitis. 1 pts had kidney damage, cerebrovasculitis and vasculitis. All patients fulfilled the Systemic Lupus Erythematosus International Collaborating Clinics (SLICC) disease classification criteria [1] for SLE Others have predominantly mucocutaneous and articular manifestations of SLE. The dose of oral glucocorticoids (GC) was: 60 mg in one patient with vasculitis, LN, cerebrovasculitis, and one patient with vasculitis received 20 mg of prednisone; in 11 patients from 10 to 5 mg; in 2 patients without oral glucocorticoids. All patients with SLE with kidney damage and vasculitis received mycophenolate mofetil or cyclophosphamide. Rituximab (RTM) was administered at a dose of 500-2000 mg, followed by the addition of belimumab (BLM) after 1-6 months at a standard dose of 10 mg/ kg once a month - a total of 7 infusions. The following parameters were evaluated: the effectiveness of therapy, the concentration of autoantibodies, the dose of oral corticosteroids initially at the time of RTM administration and then every 3 months after the initiation of BLM therapy.
Results: 13 pts demonstrated the decrease in clinical and laboratory SLE activity, starting from 3mo of follow-up. After the start of BLM infusions, a decrease in SLE activity was observed in all patients. Among them, 10 had SLEDAI-2K activity of less than 4 points. SLEDAI-2k Me 10 [10;16], after treatment of RTM and BLM 4[2;6]. Only one patient (№4) had an relapse of SLE, due to the delay

in receiving the infusion of BLM. He was receiving standard GC doses. In dynamics, a decrease anti-double DNA titres (Me 101 [36;200]U/ml vs 28 [8;67]Ед/мл), C3 (0,49 [0,42;0,78]g/l vs 0,71 [0,59;0,87] g/l), C4 (0,06 [0,045;0,1] g/l vs 0,12 [0,07;0,14] g/l) was registered. The GC dose was reduced in most patients (Table 1), but the previously prescribed immunosuppressive therapy continued. There were no cases of severe infection. We have not detected any new organ damage.

Table 1. Dose of oral glucocorticoids, mg

№ patient	Before RTM, mg	1st injection of BLM, mg	7th injection of BLM, mg	
1	20 mg	20 mg	15 mg	↓
2	7,5 mg	5 mg	5 mg	↓
3	5 mg	5 mg	5 mg	=
4	10 mg	10 mg	10 mg	=
5	5 mg	5 mg	5 mg	=
6	60 mg	7,5 mg	2,5 mg	↓↓↓
7	10 mg	2,5 mg	0 mg	↓↓↓
8	10 mg	10 mg	5 mg	↓
9	2,5 mg	2,5 mg	2,5 mg	=
10	10 mg	10 mg	5 mg	↓
11	0 mg	0 mg	0 mg	=
12	0 mg	0 mg	0 mg	=
13	15	15	10	↓
14	15	5	3,75	↓↓
15	20	10	10	↓

Conclusion: Combination therapy allows to gain control over disease activity in short time, due to the effect of RTM, while added BLM provides further prolongation of the effect achieved, minimizing the risk of flare. The use of such therapy contributes to a rapid and effective reduction in the activity of the disease, improvement of laboratory markers of SLE (at to ds-DNA, C3, C4), the use of lower doses of oral GCs. This combination may be used as a method of choice in pts with severe SLE involving vital organs, and in persistent cutaneous-articular disease and high immunological activity.

AB0535 EFFICACY AND SAFETY OF BELIMUMAB IN PATIENTS WITH CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS:A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Systematic review, Systemic lupus erythematosus, Targeted synthetic drugs

L. Yang[1,2], Q. Y. Su[1,2,3], R. X. E. Yang[1,2], J. J. Cao[1,2], P. Su[1,2], H. Niu[1,2], S. L. Liu[1,2], J. Q. LI[1,2], Q. Yu[4], P. F. He[4], X. LI[1,2,3], S. X. Zhang[1,2,3]. *[1]Shanxi Medical University, Ministry of Education, Key laboratory of Cellular Physiology, Taiyuan, China; [2]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [3]Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [4]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*

Background: Childhood-onset systemic lupus erythematosus (cSLE) is associated with higher disease severity than adult-onset lupus. Abnormal activation of B cells is a crucial link in their pathogenesis. Belimumab is a specific inhibitor of the soluble B lymphocyte stimulator and inhibits its binding to receptors and thus its activity [1,2]. However, the current clinical research evidence of this drug in children is insufficient, the relevant clinical data are mostly from prospective studies in adults,and there are no exact guidelines for clinical application in children.

Objectives: This study aimed to investigate the efficacy and safety of belimumab for treating children with cSLE.

Methods: We systematically searched PubMed, EMBASE, Wan Fang Data,Web of Science, the Cochrane Library, and Medline for randomized controlled trials, original case reports, and case series that described belimumab's efficacy in treating cSLE. A random-effects meta-analysis was performed to calculate its efficacy. Inconsistency was evaluated using the I2 and Egger tests to evaluate potential publication bias (STATA v.12.0).

Results: Five studies with 325 patients were included in the meta-analysis (Table 1). The age range of the included participants was less than 18 years; most were women. All patients received belimumab at a dosage of 10mg/kg every 2 weeks for the first three doses, then every 4 weeks thereafter. SLEDAI-2K was the main score,which was significantly reduced compared with the baseline[SMD= -1.106, 95%CI (-1.311,-0.901), P<0.001]. The number of oral corticosteroids was significantly decreased after the belimumab therapy[SMD = -1.21,95%CI (-1.72, -0.70), P<0.001]. Both Anti-double stranded DNA (Anti-dsDNA) and anti-nuclear antibodies (ANA) positive patients also decreased obviously[RR= 0.56, 95%CI (0.37,0.85), P=0.007; RR= 0.90, 95%CI (0.83,0.98), P=0.012]. Infection and thrush were the main adverse effects with rates of 26% and 4%,respectively, but all were classified as mild-moderate treatment-emergent adverse events. Serious adverse reactions are rarely reported.

Conclusion: Belimumab treatment in cSLE minimizes the use of hormones, and the incidence of adverse events such as infections was low, suggesting belimumab can effectively reduce disease activity safely and reliably. Long-term efficacy and safety still need a multicenter, large sample, long-term, in-depth research.

CORRECTION OF OMEGA-3 FATTY ACID DEFICIENCY AND IMPROVEMENT IN DISEASE ACTIVITY IN SLE PATIENTS TREATED WITH A CONCENTRATED EXTRACT OF KRILL OIL (AKM-3031)

Keywords: Diet and Nutrition, Systemic lupus erythematosus, Randomized control trial

J. E. Salmon[1], D. J. Wallace[2], V. Rus[3], P. Lipsky[4]. *[1]Hospital for Special Surgery, Rheumatology, New York City, United States of America; [2]Cedars-Sinai Medical Center, Rheumatology, Beverley Hills, United States of America; [3]University of Maryland Medical System, Rheumatology, Baltimore, United States of America; [4]AMPEL BioSolutions, Research and Development, Charlottesville, United States of America*

Background: Omega-3 fatty acids play a critical role in regulating inflammation. Patients with SLE have been reported to be deficient in omega-3 fatty acids, and deficiency could play a role in the ongoing inflammation characteristic of this disease. Previous work has produced conflicting results regarding the capacity of Omega-3 supplementation to control SLE disease activity.
Objectives: The goals of this study were to determine the level of omega-3 deficiency in SLE patients and to determine whether supplementation with a concentrated extract of krill oil rich in omega-3 fatty acids (AKBM-3031) could overcome the deficiency in SLE patients and decrease disease activity.
Methods: This was a randomized double blind controlled multicenter study of patients with active SLE (SLEDAI >/= 6). Patients meeting entry criteria were randomized to receive AKBM-3031 (4 grams/day) or identical placebo capsules containing mixed oils simulating that in a western diet (NCT03626311). Patients received investigational product or placebo daily for 24 weeks, at which time placebo patients could opt to receive AKBM-3031 for the subsequent 24 weeks, whereas those receiving AKBM-3031 continued on the medication. The primary outcome was the correction of the red blood cell omega-3 index determined by OmegaQuant. Changes in clinical features and adverse events were collected throughout the trial.
Results: 79 subjects were enrolled in the study; 97% of the patients were women and 56% were of European and 35% of African Ancestry. At baseline, the mean omega-3 index was 4.65+/- 1.09, below the lower limits of normal for the North American population (6.0). After 4 weeks of treatment with AKBM-3031, the Omega-3 index significantly increased from 4.65+/- 1.09 to 7.21+/-1.37, (p < 0.0001), whereas no significant change was noted in the patients receiving placebo. Increases in the Omega-3 index in AKBM-3031 treated patients persisted throughout the 48 weeks of the trial. Notably, when patients were changed from placebo to AKBM-3031 at 24 weeks, there was a rapid increase in the Omega-3 index (4.62+/-1.39 to 6.58+/- 1.85, p=0.0001). The total number of adverse events was less in the AKMB-3031group (186) than in the placebo group (342), most were mild or moderate and no serious adverse events were noted. Although there were no significant changes in disease activity when the entire groups were examined, there was a significant decrease in disease activity measured by SLEDAI-2K at 4, 8 and 16 weeks (p=0.0007, 0.04, 0.02, respectively) in the patients receiving AKBM-3031with high disease activity at baseline (SLEDAI >/=9).
Conclusion: Treatment of SLE patients with AKBM-3031 rapidly corrects the Omega-3 deficiency characteristic of these patients. AKBM-3031 was safe and decreased disease activity in those with more active SLE. These results suggest benefit of Omega-3 deficiency correction with AKBM-3031 in SLE patients with active disease and warrant a more extensive evaluation.

RITUXIMAB THERAPY IN LUPUS NEPHRITIS RESISTANT TO CONVENTIONAL THERAPY – A SINGLE CENTER EXPERIENCE (CASE SERIES)

Keywords: Systemic lupus erythematosus, Real-world evidence, Safety

E. Firat Senturk[1], H. Ogun[1], I. Durucan[1], B. Yurttas[2], S. Ugurlu[1]. *[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Tekirdag Ismail Fehmi Cumalioglu City Hospital, Department of Internal Medicine, Division of Rheumatology, Tekirdag, Turkey*

Background: Lupus nephritis(LN) can be a cause of morbidity and mortality in a significant portion of patients. The treatment of lupus nephritis can be challenging in some patients who are resistant to conventional immunosuppressive treatment.
Objectives: Rituximab is a promising agent for treating resistant LN patients. We evaluated the response of LN patients who were treated with rituximab treatment in our clinic retrospectively.
Methods: We evaluated LN patients who were followed and treated with at least one course of rituximab in our clinic between 2010-2022. LN was confirmed by renal biopsy. Creatinine clearence, serum creatinine, 24- hour proteinuria and Systemic Lupus Erythematosus- Disease Activity Index- 2000 (SLE-DAI-2K) were analyzed before and after Rituximab treatment. Primary end point was current prednisolone dose ≤5mg and 24-hour proteinuria ≤ 500mg. Also, we evaluated the side effect of rituximab.
Results: Forty seven patients (34 F, 13 M) were treated with rituximab. All patients had active lupus nephritis at initiation. Mean of disease duration was 10.44 ± 6.9 years. All patients were initally treated with high dose steroids. The other medications, the patients were previously treated with, were cyclophosphamide (n= 35), mycophenolate mofetil (n= 31), azathioprine (n= 6), cyclosporine (n= 2). Patients received an average of 4.1 ± 3.68 courses of rituximab (Table 1). The median value of pre-treatment proteinuria was 3050 (1370, 5175) mg/day. The median value of proteinuria after the final course was 747 (396, 1500) mg/day (p< 0.01). Serum creatinine level was changed from 0.94 ± 0.59 to 0.98 ± 0.68 (p= 0.53). Mean serum creatinine clearence was increased from 102.01 ± 43.2 to 109.1 ± 51.3 (p=0.28). Mean SLE-DAI-2K was reduced from 16.3 ± 6.2 to 7.2 ± 4.8 (p< 0.01). While initial steroid dose was 24.13 ± 18.47 mg/day, steroid dose at last rituximab course was 7.5 ± 5.8 mg/day (p< 0.01). End stage renal disease was developed in 3 (%6) patients. For primary end point of view, currrent prednisolone dose ≤ 5mg and 24-hour proteinuria ≤ 500 mg were achieved in %53.1, %36.1 of patients respectively. Both criteria was met by %25.5 of patients. During the treatment, 2 patients had serum reaction, 3 had pneumonia, 3 had herpes zoster. Three patients had hippogamaglobulinemia and treated with intravenous immunoglobulin. No one was died of lupus nephritis.
Conclusion: In lupus nephritis patients resistant to conventional therapy, rituximab can be tried as an alternative treatment choice. In our single center, most of the patients were class IV nephritis whom we observed the efficacy of rituximab. Generally, the side effects were acceptable. Rituximab could be a good option as a steroid reducing agent and exhibit a favorable clinical response in these patients.

LOW-DOSE BELIMUMAB AND ANTIMALARIAL AGENTS PREVENT RENAL FLARES IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM FOUR RANDOMISED CLINICAL TRIALS

Keywords: Systemic lupus erythematosus, bDMARD, Kidneys

A. Gomez[1,2], S. Jägerback[3], C. Sjowall[4], I. Parodis[1,2,5]. [1]*Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden;* [2]*Karolinska University Hospital, Medical Unit of Gastroenterology, Dermatology, and Rheumatology, Stockholm, Sweden;* [3]*Danderyd University Hospital, Division of Rheumatology, Stockholm, Sweden;* [4]*Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection, Linköping, Sweden;* [5]*Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden*

Background: Lupus nephritis (LN) is one of the most severe manifestations in systemic lupus erythematosus (SLE), constituting a substantial cause of end-stage kidney disease, dialysis, and mortality. Prompt and adequate treatment of LN, and prevention of renal flares are key components of disease management towards improved outcomes in patients with SLE.
Objectives: We aimed to determine the effect of the use of antimalarial agents (AMA) and different doses and pharmaceutical forms of belimumab on preventing renal flares in patients with active SLE.
Methods: We pooled data from the BLISS-52, BLISS-76, BLISS-SC and BLISS-Northeast Asia randomised clinical trials of belimumab (N=3225), that included patients with seropositive (antinuclear antibody titres ≥1:80 and/or anti-dsDNA levels ≥30 IU/mL), active SLE yet no severe ongoing renal disease. Participants were allocated to receive intravenous (IV) belimumab 1 mg/kg (N=559), IV belimumab 10 mg/kg (N=1033), subcutaneous (SC) belimumab 200 mg (N=556) or placebo (N=1077) in addition to standard therapy. Additionally, we classified patients as AMA users if they had received hydroxychloroquine, chloroquine, mepacrine, or quinine sulphate in stable doses for at least 30 days prior to the trial commencement. The outcome of the present post-hoc analysis was development of renal flares, defined according to the analysis plan within the BLISS programme. The hazard of renal flare was assessed with Cox proportional hazards regression models, adjusted for age, sex, ethnicity, previous renal involvement, baseline proteinuria and glomerular filtration rate, and use of glucocorticoids and immunosuppressants.
Results: In total, 192 patients developed a renal flare after a median of 197 days. In multivariable Cox regression analysis, use of AMA was associated with a lower risk of renal flares (HR: 0.64; 95% CI: 0.54–0.96; p=0.026). Compared with placebo, the risk of renal flares was lower among patients receiving IV belimumab 1 mg/kg (HR: 0.44; 95% CI: 0.25–0.79; p=0.006) and IV belimumab 10 mg/kg (HR: 0.63; 95% CI: 0.45–0.87; p=0.005), but not SC belimumab 200 mg (HR: 0.90; 95% CI: 0.57–1.42; p=0.648). When analysing all study arms with and without antimalarials separately, patients receiving IV belimumab 1 mg/kg along with AMA experienced the lowest rate of renal flares (18.5 (7.4–38.1) cases per 1000 person-years). Using patients who received placebo but not AMA as the reference comparator, patients receiving IV belimumab 1 mg/kg (OR: 0.30; 95% CI: 0.13–0.70; p=0.005) and patients receiving IV belimumab 10 mg (OR: 0.45; 95% CI: 0.27–0.75; p=0.002) were protected against renal flares only when belimumab use was combined with AMA.
Conclusion: In this RCT setting, belimumab and AMA protected against renal flares in patients with active seropositive SLE yet no ongoing severe renal involvement. The protective effect of IV belimumab against renal flares appeared optimal when belimumab was combined with AMA. The prominent effect of low-dose belimumab motivates investigation of the efficacy of intermediate doses of belimumab.

Background: Anifrolumab (ANI) a human monoclonal antibody to type I interferon receptor subunit 1 has been recently approved for the treatment of SLE. In SLE, the skin is not only a target but also a key- driver of the autoimmune response via the production of type I IFN.
Objectives: To evaluate the efficacy of ANI in real-life under the early access program (09/2021 – 03.2022).
Methods: A total of seven patients (all female, mean age 50 years, disease duration 15 years) with SLE- diagnosis based on ACR1997 or SLICC or EULAR/ACR 2019 classification criteria for SLE and inadequate response to prior immunosuppressive therapies received ANI from 09/2021 until 03.2022 as part of an early access program. Patients' demographics, clinical and laboratory characteristics, disease activity (SLEDAI-2K, CLASI) were recorded at baseline and first months of the administration of ANI.
Results: Active skin disease was the dominant clinical manifestation of all patients for the administration of ANI (subacute cutaneous lupus in 6/7, discoid lupus in 3/7, severe chemeltular lesions in one patient). Patients had received an average of 5.1 immunosuppressive drugs before ANI, with an inadequate response. The mean (SD) SLEDAI index at baseline was 6.9 (1.1) and the mean (SD) prednisone dose 2.7 (2.8) mg/day. In reference to the skin disease, mean (SD) CLASI (Activity/Damage) before first administration of ANI was 9.9/1.4 (6.3)/(2.2). A rapid response of the skin disease, especially the subacute cutaneous lupus lesions, was observed from the first injection of ANI. As expected, the results were less prominent in patients who had discoid lupus lesions, although patients reported subjective improvement. The mean (SD) SLEDAI, CLASI and daily prednisone dose are 3.4 (1.8), 3/1.4 (1.4/2.2) and 2.5 (2.5) mg, respectively. After a mean (SD) follow-up of 5.7 (2.0) months, one patient discontinued ANI due to VZV infection.
Conclusion: IFN inhibition is effective for the treatment of refractory cutaneous lupus manifestations. The prompt response of the dermatologic disease to ANI likely reflects the beneficial effects of neutralization of IFN on the autoimmune and vasculopathic processes in SLE.

Background: Women living with Systemic Lupus Erythematosus (SLE) are at increased risk of pregnancy complications, including preeclampsia (PE). Placental dysfunction is the key pathogenic event, but the underlying mechanisms are scarcely known.
Objectives: This study aimed to investigate global hemostatic assays in pregnant SLE patients in relation to PE and the use of anti-thrombotic prophylaxis.
Methods: Patients with SLE were sampled during the third trimester of gestation for coagulation and haemostasis (C&H) assays: 1) overall coagulation potential (OCP); 2) overall haemostatic potential (OHP); 3) overall fibrinolysis potential (OFP), plasma levels of fibrinogen and D-dimer. Pregnant healthy controls (HC) with and without PE were also analysed.
Results: Twenty-two consecutive pregnant SLE patients, 80 pregnant HC without PE, and 42 pregnant HC with PE were analysed. Disease characteristics, pregnancy features, and coagulation parameters are reported in Table 1. No thrombotic or bleeding events occurred in SLE patients. Four SLE patients experienced PE (18.2%) despite treatment with low dose acetylsalicylic acid (LDASA) ± low molecular weight heparin (LMWH). These patients displayed significantly lower OCP and OFP, but not OHP, as compared to SLE without PE. Among 4 SLE+PE patients, the 2 treated with LMWH tended to have lower OCP, OHP, and OFP values as compared to the 2 untreated patients (134.9±190.7 vs 372.3±24.6; 90.6±128.2 vs 202.2±24.1; 16.4±23.3 vs 45.4±10.1). Among SLE patients treated with LMWH, undetectable

OHP (Abs-sum)	187.4±83.8	196.5±80.4	146.4±99.1	204.4±64.8	166.9±102	173.1±46.0	195.2±36.7
OFP %	44.7±18.6	47.8±16.9[l]	30.9±22.2[m]	53±10.1[n]	34.8±21.9 [n]	29.2±12.4[l]	15.3±9.2[m]

OCP, OHP, and OFP were found in 1 out of 2 SLE+PE and 1 out of 6 SLE without PE. No differences across groups were found for fibrinogen and D-dimer levels.

Conclusion: C&H parameters were altered in SLE pregnancy as compared to HC pregnancy, either in pregnancies complicated by PE or not. LWWH is expected to reduce to zero the values of OCP, OHP, and OFP, but this phenomenon was not observed in all SLE treated patients, suggesting that the response to LMWH can be variable among SLE pregnant patients. Larger and longitudinal studies across trimesters of gestation will clarify whether C&H parameters are useful to monitor treatment effects and improve the management of SLE pregnancy.

AB0541 EFFICACY OF DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN PRIMARY SJÖGREN'S SYNDROME-RELATED INTERSTITIAL LUNG DISEASE

Keywords: Disease-modifying drugs (DMARDs), Clinical trials, Sjögren syndrome

F. Erbasan[1], T. S. Öğüt[1], M. Dibil[1], M. Nokay[1], M. E. Terzioğlu[1], V. Yazısız[1]. *[1]Akdeniz University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Antalya, Turkey*

Background: Primary Sjögren's syndrome (pSS) is mainly characterized by dry mouth and eyes due to loss of secretory function of exocrine glands, and systemic involvement can be seen [1]. One of the most important causes of morbidity and mortality in pSS is interstitial lung disease (ILD) [2]. Primary SS-related ILD (pSS-ILD) treatment is usually based on the clinician's experiences since there are insufficient clinical studies.

Objectives: To evaluate the treatment modalities applied to patients with pSS-ILD and the functional response to the treatment.

Methods: A retrospective analysis was performed, of patients with pSS-ILD, who received conventional or biological disease-modifying antirheumatic drugs between January 2004 and August 2022. Forced vital capacity (FVC%) and diffusing capacity of carbon monoxide (DLCO%) performed within 1 month before treatment and within 1 month after treatment cessation, were analyzed. The effects of DMARDs on pulmonary function and whether there was a difference in their effectiveness were evaluated.

Results: The prevalence of pSS-ILD was 7.2%. The mean age of 27 patients included in the study was 62.6±10.8, and 20 (74.1%) of the patients were female. Among all DMARDs (19/47) and first-line treatments (16/27), AZA was the most frequently used agent. Other agents used were MMF (n=11), RTX (n=8), CyC (n=5), and MTX (n=4). There was an increase in FVC% (from 80.20±22.1 to 81.6±23.0) and FEV1% (from 73.8±20.6 to 75.3±22.8) and a decrease in DLCO% (from 53.7±15.3 to 52.2±19.3) with DMARDs treatment, but the difference was not statistically significant (p=0.434, p=0.463, and p=0.652, respectively). There was a statistically non-significant decrease in %FVC with AZA and an increase with MMF, RTX, and CyC (Table 1). Also, there was no significant change in DLCO% values with AZA, MMF, and RTX (Table 1). The HRCT patterns were UIP in 13 (48.1%) patients, NSIP in 9 (33.3%), LIP in 2 (7.4%), and unclassified in 3 (11.1%). There were no significant differences in FVC% and DLCO% parameters with DMARDs treatment in patients with UIP and NSIP patterns.

Conclusion: DMARDs can stabilize pulmonary functions and delay worsening in patients with pSS-ILD.

AB0542 PRIMARY SJÖGREN'S SYNDROME AND INTERSTITIAL LUNG DISEASE. RESULTS OF AN OBSERVATIONAL COHORT

Keywords: Lungs, Disease-modifying drugs (DMARDs), Sjögren syndrome

P. Muñoz Reinoso[1], F. J. Toyos Sáenz de Miera[1], I. M. Fernández-Maeztu Palacín[1], A. Fernández Reboul Fernández[1], J. J. Pérez Venegas[1]. *[1]Hospital Universitario Virgen Macarena, Reumatología, Sevilla, Spain*

Background: Primary Sjögren's Syndrome (pSS) is a chronic systemic autoimmune disease of unknown etiology, with an estimated prevalence of 0.25% (0.15-0.43). It has a broad clinical spectrum and extraglandular manifestations such as Interstitial Lung Disease (ILD), being one of the main contributors to morbidity and mortality in patients with pSS [1].

Objectives: Analyze the clinical characteristics of patients with pSS and ILD, describe the patterns of lung involvement and the evolution of the disease as well as the treatments that were used.

Methods: Observational, retrospective, single-center study, in the *Hospital Universitario Virgen Macarena* Rheumatology department, from 2010 to 2022, including patients with pSS according to EULAR/ACR criteria and ILD. The data obtained from the medical records was analyzed by the statistical software SPSS v28. This study has been approved by the CEIC.
Results: 19 patients were included, 17 (89.5%) women, with a mean age of 66.4 years (62-71). All presented antinuclear and anti-SSA antibodies, 31.6% (6) anti-SSB antibodies and 43.8% (7) Rheumatoid Factor, 63.2% (12) hypergammaglobulinemia and none hypocomplementemia. 36.8% (7) were former smokers. The extraglandular manifestations and comorbidities are shown in Table 1. The mean age at diagnosis of ILD was 60.1 years (53.3-65.8). The time elapsed until the diagnosis was 93 months (12-198), however, in 52.6% (10) the diagnosis of ILD was prior to pSS diagnosis for approximately 17 months (6-27). The most common radiological pattern with 63.2% (12) is non-specific interstitial pneumonia, two patients presented lymphocytic interstitial pneumonia, two usual interstitial pneumonia, one organizing pneumonia and the rest of them other patterns. Two patients required lung biopsy. Prior to diagnosis, 3 patients were being treated with hydroxychloroquine, the rest had not required treatment with immunomodulators. Once diagnosed, 52.6% (10) required immunosuppressants (Graph 1). 80% (8) continue in treatment, 7 with mycophenolate mofetil with a mean duration of 48 months (20-75). 47.4% (9) required oral glucocorticoids at some point. 88.2% (15) improved or remained radiologically stable by HRCT, 73.3% (11) according to respiratory function tests (decrease in FVC <10% and DLCO <15%) and 72% (13) dyspnea remained stable or improved according to the MRC scale, with no significant differences between patients with and without treatment. The mean evolution time of ILD was 77.3 months (63-91). There were 2 deaths, one due to progression of the disease and the other due to a head trauma.
Conclusion: Interstitial lung disease is an extraglandular manifestation present in patients with pSS, therefore being essential the early diagnosis. In our case, after the diagnosis of ILD, half of the patients required immunosuppressive treatment to prevent the progression of the disease, with a large number of patients remaining currently stable.

CHARACTERISTICS AND TREATMENT OUTCOMES OF ASIAN SLE PATIENTS WITH CONCOMITANT GENITOURINARY AND GASTROINTESTINAL INVOLVEMENT

Keywords: Kidneys, Gastrointestinal tract, Systemic lupus erythematosus

K. L. Ng[1], T. Mahadevan[1], M. H. Nordin[1], A. Mohamed Ismail[1]. [1]*Raja Perempuan Zainab II Hospital, Rheumatology Unit, Kota Bharu, Malaysia*

Background: SLE is a chronic autoimmune disorder which affects multi-organ systems. We report a case series of SLE with concomitant genitourinary (GU) and gastrointestinal (GI) activity in our centre.
Objectives: To describe the characteristics, treatment response and outcomes of these cases.
Methods: The clinical notes were reviewed and descriptive statistical tests were used.
Results: 7 cases were recorded from 2019 to 2022. All were females with median age of onset 23 +/- 18.9 years old. Case 5 and 6 had prior diagnosis of SLE with lupus nephritis (LN). The initial symptoms were episodic abdominal pain, associated with vomiting and/or diarrhea. 2 cases had urinary symptoms too. The mean duration of symptoms was 4 months. All cases had severe GU and GI activity (Both BILAG A). Nearly all had clinically or biopsy-proven proliferative LN (mean 24 hour urine protein = 4.99 g/d). 3 patients also had ureterohydronephrosis and/or interstitial cystitis. Intestinal pseudo-obstruction (IPO) and lupus mesenteric vasculitis (LMV) were found in 2 and 5 cases, respectively. Serositis and mucocutaneous lesions were more frequent too. Almost all cases had high titres of ANA (≥ 1:320) and dsDNA, with prevalent positive anti-Ro. Other remarkable findings were low complements (especially C3) and normal ESR/CRP. Antiphospholipid antibodies were negative in all but one cases. Treatment wise, all had IV hydrocortisone and high dose prednisolone. 6 cases had pulsed methylprednisolone and IV cyclophosphamide therapy (NIH regimen). Case 7 had concurrent C. difficile infection and received mycophenolate mofetil (MMF) therapy once the infection resolved. In all cases, the extra renal features and urinary symptoms fully resolved. In term of LN, 4 patients did not achieve remission with NIH regimen and needed MMF therapy; and only 50% attained complete remission subsequently. In general, the outcomes of all patients were good except for Case 1 who developed contracted urinary bladder needing ileal conduit urinary diversion.
Conclusion: Concomitant IPO/LMV with LN and urinary tract abnormalities are rare clinical syndromes in SLE. Our patients shared similar clinical features as reported by Echeverry et al [1]. The treatment response was generally good with no recurrence of IPO/LMV and favourable renal outcomes.

Background: Ulcerative colitis (UC) is an inflammatory bowel disease characterized by idiopathic and recurrent mucosal inflammation, whereas disease heterogeneity has not sufficiently translated into current clinical subclassifications [1].
Objectives: This study aims to Identify and characterize subgroups of patients with similar target status and molecular biomarkers to reliably predict treatment response which is of great interest for the treatment of UC patients.
Methods: 16 microarray datasets including 602 colon tissue samples (455 patients with UC and 147 healthy controls) were both obtained from GEO database. Depend on up-regulated differentially expressed genes (DEGs),unsupervised clustering [2] was applied to group the samples and pathways and biomarkers associated with UC was unearthed by gene-set enrichment analysis. Xgboost classifier was used for evaluating the efficacy of different biologics in patients with UC.
Results: According to the 267 upregulated DEGs of UC, colon tissue samples were classified into three subtypes(A-C) with distinct molecular and cellular characteristics. Subtype A is designated as epithelial hyperplastic subtype with epithelial features while subtype C was characterized by the immune activation subtype with prominent immune cells and proinflammatory signatures. The subtype B is named mixed, which is in between the above two and is moderately activated in all signaling pathways. It is worth noting that, compared with subtype C as refractory UC patients, subtype A shows stronger correlation with the excellent reactions of biological agents such as golimumab(80%in A vs 37.5%in C), infliximab(100%in A vs 16.7%in C), vedolizumab(33.3%in A vs 0% in C) and ustekinumab(22.4%in A vs 3%in C).
Conclusion: These results, based on the most comprehensive microarray provide an in-depth understanding of the pathophysiological characteristics of UC, and build an accurate typing model for ulcerative colitis, which can benefit clinical treatment.

EFFECT OF BELIMUMAB ON CLINICAL PROFILES AND DAILY LIVING SCORE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Keywords: Biomarkers, bDMARD, Mental health

T. Ishizuka[1], K. Fujioka[1], M. Tangiku[1], H. Tani[1], A. Maeda[1], A. Kato[1]. [1]*Gifu Municipal Hospital, Center of General Internal Medicine, Gifu, Japan*

Background: Belimumab (BE) was shown to decrease disease activity, glucocorticoid intake, and flare rates, thereby suppression of damage progression, and also has been included in the 2019 EULAR recommendations on SLE management as an approved biological drug to be used in patients with a refractory response to a standard of care regimen.
Objectives: We have examined the effect of belimumab on activities of daily living score (AS), immunological data, disease activities and dose of PSL in patients with SLE.
Methods: We selected 36 cases (F/M 30/6) from 2018 to 2022 in patients with SLE treated with BE (iv or sc) to clarify the effect of BE on immunological data, disease activities (SLEDAI), AS (Lupus 26: 849, 2017), and dose of PSL after treatment for 6 months (M), 12 M and 24M.
Results: Mean BMI and duration of disease were 20.5±3.7 kg/m2 and 15.7±13.8 years. Two cases could not continue due to arthralgia and loss of hair within 24 M. After treatment with BE for 6 M and 12 M, anti-dsDNA antibodies (AU/ml) were significantly decreased for 12 M and 24 M, respectively ($p<0.05$, before 61±103, 6M 28±48, 12 M 19±23), and C3, C4 and CH50 (U/ml) were significantly increased ($p<0.05$, before 76±26, 14±7 and 28.7±10.8, 6 M 186±18, 18±7 and 35.3±9.2, 12M 85±18, 18±7 and 135.3±9.2). Levels of SLEDAI score were significantly decreased ($p<0.01$, before 12±7, 6M 5±3, 12 M 4±3 and Doses of PSL (mg) were significantly decreased ($p<0.05$-0.02, before 10.8±10.6, 6 M 6.1±3.7, 12 M 5.7±3.0). AS scores were also significantly improved ($p<0.01$-0.05), before 28.4±14.2, 12 M 14.8±15.8, 24 M 16.8±10.9). Especially, anxiety, depression and loss of concentration, which were important marker for activities of living score, were not significantly changed.
Conclusion: Effects of BE on immunological data, disease activities, and daily living scores, induction of clinical remission and dose reduction of prednisolone were tolerable without major adverse effects in patients with SLE.

DESIGN OF ANIFROLUMAB STUDY OF TREATMENT EFFECTIVENESS IN THE REAL WORLD (ASTER): A MULTI-NATIONAL, OBSERVATIONAL, POST-LAUNCH STUDY TO DESCRIBE THE CLINICAL EFFECTIVENESS OF ANIFROLUMAB IN ROUTINE CLINICAL PRACTICE IN PATIENTS WITH SLE

Keywords: Real-world evidence, Quality of life, Systemic lupus erythematosus

M. Mosca[1], C. Emmas[2], C. Nan[3], H. Stirnadel-Farrant[4], S. Chen[5], L. Carty[6], B. Desta[7], C. Seo[8], S. Chen[9], A. Sorrentino[10]. Background: Real-world evidence (RWE) on prescription medication use for systemic lupus erythematosus (SLE) is limited, and no real-world studies to date have investigated medication use post-launch with anifrolumab, a type I interferon receptor inhibitor. ASTER is the first multi-national, real-world study to examine patients with SLE receiving standard therapy who initiate anifrolumab treatment as an add-on biologic.
Objectives: To describe the study design of ASTER.
Methods: ASTER (NCT05637112) is a longitudinal, observational cohort study with 1 year of retrospective baseline data and 3 years of follow-up after first anifrolumab initiation until patient discontinuation, death, loss to follow-up or end of study (whichever occurs first). Adults with an SLE diagnosis per the 2019 European

League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) criteria for SLE who start anifrolumab per the approved country-specific label are eligible. Patients who are anifrolumab experienced, currently in anifrolumab early access/compassionate use programs, or in a clinical trial with an investigational product are excluded. Eligible patients will be enrolled at a routine clinical visit before the first anifrolumab infusion. Key study measures and data collection methods are presented in the Table 1. Patient-reported outcomes (PROs) and diaries are selected and designed based on patient feedback. Key endpoints of disease activity and the proportion of patients attaining a Lupus Low Disease Activity State will be assessed. For patients who discontinue anifrolumab, data collection will continue for the entire follow-up period, unless they withdraw consent.

Results: About 500 patients are expected to be enrolled from Austria, Canada, Denmark, France, Germany, Israel, Italy, Norway, Spain, and Sweden, with 15–200 patients per country. The study will be open for enrollment in 2023 and data collection is expected to finish in 2029. Data will be collected at baseline and at quarterly (Year 1) or biannual visits (Years 2 and 3). Electronic case report forms will be used to record patient information using the Medidata RAVE system. MyReco® software will be used to record PROs via a mobile application and collect physician-completed assessments via a web platform. Results will primarily be descriptive.

Conclusion: ASTER will provide physicians with valuable insights into the effectiveness of anifrolumab in patients with SLE in routine clinical practice. ASTER will generate comprehensive RWE of anifrolumab to inform patients about its impact on disease activity and health-related quality of life outcomes in global real-world settings.

AB0547 EVALUATION OF THE CLINICAL OUTCOME, PRESCRIPTION PATTERNS AND COST OF TREATMENT IN PATIENTS WITH LUPUS NEPHRITIS IN A TERTIARY CARE HOSPITAL

Keywords: Systemic lupus erythematosus, Rare/orphan diseases

M. Eldhose K[1], S. Kamat[1], P. Marathe[1], M. Nadkar[2], A. Sonawale[2], N. K. E[1].
[1]Seth GSMC and KEMH, Mumbai, Pharmacology and Therapeutics, Mumbai, India; [2]Seth GSMC and KEMH, Mumbai, Medicine, Mumbai, India

Background: Lupus nephritis (LN), a rare but severe renal manifestation of Systemic Lupus Erythematosus (SLE), has one of the most unsatisfactory renal disease outcomes, posing a great challenge for treatment. The clinical outcomes with various treatment regimens in LN have been studied globally in many randomized controlled trials (RCT). However, there is a paucity of data on clinical outcomes with various treatment regimens in Indian LN patients despite these regimens being extensively used in clinical practice. Only a few studies have analyzed prescription patterns in LN but none of these studies were conducted in India. Also, there is a substantial economic burden associated with SLE and LN in terms of healthcare resource utilization. The economic burden on Indian LN patients is not known and the cost of illness studies is not reported in the literature.

Objectives: The objectives of the study were to assess the clinical outcome in terms of disease activity in patients with LN at the end of induction therapy and at the end of maintenance therapy of 12 months, and to evaluate prescription patterns and cost of the treatment in patients with LN.

Methods: A prospective, observational, single-center study was conducted in the rheumatology department of a tertiary care hospital. The study was conducted in two parts. Part- 1 was cross-sectional, where the clinical outcome in LN patients at the end of maintenance therapy of 12 months was assessed (based on American College of Rheumatology- Renal Response Criteria (ACR – RRC)), while part- 2 was a longitudinal study where clinical outcome at the end of induction therapy or at the end of 6 months was assessed along with prescription patterns and cost of treatment.

Results: A total of 64 LN patients with 41 patients in Part-1 (cross-sectional) and 23 patients in Part-2 (longitudinal) satisfying the eligibility criteria were included in the final analysis. In the cross-sectional part of the study, all 41 patients showed a response to treatment at the end of maintenance therapy for 12 months (Table 1). In the longitudinal part of the study, most of the LN patients (65.21%) showed a partial response at the end of induction therapy. The prescription pattern analysis showed that 66 (57.40%) prescriptions out of a total of 115 prescriptions were complete with the average number of drugs prescribed per encounter being 10.77 ± 1.85 (Mean ± Standard Deviation). The most prescribed immunosuppressant was MMF (59%). The direct costs incurred by the patient {Rs.24001.01 (11204.36– 29110.02), (Median (interquartile range)} were much higher as compared to the indirect costs {Rs. 3000 (2000-3150), (Median (interquartile range)} due to the higher cost borne by the patient for drug therapy {Rs.16429.49 (5260.07 – 22585.04), (Median (interquartile range)}.

Table. 1. Clinical outcome in the various treatment regimens (at the end of maintenance therapy of 12 months)

Clinical Outcome	MMF	NIH	Euro lupus	Change in regimen	Total n (%)
Complete response	4	9	6	3	22 (53.70%)
Partial response	1	11	2	5	19 (46.34%)
Total	5 (12.19%)	20 (48.79%)	8 (19.51%)	8 (19.51%)	41

Conclusion: The clinical outcome at the end of 12 months of maintenance therapy was found to be satisfactory, with all the LN patients being responders to treatment. The MMF regimen was the preferred treatment regimen over the equally efficacious cyclophosphamide-based regimens due to the ease of administration and non-requirement of hospitalization during the period of the COVID pandemic. The high cost of MMF increased the direct cost borne by the patient due to its unavailability in the hospital pharmacy. Hence there is a need to review the hospital pharmacy stock at regular intervals and streamline the procurement system for drugs during public health emergencies such as the pandemic.

AB0548 EFFICACY AND SAFETY OF NIPOCALIMAB IN ADULT PATIENTS WITH ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS: DESIGN OF A PHASE 2 STUDY

Keywords: Systemic lupus erythematosus, Safety, Autoantibodies

F. Liu-Walsh[1], B. V. Hartingsveldt[2], Q. Zuraw[1], R. W. Hoffman[1], T. Rooney[1], S. Gao[1], G. Karpouzas[3], R. Gordon[1], J. H. Leu[1], C. Calderon[1], F. Zazzetti[4], A. M. Stevens[1], G. Vratsanos[1]. *[1]Janssen Research & Development, LLC, Immunology, Spring House, PA, United States of America; [2]Janssen Biologics Europe, Clinical Therapeutics, Leiden, Netherlands; [3]Harbor-UCLA Medical Center, Division of Rheumatology and the Lundquist Institute, Torrance, CA, United States of America; [4]Janssen-Cilag Argentina, Immunology Global Medical Affairs, Buenos Aires, Argentina*

Background: Systemic lupus erythematosus (SLE) is a chronic, progressive, autoimmune disorder characterized by chronic inflammation of multiple organs and tissues; mediated by autoantibodies and immune complexes. Approved treatments are few and associated with limitations including suboptimal response. Nipocalimab is a novel high affinity, fully human, aglycosylated, immunoglobulin G1 (IgG1) monoclonal antibody that selectively blocks the neonatal Fc receptor (FcRn) and displays no effector function. Clinical studies conducted with nipocalimab in healthy volunteers (NCT02828046) and in adult generalized myasthenia gravis patients (NCT03896295) demonstrated rapid and durable serum IgG and pathogenic autoantibody reductions.
Objectives: To describe the protocol of a Phase 2 study evaluating the efficacy and safety of nipocalimab in patients with active SLE (NCT04882878).
Methods: This is a phase 2, multicenter, randomized, placebo-controlled, double-blind, parallel-group study enrolling adults with active, autoantibody-positive SLE with an inadequate response to one or more standard of care treatments. The study consists of a ≤6-week screening period, a 52-week double-blind treatment period, and a 6-week follow-up period. A target of approximately 225 participants will be enrolled. Participants will be randomized in a 1:1:1 ratio to receive nipocalimab dose 1, dose 2 or placebo intravenously every 2 weeks through Week 50.
Results: The primary efficacy endpoint is the percentage of participants achieving an SLE Responder Index (SRI)-4 composite response at Week 24. Secondary efficacy endpoints assessed at Week 24 include the percentage of participants achieving: ≥50% reduction in Cutaneous Lupus Erythematosus Disease Area and Severity Index Activity score (CLASI), ≥50% reduction in active joints, ≥4 points improvement in SLE Disease Activity Index 2000 (SLEDAI 2K), and British Isles Lupus Assessment Group Composite Lupus Assessment response (BICLA); time to first disease flare; and reduction in corticosteroid use. The percentage of participants achieving an SRI-4 composite response at Week 52 will also be assessed. Safety endpoints include adverse events (AEs), serious AEs, AEs of special interest (severe infections, Grade ≥3 hypoalbuminemia), and AEs leading to treatment discontinuation through Week 58. Additional assessments include pharmacokinetic, pharmacodynamic, and immunogenicity evaluations.
Conclusion: This ongoing phase 2 study will evaluate the safety and efficacy of nipocalimab in adults with active SLE, using multiple clinical outcome measures.

AB0551 INTRAVENOUS IMMUNOGLOBULIN IN PREGNANT WOMEN WITH SEVERE ACTIVE LUPUS: A CASE SERIES

Keywords: Systemic lupus erythematosus, Pregnancy and reproduction

J. Cajamarca-Baron[1], C. Sanmiguel Reyes[1], E. Bedoya[1], A. Lamos[1], S. Rivadeneira Chamorro[1], D. Guevara[1], A. Arredondo[1], H. Cubides[1], A. Rojas-Villarraga[2], A. Escobar[1]. *[1]Fundación Universitaria de Ciencias de la Salud FUCS. Sede Centro Hospital San José, Rheumatology, Bogotá, Colombia; [2]Fundación Universitaria de Ciencias de la salud (FUCS), Research Institute, Bogotá, Colombia*

Background: Evidence on the management of pregnant patients with lupus activity is limited. The choice of pharmacological treatment is decisive for an adequate outcome.
Objectives: To show the experience of management with intravenous immunoglobulin (IVIG) in pregnant patients with severe active lupus.
Methods: Case series from January 2020 to November 2022 of pregnant patients being managed with IVIG in a hospital in Bogotá, Colombia.
Results: Out a total of 33 pregnant patients evaluated during the period, three cases of the use of IVIG in pregnant patients with severe lupus were found (Figure 1). The main involvement of lupus was renal (increased proteinuria), hematological (thrombocytopenia) and vascular [Intrauterine growth restriction (IUGR) and threatened abortion]. Average age was 30.3 years. One of the patients was diagnosed de novo with the disease during pregnancy, IVIG was given due to thrombocytopenia with resolution, but she presented fetal loss due to sepsis, in addition she had maternal vascular complications due to polyautoimmunity with antiphospholipid syndrome. The other two patients underwent IVIG at 24 weeks, one of them reached week 30 without considering new immunoglobulin applications, in the second case due to persistent proteinuria she received two additional cycles reaching 33 weeks of gestation. In both cases, a cesarean section was performed by IUGR at 30 and 33 weeks respectively. There were no complications associated with the newborns, with good response to proteinuria and resolution of cytopenias (See Table 1). There were no adverse drug events reported in any case.
Conclusion: IVIG can be a useful medication for the treatment of severe active lupus in pregnant patients, mainly in those with renal and hematological involvement. It is important to highlight IVIG has high safety and few side effects, on the mothers with lupus and their offspring's.

AB0552 EFFECT OF BELIMUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH MINIMAL OR NO STEROID

Keywords: Systemic lupus erythematosus

Y. J. Lee[1], S. M. Ahn[1], S. Hong[1], J. S. Oh[2], C. K. Lee[1], B. Yoo[1], Y. G. Kim[1]. *[1]Asan Medical Center, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); [2]Asan Medical Center, Department of Information Medicine, Big Data Research Center, Seoul, Korea, Rep. of (South Korea)*

Background: Belimumab is the only biologic agent approved for systemic lupus erythematosus (SLE). In cornerstone clinical trials, belimumab demonstrated SRI-4 response in patients with moderate disease activity, and real-world studies showed consistent findings (1¬3). In these studies, SRI-4 was significantly associated with baseline features including high SELENA-SLEDAI, dose of steroid, smoking status, BLyS level, and combining polyarthritis (2, 3). However, most previous studies have been conducted in patients with use of steroids, with mean prednisolone-equivalent dose of approximately 10 mg/day (1¬3). Therefore, the effect of belimumab has been focused on the steroid sparing.

Objectives: Here, we aimed to identify the effect of belimumab in SLE patients treated with minimal or no steroid with mild-to-moderate activity.

Methods: We retrospectively reviewed the electronic medical records of patients (age ≥ 18 years) who first received belimumab from May 2021 to June 2022 and maintained use at least 6 months. We only included patients who received prednisolone-equivalent ≤5mg or without steroid (for more than 1 year). The primary endpoint was SRI-4 response at 6 months, and secondary endpoint was improvement in serology, including C3, C4, and anti-ds DNA, at 6 months. Analysis Of Variance (ANOVA) with Bonferroni's post hoc analysis were performed to compare the continuous variables.

Results: In total, 31 patients were included, with 12 minimal steroid users and 19 non-steroid users. The mean age was 39.2 (±11.4) years, and 90.3% were female. Baseline SELENA-SLEDAI was 6.0 (4.0¬9.0). The primary endpoint was seen in 32.3% (10/31). Anemia (p=0.025), C4 level (p<0.001), and SELENA-SLEDAI (p=0.016) showed significant improvement over time during treatment. Univariable analysis showed baseline SELENA-SLEDAI and arthritis were significantly associated with SRI-4 response at 6 months, and SELENA-SLEDAI only remained significant in multivariable logistic regression analysis.

Conclusion: In our cohort study, belimumab was shown to be effective in improving SELENA-SLEDAI, anemia and low C4 in patients who did not use or did use minimal dose of steroids. Therefore, the effect of belimumab can be expected even in patients not taking steroids.

AB0554 LOW-DOSE IL-2 CHANGED THE PROPRTION OF LYMPHOCYTE SUBSETS IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME

Keywords: Sjögren syndrome, Cytokines and chemokines

X. M. Wang[1,2], Q. Y. Su[1,2,3], J. X. Zhang[1,2], P. H. Chai[1,2], H. C. LI[1,2], Q. Yu[4], P. F. He[4], X. LI[1,2,3], S. X. Zhang[1,2,3]. *[1]Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taiyuan, China; [2]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [3]Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [4]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*

Background: Primary Sjögren's syndrome (pSS) is a chronic inflammatory autoimmune illness characterized by various immune abnormalities. Abnormalities in the proportions of blood T lymphocyte subtype, that is Th17/Treg, were detected in pSS patients. Interleukin (IL)-2 is a crucial cytokine for tipping the balance of regulatory T(Treg) cells and effector T cells, which can effectively relieve pSS.

Objectives: This study aimed to systematically evaluate the changes in the number of lymphocyte subsets after low-dose IL-2 therapy for pSS.

Methods: Systematic searches of PubMed, EMBASE, Web of Science, the Cochrane Library and Medline, CNKI, CBM, and Technology Journal Database were performed. Original case reports, case series, observational studies, and clinical trials reporting the changes in lymphocyte subsets on pSS patients treated with IL-2 were included. A random-effects meta-analysis was performed to calculate the pooled efficacy. Inconsistency was evaluated by using the I [2], and Egger tests were used for the evaluation of potential publication bias (STATA v.12.0)

Results: A total of 3 studies comprising 929 patients were identified(Table 1). The numbers of Th17 cells and Tregs were significantly increased after IL-2 injection [SMD=0.325, 95%CI (0.060,0.590), P=0.016; SMD=1.085, 95%CI(0.469,1.701), P=0.001], while there were no statistical differences in the ratio of Th17/Tregs[SMD=-0.263, 95%CI (-0.602,0.076), P=0.129]between before and after IL-2 treatment(Figure 1).

Conclusion: Low-dose IL-2 was promising in treating pSS, which could promote the proliferation and functional recovery of Tregs and regulate the balance between Treg cells and effector T cells towards Treg cells.

Table 1. Available evidence, including patients with pSS treated with low-dose IL-2.

AB0555 CHARACTERISTICS OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AT THE START OF BIOLOGICAL THERAPY AND AT FIRST FOLLOW-UP

Keywords: bDMARD, Systemic lupus erythematosus

A. D. Bilous[1], M. M. Tamas[1,2], I. Mihus[2], C. Pamfil[1,2], I. Felea[1], L. Damian[1], L. Muntean[1,2], I. Filipescu[1,2], I. Szabo[1,2], S. P. Simon[1,2], S. Rednic[1,2].
[1]Emergency Clinical County Hospital Cluj-Napoca, Rheumatology, Cluj-Napoca, Romania; *[2]Iuliu Haţieganu University of Medicine and Pharmacy, Rheumatology, Cluj-Napoca, Romania*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by heterogeneity of clinical manifestations ranging from mild skin and joint disease to severe, organ or life-threatening manifestations. It has an unpredictable tendency to flare up. Given the complex pathogenesis of SLE, involving both the adaptive and innate immune systems, the efficacy of steroids, antimalarials and immunosuppressants is limited in some cases, highlighting the need for new therapies with a targeted mechanism of action. Belimumab (BEL) is approved as an add-on therapy for active LES with positive autoantibodies despite standard treatment, while Rituximab (RTX) remains for off-label use in severe manifestations in many European countries.
Objectives: The aim of the current study is to describe the characteristics of SLE patients receiving biologic therapy with Belimumab or Rituximab at baseline and at first follow-up visit in a tertiary rheumatology center.
Methods: We retrospectively analyzed the electronic medical records of patients with SLE who started treatment with BEL and/or RTX. Demographic, clinical and paraclinical data as well as disease activity score at the time of starting treatment with biologics and at first follow-up visit were collected.
Results: Eighteen SLE patients were analyzed: 88.88% female, mean age at diagnosis 32±15 years, mean disease duration 7±5 years. The first follow-up visit was performed between 4 to 6 months after baseline. Eleven (61.1%) patients were treated with BEL, 5 (27.77%) RTX and 2 (11.11%) with both BEL and RTX. Hydroxychloroquine (HQ) was co-prescribed with biologics in 16/18 patients (88.88%). Azathioprine was prescribed in 6 patients (33.33%) and mycophenolate mofetil in 4 patients (22.22%). At the start of the biological treatment, all patients received steroids with a mean dose of 20±17 mg prednisone/day. One patient was able to discontinue the steroid, while in the others the mean prednisone dose decreased to 8.5±4.8 mg/day after 4-6 months. RTX was prescribed in 5 (71.42%) patients for lupus nephritis. All patients previously received cyclophosphamide. In one case, RTX was prescribed for severe thrombocytopenia, in another because of an overlap with active rheumatoid arthritis. Belimumab was prescribed in patients with more pronounced constitutional, articular, cutaneous and hematological features and mild renal involvement. In one case, BEL was prescribed for lupic enteritis. The mean SLEDAI score before starting treatment with the biologic was 12±3; the mean SLEDAI score at the first follow-up visit was 3±2.Anti-double-stranded DNA antibodies were positive in 16 (88.88%). At the time of initiating treatment with biologics and at follow-up, C3 hypocomplementemia was present in 13 (81.25%) and 8 (50%) patients, while C4 hypocomplementemia in 8 (50%) and 5 (31.25%) respectively. No serious adverse events were reported. One patient discontinued BEL due to inefficacy.
Conclusion: Biological therapy has been shown to control the disease activity and to reduce the need for steroids in SLE patients. RTX was used in patients with more severe manifestations such as lupus nephritis and severe thrombocytopenia.

Background: Despite recent advances in the management of rheumatic diseases with the emergence of new targeted therapies, treatment options remain limited in systemic lupus erythematosus (SLE) [1] and disease may be refractory to conventional treatment.
Objectives: To evaluate the off-label use of biologics in a large cohort of lupus patients, its safety and efficacy.
Methods: Retrospective analysis of the Attikon SLE lupus cohort comprising over 800 patients in total in order to identify patients receiving off-label targeted therapies. Indication of the treatment, clinical characteristics and outcomes were recorded.
Results: A total of 52 patients received 54 off-label targeted therapies. Most of them were women (86.3%). Mean age (SD) at SLE diagnosis was 46.4 (15.2) years and mean disease duration (SD) at off-label treatment initiation was 8.8 (10.8) years. Mean SLEDAI (SD) before treatment initiation was 6.6 (3.7). The most frequently used off-label treatment was rituximab (84.6%) followed by tocilizumab (9.6%) and jak inhibitors (5.8%). The main indications were persistent, severe, refractory musculoskeletal and mucocutaneous activity (44.2%), neuropsychiatrical SLE (23.1%), hematological disease (13.5%) and lupus nephritis (11.5%).Six months after treatment, mean SLEDAI decreased in all patients to a mean of 4.3 (2.7). Mean drug survival was 2.2 (1.2) years. The dose of corticosteroids after 6 months of treatment was substantially decreased to 4.3 mg (versus 12.7 at baseline). No moderate/severe adverse effects were recorded.
Conclusion: The use of off-label targeted therapies allows disease activity improvement with a corticoid sparing effect even in a subset of patients with long-standing, refractory manifestations.

Rheumatology-Internal Medicine, sokoto, Nigeria; [4]*Lagos State University Teaching Hospital, Rheumatology-Internal Medicine, Lagos, Nigeria*

Background: Lupus vasculitis (LV) [1] is one of the secondary vasculitides occurring in the setting of systemic lupus erythematosus most commonly affecting small vessels or medium vessels, rarely large vessels. LV is commonly associated with anti-phospholipid syndrome [2]
Objectives: Case Report 42year old female, 10weeks peripartal with twin-gestation presenting with progressive difficulty in walking with associated numbness and paraesthesia of the lower limbs [3], difficulty in breathing, Fever, non-erosive polyarthralgia and polyarthritis. Her symptoms started after delivery of her set of twins after 10years of secondary infertility. On examination; generalised cutaneous vasculitic rashes, left foot drop, bilateral lower limb swelling, coarse crepitations at the lung bases, reduced power at both lower limbs2/5, reduced tone and reflexes. Reduced sensation to light and deep touch at the left foot.
Methods: To access practicable treatment modalities in resource poor settings-Nigeria.
Results: Electromyelography-Mononeuritis multiplex, HRCT-pulmonary embolism in bilateral pulmonary artery extending into the segmental artery, Doppler USS of both lower limbs-Acute deep vein thrombosis of the left internal jugular vein, ENA panel-positive dsDNA, anti-smith, anti-Ro/Anti-La, Antiphospholipid antibody panel [4]- Positive aCL, anti-B2GP1, LAC, thrombocytopenia, anaemia. Renal parameters marginally deranged. Elevated inflammatory markers.
Management High dose corticosteroids, Rescue therapy low dose Rituximab @ days 0,15 patient had minimal response, maintained on low dose prednisolone, azathioprine and physiotherapy. Trial of EUROLUPUS regimen (6 courses) of low dose cyclophosphamide [5]. Rivaroxaban for PE & DVT. Inferior venae cavae filter for DVT.
Outcome: Regained full power, tone and reflexes of her lower limbs and walked without support after 6 courses of cyclophosphamide. however, she has residual left foot drop undergoing physiotherapy. Renal parameters marginally resolved. Pulmonary embolism and deep vein thrombosis resolved.
Conclusion: Lupus Vasculitis can affect any organ systems. Modalities for treatment are according to the presentation and severity of the disease.

Background: Anifrolumab (ANI) is a monoclonal antibody to the type I interferon receptor recently approved by EMA as an add-on therapy for the treatment of moderate to severe SLE. As of this writing, real world data on its use are still lacking.
Objectives: To depict the clinical phenotype of refractory SLE patients treated with ANI. To evaluate short-term effectiveness and safety of ANI in clinical practice.
Methods: Multicenter prospective cohort study on adult patients with SLE treated with ANI for compassionate use. Demographic data, clinical and treatment history, and SLICC Damage Index (SDI) were retrieved from clinical charts. SLEDAI-2K, SLE-DAS, daily prednisone dose, number of tender (Tj) and swollen (Sj) joints, Cutaneous LE Disease area and severity index (CLASI-A), and Physician Global Assessment (PGA) were recorded at baseline, 1, 3, and 6 months of follow-up. Remission (according to 2021 DORIS definition) [1] and low disease activity (according to LLDAS definition) [2] were assessed at 6 months. Adverse events (AE) were recorded at each visit.
Results: 20 patients (90% female, 90% Caucasian, median age 48 (range 24-68), median disease duration 12 (4-27) years from 9 referral centers were included. 100% of patients had a history of articular involvement, 95% of skin rash, 50% of hematological involvement, 30% of nephritis, 25% of serositis, and 10% of neuropsychiatric involvement. Fifteen percent had a concomitant antiphospholipid syndrome and 10% Sjogren's syndrome. At baseline, 65% had an SDI>0 (median 2, 1-5). The median number of previous immunosuppressive therapies was 4 (1-7), while the median cumulative dose of prednisone was 10.3 g (5-90). Reasons for adding ANI to treatment were persistently active disease (83.3%) or disease flare (16.7%). Main active manifestations were: muco-cutaneous (70%), articular (40%), and hematological (25%). Concomitant therapies were glucocorticoids in 94.1% (pred-eq median daily dose 7.5 mg, range 0-25), conventional DMARD in 84% (31% mycophenolate, 16% azathioprine, 32% methotrexate, 5% cyclosporine), and hydroxychloroquine in 74% of cases. At 1 month after starting ANI, a significant decrease in all the activity indices was recorded: mean±SD SLEDAI from 7.6±4.2 at baseline to 6.1±3.5 (p=0.02), CLASI-A from 8.8±9.7 to 3.6±5.2 (p=0.01), and PGA from 1.3±0.5 to 1±0.5, (p=0.005), SLE-DAS from 9.6 ±6.5 to 6.8 ±5.2 (p=0.04), SJ from 1.6 ±0.6 to 0.5±0.2 (p=0.02). The improvement was maintained trough the 6 months of follow-up. A reduction in the mean daily dose of glucocorticoids was observed at all time points, but statistical significance was not reached (Table 1). LLDAS and remission were achieved by 75% of patients at 6 months of follow-up. One patient discontinued treatment after 2 infusions due to a lack of response. Nine AE were recorded, mainly mild viral infections including one herpes zoster reactivation. Only one AE (thromboembolism) led to treatment discontinuation.
Conclusion: ANI demonstrated a rapid efficacy on skin manifestation, arthritis, and overall disease activity in patients with SLE refractory to the standard of care. The good safety profile is also confirmed in this real-world analysis.

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with multisystem involvement characterized by the production of multiple autoantibodies and the consumption of complements. Rituximab, a chimeric anti-CD20 antibody, was already approved for treating B-cell lymphoma and autoimmune diseases.
Objectives: This study aimed to systematically evaluate the efficacy and safety of rituximab in treating SLE.
Methods: We systematically searched PubMed, EMBASE, Web of Science, Cochrane Library, CNKI, FDA.gov, Clinical trials.gov, Wanfang database, and Weipu database (from database inception to January 1, 2023) for studies of rituximab in the treatment of SLE. Observational studies, case series, and randomized controlled trials reporting the efficacy or safety data on SLE treated with rituximab were included in this meta-analysis. We selected the effect model according to the heterogeneity of the meta-analysis. If I2 < 50, a fixed effect model was used.
Results: A total of 8 studies with a total of 353 patients were included. After treatment with rituximab, the SLEDAI scores were significantly decreased [SMD=2.289, 95%CI (1.411,3.167), I2=64.5%, p<0.001]. Four studies mentioned clinical responses, 91.9% of patients with SLE who received rituximab had distinct clinical remission compared with 72.1% of patients with SLE who received conventional medication. The incidence of adverse events was 7.61% and 21.83%, in which pulmonary infection and gastrointestinal disease were the most common events, and no serious adverse events were reported among all these studies. Besides, we observed not only remarkable increases in complement C3 and C4 after rituximab injection [SMD=-0.838, 95%CI (-1.099,-0.577), I2=0.0%, p<0.001; SMD=-0.811, 95%CI(-1.071,-0.550), I2=0.0%, p<0.001], but also significant decreases in IgA and IgG [SMD=1.372, 95%CI (0.322,2.422), I2=95.5%, p=0.010; SMD=1.102, 95%CI(0.102,2.103), I2=93.6%, p<0.05],while there were no statistical differences in the ESR and IgM between before and after rituximab treatment (p>0.05)(Figure 1).
Conclusion: Rituximab was effective and well-tolerated for the treatment of SLE, which had a low incidence of adverse events.

AB0560 **EFFECT OF UPADACITINIB IN A PATIENT WITH PRIMARY SJOGREN SYNDROME: A CASE REPORT**

Keywords: Sjögren syndrome, Targeted synthetic drugs

M. S. Momen Majumder[1,2], S. A. Haq[2]. *[1]Bangabandhu Sheikh Mujib Medical University, Rheumatology, Dhaka, Bangladesh*; *[2]Bangabandhu Sheikh Mujib Medical University (BSMMU), Rheumatology, Dhaka, Bangladesh*

Background: Primary Sjogren syndrome (pSS) is a chronic autoimmune multisystem disease characterized by inflammation of exocrine glands, particularly the lacrimal and salivary glands, as well as multiple extraglandular involvements. Treatment is often challenging, and till now, no Disease-Modifying Antirheumatic Drugs (DMARD) have been approved for this condition. There is a lack of data about the efficacy of Janus kinase inhibitors in pSS. Here we report a patient with pSS successfully responding to upadacitinib.
Objectives: To see the efficacy of upadacitinib in the management of primary Sjogren syndrome.
Methods: A 68-year-old woman presented with pain in multiple joints for 16 years with intermittent use of NSAIDs. She had no low back pain and no self or family history of psoriasis or red eye. She denied dry mouth but required frequent water drinking during meals to aid swallowing and occasionally used artificial tears. MTX was started for her two-month articular flare and positive rheumatoid factor (RF). MTX caused severe vomiting and hyponatremia, and she was hospitalized. After the correction of hyponatremia, she was put on tofacitinib. We reevaluated the case when she came to us. She had grade 2-3 tenderness of most peripheral joints and was bedridden. Immunological parameters revealed RF 127 IU/ml (reference value <14), anti-SSA antibody 147 U/ml (normal <3.2), anti-SSB antibody 149 U/ml (reference value <8) and anti-CCP antibody; ANA, anti-ds-DNA Ab were negative. There was no erosion on the X-ray hands. Schirmer's test was positive (3 mm bilaterally). Unstimulated salivary flow after five minutes was 0.04 ml/min (≤0.1 ml/min indicates salivary hypofunction). She fulfilled the 2016 ACR/EULAR classification criteria, and we diagnosed her with primary Sjogren syndrome. Considering her age, she was switched to upadacitinib, as European Medicines Agency restricted the use of tofacitinib beyond 65 years.
Results: Her EULAR Sjogren Syndrome's Disease Activity Index (ESSDAI) [1] was six at baseline, indicating moderate disease activity. Her joint pain improved significantly within two months with infrequent use of pilocarpine in the sixth month. Six months after treatment with upadacitinib, ESSDAI came down to 2; the Patient's Global Assessment score was 02 and achieved STAR (Sjogren's Tool for Assessing Response) response 7 (STAR responder if score ≥5) [2].
Conclusion: To our knowledge, this is the first case report on the efficacy of upadacitinib in pSS. Further high-quality clinical trials are required to confirm the benefit of upadacitinib in pSS.

Background: Lupus nephritis (LN) is one of the most harmful clinical manifestation in systemic lupus erythematosus (SLE) patients. Despite of the existence of standard treatment protocols, a percentage of patients cannot be controlled with classical immunosuppresant drugs. This is the reason for exploring new therapies, such rituximab (RTX), in order to achieve a better management of LN [1,2].
Objectives: To assess the efficacy of RTX in LN treatment.
Methods: A systematic review was performed using Medline, Embase, Cochrane Library and Web of Science databases. Two independent reviewers selected the records that fitted the inclusion and exclusion criteria. Statistical analysis was carried out with Stata 15.1 for MacOS (StataCorp). Relating to meta-analysis, odds ratio (OR) was chose as measure of association in registries with control group and a prevalence meta-analysis was conducted in those registries without it.
Results: 436 papers were obtained from the search, finally 32 articles were analysed. Meta-analysis of registries with control group showed a significant higher rate of total response in LN patients treated with RTX, compared to control group (OR 2.154, 95%CI 1.271-3.650, p=0.004) after 52 weeks of follow-up (Figure 1). As well, a non-significant higher rate of complete response in LN patients treated with RTX, compared to control group (p=0.062) was found after 52 weeks of follow-up. A non-significant lower rate of partial response in LN patients treated with RTX compared to control group was found. Prevalence meta-analysis of registries without control group showed response in more than 50% of LN patients treated with RTX.
Conclusion: RTX seems to be effective in long-term treatment LN patients (52 weeks). More clinical trials are needed for clear indication of RTX for SLE treatment and its inclusion in general clinical practice.

AB0562 **BELIMUMAB FOR THE TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS IN REAL WORLD: A SINGLE CENTER STUDY**

Keywords: Real-world evidence, Kidneys, Systemic lupus erythematosus

J. J. Fragío Gil[1], P. Martinez Calabuig[1], L. Salvador Maicas[1], R. González Mazarío[2], A. Rueda[1], J. J. Lerma[1], C. Molina Almela[1], M. D. Pastor Cubillo[1], C. Campos Fernández[1]. [1]*Hospital General Universitario de Valencia, Servicio de Reumatología, València, Spain*; [2]*Hospital de Sagunto, Reumatología, Port de Sagunt, Spain*

Background: Belimumab efficacy and safety has been studied through randomized controlled trials in Systemic Lupus Erythematosus (SLE) patients even in cases with kidney involvement. However, more evidence is needed not only from long-term trials but also from real world conditions especially in Lupus Nephritis (LN) patients.
Objectives: To analyze the effectiveness and safety of Belimumab in SLE patients with data from a Real-World cohort.
Methods: A single center observational study was performed including SLE patients who had initiated treatment with Belimumab from September 2017 to January 2023. Demographic, clinical, laboratory, effectiveness and safety variables were collected. Effectiveness was evaluated according to changes from the baseline in SLEDAI-2K and disease activity markers (proteinuria, complement consumption and/or Anti DNAds). Safety data was collected including any adverse event (AE) due to any cause. AE was considered serious (SAE) if it was life-threatening or result in hospitalization, disability or in death.
Results: Overall, 15 patients were included in the study, whom baseline characteristics are exposed in the Table 1. Nine patients were still receiving the drug with a mean drug survival of 15.6 months. Belimumab allowed steroid tapering in all cases, but treatment was discontinued just in 1 patient (7%). Treatment also improved disease activity markers in all (100%) patients. Belimumab was well tolerated, and the AE reported were infection (14 events) and malaise in 1 patient. In 11 cases, infection was mild (9 upper respiratory tract infection, 1 urinary tract infection and 1 gastroenteritis). 3 severe infections were registered (1 pneumonia, 1 pyelonephritis and 1 meningitis).
Regarding LN patients, treatment exposure achieved was 10.85 patients/year. Renal Biopsy demonstrated class III in a patient (20%) and class IV in 4 patients (80%). Mean proteinuria at baseline was 6.66g/24h. In 3 cases, Belimumab was started in the first 6 months after LN diagnosis was established. In 4 cases (80%), Belimumab addition allowed significant reduction of proteinuria and corticosteroids. In 2 out 5 (40%) treatment was discontinued, one case due to an insufficient response and in the other, to a SAE (*Cryptococcus neoformans* meningitis).
Conclusion: Belimumab maintained an acceptable safety profile and an adequate effectiveness. Intravenous and subcutaneous formulations showed similar performance. Belimumab addition resulted in reduction in proteinuria and corticosteroid use.

Table 1. BASELINE CHARACTERISTICS

Characteristic	All SLE patients n=15 (100%)	No Lupus Nephritis N=10 (37%)	Lupus Nephritis n=5 (51%)

SLE, Sjön's and APS - clinical aspects (other than treatment)

AB0563 "WELL CONTROLLED" SLE PATIENTS – PHYSICIAN PERCEPTION VS PATIENT REALITY

Keywords: Patient reported outcomes, Outcome measures, Systemic lupus erythematosus

R. Rex[1], E. Hettel[1], V. Strand[2], S. May[1]. [1]*Spherix Global Insights, Market Research, Exton, United States of America*; [2]*Stanford University, Immunology/ Rheumatology, Palo Alto, United States of America*

Background: SLE patients present significant challenges in the management of their condition.
Objectives: This study aims to uncover differences in physician perceptions and real-world treatment patterns and outcomes among moderate to severely active patients in the EU5 (France, Italy, Spain, Germany, and UK).
Methods: 1,279 moderate-to-severe (M/S) adult SLE patient records were collected in collaboration with 289 EU5 rheumatologists via an online survey platform from November 2021 through January 2022.
Results: 22% of moderate-to-severe EU5 SLE patients in the chart audit were receiving belimumab to treat their SLE. In half of those cases where patients were NOT on belimumab they were not considered good candidates for the therapy. The key reason for not initiating belimumab treatment being that patients were "well-controlled" on their current pharmacologic regimen. Closer inspection of these "well-controlled" patients (n=228) at the chart level revealed clinical aspects that highlight a potential gap in patient care: The majority of SLE patients in the "well-controlled" subset had moderately active disease, but over one-in-ten were classified with severe disease. On average, 40% of "well controlled" SLE patients had one or more flares over the past year. One-third of the "well controlled" patient subset suffers from at least one moderate-to-severe manifestation of their SLE, with musculoskeletal, dermatologic, and renal manifestations being most prevalent. 29% of "well-controlled" patients have at least one moderate-to-severe symptom of their disease. These include pain/stiffness, fatigue, synovitis, malar rash, photosensitivity, edema, fever, and alopecia.

Table 1.

SLE Disease Severity	Moderate		Severe	
"Well-controlled" patients	89%		**11%**	
SLE Flares (past year)	None	1 flare	2 flares	3 flares
"Well-controlled" patients	60%	**30%**	**8%**	**2%**
Severe SLE Manifestations	Has at least one moderate-to-severe manifestation			
"Well-controlled" patients	**32%**			
SLE Manifestation	*Moderate-to-Severe Manifestation Severity*			
Musculoskeletal	**24%**			
Dermatologic	**11%**			
Renal	**6%**			
Pulmonary	**5%**			
Severe Symptoms	Has at least one moderate-to-severe symptom			
"Well-controlled" patients	**29%**			
Symptom	*Moderate-to-Severe Symptom Severity*			
Pain, stiffness	**19%**			
Fatigue	**16%**			
Synovitis	**7%**			
Malar rash	**6%**			
Photosensitivity	**6%**			
Edema	**4%**			

- Further, one-third of "well controlled" SLE patients are on steroids, with 40% on a higher dose (>5mg/day) to control their disease. The mean overall dosage of the group was 9.4mg/day, a potentially harmful dosage particularly if used long term.

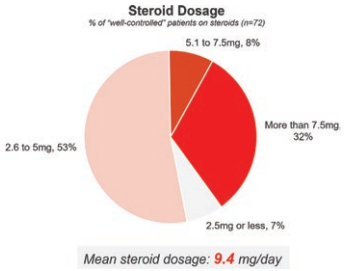

Figure 1.

Conclusion: EU5 physicians' perception of "well controlled" SLE may not align with some patients' clinical reality. Use of belimumab or other advanced therapies [1] in these cases may lead to improved patient outcomes and less reliance on steroids, which are often associated with adverse effects, even at low doses [2].

AB0564 TIGIT ACTIVATOR ALLEVIATES SYSTEMIC LUPUS ERYTHEMATOSUS BY NEGATIVELY REGULATING TH1-LIKE TREG CELL DIFFERENTIATION

Keywords: Treat to target, Cell biology, Systemic lupus erythematosus

X. MA[1], S. Yu[1], J. Gu[1], H. Jiang[1], Y. Shan[2]. [1]*The First Hospital of China Medical University, Department of Pediatrics, Shen Yang, China*; [2]*University of Occupational and Environmental Health, Japan, The First Depatment of Internal Medicine, Kitakyushu, Japan*

Background: Systemic lupus erythematosus (SLE) is a heterogeneous inflammatory chronic autoimmune disorder characterized by autoimmune tolerance deficiency [1]. T Regulatory cells (Tregs) play an important role in maintaining immune homeostasis. In inflammatory setting, the plasticity of Tregs increased with acquiring effector T helper (Th) phenotype, resulting in the reduction of immunosuppressive ability. It is reported that the frequency of Th1-like Treg cells, which has low suppressive function, increased in autoimmune diseases [2]. T cells Immunoglobulin and TIMI domain (TIGIT) is a co-inhibitory receptor, which can suppress the response of effector T cells. It is identified that the expression of TIGIT on Tregs significantly decreased in SLE [3-4]. Interferon-α (IFN-α) is a crucial pleiotropic cytokine with a high level in SLE and can promote type I immune response. IFN-α depends on AKT/mTOR signaling while phosphorylating JAK/STAT pathway to regulate the polarization of Th1 [5].
Objectives: The study is to evaluate the characteristics and differentiation mechanisms of Th1-like Treg cells in SLE patients and the role of TIGIT in regulating immunosuppressive function.
Methods: The frequency of $Foxp3^+T\text{-}bet^+$Th1-like Tregs of peripheral blood mononuclear cells (PBMCs) from SLE patients and healthy controls were analyzed by flow cytometry. PBMCs and $CD4^+$T cells were isolated and cultured under stimulation of IFN-α and/or TIGIT activator. The expression of characteristic markers of Th1-like Tregs, and the activation of AKT/mTOR/STAT pathway were assessed using flow cytometry and PCR.
Results: Th1-like Tregs with low TIGIT expression expanded in SLE patients. IFN-α promoted the conversation of Tregs to Th1-like Tregs through phosphorylated STAT4. TIGIT reactivation reversed the polarization of Th1-like Tregs and plasmablast differentiation induced by IFN-α through AKT/mTOR/STAT4 pathway.
Conclusion: Our findings indicate that the expansion of Th1-like Tregs and the decreased expression of TIGIT may contribute to the tolerance deficiency in SLE. TIGIT can reverse IFN-α-induced Th1-like Tregs and the impairment of immunosuppressive function, which is a potential therapeutic target for SLE.

AB0565 URIC ACID LEVELS, CARDIOVASCULAR RISK AND DISEASE ACTIVITY: THE BERMUDA TRIANGLE IN PRIMARY SJÖGREN'S SYNDROME

Keywords: Cardiovascular disease, Sjögren syndrome

A. Alunno[1], F. Carubbi[1], F. M. Mariani[1], C. Martini[1], E. Campanozzi[1], P. Altieri[1], C. Ferri[1]. [1]*Internal Medicine and Nephrology Division, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy*

Background: Over the last decade, several observational studies provided evidence on the association between serum uric acid (SUA) levels and cardiovascular (CV) risk in the general population and identified SUA as a risk factor worth assessing in the setting of CV prevention also in patients without gout. Patients with primary Sjögren's syndrome (pSS), as those with other systemic autoimmune diseases, have a higher CV risk compared to the general population but studies assessing the role of SUA levels in the CV scenario of pSS are lacking.
Objectives: To explore the relationship between SUA levels, CV risk and CV events in patients with pSS and without gout and/or nephrolithiasis.
Methods: We retrospectively investigated pSS patients fulfilling the 2016 ACR/EULAR classification criteria. We recorded clinical, serological and CV-related variables while SUA levels were assessed at enrollment. In eligible patients (European individuals without previous CV events or diabetes) the 10-year risk of fatal and non-fatal CV disease events was calculated using the SCORE2 (individual aged 40-69 years) and SCORE2-OP (individuals aged over 70 years) risk prediction algorithms. Adherence to the Mediterranean Diet in the previous 12 months was also measured.
Results: We observed a strong relationship between disease activity, interstitial lung disease (ILD) and the occurrence of previous CV events in a cohort of 105 pSS patients. The association between ILD and CV events was dependent on higher SUA levels but independent on other traditional CV risk factors and on adherence to the Mediterranean diet. All 3 cases of previous non-fatal stroke were reported by female patients aged <65 years, with higher SUA levels and 2 of them also had pSS-ILD. Forty (51%) of the 79 patients eligible for the calculation of the 10-year risk of fatal and non-fatal CV risk had a risk higher than the cut-off recommended for their age, 6 (7%) have the same value as the cut-off level and 33 (42%) had risk values below the cut-off recommended for their age. The 2021 update of the ESC guidelines for CV prevention, reinforced the importance that in patients with chronic inflammatory conditions such as rheumatoid arthritis, multiplication of calculated total CV disease risk by a factor of 1.5 should be considered. For speculation purposes we applied this correction factor to our cohort and observed that 10 out of 33 patients were reclassified above the cut-off level recommended by guidelines for their age while 23 remained below. Among the 33 patients with a non-corrected risk below the cut-off level recommended by guidelines (N=33), those with the highest SUA values were reclassified above the cut-off level following the application of the 1.5 correction factor. The 23 patients whose SCORE remained below the cut-off regardless of the correction factor were the youngest and showed the lowest levels of total cholesterol, LDL cholesterol and triglycerides (all p<0.05). Only 10/23 (43%) patients have at least one CV risk factor and none of them showed more than 2 CV risk factors.
Conclusion: This study is the first to investigate in depth the role of SUA in the CV scenario of pSS. Our findings underpin the importance of assessing SUA levels in pSS in addition to the other traditional CV risk factors and are in line with the ESC advise that although evidence to use the 1.5 correction factor in connective tissue diseases is not yet solid enough to inform recommendations, it seems prudent to take into account the presence of such conditions when there is doubt regarding initiation of preventive interventions to ultimately achieve a better stratification and management of CV risk.

AB0566 A COMPARATIVE ANALYSIS OF CLINICAL CHARACTERISTICS OF 86 CASES WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ASEPTIC NECROSIS OF THE FEMORAL HEAD OR NON-FEMORAL HEAD AVASCULAR NECROSIS

Keywords: Comorbidities, Systemic lupus erythematosus

J. Tian[1,1,1,1]. [1]*First Affiliated Hospital of Xi'an Jiaotong University, Rheumatology and Immunology, Xi'an, China*

Background: Symptomatic osteonecrosis of the femoral head (ONFH) and avascular osteonecrosis (AVN) are two types of osteonecrosis which is a serious complication of systemic lupus erythematosus (SLE). Even their pathophysiology of them is similar, though the onset timing, symptoms and signs, and other clinical characteristics are different.
Objectives: To compare the clinical characteristics of SLE combined with symptomatic ONFH and AVN.
Methods: We retrospectively analyzed the clinical data of 86 cases of SLE with symptomatic ONFH and AVN treated in the Department of Rheumatology and Immunology of The First Affiliated Hospital of Xi'an Jiaotong University from April 2013 to December 2021, and compared the similarities and differences between them.
Results: A total of 2730 patients with SLE were reviewed, including 60 patients combined with ONFH (male 9, female 51) and 26 patients combined with AVN (male 2, female 24). Morbility of ONFH was significantly higher than AVN. Compared with AVN group, the course of SLE was longer [(71.33±53.32) vs (48.69±35.11) months] , the time of glucocorticoids (GCs) use was longer [(67.47±51.71) vs (37.77±42.73) months], and the cumulative dosage of GCs was larger [(9.17±5.46) vs (6.02±6.66) g] in ONFH group. SLEDAI score was lower in ONFH group than in AVN group [(2.57±3.39) vs (4.46±4.81)]. The ONFH group had more Raynaud's phenomenon and lower serum Vitamin-D3 level compared with AVN group. Anti-cardiolipin antibodies (ACA) positive (15.38%) and edema as the initial symptom (46.15%) were more common in AVN group. Bilateral lesions were more common in ONFH group (68.33% vs 42.31%). All of the above differences were significant ($P < 0.05$).
Conclusion: Our results indicate that the long time and large cumulative dosage exposure of GCs, stable SLE state, Raynaud's phenomenon and low Vit-D3 value are more suggestive of ONFH than AVN. ACA positive and edema as an initial symptom are just the reverse.

AB0567 SEXUAL DYSFUNCTION IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Quality of life, Real-world evidence

M. H. Fernandes Lourenco[1,2,3], R. Pinheiro Torres[1,2,3], S. Rodrigues-Manica[3], V. Fraga[4], C. Abreu[4], R. Costa[5], C. Matos[5], B. Mendes[6], B. Samões[7], I. Silva[1,2], F. M. Pimentel-Santos[1,2,3], M. Costa[1,3], J. Branco[1,2,3], A. Sepriano[1,2,3]. [1]*Hospital Egas Moniz, Rheumatology, Lisboa, Portugal*; [2]*Nova Medical School, Faculdade de Ciências Médicas, Lisboa, Portugal*; [3]*Comprehensive Health Research Center, CHRC, Lisbon, Portugal*; [4]*Hospital Garcia de Orta, Rheumatology, Almada, Portugal*; [5]*Hospital de Santa Maria, Rheumatology, Lisboa, Portugal*; [6]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; [7]*Centro Hospitalar de Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal*

Background: Due to its multisystemic involvement, systemic lupus erythematosus (SLE) can have a significant impact on patients' quality of life (QoL). Sexual (dis)function is a key component of QoL but is often underappreciated. Little is known about sexual disfunction in SLE patients, a condition that primarily affects women during their fertile age.
Objectives: We aimed at determining the prevalence of sexual dysfunction among women with SLE and predictors thereof.
Methods: We performed a cross-sectional multicenter study in which women (18-70 years-old) with a clinical diagnosis of SLE (according to their treating rheumatologist) were included. An anonymous online questionnaire

was perfomed where data on demographics (e.g., age), symptoms of depression and anxiety [Hospital Anxiety and Depression Scale (HADS)), health-related QoL (Short Form Health Survey Index 36 Item (SF36)]) and sexual function [Female Sexual Function Index (FSFI) - a 19-item patient-report outcome that assesses female sexual function]) were collected. Data on clinical features [disease activity according to the Safety of Estrogens in Lupus National Assessment-SLE Disease Activity Index (SELENA-SLEDAI), organ involvement and evaluation of comorbidity (Charlson Comorbidity Index)] and on treatment status were collected from medical records. The main outcome was sexual dysfunction, defined as FSFI<26.5 (validated cut-off). A multivariable logistic regression was perfomed to test the association of clinical and demographic characteristics with sexual dysfunction (present vs absent).

Results: In total, 194 female patients with SLE were included (mean age 44 years-old [standard deviation (SD) 11]). The mean SELENA-SLEDAI score was 1.7 (SD: 2.2), corresponding to low disease activity, and 94% of patients were on classical disease-modifying antirheumatic drugs. The mean value of HADS was 9 (0-21), for both depression and anxiety scores. Regarding SF36, the mental component had a mean value of 61 (0-100) and the physical one of 70 (0-100). Sexual disfunction was present in 128 (66%) patients. In the multivariable analysis (Table 1), older age (OR: 1.04; 95%CI: 1.01; 1.07), higher SELENA-SLEDAI (OR: 1.18; 95%CI: 1.01; 1.40), higher HADS depression score (OR: 1.20; 95%CI: 1.01; 1.43), as well as a lower (that is, worse) SF36 mental component score (OR: 0.97; 95%CI: 0.95; 0.98) were independently associated with sexual dysfunction.

Conclusion: Sexual disfunction is common in women with SLE and is influenced by both physical and mental health components. Clinicians should consider both for the optimal management of their patients in order to improve their sexual QoL.

AB0568 CLINICAL USE OF ACTIVATED LEUKOCYTE CELL ADHESION MOLECULE, HEMOPEXIN, AND PEROXIREDOXIN 6: A POTENTIAL URINE BIOMARKER FOR KOREAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Biomarkers, Systemic lupus erythematosus

J. W. Kim[1], J. Y. Jung[1], H. A. Kim[1], C. H. Suh[1]. [1]*Ajou University School of Medicine, Rheumatology, Suwon-si, Gyeonggi-do, Korea, Rep. of (South Korea)*

Background: Systemic lupus erythematosus (SLE) is sometimes difficult to make a prompt and accurate diagnosis due to the heterogeneity of various clinical manifestations and autoantibody expression. Therefore, the development of surrogate markers specific to the diagnosis of SLE is necessary. Among biological samples, urine is non-invasive means with the advantage of being easily obtained.

Objectives: This study aimed to evaluate the ability of Activated Leukocyte Cell Adhesion Molecule (ALCAM), Hemopexin, and Peroxiredoxin (PRDX) 6 as urine biomarkers in Korean patients with SLE.

Methods: Urine samples were collected from 138 patients with SLE and 39 healthy controls (HC) with clinical data. The level of urine biomarkers were measured by enzyme-linked immunosorbent assay kits specific for ALCAM, hemopexin and PRDX 6, respectively, according to the manufacturer's protocols. The diagnostic utility of urine biomarkers was evaluated using receiver operating characteristic (ROC) curve analysis, and Pearson's correlation analysis was performed to assess the relationships between disease activity and urine biomarkers.

Results: Urinary ALCAM level was 6,760.5 ± 2,826.4 pg/ml and 1,192.6 ± 577 pg/ml in patients with SLE and HCs ($p < 0.001$). The mean levels in urinary hemopexin and PRDX6 were also significantly higher in patients with SLE compared to HCs (hemopexin, 649.8 ng/ml vs. 202 ng/ml, $p < 0.001$; PRDX6, 0.78 ng/ml vs. 0.17 ng/ml, $p = 0.003$). In patients with lupus nephritis (LN), ALCAM, hemopexin, and PRDX6 showed more significant diagnostic value, and the area under the ROC for LN was 0.850 for ALCAM (95% CI, 0.778–0.921), 0.781 for hemopexin (95% CI, 0.695–0.867), and 0.714 for salivary S100A8 (95% CI, 0.617–0.812). In addition, all urine biomarkers were significantly associated with anti-double stranded DNA (ALCAM, $r = 0.350$, $p < 0.001$; hemopexin, $r = 0.346$, $p < 0.001$; PRDX6, $r = 0.191$, $p = 0.026$) and SLEDAI (ALCAM, $r = 0.526$, $p < 0.001$; hemopexin, $r = 0.479$, $p < 0.001$; PRDX6, $r = 0.262$, $p = 0.002$) in correlation analysis.

Conclusion: Urinary ALCAM, hemopexin and PRDX 6 were significantly increased in patients with SLE compared to HCs. Thus, we propose that urinary ALCAM, hemopexin and PRDX 6 can be potential biomarkers for SLE, especially valuable in the diagnosis of LN.

Mirrahimov (NCCIM), Rheumatology, Bishkek, Kyrgyzstan*; [3]*Federal State Research Institution (FSRI) named after V.A. Nasonova, Rheumatology, Moscow, Russian Federation*

Background: Fatigue is a frequent, disabling issue in systemic lupus erythematosus (SLE). It is, however, difficult to quantify. The Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue Scale has been validated in SLE and has been successfully used to assess fatigue.

Objectives: To evaluate the application and influence factors of the Functional Assessment of Chronic Illness Therapy (FACIT-Fatigue) scale in patients with systemic lupus erythematosus (SLE)

Methods: 1061 SLE pts who fulfilled SLICC 2012 [1] criteria were enrolled into the study. The SLEDAI 2K index activity, SLICC damage index, fatigue was assessed by the FACIT-Fatigue scale from 0 to 52 (no or little fatigue 40-52, some fatigue 27-39, quite a lot of fatigue 14-26, extreme fatigue 0-13) [2]

Results: 1061 Lupus pts were studied, respectively. The pts were predominantly female (92%) and of indigenous nationality (Kazakh 10%,/ Kirghiz 54%/Russian 36%)with a mean±SD age 34,6±11,8 years. The mean disease duration (Me) was 4 [1;9], the disease activity (SLEDAI 2K) 13,23±8,74, SLICC damage index 1,36±0,82. Fatigue was detected in 828 (79%) of 1061 patients with SLE. 1061 pts were divided into two groups. The first group included 447 pts with quite a lot of fatigue and extreme fatigue (from 26 up to 0 by Facit -fatigue scale). The second one included 615 SLE pts with no or little fatigue and some fatigue). The first group pts were with higher SLE activity by SLEDAI 2 K (16,4±9,3 versus

11,5±8,4; p=0,0001), had a higher level of dsDNA (131,7±23,9 versus 94,5 ± 11,7; p=0,002), were treated with higher doses of glucocorticoids (22,33±12,3 versus 19,5±17,0 mg per day; p=0,001).

Table 1. Frequency of fatigue in different ethnic groups

Facit fatigue, Score	Russian [1], N = 386, n (%)	Kirghiz [2], N = 573, n (%)	P [1-2]	Kazakh [3], N = 102, n (%)	P [1-3]	All pts, N = 1061, n (%)
no or little fatigue, 52–40	146 (37%)	81 (14%)	< 0,0001	6 (6%)	< 0,0001	233 (21%)
some fatigue, 39–27	147 (38%)	222 (39%)	–	13 (13%)	< 0,0001	382 (37%)
quite a lot of fatigue, 26–14	80 (21%)	172 (30%)	0,01	52 (51%)	< 0,0001	304 (29%)
extreme fatigue, 13–0	13 (4%)	99 (17%)	< 0,0001	31 (30%)	< 0,0001	143 (13%)

Fatigue was significantly more common among Kazakhs (94%) and Kyrgyz (86%) than among Russians (63%) pts (Table 1). Extreme fatigue was significantly more common among Kazakhs (30%) than among Russians (4%) and Kyrgyz (17%) pts.

Conclusion: Fatigue are common (79%) in SLE pts and significantly higher among Asians pts (86-94%). Fatigue strongly associated with SLE activity.

AB0570 RELATIONSHIPS AMONG ANXIETY, DEPRESSION AND DESEASE ACTIVITY IN ASIANS SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS FROM KAZAKHSTAN AND KIRGHIZSTAN

Keywords: Quality of life, Systemic lupus erythematosus

B. Issayeva[1], G. Koilubaeva[2], E. Aseeva[3], N. Nikishina[3], A. Mesnyankina[3], S. Solovyev[3], S. Issayeva[1], M. Bizhanova[1]. *[1]Asfendiyarov Kazakh National Medical University, Rheumatology, Almaty, Kazakhstan*; *[2]National Center of Cardiology and Internal Medicine named after Academician M. Mirrahimov (NCCIM), Rheumatology, Bishkek, Kyrgyzstan*; *[3]Rheumatology, Federal State Research Institution (FSRI) named after V.A. Nasonova, Rheumatology, Moscow, Russian Federation*

Background: Depression and anxiety cause severe loss of quality of life for patients with systemic lupus erythematosus. The causes and factors that contribute to these psychological manifestations in lupus are difficult to disentangle.

Objectives: The aim of this study was to determine factors associated with anxiety and depression in Asians systemic lupus erythematosus patients (pts) from Kazakhstan and Kirghizstan.

Methods: 1060 SLE pts who fulfilled SLICC 2012 criteria were enrolled into the study. The SLEDAI 2K index activity, SLICC damage index, depressive and anxiety symptoms were assessed by the Hospital Anxiety and Depression (HAD) scale (0-21 points).

Results: 1060 Lupus pts were studied, respectively. The pts were predominantly female (92%) and of indigenous nationality (Kazakh 10%,/ Kirghiz 54%/Russian 36%)with a mean±SD age 34,6±11,8 years. The mean disease duration (Me) was 4 [1;9], the disease activity (SLEDAI 2K) 13,23±8,74, SLICC damage index 1,36±0,82. More than half of the pts (619 [58.3%]) had abnormal points by HADS scale. 1060 pts were divided into two groups. The first group included 619 SLE pts with abnormal HADS (HADS-A ≥ 8 points; HADS-D ≥ 8 points; HADS-D ≥ 8 points and HADS-A ≥ 8 points). The second one included 441 SLE pts with normal HADS. The most common were anxiety and depression (HADS-D ≥ 8 points and HADS-T ≥ 8 points) - in 346 (32.6%) pts, the second most common was anxiety disorder (HADS-T ≥ 8 points) - in 230 (22%) pts, the third - depressive disorder (HADS-D ≥ 8 points) - in 43 (4%). Such factors as age of the pts, age of SLE onset, duration of illness, SLICC damage index, SLEDAI 2 K, and dosage of corticosteroids. The pts with abnormal HADS were older (36,04±12,11 versus 29,94±11,49 years; p=0,003), with less disease duration (3,1 [0,9;8] versus 4,7 [1,5; 10]; p=0,01), with disease onset at a more later age (31,55±11,86 versus 26,43±11,39 years; p=0,0002), with higher SLE activity by SLEDAI 2 K (14,78±8,59 versus 12,22±8,30; p=0,01). The pts with abnormal HADS were treated with higher doses of glucocorticoids (22,33±12,6 versus 18,5±12,0 mg per day; p=0,005).

Table 1. Frequency of anxiety and depression in different ethnic groups

HADS score	Russian [1], n = 384, n (%)	Kirghiz 2, n = 574, n (%)	P [1-2]	Kazakh [3], n = 102, n (%)	P [1-3]	All pts, n = 1060, n (%)
Normal HADS	228 (59%)	153 (27%)	< 0,0001	60 (59%)	–	441 (42%)
Abnormal HADS	156 (41%)	421 (73%)	< 0,0001	42 (41%)	–	619 (58%)
Only HADS-A ≥ 8 points	78 (20%)	130(23%)	–	22 (21%)	–	230 (22%)
Oly HADS-D ≥ 8 points	10 (3%)	28 (5%)	–	5 (5%)	–	43 (4%)
HADS-D ≥ 8 points and HADS-A ≥ 8 points	68 (18%)	263 (46%)	< 0,0001	15 (15%)	–	346 (32%)

The frequency of anxiety and depression was significantly higher among the Kyrgyz pts (46%) than Russian (18%) and Kazakh pts (15%) (Table 1).

Conclusion: Depressive and anxiety symptoms are common (58,3%) in SLE pts and significantly higher among Asians pts (46%). Such factors as pts age, age of SLE onset, duration of illness, SLEDAI 2 K, and dosage of corticosteroids were strongly associated with abnormal HADS.

AB0571 DO ADULT WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS REACH FITNESS STANDARDS FOR MAINTAINING PHYSICAL INDEPENDENCE IN LATER YEARS? ASSOCIATIONS WITH FATIGUE AT 2-YEAR FOLLOW-UP

Keywords: Non-pharmacological interventions, Systemic lupus erythematosus, Lifestyles

B. Gavilán Carrera[1,2], A. Soriano Maldonado[3,4], J. A. Vargas-Hitos[1]. *[1]Hospital Universitario Virgen de las Nieves, Departamento de Medicina Interna, Granada, Spain*; *[2]Instituto de Investigación Biosanitaria, ibs.GRANADA, Granada, Spain*; *[3]University of Almería, Department of Education, Almería, Spain*; *[4]University of Almería, SPORT Research Group (CTS-1024), CERNEP Research Center, Almería, Spain*

Background: Maintaining physical fitness (i.e. muscle strength and cardiorespiratory fitness) is a key factor in preserving independence in later years [1]. Because people with systemic lupus erythematosus (SLE) present with reduced fitness levels [2,3], this population could be at risk of premature loss of independence. In addition, higher levels of physical fitness have been related to better SLE symptomatology, including fatigue [2,3], one of the most limiting symptoms. However, it is unclear whether physical fitness have a predictive role on future levels of fatigue in this population.

Objectives: This study aimed to analyze, in a sample of adult women with SLE: i) the proportion of participants that reach the proposed standards of fitness for muscle strength and cardiorespiratory fitness to maintain independence in the later life and ii) the association between reaching these standards of fitness and fatigue levels at 2-year follow-up.

Methods: This follow-up study included a total of 26 women with SLE (age: 41.3 ± 13.3 years) with low disease activity index (Systemic lupus erythematosus disease activity index [SLEDAI]: mean 1.0 ± 1.9). The 30-s chair stand and 6-min walk tests from the Senior Fitness Test Battery were used to assess muscle strength and cardiorespiratory fitness. The percentage of participants reaching the criterion-reference for women 60-64 years old (15 repetitions [in the 30-sec chair stand test] and 571,5 meters [in the 6-min walk test]) was calculated. Linear regression models adjusted by age were used to analyze the association of reaching the fitness criterion-reference and fatigue levels at 2-year follow up. Five dimensions of fatigue (general, physical, reduced activity, reduced motivation and mental fatigue) were assessed using the multidimensional Fatigue Inventory (MFI).

Results: A total of 42.3 % participants did not reach the criterion-reference for muscle strength and 50 % of participants did not reach the criterion-reference for cardiorespiratory fitness. Reaching the criterion-reference for cardiorespiratory fitness was associated with lower physical fatigue at 2-year follow-up (β=-0.55, P<0.05). There was no association with other dimensions of fatigue or reaching the criterion-reference for muscle strength.

Conclusion: In this relatively small sample of adult women with SLE, up to half of participants have reduced physical fitness that exposed them to a premature loss of functioning and independence in their later life. Reaching a minimum level for cardiorespiratory fitness, but not for muscle strength, predicted lower physical fatigue in the future. Exercise interventions aimed at increasing physical fitness

could be a promising approach to reduce the decline in functioning and contribute to lower fatigue in this population.

AB0572 DIFFERENTIAL BACKGROUND OF CLINICAL AND IMMUNOHISTOLOGICAL CHARACTRSITICS IN SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS COMPLICATED WITH HEART DISEASE

Keywords: Cardiovascular disease, Systemic lupus erythematosus, Rheumatoid arthritis

T. Kawamoto[1], H. Amano[1], S. Matsushita[2], K. Minowa[1], M. Matsushita[1], K. Yamaji[1], A. Amano[2], N. Tamura[1]. *[1]Juntendo University School of Medicine, Internal Medicine and Rheumatology, Tokyo, Japan*; *[2]Juntendo University School of Medicine, Cardiovascular Surgery, Tokyo, Japan*

Background: Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are often complicated by heart disease. In severe cases, heart surgery is required, but little is known about clinical background and immunohistological pathology of diseases.

Objectives: The differences in clinical and immunohistological backgrounds of each disease were examined by comparing cases of heart disease associated with SLE and RA.

Methods: From 2012 to 2021, we observed 45 patients with SLE (32 patients underwent surgery), 67 patients with RA (33 patients underwent surgery), and 8 patients with overlapping SLE/RA (3 patients underwent surgery), all complicated with heart disease. The heart disease cases were divided into the aortic valve disease (Av), mitral valve disease (Mv), ischemic heart disease (I), and aortic aneurysm disease (Aa) groups, all from patients who had visited our hospital. The SLE (S) group consisted of Av, Mv, I, and Aa in 5, 6, 11, and 13 respective cases (10 duplicate cases), and in the RA (R) group there were 24, 12, 15, and 10 respective cases (6 duplicate cases). Immunohistological analysis of patients with left atrial appendage tissue (seven SLE, six RA, and two overlapping SLE/RA patients) was performed on left atrial cardiomyocytes for anti-human IgG, IgM, and C3 antibodies. Left atrial cardiomyocytes of eight cases of heart disease with non-connective tissue disease were used as the control.

Results: The age (in years) at diagnosis of heart disease in the S and R groups was S/R: 57.6/71.5 (p=0.057), and the duration (in years) from onset of the connective tissue disease to onset of the heart disease was S/R: 22.6/10.1 (p<0.001). Anti-SS-A antibody (P=0.041), anti-U1RNP antibody (p=0.0044), and anti-CLβ2GP1 antibody (p=0.022) showed a high positivity rate in the S group. In disease I, the age at the time of diagnosis of heart disease was S/R: 51.6/70.9 years (p = 0.0083); and in disease Aa, the age and duration of disease were S/R: 63.5/74.8 years (p = 0.0088) and 29.6/7.0 years (p = 0.0013), respectively. There was no significant difference in S/R in patients suffering from diabetes, hypertension, and hyperlipidemia. Immunohistological analysis revealed IgG deposition in the cardiomyocytes in six of the seven patients in the S-alone group, while no IgG deposition was observed in six patients in the R-alone group. In two patients with overlapping S-R, IgG deposition was observed in both. In the S group, two or more antibodies of antiphospholipid antibodies, anti-Ro/SSA or anti-U1RNP antibodies, were positive in five out of the seven patients, and preoperative anti-DNA antibody elevation or complement reduction was seen in only two patients. Two of the seven patients in the S group were negative for either antibody, and a patient showed no IgG deposition uniquely in the S group. Both patients with overlapping S-R were positive for anti-CL antibody and anti-Ro/SSA antibody. In the R group, all antibodies were negative within the measured range.

Conclusion: A comparison of SLE and RA patients complicated with heart disease revealed that the SLE patients tend to be younger at diagnosis than RA patients and had a longer morbidity period. It is possible that various autoantibodies, such as antiphospholipid antibodies, anti-Ro/SSA antibodies, and anti-U1RNP antibodies were involved and had immunological effects on the myocardial tissue. In contrast, in RA patients complicated with heart disease, the autoantibodies observed in SLE were negative, and immunoglobulins were not deposited in the myocardial tissue of the RA patients who underwent surgery, suggesting that immunological involvement was poor and older diagnostic age was involved.

Background: Even though the health benefits of breast milk are well established, only a small number of research have looked at breastfeeding in people with systemic lupus erythematosus, with mixed findings. In a previous multicenter cohort investigating 119 SLE pregnancies, one-third of patients did not breastfeed after giving birth.
Objectives: To study the causes of breastfeeding avoidance with the purpose to increase the standard of care of SLE women.
Methods: A priori questionnaire was created and administered to patients by structured-phone interview (Table 1). Pregnancy outcomes were retrospectively collected.
Results: A total of 22 questionnaires of women who did not breastfeed after first birth were collected. Twelve out of 22 (54.5%) patients experienced a disease flare in the 24 months following the delivery. Healthcare professional advice (36.4%) was the most frequently reported reason for not breastfeeding, followed by the mothers' fear that medications (drugs) taken during pregnancy (22.7%) and/or the circulating autoantibodies (4.5%) could be passed onto the baby and therefore harm the new-born. In 10 (45%) cases, breastfeeding was not possible because of mother's or neonatal clinical complications. One woman did not breastfeed for a personal choice. After giving birth, only nine out of 22 patients (40.9%) declared to have had adequate breastfeeding training, with 58% of women reporting a breastfeeding-training time of less than 5 minutes in those without an adequate counselling. Most patients (21 out of 22, 95.5%) stated that they would have breastfed their child if they could.
Conclusion: Breastfeeding avoidance in women with SLE is frequently the result of a confluence of individual preference, clinical advice, and the societal context. An implementation of patients-to-patients network, together with an update of health practitioners, may help to increase the frequency of breastfeeding in women with SLE and subsequently improve patients' care.
In Figure 1 implementation points suggested by patients.

Table 1.

1. Have you received pre-conceptional counselling?	Y N
2. For how long were you able to discuss about pregnancy planning with your HP?	-One session -Multiple session
3. In pre-conceptional counselling, were you informed on breastfeeding?	Y N
4. Why did you not breastfeed?	-Healthcare professional advice -Fear that the undertaken drugs could be delivered to the baby -Fear that the autoantibodies and the disease might have been transferred to the baby -N/A
5. Who, among HP, advised you not to breastfeed	-GP -Rheumatologist -Gynecologist -Nurse/obstetrician -Training physician -N/A
6. Did you seek out different medical opinions?	Y N
7. After you gave birth, did you receive detailed information on how to breastfeed, and were you trained to do it?	Y N
8. For how long have HP informed and trained you about breastfeeding	-Less than 5 minutes -15 minutes -30 minutes -Multiple times during my hospitalization -I received training and support for several days after being discharged from the hospital
9. Were informative materials on breastfeeding provided to you by HP?	Y N
10. If you not breastfed because of temporary neonatal complications, were you trained and supported in milk production maintenance?	Y N N/A
11. The choice of not breastfeeding was influenced by society's demands?	Y N
12. Your choice of not breastfeeding was influenced by:	-Work-related issue (lack of space and time to breastfeed) -Lack of support from family members and friends -None of the aforementioned
13. Have you felt overwhelmed by the delivery and the first days that came after it?	Y N
14. Your choice of not breastfeeding was influenced by the belief that formula milk was healthier for the baby compared to the mother's milk?	Y N
15. Would you have breastfed if you could have?	Y N
16. Do you think dedicated counseling could have changed your approach to breastfeeding?	Y N
17. Do you have any suggestions on how to implement breastfeeding awareness?

Background: CLE can present as an isolated skin disease or with systemic lupus erythematosus (SLE) and is classified as chronic (CCLE; primarily discoid [DLE]), subacute (SCLE), intermittent (ICLE), or acute (ACLE). Except for erythema, skin-related signs/symptoms may vary by subtype. We conducted mixed methods research to refine and develop an optimal clinician-reported outcome measure for CLE trials.
Objectives: Evaluate the level of agreement among dermatologists and rheumatologists on CLE signs/symptoms and develop a conceptual model for CLE.
Methods: We conducted one-to-one interviews with practicing, board-certified dermatologists or rheumatologists followed by a rank-and-sort exercise, and a

literature review. Interviews included open-ended and semi-structured questions on CLE diagnosis and their patients' signs/symptoms, and data were evaluated by thematic analysis. Two quantitative activities were conducted: first, clinicians sorted a list of skin signs/symptoms as 1) not characteristic, 2) moderately characteristic, or 3) highly characteristic of CLE or cutaneous SLE disease activity. Second, they classified CLE signs/symptoms as most closely associated with CCLE/DLE, SCLE or ACLE. Data were analyzed using an informal (ranking task) or formal (classification task) consensus model.

Results: Eleven dermatologists and 10 rheumatologists (US n=13; Europe n=8) were interviewed. Most dermatologists (70%) had 5–10 years' experience managing/treating patients with CLE; 56% of rheumatologists had 21–25 years' experience. The most frequently mentioned signs included erythema/rash (100%), malar rash (71%), palpable lesions (57%) and scale (57%). Photosensitivity (76%), itch (62%) and skin pain (57%) were the most frequently mentioned symptoms. Of the 33 skin signs presented, both specialties ranked photosensitive rash (weighted average: dermatologists 3.00; rheumatologists 2.85) and erythema (2.92 and 2.81) highest. However, some key differences were identified. For example, dermatologists ranked polycyclic (2.72) and annular (2.61) lesions (typical of SCLE) as highly characteristic of CLE, but rheumatologists ranked them as low or moderately characteristic (1.55 and 2.23, respectively). Also, dermatologists ranked markers of DLE, such as follicular plugging (2.88 and 2.36), higher than rheumatologists. Consensus analysis showed robust agreement between dermatologists (eigenvalue ratio 17.95; average competence 0.86) and modest agreement between rheumatologists (6.13; 0.67) in classifying skin manifestations by CLE subtype. Manifestations with the strongest agreement included acute alopecia (ACLE n=20; SCLE n=0; CCLE/DLE n=1), malar rash (n=21; n=0; n=0, respectively), dyspigmentation without scarring (n=1; n=18; n=2), psoriasiform annular plaques (n=0; n=20; n=1), dyspigmentation with scarring (n=0; n=0; n=21), and irreversible scarring alopecia (n=0; n=0; n=21). Variation was evident for signs more often associated with SCLE, including non-scarring photosensitive dermatitis (n=8; n=13; n=0). Multidimensional scaling showed notable differences in consensus between dermatologists and rheumatologists; while coherent clusters of symptoms were mapped to the CLE subtypes by dermatologists, the pattern for rheumatologists was more diffuse, suggesting a less consistent conceptualization of SCLE and CCLE. These results, together with the literature review, were used to develop a conceptual model for evaluating CLE.

Conclusion: Despite agreement on the importance of erythema and characterization of CLE as a photosensitive rash, differences between the specialties were apparent when rating CLE signs that typically accompany non-systemic, cutaneous disease. This might reflect increased training among dermatologists in clinical-histopathologic description of lesions. The conceptual model proposed will facilitate efforts to design measurement approaches to evaluate disease activity in clinical research and practice.

Rodriguez Bellido[2,5], R. Perich Campos[2,5], G. S. Alarcon[6,7]. *[1]Universidad Cientifica del Sur, Grupo Peruano de Estudio de Enfermedades Autoinmunes Sistémicas, Lima, Peru*; *[2]Hospital Guillermo Almenara Irigoyen, EsSalud, Rheumatology, Lima, Peru*; *[3]Universidad San Ignacio de Loyola, Unidad de Investigación para la Generación y Síntesis de Evidencias en Salud, Lima, Peru*; *[4]Universidad Privada San Juan Bautista, Escuela Profesional de Medicina Humana, Ica, Peru*; *[5]Universidad Nacional Mayor de San Marcos, School of Medicine, Lima, Peru*; *[6]The University of Alabama at Birmingham, Heersink School of Medicine, Alabama, United States of America*; *[7]Universidad Peruana Cayetano Heredia, School of Medicine, Lima, Peru*

Background: Health-related quality of life (HRQoL) is impaired in systemic lupus erythematosus (SLE) patients, but its association with physicians reported disease activity is modest to none.

Objectives: To determine the impact of patients reported disease activity on their HRQoL.

Methods: We evaluated patient-reported disease activity on SLE patients from the Almenara Lupus Cohort. Disease activity was assessed using the Lupus Foundation of America Rapid Evaluation of Activity in Lupus (LFA-REAL) patient-reported outcome (PRO) which ranges between 0 and 1200 (the higher the score is, the worse the activity is); HRQoL was ascertained using the LupusQoL which ranges between 0 and 100 (the higher the score is, the better the HRQoL). Generalized estimating equations were performed for each domain of the LupusQoL and the LFA-REAL PRO measured at the previous visit; multivariable models were adjusted for possible confounders (age at diagnosis, gender, educational level, disease duration, SLEDAI-2K, SDI, prednisone dose, antimalarials and immunosuppressive drug use and the same domain of LupusQoL) measured at the same visit as the LFA-REAL PRO. B was reported per 10 units increase of the LFA-REAL PRO.

Results: A total of 259 patients and 582 visits were included. Mean (SD) LFA-REAL PRO was 242.91 (178.92). The most affected LupusQoL domains at baseline were burden to others 57.5 (SD 31.5), intimate relationship 64.1 (SD 33.1) and body image 62.6 (SD 30.7). LFA-REAL PRO predicted a worse HRQoL in all domains, even after adjustment by possible confounders (Table 1).

Conclusion: A higher patient-reported disease activity predicted a worse HRQoL in SLE patients, even after adjustment for possible confounders. Strategies to improve how the patients feel and manage their disease could be useful to improve their HRQoL. Patient-reported disease activity should be included in the evaluation of SLE patients on a regular basis.

Table 1. Impact of LFA-REAL PRO per 10-unit increase on HRQoL in SLE patients

AB0576 DEFINING INTERFERON MEDIATED CONDITIONS (DEFINITION): IFN ASSAYS AND CLINICAL FEATURES OF ESTABLISHED ANA-ASSOCIATED AUTOIMMUNE DISEASES

Keywords: Sjögren syndrome, Systemic lupus erythematosus, Undifferentiated connective tissue disease

J. Arnold[1,2], L. M. Carter[1,2], K. Dutton[1,2], S. U. Hassan[1,2], Z. Wigston[1,2], M. Y. MD Yusof[1,2], S. Dass[1,2], E. Vital[1,2]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[2]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: A large body of evidence has shown that type I IFN (IFN-I) biomarkers are associated with worse clinical features within each ANA-associated rheumatic disease (ARMD). IFN-I biomarkers also predict response to IFN-targeted and other therapies. DEFINITION is an observational study to explore the clinical associations of IFN biomarkers across the disease course and spectrum of ARMDs. This is a preliminary analysis for the subsection on the spectrum of established ARMD.
Objectives: To determine whether patients with high IFN-I biomarkers have greater impact of disease including disease activity, functional impairment and quality of life.
Methods: Adults with current or previous positive ANA and either criteria for any ARMD (SLE, pSS, IIM, SSc, MCTD) or consultant diagnosis of ARMD (may be undifferentiated if symptoms>12 months and/or treated with immunosuppressants. We collected demographics, deprivation, participation, cardiovascular risk and comorbidity variables, diagnostic criteria for each ARMD, quality of life and other patient-reported outcome measures, and therapies. Disease activity was summarised using a composite of validated instruments to classify each organ system as severe, moderate, mild or inactive (equivalent to BILAG A-D/E for SLE). IFN-I pathway activation was measured using gene expression IFN Score A and B and memory B cell tetherin. We used Spearman correlations and unsupervised hierarchical clustering and to find associations between clinical outcomes and IFN-I biomarkers.
Results: Of 294 patients, 23/294 (18%) were male, mean (SD) age was 50 (14), index of multiple deprivation decile 4.9 (3.1), Charlson comorbidity index 2.1 (1.5). Current therapy was prednisolone (24.5%), hydroxychloroquine (45.2%), methotrexate (17.7%), mycophenolate (11.9%), azathioprine (10.2%), rituximab (8.5%), cyclophosphamide (0.3%). 104 patients had SLE, 111 had UCTD, 33 and pSS, 19 had myositis, 14 had SSc and 13 had MCTD. There was a significant association between ARMD diagnosis and IFN Score A (F= 2.52, p=0.030) and memory B cell tetherin (F= 4.34, p<0.001) but not IFN Score B (F=0.66, p=0.653). In pairwise correlations only one weak relationship between SF36 PCS and memory B cell tetherin was found (R=0.33, p<0.001). No substantive relationship was found between gene expression scores and clinical features. However, unsupervised hierarchical clustering across all ARMD patients yielded 5 clusters of patients with a significant role for sociodemographic variables that revealed further relationships between IFN biomarkers and disease activity. Cluster 1: mild symptoms, low comorbidity, high affluence; Cluster 2: older, high comorbidity, high affluence; Cluster 3: younger, low affluence, poor QoL; Cluster 4: high tetherin and BILAG; Cluster 5: low IFN and BILAG.
Conclusion: There are complex relationships between IFN and clinical features across the spectrum of ARMDs. This is confounded by socioeconomic variables, which must be considered in stratification studies.

AB0577 LEFT VENTRICULAR DYSSYNCHRONY IN SUBJECTS WITH DIFFERENT SLE PHENOTYPES

Keywords: Cardiovascular disease

F. Shahab[1], H. Zachrisson[2], C. Svensson[2], M. Aneq[2], C. Sjöwall[3], D. Kylhammar[2]. *[1]Linköping University Hospital, Department of Rheumatology, Linköping, Sweden*; *[2]Deparment of Health,Medicine and Caring Sciences, Department of Clinical Physiology, Linköping, Sweden*; *[3]Division of Neuro and Inflammation Sciences, Department of Clinical and Experimental Medicine, Department of Rheumatology, Linköping, Sweden*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with highly heterogenous clinical presentation involving, e.g., skin, joints, kidneys and the cardiovascular system. In prospective studies, the incidence rates of myocardial infarction and stroke in patients with SLE have been shown to be high, but more knowledge is needed regarding early myocardial involvement and affection of the right ventricle in different SLE phenotypes.
Objectives: The aim of the present study was to investigate differences of left- and right ventricular systolic function in three, well-defined SLE phenotypes, i.e. skin- and joint involvement, lupus nephritis antiphospholipid syndrome (APS), respectively.
Methods: Transthoracic echocardiograms were performed in 60 subjects with SLE (three age- and sex-matched groups of subjects with either skin- and joint involvement, lupus nephritis or APS, respectively) included in the SLEVASK [1] cohort which represents a subgroup of the regional quality register *Clinical Lupus Register in North-Eastern Gothia* (Swedish acronym: KLURING). There were 54 women and 6 men, and the median age was 48.5 (range 28-68y) years. Left- and right ventricular dimensions and standard systolic function parameters were measured according to international guidelines. Left and right ventricular longitudinal strain and left ventricular mechanical dispersion, defined as the standard deviation of time to maximal myocardial shortening were measured by a commercially available software. Three subjects with clinically manifest heart failure were excluded.
Results: There were no significant differences in left- or right ventricular dimensions, left ventricular ejection fraction or measures of right ventricular systolic function between the three groups. Left ventricular global longitudinal strain was reduced in subjects with nephritis (p=0.012), as compared to those with skin- and joint involvement and there was a trend for lower strain also among subjects with APS (p=0.078). Left ventricular mechanical dispersion was increased among subjects with APS (p=0.015) and nephritis (p=0.032), as compared to those with skin- and joint involvement (Table 1).
Conclusion: Reduced left ventricular global longitudinal strain and greater mechanical dispersion, a sign of a more heterogonous contraction, among SLE patients with nephritis and APS indicate more severe cardiac involvement, as compared to those with skin- and joint involvement. A greater degree of mechanical dispersion is thought to reflect myocardial fibrosis and future studies should investigate the pathogenesis of such sub-clinical impairment of cardiac function in SLE and its impact on long-term prognosis.

Background: Systemic lupus erythematosus (SLE) is heterogeneous autoimmune disease. Identification of patient clusters may be useful for the management of the disease.

Objectives: To describe different SLE clusters according to sociodemographic, clinical and serological variables.

Methods: GLADEL 2.0 is an ongoing Latin-American observational cohort initiated in 2019. Variables chosen at cohort entry to stratify patients and construct clusters were selected from sociodemographic and cumulative clinical and serological variables. Hierarchical cluster analyses were performed by the Ward method on a distance matrix using the Gower's method.

Results: A total of 560 SLE patients were included in this analysis. Three clusters were identified. Cluster 1 (n=269) was characterized by more cutaneous, articular, renal and serosal involvement; serological manifestation was positive anti-dsDNA. Cluster 2 (n=194) was represented by patients who rarely had renal involvement and the most frequent clinical manifestations were cutaneous and hematological; the most frequent serological manifestations were the presence of antiphospholipid antibodies (aPLs). Cluster 3 (n=97) was characterized by a lower frequency of clinical and serological involvements, with the exception of neurological domain. Clusters 1 and 2 share hematologic manifestations and hypocomplementemia (Table 1).

Conclusion: In this cohort, three patient clusters were identified. Cluster 1 patients were characterized by renal, articular, cutaneous and serositis involvement, anti-dsDNA antibodies and hypocomplementemia, Cluster 2 patients were characterized by hematologic, cutaneous involvement, aPLs and hypocomplementemia. Cluster 3 patients presented fewer serological findings but a higher frequency of neurological involvement. Follow up of these patients will allow for elucidation of relationship of these clusters with SLE outcomes.

AB0579 ASSOCIATION OF RACE OR ETHNICITY WITH MEDICATION ADHERENCE IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Gender/diversity issues, Systemic lupus erythematosus

R. Lomanto Silva[1], G. M Swabe[2], S. E. Sattui[3], J. W Magnani[4]. [1]*University of Pittsburgh Medical Center, Internal Medicine, Pittsburgh, United States of America*; [2]*University of Pittsburgh, Internal Medicine, Pittsburgh, United States of America*; [3]*University of Pittsburgh Medical, Rheumatology, Pittsburgh, United States of America*; [4]*University of Pittsburgh, Cardiology, Pittsburgh, United States of America*

Background: Systemic lupus erythematosus (SLE) causes significant disease burden. Racial and ethnic differences in outcomes have been recognized, with increased morbidity and mortality in Black and Hispanic individuals, compared to non-Hispanic White referents. Financial barriers to treatment, such as copayments (or copays), may affect adherence to essential pharmacologic therapies, contributing to increased health adversity. Determining the contribution of copays to adherence may identify disparities in medication access and pathways to improve adherence.

Objectives: To examine the association between race or ethnicity and medication adherence.

Methods: We used administrative health claims data (Optum's De-identified Clinformatics® Data Mart Database, 2007-2021) to identify individuals with incident SLE (2 ICD-9/10 codes within 30-365 days) between 2010-19 receiving hydroxychloroquine (HCQ), azathioprine (AZA), mycophenolate mofetil (MMF), methotrexate (MTX), or combination therapy (HCQ with AZA, MMF, or MTX). Race or ethnicity were categorized as Asian, Black, Hispanic, White, or unknown. We dichotomized copays as low (<$10/30 days) or high (≥$10/30 days). Adherence was defined as proportion of days covered (PDC) ≥80%. We examined the association between race or ethnicity and adherence with multivariable-adjusted logistic regression models, using White individuals as referent. Results were then stratified by copay categories.

Results: We identified 12,510 individuals: age 54.2±15.5 years; 88.2% women; 63.2% (7910) White, 14.9% (1860) Black, and 13.8% (1729) Hispanic. A total of 9510 (76%) were on HCQ and 15% on combination therapy. Median (IQR) 30-day copays were $8 (4, 10) for HCQ, $7 (2, 10) for AZA, $10 (5, 20) for MMF, and $8 (3, 11) for MTX. Black individuals had 51% (95% CI 0.31-0.80), 30% (95% CI 0.61-0.81), and 35% (95% CI 0.45-0.94) lower odds of adhering to AZA, HCQ, and combination therapy, respectively. Hispanic individuals had 27% (95% CI 0.63-0.94) lower odds of adhering to HCQ. When stratified by low or high copay, the association between race or ethnicity and adherence did not change, and the interaction of copayment on the association between race or ethnicity and adherence was not significant (**Table 1**).

Conclusion: In this large cohort, Black and Hispanic individuals had decreased odds of adherence to SLE medications even after adjusting for several socioeconomic factors and comorbidities. The detrimental associations between copay and adherence were consistent across copay strata, suggesting that other factors contribute to racial and ethnic disparities. Factors such as polypharmacy, pharmacy deserts, transportation, mental health, cultural barriers, and health care access merit examination for their relation to adherence.

Background: Obstetric morbidity (OM) is higher in SLE women than in healthy ones. Few data on SLE pregnancy outcomes in Latin America (LA) have been reported.

Objectives: To study SLE pregnancy outcomes in LA.

Methods: GLADEL 2.0 is an observational prevalent/incident cohort started in 2019. To date, 43 centers from 10 LA countries have enrolled 1030 SLE patients (1982/1997 ACR or SLICC criteria). Women with ≥1 pregnancy were included. Past and ongoing (6, 12, 24 months follow-up) OM (miscarriages, fetal deaths, preeclampsia, prematurity, neonatal lupus) were evaluated.

Results: At inclusion, 329 women have had at least one pregnancy [median (IQR): 2 (1-3)]: Table 1. Of them, 293 (89.1%) had ≥1 live birth and 183 (55.6%) developed OM. Preeclampsia occurred in 49 (14.9%). Among 71 (21.6%) women with anti-SS-A(Ro)/SS-B(La) antibodies, 3 (4.2%) developed neonatal lupus (no cardiac involvement). Antiphospholipid syndrome (APS) was associated with higher risk of OM (52.2% vs 10.0%; p< 0.001). Of the 755 pregnancies reported, 551 (73.0%) resulted in live births, of which 79 (14.3%) were premature. The remaining pregnancies ended in 178 (23.6%) miscarriages and 41 (5.4%) fetal deaths. During 2-follow-up years (Figure 1), 24 singles pregnancies occurred. All were under antimalarials; 16 (66.7%) resulted in live births, 4 (25.0%) premature; 12 (50.0%) developed OM. There were seven (29.2%) miscarriages and one fetal loss (4.2%) related to severe preeclampsia. One cholestasis gravidarum (4.2%) lead to prematurity. There were no new cases of neonatal lupus.

Conclusion: In GLADEL 2.0 cohort, around half of the studied women presented OM being frequently related to APS. Miscarriages, prematurity, preeclampsia and fetal deaths were the most common pregnancy complications. The incidence of neonatal lupus was lower than previously reported [1].

CLINICAL AND RENAL PATHOLOGICAL FEATURES PREDICTING COMPLETE CLINICAL RESPONSE IN CRESCENTIC LUPUS NEPHRITIS

Keywords: Prognostic factors, Systemic lupus erythematosus, Kidneys

H. Fukui[1], H. Hanaoka[1], K. Saito[1], K. Hiramoto[1], S. Saito[1], J. Kikuchi[1], Y. Kaneko[1]. [1]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

Background: Lupus nephritis (LN) is one of the major manifestations of systemic lupus erythematosus, which develops in approximately 40% of patients with systemic lupus erythematosus. Clinical presentation of LN varies between patients, from asymptomatic proteinuria to rapidly progressive glomerulonephritis. Due to improvements in treatment strategy, risk of developing end-stage kidney disease (ESKD) decreased to less than 10% in developed countries, but some patients still progress to ESKD and require renal replacement therapy. Crescent formation is considered as a poor prognostic factor in LN, however pathological features correlating with clinical response and long-term renal outcome has not been fully investigated.

Objectives: To determine clinical and pathological features predicting complete clinical response (CCR) after induction therapy in crescentic lupus nephritis (CLN) comparing with non-CLN.

Methods: Patients with biopsy proven class III or IV LN from 2008 to 2017 and who could be observed more than 5-years after induction therapy were selected. They were divided into two groups according to the presence of cellular crescentic lesions. Individual pathological lesions defined in modified NIH activity and chronicity indices were evaluated. CCR was defined as urinary protein-to-creatinine ratio (UPCR) less than 0.7g/day after 12 months of treatment, according to the 2019 EULAR/ERA-EDTA recommendations for LN. Cumulative CCR rates for 5-years were compared between the two groups, and independent factors associated with CCR were investigated.

Results: Seventy-three patients (CLN, 30 patients and non-CLN, 43 patients) were included in the analysis. There was no significant difference in age (42.8 ± 2.6 vs 44.4 ± 2.1 years, p=0.63), disease duration (10.9 ± 1.9 vs 11.4 ± 1.7 years, p=0.85), eGFR (70.7 ± 4.9 vs 66.0 ± 4.1 ml/min/1.73m^2, p=0.47), and UPCR (2.3 ± 0.5 vs 2.5 ± 0.4 g/gCr, p=0.72) between the CLN and non-CL groups. Cumulative CCR rates for 5-years were not different between CLN and non-CLN groups (83% vs 84%, p=0.96). In the non-CLN group, patients who achieved CCR had lower glomerular sclerosis (0.93 ± 0.16 vs 1.75 ± 0.27, p=0.01) and interstitial fibrosis score (0.77 ± 0.12 vs 1.25 ± 0.20, p=0.049) than those who did not achieve CCR. In the CLN group, patients who achieved CCR had lower interstitial fibrosis (0.94 ± 0.14 vs 1.67 ± 0.17, p<0.01) and tubular atrophy score (0.78 ± 0.15 vs 1.58 ± 0.19, p<0.01) than those who achieved CCR, while cellular or fibrotic crescentic score did not differ between them (2.33 ± 0.23 vs 2.50 ± 0.23, p=0.65). Multivariable analysis revealed that interstitial fibrosis was negatively associated with CCR in both CLN and non-CLN groups (odds ratio [OR] 0.11, p<0.01; OR 0.33, p=0.04, respectively). We next divided CLN patients into two groups according to the interstitial fibrosis less than 25% or not, and found significantly higher cumulative CCR rate in patients with interstitial fibrosis less than 25% (p<0.01).

Conclusion: Crescent formation in the kidney pathology was not associated with cumulative CCR rates in patients with class III or IV LN, while interstitial lesion was shared by both CLN and non-CLN as a significant prognostic factor for CCR after induction therapy.

Background: Anti-phospholipid antibodies (APL) are associated with thrombotic events or pregnancy complications leading to the so-called anti-phospholipid syndrome (APS) according to the classification criteria last updated in Sydney in 2006. APL can be found in asymptomatic patients.
Objectives: We observed the clinical, biological characteristics and association with other diseases of asymptomatic APL carriers group, and we compared them with an APS patients group.
Methods: In this French multicentric retrospective cohort study we analyzed the data of 507 patients with persistent positive APL measured between 2012 and 2019. Clinical and laboratory data were collected retrospectively. Data are expressed as numbers with frequencies and medians with interquartile ranges (IQR). Qualitative and quantitative variables were compared using Fisher and Kruskal-Wallis tests. Cumulative incidence curves of relapse event were generated using Kaplan-Meier. We used Cox model to obtain Hazard Ratio (HR). Proportional hazard assumption was checked using Schoenfeld residuals. Two-sided testing was used, with p ≤0.05 considered statistically significant.
Results: We observed a majority of female patients of a younger age in the APS group when compared to the APL carriers group. Cardiovascular risk factors were similar in both groups. Systemic lupus erythematosus was more frequently associated with the APS group, but interestingly rheumatoid arthritis, ankylosing spondylarthritis and chronic kidney disease were more frequently associated with asymptomatic APL carriers. At biological level, anti-cardiolipin IgG and beta-2-glycoprotein 1 IgG positivity rates were higher in APS group than in APL carriers group, but not for lupus anticoagulant positivity. Triple-positive APL were more frequent in APS group as expected, but we found up to 13.9% of triple-positive APL in APL carriers group. We also observed a higher prevalence of ANA, anti-dsDNA, anti-SSA/SSB in the APS group. At prognostic level patients from APL carriers group had a lower mortality (2.9 % vs 9.1%, p=0.006) but the observation period for this group was slightly shorter. No thrombotic event was observed in this group during the follow-up period, while 38.8% of APS patients had a relapse (thrombotic or obstetrical event during follow-up). In our subgroup analysis comparing primary and secondary APL carriers, we observed less women than men, an older age and a higher prevalence of cancer in primary APL carriers group. Interestingly, we observed a higher rate of atypical APL in primary APL carriers subgroup, with a trend toward a significant intergroup difference (31.1% vs 21.2%, p=0.075). There was no difference in mortality among groups.
Conclusion: APL carriers group was associated with the presence of autoimmune disease, infection and cancer. We did not observe any thrombotic events in the APL carriers group during the evaluation period. APS group had a higher mortality as expected. Interestingly, we observed a higher rate of atypical APL in primary APL carriers subgroup, with a trend toward a significant intergroup difference (31.1% vs 20.2%, p=0.075). We did not find a difference in mortality between primary and secondary APL carriers subgroups.

CONCENTRATIONS OF SERUM ADVANCED GLYCATION END PRODUCTS (AGES) CARBOXYETHYLLYSINE CORRELATE WITH INDICES OF ACTIVITY AND SPECIFIC MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Biomarkers, Systemic lupus erythematosus

I. Carrión Barberà[1], L. Triginer[2], A. Ribes[2], C. Pérez[1], L. Polino[1], E. Beltrán[1], A. Pros[1], J. Monfort[1], T. C. Salman Monte[1], L. Tío[2]. [1]*Hospital del Mar, Rheumatology, Barcelona, Spain*; [2]*Institut Mar d'Investigacions Mèdiques, Investigación celular en inflamación y cartílago, Barcelona, Spain*

Background: Studies postulate that advanced glycation end products (AGEs) could have a relevant role as inducers in the chronic inflammatory pathway present in various diseases, including systemic lupus erythematosus (SLE), and that AGEs concentration could be related to disease parameters such us activity or accumulated damage. To date, these studies show conflicting results.
Objectives: To estimate correlations between the concentrations of the blood AGE carboxyethyllysine (CEL) and disease-related parameters in a population of SLE patients.
Methods: Serum CEL concentrations were determined using a specific AGEs competitive ELISA Kit in accordance with the manufacturer's instructions in 113 SLE patients. We correlated demographic and clinical data with the results, and adjusted for age and smoking status as possible confounding factors, based on previous analysis (CEL AGEs decreased significantly with age and presence of smoking habits). The indices were analyzed both as quantitative and categorized variables according to previously established categories in the literature or to medians/tertiles depending on the distribution of the variable in our sample. CEL concentrations were classified into tertiles.
Results: Table 1 shows the distribution and correlations of our cohort characteristics according to CEL tertiles. Disease duration was inversely statistically correlated with CEL concentrations, as well as haematological alterations while alopecia was directly correlated. CEL values were statistically correlated with several markers of SLE activity: SLE disease activity index (SLEDAI), erythrocyte sedimentation rate, serum IL-6, and the count of swollen joints at the moment of the blood extraction (both in the Disease Activity Score 28 and 68). No associations were found with autoantibodies, other disease questionnaires, or different blood AGEs and AGEs receptor.
Conclusion: The correlation of CEL AGEs values with different disease activity markers in SLE could indicate their potential use as a biomarker of activity in this disease and an associated specific phenotype with less haematological manifestations and more alopecia.

NOT ALL SJÖGREN IS DRY – PRESERVED GLANDULAR FUNCTION IN A SUBGROUP OF PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome, Descriptive studies

A. Lackner[1], S. Zenz[1], J. Hermann[1], J. Thiel[1], M. Stradner[1]. [1]*Medical University Graz, Deparment of Rheumatology & Immunology, Graz, Austria*

Background: Lymphocytic infiltration of the salivary and lachrymal glands is a hallmark of primary Sjögren's Syndrome (PSS). Chronic inflammation leads to progressive destruction of the glands resulting in dryness of the eyes and mouth termed sicca. The course and pace of sicca development in PSS is elusive.

Objectives: To explore the effect of symptom duration on sicca and disease activity.

Methods: Data of patients from the PSS registry of the Medical University of Graz fulfilling the 2016 ACR/EULAR classification criteria for PSS were analysed. We analysed disease duration and total duration of sicca symptoms, Schirmer's test, unstimulated salivary flow test (USF), stimulated salivary flow test (SSF) and ESSDAI (EULAR Sjögren's Syndrome disease activity index), Evaluators Global Assessment (EGA), and focus score of the initial lip salivary gland biopsy. In addition, salivary gland ultrasound (SGUS) was performed using the De Vita scoring system. Free light chains (FLC) κ and λ, IgG, rheumatoid factor (RF) IgA were determined. The patient's perspective was analysed by ESSPRI and PSS-QoL.

Results: Data from 159 PSS patients were analysed, of whom 92.6% (n=148) were female. The mean age was 59.3±12.2 years (± standard deviation), with a mean disease duration of 5.5±5.4 years and a mean sicca duration of 11.6±7.4 years. Interestingly, results of USF, SSF, and Schirmer's Test did not decrease with duration of disease or sicca. The lack of correlation was probably caused by a subset of patients in whom glandular function remained stable 10 to 33 years after the onset of sicca. We defined this subgroup of patients by an SSF >0.5ml/min and with a symptom duration >10 years (SFSD10). 19.5% (n=31) of our PSS patient were categorised into this group. SFSD10 showed a significantly higher Schirmers test (median 0 (0-35] vs 3[3-35], p<0.01), lower ESSPRI-dryness (7 [1-10] vs. 5[1-10], p<0.05), PSS-QoL dryness (11[2-22] vs. 8 [3-15], p<0.01), lower IgG (15.5 [7.4-38.1] vs. 11.2 [6.5-30.5], p<0.05) and FLC-K (25 [3.9-134] vs. 20.2 [10.3-63.6], p<0.05) compared to non-SFSD10-group. SGUS De Vita score was significantly lower in the SFSD10 subgroup (median 1 [0-2] vs. 2 [1-3], p=0.045). We found no difference in ESSDAI, focus score, antibody status, pain, fatigue or HRQL between the two groups.

Conclusion: Our results indicate the presence of a subgroup of PSS patients with preserved glandular function despite long-standing disease.

Background: Patients with Systemic lupus erythematosus (SLE) have a well-known increased risk of major comorbidities, but they are also very heterogeneous in term of prevalence of comorbid conditions. The relationship of the comorbidities with the outcomes and the severity of index disease is less known.
Objectives: Evaluate the interactions between comorbid conditions, on a large multicenter SLE cohort from RELESSER register, and its impact in severity and outcomes.
Methods: Data about 14 cumulative comorbidities, as previously defined [1], where derived from patients with SLE (ACR-97 criteria) included in the retrospective phase of RELESSER. Severity Katz Index (SKI) and SLICC/ACR Damage Index (SDI) were calculated. An unsupervised cluster analysis using K-means method was implemented to define clusters. ANOVA and Tukey tests were used to compare continuous numerical variables; Kruskal-Wallis test to discrete variables and the Chi-square test (or Fisher's exact test) to categorical ones.
Results: A total of 3658 SLE patients (ACR-97 criteria) were included. Median SKI: 2 (interquartile range (IQR):1-3); median SDI:1(IQR:0-2). Demographic data are shown in Table 1. The comorbidities considered and their prevalence were: Thyroiditis (8.3%), peptic ulcer (3.8%), severe hepatopathy (1.0%), obstructive pulmonary disease (2.7%), Diabetes (5.0%), cardiovascular event (CVE) (11.0%), cardiac arrhythmia (4.2%), pulmonary embolism (3.4%), dementia (0.7%), malignancy (5.9%); serious infection (19.3%), end stage renal disease (2.8%), osteoporosis (7.3%) and depression (17.1%). Four cluster, with markedly different comorbidity profiles and outcomes were identified (table 3): one subgroup was clustered around depression (100% of the cases) (cluster 2), another cluster (cluster 3) with > 1 serious infection (100%) and cluster 4, with 100% of CVE. In cluster 1, no patient had any of the 3 defining comorbidities in the rest of the clusters. There were no statistically significant differences between clusters in death by SLE. The clusters are characterized in more detail in table 1, where a just summary of the main comorbidities included in the analysis is displayed.
Conclusion: Cluster analysis identifies well-differentiated subgroups of SLE patients as regard comorbidities and associated mortality and severity of the disease.

Background: CD163 is a glycosylated membrane protein expressed in monocytes and macrophages that phagocytize the hemoglobin/haptoglobin complex. As a result of proinflammatory stimuli, CD163 is shedded from the cell membrane and becomes soluble CD163. Therefore, it has been shown that serum (s) and urine (u) levels of soluble CD163 increase in acute or chronic inflammatory diseases. sCD163 and uCD163 are considered as potential biomarkers reflecting disease activity in patients with systemic lupus erythematosus (SLE).
Objectives: We aimed to investigate the association of serum and urine soluble CD163 levels and renal CD163 expression with disease activity in patients with lupus nephritis (LN).
Methods: Serum and urine levels of CD163 of 45 SLE patients (active renal 20, active non-renal 15, inactive 10) and 20 healthy volunteers were tested by ELISA. Control samples were taken from 12 active renal patients after six months of treatment and 30 renal biopsy specimens were examined for CD163 expression.
Results: Of 45 participants, 37 (82.2%) were female, with a median disease duration of 113 (1-436) months and a mean age of 38,9±13 (18-68) years. Both the frequency of uCD163 positivity and its levels were significantly higher in the active LN group compared to the inactive LN (p=0,007 and 0.02 respectively) and active non-renal SLE (p=0,001 and 0.023 respectively) groups (Table 1). sCD163 and uCD163 levels of 12 patients with active LN were significantly reduced after treatment (p=0,04 and p=0,006) (Figure 1). CD163+ macrophage expression in kidney biopsies of patients with active LN correlated with sCD163 (r= 0.597 and p=0.01) and uCD163 (r=0.507 and p=0.045) levels.
Conclusion: uCD163 is a promising biomarker that can differentiate active LN from inactive LN and active extrarenal SLE changing in line with treatment response. Correlation of both s and uCD163 with CD163+ macrophage expression in biopsies suggests that it may be used as an activity parameter in patients with lupus nephritis histopathologically. Further studies are awaited to confirm these results (This study was funded by Istanbul University with the project number TTU-2021-38289)

IN-HOSPITAL MORTALITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A STUDY FROM 2010-2020

Keywords: Systemic lupus erythematosus

A. Sharma[1], M. Kumar H[1], V. Sharma[1], G. Naidu[1], V. Dhir[1], S. Jain[1]. *[1]PGIMER, Chandigarh, India, Internal Medicine, Chandigarh, India*

Background: SLE mortality depends on epidemiological, sociodemographic and clinical factors. These vary amongst different regions.
Objectives: To determine the factors predicting disease-associated mortality compared with factors affecting Infection associated mortality in SLE patients.
Methods: This was a retrospective study involving SLE patients admitted from February 2010 to January 2020. Demographic, clinical details, laboratory parameters, treatment received, and complications during the stay in the hospital were entered in a proforma. The cause of death was classified as disease-related, infection-associated, or both.
Results: There were 1156 SLE admissions and 135 in-hospital mortalities. 24 patients were excluded because of inadequate parameters or wrong codes. Among the 111 patients, 102 (91.9%) were females. Mean age at the diagnosis and mean duration of hospitalisation was 29.7 years (27.6-31.7) and 11 days (8.7-13.3) respectively. More than three-fourths of the total patients had skin (76.6%), Musculoskeletal (74.8%), Renal (81.1%) or Hematological (73%) involvement. Nearly half of the patients had Respiratory (42.3%) or Neurological (49.5%) involvement. Mortality was primarily due to disease activity (43.2%; n = 48) followed by mixed (infection and disease activity) (36%; n = 40). Isolated infection-associated mortality was less than the active disease (19.8%; n=22). A subgroup analysis of the study participants based on mortality showed that cardiac (50%) and haematological (75%) involvement were more common among the participants with disease activity. There was no significant difference between the baseline investigations and treatment administered between the groups. The details are shown in Table 1. The most common infections were due to gram-negative bacteria. Among the study participants, 45 patients (48.6%) died within six months of diagnosis. Pulmonary involvement (51.9%; n=28/54) was more common in the first six months compared to death after six months (33.3%; n=19/57) (p-value=0.04). Cardiac involvement in the form of myocarditis was more common in the later part of the disease compared to the first six months (18.5% vs 40.4%; n=10/54 vs n= 23/40.4; p-value = 0.01).
Conclusion: Disease activity alone or in combination with infection contributes more to hospital mortality than infections alone. Though patients with disease activity-associated mortality have more haematological and cardiac involvement at presentation, there are no differences in various laboratory parameters, including complement levels among the patients in the three groups.

Table 1. Comparison of Organ involvement, Investigations, and treatment administered among mortality subgroups

	Total (n=111)	Disease Activity (n=48)	Infection (n=22)	Mixed (n=40)	p-value

ADALIMUMAB FOR IMMUNE RELATED INFERTILITY: EFFICACY AND SAFETY FROM PROSPECTIVE FRENCH MULTICENTER REGISTRY

Keywords: Pregnancy and reproduction, Autoantibodies, Anti-phospholipid syndrome

N. Abisror[1], M. Cheloufi[2], C. Mcavoy[1], A. Guedon[1], O. Fain[1], G. Kayem[2], A. Mekinian[1]. *[1]Sorbonne Université, AP-HP, Hôpital Saint Antoine, Service de médecine interne et Inflammation-Immunopathology-Biotherapy Department (DMU i3), Paris, France*; *[2]Hôpital Armand-Trousseau, APHP, Sorbonne Université, Service de Gynécologie Obstétrique, FHU PREMA, Paris, France*

Background: Recurrent miscarriage (RM) is a frequent condition affecting about 1–3 % of couples and is one of the most frustrating and difficult areas in reproductive medicine since the etiology is often unknown and evidence-based diagnosis and treatment strategies are scarce. Likewise, recurrent implantation failure (RIF) is considered after at least 3 unsuccessful transfers of good quality embryos, and remains unexplained in 45 % of infertile couples.
Objectives: The primary objective of this study was to describe a real-life prospective cohort of women with unexplained RM and/or RIF under adalimumab, to analyze the impact of the treatment on live birth rates and to evaluate its safety.
Methods: The French infertility multicenter FALCO registry is an ongoing registry from 2017 including patients with unexplained recurrent miscarriages and implantation failures from several university hospitals. Inclusion criteria were [1] at least 3 recurrent miscarriages before 12 weeks of gestation and/or at least 3 implantation failures of at least 2 good quality embryos transfers; [2] absence of any cause for recurrent miscarriages and implantation failures such as uterine, genetic, infectious, hormonal, thrombophilia and autoimmune diseases. The following data was collected:

- Clinical data including age, number of pregnancies, number of consecutive miscarriages, body mass index, tobacco and alcohol use, tea or coffee consumption during pregnancy, dietary habits, presence of endometriosis, adenomyosis and assessment of the uterine cavity by hysteroscopy or hysterosonography.
- Laboratory analysis of usual recurrent miscarriages etiological screening: parental karyotypes, ovarian reserve parameters (FSH (IU/L), LH (IU/L), Estradiol (pg/ml), AFC (Antral Follicular Count), AMH rate (ng/ml)), thyroid-stimulating hormone (TSH) levels (mUI/l) and biomarkers of immune origin (antinuclear antibodies, anti TPO/TG).

Results: Overall, between 2017 and December 2022, 2686 pregnancies from 395 patients were included with prospective follow-up. These women had history of recurrent implantation failure for 102 (26%), recurrent miscarriage for 275 (70%) and both for 18 (4%). The median gravidity was 4 [2-6]. Regarding the presence of immunity biomarkers, 263 had various autoantibodies (66,6%): 130 patients (33%) with antinuclear antibodies (>1/80e), 18 patients with antiphospholipid antibodies (5%), 44 patients with positive anti thyroid peroxidase antibodies (11%), 24 with positive anti-thyroglobulin antibodies (11%), 4 with anti-transglutaminase antibodies (11%). Most recent AMH count median was 1.73 [0.87, 3.24]. Among overall pregnancies, there were 1384 miscarriages (73,6%), 269 live births (14,3%), 89 abortions (4,7%), 24 medical terminations of pregnancies (1,3%), 55 pregnancies over 12 weeks of gestation (2,9%) and 58 extrauterine pregnancies (3,1%) Among 2686 pregnancies, 494 were treated and received immunomodulatory treatment. Among these pregnancies under therapies: steroids in 332 cases (12,4%), hydroxychloroquine in 185 cases (7%), intralipids in 102 cases (3,8%), and adalimumab in 69 cases (2,6%). Patients with pregnancy under adalimumab treatment had a significantly higher rate of cumulative live birth rate than those with untreated ones: OR: 3.52 [1.63 - 7.61]; p < 0.01 after adjustment of age, pregnancy, associated treatment (progesterone, aspirin, vitamin D, prednisone). Adverse events in Adalimumab treated pregnancies were reported in 7 women: herpes and zoster reactivation in 3 cases, cystitis and bronchitis in 4 cases, and no congenital malformation and no maternal deaths.
Conclusion: In this large prospective French cohort of women with unexplained immune origin RM and/or RIF, adalimumab has been effective to obtain a live birth pregnancy.

AB0589 CANCER PREVALENCE IN SYSTEMIC LUPUS ERYTHEMATOSUS: A PORTUGUESE COHORT STUDY WITH 15 YEARS OF FOLLOW-UP

Keywords: Systemic lupus erythematosus, Malignancy, Epidemiology

A. Saraiva[1], A. Maduro[1], B. Mendes[1], A. Carones Esteves[1], M. Luis[1], J. A. P. Da Silva[1,2], L. Inês[1,3]. *[1]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; *[2]Faculty of Medicine, University of Coimbra, Rheumatology, Coimbra, Portugal*; *[3]Universidade da Beira Interior - Faculdade de Ciências da Saúde, Rheumatology, Covilhã, Portugal*

Background: An increased risk of malignancy was reported in patients with Systemic Lupus Erythematosus (SLE) [1-3].
Objectives: To estimate the prevalence of cancer in a Portuguese cohort of patients with SLE over long term follow-up.
Methods: Patients followed up between 01/01/2006 and 31/10/2021 at the Centro Universitário de Coimbra Lupus Clinic were included. All patients fulfilling SLE classification criteria (EULAR/ACR 2019 or SLICC 2012 or ACR 1999) and assessed at least in two visits were included. Cancer cases were only considered if the diagnosis was established after SLE diagnosis. Patient and SLE clinical and treatment data were collect from the cohort electronic database. Disease activity was assessed with the SLE Disease Activity Score (SLE-DAS) and organ damage with the SLICC/ACR Damage Index (SDI). Associations with malignancy were tested using the *Chi-square test*, *Fisher exact test*, *Student's t-test,* or *Mann-Whitney U test*, as appropriate. Statistical significance with Bonferroni adjustment accounting for multiple comparisons was considered for p<0.005
Results: In total, 438 patients were included (mean age: 49.6±15.8 years-old; female: 85.4%; mean disease duration: 14.2±9.8 years). At the last study visit, 68.8% were in remission, and mean SLE-DAS was 1.9±2.5. The total cumulative prevalence for cancer was 7.1% (n=31), with 4 patients presenting metastatic disease at the time of cancer diagnosis. The most common malignancies were non-melanoma skin cancer (1.1%), colorectal (1.1%), hematologic (1.1%), lung (0.7%), and breast cancer (0.7%). Cancer patients were older (64.5±14.9 vs. 48.5 years, p<0.001) and had higher any-cause mortality (35.5% vs. 5.9%, p<0.001). There were no significant differences regarding disease activity at last visit, disease duration, organ damage or cumulative immunosuppressive therapy usage (38.7% vs 54%, p=0.099). Death as a direct result of malignancy occurred in 8 (72.7%) patients, accounting for 22.9% of death in our cohort.
Conclusion: This is the first study reporting cancer prevalence in a Portuguese SLE cohort. Our results are similar to those reported by Sultan et all (5.4%) (2), but substantially lower than those reported in a Finish cohort (22%) (3).

AB0590 CROSS-SECTIONAL ASSESSMENT OF THE QUALITY OF LIFE IN SLE PATIENTS: ROLE OF DISEASE ACTIVITY, CHRONIC DAMAGE, FIBROMYALGIA SYNDROME AND MOOD DISORDERS

Keywords: Quality of life, Patient reported outcomes, Systemic lupus erythematosus

F. Natalucci[1], F. Ceccarelli[1], C. Massari[1], C. Pirone[1], G. Olivieri[1], V. Orefice[1], L. Picciariello[1], C. Ciancarella[1], C. Garufi[1], S. Mancuso[1], S. Truglia[1], F. R. Spinelli[1], C. Alessandri[1], F. Conti[1]. *[1]Sapienza University of Rome, Lupus Clinic, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Sapienza Università di Roma, Rome, Italy*

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by a wide spectrum of manifestations, potentially involving every system. This heterogeneity may influence different aspects of patients' daily life, including physical ability, working and social life, thus impacting the quality of life (QoL). Among all the SLE-related manifestations, cutaneous involvement may lead to insecurity and isolation, negatively resulting in QoL.
Objectives: The aim of the present study was to analyse the QoL in a SLE cohort, determining the potential influence of disease activity, chronic damage, comorbidities, and mood disorders.
Methods: We enrolled consecutive SLE patients, diagnosed according to 2019 ACR/EULAR criteria. Clinical and laboratory data were collected, and disease activity and chronic damage were assessed by SLEDAI-2k and SDI. As controls, we enrolled patients affected by Discoid Lupus Erythematosus (DLE) and Undifferentiated Connective Tissue Disease (UCTD). The fibromyalgia diagnosis was made according to the 2016 ACR Classification Criteria. Quality of life was evaluated by using the Lupus Quality of Life questionnaire (LupusQoL); furthermore, each patient filled out the Hospital Anxiety and Depression Scale (HADS) questionnaire.
Results: We enrolled 237 SLE patients (M/F 18/219; median age 46 years [IQR 19.5], median disease duration 156 months [IQR 180]), 24 CLE patients (M/F 5/19; median age 61.5 years [IQR 29.5], median disease duration 92.1 months, [IQR 128.5]). and 25 UCTD (M/F 1/24; median age 40 years, [IQR 21.25]; median disease duration 66 months [QR 103.9]). In SLE patients the median SLEDAI-2k value was 0 (IQR 2) and the SDI was 0 (IQR 1). Fibromyalgia was diagnosed in 69 SLE patients (29.1%), 5 CLE (20.8%), and 7 UCTD (28%). The comparison among these three groups of patients revealed for SLE and CLE patients a significantly lower mean values in the LupusQoL domain related to Body Image (BI) (73.9±27.7 and 71.3±30.9, respectively) compared to UCTD patients (87.2±19.0) [p=0.01 and p=0.03, respectively]. Focusing on SLE patients, females showed significantly lower mean values compared to males for almost all domains: Pain (P, [p=0.02]), Intimate Relationship (IR; [p=0.001]), Burden to Others (BtO [p=0.029]), Emotional Health (EH; [p=0.012]), Body Image (BI; [p=0.033]) and Fatigue (F; [p=0.002]). As expected, fibromyalgia patients had lower values in all the domains of the LupusQoL when compared to patients without this condition (p<0.001 for all comparisons, except for BI p=0.006). Moreover, as reported in Figure 1, SDI values negatively correlated with all the LupusQoL domains (Figure 1A); conversely, we found a positive correlation between SDI and both HADS domains (Anxiety [r=0.16; p=0.015]; Depression [r=0.21; p=0.0009]). As expected, a strong negative correlation was identified between LupusQoL score in each domain and both Anxiety [(BH r=-0,58, P p=-0.53, Planning p=-0.52, IR p=-0.62, EH= -0.75, BI= -0.52, F=-0.64, BtO r=-0.62); p < 0.0001 for all the analysis] and Depression [(BH r=-0,61, P p=-0.58, Planning p=-0.63, IR p=-0.61, EH= -0.55, BI= -0.60, F=-0.69, BtO r=-0.55]; p < 0.0001 for all the analysis).
Conclusion: The presented results confirmed the negative impact of SLE on the quality of life. Among the analyzed variables, female sex and fibromyalgia deeply influenced the outcome. The chronic damage showed to be one of the main determinants of impairment of the QoL in SLE patients and of the development of Anxiety and Depression, measured through the HADS questionnaire. Lastly, Anxiety and Depression may contribute to the worst QoL in SLE, underlying the need for comprehensive evaluation and management of the SLE-associated comorbidities.

Background: Vaccinations comprise a part of the antenatal care of pregnant women, including patients with systemic lupus erythematosus (SLE) who are at increased risk of adverse pregnancy outcomes (APOs). While COVID-19 vaccination has been shown to be safe in patients with SLE, data on vaccine-associated adverse events (AEs) during the antenatal and lactation period are scarce or lacking.
Objectives: To investigate the association between COVID-19 vaccination and AEs in pregnant SLE patients.
Methods: A total of 9201 complete responses were extracted on June 21st, 2022 from the COVID-19 Vaccination in Autoimmune Diseases (COVAD) 2 database, a global e-survey involving 157 collaborators from 106 countries. Among respondents, 6787 (73.8%) were women. We identified 70 (1.1%) women who were exposed to at least one COVID-19 vaccine dose during pregnancy, among those 11 with SLE. Delayed onset (>7 days) vaccine-related AEs were extracted and triangulated with disease activity, treatment changes due to flare after vaccination, and COVID-19 infections in vaccinated pregnant women with SLE. Additionally, information on health-related quality of life and physical function was recorded using PROMIS at the time of survey completion.
Results: The age of patients ranged from 28 to 39 years; 5/11 women were of Asian origin. None of these patients reported major vaccine AEs, including four patients with self-reported active SLE prior to the vaccination. None of them reported any change in the status of their autoimmune disease, and no hospitalisation or special treatment was recorded. Six women experienced minor vaccine AEs; two of them had active disease prior to vaccination. Four patients reported COVID-19 infection; two of them while they were pregnant and post-vaccination and two prior to pregnancy and vaccination. All four patients experienced symptoms of their disease, but no overt SLE flare was reported. At the time of survey completion, all patients reported their general health as being good to excellent in all aspects evaluated. Importantly, no APOs were reported. None of the patients reported thrombotic events post-vaccination, which provides some reassurance regarding COVID-19 vaccination in a patient population with a high risk for cardiovascular comorbidity and thrombosis, especially in the presence of antiphospholipid antibodies or in patients diagnosed with the antiphospholipid syndrome, a considerable portion within SLE populations. Moreover, it was reassuring to note an absence of association between experienced vaccine AEs and active disease prior to vaccination. Although minor AEs were common, they did not impair daily functioning, and the symptoms resolved in all patients after a median of 3 (IQR: 2.5–5.0) days.
Conclusion: Our report adds relevant evidence concerning the sensitive issue of COVID-19 vaccine AEs and flares in SLE patients during the antenatal and lactation period. Despite the small sample size, the findings provide some reassurance and can contribute to informed decisions regarding vaccination in patients with SLE and high-risk pregnancies due to their background autoimmune disease. Based on the present data, the risk/benefit ration of COVID-19 vaccination appears favourable, with vaccines both providing passive immunisation to the fetus and active immunisation to the mother with no signals of exacerbation of the mother's autoimmune disease.

COMPARATIVE CARDIOVASCULAR RISK IN PATIENTS WITH OLDER-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: A NATIONWIDE RETROSPECTIVE COHORT STUDY IN KOREA

Keywords: Cardiovascular disease, Systemic lupus erythematosus

J. Han[1], S. K. Cho[1], Y. Jeon[2], G. Kang[2], H. Kim[1], S. Y. Jung[3], E. J. Jang[4], Y. K. Sung[1]. [1]*Hanyang University Hospital for Rheumatic Diseases and Hanyang University Institute for Rheumatology, Rheumatology, Seoul, Korea, Rep. of (South Korea)*; [2]*Kyungpook National University, Department of statistics, Daegu, Korea, Rep. of (South Korea)*; [3]*Chung-Ang University, College of Pharmacy, Seoul, Korea, Rep. of (South Korea)*; [4]*Andong National University, Department of Information Statistics, Andong, Korea, Rep. of (South Korea)*

Background: Patients with systemic lupus erythematosus (SLE) have increased mortality related to cardiovascular disease (CVD) and the age is one of important risk factors for the development of CVDs. However, the comparative risk of CVDs in patients with older onset SLE has not been well studied.
Objectives: This study aims to compare the CVD risk in patients with SLE occurred after the age of 40 compared to those with DM.
Methods: Incident SLE patients aged over 40 years and age-sex matched (1:4:4) controls with DM or general population were identified from the nationwide claims database in Korea between 2008 and 2018. We defined CVD risk as ischemic heart disease, stroke, and cardiac death. The incidence rates (IR) and incidence rate ratio (IRR), and adjusted hazard ratio (HR) of CVDs were calculated using generalized estimating equation models.
Results: We identified 4,272 SLE, 17,003 DM, and 17,088 general population patients aged over 40 years. Their mean age was 53.1 (±9.7) and 81.7% of them were female. The IR per 1,000 person-years (PYs) of CVDs for SLE, DM, and general population were 16.8, 11.7, and 5.7, respectively. Compared to general population, patients with SLE (IRR 3.27, 95% CI 2.78-3.85) and DM (IRR 2.77, 95% CI 2.02-2.56) showed higher CVD risk compared to general population. Increased risk of CVDs in SLE patients was highest in their forties (IRR 4.13, 95% CI 3.06, 5.59). After adjusting confounders, the CVD risk of SLE (HR 1.99, 95% CI 1.66-2.38) was higher than DM (HR 1.39, 95% CI 1.22-1.58) patients.
Conclusion: Older onset SLE patients had increased CVD risk compared to general population. Even after adjustment for confounders, SLE patients showed higher CVD risk than DM patients in Korea.

SLE, Sjön's and APS - clinical aspects (other than treatment)

AB0593 **RISK FACTORS FOR HOSPITALIZATION IN SYSTEMIC ERYTHEMATOSUS LUPUS (SLE). WHAT IS AT STAKE IN THE FIRST YEAR OF THE DISEASE?**

Keywords: Prognostic factors, Systemic lupus erythematosus

D. Schilirò[1], F. Trentin[1], V. Signorini[1], E. Elefante[1], C. Stagnaro[1], L. Carli[1], F. Ferro[1], D. Zucchi[1,2], M. Maffi[1], L. Gualtieri[1], A. Valevich[1], G. Cascarano[1], C. Tani[1], M. Mosca[1]. [1]*University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*; [2]*University of Siena, Department of Medical Biotechnologies, Siena, Italy*

Background: Several risk factors for hospitalization have been identified among clinical, demographic, and laboratory features in SLE patients. However, less is known about how and how much disease expression in the first year since diagnosis may impact the outcome or predict disease course in the following years.
Objectives: To define early risk factors for hospitalization in SLE.
Methods: Observational, retrospective analysis in a monocentric cohort of SLE patients, regularly followed at our Unit. Demographics, clinical manifestations, hospitalizations over time, SLE flares and treatments at disease onset and during follow-up were collected. In particular, number and type of immunosuppressants (IS), daily and cumulative doses of glucocorticoids (GCs) at o 1 and 5 years of follow-up. Disease activity was evaluated by SLEDAI-2K score at baseline, at 1 and 5 years of follow-up while organ damage was assessed by the SLICC/ACR damage index (SDI). Disease state as modified Lupus Low Disease Activity status (LLDAS) without PGA, was evaluated at one year from SLE diagnosis. T-test and chi square test were used to estimate association between at least one hospitalization within the fifth years of disease and sex, age, and clinical manifestations at disease onset.
Results: Among 422 Caucasian SLE patients regularly followed in our centre, (87% female, mean age 47±13.2 years, follow-up duration 10.5±9.3 years) 263 (62%) had at least one hospitalization due to SLE disease activity or disease related complications within five years from disease onset. Similar hospitalization incidence rate at five years and at the last visit were found (0.19 and 0.21 patient-years respectively). Characteristics of hospitalized patients at 5 years with respect to non-hospitalized ones are reported in Table 1. Disease onset with nephritis or constitutional symptoms (fever, lymphadenopathies) and not being in LLDAs at one year were significantly associated to hospitalization within five years (p values <0.01). Moreover, number of IS, cumulative GC dose at 1 and 5 years and SDI at 5 years of follow-up resulted significantly associated with hospitalizations (p values<0.01). No correlations were found between age at disease onset, sex, diagnostic delay, other manifestations at disease onset, SDI at 1 year and the risk of hospitalization over time.
Conclusion: Hospitalizations for disease activity and its complications are frequent in SLE patients, not only in the first years of the disease. A more aggressive SLE phenotype and treatments at onset are associated with higher risk for future hospitalizations; on the other hand, being on LLDAS within one year from disease onset seems to be protective. Therefore, our data suggest that disease expression within the first year from diagnosis could be crucial to predict SLE course over time and to stratify patients at lower or higher risk for severe disease.

Table 1. Cohort characteristics

	Overall	Hospitalized patients at 5 years	Non hospitalized patients	P value
F Sex (%)	87,4	87.0	89.1	0.5
Age at onset (mean, sd)	29.1±11.8	28.7±12.2	29.9±11.2	0.3

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterized by a wide spectrum of clinical manifestations and the presence of various antibodies against antigens of the nucleus, cytoplasm, or membrane cell. Anti-La antibodies are present in 7-45% of SLE patients, usually accompanied by anti-Ro antibodies. Double anti-La and anti-Ro positivity is associated with a milder disease profile, with a lower risk of seizures and nephritis, as well as a higher frequency of arthritis. Studies analyzing the prevalence and clinical characteristics of patients with isolated anti-La+ in the absence of anti-Ro are lacking.
Objectives: To describe the demographic, clinical and serological characteristics and severity indices of anti-Ro-/La+ patients in a retrospective cohort of SLE patients and compare them with the rest of the patients.
Methods: Retrospective cross-sectional study, in which all patients with SLE (> 4 ACR-1997 criteria) registered in the RELESSER registry were included. Sociodemographic, clinical, serological and comorbidities variables were collected, as well as indicators of disease activity and severity. Patients were divided into 4 groups according to the presence of anti-Ro and anti-La: anti-Ro-/La+ group, anti-Ro+/La- group, anti-Ro+/La+ group and anti-Ro-/La- group. The anti-Ro-/La+ group was compared with the other groups.
Results: Out of 3619 SLE patients, 44 (1.2%) had anti-Ro-/La+. The mean (± SD) age was 33.77 (±16.52) years, 88.6% were female, 90.5% were Caucasian and the mean (± SD) disease duration was 135.36 (±88.46) months. The most frequent comorbidities were: smoking 48.8 %, dyslipidaemia 47.7 % and hypertension 31.8 %. 22.13% of patients had anti-Ro+/La-, 18.98% anti-La+/Ro+ and 64.02% anti-La-/Ro-. Photosensitivity and oral ulcers were observed more frequently in anti-Ro-/La+ patients compared to anti-Ro-/La- patients (60.2% vs 52.6% p=0.0471 and 59.1% vs 40.7% p=0.0194 respectively). Arthritis occurred in 77.3% of anti-Ro-/La+ patients, without significant differences with the other groups: 75.3% in anti-Ro+/La- (p=0.8588), 73.9% in anti-Ro+/La+ (p=0.7240) and 75.1% in anti-Ro+/La- (p=0.810). Twenty-five per cent of patients with isolated anti-La had lupus nephritis, with no significant differences compared to the other groups (29.5% in anti-Ro+/La- p=0.6116, 22.9% in Ro+/La+ p=0.7144 and 28.6% in Ro-/La- p=0.7364). 11.4% of anti-Ro-/La+ patients had seizures

vs 4.4% anti-Ro+/La-(p=0.0510), vs 3.3% in anti-Ro+/La+ (p=0.0218) and vs 5.2 % in anti-Ro-/La- (p=0.799). Cognitive impairment was observed in 7% of anti-Ro-/La+ patients vs 2.8% in anti-Ro+/La- (p=0.1315) vs 1.5% in anti-Ro+/la+ (p=0.0370) and vs 3.1% in anti-Ro-/La- (p=0.1492). No differences were observed in other SLE-associated clinical variables, immunological profile, degree of SLE activity or Katz severity index.

Conclusion: The prevalence of anti-La in the absence of anti-Ro in our SLE cohort was 1.2%. This group of patients presented a higher frequency of clinical manifestations such as photosensitivity and oral aphthous ulcers compared to patients with neither anti-Ro nor anti-La. In contrast with previous studies the isolated presence of anti-La is associated with greater neurological involvement in the form of seizures or cognitive impairment compared to the association of anti-Ro and anti-La or the isolated presence of anti-Ro.

AB0595 TESTING A NEW FATIGUE CHECKLIST IN SLE PATIENTS FOR EVERYDAY CLINICAL PRACTICE - AN INTERIM ANALYSIS

Keywords: Patient reported outcomes, Systemic lupus erythematosus, Quality of life

C. Duesing[1,2], J. Richter[1,2], C. Elling-Audersch[3], D. Fell[3], M. Schmid-Holl[3], O. Sander[1,2], J. Mucke[1,2], I. Haase[1,2], R. Fischer-Betz[1,2], H. Acar[1,2], T. Filla[1,2], M. Schneider[1,2], G. Chehab[1,2]. *[1]Düsseldorf, Clinic for Rheumatology, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany*; *[2]Düsseldorf, Hiller Research Center, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany*; *[3]Bonn, German-League Against Arthritis/Deutsche Rheuma-Liga Bundesverband e.V., Bonn, Germany*

Background: Fatigue is a difficult subject for both physicians and patients. It is barely addressed during consultations and can therefore burden patient-physician-relations. To improve communication regarding fatigue, we developed a checklist that includes suggestions for evaluating possible causes for fatigue. In this analysis, we describe our study population and report first results 3 and 6 months after using the checklist.

Objectives: The aims of our study are to validate the use of our newly developed fatigue checklist and to demonstrate that addressing fatigue in daily clinical practice and offering possible interventions can improve fatigue.

Methods: We recruited n=110 SLE patients with fatigue from our university hospital-based lupus reference centre in Duesseldorf. Fatigue was measured using the FSS (Fatigue Severity Scale). Our checklist included signs of depression and anxiety using the PHQ-4 (Patient Health Questionnaire), BMI (body mass index), physical activity, anemia, hypothyroidism and vitamin D deficiency. For each applicable cause, we listed possible interventions for free selection by the treating physician, such as replacement therapy (vitamin D, vitamin B12, iron, folic acid, erythropoietin), physical activity programs and psychosomatic consultations that were discussed with the patients. We re-evaluated our patients after 3 (T1) and 6 months (T2).

Results: Baseline characteristics of patients are summarized in Table 1.

Table 1. BMI=body mass index, TSH=thyroidea stimulating hormone, PHQ4=patient health questionnaire (cut-off >3 points), HAQ=health assessment questionnaire, IMET= Index for measuring restrictions on social participation (higher scores point towards more restrictions on social participation), FSS=fatigue severity scale (≥4 points equal severe fatigue)

N = 110

	n (%)	Mean (SD)
Age (years)		49.0 (12.34)
Female sex	99.0 (90.0)	
BMI (kg/m^2)		25.9 (5.55)
Disease duration (years)		19.1 (10.05)
TSH (µIU/ml)		1.5 (1.05)
25-OH-Vitamin D (ng/ml)		39.5 (15.35)
Haemoglobin (g/dl)		13.0 (1.64)
Sports activities		
>4h/week	6.0 (5.5)	
2-4h/week	18.0 (16.4)	
1-2h/week	16.0 (14.5)	
<1h/week	28.0 (25.5)	
No sport	42.0 (38.2)	
Depression (PHQ4 score)		2.3 (1.63)
Anxiety (PHQ4 score)		2.0 (1.71)
Functional status (HAQ score)		0.8 (0.49)
Participation (IMET score)		2.8 (2.31)
Fatigue (FSS score)		5.3 (1.35)

After 3 and 6 months, we re-evaluated 83 patients and saw a significant reduction in fatigue measured by the FSS score (T1: mean difference estimate 0.367 and p-value <0.001; T2: mean difference estimate 0.305; p-value <0.005).

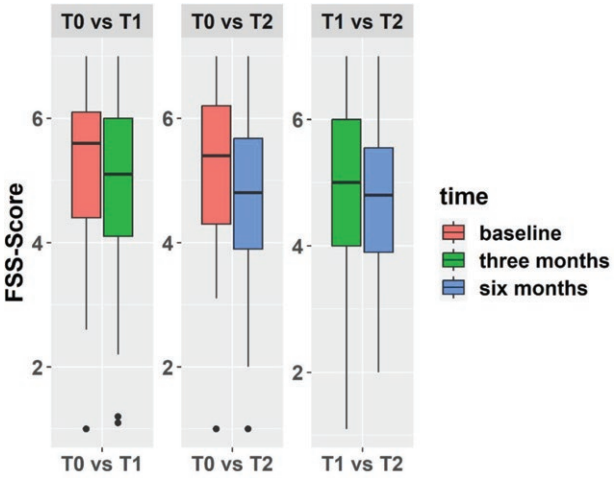

Figure 1. Comparing FSS-Scores from T0, T1 and T2

Conclusion: The preliminary analysis of our study shows for the first time that incorporation of a checklist procedure into the management of patients with fatigue may improve short-term outcome after 3 and 6 months of observation. The improvement of symptoms documented in our study occurred even though the suggested exercise program and psychosomatic counseling sessions were not available for use during the current observation period because of the COVID-19 pandemic. At present, the mechanisms behind the observed effect remain unclear. Our ongoing analysis will clarify whether an additional effect on fatigue will occur after all suggested interventions resulting from the use of the checklist have been executed. Finally, it will demonstrate whether the incorporation of our checklist into routine clinical practice is capable to reduce fatigue over a prolonged time period.

AB0596 APPLICABILITY OF THE ACR-1997, SLICC-2012, AND EULAR/ACR2019 CLASSIFICATION CRITERIA IN ADULT-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS AND CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Diagnostic tests, Systemic lupus erythematosus

X. MA[1], Y. Yin[1], X. Zhang[2], H. Jiang[1], Y. Shan[3]. *[1]The First Hospital of China Medical University, Department of Pediatrics, Shen Yang, China*; *[2]Department of Pediatrics, Benxi Central Hospital, Benxi, Department of Pediatrics, Ben Xi, China*; *[3]University of Occupational and Environmental Health, Japan, The First Depatment of Internal Medicine, Kitakyushu, Japan*

Background: Over the past few decades, several classification criteria have been proposed for systemic lupus erythematosus (SLE), including the American College of Rheumatology (ACR)-1997, Systemic Lupus International Collaborating Clinics (SLICC)-2012, and European Alliance of Associations for Rheumatology (EULAR)/ACR-2019. The sensitivity and specificity of these classification criteria are inconsistent for the various races of SLE patients [1-3]. Patients with SLE who are younger than 18 year old are called childhood-onset SLE (c-SLE), which differ from adult-onset SLE (a-SLE) in several ways. The applicability of classification criteria for c-SLE of different races were also inconsistent [4-6]. Now, there is a lack of data to verify the applicability of classification criteria in a-SLE or c-SLE in northern China.

Objectives: This study is to verify the applicability of classification criteria in a-SLE and c-SLE in northern China, and explore the most applicable disease evaluation standards.

Methods: 81 c-SLE vs 59 pediatric controls, 80 a-SLE vs 76 adult controls were included in the study. All the participants are Chinese descent living in northern China. The control groups were diagnosed with other rheumatic diseases. The diagnosis of these patients was determined by two or more rheumatologists. We reviewed the clinical manifestations and laboratory tests of these patients with respect to three classification criteria.

Results: The sensitivity of EULAR/ACR-2019 and SLICC-2012 was higher than that of ACR-1997 in a-SLE group, but there was no significant difference in the specificity, with AUCs of EULAR/ACR-2019 (0.863), SLICC-2012 (0.895), and ACR-1997 (0.865). In c-SLE group, the sensitivity of SLICC-2012 was higher than that of ACR-1997, and the specificity was not significantly different, with AUCs of EULAR/ACR-2019 (0.94), SLICC-2012 (0.945), and ACR-1997 (0.899). Increasing the threshold of EULAR/ACR-2019 from 10 to 11 can improve the specificity and accuracy for a-SLE, while from 10 to 14 can improve those for c-SLE.
Conclusion: EULAR/ACR-2019 and SLICC-2012 are the most appropriate classification criteria for a-SLE, and SLICC-2012 is more applicable for c-SLE from northern China. Adjusting the threshold of EULAR/ACR-2019 can improve the specificity and accuracy for a-SLE and c-SLE.

AB0597

CLINICAL SIGNIFICANCE OF ANTI-RHEUMATOID ARTHRITIS 33 ANTIBODY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Autoantibodies, Diagnostic tests, Clinical trials

Y. Chen[1], W. Y. Lu[1,1,1,1], D. Liu[1,1,1,1,1,1,1,1,1,1,1]. [1]*Shenzhen People's Hospital, Department of Rheumatology and Immunology, Shenzhen, China*

Background: Evidence initially showed that anti-rheumatoid arthritis (RA) 33 antibodies were highly specific for the diagnosis of RA [1]. Later studies reported that anti-RA33 was present in various connective tissue diseases (CTDs) [2]. However, the clinical significance of anti-RA33 antibodies in CTDs is still obscure.
Objectives: To explore the clinical significance and diagnostic value of anti-RA33 antibodies in CTDs, especially systemic lupus erythematosus (SLE).
Methods: A total of 565 patients with positive anti-nuclear antibodies who had been tested for anti-RA33 antibodies were included in the study. These patients were classified into RA33-positive and RA33-negative groups according to the anti-RA33 results. The association between anti-RA33 and the clinical features of CTDs was examined. Additionally, receiver operating characteristic (ROC) analysis was performed to explore the diagnostic value of anti-RA33 antibodies in SLE and SLE-related organ involvement.
Results: SLE was the most common disease in CTD patients positive for anti-RA33 (48.8%). Compared with the RA33-negative group, the proportion of patients with SLE was significantly higher in the RA33-positive group (64.3% vs. 47.1%, p=0.0164). Compared with those negative for anti-RA33, CTD patients positive for anti-RA33 had significantly higher percentages of SLE-associated antibodies (**Figure 1**). Higher proportions of SLE patients with a high disease activity (41.7% vs. 24.7%) as well as lower levels of serum complement components (50.0% vs. 27.7%) were observed in the RA33-positive group (Both p<0.05) (**Table 1**). Furthermore, CTD patients with positive anti-RA33 were more likely to suffer from mucocutaneous (46.4% vs. 33.2%, p=0.0361) and haematological involvement (51.8% vs. 35.6%, p=0.0200) as well as interstitial lung disease (25.0% vs. 11.8%, p=0.0108). ROC analysis revealed an area under the curve value of 0.634 (95% CI: 0.587 to 0.681) for anti-RA33 in the diagnosis of SLE, with a specificity and sensitivity of 92.9% and 13.5%, respectively.
Conclusion: This study reveals a significant association between anti-RA33 and the clinical features of CTDs, especially SLE, indicating a potential clinical significance of anti-RA33 in the management of SLE.

SYSTEMIC LUPUS ERYTHEMATOSUS WITH CEREBRAL HEMORRHAGE DUE TO AUTOIMMUNE ACQUIRED COAGULATION FXIII/13 FACTOR DEFICIENCY: A CASE STUDY AND LITERATURE REVIEW

Keywords: Comorbidities, Systemic lupus erythematosus

A. Aoki[1], H. Kobayashi[1]. [1]*Tokyo Medical University Hachioji Medical Care Center, Rheumatology, Hachioji, Japan*

Background: Autoimmune acquired coagulation FXIII/13 factor deficiency (AiF13D) is a rare bleeding disorder characterized by the formation of autoantibody to F13. The treatment of AiF13D requires immunosuppressive (IS) therapy in addition to hemostatic therapy. Japanese guidance recommends high-dose glucocorticoid (GC) as initial therapy while cyclophosphamide (CPA), rituximab (RIT), and ciclosporin (CYA) are administered in refractory cases. Ichinose reported that 16 of 93 (17%) AiF13D patients had autoimmune diseases (AIDs) such as systemic lupus erythematosus (SLE) [1]. The guidance recommends that IS therapy for patients with underlying AIDs should be selected based on treatment guidelines for AIDs; however, recommendations for the choice of IS drugs are unavailable.
Objectives: To report the case of our patient and to analyze the reported cases of SLE complicated AiF13D.
Methods: We searched PubMed, Google Scholar, and Ichushi Web for articles or abstracts written in English and Japanese using the following terms: [acquired FXIII/13 factor deficiency or inhibitors] and SLE.
Results: A 24-year-old woman from Southeast Asia presented to the emergency department with headache and nausea; a hematoma was noted in the right temporal lobe on head CT. Her PT, APTT, platelet count, and bleeding time were normal. She developed impaired consciousness and underwent an emergency craniotomy to remove the hematoma. During surgery, no abnormal blood vessels were noted in the brain, and the hematoma was removed. However, recurrent hemorrhages occurred on days 2 and 13 after hospitalization, and she underwent reoperation. On day 18, F13 activity was found to be less than 3%, and an F13 preparation (Fibrogamin P) was administered. A positive cross-mixing test with normal plasma was positive for the F13 inhibitor, and a diagnosis of AiF13D was made [2]. In addition, she was diagnosed with SLE based on positive antinuclear and anti-dsDNA antibodies (Ab), hypocomplementemia, and lymphopenia. PSL 50 mg (1mg/kg/day) was prescribed. Owing to the local infection after cranioplasty, no IS drugs were used. hydroxychloroquine (HCQ) and belimumab were added, while tapering PSL. During 1 year period, anti-dsDNA Ab decreased and F13 activity remained above 40% without administering Fibrogamin P (Figure 1). The reported 11 cases of SLE complicated AiF13D and this case are summarized in the Table 1. IS therapy included CPA, CPA, and RIT besides GC; belimumab was administered only in our case.
Conclusion: The prognosis of patients with AiF13D is poor. Even after weaning from acute hemorrhage, long-term IS therapy is often necessary and death by infection is common. Based on our experience, we suggest belimumab as a therapy option for SLE complicated AiF13D.

AB0599 CLINICAL AND SEROLOGICAL CHARACTERISTICS OF SERONEGATIVE PRIMARY SJÖGREN'S SYNDROME PATIENTS

Keywords: Sjögren syndrome

A. Mihai[1,2], N. Adriana Elena[3], C. Jurcut[3], B. Cristian Florin[4,5], D. Anghel[2,3], D. Opris-Belinski[6,7], R. Ionescu[7]. *[1]Carol Davila Central Military Emergency Hospital, Internal Medicine, Bucharest, Romania*; *[2]Titu Maiorescu University, Rheumatology, Faculty of General Medicine, Bucharest, Romania*; *[3]Carol Davila Central Military Emergency Hospital, Department of Internal Medicine, Bucharest, Romania*; *[4]Carol Davila Central Military Emergency Hospital, General Surgery, Bucharest, Romania*; *[5]Titu Maiorescu University, Medical-Surgical Specialties, Bucharest, Romania*; *[6]Sfanta Maria Clinical Hospital, Internal Medicine and Rheumatology Department, 011172, Romania*; *[7]Carol Davila University of Medicine and Pharmacy, Internal Medicine and Rheumatology Department, Bucharest, Romania*

Background: Sjögren's syndrome (SS) is accompanied by a number of autoantibodies as a result of B cell aberrant activation. The clinical manifestations, laboratory findings and evolution in seronegativity of a pSS patient changes compared to a seropositive pSS patient.
Objectives: This study compared the clinical and serological characteristics of seronegative and seropositive primary Sjögren syndrome (pSS) patients and the differences in terms of treatment recommended during the follow-up period.
Methods: We performed a retrospective study in a single center, with 131 patients (128 women and 3 men) diagnosed with pSS. Clinical examinations, complete blood count, inflammatory and immunological parameters were determined at the initial visit. The patients were divided into two groups through the presence or absence of pathology-specific antibodies.
Results: Nineteen of the 131 pSS patients (14.5%) were triple seronegative for ANA, anti-Ro, and anti-La autoantibodies. pSS patients with the specific antibodies absence performed accessory salivary gland biopsy and based on focus score they were diagnosed seronegative. No significant statistical differences were observed for age, sex distribution, disease activity scores and the administrated treatment, between the two groups. In terms of laboratory findings, only total proteins, RF and IgG were statistically lower in seronegative pSS patients ($p < 0.05$). While from glandular and extraglandular manifestations, singular xerostomia revealed a statistically significant between the two groups of pSS patients ($p < 0.001$). Cellular ratio, NLR was positively correlated with ESSDAI score and MLR, and negatively correlated with PLR, ESR, total proteins, IgG, C3 and C4, in seronegative pSS patients ($p < 0.05$).
Conclusion: The extraglandular manifestations and the administrated treatment, were similar for the two groups of pSS patients, while only the glandular manifestation, xerostomia, has a statistically significant difference. The hematological parameter, NLR, was statistically correlated with disease activity score and immunological markers in triple seronegative pSS patients.

AB0600 THE FOLLOW-UP OF PSS PATIENTS WITH PERIPHERAL NEUROLOGIC INVOLVEMENT IN A TERTIARY CENTER

Keywords: Sjögren syndrome

A. Mihai[1,2], C. Diana Maria[3], C. Jurcut[1], N. Adriana Elena[1], B. Cristian Florin[4,5], D. Opris-Belinski[6,7], R. Ionescu[7]. *[1]Carol Davila Central Military Emergency Hospital, Department of Internal Medicine, Bucharest, Romania*; *[2]Titu Maiorescu University, Department of Rheumatology, Faculty of General Medicine, Bucharest, Romania*; *[3]Carol Davila Central Military Emergency Hospital, Department of Neurology, Bucharest, Romania*; *[4]Carol Davila Central Military Emergency Hospital, Department of General Surgery, Bucharest, Romania*; *[5]Titu Maiorescu University, Department of Medical-Surgical Specialties, Bucharest, Romania*; *[6]Sfanta Maria Clinical Hospital, Internal Medicine and Rheumatology Department, Bucharest, Romania*; *[7]Carol Davila University of Medicine and Pharmacy, Internal Medicine and Rheumatology Department, Bucharest, Romania*

Background: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease mainly affecting exocrine glands. Extraglandular manifestations play a major role in the long-term prognosis of the disease, and neurological manifestations seem common in pSS. The early detection of haematological and immunological parameters might improve the disease evolution of patients.
Objectives: The study aimed to evaluate the predictive potential of clinical, haematological and immunological elements for the development of neurologic manifestations in pSS patients, followed for 12 months.
Methods: We performed a retrospective study in a single center, with a total of 265 patients (131 pSS patients and 134 healthy controls). Clinical examinations, complete blood count, inflammatory and immunological parameters were registered at baseline, 6 months and 12 months, for 131 pSS patients.
Results: In pSS patients, cellular count, complement fractions, and Vitamin B12 values were significantly decreased compared to healthy subjects ($p < 0.001$), while, cellular ratio- NLR, PLR, immunological and inflammatory parameters were significantly increased ($p < 0.001$) in the pSS patients. Likewise, the comparison at baseline and at every 6 months, of cellular ratios, total proteins, and gammaglobulins and disease scores revealed exponentially increased values, in pSS patients with PN. The occurrence of PN was positively correlated with neutrophils and platelets ($p < 0.05$), and negatively correlated with lymphocytes ($p < 0.05$). NLR and PLR also revealed significant positive correlations with the emergence of PN in pSS ($p < 0.05$), while for total proteins, and Vitamin B12 the correlation was negative ($p < 0.05$). The multivariate analysis confirmed the independent predictive character for PN emergence in pSS for NLR (CI95% 0.034 to 0.254, $p < 0.010$), gammaglobulins (CI95% -0.409 to -0.114, $p < 0.001$) and vitamin B12 (CI95% -0.001 to -0.001, $p < 0.001$).
Conclusion: High values for hematologic and immunological parameters were identified at baseline, while their persistent modifications during the follow-up period were observed in pSS patients with PN. NLR, gammaglobulins and vitamin B12, parameters that could become predictors for the early detection of patients at risk for the development of PN.

AB0601 **THE MENTAL HEALTH IMPACT OF SEXUAL DYSFUNCTION IN SJÖGREN'S DISEASE: A SOCIAL MEDIA APPROACH TO REAL-WORLD EVIDENCE**

Keywords: Sjögren syndrome, Mental health, Real-world evidence

M. Flurie[1], I. Alevizos[2], C. Baldini[3], M. Converse[1], K. Davidson[4], B. LaMoreaux[5], A. Amatucci[6], J. Massengale[1], J. Taylor[7], W. Li[1], C. DeFelice[1], M. Picone[1], E. R. Wassman[1]. *[1]TREND Community, Real-World Evidence, Philadelphia, United States of America*; *[2]Horizon Therapeutics, Clinical Development, Deerfield, United States of America*; *[3]University of Pisa, Department of Clinical and Experimental Medicine, Rheumatology Unit, Pisa, Italy*; *[4]Horizon Therapeutics, Patient Advocacy, Deerfield, United States of America*; *[5]Horizon Therapeutics, Rheumatology, Deerfield, United States of America*; *[6]Horizon Therapeutics, Medical Affairs, Deerfield, United States of America*; *[7]Horizon Therapeutics, Commercial Training, Deerfield, United States of America*

Background: To obtain a comprehensive understanding of the needs of individuals in a particular community, it is essential to actively listen to and interpret the patient experience. A proprietary artificial intelligence (AI) analytics engine was applied to social media conversations from an online community for those living with Sjögren's disease (SjD). Sjögren's disease is an autoimmune disease characterized by inflammation of exocrine glands, most often presenting with dryness of the eyes and mouth (sicca). Some women with SjD also report vaginal dryness and discomfort [1] lthough individuals with SjD have an increased risk for poor mental health outcomes (e.g., anxiety, depression), the unique role of vaginal dryness and the resulting mental health impact are not well understood.
Objectives: The objective of the current study was to identify specific mental health impacts associated with vaginal dryness in SjD. We also aimed to explore common topics shared by community members discussing these symptoms to understand their impact on daily living.
Methods: Data included the public subreddit r/sjogrens, which contained 3779 users and 41,406 posts/comments from October 2012 to March 2022. The proprietary AI engine used for analysis leverages natural language processing techniques to analyze text-based social media data sources. First, the engine used entity recognition to identify the most frequent clinical findings mentioned across all posts/comments. Anxiety and depression were among the most frequently mentioned mental health symptoms in conversations. The engine then extracted the most frequent dryness-related symptoms from the data, which included dry eyes, mouth, throat, and vagina. We then fit 2 logistic regression models where dryness mentions (e.g., 'dry eyes', 'vaginal dryness') predicted mentions of 'anxiety' (model 1) or 'depression' (model 2). For our exploratory analysis, we used a guided topic modeling approach to extract conversations about vaginal dryness. This involved providing a list of seed terms (e.g., 'vaginal dryness', 'vaginal pain') around which the model could converge in identifying word clusters.
Results: In total, topic modeling revealed 563 posts/comments from 345 users regarding vaginal dryness. "Vaginal dryness" was a significant predictor ($P < .001$) in both regression models, with adjusted odds ratios between 2.2 and 2.8 (95% CI, 1.9-4.2), suggesting that users mentioning vaginal dryness are 2 to 3 times more likely to mention a negative mental health outcome. Our guided topic modeling approach yielded 3 subtopics within the primary vaginal dryness topic. These included conversational topics about 'sexual discomfort', 'lubrication', and 'marital impacts' across 141 users.
Conclusion: These findings suggest that vaginal dryness and sexual dysfunction in SjD are prevalent and associated with specific negative mental health symptoms. Potential daily impacts were illuminated when topic modeling showed conversations centered on physical pain during sex (i.e., dyspareunia) and adverse impacts on marriage/relationships. This social listening approach also revealed management techniques (e.g., lubrication) for individuals experiencing sexual discomfort. Interrogating social media conversations can be invaluable to elucidating patient-reported mental health challenges in rare diseases. It remains unknown how these conversational references to negative mental health symptoms directly translate to specific mental health diagnoses (e.g., anxiety disorder) or treatment challenges in patients with SjD. Future work should comprehensively explore these symptoms so clinicians, caregivers, and patients can better understand and manage mental health in the context of chronic disease.

AB0602 SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS IN ISRAEL: GENDER DIFFERENCES IN MANIFESTATIONS, MANAGEMENT AND COMORBIDITIES

Keywords: Descriptive Studies, Systemic lupus erythematosus, Epidemiology

T. Eviatar[1,2], V. Rosenberg[3], O. Elkayam[1,2], G. Chodick[3], D. Paran[1,2]. [1]*Tel Aviv Sourasky Medical Center - Ichilov, Rheumatology, Tel Aviv, Israel*; [2]*Tel Aviv University, Faculy of Medicine, Tel Aviv-Yafo, Israel*; [3]*Maccabi Health Services, Kahn-Sagol-Maccabi Research and Innovation Institute, Tel Aviv, Israel*

Background: Prevalence, incidence, demographic and clinical characteristics of SLE are affected by race, ethnicity and socioeconomic status. The epidemiology of SLE in Israel is not well defined.
Objectives: We aimed to assess the prevalence of SLE and to describe the demographic and clinical characteristics of SLE patients.
Methods: A retrospective study using the computerized database of Maccabi Healthcare Services (MHS), a large health maintenance organization. Prevalent SLE patients on Dec 31 2020 were defined by: ICD-9 code 710.0 (≥2 diagnoses by a rheumatologist/immunologist and/or/≥3 diagnoses by a primary care physician/pediatrician and/or ≥2 diagnoses from a hospital); ≥1 a positive antinuclear antibody (ANA) test; ≥1 dispensed hydroxychloroquine (HCQ) prescription. All SLE patients were ≥10 years-old when first diagnosed; first diagnosed before Dec 31 2018; MHS members for ≥12 months before and ≥24 months after the first diagnosis of SLE. Patients diagnosed with dermatomyositis and/or systemic sclerosis were excluded. SLE patients were matched to controls from the general population of MHS members for age, sex and socio-economic status at a ratio of 1:5.
Results: We identified 1073 eligible SLE patients (prevalence rate of 55.6 per 100,000) and 5365 controls. The mean age on Dec 31 2020 was 50.7 (±14.9) and 942 SLE patients (87.8%) were female. Mean age at diagnosis was 37.2 (± 14.4). The prevalence of SLE disease manifestations is shown in Figure 1A. Since 2015 over 90% of SLE patients had ≥1 dispensed HCQ within 12 months of diagnosis, compared to only 50-70% among those diagnosed before 2015. In 2020 only 67.5% of the patients were still treated with HCQ, 24% were not taking any SLE medication, and 3.8% were treated with systemic glucocorticosteroids (GCs) alone. GCs were prescribed at least once for 74.8% of all patients, and for 30.8% in 2020. The median cumulative prednisone dose per disease year was 283 mg (IQR 0-1297.1), and was higher for males than females (630 mg [IQR 45-2028], 251.7 mg [IQR, 0-1183], respectively, P = 0.001). Compared to females, male SLE patients had a significantly higher prevalence of comorbidities (Figure 1B). Despite a similar prevalence of osteoporosis (OP) (P=0.828), use of OP medications was lower among men (M-16.2%, F-32.3%, P =0.046). Cardiovascular comorbidity and osteoporosis (OP) were more prevalent in SLE patients compared to controls (6.3% vs. 2.9%, respectively, P ≤0.001; (29.8% vs. 11.2%, respectively, P ≤0.001).
Conclusion: The prevalence of SLE in MHS in this study was found to be 1:1790. Prescription of HCQ within the first year after diagnosis has increased since 2015, however HCQ uptake decreased in the years following diagnosis, possibly due to waning compliance. GC cumulative doses were generally low, although it was three times higher in male than in female patients. Cardiovascular comorbidity and OP were more prevalent in SLE patients than in the general population, and more prevalent in male SLE patients, who usually bear a worse prognosis. Moreover, male SLE patients may be undertreated for comorbidities as manifested by higher GC doses and less OP treatment.

AB0603 WORKING TOWARDS A CORE MINIMAL DATASET FOR SYSTEMIC LUPUS ERYTHEMATOSUS STUDIES

Keywords: Clinical trials, Systemic lupus erythematosus

S. Mcdonald[1], J. Teng[1,2], M. Barraclough[1,3], I. N. Bruce[1,3]. [1]*NIHR Manchester Biomedical Research Centre, Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, The Kellgren Centre for Rheumatology, Manchester, United Kingdom*; [2]*Ruijin Hospital, Tong University School of Medicine, Department of Rheumatology and Immunology, Shanghai, China*; [3]*Faculty of Biology, Medicine and Health, The University of Manchester, Manchester Academic Health Science Centre, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*

Background: Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease and its heterogeneity means that many cohorts and clinical trials do not collect the same data, making comparative studies difficult.
Objectives: We aimed to ascertain what data is commonly collected in SLE registries/trials. Our ultimate goal is to generate a core minimal dataset for future SLE studies.#8232;
Methods: We designed and distributed a questionnaire to members of the Systemic Lupus Erythematosus International Collaborating Clinics (SLICC) as well as additional research active centres in China. Our survey included 26 questions about the types of data that are routinely collected for research. Data collected by ≥ 75% of participating centres was used as a threshold for concordance.#8232;
Results: Eighteen centres; eight from USA/Canada, five from China and five from Europe responded. Table 1 shows the data that ≥ 75% centres collected. Notably, the EULAR/ACR 2019 criteria was collected by 33.3% and even the most commonly collected patient reported outcome (PRO) - the SF36, was only collected by 53.3%. The SLICC/ACR SLE damage index did not reach our threshold (68.4%). Current treatment data collected did include drug name, dose, frequency and start date. Previous treatment reason for cessation was collected only pertaining to antimalarials. Baseline anti-dsDNA (ELISA) and Crithidia were collected by 70.6% and 52.9% respectively and baseline immunoglobulins were measured by 70.6%. Follow-up blood counts and complement C3/4 were collected by ≥ 75% of centres.

Table 1. Data that ≥ 75% centres collected

Sociodemographic	Racial background,Educational attainment,Occupation,Smoking status,Alcohol consumption,Contraception use,Pregnancy history (number of pregnancies, miscarriage, stillbirth and neonatal death)
SLE specific	Date at and age of diagnosis,Disease duration,Family history of SLE,ACR 1997 classification criteria,SLEDAI-2000 disease activity measure
Comorbidity	Diabetes,Hypertension,Bone disease/osteoporosis,Cerebrovascular disease,Ischaemic heart disease,Renal disease,Infection,Malignancy, Cardiovascular risk factors: smoking status, diabetes, hypertension and obesity, Renal data: renal biopsy, BP, serum creatinine, Urine Protein-Creatinine Ratio and estimated GFR
Baseline bloods	FBC,Complement C3/4,ESR,LFTS
Baseline immunology	Anti-cardiolipin antibody,ANA (IIF),ENA,Lupus anticoagulant,Anti-Beta2 glycoprotein
Treatment data	Current:Biologic (Name, Dose, Frequency, Start date),Immunosuppressant (Name, Dose, Frequency, Start date),Antimalarial (Name, Dose, Frequency, Start date),IV/PO Glucocorticoid (Name, Dose, Frequency, Start date),NSAID (Name only) Previous:Biologic (Name only),Immunosuppressant (Name only),PO Glucocorticoid (Name, Dose, Start date, End date),Antimalarial (Name, Start date, End Date, Reason for cessation)

Conclusion: An initial set of commonly collected data was identified. This forms the basis to start to consider a core minimum dataset for SLE. Development and further refinement of this dataset is needed, as will common definitions of each data field to allow widespread use.

AB0604 IDENTIFYING THE RISK FACTORS AND INCREASING MORTALITY OF PULMONARY ARTERIAL HYPERTENSION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Prognostic factors, Systemic lupus erythematosus, Epidemiology

Y. F. Fang[1], Y. F. Chen[1]. [1]*Chang Gung Memorial Hospital, Linkou, Division of Rheumatology, Allergy and Immunology, Department of Internal Medicine, Taoyuan City, Taiwan, Republic of China*

Background: Patients with systemic lupus erythematosus (SLE) have a risk of pulmonary arterial hypertension (PAH), which could be fatal.
Objectives: The goal of this study was to identify the risk factors for mortality in patients with PAH.
Methods: Patients with SLE treated at Chang Gung Memorial Hospital were included in this retrospective cohort study. Univariate and multivariate COX regression, as well as Kaplan–Meier survival curve analysis were conducted to investigate risks in SLE patients.
Results: The average age at diagnosis was 40.78 ± 15.92 years. A total of 42 (6.1%) of the 689 patients had PAH. Patients with PAH exhibited shorter follow-up duration, higher disease activities, higher incidence rates of comorbidities patients without PAH. Physicians preferred to use more Cyclophosphamide and less hydroxychloroquine in PAH patients. Cox regression adjusted analysis indicated that PAH (hazard ratio = 2.709, 95% CI = 1.631, 4.499, p <0.001), old age at diagnosis (HR = 1.057, 95% CI = 1.045, 1.070, p < 0.001), high SLEDAI score (HR = 1.074, 95% CI = 1.040, 1.109, p < 0.001), end-stage kidney disease (ESKD) (HR = 2.533, 95% CI = 1.620, 3.961, p < 0.001) and Cyclophosphamide treatment (HR = 1.687, 95% CI = 1.058, 2.689, p < 0.028) were all linked to increased mortality. Moreover, the Kaplan–Meier survival curve analysis revealed that patients with pericarditis had a higher mortality rate (log-rank test, p < 0.001).
Conclusion: A 6.1% proportion of SLE patients have manifestations of PAH. Moreover, SLE patients with PAH have a greater risk of mortality. Therefore, these patients need intense screening and treatment of PAH.

Background: Fatigue is one of the most common symptoms in patients with systemic lupus erythematosus (SLE) [1]. Resting-state functional magnetic resonance imaging (rs-fMRI) has emerged as a powerful tool for mapping large-scale networks in the human brain. To explore the neural mechanism of fatigue, several studies evaluated the functional connectivity between brain region of interests using rs-fMRI. However, there are still few reports on patients with SLE.
Objectives: To identify the fatigue-specific functional connectivity in patients with SLE.
Methods: rs-fMRI data were acquired from SLE patients with fatigue and healthy controls (HCs). Functional connectivity of SLE patients and HCs were analyzed and compared by ANCOVA, adjusted for age and sex. On the day of rs-fMRI imaging, SLE Disease Activity Index score with the Safety of Estrogens in SLE National Assessment modification (SELENA-SLEDAI) was assessed, and the Chalder fatigue scale, fatigue assessment questionnaire, was collected. The association among SELENA-SLEDAI, the results of the questionnaire, and functional connectivity was evaluated by correlation analysis.

Results: A total of 10 SLE patients (90% female; median age: 44 years, IQR: 33-61) and 16 HCs (63% female; median age: 41 years, IQR: 34-46) were included. In SLE patients, the median SELENA-SLEDAI was 4 (IQR: 0-10) and the median prednisolone dose was 4 mg/day (IQR: 0-10). SLE patients with fatigue showed increased functional connectivity between the right insular cortex and right thalamus compared to HCs (p=0.03). The functional connectivity between the right insular cortex and right thalamus was significantly correlated with Chalder fatigue scale, an index evaluating fatigue, in patients with SLE (r=0.71, p=0.03), whereas it did not correlated with SELENA-SLEDAI. No correlation was observed between Chalder fatigue scale and SELENA-SLEDAI.

Conclusion: We identified a specific functional connectivity between the right insular cortex and right thalamus which may be associated with fatigue in SLE patients.

AB0606 NODULAR MUCINOSIS AS INITIAL PRESENTATION OF SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Skin, Systemic lupus erythematosus

D. Zajdman Faitelson[1], M. Macedo Pérez[1], P. Rodríguez Henríquez[2], D. Guerrero Hernández[3], M. E. Vega Memije[1]. *[1]"Dr. Manuel Gea Gonzalez" General Hospital, Dermatology, Mexico City, Mexico*; *[2]"Dr. Manuel Gea Gonzalez" General Hospital, Rheumatology, Mexico City, Mexico*; *[3]"Dr. Manuel Gea Gonzalez" General Hospital, Dermatopathology, Mexico City, Mexico*

Background: Cutaneous mucinoses comprise a wide group of disorders characterized by aberrant accumulation of glycosaminoglycans between collagen bundles, that share clinical and histological characteristics, and are classified as primary and secondary [1-3]. Nodular mucinosis associated with lupus is a primary mucinosis first described in 1954 by Gold [4]. It is a distinctive but unusual cutaneous manifestation, with an incidence of 1.5%, that presents as asymptomatic, skin-colored papules or nodules on the trunk and upper extremities [2]. It can occur in patients with discoid lupus, subacute cutaneous lupus or systemic lupus erythematosus (SLE) (2,5,6). The temporal relationship with the development of SLE is variable, since in some cases it precedes it, while in others it occurs later or simultaneously, with clinical variations according to disease activity and antibody levels [6,7].

Objectives: Describe an infrequent cutaneous manifestation of SLE.

Methods: We describe a case of nodular mucinosis as an isolated clinical manifestation of SLE in a middle aged woman, with clinical improvement with methotrexate therapy.

Results: A 67-year-old female patient presented with an 8-month history of multiple skin-colored, asymptomatic nodules in face, trunk and extremities. Some of the nodules had a central depression (Figure 1 A and B). The clinical examination was otherwise unremarkable. Histological analysis of a biopsy specimen showed a circumscribed, non-encapsulated neoformation in the reticular dermis, composed of spindle cells in a storiform pattern, mixed with hyalinized collagen fibers (Figure 1 C). Alcian blue staining confirmed the presence of abundant interstitial, superficial and deep mucin, thus integrating the diagnosis of nodular mucinosis (Figure 1 D). Laboratory tests were positive for antinuclear antibodies (1:1000, coarse speckled pattern), anti-double stranded DNA (47.1 IU/ml), anti-nucleosome, anti-SSA/Ro, anti-RNP, anti-Sm antibodies and lupus anticoagulant, with a lymphocyte count of 3.6 cells/mm3 and hypocomplementemia (C4 of 15 mg/dL). A final diagnosis of nodular mucinosis associated with SLE was made and treatment was started with hydroxychloroquine 200 mg/day and prednisone 1 mg/kg/day. Improvement of skin lesions was observed after the addition of methotrexate 15 mg/weekly.

Conclusion: Our case presents a challenge to the clinician due to the atypical presentation and the absence of other systemic symptoms of SLE, as well as histologic findings similar or almost identical to other cutaneous mucinoses. This case demonstrates the importance of thorough dermatologic examination, high suspicion and directed complementary studies for the correct interdisciplinary approach to this entity.

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease affecting different organs and causing significant morbidity and mortality. Pulmonary arterial hypertension (PAH) is a rare manifestation of SLE. The prevalence of PAH in patients with SLE varies between 0.5 to 5% [1]. No screening algorithms have been developed in patients with SLE.

In patients with SSc, PAH is characterized by changes in the pulmonary vasculature and endothelial dysfunction. These microvascular changes are also present in periphery, observed with nailfold video-capillaroscopy (NVC) [2]. NVC findings may help to identify patients at a significant high risk of future development of PAH [3].

Objectives: The aim of our work is to analyze the clinical and demographic features and nailfold capillary changes of patients with SLE-related PAH compared to a group of SLE patients without PAH.

Methods: We identified and selected 20 patients with SLE and type I PAH and collected demographic, clinical and laboratory features from 8 rheumatology centers across Europe. We could perform NVC on 9 patients. We selected as controls 68 patients with SLE who underwent cardiopulmonary screening to exclude PAH: we collected demographic, clinical and laboratory features and performed NVC. The presence of SD pattern was assessed as previously described [4]. Patients satisfied the 2019 EULAR/ACR SLE classification criteria. We excluded patients with a diagnosis of mixed tissue disease and overlap syndrome.

Results: Demographic and clinical features of patients with SLE-PAH and SLE controls are shown in Table 1. All patients with SLE-PAH were female, age and disease duration were not different between the 2 groups. LAC+ and anti-RNP+ was more prevalent in patients with SLE-PAH. No differences were observed for anti-Sm, anti-Ro, anti-La and anti-phospholipid antibodies. Of clinical features, skin and CNS involvement were more prevalent in patients with SLE-PAH than in SLE controls. Raynaud's phenomenon was more prevalent in patients with SLE-PAH than in SLE controls. In patients with SLE-PAH we observed a significantly higher prevalence of scleroderma pattern at NVC than in controls: patients with SLE-PAH showed a lower number of capillary density and a higher frequency of megacapillaries. In multivariate analysis, Raynaud phenomenon and anti-RNP are predictors of PAH in patients with SLE. The McFadden's R-squared for the model is 0.30.

Conclusion: Our data show that LAC+, RNP+, Raynaud's, Skin and CNS involvement and a SD pattern at NVC is more prevalent in patients with SLE PAH than in patients with SLE without PAH. Our results point to a generalized microvascular involvement and a hypercoagulation state in patients with SLE PAH. The variables we identified could be used to implement a screening algorithm to identify patients with SLE with a high risk of developing PAH.

AB0608 CIRCULATING LEVELS OF TNF/TNFR SUPERFAMILY FACTORS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID RELATED SYNDROMES

Keywords: Biomarkers, Anti-phospholipid syndrome, Systemic lupus erythematosus

S. Bertocchi[1], E. Pedretti[1], T. Lowin[2], A. Caproli[1], S. Tamanini[1], F. Regola[1], A. Tincani[1], F. Franceschini[1], S. Piantoni[1], L. Andreoli[1], G. Pongratz[3,4]. Background: B-cell tolerance checkpoint defects are part of the pathomechanism in humoral autoimmune disorders, such as Systemic Lupus Erythematosus (SLE) and Antiphospholipid Syndrome (APS) [1]. In APS, despite the strong evidence of antibody mediated pathogenesis (aPL), specific B cell phenotype abnormalities, and the development of the disease in patients with inborn errors of immunity involving B cell ontogeny, data on the use of therapies directed toward B cells are still lacking and anticoagulation remains the corner stone of management [2].

Objectives: The aim of this study was to measure serum levels of TNF/TNFR superfamily factors which are involved in B-cell homeostasis, looking for differences among diseases.

Methods: Two hundred and twenty-seven patients [75 SLE, 62 SLE+aPL, 36 SLE+APS and 54 primary APS (PAPS)] were enrolled. The dosage was performed by high-sensitivity ELISA. Data are expressed in median (pg/ml or ng/ml for sBCMA) (1^{st}-3^{rd} quartile). P values≤0.05 were considered statistically significant (*).

Results: SLE patients had BAFF serum levels=316.61 (200.96-579.87) vs 359.26 (SLE+aPL), 615.87* (351.22-893) (SLE+APS), 483.31* (328.02-745.5) (PAPS); APRIL=4563.53 (3028.04-6236.94) vs 5080.33, 3142.60, 3424.06* (1278.25-5800.38); sBCMA=11891.15 (8859.21-15630.50) vs 14991.55, 10372.41, 14632.88; sTACI=357.37 (255.05-905.78) vs 450.51, 424.00, 486.43; sCD40L=1355.97 (651.77-2673.81) vs 985.42* (498.92-1746.94), 1023.00, 691.96* (258.19-1329.79); TWEAK=2477.49 (1772.76-3069.27) vs 2454.60, 1683.09* (583-2814.55), 2171.18. In a linear regression model including sBCMA, sTACI, BAFF, sCD40L and TWEAK as predictors, only sBCMA was associated positively with IgG anticardiolipin (p=0.003) and IgG antibeta2-glycoprotein I (p<0.001). In second approach a linear regression model was built, including diagnoses as predictor for respective TNFF member and potential cofounders BMI, gender, CRP, leukocyte levels, hormonal status and prednisone (mg/week). Levels of BAFF, sBCMA and sCD40L were clearly associated with the underlying diagnosis [predicted values for BAFF in SLE, SLE+aPL, SLE+APS, PAPS: 778.18 (p=0.007), 637.40 (p=0.035), 946.16 (p=0.002), 919.63 (p=0.005); for sBCMA: 9068.08 (p=0.004), 10655.50 (p=0.001), 8806.06 (p=0.009), 12131.52 (p=0.001); for sCD40L: 2464.84 (p<0.001), 2025.37 (p=0.001), 2018.68 (p=0.001), 1943.45 (p=0.002)]. TWEAK was not associated with diagnosis or any of the other variables included in this model. APRIL was only associated with the diagnosis of SLE [3017.76 (p=0.016)] and SLE+APL [3531.74 (p=0.007)].

Conclusion: Our study shows an association of TNF-family members with underlying diagnosis, which underscores the contribution of TNF-family members to pathogenesis. On the other hand, TNF-family members are also directly associated to certain anti-phospholipid antibodies with a significant positive association of the plasma cell activation marker sBCMA with IgG anticardiolipin and IgG antibeta2-glycoprotein I antibodies. Taken together, our results reinforcing the possible use of anti-B cell therapies in antiphospholipid related syndromes.

Background: Deucravacitinib is a first-in-class, oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis [1,2]. Deucravacitinib demonstrated efficacy across multiple outcome measures, including achievement of ≥50% reduction in Cutaneous Lupus Erythematosus Disease Area and Severity Index-Activity score (CLASI-50), in a phase 2 trial in patients with systemic lupus erythematosus (SLE) [3] and is being investigated in two phase 3 trials (NCT05617677; NCT05620407). Patients with discoid and/or subacute cutaneous lupus erythematosus (DLE/SCLE) have elevated expression of Type I interferons (IFN) [4]. Deucravacitinib mediates signaling of Type I IFN, IL-12, and IL-23 and may be an effective treatment for patients with DLE/SCLE [5].
Objectives: Results of this ongoing phase 2 trial (NCT04857034) will characterize the efficacy and safety of deucravacitinib compared with placebo in patients with active DLE/SCLE with or without SLE.
Methods: This phase 2, global, randomized, double-blind, placebo-controlled trial is enrolling adults (aged 18-75) with biopsy-confirmed clinical diagnosis of DLE/SCLE. Key eligibility criteria and study design are depicted below (**Figure 1**). Eligible patients will be randomized (1:1:1) to treatment with placebo or deucravacitinib (dose 1 or 2) for 16 weeks. At week 16, all patients randomized to placebo will be rerandomized (1:1) to treatment with deucravacitinib dose 1 or 2 until week 52. Patients originally randomized to deucravacitinib will continue treatment until week 52. The primary and secondary endpoints are depicted below (**Table 1**). This trial will also assess the safety and tolerability of 2 doses of deucravacitinib, exploratory efficacy endpoints, patient-reported outcomes, and pharmacodynamics.
Results: Planned enrollment is 75 total patients (25 per double-blind treatment group) in 8 countries in North and South America, Europe, and Asia-Pacific regions.
Conclusion: This phase 2 trial will characterize the efficacy, safety, and tolerability of deucravacitinib in patients with active DLE/SCLE.

Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune connective tissue disease with varying degrees of disease severity and organ system involvement. Disease phenotype and severity are shown to be different based on ethnicity [1,2] where Asians have been shown to have a more severe disease phenotype compared to Caucasians [2]. Infections, active SLE and cardiovascular involvement are identified as leading causes of death among Asian patients [3]. However, there is no consensus on whether this represents a more severe disease phenotype or a socioeconomically less fortunate population, owing to lack of contemporary studies in Asian settings. This study aims to explore the disease severity and organ involvement of Asian counterparts while establishing a lupus cohort in the region for follow up and future studies.
Objectives: To assess the disease severity and organ system involvement among patients with SLE in Sri Lanka based on an ongoing national multicentre lupus database.
Methods: This is a multi-centre descriptive follow-up study with plans to establish a national lupus database in Sri Lanka. 258 patients are recruited so far with a clinical diagnosis of SLE at 14 state hospitals which provide specialist rheumatology services across the country. Disease severity is assessed using the British Isles Lupus Assessment Group-2004 (BILAG-2004).
Results: Of 258 patients, 96.5% were females. Mean (SD) age of the sample was 36.1(12.7) years. Majority fulfilled ACR/EULAR 2019 criteria for classification (86.0%). Renal involvement was seen in 42.6% with 25% having active disease at the time of recruitment. Neurological involvement was seen in 18.6%. Percentages of other domain involvement were mucocutaneous 83.7%, musculoskeletal 74.4%, haematological 65.4%, constitutional 61.6%, cardiorespiratory 8.5%, gastrointestinal 2.8% and ophthalmological 1.2%. Nearly 44% had moderate or severe system involvement (BILAG A or B) in at least one organ system at the time of recruitment. Mean SLICC Damage score was 0.9 (0-8). Disease severity was not significantly determined by the fact that whether the classification criteria were met or not (p=0.17)
Conclusion: Disease severity at time of recruitment and the prevalence of major organ system involvement during the course of illness are commoner among the study population. This is in keeping with higher disease severity and organ involvement reported in the limited available studies among Asians when compared with available data for North American and European populations. This study highlights the importance of early detection and treatment with close

surveillance of disease activity among Asian patients and encourages further research on disease behaviour.

AB0611 A RANDOMISED OPEN-LABEL PILOT STUDY OF PROBIOTICS AS AN ADJUNCTIVE THERAPY FOR THE TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOUS (SLE)

Keywords: Real-world evidence, Randomized control trial, Systemic lupus erythematosus

M. S. Mohamed Said[1], M. Armugam[1], K. N. Muhammad Nawawi[1], A. Abdul Wahab[1], R. Mustafa[1]. *[1]Faculty of Medicine Universiti Kebangsaan Malaysia, Medical, HUKM, Kuala Lumpur, Malaysia*

Background: SLE is a complex inflammatory multiorgan disease that leads to multiple comorbidities and mortality. Probiotics were shown to be successful in lowering the pro-inflammatory cytokines in animal SLE models.

Objectives: This study looked at probiotics' effect on disease activity and pro-inflammatory cytokine interleukin-6 (IL-6) among SLE patients.

Methods: We performed a prospective randomised probiotic controlled analysis of those aged 18 years old and above with mild to moderate disease activity (Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) score < 13) visiting Hospital Canselor Tuanku Muhriz (HCTM) SLE clinic between December 2021 to February 2022. Patients were prescribed either twice daily probiotics (Lactobacillus spp. and Bifidobacterium spp) to ongoing therapy or maintain ongoing treatment for three months. Baseline and post-treatment Interleukin 6, disease activity score [SLEDAI 2K, Systemic Lupus International Collaborating Clinics American College of Rheumatology (SLICC/ACR) Damage index], and adverse effects following treatment were documented.

Results: There was a 7% reduction of the median (IQR) IL-6 concentration among the probiotic group, 2.28 (4.85)pg/ml at baseline versus 2.12 (2.56) pg/ml at three months; this was not statistically significant (p=0.145). In control group shows increase in level of IL-6 by 48.9% at end of treatment [1.94 (3.59) vs 2.89 (2.83), p = 0.723]. There was a substantial reduction in SLEDAI 2K among the probiotic group by 64.3%, with the mean (SD) baseline of 4.94 (3.09) versus 1.76 (3.15) at three months (p=0.01), while the reduction in the control group were 23.7 %, with the mean(SD) baseline of 4.17 (3.20) versus 3.18 (2.50) at three months (p=0.077). There were no adverse effects noted among the probiotic group.

Conclusion: The use of probiotics reduced clinical disease activity, as demonstrated by the SLEDAI 2K score reduction. The level of IL-6 reduction was insignificant statistically. However, it shows a beneficial effect of probiotics in stabilising IL-6 compared to the control group, which has increased serum IL-6 at three months. The probiotics are relatively safe to consume. These findings warrant further studies with a larger sample size, longer duration, and analysis of multiple cytokines profiles.

AB0612 THE RELATIONSHIP BETWEEN SYSTEMATIC LUPUS ERYTHEMATOSUS DISEASE ACTIVITY INDEX (SLEDAI) AND HEALTHCARE RESOURCE UTILIZATION AND COSTS IN LUPUS PATIENTS

Keywords: Real-world evidence, Systemic lupus erythematosus

J. Levy[1], E. Alemao[2], U. Sbarigia[3], D. Goldman[4], M. A. Petri[5]. *[1]Johns Hopkins Bloomberg School of Public Health, Health Policy and Management, Baltimore, United States of America*; *[2]Janssen Pharmaceuticals, Global Services, Horsham, United States of America*; *[3]Janssen Pharmaceutica NV, Global Services, Beerse, Belgium*; *[4]Johns Hopkins University, School of Medicine, Baltimore, United States of America*; *[5]The Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, United States of America*

Background: Standard sources of healthcare resource utilization (HCRU) for systematic lupus erythematosus (SLE) patients lack granular clinical information and longitudinal follow-up. Due to the heterogeneous nature of SLE, in which disease activity fluctuates with time and acute events such as flares and remissions are common, little is known about the relationship between disease activity and HCRU.

Objectives: In this study, we assess the relationship between disease activity and HCRU in patients with SLE.

Methods: We combined data from the longstanding Johns Hopkins Lupus Cohort, where SLE Disease Activity Index (SLEDAI) was collected at minimum every six-months during standardized protocol visits, with health system cost data (Casemix). Patient resource utilization and registry data were included each calendar half-year where at least 1-registry visit and 1-Casemix item was observed. We computed the annual HCRU and cost of care by type of utilization: outpatient (OP), inpatient (IP), emergency room (ER) and pharmaceutical (Rx). We described the impact of disease activity (based on the worst SLEDAI score observed in each period) on utilization and costs using mixed effect generalized linear models where categorized SLEDAI score 0 (no activity), 1-5 (mild), 6-10 (moderate), 11+ (high) is used as a predictor of outcomes, adjusted for patients fixed effects and disease characteristics.

Results: 1,111 patients contributing 5,094 patient years between 2013-2019 were included in our analysis. The average annual cost of care (and SD) by type was $5,337 (12,997), $3,896 (25,297), $215 (1,062), $3,251 (7,721) for OP, IP, ER and Rx. Regressions showed that total costs in 6-month period was 14% higher for mild, 32% higher for moderate and 76% higher for severe relative to SLEDAI score of 0 (no activity), (all p<0.001).

Conclusion: Using detailed clinical data collected via registry, combined with comprehensive utilization and costs, we have described the relationship between disease activity and HCRU over time. These estimates explain the clinical burden of the disease and can inform cost estimates in future studies of treatments that impact SLEDAI score.

AB0613 ETIOLOGY, OUTCOME AND PREDICTORS OF MORTALITY AMONG SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS PRESENTING TO EMERGENCY DEPARTMENT: A SINGLE CENTRE PROSPECTIVE STUDY

Keywords: Systemic lupus erythematosus

S. Kotwani[1], G. Naidu[2], M. Bhatia[3], S. Sharda[3], V. Dhir[2], S. K. Sharma4, M. Rathi[5], A. Sharma[2], N. Sharma[3], S. Jain[2]. *[1]PGIMER Chandigarh, Internal Medicine, Chandigarh, India*; *[2]PGIMER Chandigarh, Internal Medicine,*

Rheumatology Unit, Chandigarh, India; [3]*PGIMER Chandigarh, Internal Medicine, Emergency Unit, Chandigarh, India*; [2]*PGIMER Chandigarh, Internal Medicine, Rheumatology Unit, Chandigarh, India*; [5]*PGIMER Chandigarh, Nephrology, Chandigarh, India*

Background: Systemic lupus erythematosus (SLE) patients can present to emergency department (ED) with acute manifestations that require immediate evaluation and initiation of appropriate therapy. The reasons for ED visits could be due to disease activity or various complications arising due to therapy. However, there is paucity of data on the reasons and outcomes of SLE patients who present to ED.
Objectives: To determine the reason, 3 month outcomes and the predictors of mortality among the SLE patients who present to ED.
Methods: Single centre prospective observational study was being performed between July 2021 and December 2022. Patients of SLE fulfilling the SLICC or the 2019 ACR/EULAR classification criteria and aged above 18 years and presenting to ED were included. Written informed consent was obtained from all the subjects. Clinical and laboratory details were noted at the time of presentation to ED. The reasons for ED visits were classified into disease activity or infection or both or non-SLE related. Outcomes of death and disease activity (by SLEDAI2K) at 3 months were noted. The study was approved by the Institute Ethics Committee.
Results: A total of 61 patients were included in the study. Median age was 28 years (IQR: 24-35) and 55 (90.2%) were females. Twenty (32.8%) patients were newly diagnosed with SLE after presentation to ED, and the median duration of illness among previously diagnosed patients was 24 months (IQR: 12-48). Disease activity alone (n=41; 67.2%) was the commonest reason for ED visit followed by disease activity co-existing with infection (n=15; 24.6%) and infections alone (n=5; 8.2%). Among the 56 patients with disease activity at presentation, active disease manifestations were noted in following organs: renal (57.1%), musculoskeletal (53.6%), skin (51.8%), haematological (42.9%), serositis (39.3%), neurological (28.6%), cardiac (26.8%), gastrointestinal (14.3%) and lung (5.4%). Among the 20 patients with infections at presentation, lower respiratory tract infections were the commonest, seen in 7 (35%) patients followed by CNS infections (15%). UTI, skin and soft tissue, ear and sino-nasal and sepsis with un-identified focus were seen in 2 (10%) patients each. Infective colitis and bacterial peritonitis were identified in 1 (5%) patient each. At 3 months of follow up, 21 (34.4%) patients died, with majority (n=18; 85.7%) dying within 1 month of presentation. Deaths were significantly more in patients who presented with both disease activity and infection compared to patients who presented with only disease activity or infection (p=0.0001). Among the remaining 40 patients, 15 (37.5%) were in remission, 13 (32.5%) were in low disease activity and 12 (30%) were in moderate to high disease activity. On multiple regression analysis, presence of hypoxia (p=0.046), serum albumin less than 2.5g/dl (p=0.006) and infection (p=0.001) at presentation predicted mortality at three months (Table 1).
Conclusion: The commonest cause of ED visit by SLE patients is disease activity alone followed by disease activity and co-existing infections. Infections were present at the time of ED admission in one-third of SLE patients. Three month mortality rate was high (34.4%) and presence of hypoxia, low serum albumin and infection at presentation predicted mortality at three months.

Table 1. Multiple regression analysis for prediction of mortality.

Parameter	p value
Gender	0.164
New onset disease	0.646
Hypotension at presentation	0.074
Hypoxia at presentation	**0.046**
Severe anaemia	0.386
Low complements	0.179
Serum creatinine >1.5mg/dl	0.451
Serum albumin <2.5 g/dl	**0.006**
Renal involvement	0.359
Need of haemodialysis at presentation	0.527
Myocarditis	0.112
Diffuse alveolar haemorrhage	0.092
Haematological involvement	0.557
Neurological involvement	0.333
Enteritis	0.119
Serositis	0.721
Infections at presentation	**0.001**

AB0614 EFFECT OF COVID-19 INFECTION ON DISEASE FLARES AND HERPES ZOSTER REACTIVATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A CASE-CONTROL STUDY

Keywords: Clinical trials, Systemic lupus erythematosus

C. L. Cheung[1], C. H. To[2], L. Y. Ho[3], K. L. Chan[3], S. M. Tse[3], C. C. Mok[3]. [1]*Rutonjee Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; [2]*Pok Oi Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; [3]*Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR)*

Background: Whether COVID-19 infection worsens SLE activity is uncertain.
Objectives: To study the effect of COVID-19 infection on disease flares and herpes zoster (HZ) reactivation in patients with systemic lupus erythematosus (SLE).
Methods: Patients who fulfilled the ACR or SLICC criteria for SLE and were followed in our rheumatology clinics were retrospectively studied. We identified patients who had documented COVID-19 infection (Omicron and its variants) between February and November 2022 and a group of SLE controls who did not have COVID-19 infection randomly matched for age, sex and the time period of COVID-19 infection in a 1:2 ratio. The primary outcomes of interest were SLE flares (clinical or serological) and the occurrence of HZ infection within 90 days of COVID-19 infection. SLE flares were assessed by the SELENA flare instruments, with modifications (mild/moderate or severe). HZ infection was a clinical diagnosis based on history and physical signs by attending physicians. The rates of SLE flares and HZ reactivation were compared between COVID-infected SLE patients and controls.
Results: 91 SLE patients with COVID-19 infection (age 48.6±14.0 years; 95.6% women; SLE duration 14.2±8.3 years; 53% history of lupus nephritis) and 182 SLE controls not infected by COVID-19 (age 48.7±13.8 years; 95.6% women; SLE duration 15.2±9.0 years) were studied. Eleven of 90 (12.2%) COVID-infected patients had serious manifestations (oxygen requirement, use of mechanical ventilator, lung infiltrates on imaging studies or admission to the intensive care unit). Patients with mild COVID-19 infection were treated symptomatically or oral anti-viral agents whereas those with serious COVID-19 infection was treated with intravenous remdesivir, dexamethasone and/or biologic/targeted agents. One (1.1%) of our patients died and 7(7.7%) patients developed severe complications. Within 90 days of COVID-19 infection, 14 (15.4%) patients developed mild/moderate SLE flares and 2 (2.2%) patients had severe SLE flares. The incidence of SLE flares in COVID-19-infected patients was significantly higher than those without (17.6% vs 5.5%; p=0.001). The changes in anti-dsDNA and complement C3 levels, however, were not significantly different between the two groups. Among COVID-19 infected SLE patients, those with clinical SLE flares had significantly lower C3 values (p=0.004) but non-significantly higher anti-dsDNA titer (p=0.32) before COVID-19 infection than those without SLE flares. HZ reactivation occurred in 2 patients (2.2%) with COVID-19 infection, which was numerically higher than those not infected by COVID-19 (2 patients, 1.1%; p=0.48). No particular risk factors were identified for HZ reactivation after COVID-19 infection.
Conclusion: In this retrospective case-control study, clinical flares within 90 days were significantly more common in patients infected with COVID-19 than age and gender matched non-infected SLE controls. SLE patients with lower C3 levels were more likely to flare after COVID-19 infection. HZ reactivation occurred at a numerically higher rate after COVID-19 infection in SLE patients than controls. The results from our study support the hypothesis for a viral trigger for disease exacerbation in SLE.

AB0615 COMPLEX RELATIONSHIPS BETWEEN INFLAMMATORY/TYPE 1 AND TYPE 2 SYMPTOMS IN SYSTEMIC LUPUS ERYTHEMATOSUS AND OTHER RHEUMATIC DISEASES: A LITERATURE REVIEW AND ANALYSIS

Keywords: Patient reported outcomes, Systemic lupus erythematosus, Quality of life

T. Escoda[1], N. Jourde-Chiche[2], C. Stavris[1], F. Retornaz[1], S. Genot[1], A. Daumas[3], A. Benyamine[3], B. Granel[3], D. Cornec[4], L. Chiche[1]. [1]*Hôpital Européen, Médecine Interne, Marseille, France*; [2]*Assistance Publique Hopitaux de Marseille, Néphrologie, Marseille, France*; [3]*Assistance Publique Hopitaux de Marseille, Médecine Interne, Marseille, France*; [4]*CHU Brest, Rhumatologie, Brest, France*

Background: A better clinical stratification of patient is essential in order to propose personalized therapeutic management for patients with complex autoimmune conditions [1]. Recently, a new stratification has been proposed in Systemic Lupus Erythematous (SLE), which distinguishes different types of symptoms: those directly related to the inflammatory process or type 1 symptoms and type 2 symptoms including fatigue, pain and anxiety-depression [2].
Objectives: Our aim was to characterize the nature of the relation between type 1 symptoms, through disease activity, and type 2 symptoms, including their impact on health-related quality of life (HRQoL), in SLE, as well as in other

rheumatic diseases such as rheumatoid arthritis (RA), primary Sjögren's syndrome (pSS) and systemic sclerosis (SSc).
Methods: A narrative literature review was conducted on disease activity and type 2 symptoms. The appropriate medical subject heading (MESH) term was used for each disease and combined with the MESH terms for fatigue, depression, anxiety, pain and quality of life as well as the term "disease activity" to give the proper search keywords. Articles in English published after 2000 and related to adult patients were located on Medline via Pubmed. The selected articles had to evaluate at least one type 2 symptom and/or HRQoL using a validated scale. Similarly, disease activity had to be assessed by a validated method (usually a clinical score). Within each study, the relationship between disease activity (type 1) and type 2 symptoms or HRQoL was analyzed and classified depending on whether the correlation was present, absent, or weak.
Results: Overall, 287 articles were analysed, corresponding to 157 765 patients. For SLE (n=115 studies including 21 randomized controlled trials), we found that inflammatory activity/type 1 symptoms were mostly uncorrelated with type 2 symptoms and/or HRQoL, with several studies even showing an inverse correlation. No correlation was observed in 67.7% (64.7%), 60% (51.5%), 25% (11.2%), and 60% (53.6%) of studies (patients), and a weak correlation in 17.6% (27.9%), 16.7% (22.9%), 12.5% (61.9%), and 17.5% (34.4%) of studies (patients) for fatigue, anxiety-depression, pain, and HRQoL, respectively. These results were consistent in the other rheumatic diseases studied. Indeed, type 2 symptoms were mostly uncorrelated with disease activity/type 1 symptoms and this seemed even more pronounced for pain. There was no correlation in 45.2-92% (55.9-95%), 56.4-100% (54-100%), 66.7-100% (94-100%), 23-75% (43.4-55%) of studies (patients) and a weak correlation in 0-28.6% (0-34.4%), 0-31.2% (0-43%), 0-33.3% (0-6%), 25-28.6% (16-45%) of studies (patients) for fatigue, anxiety-depression, pain and HROQL respectively.
Conclusion: Type 2 symptoms are poorly correlated with inflammatory activity/type 1 symptoms in SLE as well as in other autoimmune rheumatic diseases. These results have important implications for clinical care and therapeutic evaluation.

AB0616 GREATER SOCIAL VULNERABILITY ASSOCIATED WITH GREATER GLUCOCORTICOID USE IN PATIENTS WITH SLE

Keywords: Systemic lupus erythematosus

A. Som[1], L. Mcmorrow[1], L. Chen[2], D. Sen[1], A. El-Qunni[1], E. Baker[3], A. Kim[1].
[1]Washington University School of Medicine, Medicine, St. Louis, United States of America; *[2]Washington University School of Medicine, Biostatistics, St. Louis, United States of America*; *[3]SLU College for Public Health and Social Justice, Behavioral Science and Health Education, St. Louis, United States of America*

Background: Patients with SLE experience substantial health disparities. Studying the effect of spatial context on health outcomes has become a focus in health disparities research. The CDC Social Vulnerability Index (SVI) characterizes census tracts by individual dimensions of social vulnerability, which create a cumulative SVI capable of identifying communities where social determinants lead to higher levels of morbidity and mortality.
Objectives: We sought to understand the level of social vulnerability where patients with SLE reside and determine if specific dimensions of social vulnerability were associated with disease activity and prednisone utilization.
Methods: At the Washington University Lupus Clinic, 324 consented subjects who met either ACR or SLICC classification criteria for SLE were enrolled and longitudinally assessed from April 2014 to August 2020. Participant addresses were recorded for each clinic visit. The census tract code was determined for the address listed for each patient's index visit which corresponds to a SVI available in the CDC database. Participants with addresses which did not correspond to a census tract code were excluded. SVI ranges from 0 to 1 with 1 being the most vulnerable; any tract with a SVI greater than the mean of 0.5 can be seen as a socially vulnerable area. Specific dimensions of SVI (socioeconomic status, household composition, race/ethnicity/language, and housing/transportation) are further elaborated in Table 1. Prednisone dosing was organized into four categories (none, >0-7.5 mg, 8-20 mg, >20 mg). SLEDAI-2000 Responder Index-50 (S2K RI-50) assessed SLE disease activity (>4 indicated active SLE). A multinomial logistic regression model analysis was used to determine association.
Results: The number of patients with SVI and prednisone data available was 272 patients. There was no significant correlation between cumulative SVI and disease activity (OR 1.15, 95% CI=0.67-1.99, p=0.6128). When examining prednisone utilization, 175 patients were not prescribed any prednisone at their index visit while 66 were on supraphysiologic doses. Average cumulative SVI was 0.511. Compared to patients with invulnerable cumulative SVI, vulnerable patients were 2.31 times as likely to have higher dose of prednisone (95% CI 1.36-3.92; p=0.0019). Of the specific dimensions, patients vulnerable in terms of socioeconomic status (OR 2.47, 95% CI 1.43-4.27, p=0.0012) and household composition (OR 2.21, 95% CI 1.28-3.83, p=0.0047) were also more likely to have higher doses of prednisone. Patients vulnerable in terms of race/ethnicity/language (OR 1.57, 95% CI 0.92-2.68, p=0.095) and housing/transportation (1.08, 95% CI 0.65-1.80, p=0.7537) were not statistically significantly likely to have higher doses of prednisone.
Conclusion: Patients who live in more socially vulnerable areas are more likely to be prescribed higher doses of prednisone, specifically patients vulnerable in terms of socioeconomic status and household composition. This is worrisome as this likely will contribute to a higher burden of damage. Consistent with other findings, our work highlights that access to social determinants is associated with health inequities.

Table 1.

SVI Dimensions	Census variables included
Socioeconomic status	Income, poverty, employment, education
Household Composition	Age, single parenting, disability
Race/ethnicity/language	Race, ethnicity, English language proficiency
Housing/transportation	Housing structure, crowding, vehicle access

Background: Lupus is a heterogenous diseases which results in significant premature mortality. Most studies have evaluated risk factors for lupus mortality using regression models which considers the phenotype in isolation. Identifying clusters of patients on the other hand may help overcome the limitations of such analyses.
Objectives: The objectives of this study were to describe the causes of mortality and to analyze survival across clusters based on clinical phenotype and autoantibodies in patients of the Indian SLE Inception cohort for Research (INSPIRE)
Methods: Out of all patients, enrolled in the INSPIRE database till March 3st 2022, those who had <10% missing variables in the clustering variables were included in the study. The cause of mortality and duration between the recruitment into the cohort and mortality was calculated. Agglomerative unsupervised hierarchical cluster analysis was performed using 25 variables that define SLE phenotype in clinical practice. The number of clusters were fixed using the elbow and silhouette methods. Survival rates were examined using Cox proportional

hazards models: unadjusted, adjusted for age at disease onset, socio-economic status, steroid pulse, CYC, MMF usage and cluster of the patients.

Results: Indian patients with lupus have significant early mortality and the majority of deaths occurs outside the hospital setting.Out of 2211 patients in the cohort, 2072 were included into the analysis. The median (IQR) age of the patients was 26 (20-33) years and 91.7% were females. There were 288 (13.1%) patients with juvenile onset lupus. The median (range) duration of follow up of the patients was 37 (6-42) months. There were 170 deaths, with only 77 deaths occurring in a health care setting. Death within 6 months of enrollment occured in in 80 (47.1%) patients. Majority (n=87) succumbed to disease activity, 23 to infections, 24 to coexisting disease activity and infection and 21 to other causes. Pneumonia was the leading cause of death (n=24). Pneumococcal infection led to death in 11 patients and SARS-COV2 infection in 7 patients. The hierarchical clustering resulted in 4 clusters and the characteristics of these clusters are represented in a heatmap (Figure-1A,B). The mean (95% confidence interval [95% CI] survival was 39.17 (38.45-39.90), 39.52 (38.71-40.34), 37.73 (36.77-38.70) and 35.80 (34.10-37.49) months (p<0.001) in clusters 1, 2, 3 and 4, respectively with an HR (95% CI) of 2.34 (1.56, 3.49) for cluster 4 with cluster 1 as reference(-Figure 1C). The adjusted model showed an HR (95%CI) for cluster 4 of 2.22 (1.48, 3.22) with an HR(95%CI) of 1.78 (1.29, 2.45) for low socioeconomic status as opposed to a high socioeconomic status (Table 1).

Conclusion: Indian patients with lupus have significant early mortality and the majority of deaths occurs outside the hospital setting. Disease activity as determined by the traditional activity measures may not be sufficient to understand the true magnitude of organ involvement resulting in mortality. Clinically relevant clusters can help clinicians identify those at high risk for mortality with greater accuracy.

Background: Systemic lupus erythematosus (SLE) SLE often mimics the symptoms of other diseases, and the interval between symptom onset and diagnosis remains long in these patients.
Objectives: To examine the variables associated with a delay to diagnosis and their impact in damage accrual and mortality in patients with SLE.
Methods: GLADEL a multi-ethnic, multi-national Latin-American SLE inception cohort was studied. Patients were recruited based on the physicians' diagnosis but 97% fulfilled the ACR criteria. Delay to diagnosis was defined as ≥6 months from the first ACR criterion to SLE diagnosis. Socio-demographic, clinical/laboratory, disease activity, damage and mortality were compared using descriptive statistical tests. Multivariable Cox regression (HR) model with damage accrual and mortality as the end points were performed.
Results: Of the 1437 included in this analysis, the median delay to diagnosis was 5.9 months (Q1-Q3 2.4–16.1) and 721 (50.2%) had ≥6 months delay in SLE diagnosis. Patients with delay in diagnosis were more frequently of female gender, older age at diagnosis, mestizo ethnicity and without medical insurance. The characteristics of patients according to delay in diagnosis are depicted in Table 1. Delay to diagnosis did not impact on disease outcome: damage accrual [HR 1.21 (IC 95% 0.78-1.88; p=0.39)] and mortality [HR 1.30, CI 95% 0.84-2.01; p= 0.24)], after adjusting for age at SLE diagnosis, gender, ethnicity and socioeconomic status.
Conclusion: In the GLADEL cohort, delay to diagnosis was associated to sex, age, thrombosis, sicca syndrome, cutaneous and neurological involvement. Furthermore, delay to diagnosis had no apparent negative impact on disease outcome (damage accrual and mortality). Early referral when there are suspicious clinical manifestations of SLE is crucial to reduce the diagnostic delay.

PREDICTORS FOR FUTURE DEVELOPMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS IN KOREAN SJÖGREN'S SYNDROME PATIENTS

Keywords: Systemic lupus erythematosus, Sjögren syndrome

B. W. Lee[1], E. J. Kwon[1], Y. Park[1], J. J. Lee[1], S. H. Park[1], S. K. Kwok[1]. [1]*Seoul St. Mary's Hospital, College of Medicine, Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Sjögren's syndrome (SS) can occur alone or in combination with other autoimmune diseases. Systemic lupus erythematosus (SLE) is the most common autoimmune disease associated with SS. The prognosis of SS is generally better than that of SLE. However, the onset of SLE in these patients may be one of the factors that increase mortality.
Objectives: This study determined the impact of demographic factors, clinical manifestations, disease activity, and serological tests at baseline on future SLE development in Sjögren's syndrome (SS) patients.
Methods: This retrospective study assessed 1,082 SS patients without other autoimmune diseases at baseline who visited our hospital between January 2012 and March 2021. We analyzed demographic features, extra-glandular manifestations (EGMs), clinical indices, and laboratory values at baseline between the two groups divided per future SLE development (SS/SLE group vs. SS group). The probability and predictors of SLE development in SS patients were estimated using the Kaplan–Meier method and Cox proportional hazards models.
Results: The median follow-up duration was 1083.5 days. Forty-nine patients (4.5%) developed SLE that met the 2012 Systemic Lupus International Collaborating Clinics or 2019 EULAR/ACR classification criteria. The baseline EULAR SS disease activity index (ESSDAI) score was significantly higher in the SS/SLE group (p<0.001). The SS/SLE group had more lymphadenopathy and renal involvement (p=0.015 and p=0.017, respectively). Shorter SS disease duration (<3 years) (hazard ratio [HR]=2.61, p=0.012), high ESSDAI (HR=3.04, p=0.024), leukopenia (HR=2.20, p=0.017), hypocomplementemia (HR=17.40, p<0.0001), and positive for anti-dsDNA (HR=19.93, p<0.0001), anti-ribonucleoprotein (RNP) (HR=2.96, p=0.025), and anti-ribosomal P (HR=2.74, p=0.048) at baseline were SLE development predictors in SS patients.
Conclusion: Shorter disease duration and higher disease activity of SS at baseline may be risk factors for future SLE development. Serologic predictors of SLE development are hypocomplementemia, leukopenia, and positivity for anti-dsDNA, anti-RNP, and anti-ribosomal P antibodies. If the above factors are observed, close monitoring will be necessary during the follow-up period, considering the possibility of future SLE development.

IMMUNE THROMBOCYTOPENIC PURPURA AND SUBSEQUENT DEVELOPMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Prognostic factors, Systemic lupus erythematosus

G. Alle[1], M. Scolnik[1], V. Scaglioni[1], J. F. Jaramillo Gallego[1], M. A. Tobar Jaramillo[1], R. N. Alvarado[1], E. Soriano[1], J. Rosa[1]. [1]*Hospital Italiano de Buenos Aires, Sección Reumatología, Buenos Aires, Argentina*

Background: Immune Thrombocytopenic Purpura (ITP) is an immune-mediated disorder, characterized by isolated thrombocytopenia (<100,000/mm^3). It is part of Systemic Lupus Erythematosus (SLE) classification criteria, and may be one of the first manifestations of the disease, often occurring years before its diagnosis.
Objectives: To assess the incidence of SLE in a cohort of patients with ITP, and to identify predictors for its development.
Methods: Retrospective cohort study. We included patients with ITP treated in a University Hospital between 2000 and 2018, with at least one year of follow-up. Patients with SLE or other secondary causes of ITP were excluded. Demographic, clinical, laboratory and treatment data were recorded. Patients meeting SLE classification criteria (ACR 1997/ SLICC 2012) during the follow-up were identified, and incidence density of SLE was calculated. Patients with ITP were grouped according to the development or non-development of SLE, and comparisons were made. Univariate analysis was performed to identify factors associated with the future development of SLE.
Results: 186 patients were included, 64.5% women, with a median age of 27.2 years (IQR 6.3-63.9). After a follow-up of 1801.4 person/years (py), 10 patients (5.4%) developed SLE, with a median time of 22.9 months (IQR 9.8-60.9) between ITP diagnosis and development of SLE. The incidence density of SLE was 5.6/1000 py (95% CI 2.9-9.9/1000 py). Patients who developed SLE had significantly higher proportion of chronic ITP (80% vs 40.3%; p 0.01), lower proportion of complete response (10% vs 54.6%; p 0.006), and more relapses (60%

DISEASE ACTIVITY PATTERNS OVER TIME IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: IMPACT ON HEALTH-RELATED QUALITY OF LIFE

Keywords: Patient reported outcomes, Systemic lupus erythematosus, Quality of life

L. Gualtieri[1], E. Elefante[1], D. Schilirò[1], C. Stagnaro[1], V. Signorini[1], D. Zucchi[1], C. Cardelli[1], F. Trentin[1], G. Cascarano[1], A. Valevich[1], L. Carli[1], F. Ferro[1], C. Tani[1], M. Mosca[1]. [1]*Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: Health-Related Quality of Life (HRQoL) in patients with autoimmune systemic diseases has a multifactorial origin. In particular, data from the literature show that in patients with Systemic Lupus Erythematosus (SLE) the correlation between HRQoL and disease manifestations is quite controversial.

Objectives: to evaluate the impact of different disease activity patterns on HRQoL and patients' perception of disease activity in a monocentric cohort of patients with SLE.

Methods: a retrospective analysis of prospectively collected data from adult consecutive patients with a diagnosis of SLE, regularly followed at the Rheumatology Unit of Pisa. For each patient, the following data were collected: demographics, disease duration, clinical and laboratory data, SELENA-SLEDAI for disease activity and SLICC-DI for organ damage, comorbidities and ongoing treatment. Three different disease patterns were defined based on disease activity status during the year before enrollment: long quiescent (LQ) if patients were in remission in each visit; chronically active (CA) if they were not in remission in each visit; relapsing-remitting (RR) if patients presented periods of remission interspersed with periods of disease activity. Only patients with at least two visits in the year before enrollment were included. We excluded patients with a major clinical event/hospitalization not SLE-related during the year before enrolment that could influence their health status. At enrollment, each patient completed the following Patient Reported Outcomes (PROs): SF-36, FACIT-F, Lupus Impact Tracker (LIT), SLAQ, Hospital Anxiety and Depression Scale (HADS).

Results: 242 SLE outpatients were enrolled, mainly female (91.7%) and of Caucasian ethnicity (96.7%); mean age 44.2.6 ± 13 years, with a median disease duration of 12 years (IQR 6 – 21). 48.8% had at least one item of organ damage with a median SLICC-DI of 1 (IQR 1-2). Moreover, 15.3% of patients had a concomitant fibromyalgia. At enrollment, median SLEDAI in the entire cohort was 2 (IQR 0-4); the most frequent active disease manifestation was skin involvement (36/242); 12 patients had active arthritis and 11 active renal disease. Almost half of the cohort (51,2%) was on a low dose of glucocorticoids (mean daily dose 4.1 ± 2.9 mg of 6-methylprednisolone); 83.9% were on Hydroxychloroquine and 52.5% on immunosuppressive therapy. We applied the disease pattern definition criteria and we found that the LQ was the most represented pattern in our cohort (63.9% of patients), followed by the RR (22%) and CA (14.1%). No significant

differences in SF-36, HADS, LIT and FACIT results were observed between the 3 groups. Only SLAQ scores resulted significantly higher in the RR group compared with the LQ one (p<0.01) (Table 1).

Conclusion: our study shows that HRQoL in SLE is not significantly influenced by disease course over time, confirming that disease activity does not represent the major determinant of patients' perception of health status. However, we found that patients' self-evaluation of disease activity is affected by the disease pattern over time. Particularly, it seems that alternating periods of disease activity to periods of remission over time may worsen the patient's evaluation of disease status, even more than a mild chronically active disease.

Nasonova, Rheumatology, Moscow, Russian Federation*

Background: Lupus Nephritis (LN) is an immune-complex mediated glomerulonephritis affecting up to 60% of all SLE patients during the disease course. A kidney biopsy is indicated in SLE patients when proteinuria stably reaches or overcomes the level of 500 mg/24 h or spot urine protein to creatinine ratio (UPCR) >500 mg/g (50 mg/mmol), especially with impaired renal function or active urinary sediment, and is generally recommended to evaluate the inflammatory findings but also to rule out other etiologies of renal involvement and to guide the need of immunosuppressive therapy.

Objectives: To investigate the histopathologic findings in first-time renal biopsies from SLE patients and evaluate the type and occurrence of histopathological findings other than LN as these may lead to a risk of inadequate therapeutic interventions.

Methods: 64 SLE patients who had a first-time onset of renal involvement from 24/11/2020 up to 24/10/2022 and subsequent renal biopsy were included in the study. All patients fulfilled the Systemic Lupus Erythematosus International Collaborating Clinics (SLICC) disease classification criteria (1) for SLE and were biopsied on clinical indication, i.e., proteinuria > 0.5 g/day or active SLE in combination with a rise in plasma creatinine, decrease in glomerular function or new onset proteinuria with concurrent active urine sediment.

Results: In total, 64 patients (female 51 (76%), Male (15 (24%) with first time presentation of renal involvement who had been subject to renal biopsy were included.. The median age at the time of biopsy was 35,34± 11,19 years. For more patient baseline characteristics, see Table 1.Fifty two (81%) had findings consistent with LN according to ISN/RPS classification system [2]. Four patients (6 %) had class I - II, 19 (30%) -class III, 13 (20%) - class IV, 8 (12%) - Class V, 2 (3%) - Class VI, 3 (4%) - Class III ± V, 3 (4% - Class IV ± V. Tvelwe patients (19%) did not have histological changes in accordance with LN. Of these, 3 had thrombotic microangiopathy, 5 had IgA nephropathy, 4 were later found to be ANCA-positive and were re-diagnosed with concomitant ANCA-associated vasculitis. Of the 12 non-LN patients, all had proteinuria > 0.5 g/day, 2 had new-onset low-grade proteinuria and concurrent active urine sediment, 2 had new-onset low-grade proteinuria with concurrent increasing SLE disease activity, and 5 patients had isolated persistent low-grade proteinuria.

Table 1. Baseline characteristics, 64 patients

Age (years) Mean (SD	
SLE duration at biopsy (years); M (IQR)	0.7 (0.4 – 7.3)
Systolic blood pressure (mm Hg); Mean (SD)	127.5 (20.8)
Ethnicity	
Caucasian; n (%)	58 (90%)
Asian; n (%)	6 (10%)
Diagnosis according to ISN/RPS	
Class I-II	4 (6%)
Class III	19 (30%)
Class IV	13 (20%)
Class V	8 (12%)
Class VI	2 (3%)
Class III ± V	3 (4%)
Class IV ± V	3 (4%)
TMA	3 (4%)
Vasculitis	4 (6%)
IgA nephropathy	5 (7%)

Conclusion: We demonstrate that renal histopathology confirmed other causes than LN in a significant proportion (19 %) of SLE patients with signs of renal involvement. Since these patients may need other therapeutic interventions than patients with classic LN, we can conclude that the renal biopsy is important in order to guide the choice of therapeutics.

SLE, Sjön's and APS - clinical aspects (other than treatment)

AB0623 RELATIONSHIP BETWEEN NUMBER OF DMARS USED AND BODY COMPOSITION IN RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Diet and Nutrition, Rheumatoid arthritis

O. E. Alvarez-González[1], J. C. Riega-Torres[1], D. C. Rubio Torres[1], D. P. Flores-Gutierrez[1], C. M. Skinner Taylor[1], J. A. Cardenas-de la Garza[1], L. R. Aguilar Rivera[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*

Background: Chronic inflammation in rheumatologic diseases alters body fat distribution and response to treatment, requiring higher doses or amounts of disease-modifying antirheumatic drugs (DMARDs) [1].
Objectives: To describe body composition of patients with rheumatoid arthtritis (RA) and systemic lupus erythematosus (SLE) and its association with the number of DMARDs used and use of corticosteroids.
Methods: A cross-sectional and descriptive study was carried out in the rheumatology service of the University Hospital ¨Dr. José Eleuterio González¨. Patients over 18 years old with diagnosis of RA or SLE were included. Body composition was assessed with InnerScan TANITA BC-533 monitor (Yesod, Japan) which uses single frequency bioelectrical impedance analysis (BIA). We report frequencies and percentages for categorical variables. For quantitative variables, we measured center trend and dispersion (means and standard deviation).
Results: We included 323 patients, 248 (79.1%) with rheumatoid arthritis (RA) and 75 (20.89%) with systemic lupus erythematosus (SLE) with an average age of 51.79 (±12.7) and 42 (±14.8) years respectively. In the RA group, BMI <25kg/m² was found in 64 (25.8%) and BMI >25kg/m² in 183 (73.8%), high total fat in 148 (59.7%), high visceral fat in 40 (16.1%), low muscle mass in 212 (85.5%), low body water in 155 (62.5%), 148 (59.7%) patients met 2 of 3 criteria for sarcopenic obesity (no muscle strength assessment) and abdominal obesity in 163 (65.7%). Details of anthropometric evaluation and DMARD schemes are shown in Table 1. We found a relationship between the 2 DMARD combined scheme with being obese type 2 (p=0.02) and prednisone use with type 3 obesity (p=0.005). In SLE group BMI <25kg/m² was found in 18 (24%) and >25kg/m² in 57 (76%), high total fat in 45 (60%), low muscle mass in 61 (81.3%), low body water in 46 (61.3%) and abdominal obesity in 51 (68%).. Being obese type 3 and having high visceral fat was related with the use of 3 DMARDs combined (p=<0.001) and having an older metabolic age was associated with intramuscular steroid use (p=0.012).
Conclusion: Sixty percent of our population met 2 of 3 criteria for sarcopenic obesity and more than 80% had low muscle mass. These parameters may increase with disease activity and the number of drugs required for control. Reference: [1] Liu, Y., Hazlewood, G. S., Kaplan, G. G., Eksteen, B., & Barnabe, C. (2017). AB0624 DUAL TRAJECTORIES OF DSDNA AND C3 CORRELATED WITH MORTALITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Real-world evidence

H. H. Chen[1], W. N. Huang[1], T. Y. Hsieh[1], Y. H. Chen[1]. [1]*TAIchung Veterans General Hospital, DIvision of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by diverse clinical manifestations with multi-organ damage and an increased risk of mortality. Several clinical characteristics have been identified as predictors of overall mortality in patietns with SLE, including oragan damage, time from onset to diagnosis > 1 year, nephropathy, male gender, older age of onset, high Systemic Lupus Eythematosus Disease Activity Index (SLEDAI) scores and high Age-adjusted Charlson Comorbidity Index (ACCI) scores. However, whether trajectories of dsDNA and C3, two of the frequently monitored immune profiles, are associated with mortality among patients with SLE is still unknow. We aimed to assess the association of mortality with dual trajectories of dsDNA and C3 within two years in a large Taiwanese lupus cohort.
Objectives: We aimed to assess the association of mortality with dual trajectories of dsDNA and C3 within two years in a large Taiwanese lupus cohort.
Methods: The study linked electronic medical record data at Taichung Veterans Genral hospital to the file of Cause of Death Data from the National Health Insurance Research Database managed by Center for Helath and Welfare Data Science in Taiwan. From Jan 1, 2000 to Mar 31, 2021, we identified 4850 patients with SLE who were followed up at TCVGH. We excluded 131 patients who were dead and 364 patients who were lost to follow-up withing 2 years. We also excluded 1999 patients who did not have at less 2 records of paired dsDNA and C3 data ever 3 months during the first two-years. We finally included 2,356 patients for trajectories analysis. The first 2 years of follow-up was used to establish trajectories of dsDNA and C3. We calculated the man ± standard deviation of dsDNA and C3 for the eight 3-month intervals and we used these data separately for trajectory determination, which was by group-based trajectory analysis with a latent class growth model, fitting the SAS Proc Traj procedure. We classified patients with SLE into 4 groups (G) based on dual trajectories of dsDNA and C3: G1- lowest dsDNA and second highest C3 trajectory (41.6%); G2- lowest dsDNA and highest C3 trajectory (32.0%); G3- second highest dsDNA and second highest C3 trajectory (19.2%); group 4, highest dsDNA and lowest C3 trajectory (7.1%). The relative risk of mortality was estimated using Cox proportional hazard model adjusting for age, gender, hypertension, diabetes mellitus and hyperlipidemia, shown as hazard ratios (HRs) with 95% confidence intervals (CIs).
Results: The proportions of female in G1-G4 were 88.0%, 87.0%, 86.7% and 84.0% respectively. The mean age in G1-G4 were 37.6 years, 41.3 years, 36.4 years and 34.7 years respectively. The mortality rates were highest in G1 (6.24 cases per 1,000 person-years), followed by G2 (5.90 cases per 1,000 person-years), G3 (5.04 cases per 1,000 person-years) and G4 (4.19 cases per 1,000 person-years). After adjusting for potential confounders, the risk of mortality in G1 was significantly higher in G2 (HR, 1.67; 95% CI, 1.10–2.53; p = 0.016), but not in G3 (HR, 1.16; 95% CI, 0.66–2.05; p = 0.605) and G4 (HR, 1.22; 95% CI, 0.51–2.91; p = 0.659) as compared to that in G2. Other significant independent predictors of mortality included age (HR, 1.05; 95% CI, 1.04–1.06; p < 0.001) and hypertension (HR, 1.83; 95% CI, 1.14–2.95; p = 0.013).

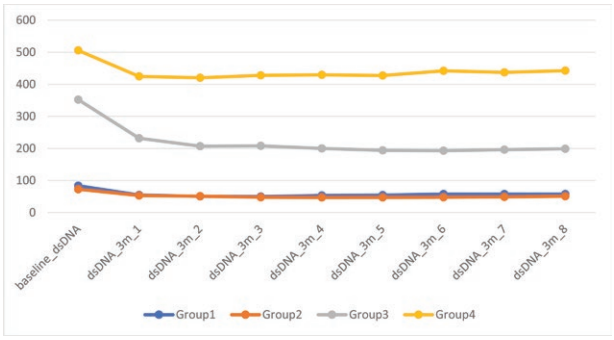

Figure 1. Trajectories of dsDNA during the first two years in four groups.

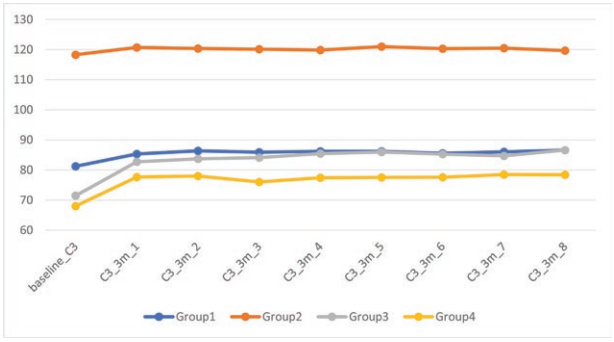

Figure 2. Trajectories of C3 during the first two years in four groups.

Conclusion: This single center study revealed that SLE patients with lowest dsDNA and second highest C3 trajectory had a significantly higher risk of mortality than SLE patients with lowest dsDNA and highest C3 trajectory.

AB0625 THE ATTRIBUTION OF NEUROPSYCHIATRIC EVENTS IN SYSTEMIC LUPUS ERYTHEMATOSUS: DATA FROM "ATTIKON" LUPUS COHORT

Keywords: Registries

D. Nikolopoulos[1], N. Kapsala[1], O. Gioti[1], S. Flouda[1], A. Pieta[1], K. Chavatza[1], T. Karageorgas[1], D. Tseronis[1], P. Katsimbri[1], D. Boumpas[1], A. Fanouriakis[1].
[1]National and Kapodistrian University of Athens Medical School, 4th Department of Internal Medicine, Attikon University Hospital, Athina, Greece

Background: The attribution of neuropsychiatric manifestations to systemic lupus erythematosus (SLE) or unrelated causes is often obscure.
Objectives: The attribution of neuropsychiatric events to lupus (SLE related) or other causes (non-SLE related) in a large SLE cohort.
Methods: Retrospective study of 707 SLE patients from "Attikon" lupus cohort [1,2]. Neuropsychiatric manifestations were classified as either primary neuropsychiatric SLE (SLE related; attributed to SLE using a combination of multidisciplinary physician judgment with attribution models [3]) or secondary NPSLE (non-SLE related; neuropsychiatric manifestations not attributed to SLE) or manifestations of uncertain attribution.
Results: 258 patients developed 345 NP events in total. Among them, 140 (40.6%) were attributed to SLE, while 148 (42.9%) were classified as secondary NPSLE. In 57 NP events, the attribution remained uncertain. Among primary NP manifestations, cerebrovascular events (n=34, 24.3%), seizures (n=25, 17.8%) and cranial neuropathies (n=18, 5.2%) were the most common, while mood disorders (n=69, 46.6%) and headache (n=22, 14.9%) were the most common secondary NPSLE. The extra-CNS clinical and serological phenotype do not differ between primary and secondary NPSLE. Patients with primary NPSLE as compared to secondary NPSLE, were more likely to accrue irreversible damage (SLICC damage index > 0) (OR=2.88, 95%CI 1.67-4.96) and develop additional neuropsychiatric manifestations (OR=3.74, 95%CI 1.98-7.09).
Conclusion: A significant proportion of NP events cannot classified as primary or secondary NPSLE. Cerebrovascular eventσ and seizures are the most common primary NP manifestations in SLE. The primary NPSLE is associated with accrual of irreversible damage and increased risk of developing additional NP manifestations.

AB0626 DIFFERENTIALLY EXPRESSED GENES (DEGS) OVERLAP AMONG BLOOD SAMPLES DATASETS FROM PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) THROUGH INTEGRATIVE BIOINFORMATICS METANALYSIS

Keywords: -Omics, Biomarkers, Systemic lupus erythematosus

R. Martinez[1], A. Gonzáles Godínez[1], I. Vasquez Tercero[2], C. Elizondo Solis[1], A. Montoya Rosales[3], M. Salinas Carmona[1], N. Macias-Segura[1].
[1]UANL - Escuela de Medicina, Immunology Department, Monterrey, Mexico; *[2]Universidad Nacional Autónoma de Honduras, Department of Physiological Sciences, Tegucigalpa, Honduras*; *[3]UANL - CIDICS, Immunomodulators Laboratory, Monterrey, Mexico*

Background: Systemic Lupus Erythematosus is an autoimmune chronic disease mainly characterized by the presence of auto-autoantibodies, and periods of flares and remission [1]. Understanding the mechanisms of physiopathology is still being the aim for several researchers. In the last 20 years multiple studies tried to look for molecular mechanisms associated to the disease using biomolecular techniques [2]. Specifically, the gene expression patterns play an important role in the pathophysiology of this disease, in which the interferon signature has been widely found in SLE patients, but also in other autoimmune diseases like rheumatoid arthritis and Sjögren's syndrome [3]. However, there is a discordance in which genes from the interferon signature are specific biomarkers for SLE, since there are multiple studies that describe the interferon signature but with different differentially expressed genes.
Objectives: We aimed to identify differentially expressed genes that overlap across different datasets of gene expression from blood samples of SLE patients using an integrative bioinformatics metanalysis.
Methods: We design a search strategy in the Gene Expression Omnibus platform to identify data sets of gene expression profile by array from blood samples of patients with SLA. The inclusion criteria were: 1) assays performed in humans, 2) the dataset include SLE patients and healthy controls, 3) expression profiling by array, 4) data analysis using GEO2R, 5) samples from blood. The exclusion criteria was: 1) incomplete information of the genes, 2) gene expression by RNAseq. Differentially expressed genes were selected when logfold change was >2 with p <0.05. Integrative bioinformatics strategy was applied. Using the platforms GeneMania and DAVID we identify overlapped genes among datasets and functional enrichment analysis of the differentially expressed genes.
Results: We selected 3 datasets that fulfill the inclusion criteria: GSE110174, GSE10325, and GSE154851. A total of 29 up-regulated genes were identified among datasets. Venn diagram shows 3 genes overlapped among all the datasets, and 1 or 2 genes overlapped between different pairs of datasets (Figure 1).

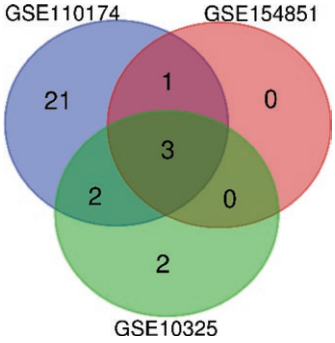

Figure 1. Venn diagram of the 3 datasets.

A prediction analysis yielded 20 co-expressed genes, that interact with the overlapped genes. A functional enrichment analysis yielded the 3 principal biological processes involving those genes: 17 genes participate in defense response to virus; 13 genes associated to response to virus; and 8 genes involved in negative regulation of viral genome replication (Table 1). Most of the genes identified belong to the interferon signature.

Table 1. Functional enrichment Analysis of the Co-Expressed genes.

Functional Enrichment Analysis		
Process	**Gene Count**	***p* Value**
Defense Response to Virus	17	8,1E-26
Response to Virus	13	1,8E-21
Negative Regulation of Viral Genome Replication	8	9,1E-14

Conclusion: We aimed to obtain upregulated genes and their co-expressed pairs through transcriptomic and functional enrichment analysis. 6 genes appeared upregulated across the 3 datasets, and 20 genes were listed as their co-expressed pairs. Those genes were involved in the processes of Defense Response to Virus, Response to virus, and Negative Regulation of Viral Genome Replication. These genes can serve as possible biomarkers for early diagnosis, and maybe even possible therapeutic targets.

AB0627 CLINICAL PROFILE OF PEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS IN A TERTIARY LEVEL HOSPITAL IN THE PHILIPPINES, YEAR 2015-2021

Keywords: Systemic lupus erythematosus

J. Garcia[1]. [1]*Region 1 Medical Center, Pediatrics, Dagupan, Philippines*

Background: Pediatric Lupus Erythematosus is a chronic systemic autoimmune disease with a higher risk of disease damage than adults with SLE.
Objectives: To profile the clinical and laboratory features and manifestations of pediatric SLE patients seen and admitted at Region 1 Medical Center from January 2015 to December 2021 and assess the association of the clinical profile with complications and mortality.
Methods: A retrospective review of medical records of all pediatric SLE patients age <18 years, admitted at Region 1 Medical Center from January 2015 to December 2021. Charts were reviewed for clinical and laboratory data extraction. Clinical data were analyzed using descriptive statistical analysis. Fisher's exact test was utilized to analyze the association of clinical profile to morbidity and mortality. Odds ratio was used to determine the degree and direction of association among significantly associated variables in the study.
Results: A total of 29 patients who fulfilled the inclusion criteria were included in the study. Average age of diagnosis is 16 years with predominance of female. The most common presenting symptom is malar rash(27.6%) followed by joint pains (10.3%) and pallor (10.3%). Patients with pediatric SLE commonly manifested with acute cutaneous rash(79.3%). Thrombocytopenia (69%) is the most common laboratory finding. Complications of SLE include renal (51.7), infection (27.6%), and cardiovascular (17.2%). Oral corticosteroid is the most common treatment which was administered to all participants. Mortality rate of 34.5% is associated to the most common cause which is SLE in activity (80%) followed by infection (60%). Neurologic manifestation and increase creatinine were found to be associated with mortality with odds ratio of >1.
Conclusion: Malar rash is the most common clinical presentation among Filipino pediatric SLE. The most common complication is renal involvement. Neurologic manifestation and non-scarring alopecia increase mortality.

AB0628 IMPACT OF SOLAR RADIATION FROM SUN EXPOSURE AND PHOTOPROTECTION PRACTICES ON DISEASE ACTIVITY AMONG SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS IN MALAYSIA

Keywords: Comorbidities, Systemic lupus erythematosus, Epidemiology

S. S. Shaharir[1], J. H. Jaafar2, C. L. Teh[3], S. A. Wan Akbar[3], C. Yaw Kiet[3], C. Seow Lin[3], B. Sachdev Manjit Singh[3], A. Jamil2, R. Mohd2, R. Mustafar2, S. Rajalingham2, M. S. Mohamed Said2, M. T. Latif[4]. [1]*Universiti Kebangsaan Malaysia, Faculty of Medicine, Internal Medicine, Cheras, Malaysia*; [1]*Universiti Kebangsaan Malaysia, Faculty of Medicine, Internal Medicine, Cheras, Malaysia*; [3]*Sarawak General Hospital, Medicine, Kuching, Malaysia*; [4]*Institute for Environment and Development (LESTARI), Universiti Kebangsaan Malaysia, Earth Sciences and Environment, Bangi, Malaysia*

Background: Systemic Lupus erythematous (SLE) is an autoimmune disease which is characterized by remission and flares. Experimental studies demonstrate that sun exposure can trigger immunomodulatory response, however, there is lacking of strong epidemiologic data regarding its role in triggering SLE flare. Malaysia has a tropical climate and hence get more exposure to the sun.
Objectives: To determine the correlations between disease activity with exposure to sun measured with solar radiation [1h (W/m^2)], and photoprotection practices among SLE patients in Malaysia.
Methods: This was a cross-sectional study involving SLE patients conducted in Universiti Kebangsaan Malaysia and Sarawak General Hospital from January 2019 until December 2019. During the study visit, disease activity was measured using Modified Systemic Lupus Erythematosus Disease Activity Index (M-SLEDAI) and The British Isles Lupus Assessment Group 2004 (BILAG). Sun Exposure and Protection Index (SEPI) was used to assessed their photoprotection practices, and patients who reported no change in their photoprotection practices for the last 2 years were included. A high SEPI score reflects an increased risk of sun exposure. Their medical records were also reviewed for retrospective assessments of the disease activity from the past 2 years (2017-2019). Clinic visits with presence of infection or recent change of immunosuppressive treatment of ≤ 3 months were excluded. Sun exposure was determined by calculating the average of daily solar radiation (mean) and the maximum solar radiation (max) within 30 days preceding the clinic visits. The hourly and daily solar radiation data was obtained from the Department of Environment (DOE) Malaysia. Correlations between the solar radiation mean, max and SEPI scores with M-SLEDAI and BILAG were determined using the Pearson's correlation coefficient correlation; while their associations with severe SLE flares (presence of BILAG A or B) were performed using Student's t-test. The associations between the effects of solar radiation and SEPI on M-SLEDAI and BILAG scores were analyzed using the generalized estimating equation (GEE) model, while considering fixed effects for repeated measures.
Results: A total of 87 patients were recruited with 514 clinic visits were recorded. There was significant correlation between the mean solar radiation with M-SLEDAI scores (rs=0.303, p<0.001). SEPI scores were significantly correlated with M-SLEDAI and BILAG scores (rs=0.098, p=0.03 and 0.421, p<0.001 respectively). Patients who had severe flare (BILAG A or B) had a higher exposure to the mean solar radiation (154.6 ± 35.9 vs 148.7 ± 19.1, p=0.011). In the GEE analysis, mean solar radiation and SEPI scores were still significantly correlated with M-SLEDAI scores; and significantly associated with severe flares p<0.05.
Conclusion: These results suggest that solar radiation has a significant impact on SLE disease activity and flare. Patients should be emphasized on the importance of photoprotection practices as this is one of the modifiable risk factors of active disease and flare.

AB0629 DEMOGRAPHIC, CLINICAL AND SEROLOGICAL CHARACTERISTICS OF SJÖGREN'S SYNDROME PATIENTS

Keywords: Real-world evidence, Sjögren syndrome

H. Baygin[1], G. Sargin[1], S. Cildag[1], T. Senturk2. *[1]Aydin Adnan Menderes University, Rheumatology, Aydin, Turkey*; *[1]Aydin Adnan Menderes University, Rheumatology, Aydin, Turkey*

Background: Sjogren's syndrome (SS); is a chronic multisystem inflammatory autoimmune disease characterized by dry eyes and mouth, involving lymphocytic infiltration of the lacrimal and salivary glands. Glandular involvement and extraglandular symptoms involving various organs and systems can be seen in patients. It can be seen in all age groups, although it is most common in those aged 45-50 years. The average female/male incidence rate is 9/1.

Objectives: Our aim in this study is to present the demographic, clinical and serological characteristics of patients diagnosed with SS.

Methods: Our study included 466 patients diagnosed with SS according to the 2016 ACR/EULAR Classification Criteria. Age, gender, primary/secondary SS status of the patients; organ involvement, salivary gland biopsy and serological features were recorded. Descriptive statistics were given as mean±standard deviation, frequency (n), and percent (%).

Results: The mean age of 466 (433 females, 33 males) patients in the study was 55.4±13.5 years. The female/male ratio was 13/1. There were 408 (87.5%) patients with primary SS diagnosis and 58 (12.5%) patients with secondary SS diagnosis. 67% of patients with a diagnosis of secondary SS had rheumatoid arthritis. The most common clinical presentation complaints were dry eye (86%) and dry mouth (67.8%). In our study, anti-nuclear antibody positivity was found to be 83.4%, rheumatoid factor positivity was 22.1%. Ro-52 antibody was positive in 56.4% of the patients. As a result of the evaluation in terms of organ/system involvement; pulmonary involvement was found in 45 patients (9.6%). Moreover; primary biliary cirrhosis in 18 (3.8%) patients, adrenal insufficiency in 1 (0.2%) patient, chronic tubulointerstitial nephritis in 2 (0.4%) patients, crescentic glomerulonephritis in 1 (0.2%) patient, optic neuropathy was found in 1 (0.4%) patient, and lymphoma was found in 1 (0.2%) patient (Table 1).

Conclusion: Sjögren's syndrome can affect almost any organ system, thus various systemic manifestations may occur. The disease is characterized by pleomorphic clinical manifestations, which can vary greatly in features and severity from one patient to another. Diagnosis of the disease is based on characteristic clinical signs and symptoms as well as specific tests including salivary gland histopathology and autoantibodies.

Table 1. Demographic, Clinical and Serological Characteristics of Sjögren's Syndrome Patients

	n	%

Background: Pregnancy in patients with systemic autoimmune diseases (SADs) are known to be at high risk for the occurrence of adverse pregnancy outcomes. Pre-conception counselling and risk stratification performed in a multidisciplinary clinical setting are essential for improving pregnancy outcomes and reducing maternal and perinatal complications in patients with SADs.
Objectives: To describe clinical, obstetric and maternal comorbidities and pregnancy outcomes in patients with SADs.
Methods: A retrospective cohort study was conducted. Inclusion criteria were patients diagnosed with SADs that were examined by the multidisciplinary pregnancy clinic. Clinical, maternal and obstetric variables were collected. The multidisciplinary team evaluated if the risk of pregnancy was high, moderate or low. Data related to pregnancy outcomes were also collected. Mean, standard deviation and proportions were calculated.
Results: A total of 41 patients interested in getting pregnancy attended our outpatient preconception clinic, with a mean age at first visit of 35.7±4.43 years. The ethnicity of the patients was: 75.6% Caucasian, 19.5% Hispanic and 4.9% Asian. Sociodemographic, clinical, treatment data, maternal and obstetric comorbidities are summarized in Table 1. Prior to preconception counselling, history of live births occurred in 61%, pregnancy loss in 32%, preterm birth in 10.5% and low-weight at birth in 11.7% of patients. 53.66% of patients were under treatment with c/tsDMARDs and/or bDMARDs and 19.5% with hydroxychloroquine. As much as 43.9% were taking ≤7.5 mg of prednisolone/day and 7.3% were taking >7.5 mg/day. After evaluation by the multidisciplinary pregnancy clinic, 51.2% of patients were classified as low risk, 39% as moderate and 9.8% as high risk for adverse pregnancy outcomes. The final assessment was conception without treatment changes for 46.3% of the patients, treatment changes before conception for 12.2%, postponement of pregnancy for 24.4% and 17% of patients were pregnant at their first visit. Of these women, 15 conceived (36.6%) after a median time of 6.25±4.5 months. Medical and obstetric complications occurred in 13% and 20% of the patients. Abortion occurred in 9.76%, preterm birth in 4.88% and low-weight at birth in 11.1% of patients.
Conclusion: 46% of patients attending our pregnancy outpatient clinic had a diagnosis of SLE. Out of the 41 patients assessed, 59% were advised to conceive and 12% were discouraged. 36.6% of patients were able to get pregnant, with a reduction in maternal and perinatal complications after preconception counselling. Well-planned pregnancies, adequate treatment and pre-conception evaluation will contribute to an improved outcome, both for the mother and the child.

AB0631 THE RELATIONSHIP OF LOWER URINARY SYSTEM SYMPTOMS WITH DEPRESSION AND ANXIETY IN PATIENTS WITH SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome, Patient reported outcomes, Descriptive Studies

N. Erdik[1], D. Karatas[1], G. Yavuzbilge[1], S. B. Acikgoz[1], S. M. Türk[1], C. Arslantürk Güneysu[1], E. Gönüllü[1]. [1]*Sakarya University, Rheumatology, Sakarya, Turkey*

Background: Sjögren's syndrome (SS) is a multisystem autoimmune disease characterized by hypofunction of salivary and lacrimal glands and possible systemic multi-organ manifestations [1]. The prevalence and severity of lower urinary tract symptoms(LUTS) are higher in autoimmune diseases such as SS [2,3]. Likewise, the prevalence of anxiety and depression is increased in patients with Primary SS [4].
Objectives: It was aimed to investigate the frequency of LUTS in patients with SS and to evaluate the coexistence of depression and anxiety in patients with and without LUTS.
Methods: Sixty-three patients, including sixty women diagnosed with Sjögren's Syndrome at Sakarya University Faculty of Medicine, Internal Medicine Rheumatology Department, were included in the study after their informed consent was obtained. All patients fulfilled the criteria for the 2016 ACR/EULAR Classification for Primary Sjögren's Syndrome. The International Prostate Symptom Score (IPSS) was used in the evaluation of LUTS, and the Beck Depression and Anxiety Scale were used for the assessment of depression and anxiety. Data were analyzed using the computer program SPSS 21. Relationships between categorical variables were evaluated with Chi-square analysis. The relationship between IPSS and Beck Depression/Beck Anxiety scale was assessed by spearman correlation analysis. p<0.05 was considered statistically significant.
Results: The mean age of the patients was 53.6±11.6 years. The median disease duration was four years (min-max: 0-40). 58 (92.1%) patients had at least one LUTS. Of the patients with LUTS, 32 (55.1%) were mild, 21 (36.2%) moderate, and 5 (8.7%) severe. Anxiety was found in 31 (49.2%) patients, and depression was found in 37 (58.7%) patients. The frequency of depression was significantly higher in patients with LUTS. Depression and anxiety were not observed in patients without LUTS. When the severity of LUTS was compared with the presence of anxiety and depression, a significant difference was found in both groups (p=0.033; p=0.032, respectively) (Table 1). There was a moderate positive correlation between the IPSS score and the Beck Depression and Beck Anxiety Scale (r:0.429 p:<0.001; r:0.481 p:0.001, respectively).

Table 1. Association of LUTS severity and anxiety/depression.

		Mild n (%)	Moderate n (%)	Severe n (%)	p value
Depression	Present	16 (50.0)	16 (76.2)	5 (100)	**0,032**
	Absent	16 (50.0)	5 (23.8)	0 (0)	
Anxiety	Present	13 (40.6)	16 (76.2)	2 (40.0)	**0,033**
	Absent	19 (59.4)	5 (23.8)	3 (60.0)	

Conclusion: In conclusion, questioning the presence of LUTS in patients with SS and referral for treatment may reduced the frequency of depression and anxiety.

AB0632 THE ASSOCIATION OF NEUROPATHIC PAIN WITH LOWER URINARY SYMPTOM SEVERITY IN PRIMARY SJÖGREN'S PATIENTS

Keywords: Descriptive studies, Patient reported outcomes, Sjögren syndrome

N. Erdik[1], A. Erdik[2], D. Karatas[1], G. Yavuzbilge[1], S. M. Türk[1], C. Arslantürk Güneysu[1], E. Gönüllü[1]. [1]*Sakarya University, Rheumatology, Sakarya, Turkey*; [2]*Sadıka Sabancı Hospital, Urology, Sakarya, Turkey*

Background: Primary Sjögren's syndrome(PSS) is a systemic autoimmune disease characterized by xerophthalmia and xerostomia and is associated with systemic visceral involvement. A wide variety of neurological complications also are characteristic features of PSS [1]. Patients with PSS can suffer from severe neuropathic pain with small fiber neuropathy.
Objectives: It is aimed to investigate the presence of neuropathic pain in patients with SS and to evaluate the severity of lower urinary tract symptoms (LUTS) in patients with or without neuropathic pain.
Methods: Sixty-two patients, including fifty-nine women diagnosed with Sjögren's Syndrome at Sakarya University Faculty of Medicine, Internal Medicine Rheumatology Department, were included in the study after their informed consent was obtained. All patients fulfilled the criteria for the 2016 ACR/EULAR Classification for Primary Sjögren's Syndrome. Neuropathic pain was divided into two groups, present and absent. International Prostate Symptom Score (IPSS) was used in the evaluation of LUTS and The Leeds Assessment of Neuropathic Symptoms and Sign Pain Scale (LANSS Pain Scale) was used for the assessment of neuropathic pain. Data were analyzed using the computer program SPSS 21. Relationships between categorical variables were evaluated with Chi-square analysis. The relationship between IPSS and LANSS Pain Scale was evaluated by spearman correlation analysis. p<0.05 was considered statistically significant.
Results: The mean age of the patients was 53.4±11.6 years. The median disease duration was seven years (min-max: 0-40). Neuropathic pain (LANSS Pain Scale>12) was observed in 18 (29%) patients. According to the LUTS questionnaire, 35(56.5%) patients were in the mild LUTS(IPSS<8), and 27(43.5%) patients were in the moderate and severe LUTS(IPSS≥8) group. The severity of LUTS was significantly higher in patients with neuropathic pain (Table 1). There was a moderate positive correlation between the IPSS score and the LANSS Pain scale (r=0.359 p=0.004).

Table 1. Association of LUTS severity and neuropathic pain.

	Neuropathic pain Present (n=18)	Neuropathic pain Absent (n=44)	p-value
IPSS<8	6 (%33.3)	29 (%65.9)	**0.019**
IPSS≥8	12 (%66.7)	15 (%34.1)	

Conclusion: In conclusion, LUTS should be questioned when neuropathic pain is observed in SS patients. Initiation of neuropathic pain treatment in SS patients may prevent the symptom severity of LUTS.

Background: Pregnancy in patients with systemic lupus erythematosus (SLE) are known to be at high risk for the occurrence of adverse pregnancy outcomes. Pre-conception counselling and risk stratification performed in a multidisciplinary clinical setting with rheumatologists, obstetricians and nephrologists are essential for improving pregnancy outcomes and reducing maternal and perinatal complications in patients with SLE.

Objectives: To describe clinical, obstetric and maternal comorbidities and pregnancy in patients with SLE and patients with other systemic autoimmune diseases (SADs).

Methods: A retrospective cohort study was conducted including patients diagnosed with SLE attending our multidisciplinary pregnancy clinic. Clinical, immunological and obstetric variables were collected. Data related to pregnancy outcomes, delivery and disease activity were also collected. Description of the sample and comparison of groups were carried out. Shapiro-Wilk test was used for variable distribution.

Preterm (n, %)	2 (10.5)	0	0.24
Low weight at birth (n, %)	2 (10.5)	0	0.24

Results: A total of 41 patients attended our outpatient preconception clinic. Comparison and description of the comorbidities, preconception counseling and pregnancy outcomes are summarized in Table 1. A total of 19 (43.2%) patients were diagnosed with SLE. Lupus nephritis was observed in 47% of the patients and 11% had received kidney transplant. Moderate SLEDAI activity (>4) was observed in 44.4%. There were 7 (37%) pregnancies after a mean time of 7.3±6 months since the first visit. SLE patients were significantly older when evaluated at the pregnancy clinic than patients with other SADs. Also, SLE patients exhibited a longer time since the last flare when evaluated at the pregnancy clinic. Significant differences were observed in treatment between both groups: more hydroxychloroquine, synthetic DMARDs and steroids were used in the SLE group. No significant differences in preconception counseling or adverse pregnancy outcomes were observed.

Conclusion: Patients with SLE took longer time since diagnosis and flare to seek pregnancy than patients with other SAD. No differences in pregnancy outcomes or risk profile were observed.

AB0634 BASELINE CLINICAL – EPIDEMIOLOGICAL CHARACTERISTICS OF THE PATIENTS IN THE IMMEX COHORT

Keywords: Descriptive studies, Systemic lupus erythematosus, Diagnostic tests

F. M. Bravo Rojas[1], M. Ocampo Torres[2], A. Ramirez Pérez[2], M. Vázquez Zaragoza[2], R. Catana Hernández[2], A. Martínez Badajoz[1], J. Hernandez Rivera[3]. *[1]ESM - Escuela Superior de Medicina - IPN, Social Service, Ciudad de México, Mexico*; *[2]XXI Century National Medical Center, Rheumatology Service, Ciudad de México, Mexico*; *[3]XXI Century National Medical Center, Nephrological Diseases Medical Research Unit, Ciudad de México, Mexico*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune inflammatory disease with a wide clinical and evolutionary spectrum. The correct classification and study of the behavior of this type of population helps to constantly improve the approach and prognosis of patients with this disease.

Objectives: Describe the clinical and epidemiological characteristics of patients with SLE included in a cohort in Mexico.

Methods: Retrospective descriptive observational study based on the clinical-epidemiological historical review on the day of inclusion in the LUPUS-IM-Mex registry. Normality tests were applied, the frequencies and percentages were calculated for the categorical variables and the means with their standard deviation or medians with interquartile range (IQR) for the continuous variables depending on their distribution. A comparison of compliance with diagnostic scores was made according to three classification criteria (ACR 1997, SLICC 2012 and EULAR 2019) according to the manifestations of each patient at the time of incorporation into the cohort.

Results: 121 patients with a diagnosis of SLE according to the 2019 EULAR (European League Against Rheumatism) criteria were included, a review of records from the period 2006 to 2022 was carried out. They were 33 years old (IQR 26–41), 81% were female, 87.6% came from the metropolitan area, 49.1% with a basic educational level. Median age at diagnosis 28 years (IQR 23-37). The time of evolution of the disease until admission to the registry was 3 years (IQR 1-5). 17.48% reported a family history of autoimmune diseases and 27.86% presented concomitant allergies to some drug. The patients underwent a comparison of the classification criteria at the first medical care contact, where it was found that 81.81% met the lupus criteria according to ACR, 94.21% by SLICC and 100% by EULAR. Regarding clinical manifestations, the presence of joint alterations was the most frequent, being present in 61.48% of the patients at the time of diagnosis, followed by mucocutaneous manifestations in 57.38%, hematological manifestations in 49.18%, renal manifestations in 45.90%, fever in 24.59%, serous in 21.31% and lastly neuropsychiatric manifestations in 4.92%. The presence of hypocomplementemia was the most frequent data (72.12%) followed by SLE-specific antibodies and finally antiphospholipid antibodies.

Conclusion: Patients with SLE at our center have both clinical and epidemiological characteristics like those reported by other cohorts. Renal involvement is greater compared to European cohorts but less than that reported in Asian cohorts. The correct and adequate classification of each patient is fundamental to improve the prognosis and correct diagnosis. Although the availability of data in our environment is limited, it is necessary to continue with the constant obtaining of information regarding the subject to be able to be on a par with international cohorts.

AB0635 HAEMATOLOGICAL MANIFESTATIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: REAL WORLD DATA FROM A CENTRE IN NORTHERN ITALY

Keywords: Systemic lupus erythematosus, Comorbidities, Descriptive studies

R. Borrelli[1], N. Rashidy[1], F. Meli[1], E. Saracco[1], F. Corradi[1], I. Badiu[1], S. Nicola[1], L. Lo Sardo[1], L. Brussino[1]. [1]*Mauriziano Umberto Hospital Emergency Room, Department of Medical Sciences,Torino, Italy*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disorder characterized by a variety of signs and symptoms; it manly affects women of childbearing age, with an estimated prevalence of 24/100,000 people in Europe and North America. Among other clinical manifestations, haematological involvement is one of the most common in SLE as it includes anaemia, leukopenia, lymphopenia, thrombocytopenia, lymphadenopathy and splenomegaly; furthermore, it is usually challenging to discriminate whether such manifestations are caused by disease or by immunosuppressants. To date, few studies tried to evaluate them using real world data.
Objectives: To evaluate haematological manifestations in patients with SLE by using real world data.
Methods: A retrospective study was performed by gathering real world data. 2019 EULAR/ACR Classification Criteria for SLE were used to discern haematological involvements in patients with a diagnosis of SLE; leukopenia, thrombocytopenia and autoimmune haemolytic anaemia (AIHA) were considered for this study. Six subgroups were formed as each condition alone and their combinations were analyzed. Logistic regression was used to calculate the odds ratio (OR) and a 95% confidence interval (CI) was chosen to assess statistical significance.
Results: One hundred and forty-two patients affected by SLE were enrolled in this study (N=142); among these, thirty met the inclusion criteria for haematological manifestations (n=30, 52 ±12.4 years, 28 F, 2 M). Three patients showed AIHA alone (10.0%), six had thrombocytopenia only (20.0%) and 8 displayed leukopenia alone (26.7%). Thirteen patients showed a combination as 6 people had both AIHA and thrombocytopenia (20.0%) and 4 manifested AIHA in association with leukopenia (13.3%); lastly, 3 patients showed thrombocytopenia with leukopenia (10.0%). The latter proved to be the most common manifestation as leukopenia was present in 15 out of 30 patients (50.0%) (Figure 4). Azathioprine (AZA), in association with hydroxychloroquine (HCQ), was used in 8 patients (26.6%), while a combination of Mycophenolate Mofetil (MMF) and HCQ was found in 5 out of 30 patients (16.7%); seventeen patients received either HCQ alone or a biologic drug (Belimumab). Among patients in therapy with AZA or MMF, the former proved to be more frequently associated with leukopenia vs MMF (OR_1=2.5); however, the result was not statistically significant ($CI_1$95% 0.77; 8;04); a similar result was observed for both patients in therapy with MMF or AZA when compared to HCQ alone or HCQ + Belimumab (OR_2=1.16, OR_3=0.46, respectively) since they did not reach statistical significance.
Conclusion: In this preliminary study, real-world data proved essential to analyze patients affected by SLE. Among many haematological manifestations, leukopenia showed to be the most frequent in agreement with data published in literature, strictly followed by thrombocytopenia and AIHA. AZA was linked with a higher percentage of leukopenia compared to MMF or other therapies but the result was not statistically significant. This study has some limitations (number of enrolled patients, possible selection bias) which require further evaluations to be properly assessed.

AB0636 FREQUENCY OF TROPICAL INFECTIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN A MEDIUM INCOME COUNTRY, USING DATA ANALYTICS TECHNIQUES

Keywords: Systemic lupus erythematosus, Artificial intelligence, Infection-related RMDs

A. Beltrán-Ostos[1,2], S. Moreno[3], J. S. Castro Villarreal[4], C. F. Valencia Arboleda[4]. [1]*Colombia, Cundinamarca, Bogotá, Colombia*; [2]*Riesgo de Fractura, Cayre IPS, Rheumatology service, Bogotá, Colombia*; [3]*Universidad de los Andes, Facultad de Medicina, Bogotá, Colombia*; [4]*Universidad de los Andes, Facultad de Ingenieria Industrial, Bogotá, Colombia*

Background: The co-occurrence of lupus (SLE) and tropical infections has been poor studied, this group of infections, prevalent in the tropics could simulate or trigger disease activity, however, some studies suggest that malaria infection could confer protection from the development of SLE, that is for this reason, studies are required to characterize this population.
Objectives: The objective of our study was to estimate de frequency of tropical infections in patients with SLE using administrative databases in Colombia.
Methods: This study was carried out using databases generated based on technical studies conducted by the Colombian Ministry of health. For the present study, databases provided contained information from 2014 to 2017, and contains the information of approximately 20 million affiliates. A person in the database was considered a patient with SLE if she met the following operative definition: a patient who has been classified with an ICD-10 diagnosis code which corresponds to SLE in an inpatient claim or if she has been classified at least two times in outpatient claims, with a difference of minimum 30 days and less than 2 years, with a ICD-10 diagnosis code corresponding to SLE. In turn, a control group matched by age and sex was randomly selected to evaluate the difference in the frequency of tropical infections in both groups. The variables considered in this part of the study were classified in two main groups: demographic, and clinical. Demographic variables include age, sex, and department (territorial entity). As for tropical infections we use the ICD-10 diagnosis code and to estimate the prevalence of tropical infections.
Results: Using the operative definition of SLE, 5527 patients were selected, and 22108 controls paired by sex and age, the average age was 43 years old in both groups, the frequency of tropical infections was low in both groups, however, we documented a higher frequency of malaria and dengue in the group of subjects with SLE when compared to controls.
Conclusion: SLE patients had similar frequency of tropical infections compared to matched controls, except for malaria and dengue infections.

AB0637 THE CLINICAL CHARACTERISTICS OF KOREAN PRIMARY SJÖGREN'S SYNDROME (PSS) PATIENTS WITH POSITIVE ANTI-DOUBLE-STRANDED DNA (ANTI-DSDNA) ANTIBODY BY THE FARR METHOD

Keywords: Sjögren syndrome

E. J. Kwon[1], B. W. Lee[1], Y. Park[1], J. J. Lee[1], S. H. Park[1], S. K. Kwok[1]. [1]*Seoul St. Mary's Hospital, College of Medicine, Catholic University of Korea, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Anti-Ro/SSA antibody is considered to play a crucial role in distinguishing the clinical features of pSS. However, the association of anti-dsDNA antibody on the characteristics and prognosis of pSS is not well known.
Objectives: We aimed to clarify the clinical characteristics of pSS patients presenting with positive anti-dsDNA antibody.
Methods: This retrospective study assessed 1255 pSS patients, fulfilling the classification criteria proposed by the American–European Consensus Group in 2002 or American College of Rheumatology/European League Against Rheumatism (EULAR) in 2016, who regularly visited Seoul St. Mary's Hospital between 2013 and 2021. Patients with other autoimmune diseases including SLE were excluded from this study. Of the total 1255 patients, 174 were in the anti-dsDNA antibody positive group (measured by using Farr assay, cut-off = 7 IU/ml) and 1081 were in the negative group. Data were compared between the two groups, including demographic features, extra-glandular manifestations (EGMs), clinical indices, and laboratory values at baseline.
Results: Patients in the anti-dsDNA (+) pSS group were younger (p = 0.015), and had higher proportion of positive finding in ocular staining score (OSS) by Sjögren's International Collaborative Clinical Alliance (SICCA) method (OSS ≥ 5) and minor salivary gland biopsy (Focus score ≥ 1) (p = 0.021 and p = 0.040, respectively). Among the EGMs, more frequent lymphadenopathy, lymphoma, pulmonary, cutaneous, renal, and CNS involvement were observed at baseline in the anti-dsDNA (+) pSS group. Total EULAR Sjögren's syndrome disease activity index (ESSDAI) scores were also higher in the anti-dsDNA (+) pSS group (median value [IQR]: 5.9 [5.1-6.7] vs 3.7 [3.4-3.9], p = 0.001). More frequency of leukopenia (p = 0.001), anemia (p = 0.001), rheumatoid factor positivity (p < 0.001), anti-Ro/SSA antibody positivity (p < 0.001), low C3 (p =0.024), low C4 (p=0.003) and hypergammaglobulinemia (p < 0.001) were found in the laboratory data in the anti-dsDNA (+) pSS group.
Conclusion: Korean pSS patients with positive anti-dsDNA antibody by Farr method showed distinct clinical characteristics at baseline including higher disease activity of SS, frequent several types of EGMs, and difference of laboratory data. Close monitoring for development of above clinical features in anti-dsDNA positive pSS patients is necessary.

AB0638 NEUROLOGICAL INVOLVEMENT IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME: A RETROSPECTIVE CROSS-SECTIONAL STUDY

Keywords: Sjögren syndrome

H. E. Konak[1], K. Gok[1], B. Armagan[1], S. C. Güven[1], E. Atalar[1], H. Apaydın[1], Y. Maraş[2], S. Erten[3]. [1]*Ankara City Hospital, Division of Rheumatology, Ankara, Turkey*; [2]*University of Health Sciences, Ankara City Hospital, Division of Rheumatology, Ankara, Turkey*; [3]*Yıldırım Beyazıt University, Department of Internal Medicine, Rheumatology Clinic, Ankara, Turkey*

Background: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease that primarily affects the exocrine glands and eventually leads to xerophthalmia and xerostomia [1]. Up to 75% of pSS patients may experience extraglandular involvement ranging from mild arthralgia to life-threatening vasculitis [2,3]. Neurological involvement, one of the most common extraglandular manifestations associated with pSS, is classified into two subgroups: peripheral nervous system (PNS) involvement and central nervous system (CNS) involvement.
Objectives: The aim of this study is to identify the types of PNS and CNS involvement in pSS patients, as well as to investigate any relationships between clinical and immunological features and neurological involvement.
Methods: We retrospectively assessed 2127 patients with an ICD-10 code for Sjögren recorded in hospital database.Among these patients, those meeting the pSS classification criteria and having neurological symptoms and an objective evaluation accordingly were enrolled.After comparing the patients with and without neurological involvement, peripheral and central involvement subtypes were also compared within themselves.
Results: A total of 199 pSS patients were enrolled and neurological involvement was found in 31.6%. Patients with neurological involvement had a higher frequency of Schirmer's test, anti-Ro/SS-A and anti-La/SS-B positivity and presence of interstitial lung disease, articular involvement, lymphadenopathy, anemia and hypocomplementemia than patients without those. In multivariate regression analysis, only articular involvement had a higher risk for the development of neurologic involvement [OR 10.01 (4.18–23.97), p0.0001]. Among the patients with PNS, the frequency of anti-Ro/SS-A positivity, low C3 and Schirmer's test positivity were statistically increased compared to those who were not in PNS (p=0.032, p=0.044, and p=0.029, respectively). In comparison to CNS involvement, patients with CNS involvement were younger, had a shorter disease duration, and had a higher frequency of anti-Ro/SS-A positivity than patients without those (p=0.041, p=0.027, and p=0.046, respectively).
Conclusion: In our study, it was shown that one third of the symptomatic pSS patients had objective neurological involvement. The presence of neurological symptoms should be considered, especially in patients with articular involvement in pSS.

Almasri[4], T. Alalwan[1], B. Alanazi[1], L. Almana[1], J. Su[5], H. Altaradi[2], K. Alhabib[2], H. Almalag[2,6], I. Almaghlouth[1]. *[1]King Saud University Medical City, Internal Medicine - Rheumatology, Riyadh, Saudi Arabia*; *[2]King Saud University Medical City, Cardiology Internal Medicine, Riyadh, Saudi Arabia*; *[3]King Saud University Medical City, Vascular Medicine, Riyadh, Saudi Arabia*; *[4]King Saud University Medical City, Cardiovascular Physiology, Riyadh, Saudi Arabia*; *[5]King Saud University Medical City, Biostation, Riyadh, Saudi Arabia*; *[6]King Saud University Medical CIty, Clinical Pharmacy, Riyadh, Saudi Arabia*

Background: Cardiovascular diseases represent a major contributor to the increased mortality. Risk factors varies according to the subtypes of cardiovascular events and perhaps racial background. Little is known about the risk of major cardiovascular events (MACE) in Saudi lupus Population.
Objectives: This study aim to examine the prevalence of MACE among Saudi SLE compared to general population and factors associated with such outcome.
Methods: This a cross-sectional study nested within two prospective cohorts to assess the period prevalence of any MACE among SLE patients who were enrolled in national prospective cohort of SLE, Saudi Arabia since its initiation in 2020. As a comparison, Prospective Urban Rural Epidemiology Study Saudi sub-cohort (PURE-Saudi) for participants who have been enrolled during the same follow up period. Participants in both studies were followed using standardized published protocol. MACE was defined as the diagnosis of Myocardial infraction, stroke or Angina. We adjust for demographics, traditional cardiovascular risk factors and the diagnosis of SLE using logistic regression models.
Results: A total of 488 with SLE and 746 from PURE were included. SLE patients were younger (40.7±12.5 compared to 49.5±8.6) and female predominant (90.6% compared to. 41.6%). Prevalence of traditional risk factors were less in SLE patients including dyslipidemia (28.9% compared to 49.4%), obesity (63% compared to 85%) diabetes (7.8% compared to 27.2%) but not HTN (19.3 compared to 18.8%). Odds of MACE were significantly related to Age and Lupus diagnosis (OR: 1.08, 95% CI: 1.04-1.11, p=0.00) and (OR: 7.64, 95% CI: 2.65-22.07, p=0.00) but not CVS risk factors (OR: 0.8, 95% CI: 0.10-6.39, p=0.83).
Conclusion: SLE patients at significant risk of MACE compared to general population. This risk is not well explained by traditional risk factors which may explain the failure of CVS risk scores to adequately stratify SLE patients. Further work is needed to understand the pathogenesis of CVS risk in SLE and subsequently mitigate it.

AB0641 CLINICAL BACKGROUND FACTORS RELATED TO SILENT OSTEONECROSIS OF THE FEMORAL HEAD UPON INITIATION OF STEROID THERAPY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Safety, Systemic lupus erythematosus, Organ damage

T. Kuroda[1], N. Tanabe[2], Y. Kurosawa[1], E. Hasegawa[1], A. Wakamatsu[1], H. Sato[1], D. Kobayashi[1], T. Nakatsue[1], Y. Wada[3], M. Nakanno[4], I. Narita[1]. *[1]Niigata University, Graduate School of Medical and Dental Sciences, Niigata city, Japan*; *[2]University of Niigata Prefecture, Department of Health and Nutrition, Faculty of Human Life Studies, Niigata, Japan*; *[3]Niigata Rinko Hospital, Department of Rheumatology, Niigata, Japan*; *[4]Nagaoka Chuo General Hospital, Department of Clinical Laboratory, Nagaoka-city, Japan*

Background: Osteonecrosis of the femoral head (ONF) occurs frequently (3-40%) in patients who are treated with corticosteroids for SLE. MRI can correctly visualize pathological abnormalities of the femoral head, and it is much more sensitive than plain radiography. To analyze the risk factors associated with steroid-induced ONF, it seems important to detect early changes in the femoral head by MRI and early clinical events caused by steroid therapy. For treatment of SLE, several strategies have been selected according to the clinical conditions of patients, and there are slight differences between multicenter hospitals. In this study, the treatment performed at

two hospitals, and the treatment strategy, selection of steroid, initial dose of steroid and drugs used together with steroid have been quite similar. Therefore, it should be possible to clarify the background factors associated with ONF.

Objectives: The purpose of this study were to clarify the factors related to silent ONF in patients with SLE and, in case of ONF, to clarify the clinical characteristics between unilateral and bilateral.

Methods: One hundred thirty-two patients (18 males and 114 females) with SLE were selected on the basis of having been newly diagnosed and requiring high-dose prednisolone, including pulse therapy with methylprednisolone, as the initial treatment. All the patients initially underwent plain radiography and MRI at the start of corticosteroids to detect any early changes in the femoral head. Subsequently these examinations were performed three months thereafter. The laboratory parameters were evaluated at the beginning of steroid treatment and at one month thereafter. All statistical analyses were performed with SPSS v. 13 (SPSS Inc., Chicago, IL, USA). Statistical tests were considered significant at a P (two sided) < 0.05, and marginal significant at P = 0.05–0.10. Tests were 2-tailed, and differences at p < 0.05 were considered significant.

Results: By three months after the start of corticosteroid treatment, asymptomatic ONF was diagnosed by MRI in 33 patients (25.0%), being bilateral in 21 patients and unilateral in 12. Serological activity (C3, C4, CH50 and anti-ds DNA antibody), renal function (eGFR, serum creatinine and urinary protein), anti-phospholipid antibodies, and SLEDAI were not correlated with asymptomatic ONF. BMI, BSA, and the initial dose of prednisolone per unit body weight, BMI and BSA were not correlated with silent ONF. Additionally, the occurrence of ION was not related to SLEDAI. However, patients with angiitis tended to increase the incidence of ONF (p=0.069). Patients with a higher triglyceride level both of before (p=0.002) and 4 weeks after the start of steroid treatment (p=0.004) and total cholesterol level 4 weeks after the start of steroid treatment (p=0.036) showed a significantly higher in patients with asymptomatic ONF. In patients with ONF, the level of creatinine clearance was tended to lower (p=0.062). In unilateral and bilateral studies, both anti-ds DNA antibody and C3 were not correlated. However, despite no difference in initial steroid dosage, CH50 was significantly lower and C4 was tended to lower in patients with unilateral ONF.

Conclusion: Asymptomatic ONF is common in patients with SLE. Both of high triglyceride and total cholesterol levels are important risk factors for ONF. In unilateral and bilateral studies, excess steroid dosage relative to serologic activity of SLE might contribute to the development of bilateral ONF. In the pathogenesis ONF, it was suggested that SLE activity and steroids are closely related.

Background: Salivary Gland ultrasound is a sensitive point of care investigation for the assessment of salivary gland dysfunction. It can be abnormal in patients with primary Sjögren's syndrome(pSS), Sarcoidosis, IgG4 disease, Systemic sclerosis, Infections and Tumors.

Objectives: To understand the utility of Anti-SSA, ANA and Anti-SSA/SSB and Salivary gland ultrasound for diagnosing primary Sjögren's Syndrome in patients with Sicca symptoms.

Methods: In the current study, In patients referred to the department of Clinical Immunology and Rheumatology, King George's Medical University, with Sicca Symptoms, a salivary Gland Ultrasound was performed and in those with abnormal ultrasound (Hocevar Score ≥1) Clinical and serological evaluation were performed. The Sensitivity and Specificity of Salivary Gland ultrasound with a Hocevar score ≥17 to diagnose primary Sjögren's Syndrome was assessed, and the utility of ANA, Anti-SSA and Anti-SSB positivity in patients with abnormal ultrasound was assessed.

Results: A total of 78 patients with sicca symptoms and abnormal salivary gland ultrasound (Hocevar Score ≥1) were included of these, 36 were diagnosed with primary Sjögren's syndrome and 42 with other diseases, including 12 with Rheumatoid arthritis, 8 with Systemic lupus erythematosus, 7 with systemic sclerosis, 4 with IgG4 related disease and 4 with Sarcoidosis. 7 patients did not have any autoimmune rheumatic disease after evaluation. The mean age of pSS patients was 36.42 ±11.68 and for non-pSS patients was 44.45 ±15.31. A Hocevar score ≥17 has a sensitivity and specificity of 80.56% and 78.57%, respectively. Adding ANA to the screening protocol improved the sensitivity but reduced the specificity while adding Anti-SSA to the screening protocol improved sensitivity, specificity, positive likelihood ration, accuracy and area under curve for diagnosing pSS.

Conclusion: Anti-SSA positivity and abnormal salivary gland ultrasound in patients with Sicca symptoms can be effective screening tools for diagnosis primary Sjögren's Syndrome.

Table 1. Performance of different Screening methods in pSS Screening

	Ultrasound	Ultrasound + ANA	Ultrasound + Anti SSA/ Anti SSB	Ultrasound + Anti SSA

AB0643 THE ANALYSIS OF RISK FACTORS FOR PRETERM BIRTH AND LOW BIRTH WEIGHT IN SLE PATIENTS WITH OR WITHOUT ATTAINED LLDAS AT THE CONCEPTION

Keywords: Systemic lupus erythematosus, Pregnancy and reproduction

H. Shimada[1], R. Wakiya[1], S. Nakashima[1], T. Miyagi[1], Y. Ushio[1], K. Sugihara[1], R. Mino[1], M. Mizusaki[1], K. Chujo[1], T. Kameda[1], H. Dobashi[1]. *[1]Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa, Japan*

Background: Women with systemic lupus erythematosus (SLE) have a higher risk for adverse pregnancy outcomes (APOs) including preterm birth (PB) and low birth weight (LBW) [1]. These APOs are revealed to be related to uncontrolled higher disease activity during pregnancy [2]. Currently, lupus low disease activity state (LLDAS), which is a comprehensive disease activity index, is suggested to be the treatment target to control damage accumulation. However, it is controversial whether achieving LLDAS during pregnancy can be a sufficient therapeutic target to prevent APOs.

Objectives: We analyze the risk factors for PB and LBW in SLE patients with or without achieving LLDAS at conception.

Methods: We used the data of SLE patients who have been treated at the planning for pregnancy from a single center cohort. We divided into LLDAS achieved

Table 1. Risk factor for PB and LBW with or without LLDAS achievement

	Achieved LLDAS			Not achieved LLDAS		
	PB (+) (n=5)	PB (-) (n=33)	P value	PB (+) (n=7)	PB (-) (n=12)	P value
Glucocorticoid use[##]	4 (80.0)	25 (75.8)	1.00	7 (100.0)	11 (91.7)	1.00

CH50, IU/l[#]	36.3±4.6	44.4±9.7	0.02*	36.8±10.5	41.1±10.3	0.36
Anti-dsDNA antibody, IU/l[#]	6.9±17.4	2.1±5.0	0.54	44.4±88.1	13.8±16.2	0.58

(Values are presented as mean ± standard deviation or number (%). [#]Wilcoxon rank sum test; [##]Fisher's exact test; *P < 0.05.)

group and LLDAS non-achieved group, and evaluated the rate of pregnancy outcomes, especially in preterm birth and low birth weight. We also analyzed the risk factors for PB and LBW from therapeutic agents (glucocorticoid use and their doses), and serum immunological parameters (C3, C4, CH50 levels and the titer of anti-dsDNA antibody).

Results: In 66 pregnancies complicated with SLE, 42 cases (63.6%) achieved LLDAS at conception, while the other 24 cases (36.4%) did not. Table 1 showed the risk factors for PB and LBW by analyzed separately for LLDAS attained group and not-achieved LLDAS group. As for PB, mean glucocorticoid dose became a risk factor in both LLDAS attained group and not-attained LLDAS group (P=0.02 and 0.01). In addition, only for the group that did not achieve LLDAS, serum C3 levels were associated with the rate of PB. On the other hand, in the group achieving LLDAS, glucocorticoid use, mean glucocorticoid dose, and serum CH50 levels were identified as risk factors for LBW in addition to serum C3 levels (P=0.04, <0.01, 0.02, and 0.045). None of these factors were associated with LBW in the SLE patients without LLDAS achievement.

Conclusion: We revealed that glucocorticoid dose during pregnancy was found to be a risk factor for PB, regardless of whether or not the LLDAS was achieved at conception. As for LBW, low levels of C3 and CH50 was shown to be a risk factor even if LLDAS could be achieved at conception. Therefore, it is important to control the immunological disease activity parameters strictly for improving pregnancy outcomes, even if LLDAS, a comprehensive disease activity index, is achieved at conception.

AB0644 OUTCOMES AND FACTORS PREDICTING MORTALITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ADMITTED TO INTENSIVE CARE UNIT

Keywords: Prognostic factors, Systemic lupus erythematosus, Descriptive studies

A. Gopalan[1], S. C. Veeravalli[1]. *[1]Krishna Institute of Medical Sciences, Rheumatology and Clinical Immunology, Hyderabad, India*

Background: SLE is a chronic autoimmune disease; the course of illness is interspersed with disease flares, infections, adverse drug events which may warrant intensive care admission. Outcomes and factors affecting mortality in these patients are not well established.

Objectives: The primary objective is to describe the outcomes and causes of mortality of SLE patients admitted to ICU. Secondary objective is to analyse factors associated with mortality.

Methods: Single centre retrospective observational study from Krishna Institute of Medical Sciences, a tertiary care hospital in South India. Patient with SLE admitted to intensive care unit due to any cause between 2016 and 2021 were included. Data was collected about the characteristics of disease prior to their admission to the ICU, as well as the clinical features, laboratory values and therapeutic measures during ICU stay. Statistical analysis was done with SPSS.

Results: Eighty seven patients were included in the study. Mean age was 33.16 ± 12.6 years and 87% were females. Most common causes for admission were infection in 51 (58%) and disease flare-up in 31 (35%) patients; 34 (39%) patients had a combination of disease flare and infection. Mean APACHE II score at admission was 17.32 and mean SLEDAI-2k score at presentation was 15.16. The mean duration of ICU stay was 6.02 ± 6.58 days. Mechanical ventilation was needed for 45 patients (51%), inotropic support in 36 patients (41%) and dialysis in 19 patients (21%). The mortality rate was 21% (19 cases), 18/19 patients had both very high disease activity and sepsis. Factors correlating with mortality (on multivariate analysis) included higher APACHE II score at presentation, presence of fever, acute kidney injury, low serum albumin, low hematocrit, low glasgow coma scale, sepsis, need for mechanical ventilation, inotropic support and renal replacement therapy.

Conclusion: Mortality rate in our study population was 21%, which is in line with observed trend in last 2 decades. The leading cause of admission to ICU in our cohort was disease flare resulting from poor compliance and infections. Mortality resulted from a combination of high disease activity with infection; a difficult to manage situation for the rheumatologist and the intensivist.

AB0645 PREVALENCE AND DESCRIPTION OF AUTOIMMUNE POLYENDOCRINE SYNDROMES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: EXPERIENCE OF A SINGLE CENTER

Keywords: Systemic lupus erythematosus, Comorbidities, Epidemiology

E. Piovani[1], G. I. Gozzoli2, P. Bizioli2, M. Taglietti2, M. Fredi2, C. Cappelli[3], F. Franceschini2. *[1]ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, Brescia, Italy*; *[1]ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, Brescia, Italy*; *[3]ASST Spedali Civili and University of Brescia, Endocrinology and Metabolism Unit, Department of Clinical and Experimental Sciences, Brescia, Italy*

Background: Autoimmune polyendocrine syndromes (APS) are a heterogeneous group of clinical conditions characterized by functional alteration of one or more endocrine glands and often associated with other systemic autoimmune diseases. Four types of APS have been described. APS-1 is a rare autosomal recessive disease due to mutation in the AIRE gene and characterized by at least two of the following manifestations: chronic mucocutaneous candidiasis, hypoparathyroidism and Addison's Disease (AD). APS-2 is characterized by AD associated with Diabetes Mellitus Type 1 (DM1) and/or autoimmune thyroid disease. APS-3 involves the association of autoimmune thyroiditis and other organic or systemic autoimmune manifestations, excluding hypoparathyroidism and AD. APS-4 is characterized by autoimmune activity against an endocrine organ in combination with at least one more endocrine or non-endocrine organ. In literature, data regarding prevalence and incidence of APS are poor, especially in the Rheumatology field.

Objectives: The primary objective of the work is to describe the prevalence of APS in a cohort of patients with Systemic Lupus Erythematosus (SLE) followed in our Department and to assess the possible association between organic autoimmune diseases and SLE. The secondary aim is to describe the timing of onset of the different autoimmune diseases and the presence of associated comorbidities and/or any feature that may predict the development of APS.

Methods: In this retrospective observational study we included the medical history, biochemical, and immunological data of patients older than 18 years of age with SLE who are actively followed at the Department of Rheumatology and Clinical Immunology of our hospital. Patients who, in addition to the diagnosis of SLE, had at least one other autoimmune disorder against an endocrine organ were included in the study.

Results: The total number of SLE patients examined is 423, with a mean age at the last evaluation of 53 (±13), 393 were female (93%) and 30 male (7%). Forty-eight patients (11.3%) have at least one other endocrinological autoimmune disease that would allow the diagnosis of APS. The sample examined is composed of 46 (96%) females and 2 (4%) males (F:M=23:1). The mean age of the patients is 52 (±14) years; the mean age of SLE onset is 36 (±14) years. No cases of APS-1 nor APS-2 were found; 45 (94%) patients are affected by APS-3; while 3 (6%) by APS-4. Forty-three (90%) patients presented two autoimmune diseases and 5 (10%) presented three autoimmune diseases. The mean age at onset of the first disease is 31 (±12) years; the second manifestation is 39 (±13) years and the third manifestation is 37 (±11) years. Concerning the timing of the onset, SLE was the first manifestation in 17/48 patients, the second manifestation in 25 patients, the third manifestation in 1 patient and in 5 patients the diseases were diagnosed at the same time. **Figure 1** shows the different conditions according to the time of onset. The mean latency between the onset of the first manifestation and the onset of the second is 9 (±9) years. The mean latency between the onset of the second manifestation and the onset of the third is 4 (±3) years.

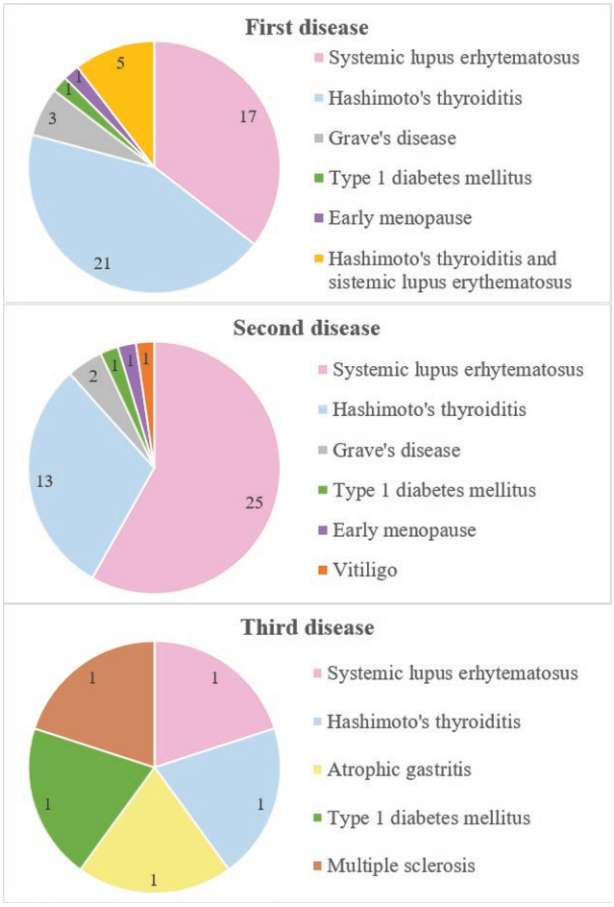

Figure 1. Time of onset of APS different pathologies

Conclusion: In our cohort of SLE patients, the prevalence of APS is quite high and occurs proportionally more in females than in males. Hashimoto's Thyroiditis (HT) is the most represented disease, followed by Graves' disease and DM1. In most cases, SLE is not the first autoimmune disease that appears in these patients. In most cases, the onset pathology is autoimmune thyroiditis. Furthermore, although the available data are scarce, in our cohort the latency between the onset of the first and second autoimmune pathology is significantly longer than the latency between the second and third manifestation.

CONCORDANCE OF THE DIAGNOSIS AND CLASSIFICATION OF SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Clinical trials, Autoantibodies, Systemic lupus erythematosus

C. Popescu[1,2], A. Minzararu[1,2], M. Agache[1,2], C. E. Ionescu[1,2], C. Codreanu[1,2]. *[1]"Dr. Ion Stoia" Clinical Center for Rheumatic Diseases, Rheumatology, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Rheumatology, Bucharest, Romania*

Background: Systemic lupus erythematosus (SLE) is a chronic, multisystemic autoimmune disease of unknown etiology. A defining characteristic is its immunological anomalies such as the production of antinuclear antibodies (ANA). Polymorphic clinical manifestations, the absence of pathognomonic signs and the absence of specific laboratory tests for SLE, make the diagnosis difficult. Although they have been developed for the homogenization of patients included in clinical trials, the SLE 2019 EULAR (European Alliance of Associations for Rheumatology)/ACR (American College of Rheumatology) classification criteria [1] can serve as a guide or diagnostic verification in individual cases from current medical practice.

Objectives: The study assessed the characteristics and consistency of the diagnosis and classification of SLE in order to measure a potential patient pool for inclusion in clinical trials.

Methods: The study retrospectively evaluated the conformity of the 2019 EULAR/ACR classification criteria in patients discharged from a single-center tertiary university rheumatology center between February 2020 and February 2022, diagnosed with SLE according to their attending rheumatologists and identified by international classification of diseases (ICD10) codes. Normally-distributed continuous variables are reported as "mean ± standard deviation". The correlation of continuous variables was studied with Spearman tests. Differences of continuous variables between nominal dichotomous subgroups were evaluated with Mann Whitney tests. Statistics were considered significant if $p < 0.05$.

Results: The study included 146 patients, of whom 92.5% were women, with an average age of 48.3 ± 13.3 years. Approximatively 7.5% of patients had negative ANA (including at repeated measurements) and 12.3% had an unknown ANA status. The method for determining ANA was ELISA (enzyme-linked immunosorbent assay; 75.3%), indirect immuno-fluorescence (2.7%) or undetermined (21.9%). Men scored a significantly higher median number of classification points than women (i.e., 21 points versus 16 points; $p = 0.020$) and they had a higher prevalence of class 3/4 nephritis (18.2% versus 3.0%; $p = 0.014$), pleuritis/pericarditis (36.4% versus 14.8%; $p = 0.064$) and oral ulcers (27.3% versus 9.6%; $p = 0.072$). Only 63.7% of SLE diagnoses also met the 2019 EULAR/ACR classification criteria. The most common manifestations not complying with these classification criteria were proteinuria (59.5% discordance), thrombocytopenia (13.6% discordance) and joint involvement (9.3% discordance). The median number of classification points correlated significantly with the median titer of ANA (*rho* = 0.301; $p = 0.001$) measured by ELISA.

Conclusion: Diagnostic reality includes ANA-negative SLE, which should be further investigated. In clinical practice, ANA are preferably determined by ELISA and their titer seems to be proportionally associated with more classifiable SLE clinical characteristics. Clinical trials have a maximum eligible SLE population of 63.7% of patients to whom additional inclusion/exclusion criteria could be applied.

THE SIGNIFICANCE OF A COMPREHENSIVE EXAMINATION OF DRY EYE DISEASE IN PRIMARY SJÖGREN SYNDROME AND ITS RELATIONSHIP TO EXTRAOCULAR MANIFESTATIONS

Keywords: Sjögren syndrome, Patient reported outcomes

G. Sevik[1], S. Akkaya Turhan[2], H. C. Yaşar[2], K. Abacar[1], A. Aliyeva[1], G. Mumcu[3], N. Inanc[1]. *[1]Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Marmara University School of Medicine, Department of Opthalmology, Istanbul, Turkey; [3]Marmara University School of Health Sciences, Health Management, Istanbul, Turkey*

Background: Inflammation of the lacrimal glands leads to ocular dryness, an important cause of decreased quality of life in primary Sjögren's syndrome (pSS) patients [1]. Limited data focuses on dry eye disease (DED) in pSS. Previous studies did not conduct a comprehensive evaluation of DED using tests to measure tear film volume or instability, ocular surface damage, meibomian gland dysfunction, and patient-reported outcomes, and the disease activity parameters were not compared with these ocular findings in pSS [2].

Objectives: The aim of this study is to conduct a comprehensive evaluation of DED features in pSS patients using various methods and compare them to pSS disease characteristics and activity.

Methods: Thirty-four patients classified as pSS according to 2016 ACR/EULAR classification criteria[1] that are followed up in rheumatology clinic were included

in the study. The patients had an ophthalmologic examination and DED evaluation on the day of their routine follow-up appointments. ESSPRI scores was recorded and laboratory tests, salivary flow rate and salivary gland ultrasonography(USG) scores of the patients were recorded from the patients' files. The ophthalmologic examination includes Schirmer's test, BUT, ocular surface staining (Oxford score), Marx's line, and noninvasive BUT (NIBUT) with the Scheimplug-Placido disk system. Ocular surface disease index (OSDI) and dry eye questionnaire-5 (DEQ-5) were used for patient-reported outcomes. The relationship between the pSS-related parameters and the ophthalmologic findings was evaluated.

Results: The patient characteristics are given in Table 1. According to the TFOS-DEWSII definition and classification report, all patients have definite DED [3]. The mean Schirmer's test, BUT, and NIBUT were 3.4±5.2 mm, 5.9±3.0 sec, and 5.9±3.9 sec, respectively. The mean OSDI score was 38.2±22.7, indicating severe DED symptoms, and the mean DEQ-5 score was 10.3±6.0. Oxford score was positive in 25 (73.5%) patients. Marx's line grading that shows meibomian gland dysfunction was 3.2±2.3. The mean ESSPRI score for dryness, pain, and fatigue were 6.5±2.1, 5.4±3.2, and 5.3±3.1, respectively. There was a significant positive correlation between the ESSPRI-dryness score and OSDI (p=0.001), DEQ-5 (p=0.004), and Oxford score (p=0.03).Also, there was a significant negative correlation between patient global assessment (PGA) of general health and DEQ-5 scores (p=0.007). And there was a significant positive correlation between PGA of disease activity and OSDI and DEQ-5 scores (p=0.02 and p=0.001). Although seventeen (50%) of the patients have decreased unstimulated salivary flow rate with a median of 0.16 (0.24) ml/min, no significant correlation was observed with DED. The results of salivary gland USG were present in 12 (35.2%) of the patients, and there were 7 patients with at least one gland with an OMERACT USG score ≥2. No significant difference was found between OMERACT USG score and DED parameters, although it remained within the statistical siginificant limit for OSDI score and OMERACT USG score ≥2 in the submandibular glands (p=0.054). There was no significant difference between the DED parameters and other pSS clinical parameters.

Conclusion: Patient-reported outcomes such as ESSPRI-dryness score, PGA of general health, and disease activity worsen as DED severity increases in pSS patients.

CYTOKINE AND CARDIOVASCULAR BIOMARKER PROFILES IN SOUTH AFRICAN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH SUBCLINICAL CARDIOVASCULAR INVOLVEMENT CHARACTERISED BY MULTIMODAL IMAGING

Keywords: Biomarkers, Heart, Systemic lupus erythematosus

T. M. Bana[1,2,3,4], M. Shey[5], P. Samuels[3,4], S. Jermy[3,4], S. Kraus[1,2,4], N. Ntusi[1,2,3,4]. [1]*Cape Heart Institute, University of Cape Town, Cape Town, South Africa*; [2]*Division of Cardiology, Department of Medicine, University of Cape Town, Cape Town, South Africa*; [3]*Cape Universities Body Imaging Centre, University of Cape Town, Cape Town, South Africa*; [4]*South African Medical Research Council Extramural Unit on Intersection of Noncommunicable Diseases and Infectious Diseases, University of Cape Town, Cape Town, South Africa*; [5]*University of Cape Town, Institute of Infectious Diseases and Molecular Medicine, Cape Town, South Africa*

Background: Cardiovascular disease (CVD) is a leading cause of morbidity and mortality in systemic lupus erythematosus (SLE). Traditional risk tools underestimate CVD risk in young SLE patients. Identification of biomarkers may have utility in predicting CV involvement in SLE.

Objectives: To profile cytokine and CV biomarkers, associated with immune activation, fibrosis, CV dysfunction, and myocardial and vascular injury, in ambulatory South African SLE patients with subclinical CV involvement.

Methods: SLE patients, without known CVD, were recruited from rheumatology clinics at an academic hospital in Cape Town, and compared to controls matched for age, gender and ethnicity. All patients underwent echocardiography, carotid Duplex ultrasound, ankle brachial index and cardiovascular magnetic resonance (CMR) to characterise early CV involvement. Blood samples were obtained and stored at -80°C. Commercially available sandwich high sensitivity (hs) ELISA and Luminex multiplex bead assays were performed according to manufacturer's protocols to quantify biomarkers. Continuous variables were compared using Independent Samples t Test or Mann Whitney U Test. Regression analysis determined the strength and direction of associations between variables using Spearman's correlation co-efficient.

Results: 49 SLE patients attending routine outpatient follow-up, and 24 controls, were enrolled. SLE patients were 35±9 years old; 90% were women; and predominantly of mixed (69%) or black African (27%) ancestry. Median disease duration was 5 (IQR:3-8) years and patients had moderate disease activity (SLEDAI-2K=7 [IQR:4-12]) and low damage scores (SLICC-DI=1 [IQR:0-1]). On CMR, a substantial proportion (86%) of SLE patients were found to have subclinical CVD, with predominantly myocardial (78%) and pericardial (27%) involvement. We observed that despite having low C-reactive protein levels (2.54mg/L vs 2.90mg/L, p=0.36), compared to controls, SLE patients had significantly increased cytokine responses, including IL 1B, IL 6, TNFa & IFNg levels (p<0.001 for all, Table 1). Markers of fibrosis were significantly different in SLE, showing elevations in TIMP 1 (p<0.001) and galectin-3 (p=0.016), and decreased levels of MMP-9 (p<0.001). On regression analysis, MMP 9 showed an inverse relationship to all CMR parameters of myocardial fibrosis, including native myocardial T1 time, extracellular volume fraction and late gadolinium enhancement percentage (Figure 1), albeit with low co-efficient values. There were no significant correlations between hs troponin T, N-terminal prohormone of brain natriuretic peptide (NT proBNP) and soluble ST2 with parameters of myocardial dysfunction nor did cytokines measured correlate with indices of disease activity. In addition, VCAM 1, a marker of vascular injury was significantly elevated in SLE (p<0.001) but did not correlate with carotid intima media thickness or ankle brachial indices. Similar to previous studies, adiponectin showed an inverse correlation with BMI, but did not correlate with any manifestations of subclinical CVD.

Conclusion: In this cohort of young South African patients with stable SLE and subclinical CVD, we found evidence of ongoing immune activation. Low MMP 9 levels may be an early signal of myocardial disease. Plasma biomarkers may be useful in predicting CVD in SLE but larger prospective studies in SLE patients with CVD are needed.

Table 1.

Cardiovascular biomarkers	SLE (n=49)	Controls (n=24)	P value
pg/ml	**median (Q1-Q3)**	**median (Q1-Q3)**	
hs TNFa	2 (1,32-2,93)	0,58 (0,35-0,98)	<0,001
hs IFNg	3,37 (1,74-5,46)	1,25 (0,40-2,69)	<0,001
hs IL 1B	0,73 (0,46-0,93)	0,32 (0,05-0,55)	<0,001
hs IL 6	2,20 (1,33-5,51)	0,90 (0,47-1,38)	<0,001
TIMP 1	30418 (29756; 31132)	27660 (24284-30294)	<0,001
MMP 9	34791 (18583-47858)	57451 (43422-65112)	<0,001
VCAM 1	930979 (708295-1484550)	489223 (397266-733182)	<0,001

AB0649 PERIPHERAL B CELLS IMMUNOPHENOTYING IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Keywords: Systemic lupus erythematosus, Cell biology, Biomarkers

C. DI Mario[1], V. Varriano[2], L. Petricca[3], A. Paglionico[2], M. R. Gigante[3], B. Tolusso[2], E. Gremese[1,2]. *[1]Fondazione Policlinico Universitario A. Gemelli, IRCCS, Immunology Research Core Facility, Rome, Italy*; *[2]Fondazione Policlinico Universitario A.Gemelli, IRCCS, Division of Clinical Immunology, Rome, Italy*; *[3]Fondazione Policlinico Universitario A.Gemelli, IRCCS, Division of Rheumatology, Rome, Italy*

Background: B cells play a central role in systemic lupus erythematosus (SLE) pathogenesis connecting innate with adaptative immunity.
Objectives: To investigate the peripheral blood B cell phenotype in a cohort of SLE patients with renal (LN-SLE) and non-renal (NR-SLE) involvement compared to healthy controls.
Methods: Ninety-nine SLE patients, 76 with active renal involvement (30 at disease onset-Early and 46 in whom LN occurred after the disease onset-Long) and 23 with non-renal disease (articular and/or cutaneous) were enrolled. Thirty-seven healthy controls were included. Clinical, laboratory and demographic data were collected at baseline and at 6 and 12 months of follow-up. Disease activity was recorded using SLEDAI-2K. The memory B cells immunophenotyping (IgD/CD27 classification) was analyzed in peripheral blood through flow cytometry. To clarify the role of key molecules in the B cells activation, IL-6 and BAFF serum levels were assayed by Enzyme-linked immunosorbent assay (ELISA).
Results: Studying the B cell subsets, a lower percentage of $CD19^{pos}$ and unswitched memory ($IgD^{pos}CD27^{pos}$) in the whole SLE cohort compared to controls (8.7±6.8% *vs* 10.5±3.5%; *p=0.002* and 10.7±13.7% *vs* 15.3±8.0%; *p<0.01,* respectively) was observed. In addition, we found higher levels of double-negative memory B cells ($IgD^{neg}CD27^{neg}$) and plasmablasts ($CD27^{pos}CD38^{pos}$) in SLE than in controls [($CD27^{neg}IgD^{neg}$ 10.3±8.3% *vs* 4.1±1.9%; *p<0.01*) ($CD27^{pos}CD38^{pos}$ 6.1±7.9% *vs* 1.0±0.5%; *p<0.01*)]. Furthermore, $CD19^{pos}$ negatively correlated with BAFF (R=-0.322; *p=0.01)*. No correlation was found between B cell subsets and the disease activity parameters. According to the organ involvement, LN-SLE and RN-SLE showed a lower percentage of $CD19^{pos}$, $IgD^{pos}CD27^{pos}$ and plasmacells and higher levels of $IgD^{neg}CD27^{neg}$ than controls [($CD19^{pos}$: LN-SLE:9.1±7.4% *vs* 10.5±4.6%; *p=0.005;* NR-SLE: 7.7±4.6%; *p=0.008*)($IgD^{pos}CD27^{pos}$:LN-SLE 10.4±14.9% *vs* 15.3±8.0%; *p<0.001;* NR-SLE: 11.8±8.6%; *p=0.006*) ($CD27^{pos}CD38^{pos}$: LN-SLE 7.5±8.4% *vs* 0.9±0.5%; *p<0.001;* NR-SLE: 1.6±2.2%; *p=0.001)* ($IgD^{neg}CD27^{neg}$: LN-SLE 10.6±8.5% *vs* 4.1±1.9%; *p<0.001;* NR-SLE: 9.6±7.3%; *p=0.006*]. According to the onset of renal symptoms, there were no differences in the distribution of the renal classes and in activity and chronicity indexes in the two groups. Analyzing the B cells subsets the Long-LN-SLE showed a lower percentage of $CD19^{pos}$ and unswitched memory ($IgD^{pos}CD27^{pos}$) compared to controls (8.6±6.5% *vs* 10.5±3.5%; *p=0.004* and 9.7±6.9% *vs* 15.3±8.0%;*p=0.001,* respectively) and higher levels of $IgD^{neg}CD27^{neg}$ (12.1±8.4%) than Early LN-SLE (8.3±8.3%;p=*0.027)*, NR-SLE (9.6±7.3%;p=*0.001)* and controls(4.1±1.9%;p<*0.001)*. Furthermore, a direct correlation was observed between serum IL-6 levels and SLEDAI in Long-LN-SLE patients (r=0.380; p=0.004).
Conclusion: Data on memory B cells immunophenotyping reveals a distinct B cells subset of SLE patients when compared to healthy controls, confirming an alteration of B cells subsets in SLE patients and strengthening the hypothesis of the pathogenetic role played by B lymphocytes in the course of LN. In particular, the higher levels of DN B cells observed in patients in which renal damage occurs after the onset of SLE reinforcing the data that these cells represents a B memory subsets characteristic of immune system overactivation conditions.

AB0650 PREVALENCE OF FATIGUE AND ITS IMPACT ON QUALITY OF LIFE IN THE PATIENTS WITH PRIMARY SJOGREN'S SYNDROME

Keywords: Quality of life, Sjögren syndrome

D. Das[1], G. Naidu2, S. Grover[3], V. Dhir2, S. K. Sharma2, A. Sharma2, S. Jain2, P. Deo2. *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, Internal Medicine II, Rheumatology, Chandigarh, India*; *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, Internal Medicine II, Rheumatology, Chandigarh, India*; *[3]Post Graduate Institute of Medical Education and Research, Chandigarh, Department of Psychiatry, Chandigarh, India*

Background: Among the extra-glandular symptoms in primary sjogren's syndrome (pSS), fatigue and pain are the most common. Fatigue is a poorly understood phenomenon with multi-faceted involvement. Therefore, it is important to assess the severity of fatigue and describe its various dimensions while assessing fatigue. On the other hand, fatigue is also one of the predictors of reduced health and quality of life in pSS.
Objectives: To assess fatigue by Fatigue Severity Scale (FSS) and Profile of fatigue (ProF) questionnaires and quality of life (QoL) with Health Assessment Questionnaire- Disability Index (HAQ-DI) and to know the association between the two in patients with pSS.
Methods: Patients fulfilling AECG 2002 and/or ACR-EULAR 2016 classification criteria for pSS were included in this prospective observational study between January 2021 to June 2022. Fatigue was assessed with FSS and ProF and QoL was assessed with HAQ-DI. Depression and somatoform disorder were assessed using PHQ9 and PHQ15 respectively. Associations with fatigue was compared using multivariate regression analysis. Written informed consent was obtained from all subjects included in the study and the study was approved by Institute Ethics Committee.
Results: Out of 125 patients, 114 (91.2%) were female and 11 (8.8%) were male with a female to male ratio of 9.6: 1. The median age at the time of inclusion into the study was 41(32-50) years. The median duration of the disease was 36 (12-60) months. The median ESSDAI and ESSPRI score were 2 (1-3) and 6 (2-9) respectively. Fifty seven (45.6%) patients had fatigue, defined as FSS of ≥4 and/or ProF ≥2 in either of the domains. Among the patients with fatigue, 12 (21%) patients scored less than 4 on FSS, 36 (63.1%) had mild fatigue, 7 (12.2%) had moderate fatigue and only 2 (3.5%) patients had severe fatigue. The mean FSS score in the cohort was 2.9 ± 1.5. The ProF mean scores were 2.7 ± 0.6 for somatic fatigue and 2.9 ± 1.3 for mental fatigue. The median HAQ-DI in patients with fatigue was significantly more compared to non-fatigue patients (0.1 vs 0.5; p <0.001; Figure 1). There was a positive correlation between fatigue score and HAQ-DI score (rpb = 0.36, n = 125, p = <0.001). The prevalence of depression and somatoform disorder were 15.2% and 28% respectively. The ESSPRI pain score, ProFAD Ocular & Oral dryness score and PHQ-9 score were positively associated with higher fatigue score.
Conclusion: Fatigue was seen in nearly half of the patients with pSS and patients with fatigue had impaired QoL as assessed by HAQ-DI. The pain, dryness and presence of depression are the predictors of fatigue in patients with pSS.

AB0651 INDIRECT HEALTH RELATED COST IN PSS PATIENTS IN RELATION TO SYMPTOM BASED ENDOTYPES

Keywords: Patient reported outcomes, Work-related issues, Sjögren syndrome

L. Deroo[1,2,3], H. Achten[1,2,3], K. De Boeck[2,3], F. Van den Bosch[1,2,3], D. Elewaut[1,2,3], I. Peene[1,2,3,4]. *[1]Ghent University, Faculty of Medicine and Health Sciences, Department of Internal Medicine and Pediatrics, Ghent, Belgium*; *[2]Ghent University, Center for Inflammation Research, VIB-UGent, Ghent, Belgium*; *[3]Ghent University Hospital, Department of Internal Medicine and Pediatrics, Rheumatology, Gent, Belgium*; *[4]AZ Sint-Jan, Rheumatology, Brugge, Belgium*

Background: Primary Sjögren's Syndrome (pSS) is characterised by oral and ocular dryness, possible development of systemic manifestations, increased lymphoma risk, and a highly diverse patient burden. To address this heterogeneity Tarn identified four endotypes based on patient-reported symptoms of dryness, fatigue, pain, anxiety and depression: low symptom burden (LSB), pain dominant with fatigue (PDF), dryness dominant with fatigue (DDF) and high symptom burden (HSB).(1)
Objectives: The aim of this study was to explore indirect health related costs in relation to symptom-based endotypes in a cohort of patients with definite and suspected pSS.
Methods: Data from the Belgian Sjögren's Syndrome Transition Trial (BeSSTT) were used in which patients positive for at least one of the 2016 ACR/EULAR classification criteria, were enrolled. Patients were considered 'definite pSS' when fulfilling these criteria, and 'suspected pSS' otherwise. The Newcastle Sjögren's Stratification Tool (NSST), developed and provided by Tarn et al., was applied to stratify the cohort into endotypes. Patients reported their current work status and sick leave in the past year and completed the Work Productivity and Activity Impairment questionnaire (WPAI).
Results: Application of the NSST tool resulted in 4 endotypes, both in definite (LSB n=23, DDF n=33, PDF n=82, HSB n=30) and suspected pSS (LSB n=14, DDF n=22, PDF n=48, HSB n=21). The majority of definite pSS patients were female (158, 88.8%) with a mean±SD age of 53.4±14.7, with no significant differences between endotypes (p=0.365 and p=0.415). Definite pSS LSB patients reported significantly less invalidity (p=0.020). A numerically higher proportion of working PDF and HSB patients reported part time employment due to health (p=0.063). However, reported working hours did not differ between endotypes. In contrast, HSB pSS patients reported significantly more productivity loss during their job than those with LSB and DDF endotypes (p<0.001), which led to a significantly higher total work impairment (p<0.001). In addition, definite pSS patients with HSB endotype reported significantly more productivity loss during daily activities besides their job (69%, p<0.001). No significant differences concerning job characteristics were observed between definite and suspected pSS patients with the same endotype.
Conclusion: Definite pSS patients with a HSB endotype encounter significantly more work impairment than those with other endotypes, which is due to a significantly higher productivity loss while working. In addition, these patients report significantly more productivity loss during daily activities besides paid work, which entails large indirect health related costs as pSS is a predominantly female disease. Moreover, the burden associated with the HSB endotype appears to influence work ability independent of a definite pSS diagnosis.

AB0652

HISTOLOGICAL RENAL FEATURES AND CYTOKINES ASSESSMENT AS POSSIBLE BIOMARKERS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND LUPUS NEPHRITIS

Keywords: Biomarkers, Cell biology, Systemic lupus erythematosus

V. Varriano[1], C. DI Mario[2], A. Paglionico[1], L. Petricca[3], M. R. Gigante[3], B. Tolusso[2], E. Gremese[1,2]. *[1]Fondazione Policlinico Universitario A. Gemelli IRCCS, Division of Clinical Immunology, Rome, Italy*; *[2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Immunology Research Core Facility, Rome, Italy*; *[3]Fondazione Policlinico Universitario A.Gemelli IRCSS, Division of Rheumatology, Rome, Italy*

Background: Lupus Nephritis (LN) management remains a challenge for the inadequacy of the traditional parameters in identifying more severe disease and preventing renal damage.
Objectives: To identify a multipanel biomarkers matrix, from histological to molecular level, aiming to improve prognostic stratification and therapeutic protocol of LN patients.
Methods: 45 SLE patients with active disease (age: 40.5 ± 11.0 years) at disease onset or at disease flare were enrolled. 6 patients with LN in persistent remission (R-LN) (age: 43.5 ± 11.9 years) were included as controls. 28 patients had an active LN and underwent ultrasound-guided renal biopsy while 15 patients with non-renal SLE (NR-SLE) displayed cutaneous or articular manifestations. Laboratory, immunological and disease activity data were collected at baseline and then at 6(T6) and 12(T12) months. Renal biopsies were evaluated according to ISN/RPS classification, assessing the activity and chronicity indexes and the active interstitial infiltrate (II) using the BANFF score system. Serum level of BAFF, IL-2, L-6, IL-17 and IFN-α were assayed in the study cohort by ELLA panel at each timepoint.
Results: Considering LN cohort, 66% of the renal biopsies belonged to class III and IV; 71.8% of LN patients had a II>5%. Performing univariate analysis for each renal outcome, focusing on histological assessment, a significant association between higher activity index and worse renal prognosis in terms of remission achievement at 12 months (*p= 0,04*), proteinuria and chronic renal damage development (*p= 0,04* and *p= 0,03* respectively) was observed. Through the ROC curve analysis, a cut-off value of activity index of 7.5 was identified (sensitivity 72.7%, specificity 66.7%) [AUC: 0.77; 95% CI, 0.56-0.98; p= 0.04] for remission achievement within 12 months and proteinuria development. Furthermore, LN patients with presence of II>5% were not only less likely to achieve early remission (*p= 0,04*) as well as those with at least one antiphospholipid antibody (ApL) positivity (*p= 0,05*), but displayed a worse renal outcome overall, though without reaching statistical significance. The analysis of circulating cytokines revealed that serum levels of IL-6 were significantly higher in patients with active disease as compared to R-LN patients, independently from renal involvement (LN: 7.6 ± 10.0 vs R- LN: 2.1 ± 2.1, *p=0.02*; NR-SLE: 11.4 ± 17.8 vs R-LN: 2.1 ± 2.1, *p=0.02*). Moreover, baseline serum level of IFNα was significantly increased in LN patients compared to R-LN (12.1 ± 36.8 vs 1.5 ± 3.6, *p=0.01*). Serum levels of IL-6 in LN patients positively correlated with disease activity index (R=0.819; p<0.001), and negatively with C3 (R= -0.608; p=0.003) and C4 (R= -0.675; p=0.01). Furthermore, serum levels of IL-6 were associated with histological severity being significantly higher in patients with II>5% (*p= 0.01*) and positively correlating with activity index (R=0.695; *p=0.01*). The evaluation of cytokines serum levels in relation to outcome achievement revealed that NR-SLE patients with favorable course had baseline higher serum level of IL-2 than those with active disease (0.6 ± 0.2 vs 0.1 ± 0.1, p=0.01). Finally, LN patients with higher serum levels of IL-6 during the follow-up were less likely to reach remission (3.7 ± 1.8 vs 2.1 ± 1.4, p=0.02) as well as LN patients with higher serum level of IL-17 (3.4 ± 8.0 vs 0.9 ± 0.3, p=0.01*).* In particular, higher baseline serum levels of IL-17 were observed in patients who developed persistent proteinuria than those who did not (2.3 ± 2.3 vs 0.7 ± 0.5, p=0.02) and tended to remain higher also during FU, together with IL-6 serum level.
Conclusion: II>5%, higher disease activity index and Apl+ represent in our study the strongest predictors of worse renal outcome, among traditional parameters. Higher IL-6 and IL-17 serum levels, at baseline and during FU, emerge as negative prognostic factor suggesting a possible role as biomarkers of more aggressive LN. IL-2 seems to have a protective role in extra renal disease.

SLE, Sjön's and APS - clinical aspects (other than treatment)

AB0653 PRESEPSIN IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL AND SEROLOGICAL ASSOCIATIONS

Keywords: Biomarkers, Systemic lupus erythematosus

O. Iaremenko[1], D. Koliadenko[1], K. Iaremenko[2]. [1]*Bogomolets National Medical University, Department of Internal Medicine #3, Kyiv, Ukraine;* [2]*Alexander Clinical Hospital, Laboratory Department, Kyiv, Ukraine*

Background: Presepsin (soluble CD14 subtype) is a newly recognized biomarker of sepsis. Recently it has been reported that presepsin levels are elevated in patients with systemic lupus erythematosus (SLE) without infection, possibly due to phagocytosis of neutrophil extracellular traps by monocytes/macrophages [1]. However, the clinical significance of presepsin in SLE remains uncertain [2].
Objectives: This study aims to evaluate the relation between serum presepsin levels and clinical manifestations, disease activity and laboratory parameters in SLE patients.
Methods: A total of 78 SLE patients (aged 38.9±12.8 years; 87.2% females) and 16 age- and sex-matched healthy controls were enrolled. Patients with infections were not included in the study. Serum presepsin levels were determined by ELISA and were analyzed in relation to SLE organ and system involvement, routine laboratory tests, inflammatory markers, serum complement levels, autoantibody spectrum, and the overall disease activity assessed by Systemic Lupus Erythematosus Disease Activity Index (SLEDAI). Mann-Whitney test, Spearman and Pearson correlation tests were used for statistical analysis.
Results: The median serum presepsin level was significantly higher in patients with SLE than in healthy controls (137 (95-197) pg/ml vs 66 (62-77) pg/ml, p<0.001). SLE males had higher presepsin concentration compared with females (180 (140-156) pg/ml vs 130 (90-170) pg/ml, p=0.02). Presepsin levels were significantly lower in SLE patients with involvement of skin (124 (84-157) pg/ml) and musculoskeletal system (111 (87-153) pg/ml) compared to those without such manifestations (164 (110-210) pg/ml, p=0.032 and 145 (122-175) pg/ml, p=0.041, respectively). However, SLE patients with fever (215 (170-1606) pg/ml vs 130 (93-166) pg/ml, p=0.004), nephritis (145 (110-197) pg/ml vs 102 (82-146) pg/ml, p=0.011), anemia (170 (126-280) pg/ml vs 130 (92-280) pg/ml, p=0.04) and thrombocytopenia (198 (170-280) vs 130 (92-161) pg/ml, p=0.049) had higher presepsin levels than those without such symptoms. Significant correlation was found between presepsin concentration and estimated glomerular filtration rate (r=-0.440, p=0.017). Presepsin levels did not correlate with white blood cell count, C3, C4, C-reactive protein, erythrocyte sedimentation rate and procalcitonin levels. Presepsin levels in patients with lupus nephritis significantly correlated with SLEDAI score (r=0.461, p=0.008) and anti-dsDNA levels (r=0.545, p<0.01); no such associations were found in SLE patients without kidney involvement.
Conclusion: Higher serum presepsin levels in SLE patients are associated with male gender, fever, kidney involvement, anemia and thrombocytopenia. Further research focused on clinical use of presepsin in SLE is warranted.

Background: The clinical utility of new antiphospholipid antibodies in cases of adverse obstetric outcomes is not well known[1].
Objectives: To assess the performance of antibodies against the phosphatidylserine prothrombin complex (IgM and IgG), onwards "anti-PS/PT" in preeclampsia or foetal growth restriction.
Methods: A case control study was performed in a private maternal general care unit. Cases were patients with preeclampsia or foetal growth restriction developed before the 37th weeks of gestation. The full sample was calculated in 92 cases and 192 controls. Controls were patients who were hospitalized in the third trimester of gestation, with age +/- 5 years old respect to the controls, without known autoimmune diseases or history of adverse obstetric outcomes. All patients were studied with general laboratory, doppler, classical antiphospholipid antibodies and anti-PS/PT IgG and IgM. We present demographic characteristics and media comparisons which were performed with T test. Categorical variables were compared with Chi square test or Fisher test if applicable. The statistical significance was established in 5% (p<0.05). Informed consent from the patients as well as approval from the institutional ethics committee were obtained.
Results: Two hundred and eighty-four pregnant women were included (192 controls and 92 cases). Demographic and clinical data of the groups are presented in Table 1. The median (IQR) anti-PS/PT IgM titles were 8 (8) MPL U/ml in cases and 9 (9) MPL U/ml in controls, p>0,05. Regarding to anti-PS/PT IgG test, the median (IQR) titles were 5.5 (3) GPL U/ml in cases and 5 (5) GPL U/ml in controls, p>0,05
Conclusion: We did not find association between ant-PS/PT both IgG or IgM in cases of foetal growth restriction or preeclampsia. It is worth to note that this study was performed in a general care maternity, therefore, high risk cases were not included. Further analysis may show the utility of this biomarkers in obstetric adverse pregnancy outcomes management, particularly in other contexts as recurrent pregnancy loss, foetal death, or early severe preeclampsia[1,2].

AB0655 PREVALENCE AND RISK FACTORS ASSOCIATED WITH THROMBOCYTOPENIA IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AT HOSPITAL DEL MAR

Keywords: Descriptive studies, Anti-phospholipid syndrome, Systemic lupus erythematosus

J. Cornudella Lema[1,2], I. Carrión Barberà[3], F. Garacia Pallarols[4], B. Sánchez González[4], T. C. Salman Monte[3]. [1]*Universitat Pompeu Fabra, School of Medicine, Barcelona, Spain*; [2]*Universitat Autònoma de Barcelona, School of Medicine, Bellaterra, Spain*; [3]*Hospital del Mar, Rheumatology, Barcelona, Spain*; [4]*Hospital del Mar, Hematology, Barcelona, Spain*

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease with a variety of manifestations, one of which is immune thrombocytopenia (ITP). Immune thrombocytopenia has been reported in 7-40% of SLE patients [1,2].
Objectives: To determine the prevalence of ITP in SLE patients and identify risk factors that correlate with ITP.
Methods: Retrospective case-control study. 407 medical records of SLE patients were reviewed: 34 patients were diagnosed with ITP (cases) and were age- and

sex-matched with 2 controls with SLE without ITP. Differences between cases and controls were analysed as well as factors associated with ITP.

Results: ITP prevalence in our cohort was 8.35% and was diagnosed at age 43.35±17.70 years (mean±st dev). No significant differences were found in demographic variables. At lupus diagnosis, controls had a higher prevalence of arthritis (p-val= 0.02), while cases presented a higher proportion of haemolytic anaemia (p-val=0.04). Along SLE disease, cases had higher antiphospholipid syndrome (APS) antibodies (lupus anticoagulant, p-val=0.01; anti-cardiolipin, p-val=0.044, anti-β2GP1, p-val=0.003). Cases presented a significantly higher SLICC than controls (p-val=0.02). Regarding treatments, cases received mycophenolate (p-val=0.02) and azathioprine (p-val=0.045) more frequently than controls.

Table 1. Characteristics of cases and controls.

VARIABLES	CASES (34)	CONTROLS (68)	P-VAL
Photosensitivity[a]	13/34 (38.2%)	37/68 (54.4%)	0.14
Arthritis[a]	17/34 (50.0%)	50/68 (73.5%)	0.02 (*)

Raynaud's phenomenon[a]	1/34 (2.9%)	10/68 (14.9%)	0.09
Low C3[a]	13/32 (40.6%)	14/64 (21.9%)	0.09
Low C4[a]	7/31 (22.9%)	6/64 (9.4%)	0.11
Low CH50[a]	5/31 (16.1%)	4/61 (6.7%)	0.15
Antinuclear antibodies[b]	34/34 (100%)	68/68 (100%)	1
Anti-dsDNA[b]	20/34 (58.8%)	41/68 (60.3%)	1
Anti-RNP[b]	5/33 (15.2%)	20/67 (29.9%)	0.14
Anti-cardiolipin[b]	15/33 (45.5%)	17/68 (25.0%)	0.04 (*)
Anti-β2GP1[b]	13/33 (39.4%)	8/66 (12.1%)	0.003(*)
Lupus anticoagulant[b]	10/33 (30.0%)	6/66 (9.1%)	0.01 (*)
Actual SLEDAI[c,d]	2.12 (Min=0, Max=13)	1.75 (Min=0, Max=12)	0.20
Actual SLICC[c]	1.12 (Min=0, Max=6)	0.41 (Min=0, Max=3)	0.02 (*)
Corticoids[e]	23/34 (67.7%)	48/68 (70.6%)	0.82
Mycophenolate[e]	14/34 (41.2%)	12/68 (17.7%)	0.02 (*)
Azathioprine[e]	9/34 (26.5%)	7/68 (10.3%)	0.045 (*)
Rituximab[e]	6/34 (17.7%)	3/68 (4.4%)	0.06

(*) Indicates statistically significant differences between cases and controls (level of confidence 95%). [a] Clinic and biochemical parameters at SLE diagnosis. [b] Immunologic parameters along SLE course. [c] Indicates mean and range. [d] SLEDAI-1 in cases. [e] Treatments along SLE course. Anti-β2GP1: Anti- β2-Glycoprotein 1. SLEDAI: SLE disease activity index. SLICC: SLE damage index

Conclusion: Patients with SLE that develop ITP seem to have a different phenotype than those without ITP, presenting less arthritis and more haemolytic anaemia at SLE disease onset, and more APS syndrome and APS antibodies along the disease. In addition, ITP was associated with a higher SLICC and with more frequent use of mycophenolate and azathioprine, possibly indicating a more severe disease, which would warrant the need of a more careful follow-up on these patients in the patients with the previously described associated characteristics.

AB0656

PERFORMANCE OF CONVENTIONAL CARDIOVASCULAR RISK SCORES IN IDENTIFYING SUBCLINICAL ATHEROSCLEROSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Autoantibodies, Cardiovascular disease, Systemic lupus erythematosus

G. Ms[1], C. Kavadichanda[1], N. Haridas[2], J. Singh[3], C. Mariaselvam[1], A. Gopal[1], M. M. Thabah[1], V. Negi[4]. *[1]JIPMER, Clinical Immunology, Pondicherry, India; [2]Stanley Medical College, Nephrology, Chennai, India; [3]JIPMER, Undergraduate Trainee, Pondicherry, India; [4]AIIMS, Bilaspur, Executive Director, Bilaspur, India*

Background: Cardiovascular disease (CVD) is a major cause of mortality in systemic lupus erythematosus (SLE) with a standardized mortality ratio of 2.4, that is underestimated by conventional CVD risk scores. Subclinical atherosclerosis, a major predictor of cardiovascular morbidity is an important target for primary prevention. Carotid intima media thickness (cIMT) and plaques are frequently used measures of subclinical atherosclerosis. Role of conventional risk scores which look at cardiovascular events, in assessment and risk stratification of subclinical atherosclerosis in SLE is not fully established.

Objectives: Assess performance of QRESEARCH database risk score-3 (QRISK3), systemic coronary risk evaluation (SCORE) and WHO (World Health Organization) CVD risk scores in assessing subclinical atherosclerosis in SLE and healthy controls. Compare SLE disease parameters between those with and without subclinical atherosclerosis.

Methods: This is a single centre cross-sectional analytical study. 79 patients with SLE without CVD and 76 age and gender matched healthy controls were enrolled. Demography, disease activity indices, autoantibodies, steroid dose were noted. Subclinical atherosclerosis (any carotid plaque or abnormal cIMT) was assessed. CVD risk was calculated by QRISK3, SCORE and WHO scores. Sensitivity, specificity, positive and negative predictive values were assessed. Agreement between scores was determined using kappa coefficient. Presence of subclinical atherosclerosis was compared with SLE disease manifestations.

Results: Subclinical atherosclerosis was seen in 52% of SLE (abnormal cIMT in 47% and carotid plaque in 8%) and 53% of healthy controls (abnormal cIMT in 47% and plaque 12%). Mean age of SLE and controls was 45±6 and 46±6 years respectively with 99% females. Average SLE duration was 96±64 months, SLEDAI was 1 ±2.3 and median SLICC ACR DI was 1 (0-2). SCORE, WHO and QRISK3 had a sensitivity of 0%, 10% and 28% in detecting subclinical atherosclerosis in SLE, 20%, 22% and 5% in controls while specificity was 0%, 82% and 79% in SLE and 97%, 91% and 100% in controls respectively. Kappa agreement was 0 for SCORE with others, 31% between QRISK3 and WHO 68% for plaque and 31% for cIMT in SLE. In healthy controls Kappa agreement was 0 for SCORE with others, 0 between QRISK 3 and WHO 15% for plaque and 31% for cIMT. SLE disease parameters were comparable among those with and without subclinical atherosclerosis. Anticardiolipin IgG (14.6% vs 2.6%) and any APLA positivity (41.5% vs 21%) were numerically higher in SLE with atherosclerosis but not statistically significant (p >0.05).

Conclusion: Sensitivity of conventional CVD scores in detecting subclinical atherosclerosis was very poor in SLE with QRISK3 and WHO score having good specificity. Hence until further scores are validated, screening for subclinical atherosclerosis using carotid ultrasound remains gold standard.

Table 1. Comparison of disease parameters among SLE patients with and without Subclinical Atherosclerosis

	SC Atherosclerosis n=41	No SC atherosclerosis n=38	P Value
Age years (Mean± SD)	42±6	45±6.1	0.38

VALIDITY OF THE SLE DISEASE ACTIVITY SCORE (SLE-DAS) IN A COHORT OF EGYPTIAN JUVENILE-ONSET SLE PATIENTS

Keywords: Systemic lupus erythematosus

B. M Medhat[1], M. Behiry[2,3], Y. Farag[4], A. Afifi[1], H. Ramadan[2], W. A Hassan[5], N. Mostafa[4]. *[1]Faculty of Medicine Kasr Al-Ainy, Cairo University, Rheumatology and Rehabilitation Department, Cairo, Egypt; [2]Faculty of Medicine Kasr Al-Ainy, Cairo University, Internal Medicine and Rheumatology Department, Cairo, Egypt; [3]Armed Forces College of Medicine, Internal Medicine Department, Cairo, Egypt; [4]Faculty of Medicine Kasr Al-Ainy, Cairo University, Pediatric Rheumatology Department,*

Cairo, Egypt; [5]*Faculty of Medicine Benha University, Rheumatology, Rehabilitation, and Physical Medicine Department, Benha, Egypt*

Background: Juvenile-onset SLE patients (JSLE) are commonly characterized by a more severe and deleterious disease. Hence, treating-to-target is crucial to attain favorable outcomes, and it relies on several factors including optimal disease activity assessment. However, data about evaluating disease activity in JSLE patients is mostly extrapolated from adult-onset patients, with data about the validity of the SLE-DAS[1] among JSLE patients lacking, to the best of our knowledge.
Objectives: Assess the SLE-DAS as a potential activity assessment tool among JSLE patients.
Methods: This cross-sectional study included 108 JSLE patients (≤16 years) managed at the rheumatology departments of Cairo University in November 2022. Adult patients with juvenile onset were not included. The SLEDAI-2K[2] was set as the gold standard. The SLE-DAS was measured through its online designed calculator (http://sle-das.eu/?)[3]. Validity and agreement between the SLE-DAS and the SLEDAI-2K were assessed through Spearmen's rho correlation and Bland-Altman plot, respectively. The correlation between both scores was evaluated among patients with and without high disease activity (HDA ≥10)[4]. Damage was measured utilizing the SLICC/SDI[5].
Results: Of 108 patients, 95 (87.9%) were females. Age at onset and assessment were 9.8 ± 2.6 and 10.8 ± 2.4 years, respectively; whereas the mean disease duration was 43.8 ± 28.1 months (Median: 36). The most common cumulative manifestations included constitutional (71.8%), renal (65%), hematologic (55.1%), and mucocutaneous (47.6%) involvement. Serositis, arthritis, and neuropsychiatric manifestations were present in 35.5%, 27.3%, and 24.5% patients, respectively. The mean SLEDAI-2K was 14.4 ± 6.8 (Median: 14), whereas the mean SLE-DAS was 25.3 ± 14.4 (Median: 23.3). 80 (74%) patients demonstrated HDA. There was a significant correlation between both the SLE-DAS and SLEDAI-2K (rho = 0.24; p=0.001). There was a significant, yet lower, positive correlation (rho= 0.24; p = 0.03) between the two scores among patients with HDA, whereas there was no significant correlation between them among those with lower disease activity [rho = - 0.2; p = 0.19]. The mean difference of agreement between both scores was 9.3 + -1.02*Average-of-Scores [Bland-Altman plot (Figure 1)]. Cross-sectionally, there was a significant correlation between the SLICC/SDI and both the SLEDAI-2K (p = 0.001) and SLE-DAS (p < 0.0001).
Conclusion: Our preliminary findings denote that the SLE-DAS could be utilized to assess disease activity among JSLE patients. Yet, its implementation among JSLE patients with lower levels of disease activity should be carefully interpreted.

PREVALENCE AND ASSOCIATION OF AUTOANTIBODIES WITH LATENT TUBERCULOSIS IN FIRST-DEGREE RELATIVES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Autoantibodies, Systemic lupus erythematosus

G. Ms[1], A. Narayanan[2], C. Kavadichanda[1], M. M. Thabah[1], S. Sarkar[2], P. B. Narasimhan[1]. [1]*JIPMER, Clinical Immunology, Pondicherry, India*; [2]*JIPMER, Preventive and Social Medicine, Pondicherry, India*

Background: Systemic Lupus Erythematosus (SLE) patients have a higher risk of tuberculosis (TB). Detection of latent TB (LTBI) by mycobacterium tuberculosis (TB) IFN-γ release assay (TB-IGRA) is an important step to retard progression to overt TB. Among IGRA positive persons, studies have noted a dose-response relationship, where those with lower baseline levels IFN-γ have lesser risk of progression to over TB. A family history of SLE exerts an increased risk of other autoimmune diseases. Although several studies reported autoantibodies in first-degree relatives (FDR) of SLE patients, association between LTBI and antibodies is not clear. The current study focused on the role of antibodies and LTBI in FDRs of SLE.
Objectives: Study the prevalence of autoantibody levels and LTBI in FDRs of SLE. Evaluate whether seropositivity of autoantibodies confers any risk of TB.
Methods: This is a single centre cross sectional study. FDRs of SLE with no past h/o TB were recruited (n=167). Demography, comorbidity and various autoantibodies were measured by Enzyme Linked Immunosorbent Assay. LTBI was assessed using TB-IGRA. Based on the results of TB-IGRA and seropositivity to antibodies, FDR were divided into 4 groups- Autoantibody positive and negative groups with and without LTBI. Basal IFN-γ and Mtb antigen specific IFN-γ levels were assessed in the unstimulated and Mtb antigen stimulated tubes.
Results: In FDRs, prevalence of autoantibodies and LTBI were 24.5% (n=41) and 25.7% (n=43) respectively. Seropositivity of various autoantibodies were comparable between those with and without LTBI. Among the antibody positive FDR, prevalence of LTBI was 34%, which is higher than the general population cohort. Next, we measured the basal IFN-γ levels in the 4 groups, where the IGRA and autoantibodies positive group had significantly (p=0.014) reduced levels of basal IFN-γ compared to IGRA positive antibody negative group. In the Mtb specific antigen tubes also, the antibody and IGRA positive group showed significantly reduced response compared to the IGRA positive and autoantibody negative group.
Conclusion: The present study showed higher prevalence of LTBI (34%) in the antibody positive FDRs of SLE. Basal and stimulated levels IFN-γ were lower in antibody positive group in contrast to SLE patients who have higher basal IFN-γ. Further longitudinal studies would be required to see the effect of these autoantibodies on LTBI and the risk of progression to TB.

AB0659 **EXTREMELY LOW FREQUENCY OF CHRONIC HEPATITIS B INFECTION IN SYSTEMIC LUPUS ERYTHEMATOSUS**

Keywords: Clinical trials, Systemic lupus erythematosus

Z. Ademoğlu[1], U. İlgen[1], K. Erol Kalkan[1], N. S. Yasar Bilge[2], T. Kaşifoğlu[2], H. Emmungil[1]. *[1]Trakya University Faculty of Medicine, Department of İnternal Medicine Divison of Rheumatology, Edirne, Turkey*; *[2]Eskişehir Osmangazi University Faculty of Medicine, Department of İnternal Medicine Divison of Rheumatology, Eskişehir, Turkey*

Background: There are few studies evaluating the frequency of chronic hepatitis B virus (HBV) infection in systemic lupus erythematosus (SLE) patients (1).
Objectives: Aim of this study is to determine the HBV seroprevalence in SLE patients and to compare it with normal population and patient control groups (rheumatoid arthritis and spondyloarthritis).
Methods: HBV serology tests [hepatitis B surface antigen (HBsAg), hepatitis B surface antibody (HBsAb), hepatitis B core antibody (HBcAb)] performed during the diagnosis of 278 SLE patient and the control group [consist of 125 rhomatoid arthritis (RA) and 125 spondhyloarthritis patient (SpA)] were analyzed retrospectively between 2005-2022 in two different centers. Patients with SLE responding to the 2019 ACR/EULAR criteria were included. HBV serology characteristics of SLE patients were compared with those of the normal population and control groups. The categorical data were presented as numbers (in percent). The chi-square test or Fisher's exact test was used to analyze the categorical variables. We compared 95% confidence intervals (95% CI) for the HBV infection rate of each variable; 95% CI which did not overlap were considered as statistically significant. Statistical significance was considered as p<0.05.
Results: HBsAg was positive in 2/278 (0.7%) in SLE patients, 6/125 (4.8%) in RA patients, and 9/125 (7.2%) in SpA patients. HBsAg positivity rate in SLE patients was lower than two different national normal population analysis [%4, (218/5960), %4,57, p=0,008] and RA (p=0,019) and SpA patients (P=0,003) (2,3). HBcAb positivity rate in SLE patients (%15) was significantly lower than both normal population (%30.6) and RA (%42.7) and SpA (%30.6) patients (Table 1). Analysis of SLE patients clinical outcomes showed that less oral ulceration (5/38 vs 57/210, p=0.067) and skin lesions (18/38 vs 140/208, p=0.018) occured in the HBcAb positive patients compared to negative patients. There was no relationship between other clinical findings and the HBcAb positivity. The HBcAb positive SLE patients were older than negative patients (51±10 vs 42±13, p<0.001).

Table 1. Hepatitis B seroprevalence of SLE and control groups

HBsAb positive and HBcAb negative	77/273 (%28.2)	26/103 (%25,2)	0,33	25/121 (%20 ,7)	0,11	463/5460 (%8,4)	**<0,001**
HBsAb and HBcAb positive	30/273 (%11)	30/103 (%29,1)	**<0.001**	25/121 (%20 ,7)	**0,01**	1212/5460 (%22,2)	**<0,001**
HBsAb negative and HBcAb positive	11/273 (%4)	14/103 (%13,6)	**<0,001**	12/121 (%9,9)	**0,02**	251/5459 (%4,6)	0.659

Conclusion: The positivity rate of HBsAg and HBcAb was lower in SLE patients than both normal population and other inflammatory disease subgroups such as SpA or RA. Lower HBsAg and HBcAb seroprevelance in SLE patients compared to normal population and also to other inflammatory diseases (SpA and RA), maybe due to specific protective mechanisms in SLE pathogenesis (like the association of familial mediterrenian fever and pestilence). This mechanism can be explained with the high interferon levels in SLE patients. To properly understand these mechanisims we need more prospective and molecular studies.

AB0660 **PREDICTIVE PARAMETERS FOR THE DEVELOPMENT OF PERIPHERAL NEUROPATHIES IN PRIMARY SJÖGREN'S SYNDROME**

Keywords: Sjögren syndrome

A. Mihai[1,2], C. Diana Maria[3], C. Jurcut[1], B. Cristian Florin[1,4], N. Adriana Elena[1], D. Opris-Belinski[5,6], R. Ionescu[6]. *[1]Carol Davila Central Military Emergency Hospital, Department of Internal Medicine, Bucharest, Romania*; *[2]Titu Maiorescu University, Department of Rheumatology, Faculty of General Medicine, Bucharest, Romania*; *[3]Carol Davila Central Military Emergency Hospital, Department of Neurology, Bucharest, Romania*; *[4]Titu Maiorescu University, Department of Medical-Surgical Specialties, Bucharest, Romania*; *[5]Sfanta Maria Clinical Hospital, Internal Medicine and Rheumatology Department, Bucharest, Romania*; *[6]Carol Davila University of Medicine and Pharmacy, Internal Medicine and Rheumatology Department, Bucharest, Romania*

Background: Sjögren's syndrome is a heterogeneous inflammatory disorder frequently involving peripheral nerves with a significant clinical and prognostic impact. The early detection of hematological and immunological parameters might improve disease control and even patients' survival.
Objectives: The objective of this study was to evaluate the predictive potential of hematological and immunological elements for the development of peripheral neuropathies (PN) in pSS patients.
Methods: In this single-centre, retrospective study, a total of 252 participants were included (131 pSS patients and 121 healthy controls). According to the neurologic examination and the result of the neuro electrophysiological examination, these patients were divided into two groups, with and without PN. Complete blood count, inflammatory and immunological parameters were determined at the initial visit. All patients underwent a periodical follow-up program when disease progression and response to therapy were monitored, including the emergence of PN.
Results: In pSS patients, cellular count, Vitamin B12 and D values were significantly decreased compared to healthy subjects ($p < 0.001$), whereas cellular ratio- NLR, PLR, immunological and inflammatory parameters were significantly increased ($p < 0.001$). In the PN patients group (41 patients 31.29%), gammaglobulins negatively correlated with vitamin B12 and total proteins ($p < 0.05$), while ESSDAI scores positively correlated with NLR and PLR ($p < 0.05$). The multivariate analysis confirmed the independent predictive character for PN emergence in pSS for NLR (CI95% 0.034 to 0.254, $p < 0.010$), gammaglobulins (CI95% -0.409 to -0.114, $p < 0.001$), vitamin B12 (CI95% -0.001 to -0.001, $p < 0.001$) and vitamin D (CI95% -0.018 to -0.006, $p < 0.001$).
Conclusion: Standard hematological and immunological parameters, widely used in assessing pSS patients, such as NLR, gammaglobulins, vitamin B12 and D, could become valid elements that might be used for the early detection of patients at risk for the development of PN. The hematological parameters related to platelets appear to be modified in patients with SS and cutaneous manifestations. However, only the neutrophil-to-lymphocyte ratio is independently associated with cutaneous involvement in these patients.

AB0661 CHANGES OF LYMPHOCYTE SUBSETS IN CONNECTIVE TISSUE DISEASE(CTD) WITH DIFFERENT TYPES OF PATHOGEN BLOODSTREAM INFECTIONS

Keywords: Adaptive immunity, Systemic lupus erythematosus

R. Su[1], C. Wang[1,1,1,1,1]. [1]*The second hospital of Shanxi Medical University, Rheumatoogy,Taiyuan, China*

Background: The underlying cause of autoimmune diseases is not known,infections, especially viral infections, is thought to be a possible reason[1].Disorder of CD4+T cells have been linked to autoimmunity, they are key players in various autoimmune diseases but are also crucial for immunity against different infections[2]. However, the immune response status of different types of infections in the context of autoimmune diseases is poorly understood.

Objectives: To evaluate the differences of lymphocyte subsets in connective tissue disease(CTD) with different types of pathogen bloodstream infections.

Methods: We analyzed 40 CTD patients with bloodstream infections, including 11 with virus infections,7 with fungal infections,13 with Gram negative bacteria infections(G- infection), 9 with Gram positive bacteria infections(G+infection), and 10 newly diagnosed CTD patients without co-infection were included as controls.The percentage and absolute numbers of lymphocyte phenotypes and CD4+ T subsets in peripheral blood were examined by flow cytometry.

Results: There were no significant difference in the percentage and absolute value of T,B,NK,CD4+T,CD8+T cells in different types of infection groups and no-infection group. Among comparison of the CD4+T subsets, the percentage of Th2 in the fungal infection was decreased than G- infection group and no-infection group,while the G- infection was increased than G+infection,and the virus infection was increased than fungal infection. The percentage of Th1,Th17 and Treg had no significant difference between different groups. Whereas for the absolute value comparison, the absolute value of Treg cells in the virus infection was higher than the fungal infection,G- infection and G+ infection, meanwhile the the fungal infection was obvious lower than no infection group. But there was no significant difference in Th1 and 17 among all groups.

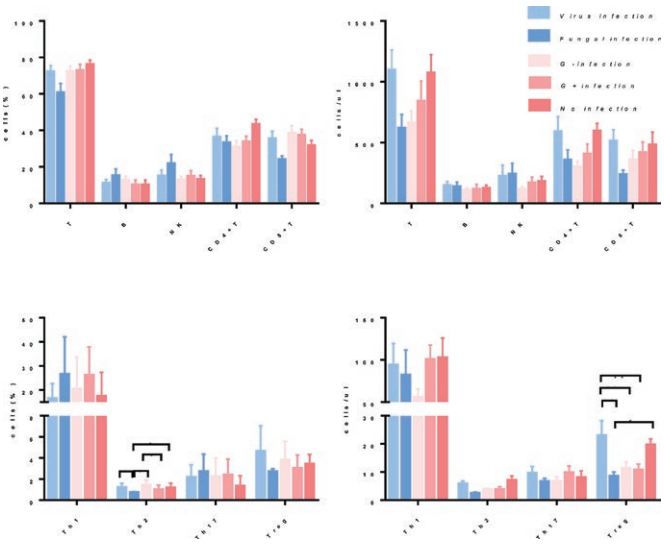

Figure 1. The comparsion about the lymphocyte subsets in different CTD groups.(*p<0.05,** p<0.001).G- infection: Gram negative bacteria infections.G+ infection:Gram positive bacteria infections.

Conclusion: Different types of pathgen blood may lead to development of specific immunological dysbalance,especially in the case of autoimmune disease hosts. CTD patients with fungal infection had lower Th2 response, higher Treg cells may be a characteristic of CTD combined with virus infection compare with other types of infection.

AB0662 PERIPHERAL PLATELET-GENERATING MEGAKARYOCYTE REDUCED IN PRIMARY SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome

J. W. Hao[1,2], Y. Qiao[1,2], J. Y. Chen[1,2], J. Qiao[1,2], S. X. Zhang[1,2], X. LI[1,2], C. Wang[1,2]. [1]*Second Hospital of Shanxi Medical University, Department of Rheumatology,Taiyuan, China*; [2]*Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology,Taiyuan, China*

Background: Primary Sjogren's Syndrome (pSS) is a complex and heterogeneous systemic autoimmune disease characterized by dysfunction of the secretory glands following chronic inflammation of lymphocytic infiltration.[1] Megakaryocytes (MKs), the precursor cells responsible for platelet production, act across the immune continuum.[2] However, the underlying pathogenesis of pSS involving megakaryocytes (MKs) is still to be elucidated.

Objectives: This study aimed to determine the changes in megakaryocyte subsets in pSS patients and to explore the role of different subsets in the pathogenesis of pSS.

Methods: The scRNA-seq dataset of five patients with pSS and five HCs were obtained from the GEO database to identify megakaryocytes (MKs) among PBMCs and further define the subpopulations. Then, cellular identity was determined by identifying the DEGs for each cluster using the Wilcoxon rank-sum test with the FindAllMarkers function and comparing the markers to known cell-type-specific genes from previous datasets. Finally, to investigate the hierarchy and developmental relationship between MK subpopulations, the monocle3 analysis was used to reconstruct pseudotime trajectories.

Results: First, four putative subpopulations (MK1-MK4) of MKs were identified by sub-clustering (Figure 1A). MK3 referred to as platelet-generating MKs, expressed key genes involved in hemostasis, cell-extracellular matrix interactions and so on. (Figure 1B) MK2 shared the same marker as MK3, but exhibited lower expression, which means MK2 may be an early stage of MK3, known as proplatelet-generating MKs. Then, compared with other MKs, MK2 and MK3 had the highest platelet activation-related and platelet aggregation-related pathways scores generated by ssGSEA (Figure 1F). Remarkably, the inflammatory response subpopulation (MK4), consisting of MKs expressing LSP11 and CD53 at high levels, was enriched in Immune system development and T-cell activation (Figure 1D). And, the proportion of the MK1, MK2, and MK4 subpopulations increased and that of the MK3 subpopulation was reduced in patients with pSS vs. HCs (Figure 1C), indicating the impaired maturation of platelet-generating MKs in pSS patients. Finally, with the trajectory analysis, we inferred that MK4 could exist independently of other MK subpopulations, and MK1 may characterize the point of initiation of a developmental trajectory (Figure 1E).

Conclusion: In summary, we have presented evidence for the reduction of peripheral platelet-generating MKs in patients with pSS, and identified changes in platelet-generating MKs via scRNA-seq analyses. The findings provide clues to the impaired maturation of platelet-generating MKs in the pathogenesis of pSS.

AB0663 **FOLLOW-UP FREQUENCY IN PATIENTS WITH SLE, 'ONE SIZE DOES NOT FIT ALL'**

Keywords: Systemic lupus erythematosus, Health services research, Real-world evidence

S. Snoeck Henkemans[1], A. Berden[2], G. Waverijn[3], I. Verberk-Jonkers[4], M. Kok[2], E. Zirkzee[2]. *[1]Erasmus MC, Rheumatology, Rotterdam, Netherlands*; *[2]Maasstad Hospital, Rheumatology, Rotterdam, Netherlands*; *[3]Maasstad Hospital, Business Intelligence, Rotterdam, Netherlands*; *[4]Maasstad Hospital, Internal Medicine, Rotterdam, Netherlands*

Background: The recommended frequency of follow-up for SLE patients ranges from monthly to yearly, although once every 3 months seems common practice. Recommendations are based on expert opinion; data on frequency of follow-up in SLE patients and its impact are very scarce. (1,2,3)
Objectives: To assess the frequency of follow-up visits in SLE patients and its relation to clinical and sociodemographic characteristics.
Methods: Patients with SLE based on the '97 ACR criteria (4), who were treated at our regional teaching hospital between 2012 and 2021, were included in the study. Frequency of follow-up was defined by the frequency at which blood tests (Hb as a key indicator) were performed for disease assessment. This frequency was related to clinical characteristics. Kruskal–Wallis and Fisher's exact test were performed.

Results: 238 SLE patients were included in the cohort; 117 patients (49%) had follow-up at an average of three months (interval 60-120 days), 59 patients (25%) had follow-up at a low intensity (interval >120), and 62 (26%) at a high intensity (interval <60 days). Characteristics of these groups are shown in Table 1. The patients with high intensity follow-up were younger, more often non-white and had more severe disease at diagnosis. Upon evaluation, these patients had a more severe disease course as demonstrated by more treatment intensifications, hospitalizations, ER visits, a higher SLICC damage index and more frequent renal involvement. Conversely, the patients that were monitored at a low intensity were older had longer disease duration and showed a more quiescent disease with less negative health outcomes. Figure 1 shows the linear relationship between the frequency of tests and the number of abnormal results in Hb.
Conclusion: This study shows that the frequency of follow-up varies substantially between SLE patients. A majority of patients had follow-up at a frequency of 3 months, patients that differed from this norm had distinct features. At this moment frequency of follow-up depends on clinical judgment of the physician. Potentially, this process might be captured in prognostic modelling. Patients at high risk should be identified and have a high frequency of follow-up, while in other patients resources could be spared.

AB0664 COMORBIDITIES IN PRIMARY SJÖGREN'S SYNDROME: A CROSS-SECTIONAL STUDY

Keywords: Comorbidities, Sjögren syndrome

J. Moussa[1], D. Dgheim[2], R. Faddoul[3], M. J. Okais[2], F. Fayad[2]. [1]*Université Saint Joseph - Campus des Sciences Médicales, Université, Beirut, Lebanon*; [2]*Hôtel-Dieu de France, Rheumatology, Bayrut, Lebanon*; [3]*Saint Joseph University of Beirut, Statistics, Bayrut, Lebanon*

Background: Patients suffering from autoimmune diseases have a higher risk of developing comorbidities compared to the general population. The screening of these comorbidities is important, for it affects the patient's quality of life as well as the physician's therapeutic decisions. The epidemiological data concerning the comorbidities associated with the primary Sjögren syndrome pSS are heterogenous, and to our knowledge, no such study exists on the scale of the Lebanese population.
Objectives: The aim of this study is to expand the knowledge around the comorbidities associated with the pSS, in a cohort of Lebanese patients. This goal is achieved by analyzing the frequency of these comorbidities and their association with the patients' biological profile.
Methods: It's a cross-sectional study conducted on a population of 61 Lebanese patients, followed in a rheumatology clinic inside of Hôtel Dieu de France University Hospital in Beirut. The mean age of this population is 54 years, and 60 out of 61 participants are women. All of these patients meet the pSS classification criteria of the American College of Rheumatology (ACR) and the European League Against Rheumatism (EULAR), established in 2016. On the one hand, the prevalence of each comorbidity is calculated, and on the other hand, the association between the patient's biological profile and the existing comorbidities has been analyzed.
Results: The most common comorbidities are: dyslipidemia (34.43%, 95% CI 23%-46%), hypertension (32.79%, 95% CI 21%-45%), obesity (26.23%, 95% CI 15%-37%), and hypothyroidism (18.03%, 95% CI 8%-28%). A significant correlation exists between hypocomplementemia (C3 and/or C4) and diabetes (p-value = 0.0026), as well as between hypocomplementemia and hypothyroidism (p-value = 0.024). Another significant correlation is noted between the presence of the rheumatoid factor and each of the following comorbidities: dyslipidemia (p-value = 0.005), diabetes (p-value = 0.0026), hypertension (p-value = 0.005), and hypothyroidism (p-value = 0.0037).
Conclusion: The Lebanese patients followed for pSS in our cohort form a population who is at risk of developing a metabolic syndrome alongside a thyroid disorder. In the light of these findings, these patients should benefit from a close cardiovascular risk factors and thyroid dysfunction screening and management, especially those presenting a particular biological profile like the presence of hypocomplementemia or the positivity of the rheumatoid factor.

AB0665 LONG-TERM EXPOSURE TO PM10 AND SYSTEMIC-LUPUS-ERYTHEMATOSUS-RELATED MORTALITY IN THE KOREAN POPULATION

Keywords: Systemic lupus erythematosus

D. J. Park[1], J. H. Kang[1], S. E. Choi[1], S. S. Lee[1]. [1]*Chonnam National University Medical School and Hospital, Rheumatology, Gwangju, Korea, Rep. of (South Korea)*

Background: The effect of air pollutants on the risk or progression of systemic lupus erythematosus (SLE) has been evaluated in several studies. However, their results were inconsistent and large-scale investigations are lacking.
Objectives: We evaluated the effect of particulate matter (PM) 10 on the risk or prognosis of SLE in a cohort drawn from a very large number of SLE cases registered in a nationwide database.
Methods: A case-cohort study consisting of 23,511 SLE cases and 204,521 cohorts was conducted using NHIS customized data. The district-specific annual average PM10 concentration for the year 2004 was estimated using a land-use regression model. A mixed Cox proportional hazard regression with random intercepts for districts was performed to evaluate the association between PM10 and the SLE risk for the general population and between PM10 and mortality for SLE patients.
Results: There was no significant association between PM10 exposure and SLE risk. However, the plot of the association between PM10 exposure and mortality in male SLE patients followed an inverted U-shape. Compared to the first quintile, the hazard ratios of mortality for the second, third, fourth, and fifth quintiles were 1.541 (95% confidence interval [CI]: 1.049–2.185), 1.278 (95% CI: 0.893–1.829), 1.395 (95% CI: 0.972–2.002), and 1.266 (95% CI: 0.881–1.818). Those associations were not significant in females.
Conclusion: A past PM10 exposure was associated with high mortality in male SLE patients. Further studies of the risk associated with a higher than average PM exposure level are needed.

AB0666 THE RELATIONSHIP BETWEEN NEUROPATHIC PAIN AND AUTOANTIBODY POSITIVITY AND SALIVARY GLAND BIOPSY IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome, Autoantibodies

C. Arslantürk Güneysu[1], D. Karatas[1], N. Erdik[1], S. M. Türk[1], G. Yavuzbilge[1], S. B. Acikgoz[1], Z. Öztürk[1], A. Karakurt[2], E. Gönüllü[1]. [1]*Sakarya University Hospital, Rheumatology, Sakarya, Turkey*; [2]*Sakarya University Hospital, Internal Medicine, Sakarya, Turkey*

Background: Sjögren's syndrome (SjS) is an autoimmune disease characterized by exocrine gland inflammation (1). Extraglandular manifestations are common in SjS. Some articles reported neuropathic pain in 40% of patients with SjS (2). Autoantibodies (SS-A, SS-B, Anti Ro-52) and salivary gland biopsy are used to diagnose SjS. The relationship between autoantibody, salivary gland biopsy results, and neurological involvement is unclear.
Objectives: In this study, autoantibody positivity and salivary gland biopsy results were compared with the frequency of neuropathic pain.
Methods: Patients with a diagnosis of Primary SjS who visited the rheumatology outpatient clinic of Sakarya University between August 2021 and August 2022 were included in the study. The results of salivary gland biopsy and autoantibody (ANA, SS-A, SS-B, Anti-Ro 52) were analyzed. The LANSS (The Leeds Assessment of Neuropathic Symptoms and Signs) pain scale was used to define neuropathic pain. Obtained data were evaluated with Chi-Square and Mann-Whitney U test.
Results: Sixty-six patients were included in the study. Patients' age (mean): 53.5±11.3 years; genders were 3 (4.5%) male and 63 (95.5%) female. While 18 (27.3%) patients have neuropathic pain, 48 (72.7%) patients did not have neuropathic pain. No statistically significant difference was found between neuropathic pain and disease duration (p=0.584). There was no difference in neuropathic pain in terms of gender (p=0.178). While the rate of neuropathic pain was 25.6% in patients with a focus on biopsy, it was 45.5% in patients without focus, and the difference was not statistically significant (p=0.270). No statistically significant correlation was found between anti-SSA, Anti-SSB, and Anti-Ro52 positivity and neuropathic pain. In ANA-negative patients, the increase in the frequency of neuropathic pain was statistically significant (p=0.031).

Table 1.

	Neuropathic Pain Present	Neuropathic Pain Absent	p
ANA			
positive n(%)	8(18,6)	35(81,4)	0,031
negative n(%)	10(43,5)	13(56,5)	
Anti-SSA			
positive n(%)	3 (13)	20(87)	0,098
negative n(%)	13 (31,7)	28 (68,3)	
Anti-SSB			
positive n(%)	1 (8,3)	11 (91,7)	0,266
negative n(%)	15 (28,8)	37 (71,2)	
Anti-Ro52			
positive n(%)	5 (22,7)	17 (77,3)	0,670
negative n(%)	10 (27,8)	26 (72,2)	

Conclusion: In this study, we did not find a relationship between antibody positivity, focus score, and the frequency of neuropathic pain.

Emmi[3,5]. *[1]Friedrich Alexander Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany*; *[2]Friedrich Alexander Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Deutsches Zentrum für Immuntherapie, Erlangen, Germany*; *[3]University of Firenze, Department of Experimental and Clinical Medicine and Internal Interdisciplinary Medicine Unit, Florence, Italy*; *[4]University of Firenze, Internal Medicine Unit IV, Florence, Italy*; *[5]Monash University, Centre for Inflammatory Diseases, Department of Medicine, Monash Medical Centre, Melbourne, Australia*

Background: Musculoskeletal inflammation is a frequent and debilitating feature of Systemic Lupus Erythematosus (SLE) that can involve all components of the joint, including extra-synovial sites such as the entheses[1]. In previous reports, enthesitis could be clearly demonstrated by musculoskeletal ultrasound (US) in small cohorts of patients with SLE[2,3]. However, SLE-enthesitis remains frequently overlooked and its prevalence in real-life cohorts as well as its clinical significance for disease classification and therapy remain to be determined.
Objectives: To assess the prevalence of US-confirmed enthesitis in a monocentric cohort of patients with SLE and to analyze the clinical associations to enthesitis during the course of disease.
Methods: Ultrasound examinations of SLE patients presenting with tender and/or swollen joints at the Lupus Unit of the Careggi University Hospital in Florence (Italy) were retrospectively analyzed to assess the presence of enthesitis. Patients with US-proven enthesitis were compared with SLE controls who showed no US-evidence of enthesitis. Clinical features and therapies were compared between the two groups at disease onset and throughout follow-up.
Results: We assessed 400 patients fulfilling EULAR/ACR classification criteria for SLE. In 106 of them, an US examination of the joints was performed. Evidence of enthesitis was found in 31/106 (29.2%) patients. Four participants were excluded due to lack of follow-up data. The remaining 71 patients without US-enthesitis were included as control group (**Figure 1**). At disease onset, all clinical features were comparable between enthesitis cases and controls. Clinical manifestations and therapy from disease onset to the last available follow-up are reported in **Table 1**. The median follow-up was of 10.0 (IQR 8.3-23.3) years for cases and 12.4 (IQR 7.2-13.3) years for controls. Patients with enthesitis were less likely to develop renal involvement (22.6% vs 46.5%, p<0.05), had more arthritis (100.0% vs 81.7%, p<0.01) and failed B-cell depleting therapies more frequently (75.0% vs 0%).
Conclusion: In SLE patients with tender or swollen joints, enthesitis is a fairly common finding. Enthesitis in SLE could be the hallmark of a distinct disease subset with less frequent renal involvement, more arthritis, and poor response to B-cell depletion, potentially requiring alternative treatments.

AB0668 **BENEFITS OF ANA SCREENING FOR NPSLE IN PATIENTS ADMITTED TO THE DEPARTMENT OF PSYCHIATRY**

Keywords: Systemic lupus erythematosus, Diagnostic tests, Autoantibodies

Y. J. Lee[1], S. M. Ahn[1], S. Hong[1], J. S. Oh[2], C. K. Lee[1], B. Yoo[1], Y. G. Kim[1]. *[1]Asan Medical Center, Division of Rheumatology, Department of Internal medicine, Seoul, Korea, Rep. of (South Korea)*; *[2]Asan Medical Center, Department of Information Medicine, Big Data Research Center, Seoul, Korea, Rep. of (South Korea)*

Background: Neuropsychiatric systemic lupus erythematosus (NPSLE) presenting with mood disorder, headache, psychosis, and cognitive impairment appears within 1 year of SLE diagnosis in more than half of cases (1, 2). Most studies have focused on the epidemiology of neuropsychiatric manifestations in patients with established SLE (3). Therefore, diagnosing NPSLE in patients who have visited the hospital with psychiatric symptoms is challenging. Although some studies have conducted anti-nuclear antibody (ANA) screening in psychiatric patients, none have occurred in an Asian population (4, 5).
Objectives: We aimed to determine the benefits of ANA screening for NPSLE in patients admitted to the department of psychiatry in Korea.
Methods: We investigated patients admitted to the department of psychiatry who underwent ANA testing between January 2015 and December 2021 at a single tertiary center in Korea. Patients diagnosed with SLE before admission were excluded from this study. Electronic medical records, including ANA titer, extractable nuclear antigen (ENA), complement, brain magnetic resonance imaging, electroencephalogram, and cerebrospinal fluid analysis, were reviewed retrospectively. Diagnosis at psychiatric hospitalization was classified according to the International Classification of Diseases (ICD)-10.
Results: Throughout the study period, 2523 patients were hospitalized, 1355 of whom underwent ANA testing. Three patients with SLE were excluded. The median age of all patients was 40 (27–58), and 897 (66.2%) were female. Of the 1355 patients, 96 (7.1%) were positive with a titer of ≥1:80, and 61 (4.5%) were positive with a titer of ≥1:160. Among the 17 patients who underwent ENA testing, 1 was positive for anti-Ro and anti-La, eventually diagnosed with Sjogren's syndrome. According to the diagnostic classification of admission, there was no significant difference in the ANA positivity rate (p=0.205).
Conclusion: There was no difference in the positivity rate of ANA in the general population when testing was performed for screening purposes on patients admitted to the psychiatric department. Additionally, none of the 1355 patients were diagnosed with NPSLE after undergoing ANA screening. Thus, the benefits of performing routine screening appear to be limited.

AB0669 CUTANEOUS LUPUS ERYTHEMATOSUS OVER THE COVID MAJOR PANDEMIC PERIOD, INCIDENCE AND CLINICAL CHARACTERISTICS

Keywords: Systemic lupus erythematosus, COVID

M. Ferraioli[1], P. Conigliaro[1], C. Bonini[1], S. Ferrigno[1], M. Teoli[2], C. Paganini[3], V. Maffei[3], M. Galluzzo[3], M. Talamonti[3], A. Bergamini[1], M. S. Chimenti[1]. *[1]Rheumatology, Allergology and Clinical Immunology, Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy*; *[2]Porphyria and Rare Diseases Unit, San Gallicano Dermatological Institute - IRCCS, Rome, Italy*; *[3]Dermatology Unit, Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy*

Background: Cutaneous Lupus Erythematosus (CLE) is a chronic inflammatory autoimmune disease with a broad spectrum of clinical manifestations and a variable course, often induced by exogenous factors. CLE is classified in specific and non-specific manifestations with the former divided in acute cutaneous LE (ACLE), subacute cutaneous LE (SCLE), chronic cutaneous LE (CCLE) and intermittent cutaneous LE (ICLE).

Objectives: To assess clinical features of CLE patients over the major pandemic period and its impact on disease characteristics.

Methods: Multi-center retrospective study conducted on consecutive CLE outpatients referring to the Rheumatology and Dermatology Units of Tor Vergata Hospital and San Gallicano Institute (Rome, Italy).

Inclusion criteria: diagnosis of CLE, age ≥ 18 years, and 4 years continuous follow-up from Mar 2018.

Data from every visit performed between Mar '18 - Feb '22 were registered for each patient, including: number of visits performed/skipped, demographics, therapy, number of skin flares (yes/no, via BILAG score) and systemic flares (yes/no, SLEDAI-2K increase ≥4 points), type of cutaneous manifestation, Sars-CoV2 infection and SLICC damage index score (SDI).

Number of visits, clinical course of disease, occurrence of Sars-CoV2 infection and therapy were compared in two periods: pre-pandemic outbreak (1 Mar 2018-29 Feb 2020) and first-wave pandemic (01 Mar 2020-28 Feb 2022).

Results: 80 patients were enrolled, 65 females, aged 55.2±14.3 with a disease duration of 32.1±19.8 (Tab 1). In the 1st period 398 visits were performed while only 180 resulted in 2nd with a number of visits/patient/year of 1.9 vs 1.1. Skipped and telemedicine visits amounted to 11 and 1 in the 1st period e to 31 and 21 in 2nd period respectively.

Statistical significant differences emerged in number of documented cutaneous flares: 28 (8.8%) in 1st period vs 42 (23.3%) in 2nd (p=0.03). A higher incidence in the 2nd period of ACLE (15% vs 30%, p<0.01), cutaneous calcinosis (0% vs 10%, p<0.01) and livedo reticularis (10% vs 1.2%, p<0.03) and a lower incidence of CCLE (13% vs 2.5% (p=0.02) were observed compared to the 1st pre-pandemic period.

Although mean SLEDAI-2k resulted significantly lower in the 2nd period (2.67 vs 2.13, p=0.02) compared to the 1st one, SLEDAI-2k score related to skin was higher in the 2nd period compared to the 1st (0.8 vs 1.1 (p=0.04). A significant reduction in the percentage of patients treated with topical therapy was registered in 2nd period (p=0.008) while other medications remained stable.

30 patients (37.5%) contracted Sars-CoV2 infection, no differences were registered between patients with infection and those that did not contract infection regarding number of visits, skin and systemic flares, SLEDAI-2K and SDI, therapy and clinical characteristics.

Conclusion: We reported how the major pandemic period – with general reduction in outpatients' medical assistance – consisted in a conspicuous increase in cutaneous flares as quantifiable in higher ACLE incidence and reduced topical treatment. At the same time, incidence of systemic flares – along with systemic treatments – remained substantially stable. In conclusion, it appears that patients suffered a burden of cutaneous manifestations after the pandemic period not associated to any systemic impact.

AB0670 MYOSITIS IN PRIMARY SJÖGREN'S SYNDROME: DATA FROM A MULTICENTRE COHORT

Keywords: Sjögren syndrome, Epidemiology, Myositis

K. Chandwar[1], S. Pandya[2], K. N. Thomas[1], P. Srivastava[3], A. Wakhlu[4]. *[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India*; *[2]Vedanta Institute of Medical Science, Clinical Immunology and Rheumatology, Ahmedabad, India*; *[3]Star Clinics, Clinical Immunology and Rheumatology, Ahmedabad, India*; *[4]Apollomedics Super Speciality Hospitals, Clinical Immunology and Rheumatology, Lucknow, India*

Background: Primary Sjögren's syndrome (pSS) is a multisystem autoimmune disease characterised by lymphocytic infiltration of the exocrine glands and their resultant dysfunction.

Muscle involvement has been given the highest weightage in the ESSDAI score Given the significant variation in prevalence (0.85–14%) and characteristics of myositis patients with pSS across studies (Owing to heterogeneous definitions and assessment) it is vital for us to understand myositis in pSS better.

Objectives: The aim of this study was to describe the prevalence of myositis in a multicentre Indian pSS cohort and to address the clinical manifestations and therapeutic strategies.

Methods: Clinical and serological data from a pSS cohort of patients were retrospectively collected and analysed. Those fulfilling the ACR/EULAR 2017 criteria for myositis and the ACR/EULAR 2012 Criteria for pSS were included. Patients with overlap features of other autoimmune rheumatic diseases were excluded.

Results: 12 (2.7%) out of 444 patients of pSS had Myositis. The mean age was 36.83 ±12.16 years, and the mean duration of follow-up was 5,46 ±5.23 years. All patients were females with a high prevalence of ANA positivity and Ro52, and Ro60 in these patients. Myositis was the presenting manifestation in 11/12 patients. Arthritis/Arthralgia (8/66%), Glandular enlargement/ Parotitis (7/58%), Lung Involvement (ILD) (5/41%), and Haematological abnormalities were also common in patients with myositis and primary Sjögren's syndrome. The 5-year survival was good, with 11/12 patients completing the 5-year follow-up. About a half patients received pulse methylprednisolone therapy followed by 1mg/kg steroid, with few patients requiring lower doses of steroids. Methotrexate was the steroid sparing drug of choice for patients with pSS myositis without lung

involvement and Cyclophosphamide in patients with lung involvement followed by Azathioprine or Rituximab maintenance, one patient was induced and maintained with low dose rituximab. Details of second-line therapy was not available for three patients. The mean ESSDAI and ESSPRI scores were high. None of our patients had Signs, symptoms or histopathological findings suggestive of IBM.

Conclusion: pSS patients with myositis had a younger age of onset with active Disease and High ESSDAI and ESSPRI scores. Myositis was the presenting manifestation in most, the proportion of patients with lung involvement in pSS myositis was much higher than is usually seen in patients with pSS and should prompt the clinician to look for clinical/subclinical lung involvement in pSS myositis patients. The Response to therapy was usually good. Unlike other cohorts, we didn't find any IBM in our set of patients – this may be due to referral bias or the rarity of IBM in the Indian population.

Table 1. Characteristics of pSS Myositis patients

N=12	n	%

AB0671 LONGITUDINAL ASSESSMENT OF HAND AND WRIST BONE DESTRUCTION BY ULTRASOUND, AND ITS ASSOCIATION WITH DISEASE ACTIVITY IN PRIMARY SJÖGREN'S SYNDROME

Keywords: Ultrasound, Inflammatory arthritides, Sjögren syndrome

A. Silva Franco[1], I. Murai[1], T. Yang[1], L. Peixoto Sales[1], L. Guedes[1], S. Pasoto[1], C. Figueiredo[1], R. M. Pereira[1]. [1]*Faculdade De Medicina Da USP, Rheumatology, São Paulo, Brazil*

Background: Primary Sjögren's syndrome (pSS) is a chronic systemic inflammatory autoimmune disease primarily affecting the exocrine glands (1). Joint damage is the main extra-glandular manifestation, usually described in 11% of patients as non-erosive polyarthritis of small joints, mainly of the upper limbs (2). Although articular bone erosion is a rare finding on hands' radiography, hand and wrist ultrasound (US) is an emerging technology in the rheumatology field used for diagnosis and follow-up disease activity through the assessment of bone articular erosions, synovitis and tissue power doppler (3).

Objectives: To evaluate joint damage by hand and wrist ultrasound, and its association with disease activity in primary Sjögren's syndrome patients in a longitudinal setting.

Methods: Ninety-seven consecutive pSS patients according to the American College of Rheumatology (ACR) and European Alliance of Associations for Rheumatology (EULAR) criteria without meeting the ACR criteria (1987) for rheumatoid arthritis were evaluated by hand and wrist ultrasound and clinical activity disease index previously by our group (3). Twelve patients of this initial evaluation were followed with hand and wrist ultrasound and clinical activity disease index. Disease activity was assessed by EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI). The US was performed by one expert blinded. Data were analyzed by Wilcoxon signed-rank test. Significance level was set at $P<0.05$.

Results: All patients were female and 8 (66.6%) were white. The time between the first and the second evaluation was 9.5 ± 1.6 years. At the first evaluation, only 1 (8.3%) patient had wrist erosion, 5 (41.6%) patients had synovitis and 4 (33.3%) patients had tissue power doppler in the US. The mean ESSDAI was 6.83 ± 5.70. At the second evaluation, 5 (41.6%) patients had wrist erosion (P=0.059), 10 (83.3%) patients had synovitis (P=0.010) and 7 (58.3%) patients had tissue power doppler in the US (P = 0.014). The mean ESSDAI was 2.33 ± 4.05 (P = 0.022). After the follow-up period, despite the improvement in the disease activity score, there was an increase in the number of erosions, mainly of the wrists, presence of tissue power doppler and synovitis.

Conclusion: This study describes a longitudinal evaluation of a small sample size of pSS. The findings show a worsening of joint assessments despite low-activity disease, indicating possible local inflammation in addition to systemic involvement.

AB0672 DETECTION OF MACROPHAGE MIGRATION INHIBITORY FACTOR IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS COMPLAINING PAINFUL DISTURBANCES: A SINGLE CENTER STUDY

Keywords: Systemic lupus erythematosus, Pain, Biomarkers

C. Pirone[1], F. Ceccarelli[1], T. Colasanti[1], E. Galosi[2], V. Orefice[1], C. Garufi[1], F. Natalucci[1], G. Olivieri[1], L. Picciariello[1], P. Falco[2], G. Di Pietro[2], F. R. Spinelli[1], S. Truglia[1], C. Alessandri[1], A. Truini[2], F. Conti[1]. [1]*Lupus Clinic, Reumatologia, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Sapienza Università di Roma, Rome, Italy*; [2]*UOC di Neurofisiopatologia e Malattie Neuromuscolari, Dipartimento di Neuroscienze umane, Sapienza Università di Roma, Rome, Italy*

Background: Neuropsychiatric Systemic Lupus Erythematosus (NPSLE) is considered one of the preeminent diagnostic and therapeutic challenges for the rheumatologist, not only due to the wide clinical heterogeneity but also because of the lack of specific diagnostic tools and biomarkers. Macrophage migration inhibitory factor (MIF) is a pleiotropic inflammatory cytokine associated with inflammatory neuropathy and neuropathic pain. This protein acts as an innate immunity modulator by promoting host inflammatory responses through induction of pro-inflammatory cytokines (including TNF and IL-6), regulating cellular processes such as T-cell proliferation, apoptosis and counter regulation of the immunosuppressive actions of glucocorticoids.
Objectives: In the present study we aimed at evaluating the serum titers of MIF in SLE patients with painful disturbances, screened for neuropathic pain, compared with healthy controls (HC) and identifying significant associations with clinical and other laboratory disease features.
Methods: Consecutive SLE patients (according to ACR 1987 criteria), with painful disturbances, were screened for neuropathic pain through a specific questionnaire (Douleur Neuropathique en 4 Questions-DN4). Subjects were enrolled in the presence of bilateral limb pain and one of the following: hypoesthesia to touch or prick; pain caused or increased by brushing; tingling, numbness and itching; electric shocks, painful cold or burning pain. We excluded SLE patients with other possible explanation for neuropathic pain including diabetes, Sjogren's syndrome and kidney impairment (eGFR <30 ml/m). For each patient the following data were collected: demographics, medical history (focusing particularly on other NPSLE manifestations), treatments, disease activity (SLEDAI-2K) chronic damage (SLICC *damage index)*, clinical and laboratory main disease data. Each patient enrolled underwent different tools specific for neuropathic pain (DN4, Neuropathic Pain Symptoms Inventory Questionnaire, Composite Autonomic Symptom Score-31 and Small Fiber Neuropathy-Symptoms Inventory Questionnaire). A concomitant fibromyalgia (FM) was evaluated by different tools including FIRST, FibroDetect and ACR 2016 criteria. MIF levels were determined by ELISA, following manufacturer's instructions in SLE patients and 38 HC matched for age and gender (Quantikine ELISA, Human MIF Immunoassay, Catalog Number DMF00B- R&D Systems).
Results: We excluded 58 subjects because of confounding factors and 25 declined the study. Therefore we enrolled 34 patients (M/F 2/32, median age 50.0 years, IQR 21.0; median disease duration 150.0 months, IQR 190.5; median SLEDAI-2k 0, IQR 2 and median SDI 1, IQR 2). MIF levels were not different between SLE and HC, median 42.8 ng/ml (IQR 49.3) and 38.3 ng/ml (IQR 46.4), respectively. FM was identified in 79.4% of SLE patients according to ACR criteria. Neuropathic pain was diagnosed according DN4 (>3) in 58.8% of SLE patients, but no significant difference in MIF levels were found between the groups. NPSLE was recorded in 35.3% of cohort (mild cognitive dysfunction in 5 subjects, headache and polyneuropathy in 3, movement disorders, psychosis, epilepsy, myasthenia and cerebrovascular accident in only one). Interestingly higher MIF serum levels were found in patients with NPSLE than in patients without overt neuropsychiatric involvement (p=0.037, Figure 1).
Conclusion: This study suggests that MIF could be a potential biomarker in NPSLE patients, however further studies are warranted to confirm this preliminary result.

AB0673 **SERUM 25 (OH) VITAMIN D LEVELS AND BONE MINERAL DENSITY IN SYSTEMIC LUPUS ERYTHEMATOSUS**

Keywords: Osteoporosis, Systemic lupus erythematosus, Vitamin D

E. B. Yilmaz[1], K. Amdahl[1], A. Zickert[1], A. Antovic[1], I. Gunnarsson[1], E. Svenungsson[1]. [1]*Karolinska Institute, Rheumatology, Stockholm, Sweden*

Background: Several disease- and treatment-related factors, such as proinflammatory cytokines, corticosteroid treatment, lupus nephritis, and impaired renal function affect serum vitamin D levels and cause accelerated osteoporosis in patients with systemic lupus erythematosus (SLE).
Objectives: We investigated serum 25(OH) vitamin D levels and bone mineral density (BMD) in female Caucasian patients with SLE. Further, we explored which treatment- and disease-related factors are most strongly associated with those measurements.
Methods: We enrolled female Caucasian SLE patients and controls in this cross-sectional study. A rheumatologist and a nurse gathered information about demographical and disease characteristics, evaluated disease activity and damage scores, and collected blood samples at the time of inclusion. SLE patients underwent DXA within one year after inclusion.
Results: A total of 325 SLE patients and 289 controls were enrolled, mean age (47 and 48 respectively, p>0,05), body mass index (BMI), smoking status, and the fraction of postmenopausal individuals did not differ between groups. 179 patients and 2 controls were on corticosteroids. Moreover, 172 patients and 14 controls were using vitamin D supplements. The SLE patients as a group had higher levels of 25(OH) vitamin D than the controls (64,2 nmol/L vs 59,4 nmol/L respectively, p=0.0021). Among SLE patients using vitamin D supplementation, those on corticosteroids had lower serum levels of 25(OH) vitamin D; this difference was not present in the supplementation naïve group. (p: 0,02, p: 0,69 respectively). In the SLE and control groups, not taking supplementation, serum 25(OH) vitamin D levels did not differ according to menopausal status (p= 0.22). Nephritis status (ever yes/no) did not affect 25(OH) vitamin D levels. Patients taking

supplements with higher disease activity (SLEDAI≥4, SLAM≥6) and more damage (SLICC/ACR Damage Index (SDI) >1) had lower serum 25(OH) vitamin D levels than those with lower disease activity/damage (*p*: 0,029, *p*: 0,049, *p*: 0,002).

Premenopausal SLE patients had higher T-scores than the postmenopausal in all measured locations (lumbar spine *p*: 0.0002, femoral neck: *p*<0,0001, total hip *p*<0,0001). Neither T-scores in the whole group, nor Z-scores in the group <40 years were correlated to serum 25(OH) vitamin D levels. (*p*> 0,05 in all locations). Variables affecting body mass index (BMD) are presented in Table 1, stratified for menopausal status.

Conclusion: Serum 25(OH) vitamin D levels are affected mainly by supplements, corticosteroid treatment, and organ damage in SLE patients. We found no correlation between serum 25(OH) vitamin D levels and BMD. Low BMD was in multivariable analyses associated with low BMI, older age, smoking, longer disease duration, and higher damage.

AB0674 PRIMARY SJOGREN SYNDROME WITH ANTICENTROMERE ANTIBODIES - A CLINICALLY DISTINCT PHENOTYPE OR AN OVERLAP SYNDROME?

Keywords: Autoantibodies, Sjögren syndrome, Cardiovascular disease

N. Cristina[1], D. Nicoara[1], L. Groseanu[1,2], D. Opris Belinski[1,2], V. Bojinca[1,2], D. Predeteanu[1,2], F. Berghea[1,2], V. Vlad[1], I. Saulescu[1,2], S. Daia-Iliescu[1,2], D. Mazilu[1,2], A. Borangiu[1,2], C. Cobilinschi[1,2], M. M. Negru[1,2], C. L. Constantinescu[1,2], D. Mardale[1,2], M. Duna[1], M. Abobului[1,2], R. Ionescu[1,2], A. Balanescu[1,2]. *[1]St Mary Hospital, Internal Medicine and Rheumatology, Bucharest, Romania*; *[2]Carol Davila University of Medicine and Pharmacy, Internal Medicine and Rheumatology, Bucharest, Romania*

Background: Anticentromere antibodies (ACA) have been reported in primary Sjogren syndrome (pSS) at lower frequencies but have recently been suggested as another clinically important marker in this disease[1]. Although several papers have been published on ACA-positive pSS, the results have been conflicting[2,3].

Objectives: To evaluate the correlation between presence of ACA and associated symptomatology, especially related to microvascular dysfunction in a Romanian cohort of patients with ACA-positive pSS.

Methods: We assessed 132 patients who met the 2016 American College of Rheumatology/European League Against Rheumatism classification criteria for pSS. For all ACA+ patients, we collected data on the presence of sclerodactyly, puffy hands, Raynaud's phenomenon, calcinosis, telangiectasia, esophageal involvement, interstitial lung disease, digital ulcerations/pitting scars, pulmonary hypertension and nailfold capillaroscopy findings.

Results: The prevalence of ACA in our pSS cohort was 13%. ACA - positive pSS patients were older than the ACA-negative patients (median, 59 years [IQR, 48 to 62] vs median, 50 years [IQR, 45 to 60]; p = 0.042), with a shorter disease duration (53 months vs 260 months, p=0.073). Most patients were female (98.7%) and had ocular and oral symptoms of dryness (98.1% and 97.8%, respectively). Among the patients with pSS, 5 patients had ACA and limited cutaneous systemic sclerosis (lcSSc). Although there was no statistical differences between the two groups, ACA-positive patients were characterized by higher prevalence of associated symptomatology related to microvascular dysfunction: RP (Raynaud's phenomenon) and telangiectasias were present in 50% of the patients (5/10), sclerodactyly and digital ulcerations (DUs) in 33% (3/10); digital gangrene was not found. 60% (6/10) of ACA+ pSS patients had abnormal findings on nailfold capillaroscopy, which were nonspecific in 2 patients (crossed capillaries), while in the remaining 1 patient had an early-pattern, 1 had an active-pattern and 2 patients had late scleroderma-pattern. The presence of ACA was positively correlated with the presence of RP (p = 0.024), DUs (p = 0.034). In our study, patients showed similar severities in extraglandular manifestations compared to the ACA-negative group. Nonetheless, we noticed that even if not statistically significant, the use of vasodilators was more common in the ACA - positive pSS patients (66.7% vs 12.2%, p = 0.911) thus supporting the hypothesis of a symptomatic microvascular dysfunction. A higher proportion of ACA+ pSS (64% vs 42%) was treated with immunosuppressive agents. No differences in mortality were found between the groups.

Conclusion: Patients in the ACA-positive group were older, had more frequent RP and digital ulcers. In our cohort, ACA - positivity had little impact on the severity of extraglandular manifestations in pSS patients. Although there were no significant differences, use of vasodilators and immunosuppressants agents was more common. This study is the first to investigate the impact of ACA positivity on the vascular manifestations of Romanian pSS patients.

AB0675 AVASCULAR NECROSIS IN A COHORT OF SLE PATIENTS IN AN AFRICAN CONTEXT

Keywords: Pain, Systemic lupus erythematosus

S. Ntshalintshali[1], R. Du Toit2, F. Moosajee2, S. Vlok[3,4]. *[1]Tygerberg Hospital, Rheumatology, Cape Town, South Africa*; *[1]Tygerberg Hospital, Rheumatology, Cape Town, South Africa*; *[3]Cape Town, Radiology, Cape Town, South Africa*; *[4]Tygerberg Hospital, Radiology, Cape Town, South Africa*

Background: There is lack of recent data in South Africa describing the burden of AVN among SLE patients. Joint replacement in South Africa remains a challenge with more than 500 days of delay in some cases hence identification of potential clinical associations for AVN development among SLE patients is an important undertaking for prevention, early detection and treatment.

OBJECTIVES:

1.To determine the current prevalence of AVN among SLE patients at Tygerberg Hospital.

2.To determine associations between the development of AVN in SLE patients and SLE related factors, complications, treatment and other comorbidities.

3.To assess the outcomes of AVN in SLE patients.

Methods: This was a retrospective case-control study. All SLE patients (N=755) seen at Tygerberg Hospital, Rheumatology Clinic over a 8 years period (2013 – 2020) were screened for inclusion. The inclusion criteria consisted an age of 18 years with a proven diagnosis of SLE using the 2019 EULAR/ACR classification criteria, and a radiological diagnosis of AVN. The clinical data, radiological data and blood investigation data were collected for analysis. The radiological data (x-rays, MRI and CT scans) were reviewed by a radiologist for the diagnosis and grading of AVN using the Ficat and Arlet method.

Results: The prevalence of AVN among the SLE population at Tygerberg Hospital was 3.4%. The median SLEDAI-2K score six months prior to the radiological diagnosis of AVN (p < 0.001) and the SDI (p < 0.001) scores were individually found to be statistically significant between the two groups. The MRI Ficat and Arlet grading (p= 0.013) was found to be more advanced when compared with x-ray grading of the same joints, although done at different points in time with a median delay of 2 months (IQR:1-5). Only 26.3% of affected joints underwent a joint replacement with a median delay of 23 months (IQR:13-52).

Conclusion: The prevalence of AVN among SLE patients at Tygerberg Hospital is slightly lower than the international and the previously reported local data. High SLEDAI-2K and SDI scores were associated with AVN development in SLE. The delay in the acquisition of MRI scan for AVN diagnosis and grading, and that of joint replacement remain as significant challenges that require special attention in the state healthcare sector.

AB0676 DELAYS IN CARE SEEKING AND DIAGNOSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS IMPACT ON DISEASE ACTIVITY AND DAMAGE

Keywords: Systemic lupus erythematosus, Epidemiology, Organ damage

G. Serna-Peña[1], D. P. Flores-Gutierrez[1], O. E. Alvarez-González[1], G. García-Arellano[1], J. A. Cardenas-de la Garza[1], A. G. Rodriguez Flores[1], M. F. Ortiz Nuño[1], I. D. J. Hernandez-Galarza[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that presents with heterogeneous manifestations, some of which can delay access to specialized attention and according to the symptom, also lead to greater damage. (1)
Objectives: Compare initial symptoms/signs and disease damage or activity in patients with SLE with medical attention or diagnostic delays.
Methods: We performed a cross-sectional study in the lupus clinic in Hospital Universitario Dr. José Eleuterio González. Patients over 15 years old with an SLE diagnosis according to the EULAR/ACR 2019 criteria and a disease duration > 1 year were included in this study. Data from current EULAR/ACR 2019 disease classification, SLE Disease Activity Index (SLEDAI), and SLICC Damage Index were collected from patient files. Delay was defined as ≥ 6 months to request medical assistance or disease diagnosis. The timeline studied was divided into time from symptom onset to first medical assessment, and time from first medical assessment to SLE diagnosis. We compared demographics and initial symptoms, SLEDAI, and SDI scores between groups with and without delays.
Results: Fifty-five patients were evaluated, 96.4% were female, mean age at diagnosis was 30.44 years +/- 12.484, and the mean disease duration was 7.25 years. The most frequent symptom in both groups was arthritis/arthralgia, followed by mucocutaneous manifestations (Table 1). Mean time for requesting medical assistance was 483.4 days +/- 959.741 and for diagnosis 91.67 days +/- 194.417. 41.98% had a delay in medical attention, 52.72% had a delay in diagnosis, and 60% (33) of all patients presented some type of delay ≥ 6 months. No statistical difference was found in SLEDAI score (mean of 2.424 +/- 3.699) (p=.740 or SLICC score (mean 0.57 +/- 0.902) (p=.587) between groups. In the group with a delay in diagnosis, the patients were older, and in the group without a delay in diagnosis lupus nephritis was more prevalent.
Conclusion: Two out of 3 patients report delay ≥ 6 months in seeking medical assistance and/or a definitive diagnosis, although no statistical difference was found in disease activity or damage scores. Younger age and renal involvement were related to a prompt diagnosis.

AB0677 CUT OFF POINT OF NEUTROPHIL-TO-LYMPHOCYTE RATIO AS A MARKER OF DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS AT HAJ ALSAFFE HOSPITAL LUPUS CLINIC FROM JUNE 2021 TO SEPTEMBER 2021

Keywords: Systemic lupus erythematosus, Prognostic factors

Z. I. T. Mahmoud[1,2], I. S. E. Mohammed[3], S. B. Hamza[4,5]. [1]*Faculty of Medicine, University of Bahri, Internal Medicine, Khartoum, Sudan*; [2]*Ziryab Research Group, President, Khartoum, Sudan*; [3]*Sudan Medical Specialization Board, Internal Medicine, Khartoum, Sudan*; [4]*Faculty of Medicine and Health Sciences, Omdurman Islamic University, Internal Medicine, Khartoum, Sudan*; [5]*Ziryab Research Group, Financial Office, Khartoum, Sudan*

Background: Systemic lupus erythematosus (SLE) is a chronic systematic autoimmune disease with high heterogeneity. SLEDAI is the standardized method to determine disease activity, neutrophils to lymphocytes ratio emerge as new method to detect disease activity. The study aim is to study the neutrophil-to-lymphocyte ratio as a marker of active disease in SLE patients.
Objectives: This study aimed to assess cut off point of neutrophil-to-lymphocyte ratio as a marker of disease activity in systemic lupus erythematosus.

Methods: A cross sectional study was conducted in Haj Al-Safi hospital. A 53 patients were studied using pretested questionnaire, a SLEDAI assessment was conducted to each patient's individually. NLR were measured from collected CBC at the time of the study. Inclusion criteria were: people aged 18 or older, SLE patient diagnosed and confirmed by new 2019 criteria, and exclude any patients with infections, malignancies, and other inflammatory diseases recorded in registry. Data were collected and analyzed using SPSS.

Results: The mean age of patients was (± SD) 39.85 (± 14.07), SLEDI score assessment was conducted for the patients, 48 (90.6 %) scored > 4 and were considered active disease according to the score, 5 (9.4 %) scored <4 and were inactive. The NLR was calculated and the mean was 2.9 (± 2.08). Receiver Operating Characteristic (ROC) was conducted, cut-off (COV) was 2.48. Area Under Curve (AUC) and was AUC=0.402 (95% CI: 0.232 to 0.572, p=0.475).The sensitivity was 47%, and the specificity was 60%.

Conclusion: This findings indicated that the Neutrophil-to-lymphocyte ratio, with a cut-off value (COV) of 2.48, could be utilized to identify the disease activity of systemic lupus erythematosus. Furthermore, by applying this NLR COV.

AB0678 INTERLEUKIN-18 AS A PREDICTOR OF SUBCLINICAL CARDIOVASCULAR AFFECTION AND DISEASE ACTIVITY IN SYSTEMIC LUPUS PATIENTS

Keywords: Biomarkers, Systemic lupus erythematosus

S. A. A. Tabra[1], M. H. Abu-Zaid[1], D. Maria[2], R. Elsharaby[3]. *[1]Tanta University Faculty of Medicine, Rheumatology and Rehabilitation, Tanta, Egypt*; *[2]Tanta University Faculty of Medicine, Cardiology, Tanta, Egypt*; *[3]Tanta University Faculty of Medicine, Clinical Pathology, Tanta, Egypt*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease which has variable clinical manifestations and causes severe organ damage [(1)]. Interleukin-18 (il-18) is a pro-inflammatory
cytokine which plays a key role in many inflammatory and cardiovascular diseases [(2)].

Objectives: Evaluation of plasma level of IL-18 in SLE patients and correlate it with the subclinical cardiovascular affection and disease activity.

Methods: Thirty lupus patients (G I), and 30 healthy age and sex matched volunteers as control group (G II) were recruited for this case control study. All participants were subjected to complete history taking and clinical assessment, lupus disease activity was measure using SLE disease activity index 2000 (SLEDAI-2K), Serum IL-18 level, CRP, C3, C4, anti dsDNA, and lipid profiles were measured. Cardiovascular assessments were done using echocardiography, flow mediated dilatation of the brachial artery (FMD), and carotid intima-media thickness (cIMT). Plasma levels of IL-18 were measured and correlated with different parameters.

Results: There were no significant differences between the patients and controls regarding demographic data (P>0.05). The mean SLEDAI-2K was 3.5±2.1. The mean plasma level of IL-18 was 432.85±165.37 pg/ml in lupus patients, while IL-18 was 195.65±82.91 pg/ml in healthy volunteers, there was significant elevation of il-18 level in lupus patients in comparison with controls. There were significantly lowering levels of C3, & C4 in lupus patients. Regarding cardiovascular assessment; SLE patients showed significantly higher lipid profile, & cIMT measures and revealed lower FMD as well as detecting echocardiographic abnormalities compared to controls. (These date were summarized in Table 1).

Serum IL-18 was positively correlated with cIMT and SLEDAI-2K, also IL-18 was negatively correlated with FMD, C3 & C4.

Table 1. Comparison between lupus patients and controls regarding different parameters

	Lupus patients (30)	Controls (30)	P value
C3 (mg/dL)	78.9±22.9	116.8±18.6	< 0.0001
C4 (mg/dL)	9.6±4.8	25.7±4.6	< 0.0001
SLEDAI-2K	3.5±2.1	-	-
cIMT (mm)	0.91±0.27	0.68±0.21	0.0005
FMD%	5.92±2.25	7.65±2.16	0.0036
IL-18 (pg/ml)	432.85±165.37	195.65±82.91	< 0.001

Conclusion: IL-18 was an independent predictor of cardiovascular events in SLE patients, also it was correlated with lupus activity.

Background: Systemic Lupus Erythematosus represents the prototype of autoimmune systemic disease, its etiology involves aberrant interactions between genetic, immunological and environmental factors, affecting multiple organs and systems; about a third of patients present ocular alterations, with a variable degree of severity from mild clinical manifestations involving external and anterior ocular segments, to severe sight-threatening disease involving posterior eye segments.

Objectives: Describe and correlate ocular and clinical findings, as well as the positivity of autoantibodies in patients with Systemic Lupus Erythematosus using structural Spectral-Domain Optical Coherence Tomography (SD-OCT).

Methods: Cross-sectional single-center study, descriptive statistics and correlation analysis were performed using Spearman's test of the ocular findings determined by (SD-OCT) and serological determinations of antiphospholipid autoantibodies, anti-nuclear antibodies, anti-DNAds and anti-Smith antibodies in patients with Lupus during the months of January 2020 to December 2020, performing general ophthalmological examination and structural Spectral-Domain Optical Coherence Tomography.

Results: 29 patients were included, 26 women and 3 men, positive antiphospholipid antibodies in 56% of the population, lupus nephritis was found by renal biopsy in 49% of the population, disease activity was determined by MEX-SLEDAI, finding >9 points in 11% and <9 points in 89% of the population.

Maculopathy was found in 24% of patients; the correlations between autoantibodies and ophthalmological abnormalities determined by SD-OCT were: Lupus anticoagulant/Maculopathy p=0.008, anticardiolipin antibodies/maculopathy p= 0.026, anti Smith/choriocapillaritis p=0.014, decreased capillary perfusion/choriocapillaritis p= 0.003 and choroiditis p= 0.012, decreased perfusion by quadrants/maculopathy p=0.043. A decrease in retinal thickness was found in 65% of the population, also in the density of ganglion and macular cells and in the density of the optic nerve head.

Conclusion: Findings in our study were predominantly choroidal, macular and capillary alterations; a specific serological correlation was found between maculopathy and chorioretinitis with positive Lupus Anticoagulant, as well as alterations in capillary perfusion in patients with positive antiphospholipid and anti-Smith antibodies.

The use of SD-OCT can provide valuable and early information on the ocular microstructure and biological system in SLE and other autoimmune diseases affecting the eyes.

THE EFFECT OF DEPRESSION, ANXIETY, AND FIBROMYALGIA ON SEXUAL DYSFUNCTION IN FEMALE PATIENTS WITH SJÖGREN'S SYNDROME

Keywords: Fibromyalgia, Sjögren syndrome

S. M. Türk[1], D. Karataş[1], N. Erdik[1], G. Yavuzbilge[1], A. Karakurt[2], S. B. Acikgoz[1], Z. Öztürk[1], C. Arslantürk Güneysu[1], E. Gönüllü[1], Y. Türk[3]. *[1]Sakarya University Hospital, Rheumatology, Sakarya,Turkey*; *[2]Sakarya University Hospital, Internal Medicine, Sakarya,Turkey*; *[3]Adatıp Hospital, Gynecology, Sakarya,Turkey*

Background: Sjogren's Syndrome is a systemic autoimmune disease that mainly affects the exocrine glands.[1] The most common clinical symptoms of Sjogren's syndrome are dry mouth and eyes. Vaginal dryness and dyspareunia may be seen in the disease, as the female genital mucosa is also affected.[2]
Objectives: To compare the results by using the female sexual function scale in patients with Sjögren's Syndrome with and without depression, anxiety, and fibromyalgia and to evaluate the patients in terms of sexual dysfunction.
Methods: Twenty-five female patients diagnosed with Sjögren's Syndrome, according to the 2016 ACR-EULAR criteria, followed in the Internal Medicine, Rheumatology Clinic of Sakarya University Faculty of Medicine, were included in the study after their consent was obtained. Beck Depression Inventory, Beck Anxiety Inventory, and Female Sexual Function Scale were administered simultaneously to the patients. The presence of fibromyalgia was evaluated according to the 2016 Modified ACR diagnostic criteria. The relationship between depression, anxiety scale scores, the presence of fibromyalgia, and female sexual function was investigated.
Results: The mean age of the patients was 49±8.1 years, and the median duration of the disease was four years. 15 (60%) patients were primary school graduates, 2 (8%) patients were secondary school graduates, 4 (16%) patients were high school graduates, and 4 (16%) patients were university graduates. 11 (44%) of the patients were in menopause. Sexual dysfunction was found in 21 (84%) patients diagnosed with Sjögren's Syndrome. There was no statistically significant difference in sexual function scale scores between those with and without menopause. No statistical difference was found in disease duration, age, and scale scores in the presence of fibromyalgia. Sexual dysfunction was more pronounced in those with depression and anxiety (p=0.003; p=0.045, respectively) (Table 1).

Table 1. Comparison of depression and anxiety and sexual function scale scores

Sjogren Patients	Depression (+)	Depression (-)	p	Anxiety (+)	Anxiety (-)	p
Female Sexual Dysfunction score Median (IQR)	17.7 (8.6)	24.4 (7.1)	**0.003**	18.4 (6.9)	23.7 (6.2)	**0.045**
Desire score	1.8 (1.8)	3.0 (1.8)	0.107	2.1 (1.8)	2.7 (2.1)	0.319
Arousal score	2.2 (2.3)	3.6 (1.8)	**0.011**	2.7 (2.1)	3.6 (2.0)	0.089
Lubrication score	3.4 (1.3)	4.2 (1.5)	0.066	3.6 (1.0)	3.9 (1.6)	0.378
Orgasm score	2.8 (2.1)	4.0 (1.2)	**0.001**	2.8 (1.9)	4.0 (1.4)	0.052
Satisfaction score	2.8 (3.0)	4.4 (1.2)	**0.033**	3.0 (2.7)	4.6 (1.5)	0.101
Pain score	3.8 (3.3)	4.2 (4.8)	0.244	4.0 (3.3)	3.6 (4.8)	0.932

Conclusion: Depression and anxiety cause lower sexual function scores in female patients diagnosed with Sjogren's syndrome. The effect of fibromyalgia has not been demonstrated, but due to the limited number of patients, studies with a larger population will be more enlightening.

Background: Pre-conception counselling and risk stratification performed in a multidisciplinary clinical setting with rheumatologists, obstetricians and nephrologists may improve pregnancy outcomes in systemic autoimmune disease (SAD).
Objectives: To compare clinical, obstetrical comorbidities and pregnancy outcomes in patients with SAD with history of pregnancy loss with patients without history of pregnancy loss.
Methods: A retrospective cohort study was conducted. A total of 41 patients with SADs that attended the multidisciplinary preconception outpatient clinic were included. Variables related to SADs, obstetric comorbidities and pregnancy outcomes were collected. Description of the sample and comparison of groups were carried out. Shapiro-Wilk test was used to study normality.
Results: The description and comparison of the comorbidities, preconception counselling and pregnancy outcomes are summarized in Table 1. A total of 18 (46%) patients had a history of pregnancy loss. Fewer patients with history of pregnancy loss, 38.5% were fit for conception compared to 54.3% of patients with a history of pregnancy loss. Deferment of pregnancy was advised for 38.5% of patients with history of pregnancy loss and 54.3% in patients without history of pregnancy loss. Patients with a history of pregnancy loss had significantly higher anti-DNAds, antiphospholipid positivity and longer time since last flare.There was no significant difference for adverse pregnancy outcomes, disease activity or treatment. Interestingly, the distribution of risk profile for adverse pregnancy was different between both groups: there were more moderate and high risk for adverse pregnancy in patients with a history of pregnancy loss.
Conclusion: Patients with a history of pregnancy loss present delay to plan a new pregnancy, higher anti-DNA and antiphospholipid positivity. No worse pregnancy outcomes were observed.

DISEASE BURDEN AND UNMET NEED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH ADVANCED THERAPY: RESULTS FROM A REAL-WORLD SURVEY IN EUROPE AND THE UNITED STATES

Keywords: Systemic lupus erythematosus, Real-world evidence, Outcome measures

R. Khandker[1], E. Igho-Osagie[1], J. Hetherington[2], E. Goddard[2], J. Milligan[2]. *[1]Merck & Co. Inc., Center for Observational and Real World Evidence (CORE), North Wales, United States of America*; *[2]Adelphi Real World, Bollington, United Kingdom*

Background: Unmet medical need continues to be significant in patients with systemic lupus erythematosus (SLE) despite the use of advanced therapies (AT) to control active disease. Fatigue, end-organ damage, and low health-related quality of life (HRQOL) remain characteristic of the disease even among those treated with AT.

Objectives: In this analysis we measured the burden of unmet medical need in SLE patients prescribed AT for ≥12 months in real-world clinical settings.

Methods: Data were drawn from the Adelphi Real World Lupus Disease Specific Programme™, a cross-sectional survey with elements of retrospective data collection of rheumatologists and their consulting patients with SLE in France, Germany, Italy, Spain, the United Kingdom, and the United States in 2021.

Rheumatologists provided information on patient demographics, clinical status, and treatment history for their next six consulting SLE patients. The same patients completed the EQ-5D-5L, Functional Assessment of Chronic Illness Therapy Fatigue Subscale (FACIT-Fatigue), and Work Productivity and Activity Impairment questionnaire (WPAI) instruments. Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) scores were derived through physician assessment of patients' current clinical manifestations. AT was defined as biologics or off-label Janus kinase inhibitors.

All data were analysed descriptively.

Results: The sample included 234 patients seen by 125 physicians. Most patients (85%) were female and the mean participant age was 45.8 (SD:13.2) years. Mean duration since diagnosis was 6.6 (5.3) years and mean duration on their current regimen was 3.3 (3.0) years.

Despite receiving AT for ≥12 months, patients continued to have moderate-high levels of disease activity. Nearly half (48%) had SLEDAI scores ≥ 10 (Mean SLEDAI = 11.4 (11.2)). Many (37%) were assessed by physicians to have moderate/severe disease. Most (62%) continued to receive steroids, with 41% of patients prescribed oral/subcutaneous steroids receiving prednisone or equivalent doses of ≥7.5 mg/day. The majority of patients (56%) were 'currently experiencing' musculoskeletal symptoms including joint tenderness and swelling; while 37% and 19% respectively, were currently experiencing mucocutaneous and renal symptoms.

Mean EQ5D-5L score was 0.70 (0.27). Mean FACIT-Fatigue score was 32.4 (12.4), compared to US general population norm of 43.6 (9.4)[1]. Overall work impairment and mean daily activity impairment measured by the WPAI were 27.4% (20.4%) and 34.9% (25.3%) respectively.

Table 1. Unmet patient need in SLE patients prescribed AT for ≥ 12 months

			Patients on AT ≥12 months (n=234)
Physician-reported patient clinical status	Mean [SD] Derived SLEDAI score		11.4 [11.2]
	Organs/body areas affected, n(%)	Musculoskeletal	131 (56%)
		Mucocutaneous	87 (37%)
		Renal	44 (19%)
Steroid use	Steroid use, n(%)		145 (62%)
	Prednisone equivalent dose, n(%)ǂ	<7.5 mg/day	n=131
		≥7.5 mg/day	77 (59%)
			54 (41%)
Patient-reported outcomes†	Mean [SD] EQ5D-5L Utility score (0= death to 1= full health) [US value set]		n=99 0.70 [0.27]
	Mean [SD] FACIT-Fatigue score (0= worst fatigue to 52= no fatigue)		n=101 32.4 [12.4]
	Mean [SD] WPAI, percentage overall work impairment*		n=45 27.4 [20.4]
	Mean [SD] WPAI, percentage activity impairment		n=98 34.9 [25.3]

ǂPatients receiving oral/subcutaneous steroids only (n=14 excluded)†Patients with incomplete or unavailable responses were excluded*Working patients only; EQ-5D-5L, EuroQol-5 Dimension-5 Level; AT, advanced therapy; FACIT, Functional Assessment of Chronic Illness Therapy; mg, milligram; SLE, systemic lupus erythematosus; US, United States; WPAI, Work Productivity and Activity Impairment

Conclusion: Unmet medical need in SLE patients remained high despite long term use of AT. Study results suggest the need for more efficacious treatment options that reduce disease activity, reduce reliance on high-dose steroids, and improve quality of life.

SLE, Sjön's and APS - clinical aspects (other than treatment)

AB0683 USEFULNESS OF A MONOGRAPHIC CONSULTATION RHEUMATOLOGY - PNEUMOLOGY

Keywords: Lungs, Work-related issues

M. Pavía Pascual[1], N. DE LA Torre Rubio[1], M. Machattou[1], P. Navarro Palomo[1], M. Alonso de Francisco[1], C. Navarro Joven[1], C. Barbadillo Mateos[1], C. Merino Argumánez[1], M. Fernandez Castro[1], B. Garcia-Magallon[1], J. Sanz[1], L. F. De Villa[1], J. Campos Esteban[1], J. L. Andréu Sánchez[1], H. Godoy[1]. [1]*Hospital Universitario Puerta de Hierro Majadahonda, Rheumatology, Madrid, Spain*

Background: Some rheumatological diseases may involve the lungs. This is something that the rheumatologist and pulmonologist must take into account in their clinical practice.
Objectives: To describe the characteristics of a group of patients with diffuse interstitial lung disease (ILD) that are being followed-up in a Rheumatology-Pneumology monographic consultation and study the usefulness of this consultation.
Methods: We reviewed the medical records of patients with a diagnosis of ILD that were being studied by both services in a monographic consultation in a tertiary hospital. A descriptive study was performed.
Results: A total of 40 patients were studied: 16 with nonspecific interstitial pneumonia (NSIP), 15 with usual interstitial pneumonia (UIP), 5 with fibrotic NSIP, 2 with cryptogenic organizing pneumonia (COP) and 2 with undefined ILD. 60% were women and the mean age was 64 years (40-80 years). Twenty patients with ILD were referred from pneumology to rheumatology. The primary reason for referral was the determination of positive antibodies (60%). Other reasons were arthritis (15%), other symptoms suggestive of connective tissue disease (15%) or the screening for collagenopathy in patients with poor outcome (10%). Ninety-five percent of patients with ILD referred to rheumatology were diagnosed with a connective tissue disease (Graph 1 and Table 1), which led to a change in treatment in 68.4% of them, with mycophenolate being the most prescribed drug, followed by rituximab. Twelve patients followed up in rheumatology with diagnosis of systemic sclerosis (n=6), rheumatoid arthritis (n=3), Sjögren's syndrome (n=2) and anti-synthetase syndrome (n=1) were referred to pneumology. The reasons for referral were the appearance of a pattern of interstitial involvement in imaging tests (chest X-ray or CT) and/or the alterations in respiratory function tests requested routinely (in the case of scleroderma) or due to respiratory symptoms (cough, dyspnea or crackles on chest auscultation). Follow-up by the pulmonologist implied a modification in the treatment in 5 out of 12 patients (41.7%) which consisted in the addition of an antifibrotic, Nintedanib in all cases. The reason for initiation was a decline in lung function demonstrated by pulmonary function tests. In 8 patients, the diagnosis of ILD and rheumatologic disease had been made in another center and they were referred for follow-up.
Conclusion: Ninety-five percent of patients with ILD referred to rheumatology were diagnosed with a connective tissue disease, which led to a change in treatment in 68.4% of them, with mycophenolate being the most frequently prescribed drug, followed by rituximab. The diagnosis of ILD in patients with rheumatologic disease was possible thanks to pulmonary auscultation, anamnesis on respiratory symptoms and the performance of imaging and functional tests. Referral of these patients to pneumology service allowed a better characterization of their pulmonary disease and the initiation of antifibrotic drugs in those with progressive fibrosing disease.

AB0684 RETROSPECTIVE STUDY ON SENSITIVITY AND SPECIFICITY OF VARIOUS CLASSIFICATION CRITERIA IN EARLY DIAGNOSIS OF SYSTEMIC LUPUS ERYTHEMATOSUS AND LINK TO DISEASE OUTCOMES

Keywords: Outcome measures, Systemic lupus erythematosus, Descriptive studies

M. S. Mohamed Said[1], S. Chu Ee[1], R. Mustafa[1]. [1]*Faculty of Medicine Universiti Kebangsaan Malaysia, Medical, HUKM, Kuala Lumpur, Malaysia*

Background: Systemic lupus erythematosus (SLE) is a multisystem inflammatory disease with heterogeneous clinical manifestations, making the diagnosis of disease challenging. To date, study on comparison of sensitivity and specificity of various SLE classification criteria among multiracial Malaysians is limited.
Objectives: To compare the sensitivity and specificity of various SLE classification criteria among multiracial Malaysians.
Methods: A retrospective study on data obtained from medical records of SLE and control cases. The sensitivity and specificity of 1997 American College of Rheumatology (ACR) revised criteria, Boston Weighted (BW) criteria, 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria, and 2019 European League Against Rheumatism (EULAR)/ACR classification criteria was calculated at baseline and at one year follow up. The link of diagnostic criteria to disease outcomes five years after diagnosis [disease damage, cardiovascular (CV) outcomes, and mortality] was studied.
Results: 420 SLE cases and 420 control cases were recruited. At baseline, the sensitivity and specificity of 1997 ACR criteria, BW criteria, 2012 SLICC criteria, and 2019 EULAR/ACR classification criteria were 69.3% and 99.3%, 89.5% and 96.7%, 94% and 97,6%, 96.4% and 96.5%, respectively. At one year follow up, sensitivity and specificity of the1997 ACR criteria, BW criteria, 2012 SLICC criteria, and 2019 EULAR/ACR classification criteria improved to 72.9% and 99.3%, 91.4% and 96.7%, 97.1% and 97,6%, 100% and 96.9%, respectively. There is statistical correlation between the 2019 EULAR/ACR classification criteria and SLICC/ACR damage index (DI), and disease relapses.
Conclusion: 2019 EULAR/ACR classification criteria demonstrated the highest sensitivity to diagnose SLE, with comparable specificity to other diagnostic criteria.

AB0685

DESCRIPTIVE STUDY OF A COHORT OF PATIENTS WITH NEUROPSYCHIATRIC MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS IN A TERTIARY HOSPITAL

Keywords: Systemic lupus erythematosus

R. J. Gil Velez[1], L. Mendez Diaz[1], I. Madroñal García[1]. [1]*Virgen del Rocio Hospital, Rheymatology, Seville, Spain*

Background: Systemic lupus erythematosus (SLE) affects 0.1% of the world population; its neuropsychiatric expressions include, from vascular headache, mood disturbances to cognitive and other severe disorders such as transverse myelitis. It represents a diagnostic challenge, since none of the syndromes is exclusive of SLE and up to 40% is attributed to other causes; specifically it is necessary to rule out central nervous system infection, uremia, thrombotic thrombocytopenic purpura, posterior reversible encephalopathy, steroid psychosis and hypertension.
Objectives: To describe the neurological/neuropsychiatric manifestations in patients with systemic lupus erythematosus, diagnostic tests used and therapeutic possibilities in a cohort of patients in a tertiary level hospital.
Methods: Retrospective descriptive study of a cohort of patients with neuropsychiatric manifestations in the context of SLE in the Rheumatology Department of the Hospital Universitario Virgen del Rocio Sevilla (2017-2022).
Results: 12 patients with neuropsychiatric manifestations were included in our study, 8 (66.6%) women, 4 (33.4%) men, with a mean age of 30 ± 6 years and mean time of diagnosis of systemic lupus erythematosus of 3.5 years. Nine (75%) SLE with joint/cutaneous involvement and 3(25%) SLE with renal involvement (focal proliferative glomerulonephritis and segmental). In 9 (75%) of the cases imaging studies both cranial MRI and PET showed inconclusive lesions and as for specific antibodies: 4 (33.3%) anti-NMDAR, 3 (25%) anti-ribosome P. Among the most frequent clinical manifestations 6 (50%) presented persistent headache, 3 (25%) psychosis, 3 (25%) memory and mood disturbances. 9 (75%) of the cases responded to anti-CD20 (rituximab) and 3 (25%) to intravenous immunoglobulin infusion.
Conclusion: The data obtained from the clinical histories were conclusive with current scientific publications. It is an entity whose diagnosis is a challenge for the clinician, and both analytical tests and imaging studies are usually non-specific. The most frequent manifestations are headache, cognitive manifestations and mood alterations (anxiety attacks, panic, euphoria). Further studies are needed to classify the risk of this entity and the relationship with specific neuronal autoantibodies.

THE NEUTROPHIL-TO-C3 RATIO (NC3R) WAS AN INFLAMMATORY MARKER IN THE ASSESSMENT OF LUPUS NEPHRITIS AND OCULAR VESSEL DENSITY IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Keywords: Biomarkers, Systemic lupus erythematosus, Kidneys

M. Maitiyaer[1], P. Li[1], H. Li[2], X. Yang[3], C. Chen[1], J. Zhang[2], W. Huang[1], Z. Liu[2], S. L. Yu[1]. [1]*The Second Affiliated Hospital of Guangzhou Medical University, Department of Rheumatology, Guangzhou, China*; [2]*The Second Affiliated Hospital of Guangzhou Medical University, Ophthalmic Center, Guangzhou, China*; [3]*The Second Affiliated Hospital of Guangzhou Medical University, E.N.T. Department, Guangzhou, China*

Background: Lupus nephritis (LN) is one of the most serious complications of systemic lupus erythematosus (SLE). An increased neutrophil to C3 ratio (NC3R) may reflect LN. NC3R is a promising predictor of LN and ocular involvement in SLE patients.
Objectives: To explore the relationship between NC3R and LN patients and ocular vessel density in SLE patients.
Methods: This retrospective study included 53 patients with LN and 80 SLE patients without kidney involvement. The differences in NC3R between patients with and without LN were evaluated. Correlations between NC3R and other variables in SLE patients were assessed. Receiver operating characteristic curves (ROC) was constructed in NC3R to predict LN. Multivariate logistic regression analysis was used to analyze the independent factor of LN. We also investigate the role of NC3R in ocular involvement in SLE patients.
Results: NC3R was increased significantly in the LN group as compared with those SLE patients without LN(7.7 vs 4.5, P=0.002). NC3R were positively correlated with 24-hour proteinuria (r=0.437, P<0.001), and SLEDAI score(r=0.389, P<0.001), and negatively correlated with C3(r=-0.346, P<0.001) and C4(r=-0.293, P=0.001). Multiple regression analysis suggested that NC3R was an independent risk factor of LN[OR: 4.41 (1.64~11.91), P=0.003]. NC3R [AUC: 0.642, 95%CI(0.540~0.744)] was useful in differentiating LN patients, and the optimal cutoff was 4.56 (sensitivity: 79.6%, specificity: 49.2%). In the high NC3R group patients, there was increased superficial vessel density.
Conclusion: NC3R was a plausible indicator to predict LN and ocular involvement. Therefore, evaluating NC3R before treatment could help clinicians to identify potential organ involvement in patients with SLE.

CHRONIC SCLEROSING SIALADENITIS, IS IT A SJÖGREN'S SYNDROME OR NOT?

Keywords: Sjögren syndrome, Epidemiology, Descriptive studies

E. J. Kwon[1,2], B. W. Lee[1], Y. Park[1], J. J. Lee[1], S. H. Park[1], S. K. Kwok[1]. [1]*The Catholic University of Korea Seoul St. Mary's Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*The Catholic University of Korea - Songeui Campus, Department of Medicine, Graduate School of Medical Science, Seoul, Korea, Rep. of (South Korea)*

Background: The Sjögren's syndrome (SS) is a chronic autoimmune disease. The classification criteria of SS have been evolved through the decades. Recent in 2016, American college of rheumatology (ACR)–European Alliance of Associations for Rheumatology (EULAR) classification requires at least one positive finding in either the labial salivary gland biopsy or anti-Ro (SSA) serology for the confirmation of SS. Chronic sclerosing sialadenitis (CSS) is unusual, underrecognized condition that affects the salivary gland, reported by H. Kutter at first. [1] Though the CSS already has been eliminated from the diagnostic criteria of SS, there is controversy in the meaning of CSS in SS. And that makes it difficult to determine whether the patient who suffers from sicca symptom is SS or not.
Objectives: Investigating the clinical meaning of CSS in association with SS by comparing the clinical and laboratory findings, we provide the extent of understanding CSS, the rare pathologic condition of salivary gland.
Methods: This study is a single center retrospective study, including patients confirmed as CSS via biopsy in Seoul St. Mary's Hospital from 2000 to 2022. (1) Patients with history of head and neck radiation, (2) graft-versus-host disease (GVHD), (3) IgG4-RD, (4) positive biopsy result in IgG4 immunohistochemistry

(IHC) staining, and (4) insufficient pathologic result to distinguish IgG4-RD from CSS were excluded. 21 of 27 CSS patients were eligible to our analysis. 4 of positivity with IgG4 in IHC staining positivity, 1 of GVHD, and 1 of prior head and neck radiation were excluded. We assessed 239 patients from 341 of the Korean Initiative of primary SS (KISS) prospective cohort study as SS control group, eligible to 2016 classification.

Results: In CSS group, only 1 of 21 was diagnosed as SS. Table 1 summarizes the result. 'CSS as SS' consisted of CSS patients meeting 2016 criteria, assuming that the CSS could be a part of SS pathology.

Table 1. The clinical characteristics of chronic sclerosing sialadenitis.

Anti-CCP Ab	0.2 ± 0.3	23.2 ± 82.4	200	**<0.001**	0.1 ± 0.3	199	**<0.001**
Stimulated salivary flow rate (ml/min)	0.65 ± 0.57	0.54 ± 1.15	103	**<0.001**	0.50 ± 0.41	99	**0.006**

Abbreviations: BMI, body mass index; Ab, antibody; EGM, extraglandular manifestations; ESSDAI, EULAR Sjögren's syndrome disease activity index; ESSPRI. EULAR Sjogren's syndrome patient reported index.

Conclusion: The CSS were once inculeded in pathologic category of SS. However, it is a distinct phenotype separated from SS in such aspects of the (1) age of onset, (2) proportion of occular manifestation, (3) autoimmune profiles, and (4) stimulated salivary flow rate. Thus, physicians should also consider the possibility of CSS in old age patient with xerostomia.

AB0688 QUALITY INDICATORS AND SATISFACTION WITH CARE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Patient reported outcomes, Systemic lupus erythematosus, Quality of care

G. Serna-Peña[1], J. A. Esquivel Valerio[1], G. García-Arellano[1], L. R. Aguilar Rivera[1], R. D. J. Castillo de la Garza[1], A. A. De León Pérez[1], E. Aguilar Rivera[1], C. E. Vázquez Pérez[1], D. Á. Galarza-Delgado[1]. *[1]Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*

Background: Quality indicators (QI) for patients with SLE were developed based on the 2019 EULAR recommendations [1]. Measuring quality of care (QOC) may provide recognition of gaps and challenges in clinical practice. Improving QOC may relate to high satisfaction with care. Satisfaction might be considered a valuable indicator to measure the success of provided care. Evidence about the relationship between quality of care and satisfaction perceived by SLE patients is scarce.

Objectives: To correlate adherence to QIs based on the 2019 EULAR recommendations and satisfaction with care in SLE patients.

Methods: We conducted a cross-sectional and retrospective study in a Lupus Clinic in Northeast Mexico. We included patients at least 18 years old who met the ACR/EULAR 2019 classification criteria for SLE. Consecutive patients were interviewed by the researchers on their last visit to assess the adherence to quality indicators developed by Chavatza et. al., based on 2019 EULAR recommendations. Medical records were revised to assess demographic data, disease activity, treatment, organ involvement, and cumulative damage. Adherence was achieved if the patient met all components of the QI. We calculated adherence as the number of fulfilled patients divided by the number of eligible patients per indicator. Satisfaction with care was evaluated with the satisfaction domain of the LupusPRO 1.7 version. The distribution was assessed with Kolmogorov-Smirnov. The Spearman correlation coefficient was obtained to determine the relationship between quality of care and satisfaction with care.

Results: Seventy patients were included with a median age of 33 (IQR, 23-48), and 90% were female. Global adherence to the 18-QIs and Satisfaction with Care score revealed no correlation using the Spearman correlation coefficient (r = 0.064, p= 0.599). Overall adherence was 62.29%. The median satisfaction with care was 100. The results of each indicator are shown in Table 1.

Conclusion: In conclusion, we did not find a correlation between satisfaction with care and QOC. The areas of quality of care that performed the lowest were the measurement of the SLEDAI-2K and the SLICC/ ACR damage index, which was an area of opportunity for improvement.

Background: Dietary habits and Physical Activity (PA) are two pivotal features of healthy life in terms of the prevention and treatment of metabolic and chronic disease [1]. Few data are available concerning these issues in isolated Sjögren's syndrome (SS) patients [2].
Objectives: Aim of the study was to assess the level of PA, the adherence to Mediterranean diet (MD) and the nutritional status of Italian patients with SS.
Methods: Consecutive patients with SS (AECG criteria 2002) were enrolled. For each patient ESSDAI, ESSPRI, SSDDI were calculated. The value of focus score was obtained in the minor salivary gland biopsy (MSG), when performed. The International Physical Activity Questionnaire (IPAQ) was administered to assess the level of physical activity; the Mediterranean Diet (MDiet) score [3] was employed to analyse adherence to Mediterranean diet (the score spans from 0 - no adherence - to 55 - maximum adherence). In a subgroup of 26 patients, the dietary habits were evaluated with a daily food diary. Sarcopenia, a muscle failure that accrue across a lifetime, was identified by a diagnostic algorithm [4] with age-differentiated cut-offs; the Hand Grip test (HGT) and the Chair Stand test (CST) were used as screening tests, the Dual Energy X-ray Absorptiometry (DEXA) was employed to confirm and to quantify Appendicular Skeletal Mass (ASM, kg/m^2). The muscular performance (6-minutes Walking Test – 6MWT) was measured to grading sarcopenia. Statistical analysis was performed with SPSS.
Results: The 130 pSS patients enrolled showed a moderate adherence to the Mediterranean Diet (median MDiet = 33, third quintile) and played a moderately PA (median MET x min/wk in the second tertile). No significant associations were found between BMI, PA, MDiet and clinimetric index of pSS (ESSDAI, ESSPRI, SSDDI). BMI was higher in older patients (R ^{2} 0.96, p 0.02). 16 out of the 26 subjects of the subgroup (61%) showed a reduction in muscle strength (HGT and/or CST) and therefore a condition of probable sarcopenia but only 6 (23%) subjects were found to be sarcopenic (ASM). Only one sarcopenic patient had a 6MWT less than 10% of the predicted value and a reduced PA in MET x min/wk. Patients' daily diet consisted of 43% of total energy coming from carbohydrate, fat represented 40% of total energy intake, the remaining 17% daily energy coming from proteins. Fat consumption is higher and complex carbohydrates intake is lower compared to the levels of energy and nutrient intake for the Italian population [5].
Conclusion: This preliminary study considering Italian women with SS shows a moderate adherence to the MD similar to what previously reported in the general female population in Europe (32.5 ± 5 DS) [6]. Moreover, considering the results obtained in the subgroup, SS patients seem to have an unbalanced diet because of an intake of fat foods higher than that recommended in the Mediterranean Diet. A possible explanation for the higher fats intake may be a lubricating effect aiding mastication and swallowing. It can be hypothesized that an unbalanced diet might be partly responsible for increasing chronic damage and the associated reduction in muscle mass.

SUBCLINICAL JOINT INVOLVEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS: ROLE OF ULTRASOUND EVALUATION

Keywords: Ultrasound, Systemic lupus erythematosus, Prognostic factors

L. M. Argolini[1], O. De Lucia[1], C. Artusi[1], A. Amati[2], C. Iannone[2], I. Magi[2], G. Cincinelli[2], M. Gerosa[1,2], R. Caporali[1,2]. [1]*ASST G.Pini-CTO, Clinical Rheumatology, Milan, Italy*; [2]*University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*

Background: Patients with Systemic lupus erythematosus (SLE) experience musculoskeletal involvement in up to 90% of cases. Clinical presentation includes arthralgia, non-erosive arthritis, erosive arthritis and Jaccoud's arthropathy [1]. Recently, thanks to the use of ultrasound (US), several studies have demonstrated the presence of a subclinical joint and peri-articular inflammatory state, especially in patients with non-specific symptoms [2]. However, studies involved a small number of patients and there is a lack of predictive factors of disease progression to more aggressive forms as well of specific and validated clinimetric indices in patients with SLE.
Objectives: To evaluate joint and peri-articular involvement in SLE patients with different patter of musculoskeletal involvement by US. To evaluate the strength of the clinimetric indices already validated in other rheumatologic diseases (DAS28, CDAI, SDAI) in patients with SLE. To analyse the predictive value of laboratory data (autoantibody profile, complement levels, acute phase reactants) in joint involvement.
Methods: Consecutive SLE patients (18-65 years old), who fulfilled the EULAR/ACR 2019 criteria, were enrolled: 20 without symptomatic musculoskeletal involvement (Group 1) 19 with arthralgias without structural joint alterations (Group 2), 11 patients with estabilshed musculoskeletal involvement (Group 3). All patients undergo ultrasound evaluation with Esaote MyLab70 device with a 6-18 mmHz linear probe; wrists, metacarpophalangeal and proximal interphalangea joints, all finger flexors, wrist extensors and flexors at the hands, elbows, long head of the biceps and Achilles tendon were evaluated. All abnormalities were defined according to OMERACT EULAR Score System. [9]. DAS28 CDAI and SDAI and the most recent blood tests (ANA ENA FR anti CCP anti DNA ESR CRP C3 C4) were recorded; hands and wrists X-ray were performed according to good clinical practice.

Results: Fifty females were enrolled. Clinical characteristics during the disease course and serological and clinimeric scores at the time of enrollement are reported in Table 1. Group 1: US detected synovitis (grade 1–3) in 7 (35%) patients, mainly wrists and hands, Group 2: US detected synovitis (grade 1–3) in 5 (26.3%) patients mainly hands, elbows and wrists. Group 3: US detected synovitis (grade 1–3) in 7 (63.7%) patients, mainly knees elbows Achilles tendon, hands.

Conclusion: Our study confirmed that the musculoskeletal involvement in SLE is underestimated. Although not statistically significant, the groups showed differences in synovitis involvement. The percentage of asymptomatic patients with ultrasound signs of synovitis, especially of the hands and wrists, is higher than expected and almost comparable with symptomatic arthralgia patients. No association with clinimetric and laboratory tests were highlighted. As expected, the group of patients with known arthritis more frequently had ultrasonographic changes and signs of systemic disease activity.Our study suggests how necessary and interesting it is to prospectively evaluate in the future how the joint disease will progress in asymptomatic patients, and who will develop, for example, bone erosions or Jaccoud's arthropathy.

AB0691 RESTLESS LEG SYNDROME AMONG PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A COMMON NEUROLOGIC MANIFESTATION

Keywords: Quality of life, Systemic lupus erythematosus, Comorbidities

K. Parperis[1], S. Philippou[1], C. Christophi[2], S. Psarelis[3]. [1]*University of Cyprus, Medical School, Nicosia, Cyprus*; [2]*Cyprus University of Technology, Biostatistics and Epidemiology, Limassol, Cyprus*; [3]*Nicosia General Hospital, Rheumatology, Nicosia, Cyprus*

Background: Restless leg syndrome (RLS) is a common neurologic condition, affecting 5 to 10 percent of adults, that can be seen in patients with autoimmune diseases, like rheumatoid arthritis; however, data in patients with systemic lupus erythematosus (SLE) are scarce. Sleep disturbances are common in the SLE population, but few studies, with a small number of patients, investigated RLS. A deeper understanding of the relationship between SLE and RLS will allow us to promptly diagnose and manage RLS.

Objectives: The aim of this study is to determine the prevalence of RLS among patients with SLE, describe the clinical characteristics of RLS, examine its impact on health-related quality of life (HRQoL), and evaluate its association with depression.

Methods: We recruited SLE patients who met the SLICC-2012 criteria from September 2020 to September 2022. Demographic data, clinical characteristics, and pain level based on a visual analogue scale (0-10) were recorded. RLS diagnosis was based on the international restless leg syndrome study group criteria, and depression was assessed by the patient health questionnaire (PHQ)-9, with scores ≥10 indicating major depressive disorder (MDD). Patient global assessment was scored from 0 to 10, with higher numbers indicating active disease. HRQOL was assessed by a disease-specific validated questionnaire, the LupusQoL; scores ranged between 0-100, with higher scores indicating better QoL. These variables were compared between SLE patients with RLS and without RLS using t-tests or Wilcoxon non-parametric tests for continuous variables, as appropriate, and the chi-square test of independence for categorical variables. A p-value ≤ 0.05 was considered statistically significant and all tests performed were two-sided.

Results: Among the 144 SLE patients included in the study, 108 were women (87.1%), with a mean age of 49 ± 15 years (range 19 - 80) and a mean disease duration of 14 ± 12 years. Forty (32%) of them met the criteria for RLS and were more likely to experience a delay in diagnosis (mean 4.6 vs 2.2 years; p=0.019) and were less likely to work (65% vs 45%, p=0.040) compared to non-RLS patients. RLS patients were more likely to have coexisting MDD (45% vs 24%, p=0.019), higher level of pain (mean 3.9 vs 2.5, p=0.007) and disease activity based on patient global assessment (mean 4.2 vs 3.2, p=0.025). Further, all the domains of LupusQoL were significantly lower in the RLS patients group suggesting worse HRQoL (Table 1).

Conclusion: One of every three SLE patients had RLS, which negative impacted the patient's HRQoL. In addition, RLS was associated with depression, higher levels of pain, and worse perceived disease activity. Therefore, clinicians should be vigilant to recognize and manage RLS in SLE patients.

Table 1. LupusQol domain scores (median (Q1, Q3)) among patients SLE patients with and without RLS

LupusQoL Domains	All patients	No RLS	RLS	P-value
Pain	75.0 (41.6, 100.0)	83.3 (58.3, 100.0)	45.8 (25.0, 75.0)	<.001
Emotional health	79.1 (58.3, 91.6)	83.3 (66.6, 95.8)	66.6 (43.7, 85.4)	0.008
Physical health	71.8 (46.8, 90.6)	78.1 (56.2, 96.8)	64.1 (31.2, 78.1)	0.001
Planning	75.0 (41.6, 100.0)	91.6 (58.3, 100.0)	66.6 (33.3, 91.6)	0.017
Intimacy	75.0 (37.5, 75.0)	75.0 (50.0, 100)	62.5 (25.0, 75.0)	0.056
Burden to others	75.0 (58.3, 100.0)	83.3 (66.6, 100.0)	66.6 (41.6, 87.5)	0.006
Body image	88.8 (66.6, 100.0)	91.6 (70.0, 100.0)	77.5 (55.0, 100.0)	0.059
Fatigue	68.7 (50.0, 87.5)	81.2 (62.5, 93.7)	50.0 (31.2, 62.5)	<.001

AB0692 SERUM INTERFERON A (IFNA) LEVELS AND SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) DISEASE ACTIVITY IN SLE PATIENTS IN ESTONIA. A PROSPECTIVE COHORT STUDY OF 40 SLE PATIENTS IN ESTONIA

Keywords: Systemic lupus erythematosus, Real-world evidence, Descriptive studies

S. Meisalu[1], K. Kisand[2], L. Haljasmagi[2]. [1]*East-Tallinn Central Hospital, Rheumatology, Tallinn, Estonia*; [2]*University of Tartu, Biomedicine, Tartu, Estonia*

Background: SLE is a rare chronic autoimmune disease with polymorphic clinical manifestation. It has been found that the interferon signature is detectable in 80% of SLE patients. With the implementation of measuring IFNα levels, additional method to evaluate SLE has been provided.

Objectives: The aim of the present study is to characterize a sample of Estonian SLE patients.

Methods: Consecutive outpatient and inpatient patients with rheumatologist diagnosed SLE (≥20 years) were enrolled in East-Tallinn Central Hospital. Two study visits were done with 6 months apart to evaluate disease activity, current treatment, organ involvement, immunological findings and comorbidities. In addition, data from medical records were collected: organ involvement and immunological findings at the time of diagnosis and initial treatment. SLE disease activity was measured using SLEDAI 2K (Systemic Lupus Erythematosus Disease Activity Index 2K) score. Blood tests were taken to measure interferon levels using Simoa (Single Molecul Array) method. To evaluate the extent of the deviation of IFNα levels in patients with SLE compared to non-autoimmune individuals, age and gender matched control group was used. Interferon score was calculated according to interferon induced gene expression in blood cells collected to RNA stabilizing tubes. Spearman correlation was used for correlation analyses and chi-square and Fisher test for the group comparison.

Results: Among 40 patients (mean age 50 (standard deviation ±12.4) years, mean disease duration 12 (±9.9) years, mean SLEDAI 2K at diagnosis 10 (±3.9)) 92.5% were females. Mean SLEDAI 2K value at entering into the study was 4 (±3.4) similar to the value after six months 4 (±5.0). Median IFNα levels during first and second study visits were respectively 133 fg/ml (IQR=560) and 117 fg/ml (IQR=477). At first and second study visit respectively 48% and 45% of patients had low IFNα levels (<100 fg/ml), 35% and 37% had high IFNα levels (100-1000 fg/ml) and 18% of patients had very high IFNα levels (>1000 fg/ml). IFNα levels correlated poorly or not significantly in either time point with SLEDAI 2K (r=0.3280, p=0.04 and r=0.5460, p=0.0004), organ involvement (for joints r= 0.2352, p=0.14 and r=0.3433, p=0.03; for skin r=0.0216, p=0.89 and r=-0.0532, p=0.76), Rituximab treatment (r=0.2061, p=0.20 and r=0.3201, p=0.05). IFNα levels correlated strongly with IFN score (r=0.9325, p<0.0005) and 78% of patients had elevated IFNa levels compared to 98 percentile of healthy controls (median IFNα level 0.5605 fg/ml, IQR=1.77). There was no statistical difference in regards of Rituximab treatment during the study in low and in high IFNα level group, respectively 16% and 38% (p=0.22) at first study visit and 12% and 43% (p=0.07) at second study visit.
Conclusion: The first analysis of Estonian SLE patients' IFNα levels and disease activity shows that measuring IFNα levels can give additional information in some SLE patients in the light of new treatments targeting IFNα, although the general correlation with disease activity and available treatment so far is low. Further studies are in progress to evaluate IFNα levels in larger Estonian SLE population to better understand possible pathogenetic mechanisms in different SLE subpopulations.

AB0693 IN-OFFICE LACRIMAL BIOMARKERS IN PRIMARY SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome, Outcome measures, Descriptive studies

F. Morales-Wong[1], J. C. Riega-Torres[2], A. J. Cavazos-Tamez[1], O. E. Alvarez-González[2], J. Mohamed Hamsho[1], C. M. Skinner Taylor[2], D. Á. Galarza-Delgado[2], K. Mohamed Noriega[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Ophthalmology, Monterrey, Mexico*; *[2]Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*

Background: Dry eye disease (DED) is characterized by loss of homeostasis of the tear film, ocular surface inflammation, ocular symptoms and neurosensory abnormalities. [1] The exposure of epithelial surface triggers a series of cellular processes that culminate in an inflammatory mediator increase, which can be measured non-invasively and affordably in a medical office. [2]
Objectives: To compare tear film osmolarity (Osm) and matrix metalloproteinase-9 (MMP-9) inflammatory biomarkers between primary Sjögren's syndrome (pSS) patients and a control group.
Methods: A prospective, cross-sectional and comparative study was conducted as part of a dry eye screening cohort by the ophthalmology and rheumatology services of the Hospital Universitario "Dr. José Eleuterio González". pSS diagnosis was made according to ACR/EULAR 2016 criteria. Control group participants were recruited as part of dry eye screening evaluations in general population. Patients under 18 years old, history of ocular disease not related to pSS, ocular surgery in the last 3 months and contact lenses wearers were excluded. All participants underwent the following dry eye tests: tear film Osm, tear film MMP-9, ocular surface disease index (OSDI) questionnaire, tear breakup time (TBUT), sicca ocular staining score (OSS), Schirmer without anesthesia (SCH) and corneal sensitivity.
Results: One eye per patient was included, 76 with pSS and 76 age- and sex-matched controls. Mean age was 53.0 ± 12.7 and 53.4 ± 16.2 (p=0.955) in pSS and control group respectively. The majority were women in pSS (74, 97.4%) and controls (74, 97.4%). We found a significant difference in the prevalence of comorbidities, with hypothyroidism (12, 18.8% vs. 1, 1.3% *p*=0.002) and depression (7, 9.2% vs 0 *p*=0.007) being more frequent in the pSS group than controls. In pSS and controls, Osm was 316.05 ± 25.54 vs 305.13±17.22 (p=0.010), positive MMP-9 in 19 (25.0%) vs 7 (9.2%) (p=0.017), OSDI was 43.52 ± 24.09 vs 34.09 ± 21.15 (p=0.012), TBUT 5.04 ± 3.36 vs 6.48 ± 2.76 (p <0.001), OSS 7.12 ± 3.50 vs 1.83 ± 1.70 (p<0.001), SCH 10.91 ± 10.05 vs 15.70 ± 9.60 (p<0.001) and sensitivity 5.56 ± 1.01 vs 5.91 ± 0.28 (p=0.032) respectively. No significant correlation was found between Osm and other dry eye variables.
Conclusion: Patients with pSS had higher Osm and OSDI, as well as more prevalence of MMP-9 detection than controls, and lower TBUT, Schirmer and corneal sensitivity. More information is needed to determine the role of tear film osmolarity and MMP-9 in the tear in the diagnosis and prognosis of pSS. However, biomarker tests are useful for the diagnosis and severity stratification of DED, being non-invasive, affordable and easy to use in the medical office.

AB0694 CORRELATION BETWEEN PATHOLOGICAL FINDINGS AND SALIVARY GLAND ULTRASOUND IN PATIENTS WITH CLINICAL SUSPICION OF SJÖGREN'S SYNDROME IN A TERTIARY HOSPITAL

Keywords: Sjögren syndrome, Ultrasound

M. Espinosa[1], M. Fernandez Castro[2], H. Godoy[2], J. L. Andréu Sánchez[2], A. Sánchez[2]. *[1]Hospital Universitario Virgen del Rocío, Internal Medicine, Seville, Spain*; *[2]Hospital Universitario Puerta de Hierro Majadahonda, Rheumatology, Madrid, Spain*

Background: Sjögren's syndrome (SS) is a chronic systemic autoimmune disease that presents a great clinical heterogeneity, which condition a significant delay in its diagnosis. The current 2016 classification criteria for SS, according to ACR/EULAR, are based on five objective tests/data, including minor salivary gland biopsy (MSGB). These criteria do not include any imaging tests2. Ultrasound of the major salivary glands (MSGU) has been consolidated in Rheumatology as a rapid, non-invasive, accessible and cost-effective test that could be useful in the evaluation of patients with Sjogren's syndrome, both for diagnosis and follow-up of these patients.
Objectives: To evaluate the correlation between the histological results obtained from the minor salivary gland biopsy (MSGB) and the findings of the major salivary gland ultrasound (MSGU) in patients with suspected Sjögren's syndrome.
Methods: It is a cross-sectional study in a consecutive cohort of patients evaluated in the rheumatology clinics of a tertiary hospital for ten months with suspicion of SS who underwent a MSGB as part of the of the usual diagnostic process and who are proposed to perform an MSGU (parotid and submandibular, bilaterally). We used the ultrasound scoring system proposed by OMERACT in 2019 that is based on the homogeneity of the glandular parenchyma individually (0-3) and a total score (0-12) is made. Demographic, clinical, and histological data were collected from the patient's clinical history after performing the ultrasound. A descriptive and inferential analysis of data is carried out.
Results: Fifty-seven patients were included, with a mean age of 56.8 years, 87% being women. Of these, 31 patients were diagnosed with Sjogren's syndrome. The rest of the patients, 26 individuals, were considered the control group. Of the 22 patients with MSGB consistent with SS, 14 had pathologic MSGU. A total ultrasound score >5 showed a sensitivity of 96% for the SS group with a negative predictive value (NPV) of 94%. The ultrasound total score was significantly higher in patients with positive SMGB and in patients diagnosed with SS compared to those with a negative BGSM and in patients not finally diagnosed with SS, respectively. The correlation between MSGB and MSGU presents a direct and significant (P< 0.01) moderate (value=0.628) association.
Conclusion: The results of our study show a moderate positive correlation between ultrasonographic and histological findings, which supports the role of ultrasonography of major salivary glands in the diagnosis of Sjogren's syndrome.

AB0695 **SJÖGREN'S SYNDROME: ORAL MANIFESTATIONS, ITS IMPACT ON ORAL QUALITY OF LIFE AND RELATIONSHIP WITH DAMAGE AND DISEASE ACTIVITY**

Keywords: Sjögren syndrome, Quality of life

L. Ingolotti[1], A. Secco[1], M. Bejarano[1], M. N. Tamborenea[1], A. L. Mercé[1], C. Arguissain[1], M. L. Martin[1], J. Morbiducci[1], V. Azcona[2], L. Teplizky[3], E. Casals[3], A. Hernandez[3], M. Marseillan[3]. [1]*Hospital General de Agudos B. Rivadavia, Rheumatology Section, Buenos Aires, Argentina*; [2]*Hospital Odontológico Dr. Ramón Carrillo, Odontology, Buenos Aires, Argentina*; [3]*Hospital General de Agudos B. Rivadavia, Odontology, Buenos Aires, Argentina*

Background: Involvement of oral cavity have been described in patients with primary Sjögren Syndrome (pSS). Research about how oral health affects the quality of life in pSS is lacking, for this reason we conducted this study.
Objectives: 1-To establish the presence and characteristics of oral involvement in patients with pSS. 2-To assess the quality of life related to oral health. 3-To assess relationship between the quality of life related to oral health and saliva production, disease activity, and damage.
Methods: An observational, analytical and cross-sectional study was conducted. Patients aged ≥18 years who met the European-American 2002 and/or ACR-EULAR 2016 classification criteria for pSS were included. Patients with another rheumatic disease and/or conditions that favor the appearance of caries were excluded. The quality of life related to oral health was evaluated by the abbreviated version of OHIP Oral Health Impact Profile questionnaire (Oral Health Impact Profile-OHIP14sp) validated in its Spanish version, a self-administered generic questionnaire (score 0-56 meaning the highest, the worst). A rheumatologist performed visual analogue scale (VAS) for xerostomia (0-100mm) ESSPRI (EULAR Sjogren's Syndrome Patient Reported Index) ESSDAI (EULAR Sjögren's Syndrome Disease Activity Index) and SSDDI (Sjögren's Syndrome Disease Damage Index). A dentist assessed oral health using the DMFT (number of Decayed, Missing, and Filled Permanent Teeth) index, it quantifies the prevalence of caries and its results are expressed as follows: 0-1.1 very low prevalence; 1.2-2.6 low, 2.7-4.4 moderate, 4.5-6.5 high and ≥6.6 very high). The O'Leary index and Loe & Silnes index were also calculated (the first evaluates dental hygiene, a value of > 10% determines poor hygiene; and the second one measures bacterial plaque categorized as 0,1,2 and 3, category 3 represents the greatest thickness and extension). Continuous variables were reported as mean and standard deviation or median and interquartile range, according to distribution. Categorical variables were reported as percentage. A multiple linear regression model was performed, taking OHIP14sp as the dependent variable, adjusted for possible confounders.
Results: 51 patients were included, 98% were female, mean age 54 (±13 years). The OHIP-14sp median was: 16 (6-25), xerostomia VAS median was 60 [30-80]. Mean of ESSPRI was 4 (± 2.6), ESSDAI median was 0 (0-2), SSDDI median was 3 [2-4]. Unstimulated saliva flow rate was positive in 75% of patients, the median was 0.7 ml (0.5-1). ANAs were positive in 90%, Anti-Ro autoantibodies were positive in 74.5%. Regardless treatment, 56% were treated with conventional DMARDs (75% received hydroxychloroquine), 4% DMARDb, and 9.8% received glucocorticoids with a median dose of 10mg/day [5-20]. 60% were treated for xerostomia xerostomia (M agonists or salivary substitute). Oral involvement occurred in 100% of patients, DMFT median was 22 [14-28]. 88% had poor dental status, O'Leary index median was 21 [13-30]. The Loe & Silnes index was 1 in 51%, 2 in 18.9% and 3 in 8%. In the univariate analysis, OHIP14sp was significantly associated with ESSPRI (β coefficient: 2.04 95% CI 0.72-3.3), xerostomia VAS (β coefficient: 0.19 95% CI 0.08-0.29) and category 2 of the Loe & Silnes index (β coefficient: 18 95% CI: 5-31). In the multivariate analysis, OHIP14sp was independently and significantly associated with xerostomia VAS (β ccoefficient: 0.19 95% CI 0.09–0.29) and category 2 of the Loe & Silnes index (β coefficient: 19 95% CI:7.7-29.7)
Conclusion: In our study the entire population included had oral involvement, with impaired oral quality of life, and related significantly with the degree of dryness measured by xerostomia. Our findings support the importance of multidisciplinary treatment with dentists to improve the degree of xerostomia, hygiene and oral condition.

AB0696 **EULAR SJOGREN'S SYNDROME PATIENT REPORTED INDEX (ESSPRI) AND OTHER PATIENT-REPORTED OUTCOMES IN ASSESSMENT OF GLANDULAR DYSFUNCTION IN SJÖGREN'S SYNDROME**

Keywords: Outcome measures, Patient reported outcomes, Sjögren syndrome

E. J. Nam[1], H. Ture[1], S. J. Lee[2], N. R. Kim[1]. [1]*Kyungpook National University Chilgok Hospital, Rheumatology, Daegu, Korea, Rep. of (South Korea)*; [2]*Kyungpook National University Hospital, Rheumatology, Daegu, Korea, Rep. of (South Korea)*

Background: Sjögren's syndrome (SS) constitutes a common autoimmune disease in which the exocrine glands, especially salivary and lacrimal glands, produce excessive immune responses with the resultant tissue damage leading to mucosal dryness. For assessment of disease activity, the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI), ESSPRI, and other patient-reported outcomes (PROs), such as visual analog scale (VAS) for symptoms, and EULAR sicca score (ESS), are performed. ESSPRI, ocular staining score (OSS), salivary flow rate (SFR), salivary gland scintigraphy (SGS), and minor salivary gland (MSG) pathology have a cooperative relationship with regard to the evaluation of glandular function and inflammation in SS, its diagnosis and therapeutic management, and patient follow-up. However, although ESSPRI is reported to show a significant correlation with PROs, the relationship between ESSPRI or RPOs and objective parameters of glandular dysfunction, especially salivary and ocular glands, is not well defined.
Objectives: To investigate whether ESSPRI or other PROs are correlated with objective parameters of glandular dysfunction in primary SS (pSS).
Methods: A total of 70 patients with pSS were included in the present study. Disease activity indexes including ESSPRI, EULAR sicca score (ESS), VAS scores for symptoms, and ESSDAI, serologic markers, SFRs, SGS, MSG biopsy, and OSS were evaluated. Correlations were calculated with the Spearman correlation coefficient.
Results: ESSPRI was a significantly correlated with its domains (dryness domain, r=0.661 p<0.001; fatigue domain, r=0.859, p<0.001; pain domain, r=0.849, p<0.001). ESSPRI showed a significant correlation with ESS (r=0.639, p<0.001), oral (r=0.522, p<0.001) and ocular dryness VAS (r=0.482, p<0.001), acute phase reactant levels (ESR, r=0.271, p=0.028; CRP, r=0.322, p=0.008), serum IgG level (r=0.322. p=0.033), and ESSDAI (r=0.371, p=0.002), while it was not correlated with SFRs, data of SGS, focus score (FS) and OSS. ESSPRI dryness domain was significantly correlated with ESS (r=0.969, p<0.001), SFRs (unstimulated, r=-0.281 p=0.025; stimulated, r=-0.263, p=0.037), data of SGS (parotid gland [PG] uptake ratio [UR], r=-0.252, p=0.044; submandibular gland (SMG) UR, r=-0.357, p=0.004; SMG ejection fraction [EF], r=-0.325, p=0.009), FS (r=0.261, p=0.050) and OSS (r=0.386, p=0.002). However, it did not demonstrate the correlation with ESSDAI, acute phase reactant levels, and serum IgG level. ESS was closely correlated with SFRs (unstimulated, r=-0.400, p=0.001; stimulated, r=-0.364, p=0.003), data of SGS (PG UR, r=-0.325, p=0.009; PG EF, r=-0.285, p=0.023; SMG UR, r=-0.424, p<0.001; SMG EF, r=-0.356, p=0.004), FS (r=0.284, p=0.032), and OSS (r=0.340, p=0.007), but not with ESSDAI, acute phase reactant levels, and serum IgG level. Oral dryness VAS was also correlated with SFRs (unstimulated, r=-0.527, p<0.001; stimulated, r=-0.470, p<0.001), data of SGS (PG UR, r=-0.417, p=0.001; PG EF, r=-0.366, p=0.003; SMG UR, r=-0.467, p<0.001; SMG EF, r=-0.377, p=0.002), and FS (r=0.288, p=0.030) but not with OSS. Ocular dryness VAS showed a significant correlation with OSS (r=0.422, p=0.001), but not with parameters of salivary gland dysfunction.
Conclusion: The present study demonstrated that ESSPRI dryness domain, ESS, and VAS for symptoms, but not ESSPRI, reflected the glandular dysfunction in SS.

Background: Vaccines are widely credited for their role in reducing the incidence and the severity of various infections. Although the safety profiles of vaccines have been proved, there still remain gaps between healthy individuals and patients with autoimmune diseases in the efficacy and adverse events of vaccinations.
Objectives: The aim of the **C**OVID-19 and **I**nfluenza **V**accine **I**n **L**upus (CIVIL) study was to compare the perception and safety profile between COVID-19 vaccine and influenza vaccine in Korean patients with systemic lupus erythematosus (SLE).
Methods: We conducted a cross-sectional study based on a 34-question web-based survey on COVID-19 and influenza vaccination in 207 medically confirmed SLE patients. Patients were recruited from 13 academic hospitals affiliated with Korean society of SLE research (KSSR) from DEC 2022 to JAN 2023. The primary outcome was the perception of patients and physicians on the vaccines, and the occurrence of side effects including flare.
Results: 94.1% of two hundred respondents were females aged in 20's (19.8%), 30's (24.3%), 40's (27.7%), 50's (16.8%), and 52% was treated more than 10 years. More than 50% of patients were in stable condition for recent 6 months (below 20mm in 100mm visual analogue scale with lower than 10mg prednisolone equivalent dose). COVID-19 vaccine (Pfizer, Moderna, AstraZeneca, Novavax) and influenza vaccine were completed in 77.7% and 87.6% of SLE patients, respectively. Reasons for willing not vaccinated included fear of lupus flare (56.3% vs 24.5%), worried about side effects (52.1% vs 26.6%), and not recommended from physicians (35.4% vs 7.4%) on COVID-19 and influenza vaccines, respectively. Adverse events (AEs) occurred much higher in COVID-19 vaccine (65.8%) than influenza vaccine (12.4%). However, only 4.4% of patients experiencing AEs from COVID-19 vaccine required hospitalization. Most common AEs were pain/redness on injection site, myalgia and/or arthralgia, fatigue, febrile sense, irregularity in menstrual period. 10.3% of patients taking COVID-19 vaccine experienced lupus flare (arthralgia, skin rash, hair loss, and deterioration of proteinuria/laboratory parameter), which lead to medication change or hospitalization.
Conclusion: COVID-19 vaccine has a worse perception and higher adverse events compared to influenza vaccine in Korean SLE patients.

Table 1. Reasons of vaccination unwillingness

Covid-19	
Fear of lupus flare	56.3%
Fear of AEs	52.1%
Recommended not to be vaccinated by medical staff	35.4%
Not sure vaccine has a preventive effect	18.8%
Recommended not to be vaccinated by peer	6.3%
Just do not want to be injected	2.1%
Influenza	
Not sure vaccine has a preventive effect	27.7%
Fear of AEs	26.6%
Fear of lupus flare	24.5%
Recommended not to be vaccinated by medical staff	7.4%
Recommended not to be vaccinated by peer	1.1%
others	10%

SYSTEMIC LUPUS ERYTHEMATOSUS OVER 80 YEARS OF AGE: A RETROSPECTIVE COHORT OF VERY LATE-ONSET IN A THIRD LEVEL HOSPITAL

Keywords: Systemic lupus erythematosus, Epidemiology

A. Crespo-Golmar[1], C. Moriano[2], X. E. Larco Rojas[2], C. Sieiro Santos[2], P. Pérez-García[2], E. Diez Álvarez[2]. [1]*Institute IDIS; Santiago University Clinical Hospital (CHUS); Musculoskeletal Pathology Group, Rheumatology, Santiago de Compostela, Spain*; [2]*University Health Care Complex of León, Rheumatology Department, León, Spain*

Background: Late-onset systemic lupus erythematosus (SLE) is designated as that developing after the age of 50 [1], [2]. It has been associated with a different prevalence of clinical manifestations, disease activity, and mortality compared to early-onset SLE.
Objectives: - To describe the clinical expression and epidemiological features of our patients diagnosed with SLE from the age of 80.
- To delimit the average survival time and mortality, as well as the main cause of death in case of it is present.
Methods: A retrospective cohort of 31 patients diagnosed with SLE with an age of onset older than 80 years and followed up at the Hospital de León between 1997-2022. All fulfill the 1992 ACR and 2012 SLICC classification criteria.
Results: The patients were mostly women, with a female/male ratio of 2.1, and a mean age at diagnosis of 84.32 ± 2.79 years. The most prevalent clinical manifestations were arthritis and inflammatory arthralgia (48.4%) and dermatological involvement (45.1%), such as acute cutaneous lupus (35.7%), discoid (7.1%) and other reactions of unspecified photosensitivity (57.1%). Leuko-lymphopenia (45.1%) and thrombocytopenia (29.3%) were also relevant. On the other hand, the cases of alopecia (3.2%), hemolytic anemia (6.45%), interstitial lung disease (ILD) with a usual interstitial pneumonia (UIP) pattern (3.2%), sensory polyneuropathy (3.2%) and chorea (3.2%). Oral ulcers were present in 12.9% of patients, as were cases of renal involvement (1 with microscopic hematuria, 1 with proteinuria > 0.5 mg/dL, 1 nephrotic syndrome, and 1 nephritic syndrome). Raynaud's phenomenon affected 16.1%, as well as serositis (4 patients with pleuritis and 2 with pericarditis). No one reported *sicca* syndrome or thrombotic events. Regarding immunological criteria, the most important findings were: ANA 97%, DNA 38%, Sm 10% and hypocomplementemia 29%. Antiphospholipid antibodies were present in 42%, and 6,5 % have triple positivity). The average survival time was 4.5 years, with a statistically significant difference in favor of women (7 vs 3.4 years; p-value = 0.0024). There were 11 losses to follow-up and 10 deaths (7 men). The fundamental causes of death were certified in 4 of the cases as infectious etiology, one due to heart failure and another due to global respiratory failure. In 4 cases the cause of death was unknown.
Conclusion: - Late-onset SLE diagnosed in people over 80 years of age is more frequent in women (2.1:1), although there is a higher proportion of men than in cases of earlier debut [1].
- The most frequent manifestations in our cohort were joint, skin, and hematological involvement.
- The main cause of death was of infectious origin.
- The average survival time was 4.5 years.
- The male sex was associated with a worse prognosis in our patients, with higher mortality (70%) and significantly lower survival.
- More research is needed to broaden our knowledge of SLE in this age group, as well as to clarify to what extent excess male mortality may be due to disease burden or is influenced by other factors (lower life expectancy, toxic habits, etc.).

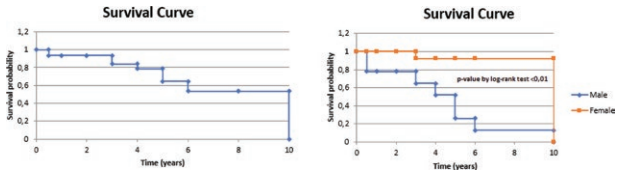

Figure 1. Average Survival Curve using Kaplan-Meier method in all patients (left) and segregated by sex (right).

AB0699

IS AUTONOMIC DYSFUNCTION MORE COMMON IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME WITH FIBROMYALGIA THAN IN PATIENTS WITHOUT FIBROMYALGIA?

Keywords: Fibromyalgia, Sjögren syndrome

D. Karatas[1], N. Erdik[1], G. Yavuzbilge[1], S. B. Acikgoz[1], S. M. Türk[1], C. Arslantürk Güneysu[1], Z. Öztürk[2], E. Gönüllü[1]. [1]*Sakarya University Faculty of Medicine, Rheumatology, Sakarya, Turkey*; [2]*Ankara Atatürk Sanatoryum Eğitim ve Araştırma Hastanesi, Rheumatology, Ankara, Turkey*

Background: Primary Sjögren's syndrome (pSS) is an autoimmune disease that primarily affects the exocrine glands, but other organs, including the nervous system, may also be affected [1]. Many studies provide evidence of autonomic dysfunction in pSS [2,3]. Although the etiology of fibromyalgia (FM) is not fully understood, data suggest that FM may be caused by autonomic nervous system dysfunction [4].

Objectives: In this study, we aimed to reveal the incidence of autonomic dysfunction in patients with pSS compared to those without fibromyalgia.

Methods: In this cross-sectional study, 64 patients who admitted to our Sakarya University Faculty of Medicine rheumatology outpatient clinic between November 2021 and August 2022 and were followed up with the diagnosis of pSS were included. The patients were divided into two groups 35 (54.7%) with fibromyalgia and 29 (45.3%) without fibromyalgia. Patients were evaluated with the Composite Autonomic Symptom Score-31 (COMPASS-31), which consists of 6 subsections including autonomic dysfunction, orthostatic, vasomotor, secretomotor, gastrointestinal, bladder and pupillomotor functions. Mann-Whitney U test and Chi-square test were used to compare the groups.

Results: The mean age of the patients was 53.8±11.3 years. There was no difference between the groups regarding sex and age (p = 0.586 and p = 0.580, respectively). The median disease duration (IQR) was 4(5) years. The mean total COMPASS-31 score was significantly higher in patients with fibromyalgia than in those without fibromyalgia (0.014). Among its subgroups, secretory dysfunction was significantly higher in patients with fibromyalgia (p=0.001). Vasomotor dysfunction is more common in patients with FM (p=0.016) (Table 1).

Conclusion: In our study, patients with pSS with fibromyalgia had a higher COMPASS-31 score than those without FM, and especially the secretory dysfunction score was higher. Since both diseases can cause autonomic dysfunction separately, it seems reasonable to have a high total COMPASS-31 score in patients with both. In addition, vasomotor dysfunction is more common in patients with FM.

HISTOPATHOLOGICAL FINDINGS IN RENAL BIOPSY OF PATIENTS WITH LUPUS NEPHROPATHY AS THE INITIAL MANIFESTATION OF SYSTEMIC LUPUS ERYTHEMATOSUS AND LONG-TERM RENAL OUTCOME IN MEXICAN POPULATION

Keywords: Systemic lupus erythematosus, Epidemiology, Descriptive studies

F. Pazos[1], E. Garduño2, N. K. Cruz2, C. E. Mendez[3]. [1]*Colonia Cuauhtémoc, Nephrology, Mexico City, Mexico*; [1]*Colonia Cuauhtémoc, nephrology, Mexico City, Mexico*; [3]*Mexican Social Security Institute, Nephrology, Mexico City, Mexico*

Background: Renal biopsy is essential in Lupus nephritis (LN) to guide treatment of lupus nephritis and provides information on classes and prognosis of lupus nephritis. Activity and chronicity index can be used as a guide for lupus nephritis treatment although little has been considered the percentage of fibrosis and tubular atrophy in the renal prognosis.

Objectives: Describe the histopathological findings in biopsies performed in patients with LN as an initial manifestation of SLE and the long-term renal outcome.

Methods: Retrospective descriptive observational study. Data on baseline demographic, biopsy records, laboratory results and treatment regime were extracted from the case notes. Normality tests were applied, the frequencies and percentages were calculated for the categorical variables and the means with their standard deviation or medians with minimums and maximums for the continuous variables depending on their distribution.

Results: Of the 61 patients who presented LN at the diagnosis of SLE, renal biopsies were performed in 80% (n=54). The median age was 30 (19-66) years, females predominated (77%). The frequencies of different classes of lupus nephropathy as well as their index of activity and chronicity and treatment used are described in Table 1. Only 30 of renal biopsies (65%) described tubulo-interstitial findings and 60% had no immunofluorescence. Another additional finding found in the renal biopsy were fibrocellular crescents, membranoproliferative pattern and podocytopathy. At the diagnosis of LN, median serum creatinine (CrS) was 0.8 (1-6) mg/dl and proteinuria 1355 (90-9450) mg/24 hrs. The remission induction treatment frequently used was the combination of mycophenolate and prednisone. However, in the second and third relapse cyclophosphamide and rituximab was preferred. Ten patients had a second relapse with complete remission in 40%, partial remission in 40%, and no response in 20%. Seven patients had more than 3 relapses and correlationate with a percentage of tubulointerstitial fibrosis greater than 25% (r=0.34, p<0.05), three of them progressed to end-stage renal disease (5%), all of them with class IV of LN. The main reasons why patients did not finish treatment were infectious processes (37%), myelotoxicity (25%), loss of social security (19%) and poor adherence (19%).

Conclusion: Frequency of class IV LN in our population is like that reported worldwide, however a higher percentage of mixed forms (IV+V) is reported. Combination of mycophenolate and prednisone was used as remission induction treatment. Although the complete remission rates are much lower than those reported (33% vs 58%). Presence of fibrosis in more than 25% is associated with progression to end-stage renal disease.

PERFORMANCE OF DRAFT 2022 ACR/EULAR CLASSIFICATION CRITERIA IN A TURKISH COHORT OF APL ANTIBODY POSITIVE PATIENTS

Keywords: Epidemiology, Anti-phospholipid syndrome, Autoantibodies

R. C. Kardaş[1], D. Yildirim[1], B. Özkızıltaş[1], I. Vasi[1], R. Duran[1], H. Karadeniz[1], A. Avanoglu Guler[1], A. Erden[1], H. Küçük[1], B. Göker[1], A. Tufan[1], M. A. Ozturk[1]. [1]*Gazi University, Department of Medicine, Division of Rheumatology, Ankara, Turkey*

Background: Revised Sapporo classification criteria is the most commonly used criteria set for the classification of antiphospholipid syndrome (APS) patients [1]. Since its revision in 2006, various other clinical and laboratory manifestations have been reported in the literature. Among these are livedo reticularis (racemosa), cutaneous ulcers, thrombocytopenia, cardiac, pulmonary and renal involvement [2]. In 2022 American College of Rheumatology Convergence meeting, new draft classification criteria have been presented [3].

Objectives: Comparing the performance of the new draft classification criteria for antiphospholipid syndrome with the revised Sapporo criteria in a Turkish cohort of antiphospholipid antibody positive patients.

Methods: Patients with a positive antiphospholipid antibody (LAC, aCL IgM or IgG, aB2GPI IgM or IgG) followed since 2016 in our institution have been included. Demographic, clinical, laboratory and radiological features of the patients were recorded retrospectively. All parameters were evaluated with reference to the 2006 revised Sapporo and 2022 draft criteria.

Results: 40 patients were included our study. 80% (N=32) of the patients were female. Average age of the patients at diagnosis or first antibody positivity was 33.9 years. 27.5% of patients (N=11) were screened for hereditary thrombophilia, with only one patient having heterozygous factor V Leiden mutation. 37% of patients (N=13) had ever smoked prior to their inclusion in the cohort. 57.5% of patients (N=23) had secondary APS, 12.5% had primary APS, 30% had isolated antiphospholipid antibody positivity. Among the secondary APS patients, vast majority had SLE (N=20). 47,5% of the patients (N=19) had a history of vascular thrombosis. 16 patients had venous and 5 patients had arterial thrombosis. Among the 32 female patients, 62,5% (N=20) had an obstetric morbidity associated with APS. 20,5% of patients (N=8) had a skin finding consistent with APS, the most common one being livedo racemosa (N=7). 50% of patients had thrombocytopenia. 20% of patients (N=8) had developed autoimmune hemolytic anemia. Only a single patients had a history of catastrophic APS. 17,5% of cases (N=7) had a positive lupus anticoagulant. Most commonly positive aPL antibody was anti-cardiolipin IgG (55%, N=22), followed by anti-B2GP-I IgG (28%, N=11). 82% of patients (N=33) had a positive ANA test, 62,5% (N=25) had low C3 and C4. Overall, 42,5% (N=17) of patients fulfilled 2006 revised Sapporo criteria, whereas 40% (N=16) ultimately fulfilled the 2022 draft criteria for classification. There was a large level of agreement between the two criteria sets, with one patient not fulfilling 2006 criteria fulfilling 2022 criteria and two patients fulfilling 2022 criteria without fulfilling 2006 criteria.

Conclusion: Our cohort of patients had a high prevalence of thrombocytopenia, as well as a significant minority having livedo racemose and autoimmune thrombocytopenia. None of the patients with isolated aPL antibody positivity were classified as APS, despite many of the fulfilling the initial screening step of the draft criteria. Longer term follow-up of patients fulfilling 2022 screening criteria may yield additional information in the future.

Vasculitis - large vessel vasculitis

AB0702 THE INCIDENCE OF LARGE VESSEL VASCULITIS IN NORFOLK, UK

Keywords: Epidemiology, Vasculitis, Real-world evidence

C. Mukhtyar[1], C. Beadsmoore[2], F. Coath[1], G. Ducker[1], K. Sisson[3], R. Watts[4]. *[1]Norfolk and Norwich University Hospital NHS Foundation Trust, Rheumatology, Norwich, United Kingdom*; *[2]Norfolk and Norwich University Hospital NHS Foundation Trust, Radiology, Norwich, United Kingdom*; *[3]Norfolk and Norwich University Hospital NHS Foundation Trust, Pathology, Norwich, United Kingdom*; *[4]University of East Anglia, Norwich Medical School, Norwich, United Kingdom*

Background: There are no data on the collective incidence of the large vessel vasculitides. The data of incidence of GCA and Takayasu arteritis in the UK has been based on clinical coding in routine administrative datasets. There are no data on the incidence of these diseases based on clinically verified diagnoses. We studied the incidence of the large vessel vasculitides in a stable population with a predominant Northern European ancestry.
Objectives: To report the incidence of large vessel vasculitis and its subsets in Norfolk, UK.
Methods: Individuals attending a secondary care hospital with a clinically verified diagnosis of primary systemic vasculitis made between 2011-2020, who lived within the NR postcode districts of Norfolk County borders were included if they met classification criteria (ACR 1990 or ACR/EULAR 2022) for GCA/ Takayasu arteritis [1-4], or had definite tissue or imaging evidence of large vessel vasculitis. The population data from the 2011 census, available from the office of national statistics was used as the denominator. If classification criteria for both GCA and TAK were met, a clinical decision was taken to decide on the subtype.
Results: 272 individuals were diagnosed with a large vessel vasculitis in a population of 454,316 above the age of 18. The annual incidence of large vessel vasculitis in Norfolk is 59.9/million in population above the age of 18. The annual incidence of giant cell arteritis is 9.9/100000 in population above the age of 50 using the ACR 1990 criteria and 10.6/100000 using the ACR/EULAR 2022 criteria. There is a marked rise in the incidence from 2017 onwards when a fast-track pathway was formally established (Table 1). There is dip in the incidence in 2020 when services were suspended during the SARS-COV2 pandemic. The annual incidence peaks at 168.5/100000 in the 9th decade of life and is commoner in females (12.3/100000) than males (7.3/100000). The annual incidence of Takayasu arteritis is 3.3/million in population above the age of 18 using the ACR 1990 criteria and 1.1/million using the ACR/EULAR 2022 criteria.
Conclusion: This is the first study that reports the incidence of all objectively diagnosed large vessel vasculitis from a secondary centre which provides services to a large stable population in the East of England. The incidence of GCA rose with the establishment of a fast-track pathway and its peak may have been affected by the SARS-COV2 pandemic. GCA is commoner in females and peaks in the 8th and 9th decades.

AB0703 TOWARDS TREAT-TO-TARGET PATIENT CENTRED CARE: DEVELOPMENT OF MULTIDIMENSIONAL DISEASE SPECIFIC PATIENT REPORTED OUTCOME MEASURES QUESTIONNAIRE FOR GIANT CELL ARTERITIS

Keywords: Remission, Patient reported outcomes, Vasculitis

Y. El Miedany[1], D. Palmer[2], M. Toth[3], M. Elgaafary[4], S. Bahlas[5], S. A. Mahran[6], M. H. Abu-Zaid[7], W. Hassan[8], W. Elwakil[9]. *[1]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom*; *[2]North Middlesex University Hospital, Rheumatology, London, United Kingdom*; *[3]King's College London - Darent Valley Hospital, General Medicine, Dartford, United Kingdom*; *[4]Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt*; *[5]King Abdul Aziz University, Rheumatology, Jeddah, Saudi Arabia*; *[6]Faculty of Medicine - Assiut University, Rheumatology and Rehabilitation, Assiut, Egypt*; *[7]Faculty of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt*; *[8]Faculty of Medicine Banha University, Rheumatology and Rehabilitation, Banha, Egypt*; *[9]Faculty of Medicine Alexandria University, Rheumatology, Physical Medicine and Rehabilitation, Alexandria, Egypt*

Background: Giant Cell Arteritis (GCA) is the commonest form of systemic vasculitis in people over the age of 50. In 2017, the OMERACT Vasculitis Working Group published a core set of domains and outcome measures for use in clinical trials in large vessel vasculitis [1] and highlighted the lack of a disease-specific patient reported outcomes (PROMs) for GCA. The OMERACT group proposed a draft core set of domains for GCA, including disease specific domains, organ and arterial function, psychosocial impact and physical function biomarkers, fatigue, pain, as well as death.
Objectives: To assess the validity, reliability and responsiveness to change of a patient self-reported questionnaire to assess for the construct outcome measures, co-morbidities and the impact of GCA and its treatment on health-related quality of life in GCA patients.
Methods: The PROMs-GCA was conceptualized based on frameworks used by the WHO Quality of Life tool and the PROMIS. Initially, cognitive interviews were conducted to identify item pool of questions. Item selection and reduction was achieved based on patients as well as an interdisciplinary group of specialists. Rasch and internal consistency reliability analyses were implemented. The questionnaire included the GCA specific physical and psychological symptoms, sense of self, symptoms severity using numerical visual analogue scale (0-10) in addition to assessment of functional disability, quality of life (QoL), review of the systems, glucocorticoids benefit:risks, comorbidities as well as motivation [2]. In addition, every patient completed HAQ and EQ-5D questionnaires.
Results: A total of 52 GCA patients completed the questionnaire. The PROMs-GCA questionnaire was reliable as demonstrated by a high standardized alpha (0.867-0.941). Content construct assessment of the PROMs-GCA/functional disability and QoL revealed significant correlation ($p< 0.01$) with both HAQ and EQ-5D. Changes in functional disability, QoL showed significant ($p< 0.01$) variation with diseases activity status in response to therapy.
Conclusion: The developed PROMs-GCA questionnaire is a reliable and valid instrument for assessment of patients living with GCA. A phased treatment regimen depending on the severity of GCA as well as the patient's preferences and comorbidities are the best approach to tailored patient management.

AB0704 EVALUATION OF THE OF THE 2022 ACR/EULAR CLASSIFICATION CRITERIA FOR GCA IN A GERMAN PATIENT COHORT

Keywords: Diagnostic tests, Ultrasound, Vasculitis

R. Bergner[1], P. Schulz[2], J. Friedrich[1]. *[1]Klinikum der Stadt Ludwigshafen am Rhein gGmbH, Medizinische Klinik A, Ludwigshafen am Rhein, Germany*; *[2]Klinikum der Stadt Ludwigshafen am Rhein gGmbH, Zentrum für diagnostische und interventionelle Radiologie, Ludwigshafen am Rhein, Germany*

Background: In 2022, the ACR and the EULAR proposed new classification criteria for Giant Cell Arteritis (GCA). While the previous classification criteria from 1990 were based on clinical and histological findings only, the new classification criteria also consider several types of imaging.
Objectives: To assess and compare the sensitivity and specificity of the ACR 1990 (1990CC) and the ACR/EULAR-2022 classification criteria (2022CC) for GCA.
Methods: In a retrospective analysis, we classified 210 patients (33 % males, median age 68 years) with suspected GCA according to the 1990CC and 2022CC. All patients attended the Klinikum Ludwigshafen between 2018 and 2022 and were examined with either ultrasound, MRI, or PET-CT. The results were compared with the final clinical diagnosis made by the attending physician.
Results: Of 210 patients under consideration, 94 had GCA. Of these 94 patients, 54 met the 1990CC, while 90 met the 2022CC (Table 1). Of the 116 non-GCA patients, 110 did not meet the 1990CC and 112 did not meet the 2022CC, amounting to a sensitivity and specificity of 0.57 and 0.96 for the 1990CC versus 0.96 and 0.97 for the 2022CC, respectively (Table 1). Overall, the correct classification proportion was 0.78 for the 1990CC and 0.96 for the 2022CC (Table 1). It was noticeable that 21 GCA patients had no cranial symptoms like temporal headache, jaw claudication, or striking temporal arteries. 18 of these patients were correctly classified by the 2022CC, but all of them were misclassified by the 1990CC. Moreover, 81 of 94 patients showed a typical ultrasound halo in at least one vessel section, which increased the sensitivity of the 2022CC.
Conclusion: Our results demonstrate that the inclusion of imaging methods increase the sensitivity of the 2022CC compared with the 1990CC, while the specificity of > 0.95 remains similar. The 1990CC were primarily developed for the classification of giant cell temporal arteritis, causing a frequent misclassification of patients with isolated extracranial large vessel vasculitis. Moreover, the 1990CC classified GCA patients without cranial symptoms only accurately in case of a positive temporal biopsy.

Table 1. Sensitivity and specificity of the 1990-ACR-Classification Criteria and 2022-ACR/EULAR-Classification criteria for GCA compared with the final clinical diagnosis of GCA.

		Clinical diagnosis positive	Clinical Diagnosis negative	Sensitivity	Specificity	Correctly classified proportion
	n=	94	116			
1990 ACR - Criteria positive	59	54	5	0.57	0.96	0.78
1990 ACR - Criteria negative	151	40	111			
2022 EULAR/ACR-Criteria positive	94	90	4	0.96	0.97	0.96
2022 EULAR/ACR-Criteria negative	115	4	112			
		ACR 1990 positive	ACR 1990 negative			
		59	151			
2022 EULAR/ACR-Criteria positive	94	56	38			
2022 EULAR/ACR-Criteria negative	116	3	113

LONG TERM SAFETY OF CONVENTIONAL AND BIOLOGIC IL-6RI IMMUNOMODULATORS AS SECOND-LINE (2L) OR THIRD-LINE (3L) TREATMENT OF POLYMYALGIA RHEUMATICA

Keywords: Safety, Vasculitis, Disease-modifying drugs (DMARDs)

A. Dikranian[1], C. Calabrese[2], C. Bingham[3], S. Fiore[4], K. Ford[4], L. Araujo[5], F. Xie[6], J. Curtis[7]. *[1]Cabrillo Center for Rheumatic Disease, Rheumatology, San Diego, CA, United States of America*; *[2]Cleveland Clinic, Department of Rheumatic and Immunologic Diseases, and Department of Infectious Disease, Cleveland, United States of America*; *[3]Johns Hopkins University, Baltimore, Rheumatology, Baltimore, Maryland, United States of America*; *[4]Sanofi, Cambridge, Medical Affairs, Massachusetts, United States of America*; *[5]Sanofi, Cambridge, Health Economics & Value Assessment, Massachusetts, United States of America*; *[6]The University of Alabama at Birmingham, Medicine, Birmingham, AL, United States of America*; *[7]The University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL, United States of America*

Background: In polymyalgia rheumatica (PMR), IL-6Ri therapy has been studied in limited number of patients in RCTs, with exposure up to 16-52 weeks, [1-3] while patients may require longer treatment in real world. Data are presented on safety of IL-6Ri and conventional immunomodulatory (CIM) therapy for up to 2 years (Y) in patients with PMR.
Objectives: Evaluate safety of IL-6Ri and CIM therapy in 2L or 3L treatment of PMR.
Methods: This was a retrospective study in US adults ≥50Y, with 1 inpatient/2 outpatient claims with PMR diagnosis ≥30 days apart, from national fee-for-service Medicare data (3/29/2016 - 6/30/2020). Patients were on ≤25 mg prednisone (PS) equivalent and started IL-6Ri (tocilizumab/sarilumab) or CIM (methotrexate/leflunomide/azathioprine) as 2L/3L therapy and had continuous enrollment ≥180 days prior to index. For 2L, index date was start of IL-6Ri/CIM with no prior use of IL-6Ri/CIM. For 3L, index date was start of IL-6Ri (with/without background CIM) or new CIM, after prior CIM. Follow-up was until the earliest of end of enrollment, death, treatment switch, or 2Y. Patients with seropositive RA, other arthritis or connective tissue disease, giant cell arteritis, organ transplant, or malignancy undergoing treatment were excluded. Stratifying by line of therapy, IL-6Ri patients were direct matched using 1:3 variable ratio matching on age, sex, index date and baseline PS equivalent dose category (<2.5, 2.5-<5, 5-<10, 10-<15, 15-<20, 20-25 mg), recency of prior CIM (3L only; 1-60, 61-180, 180+days), and then 1:1 propensity score matched using multivariate logistic regression to identify variables with SMD >0.1. We examined hospitalized infection (any and primary diagnosis), gastrointestinal perforation, major adverse cardiac events, malignancy, and drug induced liver injury. Except for infection, patients with prior events were excluded from each outcome-specific analysis. Outcomes were identified using validated or previously used claims-based algorithms. Incidence rates were reported per 100 patient-years through 2Y of follow-up, using exact Poisson for 95% CI, if events <5. Cox proportional hazards model was used to estimate adjusted hazard ratios (aHR) for infections (given paucity of other events). Sensitivity analyses examined events in Y1 and Y2 separately and stratified by 2L vs 3L.
Results: In final cohort, covariate balance for 451 matched patients (2L: 183; 3L: 268) in each arm was good. Residual imbalances were small for disability status, steroid dose category, and chronic obstructive pulmonary disease. Incidence rates and aHRs for events are shown in Table 1; aHRs were not significant for IL-6Ri vs CIM. Sensitivity analyses were consistent with primary results and generally showed incidence was similar, or numerically lower for IL-6Ri vs CIM in Y2 and lower for CIM vs IL-6Ri in Y1, for most outcomes.

Table 1. Pooled incidence rates and aHR stratified by 2L/3L of safety events for IL-6Ri and CIM-treated patients with up to 2Y exposure

Outcome	Exposure Group	Events/100PY	aHR (95% CI) IL-6Ri vs CIM
Hospitalized Infection, any	IL-6Ri	14.4 (11.8 - 17.7)	1.05 (0.79 - 1.41)
	CIM	13.4 (10.8 - 16.6)	
Hospitalized infection, primary diagnosis	IL-6Ri	9.8 (7.7 - 12.5)	1.16 (0.82 - 1.65)
	CIM	8.4 (6.4 - 11.0)	
Malignancy	IL-6Ri	0.8 (0.3 - 1.9)	NE
	CIM	2.0 (1.1 - 3.5)	
Major adverse cardiac events	IL-6Ri	2.1 (1.2 - 3.7)	NE
	CIM	2.1 (1.2 - 3.7)	
Gastrointestinal perforation	IL-6Ri	0.1 (0.0 - 0.8)	NE
	CIM	0.1 (0.0 - 0.8)	
Drug induced liver injury	IL-6Ri	0.0 (0.0 - 0.5)	NE
	CIM	0.0 (0.0 - 0.5)	

aHR, adjusted hazard ratios, controlling for covariates imbalanced with SMD >0.10; CI, confidence interval; CIM, conventional immunomodulatory therapy; NE, not estimated, inadequate sample size; PY, patient-years; IL-6Ri, interleukin-6 receptor inhibitor

Conclusion: Rates of serious adverse events for IL-6Ri vs CIM therapy with up to 2Y exposure were comparable in PMR.

AB0706 AGGLOMERATIVE HIERARCHICAL CLUSTER ANALYSIS IDENTIFIES TWO CLUSTERS OF TAKAYASU ARTERITIS BASED ON CLINICAL PHENOTYPE WHICH PREDICT ANGIOGRAPHIC FINDINGS AND MORTALITY IN A COHORT OF 200 PATIENTS

Keywords: Vasculitis, Registries

K. Singh[1], S. Ganapathy[2], C. Kavadichanda[3], U. Rathore[1], N. Jain[4], M. Ora[5], V. Agarwal[1], D. P. Misra[1]. *[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Clinical Immunology and Rheumatology, Lucknow, India*; *[2]Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Biostatistics, Puducherry, India*; *[3]Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Clinical Immunology, Puducherry, India*; *[4]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Radiology, Lucknow, India*; *[5]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Department of Nuclear Medicine, Lucknow, India*

Background: Cluster analysis is a data-driven approach to identify natural patterns of disease which may help better understand the phenotype of Takayasu arteritis (TAK), a rare large vessel vasculitis.

Objectives: To evaluate whether clusters based on clinical phenotypes of TAK predict angiographic patterns of disease or mortality.

Methods: From a retrospective cohort of TAK, agglomerative hierarchical clustering using Ward method was performed using clinical features. Optimal number of clusters were identified using elbow method and silhouette method. The hitherto identified clusters were compared for differences in clinical features, vascular involvement, and Hata's angiographic subtypes using odds ratios (OR, with 95% confidence intervals), and for survival (crude, using Kaplan-Meier curves; adjusted for gender and age of disease onset using Cox regression analyses) using STATA 16.1 I/C.

Results: Optimal number of clusters was two [Ward agglomerative coefficient 0.989; Cluster 1: 111 TAK, mean (SD) age 25.06 (9.97) years, 80.2% females; Cluster 2: 89 TAK, mean (SD) age 25.54 (10.38) years, 65.2% females]. Carotidynia, pulse or BP inequality, pulse loss, vascular bruits, upper limb claudication, lower limb claudication, and chest pain were more common in cluster 1, whereas, hypertension, renal failure, and stroke/TIA were more common in cluster 2 (Table 1). Involvement of subclavian and carotid arteries, left vertebral, brachiocephalic, ascending aorta, arch of aorta, descending thoracic aorta were more common in cluster 1, whereas, abdominal aorta, celiac, superior mesenteric, inferior mesenteric, left and right renal arteries were similar in both clusters. Hata's angiographic subtype V was more common in cluster 1 (OR 0.45, 95%CI 0.25 – 0.80), whereas, subtype IV was more common in cluster 2 (OR 6.16, 95%CI 1.70 – 22.35). Over 697 person-years of follow-up (193 patients), cluster 1 had worse survival than cluster 2 (log-rank p value 0.027, Figure 1), even after adjustment for gender and age of onset (adjusted Hazard ratio cluster 2 vs cluster 1 0.09, 95%CI 0.01 – 0.78).

Conclusion: Clinical features corresponded to vascular territories which were more common in cluster 1. Hypertension and renal failure were more common in cluster 2, which correspond to more frequent Hata's subtype IV in this cluster. Clusters based on clinical features could predict well the patterns of vascular involvement. Higher adjusted mortality rate in cluster 1 requires validation in other cohorts of TAK.

Table 1. Clinical and angiographic involvement in the two clusters

Clinical features	OR (95%CI) Cluster 2: Cluster 1	Arterial involvement	OR (95%CI) Cluster 2: Cluster 1
Constitutional	1.15 (0.66 – 2.03)	Right subclavian	0.48 (0.27 – 0.86)
Carotidynia	0.18 (0.05 – 0.63)	Left subclavian	0.49 (0.26 – 0.92)
Syncope/dizziness/ vertigo	0.64 (0.31 – 1.32)	Right carotid	0.44 (0.24 – 0.79)
Stroke/TIA	11.04 (3.68 – 33.09)	Left carotid	0.36 (0.20 – 0.64)
Vision blurring or loss	1.76 (0.82 – 3.77)	Right vertebral	-*
Pulse/BP inequality	0.18 (0.10 – 0.34)	Left vertebral	0.31 (0.11 – 0.86)
Pulse loss	0.12 (0.06 – 0.23)	Brachiocephalic	0.42 (0.21 – 0.84)
Vascular bruits	0.13 (0.07 – 0.27)	Ascending aorta	0.46 (0.22 – 0.97)
Upper limb claudication	0.09 (0.03 – 0.21)	Arch of aorta	0.44 (0.24 – 0.81)
Lower limb claudication	0.31 (0.14 – 0.68)	Descending thoracic aorta	0.38 (0.21 – 0.67)
Hypertension	2.75 (1.29 – 5.85)	Abdominal aorta	0.65 (0.37 – 1.14)
Aortic regurgitation	0.45 (0.12 – 1.75)	Celiac trunk	0.70 (0.37 – 1.32)
Renal failure	3.96 (1.37 – 11.46)	Superior mesenteric artery	0.73 (0.38 – 1.41)
Abdominal angina	0.61 (0.15 – 2.51)	Inferior mesenteric artery	0.82 (0.23 – 3.01)
Chest pain	0.18 (0.05 – 0.63)	Right renal	1.11 (0.63 – 1.95)
Heart failure	0.43 (0.16 – 1.15)	Left renal	1.09 (0.62 – 1.92)
		Pulmonary	1.27 (0.39 – 4.07)

Background: Tocilizumab (TCZ) is the only biologic therapy approved for giant cell arteritis (GCA). Clinical trials with TCZ in GCA was performed with intravenous (iv) TCZ in a phase 2 trial [1], and with subcutaneous (sc) TCZ in the phase 3 GiACTA [2]. There is general agreement on the initial/maintenance dose, but duration of TCZ therapy is not well established. In GiACTA trial, after one year on TCZ, most patients had GCA relapse after withdrawal.

Objectives: To assess the predictive factors of relapse in GCA in a clinical practice scenario.

Methods: Multicentre observational study of 471 patients with GCA. The diagnosis of GCA was performed between 2016 and 2021 according to: **a)** ACR criteria, and/or **b)** temporal artery biopsy, and/or **c)** imaging techniques.

Relapse was defined according to EULAR consensus definition [3].

From the 471 patients, we selected the patients who had available the data on relapse during follow-up. Multivariable study was conducted to identify the best set of predictors for the appearance of a relapse.

Results: GCA relapses were observed in 63 of 405 (15%) patients for whom such data was available **(Table 1).** No significant differences were observed between the two groups in demographic, clinical and laboratory characteristics or in prednisone dose at initiation of TCZ. The set of variables associated with GCA relapses were prior use of synthetic conventional disease-modifying antirheumatic drugs (scDMARDs), use of iv.TCZ, shorter time on TCZ therapy and optimization of TCZ dose **(Figure 1).**

Conclusion: GCA relapse seems related mainly to TCZ schedule and was associated with iv TCZ, and a shorter treatment time and optimization.

AB0708 PHYSICAL ACTIVITY AND POLYMYALGIA RHEUMATICA RISK: A MENDELIAN RANDOMIZATION STUDY

Keywords: Fibromyalgia, Non-pharmacological interventions, Genetics/epigenetics

J. Y. Chen[1,2], Z. Jing[1,2], Q. Feng[1,2], Y. Feng[1,2], Q. Yu[3], P. F. He[3], X. Li[1,2,4], S. X. Zhang[1,2,4]. *[1]Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Shanxi Medical University, Taiyuan, Shanxi Province, China*; *[2]Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, Shanxi Province, China*; *[3]Shanxi Key Laboratory of Big Data for Clinical Decision Research, Shanxi Medical University, Taiyuan, Shanxi Province, China*; *[4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China*

Background: Polymyalgia rheumatica (PRM)is a chronic inflammatory disorder characterized by pain and long-term morning stiffness of the neck, shoulders, hips, upper arms, and thighs [1]. Prolonged unaccustomed exercise involving muscle lengthening (eccentric) movements can lead to ultrastructural muscle destruction, impaired excitation-contraction coupling, inflammation, and muscle protein degradation to produce muscle pain [2]. This muscle pain due to exercise may be associated with muscle pain in PRM.

Objectives: This study aims to discover whether physical activity affects PRM.

Methods: We obtained GWAS data for sedentary: Time spent watching television (n=91,084), time spent using a computer (n=360,895), and time spent driving (n=310,555). Types of physical activity included moderate physical activity 10+ minutes (n= 440,266), vigorous physical exercise 10+ minutes (n=440,512), tachometer-based physical activity, Vigorous physical activity, and moderate to vigorous physical activity (UK Biobank). GWAS of PRM included 213,145 European individuals. Single nucleotide polymorphisms (SNPs) that were independent ($r^2 < 0.001$) and were strongly related to accelerometer-measured physical activity ($p < 5\times10^{-8}$, $F > 10$) were selected as instrumental variables. The inverse-variance weighted (IVW) method was the primary method, to evaluate the causal association. The weighted median, and MR-Egger were applied for further MR analysis. Cochran's Q test, MR-Egger intercept analysis, the funnel plot, and the leave-one-out analysis were used for sensitivity analysis.

Results: There was an inverse association between time spent using a computer with PRM (IVW OR: 0.32, 95% CI: 0.15–0.70, *p*: 0.004). No directional pleiotropy was revealed by the MR-Egger intercept analysis (*p*: 0.797). On the flip side, tachometer-based physical activity, vigorous physical activity, moderate to vigorous physical activity, moderate physical activity 10+ minutes, vigorous physical activity 10+ minutes, time spent watching TV (TV), and driving time were not associated with PRM(*p*>0.05). (Figure 1)

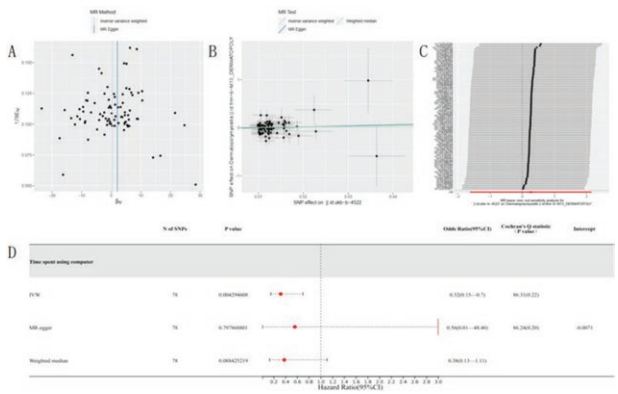

Figure 1. The causal associations between PA and PRM were evaluated by the odds ratio (OR) values of IVW, MR-Egger, and Weighted median. (A)Funnel plot, (B)scatter plot, (C) leave-one-out analysis, and (D)forest plot.

Conclusion: Computer time spent is a protective factor for PRM. Conversely, excessive exercise may be a risk factor, providing new insights into the pathogenesis of PRM.

Background: Patients with giant cell arteritis (GCA) can relapse despite glucocorticoids, methotrexate and tocilizumab treatment. The JAK/STAT signalling pathway is involved in the pathogenesis of GCA, and JAK inhibitors (JAKi) are a potential treatment alternative. Baricitinib showed positive results in a small uncontrolled study [1].

Objectives: To evaluate the effectiveness of JAKi in GCA.

Methods: Real-world, retrospective clinical practice study of patients with GCA treated with JAKi. Outcomes assessed included disease relapse and safety. A literature search for other JAKi-treated GCA cases was conducted in PubMed, Embase and the Cochrane library from inception to 12/31/2022. We compared results of the previous baricitinib study **(1)** and the baricitinib recipients in our series.

Results: We present 32 patients (27 females [84%], mean age, 72.4 years, relapsing disease 32 [100%]) that received JAKi. The initial JAKi was baricitinib (n=12), tofacitinib (n=10) and upadacitinib (n=10) (**Table 1 and Figure 1**). After a median [IQR] follow-up of 6 [3-15] months, 23 (72%) achieved and maintained remission, and 9 (28%) patients discontinued the initial JAKi due to relapse (n=7, 22%) or severe adverse events (SAEs) (n=2, 6%) including liver dysfunction and dyspnea/palpitations. The 9 patients failing the initial JAKi were switched to an alternative [JAKi (n=4) or to another immunosuppressant (n=5)]. The literature review identified another 21 GCA patients (17 females, mean age 74.2 years) treated with JAKi, mostly with baricitinib (n=18). Most of these patients benefited from JAKi therapy (**Table 1**). Patients in our series receiving baricitinib had longer disease duration (median [IQR]36 [24-48] vs 9 [7-21] months; p=0.001) and had received biologics (83% vs 6.7%; p<0.001) more frequently than those in the previous baricitinib study [1]. Remaining baseline features were similar.

Conclusion: This real-world analysis suggests that JAKi could be effective in GCA, including patients failing other immunosuppressive therapies. The results of an ongoing phase 3 randomized controlled trial are awaited to confirm or rule out this observation.

AB0710 MIXED RESPONSE TO TOFACITINIB IN INDIAN PATIENTS WITH REFRACTORY TAKAYASU ARTERITIS: A MULTI-CENTER STUDY

Keywords: Targeted synthetic drugs, Vasculitis

R. Goel[1], P. Vasanth[2], S. Padiyaru[1], R. Aithala[3], A. Patil[4], A. Jain[5], B. Pinto6, R. Jois[7], J. Mathew[1], D. Danda[1], G. Joseph[8]. *[1]Christian Medical College, Vellore, Clinical Immunology and Rheumatology, Vellore, India*; *[2]Christian Medical College, Clinical Immunology and Rheumatology, Vellore, India*; *[3]St. John's Medical College, Clinical Immunology and Rheumatology, Bengaluru, India*; *[4]Manipal Hospital, Rheumatology, Bengaluru, India*; *[5]SMS Medical College, Clinical Immunology and Rheumatology, Jaipur, India*; *[4]Manipal Hospital, Rheumatology, Bengaluru, India*; *[7]Manipal Hospital Millers Road, Rheumatology, Bengaluru, India*; *[8]Christian Medical College, Cardiology, Vellore, India*

Background: Treatment of patients with Takayasu arteritis (TAK) is challenging in-spite of the use of conventional cytotoxic agents and biologics. Tofacitinib has been reported to be effective in inducing and maintaining remission in around 80% of patients with refractory TAK [1].
Objectives: To assess the efficacy and safety of tofacitinib in Indian patients with TAK.
Methods: In this retrospective study, medical records of consecutive patients with TAK being treated with either originator or generic tofacitinib at 4 centres in India were studied. Details regarding demographics, clinical presentation, disease duration, Indian Takayasu Activity score (ITAS), laboratory markers angiography treatment and response to treatment were recorded. The disease was considered active if the patient had evidence of activity in any two of the following three domains: new clinical symptoms as evidenced by ITAS >1; persistently raised C-reactive protein (CRP) for 2 consecutive visits; new areas of arterial wall thickening or active uptake in angiography or 18FDG PETCT respectively. Good response was defined as the absence of activity in at least 2 of the 3 above-mentioned domains. In contrast, presence of carotidynia or new areas of arterial narrowing were considered as standalone indicators of disease activity. In the absence of follow up imaging, a rise in CRP from baseline visit on 2 consecutive occasions was also considered as active disease. The data is presented as mean± SD or median (Interquartile range) according to distribution of data. Fischer's exact test or Mann Whitney test was used to compare the parameters between patients with good response and no response to treatment.
Results: Twenty-seven patients (24, 88.9% females; age 30.4 ± 8.13 years) with median disease duration 48 (20-72) months were included. At diagnosis, 13 (48.1%), 6 (22.2%), 15 (55.6%) and 7 (25.9%) patients presented with constitutional symptoms, carotidynia, ischemia features and aortic regurgitation respectively. All patients had active disease while all except 1, had received a median of 3 (1-4) lines of immunosuppressants including biologics in 16 (59.3%). All patients received prior systemic steroids. The indication of switching to tofacitinib were clinical, laboratory and imaging wise activity in 19, 17 and 4 patients respectively. The median ESR, CRP, ITAS score and steroid dose at initiation of tofacitinib was 46 (25-72) mm/1st hr, 25 (16.5-44) mg/L, 0 (0-2) and 7.5 (5-10) mg/day respectively. At median follow up of 10 (5-12) months, clinically stable disease was observed in 18 (72%), normalisation of CRP in 9 (36%), decrease in CRP in 8 (32%) and non-progression of new lesions in angiography (available in 10 patients) in 8 patients. Overall, 14 (51.9%) had good response in 2 domains and were classified as responders. The responders trended to have significantly higher median disease duration as compared with non-responders (median: 60 (41-96) months vs 27 (6-63) months), p= 0.054. None of the other clinical parameters differentiated the two groups. Four patients discontinued the drug due to side effects while one patient had sudden death within 3 months of initiation on tofacitinib.
Conclusion: The response to tofacitinib was modest in Indian patients with difficult to treat TAK. Further multi-ethnic studies are required to ascertain its effectiveness in TAK.

AB0711 VASCULAR CALCIFICATIONS IN LARGE VESSEL VASCULITIS

Keywords: Imaging, Vasculitis

C. Marvisi[1], R. Fari[2], G. Besutti[2], L. Spaggiari[2], P. Mancuso[3], F. Muratore[1], E. Galli[1], P. Pattacini[2], C. Salvarani[1]. *[1]Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Rheumatology Department, Reggio Emilia, Italy*; *[2]Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Radiology Department, Reggio Emilia, Italy*; *[3]Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Epidemiology Department, Reggio Emilia, Italy*

Background: Arterial wall calcifications are a hallmark of atherosclerosis and represent an important cardiovascular risk factor. Accelerated atherosclerosis and vascular calcifications have been reported in large vessel vasculitis (LVV), but data are scarce about the amount and localizations [1].
Objectives: The aim of this study was to compare the prevalence, amount, and local distribution of arterial wall calcification evaluated on CT scan in LVVs versus lymphoma patients matched for age, sex, and year of diagnosis.
Methods: All consecutive patients diagnosed at our institution with LVVs from 2007 to 2018 with an available baseline PET-CT scan were included. Lymphoma patients were matched based on age, sex, and year of baseline PET-CT. CT images derived from baseline PET-CT scans of both patient groups were retrospectively reviewed by a single radiologist who, after setting a threshold of minimum 130 HU, semi-automatically computed vascular calcifications in three separate sites (coronaries, thoracic and abdominal arteries), quantified as Agatston, volume and mass scores. Calcifications in the two groups were compared for each site by using paired T-test. The effect of patient group was evaluated on the presence of calcifications in each site by means of adjusted conditional logistic regressions, and on the score of thoracic calcifications by means of adjusted regression.
Results: 258 patients were enrolled, including Takayasu's arteritis n=57, giant cell arteritis n=72 and lymphoma n=129. Thoracic artery calcifications were more represented in LVV patients, when compared with lymphoma patients (mean volume 2026 in LVVs vs 1014 in lymphomas, p=0.054). Coronary calcifications were higher in lymphoma patients (mean volume 104 in LVVs and 198 in lymphomas, p=0.13), whereas abdominal artery calcifications were equally distributed (mean volume 3220 in LVVs and 2712 in lymphomas). A diagnosis of LVV was associated with the presence of thoracic calcifications after adjusting by age and year of diagnosis (OR=4.13, 95%CI= 1.35-12.66; p=0.013), and with the volume score in the thoracic arteries (p=0.048).
Conclusion: When compared with lymphoma patients matched by age, sex, and year of diagnosis, LVV patients have higher calcification in the thoracic arteries, but not in coronary and abdominal arteries.

Background: The relationship between corticosteroid (GCs) treatment prior to temporal artery biopsy (TAB) and a negative result in giant cell arteritis (GCA) is controversial.
Objectives: To assess whether cumulative GCs dose and time of steroid exposure influence in TAB result.
Methods: Observational study of 191 patients diagnosed with GCA from a clinical practice of a referral center between January 2016 and December 2022 who underwent TAB. The diagnosis of GCA was made according to **a)** ACR criteria, and/or **b)** temporal artery biopsy, and/or **c)** EULAR/ACR2022 criteria, and/or **d)** imaging techniques. The biopsies were transversally sectioned into pieces and were cut from paraffin blocks and stained with hematoxilyn-eosin. A comparative study between patients with positive TAB and those with negative TAB was performed.
Results: The 191 GCA patients were divided into 2 subgroups: **a)** patients with positive TAB (n=52), and **b)** patients with negative TAB (n=139) **(Table 1)** of whom 26 (13.6%) had not received prior corticosteroid therapy versus 165 (86.4%) patients who did. Patients with positive TAB had more frequently visual symptoms and/or jaw/lingual claudication, while polymyalgia rheumatica (PmR) was less frequent. The median dose [interquartile range (IQR) 25th-75th] in the negative TAB group was 40 [25-40] mg/day and also 40 [35-60] mg/day in the positive TAB group. The median duration [IQR] of treatment in the first group was 11 [4-24] days. while in the second group it was 7 [3-13] days. The percentage of positive TAB was higher the shorter the delay between GCs treatment onset and the TAB, decreasing after 15 days from GCs therapy onset **(Figure 1)**. Finally, the cumulative pre-biopsy GCs dose was calculated with a median [IQR 25th-75th] of 484 [225-1295] mg for negative TAB patients while it was 760 [360-2185] mg in positive TAB cases.
Conclusion: Most patients with GCA were receiving GCs at the time of the TAB. Longer exposure to GCs increases the likelihood of a negative TAB, especially after 15 fays from GCs therapy onset.

FREQUENCY OF TUBERCULOSIS AND ASSOCIATED RISK FACTORS IN PATIENTS WITH BEHÇET'S SYNDROME

Keywords: bDMARD, Spondyloarthritis, Behcet's disease

M. Yıldırım[1], S. N. Esatoglu[2,3], Y. Ozguler[2,3], M. Melikoglu[2,3], I. Fresko[2,3], V. Hamuryudan[2], G. Hatemi[2,3]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Internal Medicine, İstanbul, Turkey*; [2]*Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology, İstanbul, Turkey*; [3]*Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Behcet Syndrome Research Center, İstanbul, Turkey*

Background: A considerable number of patients with Behçet's syndrome (BS) have vitreous cells on slit lamp examination at the time of diagnosis. However, the prognostic importance of vitreous cells (VC) and their association with the development of posterior uveitis (PU) requiring immunosuppressive treatment is unknown.
Objectives: We aimed to determine the prognostic importance of VU in BS patients.
Methods: The charts of 572 consecutive BS patients fulfilling ISG criteria who were registered between 2010 and 2012 were reviewed. At baseline visit 164 patients had VC in one eye or both eyes. Among the remaining patients, 229 had no eye involvement, 116 patients had bilateral pan or posterior uveitis, 14 had unilateral pan or posterior uveitis and no eye involvement in the other eye, 20 had isolated anterior uveitis, and 29 had insufficient data in their medical records. Among the 164 patients with VC, 110 patients with a follow-up of ≥2 years were included in this study (Figure 1).
Results: At baseline, among the 111 included patients (68 men, mean ± SD age: 31±9 years), 61 had VC in both eyes, 34 had VC in only one eye, and 15 had VC in one eye and PU in the other eye. There was anterior uveitis (AU) in addition to VC in the same eye in 13 patients at baseline (Figure 1). New PU developed in 26 (24%) patients during a mean follow-up of 1.9±1.1 years.7 patients that developed PU in the eye with VC had had PU in the contralateral eye at baseline. This means 7 of 15 patients with VC in one eye and PU in the contralateral eye developed bilateral PU despite treatment. 2 of these 7 patients had developed AU before they developed PU. Additionally, 6 patients that developed PU in the eye with VC had anterior uveitis in the same eye at baseline.
Conclusion: Careful follow-up is required for patients with VC since one quarter developed PU within 2 years. The presence of PU in the contralateral eye and AU in the same eye may be risk factors for the development of PU in patients with VC.

AB0714 CLINICAL CHARACTERISTICS AND RISK FACTORS ANALYSIS IN PATIENTS OF TA WITH CORONARY ARTERY CALCIFICATION

Keywords: Cardiovascular disease, Vasculitis

S. Yang[1], L. Pan[1]. [1]*Beijing Anzhen Hospital, Capital Medical University, Beijing, Rheumatology and Immunology, Beijing, China*

Background: Takayasu arteritis(TA) is a chronic inflammatory disease mainly involving large vessels, including the aorta and its main branches, pulmonary arteries and coronary arteries, which can usually lead to stenosis, occlusion, expansion, or aneurysm formation of the affected vessels [1-2].Studies have shown that 10-20% of patients with TA have coronary lesions detected by angiography.In fact, this situation is still underestimated, because most TA patients do not complete the coronary angiography examination due to the lack of cardiac symptoms, such as palpitations and chest pain [3]. Coronary artery involvement is a serious adverse factor of poor prognosis and increases mortality in TA patients, specifically showing coronary artery stenosis, occlusion, and coronary artery calcification(cac) [4]. Patients with high coronary calcification scores have an extensive coronary plaque burden, with a high risk of stress-induced ischemic events [5].
Objectives: The aim of our study is to investigate the risk factors of cac in TA patients.
Methods: This retrospective study enrolled a total of 120 TA patients.All patients were divided into two groups according to the absence or presence of cac in TA patients (90 vs 30). we measured the Agatston score and compare clinical characteristics and ancillary findings between the two groups.A logistic model was applied to determine the risk factors associated with the incidence of cac in TA patients.
Results: A total of 30 patients with TA (25%) had cac.Age,medical history of hypertension and type of Numano V are the independent risk factors for developing cac in TA patients (OR [95% CI]1.080[1.020-1.143], p = 0.008; 5.457 [1.818-16.379], p = 0.002;7.827 [1.822-33.615], p = 0.006). However it's not associated with disease activity and clinical symptom. We counted the number of risk factors for each patient and measured the integral values of the cac, and found that the integral value of cac increased with the number of risk factors.We also counted the medication status of patients before admission,and found that patients with cac had a greater proportion of statin(50%vs. 28.9%, P=0.035) than patients without it.But there was no difference in using glucocorticoid and aspirin between the two groups. Glucocorticoid accumulation was also not statistically significant.
Conclusion: Age, hypertension and Numano type V are risk factors for developing cac in TA patients.It is recommended that arteria coronaria screen in TA patients with Numano type V should be actively treated as early as possible. The severity of cac will increase with the number of risk factors, and TA patients should be actively treated and strictly controlled with blood pressure levels.

AB0715 THE LONG-TERM PROGNOSTIC VALUE OF THE "2022 ACR/EULAR CLASSIFICATION CRITERIA FOR TAKAYASU ARTERITIS": DATA FROM A LARGE MONOCENTRIC COHORT

Keywords: Vasculitis, Real-world evidence, Prognostic factors

A. Tomelleri[1], C. Campochiaro[1], E. Rinaldi[1], N. Viapiana[1], E. Baldissera[1], L. Dagna[1]. [1]*IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: The "2022 classification criteria" for Takayasu arteritis (TAK) have been developed for the purpose of classifying patients with TAK. These criteria provide a score from 0 to 22; a score ≥5 allows to classify a patient.
Objectives: To investigate whether the "2022 classification criteria" score correlates with long-term outcomes of patients with TAK.
Methods: Data of patients with TAK followed up for ≥1 year and evaluated at least once within the last year at our Vasculitis Clinic were reviewed. For each patient, the score provided by the "2022 classification criteria" at baseline was calculated and the following outcomes at 24, 60, 120 months were evaluated: glucocorticoid (GC) suspension, introduction of a conventional disease-modifying anti-rheumatic drug (cDMARD), introduction of a biologic DMARD (bDMARD), need for vascular procedure, total number of bDMARDs received. Correlation of these outcomes with the score and with different thresholds (scores ≥5, ≥6, ≥7) was evaluated. Statistical tests were performed as appropriate.
Results: 120 TAK patients were included (103 women, 87.3%); mean follow-up duration was 154±113.8 months (24 months, n=110, 60 months, n=88, 120 months, n=60). Mean age at diagnosis was 37.3±13.6 years. 112 patients (93%) were classified as having TAK (mean score, 9.5±3). Seven patients (5.8%) were only treated with GC; 110 patients (91.6%) received at least one cDMARD (mean, 1.6±1), after a mean of 23.6±61.1 months; 80 patients (66.7%) received at least one bDMARD (mean, 1.2±1.5), after a mean of 40.1±64.5 months. GCs were suspended in 44 patients (36.7%), after a mean of 102.3±93.7 months. Forty-four patients (36.7%) underwent at least one vascular procedure (mean, 0.9±1.5). No significant correlation between the five outcomes and the score was found at all three timepoints (Table 1). No significant correlation between GC suspension, introduction of a csDMARD or a bDMARD, need for a vascular procedure and a score ≥5, ≥6, or ≥7 was found at all three timepoints (Table 1). A significant correlation between the total number of bDMARDs received at 120 months and both scores ≥6 and ≥7 was found (1.3±1.5 vs 0.6±0.8, p=0.045, and 1.3±1.6 vs 0.6±0.7, p=0.035, respectively).
Conclusion: Although the "2022 classification criteria for TAK" do not seem to correlate with the long-term prognosis, in our cohort we found that a higher baseline score (≥6) is associated with a higher number of bDMARDs received during follow-up. This suggests that the score might allow to identify TAK patients with

AB0716 CLINICAL FACTORS ASSOCIATED WITH VASCULAR COMPLICATIONS (ANEURYSMS, THROMBOSIS, DISSECTION OR SURGERY) IN PATIENTS WITH GIANT CELL ARTERITIS

Keywords: Vasculitis, Real-world evidence, Imaging

H. Codes-Mendez[1], P. Moya[1,2,3], H. Park[1], A. Fernandez[4], M. Velasco Nuñez[4], B. Magallares[1,3], A. J. Barros-Membrilla[2,5], L. Sainz Comas[1], C. Díaz-Torné[1], J. L. Tandaipan[1], S. P. Fernandez-Sanchez[1], J. F. Dilme[2,6], A. Laiz[1], I. Castellví[1,3], H. Corominas[1,3]. *[1]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; *[2]Hospital de la Santa Creu i Sant Pau, Aortic Pathology Functional Unit, Barcelona, Spain*; *[3]Hospital de la Santa Creu i Sant Pau, Systemic Autoimmune Diseases Functional Unit, Barcelona, Spain*; *[4]Hospital de la Santa Creu i Sant Pau, Nuclear Medicine, Barcelona, Spain*; *[5]Hospital de la Santa Creu i Sant Pau, Cardiology, Barcelona, Spain*; *[6]Hospital de la Santa Creu i Sant Pau, Angiology, Vascular and Endovascular Surgery, Barcelona, Spain*

Background: Giant cell arteritis (GCA) typically affects cranial vessels, but it can also affect large vessels in a high percentage of patients. Vascular inflammation of the aorta and/or its main branches can cause complications of high morbidity and mortality such as aneurysms, dissection, thrombosis and/or require aortic surgery. The analysis of the different clinical and imaging patterns in patients with GCA and aortitis and their relationship with the prognosis needs more investigation. Early identification of patients with the highest risk of mortality could help predict deaths and vascular complications.

Objectives: To evaluate the clinical characteristics of patients with giant cell arteritis (GCA) who present vascular complications.

To evaluate prognostic factors associated with vascular complications in patients with GCA.

Methods: A retrospective cohort study was carried out including patients diagnosed of GCA by a multidisciplinary expert committee in aortic pathologies. A total of 71 patients followed between the years 2011-2021 who had a PET-CT at onset before receiving treatment were included. Other causes of aortitis were excluded. Vascular complication was defined as the presence of aneurysm, dissection, thrombosis, or aortic surgery during the disease. Demographic, clinical, analytical and imaging variables were collected. A descriptive study of the sample and a groups comparison, according to the presence of vascular complication, was carried out. The Shapiro-Wilk test was used to study the normality of the variables. Univariate logistic regression was performed to assess predictive factors.

Results: A total of 71 patients were included, 73.2% were female and the mean age was 79.3 (±6.7) years. During the disease, 13 patients presented aortic vascular complication. Jaw claudication (p<0.0001), fever of unknown origin (p<0.0001), anemia (p=0.001), constitutional syndrome (p<0.0001) and use of pulses of glucocorticoids (p=0.014) were associated with a higher occurrence of vascular complications. On the contrary, ischemic stroke prior to or at onset of disease (p=0.035) was the only variable associated with fewer complications with statistical significance. Cardiovascular risk factors and acute phase reactants were not associated with the appearance of complication, and either the delay of diagnosis and start of therapy. The details of the sample characteristics are described in Table 1.

Table 1. Demographic and clinical characteristics of patients according to the presence or not of vascular complication.

	Complication (n=13)	No complication (n=58)	p
GCA Classification (%)		18.9	0.944
- Cranial	15.3	24.1	
- Extracranial	23.1	56.9	
- Both	61.5		
Clinical presentation (%)			
Headache	30.77	31.58	0.945
Jaw claudication	84.6	61.4	**<0.000**
Ophtalmological signs	53.8	73.6	0.159
Scalp tenderness	61.5	80.7	0.138
Fever of unknown origin	76.9	71.9	**<0.000**
Polymyalgia rheumatica	53.8	59.6	0.702
Anemia	23	71.9	**0.001**
Constitutional syndrome	61.5	60.5	**<0.000**
Complications at onset (%)			
Aortic surgery	0 0	6.8	**0.049**
Ischemic stroke	1 7.6	5.1	**0.035**
Vascular complication	0	13.7	0.383
IV pulse GC mg/kg/d (%)	46.1	15.5	**0.014**

The univariate analysis to identify predictive factors showed that anemia (OR: 0.11 [0.02-0.48], p=0.003) was a protective factor against the occurrence of vascular complication.

Conclusion: Occurrence of new vascular complications was observed in 18.3% of patients with GCA included in our study. Jaw claudication, fever of unknown origin, anemia and constitutional syndrome, and the use of pulses glucocorticoids as treatment were associated with a greater appearance of complications, while ischemic stroke with fewer complications. Anemia proved to be a protective factor against the occurrence of vascular complications.

AB0717 DIAGNOSIS OF CRANIAL GIANT CELL ARTERITIS IN JAPAN USING VASCULAR ULTRASONOGRAPHY COMBINED WITH OTHER COMPLEMENTARY IMAGING METHODS

Keywords: Imaging, Ultrasound, Vasculitis

T. Kawamoto[1], M. Ogasawara[1], Y. Mastuki-Muramoto[1], M. Harada[1], E. Hayashi[1], M. Matsushita[1], K. Yamaji[1], N. Tamura[1]. *[1]Juntendo University School of Medicine, Internal Medicine and Rheumatology, Tokyo, Japan*

Background: The utility of vascular ultrasonography (v-US) was proved recently in European countries, due to which the technology, diagnosis, and classification methods have been spreading. However, the use of v-US is not prevalent in Japan. Therefore, giant cell arteritis (GCA) is usually diagnosed by combining v-US with other imaging methods scrupulously. Furthermore, progressive Computed Tomography Angiography (CTA) technologies, increased use of Positron Emission Tomography (PET-CT), and a high population with Takayasu disease are found in Japan.

Objectives: Giant cell arteritis of cranial type (c-GCA) can quickly lead to blindness and stroke. Therefore, a rapid and appropriate diagnostic method is required to differentiate between c-GCA cases and those mimicking c-GCA. Thus, we aimed to construct a diagnostic method for c-GCA by optimizing the available imaging methods in Japan and using v-US as a diagnosing method from Europe.

Methods: We targeted 56 patients with suspected GCA, who visited our hospital from 2019 to 2022. v-US had been performed previously in all patients and 23 patients were diagnosed with GCA. These GCA patients were classified as c-GCA vs c-GCA + Large vessel (LV)-GCA vs LV-GCA in the ratio 11: 6: 6. In this study, we established 17 cases as c-GCA, and the other 39 as mimic cases using clinical and imaging methods. Furthermore, we analyzed and compared 31 patients evaluated with v-US from 2021 to 2022 using a vascular map, which was originally made by us and we were making maps for blood flow and writing down clinical symptoms evaluated at three stages.

Results: The sensitivity of the imaging methods to c-GCA patients was high for v-US (82.3%), Temporal artery biopsy (TAB) (78.6%), and CTA (71.4%) and low for PET-CT (50.0%) and Magnetic resonance imaging angiography (MRI/A) (38.5%). However, we did not use a contrast agent for MRI/A because our main objective to perform MRI/A was to distinguish cerebral infarction. The match rate of the imaging methods between v-US and PET-CT was 87.5% (CTA: 71.4%, TAB and v-US: 64.3%, and CTA: 63.6%). Among the 39 mimic cases, 15 cases were found to be Polymyalgia Rheumatica (PMR), 6 cases were LV-GCA, 5 cases were chronic headache, and others were collagen diseases, including 2 cases of Takayasu diseases. In 31 cases (10 cases of c-GCA and 21 mimic cases) from 2021 to 2022, halo sign of v-US (p-value: 0.01), jaw claudication (p-value: 0.02), and temporal headache on both sides (p-value: 0.01) were significant statistically.

Conclusion: In this study, we constructed a flowchart to diagnose c-GCA in Japan using v-US and other complementary imaging methods. First, we distinguished GCA cases from mimic cases with high precision. Thereafter, we combined imaging methods, which contributed highly to diagnosis in our results. Lastly, we considered the accommodation of TAB. We have started using this flowchart, and this contribute to be higher rate of diagnosing GCA and decreasing blindness and stroke.

AB0718 LEVELS OF PHOSPHO-STAT3 ASSOCIATE WITH TREATMENT DURATION IN GIANT CELL ARTERITIS

Keywords: Adaptive immunity, Biomarkers, Vasculitis

I. Esen[1], M. Sandovici[1], P. Heeringa[2], A. Boots[1], E. Brouwer[1], Y. Van Sleen[1], W. Abdulahad[1,2]. [1]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; [2]*University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands*

Background: Giant Cell Arteritis (GCA) is a granulomatous inflammation of medium and large arteries, that occurs in elderly individuals. Evidence on the immunopathology of GCA indicates that the IL-6 IL-23 Th17 axis is one of the dominant pathways and the Janus kinase (JAK)/signal transducers and activators of transcription (STAT) acts downstream of this axis. Targeted IL-6 receptor blockade by tocilizumab (TCZ) emerges as a promising treatment option. However, there is no further data on which patients would benefit most. The therapeutic effect of TCZ in a substantial group of GCA patients suggests that the vasculitis is driven by the JAK/STAT pathway in these patients.
Objectives: To investigate whether phosphorylated STAT (pSTAT) signatures in GCA patients can aid the stratification of patients for personalized treatment in GCA.
Methods: To investigate the expression of pSTAT, a phosphoflow method combined with a fluorescent cell barcoding technique (FCB) was developed. Frozen peripheral mononuclear cells (PBMCs) from treatment-naive GCA patients (n=18), infection controls (INF, n=11) and age-matched healthy controls (HC, n=15) were included in this study. PBMCs were incubated with IL-6 for 30 minutes. Cells were stained for T-cell markers (CD3, CD4, CD8, CD19, CD45RO) and STAT signature markers (pSTAT1, pSTAT3, pSTAT5). Serum IL-6 levels were measured by Luminex assay. The baseline inflammation markers and pSTAT3 in prospectively followed GCA patients was assessed by Kaplan-Meier curves for prognostic analysis. The pSTAT3 activity after treatment was evaluated in paired baseline, 3 months and 1-year samples.
Results: After IL-6 stimulation, we found a lowered proportion of pSTAT3 in CD4+ memory T-cells of GCA patients and INF controls compared to HCs. In GCA patients, proportion of pSTAT3 in CD4+ memory T cells was negatively associated with ESR at diagnosis (p=0.001, r=-0.729). Considering the link between IL-6 and ESR, we stratified GCA patients according to high (>1.5pg/mL) and low (≤1.5pg/mL) serum IL-6 levels and found that that the decrease in pSTAT3 in CD4+ memory T cells was especially found in GCA patients with high serum IL-6 levels. Importantly, we found that GCA patients with low ESR and high pSTAT3 at the time of diagnosis significantly predicted long-term glucocorticoid requirement. Levels of pSTAT3 in patients with high serum IL-6 levels at diagnosis normalized after 1 year of treatment.
Conclusion: We demonstrate a relation between serum IL-6 levels and in vitro pSTAT3 expression in GCA. Importantly, our results suggest that pSTAT3 can be an important prognostic marker in GCA.

AB0719 IS AORTIC 18FDG-UPTAKE PREVALENCE UNDERESTIMATED? DATA FROM A LARGE HOSPITAL-BASED COHORT

Keywords: Epidemiology, Real-world evidence, Imaging

N. Italiano[1], F. Di Cianni[1], P. A. Erba[2], R. Talarico[1], M. Mosca[1]. [1]*University of Pisa, Rheumatology Unit, Pisa, Italy*; [2]*University of Pisa, Nuclear Medicine Unit, Pisa, Italy*

Background: Giant cell arteritis (GCA) and Takayasu arteritis (TAK) are the most common rheumatologic cause of aortitis, but it is still debated whether clinically isolated aortitis (CIA) represents a variant of such conditions or a nosologically different entity. CIA real frequency may be underestimated since it may occur without specific clinical manifestations.
Objectives: The aim of the present study was to assess the frequency of vasculitic aortic uptake in patients who undergo 18FDG-PET for any kind of clinical reason.
Methods: One-thousand consecutive patients who underwent a whole-body 18FDG-PET at the Nuclear Medicine Department of Pisa Hospital for whatsoever clinical question since January 1st, 2019 were enrolled. All the 1000 reports were separately reviewed searching for abnormal uptake of the aorta, and for the doubtful cases the images were revised with an experienced specialist in nuclear medicine. Demographic data, clinical question and provenience was collected; in case of aortic uptake, Meller grade and other sites of abnormal uptake were registered.
Results: The cohort included 439 males and 561 females with a mean age of 62.75 years. The clinical suspicion was neoplasm in 875 cases, infectious process in 55, vasculitis in 25, fever of unknown origin (FUO) in 12, lymphadenopathy

in 11, aneurysm in 4 and some other in 18. Thirteen patients (8 males and 5 females, mean age 59.69 years) showed positive aortic uptake. Among them, 6 patients underwent examination for a suspected vasculitis and 7 (53.8%) for other clinical questions (e.g. neoplasm, FUO, polymyalgia rheumatica). Of all the patients who underwent 18FDG-PET for a suspected vasculitis, 7/25 (28%) showed abnormal vascular uptake. Moreover, among the 13 positive patients, three showed isolated aortic uptake while the others also presented other large vessel involvement. Interestingly, in none of the isolated aortitis vasculitis was the clinical question for the examination (arthritis, FUO, myocarditis).
Conclusion: To our knowledge, this is the first hospital-based study aimed to assess the prevalence of 18FDG-PET aortic uptake on such a large-scale cohort. According to our results, 18FDG-PET may result positive despite the absence of clinical vasculitis-related manifestations, especially in case of CIA. For this reason, the actual prevalence of aortic uptake may be underestimated and further wide-scale studies, which are currently ongoing, are expected to better identify the characteristics of CIA patients and their long-term course.

AB0720 DEVELOPMENT OF RESPONSE CRITERIA FOR GCA: AN SLR INFORMING AN INTERNATIONAL TASK FORCE

Keywords: Systematic review, Remission, Vasculitis

C. Sanchez-Alvarez[1], M. Bond[2], M. Soowamber[3,4], D. Camellino[5], M. Anderson[6], C. Langford[7], C. Dejaco[2,8], Z. Touma9, S. Ramiro[10,11]. [1]*University of Florida, Internal Medicine, Division of Rheumatology, Gainesville, United States of America*; [2]*Hospital of Brunico (SABES-ASDAA), Rheumatology, Brunico, Italy*; [3]*Mount Sinai Hospital, Rheumatology, Toronto, Canada*; [4]*University of Toronto, Rheumatology, Toronto, Canada*; [5]*Local Health Trust 3, Rheumatology, Genoa, Italy*; [6]*Mount Sinai Hospital, Education and Research, Toronto, Canada*; [7]*Cleveland Clinic, Rheumatology, Cleveland, United States of America*; [8]*Medical University of Graz, Rheumatology, Graz, Austria*; [4]*University of Toronto, Rheumatology, Toronto, Canada*; [10]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [11]*Zuyderland MC, Rheumatology, Heerlen, Netherlands*

Background: Giant cell arteritis (GCA) is the most common form of large vessel vasculitis. While remission and relapse are common primary endpoints in randomized clinical trials (RCTs), a definition of response is missing. We conducted a systematic literature review (SLR) to inform an international task force developing new response criteria in GCA.
Objectives: To identify descriptors used to measure response to treatment and change of disease activity in GCA in RCTs and longitudinal observational studies (LOS).
Methods: An SLR was conducted using Ovid Medline, Embase, and Cochrane Central. The research question was formulated according to the PICO framework: the population included patients with GCA, any intervention or comparator was considered, and the outcomes addressed were active disease, improvement/response, remission, worsening, relapse, flare, or recurrence. RCTs and LOS with > 20 subjects and studies on qualitative research were included. Titles screening and full data extraction were performed by 2-3 reviewers. Discordant cases were discussed among reviewers until a final consensus; if not achieved, a methodologist was consulted. In case of multiple publications from the same trial and LOS, they were only considered if separate, pre-specified outcomes were reported.
Results: 10,593 studies were retrieved in the search, of which 116 were finally included. The descriptors used for the different outcomes' definition were extracted and grouped into different categories (Figure 1). Active disease was reported in 11/11 (100%) RCTs and 20/104 (19%) LOS. Active disease was predominantly defined as a combination of clinical and laboratory components. The clinical component was described as the presence of symptoms of GCA while the laboratory component mainly included ESR and CRP. Remission was reported in 8/11 (73%) RCTs and 44/104 (42%) LOS. Remission was predominantly defined as a combination of clinical and laboratory components. The clinical component was described as the resolution of clinical signs/symptoms of GCA. The laboratory component (ESR/CRP) was only considered when associated with the resolution of signs/symptoms of GCA. Relapse was reported in 11/11 (100%) RCTs and 90/104 (87%) LOS. Relapse was predominantly defined as a combination of clinical, laboratory and treatment components. The clinical component was defined as the recurrence of clinical signs/symptoms of GCA. The laboratory component included the elevation of ESR and/or CRP. The treatment component (reinstitution or increase in glucocorticoids dose) was frequently considered as a criterion for relapse. No standardized definition of response was found across studies. Most RCTs used composite endpoints (including treatment tapering/discontinuation, maintenance of remission, and absence of relapse over a certain time frame) to assess the primary endpoint – response. Fourteen imaging studies were analyzed (10 prospective and 4 retrospectives). PET-CT was the most studied imaging (n= 10), followed by ultrasound (n=3). PET activity was evaluated thorough qualitative or semiquantitative scores. Ultrasound evaluated presence of disease activity based on the intimal wall thickness/halo sign. **Conclusion:** The results of this SLR showed that an internationally accepted definition of response in GCA is elusive so far. RCTs and LOS mainly defined the extremes of the spectrum of GCA disease activity (remission and relapse) as primary endpoints. The descriptors identified will be incorporated in future phases of an international task force for the development of response criteria for GCA.

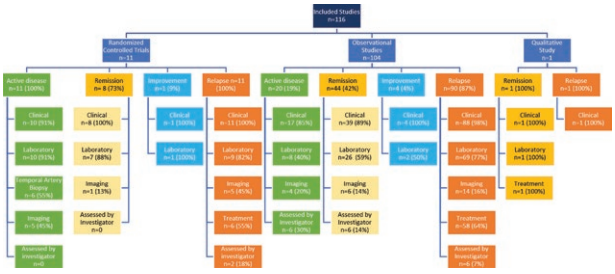

Figure 1. Components assessed in the definitions of active disease, remission, improvement, and relapse across the included studies

AB0721 CHARACTERISTICS AND LONG-TERM OUTCOME OF DISEASE PHENOTYPES IN TAKAYASU ARTERITIS WITH SUPRA-AORTIC INVOLVEMENT

Keywords: Vasculitis, Cardiovascular disease

Y. Sun[1,1,1,1], L. Wang[1], H. Chen[1], X. Dai[1], L. Ma[1], X. Kong[1], L. Jiang[1].
[1]*Zhongshan Hospital Fudan University, Rheumatology, Shanghai, China*

Background: Supra-aortic involvement was most commonly seen in Takayasu arteritis (TA), ranging from 40% to 84%. [1, 2]. The clinical manifestations were heterogeneous and prognosis differed greatly in TA with supra-aortic involvement [3, 4].
Objectives: To explore the characteristics and long-term outcomes in different phenotypes of the East China Takayasu arteritis (ECTA) cohort with supra-aortic involvement.
Methods: Patients with supra-aortic involvement were enrolled from the ongoing ECTA cohort from July 2009 to December 2021 and followed up until June 30, 2022. Patients were assigned to four phenotypes: asymptomatic (AS), constitutional symptoms (CSs), vascular-associated symptoms (VASs), and neurological severe ischemic events (SIEs). Pattern differences in clinical features were analyzed, and the cumulative incidence of severe adverse events (SAEs) was evaluated. We performed multiple logistic regression analysis to compare the phenotypes.

Results: Six hundred fifty-seven TA patients with supra-aortic involvement were included: 54 (8.2%), 72 (11.0%), 303 (46.1%), and 228 (34.7%) patients with AS, CSs, VASs, and neurological SIEs, respectively. Compared to other phenotypes, CSs had significantly higher levels of inflammatory indicators. Neurological SIEs experienced poor treatment response including lower 6-month clinical remission rate and higher drug change rate. The median follow-up period was 3.0 (1.5–13.3) years. The 5-, and 10-year cumulative SAEs incidence rates in neurological SIEs (26.0% [18.7–32.1%], and 61.5 % [30.3–78.7%]) were significantly higher than those in other patients (Figure 1). The occurrence of SAEs was 5.9 folds (3.4–10.1; p < 0.001) in patients with neurological SIEs history compared with that in those without neurological SIEs history.

Conclusion: Our findings provide new insights into the characteristics and prognosis of different phenotypes in TA with supra-aortic involvement, which may be critical for early detection strategies and stratification management of heterogeneous diseases.

AB0722

ULTRASOUND HALO COUNT IN THE DIFFERENTIAL DIAGNOSIS OF ATHEROSCLEROSIS AND LARGE VESSEL GIANT CELL ARTERITIS

Keywords: Vasculitis, Cardiovascular disease, Ultrasound

I. Monjo[1], E. Fernández-Fernández[1], J. M. Mostaza[2], C. Lahoz[2], J. Molina Collada[3], E. De Miguel[3]. [1]*La Paz University Hospital, Rheumatology, Madrid, Spain*; [2]*Hospital Carlos III, Internal Medicine, Madrid, Spain*; [3]*Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain*

Background: Giant cell arteritis (GCA) is the most common vasculitis in the elderly and large vessel involvement occurs in up to 50% of cases. Otherwise, atherosclerosis is frequent in older patients; therefore, ultrasound (US) diagnosis of GCA in these patients may be challenging.

Objectives: To determine the diagnostic discriminant validity between large vessel giant cell arteritis (LV-GCA) and atherosclerosis using US with intima-media thickness (IMT) measurements.

Methods: We included 44 patients, paired by age and sex, with LV-GCA and 42 with high-risk atherosclerosis. US examinations of the axillary, subclavian and common carotid arteries (CCA) were systematically performed using a MylabX8 system (Genoa, Italy) with a 4-15 MHz probe. IMT ≥1mm was accepted as pathological.

Results: The LV-GCA cohort included 24 females and 20 males with a mean age of 72.8±7.6 years. The atherosclerosis group included 25 males and 17 females with a mean age of 70.8±6.5 years. Mean IMT values of all arteries included were significantly higher in LV-GCA than in atherosclerosis. The frequency and localization data are shown in Table 1. Among LV-GCA patients IMT ≥1mm was seen in 31 axillary, 30 subclavian and 28 CCA. In the atherosclerotic cohort, 17 (38.6%) had IMT ≥1mm with axillary involvement in 2 patients, subclavian in 3 patients, carotid distal in 14 patients (5 bilateral) and isolated carotid proximal affectation in 1 case. A cut-off point of at least 1 pathological vessel in the summative count of axillary and subclavian arteries or at least 3 vessels in the count of six vessels, including CCA, showed a precision upper 95% for GCA diagnosis in front of atherosclerosis.

Conclusion: The IMT is higher in LV-GCA than in atherosclerosis. The proposed US halo count achieves an accuracy >95% for the differential diagnosis between LV-GCA and atherosclerosis. The axillary and subclavian arteries have higher discriminatory power, while carotid involvement is less specific in the differential diagnosis. *This study was presented in November 2022 at the ACR Convergence.

Background: There are few studies comparing clinical, laboratory, and imaging characteristics, and treatment of LV-GCA and TAK [1-3].

Objectives: To compare clinical and imaging characteristics in patients with Takayasu arteritis (TAK) and large vessel-giant cell arteritis (LV-GCA) in an Italian population.

Methods: We conducted a retrospective monocenter study comparing characteristics and outcomes of a cohort of 59 patients with TAK and a cohort of 127 patients with LV-GCA diagnosed between 1996 and 2016 and followed up for at least 24 months at Reggio Emilia Hospital (Italy).

Results: LV-GCA patients had a higher prevalence of males (p=0.003), and more frequently presented with cranial symptoms (p=0.001), fever>38°C (p=0.007), polymyalgia rheumatica (p=0.001), and hypertension.

(p=0.001), and they had higher ESR levels at diagnosis (p=0.0001). Differently, TAK patients had longer delay to diagnosis from the beginning of symptoms (p=0.048), they presented more frequently with loss of pulses of large arteries (p=0.0001), vascular bruits (p=0.001), limb claudication (p=0.003), myocardial infarction/angina (p=0.03), and hypertension induced by renal artery stenosis (p=0.001). Regarding treatment, TAK patients received a higher total and at 1 year cumulative prednisone doses (0.0001 and 0.001, respectively), they had a longer duration of prednisone therapy (p=0.008), and received during follow-up more frequently traditional immunosuppressants (p=0.0001) and biological agents (p=0.0001). Flares were more frequently observed in TAK patient (p=0.001), while no differences were observed for long-term remission. New vascular procedures during the follow-up were more frequently performedin TAK. patients (p=0.0001). Regarding imaging at diagnosis, TAK patients had more frequently vascular stenosis/occlusion (p=0.0001) and a higher number of vessels with structural damage per person (p=0.0001), while LV-GCA patients had a higher number of inflamed vessels per person (p=0.0001). Comparing the involved vascular districts at diagnosis for the presence of vessel inflammation and/or arterial damage, patients with LV-GCA had a more frequent involvement of thoracic and abdominal aorta (p=0.024 and p=0.007, respectively), and axillary, iliac and femoral arteries (p=0.018, p=0.002, and p=0.0001. respectively), while in TAK patients, brachiocephalic, celiac, mesenteric and renal arteries were more frequently involved (p=0.011, p=0.019, p=0.019, and p=0.005, respectively). At imaging arterial damage at diagnosis was more frequently observed in TAK patients, specifically at common carotid, brachiocephalic, and subclavian arteries (p=0.0001, p=0.006, p=0.0001, respectively) and descending aorta. (p=0.022). Regarding imaging during the follow-up, TAK patients developed more frequently new vascular stenosis/occlusion (p=0.0001) and new vascular thickening (p=0.002), no differences were observed for the development of new dilatation/aneurysm between the two vasculitis. In the literature review, we identified 7 papers comparing clinical and imaging characteristics of LV-GCA and TAK. Similarities and differences were found comparing our results with those of previous studies.

Conclusion: Patients with TAK and LV-GCA show a number of similarities and also differences. Indeed, it is unclear whether they are part of the same disease spectrum or they are different conditions. As more information regarding the pathogenesis and etiology becomes known, answers to these questions are like to be forthcoming.

AB0724 THE VALUE OF [18F]FDG PET/CT FOR MONITORING AND TREATMENT DECISION GUIDANCE IN LARGE VESSELL VASCULITIS: IS IT TELLING TOO LITTLE, OR MAYBE TOO MUCH?

Keywords: Imaging, Vasculitis

M. Di Cicco[1], O. M. Epis[1], E. Verduci[1], C. Casu[1], G. Segatto[1], F. Filippini[2], C. Rossetti[1], D. A. Filippini[1]. [1]*Niguarda Hospital, Rheumatology, Milan, Italy*; [2]*Politecnico di Milano, Mathematical Engineering, Milan, Italy*

Background: Large Vessel Vasculitis (LVV) are vasculitides affecting large arteries, including aorta and its major branches. LVV can cause systemic and vascular inflammation that could result in long term complications such as artery stenosis, aneurysm formation and artery dissection. LVV include giant cell arteritis (GCA) and Takayasu. CGA typycally affects people aged over 50 and involves superficial temporal arteries. Meanwhile its cranial manifestations are well recognized and can be easily diagnosed by vascular ultrasound, it has been appreciated that GCA can extend beyond the superficial cranial arteries in up to 80% of patients or even spare the temporale arteries, and ultrasound is of limited diagnostic value in these cases. The usefulness of [^{18}F]FDG PET/CT in supporting the diagnosis of LVV is well known, particularly in patients with less specific manifestations such as fever or unexplained weight loss. However, the role of [^{18}F]FDG PET/CT in monitoring the course of the disease and its complications is less well established.

Objectives: To investigate the findings of repeated [^{18}F]FDG PET/CT scan in a cohort of patients with LVV in clinical and biochemical remission.

Methods: We have evaluated 30 pts (female 67%, age 75±9) with a diagnosis of LVV based on clinical features and serological tests (T0). The diagnosis was also supported by a positive [^{18}F]FDG PET/CT scan (arterial uptake equal or superior to the liver at the aorta or at least one of its major branches). 16 patients (53%) had also GCA confirmed by positive ultrasound of the temporal arteries. All patients were started on Prednisolone (PRED) 1 mg/kg according to standard guidelines, and some were subsequently started on Tocilizumab (TCZ) due to either relapse on steroid tapering or contraindications to long term use of steroids. After at least 6 months of effective treatment and while on clinical and biological controlled disease (T1), patients were reassessed clinically and biochemically; 14 pts aldo had a repeated [^{18}F]FDG PET/CT scan. We have used a binary grading to score the second scan: 1. negative (improved compared to first study) or 2. positive (not improved compared to first study), where improvement has been defined as no uptake or uptake inferior to the liver in the same areas that were highly metabolically active at previous study, and no new sites of vascular uptake detected. Images have been assessed by a nuclear medicine doctor and reviewed by 2 rheumatologists with recognised experience in the field of vasculitides, with excellent interobserver agreement.

Results: Inflammatory markers significantly dropped between the 2 timepoints (ESR 48±28 vs 6±4 and CRP 5.9±5.4 vs 0.4±1.2, p=0.0004). Among the 14 patients that had a repeated scan, 9 (65%) showed a negative and 5 (35%) a still positive scan despite being in clinical and biochemical remission. The number of metabolically active sites was reduced with a statistically significant difference between the 2 groups (8±4 vs 3±3, p=0.02). Of the 5 pts that had a positive scan, only 1 (20%) had a positive ultrasound of the temporal arteries at the time of the diagnosis.

Conclusion: Our study revealed persistent vascular uptake on repeated [^{18}F] FDG PET/CT scan in over 1/3 of LVV patients with clinical and biological controlled disease. The significance of this residual uptake and its prognostic value is currently unknown. Therefore the routine use of [^{18}F]FDG PET/CT alone in monitoring disease activity and treatment response may be not appropriate and therapy should not be modified based on scan results only. Further research is needed in order to place the correct use of imaging in the long term monitoring of LVV.

AB0725 BARICITINIB FOR THE TREATMENT OF REFRACTORY VASCULAR BEHÇET'S DISEASE: A PILOT STUDY IN CHINA

Keywords: Targeted synthetic drugs, Vasculitis, Behcet's disease

Z. Wang[1], X. Wang[1], J. Liu[1], L. Zhang[1], W. Zheng[1]. [1]*Peking Union Medical College Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Major vessel involvement in Behçet's Disease (BD) profoundly affects morbidity and mortality. Monoclonal anti-TNF antibodies are recommended for severe and (or) refractory vascular BD (VBD) beyond glucocorticoids (GCs) and immunosuppressants (IS), while some patients are still struggling due to inadequate response and relative contraindications. Our group has previously reported the efficacy of JAK1/JAK3 inhibitor tofacitinib for treating VBD[1]. We hypothesized that the JAK1/JAK2 inhibitor baricitinib might be a potential therapeutic choice in VBD patients through a broader panel of cytokine inhibition.

Objectives: This is a single-center, one-arm, self-controlled, open-label pilot study aimed at evaluating the effectiveness and safety of the JAK1/JAK2 inhibitor baricitinib in BD patients with refractory vascular involvement.

Methods: We consecutively enrolled refractory VBD patients who received baricitinib treatment (2 mg/ day) at Peking Union Medical College Hospital between Mar 2020 and Jan 2022. Efficacy assessment mainly depends on the proportion of clinical remission after 3-month treatment. Other outcomes include disease activity, organ damage evaluation, GCs and IS-sparing effects, and side effects.

Results: A total of 17 patients (12 males) were included, with a mean age of 37.9 ± 11.9 years and a mean follow-up of 10.5±5.4 months (Table 1). Before enrollment, all patients had insufficient response or intolerance to conventional therapies and (or) biologics (five patients failed first-line anti-TNF mAb using infliximab/ adalimumab/golimumab, and two patients had second-line therapy with other anti-TNF mAb, but still responded inadequately). At the 3-month follow-up, 13 (76.5%) patients achieved a complete response and the proportion increased to 88.2% (15/17) at the last visit. Laboratory parameters ESR (13 (IQR 7–40.5) vs 8 (IQR 2–17.5) mm/h, p<0.01) and CRP (11.8 (IQR 2.5–18.5) vs 1.2 (IQR 0.6–5.2) mg/L, p<0.0001) decreased significantly 3 months after baricitinib use (Figure 1), as well as the Behçet's Disease Current Activity Form (BDCAF) score (1 (IQR 0–2) vs 0 (IQR 0–1), p<0.01) and Birmingham Vasculitis Activity Score (BVAS) (2 (IQR 0–4.5) vs 2 (IQR 0–2), p<0.01). The vasculitis damage index (VDI) and Behçet's Syndrome Overall Damage Index (BODI) remained stable (p>0.05). At the last visit, baricitinib showed a GCs-sparing effect (7.5 (IQR 5–11.3) vs 5 (IQR 3.1–10) mg/d, p<0.05), and 9 patients (52.9%) discontinued or maintained 5 mg or lower daily of GCs dosage. In addition, IS were reduced in number and dosage in 5 (29.4%) and 9 (52.9%) patients, respectively. During follow-up, baricitinib dosage was tapered to 1 mg/day or less in 6 cases (35.3%) with sustained remission. No serious adverse events were noted during the follow-up.

Conclusion: Our study suggests that baricitinib is well tolerated and effective in refractory BD patients with multi-vessel involvement. Further prospective controlled study is warranted to access the utility of bariticinib in VBD.

AB0726 C-REACTIVE PROTEIN GENE POLYMORPHISMS IN BIOPSY PROVEN GIANT CELL ARTERITIS IN NORTHERN ITALY

Keywords: Vasculitis

L. Boiardi[1], P. Macchioni[1], F. Muratore[2], E. Farnetti[3], D. Nicoli[3], C. Marvisi[2], E. Galli[4], S. Croci[5], C. Salvarani[2]. [1]*Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Rheumatology, Reggio Emilia, Italy*; [2]*University of Modena and Reggio Emilia, Rheumatology, Modena, Italy*; [3]*Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Molecular Pathology, Reggio Emilia, Italy*; [4]*University of Modena and Reggio Emilia, Rheumatology, Modena, Italy*; [5]*Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Clinical Immunology, Allergy and Advanced Biotechnologies Unit, Reggio Emilia, Italy*

Background: Previous studies have reported that four functional C-reactive protein (CRP) gene polymorphisms, namely rs1417938, rs1800947, rs1205, and rs3093059 variants, were associated with plasma CRP levels, but not with clinical manifestations of giant cell arteritis (GCA) (1)

Objectives: Aim of our study was to investigate potential associations between two other functional variants of CRP gene at position 3872G/A (rs2015) and 4741G>C (rs3093068) with susceptibility to biopsy-proven GCA, baseline clinical and laboratory findings, treatment, and disease outcomes.

Methods: 164 patients with biopsy-proven GCA, resident in Reggio Emilia area (Italy), and 198 healthy controls from the same geographic area were genotyped for 3872G/A (rs2015) and 4741G>C (rs3093068) CRP gene polymorphisms by molecular methods. Data collected for all cases included comprehensive information about clinical findings, laboratory tests, histological data, imaging, therapies, and flares. Long-term remission was defined as permanent discontinuation

of glucocorticoids without flares for at least 1 year. All patients were followed according to a standardized predefined follow-up and therapeutic protocol. At the end of the follow up period, we evaluated for each patient the number of flares, long term remission, the duration of steroid treatment and the cumulative glucocorticoid dose.

Results: Association analysis of 3872G>A polymorphism showed that allele A homozygosity was significantly more frequent in cases than in healthy controls (OR =2.32, 95% CI: 1.26-4.27, p=0.006). Association analysis of 4741G>C polymorphism showed that allele G carried by CG and GG genotypes was significantly lower in GCA patients than in controls (OR =0.35, 95% CI: 0.17-0.70, p=0.002).No significant associations were found between these 2 polymorphisms and baseline clinical manifestations. Patients homozigous for the allele A had a significantly lower frequency of CRP values >5 mg/dl at diagnosis compared to patients carrying GA or GG genotypes (44.5% vs 72.4%, p=0.018, OR 0.31, 95% CI: 0.11-0.85). Considering 4741G>C CRP gene polymorphism, patients carring G allele had at diagnosis significantly higher levels of CRP (13.2 + 5.5 vs 8.9 + 6.3 mg/dl, p=0.037) and ESR (105 + 30.6 vs 86.6 + 29.0 1st hour, p=0.040), and lower levels of Hb (10.3 + 1.2 vs 11.3 + 1.5 g/dl, p=0.044). At histological examination of temporal artery biopsy (TAB), patients homozigous for the allele A had significantly more frequent eosinophilic infiltration of the arterial wall (21.4% vs 6.0%, p=0.010, OR 4.28, 95% CI: 1.31-13.98) than patients carring allele G. Furthermore, patients carring the allele A had lower steroid treatment duration (52 + 56 vs 79 + 78 months, p=0.041), lower cumulative steroid dose (11146 + 7162 vs 18.520 + 19659 mg, p=0.017), higher frequency of steroid treatment withdrawal (61.5 % vs 39.6%, p=0.016) and of longterm remission (60.3 % vs 39.6%, p=0.024). Survival analyses demonstrated a significative differences for the duration of steroid treatment and the frequency of long term remission between the three AA, AG and GG genotypes (p=0.033 and p=0.031 respectively).

Conclusion: Single nucleotide polymorphisms of PCR gene at position 3872G/A (rs2015) and 4741G>C (rs3093068) have impact on susceptibility and outcomes of biopsy-proven GCA.

AB0727 A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PARALLEL GROUP STUDY TO EVALUATE THE EFFICACY OF METHOTREXATE AS REMISSION MAINTENANCE THERAPY AFTER REMISSION-INDUCTION THERAPY WITH TOCILIZUMAB AND GLUCOCORTICOIDS IN SUBJECTS WITH GIANT CELL ARTERITIS (METEORITICS TRIAL): STUDY PROTOCOL

Keywords: Disease-modifying drugs (DMARDs), Vasculitis, Clinical trials

L. Kreis[1], W. A. Schmidt[2], N. Venhoff[3], C. Dejaco[4], V. Schäfer[1]. [1]*University Hospital Bonn, Department of Internal Medicine III - Oncology, Hematology, Immunology and Rheumatology, Bonn, Germany*; [2]*Immanuel Krankenhaus Berlin, Medical Centre for Rheumatology Berlin-Buch, Berlin, Germany*; [3]*University of Freiburg, Faculty of Medicine, Department of Rheumatology and Clinical Immunology, Freiburg, Germany*; [4]*Medical University Graz, Graz, Rheumatology, Graz, Austria*

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis found in adults over 50 years of age and affects medium and large vessels. The standard treatment is glucocorticoids (GC). Because of the negative side effects of GC and the high prevalence of relapses GC should be combined with other immunosuppressive or immunomodulatory agents. Since the GIACTA Trial and other randomized controlled trials (RCT) assigned tocilizumab (TCZ) a GC-sparing effect, higher remission rates compared to placebo and the potency to maintain remission even without GC this biologic is a promising option to treat GCA. Due to the high costs of the TCZ treatment and the increased risk of infections, other treatment options are needed in the long term. An RCT published by Adler et al. showed that only 55% of patients remained in remission after discontinuation of intravenous TCZ therapy. It highlights the need for options to maintain remission after discontinuation of TCZ. The combination of methotrexate (MTX) and GC was also effective in reducing relapse rate and the cumulative GC doses in new or relapsing GCA.

Objectives: The primary objective of the study is to investigate whether MTX is useful for maintaining remission after remission-induction with TCZ and GC in patients with GCA. In addition, we evaluate patient and investigator reported outcomes, prevalence of aortitis, number of vasculitic vessels and change of intima-media-values during the study.

Methods: This monocentric, randomized, double-blind, placebo-controlled study estimates the efficacy of MTX through a treatment period of 12 months and a six-months follow-up. Patients who are in stable remission after treatment with GC and at least six months of treatment with TCZ for new-onset or relapsing giant cell arteritis are eligible for inclusion. Forty participants will be randomly assigned to the treatment arm (N=20) and the placebo arm (N=20). The treatment consists of 17.5 mg MTX subcutaneous weekly for 12 months as a monotherapy. In case of intolerance, elevated liver enzymes or low glomerular filtration rate a dose reduction is possible. In event of relapse an escape treatment with GC on a tapering regimen is added to the study medication. Assessments are conducted eight times during the treatment period and twice during the follow-up. An ultrasound examination takes place on every study visit to measure the intima-media-values of several arteries. Magnetic resonance imaging is performed on baseline, month 12 and 18 to detect aortitis. The primary endpoint is the time to first relapse during the 12 months therapy.

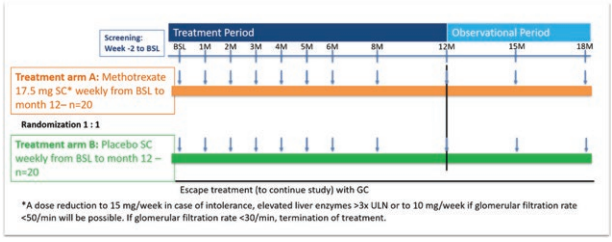

Figure 1. Study design

Arrows indicate study visits mg, milligram; SC, subcutaneous; BSL, baseline; M, month; GC, glucocorticoids; ULN, upper limit of normal.

Results: No results are available yet.

Conclusion: This is the first study that evaluate MTX as remission maintenance therapy after stable remission has been induced by GC and TCZ in GCA. MTX could be an effective, safe, inexpensive therapy agent after discontinuation of TCZ.

AB0728 AORTITIS SPECTRUM. STUDY OF 82 PATIENTS FROM A SINGLE REFERRAL CENTER

Keywords: Real-world evidence, Vasculitis

L. Sanchez-Bilbao[1], J. Loricera[1], C. Secada-Gómez[1], A. Martínez Gutiérrez[1], L. García-Alcalde[2], M. Nuñez-Sayar[2], A. Ucelay-Aristi[2], C. Álvarez-Reguera[1], A. Herrero-Morant[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, IDIVAL, Rheumatology, Santander, Spain*; [2]*Hospital Universitario Marqués de Valdecilla, Cadiovascular Surgery, Santander, Spain*

Background: Aortitis is the inflammation of the aortic wall, and can be idiopathic or associated with a cluster of infectious and non-infectious diseases. Giant-cell arteritis (GCA) and Takayasu arteritis (TA) are the most common underlying [1,2].

Objectives: To assess the causes and the main features of patients with aortitis.

Methods: Observational study of patients with aortitis from a large-vessel vasculitis monographic consultation at a referral hospital from June 2022 to December 2022. Aortitis was diagnosed by imaging techniques.

Results: We present 82 patients (52 female/ 30 male) (mean±SD age; 60.2±12.6 years). The different subtypes of aortitis were: GCA (n=69), Takayasu arteritis (n=6), other inflammatory autoimmune diseases (n=3), IgG4-related disease (IgG4-RD) (n=2), syphilis (n=1) and isolated aortitis

(n=1). The imaging techniques used for the diagnosis of aortitis were: PET/TAC (n=81), TAC (n=23), RMN (n=20) and arteriography (n=10). The main features of the patients are summarized in **Table 1**. Aortitis was most frequent in women. 50% patients had high blood pressure and dyslipidaemia. Polymyalgia rheumatica and asthenia were more frequent manifestations. The underlying diseases in the group of aortitis related to other inflammatory autoimmune diseases were: ulcerative colitis (n=1), idiopathic retroperitoneal fibrosis (n=1), and polyarteritis nodosa (n=1). The ascending thoracic aorta and the supraaortic trunks were the most frequently involved segments **(Figure 1)**.

Conclusion: Aortitis is an entity which can be isolated or secondary to infectious and non-infectious process. Among the non-infectious causes, GCA and TA are the most frequent, being common the presence of PmR and asthenia. The ascending thoracic aorta and the supraaortic trunks seems to be the most frequently involved segments.

EVALUATION OF DIFFERENT TREATMENT REGIMENS IN TAKAYASU'S ARTERITIS: A SINGLE CENTER STUDY

Keywords: bDMARD, Vasculitis, Disease-modifying drugs (DMARDs)

M. Codirenzi[1], L. Iorio[1], F. Davanzo[1], R. Padoan[1], A. Doria[1]. [1]*University of Padova, Division of Rheumatology, Department of medicine DIMED, Padova, Italy*

Background: Takayasu's arteritis (TAK) is a large-vessel vasculitis associated with high morbidity and mortality. Although new biological immunosuppressive drugs have been introduced in recent years, there is no strong evidence on which therapy is most effective to obtain a faster and lasting remission.

Objectives: The aim of the present study is to evaluate how different treatment approaches could provide better results in terms of disease activity, imaging improvement, glucocorticoids (GC) sparing and damage progression.

Methods: Inpatients and outpatients, classified as TAK, referred to our third level rare diseases center, were retrospectively assessed. We included all patients with complete clinical data and that underwent at least three consecutive visits. Patients were subdivided and compared according to five different treatment approaches: GC monotherapy, conventional disease modifying antirheumatic drugs (cDMARDs) monotherapy, anti-tumor necrosis factor (anti-TNF) monotherapy, combination therapy with cDMARDs+anti-TNF and Tocilizumab (TCZ). Demographic, clinical and laboratory data were collected. Imaging features (PET scan, magnetic resonance angiography, CT angiography, ultrasonography) were evaluated and registered. Clinical activity was assessed using the Indian Takayasu Clinical Activity Score (ITAS2010) (1) while damage according to the Large-Vessel Vasculitis Index of Damage (LVVID) [2].

Table 1. Demographic and clinical features, previous and concomitant treatment in refractory Behçet's uveitis patients treated with tocilizumab.

No	Sex/Age	Uveitis duration before TCZ (year)	Previous therapy	Indications	Concomitant medications	Number of attacks	VA (before TCZ)		VA (after TCZ)		Response to TCZ treatment
							R	L	R	L

3*	M/45	18	cs, aza, CsA, ifn, inx	induction	Anti-tuberculosis	0	1/10	1/10	1/10	2/10	remission
4¥	M/35	1	cs, aza, ada	Contraindication for TNF inhibitors	cs, mmf	0	10/10	10/10	10/10	10/10	remission
5	M/42	3	cs, aza, CsA, ifn, inx, mmf, ada	induction	cs	1	1/10	1/10	1/10	HM	active
6	M/42	4	colchicine, cs, aza, CsA, inx, anr, ifn, chlorambucil	induction	cs	5	5/10	HM	8/10	LP	active

cs: corticosteroids, aza: azathioprine, CsA: cyclosporine A, ifn: interferon alpha, inx: infliximab, ada: adalimumab, czp: certolizumab, tac: tacrolimus, mmf: mycophenolate mofetil, anr: anakinra, tcz: tocilizumab, VA: visual acuity, CF: counting fingers, m: meter, TD: terminal disease, HM: hand motion, LP: light perception, R: right, L: left*: The patient had pulmonary tuberculosis under infliximab treatment and was switched to tocilizumab. While uveitis was in remission, tocilizumab was discontinued due to the development of tuberculous lymphadenitis.¥: The patient had interstitial lung disease under infliximab treatment and was switched to tocilizumab.

Results: The study included 31 TAK patients (age 28 [21-48], 87% female) exposed to a total of 52 treatment regimens (n=4 GC monotherapy, n=17 cDMARDs, n=5 anti TNF, n=20 cDMARDs+antiTNF, n=6 TCZ). Overall clinical remission rate during the follow-up was 75% in GC treated patients, 70.6% in cDMARDs-treated, 100% in anti-TNF-treated, 80% in cDMARDs+anti-TNF-treated and 100% in TCZ-treated. Persistence of treatment was 19[8-30.75] months in GC group, 10[5.5-26.5] in cDMARDs group, 15[12-44] in anti-TNF group, 21[12.75-81.75] in cDMARDs+antiTNF group and 4 [17-64.5] in TCZ group. Treatment with cDMARDs+antiTNF and TCZ led to significant reduction of acute phase reactants (C-Reactive Protein: cDMARDs+antiTNF 31[9.1-93] vs2.9[0.4-16] mg/L, <0.001; TCZ 31.5[10.5-59]vs2.9[0.2-8.75] mg/L, 0.009) (Erythrocyte Sedimentation Rate: cDMARDs+antiTNF 43[14-84]vs17.5[10-25.75] mmh, 0.017; TCZ 15[5-55]vs5.5 [2-11.75]). Daily GC dose at last follow-up was 0 in cDMARDs+antiTNF group (25vs0 mg, p<0.001) and TCZ (11.25vs 0 mg, p<0.007). All the therapeutic regimens led to a significant reduction of disease activity at last follow-up (ITAS2010 in GC-treated 0 [0-1.5], in cDMARDs-treated 0 [0-1], in anti-TNF treated 0 [0-1], in cDMARDs+antiTNF 0 [0-0], in TCZ 0 [0-0]). LVVID did not significantly increase during follow-up in patients treated with cDMARDs, anti-TNF, cDMARDs+anti-TNF and in TCZ. Imaging data shown an improvement in metabolic activity at LFU in 33.3% of TCZ-treated patientsp and in 40% of cDMARDs+anti-TNF treated patients.

Conclusion: Anti-TNF, cDMARDs+anti-TNF and TCZ led to a statistically significant reduction in GC dosage, allowing steroid sparing. Compared to monotherapy, treatment regimens with cDMARDs+anti-TNF and TCZ could lead to a better disease control in terms of clinical activity and inflammatory markers and overall is the only therapeutic lines that provides an improvement in metabolic activity on imaging.

AB0730 TOCILIZUMAB TREATMENT IN SEVERE AND REFRACTORY BEHÇET'S SYNDROME: A CASE SERIES

Keywords: Behcet's disease, bDMARD

Z. Toker Dincer[1,2], B. Yurttas[1,2], S. N. Esatoglu[1,2], D. Ucar[2,3], U. Uygunoglu[2,4], S. Ugurlu[1,2], Y. Ozguler[1,2], E. Seyahi[1,2], M. Melikoglu[1,2], I. Fresko[1,2], V. Hamuryudan[1,2], A. Siva[4], G. Hatemi[1,2]. *[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; *[2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behcet Syndrome Research Center, Istanbul, Turkey*; *[3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophthalmology, Istanbul, Turkey*; *[4]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Neurology, Istanbul, Turkey*

Background: Tocilizumab may be an alternative for patients with Behçet's Syndrome (BS) refractory to conventional immunosuppressives and TNF inhibitors.

Objectives: We aimed to report our experience with tocilizumab in patients with BS.

Methods: We identified BS patients who were treated with tocilizumab for eye, nervous system and arterial involvement, and amyloidosis, using our hospital's electronic medical records. Demographic and clinical features, previous therapy, treatment response, outcomes, and adverse events were retrieved from patient charts.

Results: A total of 12 patients with BS (M/F: 9/3, mean age 44.4±10.3 years) were treated with tocilizumab for uveitis (n=6), parenchymal nervous system involvement (n=2), aortitis (n=2) and amyloidosis (n=2) between 2014-2022. Previous treatment modalities and treatment response for uveitis are shown in Table 1. Only 2 of the 6 patients with uveitis obtained remission with tocilizumab. Both patients with neurological involvement were refractory to tocilizumab treatment. They had previously used colchicine, steroids, azathioprine, interferon-alpha, infliximab, and adalimumab. Additionally, one had used cyclophosphamide and the other methotrexate and mycophenolate mofetil. One of the patients with amyloidosis was unresponsive and underwent kidney transplantation. The other had improvement in proteinuria, but she developed Crohn disease and infliximab was started. One patient with aortitis had used steroids, colchicine, azathioprine, cyclophosphamide, infliximab and the other had used steroids, colchicine, azathioprine, interferon-alpha and methotrexate. Both patients with aortitis obtained remission. One of them discontinued tocilizumab voluntarily, and the other due to dyslipidemia. Overall, tocilizumab was discontinued in 10/12 patients after 10.1±7.8 months. Adverse events were increased mucocutaneous lesions in one and dyslipidemia in another patient.

Conclusion: BS patients with aortitis benefitted from tocilizumab. However, our experience with tocilizumab in patients with eye and nervous system involvement was not as favorable as reported in previous case series. This may be partly due to the long disease duration before tocilizumab and the patient's 'being difficult-to-treat patients, refractory to several previous biologics including TNF inhibitors and interferon-alpha.

AB0731 CUTANEOUS AND ARTICULAR MANIFESTATIONS OF BEHÇET'S DISEASE

Keywords: Behcet's disease

Y. Abid[1], R. Amri[1], H. Tounsi[1], S. Wafa[1], I. Chaabane[1], Z. Alaya[1]. *[1]Regional Hospital Mohamed Taher Al Maamouri, Internal Medicine, Mrezga, Tunisia*

Background: Behçet's disease is a chronic inflammatory disease evolving by relapses whose etiopathogeny remains poorly elucidated. It is characterized by polymorphism and a clinical heterogeneity associating oral and genital aphthosis with systemic manifestations, notably cutaneous and articular.

Objectives: The aim of this study is to describe the epidemiological and clinical aspects of the articular and cutaneous-mucosal manifestations during Behçet's disease.

Methods: This was a monocentric, retrospective, and descriptive study. It was conducted over a period of 30 years and included all patients with Behcet's disease followed at the internal medicine department and meeting the international criteria for Behcet's disease.

Results: We collected 98 patients. A male predominance was observed (sex ratio of 2.5) with an average age of onset of the disease of 31 years. Familial forms were observed in 5.1%. Oral aphthosis was constant. The different localizations were on the inner side of the lip in 17 cases (68%), the inner side of the cheek in six cases (24%), the tongue in two cases (8%), and the gums in one case (4%). Genital aphthosis was found in 81 cases. Other manifestations were pseudofolliculitis (61 cases), erythema nodosum (7 cases), cutaneous aphthosis (4 cases), acneiform lesions (2 cases), cutaneous vasculitis (2 cases), and erythema multiforme (1 case). The pathergy test was performed in 30 cases. It was positive in 23 cases (76%). Joint involvement was present in 47 patients. The average age of diagnosis of joint involvement was 34 years. The mean time to diagnosis was 25 months. The involvement was peripheral in the majority of cases (95.7%), with the predominant site being the knees (67%). It was in the form of inflammatory arthralgias in 45 patients, associated with arthritis in 14 cases. Other manifestations were: low back pain (2 cases), sacroiliitis (1 case), bone erosion involving the hand (1 case), and popliteal cyst (1 case).

Conclusion: In Behçet's disease, the clinical manifestations are very polymorphic. Its polymorphic and non-specific clinical presentation can be a source of confusion with other pathologies. Cutaneous and articular manifestations are the most frequent.

Vasculitis - large vessel vasculitis

AB0732 OUTCOMES OF PERCUTANEOUS TRANSLUMINAL ANGIOPLASTY IN TAKAYASU ARTERITIS: A SINGLE CENTER EXPERIENCE

Keywords: Vasculitis

A. Cioltean[1,2], C. Pamfil[1,3], M. M. Tamas[1,3], L. Damian[3], S. Rednic[1,3]. [1]*'Iuliu Hatieganu' University of Medicine and Pharmacy, Rheumatology, Cluj-Napoca, Romania*; [2]*Emergency County Hospital, Rheumatology, Satu Mare, Romania*; [3]*Clinical Emergency County Hospital, Rheumatology, Cluj-Napoca, Romania*

Background: Revascularization endovascular techniques have been used with success in Takayasu arteritis (TA), but relapses sometimes appear. (1) There is much debate regarding optimal management and outcomes of patients who underwent these procedures. (2,3)
Objectives: The aim of the study was to investigate the long-term efficacy of percutaneous transluminal angioplasty (PTA) in patients with TA from a Romanian tertiary rheumatology center and factors that might influence it.
Methods: Data from clinical charts of patients with a diagnosis of TA established in the last 15 years who underwent interventional revascularization procedures were retrospectively studied. Symptoms, laboratory investigation results, data about treatment and outcome were analyzed at baseline and follow-up.
Results: There were 11 interventions of PTA in 6 patients with a diagnosis of TAK, all of them in women. The mean follow-up period was 59 months. Cardiologists were the ones who diagnosed the disease in 83% of the patients included. The mean delay in diagnosis was 74 months, while the biggest delay was of 242 months. Hypertension was the first sign of disease in 3 of the patients, while the rest complained of limb claudication (2 patients) and acute limb ischemia phenomenon (1 patient). The average disease duration until PTA was 65 months and most of them were done at the time of diagnosis (54%). PTA was performed while the disease was active in 100% of cases and biological inflammatory syndrome was present in 45% of cases. Symptoms relief was seen in all patients. Restenosis was seen in 3 cases – two of them in patients with lack of treatment adherence and one in a patient who wasn't given immunosuppression (due to delay in diagnosis). Restenosis was experienced 52 months after PTA, on average. Symptoms included relapse of limb claudication in 2 patients and hypertension and renal failure in a patient with renal artery restenosis. Inflammatory markers were raised in two cases. Clinical improvement was seen in all the patients after reintervention.
Conclusion: PTA is a valuable intervention in TA patients that significantly improves clinical symptoms. Relapses may appear especially in patients with deficient immunosuppression, and they may need revascularization interventions.

AB0733 CONCORDANCE BETWEEN THE 1990 ACR CLASSIFICATION CRITERIA AND THE NEW 2022 ACR/EULAR 2022 CRITERIA IN GIANT CELL ARTERITIS

Keywords: Diagnostic tests, Vasculitis, Epidemiology

J. Sanchez-Martin[1], J. Medina-Del Valle[2], J. Loricera[1], M. F. Garcia-Reija[2], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, IDIVAL, University of Cantabria, Santander, Spain, Rheumatology, Santander, Spain*; [2]*Hospital Universitario Marqués de Valdecilla, IDIVAL, University of Cantabria, Santander, Spain, Oral and Maxillofacial Surgery Service, Satander, Spain*

Background: Classification criteria for vasculitis, including giant cell arteritis (GCA) are under constant revision. In 2022, the American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) criteria were presented, renewing those published by ACR in 1990. They include wider range of clinical criteria and imaging tests, such as ultrasonography (US) and Positron emission tomography (PET), which has contributed to the diagnosis of a higher number of cases.
Objectives: To assess the concordance between recent 2022 ACR/EULAR giant cell arteritis classification criteria and the criteria of ACR 1990 [1,2].
Methods: Observational study of patients diagnosed with GCA who underwent temporal artery biopsy (TAB) between 2016 and 2022 in an university hospital. Concordance between both sets of criteria were analyzed with Cohen's kappa index.
Results: We present 191 patients (120 female/71 male) (mean±SD; 75±10 years). The main characteristics of the patients are shown in **Table 1**.
The Kappa index between both criteria weighted by prevalence and bias was 0.654 (moderate-high degree of agreement). Global agreement of 83% was observed, with a higher specific agreement for negative results (88%) than for positive results (67%).
Disagreement was observed in 16% of patients who were considered negative for ACR 1990 criteria but positive for ACR/EULAR 2022 criteria and in 2% who were considered positive for ACR 1990 criteria but negative for ACR/EULAR 2022. 2022 ACR/EULAR showed a higher sensitivity, and 27 additional patients were classified as GCA with these classification criteria.
Conclusion: Moderate-high concordance was found between 2022 ACR/EULAR and 1990 ACR classification criteria. However, the 2022 ACR/EULAR criteria consider a wider range of factors than the 1990 ACR criteria by introducing US and PET findings, thus increasing sensitivity and allowing a larger number of patients to be diagnosed. Cranial GCA was the most frequent phenotype observed.

AB0734 POLYPHARMACY AND COMORBIDITIES ARE NOT INCREASED AT DIAGNOSIS IN PATIENTS WITH POLYMYALGIA RHEUMATICA

Keywords: Malignancy, Comorbidities

M. A. Cimmino[1], E. Hysa[1], P. Clini[1], D. Camellino[2]. *[1]1Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, Genova, Italy; [2]3Division of Rheumatology, La Colletta Hospital, Azienda Sanitaria Locale 3, Arenzano, Italy*

Background: Polypharmacy, the prescription of multiple drugs for an individual patient, is increasing especially in ageing individuals with comorbidities. Polymyalgia rheumatica (PMR) is an inflammatory disease of the elderly causing pain and stiffness in the girdles. A recent systematic review showed that cardiovascular disease and lymphoproliferative disorders could be possibly increased in PMR patients, but the quality of the included studies was relatively poor. In addition, some comorbidities could be caused by PMR treatment and not by the disease itself.
Objectives: Our study is concerned with an evaluation of polypharmacy and comorbidities in PMR patients at diagnosis.
Methods: Patients were enrolled if they fulfilled the 2012 EULAR/ACR provisional criteria for PMR. Sex and age-matched controls were patients with hand OA diagnosed according to the 1990 ACR clinical criteria and seen in the same private outpatient clinic as patients. Both groups were interviewed at the time of diagnosis for the type and number of assumed drugs and comorbidities by the same investigator. The rheumatic diseases comorbidity index (RCDI) was used.
Results: 83 PMR patients (median 75 years, range 50-88 years, 65.1% women) and 83 controls (median 72 years, range 53-90 years, 65.1% women) were studied. Median disease duration was 2 months (0.3-8 months) and median glucocorticoid dose before assessment was 0 mg (0-750 mg). The mean number of drugs assumed by PMR patients was 2.5±2.1 in comparison with 3.0±2.2 of controls (p=0.129). PMR patients with hip pain assumed less drugs (2.1±1.8 vs. 3.7±2.3, p=0.008) and those with morning stiffness >45 minutes assumed more drugs (2.8±2.1 vs. 2.8±2.1, p=0.001). The mean RDCI was 1.58±1.29 in PMR patients and 1.45±1.36 in controls (p=0.52). The frequency of the individual comorbidities in PMR patients and controls is reported in Table 1. No difference was observed in cancer type. Number of assumed drugs and RDCI significantly correlated (r=0.58; p<0.001), and both were directly associated with age (p<0.001). At multiple logistic regression, with number of assumed drugs as dependent variable and variables which showed in univariate analysis p<0.1 as independent ones, age (p=0.007) directly, whereas hip pain (p=0.006) and fever (p=0.014) indirectly predicted number of assumed drugs. With RDCI as dependent variable, age (p=0.04) and WBC (p=0.02) directly, whereas fever (p=0.019) indirectly predicted RDCI.
Conclusion: When considered at the time of diagnosis, PMR patients do not show an increased comorbidity index nor number of assumed drugs in comparison with OA controls. Only gastric disease was lower, possibly due to the increased NSAIDs use in OA patients.

Table 1. Frequency of the individual comorbidities in PMR patients and controls (Co).

Comorbidity	PMR (n=83)	Co (n=83)	p
pneumological	11 (13.3)	9 (10.8)	0.63
CV/ictus	19 (22.9)	14 (16.9)	0.33
hypertension	45 (54.2)	39 (47)	0.35
fracture	8 (9.6)	7 (8.4)	0.79
depression	2 (2.4)	5 (6)	0.25
cancer	13 (15.7)	11 (13.3)	0.66
diabetes	7 (8.4)	5 (6)	0.55
gastric	6 (7.2)	15 (18.1)	0.036

AB0735 THE EFFECT OF NEW CLASSIFICATION CRITERIA ON THE DIAGNOSIS OF LARGE VESSEL VASCULITIS

Keywords: Vasculitis, Rare/orphan diseases, Epidemiology

C. Mukhtyar[1], C. Beadsmoore[2], F. Coath[1], G. Ducker[1], K. Sisson[3], R. Watts[4]. *[1]Norfolk and Norwich University Hospital NHS Foundation Trust, Rheumatology, Norwich, United Kingdom; [2]Norfolk and Norwich University Hospital NHS Foundation Trust, Radiology, Norwich, United Kingdom; [3]Norfolk and Norwich University Hospital NHS Foundation Trust, Pathology, Norwich, United Kingdom; [4]University of East Anglia, Norwich Medical School, Norwich, United Kingdom*

Background: GCA and Takayasu arteritis are the two recognised forms of LVV. In addition, there is recognition of LVV which are not easily classified into the two forms. Classification criteria have been proposed since 1990 and have been recently updated. Classification criteria should be able to minimise the number of cases that are unclassifiable and the number of cases that are classified into more than one set. We used both sets of criteria to test their performance in our cohort.
Objectives: To study the performance of large vessel vasculitis classification criteria in a real world cohort.
Methods: Between January 2011 to December 2020, 270 individuals were diagnosed as having LVV by virtue of having either a positive biopsy, ultrasonography, or PET scan. The ACR 1990 and the ACR/EULAR 2022 classification criteria were applied on our cohort.
Results: The mean age was 74. 181 were female. Using the 1990 criteria, 2 individuals met both classifications and 30 did not meet either. Using the 2022 criteria, 3 individuals met both classifications and 24 did not meet either. The numbers classified as having TAK has reduced from 13/270 to 2/270. The numbers classified as GCA have increased from 225/270 to 241/270. (Figure 1)
Conclusion: The new classification criteria have expanded the phenotype recognised as having GCA by including previously unclassified individuals, and narrowed the phenotype recognised as having Takayasu mostly by declassifying it as not meeting any criteria. Overall, the new criteria improve classification for 5/270 (1.8%) cases.

AB0736 EPIDEMIOLOGY OF CLINICALLY ISOLATED AORTITIS: A POPULATION-BASED STUDY

Keywords: Vasculitis, Epidemiology

M. Kaymakci[1], M. Elfishawi[1], H. Langenfeld[2], C. S. Crowson[2], W. Cornelia[1], M. Koster[1], K. J. Warrington[1]. [1]*Mayo Clinic, Division of Rheumatology, Department of Medicine, Rochester, United States of America*; [2]*Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America*

Background: Clinically isolated aortitis (CIA) refers to inflammation of the aorta without signs of systemic vasculitis or infection [1]. The diagnosis of CIA generally relies on histopathologic evaluation of aortic tissue obtained during thoracic aortic aneurysm surgery making the diagnosis more challenging. Recent studies suggest that CIA might be a limited presentation of giant cell arteritis [2]. Population-based data on the epidemiology of CIA in North America is lacking.
Objectives: The objectives of this study were to evaluate the epidemiology, clinical characteristics, and outcomes of patients with CIA.
Methods: In a defined geographical area, all possible subjects were screened for thoracic aortic aneurysm procedures with current procedural terminology (CPT) codes between January 1, 2000, and December 31, 2021. The medical records of all patients were manually reviewed. CIA was defined as histopathologically confirmed active aortitis diagnosed by evaluation of aortic tissue obtained during thoracic aortic aneurysm surgery in the absence of any infection, rheumatic disease, or systemic vasculitis. Incidence rates were age and sex adjusted to the 2020 United States total population. Mortality rates were estimated using the Kaplan-Meier method and were compared with expected mortality rates for persons of the same age, sex, and calendar year estimated using Minnesota population life tables.
Results: Eight incident cases of CIA were diagnosed during the study period (Figure 1); 6 (75%) of them were female. Median (IQR) age at diagnosis of CIA was 78.3 (70.2- 78.9) years; all were diagnosed following ascending aortic aneurysm repair. The overall age and sex adjusted annual incidence rate of CIA was 8.9 (95% CI, 2.7- 15.1) per 1,000,000 individuals over age 50 years. Histopathological evaluation demonstrated giant cell aortitis in 7 (88%) patients and lymphoplasmacytic aortitis in 1 (13%) patient. Five (63%) patients were seen by a rheumatologist and 2 (25%) were treated with glucocorticoids after the diagnosis of CIA. Most of the patients had cardiovascular signs and symptoms prior to the surgery. One patient presented with aortic dissection and contained rupture. The median (IQR) duration of follow-up was 8.7 (1.2- 12.0) years. Five (63%) patients died during follow-up; 1 (13%) within one week of surgery. The overall mortality compared to the age and sex matched general population did not differ (standardized mortality ratio: 1.58; 95% CI, 0.51 3.68).
Conclusion: This is the first population-based epidemiologic study of CIA in North America. CIA predominantly affects older women and is quite rare. In this small cohort, survival following a diagnosis of CIA was not significantly different than the general population.

AB0737 FAST TRACK PATHWAY: A GIANT STEP FOR THE DIAGNOSIS AND MANAGEMENT OF GIANT CELL ARTERITIS

Keywords: Vasculitis, Patient reported outcomes, Validation

Y. El Miedany[1], D. Affam[2], S. Rahman[2], M. Toth[3]. [1]*Canterbury Christ Church University Medway Campus - Medway Foundation Trust, Rheumatology, Gillingham, United Kingdom*; [2]*Darent Valley Hospital, General Medicine, Dartford, United Kingdom*; [3]*King's College London - Darent Valley Hospital, General Medicine, London, United Kingdom*

Background: Giant cell arteritis (GCA), a medium and large vessel vasculitis remains a formidable disease. Through feed-forward loops and a multitude of vascular complications, GCA impacts seriously negatively on both the patient's vision as well as life. In 2018, Darent Valley Hospital published its GCA management pathway [1] and launched a fast track GCA clinic in 2019. This included clinical assessment along with US examination in the rheumatology outpatients' clinic. The pathway enabled direct access to both general practitioners in primary care as well as health care professionals in secondary care to this service. Education sessions for both the primary and secondary care teams were carried out to inform them of the referral criteria and the service pathway.
Objectives: To evaluate the impact of implementing the GCA-fast track pathway on prompt diagnosis and treatment of GCA.
Methods: Retrospective cohort analysis of patients referred to the Fast Track GCA clinic. A cohort of patients with new suspected diagnosis of GCA along with acute flare ups of diagnosed GCA cases were referred to the clinic according to a set up referral criteria. All the patients referred to the clinic were offered an appointment within 24-hours and had blood tests for inflammatory markers and basic rheumatology blood profile done prior to their assessment. Diagnosis of GCA was made based on clinical examination, laboratory results and US assessment [2]. Presence of 'halo' sign, which is a non-compressible hypo-echoic ring around the artery lumen reflecting inflammation of the vessel wall was considered as a positive US finding. Steroid therapy was commenced on the same day of the diagnosis. If steroid infusion is indicated, the patient is referred to the AEC/ AMU to have the steroid infusion on the same day. Outcomes of management were assessed by GCA-patient reported outcomes as well as US assessment. The service was audited twice.
Results: During the evaluation period, 56 patients were referred to the Fast track GCA clinic. Age range 57-87 years old. 78.6% of these patients were females. 85.7% (48/56) of these patients were offered an appointment and assessed within one working day (24-hours), whereas the remaining 14.3% (8/56) were reviewed within 24-72 hours. All the patients (100%) had US examination of the temporal artery within the targeted time of maximum 72-hours from the referral date and less than 2-weeks of presenting with the temporal headache. Six patients were diagnosed as non-GCA, 5-patients migraine, 1-patient trigeminal neuralgia, 2-patients with large vessel vasculitis, 3-patients with PMR and 2-patients had flare of their previous PMR. 37-patients (66.1%) were diagnosed with GCA. No biopsies were performed. 9-patients (24.3%) required IV steroid infusion, whereas 28-patients (75.7%) started oral steroids. None of the patients included in the study suffered GCA related sight loss. No hospital admissions were required for these patients. There was significant improvement in the GCA patient reported outcomes in response to therapy, US measures as well as the inflammatory markers.
Conclusion: The developed Fast Track GCA clinic has significantly facilitated early and prompt diagnosis as well as management of GCA. Majority of the patients were reviewed within 24-hours with immediate initiation of steroid therapy. The fast-track referral pathway, combined with GP education, resulted in a significant reduction of incidences of permanent sight loss attributed to GCA (which would have resulted in loss of independence and mobility which subsequent increase health care use) and has proven to be a cost-effective practice as number of admitted patients was reduced.

AB0738

ELEVATED PLATELET COUNT IS A RISK FACTOR FOR REFRACTORY TAKAYASU ARTERITIS

Keywords: Biomarkers, Vasculitis

X. Shi[1], L. Pan[1]. [1]*Capital Medical University, Rheumatology, Beijing, China*

Background: Takayasu arteritis (TAK) is a chronic systemic vasculitis that mainly affects the aorta and its major branches. This chronic relapsing disease is relevant to significant morbidity and treatment remains challenging [1]. Early identification of refractory TAK is helpful to improve the long-term prognosis of the disease. In recent years, platelets have been recognized as important markers for various types of diseases [2]. Platelet counts may indicate the activity of autoimmune disease as well as responsiveness to anti-inflammatory therapy and presence of various comorbidities [3]. Multiple studies have demonstrated that platelet count of TAK patients was significantly increased, especially in the active phase, which was significantly higher than that in the inactive phase [4-8].
Objectives: Platelets have been recognized as important markers for various types of diseases. The aim of our study was to investigate whether platelet count could be the risk factor of refractory Takayasu arteritis (TAK).
Methods: In this retrospective study, 57 patients were divided into groups with or without refractory TAK. We compared the clinical manifestations, laboratory parameters, and medication between the two groups. The logistic regression analysis was used to identify the risk factors of refractory TAK.
Results: Among the 57 patients, 18 cases (31.6%) were considered to have refractory TAK within 1 year of initiation of medication in our hospital. Refractory TAK patients had higher level of platelet (PLT) than non-refractory TAK patients (305.5 vs. 272.0, 10^9/L, P=0.043). PLT was positively correlated with ESR (r=0.502, p < 0.001), hs-CRP (r=0.529, p < 0.001), IgA (r=0.322, p=0.016), IgG (r=0.419, p=0.001), IgM (r=0.343, p=0.010), C3 (r=0.554, p < 0.001). For PLT, the area under the ROC curve was 0.668 (95% CI 0.515 to 0.822, p=0.043) and the best cut-off value was 296.5×10^9/L. The level of PLT greater than 296.5×10^9/L was found to be statistically related to refractory TAK (OR [95%CI] 4.000 [1.233-12.974], p=0.021).
Conclusion: Clinicians should pay close attention to platelet levels in patients with TAK. For TAK patients with elevated platelet levels, earlier and more aggressive treatment is needed, and antiplatelet therapy is recommended as appropriate.

PERFORMANCE OF THE 2022 AMERICAN COLLEGE OF RHEUMATOLOGY/EULAR CLASSIFICATION CRITERIA FOR GIANT CELL ARTERITIS IN A COHORT OF PATIENTS WITH SUSPICION OF HAVING GIANT CELL ARTERITIS

Keywords: Vasculitis

A. Hemmig[1], M. Aschwanden[2], S. Imfeld[2], C. Berger[3,4], T. Daikeler[1,3].
[1]*University Hospital Basel, Department of Rheumatology, Basel, Switzerland*;
[2]*University Hospital Basel, Department of Angiology, Basel, Switzerland*;
[3]*University Hospital Basel, University Center for Immunology, Basel, Switzerland*; [4]*University of Basel, Department of Biomedicine, Basel, Switzerland*

Background: The new ACR/EULAR 2022 classification criteria for giant cell arteritis (GCA) use weighted items and incorporate findings from vessel imaging to reflect the current clinical standard. Although intended to define homogenous patient populations for research purposes when a diagnosis of medium- or large-vessel vasculitis has been made, the 2022 criteria were developed including non-vasculitis comparators. Hence, in the absence of a sensitive diagnostic gold standard, the criteria bear potential to be used for GCA diagnosis.
Objectives: To evaluate the performance of the new 2022 ACR/EULAR classification criteria for GCA when used for GCA diagnosis.
Methods: Retrospective analysis of a cohort of patients suspected of having GCA who underwent ultrasound between 12/2006 and 05/2021. GCA was diagnosed if temporal artery biopsy was positive, if the 1990 ACR criteria were fulfilled, or if at least 2/5 ACR criteria were fulfilled in combination with vasculitis on imaging.
Results: 276 patients were diagnosed with GCA, and 400 patients had a condition that mimics GCA. When applying the 2022 criteria as diagnostic criteria, sensitivity remained high with 87.3% (95% CI 82.8%–91.0%), whereas specificity was lower with 70.3% (95% CI 65.5% to 74.7%). In 35 patients (12.7%) with GCA, the criteria were not met (Table 1). These were mainly patients without cranial symptoms but having typical imaging findings in vascular territories not considered in the criteria. 119 non-GCA patients (29.8%) scored ≥6 points. Polymyalgia rheumatica (PMR) (31.9%) followed by non-vasculitic ophthalmologic diseases (15.1%) were the most frequent diagnoses among those.
Conclusion: The inclusion of polymyalgic symptoms and heavy weighting of sudden visual loss in the score led to false classification of patients with PMR and ophthalmologic diseases as GCA. For diagnostic purposes, the scoring of the criteria could potentially be adapted by applying a higher cut-off for the diagnosis of GCA or a lower weighting for polymyalgic and visual symptoms.

Fernandez-Sanchez[1], M. López I Gómez[6], A. Laiz[1], I. Castellví[1,3], H. Corominas[1,3]. *[1]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; *[2]Hospital de la Santa Creu i Sant Pau, Aortic Pathology Functional Unit, Barcelona, Spain*; *[3]Hospital de la Santa Creu i Sant Pau, Systemic Autoimmune Diseases Functional Unit, Barcelona, Spain*; *[4]Hospital de la Santa Creu i Sant Pau, Nuclear Medicine, Barcelona, Spain*; *[5]Hospital de la Santa Creu i Sant Pau, Cardiology, Barcelona, Spain*; *[6]Navarra Hospital Complex - Navarra Hospital, Rheumatology, Pamplona, Spain*

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis in individuals ≥ 50 years of age. It typically affects cranial vessels, but it can also affect large vessels in a high percentage of patients. Vascular inflammation of the aorta and/or its main branches can cause complications of high morbidity and mortality, and the presence of relapses is associated to more complications. The analysis of the different clinical and imaging patterns in patients with GCA and aortitis and their relationship with the prognosis needs more investigation. Early identification of patients with the highest risk of mortality could help predict deaths and vascular complications.
Objectives: To evaluate the demographic and clinical characteristics of patients with giant cell arteritis (GCA) who present a relapse.
To evaluate prognostic factors associated with GCA relapse.
Methods: A retrospective cohort study was carried out including patients diagnosed of GCA by a multidisciplinary expert committee in aortic pathologies. A total of 71 patients followed in the vasculitis clinic between 2011-2021 who had a PET-CT at onset before receiving treatment were included. Other causes of aortitis were excluded. Relapse was defined as a new episode of vasculitis confirmed by analysis and/or imaging test. Demographic, clinical, analytical and imaging variables were collected. A descriptive study of the sample and a groups comparison, according to the presence of vascular complication, was carried out. The Shapiro-Wilk test was used to study the normality of the variables. The relapse-free survival was analyzed using the Kaplan-Meier method. Univariate logistic regression was performed to assess predictive factors.
Results: A total of 71 patients were included, 73.2% were female and the mean age was 79.3 (±6.7) years. During the follow-up of the disease, 22 (30%) patients presented a relapse. Scalp tenderness (p<0.0001) and the complications prior to or at onset (aortic surgery [p=0.0003], ischemic stroke [p=0.0001], aneurysm/dissection/thrombosis [p=0.012]) presented a significant association with relapse. Cardiovascular risk factors and acute phase reactants were not associated with relapse during the disease, and either the diagnostic delay and start of treatment. Details of the demographic and clinical characteristics of the sample are described in Table 1.

Table 1. Characteristics of the sample according to the occurrence or not of relapse.

	Relapse (n=22)	No relapse (n=49)	p
GCA Classification (%)			0.375
- Cranial	18.2	18.3	
- Extracranial	13.6	28.5	
- Both	68.2	53.1	
Clinical presentation (%)			
Headache	22.7	35.4	0.433
Jaw claudication	63.6	66.6	0.804
Ophtalmological signs	72.7	68.7	0.736
Scalp tenderness	81.8	75	**<0.000**
Fever of unknown origin	72.7	72.9	0.987
Polymyalgia rheumatica	59.1	58.3	0.952
Anemia	72.7	58.3	0.247
Constitutional syndrome	63.6	77.1	0.240
Complications at onset (%)			
Aortic surgery	4.5	6.2	**0.000**
Ischemic stroke	9.1	4.1	**0.000**
Vascular complication	4.5	14.5	**0.012**
Treatment			
IV pulse GC mg/kg/d (%)	22.7	20.4	0.247
Oral GC, mean (SD)	48.6 (±16.4)	50.8 (±18.1)	0.631
sDMARD +/- bDMARD (%)	45.5	34.7	0.174

The relapse-free survival time in patients with GCA is shown in Figure 1. The median time (months) in relapse was 14-4 (IQR 36.1).

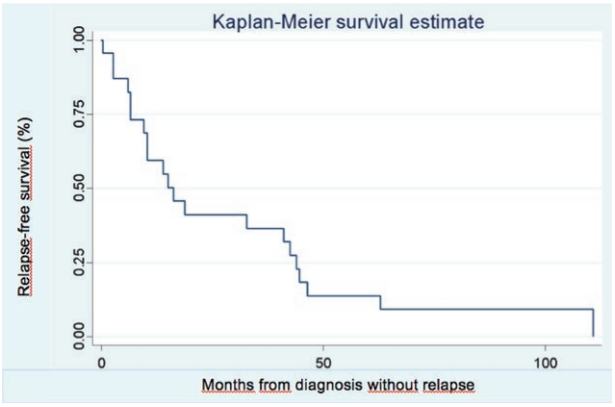

Figure 1. Kaplan-Meier curve of relapse-free survival in patients with GCA.

The univariate analysis to identify prognostic factors showed that the use of synthetic or biological disease-modifying anti-rheumathic drugs (sDMARD, bDMARD) was a protective factor against the occurrence of disease relapse, presenting a risk of relapse in untreated patients versus treated 64% higher (RR=0.64).
Conclusion: Disease relapse was observed in 30.9% of patients with GCA included in our study.
Scalp tenderness and the presence of vascular complications prior to or at onset of the disease were associated with greater occurrence of relapse. Our study suggests a possible protective effect of immunosuppressive drugs against relapse in GCA patients.

AB0741 CAN NORMAL ERYTHROCYTE SEDIMENTATION RATE AND C-REACTIVE PROTEIN LEVEL BE A REASON FOR DIAGNOSTIC DELAY IN POLYMYALGIA RHEUMATICA?

Keywords: Vasculitis, Diagnostic tests, Real-world evidence

M. Kara[1], G. Alp[2]. *[1]Republic of Turkey Ministry of Health University of Health Sciences Izmir Bozyaka Education and Research Hospital, Rheumatology, Izmir, Turkey*; *[2]Republic of Turkey Ministry of Health Izmir Katip Celebi University Izmir Atatürk Education and Research Hospital, Rheumatology, Izmir, Turkey*

Background: Polymyalgia Rheumatica (PMR) is an inflammatory disease which does not have specific diagnostic tests or pathological symptoms and is defined with clinical characteristics. Among the acute phase reactants (APR), erythrocyte sedimentation rate (ESR) and C-Reactive Protein (CRP) are laboratory findings used in the diagnosis and follow-up. Although abnormal ESR and CRP levels are included in the criteria for the classification of PMR, ESR and CRP can be observed as normal in 13% of PMR patients.
Objectives: In the study, it was aimed to determine the incidence of normal APR rates in patients diagnosed with PMR and to identify the distinguishing characteristics of these patients.
Methods: PMR patients who were clinically diagnosed at a single center were reviewed. After the presence of bursitis was demonstrated with ultrasonography (USG) in patients with normal ESR and CRP rates, they were accepted to have PMR. Patients with normal rates of ESR and CRP were compared against patients with high levels of ESR and/or CRP.
Results: In all 54 patients who were diagnosed with PMR (63% female, and mean age 65.39±7.39 years), >45 minute morning stiffness was present. Symptom duration median (IQR) was 3.5 (3) months, and ESR and CRP were found to be high in 72.2% and 83.3% of the patients, respectively. ESR and CRP were normal in 8 patients (14%), and serum amyloid A (SAA) was determined to be high in all these patients. At the time of the diagnosis, 51 patients (94%) had shoulder pain, and 41 patients (75%) suffered from hip pain. At the time of the diagnosis, median (IQR) ESR was found as 59.5 (49) mm/hour and CRP as 16.25 (38) mg/L. In 20 patients, SAA median (IQR) was 36 (26) U/L. The initial median (IQR) steroid dosage at the beginning of the treatment was prednisolone 20 mg/day. As steroid sparing therapy, methotrexate was started in 27 patients, and azathioprine was started in 4 patients. In the group with normal levels

of ESR and CRP, diagnosis median (IQR) ESR was 28 (4) mm/hour and CRP was 3.9 (1) mg/L, while in the group with high levels of ESR and CRP, diagnosis median (IQR) ESR was 76.5 (26) mm/hour, and CRP was 35.5 (60) mg/L. When the groups with normal and high levels of ESR and CRP were compared, it was found that diagnosis age was lower (p=0.027) in the normal ESR and CRP group, while the symptom duration was longer (p<0.001). When the patients were evaluated in terms of presence of at least one comorbidity, comorbidity was determined to be significantly lower in this group (p=0.01). Rheumatoid factor positivity, presence of anemia, and platelet count at the time of diagnosis and PMR exacerbation and giant cell arthritis development in the follow-up were similar. In the multiple regression analysis, when diagnosis age, symptom duration, and comorbidity were evaluated together, long symptom duration was independently associated with PMR with ESR and CRP normal levels (OR=0.045, %95 CI 0.03-0.676, p=0.025).

Table 1. Comparison between the characteristics of the patients with normal levels of ESR and CRP and those with high levels of ESR and CRP

	ESR and CRP Normal n:8	ESR and/or CRP High n:46	p
Diagnosis age, mean (±SD) (year)	61.8 (8.3)	68.57 (7.5)	***0.027***
Symptom duration, median (IQR) (month)	6 (1)	3 (1)	***<0.001***
Gender, female, n (%)	7 (87.5)	27 (58.7)	0.234
Anemia at the time of diagnosis, n (%)	3 (37.5)	23 (50)	0.706
Platelet count at the time of diagnosis, median (IQR)	315 (85)	288 (103)	0.495
SAA at the time of diagnosis, median (IQR)*	33 (34)	51.6 (94)	0.165
Rheumatoid factor, n (%)	1 (12.5)	2 (4.3)	0.388
Presence of at least one comorbidity, median (IQR)	3 (37.5)	39 (84.8)	***0.010***
Exacerbation of PMR, n (%)	0 (0)	15 (32.6)	0.089
Giant cell arthritis development, n (%)	0 (0)	3 (6.5)	1

**SAA was measured in 20 patients.*

Conclusion: Significantly younger age of diagnosis, longer symptom duration and less comorbidity were determined in the group with normal levels of ESR and CRP compared to the group with high levels of ESR and CRP. While bursitis can be demonstrated with USG in patients who are clinically evaluated to have PMR, APRs such as SAA other than ESR and CRP can also be used.

De Villa[5], C. Isasi Zaragoza[5], J. Campos Esteban[5], S. Gonzalo Pascua[6], J. L. Andréu Sánchez[5]. *[1]Hospital Universitario de Fuenlabrada, Rheumatology, Fuenlabrada, Spain*; *[2]Hospital Universitario Infanta Leonor, Rheumatology, Madrid, Spain*; *[3]Hospital Universitario Rey Juan Carlos, Rheumatology, Móstoles, Spain*; *[4]Ramón y Cajal Hospital, Rheumatology, Madrid, Spain*; *[5]Puerta de Hierro Majadahonda University Hospital, Rheumatology, Majadahonda, Spain*; *[6]Hospital Universitario de Fuenlabrada, Internal Medicine, Fuenlabrada, Spain*

Background: Polymyalgia rheumatica is a common inflammatory rheumatic disease affecting people older than 50. It is characterized by simmetrical pain and stiffness of the neck, shoulder, and pelvic girdle and associated with an increase in the concentration of positive acute phase reactants. The diagnosis is based on a clinical picture. Initial treatment consists of corticosteroids, and initial doses of 15 to 20 mg of prednisone or equivalent are usually adequate in most cases. The subgroup of patients that responds only partially to corticosteroids or develops corticosteroid resistance usually requires the introduction of a corticosteroid-sparing drug, methotrexate being the most widely used in routine clinical practice.

Objectives: To evaluate the efficacy and safety of methotrexate in patients with steroid-resistant polymyalgia rheumatica in real clinical practice.

Methods: Retrospective multicenter descriptive study of patients diagnosed with polymyalgia rheumatica in three hospitals in Madrid (Spain) treated with methotrexate as a corticosteroid-sparing agent. Clinical and demographic characteristics of the sample were analyzed and laboratory data evolution were evaluated by collecting positive acute phase reactants (ARF) (erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)) at baseline, at 6 and 12 months of treatment. Descriptive statistics were used for data presentation. The Wilcoxon test for paired data was used to contrast statistical significance, with a p<0.05 being considered significant.

Results: Overall, 58 patients were included: 26 men (44.83%) and 32 women (55.17%), with a mean age of 78.58 (±7.3) years, mean disease duration of 7.46. (±5.78) years. The mean values of CRP, ESR, dose of prednisone and MTX at baseline, at 6 and 12 months of treatment are shown in Table 1. In 52 (89.66%) patients it was possible to reduce the dose of prednisone to <5mg/24h after 12 months of treatment. No significant liver function abnormalities were observed in any of the patients.

Table 1.

	Baseline	6 months	12 months	Baseline vs 12 months p<0,05
Prednisone, mean ± SD	8,28(±4,2) mg/24h v.o	3,75(±2,8) mg/24h v.o.	2,11(± 2,63)	< 0.001
Metotrexato, mean ± SD	11,98(±3,92) mg/sem	13,19(±3,9) mg/sem	13,75(±4,23) mg/sem	0.008
PCR, mean ± SD	13,26 (±20,96) mg/dl	5,11 (±8,72) mg/dl	5,84(±7,02) mg/dl	0.124
VSG, mean ± SD	31,93(±22,4) mm	23,35(±23,07) mm	19,83(±21,6) mm	0.106

Conclusion: As a therapeutic option in steroid-resistant polymyalgia rheumatica, methotrexate seems to offer a steroid-sparing effect at 6 and 12 months of treatment. The treatment is well tolerated.

AB0743 THE IMPACT OF GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA ON FRAILTY, DAILY FUNCTIONING AND QUALITY OF LIFE IN A PROSPECTIVE LONGITUDINAL STANDARD-OF-CARE COHORT

Keywords: Patient reported outcomes, Disease-modifying drugs (DMARDs), Vasculitis

Y. Van Sleen[1], S. Arends[1], K. Van der Geest[1], M. Sandovici[1], E. Brouwer[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are often overlapping inflammatory diseases that occur in people older than 50 years. Both diseases can affect the quality of life, due to the burden of vascular inflammation and ischemia-related symptoms (GCA), joint symptoms (PMR) and systemic symptoms (GCA and PMR), in addition to the side-effects of long-term treatment with glucocorticoids.

Objectives: The goal of this study was to analyze patient reported outcome measures (PROMs), including the quality of life, in patients with GCA and PMR at the time of diagnosis and during 5 years of follow-up, in comparison with age- and sex-matched healthy controls (HCs).

Methods: We prospectively followed treatment-naïve GCA (n=56) and PMR (n=42) patients since diagnosis for up to five years in our observational GPS (GCA, PMR, SENEX) cohort. At each visit, frailty was assessed with the Groningen Frailty Indicator (GFI), daily functioning with the Health Assessment Questionnaire-Disability Index (HAQ-DI) and health-related quality of life with the Short Form (SF)-36. Data were compared to HCs (n=70) selected based on frequency matching of 10-year age cohorts stratified for gender, who were also followed for up to five years.

Results: At diagnosis, PROMs were substantially worse in GCA and PMR patients compared to HCs. GCA patients reported worse scores on the General Health domain than PMR patients, but better scores on the Physical Functioning domain, Pain domain and the HAQ. During the 5-year follow-up, we recorded a partial improvement in PROMs during the first year, which however never reached levels similar to that of HCs in most of the outcomes (Figure 1). Next, we aimed to identify the clinical factors that are most strongly associated with the

PROMs at diagnosis and during follow-up. We found that weight loss at diagnosis was associated with particularly low PROM scores, whereas inflammatory markers did not (PMR) or only moderately (GCA) associate with PROMs. Surprisingly, the physician general disease assessment (GDA) score showed no association with PROMs at diagnosis or at the 2-year visit. PROMs at the 2-year visit did correlate with the Fatigue score and patient GDA. Equivalent to the baseline visit, laboratory markers such as CRP correlated with PROMs in GCA, but not PMR patients. Finally, at the 2-year visit the use of glucocorticoids in GCA patients associated with worse PROMs, but in PMR patients with better scores on the SF-36. MTX use was associated with better PROMs, but only in GCA patients.
Conclusion: GCA and PMR patients experience both short-term and long-term impact on their frailty, daily functioning and quality of life. Medication use appears to be important in determining the patient's quality of life, although surprisingly, glucocorticoid and methotrexate use appear to affect GCA and PMR patients differently. Importantly, the physician GDA or inflammatory markers do not associate strongly with PROMs, particularly in PMR patients, indicating a need for better understanding of the disease and treatment impact on patient's life.

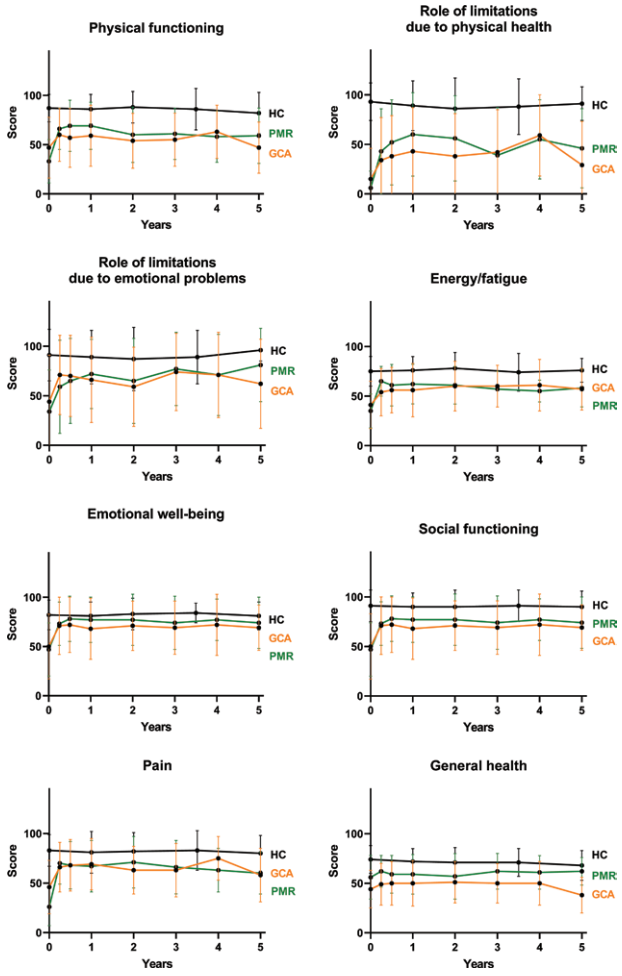

Figure 1. Scores of the eight domains of the SF-36 throughout the disease course in GCA and PMR patients.

Data, expressed as median and interquartile range, are compared to age and sex-matched HCs. Scores range from 0-100; a score of 100 indicates the most healthy outcome.

AB0744 HYPERTENSION AND AGE ARE RISK FACTORS FOR VISUAL IMPAIRMENT IN GIANT CELL ARTERITIS

Keywords: Vasculitis

F. Regola[1,2], J. Mora[1,2], F. Franceschini[1,2], P. Toniati[1]. [1]*ASST Spedali Civili of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy*; [2]*University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy*

Background: Permanent vision loss is a feared complication and a leading cause of morbidity in Giant Cell Arteritis (GCA). Prompt recognition of patients with visual manifestation is fundamental to reduce permanent vision loss occurrence.
Objectives: The study aims to evaluate risk factors for visual manifestations at disease onset in an Italian monocentric cohort of patients with Giant Cell Arteritis (GCA).
Methods: We identified 128 patients with GCA diagnosed between 2011 and 2021 in our Center. All patients were older than 50 years of age, met the 1990 ACR criteria for GCA or had a positive temporal artery biopsy or ultrasound. Medical records of all patients were reviewed and demographic, clinical, and laboratory data were collected.
Results: Fifty-five patients (43%) presented at diagnosis visual ischemic manifestations: blurred vision in 6 pts, diplopia in 6 pts, amaurosis fugax in 5 pts, partial visual loss in 23 pts and complete vision loss in 1 or 2 eyes in 12 and 3 pts respectively. Out of 38 patients with partial or complete visual loss, 36 presented Arteritic Anterior Ischemic Optic Neuropathy (AION), and 2 presented Central Retinal Artery Occlusion (CRAO). Patients with visual manifestations had a median age of 77 (IQR 73-81) years, significantly older if compared to patients without ocular symptoms (72 (67-76) years, p<0.001). Patients with ocular involvement presented more often hypertension (67 vs 44%, p: 0.009) and chronic kidney disease (7 vs 0%, p: 0.031) as comorbidity at diagnosis, while no differences were found in diabetes, cancer, coronary heart disease and dyslipidemia incidence comparing patients with and without visual manifestations. No associations between visual impairment and other cranial symptoms (headache, jaw claudication, scalp tenderness) were found, but peripheral arthritis was negatively associated with ocular manifestations. No laboratory variables were associated with ocular involvement.
Conclusion: In this large cohort of patients with GCA, partial or complete visual loss were the most frequent visual manifestations. No associations between ocular involvement and other cranial symptoms were found, while patients with peripheral arthritis had a lower risk of developing visual impairment. Age and hypertension at disease onset seem to be the most important risk factors for visual ischemic manifestations in GCA patients.

AB0745 [18F]-FDG PET/CT IN LARGE VESSEL VASCULITIS: SEMI-QUANTITATIVE [18F]-FDG PET/CT ANALYSIS AND CORRELATION WITH DISEASE ACTIVITY

Keywords: Vasculitis, Descriptive studies, Imaging

P. Fraticelli[1], G. Ghirelli[1], M. Pasquinelli[1], V. Maurizi[1], P. Pettinari[1], C. Cottignoli[2], F. M. Fringuelli[2], C. Romagnolo[2], N. Schicchi[3], L. Burroni[2], G. Moroncini[1]. [1]*Medical Clinic, Internal Medicine, Ancona, Italy*; [2]*Nuclear Medicine, Radiological Sciences, Ancona, Italy*; [3]*Radiology, Radiological Sciences, Ancona, Italy*

Background: [18F]-FDG PET/CT in a useful tool to assist diagnosis and therapy of large vessel vasculitis (LVV). Visual grading methods are commonly used in clinical practice, but these may lead to interpretation mistakes because of the confounding factors due to atherosclerosis and basal setting of the exam, reducing diagnostic accuracy for detecting active disease. Therefore, a semi-quantitative analysis based on normalization of the arterial wall uptake to the background activity or grading the arterial inflammation against a reference background, were introduced in the context of clinical studies in the last years.
Objectives: To review a series of [18F]-FDG PET/CT of LVV by applying a semi-quantitative analysis that included the standardized uptake value (SUV) and a target-to-background ratio (TBR) to evaluate possible correlations between FDG uptake, considering also a TBR cut-off, haematological inflammatory markers and the CT angiography (CTA) findings.

Methods: We reviewed our internal database for [18F]-FDG PET/CT among patients with LVV (GCA, Takayasu). Were selected [18F]-FDG PET/CT with available blood inflammatory markers and a CTA performed during the same period (permitted a range of 7 days for blood tests or 30 days for CTA), patients were all out of therapy or on stable therapy. As controls were taken ten patients undergoing PET/CT for oncologic diagnostics. The SUV maximum (SUV max) was considered that in the aortic arch or in the vascular region with higher levels of SUV. Target-to-background ratio was calculated considering average SUV in the right hepatic lobe (SUV max/SUV liver ratio). Non parametric test for correlation analysis were performed between SUV max, SUV max/SUV liver ratio and CRP (mg/dl). According previous data a cut-off of SUV max/SUV liver ratio >1.2 was considered and was then compared with CRP, for disease activity, and with CTA, to find agreement with vessel wall thickness and contrast enhancement.
Results: 33 [18F]-FDG PET/CT from 21 patients, 4 Takayasu and 17 GCA, 9M/12F, mean age 61,2 years were available for analysis, 13 out of them had at least one CTA to compare (total 21 CTA). SUV max and SUV max/SUV liver ratio in LVV resulted statistically higher than controls (Mann-Whitney test respectively U= 21, p = 0.00001 and U=76, p=0.027). Linear correlation between SUV max and CRP resulted highly significant (Spearman: r= 0,51 p = 0,006) but also correlation for SUX max/SUV liver ratio resulted significant (Spearman: r = 0,47, p = 0,011). Applying a cut-off for SUV max/SUV liver >1,2 we found a statistically significant agreement with CRP (Mann-Whitney U=43 p =0.0015). Less correlation was found when [18F]-FDG PET/CT SUV was compared with contrast enhancement and vessel wall thickening of CTAs, probably, because of the increased vessel thickness remains even in the inactive disease stages.
Conclusion: Although further studies are expected, semi-quantitative [18F]-FDG PET/CT scoring methods and simple cut off scores based on TBR analysis seems to correlate with disease activity and they could be used in the clinical practice, together with inflammation indices and other radiological imaging techniques, to offer a reliable and repeatable tool to help clinicians in managing LVV.

AB0746 CHANGES IN DIAGNOSING GIANT CELL ARTERITIS OF THE TEMPORAL ARTERY OVER A 7.7 YEAR PERIOD

Keywords: Vasculitis, Imaging, Clinical trials

M. H. Röchter[1], S. Thiesbrummel[2], H. Marchi[2], C. Fuchs[2], M. Rudwaleit3.
[1]Bielefeld University, Department of Internal Medicine and Rheumatology, Bielefeld, Germany; *[2]Bielefeld University, Faculty of Business Administration and Economics, Bielefeld, Germany*; *[1]Bielefeld University, Department of Internal Medicine and Rheumatology, Bielefeld, Germany*

Background: Temporal artery biopsy (TAB) was the diagnostic reference standard for decades in giant cell arteritis (GCA). Evidence-based EULAR recommendations regarding the use of imaging techniques in diagnosing GCA have been published in 2018 [1]. Accordingly, the use of colour Doppler ultrasonography (CDUS) should "complement the clinical criteria for diagnosing GCA, assuming high expertise and prompt availability of the imaging technique" [1]. However, sensitivity and specificity of CDUS showed substantial variation between studies (2), with the investigator's expertise assumed to be a major contributing factor [1].
Objectives: To study changes in the use of CDUS and TAB as diagnostic procedures for suspected GCA of the temporal artery over a period of 7.7 years in a single rheumatological centre.
Methods: Patients who presented to our rheumatological department between 10/2014 and 06/2022 were retrospectively identified either via a final diagnosis of GCA (ICD-10 codes M.31.4, M31.5, M31.6) or by the coded procedure of TAB (OPS 1-587.0 or 1-587.x). CDUS was performed by rheumatologists using GE Healthcare S5 machine from 2014 until spring 2016, and thereafter GE Healthcare LogiqE9 machine. A positive CDUS was defined by a non-compressible halo sign and hypoechogenic thickened vessel wall in any of the temporal arteries. We compared the frequency of use and results of CDUS and of TAB for confirming a clinical diagnosis of GCA of the temporal artery in three time periods of 2-3 years each (2014-2016, P1; 2017-2019, P2; 2020-2022, P3). Statistical significance of changes in relative frequencies was assessed via Fisher's exact test.
Results: Of 158 patients, we excluded 48 patients for the following reasons: diagnosis of aortitis or Takayasu vasculitis by other diagnostic means (n=16), final diagnosis other than GCA but undergoing TAB (n=24), already existing diagnosis of GCA with affection of the temporal artery prior to first presentation (n=7), and incomplete data sets (n=1). Of 110 GCA patients analysed, the mean age was 76.2 yrs (range 55 to 91 yrs), and 72 patients (65.5%) were female. All but one patient underwent CDUS (99.1%). Over the entire study period, the proportion of positive CDUS findings increased from 45.8% in P1 to 80.6% in P3. Conversely, the proportion of TAB evaluations decreased from 88% in P1 to 71.4% in P2 to 16.7 % in P3. In all three time periods, conducted TAB evaluations were largely positive: 77.3% in P1, 74.3% in P2, and 83.3% in P3 (Figure 1).

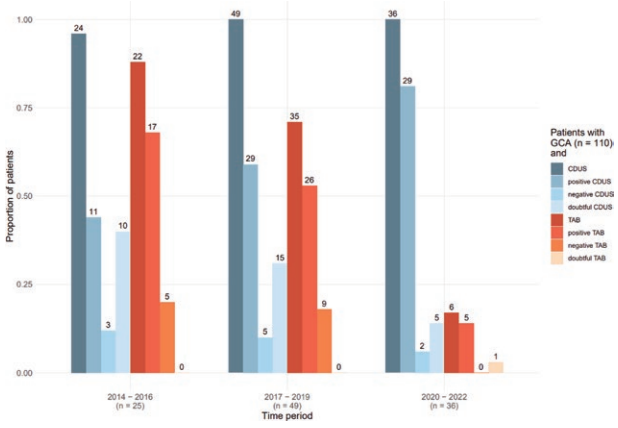

Figure 1.

In P3, 29 out of 36 (80.6%) GCA patients had a positive CDUS and were diagnosed based on CDUS alone, all of them without consecutive TAB. Only 6/36 patients (16.7%) underwent TAB: 5 patients received a positive TAB after doubtful CDUS, 1 patient received a doubtful TAB after negative CDUS. The proportion of patients who were diagnosed with GCA after positive CDUS and without TAB among all GCA-diagnosed patients that underwent CDUS of the temporal artery significantly increased when comparing P3 vs. P1 ($p<0.001$) and P3 vs. P2 ($p<0.001$), but not for P1 vs. P2 ($p=0.2$). Due to small sample size and involvement of several rheumatologists who gained experience in CDUS over the study period, an independent effect of exchanging the ultrasound machine could statistically not be assessed.
Conclusion: A significant change in using CDUS alone for diagnosing GCA of the temporal artery has taken place between 2014 and 2022, with substantial reduction of TAB evaluations especially after having obtained positive CDUS results. This change is likely due to increased expertise and confidence of the examiners (rheumatologists) in CDUS evaluations on appropriate ultrasound machines over time. Yet, data from the most recent time period indicate the ongoing need for TAB as an effective diagnostic tool in the few cases of inconclusive CDUS and high clinical suspicion of GCA.

Background: Isolated aortitis is considered a single organ vasculitis in the latest 2012 International Chapel Hill Consensus Conference revision. Despite being an increasingly diagnosed condition thanks to imaging tests, given the difficulty in completing the histological study, it is frequently unknown whether it is an isolated entity or a clinical manifestation of other vasculitis or rheumatologic entities.
Objectives: To describe the histological findings in samples of inflammatory aortic aneurysms and correlate them with their clinical presentation.
Methods: A descriptive cross-sectional study was performed. Aortic biopsies from elective aortic aneurysm surgery performed at a university hospital from 2019 to 2021 were reviewed. The samples with a non-infectious inflammatory pattern were selected. Cases of aortitis secondary to infection and/or atherosclerosis were excluded. The samples were reviewed again by a pathologist specialized in vascular wall disease and classified according to the 2015 consensus on surgical pathology of the aorta of the Society for Cardiovascular Pathology and the European Association of Cardiovascular Diseases in granulomatous pattern, lymphoplasmacytic pattern and mixed inflammatory pattern. Likewise, the pathologist, taking into account the previous classification and the findings, assigned a diagnostic orientation, only taking into account the histological findings. Demographic, clinical, laboratory data and the diagnostic orientation of the rheumatologist were collected.
Results: Of the 116 aortic tissue samples reviewed, inflammatory findings were observed in 10 (9%) of the biopsies. Characteristics of the patients whose biopsies were included are shown in Table 1. 80% of the samples came from the proximal aorta, 10% from the aortic arch, and the remaining 10% from the abdominal aorta. The mean diameter of the aneurysm was 61.7 ± 21 millimeters. The rheumatologist's clinical diagnosis for the patients included was: 1 patient with Giant Cell Arteritis, 1 patient with Takayasu's disease, 1 patient with Behçet's disease, 1 patient with HLA-B27-associated spondyloarthropathy, and 6 patients with idiopathic aortitis. Histologically, 8 patients presented a lymphoplasmacytic pattern, 1 patient a granulomatous pattern, and 1 patient a mixed inflammatory pattern. The diagnostic orientation of the pathologist coincided with the clinician in 9/10 of the cases. The most frequent final diagnosis was nonspecific isolated aortitis (7/10), followed by Giant Cell Arteritis (1/10), Takayasu's arteritis (1/10) and Behçet's disease (1/10). There is a concordance between the histological pattern and the diagnostic orientation of the pathologist with the diagnostic orientation of the clinician in 9 of the 10 cases.
Conclusion: There is a high concordance between histopathologic and clinical diagnosis in the patients included in this study. Despite this, there is a high prevalence of non-specific aortitis, yet to be identified. Non-granulomatous lymphoplasmacytic pattern is the most reported in our series of cases.

AB0748 **COGNITIVE FUNCTION IN POLYMYALGIA RHEUMATICA AND GIANT CELL ARTERITIS**

Keywords: Vasculitis, Cognitive Function, Patient reported outcomes

P. Harkins[1], S. Cowley[2], D. Kane[2], R. Conway[1]. [1]*St James Hospital, Rheumatology, Dublin, Ireland*; [2]*Tallaght University Hospital, Rheumatology, Dublin, Ireland*

Background: In the past decade our understanding of the prevalence, and indeed impact of cognitive impairment in rheumatic diseases has increased.[1, 2] An aging population, coupled with systemic inflammation have been postulated as key drivers of increased cognitive decline in these conditions. Intact cognitive function is imperative not only for quality of life and maintenance of one's functional capacity, but also for the successful therapeutic management of disease, namely the adherence to treatment regimens. Both giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) occur in those over 50 years of age, and are associated with a significant systemic inflammatory response. [3] To date, the prevalence of cognitive impairment in these conditions has not been studied.
Objectives: To explore the prevalence and possible predictors of cognitive impairment in those with PMR and/or GCA.
Methods: Participants from a multicentre longitudinal cohort study of PMR and/or GCA participated in a study visit that included an assessment of cognitive function. Cognitive function was evaluated using the Montreal Cognitive Assessment (MoCA) test which was conducted by trained interviewers. Demographics, clinical and laboratory data related to disease activity (PMR-Activity Score), neuropsychiatric symptoms (DASS-21) and patient reported outcomes (Visual analogue scale (VAS) and health assessment questionnaire (HAQ-DI)) were collected. Cognitive impairment was defined by the previously validated MoCA cut-off score of <26. A two tailed t-test, and independent chi squared test were used to analyse continuous and categorical variables respectively. A multivariable linear regression analysis was then performed.
Results: A total of 55 participants with a mean age of 70.5 (SD 7.61) were suitable for inclusion. 29 (52.7%) were female. 29 (52.7%) had isolated PMR, 8 (14.5%) had subclinical GCA with PMR, and 18 (32%) had isolated GCA. 34

(61.8%) participants were cognitively impaired, with executive skills, verbal fluency and abstraction the most affected domains. Advancing age demonstrated a statistically significant association with cognitive impairment (OR 1.12, 95% CI 1.016- 1.233, p<0.05). Notably, our analyses did not show a statistically significant association between cognitive performance and gender, BMI, functional limitation, VAS scores, neuropsychiatric symptoms, serum interleukin-6 levels or disease activity scores. Moreover, there was no statistically significant increased risk of cognitive impairment in those with GCA/ subclinical GCA versus those with isolated PMR.

Table 1. Results

Variable	Cognitively Impaired (n=34)	Normal Cognition (n=21)
Mean Age (+/- SD)	72.29 (7.66)	67.62(6.73)
Female (n)	19	10
Mean BMI (+/- SD)	28.5 (5.65)	27.83 (5.39)
Mean VAS (+/-SD)	1.26 (1.76)	1.33 (1.93)
Mean HAQ-DI score (+/- SD)	0.223 (0.455)	0.2281 (0.359)
Mean PMR- AS (+/- SD)	1.987 (2.91)	2.46 (2.81)
Mean C-reactive protein levels (mg/L) (+/- SD)	5.16 (6.93)	7.76 (7.98)
Mean Erythrocyte sedimentation rate (mm/h) (+/- SD)	14.18 (16.98)	21.05 (18.97)
Mean serum Interleukin-6 levels (pg/ml) (+/- SD)	57.6 (23.1)	16.8 (23.1)

Conclusion: The findings of our study show for the first time that the prevalence of cognitive impairment in those with PMR and/or GCA is significant. We highlight the need to address cognitive health in those with PMR and/or GCA, both in clinical settings and also future large scale research.

AB0749 FAST TRACK GIANT CELL ARTERITIS SERVICE IN A DISTRICT GENERAL HOSPITAL USING ULTRASOUND DOPPLER IMAGING

Keywords: Vasculitis, Ultrasound, Diagnostic tests

P. Kamperidis[1], A. Hall[1], R. Wickramarachchi[1], H. Perera[1], S. Panthakalam[1]. *[1]Eastbourne District General Hospital, Rheumatology, Eastbourne, United Kingdom*

Background: Giant Cell Arteritis (GCA) is the commonest large and medium artery vasculitis affecting patients aged 50 or above. It is a multisystem, inflammatory condition that can result in significant comorbidity, even mortality. Corticosteroids form the mainstay in remission induction and play a vital role in maintenance therapy. Complications can arise either due to delayed treatment, or unnecessary treatment of GCA mimics due to steroid side effects. This renders quick diagnosis a pivotal first step in its management. Temporal Artery Biopsy (TAB) has traditionally been the golden standard diagnostic modality, but it requires a surgical setting, resulting in delays. On the other hand, temporal artery Ultrasound Doppler Scan (USS) under an expert clinician has been incorporated by both BSR and EULAR in their recommendations. This offers a diagnostic tool with high specificity and sensitivity.

Objectives:

1. To set up a Fast Track GCA clinic and a referral pathway to allow timely diagnosis in an one-stop-shop outpatient (OPD) clinical setting with inhouse USS
2. To limit dependence of GCA diagnosis on TAB

Methods: We set up a weekly dedicated GCA OPD clinic at Eastbourne District General Hospital (EDGH) aiming to see patients within five days of referral. Upon review, patients were categorised to low, moderate or high GCA risk via a pretest probability score. Patients scoring high, moderate, or low but with diagnostic uncertainty, had temporal artery USS by an expert Rheumatologist on the day. We collected data on number of USS performed, scan outcomes, and TAB requests over a six-month period between May and December 2022.

Results: Total number of referred patients with suspected GCA was 50, 18 male and 32 female. Referral source was mainly via General Practice (GP) and Ophthalmology. Out of the 50 total, 49 had already been commenced on corticosteroids. All patients (100%) were seen within five days of the referral and had their pretest probability scores worked out in the clinic. Overall, 42 patients (84%) had USS and 6 (12%) were scanned within 72 hours of steroid commencement by the referrer. Eight patients (16%) were not scanned: six of them had very low probability score and were given alternative diagnoses without a diagnostic test; one was out of the window for diagnostics due to the timing of steroid commencement; one could not be scanned due to technical reasons, so a TAB was requested. Crucially, this was the only TAB requested during this period. GCA diagnosis was comfortably made for 21 out of the 42 patients scanned (50%). We ruled out GCA in the rest of the scanned patients (50%).

Conclusion: A pilot Fast Track clinic at EDGH facilitated prompt diagnosis of GCA with the use of USS. In a period of six months, we were able to confidently diagnose or rule out GCA in 100% of our scanned patients, without the need for a TAB. Such a set up enables prompt diagnosis of GCA and timely commencement of the appropriate steroid-weaning regimen, thus avoiding any future complications. Crucially, it allows the timely discontinuation of GP-commenced steroid therapy in patients with excluded GCA, thus minimising side effects of an unnecessary treatment. Typically, it takes more than three weeks to arrange a TAB. USS use also avoids an invasive procedure with potential for surgical complications. Additionally, from a Healthcare System point of view, there are certain cost-saving implications in using USS for GCA diagnosis. These range from reduced OPD clinic time and diminished demand for theatre slots and staff, to minimisation of future complications from timely commencement or discontinuation of steroid management. We also observed improved patient experience. This study confirms the integral role of USS in a Fast Track GCA Service.

AB0750 PREGNANCY DURING TAKAYASU VASCULITIS: ABOUT 24 PREGNANCIES

Keywords: Vasculitis, Pregnancy and reproduction

H. Khibri[1], F. Ibourk El Idrissi[1], A. Meghraoui[1], M. Obtel[2], C. Yasmina[1], N. Mouatassim[1], W. Ammouri[1], M. Maamar[1], H. Harmouche[1], M. Adnaoui[1], Z. Tazi Mezalek[1]. *[1]Souissi, Department of Internal Medicine-Clinical Hematology, Rabat, Morocco; [2]Faculty of Medicine And Pharmacy of Rabat, Clinical Epidemiology Service, Rabat, Morocco*

Background: TAKAYASU vasculitis is a vasculitis of the large trunks mainly affecting women of childbearing age. Pregnancy during TAKAYASU disease may be associated with maternal and/or materno-fetal complications as well as a flare-up of this vasculitis. Adequate management of TAKAYASU disease as well as regular monitoring of pregnancy is necessary.
in order to avoid these complications which can affect the maternal-fetal prognosis.

Methods: We conducted a descriptive, analytical and observational retrospective study, spanning 36 years (1984 -2020) at the internal medicine department of the UHC IBN SINA.102 patients are being followed up for Takayasu disease. We have listed the pregnancies carried out in patients during their follow-up for TAKAYASU disease.

Results: During their follow-up for TAKAYASU's disease;10 patients carried out 24 pregnancies. Their mean age was estimated at 31.78 ±12.2 years (16-51 years).2 patients had taking oral hormonal contraception. Hypertension is found in 5 patients at the time of diagnosis of TAKAYASU's disease. It was secondary to bilateral stenosis of the renal arteries in one patient. 53% pregnancies are carried to term without fetal complications in 5 patients with inactive TAKAYASU vasculitis during their pregnancies, 23% were complicated by fetal death in utero,15% termination of pregnancy (voluntary and therapeutic and spontaneous), and 12.5% growth retardation in utero. 3 (33%) patients presented with pre-eclampsia, and one (10%) patient presented with pregnancy-induced hypertension and another patient (10%)

had a hemorrhagic stroke. Only one premature delivery was performed in front of a fetal distress by caesarean section. The vaginal delivery was ensured in 45.83%, and the caesarean in 8.3%. Fetal extraction was performed vaginally for death feat in utero and pregnancy terminations. The pregnancy was responsible for a flare-up of TAKAYASU's vasculitis which went from an inactive status (NIH stage 1-2) to an active status (NIH stage 3-4) in 2/10 (20%) of the patients and was statistically linked to relapse with a significant p (p=0.009). TAKAYASU vasculitis type I was predominant (50%) followed by type V (30%).Statistical analysis showed a statistically significant link between pregnancy and carotid artery disease (P= 0.01). 8/10 patients (80%) were treated by corticosteroids and platelet aggregation inhibitor during 13/24 pregnancies (54.16%). Before the pregnancies, 7 patients had received immunosuppressive treatment such as methotrexate, cyclophosphamide in one patient and another was treated by adalumimab. Only 5 patients needed recourse to immunosuppressive therapy during their pregnancies (azathioprine). Statistical analyzes objectified a significant link between pregnancy and the use of azathioprine (p= 0.02). 4 patients received antihypertensive treatment; one patient had undergone vascular surgery for bilateral stenosis of the renal arteries.

Conclusion: TAKAYASU's vasculitis does not affect the fertility of patients with this disease. But a pregnancy carried out during the progressive form of this vasculitis can be responsible for serious maternal and fetal complications. Our study suggests links between pregnancy and relapse of TAKAYASU vasculitis, TAKAYASU's type I protective factor, and the interest of using azathioprine during pregnancies evolving on active TAKAYASU vasculitis.

We propose an internist-obstetrician collaboration in order to better manage this delicate medical situation on the maternal and fetal medical strategy.

AB0751 AXIAL SPONDYLOARTHRITIS IN PATIENTS WITH GASTROINTESTINAL INVOLVEMENT OF BEHÇET SYNDROME

Keywords: Gastrointestinal tract, Behcet's disease, Spondyloarthritis

M. Ozturk[1], S. N. Esatoglu[2,3], I. Hatemi[4], A. F. Celik[4], E. Yilmaz[5], D. Ucar[3,6], M. Melikoglu[2,3], H. Yazici[7], G. Hatemi[2,3]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey*; [2]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; [3]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behçet Syndrome Research Center, Istanbul, Turkey*; [4]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Gastroenterology, Istanbul, Turkey*; [5]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Tissue Typing Laboratory, Istanbul, Turkey*; [6]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophthalmology, Istanbul, Turkey*; [7]*Academic Hospital, Department of Rheumatology, Istanbul, Turkey*

Background: Despite attempts to lump Behçet syndrome (BS) with spondyloarthritides, controlled studies have shown that radiographic sacroiliitis is not increased in BS (BS). However, gastrointestinal involvement of Behçet syndrome (GIBS) shares common features with inflammatory bowel disease which, in turn, can be associated with spondyloarthritis.

Objectives: We wanted to test whether GIBS patients have an increased frequency of radiographic sacroiliitis or non-radiographic axial spondyloarthropathy (nr-AxSpA) compared to BS patients without major organ involvement who have only mucocutaneous and/or joint involvement.

Methods: We included 67 GIBS patients and 55 consecutive BS patients without major organ involvement. Patients were screened for axial spondyloarthritis (axSpA) using the Assessment of Spondyloarthritis International Society (ASAS) criteria. First they were questioned for chronic back pain, defined by ASAS as the presence of chronic back pain for more than 3 months with an age at onset of <45 years. Patients with chronic back pain were questioned for other spondyloarthritis features and underwent HLA-B27 testing, C-reactive protein testing, and X-ray and magnetic resonance imaging of the sacroiliac joints.

Results: Chronic back pain was reported by 24 (35%) GIBS patients and 16 (29%) BS patients without major organ involvement. Eight (12%) GIBS patients and 4 (7%) controls met ASAS criteria for axSpA (p=0.39). Four (6%) GIBS patients and 1 (2%) patient in the control group had radiographic axSpA (also termed ankylosing spondylitis), whereas 4 GIBS patients and 3 patients among the controls had nr-AxSpA. HLA B27 was positive in 2 (8%) of the GIBS patients and in 3 (19%) of the controls (p=0.33) (Table 1).

Conclusion: There was some, statistically insignificant increase in the frequency of axSpA among the GIBS patients. While the frequency of ankylosing spondylitis was consistent with previous studies, the frequency of axSpA according to the more recent ASAS criteria was found in 9.8% of the total group of BS patients. To the best of our knowledge ASAS criteria have not previously been tested in BS. They, perhaps need to be studied in a larger group of BS patients, including those with acne associated arthritis- previously shown to be associated with enthesitis (1) - together with healthy and diseased controls.

AB0752 REMAINING UNMET NEEDS FOR THE TREATMENT AND MANAGEMENT OF GIANT CELL ARTERITIS

Keywords: bDMARD, Vasculitis, Disease-modifying drugs (DMARDs)

E. Hettel[1], M. Yarnall[1], K. Murray[1]. [1]*Spherix Global Insights, Market Research, Exton, United States of America*

Background: Rheumatologists face significant challenges in the management of giant cell arteritis (GCA), with a limited armamentarium of treatment options. Physicians are largely dependent on the use of glucocorticoids, with tocilizumab being the only available advanced systemic agent for the treatment of giant cell arteritis.

Methods: An independent market analytics firm collaborated with 102 US rheumatologists to conduct an analysis of the GCA market. Data were collected via an online survey and supplemented with 8 qualitative interviews, all fielded June 16 through July 13, 2022. Research stimuli included physician demographics, patient management, use and perceptions of current treatments, as well as perceptions of potential new assets in development for GCA.

Results: The desire to minimize use of glucocorticoids is currently the greatest treatment challenge in the management of GCA. Although rheumatologists recognize the benefits of initiating newly diagnosed patients on glucocorticoids for the prevention of disease progression, including blindness caused by GCA, the negative side effects caused by long-term use gives physicians concern. While tocilizumab is used in patients with and without cerebral or ocular symptoms, most rheumatologists still rely heavily on the use of glucocorticoids, accounting for 89% of patient prescriptions in GCA, an aspect largely driven by a lack of availability for other advanced therapies. Of patients prescribed tocilizumab, 65% of patients were initiated on the drug in combination with glucocorticoids. Interviewed prescribers indicate difficulty in tapering glucocorticoids for patients on combination therapy, aiding in the desire for more steroid-sparing treatment options.

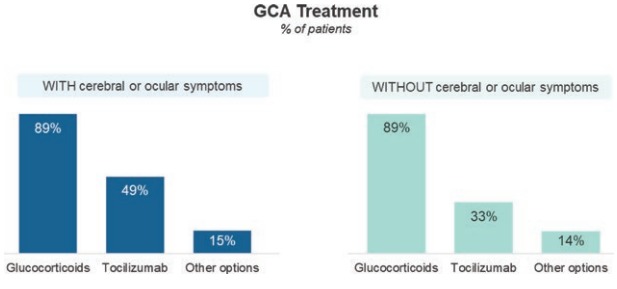

Figure 1.

Rheumatologists are excited to see new agents in development for GCA. Preference is highest for an IL-17A inhibitor, making secukinumab the leading drug of interest. Physicians also perceive secukinumab to be more of an advance over tocilizumab than upadacitinib or guselkumab.

Table 1. Product Profile Perceptions

	Considered an advance in treatment *% of respondents*	Strong level of interest *% of respondents*	% of GCA patients considered candidates
Secukinumab	52%	58%	29%
Guselkumab	42%	44%	26%
Upadacitinib	44%	41%	25%

Conclusion: With rheumatologists continuing to use tocilizumab in GCA, there is still a high need to reduce the use of steroids and for new mechanisms of actions to become available for this patient population. Physicians are eager to expand the current GCA armamentarium and anticipate these potential new agents to make have a positive impact on their management of GCA.

AB0753 EFFICACY AND SAFETY OF TOCILIZUMAB IN PATIENTS WITH VASCULITIS

Keywords: Systematic review, bDMARD, Vasculitis

J. Luo[1,2], Q. Y. Su[1,2,3], Q. LI[1,2], Y. Zhang[1,2], X. Y. LI[1,2], X. Zhang[1,2], Y. Ren[1,2], Q. Yu[4], P. F. He[4], X. LI[1,2,3], S. X. Zhang[1,2,3]. *[1]Shanxi Medical University, Academy of Microbial Ecology,Taiyuan, Shanxi, China*; *[2]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University,Taiyuan, China*; *[3]The Second Hospital of Shanxi Medical University, Department of Rheumatology,Taiyuan, Shanxi, China*; *[4]Ministry of Education, Shanxi Key Laboratory of Big Data for Clinical Decision Research,Taiyuan, China*

Background: Vasculitis is characterized by inflammation of blood vessels, leading to potential long-term sequelae, including vision loss, aneurysm formation, and kidney failure. Large vessel vasculitis encompasses Takayasu arteritis and giant cell arteritis, which cause inflammation of the aorta and its major branches. Tocilizumab, a humanized monoclonal antibody against the interleukin-6 receptor, has been associated with rapid induction and maintenance of remission in patients with vasculitis.

Objectives: This study aimed to systematically evaluate the efficacy and safety of tocilizumab therapy in vasculitis.

Methods: Eight databases (PubMed, Web of Science, Embase, Cochrane Library, Web of Knowledge, MEDLINE, Clinical Trials.gov, and FDA.gov) were searched for studies on tocilizumab treatment of vasculitis published from the date of establishment of the database to January 1, 2023. We used Stata 12.0 software to conduct a meta-analysis of the efficacy and safety of tocilizumab in patients with vasculitis using a random effect model.

Results: A total of 8 studies with a total of 823 patients were included. Either doses 162mg/week or 8mg/kg/4weeks, compared with placebo, tocilizumab significantly both promoted remission of vasculitis(RR=0.909, 95%CI: 0.768-1.075, P<0.001; RR=0.639, 95%CI: 0.410-0.994, P<0.042)(Figure 1A). No significant difference was observed in the probability of disease relapse in subgroup analysis based on different diseases(Figure 1B). In subgroup analysis based on dose, 8mg/kg/4 weeks doses significantly reduced the probability of disease relapse (RR=0.639, 95% CI: 0.410-0.994, P=0.047)(Figure 1C). The results of subgroup analysis about the rate of adverse events (AE) and serious adverse events (SAE) according to different diseases and different doses, our meta-analysis found that there was no statistical significance between tocilizumab and placebo(Figure 1E-H). It demonstrated the safety of tocilizumab therapy in vasculitis treatment.

Conclusion: Tocilizumab treatment was effective and well-tolerated in vasculitis patients.

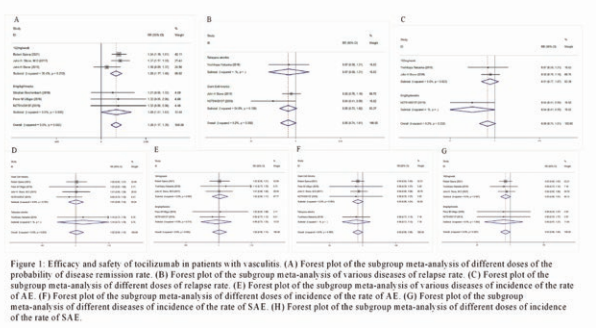

Figure 1. Efficacy and safety of tocilizumab in patients with vasculitis. (A) Forest plot of the subgroup meta-analysis of different doses of the probability of disease remission rate. (B) Forest plot of the subgroup meta-analysis of various diseases of relapse rate. (C) Forest plot of the subgroup meta-analysis of different doses of relapse rate. (E) Forest plot of the subgroup meta-analysis of various diseases of incidence of the rate of AE. (F) Forest plot of the subgroup meta-analysis of different doses of incidence of the rate of AE. (G) Forest plot of the subgroup meta-analysis of different diseases of incidence of the rate of SAE. (H) Forest plot of the subgroup meta-analysis of different doses of incidence of the rate of SAE.

AB0754 CLUSTER ANALYSIS OF ARTERIES INVOLVED IN TAKAYASU ARTERITIS

Keywords: Vasculitis

H. Liao[1], L. Pan[2]. *[1]Beijing Anzhen Hospital, Capital Medical University, Departments of Rheumatology and Immunology, Beijing, China*; *[2]Beijing Anzhen Hospital, Capital Medical University, Departments of Rheumatology and Immunology, Beijing, China*

Background: Takayasu's arteritis (TAK) is a chronic, large-vessel vasculitis that mostly affects young Asian women[1-4]. Vascular inflammation in TAK primarily invades the aorta and its major branches and often leads to arterial stenosis and aneurysms. At present, there is no relevant research report on how to identify the vascular lesions of organs in the early stage and the relationship between the affected vessels.

Objectives: To investigate the correlation of arterial involvement sites in Takayasu arteritis.

Methods: We retrospectively investigated data of 144 TAK patients. The clinical and image data of the patients were analyzed. We performed cluster analysis according to the affected artery.

Results: cluster analysis revealed five clusters of patients. In cluster one was named "abdominal aortic type". It was characterized by the involvement of arteries in the abdominal aorta, renal artery, coeliac trunk, superior mesenteric artery. In cluster two was named "cardio-cerebral arteries type". It was characterized by the involvement of arteries in the intracranial artery, coronary artery. In cluster three was named "thoracic aorta type". It was characterized by the involvement of arteries in the thoracic aorta and pulmonary artery was observed. In cluster four was named "vertebral artery type". It was characterized by the involvement of arteries in the left vertebral artery, right vertebral artery. In cluster five was named "carotid artery type". It was characterized by the involvement of arteries in the right common carotid artery, left common carotid artery, right subclavian artery, left subclavian artery, innominate artery.

Conclusion: Cluster analysis of the involved sites of Takayasu arteritis could be divided into 5 categories. It is abdominal aortic type, cardio-cerebral arteries type, thoracic aorta type, vertebral artery type and carotid artery type.

INVESTIGATING CYTOGLOBIN IN GIANT CELL ARTERITIS: ITS ROLE IN THE PATHOGENESIS AND POTENTIAL AS A BIOMARKER

Keywords: Diagnostic tests, Biomarkers, Vasculitis

L. Farrukh[1], M. Felix[2], A. Ibrahim[3], R. Peredo-Wende[4], D. Jourd'heuil[5], F. Jourd'heuil[5]. *[1]Albany Medical Center, Internal Medicine, Albany, United States of America*; *[2]Yale School of Medicine, Rheumatology, New Haven, United States of America*; *[3]Albany Medical Center, Pathology, Albany, United States of America*; *[4]Albany Stratton VA Medical Center, Rheumatology, Albany, United States of America*; *[5]Albany Medical College, Department of Molecular and Cellular Physiology, Albany, United States of America*

Background: Cytoglobin (CYBG) is a non-erythroid globin that is found in medial smooth muscle cells (SMCs) of human vessels. Recent studies have postulated that CYGB act as a pro-survival factor during conditions associated with increased oxidative stress, by upregulating anti-apoptotic factors and antioxidant pathways. In this study, we hypothesized that CYGB regulates the inflammatory and antioxidant response associated with GCA pathogenesis.
Objectives: The purpose of this study is to evaluate giant cell arteritis (GCA) vascular lesions for the expression of CYGB and its association with specific molecular markers of cellular damage. We would also like to investigate the association of CYGB with GCA pathogenesis, symptomatology, degree of systemic inflammation, patient demographics, and response to treatment.
Methods: We obtained 29 temporal artery biopsy samples, 14-biopsy positive and 15-biopsy negative, from patients who underwent temporal artery biopsy for GCA diagnosis **(Table 1)**. Inclusion criteria for the experimental group included patients over the age of 18 who had histologic evidence of GCA and met the ACR 1990 classification criteria. The control group included patients who were biopsy negative for GCA. Immunofluorescence staining for CYGB will be done on all samples to assess differential expression across the experimental and control groups. Proximity ligation assays (PLA) will be done to assess binding between cytoglobin and known pro-inflammatory markers to establish mechanistic insights for CYGB in the pathogenesis of GCA. We will also obtain clinical data including signs and symptoms at presentation, levels of serum inflammatory markers, treatment, clinical course, and outcomes.
Results: We are currently conducting validation studies of the immunofluorescence and PLA staining for specific molecular markers on temporal artery biopsy samples. Thus far, we were able to validate the immunofluorescence staining for CYGB **(Figure 1)** and the PLA for CYGB and HMGB2. Once we have established robust and reliable staining protocols for other markers, we will implement these protocols in our control and GCA groups and move forward with the analysis.
Conclusion: We previously demonstrated that overexpressing CYGB in human cardiac stem/progenitor cells (HCPCS) led to an increase in cell survival in response to oxidative stress. Whereas, silencing of CYGB in these cells, increased the rate of cell death. Similarly in rat and mouse models, it was found that CYGB contributes to vascular remodeling following injury, and the absence of CYGB led to accelerated cell death and inhibition of neointima formation. Based on these studies, we hypothesized that CYGB may play a role in the pathogenesis of different vasculitis including GCA. Once we develop this correlation, we will use this data to identify cellular and serum markers for the diagnosis of GCA. [1,2]

Table 1. Demographic and clinical features of patients who underwent temporal artery biopsy

DIAGNOSIS	GCA, 14	Non-GCA, 15
Sex (F/M)	11 F/3 M	9 F/6 M
Age (avg. years)	77.1	73.1
Ethnicity

Background: Although temporal artery biopsy (TAB) is the gold standard in the diagnosis of giant cell arteritis (GCA), the specific histopathological findings and their relationship with clinical diagnosis have not been well discussed. In recent 2022 ACR/EULAR GCA classification criteria, the presence of giant cells, predominantly mononuclear cell infiltration, and fragmentation in the internal elastic lamina have been defined for the interpretation of definitive vasculitis. [1]
Objectives: To re-evaluate TAB histopathological findings of patients with GCA recruited from 4 tertiary centres in Ankara according to the2022 ACR/EULAR Classification criteria and compare frequencies of these items with DCVAS study [2].
Methods: TAB reports of patients with GCA from 4 tertiary centres between March 2004 and February 2022 were retrospectively reviewed according to the histopathological items defined in the updated criteria. TAB reports were classified by the local physicians as normal, nondiagnostic, consistent with vasculitis but not definite, and definite vasculitis.
Results: Totally, TAB histopathologic reports of 88 patients with GCA were reviewed. The mean age of the patients at the time of TAB was 69.7(±8.5) years and 46(52.2%) were female. Twenty-eight reports without microscopic details were excluded and reports of 60 patients were reanalysed. Of the 60 patients,

46 (76.6%) met one of the defined histopathological findings of updated criteria (Figure 1). Histopathological findings of all patients with microscopic findings were detailed in the Table 1. 17(28.3%) patients had at least two histopathological findings.

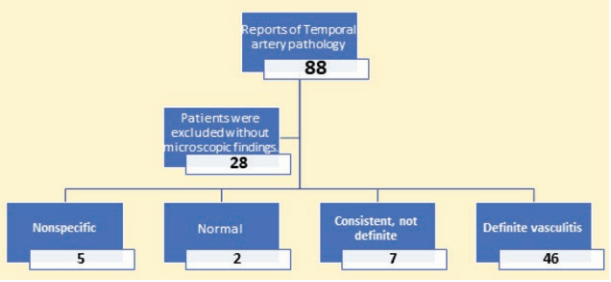

Figure 1.

Table 1. Specific histopathological findings of patients who underwent biopsy with a preliminary diagnosis of giant cell arteritis

Demographic and Histopathologic findings	DCVAS (n=705)	Our study (n=60)
Mean age,SD	73.5 ± (8.5)	69.7(±8.5)
Sex, female	**455(65)**	**46(52.2)**
Giant cells,n(%)	303(51)	18(30)
Internal elastic lamina fragmentation, n(%)	242(41)	22(36.6)
Mononuclear leukocytes (no definition of intimal/adventitial), n(%)	198193(32)	26(43.3)
Intimal thickening, n(%)	198(33)	21(35)
At least one of the defined histopathologic findings for definitive vasculitis *		46(76.6)
>=2 defined histopathologic findings for definitive vasculitis*		17(28.3%)
Vascular thrombosis, n(%)	26(4)	2(3.3)
Granuloma, n(%)	23(4)	1(1.6)
Perivascular inflammation only, n(%)	8(2)	-
Medial calcinosis, n(%)	NA	5(8.3)
Myxoid degeneration, n(%)	NA	6(10)
Adventitial mononuclear infiltration, n(%)	NA	3(5)

NA: Not applicable* defined histopathologic features are giant cells, predominantly mononuclear cell infiltration, and fragmentation in the internal elastic lamina for definitive vasculitis

Conclusion: Even giant cells were reported less in our study, updated histopathological definitions for GCA seem an excellent option to diagnose vasculitis definitively.

AB0757 TAKAYASU DISEASE: ABOUT 109 CASES

Keywords: Vasculitis

H. Khibri[1], F. Ibourk El Idrissi[1], A. Meghraoui[1], M. Obtel[2], C. Yasmina[1], N. Mouatassim[1], W. Ammouri[1], M. Maamar[1], H. Harmouche[1], M. Adnaoui[1], Z. Tazi Mezalek[1]. [1]*Souissi Rabat, Department of Internal Medicine-Clinical Hematology, Rabat, Morocco*; [2]*Faculty of Medicine And Pharmacy of Rabat, Clinical Epidemiology Service, Rabat, Morocco*

Background: TAKAYASU disease is an inflammatory vasculitis of the means and large caliber, which affects th aorta and its main branches, and which leads to the formation of arterial stenosis, thromboses and aneurysms. Touching preferably young women, it may be responsible for complications severe visceral events that may be life-threatening.

Methods: We conducted a 38-year, single-centric retrospective study (1984 and 2022) in patients followed for TAKAYASU vasculitis at the department of internal medicine and the department of vascular surgery of the Ibn Sina Hospital in Rabat. Statistical data were analyzed using SPSS 20. 0 software and KHI- DEUX analytical test.

Results: We collected 109 files. The sex ratio (F/M) was 7. 3 (96 women/ 13 men). 11. 92% of patients were male. The mean age was 34. 8 ±11. 9 (12 – 62 years). Patients who had juvenile takayasu diagnosed before 20 years of age were 11 (10%) and patients who had late-diagnosed takayasu to over 50 years of age were 14 (12. 88%). HTA was present in 44 (40. 7%) of patients at diagnosis, 11 (10. 1) of patients were taking oral contraceptives. Inflammatory syndrome was associated in 72 (66. 1%) with no statistically significant difference with a P=0. 6. Vascular symptomatology was present in 103 (95. 4%) of the cases o vascular murmur (66. 1%), pulse suppression (62. 4%), intermittent claudication (49. 5%) and ischemia (10. 1%). Extravascular symptoms were present in 47. 6% of the patients dominated by inflammatory arthralgia (18. 3%). Only one patient had asymptomatic TAKAYASU vasculitis discovered by chance during ultrasound examination for a thyroid nodule. Cardiac involvement occurred in 36 (33%) of patients and consisted mainly of valvulopathy (20. 2%) and cardiomyopathy (17. 4%). Central neurological involvement was present in 17 patients. (15. 6%) of patients with complicated HAI in 13 patients. Renal impairment was present in 35 patients (32. 11%). Ophthalmologic involvement in 26 (23. 9%) of patients was mainly represented by retinal vasculitis and optic nerve involvement. In addition, 10 patients had 24 pregnancies, 4 patients had preeclampsia, we recorded 9 abortions and half of our patients had full term pregnancies. The type of injury in our series was mainly stenosis and was found in 73 (67%) of cases. Occlusion was recovered in 21 (19. 3%) patients. Thrombosis was found in 26 (23. 9%) of patients and aneurysms in 19 (17. 4%) of patients. TAKAYASU vasculitis was Type I in 42 (38. 5%) patients, followed by Type V in 39 (35. 8%). Type IIa was present in 7 patients (6. 4%), type IIb in 4 patients (3. 7%), type III in 2 patients (1. 8%), and type IV in 14 patients (12. 8%). Most patients 104 (95. 4%) received corticosteroids and 77 (70. 6%) received immunosuppressive therapy including one on mycophenolate mofetil. 2 patients received anti-TNF therapy (adalimumab) and 1 patient received Tocilizumab. At the surgical level; 9 (8. 3%) of patients had angioplasty; A further 6 (8. 3%) underwent cardiac surgery (5 aortic valve replacement and closed-heart commissurotomy) and 15 (13. 8%) had vascular surgery. The outcome was favourable in the majority of patients. Late relapses > 6 months were reported in 25 (23. 1%) patients. There was only one death from global heart failure. We analyzed several associations such as vascular and cardiac disease, vascular and neurological disease. None returned significant with P ranging from 0. 3 to 1.

Conclusion: The results of our study are consistent with the literature and confirm the predominance of women and the stenosing nature of this vasculitis. Early diagnosis and management of the disease significantly improves the progression profile of the disease.

AB0758 TAKAYASU DISEASE IN JUVENILE FORM: ABOUT 11 CASES

Keywords: Vasculitis

F. Ibourk El Idrissi[1], H. Khibri[1], A. Meghraoui[1], M. Obtel[2], C. Yasmina[1], N. Mouatassim[1], W. Ammouri[1], M. Maamar[1], H. Harmouche[1], M. Adnaoui[1], Z. Tazi Mezalek[1]. [1]*Souissi, Department of Internal Medicine-Clinical Hematology, Rabat, Morocco*; [2]*Faculty of Medicine And Pharmacy of Rabat, Clinical Epidemiology Service, Rabat, Morocco*

Background: Takayasu disease is a non-specific inflammatory vasculitis of the large and medium caliber arteries occurring during the 2nd or 3rd decade. Attachment before the age of 20 is rare.

Methods: This is a retrospective descriptive study including patients with aged less than 20 years with Takayasu disease out of a series of 109 patients between 1984 and 2022 in a department of internal medicine and vascular surgery at the CHU INB SINA of Rabat.

Results: We identified 11 cases of patients under 20 years of age with a Takayasu disease with a sex ratio of 1 man to 2. 6 woman (8 women/ 3 men) The mean age of patients was 17 years ±2. 8 (12 - 20 years). (45. 5%) had hypertension at diagnosis, 10 patients (90. 9%) had symptomatology type of vascular murmur (54. 5. %), pulse suppression (63. 6%), lameness. intermittent (36. 4%), no ischemia (23. 1%) and one patient had extravascular: headache, fever, altered general condition... Inflammatory syndrome was present at diagnosis in 8 of our patients (72. 7%) Aortic involvement was found in 7 patients (63. 63%) predominantly due to abdominal aorta (6 patients). We identified 4 cases (36. 36. %) of arterial damage. 3 cases of cerebral arteries (27. 27%). The most common arterial disorders stenosis (72. 7%), thickening (54. 5%), thrombosis (9. 1%) and aneurysm (9. 1%). 6 patients (54. 54%) had heart disease as part of the study. Takayasu disease dominated by cardiomyopathies (4 cases), 2 cases of valvulopathy, and 1 only case of pericarditis. Associated in two cases with rhythm disturbances. 3 patients

(27. 28%) had stroke-type neurological disease, which accounted for 18. 75% of cases (16 cases/109 cases) in the global series and 3 patients had (27. 3%) two cases of blindness and one case of optic nerve damage. TAKAYASU vasculitis was type V in 5 patients (45. 5%), followed by type I in 4 patients (36. 4%). Type II and IV were present in 1 patient each; type I and IV have not been described in any of the patients. All patients received corticosteroid therapy, 9 patients (81. 8%) were initiated immunosuppressant and one patient received adalimumab, five of the patients received a. angioplasty and/ or one or more vascular surgeries, two complicated cases of restenosis. stunt artery and 1 complicated case of aorto-abdominal fistula. Four patients (45. 5%) had. had one or more relapses during their evolution. We also noted a case of tuberculosis meningoencephalitis associated with bilateral blindness in a 16-year-old patient and. two concepts of coarctation of the non-dilated aorta in a 12-year-old patient and in a. 18-year-old patient.

Conclusion: Our study is consistent with the literature and illustrates the seriousness of the juvenile takayasu as the common combination with severe heart disease, neurological and ophthalmological.

AB0759 CAN GLUCOCORTICOIDS WITHDRAWAL REPRESENT A CHALLENGE IN BEHÇET'S DISEASE? A CATEGORICAL DATA ANALYSIS IN A MONOCENTRIC COHORT

Keywords: Behcet's disease

F. Di Cianni[1], N. Italiano[1], D. Marinello[1], M. Mosca[1], R. Talarico[1]. [1]*University of Pisa, Rheumatology Unit, Pisa, Italy*

Background: When active manifestations occur in Behçet's disease (BD), systemic glucocorticoids (GCs) are essential to induce remission. Scarce evidence is available about how frequently GCs are used in the long-term as well as the reason of their withdrawal-failure.

Objectives: The aims of the study were: i) to characterize the profile of BD patients taking GCs at the last evaluation, including the reasons behind the withdrawal-failure and ii) to compare their profile with patients not taking GCs.

Methods: One-hundred patients regularly followed-up for at least 24 months were consecutively enrolled. Demographic, clinical and therapeutic data was collected, including GC assumption, daily dosage, and duration; patients were identified as GCs + or GCs -. A categorical data analysis was performed to explore the reasons of non-withdrawal in GCs+ group: recent BD relapse, inability to reduce current dosage for disease recurrence, and steroid addiction (meant as occurrence of manifestations non-BD-related).

Results: GCs+ group included 40 patients, while 60 patients were GCs- at the last evaluation. Both groups were mainly represented by females (75% GCs+, 62% GCs-). Overall mean age was 49 years and disease duration was most commonly 3–10 years. GCs+ group showed higher rates of colchicine and immunosuppressive therapy, while no significant differences were observed in terms of organ involvement. In the GCs+ group 32 patients (80%) assumed a daily prednisone equivalent dose ≤ 5 mg, because of recent relapse in 30% of cases, disease recurrence at tapering in 30% and steroid addiction in 40%. The mean cumulative GC duration in the last 2 years in GCs+ and GCs- patients was 17.3 and 1.8 months, respectively.

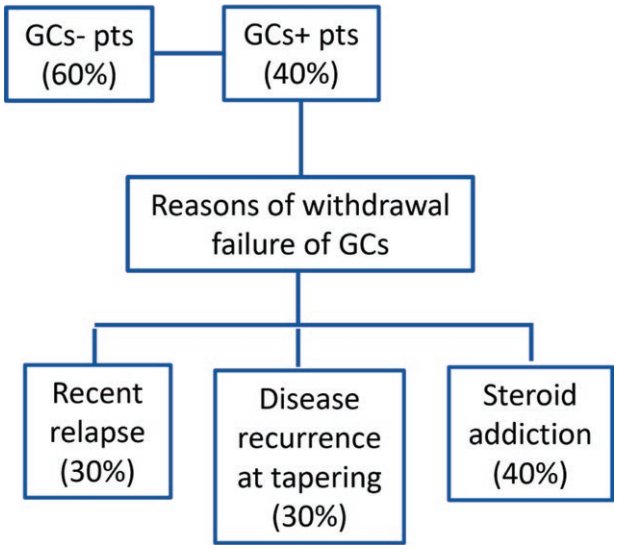

Figure 1.

Conclusion: Despite a similar control of disease activity, the main reason for GCs assumption seems to be represented by the occurrence of manifestations non-BD-related. Such acknowledgement highlights the need to improve the therapeutic approach in BD patients allowing stable steroid discontinuation, as well as stable disease remission.

AB0760 EVOLUTION OF PATIENTS WITH GIANT CELL ARTERITIS: BEFORE AND AFTER THE BIOLOGICAL ERA

Keywords: bDMARD, Vasculitis

P. Vela Casasempere[1,2,3], L. Tudela[1], R. Caño-Alameda[3], S. Gomez-Sabater[3]. [1]*Universidad Miguel Hernández (UMH), Medicina, San Juan de Alicante, Spain*; [2]*General University Hospital of Alicantet, Reumatologia, Alacant, Spain*; [3]*Instituto de Investigación Sanitaria y Biomédica de Alicante (ISABIAL), Grupo 16, Alicante, Spain*

Background: Giant cell arteritis (GCA) is the most common form of systemic vasculitis. The standard treatment to induce and maintain remission of GCA is based on the use of glucocorticoids (GC), often requiring high doses and for long periods of time. It has been associated with adverse events, sometimes severe, in up to 95% of cases (fractures, diabetes mellitus, hypertension, sepsis). In 2017, the first specific drug for this entity, tocilizumab (TCZ), an anti-IL-6 antibody, was approved. To date, there are few communications in clinical practice comparing the classical treatment scheme with the use of TCZ early.

Objectives: To compare patients treated with the standard regimen (corticosteroid monotherapy) versus those treated early with TCZ, in terms of the dose of corticosteroid received, use of immunosuppressants, and adverse events.

Methods: A retrospective observational study was carried out. Patients diagnosed with GCA in the Rheumatology section of the HGU Dr. Balmis during the period January 1, 2011, to November 1, 2021, were selected. Until 2017, patients received the standard regimen (corticosteroid monotherapy); from 2017, TCZ was associated early. Demographic data, treatment data (prednisone doses at months 1,3,6,12,18 and 24; use of immunosuppressants), and adverse events were collected. A descriptive analysis of the different variables was performed. The $\chi 2$ test or Fisher's exact test was used for the association between qualitative variables. For quantitative variables, mean comparison was performed using the t-student test.

Results: We obtained 73 patients (37% male and 63% female) with a mean age at diagnosis of 74.47 ± 8.4 years. All received initial corticosteroid treatment; 28 were also administered early TCZ (38.4%), the preferred route being subcutaneous (96.4%). The time between diagnosis and initiation of steroid treatment was a median of 0 days (median, IC 0-0), being 60 days for TCZ (IC 30-97). The use of immunosuppressants was higher in the glucocorticoid-only group than in the group treated with TCZ (57.8% vs. 21.4%, p=0.002). Prednisone dose was higher in the standard group at all follow-up time points (p<0.001). No differences were found in the occurrence of adverse events, except infections, which were more frequent in the standard treatment group (standard 28.9% vs TCZ 3.6%, p=0.008).

Conclusion: Tocilizumab allows a greater and faster reduction of corticosteroids, compared to standard corticosteroid monotherapy, lower use of other immunosuppressants, and is associated with a lower frequency of infections.

Background: inophilic granulomatosis with polyangiitis (EGPA), formerly called Churg-Strauss syndrome, is an ANCA-associated vasculitis which is mainly mediated by eosinophils. Mepolizumab (MPZ) is an anti-interleukin-5 monoclonal antibody that reduces the total number of eosinophils in peripheral blood and tissues, and its use has been approved in EGPA.
Objectives: To analyze the effectiveness and safety of MPZ in EGPA in a real life multicenter Spanish cohort.
Methods: We retrospectively analyzed the epidemiological data, comorbidities, clinical evolution and adverse effects of patients who have received MPZ in 13 Rheumatology Spanish services, through electronic medical records up to November 2022.
Results: A total of 27 patients with EGPA treated with MPZ have been analyzed. Median age at diagnosis was 53 years old, fifteen were men (55.6%), 21(77.8%) were Caucasian, 5 (18.5%) Arabic and 1 Hispanic. At diagnosis, 3 (11.1%) patients had arterial hypertension and 4 dyslipidemia (14.8%); ten patients were or had been smokers (37%). A total of 14 (51.8%) patients were ANCA positive. The Five Factor Score (FFS) was calculated just in 20 patients, and from them, 14 had a 0 result (70%) and 6 a 1 result (30%); the mean Birmingham Vasculitis Activity Score (BVAS) at diagnosis was 15. EULAR severity index was 0 in 2 patients (7.7%), 1 in 10 patients (38.5%), 2 in 9 (34.6%) and 3 in 5 patients (19.2%). Up to 23 patients (85.2%) had rhinosinusal symptoms and 19 (70.4%), had lung involvement of which 16 patients had interstitial lung disease. Sixteen (59.3%) patients had general symptoms 14 (51.9%) skin involvement and 11 (40.7%) peripheral nervous system involvement. Nine (33.3%) patients had musculoskeletal symptoms, 5 eye involvement and 5 cardiac involvement (18.5%). Regarding treatments, the mean starting dose of daily prednisone was 45 mg, 9 patients received intravenous methylprednisolone pulses (33.3%) and 16 (59.3%) required an immunosuppressant for induction, of which in 11 it was cyclophosphamide. The mean disease duration of the EGPA when MPZ was started was 51 months, and the mean follow-up during the treatment with MPZ was 16 months. The mean Birmingham Vasculitis Activity Score (BVAS) before MPZ was 9, after one month of MPZ, it dropped down to 5.4, and three months later to 4.6. The mean C reactive protein (CRP) before treatment with MPZ was 19.9 mg/L, and three months later, it was 3.3 mg/L. Before MPZ, the patients had a mean eosinophils number per microliter of 753, and after three months of treatment, it was 59 eos/µL. The mean Vasculitis Damage Index (VDI) before treatment with MPZ was 4.5 and after treatment with mepolizumab, it worsened only in 3 patients (11.1%). Twenty patients achieved a 50% clinical response according to global physician criteria (74.1%) and 12 achieved clinical remission (44.4%). The mean final prednisone dose was 2.5 mg/d. No patients had serious infections during treatment, one developed a neoplasm, and one of them withdrew MPZ due to musculoskeletal pain, switching to benralizumab (anti-IL5-receptor). Only one patient died from causes unrelated to the drug or the disease.
Conclusion: Our data about the use of MPZ in EGPA in real world practice suggest that is a quite effective and safe drug, allowing to save corticosteroids. Moreover, it seems to prevent the progression of the damage associated with the disease.

AB0762 **DIAGNOSTIC YIELD OF BIOPSIES IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS: A SINGLE CENTRE EXPERIENCE**

Keywords: Descriptive Studies, Diagnostic Tests, Vasculitis

R. Ríos-Garcés[1,2,3], J. Hernández-Rodríguez[2,3,4], S. Prieto-González[2,3,5], M. C. Cid[2,3,4], G. Espígol-Frigolé[2,3,4]. *[1]Hospital Clínic de Barcelona, Systemic Autoimmune Diseases, Barcelona, Spain*; *[2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Vasculitis Unit, Barcelona, Spain*; *[3]Universitat de Barcelona, Facultat de Medicina, Barcelona, Spain*; *[1]Hospital Clínic de Barcelona, Systemic Autoimmune Diseases, Barcelona, Spain*; *[5]Hospital Clínic de Barcelona, Internal Medicine, Barcelona, Spain*

Background: Recently published classification criteria for eosinophilic granulomatosis with polyangiitis (EGPA) [1] require, to be applied, a diagnosis of small- or medium-vessel vasculitis, without specifying how that diagnosis should be made. Histologically, EGPA is characterized by eosinophil-rich and necrotizing granulomatous inflammation together with necrotizing vasculitis, predominantly affecting small to medium vessels. Some of these features are not specific for EGPA and may be seen in other forms of ANCA associated vasculitis (AAV). Current guidelines on the management of AAV recommend biopsies to assist in establishing a new diagnosis and for further evaluation of patients with suspected relapse [2]. Therefore, biopsies are essential tools for the diagnosis, classification and management of these diseases.
Objectives: To describe the histopathological findings, diagnostic yield and the most common localizations of biopsies performed to assist in the diagnosis and follow-up of patients with EGPA.
Methods: Medical charts of patients with EGPA regularly followed at our department were reviewed to retrieve the number and localization of biopsies, as well as biopsy findings including proportion of a) eosinophil-rich extravascular inflammation, b) granulomas and/or c) necrotizing vasculitis. Biopsies were performed if patients presented symptoms in any given and most accessible localization (at diagnosis) or if they were necessary to confirm active disease (during follow-up).
Results: Among 59 EGPA patients regularly controlled at our department, a total of 163 biopsies were performed on 54 of them. In 44 patients (81.5%), 89 biopsies were performed at diagnosis and in 27 (50%), 74 biopsies were performed during follow-up. A total of 37 biopsies in 26 patients (48.1%) had proven vasculitis. A total of 7 biopsies in 5 patients (9.3%) had proven granuloma. A total of 87 biopsies in 42 patients (77.8%) had proven eosinophil-rich extravascular inflammation. The main localizations were: ear, nose and throat (ENT, 49 biopsies), respiratory (31), skin (25), gastrointestinal (GI, 18), muscular (14), nerve (12), bone marrow (8), renal (4) and temporal artery biopsy (TAB, 2). Among them, at least 1 typical histological feature detailed above was found in: ENT 38/49 biopsies (sensitivity of 77.6%), respiratory 15/31 (48.4%), skin 23/25 (92%), GI 10/18 (55.6%), muscular

4/14 (28.6%), nerve 5/12 (41.7%), bone marrow 6/8 (75%), renal 4/4 (100%) and TAB 1/2 (50%). A total of 57 biopsies performed in 29 patients (53.7%) showed none of the typical findings described above, although only 6 patients had all their biopsies without abnormal findings. These results are summarized in Table 1.

Conclusion: Multiple tissues are biopsied in clinical practice to assist in the diagnosis and evaluation of patients with EGPA, according to the multi-organ nature of this disease. Biopsies are more frequently obtained from accessible sites such as ENT or skin and usually dictated by clinical manifestations. In our cohort, the highest sensitivity was obtained from kidney, skin, ENT, bone marrow? and GI tract.

AB0763

CHARACTERISTICS OF RELAPSES IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS. A SINGLE CENTRE EXPERIENCE

Keywords: Descriptive Studies, Outcome measures, Vasculitis

R. Ríos-Garcés[1,2,3], J. Hernández-Rodríguez[1,2,3], S. Prieto-González[2,3,4], M. C. Cid[1,2,3], G. Espígol-Frigolé[1,2,3]. [1]*Hospital Clínic de Barcelona, Systemic Autoimmune Diseases, Barcelona, Spain*; [2]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Vasculitis Unit, Barcelona, Spain*; [3]*Universitat de Barcelona, Facultat de Medicina, Barcelona, Spain*; [4]*Hospital Clínic de Barcelona, Internal Medicine, Barcelona, Spain*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is a heterogeneous disease with a variable, relapsing course. Real-world data regarding specific characteristics of relapses in this patients are scarce.

Objectives: We aim to describe and analyse the relapses presented in a single-center cohort of EGPA patients.

Methods: Medical charts of EGPA patients regularly controlled at our department were reviewed to describe demographics, clinical characteristics at diagnosis and at relapse, number of relapses, disease activity at relapse, treatment of the relapses, damage accrual, and laboratory results. The definition of relapse was the same used in the MIRRA trial: a) active vasculitis (BVAS >0), b) active asthma or active nasal or paranasal sinus disease leading either to an increase in the dose of prednisone > 4mg/day, initiation of or increase in immunosuppressive therapy, or hospitalization [1].

Results: A total of 59 EGPA patients were followed regularly at our department. All fulfilled either ACR 1990 and/or MIRRA trial inclusion criteria for EGPA. The mean age at diagnosis was 51.6 years, 59.3% were female and 91.5% were Caucasian. Among them, 76.3% were ANCA positive and 23.7% were ANCA negative. The mean time of follow-up was 10.7 ± 8.2 years. During the follow-up, a total of 324 relapses were diagnosed in 47 patients, with 12 patients experiencing no relapse. A relapse-free survival analysis showed that 35% of patients had a relapse in the first year, 51% at 2 years, 59% at 3 years and 64% at 5 years. The main clinical symptoms at relapse were asthma (in 248 flares, 76.5% of them), followed by rhinitis (100, 30.9%), sinusitis (60, 18.5%), skin involvement (19, 5.9%), fever (18, 5.6%), arthralgia (16, 4.9%), lung infiltrates (15, 4.6%), myalgia (12, 3.7%), peripheral nervous system involvement (11, 3.4%), cardiac involvement (6, 1.9%), arthritis (3, 0.9%), weight loss (2, 0.6%), alveolar hemorrhage (2, 0.6%), gastrointestinal involvement (2, 0.6%) and central nervous system involvement (2, 0.6%). No renal involvement was seen at flare. Median BVAS at relapse was 2 (IQR 2-4, range 0-28). When determined, median blood eosinophils at relapse were 500 cells/mm^3 (IQR 100-1000) and in 73% of the measures eosinophils did not reach 10% of the total leucocyte count. Median CRP was 0.6 mg/dl (IQR 0.2-2.4) and median ESR 14 mm/h (IQR 8-32). ANCA were measured in 37 relapses only, being positive in 14 of them. The median prednisone dose at relapse was 6.25mg/day and the median increase for treating the relapse was 30 mg/day. In 53 relapses, patients were already taking azathioprine. In 47, mepolizumab. In 36, methotrexate. In 11, mofetil mycophenolate. When comparing patients who relapsed vs. those who did not, and those who relapsed less than 1 time every 2 years vs those who relapsed more than 1 time every 2 years, no predictive factor of relapse was seen.

Conclusion: After a mean follow-up of 10.7 years, 324 relapses were diagnosed in 59 patients. First relapse occurred in 35% of patients at 1 year and in 64% at 5 years. The clinical spectrum of relapses was predominantly asthma, followed by ear, nose and throat, being vasculitic manifestations much less frequent. No predictive factors of relapse were identified.

EVALUATION OF THE APPLICABILITY OF THE 2022 AMERICAN COLLEGE OF RHEUMATOLOGY-EUROPEAN ALLIANCE OF ASSOCIATIONS FOR RHEUMATOLOGY CLASSIFICATION CRITERIA FOR ANTINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS TO AN ASIAN POPULATION

Keywords: Organ damage, Vasculitis

R. Kuwata[1], Y. Shirota[2,3], T. Shirai[3], H. Yamashita[1], H. Sato[3], T. Takeda[2], Y. Oka[2], T. Kobayashi[1], K. Motomura[1], T. Kodera[2], H. Kaneko[1], J. Kameoka[2], H. Fujii[3], T. Ishii[3]. [1]*National Center for Global Health and Medicine, Division of Rheumatic Diseases, Tokyo, Japan*; [2]*Tohoku Medical and Pharmaceutical University, Division of Hematology and Rheumatology, Sendai, Japan*; [3]*Tohoku University Graduate School of Medicine, Department of Rheumatology, Sendai, Japan*

Background: The 2012 Chapel Hill Consensus Conference (CHCC) definitions and the 2007 European Medicines Agency (EMA) algorithm have been commonly used for the diagnosis of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) as a conventional and reliable method. Recently the 2022 American College of Rheumatology (ACR)-European Alliance of Associations for Rheumatology (EULAR) classification criteria for AAV have been released. It is well-known that patients with granulomatosis with polyangiitis (GPA) are predominantly proteinase 3 (PR3)-ANCA-positive in the U.S. and Europe, but myeloperoxidase (MPO)-ANCA-positive patients with GPA are more prevalent in Japan. However, very few studies have been available on the evaluation of the applicability of the new criteria to an Asian population.
Objectives: This study aimed to assess the applicability of the 2022 ACR/EULAR classification criteria to AAV patients from an Asian background.
Methods: This study included a total of 415 patients (mean age = 64.2 years, standard deviation [SD] = 16.3 years) diagnosed with AAV by the conventional method at three medical institutions in Japan between 2000 and 2022. Only Asians accounted for the whole population comprising 139, 128, and 148 patients (mean age = 65.2 years, SD = 15.7 years; mean age = 70.8 years, SD = 13.8 years; mean age = 56.1 years, SD = 15.8 years) diagnosed with eosinophilic granulomatosis with polyangiitis (EGPA), GPA, and microscopic polyangiitis (MPA) by the conventional method, respectively. The applicability of the new criteria to AAV patients in Japan was assessed through the verification of the consistency with the conventional diagnoses. Additionally, phenotypes of organ involvement were analyzed in each reclassified group from the conventionally-diagnosed GPA population.
Results: The patients diagnosed with EGPA and MPA by the conventional method were significantly more likely to be reclassified into the same AAV subphenotype (138 out of 139 patients [99.3%] and 145 out of 148 patients [98.0%], respectively). On the other hand, the patients diagnosed with GPA by the conventional method were less likely to be reclassified into the same AAV subphenotype (91 out of 128 patients [71.1%]). In the conventionally-diagnosed GPA population, 71 patients were reclassified as GPA, not as MPA, 20 were reclassified not only as GPA but also as MPA, and 36 were reclassified not as GPA but rather as MPA. In the group reclassified only as GPA, there were 59 patients with sinusitis, including ten patients with orbital mass lesions. In the group reclassified both as GPA and as MPA, there were 20 patients with severe organ involvement, including 15 patients with pauci-immune glomerulonephritis (PIGN).
Conclusion: The new criteria gave more weight to ANCA serology than histology and surrogate markers compared with the conventional method, which kept diagnostic consistency in the conventionally-diagnosed EGPA and MPA populations. At the same time, the new criteria occasionally led to a big diagnostic contradiction in the conventionally-diagnosed GPA population from an Asian background. In the conventionally-diagnosed GPA population, the new criteria were likely to reclassify MPO-ANCA-positive patients as MPA. However, it is noteworthy that the new criteria were still beneficial in extracting GPA patients with recurrent or severe organ involvement, including orbital masses and PIGN.

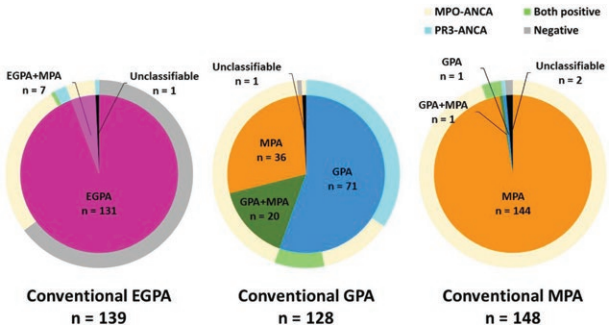

Figure. Reclassification of the conventionally-diagnosed AAV patients according to the 2022 ACR/EULAR classification criteria for AAV, including the distribution of ANCA serotypes. AAV, antineutrophil cytoplasmic antibody-associated vasculitis; ANCA, antineutrophil cytoplasmic antibody; MPO, myeloperoxidase; PR3, proteinase 3; EGPA, eosinophilic granulomatosis with polyangiitis; GPA, granulomatosis with polyangiitis; MPA, microscopic polyangiitis.

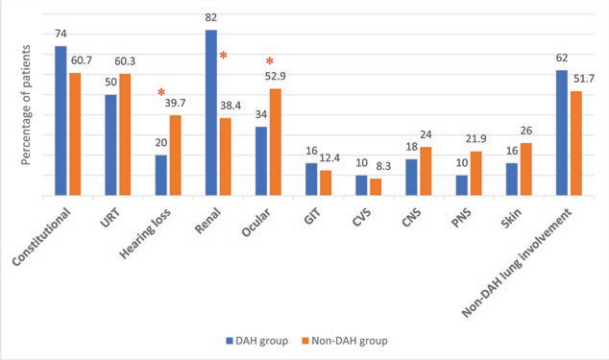
DIFFUSE ALVEOLAR HAEMORRHAGE IS ASSOCIATED WITH HIGH DISEASE ACTIVITY AND HIGH MORTALITY IN AAV PATIENTS: PROSPECTIVE OBSERVATIONAL STUDY

Keywords: Vasculitis



A. Sharma[1], G. Naidu[1], P. Deo[1], J. Samanta[1], R. Nada[2], K. Sharma[3], V. Dhir[1], R. Minz[4], S. Jain[1]. [1]*PGIMER, Chandigarh, India, Internal Medicine, Chandigarh, India*; [2]*PGIMER, Histopathology, Chandigarh, India*; [3]*PGIMER, Medical Microbiology, Chandigarh, India*; [4]*PGIMER, Immunopathology, Chandigarh, India*

Background: Diffuse alveolar haemorrhage (DAH) is a life-threatening emergency in patients with anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitides (AAV).
Objectives: To describe the clinical features and outcomes of AAV patients with DAH and compare them with non-DAH AAV patients.
Methods: Observational cohort study based on the prospective Indian Vasculitis Registry. 292 AAV patients were included in the study. DAH was diagnosed based on the clinical features and radiology findings. Fischer's exact test and Mann-Whitney U test were used for comparison. A p value of <0.05 was considered as significant.
Results: Fifty (17%) patients had DAH. Median age was 40.5 years and males constituted 54%. GPA, MPA and EGPA were the diagnoses in 39, 10 and 1 patients, respectively. Prevalence of DAH was higher in MPA (37.05%) than GPA (15.5%; p=0.0132). Haemoptysis was present in only 70% of patients while cough (76%) and breathlessness (62%) were the other respiratory symptoms. Six (12%) patients did not have any of these clinical features and were diagnosed with DAH based on radiology. DAH patients had more renal involvement (82% vs 38.4%; p<0.00001), less ocular involvement (34% vs 52.9%; p=0.0193) and hearing loss (20% vs 39.7%; p=0.0094) and higher BVASv3 score at presentation (21.6 vs 15.4; p=0.00026). Table 1 and Figure 1 shows the comparison of clinical features between the two groups. Remission induction agents used were glucocorticoids (100%), cyclophosphamide (62%) and rituximab (38%). PLEX was used in only 5 (10%) patients. Eleven (22%) patients died during follow up compared to 17 (7%) in patients without DAH (p=0.0028).
Conclusion: Presence of DAH in AAV patients was associated with high disease activity and higher mortality on follow up. Haemoptysis may be absent in a significant number of patients with DAH and hence, high index of suspicion is required to suspect and diagnose it early.

Table 1 : Clinical features of patients included in the study.

Clinical feature	DAH group (n=50)	Non-DAH group (n=242)	P value
Age	40.5 (17-80) years	44 (14-80) years	0.06876
Females	23 (46%)	146 (60.3%)	0.0828
Diagnosis			0.1143
GPA	39 (78%)	212 (87.6%)	
MPA	10 (20%)	17 (7%)	
EGPA	1 (2%)	13 (5.4%)	
Pulmonary symptoms			
Haemoptysis	35 (70%)	27 (11.2%)	<0.00001
Breathlessness	31 (62%)	41 (16.9%)	<0.00001
Cough	38 (76%)	81 (33.5%)	<0.00001
ANCA positivity	44 (88%)	189 (78.1%)	0.1253
PR3 ANCA	30 (68.2%)	153 (81%)	
MPO ANCA	14 (31.8%)	21 (11.1%)	
BVASv3 at presentation	21 (8-37)	13 (0-47)	0.00026
Induction therapy			-
Cyclophosphamide	31 (62%)	152 (62.8%)	1.0
Rituximab	19 (38%)	88 (36.4%)	0.8724
Plasma Exchange	5 (10%)	4 (1.7%)	0.0089
Others	1 (2%)	39 (16.1%)	0.0057
Deaths	11 (22%)	17 (7%)	0.0028

AB0766 STEP-DOWN TREATMENT WITH MEPOLIZUMAB FOR EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (EGPA). REAL-LIFE EXPERIENCE OF A SINGLE-CENTER COHORT

Keywords: Vasculitis

V. Batani[1], B. N. Germinario[2], M. Lanzillotta[1], A. Cariddi[1], L. Moroni[1], L. Dagna[1]. *[1]San Raffaele University Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases –, Milano, Italy*; *[2]San Raffaele University Hospital, Internal Medicine, Milano, Italy*

Background: Mepolizumab is an anti-interleukin-5 (IL-5) agent approved for EGPA at the dose of 300 mg every 4 weeks. However, from real-life studies, evidence is accruing of its comparable effectiveness at "asthma-dose" of 100 mg every 4 weeks. The preferred approach at our center is to start mepolizumab 300 mg/4 weeks and to reduce to 100 mg/4 weeks once remission is achieved (Birmingham Vasculitis Activity Score - BVAS=0), asthma is controlled (Asthma Control Test – ACT >20), eosinophil count is normalized and glucocorticoids are withdrawn (step-down approach).

Table 1

		STEP-UP STRATEGY		STEP DOWN STRATEGY	
		100 ->100	100 ->300	300 ->100	300 ->300

ACT: Asthma Control Test; BVAS: Birmingham Vasculitis Activity Score; EOS: eosinophils;EXAC: exacerbation; F-UP: follow-up; MEPO: mepolizumab; PDN: prednisone; PTS: patients; *:p < 0.05 for START vs END analysis, ** p<0.01 for START vs END analysis

Objectives: To assess the long term-efficacy of step-down treatment with mepolizumab in EGPA.
Methods: We reviewed medical charts of patients with EGPA treated with mepolizumab from April 2014 to December 2022. We divided patients by homogeneous dosing schedule and compared disease activity and characteristics at baseline and over time.
Results: We treated 38 patients for a median follow up of 38 months (IQR 29-53). Seven patients underwent a step-up approach (starting with mepolizumab 100 mg/4w and subsequent switching to mepolizumab 300 mg/4w in case of failure). Among them, only 1 patient (17%) needed a dose increase due to uncontrolled respiratory symptoms. Mepolizumab 300 mg/4w was started in 31 patients allowing a step-down in 9 (29%), without any patient having to increase the dose again. Both subgroups of the step-down strategy showed significant reduction in terms of BVAS, ACT, serum eosinophils and daily prednisone dose at last follow-up. At the same time presented a high proportion of nasal exacerbations (33 vs. 9% p=0.31). [Table 1]
Conclusion: In our experience, a step-down approach with mepolizumab in EGPA is reasonable and allows to safely reach the low-dose regimen in a great proportion of patients. Nasal polyps are the new challenge for physicians treating EGPA in an age where a steroid-free remission is an achievable target.

Background: Systemic vasculitis are rare autoimmune diseases that can lead to multiple organs and systems involvement. ANCA-associated vasculitis presents characteristics that differentiate them from other vasculitides. There is evidence that infection by (SARS-CoV-2) impacts differently in patients with various underlying diseases and different comorbidities, even generating differences in the morbidity and mortality of the viral infection.
Objectives: To describe the clinical characteristics and outcomes of SARS-CoV-2 infection in patients with systemic vasculitis.
Methods: Observational, multicenter, cross-sectional analytical study in patients 18 or older diagnosed with systemic vasculitis with confirmed SARS-CoV-2 infection (RT-PCR or serology) included in the SAR-COVID registry. Patients were evaluated from July 2020 to February 2022. Patients diagnosed with ANCA-associated vasculitis (AAV), other systemic vasculitides (Giant cell arteritis, Takayasu), and a control group of patients with other rheumatological diseases matched by age, sex, comorbidities, and date of SARS-CoV-2 infection. The survival curve of the groups was studied by Kaplan-Meier and compared through the Log-Rank Test. A Cox regression model will be performed to adjust survival for different variables (sex, age, treatments for underlying disease, treatments for viral infection, smoking, obesity, d-dimer level, and disease activity).
Results: A total of 282 out of 2694 patients in the SAR-COVID registry were included, 57.4% women with a mean age of 55.7 years (SD 14.1). Fifty-four patients in the AAV group, 32 in the other vasculitis group, and 196 controls were studied. In 51.1% of the cases, one or more comorbidities were observed. We found caucasian ethnicity at 50.7%, mestizo at 39.7%, and other ethnic groups at

9.6%. PCR made the diagnosis of COVID-19 in 81.2% of the cases. The controls had treatment with corticosteroids before the onset of symptoms in 30.1% of the cases, while 64.8% and 68.8% in the AAV group and other vasculitides, respectively ($p < 0.001$). Hospitalization was required in 53.7% of the AAV group, 37.5% in other vasculitides, and 26.2% in the control group. 5.6% of patients in the control group presented acute respiratory distress syndrome (ARDS), 15.6% in the other vasculitis group, and 22.2% in the AAV group ($p<0.001$), requiring invasive mechanical ventilation in 13% of the control group. 33.3% of the other vasculitis group and 57% of the patients in the AAV group ($p<0.001$) Complete recovery was observed in 82.3% of patients in the control group, 75% in the other vasculitis group, and 63% in the AAV group. We observed that 5.7% of the patients in the control group died from COVID-19, 9.4% from other vasculitides, and 27.8% in the AAV group ($p<0.001$). We found a lower survival in the AAV group compared to the control group ($p <0.005$). In the multivariate Cox regression model, we can see that older age (HR:1.05 IC95% 1.01-1.09 p=0.01), BMI>40 (HR:13.2 IC95% 2.1-83.2 p=0.01), and high activity of the underlying disease (HR:16 95% CI 3.7-69.4 $p<0.005$) were associated with lower survival.

Conclusion: In conclusion, we can mention that patients diagnosed with AAV presented a worse evolution of the disease caused by SARS-CoV-2 with a more frequent requirement for invasive mechanical ventilation. Likewise, these patients showed lower survival compared to other autoimmune diseases.

NEW INSIGHTS ON EPIDEMIOLOGICAL DATA AND IMPACT OF THE COVID-19 PANDEMIC ON IGA VASCULITIS IN CHILDREN AND ADULTS IN FRANCE: A NATIONWIDE COHORT

Keywords: COVID, Vasculitis, Epidemiology

V. Maisons[1], Y. Ramdani[2], C. Messaien[3], A. S. Jannot[3], B. Sautenet[1], J. M. Halimi[1], F. Maillot[2], E. Pillebout[4], A. Audemard[2]. [1]*University of Tours, Nephrology, Tours, France*; [2]*University of Tours, Internal Medicine, Tours, France*; [3]*Banque Nationale de Données Maladies Rares, DSI-I&D, APHP, Paris, France*; [4]*Hopital Saint-Louis, APHP, Nephrology, Paris, France*

Background: IgA vasculitis (IgAV) is a rare autoimmune disease affecting small vessels. It is well established that the incidence is higher in children (3 to 26 per 100,000 children/year,) [1] than in adults (0.1 to 1.8 per 100,000 individuals/year) [1]. However others epidemiological data and impact of the COVID-19 on IgAV remain overlooked [2].

Objectives: To collect and analyze epidemiological data on IgAV in both adults and children in France.

Methods: We conducted an observational study using a national database called "BNDMR" [3] (Banque Nationale de Données Maladies Rares) on IgA vasculitis (code ORPHA761), which gathered patients managed in the French rare disease expert network. The incidence was estimated from the date of diagnosis, and we calculated the median annual incidence over the period 2010-2022. We specifically assessed the north/south gradient (latitude of the residence higher/lower than the median of the latitudes), the seasonality, and the impact of the COVID-19 pandemic compared to other patients reported within the same period and addressed in the same expert centers used as controls.

Results: During this 12-year period, 1988 patients with IgAV were reported (1498 children; 490 adults). The male to female ratio was 1.57 for adults and 1.05 for children. The median IgAV annual incidence was 15 cases/year [IQR 9-30] and 82 cases/year [IQR 72-86] for adult and children cases respectively. Time to diagnosis was less than 1 month for both. Compared with other patients reported in the same expert centers, IgAV was more frequently reported in the southern part of France than in the north (OR 4.88 [95% confidence intervals: 4.17 - 5.74] in adults and OR 1.51 [1.35 - 1.68] in children). IgAV was also more frequently observed in winter than during the rest of the year in both adults (OR 1.60 [1.39 - 1.82]) and children (OR 1.22 [1.01 - 1.48]). The incidence of IgAV decreased during the COVID-19 pandemic period (from March 2020 to September 2022) in children (OR 0.62 [0.47 - 0.81]) but not in the adult population (OR 0.90 [0.76 - 1.06]).

Conclusion: Our study confirms the winter seasonality and sex ratio in IgAV [4,5], but suggests that the incidence or the reporting of IgAV decreased in children during the COVID19 pandemia, possibly due to barrier measures [6]. The observed north/south gradient need confirmation. The main limitation of this study is a possible IgAV under-reporting as this study rely only on cases addressed in expert centers.

CARDIAC AND PULMONARY INVOLVEMENTS IN BEHCET'S SYNDROME: A CASE SERIES OF 93 PATIENTS

Keywords: Cardiovascular disease, Behcet's disease, Lungs

S. Chadli[1], H. Khibri[1], M. Bourkia[2], N. Moatassim[1], W. Ammouri[1], M. Maamar[1], H. Harmouche[1], M. Adnaoui[1], Z. Tazi Mezalek[1,3]. [1]*Ibn Sina University Hospital*

Center, Internal Medicine, Rabat, Morocco; [2]*Mohammed VI University Hospital center, Internal Medicine, Tangier, Morocco*; [3]*Ibn Sina University Hospital Center, Clinical Hematology, Rabat, Morocco*

Background: Behçet syndrome (BS) is a multisystemic vasculitis of unknown etiology, frequently observed in the Mediterranean region and the Middle east. Pulmonary involvement (PI) and cardiac involvement (CI) are rarely described in BS, with a prevalence of less than 5%. However, they are entailed to high morbidity and mortality.
Objectives: Our work aims to describe the profile and outcomes of BS patients presenting with cardiopulmonary lesions.
Methods: We retrospectively conducted a descriptive and monocentric study, between 2020 and 2022, including 576 BS patients.
Results: 93 patients were enrolled (16%). The sex ratio (M/F) was 4.8 and the mean age was 3 ± 6 years [19-51]. Cardiovascular risk factors comprised smoking (26%), high blood pressure (10%), and diabetes (9%). Patients were often asymptomatic (78%) or presented with chest pain (23%), dyspnea (11.5%), dry cough (5%), and hemoptysis (5%). On chest CT angiography, we observed pulmonary artery aneurysms (70%), pulmonary artery thrombosis (24%), and alveolar hemorrhage (1%). Cardiac involvement (46%) included right intracardiac thrombosis (24%), pericarditis (10%), coronary thrombosis (4%), myocarditis (1%), and endomyocardial fibrosis (1%). Deep vein thrombosis was reported (28%) in the superior vena cava (14%), inferior vena cava (11%), and lower extremities (8%). Extravascular involvements were mostly mucocutaneous (79%), ocular (40%), articular (31%), and neurological (15%). Patients were treated with colchicine (83%), glucocorticoids (92%), curative anticoagulation (77%), cyclophosphamide (42%), azathioprine (36%), Infliximab (8%) and ciclosporin (1%). Surgery was performed for 8% of the patients. Relapse and death were recorded in respectively 15% and 7% of the cases.
Conclusion: PI and CI are serious complications of BS, often lately discovered and underdiagnosed, due to their discrete evolution. Systematic screening should thus be considered in at-risk patients, especially young males presenting with mucocutaneous lesions and venous thrombosis. Prompt and adequate immunosuppressive therapy is usually linked to favorable outcomes.

AB0770 MANAGING MEDICATION WITHDRAWAL IN ANCA ASSOCIATED VASCULITIS, A SINGLE CENTRE STUDY

Keywords: Vasculitis, Tapering, Safety

A. Abdalla[1,2], S. Skeoch[1]. [1]*Royal National Hospital For Rheumatic Diseases, Rheumatology, Bath, United Kingdom*; [2]*Mater Misericordiae University Hospital, Rheumatology, Dublin, Ireland*

Background: While ANCA- associated vasculitis (AAV) can be a life-threatening condition, once patients achieve sustained remission, it is possible to withdraw glucocorticoids (GC) and immunosuppressive therapy successfully. British [1] and European [2] guidelines advocate withdrawal of therapy in sustained remission. However, robust definitions of remission and risk of relapse on drug withdrawal are active research areas within the vasculitis community. Therefore, we took the opportunity to review & compare the clinical practice at our Tertiary Vasculitis Centre to guidelines published by the British Society for Rheumatology (BSR) [1].
Objectives: To describe the proportion of patients in remission and rates of drug withdrawal in line with BSR guidelines and evaluate if any characteristics were associated with GC-dependent remission.
Methods: We conducted a retrospective records review of all AAV patients (clinical diagnosis regardless of classification criteria) in our centre who attended for their routine care between July 2015 – August 2020. Those who lost or lacked significant follow-up information were excluded. Approval by the local clinical audit department was granted. Remission was defined per BSR guidance as a well-controlled disease by physician assessment on drug or drug-free remission. SPSS v.25 was used for statistical analysis.
Results: Sixty-five patients were included, 58% female, mean (SD) age at diagnosis of 60.7 (13.2), and 92% were Caucasians. The median (range) disease duration was five years (0.5 – 43). 33.8% were classified as GPA, 29.2% as EGPA. 55.4% had life or organ threatening disease, and 50.8% with a relapsing disease (table 1). At the time of the study, 60% of patients remained on GCs and 89% on immunosuppressive therapy. 48/65 (74%) were in clinical remission, of whom 19/48 (39.6%) were on GC plus immunosuppression, 21/48 (43.8%) were on immunosuppression alone, and 5/48 (10.4%) were in drug-free remission. In those with disease duration ≥ 10 years (n=14), 50% were deemed high relapse risk or poorly controlled and remained on a median dose of 10mg prednisolone. On univariate and multiple logistic regression analysis (reference=GC-dependent), skin involvement and a positive biopsy (83.3% non-renal) were associated with a statistically significant lower odds (OR 0.127 *P*=0.006, OR 0.207 *P*=0.04 respectively) of remaining on long term GC. In contrast, the relapsing disease was associated with increased odds (OR 4.006, *P*=0.026) of GC-dependent remission (figure 1).
Conclusion: Withdrawing treatment in AAV is challenging and achievable in a minority of patients, while the vast majority remain on long-term treatment. Skin involvement and non-renal positive biopsy may carry a positive prospect toward GC-free remission. Age, gender, disease type, ANCA status or persistent ANCA did not significantly influence the potential to stay on GC. Having a relapsing disease is the single most crucial factor significantly associated with long term treatment.

Background: The ANCA-associated vasculitis patient-reported outcome (AAV-PRO) questionnaire is a 29-item disease-specific PRO measure for AAV [1]. Originally only available in English, it has been translated into several languages in recent years to spread its use. The Italian version of the AAV-PRO questionnaire (AAV-PRO_ita) was translated in collaboration with Oxford and Bristol University (UK) and, after a preliminarily test on a single-center Italian cohort [2], it was evaluated on a large Italian cohort [3].

Objectives: To assess the internal consistency, feasibility, and reliability of the AAV-PRO_ita in the multicentric cohort of Italian AAV patients belonging to the Vasculitis Study Group of the Italian Society of Rheumatology.

Methods: The AAV-PRO_ita is describes the following disease domains: (1) organ-specific and systemic symptoms and signs(SSS); (2) physical function(PF); (3)social and emotional impact(SEI). In this study, Italian-speaking AAV patients were recruited from Italian Centres (N=17) with a large experience in the diagnosis and treatment of systemic vasculitis, belonging to the Vasculitis Study Group of the SIR. Inclusion criteria were: a confirmed diagnosis of GPA, MPA, or EGPA; ANCA positivity in at least once occasion or biopsy-proven AAV; and age ≥18 years old. Participants completed the AAV-PRO_ita at three different time-points: baseline, after 5-7 days, and at month 3.

Results: 276 AAV-patients (56.5% women) with a median age of 61 (IQR 51.5-71.6) were recruited and completed the questionnaires. The subtype of AAV was mainly GPA (146, 52.9%), followed by EGPA (77, 27.9%), and MPA (53, 19.2%). Median BVASv3 at baseline was 0 (IQR 0-3), whereas the median BVASv3 at the onset of disease was 13 (IQR 8-18). Participants had a median duration of disease of 62 (IQR 23.8-118.5) months. Patients who experienced at least one relapse, one hospitalization, and one severe infection were 41.7%, 53.3%, and 22.1%, respectively. 81.2% of the patients were on immunosuppressant therapy and 72.1% were still receiving GCs. AAV-PRO_ita questionnaire had good internal consistency (Cronbach's Alpha range 0.81-0.93) and good test-retest reliability (ICCs range 0.93-0.96). Item response rates were high overall (maximum 1.8% missing data), supporting the feasibility of the questionnaire. Concerning the domains of the questionnaire, female AAV patients scored higher (i.e. worse) in all 3 domains, especially in the SEI domain (p-value<0.001). There were also differences between patients on steroid therapy (n=199) and patients without steroid therapy (n=77), in fact, the former had higher scores on all domains, especially in the PF domain (p-value<0.001). Furthermore, patients who had at least one relapse of disease (n=114) had higher scores compared with who had never had one (n=161) on all domains (p-value<0.05). Differently, there were no differences in median scores between younger and older responders and between AAV subtypes. Duration of disease, previous hospitalizations and/or infections, BVASv3 and VDI at baseline did not influence the scores.

Conclusion: The AAV-PRO_ita questionnaire is a new 29-item, disease-specific PRO measure for use in AAV in the Italian language. It is a self-administered Italian questionnaire with good internal consistency, feasibility, and reliability. Research on treatment strategies based on steroid-sparing regimen and spreading awareness of the existence of gender differences in medicine may improve the perceived QoL of AAV patients, reducing the psychosocial impact of the chronic disease.

AZATHIOPRINE VERSUS METHOTREXATE AS INDUCTION AND MAINTENANCE THERAPY IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (EGPA): A MONOCENTRIC RETROSPECTIVE STUDY

Keywords: Vasculitis, Disease-modifying Drugs (DMARDs), Outcome measures

A. Milanesi[1,2], P. Delvino[1,2], S. Quaglini[3], C. Montecucco[1,2], S. Monti[1,2]. *[1]University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy*; *[2]IRCCS San Matteo, Division of Rheumatology, Pavia, Italy*; *[3]University of Pavia, Department of Electrical, Computer and Biomedical Engineering, Pavia, Italy*

Background: Despite the clinical differences between EGPA and the other AAVs, treatment guidelines are mostly based on the evidence available for patients with MPA and GPA, due to the lack of enough randomized controlled trials on patients with EGPA [1].

Objectives: The aim of our study is to analyse the efficacy, safety and steroid-sparing effect of azathioprine (AZA) and methotrexate (MTX) as induction and maintenance therapy in EGPA.

Methods: We collected data from 57 retrospective patients divided in 4 groups according to the treatment received (MTX/AZA as 1st line agents in patients with non-severe EGPA or as 2nd line agents in patients with severe EGPA previously treated with cyclophosphamide or rituximab). We analysed the data collected during five years of follow up from the initiation of AZA/MTX and compared

Table 1. Baseline characteristic of the population and statistical differences between therapy groups

	Total	MTX 1st line	AZA 1st line	P-value	MTX 2nd line	AZA 2nd line	P-value

the patient groups according to time to first relapse, percentage of patients in remission (defined as R1: BVAS=0, R2: BVAS=0 with prednisone ≤5mg/day, R3: BVAS=0 with prednisone ≤ 3,75mg/day – following the MIRRA definition(2)), persistence on therapy, percentage of patients with side effects and average cumulative steroid dose.

Results: There were no significant differences in the time-to-first relapse. No statistically significant differences were found in R1 remission analysis; a higher percentage of patients receiving MTX as 1st line therapy obtained R2 remission in the first 6 months (54% vs 12%, p=0,04), R3 remission wasn't achieved by any patient receiving AZA as 1st line treatment in the first 18 months of follow up (vs 35% in the MTX group, p=0.07). MTX was correlated with more adverse events (68% vs 33%, p=0.0049) still, persistence on therapy was higher for MTX (median time of suspension was >60months vs 12 months, p=0.03). The average cumulative steroid dose was lower in patients receiving MTX as a maintenance therapy compared to those receiving AZA (6g vs 10g at 5 years-follow up, p=0,039).

Conclusion: This study shows that MTX as 2nd line therapy has a better steroid-sparing effect and allows a better persistence on therapy, while as 1st line therapy it allows an earlier remission on lower prednisone dose.

Background: Behçet's disease (BD) is a rare, and severe, multisystemic inflammatory disease characterized by recurrent oral aphthous ulcers, genital ulcers, skin lesions, and both anterior and posterior uveitis; articular, vascular, gastroenteric and neurological involvement may also occur. The multi-organ involvement and the wide spectrum of clinical manifestations make the diagnosis of BD challenging. The lack of medication adherence leads to poorer health outcomes for the patients, which affect quality of life, generate economic loss for the healthcare system and trigger uncertainty for the healthcare prescribers in dealing with the disease treatment. This challenge is particularly important in BD, and for this reason, worldwide experts in BD and patient representatives living with BD gathered to launch the IMPACT_BD study.

Objectives: The objectives of IMPACT_BD are to explore the unmet needs in treatment adherence and the main reasons for low- or non-adherence, to create a tool aimed at identifying and monitoring the reasons of low treatment adherence and to plan specific actions aimed at improving treatment adherence in BD.

Methods: The methodology includes 5 phases. *Phase A. Panel creation* - The first step created a multi-stakeholder panel that included clinicians, BD patient's representatives, BD caregiver representatives and other experts (economists, psychologist, pharmacists, etc). *Phase B. Co-design process* – Ad hoc surveys were created in co-design with the different stakeholders to capture the different dimensions, barriers and needs related to treatment adherence. The survey was translated into 8 languages and launched across Social Media (*Phase C. Launch of the survey*). *Phase D. Data analysis, workshop and agreement* – Answers to the survey questions will be elaborated to identify the main barriers and unmet needs in treatment adherence. An online workshop will be organized to co-design a tool that will enable the identification and the monitoring of BD treatment adherence during the clinical follow-up of BD patients. *Phase E. Pilot phase for validation* – The final tool will be translated into different languages and will be adopted in a pilot study. The results of the pilot phase will be discussed and

refined within the panel. A list of future actions aimed at improving treatment adherence in BD patients will also be produced with the support of members of the co-design panel.

Results: The main results of the study will be represented by: the identification of the main barriers and unmet needs related to treatment adherence in BD patients, caregivers and families; the creation of a co-designed tool aimed at assessing the causes and barriers of low- or non-adherence in BD patients; and the planning of future initiatives aimed at improving treatment adherence in BD patients.

Conclusion: Assessing the barriers causing low or non-adherence in BD will provide relevant information that will support the clinicians and the other health-care professionals caring for BD patients, by improving the clinical management of the disease; by taking tangible actions aimed at increasing adherence to treatment; and therefore by improving the wellbeing of BD patients, caregivers and families.

AB0774 URINARY INTERLEUKIN (IL)-16 IN ANTI – NEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA)- ASSOCIATED VASCULITIS WITH KIDNEY INVOLVEMENT

Keywords: Biomarkers, Vasculitis, Kidneys

A. Juto[1,2], F. Faustini[1,2], A. Häyry[1], A. Larsson[3], V. Malmström[1], A. Bruchfeld[4,5,6], A. Antovic[1,2], V. Oke[1,7], I. Gunnarsson[1,2]. [1]*Karolinska Institutet, Department of Medicine, Division of Rheumatology, Solna, Stockholm, Sweden*; [2]*Karolinska University Hospital, Rheumatology, Stockholm, Sweden*; [3]*Uppsala University, Department of Medical Sciences, Clinical Chemistry, Akademiska Hospital, Uppsala, Sweden*; [4]*Karolinska Institutet, CLINTEC, Stockholm, Sweden*; [5]*Linköping University, Department of Health, Medicine and Caring Sciences, Linköping, Sweden*; [6]*Karolinska University Hospital, Department of Renal Medicine, Stockholm, Sweden*; [7]*Academic Specialist Center, Center for Rheumatology, Stockholm, Sweden*

Background: The pro-inflammatory interleukin (IL)-16 can be released by different immune cells and has been shown to be an inflammatory mediator in rheumatic diseases. Urinary (u-) IL-16 has recently been found to be associated with proliferative nephritis in systemic lupus erythematosus (SLE) and is expressed in inflammatory foci in the kidney [1,2]. However, data on u-IL-16 in other immune-mediated kidney diseases including Antineutrophil Antibody Associated Vasculitis (AAV) is lacking.

Objectives: To investigate levels of u- IL16 in AAV patients with kidney involvement compared to controls and to assess associations of u-IL16 with clinical variables.

Methods: Urine samples from 43 AAV patients were collected at the time of kidney biopsy on clinical indication. The biopsies were classified according to histopathological class [3]. Clinical variables were extracted from medical records. Forty-eight population controls were included. The u-IL16 was measured using a commercial sandwich ELISA. The cut-off for detectable IL-16 was set to ≥ 10 pg/mL. Vasculitis disease activity at the time of kidney biopsy was assessed using the Birmingham Vasculitis Activity Score (BVAS 3.0).

Results: In the AAV group, there were 25 males (58.1%), the median age was 61 years, and 22 (51.2%) were anti-PR3 positive while 21 (48.8%) were anti-MPO positive. There were 25 (58.1%) patients with GPA and 18 (41.9%) with MPA in the study. Median BVAS was 16 (interquartile range 13-21). Thirty-nine (90.7%) patients had biopsy-proven kidney involvement, whereas four patients had no histopathological signs of vasculitis. Mean eGFR (SD) was 51.1(31.9) in the AAV group and 91.6 (11.9) in the control group, respectively (p=<0.001). At inclusion and urine sampling 35 (81.4%) patients were on immunosuppressive treatment. In all, 15/43 (34.9%) patients had detectable levels of u-IL16, all of whom had biopsy-proven vasculitis (Figure). The AAV patients had significantly higher levels of u-IL16 compared to controls (p=0.027, 95% CI 1.79 – 27.6). Two controls had detectable levels of u-IL16. u-IL16 levels did not differ with respect to diagnosis (GPA/MPA) or ANCA-serotype. A positive correlation was seen between u-IL16 and BVAS (r=0.326, p=0.03), and there was a negative correlation between u-IL16 and eGFR (r= -0.330, p=0.03). Thirty-seven kidney biopsies were classified according to Berden: Focal (n=20), Crescentic (n=8), Mixed (n=6), and Sclerotic (n=3). There was a significant difference in u-IL16 levels between these groups (H (3)=8.68, p =0.034) with the highest proportion of patients with detectable u-IL16 in the sclerotic (66.7%) and crescentic (62.5%) classes. Levels of u-IL16 were not statistically significantly different between patients with or without ongoing treatment. The sensitivity for u-IL16 to correctly classify occurrence of kidney involvement in AAV patients was 38% (specificity 100%, PPV 100%, NPV 14%).

Conclusion: Urinary IL-16 was detectable in a significant proportion of AAV patients with kidney involvement and reflected disease activity and severity. As similar findings have been described in SLE, u-IL16 may be a marker of kidney inflammation in systemic immune-mediated kidney diseases. Further research is warranted to evaluate the pathogenic role of IL-16, the possible use of u-IL16 as a biomarker in clinical practice, as well as its potential as treatment target.

AB0775 EFFECTIVENESS AND SAFETY OF NON-MEDICAL SWITCH FROM RITUXIMAB ORIGINATOR TO AND AMONG BIOSIMILARS IN SMALL VESSEL VASCULITIDES PATIENTS: REAL WORLD DATA FROM A RETROSPECTIVE MONOCENTRIC STUDY

Keywords: bDMARD, Safety, Vasculitis

S. Stano[1], L. Coladonato[1], A. Capuano[1], M. Lavista[1], V. Spedicato[1], M. Fornaro[1], F. Iannone[1], F. Cacciapaglia[1]. [1]*University of Bari "Aldo Moro", Rheumatology Unit - Department of Regenerative and Precision Medicine, Ionian Area (DiMePRe-J), Rheumatology, Bari, Italy*

Background: Rituximab (RTX) is indicated for treatment of severe small vessel vasculitides (SVV), namely granulomatosis with polyangiitis (GPA) microscopic polyangiitis (MPA) and cryoglobulinemic vasculitis (CV). Currently available RTX molecules include the originator drug (RTX-Or) and two biosimilars, CT-P10 and GP2013. SVV are rare and only few studies evaluated safety and efficacy of non-medical switch (NMS) from RTX-Or to CT-P10 [1,2,3]. No data are available about clinical use of GP2013 and switching strategies between RTX biosimilars in these conditions.

Objectives: The aim of our study was to obtain real world data about effectiveness and safety of different RTX molecules, and to evaluate switching strategies from RTX-Or to and among biosimilars for treatment of patients affected by GPA, MPA and CV.

Methods: We retrospectively evaluated clinical and laboratory data of patients affected by GPA, MPA and CV, according to specific classification criteria, and treated with RTX based on expert rheumatologist indication between 2018, date of biosimilars availability, and 2022. Specifically, C-Reactive Protein (CRP), Erythrocyte Sedimentation Rate (ESR), gamma globulins, C3, C4, Five Factor Score (FFS), Birmingham Vasculitis Activity Score version 3 (BVASv3) and concomitant rheumatologic therapy were recorded. Autoimmunity was assessed as anti-neutrophil cytoplasmic antibody (ANCA) positivity for GPA and MPA and as presence of cryoglobulins in CV. All patients were followed-up for at least 12 months and received at least two cycles of therapy with RTX-Or, CT-P10 or GP2013. NMS to RTX biosimilars was performed when clinically feasible and accepted by the patient. Any safety issue associated with RTX treatment was recorded. Clinical and laboratory data were analyzed using appropriate statistical tests with SPSS.
Results: Data on 29 patients (female No. 19 - 65,5%; mean age 56.3±15.7 years old; mean disease duration 52.3±20.1 months) were available. Ten patients started therapy with RTX-Or, and all accepted NMS to CT-P10. Nine patients were treated with CT-P10 and six accepted NMS to GP2013. Twelve patients started treatment with GP2013. At baseline and during follow-up no significant differences among laboratory and clinical data of patients treated with any RTX molecule was highlighted. All patients achieved a statistically significant reduction of mean corticosteroid dose used from 20.4±12.8 mg/day of prednisone equivalents at baseline to 5.0±2.8 mg/day at 12 months (p=0.00016), and of mean BVASv3 from 20.0±4.5 at baseline to 4.7±2.3 after 12 months (p<0.00001). On average, a reduction of CRP and ESR levels, despite a small decrement of gamma globulins level was also observed. Mean C3 and C4 level resulted normal over time. ANCA positive patients decreased from 83.3% at baseline to 35.3% after one year (p=0.0059). Cryoglobulins were still detectable in 36.4% of patients after one year of RTX treatment (p=0.0039). No severe AEs were recorded, and only two CV patients treated with CT-P10 presented mild AEs: moderate lymphopenia, resolved after temporary drug withdrawal in one subject, and mild urticaria after infusion, with no new AEs after CT-P10 retreatment in the other. Of note, no AEs were observed in our cohort after NMS.
Conclusion: Our study demonstrated comparable effectiveness and safety of RTX-Or and its two biosimilars both for induction and maintenance of remission. The effectiveness and safety of NMS for RTX in SVV is confirmed, and our results grant first time evidence for safety and maintained effectiveness of treatment in such patients also after NMS between biosimilars. This practice allows economic sustainability for healthcare systems and represents a hot topic in clinical practice.

AB0776 REAL-WORLD EVIDENCE ON THE LONG-TERM USE AND DRUG SURVIVAL OF MEPOLIZUMAB IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (EGPA)

Keywords: Vasculitis, Descriptive Studies, Real-world evidence

C. Koutsianas[1], T. Karageorgas[2], C. Tsalapaki[1], E. Mavrea[1], A. Panagiotopoulos[1], D. Boumpas[2], D. Vassilopoulos[1]. *[1]Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens, School of Medicine, Hippokration General Hospital, Athens, Greece*; *[2]Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 4th Department of Medicine, National and Kapodistrian University of Athens, School of Medicine, Attikon General Hospital, Athens, Greece*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare form of ANCA-associated vasculitis in which it is frequently difficult to achieve glucocorticoid (GC) tapering without relapse. Mepolizumab (MEPO) is an approved anti-IL5 agent for EGPA but real-world evidence of its long-term efficacy and survival is scarce.
Objectives: To study the efficacy, safety, and survival of MEPO for EGPA in daily clinical practice.
Methods: Retrospective study of all patients with EGPA who received MEPO in two academic Rheumatology centers up until January 10, 2023. Demographic and clinical data were recorded at baseline (start of MEPO) and at last follow up visit.
Results: 16 patients with EGPA treated with MEPO (females: 87.5%, mean age: 52.4 years, mean disease duration at MEPO start: 4.4 years, ANCA+: 25%) were included in the study. At baseline, the median (IQR) BVASv3 was 6 (7) and the history of EGPA systemic involvement was: lung 94%, ENT 94%, musculoskeletal 50%, heart 50%, peripheral nervous system 37.5%, skin 25% and gastrointestinal 25%. The median number of EGPA relapses before MEPO use was 2, while 11/16 (69%) had previously failed various immunosuppressive (IS) (MTX, AZA, MMF, CYC) and 3/16 (18%) omalizumab treatment. At MEPO start, all patients were on GCs (median prednisolone dose: 12.5 mg/day), while 62.5% were on IS (MMF=6, MTX=2, RTX=2). During follow-up [median (IQR)=12 (19) months], there was a statistically significant reduction in GC dose (median, from 12.5 to 2.5mg/day, p=0.002, while 3/16 (19%) patients discontinued GCs), absolute eosinophil count (mean, from 1603±1163 to 84±42, p<0.001) and BVASv3 (median, from 6 to 0, p=0.007). The cumulative drug survival at 6, 12 and 18 months was 100%, 100% and 83% respectively (Figure 1). MEPO was discontinued in 2 patients due to relapsing disease, while it was well tolerated in all patients without withdrawals for safety issues. Of note, in 3 subjects (19%) MEPO was used concurrently with rituximab (RTX) with good tolerability.
Conclusion: In this real-world study of EGPA patients, MEPO was efficacious and safe, with a high retention rate and significant GC-sparing effects. Furthermore, in almost one out of five patients it was used successfully in combination with RTX. These findings confirm the RCT data in real-life, difficult to treat patients.

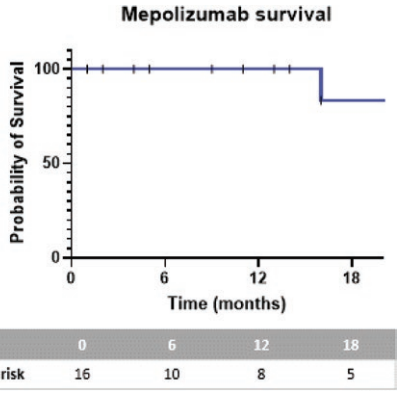

Figure 1. Mepolizumab survival (Kaplan-Meier analysis) in real-life EGPA patients

Background: External validation of the 2022 ACR/EULAR GPA, EGPA and MPA Classification Criteria is recommended by the DCVAS study group [1-3].
Objectives: Turkish Vasculitis Study (TRVaS) prospective cohort is an electronic database including 15 centres from all over Turkey. We aimed to test performance of the recent criteria sets in TRVaS cohort.
Methods: Patients diagnosed according to physicians' decisions have been recruited prospectively in TRVaS (in total 3730 patients by January 2023). 2022 ACR/EULAR and 1990 ACR Classification Criteria sets were applied to all of the patients with AAV [GPA (n=533), EGPA (n=112), MPA (n=105), and unclassified AAV (n=70)], poliarteritis nodosa (PAN, n=47) and IgA Vasculitis (n=76). Performances were analysed using sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy.
Results: For the patients with GPA, 2022 criteria had higher sensitivity and specifity compared to 1990's (83.6% vs. 71.0% and 95.6% vs. 88.6%, respectively in Table). A significant increase was observed in sensitivity for 2022 criteria for patients with EGPA (86.4% vs.59.1%) with no change in specificity. Sensitivity and specificity of 2022 MPA criteria was calculated as 83.8% and 89.8%, respectively. Using the 2022 criteria to the patients with unclassified AAV, led to classify seven (10.0%) patients as GPA and 29 (41.0%) patients as MPA. Of 47 patients with PAN, one patient fulfilled 1990 ACR and another fulfilled 2022 GPA criteria. Others were not classified as EGPA or MPA. None of the patients with IgA vasculitis fulfilled 2022 AAV criteria. Of 533 patients with GPA, 1.5% fulfilled both 2022 GPA and MPA criteria and 7.7% fulfilled only MPA criteria (Figure). In each clinically diagnosed AAVs, around 10% of patients were not classified by any 2022 criteria.
Conclusion: Using 2022 ACR/EULAR Classification Criteria, improved sensitivity and specifity for GPA and sensitivity for EGPA were observed. Additionally, half of the unclassified AAV patients could be classified as either GPA or MPA. These criteria functioned well for the discrimination of patients with AAV from other small/medium vessel vasculitides such as PAN and IgA vasculitis. In total, over 80% of the patients with AAV were accordingly classified in paralel to the clinical diagnosis in each GPA/EGPA/MPA.

HISTOPATHOLOGIC FEATURES AND CLINICAL OUTCOMES IN PATIENTS WITH EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS

Keywords: Vasculitis, Clinical Trials

E. Takamasu[1], N. Yokogawa[1], I. Takahashi[1], K. Shimada[1]. [1]*Tokyo Metropolitan Tama Medical Center, Department of Rheumatic Diseases, Fuchu, Japan*

Background: The main histological features of eosinophilic granulomatosis with polyangiitis (EGPA) are tissue eosinophilia (TE), small-vessel vasculitis (SVV), and extravascular granuloma. However, the relationship between these pathological findings and treatment response is not known.
Objectives: To explore the associations between pathological features of TE or SVV and the clinical parameters and treatment response in EGPA patients.
Methods: This is a single-center, retrospective, cohort study. Subjects who met the following were included for analysis: 1) those who fulfilled the 1990 ACR criteria and/or the 2012 revised CHCC criteria and/or the ACR/EULAR 2022 criteria, 2) those who were treated for at least 2 years in our hospital since 1/1/2010, 3) those who had undergone tissue biopsy at any site during their initial diagnostic workup. All available slides of biopsies were reviewed by a blinded pathologist expertise with vasculitis. Based on the EULAR recommendations, remission was defined as the absence of vasculitis activity (BVAS=0) with daily doses of prednisolone <=7.5mg after 2 years of treatment and refractory disease was defined as failure to attain remission.
Results: Among 37 patients diagnosed with EGPA, 30 patients were included. Total 84 biopsies (muscle 36, skin 15, nose 9, colon 8, stomach/duodenum 4, nerve 4, kidney 3, lung 2, heart 1, small intestine 1, and temporal artery 1) were reviewed. SVV, TE, and extravascular granuloma were found in 17 (56.5 %) patients, 16 (53.3 %) patients and 3 (10 %) patients, respectively. (Fig.1) SVV was associated with refractory disease (47.1 % vs 0 %, p=0.04). TE was associated with skin lesions (56.2 % vs 14.3%, p = 0.021) and inversely associated with severe peripheral neuropathy (43.8 % vs 85.8 %, p = 0.021). (Table.1) ANCA was present in 11 (36.7 %) patients. ANCA was not associated with refractory diseases (ANCA positive 36.3% vs ANCA negative 21.1%, p=0.31)
Conclusion: In EGPA, pathological evidence of SVV may be better predict poor treatment response than ANCA positivity.

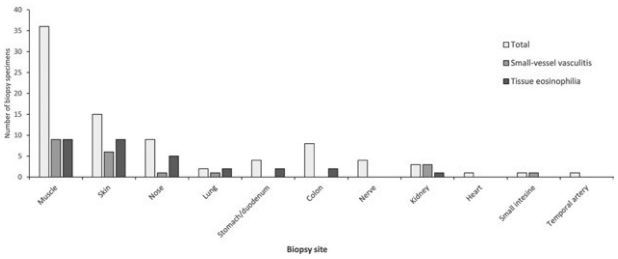

Fig.1 Biopsy sites and each number of positive pathological finding.

Table.1 Characteristics of EGPA patients with or without pathological findings.

Characteristics	Small-vessel vasculitis (SVV)			Tissue eosinophilia (TE)		
	Pts with SVV (n=17)	Pts without SVV (n=13)	P value	Pts with TE (n=16)	Pts without TE (n=14)	P value

AB0779 NAILFOLD VIDEOCAPILLAROSCOPY IN ANCA-ASSOCIATED VASCULITIS

Keywords: Diagnostic Tests, Prognostic factors, Vasculitis

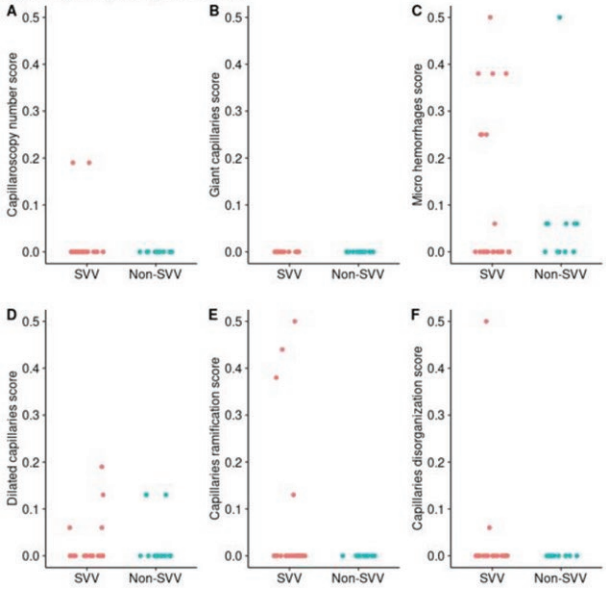
M. Sullivan[1], N. Aslam[2], A. Abril[1], C. Ball[3], F. Berianu[1]. [1]*Mayo Clinic, Department of Medicine, Division of Rheumatology, Jacksonville, United States of America*; [2]*Mayo Clinic, Department of Medicine, Division of Hypertension and Nephrology, Jacksonville, United States of America*; [3]*Mayo Clinic, Department of Quantitative Health Sciences, Jacksonville, United States of America*

Background: Nailfold videocapillaroscopy (NVC) is a simple and noninvasive tool utilized by rheumatologists for monitoring of systemic sclerosis, dermatomyositis, and Raynaud's phenomenon [1]. A capillaroscope is utilized to view the nailfold capillaries and evaluate for evidence of small vessel abnormalities, which can be seen with the aforementioned disorders. Other forms of rheumatologic disease such as ANCA-associated vasculitis (AAV) are already known to cause capillaritis. This is the proposed mechanism for some of the disease manifestations including pulmonary alveolar hemorrhage and glomerulonephritis(2, 3). We sought to clarify whether patients with AAV would have corresponding abnormalities on NVC.

Objectives:

1. Characterize NVC characteristics in patients with AAV.
2. Define the prevalence of dilated capillaries, microhemorrhages, ramifications, disorganization, and decreased density in patients with AAV compared to controls.

Methods: Patients over the age of 18 with a diagnosis of small vessel vasculitis based on Chapel Hill Criteria or confirmed on biopsy were identified for inclusion in the trial and invited to participate. Patients with co-existing disorders that are felt to impact NVC results were excluded: dialysis dependence, type 2 diabetes mellitus, Raynaud's phenomenon, CTD, acrocyanosis, erythromelalgia, recent manicure or hand trauma, routine use of vibratory tools, psoriasis, bleeding disorder, or exposure to toluene or benzoyl. NVC was performed at the time of enrollment. A semiquantitative scale calculated by 2 providers was used to score several parameters including enlarged or giant capillaries, hemorrhages, capillary density, disorganization, or ramifications. We compared baseline characteristics and NVC Scores of patients with AAV to non-AAV controls using a Wilcoxon rank sum test for continuous and ordered variables. Fisher's exact test was utilized for categorical variables.



Results: Twenty-four patients with small vessel vasculitis and 13 control patients were enrolled. One patient with cryoglobulinemic vasculitis was excluded. Baseline assessment reported in ***Table 1***. Patients with AAV tended to be older than the non-AAV controls (median 58 years vs. 40 years). Among patients with AAV, 58% were female, 83% ANCA positive. C-ANCA present in 43%, PR3 in 48%, P-ANCA in 35% and MPO in 35%. Four of the 23 patients (17.4%) had an active flare within 90 days prior to NVC assessment. We did not observe any statistically significant difference in NVC scores between AAV patients and non-AAV controls (all P>0.12, ***Table 2***, ***Figure 1***). Some non-specific NVC changes were observed in the AAV group such as ramifications and decreased density which were not observed in the control group though these did not reach statistical significance.

Conclusion: ANCA-associated vasculitis was not strongly associated with NVC abnormalities. Some non-specific changes were observed, and further research may help identify whether these abnormalities correlate with specific disease manifestations or disease activity.

Background: Accuracy of diagnosis and prompt therapeutic intervention are the mainstay in patients with ANCA-associated vasculitis(AAV) suffering from life-threatening complications [1].However, there is no definition of therapeutic window in vital AAV, nor its impact on patient outcome regarding length of hospital stay, intensive care unit(ICU) admission or survival.
Objectives: The aim of the study is to analyze the process of care from the perspective of time management in vital organ involvement AAV patients and to identify potential risk factors for ICU admission.
Methods: A retrospective multicenter study identified AAV patients with life-threatening organ involvement, defined as alveolar hemorrhage, rapidly progressive renal failure, myocarditis and cerebral granuloma. Demographic data was collected. Key time frames were recorded, namely the interval from acute symptom onset to hospital presentation, days until imaging(plain X-ray, cardiac ultrasound, CT-scan), time to therapeutic intervention with corticosteroids or biologic/non-biologic immunosuppression(cyclophosphamide or rituximab) and to renal replacement therapy(RRT) or plasmapheresis. Time to ICU admission, hospital length-of-stay, Birmingham Vasculitis Activity Score(BVAS) were also noted. Statistical analysis was performed using SPSS and Chi-square and Pearson correlation tests were applied.
Results: 66 patients with AAV were enrolled, out of which 17 fulfilled inclusion criteria. Mean age in the study group was 58.6±11.1 years old,10 patients(58.8%) were females and 7 (41.2%) males.11(64.7%) patients were c-ANCA positive, while 6 (35.3%) had p-ANCA and all were diagnosed with AAV prior to life-threatening event. Two patients had COVID-19 triggered AAV.In the study group, the most frequent critical organ suffering was rapidly progressive renal failure(12), followed by alveolar hemorrhages(10), 2 cerebral granulomas and one acute myocarditis. Three patients(17.6%) had more than one vital manifestation. Ten patients(58.8%) had more than three additional non-organ-threatening manifestations. Mean interval from AAV diagnosis to emergency admission was 30.1± 61.1 days, median 3 and from severe episode onset to hospitalization 1.65±0.18 days, median 1. There was only one death in the study group. Three patients were admitted in the ICU in 0.59±1.5 days following hospital presentation and required either RRT or plasma exchange within 2.66 days. Imaging examination was performed unanimously the day upon hospital admission. All patients received corticosteroids in the first 5.95±14.3 days, while immunosuppression was given to 13(76.5%) patients within 11.5±15.5 days from hospitalization.12 patients(70.5%) suffered from associated infections. Mean BVAS(13.6±6.76) correlated to ICU admission(p 0.013, r 0.58).Patients in ICU revealed higher BVAS(22±9.53) versus non-ICU(11.8±4.76).Hospital length of stay was 14.7±10.7 days(median 14) and showed no relationship to the type of severe organ involvement. The need for ICU caring was dominant in males(p 0.05) and confirmed in patients with proteinuria(p 0.012) and at least two major organ damage.
Conclusion: This study shows that severity risk factors for potential ICU admission for life-threatening AAV appear to be male gender, proteinuria and the number of affected organs.Moreover, BVAS should be considered a useful tool to predict patients' risk for intensive care management since a higher score indicates a more aggressive disease.However, time to investigational or therapeutic intervention did not correlate to patient outcome in AAV.

AB0781 LARGE VESSEL INVOLVEMENT IN ANTINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

Keywords: Vasculitis, Outcome measures, Descriptive Studies

M. Kaymakci[1], M. Elfishawi[1], H. Langenfeld[2], A. Hanson[2], C. S. Crowson[1,2], U. Ghaffar[1], M. Koster[1], U. Specks[3], K. J. Warrington[1]. [1]*Mayo Clinic, Division of Rheumatology, Department of Medicine, Rochester, United States of America*; [2]*Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America*; [3]*Mayo Clinic, Division of Pulmonary and Critical Care Medicine, Department of Medicine, Rochester, United States of America*

Background: Anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV) is currently categorized under the small vessel vasculitides and includes granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA) [1]. There is limited knowledge about large vessel involvement in AAV (L-AAV); mainly described in case reports and small series. L-AAV can involve temporal arteries (TA-AAV), aorta (A-AAV), and periaortic soft tissue (PA-AAV).
Objectives: The objective of this study was to investigate the characteristics of L-AAV.
Methods: Patients older than 18 years at diagnosis of TA-AAV, A-AAV and PA-AAV seen at a single institution between January 1, 2000, and December 31, 2021, were identified through a proprietary medical text search algorithm. Patients were included if diagnosed with L-AAV by the treating physician, fulfilled 2022 American College of Rheumatology/ European Alliance of Associations for Rheumatology classification criteria for GPA, MPA or EGPA, had positive ANCA, and had more than one outpatient or inpatient visit. Arteritis of the temporal artery was based on histopathology whereas the diagnosis of aortitis and periaortitis could be either based on radiology or histopathology.
Results: The study cohort consists of 36 patients with L-AAV. Of those, 23 had p-ANCA/ MPO-ANCA and 13 had c-ANCA/ PR3- ANCA. Mean (SD) age at AAV diagnosis was 63.4 (12.79); 20 (56%) were male. Seventeen patients had TA-AAV, 10 had A-AAV and 9 had PA-AAV (Table 1). Most of the patients (n=25, 69%) were diagnosed with large vessel involvement and AAV within a one-year timespan. Inflammatory markers were elevated at the time of diagnosis of large vessel involvement. Twenty-five (69%) patients had histopathologic confirmation of AAV diagnosis. There was no overlap between TA-AAV, A-AAV and PA-AAV groups. Of the 17 patients with TA-AAV, 6 had inflammation of a temporal artery branch vessel. The most frequent site of involvement in the A-AAV group was the ascending thoracic aorta, whereas in the PA-AAV group, the abdominal aorta was most frequently involved. Glucocorticoids (36/36), rituximab (19/36), and methotrexate (18/36) were the most frequent treatments. During the study period 8 patients died (4 in TA-AAV, 3 in A-AAV, and 1 in PA-AAV). There was no difference in mortality between this cohort of L-AAV patients and the general population (standardized mortality ratio: 0.98; 95% CI, 0.42- 1.93).
Conclusion: This is the largest single-center cohort of patients with L-AAV to date. Clinicians should consider L-AAV in the differential diagnosis of vasculitides especially in the context of positive ANCA and atypical organ manifestations.

Background: Many studies have reported risk factors for infection in ANCA-associated vasculitis, but the consistency of these risk factors varies between studies [1-5]. In addition, few reports have focused specifically on patients with microscopic polyangiitis (MPA) or have focused on the impact of glucocorticoids (GC) reduction on the risk of infection.

Objectives: In this study, we aimed to examine risk factors of serious infections (SI) in patients with MPA in the REVEAL cohort, a Japanese multicenter cohort. As one of the risk factors, we also focused on the pace of GC reduction.

Methods: 181 MPA patients hospitalized for induction therapy and followed for at least three months were recruited from the REVEAL cohort. We evaluated the demographic, clinical, and laboratory findings, and treatments. To assess the pace of GC reduction, GC doses at 3, 12, and 24 months were extracted, and the ratio of each to the initial dose was calculated. Univariate analysis and COX regression analysis were performed to identify risk factors for SI, defined as infections requiring hospitalization in these patients. Gray test was performed for the comparison of the cumulative incidence of SI between groups.

Results: There were 115 patients without SI and 66 patients with SI. Univariate analysis showed that age, smoking index, CRP, and GC dose ratio (3 months/initial dose) were associated with SI. In the COX regression analysis (shown in Table 1), age, CRP, and GC dose ratio (3 months/initial dose) were identified as significant risk factors (p values are <0.005, <0.005, and 0.04, respectively). In addition, the group with GC dose ratio (3 months/initial dose) ≥ 0.4 had significantly higher cumulative incidence of SI than the other group (p=0.032) (shown in Figure 1).

Conclusion: Age, CRP, and GC dose ratio (3 months/initial dose) were identified as risk factors for SI in MPA patients.

AB0783 RISK FACTORS IN HENOCH-SCHÖNLEIN PURPURA NEPHRITIS

Keywords: Vasculitis, Prognostic factors, Kidneys

S. Monov[1], T. Todorov[2], D. Monova[3]. [1]*Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria*; [2]*Medical University - Sofia, Department of General and Clinical Pathology, Sofia, Bulgaria*; [3]*Medical Institute, Medical University - Sofia, Department of Internal Medicine, Sofia, Bulgaria*

Background: Henoch - Schönlein purpura (HSP) is an immuno-mediated small-vessel vasculitis that manifests as non—thrombocytopenic purpura, arthritis or arthralgia, abdominal pain and/or kidney involvement. HSP nephritis can presented is micro- or macroscopic hematuria, proteinuria, nephrotic or nephritic syndrome, as well as acute renal failure {1,2}.

Objectives: The aim of the study is to identify risk factors associated with unfavorable outcomes in patients with HSP nephritis.

Methods: This retrospective study enrolled 68 patients with HSP nephritis. Renal and extra-renal symptoms were analyzed. A diagnosis of HSP nephritis was made when hematuria and/or proteinuria, and/or renal failure was associated with a palpable purpuric eruption or abdominal or joint pains (at least two of these three clinical signs) and predominant mesangial IgA immune deposits, confirmed by renal biopsy. The patients were subdivided into five classes according to the renal manifestation at onset of disease: 1) micro- or macroscopic hematuria; 2) mild proteinuria (<1 g/L) ± hematuria; 3) acute nephritic syndrome, defined as moderate proteinuria, hematuria, increased serum creatinine and/or hypertension; 4) nephrotic syndrome; 5) mixed nephritic-nephrotic syndrome.

Results: Of 68 patients with HSP nephritis, diagnosed by kidney biopsy, 41 (60,29 %) were male and 27 (39,71 %) - female. Age of onset was between 18 and 66 years (mean 37,28 ± 9,34). Duration of follow-up was between 2 and 28 years. 29 patients had histories of infection preceding presentation. At onset all patients had palpable purpura and urinary abnormalities (only hematuria - in 16,18 %; mild proteinuria ± hematuria – in 44,12 %; moderate or severe proteinuria and hematuria – in 39,70 %). Arthralgias were present in 49 patients (72,06 %), gastrointestinal involvement – in 32 patients (47,05 %). Renal function was impaired in 26,47 % of patients, and 51,47 % were hypertensive. Mesangial hypercellularity lesions were found in most patients (97,06 %), endocapillary proliferation – in 20,58 %, segmental sclerosis – in 32,35 %, tubular atrophy/interstitial fibrosis – in 38,23 %. Corticosteroids and cyclophosphamide were prescribed in patients who presented with severe clinical and histological features and/or rapidly progressing renal disease. During follow-up classical extra-renal organ diseases were seen in 55,88 % of patients, and hematuria and/or proteinuria – in 77,94 %. At final review 26,47 % had progression of renal failure. Risk factors for renal failure were moderate or severe proteinuria during follow-up ($p<0,001$), renal impairment at presentation ($p<0,001$), hypertension at presentation and during follow up ($p<0,05$), crescents, interstitial fibrosis and tubular atrophy ($p<0,001$). No significant difference in renal outcome was observed between patients who had relapses in extra-renal organs versus in those who did not.

Conclusion: Our results indicated that lower GFR, nephrotic syndrome, nephritic-nephrotic syndrome and crescentic nephritis were risk factors for unfavorable outcomes.

AB0784 SKULL BASE INFILTRATION AS A MANIFESTATION OF GRANULOMATOSIS WITH POLYANGIITIS

Keywords: Rare/orphan diseases, Organ damage, Vasculitis

A. Masiak[1], Z. Zdrojewski[1]. *[1]Medical University of Gdańsk, Department of Rheumatology, Clinial Immunology, Geriatrics and Internal Medicine, Gdańsk, Poland*

Background: Although upper respiratory symptoms are the most frequent localization of granulomatosis with polyangiitis (GPA) [1], infiltration of the skull base is rare.

Objectives: The aim of this analysis was the clinical characteristic of GPA patients' skull base involvement.

Methods: The retrospective analysis was performed on patients diagnosed in tertiary academic referral center (Medical University of Gdansk, Poland) between 1990 and 2022 due to GPA. Medical database of 232 GPA vasculitis patients were retrospectively reviewed, and demographics, serological, and clinical features of the patients presenting skull base infiltration throughout the disease course were recorded. Comparisons of disease characteristics and long-term outcomes were performed between patients with and without this manifestation.

Results: Among 232 patients (121 males, median age 52,5 years, 87% ANCA positive, 12,5% localized, 87,5% systemic), seven patients presented skull base infiltrations as a manifestation of GPA. It was 4 women and 3 men, aged between 27 and 72. Four patients were cANCA positive, 1 patient had atypical pANCA and 2 patients were ANCA negative. In six of them it was a first manifestation of vasculitis. Clinical characteristic of patients is summarized in table. Statistical analysis showed that patients with skull base involvement and those without this manifestation differed only in the frequency of ocular involvement - in patients with skull base infiltration, ocular involvement occurred in all cases, while among patients without infiltration it occurred in only 34.5 per cent of subjects. In terms of other parameters, there were no statistically significant differences between the groups.

Conclusion: Skull base infiltrations presenting mainly as cranial nerve palsies is rare presentation of GPA. In most of patients it is one of the first symptoms of vasculitis. It can occur in both ANCA positive and ANCA negative cases.

AB0785 ASSOCIATED FACTORS TO REMISSION IN PATIENTS WITH UVEITIS RELATED TO BEHÇET DISEASE TO THE FIRST THERAPEUTIC SCHEME

Keywords: Behcet's disease, Uveitis, Remission

M. Cosentino[1], I. Gandino[2], C. Pena[1], M. C. Baretto[2], A. Testi[1], B. M. Virasoro[3], L. Garcia[1], M. Scolnik[4], A. Ringer[5], C. Siegrist[5], B. Abdala[6], S. Chulibert[6], M. Dalpiaz[7], G. Rodriguez[1], A. Schlaen[8], C. Vanegas[8], C. Alanez[8], M. Heredia[8], M. García[1]. *[1]H.I.G.A. SAN MARTIN LA PLATA, Reumatologia, La Plata, Argentina*; *[2]Hospital General de Agudos Dr. Fernández, Reumatologia, Buenos Aires, Argentina*; *[3]Consultorio de enfermedades autoinmunes, autoinmunidad, Buenos Aires, Argentina*; *[4]Hospital Italiano de Buenos Aires, reumatologia, Buenos Aires, Argentina*; *[5]Clinica de medicina y laboratorio inmunológico especializado, autoinmunidad, santa fe, Argentina*; *[6]Hospital Provincial del Centenario, reumatologia, Santa Fe, Argentina*; *[7]Churruca, oftalmologia, JCP, Argentina*; *[8]Austral University Hospital, oftalmologia, Pilar Centro, Argentina*

Background: Behcet's disease (BE) is a systemic venous and arterial vasculitis of unknown etiology [1]. Ocular involvement is common, affecting 40-70% of patients [2], and is the main cause of morbidity. Uveitis is the most frequent common ocular clinical presentation, with a prevalence that can reach up to 90% of cases, affecting the anterior and posterior segments of the eye. Among 16-25% of the cases end in blindness, so early detection and treatment are essential [3].

Objectives: To describe the characteristics of uveitis in EB, extraocular manifestations, therapeutic lines used, and to compare the factors associated with uveitis remission to the first therapeutic scheme. In addition, evaluate the adherence to the EULAR 2018 recommendations.

Methods: Multicenter, observational, retrospective cohort study. Patients over 18 years of age with EB according to the 2014 ICBD criteria and uveitis according to the Uveitis Nomenclature Standardization Working Group (SUN). Disease remission was defined if the patient met the SUN criteria for ocular remission and if the rheumatologist did not have to change the immunosuppressant due to extraocular involvement.

Results: Fifty-five patients were included, 69.1% were men, with a mean age at diagnosis of 33.7 (SD 11.4) years old, mean age at uveitis presentation

of 37.1 (SD 19.6) years old, and a median follow-up of 2.5 (IQR 7.2) years. HLA-b51 was positive in 13/15 (86.7%). The most frequent presentation was panuveitis (49%), bilateral (69.1%) and chronic (59.6%) affectation; the first-line treatment was azathioprine (45%). According to the variables studied, acute presentations responded better to the initial therapeutic scheme (41% vs 8.3%, p 0.01) and a history of thrombosis was associated with greater refractoriness (16.7% vs 0%, p 0.03). Table 1 shows the comparison in terms of remission or refractoriness to the first therapeutic line. In relation to the year of uveitis diagnosis, 21 cases occurred after the publication of the recommendations, and adherence to the first line was observed in 66.7%. Also, a comparison was made to find out if the physician who adhered to the EULAR recommendations had a higher probability of remission, but this was not statistically significant (66.7% vs 42.9%; p 0.99). Sequelae were observed in 11/44 patients: 1 glaucoma, 3 retinal scars, 3 blindness, and 4 cataracts. The mean visual acuity of the right eye and left eye at the first visit was 6.8 (SD 3.6) and 6.6 (SD 3.7); and in the last visit, 7.4 (DE 3.5) and 7.1 (DE 3.4), respectively.

Table 1.

Characteristics	Refractory to the first scheme n= 24 (43.6%)	Remission with first scheme n= 31 (56.4%)	p value
Anterior. U, n (%)	6 (25)	12 (38.7)	0.28
Intermediate. U, n (%)	3 (12.5)	6 (19.3)	0.49
Posterior. U, n (%)	0	1 (3.2)	0.99
Panuveitis. U, n (%)	15 (62.5)	12 (38.7)	0.08
Bilateral, n (%)	19 (82.6)	19 (61.3)	0.13
Súbita, n (%)	14 (58.3)	7 (33.3)	0.09
Acute, n (%)	2 (8.3)	13 (41.9)	0.01
Chronic, n (%)	17 (70.8)	14 (45.16)	0.06
Recurrent, n (%)	5 (20.8)	1 (3.2)	0.07
Thrombosis, n (%)	4 (16.7)	0	0.03
Azathioprine, n (%)	14 (58.3)	13 (41.9)	0.22

Conclusion: In this multicenter cohort of patients with uveitis associated with EB, the most frequent form of presentation was panuveitis, as well as bilateral involvement and chronic forms. Approximately half of the patients achieved remission with the first therapeutic scheme line, regardless of the selected immunosuppressant. The acute forms could be associated with a higher probability of remission, while the history or presence of thrombosis would seem to be related to greater refractoriness. The therapeutic management presented high consistency with the current recommendations.

Background: Rituximab (RTX) is widely used in both remission induction and maintenance therapy for the new-onset ANCA-associated vasculitis (AAV)[1]. However, few studies have reported the efficacy and safety of RTX against relapsed AAV, especially in elderly patients.
Objectives: To clarify the effectiveness and safety of RTX as a remission induction therapy after relapse in elderly AAV.
Methods: We retrospectively extracted elderly (≥65 years) patients who relapsed granulomatosis with polyangiitis or microscopic polyangiitis and received remission induction therapy from J-CANVAS, a Japanese multicentre-cohort. The main exposure was the usage of RTX in the therapy. Clinical and laboratory variables at relapse and complete remission (CR) rates at week 24 and 48 after starting induction therapy were compared between patients treated with RTX (RTX group) and those with the other conventional immunosuppressive therapies (non-RTX group). The primary outcome was the CR rates at week 24, which was defined as Birmingham Vasculitis Activity Score (BVAS) version3 = 0. In addition, we performed a multivariate logistic regression analysis after adjusting for the potentially confounding factors of age, AAV-subtype, and ANCA-serotype. Patients whose data were missing at week 24 or 48 were treated as non-CR.

Results: A total of 71 patients were enrolled; 30(42%) in RTX group and 41(58%) in non-RTX group. Baseline characteristics were comparable between two groups as shown in Table1. The median age was 74 vs. 76 years with the PR3-ANCA positivity rate of 23% vs. 17%, and the median BVAS score was 11 vs. 12 points, respectively. The CR rate at week 24 was higher in the RTX group than in the non-RTX group [21(70.0%) vs 27(65.8%), p = 0.308)] and that at week 48 was significantly higher in the RTX-group [24(80.0%) vs 19(46.3%), p = 0.004)] (shown in Figure 1), with comparable doses of concomitant glucocorticoids. The adjusted odds ratios of RTX use for CR at week 24 and 48 were 1.09 (95%CI 0.38-3.10) and 4.01 (95%CI1.29-12.30). The incidence of serious infection was similar in both groups: [4(13.3%) vs 4(9.8%), p=0.638)].

Conclusion: RTX may be superior, with well tolerability, to the other conventional immunosuppressive therapies as an induction therapy in elderly patients with relapsed AAV.

INTRAVENOUS IMMUNOGLOBULIN IN ANTINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS. BIRMINGHAM VASCULITIS ACTIVITY SCORE OUTCOME IN THE DIFFERENT SUBTYPES

Keywords: Outcome measures, Vasculitis, Patient reported outcomes

F. Benavides-Villanueva[1], C. Corrales-Selaya[1], J. Loricera[1], V. Calvo-Río[1], S. Castañeda[2], J. M. Blanco Madrigal[3], N. Aviles Mendez[4], R. Blanco[1].

[1]Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; [2]Hospital de La Princesa, Rheumatology, Madrid, Spain; [3]Basurto University Hospital, Rheumatology, Bilbo, Spain; [4]Hospital Universitario Nuestra Señora del Perpetuo Socorro de Albacete, Rheumatology, Albacete, Spain

Background: Anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitis (AAV) includes granulomatosis with polyangiitis (GPA), Eosinophilic granulomatosis with polyangiitis (EGPA) and microscopic polyarteritis (MPA). AAV may be refractory to standard immunosuppressive treatment, that also may be accompanied by significant adverse events. Intravenous immunoglobulins (IVIG) may constitute a therapeutic alternative in these cases.

Objectives: To compare the effectiveness and safety of IVIG in the Birmingham Vasculitis Activity Score (BVAS) outcome on each type of clinical phenotype (GPA, EGPA and MPA).

Methods: Observational study of patients with AAV from a referral center treated with IVIG from January 2000 to December 2021. AAV diagnosis was based on a compatible clinical presentation, positive ANCA serology and/or histology. Disease activity was assessed with the Birmingham Vasculitis Activity Score (BVAS). All of them were measured at 1 month, 6 months, 1 and 2 years after IVIG onset. IVIG schedule was 2g/kg administered in 1-5 days.

Results: We included a total of 28 patients (13 females/15 males) with a mean±SD age of 57.1±18 years. The most frequent type of AAV was GPA (n=15, 53.6%), followed by MPA (n=10; 35.7%) and EGPA (n=3, 10.7%). The main features are summarized in **Table**. The reasons for using IVIG were: **a)** relapse or refractory disease (n=25); **b)** the presence (or suspicion) of infection (n=3); and **c)** both causes (n=5). The doses of IVIG were: 0.4 g/kg/day (5 days) (n=16), 0.5 g/kg/day (4 days) (n=8), and 1 g/kg/day (2 days) (n=4). There was an important, rapid and similar improvement on the BVAS score rate on each clinical phenotype **(Figure).** Three (10.7%) patients developed mild adverse events: headache (n=2), hypertension (n=1), and cutaneous rash (n=2). One patient developed congestive cardiac failure and had to stop the IVIG therapy.

Conclusion: IVIG are equally effective in AAV regardless of the vasculitis subtype.

FLOW CYTOMETRY ANALYSIS OF IMMUNE CELLS IN PATIENTS WITH BEHCET'S SYNDROME: A REAL-WORLD STUDY IN CHINA

Keywords: Real-world evidence, Behcet's disease

J. LI[1], F. Sun[1], W. Zhou[1], T. Liu[1]. [1]*Peking University People's Hospital, Department of Rheumatology and Immunology, Beijing, China*

Background: Behcet's syndrome (BS) is an autoimmune disease characterized by recurrent mucocutaneous ulcerations, vascular and nervous system involvement. While there have been a lot of researches proving that immune cells play a vital role in rheumatic disease, opinions on the effect of different immune cell subsets on BS is inconsistent. Therefore, we performed this real-world study to explore the role of immune cells in the pathogenesis of BS.

Objectives: To investigate the changes in the levels of several immune cell subsets in BS, and the correlation between the levels of different immune cell subsets and clinical features in patients with BS.

Methods: This is a retrospective, single-center study conducted in Beijing. 136 patients diagnosed with BS in rheumatology and immunology department of Peking University People's Hospital from 2018 to 2021 and 114 healthy controls (HCs) were enrolled. All patients met the International Criteria for Behcet's Disease (ICBD). We utilized flow cytometry to test the levels of $CD4^+$ T cells, $CD8^+$ T cells, B cells, NK cells and several subsets of $CD4^+$ T cells. Wilcoxon rank test and student's *t*-test were used and a P-value <0.05 was considered statistically significant.

Results: Compared to HCs, there is a decrease in the count of $CD4^+$ T cells, B cells and NK cells in BS patients. A significant increase in the frequency of IFN-γ, IL-2 and IL-4 producing $CD4^+$ T cell in BS patients were observed, which accompanied by a decreased frequency of Naïve $CD4^+$T cells. The frequency of $Foxp3^+$ Treg cells was notably increased while the proportion of CLA^+ Treg in Treg cells was significantly decreased in BS patients. BS patients' frequency of follicular helper T cells were apparently lower than HCs. There was a significant reduction of the frequency of Treg in patients with vascular involvement. The frequency of follicular helper T cells were positively correlated with joint involvement and negatively correlated with nerve involvement in BS patients. Patients with gastrointestinal involvement had a increased frequency of TNF-α, IFN-γ, IL-2 and IL-4 producing $CD4^+$ T cells and a decreased level of B cell count. Elevated level of NK cell count and decreased frequency of TNF-α, IL-2 producing $CD4^+$ T cells were found in patients with skin-mucosa involvement alone.

Conclusion: Our study confirmed that Th1 cells, Th2 cells, Treg cells, follicular helper T cells, B cells and NK cells contribute a lot to the pathogenesis of BS.

Background: Avacopan is a new approved treatment for granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA). Compared with glucocorticoids (GCs) added to standard immunosuppression with cyclophosphamide (CYC) or rituximab (RTX), avacopan proved to be non-inferior for treatment response at 26 weeks, whereas was found to be superior for sustaining remission at 52 weeks compared with a prednisone tapering schedule of 20 weeks [1].
Objectives: The aim of this prospective multicenter study was to assess efficacy and safety of avacopan in the real-life practice in GPA or MPA patients in the setting of a compassionate use program. A secondary objective was to describe the change in perceived quality of life before and during treatment.
Methods: We prospectively collected clinical and laboratory data of GPA and MPA patients who started treatment with avacopan from May 2022. Patients were recruited from Rheumatology/Nephrology Units belonging to the Vasculitis Study Group of the Italian Society of Rheumatology (SIR). At least 3 months of follow-up from start of treatment were required for data analysis. Clinical remission was defined as BVASv3 equal to 0. Patients self-completed the Italian version of the AAV-PRO questionnaire (AAV-PRO_ita) at baseline and after 3 months [2].
Results: A total of 12 patients (7 females, 5 males) with a median age of 64 (IQR 48-66.3) were recruited from 9 Italian Rheumatology/Nephrology departments. Avacopan was mainly used in relapsing disease (8/12, 66.7%) and in GPA (9/12, 75%), compared with new-onset disease (4/12, 33.3%) and MPA (3/12, 25%). The relapsed patients had a median disease duration of 12 (IQR 4.3-15.3) years and had been previously treated with other immunosuppressants, including RTX (5/8, 62.5%), CYC (5/8, 62.5%), AZA (3/8, 37.5%), MTX (2/8, 25%), and MMF (1/8, 12.5%). At the start of avacopan treatment, the median BVASv3 and VDI were 12 (IQR 8-20.8) and 2.5 (IQR 1.5-3.3), respectively. 9 out of 12 (75%) patients had renal involvement, of which 5/9 (55.6%) had rapidly progressive glomerulonephritis. Other disease involvements were ENT (5/12, 41.7%), and pulmonary (5/12, 41.7%), of which 3/5 (60%) patients had alveolar haemorrhage. Treatment was initiated with a median steroid dose of 50 (IQR 6.9-50) mg prednisone equivalent (PN-eq) and in combination with RTX at a dose of 1 gram every 2 weeks (9/12 75%) or 375 mg/m2 weekly for 4 consecutive weeks (3/12, 25%). Two patients also received 1 gram of CYC before RTX. After month 3, 10/12 (83.3%) patients were in clinical remission and the median steroid dose had decreased to 5 (IQR 2.2-10.6) mg PN-eq (**Figure 1**). The median value of creatinine did not differ from baseline (1.7 [IQR 1.3-2.4] mg/dL *versus* 1.8 [IQR 1.2-3.2] mg/dL), whereas the median value of 24-hour urine protein had decreased from 680.5 (IQR 408-2300) mg per day to 254 (IQR 169.5-488) mg per day. A total of 3 adverse events (AEs) were recorded: 1 urinary tract infection (AE grade 2), resulting in temporary suspension of avacopan, 1 herpes simplex infection and 1 dyspnea/fatigue that was self-limiting (AEs grade 1). Regarding the AAV-PRO_ita questionnaire, the percentage of the three higher severity levels in all domains had decreased from 57.2% at baseline to 31.8% at month 3. In particular, fatigue was reported by 80% of patients *versus* 55.6% of patients at baseline and at month 3, respectively.
Conclusion: Our study described the real-life practice of avacopan in GPA and MPA patients, especially relapsing patients. The clinical added value of avacopan as steroid-sparing strategy can be observed already in the early stages of therapy. Overall, avacopan appears to be an effective and safe adjunctive therapy in the active AAV.

UNILATERAL RELAPSING PRIMARY CENTRAL NERVOUS SYSTEM VASCULITIS: DESCRIPTION OF 3 CASES FROM A SINGLE INSTITUTIONAL COHORT OF 216 CASES

Keywords: Vasculitis

C. Salvarani[1], G. Hunder[2], C. Giannini[3], J. Huston III[4], R. Brown Jr[5]. *[1]Azienda USL-IRCCS di Reggio Emilia and Università di Modena e Reggio Emilia, Rheumatology, Reggio Emilia, Italy*; *[2]Mayo Clinic, Rheumatology, Rochester, United States of America*; *[3]Mayo Clinic, Anatomic Pathology, Rochester, United States of America*; *[4]Mayo Clinic, Radiology, Rochester, United States of America*; *[5]Mayo Clinic, Neurology, Rochester, United States of America*

Background: Some cases of unilateral primary central nervous system vasculitis (PCNSV) with relapsing disease involving the same brain hemisphere have been described [1].
Objectives: The aim of this study was to define the frequency and characteristics of patients with unilateral relapsing involvement in a large cohort of patients with PCNSV.
Methods: We retrospectively studied a cohort of 216 patients with PCNSV seen at the Mayo Clinic, Rochester, MN from 1983 to 2022. Data collected for all cases included comprehensive information about clinical findings, laboratory tests, imaging, CNS biopsy or autopsy, therapies, flares, follow-up functional status and cause of death. Cerebral biopsy specimens were reviewed by one neuropathologist (CG). Angiograms and MRIs were reviewed by a neuroradiologist. For the present study, we specifically identified those patients with at least two flares and imaging at diagnosis and at follow-up showing vasculitis confined to one cerebral hemisphere.
Results: Twenty-five patients (19.8%) had at least two flares. 3 of them (1.4%) had unilateral relapsing vasculitis. All 3 patients had angiography-negative and biopsy-positive PCNSV. One patient had amyloid beta-related angiitis (ABRA), while the other 2 patients had granulomatous-necrotizing and lymphocitic vasculitides, respectively. Hemisphere involvement occurred on the left in two, and on the right in one. In all three patients the main presenting clinical manifestation at diagnosis and at the time of flares was seizures. All had multiple flares (from 4 to 10) and were treated with different traditional immunodepressive drugs and rituximab (RTX) for the steroid-resistance. They received long-term treatment (more than 2 years) with fixed high-dose prednisone (PDN) (in one 40 mg/daily, in the other two 20 mg/daily) because the vasculitic process flared when the PDN dose was reduced. One patient had at MRI prominent leptomeningeal enhancement, while the other two had cerebral lesions with gadolinium enhancement. In all three patients the vasculitic process was confined to the same cerebral

hemisphere at diagnosis and during the flares, and at the last available brain MRI performed 35 months, 167 months, and 65 months after the diagnosis, respectively. All 3 patients at last follow-up had slight disability with mild cognitive impairment; one case also had mild left hemiparesis. Spinal fluid examination at diagnosis was normal in 2 patients.

Conclusion: Unilateral relapsing involvement represents a rare subset of PCNSV with peculiar characteristics and can be observed in all neuropathological patterns.

AB0791 EVALUATION OF THE EFFICACY AND COMPLICATIONS OF PLASMA EXCHANGE IN ANCA-ASSOCIATED VASCULITIS: RESULTS OF PROPENSITY SCORE MATCHING ANALYSIS IN HIGH-RISK PATIENTS

Keywords: Vasculitis

B. Ince[1], M. Bektas[1], B. Celik[2], S. Yüce[3], Y. Yalçınkaya[1], B. Artim-Esen[1], A. Gül[1], S. K. Besısık[4], M. Inanc[1]. Background: Therapeutic plasma exchange (PE) is applied in addition to standard induction therapy for patients with severe organ or system involvement in ANCA-associated vasculitis (AAV). However, prognostic significance of this approach is questioned.

Objectives: We aimed to evaluate both short- and long-term efficacy and safety of PE in our established single center cohort.

Methods: In this study, we evaluated the clinical and laboratory data of 128 patients diagnosed with AAV between 2011 and 2021. Data of patients with GFR <50 ml/min with or without diffuse alveolar hemorrhage (DAH) at the time of admission were included into the analysis. Disease activity, laboratory and follow-up data of patients who underwent PE were compared with those who did not. The analyses were repeated in the groups formed after the propensity score matching (PSM) performed according to the presence of DAH, age, gender, baseline GFR and BVAS scores.

Results: Seventy-one (55.5%) patients (F/M: 32/39, mean age± SD: 54.6±12.9) were included into the study. Thirty-nine (54.9%) patients had C-ANCA/PR3, 29 (40.8-%) patients had p-ANCA/MPO positivity. The mean follow-up was 53.6±34.7 months. In addition to high-dose corticosteroid treatment during induction therapy, IV cyclophosphamide (CYC) was used in 66 (92.9%) and rituximab was used in 3 (4.3%) patients. PE was applied in 33 (46.5%) patients. All patients who underwent PE had received CYC for induction. The median number of PE sessions was 7 (2-12). Fresh frozen plasma was used in 22 patients (66.6%) and albumin was used in 11 patients (33.3%). In patients who underwent PE, DAH and GFR<50ml/min were present in 20(28.2%) and 64(90.1%) patients, respectively. Hypotension in 3 patients, hypocalcemia in one, catheter-related thrombosis in one and transfusion reactions in 2 patients were recorded as short-term complications. In patients who underwent PD, the remission rate was low in the sixth month, and the development of severe infections and ESRD was high in the first year (Table 1). In the PSM analysis, creatinine values during the follow-up were higher in the patients who underwent PE. In both analyses, remission rates were lower in the PE group at six months, and the number of serious infections, ESRD development, and total VDI score were higher at twelve months.

Conclusion: In this retrospective study, positive effect of PE on remission and mortality in AAV could not be demonstrated. Efficacy against the development chronic renal failure and ESRD was also not observed. Despite low short-term complication rates related to PE, increased risk of severe infection which became evident with PSM analysis, was remarkable. In conclusion, these findings raise concern and should lead to careful patient selection for PE. Although an important therapeutic option for AAV patients with severe disease, limited long term benefits should be well balanced with risks.

AB0792 ADULT-ONSET IGA VASCULITIS WİTH RENAL INVOLVEMENT

Keywords: Vasculitis, Kidneys, Prognostic factors

F. Yıldırım[1], M. E. Kutu[2], Y. Çalık[2], S. Çelik[2], C. Bes[1]. [1]*University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Rheumatology, Istanbul, Turkey*; [2]*University of Health Sciences, Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Rheumatology, Istanbul, Turkey*

Background: Systemic Immunoglobuline A vasculitis (IgAV) often presents glomerulonephritis accompanying palpable purpura. Unlike children, renal involvement can be severe in adults. Especially, in the chronic period, renal involvement determines the prognosis. A significant proportion of the patients initially have pathological renal findings, while pathological renal findings may occur later in some patients.

Objectives: It was aimed to compare the clinical features of patients with renal involvement at the beginning and those with subsequent renal involvement, to determine the predictors of renal involvement and to determine the factors affecting renal prognosis.

Methods: A total of 42 adult patients with IgA vasculitis nephritis with followed between January 2018 and August 2022 in two tertiary hospitals were included in the study. The patients were divided into 2 groups as those with and without IgA vasculitis nephritis findings at the beginning. Patients' clinical and laboratory data were collected at baseline and at follow-up. and were analyzed retrospectively.

Results: Thirty (%71) of 42 patients had signs of IgA vasculitis nephritis at baseline and 12 (%29) patients, signs of nephritis appeared later. The median time between first visit and development of nephritis was 18 [IQR:6-44] days in patients whose nephritis findings appeared later. In the binary logistic regression analysis, it was determined that gastrointestinal involvement at the baseline predicted the later development of renal involvement [OR:9,399, 95% CI=1,800-49,079, p = 0,009]. Comparative results of the 2 groups with and without IgA vasculitis nephritis findings at baseline in terms of clinical features are presented in Table 1.

Table 1 : Comperative characteristics of patients presented with and without renal findings

	Patients with renal findings at initially N=30	Patients without renal findings at initially, N=12	*P*-value

S.D.: Standard Deviation**Gfr:** Glomerular filtration rate**Crp:** C-reactive Protein**ESR:** Erythrocyte Sedimantation Rate**IgA:** Immunoglobuline A

Conclusion: A significant proportion of patients with IgA vasculitis who do not have pathological renal findings at baseline may appear glomerulonephritis findings in the later follow-up period. Clinicians should be careful in terms of renal involvement. Similar to previous studies, our study revealed that gastrointestinal involvement is a risk factor for renal involvement.(1,2) Patients with initial gastrointestinal symptoms but no pathological renal findings should be followed more frequently and regularly.

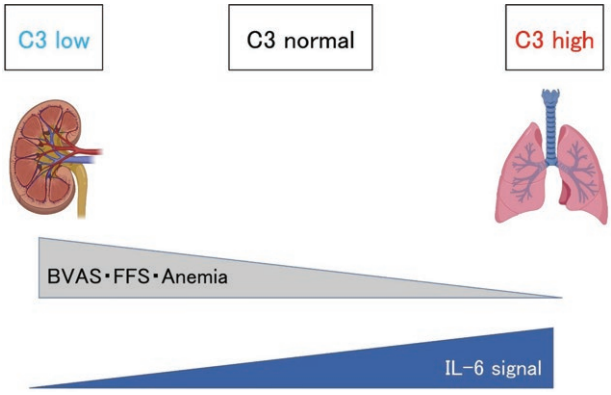
SERUM C3 LEVELS ARE ASSOCIATED WITH DISEASE PATHOLOGY IN MICROSCOPIC POLYANGIITIS: RESULTS FROM THE REVEAL COHORT

Keywords: Real-world evidence, Vasculitis

R. Watanabe[1], T. Gon[1], S. Matsuda[2], A. Okazaki[2], A. Manabe[3], M. Shoji[3], K. Kadoba[3], W. Yamamoto[4], R. Hiwa[3], T. Kotani[2], M. Hashimoto[1]. *[1]Osaka Metropolitan University Graduate School of Medicine, Department of Clinical Immunology, Osaka, Japan*; *[2]Osaka Medical and Pharmaceutical University, Department of Internal Medicine (*IV*), Osaka, Japan*; *[3]Graduate School of Medicine, Kyoto University, Department of Rheumatology and Clinical Immunology, Kyoto, Japan*; *[4]Kurashiki Sweet Hospital, Department of Health Information Management, Kurashiki, Japan*

Background: Recent studies have shown that complement C5a receptor antagonist is highly effective for treating microscopic polyangiitis (MPA), suggesting that complement is substantially involved in the pathogenesis.

Objectives: In this study, we aimed to examine whether serum C3 levels were associated with clinical characteristics, disease severity, treatment, and prognosis in the Japanese multicenter cohort.



Methods: Patients with MPA whose C3 levels were measured at diagnosis were enrolled. The diagnosis of MPA was based on the 2012 revised Chapel Hill consensus criteria. Patients were divided into three groups: low C3 (<86 mg/dL), normal C3 (86-130 mg/dL), and high C3 (>130 mg/dL) groups to compare clinical characteristics. Analysis of variance or the Kruskal–Wallis test was used when the variates were numeric, while the chi-squared test or Fisher's exact test was used when variates were categorical.

Results: A total of 158 patients (low C3: 28, normal C3: 90, high C3: 40 patients) were enrolled. Baseline characteristics did not differ between the three groups in age at onset, sex, smoking history, and MPO-ANCA positivity. Serum C3 levels (P<0.001) as well as C4 (P<0.001) and CH50 levels (P=0.0013) were significantly lower in the low C3 group. In addition, hemoglobin (P=0.0058), platelets (P<0.001), and serum CRP levels (P=0.002) were significantly lower in the low C3 group, while serum creatinine levels (P=0.001), BVAS (P=0.039), and five factor scores (P=0.005) were significantly higher in the low C3 group. Notably, the proportion of patients who fulfilled the 2022 revised ACR/EULAR classification criteria for MPA was significantly lower in the low C3 group (P=0.039). Initial prednisolone dose and survival did not differ between the three groups.

Conclusion: Low C3 levels are associated with severe disease and renal dysfunction, while high C3 levels are associated with elevated CRP levels. Serum C3 levels are closely associated with disease pathology.

A PROSPECTIVE STUDY ON RENAL INVOLVEMENT IN INDIAN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

Keywords: Outcome measures, Real-world evidence, Vasculitis

S. Ghosh[1], K. Telang[1], L. Sharma[1], G. Ekbote[1], D. Tanna[1], S. Dhuria[1], V. Singal[1], R. Gupta[1]. *[1]Medanta - The Medicity, Rheumatology & Clinical Immunology, Gurgaon, India*

Background: The ANCA-associated vasculitides (AAV) are systemic autoimmune diseases affecting small and medium-sized blood vessels. Upper airways, lungs, and kidneys are variably involved in the different types of AAV, and the consequences of a missed or delayed diagnosis of renal vasculitis are potentially life-threatening. AAV may be classified into clinical syndromes or based on their serology (Anti-PR3 or Anti-MPO). Patient survival and the risk of end-stage renal disease are closely associated with renal functional status.

Objectives: This study was undertaken to study the disease characteristics and outcomes in patients of AAV based on the presence or absence of renal involvement.

Methods: This was a longitudinal, observational study conducted at a tertiary care hospital in Northern India. Between February 2020 and December 2021, all consecutive adult patients diagnosed with AAV based on their autoantibody profiles (using indirect immunofluorescence and Line ImmunoAssay) and clinical features were included in this study after taking their informed consent. Demographic details, clinical features, laboratory parameters, disease activity, and mortality or morbidity outcomes of patients were analysed prospectively. All outcomes were compared between patients with and without renal involvement.

Results: A total of 112 patients were included in our study, with a median age of 51.5 years. 74 (66%) patients had renal involvement either in the form of Nephritic

syndrome, Nephrotic syndrome, RPRF (Rapidly progressive renal failure), Nephritic nephrotic syndrome, or Asymptomatic Urinary Sediments. c-ANCA and PR3 positivity were seen in more than two-thirds of our population, without any significant correlation with organ involvement. Patients with renal disease had a significantly higher proportion with diffuse alveolar haemorrhage (32.4% vs 10.5%, p=0.05) and palpable purpura (19.6% vs 7.9%, p-0.025), but significantly lower occurrences of nasal pathology (14% vs 42%, p=0.001) and subglottic stenosis (1.4% vs 18.4%, p=0.001). Mean BVAS at enrolment was significantly higher in the renal group (20.9 vs 12.89). Remission was achieved in 50% and 47.4% of the patients with and without renal involvement respectively. Rates of relapse (19/74 vs 14/38), refractory disease, and mortality were not significantly different among the two subgroups. The commonest organ involvement in disease flare was pulmonary involvement. 21.6% of the patients developed CKD over a median follow-up period of 18 months.

Conclusion: Kidney involvement is one of the commonest manifestations of AAV. Patients with renal involvement may have higher mean BVAS scores and an increased risk of developing alveolar haemorrhage and purpuric skin rash; while nasal pathology and subglottic stenosis occurred more frequently in patients without renal disease. Rates of remission, refractory disease, and mortality were almost similar, regardless of renal involvement, while relapses were numerically more in the non-renal AAV patients.

AB0795 MPO-ANCA ANTIBODIES: ASSOCIATED DISEASES, SPECIFICTY, AND RELATION WITH SEVERITY AND PROGNOSIS OF UNDERLYING VASCULITIS. STUDY FROM A SINGLE UNIVERSITY HOSPITAL

Keywords: Autoantibodies, Vasculitis

S. Al Fazazi[1], V. Calvo-Río[2], M. Renuncio García[3], M. Rodriguez Vidriales[4], C. Escagedo Cagigas[4], J. Irure-Ventura[3], L. Martín-Penagos[4], M. Lopez-Hoyos[3], R. Blanco[2]. *[1]Hospital Universitario Puerta del Mar, Rheumatology, Cadiz, Spain*; *[2]Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; *[3]Marqués de Valdecilla University Hospital, Immunology, Santander, Spain*; *[4]Marqués de Valdecilla University Hospital, Nephrology, Santander, Spain*

Background: Anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) include Granulomatosis with polyangiitis GPA), Microscopic polyangiitis (MPA), and Eosinophilic granulomatosis with polyangiitis (EGPA). Anti-myeloperoxidase (anti-MPO) or anti-proteinase 3 are the two main ANCA subtypes. Anti MPO specificity and correlation with the severity and prognosis of underlying vasculitis is contradictory [1].

Objectives: To assess, in patients with positive anti-MPO, **a)** associated diseases, **b)** specificity in diagnosing AAV and, **c)** relation with severity and prognosis of underlying vasculitis in a single university hospital.

Methods: Study of patients with positive anti-MPO from a University Hospital, from 2003 to 2022. ANCA was determined by standard inmunohistochemistry. The specificity of anti-MPO for diagnosis and relation with severity and prognosis of underlying vasculitis were evaluated with Receiver Operating Characteristics (ROC) curves. At diagnosis severe AAV were considered cases with renal disease (hematuria and/or proteinuria) and pulmonary involvement. In follow-up, worst prognosis was considered if the patient needed dialysis, a transplant or died.

Results: We study 101 patients with positive anti-MPO. **Table** summarizes the prevalence of these antibodies in vasculitis and non-vasculitis diseases. Most of them (76.23%) had an underlying AAV, being the most frequent MPA (33.7%). The non-vasculitis disease more frequent was neoplasm (4,9%). For anti-MPO antibodies with a diagnosis of AAV (n=77), an area under the curve (AUC) was calculated (AUC=0.8084), and a cut-off point of 41.5 IU/ml was determined (**Figure**). When the analysis was restricted to exclusively MPA (n=34), the cut-off point was 36.5 IU/ml with an AUC of 0.6435. For severity of AAV, there were significant differences in anti-MPO levels between patients with renal or pulmonary dysfunction (n=65) versus those without them (n=36) (p=0.0003), and a cut-off threshold of 60 IU/ml was established. Finally, after evaluating the illness's prognosis, an AUC= 0.5546 was found, being no significant differences between those patients who had a worse disease progression (n=19) and those who did not (n=82) (p=0.4643).

Conclusion: MPO antibodies levels, at the moment of diagnosis, may be associated to AAV diagnosis (specificity) and severity but not with disease outcome.

Background: In 2020, the Canadian Vasculitis Research Network (CanVasc) published their updated recommendations for the management of antineutrophil cytoplasm antibody (ANCA)-associated vasculitides (AAV). Since then, clinical data on the complement C5a receptor inhibitor avacopan (formerly, CCX168) has continued to expand.

Objectives: The current addendum provides further recommendations regarding the use of avacopan in AAV based on a review of newly available evidence.

Methods: An updated systematic literature review on avacopan using Medline, Embase, and the Cochrane Library was performed for publications up to September 2022. New recommendations were developed and categorized according to the EULAR grading levels, as done for previous CanVasc recommendations. A modified Delphi procedure and videoconferences were used to reach ≥80% consensus on the inclusion, wording and grading of each recommendation.

Results: Three new recommendations were developed. They focus on avacopan therapy indication and duration, as well as timely glucocorticoid tapering.

Conclusion: These 2022 addended recommendations provide rheumatologists, nephrologists, and other specialists caring for patients with AAV with guidance for the use of avacopan, based on current evidence and consensus from Canadian experts.

AB0797

ABSTRACT TITLE: OCULAR INVOLVEMENT AS AN INITIAL PRESENTATION IN SYSTEMIC VASCULITIS: AN OBSERVATIONAL STUDY

Keywords: Uveitis, Vasculitis, Behcet's disease

R. H A Mohammed[1], D. Hassan Attia[1]. [1]*School of Medicine- Cairo University, Rheumatology and Rehabilitation, Cairo, Egypt*

Background: Systemic Vasculitides are a heterogenous group of immune mediated vascular inflammatory pathologies that contributes to vessel wall necrosis and damage. Ocular manifestation with systemic vasculitides isn't uncommon as an initial presentation. Identifying the patterns of ocular involvement associated with a specific diagnosis of vasculitis might guide the diagnosis at early encounter, while if underdiagnosed or improperly treated might contribute to devastating complications [1-3].

Objectives: to survey the patterns of ocular manifestations as the initial presentation in a population of patients with systemic vasculitides.

Methods: This is an observational cohort study in which data regarding ocular involvement were retrieved from medical records. The inclusion criteria: medical records of adult patients > 18 years with the diagnosis of any form of vasculitis according to the internationally recognized criteria having ocular involvement as confirmed by an expert ophthalmologist. Exclusion Criteria: patients with additional diagnosis whether endocrinal, metabolic, neoplastic and infectious diseases.

Results: The study included a total of 328 patients with the different diagnoses of vasculitis (68.9% males and 31.1% females, their mean ages were 38.58± 11.96 years, mean disease duration of 65.35±75.84 months). Figure 1 Ocular involvement was reported in 46% of the included cases with vasculitis at initial encounter, uveitis was diagnosed in 31.1% (7.3% anterior uveitis, 10.7% posterior uveitis, 13.1% pan uveitis), optic neuritis in 3.5%, retinal vasculitis in 17%, retinal artery thrombosis was reported in 1.8%, retinal vein thrombosis in 5.4%, orbital pseudotumor in one patient with granulomatosis with polyangiitis, scleritis one patient and episcleritis one patient with granulomatosis with polyangiitis. Ocular involvement was found in 61.3% of cases with BD (uveitis in 48.2%, retinal vasculitis in 18.4) at initial encounter with uveitis being the most common.

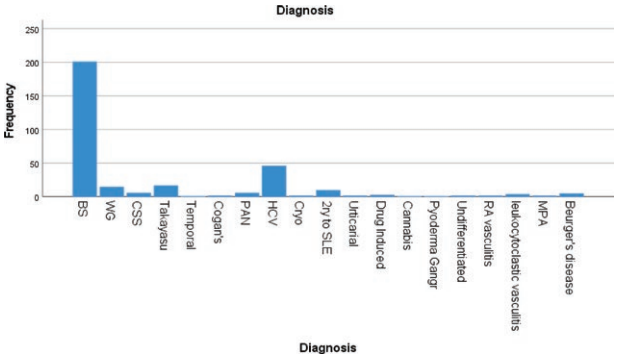

Figure1 : The Frequency of the different diagnoses of vasculitis in the Study population.

Conclusion: The patterns of ocular involvement at initial presentation might guide the diagnosis of one form of vasculitis over the other especially with incomplete forms.

AB0798 PREVALENCE AND CLINICAL SPECTRUM OF CARDIAC INVOLVEMENT IN BEHÇET'S SYNDROME: A SINGLE CENTER RETROSPECTIVE STUDY

Keywords: Cardiovascular disease, Behcet's disease, Heart

F. Bello[1], A. Bettiol[1], E. Silvestri[1], D. Malandrino[1], A. Palermo[1], M. L. Urban[1], R. Mazzotta[1], I. Costanzo[1], I. Mattioli[1], G. Emmi[1]. [1]*University of Florence, Experimental and Clinical Medicine, Firenze, Italy*

Background: Behçet's Syndrome (BS) is a systemic vasculitis, which main clinical features include mucocutaneous manifestations, pan-uveitis, non-deforming arthritis, thrombosis, central nervous system (CNS) and gastrointestinal (GI) involvement [1].
Despite being increasingly recognized as part of the clinical spectrum in BS [2,3,4], cardiac involvement has not been systematically described.
Objectives: To investigate the prevalence and clinical spectrum of cardiac manifestation in a cohort of BS patients.
Methods: Three hundred and twelve patients were retrospectively studied. All patients fulfilled the International Classification Criteria for BS [5]. Demographic, clinical, therapeutic features, and specific data on cardiac involvement were collected.
Results: Cardiac involvement was observed in 46 out of 312 patients (13.2%). The mean age at cardiac involvement diagnosis was 43 years (SD ± 13.2). Mean BS duration before cardiac manifestation onset was 5.35 years (SD ± 6.86). Female to male ratio was 1.42. Among 46 patients with cardiac involvement, 37 (80.4%) displayed a single manifestation, while 9 (19.5%) showed two or more cardiac events. BS related cardiac lesions included arrhythmias (n=12; 26%), pericarditis (n=12; 26%), ischemic heart disease (n=7; 15%), acute myocarditis (n=5; 10.8%), valvular abnormalities (n=8; 17.3%), and pulmonary hypertension (n=2; 4.3%) **(Figure 1)**. Thirteen patients (28.2%) had cardiac abnormalities classified as "other", which included patent foramen ovale, Takotsubo syndrome, cardiac amyloidosis, and aortic root aneurysm **(Figure 1)**. After the first event, remission of cardiac manifestations was achieved by all patients. Cardiac relapse occurred in 9 patients (19.5%), due to recurrent pericarditis (n=7), myocarditis (n=1), and arrhythmic manifestation (n=1). Overall clinical manifestations of BS are shown in **Table 1**. Muco-cutaneous manifestations were present in almost all patients, specifically oral aftosis was present in 45/46 (98%), genital aftosis in 26/46 (56.5), and skin manifestations in 35/46 (76%). A significant proportion of patients displayed vascular involvement (n=20; 43,4%), CNS involvement (n=20; 43.4%), and GI involvement (n=32; 69.5%). At the time of cardiac events 21/46 (45.6%) patients were receiving oral corticosteroids, 16/46 (34.7%) were receiving colchicine, 13/46 (28.2%) were receiving a traditional DMARD, while 19/46 (41.3%) were receiving a biologic DMARD **(Table 1)**.
Conclusion: Our study indicates that cardiac events are a fairly common manifestation in BS patients, pointing out the need for a routine screening of such involvement. As previously described [2], our study suggests the association between cardiac abnormalities and vascular involvement in BS. Furthermore, we found a significant proportion of patients presenting with other major organ manifestations, such as CNS and GI involvement, suggesting that cardiac involvement may reflect a more severe and systemic disease course.

AB0799 ASSOCIATION BETWEEN MUSCLE QUALITY AND MORTALITY IN PATIENTS WITH ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

Keywords: Vasculitis

J. W. Ha[1], S. S. Ahn[1], Y. Park[2], S. Lee[2]. [1]*Yongin Severance Hospital, Yonsei University College of Medicine, Internal Medicine, Yongin, Korea, Rep. of (South Korea)*; [2]*Yonsei University College of Medicine, Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Decreased muscle mass is frequently observed in patients with autoimmune rheumatic diseases; however, the relationship between muscle quality and patient outcomes has not been well understood.
Objectives: This study evaluated the influence of muscle quality on the outcomes of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV).
Methods: Records of patients with AAV (microscopic polyangiitis, granulomatosis with polyangiitis, and eosinophilic granulomatosis with polyangiitis) at the Severance Hospital having computed tomography (CT) images at disease diagnosis were retrospectively reviewed. For muscle quality measures, normal attenuation muscle area (NAMA), low attenuation muscle area (LAMA), total abdominal muscle area (TAMA), and intramuscular adipose tissue (IMAT) in the axial muscles of the middle third lumbar vertebra level was calculated. Correlations between NAMA, LAMA, and IMAT and patient characteristics and outcomes were assessed.

Results: A total of 136 patients with CT images at AAV diagnosis were identified. Correlation analyses revealed that age, female sex, total cholesterol, and alanine aminotransferase were significantly associated with NAMA. LAMA was associated with age, body mass index (BMI), five-factor score (FFS), and C-reactive protein, while a relationship between IMAT and age and BMI was observed. Cox-proportional hazard analysis demonstrated that NAMA/TAMA≤0.46 (odds ratio [OR] 5.612, 95% confidence interval [CI] 1.758-17.909, p=0.004), female sex (OR 0.228, 95% CI 0.075, 0.684, p=0.008), dyslipidemia (OR 3.819, 95% CI 1.380, 10.571, p=0.010), and FFS (OR 2.160, 1.298-3.595, p=0.003), were independent factors associated with mortality.
Conclusion: Higher mortality was observed in patients with AAV with NAMA/TAMA ≤ 0.46, indicating that cautious monitoring is required in these patients.

AB0800 EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS CLINICAL MANIFESTATIONS AND OUTCOMES: A RETROSPECTIVE COHORT ANALYSIS OF 38 PATIENTS FROM RUSH UNIVERSITY MEDICAL CENTER CHICAGO, IL, USA

Keywords: Prognostic factors, Organ damage, Vasculitis

M. Orentas[1], Y. Zhang[2], J. Fair[1], A. Bukiej[1]. *[1]RUSH University Medical Center, Rheumatology, Chicago, United States of America*; *[2]RUSH University Medical Center, Biostatistics, Chicago, United States of America*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is the rarest anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis according to incidence and prevalence reports in the literature [1]. Typical manifestations include obstructive airway disease, nasal polyps, mononeuritis multiplex, eosinophilia, and eosinophilic-predominant inflammation on biopsy [2]. Studies have been published that describe the clinical manifestations and disease outcomes but these are limited [3]. Further studies are necessary to better understand this disease.
Objectives: This study characterized the clinical manifestations and outcomes of a cohort of Rush University Medical Center (RUMC) patients with EGPA.
Methods: Retrospective cohort analysis of EGPA patients at RUMC from 1/1/2010-12/31/2021. Clinical characteristics, treatment, and outcome were analyzed, using Fisher's Exact Test and Chi-Square Test to perform comparisons.
Results: This cohort included 38 patients with EGPA. 55% were female, 68% were Caucasian, and mean age at diagnosis was 57.7 (+/- 16.3). 95% had pulmonary involvement. 37% were (ANCA) positive. There was no statistically significant difference in clinical characteristics, treatment strategies, or outcomes when comparing ANCA positive to ANCA negative patients.
Conclusion: This analysis describes the clinical characteristics, treatment, and outcomes of a cohort of RUMC patients with EGPA. Prevalence of pulmonary involvement and ANCA positivity was similar to that reported in the literature. Unlike previous studies which reported higher prevalence of neurologic and kidney involvement in ANCA positive EGPA patients our study did not find a statistically significant difference in characteristics of ANCA positive patients when compared to ANCA negative patients.

AB0801 NEW DIAGNOSTIC TOOL IN BEHCET'S DISEASE

Keywords: Behcet's disease

C. Soliz[1], J. A. Brigante[1], J. Rebak[1], L. L. Holguín Arias[1], L. Sorrentino2, G. Gómez2, A. Hamaui2, D. Dubinsky2. *[1]Sanatorio Guemes, Rheumatology, Buenos Aires, Argentina*; *[1]Sanatorio Guemes, Rheumatology, Buenos Aires, Argentina*

Background: Behcet's disease (BD) is characterized by oral, genital, and gastrointestinal manifestations. The pathergy test is used as a diagnostic tool, but this is not specific to BD, since it can be found in other diseases and can equally be negative even having the disease. Another characteristic of BD is the vascular compromise, predominantly venous. In a study, the measurement of the thickness of the common femoral vein (CVF) proved to be a diagnostic test with sensitivity and specificity greater than 80% for the cut-off value of 0.5 mm.
Objectives: To evaluate the diagnostic performance of the thickness of the posterior wall of the common femoral vein, measured by Doppler ultrasound for the diagnosis of Behcet's disease.
Methods: A multicenter pilot study was carried out to evaluate a diagnostic test. Data were collected by reviewing medical records collected from patients who met the 2014 International Criteria for Behcet's Disease (ICBD), and healthy controls. Venous Doppler ultrasound of the lower limbs was performed in both groups using an ultrasound evaluation protocol, considering posterior wall thickness of the CFV ≥ 0.5 mm as positive.
Results: 19 patients with EB and 19 healthy controls were included. The mean age of patients with DB was 47 (SD 12.6), and the median age of healthy patients was 41 years (IQR 36.5-48.5). 57.89% were mestizo in the BD group and 68.42% in the control group. The median delay in diagnosis was 19 months (IQR 11-36). The presence of HLA B51 was 63.15% and the positive pathergy test was found in 31.57%. At the time of the study, 42.10% had disease activity and a mean of 8.8 years of disease. (Table 1) The ultrasound was positive in 89.4% of patients with BD and 10.5% in the healthy group, observing a sensitivity of 94.1% and a specificity of 94.7%, with an area under the curve 0.89 ($p < 0.0001$), PPV 94.1% and NPV 94.7%. (Fig. 1) We observe a post-test probability of 0.059. The test presents LR + 17.8 (95%CI 2.5-127) and LR - 0.06 (95%CI 0.008-0.4)
Conclusion: The diagnosis of Behcet's disease is difficult because it is based mainly on clinical manifestations, so this ultrasound test has a good capacity to be used as part of the diagnosis in patients with clinical suspicion, since it has a good sensitivity and specificity profile, low cost and simplicity.

PRESENCE OF EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS IN PATIENTS WITH NASAL POLYPS AND ASTHMA. STUDY OF A SINGLE REFERRAL CENTER

Keywords: Vasculitis, Outcome measures, Biomarkers

F. Benavides-Villanueva[1], J. Loricera[1], V. Calvo-Río[1], R. Blanco[1]. [1]*Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is included in anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV). It mainly affects patients with asthma, sinusitis, allergic rhinitis, and nasal polyposis.
Objectives: To assess **a)** prevalence of clinical features of EGPA in patients with clinical history of nasal polyps and asthma, and **b)** proportion of positive ANCA (+ANCA) test in those patients.
Methods: Retrospective study of patients with clinical history of asthma and nasal polyps with histologic study from a referral center between 2021 and 2022. The measurement of ANCA were performed by chemiluminescence assay using IO-FLASH (Inova, San Diego, CA). Diagnosis of EGPA was based on ACR/EULAR 2022 criteria [**1].** Disease activity was assessed with Birmingham Vasculitis Activity Score (BVAS). All biopsies of nasal polyps were examined by the same expert pathologist to assess the presence of eosinophil aggregates.
Results: A total of 123 biopsies with eosinophil aggregates were studied between 2021 and 2022. Twenty-three patients (19%) had history of asthma. Of them, we objectified EGPA criteria in 12 patients (10% of the series of 123 patients). General features of these 12 patients are summarized in **Table**. Seven patients had more than 20 eosinophil aggregates per field in polyp biopsy. The median [IQR] BVAS score was 0[0-0]; just 2 patients showed activity measured by BVAS score (with a mean of 3 points). ANCA test was positive in 1 (8.3%) patient.
Conclusion: According to data from our series, approximately 10% of patients with nasal polyps with biopsy meet EGPA criteria.

ANCA-ASSOCIATED VASCULITIS (AAV) AND RENAL DISEASE IN A MULTIDISCIPLINARY OUTPATIENT CLINIC IN NORTHERN SPAIN

Keywords: Vasculitis, Kidneys

V. Calvo-Río[1], S. Al Fazazi[2], M. Rodriguez Vidriales[3], C. Escagedo Cagigas[3], M. Renuncio-García[4], L. Martín Penagos[3], D. Prieto-Peña[1], J. Irure-Ventura[4], C. Álvarez-Reguera[1], G. Fernández Fresnedo[3], E. Rodrigo-Calabia[3], J. C. Ruiz-San Millán[3], R. Blanco[1]. [1]*Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; [2]*Hospital Puerta Del Mar, Rheumatology, Cádiz, Spain*; [3]*Marqués de Valdecilla University Hospital, Nephrology, Santander, Spain*; [4]*Marqués de Valdecilla University Hospital, Immunology, Santander, Spain*

Background: The severity of clinical features and outcomes in previous series of patients reported with renal disease related to ANCA-associated vasculitis (AAV) vary greatly, probably due to selection bias.
Objectives: To establish the actual clinical spectrum of renal disease due to AAV in a multidisciplinary outpatient clinic in Northern Spain.
Methods: Review of 132 patients classified as having AAV between 1994 to 2022; Granulomatosis with polyangiitis (GPA), Microscopic polyangiitis (MPA) or Eosinophilic Granulomatosis polyangiitis (EGPA) was classified according to 2022 ACR/EULAR classification criteria.

Results: Renal disease was observed in 82 of 132 (62.1%) AAV (38 men/44 women), median age 61.37 years (24-87 years). **Table** reflects the main clinical findings and outcomes. Renal biopsy was performed in 44 patients (36 patients showing a pauci-immune crescentic glomerulonephritis). The remaining 38 patients were not biopsied due to patient disagreement, mild renal disease or contraindication for biopsy. The most frequent ANCA antibody specificity was MPO (64.6%) followed by PR3 (26.8%) and double positivity in 3 patients (2 MPO and PR3 and 1 MPO and MBG). 43 patients were classified as MPA (52.4%), of those, 18 patients (21.9%) had renal limited vasculitis, 27 GPA (32.9%), and 4 EGPA (4.9%). The rest of the patients had other renal disease (5 microhematuria, 1 amyloidosis, 1 diabetes nephropathy and 1 nephroangiosclerosis). Nephritic syndrome was the most common renal manifestation when the vasculitis was fully established (56.1%). The most frequent therapies used were corticosteroids (68.3%), Cyclophosphamide (46.3%), Azathioprine (35.4%), Rituximab (34.1%) and mycophenolate mofetil (23.2%). After a median follow-up of 6.23 years (7 days-22.9 years) the last median creatinine and glomerular filtration rate (GFR) was 1.4 mg/dl and 43 ml/min, respectively. Renal function worsened compared to baseline in 78.3% of MPO positive and only in 33% of PR3 positive (p=0.005). During the first 12 months follow-up, stabilization or normalization GFR (median GFR at 1 year: 50 ml/min) was observed in 47.1% with no statistical differences among ANCA groups (p=0.303). Renal outcome at the end of follow-up was poorer in MPA than GPA or EGPA (76.3%, 47.4% and 50% respectively worsened GFR from baseline). 16 patients (19.5%) needed dialysis at any moment. Total remission was achieved in 25 patients (30.5%) while relapses were observed in 17 patients (20.7%). Severe infectious was the main severe side-effect, reported in 26 patients (31.7%).

Conclusion: Most AAV patients had some grade of renal disease during follow-up and almost 20% ended up needing dialysis. Therefore this multi-systemic disease should be managed in a multidisciplinary way to establish an early diagnosis and adequate treatment, limiting chronic disease.

AB0804 THE PERFORMANCE OF ACR 1990 AND ACR/EULAR 2022 CRITERIA IN THE DIAGNOSIS OF GPA AND EGPA

Keywords: Vasculitis

P. Migliorini[1], L. Puccetti[1], M. Mantellassi[1], M. Moretti[2], A. Tavoni[1], C. Baldini[2]. *[1]University of Pisa, Clinical Immunology Unit, Dept of Clinical and Experimental Medicine, Pisa, Italy*; *[2]University of Pisa, Rheumatology Unit, Dept of Clinical and Experimental Medicine, Pisa, Italy*

Background: ANCA-associated vasculitis (AAV) are systemic disorders with involvement of multiple organs that may lead to severe damage. An early diagnosis and often an aggressive treatment is necessary to preserve organ function, but the diagnosis can be difficult at disease onset when non-specific symptoms are predominant.

To address this issue, classification criteria have been developed in 1990 and recently updated.

Objectives: To evaluate the performance of ACR 1990 and ACR/EULAR 2022 criteria in the diagnosis of GPA and EGPA.

Methods: Patients with certain or suspected diagnosis of EGPA and GPA, followed in the Rheumatology and Clinical Immunology units, have been selected for the study. Concordance has been evaluated by means of the K Cohen coefficient.

Results: Out of 50 patients with the diagnosis of GPA, 36 (72%) fulfill the ACR 1990 criteria and 41 (82%) the ACR/EULAR 2022 criteria. Out of 31 patients with the diagnosis of suspected GPA, 17 (55%) fulfill the ACR 1990 criteria and 16 (52%) the ACR/EULAR 2022 criteria. Concordance is low (K=0,1). Analyzing discordant cases, 14 patients positive only for 1990 criteria have lung involvement and in half of the cases renal involvement. Eighteen patients positive only for 2022 criteria have anti PR3 ANCA, one third nasal involvement, one third lung involvement. This reflects the higher weight of pathology, renal and lung involvement in 1990 criteria, the weight of ANCA positivity and upper airway involvement in 2022 criteria. Out of 40 patients with the diagnosis of EGPA, 13 (33%) fulfill the ACR 1990 criteria and 36 (90%) the ACR/EULAR 2022 criteria. Out of 30 patients with the diagnosis of suspected EGPA, 1 (3%) fulfill the ACR 1990 criteria and 19 (63%) the ACR/EULAR 2022 criteria. Concordance is low (K=0,13). Analyzing discordant cases, 18 patients positive only for 2022 criteria have asthma and hypereosinophilia and in half of the cases nasal poliposis. This reflects the higher weight of asthma and hypereosinophilia in 2022 criteria.

Conclusion: These data clearly indicate a higher sensitivity of the ACR/EULAR 2022 criteria, that take into account ANCA detection by the currently available sensitive and specific techniques. On the other hand, the data confirm that classification criteria can be applied only to well selected cohorts of patients, when a careful clinical and laboratory workup has excluded other diagnosis and suggested a systemic vasculitis.

Scleroderma, myositis and related syndromes

AB0805 DESCRIPTION IN FLOW IN EARLY VERSUS CLINICALLY OVERT SYSTEMIC SCLEROSIS. LASER SPECKLE CONTRAST ANALYSIS: A DESCRIPTIVE STUDY ON THE PERIPHERAL BLOOD OF THE DIFFERENT SUBTYPES OF SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Descriptive Studies, Imaging

V. Smith[1,2,3], S. Willems[1], T. Du Four[1,2], S. Wallaert[4], E. Gotelli[5], A. Cere[5], M. Cutolo[5]. *[1]Ghent University Hospital, Department of Rheumatology, Ghent, Belgium*; *[2]Ghent University Hospital, Department of Internal Medicine, Ghent, Belgium*; *[3]Vlaams Instituut voor Biotechnologie (VIB), Inflammation Research Center (IRC), Unit for Molecular Immunology and Inflammation, Ghent, Belgium*; *[4]Ghent University, Biostatistics Unit, Department of Public Health and Primary Care, Ghent, Belgium*; *[5]University of Genova, IRCCS San Martino Polyclinic Hospital, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties, Genova, Italy*

Background: Description of flow, measured by laser speckle contrast analysis (LASCA), in 'early' systemic sclerosis (SSc) versus 'clinically overt' SSc (diffuse cutaneous SSc [DcSSc] and limited cutaneous SSc [LcSSc]) has not yet been described [1].
Objectives: To investigate in an unselected, SSc cohort if baseline LASCA PBP-measurements differ between 'early' SSc and 'clinically overt' SSc.
Methods: Between September 2019 and December 2022, patients with SSc (as defined by the 2013 ACR/EULAR criteria and/or the 2001 LeRoy and Medsger criteria) were included [1,2]. A group of 20 consecutive 'early' SSc, LcSSc and DcSSc patients were recruited. Vasoactive medication was continued. LASCA was performed at baseline in standardized instrumental and environmental conditions [3]. PBP was assessed by marking regions of interest (ROI's) with fixed 1 cm diameters at the fingertips of the 2nd through 5th digit volary bilaterally. The adjusted mean PBP was calculated (expressed in perfusion units [PU]). A linear mixed model was fit with a random intercept per patient, together with a linear covariance structure to capture the residual correlations between fingers. Fixed effect terms included subset, side, finger, vasoactive medication, active smoking, history or presence of digital trophic lesions (DTL), and disease duration. Significance level was set at 0.05 and no correction for multiple testing was applied.
Results: Sixty patients with SSc (75% female, mean age 53 years, mean disease duration 73.1 months) were enrolled (table 1). Comparing the adjusted mean PBP at baseline in 'early' versus 'clinically overt' SSc, no statistical significant difference was found (144 vs. 150 PU, p=0.77) (figure 1A). Additionally within the 'clinically overt' group no significant difference was perceived between DcSSc and LcSSc (157 vs. 141, p=0.53). A wide variability was noted when observing the individual measurements of each subset (figure 1B).
Conclusion: This study with an unselected day-to-day SSc population, where patients were allowed to continue their vasoactive medication, showed there was no difference in PBP at baseline between 'early' SSc and 'clinically overt SSc' when corrected for subset, vasoactive medication, active smoking, history or presence of DTL and disease duration. Interestingly a wide variation of individual datapoints was noted in each subset, which emphasizes the heterogeneity of SSc. In conclusion, there is no inter-individual variation between the different subsets of SSc, as measured with LASCA. Future investigation is needed to enlighten us about the intra-individual changes over time.

AB0806 THE LONG-TERM COURSE OF THE HEALTH ASSESSMENT QUESTIONNAIRE IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Patient reported outcomes

S. Liem[1], S. A. Bergstra[1], J. Ciaffi[2], C. Van der Meulen[1], D. Ueckert[3], R. Schriemer[4], T. Huizinga[1], T. P. M. Vliet Vlieland[5], J. De Vries-Bouwstra[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[2]Rizzoli Orthopedic Institute, Rheumatology Unit, Department of Medicine, Bologna, Italy*; *[3]Leiden University Medical Center (LUMC), Physical Therapy, Leiden, Netherlands*; *[4]NVLE, NVLE, Utrecht, Netherlands*; *[5]Leiden University Medical Center (LUMC), Orthopedics, Physical Therapy and Rehabilitaton Medicine, Leiden, Netherlands*

Background: Functional disability in patients with systemic sclerosis (SSc) greatly influences quality of life. The Health Assessment Questionnaire-Disability Index (HAQ-DI) is an important outcome reflecting functional disability, but knowledge on its course over time in SS) is scarce.
Objectives: To describe the long-term course of functional disability in SSc patients, most importantly to investigate which patients have a worsening functional ability, and investigate its associations with disease characteristics.
Methods: SSc patients, fulfilling the ACR/EULAR 2013 criteria, were included from the Leiden CCISS cohort with annual assessments including the Scleroderma HAQ. The Scleroderma HAQ consists of the HAQ-DI (range: 0 [no difficulties] to 3 [maximum difficulties]) and five SSc-related VAS scores: Raynaud's Phenomenon, digital ulcers, gastrointestinal, pulmonary and general disease burden (range: 0 to 100). The HAQ-DI course was evaluated over the total follow-up (baseline to last available HAQ-DI) and between yearly visits. Based on a minimal clinical important difference of 0.22, patients were categorized into worsening, stable, or improvement. Baseline SSc characteristics were compared between patients with a worsening or improvement of the HAQ-DI using logistic regression. The change of the HAQ-DI and the SSc-related VAS scores over time was evaluated with linear mixed models.
Results: 517 SSc-patients were included (Table 1). The median follow-up duration was 7 years (IQR:4; 9). The mean baseline HAQ was 0.77 (SD:0.65). On group level, the HAQ-DI increased annually with 0.019 (95% CI:0.011; 0.027). Patients ≥65 years (β 0.27, 95% CI: 0.1; 0.4) and patients who died/were physically not able to come during follow-up (β 0.34, 95% CI: 0.2; 0.5) had a significantly higher HAQ-DI over time than respectively patients younger than 65 years old and patients who did not die (Figure 1). Between baseline and the last follow-up, the proportions of patients with a worsening, stable or improved HAQ-DI were 35%, 42% and 23%, respectively. Logistic regressions, adjusted for age, sex and disease duration, revealed that, at baseline, the use of immunosuppressive medication (OR: 0.5, 95% CI: 0.3; 0.9) and gastrointestinal involvement (OR: 0.6, 95% CI: 0.4; 0.9) decreased the chance of a worsening overall HAQ-DI course, whereas presence of anti-centromere autoantibodies (OR: 1.4, 95% CI: 0.8; 2.3) and pulmonary arterial hypertension (OR: 2.3, 95% CI: 0.3; 20.8) increased this. For all the VAS scores, the β of the longitudinal course for the total group was stable. Over time, most importantly, patients who died/were physically not able to come during follow-up had a 18.8 point higher pulmonary VAS (95% CI: 12.9; 24.8) and a 13.3 higher general burden of SSc VAS (95% CI: 6.5; 20.2) compared to patients who survived.
Conclusion: Over time, the average course of the HAQ-DI is stable in SSc-patients, but individual trajectories vary, with worsening occurring in one third. Importantly, use of immunosuppressives decreased the chance of worsening while presence of anti-centromere antibodies increases the chance of worsening.

PATIENT-REPORTED OUTCOMES ABOUT QUALITY OF LIFE IN PATIENTS WITH IDIOPATHIC INFLAMMATION MYOPATHY

Keywords: Quality of life, Patient reported outcomes, Work-related issues

Z. Peng[1], Y. Wang[2], N. Liu[3], S. Zhou[1], J. L. Zhao[1], D. Xu[1], M. LI[1], C. Wu[1], X. Zeng[1], Q. Wang[1]. *[1]Chinese Academy of Medical Sciences & Peking Union Medical College, Department of Rheumatology and Clinical Immunology, Beijing,*; *[2]Institute of Basic Medical Sciences Chinese Academy of Medical Sciences & School of Basic Medicine Peking Union Medical College, Department of Epidemiology and Biostatistics, Beijing, China*; *[3]The University of Hong Kong-Shenzhen Hospital, Division of Rheumatology, Department of Medicine, Shenzhen, China*

Background: Idiopathic inflammation myopathy (IIM) defines a group of chronic autoimmune-mediated diseases that most commonly affect the skin, muscles, and lungs [1]. Despite considerable advances over the past decades in improving life expectancy compared with the general population, IIM patients still experience substantially impaired health-related quality of life (HRQoL) [2].

The value of incorporating patient-reported outcomes in clinical trials is increasingly appreciated. The 36-item Short-Form Health Status Survey (SF-36) has been proposed to evaluate HR-QoL in IIM patients. However, because it is very time-consuming, the actual completion rate of the questionnaire is extremely low, and the SF-36 cannot be used directly in cost-effectiveness analyses. The EuroQol 5-Dimension (EQ-5D) is another tool for assessing HR-QoL and has been used extensively for chronic diseases. Wolfe et al. [3] verified the association between EQ-5D and SF-36 in rheumatic diseases. Moreover, workforce losses in patients with IIM are underestimated, and even health-related absenteeism imposes an economic burden on society [4].

Objectives: To explore the feasibility and validity of the EuroQol 5-dimension (EQ-5D) and Work Productivity and Activity Impairment (WPAI) surveys as patient-reported outcomes of health-related quality of life (HR-QoL) in Idiopathic inflammation myopathy (IIM).

Methods: This cross-sectional study surveyed patient's outcomes using the Manual Muscle Testing-8 (MMT-8), Myositis Disease Activity Assessment Visual Analog Scale (MYOACT), Myositis Damage Index (MDI), Disease Activity Score (DAS), and Physician/Patient Global Assessment (PGA/PtGA). HR-QoL was determined using EQ-5D, 36-item Short-Form Health Status Survey (SF-36), and WPAI questionnaire. The relationship between IIM-related parameters and HR-QoL was assessed using ordinal logistic and quantile regression.

Results: We enrolled 189 patients with IIM. Decreased MMT-8 and increased MYOACT, DAS, MDI-global, and PGA/PtGA were associated with higher EQ-5D values. For the 25^{th}–75^{th} percentile of WPAI, greater activity impairment was associated with lower MMT-8 and higher age of onset and PGA. Poorer overall working productivity impairment was associated with higher MYOACT (cutaneous and skeletal). MDI-global and PtGA were associated with increased activity and overall working productivity impairment in most quantiles ($P < 0.05$).

Conclusion: The EQ-5D and WPAI may be valid patient-reported outcomes to evaluate HR-QoL in ambulatory patients with IIM.

A PROOF OF BIOLOGICAL CONCEPT TRIAL OF CM101 TO TARGET CCL24 IN SYSTEMIC SCLEROSIS: A BIOMARKER INFORMED, PRECISION MEDICINE APPROACH

Keywords: Systemic sclerosis, Biomarkers, Clinical Trials

F. Del Galdo[1], D. Khanna[2], C. Crater[3], R. Aricha[4], J. Lawler[3], A. Mor[4], I. Vaknin[4], M. Frankel[3], M. Matucci-Cerinic[5,6]. *[1]University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[2]University of Michigan, Rheumatology, Ann Arbor, United States of America*; *[3]Chemomab Therapeutics, Ltd, Clinical Development, Tel Aviv, Israel*; *[4]Chemomab Therapeutics, Ltd, R&D, Tel Aviv, Israel*; *[5]University of Florence, Rheumatology, Florence, Italy*; *[6]IRCCS Ospedale San Raffaele, Rheumatology, Milan, Italy*

Background: Systemic sclerosis (SSc) is an inflammatory and fibrosing autoimmune disease of unknown etiology. However, it has been established that endothelial cells, immune cells, and fibroblasts play important roles in SSc initation and progression. CCL24 (eotaxin-2) is a chemokine secreted by fibroblasts and endothelial cells, which promotes trafficking of profibrotic immune cells through the CCR3 receptor. Levels of CCL24 and CCR3 in the skin and serum of patients with SSc were found to be upregulated compared with healthy controls [1]. Serum CCL24 levels have been shown to correlate with extracellular matrix turnover biomarkers, to predict decline in forced vital capacity (FVC) and the diffusion capacity of the lungs for carbon monoxide (DLCO), and to be associated with a worse digital ulcer burden in patients with SSc [1]. Blockade of CCL24 with CM101, a humanized IgG1 anti-human CCL24 monoclonal antibody, significantly reduced endothelial cell activation in vitro and in skin and lung immune cell infiltration and fibrosis in experimental SSc animal models.

Objectives: To present an innovative trial design which allows for comprehensive disease assessment and determination of the biological activity of CM101 in patients with SSc.

Methods: Informed by the predictive value of CCL24 on vascular and fibrotic clinical outcomes in a large SSc observational cohort, the CM101 clinical development team aims to bridge biomarker science and clinical trial design by implementing a phase 2a clinical trial that includes evaluation of the

biology of CCL24, effects of CCL24 blockade on biological and clinical markers of SSc activity, with comprehensive safety and efficacy assessments in patients with SSc.

Results: A biomarker driven, phase 2a, multicenter, randomized, double-blind, placebo-controlled, proof of biology study was designed to evaluate the safety, tolerability, and activity of CM101 in patients with SSc. Approximately 45 patients will be enrolled and randomized in a 2:1 ratio to receive either 10 mg/kg CM101 IV every 3 weeks (N=30 patients) or placebo (N=15 patients) for 8 treatments in the double-blind treatment period (24 weeks). All patients will have the option to receive 8 active treatments (CM101 20mg/kg IV every 3 weeks) in the open-label treatment period (24 weeks), with a follow-up period of 12 weeks. To elucidate the role of CCL24 in SSc, adults with early limited or diffuse cutaneous SSc are required to have elevated serum levels of CCL24 and clinical evidence of active disease, defined as modified Rodnan Skin Score (mRSS) ≥ 15 or presence of interstitial lung disease or current digital ulcer along with elevated C-reactive protein, erythrocyte sedimentation rate, or platelets, at trial entry. CM101 biological activity will be evaluated through a pre-defined biomarker analysis. Along with safety assessment, the clinical activity of CM101 on the vascular, dermatological, and pulmonary systems will be evaluated by nailfold video capillaroscopy, Digital Artery Volume index (DAVIX©), Digital Ulcer Clinical Assessment Score, mRSS, and FVC. The global response will be assessed by the revised Composite Response Index Systemic Sclerosis (CRISS) in conjunction with patient-reported outcomes.

Conclusion: This novel, biomarker enriched clinical trial, will determine the biological activity of CM101 in patients with active vascular or fibrotic SSc, across limited and cutaneous subsets, and inform future development of CM101 in SSc. Bridging biomarker science with clinical trial design carries the opportunity of improving the efficiency in subsequent clinical development and allows for a targetted treatment approach.

INTERSTITIAL LUNG DISEASE SECONDARY TO ANTI SYNTHETASE SYNDROME AND SYSTEMIC SCLEROSIS: DIFFERENCES IN CHARACTERISTICS AND IMMUNOSUPPRESSIVE TREATMENT RESPONSE

Keywords: Systemic sclerosis, Myositis, Lungs

T. Eviatar[1,2], O. Freund[2,3], T. Shalmon[2,4], S. Schneer[5,6], Y. Adir[5,6], O. Wand[2,7], D. Shitrit[2,7], O. Elkayam[1,2], A. Bar-Shai[2,3], A. Unterman[2,3]. Background: Anti synthetase syndrome (ASS) is an inflammatory myositis with autoantibodies against one of the aminoacyl transfer RNA synthetase. Interstitial lung disease (ILD) is a main clinical feature which dictates the prognosis and treatment. Since there are no randomized controlled trials to guide therapy, treatment strategies are extrapolated from other connective tissue diseases-related-ILD (CTD-ILD), mainly systemic sclerosis (SSc).

Objectives: Our aim was to evaluate the effect of immunosuppressive treatment (IS) on ASS-related ILD, compared with SSc-related ILD.

Methods: A multicenter observational registry, including 45 patients with CTD-ILD (ASS (n=18) and SSc (n=27)) from 3 medical centers in Israel, between 2017-2021. During follow up, 12 patients did not receive any IS, while 17 patients started IS treatment shortly after the 1st visit and 16 after a period of follow up. We compared the **monthly** change in diffusion capacity for carbon monoxide (DLCO) and forced vital capacity (FVC) percent predicted between ASS and SSc. Further analysis included a comparison between non-IS and IS treated patients. Mann-Whitney test was used to compare medians, with a p value of <0.05 considered significant.

Results: The mean±SD age was 62.9±10 and 31 (69%) were females. ILD as the presenting disease feature was more common in ASS, compared with SSc (61% vs. 11%, p<0.001). DLCO% was lower at baseline among ASS patients (44 ±13 vs. 57 ±14, p=0.004), while other lung function measures were not significantly different (table 1). Overall, 32 patients (71%) received an IS therapy. As expected, glucocorticoid treatment was more prevalent in the ASS group (n=14) compared to the SSc group (n=8) (78% vs. 30%, p=0.002). The most prevalent non-steroidal IS was mycophenolate mofetil (MMF) (96%). Two ASS and one SSc received azathioprine. There was a trend towards a monthly improvement of DLCO% among treated patients with ASS compared with SSc (median change of 0.30 vs. -0.17 percentage points, p=0.053), while among non-IS treated patients there was no difference in the decline (-0.27 vs. -0.29, p=0.853) (figure 1). When comparing CTD-ILD treated with IS, with non-treated patients among patients with ASS, IS was associated with a monthly increase in DLCO% (0.3 vs. -0.27 without IS, p=0.001), and in SSc – a lower rate of decline (-0.17 vs. -0.29, p=0.041); However, the positive change of FVC% in both ASS (0.12 vs. 0.33, p=0.217) and SSc (-0.38 vs. 0, p=0.79) patients was not statistically significant.

Table 1 , demographic and clinical characteristics of the study cohort

Variable, number (%)	ASS n=18 (%)	SSC n=27 (%)	p

CRP or ESR or KL-6	**0.53**	**40.9**	**65.7**	**0.51**	**36.8**	**64.4**	**0.56**	**57.5**	**54.1**	**0.53**	**54.5**	**51.9**

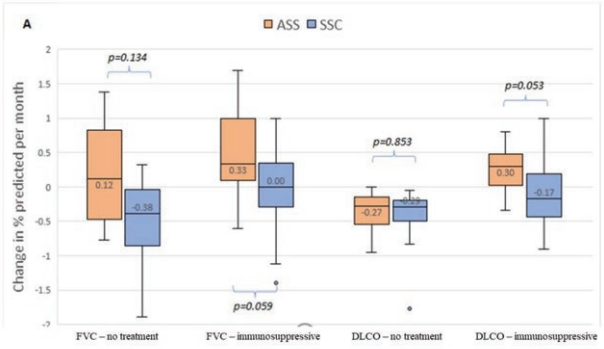

Figure 1. Median monthly change (in percentage points) of FVC% and DLCO% in ASS and SSc patients with (n=28) and without (n=28) immunosuppressive treatment. Five patients (3 SSc and 2 ASS) were excluded from this analysis due to lack of serial lung functions.

ASS, anti-synthetase syndrome; SSC, systemic sclerosis; FVC, forced vital capacity; DLCO, Diffusing capacity for carbon monoxide.

Conclusion: Immunosuppressive therapy, and specifically MMF, was associated with an improvement in DLCO% in patients with ASS and lower rate of decline in SSc. ILD in the context of ASS may responds better to immunosuppressive treatment compared to ILD in SSc. These encouraging results need to be validated in larger scaled randomized prospective studies to assess the role of MMF in ILD related to ASS.

AB0810 PERFORMANCE OF CIRCULATING BIOMARKERS FOR PREDICTING PROGRESSION OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Biomarkers

K. Yomono[1], M. Kuwana[1]. *[1]Nippon Medical School, Department of Allergy and Rheumatology, Tokyo, Japan*

Background: In patients with systemic sclerosis (SSc), progression of interstitial lung disease (ILD) is associated with an increased risk of mortality. Since the course of SSc-ILD is variable, it is critical to predict progression of ILD in clinical practice as well as in designing clinical trials. Risk factors for ILD progression include short SSc duration, male, elevated inflammatory markers and Krebs von den Lungen-6 (KL-6), and progression of skin thickness in diffuse cutaneous SSc (dcSSc).

Objectives: To investigate if inflammatory markers and KL-6 at baseline are useful to efficiently capture patients who subsequently experience ILD progression in patients with dcSSc or SSc-ILD using a single-center cohort.

Methods: Patients with dcSSc or SSc-ILD were selected from the prospective SSc registry. C-reactive protein (CRP) ≥6 mg/L and erythrocyte sedimentation rate (ESR) ≥28 mm/hour were used as inflammatory markers [1], and a cutoff level of KL-6 was provisionally set at 1,000 U/ml. ILD progression was defined as the first event developing progressive fibrosing ILD (PF-ILD) [2] or progressive pulmonary fibrosis (PPF) [3]. Receiver operating characteristic curve (ROC) analysis was used to determine the sensitivity, specificity, and area under the curve (AUC) values of individual biomarkers and their combinations for predicting ILD progression. Cumulative rates free from ILD progression were assessed using Kaplan-Meier analysis and were compared using log-rank test.

Results: We enrolled 109 patients with dcSSc and 136 patients with SSc-ILD. The median disease duration at baseline was 15 and 17.5 months for dcSSc and SSc-ILD, respectively, and 87 patients with SSc-ILD (64%) had dcSSc. During median of 37 months of follow-up of dcSSc patients, 27 (25%) and 22 (20%) developed PF-ILD and PPF, respectively; and during median of 44.5 months of follow-up of SSc-ILD patients, 43 (31%) and 36 (26%) developed PF-ILD and PPF, respectively. As shown in Table, specificity of CRP, ESR and KL-6 for predicting ILD progression was favorable (73.6-88%), but sensitivity of CRP and ESR was low (9.1-16%). KL-6 provided better sensitivity (29.2-45.2%). The combination of CRP/KL-6 showed the AUC value (0.57-0.60), with sensitivity of 38.1-52.4% amd specificity of 69.1-77.8%. Kaplan-Meier analysis found that ILD progression occurred more frequently in patients with increased KL-6 than in those without irrespective of definition of ILD progression (P = 0.0001-0.03). The same trend was observed when combination of CRP/KL-6 was used (P = 0.001-0.14).

Conclusion: Increased KL-6 at baseline is the best biomarker for predicting ILD progression in patients with dcSSc or SSc-ILD. When KL-6 was combined with CRP, sensitivity was increased by maintaining acceptable specificity, proposing use of this combination as inclusion criteria for enriching an "at risk" patients in clinical trials for dcSSc or SSc-ILD.

AB0811 NAILFOLD CAPILLAROSCOPY FINDINGS IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES AND ITS ASSOCIATION TO AUTOANTIBODIES: A CASE-CONTROL STUDY

Keywords: Biomarkers, Autoantibodies, Myositis

C. Sieiro Santos[1], J. L. Tandaipan[2], A. Mariscal[3], L. Sainz Comas[2], H. Codes[2], P. Moya[2], B. Magallares[2], L. Martínez-Martínez[3], A. M. Millán Arciniegas[2], H. Park[2], C. Díaz-Torné[2], A. Laiz[2], S. P. Fernandez-Sanchez[2], S. Ros[2], H. Corominas[2], E. Diez Alvarez[1], I. Castellví[2]. *[1]Complejo Asistencial Universitario de León, Rheumatology, León, Spain*; *[2]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; *[3]Hospital Universitari de la Santa Creu i Sant Pau, Immunology, Barcelona, Spain*

Background: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of acquired muscle diseases, which have distinct clinical, pathological and histological features. Autoantibodies are clinically useful biomarkers to help the diagnosis of IIM. Raynaud's phenomenon is very frequent and the presence of microvascular changes in IIM have been described however, the role of nailfold videocapillaroscopy NVC) for diagnosis and prognosis in IIM is not clearly established.

Objectives: The aim of this study was to study the relationship between clinical and immunological characteristics and nailfold videocapillaroscopy (NVC) abnormalities in patients with idiopathic inflammatory myopathies (IIMs).

Methods: We performed a retrospective study of IIM patients followed in a University Hospital. Patients underwent a NVC at 200x magnification. Epidemiological, clinical data and antibody status, including myositis and scleroderma antibody panel of all patients was retrieved. NVC findings including loss of capillary density, enlarged and giant capillaries, ramified capillaries, haemorrhages, thrombosis, avascular areas, disorganization of capillary architecture and subpapillary venous plexus presence were recollected, if present. For the comparison of qualitative and/or quantitative variables Fisher's exact Test or T-test was performed when necessary.

Results: 95 patients with NVC performed during the follow-up were included (66% female) with a median age at inclusion of 55.3±24 years. Median IIM duration was 6.8±7 years. 39% had Raynaud's phenomenon at first clinical evaluation and 58% of them showed NVC pathological findings. Table 1 Summarizes the epidemiological, clinical, and autoantibody status of the patients. We found an association between the presence of dysphagia and avascular areas (p=0.02) or abnormal capillary organization (p<0.01) on NVC. ILD was associated with capillary loss (p=0.04) and avascular areas (p=0.004). Anti-MDA5+ was associated with capillary loss (p=0.03), thrombosis (p=0.02) and ramified capillaries (p=0.04). Anti-Mi2+ and anti-Th/To was associated with abnormal capillary organization (p=0.017 and p=0.001). The presence of haemorrhages was associated with anti-Ku+ (p=0.048) and anti-PL12+ (p=0.046). The presence of enlarged capillaries was associated with anti-RNA-pol III (p=0.04) and anti-NXP2 (p=0.044). A significant association between anti-Ro52 (OR 2.69, CI 95% 1.05-6.8, p 0.03) and anti-Jo1 (OR 7.03 CI 95% 1.46-33.7, p 0.01) with ILD was found. Anti-PML (OR 4.32 CI 95% 1.35-10.42, p 0.038) and anti-Th/To (OR 5.82 CI 95% 1.89-13.24, p 0.04) were associated with dysphagia. Anti-MDA5 (OR 5.85 CI 95% 1.92-14.21, p 0.044) was associated with skin involvement.

Conclusion: The presence of certain autoantibodies is related to the degree of microangiopathy in IIM and associates with capillaroscopic changes. Studying the association between capillaroscopic changes with diagnostic and pathogenic autoantibodies in IIM can provide useful information regarding the current knowledge about pathogenesis, classification, and prognosis of the disease.

Table 1 : Epidemiological, clinical, immunological and NFC features and autoantibody status from patients with IIM

Clinical features	
Muscle weakness	79 (83%)
Skin findings	30 (32%)
ILD	47 (49%)
Dysphagia	18 (19%)
Raynaud's phenomenon	37 (39%)
CK elevation	45 (47%)
Cardiac disease	4 (4%)
NFC features	
Loss of capillary density	27 (28%)
Enlarged and giant capillaries	37 (39%)
Haemorrhages	36 (38%)
Thrombosis	19 (20%)
Avascular areas	26 (27%)
Disorganization of capillary architecture	24 (25%)
Subpapillary venous plexus	36 (38%)
Antibody status	
Disease-specific antibodies	
Anti-MDA5	8 (8%)
Anti-TIF1G	11 (12%)
Anti-MI2	11 (12%)
Anti-NXP2	6 (6%)
Anti-synthetase antibodies	
Anti-Jo1	13 (14%)
Anti-PL7	9 (9%)
Anti-PL12	5 (5%)
Disease-associated antibodies	
Anti-Ro52	27 (28%)
Anti-KU	6 (6%)
Antinuclear antibodies	
Others (EJ, SRP, PM-SCL75, PM-SCL100, CN1A)	61 (64%)
	22 (23%)

GASTROINTESTINAL DISORDERS IN SYSTEMIC SCLEROSIS: CLUSTER ANALYSIS AND SEVERE INVOLVEMENT PREDICTION

Keywords: Motor function, Mixed connective tissue disease, Gender/diversity issues

C. Molliere[1], A. F. Guedon[1], N. Kapel[2], F. Devassoigne[3], P. Senet Hausfater[4], F. Graiess[5], O. Fain[1,6], S. Riviere[1], A. Mekinian[1,6]. *[1]Hospital Saint-Antoine Ap-Hp, Internal Medicine, Paris, France*; *[2]University Hospitals Pitié Salpêtrière - Charles Foix, Functionnal coprology department, Paris, France*; *[3]Hospital Saint-Antoine Ap-Hp, Hematology, Paris, France*; *[4]Tenon Hospital, Dermatology, Paris, France*; *[5]Hospital Saint-Antoine Ap-Hp, Radiology, Paris, France*; *[6]Sorbonne University Pierre and Marie Curie Campus, faculté de médecine, Paris, France*

Background: Gastrointestinal tract (GIT) is the second most common organ involved in Systemic Sclerosis (SSc) after the skin, and is responsible for alteration of quality of life and SSc-related mortality.
Objectives: Since early development of organ failure is associated with poor prognosis, we need to identify risk factors associated with severe GIT involvement to prevent apparition of severe form of the disease.
Methods: We conducted an observational prospective and monocentric study which included 90 patients followed for SSc, from 26 December 2019 to 14 September 2021.
Results: We included 90 patients in this study, with 76 female sex (84.4 %) and a median age of 55.7 years (IQR 44.3-64.4). 64 had a limited cutaneous SSc (lcSSc) (71.1 %) and 26 had a diffuse cutaneous SSc (dcSSc) (28.9 %). We observed 28 patients (31.1 %) with a malnutrition and 9 patients (10 %) with at least one episode of digestive hemorrhage or small intestinal bacterial overgrowth or chronic intestinal pseudo-obstruction. The patients with malnutrition had less limited cutaneous SSc form (53.6 % vs 79 %, p = 0.027), more interstitial lung disease (57.1 % vs 27.4 %, p = 0.013) and more cardiac disease (39.3 % vs 11.3 %, p = 0.005). No patient without malnutrition died at the end of the follow-up whereas 4 patients with malnutrition died (p = 0.013). Clustering of individuals on the basis of the selected variables yielded a number of 3 clusters. Cluster 1, "Limited cutaneous systemic sclerosis" (n = 25) was only composed of lcSSc patients, presenting more frequently anti-centromeres antibodies (n = 22, 88% vs n = 9, 34.6%, p<0.001 and n = 2, 6.1%, p<0.001 in cluster 2 and 3 respectively). They had less frequently intestinal (n = 11, 44%) or anorectal involvement (n = 1, 4%) than cluster 2 (n = 24, 88.9% and n =16, 59.3%, p = 0.003 and p<0.01, respectively). They also had a better diffusing capacity for carbone monoxide (median [IQR]: 78.50 [70.25, 84.00], p < 0.001). Cluster 2 "SSc with cardio-digestive involvement" (n = 27) was composed of 20 patients with lcSSc (74.1%), less frequently than cluster 1 (n = 25, 100%, p = 0.02) and tends to be more frequently than cluster 3 (n = 19, 50%, p = 0.09). They had more frequently intestinal (n = 24, 88.9%) or anorectal involvement (n = 16, 59.3%). Regarding heart status, patients from cluster 2 had more frequently heart involvement (n = 12, 44.4 % vs n = 1, 4%, p = 0.002 and n = 5, 13.2%, p = 0.01 vs cluster 1 and 3 respectively) with higher BNP levels (median [IQR]: 91.0 [27.0, 244.5] vs 44.0 [20.0, 85.0], p = 0.03 and 27.0 [19.0, 42.0], p = 0.01 vs cluster 1 and cluster 3 respectively). They also had higher troponin levels than cluster 1 (median [IQR]: 8.5 [3.0, 21.5] vs 3.0 [2.0, 8.0], p = 0.04) and more frequently pericardial effusion (n = 7, 26.9% vs 0, 0.0% p < 0.01). Regarding treatment, they had more frequently aspirin (n = 7, 26.9% vs n = 0, 0%, p = 0.02 and n = 1, 2.6, p = 0.01 in cluster 1 and 3 respectively) and more frequently statin (n = 9, 34.6% vs n = 1, 4%, p = 0.02 and n = 1, 2.6%, p < 0.01). Cluster 3 "SSc with cutaneous and pulmonary involvement", composed of 38 patients, including 19 patients (50%) with diffuse cutaneous systemic sclerosis. They had higher modified Rodnan score (median [IQR]: 10.0 [8.0, 17.0] vs 3.0 [0.0, 6.0], p <0.001 and 7.0 [3.0, 15.0], p = 0.04 in cluster 1 and 2 respectively). They had more interstitial lung disease according to the CT-scan compared to cluster 1 (n = 24, 61.1% vs n = 5, 20%, p < 0.001) and tends to have more compared to cluster 2 (n = 24, 61.1% vs n = 11, 40.7%, p = 0.095). They also had more frequently immunosuppressive treatments than cluster 2 (n = 26, 68.4% vs n = 10, 37%, p = 0.02) but less frequently biotherapy (n = 3, 7.9% vs n = 9, 34.6%, p = 0.02)
Conclusion: This study reported the gastrointestinal manifestations in a cohort of 90 patients with SSc, with a predominance of gastro-esophageal involvement and in particular for the first time described a cluster analysis allowing classification of various clinical GIT phenotypes.

Background: Acro-osteolysis is a disabling manifestation of Systemic Sclerosis (SSc). Few is known about its prevalence and clinical associations.
Objectives: To define the prevalence of acro-osteolysis among Portuguese SSc patients, to determine the most sensitive radiological location for its diagnosis and to clarify the phenotype of SSc patients with acro-osteolysis.
Methods: A cross-sectional multicenter study was conducted evaluating SSc patients from 14 Portuguese centers, registered in the Rheumatic Diseases Portuguese Registry (Reuma.pt), that fulfilled Leroy/Medsger 2001 or ACR/EULAR classification criteria for SSc. The presence of acro-osteolysis was assessed through systematic plain radiographs of hands and feet. Statistical analysis with

independent parametric or non-parametric tests, multivariate logistic regression of the significant variables in univariate analysis and sensitivity calculation of each radiographed site for the diagnosis of acro-osteolysis were performed.

Results: We included 195 patients, of whom 167 (85.6%) were female, with a median [min, max] age of 64 [20, 90] years-old and a median [min, max] disease duration of 11.2 [2, 57] years. Regarding disease classification, 146 (75.3%) patients had limited SSc, 32 (16.5%) had diffuse SSc, 9 (4.6%) had *sine scleroderma* SSc and 7 (3.6%) had early SSc. Acro-osteolysis was present in 62 (31.8 %) patients, with the hands (n=49, 25.1%) being more frequently affected than the feet (n=22, 11.3%). The most sensitive location to detect acro-osteolysis was the hand (79.0%). The presence of overall acro-osteolysis was significantly associated with digital ulcers (p=0.001), flexion contractures (p=0.031), oesophageal (p=0.006), gastric (p=0.014) and lung (p=0.004) involvements, higher mRSS score (p<0.001), anti-topoisomerase I positivity (p=0.034) and radiological calcinosis (p=0.018). Patients with hand acro-osteolysis had longer disease duration (p=0.02) and were more often affected by digital ulcers (p=0.004), flexion contractures (p=0.041), oesophageal (p=0.001), gastric (p=0.015) and lung (p=0.001) involvements, higher mRSS score (p<0.001), anti-topoisomerase I positivity (p=0.004) and radiological calcinosis (p=0.008). No significant differences were found between patients with and without feet acro-osteolysis. In multivariate analysis, anti-topoisomerase I positivity (OR 4.6, 95%CI 1.3-16.4, p=0.017) was predictor of hand acro-osteolysis.

Conclusion: The prevalence of acro-osteolysis found in Portuguese SSc patients is within the range found in the literature (20-40%) [1]. The hands were the most sensitive location to detect acro-osteolysis – a novel aspect since, to our knowledge, this is the first study evaluating acro-osteolysis in the feet besides the hands. Our data replicated some previously reported associations between acro-osteolysis and other hand involvements (digital ulcers, calcinosis and flexion contractures) and systemic complications (esophagogastric and pulmonary systems) [2-4]. Anti-topoisomerase I positivity appears to increase the risk for hand acro-osteolysis.

CLINICAL PHENOTYPE AND ANTIBODY CORRELATIONS USING IMMUNOPRECIPITATION IN INDIAN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES FROM THE MYOCITE COHORT

Keywords: Myositis, Epidemiology, Autoantibodies

A. Loganathan[1,2], A. Rudge[3], H. Lu[2], E. Bowler[2], F. Mcmorrow[2], N. Ravichandran[4], A. K. Anuja[4], V. Agarwal[4], L. Gupta[4,5,6,7], N. Mchugh[2], S. Tansley[1,2]. [1]*Royal United Hospital, Royal National Hospital of Rheumatic Diseases, Bath, United Kingdom*; [2]*University of Bath, Department of Life Sciences, Bath, United Kingdom*; [3]*University of Bath, Department of Mathematical Sciences, Bath, United Kingdom*; [4]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Clinical Immunology and Rheumatology, Lucknow, India*; [5]*Royal Wolverhampton Hospital NHS Trust, Department of Rheumatology, Wolverhampton, United Kingdom*; [6]*City Hospital, Sandwell and West Birmingham Hospitals, Department of Rheumatology, Birmingham, United Kingdom*; [7]*The University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Centre for Musculoskeletal Research, School of Biological Sciences, Manchester, United Kingdom*

Background: There is a lack of epidemiological studies in idiopathic inflammatory myositis (IIM) to identify geographical and clinical disease variations between populations. Reviewing disease prevalence in different populations and clinical presentations may help improve our understanding of rare diseases.

Objectives: We reviewed the clinic-serological profile of 148 patients from a well-characterised MyoCite cohort of juvenile and adult patients with IIM from Lucknow, India, to determine significant clinical characteristics associated with different myositis-specific antibodies (MSA).

Methods: The MyoCite cohort is a retro-prospective dataset of adult and juvenile IIM patients (2017 ACR/EULAR criteria or diagnosed by two rheumatologists) enrolled in Lucknow, India, between 2017-2020. (1) The cohort is well-characterised with a detailed case record form and glossary outlining clinical characteristics and disease outcomes with biospecimen archiving. Sera were shipped to the NMH lab in Bath, and autoantibody status was determined using immunoprecipitation (IP). Sera with 140kDa band were characterised for NXP2 versus MDA5 using ELISA. Clinical associations for specific autoantibodies on IP were analysed by comparing each MSA to the rest of the cohort. We conducted univariate and multivariate logistic regressions, with results reported as odds ratios with 95% confidence intervals (CI). We selected variables as candidates for the multivariate logistic regression which scored a p-value ≤0.3 in the univariate analysis. A stepwise procedure was to select the final multivariate models which achieved the best fit, measured using AIC.

Results: Of 148 patients, one had dual MSA antibody specificity (Jo1/NXP2) and was excluded from analysis. The median age of onset was 35.5, with 75.2% being women. Muscle weakness was present in 88.9% of patients; 61.5% had a rash consistent with dermatomyositis (DM), 35% were diagnosed with ILD, and 41.3% experienced arthritis. Underlying malignancy was present in 1.4% at the time of enrolment. Dermatomyositis (DM) (30%) was the most common subtype of IIM, followed by anti-synthetase syndrome (ARS) (20%), overlap myositis (16%) and juvenile DM (14%). Anti-Jo1 (10.9%) was the most common MSA detected, followed by MDA5 (9.5%) (figure 1), and 43.5% of patients were seronegative. Mechanic's hands were associated with anti-Jo1 (OR 20.5 95%CI 5-77.7) and ARS antibodies (OR 11.9 95%CI 3.8-36.9). Heliotrope rash (OR 6.4 95%CI 1.5-26.7) and gottron's sign (OR 5 95%CI 1.2-20.9) were associated with anti-MDA5 (Table 1). ARS antibodies were negatively associated with weakness and heliotrope rash. NXP2 was associated with dysphonia (OR 29.1 95%CI 3.5-243), while Mi2 was associated positively with a V-sign rash (OR 7 95%CI 1.4-34.7) and negatively with fever. SAE antibodies were associated with dysphagia (OR 9.3 95%CI 1.1-76.6). Seronegative IIM was associated with hyperpigmentation (OR 4.3 95%CI 1.6-11.7) and erythematous changes (OR 2.8 95%CI 1.2-6.5) and was negatively associated with arthritis and fatigue.

Conclusion: Autoantibodies are present in nearly two-thirds of Indian patients with IIM, commensurate with other populations (Figure 1), although the prevalence of individual MSA differs. The frequency of ILD is closer to those previously reported in European cohorts than in East Asian populations. Most MSAs exhibited association with prominent cutaneous manifestations, including mechanics hands, heliotrope rash, Gottron's sign, V-sign, hyperpigmentation and erythematous changes. These differences in antibody profile and clinical characteristics from the MyoCite cohort compared to that of different geographical and ethnic populations previously reported suggest the potential influence of genetics and/or environmental factors.

AB0816 TREATMENT OF A PATIENT WITH SEVERE DIFFUSE SYSTEMIC SCLEROSIS (SSC) USING CD19-TARGETING CAR-T-CELLS

Keywords: Systemic sclerosis, Autoantibodies

C. Bergmann[1], F. Müller[2], D. Jörg[3], D. M. H. Györfi[3], S. Völkl[2], M. Aigner[2], T. Harrer[1], N. Bayerl[4], A. Atzinger[5], J. Taubmann[1], S. Boeltz[1], J. Wacker[1], M. Uder[4], T. Kuwert[5], M. Andreas[2], G. Schett[1]. Background: Several data suggest a role of B-cells in SSc-pathogenesis: disturbed B-cell homeostasis with expansion of naïve and decrease of memory B-cells (1), increased levels of B-cell stimulating factors [2] and anti-fibrotic effects of B-cell-depletion in murine fibrosis models [3]. Although first randomized controlled trials show promising effects of the CD20-targeting antibody rituximab (RTX) in SSc (4,5), the role of B-cell targeting treatments remains controversial. A possible explanation is the limited B-cell repertoire targeted by CD20-depleting antibodies that spare early B-cell precursors, which are particularly expanded in SSc, as well as plasmablasts responsible for autoantibody production. Hence, deeper and wider B-cell-depletion may be effective in SSc treatment. Recently, CD19-targeting CAR-T-cells, that are used to deeply deplete B-cells in refractory lymphoma and leukemia, showed remarkable effects in refractory systemic lupus erythematosus patients, suggesting the principle feasibility to intercept with autoimmune disease via CD19-targeting CAR-T-cells.
Objectives: To test the feasibility of treating severe SSc with CD19-targeting CAR-T-cells. Outcomes: B-cell -, absolute and relative CAR-T-cell counts, ANA-titer, SSc-specific antibodies, ^{68}Ga-FAPI-04-uptake, carpal MRI, EUSTAR activity index, mRSS, TJC, forced vital capacity (FVC), diffusion coefficient (DLCO).
Methods: This is a case study of compassionate use of CD19-targeting CAR-T-cells in a 60-year old male patient with severe, diffuse SSc (year of diagnosis 2020 (first non-Raynaud manifestation, mRSS 24 at baseline) with diffuse myocardial fibrosis, lung fibrosis, Raynaud´s phenomenon and carpal arthritis who previously failed several standard therapies including methotrexate and mycophenolate. CAR-T-cell-infusion was performed upon lymphodepletion with fludarabine (25 mg/m^2 on days -5, -4, -3) and cyclophosphamide (1g/m2 on day -3) in August 2020 as single infusion. Immunosuppressive treatment was stopped before. Main outcomes were assessed before baseline and three months after CAR-T-cell infusion.
Results: CAR-T-cells expanded remarkably and fast *in vivo* from day 3 (0.3 cells/µl; 0.1% CARs of CD3+ T cells) until day 9 (0.30.19 (1275/µl; 66,35% CARs of CD3+ T cells) and were measurable until day 51 after infusion. B-cells were completely depleted by day 7 and were not detectable until day 77. Serum-IgG levels endured above 600mg/dl. CAR-T-cell therapy was well tolerated without signs of cytokine release syndrome or cell-associated neurotoxicity syndrome. ANA titers (before baseline: 1:320) and SSc-specific antibodies (anti-RNAP III antibodies, antigen RP11) were no longer detectable three months after CAR-T-cell-infusion. In parallel, myocardial tracer uptake was reduced by 30% in ^{68}Ga-FAPI-04-PET-CT imaging, a novel imaging technique that allows the molecular assessment of fibroblast activation *in vivo*. The extent of lung fibrosis on CT scan and pulmonary function test parameters was stable or slightly improved. As analyzed by contrast supported hand-MRI, carpal arthritis improved three months after CAR-T-cell therapy. Consistently, tender joint counts improved from n=22 at baseline to n=3 at 3 months follow up. In addition, tendon friction rubs were no longer present consistent with reduction of EUSTAR activity index. Skin fibrosis showed a tendency of improvement after 3 months as analyzed by two independent assessors.
Conclusion: We show for the first time, that CAR-T-cell therapy can result in the fast loss of SSc-specific autoimmunity in a patient with severe, diffuse SSc and is paralleled by amelioration of clinical manifestations including skin- and heart-fibrosis and arthritis. Further studies with longer follow-up times and more patients will help to further characterize the role of CAR-T-cell therapy in SSc.

AB0817 CLINICAL ASSOCIATION OF ANTI-RO52 ANTIBODIES IN SYSTEMIC SCLEROSIS: A SINGLE CENTRE COHORT PRELIMINARY ANALYSIS

Keywords: Autoantibodies, Systemic sclerosis

L. M. Bianchessi[1,2], C. Bochicchio[1,2], A. Bartoletti[1,2], C. Di Giorgi[1,2], F. Cuzzocrea[1,2], M. Di Lernia[1,2], B. D'onofrio[1,2], G. Zanframundo[1,2], A. Biglia[1,2], C. Montecucco[1,2], V. Codullo[1,2], L. Cavagna[1,2]. [1]*Università di Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy*; [2]*IRCCS Policlinico San Matteo Pavia, Division of Rheumatology, Pavia, Italy*

Background: Anti-Ro52 antibodies may be detected in several Rheumatic disorders, with different clinical significances. They may occur also in systemic sclerosis (SSc), but with clinical correlates not completely established, with some reports showing their association with pulmonary arterial hypertension (PAH), and other with interstitial lung disease (ILD).
Objectives: To evaluate the clinical characteristics of anti-Ro52 positive SSc patients.
Methods: Patients aged more than 18 years, satisfying the 2017 ACR EULAR criteria for SSc referring to our SSc Unit and with at least one follow-up visit between October 2021 and October 2022 were evaluated for study participation. All patients positive for anti-Ro52 antibodes by ELISA were then included. Clinical characteristics were retrospectively collected and analysed. Pulmonary arterial hypertension (PAH) was defined by right heart catheterization, and ILD by chest high resolution computed tomography (HRCT).
Results: between the 420 SSc patients assessed, we identified 76 patients (18%) positive for anti-Ro antibodies. Only 29 patients were characterized for anti-Ro52 antibody, and 26 were positive. These patients were in prevalence females (21; 81%), with a median age at the onset of 60.5 years (Interquartile range, IQR, 48-71) and a median follow-up of 96 months (IQR 48-180). ANA were positive in 23 patients (88%), and the 2 most observed pattern were anticentromere (10; 38%) and nucleolar (9; 35%); 6 patients (23%) had cytoplasmic positivity of the ANA test. Six patients (23%) were concomitantly anti-La positive. Anti-Scl70 were found in 2 cases (8%). Other systemic sclerosis associated antibodies were positive in 6 cases (23%): anti-RNA polymerase III antibodies, and anti-Ku antibodies, in 2 cases (8%), anti-Th/To, and anti-PM-Scl100 in one case (4%). Patients had mainly limited cutaneous SSc subset (13; 50%), 5 had diffuse cutaneous SSc (19%), and the remaining 8 (31%) had no scleroderma. SSc was in overlap with other rheumatic diseases in the 50% of cases. The overlap was with Rheumatoid arthritis (RA) in 4 cases (15%), and with Sjogren syndrome (SjS) in 10 cases (38%), with one case diagnosed with both conditions. Most patients had Raynaud's phenomenon (RP) (24, 96%). The 2 patients without RP had puffy finger (PF), that were observed in 9 cases (35%). All patients performed nailfold capillaroscopy (NVC), showing scleroderma pattern in 22 cases (85%; early, 13, 50%; active 7, 27%; late 2, 8%). ILD was observed in 12 patients (46%), the HRCT pattern was mainly NSIP (10, 83%), with a cellular phenotype in the 50% of cases. Only 2 patients (17%) had UIP pattern. Ten patients (38%) had an history of smoke, but only 3 had ILD. PAH was identified in 7 patients (27%), in 3 cases concomitantly to mild ILD. Four patients (15%) had myocarditis. Dyspnoea was reported in 10 cases (38%; NYHA class: I 2, 20%; II 5, 50%; III 3, 30%).
Conclusion: In our cohort, anti-Ro52 positive patients with SSc had only rarely the diffuse subset of the disease. Clinically, these patients may have ILD, PAH, and myocarditis. The pattern of ILD was mainly NSIP, and only rarely UIP. The main overlap conditions were RA and SjS, and not rarely these patients were positive for some rare SSc rare autoantibodies, suggesting the need of a careful autoantibody profiling in this subset of patients. The characterization of anti-Ro52 antibodies in patients till now not assessed is ongoing.

AB0818

SCLERODERMA RENAL CRISIS TREATMENT WITH C5 INHIBITOR ECULIZUMAB – A REVIEW OF LITERATURE

Keywords: bDMARD, Systemic sclerosis, Targeted synthetic drugs

L. Farrukh[1], H. H. Waqar[1], S. Mehta[2], L. Shapiro[3]. [1]*Albany Medical Center, Internal Medicine, Albany, United States of America*; [2]*Albany Medical Center, Nephrology, Albany, United States of America*; [3]*Albany Medical Center, Rheumatology, Albany, United States of America*

Background: Scleroderma renal crisis (SRC) occurs in about 10% of SSc patients and is characterized by abrupt onset of hypertension, thrombotic microangiopathy (TMA), and acute kidney injury. Although prognosis has improved with the use of angiotensin-converting enzyme inhibitors (ACE-i), 40% of SRC patients still require dialysis, and 20-25% die within 1 year. The pathogenesis of SRC remains poorly understood but a growing body of evidence suggests that activation of the complement system may be involved in the disease [1]. It is hypothesized that injury to the endothelium due to persistent stimulation by the complement system creates a pathological loop responsible for thrombotic microangiopathy and target organ injury. Several case reports have shown that Eculizumab (humanized recombinant immunoglobulin G2/4 monoclonal antibody directed against the complement component C5) is effective in treating patients with SRC who presented with symptoms of thrombotic microangiopathy [2,3].

Objectives: In this study, we aimed to characterize the presentation and outcome of patients with SRC who were treated with C5 inhibitor, Eculizumab.

Methods: A literature search was conducted on PubMed and Cochrane from inception to December 2022 using MeSH terms for 'scleroderma', 'systemic sclerosis' 'scleroderma renal crisis', 'Eculizumab', and 'Solaris'. We included case reports, case series, observational studies, and literature reviews. We included patients with treatment refractory SRC who did not show improvement with ACE inhibitors or patients who had evidence of thrombotic microangiopathy (SRC-TMA).

Results: The initial search revealed 27 articles. After exclusion of non-relevant articles, data was included from 11 articles and 16 patients. The median age was 51 years, sex distribution was 4 males (33.3%) and 12 females (66.6%). Treatment with ACE-i was reported in 11 (68.75%), plasmapheresis (PLEX) in 8 (50%), steroids in 5 (31.25%), cyclophosphamide (CYC) in 3 (18.75%), calcium channel blockers (CCB) in 2 (12.5%) and Rituximab (RTX) in 2 (12.5%) of the patients. Renal replacement therapy (RRT) was required in 10 patients (62.5%). 8 out of 10 patients (80%) were reported to have clinical improvement with Eculizumab (Eculi) therapy **(Table 1).**

Conclusion: Recent clinical studies have focused on the role of complement activation in the pathogenesis of SRC and results suggest the use of C5 inhibitor in the treatment of refractory SRC. Serum complement levels and renal histological findings could help us identify patients who could benefit from Eculizumab. These findings should prompt testing on a larger cohort of SRC-TMA patients. However, based on the positive anecdotal evidence, it is reasonable to treat SRC patients with eculizumab in whom complement-mediated TMA is suspected.

CLINICAL AND IMMUNOLOGICAL PROFILES OF PATIENTS WITH ANTI-SYNTHETASE SYNDROME: A RETROSPECTIVE COHORT STUDY FROM A TERTIARY CENTRE

Keywords: Autoantibodies, COVID, Myositis

O. M. Resteu[1], L. Muntean[1,2], D. A. Vaida-Voevod[2], A. Marian[1], S. P. Simon[1,2], I. Filipescu[1,2], M. M. Tamas[1,2], C. Pamfil[1,2], I. Szabo[1,2], L. Damian[1], I. Felea[1], S. Rednic[1,2]. [1]*Clinical Emergency County Hospital, Rheumatology, Cluj-Napoca, Romania*; [2]*Iuliu Hatieganu University of Medicine and Pharmacy, Rheumatology, Cluj-Napoca, Romania*

Background: Anti-synthetase syndrome (ASS) is a rare auto-immune condition that combines autoantibodies and specifics clinical manifestations, including myositis, interstitial lung disease (ILD), polyarthritis, mechanic's hands, Raynaud's phenomenon, and unexplained fever. The hallmark of this syndrome is the presence of anti-aminoacyl-tRNA-synthetase (ARS) antibodies. Several anti-ARS antibodies have been described, anti-Jo1 being the most common, followed by anti-PL7, anti-PL12, anti-OJ, anti-EJ, anti-KS, anti-YRS, and anti-Zo. According to a recent epidemiological survey, the rising number of patients with autoimmune diseases, including idiopathic inflammatory myopathies (IIM) coincides with the COVID-19 pandemic.

Objectives: To evaluate the clinical characteristics of ASS patients with different anti-ARS antibodies from a tertiary rheumatology center.

Methods: We conducted a retrospective, single-centered study on consecutive patients diagnosed with ASS from 1 January 2015 to 31 December 2022. Clinical and serologic data were obtained by medical records review from hospital database. Myositis-specific antibodies (MSA) and myositis-associated antibodies (MAA) were tested using commercial ELISA kits. We included all patients fulfilling Connor's criteria for ASS.

Results: Sixty-one patients (44 females) with mean age 54.4 (13.8) years were included. The most frequently reported clinical manifestation was arthralgia (68.8%), followed by Raynaud's phenomenon (67.2%), ILD (65.6%), myositis (46%), mechanic's hands (44.3%), arthritis (39.3%), and fever (18.0%). The typical triad for ASS, including myositis, arthritis and ILD was present in 17 patients. Twenty-eight (45.9%) patients were PL7+, 21 (34.4%) were Jo1+, 3 (4.9%) were PL12+, and 2 (3.2%) were OJ+. Seven patients were positive for more than two anti-ARS antibodies. The most frequently found MAA was anti-Ro52 (n=23, 37.7%). Of the 61 patients included, 41 (67.2%) patients were diagnosed in the last 3 years (COVID-19 pandemic). The most frequently detected MSA in ASS patients diagnosed during COVID-19 pandemic was anti-PL7 (25/28), while anti-Jo1 was the most common MSA in ASS patients diagnosed before 2020 ($p<0.05$) (Fig 1). The anti-Jo1+ patients were younger, have significantly more frequent muscle involvement and significantly higher levels of CK than anti-PL7+ patients ($p<0.05$). The co-occurance of anti-Ro52 antibodies was more frequently observed in anti-Jo1+ patients (n=11, 52.4%) than in anti-PL7+ patients (n=6, 21.4%) ($p<0.05$). We did not find statistically significant differences between ASS groups regarding sex, disease duration, clinical manifestations including dermatologic lesions, Raynaud's phenomenon, arthralgia/arthritis, ILD, fever, and cancers (all $p>0.05$).

Conclusion: ASS patients have heterogenous manifestations, and different types of anti-ARS antibodies are associated to distinct clinical and immunological features. The COVID-19 pandemic led to increase prevalence of ASS cases and to a remarkable shift in the anti-ARS antibodies profile, with increased frequency of anti-PL7 antibodies. Further studies are needed to investigate the link between SARS-CoV-2 infections and myositis.

AB0820 THE RISK OF MALNUTRITION IS A PROBLEM ASSOCIATED WITH SYSTEMIC SCLEROSIS

Keywords: Diet and Nutrition, Patient reported outcomes, Systemic sclerosis

L. Cano Garcia[1], R. Redondo[1], N. Al Mashhadani[1], M. D. C. Ordoñez Cañizares[2], N. Mena-Vázquez[1], S. Manrique Arija[1]. [1]*Hospital Regional Universitario de Málaga; Instituto de Investigación Biomédica de Málaga (IBIMA)., Rheumatology, Málaga, Spain*; [2]*Hospital Universitario Nuestra Señora de la Victoria; Instituto de Investigación Biomédica de Málaga (IBIMA), Rheumatology, Málaga, Spain*

Background: Malnutrition is a serious health problem that worsens comorbid processes, increases hospital stays, infections and mortality. In addition, in chronic patients, it increases the complexity of the processes and the fragility of the patient who suffers from it.
Objectives: To describe the prevalence of malnutrition and malnutrition risk and its associated factors in a series of patients with Systemic Sclerosis (SSc).
Methods: Design: Cross-sectional descriptive study. **Participants**: consecutive recruitment of patients with SSc (ACR/EULAR 2013 criteria) followed up in our unit. Follow-up of these patients is usually carried out every 3 to 6 months in consultation and all patients were registered in a database. 90% of the patients accepted and signed the consent, the rest refused due to travel or work difficulties. **Variables:** The main variable was malnutrition or risk of malnutrition defined according to the Mini Nutritional Assessment (MNA) questionnaire, malnutrition was defined with a score less than or equal to 7, risk of malnutrition with scores between 8 and 11, and normal nutrition with values greater than 11. Clinical data, anthropometric and laboratory values were collected, as well as sarcopenia according to the European Working Group on Sarcopenia in Older People (EWGSOPII) and Short Physical Performance Battery (SPPB) criteria. **Statistical analysis:** descriptive, bivariate and a multiple linear regression model to identify factors associated with malnutrition and risk of malnutrition.
Results: 52 patients were included, of whom 51 (98.1%) were women, with a mean (SD) age of 60.8 (11.0) years. 17/52 patients (32.7%) were at risk of malnutrition and 1/52 patients (1.9%) were malnourished (Table 1). Patients at risk of malnutrition and malnutrition compared with patients with normal nutritional status, more frequently had diffuse skin involvement (38.9% vs 14.7%; p= 0.05), sarcopenia (44.4% vs 11.8%; p=0.01), severe sarcopenia (27.8 vs 2.9; p=0.01), weight loss (100.0 vs 55.6%; p<0.001) and polypharmacy (94.4% vs. 67.6%, p=0.02). Likewise, patients at risk of malnutrition and malnutrition had lower mean values (SD) in calcium levels (8.7 [2.1] vs 9.2 [0.42]; p=0.05), circumference lesser left calf (32.8 [3.0] vs 35.4 [6.0]; p = 0.03), and in the SPPB functional grade (8.1 [4.2] vs 9.8 [2.9]; p = 0.06) and higher PCR values (10.5 [11.1] vs 7.1 [7.0]; p = 0.06). In multivariate analysis, the only factor associated with malnutrition in SSc was sarcopenia (B [95% CI], -2.521 [-4.867, -0.175]; p=0.036) (R2=0.115).
Conclusion: Malnutrition has serious consequences for the health of people with SSc, including the development of sarcopenia, a condition that predicts disability, hospitalization, and premature death.

Table 1. Clinical-epidemiological characteristics of the 52 patients in SSc

Variable	ES n=52
Woman, n (%)	51 (98,1)
Age, mean (SD)	60,8 (11,0)
Limited skin patern, n (%)	40 (76,9)
Disseminated skin patern, n (%)	12 (23,1)
DILD, n (%)	17 (32,7)
HTAP, n (%)	5 (9,6)
Anti-Centromere, n (%)	28 (53,8)
Anti-Sl70, n (%)	10 (19,2)
Other antibodies, n (%)	9 (17,3)
MNA Normal nutritional status n (%)	34 (64,5)
MNA Risk of malnutrition, n (%)	17 (32,7)
MNA malnutrition, n (%)	1 (1,9)
Sarcopenia, n (%)	12 (23,1)
Sarcopenia severe, n (%)	6(11,5)
Right calf circumference, mean (SD)	34,5 (5,5)
Left calf circumference, mean(SD)	34,5 (5,3)
Weight loss >1kg in the last 3 months, n (%)	25 (48,1)
Polypharmacy, n (%)	12 (23,1)
CPR mg/dl, mean (SD)	8,3 (8,7)
Calcium mg/L mean (SD)	9 (1,2)
Prealbúmin mg/dl, mean (SD)	21,4 (4,6)

Abreviaturas. SSc: sistemic sclerosis; DE: standard deviation; DILD: diffuse interstitial lung disease; HTAP: pulmonary arterial hypertension; MNA: mini nutritional assesment; CPR: c reactive protein.

AB0821 VALIDITY AND RELIABILITY OF MEASUREMENT OF PERIPHERAL OXYGEN SATURATION DURING THE 6-MINUTE WALK TEST IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Lungs, Validation, Systemic sclerosis

A. Lynggaard Riis[1], E. Naeser[1], K. T. Aaen[1], H. Hovgaard[2], P. Juhl-Olsen[2], E. Bendstrup[3], K. Soendergaard[1]. [1]*Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark*; [2]*Aarhus University Hospital, The Department of Anaesthesiology and Intensive Care, Aarhus, Denmark*; [3]*Aarhus University Hospital, Centre for Rare Lung Diseases, Department of Respiratory Diseases and Allergy, Aarhus, Denmark*

Background: The 6-Minute Walk Test (6MWT) is a standardised method routinely used to screen for and monitor interstitiel lunge disease and/or pulmonary arterial hypertension in patients with systemic sclerosis (SSc). Studies shows that esaturations during the 6MWT are associated with severity of pulmonary manifestations in patients with SSc [1]. Digital sensors are commonly used to measure peripheral oxygen saturation (SpO_2) during the 6MWT. However, digital-based sensors may have important limitations in patients with SSc due to disease-related microangiopathy, Raynaud's phenomenon, sclerodactyly and motion artifacts during the 6MWT [2]. Sensors located at more central body positions may therefore be more accurate as these as less prone to Raynaud attacks.
Objectives: To determine the validity and re-test reliability of peripheral oxygen saturation measured at the finger, forehead, and ear during the 6MWT in patients with SSc.
Methods: 82 patients with SSc had an arterial line placed while performing the 6MWT. Peripheral oxygen saturation was simultaneously measured by finger, forehead, and earlobe sensors and compared to the arterial oxygen saturation (SaO_2) measured before and after the 6MWT. 40 patients repeated the 6MWT one week later. We used Bland-Altman plots to display the agreement between SpO_2 and SaO_2, and between the minimal SpO_2 ($minSpO_2$) one week apart. The intraclass correlation coefficient (ICC, 95% confidence interval 95% CI]) for repeated measurement of minSpO2 was calculated.
Results: The mean difference (SpO_2 - SaO_2, ± standard deviation [SD]) after the 6MWT was –3.3% (±4.82), 0.15% (±1.55), and 1.36% (±1.93) for the finger, forehead, and earlobe, respectively (Table 1).
The finger $minSpO_2$ also demonstrated the poorest re-test reliability: The mean difference in $minSpO_2$ (visit2-visit1, ±SD) was 1.28% (±5.3), 0.74% (±4.36) and –1.10% (±2.87),). The ICC (95% CI) showed good agreement using the ear and forehead probe (ICC_{ear} = 0.89 [0.80; 0.94]; $ICC_{forehead}$ = 0.88 [0.60; 0.87]), while a modest reliability was found using the finger probe (ICC_{finger} = 0.65 [0.43; 0.80]).
Conclusion: Peripheral oxygen saturation should be measured using either the earlobe or forehead during the 6MWT in patients with SSc.

AB0822 SYSTEMIC SCLEROSIS ASSOCIATED ANTIBODIES POSITIVITY IN SYSTEMIC SCLEROSIS PATIENTS: SINGLE VS. COMBINATION

Keywords: Systemic sclerosis, Biomarkers, Autoantibodies

L. Tío[1], L. Triginer[1], I. Carrión Barberà[2], A. Guillen-Del-Castillo[3], A. Ribes[1], L. Valencia Muntalà[3], J. Monfort[2], T. C. Salman Monte[2], C. P. Simeon Aznar[3], J. Narváez[4], A. Pros[2]. [1]*Institut Mar d'Investigacions Mèdiques, Investigación celular en inflamación y cartílago, Barcelona, Spain*; [2]*Hospital del Mar, Rheumatology, Barcelona, Spain*; [3]*Hospital Vall d'Hebron, Rheumatology, Barcelona, Spain*; [4]*Hospital de Bellvitge, Rheumatology, Barcelona, Spain*

Background: Autoantibodies (abs) are one of the most widely used tools currently in systemic sclerosis (SSc) as biomarkers. It has been described that 95% of patients with SSc have at least one ab and ≈5% >1. When looking only at abs associated with SSc (SSc-ab) that prevalence is reduced to 2.6%. The combination usually confers different clinical characteristics compared to those with positivity for a single ab.
Objectives: To determine the prevalence of the combination of SSc-ab in a series of patients diagnosed with SSc, and to analyze the clinical differences between those with positivity for a single vs multiple SSc-ab.
Methods: Retrospective study of 134 patients with SSc in whom the SSc-ab profile was systematically determined by an immunoblot (Euroimmun®) which included anti-topoisomerase (ATA), anti-centromere (ACA), anti RNA-Polymerase III (ARA), anti-U3-RNP (U3), anti-Th/To (Th/To), anti-Ku (Ku), anti-PmScl (PmScl) and anti-U1-RNP (U1) abs. Demographic and clinical differences were studied between those with positivity for a single ab vs those with more than one. Differences were identified using Fisher's exact test, and Mann-Whitney.
Results: Table 1 shows the SSc-ab profile of our patients: 128/134 (96%) were ANA+, 111 (82%) had 1 SSc-ab, 8 (8%) had 2 and 3 (2.3%) had 3 concomitant SSc-ab. Ku was found in combination with other ab in all patients and was present in the 3 patients with 3 ab. When analyzing patients with combined vs sole abs, we found the following statistically significant differences: the limited cutaneous SSc subtype associated with ACA was lost in the combinations ACA-U1-Ku+ and ACA-Ku+, being 0/1 patients (0%, p=0.038) and 0/1 patients (0%, p=0.039), respectively). Patients with ATA-ARA+ had a higher modified Rodnan skin score vs ATA+ (18.33 ± 2.08 vs 9.67 ± 5.59, p=0.036). No other statistically significant differences were found in any other characteristics in the patients with ≥1 vs 1 ab, although a trend toward some clinical differences was seen in ACA-U1-Ku+ patients, with more digestive symptoms and interstitial lung disease, and less myositis than ACA+. Additionally, patients ACA-PmScl-Ku+ seemed to have less myositis than those with PmScl+, and patients ACA-Ku+ less myositis than those ACA+.
Conclusion: The concomitant presence of more than 1 SSc-ab is more frequent in our cohort than initially described (8%), likely due to the systematic detection carried out in our study. Anti-Ku was the most frequent ab in combination to others. The combination of abs may change the characteristic clinical phenotypes associated to them when found in isolation. We saw some differences in our study, although conclusions cannot be drawn due to the limiting sample size. The implementation of routine immunoblots as ab screening to achieve a better characterization of patients could be a helpful tool for medical professionals, as these combinations of SSc-ab may have prognostic implications.

Background: In systemic sclerosis (SSc), the role of oral anticoagulants (OACs) for treating or preventing the occurrence of digital ulcers (DUs) is not well understood. Given the low prevalence of OACs used in these patients, standard frequentist statistics are not suitable to capture the effect of OACs on DUs conclusively. However, a Bayesian statistical approach, which incorporates prior knowledge, can deal with a low prevalence of outcome or exposure and might provide conclusive evidence.

Objectives: To assess the effectiveness of a therapy with OACs on DUs in patients with SSc.
Methods: This study used prospectively collected data from the European Scleroderma Trials and Research group (EUSTAR) registry. Patients fulfilling the 2013 ACR/EULAR SSc classification criteria with complete longitudinal data on the presence of DUs and OACs were included in the analysis. The Bayesian prior probability distribution was created by capturing SSc experts' opinion on the probability of absence of DUs with and without OACs and their degree of uncertainty using a questionnaire. In addition, participants ranked factors that influence the presence or absence of DUs as confounding factors using a numeric rating scale. The outcome was the absence of DUs at the last follow-up visit in SSc patients from the EUSTAR cohort, after one year of exposure to OAC. A nearest neighbor matching algorithm using Bayesian Additive Regression Trees with uniform priors generated a cohort with two groups of patients (treated and non-treated with OACs), which were balanced for age, sex, anti-Scl-70 antibody positivity, joint contractures, use of platelet inhibitors, use of prostacyclin analogues, use of any endothelin receptors antagonists or any phosphodiesterase type 5 inhibitor. The matching algorithm generated two balanced groups of treated and untreated patients (imbalance < 10%). A Bayesian logistic regression was implemented to estimate the effect of OACs on DUs. This model incorporated the priors elicited from experts' beliefs and was adjusted for the above mentioned factors that influence the absence of DUs, as well as modified Rodnan skin score, disease duration, season, left ventricular ejection fraction, presence of pulmonary hypertension, C-reactive protein elevation, arterial hypertension and any previous DUs.
Results: Of the 6,424 patients enrolled in the EUSTAR registry, 663 (10.3%) had current digital ulcers, 2556 (39.8%) had previous DUs and 143 (2.2%) were exposed to OACs at their last follow-up visit. Mean age was 59 (SD: 13.6) years, 933 (14.5%) were males, mean disease duration was 13.1 (SD: 8.7) years, 4,454 (69.3%) had a limited *cutaneous SSc and* 1510 (23.5%) had C-reactive protein elevation. The median probability for the absence of DUs after exposure of one year to OACs was 70-75%, the pessimistic and optimistic probability were 70-75% and 80-85% respectively. After incorporation of the prior experts' opinion, the unadjusted analysis revealed that the use of OACs was associated with absence of DUs at the last follow-up visit (OR 2.05, 95%CrI 1.63 to 2.46). In the adjusted analysis, the effect is OACs was slightly stronger (OR 2.15, 95%CrI, 1.71 to 2.52). The results of the analysis where the priors from experts were withheld (and uniform priors were set) are illustrated in figure 1.
Conclusion: This study indicates with incorporation of Bayesian priors that represent experts' beliefs, a positive effect of OACs for the DUs in SSc.

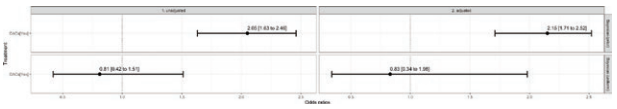

Figure 1. Effect of OACs on the absence DUs related to SSc at the last follow-up visit. Bayesian (priors): Analysis where the prior knowledge from the experts was incorporated into the model. Bayesian (uniform): Analysis where the prior knowledge from the experts was not incorporated into the model and a uniform/uninformative/neutral prior was used. OACs: Oral anticoagulants.

THE ROLE OF IMMUNOSUPPRESSIVE THERAPY IN GASTROINTESTINAL INVOLVEMENT AND ITS IMPACT ON QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS - A COHORT STUDY

Keywords: Systemic sclerosis, Gastrointestinal tract

I. Genrinho[1,2], T. Santiago[3], A. Carones Esteves[3], A. Barcelos[2], C. Mazeda[2], I. Santos[1], M. Couto[1], F. Campos Costa[4], T. Beirão[4], G. Terroso[5], M. Rato[5], P. Ferreira[6], P. Background: Gastrointestinal (GI) disease is a major cause of morbimortality in systemic sclerosis (SSc) and affects up to 90% of patients. GI manifestations are frequently unrecognized in early phases and there are few data suggesting the potential effect of immunosuppression (IS) in GI tract.
Objectives: The aim of this study was to evaluate the role of IS in GI involvement and its impact on health-related quality of life (HRQoL) in SSc patients.
Methods: A cross-sectional multicenter study was conducted, enrolling SSc patients that fulfilled the 2013ACR/EULAR criteria or presented the EUSTAR criteria for very early diagnosis of SSc (VEDOSS). Patients were requested to answer UCLA Scleroderma Clinical Trial Consortium Gastrointestinal Tract, SHAQ and Short Form Health Survey (SF36) measures. Social-demographic and clinical data were collected. GI involvement was determined by the presence of one of the following: GI symptoms for at least 3 of the last 7 days, abnormalities in GI exams and/or use of GI pharmacological therapies. IS was defined as exposure to at least one of the following: mycophenolate mofetil (MMF), cyclophosphamide (CYC), methotrexate (MTX), azathioprine (AZA), leflunomide, glucocorticoids (>10mg/d prednisone-equivalent), rituximab, tocilizumab, and abatacept, for more than 6 months. General descriptive analysis and independent parametric or non-parametric tests were performed using SPSSv26.
Results: One-hundred and one patients were included, 83 female (82.2%), with a mean age of 56.8±12.39 years-old and a mean duration of disease of 67.2±72.5 months. Sixty-four patients (63.4%) had limited SSc, 30 (29.7%) diffuse and 7 (6.9%) presented VEDOSS. Forty patients were under IS therapy, being the MTX the most frequent drug in 21.8%, followed by MMF in 11.9% and AZA in 5.9%. Seventy-two patients (71.3%) had GI involvement, where clinical manifestations were present in 72.2% patients, abnormalities in GI exams in 44.4% and GI pharmacotherapy was used in 41.7% patients. Patients with GI involvement were significantly more frequent under IS therapy (p=0.044), although no differences were found in severity of symptoms in UCLA domains between patients with and without IS. On the other hand, patients without GI involvement and under IS therapy presented significantly higher total UCLA score (mean 0.10±0.11 vs 0.11±0.18 for patients with and without IS therapy respectively, p=0.046). IS group was significantly more frequent under GI pharmacotherapy (p=0.006), being the proton pump inhibitors (PPI) the most significantly prescribed drug (55% vs 16.4% for patients with and without IS respectively, p<0.01). IS group had significantly higher SHAQ scores in total item (p=0.001) and overall disease severity VAS (p=0.009). Regarding HRQoL patients under IS present significantly lower SF36 scores for physical functioning (p=0.001), physical role functioning (p=0.002), physical component summary (p=0.001) and general health perception (p=0.036).
Conclusion: Patients with GI involvement were more frequent under IS, although no differences were found in severity of symptoms in UCLA domains when compared to those without IS. IS therapy was associated with worst HRQoL probably due to more severe multi-organ disease and were treated more often with PPI. Investigation is needed to evaluate the potential effects of IS in GI tract, as

patients with absence of GI involvement presented higher UCLA scores when IS therapy was given, which may reflect the potential GI complaints as an adverse effect by therapy, rather than involvement by the SSc.

AB0825 EFFICACY OF AUTOLOGOUS PLATELET RICH PLASMA ON MORPHEA: A COMPARATIVE CLINICAL AND ULTRASONOGRAPHIC FOLLOW UP STUDY

Keywords: Ultrasound, Skin, Systemic sclerosis

E. Elnaquip[1], M. Makki[2], M. Mansour[2], A. Moshrif[3]. [1]*Ras Eltin General Hospital, Dermatology, Alexandria, Egypt*; [2]*Al-Azhar University, Dermatology, Assiut, Egypt*; [3]*Al-Azhar University, Rheumatology department, Assiut, Egypt*

Background: Morphea is a subtype of limited scleroderma characterized by atrophic changes. There are multiple treatment modalities for morphea, but all have limited success to restore atrophy.

Objectives: To evaluate the efficacy and safety of paltelet rich plasma (PRP) to restore skin changes in morphea such as (skin atrophy, dyspigmentation and adnexal destruction) by ultrasound and Localized Scleroderma Cutaneous Assessment Tool (LoSCAT).

Methods: Nine morphea patients (21 lesions) were diagnosed clinically and by histopathology. Intradermal PRP was injected into morphea lesion once weekly for 12 sessions. The disease severity and damage were evaluated at baseline, after the last session (3 months later) and at 6 months follow up using (LoSCAT). Echogenicity and skin layer thickness were measured by musculoskeletal ultrasound with high frequency linear probe.

Results: The mean age of our patients was 21.8 ± 8.4 years (range: 11 to 36 years). The mean duration of morphea lesions was 5.96 ± 2.4 years (range: three months to 20 years). The LoSCAT score showed a significant improvement with a mean reduction from 13 ± 7.3 up to 7.33 ± 6.8 after therapeutic endpoint (at 3 months) reaching to 6.44 ± 7.1 after 6 months follow up with p-value = 0.008 and 0.014 respectively. The activity index (LoSAI) also showed a significant lowering in the score at both timepoints with p-value =0.02 and 0.04 respectively. The significant difference in size between morphea lesions and healthy control areas by US (1.77± 1.13 vs 3.29 ± 1.72; p = 0.007) has been vanished after treatment (at 3 month; p= 0.17 and at 6 month; p=0.53). There was a significant positive correlation between the duration of the lesion and the improvement assessed by ultrasound with p-value = 0.01. As regard adverse effects all patients reported having pain during PRP injection, transient edema of face reported by 4 patients (45%) and only 2 patients showed transient erythema. fig 1.

Conclusion: Autologous PRP is a safe technique with great aesthetic outcomes as filling up of contour defects and correction of both hyper and hypopigmentation in addition to softening of the indurated lesions.

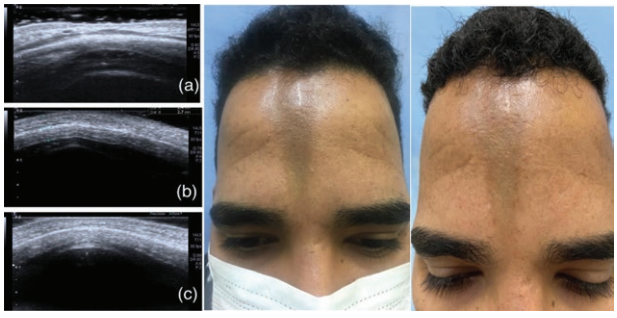

Figure Ultrasound (greyscale; transverse view) (a) before treatment shows morphea lesion in between two healthy areas. The lesion shows dermal and subcutaneous atrophy at end-stages with Loss of the border between dermis and subcutaneous tissue. (b) after treatment shows marked increase in dermal and subcutaneous thickness (c) remained improvement after 6 months of the end of treatment (d& e: photos for the same patient before treatment & at six-month follow up).

AB0826 EXPLORING THE POTENTIAL GENDER DIFFERENCE IN MYOSITIS: DISEASE PHENOTYPE AND ANTIBODY PROFILE FROM A SINGLE-CENTER ITALIAN COHORT

Keywords: Autoantibodies, Myositis, Gender/diversity issues

E. Cela[1], P. Triggianese[1], B. Kroegler[1], A. D'antonio[1], P. Conigliaro[1], S. Modica[1], E. Greco[1], A. Bergamini[1], M. S. Chimenti[1]. [1]*Rheumatology, Allergology and Clinical Immunology, University of Rome "Tor Vergata", ROME, Italy*

Background: Idiopathic inflammatory myopathies (IMM) include a heterogeneous group of rare autoimmune diseases with a large spectrum of muscular and systemic manifestations, mainly involving skin and lung [1,2]. Myositis specific antibodies (MSA) and myositis associated antibodies (MAA) have been described in IMM patients potentially correlating to disease outcome [3]. As well documented, autoimmune diseases present with a clear gender bias with a greater prevalence among women. To our knowledge, no studies has explored the potential gender difference in IIM patients.

Objectives: The aim of the study was to explore differences in disease features, clinical outcome, antibody profile, and treatments in IMM patients according to the gender.

Methods: In an observational study, we included patients with a defined IIM diagnosis who were referred to 3rd level Rheumatology Unit "Tor Vergata" University Hospital in Rome (Italy) for the past 5 yrs (to Dec 2022). Inclusion criteria were i. a defined diagnosis of dermatomyositis (DM), polymyositis (PM), and anti-synthetase syndrome (ASS), in accordance with the 2017 EULAR/ACR criteria, ii. age ≥ 18 y.o., iii. availability of medical records and consent to study. Data comprised: disease duration and diagnostic delay, clinical phenotype, treatments, and autoantibodies including anti-nuclear antibodies (ANA), MSAs (anti -MDA5, -NXP2, -SAE, Mi2, -TIF1, anti-tRNA synthetase, -Jo1, -PL7, -EJ), and MAAs (anti-PM/Scl, -Ro52, -Ku, U1RNP).

Results: The study cohort comprised 31 patients who met the inclusion criteria, with a similar gender distribution [n= 17 (54.8%) females and n=14 (45.2%) males]. The median age at symptoms onset was similar in both groups (59±13.3 vs 58.6±12.6 yrs) while males experienced slightly longer diagnostic delay (10.7±14.4 vs 8.7±9.6 months) and disease duration (30±29 vs 21±20 months) than females (P <0.05 for both). No significant difference in the distribution of IIM occurred between the two groups with a half of patients affecting mostly by DM (F 76.5% *vs* M 50%). However, both PM (F 6.5% *vs* M 21.4%) and ASS (F 6.5% vs M 28.6%) were moderately prevalent in males. Skin involvement occurred similarly in both groups while lung disease occurred about twofold in males (57.1%) than females (29.4%). Most patients in the cohort showed ANA titre≥ 1:160, with a comparable rate in females and males (64.7% vs 64.3%), and a positivity for at least one MSA and MAA. A double positivity of MSA occurred in 6.5% of the cohort, all females (MDA5/anti NXP2 and MDA5/EJ). The whole cohort had undergone steroids as 1st line therapy: as steroid-sparing agents, the main difference on treatments occurred for the mycophenolate mofetil which resulted significantly more administered in males (57.14%) than females (6%, P 0.002). Furthermore, among patients with lung involvement (n=13), the need to treat the progression of interstitial lung disease, by using the antifibrotic agent (nintetanib), resulted only in males (15%).

Conclusion: Our preliminary findings suggest that IMM can present a gender difference in disease outcome by showing a longer diagnostic delay and a higher respiratory involvement in male patients. These data might highlight a possible gender-oriented approach in accordance with a different disease profile and treatment strategies but require further investigations in a larger cohort.

AB0827 CLINICAL SIGNIFICANCE OF SERUM FERRITIN IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis

S. Markovich Sholomon[1], Y. Braun-Moscovici[2], A. Balbir-Gurman[2]. [1]*Rapaport Faculty of Medicine, Technion, Rheumatology Institute, Rambam Health Care Campus, Haifa, Israel*; [2]*Israel, Rheumatology Institute, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion, Haifa, Israel*

Background: The main systemic sclerosis (SSc) manifestations are skin thickening, microangiopathy and ischemic changes in tissues, fibrotic damage to the lungs, heart, kidneys, and digestive system, arthritis, and myopathy. Acute phase reactants (APR) like erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) reflect inflammation activity in various inflammatory conditions. Ferritin is a protein bound to iron; low serum ferritin indicates iron deficiency and/or anemia. Instead, high ferritin levels are associated with inflammatory and non-inflammatory conditions such as dermatomyositis, pulmonary fibrosis, lupus, systemic COVID-19, vasculitis, tissue damage, thromboembolic complications, and metastatic cancer. The possible role of ferritin in SSc as APR is unclear.
Objectives: We aimed to assess whether ferritin levels can reflect the severity of SSc and predict the outcome.
Methods: 241 files of SSc patients with information on serum ferritin level (ferritin over 300 mg/dL is considered elevated) who visited the Rambam Rheumatology Institute in the years 2004-2021were used for retrospective analysis. Patients' demographic, clinical, laboratory, imaging, and respiratory function data were collected from electronic hospital files. Statistics included Student's T-test, Pearson's chi-squared test, and Kaplan-Meier curve; statistical significance was determined as p<0.05.
Results: 36 patients (FerEl-SSc) had elevated ferritin values; the rest (n=205) represented the second group (FerNor-SSc). Significant differences were seen in gender (male 44.4% - 15.6%), disease duration (4.56 - 7.7 years), modified Rodnan skin score (12.3 - 6.9), as well as in incidence of lung (65.7% - 38.7%), heart (51.4% - 21.1%), and renal (28.6% - 5.9%) involvement. Increased ferritin correlated with elevated ESR, CRP, creatinine, creatine kinase, troponin, and reduced hemoglobin, impaired pulmonary function tests and reduced left ventricular ejection fraction on echocardiography. Patients with elevated ferritin had a significant increase in mortality rates (52.8% and 35.1%) and non-significant reduction in survival.
Conclusion: Our study demonstrated that ferritin has a potential as a sensitive marker for SSc severity in term of skin thickening, vital organ complications, and mortality. The ferritin test is simple and inexpensive, it can add to the complex SSc assessment and contribute to treatment decision-making in complicated SSc.

AB0828 THE DIAGNOSTIC AND PROGNOSTIC VALUE OF COMMERCIAL LINE BLOT ASSAY IN TAIWANESE PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Autoantibodies, Diagnostic Tests

T. H. Yen[1], W. N. Huang[1], Y. M. Chen[1]. [1]*Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China*

Background: Emerging evidence has demonstrated the clinical utility of scleroderma-specific autoantibodies in systemic sclerosis (SSc) [1]. However, the diagnostic performance and prognostic value of line bot assay (LIA) in Taiwanese patients was unknown.
Objectives: Our aim is to evaluate the diagnostic performance of a commercial LIA and the prognostic value of SSc-specific antibodies and anti-Ro52 in Taiwanese population.
Methods: We retrospectively enrolled all individuals tested by the LIA with 13 antigens between 2020 and 2021 in Taichung Veterans General Hospital. The diagnosis of the scleroderma was based on the 2013 ACR/EULAR classification criteria. The positive result of the semi-quantitative test was presented as +, ++ and +++ based on the signal intensity. If multiple antibodies were detected, the patient will be categorized according to the antibody with the highest signal intensity. Multivariable logistic regression was used to evaluate the association between autoantibody subtype and clinical phenotype.
Results: A total of 896 patients (209 SSc, 293 non-SSc CTD, 394 non-CTD) were retrospectively analyzed. ROC analysis of LIA showed numerically higher AUC excluding anti-Ro52 in comparison with whole panel. After excluding anti-Ro52, the LIA exhibited sensitivities of 79.9%, 65.1%, 56.0% and specificity of 44.8%, 65.2%, 72.8% for diagnosis of SSc at different cutoff values respectively (signal intensities 1+, 2+ and 3+). An overall diagnosis performance of AUC 0.674, 65.36% accuracy, 36.36% positive predictive value (PPV), 86.18% negative predictive value (NPV), 1.89 positive likelihood ratio (LR+), 0.53 negative likelihood ratio (LR-) was determined at the optimal cutoff of 2+. For SSc patients, we observed significantly higher risk of diffuse-type scleroderma in participants with negative autoantibodies, anti-Scl-70, anti-RNA polymerase III and anti-Ro-52 positive (OR: 12.28, 95% CI: 3.19-47.19, p <0.001; OR: 33.56, 95% CI:8.91-126.51, p <0.001; OR:18.32, 95% CI:4.16-80.71, p <0.001; OR:2.00, 95% CI:1.05-3.83, p=0.036, respectively, Table1) as compared to the counterparts. Development of ILD was more frequently seen in SSc patients with autoantibody negative, anti-Scl-70, and anti-Ro52 positive (OR: 8.48, 95% CI: 2.79-25.75, p < 0.001; OR:16.91, 95% CI: 5.61-50.95, p <0.001; OR:2.58, 95% CI: 1.35-4.96, p=0.004, respectively) as compared to counterparts. Anti-Ro52 positive was also associated with PAH and GI tract involvement (OR 3.26, 95% CI: 1.18-8.99, P=0.023; OR: 2.86, 95% CI: 1.28-6.39, p=0.011). In addition, we found combination of anti-Scl-70 and anti-Ro52 positive was associated with the highest rate of ILD (Figure 1).
Conclusion: We demonstrated the diagnostic performance of LIA in Taiwanese patients with optimal cutoff defined and also the prognostic values of autoantibodies. Moreover, anti-Ro52 was associated with higher risk of various organs involvement including ILD, PAH and GI tract involvement.

AB0829 PROGRESSION OF ILD (INTERSTITIAL LUNG DISEASE) IN PFT (PULMONARY FUNCTION TEST) AND HRCT (HIGH RESOLUTION COMPUTERIZED TOMOGRAPHY) ACCORDING TO CTD (CONNECTIVE TISSUE DISEASE) IN 12 MONTHS

Keywords: Systemic sclerosis, Rheumatoid arthritis, Lungs

C. L. Garcia Gomez[1], M. Enjuanes[2], E. Abad Plou[2], L. Vega-Álvarez[2], O. Ibarguengoitia[3], I. Calvo[3], E. Galindez[2], J. M. Blanco[2], M. R. Exposito-Molinero[2], I. Torre[2], E. Cuande[2], A. R. Inchaurbe[2], I. Gorostiza[4], M. L. García Vivar[2], M.

E. Ruiz Lucea[2]. [1]*Basurto University Hospital, Rheumatology, Bilbo, Spain*; [2]*Basurto University Hospital, Rheumatology, Bilbao, Spain*; [3]*Galdácano Hospital, Rheumatology, Bilbao, Spain*; [4]*Basurto University Hospital, Statistics, Bilbo, Spain*

Background: ILD is an important cause of morbidity and mortality in CTD. Moreover, it can be the first clinical feature of a CTD.
Objectives: To evaluate progression of ILD in 12 months through HRCT and PFT according to the kind of CTD (systemic sclerosis, myositis, Sjögren's syndrome, rheumatoid arthritis, mixed connective tissue disease, systemic lupus erythematosus), vasculitis, sarcoidosis and interstitial pneumonia with autoimmune features (IPAF).
Methods: A restrospective single tertiary center cohort study in CTD-ILD outpatients seen between 2012 and 2022. Sociodemographic, clinical and serological data, PFT and HRCT results were collected. ILD patterns were classified into usual interstitial pneumonia (UIP), inconsistent UIP, nonspecific interstitial pneumonia (NSIP), fibrosing NSIP, organizing pneumonia (OP), interstitial lymphoid pneumonia and associated to sarcoidosis. Progression of ILD was defined in PFT as: decline ≥ 10% in FVC ≥ 15% in DLCO. Progression of ILD in HRCT was considered according to radiologists'criteria.
Results: Data regarding 83 ILD-CTD patients is shown in Table 1. 54,1% of the patients complained of dyspnea at diagnosis of ILD. Immunosuppression prescribed is shown in Table 1. Treatment was not required in all cases at. diagnosis of ILD. Pulse steroids, mycophenolate and rituximab are some of the most prescribed treatments. UIP was the most prevalent pattern in 40% of the patients with RA (rheumatoid arthritis) but also was present in 28% of non-RA patients. 40% of RA and 28% of non-RA had UIP.

Image 1 shows progression in HRCT and PFT per CTD. Globally, 21,7% (n 14) of the patients progressed according to HRCT criteria and 16,7% (n 12) according to PFT criteria.

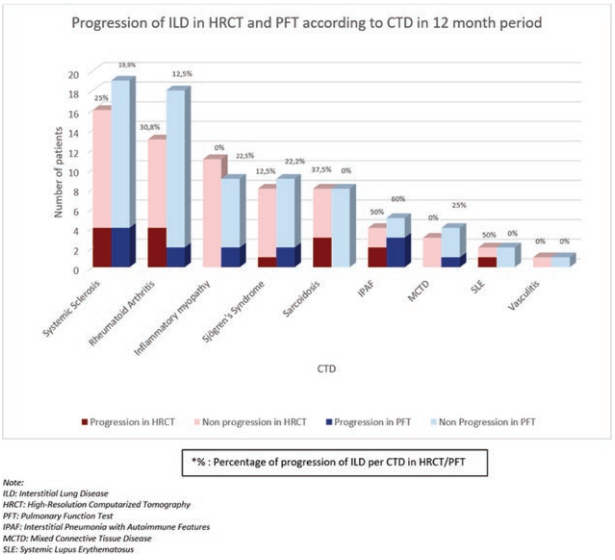

Image 1.

Conclusion: Close follow-up and treatment show non-progression in approximately 80% of the patients. In our series, patients with more progression (as found in literature) are systemic sclerosis, RA and IPAF. More studies must be done to identify best treatments and predictors to avoid progression of ILD.

EXAMINATION OF EXERCISE STRESS ECHOCARDIOGRAPHY AND BIOMARKERS IN SYSTEMIC SCLEROSIS PATIENTS FOR THE EARLY DETECTION OF PULMONARY ARTERIAL HYPERTENSION AND MYOCARDIAL INVOLVEMENT

Keywords: Systemic sclerosis

D. Ladóczky-Hulló[1], B. Morvai-Illes[2], P. Bencsik[3], L. Kovács[1], G. Ágoston[2]. [1]*Albert Szent-Györgyi Medical School, University of Szeged, Department of Rheumatology and Immunology, Szeged, Hungary*; [2]*Albert Szent-Györgyi Medical School, University of Szeged, Department of Family Medicine, Szeged, Hungary*; [3]*Albert Szent-Györgyi Medical School, University of Szeged, Department of Pharmacology and Pharmacotherapy, Szeged, Hungary*

Background: The leading causes of death in patients suffering from systemic sclerosis are interstitial lung disease, malignancy and pulmonary arterial hypertension, but several other cardiovascular complications affect their quality of life.
Objectives: Our investigation aimed to examine biomarkers relating to active fibrotic changes in the myocardium and pulmonary vasculature and to find potential correlations with pathological findings detected by exercise stress echocardiography.
Methods: 28 consecutive systemic sclerosis patients attending our outpatient clinic underwent complete physical examination and routine blood tests. At the same day, resting and stress echocardiography were performed with supine bicycle exercise stress, and serum NT-proBNP, galectin-3 and soluble suppression of tumorigenesis-2 (sST-2) levels were measured. Patients with defined cardiological disease (systemic sclerosis-related manifestation or co-morbidity), interstitial lung disease, overt pulmonary hypertension or severe musculoskeletal disorder (active myositis, arthritis and severe lower limb osteoarthrosis) were excluded from the cohort.
Results: 27 female and 1 male patient participated in the study, aged 55,09±13,05 years. Median serum galectin-3 level was 58.57±31.48 ng/ml, in 24 patients, it was found to be elevated (normal range: >22,1 ng/ml, 85.71%). The sST-2 median level was 108,39±44,06 ng/ml, increased in 27 patients (normal range>35 ng/ml, 96,43%). Elevated levels of NT-proBNP were found in 24 patients. On echocardiography performed at rest, normal pulmonary arterial pressure was calculated in all 28 patients, while in the majority of them (in 23 patients), stress-induced pulmonary arterial hypertension (SIPAH) occurred at different grades of bicycle exercise. In those patients, the NT-proBNP level was also significantly higher (161,4± 85 vs 93,5± 61

pg/ml in those without SIPAH, p <0,05). Serum galectin -3 level showed a negative correlation with the peak heart rate measured at the maximal stress (r=0,48, p<0,05), and Tricuspid Annulus Plane Systolic Excursion (TAPSE) was lower at rest and on exertion in all patients whose galectin-3 level was found to be elevated. (p<0,05)

Conclusion: Biomarkers such as galectin-3 and NP-proBNP provide objective information about the ongoing pathophysiological changes of the myocardium in systemic sclerosis patients. A subset of patients with normal pulmonary arterial pressure at resting echocardiography develops SIPAH. The combination of echocardiographic findings with serum levels of NT-proBNP and galectin-3 may help to identify systemic sclerosis patients with a higher risk of progressive pulmonary arterial or myocardial involvement. Our ongoing project is to follow up these patients with annual examinations.

AB0831 CLINICAL PHENOTYPE OF ANTINUCLEAR ANTIBODY NEGATIVE SYSTEMIC SCLEROSIS IN A COHORT OF SYSTEMIC SCLEROSIS ROMANIAN PATIENTS

Keywords: Autoantibodies, Systemic sclerosis, Organ damage

N. Cristina[1], D. Nicoara[1], L. Groseanu[1,2], D. Predeteanu[1,2], V. Bojinca[1,2], D. Opris Belinski[1,2], I. Saulescu[1,2], S. Daia-Iliescu[1,2], D. Mazilu[1,2], A. Borangiu[1,2], M. M. Negru[1,2], C. Cobilinschi[1,2], D. Mardale[1,2], C. L. Constantinescu[1,2], M. Duna[1], V. Vlad[1], F. Berghea[1,2], M. Abobului[1,2], R. Ionescu[1,2], A. Balanescu[1,2]. *[1]St. Mary's Clinical Hospital, Internal Medicine and Rheumatology, Bucharest, Romania*; *[2]University of Medicine and Pharmacy "Carol Davila", Internal Medicine and Rheumatology, Bucharest, Romania*

Background: Autoantibody formation is one of the hallmarks of systemic sclerosis (SSc). Previous studies suggested that SSc patients who are antinuclear antibody (ANA) negative constitute a distinct subset of SSc patients associated with a better prognosis, defined by male dominance, less vasculopathy and more frequent lower gastrointestinal involvement [1,2].

Objectives: To examine clinical and serologic correlations of Romanian SSc patients without ANA/SSc-related autoantibodies (Abs).

Methods: This was a single-center retrospective study which enrolled 270 SSc. The presence for both circulating SSc-related autoAbs and ANA was screened. Demographic and clinical features, symptoms and parameters related to a specific organ involvement according to MEDS evaluation sheets, were evaluated.

Results: We identified a population of 32 (12%) patients who had neither SSc-related autoAbs nor ANA. The group comprised 27 females and 5 males, with a mean age of 59.7 (±14.3) years, most of them with diffuse subset (25/32). ANA/SSc-related autoAbs negative patients had a significantly younger disease onset (48 [8-76] vs 60.5 [20-81] years, P <.005), longer disease duration (6 [0.1-50] vs 2 [0.1-25] years, P <.001), lower mRSS (7 [2-21] vs 9 [1-23], P <.001) but higher European Scleroderma Study Group (ESSG) activity index (5.3 [0.1-50] vs 2.9 [0.1-25] P <.001), higher proportion of synovitis (42% vs 16%, P <.001) and calcinosis (42% vs 17%, P <.001). For organ involvement, although the absence of SSc-related autoAbs was positively correlated with presence of digital ulcers (P < 0.001), heart and severe pulmonary involvement (P < 0.001), we didn't find a statistically significant difference between the two groups. Patients negative for ANA/SSc-related autoAbs more frequently received corticosteroids (58% vs 14%, P <.0001) and immunosuppressants (16% vs 0.5%, P <.0001) than those positive SSc-related Abs. No differences in mortality were found between the groups.

Conclusion: Our data revealed that ANA/SSc-related autoAbs negative patients are younger and have more frequently diffuse skin involvement, inflammatory arthritis, and calcinosis. Although digital ulcers, severe pulmonary and heart involvement were more common, there was no statistically difference between the two groups. Even though overall disease activity index was significantly higher in seronegative SSc patients, no difference in mortality were found between the groups. Whether the absence of detectable autoAbs persists and is to be viewed as a favorable prognostic factor are questions to be addressed by future studies.

AB0832 CHRONIC INTESTINAL PSEUDO-OBSTRUCTION IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Gastrointestinal tract, Systemic sclerosis, Diet and Nutrition

I. Blazquez[1], A. Guillen-Del-Castillo[1], J. Corada[1], C. Codina[1], A. Gil[1], J. Mestre[1], A. Antón[1], J. Perurena-Prieto[2], C. Malagelada[3], L. Alcala-Gonzalez[3], C. P. Simeon Aznar[1]. *[1]Hospital Universitari Vall d'Hebron, Internal Medicine Department. Systemic Autoimmune Diseases Unit, Barcelona, Spain*; *[2]H. Universitari Vall d´Hebron, Immunology Department, Barcelona, Spain*; *[3]H. Universitari Vall d´Hebron, Gastroenterology Department. Motility Unit, Barcelona, Spain*

Background: Chronic intestinal pseudo-obstruction (CIPO) is one of the gastrointestinal manifestations related to systemic sclerosis (SSc). Despite its low incidence (5%), it burdens a high morbimortality.

Objectives: The objective of the present study was to analyse a selected cohort of patients with SSc and CIPO and to describe the treatments they received, the response to them and the clinical outcome.

Methods: SSc patients diagnosed with CIPO were selected for the study. There was analysed the baseline clinical variables, the period between the diagnosis of SSc and CIPO, the received therapies, and the clinical outcome.

Results: All the seven cases we studied were women, with a median (interquartile range, IQR) age at SSc diagnosis of 46.2 years (34-52). All of them met the ACR/EULAR 2013 classification criteria for SSc. Five (71.4%) of the patients presented diffuse cutaneous SSc (dcSSc), while the other two had the limited cutaneous SSc (lcSSc) subset. The median period between the SSc diagnosis and CIPO was 7.1 years (1.84-15.96). Concerning basal characteristics, 4 (57.1%) patients presented cardiac involvement, 3 (42.8%) arthritis, 3 (42.8%) interstitial lung disease, and 1 (14.2%) pulmonary arterial hypertension. Regarding specific SSc autoantibodies, anti-centromere antibodies were detected in 2 (28.6%) patients, anti-U1RNP in 2 (28.6%) and anti-RNA polymerase III in 1 (14.2%). Six (85.7%) had concomitant small intestinal bacterial growth (SIBO), with positive response to courses of antibiotics. Regarding CIPO treatment, all of them received dietetic recommendations, 6 (85.7%) prokinetics (cinitapride, prucalopride or erythromycin) and 4 (57.1%) the somatostatin analogue octreotide subcutaneous (sc). At CIPO onset, 3 (42.8%) patients had serious oral intolerance, two of them required parenteral nutrition (PTN), while the other received intravenous immunoglobulins (IVIG) and percutaneous endoscopic gastrostomy. During the first year of follow-up after an adequate initial response to treatment, 5 (71.7%) patients had a relapse into CIPO symptoms. Among them, one improved after initiating octreotide sc, 3 required PTN, 2 IVIG and 1 case was treated with adalimumab. Four (57.1%) patients died during the follow-up, three of them as a consequence of gastrointestinal complications related to CIPO, and the fourth because of sudden death.

Conclusion: CIPO is a gastrointestinal manifestation of SSc, that despite its low prevalence, it represents a high morbi-mortality. Patients with dcSSc might have a higher susceptibility for CIPO. There is a substantial variability period between the SSc onset and the appearance of CIPO related symptoms. Diet recommendations, prokinetics and octreotide are common initial therapies, reserving IVIG and PTN for refractory cases or with more aggressive onset. Notwithstanding, the mortality related to this gastrointestinal involvement is certainly significant.

AB0834 VALIDITY AND PSYCHOMETRIC CHARACTERISTICS OF THE DURUÖZ HAND INDEX IN TURKISH PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Outcome measures, Systemic sclerosis, Validation

M. T. Duruöz[1], Y. Karabulut[2], N. Öz[1], D. Erdem Gürsoy[3], H. H. Gezer[4], S. Acer Kasman[5]. *[1]Marmara University Faculty of Medicine, Rheumatology Division, Department of Physical Medicine and Rehabilitation, Istanbul, Turkey*; *[2]Yıldırım Doruk Hospital, Rheumatology, Bursa, Turkey*; *[3]Prof. Dr Cemil Taşcioğlu City Hospital, Rheumatology, Istanbul, Turkey*; *[4]Ümraniye Research and Training Hospital, Rheumatology, Istanbul, Turkey*; *[5]Kartal Dr Lutfi Kirdar City Hospital, Rheumatology, Istanbul, Turkey*

Background: The Duruöz Hand Index (DHI) is a self-report questionnaire that was developed for evaluating the functional status of hands in patients with

rheumatoid arthritis and subsequently validated in many cultures and various rheumatic patient groups [1].

Objectives: The aim of the study was to investigate the validity and psychometric properties of DHI in patients with systemic sclerosis (SSc).

Methods: Patients diagnosed with SSc according to the EULAR/ACR 2013 system were included [2]. Demographic and clinical characteristics of the patients were recorded. Functional assessments of the hands were evaluated with DHI, Keitel Functional Index (KFI), visual analog scale (VAS) for disability, VAS-Handicap for handicap, and Health Assessment Questionnaire (HAQ). Short Form-36 (SF36) was used for assessing quality of life. Disease activity was assessed with European Scleroderma Study Group (EScSG) activity index and VAS doctor's opinion for activity. Modified Rodnan skin score (mRSS), VAS-Hand pain, VAS-Raynoud, swollen joint count (SJC), tender joint count (TJC), Pittsburgh sleep quality index (PSQI), and CRP levels were also noted. For the reliability analysis, internal consistency (Cronbach's alpha) and test-retest reliability (ICC); and for the validity analysis face, content, convergent, and divergent validities were applied. Face and content validities were evaluated via cognitive debriefing interviews with the patients. The correlations of the DHI with KFI, VAS-disability, VAS-Handicap, and HAQ were analyzed for convergent validity. The correlations of the DHI with other measurements (non-functional) were analyzed for divergent validity.

Results: Seventy-three patients with a mean age of 48.6 (SD 12.8) years were recruited and 57 of them were women. Cognitive debriefing showed the DHI to be clear, understandable, and relevant. It was easy to complete and calculate, with the 5 minutes and 30 seconds, respectively. The Cronbach's alpha coefficient for internal consistency was 0.973 and ICC for test-retest reliability was 0.993 (95%CI 0.981-0.997). DHI showed good to moderate correlations with the functional measurements indicating its convergent validity and moderate to non-significant correlations with the non-functional parameters supporting its divergent validity (Table 1).

Conclusion: DHI is a quite practical, reliable, and valid instrument to assess hand function in patients with SSc.

AB0835 CAPILLAROSCOPIC FINDINGS IN PATIENTS WITH SJÖGREN'S SYNDROME, SYSTEMIC SCLEROSIS, AND PRIMARY RAYNAUD'S PHENOMENON IN A HIGH-COMPLEXITY CENTER IN MEDELLÍN, COLOMBIA 2016-2022

Keywords: Sjögren syndrome, Real-world evidence, Systemic sclerosis

S. Hoyos-Patiño[1], A. Arango-Martínez[2], L. M. Rodríguez Padilla[3], A. Chavarriaga Restrepo[4], C. J. Velásquez-Franco[5]. [1]*Universidad Pontificia Bolivariana, Internal Medicine, Medellin, Colombia*; [2]*Universidad Pontificia Bolivariana, School of Health Sciences, Medellin, Colombia*; [3]*Universidad Pontificia Bolivariana, Associate Proffesor, School of Health Sciences, Medellin, Colombia*; [4]*Clinica Universitaria Bolivariana. Clinica CES, Rheumatology, Medellin, Colombia*; [5]*Universidad Pontificia Bolivariana, Rheumatology, Medellin, Colombia*

Background: In Sjögren's syndrome (SS), it has been suggested that capillaroscopy could be useful to identify patients with characteristics of overlap syndromes and risk of evolving into another connective tissue disease, in addition to determine extraglandular systemic involvement. The published information is scarce, as its comparison with systemic sclerosis (SSc) and primary Raynaud's phenomenon (pRP); in addition, different optical instruments other than the videocapillaroscope with 200x magnification have been used.

Objectives: To assess capillaroscopic findings in patients with SS compared to subjects with SSc and pRP at a national capillaroscopy reference center in Medellín, Colombia, between 2016 and 2022.

Methods: An analytical cross-sectional observational study was carried out. Patients over 18 years who met 2016 ACR/EULAR, 2013 ACR/EULAR, and 2014 international criteria for SS, SSc, and pRP, respectively, confirmed by a rheumatologist, were included. Capillaroscopic variables were analyzed (number of capillaries per millimeter, dilated capillaries, megacapillaries, abnormal capillaries, microhemorrhages, avascular zones, arborescent capillaries, capillary disorganization, and capillaroscopic pattern). Qualitative variables were expressed by absolute and relative frequencies and the quantitative by the median and interquartile range (IQR) due to the heterogeneous distribution of data.

Results: In total, there were 195 patients, of which 181 (92.8%) were female; the median age was 53 years (IQR:39-62). The most frequent capillaroscopic finding in SS was the presence of dilated capillaries (n=36; 55.4%). A higher frequency of global capillaroscopic abnormalities was observed in the SSc group compared to the other groups (p<0.0001 in all comparisons). There was no difference in the frequency of arborescent capillaries between the SS and SSc groups. In the SS group, either scleroderma pattern was found in 18.5% (n=12) (Table).

Table. Capillaroscopic findings in 195 patients with Sjögren's syndrome, systemic sclerosis, and primary Raynaud's phenomenon in a capillaroscopy reference center in Medellín, Colombia.

Findings	SS (n=65) n (%)	SSc (n=65) n (%)	RF (n=65) n (%)	p-value **
Decreased capillary density	8 (12.3)	28 (43.1)	0 (0)	<0.0001
Dilated capillaries	36 (55.4)	51 (78.5)	9 (13.8)	<0.0001
Megacapillaries	10 (15.4)	31 (47.7)	0 (0)	<0.0001
Abnormal capillaries	22 (33.8)	36 (55.4)	6 (9.2)	<0.0001
Microhemorrhages	16 (24.6)	33 (51.6)	1 (1.5)	<0.0001
Avascular zones	12 (18.5)	29 (44.6)	0(0)	<0.0001
Arborescent capillaries*	3 (10.7)	2 (10.5)	0 (0)	0.254
Capillary disorganization	22 (33.8)	33 (50.8)	5 (7.7)	<0.0001
Highest capillary diameter (um+)	21.4 (16.9-34.0)	41 (21.4-97.0)	15 (13.1-17.6)	<0.0001 ++
Capillaroscopic pattern				<0.0001
No scleroderma – normal	32 (49.2)	14 (21.5)	65 (100)	
Non-specific abnormalities	21 (32.3)	21 (32.3)	0 (0)	
Early scleroderma	3 (4.6)	3 (4.6)	0 (0)	
Active scleroderma	8 (12.3)	18 (27.7)	0 (0)	
Late scleroderma	1 (1.5)	9 (13.8)	0 (0)	

*Total (n=61), Sjögren's syndrome (n=28), Systemic sclerosis (n=19), Primary Raynaud's phenomenon (n=14)+Median (p25-p75), Raynaud's phenomenon (n=64)** Chi square test ++ Kruskal-Wallis test

Conclusion: Patients with SSc and SS have a high prevalence of capillaroscopic abnormalities with statistically significant differences compared to the pRP group. The high frequency of dilated capillaries in SS stands out, as well as common arborescent capillaries and scleroderma patterns.

AB0836 ANTI-SAE ANTIBODY-POSITIVE DERMATOMYOSITIS: CLINICAL CHARACTERISTICS FROM AN ITALIAN COHORT

Keywords: Myositis

R. Depascale[1], A. Ghirardello[1], E. Zanatta[1], M. Gatto[1], M. Zen[1], L. Iaccarino[1], A. Doria[1]. [1]University of Padua, Rheumatology, Padua, Italy

Background: Anti-small ubiquitin-like modifier-1 activating enzyme (anti-SAE) antibodies are rare myositis-specific antibodies, which are mainly associated with cutaneous involvement in inflammatory myositis (IIM).
Objectives: To analyse clinical characteristics of anti-SAE positive Dermatomyositis (DM) patients in a monocentric cohort. We focused on clinical manifestations and type of organ involvement.
Methods: In a monocentric cohort of 169 patients with IIM, anti-SAE antibody positive patients were included in the study. Anti-SAE antibodies were investigated by immunoblotting. We considered the presentation symptoms at disease onset and during follow-up, focusing on musculoskeletal, cutaneous and pulmonary domains. Muscular involvement was evaluated by Manual Muscle Test-8 and creatin kinase (CK) levels. To determine interstitial lung disease (ILD), high-resolution computed tomography (HRCT) was performed at diagnosis and during follow-up and evaluated by an expert radiologist. Skin and joint involvement was evaluated by clinical judgment. Therapeutic approach was also considered.
Results: Of the 169 patients with IIM, 6 were positive for anti-SAE antibodies (3,5%). Among them, five were female and one male. The mean age at onset of symptoms was 46.3 years (range 5-78 years). Cutaneous manifestations were the most prevalent clinical features at disease onset. Indeed, all of the patients had photosensitive rash, heliotrope rash and Gottron papules. Mechanic's hands were noted only in one patient with ILD. Four (70%) had arthritis. Muscular involvement, which was mostly mild, was evidenced by muscular weakness and high levels of CK (mean value 538 U/l) in 30% of patients (n=2). Three patients (50%) had radiological evidence of ILD at onset or during follow-up. Non-specific Interstitial Pneumonia (NSIP) was the main pattern found. Story of malignancy was noted only in the male patient. Half of the patients (n=3) were treated with methotrexate (MTX). Because of drug intolerance, MTX was substituted by mycophenolate mophetil (MMF) in two of them. One patient received intravenous immunonoglobulin (IGIV) and cyclophosphamide (CYC) for persistent cutaneous disease activity.
Conclusion: In our small cohort of patients, anti-SAE antibodies were strongly associated with skin disease, in one case severe. Lung involvement was another common clinical feature described and malignancy was noted in one case.

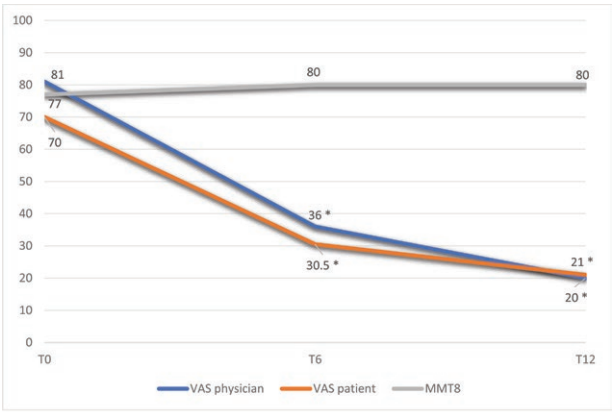
AB0837

EFFECTIVENESS AND SAFETY OF RITUXIMAB AND MYCOPHENOLATE MOFETIL COMBINATION THERAPY FOR IDIOPATHIC INFLAMMATORY MYOPATHIES: A MONOCENTRIC REAL-LIFE STUDY

Keywords: Myositis, bDMARD, Lungs



C. Campochiaro[1], G. De Luca[1], G. Trignani[1], A. Tomelleri[1], M. Matucci-Cerinic[1], L. Dagna[1]. [1]*IRCCS San Raffaele, Vita-Salute San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: Due to a lack of robust clinical evidence, no defined recommendations for the treatment of refractory idiopathic immune myopathies (IIMs) exist. Hence, management of IIMs is still challenging.
Objectives: To assess the real-life effectiveness and safety of rituximab (RTX) and mycophenolate mofetil (MMF) combination therapy in severe and refractory IIMs.
Methods: Adult patients with IIMs ('2017 EULAR/ACR classification criteria'[1]) followed up at our Myositis Clinic and treated with a combination of RTX and MMF were identified. IMACS six core set measures (i.e., VAS physician; VAS patient; MMT8; HAQ; muscle enzymes; extramuscular assessment, including MITAX, MYOACT scores) were recorded at three different time points (baseline, 6-month, and 12-month after first RTX infusion). Subgroup analyses according to the involvement of specific organs (heart, lung) were performed. Safety was evaluated.
Results: We identified 20 IIM patients (ASS, n=12; dermatomyositis, n=2; polymyositis, n=2; immune-mediated necrotizing myopathy, n=1; overlap myositis, n=3). Median age was 61 (48-71) years; 14 patients were women (70%). Myocarditis and interstitial lung disease (ILD) were identified in 7 (35%) and 15 (75%) patients, respectively; 6 patients (30%) had arthritis and 3 (15%) had dysphagia. MMF was started after a median of 2 (0-76) months since diagnosis. RTX was always started after MMF (after a median of 22.5 (10-122) months), and administered at a dose of 1 g 2-week apart repeated 6 monthly. MMF dose was reduced in all patients (to 1 g daily, n=3, 15%; to 2 g daily, n=17, 85%) after RTX introduction. Adjunctive treatments were glucocorticoids (n=17), hydroxychloroquine (n=5), intravenous immunoglobulins (n=3). At 6 months, IMACS core set measures significantly improved all but MMT8 (**Figure**). A significant reduction of CPK and CRP levels and of prednisone (PDN) daily dose was observed (**Table**). In addition, a reduction in troponin T levels in patients with myocarditis and a stabilization of functional parameters in patients with ILD were observed (**Table**). At 12 months, a further reduction in the PDN dose and a further significant reduction in troponin T levels in patients with myocarditis were observed (**Table**). No patient had severe infections; 10 patients (50%) had mild infections (the most common upper respiratory tract infection, n=6).
Conclusion: Combination treatment with RTX and MMF could represent an effective and safe option in patients with severe and refractory IIMs.

PULMONARY AND CARDIOVASCULAR MANIFESTATIONS IN SYSTEMIC SCLEROSIS: RESULTS FROM A SSC PATIENTS COHORT AT A TERTIARY CENTRE OF NW GREECE

Keywords: Lungs, Cardiovascular disease, Systemic sclerosis

N. Gerolymatou[1], N. Koletsos[1], M. Karakosta[1], T. E. Memi[1], A. Drosos[1], P. Voulgari[1]. [1]University Hospital of Ioannina, Rheumatology Clinic, Ioannina, Greece

Background: Systemic Sclerosis (SSc) is a connective tissue disease affecting multiple systems, including the respiratory and cardiovascular systems. Among the various disease complications, interstitial lung disease (ILD), pulmonary arterial hypertension (PAH) and -lately recognized- myocardial fibrosis (MF), are those mainly related to reduced life expectancy.
Objectives: We aimed to evaluate the prevalence of SSc complications and to investigate possible associations with patients' clinical and serological characteristics.
Methods: Patients fulfilling the ACR/EULAR 2013 Scleroderma criteria, who were followed at our tertiary rheumatology centre between January 2018 and December 2022, were included in our cohort. Demographic, clinical, and serological characteristics, as well as imaging data (high-resolution chest CT, cardiac MRI) were used in our retrospective analysis.
Results: Ninety-one patients were included in our study, with 39.6% of them having diffuse cutaneous SSc. Most patients were female (81.3%), with a mean age at diagnosis 50.3 ±14.5 years and a mean disease duration 10.2 ±9.0 years. Leaving aside Raynaud's phenomenon and sclerodactyly, gastrointestinal involvement (71.4%), ulcers (46.2%) and arthritis (45.1%) were among the most prevalent clinical manifestations. Mean baseline FEV1 and FVC values were normal (83.4%±16.8 and 84.4%±18.5 respectively, while mean baseline DLCO was pathological (62.6±18.9). All patients underwent a high-resolution CT early at diagnosis and upon rheumatologist's/pulmonologist's judgement afterwards. Eighty-one patients (89.0%) were diagnosed with interstitial lung disease (76.0% had NSIP pattern, 24.0% UIP pattern). Patients with NSIP had better scores in lung function tests than those with UIP pattern (Mean difference in FEV1, FVC and DLCO were 13,3%, 17,7%, and 12% respectively, p<0.05 for all comparisons). Positivity for anti-topoisomerase antibody (Scl-70) presented an OR=24.9 (p=0.001) for ILD, while ACA and anti-CENP-B were negatively associated (OR=0.114, p=0.003 and OR=0.164, p=0.024, respectively). Pulmonary hypertension based on echocardiogram findings was reported in 18/91 patients (19,8%), however PAH based on right heart catheterization (RHC) was confirmed in 11 of them (12,1% of total patients). Anti-Ro52 positivity was associated with PH (OR=4.45, p=0,005) and PH-ILD coexistence (OR=5.18, p=0,002), however no association was found for ILD presence in this cohort. There was also a trend for PAH-RHC, but it did not reach statistical significance. Cardiac MRI was performed in 24 patients, and non-ischemic myocardial fibrosis (compatible with SSc involvement) was identified in 18/24. The mean disease duration in MF group was longer (8.7 ±7.3 vs 3.3 ±4.3, p=0.040). Gastrointestinal involvement seems to confer an increased risk for this complication (OR=10.0, p=0.038).
Conclusion: The estimated ILD prevalence in our study is significantly higher than the one reported in the literature. As a referral centre, the patients reaching to our department probably have worse organ involvement than the average patient of primacy care setting. In addition, universal screening with a baseline HRCT and close monitoring lead to an earlier identification of this population. Anti-Ro52 has been recently reported as an independent risk factor for PAH. Our results could not verify this observation, probably due to the relatively small number of PAH patients in our study. Cardiac MRI availability and radiologist's experience are essential for MF diagnosis. It is our belief that larger studies are necessary to evaluate this population.

SAFETY OF LOW-DOSE ACETYL SALICYLIC ACID IN PATIENTS WITH SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY

Keywords: Safety, Cardiovascular disease, Systemic sclerosis

G. Pellegrino[1], M. D'orsi[1], M. Cadar[1], I. Bisconti[1], D. M. Reza Beigi[1], F. R. Di Ciommo[1], S. Truglia[1], F. Conti[1], V. Riccieri[1]. [1]Sapienza University of Rome, Department of Internal Medicine, Anesthesiology and Cardiovascular Sciences, Rome, Italy

Background: The low-dose acetyl salicylic acid (ASA) is often used among patients with Systemic sclerosis (SSc) in clinical practice since its use is not mentioned in any official document concerning the management of SSc [1]. Recently, a study from EUSTAR database demonstrated that anti-platelet therapy is a protective factor for digital ulcers onset, while Valentini et al associated the use of ASA with a lower incidence of primary cardiac involvement in SSc patients [2,3]. On the other hand SSc has been shown to be one of the autoimmune diseases with the highest CV risk [4]. The publication of 2022 EULAR Recommendations on cardiovascular (CV) involvement in rheumatic diseases asserting that *"the use of ASA in SSc is not recommended for primary prevention"* because of "*data about this topic were not find"* caused uncertainty to justify the use of this drug [5].
Objectives: Aim of our study was to evaluate the safety of ASA in a cohort of pts affected by SSc.
Methods: We retrospectively analyzed data from patients with SSc, fulfilling the 2013 ACR/EULAR classification criteria [6], followed in our Scleroderma Clinic, receiving ASA. Analysis included data from subjects that were not treated with ASA, as control group. Exclusion criteria were CV disorders and/or major bleeding occurred before the evaluation, treatment with ASA started before the diagnosis of SSc, Helicobacter pylori-related gastritis or other causes of gastritis not SSc-related, tumors, anticoagulant or other anti-platelet therapies. Demographic, clinical, ongoing therapies data were examined; conventional cardiovascular risk factors, instrumental and laboratory assessments were collected and the CV risk was calculated using the SCORE2 and/or SCORE2-OP [7]. All data were collected for a follow-up time variable from 2 to 10 years since ASA was prescribed (for *cases*) and since the first rheumatologic visit after diagnosis was done for *controls* (T0). Safety data included the following variables:

- major bleeding (requiring blood transfusion and/or leading to death)
- minor bleeding
- intracranial hemorrhage
- ocular hemorrhage requiring immediate treatment
- gastroenteric tract hemorrhage
- gastroenteric tract neoplasm
- gastric ulcer

- allergy to ASA

Results: Data were collected from 121 SSc pts, 71 *cases* and 50 *controls*. From the analysis of gastroenteric involvement at T0 *control* pts showed more frequently endoscopic gastroenteric lesions of the upper gastroenteric tract respect to *cases* (N-% *controls vs cases*: 8-16% vs 4-6%; p-value 0.0039). Among traditional CV risk factors we found that *cases* were more frequently smokers than *control*s (N-% *cases* vs *controls*: 15-21% vs 2-4%; p-value 0.007), but no difference was found with either of the other traditional CV risk factors or with the CV risk scores, calculated with SCORE2, between *cases* and *controls.* Our analysis didn't reveal any significant difference on the occurrence of adverse events concerning ASA safety between the two groups: after 1 year of treatment with ASA, 4 subjects showed minor bleeding and in one case a gastric neoplasm was diagnosed; after 2 years of treatment 2 pts reported minor bleeding, while just 1 case showed minor bleeding after 5 years of treatment. Among *controls*, the onset of gastric ulcers in one subject only was reported after 2 years of follow-up.
Conclusion: Despite the long period of ASA treatment, we didn't find a significative increase in the frequency of related adverse events in our pts. ASA seems to be a manageable therapy and, since the high CV risk associated with SSc [4], very similar to that showed by pts with diabetes mellitus where in some cases the use of ASA in primary prevention is recommended, we suggest a reassessment of EULAR Recommendations together with other studies on larger cohort of SSc pts, in order to confirm the safety of ASA.

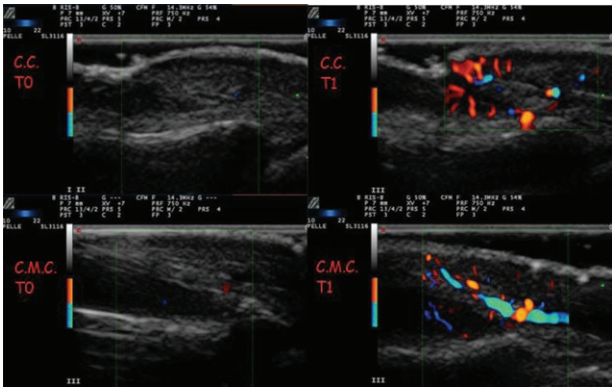
ACUTE VASCULAR EFFECTS OF INTRAVENOUS ILOPROST IN SCLERODERMA PATIENTS CAN BE DETECTED BY POWER DOPPLER EXAMINATION OF THE FINGER SUBCUTANEOUS TISSUE

Keywords: Systemic sclerosis, Imaging

S. Testoni[1], L. Magnani[2], A. Spinella[1], C. Salvarani[1,2], D. Giuggioli[1], P. Macchioni[2]. [1]*Università degli studi di Modena e Reggio Emilia, Rheumatology Unit, Modena, Italy*; [2]*IRCSS Santa Maria Nuova, Rheumatology Unit, Reggio Emilia, Italy*



Background: Intravenous iloprost (ILO) is used in the treatment of refractory Raynaud phenomenon and scleroderma (SSc) digital ulcers. To date, there are no recommended imaging modalities to monitor ILO vascular effects. So far few studies explored ultrasound (US) as a tool to assess vascular subcutaneous involvement in patients affected by SSc.
Objectives: We aim to evaluate the acute vascular effects of intravenous ILO infusion by power Doppler US (PDUS) examination at periungual (PU) and finger pulp (FP) subcutaneous areas in a consecutive series of SSc patients.
Methods: Ten consecutive SSc patients who met the ACR/EULAR criteria for SSc referring to our tertiary center for ILO infusions were enrolled in the study. FP and PU vascularization of the 1st, 2nd and 3rd finger of the dominant hand were evaluated before and after ILO infusion (dosage 0.5-2.0ng/kg/min for 4-6 hours) using an Esaote MylabClassC, (Genoa, Italy) machine equipped with a 22-8 Mhz multifrequency linear probe. All the exams were performed after at least 30 minutes of acclimation in a room with an ambient temperature ranging from 20 to 22C by the same operator (PM). All the images with the highest presence of PD signal were stored for subsequent examination by a rheumatologist (ST) blind to the sequency of the images. The presence of PD signal in every image was scored according to a semiquantitative 0-3 scale (grade 0 no vessels; grade 1: 1-2 visible vessels; grade 2: 3 to 5 vessels, and grade 3 more than 5 vessels). The value of each finger (FP & PU) were summed up to obtain a total patient PD score and values before and after ILO treatment were compared by T-test for paired samples. Single fingers PD improvements after infusion were summed obtaining total improvement respectively for the PU and FP areas.
Results: Clinical and laboratory features of the enrolled patients are reported in Table 1. Mean total PU PD score was 4.2±2.2 at T0 and increased to 7.3±2.5 after treatment **(p=0.012).** Mean FP total PD score was 2,2±1,81 at T0 and remained unchanged (2,8±1,68) at T1 (p= 0,475). The median number of fingers/patient with PU PD improvement after treatment was 2 (1-3), while the median number of fingers/patient with FP PD improvement was 0,5 [0-3].
Conclusion: PDUS examination of the PU area could demonstrate an ILO acute effect in SSc patients with long-lasting disease.

CONCORDANCE AND PROGNOSTIC RELEVANCE OF DIFFERENT DEFINITIONS OF SYSTEMIC SCLEROSIS INTERSTITIAL LUNG DISEASE PROGRESSION

Keywords: Systemic sclerosis, Lungs, Outcome measures

E. De Lorenzis[1,2], G. Natalello[2], S. Di Donato[1], L. Verardi[2], P. G. Cerasuolo[2], V. Kakkar[1], M. A. D'agostino[2], F. Del Galdo[1], S. L. Bosello[2]. [1]*Scleroderma Program, Leeds Institute of Rheumatic and Musculoskeletal Medicine University of Leeds, Leeds Institute of*

Rheumatic and Musculoskeletal Medicine University of Leeds, Leeds (United Kingdom), Leeds, United Kingdom; [2]*Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy., Rheumatology Department, Roma, Italy*

Background: Interstitial lung disease (ILD) is a common complication of systemic sclerosis (SSc) with a variable natural history and prognosis. Several definitions of SSc-ILD progression have been proposed including minimal clinical important worsening of forced vital capacity (FVC MCIW), EUropean Scleroderma Trials and Research group (EUSTAR) progression, Outcome Measures in Rheumatology Clinical Trials (OMERACT) progression, and Erice ILD working group progression. The aim of the study was to assess concordance and prognostic value of these different definitions in SSc-ILD patients overall and specific clinical subsets.
Objectives: Progression status was assessed in consecutive SSc-ILD patients over a period of 24 months and the mortality related to SSc-ILD was compared between progressors and non-progressors according to different definitions in the subsequent 60 months. Severe baseline pulmonary functional impairment was defined for a combination of FVC<80% and alveolar diffusion of CO (DLco) <60% of predicted.
Methods: Progression status was assessed in consecutive SSc-ILD patients over a period of 24 months and the mortality related to SSc-ILD was compared between progressors and non-progressors according to different definitions in the subsequent 60 months. Severe baseline pulmonary functional impairment was defined for a combination of FVC<80% and alveolar diffusion of CO (DLco) <60% of predicted.
Results: The retrospective analysis included 245 SSc-ILD patients (age 54.6±13.2 years, male 18.8%) with a 54.7% prevalence od diffuse cutaneous variant and a median disease duration of 4 years (IQR 2-8). Disease duration ≤ 3 years, severe pulmonary functional impairment, and pulmonary artery systolic pressure (PASP) 40 mmHg were reported in the 47.8%, 18.0% and 17.1% of patients, respectively. Twenty-six deaths were reported among enrolled patients and progression according to FVC MCIW (HR 2.27, 95% IC 1.03 - 4.97, p=0.041), OMERACT (HR 2.90, 95% IC 1.28 - 6.57, p=0.011), and Erice criteria (HR 11.02, 95% IC 2.38 - 51.08, p=0.002) were associated with mortality in the whole cohort. Prognosis prediction, considering the 4 different definitions of progression status, was challenging (independently from the adopted criteria) in patients with disease duration >3 years, mild pulmonary function test impairment, and PASP ≥40 mmHg. Erice criteria performed better in patients with disease duration ≤3 years, limited cutaneous variant, and PASP <40 mmHg, while OMERACT criteria in patients with diffuse cutaneous variant, and severe baseline pulmonary functional impairment.
Conclusion: The proposed progression definitions of SSc-ILD are not interchangeable, since up to one third of progressors could be misdiagnosed using different criteria. Regardless of the criteria used, progressor patients presented more frequently a diffuse skin variant of the disease, a shorter disease duration and worse baseline functional impairment of the lung.

AB0842 HIGH BRONCHOALVEOLAR FLUID NEUTROPHILS INDEPENDENTLY PREDICT 15-YEAR MORTALITY IN SCLERODERMA PATIENTS WITH INTERSTITIAL LUNG DISEASE NAIVE TO IMMUNOSUPPRESSANT

Keywords: Lungs, Innate immunity, Systemic sclerosis

G. Natalello[1], E. De Lorenzis[1,2], L. Verardi[1], P. G. Cerasuolo[1], G. Alonzi[1], S. Fiore[1], A. Zoli[1], S. Di Murro[1], M. A. D'agostino[1], S. L. Bosello[1]. [1]*Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy., Rheumatology Department, Roma, Italy*; [2]*Scleroderma Program, Leeds Institute of Rheumatic and Musculoskeletal Medicine University of Leeds, Rheumatology Department, Leeds, United Kingdom*

Background: Scleroderma interstitial lung disease (SSc-ILD) has a variable and poorly predictable course. Data on independent role of bronchoalveolar lavage fluid (BALF) analysis in prognostic stratification of SSc-ILD patients are conflicting. We wanted to retrospectively evaluate the role of BALF analysis to predict severe course of disease in our cohort of SSc-ILD.
Objectives: We wanted to retrospectively evaluate the role of BALF analysis to predict severe course of disease in our cohort of SSc-ILD.
Methods: Forty SSc-ILD patients naive to immunosuppressants underwent comprehensive clinical evaluation, bronchoalveolar fluid analysis with total and differential leukocyte count, pulmonary function tests (PFTs), high-resolution computed tomography (HRCT). All the patients had fibrosing lung disease affecting more than 10% of lung volume on HRCT. Baseline alveolar (AS) and interstitial score (IS) on HRCT were computed. The 15-year crude mortality rate was retrospectively assessed.
Results: The enrolled patients (pts) (male 20.0%, aged 53.9±13.0 years) had a disease duration of 4.3±3.4 years. Diffuse LeRoy variant was reported in 47.5% of patients and anti-Scl70 and anti-centromere antibodies were detected in 57.5% and 12.5% of pts, respectively. The average AS and IS were 6.5±4.8 and 6.2±2.7, respectively, while 25.0% had FVC≤80% and 35.0% had DLco≤50%. During follow-up 18 pts received immunosuppressants. BALF neutrophilia (≥3.0%), eosinophilia (≥1.0%) and lymphocytosis (≥15.0%) were reported in 40.0%, 16.0% and 5.0% of patients, respectively. Twenty-five pts (62.5%) died within 15 years after bronchoscopy with a mean survival of 12.7 years (95% IC 11.5-13.9) overall. Fifteen-year mortality was predicted by BALF alveolitis (HR 2.87, 95% IC 1.26-6.56), and neutrophilia (HR 3.74, 95% IC 1.64-8.55), log-transformed absolute count of total cells (HR 2.52, 95% IC 1.12-5.58), neutrophils (HR 1.80, 95% IC 1.28-2.54), and eosinophils (HR 1.31, 95% IC 1.05-1.62), and percentages of neutrophils (HR 1.8, 95% IC 1.26-2.73) and eosinophils (HR 1.32, 95% IC 1.01-1.73). Only absolute and relative neutrophil counts were independently associated with mortality also in all models adjusted for demographics (age, gender), main disease traits (diffuse LeRoy variant, anti-Scl70 positivity), baseline pulmonary function tests (FVC, DLco), baseline HRCT involvement (AS, IS) and presence of vascular involvement (pulmonary hypertension, digital ulcers).
Conclusion: High BALF neutrophils were associated with high 15-year mortality independently from other established clinical risk factors. Given the negative prognosis of SSc-ILD, its poorly predictable clinical course, and the availability of new promising biomarkers, BALF analysis may be considered in assessing these pts to improve prognosis prediction.

AB0843 THE EXPRESSION PROFILING OF CIRCULATING MIRNAS IN SYSTEMIC SCLEROSIS

Keywords: Genetics/Epigenetics, Systemic sclerosis

S. Machhua[1], R. Minz[1], S. K. Sharma[1,2], Y. Kumar[1], S. Singh[3], S. Anand[1], S. Handa[4]. [1]*Post Graduate Institute of Medical Education & Research, Chandigarh, Immunopathology, Chandigarh, India*; [2]*Post Graduate Institute of Medical Education & Research, Chandigarh, Internal Medicine, Chandigarh, India*; [3]*Post Graduate Institute of Medical Education & Research, Chandigarh, APC, Chandigarh, India*; [4]*Post Graduate Institute of Medical Education & Research, Chandigarh, Department of Dermatology, Venereology and Leprosy, Chandigarh, India*

Title: The expression profiling of circulating miRNAs in systemic sclerosis.
Background: Systemic sclerosis (SSc) is a rare chronic disease of unknown etiology. Genetics plays an important role in SSc's pathogenesis; however, considering genetic factors alone does not explain the disease's occurrence, epigenetic influences are also believed to contribute to SSc development [1]. miRNAs are reported to be aberrantly expressed in SSc patients and, therefore, potential contributors to its pathogenesis. The role of miRNAs in SSc is just beginning to unravel [2].
Objectives: To investigate the expression profile of circulating miRNAs in SSc.
Method: Whole blood miRNA (84 miRNAs involved in human fibrosis) transcripts were identified by miScript miRNA PCR Array using RT-qPCR.
Results: Fourteen miRNAs (6 upregulated -hsa-miR-145-5p, hsa-miR-150-5p, hsa-miR-18a-5p, hsa-miR-195-5p, hsa-miR-223-3p, hsa-miR-29c-3p; 8 down-regulated- hsa-miR-211-5p, hsa-miR-217, hsa-miR-31-5p, hsa-miR-328-3p, hsa-miR-335-5p, hsa-miR-382-5p, hsa-miR-449a, and hsa-miR-661) showed differential expression compared to controls. IPA (Ingenuity Pathway Analysis) predicted miRNA-mRNA targets gene (hsa-miR-145-5p, hsa-miR-18a-5p, and hsa-miR-449a- TGFβ1), were validated through qRT-PCR and found to be dysregulated in the SSc patients. DIANA-Mir Path v3.0 pathway analysis showed dysregulated miRNAs were associated with pathways implicated in SSc's pathogenesis (Figure 1).
Conclusion: The differentially expressed miRNA and their putative mRNA targets and associated pathways may provide diagnostic biomarkers as well as point to therapeutic targets for SSc treatments.

AB0844 ARTERIAL ISCHEMIC EVENTS AND VENOUS THROMBOSIS IN SYSTEMIC SCLEROSIS: DATA FROM A MONO-CENTRIC STUDY

Keywords: Cardiovascular disease, Comorbidities, Systemic sclerosis

A. Dellal[1], O. Fain[2], A. Mekinian[3]. [1]*Intercommunal Hospital Group Le Raincy Montfermeil, RHEUMATOLOGY, Montfermeil, France*; [2]*Hospital Saint-Antoine Ap-Hp, Internal medicine, Paris, France*; [3]*Hospital Saint-Antoine Ap-Hp, INTERNAL MEDICINE, Paris, France*

Background: Systemic sclerosis is a systemic autoimmune disease characterized by vasculopathy (Raynaud phenomena), pulmonary arterial hypertension (PAH), and renal crisis), fibrosis of skin and visceral organs (notably the gut, heart, and lungs), and musculoskeletal inflammation (joints, muscles, and tendons) **[1].** Inflammation drives atherosclerosis and contributes to cardiovascular (CV) disease **[2]**. A few studies have examined the incidence of individual macrovascular manifestations such as myocardial infarction, stroke, peripheral artery disease, and venous thromboembolism **[3-4-5].**
Objectives: Our aim to estimate the incidence and the **arterial ischemic events and venous thrombosis** rates of SSc in our database. We also investigated underlying **the classical risk factors for venous thromboembolism (VTE)** unprovoked (deep venous thrombosis and pulmonary emboli not associated with cancer, recent surgery, hospitalization, fracture and pregnancy) and ASCVD (myocardial infarction and stroke).
Methods: In a retrospective cohort of SSc patients between 2005 and 2017, arterial ischemic events (myocardial infarction, ischemic stroke), venous thrombosis, risk Factor (Hyperlipidemia, Smoking, Diabetes, hypertension, abdominal obesity), classical risk factors for venous thromboembolism, as well as cardiac, cutaneous and immunological characteristics were assessed.
Results: The study population comprised 212 patients (86 % female) with a diagnosis of SSc. We identified a total of 7 (3%) and 26 (12%) patients have respectively an only arterial ischemic events or venous thrombosis, and 6 (3%) additional patients have both arterial and venous thrombosis, with an event during median 10(5-34) and 6 (0-55) years of follow-up. Venous thrombosis (VT) is present in 26 patients (12 %), active or historic neoplasia is present in 4 patients (15%) of VT. In comparison of patient without VT, 20 patients (11%) have a neoplasia. Arterial ischemic events are also most frequent in female sex n=6 (86 %) with all patients (100%) have a limited sclerosis, antinuclear antibodies and Raynaud phenomena, but no difference with the control group without thrombotic events. The prevalence of most cardiovascular disorders was found to be higher in the SSc with limited sclerosis than in diffuse sclerosis. The tobacco use, alcohol is not associated of increase risk of thromboembolic events. The presence of other autoimmune tissue disorders is not significant (p>0.0003) associated of increase rate among patients with SSc with thrombotic events than without. Further adjustment for medications (aspirin, NSAIDs, glucocorticoids, statins, oral anticoagulants, and platelet inhibitors) and comorbidities yielded results similar to the main analyses, except for ischemic stroke.
Conclusion: In this monocentric study, SSc was associated with greater risks of venous thrombosis and ischemic events, with a mortality rate in group with arterial ischemic events. There is no significant statistic difference associated of the classical risk factors of venous thromboembolism, comorbidity and the arterial ischemic events and venous thrombosis in systemic sclerosis.

AB0845 A NOVEL MARKER IN SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE: PEROXIREDOXIN-4

Keywords: Biomarkers, Systemic sclerosis, Lungs

G. T. Alp[1], H. Karadeniz[2], I. Vasi[2], A. Avanoglu Guler[2], A. Erden[2], H. Küçük[2], Ö. Gülbahar[3], A. Tufan[2], M. A. Öztürk[2]. [1]*Gazi University Faculty of Medicine, Internal Medicine, Ankara, Turkey*; [2]*Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey*; [3]*Gazi University Faculty of Medicine, Medical Biochemistry, Ankara, Turkey*

Background: Krebs von den Lungen-6 (KL-6) and surfactant protein D (SP-D) are suggested as useful markers for the evaluation of systemic sclerosis associated interstitial lung disease(SSc-ILD)[1-3]. Increased expression of Peroxiredoxin-4(PRDX-4) mRNA had been demonstrated in the lung tissue of patients with ILD[4]. PRDX-4, a member of peroxidases family, has not been studied as a marker in SSc-ILD before.
Objectives: Aim of this study was to assess the clinical significance of serum PRDX-4 as a viable alternative to KL-6 and SP-D in patients with SSc-ILD.
Methods: The serum PRDX-4, KL-6 and SP-D levels were determined by ELISA in 61 patients with SSc(34 with ILD and 27 without ILD) and 28 healthy controls. Lung function parameters were assessed, the extent of ILD was measured by a HRCT score.
Results: PRDX-4 levels were significantly higher in patients with SSc-ILD than in SSc without ILD patients and controls[14.27(26.14) vs. 10.17(3.22) vs. 9.68(2.06)ng/ml, median,(IQR), p=0.001). KL-6 levels were also remarkbly different between groups[134.25(224.28) vs. 103.90(34.81) vs. 92.84(29.16) U/ml, median,(IQR), p=0.002)]. Moreover PRDX-4, KL-6 and SP-D levels in patients with progressive ILD were significantly higher in stable ILD patients(p<0.001). PRDX-4, KL-6 and SP-D were correlated each other(p<0.01). Receiver operator characteristic curve analysis demonstrated high sensitivity and specificity of PRDX-4 for the determination of SSc-ILD and progressive pulmonary fibrosis. (AUC:0.705, p<0.01 and AUC:0.936, p<0.001).
Conclusion: PRDX-4 is more sensitive and spesific than KL-6 and SP-D and it is a potentially useful marker in assessing interstitial lung disease and progressive pulmonary fibrosis in patients with SSc.

AB0846

EFFICACY OF RITUXIMAB IN IDIOPATHIC INFLAMMATORY MYOPATHIES. EXPERIENCE ON 36 PATIENTS FROM A PROSPECTIVE MONOCENTRIC COHORT

Keywords: Myositis

A. Gamba[1], L. Iaccarino2, E. Cocconcelli[3], E. Zanatta2, R. Depascale2, L. Ienna2, E. Balestro[3,3], M. Zen2, M. Gatto2, A. Doria2. *[1]Padova University Hospital, Department of Rheumatology, Padova, Italy*; *[1]Padova University Hospital, Department of Rheumatology, Padova, Italy*; *[3]Padova University Hospital, Department of Pneumology, Padova, Italy*

Background: Idiopathic inflammatory myopathies are a heterogeneous group of autoimmune disorders characterized by muscle inflammation frequently associated with the involvement of other organ systems. Due to variety of presentations and severity degree, treatment of inflammatory myopathies is challenging. Considering the immunopathogenic role of B cell in myositis, Rituximab (RTX), as B cell depleting agent, could be an effective therapy in patients refractory to others immunomodulatory drugs.
Objectives: The aim of the present study is to demonstrate the efficacy of RTX for the treatment of idiopathic inflammatory myopathies in multi refractory patients. We also considered the effectiveness of a low-dose RTX as a remission-maintenance therapy.
Methods: From a monocentric cohort of patients with inflammatory myopathies, we considered all patients who have been treated with RTX (2 infusions of 1 gram, week 0-2). We also considered low-dose RTX as a single dose of 1g every 6 months. The response to RTX was considered based on physician judgement (complete CR, partial PR, no-response NR), focused on muscle and lung manifestations. Improvement in muscle involvement was based on reduction of 30% of creatine kinase levels and/or an increase in Manual Muscle Test score (MMT-8) of 20%. Interstitial Lung disease (ILD) was evaluated by pneumologist judgement based on chest computer tomography and spirometry. A response was considered partial if it was maintained less than 6 months from RTX administration and complete if it persisted more than 6 months.
Results: Thirty-six patients were included, 15 with diagnosis of polymyositis, 13 with antisynthetase syndrome, 6 with dermatomyositis, 1 with inclusion body myositis and 1 with necrotizing myopathy. Anti-Jo1 autoantibodies were found in 12 patients, anti-SSA in 9, anti-SRP in 5, anti-PM/Scl 75 in 2, anti-Mi2 in 2, anti-PL7 in 1, anti-PL 12 in 1, anti-SSB in 1, anti-TIF1-γ in 1, anti Ku in 1 and anti Sp100 in 1. Most patients (50 %, n=18) were treated with RTX for muscle involvement, 17 % (n= 6) for ILD, 33 % (n=12) for both muscular and lung disease. All patients received oral glucocorticoid before starting RTX administration. The others previous therapies were: methotrexate in 72% of patients, mycophenolate mofetil in 50%, IVIG in 27%, azathioprine in 22%, hydroxychloroquine in 14%, cyclosporine in 14%, leflunomide in 11%, tacrolimus in 3%, cyclophosphamide in 3%. We observed CR to RTX in 70% of patients, PR in 19%, NR in 11%. In the subgroup treated for muscle involvement (n=18), we found a CR in 10 patients, a PR in 5 and NR in 3. In patients with ILD, 5 patients got a CR and 1 PR. In the group of patients with both lung and muscle manifestations, we observed 10 CR, 1 with PR and 1 with NR. Five patients were treated with a low dose maintenance therapy after having achieved remission with standard dose. Three patients had a diagnosis of polymyositis, one of dermatomyositis and one of antisynthetase syndrome. Patients received a minimum of 3 infusions and a maximum of 5 infusions of low dose RTX.Therapy was administrated for an average of 3 years. All of them maintained a CR to RTX.
Conclusion: In our cohort, RTX was effective in 89% multi-drug refractory patients and the low-dose was efficacious as a maintenance therapy in all cases.

COMORBIDITIES IN IDIOPATHIC INFLAMMATORY MYOPATHIES: DATA FROM THE MYOCITE COHORT

Keywords: Autoantibodies, Myositis, Comorbidities

E. Conticini[1], T. Khursheed[2], A. K. Anuja[3], V. Agarwal[3], L. Gupta[4,5,6]. *[1]University of Siena, Rheumatology Unit, Department of Medicine, Surgery & Neurosciences, Siena, Italy*; *[2]Pakistan Institute of Medical Sciences, Rheumatology, Islamabad, Pakistan*; *[3]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India*; *[4]Royal Wolverhampton Hospitals NHS Trust, Department of Rheumatology, Wolverhampton, United Kingdom*; *[5]City Hospital, Sandwell and West Birmingham Hospitals NHS Trust, Department of Rheumatology, Birmingham, United Kingdom*; *[6]Centre for Musculoskeletal Research, School of Biological Sciences,The University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom*

Background: Patients affected by idiopathic inflammatory myopathies (IIM) may suffer from comorbidities such as cancer and cardiovascular diseases, calling for optimized evaluation and additional management(1, 2).
Objectives: We aimed to explore the prevalence and profile of comorbidities in a cohort of Indian patients diagnosed with IIM, and to explore their association with a disease subtype and autoantibodies.
Methods: Information on demographics, disease subtype and autoantibodies in Indian patients with IIM were extracted from the MyoCite dataset. Comorbidities were classified as autoimmune, cardiovascular, cancer, infections, Diabetes Mellitus and others. Pearson's chi-square and Fisher's exact test were used to assess differences in the occurrence of any comorbidity between the various IIM subtypes and antibodies.
Results: Of 250 patients (F:M 3.9:1, median age 36.0 ± 15.4), the majority (110, 44.0%) were diagnosed with dermatomyositis (DM), followed by overlap myositis (OM) (59, 23.6%) and anti-synthetase syndrome (ASS) (45, 18.0%). Patients with comorbidities had a higher median age (40 ± 13.9 years) compared to patients without comorbidities (35 ± 16 years) without any statistical significance. A statistically significant increase (P<0.001) in female to male ratio was observed in patients with comorbidities (10.5:1) compared to patients without comorbidities (2.3:1). Female gender was associated with higher odds of any comorbidity (OR = 4.58; 95 CI = 2.17-9.65). Comorbidities were identified in nearly half (115, 46.0%) of the patients, with autoimmune comorbidities being the most common (72/115, 62.6%) followed by cardiovascular (38/115, 33.0%) and infections (24/115, 20.9%). Hypertension was identified as the most common comorbidity (38/115 33.0%) overall, followed by thyroiditis (26/115, 22.6%) and mixed connective tissue disease (23/115, 20.0%). Statistically significant differences (P<0.001) in frequency of comorbidities was observed in DM (OR = 0.21; 95 CI = 0.12-0.36) and OM (OR = 136.3; 95 CI = 18.44-1008.45).
Conclusion: Despite younger population with IIM, comorbidities are frequently reported in nearly half of Indian patients with IIM. It is noteworthy that autoimmune comorbidities and infections are fairly common with substantial cardiovascular risk calling for optimized assessment and care.

AB0848 DISEASE BURDEN IS ASSOCIATED WITH POOR PATIENT-REPORTED OUTCOMES IN WOMEN'S HEALTH-RELATED DOMAINS OF QUALITY OF LIFE IN SYSTEMIC SCLEROSIS: A STUDY ON 100 PATIENTS BY A MULTIDIMENSIONAL QUESTIONNAIRE

Keywords: Systemic sclerosis, Quality of life, Gender/diversity issues

M. G. Lazzaroni[1], L. Moschetti[1], E. Pedretti[1], A. Lojacono[2], S. Zatti[3], F. Ramazzotto[3], A. Tincani[1], F. Franceschini[1], P. Airò[1], L. Andreoli[1]. *[1]ASST Spedali Civili of Brescia, University of Brescia, Rheumatology and Clinical Immunology, Brescia, Italy*; *[2]ASST Garda, Desenzano del Garda, Obstetrics and Gynaecology, Brescia, Italy*; *[3]ASST Spedali Civili of Brescia, University of Brescia, Obstetrics and Gynaecology, Brescia, Italy*

Background: Systemic Sclerosis (SSc) affects mostly women, with a significant impact on different domains of their quality of life (QoL).
Objectives: We aimed to identify clinical and demographic features of SSc women associated with impairment in specific QoL domains related to women's health (gynecological issues, sexual dysfunction, family planning), by means of a multidimensional ad hoc-created questionnaire [1].
Methods: The questionnaire was administered to consecutive SSc female patients attending our Unit over one year (May 2021-January 2022). The Female Sexual Function Index (FSFI) questionnaire was also administered. Clinical and demographic data were retrieved from clinical charts.
Results: One hundred women were enrolled, with a median [IQR] age of 59 [43-67] years, median disease duration of 11 [6-17] years; 75% had limited cutaneous involvement (lcSSc); 43% had anti-centromere antibodies; 48% had received diagnosis during reproductive age (<45 years). Non-regular gynecological follow-up visits were reported by 40% of patients. They were older at diagnosis and at questionnaire, more frequently post-menopausal (p:0.003, OR 4.96, 95%CI 1.68-16.6) and required immunosuppression more frequently (p:0.006, OR 2.37, 95%CI 1.02-5.50) than those regularly attending visits (Table 1). A negative impact of SSc on sexual function was reported by 60% of patients. Among the 39 patients who compiled the FSFI questionnaire, 24 (62%) displayed sexual dysfunction (score ≤26.55). These women were older and more treated (p:0.013, OR 7.50, 95%CI 1.69-33.3) as compared to patients with normal sexual function (Table 1). Among 48 patients who were diagnosed during reproductive age, 54% wished for a pregnancy after diagnosis and 30% did not reach the desired family size. These were more frequently affected by digital ulcers (p:0.040, OR 10.3, 95%CI 1.03-103) as compared to those who satisfied their family plan (Table 1).
Conclusion: Older age at diagnosis, digital ulcers, and immunosuppressive treatment were associated with a negative impact on women's health-related domains of QoL in SSc patients. The disease burden impairs sexual function and adherence to regular gynecological visits and receiving diagnosis during reproductive age increases the likelihood for a reduced family size. Clinicians caring for SSc women should be aware of the relevance of these domains of QoL, not usually considered in everyday practice as treatment targets.

AB0849 JAK INHIBITORS IMPROVE SEROPOSITIVE REFRACTORY MYOSITIS: SINGLE CENTER EXPERIENCE

Keywords: Myositis, Targeted synthetic drugs, Safety

M. Kosmetatou[1], G. S. Moysidou[1], S. Flouda[1], N. Michalakeas[2], M. Gerohristou[3], A. Filippopoulou[1], K. Zoupidou[1], P. Katsimpri[1], D. Boumpas[1], C. Mavragani[1,2]. *[1]Athens, Rheumatology and Clinical Immunology Unit, 4th Department of Internal Medicine, Attikon University Hospital, Athens, Greece*; *[2]National and Kapodistrian University of Athens, Greece, Departments of Physiology and Pathophysiology, School of Medicine, Greece & Joint Academic Rheumatology Program, National and Kapodistrian University of Athens, Greece, Athens, Greece*; *[3]National and Kapodistrian University of Athens, Athens, Greece, 1st Department of Dermatology-Venereology, Faculty of Medicine, Andreas Sygros Hospital, National and Kapodistrian University of Athens, Athens, Greece, Athens, Greece*

Background: Inflammatory myopathies are heterogeneous with variable clinical course and prognosis [1]. Despite conventional treatment, some patients are refractory [2].
Objectives: To describe the efficacy and safety of JAK inhibitors (JAKi) in patients with refractory dermatomyositis (DM).
Methods: Retrospective analysis of 6 patients with active DM, refractory to previous immunosuppressive treatment including methotrexate, rituximab, mycophenolate mofetil, cyclophosphamide and intravenous immunoglobulin. Demographical, clinical characteristics, outcomes and adverse events after JAKi administration were recorded.
Results: 83.3% of the patients were women, with mean age 62.4±10.9 years. All patients had long-standing disease with mean disease duration 9±8.1 years. Three patients were seropositive: one with positive anti-MDA5 antibodies, one with association of anti-Jo1 and anti-Ro52 antibodies and the latter with positive anti-Ro52 antibodies. The most frequently used JAKi was upadacitinib (50%), followed by tofacitinib (33.3%) and baricitinib (16,6%). Mean daily dose of corticosteroids at baseline was 8. 5mg.Prior to treatment with JAKi, mean muscle strength was 108±35, with mean CPK levels of 997±2244. Four patients had active skin rash. After a mean follow-up period of 7.6 months, all four patients with persistent skin involvement had clinical response (MMT-8=127±30). Muscle strength was improved in 4 patients (66.6%). Of note, the two patients that did not respond to JAKi were seronegative with marked muscular atrophy. One patient discontinued treatment due to severe thrombocytopenia. No other adverse events were recorded.
Conclusion: In this case series, JAKi treatment resulted in clinical improvement in seropositive patients with longstanding, refractory DM with acceptable safety profile. Prospective data are necessary to confirm these preliminary findings and define the subset of DM patients most likely to benefit from JAKi treatment.

EQ5D-5L BASED HEALTH UTILITY SCORES AND QUALITY ADJUSTED LIFE YEARS(QALY) IN IDIOPATHIC INFLAMMATORY MYOSITIS: A PROSPECTIVE STUDY

Keywords: Descriptive Studies

C. Kavadichanda[1], .P. [2], M. Gorijavolu[1], S. K. Dunga[1], S. Kar[2]. [1]*JIPMER, Clinical Immunology, Pondicherry, India*; [2]*JIPMER, Preventive and Social Medicine, Pudducherry, India*

Background: Idiopathic inflammatory myopathies (IIM) are a heterogenous group of diseases manifesting with involvement of the musculoskeletal, mucocutaneous and pulmonary domains. Studies have shown that the health-related quality of life (HQoL) in IIM is poorer than that in the general population with decreased muscle strength being associated with low HQoL [1]. However, majority of the studies are cross sectional and the data on the use of EQ5D-5L based health utility measures in myositis is sparse.

Objectives: To quantify the EQ5D-5L based health utilisation scores and QALY in a cohort of IIM. To identify the determinants of gain in QALY in IIM.

Methods: This was a single center prospective study involving patients with IIM classified using the 2017 EULAR/ACR classification criteria. Patients were recruited between 2018 February and July 2022. All the patients were evaluated at 3 and 6 months with Manual muscle testing of 8 muscle groups (MMT-8), Functional index 3(FI3) and 2 minute walk distance (2MWD), besides the other components in the core set measures. EQ5D-5L was administered to all the patients during each of their visits. The health utility scores for EQ5D-5L health states specific for Indian population was used and QALY was calculated across three time points (0, 3 and 6 months). Individuals with MMT8 of <55 or those who had extra muscular disease activity of > 6 were considered severe disease. Those who had an MMT8 of > 74 and extramacular disease activity VAS of <2 were considered inactive disease and the rest as moderate disease. Linear regression models for identifying the role of change in MMT8, FI3 in predicting gain in health utility scores at 3 and 6 months were constructed.

Results: There were 54 patients with IIM included in this study. The mean ±SD age of the cohort was 37.35±10.15 years and 41 of them were females. Interstitial lung disease was present in 24 patients. There were 30 dermatomyositis, 18 antisynthetase syndromes, 3 immune meditated necrotizing myopathies and 3 polymyositis. The median (IQR) of extra-muscular disease activity in the cohort was 2.3 [0-5]. Fourteen patients had severe myositis and 16 had inactive disease at baseline. The baseline and change in health-related quality and the impact of achieving early disease response is represented in Figure 1. Upon linear regression modelling with change in health utility scores as dependent variable, both between 0-3 months and 6 to-12 months the severity of disease at baseline determined the change. Improvement in MMT-8 and FI3 had significant predictability between 0-3 months but only change in MMT-8 had significant effect on improvement in health utility score between 3 and 6 months when adjusted for age and baseline disease status (Table 1).

Conclusion: The health-related quality of life at baseline and its improvement on follow up is extremely low in individuals with severe IIM. Achieving inactive disease status within 3 months results in significant QALY gain. Improvement in muscle power significantly determines improvement in health related quality of life when adjusted for other factors.

AUTOLOGOUS HEMATOPOIETIC STEM–CELL TRANSPLANTATION IN SEVERE AND REFRACTORY SYSTEMIC SCLEROSIS. LONG-TERM MULTICENTRE STUDY

Keywords: Systemic sclerosis, Skin, Lungs

I. Gonzalez-Mazon[1], G. Espinosa[2], C. De la Puente Bujidos[3], A. Martínez Gutiérrez[1], C. Secada-Gómez[1], R. Blanco[1]. [1]*University Hospital Marques de Valdecilla, Rheumatology, Santander, Spain*; [2]*Hospital Clinic, Internal Medicine, Autoimmune Diseases, Barcelona, Spain*; [3]*University Hosptital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: Pharmacological therapy does not reverse the natural course of systemic sclerosis (SS). Autologous hematopoietic stem-cell transplantation (AHSCT) has been used in refractory autoimmune diseases, including SS. The

AHSCT is based on the ablation of the immunoreactive system with high doses of chemotherapy and a subsequent regeneration of the immune system.
Objectives: Study of the efficacy of AHSCT in a multicentric cohort of patients with SS.
Methods: Descriptive study of patients with SS (ACR/EULAR 2013 criteria) treated with AHSCT between 2002 and 2022. These clinical variables were reviewed (Raynaud's phenomenon, pulmonary interstitial involvement, digital ulcers, presence of sclerodermic renal crisis) and activity index variables (Modified Rodnan Score, HAQ-DI).
Results: We included 11 patients with a mean age of 43±12.1 years, with a mean time of disease of 17±12.6 months. In all cases but one, the initial diagnosis was diffuse cutaneous SS, refractory to corticosteroids and at least one DMARD (Methotrexate n=7, Rituximab n=4, Azathioprine n=3, Tocilizumab n=1). One patient had a limited cutaneous SS and was treated with AHSCT due to a concomitant Hodgkin lymphoma. All patients (100%) had positivity for anti-nuclear antibodies and 8 (72.7%) for anti-Scl70. 11 patients (100%) presented Raynaud's phenomenon and sclerodactyly and 9 (81.8%) suffered from skin ulcers. 7 patients (63.6%) had interstitial lung disease and 1 patient had history of sclerodermic renal crisis. The conditioning treatment for the AHSCT was cyclophosphamide and anti-thymocyte globulin with the exception of 1 patient who developed an infusion reaction (in which the globulin was stopped) and 1 patient with Hodgkin lymphoma (who received a different chemotherapy schedule). After the AHSCT, 1 patient (9.1%) died of cardiorespiratory arrest after acute pulmonary edema the day +45. Other adverse events observed where febrile neutropenia (n=8, 72.7%), mucositis (n=4, 36.4%), confirmed infection (n=3, 27.3%) and serum sickness (n=3, 27.3%). The response of AHSCT is summarized in **table**. An improvement in Modified Rodnan Score, skin ulcers and HAQ-DI was observed.
Conclusion: AHSCT can be a therapeutic option in refractory and severe SS. These hopeful data must be ratified in larger studies.

Table.

	BASAL	6 MONTHS	12 MONTHS
Skin involvement			
Raynaud – n (%)	11 (100)	10 (90.1)	9 (81.8)

AB0852 CLINICAL CHARACTERISTICS, MYOSITIS AUTOANTIBODY PROFILE AND EARLY TREATMENT RESPONSE IN IDIOPATHIC INFLAMMATORY MYOSITIS - A SINGLE CENTRE EXPERIENCE FROM SOUTH INDIA

Keywords: Myositis, Autoantibodies

H. Gangadharan[1], R. Thomas[2], R. T R[1]. [1]*Government Medical College Kottayam, Department of Internal Medicine, Kottayam, India*; [2]*Government Medical College Kottayam, Department of Community Medicine, Kottayam, India*

Background: Idiopathic inflammatory myopathies (IIM) is a rare heterogenous group of diseases with varying involvement of muscle, skin, joints and lung. There is a paucity of prospective cohort studies in IIMs from India which assess the treatment response and clinico serological profile of patients with IIM.
Objectives: To describe the clinical characteristics, autoantibody profile and early treatment response in a prospective cohort of patients with IIM attending the Rheumatology clinic of a tertiary care teaching hospital in South India between October 2020 and June 2022. To compare IIM patients with interstitial lung disease (ILD) and IIM patients without ILD.
Methods: A prospective cohort of 37 consecutive adult patients fulfilling the 2017 EULAR ACR classification criteria of IIM was studied. The demographic data and clinical characteristics was recorded using a structured proforma. Muscle power was assessed by manual muscle testing (MMT8) in all patients. Myositis specific autoantibodies (MSA)and myositis associated autoantibodies (MAA) to 16 antigens were performed in all patients by line blot assay using Euroimmun (Luebec, Germany) as per manufacturer's instruction. All patients with MMRC grade 2 or more dyspnoea and/or dry cough and a restrictive pulmonary function test underwent HRCT chest for the diagnosis of ILD. Treatment response was assessed at 6 months based on the 2016 ACR/EULAR criteria for minimal, moderate and major clinical response. The various demographic, clinical and serological parameters were compared between patients with ILD and those without ILD. Comparisons between groups were made with the chi-squared test/Fisher's exact test when testing categorical variables and the Mann-Whitney *U* test or Independent samples' t test for continuous data. Multivariate analysis was done to find the independent factors associated with interstitial lung disease.
Results: 24 patients were female (64.9%) and the mean age of the study population was 46.7 ± 14 years. The median disease duration was 8 months (13 months). The most common symptoms were dyspnoea (59.5% of patients), proximal muscle weakness (56.8%), SICCA (35.1%) and photosensitive rash (32.4%). Mechanics hand was seen in 29.7% of patients, heliotrope rash in 24.3%, Gottron's papule in 18.9% and Gottron's sign was seen in 16.2% of patients. The median creatinine kinase (CK) level was 309 Units/L (1794) and median MMT 8 score was 78. 15/37 patients (40.5%) had dermatomyositis, 13/37 (35.1%) patients had anti synthetase syndrome, 4/37(10.8%) had biopsy proven necrotizing myopathy, 3/37 (8.1%) had overlap myositis and 2/37 (5.4%) had pure polymyositis. The most common MSA was anti Jo1 (7/37, 18.9%) followed by anti MDA5 (5/37, 13.5%) and anti PL12 (4/37, 10.8%) and the most common MAA was Ro52 (6/37,16.2%). 7/37 patients (18.9%) were negative for any of the MSA/MAA. Clinically amyopathic myositis was seen in 19/37 (51.4% of patients). ILD was seen in 20/37 patients (54.1%) and rapidly progressive ILD (RP ILD) was seen in 5/20 ILD patients (25%). The most common immunosuppressive agent used was corticosteroid (37/37) followed by mycophenolate mofetil (17/37,45.9%), methotrexate (9/37, 24.3%) and Rituximab (7/37,18.9%). After 6 months of treatment, 13/37 (35.1%) patients showed major response, 16/37 (43.2%) moderate response and 3/37(8.1%) patients showed minimal response. There were 5 deaths, 3 of which was due to pneumonia, 1 due to RP ILD, and 1 due to respiratory muscle weakness. On univariate analysis median disease duration, arthritis, CK levels, MDA 5 positivity and MSA/MAA positive status were associated with ILD. However, on multivariate analysis none of the factors showed any significant association with ILD.
Conclusion: The frequency of ILD is high in our cohort of IIM patients and as a significant proportion had no objective muscle weakness, the use of myositis autoantibody panel is warranted for early detection of such cases.

AB0853 ENDOTHELIAL DISFUNCTION MARKERS CAN BE REDUCED IN SYSTEMIC SCLEROSIS PATIENTS BY NUTRITIONAL TREATMENT

Keywords: Systemic sclerosis, Diet and Nutrition

A. Wojteczek[1], Z. Zdrojewski[1], S. Małgorzewicz[2]. [1]*Medical University of Gdańsk, Department of Internal Medicine, Connective Tissue Diseases and Geriatrics, Gdańsk, Poland*; [2]*Medical University of Gdańsk, Department of Clinical Nutrition, Gdańsk, Poland*

Background: Systemic sclerosis is a chronic autoimmune disease which is represented by progressive fibrosis, vascular impairment and immune abnormalities. In recent years metabolic and endothelial factors were reported as elements which play role in pathogenesis of systemic sclerosis (SSc). Adipokines, mediators secreted by adpiose tissue, depends on fat mass and nutritional status. Ghrelin, a gut hormone, is a key regulator of metabolism of glucose, meal initiation and appetite. Another metabolic factor myostatin, is a myokine produced by muscles and is negative regulator of muscle growth. Endothelial factors auch as endothelin 1 (endogenous vasoconstrictor, mainly secreted by endothelial cells) and asymmetric dimethylarginine (ADMA, endogenous nitric oxide inhibitor) are important markers for vascular dysfunction.
Objectives: The aim of the study was to evaluate serum concentration of ghrelin, myostatin, adiponectin, wisfatin, chemerin, leptin, interleukin 6 (IL-6), endothelin 1 and ADMA in relation to the nutritional status of patients with SSc, and impact of nutritional treatmet on their levels.
Methods: Study population consisted of 56 SSc patients (47 females, 9 males) and 49 healthy persons (42 females and 7 males). Demographic and clinical

data were recorded. Assessment of nutrition based on 7-SGA and laboratory tests were done.

Results: SSc patients had significantly higher levels of nonacylated ghrelin (478,5±289,9 vs 347,7 ±294,8 pg/ml; p=0,018), IL-6 (30,7±29,7 vs 3,16±26,15 ng/ml; p=0,001), endothelin 1 (2,71±1,67 vs 1,96±1,02 pg/ml; p=0,002) and ADMA (1,37±0,45 vs 1,23±0,23 um/l; p=0,025) than control population. From 56 SSc patients 40 (71%) were well-nourished and 16 (29%) had nutritional disbalance. In those subgroups significantly higher levels of endothelin 1 (3,32±2,02 vs 2,58±1,71 pg/ml, p=0,043) and ADMA (3,32±2,02 vs 2,58±1,71 um/l, p=0,043) had malnourished patients. No statistically significant results in other parameters were observed. Dietary recommendations and high protein oral nutritional suplement (200 ml/day, containing 250 kcal and 19 g of protein) were given for 3 months to all 16 SSc patients with nutritional disorder. After 3 and 12 months patients were re-evaluated. Significantly higher levels of myostatin were noticed after 1 year after initial assesment (p=0,001). Opposite effect were seen with endothelin 1 and wisfatin, where in last evaluation both gain the lowest results (p<0,001,p=0,039).

Conclusion: Higher levels of endothelin 1 and ADMA confirm that vascular damage is crucial in SSc patients. Proper nutritional treatment in undernourished SSc patients can reduce levels of markers involved in endothelial disfunction, such as endothelin 1 and wisafatin.

AB0854 CLINICAL CHARACTERISTICS OF PATIENTS WITH AMINOACYL-TRNA SYNTHETASES COMPARED WITH OTHER MYOSITIS ANTIBODIES IN A COHORT OF INFLAMMATORY MYOSITIS

Keywords: Autoantibodies, Myositis, Epidemiology

M. H. Kim[1]. [1]*Seoul National University Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: The Idiopathic Inflammatory Myositis (IIM) are heterogeneous with different clinical profiles associated with various myositis autoantibodies. Among the Myositis specific antibodies (MSA), antibodies against aminoacyl-tRNA synthetases(ARS) is related to the clinically unique IIM subsets, Antisynthetase syndrome(ASS).

Objectives: The aim of this study was to identify the prevalence and clinical features of patients with ARS autoantibodies compared with other myositis antibodies in a single center cohort of IIM in Korea.

Methods: Adult patients diagnosed with IIM and positive for myositis antibodies were recruited in the myositis cohort from January 2020 to December 2022. Retrospective analysis was performed based on the clinical data including clinical features, laboratory data, high-resolution CT (HRCT) findings, and pulmonary function manifestations.

Results: Among 82 patients, 25 patients were positive for ARS autoantibodies and 57 patients had other myositis antibodies. The most common ARS antibody was anti-EJ (n=10) followed by anti-PL-7 (n=8). MSA other than ARS antibodies included anti-SRP (n=6), anti-TIF1γ (n=11) and anti-MDA-5(n=19). Anti-Ro52 was detected in 48 patients and 79.2% of which were accompanied by other antibodies. The most common clinical manifestations of patients with ARS antibodies were respiratory symptoms, more commonly experienced than patients with other myositis antibodies (84% vs. 47.4%, p=0.002). Meanwhile, muscle weakness (32.0% vs. 61.4%) and dysphagia (8.0% vs. 33.3%) were less frequently exhibited compared with those with other myositis antibodies. In regard to laboratory findings, the ARS antibodies positive group showed higher inflammatory markers than other myositis antibodies group, the mean (SD) of erythrocyte sedimentation rate (ESR) was 53.6 (34.6) and 33.8 (24.3), respectively. Anti-Ro52 and anti-nuclear antibodies (ANA) cytoplasmic pattern were more detected in the ARS antibodies positive group. Interstitial lung disease (ILD) was also more commonly detected in patients with ARS antibodies than other myositis antibodies group (88.0% vs. 59.6%) and non-specific interstitial pneumonia (NSIP) was the most frequent pattern of ILD. However, there were no significant differences in the baseline pulmonary function between the two groups.

Conclusion: Patients with ARS antibodies experienced more respiratory symptoms while muscle weakness is less common clinical manifestations than patients with other myositis antibodies. Moreover, higher inflammatory markers and ANA cytoplasmic pattern along with Anti-Ro52 were more commonly detected in the ARS antibodies positive group.

Background: Dersimelagon (MT-7117), a novel synthetic, oral, selective melanocortin-1 receptor agonist, demonstrated disease-modifying effects in preclinical models of systemic sclerosis (SSc). MT-7117 reduces inflammation, vascular dysfunction, and fibrosis through its pleiotropic effects on inflammatory cells, endothelial cells, and fibroblastsis, and is as a potential therapeutic agent for the treatment of SSc. A phase 2 proof of concept clinical trial (MT-7117-G02) in subjects with diffuse cutaneous SSc (dcSSc) is ongoing (NCT04440592). 73 subjects (target 72) were enrolled over 22 months at 33 sites in 8 countries.

Objectives: Evaluate the demographics, baseline disease characteristics and the standard of care of the subjects randomized in MT-7117-G02 study to examine variability of these parameters by the geographic regions (North America [NA], Europe [excluding Poland], and Poland). Population in Poland was analyzed separately due to delayed inclusion in the study and the highest enrollment rate.

Methods: MT-7117-G02 is a Phase 2, multi-center, randomized, double-blind, placebo-controlled, 52-week parallel-group study to evaluate the efficacy, safety, and tolerability of MT-7117 in subjects with dcSSc. Eligible subjects were randomized 1:1 to either MT-7117 QD or matching placebo and stratified by the autoantibody status of anti-RNA Polymerase III at screening (positive or negative). The primary endpoint

is the American College of Rheumatology Combined Response Index in Diffuse Cutaneous Systemic Sclerosis (ACR CRISS) composite score at Week 52. The study included subjects who have been diagnosed with dcSSc ≥ 18 years of age and a disease duration ≤ 5 years who are on a stable standard of care treatment, receiving one stable concomitant immunosuppressant (Mycophenolate/Mycophenolic acid [MMF], Methotrexate [MTX], Hydroxychloroquine [HCQ], or Azathioprine [AZA]). Eligibility included the baseline Modified Rodnan skin score (mRSS) of 15-45 units and Forced Vital Capacity (FVC%) predicted > 50%.

Results: Most of enrolled subjects were middle-aged White females and approximately half received one immunosuppressant (Table 1). MMF was the most frequently used immunosuppressant followed by MTX. Approximately ¾ of the subjects had normal CRP with comparable distribution across the regions. There were neither regional differences in the baseline mRSS nor in the predicted FVC%. The overall average frequency of anti-RNA Polymerase III antibody positivity was 20.5%, with the lowest proportion in Poland (15.4%). The average frequency of anti-Scl-70 positivity was 50.7% with the lowest proportion in NA (23.5%). Subjects in NA were more likely to be on MMF.

Table 1 : Baseline demographics and disease characteristics by Regions (Blinded)

	Mean (SD) or n (%)			
	Overall	North America*	Europe†	Poland
Number	73 (100 %)	17 (23.3 %)	30 (41.1 %)	26 (35.6 %)
Age (yrs)	51.6 ± 12.4	54.7 ± 12.5	52.2 ± 10.6	48.9 ± 14.2
Disease duration (yrs)	2.0 ± 1.4	1.7 ± 1.4	1.9 ± 1.3	2.2 ± 1.6
Female	55 (75.3 %)	15 (88.2 %)	22 (73.3 %)	18 (69.2 %)
White	65 (89.0 %)	11 (64.7 %)	28 (93.3 %)	26 (100 %)
Anti-RNA-Poly III positive	15 (20.5 %)	4 (23.5 %)	7 (23.3 %)	4 (15.4 %)
Anti- Scl-70 positive	37 (50.7 %)	4 (23.5 %)	16 (53.3 %)	17 (65.4 %)
Normal CRP (≤ 5.0 mg/L)	58 (79.5 %)	13 (76.5 %)	22 (73.3 %)	23 (88.5 %)
Any immunosuppressant‡	41 (56.2 %)	10 (58.8 %)	17 (56.7 %)	14 (53.8 %)
MMF	24 (32.9 %)	7 (41.2 %)	9 (30.0 %)	8 (30.8 %)
MTX	14 (19.2 %)	1 (5.9 %)	7 (23.3 %)	6 (23.1 %)
HCQ	7 (9.6 %)	1 (5.9 %)	4 (13.3 %)	2 (7.7 %)
AZA	2 (2.7 %)	1 (5.9 %)	1 (3.3 %)	0
mRSS (0-51)	24.8 ± 7.9	23.1 ± 9.2	25.3 ± 7.9	25.2 ± 7.2
FVC% predicted	88.0 ± 17.9	88.7 ± 20.2	82.0 ± 16.9	94.4 ± 15.5

*US and Canada† UK, Germany, Spain, Italy, and Belgium‡ Includes MMF, MTX, HCQ, and AZA

Conclusion: There were no major differences in the baseline demographics such as disease duration, sex and age, and no major differences in disease severity as well as the percentage of use of immunosuppressants among the regions although some variation in SSc autoantibody specificity were observed.

A MULTI-NATIONAL SURVEY TO IDENTIFY THE CLINICIANS' PERSPECTIVES CONCERNING PROTON PUMP INHIBITORS IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Gastrointestinal tract

G. Bandini[1], A. Alunno[2], F. Oliveira Pinheiro[3], C. Campochiaro[4], I. Galetti[5], P. Matucci Cerinic[6], B. Ruaro[7], L. Dagna[4], M. Matucci-Cerinic[4,8], Z. Mcmahan[9], M. Background: Proton Pump Inhibitors (PPIs) are widely used in the management of gastro-oesophageal problems in SSc. However, there is little evidence to support their empirical use in SSc, and long-term safety concerns have been highlighted in the general population [1,2].

Objectives: To examine clinicians' perspectives concerning PPI use in patients with SSc.

Methods: An online survey in the English language targeting healthcare providers (HCP) involved in the care of patients with SSc was developed and distributed through international physician networks and social media. The survey was lauched on 27th November 2022 and kept open for 3 weeks.

Results: Responses from 227 HCP from 36 countries were obtained. The majority (86.3%) were between 30-70 years old. Female and male gender were equally represented (M:48%, F:52%). Most respondents practiced in a university hospital (86%), the most common specialties represented were rheumatology (70.5%), internal medicine (10.6%), and gastroenterology (7.5%). The majority of respondents (87%) agreed that gastroesophageal reflux disease (GERD) is a major cause of morbidity in SSc. Lifestyle modifications/non-pharmacological approaches alone were seldom (16%) considered as effective in controlling GERD symptoms. Only half of responders either 'agreed' (43%) or 'strongly agreed' (11%) that solid evidence supports PPI efficacy in SSc. PPIs were prescribed by 93% of HCP with the most commonly prescribed compounds being pantoprazole (74%), esomeprazole (72%), omeprazole (72%), and lansoprazole (68%). PPIs were mainly prescribed for: 1) symptomatic GERD unresponsive to lifestyle modification (95%); 2) objective evidence of GERD (e.g., on endoscopy) (82%); 3) hoarseness or respiratory symptoms where GERD is implicated (71%). Over 80% reported prescribing the "maximum (or even higher)" PPI dose in patients with refractory GERD, and said they would initiate combination therapy (e.g., PPI plus prokinetic agent) in case of dysphagia and/or evidence of dysmotility (84%). Over 80% reported that they would perform further diagnostic investigation/s to better characterize the GI manifestations in such cases (69% would perform H. Pylori test). There was significant heterogeneity regarding safety of long-term treatment with PPI in SSc: 34% agree that side effects are a major concern, 25% disagree and 36% were neutral. The three potential PPI adverse events of highest concern among the group were: 1) small intestinal bacterial overgrowth (5.5), osteoporosis and increased risk of fracture (5.4), and 3) drug interactions (5.2), (0-10, where 10 is 'very concerned'). There was no clear consensus whether PPI dose and/or frequency should be reduced in patients with refractory calcinosis: 'disagree' = 25.3%, 'neutral' = 48.4%, and 'agree' = 22.6%. In addition, around half of responders considered that patients should be on high-dose PPI long-term after lung transplantation ('agree' or 'strongly agree' = 49.8%) or were 'neutral' (42.9%) There were differences in attitudes towards the use of GI surgery for refractory GERD where 45.2% of respondents agreed and 45.6% considered their opinion 'neutral'. Half of the responders agreed that GI surgery in SSc is associated with frequent complications, such as worsening of dysphagia.

Conclusion: Various PPIs are often prescribed at maximum doses to control symptoms of GERD in SSc. Potential concerns about long-term side effects are acknowledged by prescribing physicians. There is a significant heterogeneity in attitudes towards surgical intervention for refractory GERD and still need to be better defined. Further research and practical treatment recommendations pertaining to PPIs in SSc are urgently warranted.

ANTI-THYMOCYTE GLOBULIN EXPOSURE IS ASSOCIATED WITH TREATMENT RESPONSE IN PATIENTS WITH DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS UNDERGOING AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION

Keywords: Biomarkers, Systemic sclerosis

Y. H. Chiu[1,2], A. Drijver[1], R. Admiraal[3], A. Van Rhenen[4], S. Nierkens[5], J. M. Van Laar[1], J. Spierings[1]. *[1]University Medical Centre Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands*; *[2]Tri-Service General Hospital, National Defense Medical Center, Division of Rheumatology/Immunology/Allergy, Taipei, Taiwan, Republic of China*; *[3]Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands*; *[4]University Medical Centre Utrecht, Department of Haematology, Utrecht, Netherlands*; *[5]University Medical Centre Utrecht, Center for Translational Immunology, Utrecht, Netherlands*

Background: Autologous haematopoietic stem cell transplantation (HSCT) ameliorates event-free survival, skin thickening and lung function in patients with progressive diffuse cutaneous systemic sclerosis (dcSSc). Anti-thymocyte globulin (ATG) is a key lymphoablative constituent of conditioning protocols and is administered in a body weight-based dose. Response to HSCT and occurrence of infections is still highly variable across dcSSc patients. Studies in haemato-oncological patients suggest that ATG exposure varies across subjects and impacts outcomes [1].
Objectives: To explore the relation between rabbit derived ATG exposure, lymphocyte reconstitution and clinical outcomes in patients with dcSSc undergoing autologous HSCT.
Methods: We retrospectively analysed patients with dcSSc undergoing autologous HSCT between 2014 and 2020. ATG levels were measured in cryopreserved serum samples at four time points (day 1 and week 1, 2 and 4) after stem cell reinfusion. ATG exposure was estimated using population pharmacokinetics models [1]. Treatment response was defined as pulmonary stabilisation (with no decline more than 10% in forced vital capacity and 15% in diffusing capacity for carbon monoxide) and/or skin improvement (modified Rodnan skin score reduction of more than 30%). Differences between groups were examined with Wilcoxon rank-sum test for contentious variables and Fisher exact test for categorical variables.
Results: Fifteen patients were included in this study with median age 43 years-old (IQR 37–50). During a median follow-up of 45 months (IQR 19—66), 73% (n=11) of patients had a treatment response, and 27% (n=4) were non-responders. Eight (73%) responders achieved long-term remission and three (27%) responders had progressive disease in the follow-up, at a median time of eight months (IQR 5—17) post-HSCT. Although all patients received the same weight-based ATG dosage (7.5 mg/kg), ATG exposure varied across patients. ATG exposure was higher in responders than non-responders (p = 0.026, Table 1) but was not correlated with lymphocyte reconstitution or infection rate.
Conclusion: In our study, ATG exposure highly varied across dcSSc patients undergoing HSCT despite the same weight-based dosage. Responders had a higher ATG exposure than non-responders. More research into optimal ATG dosing is needed to improve HSCT outcomes.

PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS: A NATIONAL INPATIENT ANALYSIS

Keywords: Lungs, Systemic sclerosis

F. Sami[1], S. A. Sami[2], S. Arora[3], V. Reyes Pinzon[4], L. Farrukh[5], R. Atluri[6]. *[1]John H. Stroger Hospital of Cook County, Internal Medicine, Chicago, United States of America*; *[2]Trinity Health Oakland Campus, Internal Medicine, Pontiac, United States of America*; *[3]John H. Stroger, Jr. Hospital of Cook County, Rheumatology, Chicago, United States of America*; *[4]John H. Stroger, Jr. Hospital of Cook County, Internal Medicine, Chicago, United States of America*; *[5]Albany Medical Center, Internal Medicine, Albany, United States of America*; *[6]John H. Stroger, Jr. Hospital of Cook County, Internal Medicine, Chicago, United States of America*

Background: Pulmonary arterial hypertension (PAH) is a chronic, progressive, and eventually fatal complication of Systemic Sclerosis (SS), affecting the prognosis and quality of life. Risk of PAH in SS is substantially high, and it causes early mortality. Non-specific manifestations of PAH can result in delayed diagnosis and result in poorer outcomes.
Objectives: We aim to study the prevalence and epidemiology of pulmonary arterial hypertension in SS, and impact of PAH on adult scleroderma hospitalizations in the United States population. We also aim to estimate the effect of PAH in SS on utilization of healthcare resources.
Methods: We utilized the National Inpatient Sample (NIS) to obtain pertinent data. Total adult hospitalizations with primary diagnosis of SS and coexistent comorbidity of PAH were extracted from 2016-2019. We studied the demographic and epidemiological differences as well as mortality outcomes. Healthcare burden was estimated from total hospital charges (THC) and length of stay (LOS). Secondary outcomes including pulmonary embolism, atrial flutter/fibrillation, pneumonia, sepsis, cardiac & renal failure and ventilator requirements were also studied. Statistical analysis was performed on STATA, with linear and logistic regression analyses.
Results: Out of 126,685 adult scleroderma hospitalizations between 2016-19, 21930 (17%) presented with concurrent pulmonary hypertension. Females were significantly more in this group compared to patients with SS without PAH, representing approximately 85% of total admissions. Patients with PAH had a higher mean age (64.85±13.29 vs 62.56±14.51, P 0.000) as well. In terms of racial demographics, there was a significantly higher proportion of African American and significantly less Asians in the study group. Charlson comorbidity index was also higher >3 in the PAH group. PAH was associated with higher adjusted odds ratio (aOR) for mortality (aOR: 1.39, p<0.001), increased LOS (6.64 vs 6.0 days, p<0.001) increased THC ($83813 vs $71016, p <0.001). It was also associated with significantly higher odds for cardiac failure (aOR 3.13) and ventilator requirement (aOR 2.15). Secondary outcomes of kidney failure, Pulmonary embolism, atrial flutter/fibrillation, and pneumonia recorded a significantly higher aOR for patients with PAH. No significant difference in cardiac arrest, sepsis, or respiratory failure was noted.
Conclusion: Pulmonary arterial hypertension in scleroderma is associated with worse overall outcomes in terms of mortality and morbidity, as well as much higher healthcare burden compared to SS without PAH. Also, PAH disproportionately affects African-american & Asian populations. Although advancements have been made in the treatment of PAH in SS, there still remains room for efforts directed towards early diagnosis and management to further improve outcomes for scleroderma patients.
References: none.

Table 1. Characteristics and Outcomes of adult scleroderma hospitalizations with & without PAH

AB0859 CLINICAL COURSES AND PREDICTORS OF LEFT VENTRICULAR SYSTOLIC DYSFUNCTION IN SYSTEMIC SCLEROSIS

Keywords: Cardiovascular disease, Systemic sclerosis, Prognostic factors

J. Werakiat[1], B. Pussadhamma[1], A. Mahakkanukrauh[1], S. Suwannaroj[1], C. Foocharoen[1]. [1]*Khon Kaen University, Department of Medicine, Faculty of Medicine, Khon Kaen, Thailand*

Background: Left ventricular systolic dysfunction (LVSD) is a cardiac involvement, resulting in its being the leading cause of death among patients with systemic sclerosis (SSc). Currently, no predictor of LVSD has been defined by longitudinal data for follow-up among SSc patients.
Objectives: We aimed to define the clinical course and predictors of LVSD among SSc patients.
Methods: We conducted a cohort study among adult SSc patients who were followed up at the Scleroderma Clinic, Khon Kaen University, between 2013 and 2020. Semi-parametric Cox regression analysis with robustness clustering by cohort identification number was used for evaluating the predictors of LVSD.
Results: Among the 55,056 person-years, LVSD was defined in 35 of 419 SSc patients for an incidence of 0.25 per 100 person-years. The majority were female (23 cases) with diffuse cutaneous SSc (dcSSc) (26 cases). The median duration of the disease was 8.5 (IQR 4.9-12.9) years. Every 1-point increase in the modified Rodnan skin score (mRSS) and salt and pepper skin were strong predictors of LVSD, with a respective adjusted hazard ratio (HR) of 1.05 and 3.17. During follow-up, 26 cases (74.3%) had worsening LVSD. The strong predictors of the worsening of LVSD were every 1-point increase in mRSS (HR 1.05), every 1 mg increase in prednisolone treatment (HR 1.05), and every 1 U/L increase in creatine kinase (CK) (HR 1.001). Meanwhile, mycophenolate treatment was a protective factor against the worsening of LVSD in SSc (HR 0.15).
Conclusion: LVSD was frequently found in dcSSc, and most cases worsened during follow-up. The severity of skin thickness increases the risk of LVSD. High mRSS, steroid use, and high CK were predictors of worsening LVSD, while mycophenolate treatment might prevent the progression of LVSD. Steroids should be prescribed with caution to patients with longer disease duration.

Background: Systemic sclerosis (SSc) is an autoimmune connective tissue disease characterized by progressive cutaneous and visceral fibrosis, and disseminated vasculopathy [1]. Due to clinical features, SSc patients may present low muscle mass, which impacts negatively on their daily activities and physical function [2,3]. There are several methods to assess muscle mass such as magnetic resonance imaging (MRI), computed tomography (CT) and dual-energy radiological absorptiometry (DXA). However, the high costs of the equipment and the lack of portability make them uncommon tools in clinical practice. In this sense, ultrasonography has been used to evaluate muscle mass in different populations [4].
Objectives: To assess the quadriceps muscle thickness and to verify associations with clinical features, muscle strength and physical performance in SSc women.
Methods: In this cross-sectional study, patients with SSc according to the 2013 ACR-EULAR classification criteria were included. Age in years (y), disease duration (y), modified Rodnan skin score (mRSS), the European Scleroderma Trials and Research Group (EUSTAR) SSc activity index (EScSG-AI), and the health assessment questionnaire (HAQ) were assessed. The muscle thickness was assessed by a real-time ultrasound device (Esaote S.p.A MyLab 50 X Vision; SãoPaulo, Brazil). An experienced ultrasound evaluator analyzed the muscle thickness of vastus lateralis (VL, cm), rectus femoris (RF,cm), vastus intermedius (VI,cm), and vastus medialis (VM,cm). Muscle strength was assessed by handgrip (HGS,kg) and physical performance was assessed by short physical performance battery (SPPB,points). Frequency analysis and Pearson's or Spearman's correlation coefficients were explored as appropriate. The significance was considered when $p<0.05$.
Results: We included 45 patients with SSc, 32 (71.1%) with diffuse disease. The median age was 62.00 (54.50-66.50) years and the disease duration was 10.91 (4.88-18.68) years. The median of EScSG-AI was 1.33 (0.33-2.34), the mRSS was 4.00 (2.00-8.00) and the HAQ was 0.62 (0.25-1.06). The mean of muscle thickness were: VL 1.38 + 0.32 cm, RF 1.06±0.35 cm, VM 1.16±0.47 cm, and VI 1.17±0.33 cm. The mean of HGS was 18.64±9.71kg and the median SPPB was 10.00 (9.00-11.50) points. The disease activity by EScSG-AI was negatively associated with VL ($r = -0.410$, $p = 0.016$) and VI ($r= -0.394$, $p = 0.021$). In addition, HGS was positively associated with VM ($r= 0.435$, $p = 0.003$) and SPPB was positively associated with VL ($r= 0.354$, $p = 0.017$).
Conclusion: Low quadriceps muscle thickness is associated with higher disease activity. As expected, our findings suggest that there are positive associations between muscle thickness with strength and physical performance in SSc women. Our findings highlight the importance of aiming for disease activity control because it may indirectly influence the muscle mass of SSc women.

AB0861 INCIDENCE AND PREVALENCE OF SYSTEMIC SCLEROSIS IN THAILAND IN YEAR 2017-2020: A DATABASE FROM THE MINISTRY OF PUBLIC HEALTH

Keywords: Epidemiology, Systemic sclerosis

C. Foocharoen[1], C. Ngamjarus[2], P. Pattanittum[2], S. Suwannaroj[1], P. Pongkulkiat[1], T. Onchan[1], L. Wattanasukchai[3], J. Chaiyarit[4], A. Mahakkanukrauh[1]. [1]*Khon Kaen University, Department of Medicine, Faculty of Medicine, Khon Kaen, Thailand*; [2]*k, Department of Epidemiology and Biostatistics, Faculty of Public Health, Khon Kaen, Thailand*; [3]*Khon Kaen University, Clinical Epidemiology Unit, Faculty of Medicine, Khon Kaen, Thailand*; [4]*Khon Kaen University, Department of Statistics, Faculty of Science, Khon Kaen, Thailand*

Background: A better understanding of the epidemiological profile of systemic sclerosis (SSc) in Thais could improve care, human resource deployment, and public health budgeting.
Objectives: We aimed to determine the incidence and prevalence of SSc in Thailand between 2017 and 2020.
Methods: A descriptive epidemiological study was performed using the Information and Communication Technology Center, Ministry of Public Health database, comprising all types of healthcare providers during the study period. Demographic data of patients having a primary diagnosis of M34 systemic sclerosis and over 18 years of age between 2017 and 2020 were reviewed. The incidence and prevalence of SSc were calculated as well as their respective 95% confidence intervals (CIs).
Results: The number of SSc cases in 2017 was 15,920 from a total Thai population of 65,204,797. The prevalence of SSc in 2017 was 24.4 per 100,000 populations (95% CI 24.0-24.8). The prevalence of SSc among women was 2 times greater than among men (32.7 vs. 15.8 per 100,000). The incidence of SSc was stable from 2018 to 2019 but dropped slightly in 2020 (7.2, 7.6, and 6.8 per 100,000 person-years, respectively). Most SSc cases were in northeastern Thailand (11.6, 12.1, and 11.1 per 100,000 person-years from 2018-2020, respectively) and the peak was between 60-69 years of age (24.6, 23.8, and 20.9 per 100,000 person-years from 2018 to 2020, respectively).
Conclusion: SSc is a rare disease among Thais. The disease was commonly revealed in late middle-aged women with a peak at age 60-69 years, mainly from the Northeast regions. The incidence remained stable during the study period, albeit during the emergence of the coronavirus pandemic a slight decline was recorded.

AB0862 NAILFOLD CAPILLAROSCOPY FOR PREDICTION OF NOVEL SEVERE ORGAN INVOLVEMENT IN SYSTEMIC SCLEROSIS

Keywords: Organ damage, Prognostic factors, Systemic sclerosis

C. Sieiro Santos[1], P. Pérez-García[1], J. Ordas Martínez[1], C. Moriano[1], C. Álvarez Castro[1], I. González Fernández[1], E. Diez Alvarez[1]. [1]*Complejo Asistencial Universitario de León, Rheumatology, León, Spain*

Background: Nailfold capillaroscopy (NFC) has been suggested as a potential biomarker of disease severity in systemic sclerosis (SSc). Several studies report the association between capillary loss and disease severity however, the association of NFC abnormalities with novel severe organ involvement/progression in SSc has not been evaluated.
Objectives: We aim to evaluate the association of nailfold capillaroscopy (NFC) with novel major organ involvement/progression in SSc.
Methods: Follow-up data from patients with SSc registered between 2000 and 2022 were analysed. Patients underwent NFC at baseline. Novel severe organ involvement/progression was defined as new or progressive involvement of peripheral vasculature, lungs, heart, skin, gastrointestinal, kidney, musculoskeletal at 12 and 24 months of follow-up. The following NFC parameters were evaluated: capillary density, haemorrhages, enlarged and giant capillaries, avascular areas, organization of capillary architecture and scleroderma pattern (early/active/late). Logistic regression modelling was run to assess associations between NFC parameters and the occurrence of novel severe organ involvement and/or progression and risk factors.
Results: 113 patients with SSc were included, 70 patients (61%) developed novel overall severe organ involvement/progression: 39 patients (56%) during the first 12 months and 31 patients (44%) from 12 to 24 months of follow-up. 11% of patients developed novel peripheral vascular involvement, 21% developed novel interstitial lung disease (ILD), 11% had progression of known ILD, 6% had novel pulmonary hypertension, 11% had skin progression, 10% had novel heart involvement, 10% had novel gastrointestinal involvement, 6% had scleroderma renal crisis and 13% had novel musculoskeletal involvement. Table 1 summarizes the significant associations between NFC and novel severe organ involvement/progression during follow-up. Loss of capillary density was associated with overall severe organ involvement (p 0.002), peripheral vascular involvement (p 0.03), new ILD (p 0.04) and skin progression (p 0.01); avascular areas were associated with overall severe organ involvement (p 0.03), new ILD (p 0.03) and progression of ILD (p 0.02) and scleroderma pattern was associated with overall severe organ involvement (p 0.03), peripheral vascular involvement (OR p 0.04), new ILD (p 0.004), progression of ILD (p 0.03) and skin progression (p 0.04).
Conclusion: NFC may be a potential biomarker in SSc for predicting novel severe organ involvement and/or progression. Abnormal capillary density, avascular areas and scleroderma pattern are predictors of overall severe organ involvement, peripheral vascular involvement, novel and progression of ILD and skin progression.

Clinical Immunology, Rozzano, Milan, Italy; [2]*IRCCS Humanitas Research Hospital, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy*

Background: Cancer-associated myositis (CAM) remains a clinical challenge and established risk factors include older age, male sex, dermatomyositis (DM), and specific antibodies, including anti-TIF1gamma and -MJ/NXP2 [1]. However, a recent report suggests a lower risk of malignancy in -TIF1gamma positive patients with other concurrent autoantibodies (2,3), whereas the protective role against malignancy of antisynthetase or anti-Mi-2 antibodies is being questioned [1].
Objectives: To describe the demographic, clinical, and serological characteristics of a cohort of patients with CAM in a specific autoantibody profile.
Methods: Retrospective cohort analysis on electronic clinical charts, autoantibody analysis by serum immunoprecipitation and ELISA.
Results: Malignancy was observed in 17/73 (23%) patients with IIM, in 13/17 (76%) within 5 years before or after IIM diagnosis and cancer relapse or progression in 7 cases; 2/17 were men with a median age of 56 years. Breast cancer was the most frequent, followed by lung, thyroid, ovarian, and lymphoma. Four patients died, three for cancer-related complications and one for severe refractory IIM. Muscle injury was observed in 13/17 (76%) while 2/17 experienced dysphagia. Skin lesions were present in 14/17 (82%) patients, while ILD (24%) and arthritis (18%) rarely occurred; no cases of myocardial involvement were described. Anti-Ro52 was the most common antibody (5/17 – 29%) in our cohort, detected as the only specificity in 2/5 cases. Anti-TIF1gamma was described in 4/17 (24%, one case with concurrent -Ro52), followed by antisynthetase (3 – 18%), -Mi-2 (2 – 12%), -MJ/NXP2, -SAE1, -SRP (1 each – 6%). Combined anti-E2/E3 PDH (AMA) and anti-Ro positivity was found in a patient who developed lymphoma and cholangiocarcinoma within two years from IIM. We compared CAM patients with (n=4) and without (n=13) serum anti-TIF1gamma (Table 1). Albeit not reaching statistical significance, dysphagia and skin disease were more frequently observed with anti-TIF1gamma, whereas arthritis, Raynaud's phenomenon, and capillaroscopy alterations were rarer in such group. Prevalence of early-stage cancer seemed more frequent with anti-TIF1gamma. 3/13 patients without anti-TIF1gamma died due to cancer-related causes; the only death observed in the TIF1gamma positive group was due to progressive IIM, and occurred in a patient with complete cancer remission.
Conclusion: We observed that DM remains the most common clinical subset of CAM, but other myositis phenotypes can be also observed. Anti-TIF1gamma remains the more prevalent autoantibody in CAM along with anti-Ro52. The role of AMA positivity may warrant further investigation, particularly in patients with seronegative CAM.

AB0864 IDIOPATHIC INFLAMMATORY MYOPATHIES AND CANCER RISK STRATIFICATION

Keywords: Myositis, Malignancy

A. Hočevar[1], M. Tomsic[1], K. Perdan-Pirkmajer[1]. [1]*University Medical Center Ljubljana, Department of Rheumatology, Ljubljana, Slovenia*

Background: Patients with idiopathic inflammatory myopathies (IIMs) are at increased risk of cancer, particularly in the first ±3 years of the disease, and a cancer risk stratification was proposed recently [1], to improve cancer screening in IIMs.
Objectives: The aim of our retrospective study was to determine the frequency, temporal relations, and cancer types, as well as to evaluate the performance of proposed cancer risk stratification tool in our well-defined IIM cohort.
Methods: We analyzed medical records of IIM patients diagnosed between January 2005 and December 2020 and followed at our rheumatology centre of a median (IQR) 72.6 (35.1; 126.9) months. The development of cancer, its location and temporal relationship to IIM diagnosis were extracted. We applied the proposed cancer risk stratification [1] in a cohort of our patients.
Results: In a cohort of 175 IIM patients (122 females, 69.7%), 38 patients (21.7%; 24 females (19.7%) and 14 males (26.4%)) developed 41 cancers. Fifteen cancers (39.5%) were diagnosed or were active/relapsing within the two years prior to diagnosis of IIM, 10 cancers (26.3%) were diagnosed concurrently with IIM, and 16 (39.0%) cancers were diagnosed during the IIM follow up (9 (22.0%) of them during the first 3 years of the follow up) (Figure 1, Panel A). The most frequently diagnosed cancers were breast and gynaecologic cancers in females (20.0% each), and urogenital cancers in men (43.8%). The cancer location (overall and sex stratified) is presented in Table 1. The Figure 1, panel B shows the stratification of patients to their estimated risk of developing cancer, and the actual proportion of patients who develop cancer. Based on the estimated risk, 6.3%, 46.3% and 47.4% IIM patients were allocated into low-, intermediate- and high-risk group, respectively. While there were no episodes of cancer from -2 years to +3 years of follow up in the low-risk group, 12.5% patients in the intermediate-risk group, and 31.3% in the high-risk group developed cancer during this time interval.

Table 1. Location of cancer in IIM patients

Cancer location/type	All cancers (41 episodes)	Cancer in males (16 episodes)	Cancer in females (25 episodes)
Head and Neck	4 (9.8%)	2 (12.5%)	2 (8.0%)
Lung	4 (9.8%)	1 (6.3%)	3 (12.0%)
Breast	5 (12.2%)	0	5 (20.0%)
Colonic	3 (7.3%)	0	3 (12.0%)
Renal	2 (4.9%)	2 (12.5%)	0
Bladder	1 (2.4%)	1 (6.3%)	0
Gynaecologic	5 (12.2%)	-	5 (20.0%)
Prostatic	2 (4.9%)	2 (12.5%)	-
Testicular	2 (4.9%)	2 (12.5%)	-
Skin – melanoma	4 (9.8%)	1 (6.3)	3 (12.0%)
Skin – NMSC	2 (4.9%)	1 (6.3%)	1 (4.0%)
Lymphoma	2 (4.9%)	2 (12.5%)	0
Leukaemia	1 (2.4%)	1 (6.3%)	0
Unknown origin	4 (9.8%)	1 (6.3%)	3 (12.0%)

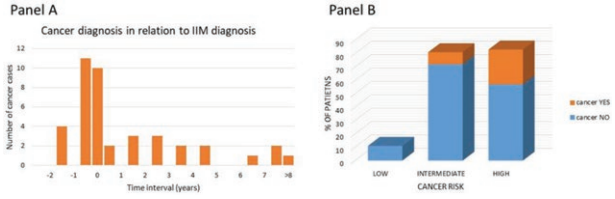

Figure 1. Panel A: Diagnosis of cancer in time relation to IIM. Panel B: Cancer risk stratification and actual development of cancer Legend: Panel A: time interval between the diagnosis of cancer in relation to the diagnosis of idiopathic inflammatory myopathy (Time 0).

Conclusion: Cancer affected a fifth of our IIMs patients. Almost a third of patients who were at high risk of cancer had cancer associated myositis.

AB0865 BODY COMPOSITION ASSESSMENT IN PATIENTS WITH SYSTEMIC SCLERODERMA

Keywords: Systemic sclerosis, Sarcopenia

M. Ajdynan[1], N. Melkonyan[1], N. Zhuravleva[2], E. Guryanova[2], V. Diomidova[3]. [1]*Yerevan State Medical University, Department Internal Diseases, Yerevan, Armenia*; [2]*Chuvash State University by I. N. Ulianov, Department Internal Diseases, Cheboksary, Russian Federation*; [3]*Chuvash State University by I. N. Ulianov, Department Propedeutics of Internal Diseases, Cheboksary, Russian Federation*

Background:
Objectives: To assess the body composition in patients with systemic scleroderma (SS) and to determine the frequency of sarcopenia (SP).
Methods: 43 patients with SS were included (90% women), mean age 49.75±7.3 years. The patients underwent: dual-energy X-ray absorptiometry of the whole body (DXA), assessment of muscle strength (carpal dynamometry, lifting from a chair 5 times) and functional state of the muscles (short set of tests for assessing physical fitness (SST APF), determination of body mass index (BMI). In order to interpret the results of the study, appendicular muscle mass (AMM) - the sum of the muscle mass of the legs and arms, appendicular muscle index (AMI) - the ratio of AMM (kg) to height squared (m2) was determined. The diagnosis of sarcopenia was made in accordance with the updated EWGSOP2 criteria.
Results: In patients with SS, the average content of bone mineral was 2.0±0,1 kg, and adipose tissue - 25.0±1,9 kg, which turned out to be an average of 28.0% of the total weight of patients. Among the examined individuals, the frequency of obesity according to DXA (fat > 35% of body weight) was 50%, while obesity calculated by BMI (≥30 kg/m2) was detected in 6 (14.2%), and overweight (25-30 kg/m2) - in 16 (35.8%) patients. The content of total muscle mass averaged 42.7 kg, and AMM -18.2 kg, while the average AMI was 6.7 kg/m2. Low AMM was found in 4 (9.5%), and a decrease in AMM and AMI was found in 6 (14.2%) individuals. Low muscle strength according to the results of carpal dynamometry and/or the "Get up from the chair" test was found in 22 patients (52.3%), while confirmed SP (decrease in muscle strength and muscle mass) was diagnosed in 14 (33.3%) patients. When assessing the functional state of the muscles in 18 (42.8%) patients, the walking speed was <0.8 m/s, and the SST APF was less than 8 points in 24 (57.1%) patients. Severe SP (low muscle strength, low muscle mass and low physical capacity) was confirmed in 8 people (19.4% of the entire group of patients and 75% of confirmed SP). One patient with SP had a fat content of more than 35%, thus diagnosing sarcopenic obesity.
Conclusion: The results of the pilot study showed that 50% of patients with SS were obese, 33.3% - SP and 4.7% sarcopenic obesity. Thus, 12% of patients with SS had SP, which requires further study of this problem in order to identify specific risk factors for SP and develop methods for its prevention in patients with SJS.

AB0866 **SEASONAL VARIATION OF SERUM KL-6 LEVELS IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED WITH INTERSTITIAL LUNG DISEASE**

Keywords: Systemic sclerosis

H. Hirose[1], T. Higuchi[1,2], K. Takagi[3], A. Tochimoto[1], Y. Kawaguchi[1], M. Harigai[1]. [1]*Tokyo Women's Medical University Hospital, Division of Rheumatology, Department of Internal Medicine, Shinjuku-ku, Japan*; [2]*Tokyo Women's Medical University, Division of Multidisciplinary Management of Rheumatic Diseases, Division of Rheumatology, Department of Internal Medicine, Sinjuku-ku, Japan*; [3]*Adachi Medical Center, Tokyo Women's Medical University, Department of Internal Medicine, Adachi-ku, Japan*

Background: Recent studies have shown that serum KL-6 levels were useful for diagnosing and estimating prognosis in patients with systemic sclerosis-associated with interstitial lung disease (SSc-ILD) [1-4]. Additionally, KL-6 has the potential for assessing the activity of SSc-ILD; however, it may fluctuate irrespective of disease activity [5]. Identifying the reasons for fluctuation will lead to the utilization of this non-invasive tool. Based on our clinical experience, serum KL-6 levels may have seasonal variations.
Objectives: We aimed to evaluate whether serum KL-6 levels are affected by season in patients with SSc with ILD (SSc-ILD).
Methods: This is a single-center, retrospective observational study. The diagnosis of SSc was according to the 2013 ACR/ EULAR classification criteria, and the presence of ILD was confirmed by computed tomography (CT) or high-resolution CT (HRCT). We defined summer as July to September and winter as December to January. SSc-ILD patients with data of serum KL-6 levels in the 2015 winter (from December 2014 to January 2015), 2015 summer, and 2016 winter were included. Patients with comorbidities that could affect serum KL-6 levels, such as malignancy, pneumocystis pneumonia and alveolar proteinosis, and patients who did not confirm the change in the extent of ILD by chest CT during the observational period were excluded. The extent of ILD was calculated as the average of CT images at the five predefined levels [6], and scoring was blinded. Differences in serum KL-6 levels between summer and winter were analyzed by the Wilcoxon signed-rank test, followed by the Bonferroni correction for adjusting multiple comparisons.
Results: Sixty patients with SSc-ILD were included. 53 (88%) patients were female. At baseline, the median age was 61 (interquartile range [IQR]: 44–66) years, and the median disease duration was 7.7 (IQR: 4.2–13) years. 34 (57%) patients had diffuse cutaneous SSc (Table 1). Regarding the extent of ILD, 18 (30) patients had a lesion area greater than 20%. Eight (15.4%) patients had changed in the extent of ILD, and 52 (84.6%) patients were unchanged. Serum KL-6 levels were significantly higher in the winter than in the summer (2015 summer vs 2015 winter: 585 IU/L vs 648 IU/L, $p < 0.0001$; 2015 summer vs 2016 winter: 585 IU/L vs 690 IU/L, $p < 0.0001$). However, there was no difference between the 2015 winter and 2016 winter ($p=0.62$) (Figure 1). Regarding 52 patients with stable ILD, similar results were obtained (2015 summer vs 2015 winter: 736 IU/L vs 860 IU/L, $p < 0.0001$; 2015 summer vs 2016 winter: 736 IU/L vs 815 IU/L, $p < 0.0001$; 2015 winter vs 2016 winter: 815 IU/L vs 860 IU/L, $p =0.63$).
Conclusion: Serum KL-6 levels may fluctuate regardless of the activity of SSc-ILD. The result of our study may aid the interpretation of serum KL-6 testing.

AB0867 LOW STARTING DOSE AND TITRATION OF NINTEDANIB FOR SSC-ILD: ANALYSIS OF TOLERABILITY IN A SINGLE-CENTER COHORT

Keywords: Systemic sclerosis, Real-world evidence, Lungs

E. Fiorentini[1], F. Bonomi[1], L. Cometi[1], G. Lepri[1], S. Bellando-Randone[1], S. Guiducci[1]. [1]*Careggi University Hospital, Rheumatology, Firenze, Italy*

Background: Interstitial lung disease (SSc-ILD) is a common manifestation of Systemic Sclerosis (SSc) and to date few therapies are available [1]. Nintedanib (NTD) is a promising drug, but its use is often limited by intolerance, mainly by gastrointestinal adverse events (GI AEs). As reported in the SENSCIS trial [2] GI AEs related to NTD treatment (150mg bid) occur in >70% of cases, in particular diarrhea (75.7%), nausea (36.7%), vomit (24.7%), weight loss (11.8%), abdominal pain (11.5%) and alterations of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) (13.9%).
Objectives: We investigated the safety and tolerability of an up-titration strategy of NTD until the maximum tolerated dose (max 150mg bid) in our cohort of SSc-ILD patients.
Methods: Evaluation of SSc patients followed at our Rheumatology Unit, treated with NTD according to clinical indication with a dose escalation regimen: 100mg die for 7 days, then 100mg bid for 7 days, then 150mg + 100mg/die for 7 days, and finally 150mg bid. At baseline, demographic, clinical and disease features were collected. NTD GI tolerability was clinically evaluated at 1 (T1), 3 (T3) and 6 (T6) months from the beginning of the treatment.
Results: 12 SSc-ILD patients were enrolled, all females, with a mean age of 62.5 ± 12.7 years and disease duration of 9.2 ± 6.8 years (from the first non-Raynaud symptom). The more frequent disease specific antibody was anti-topoisomerase I (50%) followed by anti-centromere (8.3%). ILD pattern at HRCT was non-specific interstitial pneumonia (NSIP) in 25% of the patients, fibrosing NSIP in 50% and usual interstitial pneumonia (UIP) in 25%. The mean FVC % predicted was 71.2% (± 15.9%) and the mean DLCO 50.4% (± 14.4%). Indications for NTD prescription were fibrosis >10% (25%), FVC decline 5-10% + clinical or imaging worsening (33.3%), clinical and/or imaging worsening (41.7%). GI involvement due to SSc at baseline was present in 75% of patients: gastrointestinal reflux in 66.7%, dysmotility, vomit, and dyspepsia in 8.3% each. Table 1 shows GI AEs at T1, T3 and T6 from NTD beginning. At T6 50% of patients had nausea, 50% diarrhea, 37.5% abdominal pain and 25% referred weight loss. No one showed vomit and AST/ALT alterations. Only 3 patients reached 150mg bid (Figure 1), while 4 got at least to 100 mg bid and 1 patient suspended the drug after 3 months due to vomit.
Conclusion: These data, although limited to a small cohort, suggest that a gradual dose escalation of NTD in SSc-ILD may improve the tolerability of the drug, with a lower incidence of GI AEs (≤50%) and AST/ALT elevation. Although only 3 patients reached the maximum dose, most of the cohort managed to do at least 100 mg bid. This approach can be a good compromise in the management of ILD in SSc patients, knowing that the dose reduction to 100 mg bid does not significantly compromise the efficacy of NTD in reducing disease progression [3]–[5]. Studies of larger populations are needed to support these data.

AB0868 IMMUNE CHECKPOINT INHIBITOR-ASSOCIATED MYOPATHY

Keywords: Myositis, Targeted synthetic drugs

M. Pavía Pascual[1], N. De La Torre Rubio[1], M. Machattou[1], P. Navarro Palomo[1], C. Navarro Joven[1], M. Alonso de Francisco[1], C. Barbadillo Mateos[1], C. Merino Argumánez[1], H. Godoy[1], M. Fernandez Castro[1], B. Garcia-Magallon[1], J. Sanz[1], L. F. De Villa[1], J. L. Andréu Sánchez[1], J. Campos Esteban[1]. [1]*Hospital Universitario Puerta de Hierro Majadahonda, Rheumatology, Madrid, Spain*

Background: In recent decades, immunotherapy has changed the management and prognosis of cancer patients. Immune checkpoint inhibitors, such as those targeting PD-1 and PD-L1, are used for some types of cancer; however, their use has been associated with the appearance of immune-mediated adverse events. Among these, those related to the field of rheumatology are relatively frequent, joint involvement being the most common, followed by muscle involvement (myalgias 4%, myositis 1%).
Objectives: To describe oncologic patients who developed immune checkpoint inhibitors- related myositis.
Methods: All patients from the oncology department of a tertiary hospital, referred to rheumatology and diagnosed with immune-mediated myositis due to immune checkpoint inhibitors were collected. A descriptive analysis was performed.
Results: Five patients were analyzed, 60% male, with a mean age of 65.8 years (56-78 years). The types of cancer were: melanoma (n=2), gastroesophageal

junction cancer (n=1), cavum cancer (n=1) and pancreatic cancer (n=1); all in advanced stages with lymph node and/or metastatic involvement. The immunotherapy employed was: Nivolumab (PD-1 inhibitor) in three patients, Pembrolizumab (PD-1 inhibitor) in one patient and Darvalumab (PD-L1 inhibitor) in one patient; all at standard doses. Mean time from onset of symptoms was 4 months from drug initiation (1-10 months). In all 5 cases, the drug was discontinued with the onset of clinical symptoms and oral prednisone was prescribed at a dose between 10 and 20 mg per day. The symptom present in all patients was pain and weakness of proximal limbs (100%). In addition, one patient had ankle arthritis and another had dermatomyositis with typical cutaneous involvement (heliotrope erythema, V sign). In 3 patients there was an elevation of CK levels that resolved one month after discontinuation of the drug. Also, 3 patients, developed myositis-specific antibodies (AntiPM75 and Anti MI2, anti-PL7 and anti-TIF1gamma) that disappeared with drug withdrawal. One patient had anti-Ro52 and Ro60 antibodies that remain positive. Two patients underwent muscle MRI: one showed fatty infiltration in the gluteal musculature and atrophy with fatty infiltration in the right rectus femoris (image); in the other patient, signs of inflammatory myositis in the bilateral adductor group and in the right gluteus medius and gluteus minimus and fibrosing myositis in the iliac muscle was described. In both cases, the signs of myositis had disappeared in the control PET scan 5 months after drug discontinuation. In 4 patients, symptoms subsided in less than one month. One patient required the association of methotrexate to achieve corticosteroid withdrawal.

Conclusion: In our hospital, a total of 5 patients undergoing oncological treatment with immune checkpoint inhibitors have developed, in a mean time of 4 months from the start of the drug, a myopathy associated in 60% with the appearance of myositis-specific antibodies. This represents 1.8% of the total number of patients treated with these three drugs in our hospital.

Withdrawal of the drug and treatment with prednisone at intermediate doses allowed clinical remission and normalization of laboratory and imaging tests.

AB0869 ANTI-NUCLEAR AUTOANTIBODIES IN ANTI-U1RNP POSITIVE SYSTEMIC SCLERODERMA PATIENTS

Keywords: Systemic sclerosis

S. Dahmani[1], N. Zhuravleva[2], T. Smirnova[3], V. Diomidova[3]. *[1]Morocco,"Rahmani" Pharmacy, Casablanca, Morocco*; *[2]Russia,"Chuvash State University named after I. N. Ulyanov", Cheboksary, Russian Federation*; *[3]"Chuvash State University named after I. N. Ulyanov","Chuvash State University named after I. N. Ulyanov", Cheboksary, Russian Federation*

Background: In patients with systemic scleroderma (SSD) with overproduction of anti-U1ribonucleoprotein, there are features in the clinical picture and course of the disease.

Objectives: The aim of the study is to study the level of major autoantibodies in patients with systemic scleroderma who are positive for anti-U1ribonucleoprotein.

Methods: The study included 55 patients (48 women and 7 men, mean age 41.5±11.5 years), positive for anti-U1ribonucleoprotein and meeting the American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) 2013 classification criteria for systemic scleroderma. Defined autoantibodies (AT): rheumatoid factor (RF), antibodies to cyclic citrullinated peptide (ACCP), anticentromeric antibodies (ACA), antibodies to the nonhistone chromosomal protein Scl-70 (anti-Scl-70), antibodies to RNA polymerase III (anti-RNAP III), antibodies to cytoplasmic antigen (anti-Ro), antibodies to cytoplasmic antigen SS-B (La) associated with RNA polymerase III (anti-La), antibodies against DNA (anti-DNA), antibodies to U1-, U2-, U4-ribonucleoproteins (anti-Sm (Smith)), antibodies to cardiolipin (AKL), anti-synthetase antibodies to cytoplasmic antigen (anti-Jo1). After 2 years of complex therapy, these patients were examined.

Results: In patients of the study group, the clinical picture was dominated by inflammatory lesions of the joints and muscles, and skin manifestations were not very pronounced. Interstitial lung disease was detected in 47% of cases. Intersections with diseases (rheumatoid arthritis, systemic lupus erythematosus) were detected in 23% of cases and a combination with Sjögren's syndrome in 21.3%. Other antibodies were often detected: RF (27%), anti-Ro (31%), anti-DNA (32%), rarely - anti-Sm (13%), ACCP (7%), anti-La (5%), ACA (7%), anti-Scl70 (4%), ACL (3%). Anti-Jo1 and anti-RNAP-III were not detected in any of the patients. In patients with systemic scleroderma, highly positive for anti-U1RNP (more than two upper limits of normal) compared with low positive, RF, anti-Ro, anti-DNA were significantly more common (p=0.00). In dynamics after 2 years, high titers of anti-U1RNP persisted in 65% of patients, while other autoantibodies were detected with the same frequency. In patients with an initially low titer of anti-U1RNP, their disappearance was noted.

Conclusion: In patients with systemic scleroderma and overproduction of anti-U1RNP, inflammatory musculoskeletal manifestations predominate and are often associated with Sjögren's syndrome and overlap syndrome. High positivity for antiU1RNP was accompanied by a persistent increase in the levels of RF, anti-Ro, and anti-DNA.

AB0870 ANTI-HMGCR AUTOANTIBODY LEVELS IN THE FOLLOW-UP OF STATIN-INDUCED IMMUNE-MEDIATED NECROTIZING MYOPATHY. MULTICENTRIC STUDY OF 24 PATIENTS

Keywords: Myositis, Autoantibodies, Diagnostic Tests

D. Martínez-López[1], D. Prieto-Peña[2], C. Corrales-Selaya[2], P. Szczęsny[3,4], A. Notarnicola[5,6,7], M. López Hoyos[8], R. Blanco[2], I. E. Lundberg[5,6,7], M. Dastmalchi[5,6,7]. *[1]Hospital de Sierrallana, Rheumatology,Torrelavega, Spain*; *[2]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*; *[3]National Institute of Geriatrics, Rheumatology and Rehabilitation, Rheumatology, Warsaw, Poland*; *[4]Medical University of Warsaw, Neurology, Warsaw, Poland*; *[5]Department of Medicine, Karolinska Institute, Rheumatology, Stockholm, Sweden*; *[6]Karolinska University Hospital, Department of Gastro, Dermatology and Rheumatology, Stockholm, Sweden*; *[7]Karolinska Institutet, Center for Molecular Medicine, Stockholm, Sweden*; *[8]Hospital Universitario Marqués de Valdecilla, Immunology, Santander, Spain*

Background: Statin-induced immune-mediated necrotizing myopathy (IMNM) is associated with anti-3-hydroxy-3-methylglutaryl-CoA reductase (HMGCR) autoantibodies. It is characterized by elevated creatine kinase (CK) levels, and severe muscle weakness. Measuring disease activity is problematic, since it is challenging to differentiate it from damage. The utility of the quantitative analysis of anti-HMGCR autoantibodies during the follow-up has not been thoroughly studied.

Objectives: To assess the usefulness of measuring the levels of anti-HMGCR autoantibodies in relation to response to treatment.

Methods: We included patients all consecutive patients diagnosed with statin-induced IMNM according to the definition of the European Neuromuscular International Workshop 2016 (1) and positivity for anti-HMGCR autoantibodies in two centers from Spain and Sweden from January 2017 to November 2022. All patients were followed for at least 3 months to be included. Clinical data was extracted retrospectively from the patients' clinical records. Remission was defined as no disease activity assessed by expert rheumatologists according to 2016 ACR/EULAR response criteria in myositis. Moderate and high disease activity was defined when physician global activity score was higher than 2 or 3 (on a Likert scale) respectively [2,3]. Anti-HMGCR autoantibodies level was measured at the time of diagnosis and at a variable period of time after treatment.

Results were obtained using the chemiluminescence immunoassay (CLIA) method. Negative anti-HMGCR was considered as levels lower than 20 U/ml.

Results: Our group combined of 24 patients. Main features of the patients are summarized in the **TABLE 1**. 21 (87.5%) patients reached clinical remission or low disease activity. However, 3 patients (12.5%) remained with moderate activity of the disease. None of the patients had high disease activity. Anti-HMGCR levels at diagnosis were higher than 100 U/ml in 23 patients (95.8%) and above 200 in 11 patients (45.8%). However, anti-HMGCR levels after treatment were significantly lower in patients in remission (p=0.035). Numeric levels in patients at diagnosis of the disease and after treatment are shown in the **FIGURE 1**. Most of the patients at diagnosis (with high activity of the disease) had high anti-HMGCR levels (22 patients, 91.7% had levels above 100 U/ml). After treatment, most patients in remission had low (n=3, 14.3%) or negative (n=9, 42.9%), while patients with moderate activity had higher levels (n=2, 66.7% with levels above 100 U/ml). However, 6 patients in remission (28.6%) still had levels above 100 U/ml.

Conclusion: Anti-HMGCR autoantibodies levels evaluation can be used in parallel with other tools to accurately measure disease activity in patients with statin-induced IMNM. However, more studies are needed to confirm these results.

Background: Statin-induced immune mediated necrotizing myopathy (IMNM) is a subtype of inflammatory myopathy associated with anti-3-hydroxy-3-methylglutaryl-CoA reductase (HMGCR) autoantibodies. This condition is characterized by progressive muscle weakness leading to severe disability. Treatment is not well established, but usually includes high doses of glucocorticoids (GCs). Therapeutic effects are often disappointing. Side effects are common and related to the high doses of GCs. Intravenous immunoglobulins (IVIG) may be effective in the treatment of IMNM.

Objectives: To compare two therapeutic protocols in IMNM; **a)** standard therapy including high doses of GCs, and **b)** a GC-free protocol.

Methods: Patients consecutively diagnosed with statin-induced IMNM in our centers from January 2017 to November 2022 and followed for at least 3 months were included. IMNM was diagnosed according to the definition of the European Neuromuscular International Workshop 2016 [1]. Clinical data was extracted retrospectively from the patients' clinical records. Remission was defined as no disease activity according to 2016 ACR/EULAR response criteria in myositis [2,3].

Table 1. General features of 24 patients diagnosed with HMGCR positive IMNM.

Variables	Total (n=24)	Glucocorticoid group (n=19)	Glucocorticoid-free group (n=5)	P (steroids vs no steroid)
Age (years), mean ± SD	68.2 ± 7.2	69.2 ± 6.9	64.4 ± 8	0.2
Sex (women), n (%)	10 (42)	8 (42.1)	2 (40)	0.7
Comorbidities (n, %)				
Hypertension	17 (70.8)	13 (68.4)	4 (80)	0.96
Diabetes mellitus	15 (62.5)	11 (57.9)	4 (80)	0.7
Cardiovascular disease	7 (29.2)	6 (31.6)	1 (20)	0.96
Analytical values at diagnosis, mean ±SD				
CK (ukat/L)	114 ± 104	134± 108	40 ± 34	0.07
Treatments, n (%)				
Intravenous GC	8 (33.3)	8 (42.1)	0	0.2
Oral GC	19 (79.2)	19 (100)	0	**0,0001***
MTX	18 (75)	15 (78.9)	3 (60)	0,8
AZA	3 (12.5)	3 (15.8)	0	0,8

RTX	4 (16.7)	3 (15.8)	1 (20)	0,7
Muscle strength assessment				
MMT-8 at diagnosis	64.4 ± 12	63.7 ± 10.4	67.3 ± 19.4	0.6
MMT-8 after treatment	77.6 ± 4.2	77.2 ± 4.6	79.5 ± 1.5	0,3
Remission				
Patients achieving remission, n (%)	21 (87.5)	16 (84.2)	5 (100)	0.8
Time to clinical remission (months), mean ± SD	5.2 ± 2.3	5.5 ± 2.5	4.1 ± 1.1	0.2
Time to CK normalization (months), mean ± SD	4.1 ± 1.6	3.9 ± 1.7	4.9 ± 1.3	0.3

AZA: Azathioprine; CK: Creatine kinase; GC: Glucocorticoids; IVIG: Intravenous immunoglobulins; MTX: Methotrexate; RTX: Rituximab Upper limit for CK: < 4.7 ukat/L for men and 3.5 ukat/L for women.*: p < 0.05

Treatment was assigned to the patients considering the current recommendations and contraindications of the therapies available. In patients with comorbidities that limit the use of glucocorticoids, a steroid-free regime was agreed through a shared decision between the physician and the patient.

Results: We included 24 anti-HMGCR positive patients. Main features and treatment of the patients are summarized in **TABLE 1**. A GC-free regimen based on the use of IVIG 2g/kg every month for at least 3 months was used in 5 (20.8%) patients. The remaining received standard treatment including GCs. At baseline, general demographic data, MMT-8 and CK levels were similar in both groups. Comorbidities were higher in patients treated with the GCs free protocol. Remission or low disease activity was achieved in 21 patients (87.5%), including all 5 patients who did not receive GCs (after a mean of 4.1 ± 1.1 months). However, 3 (15.8%) of the 19 patients receiving glucocorticoids did not achieve remission or low disease activity. The time to remission or CK normalization was similar in both groups.

Conclusion: In our series of patients with anti-HMGCR positive IMNM, we found that patients can achieve remission without glucocorticoid treatment.

AB0872 RELAPSES OF 129 PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Disease-modifying Drugs (DMARDs), Prognostic factors, Myositis

J. Choi[1], J. Kim[2], B. Ghang[2], B. Yoo[3]. *[1]Jeju National University School of Medicine, Student, Jeju, Korea, Rep. of (South Korea)*; *[2]Jeju National University School of Medicine, Jeju National University Hospital, Jeju, Republic of Korea, Rheumatology, Jeju, Korea, Rep. of (South Korea)*; *[3]Asan Medical Center, University of Ulsan College of Medicine, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: A high dose of glucocorticoid is suggested as initial management of Idiopathic inflammatory myopathies(IIMs), and immunosuppressive agents are added in severe cases [1]. However, since the diseases are rarely diagnosed, few studies have addressed the issue regarding the use of immunosuppressive agents with limited evidence [2]. The treatment of IIMs largely relies on empirical evidence and small studies [3]. As a results, The immunosuppressives have been indeed administered at the discretion of the physicians in practice. The initial glucocorticoid treatment usually leads to a stable phase for IIMs where clinical symptoms are improved, and glucocorticoids are tapered to low doses. A relapse is occasionally observed in clinical practice as the recurrence of muscle or cutaneous manifestations during and after glucocorticoids tapering, although there is no consensus on the definition regarding the relapse of IIMs [4]. Therefore, it is poorly understood which factors are essential to predicting the relapse of IIMs.

Objectives: Few studies have assessed risks for the relapse of idiopathic inflammatory myopathies (IIMs). We investigated relapse in patients with IIMs.

Methods: Patients who were newly diagnosed with IIMs and underwent muscle biopsy between 2000 and 2017 were retrospectively reviewed. The relapse of IIMs was defined as the recurrence of muscle or cutaneous manifestations after reaching the stable phase, leading to ≥50 % increase in the glucocorticoid dosage. The factors associated with the relapse of IIMs were investigated by Cox proportional hazards analysis.

Results: Of the 105 patients with IIMs, relapse was observed in 65 patients (62%). The titer of an antinuclear antibody (ANA) was higher in the relapse group than in the non-relapse group (P = 0.033). In multivariable analysis, three factors were associated with the relapse of IIMs: histopathologic features consistent with IIMs (model 1; HR, 1.69; 95% CI, 1.01-2.83, P = 0.0453) and the use of immunosuppressants before relapse (model 2; HR, 0.50; 95% CI, 0.29-0.86, P = 0.0132). Doubling of ANA titer showed a trend toward an association with relapse albeit without statistical significance (model 1; HR, 1.13; 95% CI, 1.00-1.27, P = 0.0517).

Conclusion: The use of immunosuppressants during a period of tapering glucocorticoid in the initial treatment would help reduce the risk of relapse of IIMs.

Table 1. Factors associated with the relapse of Idiopathic inflammatory myopathies in univariate and multivariable analyses.

	Model 1			Model 2			Model 3		
Factors	HR	95% CI	*P*	HR	95% CI	*P*	HR	95% CI	*P*

AB0873 WHOLE BODY INSULIN SENSITIVITY IS INCREASED IN SYSTEMIC SCLEROSIS

Keywords: Diet and Nutrition, Cardiovascular disease, Systemic sclerosis

J. Ciaffi[1], P. Ruscitti[2], I. Di Cola[2], V. Pavlych[2], N. Italiano[2], M. Gentile[2], M. Tomassetti[1], T. Huizinga[3], J. De Vries-Bouwstra[3], F. Ursini[1,4], P. Cipriani[2]. *[1]IRCCS Istituto Ortopedico Rizzoli, Medicine & Rheumatology Unit, Bologna, Italy*; *[2]University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy*; *[3]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[4]Alma Mater Studiorum - Università di Bologna, DIBINEM, Bologna, Italy*

Background: The prevalence of type 2 diabetes (T2D) is increased in rheumatoid arthritis (RA) and other inflammatory diseases, while the available evidence suggests that in systemic sclerosis (SSc) it is lower than in the general population [1]. Insulin resistance and ß-cell dysfunction are the main mechanisms in the pathophysiology of T2D. However, mechanisms underlying the negative association between SSc and T2D have not been elucidated.

Objectives: We aimed to evaluate whole-body insulin sensitivity in SSc patients and to compare the results with controls with no autoimmune rheumatic disease (non-ARD) and with patients affected by RA. Additionally, we investigated whether insulin sensitivity was associated with SSc characteristics.

Methods: The study population was composed of consecutive adult SSc patients. For comparison, non-ARD and RA patients were included. All were screened for T2D before inclusion. Individuals with a diagnosis of diabetes and those using corticosteroids or insulin-sensitizing agents were excluded. The whole-body insulin sensitivity index (ISI) was estimated from glucose and insulin concentrations obtained during the oral glucose tolerance test (OGTT) using the equation proposed by Matsuda [2], which is validated against euglycemic insulin clamp and provides reliable estimates of glucose homeostasis. Insulin resistance (HOMA-IR) was calculated.

Results: A total of 41 SSc patients, 41 individuals with RA and 82 non-ARD control patients were recruited. SSc patients were significantly older and had lower BMI than controls with RA, but had comparable characteristics with non-ARD patients (Table 1). The ISI was significantly higher in SSc patients compared with RA controls [8.01 (4.85 – 12.62) vs 3.39 (1.93 – 6.14), p <0.001] and with non-ARD patients [8.01 (4.85 – 12.62) vs 4.38 (3.39 – 6.37), p <0.001]. Significant differences emerged also when analysing the HOMA-IR, which was lower in SSc patients than in RA [0.98 (0.66 – 1.52) vs 2.02 (1.36 – 3.63), p <0.001] and non-ARD [0.98 (0.66 – 1.52) vs 1.74 (1.28 – 2.28), p <0.001]. In normal weight individuals (BMI from 18.5 to 24.9), median ISI was higher in the SSc group than in RA (p =0.007) and non-ARD controls (p <0.001). In overweight and obese cases (BMI ≥25) ISI was also higher in the SSc group than in RA (p =0.003) and non-ARD controls (p =0.017) (Figure 1). In the SSc group, patients with diffuse cutaneous disease had significantly higher ISI than individuals with limited cutaneous SSc [11.60 (8.59 – 20.13) vs 6.58 (4.91 – 11.63), p = 0.027]. In univariate analysis, ISI was significantly correlated with BMI (rho= -0.468, p= 0.002), fasting insulin (rho= -0.715, p <0.001), and modified Rodnan skin score (rho= 0.422, p= 0.006. In multiple linear regression model adjusted for BMI and fasting plasma insulin, the association between ISI and modified Rodnan skin score was lost (r^2 = 0.27, p= 0.095).

Conclusion: The findings of our study suggest that patients with SSc are more insulin sensitive than those with RA and even than individuals without inflammatory diseases. This is the first time that whole-body insulin sensitivity is assessed in SSc using a validated and reliable method, contributing unique data to the knowledge about glucose homeostasis in SSc.

EPIDEMIOLOGY AND CLINICAL FEATURES OF IDIOPATHIC INFLAMMATORY MYOPATHIES IN SINGLE REGION IN NORTHERN SPAIN

Keywords: Descriptive Studies, Myositis, Epidemiology

C. Corrales-Selaya[1], D. Martínez-López[2], D. Prieto-Peña[1], J. L. Martín-Varillas[3], R. Blanco[1]. [1]*Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; [2]*Sierrallana Hospital, Rheumatology, Torrelavega, Spain*; [3]*Hospital Comarcal de Laredo, Rheumatology, Laredo, Spain*

Background: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of disorders characterized by proximal muscle weakness and inflammation. The main subtypes of IIM are dermatomyositis (DM), polymyositis (PM), inclusion body myositis (IBM), immune-mediated necrotizing myopathy (IMNM) and antisynthetase syndrome (ASS). Prevalence and incidence vary depending on the geographic location.

Objectives: To describe the epidemiological and clinical features of IIM in a single region in northern Spain.

Methods: We included all consecutive patients diagnosed with IIM in the region of Cantabria, excluding IBM, from January 2000 to December 2022. IIM was diagnosed by expert rheumatologists according to **a)** EULAR/ACR 2017 classification criteria of IIM in PM and DM, **b)** Definition of the European Neuromuscular International Workshop 2016 in IMNM and **c)** Connor's criteria in ASS.

Table 1. Main demographic, clinical features, laboratory findings and treatments in 63 patients diagnosed with IIM.

Data regarding demographics features, clinical findings, laboratory tests and treatments were extracted from the patients' clinical records.
Results: We included a total of 63 patients, mean age at diagnosis 52.1±19.3 years. Most of the patients were women (n=44, 69.8%). Main features are shown in **TABLE 1**. Prevalence of IIM was 10.8/100.000 population. The incidence rate was 4.9 cases per million persons per year. An upward trend in annual incidence was observed from 1.7 in 2000 to 15.4 per million in 2018 **(FIGURE 1)**. The most common IIM subtype was DM (n=34, 54%). Gottron papules, muscle weakness and Interstitial lung disease were the most frequent manifestations in DM, IMNM and ASS group, respectively. The most frequent autoantibody was anti-Ro 52 (n=12, 19%), however in 28 patients (44.4%) none was detected. Most used treatments were glucocorticoids (n=61, 96.8%), azathioprine (n=30, 47.6%), intravenous immunoglobulins (n=29, 46%) and rituximab (n=29, 46%).
Conclusion: We describe the prevalence, incidence rate, clinical features and main treatments used in IIM in our area. An upward trend in annual incidence was observed in our study.

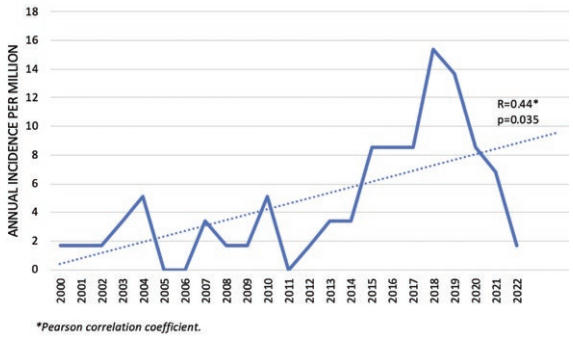

Figure 1. Annual incidence of IIM from 2000 to 2022.

AB0875 CANCER, DYSPHAGIA, AND HEART INVOLVEMENT IN PATIENTS WITH INFLAMMATORY MYOSITIS AND INTERSTITIAL LUNG DISEASE

Keywords: Lungs, Heart, Myositis

A. Ceribelli[1], A. Tonutti[1], N. Isailovic[2], M. De Santis[1], C. Selmi[1]. [1]*IRCCS Humanitas Research Hospital and Humanitas University, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy*; [2]*IRCCS Humanitas Research Hospital, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy*

Background: Interstitial lung disease (ILD) is a leading cause of morbidity and mortality in patients with inflammatory myositis (IIM) [1]. The risk of ILD is higher with myositis-specific (MSA, e.g. antisynthetase, MDA5) and -associated antibodies (MAA, e.g. Ro52) [2], while negatively associated to malignancy [3]. IIM specific clinical phenotypes and ILD are treated with glucocorticoids, mycophenolate mofetil or rituximab (4), and characterizing IIM organ involvement is a major task to optimize diagnostic and therapeutic choices. In particular, cardiomyopathy is emerging as a leading cause of morbidity in IIM [5].
Objectives: To assess the demographic, clinical, and serological features of patients with IIM-associated ILD.
Methods: We retrospectively analyzed clinical data of 73 patients with IIM followed at our center in 2015-2022; sera were analyzed for autoantibodies (ANA-HEp-2 IFA; ENA; MSA/MAA and anti-E2/E3 PDH by immunoprecipitation) as per protocol. ILD was defined by positive high-resolution computed tomography (CT) scan; heart magnetic resonance imaging (MRI) was performed when symptoms, ECG, or echocardiographic alterations were present.
Results: ILD was detected by high-resolution CT scan in 33/73 (45%) patients (Table 1), with no significant differences in terms of age, sex, and smoking history. Serum ANA were detected in 60/73 (82%) patients, with no difference between ILD and no-ILD groups. Arthritis was more frequent in patients with ILD; there was no difference in terms of muscle damage, skin lesions (heliotrope rash, Gottron's papules, periungeual erythema), and Raynaud's phenomenon according to the presence of ILD. Dysphagia and heart disease at MRI were more prevalent in patients with ILD. Patients with ILD also had lower prevalence of malignancy. Anti-Ro52 and antisynthetase antibodies were significantly associated with ILD. Anti-MJ/NXP2 antibodies were observed only in the group without ILD, but such association was not statistically significant. The prevalence of anti-TIF-1gamma antibodies did not differ between the two groups; 3/5 (60%) patients in the group without ILD developed malignancy vs only 1/4 (25%) in patients with ILD.
Conclusion: There is a higher prevalence of dysphagia and heart involvement in patients with IIM and ILD, a highly prevalent manifestations of IIM, thus suggesting dedicated therapeutic strategies. ILD correlates with antisynthetase and -Ro52 positivity, with a negative association with malignancy, particularly in anti-TIF1gamma positive patients.

AB0876 IMPACT OF AUTOANTIBODY PROFILE ON FUTURE ORGAN INVOLVEMENT IN SYSTEMIC SCLEROSIS: DISEASE FREE SURVIVAL IN DIFFERENT PATIENT GROUPS

Keywords: Systemic sclerosis, Autoantibodies

M. Can[1], B. Demir[1], N. Aliyeva[2], S. Amikishiyev[2], B. Artim-Esen[2], A. Gul[2], M. Inanc[2], Y. Yalçınkaya[2]. [1]*Istanbul University, Internal Medicine, İstanbul, Turkey*; [2]*Istanbul University, Internal Medicine, Rheumatology, İstanbul, Turkey*

Background: Some specific autoantibodies were known to be associated with cutaneous subtype, type of organ involvement and prognosis in systemic sclerosis (SSc).
Objectives: The aim of our study was to evaluate the impact of autoantibody profile on the course of SSc regarding new organ involvement over time.
Methods: The data of 206 consequitive patients (189 women) with SSc who were followed up at least 12 months were retrospectively analyzed. Associations between the autoantibodies (anti-nuclear antibody (ANA) (27.7%, n=57), anti-Scl70 (47.1%, n=97) and anti-centromere (ACA) (22.3%, n=46)) and disease-free survival (without new organ involvement) were evaluated in SSc patients with a mean follow-up time of 101.26±71.02 months.
Results: Anti-Scl70 was associated with diffuse cutaneous disease involvement, digital ulcers, arrhythmia, and interstitial lung disease (ILD) (OR:3.43, p<0.001, OR:1.835, p=0.033, OR:4.06, p=0.038 and OR:2.393, p=0.006, respectively). ACA was associated with PAH (OR:3.319, p=0.040) and protective against diffuse skin involvement, flexion contractures and ILD (OR:0.203, p=0.001,

OR:0.251, p=0.012 and OR:0.288, p=0.008, respectively). In ACA (+) group, new organ involvement was observed less frequently (HR: 0.523 (95% CI (0.29-0.94), p=0.030) and after a longer time period when compred to ACA (-) group (82.65±14.5 vs 53.98±5.49 months, p=0.026). At the 5th and 8th years of the follow-up, half of the ACA(+) patients did not develop new organ involvement. In the ACA(-)[(ANA(+) or antiScl70(+)] group, new organ involvement was detected in >67% within 5 years and in >80% within 8 years (figure-1, table-1).

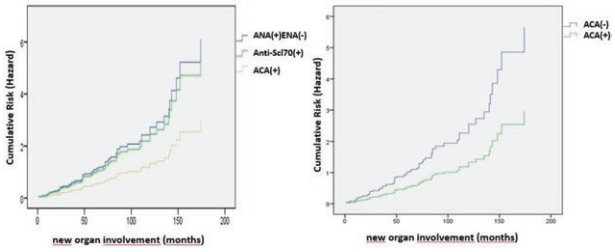

Figure 1. Cumulative risk of the new organ involvement for different systemic sclerosis patient groups according to autoantibody profile over time.

Table-1 Time to New Organ Involvement and Disease-Free Survival according to Autoantibody Profile in SSc Patients

	Time to New Organ Involvement		Disease-Free Survival without New Organ Involvement		
	Mean (months)	CI 95%	2.year	5.year	8.year
ACA(+) (n=17)	82,65±14,5	54,25±111,1	%76.5(±10.3)	%52.9(±12.1)	%47.1(±12.1)
ANA(+)-ENA(-) (n=18)*	52,06±9,31	33,82±70,29	% 61.1(±11.5)	%33.3(±11.1)	%16.7(±8.8)
Anti-scl70(+) (n=36)	54,95±6,88	41,45±68,44	%72.2(±7.5)	%38.9(±8.1)	%16.7(±6.2)
*ACA(-)(n=54)^*	*53,98±5,49*	*43,22±64,75*	*%68.5 (±6.3)*	*%37.0 (±6.6)*	*%11.1 (±4.3)*

* p=0,026, ^p=0,026 compared to ACA(+) patients, Log Rank (Mantel-Cox)test

Conclusion: Although ACA(+) patients are considered to have a better prognosis, some patients may develop new or worsening manifestations after a longer time period. The prognosis of ANA or anti-Scl70(+) patients was shown to be more severe and most patients had new organ involvement within the first 5 years of the disease, warranting a careful evaluation and efficacious treatment at this period.

AB0877 TARGETING VASCULOPATHY TO SLOW FIBROSIS IN SYSTEMIC SCLEROSIS (SSC): DESIGN OF A PHASE II STUDY WITH A SOLUBLE GUANYLATE CYCLASE ACTIVATOR (SGCA)

Keywords: Systemic sclerosis, Biomarkers, Randomized control trial

D. Khanna[1], M. Flack[2], T. Litzenburger[3], N. Fagan[4], O. Distler[5]. *[1]University of Michigan Scleroderma Clinic, Department of Internal Medicine, Ann Arbor, United States of America*; *[2]Boehringer Ingelheim Pharmaceuticals, Inc., TA Inflammation Medicine, Ridgefield, United States of America*; *[3]Boehringer Ingelheim Pharma GmbH & Co. KG, TMCP Therapeutic Areas, Biberach, Germany*; *[4]Boehringer Ingelheim Pharmaceuticals, Inc., Global Biostatistics & Data Sciences, Ridgefield, United States of America*; *[5]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland*

Background: The pathophysiology of SSc involves a complex interplay between immune dysfunction, vasculopathy, and fibrosis. The soluble guanylate cyclase (sGC) pathway has been shown to improve vascular endothelial function. We designed a Phase II study to test whether treatment of vasculopathy with an sGCa could slow the progression of fibrosis in patients with early progressive SSc and vasculopathy.

Objectives: To design a randomized, double-blind, placebo-controlled trial to evaluate the progression of fibrosis in patients with SSc treated with an sGCa.

Methods: We reviewed criteria used in published clinical trials to define early progressive disease, as well as clinical and biomarker features from existing studies and registries that are predictive of more rapid progression of fibrosis [1, 2]. Specifically, we looked for features of vasculopathy associated with progression of skin and lung fibrosis [3]. We performed a rigorous review of investigator- and patient-reported outcomes to test the hypothesis that amelioration of vascular symptoms could slow the progression of fibrosis in patients with SSc.

Results: Progressive disease was defined as having diffuse cutaneous SSc with evidence of active disease as defined by clinical and biomarker criteria. The clinical criteria were similar to those used in previous trials, but we developed a novel biomarker strategy using KL-6 in addition to C-reactive protein (CRP) and erythrocyte sedimentation rate. These biomarkers identify additional patients at risk for progressive lung fibrosis. Significant vasculopathy was defined as having digital ulcers or a history of digital ulcers and/or Raynaud's phenomenon requiring medical treatment or associated with elevated CRP. We developed a hierarchy of primary, key secondary, and secondary endpoints, including forced vital capacity, modified Rodnan skin score, revised Composite Response Index in Systemic Sclerosis, Health Assessment Questionnaire-Disability Index, digital ulcer burden, and Raynaud's symptom scoring, to investigate whether amelioration of vascular symptoms could slow decline in lung function over 48 weeks and reduce the progression of skin fibrosis and other disabilities associated with SSc. We determined that a sample size of 100 patients was sufficient to obtain 80% power to observe changes in lung and skin fibrosis.

Conclusion: We designed a 48-week randomized, double-blind, placebo-controlled Phase II trial enrolling 200 patients with early progressive SSc and significant vasculopathy to test whether targeting vasculopathy with a novel sGCa can slow the progression of fibrosis in patients with SSc. The trial is now active, and additional details are available at NCT05559580.

AB0878 SAFETY AND EFFICACY OF MESENCHYMAL STEM CELLS TRANSPLANTATION IN SYSTEMIC SCLEROSIS

Keywords: Safety, Systemic sclerosis, Clinical Trials

N. Krivoruchko[1], L. Zaripova[1], M. Askarov[1], A. Baigenzhin[2], T. Karibekov[3], G. Shaimardanova[4], S. Bekturganova[5]. *[1]National Scientific Medical Center, Institute of fundamental and applied medicine, Astana, Kazakhstan*; *[2]National Scientific Medical Center, The Chairman of the Board, Astana, Kazakhstan*; *[3]National Scientific Medical Center, Deputy Chairman of the Board, Astana, Kazakhstan*; *[4]National Scientific Medical Center, Pathological department, Astana, Kazakhstan*; *[5]National Scientific Medical Center, Department of therapy and cellular technologies, Astana, Kazakhstan*

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease characterised by vasculopathy and tissue fibrosis of the skin and various internal organs. Currently available treatments for SSc have limited efficacy, and the disease still has poor prognosis. New therapeutic approaches such as mesenchymal stem cell (MSC) transplantation are of great interest. MSCs are known as multi-potent progenitor stromal cells that self-renew and differentiate toward multiple mesenchymal cell lineages [1, 2].

Objectives: to evaluate the efficacy and safety of bone marrow MSCs transplantation in SSc.

Methods: Twenty-five patients with a reliable diagnosis of SSc refractory to classical immunosuppressive therapy were divided between main and control group. Patients from the main group underwent transplantation of MSCs in combination with high-dose immunosuppressive therapy (HIST) (n=14), while the control group was observed on the background of traditional immunosuppressive therapy without cell transplantation (n=11). Both groups were comparable in age, gender

of patients, duration and severity of the disease. The degree of induration of the skin was evaluated using the modified Rodnan skin score (mRSS). The disease activity was assessed using the EScSG scale. Anti-nuclear antibodies (ANA), anti-SCL-70 were examined by indirect immunofluorescence, cytokines (IL-1B, IL-6, IL-10, TNF-α) - by ELISA. All patients underwent CT scan of the thoracic segment, echocardiography with determination of mean pulmonary artery pressure (mPAP) and spirography. Statistical analysis was carried out by GraphPad Prism version 8.
Results: Before MSC transplantation, SSc patients in both groups demonstrated an increase in ANA, C-reactive protein (CRP), IL-1, IL-6, TNFα, with the background of severe skin induration. After transplantation of MSCs with HIST a pronounced clinical effect was noted: induration and dense swelling of skin, muscle contractures, vasospasm attacks (Raynaud syndrome) significantly decreased, dysphagia was relieved. In addition, a significant decline in skin density according to mRSS was observed (from 22.13±2, 52 to 9.8±0.93, p=0.03). A significant reduction in EScSG was registered from 3.21 to 2.48 points (p=0.05). Six months after transplantation patients with SSc demonstrated a decrease in CRP from 10.14±2.01 to 3.28±1.31. Parameters of the cytokine profile with a moderate decrease for IL-1, IL-6 and TNFα (p<0.05). According to the results obtained patients who underwent BM-MSCs transplantation demonstrated 54% decrease in mPAP, from 41.4 ± 10.87 to 26.8 ± 3.27. In SSc patients in the control group high levels of cytokines, mRSS, and mPAP were recorded during the observation period. No cases of death or severe complications associated with MSCs transplantation with HIST have been registered.
Conclusion: The conducted research demonstrated the therapeutic effect of MSC transplantation consisted in the decrease of the induration of skin, the activity of SSc and the severity of pulmonary hypertension, as well as normalizing the levels of proinflammatory cytokines.

AB0879 SAFETY AND EFFECTIVENESS OF RITUXIMAB TREATMENT FOR SYSTEMIC SCLEROSIS: AN UPDATE OF OUR CLINICAL EXPERIENCE

Keywords: bDMARD, Systemic sclerosis

A. Spinella[1], G. Sandri[1], M. De Pinto[1], R. Greco[1], L. Magnani[2], G. Amati[1], F. Lumetti[1], S. Cerri[3], C. Salvarani[1,2,4], D. Giuggioli[1,5]. *[1]University of Modena and Reggio Emilia, Scleroderma Unit, Rheumatology Unit, Modena, Italy*; *[2]AUSL-IRCCS of Reggio Emilia, Unity of Rheumatology, Reggio Emilia, Italy*; *[3]University of Modena and Reggio Emilia, Center for Rare Lung Disease, Department of Specialized Medicine, Respiratory Disease Unit, Modena, Italy*; *[4]University of Modena and Reggio Emilia, Department of Surgery, Medicine, Dentistry and Morphological Sciences with Transplant Surgery, Oncology and Regenerative Medicine Relevance, Modena, Italy*; *[5]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy*

Background: The treatment of systemic sclerosis-SSc is challenging because of its complex pathogenesis. Data on Rituximab-RTX use in SSc are still conflicting but information from case reports or non-randomized clinical trials are somehow promising.
Objectives: According to our previous experience, we newly evaluated the safety and effectiveness of rituximab (RTX) in systemic sclerosis (SSc) patients. In addition, we compared the efficacy of RTX taken alone or in combination with Mycophenolate mofetil (MMF).
Methods: We collected data from 43 SSc subjects referred to the Scleroderma Units of Modena and Reggio Emilia (M/F 10/33, age 54,19±13,75SD years, disease duration 10,5±6,56SD years, lc/dcSSc 19/24). Our patients were treated with RTX (4 weekly/infusions/375 mg/m^2) between January 2004 and January 2022. The main indications to RTX treatment were: interstitial lung disease, skin fibrosis, and/or articular involvement unresponsive to previous therapies. Clinical information and blood exams were evaluated before (T0), 6 months (T1), and 12 months (T2) after RTX administration. Pulmonary function tests-PFTs, high-resolution computed tomography-HRCT of the lungs, and echocardiogram were performed at T0 and T2.
Results: The extent of skin sclerosis measured by means of modified Rodnan skin score-mRSS decreased from 14,83±10,37SD at T0 to 11,56±7,91SD at T2, and this result was more evident in diffuse cutaneous subsets. Melanodermia and skin tightening significantly improved during follow-up (p<0.0001). Arthritis revealed a good response too leading to a marked reduction of swollen/tender joints (p<0.0001). HAQ and NRS scores also showed a significant amelioration from T0 to T2 (p<0.0001). Inflammatory indices (ESR and CRP) normalized in almost all subjects (p<0.0001). Lung fibrosis at chest-CT remained stable during the entire follow-up. DLCO % improving was more evident in patients with combination RTX+MMF (p<0.0001). No pulmonary arterial hypertension-PAH progression was observed in subjects with a previous diagnosis, while no patient presented a new diagnosis of PAH. No significant side effects were observed.
Conclusion: Our results further support the effectiveness and safety of RTX in the treatment of SSc patients. The improvement of skin sclerosis, arthritis, and pulmonary function were the main results. The role of the association RTX-+MMF is intriguing for the preliminary correlations with SSc cardio-pulmonary involvement. Immunomodulatory therapies are successful and encouraging in the management of SSc, and the correct positioning of these drugs is worthy of further investigations.

AB0880 CORRELATION BETWEEN THE RESULTS OF NAIL FOLD CAPILLAROSCOPY AND OPTICAL COHERENCE TOMOGRAPHY ANGIOGRAPHY IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Diagnostic Tests

K. Romanowska-Prochnicka[1,2], K. Paczwa[3], M. Rerych[3], M. Olesińska[2], R. Różycki[3], J. Gołębiewska[3]. *[1]Medical University of Warsaw, Department of Biophysics, Physiology and Pathophysiology, Faculty of Health Sciences, Warsaw, Poland*; *[2]National Institute of Geriatrics, Rheumatology and Rehabilitation, Department and Polyclinic of Systemic Connective Tissue Diseases, Warszawa, Poland*; *[3]Military Institute of Aviation Medicine in Warsaw, Poland, Department of Ophthalmology, Warsaw, Poland*

Background: Vasculopathy of blood vessels are, apart from immunological disorders, an important.
common pathogenetic link of dangerous organ complications in systemic sclerosis (SSc). Endothelial damage is one of the mechanisms leading to disorders of vascular hemostasis, platelet activation, thrombosis causing coagulopathy and microangiopathy. Nailfold capillaroscopy (NC) is a non-invasive diagnostic tool for the detection and monitoring patients with SSc and current methods of the assessment of microcirculation and capillary structure within the nail folds. Although vascular pathologies can occur in other organs including the organ of vision. Optical coherence tomography angiography (OCT A) is a noninvasive imaging method of microvasculature of the retina and choroid providing the assessment of retinal perfusion.
Objectives: The aim of the study was to evaluate the correlation between the optical coherence tomography (OCT) and optical coherence tomography angiography (OCTA) parameters and capillaroscopic results.
Objectives: The aim of the study was to evaluate the correlation between the optical coherence tomography (OCT) and optical coherence tomography angiography (OCTA) parameters and capillaroscopic results.
Methods: 31 patients (pts) with SSc diagnosed were included to the study. Mean age of the patients was 35,1 (8,3). Capillaroscopy was performed. The modified Rodnan Skin Score (mRSS) examination was taken by one assessor at the time of the study. There were measured HRCT, proBNP. echocardiography. Finger ulcers were observed in physical examination. OCTA scans were collected from 31 patients. 61 eyes were included to the study to assess changes in retinal microcirculation. Foveal avascular zone (FAZ) in superficial plexus and deep plexus, parafoveal mean superficial vessel density and parafoveal mean deep vessel density were correlated to NF findings and other parameters used in rheumatic examination. All the statistical procedures were performed by using STATGRAPHICS Centurion, version 19.4 (Statgraphics Technologies, Inc., The Plains, Virginia, USA).
Results: In our study group 74 % has diffuse Scc, 26% has limited SSc. InNC: 5 pts has early pattern, 12 has active pattern,9 pts has late pattern. Only one person has pulmonary arterial hypertension (PAH) and 8 pts have active finger ulcers. Interstitial lung disease was observed in 12 pts. (67% has non-specific interstitial pneumonia (NSIP) and 33% usual interstitial pneumonia (UIP)). Elevated proBNP were detect in 17,8% The parafoveal mean superficial vessel density correlated positively and statistically significantly with mRSS (p=0,0460). Patients with early scleroderma pattern in capillaroscopy showed larger superficial FAZ (0,4± 0,07 mm^2) than pts with active (0,24 ± 0,09 mm^2) and late (0,22 ±0,09 mm^2). There was correlation between deep FAZ area and scleroderma pattern showing larger FAZ in pts with active (0,46±0,14 mm^2) than pts with active

(0,2 ±0,12 mm^2) and late (0,17±0,13 mm^2). Statistically significant difference was found between interstitial lung disease NSIP and UIP in correlation with deep FAZ area. Pts with NSIP had larger FAZ (0,32 ±0,14 mm^2) than UIP pts (0,17 ±0,12 mm^2). Moreover, NSIP pts had higher parafoveal mean superficial vessel density (42,21% ±1,69) than UIP (39,89 ±1,23). NSIP pts had also higher mean parafoveal deep vessel density (43,58 ±1,5 %) than UIP pts (41,72 ±1,55 %).

Conclusion: In conclusion, our findings indicate ocular vascular abnormalities in patient with SSc. The results show the important role of OCTA in diagnosis, monitoring and prognosis of microvascular changes in SSc. Moreover, NF correlate with FAZ.

Background: Hand function deterioration is a major multifactorial driver of disability in Systemic Sclerosis (SSc) whose rate has been poorly described.

Objectives: The aim of this study is to describe incidence and risk factors of hand functional worsening in a longitudinal, multicenter, observational SSc cohort.

Methods: Hand involvement and disability were evaluated in consecutively enrolled patients for 24 months. Patient-reported hand impairment was captured with Cochin Hand Disability Score (CHFS) and the corresponding minimal clinical important differences (MCID) and patient acceptable symptom state (PASS). Clinical association with CHFS change over time and clinically meaningful worsening (MCID-Worsening) were investigated.

Results: Three-hundred-ninety-six patients from 10 centres were evaluated and 201 SSc (age 55.7±12.2 years, male 13.4%) were included in the final analysis. Median (IQR) disease duration was 5 (2-11) years while the proportion of patients with diffuse cutaneous variant was the 29.9%. Fifty-six (27.8%) patients had a CHFS ≥PASS at baseline. CHFS increased over time 35.8% of patients reaching CHFS≥PASS ($p<0.001$), and 52.2% of patients reporting MCID-Worsening at 24 months. A LASSO model simultaneously exploring the effects of multiple baseline clinical variables showed that MCID-Worsening was associated with male gender, LeRoy diffuse variant, late capillaroscopy pattern, shorter disease duration, absence of digital ulcers, presence of tenosynovitis, pain, Raynaud's phenomenon, and global and hand disability severity, together with treatment with immunosuppressants, vasoactive medications, and second-line analgesics.

Conclusion: Hand function tends to deteriorate over time in one SSc patient in two despite available therapies and clinical assessment support risk stratification. These results pave the way to inform design of intervention studies aimed at improving the outcome of this major driver of disability in SSc.

AB0882 ADVANCED GLYCATION END PRODUCTS IN SYSTEMIC SCLEROSIS

Keywords: Prognostic factors, Organ damage, Biomarkers

L. Triginer[1], L. Tío[2], I. Carrion[2,3], A. Guillen-Del-Castillo[4,5], A. Ribes[2], L. Valencia Muntalà[1,6], J. Monfort[2,7], T. C. Salman[2,7], A. Pros[2,7], J. Narváez[1,6], C. P. Simeon Aznar[4,5]. *[1]IDIBELLL, Unitat Funcional de Malalties Autoinmunes Sistèmiques (UFMAS), Barcelona, Spain*; *[2]IMIM (Hospital del Mar Medical Research Institute), Barcelona, Infammation and Cartilage Cellular Reseach Group, Barcelona, Spain*; *[3]Hospital del Mar, Servei de Reumatologia, Barcelona, Spain*; *[4]Hospital Universitario Vall d'Hebron, Department of Internal Medicine, Barcelona, Spain*; *[5]VHIR, Systemic Diseases, Barcelona, Spain*; *[6]Hospital Universitari de Bellvitge, Department of Rheumatology, Barcelona, Spain*; *[7]Barcelona, Servei de Reumatologia, Barcelona, Spain*

Background: Studies have postulated that advanced glycation end products (AGEs) could have a relevant role as inducers in the chronic inflammatory pathway present in various diseases -- including systemic sclerosis (SSc). Similarly, that the concentration of AGEs maybe related to nailfold capillaroscopy SSc changes, the diffuse skin subtype, or calcinosis. Validation studies have shown that skin autofluorescence is strongly related to AGEs levels in skin biopsies.

Objectives: To characterize and identify association between the concentrations of AGEs, measured by cutaneous autofluorescence, and disease parameters in SSc patients.

Methods: AGEs concentrations were measured by skin autofluorescence (Age Reader Mu Connect from Diagnostics Technologies BV®) in 179 SSc patients and correlated with demographic and clinical data. Cumulated AGEs were distributed in tertiles. Categorical data was described with frequencies, whereas continuous variables were displayed as mean (standard deviation). ANOVA tests were conducted to explore the linear association of demographics and clinical features with the cumulated AGEs value. Regression models were adjusted by age (M1), and also by smoking status (M2 = M1 + smoker).

Results: Table 1 shows the distribution and correlation of the most relevant patients characteristics studied according to AGEs levels classified in tertiles. Male gender (p-value M1=0.008, M2=0.003) and anticentromere antibodies (ACA) (p-value M1=0.010, M2=0.034) were statistically significant associated with higher AGEs levels. In addition, AGEs levels were inversely correlated with obesity as a categorical variable with statistical significance (p-value M1=0.036, M2=0.022). Although not statistically significant, there was a trend towards higher values of AGES (p-value 0.05 - 0.1) in patients with esophageal involvement and skin manifestations (either diffuse or limited cutaneous subtype) and lower prevalence of anti-topoisomerase antibodies (ATA). No associations with other characteristics were found.

Conclusion: Higher AGEs levels were independently associated to male gender, ACA positivity and inversely with obesity. AGEs might be involved in the

aethiopathological pathways leading to skin and esophageal manifestations. Finally, the disease mechanism in obese SSc patients might indicate a milder disease, as they present lower AGEs values, opposing to what has been described in healthy subjects. This could indicate less severe gastrointestinal disease leading to malnourishment.

AB0883 IDIOPATHIC OPHTHALMIC MYOSITIS: CLINICAL PRESENTATION, THERAPEUTIC APPROACH AND IMAGING DIFFERENTIATION FROM GRAVES OPHTHALMOPATHY

Keywords: Myositis

S. Ziaragkali[1], O. Argyropoulou[1], G. Boutzios[1], S. Chatzi[1], E. Papadaki[2,3], A. Karantanas[2,3], A. Tzioufas[1], M. N. Manoussakis[1]. [1]*School of Medicine, National and Kapodistrian University of Athens, Department of Pathophysiology, Athens, Greece*; [2]*Heraklion University Hospital, Department of Medical Imaging, Heraklion, Greece*; [3]*Medical School, University of Crete, Department of Radiology, Heraklion, Greece*

Background: Idiopathic ophthalmic myositis (IOM) represents a rare autoimmune ophthalmoplegia of unknown etiology, that may mimic predominantly Graves' ophthalmopathy (GO). IOM is characterized by pronounced inflammatory infiltration of extraocular muscles leading to fibrosis and eye-threatening complications, if remains untreated [1,2]. The rarity and clinical heterogeneity of the disease pose diagnostic and therapeutic challenges.

Objectives: To describe the clinical phenotype, therapeutic interventions and clinical course of IOM and to define the distinct imaging features that differentiate IOM from GO.

Methods: This is a single-center, retrospective, observational study of 14 consecutive patients with IOM followed-up between 2017 and 2022. Cumulative clinical, laboratory and imaging data from the medical records until last follow-up were analyzed. The detailed orbital magnetic resonance (MRI) findings of 11 IOM patients were compared to those of 16 age- and sex-matched GO patients.

Results: IOM patients studied (men: 9/14, median age at disease onset: 46 years, median follow-up time: 15.5 months), presented subacute clinical course in 57%, whereas most common clinical manifestations were unilateral exophthalmos (79%), diplopia (71%), eyelid drop and/or swelling (50%). Extraocular muscle inflammation most commonly involved horizontal recti (median number of affected muscles: 2) and predominantly caused restrictive motility disturbance (71%). Anemia of chronic disease occurred in 36% of patients, however, erythrocyte sedimentation rate and c-reactive protein levels were found within normal limits. Myositis specific or other autoantibodies were not detected. Orbital MRI assessments revealed significantly more frequent occurrence of intraconal/extraconal fat edema (in at least one eye) in IOM patients (64.0%), compared to GO patients (25.0%, p-value 0.01). In addition, the abnormal contrast enhancement in extraocular muscles was present in 91.0% and 75.0% of IOM and GO patients, respectively, whereas tendon involvement was observed exclusively in IOM patients (18.2%). In all patients, the mainstay of therapy was steroids. IOM patients were treated with various combinations of corticosteroids and c-DMRD/b-DMRD (methotrexate, mycophenolate-mofetil, azathioprine, rituximab, tocilizumab), whereas GO patients mainly received corticosteroids with/or without tocilizumab.

Conclusion: IOM is a potentially severe organ-specific disease with heterogeneous clinical presentation. Early diagnosis and aggressive immunosuppressive treatment are required to prevent permanent eye-threatening complications. IOM should be considered in the differential diagnosis of exophthalmos, while MRI-imaging may help in differentiating IOM from GO. Studies are underway to delineate tissue-specific alterations of the inflamed extraocular muscles and involving larger series of patients.

AB0884 THE IMPORTANCE OF RENAL IMPAIRMENT IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Kidneys

L. Božić Majstorović[1], I. Ovčina[1]. [1]*University Clinical Centre of the Republic of Srpska, Department of Rheumatology, Banjaluka, Bosnia and Herzegovina*

Background: Systemic sclerosis (SS) is an autoimmune disease characterized by fibrosis and vascular abnormalities. Studies have shown that renal impairment is increased in SS, but this fact is neglected during diagnostic evaluation [1]. As a control group, patients with rheumatoid arthritis (RA) were selected because the renal involvement was as high as 9% although the kidneys were not the target organs in the disease [2]. Comparation of renal function (RF) between patients with SS and RA have not yet been described.

Objectives: The main goal was to detect correlation between clinical features and renal impairment in SS and to compare the renal impairment in patients with SS to patients with RA.

Methods: The 30 patients diagnosed with SS were included in the study. The demographics, modified Rodnan skin score (mRSS), EUSTAR DAI, diffusing capacity for carbon monoxide (DLCO) and immunology parameters were collected. Evaluation of RF was done by using: serum creatinine (SC), creatinine clearance (CC), proteinuria from 24h urine specimen and renal parenchym thickness (RPT) with abdominal ultrasound. To compare the renal impairment, the 30 patients diagnosed with RA without history of glomerulonephritis, diabetes mellitus, hypertension or urinary tract infection were enrolled as a control group.

Results: The 86.7% patients were female, mean age was 57.07±10.41 and mean disease duration was 73.6±68.73 months. Raynaud phenomen had 93.3% patients, digital ulcers (DU) 43.3% and the mean of mRSS was 21.43±9.5. Antinuclear antibodies had 83.3% patients, 46.7% had anti-Scl-70 antibodies and 43.3% had anticentromere B antibodies. The mean of EUSTAR DAI was 4.85±2.56 and DLCO 60.57±16.60. Regarding RF, the mean value of SC was 70.67µmol/l, CC 83.08 ml/min, proteinuria 0.17 g/l and RPT was reduced in 46.7% patients. We correlated clinical features with RF parameters in patients with SS. Significantly reduced RPT was observed in patients with higher mRSS (p=0.035) and in patents with DU (p=0.05). No association was observed between RF and other clinical features. Our results showed significant difference in all RF parameters, between patient and control group. SC (p=0.004) and proteinuria (p=0.03) were significantly higher in SS compared with RA. CC was significantly higher in RA than in patients with SS (p=0.005). RPT was significantly reduced (p=0.000) in SS compared to patients with RA. The results are displayed in Table 1.

Table 1. RF parameters in SS and RA group

	SS	RA	p
Gender F (%)	26 (86.7)	27 (90)	/
Age	57.07±10.41	50.07 ± 10.31	/
Serum creatinine	70.67 ± 17.77	59.87 ± 8.25	**0.040**
Creatinine clearance	83.08 ± 26.16	99.49 ± 16.59	**0.005**
Proteins/24h urine	0.17 ± 0.19	0.09 ± 0.05	**0.030**
Parenchymal thickness (%)	14 (46.7)	1 (3.3%)	**0.000**

RF-renal function; SS-systemic sclerosis; RA-rheumatoid arthritis

Conclusion: Presence of DU and high values of mRSS can be asocciated with renal damage and that indicates the need for evaluation of the RF. The renal impairment in our study was more significant in patients with SS than in those with RA. More studies are necessary to establish this correlation.

AB0885 HIGH RESOLUTION IMPEDANCE MANOMETRY IN DERMATOMYOSITIS ALLOWS THE CHARACTERIZATION OF ESOPHAGEAL DYSMOTILITY AND THE PROFILING OF DIFFERENT CLINICAL AND SEROLOGICAL SUBSETS

Keywords: Diagnostic Tests, Gastrointestinal tract, Myositis

C. Rizzo[1], L. La Barbera[1], F. Camarda[1], D. Donzella[1], G. Barletta[2], S. Bonventre[2], G. Guggino[1]. [1]*University of Palermo, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Rheumatology Unit, Palermo, Italy*; [2]*University of Palermo, Department of General Emergency and Transplant Surgery, General and Emergency Surgery Unit, Esophageal Motility Disorder Section, Palermo, Italy*

Background: Esophageal involvement is common in dermatomyositis (DM), occurring in up to 54% of patients [1]. It can lead to severe complications, such as malnutrition and aspiration pneumonia. Therefore, esophageal assessment is of foremost importance to drive patients management. Recently, high-resolution impedance manometry (HRiM) has emerged as a promising technique to assess esophageal motility and has already been tested in systemic sclerosis [2].

Objectives: To evaluate esophageal motility by HRiM in DM and correlate the alterations to clinical and serological disease domains.

Methods: We analyzed HRiM findings in 15 consecutive DM patients enrolled in our clinic between December 2021 and December 2022. All patients received a rheumatological assessment, including screening questions for dysphagia, and underwent HRiM. All HRiM parameters (Integrated relaxation pressure (IRP), percentage of LES relaxation, distal contractile integral (DCI), distal latency (DL), upper esophageal sphincter (UES) pressure) were studied, coupled with impedance findings (esophageal clearing and bolus transit time). The report followed the Chicago Classification v.4.0 for esophageal motility disorders. The associations between HRiM findings and DM features were evaluated.

Results: DM patients were divided according to their serological status: 5 Mi2 (33%), 6 MDA5 (40%), 2 Ku (13%), 1 NXP2 (6.6%), 6 Ro52 (40%). Asymptomatic patients presenting at least one HRiM alterations were 4 (26.7%). Among HRiM parameters, 83.3% MDA5 patients and 50% Ro52 patients showed high UES pressure (Figure 1), in contrast to the other serological groups. Among impedance findings, incomplete bolus clearance was detected in MDA5 (67%) and in Ro52 patients (50%). Notably, the only NXP2 patient showed 100% of incomplete bolus clearance. Considering the Chicago classification v.4.0, only 16.7% of MDA5 patients had a normal esophageal motility, the rest presenting absent contractility (33.3%) and ineffective esophageal motility (IEM) (50%). Distal esophageal spasm was evidenced only in Mi2 patients (40%). All patients with concomitant manometric and impedance alterations were MDA5 positive. DM patients with high UES, IEM or impedance abnormalities presented higher rate of lung involvement and active Raynaud's phenomenon (Table 1). No relation with ongoing treatment emerged.

Conclusion: We describe for the first time HRiM findings in DM. Anti-MDA5 patients appear to have a more severe esophageal involvement, even in absence of reported dysphagia, followed by anti-Ro52 patients. Interestingly, the same subsets show higher prevalence of lung involvement and Raynaud's phenomenon, suggesting a possible pathogenetic link between esophageal, lung and microvascular disease. Asymptomatic patients may present occult esophageal motility disorders detected by HRiM. Further validation of our findings are required to definitely include HRiM in the workup of DM patients as a diagnostic, prognostic and monitoring tool.

AB0886 PROGRESSIVE INTERSTITIAL LUNG DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

Keywords: Systemic sclerosis

G. Cuomo[1], C. Di Vico[1], D. Perretta[1], C. Iandoli[1], R. Ciaburri[1], P. Adamo[1]. [1]*Seconda Università degli Studi di Napoli, Precision of Medicine, Caserta, Italy*

Background: A subset of patients with systemic sclerosis associated interstitial lung disease (SSc-ILD) develop progressive ILD, which is associated with higher mortality, but the prevalence of progressive ILD and the overall disease course and patterns of SSc-ILD are unknown. Current clinical practice emphasises treatment initiation. of SSc-ILD patients with progressive ILD.

Objectives: To identify progression patterns and risk factors predictive for progressive interstitial lung disease (ILD) in patients with systemic sclerosis-associated ILD (SSc-ILD)

Methods: Within our database, patients included since 2000 aged ≥18 years fulfilled the SSc classification criteria and had lung imaging data available and had measurements of forced vital capacity (FVC) at baseline and after 12±3 months. **A** decline in FVC of ≥10%, or a decline in FVC of 5% to 10% along with a decline in DLCO of 15%, is a proposed definition of progressive fibrosis.

Results: From our database of the 813 patients included 210 (25.8%) had evidence of SSc-ILD on imaging, 134 (63.8%) at basal and 76 (36.2%) over time. The proportion of

patients with SSc-ILD who experienced progressive ILD during the initial 12±3-month period was 30.9% (65 pt) (FVC), either moderate 35 pts 53.8% (FVC decline 5% to 10%) or significant 30 pts 46.2% (FVC decline >10%), 76 (36.2%) were stable and 69 (32.8%) had improvement. In our population, the strongest predictive factors for FVC decline over 12 months were higher modified Rodnan skin score at basal.

Conclusion: Novel treatment concepts, with treatment initiation before FVC decline occurs, should. aim for prevention of progression to avoid irreversible organ damage in SSc-ILD that shows a heterogeneous and variable disease course, and thus monitoring all patients closely is important.

AB0887 THE EFFECTIVENESS AND SAFETY OF MESENCHYMAL STEM CELLS IN TREATMENT OF SYSTEMIC SCLEROSIS: SYSTEMATIC REVIEW

Keywords: Systemic sclerosis, Systematic review

L. Zaripova[1], Z. Bekniyazova[2], E. Insibayeva[2], A. Kambar[2], N. Imanbaeva[2], S. Tuganbekova[2]. *[1]National Scientific Medical Center, Department of Scientific and Innovation Management, Astana, Kazakhstan*; *[2]Astana Medical University, Department of Internal Diseases №4, Astana, Kazakhstan*

Background: Systemic scleroderma, or systemic sclerosis (SSc) is an autoimmune disease with high morbidity and mortality, characterised by fibrosis of the skin and internal organs. In the last decade, alternative methods of treatment of SSc resistant to standard immunosuppressive therapy have been actively studied. Of interest are the data about mesenchymal stem cells (MSCs) with their immunomodulatory properties, the ability to self-renew and differentiation.

Objectives: to evaluate the safety and effectiveness of MSCs transplantation in SSc refractory to standart therapy by a systematic review.

Methods: The search was conducted on PubMed and Google Scholar platforms using the following strategy: "Systemic sclerosis" + "Mesenchymal stem cells". All articles presented in the public domain published before 01.12.2022 in the format of case descriptions, clinical and multicenter studies (Case Reports, Clinical Studies, Clinical Trials, Multicentre Studies) were analyzed. The effectiveness of MSCs was evaluated using the index of systemic sclerosis activity and the modified Rodnan skin score (mRSS), diffusing Capacity of the lungs for carbon monoxide (DLCO), the Mouth Handicap in Systemic Sclerosis (MHISS), the Cochin Hand Functional Disability Scale (CHFS),left ventricular ejection fraction (LVEF), EASTAR 2017 Disease Activity Index, visual analog scale (VAS), manifestations of Raynaud's syndrome, laboratory parameters (ESR, CRP), immunological parameters (ANA, Scl-70). The safety assessment included the registration of various adverse events during and after transplantation.

Results: For the period from 2010-2022, fifty publications were found on the topic of MSCs transplantation in SSc, of which 15 publications met the above criteria and were included in the study. The data of 417 patients who underwent transplantation of MSCs obtained from various biological sources (bone marrow - 7, adipose tissue - 5, umbilical cord - 1) were analyzed. The average age of the patients was 42.42 ± 10.79 y.o. The results obtained suggested that there was a significant decrease in the activity of SSc compared to the baseline level of mRSS scale from 21.81± 7.2 to 4.5 ± 5.4, the number of finger ulcers decreased, there was an improvement in mouth opening assessed by the MHISS scale, 2.5 fold decrease in the level of Scl-70, and 2-fold decrease in VAS (p=0.05). The assessment of all patients (n=417) who underwent MSCs transplantation revealed a few side effects, such as postoperative consequences (bruising, swelling and soreness of the donor site, resolved within 14 days), a superficial wound infection (1 patient), which succumbed to oral antibacterial therapy and no further surgical intervention was required. Pulmonary hypertension was diagnosed in 5 patients 24 months after MSCs transplantation; ventricular arrhythmias requiring treatment with carvedilol was observed in 1 patient four months after MSCs transplantation. Restrictive cardiomyopathy and chronic fibrosing myocarditis developed in 1 patient. 6 patients who underwent liposuction had transient paresthesia, which was completely eliminated after a few weeks; 1 patient dropped out due to dizziness after lidocaine injection. 2 patients complained about digital ulcers developed within 24 months. No tumor-related events were observed. The mortality rate consisted in 1.19%, the survival rate was 98.81%. Cause of death (5 cases in total): pneumonia- 1, lung cancer- 1, unknown – 2 patients. One patient died from sudden cardiac arrest due to ventricular fibrillation.

Conclusion: According to the analysis of data from different up-to-date research, MSCs transplantation in SSc patients improved the degree of skin thickening, lung function and mouth opening, as well as relieved ulcers and finger pain without serious side effects. Thus, MSCs can be suggested as an effective and promising therapeutical approach for patients with SSc resistant to standard immunosuppressive therapy.

Background: Immune Mediated Necrotizing Myopathy is a type of autoimmune myopathy which is commonly associated with the use of statins. Common antibody detected in these patients would be HMGCoA reductase antibodies. Significant muscle necrosis with paucity of cellular infiltration is the characteristic histological feature.
Objectives: To describe clinical and therapeutic characteristics of anti HMGCoA reductase antibody positive necrotizing myopathy.
Methods: Cohort of patients with myositis were selected. The myositis antibody panel was assessed and patients with HMGCoA reductase antibody were selected. Diagnosis was made based on the 2017 EULAR/ ACR criteria [1]. Clinical manifestations, statin use, investigations, treatment offered, and outcome were described.
Results: Of the selected 5 cases, all the patients were middle aged with 3 males and 2 female patients. All 5 patients were on statins and 3 of them were on statins for many years prior to development of myopathy. None of the cases had other systemic involvement including dermatological or cardiac involvement. All 5 patients were positive for HMGCOA reductase antibodies. One patient had CLL which never required any specific treatment and another was incidentally found to have an atypical lipoma which was managed conversatively. All patients required steroids with either Methotrexate and Mycophenolate mofetil. Three of the patients received intravenous immunoglobulin therapy with good response. All of the patients had made a complete recovery though 2 of them required prolonged rehabilitation.
Conclusion: Statin induced necrotising myopathy patients could develop the disease after many years of statin therapy. It is possible that changes in the drug or the dose could act as a precipitant. This cohort of patients tend to be treated with intravenous immunoglobulin in addition to other conventional treatments. In spite of having very severe disease at the onset, with timely and appropriate immunosuppression and rehabilitation patients appeared to have a good outcome.

AB0889 FILGOTINIB FOR THE TREATMENT OF SYSTEMIC SCLEROSIS OVERLAP RHEUMATOID ARTHRITIS: DATA FROM OUR PRELIMINARY EXPERIENCE

Keywords: Targeted synthetic drugs, Systemic sclerosis, Rheumatoid arthritis

M. De Pinto[1], A. Spinella[1], L. Gavioli[1], G. Amati[1], A. Rai[1], F. Goatelli[1], P. Macripo'[1], F. Lumetti[1], O. Secchi[1], G. Sandri[1], C. Salvarani[1,2,3], D. Giuggioli[1,4]. Background: Systemic sclerosis is a connective tissue disease characterized by endothelial disfunction and fibrosis of the skin and internal organs. JAK inhibitors has shown efficacy in reducing cutaneous and pulmonary fibrosis in mice models of SSc, but only few case reports and no RCTs are reported in literature. SSc is frequently associated with other autoimmune diseases and SSc- Rheumatoid arthritis (RA) is one of the most common SSc-Overlap Syndrome. Filgotinib is an oral selective JAK1 inhibitor, recently approved for the treatment of RA.
Objectives: The aim of our work was to assess efficacy and safety of Filgotinib for the treatment of cutaneous, visceral and articular involvement in patients affected by SSc overlap RA.
Methods: Prospective, open-label, monocentric study in which 5 patients affected by SSc overlap RA (M/F 0/5, age 57,80±16,62DS years, disease duration 11,6±7,89 DS years, limited/diffuse subset 3/2) referring to the Scleroderma Units of Modena and Reggio Emilia between October 2021 and July 2022, were enrolled. All patients satisfied both ACR/EULAR criteria for SSc and RA and were already in treatment with standard therapy (prostanoids, calcium-channel blockers a/o endothelin-receptors inhibitors a/o phosphodiesterase type 5 inhibitors) and had an inadequate response or were intolerant or had contraindication to one or more DMARDs or bDMARDs. Patients received Filgotinib 200 mg once daily for a period of 24 weeks. Articular, cutaneous and visceral involvement were assessed according to clinical practice at the baseline and at 12th and 24th week after the start of the treatment.
Results: All patients showed a significant improvement in articular involvement at 24th week, in particular a significant reduction in tender joint count (TJ, p=0,003), SDAI/CDAI (p=0,012/0,008) and pain numerical rating scale (NRS, p=0,035) was reported. A trend of improvement of DAS28 (p=0,055) was also observed. Notably a significant reduction in TJ (p=0,023) and a trend of improvement of SDAI/CDAI (p=0,059/0,051) was already seen at 12th week. The extent and severity of skin involvement assessed through modified Rodnan Skin Score (mRSS) remained stable during follow-up (p=0,918). No improvement or worsening of exertional dyspnea measured by means of Borg scale was reported. No drug-related side effects were recorded during follow-up and none of the patients discontinued the treatment. No deaths were reported.
Conclusion: According to our preliminary data, Filgotinib was effective, safe and well tolerated in the treatment of articular involvement in patients affected by SSc overlap RA. Further analysis on a larger number of patients and control group are needed to confirm our data. Patients' enrollment with assessment of efficacy on skin and lung involvement is currently ongoing.

AB0890 EARLY SYSTEMIC SCLEROSIS PATIENTS SHOW A SLOW DISEASE COURSE

Keywords: Systemic sclerosis, Epidemiology

M. Käyrä[1], S. Kortelainen[2], J. Paltta[2], L. Pirilä[2], H. Vähänikkilä[3], R. Kaarteenaho[4,5], J. Huhtakangas[6]. [1]*Oulu University Hospital, Division of Rheumatology, Oulu, Finland*; [2]*Turku University Hospital, Rheumatology and Clinical Immunology, Turku, Finland*; [3]*University of Oulu, Faculty of Medicine, Oulu, Finland*; [4]*University of Oulu, Research Unit of Biomedicine and Internal Medicine, Oulu, Finland*; [5]*Oulu University Hospital, Center of Internal Medicine and Respiratory Medicine and Medical Research Center (MRC) Oulu, Oulu, Finland*; [6]*Kuopio University Hospital, Division of Rheumatology, Kuopio, Finland*

Background: Systemic sclerosis is a heterogenous immune-mediated connective tissue disease characterized by vasculopathy and progressive tissue and organ fibrosis. [1]
Objectives: Our aim was to determine characteristics of Finnish patients with systemic sclerosis (SSc) and early SSc that were followed during 1996-2018 in two university hospitals in Finland.
Methods: The data of patients with SSc with ICD-10 diagnostic code (M34) were collected retrospectively from medical registers. The patients were reclassified into different subsets based on the ACR/ EULAR (American College of Rheumatology and European League Against Rheumatism) 2013 classification criteria of the SSc. Early SSc was defined as a condition that did not fulfil the classification criteria (less than 9 points). Diffuse (dcSSC), limited cutaneous (lcSSc), overlap and sine scleroderma subsets were differentiated by their clinical phenotype.
Results: 336 patients were obtained after re-evaluation of data. Out of 336 patients 40 (11.9%) patients had dcSSc, 222 (66.1 %) lcSSc, 16 (4.8%) SSc-overlap syndrome, 2 (0.6%) SSc sine scleroderma and 56 (16.7%) early SSc. The early SSc group did not develop any of the most severe manifestations such as interstitial lung disease (ILD), the incidence of which was 32.7/1000 patient years in the whole SSc group, n=280, pulmonary arterial hypertension (PAH) (14.3/1000 patient years), renal crisis (RC) (3.5/1000 patient years), myocarditis (1.2/1000 patient years) during the 4.3 [IQR 1.9-6.7] years of follow-up. The SSc group had significantly more other manifestations as digital ulcers (41.1 vs. 6.7/1000 patient years, p<0.001, SSc and early SSc, respectively), reduced mouth opening (44.3 vs. 10.1, p<0.001) and manometry positive oesophageal dysmotility (21.1 vs. 10.3, p=0.007) than patients with early SSc. ILD was diagnosed 2.8 (SD 4.5) years, PAH 5.6 (SD 8.7) years and RC 0.2 (SD 0.3) years after the onset of the first non-Raynaud's phenomenon symptom in SSc patients. The patients with dcSSc had worse survival than lcSSc patients (after 5 years 81.9% vs 91.6%,

after 10 years 67.3% vs 82.9%, p<0.001 and HR=2.7 (1,6-4,4), p<0.001). The SSc-overlap and early SSc subsets did not have difference in survival when compared to lcSSc subset.

Conclusion: Disease course of patient with early SSc was slow or mild since none of them developed any severe complication during the median follow-up time of 4.3 years.

PROOF OF CONCEPT OF THE USE OF CO-DESIGNED 3D PRINTED ASSISTIVE DEVICES WITHIN AN OCCUPATIONAL THERAPY INTERVENTION IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Physical therapy/Physiotherapy, Health Services Research

A. Spinella[1], F. Gherardini[2], E. Dalpadulo[2], D. Giuriati[3], V. Bettelli[4], M. De Pinto[1], G. Amati[1], O. Secchi[1], M. T. Mascia[1], G. Sandri[1,3,5], D. Giuggioli[1,5]. *[1]University of Modena and Reggio Emilia, Scleroderma Unit, Rheumatology Unit, Modena, Italy*; *[2]University of Modena and Reggio Emilia, Department of Engineering "Enzo Ferrari", Modena, Italy*; *[3]University of Modena and Reggio Emilia, Occupational Therapy Master's Degree, Modena, Italy*; *[4]Azienda Ospedaliero-Universitaria, Baggiovara, Rehabilitation Medicine, Modena, Italy*; *[5]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of Children and Adults, Modena, Italy*

Background: Despite the positive impact of assistive devices (ADs) on the daily lives of people with disabilities, many of them are initially adopted and then regrettably abandoned. Even though the AD of an individual patient might fit his/her needs, up to 7 out of 10 people stop using it. On the one hand this may be linked to an improvement in their health, on the other, the devices may not be ergonomically suitable for long-term use. Previous studies have highlighted the possibility that co-designed and customised 3D printed assistive devices can benefit patients with rheumatic diseases which impair daily activities, especially manual ones. Among the 29 patients with Systemic Sclerosis who took part in the joint prevention clinic workshop at the University-Hospital of Modena (Italy), in 2019 4 patients actively joined the 3D printing project for the co-designing of ADs.

Objectives: This work has two main goals: firstly, to check whether in the short term the co-design approach is able to guarantee better acceptance of ADs and a lower abandonment rate. Secondly, to check during follow-ups, if the patients are satisfied and regularly use their ADs and if their daily activities remain unchanged.

Methods: The development of the ADs begins with co-design sessions which involve the patient, an Occupational Therapist and a designer. The AD is digitally modelled and 3D printed. Subsequently it is delivered to the patient following a number of training sessions. Using standardized tests such as PIADS (Psychosocial Impact of Assistive Devices Scale) and QUEST (Quebec User Evaluation of Satisfaction with assistive Technology) at the time of delivery of the ADs, then after 3 years, we assessed the level of satisfaction of the 4 patients enrolled, the condition of the ADs and their actual use.

Results: In 2019 each of the 4 patients received at least one AD, which they used on a regular daily basis [i.e. a device to open a moka pot (an Italian coffee machine); a token for a shopping trolley; a pen grip handle; a multiple key turner]. The results of the PIADS following delivery and in the 3-years follow-up were positive. The QUEST results were also positive. After 3 years the ADs were still being used regularly. Moreover, in 2022, 2 patients co-designed and 3D printed new ADs in response to new or altered needs.

Conclusion: In both the long and short term, ADs are still being used regularly and patients are still enjoying the benefits. After 3 years none of the ADs displayed any significant wear or breakage, thus their effectiveness was not compromised. Finally, the satisfaction of the patients with the co-designed ADs remained unaltered over time. Co-design 3D printed devices have therefore proven to effectively reduce the AD abandonment rate.

>65	1.849.000	55%	186	51,6%	0,353	>65	1.644.000	52,2%	88	51,1%	0,842

Background: A proinflammatory and immunosuppressive role of cigarette smoking has been suggested in rheumatic and autoimmune conditions, with former and current smokers having increased susceptibility to the development of several diseases [1]. Conversely, a study from the United States showed that ever-smoking was not associated with a significant risk to develop systemic sclerosis (SSc) [2]. Up to date, no other study addressed smoking as a possible risk factor for developing SSc.

Objectives: The aim of our study was to investigate whether smoking is a risk factor for disease susceptibility in SSc in the Dutch population.

Methods: At Leiden University Medical Center, the prospective Combined Care in Systemic Sclerosis (CCISS) cohort was initiated in 2009 and, as of January 2022, 708 SSc patients have been included. Information about smoking history was collected at time of enrolment in the cohort, allowing patients to be categorized into never-smokers and ever-smokers. Data about smoking habits in the Dutch population from 2014 to 2021, stratified for sex and age (12-25; 25-45; 45-65; >65 years) are accessible from the Dutch Central Bureau of Statistics website (https://opendata.cbs.nl/#/CBS/nl/dataset/ 83385NED/table?dl=6A354). The prevalence of ever-smokers in the CCISS cohort was compared with the prevalence of ever-smokers in the general Dutch population using chi-square tests. Due to the limited number of young SSc patients, only individuals aged 25 or above were included in the analysis. In order not to miss potentially relevant differences attributable to changes in smoking habits during time, two index years were chosen for the current analysis, 2015 and 2021. Age of the SSc patients who were enrolled in the CCISS cohort at the time of the index years was calculated. Patients who had died before each index year were excluded from the relative analysis. Official data about the Dutch population size and age composition were retrieved from the Dutch Central Bureau of Statistics website (https://www.cbs.nl/visualisaties/dashboard-bevolking/bevolkingspiramide).

Results: Details about the population size in each age range and the number of patients included in the study are reported in Table 1. No statistically significant differences emerged in the comparison of ever-smoking rates between SSc patients and the general Dutch population both in men and women and in each of the three age categories (all p-values > 0.05).

Conclusion: Our study demonstrates that the percentage of ever-smoking individuals is comparable in SSc patients and in the Dutch population. Although the stratification might have decreased the statistical power of our analysis, we can conclude that smoking does not confer an increased risk for the development of SSc in the Netherlands.
